Michael J. Somers,[1] Arnaud Devresse,[2] Richard G. Willey,[3] Michael D. Murphy,[3] Anne-Laure A. Sellier-Leclerc,[4] Cristin Kaspar,[3] Justine Bacchetta.[5] *[1]Division of Pediatric Nephrology, Boston Children's Hospital, Boston, MA; [2]Department of Nephrology, Cliniques Universitaires, Brussels, Belgium; [3]Alnylam Pharmaceuticals, Cambridge, MA; [4]Division of Pediatric Nephrology-Rheumatology, Hôpital Femme-Mère-Enfant, Lyon, France; [5]Lyon Est Medical School, Hospices Civils de Lyon, Lyon, France.*

Background: Primary hyperoxaluria type 1 (PH1), a rare autosomal recessive disorder associated with hepatic oxalate overproduction, leads to progressive kidney damage. Prior to availability of the RNA interference therapeutic lumasiran, reported graft survival rates after isolated kidney transplantation (iKT) in PH1 patients (pts) were poor: 54% at 3 months (M) and 46% at 1 year (y). Phase 2 (NCT03350451) and 3 Phase 3 trials (ILLUMINATE-A, NCT03681184; ILLUMINATE-B, NCT03905694; and ILLUMINATE-C, NCT04152200) have shown sustained urinary oxalate and plasma oxalate (POx) reduction and acceptable safety with lumasiran across a wide range of ages and baseline (BL) kidney function. Long-term follow-up allows evaluation of native kidney survival and iKT outcomes in lumasiran-treated pts.

Methods: Descriptive kidney function data from lumasiran clinical trials and post-transplant outcomes in pts following iKT were compiled.

Results: Mean annual rates of eGFR change (mL/min/1.73m^2/y) were –0.6 over 48 M in the Phase 2 trial (N=20), –1.2 over 48 M in ILLUMINATE-A (N=35), and –0.8 over 30 M of follow-up in ILLUMINATE-B (N=15). The range of BL eGFR values was 32–174 mL/min/1.73m^2 in these 3 trials. ILLUMINATE-C enrolled PH1 pts with advanced kidney disease; pts were assigned to Cohort A (not on hemodialysis [HD]) or Cohort B (on HD). Three pts in Cohort A, who had the lowest BL eGFR (8.6–16.5 mL/min/1.73m^2), required HD before the M36 data cutoff; the other 2 remaining Cohort A pts (BL eGFR 24.0, 34.1 mL/min/1.73m^2) had annual rates of eGFR decline of –2.3 and –0.9 mL/min/1.73m^2/y, respectively, over 36 M. Five Cohort B pts underwent iKT as of M36. All 5 had POx reduction from BL prior to transplantation, and further reduction post-transplant indicating improved POx clearance with functioning kidney grafts. No patients experienced oxalate nephropathy post-transplantation. All 5 remained HD-free and continued lumasiran treatment post-transplant as of M36.

Conclusions: Lumasiran treatment for PH1 resulted in minimal annual eGFR decline over 30 to 60 M in pts with BL CKD stages 1–4, and effectively lowered POx to allow for iKT, rather than liver-kidney transplantation, in some pts with end-stage kidney disease.

FR-PO705

Analysis of Underlying Diseases Associated with Kidney Stones in Korean Children and Adolescents

Heeyeon Cho, Jinwoon Joung. *Samsung Medical Center, Gangnam-gu, Seoul, Republic of Korea.*

Background: Recently, the prevalence of kidney stones occurring in children and adolescents is increasing worldwide. The renal stones may appear as the clinical manifestations of underlying diseases or as a complication of the treatment. Therefore, this study aimed to analyze the underlying diseases including genetic causes and assess clinical outcomes of Korean children with nephrolithiasis.

Methods: From January 2022 to December 2023, we retrospectively analyzed demographic data for patients aged 0 to 18 who were newly diagnosed with kidney stones using ultrasonography who visited Samsung Medical Center. Medical records including sex, gestational age, underlying disease, medication history, genetic analysis, and ultrasonography were retrospectively reviewed. The authors reviewed whether there was the underlying diseases or interventions related to kidney stones, and if such an underlying disease was not confirmed at the time of diagnosis, a genetic test such as whole exome sequencing was performed to distinguish hereditary kidney disease.

Results: A total of 102 patients were diagnosed with kidney stones, and the male to female ratio was 1.04. The average age at diagnosis was 76 months. The underlying diseases were prematurity (45.0 %), tubulopathy after chemotherapy in pediatric patients with malignancy (13.8 %), hereditary disease confirmed through genetic testing (13.8%), and congenital anomalies of the kidney and urinary tract (CAKUT) with hydronephrosis or cyst (12.7%). In addition, underlying diseases such as congenital heart disease requiring diuretic treatment (5.9%), epilepsy taking anti-seizure medication that cause stones (3.9%), and inflammatory bowel disease (2.9%) were found. There were two cases in which these underlying diseases were not found. There were 2 cases that required urological surgery, and 1 case had renal function decline of chronic kidney disease stage 3.

Conclusions: This study suggests that kidney stone may appear in association with various underlying diseases and be a clinical clue of hereditary disease. Therefore, the screening for stone in patients with relevant underlying disease or the active evaluation of the genetic cause should be considered. The prognosis for surgery or decline in renal function is relatively favorable.

FR-PO706

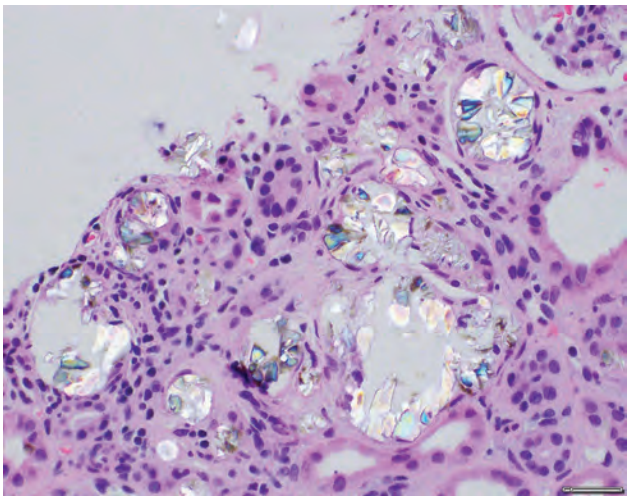
Little Stones, Big Trouble: Nutritional Oxalosis in a Child

Vivian Shi, Xixi Zhao. *Stanford University, Stanford, CA.*

Introduction: Oxalate nephropathy is a rare condition that results in acute kidney injury and chronic kidney disease. Although primary hyperoxaluria (PH) accounts for the majority of cases of oxalate nephropathy in pediatrics, our case highlights the importance in considering secondary causes. We present a case of a 9-year-old girl with kidney injury requiring dialysis due to nutritional oxalosis.

Case Description: A 9-year-old female with a history of failure to thrive presented with bilateral leg pain. Physical exam revealed extreme cachexia. Admission labs were notable for Na 101, K 6.6, BUN 157, and creatinine 8.56 (previous baseline 0.38 obtained 16 months prior), which prompted emergent hemodialysis (HD). Kidney biopsy showed diffuse oxalate crystals and severe interstitial fibrosis with tubular atrophy. Systemic oxalosis workup was negative. Genetic testing for PH was negative. A review of patient's diet prior to illness revealed large consumption of many high oxalate containing foods, including nuts, spinach, chocolates, as well as daily vitamin C supplements. Elevated plasma oxalate levels normalized with maintenance HD and diet control. She continued on HD until kidney transplantation.

Discussion: The patient presented at a young age with sudden end stage kidney disease due to oxalate nephropathy. Differentiating PH from secondary hyperoxaluria is crucial in determining the treatment of choice. PH is a rare inborn error of glyoxylate metabolism that results in hepatic overproduction of oxalate, leading to increased urinary excretion and kidney disease. Secondary hyperoxaluria can result from increased dietary intake or enteric hyperoxaluria. This case highlights the need for genetic testing and considering secondary causes of hyperoxaluria in pediatrics. The case also emphasizes the need for regular monitoring of nutritional sources in pediatric patients with failure to thrive, since their diet may be high in a single nutritional compound such as oxalate.



Oxalate crystals

FR-PO707

A Case Series of Thromboelastography (TEG) to Describe Patterns of Uremic Thrombocytopathy in Pediatric Kidney Dysfunction

Shrea Goswami, Evan A. Rajadhyaksha, Andrew L. Schwaderer, Michelle C. Starr. TEG Team. *Riley Hospital for Children at Indiana University Health, Indianapolis, IN.*

Introduction: Renal azotemia can contribute to platelet dysfunction and subsequent bleeding risk. Thromboelastography (TEG) is commonly used to evaluate bleeding risk in patients with liver pathology and trauma, however, TEGs role in kidney dysfunction is unclear. We report TEG results in a case series of children with kidney dysfunction and describe TEG changes after dialysis.

Case Description: TEGs were collected from 8 patients (10 TEG samples). Ages ranged from 15 days to 18 years old, 3 had AKI and 5 had ESKD. All had urea (BUN) ≥50 mg/dL at first TEG sample. We found no significant relationship between BUN and markers of platelet inhibition (adenosine diphosphate, ADP% inhibition) nor clotting strength (maximum amplitude, MA) **(Fig 1)**. In 2 patients with pre/post hemodialysis (HD) TEGs, we saw an increase in inhibition and decrease in clot strength after dialysis **(Fig 2)**. This paradoxical increase in clot inhibition and decrease in clot strength is of unclear etiology but may represent correction of a previously hypercoagulable state.

Discussion: The absence of an identifiable relationship between urea and ADP% inhibition/MA in this case series may be secondary to the heterogeneity of the cohort (age, underlying disease process, azotemia duration). The paradox of increased clot inhibition and decreased clot strength with urea reduction may relate to decreased fibrinogen/vonWillebrand factor due to dialysis. Our case series is in accord with existing literature, which suggests TEG may have limited use in diagnosing uremic platelet dysfunction. Future longitudinal studies may clarify the utility of TEG to create hemostatic profiles for patients with kidney dysfunction.

Automated Learning and Early Recognition Technology for Neonatal AKI (ALERT-NAKI)

Tahagod Mohamed,[1,3] Jonathan L. Slaughter,[1,3] Sven Bambach,[1] Jacqueline K. Magers,[1] Laura Rust,[1,3] Shama Patel,[1,3] Steve Rust,[1] John D. Spencer,[1,3] Francis P. Wilson.[2] *[1]Nationwide Children's Hospital, Columbus, OH; [2]Yale University, New Haven, CT; [3]The Ohio State University College of Medicine, Columbus, OH.*

Background: Neonatal acute kidney injury (AKI) is underrecognized despite its high prevalence and known adverse effects on short- and long-term outcomes. Evidence-based tools for providers to predict and recognize neonatal AKI risk are limited. Under recognition of neonatal AKI prohibits providers from timely interventions on modifiable AKI risk factors. We hypothesized that neonatal AKI occurrence can be predicted by utilizing existing EHR data and machine learning algorithms.

Methods: Using retrospective EHR data from 5400 infants admitted in 2017-2021 to our level IV NICU for >183,000 patient days, we trained a machine learning model to predict neonatal AKI occurrence. Data were collected after local IRB approval. Known neonatal AKI risk factors were identified from existing literature. Neonatal AKI was defined by changes in serum creatinine (sCr) and urine output (UOP) according to the neonatal modification of KDIGO criteria. We used least absolute shrinkage and selection operator (LASSO) algorithm to identify reliable neonatal AKI predictors and to develop a predictive model. The area under the curve (AUC) was utilized to evaluate model performance

Results: When provided with 34 known neonatal AKI risk factors, LASSO chose 8 reliable predictors including fluid balance status, hypotension requiring vasopressors, invasive ventilation, FiO2%, congenital anomalies of the kidneys and urinary tract, sepsis, sCr monitoring and value changes. The model predicts significant changes in sCr and UOP during the next 48 hours with an AUC of 0.76, **Figure 1**.

Conclusions: Neonatal AKI can be reliably predicted by utilizing machine learning algorithms and available EHR data. This is the first step to empower providers with evidence-based tools to improve neonatal AKI prediction and recognition and to allow time for intervention on modifiable risk factors before kidney injury occurs.

FR-PO709

Impact of Tobacco Smoke on Pediatric Kidney Function: Evidence from Urine Cotinine Levels

Jeong Yeon Kim. *Chungnam National University, Daejeon, Republic of Korea.*

Background: Tobacco smoking is a well-established risk factor for the development of chronic kidney disease (CKD) in adults. Additionally, exposure to tobacco smoke impacts pediatric kidney function and the progression of CKD. Urine cotinine (uCot), a metabolite of nicotine, serves as a biomarker for tobacco smoke exposure and is a more reliable indicator of CKD risk compared to self-reported smoking. This study evaluated the association between uCot levels and pediatric kidney function.

Methods: Data were extracted from the Korea National Health and Nutrition Examination Survey (KNHANES) conducted between 2019 and 2021. A total of 195 children aged 10–18 years were included in the analysis. The estimated glomerular filtration rate (eGFR) was calculated using the bedside Schwartz equation. Demographic and clinical characteristics of the study population were reported as weighted values. Weighted regression analysis was used to analyze the association between uCot levels and kidney function.

Results: Of the 195 children, 68.2% were male, with a mean age of 15.3±0.2 years. The mean eGFR was 99.4±1.8 ml/min/1.73m², and the mean urine albumin-to-creatinine ratio (uACR) was 7.1±0.5 mg/g. The mean uCot level was 327.0±50.5 ng/mL, and the mean uCot-to-creatinine ratio (uCCR) was 173.2±27.1 ng/mg. Among the children, 28.6% were exposed to secondhand smoke from parents, and 37.6% were smokers. Smoking was positively associated with uCot levels ($p<0.0001$) and uCCR ($p<0.0001$). However, parental secondhand smoke exposure did not show a significant association with uCot levels or uCCR. Both uCot levels ($R^2=0.07$, regression coefficient estimate=-0.009, $p<0.0001$) and uCCR ($R^2=0.04$, regression coefficient estimate=-0.01, $p=0.0123$) were negatively associated with eGFR. While smoking showed a significant negative association with eGFR ($R^2=0.02$, regression coefficient estimate=-9.5, $p<0.001$), parental secondhand smoke exposure did not exhibit a clinically significant association with eGFR. Neither uCot nor uCCR showed significant associations with uACR.

Conclusions: In conclusion, tobacco smoking negatively impacts kidney function in the pediatric population and can be monitored using uCot levels or uCCR. In this study, parental secondhand smoke exposure did not affect the kidney function of healthy children. Therefore, uCot levels in children could help identify those at high risk for developing CKD.

FR-PO710

AKI in Patients with Multisystem Inflammatory Syndrome in Children

Jennifer K. Nhan, Marva M. Moxey-Mims, Sun-Young Ahn. *Children's National Hospital, Washington, DC.*

Background: Multisystem inflammatory syndrome in children (MIS-C) is a rare but serious condition associated with COVID-19 with over 9300 cases between May 2020 and January 2023 reported in the US. There are limited published studies on the effects of MIS-C on kidney function in the pediatric population. Etiologies of acute kidney injury (AKI) proposed were cardiac dysfunction, hyperinflammatory state and exposure to nephrotoxins for COVID-19 treatment. However, more large-scale studies are needed to further elucidate the clinical characteristics of kidney injury in children with MIS-C.

Methods: We performed a retrospective study of patients between the ages of 0-21 years diagnosed with MIS-C, who were hospitalized at Children's National Hospital between March 2020 and January 2023. To assess kidney injury, we evaluated serum chemistry, inflammatory markers and urine laboratory values. The Kidney Disease: Improving Global Outcomes (KDIGO) criteria were used to identify 29 patients with AKI and 104 patients without AKI.

Results: Among patients with AKI, 79.3% were male and 20.7% were female. Patients with AKI had significantly higher peak CRP levels than non-AKI patients (22.23 vs 16.26 mg/dl, $p<0.001$). Serum cytokine levels, including TNF-α, IL-1, IL-6, IL-8, and IL-12, were not significantly different between the 2 groups. Patients with AKI had significantly lower levels of albumin at nadir and discharge. A higher proportion of patients with AKI compared to those without AKI were exposed to inotropes (27.6 vs 11.5%,$p=0.04$), vasopressors (79.3 vs 43.3%,$p=0.001$) and mechanical ventilation (24.1 vs 3.8%,$p=0.002$). Urine protein to creatine ratios were similar between AKI and non-AKI patients. Patients with AKI were more likely to have received steroids (55.2 vs 24%,$p=0.003$) and/or anakinra (93.1 vs 59.6%,$p<0.001$), than those without AKI.

Conclusions: The degree of elevation in CRP reflects the hyperinflammatory state in MIS-C patients, which corresponded with AKI development. MIS-C patients who required ventilatory and cardiac support had higher rates of AKI. Receiving steroids and/or anakinra reflects the severity of illness in patients with AKI. This is the largest single center study, to our knowledge, of features and risk factors for AKI in children with MIS-C.

FR-PO711

Predicting Mortality Risk in Neonatal Patients with AKI with an Artificial Neural Network Algorithm

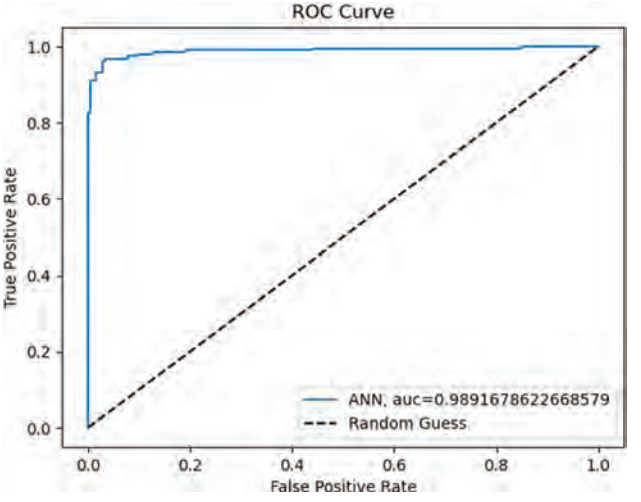
Aadi H. Pandya, Arnav Vyas, Maximilian Dawson, Sidharth K. Sethi, Kianoush Kashani, Rupesh Raina. *Akron Nephrology Associates/Cleveland Clinic Akron General Medical Center, Akron, OH.*

Background: Acute Kidney Injury (AKI) presents a substantial burden in healthcare, especially in the neonatal intensive care unit. Physiological variability and limited biomarkers complicate care for neonatal patients, and artificial intelligence shows promise for clinical implications in neonatal AKI.

Methods: Five deep learning models were tested with two independent neonatal patient datasets sourced from eleven healthcare centers. Data preprocessing techniques were enforced to amalgamate these datasets, followed by SMOTE to augment the imbalanced deceased patient class. The data was subsequently split into training and testing cohorts. Initial modeling was conducted with 36 training features, after which feature reduction techniques, including Recursive Feature Elimination, were utilized to isolate the top ten most influential features, creating parsimonious models.

Results: From both datasets, 1,362 patients with a median age of 14.10 hours were included in this study. The chosen algorithm was a custom-constructed Keras sequential artificial neural network (ANN) architecture with excelling validation-cohort metrics: AU-ROC = 0.9859; AU-PRC = 0.9919; accuracy = 0.9731; sensitivity = 0.9657; specificity = 0.9805. Given ten patient parameters for a neonate patient at risk of AKI, the model calculates a mortality risk level, which can be further utilized to dictate the potential intensification of patient treatment procedures. The robustness and generalizability of the ANN-based model were confirmed through K-fold cross-validation studies.

Conclusions: This study implements an ANN algorithm to predict mortality risk for neonates susceptible to AKI based on ten input parameters. Utilizing this healthcare-based deep learning model provides insight to aid physicians in patient management.



FR-PO712

Perceptions and Practice Surrounding Pediatric CRRT Liberation

Evan A. Rajadhyaksha,[1] Dana Y. Fuhrman,[4] David T. Selewski,[3] Shina Menon,[2] Katja M. Gist,[5] Michelle C. Starr.[1] *[1]Riley Hospital for Children at Indiana University Health, Indianapolis, IN; [2]Seattle Children's Hospital, Seattle, WA; [3]Medical University of South Carolina, Charleston, SC; [4]UPMC, Pittsburgh, PA; [5]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

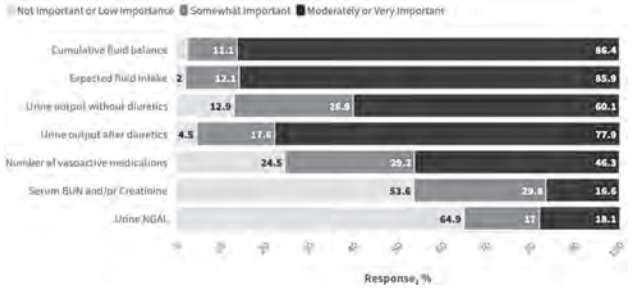
Background: Recent work by WE-ROCK reports a lower likelihood of Continuous Renal Replacement Therapy (CRRT) liberation with longer duration of therapy or low urine output. However, approaches to CRRT liberation and factors influencing decision-making remain inadequately studied.

Methods: A survey was distributed internationally through WE-ROCK to characterize perceptions and practice surrounding CRRT liberation in pediatric patients.

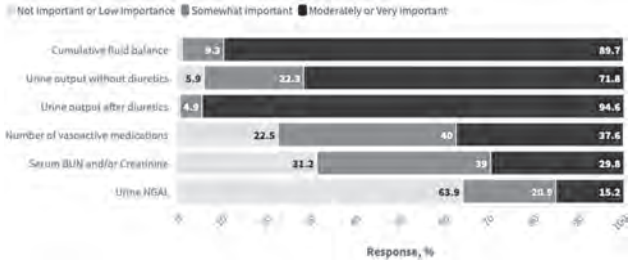
Results: Of 206 respondents, 37% were nephrologists and 63% were intensivists. Fourteen countries were represented (85% USA). Few (4%) reported an institutional standardized approach to CRRT liberation, though 28% had a personal approach. Reported approaches most often (59%) included loop and thiazide diuretics, given at median 4h after stopping CRRT (IQR 2-6h). Cumulative fluid balance and expected fluid intake were rated the most important factors in determining readiness to attempt liberation **(Figure 1A)**, followed by urine output in response to diuretics. Cumulative fluid balance and urine output in response to diuretics were considered most important in determining CRRT liberation success **(Figure 1B)**. Nephrologists were more likely than intensivists to rate native urine output (73% vs. 48%, $p=0.01$) and number of vasoactive medications (62%

vs. 38%, *p*=0.04) as important determinants of readiness to attempt CRRT liberation, and they placed higher importance on spontaneous urine output (85% vs 65%, *p*=0.03) for determining successful liberation.

Conclusions: These findings provide a first look at current CRRT liberation practices in pediatrics. Variation in approach to CRRT liberation and differences in stakeholders' perceptions of factor importance highlight the need for further research and standardization.



Factors in Determining Readiness to Liberate from CRRT



Factors in Determining CRRT Liberation Success

FR-PO713

Rasburicase for Treatment of Hyperuricemia-Related Neonatal AKI

Evan A. Rajadhyaksha, Michelle C. Starr. *Riley Hospital for Children at Indiana University Health, Indianapolis, IN.*

Introduction: Up to 10% of neonates with Trisomy 21 (T21) will develop Transient Myeloproliferative Disorder (TMD). Though tumor lysis syndrome (TLS) has been described with treatment of TMD, acute kidney injury (AKI) from hyperuricemia without TLS in this population has not been reported. We describe the case of a preterm neonate with T21, TMD-spectrum leukocytosis, and hyperuricemia-related AKI who was treated with recombinant uricase.

Case Description: A 31 weeks' gestation, low-birth weight neonate was born with T21 and severe leukocytosis (56,000 k/cumm) with blasts, along the spectrum of TMD. Hyperuricemia (8.6 mg/dL) followed, and with elevated lactate dehydrogenase (1516 U/L) was presumptively secondary to high cell turnover. Within the first 3 days of life, he developed stage 3 AKI, with rising urea (BUN) and creatinine (Cr) and decreased urine output, for which the nephrology team was consulted. Suspecting his rapidly progressive AKI may be secondary to hyperuricemia-related injury, and with the goal of avoiding renal replacement therapy (RRT) given the considerable risk associated with initiating RRT in an infant this size (1750 g), a single dose of rasburicase (0.2 mg/kg) was administered to treat the hyperuricemia. Following administration, BUN and Cr dropped precipitously (Figure 1), urine output increased by 67%, and he avoided RRT.

Discussion: Given his T21 and TMD, this neonate was at increased risk for hyperuricemia, and his response to rasburicase suggests that he suffered from hyperuricemia-related AKI. Uric acid mediates AKI through both reduction in renal blood flow and proximal tubule (PT) toxicity, and he may have been particularly susceptible to this PT toxicity given his prematurity. This case demonstrates that hyperuricemia should be considered in the differential for AKI in neonates with T21 and TMD-spectrum disease, and that recombinant uricase is an effective treatment that may help to preserve kidney function and avoid RRT.

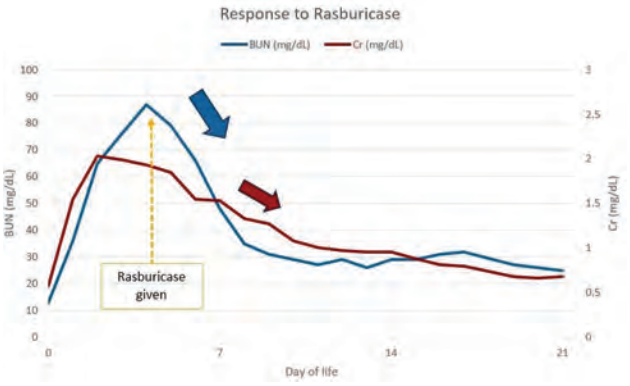


Figure 1. Trend in kidney function tests (BUN and Cr) following rasburicase on day of life 4.

FR-PO714

Advantages of Acute Peritoneal Dialysis in Children: Lessons from a Large Escherichia coli O157:H7 Outbreak in Calgary

Naji Al Dhawi,[1,2] Susan M. Samuel,[1,2] Lorraine A. Hamiwka,[1,2] Andrew W. Wade,[1,2] Alyssa J. Archibald,[1,2] Silviu Grisaru.[1,2] *[1]Alberta Children's Hospital, Calgary, AB, Canada; [2]University of Calgary, Calgary, AB, Canada.*

Introduction: Technical innovations in extracorporeal kidney replacement equipment have significantly expanded the availability of these modalities for children and small infants with oligo-anuric acute kidney injury (AKI), rapidly replacing the traditional preference for acute peritoneal dialysis (APD) in this age group. In September 2023, an unprecedented outbreak of O157:H7 Shiga toxin-producing E. coli (STEC), predominantly affecting daycare children aged 2 to 4 years, occurred in Calgary, AB, Canada. Infections were acquired from contaminated food item provided by a central kitchen to multiple daycares. This report aims to highlight the advantages of APD during this outbreak.

Case Description: 356 children tested positive for Shiga toxin 1 and 2, having been infected with an E. coli O157:H7 pathogen. Approximately 250 exhibited symptoms of gastroenteritis, and 27 children developed hemolytic uremic syndrome (STEC-HUS), characterized by anemia, thrombocytopenia, and acute kidney injury. A consistent management approach to oligo-anuria associated with (STEC-HUS) was applied. Transfusions of packed red cells were performed as necessary; however, platelet transfusions were avoided, and antibiotics were reserved for prophylactic prevention of peritonitis and management of other confirmed infections. Within 4 days (September 4 – 8), seven swan neck PD catheters were inserted by two pediatric urologists in children who developed oligo-anuria secondary to STEC-HUS. Continuous PD was performed in 8 children on pediatric wards for an average of 10.3 ± 2.4 days. Two children experienced serious extrarenal complications, but there were no fatalities, and all affected children recovered normal estimated glomerular filtration rates by three months post-infection.

Discussion: In children, APD remains an effective form of acute kidney replacement therapy (KRT), that is accessible outside intensive care units. Since this is an important advantage in an outbreak scenario, pediatric centers should maintain skills and capacity necessary to initiate APD in large numbers of children. In addition, outcomes of childhood oligo-anuric STEC-HUS may be influenced by the choice of acute KRT modality, a hypothesis that needs to be explored in prospective clinical trials.

FR-PO715

Urinary Neutrophil Gelatinase-Associated Lipocalin in Preterm Neonates

Nicole Asdell,[1] Tahagod Mohamed,[1] Shivam Joshi,[2] Elizabeth Bonachea,[1] Jonathan L. Slaughter.[1] *[1]Nationwide Children's Hospital, Columbus, OH; [2]The Ohio State University, Columbus, OH.*

Background: Acute kidney injury (AKI) is common in hospitalized preterm neonates. Urinary neutrophil gelatinase-associated lipocalin (uNGAL) is a promising noninvasive biomarker for detection of AKI. However, normal values of uNGAL in preterm neonates without AKI are poorly characterized limiting its' clinical utility in this population.

Methods: Neonates born < 32 weeks GA admitted to our level IV NICU who didn't have AKI, UTI, NEC, or sepsis were included. Urine was collected in the first postnatal week (n=100) and patients were categorized to 3 GA groups (23-25, 26-28, 29-31 weeks). uNGAL and urine creatinine (uCr) concentrations were evaluated using immunoturbidimetry and an enzymatic assay respectively. The Chi-squared test was used to examine the association between categorical variables and GA groups, while the Kruskal-Wallis rank sum test and ANOVA were used to identify differences in the distribution of continuous variables across GA groups. Pearson's correlation assessed

the relationship between GA and uNGAL and GA and the uNGAL/uCr ratio. Statistical significance was determined at an alpha level of 0.05.

Results: The median uNGAL for infants born 23-25, 26-28, and 29-31 weeks were 653, 205, and 78 ng/dL respectively. Similarly, the uNGAL/uCr ratios at these GA were 62,19, and 7.9 ng/dL respectfully. Baseline concentrations of both uNGAL (R=-0.606, p<0.001) and uNGAL/uCr (R=-0503, p= <0.0001) decreased as GA increased.

Conclusions: Baseline urinary NGAL levels were shown to be elevated in preterm neonates. NGAL is present in the urine as early as 23 weeks gestation and its' concentration decreases with increasing gestational age.

Funding: Private Foundation Support

Plasma Renin as a Biomarker for AKI and Mortality in Neonates Undergoing Mechanical Circulatory Support

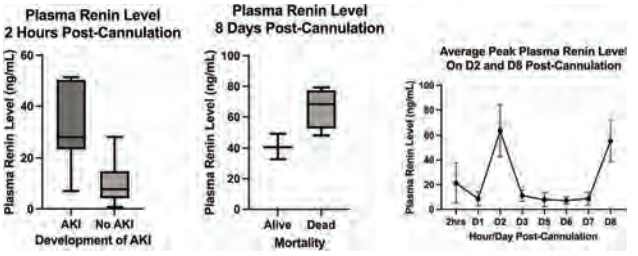
Michael F. Young, Esther Y. Pascal, Vidhi Tyagi, John D. Spencer, Andrew R. Yates, Tahagod Mohamed. *Nationwide Children's Hospital, Columbus, OH.*

Background: Extracorporeal membrane oxygenation (ECMO) is a life-saving intervention for neonates with severe cardiorespiratory failure. Acute kidney injury (AKI) is associated with mortality in children receiving ECMO. Renin is essential for homeostasis and has been studied as a novel biomarker for predicting AKI and mortality in critically ill adults. Its role as biomarker for AKI and mortality in neonates requiring ECMO support is unknown. We hypothesized that neonates who develop AKI have higher plasma renin levels following ECMO initiation.

Methods: Single center study evaluating term neonates admitted to the ICU at Nationwide Children's Hospital requiring ECMO support between 3/2015 and 12/2018. Baseline renal function was normal in all neonates prior to initiating ECMO. Plasma renin levels were collected daily beginning 2 hours through day 8 after cannulation and analyzed using ELISA. Diagnosis of AKI was based on KDIGO.

Results: Cohort included 12 term neonates with 13 ECMO initiations. The most common comorbidities were congenital diaphragmatic hernia (58%, N = 7) and congenital heart disease (42%, N = 5). Most patients were initially placed on venous-arterial (VA) ECMO (85%, N = 11). Mortality rate was 67% (N = 8). Plasma renin levels were highest on days 2 and 8 post-cannulation, regardless of circuit type. On average, day 2 levels were 7-fold higher and day 8 levels were 6-fold higher than day 1 levels. There was no significant difference between peak plasma renin levels on days 2 and 8 (p = 0.38). Higher levels of plasma renin 2 hours and 8 days after cannulation were associated with development of AKI (p = 0.015) and mortality (p = 0.036), respectively.

Conclusions: Elevated plasma renin 2 hours after cannulation and day 8 post-cannulation was associated with AKI and mortality, respectively suggesting that plasma renin can be used as a prognostic biomarker in neonates receiving ECMO. Further studies should evaluate the renin-angiotensin-aldosterone system as a potentially modifiable target in preventing AKI and mortality in patients receiving ECMO.



FR-PO717

Quantification of Uremic Toxins in Pediatric CKD: A Potential Biomarker and Mechanistic Driver of Cardiorenal Syndrome

Heshini Dalpathadu,[1] Andrew W. Wade.[2,1] *[1]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [2]Alberta Children's Hospital Research Institute, Calgary, AB, Canada.*

Background: Cardiovascular disease is the leading cause of morbidity and mortality among pediatric chronic kidney disease (CKD) patients. This pathological interaction between the heart and kidneys, known as cardiorenal syndrome (CRS), may be caused by the accumulation of uremic toxins. Compared to adults, CRS is understudied in pediatric patients, and consequently, their composition and levels of uremic toxins are not well established. Currently, there are no definitive clinical guidelines for treating cardiovascular complications in pediatric CKD patients. Furthermore, findings from adults cannot be extrapolated to children due to the presence of preexisting cardiac (and chronic) disease in this population.

Methods: To address this gap in knowledge of CRS in children, we collected blood samples longitudinally from pediatric patients (mean age 8.3±4.9 years; 58.3% males and 41.7% females). These included 3 CKD patients with cardiac dysfunction, 3 CKD patients with resolved cardiac dysfunction, and 6 control patients who had CKD without cardiac dysfunction. Cardiac dysfunction was defined as cardiac ejection fraction <50%.

Results: In children with CKD and no cardiac dysfunction (n=13), concentrations of indoxyl sulfate (IS) and fibroblast growth factor-23 (FGF23) were 355.1±147.9 ng/mL and 54.1±45.5 ng/mL, which are 24-fold lower and 42-fold higher, respectively than levels seen in adults. Levels of p-cresyl sulfate (4.0±1.3 ng/mL) and trimethylamine N-oxide (34.1±11.5 ng/mL) (n=28) were not significantly different from adults. In patients with CKD and ongoing cardiac dysfunction (n=3), IS and FGF23 concentrations increased to 3,245.3±431 ng/mL and 2,206.7±974.9 ng/mL, respectively. The levels of IS and FGF23 normalized in children whose cardiac dysfunction resolved (n=5). We further investigated these findings using an *in vitro* model. Human induced pluripotent stem cells were differentiated to beating cardiomyocytes and exposed to IS (4000-8000 ng/mL). Following exposure, initial results show that the beating rate decreased from 52±15 to 26±7 beats per minute.

Conclusions: Our results highlight important pediatric differences in the serum concentrations of IS and FGF23. Our in vitro model recapitulates the effects of uremic toxins on cardiac function and provides insight into the mechanism of cardiorenal syndrome.

Clinical and Genetic Differences between Congenital and Infantile Nephrotic Syndrome

Yuta Inoki, Tomoko Horinouchi, Yuka Kimura, Yuta Ichikawa, Yu Tanaka, Chika Ueda, Hideaki Kitakado, Atsushi Kondo, Nana Sakakibara, Tomohiko Yamamura, Shingo Ishimori, China Nagano, Kandai Nozu. *Department of Pediatrics, Kobe University Graduate School of Medicine, Hyogo, Japan.*

Background: More than half of the patients with congenital nephrotic syndrome (CNS) or infantile nephrotic syndrome (INS) are known to have a monogenic etiology. However, the difference in clinical course, disease-causing gene, and genotype-phenotype correlation between genetic CNS and INS remains unknown.

Methods: Patients diagnosed with nephrotic syndrome within the first year of life and referred to our hospital for genetic analysis were enrolled. In patients with identified causative genes, characteristics and their renal outcome were compared between CNS and INS patients.

Results: Among 74 patients enrolled, disease-causing genetic variants were detected in 52 patients. The median age at development of end-stage kidney disease (ESKD) in the CNS and INS groups was 13.2 and 20.0 months old, respectively ($P = 0.13$). Compared to the CNS patients with *NPHS1* variants, the age at development of ESKD was significantly earlier in CNS patients with the other variants (1.0 vs. 31.0 months old; $P < 0.001$). In patients with pathogenic variants other than *NPHS1*, there was significant difference in the age at development of ESKD between CNS and INS patients (1.0 vs. 17.0 months old; $P < 0.001$). All INS patients with *NPHS1* variants had no truncating variants. Patients with no truncating variant did not develop ESKD during follow-up, and the age at ESKD

in patients with no truncating variant was significantly later than in those with biallelic or monoallelic truncating variants (- vs 31.0 months old; $P = 0.025$). In addition, among patients with *WT1* pathogenic variants, those with severe variants, exon 8 or 9 missense variants in DNA-binding regions, developed ESKD significantly earlier than those without severe variant (1.5 vs. 15.0 months old; $P = 0.0058$). All of the CNS patients and 37.5% (3/8) of the INS patients had severe variants.

Conclusions: Our findings suggest that whether CNS onset or INS onset could influence renal prognosis in patients with genetic nephrotic syndrome who are less than 1 year old. Moreover, among patients with pathogenic variant in the same gene, INS patients can be more likely to have a mild genotype and good renal prognosis.

FR-PO719

A Novel Multimethylation Site Assay to Predict Steroid-Resistance in Initial Treatment of Nephrotic Syndrome

Wang Yinfeng,[1,2] Junzhen Zhu,[2] Tingya Jiang.[2] *[1]Jiangsu University, Zhenjiang, China; [2]AlloDx Biotech, Shanghai, China.*

Background: Approximately 20% of nephrotic syndrome (NS) patients exhibit steroids-resistant nephrotic syndrome (SRNS). If SRNS can be identified prior to the initial treatment, potential adverse effects associated with subsequent steroid use can be reduced by employing alternative immunosuppressive agents. Current research shows that about 30% of SRNS are caused by genetic mutations associated with podocytes. However, the causes of the other of 70% SRNS cases are unknown. In this study, we confirmed the correlation of gene methylation changes with SRNS and established an REscore to predict SRNS by detecting the multi-CpG sites of specific gene

Methods: Frozen peripheral blood mononuclear cell (PBMC) samples from 25 non-genetic NS patients (12 SRNS and 13 non-SRNS) were retrospectively enrolled in this study. Systematic investigation into the DNA methylation in the promoter regions of three genes: NLRP3,NR3C1 and CASP1. Multiplexed target bisulfite sequencing (Target-BS) and a risk prediction model (Random Forest, RF) were established to distinguish SRNS and non-SRNS with 15 patients for training and 10 patients for validating

Results: We investigated 37 CpG sites covered in total,and finally found out that 7 sites showed significant differences between the SRNS and non-SRNS group ($p < 0.05$). The 7 sites were analyzsed using RF model to obtain a resistance score (REscore) for predicting the response to steroid in NS. The results of the ROC analysis showed an AUC of 0.98,sensitivity of 90%,specificity of 100%,with a cutoff value REscore is 0.74,positive predictive value (PPV) was 100%,and the negative predictive value (NPV) was 93.3% in the training set. In the validation set,the RF model achieved an AUC of 0.92,sensitivity of 83.3%,specificity of 100%,PPV of 100%, and NPV of 80%

Conclusions: In conclusion, this study identified significant changes methylation markers in the NLRP3,NR3C1 and CASP1 genes in patients with SRNS. Furthermore,the RF model was used to create the REscore, which can effectively predict the risk of SRNS. It is need more samples and more pathological type of nephropathy to verify the conclusion of this study in future

FR-PO720

Comparative Effectiveness of Cyclophosphamide and Calcineurin Inhibitors in Childhood Nephrotic Syndrome

Cal Robinson,[1,2] Josefina A. Brooke,[1] Rahul Chanchlani,[3] Brian H. Cuthbertson,[4] Vaneet Dhillon,[1] Eddy Fan,[2] Christoph Licht,[1] Ashlene M. McKay,[1] Damien G. Noone,[1] Rachel J. Pearl,[1] Seetha Radhakrishnan,[1] Veronique Rowley,[1] Chia Wei Teoh,[1] Jovanka Vasilevska-Ristovska,[1] Rulan S. Parekh.[5] *[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]McMaster Children's Hospital, Hamilton, ON, Canada; [4]Sunnybrook Research Institute, Toronto, ON, Canada; [5]Women's College Hospital, Toronto, ON, Canada.*

Background: Nephrotic syndrome is a common pediatric kidney disease with high morbidity. Cyclophosphamide and calcineurin inhibitors are the most used second-line medications, but their comparative effectiveness is unknown.

Methods: Using target trial methods, we emulated a pragmatic, open-label clinical trial using Insight into Nephrotic Syndrome: Investigating Genes, Health, and Therapeutics study data. We included children (1-18yr) diagnosed with nephrotic syndrome from 1996-2019 in Toronto, Canada that initiated cyclophosphamide or calcineurin inhibitors. Randomization was emulated by propensity score overlap weighting. The primary outcome was time-to-relapse, analyzed by weighted Cox proportional hazards models.

Results: Of 578 children, 252 started cyclophosphamide and 131 calcineurin inhibitors. Baseline characteristics were balanced after propensity score weighting. During median 5.5-year (IQR 2.5-9.2) follow-up, there was no difference in relapses after calcineurin inhibitor vs. cyclophosphamide (HR 1.25, 95%CI 0.84-1.87). There were also no differences in relapses by 1, 2, or 5-years, hypertension, or chronic kidney disease. Calcineurin inhibitor use was associated with hospitalization (HR 1.83, 95%CI 1.14-2.92) and intravenous albumin use (HR 2.81, 95%CI 1.65-4.81).

Conclusions: There was no difference in risk of relapse after cyclophosphamide vs. calcineurin inhibitor treatment in childhood nephrotic syndrome. Cyclophosphamide treatment is shorter in duration and more accessible in low-to-middle income countries.

Funding: Government Support - Non-U.S.

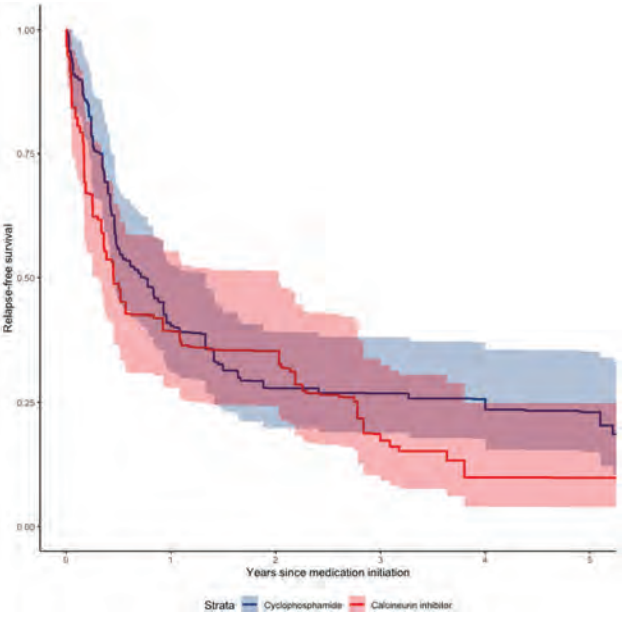

Figure. Weighted relapse-free survival after cyclophosphamide vs. calcineurin inhibitor initiation

FR-PO721

An Increase in TCR/BCR Repertoire Clonality by Prednisolone Therapy and Recovery of the Diversity by Rituximab in Childhood Idiopathic Nephrotic Syndrome

Tomoko Horinouchi,[1] Yuka Kimura,[1] Yuta Inoki,[1] Yuta Ichikawa,[1] Yu Tanaka,[1] Hideaki Kitakado,[1] Chika Ueda,[1] Nana Sakakibara,[1] China Nagano,[1] Tomohiko Yamamura,[1] Junya Fujimura,[2] Naohiro Kamiyoshi,[3] Shingo Ishimori,[1,4] Hiroshi Kaito,[5] Yuko Shima,[6] Yukio Nakamura,[7] Asako Sakai,[8] Izumi Okugaito,[8] Kandai Nozu,[1] Kazumoto Iijima.[9,10] *[1]Department of Pediatrics, Kobe University Graduate School of Medicine, Kobe, Japan; [2]Department of Pediatrics, Kakogawa Central City Hospital, Kakogawa, Japan; [3]Department of Pediatrics, Japanese Red Cross Society Himeji Hospital, Himeji, Japan; [4]Department of Pediatrics, Takatsuki General Hospital, Takatsuki, Japan; [5]Department of Nephrology, Hyogo Prefectural Kobe Children's Hospital, Kobe, Japan; [6]Department of Pediatrics, Wakayama Medical University, Wakaya, Japan; [7]Repertoire Genesis Inc., Ibaraki, Japan; [8]Zenyaku Kogyo Co., Ltd., Tokyo, Japan; [9]Hyogo Prefectural Kobe Children's Hospital, Kobe, Japan; [10]Department of Advanced Pediatric Medicine, Kobe University Graduate School of Medicine, Kobe, Japan.*

Background: In diseases related to autoimmunity, it is known that the T-cell receptors (TCR) / B-cell receptors (BCR) repertoire along with lymphocyte subpopulations exhibits various characteristics, but there is no data available for idiopathic nephrotic syndrome (NS) in children.

Methods: We conducted TCR / BCR repertoire analysis on peripheral blood mononuclear cells using high-throughput sequence method on 45 pediatric nephrotic syndrome patients and 11 non-nephrotic individuals with abnormal urinalysis as controls, totaling 96 samples (control n=11; initial-onset NS n=70; complicated NS with rituximab (Rtx) treatment n=15).

Results: There was no significant difference in the diversity of TCR/BCR repertoires between the control group (n=11) and the initial-onset pretreatment NS group (n=36). When comparing pairs before and after prednisolone (PSL) therapy (n=34), the diversity of TCR/BCR repertoire was decreased; Shannon index (e.g. TRA 6.99 (SD 0.99) vs 6.05 (SD 1.17) $p<0.0001$, IgM 7.79 (SD 0.85) vs 7.52 (SD 0.91) $p<0.03$). In patients with pre-Rtx treatment complicated NS (n=9), the diversity of TCR/BCR repertoire was decreased significantly compared to patients with initial-onset NS; Shannon index (e.g. TRA 6.97 (SD 0.97) vs 5.32 (SD 1.15) $p<0.0003$, IgM 7.78 (SD 0.86) vs 6.69 (SD 0.83) $p<0.003$). After Rtx treatment, when B cells recovered, recovery of the diversity was also observed (n=6).

Conclusions: While no changes were observed in initial-onset NS, PSL treatment led to an increase in specific clones. A decrease of diversity in TCR/BCR repertoires was seen in complicated NS requiring Rtx, while diversity recovered after rituximab administration, likely promoting restoration of immune tolerance.

FR-PO722

Risk Factors for Rituximab Dependency in Pediatric and Young-Adult Patients with Refractory Nephrotic Syndrome

Nao Uchida. *Tohoku University Hospital Department of Pediatrics, Sendai, Japan.*

Background: Rituximab (RTX) has been shown to be effective for childhood-onset refractory nephrotic syndrome and is being administered worldwide. While steroid discontinuation is possible in many patients after RTX, a certain number of patients cannot be weaned from RTX administration due to relapses of nephrotic syndrome after B cell recovery.

Methods: this is a single-center, retrospective study. Twenty-five patients with refractory nephrotic syndrome who received RTX at our department from January 2011 to November 2021 were recruited in this study. They were divided into two groups; a group that could not be weaned from RTX administration (group A) and a group that could be controlled without RTX for more than two years (group B).

Results: There were 10 patients in group A (male:female = 7:3) and 15 patients in group B (male:female = 7:8). The patients in group A had a significantly higher age at first RTX administration than the patients in group B (12±4.0; 7.8±3.7 years, $p<0.05$), and a longer period from the onset of nephrotic syndrome to RTX administration (8.1±4.0; 4.1± 3.2, year, $p<0.05$). The IgG level at the first administration was significantly higher in group A (708.8±220.0; 467.2±263.6, mg/dL, $p<0.05$), perhaps due to the older age of the patients, but the IgG levels at the final examination were not significantly different between the two groups (649.5±244.7; 723.8±337.2, mg/dL, $p=0.59$). There was no significant difference in age at onset between the two groups (3.9±1.7; 3.7±3.3 years, $p=0.82$).

Conclusions: The rate of RTX dependence was as high as 40% in our hospital. The age at the first RTX administration was higher in the dependent group (group A), suggesting a relationship between the immunological developmental process and the efficacy and sensitivity of RTX. Because side effects of long-term use of RTX have not been fully understood, we should be cautious in maintaining therapy with RTX. Limitations were; 1) the number of patients who were analyzed in this study was small; 2) the preference of RTX was affected by other factors due to the fact that RTX has few side effects regarding blood pressure, blood glucose level or physical appearance, with the exception of infusion reactions and various kinds of immunological deficits.

FR-PO723

Urinary Lipid Biomarkers Predict Progression in Focal Segmental Glomerulosclerosis

Jacob A. Humphrey,[1] Aaron M. Armando,[2] Oswald Quehenberger,[2] Jonathan P. Troost,[3] Elif Erkan.[1] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]University of California San Diego, La Jolla, CA; [3]University of Michigan, Ann Arbor, MI.*

Background: Focal Segmental Glomerulosclerosis (FSGS) is the most common glomerular cause of pediatric end stage kidney disease. We propose that patients with FSGS display a unique milieu of urinary and serum free fatty acid (FFA) and phospholipid (PL) profiles that can serve as biomarkers for prediction of diagnosis and prognosis in FSGS.

Methods: Urine and serum samples were obtained from 30 patients with FSGS and MCD as an ancillary study to Nephrotic Syndrome Study Network (NEPTUNE) cohort. Healthy controls were obtained from Discovery biobank, Cincinnati Children's Hospital. We included patients aged 2-21 years with biopsy proven FSGS or MCD, urine protein to creatinine ratio (UPCR) of >1 and eGFR >60mL/min/1.73m^2. We excluded patients with DM, systemic disease, organ/bone marrow transplantation, or known genetic cause of FSGS. Targeted lipidomic analysis was performed by mass spectrometry to measure PL and FFA in samples. Disease progression was defined as a 20% decrease in eGFR. Logistic regression models with unadjusted/adjusted models for age, race and proteinuria were utilized to determine ROC curves and AUC.

Results: Mean follow up was 48 months (IQR 30-56 months). Serum arachidic acid ($p = 0.02$) and very long chain fatty acid (VLCFA) cerotic acid ($p = 0.02$) were elevated in FSGS patients. Urinary omega-3 FA, eicosapentaenoic acid (AUC 0.86, $p = 0.0007$) and omega-6 FA, arachidonic acid (AA) (AUC 0.76, $p=0.002$) and AA by products polyunsaturated adrenic acid (AUC 0.9, $p = 0.01$), docosapentaenoic acid (n3 and n6, AUC 0.93 and 0.84, $p = 0.003$ and 0.01, respectively) and PL metabolite lysophosphatidylcholine (LPC)(AUC 0.8, $p = 0.004$) predicted FSGS progression by univariate analysis in adjusted and unadjusted models.

Conclusions: Lipidomic analysis of serum and urine samples provided key information in pathophysiology of FSGS and identified potential biomarkers. Elevated serum levels of VLCFA in patients with FSGS suggest peroxisomal dysfunction and defective fatty acid β oxidation. Elevated urine AA and its metabolites in association with membrane PL and LPC serve as potential biomarkers for progression in FSGS. We postulate that increased activity of proinflammatory AA and LPC driven by phospholipase A2 contributes to progression in FSGS.

Corticosteroids Augment Cyclosporine Nephrotoxicity in Pediatric Nephrotic Syndrome: Potential Role of CD163+ M2-type Macrophage

Yuji Matsumoto, Tomomi Kondo, Takuma Ando, Naonori Kumagai, Yohei Ikezumi. *Fujita Health University School of Medicine Department of Pediatrics, Toyoake, Japan.*

Background: Cyclosporin A (CsA) is an effective steroid-sparing agent for patients with steroid-dependent nephrotic syndrome (SDNS), however, it can cause chronic interstitial damage. We previously reported that alternativley-activated (M2) macrophages (MQ) are intimately involved in interstitial fibrosis pathogenesis in chronic progressive kidney disease. In this study, we investigated the possible involvement of M2 MQ in CsA nephrotoxicity in SDNS.

Methods: A total of 33 children diagnosed with SDNS who were treated with CsA for more than 2 years were investigated. Thirteen biopsy specimens from age-matched SDNS children who had not received CsA treatment were used as the control. Renal fibrosis was assessed by Masson chrome staining of biopsy sections. Sections were also stained for α-smooth muscle actin (α-SMA), type I collagen, CD68 (total MQ) and CD163 (M2 marker). Urine levels of CCL2 were measured by ELISA. Cultured human monocyte-derived MQ were stimulated with dexamethasone (Dex) for 48hr and RNA levels compared to control cells.

Results: The CsA-treated group showed a significant increase in interstitial fibrosis (10.8 vs 6.7%, $P<0.001$) with accumulation of interstitial CD163$^+$CD68$^+$ MQ (10.8 vs 7.9/HPF, $P<0.001$) compared with SDNS control patients. There was a significant correlation between the degree of interstitial fibrosis and the number of interstitial CD163$^+$ cells ($p<0.001$), and between interstitial fibrosis and the dose of steroid used during CsA treatment ($p<0.001$), while no correlation was found between the dose of steroid used before CsA treatment and histological changes. Stimulation of MQ with Dex induced up-regulation of CD163 and cytokines and growth factors associated with inflammation and fibrosis (*CCL2*, *NOS1*, *NOS2*, *FGF-8*, *FGF-21* and *CTGF*). Immunostaining revealed significant expression of CTGF and CCL2 in biopsies from CsA group which co-localized with CD163$^+$MQ. In addition, the urine CCL2/creatinine ratio was increased 4-fold in CsA group vs control group (940.0 vs 204.1, $P=0.012$)

Conclusions: Our findings suggest that CD163$^+$ M2-type MQ may participate in the development of interstitial fibrosis induced by CsA. Steroid treatment during CsA treatment might contribute to augment CsA nephrotoxicity through the production of pro-fibrotic and pro-inflammatory factors.

FR-PO725

Macrophage Activation Syndrome in an Adolescent Male with Dialysis-Dependent Kidney Failure and Systemic Lupus Erythematosus Flares

Subashini Azhagappa, Syeda Asfia Hussain, Asma B. Shaoba, Oluwatoyin F. Bamgbola. SUNY Downstate Pediatric Nephrology. *SUNY Downstate Health Sciences University, New York City, NY.*

Introduction: MAS is a life-threatening dysregulation of the immune system that progresses to multisystem organ failure. It occurs typically in systemic juvenile idiopathic arthritis (sJIA) & rarely in SLE. We describe a unique instance in an adolescent male with SLE who developed MAS.

Case Description: This case is of a 17-year-old African American male with family history of severe SLE, diagnosed at age 12. He developed class IV lupus nephritis, deep vein thrombosis, & pulmonary embolism 2 years later. He failed therapy with Mycophenolate mofetil, Cyclophosphamide, Rituximab and Belimumab & was dialysis dependent in less than 1 year of kidney disease. Before the current illness, he had recurrent hypotension, pancytopenia, low complement, & high serological markers for 10 months. At presentation, he had fever, emesis, diarrhea & fluid-resistant hypotension. He recieved empiric antibiotics & pulse steroids, however, he developed respiratory failure, tonic-clonic seizure, hyperglycemia, and pancreatitis. Lab values were consistent with MAS (Fig 1), including HScore >250, signifying a >99% probability of MAS. MRI showed a chronic atrophic cerebral cortex. Infectious workup was negative. He responded to infusions of Anakinra.

Discussion: Severe SLE was complicated by MAS in our patient which is rare. Recurrent hypotension before MAS, suspicious of cytokine storm, has not been described. Rapid involvement of the liver, pancreas, central nervous system and acute increase in ferritin lead to a diagnosis. Frequent relapses, chronic cytopenia, intense immunosuppression, & intractable hypotension may precede MAS as seen in our case. Early treatment may reverse clinical deterioration, improving survival.

Fig 1: Laboratory data of a 17-year-old dialysis-dependent male with severe SLE that complicated by MAS compared to diagnostic criteria.

Laboratory Parameters	Measured value	Diagnostic Criteria
Hemoglobin (g/L)	9.5	≤9.0
White blood cell count (K/uL)	0.66	≤4.0
Platelet count (K/uL)	40	≤150
S. ferritin (ng/mL)	> 40,000	>500
S. fibrinogen (mg/dL)	105	≤150
S.triglycerides (mg/dL)	>1000	>178
Aspartate Aminotransferase (U/L)	506	>40
LDH (units/L)	363	>567
Clinical Criteria: Fever (>38°C) Hepatomegaly (≥3 cm below the costal margin) Splenomegaly (≥3 cm below the costal margin) Hemorrhagic manifestations (purpura, easy bruising, or mucosal bleeding) Central nervous system dysfunction (irritability, disorientation, lethargy, headache, seizures, or coma)		

FR-PO726

Area Deprivation and Mineral Metabolism in Pediatric CKD

Marciana Laster,[1,2] Bradley A. Warady,[3,5] Susan L. Furth.[4] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Riley Hospital for Children at Indiana University Health, Indianapolis, IN; [3]University of Missouri-Kansas City School of Medicine, Kansas City, MO; [4]The Children's Hospital of Philadelphia, Philadelphia, PA; [5]Children's Mercy Kansas City, Kansas City, MO.*

Background: CKD-MBD is a comorbidity of CKD that leads to poor growth, fractures and cardiovascular death. Levels of PTH and vitamin D differ by racial-ethnic group. Given that race is a social construct that coincides with a disproportionate burden of poverty within minorities, a complete understanding of racial differences must consider socioeconomic status (SES). The objective of this study is to define the relationship between SES and MBD markers including phosphate, calcium, intact parathyroid hormone (PTH), and 25-hydroxyvitamin D (25OHD).

Methods: In 540 participants from the CKID cohort, we assessed the relationship between area deprivation index (ADI), median household income (MHI) and longitudinal CKD-MBD biomarkers using linear mixed effects models with backward selection (p value <0.1). Biologically relevant variables including age, sex, and medication use were maintained in all models. Categories of deprivation (high vs. low) were defined according to previous standards as a value >=113.45.

Results: 11.8% of participants lived in areas of high deprivation. Race differed between high and low deprivation cohorts (Table 1). In linear mixed effects models (Table 2), increasing deprivation was associated with lower 25OHD and increasing MHI with higher 25OHD. Stratification by Black and non-Black race demonstrated a persistent relationship but of greater magnitude in Black race. Of the other markers, only intact PTH demonstrated a trend with increasing MHI which predicted decreased PTH (Table 2).

Conclusions: Vitamin D status as reflected by 25OHD is related to area-level social metrics including ADI and median neighborhood income. Persistence upon racial stratification helps to untangle the structural contributors to vitamin D status. Further studies are needed to understand the specific contributors to this finding.

Funding: NIDDK Support

Bridging the Gap: Assessing Nephrology Transition Practices in Pediatric and Adult Care Settings

Andrew Vissing,[1,2] Priya S. Verghese,[2] Angelina M. Dixon,[3] Cybele Ghossein.[1] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Ann & Robert H Lurie Children's Hospital of Chicago, Chicago, IL; [3]University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: The transition from pediatric to adult care can be challenging for young adults living with kidney disease. The International Society of Nephrology has recommended establishing a transition process for this vulnerable population; however, the prevalence of transition clinics or standardized transition processes (established approaches for transitioning patients at an institution) is currently unknown. Our study surveyed pediatric and adult nephrology programs nationwide to explore the current state of transition practices.

Methods: Four different surveys were created to assess transition practices in adult and pediatric general nephrology and transplant nephrology care. Surveys were distributed via email to the leadership of academic general and transplant nephrology programs. Listservs and online forums were also used for survey distribution.

Results: The overall response rate for all four surveys was 38.5%. The percentage of programs that had transition clinics or an established process for transitioning care for young adult patients are shown in Table 1. Amongst adult and pediatric centers that indicated partnerships in transitions of care, a large discrepancy existed in how transitions were performed. Between affiliated adult and pediatric programs, 54.8% of general nephrology programs and 46.7% of transplant programs were misaligned in their reported transition of care procedures.

Conclusions: By examining the presence of transition clinics and processes, we reveal the lack of standardized transition planning for young adults with kidney disease. Furthermore, our study highlights the lack of coordination between affiliated adult and pediatric centers in implementing transition plans for this at-risk demographic. Future studies will aim at examining the benefits and obstacles of established transition clinics and processes.

Presence of Transition Clinics and Processes at Nephrology Programs

Programs	Programs with a Transition Clinic	Programs with a Transition Process	Programs without a Transition Clinic or Process
Adult General Nephrology (n=71)	13 (18.3%)	24 (33.8%)	34 (47.9%)
Adult Transplant Nephrology (n=37)	11 (29.7%)	15 (40.5%)	11 (29.7%)
Pediatric General Nephrology (n=49)	8 (16.3%)	28 (57.1%)	13 (26.5%)
Pediatric Transplant Nephrology (n=31)	6 (19.4%)	22 (71.0%)	3 (9.7%)

FR-PO728

Obstacles in Establishing Transition Clinics in Pediatric and Adult Medical Centers

Andrew Vissing,[1,2] Priya S. Verghese,[2] Angelina M. Dixon,[3] Cybele Ghossein.[1]
[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Ann & Robert H Lurie Children's Hospital of Chicago, Chicago, IL; [3]University of Colorado Anschutz Medical Campus, Aurora, CO.

Background: In 2011, the International Society of Nephrology published a consensus statement regarding the importance of a transition process from pediatric to adult care for young adults with kidney disease, ideally facilitated through transition clinics. Despite this recommendation, institutions continue to struggle with the transfer and transition of care for this group. Here we report on potential barriers to implementing this recommendation.

Methods: Four different surveys were created to assess transition practices in adult and pediatric general nephrology and transplant nephrology care. Surveys were distributed via email to the leadership of academic general and transplant nephrology programs. Respondents without a transition clinic were asked to identify the primary obstacles to establishing such a clinic. The identified obstacles were classified into one or more of the following categories: logistics, resources, provider-related, patient-related, or absence of need/obstacles. Fisher's exact test was used ($P < 0.05$) to compare frequencies of obstacles between the adult and pediatric programs.

Results: There were a total of 119 comments. The most frequently mentioned barrier for adult programs was resources (53%) and for pediatric programs was provider-related (52.8%). Patient-related obstacles were statistically less cited in adult programs compared to pediatric programs (1.5% vs 15.1%, $P = 0.01$). Adult programs were more likely to mention no perceived need/obstacles compared to pediatric programs (16.7% vs 3.8%, $P = 0.04$). There was no statistical difference in how frequently other obstacles were mentioned between the two groups.

Conclusions: Despite guidelines recommending pediatric to adult transition programs for young adults, transition clinics remain uncommon in nephrology transitions of care. Resource availability as well as provider-related obstacles, are the main perceived barriers by both pediatric and adult programs. Future work will involve understanding and overcoming these barriers.

Obstacles for Establishing a Transition Clinic

Obstacles	Adult Programs (n=66)	Pediatric Programs (n=53)	p-value
Logistics	17 (25.8%)	19 (35.8%)	0.32
Resources	35 (53.1%)	24 (45.3%)	0.46
Provider-related	29 (43.9%)	28 (52.8%)	0.36
Patient-related	1 (1.5%)	8 (15.1%)	0.01
No Perceived Need or Obstacles	11 (16.7%)	2 (3.8%)	0.04

FR-PO729

Molecular Regulation of Podocyte Development by Transcription Factor 21

Vidhi Dalal,[1,2] Yalu Zhou,[2] Dilip K. Deb,[2] Hiroshi Maekawa,[2] Margaret E. Fain,[2] Anthony Chang,[3] Eunah Chung,[2] Joo-Seop Park,[2] Susan E. Quaggin.[2]
[1]Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]University of Chicago Pritzker School of Medicine, Chicago, IL.

Background: Transcription factor 21 (Tcf21) is expressed in developing podocytes from the S-shaped body onwards. Our laboratory previously showed that deletion of *Tcf21* from podocyte precursors at the S-shaped stage of glomerular development in mice resulted in abnormal podocyte morphology, impaired glomerular basement membrane (GBM) formation, and defects in foot process formation, underscoring a vital role for *Tcf21* in normal podocyte development and function. However, the molecular mechanism(s) by which *Tcf21* regulates podocyte development are not well-understood. To address this gap in knowledge, we performed single cell RNA sequencing (scRNAseq) of kidneys from mice with *Tcf21* deletion.

Methods: *Tcf21* was deleted from podocyte precursors at the S-shaped stage of glomerular development using Cre recombinase driven by the *Pax8* promoter. 2 mutant mice and 2 littermate controls were euthanized at 2 weeks of age, and their kidneys were subjected to single cell digestion. 20,000 cells were captured from each of the 4 samples for scRNAseq. Library preparation was completed, and the samples are awaiting sequencing.

Results: Mutant mice had substantial proteinuria (100-500 mg/dL versus negative to trace urine protein for littermate controls). On histology, proximal tubular protein reabsorption droplets were noted in kidneys of both mutant mice, and glomerular crescent formation was noted in the kidney of one mutant mouse. Kidneys from control mice appeared normal. The mutant mice did not have significant glomerulosclerosis, suggesting that podocyte injury was still in its early stages. ScRNAseq will be used to determine changes in expression of podocyte structural genes, GBM genes, and transcription factors after *Tcf21* deletion. The CellChat package in R will be used to identify changes in how mutant podocytes interact with surrounding glomerular cells.

Conclusions: *Tcf21* deletion from podocyte precursors caused proteinuria and severe defects in podocyte development. ScRNAseq is a first step to unravel the molecular mechanism(s) by which *Tcf21* regulates podocyte structure and the interaction of podocytes with other glomerular cells. Ultimately, understanding the mechanisms that are required for normal podocyte structure and function will also help us understand how podocytes become dysregulated in disease states.

Effects of Sex and Kidney Mass on Podocyte Density in Rats

Patrick S. Means,[1] Blakeley D. Griffin,[1] Suzanna Camp,[1] Jacqueline M. Chivers,[1] Christian C. Story,[1] Purva R. Chopde,[4] Geoffrey A. Williamson,[4] Karen A. Griffin,[2,3] Aaron J. Polichnowski.[1]
[1]East Tennessee State University James H Quillen College of Medicine, Johnson City, TN; [2]Loyola University Chicago Stritch School of Medicine, Chicago, IL; [3]Edward Hines Junior VA Hospital, Hines, IL; [4]Illinois Institute of Technology, Chicago, IL.

Background: Chronic kidney disease (CKD) progresses faster in males; however, the underlying mechanisms are not well understood. We investigated sex differences in podocyte density in rats with intact kidneys and uninephrectomy (UNX) to understand its potential role in the sex disparity in CKD progression.

Methods: Sprague-Dawley rats (10-13-week-old) underwent UNX (n=8/sex) or sham UNX (n=8/sex). Six weeks later, kidneys were perfusion-fixed and podocytes were detected using Wilms' Tumor 1 1° Ab, Cy-3 2° Ab, and DAPI. Podocyte density was assessed in 20 glomeruli/left kidney/rat in a blinded fashion according to Venkatareddy et al. (PMID 24357669). Data were compared using a 2-way ANOVA with Sidak post hoc analysis and linear regression. Data are mean±SE, and P<0.05 was considered statistically significant.

Results: As shown in Table 1, body weight, kidney weight, and glomerular tuft volume were greater (P<0.05) in male vs. female rats within both intact and UNX groups. Within both sexes, kidney weight and glomerular tuft volume, but not body weight, were greater (P<0.05) in UNX vs. intact groups. No significant differences in the total number of podocytes per glomerular tuft were observed between sexes or between intact and UNX groups. On average, podocyte density was ~10% lower in males vs. females and ~17% lower in UNX vs. intact groups. As shown in Figure 1, a robust correlation (P<0.05) was observed between podocyte density and glomerular tuft volume, but not the total number of podocytes per glomerular tuft.

Conclusions: Sex differences in podocyte density are largely dependent on sex differences in kidney size and glomerular tuft volume, which may contribute to the sex disparity in the rate of CKD progression.

Funding: Other NIH Support - NHLBI

Table 1

Group	Body Weight (grams)	Kidney Weight (grams)	Glomerular Tuft Volume ($\mu m^3 \times 10^6$)	Total Number of Podocytes per Glomerular Tuft	Podocyte Density (podocytes / 10^6 μm^3)
Intact					
Female (n=8)	321 ± 13	1.4 ± 0.1	1.2 ± 0.1	142 ± 7	120 ± 8
Male (n=8)	503 ± 18[#]	2.3 ± 0.1[#]	1.6 ± 0.1[#]	157 ± 5	101 ± 3[#]
UNX					
Female (n=8)	324 ± 12	2.3 ± 0.1*	1.5 ± 0.1*	143 ± 7	94 ± 5*
Male (n=8)	525 ± 9[#]	3.6 ± 0.1*[#]	1.8 ± 0.1*[#]	162 ± 6	89 ± 4

Data are mean ± standard error. [#] P<0.05 vs. respective female group; * P<0.05 vs. respective intact group. UNX = uninephrectomy.

Protective Role of Active Vitamin D in Transforming Growth Factor (TGF)-β1-Associated Podocyte Injury through Inhibition of p21 Upregulation

Takehiko Wada,[1] Kaichiro Sawada,[2] Hirotaka Komaba,[2] Masafumi Fukagawa.[2]
[1]Toranomon Hospital, Tokyo, Japan; [2]Tokai University School of Medicine, Isehara, Japan.

Background: Podocyte cell death is closely associated with proteinuria-related kidney diseases and the progression of glomerulosclerosis. Transforming growth factor-β1 (TGF-β1) has long been recognized as a key player in the pathogenesis of diabetic kidney disease (DKD). Our previous studies have demonstrated that the cell cycle regulatory protein p21 is involved in this process. However, therapeutic approaches to inhibit this pathway have not been developed.

Methods: To confirm the albuminuria-suppressing effects of active vitamin D, we utilized a streptozotocin-induced diabetic mouse model. These mice were administered paricalcitol, an active form of vitamin D, thrice weekly to observe its effects. *In vitro* experiments using temperature-sensitive mouse podocytes were conducted to assess TGF-β1-induced cell motility and determine cell cycle regulatory molecule expression. We also investigated the change of these expressions in the presence of active vitamin D. Additionally, we evaluated changes in the expression of vitamin D receptors to examine alterations in signaling pathways in the presence of active vitamin D.

Results: Administration of paricalcitol significantly suppressed albuminuria in the DKD model mice. In cultured podocytes, the increased cell motility induced by TGF-β1 in the scratch assay was inhibited in the presence of paricalcitol. Under these conditions, examination of the expression of cell cycle regulatory proteins revealed that TGF-β1 stimulation led to an increased expression of p21, which was suppressed when paricalcitol was present. Additionally, paricalcitol was found to enhance the mRNA expression of the vitamin D receptor, suggesting a potential positive feedback mechanism in vitamin D signaling in podocytes.

Conclusions: Active vitamin D exerts a protective effect against TGF-β1-induced podocyte injury in DKD, potentially through the suppression of p21 induction.

Loss of Vasorin (VASN) Promotes Podocyte Cell-Cycle Reentry and Dedifferentiation: A Novel FSGS Mechanism and Disease Modifier?

Pierre-Louis Tharaux,[1,2] Julien Dang,[1] Nassim Mahtal,[1] Anis Chaba,[1] Alexandre Karras,[1,3] Nicole Endlich,[4,5] Olivia Lenoir.[1,2] *[1]Paris Centre de Recherche Cardiovasculaire, Paris, France; [2]Universite Paris Cite UFR de Medecine, Paris, France; [3]Hopital Europeen Georges Pompidou, Paris, France; [4]Universitatsmedizin Greifswald, Greifswald, Germany; [5]NIPOKA GmbH, Greifswald, Germany.*

Background: Podocyte loss of quiescence contributes to focal segmental glomerulosclerosis (FSGS) and crescentic glomerulonephritis (CGN). Here, we characterized the role of Vasorin (VASN), a protein highly expressed in mature podocytes.

Methods: We combined laser capture microdissection with RNA sequencing of human glomeruli, RNAscope-based *in situ* hybridization, immunostaining, and mouse models with selective targeting of the *Vasn* gene in podocytes and cultures of human podocytes.

Results: VASN mRNA is strongly expressed in healthy human and mouse glomeruli with a podocyte-specific pattern. Both global and podocyte-specific, constitutive or inducible gene deletion of *Vasn* in mice induced nephrotic syndrome and kidney failure after day 14, with podocyte dedifferentiation and loss and severe FSGS, indicating a fundamental role of VASN in podocyte homeostasis. Furthermore, we measured markedly decreased VASN expression in podocytes of patients with FSGS and ANCA-associated CGN but not with Minimal Change Disease and Membranous Nephropathy. We then wondered whether VASN abundance could be a disease modifier. Mice with podocyte-specific heterozygous deletion of *Vasn* displayed accentuated podocyte loss, albuminuria, and kidney failure when challenged with diabetes or CGN experimental models. Human podocytes transduced with lentiviral VASN-targeting shRNA (shVASN) displayed increased focal adhesion dynamics, enhanced migratory capacity, and epithelial-mesenchymal transition (EMT). shVASN podocytes had a higher proliferative capacity and increased cell-cycle reentry. Accordingly, shVASN podocytes and isolated mouse VASN-deficient glomeruli displayed up-regulation of genes involved in cell metabolism, adhesion, and EMT and down-regulation of genes involved in the S to G2/M phase transition. We confirmed that VASN deficiency increased podocyte proliferation *in vivo* and urinary shedding.

Conclusions: These findings indicatte the role of VASN as an essential master protein that maintains podocyte quiescence and homeostasis during health and kidney diseases. VASN controls mechanisms driving podocyte cell-cycle reentry and detachment, promoting extracapillary diseases. VASN expression level may also discriminate various glomerular diseases trajectories.

FR-PO733

The Role of Combinatorial Inflammatory and Senescence-Associated Secretory Phenotype (SASP) Signaling Pathways in Podocyte Aging

Jana Sharara,[1] Jeffrey W. Pippin,[2] Alexander A. Zarouk,[1] Uyen Tran,[1] Stuart J. Shankland,[2] Oliver Wessely.[1] *[1]Cleveland Clinic, Cleveland, OH; [2]University of Washington, Seattle, WA.*

Background: Podocytes play a pivotal role in maintaining the integrity and function of the glomerular filtration barrier. In the aged kidney, podocytes undergo shortened lifespan and reduced health-span, characterized by altered morphology, decreased cellular proliferation, and impaired function. This age-associated podocyte senescence could contribute to the decline in renal function observed in elderly individuals and increase susceptibility to various renal pathologies. Previous findings show that multiple inflammatory and senescence-associated secretory phenotype (SASP) pathways are upregulated in aged and injured podocytes. We hypothesize that these pathways contribute to decline in podocyte function via autocrine and paracrine signaling.

Methods: To investigate the numerous inflammatory and SASP pathways upregulated in podocyte aging/injury, a classic one-factor-at-a-time approach which tests each pathway individually is impractical and also does not consider synergistic interactions. To holistically address the complexity of the aging and injury secretome, our study implements a Design-of-Experiment (DoE) approach. In this approach, all inflammatory and SASP pathways are altered simultaneously through computer-generated experiments to obtain optimal results and quality. This allows us to directly identify which specific combination of inflammatory cytokines and SASP proteins secreted from aged/injured podocytes are causally involved in altered podocyte function.

Results: We performed DoE approaches in well-characterized young and aged primary mouse podocytes. We interrogated 13 different antagonists to various inflammatory and SASP pathways and studied two outcomes, apoptosis and senescence. The DOE identified pathways with the most robust pro- and anti-aging and injury responses. These specific combinations were then characterized and analyzed, using a more traditional approach by assessing the inflammatory/aging phenotype with mRNAseq, qPCR, and immunohistochemistry.

Conclusions: The DoE approach provides a comprehensive understanding of the interplay between inflammatory and SASP pathways in podocyte aging and disease. It offers potential targets for therapeutic intervention that may lead to the development of novel treatments to preserve kidney function in the elderly.

Podocyte Cell Cycle in Aging

Laura Perin,[1,2] Xiaogang Hou,[1] Valentina Villani,[1] Charmi Dedhia,[1] Paola Aguiari,[1] Roger E. De Filippo,[1,2] Kevin V. Lemley.[1,2] *[1]Children's Hospital Los Angeles, Los Angeles, CA; [2]University of Southern California, Los Angeles, CA.*

Background: Glomerulosclerosis is a prominent pathologic change of aging kidneys associated with hypertrophy and loss of podocytes. Podocytes are quiescent cells, but under a pathological state, they re-enter the cell cycle which promotes their loss when they cross the G1/S checkpoint. Here we study how the podocyte cell cycle phases change during aging in male vs female mice.

Methods: We established a FUCCI mouse (fluorescent ubiquitination-based cell cycle indicator) with fluorescent reporters exclusively in podocytes (Pod/FUCCI) to study cell cycle dynamics during aging in male and female mice. We analyzed n=8 males and n=12 females at 2-4m; n=17 males and n=15 females at 1 year, and n=29 males and n=24 females at 2 years of age. Podocytes were isolated by flow cytometry based on their cell cycle phase and podocyte loss was quantified by WT1 staining for all the time points. RNA seq was performed to study transcriptomics changes in podocytes at different cell cycle phases (G0 vs G1) at different ages.

Results: Podocyte number per glomerulus decreased during aging and podocyte loss was accompanied by an increase in glomerular size (hypertrophy) both in males and females. Flow cytometry results showed that in males, 92% of the podocytes at 4m were in G0 compared to 83% at 1 year and 81% at 2 years, while podocytes in the G1 phase increased from 4% at 4m to 12% and 17% at 1 year and 2 years, respectively. In female mice, 90% of podocytes were in G0 at 4m compared to 91% at 1 year and 79% at 2 years, 8% of the podocytes were in G0 at 4m compared to 3.5% and 17% at 1 year and 2 years, respectively. Sequencing results indicate that important molecular singling regulate the entrance in G1 phase, especially at later ages and that these signalings are different between males and females, highlighting the importance of sex differences related to the regulation of podocyte cell cycle phases.

Conclusions: Our data confirm, for the first time, that changes in podocyte cell cycle during aging differ between males and females, especially in relation to the G1 phase. Understanding the mechanisms that regulate cell cycle progression will help to identify new pathways that can be targeted to prevent podocyte loss and kidney disease accounting for sex differences.

FR-PO735

Extracellular Vesicle and Modulation of miR-93 in Kidney Diseases

Laura Perin,[1,2] Charmi Dedhia,[1] Valentina Villani,[1] Xiaogang Hou,[1] Paolo Neviani,[1] Geremy Clair,[3] Velia Alcala,[1] Paola Aguiari,[1] Giuseppe Orlando,[4] Roger E. De Filippo,[1,2] Stefano Da Sacco,[1,2] Benedetta Bussolati,[5] Sargis Sedrakyan.[1,2] *[1]Children's Hospital Los Angeles, Los Angeles, CA; [2]University of Southern California, Los Angeles, CA; [3]Pacific Northwest National Laboratory, Richland, WA; [4]Atrium Health Wake Forest Baptist Medical Center, Winston-Salem, NC; [5]University of Torino, Torino, Italy.*

Background: Modulation of miRNA expression in glomerular cells is associated with renal disease. MiR-93, a potent regulator of glomerular damage, is downregulated in glomeruli of mice with Alport syndrome (AS, a renal disease characterized by a mutation in *col4a5* gene) and in glomeruli of AS patients. Here, we investigated the role of extracellular vesicles (EVs) from human amniotic fluid stem cells (hAFSC) in disease-modifying activity in vitro and in vivo by regulation of miR-93 and its targets.

Methods: AS and WT glomeruli were characterized by bulk RNA-seq. hEVs, isolated by ultracentrifugation, were characterized by Exoview, TEM, super resolution microscopy, miRNA-seq, and proteomics. Expression of miR-93 was silenced in hEVs using a specific miR-93 antigomiR (KD-hEVs). Transfer and modulation of miR-93 (and its targets) in human glomerular cells was evaluated in vitro. hEV disease-modifying activity was evaluated by bulk RNA-seq in vitro, in AS mice by biodistribution, renal function, survival, and by spatial transcriptomics (ST) using the Visium 10X Genomics. Data were confirmed in AS patient biopsy using CosMX SMI (Nanostring).

Results: Glomerular endothelial cells are responsible for downregulation of miR-93 along disease progression. RNA-seq revealed alteration of miR-93 targets in AS glomeruli. Cell damage decreased expression of miR-93 and its targets, which were prevented by normal hEVs and not by KD-hEVs. hEV proteomics and miR-seq identified specific cargo and pathways central to disease progression. When injected in AS mice, hEVs localized in the kidney, ameliorated proteinuria, and prolonged lifespan compared to KD-hEVs. ST data showed that hEV injection upregulated important pathways responsible for glomerular regeneration, slowing down AS progression. Analysis of CosMX SMI also showed alteration of miR-93 targets in human AS patients.

Conclusions: hEVs modulated pathways that are central to glomerular homeostasis and improved kidney function by miR-93 transfer. These data suggest hEVs and modulation of miR-93 signaling might be important in translational settings.

FR-PO736

Senescent Podocytes in Human Obesity Release Urinary Extracellular Vesicles (uEVs)

Mina H. Al Saeedi, Xiang yang Zhu, Aleksandar Denic, Andrew D. Rule, Li Xing, Lei Zhang, Hui Tang, Kyra L. Jordan, Amir Lerman, Mary E. Fidler, Aleksandra Kukla, Lilach O. Lerman. Nephrology and Hypertension. *Mayo Foundation for Medical Education and Research, Rochester, MN.*

Background: Obesity induces cellular senescence, which is implicated in renal disease progression. Senescent cells are characterized by the expression of senescence markers like P19, a cyclin-dependent kinase inhibitor, and possibly pro-inflammatory monocyte chemoattractant protein (MCP)-1. However, whether podocytes marked by podocalyxin (Podxl)+ undergo senescence in obesity is unclear. We hypothesized that patients with obesity show elevated levels of P19+/Podxl+/MCP1+ uEVs suggestive of podocyte senescence

Methods: Blood and urine samples were collected from 21 obese (OB) and 10 lean subjects for uEVs quantification (NanoSight) and characterization (Flow Cytometry) for P19, Podoxl, and MCP1 expression (Fig1). Their fraction out of total uEVs was correlated with body mass index (BMI), urinary protein, kidney injury molecule (KIM)-1, and insulin levels

Results: OB subjects had elevated BMI but preserved renal function (Table). The total uEV number was similar in OB and lean, but the fractions of P19+/Podxl+ and P19+/Podoxl+/MCP1+ uEVs were higher in OB and directly correlated with BMI. P19+/Podoxl+/MCP1+ uEVs also correlated with urine protein, KIM1, and insulin levels (Fig2)

Conclusions: Senescent podocytes in obese subjects with preserved renal function shed uEVs in proportion to obesity severity. The uEVs fraction shed by a subset of inflamed (MCP1+) senescent podocytes further correlates with renal injury markers. These may serve as early markers of glomerular senescence and guide the management of patients with obesity

Funding: NIDDK Support, Other NIH Support - DK120292 (NIDDK) and HL158691 (National Heart, Lung, and Blood Institute)

FR-PO737

Role of Cargo Receptor Surf4 in Podocyte Proteostasis

Andrey V. Cybulsky, Joan Papillon, Christian-Landry Konde Bilogui. *McGill University, Montreal, QC, Canada.*

Background: Protein misfolding in the endoplasmic reticulum (ER) of podocytes/glomerular epithelial cells (GECs) induces ER stress, and contributes to the pathogenesis of glomerular diseases. The unfolded protein response (UPR) and autophagy may be activated to sustain proteostasis. In GECs during ER stress, the COPII vesicle component Sec23B localizes in autophagosomes along with collagen IV-α5 (COL4A5). Thus, the secretory pathway is redirected to ERphagy (ER-specific autophagy), with COL4A5 being a potential ERphagy substrate. In GECs, ERphagy was facilitated by the activation of the UPR transducer IRE1α. Discovery proteomics in GECs exposed to ER stress showed that IRE1α facilitated expression of Surf4, an ER-COPII vesicle cargo receptor. The present study examines whether Surf4 may redirect misfolded proteins for autophagosomal degradation.

Methods: We studied IRE1α-replete (control) GECs in culture and GECs with genetic knockout (KO) of IRE1α. Immunofluorescence microscopy was used to quantify autophagosome number/area by setting a suitable particle size/threshold.

Results: Basal Surf4 expression was greater in control compared to IRE1α KO GECs. During ER stress induced with tunicamycin (TM), there was activation of the UPR, although Surf4 did not increase above basal levels. TM increased LC3-II and Surf4 particle areas, as well as colocalization of LC3 and Surf4; increases were smaller in KO GECs compared to control. Thus, during ER stress, a subset of Surf4 localizes in autophagosomes. TM increased COL4A5 particle area and colocalization of Surf4 with

COL4A5 in control and KO GECs, implying that during ER stress, some of the COL4A5 localizes in autophagosomes. The GEC toxin adriamycin (ADR) induced autophagy (LC3-II), but not the UPR. Unlike TM, ADR did not promote localization of Surf4 or COL4A5 in autophagosomes. However, both TM and ADR could enhance colocalization of LC3-II and Hsp60 (a mitochondrial protein), consistent with mitophagy. Analysis of a human glomerular gene expression dataset showed increased Surf4 and UPR gene expression in membranous nephropathy and focal segmental glomerulosclerosis compared to healthy controls.

Conclusions: During ER stress, Surf4 is redirected from the secretory pathway to autophagosomes. Surf4 may help deliver misfolded ER cargo such as COL4A5 for degradation. This represents a novel role for Surf4 in sustaining proteostasis.

FR-PO738

Synergistic Effects of Endoplasmic Reticulum-Associated Degradation and Autophagy in Podocyte Function

Xiaoqiong Wei, Ling Qi. *University of Virginia, Charlottesville, VA.*

Background: Podocytes are specialized epithelial cells, key to the kidney glomerular filtration barrier, through which the blood is filtered by forming interdigitating foot processes with neighboring podocytes. The slit diaphragm is a specialized cell junction composed of multiple proteins including nephrin to connect foot processes. Impaired biosynthesis of these proteins leads to foot process effacement and renal failure. Endoplasmic reticulum (ER)-associated degradation (ERAD) and autophagy are two major protein quality-control machineries to maintain protein homeostasis. However, the crosstalk between these two quality-control systems has not yet been investigated in the podocyte function.

Methods: The podocyte-specific Sel1L and Atg7 double knock-out mice (DKO) were generated. Mouse body weight and survival curves were recorded. Urine samples from mice at 1, 3, and 5 weeks of age were collected to assess the abundance of albumin. Kidneys from wild-type (WT), Sel1L knock-out, Atg7 knock-out and DKO mice were collected for histology examination by H&E staining, ultrastructure observation via scanning electron microscopy (SEM) and transmission electron microscopy (TEM), as well as determination of abundance and cellular location by immunofluorescence staining and western blot.

Results: DKO mice exhibited severe early onset renal failure at 3 weeks of age and premature death as early as 6 weeks of age, while Sel1L knock-out mice died with a median life span of ~14 weeks. Atg7 knock-out mice were normal like WT mice until 1 year of age. At 3 weeks of age, large protein casts were only observed in the renal tubules of DKO mice. SEM and TEM revealed that DKO mice developed effaced foot process much earlier than Sel1L knock-out mice. Mechanismlly, nephrin, an ERAD substrate, accumulated in the ER of Sel1L-deficient podocytes. In the absence of ERAD, ATG7 deficiency increased nephrin accumulation in the ER, further impairing its trafficking to the cell membrane.

Conclusions: ERAD and autophagy synergistically regulate podocyte function. Deficiencies in ERAD and autophagy lead to podocyte foot process effacement and subsequent renal failure by affecting nephrin maturation and cell membrane trafficking.

Funding: NIDDK Support

FR-PO739

Mechanisms and Implications of Podocyte Autophagy in Alport Syndrome

Rachel Njeim, Maria Ficarella, Antonio M. Fontanella, Haley Gye, Jin Ju Kim, Alla Mitrofanova, Hassan Ali, Sandra M. Merscher, Alessia Fornoni. *University of Miami Miller School of Medicine, Miami, FL.*

Background: Alport syndrome (AS) is a hereditary disease affecting the glomerular basement membrane, leading to renal fibrosis and end stage renal disease. We have previously shown that the accumulation of lipid droplets (LD) in podocytes contributes to the pathogenesis of proteinuric kidney diseases, including AS. Chaperone-mediated autophagy (CMA) is a selective lysosomal pathway for the degradation of cytosolic proteins. Recent studies suggest that CMA also plays a crucial role in LD breakdown, a process termed chaperone-mediated lipophagy (CML). We hypothesized that dysregulated autophagy in AS exacerbates LD accumulation in podocytes, thus driving disease progression.

Methods: Publicly available CKD and AS patient RNASeq datasets (NephroSeq, GSE134011) were used to analyze differential gene expression of various autophagy markers. Autophagy genes were determined by QRT-PCR and Western blot analysis of proteins isolated from kidney cortices and immortalized podocytes derived from wildtype (WT) and Col4a3 knockout (AS) mice. To investigate lipophagy, podocytes were treated with Lalistat, a lysosomal acid lipase inhibitor, and LD accumulation was assessed. Unbiased phenotypic profiling (Cell Painting) will be employed to further investigate the role of autophagy in WT and AS podocytes treated with autophagy inducers.

Results: Transcriptomic analysis showed altered expression of various autophagy genes. LD accumulation was significantly increased in AS compared to WT podocytes. PLIN2 protein expression was significantly increased in LD isolated from AS compared to WT podocytes. mRNA and protein expression of the rate-limiting enzyme of CMA, LAMP2A, was significantly increased in AS podocytes and in kidney cortices of AS mice, suggesting activation of CML. LC3II/I and GATE16 expression were significantly increased and p62 significantly decreased in AS, further supporting activation of autophagy in AS. Treatment of AS podocytes with Lalistat further increased LD accumulation in AS podocytes, indicating that lipophagic flux is efficient in AS podocytes and that the observed LD accumulation may be attributed to lysosomal LD accumulation.

Conclusions: Taken together, our findings suggest that autophagy and CML are functional in AS but are not sufficient to reduce LD accumulation and prevent podocyte lipotoxicity.

Extracellular Vesicles Rebalance Glomerular Endothelial Lipid Metabolism in CKD

Sargis Sedrakyan,[1,2] Hasmik Soloyan,[1] Geremy Clair,[3] Janielle M. Cuala,[2] Hripsime Chomoyan,[1] Qi Zhang,[1] Matthew E. Thornton,[2] Senta K. Georgia,[1,2] Paolo Cravedi,[4] Andrea Angeletti,[5] Roger E. De Filippo,[1,2] Stefano Da Sacco,[1,2] Laura Perin.[1,2] *[1]Children's Hospital Los Angeles, Los Angeles, CA; [2]University of Southern California Keck School of Medicine, Los Angeles, CA; [3]Pacific Northwest National Laboratory, Richland, WA; [4]Icahn School of Medicine at Mount Sinai, New York, NY; [5]Istituto Giannina Gaslini, Genova, Italy.*

Background: Chronic kidney disease (CKD) affects more than 10% of the population worldwide, and our understanding of the mechanisms in many forms of CKD are poorly understood. Alport syndrome (AS), is a form of CKD caused by mutations in the collagen IVα3, α4, or α5 gene. Even though injury to glomerular endothelial cells (GEC) in AS is well established, the role of GEC in Alport progression has not been elucidated. Here, we describe the role of mitochondria and lipid metabolism in GEC injury in an animal model of AS, and the potential of using amniotic fluid stem cell (AFSC) derived extracellular vesicles, (EVs) as a rescue strategy to restore glomerular homeostasis.

Methods: The phasor approach to fluorescent lifetime imaging microscopy (FLIM) and flow cytometry was applied to evaluate the mitochondria and metabolic changes in GEC in AS vs WT mice. GEC isolated by FACS from Tek-tdT reporter AS and WT mice were compared by bulk RNA-seq, lipidomic and flow cytometric analysis. In vitro, silencing experiments on primary human primary GEC were performed to study the role of fatty acid synthase (FASN) in mitochondrial dysfunction and GEC damage. FASN-carrying AFSC-EVs and control EVs were applied both *in vitro* and *in vivo* to restore lipid homeostasis in GEC.

Results: FLIM studies showed strong correlation between the metabolic state of GEC and the age and severity of disease in AS mice. RNA-seq analysis revealed changes in the pathways associated with lipid metabolism and mitochondria function. Mitochondrial dysfunction was confirmed using flow cytometric analysis of the MitoTracker signal in tdTomato expressing GEC. Lipidome analysis revealed high abundance of triglycerides in AS GEC. We confirmed accumulation of lipid droplets in the glomeruli of AS mice and in FASN KO human primary GEC, *in vitro*. These results suggest potential mitochondrial dysfunction in GEC. AFSC derived EV treatment restored lipid homeostasis in GEC, both in vitro and in vivo.

Conclusions: We report for the first-time mitochondrial dysfunction in Alport GEC, and the ability of AFSC-derived EVs to rescue this phenotype. Better understanding of the metabolic changes in AS GEC could lead to the development of targeted new therapies also for other forms of CKD.

APOM Deficiency Affects Kidney Function in an Experimental Mouse Model of Alport Syndrome

Judith T. Molina David, Matthew Tolerico, Jin Ju Kim, Antonio M. Fontanella, Arianna Carrazco, Sandra M. Merscher, Alessia Fornoni. Katz Family Div of Nephrology and Hypertension/Peggy and Harold Katz Family Drug Discovery Center. *University of Miami Miller School of Medicine, Miami, FL.*

Background: We have previously reported that glomerular APOM deficiency correlates with eGFR in patients with glomerular diseases enrolled in the Nephrotic Syndrome Study Network (NEPTUNE). However, little is known about the significance of APOM deficiency in kidney disease development and progression. With this study, we investigate if APOM deficiency occurs in Alport Syndrome (AS) and how ApoM deficiency may contribute to disease progression. We first analyzed glomerular APOM expression in a mouse model of progressive renal disease associated with AS (Col4a3 KO mice) and in podocytes isolated from Col4a3 KO mice. We found reduced mRNA and protein expression of APOM in glomeruli and podocytes isolated from Col4a3 KO mice.

Methods: To investigate if APOM replenishment would improve renal function in this mouse model, we injected Col4a3 KO mice with human recombinant APOM

(rhAPOM). Three groups of mice were studied, n=6 mice per group: (1) Col4a3 +/+ (WT) + vehicle, (2) Col4a3 -/- (KO) + vehicle, and (3) Col4a3 -/- (KO) + rhAPOM. rhAPOM was administered by weekly ip injection starting at 4 w of age and until sacrifice at 8 w of age. APOM protein levels in podocytes were measured by Western blot analysis. Serum and urine samples were used to determine blood urea nitrogen (BUN), creatinine, and urinary albumin/creatinine ratios (ACR). Triglyceride content (TG) was assayed using a colorimetric kit and lipid droplets (LD) content was using the OPERA screening system. Histological analysis was performed by Periodic Acid Schiff (PAS), renal fibrosis was evaluated by Picro Sirius Red (PSR), renal lipid content was determined by Oil Red O (ORO) and WT1 to detect podocytes number.

Results: Glomerular APOM mRNA and protein expression were markedly reduced in Col4a3 KO mice when compared to WT mice. Treatment of Col4a3 KO podocytes with rhAPOM reduce TG levels and LD content and treatment of Col4a3 KO mice with rhAPOM normalized renal APOM levels and resulted in a significant reduction of serum BUN and creatinine levels, a reduced ACR.

Conclusions: rhAPOM treatment protected from the development of glomerulosclerosis and kidney fibrosis.

FR-PO742

Impact of Glomerular Basement Membrane Stiffness on Podocyte Metabolism in Alport Syndrome

Jin Ju Kim,[1,2] Maria Ficarella,[1,2] Judith T. Molina David,[1,2] Flavia Fontanesi,[3] Sandra M. Merscher,[1,2] Jeffrey H. Miner,[4] Alessia Fornoni.[1,2] *[1]University of Miami Katz Family Division of Nephrology and Hypertension, Miami, FL; [2]Peggy and Harold Katz Drug Discovery Center, University of Miami, Miller School of Medicine, Miami, FL; [3]University of Miami Miller School of Medicine Department of Biochemistry, Miami, FL; [4]Washington University School of Medicine, Division of Nephrology, St. Louis, MO.*

Background: Cells utilize mechanotransduction to sense mechanical cues, which regulate behaviors like proliferation and apoptosis. These pathways are linked to metabolic processes, with ECM stiffness influencing cellular metabolism and cytoskeletal integrity. Stiff ECM promotes glycolysis, while soft ECM suppresses it, affecting glucose utilization. Key pathways involve phosphofructokinase 1(PFK1) in glycolysis and tripartite motif-containing protein 21(TRIM21) in protein degradation, with TRIM21 activity inhibited by actin-mediated sequestration. In Alport Syndrome(AS), mutations in type IV collagen genes lead to a softer, more degradable glomerular basement membrane(GBM) composed of α112 chains of collagen IV. This study investigates the impact of GBM stiffness on podocyte metabolism and structure, focusing on stressfiber formation and mitochondrial function.

Methods: Immortalized AS and WT podocytes were created by breeding Col4a3KO mice with H-2kb-tsA58 transgenic mice, then cultured on soft(1.5 kPa) and stiff(10-12 kPa) gelatin hydrogel matrices. Mitochondrial respiration was measured using a high-resolution respirometer. CPT1A, PFK1, and TRIM21 expression were assessed via western blot. Mitochondrial function was evaluated through ATP production and mitochondrial membrane potential(MMP) assays. Stress fiberformation and TRIM21 colocalization were analyzed using immunofluorescence microscopy.

Results: Fatty acid oxidation(FAO) was significantly increased in AS podocytes compared to WT podocytes($P<0.05$), with higher CPT1 expression in AS podocytes. Actin cytoskeleton rearrangement was observed in WT podocytes on soft matrices compared to stiff matrices. Mitochondrial function was impaired in AS podocytes, as indicated by reduced ATP production($P<0.05$) and decreased MMP($P<0.01$). Decreased PFK1 and increased TRIM21 activity were observed in podocytes on soft matrices, suggesting suppressed glycolysis and enhanced protein degradation and stress response.

Conclusions: Changes in GBM stiffness in AS mice may lead to a metabolic shift in podocytes from glycolysis to fatty acid oxidation, reduced stress fibers, and impaired mitochondrial function. These findings underscore the importance of ECM stiffness and related mechanotransduction pathways in developing treatments for AS and potentially other glomerular diseases.

FR-PO743

Identification of Novel Therapeutic Targets for Alport Syndrome Using Near Super-Resolution Imaging of Podocytes

Kaye E. Brathwaite, Queen Polin, Pongpratch Puapatanakul, Chengqing Qu, Hani Suleiman, Jeffrey H. Miner. *Washington University in St Louis, St Louis, MO.*

Background: Alport Syndrome is a rare disease currently without a cure. It is characterized by hematuria and proteinuria and eventual ESKD. Obtaining a deeper understanding of the alterations to the cytoskeletal architecture of podocytes from their interactions with the abnormal glomerular basement membrane (GBM) in Alport syndrome is one promising approach to identify novel therapeutic targets. Sarcomere-like structures (SLSs), are intertwining actin and myosin that form in areas of podocytes where foot processes become effaced. We hypothesize that SLSs are different in frequency in Alport mouse podocytes compared to COL4A3 rescued mouse podocytes.

Methods: We performed magnified analysis of proteome (MAP) expansion microscopy of kidneys from wild type, Alport and rescued mice. Col4a3-/- Alport mice are rescued using a doxycycline-inducible Col4a3 transgene in podocytes, which normalizes the GBM and extends the time to ESKD. Doxycycline was started at 2 or 6 weeks of age and mice sacrificed 6 weeks later. Incubating paraffin embedded tissue in a high concentration of acrylamide, we expanded mouse kidney tissue near 4 times its original size. Antibody staining with synaptopodin and myosin was performed on expanded kidney sections. Airyscan confocal microscopy was used to image SLSs and images were analyzed using the ImageJ software.

Results: Airyscan was used to demonstrate sarcomere-like structures (SLSs) in our mouse models. The percentage of the capillary wall covered with SLS was determined using the ImageJ software to identify alternating synaptopodin and myosin. Sarcomere-like structures were significantly less in mice rescued at 2 weeks compared to Alport mice. SLS were also less in mice induced at 2 weeks compared to those at 6 weeks of life. SLS were more organized throughout glomerular capillary loops in rescued mouse podocytes compared to Alport mouse podocytes.

Conclusions: SLS are significantly reduced in podocyte foot processes in Alport mice successfully rescued at 2 weeks of life compared to those induced at 6 weeks of life. Utilizing restoration of the GBM in the inducible rescue mice to study its impact on podocyte cytoskeletal architecture, could provide the key to understanding mechanisms at play in maintenance of foot processes and the glomerular filtration barrier in Alport syndrome.

FR-PO744

Genetic NRF2 Activation Worsens Kidney Injury in an Alport Syndrome Mouse Model

Desmond Ng,[1,2] Hannah L. Hartman,[1] Hsuan Yeh,[1] Josie Gilbert,[1] Joy A. Stewart,[1] Corry D. Bondi,[1] Jeffrey H. Miner,[4] Roderick J. Tan.[1,3] *[1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]Carnegie Mellon University, Pittsburgh, PA; [3]US Department of Veterans Affairs, Washington, DC; [4]Washington University in St Louis School of Medicine, St Louis, MO.*

Background: Alport syndrome (AS) is caused by mutations in type IV collagen, resulting in abnormal glomerular basement membrane, proteinuria, and progressive kidney disease. The KEAP1/NRF2 pathway mitigates cellular damage through upregulation of antioxidant and detoxifying genes. KEAP1 is an endogenous inhibitor of NRF2. Bardoxolone methyl (CDDO-Me) induces NRF2 through disruption of the KEAP1-NRF2 interaction and was tested as a treatment for AS in human clinical trials. While CDDO-Me increased estimated glomerular filtration rate (GFR), it was unclear if CDDO-Me meaningfully altered disease progression. In addition, CDDO-Me exposure was associated with paradoxical worsening of proteinuria. To determine the effects of NRF2 activation in AS, we examined how genetic reduction in *Keap1* expression (hypomorphism) affected AS in a mouse model. We hypothesized that higher NRF2 activity would worsen proteinuria and overall kidney injury in AS.

Methods: AS mice possessing a deletion mutation in *Col4a3* were bred with *Keap1* hypomorphic (HM) mice to generate double mutant *Col4a3*$^{-/-}$ *Keap1*$^{HM/HM}$ progeny. Proteinuria was measured over the course of 30 weeks using an albumin ELISA. GFR was measured through the transdermal measurement of FITC-sinistrin clearance. We performed histology and qPCR for renal injury biomarkers to assess overall injury. We used electron microscopy to examine podocyte foot process effacement and basement membrane ultrastructure.

Results: Consistent with their lower expression of *Keap1*, the double mutant mice exhibited higher expression of *Nrf2* target genes compared to single mutant *Col4a3*$^{-/-}$ mice. The double mutants exhibited significantly more proteinuria throughout the time course and a lower GFR compared to mice with only the *Col4a3*$^{-/-}$ mutation. Double mutants also exhibited more interstitial fibrosis and increased biomarkers of glomerular injury, tubular injury, and inflammation. Electron microscopy revealed extensive foot process effacement and basement membrane thickening that did not differ between groups.

Conclusions: Our findings demonstrate that excessive NRF2 activity worsens AS kidney injury in mice. These findings suggest that NRF2 has deleterious actions in AS and that NRF2 inducers such as CDDO-Me should be avoided in the treatment of this disease.

Dysregulated Glomerular S1P Metabolism Contributes to Glomerular Injury

Antonio M. Fontanella, Matthew Tolerico, Judith T. Molina David, Rachel Njeim, Arianna Carrazco, Haley Gye, George W. Burke, Alla Mitrofanova, Sandra M. Merscher, Alessia Fornoni. *University of Miami Miller School of Medicine, Miami, FL.*

Background: Genetic defects in sphingosine-1-phosphate (S1P) lyase (SGPL1) are associated with steroid-resistant nephrotic syndrome (NS), suggesting a causative role of S1P and aberrant sphingolipid (SL) metabolism in glomerular injury. S1P is a sphingolipid which, in the absence of its carrier, Apolipoprotein M (APOM), causes pro-apoptotic signaling. We demonstrated that altered glomerular APOM and SL related gene expression in patients with glomerular disease correlates with poor renal outcome. Alport Syndrome (AS) is an inherited glomerular disease (GD), most frequently caused by Col4a3 gene mutations, where lipid accumulation is thought to play a role in its pathogenesis. This study aims at investigating the role of APOM deficiency and S1P signaling in renal injury using Alport Syndrome as a model of APOM deficient glomerular disease.

Methods: Publicly available glomerular expression data of SL related genes in glomeruli of CKD patients and in wildtype (WT) and Col4a3 knockout (Col4a3 KO) mice were analyzed. The SL content in renal cortices of the mice was also assessed. Mice were treated with 0.1uM S1P and urine ACR and renal histology were analyzed. Immortalized murine control (IMWT) and Col4a3 KO (IMAL) podocytes, and APOM knockdown (siAPOM) or scramble control (SC) human podocytes were treated with S1P or an Sgpl1 inhibitor. SL related gene expression was analyzed by qRT-PCR and Western blot. Apoptosis was assessed.

Results: Multiple SL related genes, including APOM, showed similar differential expression in glomeruli of patients with NS, in glomeruli of Col4a3 KO mice and in IMAS. Renal cortical S1P content was significantly increased Col4a3 KO and S1P treatment of Col4a3 KO mice, of IMAL and siAPOM podocytes, but not of controls, resulted in increased ACR and apoptosis, respectively.

Conclusions: Our data suggest that aberrant SL metabolism may contribute to glomerular injury. The observation that Col4a3 KO, IMAL and siAPOM but not controls were susceptible to S1P-mediated injury suggests a role for APOM deficiency in this process. Targeting pathways involved in the APOM/S1P signaling axis may represent novel treatment options for patients with glomerular diseases.

Protective Effect of GIT2 against Podocyte Injury in Mice

Jun Matsuda,[1] Naoyuki Shimada,[1] Kana Asano-Matsuda,[1] Maho Tokuchi,[1] Agnieszka Masztalerz,[2] Serge Lemay,[2] Tomoko Takano,[2] Yoshitaka Isaka.[1] *[1]Department of Nephrology, Osaka University Graduate School of Medicine, Suita, Japan; [2]Division of Nephrology, McGill University Health Centre, Montreal, QC, Canada.*

Background: Podocytes have an intricate structure featured by numerous actin-based projections called foot processes (FP). Rho GTPases, including Rac1, play important roles in actin cytoskeletal remodeling required for cell morphology and adhesion. We previously showed that Rac1 activation in podocytes causes FP effacement and proteinuria, but the upstream regulatory mechanism directing Rac1 is largely unknown. Recently, we identified focal adhesion protein GIT2 as one of the Rac1-interacting proteins in immortalized human podocytes, and showed that GIT2 knockdown elicited Rac1 activation.

Methods: The protein and mRNA expression of GIT2 in mice kidney were studied by immunoblotting and *in situ* hybridization, respectively. *Git2*-floxed mice were established using CLICK (CRISPR with long single-stranded DNA inducing conditional knockout alleles). They were then crossed with NPHS2-Cre mice to generate podocyte-specific *Git2* knockout (KO) mice. KO mice and age-matched controls were subjected to the minimal change disease model by lipopolysaccharide (LPS) or the salt-sensitive hypertension model by uninephrectomy (UNx) with deoxycorticosterone acetate (DOCA)/salt.

Results: GIT2 was relatively enriched in glomeruli including podocytes in the kidney. In KO mice, glomerular expression of GIT2 protein was significantly reduced compared with controls. When challenged with LPS, KO mice showed sustained high levels of proteinuria, resulting in a significantly higher urine albumin to creatinine ratio (ACR) at 48hours compared with controls. When treated with UNx-DOCA/salt, systolic blood pressure was increased similarly at day14 in both KO and control mice. While UNx-DOCA/salt induced a significant increase of ACR in both mouse groups, KO mice tended to have more severe proteinuria. Rac1 inhibitor NSC23766 significantly decreased ACR in UNx-DOCA/salt-treated KO mice. Serum UN was significantly increased in UNx-DOCA/salt-treated KO mice compared with controls. In both LPS and UNx-DOCA/salt models, FP effacement was exacerbated in KO mice compared with controls.

Conclusions: In the current study, we demonstrated that GIT2 protects podocytes and glomerular function against injury. GIT2 may become a new therapeutic target on the Rac1 pathway in podocytopathy.

FR-PO747

GIT2 Maintains Podocyte Architecture through Suppressing Rac1 Activity and Focal Adhesion Turnover

Naoyuki Shimada,[1] Jun Matsuda,[3] Maho Tokuchi,[1] Kana Asano-Matsuda,[1] Tomoko Takano,[2] Yoshitaka Isaka.[1] *[1]Department of Nephrology, Osaka University Graduate School of Medicine, Suita, Japan; [2]Division of Nephrology, McGill University Health Centre, Montreal, QC, Canada; [3]Department of Nephrology, Osaka University Graduate School of Medicine, Suita, Japan.*

Background: Podocyte foot processes are supported by the actin cytoskeleton which is precisely organized by Rho GTPases including Rac1. Overactivation of Rac1 in podocytes causes structural changes in foot processes and proteinuria. To elucidate the regulatory mechanism of Rac1, we performed proximity-based ligation assay and identified GIT2 as a Rac1-interacting protein in immortalized human podocytes (HP).

Methods: Subcellular localization of endogenous GIT2 in HP was examined by immunocytochemistry. HP with GIT2 knockdown (KD), GIT2 overexpression (OE) and control (CTRL) cells were established using lentiviral transduction. Rac1 activity was assessed by pull-down assay. Cell areas were quantified in fixed cells stained by phalloidin. Focal adhesion dynamics were analyzed using time-lapse fluorescence microscopy in cells transfected with mRFP-paxillin. Subcellular localization of the tyrosine phosphatase, PTP1B, was monitored using time-lapse fluorescence microscopy.

Results: GIT2 localized with paxillin in focal adhesions. GTP-bound (active) Rac1 levels were significantly higher in GIT2 KD HP than in CTRL. GIT2 KD elicited cell spreading with marked lamellipodial protrusions, which was significantly attenuated by the Rac1 inhibitor NSC23766. GIT2 KD HP had smaller focal adhesions than CTRL. Focal adhesion disassembly rate was significantly higher in GIT2 KD HP, resulting in shorter focal adhesion lifetime. Among the major focal adhesion proteins, tyrosine phosphorylation of p130Cas protein was most prominently increased in GIT2 KD HP, as compared with CTRL. PTP1B localization to focal adhesions was impaired in GIT2 KD HP. The phenotypes observed in GIT2 KD HP shown above were reversed by GIT2 OE.

Conclusions: We demonstrated that GIT2 suppresses Rac1 activity in focal adhesions and contributes to maintaining podocyte morphology and function. Furthermore, we showed that GIT2 facilitates translocation of the PTP1B to focal adhesions where it dephosphorylates p130Cas, thereby suppressing local Rac1 activity.

FR-PO748

Loss of FAM114A1 Attenuates Glomerular Injury by Preserving the Podocyte Cytoskeleton

Norifumi Hayashi,[1,2] Hitoshi Yokoyama,[1] Kengo Furuichi,[1] Laurence H. Beck.[2] *[1]Kanazawa Ika Daigaku, Kahoku-gun, Japan; [2]Boston University, Boston, MA.*

Background: Transcriptomic analysis of microdissected human glomeruli has suggested novel molecular signatures associated with MN by revealing several genes differentially upregulated in MN compared to other glomerular diseases. We focused on a novel protein, Family with sequence similarity 114 member A1 (FAM114A1) that was identified as the top classifier gene in the dataset.

Methods: To detect exact localization of FAM114A1 in glomeruli, we applied immunofluorescence (IF) staining with normal human kidney specimens. Staining area was compared to determine if the expression of FAM114A1 increased at the protein level in human MN and rat passive Heymann nephritis (PHN). We knocked down *FAM114A1* in cultured podocytes by siRNA transfection and conducted functional assays. We investigated protein structure of FAM114A1 in silico. To detect interacting proteins, affinity pulldown assay was performed using FAM114A1-3XFLAG protein and human glomerular extract. To determine the role of FAM114A1 in vivo, we analyzed *Fam114a1* conventional knockout mice and conducted lipopolysaccharide (LPS) -induced albuminuria tests.

Results: IF studies showed the expression of FAM114A1 in the kidney was podocyte-specific and FAM114A1 mainly localized to podocyte primary and foot processes. The expression of FAM114A1 was increased in the human MN and rat PHN model. In cultured podocytes, FAM114A1 was colocalized with F-actin and adhesion molecules. Silencing *FAM114A1* affected podocyte cytoskeletal development and podocyte cell migration. Affinity pulldown screening revealed that FAM114A1 interacts with several cytoskeleton-associated proteins. Mice lacking *Fam114a1* displayed no overt proteinuria and histopathological abnormalities in glomeruli. However, the genetic loss of *Fam114a1* attenuated albuminuria induced by LPS injury.

Conclusions: These findings suggest that glomerular injury can increase FAM114A1 expression which might promote podocyte cytoskeletal disruption. Loss of FAM114A1 could protect against glomerular injury by maintaining podocyte foot process structure.

FR-PO749

Characterization of Rho-Family of Small GTPases Interactome in Podocytes

Sajida Ibrahim, Zachary Nurcombe, Lamine Aoudjit, Jun Matsuda, Thomas M. Kitzler, Tomoko Takano. Takano Lab. *Research Institute of the McGill University Health Centre, Montreal, QC, Canada.*

Background: Podocyte injury is the major cause of proteinuria, a hallmark of kidney diseases and an important risk factor for progression to kidney failure. Rho GTPases play critical roles in podocyte cytoskeleton regulation and their alteration leads to foot process effacement. However, their regulatory mechanisms and signaling networks are largely unknown. Here, we investigated the interactomes of RhoA, Rac1, and Cdc42 in podocytes.

Methods: We defined Rho GTPases interactomes in human podocytes (HP) using the proximity-dependent biotinylation assay (BioID). We generated RhoA guanine nucleotide exchange factors (GEFs) KO lines by CRISPR/Cas9 and KIAA1522 KD zebrafish by morpholinos. We used CRISPR/Cas9 to generate systemic Arhgef6 KO mice then adriamycin and LPS injections to induce FSGS phenotype.

Results: Network analysis revealed that ~50% of the interactions are unique to podocytes while enrichment analyses highlighted biological processes related to cell adhesion and cell shape organization. BioID revealed a large panel of potential effectors, including the uncharacterized protein KIAA1522. We found that KIAA1522 translocates to filopodia in response to Cdc42 activation. KIAA1522 KD in Zebrafish induced pericardial effusion, similar to Nephrin KD. BioID also identified 20 GEFs, eleven of which interacted with RhoA. Analyses of public scRNAseq datasets showed that RhoA regulators are highly enriched in primary human podocytes. KO of the majority of identified RhoA-GEFs reduced podocyte migration, cell size and basal RhoA activity, with ARHGEF12 KO having the highest impact on RhoA activity. In addition, BioID detected ARHGEF6 as a Rac1-specific GEF. Interrogation of public transcriptomic datasets showed that Arhgef6 expression is low in healthy kidneys and increases in glomeruli with FSGS. uACR analysis showed that Arhgef6 KO mice are protected against proteinuria 5 weeks post-ADR and 24h post-LPS injections. KO mice were also resistant to ADR-induced weight restriction.

Conclusions: We dissected for the first time the upstream regulators and downstream effectors of Rho GTPases in podocytes. We identified KIAA1522 as a novel Cdc42 effector. We identified RhoA as a predominant Rho GTPase in podocytes and uncovered its key regulators. Our findings suggest that increased ARHGEF6 expression might be implicated in FSGS progression.

Molecular Mapping of Injury-Induced Contractile Actomyosin Phenotypes in Podocytes Using Expansion Microscopy

Pongpratch Puapatanakul,[1,2] Dema Yaseen Alsabbagh,[1] Ewa Langner,[1] Moe Mahjoub,[1] Jeffrey H. Miner,[1] Guy M. Genin,[3] Hani Suleiman.[1]
[1]*Washington University in St Louis School of Medicine, St Louis, MO;* [2]*Chulalongkorn University, Bangkok, Thailand;* [3]*Washington University in St Louis, St Louis, MO.*

Background: The reorganization of actin cytoskeletons into sarcomere-like structures (SLSs), characterized by the periodic intertwining of synaptopodin and myosin IIA, has been previously observed in injured podocytes both in vivo and in vitro.

Methods: To further investigate SLSs in three dimensions at super-resolution, we employed Ultrastructure Expansion Microscopy (U-ExM) on kidney tissues. Deparaffinized 5-µm kidney sections from wild-type mice and mice with nephrotic syndrome (Cd2ap-/-, adriamycin nephropathy) were anchored and embedded in acrylamide-rich hydrogels, denatured at 95C, expanded isotropically in water, and immunolabeled with relevant antibodies. The expanded samples were then imaged in z-stacks using an Airyscan confocal microscope.

Results: U-ExM enabled en-face visualization of individual foot process boundaries by staining for nephrin, a major slit diaphragm protein. In healthy podocytes, actin and the actin-binding protein synaptopodin appeared in longitudinal bundles in foot processes, while myosin IIA was present in cell bodies and major processes, but absent from foot processes. In both injury models, there was a significant increase in foot process width, indicating foot process effacement. Within the widened foot processes, actin cables were disrupted and reorganized into antiparallel bands, alternating with myosin IIA that relocated from the major processes, forming SLSs (Fig.1A). Tropomyosin 1/2 and Caldesmon, important components of actomyosin bundles in smooth muscle and non-muscle cells, were found only in mesangial cells in healthy controls, but were present in the effaced foot processes as part of SLSs, in locations corresponding to myosin IIA and actin, respectively (Fig.1B-C).

Conclusions: Injured podocytes establish SLSs with a molecular composition similar to muscle sarcomeres, suggesting this contractile machinery is an adaptive response against detachment, opening avenues for future therapeutic interventions aimed at preventing podocyte loss and progression to kidney failure.

Funding: NIDDK Support, Other NIH Support - R01 Grant, Private Foundation Support

The Actin Cytoskeleton of Injured Podocytes Transforms from a Disorganized Meshwork into Organized Contractile Sarcomere-Like Structures

Pongpratch Puapatanakul,[1,2] Ewa Langner,[1] Chengqing Qu,[3] Shumeng Jiang,[3] Moe Mahjoub,[1] Guy M. Genin,[3] Jeffrey H. Miner,[1] Hani Suleiman.[1]
[1]*Washington University in St Louis School of Medicine, St Louis, MO;* [2]*Chulalongkorn University, Bangkok, Thailand;* [3]*Washington University in St Louis, St Louis, MO.*

Background: Podocytes develop synaptopodin (Synpo)-myosin IIA (MyoIIA)-positive sarcomere-like structures (SLSs) in proteinuric kidney diseases. SLSs are mechanosensitive and may prevent detachment and contribute to recovery. To better understand SLSs biology, we investigated their development in vivo at different stages of injury.

Methods: The Adriamycin nephropathy mouse model was used to portray ongoing podocyte injury. Kidneys were collected at 3, 5, 7, 9, and 14 days post-Adriamycin injection. We combined Ultrastructural Expansion Microscopy and high-resolution confocal imaging to visualize podocyte foot processes (FPs) and SLSs. The extent of SLSs was evaluated by the percentage of SLS area per total FP area.

Results: Albuminuria was evident as early as day 2 and became pronounced by days 5-7. By light microscopy, glomeruli appeared normal on day 5, but segmental sclerosis was observed on days 9 and 14. SLSs were observed focally and segmentally starting from day 3. SLS area percentage increased over time, reaching nearly 100% by day 9. A progression of three Synpo and MyoIIA patterns in SLSs was observed (Fig.1A-C). Pattern 1: Synpo occupying most of the FP space with a few areas infiltrated by MyoIIA. Pattern 2: Alternating, disorganized Synpo-MyoIIA, with Synpo-positive bundles retained at the FP periphery. Pattern 3: Periodic, well-organized Synpo-MyoIIA striations, perpendicular to the original longitudinal axis, with peripheral Synpo bundles gone. Pattern 1 was dominant on day 3, while Pattern 3 represented over 80% of SLSs from day 7 onward. Pattern 2 became dominant on day 5, then yielded to Pattern 3 (Fig.1D).

Conclusions: Correlation between SLS patterns and timing after injury suggests that SLSs undergo stages of development from less organized actomyosin to well-organized sarcomeric patterns that exert longitudinal contractile forces. Further clinical correlation of SLS patterns may aid in predicting the fate of podocytes and disease prognosis.

Funding: NIDDK Support, Other NIH Support - R01 Grant, Private Foundation Support

N-ethylmaleimide Sensitive Factor (NSF) Is Essential for Maintaining Podocyte Focal Adhesion

Atsuhiro Imai, Kazunori Inoue, Hiroki Okushima, Ayumi Matsumoto, Isao Matsui, Yoshitaka Isaka. *Department of Nephrology, Osaka University Graduate School of Medicine, Suita, Japan*.

Background: Focal adhesion proteins in podocytes are critical for attaching to the glomerular basement membrane. Reduction in these proteins causes podocyturia, frequently observed in focal segmental glomerulosclerosis patients. We aimed to explore the regulation of focal adhesion molecules in podocytes.

Methods: We used a mouse model in which the Talin1 gene (*Tln1*) can be specifically knocked out in podocytes by administering doxycycline (Dox). These mice, referred to as *Tln1* cKO mice, develop progressive proteinuria and eventually experience renal failure (*J Clin Invest.* 2019 1;129(3):1295-13). We focused on the early phase of podocyte injury by examining *Tln1* cKO mice 10 days after Dox treatment (*Tln1* cKO 10d), as they showed proteinuria without elevated serum creatinine at this stage. We performed single-cell RNA sequencing (scRNAseq) on kidney samples from *Tln1* cKO 10d mice and analyzed the differentially expressed genes (DEGs). Based on the DEG analysis results, we generated another mouse model with podocyte-specific knockout of the *Nsf* gene (*Nsf* cKO mice). Using primary cultured podocytes from these *Nsf* cKO mice, we investigated the role of NSF in focal adhesion.

Results: *Nsf* was significantly down-regulated in *Tln1* cKO 10d mice podocytes. Notably, *Nsf* cKO mice developed proteinuria as early as 2 weeks of age and succumbed to end-stage kidney disease by 9 weeks. *Nsf* cKO podocytes showed a marked reduction in cell spreading, decreased mature Integrin α3β1, and increased immature Integrin α3. Immunofluorescence staining indicated expansion of the ER and ER-Golgi intermediate compartment (ERGIC) area in *Nsf* cKO podocytes. Additionally, COP2 and COP2 associated SNARE protein increased in *Nsf* cKO podocytes. These findings suggested that the deletion of *Nsf* in podocytes leads to a disruption in ER-to-Golgi transport, thereby impairing the trafficking of focal adhesion proteins such as Integrin α3.

Conclusions: NSF plays a crucial role in maintaining podocyte focal adhesions by regulating ER-to-Golgi transport and the trafficking of proteins such as Integrin α3β1. This study provides new insights into the molecular mechanisms of podocyte injury and kidney disease progression.

FR-PO753

Mathematical Modeling of Podocyte Adhesion Highlights the Role of Cell Contractility and Fluid Shear Stress on Kidney Function

Shumeng Jiang,[1] Pongpratch Puapatanakul,[2] Chengqing Qu,[1] Ewa Langner,[2] Moe Mahjoub,[2] Jeffrey H. Miner,[2] Guy M. Genin,[1] Hani Suleiman.[2,3]
[1]Washington University in St Louis, St Louis, MO; [2]Washington University in St Louis School of Medicine, St Louis, MO; [3]The University of Texas Southwestern Medical Center, Dallas, TX.

Background: Diseases of the kidney's glomerular filtration barrier can lead to podocyte detachment, which impairs filtration and ultimately leads to end-stage kidney disease. However, the mechanisms responsible for securing podocyte attachment to the glomerular basement membrane (GBM), as well as how these malfunctions in pathological conditions, are not fully understood.

Methods: In order to predict the stability of podocyte attachment, we developed a mathematical model of the actin cytoskeleton in podocyte foot processes and their connections to the GBM. This model considers forces from filtration shear and cell contraction, and their impact on the stability of integrin bonds that connect foot processes to the GBM.

Results: Our modeling reveals that specific integrin patterning in the foot processes and a balance between extrinsic and intrinsic stresses play a crucial role in maintaining stable attachment of podocytes. These findings were further supported by a new mouse model with controllable glomerular filtration rate (GFR) and cell contractility. The use of expansion microscopy (ExM) and super-resolution imaging confirmed the predicted integrin patterns, while assessments of kidney injury validated our predictions regarding the stability of podocyte attachment under varying environmental forces.

Conclusions: Our simulations and mouse model verifications emphasize the significance of mechanical stresses, specifically cell contractility and fluid shear stress, in maintaining glomerular filtration function. This insight presents new therapeutic opportunities for chronic kidney diseases by manipulating these mechanical cues.

Mechanism of TPPP3-Affecting Podocyte Cytoskeleton Stability by Regulating the Acetylation Level of α-Tubulin

Qilin Chen,[1,2] Li Qiu.[1,2] *[1]Children's Hospital of Chongqing Medical University National Clinical Research Center for Child Health and Disorders, Chongqing, China; [2]Children's Hospital of Chongqing Medical University Ministry of Education Key Laboratory of Child Development and Disorders, Chongqing, China*.

Background: Podocytes exhibit a unique cytoskeleton architecture, which is closely related to their function in maintaining the kidney filtration barrier. As the core structure of the skeleton network, microtubules (MTs) play a key role in supporting and maintaining the skeleton network, but there is a lack of understanding of podocyte MTs.

Methods: Single cell transcriptome sequencing and spatial transcriptome sequencing were performed on children 's kidneys. Immunofluorescence (IFA), immunohistochemical (IHC) and western blot (WB) were used to determine the expression of TPPP3, α-tubulin, acetylated tubulin (Ace-tubulin), actin microfilaments. *TPPP3*-siRNA was used to knock down podocytes, and WB was used to verify the knock-out results.

Results: Single-cell combined spatial transcriptome sequencing of children's kidneys revealed that human podocytes significantly expressed tubulin-related molecule TPPP3. The results of IHC, IFA and WB confirmed that TPPP3 was specifically expressed in the nucleus and cytoplasm of human glomerular podocytes. Surprisingly, TPPP3 was not expressed in kidneys and podocytes of mice and rats. The expression of TPPP3 was significantly increased in HPC differentiation stage compared with HPC in proliferative stage without podocyte molecular characteristics. When TPPP3 was knocked down by siRNA, the results of cell fluorescence and WB showed that the Ace-tubulin was significantly decreased, and the filamentous structure of Ace-tubulin and α-tubulin was broken, the continuity was destroyed. It is worth noting that knockdown of TPPP3 in HPCs directly leads to decreased actin (F-actin) and structural disorder. Furthermore, using drug intervention, increasing the level of microtubule acetylation can partially restore the microtubule structure damage caused by knockdown of TPPP3. In addition, the results of IFA and IHC confirmed that the expression of TPPP3 in glomeruli of MCD and FSGS patients was decreased. The in vitro podocyte injury model suggested that the expression of slit membrane protein Podocin and TPPP3 was decreased.

Conclusions: Human podocytes specifically expressed microtubule-associated protein TPPP3, which maid be involved in regulating the level of acetylated tubulin and affecting the cytoskeleton such as actin microfilaments in podocytes

FR-PO755

Identification of Crb2 Partner Proteins in Podocytes Using BioID

Soichiro Suzuki, Sajida Ibrahim, Lamine Aoudjit, Simon Leclerc, Serge Lemay, Tomoko Takano. *Research Institute of the McGill University Health Centre, Montreal, QC, Canada*.

Background: Crb2 is an essential protein expressed at the slit diaphragm of podocytes and its mutations cause hereditary nephrotic syndrome. We also reported that anti-Crb2 antibodies may be causal in idiopathic nephrotic syndrome. However, how Crb2 functions in podocytes is not fully understood. To obtain insight into the signaling pathways of Crb2, we conducted proximity-dependent biotinylation and proteomics (BioID).

Methods: BioID is based on the fusion of a promiscuous *E.coli* biotin ligase (BirA) to a target protein, Crb2. Intracellular domain of human Crb2 (1223-1285aa) was subcloned downstream of the extracellular/transmembrane domain of IL2R, conjugated with BirA, and expressed in human podocytes. As a control, human podocytes expressing GFP-BirA were used. Biotinylated proteins were captured and analyzed by mass spectrometry. Results (n=3) were analyzed using Scaffold 5.

Results: Protein identification by BioID revealed 328 proteins exhibiting significant interaction with Crb2 (compared with GFP-control, $p<0.05$). Identified proteins were analyzed by enrichment analysis using Reactome pathways and gene ontology annotations. The results showed that Crb2 partner proteins are predominantly involved in Rho, Rac and Cdc42 GTPase signaling pathways, covering 20 out of the 25 most significantly enriched Reactome pathways. Furthermore, Crb2 interactors significantly contribute to actin cytoskeleton organization (GO ID 30036, adjusted p-Value 4.70E-08) and cell adhesion (GO ID 7155, adjusted p-Value 1.91E-06). Of interest, ARHGEF26, an upstream activator of Rho family proteins, was identified as one of the Crb2 interactors. We confirmed the interaction by co-immunoprecipitation and immunostaining showed ARHGEF26 and Crb2 colocalization in both immortalized human podocytes and mouse glomeruli. Analysis of public scRNAseq datasets showed that ARHGEF26 expression in the kidney is highly specific to podocytes. CRISPR/Cas9 KO of ARHGEF26 in podocytes reduced RhoA and Rac1 activation as well as cell projection formation in response to EGF.

Conclusions: Crb2 plays a crucial role as a cytoskeletal regulatory protein in podocytes, and alterations in Crb2 signaling will likely lead to cytoskeletal changes and subsequent podocyte injury. We are investigating the identified proteins to elucidate their roles in Crb2 signaling, with the goal to identify novel therapeutic targets.

FR-PO756

Molecular Architecture of the Kidney Slit Diaphragm Revealed by Cryo-electron Tomography

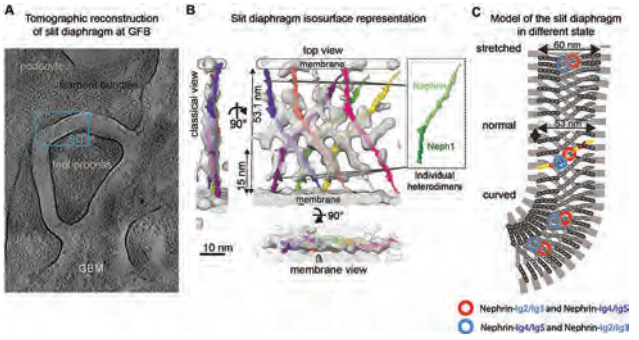
Alexandra N. Birtasu,[1] Konstantin Wieland,[1] Florian Grahammer,[2] Achilleas Frangakis.[1] *[1]Goethe-Universitat Frankfurt am Main, Frankfurt am Main, Germany; [2]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

Background: In this contribution, we will present the molecular architecture of the slit diaphragm (SD), the primary cell-cell junction between podocytes, as imaged by cryo-electron tomography (cryoET) at nanometer resolution. The molecular components of the SD are known from comprehensive mass spectrometry and other studies. Here, we put this information into the context of our cryoET images and depict the SD as an elaborate network of criss-crossing molecules resembling a molecular sieve.

Methods: We isolated mouse glomeruli using the sieving method and vitrified them by high-pressure freezing. Next, we used cryo-focused ion beam milling for specimen thinning, and cryo-electron tomography to visualize the vitreous lamellae obtained from the frozen glomeruli.

Results: Our images show that the SD resembles a fishnet pattern. Fitting of the molecular components provides detailed insights into its structural organization. We construct a blueprint of the SD, describing the complex interaction pattern with multiple contact sites between the molecules Nephrin and Neph1

Conclusions: The SD is a quasi-crystalline, sheet-like molecular polymer that provides the necessary stability and flexibility to compensate for mechanical forces occurring within glomeruli. This advances the understanding of SD biology and holds promise for future studies on structural changes of the SD.



FR-PO757

Deciphering the Role of Slit-Diaphragm Interactors in Podocyte Integrity and Glomerular Diseases

Badr Khbouz, Bernhard Dumoulin, Hui Wu, Tobias B. Huber, Florian Grahammer. *Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

Background: Renal filtration is determined by the slit-diaphragm (SD), a cell-cell junction between the foot processes of renal podocytes. Through an unbiased screening approach, we have identified several interaction partners of the SD core proteins Nephrin, Neph1 and Podocin. Here, we investigate the role of two of them: the natriuretic peptide receptor 3 (NPR3), a member of the ANP Receptors, and MER Proto-Oncogene, Tyrosine Kinase (MERTK), a member of the TAM receptor tyrosine kinases.

Methods: Podocyte specific knockout C57BL/6 mice (*NPR3*$^{-/-}$) and (*MERTK*$^{-/-}$) were used. *NPR3*$^{-/-}$ and *WT* mice (n=54) were exposed (or not) to unilateral nephrectomy followed by Deoxycorticosterone acetate (DOCA) high salt hypertension model. After weekly measurements of blood pressure (BP) and albuminuria (6 weeks), the kidneys and blood were harvested for functional and tissue assessment. Next *NPR3*$^{-/-}$ and *WT* mice (n=20) were subjected to the Adriamycin nephropathy model, 10 days' post treatment, urine, blood and kidney were collected for analysis. Lastly, *MERTK*$^{-/-}$ and *WT* mice (n=26) were exposed to nephrotoxic serum induced nephritis (NTN) model, with the assessment of albuminuria and glomerular damage 4 and 8 days' post-treatment.

Results: Following DOCA administration, the systolic BP, kidney weight, glomerular tuft volume, and albuminuria were increased in treated animals compared to controls ($p<0,01$), *NPR3*$^{-/-}$ mice showed intermedium profile between *WT* and *controls*. Adriamycin treatment induced a mild albuminuria in *WT*, unlike *NPR3*$^{-/-}$ mice ($p<0,05$). Blood Urea Nitrogen (BUN) was not different. Following NTN treatment, albuminuria levels and glomerular damage were increased in both genotypes, yet this phenotype was significantly more severe in *MERTK*$^{-/-}$ mice compared to *WT* animals.

Conclusions: Given that both NPR3 and MERTK are involved in cellular signaling, these results suggest a potential role of these interactors in the dynamic adaptation of podocyte and/or SD function. The molecular mechanisms behind these dynamic changes are currently being deciphered.

FR-PO758

Fluid Flow Shear Stress-Induced Podocyte Glycosylation Changes: Implications for Glomerular Function

Tarak Srivastava,[1] Jan Novak,[3] Stacy D. Hall,[3] Colin Reily,[3] Mukut Sharma.[2] *[1]Children's Mercy Kansas City, Kansas City, MO; [2]Kansas City VA Medical Center, Kansas City, MO; [3]The University of Alabama at Birmingham Department of Cell Developmental and Integrative Biology, Birmingham, AL.*

Background: We have demonstrated that hyperfiltration-induced increase in fluid flow shear stress (FFSS) causes podocyte injury and loss of glomerular function following unilateral nephrectomy (UNx) in rodent models. To explain how glycosaminoglycans (GAGs) on cell surfaces respond to FFSS, Tarbell (J Intern Med. 2006:339) introduced the 'wind in the trees' model. Here, GAGs, akin to branches of proteoglycans in the glycocalyx, detect fluid flow (wind) and convey the force to the membrane/actin cytoskeleton network (ground) through the core protein (tree trunk). To address the chain of events and mechanism of FFSS-induced podocyte injury, we hypothesize that increased FFSS affects the membrane glycoproteins with extensive network of glycans exposed to the environment.

Methods: Differentiated immortalized murine podocytes were treated with FFSS (2 dynes/cm^2) for 2 h (37°C, 5% CO_2) and studied at the end of FFSS treatment, and 2 h and 24 h post-FFSS were termed End-FFSS, Post-2h, Post-24h and Control (untreated). Western blot analysis of podocyte glycoproteins was performed using lectins specific for high-mannose glycans (GNL), *N*-glycans with 3 and 4 antennas (PHA), alpha2,3-linked sialic acid (MAA), alpha2,6-linked sialic acid (SNA), and core 1 *O*-glycans (jacalin). RT-qPCR using Qiagen PCR arrays was performed to determine changes in gene expression of selected glycosylation enzymes.

Results: Lectins GNL, PHA, and SNA reacted with more glycoproteins of a wide range of molecular mass compared to MAA and jacalin. Podocytes at End-FFSS and Post-2h showed increased alpha2,6- and alpha2,3-linked sialic acid and more tri- and tetra-antennary *N*-glycans compared to Control. Post-24h samples showed results comparable to Control. Gene expression of specific glycosyltransferases, such as sialyltransferases and GlcNAc-transferases was upregulated at End-FFSS or Post-2h compared to Control and reverted to Control levels.

Conclusions: Brief FFSS caused immediate changes in podocyte glycosylation including *N*-glycosylation consistent with increased branching and sialylation. These transient but substantial changes were paralleled by changes in the expression of specific glycosylation enzymes. Persistent hyperfiltration-induced increase in FFSS may result in lasting changes in glycan metabolism and thus alter the membrane interface leading to functional changes.

FR-PO759

Change of Podocyte-Glomerular Basement Membrane Interaction in Glomerular Disease or Under Fluid Shear Stress

Minseob Eom,[1] Ji-Hee Kim,[2] Bao T. Dang,[1] Jae Won Yang,[1] Seung-Kuy Cha,[1] Jae seok Kim.[1] *[1]Yonsei University Wonju College of Medicine, Wonju, Gangwon-do, Republic of Korea; [2]Soonchunhyang University, Asan, Chungcheongnam-do, Republic of Korea.*

Background: The interaction between podocyte and glomerular basement membrane (GBM) determines podocyte stability. We hypothesized that the interaction between podocyte and GBM changed in response to adverse conditions, such as glomerular disease or fluid shear stress (FSS). Here, we aimed to explore the podoctye-GBM interaction in glomerular disease or under FSS through investigating changes of integrin (ITG) αVβ3, fibronectin, and uPAR.

Methods: We performed immunohistochemical staining for ITG β3, fibronectin, and uPAR in human kidney tissues obtained from patients with trauma (control) and nephrotic syndrome (NS). Furthermore, we exposed conditionally immortalized human podocyte cells to 200 rpm of FSS and observed changes in the expression of ITG β3, fibronectin, and uPAR. Lastly, we evaluated cell viability depending on the condition of dish coating.

Results: The results showed that ITG β3 expression was lower in the NS group, while the expressions of activated ITG β3, fibronectin, and uPAR were higher compared to the control (Figure 1). Furthermore, FSS increased the expressions of activated ITG β3, fibronectin, and uPAR (Figure 2). Dish coating with collagen or fibronectin improved cell viability compared to a non-coated dish under FSS.

Conclusions: ITG αVβ3 is activated in glomerular diseases or under FSS. The activation of ITG αVβ3 is associated with increased fibronectin and uPAR. The improvement of cell viability in a coated dish suggests that the interaction between extracellular matrix and activated ITG αVβ3 contributes to increasing podocyte stability.

Funding: Government Support - Non-U.S.

Diabetes and SGLT2 Inhibitor Treatment Alter Podocyte Glycocalyx

Alejandra Becerra Calderon, Hasen Alkoraishi, Audrey Izuhara, Sachin K. Deepak, Greta H. Trogen, Janos Peti-Peterdi, Georgina Gyarmati. *University of Southern California, Los Angeles, CA.*

Background: The glycocalyx between the podocyte foot processes and the glomerular basement membrane (GBM) has been difficult to study in vivo, therefore its function remains elusive. Recently we developed and initially characterized the Pod-Sdc1-GFP mouse model with podocyte specific genetic labeling to study the physiological role of podocyte glycocalyx. Here we aimed to visually demonstrate the alterations in podocyte glycocalyx in diabetes with and without SGLT2i treatment in vivo.

Methods: New genetic mouse models were generated by the knock-in of pCAG-Lox-STOP-Lox-EGFP-Sdc1 to generate animals with Cre-dependent expression of a syndecan-1 (Sdc1) fusion protein with N-terminal, extracellular GFP. Sdc1-GFP^{flox} animals were crossed with Podocin-Cre mice for the specific genetic labeling of the glycocalyx in podocytes. Intravital multiphoton microscopy (MPM) was used to measure changes in the depth of glycocalyx and corresponding changes in GFB function in vivo over time in streptozotocin induced diabetic kidney disease with or without SGLT2i empagliflozin treatment. Alexa-594 conjugated wheat germ agglutinin (WGA) lectin was used to label the glycosaminoglycan (GAG) component of the glycocalyx, and Alexa-680 conjugated albumin was used to visualize GFB permeability.

Results: Co-localization of genetic GFP and Alexa-594 WGA confirmed podocyte glycocalyx labeling. MMP9 injection significantly reduced podocyte glycocalyx thickness and resulted in glomerular albumin leakage confirming podocyte glycocalyx functionality. In vivo MPM imaging in diabetic mice revealed a significant decrease in glycocalyx thickness on both the apical and the basal surface (0.76+/-0.01 um) compared to control (1.03+/-0.02 um) and increased GFB permeability. SGLT2i treatment restored podocyte glycocalyx thickness (0.9+/-0.01 um) and reduced albumin leakage in diabetic mice but not in healthy control animals (1.01+/-0.01 um).

Conclusions: In conclusion, the specialized podocyte glycocalyx at the GBM may function as an important new layer of the GFB, may play an important role in the disruption of GFB functions in diabetic kidney disease, and may be involved in the pleiotropic renoprotective effects of SGLT2i treatment.

FR-PO761

Endosomal Recycling and Proteasomal Degradation of R168H Variant Podocin Contributes to Nephrotic Syndrome Pathophysiology

Aude Dorison,[1,2] Inês P. Santos,[3] Irene Ghobrial,[1,2] Rachel Lam,[1,2] Katrin Stuber,[4] Jillian C. Danne,[5] Michael M. See,[1,2] Georg Ramm,[5] Fernando J. Rossello,[1,2] Mirana Ramialison,[1,2] Kristina B. Emdal,[4] Melissa H. Little.[1,2] *[1]Murdoch Children's Research Institute, Parkville, VIC, Australia; [2]Novo Nordisk Foundation Center for Stem Cell Medicine - reNEW Melbourne, Melbourne, VIC, Australia; [3]Novo Nordisk Foundation Center for Stem Cell Medicine - reNEW Copenhagen, Copenhagen, Denmark; [4]NNF Center for Protein Research, University of Copenhagen, Copenhagen, Denmark; [5]Monash University, Melbourne, VIC, Australia.*

Background: Nephrotic syndrome (NS) arising from *NPHS2* variants is most common in children over 3 months of age. Using stem-cell derived kidney organoid podocytes, we previously reported distinct mistrafficking of specific missense *NPHS2* variants, with a distinct Golgi accumulation of the p.R168H variant podocin. While a novel mislocalisation for this variant, the pathophysiology of this mistrafficking remained unclear.

Methods: Induced human pluripotent stem cells generated from a homozygous (HOM) *NPHS2* p.R168H patient, healthy heterozygous (HET) parent and healthy wild type (WT) individual were differentiated into kidney organoids. Organoid glomeruli isolated from each genotype were analysed by transcriptomics and proteomics followed by gene set enrichment analyses. Immunostaining and immunogold electron microscopy (EM) were performed to validate omics data and study PODOCIN subcellular localisation in podocytes.

Results: Glomerular proteomics revealed significant differences in protein prevalence and ubiquitination between HOM and healthy podocytes. Reduced diglycine-modified lysine residues suggested preferential inhibition of YAP1 ubiquitination in HOM podocytes. This was supported by a trend of increased nuclear translocation for this transcription coregulator. A combined analysis of proteomics and transcriptomics revealed reduced ER-to-Golgi trafficking (decreased KDELR1/2, SURF4 and PDCD6) but increased recycling endosome activity (elevated RAB25) in HOM podocytes, suggesting a return from the membrane to the Golgi of the variant protein. This was confirmed using immunogold EM which detected p.R168H at the membrane, in multivesicular bodies, endosomes and Golgi while the WT protein was mainly located at the membrane. Finally, while lysosomal trafficking was reduced, p.R168H protein levels were elevated upon treatment with a proteasomal inhibitor, Bortezomib.

Conclusions: Our data indicate that p.R168H variant podocin can reach the slit-diaphragm but is then recycled back to the Golgi and/or targeted for degradation by the proteasome. This variant-specific pathophysiology will assist in the design of treatments for this form of genetic NS.

FR-PO762

Podocytes Derived from Patients with Proteinuria Associated with Truncating Mutation in CLCN5 Display Increased Apoptosis and Defective Endocytosis

Brandon M. Lane,[1,2] Megan Chryst-Stangl,[1,2] Sue Zhang,[1] Guanghong Wu,[1,2] Rasheed A. Gbadegesin.[1,2] *[1]Duke University, Durham, NC; [2]Duke Molecular Physiology Institute, Durham, NC.*

Background: Pathogenic mutations in the gene encoding Chloride Voltage gated channel 5 (CLCN5) are generally associated with Dent Disease, a tubular disorder characterized by nephrolithiasis. However, a few *CLCN5* variants have also been reported to cause nephrotic syndrome (NS) phenotypes. We previously identified a novel segregating hemizygote truncating mutation (c. 1199del, p.Gly400ValfsTer29) in *CLCN5* in a family with four affected boys with NS phenotypes and biopsy proven focal segmental glomerulosclerosis (FSGS). *CLCN5* encodes a member of the chloride ion channels and ion transporters that regulate endosomal acidification and receptor-mediated endocytosis in tubules but is also expressed in the podocyte. However, it is unknown if pathogenic mutations that produce NS phenotypes can affect podocyte homeostasis.

Methods: To determine if pathogenic mutations in CLCN5 can alter podocyte homeostasis, we examined endocytosis and apoptosis phenotypes in iPSC-derived podocytes from patients with *CLCN5* mutations and their unaffected family members. We also examined the effect of CLCN5 gene deficiency in multiple immortalized podocyte cell lines by using lentiviral based gene knockdown. Automated live-cell imaging of internalized fluorescent pHrodo labeled dextran molecules was used quantify the endocytosis of small molecules. Live-cell imaging of fluorescent reporters of caspase 3 activity as well as propidium iodide were used to measure podocyte viability when podocytes were exposed to serum starvation.

Results: Podocytes derived from the affected family members with the truncating *CLCN5* variant displayed decreased endocytosis of fluorescent dextran molecules and increased apoptosis compared to podocytes from unaffected family members ($p<0.001$ for both assays). Immortalized podocytes with *CLCN5* gene deficiency displayed similar phenotypes.

Conclusions: Pathogenic variants in *CLCN5* capable of inducing NS phenotypes cause decreased podocyte endocytosis. These reductions in endocytosis likely contribute to the reduced viability associated with deficiencies in *CLCN5*. Further investigation is required to determine if additional processes contribute to the increased apoptosis in *CLCN5* deficient podocytes.

FR-PO763

Synaptobrevin, a Major Protein of v-SNARE, Participates in Maintenance of Foot Processes of Podocytes: Downregulation of Synaptobrevin Is an Initiation Event Leading to Podocyte Injury in Minimal Change Nephrotic Syndrome (MCNS) Model

Takashi Nagai, Mutsumi Kayaba, Ying Zhang, Guoqing Chang, Yoshiyasu Fukusumi, Hiroshi Kawachi. *Department of Cell Biology, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: Podocytes contain synaptic-like vesicle that contributes to maintaining specialized podocyte morphology and function. We reported synaptic vesicle protein 2B (SV2B) is expressed on the vesicle and plays a critical role in podocytes. However, the molecular basis and the function of the vesicle are not well understood. Synaptobrevin is a v-SNARE expressed on the synaptic vesicle and plays a central role in docking to plasma membrane. In this study we investigated the association with SV2B, expression and localization, and physiological and pathological roles of synaptobrevin in podocytes.

Methods: Association with SV2B was analyzed with SV2B-deleted podocytes. The expression in normal and injured podocyte was analyzed. The function was elucidated with cultured podocyte treated with siRNA for synaptobrevin.

Results: The expression of synaptobrevin was lowered in SV2B knockdown cultured podocyte (24.7±6.4%, $p< 0.05$). Synaptobrevin was restrictedly expressed in podocyte in glomeruli. In both rat and human kidney sections synaptobrevin was detected as a dot-like pattern along capillary loop. Major parts of synaptobrevin were co-stained with synaptopodin, a marker of foot processes. mRNA expression of synaptobrevin was decreased already at 1h in PAN nephropathy, a mimic of MCNS (37.9±16.4 % to normal) and the synaptobrevin staining became discontinuous on day 10, when proteinuria peaked and foot processes effacement was broadly detected (score: 2.23 ±0.03 vs. normal; 3.74±0.06, $p<0.05$). The expression of synaptobrevin in cultured podocytes increased with differentiating (2.88 times higher). If synaptobrevin was deleted, podocyte changed to round shape and the rate of podocytes possessing processes was lowered (19.3±4.7% vs. 34.0±2.6%, $p<0.01$), and mRNA expressions of slit diaphragm molecules were lowered (nephrin, 50.9±1.9%; CD2AP, 47.3±3.2%, $p<0.05$).

Conclusions: Synaptobrevin participates in maintenance of foot processes of podocytes in cooperation with SV2B. Downregulation of synaptobrevin is involved in effacement of foot process and consequent downregulation of slit diaphragm molecules, which leading to proteinuria. Synaptobrevin can be an early marker and a therapeutic target of podocyte dysfunction.

FR-PO764

Identification of RNASE1 as a Novel Contributor to Cytoskeleton Remodeling in Podocytes

Patricia Bolanos-Palmieri,[1] René Krüger,[1] Evren U. Azeloglu,[2] Mario Schiffer.[1] *[1]Universitatsklinikum Erlangen Medizinische Klinik 4 Nephrologie und Hypertensiologie, Erlangen, Germany; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: A dynamic cytoskeleton is critical to the health and function of the podocytes as it provides structural and signalling support to the cell. We have previously shown that recovering the cytoskeleton can be a viable strategy to treat podocyte dysfunction. In this project, we used a unique human peptide library to identify native bioactive peptides with the capacity to modify the podocyte cell structure and cytoskeleton.

Methods: To test the fractions derived from the hemofiltrate peptide library, protein kinase C epsilon knockout mouse podocytes (PKCε KO) were used as a model for cytoskeletal dysfunction. After iterative tests in cell culture, the bioactive fraction was selected and the candidate peptide (CP) was identified by mass spectrometry. We used a purified recombinant version of the CP to test its effect on PKCε KO cells and on dasatinib treated human podocytes. Morphological changes were quantified by imaging components of the cytoskeleton. Possible mechanistic targets were analyzed by western blot and transcriptomics.

Results: Using PKCε KO podocytes we systematically tested the hemofiltrate and were able to identify one fraction capable of influencing cell morphology. Further analysis showed that RNASE1 could be a mediator of the observed structural changes. To explore this, additional tests were performed using recombinant RNASE1 which showed that exposing the PKCε KO podocytes to RNASE1 lead to an increase in cell spreading and number of focal adhesions resulting in improved cell attachment and cell morphology that more closely resemble that of wild type podocytes. This result was further confirmed using other injury models like human podocytes exposed to dasatinib. Preliminary data looking into the mechanisms involved in cytoskeleton rearrangement in response to RNASE1 suggest that there may be differential tyrosine kinase signalling in podocytes treated with RNASE1. Additionally, RNA sequencing identified 18 differentially regulated genes as candidates for further analysis.

Conclusions: This systematic approach led to the identification of a novel candidate protein able to positively alter podocyte morphology. By modifying the structural changes that result from injury, RNASE1 could provide new insights into the molecular mechanisms that result in podocyte dysfunction and proteinuria as well as open new avenues for treatment.

FR-PO765

Forces of Filtrate Flow on Podocyte Foot Processes Studied by Three-Dimensional and Two-Dimensional Computational Fluid Dynamics

Alexander Fuhrmann,[1] Balazs Pritz,[1] Karlhans Endlich,[2] Wilhelm Kriz.[3] *[1]Karlsruher Institut fur Technologie, Karlsruhe, Germany; [2]Universitatsmedizin Greifswald, Greifswald, Germany; [3]Universitat Heidelberg, Heidelberg, Germany.*

Background: The glomerular filtration barrier is exposed to forces arising from filtration pressure and filtrate flow. Filtrate flow acts on podocyte cell bodies in Bowman's space and on foot processes (FPs) lining the filtration slit. Besides a previous estimate of 8 Pa (Endlich & Endlich, *Semin. Nephrol.* 2012), the magnitude of shear stress to FPs remains unknown.

Methods: We used numerical flow simulations to study forces arising from glomerular filtration. Simulations were run with a 3D model of a filtration unit and the filtration parameters of the rat kidney. The filtration unit consisted of fenestrated endothelium, the GBM, and two opposing halves of FPs bridged by the slit diaphragm (SD). The GBM was modeled as a porous medium, the SD as a zipper structure (Rodewald & Karnovsky, *J. Cell Biol.* 1974).

Results: Filtrate flow exerted a mean wall shear stress (WSS) of 39 Pa with a maximum of 152 Pa on the plasma membrane of FPs and up to 250 Pa on the SD zipper structure. After crossing the GBM and converging into the filtration slit, filtrate flow is markedly accelerated. Thus, the filtration slit acts like a nozzle explaining the high shear stress on FPs. SD accounted for 25% of the hydrodynamic resistance of the glomerular filtration barrier. Based on the results of the 3D model, we developed a 2D model with 20-fold reduced computing time to perform extensive parameter variations. In the 2D model, GBM and SD were both represented as porous media with independent viscous resistances. When SD resistance was increased (and GBM resistance was lowered in such a way to keep filtrate flow velocity constant) WSS increased noticeably. Reducing the filtration slit width by 25% from 40 to 30 nm almost doubled WSS, demonstrating the non-linearity of the nozzle effect. On the other hand, increasing filtrate flow velocity by 50 and 100% increased WSS by 47 and 94%, respectively, in a practically linear way. Changes in net filtration pressure did not affect WSS, as long as filtrate flow velocity was kept constant.

Conclusions: Our data demonstrate that FPs are likely to experience high levels of wall shear stress in the filtration slit that markedly exceed levels of endothelial wall shear stress. Two factors were identified to account for the high shear stress: the nozzle geometry of the filtration slit and the hydrodynamic resistance of the slit diaphragm.

Synaptopodin-Enhanced Podocytes Perpendicular Force Resistance In Vivo and In Vitro

Chengqing Qu,[1] Shumeng Jiang,[1] Jeffrey H. Miner,[2] Guy M. Genin,[1] Hani Suleiman.[2] *[1]Washington University in St Louis, St Louis, MO; [2]Washington University in St Louis School of Medicine, St Louis, MO.*

Background: Focal adhesions are able to resist shear forces in almost all types of cells. However, kidney podocytes face a unique challenge as they must also withstand stress that is perpendicular to their basement membrane. We hypothesis that synaptopodin, a specialized actin-binding protein that is highly expressed in podocytes, acts as a linker to facilitate the resistance of focal adhesions to these perpendicular forces.

Methods: We developed an in vitro system to study the impact of perpendicular forces on cells cultured on hydrogels with defined stiffness and coated with Laminin a5b2g1. By applying centrifugal forces, this setup was able to mimic the perpendicular forces experienced by podocytes in their natural glomerular microenvironment. We used primary podocytes taken from both wild-type control (WT) mice as well as mice lacking synaptopodin (Synpo KO). We compared these cells to osteosarcoma cells (U2OS cells), a bone cancer cell that also highly express synaptopodin. We assessed the cellular responses to the centrifugal forces using morphological analysis as well as immunostaining for integrins, synaptopodin, a-actinin-4, myosin IIA and actin. We also used AAV8-TBG-Ren1 virus to increase the blood pressure in vivo and further increased the detaching force on the podocytes from the basement membrane.

Results: The WT primary podocytes spread and form a continuous skirt of integrins at their periphery. The continuous integrin is colocalized with synaptopodin and maintains the sarcomere like structure (SLS) at the periphery. However, Synpo KO primary podocytes do not exhibit this continuous integrin b1 pattern at the cell periphery. Instead, Synpo KO cells show a diffuse pattern and are likely to detach. After the injection of AAV8-TBG-Ren1virus in WT and Synpo KO mice, we observed the severe proteinuria with Albumin/Creatinine ratio (ACR) measurement.

Conclusions: We discovered a mechanical role for synaptopodin in podocytes. When centrifugal force is applied, WT primary podocytes can withstand these perpendicular forces by significantly rearranging their focal adhesions. A deficiency in synaptopodin weakens the podocytes' ability to respond to these forces and is linked to increased detachment. This function of synaptopodin may play a crucial role in podocyte adhesion to the basement membrane during their responses to elevated stresses and injury.

FR-PO767

Investigation of Alternative Splicing in Mechanically Stretched Podocytes as a Model for Glomerular Hypertension

Nicole Endlich,[1,2] Felix Kliewe,[1] Francescapaola Mattias,[1] Elke Hammer,[6] Olga Tsoy,[3] Alexander Gress,[4] Stefan Simm,[5] Jan Baumbach,[3] Uwe Völker,[6] Karlhans Endlich.[1] Endlich Lab. *[1]Department of Anatomy and Cell Biology, University Medicine Greifswald, Greifswald, Germany; [2]NIPOKA GmbH, Greifswald, Germany; [3]Institute for Computational Systems Biology, University of Hamburg, Hamburg, Germany; [4]Department of Drug Bioinformatics, Helmholtz Institute for Pharmaceutical Research Saarland (HIPS), Helmholtz Centre for Infection Research (HZI), Saarbrücken, Germany; [5]Institute of Bioinformatics, University Medicine Greifswald, Greifswald, Germany; [6]Interfaculty Institute for Genetics and Functional Genomics, University Medicine Greifswald, Greifswald, Germany*.

Background: Alterations in pre-mRNA splicing play an important role in disease pathophysiology. However, the role of alternative splicing (AS) in hypertensive nephropathy (HN) has not been investigated. The purpose of the Sys_CARE (Systems Medicine Investigation of AS in Cardiac and Renal Diseases) project was to identify AS events that play a role in the development and progression of HN.

Methods: Cultured mouse podocytes were exposed to mechanical stretch for 3 days under low and high stretch conditions using the *Stretchy* apparatus (NIPOKA GmbH, Greifswald). Subsequently, mRNAs and proteins were analyzed by RNA-Seq and LC-MS/MS. Splicing and transcript expressions were studied with bioinformatical tools.

Results: Transcriptome analyses of mechanically stretched podocytes by RNA-seq showed that mechanical stress leads to a high number of differentially expressed genes compared to unstretched podocytes. GO analysis revealed that a higher number of actin-binding genes were down- and mRNA processing genes were up-regulated. To identify alternative splicing (AS) events, different AS tools were used. We found a wide variety of splice events. The most frequent event was exon skipping, followed by intron retention. We found 290 alternatively spliced genes after mechanical stretch, which were detected with three different splice analysis tools (rMATS, leafcutter, Whippet). Out of these candidates, the IsoformSwitchAnalyzeR identified 17 genes exhibiting significant isoform switches. To prioritize the candidates, we performed a screening that included only those genes that were identified by proteomic analysis, are expressed in podocytes *in vivo* or showed an altered expression patterns in glomerular disease. This screening led to the two candidates Shroom3, an actin-binding protein, which is crucial for podocyte morphology and function and Myosin light chain 6 (Myl6), a component of the myosin motor protein complex.

Conclusions: Mechanical stretch of cultured mouse podocytes, which is an excellent model to simulate hypertensive nephropathy, leads to alterations in isoform expression due to alternative splicing. These changes in the expression of isoforms, such as Shroom 3 and Myl6, have the potential to play a key role in the pathophysiology of hypertension-induced nephropathy.

FR-PO768

Liquid-Liquid Phase Separation of Lmx1b Contributes to Its Gene-Regulatory Effects, Including Noncanonical Wnt Signaling in Podocytes

He Chen,[1,2] Richard A. Tillmann,[1,2] Antonios Papadakis,[2] Eva Wiesner,[1,2] Andreas Beyer,[2] Thomas Benzing,[1,2] Martin Kann.[1,2] Nephrolab. *[1]Universitatsklinikum Koln, Koln, Germany; [2]Exzellenzcluster CECAD in der Universitat zu Koln, Koln, Germany*.

Background: Lmx1b is a transcription factor (TF) that is essential for podocyte maintenance. However, the function and mechanism of action of Lmx1b in podocytes remain poorly understood. Liquid-liquid phase separation (LLPS) has gained attention as a key mechanism for regulating transcription via the formation of nuclear transcriptional condensates, which is mediated by multivalent interaction between TFs, coactivators and general transcriptional machinery. Here, we investigate if Lmx1b undergoes LLPS as a biophysical mechanism of action and elucidate gene-regulatory effects of Lmx1b loss of function in podocytes *in vivo*.

Methods: Tamoxifen inducible conditional podocyte-specific Lmx1b knockout mice (Lmx1b-ipko) and cell lines were used as model systems. LLPS was investigated using recombinant proteins *in vitro* as well as in cell culture by overexpression. Lmx1b-ipko mice were phenotyped by STED microscopy. The gene-regulatory effects of Lmx1b *in vivo* were assessed in a time-series approach by glomerular Multiome (snRNAseq & snATACseq). The effect of Wnt ligands on the level of calcium and the actin cytoskeleton in podocytes was investigated *ex vivo* using acute kidney slices from transgenic mice expressing fluorescent actin reporter and calcium sensor.

Results: Tamoxifen induction in Lmx1b-ipko mice resulted in a progressive, time-dependent FSGS phenotype. Here, Lmx1b staining in podocyte nuclei showed speckled pattern in STED, suggesting nuclear condensation formation *in vivo*. Recombinant Lmx1b can undergo LLPS *in vitro*. Live cell imaging of eGFP.Lmx1b demonstrated that an intrinsic disordered region in Lmx1b is essential for driving LLPS in cells. Transcriptional effects of Lmx1b revealed by Multiome analysis indicated a progressive dysregulation of the non-canonical Wnt signaling pathway, in particular an upregulation of Wnt5b. In an *ex vivo* podocyte reporter system, the stimulation of glomeruli using Wnt5b resulted in increased calcium signals and altered actin cytoskeleton indicative of podocyte damage.

Conclusions: We determined that LLPS of Lmx1b is a key mechanism of its gene-regulatory action. Lmx1b-dependent gene regulation can be linked to non-canonical Wnt signaling in podocytes as novel downstream effects for mediating podocyte damage.

FR-PO769

Influence of Mitochondrial Signals on Metabolic Signaling Pathways in Podocytes

Katrin Reitmeier,[1,2] Johanna Odenthal,[1,2] Bernhard Schermer,[1,2] Thomas Benzing,[1,2] Paul T. Brinkkoetter.[1,2] Nephrolab Cologne. *[1]University of Cologne Center for Molecular Medicine Cologne, Cologne, Germany; [2]Exzellenzcluster CECAD in der Universitat zu Koln, Koln, Germany*.

Background: Mitochondrial signals are of interest in podocyte research due to the identification of single gene mutations associated with glomerular diseases, including a cluster of genes linked to mitochondrial dysfunction. We recently identified a link between structurally impaired mitochondria due to the loss of PHB2, a protein essential for the fusion of mitochondria, and hyperactivation of the Insulin signaling cascade in *Phb2* deficient podocytes. The mouse model revealed that hyperactive Insulin signaling causes a severe glomerular phenotype and premature death of the animals. This phenotype was ameliorated by blocking of insulin receptor signaling via double knockout of the Insulin and IGF-1 receptor (Ising et al. 2015).

Methods: We use *Drosophila melanogaster* nephrocytes to examine the signaling mechanism from dysfunctional mitochondria to the Insulin receptor. These podocyte-equivalent cells exhibit functional and structural similarities with mammalian podocytes, making them an established model for podocyte research. We employ nephrocyte-specific RNAi-mediated knockdown and simultaneous overexpression of target genes. The effects are assessed by performing fluorescent tracer uptake assay and immunofluorescence staining to evaluate nephrocyte filter function and morphology.

Results: We successfully replicated the phenotype observed in the PHB2 knockout mouse model in nephrocytes. Phb2 depletion led to a functional and morphological phenotype, and insulin signaling hyperactivation. We were able to interfere with and rescue this phenotype by overexpressing a functionally disabled insulin receptor variant. Notably, elevated ROS levels were observed upon Phb2 knockdown, even when insulin signaling was blocked. We hypothesized that ROS transduce a signal from dysfunctional mitochondria to the insulin receptor. To test this, we overexpressed SOD1 in the Phb2 knockdown background, which depleted ROS levels and significantly rescued the Phb2 phenotype.

Conclusions: Our results demonstrate that nephrocytes are a suitable model to study the link between dysfunctional mitochondria and insulin signaling hyperactivation. We propose a signaling mechanism where mitochondrial dysfunction elevates mitochondrial ROS levels, sensitizing podocytes to insulin signaling by targeting the insulin receptor and initiating receptor autophosphorylation.

Elovl7 Enhances Podocyte Ferroptosis in Glomerulopathy by Participating in Polyunsaturated Fatty Acid Elongation

Minchao Kang,[1] Linnan Bai,[1] Qiu-yu Li,[3] Yi Wang,[2] Junnan Wu.[1] *[1]Zhejiang University School of Medicine Sir Run Run Shaw Hospital, Hangzhou, China; [2]The First Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou, China; [3]Zhejiang University School of Medicine Children's Hospital, Hangzhou, China*.

Background: Podocytes are terminally differentiated visceral epithelial cells that form a crucial part of the glomerular filtration barrier. Podocytopathy is becoming increasingly prevalent worldwide. However, the mechanisms underlying podocyte injury remain unclear. Numerous studies have attributed podocyte loss in glomerular diseases to apoptosis, and research on podocyte-targeting therapies has emerged. This study aims to elucidate the specific mechanisms of injury and the ultimate mode of death of podocytes.

Methods: We performed single-nucleus RNA sequencing (snRNA-seq) on kidney tissues from various glomerular diseases, including adriamycin-induced nephropathy (AN), chronic kidney disease (CKD), minimal change disease (MCD), and obesity-related glomerulopathy (ORG). Cell death pathway scoring on podocytes identified the predominant form of podocyte death. Gene enrichment analyses along with pseudo-time analysis revealed multiple lipid metabolism pathways associated with podocyte

injury. Targeted lipidomics on adriamycin-stimulated Mpc5 cells (Mouse Podocyte Clone-5) and metabolic pathway scoring pinpointed changes in phospholipid types and lipid metabolism pathways. Conditional knockout mice and intracellular knockdown experiments were conducted to validate the impact of key gene in the lipid metabolism pathway we screened.

Results: Cell death pathway scoring on podocytes demonstrated elevated ferroptosis scores in nephropathies with severe podocyte injury, such as AN and CKD. Additionally, Injured podocytes had higher levels of phospholipids with long-chain unsaturated fatty acid side chains, which are sensitive to ferroptosis, compared to the control group. Metabolic pathway scoring revealed dysregulation of Elovl7-involved fatty acid elongation in the podocytes of the AN group. Podocyte-specific Elovl7 knockout in mice and Elovl7 knockdown in Mpc5 cells abolished the elevated levels of phospholipids with long-chain polyunsaturated fatty acids and lipid peroxides.

Conclusions: In summary, we found substantial podocyte loss and annotated a subset of injured podocytes in snRNA-seq data from podocytopathies. This may be due to the increased synthesis of long-chain polyunsaturated fatty acids mediated by Elovl7, which eventually leads to the accumulation of intracellular lipid peroxidation and ferroptosis.

FR-PO771

SMPDL3b Overexpression Is Associated with STING Activation in Podocytes in CKD

Alla Mitrofanova, Antonio M. Fontanella, Veronika Semenova, Rachel Njeim, Judith T. Molina David, George W. Burke, Sandra M. Merscher, Alessia Fornoni. *University of Miami Miller School of Medicine, Miami, FL.*

Background: Chronic kidney disease (CKD) is a global health challenge marked by rising incidence, prevalence, and poorly understood pathogenesis. Our prior work suggests that sphingolipids, especially sphingomyelin phosphodiesterase acid-like 3b (SMPDL3b), regulate podocyte function and survival. Sphingolipids also modulate inflammation, a key driver of CKD progression. Our recent findings link STING activation to podocyte foot process disruption, proteinuria, and CKD progression. Here, we aim to explore if increased SMPDL3b expression leads to podocyte injury through chronic STING activation.

Methods: Illumina sequencing RNA data analysis, qRT-PCR and Western blot analysis were used to characterize the immortalized control (CTRL) or overexpression (SMP OE) human podocytes. Cells were treated with c-diAMP (10μM), a STING specific agonist, for 24h. 8-week-old mice with podocyte specific Smpdl3b deficiency ($pSMP^{fl/fl}$) or overexpression ($pSMP^{Tg}$) were used to evaluate glomerular STING activation. $pSMP^{fl/fl}$ and $pSMP^{Tg}$ mice were intraperitoneally injected with a single dose of c-diAMP, 50mg/kg or 5% DMSO and sacrificed 72h after injection, followed by urinary albumin-to-creatinine ratio (ACR), histological and serum analyses. Two-tailed t-test or One-Way ANOVA followed by Tukey's post-test were used to detect statistical changes.

Results: We observed significant changes in the expression of genes related to cytosolic DNA sensing pathways in SMP OE podocytes. Both *in vitro* and *in vivo* experiments revealed elevated levels of STING phosphorylation (pSTING). Treatment with c-diAMP increased pSTING levels in control podocytes but not in SMP OE podocytes. While baseline proteinuria was absent in both $pSMP^{fl/fl}$ and $pSMP^{Tg}$ mice, administration of c-diAMP led to a notable increase in ACR specifically in $pSMP^{Tg}$ mice. No significant changes in body weight or levels of serum BUN and creatinine in either $pSMP^{fl/fl}$ or $pSMP^{Tg}$ mice following c-diAMP treatment. TEM analysis revealed FPE in control and $pSMP^{Tg}$ mice treated with c-diAMP, but not in $pSMP^{fl/fl}$ mice.

Conclusions: Our data indicate that SMPDL3b overexpression is associated with STING activation in podocytes *in vitro* and STING-dependent proteinuria *in vivo*.

FR-PO772

Elevated Expression of Isthmin-1 Impairs Glomeruli Filtration Leading to Proteinuria in CKD

Ge Gao,[1,2] Zhongjun Zhou.[2] [1]*Guangdong Provincial People's Hospital, Guangzhou, China;* [2]*The University of Hong Kong Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong.*

Background: The incidence of chronic kidney disease (CKD) accounts for 10 to 13% in adults and is usually accompanied by cardiovascular diseases, exhibiting high morbidity and mortality. We observed upregulated Isthmin-1 (Ism1) in nephropathy models and aging kidneys. Ism1 transgenic (*Ism1 Tg*) mice exhibited focal segmental glomerular sclerosis (FSGS) and impaired cytoskeleton in podocytes and proteinuria, as shown by podocyte foot process effacement. In contrast, loss of Ism1 can protect mice from undergoing Adriamycin-induced FSGS and cytoskeleton injury in podocytes. However, the mechanism remains unresolved.

Methods: As a secreted protein, Ism1 functions through interacting with receptor to activate or inhibit the downstream signaling. Since ligand-receptor interaction is normally transient and weak, we took advantage of HRP-induced proximity labelling in kidney tissues to search for the potential receptor of Ism1 in glomeruli.

Results: Based on our unbiased screening of receptors with consideration to kidney phenotypes in genetically modified mice, we identified a specific Integrin as a potential receptor of Ism1 in the adult kidney. The interaction between Ism1 and this Integrin was validated in 293T cells. In addition, Ism1 triggered the activation of specific Integrin signaling, leading to the impairment of the podocyte cytoskeleton. We therefore propose that elevated Ism1 results in podocyte cytoskeleton injury by activating Integrin signaling.

Conclusions: Our findings highlight the critical role of Ism1 in the pathogenesis of kidney diseases and provide a novel target for alleviating podocyte injury and CKD.

TAZ Shows Limited Ability to Substitute for YAP in Preserving Podocytes, Demonstrating Distinct Roles of the Transcriptional Regulators at the Kidney Filtration Barrier

Lioba Ester,[1,2] Eva Wiesner,[1,2] He Chen,[1,2] Paul Diefenhardt,[1,2] Paul T. Brinkkoetter,[1,2] Thomas Benzing,[1,2] Martin Kann,[1,2] Bernhard Schermer,[1,2] Inês Cabrita.[1,2] [1]*Universitatsklinikum Koln, Koln, Germany;* [2]*Exzellenzcluster CECAD in der Universitat zu Koln, Koln, Germany.*

Background: Podocytes must effectively adapt to considerable mechanical forces at the filtration barrier throughout an organism's lifespan. However, the precise molecular mechanisms governing podocyte adaptation to such mechanical stressors remain elusive. YAP and TAZ, two paralogous transcriptional regulators, have emerged as pivotal mechanotransducers capable of sensing and transducing mechanical stimuli to regulate transcriptional activity.

Methods: We employed conditional deletion targeting Yap (YAP^{pKO}), Taz (TAZ^{pKO}), or both (YAP^{pKO}/TAZ^{pKO}) specifically in podocytes to delineate the distinct and shared roles of YAP and TAZ in podocyte homeostasis. Utilizing single-nucleus RNA sequencing (snRNA-Seq) analysis of isolated glomeruli, we elucidated overlapping and unique transcriptional responsibilities of these regulators.

Results: Conditional deletion of Yap in podocytes resulted in foot processes effacement and progressive renal failure, whereas Taz deletion did not cause disease. Notably, simultaneous deletion of Yap and Taz led to a neonatal lethal phenotype. Intriguingly, even mice lacking three out of the four Yap and Taz alleles proved non-viable, revealing a compensatory capacity shared between these two regulators. Our snRNA-Seq analysis unveiled an AP-1-dominated stress response as one of the compensatory mechanisms, evident in a subcluster of both YAP- and TAZ-deficient podocytes. Furthermore, dysregulation of Rho-GTPase activity, contributing to actin cytoskeleton de-arrangement, emerged as a primary driver of injury in YAP^{pKO} podocytes. Lastly, the loss of ERBB4 expression in YAP^{pKO}, but not in TAZ^{pKO}, delineated a key distinction between the two regulators, emphasizing a YAP-specific role in regulating ERBB4 signaling to sustain podocyte survival.

Conclusions: Our study comprehensively dissects the distinct and overlapping functions of YAP and TAZ in podocyte homeostasis. Through snRNA-Seq analysis, we identified several pivotal molecular mechanisms, some of which are shared by both regulators while others are dependent solely on YAP. Notably, while YAP can adequately compensate for loss of TAZ, TAZ lacks the capacity to effectively substitute for YAP, resulting in podocyte injury in the absence of YAP.

FR-PO774

Functional Role of the Mechanosensitive Channel Piezo for Nephrocyte Biology

Karl K. Alornyo,[1] Paris Hazelton-Cavill,[1] Kristina Schulz,[1] Ilka Edenhofer,[1] Maja Lindenmeyer,[1] Christian Lohr,[2] Tobias B. Huber,[1] Barry Denholm,[3] Sybille Koehler.[1] [1]*Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany;* [2]*Universitat Hamburg Fakultat fur Mathematik Informatik und Naturwissenschaften, Hamburg, Germany;* [3]*Biomedical Sciences, University of Edinburgh, Edinburgh, United Kingdom.*

Background: Due to their position on glomerular capillaries, podocytes are continuously counteracting biomechanical filtration forces. Most therapeutic interventions known to generally slow or prevent the progression of chronic kidney disease appear to lower the biomechanical forces on podocytes, highlighting the critical need to better understand podocyte mechano-signalling pathways.

Methods: Here we investigated the hypothesis that the mechanotransducer Piezo is involved in a mechanosensation pathway in *Drosophila* nephrocytes, the podocyte homologue in the fly.

Results: Our data show Piezo is expressed in nephrocytes where it localises to the nephrocyte diaphragm. Loss of function analysis in Piezo depleted nephrocytes revealed a morphological and functional phenotype. Further, we show that elevated Piezo expression levels resulted in Rho1 hyperactivity and accumulation of actin stress fibres, culminating in a severe nephrocyte phenotype, suggesting that pathway hyperactivity is detrimental as well. Interestingly, expression of Piezo, which lacks mechanosensitive channel activity, did not result in a severe nephrocyte phenotype and activation of Rho1, suggesting the observed changes in Piezo wildtype overexpressing cells are caused by

the mechanosensitive channel activity. Further, pharmacological activation of Piezo with Yoda1 caused a significant increase of intracellular Ca^{++} upon exposure to mechanical force in nephrocytes, as well as filtration disturbances and Rho1 activation. Moreover, blocking Piezo activity using the tarantula toxin GsMTx4 reversed filtration disturbances, Rho1 hyperactivation as well as actin stress fibre accumulation in nephrocytes overexpressing Piezo.

Conclusions: Taken together, these data show that Piezo plays an important role in nephrocyte mechanotransduction and mediates downstream signalling such as Rho1 activation and actin stress fibre formation.

FR-PO775

Topology and Structure of Membrane-Inserted APOL1

John C. Edwards, Jonathan M. Bruno. *Saint Louis University School of Medicine, St Louis, MO.*

Background: ApoL1 is an amphipathic protein that enters membranes at low pH and after titration to neutral pH, functions as a non-selective cation channel. Prior studies provide a model of membrane topology of active channel (Schaub et al., JBC (2021) 297: 101009): two loops span the membrane between positions 177 and 228 and positions 257 and 356, generating two segments exposed to the trans compartment. The segment from 335 to 356 forms a homodimer with the same segment of another molecule, forming the ion pore. A leucine zipper structure in the C-terminus is implicated in stabilizing the homo-dimer. We sought gain a fuller understanding of the sequences and environmental determinants that allow ApoL1 to form a functional pore.

Methods: Using purified recombinant ApoL1 constructs and pre-formed phospholipid membranes: 1. Accessibility of 26 single cysteine substitution mutants for modification from the cis and trans compartment was determined under a variety of conditions 2. Proximity of individual cysteines in membrane-inserted protein complexes was determined with crosslinking reagents 3. Effect of elimination of charged amino acids in the first transmembrane loop on membrane topology, activity, and pH sensitivity of membrane association was assessed 4. Effect of disruption of putative leucine zipper motif on dimerization, topology and activity was determined

Results: Cysteine accessibility confirms the topology model and demonstrates an additional trans-accessible segment in protein associated under optimal Cl permeability conditions. Crosslinking membrane-inserted cysteine-labelled protein identifies multiple sites of proximity between the dimers in addition to the pore-forming transmembrane segment. Elimination of the three glutamates in the first transmembrane loop alters the pH sensitivity of membrane association, but also eliminates activity and does not allow stable formation of the first transmembrane loop. Disruption of the leucine zipper motif eliminates activity, crosslinking at the pore segment, and stable formation of the first transmembrane loop.

Conclusions: The data provide new constraints on any model of membrane inserted ApoL1 structure. Most importantly, the leu zipper data indicates a direct interaction between the C-terminal segment and the first transmembrane loop, suggesting a structural basis for the effects of the C-terminally located disease-associated sequence variants that activate the channel.

FR-PO776

Hypoxia-Induced Peroxisomal Stress Mediates Cytotoxicity of APOL1 Variants

Ji Young Kim, Isaac Z. Karel, Pei-Hui Lin, Navjot Pabla, Sethu M. Madhavan. *The Ohio State University, Columbus, OH.*

Background: *APOL1* variants (*G1* and *G2*) are critical drivers of CKD in individuals of African ancestry. Not all individuals with *APOL1* kidney risk variants (KRVs) develop kidney disease, consistent with the need for a “second hit” like interferon or hypoxia to initiate disease. The mechanisms that cause CKD under the influence of these triggers remain uncertain. This study aims to identify “second hit” trigger genes and pathways in order to develop therapeutic approaches to modify their function.

Methods: A genome-wide siRNA and CRISPR screen on ~20,000 genes (3 targets/gene) was conducted in HEK293 cells expressing APOL1-G0, G1, and G2 under hypoxia ($1\%O_2$) using cytotoxicity as the readout, which identified peroxisomal genes. Individual targets were validated by siRNA knockdown. APOL1 localization to peroxisomes was analyzed using proximity biotinylation, peroxisome isolation and STORM imaging, and peroxisomal stress was measured by catalase activity in HEK293 cells and human podocytes. Candidate drug screening was performed in HEK293 cells. Peroxisomal localization of APOL1 in healthy human kidneys and FSGS was examined by PEX14 immunohistology. Glomerular peroxisomal protein expression (healthy kidneys n=4, FSGS n=12) was analyzed by mass spectrometry.

Results: Hypoxia increased APOL1-G1 and G2 cytotoxicity in HEK293 cells and human podocytes. siRNA and CRISPR screens revealed that knockdown of genes involved in peroxisome biogenesis or *Peroxins* (*PEX3, PEX5, PEX11, PEX13, PEX16, PEX19, FIS1)* intensified APOL1 KRV-induced cytotoxicity under hypoxia. STORM imaging and fractionation studies showed translocation of APOL1s to peroxisomes under hypoxia. A C-terminal peroxisomal targeting signal facilitated this translocation, leading to increased catalase activity by APOL1 KRVs, indicating peroxisomal stress. Enhancing peroxisomal function genetically (PEX overexpression) or pharmacologically (PPAR-α agonists) alleviated hypoxia-induced APOL1 KRV cytotoxicity. APOL1 co-localized with peroxisomes in podocytes of healthy human kidneys, while Peroxin expression in glomeruli was reduced in FSGS.

Conclusions: Peroxisomal genes are novel genetic modifiers of APOL1 nephropathy, protective against podocyte dysfunction caused by APOL1 KRVs under hypoxic conditions. Augmenting peroxisomal function represents a potential therapeutic strategy to ameliorate CKD associated with APOL1 KRVs.

FR-PO777

Lysosomal Cathepsin B Assists to Withstand Mechanical Stress in Podocytes

Franziska Theilig,[1] Magdalena Westermann,[1] Felix Kliewe,[2] Makhabbat Saudenova,[1] Alexander Siebertz,[1] Fatih Demir,[3] Markus M. Rinschen,[3] Nicole Endlich,[2] Eileen Dahlke.[1] *[1]CAU Kiel Institute of Anatomy, Kiel, Germany; [2]University Greifswald Institute of Anatomy and Cell Biology, Greifswald, Germany; [3]Aarhus University Department of Biomedicine, Aarhus, Denmark.*

Background: During filtration podocytes are exposed to mechanical stress and have to buttress the glomerular filter against the filtration pressure. Especially, glomerular hypertension is thought to damage podocytes with concomitant foot process effacement and urinary podocyte loss. Lysosomes are important regulators of cellular physiology and act on cell stress with a lysosomal stress response. Aim of this study was to identify the role of lysosomes and the lysosomal hydrolase cathepsin B (CTSB) in mechanical stress of podocytes.

Methods: Immortalized mouse podocytes and primary podocytes isolated from CTSB -/- and respective control mice were exposed to mechanical stress and examined by immunocytochemistry (ICC) and western blot (WB) analysis. In addition, immortalized mouse podocytes were treated with the CTSB inhibitor CA074Me and morphological alterations were determined. Isolated glomeruli of CTSB -/- and respective control mice were used for proteomic and N-terminomic analysis.

Results: Immortalized podocytes underwent mechanical stress demonstrated an increased expression of lysosomes, lysosomal hydrolases (CTSB, CTSL) and an augmented autophagy (p62, LC3). Inhibiting CTSB in podocytes with mechanical stress revealed lower stress resistance characterized by increased detachment rate and alterations in the number and length of cell processes. N-terminomic analysis of glomeruli from CTSB -/- and control mice showed significant less proteolytic processing of intermediate filaments, actin binding and associated proteins and focal adhesion proteins. WB and ICC analysis of identified proteolytic processed protein confirmed cleavage and demonstrated an altered expression level.

Conclusions: Our data show that mechanical stress in podocytes leads to a lysosomal stress response to increase the expression level of CTSB to induce processing of cytoskeletal associated proteins and adhesion proteins to cope with and withstand higher levels of mechanical stress.

FR-PO778

Cathepsin B Alleviates the Development of Focal Segmental Glomerulosclerosis

Franziska Theilig,[1] Mairon Trujillo Miranda,[1] Jessica Promnitz,[1] Makhabbat Saudenova,[1] Magdalena Westermann,[1] Geraldine Mollet,[4] Theresa Riebeling,[3] Stefan Krautwald,[3] Fatih Demir,[2] Markus M. Rinschen,[2] Eileen Dahlke.[1] *[1]CAU Kiel Institute of Anatomy, Kiel, Germany; [2]Aarhus University Department of Biomedicine, Aarhus, Denmark; [3]University Clinic Schleswig-Holstein, Department of Nephrology, Kiel, Germany; [4]Université Paris Cité, Laboratory of Hereditary Kidney Diseases, Inserm UMR1163, Imagine Institute, Paris, France.*

Background: Focal segmental Glomerulosclerosis (FSGS) is one of the most typical histopathological causes of glomerulopathy affecting primarily the podocyte. Lysosomes are responsible for the degradation of molecules via hydrolytic enzymes, such as cathepsin B (CatB) and may serve as a platform mediating cellular signaling in podocytes. Additionally, podocyte stress is associated with lysosome dysfunction. In this study we aim to explore the role of CatB in the progression of podocyte dysfunction to FSGS.

Methods: Podocyte-specific NPHS2 deleted mouse model ($Pod^{Cre}NPHS2^{flox}$) leading to FSGS development were used and cross-bred for additional podocyte-specific or complete CatB deletion. Renal function parameter analysis, histolmorphological analysis, transmission electron microscopy (TEM) imaging and immunohistochemistry (IHC) were performed after 3 weeks of induction. Isolated glomeruli from the mouse models were analyzed by proteomic/N-terminomic analysis.

Results: Renal function parameter demonstrated higher BUN, plasma creatinine levels and proteinuria in Pod^{Cre}NPHS2^{flox} compared to Pod^{Cre}NPHS2^{flox} with CatB deletion and to control. Morphological analysis revealed higher glomerular and tubulointerstitial damage score in PodCreNPHS2flox compared to Pod^{Cre}NPHS2^{flox} with CatB deletion and to control. IHC revealed an increased expression of TFEB, LAMP1 and galectin 3 in Pod^{Cre}NPHS2^{flox} which was attenuated by additional CatB deletion. TEM analysis demonstrated a significant increase in mitochondrial and podocyte injury in Pod^{Cre}NPHS2^{flox} compared to control and mice with additional CatB deletion which corroborates with higher processing of various mitochondrial proteins identified by N-terminomic analysis. Inflammasome activation was strongly induced in Pod^{Cre}NPHS2^{flox} compared to control and tom mice with additional CatB deletion.

Conclusions: CatB deletion prevents the development of FSGS, keeping the Pod^{Cre}NPHS2^{flox} mouse model to a minimal change disease. In FSGS progression, CatB induces inflammasome activation and spreading and mitochondria dysfunction, showing that CatB may be an option to target FSGS treatment.

Angiotensin II Increases Nephrin Endocytosis via AT1-Receptor ERK 1/2 Activation

Eva Koenigshausen, Ulf Zierhut, Martin Rütze, Lars C. Rump, Lorenz Sellin. *Heinrich-Heine-Universitat Dusseldorf, Dusseldorf, Germany.*

Background: Albuminuria is characterized by a disruption of the glomerular filtration barrier, which is composed of the fenestrated endothelium, the glomerular basement membrane, and the slit diaphragm. Nephrin is a major component of the slit diaphragm. Apart from hemodynamic effects, Angiotensin II (Ang II) enhances albuminuria by β-Arrestin2 dependent nephrin endocytosis.

Methods: 1. Isolated mouse glomeruli were stimulated with Ang II and co-immunopreciptiation of nephrin with β-Arrestin 2 performed. 2. Differentiated murine podocytes were stimulated with Ang II and biotinylation assay with immunoprecipitated nephrin performed. 3. HEK293T cells were pretreated with AT1-receptor blockers candesartan and irbesartan before treatment with Ang II. 4. An AT1-receptor mutant, defective of EGFR transactivation and β-Arrestin 2 recruitment, was used as well as mutant β-Asrrestin2 K11/K12R. Different ERK 1/2 inhibitors were tested. Immunofluorescence imaging was performed in Cos7 cells.

Results: Ang II increases nephrin-β-Arrestin2 binding in murine glomeruli and endocytosis in murine podocytes. Blocking the AT1 receptor with candesartan and irbesartan reduces the Ang II-mediated nephrin-β-Arrestin2 interaction. The inhibition of MAPK ERK 1/2 blocks Ang II-enhanced nephrin-β-Arrestin2 binding. ERK 1/2 signaling, which follows AT1 receptor activation, is mediated by G-protein signaling, EGFR transactivation, and β-Arrestin2 recruitment. A mutant AT1 receptor defective in EGFR transactivation and β-Arrestin2 recruitment reduces the Ang II-mediated increase in nephrin β-Arrestin2 binding. The mutation of β-Arrestin2^{K11,K12}, critical for AT1 receptor binding, completely abrogates the interaction with nephrin, independent of Ang II stimulation. β-Arrestin2^{K11R,K12R} does not influence nephrin cell surface expression.

Conclusions: The data presented here deepen our molecular understanding of a blood-pressure-independent molecular mechanism of AT-1 receptor blockers (ARBs) in reducing albuminuria by nephrin endocytosis. MAP kinase signalling events play a relevant role in Ang II mediated nephrin endocytosis.

FR-PO780

Genotype-Phenotype Correlations in Congenital Nephrotic Syndrome Associated with Nephrin Gene C-terminal Mutations

Ewelina Hejenkowska, Agnieszka Swiatecka-Urban. *University of Virginia, Charlottesville, VA.*

Background: Nephrin is a transmembrane protein forming homo- and hetero-dimeric interactions critical to the function of the glomerular slit diaphragm (SD). Homozygous nephrin gene mutations lead to congenital nephrotic syndrome (CNS). Loss of the last 132 aa at the nephrin C-terminal tail (p.R1109X) leads to more severe symptoms than the absence of the last 81 aa (p.R1160X), but the mechanism is not understood. The R1109X nephrin is thought to lack SD localization, while the R1160X mutant retains the SD localization. Studies were performed to test the hypothesis that the sequence between aa 1109 and 1160 in the nephrin C-terminal tail is critical for its plasma membrane (PM) localization.

Methods: Immortalized human podocytes were transfected with wild-type (WT) nephrin, R1109X, or R1160X. The nephrin PM localization at steady state was examined by cell surface biotinylation and western blotting. The nephrin PM stability was examined over time in the presence of cycloheximide to inhibit new protein translation.

Results: Similar to nephrin R1160X, the R1109X mutant was expressed at the PM, and both had lower PM abundance at steady state, compared to WT nephrin. Nephrin R1160X was more stable at the PM, compared to WT nephrin while the PM stability of nephrin R1109X was similar to WT. The total cellular stability of nephrin mutants was similar to WT nephrin.

Conclusions: Unlike the previous report, we demonstrate that nephrin R1109X traffics to the PM in human podocytes, and thus, the C-terminal sequence between aa 1109 and 1160 is not essential to PM localization. The decreased PM abundance and similar PM and total cellular stability suggest that the R1109X truncation decreases nephrin biosynthetic processing but does not alter its PM dynamics or degradation. The decreased abundance and increased stability of nephrin R1160X at PM suggest that R1160X truncation impairs biosynthetic processing and PM dynamics. Our data provide novel insights into the role of the nephrin cytoplasmic tail domain. Ongoing studies focus on examining protein-protein interactions affected by the nephrin truncations to understand their genotype-phenotype correlations in CNS further.

Podocyte EGR1 Expression in Patients with Primary Focal Segmental Glomerulosclerosis and Minimal Change Disease

Masahiro Okabe,[1] Kentaro Koike,[1] Nobuo Tsuboi,[1] Taiji Matsusaka,[2] Takashi Yokoo.[1] [1]*Jikei University School of Medicine, Tokyo, Japan;* [2]*Tokai University School of Medicine, Ieshara, Japan.*

Background: We have reported that early growth response 1 (EGR1) expresses in injured podocytes from early stage in an inducible podocyte-injury mouse model, NEP25. We also found that the percentage of EGR1-positive podocytes (%EGR1pod) is associated with podocyte injury in patients with glomerular diseases. Primary focal segmental glomerulosclerosis (pFSGS) and minimal change disease (MCD) both present nephrotic syndrome but have very different prognoses, suggesting a potential difference in the degree of podocyte injury between these two conditions. In this study, we aim to examine the difference in podocyte EGR1 expression between patients with pFSGS and MCD.

Methods: Adult patients with biopsy-proven pFSGS or MCD who presented acute-onset nephrotic syndrome were enrolled from Jikei University Hospital, Japan, and Jikei University Daisan Hospital, Japan, between 2001 and 2020. Patients over 70 years of age and patients with serum creatinine levels greater than 1.5 mg/dL were excluded. The %EGR1pod was determined through immunohistochemistry and was compared between the pFSGS and MCD groups.

Results: Patients with pFSGS (n = 9) were significantly older than those with MCD (n = 63) (median, 51 [Interquartile range (IQR), 50–58] vs 39 [29–48] years, P = 0.003), but there was no significant difference in sex, urinary protein level, serum albumin level, or serum creatinine level. The %EGR1pod was significantly higher in the pFSGS group than the MCD group (3.02 [2.60–4.97]% vs 0.68 [0.38–1.53]%, P < 0.001) (Figure 1A). Receiver operating curve (ROC) analysis revealed an area under the curve (AUC) of 0.945 [95% confidence interval, 0.876–1] for distinguishing between pFSGS and MCD patients (Figure 1B).

Conclusions: Stronger podocyte injury was observed in patients with pFSGS than in those with MCD, which may impact kidney prognosis. The %EGR1pod may be a useful marker for differentiating pFSGS from MCD.

Relative Roles of CCL5 on Podocytes and Macrophages in Glomerular Injury

Issei Okunaga, Ika N. Kadariswantiningsih, Maulana A. Empitu, Kaho Yamasaki, Masashi Aizawa, Katsuhiko Asanuma. *Chiba Daigaku, Chiba, Japan*.

Background: We had previously reported that Notch2 activation reduces podocyte damage, and now we have identified and analyzed C-C motif chemokine ligand 5 (CCL5) as the downstream molecule. CCL5 is a secreted protein that acts on macrophages (Mϕ), T cells, and epithelial cells, but its role in glomerular injury is controversial. An earlier study has shown that a functional CCL5 antagonist attenuates glomerulonephritis, while another study reported that it exacerbates glomerular damage in glomerular disease models. Using *in vitro* and *in vivo* studies, we delved into the role of CCL5 in podocytes and bone marrow-derived cells.

Methods: We performed immunostaining of human kidney samples to investigate the expression of CCL5 in glomerular disease. Cultured CCL5 knockout (KO) podocytes and CCL5 KO mice were created. Cultured WT podocytes and CCL5 KO podocytes were treated with adriamycin (ADR), and then the apoptosis rate was evaluated. WT and CCL5 KO mice were injected with ADR to induce nephropathy, and then we investigated the kidney pathology. We performed bone marrow transplantation in WT and CCL5 KO mice to study the CCL5 function in podocytes or bone marrow-derived cells.

Results: We found that CCL5 expression in glomeruli was upregulated in patients with glomerular disease and in ADR-induced nephropathy mice. ADR-induced injury in cultured WT podocytes was ameliorated by exogenous CCL5 administration and exacerbated by CCL5 deficiency. These *in vitro* studies suggested that CCL5 has a protective role in injured podocytes. Next, to check the role of CCL5 *in vivo*, ADR nephropathy mice were used. Unexpectedly, ADR-induced nephropathy was ameliorated in CCL5 KO mice. To elucidate the discrepancy, we transplanted the bone marrow of CCL5 KO mice to ADR-induced nephropathy WT mice. The transplantation of CCL5 KO bone marrow ameliorated the ADR-induced nephropathy in the WT mice.

Conclusions: CCL5 exacerbates ADR nephropathy via bone marrow-derived cells but plays a protective role in podocytes. The results suggest that CCL5 has ambivalent cellular effects in glomerular diseases.

Unveiling Functional Renin-Angiotensin System-Related Signaling in Parietal Epithelial Cells

Mykhailo Fedoriuk,[1] Mariia Stefanenko,[1] Justin P. Van Beusecum,[2,1] Daria Ilatovskaya,[3] Oleg Palygin.[1] *[1]Medical University of South Carolina, Charleston, SC; [2]Ralph H. Johnson VA Medical Center, Charleston, SC; [3]Augusta University, Augusta, GA.*

Background: The Bowman's capsule envelops the kidney's glomerular tuft, comprised of a single layer of parietal epithelial cells (PECs) that form a vital barrier between the urinary space and the renal interstitium. When PECs undergo pathophysiological activation, they transition from their usual quiescent state to one characterized by proliferation and migration towards the glomerular tuft, causing glomerular injury. Numerous proteinuric kidney diseases are linked to PEC activation, yet the precise mechanisms governing functional receptor signaling in these cells remain poorly understood. This study aims to explore the presence of components of the renin-angiotensin system (RAS) and the corresponding intracellular mechanisms within PECs.

Methods: The vibrodissociation technique was utilized to obtain freshly isolated Bowman's capsules with PECs from discarded adult male human transplant tissues and 12-week-old Wistar male and female rats. Live confocal microscopy detected changes in intracellular Ca^{2+} concentrations (Fluo8) and nitric oxide (NO; DAF-FM) response to acute Ang II applications. Scanning electron microscopy (SEM) was used to examine the PECs structure.

Results: In SEM, we confirmed the intact nature of the isolated PECs of the Bowman capsule. The acute administration of Ang II peptide elicited rapid NO production in cells isolated from both males and females, while no significant intracellular Ca^{2+} influx in response to Ang II. To identify the functional receptor responsible for Ang II signaling in PECs, we preincubated cells with AT1R or AT2R blockers (Losartan and PD123319, respectively). Our findings demonstrated that Ang II facilitates NO production via AT2R activation, which held true in both sexes. Importantly, in separate experiments, we confirmed the similarity of these signaling mechanisms between the rat and human species.

Conclusions: Our research offers insight into Ang II-mediated signaling within PECs. For the first time, we present evidence establishing a direct link between Ang II and redox homeostasis in PECs. Further exploration utilizing this newly developed approach will be crucial for understanding the involvement of PECs in glomerular function and devising potential treatments targeting the hyperplasia of activated PECs and associated chronic kidney pathologies.

FR-PO784

Parietal Epithelial Cell (PEC)-Specific Knockout of Integrin-αv Attenuates PEC Activation and Proliferation in Proliferative Glomerulopathy

Deepa Sathee, Anirudh Krishnan, Yiqing Guo, Robert Bronstein, Sandeep K. Mallipattu. *Stony Brook University Renaissance School of Medicine, Stony Brook, NY*.

Background: Parietal epithelial cell (PEC) activation and proliferation contributes to crescent formation, leading to glomerulosclerosis and eventual loss of kidney function in proliferative glomerulopathies. Our previous single nucleus RNA-seq in mice with proliferative glomerulopathy demonstrated an enrichment in Integrin avb6 signaling in activated PECs. Here, we investigate the role of Itgav in PEC activation and proliferation in models of proliferative glomerulopathy.

Methods: Mouse PECs with Itgav knockdown (*Itgav-/-*) were generated by lentiviral method. RTPCR was employed for determining PEC activation markers. Scratch assay was performed to assess the migration pattern. PEC-specific inducible *Itgav-/-* mice were generated using the "tet-on" system. NTS (Nephrotoxic serum) was used as a model of proliferative glomerulopathy. Albuminuria, histopathological assessment for crescent formation, PEC markers and fibrotic markers were measured.

Results: *Itgav-/-* PECs showed a reduction in activated PEC markers (CD44, CD74, CCND1, DOCK10, FOSL2, CLDN1) as compared to control cells. In addition, *Itgav-/-* PECs exhibited changes in morphology, less proliferation (MTT, cell count) and migration as compared to control cells. PECs treated with monoclonal-ab against avb6 also attenuated PEC activation and proliferation. NTS-treated *Itgav-/-* mice showed a decrease in albuminuria at day 7 post-NTS as compared to NTS-treated WT mice, with a decrease in activated PECs (reduced CD44 expression) and fibrotic markers (α-SMA, picrosirius red).

Conclusions: These data suggest that loss of Itgav in PECs attenuates PEC activation, cell migration, crescent formation and eventual fibrosis in models of proliferative glomerulopathy.

Murine Model of Glomerular Thrombotic Microangiopathy Results in Glomerular Endothelial-to-Mesenchymal Transition

Patrick Droste,[1,2] Sonja Djudjaj,[1] Barbara M. Klinkhammer,[1] Eva M. Buhl,[1] Elisabeth Kemter,[3] Peter Boor.[1,2] Laboratory of Nephropathology. *[1]Institute of Pathology, University Hospital RWTH Aachen, Aachen, Germany; [2]Department of Nephrology and Clinical Immunology, University Hospital RWTH Aachen, Aachen, Germany; [3]Institute of Molecular Animal Breeding and Biotechnology, Gene Center and Department of Veterinary Sciences, Ludwig-Maximilians-Universität München, München, Germany*.

Background: Thrombotic microangiopathies (TMAs) are rare diseases with a poor prognosis and a multifaceted manifestation pattern. The pathological processes in the glomerulus during TMA are incompletely understood, also because very few animal models are available. Here, we characterized a murine model with glomerular-limited endothelial cell injury with thrombi.

Methods: Eight-week-old healthy wild-type littermate mice were compared with mutated diseased mice (generated by random mutagenesis). Perfused kidneys were investigated with histological, immunohistochemical, and immunofluorescence stainings combined with RNA *in situ* hybridization by quantitative optical sectioning and image analysis. Transmission electron microscopy was used to study ultrastructural alterations. Renal functional, hemolysis, and complement system parameters were assessed in serum and urine.

Results: The mice developed a spontaneous phenotype with diffuse and global signs of glomerular TMA resulting in impaired kidney function, decreased body weight, and lifespan. The glomeruli were enlarged and showed thrombi, double contours of the glomerular basement membrane (GBM) with cell interposition, and endothelial cell swelling. Mesenchymal markers were expressed in a unique circular pattern around the capillaries in the glomerulus colocalized with the double contour of the GBM. The glomerular endothelial cells lost part of their characteristic endothelial markers, displayed *de novo* expression of mesenchymal markers, and showed ultrastructural features of mesenchymal cells, suggesting an endothelial-to-mesenchymal transition. The progressive course of the disease was further documented by the development of interstitial fibrosis and inflammatory cell infiltrations in the kidney cortex. No signs of hemolysis or serological evidence of complement activation were detected, suggesting a glomerular-limited disease.

Conclusions: The present mouse model showed typical signs of endothelial injury and glomerular remodeling found in TMA, revealing a novel pathological process of chronic glomerular injury in TMA via glomerular endothelial-to-mesenchymal transition.

FR-PO786

Glomerular Endothelial Plasmalemma Vesicle-Associated Protein (PLVAP) Is Re-expressed in Thrombotic Microangiopathy and Associated with Endothelial Cell Dedifferentiation and Increased Permeability

Chelsea C. Estrada,[1,2] Craig Wilson,[2,1] Sumaya Ahmed,[2] Nehaben A. Gujarati,[2] Sandeep K. Mallipattu.[2,1] *[1]Northport VA Medical Center, Northport, NY; [2]Stony Brook University, Stony Brook, NY.*

Background: GEnC injury is a common feature across the wide spectrum of glomerular diseases and is the inciting event that drives downstream glomerular changes and eventual chronic kidney disease in both Diabetic Kidney Disease (DKD) and Thrombotic Microangiopathy (TMA). We recently reported the development of subacute TMA and GEnC injury in mice with the combined double knockout of endothelial *Klf4* and *Nos3* (DKO), compared with wild type mice (*Klf4*$^{fl/fl}$) or single endothelial knockout of either *Klf4* (*Klf4*$^{\Delta EC}$) or eNOS (*Nos3*$^{-/-}$), however the mechanism(s) of GEnCs response to injury are poorly understood.

Methods: Single-cell RNAseq libraries were generated from frozen kidney cortex from 12-wk old male mice in each group (*Klf4*$^{fl/fl}$, *Nos3*$^{-/-}$, *Klf4*$^{\Delta EC}$, DKO), which were analyzed in R using Seurat. The differentially expressed genes (DEG) were further examined with ClusterProfiler. Immunofluorescence (IF) for PLVAP was performed in the four groups. Immortalized murine GEnCs with stable *Plvap* overexpression were generated with lentiviral delivery and gene expression was measured with rt-PCR. Proliferation was measured with the MTS assay and monolayer permeability was measured with a transwell system.

Results: Using SnRNAseq, pathway analysis of the upregulated DEGs of the endothelial cluster revealed perturbation in pathways involved in angiogenesis, permeability, focal adhesion and cytoskeletal organization in DKO mice. We identified *Plasmalemmal Vesicle like-protein (Plvap*), a component of fenestral diaphragms and previously shown to be re-expressed in injured GEnCs in DKD, as upregulated specifically in the GEnC cluster in TMA, which was confirmed using IF. Overexpression of *Plvap* (*Plvap-ORF*) in immortalized GEnCs resulted in increased proliferation at 37 degrees compared with control cells (*EV*), as well as loss of the mature differentiation marker *Ehd3*. GEnC monolayers with *Plvap-ORF* had increased permeability compared with *EV* cells, as well as increased expression of *Cav-1* and *Vcam1*, both associated with EC permeability.

Conclusions: *Plvap* is upregulated in injured GEnCs in TMA and is associated with increased permeability and endothelial cell dedifferentiation. Whether this is a driver versus response to GEnC injury is yet to be determined and the focus of future studies.

FR-PO787

Shiga Toxin Downregulates the uPAR/uPA Fibrinolytic Pathway in Human Umbilical Vein Endothelial Cells and on Glomeruli of a Murine Model of Enterohemorrhagic Hemolytic Uremic Syndrome

Celestina Mazzotta,[1,2] Julie R. Ingelfinger,[1,2] Julia Davies,[1] Gregory L. Stahl,[2,3] Eric F. Grabowski.[1,2] *[1]Massachusetts General Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Brigham and Women's Hospital, Boston, MA.*

Background: Coagulation and fibrinolysis ensures balanced hemostasis through the coordinate interaction of pro-coagulant/fibrinolytic factors and the activation of the complement systems. Enterohemorrhagic hemolytic uremic syndrome (eHUS), caused by Shiga toxin results in a prothrombotic microenvironment in the kidney, especially in the glomeruli, with platelet and fibrin deposition and activation of the lectin pathway of complement. We used human umbilical vein endothelial cell (HUVECs) and kidneys of our murine model of eHUS (MBL$^{+/+}$2mbl1$^{-/-}$mbl2$^{-/-}$) to study the expression of the fibrinolytic pathway: urokinase-type Plasminogen Activator (uPA) and urokinase Plasminogen Activator Receptor (uPAR).

Methods: Using immunofluorescence (IF) and western blot, uPA and uPAR were evaluated in HUVECs treated with TNF-α, Stx-1 or both, *vs.* control. Expression of uPA and uPAR was studied with IF in kidneys of mice treated with Stx-2, +/- anti-MBL2 antibody (3F8), anti-factor XIa antibody (3G3), or both, *vs.* untreated mice. In kidneys of our mouse model, colocalization of uPAR/PAI-1 and uPA/PAI-1 (Plasminogen Activator Inhibitor-1) was evaluated.

Results: Stx-1, TNF-α or both significantly reduced uPA and uPAR expression in HUVECs. The glomeruli of mice treated with Stx-2 showed decreased levels of uPA and uPAR *vs* mice treated with Stx-2 +3F8, or +3G3, or both. Endothelial cells in mouse glomeruli treated with Stx-2 expressed low levels of uPA and uPAR *vs.* untreated mice and *vs.* Stx-2+3F8, or +3G3 or both. The levels of PAI-1 in kidneys increased in mice treated with Stx-2 *vs.* Stx-2+3F8 or +3G3, or both. PAI-1/uPAR and PAI-1/uPA colocalization significantly increased in glomeruli of mice treated with Stx-2 compared to Stx-2+3F8 or +3G3, or both.

Conclusions: In the presence of Stx-1, TNF-α, or both, uPA and uPAR expression declined in HUVECs. The glomeruli of mice treated with Stx-2 showed reduced levels of uPA and uPAR which are restored with 3F8, 3G3 or both. Our findings provide evidence that the fibrinolytic pathway mediated by uPA/uPAR is affected in the presence of Stx, suggesting that the higher deposition of fibrin and the thrombotic events in the kidney might be generated by dysregulated fibrinolysis modulated by uPA/uPAR.

Effects of Nanoplastic Particles on the Kidney

Melina Yarbakht,[1] Michelle Hinrichs,[1] Marie Hecker,[1] Mustafa Kocademir,[3] Zeynab Mirzaei,[2] Mario Schiffer,[1] Janina Müller-Deile.[1] *[1]Universitatsklinikum Erlangen Medizinische Klinik 4 Nephrologie und Hypertensiologie, Erlangen, Germany; [2]Innovative Institute for Nanotechnology and Correlative Microscopy e.v. INAM, Forcheim, Germany; [3]Fraunhofer-Institut fur Keramische Technologien und Systeme IKTS - Standort Forchheim, Forchheim, Germany.*

Background: Nanoplastic particles as a new type of emerging pollutant have become a huge scientific concern. Due to the common existence of plastic particles, they have a potential effect on human health. However, it is not known if these particles can reach the kidney or have disease causing potential.

Methods: Fluorescence-labelled carboxylated polystyrene nanoplastic particles with a size of 0.05 µm were used to scan their potential effect on kidney cells. Cultured immortalized human podocytes and human glomerular endothelial cells as well as zebrafish larvae were exposed to the particles. Quantitative PCR, cell viability tests and phalloidin staining were performed after particle exposure. 3D construction models visualized the location of particles. Furthermore, tracking of particle uptake in both cultured glomerular cells and zebrafish was done by immunofluorescent microscopy and Raman spectroscopy.

Results: Both, podocytes and glomerular endothelial cells were able to take up polystyrene nanoplastic particles although expression of cell specific markers did not seem to be affected. However, morphology and cytoskeleton of cells were altered due to the particle showing their general effect on glomerular cells. Nanoplastic particles were incorporated in the zebrafish larvae through the digestive system and they could also be detected in the glomerular region of larvae. Electron microscopy revealed the ultrastructural localization of the particles. In zebrafish with glomerular damage nanoparticle were more likely to pass the glomerular basement membrane to reach the podocytes.

Conclusions: Polystyrene nanoplastic particles can be incorporated via the digestive system, reach the kidney and be taken up by glomerular cells which is facilitated in glomerular diseased state with impaired glomerular filtration barrier.

Atopic Dermatitis-Like Chronic Inflammation May Be Associated with Kidney Inflammation

Arisa Ikeda, Ge Peng, Wanchen Zhao, Alafate Abudouwanli, Shigaku Ikeda, Francois Niyonsaba, Yusuke Suzuki. *Juntendo Daigaku Igakubu Daigakuin Igaku Kenkyuka, Bunkyo-ku, Japan.*

Background: Cross-sectional and case control studies recently indicated the association between renal abnormalities and atopic dermatitis (AD). AD causes not only skin lesions, but also the dysregulation of a wide range of cytokines in the serum. S100A8/9 is one of the calcium binding proteins belonging to the S100 family, derived from neutrophils and macrophages, and also involved in chronic inflammatory diseases such as AD. However, the underlying mechanism of S100A8/9 for a potential link between kidney diseases and AD remains unknown.

Methods: To evaluate the status of kidney functions of patients with AD, we analyzed the serum and urine samples of US adults from the National Health and Nutrition Examination Survey (NHANES). In addition, a chronic AD-like mouse model was induced by repeatedly applying 2,4-dinitrochlorobenzene on the ears and back. The renal function was evaluated by urine and serum examinations, histological staining and electron microscopy imaging of kidneys. The expression of glomerular filtration barrier proteins was evaluated by immunoblotting and immunofluorescence staining. Furthermore, real-time PCR and ELISA assays were performed both in vivo and in vitro to analyze kidney inflammation.

Results: Analysis of NHANES data confirmed the upregulation of urine protein creatinine ratio and downregulation of estimate GFR in patients with AD compared to the healthy subjects. In addition, AD-like mice showed higher albuminuria and serum creatinine than control mice. Moreover, these mice had an increase in glomerular cell infiltration, including neutrophils and macrophages, and foot process effacement of podocytes, indicating dysfunction of glomerular filtration by AD-like inflammation. Kidneys from AD mice showed downregulated expression of glomerular filtration barrier proteins. Concurrently, S100A8/9 was found to be elevated in the serum and renal cortex of these mice. Expression of S100A8/9 in the renal cortex correlated with the status of albuminuria and AD-like inflammation.

Conclusions: Our findings suggest that dysfunctional glomerular filtration and reduced kidney function in AD-like mice might be correlated with the increased levels of S100A8/9 derived from neutrophils and macrophages.

FR-PO790

Bone Marrow Inflammation and Alteration Fuel CKD Progression

Ryan Spear,[1] Alexis P. Jimenez Uribe,[1] Yanxia Cao,[1] Steve Mangos,[1] Flavio Vincenti,[2] Jochen Reiser,[3] Eunsil Hahm.[1] *[1]Rush University, Chicago, IL; [2]University of California San Francisco, San Francisco, CA; [3]The University of Texas Medical Branch at Galveston, Galveston, TX.*

Background: Altered hematopoiesis in the bone marrow (BM) is commonly found in various conditions associated with CKD, including infection, chronic inflammation, diabetes, CVD, cancer, and aging. Our group recently identified BM-derived immature myeloid cells as key contributors to glomerular dysfunction in mice. Despite its potential importance in CKD development, the role of the central immune system, specifically the BM, has not been thoroughly interrogated in humans. Here, for the first time, we examine human BM in CKD and uncover how altered BM myelopoiesis contributes to the progression of CKD.

Methods: BM samples from CKD patients (4 primary and 5 secondary FSGS, 1 non-FSGS) and healthy donors (7) were analyzed. In vitro myelopoiesis was complete using human hematopoietic stem cells. Cellular and molecular characteristics were assessed with flow cytometry, ELISA, scRNA-, RNA- and ATAC-seq. Functional studies included high-throughput IF assays on cultured podocytes and filtration function assays in a transgenic zebrafish model.

Results: CKD patients exhibited significantly elevated levels of TNFα and suPAR, with a myeloid-biased hematopoiesis and increased inflammatory monocytes expressing uPAR. scRNA-seq revealed increased monocyte activation via upregulated genes associated with proinflammatory cytokine and signaling pathways. Consistently, in vitro myelopoiesis demonstrated that TNFα skews hematopoietic differentiation towards activated monocytic lineage cells. These TNFa-driven monocytic subsets exhibited increased uPAR expression, suPAR secretion, and altered transcriptomic, epigenetic, and motif binding profiles. These profiles showed enhanced expression and chromatin accessibility to genes similar to those in patients' BM. Significant cytoskeletal rearrangement was observed in cultured podocytes treated TNFa-induced myeloid cell secreted factors (TIMCSFs) or FSGS patient serum but not by TNFa alone. Similarly, TIMCSFs led to filtration dysfunction in a transgenic zebrafish model.

Conclusions: This study reveals the functional connection between BM myelopoiesis and CKD in humans. Our findings suggest that TNFα, driven by chronic inflammation, plays a key role in altering BM myeloid cells, thereby contributing to glomerular dysfunction in CKD patients. These findings highlight the BM-kidney axis as a potential novel therapeutic target for CKD.

Increased Type 2 Innate Lymphoid Cells (ILC2s) in Patients with Idiopathic Nephrotic Syndrome (INS)

Chang-Yien Chan,[1,2] Liangjian Lu,[2] Sharon Teo,[2] Kar Hui Ng,[1,2] Hui Kim Yap.[1,2] *[1]National University of Singapore, Singapore, Singapore; [2]Khoo Teck Puat-National University Children's Medical Institute, National University Health System, Singapore, Singapore.*

Background: Th2 cytokine producing ILC2s have been implicated in steroid-dependent and resistant allergic asthma. We have previously reported elevated Th2 cytokine production in steroid-dependent nephrotic syndrome (SDNS). This study therefore aimed to characterize ILC2s in INS patients in relapse.

Methods: 14 patients with childhood-onset INS (relapse and remission) and 7 age-matched healthy controls were recruited. ILC subsets were analysed using flow cytometry. ILC2s were cultured with IL-33, IL-25, TSLP (10ng/ml) and IL-2 (20ng/ml) for 72h and culture supernatants were harvested for cytokine quantification. To investigate the response of ILC2s to steroids, cells were incubated with or without Dexamethasone (DEX) (0.1μmol/ml). Statistical analysis was done using Mann-Whitney U tests, Wilcoxon signed-rank test for paired samples and ANOVA with repeated measures.

Results: Relapse INS patients had higher proportion of ILC2s compared to controls (19.0±2.2% vs 9.6±2.3%, p=0.01). Paired analysis in INS patients showed significant decrease in ILC2s during remission compared to relapse (p=0.01). Additionally, cytokine profiles in relapse INS patients showed significantly increased Th2 cytokines IL-5 and IL-13, and Th2-related cytokines IL-9, IL-10 and Eotaxin (Table 1). ILC2s in relapse INS patients also had significantly higher levels of IL-12, IFNγ, RANTES and VEGF. Incubation with DEX increased ILC2s by 5.8±1.1% (p<0.001), which was similar in both patients and controls (p=0.83 for interaction).

Conclusions: ILC2s were significantly elevated in relapse INS patients. This was associated with classic Th2 signature following culture in cytokine conditioned medium, which was not suppressible by DEX.

FR-PO792

Selective B Cell Expansion Occurs in a Subset of Patients with Idiopathic Nephrotic Syndrome and Is Associated with Rituximab Response

Chang-Yien Chan,[1,2] Chenshi Lin,[1] Jian-Zhou Cui,[1] Jinmiao Chen,[3] Hui Kim Yap,[1,2] Liangjian Lu.[2] *[1]National University of Singapore, Singapore, Singapore; [2]Khoo Teck Puat-National University Children's Medical Institute, National University Health System, Singapore, Singapore; [3]Agency for Science Technology and Research, Singapore, Singapore.*

Background: Rituximab response in idiopathic nephrotic syndrome (INS) is highly heterogenous. This may be because only a sub-group of patients have B-cell driven disease, while others have T-cell driven disease. We aimed to investigate the extent of B-cell dysregulation in INS, and correlate this with Rituximab response.

Methods: 11 patients with relapsed steroid-sensitive INS were recruited together with 16 healthy controls, and B-cell subsets enumerated by flow cytometry. Single-cell RNA sequencing (scRNA-seq) was used to further characterize baseline B-cells in 4 patients with bifurcated Rituximab response (2 early relapse by 7 months, 2 sustained remission).

Results: INS patients had elevated CD27-IgD+ naïve B-cells (14±1.8% lymphocytes vs 8.1±0.7%, p=0.002) as well as elevated CD27+IgD- switched memory B-cells (2.8±0.7% vs 1.6±0.2%, p=0.05). K-means clustering of the cohort into 2 groups using these 2 parameters resulted in 7 patients clustering with all controls, and the remaining 4 patients with marked naïve and switched memory B-cell expansion forming a separate cluster (p=0.019). Detailed B-cell subclustering utilizing scRNA-seq revealed sustained Rituximab response was associated with expansion of an atypical B-cell cluster (2.4±1.9 vs 0.2±0.09% B-cells) that was IgD+CD27+/-CD24+CD38- and expressed PAX5 and elevated IL15. Furthermore, differentially expressed genes in B-cells showed that poor Rituximab response was strongly associated with upregulated "positive regulation of T-cell activation" (p<0.00002) and "Th17 cell differentiation" (p<0.0001), suggesting a primarily T-cell driven disease in these patients.

Conclusions: INS patients who demonstrate a good response to Rituximab likely have B-cell driven disease characterized by expansion of specific B-cell subsets.

FR-PO793

T Cell Hyporesponsiveness in Focal Segmental Glomerulosclerosis Responsive to Rituximab Is Associated with B Cell Activation and Production of Podocyte Damaging Factors

Liangjian Lu,[1] Chang-Yien Chan,[2,1] Sharon Teo,[1] Kar Hui Ng,[2,1] Hui Kim Yap.[2,1] *[1]National University Health System, Singapore, Singapore; [2]National University of Singapore, Singapore, Singapore.*

Background: The mechanistic basis of Rituximab response in idiopathic nephrotic syndrome (INS) remains uncertain. We previously showed that Rituximab-response in childhood-onset focal segmental glomerulosclerosis (FSGS) was associated with T-cell hypo-responsiveness. We aimed to investigate if dysregulated B-cell activity was associated with T-cell hypo-responsiveness prior to Rituximab.

Methods: 37 patients with childhood-onset FSGS were recruited. Rituximab was administered for clinical indications, with response defined as the ability to wean off steroids and calcineurin inhibitors by 3 months after Rituximab while remaining in complete remission. T-cell hypo-responsiveness was determined by stimulated INFγ production <2.5%. B-cell activation was measured by flow cytometry of activation markers and multiplexed cytokine analysis without further stimulation. Podocytes were incubated with B-cell conditioned media, and stained for F-actin with phalloidin. Staining was scored from 0-3, with higher scores reflecting greater abnormality, i.e. more cortical F-actin and less stress fibres. Comparison between groups was performed using t-test, Wilcoxon rank-sum test or Fisher's exact test.

Results: Baseline T-cell hypo-responsiveness was associated with Rituximab response (65% vs 29%, p=0.049). Comparing T-cell hypo-responsive and normo-responsive patients, total CD19+ B-cells were unchanged (p=0.6), but CD19+ CD80+ B-cells were increased (16% (IQR 11-26) vs 5% (IQR 5-9), p=0.006). There was a striking upregulation in resting B-cell cytokine production in patients with T-cell hypo-responsiveness, including INFγ (p= 0.005), IP10 (p=0.014) and TNFα (p=0.022). Podocytes incubated with B-cell conditioned medium from T-cell hypo-responsive patients demonstrated increased F-actin score (2.05±0.11 vs 1.36±0.15, p=0.02), but not when B-cells from T-cell normo-responsive patients were used (p=0.14). Repeat analysis 6 months post-Rituximab revealed no differences in B-cell cytokine production.

Conclusions: The association between Rituximab response and T-cell hypo-responsiveness likely reflects underlying B-cell activation, with B-cell mediated production of podocyte damaging factors. T-cell hypo-responsiveness may be an epiphenomenon reflecting T-cell exhaustion from chronic B-cell stimulation.

FR-PO794

B Cells Are Essential for Proteinuria Induction in a Mouse Model of Autoimmune Idiopathic Nephrotic Syndrome

Simon Leclerc,[1,2] Lamine Aoudjit,[1,2] Tomoko Takano.[1,2] *[1]Research Institute of the McGill University Health Centre, Montreal, QC, Canada; [2]McGill University Faculty of Medicine and Health Sciences, Montreal, QC, Canada.*

Background: The idiopathic nephrotic syndrome (INS) is defined by heavy proteinuria, hypoalbuminemia, and edema. This occurs when the kidney's specialized epithelial cell, the podocyte, is injured by mechanisms that are still unknown. The recent discovery of autoantibodies targeting podocyte proteins like nephrin and Crb2 in human patients hints at the role of B cells and autoantibodies in INS, but their exact role is still unclear. Our objective is to establish if B cells are essential for the induction of proteinuria in a mouse model of autoimmune INS.

Methods: As previously published (Hada et al., J Am Soc Nephrol, 2022), 19 C3H/HeN mice were immunized three times at 2-wks intervals with recombinant Crb2, a transmembrane protein expressed at the podocyte slit diaphragm. One week after the first immunization, 10 mice received anti-CD20 (MB-11, BioXCell) to deplete B cells and 9 an isotype control. Serum and urine were tested for anti-Crb2 antibody and albuminuria, respectively. Inguinal lymph nodes and spleens were immunophenotyped at 6 wks.

Results: Mice that received anti-CD20 ('treated') showed a 95% decrease in circulating CD19+ B cells at 2 and 4 wks. At 6 wks, no treated mice (0/10) developed INS compared to 88% (8/9) of the mice receiving the isotype control ('control'). Anti-Crb2 antibody titers were lower in treated mice (1591±759 *vs.* 7207±3985 µg/mL, $p<0.003$). In the inguinal lymph nodes of treated mice, a respective 50% and 80% decrease in the number of CD4+ and CD19+ cells ($p<0.001$) were observed compared to controls. This was driven by a 75% decrease in switched memory B cells (CD19+ IgD- IgM- IgG+; $p<0.005$). The germinal centers in the inguinal lymph nodes of treated mice were reduced in size ($p<0.007$) and showed a reduced number of IgG+ positive B cells ($p<0.003$).

Conclusions: These results suggest that autoantibody-producing B cells are essential for proteinuria induction in this mouse model of autoimmune INS. Moreover, their role may not be limited to autoantibody production, as their crosstalk with T cells is likely significant. A better understanding of these mechanisms is crucial to develop targeted treatments for patients with autoimmune INS.

FR-PO795

Desialylated IgM by Idiopathic Nephrotic Syndrome Subjects Induce Proteinuria and Podocyte Injury

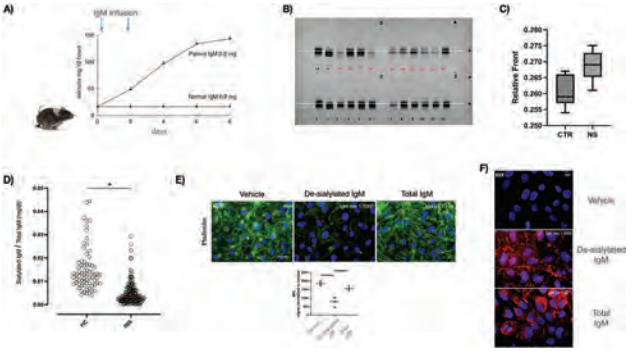
Xhuliana Kajana,[1] Sonia Spinelli,[1] Gianluca Caridi,[1] Gian Marco Ghiggeri,[1] Maurizio Bruschi,[1] Paolo Cravedi,[2] Andrea Angeletti.[1] *[1]Istituto Giannina Gaslini, Genova, Italy; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: IgM deposition is a common finding in the glomeruli of patients with idiopathic nephrotic syndrome (INS) and represents a risk factor for poor treatment response and disease progression. However, the pathological role of IgM in INS is controversial. Sialylation is a post-translational modification that significantly affects IgM function, but its role in the pathogenesis of INS is unknown.

Methods: IgM derived from patients with INS and controls (HC) were injected in 8 Sprague-Dawley rats. Sialylation induces an anionic charge to proteins, therefore, we tested the charge of IgM derived by 12INS and 12HC, as an indirect sign of sialylation, measuring IgM migration through an electrophoretic assay. To test a larger cohort (220 INS and 75 HC), we developed an ELISA and we measured the sialylation of IgM through incubation with biotinylated *Sambucus nigra* agglutinin. Immortalized human podocytes were exposed to total and desialylated IgM (obtained through desialylation of total IgM).

Results: IgM from INS induced higher levels of proteinuria compared to IgM from HC in rats. (**Fig1A**). IgM purified from patients with INS (red) had a significative higher cationic charge than IgM from controls (black) (**Fig1B**), as summarised in **Fig1C**. In a larger cohort, the ratio between the sialylation of IgM and total IgM was significantly lower in INS than HC (**Fig1D**). Co-incubation with desialylated IgM, but not total IgM altered the cytoskeletal protein phalloidinin of human podocytes, as evidenced in **Fig1E**. Intact IgM is internalized, while desialylated IgM remains on the podocyte surface (**Fig1F**), suggesting a different interaction of these types of IgM with podocytes.

Conclusions: IgM sialylation in INS is lower than HC and de-sialylated IgM induces *in vivo* proteinuria and *in vitro* podocyte damage. We recently demonstrated a causal link between IgM and disease relapse in a clinical study of patients with INS (DOI: 10.1016/j.ekir.2024.04.006). Overall, these data support that sialylation of IgM may play a pathogenic role in INS.



FR-PO796

Anti-nephrin Autoantibodies Cause Minimal Change Disease

Felicitas E. Hengel, Silke Dehde, Oliver Kretz, Tobias B. Huber, Nicola M. Tomas. *Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

Background: Circulating autoantibodies against the podocyte slit diaphragm protein nephrin have recently been identified in patients with podocytopathies. However, whether these autoantibodies cause the observed minimal change disease phenotype with nephrotic syndrome is unknown.

Methods: Using immunoprecipitation and subsequent Western blotting, we screened patient-derived anti-nephrin autoantibodies for reactivity with glomerular extracts from multiple species. Anti-nephrin autoantibody containing patient IgG (further referred to as anti-nephrin IgG) or control human IgG was then transferred to animals that were identified to react with anti-nephrin IgG. Upon IgG transfer, animals were monitored for proteinuria, serum anti-nephrin IgG, and morphological lesions.

Results: The passive transfer of human anti-nephrin IgG resulted in substantial proteinuria and detectable anti-nephrin IgG in animal serum samples. Anti-nephrin IgG further induced podocyte foot process effacement in the absence of electron-dense deposits in electron microscopy, while Periodic-Acid-Schiff staining revealed no histological changes. Immunofluorescence analyses showed sparse positivity for human IgG at the glomerular filtration barrier, while it was absent in animals that received control IgG.

Conclusions: Our study demonstrates for the first time the direct pathogenicity of patient-derived anti-nephrin autoantibodies in the development of a podocytopathy with minimal change lesions. Further studies are necessary to better understand the molecular mechanisms of anti-nephrin autoantibody action on podocytes.

FR-PO797

A Novel Subtype of Minimal Change Disease

Unnati Bhatia,[1] Ritu Calla,[2] Nishant Aggarwal,[1] Abhishek Swami.[1] *[1]Corewell Health Beaumont Hospital, Royal Oak, MI; [2]St Bernards Medical Center, Jonesboro, AR.*

Introduction: Minimal change disease (MCD) is a podocytopathy which causes failure of the glomerular filtration barrier by loss of slit diaphragm architecture. Etiology is unclear. It is characterized by normal light microscopy and negative immunofluorescence(IF) with diffuse foot process effacements noted on electron microscopy(EM) however punctate IgG staining on biopsy may indicate a novel autoimmune mechanism.

Case Description: A 59 yo Caucasian male with history of CKD 3b(baseline S.Cr 1.8-2), cerebral palsy complicated by chronic urinary retention with supra-pubic catheter, HTN presented with worsening B/L lower extremity edema and weight gain. The physical exam showed anasarca. Labs showed S.Cr 2.77, serum albumin 1.5 g/dl, urine albumin creatinine ratio 11,905 mg/g, dyslipidemia. UA showed 4+ proteinuria, >20 RBCs, >20 hyaline casts. Further workup for nephrotic syndrome including PLA2R antibody, HIV, hepatitis, syphilis, SPEP/UPEP, free light chains, complement levels, ANA, ANCA, cryoglobulins was negative. Kidney biopsy was consistent with MCD, mild acute tubular injury and interstitial fibrosis, moderate thickening of arteries and tubular atrophy. IF showed positive granular staining for IgG in Bowman's space and GBM. EM showed

diffuse effacement of foot processes and was unremarkable for immune complex deposits or fibrillary materials. Oral prednisone was started with plan for slow taper. Edema improved with diuretic therapy.

Discussion: MCD is characterized by diffuse effacement of podocyte foot processes on EM, absence of dense deposits or immune complexes and unremarkable LM. This case is unique with positive findings on IF showing positive granular staining for IgG in Bowman's space and GBM. Underlying molecular mechanisms are debatable, however efficacy of B-cell targeted therapies in steroid dependent and relapsing cases suggests autoantibody etiology. Anti-nephrin autoantibodies have been associated with massive proteinuria in animal models and as alloantibodies in post transplant children with congenital nephrin deficiency. A recent study (Watts et al.) hypothesized punctate IgG staining may represent in situ binding of nephrin autoantibodies resulting in redistribution of nephrin and disruption of intercellular junctions between podocytes. Further research is needed to establish prognostic significance of this subclassification of MCD and the role for targeted treatment.

FR-PO798

Investigation of NOD-Like Receptor Thermal Protein Domain Associated Protein 3 Inflammasome/Pyroptosis Stimulation through the CD36 Activation in Adults with Minimal Change Disease

Yuki Kajio, Taihei Suzuki, Kazuki Kobayashi, Hirokazu Honda. *Showa University School of Medicine, Tokyo, Japan.*

Background: Minimal change disease (MCD) basically occurs in childhood. Although MCD well reacts to the steroid therapy, adult onset MCD have frequent recurrency and need prolonged immunosuppressive therapy, compared to childhood MCD. Accordingly, the investigation for the pathogenesis of adult MCD has been required. MCD is usually accompanied with severe dyslipidemia. Oxidized low-density lipoprotein (ox-LDL) is known to work as a damage-associated molecular patterns through CD36, and trigger NOD-like receptor thermal protein domain associated protein 3 (NLRP3) inflammasome and programmed cell death called pyroptosis. The relationship between the pathogenesis of MCD and NLRP3 inflammasome/ pyroptosis has not been understood fully. In this study, we assessed the factors which are regarding to NLRP3 inflammasome/ pyroptosis cascade in the patients diagnosed as MCD in our university hospital.

Methods: We performed histological and clinical assessment using kidney sections and urine samples taken from the MCD patinets (N=56), compared to the kidney doners (N=15) and health volunteers (N=15). Secondary MCD, the patients with any clinical data defect, and the patients without urine sample at the timing of renal biopsy (RBx) were excluded.

Results: Total 26 MCD patients were finally enrolled in this study. The number of the podocytes was lower in MCD than that of the control. Urinary ox-LDL levels were higher in MCD, compared to the control. Analysis of immunofluorescent staining revealed that NLRP3 and CD36 were activated in MCD podocytes. Urinary interleukin (IL)-18 levels increased in the MCD patients. Steroid therapy applied before RBx contributed to maintaining the number of podocytes in glomeruli and reduce urinary ox-LDL and IL-18 levels.

Conclusions: In this study, NLRP3 inflammasome cascade seemed to be activated *via* upregulation of CD36 in podocytes and the elevation of urinary ox-LDL. The elevation of urinary IL-18 levels could suggest that pyroptosis might occur in MCD, further studies are required to detect certain pyroptosis in podocytes.

FR-PO799

Role of LDL-Scavenger Receptor CD36-Positive Macrophages in Refractory Nephrotic Syndrome with Hyperlipidemia under High-Dosage Steroid Treatment

Yohei Ikezumi,[1] Tomomi Kondo,[1] Takuma Ando,[1] Yuji Matsumoto,[1] David J. Nikolic-Paterson,[2] Naonori Kumagai.[1] *[1]Fujita Health University School of Medicine Department of Pediatrics, Toyoake, Japan; [2]Monash University Department of Medicine, Clayton, VIC, Australia.*

Background: Most cases of pediatric nephrotic syndrome (NS) are steroid-sensitive (SSNS); however, about 10% of cases are steroid-resistant (SRNS), and some patients develop SRNS during treatment. We have previously reported that chronic lesions, including matrix expansion and fibrosis, seen during steroid therapy are associated with increasing numbers of macrophages (MQ). This study examined expression of the LDL-scavenger receptor (CD36) in MQ in pediatric SRNS.

Methods: Renal biopsies and clinicopathological findings from 25 children with SSNS and 18 children with SRNS were compared. The number of glomerular $CD36^+CD68^+$ MQ was assessed by immunofluorescence staining. Urine levels of CCL2 were measured by ELISA. Cultured human monocyte-derived MQ were stimulated with dexamethasone (Dex) and/or oxidized LDL (oxLDL) for 48hr and RNA levels compared to control cells.

Results: Children with SRNS has significantly lower serum albumin levels, higher serum levels of total cholesterol and LDL cholesterol, higher proteinuria and were on higher doses of Prednisolone at time of biopsy (all $P<0.01$ vs SSNS). Combined stimulation of cultured MQ with Dex plus ox-LDL induced up-regulation of mRNA levels of *CD36*, cytokines and growth factors associated with inflammation and fibrosis (*CCL2, IL25, NOS2, FGF1, FGF2, CTGF*), and extracellular matrix proteins (*COL1A2, COL4A1, COL4A2, COL13A1*). Immunostaining showed a 3-fold increase in the number of glomerular $CD36^+CD68^+$ MQ in SRNS vs SSNS (2.3 vs 0.8, $P<0.001$), and revealed expression of FGF1, AGT and CCL2 in biopsies from SRNS patients which co-localized with glomerular $CD36^+CD68^+$ MQ. In addition, the urine CCL2/creatinine ratio was increased 5-fold in SRNS vs SSNS patients (986.2 vs 200.8, $P=0.012$).

Conclusions: The significant hyperlipidemia seen in steroid-treated pediatric SRNS was associated with a substantial increase in the number of glomerular $CD36^+CD68^+$ MQ. In vitro studies support a direct link between steroids and ox-LDL in stimulating MQ expression of CD36 and of the genes involved in both inflammation and fibrosis. Thus, cholesterol processing $CD36^+CD68^+$ MQ may contribute to resistance to treatment in SRNS through the production of pro-fibrotic and pro-inflammatory factors.

Podocyte Exopher Formation as a Novel Pathomechanism in Membranous Nephropathy

Catherine Meyer-Schwesinger,[1] Karen Lahme,[1] Wiebke Sachs,[1] Sarah Froembling,[1] Kristin Surmann,[2] Roland Thuenauer,[3] Stephanie Zielinski,[1] Johannes Brand,[1] Stephan Michalik,[2] Marina Zimmermann,[4] Thorsten Wiech,[5] Tobias N. Meyer,[7] Lars Fester.[6] *[1]Institute of Cellular and Integrative Physiology, Center for Experimental Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Interfaculty Institute for Genetics and Functional Genomics, University Medicine Greifswald, Greifswald, Germany; [3]Technology Platform Microscopy and Image Analysis (TP MIA), Leibniz Institute of Virology, Hamburg, Germany; [4]Institute of Medical Systems Biology, Center for Biomedical AI, Center for Molecular Neurobiology, Hamburg, Germany; [5]Institute of Pathology, Nephropathology Section, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [6]Institute of Neuroanatomy, Medical Faculty, University of Bonn, Bonn, Germany; [7]Nephrology, Asklepios Klinikum Barmbek, Hamburg, Germany.*

Background: Membranous nephropathy (MN) is caused by autoantibody binding to podocyte foot process antigens such as THSD7A and PLA_2R1. The mechanisms of the glomerular antigen/autoantibody deposition and clearance are unknown.

Methods: We explore the origin and significance of glomerular accumulations in (1) diagnostic and follow-up biospecimens from $THSD7A^+$ and PLA_2R1^+-MN patients compared to nephrotic non-MN patients, and (2) in experimental models of $THSD7A^+$-MN.

Results: We discovered podocyte exophers as correlates of histological antigen/autoantibody aggregates found in the glomerular urinary space of MN patients. Exopher vesicle formation represents a novel form of toxic protein aggregate removal in *Caenorhabditis elegans* neurons. In MN patients, podocytes released exophers to the urine. Enrichment of exophers from MN patient urines established them as a glomerular exit route for antigens and bound autoantibody. Exophers also carried disease-associated proteins such as complement and provided a molecular imprint of podocyte injury pathways. In experimental $THSD7A^+$-MN, exophers were formed from podocyte processes and cell body. Their formation involved the translocation of antigen/autoantibody from the subepithelial to the urinary side of podocyte plasma membranes. Urinary exopher-release correlated with lower albuminuria and lower glomerular antigen/autoantibody burden. In MN patients the prospective monitoring of urinary exopher abundance and of exopher-bound autoantibodies was additive in the assessment of immunologic MN activity.

Conclusions: Exopher-formation and release is a novel pathomechanism in MN to remove antigen/autoantibody aggregates from the podocyte. Tracking exopher-release will add a non-invasive diagnostic tool with prognostic potential to clinical diagnostics and follow-up of MN patients.

FR-PO801

Serial Changes of Molecular Expression of Slit Diaphragm Proteins in Post-transplant FSGS Recurrence Associated with Anti-nephrin Antibodies

Yoko Shirai,[1] Kenichiro Miura,[1] Sekiko Taneda,[1] Kazuho Honda,[2] Kenji Tanabe,[1] Motoshi Hattori.[1] *[1]Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan; [2]Showa Daigaku, Shinagawa-ku, Japan.*

Background: Recently, we reported very early pathological changes in podocytes in patients with post-transplant recurrence of focal segmental glomerulosclerosis (rFSGS) associated with circulating anti-nephrin antibodies (abs), suggesting that anti-nephrin abs are a possible candidate for circulating factors involved in the pathogenesis of rFSGS (Hattori et al, Am J Transplant, 2022; Shirai et al, Kidney Int, 2024). Here, we analyzed serial changes of molecular expression of slit diaphragm proteins in post-transplant FSGS recurrence associated with anti-nephrin abs, using serial graft biopsies.

Methods: We analyzed four kidney transplant recipients with childhood-onset primary FSGS who had positive circulating anti-nephrin abds and underwent serial graft biopsies including 1 hour graft biopsy (1hGBx). All patients underwent whole exome sequencing and no pathogenic variants in FSGS-related genes were identified. Dual immunofluorescence staining images of IgG and nephrin, CD2-associated protein (CD2AP), and podocin were obtained using the structured illumination microscopy.

Results: In all 4 rFSGS patients, 1hGBx showed punctate IgG deposition co-localizing with nephrin that had altered distributions from foot process to podocyte intracellular area. CD2AP was diffusely expressed in podocyte cell bodies before re-perfusion, and 1hGBx showed granular aggregation of CD2AP. In graft biopsies during recurrence (rGBx) obtained at median POD 38 (IQR, 18, 55), the expression of nephrin and CD2AP was decreased in all patients. In contrast, foot process expression of podocin was neither decreased nor altered in 1hGBx and rGBx specimens of three patients. In the remaining one patient, who did not respond to treatment and rapidly progressed to graft loss, expression of podocin was neither decreased nor altered in 1hGBx, but was decreased without altered localization in rGBx.

Conclusions: Nephrin showed altered distributions from foot process to podocyte intracellular area, and CD2AP showed decreased expression and granular aggregation at very early phase of exposure to anti-nephrin abs. In contrast, podocin localization was not altered even after progression of FSGS recurrence. These findings may contribute to better understanding the mechanism of podocyte injury associated with anti-nephrin abds.

FR-PO802

Target Protein of Passive Heymann Nephritis and Its Role in the Mechanism of Proteinuria in Membranous Nephropathy (MN)

Renan G. Diniz,[1,2] Ashok K. Singh.[2] *[1]University of Illinois Chicago, Chicago, IL; [2]Hektoen Institute LLC, Chicago, IL.*

Background: PHN is an established rat model of human MN. However, the target protein of PHN on the glomerulus is unknown and so is also the mechanism of proteinuria in PHN. Because of the striking similarity of the staining patterns of PHN and podocalyxin (PDX) we hypothesize that the target protein of the PHN antibody could likely be PDX. We examined this hypothesis by quantifying PDX in PHN rats at the time of proteinuria.

Methods: Rats were divided into one control (Cont) and six experimental (EX) groups. EX received 1 mL iv anti-gp600 antiserum to induce PHN while\ Cont received 1 mL of iv saline. PHN was confirmed by a strong glomerular capillary wall staining as seen by indirect immunofluorescence (IF). Rats were maintained by ad libitum access to food and water. Proteinuria was assessed at the end of each week until 6 weeks. At 6 weeks rats were euthanized and kidney was fixed with 10% buffered formalin. PDX was stained by IF and quantified using the Image J software. Data were statistically analyzed and compared using student t test and ANOVA.

Results: Proteinuria was significantly elevated progressively from 1-6 weeks in EX (208mg/24h at 6 weeks). PDX staining in EX was significantly reduced by 25% at 6 weeks compared to Cont (36.6 ± 1.9 vs 48.4 ± 2.6 intensity units/glomerulus; p< 0,05) (Figure 1 below)

Conclusions: In conclusion, reduction of PDX in PHN suggests that the target of PHN antibody, and by analogy in MN, appears to be PDX, a podocytic protein that is known to be coupled with the actin cytoskeleton of the cell and therefore important in maintaining the foot process structure of the podocytes. We speculate that the reduction of PDX could be the mechanism of proteinuria in MN as its loss must disrupt the foot process architecture of the podocytes leading to the breakdown of the glomerular filtration.

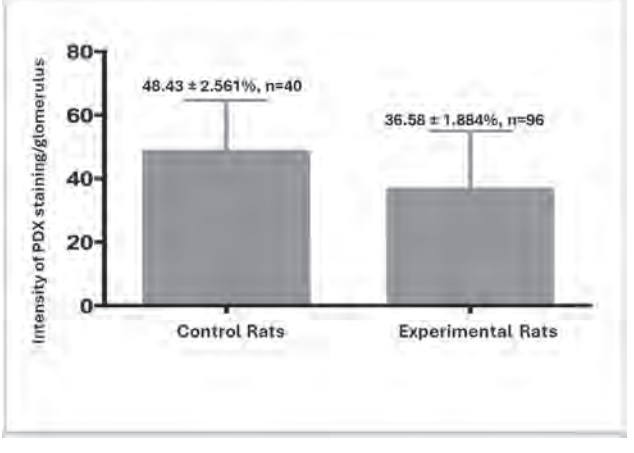

Figure 1: PDX staining in Cont and EX: intensity units/glomerulus

FR-PO803

Deciphering Antigen-Specific Glomerular Injury Mechanisms in Membranous Nephropathy via Single-Cell RNA Sequencing (scRNA-seq) and a Glomerulus-on-a-Chip Model

Stefano Da Sacco,[1] Laura Perin,[1] Qi Zhang,[1] Jack F. Wetzels,[3] Roger E. De Filippo,[1] Paolo Cravedi.[2] *[1]Children's Hospital Los Angeles, Los Angeles, CA; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Radboud Universiteit, Nijmegen, Netherlands.*

Background: Primary membranous nephropathy (MN) is a prevalent cause of adult nephrotic syndrome, caused by anti-podocyte antibodies targeting proteins like PLA2R1 and THSD7A in the glomerular subepithelial space. This study explores the effects of these antibodies on glomerular cells using single-cell transcriptomics within a human glomerulus-on-a-chip (GOAC) model.

Methods: Human primary podocytes and glomerular endothelial cells were cultured within GOACs and subjected to sera containing anti-PLA2R or anti-THSD7A antibodies for a duration of 72 hours. Sera from healthy donors served as controls. Albumin permeability assays confirmed cellular injury, and single-cell RNA sequencing (scRNA-seq) was performed at a depth of 80,000 reads per cell, with subsequent detailed transcriptomic evaluations, followed by comprehensive transcriptomic analysis.

Results: Anti-PLA2R and anti-THSD7A exposure induced albumin leakage in GOACs, signaling injury. scRNA-seq revealed a pronounced activation of the complement pathway. For example, in podocytes, antigen-specific injury-related pathways such as EIF2 and mTOR signaling, and PTEN in glomerular endothelial cells, exhibited differential responses to anti-PLA2R sera, as opposed to anti-THSD7A or healthy sera, suggesting that concurrent early injury mechanisms drive podocyte dysregulation together with the complement cascade.

Conclusions: The study validates the application of scRNA-seq for the analysis of human cells in GOACs exposed to MN patient-derived sera. This methodological synergy offers insights into the pathogenic mechanisms at play in MN, providing a foundation for the identification of new therapeutic avenues for glomerular disorders.

FR-PO804

Differential Expression of Renal and Hepatic PCSK9 during Development of Hypercholesterolemia in the Passive Heymann Nephritis Rat Model of Nephrotic Syndrome

Eduardo Molina-Jijon,[1] Camille E. Mace,[1] Carmen Avila-Casado,[2] Lionel C. Clement.[1] *[1]Rush University Medical Center, Chicago, IL; [2]University of Toronto, Toronto, ON, Canada.*

Background: Proprotein convertase subtilisin/kexin type 9 (PCSK9) plays an important role in the regulation of LDL-c levels in the liver. In the kidney, PCSK9 is expressed in the cortical collecting duct (CCD) where it plays a role of chaperone protein for the epithelial sodium channel. We showed increased PCSK9 expression in kidney biopsies of patients with primary glomerular disease and its implication in the initiation of development of hypercholesterolemia in the Buffalo-Mna rat (model of focal and segmental glomerulosclerosis) and the Rrm2b$^{-/-}$ mouse (model of collapsing glomerulopathy) (Molina-Jijon et al, 2020) following proteinuria. We then studied the expression of PCSK9 in the PHN rat (model of Membranous Nephropathy (MN)).

Methods: Male Sprague-Dawley rats were injected twice with sheep serum (Controls, 750 µl/rat on Day 0 and Day 1) or sheep anti-Fx1A antibody (PHN, 750 µl/rat on Day 0 and Day 1). Rats were euthanized on Days 3, 7, 10 and 17 after first injection. Proteinuria, PCSK9 and total cholesterol serum levels were assessed. PCSK9 gene and protein expression in liver and kidney were studied by Real Time PCR, Western blot, and confocal microscopy. Human patient kidney sections were stained with PCSK9 and AQP2 antibodies to study PCSK9 protein expression and localization.

Results: Control rats do not develop proteinuria neither hypercholesterolemia nor have high levels of serum PCSK9. PHN rats develop proteinuria from day 3 (4.26 ± 0.98 mg/18h, P<0.01; 198.73 ± 21.22 mg/18h at day 17, P<0.001), high serum PCSK9 levels from day 7 (60.427 ± 73.33 ng/ml, P<0.05; 1,404.96 ± 280.29 ng/ml at day 17, P<0.001), and hypercholesterolemia from day 7 (184.49 ± 7.98 mg/dL, P<0.001; 352.58 ± 29.16 mg/dL at day 17, P<0.001). PCSK9 protein and gene expression increased in the kidney but not in the liver at the same time points studied.

Conclusions: As PHN rats develop NS, PCSK9 protein level increases in the kidney, but not in the liver. CCD-PCSK9 may play a role in the initiation of hypercholesterolemia in MN-related NS. CCD-PCSK9 could become a new therapeutic target to prevent development of hypercholesterolemia in NS patients in which prolonged hypercholesterolemia may worsen kidney disease and increase risk of cardiovascular disease.

Kidney NELL1 Expression Peaks during Onset of Autoimmunity in Genetically Predisposed SKG Mice

Lisa T. Kumasaka,[1] Amy L. Seufert,[2,3] Rupali S. Avasare,[2] Emily E. Vance,[2,3] Ruth J. Napier.[2,3] *[1]Oregon Health & Science University School of Medicine, Portland, OR; [2]Oregon Health & Science University, Portland, OR; [3]Portland VA Medical Center, Portland, OR.*

Background: Inflammation is a key process in disease, including autoimmune disorders and cancer. Neural Epidermal Growth Factor-Like 1 (NELL1) is a multifunctional protein involved in various cellular processes, including development and tissue repair. Understanding the relationship between inflammation and NELL1 expression can provide insights into inflammatory mechanisms underlying tissue-specific pathologies, including the autoimmune kidney disease, NELL1-Membranous Nephropathy (MN).

Methods: SKG mice were given one intraperitoneal injection of zymosan to induce T cell-mediated inflammation, followed by weekly clinical scoring for joint swelling, redness, or deformities (Rosenzweig et al., 2023). Mice were euthanized at 2, 4, and 8 weeks post-zymosan, kidneys and brains were harvested and stored in RNAlater. Tissues were homogenized, RNA isolated, and expression of Nell1 was measured via qRT-PCR.

Results: Inflammatory conditions due to zymosan induced autoimmune arthritis coincided with higher NELL1 expression levels in the kidney tissue of SKG mice compared to naïve SKG mice that did not receive the zymosan injection. NELL1 expression peaked at the 2-week post zymosan injection and showed a progressive decline at the 4-week and 8-week time points. While NELL1 expression does coincide with arthritic inflammation in this model, it is important to note that NELL1 does not peak when severity of autoimmune arthritis peaks.

Conclusions: Our research shows NELL1 mRNA expression is enhanced in zymosan induced autoimmune arthritic mice kidneys compared to naïve controls. Interestingly, NELL1 expression is elevated prior to peak arthritis. Our work provides foundational knowledge for the development of a mouse model to study mechanisms of kidney inflammation that drive the development of NELL1 MN.

SARS-CoV-2 Protein Deposition Enhances Renal Complement Activation and Aggravates Kidney Injury in Membranous Nephropathy after COVID-19

Hong Cheng,[1] Guo-qin Wang,[1] Lei Yang,[1] Xiao-yi Xu,[1] Weiyi Guo,[1] Li-jun Sun,[1] Yan-yan Wang,[1] Wenrong Cheng,[1] Nan Ye,[1] Lingqiang Kong,[1] Xiaoyi Zhao.[2] *[1]Beijing Anzhen Hospital Affiliated to Capital Medical University, Chaoyang-qu, China; [2]Affiliated Hospital of Chifeng University, Neimenggu, China.*

Background: COVID-19 has been reported to be associated with the occurrence and recurrence of membranous nephropathy (MN). The clinicopathological characteristics and complement system activation of MN after COVID-19 are unclear.

Methods: A total of 38 patients with biopsy-proven MN who developed new onset proteinuria after COVID-19 were enrolled in this study. One hundred patients with primary MN diagnosed before COVID-19 pandemic as control. Renal immunohistochemical staining for SARS-CoV-2 nucleocapsid protein was performed in 38 patients with MN after COVID-19. Serum membrane attack complex (MAC) was detected by enzyme-linked immunosorbent assay. Glomerular staining for the complement proteins in different pathways were detected by immunohistochemical.

Results: Thirteen of 38 patients had positive staining for SARS-CoV-2 nucleocapsid protein. Compared with control-patients, the clinical manifestations were more severe in patients after COVID-19. Patients with positive SARS-CoV-2 staining had a higher proportion of nephrotic syndrome, lower level of serum albumin, and greater severity of renal interstitial fibrosis than those of patients with negative SARS-CoV-2 staining. Serum MAC level and renal MAC staining intensity of MN after COVID-19 were significantly higher than those of control-patients. MAC expression in MN patients with positive SARS-CoV-2 staining was stronger than that in both control-patients and MN after COVID-19 with negative SARS-CoV-2 staining. Meanwhile, the expression trend of factor H was consistent with that of MAC.

Conclusions: Excessive activation of the complement system aggravated symptoms in MN after COVID-19. The complement alternative pathway might be involved in renal injury. Therapeutic strategy targeting the complement system may need to be considered.

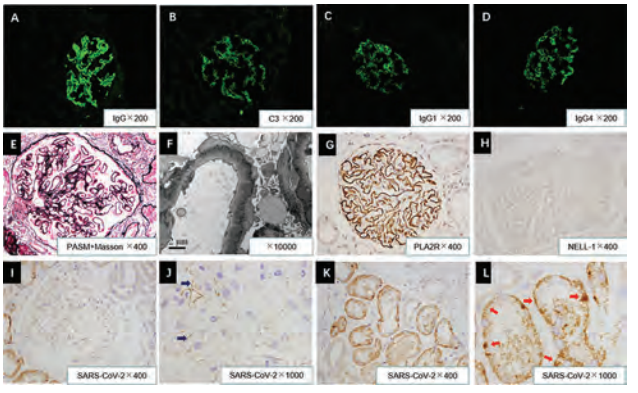

Figure. The renal pathologic images of a patient with PLA2R-positive MN patient after COVID-19 who also is positive for SARS -COV-2 staining.

ACE in Neutrophils Ameliorates Glomerular Damage in Immune Complex-Mediated Crescentic Glomerulonephritis via Complement C3 and C and N Domains of ACE

Suguru Saito,[1] Zakir Khan,[1] Ellen A. Bernstein,[1] Yoshihiko Kanno,[2] Kenneth E. Bernstein,[1] Michifumi Yamashita.[1] *[1]Cedars-Sinai Medical Center, Los Angeles, CA; [2]Tokyo Medical University, Tokyo, Japan.*

Background: Angiotensin-converting enzyme (ACE) is composed of catalytically active C and N domains, and widely known to regulate blood pressure as a major component of the renin-angiotensin system. We recently reported that glomerular injury of immune-complex (IC) mediated crescentic glomerulonephritis (GN) was attenuated in the mice overexpressing ACE specifically in neutrophils (NeuACE mice). Mechanistically, the renoprotective role was mediated by complement C3b-complement receptors 1/2 (CR1/2): C3b-CR1/2 axis. NeuACE mice showed increased level of serum C3b. NeuACE neutrophils exhibited enhanced IC uptake with elevated surface expressions of CR1/2 and FcγRs. Here, we further investigate the precise mechanism of the neutrophilic ACE-mediated renoprotective effects in GN.

Methods: Nephrotoxic serum nephritis (NTN) was induced in the mice with four different conditions, and analyzed in renal function and histology: 1) Neutrophils were depleted in WT and NeuACE mice by administering anti-neutrophil Ab. 2) ACE-overexpressed neutrophils were adoptively transferred into WT mice. 3) ACE C-domain KO (Tg-CKO) mice, ACE N-domain KO (Tg-NKO) mice, and WT-ACE transgenic (Tg-ACE) mice were also examined. 4) Lastly, NeuACE mice that lack complement C3 (NeuACE-C3KO) and C3KO mice were compared.

Results: 1) WT mice without neutrophils showed amerioliated glomerular injury in proteinuria and histology, while NeuACE mice lacking neurophils lost the renoprotective effect. In WT mice, neutorphils are needed for glomerular injury; in NeuACE mice, neutrophils are required for the renoprotection. 2) WT mice with ACE-overexpressing neutrophils exhibited less severe glomerular injury. 3) Tg-CKO or Tg-NKO showed partially lost the renoprotective role compared with Tg-ACE mice, likely both C and N domains are needed for full renoprotection. 4) Furthermore, NeuACE-C3KO mice did not show the renoprotective effects of overexpressed ACE in neurophils anymore, compared with C3KO mice. Complement C3 is essential for the renoprotective role of overexpressed ACE in neutrophils in NeuACE mice.

Conclusions: The renoprotective effects of overexpressed ACE in NeuACE mice in IC-mediated GN require specifically neutrophils, both C and N domains of ACE, and complement C3.

FR-PO808

The Role of von Willebrand Factor (vWF) in the Pathogenesis of C3 Glomerulopathy (C3G)

Zixin Hua. *Peking University First Hospital, Beijing, China.*

Background: C3G is caused by dysregulation of complement activation. Our previous study found that C3G patients showed rare variants in vWF. However, role of vWF in C3G's pathogenesis remains unclear.

Methods: The levels of vWF in plasma, urine and kidney specimens of C3G patients were detected and their associations with clinicopathological data were analyzed. A *VWF*-knockout C3G ($FH^{m/m}P^{-/-}VWF^{m/m}$) mice was generated using the CRISPR/Cas9 system to examine the cellular and molecular mechanisms.

Results: The urinary level of vWF/Cr in C3G patients was associated with level of serum creatinine (r=0.627, *P*<0.001), proteinuria (r=0.505, *P*=0.010), serum C3 (r=-0.582, *P*=0.004), and was a risk factor for worse prognosis (HR 1.294, 95% CI 1.050-1.595, *P*=0.015). VWF was co-localized with C3 and C5b-9 in kidneys. Compared with $FH^{m/m}P^{-/-}$ mice, $FH^{m/m}P^{-/-}VWF^{m/m}$ mice showed significantly higher levels of serum creatinine (140.70±61.87vs31.39±12.28μmol/L,*P*<0.001),proteinuria(3.50±2.25vs0.86±0.11g/mol, *P*<0.001), more severe renal pathological manifestations, more renal C3 and C5b-9 deposition, and worse prognosis (*P*=0.001). *VWF* gene deficiency was associated with complement factor H (FH) overexpression in $FH^{m/m}P^{-/-}VWF^{m/m}$ mice.

Conclusions: The levels of vWF were associated with disease severity and poor prognosis of C3G patients. *VWF* gene deficiency led to the aggravation of kidney damage and FH overexpression in C3G mouse model, which indicated that vWF might play a protective role in the pathogenesis of C3G.

Complement C3 Contributes to the Pathogenicity of Galactose-Deficient IgA1-Containing Immune Complexes in IgA Nephropathy

Stacy D. Hall,[1] Graham Gurganus,[1] Zhi qiang Huang,[1] Barbora Knoppova,[1] Shihong Qiu,[1] Rodney G. King,[1] Shigeaki Nakazawa,[1,3] Nicolas Maillard,[2] Zina Moldoveanu,[1] Dana V. Rizk,[1] Bruce A. Julian,[1] Matthew B. Renfrow,[1] Todd J. Green,[1] Jan Novak.[1] *[1]The University of Alabama at Birmingham, Birmingham, AL; [2]Hospital and University Jean Monnet of Saint-Etienne, Saint-Etienne, France; [3]Osaka Daigaku Daigakuin Igakukei Kenkyuka Igakubu Igaku Senko, Suita, Japan.*

Background: IgA nephropathy (IgAN) is an autoimmune kidney disease wherein circulating immune complexes (IC) contain IgA1 with some *O*-glycans deficient in galactose (galactose-deficient IgA1; Gd-IgA1) bound by IgG autoantibodies specific for Gd-IgA1. Additional serum components, such as complement proteins, can be also associated with these IC. Some of these Gd-IgA1-containing IC deposit in the glomeruli and induce kidney injury. In this study, we assessed the role of complement C3 in the pathogenicity of Gd-IgA1-IgG IC.

Methods: IC from native or IgA1-depleted sera of patients with IgAN were isolated by size-exclusion chromatography. Engineered IC were formed using recombinant polymeric Gd-IgA1 and recombinant IgG autoantibodies specific for Gd-IgA1 in C3-depleted or C3-repleted serum and isolated by size-exclusion chromatography. Biological activity of the isolated IC or engineered IC was determined based on their capacity to induce cellular proliferation of cultured primary human mesangial cells. IgA, Gd-IgA1, and IgA-IgG and IgA-C3 complexes were determined by ELISA. SDS-PAGE immunoblotting under non-reducing conditions was used to determine covalent association of C3 with IgA or IgG. Reducing conditions were used to determine C3 processing, i.e., presence of alpha-chain or its fragments indicative of C3, C3b, and iC3b, respectively.

Results: IC >700 kDa from IgAN sera increased cellular proliferation of quiescent mesangial cells by 2-4-fold. These IC contained IgA, IgG, and C3; C3 was covalently associated with IgA and IgG. C3 molecular forms included C3, C3b, and iC3b. Removal of IgA1 from sera removed these stimulatory IC; the resultant preparations were devoid of IgA, IgG, and C3. To confirm the role of C3, we used engineered IC formed in C3-depleted or repleted serum. C3 was required for formation of large-molecular-mass engineered IC that stimulated mesangial cells to proliferate. Moreover, IgA and IgG formed covalent complexes with C3 in C3-repleted serum; these engineered IC contained C3, C3b, and iC3b.

Conclusions: In summary, C3 has a central role in the formation of Gd-IgA1-containing IC with a nephritogenic capacity for IgAN.

Engineering of CX3CR1-Expressing Induced Regulatory T-Like Cells (iTregs) to Treat Acute Glomerulonephritis

David L. Puetz,[1,2] Jasper F. Nies,[2,1] Claudio Sierra Gonzalez,[2,1] Bastian Trinsch,[2,1] Paul T. Brinkkoetter,[2,1] Bernhard Schermer,[2,3] Thomas Benzing,[2,1] Paul Diefenhardt,[2,1] Sebastian Braehler.[2,1] *[1]University of Cologne Center for Molecular Medicine Cologne, Cologne, Germany; [2]Universitatsklinikum Koln, Koln, Germany; [3]Exzellenzcluster CECAD in der Universitat zu Koln, Koln, Germany.*

Background: T cell based strategies emerge as a targeted treatment option for autoimmune diseases including glomerulonephritis. T regulatory cells (Tregs) are uniquely equipped to dampen inflammation and thus prevent excessive tissue damage. To harness their full potential, however, they have to be directed to the site of inflammation. The chemokine receptor CX3CR1 detects CX3CL1, which has been shown to be selectively expressed in kidneys during GN. This study aims to engineer CX3CR1 expressing Tregs by retroviral transduction of Foxp3 and Cx3cr1 and assess their suppressive – and ultimately - therapeutic potential in GN.

Methods: A retroviral vector was generated containing the coding sequences of Foxp3 and Cx3cr1 linked by a P2A site. Subsequently, primary naïve murine T cells were transduced *in vitro*. The generated T cells (termed *induced Treg like cells; iTregs*) were examined with regards to known Treg markers using flow cytometry. In addition, their suppressive function was assessed *in vitro* by T cell proliferation assay and ELISA.

Results: Viral transduction of primary mouse T cells resulted in the generation of iTregs expressing FOXP3 as well as CX3CR1 with a high transduction efficiency. Interestingly, these cells expressed the Treg markers CD25, CTLA-4, PD-1, GITR, ICOS and Helios to a similar degree as naturally occurring Tregs. Confirming their regulatory nature, proliferation of T effector cells was suppressed by these iTregs *in vitro*. In addition, they produced copious amounts of the anti-inflammatory cytokine IL-10, suggesting immunosuppressive functionality.

Conclusions: Retrovirally engineered CX3CR1+ iTregs have suppressive functions *in vitro* and obtain a Treg like phenotype. Future studies will assess their behaviour and migratory preferences *in vivo*. Ultimately, their therapeutic potential will be tested in a murine model of acute glomerulonephritis.

Deciphering Complement Activation Mechanisms in Childhood IgA Nephropathy

Srishti Sahu,[1,2] Natalie Patey,[1,2] Arnaud Bonnefoy,[1,2] Stephan Troyanov,[3,2] Anne-Laure Lapeyraque,[1,2] Cambier Alexandra.[1,2] Cambier's Laboratory.
[1]Centre Hospitalier Universitaire Sainte-Justine, Montreal, QC, Canada; [2]Universite de Montreal Faculte de Medecine, Montreal, QC, Canada; [3]Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada.

Background: The complement pathway plays a crucial role in the development of IgA nephropathy (IgAN), as evidenced by the association of complement C3 with IgA deposits. However, the specific mechanisms that trigger complement pathway activation remain poorly understood. Recent research has implicated soluble CD89 (sCD89) in kidney inflammation among childhood IgAN (cIgAN) patients. Thus, this study seeks to understand how sCD89 activates collectin 11—a crucial initiator of the lectin pathway—ultimately resulting in the formation of C5b-9 and subsequent kidney inflammation.

Methods: A prospective cohort of cIgAN patients was enrolled in the study (n=52). The levels of soluble C5b-9 (sC5b-9) and collectin-11 (C-11) were determined in both the urine and plasma of these patients using ELISA. These levels were correlated with biological, histological and clinical data. Kidney biopsies were assessed for inflammation and C5b-9 deposition. Next, we evaluated the expression and secretion of C-11 in human mesangial cells (HMCs) using RT-PCR and ELISA respectively. HMCs were stimulated with cIgAN plasma or recombinant sCD89 (rsCD89). Additionally, to detect the presence of C-11 within circulating immune complexes (CICs) we used sCD89 immunoprecipitation.

Results: Our research findings demonstrate several significant associations in cIgAN patients. sC5b-9 correlates with lower eGFR and increased proteinuria. Elevated levels of sC5b-9 were also linked to cellular inflammation, glomerulosclerosis and fibrotic crescents. Notably, we found that plasma sC5b-9 is linked to endocapillary deposition of C5b-9 in kidney glomeruli. Furthermore, C-11 levels are elevated in cIgAN patients compared to healthy controls. There exists a positive correlation between plasma C5b-9 and C-11 levels. Our *in vitro* results indicate that C-11 is expressed and secreted by the HMCs, with its upregulation upon stimulation by cIgAN plasma and rsCD89. Interestingly, we also observe the presence of C-11 within the CICs.

Conclusions: Our study indicates that both sC5b-9 and C-11 are associated with disease severity in cIgAN. They show promise as prognostic markers for cIgAN, potentially obviating the need for invasive kidney biopsy procedures. Additionally, the interplay between C-11 and sCD89 may provide insights into the underlying mechanisms of complement pathway activation in cIgAN.

FR-PO812

In Vivo Evidence of Complement Requirement for Mesangioproliferative Activity of Immune Complexes Containing Galactose-Deficient IgA1 in IgA Nephropathy

Zina Moldoveanu, Stacy D. Hall, Graham Gurganus, Lea Novak, Zhi qiang Huang, Shihong Qiu, Todd J. Green, Jan Novak. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: Patients with IgA nephropathy (IgAN) have distinctive immune complexes (IC) in the circulation containing IgA1 with some *O*-glycans deficient in galactose (Gd-IgA1) bound by IgG autoantibodies (AuAb) specific for Gd-IgA1. Additional serum proteins, such as complement components, often associate with these IC. Some of these Gd-IgA1-containing IC deposit in the glomeruli and induce kidney injury. Here we have tested the role of complement C3 in the pathogenicity of these IC by using our passive mouse model of IgAN in which the intravenous (i.v.) injection of pre-formed complexes containing human Gd-IgA1 and IgG AuAb induce mesangioproliferative glomerular injury.

Methods: We used engineered IC (EIC) formed *in vitro* from recombinant human polymeric Gd-IgA1 and recombinant human IgG AuAb. The amount of Gd-IgA1, IgG, and IgG-IgA IC were determined by ELISA. Serum complement C3 was depleted by intraperitoneal (i.p.) injection of cobra venom factor (CVF). We have optimized the CVF dose and established the conditions in which C3 was <99% depleted from the circulation 1 day after CVF injection, and this depletion was maintained for at least 5 days. C3 was analyzed by SDS-PAGE and immunoblotting. One day after CVF injection that depleted C3, EIC were administered i.v. on three consecutive days to a group of nude mice and to another group without CVF treatment. A control group of mice received only CVF, and other control mice did not receive either EIC or CVF. The pathologic glomerular changes were evaluated by quantitative morphometry using H&E-stained sections of kidneys harvested one day after the last EIC dose. At least 25 glomeruli were analyzed for each mouse.

Results: The results showed that EIC administration increased glomerular cellularity compared to control (P=0.0001) and that CVF blocked that effect (P=0.021). CVF alone did not alter glomerular cellularity. Our data indicate that CVF-mediated C3 depletion prevented mesangioproliferative changes induced by EIC *in vivo*.

Conclusions: These results provide experimental evidence *in vivo* that complement C3 is required for the pathogenic activity of Gd-IgA1-containing IC in IgAN, confirming our *in vitro* findings with cultured human mesangial cells.

FR-PO813

Transferrin Receptor 1 Mediates Lysosomal Accumulation of Galactose-Deficient IgA1 in Mesangial Cells, Contributing to IgA Nephropathy

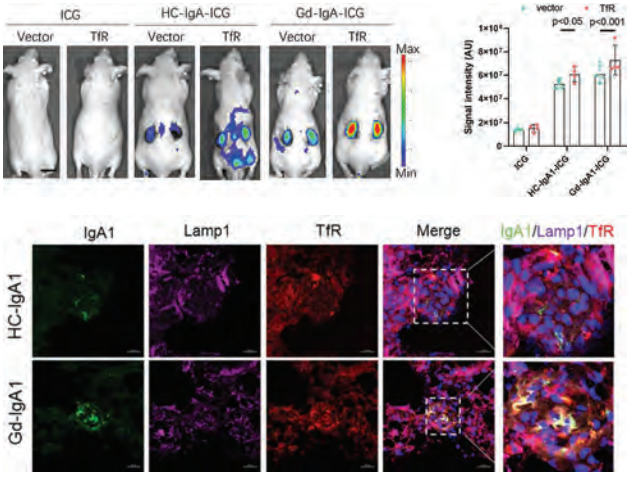
Mengting Fang, Meijun Si, Xueqing Yu. *Guangdong Provincial People's Hospital, Guangzhou, China.*

Background: The deposition of Gd-IgA1 in the mesangium is a pathological characteristic of IgA nephropathy (IgAN), but the mechanism remains unclear.

Methods: We used CRISPR/Cas9 to screen for potential membrane proteins mediating the binding of mesangial cells to Gd-IgA1 and identified transferrin receptor 1 (TfR1) as one of the candidates. *In vitro*, we overexpressed and knocked down TfR in mesangial cells and explored its influence on Gd-IgA1 binding with mesangial cells. *In vivo*, we overexpressed TfR in BALB/c nude mice via AAV9, injected with ICG, HC-IgA1-ICG, and Gd-IgA1-ICG (i.v.), and then monitored the deposition intensity of IgA1 in kidneys by intravital fluorescent imaging. We also validated our finding on renal tissues from patients with IgAN. TfR expression and localization were detected.

Results: We observed that Gd-IgA1 showed significantly reduced binding to mesangial cells in the TfR knockdown group compared to controls. Conversely, Gd-IgA1 demonstrated significantly increased binding to mesangial cells in the TfR overexpression group compared to controls. We demonstrated that Gd-IgA1 deposition in kidneys was significantly enhanced in TfR overexpression mice, and Gd-IgA1 was found co-localized with TfR and the lysosomal marker lamp1 in renal. To validate our finding, we performed immunohistochemical staining and revealed that TfR expression was significantly increased in glomeruli of patients with IgAN compared to para-cancercontrols, and TfR was found co-localized with IgA. Transmission electron microscopy (TEM) and immunoelectron microscopy (IEM) revealed the presence of IgA1 protein accumulation in the lysosomes of mesangial cells in patients with IgAN.

Conclusions: Our research elucidates that TfR in mesangial cells promotes the binding and endocytosis of Gd-IgA1, leading to intracellular aggregation in lysosomes and have potential novel strategies for IgAN therapy.



FR-PO814

CD89 Triggers APRIL Activation in Pediatric IgA Nephropathy

Cambier Alexandra,[1] Lison Lachize Neanne,[1,2] Natalie Patey,[1] Renato C. Monteiro,[4] Olivia Boyer,[3] Julien Hogan.[5] Cambier's Laboratory.
[1]Centre Hospitalier Universitaire Sainte-Justine, Montreal, QC, Canada; [2]Universite de Montreal Faculte de Medecine, Montreal, QC, Canada; [3]Hopital Universitaire Necker-Enfants Malades, Paris, France; [4]Centre de Recherche sur l'Inflammation, Paris, France; [5]Emory University, Atlanta, GA.

Background: IgAN, characterized by renal deposition of IgA, involves a multi-hit development with formation of circulating immune complexes (CICs) containing Gd-IgA1 and sCD89, contributing to renal inflammation. A Proliferation-Inducing Ligand (APRIL) is implicated in the immune response. The aim of this study is to investigate APRIL implication, especially in children with IgAN (cIgAN), who often exhibit more inflammation than adults.

Methods: First, we evaluated APRIL levels in human mesangial cells (HMC) after stimulation with recombinant sCD89 (rsCD89) or plasma from cIgAN patients. Subsequently, we conducted a comprehensive international cross-sectional study

involving 86 cIgAN patients and 48 control recruited from France and Canada. Our investigation included quantification of APRIL plasma levels and CICs, which were then compared with biological, clinical, and histological characteristics of the disease. Additionally, we performed immunohistochemistry analysis on kidney biopsies from cIgAN patients to visualize APRIL staining patterns.

Results: We demonstrated first that stimulations with cIgAN plasma and rsCD89 induced inflammation in HMC, leading to increased APRIL mRNA and protein production. We observed elevated levels of Gd-IgA1, sCD89-IgA1, sCD89 and soluble APRIL in the plasma of cIgAN patients compared to control subjects. Moreover, we found evidence suggesting that APRIL may be trapped within CICs, colocalizing with IgA in same-size complexes in Western blot experiments. Plus, IgA-APRIL and CD89-APRIL complexes were detected in cIgAN samples using ELISA and immunoprecipitation techniques. Levels of CICs correlated with plasma APRIL levels, and presence of IgA-APRIL and CD89-APRIL in CICs was linked to a worst initial clinical presentation, prognosis with kidney failure and relapses with persistent proteinuria. Staining of cIgAN biopsies revealed the presence of APRIL deposits within the glomerulus in the mesangium and near the Bowman capsule.

Conclusions: Our research highlights the role of APRIL in the pathways of cIgAN, with sCD89 as a potential trigger of APRIL activation in HMCs. APRIL holds promise as a valuable biomarker, offering a non-invasive means to detect forms of cIgAN with the worst progression, thereby potentially reducing reliance on biopsy. APRIL inhibition as therapeutic strategy presents an exciting opportunity for cIgAN treatment.

FR-PO815

Mechanism of Intestinal IgA Class Switching Regulated by TRIM21 through Downregulation of AID (Activation-Induced Cytidine Deaminase) in IgA Nephropathy

Qian Chen, Ming Xia, Hong Liu. *The Second Xiangya Hospital of Central South University Department of Nephrology, Changsha, China.*

Background: IgA nephropathy (IgAN) is the most common primary glomerular disease and the leading cause of end-stage renal disease (ESRD). At present, the 'multi-hit hypothesis' is a generally recognized pathogenesis of IgAN. However, the mechanism that initially triggers abnormal IgA synthesis has not been fully elucidated, specific treatment options are still lacking. Studies have shown that aberrant class switching of IgA antibodies in B cells within intestinal peyer patches plays a central role in generating pathogenic IgA. TRIM21 (Ro52/SS-A1) is an E3 ubiquitin ligase that participates in cellular immune response and antibody production. This study aims to elucidate the underlying mechanism of TRIM21 in regulating intestinal IgA class switching.

Methods: IgA deposition in the Intestinal tract was detected by immunofluorescence. The expression level of AID in peyer patches was detected by immunohistochemical staining and Western Blot. The mRNA levels of IgA transcripts in peyer patches were detected by RT-qPCR. To investigate the mechanism of TRIM21 influencing the down-regulation of IgA-switching enzyme AID by inhibiting NF-κB pathway. The interaction of TRIM21 with IκBα was analyzed by CO-IP. The change of protein ubiquitination was analyzed by Western Blot.

Results: Upon knocking out TRIM21, there was an increase in AID expression and IgA class switch. Additionally, the NF-κB pathway was activated, leading to increased AID expression in B cell lines Following the administration of an NF-κB pathway inhibitor, the AID expression in TRIM21 knockdown cells was restricted, and there were alterations in the overall protein ubiquitination levels. TRIM21 was identified to interact with IκBα, an inhibitory protein of NF-κB.

Conclusions: The findings of this study reveal that TRIM21 acts as a negative regulator of AID expression, and IgA class switching. Through ubiquitination of IκBα, TRIM21 exerts a negative effect on the NF-κB pathway, thereby upregulating AID expression. Our study provides a promising aspect of TRIM21 in IgAN through the NF-κB signaling pathway. Our study reveals the role of TRIM21 in immune response and the development of IgAN.

FR-PO816

KLF4 Promotes Gd-IgA1 Synthesis in B Cells of IgA Nephropathy

Yangang Gan, Qiongqiong Yang, Li Hao, Jiajia Li, Wenchao Li, Hao Yu, Weicong Zeng. *Sun Yat-Sen Memorial Hospital, Guangzhou, China.*

Background: B cells are thought to perform a crucial function in IgA nephropathy (IgAN) pathogenesis by generating abnormal IgA1 and antibodies. Nonetheless, the machinery behind the aberrant gene expression of B cells in IgAN patients remains ambiguous.

Methods: This study has revealed an extensive range of differences in chromatin accessibility within the B cells of IgAN via ATAC-seq evaluation of active DNA regulatory components.

Results: B cells of IgAN were noted to display enhanced chromatin accessibility in genes affiliated with transcription regulation. Moreover, KLF4 was also recognized as a crucial transcription factor supporting the generation of IgA1 and galactose-deficient IgA1 (Gd-IgA1). In vitro, the knockdown of KLF4 suppressed the production of Gd-IgA1 in IgA-secreting cell lines. The study further showed that KLF4 could regulate the expression of genes related to the intestinal immune network for IgA production through RNA-seq. Combining ChIP-seq and RNA-seq, it was found that KLF4 can bind to the IL-6 promoter and regulate its expression. Mechanistically, a luciferase reporter assay verified that KLF4 directly binds to the cis-regulatory element of IL-6 and promotes its expression. KLF4 knockdown has been demonstrated to mitigate renal lesions and mesangial hypercellularity in IgAN mice.

Conclusions: Findings from this study reveal a mechanism mediated by chromatin underlying the differential responses of B cells in IgAN and identify KLF4 as a potential therapeutic target of IgAN.

Funding: Government Support - Non-U.S.

Clinical Evidence That Defines IgAN as a Tissue-Specific Autoimmune Glomerulonephritis

Yoshihito Nihei,[1] Ayako Koizumi,[1] Jonathan Barratt,[2] Hitoshi Suzuki,[1,3] Yusuke Suzuki.[1] *[1]Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; [2]Leicester General Hospital, Leicester, United Kingdom; [3]Department of Nephrology, Juntendo University Urayasu Hospital, Chiba, Japan.*

Background: IgA nephropathy (IgAN) is thought to be mediated by immune complexes containing galactose-deficient IgA (Gd-IgA1) and antigen specificity of glomerular IgA has not been emphasized in the pathogenesis of IgAN. However, we recently reported that IgA-type autoantibodies against mesangial cells (anti-β2-spectrin and anti-CBX3 IgA) were detected in the sera of IgAN model mice (**Sci. Adv. 2023. Life Sci. Alliance 2024**). Here, we aimed to show clinical evidence of these IgA autoantibodies in human IgAN.

Methods: Patients with biopsy-proven IgAN (n=119) and the other kidney disease (DC: disease control, n=51) were recruited from Juntendo University Hospital in Japan (70 IgAN and 32 DC patients) or Leicester General Hospital in the UK (49 IgAN and 19 DC patients). Serum anti-β2-spectrin and anti-CBX3 IgA were measured by ELISA. Glycosylation of purified anti-β2-spectrin and anti-CBX3 IgA were analyzed by western blot (WB) using anti-Gd-IgA1 antibody.

Results: Anti-β2-spectrin and anti-CBX3 IgA were more frequently detected in patients with IgAN than DC in both Japan and the UK cohort (**Figure 1**). Overall, 30 of 119 IgAN and 3 of 51 DC patients were positive for anti-β2-spectrin IgA (sensitivity, 25.2%; specificity, 94.1%), while 48 of 119 IgAN and 3 of 51 DC patients were positive for anti-CBX3 IgA (sensitivity, 40.3%; specificity, 94.1%). Sixteen IgAN patients were positive for both anti-β2-spectrin and anti-CBX3 IgA. WB analysis revealed that the purified serum anti-β2-spectrin and anti-CBX3 IgA from IgAN patients were enriched for Gd-IgA1 than the total serum IgA (**Figure 2**).

Conclusions: The anti-β2-spectrin and anti-CBX3 IgA are detected in IgAN patients with high specificity. Furthermore, these IgA-type autoantibodies have the property of galactose deficiency, namely, anti-mesangium Gd-IgA1 are present in circulation of IgAN patients. Thus, we provide clinical evidence that anti-mesangium IgA is involved in the pathogenesis of human IgAN and defines IgAN as a tissue-specific autoimmune glomerulonephritis.

A Human Origin Anti-GdIgA1 Antibody and Its Implications in IgA Nephropathy

Haipei Tang, Huikun Zeng, Zhenhai Zhang, Xueqing Yu. *Guangdong Provincial People's Hospital, Guangzhou, China.*

Background: IgA nephropathy (IgAN) is a common kidney disease where IgA deposits in the mesangial region, leading to mesangial cell proliferation. The underlying mechanism of IgAN remains unclear. The 'four-hit' hypothesis proposes that immune

complexes formed by Galactose-deficient IgA1 (GdIgA1) and anti-GdIgA1 are crucial in the disease. However, the reasons for the deposition of these immunoglobulins in the mesangial region and their role in the disease process are not yet understood.

Methods: The study collected GdIgA1 binding B cells from peripheral blood and sequenced through scBCR-Seq. A set of candidate antibodies was then synthesized and screened. Among these candidates, P4 showed high affinity for GdIgA1. The study investigated the binding affinity between mature and naïve P4 by reverting sequences to germline. Furthermore, P4, HAA, and KM55 were used to compare the GdIgA1 levels in IgAN patients and healthy controls. Finally, preliminary in vitro experiments were conducted to explore the role of P4 in the pathogenesis of IgAN.

Results: High-affinity anti-GdIgA1 antibody (P4) was obtained in peripheral blood B cells (PBMCs), encoded by IGHV3-64D|IGHJ4, IGKV1-39|IGKJ2 and IGHA2, with a KD value of 1.508×10^{-8}(M) to GdIgA1. Heavy chain dictated the binding to GdIgA1, while the light chain affected the affinity slightly. Most importantly, P4 in naïve state did not bind to GdIgA1 which indicate it was elicited by antigens other than GdIgA1. P4 exhibited comparable ability in measuring serum GdIgA1 levels with KM55 and HAA. A larger validation set conducted by third-party laboratory confirmed the potential of P4 in clinical usage. In vitro experiments revealed that co-stimulation of mesangial cells with P4 and GdIgA1 upregulates the Wnt pathway and potentially cause the proliferation of the mesangial cell while neither P4 nor GdIgA1 alone had this effect.

Conclusions: In summary, the discovery of a high-affinity anti-GdIgA1 antibody, P4, holds promise for effectively measuring GdIgA1 levels. The study's findings suggest that high-affinity anti-GdIgA1 auto-antibodies may be induced by antigens mimicking the hinge region of GdIgA1. Moreover, the upregulation of the Wnt pathway by co-stimulation of P4 and GdIgA1 highlights the critical role of P4. Further exploration of the molecular and cellular mechanisms of IgAN may offer valuable insights.

Cell-Surface Glycosylation Identifies Subpopulations of B Cells in IgA Nephropathy with Distinct Signaling Corresponding to the Production of the Main Autoantigen, Galactose-Deficient IgA1

Taylor Person,[1] Dana V. Rizk,[2] Jan Novak,[1] Colin Reily.[2,1] *[1]Department of Microbiology, University of Alabama at Birmingham, Birmingham, AL; [2]Department of Medicine, Nephrology Division, University of Alabama at Birmingham, Birmingham, AL.*

Background: Patients with IgA nephropathy (IgAN) have elevated levels of circulating autoantigen, galactose-deficient IgA1 (Gd-IgA1), that is recognized by IgG autoantibodies. Some of the resultant immune complexes deposit in the glomeruli and induce kidney injury. Based on the polymeric form of Gd-IgA1 in the circulating immune complexes and synpharyngitic hematuria at disease onset/activity, we hypothesize that only a subpopulation(s) of IgA1-secreting cells is responsible for Gd-IgA1 production, and that abnormal cellular responses further enhance Gd-IgA1 levels in circulation. However, as the autoantigen is released from B cells, identification of those subpopulations is difficult. Here we report that distinct cell-surface glycosylation and cellular responses to CpG-ODN (oligodeoxynucleotides) stimulation, are associated with Gd-IgA1 production and distinct intracellular signaling.

Methods: Immortalized IgA1-producing cells derived from peripheral blood of IgAN patients and healthy controls were stimulated with CpG-ODN (2 ug/mL) for 30 min and then stained with HPA and PNA to detect cell-surface GalNAc and GalNAc-Gal glycoconjugates and anti-IgA antibody to identify IgA-positive cells. Intracellular signaling was assessed using fluorochrome-conjugated antibodies specific for pSTAT1, pSTAT3, pSTAT5, pSTAT6, p38-MAPK, pERK1/2, p65-NF-kB, with flow cytometry readout using a BD FACSymphony with spectral compensation. Cells were incubated for 48 h for analyses of IgA and Gd-IgA1 in cell-culture supernatants by ELISA.

Results: CpG stimulation decreased the number of HPA^+/PNA^+ cells ($p<0.05$) as well as the amount (detected as median fluorescence index; MFI) ($p<0.05$). Cells with high HPA vs. low HPA differed in baseline and CpG-induced pSTAT3 ($p<0.02$), pSTAT5 ($p<0.01$), and pMEK1/2 ($p<0.01$). Cells with high HPA^+/PNA^+ showed significant correlation between Gd-IgA1 production and p38-MAPK ($p<0.01$), pSTAT3 ($p<0.01$), and p65 NF-kB ($p=0.05$) after CpG stimulation.

Conclusions: Differential cell-surface glycosylation identified differential cellular signaling, both baseline and CpG-induced, that correlated with Gd-IgA1 production. Further characterization of these cell subpopulations will provide insight into mechanisms involved in IgAN pathobiology.

Loss of GalNAc-T14 Links O-glycosylation Defects to Alterations in B Cell Homing in IgA Nephropathy

Nicholas J. Steers,[1] Sindhuri Prakash-Polet,[1] Isabel Robbins,[1] Jenna Simpson,[1] Sharvari Pathak,[1] Kelsey O. Stevens,[1] Simone Sanna-Cherchi,[1] Vivette D. D'Agati,[1] Jan Novak,[2] Ali G. Gharavi.[1] *[1]Columbia University Irving Medical Center, New York, NY; [2]University of Alabama at Birmingham, Birmingham, AL.*

Background: Defects in *O*-glycosylation of IgA1 are a characteristic finding in IgA nephropathy (IgAN). It is not known if aberrant *O*-glycosylation can impact IgA homeostasis, such as B-cell residence, homing, and migration. Up to 20 different *N*-ace tylgalactosaminyltransferases (GalNAc-Ts) can initiate *O*-glycosylation of proteins in humans.

Methods: We studied the circulating IgA, and the mucosal and non-mucosal tissue resident B-cells in *Galnt14-/-* and WT mice using ELISA and flow cytometry.

Results: *GALNT14* is expressed in human and murine lymphoid tissues, specifically within germinal centers, the major site for B-cell maturation, antibody class switching, and proliferation. We have identified a heterozygous predicted loss-of-function (LOF) variant in *GALNT14* in a family with IgAN. *Galnt14*-null mice had elevated serum IgA levels compared to WT mice (0.88±0.2 mg/ml and 0.37±0.1 mg/ml, respectively, $P<0.01$), and the *Galnt14*-null mice developed glomerular IgA deposition with aging and after induction of sterile colitis. *Galnt14*-null mice also displayed an attenuated mucin layer in the colon and redistribution of IgA-producing cells from mucosal to systemic sites. A significant decrease in the percentage of IgA+ B-cells was observed in the Peyer's patches of *Galnt14-/-* mice compared to WT mice (20.2±3.7% and 24.4±3.8%, respectively, $P<0.01$), and an increase in the percentage of IgA+ B-cells was observed in non-mucosal tissues of *Galnt14-/-* mice compared to WT mice (spleen: 4.2±0.9% and 3.0±0.7%, respectively, $P<0.01$; PMBC: 3.9±0.7% and 2.6±0.4%, respectively, $P < 0.01$). The increased IgA in the circulation in *Galnt14-/-* mice correlated with the increased IgA+ B-cells in the circulation ($P<0.01$) and the reduced IgA+ B-cells in the Peyer's patches ($P<0.01$). Analysis of the germinal center B-cells in *Galnt14-/-* mice demonstrated a reduction on the *O*-glycosylation of cell-surface molecules. Finally, adoptive-transfer experiments indicated impaired homing of spleen-derived *Galnt14*-deficient B-cells, resulting in increased retention in peripheral blood.

Conclusions: These findings suggest that abnormalities in *O*-glycosylation alter mucosal immunity and B-cell homing, pointing to an expanded role of aberrant *O*-glycosylation in the pathogenesis of IgAN.

FR-PO821

Distinct O-glycoforms Profiles in the Hinge Region of Immunoglobulin A1 in Patients with IgA Nephropathy and IgA Type Multiple Myeloma

Xinfang Xie,[1] Wanhong Lu,[1] Yong Zhang.[2] *[1]The Frist Affiliated Hospital of Xi'an Jiaotong University, Beijing, China; [2]West China Hospital, Sichuan University, Chengdu, China.*

Background: Galactose-deficient IgA1 (GdIgA1) is critical in the formation of circulating IgA polymer and poly-IgA immunodeposits in IgA nephropathy (IgAN). However, very rare patients with IgA type multiple myeloma(IgAMM) complicated by IgAN, although IgAMM patients had signigicantly high IgA1 and limited data also showed higher GdIgA1 composition in purified IgA1 from IgAMM patients. In this study we aimed to investigate the GdIgA1 levels, polyIgA1 levles and IgA1 O-glycoforms profiles in the hinge region (HR) of IgA1 from patients with the two diseases respectively.

Methods: 25 patients with IgA type multiple myeloma and 66 patients with IgAN were included in the study. Plasma IgA, GdIgA1, CD89 captured polyIgA1 and IgA-IgG complex were detected by ELISA. Total IgA1 was purified from the plasma of the participants. The variation in O-glycoforms in HR of purified plasma IgA1 was evaluated by using mass spectrometry of EThcD-sceHCD MS/MS fragmentation mode.

Results: IgAMM patients included were older than IgAN patients (68.6±10 vs. 32±8 ys). Compared with IgAN patients, IgAMM patients had significantly higher levels of IgA1 (39.7±26.1 vs. 3.1±1.1 mg/ml, $p<0.05$), GdIgA1 (28.8±7.1 vs. 4.9±0.3 ug/ml, $p<0.01$) and CD89 captured polyIgA1(13.6±3.1 vs. 3.8±0.4 ug/ml, $p<0.01$). While GdIgA1/IgA levels were much higher in IgAN, and IgAN patients had higher IgA-IgG complexes. EThcD-sceHCD MS/MS showed the number of Nacetylgalactosamine (GalNAc) bound to one HR was higher in IgAN patients. The proportions of GalNAc4 (defined as O-glycans bound to one HR at 4 sites) and GalNAc5 were highest in all patients. The proportions of 3-5 galactose/HR were higher and 4 galactose/HR were with the highest proportions in both diseases (61.8%±11.1% vs. 52.8%±4.4% $p<0.05$, IgAMM vs. IgAN). Galactose deficiency profile per HR were investigated, we found deficiency of 1-2 galactose/HR were most common, and significant higher percentages of total galactose deficiency/HR were detected in IgAN than IgAMM group (87.7%±1.9% vs. 34.9%±6.1% $p<0.01$). PCA analysis indicated that the O-glycoforms profiles of IgA1 differed greatly between the two diseases.

Conclusions: Distinct IgA1 O-glycoforms profiles in HR were showed in IgAN and IgAMM. Our data also supported higher levels of GdIgA1/IgA1 and IgA-IgG complexes play crucial roles in the pathogeneisis of IgAN.

FR-PO822

Identification of the Localization of the Pathogenic IgA Autoantibodies on Mesangial Cells in IgA Nephropathy

Kazuaki Mori,[1] Yoshihito Nihei,[1] Hitoshi Suzuki,[1,2] Yusuke Suzuki.[1]
Dept of Nephrology, Juntendo University Faculty of Medicine. *[1]Department of Nephrology, Juntendo University Faculty of Medicine, Bunkyo, Japan; [2]Department of Nephrology, Juntendo University Urayasu Hospital, Urayasu, Japan.*

Background: IgA nephropathy (IgAN) has been considered as an immune complex-mediated disease, and its possible existence of autoantigens has not been clarified. Recently, we discovered IgA autoantibodies specific to mesangial cells (MCs) in the sera of its patients. We identified two autoantigens targeted by these IgA (β2-spectrin and CBX3), both of which are originally known for their intracellular existence. Although *in vivo* studies with monoclonal antibodies against the autoantigens revealed their selective expressions on MC surfaces, their mechanisms have not been elucidated. To investigate them, we aimed to establish methods to visualize the MC-surface expression of these autoantigens *in vitro*.

Methods: For immunofluorescence microscopy (IFM), human primary MCs (HMCs) were cultured on cover glasses for 24 hours. The HMCs were fixed with methanol for intracellular protein staining or 4% paraformaldehyde (4%PFA) for cell-surface protein staining and stained with anti-β2 spectrin or CBX3 antibody and with DAPI. For immune electron microscopy (IEM), 24h-cultured HMCs were fixed with 4%PFA and stained with anti-β2 spectrin or CBX3 antibody and then with colloidal gold. To perform transmission electron microscopy, these cells were fixed with 2.5% glutaraldehyde in 0.1M phosphate buffer and then with 2% OsO_4 in the same buffer followed by dehydration with a graded series of ethanol and embedded in Epok-812. Ultrathin sections were removed, and uranyl acetate and lead citrate were applied.

Results: By IFM analyses after application of methanol on the HMCs, we detected the intracellular expression of β2 spectrin and CBX3. And then by IFM analyses after application of 4%PFA on the HMCs, cell-surface β2 spectrin and CBX3 were detected. To elucidate their locations either on the cell surfaces or inside of the cells, we utilized IEM and clearly visualized their cell-surface locations with continuous cell membranes.

Conclusions: We identified the localization of β2 spectrin and CBX3 on the surfaces of HMCs by both IFM and IEM. We will utilize these methods to investigate the mechanisms of the MC-surface expression of each of these autoantigens and their relations with clinical features of IgAN.

Fc Receptor TRIM21 Degrades Mesangial Intracellular IgA and Inhibits Cell Proliferation in IgA Nephropathy

Haiyang Liu,[1,2] Hong Liu.[1] The Second Xiangya Hospital of Central South University. *[1]The Second Xiangya Hospital of Central South University Department of Nephrology, Changsha, China; [2]The Second Xiangya Hospital of Central South University Department of Geriatrics, Changsha, China.*

Background: IgA nephropathy (IgAN) characterized by abnormal deposition of IgA in the mesangial area in renal biopsy. Mesangial cells have the function of transferring IgA into cells' cytoplasm. Tripartite motif containing-21 (TRIM21) is a cytosolic ubiquitin ligase and antibody receptor, studies showed that IgA neutralizes adenovirus infection in an intracellular TRIM21- dependent manner.

Methods: 1. Screening IgA receptor in IgAN patients The expression level of IgA receptor genes in the glomerulus in IgAN was screened using datasets GSE93798 in the Gene Expression Omnibus (GEO). The protein expression were confirmed by staining utilized in the renal biopsy samples. 2. Knock out or over-expression TRIM21 in vivo and vitro model of IgAN The vivo mice IgAN model was made by oral mucosal immunization. The vitro model was made by aggregated IgA1 (aIgA1) added to human mesangial cells (HMCs). 3. Inhibit ubiquitin-proteasome pathway in vitro IgAN model MG132 or a corresponding amount of DMSO was added to the medium for different time intervals before the vitro experiment.

Results: 1. TRIM21 is upregulated and expressed in the mesangial cells of IgAN. 2. The upregulation of TRIM21 in the glomeruli of IgAN patients is associated with higher serum creatinine levels. 3. The upregulation of TRIM21 in the glomeruli was co-localizes with IgA. 4. Loss of TRIM21 in IgAN mice induces massive IgA deposition in the mesangial region. 5. Inhibiting TRIM21 in IgAN causes serious mesangial cell proliferation both In Vivo and In Vitro. 6. IgA enters the mesangial cells and is degraded through the ubiquitin-proteasome pathway. 7. TRIM21 regulates IgA degradation in mesangial cells via the ubiquitin-proteasome pathway.

Conclusions: This study illustrates that the increased TRIM21 in the glomeruli of IgAN could degrade the IgA in mesangial cells and inhibit cells proliferation, the mechanism involves the protease ubiquitination pathway. These results suggest TRIM21 may be a novel therapeutic target for degrading IgA in mesangial cells of IgAN.

FR-PO824

Cell Type Specificity of FcγRIIB Involving NLRP3 Inflammasome and Dectin-2 in a Mouse Model of IgA Nephropathy

Shuk-Man Ka,[1] Ann Chen.[2,3] *[1]Department of Medicine, National Defense Medical Center, Taipei, Taiwan; [2]Department of Pathology, Hualien Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Hualien, Taiwan; [3]Taiwan Autoantibody Biobank Initiative, Hualien Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Hualien, Taiwan.*

Background: IgA nephropathy (IgAN) is the most common form of glomerulonephritis and represents a leading cause of end-stage renal disease. Ample evidence confirms the deposition of IgA and IgG and the filtration of mononuclear leukocytes in renal biopsy specimens from IgAN patients. Previously, we established an experimental IgAN model in B cell-deficient mice, which implicated interactions between Fcγ receptors (FcγRs) in the pathogenesis of IgAN. Although it is generally accepted that FcγRIIB plays a regulatory role in humoral responses, it remains unknown whether this function and the cell type-specificity of FcγRIIB are reno-protective in IgAN.

Methods: We observed a dramatic increase in albuminuria, renal function impairment, and renal injury in FcγRIIB knockout mice with induced IgAN. Utilizing a mouse model of IgAN and three different types of FcγRIIB-deficient mice, including CEBP/α Cre (myeloid cells), CD11c Cre (dendritic cells) and CD19 Cre (B cells) in floxed FcγRIIB mice, as well as several specific cell models.

Results: We demonstrated that macrophage- and dendritic cell-specific FcγRIIB deficiency blunted the activation of the NLRP3 inflammasome and inhibited the development of IgAN. Moreover, activation of the inflammasome was induced by IgA immune complexes dependent on TLR4/MyD88 signaling, associated with crosstalk between TLR4 and Dectin-2.

Conclusions: These results suggested that activation of FcγRIIB and its downstream signaling pathways could moderate progression of IgAN involving the suppression of the NLRP3 inflammasome. A cell type-specific targeting FcγRIIB may help in establishing a therapeutic strategy for this renal disease.

FR-PO825

Establishment of Human IgG Autoantibodies Derived from Patients with Lupus Nephritis and Deposition of Resultant Human IgG-Containing Immune Complexes in the Kidney and Skin of Mice

Shuk-Man Ka,[1,3] Ann Chen.[2] *[1]Department of Medicine, National Defense Medical Center, Taipei, Taiwan; [2]Department of Pathology, Hualien Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Hualien, Taiwan; [3]Taiwan Autoantibody Biobank Initiative, Hualien Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Hualien, Taiwan.*

Background: In Taiwan, lupus nephritis (LN) has a trend of 4.3–13.4% rate of progression to end-stage renal disease (ESRD). Treatment for LN mainly relies on glucocorticoids and other immunosuppressants, but targeting more specific pathogenic molecules from the upstream pathways involved in the development and progression of the disease, e.g., etiological autoantibodies (autoAbs), is crucial and remains a unmet medical need.

Methods: We have recently established a human hybridoma platform to generate two human IgG against dsDNA autoantibodies (autoAbs) using peripheral blood mononuclear cells (PBMCs) from LN patients (LiuK-NDMC-01 and LiuK-NDMC-02) to which we performed sequencing and tests for capacity of inducing inflammatory responses and deposition of immune complexes (ICs) in the kidney and skin of ASID mice that mimics the human disease.

Results: By injecting intravenously a single dose of the LiuK-NDMC-01 autoAb against dsDNA and human dsDNA extracted from a human THP-1 monocyte cell line, renal deposition of the human IgG-containing ICs in ASID mice was induced. Immunofluorescence examination showed deposition of human IgG and C3 diffusely in the kidney and IgG in the skin. This effect was also confirmed by a Western blot analysis using renal proteins extracted from the ASID mice. Moreover, increased NLRP3 inflammasome-mediated IL-1β secretion was observed in human macrophages that were primed with the ICs containing the LiuK-NDMC-01 autoAb and dsDNA compared with saline-control counterparts.

Conclusions: Collectively, two new human IgG autoantibodies were established using PBMCs from LN patients. One of these human IgG autoAb was further validated for deposition of the IgG-containing ICs in both the kidney and skin, mimicking LN patients. The ICs was shown to induce inflammatory reaction as demonstrated by resultant activation of NLRP3 inflammasome and subsequent IL-1β secretion in human macrophages.

FR-PO826

Serum Levels of APRIL Correlate with Proteinuria in IgA Vasculitis: Findings from the GIGA-Kids Study

Josep Miquel Blasco Pelicano,[1,2] Cecilia C. Berrouet,[3] Lee G. Andrews,[4] Asher D. Schachter,[4] Aftab S. Chishti,[5] Margaret C. Hastings,[6] Joseph T. Flynn,[7] William E. Smoyer,[8] Raoul D. Nelson,[9] Krzysztof Kiryluk.[3] The GIGA-kids Study. *[1]Columbia University Irving Medical Center, New York, NY; [2]Hospital Clinic de Barcelona, Barcelona, Spain; [3]Columbia University, New York, NY; [4]Visterra Inc, Waltham, MA; [5]University of Kentucky, Lexington, KY; [6]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [7]Seattle Children's Hospital, Seattle, WA; [8]Nationwide Children's Hospital, Columbus, OH; [9]University of Utah Health, Salt Lake City, UT.*

Background: IgA vasculitis (IgAV) is the most common systemic vasculitis in children and is characterized by variable kidney involvement. As in IgA nephropathy (IgAN), IgAV nephritis (IgAVN) is associated with increased levels of galactose deficient IgA1 (Gd-IgA1) and anti-glycan antibodies. While elevated levels of APRIL correlate with IgAN progression, the role of APRIL in IgAVN is unclear.

Methods: The GIGA-kids (Genomics of IgA-related disorders in kids) study aims to recruit 1,000 pediatric cases of IgAN and IgAV for genetic and biomarker studies. Here, we analyzed biomarkers for the first 495 GIGA-kids participants, including 54 with IgAV, 260 with IgAVN, 169 with IgAN, and 12 healthy pediatric controls. Serum levels of APRIL, Gd-IgA1, and anti-glycan-antibodies were measured in all 495 participants and correlated with disease status and severity.

Results: Among all biomarkers tested, serum levels of Gd-IgA1 were significantly elevated in IgAN and IgAVN cases compared to healthy controls (p=0.013, and p=0.0079, respectively). Neither Gd-IgA1 nor anti-glycan antibody levels correlated with proteinuria among IgAN or IgAVN cases. In contrast, APRIL levels were significantly associated with higher proteinuria in IgAVN before and after adjustment for age, sex, race/ethnicity and immunosuppression (p=0.0033 and p=0.0064, respectively). This association was not statistically significant in the IgAN cohort, which was potentially due to a smaller sample size and lower acuity of IgAN vs IgAVN.

Conclusions: Serum APRIL levels were positively correlated with proteinuria, and Gd-IgA1 levels were elevated in pediatric IgAVN, supporting the involvement of APRIL in the pathogenesis of nephritis. Therapeutic strategies targeting APRIL in IgAN may also benefit patients with IgAVN.

Funding: Other NIH Support - Pediatric Nephrology Research Consortium, Commercial Support - Visterra, Private Foundation Support

Upregulation of Type I Interferon Pathway in Microscopic Polyangiitis

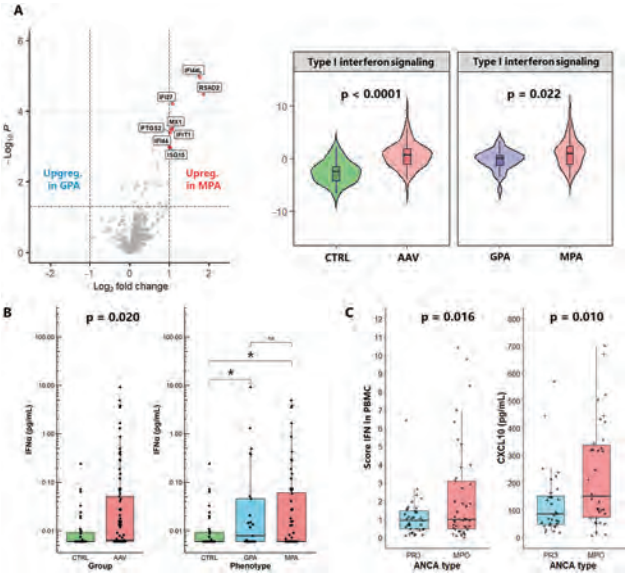
Benoit Brilland,[1] Andrea Boizard-Moracchini,[2] Nathalie Merillon,[1] Giorgina B. Piccoli,[3] Patrick Blanco,[2] Jean Francois Augusto.[1] Maine-Anjou Registry Research Group. *[1]CHU Angers, Angers, France; [2]Centre Hospitalier Universitaire de Bordeaux Groupe hospitalier Pellegrin, Bordeaux, France; [3]Centre Hospitalier du Mans, Le Mans, France.*

Background: The two main types of ANCA-associated vasculitis (AAV), microscopic polyangiitis (MPA) and granulomatosis with polyangiitis (GPA), share common characteristics but also differ on many aspects (epidemiological, genetic, clinical, outcomes). To identify more specific targetable pathways, we compared the kidney transcriptome of MPA vs. GPA patients with AAV-glomerulonephritis (AAV-GN) and further characterized pathways of interest.

Methods: Immune gene transcript analysis (n = 750) was performed on RNA extracted from 97 adult AAV-GN kidney biopsies from the French Maine-Anjou Registry using NanoString technology (33 GPA, 64 MPA). Significant transcripts were examined to identify immune pathways of interest. We assessed IFNα levels with an ultrasensitive method. We also used a publicly available dataset to explore these identified pathways.

Results: Eight genes were found differentially expressed, all being upregulated in MPA (logFC > 1, q-value < 0.05). Seven belonged to the type I interferon (IFN-I) signaling pathway (**Figure 1A**). Nearly 20% of AAV-GN patients displayed elevated IFNα levels (**Figure 1B**, p = 0.02), which correlated with IFN-I activation in kidneys. Analyzing unpublished publicly available data, we identified a significantly more pronounced IFN-I related signature (expression of interferon regulated genes in PBMC and levels of CXCL10 in serum) in MPO-AAV vs PR3-AAV (**Figure 1C**).

Conclusions: We identified a type I interferon signature in AAV-GN, both in kidneys and in blood, especially in patients with MPA (or MPO-AAV) in comparison to GPA (or PR3-AAV). This is in line with previous evidence suggesting a role for IFN-I in AAV and especially in MPO-AAV. This signature may help gain a deeper understanding of the AAV-GN pathogenesis and provide insights for developing new therapeutic options.



FR-PO828

Siglec-9 and Its Ligand in ANCA-Associated Vasculitis

Dana Kidder,[1] Catriona Walls,[2] Jon Yoldi,[2] Simon C. Satchell,[3] Cosimo De Bari.[2] *[1]NHS Grampian, Aberdeen, United Kingdom; [2]University of Aberdeen, Aberdeen, United Kingdom; [3]University of Bristol Bristol Renal, Bristol, United Kingdom.*

Background: Sialic acid-binding Ig-like lectin 9 (Siglec-9) is expressed on leukocytes. The expression and role of siglec-9 and its ligand in the context of ANCA-associated vasculitis (AAV) is unknown.

Methods: Leukocytes and serum were isolated from venous blood and siglec-9 expression analysed by flow cytometry/ELISA. Leukocytes were stimulated with MPO/PR3 to assess Siglec-9 shedding. An Fc protein was used to identify ligands under inflammatory conditions (TNF-α/C5a) on conditionally immortalised glomerular endothelial cells (ciGEnC) or AAV renal sections. BulkRNA sequencing will hilight biological relevance of ligand interactions.

Results: Neutrophils and intermediate monocytes from MPO-AAV patients had reduced Siglec-9 expression versus PR3-AAV. Stimulation of neutrophils with MPO, not PR3, induced a shedding phenotype (Fig. 1). Analysis of serum showed decreased Siglec-9 in MPO-AAV compared to PR3-AAV. A positive correlation of serum Siglec-9

was detected with disease activity and MPO-ANCA titre. Siglec-9 ligand was identified on glomerular endothelial cells from kidney biopsies of AAV patients and two distinct patterns of expression on ciGEnC, which was altered under inflammatory conditions.

Conclusions: Cellular and serum Siglec-9 expression differs in MPO and PR3-AAV and may be influenced by ANCA serotype. Positive Siglec-9 ligand expression on ciGEnC suggests a direct interaction between Siglec-9 on leukocytes and glomerular endothelium. Our data suggest a possible role for Siglec-9/ligand interactions in the context of AAV - but further study is required to assess the biological relevance of these findings.

Funding: Clinical Revenue Support

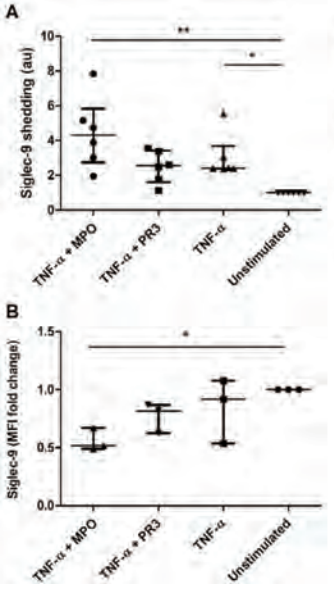


Figure 1 – MPO-ANCA induces Siglec-9 shedding. Neutrophils were stimulated with TNF-α, MPO-ANCA or PR3-ANCA. A) Shedding was increased with MPO-ANCA stimulation (n = 6). B) Cellular expression was decreased with MPO-ANCA stimulation (n = 3). Data shown is median ± IQR. * P < 0.05; ** P < 0.01

Elderly Patients' Prognostic Disadvantage Might Be Substantiated by Distinct Tubulointerstitial Lesions in Newly Diagnosed ANCA-Associated Renal Vasculitis

Eva Baier, Bjoern Tampe. *Universitatsmedizin Gottingen Klinik fur Nephrologie und Rheumatologie, Gottingen, Germany.*

Background: Although advanced age negatively predicts renal survival in antineutrophil cytoplasmic antibody (ANCA-) associated renal vasculitis (AArV), histopathological lesions substantiating this prognostic disadvantage remain elusive. Thus, we aimed to identify histopathological correlates in relation to patient's age in newly diagnosed AArV.

Methods: A total of n=45 biopsy-affirmed AArV cases were enrolled in a single-center retrospective cohort study. Receiver operating characteristics (ROC) curve analyses enabled group dichotomization. Age subgroups were compared concerning clinicolaboratory and histopathological parameters. Correlative analyses were performed regarding tubulointerstitial lesions and complement deposition in distinct renal compartments.

Results: Serum C4 levels inversely correlated with patient's age (β=-0.32, *p=0.009*). Maximized Youden index of ROC curve analyses for serum C4 levels (AUC 0.7, *p=0.044*) provided an age cut-off of 54 years enabling group dichotomization. Significantly more interstitial fibrosis (ci, *p=0.0415*), interstitial inflammation (i-IFTA, *p=0.0062*) and tubulitis (t-IFTA, *p=0.0069*) in areas of scarred cortex (IFTA) was observed in the elderly's subgroup. C4d-deposited interlobular arteries prevailed more often in the elderly (*p=0.0031)* and were associated with interstitial fibrosis *(*β=0.31, *p=0.038*) and crescent formations (β=0.44, *p=0.009*).

Conclusions: We here show that age-dependency of renal survival in AArV might be substantiated by specific histopathological lesions characterized by interstitial fibrosis and complement deposition in the tubulointerstitial compartment of the elderly. A latent complement-driven interstitial fibrogenesis might constitute to a vulnerability of the elderly to be severely affected by an acute flare of AArV.

Patient-Derived Cell Line as an In Vitro Model System for Autoantigen-Specific B Cells in Myeloperoxidase-ANCA

Young-Hyun Moon,[1] Dhruti P. Chen,[1] Justin J. Taylor,[2] Ronald Falk,[1] Donna O. Bunch.[1] *[1]The University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; [2]University of Virginia School of Medicine, Charlottesville, VA.*

Background: Autoantigen-specific B cells are important in ANCA vasculitis but are rare and hard to study. Existing myeloperoxidase (MPO)-ANCA vasculitis mouse models have been insightful although limited by their non-human nature, time intensiveness and cost. We hypothesized that a patient-derived B cell line could be modulated to differentiate into antibody-producing cells and establish an in vitro model system to inform specific targeting of human B cells.

Methods: We created Epstein-Barr virus immortalized B cell lines with PBMCs from patients with ANCA vasculitis (23 MPO, 23 PR3). Two lines were cultured in "B cell media" (IMDM, penicillin-streptomycin, 10% FBS, GlutaMax, β-ME, CD40L, CpG) with or without MPO autoantigen and IL-21. Autoantibody production was tracked longitudinally by testing supernatants for anti-MPO IgG by ELISA. Cells were stained with allophycocyanin (APC)-tagged MPO-tetramers, positively selected for APC, and analyzed by flow cytometry.

Results: Immortalized cells maintained expression of B cell markers (CD19, CD22) and 4% MPO-specificity. Cells cultured with MPO and IL-21 had more CD27high/CD22low B cells, consistent with plasmablast differentiation, in both parent (9%) and antigen-specific populations (15%) compared to cells cultured without MPO or IL-21 (5 and 10% respectively) (**Fig 1a**). This cell line produced ANCAs; cells cultured with MPO and IL-21 produced more autoantibody than cells grown without (**Fig 1b**). Cells cultured to 92 days maximally had 29% MPO-specificity.

Conclusions: We developed immortalized patient-derived B cell lines that maintain antigen-specificity in culture, with targetable B cell markers, and inducible autoantibody production. This system could be used to test B cell-depleting and autoantigen-specific therapies. In summary, an immortalized patient-derived cell line offers a viable model system of autoantigen-specific B cells in ANCA vasculitis.

Hydralazine-Associated Anti-neutrophilic Cytoplasmic Antibody (ANCA)-Associated Vasculitis: A Model of Drug-Associated Autoimmunity

Gang Xi,[1] Olivier Lardinois,[2] Peiqi Hu,[1] Elizabeth A. McInnis,[1] John S. Poulton,[1] Meghan E. Free,[1] Dhruti P. Chen,[1] Evan Zeitler,[1] Eve Wu,[1] Vimal K. Derebail,[1] J. Charles Jennette,[1] Ronald Falk.[1] *[1]The University of North Carolina at Chapel Hill Kidney Center, Chapel Hill, NC; [2]Mass Spectrometry Research and Support Group, National Institute of Environmental Health Sciences, NIH, Research Triangle Park, NC.*

Background: Drug-associated autoimmunity is a recognized phenomenon, but underlying mechanisms are not completely elucidated. We previously demonstrated that hydralazine adduct formation on myeloperoxidase (MPO) resulted in production of anti-hydrazone MPO antibodies, which contributed to development of hydralazine associated ANCA vasculitis. Here, we examine additional disease-associated drugs *in vitro* and further explored the *in vivo* effects of modified MPO using mouse models.

Methods: Aminoguanidine (AG)- or propylthiouracil (PTU)-modified myoglobin (Mb) were analyzed with reverse phase HPLC and electrospray mass spectrometry. Levamisole- or AG-modified MPO were used to investigate the mechanism by which drugs could modify MPO. Unmodified and modified mouse recombinant MPO (rmMPO) were injected into wild type C57BL/6 mouse or MPO null mice. Mouse T cells were isolated for ELISpot assays 4 weeks after immunization. Splenocytes from immunized mice were isolated and injected into Rag2 $^{-/-}$ mice to study the pathogenic activity of modified MPO. After 2 weeks, mice were sacrificed. Serum IgG and IgM were measured with ELISA and kidneys were collected for histology.

Results: Mass spectrometry data showed that, like hydralazine, the amine group of AG bound to a carbonyl group of Mb. PTU bound to Mb via sulfenic/sulfinic/sulfonic derivatives to generate a PTU adduct. AG was able to competitively block hydrazone adduct formation on MPO. Levamisole, like PTU, bound to MPO with sulfenic derivatives and was unable to prevent hydrazone formation on MPO. ELISpot data revealed that hydralazine-modified rmMPO only stimulated IL-17a production while unmodified rmMPO stimulated both IFNγ and IL-17a production. Anti-rmMPO or anti-hydralazine modified MPO IgG were detected, but IgM was undetectable in both settings. Splenocytes from MPO$^{-/-}$ mice immunized with hydralazine modified rmMPO caused glomerulonephritis when injected into Rag2$^{-/-}$ mice.

Conclusions: Our current study suggest that different drugs may bind to MPO via different mechanisms but can still induce ANCA by similarly forming an adduct on MPO. Animal models clearly demonstrate hydralazine-modified MPO stimulates T-cell activation and pathogenic IgG that induces ANCA glomerulonephritis in mice.

FR-PO832

Perlecan Is a Novel Target of Autoantibodies in Anti-glomerular Basement Membrane Disease

Huang Kuang, Zhao Cui, Ming-Hui Zhao. *Peking University First Hospital Department of Nephrology, Beijing, China.*

Background: Anti-glomerular basement membrane (anti-GBM) disease is an autoimmune kidney disease in which autoantibodies are directed against GBM components. Type IV collagen and laminin α5β2γ1 (LM521) within GBM are two major target antigens in anti-GBM disease. Perlecan is a type of heparan sulfate proteoglycan, ubiquitously expressed in basement membranes, and a target of antibodies implicated in allograft rejection. The present study aimed to investigate whether perlecan could be recognized by anti-GBM antibodies, and further analyzed the properties and clinical associations of anti-perlecan antibodies.

Methods: A total of 108 patients diagnosed with anti-GBM disease between January 2000 to December 2018 were included in the study. Additionally, one hundred patients with various active glomerular diseases were utilized as disease controls, along with 20 health controls. IgG antibodies against perlecan were detected by enzyme-linked immunosorbent assay and immunoblot.

Results: Circulating IgG antibodies against perlecan were detected in 18.5% (10/108) of the anti-GBM patients, but not in healthy controls or any other disease controls. Anti-perlecan IgG antibodies were predominantly of IgG3 subclass. Patients with anti-perlecan autoantibodies had a higher prevalence of lung hemorrhage than those without (55.0% vs 26.1%, $P = 0.012$). A "triple-positive" subgroup in anti-GBM disease was identified, who had circulating autoantibodies simultaneously against type IV collagen, laminin 521, and perlecan. This subgroup had the highest prevalence of lung hemorrhage (66.7%, 10/15) and incidence of end-stage kidney disease events (93.3%, 14/15), indicating a more aggressive immune-mediated tissue injury among these patients.

Conclusions: Perlecan was identified as another novel target in anti-GBM disease and expanded the repertoire of target antigens of anti-GBM antibodies. The discovery of autoantibodies against perlecan identified a triple-positive subgroup with more severe clinical phenotype among patients with anti-GBM disease. The pathogenic role of autoimmunity against perlecan and the pathophysiology of the co-presence of three autoantibodies merit further investigation in future.

FR-PO833

HSP27 Promotes Activation of Parietal Epithelial Cells and Crescent Formation in Crescentic Glomerulonephritis

Lisa Melis,[1,2] Hamza Sakhi,[6] Morgan Gallazzini,[4] Léonie Pate,[1] Carmen Garrido,[7] Vincent Audard,[5] Khalil El Karoui.[1,3] *[1]Inserm U1155, Paris, France; [2]Sorbonne Universite, Paris, France; [3]Hopital Tenon, Paris, France; [4]Institut Necker-Enfants Malades, Paris, France; [5]Hopital Henri Mondor, Creteil, France; [6]Institut Mondor de Recherche Biomedicale, Creteil, France; [7]INSERM U1231, Dijon, France.*

Background: Crescentic glomerulonephritis (CrGN) is the most severe form of kidney disease. CrGN is characterized by a pathological accumulation of parietal epithelial cells (PEC) forming the cellular "crescent" in the urinary space leading to end stage renal disease in 30-50% of cases. While current treatments consist of immunosuppressive therapies, none of them directly targets molecular pathways associated with crescent formation and PEC activation. Heat Shock Protein 27 (HSP27) is a stress-induced chaperone protein largely known for its anti-apoptotic and pro-proliferative effect in cancer. Here, we aim to investigate whether HSP27 is involved in PEC activation and crescent formation.

Methods: To explore the role of HSP27, we used a nephrotoxic serum (NTS)–induced crescentic glomerulonephritis preclinical model and biopsies from patients diagnosed with CrGN. In vitro, we used primary cell cultures of PEC, either with or without HSP27 knockdown, to examine migration, proliferation, and the expression of activation markers (CD44, EGF receptor activation).

Results: HSP27 is largely overexpressed in PEC within glomerular crescents in both patients with CrGN and in kidneys from NTS-treated mice. Targeting of HSP27 with the antisense oligonucleotide (OGX-427) results in reduced development of crescents in the NTS model. In vitro, pharmacologic or genetic silencing of HSP27 in PEC induces a reduction in cellular migration and activation (measured by CD44 expression). These data suggest that HSP27 could promote crescents formation by promoting PEC activation and proliferation. To better understand, we explored the EGFr pathway known to be involved in glomerular epithelial cells activation. Silencing of HSP27 leads to a reduction in the activation of the EGF receptor, explaining at least part of the impact in PEC activation.

Conclusions: Taken together, our data highlight a role for HSP27 in the development of crescent lesions and pave the way for innovative therapeutic approaches for CrGN patients.

FRA-2 (Fosl2) Epigenomic and Splicing Dynamics in Crescentic Glomerulopathies

Robert Bronstein,[1] Nehaben A. Gujarati,[1] David J. Salant,[2] Sandeep K. Mallipattu.[1] *[1]Stony Brook University, Stony Brook, NY; [2]Boston University, Boston, MA.*

Background: Proliferative glomerulopathies are end-stage kidney diseases. Their complex etiology is apparent in disorders like diabetes, sickle cell disease and HIV. There are no curative therapies, therefore a more mechanistic view of disease features is needed. A patho-proliferative cell in the kidney glomerulus is the parietal epithelial cell (PEC) lining the inner wall of Bowman's capsule, and growing evidence shows it contributes to disease progression - forming crescentic lesions in diseases such as focal segmental

glomerulosclerosis. Our two mouse models of proliferative glomerulopathy (nephrotoxic serum nephritis and podocyte-specific *Klf4* knock-down) identify transcription FRA-2 as crucial to disease progression.

Methods: 10X Multiomic datasets were generated from nephrotoxic serum (NTS – Days 0,7 & 14) and podocyte-specific *Klf4* deletion models of proliferative glomerulopathy. Seurat (RNA) and ArchR (ATAC) were the primary R tools used in bioinformatic analysis, with: CellChat, Monocle3 & clusterProfiler. FRA-2 immunoprecipitation and mass spectrometry (RIME) was performed in a PEC cell line, as were *Fosl2* knock-down experiments.

Results: Analysis of multiomic features after glomerular injury identified *Fosl2* and its motif as enriched in PECs (**Fig. 1A)**. Ligand-receptor interactions in NTS dataset pointed to PEC-specific *Spp1/Cd44* interactions as conserved molecular features in these disease models (**Fig. 1B)**. RIME analysis of *Fosl2* interactors showed enrichment in splicing factors, in agreement with Fosl2+/Cd44+ sub-clusters 1&2 (**Fig. 1C)**. Knock-down of *Fosl2* in an immortalized PEC cell line resulted in a reduction in *Cd44* isoforms V7-V9 (**Fig. 1D)**. Gene-Splice Junction (SJ) relationships in the temporal and pseudo-time transition between PECs and Myofibroblasts point to isoform switching of key fibrosis genes (**Fig. 1E)**.

Conclusions: These data suggest that FRA-2 (*Fosl2*) is a regulatory TF in proliferative glomerulopathies across the crescentic to fibrotic boundary (Day 7 to 14) - through the modification of alternative splicing dynamics.

Hypoxia-Inducible Factor (HIF) Activation in Podocytes Exacerbates Crescentic Glomerulonephritis

Yu Kurata,[1] Tetsuhiro Tanaka,[2] Mai Sugahara,[1] Imari Mimura,[1] Masaomi Nangaku.[1] *[1]Tokyo Daigaku Daigakuin Igakukei Kenkyuka Naikagaku Senko Jinzo Naibunpi Naika, Bunkyo-ku, Japan; [2]Tohoku Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Sendai, Japan.*

Background: Hypoxia-inducible factor (HIF) is a transcription factor that mediates cellular responses to hypoxia. Although various studies have explored the effects of HIF activation in renal diseases, the role of HIF in podocytes remains unclear. We established podocyte-specific HIF-prolyl hydroxylase (PH) 1/2/3 conditional knockout mice, in which HIF was specifically activated in podocytes. To examine the role of HIF activation in podocytes during glomerular injury, we subjected these mice to crescentic glomerulonephritis induced by nephrotoxic serum (NTS).

Methods: We crossed Podocin-Cre mice with HIF-PH1/2/3 triple-floxed mice to generate podocyte-specific HIF-PH1/2/3 conditional knockout (KO) mice. Cre-negative littermates were used as controls (WT mice). Crescentic glomerulonephritis was induced by the intravenous administration of NTS (1.2 μL/g). NTS was produced by immunizing sheep with isolated rat glomeruli.

Results: First, we confirmed podocyte-specific HIF-1 activation in KO mice by immunohistochemical staining. There were no significant differences in the histological findings of the kidney, kidney function, and urinary albumin levels between WT and KO mice. Next, we induced nephrotoxic serum nephritis (NTN). On day 7, KO mice exhibited significantly higher urinary albumin levels th WT mice. Histological analysis revealed exacerbated glomerular crescent formation and tuft necrosis in KO mice. The number of Ki-67-positive parietal epithelial cells (PECs) and CD44-positive glomeruli significantly increased in KO mice. Glomerular deposition of sheep IgG and mouse IgG was similar in WT and KO mice. To further investigate the underlying mechanism, we conducted bulk RNA-seq of the isolated glomeruli. Comparison of WT and KO mice subjected to NTN identified a total of 167 differentially expressed genes (DEGs). Enrichment analysis revealed that the DEGs were significantly enriched in leukocyte chemotaxis, DNA-templated DNA replication, positive regulation of cell death, regulation of leukocyte activation, and positive regulation of cell migration.

Conclusions: HIF activation in podocytes worsened glomerular injury in a crescentic glomerulonephritis model. Aggravated inflammatory responses and excessive PEC activation may exacerbate glomerular injury.

A Case of Collapsing FSGS: Lupus Podocytopathy or APOL1-Mediated Kidney Disease?

Kavita Mistry,[1] Isaac E. Stillman,[2] Stewart H. Lecker.[1] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: High risk APOL1 alleles are a key driver of proteinuric kidney disease in the Black population. Although the combined allele frequency among African Americans is 34%, only a minority of individuals with two APOL1 risk alleles go on to develop kidney disease, suggesting the need for a second hit.

Case Description: A 59-year-old African American woman with a history of undifferentiated connective tissue disease and monoclonal gammopathy of unknown significance (MGUS) presented with 6 weeks of fevers of unknown origin, fatigue and malaise. Vital signs were normal and physical exam revealed axillary lymphadenopathy. Creatinine was 0.7 mg/dL with albumin of 3.0 g/dL and 2.8 g/g proteinuria. SPEP and UPEP revealed monoclonal IgG kappa light chain estimated at 84 mg/day in urine. Bone marrow biopsy revealed 9% plasma cells consistent with MGUS. Infectious diseases workup was negative apart from positive CMV IgM. Nephrology and rheumatology were consulted and recommended workup as follows: ANA positive 1:1280, dsDNA positive 1:1280, C3 slightly low at 84 mg/dL, C4 normal, anti-PLA2R IgG negative, HIV and hepatitis B/C serologies negative, and positive antibodies for RNP, anti-Sm, SS-A and SS-B. The patient was started on prednisone 60 mg/day for presumed lupus nephritis. A renal biopsy was performed and revealed collapsing focal segmental glomerulosclerosis (cFSGS) with negative immunofluorescence. Electron microscopy revealed extensive foot process effacement with no subendothelial deposits and rare subepithelial deposits, consistent with lupus podocytopathy. The patient was discharged on ARB and SGLT2 inhibitor and proteinuria improved to 0.3 g/g. Steroids were tapered off and mycophenolate was initiated. APOL1 genotyping returned as high risk G2/G2. Mycophenolate was tapered off due to gastrointestinal side effects with no rebound increase in proteinuria, suggesting that this patient's cFSGS was driven by APOL1-mediated kidney disease triggered by CMV infection rather than by lupus podocytopathy.

Discussion: This report adds to a growing literature of cases that describe cFSGS in patients with high risk APOL1 alleles after viral infection. The biological basis for the development of cFSGS in patients with APOL1 high risk genotype, lupus and viral infection remains to be elucidated, although can be presumed to result from parallel, additive and/or synergistic processes.

FR-PO837

Effaced but Not Erased: A Case of Consecutive Recurrences of Lupus Podocytopathy in Kidney Transplants

Renuka Tolani, Nibras Fakhri, Luan D. Truong, Angelina Edwards, Sadhna Dhingra. *Houston Methodist, Houston, TX.*

Introduction: Lupus podocytopathy is considered a distinct subtype of lupus nephritis. Histologically it can present as minimal change disease (MCD) and/or Focal segmental glomerulosclerosis (FSGS). We present a case of lupus podocytopathy in a 29 year old woman that relapsed in 2 consecutive transplants.

Case Description: At first presentation patient had serology positive for lupus, urine protein/creatinine ratio (UPCR) of 10, native kidney biopsy showed lupus podocytopathy with minimal change features. After living unrelated kidney transplant, there was delayed graft function and dialysis was initiated. Induction immunosuppression was changed from Simulect to thymoglobulin, and belatacept, mycophenolate and prednisone were chosen for calcineurin-inhibitor avoidance. Patient noted to have malar rash, serology positive for antinuclear anitbodies 1:320, and double stranded DNA. Wedge allograft biopsy 3 days post-transplant showed recurrent Lupus podocytopathy. Patient was treated with Cytoxan, plasmapheresis, plaquenil and steroids; discharged off dialysis. Patient was then readmitted 2 weeks later for acute renal injury; restarted on dialysis. 24 hour urine collection showed 25 grams protein. Repeat allograft biopsy showed collapsing variant of FSGS. Patient was treated with plasmapheresis and immunosuppression with no response, progressed to graft failure with dialysis dependence Patient received a second living unrelated kidney transplant 3 years later with Thymoglobulin induction. As a means to reduce the risk of recurrence, patient received pre and post-transplant plasmapheresis and 4 doses of rituximab. She was discharged with creatinine 1 mg/dL but nephrotic proteinuria present with UPCR 6. A protocol biopsy showed recurrent podocytopathy/ focal segmental glomerulosclerosis. Patient was maintained on plasmapheresis, with stable allograft function.

Discussion: Lupus podocytopathy is not a benign lesion. It requires vigilance for specific diagnosis and aggressive immunosuppression for treatment. Classically patients with FSGS subtype are less likely to respond to treatment, particularly with the collapsing variant. Even those with MCD features, may have relapsing events.

FR-PO838

Neutrophils Generate Higher Levels of Reactive Oxygen Species after Stimulation by Inactive vs. Active Lupus Nephritis Serum

Rebecca Lightman, Nicholas A. Shoctor, Makayla Brady, Shweta Tandon, David W. Powell, Dawn J. Caster. *University of Louisville School of Medicine, Louisville, KY.*

Background: There is increasing evidence for the role of neutrophils in lupus nephritis (LN) pathogenesis. Release of reactive oxygen species (ROS) by neutrophils may be a source of glomerular damage in LN. Our previous work investigating LN neutrophil ROS generation suggested the possibility of endogenous neutrophil activators in LN serum. To further this investigation, we aimed to identify differences in healthy donor neutrophil activation in response to different LN serum treatments based on active versus inactive disease.

Methods: Neutrophils were isolated from whole blood of 6 healthy donors. Cell treatment groups included untreated, 10% pooled active LN serum, 10% pooled inactive LN serum, or 10% pooled healthy donor platelet poor plasma (PPP). Active disease was defined as urine-protein-to-creatinine ratio greater than 500. Active and inactive LN serum samples were paired from 3 LN patients on different dates. ROS generation was measured using superoxide assay.

Results: Results were calculated using Dunn's multiple comparisons test. Statistics were performed with GraphPad Prism 10.2.1. Neutrophil stimulation with healthy donor PPP, active LN serum, and inactive LN serum resulted in more ROS generation than in the untreated condition ($p=0.009$, $p<0.0001$, $p<0.0001$). Healthy donor PPP resulted in less ROS generation than either active or inactive LN serum ($p=0.0009$, $p<0.0001$). Treatment with inactive LN serum caused the highest level of ROS generation, more than the active LN serum treatment ($p<0.0001$).

Conclusions: Serum from inactive LN stimulated neutrophils to produce the most ROS despite lower clinical disease activity than active LN. These results may be attributable to differences in serum contents related to disease status. These data warrant further investigation to characterize serum contents for active and inactive LN. Greater sample size and a bigger patient pool may further our understanding of these differences. Improving understanding of serum characteristics by disease status may have implications for experimental designs in LN research, for elucidating patterns of remission and relapse in LN, and for future clinical LN management.

FR-PO839

Immunologic Changes over Time in Repeat Kidney Biopsies from the AURORA Studies of Voclosporin in Lupus Nephritis

Samir V. Parikh,[1] Maddalena Bolognesi,[2] Ivana Grbesa,[3] Brad H. Rovin,[1] Giorgio Cattoretti,[2] Vincenzo L'Imperio,[2] Arnon Arazi,[4] Lucy S. Hodge,[5] Ernie Yap.[5] *[1]The Ohio State University Wexner Medical Center, Columbus, OH; [2]Universita degli Studi di Milano-Bicocca, Milano, Italy; [3]Qiagen Digital Insights, Sibenik, Croatia; [4]The Broad Institute, Cambridge, MA; [5]Aurinia Pharmaceuticals Inc, Edmonton, AB, Canada.*

Background: The AURORA 1 and 2 studies investigated the use of voclosporin (VCS) plus standard-of-care (SOC) for the treatment of lupus nephritis (LN). All patients underwent a kidney biopsy for enrollment (Bx1), and a subset of patients elected to undergo a second biopsy (Bx2) to assess how histology of the kidney changes in response to treatment. Here we have used multiplex immunofluorescence (mIF) to investigate changes in the immunologic landscape of the kidney in response to immunosuppression using these paired biopsies.

Methods: Formalin-fixed paraffin-embedded tissue sections were stained with MILAN technology with a 10-marker panel. Sequential acquisitions for each biopsy were registered, and autofluorescence subtracted. Dedicated ImageJ-based pipelines were used to measure total biopsy areas and immunopositive markers and/or to count cells and related positivity for markers of interest.

Results: A total of 27 paired samples were available for mIF (17 and 10 from VCS- and SOC-treated patients, respectively). CD34 and Ki67 were significantly overexpressed in Bx2 compared to Bx1 (Table 1). Within each treatment group, there was a trend toward upregulation of CD34; the differences were not statistically significant (adjusted p-values of 0.07 [VCS] and 0.12 [SOC], respectively).

Conclusions: CD34 and Ki67, which have been implicated in tissue regeneration and healing in glomerulonephritides, showed significantly higher expression in repeat biopsies of patients with LN treated with immunosuppression during the AURORA trials. The lack of difference within each treatment group may indicate a lack of concordance between clinical response and immunological landscape but may also be reflective of the small sample size. The potential utility of CD34 and Ki67 as biomarkers of response requires further investigation.

Funding: Commercial Support - Aurinia Pharmaceuticals Inc.

Table 1. 10-marker multiplex immunofluorescence panel

Antigen	Fold-change Bx2 vs Bx1*	p-value

CD34	1.3370	0.0037

*VCS and SOC treatment groups combined
Multiplex immunofluorescence results were analyzed in QIAGEN OmicSoft Studio (v12.6.3.5). Normality of the variables was tested by the Shapiro-Wilk normality test. For comparisons of groups, statistical significance was estimated by the Wilcoxon rank-sum test. Bx, biopsy.

FR-PO840

Role of Hexokinase 2-Mediated Enolase 1 Translocation in Podocyte Injury

Zilv Luo. *The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.*

Background: Lupus nephritis (LN) is one of the most common and serious complications of systemic lupus erythematosus. Podocyte injury is associated with proteinuria and renal impairment in LN, and podocyte is dependent on glycolysis. However, the relationship between glycolysis and LN remains unclear. Hexokinase 2 (HK2) and enolase 1 (ENO1) are the glycolytic enzymes in cytoplasm. In physiological conditions, different glycolytic enzymes can form complexes, which contribute to their intracellular localization. In pathological conditions, the intracellular localization of glycolytic enzymes would be altered. Notably, cell membrane-localized ENO1 has the activity of plasminogen binding receptor, and is associated with cell adhesion and integrin beta3 activation.

Methods: In lupus mice and interferon α-stimulated cultured podocytes, immunohistochemical and immunofluorescent staining were performed to examined the expression patterns of ENO1 and HK2, and the binding of HK2 and ENO1 by Co-IP. After interfering with siHK2 in cultured podocytes, the intracellular localization of ENO1 and integrin expression were detected.

Results: WB and IF showed the downregulation of HK2 and the upregulation of ENO1 in lupus mice and interferon α-stimulated cultured podocytes. In addition, interferon α increase the ENO1 localization on podocyte membrane compared with control group. siHK2 increased the ENO1 localization at the cell membrane surface, accompanied by downregulation of integrins. (Figure)

Conclusions: HK2 binds to ENO1 and restricts ENO1 in podocytes. In LN conditions, the dissociation of ENO1 and HK2 leads to an increased localization of ENO1 at the cell membrane, which lead to LN podocyte injury by affecting podocyte adhesion and influencing integrin beta3 expression.

Funding: Government Support - Non-U.S.

EPHB2 Mediates Inflammation in Podocytes of Lupus Nephritis

Huajing Peng, Zilv Luo, Wei Chen. *The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.*

Background: Podocyte injury in lupus nephritis (LN) is a critical contributor to the substantial proteinuria observed in LN patients. However, the potential for a unique inflammatory pattern of podocyte injury specific to lupus nephritis remains to be elucidated. The erythropoietin-producing hepatocellular receptor (Eph) family, the largest

group of receptor tyrosine kinases, have been implicated in a wide range of diseases. Elevated expression of EPHB2 has been observed in the kidneys of models with IgA nephropathy (IgAN) and ischemia-reperfusion (IR) injury. However, the specific role of EPHB2 in the context of podocyte injury in lupus nephritis remains unknown.

Methods: To investigate the underlying mechanisms, we developed a nephrotoxic nephritis (NTN) mouse model of lupus and an IFNα-stimulated podocyte injury model. We observed changes in proteinuria and renal pathology in the mice. The expression of inflammatory proteins like MMP7, VCAM-1 and the activity of the NFκB pathway were assessed using Western blotting, and immunofluorescence. Additionally, we utilized adenoviral vectors to interference with EPHB2 expression in vivo and in vitro. Similar methods were employed to detect and compare the expression of inflammatory molecules before and after EPHB2 interference.

Results: In vivo experiments revealed that NTN lupus mice exhibited significantly increased proteinuria and severe glomerulosclerosis. In vitro, IFNα stimulation led to cytoskeletal protein disruption in podocytes. Elevated expression of MMP7 and VCAM1, as well as increased activity of the NFκB pathway, were observed in the renal cortex of NTN lupus mice and in IFNα-stimulated podocytes. Interference with EPHB2 expression in the kidney resulted in a significant reduction in proteinuria and alleviation of glomerulosclerosis in NTN lupus mice. Additionally, the expression of MMP7 and VCAM1, as well as the activity of the NFκB pathway, were significantly reduced in both the renal cortex and IFNα-stimulated podocytes after EPHB2 expression was inhibited.

Conclusions: High expression of EPHB2 in podocytes is implicated in the activation of renal inflammation in LN. Interfering with EPHB2 expression in vivo and in vitro have been shown to alleviation podocyte inflammation and improve renal outcomes by inhibiting the NFκB pathway. Intervention targeting EPHB2 represents an effective strategy for controlling inflammation activation in LN podocytes.

FR-PO842

Roxadustat Regulates the NKA/Src/HIF-1/ROS Signaling Pathway to Improve Kidney Outcomes in Mice with Lupus

Changxuan Liu, Danni Shao. *The Central Hospital of Wuhan, Wuhan, China.*

Background: Sustained release of ROS can aggravate podocyte injury in lupus nephritis. NKA(Na-K-APTase)is widely distributed in renal tissues and releases a large number of ROS after activation, which promotes the apoptosis of renal tubular epithelial cells/podocytes. Roxastat, as an inhibitor of HIF-1, can inhibit the release of ROS. We speculate that Roxastat may disrupt the positive feedback loop of ROS release by stabilizing HIF-1 protein and blocking the damage of tubular epithelial cells/podocytes, thereby protecting kidney tissue and delaying the progression of disease.

Methods: Mice were divided into the following groups: 1. Control group; 2. 2. MRL/LPR model group (lupus group); 3. Roxastat intervention group(Roxa group); Biochemical indexes: urine protein, Scr, BUN; The WB method was used to detect NKA, p-Src, HIF in mouse kidney tissue. Annexin V/PI flow cytometry was used to detect apoptotic cells. The ROS content in mouse kidney tissue was detected by flow cytometry with DCFH-DA probe method. MCP-1 and NGAL were detected by ELISA.

Results: 1. Proteinuria in MRL/LPR group was significantly up-regulated compared with control group (499.36±77.67vs45.68±23.66mg/L, $p < 0.001$), and down-regulated in Roxa group (499.36±77.67vs277.44±45.67 mg/L, $P < 0.001$). $p < 0.001$); 2. Scr in MRL/LPR group was increased (314.18±23.67vs106.63±15.67umol/L, $p < 0.05$), but decreased in Roxa group (243.54±17.33vs314.18±23.67umol/L, $p < 0.05$); 3. MCP-1 in MRL/LPR group was significantly up-regulated (437.84±50.5vs119.90±28.9pg/ml, $p < 0.001$)., but decreased in Roxa group(321.38±13.5vs437.84±50.5pg/ml, $p < 0.001$). 4. Annexin V/PI showed up-regulated in MRL/LPR group (30.05%±2.05%vs0.21%±0.02%); decreased in Roxa group (16.23%±2.23%vs 30.5% ±2.05%). 5. The ROS release was detected by DCFH-DA : which was up-regulated in MRL/LPR group (39.88%±2.88%vs3.28%±0.28%); lower in Roxa group (26.54%±2.54%vs39.88%±2.88%).

Conclusions: Roxastat may reduce the release of ROS by NKA/Src/HIF-1, thereby improving the injury of tubule/podocyte, reducing the excretion of proteinuria, and delaying the progression of lupus nephritis.

A Novel Lectin-Glycan Axis in Lupus Nephritis

Rohit Upadhyay,[1] Hao Li,[2] George C. Tsokos,[2] Rhea Bhargava.[1] *[1]Tulane University School of Medicine, New Orleans, LA; [2]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Lupus nephritis (LN) is one of the most serious complications of systemic lupus erythematosus (SLE) that can lead to end-stage kidney disease and increased mortality. We have previously demonstrated that immunoglobulin (IgG) in LN patients is aberrantly glycosylated and can lead to podocyte injury. Specifically, fucose on IgG can be pathogenic to podocytes while galactose can be protective. CLEC7A (C-type lectin domain containing 7A or Dectin1) is a transmembrane lectin receptor which functions as a pattern-recognition receptor and is the only known mammalian receptor to recognize fucose on IgG. Here, we evaluated the role of this lectin-glycan axis in podocyte injury in LN.

Methods: Human podocytes were exposed to serum/ IgG from healthy subjects, SLE, LN and LN-remission patients. Curdlan (ligand for CLEC7A) was used to activate inflammatory response and CLEC7A signaling. Flow-cytometry assisted calcium flux, immunocytochemistry, qPCR, western blotting, wound healing assay, phalloidin staining and silencing of CLEC7A were utilized to delineate CLEC7A signaling in human podocytes. Frozen kidney biopsies from individuals with LN and controls were stained with CLEC7A and SYK.

Results: Podocytes exposed to serum or IgG from LN patients, overexpressed CLEC7A and inflammatory pathway genes. Curdlan and LN-derived IgG (LN-IgG) altered podocyte cytoskeleton and motility along with decreasing nephrin expression. IgG bound to CLEC7A in podocytes while deglycosylation of LN-IgG disrupted CLEC7A binding and normalized podocyte cytoskeleton, motility and nephrin expression. In addition, curdlan and LN-IgG increased Ca flux compared to deglycosylated LN-IgG. More importantly, we found that curdlan and LN-IgG activated spleen tyrosine kinase (Syk) in human podocytes and its pharmacological inhibition effectively prevented LN-IgG induced podocyte injury. Translationally immunofluorescence staining of kidney biopsy tissue revealed increased podocyte CLEC7A and Syk expression in LN. Furthermore, de-glycosylation of LN-IgG and silencing CLEC7A protected podocytes from injury in LN.

Conclusions: To our knowledge this is the first study to demonstrate the role of lectins recognizing specific carbohydrates in podocyte injury and LN. Our data provides a novel mechanistic insight and reveals several novel therapeutic targets for LN.

FR-PO844

Global Lactylome Reveals Lactylation-Dependent Mechanisms Underlying Th17 Differentiation in Lupus Nephritis

Mingyang Zhang. *Army Medical University, ChongQing, China.*

Background: The dysregulation of $CD4^+$T cell differentiation is closely related to the occurrence and development of lupus nephritis, Metabolic reprogramming from oxidative phosphorylation to glycolysis and accumulation of lactate are involved in this process. lactate-derived lactylation regulated the aberrant activation and differentiation of T cells. However, the underlying mechanisms remain unclear.

Methods: Western blot and immunofluorescence were used to show the changes of lactylation level of $CD4^+$T cells in MRL/Lpr mice at different stages of disease. The impact of reducing and increasing lactylation by intraperitoneal administered of the pyruvate dehydrogenase kinase dichloroacetate (DCA) and rotenone, aiming to assess their disease progression of lupus nephritis (LN). Global lactylome reveals important differential lactylation modification sites, and ChIP-seq was used to analyze the key downstream genes regulated by lactylation modification sites, thus influencing the differentiation process of $CD4^+$ T cells.

Results: we find that lactate-derived lactylation regulated $CD4^+$T cell differentiation. Lactylation levels in $CD4^+$T cells increased with the progression of lupus nephritis (LN). Inhibition of lactylation suppressed TH17 differentiation and attenuated LN inflammation. The global lactylome revealed the landscape of lactylated sites and proteins in the $CD4^+$T cells of normal and MRL/Lpr mice. Specifically, hyperlactylation of Ikzf1 at Lys^{373} promoted Th17 differentiation by directly modulating the expression of Th17-related genes. However, Delactylation of Ikzf1 at Lys^{373} impaired TH17 differentiation.

Conclusions: Ikzf1 Lactylation is involved in the pathogenesis of lupus nephritis by specifically promoting Th17 differentiation,It may become a potential therapeutic target for delaying the progression of lupus nephritis.

Elucidating Lupus Nephritis (LN) Pathogenesis by Evaluating the Intersection between Glycomics and Metabolism

Rhea Bhargava,[1] Rohit Upadhyay,[1] Jing Chen,[1] Prasad V. Katakam,[1] George C. Tsokos.[2] *[1]Tulane University, New Orleans, LA; [2]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Lupus nephritis (LN) is the most devastating complication of systemic lupus erythematosus (SLE). Patients with LN have higher mortality than SLE patients without LN. The ability to accurately identify SLE patients destined to develop LN could shift the current management to prevention. Podocyte injury is an early event in LN and occurs by exposure to aberrantly glycosylated IgG. Here, we demonstrate that in LN, aberrantly glycosylated IgG can reprogram podocyte metabolism leading to podocyte injury.

Methods: Human podocytes were exposed to IgG with and without treatment with PNGase from healthy subjects, SLE, LN and LN-remission patients. ATP rate, glycolytic rate assay and untargeted metabolomics were performed. Podocyte injury was evaluated by scratch assay, phalloidin staining and nephrin expression. Urine podocytes were isolated and targets were validated by droplet digital PCR in urine and urine cells.

Results: Glycolysis was the primary process for energy production in podocytes. Podocytes exposed to LN IgG had a lower rate of glycolysis compared to deglycosylated and healthy IgG. Untargeted intracellular metabolomics revealed 332 metabolites across the 9 samples. A total of 56 metabolites were significantly different between cells treated with LN vs deglycosylated LN IgG. Metabolite set enrichment analysis (MSEA) was carried out in reference to the database of pathway-associated metabolite sets (SMPDB). Glycolysis was the most enriched pathway with 5 hit compounds (pyruvic acid, phosphoenolpyruvic acid, 2-phosoglycerate, 3 phosphoglycerate, fructose 1,6 biphosphate) that were differentially regulated. The fold enrichment for the pathway was 8.4. These metabolites were validated in urine/urine cells isolated from 15 SLE patients with and without LN. Urine pyruvate and PKM levels in cells were found to differentiate active LN from controls.

Conclusions: To our knowledge this is the first study to demonstrate a link between glycoproteins regulating cell metabolism. These data plausibly suggest that LN-derived IgG leads to significant podocyte injury by reducing their ability to compensate for the increased energy supply required for repair and maintenance of their shape and structure, leaving them vulnerable to any stress and possibly accelerating LN.

FR-PO846

Significant Correlation of Antibody Repertoire Perturbations to Clinical Manifestations in Lupus Nephritis

Huikun Zeng, Haipei Tang, Zhenhai Zhang, Xueqing Yu. *Guangdong Provincial People's Hospital, Guangzhou, China.*

Background: Lupus nephritis (LN), characterized by immune complex formation through autoantibodies recognizing multiple autoantigens and kidney deposition, is a major cause of morbidity and mortality that affects up to 60% of the SLE population during disease. However, detailed antibody repertoire profiling of all 5 isotypes and 9 subtypes remains unclear. Moreover, whether and the extent to which antibody repertoire features associate with important clinical manifestations of LN is unclear.

Methods: PBMC samples for 58 LN patients and 58 healthy controls were collected. Using a highly accurate repertoire sequencing strategy developed in our lab, we acquired antibody repertoires of all nine subtypes with single experiment. The base errors and amplification bias intrinsic to antibody repertoire sequencing were further corrected using the bioinformatics pipeline of DUMPArts. The isotype specific repertoire features were then compared between patients and healthy controls.

Results: Preferential up- and down-regulation of various IGHV genes in IgM, IgD, IgG, and IgA and subtypes of IgG and IgA indicate the perturbation of antibody repertoire for both naïve and activated B cells. The CDR3s of LN patients were significantly shorter than those in healthy controls in almost all isotypes. The SHMs were lower in repertoires of activated isotypes for LN patients while the SHMs in IgD repertoire were significantly higher, which suggests IgD+ B cells may be important for the disease severity. Evidenced clonal expansion in IgM and IgD compared to the activated isotypes (IgG, IgA, IgE). Combined repertoire-based features and support vector machine (SVM) model could distinguish LN patients from healthy donors with high accuracy.

Conclusions: Our results demonstrated multi-faceted nonunanimous perturbations of the antibody repertoire. The findings of significant changes in naïve repertoire compartment, especially changes in IgD. Repertoire features might serve as a biomarker for disease severity.

Na+-K+-ATPase Enables Pathological B Cell Survival and Leads to Glomerular Basement Membrane (GBM) Thickening in Lupus Nephritis

Tayyaba Ishaq, Irene Chernova. *Yale University School of Medicine, New Haven, CT.*

Background: The kidney in lupus nephritis (LN) is characterized by a significant immune cell infiltrate and glomerular pathology. How lymphocytes lead to the characteristic damage of glomerular structures in LN is poorly understood. We recently published that intrarenal B lymphocytes upregulate Na^+-K^+-ATPase (NKA) in LN and that pharmacologic or genetic blockade of NKA results in fewer intrarenal B cells and reduced albuminuria, dependent on the genotype of the immune cell and not the host. As changes in kidney B cells were the only notable difference between control and NKA-inhibited mice, we hypothesize that kidney B cells affect glomerular basement membrane (GBM) structure and that mice with fewer kidney B cells would have preserved GBM and improved albuminuria.

Methods: We compared lupus-prone MRL^{lpr} and MRL^{lpr}.*Fxyd2*$^{-/-}$ mice—which lack a gamma NKA subunit and have fewer intrarenal B cells—to define glomerular pathology. Podocyte and GBM pathology were investigated using immunofluorescence (IF), electron microscopy (EM) and real-time PCR.

Results: We found that MRL^{lpr} mice have proteinuria and thickened GBM on EM as compared to non-lupus B6 mice (277nm and 162nm, respectively, $p<0.0001$). Both proteinuria and GBM thickness were significantly improved in MRL^{lpr}.*Fxyd2*$^{-/-}$ mice as compared to MRL^{lpr} controls (200nm and 277nm, respectively, $p<0.0001$). We found immune complex deposits in both genotypes, with no notable differences on EM. IF showed homogeneously thickened collagen IV staining in MRL^{lpr} as compared to MRL^{lpr}.*Fxyd2*$^{-/-}$ mice ($p<0.0001$) while whole-kidney gene expression studies confirmed that the increased expression of glomerular collagen IV genes in MRL^{lpr} was reduced in the MRL^{lpr}.*Fxyd2*$^{-/-}$ mice. We are currently investigating collagen IV expression in contributing cell types (i.e. podocytes and endothelial cells) as well as looking at metalloproteinases to see if collagen breakdown is affected. Additionally, we are characterizing lupus kidney cytokine profiles to test the hypothesis that B cell-derived cytokines are promoting abnormal collagen deposition in LN.

Conclusions: We show that lupus-prone MRL^{lpr} mice have a significantly thickened GBM when compared to non-lupus and MRL^{lpr}.*Fxyd2*$^{-/-}$ animals, likely due to abnormal collagen IV deposition. We are currently investigating whether these findings are due to differences in intrarenal B cell numbers and cytokine levels.

NLRP3 Inflammasome Gene Expression Profile and Treatment Response in Lupus Nephritis: A Prospective Cohort Study

Camila B. Oliveira, Gisele Vajgel, Denise M. Costa, Paula S. Sandrin-Garcia. PatGen. *Universidade Federal de Pernambuco, Recife, Brazil.*

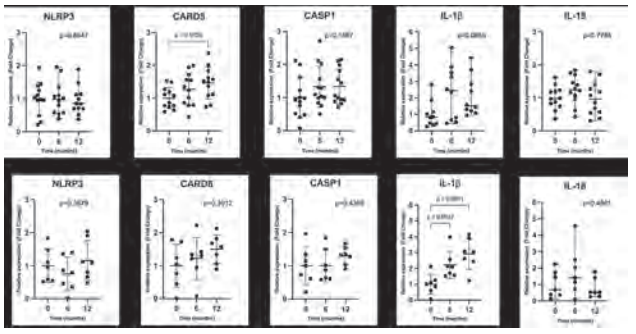
Background: Lupus nephritis (LN) is a severe complication of SLE characterized by inflammation and immune complex deposition in the kidneys, leading to progressive renal damage and impaired function. The inflammasome plays a crucial role in the innate immune response, has been implicated in the pathogenesis of LN. The aim of this study was to evaluate de gene expression profile of inflammasome NLRP3 in LN patients according to treatment response.

Methods: A prospective cohort study of adult patients with biopsy-proven active LN (class III, IV, and/or V). Clinical, laboratory, and histopathological data were collected at baseline (T0), 6 months (T6), and 12 months (T12) of immunosuppressive treatment. Gene expression of NLRP3, CARD8, CASP1, IL-1B, and IL-18 in peripheral blood mononuclear cells was analyzed using RT-qPCR. Treatment response was classified as primary efficacy renal response (PERR) or non-primary efficacy renal response (no-PERR).

Results: Twenty patients with active LN were included in the study. The mean age was 31.9 ± 8.3 years, with 19 females and 1 male. Laboratory evaluation showed median sCr 0.8 (0.7-1.3), median eGFR 103 (54-119), median 24-hour urine protein 3.3 (1.7-4.9). The mean SLEDAI score was 14.6 ± 4.4 and 95% of patients had complement C3 consumption (mean C3 57.2 ± 22.6 mg/dl). Among the 20 patients, 65% achieved PERR after 12 months of therapy. Gene expression analysis revealed that IL-1B expression was significantly higher in the no-PERR group after 12 months. Other inflammasome genes did not show significant changes between the groups.

Conclusions: The differential expression of NLRP3 inflammasome components, especially IL-1B, highlights its potential role as a biomarker for predicting treatment response in LN patients.

Funding: Private Foundation Support



Gene expression of inflammasome NLRP3 in patients with active LN divided by treatment response: primary efficacy renal response (PERR) and with no-PERR. At baseline (T0), 6 months (T6) and 12 months (T12). PERR, primary efficacy renal response

FR-PO849

Concomitant Sparsentan (SPAR) and SGLT2 Inhibitors in Adults with IgA Nephropathy in the Ongoing Phase 2 SPARTACUS Trial

Isabelle Ayoub,[1] Sydney Tang,[2] Laura Kooienga,[3] Priscila Preciado,[4] David S. Lee,[4] Stephanie Moody,[4] Brad H. Rovin.[1] *[1]Division of Nephrology, Ohio State University Wexner Medical Center, Columbus, OH; [2]Division of Nephrology, Department of Medicine, The University of Hong Kong, Queen Mary Hospital, Hong Kong, China; [3]Colorado Kidney Care, Denver, CO; [4]Travere Therapeutics, Inc., San Diego, CA.*

Background: SPAR is a nonimmunosuppressive, dual endothelin angiotensin receptor antagonist (DEARA) approved in the US and EU for adults with IgAN. In patients (pts) with IgAN, SPAR showed sustained proteinuria reduction and preservation of kidney function in the phase 3 PROTECT trial. In a subgroup analysis from DAPA-CKD and EMPA-KIDNEY, SGLT2is reduced the risk of progression to kidney failure in pts with IgAN. The combination of SPAR and an SGLT2i may therefore provide therapeutic benefits with potentially additive kidney protection. The ongoing phase 2 SPARTACUS trial will evaluate the efficacy and safety of SPAR added to an SGLT2i in adults with IgAN.

Methods: SPARTACUS is a 28-wk, open-label, multicenter study of the efficacy and safety of SPAR added to a stable SGLT2i in pts with IgAN at high risk of disease progression. Pts had biopsy-proven IgAN, urine albumin-to-creatinine ratio (UACR) of ≥0.3 g/g, and an estimated glomerular filtration rate (eGFR) of ≥25 mL/min/1.73 m^2 despite a stable SGLT2i and maximized renin-angiotensin-system inhibition for ≥12 wk. Endpoints include change from baseline in UACR at wk 24 (primary); achievement of UACR of <0.2 g/g or 30% or 50% reduction in UACR at wk 24 (secondary); change from baseline in UACR, urine protein-to-creatinine ratio, eGFR, and blood pressure at each visit (secondary); and adverse events. We describe pts in a prespecified interim analysis 24 wk after ≈20 pts were enrolled.

Results: Pt demographics and baseline characteristics are reported in the **Table**.

Conclusions: Enrollment in SPARTACUS will allow for assessment of the efficacy and safety of SPAR added to a stable SGLT2i in pts with IgAN. The presentation will include data from the interim analysis.

Funding: Commercial Support - Travere Therapeutics, Inc.

Cardiorenal Outcomes in Patients with IgAN: The FinnGen Study

Tomas J. Visser,[1] Laura Pyle,[2] Phoom Narongkiatikhun,[8] Ye Ji Choi,[10] David Cherney,[4] Rodosthenis S. Rodosthenous,[9] Krzysztof Kiryluk,[5] Petter Bjornstad,[3] Teemu Niiranen,[6] Patrik Finne,[7] Daniel Gordin.[7,11] FinnGen. *[1]Helsingin Yliopisto Laaketieteellinen Tiedekunta, Helsinki, Finland; [2]University of Colorado Anschutz Medical Campus, Aurora, CO; [3]University of Colorado Anschutz Medical Campus School of Medicine, Aurora, CO; [4]Toronto General Hospital, Toronto, ON, Canada; [5]Columbia University, New York, NY; [6]Turun Yliopisto Laaketieteellinen Tiedekunta, Turku, Finland; [7]Helsingin Seudun Yliopistollinen Keskussairaala, Helsinki, Finland; [8]Chiang Mai University, Chiang Mai, Thailand; [9]Helsingin Yliopisto Suomen Molekyylilaaketieteen Instituutti, Helsinki, Finland; [10]University of Colorado Anschutz Medical Campus, Aurora, CO; [11]Minerva Foundation Institute for Medical Research, Helsinki, Finland.*

Background: Long-term cardiorenal outcomes of Immunoglobulin A Nephropathy (IgAN) are incompletely understood. We assessed kidney function and cardiorenal events in patients with IgAN in the FinnGen study, which covers approximately 10% of the Finnish population (N=520210).

Methods: Patients with IgAN were identified using Finnish ICD10 diagnosis codes. The outcomes of interest were annual estimated glomerular filtration rate (eGFR) decline, start of kidney replacement therapy (KRT), and major adverse cardiovascular events (MACE). Out of 889 patients with IgAN, 265 were selected based on available data for eGFR. We compared outcomes in patients with IgAN (cases) vs. those with diabetes (controls), being the most common group requiring KRT in Finland. Cases (n=265) and controls (n=1060) were matched by eGFR, age, sex, and birth year (ratio 1:4). Multivariable-adjusted Cox regression and mixed-effects models were used to compare the groups.

Results: Annual eGFR decline was more rapid in patients with IgAN (-2.26; 95% Confidence Interval [95% CI] -2.33, -2.18 ml/min/1.73 m^2 per year) compared to those with diabetes (-1.28; 95% CI -1.43, -1.12 ml/min/1.73 m^2 per year). The cumulative incidence of KRT and MACE in patiens with IgAN and diabetes is shown in Figure 1. The risk for KRT was higher in individuals with IgAN compared to those with diabetes (Hazard Ratio [HR] 4.63; 95% CI 3.49, 6.16). However, the risk for MACE was lower in patients with IgAN (HR 0.61; 95% CI 0.47, 0.88) compared to patients with diabetes.

Conclusions: In this large register study, we demonstrated that patients with IgAN had a faster decline in eGFR and greater risk for KRT compared to patients with diabetes. In contrast, risk for MACE was lower in IgAN compared to diabetes in long-term follow-up.

Funding: Private Foundation Support

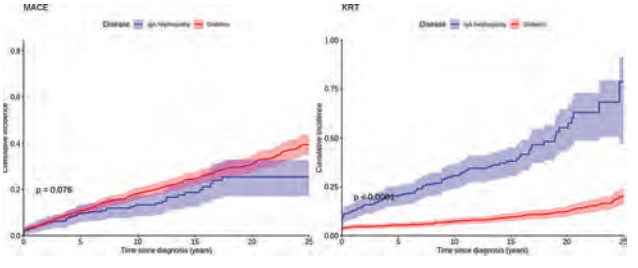

Figure 1: Cumulative incidence of major adverse cardiovascular events (MACE) and kidney replacement therapy (KRT) from diagnosis in patients with IgA nephropathy and diabetes.

FR-PO851

Concomitant Sparsentan (SPAR) and SGLT2 Inhibitors in Patients with IgA Nephropathy in the PROTECT Open-Label Extension (OLE)

Laura Kooienga,[1] Robert Malecki,[2] Priscila Preciado,[3] Heeral Nandola,[3] Alex Mercer.[4] On behalf of the DUPRO Steering Committee and PROTECT Investigators. *[1]Colorado Kidney Care, Denver, CO; [2]Nephrology Department of MSS in Warsaw, Warsaw, Poland; [3]Travere Therapeutics, Inc., San Diego, CA; [4]JAMCO Pharma Consulting, Stockholm, Sweden.*

Background: SPAR, a nonimmunosuppressive, dual endothelin angiotensin receptor antagonist (DEARA), demonstrated superior efficacy for proteinuria reduction and better preservation of kidney function vs irbesartan in pts with IgAN in the PROTECT trial. SPAR combined with an SGLT2i may offer additive kidney protection. We report data from pts who were prescribed an SGLT2i added to ongoing SPAR treatment in the PROTECT OLE.

Methods: Pts who completed the PROTECT double-blind period and met eligibility criteria were enrolled in the PROTECT OLE. All pts received SPAR (target dose, 400 mg/d). Concomitant SGLT2i treatment could be initiated at any time during the OLE at investigator discretion. Pts were excluded from this analysis if they participated in the

randomized controlled OLE SGLT2i substudy. Body weight, systolic and diastolic blood pressure, and urine protein-to-creatinine ratio (UPCR; based on 24-h urine sample) were evaluated at baseline (defined as the OLE visit closest to SGLT2i start) and at weeks 12, 24, 36, and 48 after baseline. Treatment-emergent adverse events (TEAEs) were examined.

Results: At data cutoff, 62 pts (mean [SD] age, 46 [11.3] y; female, n=16 [26%]) had received SPAR and add-on SGLT2i in the OLE. Median (IQR) time from OLE start to SGLT2i start was 273 (148.0-429.0) days. Summary data for body weight, blood pressure, and proteinuria over the 48 weeks are presented in the **Table.** Body weight and blood pressure remained relatively stable. Forty-one (66%) pts had TEAEs; the most common were COVID-19, hyperkalemia, hypertension, and hypotension.

Conclusions: These data show that an SGLT2i added to a stable dose of SPAR is generally well tolerated and may lead to further reductions in proteinuria. The safety and efficacy of sparsentan with or without concomitant SGLT2i treatment are also being investigated in a separate randomized substudy within the PROTECT OLE.

Funding: Commercial Support - Travere Therapeutics, Inc.

FR-PO852

First Real-World Evidence of Sparsentan Efficacy in Patients with IgA Nephropathy Treated with SGLT2 Inhibitors

Moritz Schanz, Severin Schricker, Andrea Schwab, Joerg Latus. *Robert-Bosch-Krankenhaus GmbH, Stuttgart, Germany*.

Background: Following the publication of the PROTECT trial, sparsentan, a dual-acting antagonist for both the angiotensin II receptor type 1 and the endothelin receptor type A, has emerged as a promising therapeutic agent for the treatment of IgA nephropathy and is currently under review for approval in Europe. However, real-world evidence, particularly on the additive antiproteinuric effect under SGLT2 inhibitors, which were an exclusion criterion in the double-blind period of the PROTECT trial, is lacking.

Methods: We started treating n=7 patients with sparsentan with IgA nephropathy from December 2023 through the Managed Access Program prior to official launch. Patients were stable under maximum tolerated RAAS and SGLT2 inhibitor therapy with an eGFR >30 ml/min/1.73 m2 and a urine protein-creatinine ratio (UPCR) >0.75 g/gCreatinine. All patients provided their informed written consent. Statistical analysis was conducted using the Wilcoxon matched-pairs signed rank test.

Results: Of the seven patients, the median (IQR) baseline eGFR (CKD-EPI) was 35 mL/min/1.73 m² (29-69) and the median (IQR) baseline UPCR was 1.79 g/g (0.94-3.84). The median blood pressure before initiating sparsentan was 130/80 mmHg. After initiating sparsentan, the UPCR significantly decreased (p=0.016) to a median of 0.86 g/g (IQR: 0.63-2.12) in the 2-week follow-up and further significantly declined (p=0.031) to a median of 0.67 g/g (0.43-1.07) after 6 weeks, corresponding to a relative reduction of proteinuria greater than 60%. A similar significant reduction was observed for the urine albumin-creatinine ratio (UACR). No serious adverse events were reported.

Conclusions: In a real-world setting, sparsentan demonstrates a significant effect on proteinuria and albuminuria as early as 2 weeks after initiation, resulting in a relative reduction of UPCR greater than 60% after 6 weeks, even in patients already being treated with SGLT2 inhibitors and steroids.

FR-PO853

Safety and Efficacy of Iptacopan in Patients with IgA Nephropathy with Baseline eGFR 20 to <30 mL/min: Phase 3 APPLAUSE-IgAN Subcohort Results

Dana V. Rizk,[1] Dmitrij Kollins,[2] Olympia Papachristofi,[2] Thomas Hach,[2] Severina Jacinto-Sanders,[2] Tobias Merkel,[2] Robert L. Schmouder,[3] Kenneth M. Kulmatycki,[4] Ronny W. Renfurm,[2] Vlado Perkovic.[5]
[1]University of Alabama at Birmingham, Birmingham, AL; [2]Novartis Pharma AG, Basel, Switzerland; [3]Novartis Pharmaceuticals Corporation, East Hanover, NJ; [4]Novartis Institutes for Biomedical Research, Cambridge, MA; [5]University of New South Wales, Sydney, NSW, Australia.

Background: Treatment of patients (pts) with advanced IgAN and estimated glomerular filtration rate (eGFR) <30 mL/min/1.73m² is limited to supportive care. Iptacopan specifically binds Factor B and inhibits the alternative complement pathway (AP), which is involved in IgAN pathogenesis. We present results from the APPLAUSE-IgAN subcohort with baseline eGFR 20-<30 mL/min/1.73 m².

Methods: APPLAUSE-IgAN (NCT04578834), a Phase 3, randomized, double-blind, placebo (pbo)-controlled trial, enrolled adults with biopsy-confirmed IgAN with proteinuria ≥1 g/g despite stable supportive therapy. Pts were randomized 1:1 to iptacopan 200 mg or pbo twice daily for 24 months while remaining on supportive therapy. Safety, efficacy, and pharmacokinetics (PK) of the low baseline eGFR subcohort were descriptively assessed at Month (M) 9 at time of interim analysis (IA).

Results: The analysis included 27 pts (13 iptacopan, 14 pbo) randomized to the low eGFR cohort at time of IA. Baseline demographic and disease characteristics were similar for iptacopan vs pbo: median (IQR) 24h urine protein-creatinine ratio (UPCR) 2.1 (1.7-2.5) vs 1.8 (1.4-2.4) g/g; mean (SD) eGFR 24.7 (2.8) vs 25.8 (2.9) mL/min/1.73m². All pts received maximally approved/tolerated RASi doses. Serious adverse events (AEs) occurred in 2 pts in each arm and AEs leading to treatment discontinuation in 1 pt in each arm. The most frequent AE was COVID-19 (23.1% iptacopan, 35.7% pbo). Proteinuria (24h-UPCR and 24h urine albumin-creatinine ratio) decreased from baseline to M9 in the iptacopan arm but increased in the pbo arm (**Table**). At M9, the relative reduction in median 24h-UPCR was 34.5% for iptacopan vs pbo, consistent with the primary analysis. PK data will be presented.

Conclusions: In pts with baseline eGFR 20-<30 mL/min/1.73m², iptacopan was well tolerated with a favorable safety profile, and decreased proteinuria vs pbo (34.5% at M9). Iptacopan may therefore represent a potential treatment option for pts with low eGFR.

Funding: Commercial Support - Novartis Pharma AG

Table. Descriptive statistics of proteinuria outcomes in the low eGFR population

Proteinuria measure	Unit	Iptacopan (n=11)*		Placebo (n=10)*	
		Baseline	Month 9	Baseline	Month 9
24h-UPCR (g/g)	Median (IQR)	2.07 (1.68, 2.54)	1.49 (1.16, 2.24)	1.78 (1.40, 2.17)	2.06 (1.39, 3.38)
	Median (IQR) % reduction	-	28 (-3, 35)	-	-10 (-56, 19)
24h-UACR (g/g)	Median (IQR)	1.66 (1.26, 2.08)	1.17 (0.90, 1.80)	1.57 (1.09, 1.80)	1.71 (1.05, 2.50)
	Median (IQR) % reduction	-	27 (-3, 45)	-	-8 (-46, 26)

*Patients with available measurements at baseline and Month 9. 24h-UACR, urine albumin–creatinine ratio from 24h collection; 24h-UPCR, urine protein–creatinine ratio from 24h collection; IQR, interquartile range.

FR-PO854

Results from Longer Follow-Up with Povetacicept, an Enhanced Dual BAFF/APRIL Antagonist, in IgA Nephropathy (RUBY-3 Study)

Arvind Madan,[1] Rajesh Yalavarthy,[2] Dong Ki Kim,[3] Ju young Moon,[4] Inwhee Park,[5] Sreedhar A. Mandayam,[6] Frank B. Cortazar,[7] Sung Gyun Kim,[8] Rupert H. Davies,[9] Amanda M. Enstrom,[9] Heather Thomas,[9] Jiahua Li,[9] Stanford L. Peng,[9] James A. Tumlin.[10,11]
[1]Central Florida Kidney Specialists, Orlando, FL; [2]Western Nephrology, Arvada, CO; [3]Seoul National University Hospital, Seoul, Republic of Korea; [4]Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea; [5]Ajou University School of Medicine, Suwon-si, Republic of Korea; [6]The University of Texas MD Anderson Cancer Center, Houston, TX; [7]New York Nephrology Vasculitis and Glomerular Center, Albany, NY; [8]Hallym University Sacred Heart Hospital, Anyang-si, Republic of Korea; [9]Alpine Immune Sciences, Inc., Seattle, WA; [10]NephroNet Clinical Trials Consortium, Atlanta, GA; [11]Emory University School of Medicine, Atlanta, GA.

Background: BAFF and/or APRIL inhibition has shown promise in IgAN, lupus, LN, and pMN, with the potential to exert a disease-modifying effect. Povetacicept (ALPN-303) is an Fc fusion protein of a variant TACI domain engineered for more potent dual BAFF/APRIL inhibition vs WT TACI or anti-BAFF/-APRIL Abs. In healthy volunteers, povetacicept mediated on-target reductions in Ab-secreting cells and levels of Ig, including the IgAN-specific biomarker Gd-IgA1. Earlier results from the ongoing RUBY-3 study of povetacicept (NCT05732402) showed good tolerability and promising improvements in IgAN disease activity, including UPCR reductions and stable renal function, accompanied by Gd-IgA1 reductions (Tumlin J, et al. Poster MON-304 presented at WCN 2024).

Methods: RUBY-3 is an open-label, multiple ascending dose, ph 1b/2a study of povetacicept 80 or 240 mg SC Q4W for 24 wk, followed by a 28-wk extension; participants (pts) meeting prespecified criteria at 48 wk may enter an optional 52-wk extension. Eligible pts are aged ≥18 y with IgAN, pMN, LN, or ANCA-associated vasculitis (biopsy-confirmed diagnosis required for IgAN, pMN, and LN). Pts must be on maximally tolerated ACEi/ARB therapy, with well-controlled BP, and disease-specific immunosuppressive therapy where applicable. Primary objective: safety; secondary objectives: PK, PD, immunogenicity, biomarkers, efficacy.

Results: As of 1 Mar 2024, 41 pts with IgAN have enrolled, with 12 and 29, respectively, at the povetacicept dose levels of 80 and 240 mg SC Q4W. Povetacicept was well tolerated at both dose levels. At 9 mo (n=6), a 64% reduction in UPCR and 69% reduction in Gd-IgA1 were achieved with povetacicept 80 mg; 67% of pts achieved remission, all pts with hematuria at BL had hematuria resolution, and stable renal function was observed. At the time of presentation, ≥20 pts are expected to have completed 36 wk across both dose levels and updated findings will be reported.

Conclusions: Experience with povetacicept to date strongly supports its further development in glomerulonephritis and particularly in IgAN, for which a pivotal trial (RAINIER) is in preparation and planned for initiation later this year.

AFFINITY Study: 1-Year Results of Atrasentan in IgA Nephropathy

Jonathan Barratt,[1] Sung Gyun Kim,[2] Lesley A. Inker,[3] David K. Packham,[4] Dwarakanathan Ranganathan,[5] Michelle N. Rheault,[6] Mark Vishnepolsky,[7] Yasmin G. Brahmbhatt,[8] Yi Wang,[9] Valeria Beckett,[8] Seung Hyeok Han.[10]
[1]University of Leicester, Leicester, United Kingdom; [2]Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea; [3]Tufts Medical Center, Boston, MA; [4]Melbourne Renal Research Group, Reservoir, VIC, Australia; [5]Royal Brisbane and Women's Hospital, Herston, QLD, Australia; [6]University of Minnesota Twin Cities Division of Pediatric Nephrology, Minneapolis, MN; [7]Kidney Specialists of Southern Nevada, Las Vegas, NV; [8]Chinook Therapeutics Inc, A Novartis Company, Seattle, WA; [9]Novartis Pharmaceuticals Corporation, East Hanover, NJ; [10]Severance Hospital, Seodaemun-gu, Seoul, Republic of Korea.

Background: Endothelin A (ET_A) receptor activation drives kidney dysregulation in glomerular diseases (GD). Atrasentan, a potent, selective ET_A receptor antagonist, has been shown to reduce proteinuria and may preserve kidney function in patients (pts) with IgAN and other GD. AFFINITY is a Phase 2, open-label basket study evaluating the efficacy and safety of atrasentan in pts with GD. We present results from the IgAN cohort through 1 year (52 wks) of treatment.

Methods: The IgAN cohort included adults with biopsy-proven IgAN; eGFR ≥30 mL/min/1.73m^2, UPCR ≥0.5 g/g and <1.0 g/g (first morning void), and on max. tolerated/stable RASi for ≥12 wks. Pts took 0.75 mg oral atrasentan daily for 52 wks. The primary endpoint was change in 24h UPCR from baseline (BL) to Wk 12.

Results: The IgAN cohort enrolled 20 pts (median age 44.5 y, 50% women, 45% White, 45% Asian); 19 pts completed 52 wks of treatment. BL median 24h total urine protein was 1.2 g/d, 24h UPCR was 0.8 g/g, eGFR was 46 mL/min/1.73m^2, and systolic/diastolic blood pressure (BP) was 128/82 mmHg. Reduction in 24h UPCR was evident by Wk 6 (LS mean % change from BL -38.2% [95% CI: -46.6, -28.5]), and sustained through Wk 12 (-48.4% [-56.4, -39.0]) to Wk 52 (-45.4% [-60.7, -24.0]; Fig). Atrasentan was well tolerated with no treatment-related serious adverse events (AEs) or deaths. AEs were seen in 18 pts; one pt discontinued treatment at Wk 13 due to an AE of headache considered treatment related. There was no evidence of significant fluid retention (no clinically meaningful mean changes from BL in body weight, brain natriuretic peptide, or BP).

Conclusions: Atrasentan, in addition to standard of care, was well tolerated and resulted in a clinically meaningful, stable reduction in proteinuria over 1 year of treatment, supporting its therapeutic potential in IgAN. The ongoing global Phase 3 ALIGN study (NCT04573478) is evaluating the effect of atrasentan on proteinuria and kidney function in pts with IgAN.

FR-PO856

A Phase 1/2 Trial of Zigakibart in IgA Nephropathy

Jonathan Barratt,[1] Biruh Workeneh,[2] Sung Gyun Kim,[3] Eun Young Lee,[4] Chun Lam,[5] Erin L. Filbert,[6] Bess Sorensen,[6] Yuanbo Song,[5] Zeeshan Khawaja,[6] Laura Kooienga.[7]
[1]University of Leicester, Leicester, United Kingdom; [2]The University of Texas MD Anderson Cancer Center, Houston, TX; [3]Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea; [4]Soonchunhyang University Cheonan Hospital, Cheonan, Republic of Korea; [5]Novartis Pharmaceuticals Corporation, East Hanover, NJ; [6]Chinook Therapeutics Inc, A Novartis Company, Seattle, WA; [7]Colorado Kidney Care, Denver, CO.

Background: IgAN is the leading cause of primary glomerulonephritis with limited treatment options. Zigakibart is a novel investigational, humanized monoclonal antibody that blocks A PRoliferation-Inducing Ligand (APRIL), a cytokine elevated in patients with IgAN, which promotes pathogenic galactose-deficient IgA1 production, leading to inflammation and kidney injury.

Methods: ADU-CL-19 is an ongoing Phase 1/2 trial (NCT03945318) of zigakibart. Part 3 enrolled patients ≥18 years with biopsy-proven IgAN, total urine protein ≥0.5 g/24h or UPCR ≥0.5 g/g, eGFR ≥30 mL/min per 1.73 m^2, and on stable/optimized dose of RASi for ≥3 months prior to screening (or RASi intolerant). Patients received zigakibart 450 mg Q2W IV, transitioning to 600 mg Q2W SC at ≥24 weeks (Cohort 1) or 600 mg Q2W SC (Cohort 2) for up to 124 weeks. Key objectives include safety, tolerability, immunogenicity, pharmacodynamic effects, and preliminary effects on proteinuria and eGFR.

Results: Overall, 40 patients were enrolled (n=10 [Cohort 1], n=30 [Cohort 2]); median age 38.5 years; 70% male; 60% White and 33% Asian. Zigakibart was well-tolerated with no adverse events (AEs) leading to study drug discontinuation or deaths. AEs were observed in 34 (85%) patients, most commonly infections (78%) of Grade 1 or 2 in severity; one patient experienced Grade 3 infections. One patient experienced infections deemed treatment related. IgA and IgM levels were reduced by 71% and 79% from baseline, respectively, through Week 76, while reduction in IgG was mild to modest (35%). At Week 76, proteinuria, measured as UPCR from a 24h collection, was reduced by 57% from baseline, and eGFR remained stable (Fig. 1A, 1B). Circulating lymphocyte counts remained stable through the study (Fig. 1C, 1D).

Conclusions: Zigakibart was well tolerated and led to sustained, clinically meaningful reductions in proteinuria and eGFR stabilization in patients. The global Phase 3 BEYOND study (NCT05852938) is also evaluating the efficacy and safety of zigakibart in adults with IgAN.

FR-PO857

Safety, Tolerability, and Efficacy of Mezagitamab (TAK-079) as Add-On to Standard of Care Therapy in Individuals with Primary IgA Nephropathy: Interim Results from an Open-Label Phase 1b Study

Jonathan Barratt,[1] Yusuke Suzuki,[2] Van Anh Nguyen,[3] Iwona Dobler,[3] Cheryl Li,[3] MK Farmer.[3]
[1]Department of Cardiovascular Sciences, University of Leicester, Leicester, United Kingdom; [2]Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; [3]Takeda Development Center Americas Inc, Cambridge, MA.

Background: IgA nephropathy (IgAN) is the most prevalent form of primary glomerulonephritis worldwide and is associated with a poor prognosis including progression to end-stage kidney disease or death in some cases. Therapeutic options for IgAN are limited. Mezagitamab, a fully human anti-CD38 IgG1 monoclonal antibody, depletes plasma cells, plasmablasts, and natural killer cells expressing CD38. Mezagitamab depletes cells that produce galactose-deficient IgA1 (Gd-IgA1) and autoantibodies, which results in decreased immune complex formation, potentially reducing proteinuria/promoting stabilization of kidney function over time.

Methods: This open-label, single-arm, phase 1b, multicenter study (NCT05174221), evaluated mezagitamab as an add-on to standard of care therapy (ACEi, ARB) in IgAN. Eligible participants had biopsy-proven disease/proteinuria by urine protein to creatinine ratio (UPCR) ≥1 mg/mg or urine protein excretion (UPE) ≥1 g/24 hours, despite optimized renin-angiotensin-aldosterone system therapy. Participants received subcutaneous mezagitamab 600 mg once weekly for 8 weeks, then 600 mg every 2 weeks for 16 weeks (16 total doses). Primary endpoint was percentage of participants with treatment emergent adverse events (TEAEs). Secondary and exploratory endpoints included serum IgA and Gd-IgA1 levels, percentage change from baseline in UPCR, and change from baseline in eGFR. Results are from a prespecified interim analysis.

Results: Seventeen participants enrolled (mean age 40.8 years, 53% female, 71% Asian). No serious TEAEs, discontinuations due to TEAEs, grade ≥3 infectious TEAEs, or opportunistic infections were reported. Most common TEAEs were upper respiratory tract infection (35.3%), pyrexia (23.5%), and oropharyngeal pain (23.5%). There were rapid and sustained reductions from baseline levels in serum IgA (nadir −70.1%) and Gd-IgA1 (nadir −62.2%). At Week 36, a 54.9% mean reduction in proteinuria (UPCR) was observed. Renal function (eGFR) remained stable though Week 36.

Conclusions: Mezagitamab was generally well tolerated as an add-on to standard of care therapy. Rapid and sustained reductions in UPCR, serum IgA, and Gd-IgA1 levels were seen with stable eGFR.

FR-PO858

Concordance of Proteinuria Thresholds between Chinese and UK Cohorts with IgA Nephropathy

Jonathan Barratt,[1,2] David Pitcher,[6] Ceri Hirst,[3] Daniel P. Gale.[4,5] *[1]University of Leicester, Leicester, United Kingdom; [2]Leicester General Hospital, Leicester, United Kingdom; [3]Novartis Pharmaceuticals UK Ltd, London, United Kingdom; [4]Royal Free Hospital, London, United Kingdom; [5]University College London, London, United Kingdom; [6]UK Kidney Association, Bristol, United Kingdom.*

Background: IgA nephropathy (IgAN) is a heterogenous disease with various clinical manifestations, including proteinuria. Proteinuria is a surrogate endpoint for predicting long-term outcomes in IgAN, with KDIGO guidelines identifying proteinuria <1 g/day as a therapeutic target. However, a recent study in China suggests a lower threshold of <0.3 g/day (approximately 26 mg/mmol), with patients below this level having a reduced risk of reaching 50% estimated glomerular filtration rate (eGFR) reduction or end-stage kidney disease (Tang et al. 2024; https://doi.org/10.1053/j.ajkd.2023.12.016). Here, we used the UK RaDaR registry, one of the largest and most comprehensive population-based datasets for patients with IgAN, to evaluate and compare the population differences of IgAN patients in the RaDaR UK and Chinese cohorts. Additionally, we evaluated the concordance of proteinuria findings between these two populations.

Methods: We analyzed a population of 3493 adults with biopsy proven IgAN enrolled on the RaDaR registry up to September 2022 and compared population characteristics and proteinuria findings to the Chinese cohort.

Results: Compared to the Chinese cohort, patients on the UK registry were more likely to be male (70.5% vs 51.4%) and were on average older (42.8 ± 14.4 years vs 36.5 ± 12.0 years). RaDaR patients had a higher stage of chronic kidney disease (69.2% Stage 3+ vs 30.8%), and eGFR was lower (47.8 ± 31.0 vs 78.43 ± 30.45 mL/min/1.73 m^2). During follow-up, 2040 (58%) of UK registry patients progressed to kidney failure with a median survival time of 8 (7.5-8.7) years. Survival time was directly correlated with proteinuria, with a notably lower median survival time in patients with proteinuria ≥100 mg/mmol (HR 3.072 (95% CI 2.32-4.06). The median survival for patients with proteinuria <50, 50-99, 100-199, 200-299 and >300 mg/mmol was 10.4 (7.3-NE), 9.7 (7.6-NE), 5.8 (4.3-7.7), 3.3 (2.1-4.8) and 1.4 (0.9-1.9) years, respectively.

Conclusions: While there are population differences between patients with IgAN across cohorts, patients with specific characteristics have a consistently poorer prognosis. Proteinuria levels indicate that risk of kidney failure persists even in patients below the recommended threshold. Therefore, a lower threshold for treatment goals warrants consideration.

FR-PO859

Impact of Nefecon on Complement Pathways in IgA Nephropathy: An Analysis of Lectin, Alternative, and Terminal Pathways

Nadia Nawaz, Roisin C. Thomas, Jonathan Barratt. *University of Leicester College of Life Sciences, Leicester, United Kingdom.*

Background: Complement system activation is increasingly recognized as a critical factor mediating glomerular damage in immunoglobulin A (IgA) nephropathy (IgAN), and can be a predictor of poor outcomes. Nefecon, a targeted-release formulation of budesonide for the treatment of IgAN, targets the gut-associated lymphoid tissue of the distal ileum. In the Phase 3 NefIgArd trial, 9 months of Nefecon 16 mg/day treatment significantly reduced proteinuria and slowed kidney function decline compared with placebo. In the Phase 2b NEFIGAN trial, biomarker analyses supported a role for Nefecon in modulating complement activation in IgAN. In this analysis, we investigated the effects of Nefecon on complement pathways in the NefIgArd trial.

Methods: Patients with IgAN received Nefecon 16 mg/day or placebo for 9 months on top of supportive care, followed by a 15-month observational period off study drug. Commercially available enzyme-linked immunosorbent assays were used to measure serum levels of mannan-binding lectin serine protease 2 (MASP2; lectin pathway), Factor B (alternative pathway) and complement 5 (C5; terminal pathway) at 3, 6, 9, 12, and 18 months (Nefecon group, n=110; placebo group, n=113). Unpaired t-tests were used to compare groups at each timepoint (significance threshold of $p<0.05$).

Results: Nefecon 16 mg/day treatment for 9 months resulted in a significant and sustained reduction in serum levels of factor B (3 months, $p<0.0001$; 6 months, $p<0.0001$; 9 months $p<0.0001$; 18 months $p=0.04$) vs placebo. By contrast, Nefecon treatment did not change serum levels of MASP2 or C5 at any timepoint.

Conclusions: The effect of Nefecon on complement pathways was analysed by examining representative proteins of the lectin, alternative, and terminal pathways. Nefecon specifically and significantly reduced serum levels of the alternative pathway protein, Factor B. This effect is likely to impact positively on reducing glomerular inflammation and provides additional support for the kidney-protective action of Nefecon in IgAN. This effect was specific for Factor B, as no significant effect was observed on critical lectin and terminal pathway proteins. We are currently investigating the mechanisms responsible for this specific modulation of the alternative pathway, which may obviate the need for additional complement inhibition for the treatment of IgAN.

FR-PO860

Studying IgA Nephropathy at a Population Level over a 21-Year Period

Sinead Stoneman,[1] Jialin Han,[1] Jonathan Barratt,[2] Mohammad Atiquzzaman,[1] Sean Barbour.[1,3] *[1]Division of Nephrology, Department of Medicine, University of British Columbia, Vancouver, BC, Canada; [2]University of Leicester Department of Cardiovascular Sciences, Leicester, United Kingdom; [3]BC Provincial Renal Agency, Vancouver, BC, Canada.*

Background: Individuals with IgA nephropathy [IgAN] risk progression to end-stage kidney disease [ESKD] and death. Studies in IgAN to date have been mostly single- or multi-center research cohorts with inclusion criteria and selection bias that limits generalizability. Herein we report the methodology used to study outcomes of adult IgAN at the population level in a large Canadian province.

Methods: This is a population-level cohort study of adults ≥18 years with IgAN using the British Columbia [BC] Glomerulonephritis [GN] Registry. All kidney biopsies are processed by nephropathologists in a single center. Any biopsy with GN is automatically registered in the BC GN Registry, which links with healthcare administrative databases to capture comorbidities, laboratory data, treatment and outcomes.

Results: The BC GN Registry successfully captured 1382 individuals with primary IgAN over 21 years from 2000 to 2020. At the time of biopsy, median age was 44.3 years, eGFR was 54.1 ml/min/1.73m^2, and proteinuria was 1.4 g/day (Table 1); 92.4% and 88.1% of patients had available eGFR and proteinuria. During follow-up, there were 19 (IQR 9, 38) and 12 (IQR 4, 25) eGFR and proteinuria measurements per patient, which were measured every 1.2 (IQR 0.4, 3.0) and 2.8 months (IQR 1.1, 4.8) respectively. The 20-year risk of ESKD was 49.4% and of death was 15.6% (Figure 1).

Conclusions: We demonstrate the feasibility of using a provincial biopsy registry linked with administrative databases to study IgAN at the population-level in a large multi-ethnic Canadian province. The structure of the BC GN Registry captures all patients in BC with IgAN without selecting bias. Future steps will be to study treatment patterns, clinical outcomes, and healthcare utilization.

Baseline Characteristics and Associations of Using SGLT2 Inhibitors in IgA Nephropathy in China: Results from the CPO-IGAN

Chaosheng Chen,[1] Ji Zhang,[1] Gengru Jiang,[2] Rong Wang,[6] Chuanyan Zhao,[3] Qinkai Chen,[11] Min Chen,[10] Hen Xue,[5] Niansong Wang,[4] Qiuling Fan,[12] Guoping Qiu,[7] Hongbo Ma,[8] Lixia Yu.[9] *[1]The First Affiliated Hospital of Wenzhou Medical University, Wenzhou, China; [2]Shanghai Jiaotong University School of Medicine Xinhua Hospital, Shanghai, China; [3]Northern Jiangsu People's Hospital, Yangzhou City, China; [4]Shanghai 6th Peoples Hospital Affiliated to Shanghai Jiao Tong University, Shanghai, China; [5]Ya'an People's Hospital, Ya'an, China; [6]Shandong Provincial Hospital, Jinan, China; [7]Jiujiang First People's Hospital, Jiujiang, China; [8]Zibo Central Hospital, Zibo, China; [9]Kunshan First People's Hospital, Kunshan, China; [10]Chengdu First People's Hospital, Chengdu, China; [11]First Affiliated Hospital of Nanchang University, Nanchang, China; [12]Shanghai General Hospital, Shanghai, China.*

Background: IgA nephropathy (IgAN) is most common primary glomerular disease in China. The 2024 KDIGO CKD guideline recommends Sodium-glucose co-transporter 2 inhibitors (SGLT2i) as first-line treatment for CKD. SGLT2i use in Chinese IgAN patients is understudied. The Clinical Practice Optimization Initiative for Chinese Patients with IgA Nephropathy (CPO-IGAN) is the first nationwide project with the aim of optimizing clinical practices in IgAN across China.

Methods: As of March, 2024 we recruited 2783 IgAN patients from 33 hospitals across 12 provinces. And for the SGLT2i sub-group, we have extracted and analyzed the data pertaining to IgAN patients administered with SGLT2i.

Results: In total, 2264 Primary IgAN patients were included, 100 of whom had initiated SGLT2i therapy at the baseline: The median age was 42 years, 46% were females and the median (IQR) of eGFR was 88.29 mL/min/1.73 m2 and 24-hour urinary protein was 1269 mg/day (Table 1). The non-SGLT2i group and SGLT2i group, mainly differing in age, the initial treatment post-diagnosis and comorbidity(Table 1). More than half of patients using SGLT2i were concentrated in 2023(51%). A logistic regression analysis indicated that the clinician's selection of SGLT2i was correlated with comorbidity of Type 2 diabetes (OR = 11.82, P < 0.001) (Table 1). Post-follow-up effects of SGLT2i is undergoing.

Conclusions: This study indicates that SGLT2i were used in IgAN patients in China. The association of SGLT2i using with diabetic status suggests that nephrologist may consider SGLT2i more as a diabetes medication than as a treatment for CKD. The critical need for enhancing clinician awareness and education about SGLT2i's benefits for IgAN patients.

Funding: Clinical Revenue Support

Disease Burden of IgA Nephropathy (IgAN): A Linguistic Analysis of Global Social Media Conversations over Time: A Comparison of Results, 2019-2023

Dorothee Oberdhan,[1] Sarah N. Ali,[1] Erin Morea,[2] Akansha Batra,[2] Jennifer Dandy.[2] *[1]Otsuka Pharmaceutical Development and Commercialization Inc, Princeton, NJ; [2]Real Chemistry International LLC, New York, NY.*

Background: The treatment landscape for Immunoglobulin A Nephropathy (IgAN) has evolved with the approval of several new therapies for patients requiring a comparative evaluation of a prior and updated ethnographic study to understand changes in patient experiences of disease manifestations, disease impact, and treatment of IgAN as described by patients, caregivers, and healthcare providers (HCPs).

Methods: We compare results from two social listening studies using the same methodology to capture global, public, social media (i.e., X, Reddit, etc.) posts from Period 1: 5/1/2019 – 5/30/2021 and Period 2: 12/1/2022 – 12/31/2023, using technologies such as web crawlers and data partnerships. Sociolinguists analyzed the posts in the native language using qualitative and quantitative methods.

Results: Overall, total social media posts describing the disease experience of individual patients with IgAN from Period 1 to Period 2 increased (1,024 to 1,165) and was comprised of identifiable patients (902, 1,105), caregivers (102, 39), and HCPs (20, 21) respectively. Posts increased from Japan (+106), the United Kingdom (+40), South Korea (+32), Germany (+37), and Canada (+19) and decreased from the United States (-59) and France (-39). Posts about symptoms were similar (229 to 248); treatments increased (627 to 723) and impact decreased (400 to 233). Post characteristics over time are detailed in Table 1 below.

Conclusions: This comparative analysis of real-world social media posts assessed discussion trends of patients with IgAN to better understand their experiences. Social media conversations increased over time and their global distribution, patient characteristics, and content changed. This analysis demonstrates that patient experiences of IgAN are not static; regular updates to detect changes in patient experiences of disease manifestations, disease impact, and treatment of IgAN can help inform future research studies.

Disease Burden of IgA Nephropathy: An Updated Linguistic Analysis of Global Social Media Conversations

Dorothee Oberdhan,[1] Sarah N. Ali,[1] Erin Morea,[2] Akansha Batra,[2] Jennifer Dandy.[2] *[1]Otsuka Pharmaceutical Development and Commercialization Inc, Princeton, NJ; [2]Real Chemistry International LLC, New York, NY.*

Background: New therapies have been approved to treat Immunoglobulin A Nephropathy (IgAN) and a refresh of a prior ethnographic study is needed to understand patient experiences of disease manifestations, disease impact and treatment of IgAN as described by patients, caregivers and healthcare providers (HCPs).

Methods: A social listening methodology captured public social media (e.g., X, Reddit) posts from 12/1/2022-12/31/2023 globally, using technologies such as web crawlers and data partnerships. Sociolinguists analyzed the posts in the native language using qualitative and quantitative methods.

Results: A total of 1,165 posts described the experience of individuals with IgAN from 1,105 identifiable patients, 39 caregivers and 21 HCPs. Countries with the most posts were Japan (66%), the United States (13%), the United Kingdom (7%) and South Korea (4%). In the analysis, a single post could report multiple patient experience characteristics. Disease manifestations were reported in 248 posts (21%); the top described were hematuria (35%), proteinuria (33%) and pain (12%). Treatments were reported in 723 posts (62%); the top described were steroids (62%) and lifestyle management (16%). Impact of disease was reported in 233 posts (20%). Top impacts described were Emotional (e.g., disease progression anxiety, depressive thoughts about their disease and fear about their chronic illness with "no cure") (57%), Physical (e.g., "extreme" fatigue/pain and impact on mobility/sleep) (22%) and Work/School (e.g., ability to function, stigma/pressures to contribute with a chronic illness, concern of symptoms/diagnosis and impact on military status (7%). Approved IgAN therapies were only mentioned in US posts (12%).

Conclusions: This updated analysis of real-world social media posts assessed discussion trends of patient experiences with IgAN and suggested that IgAN's effect on patients may arise more from disease manifestations and treatments. Although patients described heightened anxiety over their kidney function levels, and patients and caregivers highlighted the desire for advanced treatments that protect kidney function, surprisingly, newly approved therapies for IgAN were rarely mentioned. With the advent of newer therapies, this update demonstrates the importance of capturing IgAN patient experiences to inform research.

Dapagliflozin Alters Extracellular Vesicle MicroRNAs in Patients with IgA Nephropathy

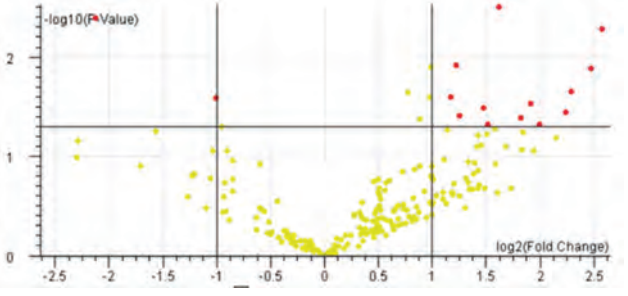
Kootae Park, Soon hyo Kwon. *Soonchunhyang University Hospital, Seoul, Republic of Korea.*

Background: Extracellular vesicle (EV) containing microRNAs (miRNAs) play a crucial role in regulating gene expression in a variety of tissue and contribute to the pathophysiology of various renal disease. Sodium glucose co transporter 2 inhibitors (SGLT2i) has improved renal outcomes in IgA nephropathy (IgAN). This study aims to explore how dapagliflozin affect EVs-miRNAs in IgAN patients.

Methods: We prospectively enrolled 26 biopsy-proven IgAN patients who had not previously been treated with SGLT2i. The participants were received dapagliflozin (10 mg/day). Serum samples were collected both before treatment and after 6 months of dapagliflozin therapy. Using RNA sequencing, we assessed the serum EV-miRNAs profile of all participants.

Results: The cohort predominantly consisted of male (n=15, 64%) with a mean age was 48.6 ± 12.2 years. Dapagliflozin reduced estimated GFR over the study period (73.9 ± 23.7 vs 69.8 ± 21.5 mL/min, p = 0.012). RNA sequencing revealed differential expression of 21 miRNAs in before and after dapagliflozin. Biological pathway analysis of these miRNA indicated that they are likely involved in proteoglycan in cancer and Hippo signaling pathway (Figure 1).

Conclusions: Dapagliflozin alters the EVs-miRNAs expression profile in IgAN patients. These miRNAs may be promising candidates for the predicting prognosis and treatment of IgAN.



FR-PO865

Efficacy and Safety of Telitacicept in IgA Nephropathy: A Real-World Study

Lingqiu Dong, Wei Qin. *West China Hospital of Sichuan University, Chengdu, China.*

Background: IgA nephropathy (IgAN) is the most common primary glomerular disease in the world. Telitacicept is a humanized fusion protein composed of a transmembrane activator and calcium-modulating cyclophilin ligand interactor receptor and human IgG. This study was designed to evaluate the efficacy and safety of telitacicept in patients with IgAN.

Methods: Biopsy-proven IgAN patients with 24-hour proteinuria greater than 0.5 g/day who received telitacicept 240 mg once a week were recruited in this study and 1:1 matched with patients received supportive treatment only or immunosuppressive treatment by propensity score matching. The primary outcome was the change from baseline in 24-hour proteinuria over the 3-month follow-up.

Results: Twenty-one patients in each group were enrolled. The mean eGFR was 80.1 ml/min/1.73m^2, and the median 24-hour urine protein was 1.48 g/day. At the end of the 3-month follow-up, telitacicept reduced median proteinuria by 0.72 g/d (54.6%) from baseline, compared with a reduction of 0.18 g/d (20%) in the supportive treatment group ($P < 0.001$), and 1.12 g/d (72.1%) in the immunosuppressive treatment group ($P = 0.814$). Preserved eGFR levels were observed in the telitacicept group (1.9 ml/min/1.73 m2

[4.3%]), while the eGFR level declined in the supportive treatment group (- 2.9 ml/min/1.73 m^2 [- 5.8%]) and immunosuppression group (- 6.1 ml/min/1.73 m^2 [- 8.4%]). No serious adverse events were observed in the telitacicept treatment group. Injection site reactions were more prevalent in the telitacicept group, meanwhile immunosuppression group had more respiratory tract infections.

Conclusions: Telitacicept can reduce proteinuria in patients with IgAN and showed a favourable safety profile.

Results from a Real-World Case Series of Patients with IgAN Who Received at Least 9 Months of Tarpeyo

Christopher Ngai,[1] Giancarlo Pesce,[2] Sarah Zaidi,[2] Nadia Petiot,[2] Ramin Tolouian,[1] Terri Madison.[1] *[1]Calliditas Therapeutics AB, New York, NY; [2]Certara Inc, Princeton, NJ.*

Background: Tarpeyo, a targeted-release formulation of budesonide, is currently the only FDA-approved treatment for IgA nephropathy (IgAN) to significantly reduce the loss of kidney function. This research evaluated safety and effectiveness outcomes in a cohort of Asian-American patients who received ≥ 9 months of Tarpeyo in a real-world setting.

Methods: Patients with IgAN who received Tarpeyo for ≥9 consecutive months at the Chinatown Kidney Care (CKC) practice (NY, USA) before Nov 30 2023 (data abstraction cutoff) were included in this retrospective analysis. Data were abstracted from patient-level electronic medical records.

Results: For the 30 patients meeting eligibility criteria, the mean age was 46 years, 57% were male, and 100% were Asian-American. Patients received Tarpeyo for an average 11.7 months and were followed-up for an average 14.6 months since Tarpeyo initiation. On average, eGFR was 68.4 mL/min/1.73m^2 at Tarpeyo initiation, which was 6.7 mL/min/1.73m^2 lower than when first seen at CKC (annual decrease until Tarpeyo initiation: 0.6 mL/min/1.73m^2). After Tarpeyo initiation, eGFR increased by average 3.6 mL/min/1.73m^2 in 9 months [Figure]. Overall, adverse events (AEs) were observed in 2 patients; both were mild and resolved. In one patient the AE resulted in a dose reduction. Preliminary results for a subgroup of patients treated for > 9 months (n=23, mean Tarpeyo treatment duration=12.5 months) showed continued preservation of kidney function without an increase in incidence of serious AEs.

Conclusions: Results from this case series demonstrated that real-world use of Tarpeyo was well-tolerated and can reduce loss of kidney function in patients who receive ≥9 months of treatment.

Funding: Commercial Support - Calliditas Therapeutics AB

	First eGFR measurement at CKC	Tarpeyo initiation (index)	+3 months after index	+6 months after index	+9 months after index

Patient-Reported Outcomes (PROs) Use in IgA Nephropathy (IgAN)

Michelle M. Richardson,[1,2] Sarah N. Ali,[1] Hema K. Gandhi,[1] Dorothee Oberdhan.[1] *[1]Otsuka Pharmaceutical Development and Commercialization Inc, Princeton, NJ; [2]Tufts University School of Medicine, Boston, MA.*

Background: Immunoglobulin A Nephropathy (IgAN) is a progressive disease with high patient-reported burden and disease-related impact. New therapies could alter the course of disease, presenting the need for appropriate measurement of patient-reported outcomes (PROs). PRO requirements include content validity, acceptable measurement properties, information on meaningfulness and most importantly, must be fit for context of use (e.g., screening, diagnosis, likelihood of being impacted by treatment). With the advent of newer therapies, assessing PROs used in IgAN clinical trials is needed to evaluate their applicability for regulatory use.

Methods: We conducted a targeted MEDLINE search for PROs used in IgAN clinical trials from 2021-2024 to update a 2021 systematic review, compiled the PROs used and evaluated individual instrument characteristics: context of use, purpose and meaningful change over time.

Results: 464 articles were identified, 11 remained after title and abstract review and 3 underwent full text review and were included. Of the 7 clinical trials (6 from the previous search, 1 newly identified), 1 was an interventional trial of the effects of exercise on depression symptoms, 1 was an observational longitudinal study, 2 were cross-sectional studies, and 3 were studies of PRO development work. Two studies enrolled only patients with IgAN, the others enrolled <10 IgAN patients each. 19 different PROs were used throughout the included studies: only 1 was specific to kidney disease (Peds QL ESRD module), 5 were generic measures, 14 were disease- or symptom-specific measures (e.g., depression, anxiety, mobility) 11 were for use in adults and 8 in pediatrics. No PRO met context of use or responsiveness criteria.

Conclusions: This review evaluated 19 PROs used in IgAN clinical trials. The only interventional longitudinal trial that was identified tested a life-style intervention and did not report responsiveness. One PRO was kidney-disease specific but was only used in pediatric patients. Currently, published studies of PROs in IgAN clinical trials do not provide sufficient information to support regulatory use and additional evidence is needed. In future research, selecting a high-quality PRO that is integrated with other clinical trial outcomes and most effective for regulatory use requires attention to context of use, purpose and meaningful change.

FR-PO868

Patient-Reported Outcomes in the PROTECT Clinical Trial Comparing Sparsentan with Irbesartan for IgA Nephropathy

Shikha Wadhwani,[1] Mark E. Bensink,[2] John D. Peipert,[1] Isabelle Ayoub,[3] Priscila Preciado,[2] Diana Garbinsky,[4] Lee Bennett,[4] Wu Gong,[2] Jula K. Inrig,[2] Radko Komers.[2] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Travere Therapeutics Inc, San Diego, CA; [3]The Ohio State University Wexner Medical Center, Columbus, OH; [4]RTI Health Solutions Research Triangle Park, Research Triangle Park, NC.*

Background: In the phase 3, double-blind PROTECT trial (NCT03762850), sparsentan (SPAR), a dual endothelin and angiotensin II receptor antagonist (DEARA), showed efficacy in reducing proteinuria and preserving renal function compared with a maximally tolerated dose of irbesartan (IRB) in patients with immunoglobulin A nephropathy (IgAN). Safety profiles for the two treatments were similar. This analysis aimed to evaluate the effect of SPAR compared with IRB on patient-reported outcomes (PROs) in patients with IgAN enrolled in PROTECT.

Methods: Adult patients were randomized to receive SPAR or IRB for 110 weeks. The Kidney Disease Quality of Life–36 (KDQOL-36) PRO measure was administered at baseline and at weeks 24, 48, 70, 94, and 110. Changes from baseline in Physical Component Summary, Mental Component Summary, Bodily Pain, and kidney-targeted subscale scores were analyzed using least-squares means from mixed models for repeated measures. A score change of 5 was considered clinically meaningful. Time-to-event endpoints, including first improvement, were analyzed using Cox models.

Results: Baseline KDQOL-36 scores were similar for patients randomized to SPAR and IRB. In general, least-squares mean changes from baseline indicated an improvement in Burden of Kidney Disease (BKD) score (week 110 difference [SPAR – IRB], 5.1; 95% confidence interval [CI], 0.45-9.67; $P < 0.05$]), while other scores were stable through week 110. Hazard ratios for time to first improvement in BKD score (1.51; 95% CI, 1.15-1.97) favored SPAR (Figure A).

Conclusions: For patients with IgAN, analysis of PROs from the PROTECT trial suggests that patients receiving SPAR have less burden of kidney disease over time and a general trend toward improved health-related quality of life compared with those receiving a maximally tolerated dose of IRB.

Funding: Commercial Support - Travere Therapeutics

FR-PO869

Complement and B Cell Modifying Pipeline to Address Unmet Needs in IgA Nephropathy (IgAN)

Justin Snyder, Meghan Weiss. *Spherix Global Insights, Exton, PA.*

Background: Therapeutic developments for IgA nephropathy (IgAN) are at the forefront of innovation, supported by the accelerated approval of two recently apprproducts and a robust pipeline with various mechanisms of action. In upcoming years, new products will likely be available that will further help physicians address IgAN at the pathogenic level.

Methods: Data from 454 audited patient charts were collected in partnership with 142 US nephrologists in January 2024 and in partnership with an additional 105 US nephrologists in February 2024 via online surveys.

Results: With the approvals of delayed-release oral budesonide and sparsentan in IgAN, most nephrologists (80%) indicate that they feel better equipped to treat their IgAN patients. Currently, 72% and 66% of nephrologists are using budesonide or sparsentan, respectively, positioned as third-line or later treatments after RAASi and SGLT2 inhibitors. However, nearly half (46%) remain unconvinced that they can achieve the desired proteinuria goals with only the existing therapies. It is theorized that the Peyer's patches are the main source of the galactose-deficient (Gd) IgA1 antibodies that cause damage and inflammation to the kidneys, yetand almost one-half (4357%) of nephrologists are unconvinced that targeting the Peyer's patch is an important goal in treatment. However, 68% of nephrologists agree that IgAN is a B-cell mediated disease, where the root cause of Gd-IgA1 production comes from overstimulated B-cells and plasma cells. Additionally, 76% believe that the complement system plays an active role in the pathogenicity of IgAN. There are several IgAN pipeline agents that potentially target B-cell and plasma factors. Two products that are in Phase 3 trials include iptacopan, which is a complement factor B inhibitor, and atacicept, which is a B lymphocyte stimulator (BlyS) inhibitor and a proliferation-inducing ligand (APRIL) inhibitor that targets B cells and plasma cells. If approved, nephrologists indicate that they would be at least somewhat likely to prescribe iptacopan or atacicept to approximately one-third of the IgAN patients included in the study.

Conclusions: Nephrologists continue to see an unmet need in the IgAN space, leaving room for new market entrants to effectively treat the root cause of the disease and further enable physicians to individualize treatments.

FR-PO870

Exploring the Impact of Loin Pain in IgA Nephropathy: A United Kingdom-Wide Mixed-Methods Qualitative Study and Pilot Survey

Kristina L. Newman,[1,2] Jonathan Barratt,[1,3] Justyna Szklarzewicz,[1,3] Lydia E. Roberts,[1] Roisin C. Thomas,[1] Alice C. Smith,[1] Zoe E. Plummer,[5] Susan Pywell,[5] Sherry Masoud,[5,6] Daniel P. Gale,[4] David Pitcher,[5] Haresh Selvaskandan.[1,3] Mayer IgAN Group and RaDaR. *[1]University of Leicester, Leicester, United Kingdom; [2]Nottingham Trent University, Nottingham, United Kingdom; [3]Leicester General Hospital, Leicester, United Kingdom; [4]Royal Free London NHS Foundation Trust, London, United Kingdom; [5]UK Kidney Association, Bristol, United Kingdom; [6]University College London, London, United Kingdom.*

Background: Loin pain (LP) is a commonly reported symptom by patients with IgA nephropathy (IgAN). Currently there is little known about the frequency of LP, the impact of LP on quality of life or appropriate strategies to manage LP in IgAN.

Methods: An online pilot survey was developed with input from IgAN patients and the National Registry of Rare Kidney Diseases (RaDaR). The survey recorded demographic, kidney disease, and LP parameters, alongside The Kidney Symptom Score, Short-Form McGill Pain Questionnaire-2, Pain Self-Efficacy Questionnaire, and Brief Illness Perception Questionnaire. A separate semi-structured interview study with patients, carers and healthcare professionals (HCPs) explored experiences of loin pain through thematic analysis.

Results: 366 patient responses were analysed. 261 (71.1%) experienced LP; 28% currently, 33% in the last month, and 39.1% in the past. 70.7% experienced LP at least monthly. 80.5% reported LP as always the same, with 'aching' being the most common descriptor used. LP was associated with a poorer self-perception of mental and physical health, and strongly associated with the presence of systemic symptoms including itching, anorexia, and loss of libido. Only 41.6% could manage their LP with analgesics. 44.7% spoke to HCPs about LP, but 61.7% did not find this helpful. LP affected mobility in 43.9%. 48 interviews were conducted; 21 patients, 14 carers, and 13 HCPs (27% male, 73% female, 70% White British, age range 23-75 years). Five themes were developed in the thematic coding process; 1) 'Achy pain' in the 'kidney area'; 2) Managing LP with limited options; 3) LP as a warning: anxiety of declining kidney function; 4) Impact to daily life dependent on severity; 5) Differing opinions between patients and healthcare professionals.

Conclusions: Loin pain is a common symptom in patients with IgAN, affecting the majority of respondents. It has a negative impact on quality of life and self-perception of physical and mental health. Despite this, options to manage LP in IgAN remain limited, with HCPs having little knowledge or insight into optimal management strategies. Further work is being undertaken to explore these themes in other kidney diseases.

FR-PO871

Conceptual Model of the Patient Experience of IgAN: A Qualitative Literature Review and Model Update

Sarah Knight,[1] Greg Davis,[1] Tamara Al-zubeidi,[1] Sasikiran Nunna,[2] Hema K. Gandhi,[2] Sarah N. Ali,[2] Michelle M. Richardson,[2,3] Dorothee Oberdhan.[2] *[1]Clarivate Analytics UK Limited, London, United Kingdom; [2]Otsuka Pharmaceutical Development and Commercialization Inc, Princeton, NJ; [3]Tufts University School of Medicine, Boston, MA.*

Background: A robust conceptual model (CM) is an essential foundation to inform clinical outcome assessments (COAs) for patient-centered trials in immunoglobulin A nephropathy (IgAN). This study updated a previous CM of adult and pediatric patient experiences of IgAN including disease manifestations, treatment side-effects and impact on functioning and well-being.

Methods: A targeted review of "A Summary of Survey Results and Call to Action from the IgA Nephropathy Foundation", a 2021 IgAN Disease Burden Global Analysis (internal report) and an updated qualitative literature search was conducted to identify patient-reported concepts to update a previous CM. Semantic, qualitative and directed content analysis techniques, aided by ATLAS.tiv9, were used. Relevant concepts were coded and cross-checked against the previous CM and newly identified codes were flagged and evaluated for inclusion into the update. The domains were refined by grouping related concepts, where applicable.

Results: In addition to the two reports, three new studies were identified from the literature review, one of which was the development paper for the previous CM. A comparison of the previous and updated CM is detailed in Table 1. Data sources did not reveal the most salient/bothersome experiences, and a large portion of the new concepts were not reported by age groups.

Conclusions: This updated CM identified new symptoms and impacts of IgAN in adult and pediatric patients that can be used to inform the selection, development and/or amendment of COAs for future IgAN clinical trials. Patient and clinician input is needed to differentiate symptoms and impacts by age groups and to clarify relationships between concepts and domains.

Table 1: Comparison of existing to updated CM

Domains	Previous CM	Updated CM
Disease manifestations	Swelling/puffiness (edema); pain/aches/discomfort; fatigue; weight gain; sleep problems; urinary problems; gastrointestinal problems	Edema locations; hematuria and proteinuria; swollen tonsils and respiratory problems; kidney discomfort and back/flank pain; disrupted sleep; vitamin D deficiency and frequent infections
Impact	Emotional/psychological wellbeing; physical functioning/activities of daily living; social functioning; work/school and relationships	Feeling unequipped to manage disease alone; school attendance; family and friend relationships; diagnosis delay; misdiagnosis or lack of clinician familiarity with IgAN, dietary restrictions, dialysis restrictions and length, shock and regret at prolonged diagnosis

FR-PO872

Implications of Proteinuria Remission on Estimated Glomerular Filtration Rate (eGFR) Trajectory in Patients with IgA Nephropathy in the PROTECT Trial

Hiddo J. Heerspink,[1,2] Vladimir Tesar,[3] Radko Komers,[4] Bruce M. Hendry,[4] Priscila Preciado,[4] Edward Murphy,[4] Brad H. Rovin.[5] On behalf of the DUPRO Steering Committee and PROTECT Investigators. *[1]Department of Clinical Pharmacy and Pharmacology, University of Groningen, Groningen, Netherlands; [2]The George Institute for Global Health, University of New South Wales, Sydney, NSW, Australia; [3]Department of Nephrology, General University Hospital, Charles University, Prague, Czechia; [4]Travere Therapeutics, Inc., San Diego, CA; [5]Division of Nephrology, Ohio State University Wexner Medical Center, Columbus, OH.*

Background: In PROTECT, sparsentan (SPAR) reduced proteinuria and increased the proportion of pts achieving complete proteinuria remission (CR; urine protein excretion [UPE] <0.3 g/d) (31%) vs irbesartan (IRB) (11%). Lower proteinuria and CR are associated with slower kidney function decline in IgAN. To explore this relationship in PROTECT, we determined eGFR trajectories in pts whose proteinuria fell to low levels.

Methods: PROTECT is a randomized, double-blind trial of efficacy and safety of SPAR vs active-control IRB in adults with IgAN at risk of progression to kidney failure despite maximum RASi. In this analysis, 404 randomized pts were pooled and grouped by achievement of CR or UPE <0.5 g/d at any time over 110 wk. Outcomes were absolute (abs) change from baseline (BL) in eGFR at wk 110 and chronic (wk 6 to 110) and total (d 1 to wk 110) eGFR slopes (adjusted for BL UPE).

Results: While BL age, sex, and race were similar in pts achieving low UPE vs those who did not, BL UPE was lower and eGFR higher in the low proteinuria pts (**Table**). The abs decline in eGFR and the loss of eGFR over time were substantially lower in pts with CR or UPE <0.5 g/d vs those who did not achieve these targets.

Conclusions: In IgAN, achievement of low proteinuria is strongly predictive of better long-term kidney function. eGFR preservation was more evident in pts who achieved low proteinuria vs those who did not; notably, in pts who achieved CR, the mean rate of kidney function decline (eGFR chronic slope) was <1.0 mL/min/1.73 m^2/y. As SPAR-treated pts achieved proteinuria remission more frequently vs IRB in PROTECT, this analysis further supports the benefit of SPAR for long-term preservation of kidney function.

Single-Cell Transcriptomics Tracking the Evolution of Cell and Gene Expression in Blood and Urine Cells of a Patient with IgA Nephropathy before, during, and after Therapy

Francesco P. Schena,[1] Monica Limardo,[3] Deborah D'Aliberti,[2] Silvia Spinelli,[2] Rocco Piazza,[2] Vincenzo L'Imperio,[2] Sharon N. Cox.[1] *[1]Universita degli Studi di Bari Aldo Moro, Bari, Italy; [2]Universita degli Studi di Milano-Bicocca, Milano, Italy; [3]ASST-Lecco, Lecco, Italy.*

Background: Longitudinal studies on IgAN patients with active renal lesions at an early stage of the disease using parallel single-cell transcriptomics (scRNA) during therapeutic intervention have never been conducted. Our objective was to investigate transcriptomic variations at a single-cell level in PBMCs and urinary cells before, during, and after therapy.

Methods: The IgAN patient with active renal lesions (E1,C1) was followed up for one year after undergoing 4 months of pulse and oral corticosteroids and supportive therapy. PBMCs and urinary cells were collected at baseline, during therapy (at the 2nd and 4th month), and after 4 months. Cells were processed using a Chromium 10x platform. Libraries were obtained with a Single Cell 3′ Kit followed by sequencing on a Novaseq 6000. Data analysis included read processing with Cell Ranger v. 7.1.0 and Seurat v. 5.0. Unique Molecular Identifiers were regressed out, followed by PCA for dimensionality reduction. UMAP was applied for further reduction and cluster identification using FindNeighbors and FindClusters algorithms. SingleR was used for cell type identification, followed by manual curation. Differentially expressed genes were obtained comparing scRNA profile obtained from 2 healthy control donors using Wilcoxon nonparametric tests.

Results: Laboratory data revealed stable eGFR and progressive reduction of proteinuria (from 1.5 g to 0.2 g/day) after 1 year. scRNA data analysis showed significant transcriptional changes in IgAN, particularly affecting genes associated with B and T cell receptors, as well as the complement cascade. An inversion of the CD4/CD8 ratio and increase in the monocytic fraction were found. Specific changes in gene expression and cell type composition were noted upon treatment and ongoing analysis is evaluating the effect of corticosteroids on urinary cells.

Conclusions: Transcriptional and cell type composition changes were found in PBMCs at a single cell resolution in IgAN, particularly demonstrating specific alterations during corticosteroid therapy.

Investigating Circulating Inflammatory Proteins in IgA Nephropathy: Implications for Disease Progression

Hiroki Kobayashi, Masanori Abe. *Division of Nephrology, Hypertension, and Endocrinology, Nihon University School of Medicine, Tokyo, Japan.*

Background: Immunoglobulin A nephropathy (IgAN), the most common primary glomerulonephritis globally, involves complex inflammatory processes contributing to kidney damage. This study aims to elucidate the relationship between circulating inflammatory proteins and the kidney disease progression of IgAN, and comparing the circulating level of proteins with other autoimmune nephritis.

Methods: This cohort study included 134 Japanese patients with biopsy-proven IgAN, alongside groups with membranous nephritis (MN, n=24), minimal change disease (MCD, n=23), and lupus nephritis (LN, n=23), collected from Nihon University School of Medicine Itabashi Hospital, Tokyo, between 2009-2018. Serum samples were analyzed pre-biopsy for 10 inflammatory proteins (TNF-R1, TNF-R2, LTBR, TNF-R4, TNF-R6B, CD27, TNF-R10A, RELT, EDA2R, and IL-1RT1) that we previously identified as important biomarker for future progression to ESKD in diabetic kidney disease. Kidney function was assessed using eGFR and proteinuria levels, with histological evaluation based on the MEST score.

Results: TNF-R1 and TNF-R2 showed significant increases in all patient groups compared to healthy controls, with statistical significance. For LTBR, TNF-R4, TNF-R6B, TNF-R10A, RELT, and EDA2R, the levels increased with advancing stages in the IgAN group; however, no increase was observed at the normoalbumiuric stage. Additionally, while levels rose in both the MN and Lupus groups, no increase was observed in the MCD group. On the other hand, for CD27, a significant elevation was noted as early as the normoalbumiuric stage compared to healthy controls. Multivariate logistic analysis identified CD27 as an independent predictor of tubular atrophy/interstitial fibrosis in IgAN. Furthermore, TNF-R1, TNF-R2, LTBR, CD27, and EDA2R were significantly associated with the risk of progression to the composite outcome (CKD stage 3, 30% eGFR decline, and ESKD by Cox regression analysis, emphasizing their potential as biomarkers for IgAN progression.

Conclusions: Elevated levels of specific TNFR family proteins and CD27 are strongly associated with IgAN progression, underscoring their utility in predicting kidney function decline. Future studies should focus on these biomarkers for early intervention strategies.

Unsupervised Learning with Network Biomarkers for Risk Stratification in IgA Nephropathy and Its Clinical Implications

Jiaxing Tan. *West China Hospital of Sichuan University, Chengdu, China.*

Background: This study integrated network biomarkers with unsupervised learning clustering (KMN) to refine risk stratification in IgA nephropathy (IgAN) and explore its clinical value, addressing the limitations of existing models that heavily rely on renal indicators and lack therapeutic guidance.

Methods: Involving a multicenter prospective cohort, we analyzed 1,460 patients and validated the approach externally with 200 additional patients. Deeper metabolic and microbiomic insights were gained from two distinct cohorts: 63 patients underwent ultra-performance liquid chromatography-mass spectrometry (UPLC-MS), while another 45 underwent fecal 16s RNA sequencing.

Results: Our study utilized hierarchical and k-means clustering methods, integrating renal, extrarenal, and network biomarkers to analyze a cohort with an average follow-up of 58.8 months. This approach identified four distinct patient clusters, with severity and prognosis worsening from Cluster 1 to Cluster 4. The k-means network biomarker (KMN) method emerged as the most effective, achieving an Area Under the Curve (AUC) of 0.77, significantly outperforming the International IgAN Prediction Tool (IIgAN-PT) and RF-RG schemes, which recorded AUCs of 0.72 and 0.69, respectively. Longitudinal analysis over three years highlighted significant differences across clusters in urinary protein and serum creatinine levels—Cluster 1 exhibited stable kidney function while Cluster 4 showed rapid progression towards renal failure. The KMN stratification facilitated personalized treatment, advocating for ACEI/ARBs for lower-risk groups and immunosuppressive therapy for higher-risk groups. It also revealed potential links between IgAN progression and alterations in serum metabolites and gut microbiota. These findings suggest a correlation, though further research is required to establish causality and deepen our understanding of IgAN's underlying mechanisms.

Conclusions: The effectiveness and applicability of the KMN scheme indicate its substantial potential for clinical application in IgAN management.

FR-PO876

Validation of the Klinrisk Kidney Disease Progression Model in Individuals with IgA Nephropathy

Bryce Barr,[1] Ryan J. Bamforth,[2] Thomas W. Ferguson,[2] Oksana Harasemiw,[2] Ian W. Gibson,[1] Olivier Tremblay-Savard,[1] Navdeep Tangri.[1,2] *[1]University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; [2]Seven Oaks General Hospital, Winnipeg, MB, Canada.*

Background: IgA nephropathy is the most common primary glomerulonephritis worldwide, and leads to kidney failure in a significant proportion of those affected. Recent clinical trials have relied on persistence of proteinuria >1 g/day as the best predictor of poor long-term kidney outcomes, and other tools rely on detailed clinopathologic data which may not be readily available. We sought to validate the Klinrisk prediction model in a population-based cohort of all individuals aged 18 years and older with IgA nephropathy in the Canadian province of Manitoba from 2002 to 2019, inclusive.

Methods: Participants were identified from the Manitoba Glomerular Diseases Registry. Klinrisk is a machine learning model constructed using random forests that uses routinely collected laboratory data to predict the risk of a composite of 40% decline in eGFR or kidney failure, defined as receipt of dialysis for at least 3 months or kidney transplantation. Discrimination was assessed using area under the receiver operating characteristic curves (AUC). Calibration was assessed using Brier scores, and calibration plots to compare predicted with observed risk.

Results: A total of 230 individuals with biopsy-proven IgA nephropathy were included in the analysis. Median age at biopsy was 41.5 years, median eGFR was 51.5 mL/min/1.73m^2, and median ACR was 158 mg/mmol. At 2 and 5 years, 73 and 89 individuals reached the primary outcome, respectively. Model discrimination was good, with an AUC of 0.878 (95% CI 0.830, 0.925) at 2 years and 0.827 (95% CI 0.760, 0.894) at 5 years. Calibration was appropriate, with Brier scores of 0.142 and 0.167 at 2 and 5 years. Visual inspection of the calibration plots showed under-prediction at higher levels of observed risk.

Conclusions: The results demonstrate the utility of the Klinrisk model in predicting kidney failure among individuals with IgA nephropathy. Our results are limited by a small sample size and require confirmation in a separate cohort. If confirmed, Klinrisk could be implemented in a clinical setting to predict individual kidney failure risk to aid treatment decisions, or in a research setting to identify high-risk individuals for participation in clinical trials using routinely available data.

FR-PO877

Analysis of Time to Referral and Kidney Biopsy in IgA Nephropathy in Five European Countries

Philipp Csomor,[1] Meghan Weiss,[2] Justin Snyder,[2] Lucy Santos.[1] *[1]Vifor Pharma Management AG, Glattbrugg, Switzerland; [2]Spherix Global Insights, Exton, PA.*

Background: IgAN is the most common form of primary glomerulonephritis globally, yet time to referral and kidney biopsy is often protracted. This study investigated real-world management of IgAN patients from referral to biopsy in five European countries using a physician questionnaire and patient chart review.

Methods: From 21 Dec 2023 to 31 Jan 2024, physicians from France, Germany, Italy, Spain and the UK completed a questionnaire on IgAN management and a patient chart audit. Physicians were required to have ≥50 CKD stage 1–4 patients, including ≥4 non-dialysis IgAN patients. Patient chart inclusion criteria included ≥13 years of age; non-dialysis IgAN; estimated glomerular filtration rate ≥15 mL/min/1.73 m^2.

Results: 272 physicians completed the questionnaire and chart audits on 514 IgAN patients. 71% of patients were referred to their current physician by a primary care physician and 6% by another nephrologist, of which 24% of these patients were referred for specialised care. For 94% of patients, urine lab and/or blood work results triggered referral. 62% of nephrologists advocate CKD stage 1/2 as the ideal time for referral to specialised care, yet 28% of patients were perceived by their physician as being referred late or extremely late. In the UK, France and Germany, ≥60% of patients were referred to a nephrologist pre-diagnosis, compared with ≤55% in Spain and Italy. 72% of nephrologists agreed that all suspected glomerular disease patients should undergo a biopsy, and few reported having difficulties in ordering or having a biopsy performed; however, 9% of patients are presumed to have IgAN without a confirmatory biopsy. On average, patients had a kidney biopsy 4.1 months after they were referred. For patients biopsied after 6 months or more, reasons for delay included the physician's perception that the patient was not in good enough health for the procedure and that a biopsy was not deemed clinically relevant at the time.

Conclusions: Many physicians perceive that IgAN patients are referred to them late or extremely late. Furthermore, not all suspected IgAN cases receive a timely confirmatory biopsy. This study highlights the need for earlier referrals of IgAN patients and emphasises the need for timely kidney biopsies to confirm diagnosis.

FR-PO878

Follow-Up Kidney Biopsy Might Be a Mandatory Procedure after Treatment in IgA Nephropathy

Byoung-Soo Cho,[1] Won-Hee Cho.[2] *[1]Dr.Cho's Kidney Clinic, Seoul, Republic of Korea; [2]Sahm-Yook General Hospital, Seoul, Republic of Korea.*

Background: IgA nephropathy is one of the most common chronic glomerulonephritis and 30-45% fall into CKD over a period of 20 to 25 years. Lots of therapeutic regimens have been tried such as ARB, ACEi, omega-3, corticosteroids, endothelin inhibitors, Nefecon, complement inhibitors[K1], finerenone, methylprednisolone pulse, SGLT2 inhibitor etc, however need a longterm follow up studies to confirm the efficacy. Disappearance of proteinuria has long been regarded as surrogate marker of treatment effect, however we have reported that disappearance of proteinuria could not be a surrogate marker after treatment (2022 ASN) At this time we compare the pathological changes who showed clinically improved by methylprednisolone pulse therapy in IgAN.

Methods: During last 10 years our clinic performed 1,982 cases of renal biopsy were done, of which 619 cases (31.2%) were IgAN. We performed follow up renal biopsies in 160 cases (25.8%), who showed clinical improvement include normalized urinalysis findings. Follow up renal biopsy findings were divided into 3 groups : group A: improved renal pathology, group B: no significant pathological changes and group C: aggravated pathological finding One cycle of MP pulse therapy consists of MP (20-30mg/kg, max 1gm/day) IV for 3 consecutive days. Depends on the severity, we performed 3-17 cycles every 2 weeks

Results: Male to female ratio were 81:79, Mean ages were 33 years old. Of the 169 follow up cases 83 (51.9%) showed improved pathologically (Group A) such as disappearance of electron dense deposits, restoration of foot processes, decreased mesangial proliferation, 63 cases (39.3%) showed no significant changes (Group B) and 14 cases (8.8%) showed aggravated pathological changes such as increased glomerulosclerosis, tubular atrophy and interstitial fibrosis

Conclusions: Among the 160 cases of clinically improved cases, only 83 (51.9 %) were pathologically improved, Normalized urinary findings could not be a prognostic marker of improved pathology and so group B & C patients need a careful follow up Follow up renal biopsy might be a mandatory procedure to define the efficacy of treatment in IgA nephropathy

FR-PO879

A 10-Year Analysis of IgAN Management in China: Results from the CPO-IGAN Study

Fujun F. Lin,[1] Gengru Jiang,[1] Rong Wang,[2] Chaosheng Chen,[3] Qinkai Chen,[18] Wenge Li,[4] Chang Ying Xing,[17] Niansong Wang,[5] Hongli Jiang,[16] Zhenhua Yang,[6] Yonggui Wu,[7] Ping Fu,[8] Hong Liu,[9] Qiuling Fan,[10] Hen Xue,[11] Guangyu Bi,[12] Qinghong Zhang,[13] Xinjian Li,[14] Siyi He,[15] Bingbing Zhu.[15]

Ltd, Shanghai, China; [16]The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; [17]The First Affiliated Hospital of Nanjing Medical University, Nanjing, China; [18]First Affiliated Hospital of Nanchang University, Nanchang, China.

Background: Nationwide data on the treatment of IgA nephropathy (IgAN) in Chinese patients remains unclear. Clinical Practice Optimization Initiative for Chinese Patients with IgA Nephropathy (CPO-IGAN), the first nationwide project to optimize IgAN clinical practices in China, conducted a 10-year nationwide analysis to assess adherence to evidence-based guidelines.

Methods: This retrospective study recruited biopsy-proven IgAN patients across China from January 2015,age ≥18 years with at least one follow-up after treatment initiation. Demographic factors, comorbidities, laboratory results, renal histology reports and therapeutic regimens were collected from clinical information systems.

Results: By April 2024, 2229 IgAN patients from 33 tertiary hospitals in 12 Chinese provinces had been recruited. Table 1 summarizes the clinical characteristics at the time of renal biopsy.74.3% and 5.4% of patients received RASi and SGLT2i as supportive treatment respectively. As shown in Table 2, SGLT2i use increased after the 2021 publication of the DAPA-CKD IgAN subgroup results.46.0% and 6.2% of patients recevied corticosteroids and MMF, and Figure 1 shows the characteristics of these patients. MMF use increased following the KDIGO 2021 guideline recommending it for Chinese IgAN patients.

Conclusions: Optimized treatment of IgAN in China, including the addition of SGLT2i as the new standard of care needs to be implemented. Accordingly,CPO-IGAN will conduct nationwide training to raise awareness among Chinese nephrologists. Given the high use of corticosteroids and MMF in Chinese IgAN patients, disease progression and long-term prognosis will be analyzed through further longitudinal studies by CPO-IGAN.

Table 1 Characteristics of Patients at the Time of Initial Renal Biopsy (N=2,229)

Characteristics	Description
Age, years

IgA Nephropathy and Impact of Proteinuria Level and CKD Stage on Health Care Resource Utilization in Germany

Thilo Schaufler,[1] Antonio Ramirez de Arellano,[1] Sonali Dasgupta.[2] *[1]CSL Vifor, Glattbrugg, Switzerland; [2]IQVIA Inc, Wayne, PA.*

Background: Proteinuria ≥1.0 g/day is a risk factor for immunoglobulin A nephropathy (IgAN) progression. This study describes the impact of proteinuria level and chronic kidney disease (CKD) stage on healthcare resource utilization (HRU) and costs among patients with IgAN in Germany.

Methods: Eligible patients had ≥1 ICD-9 583.9, ICD-10 N02.8, or ICD-10 N02.9 code between 2015 and 2022. CKD stage was defined by ICD-10 N18 code and estimated glomerular filtration rate. Patients were divided into two subgroups based on proteinuria: <1 g/day and ≥1 g/day. Average HRU costs for in-patient and out-patient visits were calculated based on German Diagnosis-Related Groups Statistic 2022 and published literature. Owing to data unavailability in the German database, emergency visit counts were extrapolated using German base rates updated with costing ratios and patient count ratios from the UK and Spain.

Results: We identified 1,600 patients with IgAN (mean age 58 years, 67% male). For all visit types combined, the mean total cost per patient was >14-fold higher for CKD stage 5 than stage 1 (€57,977 vs €4,046). Mean total cost per patient was >2.5-fold higher with proteinuria ≥1 g/day than with <1 g/day (€5,530 vs €2,154) (Figure 1). Out-patient visits were low compared with other markets and likely underreported. For in-patient and out-patient visits, HRU increased with advancing CKD and higher proteinuria level (Figure 2).

Conclusions: In patients with IgAN in Germany, advanced CKD stage and elevated proteinuria were associated with higher HRU and costs. Treatments that reduce proteinuria can slow disease progression and prevent rapid kidney function decline while potentially reducing IgAN-related HRU and associated costs.

Funding: Commercial Support - CSL Vifor

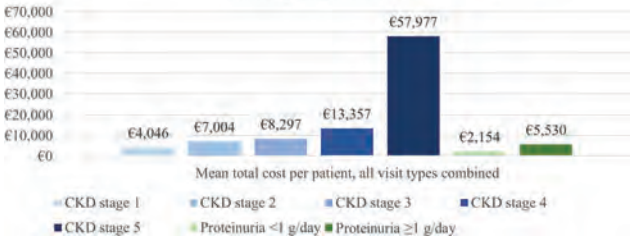

Figure 2. Average number of visits per patient per year, breakdown by chronic kidney disease stage and proteinuria level

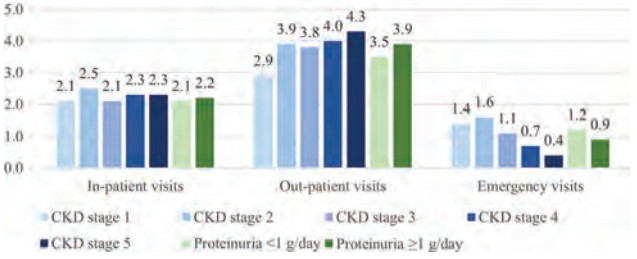

FR-PO881

Impact of Proteinuria Level and CKD Stage on Health Care Resource Utilization among Adults with IgA Nephropathy in Spain

Thilo Schaufler,[1] Antonio Ramirez de Arellano,[1] Sonali Dasgupta.[2] *[1]CSL Vifor, Glattbrugg, Switzerland; [2]IQVIA Inc, Wayne, PA.*

Background: Patients with immunoglobulin A nephropathy (IgAN) and proteinuria ≥1.0 g/day are at increased risk of disease progression. This study assessed the impact of chronic kidney disease (CKD) stage and proteinuria level on healthcare resource utilization (HRU) and costs among patients with IgAN in Spain.

Methods: Patients who were included had ≥1 ICD-9 583.9, ICD-10 N02.8, or ICD-10 N02.9 code recorded between 2015 and 2022. CKD stage was defined by ICD-10 N18 code and estimated glomerular filtration rate. Patients were divided into two subgroups based on proteinuria: <1 g/day and ≥1 g/day. Average HRU costs for in-patient, out-patient and emergency visits were calculated using Official Journal of the Catalan government prices for 2020 and published literature.

Results: 1,080 patients with IgAN (mean age 53 years, 66% male) were identified. The mean total cost per patient with CKD stage 5 was >12-fold higher than for stage 1 (€56,858 vs €4,449). Mean total cost per patient was >2-fold higher with proteinuria ≥1 g/day than with <1 g/day (€5,236 vs €2,449) (Figure 1). Average number of visits per year increased with advancing CKD stage for all visit types, and with higher proteinuria level for out-patient and emergency visits (Figure 2).

Conclusions: In Spanish patients with IgAN, advanced CKD stage and elevated proteinuria were associated with higher HRU and costs across visit types. Interventions to lower proteinuria may help prevent rapid kidney function decline and reduce IgAN-related HRU and costs.

FR-PO882

Combination of Acanthocyturia and Elevated Serum IgA Level for the Diagnosis of IgA Nephropathy

Ayaa M. Zarm, Ana I. Stark, Rosemary Kovacic, Swetha Rani Kanduri, Juan Carlos Q. Velez. Ochsner Group. *Ochsner Medical Center, New Orleans, LA.*

Background: Serum IgA level (sIgA) has been assessed as a clinical test for the diagnosis of IgA nephropathy (IgAN). Its performance has been modest with sensitivity (SENS) and specificity (SPEC) around 65%. However, studies had tested its performance independently of urinary findings. We hypothesized that idenitfication of acanthocyturia by microscopic examination of the urinary sediment (uSEDI) may increase the pre-test probability of IgAN and, therefore, the diagnostic yield of sIgA may improve when utilized in cases where acanthocyturia is present.

Methods: We prospectively collected data of patients seen in nephrology consultation who had a urine specimen subjected to uSEDI as part of the clinical evaluation over a 5-yr period. Within this cohort, we identified cases in which: 1) urinary acanthocytes were identified by uSEDI; 2) a kidney biopsy was perfomed; and 3) sIgA was obtained as part of the diagnostic work up. Normal range of sIga for our hospital laboratory is 40-350 mg/dL. We assessed the diagnostic performance of sIgA.

Results: Among 801 patients assessed by uSEDI, 240 (30%) underwent kidney biopsy. Urinary acanthocytes were identified in 96 (40%), and 49 (51%) had sIgA measured. Mean age was 53 years, 45% women, 71% white and 27% black. Median serum creatinine was 2.2 (0.6-19.2) mg/dL. Diagnosis was IgAN in 22 (24%), pauci immune glomerulonephritis (GN) in 18 (20%), lupus GN in 8 (9%), other proliferative or infection-related GN (IRGN) in 9 (10%), and thin basement membrane nephropathy in 5 (5%). One case was IgA-dominant IRGN. Median sIgA was higher in IgAN or IgA-dominant IRGN than in others (360 vs 253 mg/dL, p=0.012). Using the laboratory normal range, sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of elevated sIgA for identifying IgAN (or IgA-dominant IRGN) were 53%, 68%, 42% and 77%. The AUROC for sIgA for IgAN diagnosis was 0.74 (95% CI 0.59-0.88, p=0.013). The optimal cuttoff was 327 mg/dL. Notably, all IgAN cases were ≥ 230 mg/dL.

Conclusions: sIgA performs modestly as a diagnostic test for IgAN. Adjusting the cutoff to a level within normal range increases the NPV. We suggest that in patients with acanthocyturia, sIgA may be part of the serological work up.

FR-PO883

IgA Nephropathy: A Timeline from Hematuria/Proteinuria to Nephrology Referral and Kidney Biopsy

Zain AlShanableh, Syeda B. Ahmad. *UPMC, Pittsburgh, PA.*

Background: IgA nephropathy (IgAN) is the most common cause of glomerulonephritis with hematuria being its hallmark finding. This study is aimed to look at the time between the development of hematuria and/or proteinuria and nephrology referral as well as time to biopsy.

Methods: We did a retrospective analysis of patients seen at UPMC seen by UPP nephrology who underwent a kidney biopsy from 1/1/20 to 3/13/24. The onset of hematuria and/or proteinuria was noted and compared to when the nephrology referral was made. The time in days between the first nephrology appointment and renal biopsy was also noted. Exclusion criteria were patients with secondary causes of IgA or those not seen by UPP nephrology.

Results: Preliminary data analysis revealed a total of 15 patients that were included. There were 8 men, 7 women, average age 43, 3 Asians and 12 Caucasians/White. Time between onset of hematuria/proteinuria to nephrology referrals ranged from 0 to 3633 days with a mean of 747 days. Whereas time between first nephrology encounter and biopsy ranged from 2 to 815 days with a mean of 149 days.

Conclusions: Recent data from UK registry indicates that patients with IgA nephrology and proteinuria have worse outcomes. With several novel treatments emerging for IgA Nephropathy, early referral and diagnosis is crucial to prevent progression to ESRD.

FR-PO884

Exploring Kidney Function Decline and Proteinuria in IgA Nephropathy: Insights from a Single-Center Study

Joana P. Dias,[1] Vitória V. Paes de Faria,[1] Maria B. Bessa,[1] Rute Carmo,[1] Clara Almeida,[1] Ana Marta Gomes.[1,2] *[1]Unidade Local de Saude de Vila Nova de Gaia/Espinho, Vila Nova de Gaia, Portugal; [2]Universidade do Porto Unidade Multidisciplinar de Investigacao Biomedica, Porto, Portugal.*

Background: IgA nephropathy (IgAN) is the most common form of primary glomerulonephritis and a major cause of CKD worldwide. Reduction in proteinuria is a surrogate end point for IgAN. We aimed to assess demographic, clinical, histologic and analytic characteristics of our population and determine if there was any association with renal function decline.

Methods: Disease progression was classified as the need for dialysis initiation or doubling of creatinine by the end of follow-up. Patients with secondary IgA were excluded. Data were analyzed using parametric and non-parametric tests.

Results: Data on 26 patients were included. Results are shown in image 1. Progressors exhibited significantly lower hemoglobin, albumin and eGFR at diagnosis, and higher mean proteinuria during follow-up. At the last visit, they continued to show significantly lower hemoglobin and eGFR, and higher proteinuria. Non-progressors had higher usage of ACEi and iSGLT2. The linear regression revealed a significant association between mean proteinuria and eGFR (r = -,673, p<0,001).

Conclusions: In our study, progressors had significantly lower renal function at baseline, which could have limited the extent of our intervention. The lower levels of hemoglobin and albumin in progressors align with the expected findings given their reduced eGFR. Additionally, our study shows that progressors experienced higher proteinuria during follow-up, emphasizing the association between poorer kidney function, higher proteinuria and disease progression. Our findings underscore the significance of proteinuria as a predictor of renal function decline in IgAN, aligning with existing literature. Given the retrospective nature of our study and its inherent limitations, such as small sample size and lack of comprehensive exploration of biomarkers, determining the ideal threshold for proteinuria reduction was beyond the scope of this investigation.

	Progressors (n=12)	Non-progressors (n=14)	P value

Nonalbumin Protein-to-Creatinine Ratio in IgA Nephropathy: Clinical and Pathological Correlations

Go Kanzaki, Kotaro Shimoyama, Hideaki Kuno, Saeko Hatanaka, Hirokazu Marumoto, Takaya Sasaki, Kotaro Haruhara, Kentaro Koike, Hiroyuki Ueda, Nobuo Tsuboi, Takashi Yokoo. *Tokyo Jikeikai Ika Daigaku, Minato-ku, Japan.*

Background: Although albuminuria is beneficial for the early detection of kidney disease, it is insufficient for the characterization of tubular and hyperfiltration proteinuria. This study evaluated the non-albumin protein-to-creatinine ratio (NAPCR) in patients with IgA nephropathy, from both clinical and pathological perspectives.

Methods: This study included 59 patients diagnosed with IgA nephropathy via kidney biopsy at our hospital between June 2022 and November 2023. NAPCR (g/gCr) was determined by subtracting urinary albumin (ACR) from urinary protein (PCR). The clinical grade (C-grade) of IgA nephropathy at the time of biopsy was assessed according to the criteria of the Japanese Society of Nephrology (JSN) criteria. Histological severity was classified based on the JSN histological grading criteria or the Oxford classification. Risk stratification for dialysis was determined by combining clinical and histological grades (H-grade) according to the JSN and categorized into low, medium, high, or super-high risk of progression to end-stage kidney disease (ESKD).

Results: he average age of the patients was 48 years (31 males, 53.4%). The mean estimated glomerular filtration rate (eGFR) was 56.3 ml/min/1.73m^2. The average PCR was 0.51 g/gCr, and the ACR was 0.35 g/gCr. Higher NAPCR values correlated with increased clinical and histological severity (Table), whereas PCR did not correlate with histological severity.

Conclusions: NAPCR was significantly associated with clinical and histological severity of IgA nephropathy.

Table. NAPCR and Clinical Pathological Categories

	ALL	NAPCR Grade1	NAPCR Grade2	NAPCR Grade3	p-value
Glomerulosclerosis/global sclerosis (%)	16.2 [0.7-33.9]	8.00 [0.00-15.8]	27.1 [6.79-43.8]	21.7 [0-55-33.3]	0.028

Revisiting Gross Hematuria in IgA Nephropathy in the COVID-19 Era

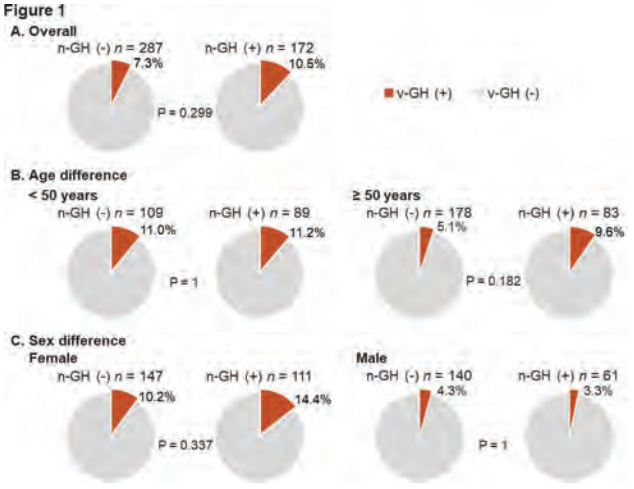
Masahiro Okabe, Nobuo Tsuboi, Saeko Hatanaka, Kotaro Haruhara, Shinya Yokote, Takaya Sasaki, Hiroyuki Ueda, Takashi Yokoo. *Jikei University School of Medicine, Tokyo, Japan.*

Background: Sudden gross hematuria is occasionally observed in patients with IgA nephropathy (IgAN) after COVID-19 mRNA vaccination (v-GH), which is similar to that after acute mucosal infection as part of the natural history of IgAN (n-GH). V-GH and n-GH may share a clinical background or immune mechanism, although the relationship between the development of v-GH and n-GH is not yet clear. Therefore, we aimed to determine the effect of n-GH on the development of v-GH in patients with IgAN.

Methods: Adult patients with IgAN who received COVID-19 mRNA vaccinations were enrolled from four hospitals in Japan. The incidence of v-GH in patients with n-GH was compared with that in patients without n-GH.

Results: Among 459 participants, 287 (63%) did not have a history of n-GH, while 172 (37%) did. Of the patients without n-GH and with n-GH, 21 (7.3%) and 18 (10.5%), respectively, had v-GH, with no statistically significant difference between the groups (Figure 1A). Subgroup analyses demonstrated that this relationship was not changed by age and sex (Figure 1B and 1C). Multivariable analysis including previously reported related factors such as age, sex, and the presence of microscopic hematuria showed no significant association of n-GH with the development of v-GH (Odds ratio 0.89 [95% confidence interval 0.43–1.83]).

Conclusions: Despite some possible similarities in pathogenesis, we failed to demonstrate a clear relationship between v-GH and n-GH, suggesting the involvement of factors specific to each condition. To better understand the pathogenesis of IgAN, further studies are warranted to elucidate the various immunological activation pathways that are commonly or differentially involved in the development of gross hematuria due to infection or vaccination.



FR-PO887

Successful Use of Rituximab in Patients with IgA Nephropathy and Podocytopathy: A Case Series

Mingfang Sun, Dai H. Zi. *Daping Hospital & Research Institute of Surgery, Army Medical University, ChongQing, China.*

Background: IgA nephropathy (IgAN) with podocytopathy is a rare pathological type of glomerular disease. The use of rituximab (RTX) in the treatment of glomerular diseases has increased in recent decades, but the efficacy of rituximab in the treatment of IgAN with podocytopathy has rarely been reported.

Methods: A single-center retrospective study of IgAN patients with podocytopathy who were treated with RTX as second-line therapy was conducted at our center from 2019 to 2022. The aim of this study was to investigate the efficacy and safety of RTX in IgAN patients with podocytopathy.

Results: Seven out of eight patients met the criteria for complete remission following RTX therapy. Only one patient had adverse events (infectious diarrhea and pulmonary infection). Seven patients had complete remission at the time of the last follow-up, and 1 patient experienced relapse six months after RTX therapy. The maximum relapse time after RTX therapy was 20 months, while the maximum relapse-free time before RTX therapy was only 6 months. The number of relapses before RTX therapy (per year) was 1-4; however, seven patients did not relapse and maintained remission at the last follow-up despite steroid withdrawal after RTX therapy.

Conclusions: Overall, RTX effectively reduced proteinuria, increased the maximum relapse-free time and reduced the number of relapses per year and helped patients stop steroid use as soon as possible. RTX also helped most patients achieve clinical remission. RTX appears to be an effective and safe alternative for IgAN patients with podocytopathy with steroid dependance or frequent relapse.

Transcriptome Profiles of IgA Nephropathy after COVID-19 mRNA Vaccination

Satoru Sanada, Kanji Chida, Mitsuhiro Sato. *Japan Community Health Care Organization Sendai Hospital, Sendai, Japan.*

Background: The onset of IgA nephropathy has not been fully understood, however, tonsillitis is known to associate with gross hematuria and disease progression. In the previous several years, we have experienced COVID-19 vaccines which have triggered IgA nephropathy with gross hematuria.

Methods: We assessed the clinical features of 13 patients with vaccine-associated IgA nephropathy. Then we measured RNA expressions of peripheral blood mononuclear cells in patients with tonsillitis-associated (n=3) and vaccine-associated IgA nephropathy (n=3). Differential expression analysis and enrichment analysis were performed.

Results: Most of gross hematuria in vaccine-associated IgA nephropathy occurred within one day after vaccinations and all cases of hematuria appeared after the second and subsequent shot. RNA sequencing identified 76 differentially expressed genes (DEGs) between tonsillitis-associated and vaccine-associated IgA nephropathy, which were enriched in gene ontology terms “MHC protein complex” and “MHC class I protein complex”. DEGs upregulated in tonsillitis-associated IgA nephropathy were related to regulation of T cell activation via T cell receptor contact with antigen bound to MHC molecule on antigen presenting cell. However, the upregulated gene set of vaccine-associated IgA nephropathy was related to positive regulation of T cell activation.

Conclusions: The antigen presenting process could be different between tonsillitis-associated and vaccine-associated IgA nephropathy which may be crucial for their pathogenesis. Immune reaction of antigen presenting cells to extracellular vesicles containing mRNA vaccine could be a key to understand vaccine-associated IgA nephropathy.

FR-PO889

Characterization of Patients with Active Glomerular Inflammation in IgAN: Data from the Adelphi DSP

Briana C. Ndife,[1] Carolina A. Aldworth,[1] Jonathan de Courcy,[2] Emma Chatterton,[2] Jade Garratt-Wheeldon,[2] Richard A. Lafayette.[3] *[1]Novartis Pharmaceuticals Corporation, East Hanover, NJ; [2]Adelphi Group Ltd, Bollington, United Kingdom; [3]Stanford University Department of Medicine, Stanford, CA.*

Background: Immunoglobulin A nephropathy (IgAN), the most common primary glomerulonephritis, is characterized by the deposition of immune complexes in the glomerular mesangium and a multitude of inflammatory responses. Active glomerular inflammation in IgAN is poorly defined. We describe active glomerular inflammation in a real-world, multi-country setting, using MEST-C scores and hematuria.

Methods: Data were drawn from the Adelphi Real World IgAN Disease Specific Programme™, a cross-sectional survey of IgAN-treating physicians, including retrospective data, in China, France, Germany, Italy, Japan, Spain, UK, and the USA, from June–October 2021. Physicians reported data on patient (pt) demographics, MEST-C scores, and clinical characteristics. Analyses were descriptive. Active glomerular inflammation was defined using MEST-C scores at diagnosis of M1, E1, or C1/2 and/or hematuria persisting from diagnosis to survey. Declining eGFR (≥40% reduction from diagnosis to survey) and proteinuria ≥1g/day at survey, despite treatment with supportive care (ACEi, ARB, or SGLT2i), were assessed within the population.

Results: Nephrologists (n=271) completed records for pts who had received supportive care for ≥3 consecutive months during their treatment history (n=1254). Mean (SD) pt age was 43 (14) years, 60% were men, and median (IQR) time since IgAN diagnosis was 2 (1–5) years (n=1201). M1, E1, or C1/2 was reported for 59% (n=741) of pts. Within this population, mean (SD) age was 42 (14), 61% were men, and median (IQR) time since diagnosis was 2 (1–4) years. Proteinuria ≥1g/day despite treatment was noted in 32% (n=239) and declining eGFR in 4% (n=29). 30% had persistent hematuria (n=223). M1, E1, or C1/2 and/or persistent hematuria were reported for 67% (n=837) of pts. Within this population, mean (SD) age was 42 (14), 61% were men and median (IQR) time since diagnosis was 2 (1–4) years. Proteinuria ≥1g/day despite treatment was noted in 31% (n=263), and declining eGFR in 4% (n=31).

Conclusions: IgAN pts with active glomerular inflammation can be identified from pt charts within this dataset, and many pts had multiple indicators of active glomerular inflammation. Further research is needed to improve the treatment and management of IgAN pts and further validate the active glomerular inflammatory phenotype.

Visualization of Remission Status in IgA Nephropathy Using the Multistate Model

Keiichi Matsuzaki,[1] Hitoshi Suzuki,[2] Takashi Sozu,[3] Keita Hirano,[4] Takashi Yasuda,[5] Takashi Yokoo,[4] Yusuke Suzuki.[6] *[1]Department of Public Health, Kitasato University School of Medicine, Sagamihara, Japan; [2]Department of Nephrology, Juntendo University Urayasu Hospital, Urayasu, Japan; [3]Department of Information and Computer Technology, Faculty of Engineering, Tokyo University of Science, Tokyo, Japan; [4]Division of Nephrology and Hypertension, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, Japan; [5]Akihabaraizumi Clinic, Tokyo, Japan; [6]Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan.*

Background: Transition of urinary abnormalities during the clinical course of IgA nephropathy (IgAN) is associated with renal prognosis. We had proposed new criteria for clinical remission in patients with IgA nephropathy (Clin Exp Nephrol, 2014), and reported the association for renal prognosis (Clin Exp Nephrol, 2021). Multi-state model enables the visual interpretation of the transition to each state over time from the multistate transition probability diagram. The aim of study is to estimate the transition probabilities of remission status both hematuria and proteinuria.

Methods: We extracted the 904 Japanese adults patients with biopsy-proven IgAN (male 50.1%, median age 35.0) from the multicenter cohort study which was previously reported (JAMA Netw Open. 2019). Baseline characteristics were evaluated at biopsy, and clinical data including serum creatinine, urinary findings, treatment options were collected at every visit. Multistate-model during 5 years after biopsy was defined using the proposed remission criteria, for patients with hematuria or patients with proteinuria, respectively. Stacked prediction probabilities of remission was calculated at 5 years after renal biopsy.

Results: 824 patients were included in the analysis for patients with hematuria, and 748 patients were included in the analysis for patients with proteinuria. Tonsillectomy was performed for 198 patients with hematuria, and for 179 patients with proteinuria. While the entire cohorts, the stacked prediction probabilities for remission of hematuria was 0.32 and of proteinuria was 0.30. Figure shows that the stacked transition probabilities of remission status by urinary abnormalities and tonsillectomy. In both criteria of hematuria and proteinuria, tonsillectomy derived higher probabilities in remission than without tonsillectomy (hematuria: 0.50 vs 0.26, proteinuria: 0.42 vs 0.26).

Conclusions: In present study, we proposed visualization of the remission status. Tonsillectomy leads to higher remission rate both hematuria and proteinuria.

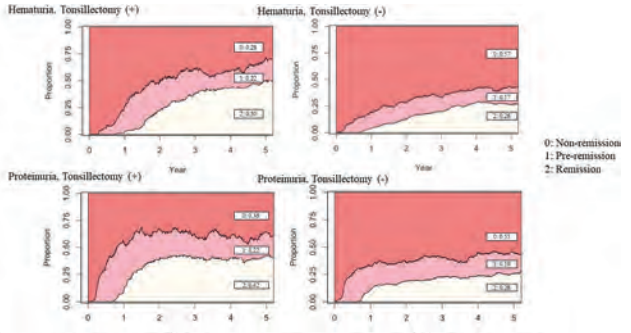

Figure: Stacked prediction probabilities of remission status by urinary abnormalities and with/without tonsillectomy

FR-PO891

Dasatinib Blocks Mesangial Cell Activation by IgA1-Containing Immune Complexes in IgA Nephropathy In Vitro and In Vivo

Zhi qiang Huang, Stacy D. Hall, Joshua C. Anderson, Zina Moldoveanu, Lea Novak, Shihong Qiu, Todd J. Green, Bruce A. Julian, Christopher D. Willey, Jan Novak. *University of Alabama at Birmingham, Birmingham, AL.*

Background: IgA nephropathy (IgAN) is caused by deposition of circulating immune complexes (IC) consisting of galactose-deficient IgA1 (Gd-IgA1) and anti-Gd-IgA1 autoantibodies. These IC activate mesangial cells (MC) and induce kidney injury but the mechanisms of these effects are unknown. We have identified signaling pathways induced in MC by Gd-IgA1-containing IC and targeted them using dasatinib, a broad-spectrum kinase inhibitor.

Methods: IC from sera of patients with IgAN (native IC) or engineered IC formed *in vitro* from polymeric Gd-IgA1 and recombinant IgG autoantibodies in human serum were isolated by size-exclusion chromatography. IC-depleted samples served as controls. In cultured primary human MC, biological activities of native IC or engineered IC were assessed for their capacity to induce cellular proliferation and activate protein-tyrosine kinases, without or with dasatinib in the culture medium. In our passive mouse model of IgAN, nude mice received an intravenous dose of engineered IC (every other day x 3 doses) without or with dasatinib (30 mg/kg/d by gavage; n=5 in each group). Control mice did not receive any IC. Glomerular cellularity was evaluated by quantitative morphometry.

Results: Compared to control samples, native and engineered IC increased proliferation of MC in culture by 4.0±2.2-fold and 2.9±0.7-fold, respectively. Kinomic profiling identified multiple activated signaling pathways. These pathways overlapped and encompassed 20 up-regulated kinases, including signaling pathways involving Src-family kinases and protein-tyrosine kinases in the EGF, VEGF, and PDGF pathways. Several up-regulated kinases, including Syk, Tec, Axl, and Eph, are involved in cellular proliferation or trans-activation of other kinases. Dasatinib inhibited upregulation of these kinases and cellular proliferation. In the mouse model of IgAN, engineered IC increased glomerular cellularity (P<0.0001 vs. control mice); dasatinib prevented these changes (P<0.0001 *vs.* mice given only engineered IC).

Conclusions: Gd-IgA1-containing ICs activated multiple signaling pathways in MC in culture and stimulated cellular proliferation *in vitro* and *in vivo*. Dasatinib blocked these effects, suggesting its potential utility for IgAN treatment.

Histopathological Outcomes and Clinical Correlates of IgA Nephropathy: A 10-Year Single-Center Study of 68 Biopsy-Confirmed Cases in Saudi Arabia

Sultan Al Dalbhi, Asma M. Alotaibi. *Prince Sultan Military Medical City, Riyadh, Saudi Arabia.*

Background: IgA Nephropathy (IgAN) is the most common form of primary glomerulonephritis worldwide, and often leads to cause of end-stage renal disease (ESRD), This study analyzes trends in biopsy-confirmed IgA Nephropathy (IgAN) over a ten-year period and evaluates correlations between clinical/laboratory parameters and histopathological features to identify factors influencing disease progression and patient prognosis.

Methods: A retrospective observational study of 68 biopsy confirmed IgAN cases from 2013 to 2022 was conducted. Correlations between clinical/laboratory parameters and histopathological features were examined using statistical methods, including trend and correlation analysis.

Results: The incidence rate of IgAN showed variability over the years. Significant correlations were found between age, serum creatinine, eGFR, and histopathological features. Age positively correlated with mesangial hypercellularity (p=0.22) and interstitial fibrosis (p=0.12), while serum creatinine positively correlated with mesangial hypercellularity (p=0.04), tubular atrophy (p=0.09), and interstitial fibrosis (p=0.01). eGFR negatively correlated with these features (all p<0.05). The comparison between non-COVID-19 (2013-2019) and COVID-19 (2020-2022) periods showed no significant difference in incidence rates (p=0.158).

Conclusions: This study emphasizes the importance of tailored treatment strategies for IgAN and underscores the need for further research into factors influencing disease progression. The positive correlations between age, serum creatinine, and histopathological severity highlight the need for comprehensive patient monitoring.

Table 1: Annual Incidence Rate of IgA Nephropathy

Year	IgAN Cases	Total Biopsies	Incidence Rate (%)
2013	7	70	10.0
2014	9	80	11.25
2015	8	55	14.55
2016	10	60	16.67
2017	5	95	5.26
2018	7	85	8.24
2019	8	90	8.89
2020	4	50	8.00
2021	6	75	8.00
2022	3	60	5.00

Table 4: Correlation Matrix of Laboratory Parameters and Histopathological Features with p-values

Laboratory Parameter	Mesangial Hypercellularity	Endocapillary Hypercellularity	Segmental Sclerosis	Tubular Atrophy	Interstitial Fibrosis
Serum Creatinine	0.25 (p=0.04)	-0.15 (p=0.22)	0.18 (p=0.13)	0.20 (p=0.09)	0.30 (p=0.01)
eGFR	-0.30 (p=0.01)	0.20 (p=0.09)	-0.22 (p=0.06)	-0.25 (p=0.04)	-0.35 (p=0.00)
Proteinuria	0.15 (p=0.21)	0.10 (p=0.38)	0.12 (p=0.31)	0.18 (p=0.13)	0.22 (p=0.06)
Hemoglobin	-0.10 (p=0.38)	0.08 (p=0.48)	-0.05 (p=0.66)	-0.12 (p=0.31)	-0.15 (p=0.21)

FR-PO893

Comparative Efficacy and Safety of New Therapies for IgA Nephropathy: A Systematic Review and Network Meta-Analysis

Larissa A. Lucena,[1] Deivyd V. Cavalcante,[5] Larissa C. Hespanhol,[2] Caroline C. Balieiro,[3] Pedro Romeiro,[6] Paulo d. Castro,[7] Ocilio d. Ribeiro Gonçalves,[8] Rafael A. Rego,[1] Antonio L. Arruda de Oliveira,[1] Rafael Costa Borges,[1] Luis Claudio Santos Pinto,[4] Rodrigo A. de Oliveira.[1] *[1]Universidade Federal do Rio Grande do Norte, Natal, Brazil; [2]Universidade Federal de Campina Grande, Cajazeiras, Brazil; [3]Universidade do Estado do Amazonas, Manaus, Brazil; [4]Centro Universitario da Amazonia, Belem, Brazil; [5]Universidade Federal do Maranhao, Sao Luis, Brazil; [6]Centro Universitario de Maceio, Maceio, Brazil; [7]Universidade de Sao Paulo, Sao Paulo, Brazil; [8]Universidade Federal do Piaui, Teresina, Brazil.*

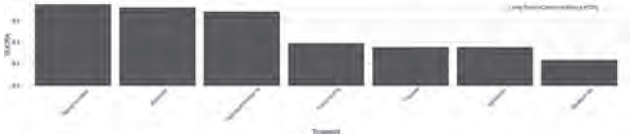
Background: Immunoglobulin A nephropathy (IgAN) can lead to progressive renal dysfunction. This network meta-analysis evaluated novel therapies targeting IgAN's mechanisms, comparing their efficacy and safety to standard care, aiming to optimize clinical management based on current evidence.

Methods: We evaluated 11 randomized controlled trials involving 861 IgAN patients published in the past 10 years. A Bayesian network meta-analysis compared the efficacy of various treatments against placebo, using mean differences and SUCRA values. We searched PubMed, Embase, and Cochrane Central databases to identify studies evaluating primary outcomes: Urine Protein/Creatinine Ratio (UPCR) and estimated Glomerular Filtration Rate (eGFR) change over time.

Results: Mycophenolate (0.754), Atacicept (0.724), and Hydroxychloroquine (0.686) ranked highest in SUCRA values for UPCR reduction. Mycophenolate significantly reduced proteinuria with a mean difference of –0.59 (95% CrI: –1.7, 0.55). Atacicept and Hydroxychloroquine had mean differences of –0.50 (95% CrI: –1.4, 0.38) and –0.46 (95% CrI: –1.6, 0.62). Iptacopan and Budesonide showed limited efficacy, with mean differences of 0.046 (95% CrI: –1.1, 1.2) and 0.17 (95% CrI: –0.60, 0.93). For eGFR preservation, Telitacicept (0.739) (MD 8.1; 95% CrI –6.6, 22.0) and Mycophenolate (0.724) (MD 8.1; 95% CrI –7.3, 23.0) ranked highest, followed by Budesonide (0.712)

(MD 6.5; 95% CrI −1.1, 15.0) and Atacicept (0.550) (MD 4.0; 95% CrI −7.0, 17.0). Hydroxychloroquine (0.436) (MD 2.4; 95% CrI −11.0, 16.0), Iptacopan (0.415) (MD 2.0; 95% CrI −12.0, 16.0), Placebo (0.250), and Fluticasone (0.175) (MD −2.8; 95% CrI −17.0, 11.0) demonstrated lower efficacy in preserving kidney function.

Conclusions: This systematic review and network meta-analysis indicate Mycophenolate and Telitacicept are most effective in reducing UPCR and improving eGFR, suggesting these as preferable treatments for IgAN patients.



FR-PO894

Specificity of Nefecon in Targeting Pathogenic IgA in IgA Nephropathy While Preserving Systemic Humoral Immunity

Roisin C. Thomas, Nadia Nawaz, Jonathan Barratt. *University of Leicester College of Life Sciences, Leicester, United Kingdom*.

Background: Nefecon, an FDA- and EMA-approved targeted-release formulation of budesonide, is recognized for its efficacy in treating immunoglobulin (Ig) A nephropathy (IgAN) by specifically targeting the gut-associated lymphoid tissue (GALT). In the Phase 2b NEFIGAN trial, Nefecon 16 mg/day significantly reduced levels of pathogenic galactose-deficient IgA1 (Gd-IgA1) and IgA-containing immune complexes (IgA-IC) vs placebo, but not IgA1, total IgA, or total IgG. Subsequently, an interim analysis of the larger Phase 3 NefIgArd trial confirmed that Gd-IgA1 ($p<0.0001$) and IgA-IC ($p=0.0169$) were significantly reduced by 9 months of Nefecon 16 mg/day treatment vs placebo. The trial also showed significant proteinuria reduction and kidney function benefit over 2 years with Nefecon vs placebo. Here, we assess the effect of Nefecon on total serum Ig levels in NefIgArd.

Methods: In NefIgArd, patients with IgAN received Nefecon 16 mg/day or placebo for 9 months on top of supportive care, followed by a 15-month observational period off study drug. Enzyme-linked immunosorbent assays (ELISAs) were used to measure serum levels of IgA1, total IgA, and anti-tetanus toxoid antibodies (Nefecon group, n=110; placebo group, n=113), as well as serum levels of total IgG (Nefecon, n=32; placebo, n=38 [at 9 months]). An in-house ELISA was used to measure serum anti-tetanus toxoid Igs; commercial ELISAs were otherwise used. Serum Ig levels were compared between groups at baseline, 3, 6, 9, 12, and 18 months, using unpaired t-tests (significance level $p<0.05$).

Results: There was no significant change from baseline in anti-tetanus toxoid Igs, total IgA, or total IgG levels following Nefecon 16 mg/day treatment for 9 months. There was a slight reduction from baseline in IgA1 at 3 months with Nefecon ($p=0.02$), with no reductions at any other timepoint.

Conclusions: The ability of Nefecon to specifically modulate pathogenic Gd-IgA1 production in the GALT, while leaving systemic IgA responses and total IgA and IgG levels unchanged, supports its use as a generally well tolerated, targeted, locally-acting treatment option for IgAN. Unlike other B cell–directed therapies currently in development for IgAN, Nefecon does not impair systemic humoral immunity and, therefore, offers a therapeutic advantage by selectively reducing pathogenic Gd-IgA1 while preserving overall serum Ig levels.

FR-PO895

The Role of Complement and JAK/STAT Pathway in IgA Nephropathy

Mateus J. Luvizotto, Precil D. Neves, Luis Yu, Lectícia Jorge, Cristiane B. Dias, Viktoria Woronik. *Universidade de Sao Paulo, Sao Paulo, Brazil*.

Background: IgA nephropathy is the most frequent primary glomerulopathy worldwide and an important cause of End-Stage Renal Disease. The pathophysiology of the disease is not very well established and complement-activation pathways is involved in IgAN. JAK/STAT signaling pathway may play an important role in the pathogenesis of the disease.

Methods: A retrospective analysis was performed on all IgAN patients diagnosed by kidney biopsy between 2002 and 2016. Clinical and laboratory data were collected at baseline and at the end of follow up. Kidney tissue sections were stained with antibodies specific for CD68 and for components of JAK-STAT pathway, including JAK2, JAK3, p-STAT and STAT3. As controls 6 renal tumor border tissues were used. CD68 positive cells were quantified in glomeruli and tubulointerstitium and correlated with MEST score.

Results: Clinical features are summarized in Table 1. Mean follow-up time in the study population was 102 months. More than half of patients achieved remission and 31.1% achieved the primary outcome primary outcome that was defined as ESRD or doubling of baseline creatinine. Staining for JAK3 was observed observed in the renal tubule and glomeruli. Staining for JAK3 was enhanced in patients with IgAN compared to controls. Interstitial CD68-positive cells showed correlation with initial and final eGFR, proteinuria and intersticial fibrosis. Logistic regression analysis showed that CD68-positive cells were significantly associated with progression to ESRD and hematuria.

Conclusions: The role of complement and JAK/STAT pathway in IgAN may provide potential targets and rationale for development of targeting therapy of the disease.

Clinical and laboratory data at the time of biopsy and at the end of follow-up

n	63
Age (years)	33.00 [24.50-46.00]

FR-PO896

Urine Complement Activation Products in IgA Nephropathy

Xiaolan Zhang,[1] Li Zhang,[2] Anjali A. Satoskar,[1] Daniel J. Birmingham,[1] Brad H. Rovin.[1] *[1]The Ohio State University Wexner Medical Center, Columbus, OH; [2]The First Hospital of Jilin University, Changchun, China*.

Background: Complement activation appears to play an important mechanistic role in kidney injury in IgA Nephropathy (IgAN). In most patients with IgAN overt systemic complement consumption is not observed as measured by levels of serum complement components C3 and C4. To evaluate the possibility that complement activation occurs primarily within the kidney in IgAN we tested patient urine samples for the presence of complement activation products (CAPs), and correlated levels with the Oxford MEST-C score to determine the relationship of CAPs with kidney injury.

Methods: Serum and spot urine samples were collected from 80 IgAN patients at the time of diagnostic kidney biopsy and 29 healthy volunteers. Biopsies were classified by the Oxford MEST-C score. The CAPs assessed were fragment Ba that is generated during activation of the alternative pathway (AP), C5a, and the terminal pathway membrane attack complex C5b-9. These were measured by ELISA (C5a and C5b-9) or EIA (Ba). ANOVA, nonparametric Wilcoxon test, and multiple linear regressions were done using JMP17 pro for data analysis.

Results: Ba, C5a and C5b-9 did not correlate with serum C3 or C4 levels. Ba, C5a, and C5b-9 were 98, 44, and 2600-fold higher, respectively in the urine of IgAN patients than healthy individuals ($p<0.0001$ for all). C5a measured in IgAN patient serum collected at the same time as urine (n=40) showed no relationship with urine C5a. Although urine C5a and urine C5b-9 did not correlate with any MEST-C component, the level of urine Ba increased 1.6 and 6.4-fold in patients with T1 and T2 Oxford MEST-C lesions, compared to patients with T0 lesions ($p=0.0005$). Similarly, compared to patients with S0 lesions, Ba was 4.6-fold higher in patients with S1 lesions ($p=0.0004$). Interestingly Ba did not correlate with M, E, or C lesions. Ba increased with decreasing eGFR ($R^2=0.35$, $p<0.0001$).

Conclusions: CAPs are found in the urine of patients with IgAN. The lack of association of simultaneously collected urine and serum C5a, and the large molecular mass of C5b-9 suggest CAPs appearing in the urine of IgAN patients are due to intra-renal complement activation. Unexpectedly, CAPs did not correlate with the inflammatory components of MEST-C score. Ba, a marker of AP activation, did however associate with chronic damage in IgAN, perhaps suggesting a role for the AP in mediating kidney fibrosis.

Serum GDF15 Could Predict Cardiorenal Prognosis in Patients with IgA Nephropathy

Hong Cheng, Ziwei Wei, Weiyi Guo, Xiao-yi Xu, Guo-qin Wang, Li-jun Sun, Hong-rui Dong, Lingqiang Kong. *Beijing Anzhen Hospital Affiliated to Capital Medical University, Beijing, China*.

Background: To investigate the correlation between serum GDF15 and the clinical and pathological characteristics of patients with immunoglobulin A nephropathy (IgAN) and further explore its relationship with the cardiac and renal prognosis of IgAN patients.

Methods: This study enrolled 104 patients who were diagnosed with primary IgAN at our center from January 2018 to December 2022 and were regularly followed up for at least one year. Serum GDF15 was measured, and the correlation between serum GDF15 and the clinical and pathological characteristics of patients with IgAN at the time of renal biopsy was analyzed. Furthermore, the relationship was analyzed between the serum GDF15 and the cardiac and renal prognosis of patients with IgAN.

Results: We found that serum GDF15 levels were positively correlated with 24h urinary protein quantification ($r=0.405$, $P<0.001$), negatively correlated with eGFR ($r= -0.606$, $P<0.001$), and were higher in patients correlated with tubular atrophy or

interstitial fibrosis, crescent-shaped lesions, and intrarenal arteriolar lesions. The median GDF15 825.60 pg/ml was used as the cut-off value to divide IgAN patients into a high-level GDF15 group (Group High, n= 52) and a low-level GDF15 group (Group Low, n=52). Compared to Group Low, IgAN patients in Group High presented with had a higher proportion of diabetes mellitus (P=0.002) and basic cardiovascular disease (P=0.005), had higher levels of systolic blood pressure (P=0.019023), BMI (P=0.031), initial urinary proteins (P<0.001), blood creatinine (P<0.001), blood total cholesterol (P=0.045), complement C4 (P=0.008), and left ventricular mass index (P=0.008), while having lower levels of blood albumin (P=0.002) and eGFR (P<0.001). Moreover, the cardiac and renal prognosis was significantly worse in patients of Group High (P=0.002).

Conclusions: High serum GDF15 levels correlated with disease severity in IgAN, and high serum GDF15 levels may suggest a poorer cardiorenal prognosis in IgAN patients.

FR-PO898

Comparative Proteomic Analysis of Laser Microdissected Glomeruli and Tubules in IgA Nephropathy

Kazuo Takahashi,[1,2] Yudai Tsuji,[1] Sei Saitoh,[3] Yukako Ohyama,[1,2] Masaya Hirayama,[1,4] Naotake Tsuboi.[2] *[1]Department of Biomedical Molecular Sciences, Fujita Health University School of Medicine, Toyoake, Japan; [2]Department of Nephrology, Fujita Health University School of Medicine, Toyoake, Japan; [3]Department of Disease Systems Analysis Medicine, School of Medical Sciences, Fujita Health University, Toyoake, Japan; [4]Department of Morphology and Diagnostic Pathology, School of Medical Sciences, Fujita Health University, Toyoake, Japan.*

Background: IgA nephropathy (IgAN) is the most common glomerulonephritis worldwide, and 30–40% of cases progress to end-stage kidney disease. Although the glomerular mesangium is the leading site of IgA deposition in IgAN, tubulointerstitial lesions vary among patients. A new workflow for laser capture microdissection coupled with mass spectrometry (MS) was developed. Using this workflow for glomeruli and tubules, we attempted to detect molecules associated with the pathogenesis and disease progression in IgAN.

Methods: Using the treatment protocol for IgAN at the Fujita Health University Hospital, patients with IgAN were divided into immunosuppressive (tonsillectomy and steroid pulse therapy, n=19) and conservative (n=14) therapy groups. Glomerular and tubular cross-sections were microdissected from stored formalin-fixed paraffin-embedded kidney biopsy tissues and control kidney tissues (n=10) purchased from OriGene Technologies. Samples were analyzed using liquid chromatography-mass spectrometry, and the relative amounts of glomerular and tubular proteins were compared between the groups.

Results: Glomerular proteomic analysis quantified 1807 proteins, of which 85 had significantly different abundances in patients with IgAN than in controls. Comparing the different treatment groups of patients with IgAN, 78 proteins showed significantly different abundances. These proteins are mainly a part of the complement system and are a group of extracellular matrix proteins. Tubular proteomic analysis quantified 2354 proteins, of which 73 were significantly differentially expressed between patients with IgAN and controls. When comparing the different IgAN treatment groups, 75 proteins showed significantly different abundances. These proteins include extracellular matrix and epithelial-mesenchymal transition proteins.

Conclusions: Using LMD-coupled MS, we demonstrated that the complement system in the glomerular lesion and the epithelial-mesenchymal transition system in the tubular interstitial lesion differed between different treatment groups. Investigating the relationship between these molecules and kidney prognosis is crucial for discovering new biomarkers to determine kidney prognosis.

Efficacy and Safety of Dapagliflozin in the Treatment of Adult Primary IgA Nephropathy: A Single-Center, Prospective, Open, Randomized Controlled Study

Xiao Fei, Wang Ling, Dai H. Zi. *Department of Rheumatology and Clinical Immunology, Daping Hospital, Army Medical University (Third Military Medical University), Chongqing, China.*

Background: Despite optimized renin-angiotensin-aldosterone system (RAAS) inhibition, 20 % ~ 40 % of immunoglobulin A nephropathy (IgAN) patients will progress to end-stage renal disease within 10 ~ 20 years after diagnosis. We evaluated the efficacy and safety of dapagliflozin, when added to the treatment regimen of patients with IgAN.

Methods: Participants had IgAN proven by kidney biopsy(proteinuria with protein excretion of 0.3-3.5 g/d, serum albumin > 30g/L and estimated glomerular filtration rate(eGFR)) > 30 mL/min/1.73 m^2) and were receiving optimized RAAS inhibitor therapy. Patients were randomly assigned 1:1 to receive daily oral dapagliflozin or not for 6 months. The primary outcome was percentage change in 24-hour urine protein excretion(24HUPE), first-morning urine albumin-creatinine ratio (UACR) between baseline and 6 months.

Results: 60 participants (mean eGFR, 83.17 mL/min/1.73 m2; median 24HUPE 0.77 g/d; median UACR 636mg/g.Cr) were recruited and randomly assigned to receive dapagliflozin(n = 30) or not (n = 30). Percentage change in 24HUPE at 6 months was significantly different between the dapagliflozin group and the control group (45.8% [inter quartile range (IQR), 65.2%, 4.2%] vs 10.1% [IQR, –46.1%, 53.1%]; P < 0.05, respectively). At 6 months, median 24HUPE level was significantly lower in the dapagliflozin group than control group (0.35 [IQR, 0.18, 0.75] g/d vs 0.62 [IQR, 0.37, 1.21] g/d; P < 0.05, respectively). The change trend of UACR was the same as that of 24HUPE. No serious adverse events were recorded during the study in either study group.

Conclusions: Dapagliflozin in addition to optimized RAAS inhibition significantly reduced proteinuria in patients with IgAN over 6 months without evidence of adverse events. These findings require confirmation in larger treatment trials.

FR-PO900

Analysis of Clinical Risk Factors of Prognosis in IgA Nephropathy Based on Machine-Learning Approaches

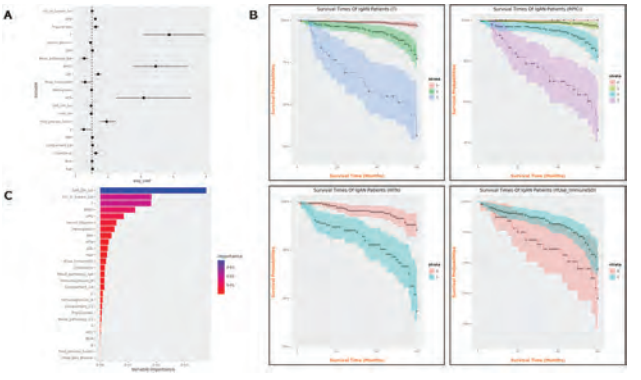
Qin Zhu. *Hangzhou Hospital of Traditional Chinese Medicine, Hangzhou, China.*

Background: Immunoglobulin A nephropathy (IgAN) is one of the leading causes of end-stage kidney disease (ESKD). Many studies have shown the significance of pathological manifestations in predicting the outcome of patients with IgAN. Evaluating prognosis by using baseline clinical characteristics is beneficial for both clinicians and patients.

Methods: A dataset of 892 patients with IgAN is used to develop prediction model for estimating the prognosis of patients with IgAN based on the cox regression and random forest algorithm. The 5-year ESKD prediction models using clinical variables were developed to evaluate the probability of ESKD or doubled serum creatinine(Scr). Cross-validation were implemented to mitigate bias, while the area under the receiver operating characteristic curve (AUROC) was used for model evaluations.

Results: For the 5-year ESKD prediction model, the base model achieved an AUROC of 0.86 (95% CI: 0.75–0.97). Six clinical factors exhibited statistical significance ($p < 0.05$) in predicting IgAN prognosis: BMI (HR: 1.025, 95% CI: 1.003-1.047, p = 2.25×10–2), cholesterol (HR: 1.24, 95% CI: 1.097-1.398, p = 5.42×10–4), and T in Oxford classification (HR: 2.747, 95% CI: 1.573-4.797, p = 3.79×10–4) were identified as risk factors, while estimated glomerular filtration rate (eGFR) (HR: 0.964, 95% CI: 0.947-0.982, p = 1.16×10–4), use of immunosuppressive drugs (HR: 0.498, 95% CI: 0.264-0.941, p = 3.19×10–2), and renal pathology IgA (HR: 0.603, 95% CI: 0.386-0.940, p = 2.57×10–2) exhibited a protective effect against ESKD or doubled Scr.

Conclusions: A prediction model incorporating clinical characteristics was constructed to estimate prognosis in patients with IgAN. The findings suggest that BMI, cholesterol, and T score in Oxford classification increase the risk of ESKD or doubled Scr, while higher eGFR, immunosuppressive drug use, and renal pathology IgA confer a protective effect. Further validation through randomized controlled trials is warranted to corroborate these findings.



FR-PO901

Serum MCP-1 and TGF-β as Biomarkers of Immunosuppressive Treatment Effectiveness in IgA Nephropathy

Junseok Jeon,[1] Younmin Yoon,[2] Kyungho Lee,[1] Jung eun Lee,[1] Wooseong Huh,[1] Hye Ryoun Jang.[1] *[1]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; [2]Chosun University Hospital, Chosun University School of Medicine, Gwang-ju, Republic of Korea.*

Background: IgA nephropathy (IgAN) is the most common form of glomerulonephritis, and a significant proportion of patients progress to end-stage kidney disease. Predicting patient prognosis and response to immunosuppressive therapy is crucial for proper management. We aimed to investigate the clinical factors and biomarker for response to immunosuppressive therapy in patient with IgAN

Methods: This retrospective study included adult patients who were diagnosed with biopsy-proven IgAN between 2010 and 2020. Study variables included clinical and pathological variables and biomarkers, including serum and urine MCP-1, RANTES, TGF-beta, and VEGF, and tissue CD45+ cells. Outcome was the good prognosis defined as urine protein to creatinine ratio (uPCR) ≥ 50% reduction or < 0.5 mg/mg and estimated glomerular filtration rate (eGFR) ≥ 60 mL/min/1.73 m2 or decrease < 5 mL/min/1.73 m^2 at one year from the kidney biopsy.

Results: Mean age, eGFR, and uPCR were 44.3 ± 12.7 and 42.0 ± 13.3 years; 56.9 ± 29.4 and 68.6 ± 30.7 mL/min/1.73 m^2; 2.1 ± 1.6 and 1.6 ± 1.6 mg/mg in the control and gool prognosis groups, respectively. A good prognosis at one year is a good reflection of long-term renal outcomes. High body mass index, no hypertension, high eGFR, low uPCR, low histologic grade, and immunosuppressive therapy were predictors of good prognosis. After adjusting with clinical and pathological variables, lower serum MCP-1 and higher serum TGF-β were associated with good prognosis in patients with immunosuppressive therapy, but not with conservative therapy. The proportion of CD4+ cells were not associated with prognosis in patients with immunosuppressive therapy.

Conclusions: Immunosuppressive therapy was associated with good prognosis in patients with IgAN, although there may be selection bias. Serum MCP-1 and TGF-β have the potential to be biomarkers for the effectiveness of immunosuppressive therapy in patients with IgAN.

Novel Serodiagnostic Biomarkers for IgA Nephropathy Using Matrix-Assisted Laser Desorption Ionization-Time of Flight (MALDI-TOF) Mass Spectrometry Glycoprofiling of IgA1

Shigeaki Nakazawa,[1] Jan Novak,[2] Norio Nonomura,[1] Yoichi Kakuta.[1]
[1]Osaka Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Suita, Japan; [2]The University of Alabama at Birmingham, Birmingham, AL.

Background: IgA nephropathy (IgAN) is one of the most common primary glomerulonephritides worldwide, with many patients progressing to kidney failure. IgAN is characterized by IgA1 glomerular immunodeposits enriched for galactose-deficient IgA1 glycoforms (Gd-IgA1). Human IgA1 hinge region contains 3-6 clustered *O*-glycans, and patients with IgAN have elevated serum levels of Gd-IgA1. Gd-IgA1 glycoforms have *N*-acetylgalactosamine (GalNAc) residues exposed and available for binding by a GalNAc-specific lectin (e.g., from *Helix pomatia*; HPA). These Gd-IgA1 glycoforms can be also recognized by autoantibodies specific for Gd-IgA1, resulting in the formation of nephritogenic immune complexes. Previously, we comprehensively analyzed IgA1 *O*-glycan profiles using MALDI-TOF mass spectrometry (MS). We determined that IgAN patients have elevated serum levels of Gd-IgA1 and that these glycoforms have reduced number of Gal residues. In this study, we assessed whether the IgA1 *O*-glycan profiling can provide diagnostic-level data for IgAN.

Methods: Kidney-transplant recipients who underwent transplantation at Osaka University Transplant Group from 2013 to 2024 were recruited, with kidney donors serving as controls. The volunteers were divided into two cohorts: a discovery cohort (n=85) and a validation cohort (n=46). Serum IgA was isolated, digested with trypsin, and the released IgA1 hinge-region glycopeptides were isolated and analyzed by MALDI-TOF MS on a BRUKER Ultraflex instrument. An IgAN-MS index was calculated using multiple regression analysis based on the relative representation of specific glycoforms of IgA1 hinge-region glycopeptides. A cut-off value was determined by ROC curve analysis in the discovery cohort, and the diagnostic ability was tested in the validation cohort.

Results: In the discovery cohort, setting a cut-off value of 0.38 yielded a high diagnostic performance with an AUC of 0.89. This diagnostic performance was confirmed using the validation cohort, with a sensitivity of 72% and specificity of 68%.

Conclusions: In summary, analysis of IgA1 *O*-glycoforms by MALDI-TOF MS represents a novel, noninvasive biomarker for IgAN that can provide another level of information in addition to kidney-biopsy evaluation.

Urinary Proteomics Identify Biomarkers for Predicting Complete Remission of Proteinuria in Pediatric IgA Nephropathy

Jianmei Zhou, Xuhui Zhong, Jie Ding. *Peking University First Hospital, Beijing, China.*

Background: This study aimed to identify urinary biomarkers for predicting complete remission (CR) of proteinuria in pediatric IgAN.

Methods: We enrolled pediatric patients with biopsy-proven IgAN from the Registry of IgA Nephropathy in Chinese Children (RACC, NCT03015974). Patients were divided into CR (defined as 24-hour urinary protein ≤200 mg/d or protein:creatinine ratio ≤200 mg/g) group and non-complete remission (NCR) group, according to whether they achieved CR within 6 months after the baseline. We profiled the proteome of baseline urine samples with data-independent acquisition mass spectrometry. Based on three machine-learning algorithms (including least absolute shrinkage and selection operator, random forest, and support vector machine), the biomarkers with the best ability to distinguish between CR group and NCR group were selected. The added value of these biomarkers on the clinical-pathological parameters were evaluated. The enrichment analysis for differentially expressed proteins were used to analyze the biological process associated with CR of proteinuria.

Results: A total of 48 children were enrolled, including 34 children in the CR group and 14 children in the NCR group. The urine proteomics quantified a total of 1,721 proteins in baseline urine samples. The following four urinary biomarkers with the best predictive performance were identified: complement component C8 alpha chain, pigment epithelium-derived factor, tyrosine-protein kinase Yes and ribonuclease P protein subunit p38. Compared with clinical-pathological parameters alone, the addition of the new biomarkers on the clinical-pathological parameters significantly increased the predictive accuracy for CR of proteinuria (AUC from 0.819 to 0.969, P<0.001). The differentially expressed proteins between the two groups were mainly enriched in the complement coagulation pathway, regulation of actin cytoskeleton, regulation of apoptosis, and etc.

Conclusions: The addition of the new urinary biomarkers identified by urine proteomics on the traditional clinical-pathological parameters could significantly improve the model fit for predicting CR of proteinuria in pediatric IgAN, thus helping achieve accurate prediction. Proteinuria remission might be associated with complement and coagulation pathway, regulation of actin cytoskeleton, regulation of apoptosis, and etc.

IgA Nephropathy (IgAN) in Pediatric Patients: A Kidney Health Initiative (KHI) Artificial Intelligence (AI)-Assisted Literature Review

David T. Selewski,[1] Eleanor M. Kerr,[8] Cecile Fajardo,[10] Barbara S. Gillespie,[13] Sai Prasad N. Iyer,[9] Myda Khalid,[3] Radko Komers,[4] Koichi Nakanishi,[5] Raoul D. Nelson,[6] Jun Oh,[7] Lokesh N. Shah,[10] Nicholas J. Webb,[12] Xuhui Zhong,[11] Howard Trachtman.[2] KHI Pediatric IgA Nephropathy Work Group.
[1]Medical University of South Carolina, Charleston, SC; [2]University of Michigan, Ann Arbor, MI; [3]Indiana University, Bloomington, IN; [4]Travere Therapeutics Inc, San Diego, CA; [5]University of the Ryukyus, Nishihara, Japan; [6]University of Utah Health, Salt Lake City, UT; [7]Universitat Hamburg, Hamburg, Germany; [8]Ripple Effect, Rockville, MD; [9]SeaStar Medical, Denver, CO; [10]Otsuka America Inc, San Francisco, CA; [11]Peking University, Beijing, China; [12]GSK plc, Brentford, United Kingdom; [13]University of North Carolina, Chapel Hill, NC.

Background: With proteinuria as an accepted reasonably likely surrogate endpoint in IgAN, availability of accelerated approval of new therapies has resulted in a surge of randomized clinical trials (RCT) for adults. There is a need to characterize the disease in pediatric patients and define a regulatory pathway for approval of new therapies in this age group. The KHI convened a work group to address this knowledge gap and conducted an AI-supported literature review of pediatric IgAN to determine similarities and differences in children and adolescents vs adults.

Methods: Published literature through 2023 was compiled using DistillerSR software and reviewed manually in a 2-step process by title, abstract, and full text if needed. Articles that combined adult and pediatric patients without the ability to analyze pediatric patients separately, that did not report IgAN as a separate entity, had a sample size less than 10, case reports, reviews, duplicate reports, and articles that focused on IgA vasculitis were excluded. Relevant content was extracted using Elicit, an artificial intelligence tool, validated, and reviewed by the work group.

Results: 84 articles were included after preliminary review and classified into the following subgroups: Natural History/Epidemiology (n=41), Clinical Trials (n=10) and Biomarkers (n=33). Prompts were engineered for use in the AI extraction tool, allowing for systematic extraction of study characteristics, e.g., study design, trial region, sample size, patient characteristics, and outcome measures. Analysis of the papers is underway and is anticipated to be completed by August 2024.

Conclusions: AI-supported methods provide a novel strategy for future extensive literature reviews. They can identify in-scope articles, extract and expedite the review of large amounts of relevant data, and foster wider application in clinical research. The KHI-sponsored project will identify areas of similarity and difference regarding the clinical course, response to therapy, and clinically relevant endpoints in pediatric vs adults with IgAN to guide extrapolation of data from adults with IgAN to affected children and facilitate the performance of RCT in the pediatric age range.

FR-PO905

Profiles of IgA Deposition and Patterns in Kidney Diseases

Jiarong Song,[1,2] Xuejing Zhu,[1,2] Shuguang Yuan,[1] Hong Liu,[1,2] Yifu Li.[2,3]
[1]The Second Xiangya Hospital of Central South University Department of Nephrology, Changsha, China; [2]Institute of Nephrology, Central South University, Changsha, China; [3]The Second Xiangya Hospital of Central South University Center for Medical Research, Changsha, China.

Background: IgA is the most abundant type of antibodies in human body. It involved in the susceptibility of mucosal pathogens in celiac disease, inflammatory bowel diseases and certain kidney diseases. Kidney biopsy with dominant or co-dominant mesangial IgA

staining is required for diagnosis of IgA nephropathy (IgAN). However, there are IgA depositions or not in other kidney diseases or its pattern was not fully understood.

Methods: This retrospective study reviewed the renal biopsy records between August 2011 and November 2022 from a single medical center in Changsha, China. Relevant clinical and histological records were documented for standard diagnosis. Grouping the IgA deposit patterns as "Mesangial area only", "Glomerular capillary loops only" and "co-staining" were based on immunofluorescence staining records, which summarized the IgA deposition and pattern profiles in kidney diseases.

Results: Totally 12,205 cases of renal biopsy were performed in the period. Finally 12,102 cases were enrolled for analysis after removal of the cases with incompleted data. 7,040 of 12,102 cases (58.17%) had IgA positive staining. Among them, 4,034 cases (57.30%) were diagnosed as IgAN. The most common IgA staining positive diseae is IgAN (100%), IgA vasculitis nephritis (95%), Lupus nephritis (75%), and HBV-associated nephropathy (60%), see detail in Table 1. The IgA deposition pattern differnece had been noted in major IgA associated disease (Table 2).

Conclusions: Mesangial IgA deposition is a histopathologic hallmark of IgAN, however, IgA deposits in kidney is also common in some IgA associated diseases such as IgAVN, LN and HBVAN. Whether deposition intensity and patterns of IgA is associated with hetergenous clinical phenotypes needs further investigation.

Table 2. IgA deposition patterns in major IgA associated kidney diseases

Pattern	IgAN	IgAVN	LN	HBVAN
Mesangial area only	3389(84.01%)	346(77.93%)	81(13.48%)	182(53.37%)
Glomerular capillary loops only	0	7(1.58%)	220(36.61%)	75(21.99%)
co-staining	645(15.99%)	91(20.50%)	300(49.92%)	84(24.63%)

Table 1 IgA deposition rates in different kidney diseases

Diseases	IgA deposits	Total cases	Positive rate
IgA nephropathy(IgAN)	4034	4034	1.00
IgA vasculitis nephritis(IgAVN)	444	466	0.95
Lupus nephritis(LN)	601	804	0.75
HBV-associated nephropathy (HBVAN)	341	572	0.60
Endocapillary proliferative glomerulonephritis (EPGN)	36	80	0.45
Membranous nephropathy(MN)	571	1761	0.32
Membranoproliferative glomerulonephritis(MPGN)	52	165	0.32
Diabetic kidney disease	140	467	0.30
Renal amyloidosis	57	224	0.25
IgM nephropathy(IgMN)	14	56	0.25
Anca associated vasculitis(AAV)	14	58	0.24
Minimal change disease (MCD)	221	917	0.24
Focal segmental glomerulosclerosis (FSGS)	262	1437	0.18
Monoclonal immunoglobulin deposition disease (MIDD)	10	200	0.05

FR-PO906

Sparsentan (SPAR) in Combination with SGLT2 Inhibitors (SGLT2i) in Patients with IgA Nephropathy (IgAN): A Case Series

Prasanth Ravipati,[1] Gates Colbert,[2] Sarah J. Evans,[3] Agness Pelts Block,[4] Christopher Gisler,[4] Renuka Sothinathan.[5] *[1]University of Nebraska Medical Center, Omaha, NE; [2]Texas A&M College of Medicine, Dallas, TX; [3]DuBois Nephrology Associates, DuBois, PA; [4]Travere Therapeutics, Inc., San Diego, CA; [5]Virginia Nephrology Group, Arlington, VA.*

Introduction: SPAR is a nonimmunosuppressive, dual endothelin angiotensin receptor antagonist (DEARA) that is approved in the US and EU for adults with IgAN at risk of rapid disease progression. Previously reported evidence from a small number of pts with IgAN in the PROTECT open-label extension study support an additive benefit in proteinuria reduction with an SGLT2i added to SPAR, but evidence on the combination treatment in the real-world setting is limited. Here we report a series of 4 pts with IgAN receiving SPAR in combination with an SGLT2i.

Case Description: Four pts with biopsy-proven IgAN (aged 29-62 y) received SPAR (400 mg/d; dose increased from 200 mg/d after 2 weeks [or at closest follow-up visit]) in combination with the SGLT2i dapagliflozin. Individual case details are summarized in the **Table.** Three pts received prior steroid/immunosuppressive treatment (tx; alone or in combination with a renin-angiotensin system inhibitor [RASi]); 1 pt received a prior RASi (losartan) alone. Duration of follow-up on SPAR tx ranged from 3 to 7 mo, with all pts still receiving SPAR + SGLT2i combination tx at last follow-up. A decrease in proteinuria (urine protein-to-creatinine ratio [UPCR]) was seen in all pts regardless of eGFR at initiation. One pt achieved complete remission of proteinuria (UPCR <0.3 g/g) after 3 mo of SPAR + SGLT2i tx. In all pts, proteinuria improved to a greater extent with SPAR + SGLT2i than it had from diagnosis to the end of previous treatment. All pts had hematuria at SPAR initiation; it resolved in 1 pt after 8 mo on SPAR + SGLT2i. Blood pressure was generally stable with the combination tx. SPAR + SGLT2i tx was generally well tolerated, with no liver function test elevations.

Discussion: This case series supports the safety and efficacy of SPAR in combination with the SGLT2i dapagliflozin in pts with IgAN; improvements were observed in proteinuria regardless of eGFR or UPCR at SPAR initiation. Cases also highlight an additive benefit of SPAR, with greater proteinuria improvements achieved with SPAR + SGLT2i than previous treatment.

Table. Case Summaries

Sparsentan (SPAR) in Patients with Prior or Concurrent Immunosuppressive Treatment (IST) for IgA Nephropathy (IgAN): A Case Series

Luis E. Velez,[1] Reva Siva,[2] Agness Pelts Block,[3] Christopher Gisler,[3] Pablo Garcia.[4] *[1]South Texas Renal Care Group, San Antonio, TX; [2]Virginia Nephrology Group, Arlington, VA; [3]Travere Therapeutics, Inc., San Diego, CA; [4]University of New Mexico School of Medicine, Division of Nephrology, Albuquerque, NM.*

Introduction: SPAR is a nonimmunosuppressive, dual endothelin angiotensin receptor antagonist (DEARA) approved in the US and EU for the treatment of adults with IgAN. Little is known about the effects of SPAR in patients receiving IST for IgAN. We report a series of 5 cases involving patients with IgAN who received SPAR after previous IST or initiated SPAR in addition to ongoing IST.

Case Description: Five patients with biopsy-proven IgAN (ages 21-71 y) initiated SPAR (400 mg/d; dose increased after 2 weeks at 200 mg/d) after discontinuing IST (n=3; IST discontinued due to insufficient response or completion of treatment course) or in addition to ongoing IST (n=2). Individual case details are summarized in the **Table**. Duration of follow-up on SPAR ranged from approximately 4 to 6 mo; all patients were receiving ongoing SPAR treatment at last follow-up. A decrease in proteinuria (urine protein-to-creatinine ratio [UPCR]) was seen in all patients after SPAR treatment, regardless of estimated glomerular filtration rate (eGFR) or UPCR at initiation, with 2 achieving complete remission (UPCR <0.3 g/g). Overall, there were no major fluctuations in blood pressure or eGFR decline at follow-up, with an improvement in eGFR seen in 1 patient. Of 4 patients with hematuria at SPAR initiation, hematuria improved in 1 patient and resolved in 2 patients. SPAR was generally well tolerated by these patients. In 1 patient, SPAR treatment was briefly interrupted due to elevated liver function tests but was resumed (initially at 200 then 400 mg/d) without further issue.

Discussion: These cases support the safety and efficacy of SPAR in patients with previous or ongoing IST. Improvements in proteinuria were observed regardless of eGFR or UPCR at SPAR initiation, including in patients in whom target proteinuria was not achieved with IST alone.

Table. Case Summaries

Age, y	Sex	Race or ethnicity	Time since IgAN diagnosis	Other treatment history (duration)	Steroid/IST (duration)	Duration of follow-up on SPAR (mo)*	UPCR at SPAR initiation,† g/g	UPCR at Follow-up, g/g	eGFR at SPAR initiation,† mL/min/1.73 m²	eGFR at follow-up, mL/min/1.73 m²

Is Age Just a Number? A Comparative Analysis of Glomerular Disease across Ages from the CureGN Network

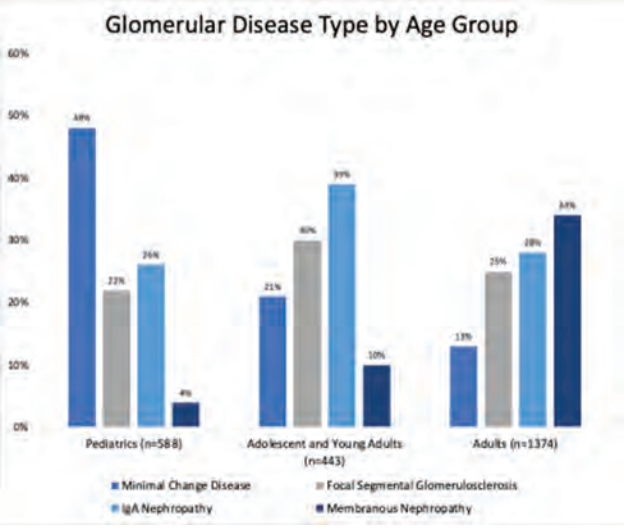
Andrew Vissing,[1,2] Shikha Wadhwani,[1] Abigail R. Smith,[1] Jerome C. Lane,[2] Cybele Ghossein,[1] Jill Krissberg.[2] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Ann & Robert H Lurie Children's Hospital of Chicago, Chicago, IL.*

Background: Currently, there is limited research that investigates the characteristics and outcomes of adolescents and young adults (AYA) living with glomerular disease (GD). Our study seeks to understand how this group fares compared to younger and older patients.

Methods: Cure Glomerulonephropathy (CureGN) network is a multicenter prospective cohort study of children and adults with biopsy-proven GD diagnosed by biopsy within 5 years prior to enrollment. For our study, patients were categorized into the following groups: pediatric (≤13 years of age), AYA (14 to 25 years of age), and adult (≥26 years of age). Demographics and baseline disease characteristics were collected at enrollment and compared across age groups.

Results: The study included 2,405 patients (588 pediatric, 443 AYA and 1,374 adult). The prevalence of GD varied by age with minimal change disease being the most common in pediatrics (47.6%), IgA nephropathy in AYA (39.1%), and membranous nephropathy in adults (33.8%). More pediatric patients had active disease at enrollment (77.2% vs 68.9% in AYA and 69.4% in adults) but were also more likely to have reached complete remission at some point prior to enrollment (49.7% vs 32.1% in AYA and 22.3% in adults). Adults exhibited the lowest eGFR at enrollment (68.7 ml/min/1.73m^2 vs 86.0 ml/min/1.73m^2 in AYA and 104.6 ml/min/1.73m^2 in pediatrics).

Conclusions: This study highlights that AYA with GD have unique clinical characteristics when compared to either pediatric or adult populations. Recognizing this can help guide treatment and management strategies. Ongoing analysis for this project will explore whether AYA with GD have renal outcomes that differ compared to their younger and older counterparts.



FR-PO909

Sex Differences in Glomerular Diseases and Their Long-Term Outcomes

Aglaia Chalkia, Emelina Stambolliu, Margarita Bora, Elpiniki Stathopoulou, Athanasios Papras, Dimitrios I. Petras. *Hippokration General Hospital, Athens, Greece.*

Background: Sex differences in kidney diseases have received limited attention. Research in this area is crucial for developing targeted prevention and intervention strategies that address the unique needs and risk factors of diverse populations.

Methods: Retrospective, single-centre study at a reference centre for glomerular diseases. We evaluated the prevalence of glomerular diseases among males and females in terms of clinical characteristics and long-term outcomes. Logistic regression analysis and time-to-event analyses were employed.

Results: 232 patients were included; 63% male and 37% female. The most common glomerular disease in males was IgA nephropathy (29%), while females most frequently presented with ANCA-associated glomerulonephritis (19%) and FSGS (19%). Notably, IgG4-related nephritis and membranoproliferative glomerulonephritis were observed only in males. At diagnosis, hypertension was more prevalent in males (71% vs 56%, p=0.035). There were no significant differences in the severity of kidney disease between sexes with the total cohort having a median (interquartile range) eGFR of 51 (25-85) ml/min/1.73m^2 and proteinuria 3 (1-6) gr/24h]. During the first year, females had a higher likelihood of infections compared to males (adjusted odds ratio OR 3.0 [95% CI 1.31-7.3], p=0.01), after adjusting for the type of immunosuppressive treatment. Renal recovery at 1st year was similar between the sexes, with males and females showing comparable eGFR increases [8±19 vs 11±21 ml/min/1.73m^2, p=0.50] and decreases in proteinuria [57% (0-90) vs 55% (0-83), p=0.35]. Over a median follow-up of 2 years (0.5-4), the 5-year overall survival rate was 90% with no significant difference between males and females (log-rank, p=0.181). In the total cohort, the 5-year renal survival rate was 86%. However, in the subgroup of patients with baseline eGFR<30ml/min/1.73m^2, males tended to have worst renal survival (log-rank, p=0.087).

Conclusions: This study highlights sex differences in glomerular diseases, particularly in infection rates and hypertension prevalence. Despite these differences, long-term survival rates were similar between sexes. However, males with severe kidney disease at baseline showed a trend towards worse renal survival.

FR-PO910

Incident Diabetes in Glomerular Diseases

Samuel Haddad,[1] Calvin Andrews,[5] Margaret Helmuth,[4] Abigail R. Smith,[3] Cynthia C. Nast,[2] Amy K. Mottl.[1] *[1]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Cedars-Sinai Medical Center, Los Angeles, CA; [3]Northwestern University, Evanston, IL; [4]University of Michigan, Ann Arbor, MI; [5]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: Glomerular diseases (GDs) can result in significant kidney morbidity. Comorbid diabetes (DM) can occur following GD onset and may exacerbate the rate of decline in eGFR. We examined risk factors for incident DM, and the association of incident DM with major adverse kidney events (MAKE).

Methods: Adults with MCD, FSGS, MN, or IgAN enrolled in the prospective CureGN observational cohort study were included. Multivariable Cox regression models of time from biopsy to incident diabetes and MAKE (40% decline in eGFR or ESKD) were fitted. The base model associated age at biopsy, sex, racial/ethnic minority, family history of DM, and BMI with incident DM risk. Additional models sequentially tested GD diagnosis (IgAN, FSGS, MCD, MN), smoking, baseline eGFR, and time-dependent steroid or CNI use. Associations between time-dependent diabetes incidence and MAKE were adjusted for base model covariates.

Results: Of 1,729 adults enrolled in CureGN, 142 developed incident DM (Table); median (IQR) time from biopsy to DM was 23 (5-58) months. Older age, higher BMI, and smoking history were associated with higher risk of incident DM; no associations between steroid and CNI use and risk of incident DM in GD were detected (Figure). No association between incident DM after GD diagnosis was detected for MAKE (HR=0.99; 95% CI: 0.66-1.50).

Conclusions: Long-term risks of incident DM in GD remain to be determined.

Funding: NIDDK Support

Smoking history, eGFR, steroid and calcineurin inhibitor (CNI) use were added to the base model sequentially.

FR-PO911

Pregnancy Outcomes in Patients with Primary Glomerular Diseases and the Impact on Kidney Outcomes

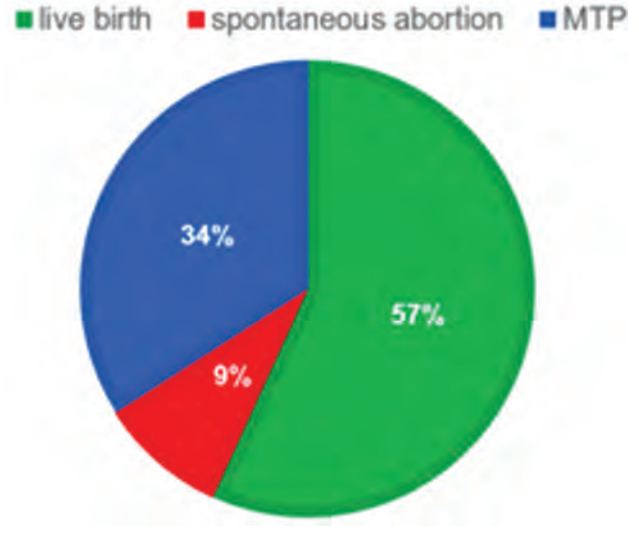
Jaideep Menda, Snikitha Tummala, Arunkumar Subbiah, Sandeep Mahajan, Dipankar M. Bhowmik, Soumita Bagchi. *All India Institute of Medical Sciences, New Delhi, India.*

Background: Primary glomerular diseases frequently affect women in childbearing age. There is a dearth of information about the impact of pregnancy on the outcome in such diseases. This retrospective cohort study examines pregnancy outcomes in women with biopsy-proven primary glomerular disease and the impact on renal survival.

Methods: We assessed the medical records of women in child bearing age (18-45 years) diagnosed with biopsy proven primary glomerular disease (IgAN, FSGS, MGN, MCD) from 2012- 2022 at a single centre AIIMS New Delhi. Patients with end stage kidney disease (ESKD) at the time of biopsy and/or at time of conception and those who had undergone kidney transplantation were excluded. Pregnancy and Kidney outcomes were recorded. Relapse was defined as increase in proteinuria to >3.5g/day (>1g/day for IgAN) and renal disease progression as >40% sustained decline in eGFR and/or ESKD.

Results: Of 238 women assessed, 81 were lost to follow up and 125 did not conceive after biopsy. 44 pregnancies were documented in 32 women (IgAN n=21, FSGS n=6, MGN n=10, MCD n=7). The median age of conception was 28.5 (25.2-33.0) years and the median time from biopsy to conception was 3 (2-5.8) years. 15 pregnancies (34%) were medically terminated, 4 (9%) resulted in spontaneous abortions, and 25 (57%) culminated in live births. 12 of 44 (27%) pregnancies occurred while the patient was on ACEi/ARBs of which 7 pregnancies resulted in live births. 12 out of 25 live births were premature and IUGR below 10th percentile affected 15 pregnancies. Preeclampsia affected 6 pregnancies. From a renal perspective, 9 women had active disease at the time of conception. 7 (33%) women had a relapse of kidney disease during pregnancy and 2 (9.5%) women relapsed immediate postpartum. 8 of these 10 women received steroids during pregnancy. In 6 women, there was renal disease progression, of which 1 developed ESKD.

Conclusions: Pregnancy is associated with adverse maternal and fetal outcomes in women with primary glomerular diseases.



Distribution of pregnancy outcomes

	All (n= 25)	IgA (n=11)	FSGS (n=2)	MGN (n=6)	MCD (n=6)
Pregnancy outcomes					
Preeclampsia	6	4	2	0	0

Comprehensive Druggable Genome-Wide Mendelian Randomization Reveals Therapeutic Targets for Kidney Diseases

Zhihang Su, Rui Xue, Qijun Wan. *Shenzhen Second People's Hospital, Shenzhen, China.*

Background: Kidney diseases, including membranous nephropathy (MN), IgA nephropathy (IgAN), and chronic kidney disease (CKD), present global health challenges due to their prevalence and severe outcomes. Mendelian randomization (MR) has been used extensively to repurpose drugs and identify novel targets. Thus, our study aims to identify therapeutic targets for kidney diseases, analyze their mechanisms, and assess potential side effects.

Methods: Integrated with currently available druggable genes, Summary-data-based Mendelian Randomization (SMR) analysis was conducted to estimate the causal effects of blood expression quantitative trait loci (eQTLs) on kidney diseases. To validate the identified genes, a replication study was performed using distinct blood eQTL and disease genome-wide association study (GWAS) data sources. eQTL data was obtained from eQTLGen and GTEx v8.0, with sample sizes of 31,684 and 15,201, respectively. The data on kidney diseases was sourced from the Kiryluk Lab, CKDgen, and the Finngen consortium, with sample sizes ranging from 7,979 to 412,181. The study population consists of European individuals. Subsequently, two-sample MR and colocalization analysis were employed for further validation. Finally, the potential side effects of the identified key genes in treating kidney diseases were assessed using phenome-wide MR and mediation MR.

Results: After correcting for the false discovery rate, a total of 20, 23, and 6 unique potential genes were found to have causal relationships with MN, IgAN, and CKD, respectively. Among them, MN showed validated associations with one gene (HCG18), IgAN demonstrated associations with four genes (AFF3, CYP21A2, DPH3, HLA-DRB5), and chronic kidney disease (CKD) displayed an association with one gene (HLA-DQB1-AS1). Several of these key genes are druggable genes. Further phenome-wide MR analysis revealed that certain genes may be associated with diabetes and fat metabolism, suggesting that these factors could potentially serve as mediators.

Conclusions: This study presents genetic evidence that supports the potential therapeutic benefits of targeting these key genes for treating kidney diseases. This is significant for prioritizing drug development efforts for kidney disease treatments.

Immunosuppressive Therapy (IST)-Related Adverse Events in Patients with Glomerular Disorders (GDs)

Andrea Lim,[1] Belia O. Roybal,[3] Mimi J. Yao,[1,2] Aida Shirazi,[1] Jessica B. Lapasia,[1] Ali Poyan-Mehr.[1] *[1]Kaiser Permanente San Francisco Medical Center, San Francisco, CA; [2]University of California San Diego, La Jolla, CA; [3]Kaiser Permanente Division of Research, Oakland, CA.*

Background: Treatment-emergent adverse events (TAE) in GD patients include infection (IF) and gastrointestinal bleed (GI). Unfortunately, data about TAE prevalence in GD patients receiving IST is scant, and effectiveness of prophylaxis is unknown.

Methods: In this retrospective study, we identified 806 patients with a biopsy-proven GD diagnosis between 1/1/2010 and 10/31/2022 who were treated with IST. We evaluated TAE prevalence within an 18-month follow-up period from time of treatment initiation. We also evaluated risk-modifying factors with baseline clinical characteristics.

Results: The proportion of those with IF- or GI-TAE was highest in vasculitis-related GD (37.4% and 30.1%, respectively) compared to other GD diagnosis categories. Further, IF and GI-TAEs were more prevalent in patients treated with glucocorticoids than other IST (66.4% and 72.6%, respectively). Significant differences in baseline characteristics exist between those with and without TAEs.

Conclusions: Our preliminary results find that IF- and GI-TAEs appear to be more prevalent in those treated with glucocorticoids and those with vasculitis-related GD. A multi-regression analysis is being conducted to identify factors that can identify those at high risk for TAEs.

Immunosuppressant Use in Infective Endocarditis-Associated Glomerulonephritis: A Systematic Review

Mostafa G. Aly,[1,2] Reem Sayad,[3] Leenah N. Sherif,[5] Muhammed Edib Mokresh,[4] Mohamed Mohamed Shawqi,[6] Yasmine A. Mohammed,[3] Eslam A. Hawash,[7] Ahmed M. Ali,[3] Ahmed Saad Elsaeidy.[7] *[1]Nephrology Unit, Internal Medicine Department, Assiut University, Assiut, Egypt; [2]Nephrology Department, Sana-Klinik Hof, Hof, Germany; [3]Assiut University Faculty of Medicine, Assiut, Egypt; [4]Hamidiye International School of Medicine, University of Health Sciences, Istanbul, Turkey; [5]Emergency Department, Faculty of Medicine, Menoufia University, Menoufia, Egypt; [6]Emergency Medicine Department, Faculty of Medicine, Benha University, Benha, Egypt; [7]Benha University Faculty of Medicine, Benha, Egypt.*

Background: Patients with infective endocarditis (IE) can develop various renal diseases, including infection-related glomerulonephritis (GN). Antibiotics are essential for eradicating the infection. However, the prognosis for renal function remains poor. The use of immunosuppressants in IE-associated GN is still debated. This systematic review examines the role of immunosuppressants in managing these cases.

Methods: A comprehensive search was performed across four databases: PubMed, Scopus, MedLine, and Web of Science up to April 2024. We included studies that investigated patients with any type of GN due to IE who were treated with immunosuppressants. Data extraction was conducted using a standardized sheet, and study quality was assessed using the JBI critical appraisal tool.

Results: The review incorporated 55 studies encompassing 84 cases, 65 of whom were male. The median age was 46.5 years. Predisposing factors and cardiac and renal manifestations are detailed in Figure 1. Immunosuppressants used included steroids (oral and/or IV), cyclophosphamide, rituximab, azathioprine, mycophenolate mofetil, and hydroxychloroquine. Thirty cases required dialysis. Following immunosuppressive

therapy, 69 cases improved, 10 worsened, and 5 showed no improvement in renal function. There were 10 fatalities, with 4 cases due to sepsis, 3 due to congestive heart failure, 1 due to cardiac arrhythmia, 1 due to renal failure, and 1 due to an unreported cause. Additional treatments included plasma exchange, with 9 cases receiving plasmapheresis/plasma exchange. Of these, 8 patients showed marked renal function improvement, and 1 patient showed partial improvement. Three patients also received IVIG.

Conclusions: Immunosuppressive therapy led to renal function improvement in the majority of cases, suggesting its potential benefit in managing IE-related GN. However, variability in response and significant mortality highlight the need for individualized treatment strategies and further research to optimize management. **Legend** Figure 1: PRISMA Flowchart for the selection of studies and an algorithm summarizing the included cases.

Long-Term Risk of ESKD in Postinfectious Glomerulonephritis

Rune Bjoerneklett, Lars S. Bostad, Thomas Knoop, Leif H. Bostad.
Department of Clinical Medicine, University of Bergen, Bergen, Norway.

Background: Kidney biopsy is usually not required for the diagnosis of post-infectious glomerulonephritis (PIN). When kidney biopsies are nevertheless performed for example in patients with PIN and severe or atypical clinical presentations, the light microscopic picture is characteristic in the form of endocapillary glomerulonephritis. The immunological picture is however less specific for PIN as in many cases this is dominated by complement factor C3 deposits. In such cases, PIN can theoretically be confused with complement 3 nephropathy (C3N) based on the immunological findings. While PIN is considered a self-limiting condition with a good prognosis, C3N, often has a progressive course leading to end-stage kidney disease (ESKD) in a significant proportion of patients. To what extent confusion of PIN versus C3N has occurred in clinical practice in Norway is unknown. As such prognostic data is limited we have analyzed the very long-term risk of ESKD in patients with biopsy-verified PIN registered in the Norwegian Kidney Biopsy Registry (NKBR) in the period 1991-2012.

Methods: Cases of biopsy-verified PIN 1991-2012 including demographic, clinical, laboratory, and histological variables at the time of diagnosis were retrieved from the NNBR. The cohort was linked with the Norwegian Kidney Registry for identification of patients with ESKD by May 1, 2024.

Results: We identified 82 patients with PIN. Men; 45 (55%), age; 35 years (SD 22), systolic BP; 140 mmHg (SD 24), diastolic BP; 80 (SD 14), hypertension 42 (51%), eGFR 58 ml/min/1.73m2 (SD 37), eGFR<15; 12 (15%), eGFR 15-29; 8 (10%) and eGFR 30-59; 26 (32%), serum albumin; 31 gram/liter (SD 6), proteinuria; 3.8 gram/24 hours (SD 4.2), nephrotic syndrome; 20 (24%), crescents; 26 (32%), >50% tubulointerstitial fibrosis; 17 (21%) and isolated C3 positivity 29 (35%). During an average observation time of 21 years, there were no patients who progressed to ESKD.

Conclusions: Despite many cases with severe kidney affection at the time of diagnosis, no patients with PIN progressed to ESKD during a very long follow-up time. A C3N resembling immunological image is not associated with the risk of ESKD in patients with PIN.

Corticosteroids after Hemodialysis May Improve Kidney Function in Infection-Related Glomerulonephritis

Evani Patel, Kwon Soo Kim, Andrew Murphy. *Penn Medicine, Philadelphia, PA.*

Introduction: Staphylococcus-associated Glomerulonephritis (SAGN) is an uncommon renal phenomenon following staphylococcal bacteremia, where management involves intravenous antibiotics. We report a case of severe, persistent SAGN requiring hemodialysis, with improvement through glucocorticoids, thus, paving a path for the reassessment of guidelines for SAGN after the use of antibiotics.

Case Description: A 74-year-old male with a history of end-stage renal disease, kidney transplant and now on tacrolimus, nephrectomy for oncocytoma presented with a right foot digit gangrene and septic shock. Workup was remarkable for a urinalysis consistent with a UTI, and blood cultures showing methicillin-susceptible staphylococcal aureus. His course was further complicated by endocarditis, worsening creatinine from baseline, and volume expansion refractory to diuretics requiring hemodialysis. Following 4 sessions, his creatinine continued to rise. Due to a broad set of differentials including transplant rejection, thrombotic microangiopathy and tacrolimus toxicity, a renal biopsy was performed. At this time, he had a negative ANCA-level and hypocomplementemia with C3, most consistent with IRGN which was later confirmed by biopsy. Given the severity of his AKI requiring HD, a decision was made to treat with a course of 500mg IV methylprednisolone followed by 5mg Prednisone daily, after which his creatinine down-trended and he did not require further dialysis.

Discussion: Infection-related glomerulonephritis (IRGN), more specifically SAGN, involves the deposition of preformed immune complexes during, or a few days following concurrent infection. It is presumed that treatment with antibiotics will reduce antigen production, and therefore, decrease kidney inflammation. Previous studies show that treatment with corticosteroids is ill-advised as it poses a risk of recurrent sepsis and increases mortality. Our case highlights three pearls: the uniqueness of a severe acute kidney injury requiring hemodialysis, the importance of a kidney biopsy for an unclear etiology, and the initiation of high-dose corticosteroids in an immunocompromised individual for uncontrolled glomerulonephritis. This case brings to light the need to constantly evaluate the driving process of SAGN, whether it is inflammation or infection, to determine if an immunosuppressive approach should be taken.

FR-PO917

Efficacy of Pneumocystis jirovecii Pneumonia Prophylaxis in Preventing Infections among Patients with Kidney Disease Receiving Rituximab Therapy

Jing Miao, Pajaree Krisanapan, Maria Jose Vargas-Brochero, Charat Thongprayoon, Lisa E. Vaughan, Fernando C. Fervenza, Ladan Zand. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Pneumocystis jirovecii pneumonia (PJP) prophylaxis is frequently used in kidney disease patients during rituximab (RTX) therapy. However, the effectiveness of PJP prophylaxis in this context is uncertain.

Methods: This retrospective study included adult patients with AAV, LN, MN, primary podocytopathy who began RTX therapy between 2012 and 2022. The association between treatment group (with vs. without PJP prophylaxis at RTX initiation) and the risk of incident infection post-treatment was analyzed using Cox proportional regression model. Patients were censored at death, transplantation, loss to follow-up, or one year post-treatment initiation, whichever came first.

Results: A total of 441 patients met inclusion criteria. At the time of first dose of RTX, 316 (72%) were on PJP prophylaxis, and 125 (28%) were on RTX alone (Fig.). AAV patients were more likely to receive PJP prophylaxis with RTX, whereas MN patients were more likely to receive RTX alone (*P<0.001*). Overall, no significant difference in infection risk was found between the groups (HR [95% CI], 0.92 [0.57, 1.47], *P=0.71*). Adjusting for kidney disease type, PJP prophylaxis was linked to a lower infection risk, though not statistically significant (HR, 0.67 [0.39, 1.15], *P=0.15*). Stratified by kidney disease type, PJP prophylaxis was associated with a lower infection risk in both AAV patients (HR 0.74 [0.34, 1.65], *P=0.46*) and non-AAV patients (HR 0.61 [0.28, 1.33], *P=0.21*), but not statistically significant.

Conclusions: The study found no significant protective effect of PJP prophylaxis on incident infections in kidney disease patients receiving RTX treatment. However, a reduced risk was noted when adjusting for disease types and in AAV patients. Further research is needed to evaluate these findings.

Table. Characteristics and incident infections in patients at first initiation of RTX therapy, overall and by treatment group

	Total (n=441)	RTX only (n=125)	PJP + RTX (n=316)	P value

Estimating Causal Effects of Glucocorticoid Use on Infection Rates in Glomerular Diseases Using a Novel Marginal Structural Proportional Rates Model

Jarcy Zee,[1,2] Qian Liu,[2] Dorey A. Glenn,[3] Michelle Denburg,[2,1] Douglas E. Schaubel.[1] *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]The Children's Hospital of Philadelphia, Philadelphia, PA; [3]The University of North Carolina at Chapel Hill Kidney Center, Chapel Hill, NC.*

Background: Estimation of time-varying glucocorticoid treatment effects on infections have been limited to risks of first infection events, thus ignoring recurrent infections. Given the common recurrences of infections in patients with glomerular disease, and the need to account for time-dependent confounders, novel statistical methods are required to estimate causal treatment effects on recurrent outcomes.

Methods: We developed a marginal structural proportional rates model (MSPRM) to estimate the causal effect of a time-varying treatment on recurrent outcomes in the presence of time-dependent confounding. We derived estimation and inference procedures and conducted simulations to demonstrate model performance. We used the MSPRM to estimate the effect of time-varying glucocorticoid use on recurrent infection-related acute care events (hospitalizations or ER visits) accounting for proteinuria and serum albumin over time in the Cure Glomerulonephropathy (CureGN) study. Baseline confounders included age, sex, race, Hispanic ethnicity, glomerular disease type, eGFR, comorbidities, tobacco use, and time from biopsy to CureGN enrollment.

Results: Out of N=2496 CureGN study participants, N=405 had at least one infection, with a total of 590 infections. The MSPRM estimated that glucocorticoid use increased rates of infection by 1.70 (95% CI 1.32-2.18) times compared to no use (Figure). Based on simulations, the MSPRM has little bias compared to standard proportional rates models, which suffer from confounding and/or overadjustment bias.

Conclusions: The MSPRM can estimate causal time-varying treatment effects on recurrent time-to-event outcomes using weights to balance time-dependent confounders. Including recurrent events can better capture disease burden and morbidity compared to only considering the first event, and our proposed model provides a semi-parametric method to analyze these longer-term outcomes.

Funding: Private Foundation Support

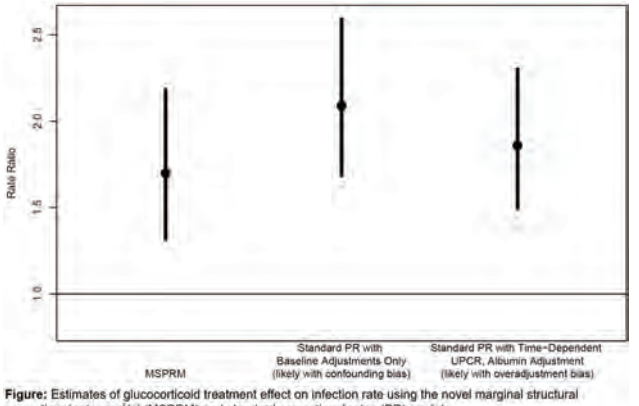

Figure: Estimates of glucocorticoid treatment effect on infection rate using the novel marginal structural proportional rates model (MSPRM) and standard proportional rates (PR) models.

FR-PO919

A Needs Assessment of HIV Providers in the Evaluation of Kidney Function in People Living with HIV

Rachel Shulman, William R. Short, Amanda L. Binkley, Amanda K. Leonberg-Yoo. *University of Pennsylvania, Philadelphia, PA.*

Background: Kidney disease is common in people living with HIV (PLHIV). Unique factors in HIV, including sarcopenia and certain antiretroviral drugs, can make creatinine unreliable. HIV providers are often the primary healthcare resource for PLHIV and the recognition of kidney disease lies in their hands.

Methods: We conducted a pilot survey of HIV providers in the University of Pennsylvania Health System. Questions focused on (1) current clinical practices for kidney function assessment, (2) identifying knowledge and attitudes for best clinical practices for kidney function assessment, and (3) identifying care gaps in the management of PLHIV.

Results: A total of 22 providers responded to the survey, including 16 physicians, 2 infectious disease pharmacists, 1 advanced practitioner. For routine care of PLHIV, most providers assess kidney function with a serum creatinine and urinalysis (95% and 68%, respectively). For PLHIV with an elevated creatinine, 95% of providers (n=21) would obtain a repeat creatinine. Only 23% (n=5) would obtain a cystatin C. To determine drug dosing, 32% of providers (n=7) use an estimated GFR (eGFR) equation, 9% (n=2) use Cockcroft Gault creatinine clearance, and 14% (n=3) use serum creatinine. Nearly half of providers (n=10, 45%) responded "I am not sure". Only 18% of providers (n=4) felt comfortable with the use of cystatin C. There was variable practice in nephrology referral, with 41% of providers (n=9) referring at an eGFR<60mL/min/1.73m^2 and 21% (n=5) at 45mL/min/1.73m^2. Only 21% (n=5) waited until the KDIGO guideline of 30mL/min/1.73m^2.

Conclusions: In this pilot survey, HIV providers reported high uncertainty regarding kidney function measurement and the identification of kidney disease. HIV providers may benefit from targeted education to reduce medication errors related to drug dosing as well as appropriate nephrology referrals.

Funding: NIDDK Support

The Spectrum of Biopsy-Proven Kidney Disease in People Living with HIV in Tertiary-Care Centers in Mexico City

Adrián Esteban Caballero-Islas,[1] Carlos Ascencion Lopez,[1] Lillana Pacchiano,[1] Arnulfo Mendoza,[1] Jose A. Leon Ortiz,[1] Marcos G. Nava,[1] Enzo C. Vasquez Jiménez,[2] Gustavo A. Casas-Aparicio.[1] *[1]Instituto Nacional de Enfermedades Respiratorias, Mexico, Mexico; [2]Hospital Juarez de Mexico, Mexico City, Mexico.*

Background: People living with HIV are prone to kidney disease as a result of multiple mechanisms; those directly related to the virus, drug effects, and related infections. Kidney biopsy allows a more accurate approach to kidney disease in this setting.

Methods: A retrospective study that included all HIV-positive patients with a clinical indication for a kidney biopsy was performed between January 2018 and May 2024 at 3 centers in Mexico City. Data was collected at the time of the biopsy

Results: Eighteen kidney biopsies were included. The mean age was of 44.7 years and the median time from diagnosis to biopsy was 92 months(4.5-128). The most common indication was nephrotic syndrome(61%). Glomerular lesions were the most frequent finding(83%) and immune complex-mediated glomerular disease the most prevalent lesion. Among diabetic patients, 60% presented lesions not related to diabetes.

Conclusions: In our study, immune complex-mediated glomerular disease was the most common diagnosis. In individuals with diabetes, 60% had a kidney disease not related to diabetes, emphasizing the importance of performing biopsies to improve outcomes.

Age, yrs(mean±SD)	44.7±13.6
Male,n(%)	16(89)
Serum creatinine,mg/dL(median, IQR)	1.76(1.18-2.34)
eGFR, mL/min/1.73 m2	44.9(34.1-71)

Development of Machine Learning-Based Biopsy Algorithm for Kidney: Multicenter-Based Model Development and Validation Study in South Korea

Hae-Ryong Yun, Hyung Woo Kim, Jung Tak Park, Seung Hyeok Han, Shin-Wook Kang, Tae-Hyun Yoo. *Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea.*

Background: Kidney biopsy has become an essential procedure for microscopic assessment of kidney disease. However, the decision of kidney biopsy can be inconsistent due to the complexity of interpreting patient data and varying clinician expertise. Therefore, based on three nephrologists' decisions, we developed three machine-learning (ML) algorithms, integrating them into a biopsy recommendation algorithm for kidney.

Methods: First, using 8,228 patients with proteinuria, hematuria, and/or unexplained kidney function abnormalities who visited outpatient clinics between 2010 and 2018, we trained a deep-learning algorithm to mimic nephrologists' decisions for kidney biopsy. Subsequently, we tested the performance of the biopsy algorithm on 760 patients who underwent kidney biopsy between 2020 and 2023 in Severance Hospital. The XGBoost was employed to develop the algorithm and the confusion matrix was used to evaluate the performance of the algorithm.

Results: Among the 8,228 patients, the number of cases in which nephrologists decided to conduct kidney biopsy was 1,290 (15.6%), 1,261 (15.3%), and 1,106 (13.4%), respectively. The area under the receiver operating characteristic curve (AUROC) for each ML-algorithm was 99.6%, 99.8%, and 97.0%, respectively. These results suggest that each algorithm closely emulates the decisions of corresponding nephrologists in determining the need for kidney biopsy, demonstrating proficiency in accurately replicating clinical decisions. The integrated final kidney biopsy algorithm, combining the three algorithms, achieved an AUROC of 99.5%. Finally, we applied the algorithm to the patients who underwent kidney biopsy. Among the 760 patients, 659 (86.7%) received a diagnosis of glomerular, tubule-interstitial, or inherited diseases. The AUROC for the algorithm was 86.2%. In addition, the positive predictive value of the algorithm was 100.0 %.

Conclusions: We developed an ML-algorithm to emulate nephrologists' decisions on kidney biopsy. We expected that this algorithm could support clinicians in strengthening the decision-making process and simplifying patient management workflows for kidney biopsy in primary care.

Kidney Biopsy Practice Varies in the United States and Internationally

Michael Toal,[1,2] Christopher Hill,[2] Michael P. Quinn,[1] Ciaran O'Neill,[1] Alexander P. Maxwell.[1] *[1]Queen's University Belfast Faculty of Medicine Health and Life Sciences, Belfast, United Kingdom; [2]Belfast City Hospital, Belfast, United Kingdom.*

Background: There is substantial variation in kidney biopsy practices between countries, however the reasons for this are unclear due to limited research.

Methods: A case-vignette questionnaire was developed. A biopsy propensity score (0-44) was generated from responses to indications and contraindications, which categorised respondents into one of five categories for instant feedback. Dissemination occurred by email, social media and the National Kidney Foundation.

Results: 1181 nephrologists/fellows from 83 countries participated, making this the largest international study of kidney biopsy practice. The mean score was 24.2 (higher score=increased propensity). The US was the largest national group with 293 participants from 43 states. US mean=24.6. A biopsy was most likely for nephrotic and nephritic syndromes and least likely in the setting of reduced kidney size. An adjusted multiple linear regression model demonstrated significantly higher scores for males, younger participants and those who performed biopsy more frequently (p=0.01). A previous severe complication (requiring intervention/death) did not affect propensity (p=0.76). In countries with over 20 participants, the mean score ranged from 22.1 (Nigeria) to 26.9 (Mexico) (p<0.001). There were significant differences between the 18 US states with 5 or more participants (p=0.003) and mean score ranged from 20.3 (WI) to 29.2 (NJ & VA) (Fig.1). Increased propensity was demonstrated in states with higher nephrologist density and lower deprivation levels (p=0.002).

Conclusions: International and US kidney biopsy practice is highly variable. Ease of access to biopsy may influence propensity. State-level disparities could be affected by socioeconomic factors and nephrologist availability. The significant variations in kidney biopsy practice warrants further examination, given its potential implications for timely care and resource use.

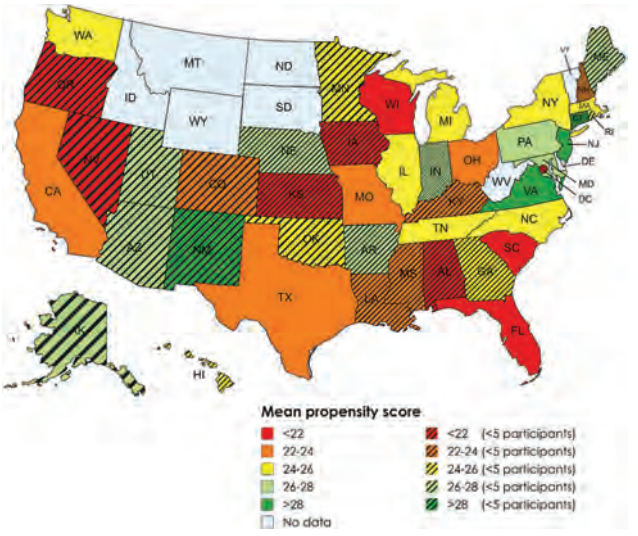

Fig. 1 Propensity score by US state

FR-PO923

Paradox of Precision: More Parameters, Fewer Complications in Kidney Biopsy Outcomes

Joao M. E Lima Souza, Marclebio M. Dourado, Maria Z. Nogueira de Azevedo, Ana Paula Gueiros, Thiago Vinícius P. Paiva, Breno M. Sá, Tiago M. Freitas. *Universidade Federal de Pernambuco, Recife, Brazil.*

Background: Kidney biopsy is definitive for diagnosis of various glomerular diseases. Although minimal, this procedure is not done without risks. There is still no consensus regarding on best pre-biopsy protocol

Methods: Retrospective analysis of all post-renal biopsy complications in a single center after a change to a more restrictive protocol, starting in November 2018 until December 2022. All biopsied patients met the pre-established parameters showed in table 01. If any parameter was out of range, a specific intervention was performed (transfusion, antihypertensive, dialysis). Complication rate was also analyzed within after the procedure: fall in hemoglobin levels, blood transfusion, need for hemodynamic intervention, refractory pain, nephrectomy, and death.

Results: A total of 370 patients were included in the study, the majority being female [243 patients (65.6%)], and 88.9% of the biopsies performed on native kidneys. The age range varied from 4 to 76 years, with the majority between 14 and 53 years (81.6%). Regarding pre-biopsy parameters, the average hemoglobin was 11.3g/dL; platelets, 251,000/mm3; INR 1.09; systolic pressure 126mmHg and diastolic 79mmHg. In terms of glomerular filtration rate (GFR) and BUN, about 23.6% of patients had a GFR below 30mL/min, with BUN > 65, requiring pre-biopsy dialysis. Following this protocol, major complications occurred in only 4.86% of patients (10 patients with macroscopic hematuria, 6 patients requiring blood transfusion, 2 with intense pain). There were no instances requiring hemodynamic intervention, nephrectomy, or resulting in mortality. There was no association of complications with age, biopsy indication, or final diagnosis.

Conclusions: A comprehensive renal biopsy protocol with well-defined parameters proved to be effective and feasible, with minimal complication rates.

Parameters	Value	Necessary intervention if required
hemoglobin (g/dL)	≥ 9.0	Transfusion
plaquetas (mm3)	> 100.000	Transfusion
International Normalized Ratio (INR)	< 1,4	Transfusion
Systolic blood pressure (mmHg)	< 140	antihypertensive medication 1 hour prior
Diastolic blood pressure (mmHg)	< 90	antihypertensive medication 1 hour prior
Blood urea nitrogen (BUN)	< 65	Dialysis

FR-PO924

Kidney Biopsy Quality Improvement Study

Niveditha Girimaji Satishchandra, Duncan B. Johnstone, Reem Mustafa.
The University of Kansas Medical Center, Kansas City, KS.

Background: Kidney biopsy is essential for definitive diagnosis of kidney disease. Recent data indicate an increasing biopsy miss rate and inadequacy. Most retrospective analyses report kidney biopsy major complications in 1-2% of patients, and inadequate tissue for diagnosis in 14%. The study aimed to review the adequacy and complications of kidney biopsy.

Methods: A retrospective single-center quality improvement study of patients who underwent renal biopsies between January-2020 and December-2023. Univariate and binomial logistic regression was used to predict adequacy and complications.

Results: Study included 181 patients, 72(39.8%) were male. Mean age and BMI was 52.9±17.3 years and 29.5±7.8 kg/m^2. Mean baseline serum creatnine and hemoglobin(Hb) was 2.36±1.75 mg/dL and 11.25±2.4 g/dL.28.8% patients had stage 2 or 3 AKI. Mean eGFR in CKD stages <3 was 32.18 ± 15.94 ml/min.5.5% were on active anticoagulation.18 Gauge needle was used in all biopsies. 126(69.6%) biopsies were determined to be adequate(defined >= 10 glomeruli on LM, 1 glomerulus on IF and EM). Sex, age, BMI, length of kidney, and creatinine did not predict the likelihood of adequate sample. Total number of major complications was 11(6.1%) with 4(2.2%) requiring embolization or angiography, 5(2.7%) requiring transfusions <7 days, and 2(1.1%) requiring both. Among age, sex, creatinine, platelet, INR, number of passes, total core length, active anticoagulation, AKI, baseline Hb, pre-biopsy SBP and DBP, and radiologist, total core length predicted major complications on univariate analysis(p=0.04) and just missed significance on logistic regression(p=0.06).

Conclusions: One-third of kidney biopsies were inadequate with rare but considerable major complications. No specific predictors linked current biopsy protocols to adequacy. Total core length correlated to major complications. A shallower, wider biopsy with 16G needle would strike a balance between adequacy and minimizing complication. This study is limited by small sample size.

Binomial linear regression for adequacy of sample

Variable		Adequate Sample ª	Sample not Adequate ª	p value
		n = 126	n = 55	
Sex	Female	77 (61.2%)	32 (58.1%)	0.69
Age (Years)		51.4 ± 18.3	56.4 ± 14.4	0.07
BMI (kg/m^2)		29.4 ± 8.04	30.0 ±7.2	0.41
Kidney Length (Cm)		10.9 ± 1.3	11.2 ± 1.6	0.33
Creatinine(mg/dl)		2.2 ± 1.6	2.8 ± 1.9	0.08

Univariate analysis for major complications

Variable		Major Complication ª	No complication ª	p value
		n = 11	n = 170	
Sex	Female	5(45.45%)	104(61.17)	0.31
Age (Years)		51.8 ± 12.1	53.0 ± 17.6	0.832
Number of Passes		3.1 ± 0.3	3.3 ± 0.9	0.364
SBP before biopsy(mmhg)		125.1 ± 16.6	128.7 ± 16.4	0.49
Hemoglobin(g/dl)		10.22 ± 2.1	11.3 ± 2.4	0.14
Platelet * 10^3		197.7 ± 100.1	266.1 ± 115.6	0.07
Creatinine(mg/dl)		2.9 ± 2.3	2.3 ± 1.7	0.30
Active Anticoagulation	Yes	2(18.18%)	8(5.06%)	0.12
Total Core Length(cm)		3.3 ± 0.9	2.7 ± 0.8	0.04

Importance of Integrating Clinical, Serological, Morphological, and Genetic Data to Optimize Care and Prognostication for Patients with Glomerular Diseases

Thien Kim N. Co,[1] Cynthia C. Nast,[2] Tiane Dai,[1] Ryan Peretz,[1] Sharon G. Adler.[1] *[1]Harbor-UCLA Medical Center, Torrance, CA; [2]Cedars-Sinai Medical Center, Los Angeles, CA.*

Introduction: KDIGO 2021 Clinical Practice Guideline for the Management of Glomerular Disease states that kidney biopsy is not needed to confirm the diagnosis for patients with nephrotic range proteinuria and a positive anti-PLA2R antibody test, especially if kidney function is normal or if there are contraindications. Our case highlights the importance of integrating clinical information, kidney biopsy findings, serologies, and genetics in patients whose clinical course do not progress as expected.

Case Description: A 63-year-old male with diabetes mellitus type 2 (DM), hypertension and hyperlipidemia was referred for nephrotic range proteinuria (4,311 mcg/mg). Serological evaluation was negative except for positive anti-PLA2R antibody with negative urine/serum protein electrophoresis, Hepatitis B, Hepatitis C, HIV, and RPR. Kidney size was normal. Urine sediment was inactive. Kidney biopsy showed membranous nephropathy (PLA2R positive), focal and segmental glomerulosclerosis with glomerulomegaly, features suggestive of renal vein thrombosis, and mild to moderate arterio- and arteriolosclerosis. Imaging ruled out venous thrombosis. He was treated with Rituximab and steroids, attaining complete serological remission with negative anti-PLA2R antibody after 9 months. However, 12 months after serologic remission, he had persistent proteinuria of ~2-3g, suggesting a secondary process. Given the FSGS with glomerulomegaly, genetic testing was performed (Natera Renasight) which identified a heterozygous likely pathogenic variant in the gene COL4A3 mutation; pathogenic variants in COL4A3 are associated with Alport Syndrome with either autosomal dominant or recessive inheritance patterns. Audiological evaluation revealed reduced hearing. Ophthalmological evaluation is pending.

Discussion: If a kidney biopsy was not pursued, the persistent proteinuria might have been attributed to secondary FSGS or DM. However, the biopsy findings led to genetic testing, which revealed concern for concomitant Alport syndrome. This case underscores the importance of integrating clinical, serological, histological, and genetic information to evaluate an unexpected clinical course. With these advances, we aim to tailor medical therapy and genetic counseling to address each patient's unique clinical picture.

FR-PO926

Tangential Approach: An Innovative Technique in Ultrasound-Guided Native Kidney Biopsy (KB)

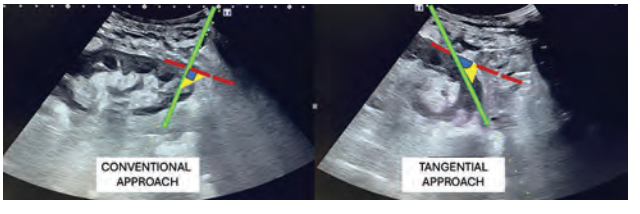
Haridian Sosa Barrios,[1,2] Cristina Riaza Ortiz,[1] María del Pilar Morán Magro,[1] Victor Burguera,[1] Irene Minguez,[1] Jorge Sánchez,[1] Milagros Fernandez-Lucas,[1,2] Maite Rivera Gorrin.[1,2] *[1]Hospital Universitario Ramon y Cajal, Madrid, Spain; [2]Universidad de Alcala Facultad de Medicina y Ciencias de la Salud, Alcala de Henares, Spain.*

Background: KB is the gold standard to diagnose renal pathology, but not without complications. In the conventional approach (CA) the needle enters the kidney at 60-90 degrees. The tangential approach (TA) is proposed as an alternative since it minimizes crossing the renal sinus (angle less than 60 degrees) and vessels of larger caliber (Figure 1). Objective: to demonstrate the non-inferiority of TA in native KB versus CA in terms of diagnostic yield and complications.

Methods: Retrospective single center study (May 2022-March 2024). Demographic data, KB and complications comparing CA vs TA were collected. The physician performing the KB chose one approach or the other according to the patient's anatomical characteristics and personal preferences.

Results: A total of 102 patients were biopsied, 65 (63.7%) male, mean age 54.18±17.3 years, 51% hypertensive. Twenty-two patients were anticoagulated/anti-aggregated and 24 required intravenous desmopressin preKB. Lower pole was biopsied in all cases, 86.3% left kidneys and only in one case both were biopsied. The mean number of passes was 2.5 (N.S.), with a mean yield of 2 cylinders. Cost-effectiveness of BR: Both the percentage of valid samples for diagnosis and the percentage of cortical obtained was statistically superior for AT, not so for the mean number of glomeruli obtained 18±11 vs 19±9 (p=0.647). Complications There were no statistically significant differences regarding major or minor complications. - Major: One patient required embolization and transfusion of blood products (CA). - Minor: We found statistically significant difference in the rate of asymptomatic arterio-venous fistulae (p=0.003), but not in minor hematoma or hematuria.

Conclusions: Native KB by TA is a novel technique. In our study, TA showed higher diagnostic yield without increasing complications, probably because large vessels are avoided during the procedure. We propose this alternative approach in selected cases, but larger prospective studies are needed.



FR-PO927

Glomerular Diameter Is Associated with Reduction in Urinary Protein during Treatment with Dapagliflozin, a SGLT2 Inhibitor, in Patients with CKD

Hiroaki Komatsu, Arata Osanami, Keitaro Nishizawa, Masato Furuhashi.
Sapporo Ika Daigaku, Sapporo, Japan.

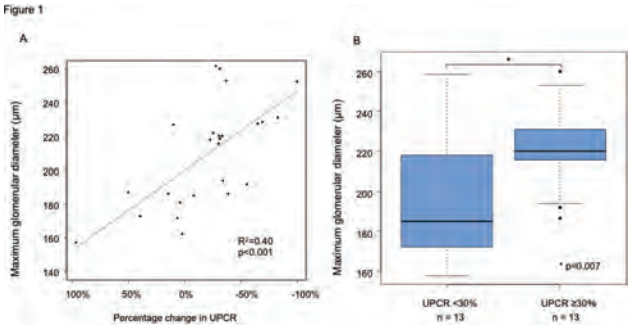
Background: Several clinical trials have shown that sodium-glucose cotransporter 2 (SGLT2) inhibitors have protective effects against chronic kidney disease (CKD) complicated with or not complicated with type 2 diabetes mellitus (DM). Since one of the renoprotective mechanisms by SGLT2 inhibitors is supposed to reduce glomerular hyperfiltration, we hypothesized that glomerular diameter, which can represent abnormal glomerular hemodynamics, is associated with reduction in urinary protein after the initiation of treatment with SGLT2 inhibitors.

Methods: This study was a retrospective multicentered study using 26 adult patients with CKD (mean age: 50±14 years) who underwent kidney biopsy and were then treated with dapagliflozin, an SGLT2 inhibitor, during the period between April 2019 to March 2024 in Sapporo Medical University Hospital and Steel Memorial Muroran Hospital. The association of glomerular diameter with changes in urinary protein before and 4-8 weeks after the initiation of treatment with dapagliflozin were investigated.

Results: Levels of median estimated glomerular filtration rate and urinary protein at baseline were 53 [interquartile range: 32.3-69.9] mL/min/1.73m^2 and 1.5 [0.69-2.84] g/gCre, respectively. Prevalences of DM and use of renin-angiotensin-system blockers were 15% and 88.4%, respectively. Maximum glomerular diameter was significantly and positively correlated with change (before – after) in urinary protein-to-creatinine ratio (UPCR) (R^2=0.40; p<0.001; Figure 1A). Maximum glomerular diameter was significantly larger in patients who achieved ≥30% reduction in UPCR after the initiation of treatment with dapagliflozin than in patients who achieved <30% reduction in UPCR (220 [215, 231] vs. 185 [172-218], p=0.007; Figure 1B).

Conclusions: Glomerular diameter is associated with reduction in urinary protein after the initiation of treatment with dapagliflozin in patients with CKD.

Figure 1



FR-PO928

Association of Serum Uric Acid with Podocyte Injury and Kidney Histopathologic Lesions

Sophia H. Rosan,[1] Ashish Verma,[1] Sophie E. Claudel,[1] Ragnar Palsson,[5] Anand Srivastava,[2] Tobias B. Huber,[3] Isaac E. Stillman,[4] Joel M. Henderson,[1] Sushrut S. Waikar,[1] Insa M. Schmidt.[1] *[1]Boston Medical Center, Boston, MA; [2]University of Illinois Chicago, Chicago, IL; [3]Universitat Hamburg Medizinische Fakultat, Hamburg, Germany; [4]Icahn School of Medicine at Mount Sinai, New York, NY; [5]Massachusetts General Hospital, Boston, MA.*

Background: Hyperuricemia may impair podocyte function by promoting oxidative stress and inflammatory responses, but these effects have not been comprehensively studied in patients with chronic kidney disease (CKD). This study explores the association between serum uric acid (SUA) levels, histopathologic lesions, and podocyte injury evidenced by foot process effacement (FPE) in patients with biopsy-confirmed kidney disease.

Methods: We measured SUA levels in 519 individuals enrolled into the Boston Kidney Biopsy Cohort, a cohort of individuals with biopsy-confirmed semi-quantitative assessment of histopathology. We assessed the correlation between SUA, estimated glomerular filtration rate (eGFR), and proteinuria using Spearman correlation coefficients. Multivariable linear regression models tested the associations of SUA levels with histopathologic lesion severity and FPE.

Results: The mean SUA level was 8.3±2.6 mg/dL, the mean eGFR was 57±36 ml/min/1.73m^2, and the median proteinuria [IQR] was 3.0 [0.4–4.0] g/g creatinine. SUA levels correlated negatively with eGFR and positively with proteinuria (r = -0.28, p<0.001 and r = 0.18, p<0.001, respectively) (**Figure 1a**). After multivariable adjustment for age, sex, race, and eGFR, more severe segmental sclerosis was associated with higher SUA levels (β= 0.64, p=0.020) (**Figure 1b**). More severe FPE was also associated with higher SUA levels. This relationship remained consistent in multivariable models after adjustment for demographics, eGFR, and proteinuria (β = 0.52, p = 0.048) (**Figure 1c**).

Conclusions: This study demonstrates an association between hyperuricemia and podocyte injury. Further research is needed to determine whether urate-lowering therapy could help reduce podocyte injury and potentially delay the onset of CKD.

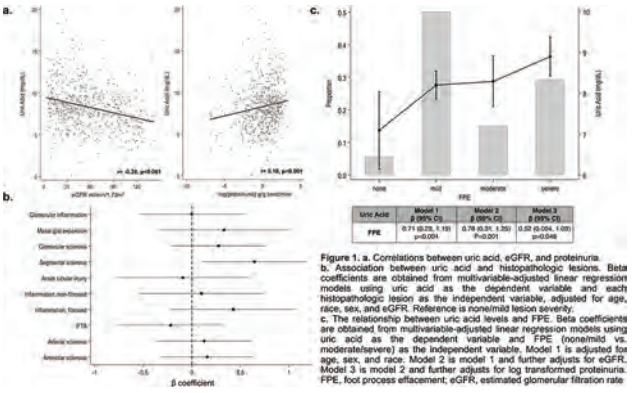


Figure 1. a. Correlations between uric acid, eGFR, and proteinuria. b. Association between uric acid and histopathologic lesions. Beta coefficients are obtained from multivariable-adjusted linear regression models using uric acid as the dependent variable and each histopathologic lesion as the independent variable, adjusted for age, race, sex, and eGFR. Reference is none/mild lesion severity. c. The relationship between uric acid levels and FPE. Beta coefficients are obtained from multivariable-adjusted linear regression models using uric acid as the dependent variable and FPE (none/mild vs. moderate/severe) as the independent variable. Model 1 is adjusted for age, sex, and race. Model 2 is model 1 and further adjusts for eGFR. Model 3 is model 2 and further adjusts for log transformed proteinuria. FPE, foot process effacement; eGFR, estimated glomerular filtration rate

FR-PO929

Association of Podocyte Injury with Kidney Histopathologic Lesions and Disease Progression

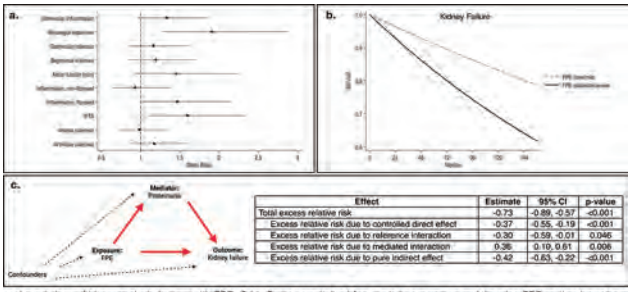
Marius Wittig,[1] Ashish Verma,[5] Andrea Bellavia,[7] Sophia H. Rosan,[5] Sophie E. Claudel,[5] Aditya L. Surapaneni,[6] Ragnar Palsson,[2] Anand Srivastava,[3] Isaac E. Stillman,[4] Morgan Grams,[6] Eugene P. Rhee,[2] Tobias B. Huber,[1] Joel M. Henderson,[5] Sushrut S. Waikar,[5] Insa M. Schmidt.[5] *[1]Universitat Hamburg Medizinische Fakultat, Hamburg, Germany; [2]Massachusetts General Hospital, Boston, MA; [3]University of Illinois Chicago, Chicago, IL; [4]Icahn School of Medicine at Mount Sinai, New York, NY; [5]Boston Medical Center, Boston, MA; [6]NYU Langone Health, New York, NY; [7]Harvard Medical School, Boston, MA.*

Background: Foot process effacement (FPE), a marker of podocyte injury observable via electron microscopy (EM), is critically involved in the pathophysiology of proteinuria and kidney disease progression in glomerular diseases. The association of FPE with histopathologic lesions and adverse clinical outcomes across a range of kidney diseases has not yet been explored.

Methods: We developed a semi-quantitative scoring system to assess FPE severity using EM reports from 813 participants in the Boston Kidney Biopsy Cohort (BKBC), a prospective cohort of individuals with biopsy-confirmed kidney disease and pathologist-adjudicated assessment of histopathology. Logistic regression models assessed the relationship between FPE severity and histopathologic lesions. Accelerated failure time models examined the relationship between FPE and progression to kidney failure. Lastly, we employed mediation analyses to decompose the effect of FPE severity on kidney failure, exploring the role of proteinuria as a mediator in this pathway.

Results: Mean eGFR was 58.4 ±35.6 ml/min/1.73m^2 and median proteinuria (IQR) was 1.6 [0.4–4.0] g/g creatinine. Six % had no FPE, 50% had mild FPE, 15% had moderate FPE, and 29% had severe FPE. After multivariable adjustment, more severe mesangial expansion (OR 1.91, 95% CI 1.26 to 2.88, p=0.002) and more severe interstitial fibrosis/tubular atrophy (OR 1.60, 95% CI 1.09 to 2.33, p=0.015) were significantly associated with more severe FPE (**Figure 1a**). In the fully adjusted model, moderate or severe FPE was associated with a 2-fold higher hazard of progression to kidney failure compared to none or mild FPE (HR=2.01 (95% CI 1.41, 2.87), (**Figure 1b**). Mediation analysis showed that FPE affected kidney failure survival times through both direct effects (-0.37) and indirect effects via proteinuria (-0.42), both p<0.01 (**Figure 1c**).

Conclusions: FPE is linked to glomerular and tubulointerstitial patterns of injury and may serve as a prognostic tool for assessing the risk of disease progression across a range of kidney diseases. Further research on the mechanistic links between FPE severity and adverse kidney outcomes is needed to evaluate targeting podocyte integrity in therapeutic strategies.



a. Associations of histopathologic lesions with FPE. Odds Ratios are derived from logistic regression models using FPE as the dependent and each histopathologic lesion as the independent variable. Models are adjusted for age, race, sex, and eGFR. b. Adjusted survival curves show the association between FPE and time-to-kidney failure (defined as the need for kidney replacement therapy). Results are obtained from accelerated failure time exponential models. Models are stratified by site and adjusted for age, sex, race, log(proteinuria), primary clinicopathologic diagnosis, and eGFR. c. Decomposition of the relationship between FPE, proteinuria, and kidney failure using mediation analysis. IFTA, interstitial fibrosis/ tubular atrophy; FPE, foot process effacement

Targeting Podocyte Calcium Influx with TRPC6 Inhibitor BI 764198: Implications for Glomerular Filtration Barrier Protection

Stefano Da Sacco,[1] Qi Zhang,[1] Steven S. Pullen,[2] Laura Perin.[1]
[1]Children's Hospital Los Angeles, Los Angeles, CA; [2]Boehringer Ingheleim Pharmaceuticals, Ridgefield, CT.

Background: The glomerular filtration barrier (GFB) is essential for blood homeostasis, with podocyte function being vital for GFB integrity. Damage to podocytes leads to foot process effacement, apoptosis, and compromised glomerular permselectivity. Activation of the TRPC6 channel-mediated calcium influx in podocytes induces actin cytoskeleton rearrangement, leading to impaired filtration barrier function. This study evaluates the efficacy of TRPC6 inhibitor BI 764198 in mitigating TRPC6-mediated podocyte effects and elucidates its action mechanism.

Methods: Primary human podocytes and glomerular endothelial cells (GECs) were cultured in high glucose and exposed to angiotensin II, with or without TRPC6 inhibitor BI 764198. Cellular responses were gauged using immunofluorescence and qPCR. Calcium influx was monitored with Fura Red and Fluo-4 dyes. The inhibitor's protective effect on the GFB was also tested using a glomerulus-on-a-chip model and single cell-RNAseq and proteomics analyses were performed on collected cells and filtrate.

Results: High glucose upregulated TRPC6 expression in podocytes but not in GECs, thus highlighting the specificity of the TRPC6 activity in podocytes. Angiotensin II induced a significant calcium influx in podocytes, which BI 764198 effectively inhibited. GECs showed no calcium response to angiotensin. BI 764198 successfully reduced albumin leakage in the glomerulus-on-a-chip, indicating barrier protection. Preliminary scRNAseq and proteomics data support BI 764198's role in preventing TRPC6-mediated podocyte injury.

Conclusions: The findings provide in vitro validation of the therapeutic potential of the selective TRPC6 inhibitor BI 764198, shedding light on its protective mechanism of action.

STING Pathway Activation Is Associated with Poor Prognosis in Acute Tubulointerstitial Nephritis

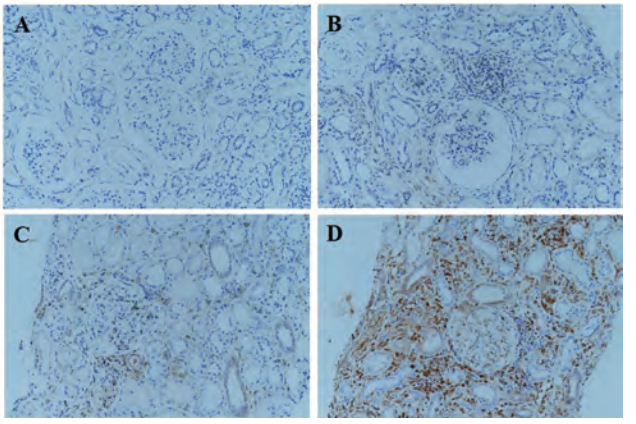
Byung chul Yu, Soo Jeong Choi, Moo Yong Park, Jin kuk Kim.
Soonchunhyang University Hospital Bucheon, Bucheon, Gyeonggi-do, Republic of Korea.

Background: We hypothesized that acute tubulointerstitial nephritis (ATIN) pathogenesis may be associated with mitochondrial injury and that the degree of mitochondrial injury at the time of diagnosis may serve as a valuable prognostic marker.

Methods: We prospectively enrolled 41 patients with ATIN. We analyzed the signal intensity of immunohistochemical (IHC) staining of the stimulator of interferon genes (STING) in kidney tissues at diagnosis as a proxy of mitochondrial injury in patients with ATIN. We evaluated clinical outcomes including achievement of complete remission (CR), defined as a doubling of estimated glomerular filtration rate (eGFR) compared with baseline values or eGFR≥ 60 mL/min/1.73m^2 at 1 year after diagnosis.

Results: A single pathologist categorized the signal intensity of the IHC staining from negative to 3+ (Figure 1). Patients were divided into the low- (n = 22) and high- (n = 19) intensity groups, with a cut-off of 2+. The mean baseline eGFR did not differ between low- and high-intensity group (24 ± 16 vs. 21 ± 14 mL/min/1.73m^2, p = 0.541). The mean eGFR at 1 year after diagnosis were higher in the low- than in the high-intensity group (56 ± 25 vs. 39 ± 22 mL/min/1.73m^2, p = 0.032). More patients achieved CR in the low- than in the high-intensity group (81.8 vs. 47.4%, p = 0.020). Low-intensity group was associated with CR (hazard ratio, 4.61; 95% confidence interval, 1.62 to 9.76, after adjustment for confounding factors including etiology, underlying pathological lesions, and presence of immunosuppressant administration).

Conclusions: More severe mitochondrial injury, indicated by a high for STING IHC signal intensity at diagnosis, could be used as a prognostic marker to predict a poor prognosis in ATIN.



Representative images of immunohistochemistric staining for STING on kidney tissue obtained from patients with acute tubulointerstitial nephritis. Patients were classified into negative (A), 1+ (B), 2+ (C), and 3+ (D) according to the IHC signal intensity.

FR-PO932

Discovery of a Small Molecule with an Inhibitory Role for RAB11 with Validation in Nephrocytes

Camille Lempicki,[1] Julian Milosavljevic,[1] Christian Laggner,[2] Konrad Lang,[1] Tobias F. Hermle.[1] *[1]Renal Division, Department of Medicine, Faculty of Medicine and Medical Center - University of Freiburg, Freiburg, Germany; [2]Atomwise Inc, San Francisco, CA.*

Background: DNA variants in *TBC1D8B* have been discovered as a monogenic cause of nephrotic syndrome. TBC1D8B dysfunction has been linked to disinhibition of RAB11. No specific small molecule inhibitor for RAB11 has been described so far but might offer potential therapeutic value.

Methods: To identify candidate compounds, the proprietary AtomNet platform was utilized for deep learning-based computational screening. For experimental confirmation, we employed an *in vitro* platform reflecting RAB11 activity through the exocytosis of GFP. We further examined autophagy, which independently relies on RAB11. Toxicity was assessed by Annexin V/propidium iodide exposure and flow cytometry in cultured podocytes. Toxicity in vivo was studied by exposure of *Drosophila* larvae. In podocyte-like *Drosophila* nephrocytes, we further explored the impact of feeding the compound on subcellular localization of endogenous Rab11 and endocytic nephrocyte function.

Results: From 94 candidate molecules identified *in silico*, we confirmed nine compounds through a decrease of secretory GFP in the cellular supernatant, which suggests efficient inhibition of RAB11. We then validated three compounds by measuring a decrease in autophagic flux suggesting inhibition on another cellular function dependent on RAB11. All three inhibitors showed druglike properties. Flow cytometry after Annexin V/propidium iodide exposure indicated absence of toxicity for these chemicals. The survival rate of *Drosophila* larvae fed with the inhibitors was unaffected compared to the control, similarly suggesting low toxicity *in vivo*. *Drosophila* larvae exposed to compound with highest oral bioavailability showed subcellular dispersal of endogenous Rab11 and a decrease in RAB11-dependent nephrocyte function.

Conclusions: We identified three small molecules exhibiting inhibitory function for Rab11. This discovery may open avenues for treating RAB11-associated nephrotic syndrome and other RAB11-associated disorders.

Computationally Derived Characterization of Tubular Changes in Relation to the Development of Interstitial Fibrosis

Fan Fan,[1] Qian Liu,[2] Jarcy Zee,[3,2] Takaya Ozeki,[8] Dawit S. Demeke,[4] Bangchen Wang,[5] Jackson Jacobs,[6] Manav P. Shah,[6] Alton B. Farris,[7] Laura H. Mariani,[8] Kyle J. Lafata,[9] Yijiang Chen,[10] Lawrence B. Holzman,[11] Jeffrey B. Hodgin,[4] Anant Madabhushi,[6,12] Laura Barisoni,[5,13] Andrew Janowczyk.[6,14] *[1]Emory University, Atlanta, GA; [2]The Children's Hospital of Philadelphia Research Institute, Philadelphia, PA; [3]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [4]University of Michigan Department of Pathology, Ann Arbor, MI; [5]Duke University Department of Pathology, Durham, NC; [6]Emory University School of Medicine, Atlanta, GA; [7]Emory University Department of Pathology and Laboratory Medicine, Atlanta, GA; [8]University of Michigan Department of Internal Medicine, Ann Arbor, MI; [9]Duke University Department of Radiation Oncology, Durham, NC; [10]Stanford University Department of Radiation Oncology, Stanford, CA; [11]University of Pennsylvania Department of Medicine, Philadelphia, PA; [12]Atlanta Veterans Administration Medical Center, Atlanta, GA; [13]Duke University Department of Medicine, Durham, NC; [14]Department of Oncology, Division of Precision Oncology, University Hospital of Geneva, Geneva, Swaziland.*

Background: The development of interstitial fibrosis & tubular atrophy (IFTA) is a progressive process. Visually it is challenging to quantify the spectrum of tubular changes from normal to atrophy and their spatial relationship with degree of interstitial fibrosis. This study utilizes computational image analysis to uncover tubular pathomic signatures that reflect the spectrum of tubular changes and their relationship with the microenvironment.

Methods: Cortex, pre-, mature-, and non-IFTA sub-regions were manually segmented in n=254 NEPTUNE/CureGN PAS-stained whole slide images (WSIs, n=135 FSGS,119 MCD/MCD-like). We developed and applied segmentation algorithms for tubular epithelium, lumen, nuclei, and basement membranes (288,172 tubules and 323,6081 nuclei) on 13 nephrectomies (reference tissue) and the NEPTUNE/CureGN dataset. 9 out of the 99 extracted, hand-crafted tubule-level features were previously shown to be associated with clinical outcomes and mapped to WSIs to identify the spectrum of tubular pathomic signatures across non-, pre-, and mature- IFTA regions.

Results: A progressive simplification of the tubular epithelium, thickening/area of the tubular basement membranes, and decreased nuclear distance to lumen from normal to full tubular atrophy was witnessed as one transitions between less to more diseased regions (Figure 1.1). The trajectory of tubular changes corresponds to the development of interstitial scarring (Figure 1.2).

Conclusions: Clinically relevant computationally derived tubular characteristics quantify the tubular changes across the spectrum of IFTA development, providing insights into tubule-level heterogeneity and atrophy pathway. This level of detail and quantification is not possible with human assessment alone and opens new opportunities for disease trajectory and biomarker studies.

Podocyte-Derived Vesicles as Urinary Markers of Kidney Function

Luisa Schnobrich,[1] Klaus J. Stark,[2] Hayo Castrop.[1] *[1]Universitat Regensburg Fakultat fur Biologie und Vorklinische Medizin, Regensburg, Germany; [2]Universitat Regensburg Fakultat fur Medizin, Regensburg, Germany.*

Background: Changes in the integrity of the glomerular filtration barrier (GFB) cause the endocytosis of albumin by podocytes from the subpodocyte space, as shown by intravital imaging in rats. Albumin-containing podocyte-derived vesicles are subsequently released into the urinary space and can be recovered from the urine. These vesicles are characterized by the presence of podocalyxin. Based on these results we hypothesized that urinary vesicular albumin (vACR) and vesicular podocalyxin (vPCR) may serve as early biomarkers of changes of the integrity of the GFB in humans.

Methods: Urinary vesicles were isolated by ultracentrifugation from spot urine samples collected from participants of a prospective study, a cohort of mobile elderly subjects (aged 70 years +). Urine samples were collected and an array of clinical parameters was determined at baseline (BL: n = 626), after 3 years (follow-up 1: n = 626) and after 7 years (follow-up 2: n = 197). Vesicular albumin and podocalyxin concentrations were measured using commercially available ELISA kits and results were normalized to urinary creatinine concentration. Using SPSS 28.0.0.0 the association between vesicular parameters and clinical parameters (eGFRCys, urinary albumin/creatinine ratio (uACR), and alpha-1-microglobulin/creatinine ratio (a1M/Cr)) were determined.

Results: A negative association between eGFRCys and vACR was observed for all time points ($p<.001$). Annual changes in eGFRCys were not predicted by vesicular variables. Linear regression analysis between vACR or vPCR and uACR or a1M/Cr, both adjusted for age, sex and eGFRCys, showed a positive association between the variables at all timepoints ($p<.05$). Thus, elevated vACR and vPCR were accompanied by increased uACR and a1M/Cr concentrations. Increased vACR and vPCR concentrations at baseline were associated with a reduced increase of uACR over time, suggesting that the formation of podocyte-derived vesicles reduces the progression of albuminuria by some protective effect on the filtration barrier ($p<.01$).

Conclusions: In summary, increased vACR is associated with decreased GFR, and both vACR and vPCR are associated with the degree of albuminuria and tubular dysfunction. Our data suggests that both vACR and vPCR may serve as new biomarkers of kidney function and may predict the development of albuminuria over time.

Funding: Government Support - Non-U.S.

FR-PO935

Dysmorphic vs. Isomorphic Microhematuria in the Diagnostic Approach of Glomerular Diseases

Jorge A. Sanchez, Sheila Bermejo Garcia, Hector L. Bedoya, Marina López-Martínez, Gerson B. Redondo, Jorge I. Zamora Carrillo, Marc Patricio-Liébana, Natalia Ramos, Irene Agraz Pamplona, Maria Jose Soler. *Hospital Universitari Vall d'Hebron, Barcelona, Spain.*

Background: Dysmorphic microhematuria has been related to glomerulonephritis(GN). This technique has a high specificity with variable sensitivity. The objective of study was to evaluate patients with GN and to study the prevalence of dysmorphic and isomorphic microhematuria and to evaluate factors associated with dysmorphia.

Methods: Retrospective study of patients with GN associated with microhematuria in our hospital from 2013 to 2024. Clinical and analytical characteristics of the patients were analyzed comparing patients who presented or not dysmorphic red blood cells (dRBCs).

Results: 119 patients diagnosed with GN were included:68 men(57.1%), mean age 51.6(±19) years, 55.5%(n=66) hypertension. At the time of the kidney biopsy, creatinine 1.8[0.9-3.6]mg/dl, eGFR 44[15-81] mL/min/m^2 and albumin/creatinine ratio 650[281-1634]mg/gr. The more frequent indication of kidney biopsy was proteinuria and microhematuria(n=52, 43.7%). IgA nephropathy(n=34, 28.6%) was GN with more prevalence. 105 patients(88.2%) had microhematuria, of which 51(48.6%) had dRBCs. Patients with cryoglobulinemia, anti-GBM and IgA Nephropathy, a higher percentage of dRBCs was detected(80%, 57% and 51.6%, respectively p=0.013). A higher prevalence of dRBCs in acute kidney injury, proteinuria and microhematuria as indication of kidney biopsy (p=0.046). Furthermore, patients with hypertension(p=0.013) and men(p=0.038) presented more prevalence of dRBCs. However, patients who did not present dRBCs had a higher ischemic heart disease(p=0.019), antiplatelet agents(p=0.016), protein/creatinine ratio(p=0.043) and positive urine culture(p= 0.046). In the logistic regression analysis, low protein/creatinine ratio(1.03-9.09 OR:3.06, p=0.044) was the only variable associated with the presence of dysmorphia. A ROC curve was obtained with an AUC of 0.72(0.619-0.822 p<0.001). The sensitivity was 31.9% and specificity 91.5%.

Conclusions: Patients with GN and microhematuria, dysmorphia was detected in approximately half of patients. The absence of hypertension, ischemic heart disease, antiplatelet agents, negative urine culture and lower level of proteinuria were related to the presence of dysmorphia, with a sensitivity 31.9% and a specificity 91.5%.

FR-PO936

Urinary White Blood Cell Casts Suggest Presence of Crescentic Lesions in Acute Glomerulonephritis

Muner Mohamed,[1,2] Khalid M. Mohammed,[3] Dustin R. Chalmers,[4] Vipin Varghese,[5] Swetha Rani Kanduri,[1,2] Juan Carlos Q. Velez.[1,2] Ochsner Group. *[1]Ochsner Health, New Orleans, LA; [2]The University of Queensland, Brisbane, QLD, Australia; [3]Tanta University, Tanta, Egypt; [4]Louisiana State University, Baton Rouge, LA; [5]University of Michigan, Ann Arbor, MI.*

Background: Unlike standard dogma of their association with acute interstitial nephritis, urinary white blood cell casts (uWBCC) are more commonly detected in cases of acute glomerulonephritis (GN). However, granular aspects of this association have not been explored. We hypothesized that uWBCC may correlate with specific morphological histopathological findings in GN.

Methods: We prospectively collected data of patients seen in nephrology consultation who had a urine specimen subjected to microscopic examination of the urinary sediment (uSEDI) as part of the clinical evaluation. Within this cohort, we identified cases in which a kidney biopsy was performed and a diagnosis of GN was made. We assessed the performance of uWBCC in predicting specific lesions in GN: cresentic/necrotizing (Cresc/Necr) lesions, endocapillary proliferation (EC) or intersitial inflammatory inflitrate (III).

Results: Among 801 patients assessed by uSEDI over a 5-year period, 107 (15%) had biopsy-proven GN. Within that group, 24 (22%) had uWBCC. Mean age was 54 years, 51% women, 50% white and 38% black. Median serum creatinine at diagnosis was 3.6 (0.7-15.6) mg/dL. Biopsy diagnosis was pauci immune GN in 6 (25%), IgA nephropathy in 6 (25%), lupus GN in 3 (13%) and other proliferative or infection-related GN in 9 (37%). The sensitivity (SENS), specificity (SPEC), positive predictive value (PPV) and negative predictive value (NPV) of uWBCC for identifying Cresc/Necr lesions were 34%, 90%, 71% and 28%, respectively, whereas the SENS, SPEC, PPV and NPV of uWBCC for identifying EC were 28%, 80%. 38% and 27%. Also, the SENS, SPEC, PPV and NPV of uWBCC for III were 75%, 48%, 38% and 96%. Notably, 6 out of 9 GN cases with uWBCC and III also had Cresc/Necr lesions.

Conclusions: Identification of uWBCC by uSEDI in patients GN is fairly specific to predict Cresc/Necr lesions. This observation suggests that WBCs contained in casts likely originate from circulating cells that travel from the glomerular capillary lumen into the Bowman space through glomerular basement membrane (GBM) breaks. In addtion, absence of uWBCC is highly predictive of absence of III. These findings offer diagnostic/therapeutic insight for the clinician in anticipation of a kidney biopsy.

FR-PO937

Value of Diffusion Kurtosis Imaging in Assessing IgG4 Kidney Disease: A Feasibility Study

Fei Teng, Xiaoxiao Zhang, Gu-Mu-Yang Zhang, Xuemei Li, Hao Sun, Ke Zheng. *Peking Union Medical College Hospital, Beijing, China.*

Background: Immunoglobulin G4 (IgG4)-related kidney disease (IgG4-RKD) is pathologically featured by interstitial IgG4+ plasma cell infiltration and interstitial fibrosis, and often leads to chronic kidney dysfunction. Our study aims to explore the use of invasive diffusion kurtosis imaging (DKI) in assessing IgG4-RKD and to evaluate the potential of DKI-based quantitative parameters in the clinical assessment of IgG4-RKD.

Methods: A prospective study was conducted on 23 IgG4-RKD patients who underwent bilateral renal MRI with T1WI, T2WI, and DKI sequences. Two radiologists evaluated the MR images and determined the distribution pattern and signal intensity of the renal lesions. The mean kurtosis (MK), mean diffusivity (MD), and apparent diffusion coefficient (ADC) of the renal parenchyma, cortex, and medulla were measured. Correlation analysis with clinical indicators such as creatinine, estimated glomerular filtration rate (eGFR), IgG4, IgG, complement, and erythrocyte sedimentation rate (ESR) was performed, and interclass correlation coefficient (ICC) was used to evaluate consistency of measurement.

Results: IgG4-RKD showed bilateral (90.91%), multiple (95.24%) and wedge- or round-shaped renal parenchymal lesions (90.91%) with iso-signal on T1WI (80.96%), low signal on T2WI (85.71%) and high-signal on DKI (95.24%). MK, MD, and ADC did not differ between the left and right kidneys. There were no significant differences in MK and ADC in the renal parenchyma, renal cortex, and renal medulla, but MD was higher in the renal cortex. There was a strong negative correlation between eGFR and renal cortical MK (r = 0.66, p = 0.002), as well as a weak positive correlation between serum IgG4/IgG and parenchymal ADC (r=0.37, p=0.038). The C4 was positively correlated with MD-P (r=0.51, p=0.118), and ESR was positively correlated with renal parenchymal MK (r=0.58, p=0.005). The agreement of DKI parameters was moderate to good, except for bilateral renal medullary MD.

Conclusions: DKI images can be used to assess IgG4-RKD renal imaging alterations, and the quantitative parameter MK obtained on the basis of DKI correlates with serum creatinine, eGFR and IgG4/IgG ratio. DKI images have the potential to assess IgG4-RKD clinical condition.

FR-PO938

Variations in Creatinine Generation among Patients with Glomerular Diseases

Shalini S. Ramachandra,[1] Melody Chiang,[2] Michael Arbit,[2] Dorey A. Glenn,[3] Laura H. Mariani,[2] Jarcy Zee.[1,4] *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]University of Michigan Department of Internal Medicine, Ann Arbor, MI; [3]The University of North Carolina at Chapel Hill Kidney Center, Chapel Hill, NC; [4]The Children's Hospital of Philadelphia Research Institute, Philadelphia, PA.*

Background: Estimation of glomerular filtration rate (eGFR) assumes that creatinine generation (CrG) is relatively stable, but the relationship between CrG variability and glomerular disease activity is unknown.

Methods: CrG was calculated using 24-hour timed urine collections from children and adults with MCD, FSGS, MN, IgAN, or non-biopsied pediatric nephrotic syndrome enrolled in the NEPTUNE and CureGN cohort studies. Intraclass correlation coefficients (ICC) were used to estimate CrG variability within individuals over time. Multivariable linear mixed models were used to identify: (1) factors associated with CrG and (2) the impact of change in CrG (ΔCrG) on changes in serum creatinine (ΔSCr), adjusting for simulated true GFR.

Results: A sample of 4626 CrG measurements were analyzed from 1081 study participants (26.7%<18 years). A moderate correlation between intra-individual measurements overall (ICC = 0.517, 95% CI: 0.482, 0.548), and a weak correlation among non-biopsied pediatric participants (ICC = 0.241 (95% CI: 0.000, 0.558) were observed. Among all pediatric participants, factors significantly associated with CrG included age, sex, weight status, and urine protein [Figure 1A]. Among adults, age, sex, disease diagnosis, weight status, eGFR, steroid use, and non-steroid immunosuppressant (IST) use were significantly associated with CrG [Figure 1B]. After adjustment for simulated true GFR (based on ρ=0.512 correlation with ΔCrG and ρ=-0.835 correlation with ΔSCr) and other covariates, every 10 mg/kg/day increase in ΔCrG was associated with a 0.48 mg/dL increase in ΔSCr (p < 0.001).

Conclusions: Creatinine generation was highly dynamic within individuals over time and varied with glomerular disease activity and treatments. The impact of changes in creatinine generation on estimation of kidney functions is potentially large. Accounting for these changes and/or routine use of other markers to measure kidney function may be beneficial for patients with glomerular disease.

Funding: NIDDK Support

FR-PO939

Air Quality and Kidney Health: Assessing the Effects of PM10, PM2.5, CO, and NO2 on Kidney Function in Primary Glomerulonephritis

Jinyeong Yi,[1] Yun Jung Oh,[2] Julee You,[3] Jiwon Ryu.[3] *[1]Seoul National University College of Medicine, Jongno-gu, Seoul, Republic of Korea; [2]H Plus Yangii Hospital, Seoul, Republic of Korea; [3]Seoul National University Bundang Hospital, Seongnam, Republic of Korea.*

Background: Although extensive research has established associations between exposure to air pollution and chronic disease, such as cardiovascular disease and diabetes, the nuanced impact on specific kidney pathologies like primary glomerulonephritis (GN)—an immunological kidney disorder—remains underexplored. Given the increasing burden of GN and the notable gap in research on its relation to air quality, our study focuses on exploring the long-term effects air pollutants on renal function in patients with primary GN.

Methods: This retrospective cohort study analyzed 1,394 primary GN patients diagnosed at Seoul National University Bundang Hospital and Seoul National University Hospital. We used time-varying Cox regression and linear mixed models (LMM) to determine the impact of yearly average air pollution levels on renal function deterioration and change in estimated glomerular filtration rate (eGFR). Renal function deterioration (RFD) is defined as a sustained eGFR less than 60 mL/min per 1.73 m^2.

Results: Over a mean follow-up of 5.1 years, 350 patients developed RFD. Notably, increased interquartile range (IQR) levels of air pollutants—PM_{10} (particles ≤10 micrometers, HR 1.383, 95% CI 1.194–1.601), $PM_{2.5}$ (particles ≤2.5 micrometers, HR 1.341, 95% CI 1.15–1.564), CO (carbon monoxide, HR 1.254, 95% CI 1.092–1.441), and NO_2 (nitrogen dioxide, HR 1.174, 95% CI 1.017–1.356)—were significantly linked to higher RFD risk, after adjusting for demographic and health factors. Additionally, exposure to PM_{10} and $PM_{2.5}$ was associated with decreased eGFR.

Conclusions: This study demonstrates a significant relationship between exposure to air pollution and renal function in primary GN, highlighting the importance of environmental factors in immune-mediated kidney disease.

FR-PO940

Demographics and Trends of Tubulointerstitial Nephritis-Related Mortality in the United States, 1999-2020

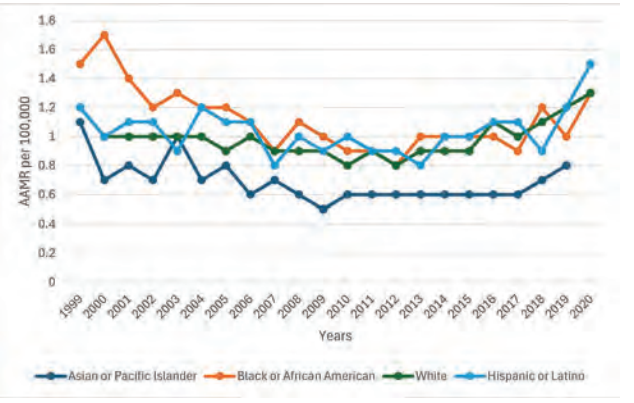
Badar U Din Shah,[1] Wania Rehman,[2] Muhammad Talha Shaukat,[2] Malik S. Hayat,[2] Muhammad Mukarram Shoaib,[2] Aqeeb Ur Rehman,[3] Aleenah Mohsin,[4] John W. O'Bell.[4] *[1]Geisinger Health, Danville, PA; [2]King Edward Medical University, Lahore, Pakistan; [3]The University of Alabama at Birmingham Heersink School of Medicine, Birmingham, AL; [4]Brown University, Providence, RI.*

Background: The incidence of tubulointerstitial nephritis as a cause for mortality is on the rise in the US. In this study, we aim to investigate the patterns of mortality associated with it spanning from 1999 to 2020 in the United States.

Methods: Data was extracted from the CDC WONDER database from 1999 to 2020. Age-adjusted mortality rate (AAMR) per 100,000 individuals and annual percent changes (APC) with 95% Confidence Intervals (CI) were calculated using Joinpoint regression for different epidemiological cohorts stratified by gender, race, and locale (metropolitan vs. non-metropolitan).

Results: From 1999 to 2020, a total of 37,611 deaths were reported due to tubulointerstitial nephritis. The overall AAMR showed a gradual decline from 1999 to 2012 followed by a progressively increasing trend from 2012-2020, with an APC of -2.1853 and 5.0345 respectively. The analysis revealed significant disparities in mortality rates among different demographic groups and geographical regions. The mortality rates were found to be higher in female patients (AAPC: 0.3% (95% CI -0.74 to 1.35)), Latino/Hispanic patients (AAPC: 1.5% (95 % CI 0.87 to 3.97)) and residents of metropolitan areas (AAPC: 1.22% (95% CI -1.75 to 4.28)).

Conclusions: Our study revealed an increasing trend of tubulointerstitial nephritis-related mortality from 2012 onwards with demographic and geographical disparities, which underscores the necessity for further research to address these disparities and mitigate the rising mortality associated with tubulointerstitial nephritis.



Trends of mortality due to tubulointerstitial nephritis across different races in the United States;1999-2020

FR-PO941

Demographics and Trends of Mortality Due to Nephritic Syndrome in the United States, 1999-2020

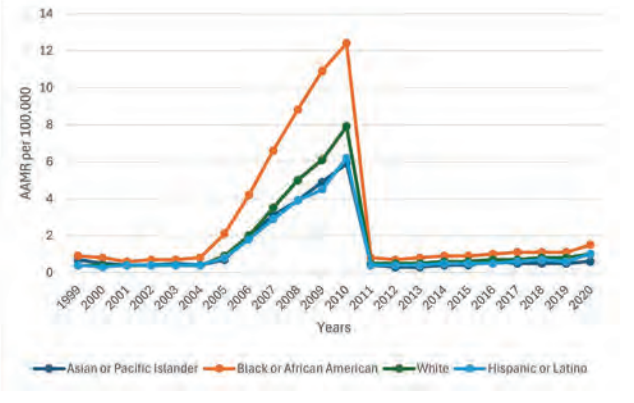
Badar U Din Shah,[1] Muhammad Talha Shaukat,[2] Wania Rehman,[2] Malik S. Hayat,[2] Fatima Shahid,[2] Aqeeb Ur Rehman,[3] Aleenah Mohsin.[4] *[1]Geisinger Health, Danville, PA; [2]King Edward Medical University, Lahore, Pakistan; [3]The University of Alabama at Birmingham Heersink School of Medicine, Birmingham, AL; [4]Brown University, Providence, RI.*

Background: The mortality rate associated with nephritic syndrome in the US is on the rise. We analyze mortality trends from 1999 to 2020 using age-adjusted mortality rates (AAMR) to identify disparities among different demographic groups.

Methods: Data was extracted from the Centers for Disease Control and Prevention Wide-Ranging Online Data for Epidemiological Research (CDC WONDER) database from 1999 to 2020. Age-adjusted mortality rate (AAMR) per 100,000 individuals and annual percent changes (APC) with 95% Confidence Intervals (CI) were calculated using Joinpoint regression analysis for different epidemiological cohorts stratified by gender, race, and locale.

Results: From 1999-2020, 120103 nephritic syndrome-related deaths were documented. APC of 89.21 from 2003-2007, 26.75 from 2007-2010, and 14.2 from 2013-2020 indicate an increasing trend in AAMR from 1999-2020. However, there was a notable drop in nephritis associated mortality between 2010 and 2013 (APC= -62.73). Certain groups experienced consistently higher death rates, including African Americans (average annual percentage change (AAPC):2.72, 95% CI:-3.8 to 9.7), males (AAPC:4.04, 95% CI:-0.9 to9.2), individuals aged 85 and older. The Midwest region had the highest mortality rates (AAMR:1.8), followed by the South and West (AAMR:1.7) and the Northeast (AAMR 1.3). Specific states with high mortality rates included Tennessee, South Carolina, Minnesota, Wisconsin and Oregon. There was no significant difference in mortality rates between metropolitan (AAPC:3.62) and non-metropolitan areas (AAPC: 3.90).

Conclusions: The rise in nephritic syndrome-related mortality from 1999 to 2020 is concerning and underscores the need for focused research and targeted interventions. Continued efforts are essential to ensure equitable access to effective treatments and improve patient outcomes across all affected demographic groups.



Mortality trends of nephritic syndrome across different races

FR-PO942

Trend Analysis of Renal Tubulointerstitial Disease-Related Mortality, 1999-2020

Mohammad Ammar ur Rahman,[1] Ahmed J. Chaudhary,[2] Eisha Moazzam,[1] Luqman Munir,[1] Amna Khalid,[1] Haram Aftab,[1] Azka Ijaz.[1] NEURALKEy. *[1]King Edward Medical University, Lahore, Pakistan; [2]Detroit Medical Center, Detroit, MI.*

Background: Renal tubulointerstitial disease is a term which encompasses primary injury of renal structures resulting in inflammation of kidney and the surrounding tissues (interstitial tissues), hence it is also referred to as tubulointerstitial nephritis. It can a result of a hypersensitivity reaction to certain medications, exposure to heavy metals and infections. For treatment, removing the causative agent is preferred followed by corticosteroid therapy. The aim of this study was to analyze the trend of deaths as a result of renal tubulo-interstitial disease in the US from 1999 to 2020 using age-adjusted mortality rate (AAMR) and to identify variations among key demographic variables.

Methods: We obtained death certificates from 1999 to 2020 from the website of Centers for Disease Control and Prevention Wide-ranging Online Data for Epidemiologic Research (CDC WONDER). AAMR per 1,000,000 people and annual percent change (APC) with 95% confidence interval were determined. Joinpoint Regression Program was used to determine trends among demographics groups (gender, age, race, urban/rural).

Results: In total, 7,341 deaths due to renal tubulointerstitial diseases were recorded. The age-adjusted mortality rate (AAMR) surged from 15.228 in 1999 to 17.962 in 2020. The annual percentage change (APC) in AAMR indicated following trends: from 1999 to 2011, the APC was -2.1150, demonstrating a decline; from 2011 to 2018, the APC rose to 3.8974; and from 2018 to 2020, the APC showed a noticeable peak at 9.5021. On analysis, higher mortality rates were recorded among Black individuals, those living in rural areas, the residents of western region, males, and individuals aged 85 years and older.

Conclusions: The mortality rate due to renal tubulointerstitial diseases has experienced a concerning rise in the last two decades. Persistent disparities among the demographic variables highlight the need for further investigation and intervention.

FR-PO943

Changes in the Spectrum of Kidney Diseases: A 14-Year Kidney Biopsy Study from a Single Center

Zishan Lin, Shidong Xie, Wenfeng Wang, Tao Hong, Jianxin Wan, Yanfang Xu. *The First Affiliated Hospital of Fujian Medical University, Fuzhou, China.*

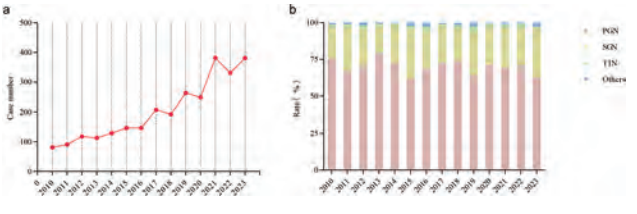
Background: CKD is a critical global public health concern. Early detection and treatment are crucial in preventing progression. Renal biopsy remains a cornerstone in diagnosing various kidney diseases. Recent decades have seen shifts in the disease spectrum, driven by factors like hepatitis B, diabetes, and aging. The study aims to investigate the changing spectrum of kidney diseases for disease prevention and public health interventions.

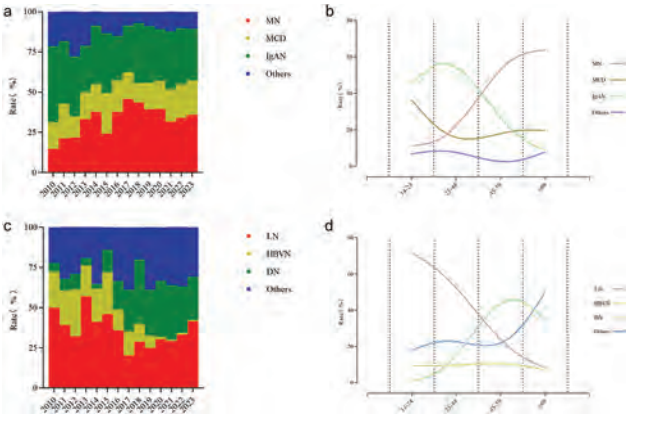
Methods: Patients (≥14 years of age) who underwent renal biopsy at the First Affiliated Hospital of Fujian Medical University from January 2010 to December 2023 were included in the study. Clinicopathological data was collected.

Results: This study involved 2832 patients. Annual renal biopsy numbers rose from 81 in 2010 to 381 in 2023 (Fig 1A). Primary glomerulonephritis (GN) was the leading cause of kidney diseases (Fig 1B). Patients aged ≥60 years grew from 9.3% in 2020 to 23.2% in 2023, showing a demographic shift towards an older population. MN, IgAN, and MCD were the most common primary GN subtypes, representing 34.9%, 34.5%, and 18.5% of cases, respectively (Fig 2A). From 2010 to 2023, MN cases increased from 14.8% to 36.0%. MN predominantly occurred in the elderly, with rising prevalence with age (Fig 2B). LN, DN, and HBVN were the top secondary GN causes, accounting for 34.3%, 24.8%, and 9.0% of cases, respectively (Fig 2C). DN notably rose from 5.6% in 2010 to 40.0% in 2018. HBVN incidence consistently declined. LN primarily affected younger patients, while DN was more prevalent in older individuals, peaking at 43.8% in the 45-59 age group (Fig 2D).

Conclusions: The spectrum of kidney disease has changed within the last 14 years. The relative frequency of MN and DN increased significantly, while that of HBVN decreased significantly.

Funding: Government Support - Non-U.S.





FR-PO944

Geospatial Mapping to Identify Primary Glomerulonephritis Hot Spots in Saskatchewan

Bhanu Prasad,[1] Aditi Sharma,[2] Aarti Garg,[2] Abdul Raouf,[5] Matthew Patterson,[4] Pouneh P. Dokouhaki.[3] *[1]Regina General Hospital, Regina, SK, Canada; [2]University of Regina, Regina, SK, Canada; [3]The University of British Columbia, Vancouver, BC, Canada; [4]University of Saskatchewan, Saskatoon, SK, Canada; [5]Saskatchewan Polytechnic - Regina Campus, Regina, SK, Canada.*

Background: Saskatchewan (SK), a province rich in oil, minerals, and agriculture, with 1.2M population, is principally served by its two urban renal centers in Regina and Saskatoon. There is a lack of comprehensive data on the association of GN subtypes with rural-urban divide, and geographic hotspots like mines and refineries. Utilizing the kidney biopsy, our objective was to identify clusters of GN subtypes, calculate yearly incidence rates, urban/rural comparisons, and distance and travel time to access care.

Methods: A centralized provincial kidney pathology database was used to capture all incident cases of biopsy-proven GN in the adult population from 2002 - 2018. Only patients with primary GN were included (n=1372). Demographic attributes, 3-digit postal codes, lab parameters, definitive GN diagnosis, the date of biopsy, dialysis start, and death were collected and analyzed. To analyze the variation of GN across different regions in SK we used SaTScan v10.1.3 software. The population data from Census 2016 was used as a reference, and age and sex were taken as covariates.

Results: GN incidence increased from 4.6 to 13.6 per 100,000 persons from 2002 to 2018 ($p<0.001$). GN incidence was higher in rural areas than in urban areas ($p<0.001$). Significantly higher dialysis progression rates were seen for rural and remote areas ($p<0.01$). We identified a geospatial cluster of 345.7 km^2 for lupus nephropathy (Figure 1(f)), with an incident rate ratio of 1.73, a relative risk of 2.7, and a Log likelihood ratio of 13.87. No significant clusters were identified for any other subtypes of GN.

Conclusions: We identified a geographic cluster for lupus nephropathy, encompassing both urban and rural areas. While there was a higher incidence of MN and AGBM in rural areas, we did not identify any geographic clusters for the same. Addressing and understanding the multifaceted factors driving these disparities are essential steps towards easing the burden of GN on impacted communities.

Figure 1: Lupus Cluster in the entire province (highlighted in red). The inset on the left represents regions that are part of the lupus cluster in Saskatoon.

FR-PO945

Incidence of Glomerulonephritis and Clinical Outcomes of Kidney Biopsy Patients at the National and Transplant Kidney Institute, 2016-2022

Melanie T. Estolas. *National Kidney and Transplant Institute, Quezon City, Philippines.*

Background: Glomerulonephritis remains a predominant cause of end stage kidney disease and is potentially reversible but entails a kidney biopsy for definitive diagnosis, management decisions and prognostication. There is limited data on incidence of glomerular diseases in the Philippines, and a national kidney biopsy registry is lacking for the years 2016 and onwards.

Methods: A total of 2249 patients who had native kidney biopsy at NKTI from 2016-2022 were identified and a retrospective review of their chart records, laboratory results and kidney biopsy findings was done, with a follow up for at least 12 months.

Results: The median age for kidney biopsy was 34 years with a higher female prevalence (56.16%). Primary glomerulonephritis comprised 74.17% of cases and secondary GN for 23.5%. IgA nephropathy at 45.86% and FSGS at 19.78 were the most common for primary GN. For secondary GN, Lupus nephritis was the most prevalent at 56.7%. IgAN had the highest incidence of complete and partial remission. Progression to ESRD requiring dialysis was almost similar for IgAN and FSGS.

Conclusions: IgA nephropathy is still the most prevalent type of primary glomerulonephritis in this single center study, while Lupus nephritis is the most common secondary GN. A significant overall improvement in kidney function and proteinuria was noted on follow up.

FR-PO946

Enhancing Patient Comprehension of Glomerular Disease Terminology: Role of Artificial Intelligence (AI) in Simplifying Medical Communication

Yasir Abdelgadir, Charat Thongprayoon, Iasmina Craici, Wisit Cheungpasitporn, Jing Miao. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Glomerular disease is complex and difficult for patients to understand due to its involvement in various areas such as renal anatomy, pathophysiology, immunology, genetics, and diverse treatment strategies. This study employed the AI language model ChatGPT to simplify glomerular disease terms, proposing a new way to improve patient comprehension of this condition.

Methods: Seventy-three terms related to glomerular disease were analyzed using GPT-4 through two inquiries: one for easy-to-understanding and another for patients with an education level of 8th grade or lower. GPT-4's accuracy was scored from 1 (incorrect) to 5 (correct and comprehensive), and readability was assessed using the Consensus Reading Grade (CRG) Level, incorporating the Flesch-Kincaid Grade (FKG) and SMOG indices. Paired t-test compared the accuracy and readability of both inquiries.

Results: GPT-4's easy-to-understanding explanations of glomerular disease terms averaged a 12th-grade readability level (12.5 by CRG and 12 by FKG), reflecting the topic's complexity (Fig.). When inquired for patients with 8th grade or lower, readability improved, averaging 9.7 by CRG and 8.7 by FKG, with the SMOG index indicating a further reduction from 10.2 to 7.2. However, the accuracy in GPT-4's explanations for patients at or below the 8th-grade level was significantly lower than that for easy-to-understanding explanations (*p=0.01*).

Conclusions: While GPT-4 effectively simplified information about glomerular diseases, it compromised its accuracy in the process. Although ChatGPT has the potential to contribute to enhancing patient understanding of glomerular disease, it is crucial to closely examine and work on improving its accuracy when generating simplified explanations with human nephrologist to ensure that the information provided is not only easy to understand but also medically accurate and appropriate for patient education.

Fig. Accuracy and Readability of GPT-4's Explanations of Glomerular Disease Terms in Different Inquiries

	GPT-4's explanations for easy-to-understanding	GPT-4's explanations for patients at or below 8th grade	P value
Accuracy [a]	4.44 ± 0.51	4.26 ± 0.35	0.01[c]
CRG level [b]	12.52 ± 1.20	9.69 ± 0.78	<0.0001 [c]
FKG level	12 ± 1.46	8.72 ± 0.85	<0.0001 [c]
SMOG Index	10.17 ± 1.15	7.24 ± 0.85	<0.0001 [c]

[a] Accuracy, scaled from 1 to 5: 1=Completely incorrect, 2=Mostly incorrect, 3=Partly correct and partly incorrect, 4=Correct but not comprehensive, and 5=Correct and comprehensive. The accuracy is assessed independently by two nephrologists and the average score is used for each explanation.

[b] Consensus Reading Grade (CRG) Level is calculated through a free online Readability Scoring System (https://readabilityformulas.com/readability-scoring-system.php) based on 7 readability metrics: the Automated Readability Index, Gunning Fog Index, Flesch-Kincaid Grade (FKG) Level, Coleman-Liau Index, Simple Measure of Gobbledygook (SMOG) Index, Linsear Write Formula, and the FORCAST Readability Formula. When writing content for the general public, aim for a reading level equivalent to around 8th grade. ***The FKG test is used extensively in the field of education. SMOG index is also widely used, but particularly for checking health messages.***

[c] A paired two-sided t test.

FR-PO947

Hypercalcemia in IgG4-Related Tubulointerstitial Nephritis: An Unusual Presentation

Ravi K. Singh. *Jaypee Hospital, Noida, Noida, India.*

Introduction: Tubulointerstitial nephritis IgG4 type (TIN-IgG4) is a rare autoimmune kidney condition characterized by IgG4-positive plasma cell infiltrates, leading to renal interstitium inflammation and fibrosis. Associated with IgG4-related disease affecting various organs, diagnosis involves elevated IgG4 levels, with hypercalcemia hinting at parathyroid involvement. This case presents TIN-IgG4 with hypercalcemia without parathyroid abnormalities, detailing clinical presentation, diagnostic workup, and treatment strategies.

Case Description: A 30-year-old female (a known case of cholelithiasis and hypothyroidism) presented with malaise, vomiting, abdomen pain and dizziness for 3-5 days. Investigations showed hypercalcemia, 24-hour urinary calcium of 288 mg/dL, creatinine of 770 mg/day and protein of 301 mg/dL (Table). Ultrasound showed signs of medullary nephrocalcinosis. There was no evidence of parathyroid adenoma. Renal biopsy confirmed the diagnosis of TIN-IgG4 based on histopathological findings of interstitial fibrosis, tubular atrophy, and abundant IgG4-positive plasma cell infiltration. Serological testing for free light chains (Kappa and Lambda), renal ultrasound and CT, and histopathological examination of renal tissue were obtained. Serum IgG4 level was elevated and imaging findings supported TIN-IgG4 diagnosis. Denosumab, steroids along with her routine thyroid medications were initiated. Long-term management involves regular monitoring of renal function, disease activity, and avoiding potential complications such as renal failure or systemic involvement.

Discussion: Early recognition and intervention in TIN-IgG4, including thorough evaluations for hypercalcemia, are crucial for favorable outcomes and preventing disease progression.

Laboratory values on admission

Laboratory Tests	Values	Urine report/24 hrs	Values
Serum urea	72 mg/dL	Calcium	288 mg
Serum creatinine	3.04 mg/dL	Creatinine	770 mg
PTH	7 pg/mL	Protein	301 mg
Kappa free light chain	56.70 mg/L	–	–
Lambda free light chain	29.20 mg/L	–	–
1,25 dihydroxyvitamin D3	13.7 pg/mL	–	–
Total IgG	15.90 g/L	–	–

IgG, immunoglobulin G; P-ANCA, perinuclear antineutrophil cytoplasmic antibodies; PHT, parathyroid hormone.

FR-PO948

A Case of Lupus-Negative Full-House Staining on Kidney Biopsy, Causing Nephrotic Syndrome during Pregnancy

Prathap Simhadri,[1,2] Renish Contractor,[1] Michael R. Filoramo,[1] Prabhat Singh,[3] Deepak Chandramohan.[4] *[1]Florida State University Daytona Beach Regional Medical School Campus, Daytona Beach, FL; [2]AdventHealth East Florida, Daytona Beach, FL; [3]Christus Spohn Health System, Corpus Christi, TX; [4]The University of Alabama at Birmingham, Birmingham, AL.*

Introduction: Systemic lupus erythematosus (SLE) is a systemic autoimmune disease and is recognized by a constellation of clinical, laboratory, and histopathological findings. Lupus nephropathy is a common manifestation of SLE, with immune-mediated inflammatory damage to the glomerulus leading to end-stage renal disease. The literature has described a small subset of patients demonstrating renal limited "lupus-like nephropathy", defined by pathological biopsy findings typical of lupus nephropathy without systemic manifestations or laboratory biomarkers of the disease. A full-house stain, identified by positive immunofluorescence staining of all three isotypes of immunoglobulins, is a pathological finding highly associated with SLE. This pathological pattern has been associated with renal-limited lupus-like nephropathy. However, few studies have identified full-house renal-limited "lupus-like nephropathy" in pregnancy.

Case Description: A 24-year-old G1P0 woman at 14 weeks gestation was referred to nephrology for further evaluation of proteinuria. At 16 weeks gestation, 24-hour urine revealed 14 g of proteinuria and a serum albumin level of 1.52 mg/dL. The patient was ANA positive and had elevated C1q antibody titer but negative for other SLE autoantibodies, including anti-Sm, anti-dsDNA, normal C3, and C4 complements. Biopsy revealed membranous nephropathy with positive staining for IgG, IgA, IgM, C3, C1Q, and Lp-PLA2, consistent with full-house immunoglobulin staining. She was started on 500 mg pulse dose methylprednisolone for 3 days, which was gradually tapered to 5 mg daily, and cyclosporine 75 mg BID. Successfully induced at 36 weeks, she delivered a baby with 50% percentile birth weight. Six-month follow-up revealed 1g protein on 24-hour urine collection and normal C3/C4 levels. She continues exhibiting no signs of SLE, and the C1q antibody titer improved.

Discussion: A 24-year-old pregnant female presented with pathological evidence of full-house renal limited "lupus-like nephropathy" without clinical or laboratory evidence consistent with SLE. This case adds to the limited literature describing this condition and more evidence is essential to guide proper treatment and management.

FR-PO949

Spontaneous Remission of Minimal Change Disease during Pregnancy

Henry Yip, Claire Kim, Hira Tahir, Navdeep Kaur. *Stony Brook University Hospital, Stony Brook, NY.*

Introduction: Minimal change disease (MCD) is a pediatric predominant glomerulonephropathy which can cause nephrotic syndrome (NS). Current societal guidelines for the management MCD in adults is based on observational data from the pediatric population, creating limitations in management. In this case we present a case of new onset MCD in a pregnant adult.

Case Description: A 34 year old female with no past medical history who is one month pregnant presents for evaluation of new onset edema. Initial testing found urine protein:creatinine ratio (UPCr) 4.5, urine microalbumin creatinine ratio (UMACR) 2.9, serum albumin of 2.9g/dL. Serum creatinine was 0.49 mg/dl. Further serologic and infectious workup was negative; genetic testing was performed and was inconclusive. A 24-hour urine collection showed 6 grams of protein. A biopsy was performed, with no findings on light microscopy and podocyte effacement on electron microscopy. Maternal fetal medicine (MFM) started her on aspirin and enoxaparin for venous thrombosis (VTE) prophylaxis. Repeat UPCr had decreased to < 3 by her 18th gestational week and a joint decision was made to defer treatment with monitoring given improvement in proteinuria. Patient delivered on time without any complications. UPCr continued to trend down and at her one month postpartum visit, urinalysis showed no protein in urine.

Discussion: Nephrotic syndrome occurs in 0.012% of all pregnancies, and specifically minimal change disease predominantly occurs in children making the presence of new onset MCD during pregnancy uncommon. Adults also tend to have a higher incidence of relapse and take longer to achieve remission. Our electron microscopy showed 40-50% podocyte effacement which could suggest secondary MCD however her history and genetic testing were negative. Although multiple therapeutic options for MCD exist, management in the adult and pregnant populations are not well defined. There have been reports of spontaneous remission of MCD however this appears to be rare and not well described. In our case at her two month postpartum follow up, she has stayed in remission since gestational week 18 without treatment, and highlights the lack of research regarding MCD management in adults, as well any additional accommodations for the pregnant population.

FR-PO950

Minimal Change Disease (MCD) and Human Chorionic Gonadotropin (hCG)-Mediated Thyrotoxicosis during Pregnancy

Laura Aponte Becerra, Gilbert W. Moeckel, Maryam Gondal. *Yale University, New Haven, CT.*

Introduction: Thyroid hormones influence cardiac output and RAAS activity with effects in GFR. Proteinuria has been associated with hypothyroidism but rarely with hyperthyroidism or Graves' disease in non-pregnant adults. This is a case of AKI with severe proteinuria due to MCD in a woman presenting with hyperemesis gravidarum and gestational thyrotoxicosis.

Case Description: A 19-year-old woman at 14 weeks of gestation presented with 4 weeks of hyperemesis accompanied by myalgias, fainting, and muscle weakness. Patient was normotensive, with dry skin and without peripheral edema. Labs showed AKI with creatinine (Cr) of 3.09mg/dL from a normal baseline, BUN of 123mg/dL, hypokalemia, hypophosphatemia, elevated CK of 663 U/L, transaminitis with direct bilirubinemia of 2.4 mg/dL and hypoalbuminemia of 3.0g/dL. TSH was undetectably at <0.005uIU/mL low with elevated free T4 at 4.07ng/dL and normal T3, antithyroid antibodies were negative. Diagnosis of HCG-mediated thyrotoxicosis was made. Urine studies showed total protein-to-Cr ratio of 10.3mg/mg and an albumin-to-Cr ratio of 5.7mg/mg. Kidney biopsy showed diffuse and severe acute tubular injury with myoglobin cast nephropathy. Electron microscopy showed global effacement of foot processes, vacuolization and microvillus transformation of podocytes and the absence of immune deposits. Patient received intravenous fluids, electrolyte replacement and symptomatic treatment of thyrotoxicosis with Propranolol. Emesis improved and she was able to tolerate an oral diet. At 17 weeks of gestation, creatinine had returned to baseline with mild proteinuria and no albuminuria. TSH and free T4 normalized.

Discussion: MCD is rare in pregnancy, the etiology is unclear and management includes initiation of immunosuppression. High HCG levels during the first trimester of pregnancy can trigger thyrotoxicosis given structural homology with TSH and hyperemesis. In this case, we observed normalization of albuminuria and thyroid hormone levels as HCG levels dropped with pregnancy progression. We hypothesize that hyperfiltration from pregnancy and increased cardiac output due to increased thyroid activity could have played a role in proteinuria leading to podocyte effacement. Whether immune or inflammatory mechanisms are involved in the interaction between thyroid and kidney disease during pregnancy is unknown.

FR-PO951

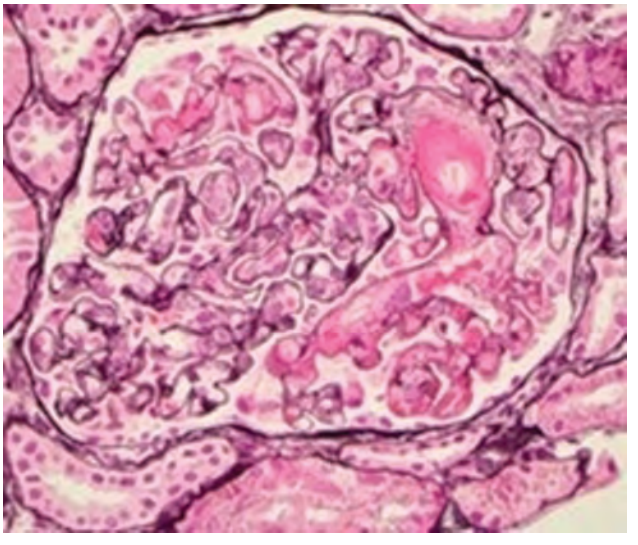
Not All Proteinuria in Pregnancy Is Preeclampsia

Iqra Naeem,[1] Ahmad Basharat,[1] Rebecca Blonsky,[1] Weixiong Zhong.[2] Marshfield Clinic and Health System, Dept of Internal Medicine and Dept of Nephrology; University of Wisconsin Madison, Dept of Pathology. *[1]Marshfield Clinic Health System, Marshfield, WI; [2]University of Wisconsin-Madison, Madison, WI.*

Introduction: Atypical hemolytic uremic syndrome (aHUS) is a rare disease caused by dysregulation of the alternative complement cascade leading to uncontrolled terminal complement activation causing a systemic thrombotic microangiopathy (TMA). Nephrotic syndrome is a rare presentation of aHUS. We present a case of a pregnant patient presenting with nephrotic syndrome as the sole manifestation of renal limited aHUS.

Case Description: 27-year-old female with history inclusive of prematurity presented at 19 weeks gestation with new onset severe hypertension and anasarca. Patient was found to have 4.268 g/24hr of proteinuria. She was started on steroids while serologic workup for nephrotic syndrome was completed. Her hypertension was treated with diuretics and calcium channel blocker. The patient did not respond to steroids and serologic work up was non-revealing including CBC and LFTs. Patient had pregnancy complication with severe fetal growth restriction and near reversal of placental flows. Kidney biopsy showed findings consistent with acute on chronic TMA as shown in figure. Serologic workup for aHUS demonstrated elevated levels of complement factor Bb. Other potential causes for TMA were negative as was genetic testing. Unfortunately, she lost her pregnancy at 21 weeks gestation, and we changed her antihypertensives to ACE-I. The proteinuria peaked at 9.87 g/g and following addition of ACE-I improved to 1.333 g/g. Eculizumab was the started following appropriate vaccination with remission allowing for decreasing doses of ACE-I.

Discussion: Pregnancy-triggered aHUS can occur during pregnancy and up to 60 days postpartum and accounts for 7% of all aHUS cases. Typically, aHUS present as a systemic TMA with extrarenal manifestations. Isolated nephrotic syndrome is rare, particularly in adults, making this case unique. Eculizumab remains the mainstay of treatment with better outcomes when initiated early in the disease course.



FR-PO952

Long-Term Resolution of HIV-Associated Nephropathy (HIVAN) after Treatment with Highly Active Antiretroviral Therapy (HAART)

Mohamed T. Elkhodary,[1] Barry M. Wall.[2,1] *[1]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [2]Veterans Affairs Medical Center, Memphis, TN.*

Introduction: HIVAN is strongly associated with APOL1 homozygosity. There is usually a second hit, HIV infection being the prototype, which facilitates or precipitates the onset of collapsing focal segmental glomerulosclerosis (FSGS). Removal of this second hit could potentially allow renal recovery. We describe a patient who developed nephrotic range proteinuria and renal failure secondary to HIVAN, necessitating hemodialysis, who recovered renal function following HAART and has had long-term preservation of renal function with no opportunistic infections.

Case Description: 47-year-old African American male with bipolar disorder and CKD 3a presented in 2010 with fever, diaphoresis, and a gluteal abscess. Serum creatinine was markedly elevated, 8.0 mg/dl. Urinalysis was positive for +2 proteinuria, but negative for RBCs, WBCs, or cellular casts. UPCR was 7.75 mg/g. On imaging, kidneys were enlarged with increased echogenicity. Serological investigations were negative and

complement levels were normal. Tests for RPR and hepatitis C were negative. HBsAg was positive. HIV-1 / 2 western blot returned positive with reduced CD4 count, 52 cells/μL, and HIV viral load of 246,940 copies/ml. He required hemodialysis support. Renal biopsy demonstated collapsing FSGS. HAART was initiated with continued outpatient hemodialysis. CD4 count improved and HIV viral load markedly decreased within 5 months of starting HAART. Renal function gradually improved and hemodialysis was discontinued. Proteinuria markedly improved, and he has maintained a stable serum creatinine (2.1 mg/dl) for 14 years while continuing antiviral treatment with nondetectable HIV viral load, CD4 count remaining >250 cells/μL and no opportunistic infections.

Discussion: HIVAN is driven by direct infection of kidney epithelial cells with HIV and subsequent HIV gene expression, particularly in patients of African ancestry with APOL1 homozygosity. Histologically, HIVAN results in a collapsing form of FSGS with tubular dilation and interstitial inflammation. HIVAN typically presents with rapid decline in kidney function with nephrotic range proteinuria. The risk increases if the patient has CD4 < 200 cells/μL, and /or high viral load. Early initiation of HAART can be associated with improvement in CD4 counts and HIV viral load, and can lead to subsequent long term improvement in GFR and proteinuria.

FR-PO953

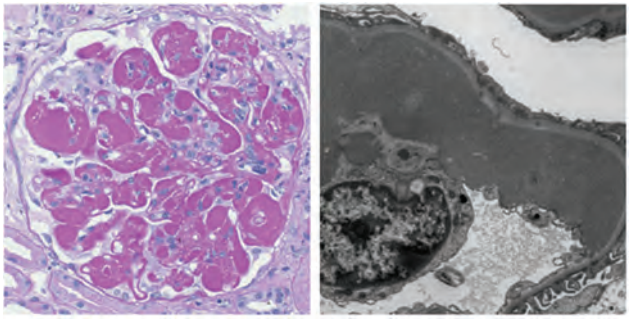
Lymphoplasmacytic Lymphoma with Extensive Subendothelial Deposits Resembling Wire Loop Lesions: A Case Report

Shinichiro Ogawa, Hidekazu Ikeuchi, Masato Kinoshita, Junya Suwa, Hiroko Hamatani, Yoriaki Kaneko, Keiju Hiromura. *Gunma Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Maebashi, Japan.*

Introduction: Lymphoplasmacytic lymphoma (LPL) is an indolent B-cell non-Hodgkin lymphoma that primarily involves lymphocytes differentiating into plasma cells producing IgM-type immunoglobulins. It can occasionally present with renal impairment. Here, we report a rare case of LPL with renal lesions resembling wire loop lesions of lupus nephritis.

Case Description: A 65-year-old male presented with leg edema and proteinuria. A renal biopsy revealed numerous glomeruli with wire loop-like lesions (Left Figure). IF staining showed deposits of IgG, IgA, IgM, C3, and C1q in the mesangial and subendothelial regions, with positive κ light chain. Congo-red staining was negative. Electron microscopy identified extensive subendothelial deposits (Right Figure). Tests for antinuclear and anti-DNA antibodies were negative, with no extrarenal manifestations of systemic lupus erythematosus. Immunoelectrophoresis detected an IgM-κ type M protein in the serum, and cryoglobulins were negative. A bone marrow biopsy confirmed LPL. Upon presentation, the laboratory results were as follows: serum creatinine (S-Cr) 1.49 mg/dL, urine protein/creatinine ratio 1.54 g/gCr, and CH50 <14.0 U/mL. The patient was started on DRC therapy (dexamethasone, rituximab, and cyclophosphamide), resulting in a decreasing trend in IgM to 128 mg/dL, proteinuria to 0.37 g/gCr, and S-Cr to 1.41 mg/dL at 6 months.

Discussion: Renal complications of LPL include hyperviscosity syndrome, amyloidosis, and cryoglobulinemia. This case featured widespread subendothelial deposits, resembling lupus nephritis wire loop lesions. To our knowledge, such lesions have not been previously reported in LPL. Chemotherapy led to reductions in IgM levels, proteinuria, and improved renal function, indicating monoclonal IgM's role in forming these lesions.



FR-PO954

A Viral Conundrum: Hepatitis D and Immune-Complex Glomerulonephritis

Sneha M. Vaddadi, Nasim Wiegley, Shubha Ananthakrishnan, Niti Madan. *UC Davis Health, Sacramento, CA.*

Introduction: Viral-associated glomerulonephritis (GN) is a well-recognized phenomenon, notably seen with hepatitis B (HBV), hepatitis C and HIV. These viral infections can lead to diverse histologic glomerular lesions, including immune-complex GN. There is little literature on Hepatitis D (HDV) associated GN. It is considered a hybrid virus as it uses HBV's surface antigen (HBsAg) as its envelope protein for replication. We present a case of nephrotic syndrome, with biopsy-proven immune-complex GN with active HDV infection.

Case Description: 42-year-old South Asian woman G8P7 at 14w gestation with past medical history of chronic HBV, HDV, and latent TB presented with acute kidney injury (creatinine 1.3 mg/dL, baseline 0.92 mg/dL) and new nephrotic syndrome with urine protein-to-creatinine ratio 3.5 g/g and albumin 2.8 g/dL. Initial kidney biopsy deferred due to pregnancy. Course was complicated by severe pre-eclampsia requiring emergent C-section, and postpartum kidney biopsy with evidence of immune-complex GN with segmental sclerosis. HDV viral load was elevated to 270k, HBV viral load negative, and autoimmune serologies were negative. Glomerular disease was determined to be due to chronic Hepatitis B and coinfection with active Hepatitis D.

Discussion: There are few reports establishing a correlation between hepatitis D and immune-complex GN. In this patient with chronic HBV and HDV co-infection, there was high suspicion of the hepatitis D being the causative pathogen given the elevated viral load. Immunosuppressive therapy was deferred for the patient's GN, and HDV treatment was initiated with an experimental regimen (Bulevirtide and Tenofovir), with improvement of the viral load and proteinuria from peak 5.7 g/g to 1.2 g/g. This case demonstrates a potential novel association between hepatitis D and immune-complex GN, responsive to Hep D targeted anti-viral therapy.

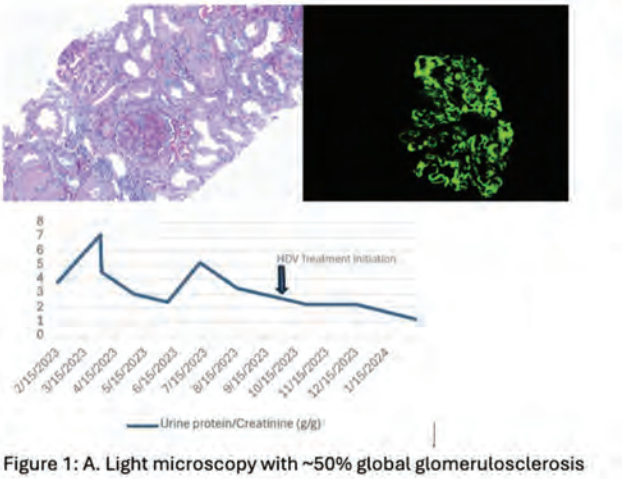


Figure 1: A. Light microscopy with ~50% global glomerulosclerosis with several segmentally sclerotic glomeruli.
B. Full-house positivity on immunofluorescence.
C. Urine protein/Creatinine over time, with initiation of HDV treatment.

FR-PO955

THSD7A-Associated Membranous Nephropathy Involves Both Complement-Mediated and Autonomous Podocyte Injury

Jing Liu, Yan Ge, William T. Gunning, Lance D. Dworkin, Rujun Gong. *The University of Toledo Medical Center, Toledo, OH.*

Background: As a distinctive subtype in the serology-based classification of membranous nephropathy (MN), thrombospondin type 1 domain containing 7A (THSD7A)-associated MN has attracted increasing interest, because THSD7A is also expressed in preclinical species, facilitating the study of its role in MN. This study aimed to establish models of THSD7A-associated MN by using a commercial antibody. Potential pathomechanisms and therapeutic efficacy of repository corticotropin injection (RCI; Purified Cortrophin® Gel, ANI Pharmaceuticals, Inc.) were tested in this model.

Methods: Primary mouse podocytes were cultured in complete medium supplemented with fetal bovine serum containing complements or preheated to inactivate heat-labile complements, followed by exposure to a commercial rabbit anti-THSD7A antibody. *In vivo*, mice were injected with the anti-THSD7A antibody and treated with RCI or vehicle. To deplete complement, some mice were treated with cobra venom factor (CVF).

Results: Mice developed massive proteinuria upon anti-THSD7A antibody insult, concomitant with histologic lesions of glomerular injury, including epimembranous or intramembranous electron-dense deposits in glomeruli as well as variable podocyte foot process effacement on electron microscopy, reminiscent of glomerular ultrastructural changes in human MN. Complement depletion with CVF only partially attenuated proteinuria and glomerular injury in this model, suggesting that complement-independent pathomechanisms also contribute. Consistently, in cultured primary podocytes, exposure to the anti-THSD7A antibody caused evident podocytopathic changes, such as disruption of the actin cytoskeleton integrity, podocyte hypermobility, oxidative stress and apoptosis. These signs of podocyte injury were preserved, although to a lesser extent, after complement inactivation, denoting an autonomous podocytopathic activity of this antibody. As an FDA-approved treatment option for primary nephrotic glomerulopathies including MN, RCI appeared to be beneficial in this model and significantly attenuated proteinuria and glomerular injury.

Conclusions: Both complement-dependent and autonomous podocytopathy are involved in the mouse model of THSD7A-associated MN, which could be attenuated by RCI. This model, based on the use of a commercial anti-THSD7A antibody, could be an important tool for MN research.

FR-PO956

Integrating Histopathology-Based Analysis with Spatial Transcriptomics of Human Kidneys: Towards Precision Pathology

Pierre Isnard, Dian Li, Qiao Xuanyuan, Haojia Wu, Benjamin D. Humphreys. *Washington University in St Louis, St Louis, MO.*

Background: During spatial transcriptomic (ST) data analysis, computationally-annotated clusters are often superimposed on a histological image without any consideration of the tissue morphology by standard light microscopic pathologic evaluation, thereby ignoring important information that can help interpretation of the ST data

Methods: We conduct a histopathological-based analysis (by a practicing renal pathologist) of spatial transcriptomics (10X genomics, Visium) on 4 human kidney samples with CKD corresponding as closely as possible to how a kidney biopsy is interpreted in clinical practice

Results: We first validated the relevance of this pathological-based clustering by showing that the DEGs and cell composition of each cluster were those expected in relation to the structure analyzed. By examining each sector independently, we showed in particular that ST data can be used to confirm the diagnosis of different structures (TLS, tumor). We also showed how this strategy could be used to: identify potential diagnostic biomarkers, determine cell composition, or study molecular pathways specific to a lesion. We performed a comparative molecular analysis of healthy and pathological glomerular and tubular segments. We could identify several known cellular and molecular mechanisms behind kidney lesions in CKD and were able to identify potential candidate genes in glomeruli (FXYD5, CXCL12) and tubules (TMSB4X, NQO1, MGST1, SQSTM1) possibly involved in disease progression or acting as defense mechanisms. Finally, we show that this pathological-based clustering could be transferred to study other human kidney ST Visium data (nephrectomy sample or needle kidney biopsies). This last result implies that our pathological clustering is potentially not restricted to the analysis of a single slide, and could be projected coherently onto another slide, paving the way for the constitution of spatial molecular banks of lesions and structure as slide analysis progresses

Conclusions: In conclusion, we show the feasibility of a morphological-based approach to interpreting ST data, helping to improve our understanding of kidney lesions in CKD, at both cellular and molecular levels. This work introduces a method to combine traditional histopathology with ST data to pave the way for the future of molecular microscopy and precision pathology

Computational Characterization of Arteries/Arterioles in FSGS/Minimal Change Disease

Jin Zhou,[1] Dawit S. Demeke,[2] Xiang Li,[1] Timothy A. Dinh,[2] Christopher L. O'Connor,[2] Qian Liu,[5] Jarcy Zee,[7,5] Yijiang Chen,[3] Andrew Janowczyk,[4,6] Lawrence B. Holzman,[8] Laura H. Mariani,[2] Markus Bitzer,[2] Laura Barisoni,[1] Jeffrey B. Hodgin,[2] Kyle J. Lafata.[1] *[1]Duke University, Durham, NC; [2]University of Michigan, Ann Arbor, MI; [3]Stanford University, Stanford, CA; [4]Emory University, Atlanta, GA; [5]The Children's Hospital of Philadelphia, Philadelphia, PA; [6]Hopitaux Universitaires Geneve, Geneve, Switzerland; [7]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [8]University of Pennsylvania, Philadelphia, PA.*

Background: The clinically used semi-qualitative scoring of arteriosclerosis is poorly standardized and reproducible. We developed a computational pipeline to precisely and reproducibly characterize the morphology of arteries/arterioles using digital kidney biopsies.

Methods: One trichrome-stained whole slide image (WSI) from N=229 NEPTUNE/CureGN participants with focal segmental glomerulosclerosis (N=128) or minimal change disease (N=101) was used. We developed, applied, and quality controlled deep learning models for segmentation of muscular vessels and intra-vascular compartments (lumen, intima, media). Each vessel was classified into (i) arcuate and (ii) interlobular artery, (iii) 2 muscle layers arteriole, and (iv) 1 muscle layer arteriole and venule. (i), (ii), and (iii) were visually scored for arteriosclerosis (0-3). Intra-arterial thickness was measured using radial sampling and ray casting, with average intima-media thickness ratio computed for each artery/arteriole for correlation with visual scores. These features were summarized for each WSI using aggregation metrics (median, 75th percentiles) for association with disease progression (40% eGFR decline or renal failure).

Results: N=1509 arterioles, 695 interlobular and 131 arcuate arteries were segmented. There was a statistically significant correlation between arteriosclerosis scores and intima-media thickness ratio average (Spearman ρ=0.28, $p<0.0001$ for arterioles; ρ=0.67, $p<0.0001$ for interlobular arteries; ρ=0.70, $p<0.0001$ for arcuate arteries). Arteriole features aggregated at median and 75th percentiles associated with disease progression (log-rank $p<0.1$). No association was identified in arcuate and interlobular artery features (log-rank $p>0.1$).

Conclusions: We developed a novel approach to automatically segment arteries/arterioles sub-compartments and to computationally characterize morphologic features of arteriosclerosis. This technique demonstrated potential as a promising reproducible tool to aid pathologists' clinical assessment.

Phospholipase A2 Receptor (PLA2R)-Positive Membranous Nephropathy by Laser Microdissection and Mass Spectrometry in Patients with Negative Routine Immunofluorescence Microscopy for PLA2R on Kidney Biopsy

Ilario Russo,[1,2] Ladan Zand,[1] Fernando C. Fervenza,[1] Benjamin J. Madden,[4] Sanjeev Sethi.[3] *[1]Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN; [2]Universita degli Studi di Bari Aldo Moro Dipartimento di Medicina di Precisione e Rigenerativa e Area Jonica, Bari, Italy; [3]Mayo Clinic Department of Laboratory Medicine and Pathology, Rochester, MN; [4]Mayo Clinic Minnesota, Rochester, MN.*

Background: The discovery of novel antigens in membranous nephropathy (MN) was done using laser microdissection followed by mass spectrometry (LMD/MS). Direct immunofluorescence microscopy (IF) for PLA2R was used to classify MN into PLA2R-positive MN and PLA2R-negative MN. PLA2R-negative MN cases were then used to detect novel antigens.

Methods: 250 cases of PLA2R-negative MN were studied in the discovery cohort. All 250 cases had bright granular staining for IgG and were negative for PLA2R along the glomerular basement membrane by IF. The glomeruli were microdissected and the peptides were separated with a high-performance liquid chromatography (HPLC) system coupled to a Mass Spectrometer. Protein quantification was obtained via spectral counting.

Results: 10 out of 250 (4%) patients with negative IF studies for PLA2R were positive for PLA2R on LMD/MS. Baseline PLA2R counts are typically in the range of 0-5 in PLA2R negative cases. The total spectral count (TSC) in the PLA2R positive by LMD/MS ranged from 13 to 75 (avg 39.5, ± 20.56) in the 10 cases. Only 3 cases showed moderate TSC of 13, 15 and 18, whereas the remaining cases shows high TSC ranging from 28 to 75. Of the available data in 7 patients, 2 had positive serum anti-PLA2R antibodies. The baseline clinical and demographic characteristics are shown in Table 1.

Conclusions: LMD/MS is a new methodology to detect the antigens in MN. 4% of PLA2R-negative MN by IF were positive for PLA2R by LMD/MS. LMD/MS appears to be more sensitive in detecting PLA2R than conventional IF.

Patient Number	Spectral Count	Age	Gender	Anti-PLA2R	uProt (g/24h)	eGFR (ml/min/1.73m2)	serum Albumin (g/dl)

Fewer Podocytes Associate with Progressive CKD Independent of Glomerular Volume and Nephrosclerosis or Clinical Characteristics

Aleksandar Denic,[1] Mahesh Kumar,[1] Fnu Aperna,[1] Afsana Ansari Shaik,[1] Aidan F. Mullan,[1] Mariam P. Alexander,[1] Jeffrey B. Hodgin,[2] Andrew D. Rule.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]University of Michigan, Ann Arbor, MI.*

Background: Per podometric hypothesis, podocyte loss leads to glomerulosclerosis and proteinuria, eventually leading to chronic kidney disease (CKD). Podometrics include the podocyte density, volume, and number per glomerulus. Prior studies investigated podometrics in kidney donors, autopsy kidneys or patients with specific kidney diseases such as IgA nephropathy. The goal of this study is to investigate associations between podometrics and progressive CKD in patients with radical nephrectomy.

Methods: We evaluated the WT1 (stains podocyte nuclei) and Glepp1 (stains podocyte cytoplasm) wedge sections of renal parenchyma from radical nephrectomies due to kidney tumor performed between 2000 and 2021. QuPath software was used to quantify number of WT-1 positive cells and Glepp-1 positive area within a glomerular tuft. Progressive CKD was defined as dialysis, kidney transplantation, sustained eGFR <10 ml/min per 1.73m^2 or sustained 30% eGFR decline from the post-nephrectomy eGFR during follow-up to March 2024. Each case of progressive CKD was age-sex-matched to 1 control without progressive CKD. Logistic regression models assessed the risk of progressive CKD with podometric measures adjusting for glomerular volume, nephrosclerosis and clinical characteristics (age, sex, body mass index, diabetes, hypertension, baseline eGFR, and 24 hour urine protein).

Results: There were 35 cases and 35 controls. Compared to cases, controls had higher podocyte density (207 vs. 158 per 10^6 μm^3, p=0.004), higher podocyte number per glomerulus (503 vs. 422, p=0.01), but smaller total podocyte cell volume (3,286 vs. 3,868 μm^3, p=0.047). Lower podocyte density and larger podocyte cell volume associated with hypertension. Lower podocyte density and lower podocyte number per glomerulus associated with progressive CKD (**Table**).

Conclusions: Fewer podocytes in glomeruli are strongly associated with progressive CKD independent of established clinical and histological prognostic factors for CKD.

Pathologic Spectrum of Kidney Disease Associated with Snake Bites

Anila A. Kurien, Jansi Prema K.S, Malathi Cv. *Renopath Center for Renal and Urological Pathology Pvt Ltd, Chennai, India.*

Background: Snake bites are a rare cause of acute renal failure, of which the underlying pathology is poorly understood. We present a series of 216 patients from India who developed kidney failure in temporal association with snake bites to demonstrate the spectrum of histopathologic findings in this setting

Methods: Patients with history of snake bite who underwent kidney biopsy from 2013-2024 were identified from the kidney pathology archives of the Renopath Center for Renal and Urologic Pathology in Chennai, India. Demographics, laboratory values and pathologic data were reviewed

Results: A total of 216 patients who underwent a kidney biopsy with history of recent snake bite were identified. Biopsies were received from 52 centers throughout India. There were 123 males(56.9%) and 93 females(43.1%), mean age was 44.7±14.3 years. All but one patient presented with acute kidney injury with a mean serum creatinine of 6.9±3.2 mg/dL. Of 216 biopsies, 211 were adequate for diagnosis. Biopsy diagnoses from this cohort of patients included acute tubular injury(ATI, n=64), acute interstitial nephritis(AIN,n=58), acute tubular injury combined with acute interstitial nephritis (ATI/AIN,n=28), renal cortical necrosis alone(n=11), thrombotic microangiopathy(TMA,n=48), mesangioproliferative glomerulonephritis(n=1), and IgA nephropathy with acute interstitial nephritis(n=1). Pigmented casts, seen in the setting of intravascular hemolysis or rhabdomyolysis, were present in 32 cases of ATI(50% of those with ATI), 9 ATI/AIN cases(32%), and 3 patients with TMA(6%). Immunohistochemical stain confirmed hemoglobin pigment in 18 and myoglobin pigment in 11 cases. Two patients with ATI had both hemoglobin and myoglobin casts. Concurrent cortical necrosis was present in 23 patients with TMA(48%). Nearly all cases were without chronic changes on biopsy. Mean global glomerulosclerosis was 7.0%. The majority of patients lacked interstitial fibrosis and tubular atrophy(no IF/TA,92.8%). Arteriosclerosis was seen in 18.1% biopsies

Conclusions: The major histopathologic diagnoses in patients with acute renal failure with a recent history of snake bite, in descending order are ATI(30.3%), AIN(27.5%), TMA(22.7%), ATI/AIN(13.3%), and renal cortical necrosis(5.2%). Hemoglobin and myoglobin casts were commonly seen in ATI and AIN cases, suggesting hemolysis and/or rhabdomyolysis as etiologic drivers of disease

FR-PO961

Clinicopathologic Findings in Kidney Biopsies from Patients with Pancreatitis

Anila A. Kurien,[1] Jansi Prema K.S,[1] Malathi Cv,[1] Tiffany Caza.[2] *[1]Renopath Center for Renal and Urological Pathology Pvt Ltd, Chennai, India; [2]Arkana Laboratories, Little Rock, AR.*

Background: Patients developing acute kidney injury (AKI) in the setting of pancreatitis rarely undergo kidney biopsy, however, histopathologic findings vary and biopsies can inform proper diagnosis and treatment. We present a series of 62 patients with acute or chronic pancreatitis who underwent kidney biopsy to demonstrate the spectrum of pathologic diagnoses in this setting.

Methods: Patients with a clinical history of pancreatitis were identified from renal pathology archives at the Renopath Center for Renal and Urological Pathology in Chennai, India. Clinical data, laboratory values, and histopathology were reviewed

Results: A total of 62 patients with pancreatitis who underwent a native kidney biopsy were identified. The mean age of patients was 35 ± 13 years. There was male predominance (85.5%). Twelve patients had a history of diabetes (19%) and 28 had hypertension (45%). All patients presented with AKI or rapidly progressive renal failure with a mean creatinine of 2.5 ± 2.3 mg/dL. Of the 62 patients, 54 had acute pancreatitis (87%) and 8 had chronic calcific pancreatitis (13%). Six patients had recurrent pancreatitis (10%). Fifteen patients had ≥ 1 diagnosis (24.2%). These included 16 separate entities. Diagnoses included, in descending order, thrombotic microangiopathy (TMA, n=21), acute tubular injury (ATI, n=19), ATI with pigmented casts (n=8), diabetic glomerulopathy (n=6), acute interstitial nephritis (n=4), renal cortical necrosis (n=4), chronic tubulointerstitial nephritis (CTIN, n=3), crescentic glomerulonephritis (n=2), proliferative glomerulonephritis (n=2), renal papillary necrosis (n=1), nephrocalcinosis (n=1), minimal change disease (n=1), IgA nephropathy (n=1), arterionephrosclerosis (n=1), collapsing glomerulopathy (n=1), and extramedullary hematopoiesis (n=1). For patients with TMA, 10 had concurrent cortical necrosis (47.6%). Of patients with ATI with pigmented casts, 3 had myoglobin-positivity (consistent with rhabdomyolysis), and 1 was both myoglobin and hemoglobin positive. Of patients with CTIN, one was IgG4-related disease. Of crescentic glomerulonephritis cases, one was pauci-immune and one was anti-GBM disease

Conclusions: Patients presenting with renal failure in the setting of pancreatitis had a wide array of diagnoses, supporting use of biopsy in management of these critically ill patients.

FR-PO962

Temporal and Demographic Trends in Medical Kidney Disease Epidemiology in the Southwestern United States, 1993-2022

Akira Takahashi,[1] Daisuke Kiyozawa,[1] Takamasa Miyauchi,[1] Yi Mi Kevin Ren,[1] Toshiki Doi,[2] Hae Yoon Grace Choung,[1] Mercury Y. Lin,[1] Jean Hou,[1] Takao Masaki,[2] Yoshinao Oda,[3] Mark Haas,[1] Cynthia C. Nast,[1] Michifumi Yamashita.[1] *[1]Cedars-Sinai Medical Center, Los Angeles, CA; [2]Hiroshima University Hospital, Hiroshima, Japan; [3]Kyushu University, Fukuoka, Japan.*

Background: Epidemiological study identifies the prevalence of disease, and could provide the important information to shine new light on the pathogenesis and a basis for further hypothesis-driven research**.** In the United States, there is only a single large-scale epidemiological study for glomerular diseases from the Southeast. Here, we describe 30-year temporal and demographic trends in biopsy-proven, not only glomerular but also non-glomerular diseases in the Southwestern United States.

Methods: We selected native kidney biopsy cases classified into one of 35 widely recognized and common renal disease categories, referred to the Division of Renal Pathology at Cedars-Sinai Medical Center between 1993 and 2022. Biopsy era (1993-2002, 2003-2012, and 2013-2022) and demographics (age, sex, and race) were our primary and secondary predictors, respectively, and the relative frequency of each glomerular/non-glomerular disease subtype was our primary outcome.

Results: 57,613 patients were identified, with a mean age 51.0 (±19.2) years, 52.2% men, 53.8% White, 19.5% Latino, 11.0% Black, 10.2% Asian, and 5.5% other race. Glomerular disease frequency was always higher than non-glomerular disease frequency. Among the glomerular diseases, the frequency of diabetic glomerulosclerosis was constantly and rapidly increasing (9.3%, 15.6%, and 23.8%, each 10 years), while those of other common glomerular disease subtypes were decreasing except for ANCA/pauci-immune glomerulonephritis. Among the non-glomerular diseases, acute tubular necrosis was increasing in the frequency. These temporal trends were largely preserved in all studied demographic subgroups (sex, race, age), although there were several cross-sectional differences of glomerular disease frequencies within each demographic subgroup.

Conclusions: We provided the largest and latest epidemiological data about native kidney biopsy, which may provide valuable insights for nephrologists and pathologists to characterize various kidney diseases and its outcomes in the future, as well as to predict the relative likelihood of a disease diagnosis in a daily medical practice.

FR-PO963

Long Noncoding RNA Associated with Exacerbation of IgA Nephropathy by Exposure to Fine Particulate Matter

Daun Song, Ji won Lee, Se-Hee Yoon, Sung-Ro Yun, Won Min Hwang, Yohan Park. Div of Nephrology, Dept of Internal Medicine. *Konyang University Hospital, Daejeon, Republic of Korea*.

Background: The pathophysiology of IgA nephropathy has been extensively elucidated. However, little is known about long non-coding RNAs (lncRNAs) associated with exacerbation of IgA nephropathy. Fine particulate matter is a significant emerging environmental issue, yet its impact on the exacerbation of IgA nephropathy has not been studied. This study aims to investigate the exacerbation of IgA nephropathy by exposure to fine particulate matter and to explore the associated lncRNAs in a spontaneous IgA nephropathy animal model.

Methods: This study used high serum IgA (HIGA) mice as disease group and BALB/c mice as control group, with a total of twelve 8-week-old mice divided into fine particulate matter exposure groups (HIGA-E:3, BALB/c-E:3) and non-exposure groups (HIGA-NE:3, BALB/c-NE:3). Fine particulate matter exposure was conducted using a sealed cage system, with exposure for 1 hour at a time, 5 times a week, for 12 weeks. The mice were sacrificed at 24 weeks of age. B-cells were separated from the spleen using magnetic-activated cell sorting. RNA isolation was performed from the extracted live B-cells, and total RNA sequencing was conducted.

Results: Regardless of exposure, the HIGA groups had significantly higher serum IgA levels compared to the BALB/c groups. IgA lectin binding assays showed higher levels of glycosylated IgA in the HIGA-NE than in the HIGA-E group, suggesting higher levels of pathologic IgA in the HIGA-E group. Increased expressions of toll-like receptor (TLR)-9 were observed in the lungs of BALB/c-E and HIGA-E groups, with significantly elevated serum APRIL and BAFF levels in the HIGA-E group. Kidney pathology results showed the strongest mesangial IgA deposit and the highest renal injury score in the HIGA-E, followed by the HIGA-NE group (7.7±0.6 vs. 5.3±0.6, P=0.043). Splenic B-cell RNA sequencing revealed more than a two-fold decrease in the expression of specific lncRNAs (Gm54045, Chaserr, LOC115487771, 2310058N22Rik) in the HIGA-E compared to the HIGA-NE group.

Conclusions: Fine particulate matter increases lung TLR-9 expression, leading to elevated BAFF, APRIL, and pathologic IgA levels, and exacerbates IgA nephropathy in the HIGA mice. This exacerbation is associated with a decrease in specific lncRNAs in splenic B-cells, suggesting these lncRNAs may serve as potential therapeutic or diagnostic targets.

FR-PO964

Clinicopathologic Features of Karyomegalic Tubulointerstitial Nephritis

Tiffany Caza,[1] Christopher P. Larsen,[1] Anila A. Kurien.[2] *[1]Arkana Laboratories, Little Rock, AR; [2]Renopath Center for Renal and Urological Pathology Pvt Ltd, Chennai, India*.

Background: Karyomegalic interstitial nephritis (KTIN) is a very rare genetic tubulointerstitial kidney disease caused by mutations in the FAN1 gene. Less than 100 cases have been reported to date, the majority in case reports or small case series. Here, we examine a series of 16 patients of KTIN to further characterize clinical and pathologic features of the disease.

Methods: Patients with a diagnosis of KTIN were identified from renal pathology archives at Arkana Laboratories (USA) and the Renopath Center for Renal and Urological Pathology (India). Clinical data, laboratory values, and histopathology were reviewed.

Results: Sixteen patients with KTIN who underwent kidney biopsy were identified, including eight from the United States and eight from India. These included 15 patients whom had a native biopsy and one with an allograft biopsy (transplant from a sibling). There was male predominance (87.5%) with a mean age of 42 ±12 years. Five patients had a history of hypertension (31.3%) and six had diabetes mellitus (37.5%). None had a history of malignancy. Three patients had a positive family history of kidney disease. All presented with chronic kidney disease, with a mean serum creatinine of 2.9 ± 1.0 mg/dL. Nine had proteinuria of 1+ or greater, three were nephrotic range. Kidney biopsies from all patients demonstrated acute tubular injury with markedly enlarged nuclei. There was chronic injury present in the majority of cases, with a mean global glomerulosclerosis of 31.6 ± 22.4%. There was interstitial inflammation and tubulitis seen in 12 patients, six which had only mild inflammation (10-25% cortex). Interstitial inflammation was lymphoplasmacytic in 11 and one was neutrophil-rich. All cases were negative for SV40 and CMV, ruling out viral cytopathic effects. Eight had a second kidney biopsy diagnosis, including 2 with IgA nephropathy, 2 with minimal change disease, 1 with thin glomerular basement membranes, 1 with focal segmental glomerulosclerosis, 1 with chronic active pyelitis, and 1 with T cell mediated rejection.

Conclusions: KTIN patients were predominantly males presenting in middle age with chronic kidney disease and proteinuria. The majority of patients had no greater than mild interstitial inflammation, of which is lymphoplasmacytic in character. A concurrent second kidney biopsy diagnosis was present in one-half of patients.

FR-PO965

Spectrum of Kidney Pathology in Patients with Syphilis

Tiffany Caza, Christopher P. Larsen. *Arkana Laboratories, Little Rock, AR*.

Background: Syphilis has been associated with multiple kidney diseases, primarily studied within small series. A large cohort of patients with active syphilis who underwent kidney biopsy were examined to evaluate the histopathologic spectrum and clinicopathologic features of disease.

Methods: Patients with syphilis who underwent a native kidney biopsy were identified from the renal pathology archives at Arkana Laboratories from 2006-2024. Patients were identified through a listed clinical history of syphilis in the medical record and/or positive laboratory testing for RPR or anti-treponemal antibodies. Patients with a remote or treated syphilitic infection were excluded.

Results: A total of 111 patients with syphilis who underwent kidney biopsy were identified. The mean age was 42.0 ±14.5 years and there was male predominance (86.5%). The majority of patients presented with acute kidney injury with a mean serum creatinine of 4.4 ± 3.8 mg/dL. Co-infections were common, with HIV in 53 (47.7%), HBV in 9 (8.1%), and HCV in 9 (8.1%). The most common disease states, in descending order, included membranous nephropathy (MN) (n=29), HIV-associated diseases (n=21), acute interstitial nephritis (AIN, n=11), acute tubular injury (n=11), infection-associated glomerulonephritis (n=9), and IgA nephropathy (n=8). The remaining patients had various diagnoses unlikely to be associated with syphilitic infection, such as diabetic glomerulosclerosis (n=12) and arterionephrosclerosis (n=7), among others. Of 29 patients with MN (26.1%), 2 were PLA2R+, 2 were EXT+, and the remaining were PLA2R negative of unknown type. Staining for multiple immune reactants was common in MN cases with IgA staining in 24.1%, IgM in 34.5%, C3 in 89.7%, C1q in 44.8%, and 10.3% were 'full-house'. Of 21 patients with HIV-associated pathology (18.9%), 17 had collapsing glomerulopathy (HIVAN) and 7 had mesangial immune complex deposition (HIVICK). Of 11 patients with AIN, 5 were plasma cell rich, 1 was neutrophil rich, and the remaining had mixed infiltrates. Three of 8 patients with IgA nephropathy were secondary to liver disease related to viral hepatitis.

Conclusions: The most common kidney biopsy diagnosis seen in patients with syphilis was membranous glomerulopathy. Disease associated with co-infections, particularly HIV and viral hepatitis, were also common in this setting.

FR-PO966

IgM-Positive Plasma Cells in Lip Biopsy Specimens from Patients with Tubulointerstitial Nephritis with IgM-Positive Plasma Cells (IgMPC-TIN)

Naoki Takahashi,[1] Toshio Imafuku,[5] Takahisa Kawaguchi,[2] Akira Iguchi,[3] Yawara Yamashita,[4] Kenji Kasuno,[1] Masayuki Iwano,[1] Tadashi Toyama.[1] *[1]Fukui Daigaku, Fukui, Japan; [2]Kawasaki Shiritsu Kawasaki Byoin, Kawasaki, Japan; [3]Nagaoka Sekijuji Byoin, Nagaoka, Japan; [4]Kagoshima Daigaku, Kagoshima, Japan; [5]Shonan Clinic, Kamakura, Japan*.

Background: In 2017, we introduced the concept of tubulointerstitial nephritis with IgM-positive plasma cells (IgMPC-TIN), in which many IgM-positive plasma cells infiltrate the renal interstitium. Although IgMPC-TIN may be part of a systemic disease, few reports have evaluated IgMPC infiltration in organs other than the kidney and liver in patients with IgMPC-TIN. In this study, we investigate whether many IgMPC infiltrates are also present in lip biopsy specimens of patients diagnosed with IgMPC-TIN on renal biopsy.

Methods: We collected lip biopsy specimens from a total of 18 patients from our hospital and collaborating centers nationwide: 8 patients (IgMPC-TIN group) (7 with Sjögren syndrome) diagnosed with IgMPC-TIN by renal biopsy and 10 patients (non-IgMPC-TIN group) with other diseases (3 with IgG4-related disease, 4 with Sjögren syndrome and 3 with SLE). We used an immunoenzymatic method to do double staining with IgM and CD138 and then counted PC and IgMPC and calculated the percentage of IgMPCs among all PCs in each group. We calculate the cut-off values, sensitivity, and specificity using ROC analysis (SigmaPlot 15.0).

Results: In lip biopsy, the average number of plasma cells (PCs) in the three fields of view was not significantly different (94 vs. 90/high-power field (HPF), P=0.895). The IgMPC-TIN group had a significantly higher average number of infiltrated IgMPCs in the three fields of view (44 vs. 9/HPF, P<0.001), the maximum number of IgMPCs (59 vs. 11/HPF, P<0.001), and a significantly higher percentage of IgMPCs among all PCs (46% vs. 10%, P<0.001). The cut-off values (sensitivity and specificity, respectively) by ROC analysis were the percentage of IgMPCs among all PCs 17.2% (100% and 90%), the average number of IgMPCs 18.8/HPF (87.5% and 90%) and the maximum number of IgMPCs 23.5/HPF (87.5% and 90%). In renal and lip biopsies, there was no significant correlation between the percentage of IgMPCs among all PCs, the average number of IgMPCs in the three fields of view, and the maximum number of IgMPCs.

Conclusions: The IgMPC-TIN group had more IgMPCs in lip biopsies than the non-IgMPC-TIN group. The percentage of IgMPCs among all PCs was most useful in determining IgMPC-associated salivary gland findings. IgMPC-TIN may be a renal manifestation of a systemic disease with IgMPC infiltration.

A Rare Case of Leukocyte Chemotactic Factor 2 (ALECT2)-Associated Amyloidosis and Membranoproliferative Glomerulonephritis (MPGN) Associated with Cryoglobulinemia

Stefani M. Thompson, Lalathaksha Murthy Kumbar. *Henry Ford Health System, Detroit, MI.*

Introduction: Membranoproliferative glomerulonephritis (MPGN) associated with cryoglobulinemia is an uncommon renal condition, often secondary to infectious or autoimmune etiologies. Hepatitis B infection less frequently manifests as cryoglobulinemia compared to hepatitis C. Concurrently, Leukocyte chemotactic factor 2 amyloidosis (ALECT2) is an exceedingly rare form of amyloidosis, characterized by the deposition of leukocyte chemotactic factor 2 protein in the kidneys, with a higher prevalence among individuals of Mexican descent. The simultaneous presence of MPGN from cryoglobulinemia and ALECT2 in a single kidney biopsy represents a rare diagnostic finding. Here, we present a unique case of a patient with hepatitis B induced MPGN associated cryoglobulinemia and concurrent ALECT2.

Case Description: We present the case of a 68-year-old male with a medical history notable for hypertension, lower extremity rash with biopsy consistent with leukocytoclastic vasculitis, and post herpetic neuralgia who presented with chest pain and dyspnea attributed to a pericardial effusion and found to have acute kidney injury. Urinalysis revealed hematuria and proteinuria while urine microscopy demonstrated 3-4 dysmorphic red blood cells per high-powered field. Serological investigations revealed positive antinuclear antibodies, positive rheumatoid factor, trace cryoglobulin, and decreased C3 and C4 levels. Steroids were started for a suspected flare of overlap syndrome. Kidney biopsy histopathology revealed features consistent with MPGN Type II cryoglobulinemia and immunohistochemical staining confirmed ALECT2 presence within the amorphous deposits, positive for amyloidosis. The coexistence of MPGN and ALECT2 in the context of cryoglobulinemia secondary to hepatitis B infection was noted as exceedingly rare. The patient was started on Entecavir for hepatitis B treatment.

Discussion: This case shows the diagnostic challenges posed by MPGN in the backdrop of active hepatitis B infection and cryoglobulinemia. The additional discovery of ALECT2 raises questions regarding its clinical implications and significance. Further research and case reports are imperative to unravel potential relationships and underlying mechanisms associated with ALECT2 and cryoglobulinemia.

FR-PO968

10 Years of C3 Glomerulopathy in the Netherlands: A Large Cohort of a Rare Kidney Disease

Rick H. Overwijk,[1] Fiona R. Kolbinger,[2] Mark Eijgelsheim,[1] Andreas Kronbichler,[3] Ingeborg M. Bajema.[1] *[1]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [2]Purdue University, West Lafayette, IN; [3]Medical University Innsbruck, Innsbruck, Austria.*

Background: C3 glomerulopathy (C3G) is a rare but devastating disease affecting both children and adults. It frequently leads to end stage kidney disease within ten years after diagnosis and no specific treatment exists. C3G is used as a collective term for dense deposit disease (DDD) and C3 glomerulonephritis (C3GN) and is thought to sometimes occur in post-infectious settings (C3-PIGN). Currently little is known about the occurrence and distribution throughout the population. In this study we analyzed a large cohort of C3G patients in the Netherlands regarding disease distribution in relation to geographical factors and histopathological findings.

Methods: A search in the Dutch national pathology database (PALGA) was performed. All patients diagnosed with C3G from January 2014 until December 2023 were identified by two independent observers. Cross tabulations were used to determine the correlation of disease subtypes and glomerular patterns, and their geographical distribution. Non-parametric analysis was used to evaluate the age distribution at diagnosis.

Results: The selection resulted in a cohort of 280 patients consisting of: C3GN (101), DDD (39), unspecified C3G (106), C3-PIGN (29) and other (5). The median age of diagnosis was 19 for DDD and 58 for C3GN, showing that age distribution depends on C3G subtype ($p<0.001$). C3G subtypes were also associated with glomerulonephritis patterns ($p<0.001$), with DDD and C3G associated with mesangiocapillary pattern and C3-PIGN with endocapillary or exudative pattern.

Conclusions: This large cohort is a stepping stone for better characterizing contributing factors in the etiology of C3G and can potentially demystify this rare and devastating disease.

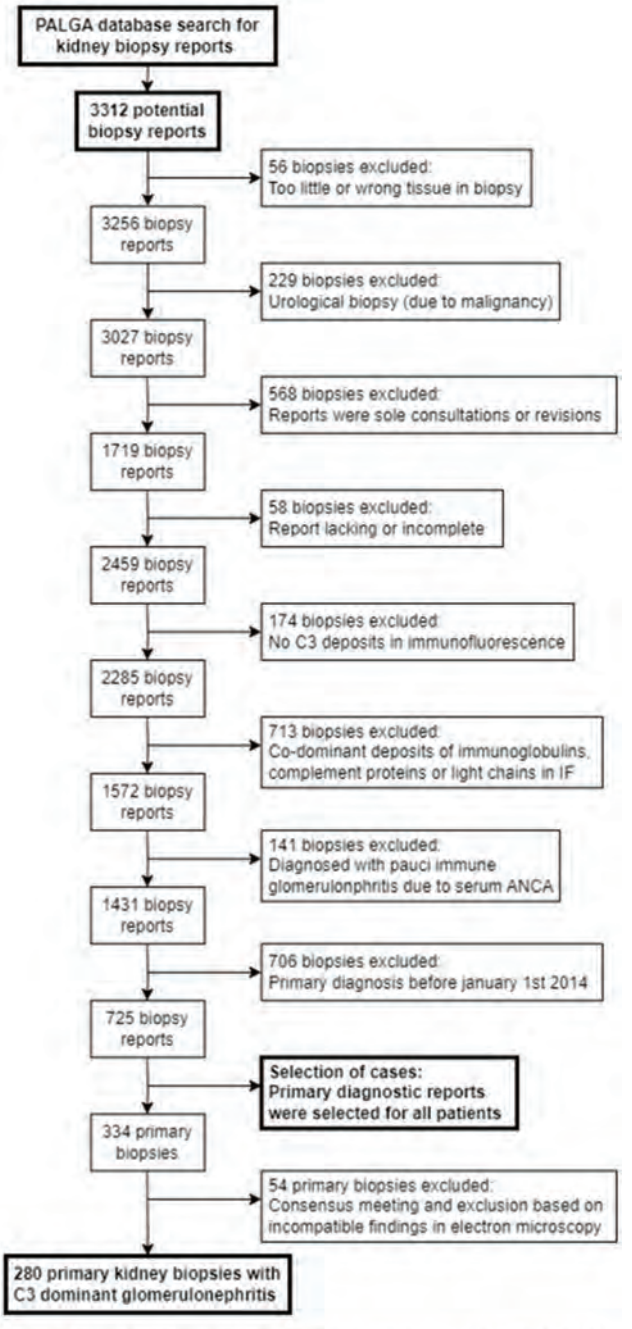

Figure 1: Flowchart of case selection showing excluded cases and applied criteria.

FR-PO969

Glomerular Intracytoplasmic Vacuolization in a Patient Receiving Polyethylene Glycol Biopharmaceutical

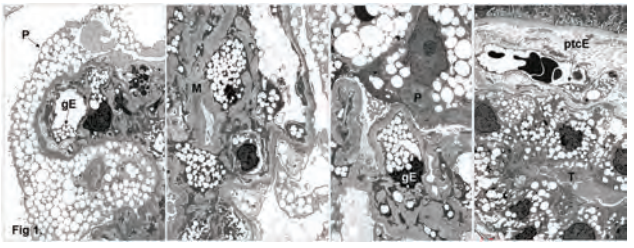
Shamila Mauiyyedi,[1] Amit Lahoti,[2] Amanda Tchakarov.[1] *[1]The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX; [2]The University of Texas MD Anderson Cancer Center Division of Cancer Medicine, Houston, TX.*

Introduction: Conjugation of biologics to HMW polyethylene glycol (PEG) enhances drug delivery/efficacy by extending half-life. Clearance of PEG causes cellular vacuolization by light microscopy in liver, spleen, brain and kidney in animal models. No human study, electron microscopy, or impact on cell function are reported. We report the first case of marked glomerular cytoplasmic vacuolization in a patient who received PEGylated nucleoside analog.

Case Description: A 67 year old male received PEGylated nucleoside analog for metastatic gastric carcinoma. Within 4 weeks of the drug being stopped due to disease progression, the patient developed 7 g/day proteinuria, cough, dyspnea, and edema. Studies

showed a normal C3, C4 and negative ANCAs. Renal biopsy revealed focal segmental glomerulosclerosis with enlarged, reactive, vacuolated podocytes along with acute tubular epithelial injury with areas of tubular epithelial vacuolization. Immunofluorescence was negative. Electron microscopy (Fig. 1) revealed extensive intracytoplasmic vacuolization in glomerular podocytes (P), endothelium (gE), mesangial cells (M), tubular epithelial cells (T) and peritubular capillary endothelium (ptcE). Vacuoles were membrane bound, colorless and variably sized 0.3-6.5 μm. Some vacuoles contained granular material but majority were empty. No zebra bodies were seen. Podocytes had the most prominent vacuoles plus extensive foot process effacement.

Discussion: We report the first case of marked intracytoplasmic vacuolization related to PEG in renal glomerular, endothelial and tubular cells. Animal studies suggest vacuolization may be an adaptive response to clear PEG rather than a toxic effect. However, we hypothesize that PEG vacuoles can alter cell function with pathological changes and adverse clinical outcome, such as the podocytopathy seen in this case. Further clinical studies are needed to understand the safety of PEGylated therapies.



FR-PO970

Clinical, Histopathologic, and Molecular Characterization of Allograft Mesangial Glomerulopathy

Kelly D. Smith, Yuan Huang, Christopher D. Blosser, Nicolae Leca, Behzad Najafian, Shreeram Akilesh. *University of Washington, Seattle, WA.*

Background: Donor-derived cell-free DNA (dd-cfDNA) is a non-invasive biomarker used to detect allograft rejection. In the absence of other signs of graft dysfunction elevated levels of dd-cfDNA can prompt allograft biopsy. We describe three donor specific antibody (DSA)-negative, dd-cfDNA positive patients with an allograft mesangial glomerulopathy that is histologically distinct from traditional transplant glomerulitis (Figure 1).

Methods: Kidney allograft biopsies from 2018-2022 that had dd-cfDNA testing were reviewed to identify DSA-negative, dd-cfDNA-positive cases with mesangial proliferative glomerulopathy. Clinical and pathologic data were collected. Biopsy material from mesangial proliferative glomerulopathy cases were analyzed using digital spatial profiling (GeoMx, Nanostring) and compared to DSA-negative, dd-cfDNA positive and without obvious transplant glomerulopathy. Biopsies were hybridized with the Whole Transcriptome Atlas and bound probes were collected, sequenced and quantified from glomerular and tubulointerstitial regions of interest (ROI).

Results: Patients with mesangial glomerulopathy had fluctuating dd-cfDNA levels but maintained stable renal function (follow-up period 5-7 years post-transplant). The biopsies demonstrated a histologically unique form of allograft mesangial glomerulopathy. Analysis of glomerular ROI from control (17), mesangial glomerulopathy (11) and DSA-/cfDNA+ patients without glomerulopathy (37) revealed PD-L1 signaling as the most enriched pathway for differentially expressed genes in allograft mesangial glomerulopathy.

Conclusions: This small cohort of patients with allograft mesangial glomerulopathy exhibited fluctuating levels of dd-cfDNA, but stable allograft function. DSP analysis supports a distinct molecular pathophysiology for allograft mesangial glomerulopathy compared to DSA-/cfDNA+ glomerulitis.

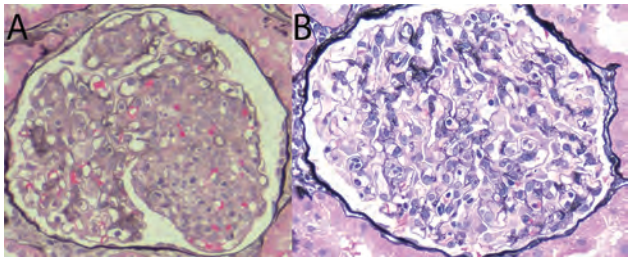


Figure 1. DSP uncovers gene expression differences in allograft mesangial glomerulopathy. A) Glomerulus from a patient with allograft mesangial glomerulopathy. B) Glomerulus from a patient with DSA-/cfDNA+ glomerulitis.

FR-PO971

Erythrocyte Glycocalyx Reports Glomerular Endothelial Glycocalyx Damage in Disease and Predicts Glomerular Albumin Permeability

Matthew J. Butler, Michael Crompton, Raina D. Ramnath, Rebecca R. Foster, Simon C. Satchell. Bristol Renal. *University of Bristol, Bristol, United Kingdom.*

Background: The endothelial glycocalyx (EnGlx) is damaged in acute and chronic kidney diseases contributing to the development albuminuria and vascular damage. However, directly detecting EnGlx loss has proven difficult, limiting research and slowing the development of targeted therapeutics. The red blood cell (RBC) and endothelial glycocalicies contain shared components. Both are exposed to circulating sheddases. We hypothesised therefore that the RBCGlx could provide a surrogate measure of EnGlx damage.

Methods: RBC from male Wistar rats and human trials were labelled with fluorescently tagged Glx-binding lectins and rhodamine 18. Images were obtained using confocal microscopy. Analysis was 'blinded', using machine learning to identify RBC and custom analysis software to measure the distance between Gaussian modelled fluorescence profile peaks to provide a measure of RBCGlx 'depth'.

Results: In rats (control, STZ (diabetic), STZ spironolactone (treated)) we confirmed a linear corelation between RBCGlx and glomerular EnGlx depth(r^2 0.72, $p<0.0001$, n=19). RBCGlx thickness also corelated with cardiac capillary EnGlx thickness measured using electron microscopy (r^2 0.78, p=0.0016, n=8). Serial blood samples confirmed significant RBCGlx damage 4 weeks after STZ, however a significant therapeutic response to spironolactone was detected 2 weeks after treatment. In all groups RBCGlx thickness corelated with ex vivo glomerular albumin permeability (MOA lectin, r^2 0.95, $p<0.0001$, n=9,) suggesting RBCGlx damage can be used to predict glomerular damage. On human kidney biopsies (minimal change nephropathy and thin basement membrane disease) RBCGlx thickness corelated (r^2 0.9226, $p<0.0001$, n=12) with cortical capillary EnGlx thickness. Measuring the RBCGlx in healthy pregnant women (venous blood) we confirmed a corelation with sublingual GlycoCheck™ readings (r^2 0.25, p=0.007, n=27). In patients with COVID-19 we rapidly confirmed significant RBCGlx damage (t-test, p=0.0002, n=26,) supporting published work suggesting EnCGlx damage.

Conclusions: Our test provides a reliable surrogate marker of EnGlx damage in kidney disease and predicts endothelial function. Larger human trials are underway to investigate the full potential of this major discovery in renal and cardiovascular disease monitoring and therapeutics.

FR-PO972

Detection of Autotaxin and Lysophosphatidic Acid Receptors in Glomerular Diseases within Glomerulus

Naonori Kumagai, Masaya Hirayama, Takuma Ando, Tomomi Kondo, Yuji Matsumoto, Yohei Ikezumi. *Fujita Ika Daigaku, Toyoake, Japan.*

Background: Lysophosphatidic acid (LPA) is a lysophospholipid that acts as a chemical mediator. It acts through six dedicated receptors, LPA receptor 1-6 (LPAR1-6). LPA is mainly produced by autotaxin (ATX) in blood from lysophospholipids in blood as a substrate. Moreover, LPA is produced by mPA-PLA within cells from phosphatidic acid in the cells as a substrate. be. The Pathophysiological role of the LPA and ATX in glomerular diseases within glomerulus remains unclear.

Methods: Immunostaining for LPAR1-5 and ATX was performed on renal biopsy specimens of pediatric glomerular diseases such as lupus nephritis, membranous nephropathy, idiopathic nephrotic syndrome, IgA nephropathy, and mesangioproliferative glomerulonephritis (MPGN). Moreover, ATX mRNA was detected by in situ hybridization.

Results: LPAR1-5 and ATX were strongly stained in lupus nephritis and membranous nephropathy. They were stained negative to weakly positive in the other glomerular diseases. ATX mRNA was detected in mesangial cells in IgA nephropathy and MPGN, however, was hardly detected in lupus nephritis and membranous nephropathy.

Conclusions: In systemic lupus erythematosus and lupus nephritis, ATX is assumed to be produced in macrophage and released into blood, resulting in elevated concentration in blood and urine. Taken together with the present study, these findings imply that in systemic lupus erythematosus and lupus nephritis ATX in blood is deposited in the glomerulus and LPA is produced in situ. Produced LPA acts in an autocrine and/or paracrine manner through LPA receptors and are involved in pathophysiological role. Conversely, in IgA nephropathy and MPGN, ATX is produced in situ within the glomerulus and is involved in the pathophysiological role. It is needed to elucidate the pathophysiological role of LPA and ATX in each glomerular disease within glomerulus.

FR-PO973

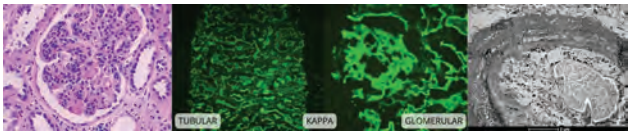
Monoclonal Immunoglobulin Deposition Disease (MIDD) or Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits (PGNMID): Which Diagnosis Fits Better?

Alexandre B. Liborio,[1] Rafaela J. Linhares,[3] Louise Salles,[3] André C. Teixeira,[2] Dulce M. Barrero.[3] *[1]Universidade de Fortaleza, Fortaleza, Brazil; [2]Centro Universitario Christus, Fortaleza, Brazil; [3]Hospital Geral de Fortaleza, Fortaleza, Brazil.*

Introduction: MIDD and PGNMID originate from monoclonal immunoglobulin-glomerular deposits. In MIDD, IF shows κ light chain restriction in up to 90% of cases and tubular basement membrane (TBM) involvement in 100% of cases. In PGNMID, LM shows proliferative or MPGN, and IF, by definition, reveals monotypic deposits restricted to the glomeruli (unlike MIDD), with IgG in 90% of cases. We describe a patient with renal-limited disease presenting a PGNMID-compatible clinical course/light microscopy findings but an IF-based diagnosis of MIDD.

Case Description: 48-year-old male presented with dialysis-requiring renal failure, hematuria (more than 100 RBC/HPF), proteinuria of 4.6g/24h and hypoalbuminemia. Due to clinical suspicion of RPGN, high-dose corticoid therapy was initiated. Renal biopsy (figure) demonstrated hypercellularity due to leukocytes and duplication of the GBM. Red congo negative. IF was positive only for κ light chains (4+/4) in both the GBM and TBM. Electron microscopy did not show glomeruli but non-organized electron-dense deposits in TBM. Renal response ocurred one month after corticoid therapy (sCr:1.56 mg/dL and proteinuria, 177 mg/24h). Corticoid withdrawal was followed by worsening renal function, leading to reintroduction with new response. A κ peak was present in the urine and despite no evidence of multiple myeloma, bortezomib was added.

Discussion: This case has features that prompt us to reconsider the most fitting diagnosis and, in any case, expand our understanding of the spectrum of glomerular involvement by monoclonal deposits. Although the IF findings (κ restriction and deposits in the TBM) and the initial presentation can be compatible with MIDD, the dramatic and rapid glucocorticoid response aligns with the clearance of inflammatory cells, a main feature of PGNMID as the primary pathologic substrate. Patients with MIDD treated with bortezomib had renal remission, but only after several months (PMID: 30578255). Therefore, we suggest that PGNMID is the most appropriate and more informative diagnosis for clinicians' management; alternatively, two concominant diagnosis can be considered



FR-PO974

A Rare Case of Granulomatosis with Polyangiitis Presenting with Esophagitis

Greeshma A. Thomas, Tyler Morgan, Rupinder Kaur, Nabeel Siddiqui, Olawale M. Osunsanya. *Southeast Health, Dothan, AL.*

Introduction: Granulomatosis with polyangiitis (GPA) is a rare autoimmune disorder characterized by necrotizing granulomas, mainly affecting the upper respiratory tract, lungs, and kidneys. The typical presentation of kidney involvement is in the form of RPGN. The exact etiology of GPA remains unknown. Diagnosis should be suspected in any patient with nonspecific constitutional symptoms, clinical evidence of glomerulonephritis with upper or lower respiratory tract involvement, and lab evidence of positive ANCA serology. Here, we present a case of a patient with a baseline serum creatinine of 1.5 who initially presented with esophagitis and was ultimately found to have GPA.

Case Description: 76 y/o Caucasian female with PMH of hyperlipidemia, anemia, and GERD who initially presented to outside facility due to weakness and diarrhea. Found to be COVID-19 positive and anemic, with Hb 7.6 and a Hct 23. She underwent EGD and colonoscopy, which revealed esophagitis, esophageal candidiasis, and gastritis. She was discharged after receiving conservative management. She presented again to the same facility 2 weeks later with acute hypoxic respiratory failure. Labs revealed Hb of 5.6 and Cr of 10.40. After initial stabilization, she was transferred to our facility for higher care. Labs revealed Hb 8.2, Na 131, K 5.8, S. Cr 10.58, GFR 3.6. Urinalysis- 2+ protein, 3+ blood, leuk esterase, and many bacteria. ANA, C3, C4, PR3-ANCA, and GBM Ab negative. Protein electrophoresis revealed an M spike. Her C-ANCA titer was found to be greater than 1:640. A kidney biopsy showed necrotizing and crescentic glomerulonephritis with mild interstitial fibrosis and tubular atrophy, consistent with GPA. She was initially started on SLED followed by HD with steroids and Rituximab.

Discussion: Due to the wide variety of possible associated clinical manifestations, initial diagnosis of GPA can be difficult. In the case presented in this paper, the patient initially presented to an outside hospital with esophagitis. She did not undergo further workup for her symptoms and presentation until she re-presented with AKI and respiratory distress. At that time, GPA rose on the differential and was confirmed via kidney biopsy. This case showcases a rare presentation of GPA with esophagitis, which we hope to highlight to improve physician awareness.

FR-PO975

Quantification of Urine Podocytes (Podo) Using Imagining Flow Cytometry (IFC)

Alireza Ayoubi, Abbal Koirala, Jonathan R. Fromm, Behzad Najafian. *University of Washington System, Seattle, WA.*

Background: Podo injury and loss contribute to the progression of most kidney diseases causing ESRD. Quantification of Podo in the urine is a noninvasive approach for early detection of glomerular injuries and monitoring kidney disease progression. Current approaches for urine Podo quantification are time-consuming and difficult to standardize. We aimed to develop a standardized, faster approach using IFC

Methods: Laboratory standards for positive and negative controls were developed using human Podo (markers: podocalyxin, GLEPP1), urothelial (marker: UPK3) and proximal tubular (marker: LRP2) cell lines. Validation process included sensitivity, specificity, linearity and lower limit of quantification. Limited urine samples from patients were examined. IFC was done using Mark-II Imagestrem. Data was analyzed using IDEAS software.

Results: IFC reliably separated Podo from urothelial and proximal tubular cells. There was close to perfect correlation between podocalyxin and GLEPP1 signals. Analysis of triplicate samples at 5 dilutions demonstrated linearity down to a lower limit of quantification of 500 Podo/75 uL of analyte. IFC of spot urine samples from 5 random patients with membranous nephropathy, pauci-immune glomerulonephritis, diffuse lupus nephritis, IgA nephropathy and Fabry disease quantified a range of 4-146 Podo/ml urine with a detection sensitivity of 0.07% of total events captured.

Conclusions: We have developed laboratory standards for the quantification of urine Podo and have validated IFC protocols. In contrast to conventional flow cytometry, IFC is capable of detecting rare cells and can be a powerful tool to quantify urine Podo loss. Further work is needed to explore podocyturia variability in healthy and disease conditions.

NIH Activity and Chronicity Indices in Lupus Nephritis: A Critical Analysis

Valentina Querin,[1] Fiammetta Ravaglia,[2] Augusto Vaglio,[1,3] Ingeborg M. Bajema.[4] *[1]Department of Biomedical, Experimental and Clinical Sciences "Mario Serio", University of Florence, Florence, Italy; [2]Nephrology and Dialysis Unit, Santo Stefano Hospital, Prato, Italy; [3]Nephrology and Dialysis Unit, Meyer Children's University Hospital - IRCCS, Florence, Italy; [4]Universitair Medisch Centrum Groningen Pathologie en Medische Biologie, Groningen, Netherlands.*

Background: Inclusion of NIH activity and chronicity indices (AI & CI) in the ISN/RPS classification of lupus nephritis (LN) aims to provide a more precise characterization of the amount of active/chronic lesions next to the lupus class. AI is based on 6 lesions (range 0-24) and CI on 4 lesions (range 0-12). We here report how the AI and CI values vary in a large multicenter cohort; which lesions in particular determine the index; and what their relation is to lupus class.

Methods: We collected 86 LN kidney biopsies from 2 international centers, excluding those with <10 scorable glomeruli or with a concomitant glomerular disease. We calculated the NIH AI and CI according to the 2018 ISN/RPS classification revision. We used Pearson's coefficient to explore correlations and One-way ANOVA to analyze AI and CI distribution in the classes.

Results: More than 90% of the biopsies showed an AI <10 (4.5±3.7) and a CI <8 (2.6±2.7). Class IV (±V) had the highest AI, classes I/II had an AI of 0. Endocapillary hypercellularity was the most common active lesion (table), showing the strongest correlation with neutrophils ($r=0.71$, $p<0.001$). Cellular crescents correlated with fibrinoid necrosis and interstitial inflammation ($r=0.317$, $p=003$; $r=0.415$, $p<0.001$). There were no differences over classes in CI distribution. Interstitial fibrosis, tubular atrophy and glomerulosclerosis were related to each other ($p<0.001$) but not to fibrous crescents.

Conclusions: In this cohort, AI and CI scores were medium-low and rarely reached the highest values. Endocapillary hypercellularity was the most common lesion driving AI score. It is crucial to reassess if the lesions included in AI and CI reflect the actual activity and chronicity of LN. Investigating potential modifications of the indices may lead to a more balanced and accurate scoring system.

Variables	Patients (n=86)
Age in years at kidney biopsy, mean (SD)	31.6 (17.5)
> 18 years, n (%)	58 (67.4)
Female gender, n (%)	61 (70.9)
Histological class, n (%)	
I	1 (1.2)
II	4 (4.7)
III	24 (27.9)
IV	39 (45.3)
V	10 (11.6)
III+V	3 (3.5)
IV+V	5 (5.8)
NIH AI, mean (SD)	4.5 (3.7)
Endocapillary hypercellularity, n (%)	65 (75.6)
Neutrophils/karyorrhexis, n (%)	51 (59.3)
Fibrinoid necrosis, n (%)	12 (14)
Hyaline deposits, n (%)	26 (30.2)
Cellular/fibrocellular crescents, n (%)	30 (34.9)
Interstitial inflammation, n (%)	27 (31.4)
NIH CI, mean (SD)	2.6 (2.7)
Total glomerulosclerosis score, n (%)	47 (54.7)
Fibrous crescents, n (%)	12 (14)
Tubular atrophy, n (%)	41 (47.7)
Interstitial fibrosis, n (%)	44 (51.2)

Table. Demographic and histologic characteristics of the LN cohort

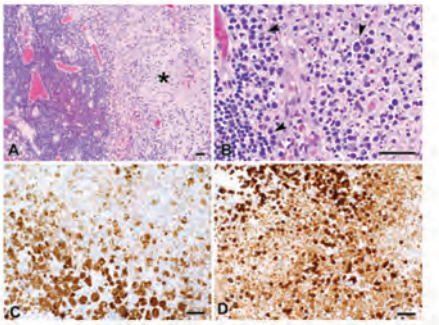

Figure 1: The excisional lymph node biopsy showed areas of necrosis alternating with preserved nodal architecture (Fig. 1A). Tissue at the edges of the lesions contained numerous plasma cells (Fig. 1B) and CD68-positive macrophages (Fig. 1C), but neutrophil infiltration was minimal. Lesional and perilesional tissue contained abundant CD3-positive T-cells (Fig. 1D).

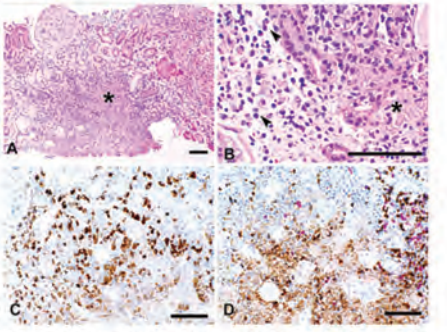

Figure 2: The percutaneous renal biopsy contained an area of dense interstitial inflammation and necrosis with features similar to those seen in the lymph node (Fig. 2A and 2B). As with the lymph node biopsy, CD68-positive macrophages were numerous (Fig. 2C), and the areas of necrosis and surrounding tissue contained abundant CD3-positive T-cells (Fig. 2D). No hematoxylin bodies were seen in either biopsy.

FR-PO977

Renal Necrotizing Histiocytic Lesions in a Patient with Systemic Lupus Erythematosus (SLE)

Rasha Raslan, Maria Fernanda Ortiz Kaemena, Anand S. Lagoo, David N. Howell. *Duke University Health System, Durham, NC.*

Introduction: Patients with SLE can develop lupus lymphadenitis (LL) with necrotizing lesions in lymph nodes and is difficult to distinguish from Kikuchi-Fujimoto Disease (KFD). There have been no cases depicting histological evidence of necrotizing lymphadenitis in the kidney

Case Description: A 35 year old female with SLE presented with fevers & cervical lymphadenopathy. Extensive workup for infections was negative. A lymph node and native kidney biopsy were performed (figures 1 & 2). These showed a necrotizing inflammatory process with CD8 + T cells, plasma cells and macrophages

Discussion: KFD & LL have both distinct and overlapping features. On histology, KFD is characterized by patchy areas of necrosis with abundant karyorrhectic nuclear debris. Neutrophils & eosinophils are typically absent. Immunohistochemical testing often shows CD3 & CD8 T cells. Presence of neutrophils, hematoxylin bodies, & abundant plasma cells is more consistent with LL. C4d staining (more common in LL) may be useful in distinguishing the two. There are reports of AKI in patients with KFD, however, direct involvement of renal parenchyma by necrotizing inflammation recapitulating lymphadenitis is not documented. One explanation is an over-active immune response that leads to localized inflammation in nearby tissues. KFD is typically limited to lymph nodes, so how it spreads to distant organs is less clear. Possible explanations include migration of inflammatory cells from elsewhere, or de novo inflammatory process that initiated in the kidney. It is unclear why this necrosis predominantly involves histiocytes and not neutrophils. Our case highlights another entity that can be encountered in a patient with SLE & the need for renal biopsies when a diagnosis is not clear. Obtaining an adequate sample is important to not miss other pathological processes

FR-PO978

Hydroxychloroquine (HCQ)-Associated Zebra and Myeloid Bodies in Patients with Systemic Lupus Erythematosus (SLE)

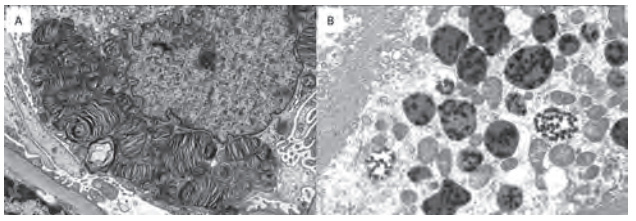
Shun Manabe,[1] Momoko Seki,[1] Yusuke Ushio,[1] Yuki Kawaguchi,[1] Shizuka Kobayashi,[1] Shiho Makabe,[1] Naoko Ito,[1] Hiroshi Kataoka,[1] Sekiko Taneda,[1] Kazuho Honda,[2] Junichi Hoshino.[1] *[1]Tokyo Women's Medical University, Shinjuku-ku, Japan; [2]Showa University, Shinagawa-ku, Japan.*

Background: Zebra and myeloid bodies are characteristic findings in Fabry disease. However, the presence of lamellar bodies (LBs) in HCQ-treated patients (HCQ+) occasionally poses a diagnostic challenge in differentiating Fabry disease. Here we aimed to elucidate the histological features of kidney biopsy associated with HCQ treatment.

Methods: We analyzed SLE patients who underwent kidney biopsy from 2019 to 2024. Electron microscopic (EM) images were evaluated for the maximum number of LBs within involved cells, presence of curvilinear bodies, and intracellular vesicles with osmiophilic granules. We evaluated four Fabry disease cases similarly.

Results: A total of 37 SLE patients, including 17 HCQ+, underwent kidney biopsy. No case was clinically suggestive for Fabry disease. EM images were taken from 23 patients (Female 20, mean age; 43.5±12.5), including 12 HCQ+. LBs were observed in all 12 HCQ+ (Figure A) and in three (27.2%) cases without HCQ treatment (HCQ-). The maximum number of LBs ranged from one to 49, median (IQR); 2.5 (1-4), in HCQ+, and one, one, and 4 in HCQ-. Of 4 HCQ+ with a single LB, 2 had initiated HCQ less than 10 days prior. A HCQ- with 4 LBs were treated with sertraline; a medicine can be associated with LB. Among Fabry disease patients, the number ranged from 59 to 141 (median, 79.0). Curvilinear bodies were observed in three HCQ+ only. Intracellular vesicles with osmiophilic granules within proximal tubular cells (Figure B) were observed in 7 out of 10 (70%) HCQ+ with images of proximal tubules, and none of (0%) HCQ-. One case underwent globotriaosylceramide 3 staining with a positive result. Three HCQ+, with 4, 5, and 49 LBs, including a case with urinary mulberry cells, underwent genetic testing for α-galactosidase A with normal results.

Conclusions: The appearance of LBs might be a universal phenomenon associated with HCQ treatment, though the number of LBs was apparently smaller than in Fabry disease. The number of LBs and presence of intracellular vesicles with osmiophilic granules might help differentiate HCQ-associated LBs from Fabry disease.



FR-PO979

A Diagnostic Challenge of AL Amyloidosis in a Patient with Positive Immunohistochemistry for AA Amyloidosis Later Confirmed to be AL Amyloidosis by Mass Spectrometry

Saad A. Alshihri, Gabriel B. Lerner. *Yale University School of Medicine, New Haven, CT.*

Introduction: We present a case of a 64-year-old male with progressive orthostatic hypotension and multi-organ dysfunction ultimately diagnosed with AL amyloidosis following renal biopsy and mass spectrometry analysis. The case underscores the diagnostic challenge posed by atypical presentations of amyloidosis and highlights the importance of kidney biopsy in diabetic patients with proteinuria that does not fit the typical presentation. It also emphasizes the utility of mass spectrometry in indentifying the amyloid subtype.

Case Description: This is a 64-year-old Hispanic male with a history of type 2 diabetes, hypertension, hyperlipidemia, and cerebrovascular accident who had a 3-year history of dizziness and orthostatic hypotension progressing to syncopal attacks, unintentional weight loss, paresthesia of the lower extremity and generalized weakness. Despite extensive evaluations, including neurologic and malignancy workups, the underlying cause remained elusive. Nephrology consultation was sought due to significant proteinuria with UPCR of 19 g/g. Renal biopsy revealed Congo red-positive amyloid deposits with positive immunohistochemistry for AA amyloidosis, but there was lambda restricted staining on IF with no kappa staining suggested a possible AL amyloidosis. Serum and urine electrophoresis along with serum IFE were negative for abnormal bands, urine IFE showed discrete monoclonal bands. Subsequent mass spectrometry analysis identified AL amyloidosis, and bone marrow biopsy with approximately 15% lambda light chain restricted plasma cells prompting initiation of CyborD chemotherapy. However, advanced multi-organ involvement, including cardiac and gastrointestinal manifestations, led to a palliative care approach.

Discussion: This case highlights the importance of considering amyloidosis in the differential diagnosis of patients with orthostatic hypotension. Kidney biopsy is a valuable tool for establishing the diagnosis, with mass spectrometry emerging as a novel modality for accurate subtyping. Early recognition of AL amyloidosis is crucial for timely intervention and prevention of further amyloid deposition, as prognosis is poor in advanced disease stages with multi-organ involvement.

FR-PO980

Percutaneous Kidney Biopsy of Native Kidneys in Adults: A Single-Center, 40-Year Experience

Stephen M. Korbet, William L. Whittier. *Rush University Medical Center, Chicago, IL.*

Background: Percutaneous renal biopsy (PRB) of native kidneys is an essential tool in the diagnosis and management of renal disease. We report one of the largest single center experiences on the success and safety of the procedure.

Methods: From 6/1983 to 12/2022, 1384 adults underwent PRB using real-time ultrasound guidance using predominantly automated 14- (n 839) or 16- (n 312) gauge needles. An attending nephrologist or a fellow (85% of biopsies) under the supervision of an attending nephrologist performed all biopsies. Following the procedure, patients were observed for 24 hours. A complication was defined by the need for an intervention, such as a transfusion of blood products or invasive radiologic or surgical procedure, or those resulting in the need for readmission or death. Data was collected prospectively in 1153 (83%) biopsies. Statistical analysis was performed using the Mann-Whitney test and Wilcoxon matched pairs test for continuous data or the Fisher's exact test for categorical data. Data are reported as mean ± standard deviation (SD) and a p-value of < 0.05 was considered significant.

Results: Pts were 46±17 yo, 38% were male, 38% white and 43% AA. The serum creatinine (SCr) was 2.3±2.4 with 47% >1.5 mg/dl. The pre-PRB hemoglobin (Hgb) was 11.7±2.2 and the post-PRB Hgb was 10.7±2.1 g/dl (delta 0.97 g/dl, P <0.0001). Adequate tissue for diagnosis was obtained in 99% of biopsies. The total glomeruli (light + immunofluorescence microscopy) per biopsy was 30±14 with 77% having ≥20 glomeruli. Significantly more glomeruli were obtained using the 14 vs 16-gauge automated needle (32±14 vs 27±11, P <0.0001) with 81 vs 74% having ≥20 glomeruli (P 0.01). Complications occurred in 7.0% of biopsies with transfusions required in 5.6% of biopsies. There was 1 (0.09%) death from post-PRB bleeding. There was no difference in complication rate (7.0 vs 8.0%, P 0.6) or transfusion requirement (5.6 vs 5.8%, P 0.9) for PRB with a 14- vs 16- gauge needle. Complications post-PRB were identified in ≤8 hrs in 73%, ≤12 hrs in 84% and ≤24 hrs in 90% of pts with 10% of complications occurring >24 hrs post-PRB.

Conclusions: PRB of native kidneys using real-time ultrasound with an automated needle remains a successful and safe procedure. We find that the use of a 14-gauge automated needle not only provides a larger biopsy sample but is as safe as a 16-gauge automated needle.

FR-PO981

Clinicopathological Features and Prognostic Outcomes of Adenovirus Nephritis: A Systematic Review of 51 Cases

Khanh Duy Doan,[1] Clarissa A. Cassol.[2] [1]*Temple University, Philadelphia, PA;* [2]*Arkana Laboratories, Little Rock, AR.*

Background: Adenovirus nephritis is a rare condition primarily associated with kidney allografts, presenting significant diagnostic and management challenges.

Methods: A systematic review was conducted on published data concerning adenovirus nephritis.

Results: 36 studies comprising 51 cases (47 allograft kidneys, 4 native kidneys) were included. Median age is 45 years and males are predominant. 72.3% occurred within the first year post-transplantation. Presentations included fever (72.5%), gross hematuria (52.9%), dysuria (39.2%), and graft pain (17.6%). Kidney biopsy patterns was shown in table 1. Adenovirus immunohistochemistry demonstrated high sensitivity (94.1%), while electron microscopy identified viral particles in 45% of cases. Immunosuppressive treatment reduction occurred in most patients (95.7%), with only 36.2% receiving antiviral therapy. Allograft failure was rare (4.4%), despite aggressive presentation, with 84.4% of patients experiencing creatinine normalization post-treatment.

Conclusions: Adenovirus immunohistochemistry showed high sensitivity, albeit limited availability. Despite its aggressive presentation, adenovirus nephritis infrequently results in graft failure.

Kidney biopsy results

	Cases (51)	Percentage (%)
Tubulointerstitial inflammation	47	92.2
Granuloma	30	58.8
Viro-pathic changes	28	54.9

FR-PO982

Discovering the Etiology of a Rare Diagnosis of Anti-brush Border Antibody (ABBA) Disease

Jessenia A. Contreras, Sumie Iwasaki. *Kaiser Permanente Northern California Region, San Francisco, CA.*

Introduction: Anti-low density lipoprotein receptor related protein 2 (Anti-LRP2) nephropathy (a.k.a. anti-brush border antibody (ABBA) disease) is a rare entity with only around 67 cases confirmed by LRP2 immunostaining and indirect immunofluorescence. It is common in white men around the age of 70s, and there is often an association with autoimmune diseases, paraneoplastic syndromes, or monoclonal gammopathy. LRP2 is found in multiple organs, but within the kidneys, LRP2 is expressed only in proximal tubular (PT) brush borders. The disease causes acute tubular injury (ATI) via immunoglobulin G (IgG) immune complex deposits along the PT basement membrane and circulating autoantibodies to the PT brush border protein LRP2. We report a case of ABBA and the process of evaluating the etiology.

Case Description: A 74-year-old man with history of dextrocardia s/p heart transplant, osteopenia, and CKD stage IV presented with back pain and weakness, with hypercalcemia [13 mg/dL], anemia, and acute on CKD. PET scan was negative. Calcium supplements were discontinued on admission, and he was treated with IV fluids with some improvement in hypercalcemia but not in renal function. Hypercalcemia workup revealed suppressed PTH, elevated vitamin D 25- OH and ACE levels, small M-protein spike on SPEP and IgG kappa on serum immunofixation; PTHrP, Vitamin D 1,25- OH2, TSH, ANCA, ANA panel, and kappa/lambda light chain ratio were normal. He had a recent history of Epstein- Bar Viremia but no signs of PTLD. Imagings were unremarkable. Renal biopsy showed ATI with tubular membrane disease deposits consistent with ABBA. Confirmatory testing for anti-LRP2 was sent to Arkana. The patient had worsening renal function and started on dialysis.

Discussion: This rare case of ABBA assesses potential etiologies. There could be an association between ABBA and heart transplant but there were no indications to check DSAs. Regarding his hypercalcemia, LRP2 is also located in the parathyroid gland, and unclear whether the autoantibodies affected the calcium sensing receptor. We are continuing to rule out other possibilities prior to initiating treatment, but most patients with ABBA do not respond to immunosuppressants and have poor prognosis.

FR-PO983

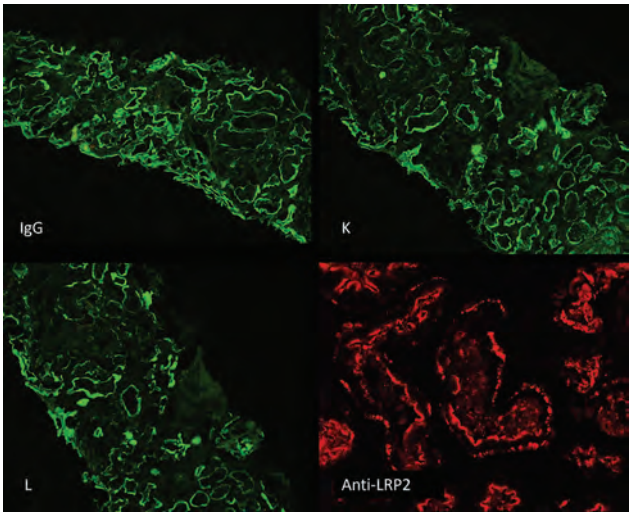
Kidney Dysfunction in Hematologic Malignancy Unveiling Anti-brush Border Antibody Disease

Paul W. Davis,[1] Alessia Buglioni,[1] Christopher P. Larsen,[2] Wisit Cheungpasitporn,[1] Silvia Titan.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Arkana Laboratories, Little Rock, AR.*

Introduction: Anti-brush border antibody disease (ABBA) is a rare disorder where antibodies target the low-density lipoprotein receptor-related protein 2 (LRP2 or megalin). Despite its rarity, ABBA warrants consideration in the differential of renal injury of unknown etiology or when IgG deposits in the TBM are seen. We present a case of ABBA with malignancy discussing diagnosis and treatment.

Case Description: The patient, a 56 year-old-male with a PMHx of HTN, DM, stroke, and PE (on apixaban) presented with worsening renal function. Two years ago with normal sCr and Hgb levels, he had knee replacement complicated by infections, treated with long term antibiotics. Anemia persisted, prompting a bone marrow biopsy revealing LGLL, treated with cyclophosphamide. Exam: normal BP, pallor and BLE edema. Labs: Hgb 9.1 g/dL, Cr: 1.9 mg/dL, eGFRcr 42 mL/min/BSA, cysC 2.1 mg/L, eGFRcys 29 mL/min/BSA and eGFRcrcys 34mL/min/BSA, glucose 156 mg/dL, urine: UACR 82 mg/g, UPCR 0.56 mg/mg, RBP 97905 mcg/24 hours, and negative for RBCs or Hgb; small serum monoclonal IgG kappa, positive ANA Hep-2 substrate 1:160, anti-DS DNA 145 IU/mL, positive lupus anticoagulant. Renal ultrasound: bilateral mild cortical thinning. Kidney biopsy findings were consistent with ABBA disease. Treatment: Prednisone and mycophenolate. Cr remains stable, Hgb is improved.

Discussion: This case emphasizes considering ABBA in the differential of AKI or CKD of unknown causes. It may occur alone or with systemic diseases, notably hematological malignancies and auto-immune conditions. Diagnosis relies on biopsy showing IgG TBM deposits, with positive IF staining for LRP2 within TBM or serologic confirmation of anti-LRP2 antibodies by indirect IF on normal kidney. High CKD progression risk stresses the need for researching biomarkers and treatment options.



Proximal TBM granular staining positive for IgG, kappa, lambda, and anti-LRP2

FR-PO984

Diagnostic Utility of Urinary Sediments in Light-Chain Proximal Tubulopathy (LCPT): Report of Three Cases

Anna Nakai, Shun Manabe, Momoko Seki, Yusuke Ushio, Hiroshi Kataoka, Junichi Hoshino. *Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan.*

Introduction: LCPT is characterized by crystals within proximal tubular epithelial cells and is typically associated with Fanconi syndrome. However, in cases without Fanconi syndrome, diagnosing LCPT is challenging. Microscopic analysis of urinary sediments may be valuable for LCPT, as cells and casts might contain light chain-derived crystals. Although their diagnostic value remains underreported, we present three cases of LCPT without Fanconi syndrome, where urinary sediments with crystals were crucial in understanding their condition.

Case Description: A 54-year-old female with macroglossia, carpal tunnel syndrome, subcutaneous nodules, and IgA-κ type M protein was diagnosed with AL amyloidosis. Urine protein was 5.3 g/gCr, and serum creatinine (sCr) was 1.09 mg/dL. However, urinary sediments revealed crystals within tubular epithelial cells, inconsistent with amyloidosis. Kidney biopsy was negative for amyloid deposition, and LCPT was diagnosed. A 55-year-old male with psoriasis and hypertension experienced a gradual decline in renal function. sCr level was 1.92 mg/dL. Urinary sediments revealed crystals within tubular epithelial cells and casts. Light chain staining of the sediments was positive for kappa light chain only. IgG-κ type M protein was identified, and kidney biopsy demonstrated LCPT with significant tubular casts containing crystals. A 66-year-old female presented with fever, edema, and impaired renal function. sCr level was 2.41 mg/dL. IgG-κ type M protein was detected. Urinary sediments were suspicious for crystals within tubular epithelial cells and macrophages. Immunostaining and electron microscopic analysis of cell blocks confirmed crystals in both cell types. Kidney biopsy disclosed LCPT and crystals within interstitial macrophages. Moreover, a biopsy of a subcutaneous soft mass detected histiocytes containing crystals. These findings led to a diagnosis of Crystal-Storing Histiocytosis.

Discussion: Direct observation of tubular epithelial cells and casts in urine supported the diagnosis of LCPT. Immunostaining and electron microscopic analysis were informative for identifying the origin of crystals, the type of light chain, and the cell type containing crystals, deepening the understanding of the patient's condition without invasive kidney biopsy. Further consideration is required.

FR-PO985

IgG Kappa Monoclonal Gammopathy of Renal Significance (MGRS) Manifesting as Noncrystalline Light-Chain Proximal Tubulopathy (LCPT) with Fibrils

Alcino Gama, Veronica Zamora-Olivencia, Carla L. Ellis. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Introduction: LCPT is a rare manifestation of paraproteinemia (5% of MGRS cases). It can present with crystalline or non-crystalline deposition in the tubular epithelium and is more commonly associated with kappa light chain (KLC) predominance. Clinically, it presents with a variable degree of CKD, proteinuria, and/or Fanconi syndrome.

Case Description: A 53 y/o male with IgG kappa MGUS (serum IgG 1.6 mg/dL, free KLC 13.5 mg/dL, kappa/lambda (K/L) 14.3, bone marrow with 7% plasma cells and no anemia, hypercalcemia, or bone lesions) was referred to nephrology due to eGFR of 68 mL/min. Clinical exam was unremarkable. Urinalysis showed trace blood and non-nephrotic proteinuria: 0.9 g/24h with a 0.3 g M-spike on UPEP. There was no Fanconi syndrome. All other serologies were negative. A renal biopsy was performed. Light microscopy showed diffuse, acute tubular injury with epithelial cell swelling, ballooning type vacuolization and granular cytoplasmic inclusions (Fig 1A). No definitive crystalloid structures, tubular necrosis, or tubulitis were identified. Frozen immunofluorescence (F-IF) showed a slight kappa predominance in tubular cell droplets compared to lambda (Fig 1B-C). Immunohistochemical (IHC) staining showed markedly increased staining with Kappa relative to Lambda in tubular epithelial cells (Fig 2A-B). Congo red was negative. EM showed fibrillar inclusions arranged in parallel arrays, ~10.2 nm (Fig 2C). The patient has been treated with daratumumab and bortezomib for six months with no evidence of disease progression and has sutained stable levels of KLC (5.8 mg/dL), with K/L 14.5.

Discussion: This case represents a rarely reported variant of non-crystalline LCPT with fibrils and without significant renal dysfunction. KLC monoclonality was more evident in IHC than in F-IF staining. While paraffin IF (P-IF) is the standard for a diagnosis of LCPT, this case represents a variable technique that can be helpful in settings with limited access to P-IF technology.

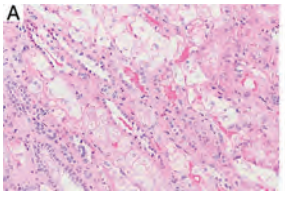


Figure 1. A: Diffuse acute tubular injury with ballooning type vacuolization and granular cytoplasmic inclusions (H&E, 400x). B/C: F-IF for for Kappa (B, 400x) slightly increased in tubular epithelial cells compared to Lambda (C, 400x).

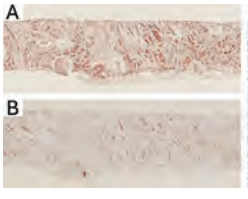

Figure 2. A/B: IHC for Kappa (A, 40x) markedly positive in tubular epithelial cells compared to Lambda (B, 40x). C: EM highlighting fibrillar inclusions arranged in parallel arrays, measuring in average 10.2 nm.

FR-PO986

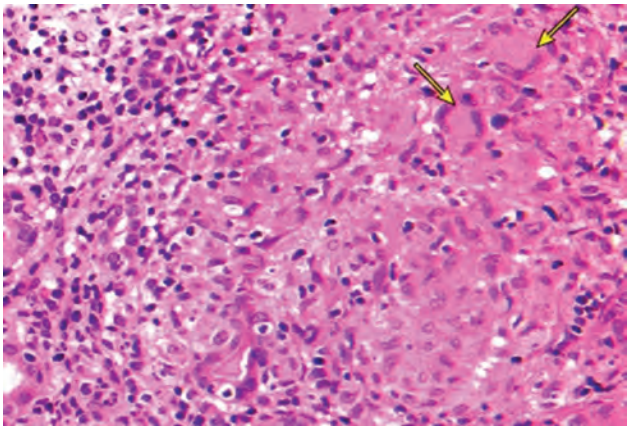
A Rare Case of Renally Limited Sarcoidosis

Fatima Raza, Arda Akoluk. *The University of Texas at Tyler, Tyler, TX.*

Introduction: The most common manifestations of sarcoidosis involve the lung. The prevalence of renal involvement in sarcoidosis is variable, with some studies reporting approximately 6% of sarcoidosis case presenting with renal manifestations. However, the majority of these cases present with concurrent extrarenal manifestations. We present a case of sarcoidosis diagnosed with manifestation limited to the kidneys and the workup it entailed.

Case Description: The patient is a 68 yo male with chronic low back pain, atrial fibrillation, CAD who presented to ED for evaluation of diarrhea. He was found to have renal insufficiency on that admission which was thought to be secondary to dehydration. In December 2020 he presented again with renal insufficiency and hypercalcemia. He underwent workup including kidney biopsy in January of the which showed noncaseating granulomatous interstitial nephritis. Autoimmune workup was negative, inflammatory markers unremarkable, BUN 54, Cr 3.67. Chest x ray was normal. He was initiated on dialysis. Patient's review of systems was negative except for fatigue and chronic bilateral knee pain. Initially, kidney biopsy was thought to be drug induced noncaseating granulomatous interstitial nephritis from chronic NSAID use as patient did not have chronic hypercalcemia and pathology was not typical for renal sarcoidosis. Subsequently, patient was found to be recurrently hypercalcemic with elevated PTH RP, high ACE. He was treated in the acute setting with pamidronate infusion and prednisone daily He was found to have no other organ involvement of his sarcoidosis. He was subsequently evaluated for renal transplant.

Discussion: Renally limited sarcoidosis is a rare presenstation and renal biopsy is essential for diagnosis. Typical findings on renal biopsy are noncaseating granulomas and giant cell formation, but athology findings on renal biopsy may vary and a broad differential should be considered. Workup should include chest radiograph and PFTs. Treatment typically consists of prednisone and if needed, supportive care with dialysis.



FR-PO987

Histopathologic and Clinical Characteristics of Nephropathies in Burmese Refugees

Hannah S. Hyaduck,[1,2] Irene Nunuk,[1] Shunhua Guo,[1,2] Carrie L. Phillips,[1,2] Michael T. Eadon,[1] Jessica L. Hata.[1,2] *[1]Indiana University Health Inc, Indianapolis, IN; [2]Indiana University School of Medicine, Indianapolis, IN.*

Background: Understanding the spectrum of nephropathies among cultural minorities may be beneficial for nephrologists and pathologists serving multicultural communities. Myanmar (formerly Burma) has been challenged by natural disasters, civil war, poverty, oppression, and human rights violations, displacing many Burmese people to the United States. This population continues to experience limited access to healthcare and poor health outcomes.

Methods: We identified 50 kidney core biopsies from 48 Burmese patients from 2006-2024. The biopsies were examined by light (LM), immunofluorescence (IF), and electron (EM) microscopy using conventional methods. Biopsies were scored by LM using the Oxford Criteria. Podocyte foot process effacement was assessed by EM.

Results: 20 patients were male and 28 were female with a mean age of 32.5 years (range 11-53 years). 34 (71%) had IgA nephropathy (IgAN), 10 (21%) had Lupus nephritis (LN), and 4 (8%) had minimal change disease, amyloidosis, thrombotic microangiopathy, or acute tubular necrosis. Most patients with IgAN presented with hematuria and proteinuria. The average urine protein-creatinine ratio was 3.8 grams with a median creatinine of 0.92 mg/dL. 35% had hypertension with rare other comorbidities; the average body mass index was 24.4 kg/m^2. Additional findings in IgA patients included increased rates of segmental sclerosis (S1, 71%) and mesangial hypercellularity (M1, 71%), endocapillary hypercellularity and crescent formation (E1 16% and C1 19%, respectively), and no cases with >25% crescents. Tubulointerstitial fibrosis was mild overall (68% T0, 19% T1). Podocyte injury was prominent with 41% of cases showing >50% foot process effacement and 26% with glomerular collapsing features, tubular microcystic change, and/or increased tubular protein resorption droplets. Moderate and severe arterial and arteriolosclerosis were present at 43% and 44%, with 35% showing moderate to severe hyalinosis.

Conclusions: Burmese patients with IgAN had greater than expected rates of segmental sclerosis, podocyte injury, proteinuria, and vascular disease, raising the possibility of an underlying genetic predisposition to podocyte and endothelial injury. Advancing our understanding of the nephropathy spectrum in Burmese immigrant patients may lead to improved strategies for disease prevention and management.

FR-PO988

Clinicopathologic Features of CKD Kidney Precision Medicine Project (KPMP) Participants

Ramya Narasimhan,[1] M. Luiza A. Caramori,[4] Sushrut S. Waikar,[1] Laura H. Mariani,[3] Glenda V. Roberts,[5] Joel M. Henderson,[1] Sylvia E. Rosas.[2] Kidney Precision Medicine Project (KPMP). *[1]Boston Medical Center, Boston, MA; [2]Joslin Diabetes Center, Boston, MA; [3]University of Michigan, Ann Arbor, MI; [4]Cleveland Clinic, Cleveland, OH; [5]Kidney Research Institute, University of Washington, Seattle, WA.*

Background: Patients with CKD have significant heterogeneity in the patterns of kidney (Kd) lesions. Herein, we analyzed research KPMP Kd biopsies (Bx) to determine if clinical features were associated with histopathologic patterns in CKD ppts with diabetic (DN) or vascular (VN) nephropathy.

Methods: Ppts recruited from 15 US centers underwent comprehensive clinical evaluation and research KdBx. Histopathology was assessed by two renal pathologists on whole slide images and consensus score assigned for morphologic features. Clinicopathologic diagnoses (Dx) were adjudicated by a committee of consortium members in 154 CKD Bx, and ppts assigned a primary Dx of DN, VN, "other", or "could not determine."

Results: 42% of Bx had DN and 32% had VN as primary Dx. Age was 58±12 vs. 63±11 yrs (*p=0.02), and* 32% vs. 10% were of Hispanic ethnicity *(p=0.01)* in the DN and VN cohort, respectively. UACR (median; 95%CI) was higher (*p<0.005)* in DN [1176 (833-2393)] vs. VN [191 (39-579) mg/g] ppts. There were no differences between DN and VN ppts in the proportion of females (45 vs.40%) and African Americans (32 vs.35%), or in BMI (32±7 vs. 30±6 Kg/m^2) and eGFR (55±22 vs. 47±18 mL/min/1.73 m^2). The presence and/or severity of global and segmental glomerulosclerosis, podocytopathy, interstitial fibrosis/tubular atrophy, and interstitial eosinophils were not different between groups, while arteriolar hyalinosis was more frequent in DN ppts (Table). Acute tubular injury was seen in the majority of DN and VN Bxs.

Conclusions: Protocol research KdBx are feasible and safe in CKD. Relative to KPMP CKD entry criteria, most ppts exhibited features of DN or VN and varying extent of chronic histopathologic changes. Unanticipated acute histopathologic changes including acute tubular injury were also commonly observed. Work is underway to further examine relationships between clinical features, histopathologic and -omics findings in KPMP ppts.

Funding: NIDDK Support

Histopathologic Features	DN (n=65) %	VN (n=48) %	*p-value*

30 Years of Kidney Biopsy Data in Western Mexico

Maria de la Luz Alcantar Vallin, Marisol Lopez, Jorge L. Padilla Armas, Susana M. Sainz Del Real, Jonathan Chavez, Estefania Villalvazo Maciel, Andres Aranda, Martha K. Franco Garcia, Carlos E. Orozco, Fernando Cruz Aragon, Guillermo Navarro Blackaller, Ramon Medina. *Hospital Civil de Guadalajara Unidad Hospitalaria Fray Antonio Alcalde, Guadalajara, Mexico.*

Background: A kidney biopsy provides the best opportunity to establish the etiology of the Chronic Kidney Disease (CKD), thereby improving management and predicting prognosis.

Methods: A retrospective study was conducted that included adult patients who underwent renal biopsy between 1990 and 2019, performed by nephrologists in 4 centers in western Mexico and analyzed by 2 nephropathologists.

Results: In the 30 years of study, 1933 kidney biopsies were studied, FSGS was the most frequent finding in 28%, followed by Lupus Nephritis. Table 1. We found predominance of lupus nephritis in women and IgAN in men.

Conclusions: In Western Mexico, FSGS is the most frequent histological findings. In the last two decades, we observed a increase in lupus nephritis, pauci-immune glomerulonephritis and tubulopathies, which could be related to changes in causal factors. In the last decade we also observed a greater number of kidney graft biopsies, compatible with the increase in the number of kidney transplants performed. We consider that the proportion of the chronic kidney disease burden constituted by glomerulonephritis would be illuminated by dissecting it through a comprehensive epidemiological approach.

Quantification of Urine Podocytes (Podo) and Their Globotriaosylceramide (GL3) Content Using Imaging Flow Cytometry

Alireza Ayoubi, M. Brendan Shannon, Behzad Najafian. *University of Washington, Seattle, WA.*

Background: Fabry disease (FD) is a lysosomal storage disease caused by a deficiency of α-galactosidase A (α-Gal-A) leading to intracellular GL3 (main α-Gal-A substrate) leading to critical end-organ damage. Podo injury and loss play key roles in FD nephropathy pathogenesis. We aimed to develop a non-invasive assay for quantification of urine Podo and intracellular GL3 content.

Methods: A CRISPR/Cas9 GLA knock-out (KO) conditionally immortalized human Podo cell line and its wild type (WT) counterpart were used as laboratory controls. Urothelial and proximal tubular cell lines were used as negative controls. IFC protocols for Podo and GL3 quantification were validated. 37 ml random urine sample from a male patient with FD who had been on enzyme replacement therapy (ERT) for over 20 years was analyzed using IFC.

Results: IFC reliably separated Podo from urothelial and proximal tubular cells in our laboratory controls based on GLEPP1 expression. In addition, IFC reliably detected intracellular GL3 with a granular pattern based on CD77 staining intensity. The GLA-KO Podo showed 2.4 fold greater GL3 signal compared to the WT Podo. 41% of GL3 signal in GLA-KO Podo was colocalized with LAMP1, consistent with both intra- and extra-lysosomal GL3 accumulation. IFC of the urine sample from the FD patient showed 124 Podo (~3 Podo/ml urine) as a distinct population with variable intracellular GL3, likely reflecting an ERT effect (Figure).

Conclusions: IFC is a powerful tool for the quantification of rare cells in the urine, such as Podo. In FD patients, quantifying urine Podo and their GL3 content may serve as potentially useful non-invasive biomarkers of kidney involvement and evaluation of treatment effect.

Deep Phenotyping of Urinary Cells with Cytometry by Time of Flight Reveals CD8+CD38+ T Cells as a Biomarker to Detect T Cell-Mediated Rejection

Nina Goerlich,[1,2] Diana Metzke,[2] Emil Grothgar,[2] Leonie F. Wagner,[2] Mira Choi,[2] Lennard Ostendorf,[2] Pouneh Mirkheshti,[2] Jan Klocke,[2] Fabian Halleck,[2] Klemens Budde,[2] Paolo Cravedi,[1] Miguel Fribourg,[1] Kerstin U. Amann,[3] Sabine Baumgart,[4] Philipp Enghard.[2] Translational Transplant Research Center. *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Charite Universitatsmedizin Berlin, Berlin, Germany; [3]Universitatsklinikum Erlangen, Erlangen, Germany; [4]Universitatsklinikum Jena, Jena, Germany.*

Background: Non-invasive monitoring and early detection of rejection are of high priority in kidney transplantation. Previously, we established urine flow cytometry (FC) as tool for non-invasive rejection detection. We hypothesized that an even deeper phenotyping of urinary cells improves the diagnostic yield of urinary T cells. Therefore, we established Cytometry by time of flight (CyTOF) analysis of urine cells to derive an improved biomarker for the detection of rejection in kidney transplant recipients (KTR). Our findings were subsequently validated in a FC-based validation cohort.

Methods: A total of 140 urine samples from KTR were analyzed from patients undergoing indication transplant biopsy. We developed a method for preserving urinary cells, enabling analysis using FC and CyTOF. Our antibody panel comprised 41 targets on kidney infiltrating immune cells and graft parenchymal cells. During data analysis,

cells were clustered according to differential protein expression patterns and cluster identities were manually curated. Proportional patterns of different cell types per sample were correlated with pathological diagnoses indicated by reports of biopsies. CD8+CD38+HLA-DR+ T cells were identified as a potential biomarker for T cell-mediated rejection (TCMR) with CyTOF, which was confirmed in a validation cohort using FC.

Results: By utilizing CyTOF combined with a clustering approach, we identified CD8+CD38+HLA-DR+ T cells as a potential biomarker for TCMR. We translated our finding to FC and validated urinary CD8+CD38+, CD8+HLA-DR+, and CD8+CD38+HLA-DR+ T cells as a biomarker for TCMR in a validation cohort of 83 KTR. CD8+CD38+ T cells showed the best performance in identifying TCMR, showing an even higher AUC in this validation cohort (AUC 0.898) than our prior published urinary biomarkers to detect TCMR.

Conclusions: Urinary cell signature analysis by CyTOF is feasible and enables identifying potential new biomarkers in kidney transplantation. KTR with TCMR showed increased urinary CD8+ CD38+ T cells, which could be validated in a separate cohort by FC. We plan to test the capability of urinary CD8+CD38+ T cells to detect TCMR in a prospective trial.

Investigating Hepatocyte Nuclear Factor 4 Alpha as a Central Regulator of Kidney Graft Repair

Slaghaniya Neupane,[1] Stefan Petrovic,[2] Aninda D. Saha,[5] Maya A. Allen,[1] Nadia Sachewsky,[2] Rohan John,[2] Markus Selzner,[2] Lisa Robinson,[4] Sergi Clotet Freixas,[3] Ana Konvalinka.[1,2] *[1]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; [2]University Health Network, Toronto, ON, Canada; [3]McMaster University, Hamilton, ON, Canada; [4]Sick Kids Foundation, Toronto, ON, Canada; [5]Stanford Medicine, Stanford, CA.*

Background: Kidney transplantation is the optimal treatment for end-stage kidney disease. However, ischemia-reperfusion injury (IRI) harms all transplanted kidneys, limiting their short- and long-term survival. Previously, we determined that superior kidney function/structure after IRI is associated with preserved expression of mitochondrial proteins during normothermic *ex vivo* kidney perfusion (NEVKP). We identified a potential transcriptional regulator of these mitochondrial proteins, hepatocyte nuclear factor 4a (HNF4A), which may present a novel target for kidney repair. Our goal is to determine whether a novel HNF4A agonist, N-trans caffeoyltyramine (NCT), protects kidneys from IRI. We will evaluate the effectiveness of NCT treatment *in vitro* studying male and female primary proximal tubular cells (PTECs), and *in vivo* studying male and female mice.

Methods: First, we inhibited HNF4A in primary male and female PTECs, using a pharmacologic or genetic approach. We then assessed gene expression, cell death and mitochondrial function. Next, we treated PTECs with NCT/vehicle and examined cell death and expression of HNF4A target genes. Lastly, male and female mice were subjected to bilateral IRI, and kidney function and structure were assessed on post-operative day 2 and 14.

Results: HNF4A inhibition *in vitro* increased PTEC death and decreased mitochondrial function, while NCT increased the expression of *HNF4A* and mitochondrial genes, suggesting that NCT may be protective. We developed a sex-specific model of bilateral IRI and demonstrated that warm ischemia (27-minutes in males, 40-minutes in females) impairs kidney function on post-operative day 2, indicated by elevated serum creatinine and tubular injury. Mice also developed tubulointerstitial fibrosis on post-operative day 14.

Conclusions: Based on the preliminary results, HNF4A is important for the metabolic function and viability of PTECs. We will next administer NCT to mice prior to IRI and examine whether HNF4A agonist preserves mitochondria and improves kidney function and structure.

FR-PO993

MIF-CD74 Pathway and Its Effect on Effector T Cell Exhaustion in Alloimmunity

Nour K. Younis,[1] Nadim Al Rahy,[1] Zhabiz Solhjou,[1] Abdullah B. El Kurdi,[2] Hengcheng Zhang,[1] Soltan Al Chaar,[1] Houda Djebli,[1] Andrew P. Badaoui,[1] John Y. Choi,[1] Marta Piecychna,[3] Edward H. Doherty,[3] Richard Bucala,[3] Jamil R. Azzi.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]American University of Beirut, Beirut, Lebanon; [3]Yale University, New Haven, CT.*

Background: Our recent clinical study has shown a significant upregulation of CD74, the cognate receptor for the cytokine MIF, in the urinary exosomal mRNAs of kidney transplant recipients during rejection, highlighting this pathway's role in alloimmunity.

Methods: WT, CD74-/-, and RAG-/- B6 ($H2^b$) mice were transplanted with fully mismatched BALB/c ($H2^d$) hearts. Single-cell RNA sequencing and immunophenotyping were conducted on allografts, draining lymph nodes(dLNs), and spleens. Additionally, various studies were performed to evaluate the effect of MIF-CD74 on T cells

Results: Fully mismatched heart transplants survived indefinitely in CD74-/- hosts. Despite that, CD74-/- recipients had significantly higher % of CD8 and CD8 effector T cells in their dLNs and spleens. Also, CD74-/- T cells exhibited a more exhausted phenotype, with higher expression of LAG3 and PD1, lower CD127, and less release of Granzyme B compared to WT cells. Moreover, flow-sorted CD74-/- CD8 effector T cells exhibited lower memory response to donor antigens in vitro. CD74-/- CD4 effector T cells displayed a similar exhaustion phenotype as CD8 effector T cells. Additionally, compared to WT cells, both CD74-/- CD4 and CD8 T cells were less capable of proliferating in vitro when stimulated non-specifically, and less capable of inducing rejection in a RAG-/- heart transplant model. Our single-cell data on allograft-infiltrating T cells supported these findings. WT CD4 and CD8 effector T cells were less clonally diverse than CD74-/- cells, indicating that WT effector T cells are more antigen-specific and capable of allograft rejection. Moreover, exhaustion gene signature and pathways were significantly upregulated in CD74-/- effector T cells, while activation gene signature and pathways such as allograft rejection, IFN-g signaling, and complement were downregulated. This impairment of effector T cells in CD74-/- recipients was accompanied by superior regulatory T cell function, as we previously described.

Conclusions: CD74 deletion impairs effector T cell proliferation and activation while enhancing regulatory T cell function. The MIF-CD74 pathway exerts a differential effect on effector T cells vs regulatory T cells, potentially explaining its role in allograft rejection.

FR-PO994

Structural Identification of Immunodominant Human Leukocyte Antigen (HLA) Epitopes Targeted by HLA-Specific Antibodies in Kidney Allograft Recipients

Aaron Lucander, John Killian, Rodney G. King, Todd J. Green, Frances E. Lund. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: Donor-specific antibody (DSA) targeting Human Leukocyte Antigen (HLA) mismatches causes kidney allograft damage and loss. Currently, there are no reliable methods to predict which HLA epitopes will be recognized by alloreactive B cells and antibodies (Abs), thus limiting optimal matching of kidney transplant (KT) donors and recipients. The purpose of this study was to define structural determinants of HLA immunogenicity by identifying HLA epitopes recognized by DSA.

Methods: B cells reactive with donor HLA-A*01:01 (A1) were isolated from blood and allograft of a KT recipient, then B cell receptors (BCR) from these allospecific B cells were cloned and expressed as monoclonal antibodies (mAbs, n=50). Coupling BCR-repertoire sequencing of B cells from peripheral blood and allograft with serum immunoglobulin proteomics, clonally-expanded lineages of A1-specific B cells were identified and linked to DSA in circulation. Three mAbs (E07, L02, M07), each representing distinct immunodominant clonal lineages, were complexed with A1 and the HLA epitopes recognized by these mAbs were determined by either X-Ray Crystallography or Cryo-Electron Microscopy. Epitopic overlap with other A1-reactive mAbs (n=47) and polyclonal DSA in the serum of other A1-mismatched KT recipients (n=11) was assessed by cross inhibition studies and A1 single amino acid point mutants.

Results: The E07, L02, and M07 epitopes are distinct and collectively encompass most solvent-accessible mismatched residues (15/20, 75.0%) on the membrane-distal face of A1. All other A1-specific mAbs (n=47) recognize HLA epitopes that overlap with those of E07, L02, or M07 and mAbs with shared epitopes exhibit common binding to specific mismatched HLA residues. Other KT recipients (n=11) who received a mismatched A1 allograft produced Abs that recognized the same immunodominant A1 epitopes and targeted the same mismatched residues irrespective of their self HLA alleles.

Conclusions: In our cohort of KT recipients, DSA preferentially targeted mismatched residues exposed on the membrane-distal face of HLA, recognizing a limited number of immunodominant epitopes. These results indicate that mismatched residues in HLA are differentially recognized by the immune system suggesting that some HLA residue mismatches may be more likely to elicit DSA responses than others.

Urinary Single-Cell RNA Sequencing of Kidney Allograft Recipients Detects Podocyte Epithelial-to-Mesenchymal Transition in Kidney Transplant Recipients

Thangamani Muthukumar,[1] Aziz Belkadi,[2] Carol Y. Li,[1] Gaurav Thareja,[2] Darshana M. Dadhania,[1] Manikkam Suthanthiran.[1] *[1]Weill Cornell Medicine, New York, NY; [2]Weill Cornell Medicine-Qatar, Doha, Qatar.*

Background: Podocytes undergo epithelial-to-mesenchymal transition (EMT) under states of cellular stress. We did urinary scRNA-Seq of kidney transplant recipients and detected the presence of podocyte EMT.

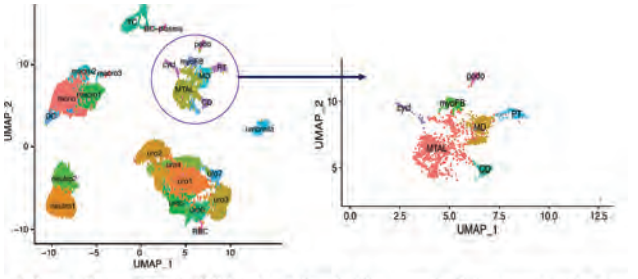
Methods: We obtained urine samples from 12 kidney transplant recipients (7 biopsy-matched urine samples [3 ABMR, 1 TCMR, and 3 no-rejection] and 5 stable patients without biopsy). We processed them fresh for scRNA-Seq on a 10x Chromium platform/

Illumina sequencer. We used the Seurat package for computational analysis. We defined cell types based on the expression of established lineage marker genes.

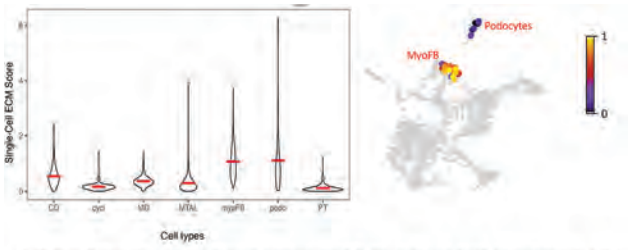
Results: We generated 19404 high-quality single-cell transcriptomes from the urine of 12 kidney transplant recipients (Fig.1). Extracellular matrix (ECM) includes collagens, glycoproteins, and proteoglycans. We applied the single-cell ECM expression score *(Kuppe et al. Nature 2021)* to various kidney parenchymal cells. The podocyte score was highest among the kidney parenchymal cells and was similar to the myofibroblast score (Fig.2 left). To confirm podocytes' EMT, we ordered cells pseudo-temporally using *scVelo* (uses RNA velocity graph to draw descendants/ancestors coming from specified starting cells). Our analyses revealed a potential transition from podocytes (starting cells), but not other cells, to myofibroblasts (terminal states) (Fig.2 right).

Conclusions: By scRNA-Seq of urinary cells, we detected EMT in the podocytes of kidney transplant recipients. The role of the podocyte EMT in kidney allografts has not been well studied. Further characterization of podocyte EMT will help decipher the mechanisms underlying kidney allograft fibrosis.

Funding: Other NIH Support - NIAID



Left panel: Major cell types in 19,404 single cells from the 12 urine samples. Kidney parenchymal cells are shown within the circle.
Right panel: Kidney parenchymal cells



Left pane: Podocytes express ECM genes similar to myoFB. The single-cell ECM expression score is the highest for myofibroblasts and podocytes.
Right panel: Velocity graph showing the pseudotime trajectory. Podocytes were chosen as the root of origin (pseudotime = 0). The orientation of the cell types is the same as shown in the right panel of Fig 1.

FR-PO996

Ex Vivo Allogeneic Expansion of Peripheral Blood Mononuclear Cells (PBMCs) from Stable Kidney Transplant Recipients Differentially Regulates Long Noncoding RNA Expression

Anil K. Chandraker,[1] Brittany L. Schreiber,[2] Sudipta Tripathi.[1] [1]*University of Massachusetts Chan Medical School, Worcester, MA;* [2]*Brigham and Women's Hospital, Boston, MA.*

Background: We have successfully expanded human Antigen Specific T Regulatory cell enriched Lines (ASTRLs) from stable kidney transplant recipients. Characterization of this preclinical heterogenous cell therapy product to gain greater insight and to interpret how this cellular heterogeneity can be leveraged particularly in its clinical therapeutic applications is pertinent. The purpose of this study is to understand the cellular heterogeneity of *ex vivo* expanded ASTRLs using cutting edge single cell RNA sequencing. This will provide information about unexplored/ pathways that play a role in cell-cell interaction in heterogenous cell therapy products.

Methods: Single cell RNA sequencing was performed on frozen samples of pre-expanded PBMCs and a post-expanded ASTRL from 5 stable kidney transplant recipients using the 10X Genomics platform. The gene expression counts and TCR/BCR clonotypes were generated using Cellranger pipelines with the human genome reference (GRCh38). The data were imported and analyzed using Seurat and djvdj in R.

Results: Single cell gene expression profile show ASTRLs are enriched for T and NK cell populations and contain very few B cells and monocytes. UMAP clustering distinguishes the CD4+ T cell compartment in all the five ASTRLs as a distinct T cell subset as expected and very similar to the corresponding PBMC samples. Our data shows a number of long noncoding RNA are differentially expressed both in the CD4 and CD8 compartment of ASTRLs in comparison to the PBMC samples. GATA3-AS1, the lncRNA contiguous to GATA3 and essential for the transcription of IL-5 and IL-13, is upregulated 3-fold in the CD4 compartment of ASTRLs, corroborating our previous observation that ASTRLs exhibit a Th2 type Treg phenotype and produce a significantly high levels of IL-13. LINC00402 known as a regulator of allogeneic response in transplantation is 6-fold downregulated in ASTRLs validating the regulatory nature of ASTRLs, that are donor antigen specific. We also observe multiple lncRNA associated with cholesterol biosynthesis and fatty acid oxidation pathways upregulated >2-fold in ASTRLs in comparison to PBMC.

Conclusions: Examination of the differential expression of lncRNAs in ASTRL shows a bias towards fatty acid metabolism and aTh2 like Treg phenotype.

Kidney Transplantation in Mice Leads to Allograft-Restricted Activation and Maintenance of Allospecific Memory T Cells

Bo Wang,[1,2] Laurence Kupferschmid,[1] Frederic Arnold,[1] Xudong Liu,[1] Sagar -,[3] Christoph Schell,[4] Yakup Tanriver.[1,5] [1]*Institute of Microbiology and Hygience, Faculty of Medicine, University of Freiburg, Freiburg, Germany;* [2]*Factuly of Biology, University of Freiburg, Freiburg, Germany;* [3]*Department of Internal Medicine II, Medical Center, Faculty of Medicine, University of Freiburg, Freiburg, Germany;* [4]*Institute of Surgical Pathology, Medical Center, Faculty of Medicine, University of Freiburg, Freiburg, Germany;* [5]*Department of Internal Medicine IV, Medical Center, Faculty of Medicine, University of Freiburg, Freiburg, Germany.*

Background: Pre-existing allospecific memory T cells are rapidly activated in response to allografts, expressing functions that mediate graft injury and failure, directly impacting patient survival. However, the early dynamics of their activation, graft infiltration, and effector functions remain largely unclear. Therefore, it is crucial to gain an in-depth understanding of their activation, migration, and effector functions during transplantation, including their ability to recruit other immune cells to drive allograft rejection.

Methods: To address those open questions, we infected recipient mice (wt) with OVA expressing Listeria monocytogenes (*LM-OVA*) to generate allospecific memory against OVA. Four weeks later, we transplanted kidneys from Act-mOVA transgenic mice, which express ovalbumin ubiquitously as an alloantigen. Then, we use fluorochrome-conjugated SIINFEKL: H2-Kb tetramer (SIIN-tet) to follow the dynamics of the endogenous CD8 T cells response against OVA after kidney transplantation. Finally, single cell RNA sequencing was used to obtain a comprehensive understanding of the immune cell landscape within allogenic kidney grafts on day 14.

Results: We show that in contrast to pathogen-activated memory T cells allospecific memory T cells are not activated in secondary lymphoid organs but rather directly in the allograft, where they are a maintained by forming a stem-like population, proliferate and differentiate in response to their cognate antigen. This interaction leads to the recruitment and activation of various immune subsets, ultimately resulting in allograft rejection. In addition, the scRNA-seq data expose a complex composition of myeloid and lymphoid immune cell subsets and pathogenic transcriptional states in the kidney allograft, which is orchestrated by the T cell memory response.

Conclusions: Allospecific memory T cells have a unique response pattern, which will help to devise new strategies to prevent and treat allograft rejection that is mediated by memory T cells

FR-PO998

The Yin and Yang of Acute Rejection in Kidney Allografts

Zahraa Khan,[1,2] Carol Y. Li,[1] Sheavonnie Wright,[1] Alex Devito,[1] Mia Montecillo,[1] Darshana M. Dadhania,[1] Thangamani Muthukumar,[1] Manikkam Suthanthiran.[1] [1]*Weill Cornell Medicine, New York, NY;* [2]*NewYork-Presbyterian Weill Cornell Medical Center, New York, NY.*

Background: Acute rejection undermines the life - prolonging benefit of kidney transplantation. We and others have demonstrated that acute rejection is exemplified by proinflammatory effectors such as cytopathic granzyme B, perforin and pro - inflammatory cytokines such as interferon gamma and interleukin 2. Because preclinical models have elucidated the essential role of negative regulators of immunity such as CTLA4 and PD1 in limiting inflammation, we tested the hypothesis that acute rejection is also associated with the over expression of the prototypic negative regulator CTLA4. We tested our novel postulate by urinary cell mRNA profiling, an accurate reflector of immune events in a rejecting kidney allograft.

Methods: We isolated RNA from biopsy matched urine samples, reverse transcribed to cDNA and measured absolute mRNA levels of CTLA4 using preamplification enhanced real time quantitative PCR assays in 58 biopsy - matched urine samples from 52 recipients with acute T cell mediated rejection and 176 biopsy matched urine samples from 158 recipients with biopsies without rejection features (NR).

Results: The median (IQR) absolute copy number of CTLA4 mRNA in TCMR - biopsy matched 58 urine samples was 720 copies (197 - 2906) per microgram of total RNA compared to 167 copies (12.5 – 448) per microgram of total RNA in NR - biopsy matched 176 urine samples (P - value < 0.0001). Figure 1, the Box and Whisker plots, in addition to showing the distribution of CTLA4 mRNA copy numbers stratified by biopsy diagnosis, show significant overexpression of 18S normalized, log10 transformed CTLA4 mRNA in urine samples matched to TCMR biopsies compared to urine samples matched to NR biopsies (P-value <0.0001). Figure 2, Receiver operating Characteristic Curve analysis showed urinary cell level of CTLA4 discriminates TCMR biopsy matched urine from NR biopsy – matched urine samples and the area under the curve (AUROC) was 0.71 (95% Confidence interval 0.63 – 0.8, P-value < 0.0001) to distinguish TCMR from NR.

Conclusions: Our finding demonstrating over expression of CTLA4 mRNA during an episode of acute T cell mediated rejection has identified a counter regulatory mechanism to limit the proinflammatory forces associated with acute rejection. The finding also advances a mechanistic rationale for the use of CTLA4-Ig for the treatment of acute TCMR.

FR-PO999

Molecular Signatures of Reperfusion in Ischemic Donor Kidneys: Distinguishing Rejection and Nonrejection Risk Genotypes through Single Nuclear RNA Sequencing

Cem Kuscu,[1] Murat Dogan,[1] Canan Kuscu,[1] Henry B. Randall,[2] Krista L. Lentine,[2] John C. Edwards,[2] Ajay Jain,[2] Mustafa Nazzal,[2] Yasar Caliskan.[2]
[1]The University of Tennessee Health Science Center, Memphis, TN; [2]Saint Louis University, St Louis, MO.

Background: *LIMS1* rs893403 homozygous GG genotype in donors is associated with decreased risk of T-cell mediated rejection after kidney transplantation. However, the effects of ischemia and reperfusion injury (IRI) on donor kidney expression profile at single cell level have not been studied in a human kidney model. Using non-utilized human kidneys, we investigated the effects of IRI on the nuclear expression of LIMS1, GCC2, and associated genes in donor kidneys with different genotypes and compared results between ex-vivo normothermic machine perfusion (NMP) model and cold static storage (CS).

Methods: Deceased donor kidneys (n=5) on CS underwent 6-hr NMP (n=5) following CS. Cells at baseline on CS and after 6 hrs of NMP were harvested. Single nucleus transcriptomics of the donor kidneys after 6 hrs of NMP was directly compared with the profile on baseline CS. Specimens sharing the same genotype were subsequently processed together using the droplet-based 10X Genomics approach.

Results: Three kidneys possessed the AG allele (donor rejection risk genotype), while two exhibited the GG allele (donor non-rejection risk genotype) for the *LIMS1* gene (rs893403). The study yielded a collection of over 60,000 cells accompanied by 2 billion reads. 13 unique kidney cell types were identified using Seurat (v7.0). SnRNA-seq analyses showed induction of LIMS1 and GCC2 in tubule cells particularly in ischemic donor kidneys with non-rejection risk genotype (GG) after NMP. LIMS1 and GCC2 expression increase is significant in proximal and distal tubule cells after 6 hrs of NMP in non-rejection risk kidneys (GG) (Fig1a, 1b). Transcriptomic response to NMP is different in kidneys with GG and AG genotypes (Fig 1c).

Conclusions: NMP significantly increased the LIMS1 and GCC2 expression on proximal and distal tubule cells with *LIMS1* rs893403 GG variant but not on the kidney with AG variant. Donor *LIMS1* genotype is important in the transcriptomic response to IRI.

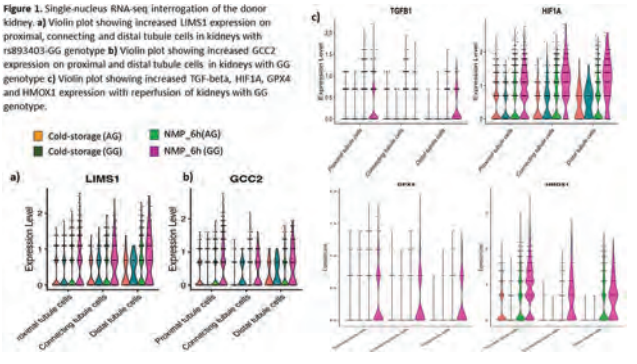

Figure 1. Single-nucleus RNA-seq interrogation of the donor kidney. **a)** Violin plot showing increased LIMS1 expression on proximal, connecting and distal tubule cells in kidneys with rs893403-GG genotype **b)** Violin plot showing increased GCC2 expression on proximal and distal tubule cells in kidneys with GG genotype **c)** Violin plot showing increased TGF-betA, HIF1A, GPX4 and HMOX1 expression with reperfusion of kidneys with GG genotype.

FR-PO1000

Urinary Extracellular Vesicles: Early Indicators of Kidney Allograft Injury after Transplantation

Maja Vodusek,[1,2] Maja Stalekar,[3] Katja Goricar,[2] Marija Holcar,[2] Polona Kogovšek,[3] Metka Lenassi,[2] Miha Arnol.[1] *[1]Department of Nephrology, University Medical Centre Ljubljana, Ljubljana, Slovenia; [2]Institute of Biochemistry and Molecular Genetics, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia; [3]Department of Biotechnology and Systems Biology, National Institute of Biology, Ljubljana, Slovenia.*

Background: Allograft biopsy is the standard method for assessing the status of transplanted kidneys. Our aim was to determine whether urinary extracellular vesicles (uEVs) and their characteristics can predict kidney injury (KI) one year after transplantation (Tx).

Methods: In a prospective longitudinal study, 49 well-defined adult kidney transplant patients were followed up 1, 3, 6 and 12 months post-Tx. Blood and second morning urine samples were collected at each visit. At the time of surveillance biopsy (Bx) (382 (330-404) days post-Tx), patients were categorized into two groups based on histologic and molecular analysis (MMDx) of allograft tissue: normal histology (NH, n=33, 67%) or KI (rejection and non-rejection; n=16, 33%). uEVs were isolated by size exclusion chromatography and their characteristics were analyzed by nanoparticle tracking analysis, genotyping and digital droplet PCR.

Results: After 6 months, the KI group had higher uEV mode size (P=0.0229) and increased uEV DNA copy number normalized to urine creatinine (P=0.0055; Figure). Using a multivariable model at 6 months, we were able to predict the diagnosis of KI at the time of surveillance biopsy with an area under the curve of 0.88 (95% CI: 0.77 to 0.99), a sensitivity of 0.69 and a specificity of 0.89 (P=0.0001). The negative predictive value was 86% and the positive predictive value was 75%.

Conclusions: Our results emphasize the potential of uEV characteristics for monitoring and early diagnosis of kidney allograft injury, which could reduce the need for invasive biopsy procedures.

Gut Microbiome Alterations Precede Graft Rejection in Kidney Transplantation Patients

Johannes Holle,[1,2] Rosa P. Reitmeir,[2] Felix Behrens,[1] Daniela Schindler,[3] Markus Gerhard,[3] Jun Oh,[4] Ulrike Löber,[2] Nicola Wilck,[1] Hendrik Bartolomaeus.[1] *[1]Charite Universitatsmedizin Berlin, Berlin, Germany; [2]Max Delbruck Centrum fur Molekulare Medizin Experimental and Clinical Research Center, Berlin, Germany; [3]Deutsches Zentrum fur Infektionsforschung eV Standort Munchen, Munchen, Germany; [4]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany*.

Background: Kidney transplantation (KT) is the optimal treatment for end-stage kidney disease, with graft survival critically affected by the recipient's immune response. The role of the gut microbiome in modulating this immune response remains underexplored. Our study investigates how microbiome alterations might associate with allograft rejection.

Methods: We analyzed existing biomaterials of a multicenter prospective study involving 217 KT recipients and 28 kidney donors from the German Center for Infection Research. Changes in the gut microbiome were analyzed using 16S rRNA gene amplicon sequencing and functional predictions (PICRUSt2) and quantitative PCRs for the production potential of propionate and butyrate. Propensity score matching was utilized to compare patients who experienced graft rejection with those who did not.

Results: The gut microbiome showed gradual recovery post-KT, marked by an increase of Shannon diversity and SCFA-producing bacterial taxa. However, prior to graft rejection, significant alterations were noted in microbiome composition, characterized by a decrease in microbial diversity and SCFA-producing taxa. Post-rejection analysis revealed normalization of these microbiome features. Functional analysis highlighted a decreased potential for SCFA production in patients prior to rejection. Comparison to published associated microbiome signatures from chronic kidney disease (CKD) patients demonstrated a partial overlap of the microbiome alterations preceding graft rejection with the alterations typically found in CKD.

Conclusions: Our findings suggest that alterations in the gut microbiome composition and function may precede and influence KT rejection, suggesting potential for use as biomarker and early therapeutic microbiome-targeting interventions to improve transplant outcomes.

FR-PO1002

Podocyte Injury in Kidney Allograft with Chronic Antibody-Mediated Rejection: Late Occurrence and Association with Glomerular Basement Membrane Thickening

Dema Yaseen Alsabbagh, Pongpratch Puapatanakul, Jeffrey H. Miner, Sanjay Jain, Tarek Alhamad, Hani Suleiman. *Washington University in St Louis, St Louis, MO*.

Background: The histologic hallmarks of chronic antibody-mediated rejection (CAMR) are evidence of endothelial injury and glomerular basement membrane (GBM) thickening and double contour without immune complex depositions. Our previous data show that endothelial injury is the primary injury that causes initial GBM thickening. However, proteinuria is usually present suggesting podocytes are also injured, but this has not been extensively studied. Recently, we described sarcomere-like structures (SLSs), a feature of injured podocytes and cytoskeletons rearrangement that is found in various glomerular diseases. We aim to assess the prevalence of SLSs in various stages of CAMR.

Methods: We utilized super-resolution imaging of kidney tissues to investigate the association between GBM changes in transplant glomerulopathy and podocyte injury at various stages of CAMR. Paraffin sections from 9 allograft biopsies with CAMR and 7 nephrectomy controls were analyzed. Immunofluorescence staining for synaptopodin and myosin IIA was performed to visualize SLSs, Nephrin and laminin α5, Col4a1a1a2 and Col4a3a4a5 were used to label the slit diaphragms and GBM.

Results: Compared with the control samples, laminin α5 staining shows a significant GBM thickening in CAMR biopsies. In the thickened areas of the GBM, increase in Col4a1a1a2 was observed, especially, on the endothelial side of the GBM with no changes in the Col4a3a4a5. SLSs, defined by presence of alternating synaptopodin and myosin IIA clusters in podocyte foot processes, were observed predominantly in CAMR groups. The extent of SLSs in advanced stages of CAMR (Banff cg2-3) was significantly higher when compared to earlier stages (Banff cg1a-b) and was present in areas with foot process effacement as suggested by low, blunt nephrin density. The chance of SLSs occurrences was significantly higher as GBM thickness increased.

Conclusions: The positive correlation between podocyte injury and the degree of GBM thickening in CAMR where the injury starts primarily from antibody-mediated endothelial damage suggests that alterations in the GBM convey injurious signals to podocytes. This finding provides new insight into the progression of CAMR and, if incorporated into the disease classification, may enhance prognostic evaluation.

FR-PO1003

Epithelial Injury Patterns Induced by Acute T Cell-Mediated Rejection in Kidney Transplants

Lorenz Jahn,[1] Anna M. Pfefferkorn,[2] Janna Leiz,[1] Vera A. Kulow,[3] Svjetlana Lovric,[1] Jessica Schmitz,[6] Jan H. Braesen,[6] Irina Scheffner,[1] Michael Fähling,[3] Felix Aigner,[4] Kai M. Schmidt-Ott,[1] Wilfried Gwinner,[1] Philip F. Halloran,[5,7] Muhammad Imtiaz Ashraf,[2] Christian Hinze.[1] *[1]Department of Nephrology and Hypertension, Hannover Medical School, Hannover, Germany; [2]Department of Surgery, Experimental Surgery, Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin and Berlin Institute of Health, Berlin, Germany; [3]Institute for Translational Physiology, Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Berlin, Germany; [4]Department of Surgery, Krankenhaus der Barmherzigen Brüder, Graz, Austria; [5]University of Alberta Alberta Transplant Applied Genomics Centre, Edmonton, AB, Canada; [6]Institute of Pathology, Nephropathology Unit, Hannover Medical School, Hannover, Germany; [7]Department of Medicine, Division of Nephrology and Transplant Immunology, University of Alberta, Edmonton, AB, Canada*.

Background: Acute T-cell mediated rejection (TCMR) remains a major challenge after kidney transplantation, posing risks for the long-term outcome of the transplant. Previous research highlighted the importance of TCMR-induced renal epithelial injury for transplant outcome. Yet, the detailed cellular origin of these injury responses and the associated gene expression profiles remain poorly understood.

Methods: To induce acute rejection, we used two different mouse models (C57BL/6 and BALB/c) for allogeneic kidney transplantation and syngeneic controls. We analyzed the molecular changes in renal gene expression during TCMR by using single nucleus RNA sequencing (snRNA-seq) and spatial transcriptomics on the kidneys 7 days post-transplant. Differentially expressed genes between allogeneic and syngeneic kidneys were analyzed and a published gene set predictive of allograft outcomes was investigated per cell type. All results were compared to our snRNA-seq data from three human TCMR kidney biopsies and three stable allografts.

Results: Mouse kidneys from allogeneic transplantation showed all histological hallmarks of TCMR. SnRNA-seq revealed a strong gene expression response, especially in C57BL/6 kidneys transplanted into BALB/c mice, most pronounced in kidney epithelial cells, particularly in the proximal tubules (PT) and thick ascending limbs (TAL), inducing distinct injury-associated cell states. Spatial transcriptomics identified a heterogeneous spatial distribution of these cell states between cortex and medulla. Published genes indicative of allograft outcome were mostly expressed in injured PT and TAL but showed heterogeneous differential expression in the different injured PT and TAL cell states. Cross-species analysis revealed a substantial overlap of epithelial cell states between mouse and human TCMR.

Conclusions: Our study offers a detailed exploration of cell type-specific gene expression changes during TCMR in humans and mice. The analysis of allograft outcome-associated genes revealed their origin from various injured epithelial cell states. This insight may help identify injured cell states most responsible for reduced graft function, potentially enabling targeted therapeutic interventions.

FR-PO1004

A Mouse Model for "Definitive" Polyomavirus Nephropathy with Lytic Viral Replication

Volker Nickeleit, Dalton R. Butcher, Bawana D. Thompson, Harsharan K. Singh. *The University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC*.

Background: A mouse model for polyomavirus nephropathy (PyVN) with lytic viral replication has not been described. Studies of PyVN based on observations in kidney transplants have limitations due to concurrent alloimmune injury. Aim: Characterization of a model of PyVN in native mouse kidneys.

Methods: Black Swiss mice i.p. injected with murine strain A2 PyV (MUPyV; $1x10^7$ PFU) reliably developed PyVN. Animals (n>100) were sacrificed at different intervals (end point 54 weeks). Testing performed: light microscopy (LM), electron microscopy (EM), immunohistochemistry (IHC), plasma anti-MUPyV antibody titers, PCR (kidney, plasma, urine), genetics on MUPyV stability.

Results: PyVN with lytic replication occurred in all animals 2 weeks post infection. It peaked at 2-5 weeks (Fig: IHC for PyV-Capsid Protein-1; viral replication in 6.1% (median) of cortical tubules), subsequently decreased (weeks 6-30) and ultimately cleared by LM/IHC in all animals (weeks 47-54). At the end of follow-up subclinical infections (positivity in kidney/plasma/urine only by PCR; no changes by LM/IHC) were only seen in 15% of mice. Viral progeny were detected in the cytoplasm and nuclei of tubular and some mesenchymal cells by EM. Viral injury dominated in distal tubules and cortical collecting ducts. It was associated with inflammation rich in CD3+and CD4+ cells (75%) with fewer admixed myofibroblasts and F4/80+ histiocytes (20%-40%). Fibrosis did not occurr. During PyVN, MUPyV remained genetically stable. In week 3-5 post infection animals mounted a transient IgM reponse that disappeared during week 6-30 when IgG

titers peaked. At the end of follow-up IgM was no longer detected while IgG titers were low positive in 92% of animals.

Conclusions: Our PyVN mouse model in native kidneys is robust. Morphologic, molecular, genetic, and immunologic changes mimick human disease whereas scarring is absent. The model is well suited for targeted studies/ interventional drug trials.

FR-PO1005

Characterization of the BKPyV-Specific Memory B Cell Response in KTx Recipients and Blood Donors

Patrick Affeldt, Christoph Kreer, Roman-Ulrich Mueller, Gertrud Steger, Florian Klein. *Universitatsklinikum Koln, Koln, Germany.*

Background: While BK-Polyomavirus (BKPyV) infection is asymptomatic in immunocompetent individuals, it causes Polyomavirus-associated Nephropathy (PyVAN) in about 10% of all kidney transplant (KTx) recipients. PyVAN is one of the leading causes of premature graft function loss. Importantly, there is currently no virus-specific therapy available. Since the presence of BKPyV-directed antibodies has been associated with control of BKPyV infections, we set out to analyze the memory B-cell response against BKPyV on a single-cell level and isolate BKPyV neutralizing monoclonal antibodies (mAb).

Methods: Two cohorts of i.) 200 kidney transplant recipients (KTx) and ii.) 100 blood donors (BD) were screened for plasma neutralization against BKPyV genotypes Ib2 and IV using a pseudovirus neutralization assay. Based on plasma neutralizing activity, we selected the top 5 KTx and 5 BD neutralizers and isolated BKPyV-VP1-specific IgG+ memory B cells from peripheral blood mononuclear cells (PBMC) via Fluorescence activated cell sorting (FACS). Naturally paired heavy and light chain sequences were generated by total RNA reverse transcription and a BCR-specific nested PCR following sequence analysis. Clonality was inferred from IgBLAST annotated sequences and at least one antibody from each identified BKPyV-reactive B cell clone was selected for recombinant antibody production. Monoclonal antibodies were eventually evaluated for VP1-binding and neutralization against BKPyV genotypes (I-IV).

Results: Higher neutralization titers and BKPyV cross neutralizing activity against genotypes I-IV was observed in sera from KTX patients compared to the BD group. 1089 BKPyV specific memory B-cells from the top 5 neutralizers from each group were isolated and 768 memory B-cell receptor sequences analyzed. As a first proof of principle, 16 mAbs (5 BD, 11KTx) were produced and screened for neutralizing activity against all genotypes. Of those, mAb COR32_1_C2(KTx) showed a potent cross neutralizing activity (max. IC_{50} <0.03 ug/ml) against all genotypes.

Conclusions: We established a pipeline to isolate BKPyV-Vp1-specific antibodies from human peripheral blood and found BKPyV-neutralizing antibodies in both the BD and the KTX group. Importantly, we identified COR32_1_C2 (KTx) as a promising candidate with highly potent neutralizing activity against all BKPyV genotypes.

FR-PO1006

Arteriolar Molecular Pathways in Children after Kidney Transplantation with Preceding Peritoneal Dialysis

Maria Bartosova,[1] Conghui Zhang,[1] Gesine Messerschmidt,[1] Iva Marinovic,[1] Rebecca Herzog,[2] Betti Schaefer,[1] Ariane Zaloszyc,[4] Jun Oh,[3] Klaus Kratochwill,[2] Claus Peter Schmitt.[1] International Pediatric Peritoneal Biobank. *[1]UniversitatsKlinikum Heidelberg, Heidelberg, Germany; [2]Medizinische Universitat Wien, Wien, Austria; [3]University Hospital Hamburg, Hamburg, Germany; [4]University Hospital Strasbourg, Strasbourg, France.*

Background: Patients on peritoneal dialysis (PD) suffer from accelerated vascular disease. Following kidney transplantation (KTx) vascular disease progresses, underlying molecular pathomechanisms are uncertain.

Methods: Omental arterioles microdissected from age-matched children (median 6,5y) with chronic kidney disease (CKD5), on PD with neutral pH, low-GDP-PD fluids, and from children 4-5 weeks after successful KTx and preceding PD (n=5-8/group) underwent multi-omics followed by gene set enrichment-, gene ontology and protein interaction analysis. Key pathways were validated in independent cohorts by quantitative immunohistochemistry (n=15/group) and *in vitro.*

Results: 5000 most variable arteriolar transcripts (p-value<0.05,|r| >0.5) were grouped into 23 modules, 8 significantly differed between CKD5, PD and KTx, one was PD-specific, seven were KTx-specific. PD-specific module was associated with muscle cell proliferation, detoxification, complement activation, with thrombospondin as hub gene. In independent cohorts, thrombospondin and terminal complement complex were higher in PD children vs. CKD5/KTx. KTx-specific modules related to fatty acid biosynthesis, negative regulation of RNA metabolism, cell cycle arrest, and apoptosis. Key drivers of fibrotic process in PD (TGF-ß/pSMAD2/3) persisted high after KTx, cell cycle arrest marker p16 and apoptosis marker cCasp3 were higher after KTx vs. PD/CKD5. Multi-omics demonstrated upregulation of lipid and fatty acid biosynthesis after KTx, with the hub gene fatty acid synthase (FASN). Intima and media FASN were three-fold higher after KTx vs. PD/CKD5, arteriolar triacylglycerols (TAG) two-fold higher in KTx vs. PD/CKD5. Arteriolar lipidomics revealed long chain TAG in all groups, short chain TAG were increased in KTx arterioles. *In vitro*, methylprednisolone and tacrolimus, but not mycophenolate increased FASN abundance and activity in human arterial endothelial and vascular smooth muscle cells.

Conclusions: Following KTx, PD-induced complement activation is reversed to CKD level, but profibrotic pathway activation persists and cell cycle arrest, apoptosis and fatty acid biosynthesis increase. Methylprednisolone and tacrolimus presumably activate hub gene FASN, and increase vascular short chain triacylglycerol content.

Plasma-Derived Extracellular Vesicles of Antibody-Mediated Allograft Rejection Kidney Transplant Patients Mediate Reprogramming of Human Podocytes: Role of SGLT2 Inhibitors

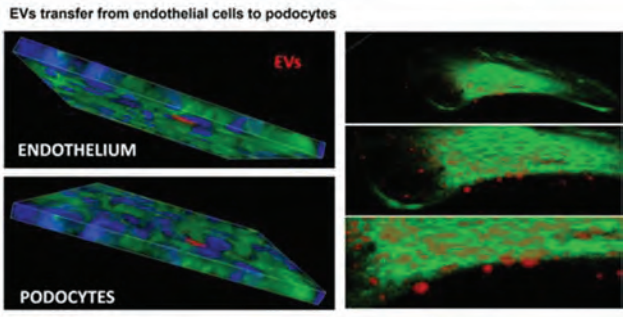
Giuseppe Castellano,[1,2] Silvia Armelloni,[1] Deborah Mattinzoli,[1] Min Li,[1] Masami Ikehata,[1] Valentina Bollati,[1,2] Matteo Abinti,[1] Manuel A. Podestà,[1] Carlo Alfieri.[1,2] *[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Universita degli Studi di Milano, Milano, Italy.*

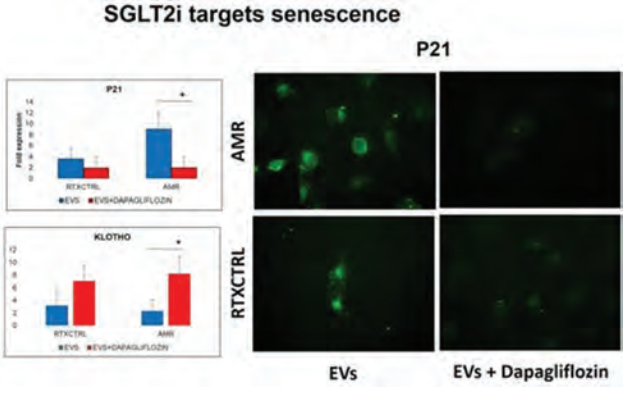
Background: Extracellular vesicles (EVs), cell-derived particles, contribute to kidney diseases. Their role in antibody-mediated allograft rejection (AMR) is unclear. We aim to test their impact on human immortalized podocytes (PODO) and evaluate Dapagliflozin (Dapa) role as a pharmacological approach.

Methods: The study involved 28 Rtx patients (14 with AMR, 14 stable CTRL). PODO were exposed to plasma-EVs for 24h, then 100nM Dapa for 24h. Ultracentrifugation at 110,000g was used, followed by Nanosight counting and flow cytometry per MISEV2018. PKH26-EVs were used to examine PODO incorporation via Z-stack microscopy. RNA and protein were extracted for analysis, and cells were fixed for immunostaining.

Results: PODO incorporated and shared EVs. AMR-EVs increased CD9, a cell activation marker (p=0.028), induced a senescence-associated secretory phenotype in PODO (MCP1 p=0.041, TNFalpha p=0,046), and raised cytoskeletal rearrangement. They also increased the expression of EMT proteins like VIM (p=0.026), senescence P21 (p=0.04), inflammation CD44 (p=0.034), and decreased Klotho (p=0.002) (fig.1). Dapa incubation reduced PODO activation, decreasing P21 expression (p=0.039) and increasing Klotho (p=0.047), thus abrogating inflammaging (fig.2).

Conclusions: Our findings demonstrate that plasma AMR-EVs induce PODO reprogramming processes, comprising senescence, cytoskeleton rearrangement, secretion of inflammatory cytokines, decrease of nephroprotective protein Klotho and senescence increase. Dapa can efficiently counteract this pathogenic process.





FR-PO1008

Delivery of Point-of-Care Adipose-Derived Regenerative Cell Population to Kidneys during Normothermic Machine Perfusion

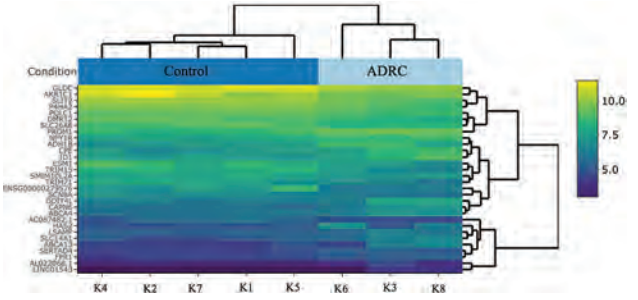
Robert Pearson,[1,2] William G. Norton,[1] Patrick B. Mark,[2] Marc J. Clancy.[1]
[1]Queen Elizabeth University Hospital, Glasgow, United Kingdom;
[2]University of Glasgow, Glasgow, United Kingdom.

Background: Normothermic machine perfusion (NMP) of kidneys provides a period of assessment prior to implantation with the potential benefit of improving organ utilisation. Furthermore, it provides an opportunity to deliver therapeutics without negotiating the systemic circulation. The immunoregulatory properties of adipose-derived regenerative cells (ADRC) have been shown in numerous organ systems, including the kidney, and can be readily extracted from adipose tissue without the need for culture expansion.

Methods: Eight declined human kidneys were randomised to four hours of blood-based NMP with (n=3) or without (n=5) the administration of ADRC. The ADRC population was extracted from 150ml of donor peri-renal adipose tissue using the approved Celution® 800/CRS System and delivered directly via the arterial limb of the perfusion circuit. Samples of urine, perfusate and graft biopsies were taken for subsequent analysis.

Results: ADRC harvest from peri-renal tissue had a cell viability of 78-85% with cell number of between 1.2 and 1.4 million. There were no adverse events, such as glomerular thrombus, with NMP + ADRC. There were no apparent differences between NMP + ADRC and NMP alone with regard to urine output, perfusion parameters or histological grading of acute tubular injury. RNA sequencing demonstrated 24 differentially expressed genes with NMP + ADRC. Gene ontology analysis revealed upregulated biological processes within the ADRC group including nephron tubule epithelial cell differentiation.

Conclusions: ADRC were successfully extracted from donor perirenal tissue and delivered at point-of-care without culture expansion to kidneys during NMP, with no apparent adverse haemodynamic effect nor adverse histological change. Although theoretically desirable differential gene expression was demonstrated, further studies incorporating implantation will be required to assess whether this appoach provides meaningful clinical benefit.



Heatmap of top 24 differentially expressed genes

FR-PO1009

Recurrence of Atypical Hemolytic Uremic Syndrome (HUS) after Kidney Transplantation in Patients with the Complement C3 p.Arg161Trp Variant

Lieke ter Steeg,[1] Romy N. Bouwmeester,[1] Caroline Duineveld,[2] Anne-Els van de Logt,[2] W.A.G. van der Meijden,[2] Lambertus P. Van den Heuvel,[1,3] Kioa L. Wijnsma,[1] Jack F. Wetzels,[2] Nicole Van De Kar.[1] *[1]Radboud University Medical Center, Amalia Children's Hospital, Radboud Institute for Molecular Life Sciences, Department of Pediatric Nephrology, Nijmegen, Netherlands; [2]Radboud University Medical Center, Radboud Institute for Health Sciences, Department of Nephrology, Nijmegen, Netherlands; [3]University Hospitals Leuven, Department of Pediatrics/Pediatric Nephrology, Department of Development and Regeneration, Leuven, Belgium.*

Background: Graft loss due to disease recurrence is a major concern in kidney transplant (KTx) recipients with complement-mediated atypical hemolytic uremic syndrome (CaHUS). Gain-of-function mutations have been identified by KDIGO as a high risk factor for recurrent CaHUS. We describe a large cohort of transplant recipients with the common Dutch variant C3 p.Arg161Trp.

Methods: We retrospectively analyzed the outcome after first KTx in CaHUS patients with this variant. None of the patients received eculizumab prophylaxis, according to the Dutch guideline. Relapses were defined as restart of treatment (eculizumab or plasmapheresis) by treating physician.

Results: This study included 15 CaHUS patients with the C3 p.Arg161Trp variant. Median (range) time between first presentation of CaHUS and KTx was 6 (1-23) years, and median (range) follow up time after KTx was 6 (0-12) years. Treatment for suspected CaHUS recurrence was initiated in 5 (33%) patients. Median (range) time between KTx and recurrence was 10 (4-46) months. A trigger was identified in all patients with recurrence and included rejection (n=3) and infection (n=2). Two relapses, occurring at 4 and 10 months, were characterized by acute kidney disease and systemic thrombotic microangiopathy (TMA). Notably, one relapse, occurring after 4 years, presented only with slow eGFR loss and signs of chronic TMA in kidney biopsy. Laboratory data was missing for two relapses. Recurrence was treated with eculizumab (n=2) or plasmapheresis (n=3). Graft loss occurred in two patients, both treated with plasmapheresis. In patients treated with eculizumab, kidney function improved to baseline or stabilized. One patient experienced two more relapses, after eculizumab discontinuation, in subsequent years without graft loss.

Conclusions: CaHUS patients with the C3 p.Arg161Trp variant show low risk of early recurrence after kidney transplantation. Post-transplant recurrence may present solely with gradual loss of kidney function.

FR-PO1010

Impact of Mannose-Binding Lectin (MBL) on Graft Survival in Transplant Recipients with IgAN

E. D. Stea, Ighli di Bari, Tommaso M. Marvulli, Rossana Franzin, Adele Mitrotti, Simona Simone, Paola Pontrelli, Loreto Gesualdo. *Department of Precision and Regenerative Medicine and Ionian Area (DiMePre-J), Nephrology and Urology Units, University of Bari Aldo Moro, Bari, Italy.*

Background: The progression of IgAN has been linked to functional defects and serum levels of MBL. Specific SNPs in the promoter and exon1 of the MBL2 gene are associated with these qualitative/quantitative deficiencies. Given that deregulation of the lectin pathway may impact IgAN progression in native kidneys, we evaluated whether MBL2 SNPs and MBL levels affect graft survival in kidney transplant recipients with IgAN.

Methods: We enrolled 60 kidney transplant patients diagnosed with IgAN in the native kidney. The MBL2 variants (promoter: L/H, Y/X, P/Q alleles and exon1: A/O allele) were analyzed by Sanger sequencing.MBL levels were measured using

ELISA kit. Clinical data at baseline and during the follow-up were collected. An eGFR <60mL/min/1.73m2 (CKD-EPI) was considered the primary outcome in univariate and multivariate analyses.

Results: No significant impact of MBL2 genotype and serum levels on demographic features, donor variables, transplant-related variables, recurrence, and DGF was found. However, patients with the "O" allele exhibited higher creatinine values at the time of graft biopsy and lower MBL serum levels (P<0.001). The "L" and "Y" alleles were linked to faster disease progression in native kidneys but not during transplantation. Notably, patients with low MBL levels had worse graft outcome (P = 0.0023) over an average follow-up of 151 months.

Conclusions: Low MBL levels are associated with graft dysfunction in kidney transplant recipients with IgAN. This finding highlights the importance of monitoring MBL levels as a potential marker for graft prognosis in these patients.

Immune Cells in Compensatory Kidney Hypertrophy after Unilateral Nephrectomy

Qisen Guo, Mahta F. Gooya, Shishir K. Patel, Hyun Jun Jung, Sanjeev Noel, Hamid Rabb. *Johns Hopkins Medicine, Baltimore, MD.*

Background: The mechanisms of compensatory renal hypertrophy (CRH) following unilateral nephrectomy (UNx) are incompletely understood. We hypothesized that immune cells are involved in the compensatory increase in kidney size and function.

Methods: C57BL/6J mice underwent left kidney UNx. GFR was measured by transdermal FITC-sinistrin clearance. Kidney mononuclear cells were harvested from the remnant kidney and immunophenotyped via flow cytometry. Single-cell RNA sequencing (scRNA-seq) was performed on CD45+ cells post-UNx to capture gene expression changes. Adaptive immunity in CRH was evaluated using *Rag1*$^{-/-}$ mice lacking T and B cells.

Results: Kidney to-body weight ratio (KW:BW) for the remnant kidney increased at 24hr (5.5±0.2 mg/g baseline vs 6.7±0.1 mg/g 24hr; *P*<0.001) and 8wk (8.1±0.3 mg/g) while GFR fell at 4hr (47.6±6.5% average WT baseline; *P*<0.001) then rose at 24hr (73.5±4.4% vs 4hr; *P*<0.01) and stabilized throughout the 8wk period. Flow cytometry showed that, compared to baseline (56.7±2.2% CD4; 31.2±1.9% CD8; 11.8±0.8% CD4-CD8-), CD4 T cells increased at 4hr (67.5%; *P*<0.01) and 8wk (65.7±1.3%; *P*<0.05), CD8 T cells decreased at 4hr (15.8±3.5%; *P*<0.001) and 72hr (13.2±1.5%; *P*<0.001), and CD4-CD8- double negative T cells rose at 72hr (31.2±2.7%; *P*<0.001). PD1+CD4 T cells were elevated at 4wk (31.5±2.1%) compared to 1wk (14.8±1.3%; *P*<0.05) and 8wk (16.0±1.7%; *P*<0.05). TIGIT+CD8 T cells rose at 4hr compared to baseline (3.2±1.3% vs 1.0±0.2%; *P*<0.05). scRNA-seq showed changes in B cells (16.7% control, 22.6% 24hr, 16.0% 1wk, 20.5% 4wk), neutrophils (1.5% control, 10.8% 24hr, 5.8% 1wk, 2.6% 4wk), and NK cells (6.5% control, 8.5% 24hr, 12.6% 1wk, 12.9% 4wk). *Rag1*$^{-/-}$ GFR was increased compared to WT at 4hr (68.9±4.4% average *Rag1*$^{-/-}$ baseline; *P*≤0.05), 1wk (90.0±4.3%; *P*<0.01), and 4wk (93.3±3.9%; *P*<0.05). KW:BW at 4wk and 8wk were similar for WT vs *Rag1*$^{-/-}$.

Conclusions: Immune cells in the remnant kidney quantitatively and phenotypically change after UNx, seen in flow cytometry and scRNAseq. T and B cell deficiency led to increased GFR at select time points after UNx. Immune cells may participate in the compensatory GFR increase after UNx with implications for kidney donors, transplant recipients, recovery from AKI, and CKD progression.

FR-PO1012

Deep-Learning Based Pathological Assessment in Frozen Procurement Kidney Wedge Biopsies: An Independent Validation Study

Zhengzi Yi, Weijia Zhang. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: In order to minimize observer variability and avoid inappropriate discard pre-transplant, a deep-learning based pathological assessment pipeline in frozen procurement kidney needle biopsies has been developed and was shown to be able to accurately capture normal/sclerotic glomeruli, arteries/arterial intimal fibrosis regions and tubules. A composite Kidney Donor Quality Score (KDQS) was derived and used in combination with clinical factors to predict graft loss or assist organ utilization. However the performances of pipeline and graft loss model in frequently performed wedge biopsies were not thoroughly investigated.

Methods: We processed an independent cohort of procurement kidney wedge biopsies (n=786) which were mostly transplanted in 2019-2021 and were provided by Gift of Hope OPO center. Clinical data were obtained from OPTN under institutional IRB approval. Glomerulosclerosis grade was the only available pathologists' score and was used to correlate with digital feature Sclerotic Glomeruli%. Performance of pre-trained 1-year graft loss model using KDQS and clinical factors: cold ischemic time (CIT), use of pump and induction therapy was also evaluated.

Results: The digital feature Sclerotic Glomeruli% was strongly correlated with pathologists' glomerulosclerosis grade (R=0.63, *p*=1.8e-62). Sclerotic Glomeruli% (6m: *p*=9.6e-07, 12m: *p*=4.4e-07), Arterial Intimal Fibrosis% (6m: *p*=0.003, 12m: *p*=4.8e-05), and Interstitial Space Abnormality% (6m: *p*=0.003, 12m: *p*=0.016) were all significantly correlated with post-transplant eGFR. The KDQS was significantly associated with graft loss (*p*=5.4e-04, HR=1.39). Both individual and composite digital features were superior to the pathologists' glomerulosclerosis grade in association with graft outcomes. By applying the pre-trained 1-year graft loss model to wedge biopsy cohort using KDQS and clinical factors, we obtained an AUC of 0.67, which surpassed the model performance using clinical factors (AUC=0.53) or KDPI (AUC=0.57) alone. KDQS>=7 identified 5 kidneys could have been discarded within which 1 patient lost graft at day 122, 3 patient had 12m eGFR<=32, the rest patient had moderate eGFR (47) at 6m.

Conclusions: This study further validated the previously trained needle biopsy based method in wedge biopsies, therefore expended the utility of our deep-learning pipeline in clinical practice.

Inflammatory Status in Deceased Kidney Donors Led by Impaired Mitochondrial Metabolism through the HIF1α Hypoxia Pathway

Elena Guillen-Gomez,[1] Jordi Vilardell,[1] Yolanda Arce,[1] Irene Silva,[1] Sonia Fernandez-Veledo,[2] Carme Facundo,[1] Beatriz Bardaji de Quixano,[1] Montserrat M. Diaz Encarnacion.[1] Group of Renal Inflammatory Diseases (GERI). [1]*Fundacio Puigvert, Barcelona, Spain;* [2]*Hospital Universitari de Tarragona Joan XXIII, Tarragona, Spain.*

Background: The type of kidney donor determines prognosis of recipient's renal function, being worst in deceased donors' (DD) grafts than in living donors' (LD). This is due to the pre-implantation inflammation status and development of fibrotic processes in DD, related to hypoxia status, where even the cause of death can make a difference. Mitochondrial succinate dehydrogenase (SDH) complex is associated to inflammatory markers and macrophages. Succinate plays a key role in inflammatory processes. HIF-1α is a transcription factor regulated by succinate and hypoxia, setting a link between cellular energy metabolism, oxygen levels and response to stress situations. The aim of this study is to determine whether hypoxia processes through HIF-1α can increase renal succinate and induce infiltration of inflammatory cells in DD.

Methods: Expression of 159 genes was analyzed from pre-implantation kidney biopsies of 47 kidney DD and 19 LD to determine effect of hypoxia on kidney inflammation/fibrosis. Genes with strong positive correlation with HIF1α were grouped in functional clusters. Serum succinate levels were measured in 27 brain-death DD (BD-DD) and 10 healthy volunteers (HV) (comparable to LD). Levels of 18 monocyte/macrophage cytokines stimulating pro-inflammatory (M1) or restorative (M2) macrophages were determined in serum of BD-DD and HV, and the expression of characteristic cell markers in circulating monocytes extracts of these subjects.

Results: DD exhibited higher serum succinate levels while showing lower renal mRNA of SDH subunits ($p<0.001$) vs LD. DD grafts showed significantly increased levels of HIF-1α ($p<0.001$), suggesting enhanced hypoxia status. 24 (out of 159) genes were found only in DD samples, all showing a strong correlation with HIF-1α in DD (Rho > 0.5). Both cytokines involved in monocyte recruitment and adhesion and serum levels of pro-inflammatory IL-6 were higher in BD-DD vs HV. Anti-inflammatory M2 proteins were significantly increased in DD monocyte protein extracts.

Conclusions: Pre-implantation inflammation assessment in DD kidneys and monitoring of circulating monocytes in transplanted patients may contribute to determine renal prognosis and improve transplantation outcome.

FR-PO1014

Mechanism of Impaired Protein Homeostasis in Kidney Grafts following Cold Storage and Transplant

Seongok Lee, Nirmala Parajuli. *University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: Cold ischemia is an unavoidable event during the cold storage (CS) process of donor kidneys before transplantation. We have previously reported that CS impaired protein homeostasis in transplanted rat kidneys and reduced graft function. However, the mechanisms of how CS contributes to graft damage are largely unknown.

Methods: Isolated donor rat kidneys were stored in a University of Wisconsin (UW) solution at 4°C for 0 or 18 hours, followed by transplantation to recipient rats (CS+Tx). To simulate an in vitro model of CS+Tx, rat or human proximal tubular cells (PTCs) were incubated in UW solution at 4°C for CS, followed by rewarming (RW) with normal media at 37°C (CS+RW).

Results: Two members of 70-KDa heat shock proteins (HSPs) were dysregulated—a robust increase of Hsp72 and a decrease of Hsc70—in kidney grafts after CS+Tx. CS+Tx decreased HSF1, a stress-activated transcription factor that induces HSPs, along with its band shift in western blot, suggesting that the CS injury contributes to a post-translational modification of HSF1 in rat kidneys. To further elucidate the CS-mediated changes of these proteins in PTCs, renal cells were exposed to CS+RW. Consistent with in vivo data, CS alone increased HSF1 in PTCs, and rewarming episode increased Hsp72 and decreased Hsc70 and HSF1 proteins in a time-dependent manner. To assess protein localization during CS+RW, we performed immunocytochemistry (ICC), which revealed a dense staining pattern of HSF1, Hsp72, and Hsc70 proteins after CS+RW. Unlike western blot data, Hsc70 or HSF1 levels remained unchanged after ICC, suggesting that CS+RW induces aggregation of Hsc70 or HSF1 in PTCs. Adding HS-72, a specific inhibitor of Hsp72, to the CS solution partially restored Hsc70 levels, reduced aggregation of Hsp72, increased HSF1 level, and improved cell viability after rewarming in PTCs. Finally, the addition of HS-72 during CS improved graft function after CS+Tx.

Conclusions: These data indicate that the CS-mediated increase of Hsp72 protein is a negative regulator of kidney function. Inhibiting Hsp72 during CS improves PTCs health and graft function and therefore HS-72 could be a potential therapeutic during CS to improve outcomes after kidney transplantation.

Cold Storage-Mediated Activation of P38MAPK-MK2 Axis Induces Kidney Injury after Transplantation

Dinesh Bhattarai, Nirmala Parajuli. *University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: Most donor kidneys undergo cold storage (CS) before transplantation (Tx), but this often results in suboptimal outcomes because CS activates cellular pathways that damage kidney tissue. Previously we showed that normal proteasome function is needed to maintain kidney function and CS followed by transplantation (CS+Tx) reduces proteasome function and increases inflammation in rat renal grafts; however, the mechanisms behind the CS-mediated proteaome dysfunction and inflammation remain unclear.

Methods: In vivo rat kidney CS followed by transplantation (CS+Tx) and in vitro rat renal cell CS followed by rewarming (CS+RW) models were used. Proteasome function was assessed using renal cell extract and fluorescent-based peptide substrates. Protein levels were evaluated using renal extracts and western blotting analysis.

Results: CS increased phosphorylation of P38MAPK in rat renal cells in a time-dependent manner, suggesting activation of P38MAPK pathway. Inhibiting P38MAPK with a selective inhibitor, VX-745, during CS followed by rewarming restored the proteasome activity and mitigated cell injury in rat renal cells, suggesting that P38MAPK negatively regulates proteasome function in renal cells during CS+RW. We evaluated MK2, a downstream signaling molecule of P38MAPK activation that promotes inflammation in eukaryotic cells. We observed that CS+RW increased MK2 activation in rat renal cells. Finally, inhibiting P38MAPK with VX-745 during CS reduced activation of MK2 in renal cells following rewarming, suggesting that the p38PMAK could be a critical regulator of CS-mediated inflammation via MK2 pathway.

Conclusions: Our data indicate that the P38MAPK is a contributor of CS-mediated proteasome dysfunction and renal injury. Similarly, P38MAPK-MK2 axis may promote inflammation in renal cells during CS+Tx and this pathway may serve as a new therapeutic target to improve the outcomes of kidney transplantation and potential clinical applications during organ transplant.

Cold Storage Exacerbates Complement Pathway Activation in Kidneys following Transplantation

Madison K. Mcgraw, Nirmala Parajuli. *University of Arkansas for Medical Sciences College of Medicine, Little Rock, AR.*

Background: Cold storage (CS) of kidneys is a vital process that enables the transport of kidneys sourced from deceased organ donors to the desired recipient. Our lab previously reported that the complement system (C3 and C5b-9) is activated in kidneys after CS combined with kidney transplantation (CS+Tx). Here, we have chosen to focus on the C5 component upstream of C5b-9, as it is a clinically relevant therapeutic target in organ transplants. It is published that reactive oxygen species (ROS) increases localization of C5aR1, a receptor for the cleaved C5 protein C5a, to mitochondrial membranes contributing to the dysfunction of oxidative phosphorylation. Interrogating oxidative stress caused by Tx and the involvement of the C5a/C5aR1 axis is vital.

Methods: Lewis rat kidneys were removed from the donor rat, flushed, and placed in University of Wisconsin (UW) or CS solution at 4°C. After 18 hours of CS exposure, the left kidney was transplanted into a recipient rat for 1 post-operative day of reperfusion. Autotransplant (transplant with no CS) and Sham surgeries were used as controls. The proteome of rat kidney homogenates was analyzed using tandem mass-tag (TMT) mass spectrometry. C5 and C5aR1 were further characterized via SDS-PAGE western blotting and immunohistochemistry (IHC).

Results: In the TMT dataset, 5,951 individual proteins were identified in all animal groups. Pathway analysis revealed significant complement dysregulation, and 34 complement proteins were differentially abundant in CS+Tx compared to ATx, suggesting that CS intensifies complement activation. The level of C5 protein was increased after CS+Tx in rat kidneys. Intriguingly, C5 was increased in isolated mitochondria fractions, and this increase correlated with mitochondrial injury. C5aR1 predominantly localizes in the renal medulla and distal tubules in Sham and ATx, but displays diffusely positive staining in the cortex after CS+Tx.

Conclusions: We have identified significant dysregulation of the complement pathway during CS+Tx. Increased C5 in the mitochondrial fraction after CS+Tx suggests the involvement of the C5a/C5aR1 axis. Future studies will clarify the role of C5a/C5aR1 in the mitochondria during CS+Tx.

Isolation of Extracellular Vesicles and Associated Biomarkers from Organ Preservation Fluid in Kidney Transplantation

Leonie Kubitza,[1] Tobias Tertel,[2] Moritz Kaths,[3] Johannes Jaegers,[1] Bernd Giebel,[2] Lars Pape,[1] Marvin Droste,[4] Anja K. Büscher.[1] *[1]Universitatsklinikum Essen Klinik fur Kinderheilkunde II, Essen, Germany; [2]Universitatsklinikum Essen Institut fur Transfusionsmedizin, Essen, Germany; [3]Universitatsklinikum Essen, Essen, Germany; [4]Universitatsklinikum Dusseldorf, Dusseldorf, Germany.*

Background: Donor kidneys are in short supply and many potentially preventable complications lead to loss of organ function. Biomarkers may help to detect these at an early stage. Analyzing extracellular vesicles (EVs) from organ perfusate could be a non-invasive way to obtain information about the donor organ prior to transplantation. Since there is no standardized method to isolate EVs from organ perfusate yet, we compared several common purification methods. Finally, to the best of our knowledge, we demonstrate the first in-depth proteomic analysis of perfusate-derived EVs.

Methods: Purification of EVs from kidney allograft perfusate was performed by ultrafiltration (UF), precipitation (PEG), size exclusion chromatography (SEC), and ultracentrifugation (UC), respectively, as well as a combination of these. Following purification, EVs were detected by electron microscopy, immunocapturing-based flow cytometry and nanoscale imaging flow cytometry. Particle-to-protein ratios were calculated to determine sample purity. EV protein composition was analyzed by mass spectrometry and bioinformatic analysis of the EV proteome.

Results: Electron micrographs demonstrated the successful purification of EVs. Microbead-based immunoprecipitation indicated the presence of the vesicular tetraspanins CD9, CD63 CD81 and of CD235a and semi-quantitative multiplex analysis the composition of the EV fraction of several subtypes. Imaging Flow Cytometry and nanoparticle tracking revealed that UC purified more EV marker-carrying nanoscale objects and bulk nanoparticles than the combinations UF-SEC and PEG-SEC, however, accepting a lower grade of purity. Impurity induced by hemolysis was associated with an increased ratio of CD63+/CD235a+-EVs. Proteomic analysis revealed that the preparations were highly enriched for vesicular proteins.

Conclusions: For the first time, we tested different EV purification methods for organ preservation fluid. Depending on the aim of research, the applied methods can be used according to their advantages to isolate EVs from organ perfusate. In addition, we have generated a proteome dataset from perfusate-derived EVs that can serve as a reference for further studies, for example in biomarker analyses.

Alginate Microencapsulation Enhances Islet Function by Protecting against IL-1β

Dahlia A. Abdulsattar, Sophia H. Roberts, Shahab Hafezi, John Cashin, Dina Ibrahim, Batool Arif, Maria S. Remedi, Tarek Alhamad, Yiing Lin, Mohamed A. Zayed. Zayed Lab. *Washington University in St Louis School of Medicine, St Louis, MO.*

Background: Islet transplantation is a potential therapeutic avenue for type 1 diabetes mellitus. However, the lack of an effective vehicle for transplantation poses a challenge in sustaining long-term islet viability and shielding from immune rejection *in vivo*. Alginate encapsulation can be a promising strategy to optimize the microenvironment of transplanted cells. The most utilized form is sodium alginate for its natural biocompatibility. We hypothesize encapsulation of islets within alginate can enhance their viability and protect against detrimental effects of Interleukin-1 beta (IL-1β), a pro-inflammatory cytokine known to impair islet viability and function.

Methods: Pancreatic islets were purchased from Prodo Laboratories, Inc. (Aliso Viejo, CA). Islets were encapsulated in alginate utilizing a custom 3D-printed droplet generator and cured with barium chloride (10 mM BaCl). Microencapsulated islets were cultured in PRODO media supplemented with IL-1β (50 pmol/L). After 48 hours, viability was assessed utilizing Calcein AM and Ethidium homodimer-1 staining. Furthermore, islet function was evaluated using Glucose Stimulated Insulin Secretion (GSIS). ELISA was used to detect c-peptide production and glucagon release and islet viability was quantified using ImageJ.

Results: Non-encapsulated islets demonstrated a significant increase in c-peptide production in the presence of IL-1β ($p < 0.01$; Figure 1A). On the other hand, microencapsulated islets demonstrated an increase in c-peptide production. A similar response was observed with glucagon release for non-encapsulated ($p < 0.01$; Figure 1B) and microencapsulated islets treated with IL-1β. There was no significant change in viability for encapsulated and non-encapsulated islets exposed to IL-1β.

Conclusions: Encapsulation of pancreatic islets appears to protect islets from pro-inflammatory stress, thereby preserving their functionality. This microencapsulation holds potential for enhancing islet transplantation and longevity of islets *in vivo*. While encapsulated islets exhibit comparable viability to non-encapsulated islets, their function is improved when treated with IL-1 β.

Association of Long-Term Exposure to Air Pollution with Population-Level Rates of Incident ESKD in the United States

Kirsten L. Johansen,[1,2] Jiannong Liu,[1] Paul E. Drawz,[2] James B. Wetmore,[1] David T. Gilbertson,[1] Nicholas S. Roetker,[1] Eric D. Weinhandl,[3,1] Jesse D. Berman.[4] *[1]Hennepin Healthcare Research Institute Chronic Disease Research Group, Minneapolis, MN; [2]University of Minnesota Twin Cities, Minneapolis, MN; [3]Davita Clinical Research, Minneapolis, MN; [4]University of Minnesota Twin Cities School of Public Health, Minneapolis, MN.*

Background: Patient-level analyses suggest that long-term exposure to air pollution is associated with higher risk of incident end-stage kidney disease (ESKD). We sought to examine the extent to which geographic variations in the rate of incident end-stage kidney disease (ESKD) are correlated with long-term exposure to air pollution.

Methods: We used air pollution models from NASA's Socioeconomic Data and Applications Center to estimate long-term exposure to fine particulate matter <2.5 μm in aerodynamic diameter ($PM_{2.5}$) at the county level. We calculated the 10-year average $PM_{2.5}$ concentration from 2007-2016 and assigned each county the value derived from the county's population-weighted centroid based on the 2010 US Census. We used data from the US Renal Data System to calculate county-level rates of incident ESKD in 2018-2022 based on population estimates from the 2020 Census. We mapped $PM_{2.5}$ concentration and examined the association between $PM_{2.5}$ concentration and the subsequent incidence of ESKD among counties with ≥15,000 residents (excluding 3.4% of the population residing in counties too small to generate stable ESKD incidence).

Results: There was wide variation in exposure to $PM_{2.5}$ with large areas in the Midwest and Southeast having levels ≥10 μg/m^3 (left panel of Fig). There was also considerable variation in incident ESKD rates, from 64 to 16,789 per million population. $PM_{2.5}$ concentration was significantly correlated with incident ESKD rate (Spearman correlation =0.26; right panel of Fig).

Conclusions: Long-term exposure to air pollution was associated with rates of incident ESKD at the population level. Further analysis is needed to examine whether this association may partially explain racial/ethnic and socioeconomic disparities in rates of incident ESKD.

FR-PO1020

Relationship between Exposure to the Natural Environment and Psychological Well-Being in People Living with CKD

Gurneet K. Sohansoha, Eleanor M. Taylor, Courtney J. Lightfoot, Ella C. Ford, Roseanne E. Billany, Noelle Robertson, Alice C. Smith. *University of Leicester, Leicester, United Kingdom.*

Background: The natural world is beneficial to human health and wellbeing. People with CKD often experience psychological distress which can result in poor health outcomes. We explored the association between exposure to the natural environment and psychological wellbeing in CKD.

Methods: 319 participants across CKD stages (188 non-dialysis, 70 kidney transplant recipients, 40 haemodialysis and 21 peritoneal dialysis) from 9 UK NHS hospitals completed an online survey comprising the Distress, Anxiety, Stress Scale (DASS-21), 12-Item Short Form Health Survey (SF-12) and bespoke questions relating to access to and time spent in the natural environment. Data were analysed using frequency analysis, multiple linear regression, and logistic regression.

Results: Access to and time spent in the natural environment was similar for the different CKD groups. In the summer, 45% of participants spent more than an hour a day, at least five days a week, in the natural environment, whilst in the winter, this was only 19% of participants. Increased exposure to the natural environment was significantly associated with lower levels of depression (p<0.001), anxiety (P=0.002), and stress (p=0.029), and higher levels of mental health-related quality of life (HRQoL) (P<0.001). Participants reporting greater exposure to the natural environment were less likely to report experiencing stress (OR: 11.118, P=0.002) or depression (OR: 4.109, P<0.001).

Conclusions: Greater exposure to the natural environment is associated with better psychological wellbeing and mental HRQoL in people with CKD, suggesting the value of the natural world. Healthcare professionals should support people with CKD to access and engage with the natural environment. This data could inform the development of nature-based interventions for people with CKD to improve HRQoL.

FR-PO1021

Developing City-Level Nephrology Indicators Using Open Data

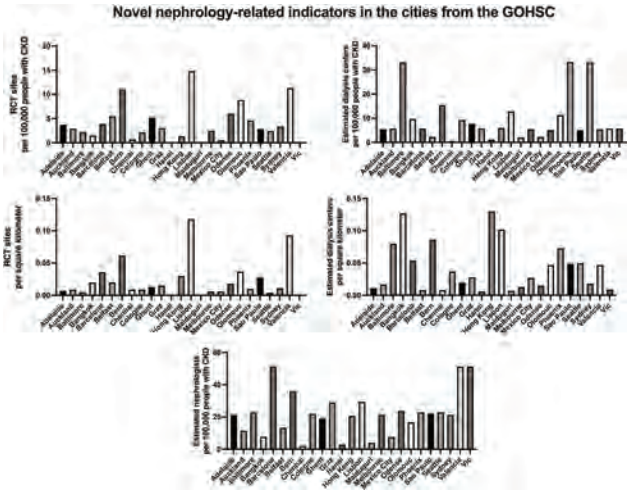
Gabriel Cojuc,[1,2] Alan Braverman-Poyastro,[4] Alejandra De Las Fuentes,[5] Andrea Mizrahi Drijanski,[4] Briana Rodriguez-Paniagua,[3] Alberto Nordmann-Gomes,[1] Alberto Moscona-Nissan,[3] Alberto Guijosa,[3] Vianca A. Canaviri,[6] Denisse N. Tinajero Sánchez,[1] Bhavna Chopra,[2] Ricardo Correa-Rotter,[1] Juan Carlos Ramirez-Sandoval.[1] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [2]Beth Israel Deaconess Medical Center, Boston, MA; [3]Universidad Panamericana, Ciudad de Mexico, Mexico; [4]Red de Universidades Anahuac, Naucalpan de Juarez, Mexico; [5]Hospital Universitario Dr Jose Eleuterio Gonzalez, Monterrey, Mexico; [6]Hospital Obrero No 1, La Paz, Bolivia, Plurinational State of.*

Background: Sustainable Development Goal 11—sustainable cities and communities— holds the potential to improve kidney health by enhancing access to CKD care. Most nephrology indicators overlook local heterogeneity. We aimed to develop novel city-level nephrology indicators.

Methods: We obtained data from open sources (Global Burden of Disease, WHO, ISN-GKHA, Global Observatory of Healthy and Sustainable Cities [GOHSC]) and from our systematic review of pharmacologic CKD randomized controlled trials (RCTs). We selected 214 RCTs with GOHSC participant cities. We calculated the following indicators: CKD-prevalence-adjusted (per 100,000 with CKD) RCT sites [95% CI], nephrologists, and dialysis centers; RCT sites and dialysis centers per km^2, RCTs/nephrologist, and CKD stage 5 RCTs per dialysis center.

Results: Among GOHSC, Lisbon had the highest number of CKD-prevalence-adjusted RCT sites (14.8 [13.7-16.1]), and Mexico City had the lowest (0.5 [0.5-0.6]). Spanish cities had the highest prevalence-adjusted nephrologists, and United States cities had the highest prevalence-adjusted dialysis centers (51.3 [47.7-55.4] and 33.21 [31.2-35.6], respectively), while Chennai had the lowest (2.1 [2.0-2.3] and 0.6 [0.6-0.6], respectively). Lisbon had the most RCT sites/km^2 (0.1), Seattle had the fewest (0.004). Hong Kong had the highest dialysis centers/km^2 (0.1), and Hanoi had the lowest (0.006). Odense had the highest RCTs/nephrologist (2.8) and stage 5 CKD RCTs per dialysis center (8.3), and Cologne and Baltimore had the lowest (0.1 and 0.03, respectively).

Conclusions: City-level, standardized nephrology indicators should be developed for policymaking and benchmarking. We provided an initial comprehensive model for further global elaboration.



FR-PO1022

Barriers to Participation in CKD Clinical Trials: A 25-City Analysis

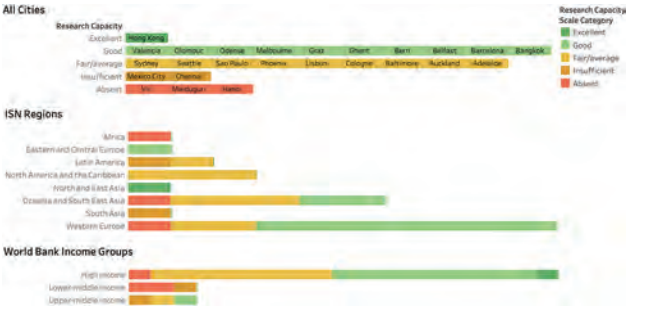
Gabriel Cojuc,[1,2] Alan Braverman-Poyastro,[4] Alejandra De Las Fuentes,[5] Briana Rodriguez-Paniagua,[3] Andrea Mizrahi Drijanski,[4] Alberto Nordmann-Gomes,[1,3] Alberto Moscona-Nissan,[3] Alberto Guijosa,[3] Denisse N. Tinajero Sánchez,[1] Vianca A. Canaviri,[1,6] Bhavna Chopra,[2] Ricardo Correa-Rotter,[1] Juan Carlos Ramirez-Sandoval.[1] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [2]Beth Israel Deaconess Medical Center, Boston, MA; [3]Universidad Panamericana, Ciudad de Mexico, Mexico; [4]Red de Universidades Anahuac, Naucalpan de Juarez, Mexico; [5]Hospital Universitario Dr Jose Eleuterio Gonzalez, Monterrey, Mexico; [6]Hospital Obrero No 1, La Paz, Bolivia, Plurinational State of.*

Background: Access to healthcare among those with limited resources, alongside several other factors, may influence participation in randomized controlled trials (RCTs). We aimed to identify barriers to CKD RCT participation in the cities from the Global Observatory of Healthy and Sustainable Cities (GOHSC).

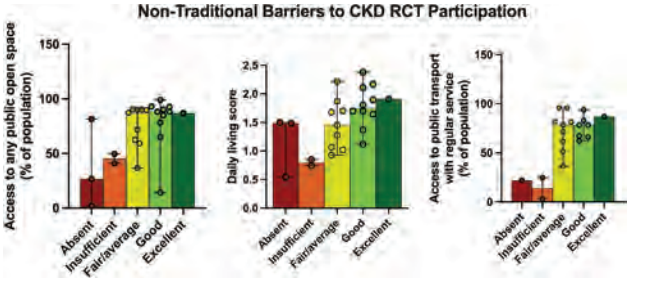
Methods: Cross-sectional study of 214 pharmacologic CKD RCTs published between 2003-2023 and including participants from 146 GOHSC research sites. We obtained indicators from WHO, GOHSC, ISN-GKHA, and GBD. We developed a three-point *CKD research capacity scale* with six variables (population-weighted RCTs, sites/km^2, funding, site span, facility type, RCTs/site). We classified *research capacity* as absent (0-1 points), insufficient (2-4), fair (6-7), good (7-8), or excellent (9-10) and compared financial, urban, and healthcare variables across categories.

Results: Odense had the highest population-weighted RCTs (7.01 RCTs/100,000 population), and Mexico City had the lowest (0.06). Compared with cities with absent or insufficient *research capacity*, those with good or excellent *research capacity,* had higher health expenditures, more nephrologists, public CKD care coverage, and dialysis centers. We identified non-traditional barriers to CKD RCT participation. Daily living score, access to public transport, open space, and a fresh food market were higher in cities with better *research capacity.*

Conclusions: Urban, financial, and healthcare barriers may affect RCT participation in the GOHSC. International initiatives should address local disparities in CKD research capacity.



Research capacity scale results



FR-PO1023

Does Clinical Utility of the Kidney Failure Risk Equation in Routine Clinical Practice Vary by Socioeconomic Status?

Heather Walker,[1] Shabana Khan,[1] Bhautesh D. Jani,[1] Katie I. Gallacher,[1] Patrick B. Mark,[1,2] Michael K. Sullivan.[1,2] *[1]University of Glasgow College of Medical Veterinary and Life Sciences, Glasgow, United Kingdom; [2]Queen Elizabeth University Hospital, Glasgow, United Kingdom.*

Background: Risk prediction models such as the kidney failure risk equation (KFRE) have been recommended to identify patients at heightened risk of kidney failure requiring treatment (KFRT). Incorporating KFRE into clinical practice may be limited by rates of albuminuria testing. We used routine healthcare data to ascertain albuminuria testing rates in CKD by sub-groups including socio-economic deprivation, age or sex.

Methods: We used routine healthcare data for all adults in NHS Greater Glasgow, UK (population approximately 1.5mill). Two cohorts and analyses were performed. Analysis 1 cohort: CKD G3-5 (eGFR<60mL/min/1.73m^2 for >90 days without KFRT). Analysis 2 cohort: as per cohort 1 with albuminuria values within 6 months of meeting CKD diagnostic criteria. Analysis 1 used logistic regression models to quantify associations between predictor variables and albuminuria testing. Analysis 2 assessed the predictive performance of KFRE.

Results: Cohort 1 included 10,874 adults. Albuminuria testing was missing in 55.5% of people. Individuals most likely to have albuminuria testing were those aged 40-50 years (adjusted odds ratio (aOR) 1.83 (95% confidence interval (CI) 1.15-2.91), p=0.01) and those living in the least socioeconomically deprived areas (aOR 1.11 (95% CI 1.00-1.23), p=0.01). Individuals least likely to have albuminuria testing were females (aOR 0.86 (95% CI 0.79-0.93), p<0.001), those with hypertension (aOR 0.69 (95% CI 0.63-0.77), p<0.001) and those without a diagnosis of diabetes (aOR 0.43 (95% CI 0.39-0.47), p<0.001). Cohort 2 included 4,902 adults, median eGFR 51.5 ml/min/1.73m^2. The highest albuminuria and KFRE risk values were identified in males, those aged 40-50 years old, people with a diagnosis of diabetes and individuals living in the most socio-economically deprived areas. KFRE model performance at five years was good but with over prediction at higher KFRE predicted risk groups (AUC 0.82).

Conclusions: KFRE performed well in this large observational population-based study using routinely collected data. KFRE could only be calculated for less than half of adults with CKD due to low rates of albuminuria testing, particularly for females, those without diabetes and those living in the most deprived areas.

Redefining Strategies for Kidney Disease Screening in Low-Resource Settings

Sanjib K. Sharma,[1] Ujwal Gautam,[1] Urza Bhattarai,[1] Pradip Katuwal,[1] Nensi Shah,[1] Srista Manandhar,[1] Sigiriya Aebischer Perone,[2] Kathrine Zimmermann,[2] Olivia Heller,[2] François Chappuis.[2] *[1]BP Koirala Institute of Health Sciences, Dharan, Nepal; [2]Hopitaux Universitaires Geneve, Geneve, Switzerland.*

Background: Equitable access to kidney care remains a major challenge in low- and middle- income countries (LMICs) like Nepal. Kidney, Hypertension, Diabetes, and Cardiovascular diseases (KHDC) program was formed in 2003 as part of an initiative from ISN for detection and management of major Non-Communicable Diseases (NCDs) in LMICs. The program, has since, shifted priorities from population-based mass screening to a targeted hish-risk approach. An integrated modality to improve service delivery on NCDs, including CKD, at primary care facilities was implemented in a municipality of Eastern Nepal. We present here an analysis of secondary data of risk factors among individuals with kidney disease.

Methods: Capacity building on early detection and management of NCDs, including CKD, was provided to 42 non-physician healthcare providers (HCPs). This was followed, between 2019 and 2023, by population-based screening among 14,517 individuals. Individuals were assessed for risk factors and NCDs through self-report forms, BMI, waist hip ratio, blood pressure, dipstick urine test, serum creatinine, fasting blood glucose and HbA1c measurements. Positively screened individuals were managed at primary care facilities. Kidney disease was defined as either or both of proteinuria and raised serum creatinine.

Results: Kidney disease was detected among 3.1% (n=454) with 88.3% of them having no prior history. 2.6% (n=375) and 1.2% (n=168) had proteinuria and elevated serum creatinine, respectively. Males were more likely [OR: 1.69 (95% CI: 1.38 – 2.06)] to exhibit kidney disease. Hypertension [OR: 2.51 (95% CI: 2.05 – 3.07)] and raised fasting glucose [OR: 2.81 (95% CI: 2.26 – 3.49)] were associated with occurrence of kidney disease. 132 cases required referral for further evaluation and kidney biopsy.

Conclusions: Population based screening strategies employed for early detection of kidney disease highlighted a significant disease burden. While integrating CKD screening as a part of regular NCD care is plausible, further exploration of the risk factors' distribution within the population can be crucial in directing the screening efforts to the high-risk groups. Competency based trainings can be an effective means to mobilize available resources through task sharing as outlined by the KHDC experience.

Social Risk Factors Associated with Disparate Posthospitalization Care among AKI Survivors

Tomonori Takeuchi,[1,2] Seda Babroudi,[3] Lama Ghazi,[1] Orlando M. Gutierrez,[1] Javier A. Neyra.[1] *[1]The University of Alabama at Birmingham, Birmingham, AL; [2]Tokyo Ika Shika Daigaku, Bunkyo-ku, Japan; [3]Tufts Medical Center, Boston, MA.*

Background: The 2012 Kidney Disease Improving Global Outcomes (KDIGO) acute kidney injury (AKI) practice guideline recommends kidney function to be reassessed within 3 months of AKI occurrence. The purpose of this study was to evaluate the association of social risk factors with receipt of post-hospitalization AKI care within 3 months among KDIGO stage 2 and 3 AKI survivors of intensive care unit (ICU) hospitalization.

Methods: Using data from a single academic center in the Southwestern United States, we retrospectively evaluated the association of insurance status, Area Deprivation Index (ADI), and Rural Urban Commuting Area (RUCA) code with receipt of post-AKI care. Patients aged ≥18 years hospitalized in the ICU with KDIGO stage 2 or 3 AKI between 10/2014 and 9/2017 who survived 90 days post-hospital discharge and did not require dialysis were included. Receipt of post-AKI care was defined as occurrence of a clinic visit and serum creatinine measurement within 90 days of hospital discharge. Multivariable logistic regression was performed, adjusting for patient demographics, comorbidities, and AKI severity.

Results: Of 1491 critically-ill AKI survivors, mean (SD) age was 55.8 (17.1), 40.2% were Black, 9.7% were uninsured, 30.2% lived in a neighborhood with the highest disadvantage, and 6.8% lived in a rural neighborhood. Only 536 (35.9%) patients received post-AKI care within 3 months. Uninsured status (aOR 0.44 [95% CI, 0.27, 0.68]) and living in a neighborhood of socioeconomic deprivation (highest tertile of ADI, aOR 0.72 [95% CI, 0.58, 0.89]) were significantly associated with decreased odds of receiving post-AKI care after adjustment (Table 1).

Conclusions: Only one-third of critically-ill KDIGO stage 2 or 3 AKI survivors had an outpatient visit and a serum creatinine measurement within 3 months of hospital discharge. Uninsured status and high neighborhood area deprivation significantly and negatively associated with follow-up, suggesting presence of socioeconomic disparities in post-AKI care.

Funding: Other NIH Support - National Center for Advancing Translational Sciences, National Institutes of Health, Award Number TL1TR002546

Medicaid and Dual Eligibility Are Negatively Associated with Kidney Function Recovery in Patients with AKI Receiving Outpatient Dialysis

Seda Babroudi,[1] Hocine Tighiouart,[2,1] Daniel E. Weiner,[1] Javier A. Neyra,[3] Ronald Sanders,[4] Harold Manley,[4] Eduardo K. Lacson,[4,1] David A. Drew.[1] *[1]Tufts Medical Center, Boston, MA; [2]Tufts Medical Center Institute for Clinical Research and Health Policy Studies, Boston, MA; [3]UAB Hospital, Birmingham, AL; [4]Dialysis Clinic Inc, Nashville, TN.*

Background: Access and quality of social risk data in patients with acute kidney injury receiving outpatient dialysis (AKI-D) are severely limited. However, Medicare-Medicaid dual eligibility status is an indicator of social risk and has been previously associated with worse dialysis outcomes among maintenance hemodialysis patients. We sought to explore the relationship of insurance status at baseline with kidney function recovery among patients with AKI-D.

Methods: Using a multi-center retrospective cohort design, we evaluated the association of insurance status at baseline with kidney function recovery to dialysis independence among patients with AKI-D who initiated hemodialysis between 2017 and 2021 at a medium-sized dialysis provider. We used Cox proportional hazard models adjusting for demographics, comorbidities, hemodialysis characteristics previously associated with recovery, and other social risk factors (modified area deprivation index, rurality of primary residence).

Results: Among 2,544 patients with AKI-D across 238 dialysis facilities, mean (SD) age was 65 (14) years, 58% were men, and 19% were Black. The most common primary insurer was Medicare/Medicare Advantage/Veterans Affairs (47%), with 17% dual eligible, and 12% insured with Medicaid. 857 (34%) patients recovered kidney function with a median (IQR) follow-up time of 103 (28, 180) days from first outpatient hemodialysis session. Medicaid and dual eligibility negatively associated with kidney function recovery when compared to Medicare/Medicare Advantage/Veteran Affairs as the primary insurer, even after multivariable adjustment (aHR 0.54, 95% CI 0.34, 0.84; aHR 0.67, 95% CI 0.47, 0.95, respectively) (Table 1).

Conclusions: Medicaid and dual eligible status negatively associated with kidney function recovery among patients with AKI-D, suggesting a role for upstream socioeconomic factors associated with insurance coverage to be used in future research exploring health disparities and shaping health policy in this population.

Out-of-Pocket Expenditures for Patients with CKD in the Medical Expenditure Panel Survey (MEPS)

Abhishek K. Das,[1] Sri Lekha Tummalapalli.[2] [1]*Johns Hopkins University, Baltimore, MD;* [2]*Weill Cornell Medicine, New York, NY.*

Background: Chronic kidney disease (CKD) affects 37 million Americans and nearly half of patients with CKD report experiencing financial hardship from medical bills. Out-of-pocket healthcare costs are a key source of financial strain. An analysis of 2002-2011 data from the Medical Expenditure Panel Survey (MEPS) found that average out-of-pocket costs declined from $1,707/yr to $1,218/yr during the study period. Prescription drugs accounted for $730/yr in costs in 2010/2011. Recent novel therapeutics such as SGLT2 inhibitors may contribute to excess out-of-pocket costs and more contemporary estimates are needed.

Methods: We used data from the Medical Expenditure Panel Survey (MEPS), which is a nationally representative set of extensive surveys of individuals, their medical providers, and employers across the United States. We used the full-year household component consolidated data files from 2018 to 2021 and restricted to individuals with ICD-10 codes for CKD (N18). We examined mean out-of-pocket costs per year for inpatient hospital stays, emergency department visits, hospital outpatient visits, office-based visits, and prescription medicines. Sample weights were applied to account for the complex survey design.

Results: Among the 115,114 people surveyed by MEPS from 2018-2021, we restricted to 291 observations from 141 patients with diagnosis codes for CKD. Average out-of-pocket costs were $234.53/yr for inpatient costs, $135.89/yr for emergency department visits, $143.04/yr for hospital outpatient visits, $833.93/yr for office-based visits, and $783.77/yr for prescription medicine costs.

Conclusions: Patients with CKD experienced higher out-of-pocket costs in 2018-2021 compared with prior estimates. Prescription medicine costs accounted for a higher share of out-of-pocket expenditures, which may be attributable to novel therapeutics for CKD. Health policy levers such as the Medicare Part D out-of-pocket spending caps in the Inflation Reduction Act may lessen the financial burden of CKD and its complications.

FR-PO1028

Switching Back to Medicare Fee-for-Service after 1 Year of Medicare Advantage Coverage among Patients with ESKD

Jiannong Liu,[1] James B. Wetmore,[1,2] Haifeng Guo,[1] David T. Gilbertson,[1] Nicholas S. Roetker,[1] Kirsten L. Johansen.[1,2] [1]*Chronic Disease Research Group, Hennepin Healthcare Research Institute, Minneapolis, MN;* [2]*University of Minnesota Twin Cities, Minneapolis, MN.*

Background: Medicare beneficiaries with end-stage kidney disease (ESKD) were able to switch from Medicare fee-for-service (MFFS) to Medicare Advantage (MA) starting in 2021. About 11.6% of dialysis patients (pts) and 5.4% of kidney transplant (Tx) pts switched in 2021. This study assessed how many pts switched back to MFFS in 2022, a potential indicator of dissatisfaction with the program.

Methods: We used United States Renal Data System data to identify adult ESKD pts who switched from MFFS to MA in 2021 and survived to 2022. "Switching back" was defined as enrollment in MFFS in January 2022. For comparison, we assessed the rate of switching to MFFS in 2022 among those ESKD pts who were continuously enrolled in MA 2020-2021. Analyses were stratified by ESKD modality.

Results: Among 31,972 pts (27,644 dialysis, 4,328 Tx) who switched from MFFS to MA in 2021, 1.41% of dialysis pts and 1.52% of Tx pts switched back to MFFS in 2022, whereas only 0.50% of dialysis pts and 0.44% of Tx pts switched to MFFS in 2022 among those who were continuously enrolled in MA. Among dialysis pts who switched to MA in 2021, switching back to MFFS was more common among those who were older (2.79% in 75-85 years and 2.92% 85+), Asian (2.50%) or Other race (2.49%), or living in Northeast (2.03%); and less common in younger groups, Black or Hispanic, and Medicare-Medicaid dual enrolled (Table). The pattern was less clear among dialysis pts who were in MA 2020-2021 and among Tx pts.

Conclusions: One year after switching from MMFS to MA in 2021, a small percentage switched back. However, the switch rate was triple that of pts who were originally in MA. Further studies should assess if switching back is related to the quality of services in MA compared with MFFS.

Likelihood of Switching from Medicare Fee-for-Service Coverage to Medicare Advantage among Patients on Maintenance Dialysis in 2022

Jiannong Liu,[1] Haifeng Guo,[1] James B. Wetmore,[1,2] Nicholas S. Roetker,[1] David T. Gilbertson,[1] Kirsten L. Johansen.[1,2] [1]*Chronic Disease Research Group, Hennepin Healthcare Research Institute, Minneapolis, MN;* [2]*University of Minnesota Twin Cities, Minneapolis, MN.*

Background: Medicare beneficiaries with end-stage kidney disease (ESKD) were able to switch from traditional Medicare fee-for-service (MFFS) to Medicare Advantage (MA) during open enrollment periods for the first time in 2021. About 11.6% of MFFS dialysis patients switched to MA in 2021, and switching was more common among patients who were younger, Black or Hispanic, poor or low-income, and living in the South. This study assesses whether patterns in switching were similar in 2022.

Methods: Using the United States Renal Data System data, we examined who switched to MA in January 2022 among adult (age ≥18 years) dialysis patients covered by MFFS as primary payor as of December 2021.

Results: In total, 240,360 patients were included; 6.5% switched from MFFS to MA in 2022. Switching was most common in individuals who were aged 55-64 years (9.0%), Black race (9.4%), Medicare-Medicaid dual enrolled (8.0%), in Medicare Part D (6.8%), or living in the South (8.4%) and least common among those who were aged 85+ (2.6%), Asian (3.7%), non-dually enrolled (5.4%), not in Medicare Part D (5.5%), or living in the Northwest (4.7%) (Table). The adjusted odds ratios for switching and the corresponding 95% confidence intervals are shown in the Table.

Conclusions: A smaller percentage of MFFS patients switched to MA in 2022 than in 2021, although switchers shared similar characteristics in both years. The availability of zero-premium plans and lower out-of-pocket spending limits will continue to incentivize switching to MA. However, whether the pre-authorization requirement and limited provider network will affect the quality of care or the rate of switching back to MFFS needs to be monitored.

Associations of Income Variability and Incident ESKD in Diabetes: A Population-Based Cohort Study

Min Woo Kang, Sehoon Park, Dong Ki Kim, Yong Chul Kim, Kook-Hwan Oh, Jinsun Lee. *Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.*

Background: Studies analyzing the association between income variability and incident end-stage kidney disease(ESKD) among individuals with type 2 diabetes(T2D) are limited.

Methods: Based on data from the Korean National Health Insurance Service, 1,481,371 adults aged 30-64 with no history of kidney disease were identified among individuals with T2D who underwent health checkups from 2015 to 2016. Annual income levels from the preceding 4 years to the baseline year were categorized into four quartiles. Income parameters were analyzed in three aspects: (1) cumulative number of years belonging to a specific income status quartile, (2) income volatility, and (3) changes in income status between the initial and end points during the observation. The primary outcome was defined as the first occurrence of incident ESKD, followed up until December 31, 2020. Cox proportional hazard models were used to estimate hazard ratios(HRs) and 95% confidence intervals(CIs).

Results: Persistent low income status over 5 years was associated with an increased risk of ESKD (HR 5years vs. 0years: 1.54, 95% CI 1.33-1.78; Ptrend<0.0001). High income volatility was associated with an increased risk of ESKD (HR highest vs. lowest quartile: 1.43, 95% CI 1.27-1.60; Ptrend<0.001). Irrespective of initial income status, individuals whose income status declined during the 5 years of observation, comparing between the initial and end points, had an increased risk of ESKD. The increase in ESKD risk was most pronounced among those whose income status declined steeply from the highest to the lowest quartile (HR steepest decline vs. unchanged: 1.58, 95% CI 1.19-2.09; Ptrend=0.0025).

Conclusions: Among adults aged 30–64 with T2D, individuals with more persistent low income status, higher income volatility, and steeper income decline had a significantly increased risk of ESKD.

FR-PO1031

Impact of Population Health Management to Modify Disparate Use of SGLT2 Inhibitors/Glucagon-Like Peptide 1 Receptor Agonists (GLP-1 RAs)

Linda-Marie U. Lavenburg,[1,2] Zhuoheng Han,[1] Mitra Mosslemi,[1] Alaa A. Alghwiri,[1] Thomas D. Nolin,[1,2] Melanie R. Weltman,[1,2] Jonathan G. Yabes,[1] Manisha Jhamb.[1,2] *[1]University of Pittsburgh, Pittsburgh, PA; [2]UPMC, Pittsburgh, PA.*

Background: Negative social determinants of health (SDOH) are associated with more CKD incidence and progression, partly due to suboptimal management. Sex and age differences in CKD management also exist. We studied whether population health management (PHM) modified the association of demographic differences and SDOH factors with initiation of SGLT2i or GLP1RA.

Methods: In this exploratory analysis of the Kidney Coordinated HeAlth Management Partnership (KCHAMP) trial which cluster randomized 101 primary care offices to control arm vs PHM intervention (nephology e-consult, CKD education, and pharmacist medication review). Enrolled patients with type 2 diabetes, not on baseline SGLT2i/GLP1RA were included. Associations between SGLT2i/GLP1RA initiation with a priori factors were examined in the control arm using Poisson regression with random practice intercept, adjusted for age, gender, race, BMI, Charlson Comorbidity Index, follow-up time as the offset. Effect modification by KCHAMP was assessed using interaction terms. Significance level 0.2 was used.

Results: Cohort had 891 patients (402 KCHAMP; 489 Control); 55% female; 11% black race/other; 89% white race; with mean±SD age 73±9yrs; BMI 33±7kg/m^2; HbA1c 7.3±1.5%; and 18% were rural living. In the control arm, gender (IRR [95%CI] 1.07 [0.99-1.17]), and HbA1c (1.05 [1.02-1.10]) were significantly associated with SGLT2i/GLP1RA initiation. KCHAMP had a marginally significant interaction effect with BMI (1.06 [1.00-1.12]; p = 0.20).

Conclusions: We found disparities in SGLT2i/GLP1RA use due to age and gender. But, SDOH factors were not associated with drug use. The association between some factors (age, gender, BMI, HBA1c) with the initiation of drugs slightly differed between control and KCHAMP. We were under-powered to detect interaction effects of K-CHAMP, yet a marginally significant intervention interaction effect with BMI, suggests that KCHAMP may increase SGLT2i/GLP1RA use in those with higher BMI.

Community Health Center Penetration and Kidney Outcomes among Nonelderly Adults with Incident ESKD

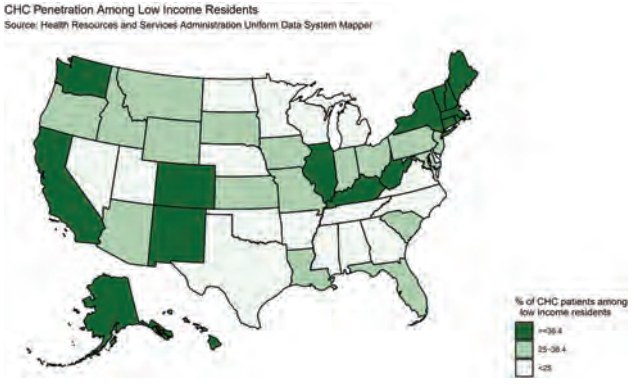
Yoshio N. Hall,[1,2] Wyatt P. Bensken,[4] Suzanne E. Morrissey,[4] Indhira De la Cruz Alcantara,[5] Mark L. Unruh,[3] David K. Prince.[2] *[1]VA Puget Sound Health Care System Seattle Division, Seattle, WA; [2]University of Washington, Seattle, WA; [3]University of New Mexico School of Medicine, Albuquerque, NM; [4]Oregon Community Health Information Network, Portland, OR; [5]Sea Mar Community Health Centers, Seattle, WA.*

Background: In the US, populations who experience kidney health disparities often rely on Community Health Centers (CHCs) for affordable ambulatory care.

Methods: We conducted a retrospective cohort study to examine whether CHC penetration of the state-level low-income population was associated with prevalent kidney disease risk factors, ESKD incidence, process measures reflective of pre-ESKD care quality, and 1-year ESKD survival and kidney transplantation. We studied 318,809 nonelderly adults aged 18-64 years who initiated treatment for ESKD in the US during 2016-2020 and the population characteristics of all 1,370 HRSA CHCs and 51 states for the same time period.

Results: CHC penetration among low-income residents (percentage of low-income residents who were CHC patients in each state) was highest among states in the northeast and lowest among states in the south (mean 35.5% [SD, 19.2%]). The prevalence of diabetes, high blood pressure and obesity were respectively lower in states with high versus low CHC penetration. There were no significant differences in age- and sex-standardized ESKD incidence according to CHC penetration. In individual-level analyses, higher CHC penetration was significantly associated with a higher likelihood of prolonged nephrology care (adjusted OR: 1.04 [95%CI: 1.03-1.05]), arteriovenous fistula or graft usage at hemodialysis initiation (1.11 [1.09-1.12]), home dialysis usage (1.04 [1.02-1.05]), and 1-year kidney transplant (1.09 [1.05-1.12]) and ESKD survival (1.06 [1.04-1.07]). CHC penetration was not associated with the likelihood of pre-emptive kidney transplant (1.00 [0.96-1.04]).

Conclusions: Higher CHC penetration of low-income populations was associated with a lower prevalence of kidney disease risk factors, and better preparedness for, and higher survival after, ESKD onset. These findings warrant additional study into the role and impact of Community Health Centers in addressing longstanding disparities in kidney health.



FR-PO1033

Pilot Data from a Community Health Worker Intervention for Patients on Hemodialysis

Tessa K. Novick,[1] David A. Giraldo,[1] Michelle M. Osuna-Diaz,[1] Elizabeth Jacobs,[1] Deidra C. Crews.[2] *[1]The University of Texas at Austin Dell Medical School, Austin, TX; [2]Johns Hopkins Medicine, Baltimore, MD.*

Background: Health-related social needs, such as housing and food insecurity, are common among hemodialysis patients. Social needs are associated with worse outcomes and pose barriers to care. Community-health worker (CHW) interventions have been successful at addressing social needs in other populations.

Methods: We piloted a single-arm, two-month CHW intervention for in-center hemodialysis patients who were eligible for Medicaid at three dialysis facilities in Austin, Texas. Objectives were to determine (1) the feasibility and acceptability of using a CHW to improve community resource navigation to social needs assistance, and (2) how measures of treatment attendance, patient reported stress, and mental health and clinical parameters performed in this population.

Results: Of the 17 enrolled participants to date, mean (SD) age was 56 (9) years, 67% were male, 50% identified as Black, 50% as Hispanic, 100% reported annual income <$25,000, and health related social needs were high (70%, 65%, 47%, and 24% reported housing, food, transportation and utility needs, respectively). Baseline hemodialysis treatment attendance, mental health, and clinical parameters were poor (Figure). All eligible patients approached agreed to participate, however CHW case load and burden of participants'social needs necessitated slowing the pace of enrollment.

Conclusions: Social needs were prominent among hemodialysis patients with low socioeconomic status and were associated with mental health concerns and emotional distress, supporting the importance of developing interventions to address them.

Why Am I on Dialysis? Exploring the Gap between Patient Perspectives and Clinical Diagnosis of Kidney Disease in California's Central Valley

Marimar Contreras Nieves,[1] Angelina J. Powers,[1] Stefan A. Jaskulak-Gonzalez,[1] Esteban Banda,[1] Xue Yu,[1] Manjula Kurella Tamura,[1,2] Shuchi Anand.[1] *[1]Stanford University, Stanford, CA; [2]VA Palo Alto Health Care System, Palo Alto, CA.*

Background: In the agricultural hub of California's Central Valley, where the incidence of end-stage kidney disease (ESKD) is amongst the highest in the nation, investigating the discrepancies between patients' understanding of their kidney disease and their clinical diagnoses holds critical importance, given potential communication barriers including due to language differences, and varying health literacy levels.

Methods: We interviewed 163 patients (range 18-60 year-old) undergoing hemodialysis in Soledad, Salinas, and Fresno, California. We compared the agreement between patients' reported diagnosis with those documented by clinicians in the CMS 2728. Chi-squared and Mann-Whitney U tests were performed to assess whether the agreement differed by age, gender, and educational background. Educational background was categorized as follows: absence of formal schooling, completion of less than 9th grade, completion of 9th to 11th grade, graduation from high school or obtaining a GED (General Educational Development) equivalent, partial completion of college or attainment of an Associate's degree (AA), and attainment of a college degree or higher.

Results: The survey response rate among those eligible and approached was 80%. The median age of respondents was 49 years (25th, 75th percentile 40, 55 years), 68% were men, and 79% were Hispanic. Patient agreement with clinician documented causes was highest for diabetes (71%) and lowest for hypertension (31%) (Table 1). Agreement rates did not differ by age, gender, or education level.

Conclusions: There was poor concordance between the cause of ESKD documented in clinical records and patients' understanding, particularly for those with a clinical diagnosis of hypertensive kidney failure or unknown. The findings could indicate both communication gaps, but also inaccuracies in the CMS 2728 categories or the clinician's diagnosis.

Funding: NIDDK Support

Table 1: Cause of ESKD and Agreement Between Patients' and Clinicians' Diagnosis

Clinician designated cause of ESKD	N (%)	Agreement with patient perceived cause (%)
Diabetes	79 (48)	71
Hypertension	26 (16)	31
Glomerular Disease	11 (7)	64
Unknown	33 (20)	36

FR-PO1035

Crash Dialysis Starts in Northern Alberta: Demographics, Outcomes, and Uptake of Home Therapies

Bernadine Jugdutt, Feng Ye, Aminu K. Bello, Nikhil A. Shah. *University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada.*

Background: "Crash" dialysis starts (i.e. emergency hemodialysis initiation) remain a frequent occurrence, despite guidelines for early referral. They are associated with higher healthcare costs and worse patient outcomes. Better understanding of the crash lander population is key to targeting interventions to reduce crash starts and improve outcomes.

Methods: We performed a retrospective chart review of patient initiating hemodialysis (HD) in northern Alberta from 2008-2019. Patients with prior renal replacement therapy or short-term HD were excluded. Patients were categorized into planned HD starts (>3 months Nephrology exposure) and unplanned (<3 months), with subdivisions for late exposure (2 weeks - 3 months) and no exposure (<2 weeks). Demographics, uptake of home therapies, and short-term outcomes were compared between groups using Kruskal-Wallis for continuous variables and χ^2 for categorical; $p<0.05$ indicated significance.

Results: 2,685 adult patients were included; of those, 28.1% had an unplanned HD start, and 19.7% started HD with no prior exposure to Nephrology. Crash dialysis patients were more likely to live rurally (17.2% vs 13.7%, p=0.022), and reported fewer instances of comorbid conditions including diabetes, hypertension, cardiovascular disease, and stroke. While percentage conversion to home therapies and listing for renal transplant was similar between groups, there was a higher prevalence of conversion to peritoneal dialysis specifically in the unplanned group at 1 year (9.4% vs 6.4%, p=0.007) and at the end of the study (13.0% vs 8.6%, p<0.001), and a lower prevalence of conversion to home hemodialysis as compared to the planned group. Unplanned HD starts had longer initial hospitalizations, earlier re-hospitalizations, and longer waits to achieve permanent access.

Conclusions: Despite optimal referral guidelines, crash dialysis starts remain a significant problem in Alberta and demonstrate worse short-term outcomes than their planned HD counterparts, emphasizing the need for further quality improvement work in this area.

Short-term outcomes for unplanned vs planned hemodialysis (HD) patients

	Unplanned	Planned	p-value
Mean length of hospital admission for HD initiation (days)	33.9	31.7	0.032
Length of time (days) to obtain permanent access	9.7	3.0	<0.001
Mean time (months) to next all-cause hospitalization	10.9	12.6	<0.001
Conversion to fistula access, N (%)	281 (37.3%)	1,199 (62.2%)	<0.001

FR-PO1036

Comparison of Clinical and Sociodemographic Characteristics of Hemodialysis Modalities

Belen Alejos,[1] Kaitlyn R. Croft,[1] Anke Winter,[1] Adrian M. Guinsburg,[2] Jeffrey L. Hymes,[3] John W. Larkin,[3] Len A. Usvyat,[3] Martin E. Guinsburg,[2] Franklin W. Maddux.[4] *[1]Fresenius Medical Care, Bad Homburg, Germany; [2]Fresenius Medical Care, Buenos Aires, Argentina; [3]Fresenius Medical Care, Waltham, MA; [4]Fresenius Medical Care AG, Bad Homburg, Germany.*

Background: Hemodiafiltration (HDF) is a well-established kidney replacement therapy. However, the selection of the dialysis modality is normally made according to individual characteristics. We aimed to compare clinical and sociodemographic characteristics (with special interest in mineral bone disease (MBD) markers) according to hemodialysis modality among patients treated in 4 countries in Latin America in the first version of the global database (Apollo Dial DB).

Methods: Apollo Dial DB includes adult dialysis patient data from a global kidney network during Jan 2018-Mar 2021 (Fresenius Medical Care, Bad Homburg, DE). Data anonymization was performed in alignment with recommendations from a re-identification risk determination (Privacy Analytics, Ontario, CA). We included patients with HD or HDF for >90 days, with >90% of their assigned treatment for 12 weeks.

Results: A total of 20,350 patients were analyzed, 17,916 (88%) patients on HD, 2,434 (12%) on HDF. Figure shows differences in sociodemographic and clinical characteristics of the patient groups. Patients in HDF group were younger, had higher vintage, lower prevalence of preexisting CVD and diabetes, higher prevalence of fistula as vascular access, larger use of Vitamin D analogs, phosphate binders and calcimimetics. OCM Kt/V and blood flow were higher among HDF compared to HD. Slightly higher target achievement were observed for calcium and phosphate parameters on HDF group.

Conclusions: Prescription of HDF as kidney replacement therapy is not solely determined by specific guidelines but significantly influenced by various patients' characteristics that may lead to selection bias when analyzing the treatment effect. Hyperphosphatemia is particularly an indication for HDF in most LatAm countries, therefore future research is needed to evaluate how HDF affects MBD markers independently of other patient's factors.

Funding: Commercial Support - Fresenius Medical Care

Figure: Differences in patients characteristics according to hemodialysis modality

	HD (n=17916)	HDF (n=2434)	P-value
Age (years), mean (SD)	55.7 (16.4)	53.1 (16.7)	<0.001
Female gender, n (%)	10487 (58.5)	1634 (67.1)	<0.001
Preexisting diabetes, n (%)	7034 (39.3)	723 (29.7)	<0.001

Target 130-585, n (%)	8525 (57.4)	1335 (56.1)	0.256

FR-PO1037

Social Risk Factors and Quality of Life in Patients on Hemodialysis

Hailey Yetman,[1] Huei Hsun Wen,[1] Lin-Chun Wang,[2] Zijun Dong,[2] Lela Tisdale,[2] Yvette Foby,[2] Mariam M. Olagoke,[2] Stephan Thijssen,[2] Peter Kotanko,[2,1] Girish N. Nadkarni,[1] Lili Chan.[3] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Renal Research Institute, New York, NY; [3]Icahn School of Medicine at Mount Sinai Department of Medicine, New York, NY.*

Background: Hemodialysis (HD) patients often have lower quality of life (QoL) than non-HD patients. While social risk (SR) factors are linked to poor health and low QoL, their association with QoL in HD patients remains unstudied.

Methods: We surveyed HD patients at five dialysis units using the Kidney Disease Quality of Life (KDQOL) and the AHC Health-Related Social Needs Screening Tool (AHC-HRSN), evaluating their access to housing, food, transportation, utilities, and safety. We calculated physical component score (PCS), mental component score (MCS), burden score, symptoms of kidney disease score, and effect of kidney disease score using the KDQOL. Lower scores indicate an increased negative impact of kidney disease. The relationship between unmet SR and each of the sub-scores was investigated using the two-tailed Wilcoxon Rank Sum test.

Results: We studied 324 patients; high burdens of unmet SR were observed (Fig. 1A). Lower PCS and lower symptom scores were significantly associated with having at least one unmet SR factor, specifically in housing, food, and transportation insecurity (Fig. 1B, C). Lower MCS was significantly linked to having at least one unmet SR factor, including housing insecurity and unsafe environments (Fig. 1D). Lower burden score was significantly related to experiencing at least one unmet SR factor, including housing, food, transportation, and utilities insecurity (Fig. 1E). Lower effect score was significantly linked to having any unmet SR (Fig. 1F).

Conclusions: Unmet SR factors are common and associated with lower QoL in HD patients. Improved screening and attempts to address unmet SR may improve QoL in HD patients.

FR-PO1038

Dialysis Disparities: A Systematic Review of Homelessness and ESKD Care Challenges

Phong T. Nguyen,[1] Prakrati C. Acharya,[2] Charat Thongprayoon,[3] Sadhana Gonuguntla,[2] Jennifer Zhang,[2] Supawadee Suppadungsuk,[3] Pajaree Krisanapan,[3] Jing Miao,[3] Adeel Ahmad,[2] Wisit Cheungpasitporn.[3] *[1]William Beaumont Army Medical Center, El Paso, TX; [2]Texas Tech University Health Sciences Center El Paso, El Paso, TX; [3]Mayo Clinic Minnesota, Rochester, MN.*

Background: Patients with end-stage kidney disease (ESKD) who are homeless face challenges including medication storage, transportation, adherence to restrictions, dialysis treatments and exacerbating health issues

Methods: We conducted systematic reviews in OVID Medline, Embase, and Cochrane databases up to March 2024 to examine demographic data, substance use, dialysis access, mental health, healthcare utilization, and transplantation outcomes for homeless ESKD patients. Data categories included demographics such as age, ethnicity, and urban vs. rural living; types of dialysis access; psychiatric conditions; and outcomes, including survival rates, hospital visits, and transplantation suitability. The protocol was registered in PROSPERO CRD42024509023.

Results: 6 studies were identified involving 986 homeless ESKD individuals. The prevalence of homelessness among ESKD patients varied from 0.35% to 32.6%, with varying sample sizes in these studies. 4 studies with a total of 58003 ESRD patients, had 900 homeless patients, thus with a prevalence of 1.5%. The largest study involved veterans, demonstrating that approximately 3% had both ESKD and homelessness. Black patients were particularly affected with over half of the patients being Black in all studies. ESKD patients who were burdened by homelessness were associated with a high risk of 90-day hospital readmission (OR 2.92, 95% CI: 1.02, 13.16, p= 0.05). Patients with unstable housing had a higher risk of death compared with patients with stable housing in one study (adjusted hazard ratio [AHR], 1.20 [95% CI: 1.04-1.37]), with Kaplan-Meier analysis demonstrating 1-year and 4-year survival rates of 94.4% and 80.6%, respectively. Homelessness is an independent risk factor for ESKD, with incidence rates of ESKD significantly higher than stable housing peers (10.9 vs. 7.4 per 1000 person-years) in one study. These patients also faced mental health and substance abuse disorders.

Conclusions: Homelessness significantly impedes the management of ESKD. The data highlight the critical need for integrated healthcare services, including stable housing and mental health support. Future research should focus on comprehensive data collection to better address the barriers faced by homeless ESKD patients in getting necessary treatments

FR-PO1039

Trainee Awareness of Transplant Barriers for Undocumented Immigrants

Katherine M. Rizzolo,[1,2] Santhoshi R. Bavi,[1,2] Kurtis A. Pivert,[4] Lilia Cervantes.[3] *[1]Boston Medical Center, Boston, MA; [2]Boston University, Boston, MA; [3]University of Colorado Anschutz Medical Campus, Aurora, CO; [4]American Society of Nephrology, Washington, DC.*

Background: Undocumented immigrants face no regulatory barriers to receive a transplant based on immigration status; the primary barrier is lack of affordable insurance. Our objective was to evaluate nephrology trainee knowledge of eligibility and barriers to kidney transplants for undocumented immigrants and understand their referral practices for this population.

Methods: We analyzed deidentified responses from 450 fellows completing our 8-question instrument in ASN's 2023 survey of US nephrology fellows. Data were summarized as mean ± SD (continuous variables) or counts/percentages/frequency distributions (categorical).

Results: Results are summarized in Table 1.55.5% of participants identified as male, with a mean age of 33.9 years (SD 4.2 years), 88.8% were in adult programs. 54.8% reported treating undocumented immigrants in their nephrology clinic, yet the minority of respondents correctly identified that undocumented people are eligible for living donor (39.1%) and deceased donor transplantation (31.7%). 44.6% were unsure of what insurance was available to undocumented people. The highest rated barriers to transplant were lack of insurance (56.8%) and financial support (52.6%).

Conclusions: This research demonstrates a gap in nephrology trainee knowledge of undocumented immigrants' eligibility and barriers to kidney transplantation. As nephrology trainees often work in health safety net settings where undocumented people seek care, building clinician awareness and knowledge is critical for health equity in transplant care for undocumented individuals. This work may inform future initiatives to include the care of immigrant populations in nephrology trainee education and strengthen health equity efforts.

Barriers to Kidney Transplantation in the Largest Safety Net Hospital in New York: A Quality Improvement Project

Adrianne F. Basa,[1,2] Nicole Ali,[1] Robin G. Layman,[1] Nina J. Caplin.[1,2] *[1]NYU Langone Health, New York, NY; [2]New York City Health and Hospitals Bellevue, New York, NY.*

Background: Kidney transplant (KT) is the preferred treatment for patients with ESKD because of increased survival and improved quality of life. However, there is a lower rate of transplant among underserved patients. Bellevue Hospital Center (BHC) is a safety net hospital and serves primarily a disadvantaged population. It was observed that a minority of BHC patients receiving dialysis or CKD5 had been referred for transplant evaluation. The goal of this QI project is to assess if a new approach to systematic and coordinated referral would help rectify the disparity in this population and identify the obstacles BHC patients experience.

Methods: The renal staff identified admitted patients who might qualify for transplantation. The patients' names were sent to the NYU transplant coordinator. We interviewed patients to discuss obstacles to scheduling appointments, completing screening, and receiving a transplant. A chart review correlated referral patterns with dialysis unit (DU) CMS ratings, location and patients' home address. We conducted a zoom lecture for interested patients to reinforce the benefits of KT.

Results: From March 2023 to September 2023, 38 patients were referred for KT evaluation. 53% scheduled an appointment with a transplant center. 47% were interviewed. INTERVIEWED PATIENTS 55% of patients live in Brooklyn, 27% in Manhattan, 16% in the Bronx, and 5% in Queens. 58% of the DU are located in a zip code with median household income of less than $60,000. The average CMS rating of the dialysis units is 3.5. 72% had called and received an appointment within a month. 3 completed evaluation and one was transplanted; 61% are still undergoing evaluation. Reasons patients had for not calling: uncertain how to proceed, forgot to call or forgot about the referral. 44% wanted to join a virtual class to learn about KT. 2 patients attended the virtual class.

Conclusions: There is a disparity in the rates of referral to transplant centers among underserved patients. To address this disparity at BHC, we created a coordinated referral system with our affiliated transplant center. We also identified some barriers that impede the completion of this cumbersome process. Facilitating the process of kidney transplant evaluation and providing more support would benefit our underserved population and enable more access to this superior treatment option.

FR-PO1041

Socioeconomic Factors Affect Access to Kidney Transplant in the Ohio River Valley

Catherine E. Kelty,[1] Adam S. Wilk,[1] Oluwafisayo O. Adebiyi,[1] Asif A. Sharfuddin,[1] Jonathan A. Fridell,[1] Syed J. Sher,[1] Anne M. Huml,[2] Stephen O. Pastan,[3] Sharon M. Moe,[1] Rachel E. Patzer.[4,1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Cleveland Clinic, Cleveland, OH; [3]Emory University, Atlanta, GA; [4]Regenstrief Institute Inc, Indianapolis, IN.*

Background: Kidney transplant (KTx) improves patient survival and quality of life compared to dialysis, though many inequities exist due to social factors critical for fostering KTx access. To improve equity in KTx in the Ohio River Valley (IN, KY, OH), we must first understand the social drivers of health affecting access in our region.

Methods: Adult patients with incident end stage kidney disease residing in IN, KY, or OH at dialysis start among n=680 dialysis facilities from January 2016-June 2020 (followed through June 2021) were assessed. U.S. Renal Data System data were linked to referral and evaluation data from n=4 KTx centers contributing to the Early Steps to Transplant Access Registry and ZIP code-level characteristics from the 2021 American Community Survey. Associations were assessed between social and clinical variables and key outcomes: 1) evaluation start within 6 months of referral among referred patients, 2) waitlisting within 6 months of evaluation start among all evaluated, and 3) days between these events. Associations were examined—overall and in patient samples stratified by ZIP code-level median household income tertiles—by multivariable logistic regression and log rank test.

Results: Of n=8824 referred patients, 3265 (37%) started evaluation within 6 months and 981 (11%) were waitlisted within 6 months. More patients starting evaluation within 6 months were from high-income areas (39%) vs. middle (29%) and low (32%) ($p<0.001$). Overall, access to KTx was poorer for low-income (vs. high-income), as well as for Medicaid-insured (vs. commercial), Black (vs. non-Hispanic White), and female (vs. male) patients. Inequities were broadly consistent across income groups. For example, Medicaid-insured patients had a longer median time from evaluation start to waitlisting (197 days) vs. commercial insurance (121 days) in low-income areas ($p=0.004$); this disparity was 189 vs. 115 days for high-income ($p=0.047$).

Conclusions: Patients with Medicaid or living in low-income ZIP codes in the Ohio River Valley had reduced access to prewaitlisting KTx services relative to patients with commercial insurance or in high-income areas. This suggests that interventions to improve equity in KTx access should target patients in low-income areas and those without private insurance.

FR-PO1042

Nonadherence and Patient Empowerment on the Path to Kidney Transplant

Jennifer L. Mcdonnell, Ellen Idler, Monique Hennink, Adam S. Wilk. *Emory University, Atlanta, GA.*

Background: Compared to dialysis, kidney transplant conveys quality of life and survival benefits, yet only 15% of incident patients are waitlisted or receive a kidney transplant within 1 year of dialysis start. KDIGO guidelines recommend that patients with past non-adherence be considered for kidney transplant, but many kidney care professionals (KCPs) consider transplant to be contraindicated for these patients, potentially contributing to low waitlisting rates among eligible patients. Patients' understanding of non-adherence and its perceived impact on their access to kidney transplant is not well understood.

Methods: We conducted 20 in-depth interviews during 2024 with hemodialysis patients in the US. A semi-structured interview guide was used to explore what non-adherence means to patients in the context of kidney transplant. We purposively recruited patients by age, race, SES, gender, and transplant status to achieve a diverse sample. Interviews were conducted via phone and Zoom and were recorded and transcribed verbatim. We used MAXQDA software to manage data. A grounded theory approach was used to collect and analyze data.

Results: Preliminary results indicate that patients experience tension between being empowered to understand and manage their care and meeting their KCPs' expectations for adherence. Patients described non-adherence as ambiguously defined by KCPs, encompassing a range of behaviors from occasionally missing dialysis treatments to being considered a "difficult patient". Some patients described being labeled "non-compliant" by KCPs when attempting to advocate for their care (e.g., asking questions about recommended testing or expressing concerns about the iatrogenic or social consequences of treatment), resulting in their KCPs denying them referral or waitlisting. Women and Black patients, more often than men and white patients, reported that their efforts to actively engage in their health care were perceived as insubordinate ("If somebody doesn't like what you're saying, they can label you as non-compliant. It's such a scary term for patients.")

Conclusions: Patients consider non-adherence an ambiguously defined and "scary" label that can interfere with their access to kidney transplant. Evidence-based protocols for assessing adherence are needed to reduce potential bias in eligibility decisions when KCPs perceive patients as "non-compliant".

FR-PO1043

It Takes a Village: Barriers to Optimal Pediatric ESKD Care

Judith S. VanSickle, Darcy K. Weidemann, Bradley A. Warady. *Children's Mercy Kansas City, Kansas City, MO.*

Background: Kidney transplantation (KT) is the preferred method of treatment for children with end stage kidney disease (ESKD). Pre-emptive KT (PKT) is associated with improved patient and graft survival. The effect of social isolation due to insufficient family support (IFS) or underlying psychosocial conditions have not been evaluated as a potential additional influential factor in the pediatric ESKD population.

Methods: Single-center, retrospective chart review of 177 children who received ESKD care (dialysis only (D), dialysis followed by KT (D-KT), and PKT only) in our center from 2010 to 2020. Based on patient addresses, neighborhood disadvantage was categorized using the Child Opportunity Index (COI). Pediatric pre-KT psychology evaluations of all patients referred for KT during the study period were reviewed to identify additional barriers to PKT based on 4 standardized questions: AK=adequate knowledge about transplant, AT=ability to adhere to the treatment based on previous history, Psych= relevant mental health issues likely impacting on transplant success in the parents or in the child and evidence of IFS. Groups were compared based on race (R), modalities, and COI groups. Differences in characteristics between groups were determined by the chi-square test. Multinomial logistic regression analysis was conducted to identify the most significant factors influencing receipt of PKT.

Results: PKT was more likely among white children ($p=0.037$) but was not associated with COI ($p=0.095$). Only IFS and Psych in child correlated with a decreased likelihood of PKT;. Subjects were more likely to remain on D if they had IFS ($p<0.001$) or had a Psych in child ($p= 0.002$). IFS was more likely among non-white ($p=0.003$), and families who lived in low COI areas ($p<0.001$). However, Psych in child did not correlate with R ($p=0.54$) or COI (0.67). Multinomial logistic regression was conducted using 4 variables (COI, R, Psych in child and IFS) to evaluate the likelihood of receiving a PKT: with only having no psychiatric illness in the child (LR=8.69, $p=0.013$, OR:0.15 95% CI: 0.032-0.698) and sufficient family support (LR=16.965, $p<0.001$, OR: 5.98, 95% 0.728-49.17) were significant contributing factors to receive a PKT.

Conclusions: Psychosocial issues appear to play a significant role in access to transplant care, with social support from family being a significant predictor for PKT.

Examining Insurance-Related Disparities in Kidney Transplantation Access and Outcomes: A Systematic Review and Bibliometric Analysis

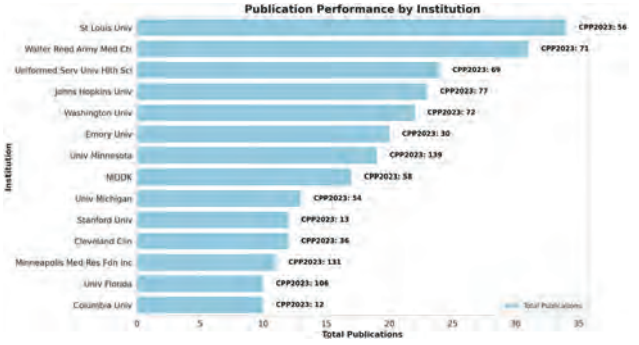
Oscar A. Garcia Valencia,[1] Supawadee Suppadungsuk,[1] Charat Thongprayoon,[1] Caroline Jadlowiec,[2] Napat Leeaphorn,[3] Pooja Budhiraja,[2] Wisit Cheungpasitporn.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Mayo Clinic Arizona, Scottsdale, AZ; [3]Mayo Clinic in Florida, Jacksonville, FL.*

Background: Equitable access to kidney transplantation is vital for patients with end-stage kidney disease, however insurance and social determinants significantly affect access and outcomes. This study examines disparities in waitlisting, access, and post-transplant outcomes based on insurance types, focusing on promoting diversity and equity in kidney health.

Methods: This systematic review and bibliometric analysis from MEDLINE, EMBASE, and Cochrane Database searches up to November 2023, assessed the impact of insurance types on kidney transplantation disparities. The systematic review followed PRISMA guidelines, and the bibliometric analysis examined research trends, leading institutions, and citation impact.

Results: St. Louis University and Walter Reed Army Medical Center lead in publications and citation impact. A systematic review of 15 U.S. studies (2008-2023) revealed disparities in waitlisting and outcomes linked to insurance. Medicare beneficiaries have better survival rates. African Americans on Medicaid are less likely to be added to the waitlist. Public insurance holders have fewer preemptive transplants, heightened mortality and allograft failure rates. Alarmingly, over a quarter of transplant ethics consultations highlight insurance limitations affecting treatment. Those holding dual (private/public) insurance exhibit higher rates of medication nonadherence. Medicare's coverage expansion to include immunosuppressive drugs might help mitigate these disparities.

Conclusions: Our systematic review and bibliometric analysis reveal disparities in kidney transplant outcomes influenced by insurance and social factors. Public insurance holders, especially Medicare or Medicaid beneficiaries, face significant obstacles in transplant access and increased post-transplant risks. Addressing these disparities in kidney transplantation and recognizing the contributions of leading research institutions and investigators is crucial.



FR-PO1045

Amplifying Patient Voices: Artificial Intelligence (AI)-Driven Insights from Kidney Health Discussions on Reddit

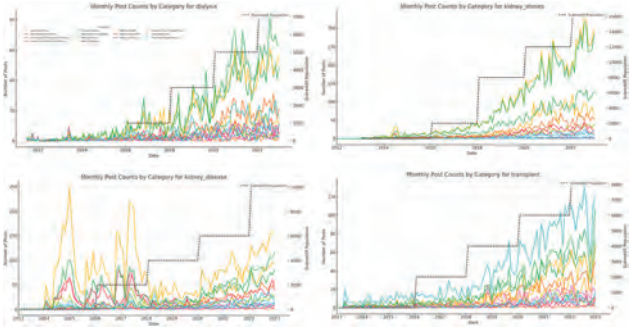
Rajesh Anumolu,[1,2] Aaron Delory,[3] Anil K. Chandraker.[1,2] *[1]University of Massachusetts Chan Medical School, Worcester, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]IO Design Team LLC, Danvers, MA.*

Background: Advancements in technology and social media have revolutionized discussions on medical conditions, surpassing traditional data collection methods in scope and speed. With over 850 million monthly users, platforms like Reddit provide a vast source of user-generated content. By utilizing large language models (LLMs), these discussions can be systematically analyzed to assess community sentiments, track conversations, identify trends, and address unmet needs. This approach offers valuable insights for o guide research, inform product development, and enhance patient support strategies.

Methods: The study analyzed 39,637 posts from subreddits related to kidney health, including /r/dialysis, /r/kidneydisease, /r/kidneystones, and /r/transplant. LLMs were used to categorize and evaluate the content, specifically leveraging OpenAI's Chat GPT-4 to identify trends and insights within each subreddit.

Results: By 2022, kidney-related subreddits saw significant growth: Dialysis (7,000), Kidney Disease (10,000), Kidney Stones (16,000), and Transplant (8,000) subscribers. Discussions often focused on medical queries, treatment experiences, and financial concerns, highlighting the need for advice and support. Spikes in activity correlate with policy changes, economic factors, or medical research, with advocacy events driving periodic increases. Steady population growth and increased post volume indicate active participation. Understanding these trends and the sentiment helps better address community needs.

Conclusions: These insights help healthcare professionals, researchers, and pharmaceutical companies support patient communities, inform product development, and enhance care strategies. LLMs provide real-time insights into patients' states, helping identify issues and adjust care. They study patient experiences, public health trends, side effects, satisfaction, and unmet needs. LLMs highlight health disparities, guiding interventions and inclusive policies. Analyzing social media data with LLMs helps stakeholders understand patient trends, improving outcomes and support strategies.



FR-PO1046

Peer-to-Peer Patient Partner Recruitment: Enhancing Peer Engagement for Successful Patient Partner Recruitment in a National Kidney Health Research Network

Melanie D. Talson,[1,2] Claudia Wilde,[1,2] Charles L. Cook,[2] Kelly Loverock.[2] Can-SOLVE CKD Network. *[1]The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada; [2]Can-SOLVE CKD Network, Vancouver, BC, Canada.*

Background: Patient partnership in kidney health research is recognized as an equitable approach to improving patient outcomes. *Patient Partners/People with Lived Experience* (PWLE) are co-researchers with lived experience of illness as patients or caregivers. Methods to recruit PWLE are poorly understood and not widely reported on. Together with two PWLE as co-researchers, we present successful PWLE recruitment strategies within the national Can-SOLVE CKD research network, funded in part by the Canadian Institutes of Health Research's Strategy for Patient-Oriented Research whose focus is on transforming kidney research through meaningful patient engagement. We present the results of the co-development of practical PWLE recruitment methods and tools, including a peer-to-peer recruitment strategy.

Methods: We conducted an environmental scan of existing research in academic publications; gathered data from the network's nine project reports and reviews, from the network website that connects researchers with PWLE; and, finally we conducted a survey and roundtable discussions with two network patient advisory councils to identify the most effective recruitment methods and strategies. Data were consolidated and analyzed thematically to identify successes and challenges to inform the development of a PWLE recruitment toolkit.

Results: A common challenge among researchers is the recruitment of PWLE; especially for recruiting ethnically- and gender-diverse participants. Effective PWLE recruitment strategies are categorized thematically along socio-spatial distances, including: (1) macro-level; (2) meso-level; and (3) micro-level and temporally according to illness/treatment stabilization. Peer engagement in the form of peer-to-peer recruitment is the most common route to patient partnership; however, a multi-faceted approach is the most effective way to reach the most diverse participants.

Conclusions: Recruiting PWLE as partners in research in the kidney health research context may present some challenges, especially for harder-to-reach participants; however, by targeting various levels of reach, considering timing of recruitment and promoting peer-to-peer recruitment will enable a strategy for success.

Can-SOLVE CKD: Capturing Our IDEA Journey as a Patient-Oriented Kidney Research Network

Keila L. Turino Miranda,[1] Jocelyn M. Jones,[2] Heather Harris,[2] James W. Scholey,[4,2] Melanie D. Talson,[2] Michelle Hampson,[2] Charles L. Cook,[2] Julie Wysocki,[6,7] Taylor Hainstock,[5] Selina Allu.[2,3] *[1]McGill University, Montreal, QC, Canada; [2]Can-SOLVE CKD, Vancouver, BC, Canada; [3]University of Calgary, Calgary, AB, Canada; [4]University of Toronto, Toronto, ON, Canada; [5]BC Support Unit - Island Health, Victoria, BC, Canada; [6]Kidney Foundation of Canada, Montreal, QC, Canada; [7]KRESCENT, Montreal, QC, Canada.*

Background: Despite increasing recognition that Inclusion, Diversity, Equity, and Accessibility (IDEA) principles are essential to research, how to meaningfully quantify and apply these principles at a network level is unclear. Here, we outline a holistic approach taken by our patient-oriented kidney research network, Can-SOLVE CKD.

Methods: A multidisciplinary team, composed of patient partners, researchers, clinicians, and network partners, co-developed a series of 7 brainstorming workshops (3 groups; 19 patient partners, 17 researchers/clinicians, 13 staff from July 2023 to January 2024) to identify the network's existing IDEA strengths and key priorities. A thematic analysis identified themes to inform the network's IDEA mobilization plan.

Results: Four themes were identified: (1) Strength in existing network culture through Indigenous input and patient-oriented approach, establishing culturally safe spaces and ensuring systematic support and safety in communication; (2) Barriers in equitable participation due to a fragmented understanding of opportunities and accommodation limitations; (3) Ensuring permanence within the broader health context via maintenance concerns, awareness of network initiatives and promoting kidney health equity; and, (4) Outreach at the public, network and team levels focused on overcoming recruitment barriers and enhancing impact. This reveals an opportunity to tailor implementation strategies based on the scale of change within the network, ensuring that IDEA interventions are appropriately calibrated to the magnitude of the mobilization plan.

Conclusions: Meaningful assessment and application of IDEA principles requires the involvement of people with diverse lived experiences. We describe a collaborative, holistic approach our patient-oriented kidney research network has taken to identify core strengths and guide our IDEA strategy moving forward.

Effects of Orally Ingested Microplastics on the Structure and Function of the Kidneys

Hannah Triebel, Frank Schweda, Hayo Castrop. *University of Regensburg, Institute of Physiology, Regensburg, Germany.*

Background: Plastics are chemically inert and durable materials with long-term deposition in the environment. Little is known about the functional consequences of oral microplastic (MP) ingestion. Most MP particles in the environment consist of fibers and irregular fragments. The size, shape, and composition of the MP particles presumably determine the degree of MP toxicity. Thus, fibers are generally more critical than aspherical fragments, and fragments are more problematic than spherical particles. In the present study we assessed the distribution of MP particles in the organism and the consequences of MP deposition in the kidney. We hypothesized that sharp and aspheric particles, mimicking the real-world situation of MP in the environment, are more deleterious compared with spherical particles.

Methods: Aspheric and spheric MP of different polymers were synthetized, and fluorescence labeled (polystyrene, polypropylene, polyethylene terephthalate, 1-50 µm). The deposition of the labeled particles was determined in mice after oral gavage (2.5 mg/d, 5 or 10 consecutive days, 30 mice (n=6 each)). 3-D histological assessment was performed by fluorescence confocal microscopy of thick tissue sections. In addition, the quantitative organ distribution was determined in vivo using MP with embedded upconverting nanoparticles ($NaYF_4$:Yb,Tm).

Results: We found a considerable enrichment of MP particles in the kidney. Furthermore, MP particles were present in renal blood vessels including glomerular capillaries. Large MP particles (> 5 µm) were also found in the lumen of some tubules of the renal cortex and were accompanied by an influx of immune cells, suggesting a pro-inflammatory effect of MP particles. Experiments using the isolated perfused kidney model showed the increased tubular uptake of labeled albumin in nephrons in which particles were located, suggesting a loss of the integrity of the filtration barrier with subsequent passage of particles from glomerular capillaries into the tubular system.

Conclusions: In summary, ingested MP particles with properties similar to those found in the environment, compromise the structural and functional integrity of the kidney and may trigger local inflammatory responses leading to kidney injury.

FR-PO1049

Effects of Type of Protein Intake on Risk of Kidney Disease Progression among Patients with Nondialysis-Dependent CKD: A Systematic Review

Michelle M. Wong,[1] Dani Renouf,[2] Megan Borkum,[1] Emily Lauren L. Simms,[1] Nicole Huang,[3] Adeera Levin.[1] *[1]University of British Columbia, Vancouver, BC, Canada; [2]St. Paul's Hospital, Vancouver, BC, Canada; [3]Fraser Health Authority, Surrey, BC, Canada.*

Background: While diets restricted in protein quantity are recommended by kidney nutrition guidelines, the effect of the type of protein on CKD progression is not known. Thus, we performed a systematic review to assess the effects of plant-based diets on CKD progression.

Methods: We searched MEDLINE, EMBASE, Cumulative Index of Nursing and Allied Health Literature, Education Resources Information Center, Cochrane Central Register of Controlled Trials, Web of Science from January 1990-November 28, 2022. We included RCTs and observational studies with prospectively-collected data assessing type of protein in patients with non-dialysis CKD. The primary outcome was progression to kidney failure. Secondary outcomes included change in eGFR, albuminuria, all-cause mortality, quality of life. Two authors independently screened titles/abstracts, reviewed full text articles, and extracted data. Meta-analysis was not possible due to variability in outcome reporting and sparse data. Risk of bias was assessed using the Nutrition Quality Evaluation Strengthening Tools.

Results: Eight studies assessing type of protein or dietary patterns emphasizing plant-based food were included. There were 3 RCTs (N=179 patients), which assessed soy protein (2 studies) and Mediterranean diet (1 study) *vs.* control diets. There were 5 cohort studies (N=4221) assessing plant-based protein intake (3 studies), Mediterranean diet score (1 study), and DASH diet score (1 study). While RCTs demonstrated inconsistency in eGFR outcome, cohort studies demonstrated that higher plant-based protein intake and higher DASH/Mediterranean diet scores were associated with lower risks of end-stage kidney disease and mortality (Figure). Risk of bias was high in RCTs due to selection bias.

Conclusions: Our systematic review of type of protein on CKD progression demonstrated reduced risk of CKD progression in cohort studies, but RCT evidence was limited.

Figure. Summary of Findings

Outcome	Type of Study	Intervention/ exposure of interest and comparator	Range of Effects	# of studies by result	# of participants (# of studies)	Certainty of Evidence
Kidney Failure (ESKD)	RCT Cohort	N/A High vs. low DASH diet score	N/A Adjusted HR 0.38 (95% CI 0.26-0.53) to 0.83 (95% CI 0.69-0.99)	0 2 studies favored high DASH diet score	0 3513 (2)	N/A Moderate
Change in eGFR	RCT	Soy protein diet; Mediterranean diet vs. control diet	% change: -5.9% plant-based diet vs. +11.3% control diet (p=0.048) Mean difference: 0.15 to 0.60 ml/min/1.73 m^2 (95% CI -1.21-2.41)	1 study favored soy protein diet 2 studies: no statistically significant difference	179 (3)	Low
	Cohort	Plant protein as a continuous measure	Adjusted change in eGFR: 0.17 (95% CI -0.03 - 0.38) to 1.60 (-19.7 - 22.3) ml/min/1.73 m^2 for each 10 g/day of plant protein	1 study favored higher plant-based protein intake 1 study: no statistically significant difference	858 (2)	Moderate
Mortality	Cohort	High vs. low DASH diet score; High vs. low plant protein intake to total protein ratio	Adjusted HR 0.67 (95% CI 0.46-0.96) to 1.07 (95% 0.84-1.35)	2 studies favored of high DASH diet score or high plant protein diet 1 study: no statistically significant difference	4578 (3)	Moderate

FR-PO1050

Beverage Patterns and Risk of CKD Progression in the Diet, CKD, and Apolipoprotein L1 (DCA) Study

Tolulope V. Adebile,[1] Runqi Zhao,[1] Theophilus I. Umeizudike,[7] Bolanle A. Omotoso,[2] Nanna R. Ripiye,[3] Yemi R. Raji,[4] Ernestina Eduful,[12] Rasheed A. Gbadegesin,[5] Edward P. Kwakyi,[6] Manmak Mamven,[3] Adaobi Solarin,[7] Ifeoma I. Ulasi,[8] Dwomoa Adu,[6] Akinlolu Ojo,[9] Sushrut S. Waikar,[1] Rulan S. Parekh,[10] Diane C. Mitchell,[11] Titilayo O. Ilori.[1] *[1]Boston University Chobanian & Avedisian School of Medicine, Boston, MA; [2]Obafemi Awolowo University Teaching Hospital Complex, Ile-Ife, Nigeria; [3]University of Abuja Teaching Hospital, Gwagwalada, Nigeria; [4]University of Ibadan and University College Hospital, Ibadan, Nigeria; [5]Duke University Medical Center, Durham, NC; [6]Department of Medicine and Therapeutics, University of Ghana Medical School, Accra, Ghana; [7]Lagos State University College of Medicine, Ojo, Nigeria; [8]College of Medicine, University of Nigeria, Nsukka, Nigeria; [9]The University of Kansas School of Medicine, Kansas City, KS; [10]Department of Medicine, Women's College Hospital, Hospital for Sick Children and University of Toronto, Toronto, ON, Canada; [11]Texas A&M AgriLife Research, College Station, TX; [12]The Bank Hospital, Accra, Ghana.*

Background: A few studies have established a relationship between beverage patterns and CKD progression, with sugar-sweetened beverages increasing the risk of CKD. We aim to identify beverage consumption patterns of well-phenotyped West Africans with CKD and examine their association with CKD progression.

Methods: We conducted a prospective analysis from the DCA cohort (n=748) to investigate diet-gene interactions in APOL1. We included data from a subset of

participants with complete information on beverage intake from the 24-hour dietary recalls. CKD progression was defined as ≥40% decline from baseline eGFR at enrollment to DCA (2021-2023) and initiation of dialysis. Beverage consumption patterns were identified through principal component (PC) analysis, and their associations with CKD progression were analyzed using multivariate Cox proportional hazard models.

Results: There were 52 cases of CKD progression over a median follow-up period of 31 (IQR: 33.41,25.17) months. We identified four beverage patterns (Table), of which Low Sugar-Sweetened Beverages Plus Alcohol Beverage Pattern demonstrated a significantly lower risk of CKD progression [tertile 2 vs 1 HR: 0.42, 95% CI: 0.19,0.93].

Conclusions: The Low Sugar-Sweetened Beverages Plus Alcohol Beverage Pattern was associated with lower risk of CKD progression, indicating that moderate adherence to this pattern is linked to a reduced risk of CKD progression. The study is the first to establish the beverage patterns of well-phenotyped West African CKD patients and their association with CKD progression. Future investigations should conduct long-term prospective studies to validate and further explore the observed association.

Funding: NIDDK Support, Commercial Support - Department of Medicine, Boston Medical Center.

Table: Association of Beverage Consumption Patterns* in the Diet, CKD, and APOL1 study with CKD Progression (n =304)

	Tertile of Beverage Patterns'			Continuous	P-value
	Tertile 1	Tertile 2	Tertile 3		
Alcoholic Beverage Pattern (PC1)					
Model 1	1 (ref)	1.64 (0.75, 3.59)	2.16 (0.10, 4.65)	1.10 (0.80, 1.52)	0.55
Model 2	1 (ref)	1.67 (0.74, 3.74)	2.01 (0.84, 4.80)	1.07 (0.79, 1.46)	0.65
Dairy and Tea Beverage Pattern (PC2)					
Model 1	1 (ref)	0.53 (0.23, 1.21)	0.89 (0.44, 1.79)	0.95 (0.72, 1.26)	0.74
Model 2	1 (ref)	0.53 (0.22, 1.27)	1.04 (0.50, 2.17)	0.96 (0.71, 1.30)	0.79
Low Sugar-Sweetened Beverages Plus Alcohol Beverage Pattern (PC3)					
Model 1	1 (ref)	0.58 (0.31, 1.10)	1.01 (0.47, 2.17)	1.05 (0.80, 1.36)	0.74
Model 2	1 (ref)	**0.42 (0.19, 0.93)**	0.64 (0.27, 1.48)	1.03 (0.77, 1.36)	0.86
Medium Sugar-Sweetened Beverage Pattern (PC4)					
Model 1	1 (ref)	0.80 (0.45, 1.43)	0.59 (0.20, 1.74)	0.84 (0.58, 1.23)	0.38
Model 2	1 (ref)	0.93 (0.50, 1.75)	0.37 (0.10, 1.41)	0.81 (0.53, 1.23)	0.32

** Each beverage consumption pattern was defined by the correlation of the PCs with the beverage consumed (±0.20).*

' The participants received a score for each pattern based on their consumption and the PC scores were divided into three equal groups to facilitate comparisons. Tertile 3 represents the highest adherence to a specific beverage pattern, tertile 2 moderate, and tertile 1 the lowest.

Model 1: adjusted. for age, sex, and Pid site.

Model 2: adjusted for Hypertension, age, Sex, Education, Income, Smoking, Diabetes, proteinuria, baseline eGFR, BMI, Total Energy (per 1,000 KCAL), and Pid site.

The proportional assumption was tested, with no violations observed.

FR-PO1051

Kidney Function and Ultra-processed Food Intake among Older Puerto Rican Adults Living in Boston

Kristin Leonberg,[1] Kaylea D. Flanagan,[2] Katherine L. Tucker,[2] Tammy Scott,[1] Manish Maski,[3] Elena N. Naumova.[1] *[1]Tufts University Friedman School of Nutrition Science and Policy, Boston, MA; [2]University of Massachusetts Lowell, Lowell, MA; [3]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Ultra-processed food (UPF) intake has been associated with higher chronic kidney disease (CKD) risk and disease progression. These foods are ready-to-eat industrial formulations offering convenience and lower cost, but lower nutritional value. Trends in increased consumption have been reported among the general United States (US) population across the lifecycle and among population subgroups. Previous reports indicate that, in the US Hispanic population, 63% of energy intake is from UPF. However, these studies do not provide specific information on the Puerto Rican (PR) subpopulation, as the composition of the Hispanic race/ethnic groups remain unclear. We, therefore, aimed to describe kidney function and UPF intake and their trends among older adults enrolled in the Boston Puerto Rican Health Study (BPRHS).

Methods: The BPRHS is a longitudinal cohort of older PR adults in the Boston area, established in 2004. We estimated kidney function (eGFR) using the 2021 CKD_{epi} equation (without race) at baseline, and ~2 and ~6-year follow-ups. We estimated the percentage of energy intake (Pkcal) from UPF using dietary data collected with a food frequency questionnaire, and identified UPF based on the Nova processed food classification system at baseline and ~2-y follow-up.

Results: At baseline, 1371 (71% female) adults with mean (SD) age 57.1 (7.6) y had eGFR and Pkcal-UPF data available. Mean (SD) eGFR was 91 (±18.0) mL/min/1.73m^2. Mean (SD) Pkcal-UPF was 27% (±12%) and did not differ between males and females (P = 0.43). A total of 1145 (71% female) adults had eGFR and Pkcal-UPF data available at the ~2-year follow-up. Mean eGFR decreased by 3% (87.9 mL/min/1.73m^2) after ~2-y and Pkcal-UPF remained similar, representing 26% (±12%) dietary intake.

Conclusions: Among participants enrolled in BPRHS, the Pkcal-UPF was relatively low, relative to reports from other populations. Further evaluation is needed to assess the temporal association between Pkcal-UPF and eGFR decline in this population.

FR-PO1052

Association between Healthy Dietary Patterns and CKD: Findings from the Korean National Health and Nutrition Examination Survey (KNHANES), 2019-2021

Minsang Kim,[1] Kyungdo Han,[2] Sehoon Park,[1] Jin hyuk Paek,[3] Woo Yeong Park,[3] Kyubok Jin,[3] Seungyeup Han,[3] Dong Ki Kim,[1] Yaerim Kim.[3] *[1]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [2]Soongsil University, Dongjak-gu, Seoul, Republic of Korea; [3]Keimyung University School of Medicine, Daegu, Republic of Korea.*

Background: A healthy dietary pattern is linked to a lower risk of developing chronic kidney disease (CKD) and its progression. Considering the different dietary pattern by country, we aim to evaluate the impact of dietary pattern on the risk of incident CKD using the Korean Healthy Eating Index (KHEI), a tool designed to assess diet quality in Koreans.

Methods: In this cross-sectional study, we included participants ≥19 years-old in the eighth Korean national health and nutrition examination survey conducted from 2019 to 2021. The KHEI consists of 3 categories and 14 components (eight for adequacy, three for moderation, three for balance), with a higher KHEI indicating healthier eating habits. CKD was defined as an estimated glomerular filtration rate <60 mL/min/1.73m^2 or urine albumin-creatinine ratio ≥30 mg/g. The risk of CKD was evaluated according to the quartiles of the KHEI using logistic regression analysis, adjusted for various clinicodemographic characteristics.

Results: In total, 12,454 participants were included in this study. Those in the higher quartile of the KHEI were older, had lower proportions of men, current smoker, and heavy alcohol drinker. Although there were higher proportion of CKD or lower eGFR in the highest quartile of KHEI, adjusted mean of KHEI was lower in participants with CKD. Among the subcategories of KHEI, there was no difference in moderation or energy balance, but the score of most components in adequacy category were higher in participants with CKD (Figure 1). Participants in the highest quartile of KHEI had a significantly lower risk of CKD (adjusted odds ratio, 0.75 [0.60–0.95]) compared to those in the lowest quartile (Table 1).

Conclusions: The dietary pattern representing KHEI is associated with various characteristics including comorbidities. A greater KHEI decreased risk of incident CKD, and healthy eating pattern would be suggested especially in participants with a risk of CKD.

FR-PO1053

Effects of Sulforaphane Supplementation on Gut Microbiota in Nondialysis-Dependent Patients with CKD

Denise Mafra,[1,2] Marcia M. Ribeiro,[2] Isadora Britto,[2] Bruna R. de Paiva,[1] Ludmila F. Cardozo,[1] Pedro Ivo N. de Almeida,[3] Henrique F. Santos.[1] *[1]Universidade Federal Fluminense, Niteroi, Brazil; [2]Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil; [3]Fundacao Oswaldo Cruz, Rio de Janeiro, Brazil.*

Background: Gut dysbiosis is associated with systemic inflammation and the accumulation of uremic toxins. Sulforaphane isothiocyanate (SFN) is a bioactive compound derived from cruciferous vegetables that may mitigate gut dysbiosis. SFN has anti-inflammatory and antioxidant properties, improving permeability and intestinal function and impacting dysbiosis. This study aimed to explore the effects of SFN supplementation on gut microbiota in patients with CKD.

Methods: This study was a placebo-controlled longitudinal study. The patients were randomly assigned to either the intervention group, which received 400 ug/day of SFN, or the placebo group, which received corn starch for 30 days. We assessed the fecal microbiome using high-throughput sequencing of 16S rRNA gene amplicons on the Illumina MiSeq platform. The data was processed using the QIIME 2 software package. We calculated the alpha diversity using RStudio and the phyloseq library. We used a network of nodes and edges to represent the genus-level taxa and the correlations between them. We analyzed the co-occurrence patterns using the SparCC algorithm and the SpiecEasi library in R. The PageRank algorithm was used to identify the core members of each microbiome. We performed Kruskal-Wallis and PERMANOVA tests to analyze differences between profiles.

Results: 16 patients participated (12 women, age 61.4 ± 11.6 years, BMI 30.1 ± 7.0 kg/m^2, and glomerular filtration of 37.4 ± 12.9 mL/min). We constructed gender co-occurrence networks for SFN and placebo groups. After the intervention, the frequency of genera Bacteroidetes, Firmicutes, and Proteobacteria was reduced (Fig 1).

Conclusions: The intervention simplified the co-occurrence network of microbial generation in the gut of non-dialysis CKD patients. Expressing the ability of SFN to modify the diversity of the gut microbiota.

Funding: Government Support - Non-U.S.

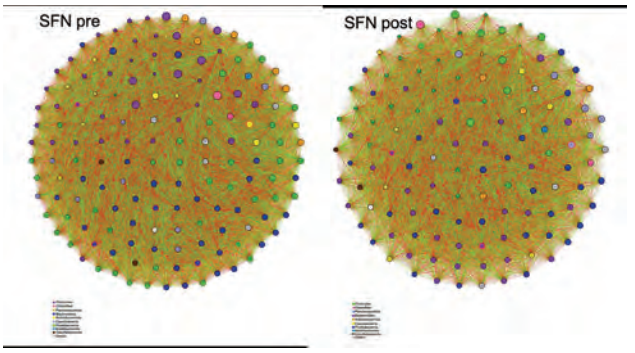

Fig 1. Co-occurrence measures in patients who received SFN

FR-PO1054

Effects of Propolis Supplementation on the Gut Microbiota in Patients Undergoing Hemodialysis: A Randomized Controlled Clinical Trial

Denise Mafra,[1,2] Larissa d. Fonseca,[1] Marcia M. Ribeiro,[2] Júnia Schultz,[3] Andresa Berretta,[4] Marcelo Ribeiro-Alves,[5] Alexandre Rosado.[3] *[1]Universidade Federal Fluminense, Niteroi, Brazil; [2]Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil; [3]King Abdullah University of Science and Technology, Thuwal, Saudi Arabia; [4]Apis flora, Ribeirão Preto, Brazil; [5]Fundacao Oswaldo Cruz, Rio de Janeiro, Brazil.*

Background: Several studies have shown that propolis (resin made by bees) could modulate gut microbiota *in vitro* and animal models. However, no study has been conducted on patients with chronic kidney disease (CKD) undergoing hemodialysis (HD). This study aimed to evaluate the effects of propolis supplementation on the gut microbiota of CKD patients undergoing HD.

Methods: This is a longitudinal, double-blind, placebo-controlled trial with 42 patients randomized into two groups: one group received propolis (4 capsules of 100 mg/day containing concentrated and standardized dry EPP-AF® green propolis extract), and the other group received a placebo (4 capsules of 100 mg/day containing microcrystalline cellulose, magnesium stearate, and colloidal silicon dioxide) for two months. Gut microbiota composition was assessed by extracting fecal DNA, PCR amplification of the V4 region of the 16S rRNA gene, and short-read sequencing on the Illumina NovaSeq PE250 platform.

Results: Forty-one patients completed the study, with twenty in the placebo group [45.5 ± 14 years, seven men and 13 women, BMI 24.8± 6.8 kg/m^2, time on HD 44.5 ± 46.5 months, Kt/V 1.7 ± 0.58] and twenty-one in the propolis group [45 ± 12 years, eight men and 13 women, BMI 22.8 ± 3.7 kg/m^2, time on HD 68 ± 60 months, Kt/V 1.66 ± 0.44]. The obtained data revealed that propolis supplementation increased the gut microbiota's evenness and richness (observed) (**Fig. 1**).

Conclusions: Short-term supplementation with EPP-AF® propolis dry extract seems to increase the alpha diversity of gut microbiota in patients with CKD on HD.

Funding: Government Support - Non-U.S.

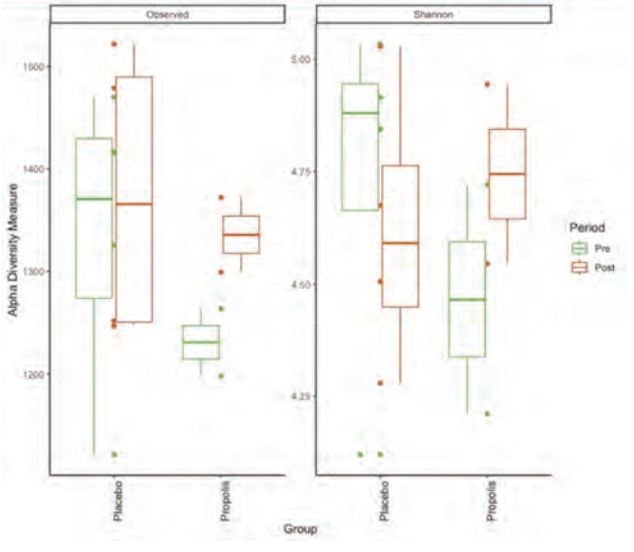

Fig 1. Alpha-diversity of CKD (HD) patients' gut microbiota on propolis and placebo supplementation. (A) Observed zOTUs (richness) and (B) Shannon index (diversity).

FR-PO1055

Impact of Fermentable and Viscous Dietary Fiber on Gut-Derived Uremic Toxins in Rats with Progressive CKD

Annabel Biruete,[1,2] Kalisha O'Neill,[2] Kathleen M. Hill Gallant,[4,2] Henriette de Loor,[3] Pieter Evenepoel,[3] Neal X. Chen,[2] Sharon M. Moe.[2] *[1]Purdue University, West Lafayette, IN; [2]Indiana University School of Medicine, Indianapolis, IN; [3]Katholieke Universiteit Leuven, Leuven, Belgium; [4]University of Minnesota Twin Cities, Minneapolis, MN.*

Background: Dietary fiber has been shown to lower gut-derived uremic toxins. However, this effect may depend on the fiber's physicochemical properties. Our goal was to examine the dietary fiber impact based on their fermentability (i.e., metabolized by the gut microbiota) and viscosity (i.e., gel-forming capacity) properties on circulating and urinary microbially-derived uremic toxins in a rat model of progressive CKD.

Methods: 22-wk-old Cy/+ male rats (~50% kidney function of normal; CKD hereafter) were randomly assigned to one of four treatments (all 10% w/w; **Table 1**). Treatments lasted 10 wk and rats were euthanized at 32-33 wk of age (kidney failure; ~15% of normal). During the last week of the study, rats were placed in metabolic cages for 3 days for urine collection. Serum and urine creatinine (Cr) were analyzed using colorimetric assays; indoxyl sulfate, P-cresyl sulfate, and phenyl sulfate were quantified in urine (normalized to Cr) and serum by ultra-performance liquid chromatography-tandem mass spectrometry. One-way ANOVA was used to test the effect of dietary fiber types on outcomes with post-hoc comparisons vs. cellulose.

Results: At 32-33 wk, serum indoxyl sulfate was not different between treatments, but urinary indoxyl sulfate was 2-3 times higher with pectin compared to cellulose ($p=0.008$). Serum P-cresyl sulfate was lower in the inulin and psyllium groups compared to cellulose ($p<0.0001$), but urinary P-cresyl sulfate was 7-17 times higher in pectin compared to cellulose ($p<0.0001$). Serum phenyl sulfate was lower in the psyllium and pectin groups compared to cellulose ($p<0.0006$), but urinary phenyl sulfate was lower in all groups compared with cellulose ($p<0.009$). Of note, serum and urine phenyl sulfate concentrations were near zero in the psyllium-treated rats.

Conclusions: Aromatic amino acid-derived uremic toxins were differentially impacted by dietary fiber types in rats with progressive CKD. This suggests that fiber's fermentability and viscosity properties are important to consider in future trials.

Treatment	Fermentable	Viscous
Cellulose	No	No
Inulin	Yes	No
Psyllium	No	Yes
Pectin	Yes	Yes

FR-PO1056

Investigating the Correlation between Serum Cholinesterase Levels and Kidney Function

Chenyu Lei, Xinyi Fu, Wenjing Cai, Qingying Shi, Anning Xu, Linlin Yuan, Xinling Liang, Zhiming Ye, Zhilian Li. *Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangdong, China.*

Background: Serum cholinesterase is a commonly used biomarker for organophosphate poisoning and liver function assessment. However, the relationship between serum cholinesterase levels and renal function, as defined by estimated Glomerular Filtration Rate (eGFR), remains poorly understood. This retrospective study aimed to explore the correlation between these two biomarkers in a large patient cohort.

Methods: We retrospectively analyzed data from 488,118 patients aged 18 years or older with renal and liver function data from Guangdong Provincial People's Hospital from January 2019 to October 2023. Patients with abnormal liver function tests were excluded. Patients were stratified into five groups based on estimated glomerular filtration rate (eGFR) according to KDIGO CKD staging guidelines. Serum cholinesterase levels were compared across these groups using the Kruskal-Wallis test. Statistical analyses were performed using SPSS version 22.0.

Results: The median serum cholinesterase in the study population was 7837.00 U/L (IQR: 6693.00 - 9018.00 U/L). A significant inverse correlation was observed between serum cholinesterase levels and eGFR ($p < 0.01$). Median serum cholinesterase levels decreased progressively with declining eGFR, as shown below: eGFR ≥ 90 mL/min/1.73 m^2: 7917.0 (6789.0, 9097.0) U/L eGFR 60-89 mL/min/1.73 m^2: 7888.0(6768.0,9035.0)U/L eGFR 30-59 mL/min/1.73 m^2:7251.0(6097.0,8451.0)U/L eGFR 15-29 mL/min/1.73 m^2: 6201.0(4982.5,7468.5)U/L eGFR < 15 mL/min/1.73 m^2: 5907.0(4861.0,6980.0) U/L Pairwise comparisons between each eGFR group also revealed statistically significant differences ($p < 0.01$).

Conclusions: Our findings demonstrate a clear association between serum cholinesterase levels and renal function decline. As eGFR decreases, serum cholinesterase levels significantly decrease, suggesting a potential role for serum cholinesterase as a marker of renal dysfunction progression. Further research is warranted to explore the clinical implications of this association.

FR-PO1057

Association between Dietary Fiber Intake and Uremic Pruritus in Patients with CKD

Yihuan Cai, Qianqian Han, Fengchu Qing, Qiongqiong Yang. *Sun Yat-Sen Memorial Hospital, Guangzhou, China.*

Background: Uremic pruritus is one of the common symptoms of chronic kidney disease (CKD). Previous studies suggest that mild-inflammation may be one of the causes. The role of dietary fiber in reducing inflammatory factors has become increasingly recognized. It is not clear whether the level of intake of dietary fiber is related to the itchiness in CKD patients.

Methods: This was a cross-sectional study that included patients with CKD stages 1-5 and excluded those who used hormones and immunosuppressants within 3 months and suffered from other skin diseases. The level of itchiness was assessed by visual analog scale (VAS). Patients were classified as pruritus group(VAS >0) and non-pruritus group(VAS = 0). Dietary fiber intake was recorded using a 3-day dietary survey method. The differences in intake of total dietary fiber, vegetable dietary fiber, and cereal dietary fiber were compared between different groups.

Results: A total of 151 patients were included in this study, with a median age of 49.00 (37.00, 58.00) years and a median eGFR of 28.07 (8.27, 77.00) ml/min/1.73m^2. A total of 42 (27.81%) patients had pruritus, the mean itch VAS score was 5.28±0.35. Compared to patients without pruritus, CKD patients with pruritus were older [53.50(45.75, 61.00) years *vs* 47.00(34.00 56.00) years, *P*=0.003], lower glomerular filtration rate [9.87 (5.23, 37.35) ml/min/1.73m^2 *vs* 36.15 (12.04, 83.98) ml/min/1.73m^2, *P* <0.001], blood potassium [4.37(3.89,4.82) mmol/L *vs* 4.07(3.70,4.43) mmol/L, *P* =0.018], and had higher eosinophil levels [0.22(0.13,0.40) x 10^9/L *vs* 0.16(0.08,0.26) x 10^9/L, *P*=0.007]. For dietary fiber intake, pruritic patients consumed less vegetable dietary fiber than non-pruritic patients [3.55(2.20,5.03) g/day *vs* 4.40 (2.55,6.40) g/day, *P*=0.011], but there was no difference in terms of grain dietary fiber [2.55(1.78,3.33) g/day *vs* 2.30(1.50. 3.20) g/day, *P*=0.419]. In unadjusted logistic regression, lower vegetable dietary fiber was associated with a higher risk of itching (OR:0.819, 95% CI: 0.695-0.965, *P*=0.017). However, after adjusting for age, serum creatinine, and blood potassium, vegetable dietary fiber was not associated with the risk of itching (*P*=0.059).

Conclusions: Patients with pruritus in CKD consumed less vegetable dietary fiber than those without pruritus. Low levels of vegetable dietary fiber intake may be associated with uremic pruritus.

FR-PO1058

Dietary Fiber Intake and Mental Health in a Multicenter Prospective Hemodialysis Cohort

Yoko Narasaki,[1] Amy S. You,[1] Silvina Torres Rivera,[1] Danh V. Nguyen,[2] Kamyar Kalantar-Zadeh,[3] Connie Rhee.[1] *[1]University of California Los Angeles, Los Angeles, CA; [2]University of California Irvine, Irvine, CA; [3]Harbor-UCLA Medical Center, Torrance, CA.*

Background: While studies in CKD patients show dietary fiber intake is associated with better health outcomes including lower incidence of CKD, risk of CV events, generation of uremic toxins and inflammatory markers, and less symptom burden (i.e., constipation), little is known about the impact of dietary fiber intake on mental health. We thus sought to examine the relationship of dietary fiber intake with depression in a prospective HD cohort.

Methods: Among 584 HD patients from the multicenter NIH MADRAD cohort recruited across 16 outpatient dialysis clinics, information regarding dietary fiber intake obtained via protocolized Food Frequency Questionnaires (FFQs) and depression severity ascertained by the Beck Depression Inventory-II (BDI-II) administered over 10/2011-9/2022. We examined associations of dietary fiber intake categorized as quartiles with likelihood of having a low (more favorable) BDI-II score (i.e., lowest quartile [Q1]) using multivariable logistic regression models.

Results: The mean±SD of age of the cohort was 54±15 years, among whom 55% were male, 33% were of Black race, and 48% were of Hispanic ethnicity. In unadjusted, case-mix, expanded case-mix, and expanded case-mix+laboratory adjusted analyses, the highest quartile (Q4) of residual dietary fiber intake was associated with higher likelihood of a lower (more favorable) BDI-II score (Ref: Q1, Table 1). In the expanded case-mix+laboratory models, compared to patients with the lowest quartile (Q1) of fiber intake, those with the highest quartile (Q4) of fiber intake had a 2.3 higher likelihood of having a more favorable BDI-II score.

Conclusions: In a well-characterized prospective HD cohort, higher dietary fiber intake was associated with lower likelihood of depression. Further studies are needed to determine the causal mechanisms underlying dietary fiber intake and mental health in this population.

FR-PO1059

Effects of Intradialytic Parenteral Nutrition on Blood Glucose in Patients on Maintenance Hemodialysis: A Multicenter, Randomized, Open-Label Study

Miyuki Tani,[1] Michihiro Hosojima,[2] Hideyuki Kabasawa,[2] Eiichiro Kanda,[3] Miho Nagai,[4] Toshiko Murayama,[5] Satoru Kamoshita,[1] Akiyoshi Kuroda,[6] Yoshihiko Kanno.[4] *[1]Medical Affairs Department, Research and Development Center, Otsuka Pharmaceutical Factory, Inc., Tokyo, Japan; [2]Department of Clinical Nutrition Science, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [3]Department of Health Data Science, Kawasaki Medical School, Okayama, Japan; [4]Department of Nephrology, Tokyo Medical University, Tokyo, Japan; [5]Department of Health and Nutrition, Faculty of Human Life Studies, University of Niigata Prefecture, Niigata, Japan; [6]Research and Development Center, Otsuka Pharmaceutical Factory, Inc., Tokyo, Japan.*

Background: The intradialytic parenteral nutrition (IDPN) is reported to improve the nutritional status in the dialysis patients. However, effects of IDPN on the blood glucose (BG) are not enough studied while intra-dialysis unconscious hypoglycemia is the issue if the patients are malnourished.

Methods: Study patients were 27 maintenance hemodialysis patients. The investigational (IE) group received the IDPN with ENEFLUID® (550mL; energy, 310kcal; glucose, 37.5g; amino acids, 15g; lipid, 10g) 3 times a week for 12 weeks (wks); control (CT) group did not. The interstitial fluid glucose concentration was monitored every 15 minutes 2 wks after study initiation and before study completion. Outcomes: frequencies and durations of hypoglycemia (BG<70mg/dL) and hyperglycemia (BG>180mg/dL) per 24 hours, area over the curve for glucose<70mg/dL (AOC) per 24 hours, area under the curve for glucose>180mg/dL (AUC) per 24 hours, and Time in Range (BG, 70-180mg/dL). The Mann-Whitney U test was used for the intergroup comparisons.

Results: Mean age was 70.6 and mean body mass index was 19.9 for the study patients. Patients used for the statistical analysis were 14 in the IE group and 13 in the CT group; however, 2 of the IE group withdrew and could not receive the BG monitoring 2 wks before study completion. The median [interquartile range (IQR)] frequency of hypoglycemia during dialysis for 2 wks were smaller in the IE group than in the CT group resulting in a significant difference between 2 groups: 2 wks after study initiation, 0.0 (0.0-2.0) in the IE group and 6.9 (0.0-56.7) in the CT group; P=0.01; 2 wks before study completion, 0.0 (0.0-7.6) in the IE group and 12.0 (0.0-30.3) in the CT group; P=0.04. Similar results were obtained for the duration of hypoglycemia and AOC. No intergroup difference was observed for the frequency and duration of hyperglycemia and AUC. The median (IQR) Time in Range during dialysis for 2 wks after the study initiation was 100 (98-100)% in the IE group and 86 (41-99)% in the CT group (P=0.005), showing that higher proportion of the IE group patients achieved the target BG.

Conclusions: The IDPN with ENEFLUID® in the maintenance hemodialysis patients may suppress the hypoglycemia while not increasing the hyperglycemia.

FR-PO1060

Efficacy and Safety of Intradialytic Parenteral Nutrition Using ENEFLUID in Malnourished Patients Receiving Maintenance Hemodialysis: A Multicenter, Randomized, Open-Label Study

Hideyuki Kabasawa,[1] Michihiro Hosojima,[1] Eiichiro Kanda,[2] Miho Nagai,[3] Toshiko Murayama,[4] Miyuki Tani,[5] Satoru Kamoshita,[5] Akiyoshi Kuroda,[6] Yoshihiko Kanno.[3] *[1]Department of Clinical Nutrition Science, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [2]Department of Health Data Science, Kawasaki Medical School, Okayama, Japan; [3]Department of Nephrology, Tokyo Medical University, Tokyo, Japan; [4]Department of Health and Nutrition, Faculty of Human Life Studies, University of Niigata Prefecture, Niigata, Japan; [5]Medical Affairs Department, Research and Development Center, Otsuka Pharmaceutical Factory, Inc., Tokyo, Japan; [6]Research and Development Center, Otsuka Pharmaceutical Factory, Inc., Tokyo, Japan.*

Background: The objective of this study was to investigate the efficacy and safety of intradialytic parenteral nutrition (IDPN) using ENEFLUID® (310 kcal, 550 mL) in mild-moderate malnutrition patients receiving maintenance hemodialysis.

Methods: A total of 40 adult patients with a Nutritional Risk Index-Japanese Hemodialysis (NRI-JH) score of 5-10 were enrolled in this multicenter, randomized, open-label study. Patients in the intervention group received IDPN using ENEFLUID® via the dialysis circuit 3 times a week for 12 weeks; those in the control group did not. The primary endpoint was change in serum transthyretin (TTR). The secondary endpoints were changes in nutritional laboratory tests, nutritional parameters, food intake.

Results: For both groups, mean age (72.1±11.4 years) and BMI (20.3±3.0), and median NRI-JH score [7.0 (interquartile range, 6 – 8)], did not differ. One patient withdrew before intervention, leaving 20 intervention and 19 control patients. Mean (95% confidence interval) change in serum TTR (mg/dL) at 12 weeks did not differ between groups: Intervention, 1.0 (-1.1 – 3.2); Control, -0.3 (-2.4 – 1.9); Intragroup difference, 1.3 (-1.7 – 4.3); P = 0.41. The values reflecting protein intake at 12 weeks compared to those on the study initiation day increased in the intervention group [the changes of blood urea nitrogen, 9.4 (2.6 – 16.2) mg/dL; P = 0.007, and normalized protein catabolic rate, 0.10 (0.02 – 0.18) g/kg/day; P = 0.02]. Mean food protein intake (g/kg/day) at 12 weeks increased in the intervention group and decreased in the control group, and differed between groups: Intervention, 0.12 (-0.03 – 0.28); Control, -0.18 (-0.43 – 0.08); Inter-group difference, 0.30 (0.00 – 0.60); P = 0.050. No adverse events occurred.

Conclusions: In patients with mild to moderate malnutrition receiving ENEFLUID® for 12 weeks as IDPN, serum TTR was not improved, decreases in protein intake was mitigated, no adverse events occurred (Trial registration: jRCTs031220296).

FR-PO1061

Comparison of Nutritional Outcomes between Different Techniques of Intradialytic Amino Acid Infusion in Patients on Hemodialysis: A Randomized Controlled Trial

Sophon Dumrongsukit, Yingyos Avihingsanon, Somchai Eiam-Ong, Piyawan Kittiskulnam. *King Chulalongkorn Memorial Hospital Department of Internal Medicine, Bangkok, Thailand.*

Background: Amino acid (AA) loss during catabolic process of dialysis deteriorates protein-energy status of hemodialysis (HD) patients. Therefore, AA replacement is crucial. This study aimed to compare intradialytic amino acid (IDAA) infusion between loading and continuous intradialytic infusion technique, which could provide better AA retention indicated by serum albumin levels.

Methods: This randomized controlled trial (TCTR 20230401003) involved high flux membrane HD patients with a serum albumin level between 3.5 and 3.9 g/dL. Those were randomly assigned in a 1:1 ratio to loading group that started with 50% glucose 100 ml infused for 20 minutes, followed by AA 200 ml infused for 20 minutes at the last hour of the session, or continuous group that administered 50% glucose 100 ml after starting HD followed by AA 200 ml until the end of HD, with a total duration of approximately 3.5 hours. The primary outcome was the difference of albumin levels after 3 months of IDAA supplementation between the two techniques.

Results: A total of 48 HD patients completed the study (n=24 per group). The mean age was 68.9±12.8 years with average MIS of 6.4±2.8 points. Baseline characteristics were not different between groups. Despite comparable energy and protein intake, serum albumin levels were significantly increased in continuous group after 3 months of IDAA (from 3.75±0.14 to 3.94±0.22 g/dL, $p<0.01$) whereas it was still unchanged in the loading group (from 3.76±0.11 to 3.88±0.36 g/dL, $p=0.21$). The average total AA losses in dialysate were not significantly different between the continuous and loading groups (6.7±1.4 VS 7.8±3.7 g/session, respectively, p=0.17). Both plasma essential (p=0.59) and non-essential AA levels (p=0.66) between groups were also similar at the end of study. Muscle mass, strength, and gait speed did not differ between both groups (all p>0.05). Neither volume overload nor hyperglycemia requiring additional insulin therapy was found throughout the study.

Conclusions: IDAA supplementation using continuous infusion during dialysis session appears to be superior to a loading technique in terms of an improvement in serum albumin levels, a survival surrogate among HD patients. The impact of IDAA on clinical outcomes may require larger scale with longer period of study.

Declining Serum Albumin in the Shadow of Stable Body Mass Index: A Mortality Indicator in Predialysis CKD

Menaka Sarav,[1] Prabin Shrestha,[2] Adnan Naseer,[2] Fridtjof Thomas,[2] Keiichi Sumida,[2] Kamyar Kalantar-Zadeh,[3] Csaba P. Kovesdy.[2] *[1]Yale University School of Medicine, New Haven, CT; [2]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [3]University of California Los Angeles, Los Angeles, CA.*

Background: Patients with CKD often experience alterations in body composition and nutritional status as their kidney function declines. Body Mass Index (BMI) has been used as a nutritional marker but may not reflect these changes accurately due to concomitant muscle wasting and fluid retention. The role of alternative nutritional measures such as serum albumin in patients with CKD and stable BMI is unclear.

Methods: We analyzed data from a nationwide cohort of 20,164 US Veterans with stable BMI and multiple serum albumin levels who transitioned to kidney replacement therapy from October 2007 through March 2015. We calculated slopes of serum albumin using mixed effects models for three years preceding dialysis. We examined the association of albumin slope with post-dialysis mortality using Cox models adjusted for demographic characteristics, comorbidities, and baseline eGFR and serum albumin.

Results: The cohort had a mean age of 64 years, with 96% male and 30% African American participants. Despite maintaining stable BMI, 81% of patients displayed a decline in serum albumin levels in the pre-dialysis period (median slope: -0.09 g/dl/year, 25th and 75th percentile: -0.17, -0.02). A steeper decline in serum albumin over time was associated with significantly higher post-dialysis mortality (multivariable-adjusted hazard ratio associated with -1 g/dl/year decline in serum albumin: 1.86, 95% confidence interval: 1.65-2.10, p<0.001).

Conclusions: A significant proportion of patients with advanced CKD display a clinically relevant decline in serum albumin despite maintaining a stable BMI. Our study highlights the inadequacy of stable BMI as a marker of nutritional adequacy in advanced CKD, emphasizing the need for comprehensive nutritional assessments in CKD management.

Funding: NIDDK Support

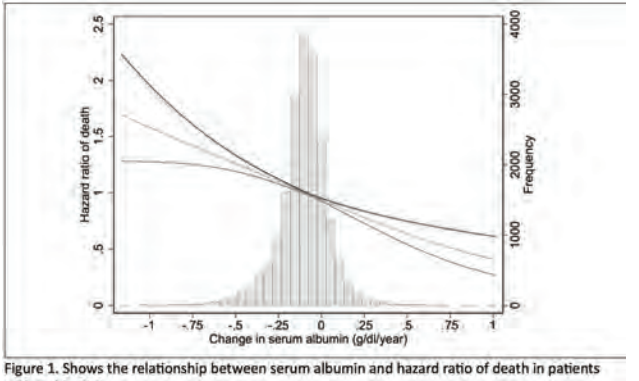

Figure 1. Shows the relationship between serum albumin and hazard ratio of death in patients with stable BMI.

Figure 1. Shows the relationship between serum albumin and hazard rate of death in patients with stable BMI.

A Journey through Low-Energy Diets in Adults with Kidney Disease: Insights from the Slow-CKD Feasibility Study

Marguerite M. Conley,[1,2] Nicole J. Scholes-Robertson,[6] Soraya L. Cunningham,[1] Kirsten S. Hepburn,[4,3] Hannah L. Mayr,[1,3] David W. Mudge,[5,3] Justin J. Holland,[2] David W. Johnson,[5,3] Andrea K. Viecelli,[5,3] Helen L. MacLaughlin.[2,4]
[1]Department of Nutrition and Dietetics, Princess Alexandra Hospital, Brisbane, QLD, Australia; [2]Queensland University of Technology Faculty of Health, Kelvin Grove, QLD, Australia; [3]The University of Queensland, Brisbane, QLD, Australia; [4]Kidney Health Service Metro North Hospital and Health Service, Brisbane, QLD, Australia; [5]Department of Kidney and Transplant Services, Brisbane, QLD, Australia; [6]School of Public Health, the University of Sydney, Sydney, NSW, Australia.

Background: Low energy diets (LEDs) (800-1000 kcal/day) are a proven approach in diabetes management to achieve 10 to 15kg weight loss and diabetes remission. LEDs are an emerging strategy for obesity management in CKD. Understanding consumer experiences of LED programs is critical to help explore feasibility, acceptability and future development and translation. The aim of this study is to describe participants' experiences of, and satisfaction with being involved in a LED weight loss randomized controlled trial (RCT).

Methods: Participants living with stages 1-3 CKD and BMI >30kg/m^2 from the SLOW-CKD feasibility RCT participated in semi-structured interviews. Interviews were audio-recorded, transcribed verbatim and analyzed using thematic analysis. The questions explored participants' experiences and perceptions of following a 3-month LED followed by a 3-month weight maintenance program, or receiving usual care (UC) weight loss support, and participating in a RCT.

Results: Twenty-five adults (14 intervention, 11 UC) were interviewed. Six themes emerged reflecting the lifelong mental and physical struggle of living with obesity; varied motivation to join the study; the importance of health professional and peer support, flexible study appointments and LED approach; and benefits beyond weight loss. After overcoming initial challenges, intervention participants adapted to the LED and were pleased with their commitment and success, many noting improvements in eating habits, diet quality, physical function, and sleep. Several UC participants expressed disappointment and a sense of missed opportunity.

Conclusions: Our findings recognize the uphill battle faced by adults living with CKD and excess weight. Various internal and external factors influenced their decision to start and continue their weight loss journey. LED programs are acceptable if individualised and backed by trusted healthcare professionals. Our findings support LED use in clinical practice and further research on effectiveness on slowing CKD progression. Future trials should include innovative ways to strike balance between scientific rigour and minimising randomisation disappointment.

FR-PO1064

Effects of a Low-Protein Diet in Patients with CKD Taking Renin-Angiotensin System Inhibitors: A Post Hoc Subanalysis of the RICE Study

Michihiro Hosojima,[1] Hideyuki Kabasawa,[1] Mai Tanaka,[1] Akihiko Saito,[2] Ichiei Narita.[3] *[1]Department of Clinical Nutrition Science, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [2]Department of Applied Molecular Medicine, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [3]Division of Clinical Nephrology and Rheumatology, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan*.

Background: Globally, evidence for dietary therapy in patients with chronic kidney disease (CKD) is lacking, and there is an urgent need to accrue such evidence. Previously, we conducted the "Randomized Crossover Trial of Therapeutic Specialized Foods (Low-Protein Rice) for Patients with Chronic Kidney Disease (RICE Study) (Clinical Trial registration number: UMIN000015630)" and demonstrated that the use of low-protein rice (LPR) improves adherence to recommended protein-restricted diets and leads to a reduction in urinary protein in CKD patients. However, some opinions suggest that most reports supporting a low-protein diet (LPD) were conducted before the widespread use of renin-angiotensin system (RAS) inhibitors. Hence, it is crucial to investigate the impact of LPDs on CKD patients who are on RAS inhibitors.

Methods: The RICE study included 104 patients with CKD (Stages G3aA2 to G4) who were randomly assigned to receive nutritional counseling every four weeks alone (control group) or in addition to LPR (LPR group) for 24 weeks. The primary outcome was estimated dietary protein intake determined using the Maroni formula. The secondary outcomes included creatinine clearance (CCr) and urinary protein on the basis of 24-hour urine collection. In this sub-analysis, we targeted only patients taking RAS inhibitors (42 in each group) and conducted similar evaluations.

Results: Protein intake decreased from 1.00 g to 0.90 g/kg ideal body weight (IBW)/day in the control group and from 1.01 g to 0.77 g/kg IBW/day in the LPR group. Adjusted protein intake at baseline showed a decrease of 0.14 g/kg IBW/day (95% CI, 0.0003 to 0.27 g/kg IBW/day) in the LPR group compared to the control group at 24 weeks (P = 0.049). Similarly, urinary protein levels decreased significantly by 0.45 g/day (95% CI, 0.15 to 0.74 g/day) in the LPR group compared to the control group at 24 weeks (P = 0.003). There was no significant difference in CCr between the two groups at 24 weeks.

Conclusions: The LPD using LPR is effective in achieving protein restriction and may contribute to the reduction of urinary protein levels, even in patients with CKD taking RAS inhibitors. Further detailed verification, including prospective studies, is required in the future.

FR-PO1065

Association of Macronutrients with CKD Progression in West Africans

Edward P. Kwakyi,[1] Runqi Zhao,[2] Yemi R. Raji,[3] Manmak Mamven,[4] Tolulope V. Adebile,[2] Adaobi Solarin,[5] Nanna R. Ripiye,[4] Theophilus I. Umeizudike,[5] Ifeoma I. Ulasi,[6] Dwomoa Adu,[1] Rasheed A. Gbadegesin,[7] Rulan S. Parekh,[8] Akinlolu Ojo,[9] Diane C. Mitchell,[10] Sushrut S. Waikar,[2] Titilayo O. Ilori.[2] *[1]University of Ghana Medical School, Accra, Ghana; [2]Boston Medical Center, Boston, MA; [3]University of Ibadan and University College Hospital, Ibadan, Nigeria; [4]University of Abuja, Abuja, Nigeria; [5]Lagos State University Teaching Hospital, Lagos, Nigeria; [6]University of Nigeria, Nsukka, Nigeria; [7]Duke University School of Medicine, Durham, NC; [8]Women's College Hospital, Toronto, ON, Canada; [9]Kansas State University, Manhattan, KS; [10]Texas A&M University System, College Station, TX*.

Background: Dietary modifications slow chronic kidney disease (CKD) progression. However, the association of macronutrients with CKD progression is not well understood.

Methods: We obtained 24h dietary recall data from participants in the Diet, Apolipoprotein L1 and CKD (DCA) study. We determined macronutrient consumption (g/day) for protein, carbohydrates, polyunsaturated fatty acids (PUFAs), monounsaturated fatty acids (MUFAs) and saturated fats; and expressed consumption in quartiles. Our outcome was the total eGFR slope over 3 years. We used a mixed effect linear regression model with the clinical center as a random effect to evaluate the association of macronutrient consumption with total eGFR slope. The results were expressed as beta coefficients with 95% confidence intervals.

Results: We analyzed data from 510 participants: mean age 49 (SD=18) years, 53% male, and mean eGFR was 71ml/min/1.73m^2 (SD=39). In the adjusted models compared to the lowest quartiles of consumption (Q1), Q4 of carbohydrate consumption and PUFAs consumption were associated with a positive eGFR slope change; and saturated fats (Q4 vsQ1) was associated with eGFR slope decline. The p for trend was significant moving from lower to higher polyunsaturated fatty acid consumption (Table 1).

Conclusions: To our knowledge, this is the first study showing the association of macronutrients with CKD progression in a well-phenotyped West African CKD population. Our observations of a positive association between saturated fat consumption and CKD progression and a protective effect of PUFAs are consistent with previous publications. Carbohydrate consumption results were likely due to the higher quality carbohydrates consumed in West Africa.

Funding: NIDDK Support

Table 1. Association of Macronutrient Consumption (g/day) with eGFR Slope (ml/min/1.73m2/year) in a West African Cohort of CKD patients.

A Center for Nutrition Care to Provide Renal Nutrition Therapy to Patients with CKD

Abril G. Espinoza,[1] Julia Nava,[2] Nadia I. Aldana Solis,[2] Araceli Aguilar Gamiño,[2] Sara De La Rosa Diez,[2] Adriana Salinas Rico,[1] Joel D. Kopple.[3] CEAN. *[1]Fresenius Kabi Mexico SA de CV, Tijuana, Mexico; [2]Fresenius Kabi Mexico SA de CV, Ciudad de Mexico, Mexico; [3]The Lundquist Institute, Torrance, CA.*

Background: It is often time-consuming and difficult to both explain the importance of dietary therapy to CKD patients and locate expert renal dietitians. This may discourage physicians and patients from seeking nutritional therapy. This paper describes a novel program that provides nutritional care to people with chronic kidney disease (CKD)

Methods: This is an observational study of the structure and function of CEAN (Centro de Atencion Nutricional – Center for Nutritional Care) Centers in metropolitan areas in Mexico that provide nutritional care to patients with CKD. Data on nutritional outcomes to treatment were obtained retrospectively from the clinic electronic records

Results: The centers consist of several connected offices and are staffed by licensed dietitians who have undergone training in renal nutrition and are experienced in treating patients with CKD. Any licensed physician in Mexico can refer patients to these centers for nutritional assessment and counseling. Patients are followed in the CEAN Center at varying intervals; almost 50% of the patients make four or more follow-up visits to the Center. A comparison of several nutritional measures obtained at the patient's initial baseline visit and at their tenth visit indicate that patients have reduced their dietary protein intake with no reduction in serum albumin or handgrip strength. Body mass index, which averaged in the overweight range, decreased slightly.

Conclusions: The CEAN Centers in Mexico provide an unusual opportunity to provide sophisticated nutritional assessment, dietary therapy and nutritional follow-up for patients with CKD. Preliminary data suggest good nutritional responses to treatment in these centers. Clinical trials are needed to examine more definitively whether these centers improve nutritional and clinical outcomes in patients with CKD

FR-PO1067

Associations of Kidney Dietary Adherence with Kidney Function among Veterans with Diabetic Kidney Disease

Luis M. Perez,[1] Otis D. Wilson,[2,3] Jefferson L. Triozzi,[2,3] Christine D. Jones,[1,4] Adriana Hung,[2,3] Talat Alp Ikizler,[2,3] Yan Sun,[5,6] Sridharan Raghavan.[1,4] Million Veteran Program. *[1]Veterans Affairs, Aurora, CO; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Veterans Affairs, Nashville, TN; [4]University of Colorado Anschutz Medical Campus, Aurora, CO; [5]Emory University, Atlanta, GA; [6]Veterans Affairs, Atlanta, GA.*

Background: Dietary management of chronic kidney disease (CKD) is a key component of improving clinical outcomes, quality of life, and potentially delaying or preventing the progression of kidney disease. Despite debate regarding CKD dietary guidelines, Kidney Foundation Kidney Disease Outcomes Quality Initiative (KDOQI) recommendations for dietary management and CKD medically tailored meal (MTM) standards provide a foundational basis for nutritional interventions. The aim of this study was to evaluate the relationship between dietary patterns and diabetic CKD progression among Veterans in the VA Million Veteran Program (MVP).

Methods: We studied 11,477 Veteran MVP participants with diabetic CKD with nutrition and health data available. We developed a CKD diet score reflecting patient adherence to eight nutrient recommendations (0-2 points each; total of 16 points) based on KDOQI and MTM standards. We calculated potential renal acid load (PRAL in mEq/d) as a second dietary predictor variable. We used generalized linear models to estimate the association of the CKD diet score with co-primary study outcomes, estimated glomerular filtration (eGFR) at 0- and 12-months and 12-month progression to end-stage kidney disease (ESKD; eGFR <15 mL/min/1.73m^2). Models were incrementally adjusted for age, body mass index (BMI), race/ethnicity, smoking, medications, baseline eGFR, hemoglobin a1c, blood pressure, and cardiovascular disease.

Results: Participant demographics were mean (± standard deviation) age 71 ± 9 years, BMI 32.5 ± 6.5 kg/m^2, 97.2% male, and baseline eGFR 40.4 ± 18.1 mL/min/1.73m^2. Higher CKD diet scores, β 0.360 (95% confidence interval 0.091 to 0.629, p=0.01), and lower PRAL values, β -0.077 (-0.098 to -0.056, p<0.01), were associated with higher baseline (0-month) kidney function in fully adjusted models. However, CKD diet scores and PRAL were not associated with 12-month eGFR change or ESKD progression (both p>0.05) in any models.

Conclusions: In adults with diabetic CKD, kidney dietary adherence and lower PRAL were associated with higher kidney function at baseline, but not eGFR change or reduced ESKD progression over a one-year period. Further research is needed to understand and isolate the mid- to long-term impacts of diet for kidney disease progression.

FR-PO1068

Association of Appetite, Oral Frailty, and Oral Health-Related Self-Efficacy with Kidney Replacement Therapy

Shiho Kosaka,[1] Yuki Ohara,[4] Masaaki Yanishi,[3] Tsuguru Hatta,[5] Masami Hamada.[2] *[1]Toho Daigaku, Ota-ku, Japan; [2]Josai Kokusai Daigaku, Togane, Japan; [3]Kansai Ika Daigaku, Hirakata, Japan; [4]Tokyo Metropolitan Institute for Geriatrics and Gerontology, Tokyo, Japan; [5]Hatta Naika Clinic, Kyoto, Japan.*

Background: Patients with hemodialysis (HD) have a high risk of xerostomia and periodontal disease and an increased likelihood of developing gingival hyperplasia after kidney transplantation (KTX) owing to their use of immunosuppressive drugs. However, we are not aware of published studies on the association of oral frailty status and appetite with kidney replacement therapy. To examine the association between appetite, oral frailty, and oral health-related self-efficacy (OSE) in patients with HD and KTX recipients.

Methods: The following were investigated in patients with HD and KTX recipients by using a questionnaire: demographics (age, sex, height, weight, blood test results, blood pressure, and number of teeth), appetite (CNAQ-J), oral frailty (Oral Frailty Checklist), and OSE (OSE Scale). We statistically analyzed participants after allocating them to two groups: low and high risk for oral frailty. We used χ-squared tests for categorical variables, t-tests for normally distributed continuous variables, Wilcoxon rank-sum tests for non-normally distributed continuous variables, and multiple and logistic regression analysis to examine related factors. This study was approved by the Ethics Committee.

Results: Sixty-one patients with HD and 42 KTX recipients were included in this study. Appetite (HD, 28.9±47.4 vs. KTX, 30.5±3.2; p=0.021) and oral frailty (HD, 3.5±5.7 vs. KTX, 2.39±2.0; p=0.022) scores were both significantly better in KTX recipients, but no significant differences were observed in OSE between the groups. Multivariate analysis revealed that the incidence of oral frailty was 73% lower among KTX recipients (odds ratio [OR], 0.27; 95% confidence interval [CI], 0.11 to 0.62) than that among patients undergoing HD, but the incidence was not significantly different when adjusted for age and sex (adjusted OR, 0.53; 95% CI, 0.18 to 1.52).

Conclusions: In this study, appetite was better and oral frailty was lower among KTX recipients than those among patients with HD. However, whether kidney transplantation has a positive impact on oral frailty and appetite compared to dialysis is difficult to determine, because KTX recipients were significantly younger, and multivariate analysis revealed no significant differences. Longitudinal studies with age- and sex-matching should be performed to determine whether such associations exist.

FR-PO1069

Monitoring of Dietary Sodium Intake by Salt-Meter Decreases Serum Sodium and Blood Pressure in Patients on Hemodialysis

Wilaiporn Akkabut, Surasak Kantachuvesiri. Ramathibodi Hospital. *Mahidol University Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand.*

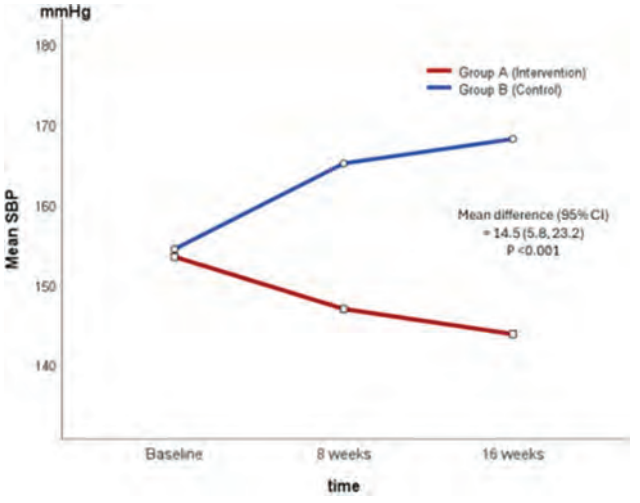
Background: Excessive sodium intake increases the extracellular fluid volume and osmolarity in hemodialysis patients. This study aimed to investigate the efficacy of self-monitoring of sodium intake by using salt meter and nutrition education in HD patients.

Methods: A quasi-experimental study was conducted at Ramathibodi Hospital in Bangkok, Thailand, during July 2023 to February 2024. Hemodialysis patients were randomized to receive intensive dietary education in combination with dietary diary and salt meter for 8 weeks (group A) or standard dietary education alone (group B). Body composition and sodium-related outcomes were measured at baseline, 8 and 16 weeks after recruitment.

Results: 46 patients were enrolled, 21 in group A and 25 in group B. The mean age was 64.8 years, and 52.2% were males. Mean baseline interdialytic weight gain (IDWG) was 3.6 kg, mean SBP and DBP were 153.9 and 74.8 mmHg, respectively. Mean IDWG in group A were stable from baseline to 16 weeks whereas mean IDWG in group B increased from baseline by 0.9 and 1.2 kg at 8 and 16 weeks, respectively (p<0.05). At 16 weeks, mean SBP of participants in group A decreased by 9.7 mmHg from baseline (p<0.05). Group B's mean SBP increased by 10.7 mmHg at 8 weeks and 13.7 mmHg at 16 weeks (p<0.05). The trends were similar for DBP. Serum sodium levels in group A decreased from baseline by 1.8 mmol/L at 8 weeks (p<0.01). Interestingly, at 16 weeks, participants in group A had significantly less %BF and more %FFM compared to baseline.

Conclusions: The use of salt meter and intensive dietary education for self-monitoring sodium intake for 8 weeks was more effective in controlling blood pressure than standard education alone. Decreased serum sodium levels while applying the intervention demonstrated adherence to less salt intake. A salt meter and dietary diary should be considered to control sodium consumption in hemodialysis patients.

Funding: Other NIH Support - Ramathibodi Hospital



FR-PO1070

Effects of High-Dietary Salt on Immune Cells and Microbiome: Results from a Randomized Clinical Trial

Harithaa Anandakumar, Hendrik Bartolomaeus, Sofia K. Forslund, Nicola Wilck. *Charite Universitatsmedizin Berlin, Berlin, Germany.*

Background: High dietary salt intake ranks among the most prominent risk factors and has been tied to hypertension and mortality. The mechanisms responsible are incompletely understood and have been extended to inflammatory and microbiome-associated processes. Building on preliminary data, the present study investigates whether a moderate increase in salt intake in healthy subjects primes host physiology to a more transiently unstable state, potentially leading to changes in the microbiome-immune axis.

Methods: We conducted a prospective, randomized, double-blinded trial to evaluate the effect of high dietary salt in healthy participants (NCT03024567), where the intervention group (n = 19) was given 6g of salt (NaCl) in addition to their daily normal salt intake, essentially doubling the recommended salt intake against a placebo group (n=19) for 14 days. Clinical parameters, stool and PBMC were collected at baseline and day 14. Shotgun metagenomic sequencing, metabolomics (stool and serum), and single-cell sequencing (CITEseq) of whole PBMCs and CD4+ sorted T cells was performed.

Results: The results confirm previous findings showing an increase in the dissimilarity of the microbiome composition under a high salt diet. Differential abundance of the microbiome's functional space, as quantified by functional gut-specific modules, picked up a salt-specific module (M00494, NatK-NatR (sodium extrusion) two-component regulatory system) in the salt group. Furthermore, among all immune cell subsets, we detected 500 common differently expressed genes (DEGs) solely in the salt group. Most of which belonged to to mitochondrial respiration and energy metabolism. Interestingly, we found appr. 8000 DEG in naïve T helper cells and 4000 DEGs in naïve cytotoxic T cells. Commonly, we detected a gene set enrichment for mitochondrial respiration in naïve T cell populations (CD4, CD8), functionally validated by Real Time Cell Metabolic Analysis (Seahorse).

Conclusions: Our study is among the first to utilize different omics techniques to identify high-salt-induced changes in the microbiome and immunome in healthy individuals that may be relevant to the development of pathological conditions in the long term.

FR-PO1071

Levels of the Endogenous Nephrotoxin Adenine in Healthy Humans and Effects of Diet

Subrata Debnath, Yan Du, Christiane L. Meireles, Shane Matta, Richard Montellano, Afaf Saliba, Carlos Lorenzo, Kumar Sharma. *The University of Texas Health Science Center at San Antonio, San Antonio, TX.*

Background: Recent publications indicate that endogenous adenine is likely in the causative pathway for kidney disease in humans and urine adenine/creatinine ratio (UAdCR) is a mechanistic biomarker for ESKD in prospective studies of patients with DKD. However, adenine level in urine of healthy individuals has not been well studied. It is also not known if adenine levels vary according to age, gender, and body mass index (BMI). To shed light on these we conducted two separate studies.

Methods: In one study (Healthy Study), we determined adenine concentrations using validated HPLC-MS/MS analysis in random urine samples collected from apparently healthy individuals (n=122, age 18-89 yrs) without diabetes and hypertension and with eGFR >90 mL/min/1.73m^2. We also performed a post-hoc analysis of the KETO Study (NCT05071287) data that randomized 60 individuals (age 25-82 yrs) with eGFR of >60 mL/min/1.73m^2 to either low-fat or keto diet for 6 months with primary outcome of weight change.

Results: In the Healthy Study, mean±SD urine adenine/creatinine ratio (μM/mM) in females (n=60; 0.052 ± 0.065) was significantly higher compared to males (n=62; 0.010 ± 0.012, P = 0.0016). Similar significant difference was noted in the KETO Study. Urine adenine level did not correlate with age in either study. In the KETO Study, BMI declined in both males and females at 3-Mon and 6-Mon compared to Baseline values (P for all <0.01) but did not correlate with UAdCR. Compared to Baseline, UAdCR level declined significantly only in females at 6-Mon (0.06 ± 0.01 vs 0.03 ± 0.05, P=0.04). There was no correlation of eGFR or UACR with the UAdCR.

Conclusions: Reduction in urine adenine/creatinine ratio observed in females was similar with both type of diets, suggesting that weight reduction by diet may be reno-protective. Further work is warranted to explore mechanistic pathway for higher urine adenine/creatinine ratio in females and clinical implications of these novel findings.

You Are What You Eat: Should It Be All Meat?

Hannah E. Wilson, Sharon M. Moe. *Indiana University School of Medicine, Indianapolis, IN.*

Introduction: Fad diets have exploded in popularity with the advent of social media. Support for one such diet, the carnivore diet, stems solely from historical and anecdotal evidence. The effect of the carnivore diet on kidney stones is of interest as its effect has not been described, and higher animal protein diets are counter to current management guidelines.

Case Description: A 73 y/o man with a history of kidney stone disease, gout, and hypertension presented to nephrology for follow up. Kidney stones were first seen incidentally on X-Ray at age 45 followed by first stone passage at age 55 and 9 lithotripsies. He was referred to stone clinic in 2012 for 90% CaOx/10% CaP stones and started HCTZ and a low sodium, low protein diet. He subsequently was increased to 25 mg chlorthalidone in 2018 due to continued stone growth, after which he no longer formed more stones. 6 months before his nephrology appointment in 2023, the patient had 2 gout attacks 2 weeks apart. His PCP advised him to view a popular physician-made YouTube video on the carnivore diet as a treatment for gout. Following advice from his PCP, the patient modified his diet to include 90% meat with rare fruit and vegetable consumption. Table 1 shows 24-hr urine studies done six months before and six months after the change to the carnivore diet.

Discussion: Urine studies demonstrate a doubling of uric acid and uric acid supersaturation despite similar volumes, increasing risk for uric acid and calcium oxalate stones. Urine studies also demonstrate an increase in urine calcium, likely due to increased sodium intake or increased acid load from high purine consumption. Citrate decreased as expected, likely due to acid load and reduced fruit/vegetable. The increase in oxalate confirms disputed study findings that urinary oxalate excretion increases in high animal protein diets. One rationale is that lower dairy intake may have increased intestinal oxalate absorption due to reduced calcium to bind oxalate. Our patient demonstrates an increased risk of stone formation after adoption of the carnivore diet. This presents a need for high-quality evidence to examine fad diets and necessitates informing patients of the potential harms of pursuing health information on social media.

	Vol	SS CaOx	Ca	Ox	Cit	SS CaP	pH	SS UA	UA
Before Carnivore Diet:	2.95	3.47	181	47	303	0.25	5.631	1.14	0.883

Detailed History Unravels the Mystery: An Unusual Case of Almond Breeze Hypercalcemia

Johnathon Phillips,[1] Swetha Rani Kanduri,[1] Juan Carlos Q. Velez,[1,2] Karthik Kovvuru.[1,2] *[1]Ochsner Health, New Orleans, LA; [2]UQ-Ochsner Clinical School, New Orleans, LA.*

Introduction: Serological tests play a vital role in teasing out the etiology of hypercalcemia. However, obtaining a thorough history is required to unravel a mystery. Herein, we report an unusual case of a patient with chronic kidney disease (CKD) presenting with hypercalcemia and acute kidney injury (AKI) due to consumption of excess almond breeze milk.

Case Description: A 66-year-old male with uncontrolled type 2 diabetes mellitus and hypertension was admitted to the hospital due to severe hypercalcemia [serum calcium (sCa) 15.4 mg/L] and acute on chronic kidney injury (serum creatinine 3.7 mg/dL, baseline of 1.5-1.8 mg/dL). Upon admission, he was drowsy but arousable. According to his wife, he was not in his usual state of health for over a week. Denied intake of over-the-counter medications, vitamin supplements. Additional laboratory data included blood urea nitrogen (BUN) 51 mg/dL, bicarbonate 23 mmol/L, albumin 3.8 g/dL, ionized calcium 1.5 mmol/L. Serological work up revealed suppressed parathyroid hormone (PTH) of 14.5 pg/mL, normal PTH-related peptide of 1.0 pmol/L, vitamin D 29 nm/L, 1,25-dihydroxy vitamin D 10 pg/mL, and a serum protein electrophoresis negative for monoclonal bands. Renal ultrasound unremarkable. Upon further inquiry, wife reported habitual drinking of a gallon of milk every day for years and a recent switch to sugar-free

almond breeze milk 3 weeks prior to index hospital admission, in an attempt to control his blood glucose levels. Upon review of the product label of almond breeze milk, 1 cup contains 450 mg of calcium which corresponds to 7 g of calcium/gallon of almond breeze, which is 50% more calcium than regular milk. The patient was treated with IV normal saline and calcitonin. sCa improved to 10.2 mg/dL and patient was discharged home and instructed to avoid almond breeze milk. sCa remained within normal limits at a follow-up clinic visit.

Discussion: With increasing availability of highly fortified drinks and supplements, patients with CKD are at risk of ingesting higher than recommended dosages potentially leading to ill effects. In addition to obtaining a thorough history, advising patients with CKD to pay attention to product labels and discuss them with physicians is highly encouraged.

FR-PO1074

Changes in Vitamin and Mineral Intake after a Whole-Food, Plant-Based Nutrition Education Program in Hypertensive Patients with CKD

Scott E. Liebman,[1] Janany J. Sabescumar,[1] Rebeca D. Monk,[2,1] Shamsul Hasan,[3] Anne Zhang,[1] Susan Friedman,[1] Thomas M. Campbell,[1] Ted D. Barnett,[4] Erin K. Campbell,[1] Nellie Wixom.[1] *[1]University of Rochester Medical Center, Rochester, NY; [2]Highland Hospital, Rochester, NY; [3]UPMC, Pittsburgh, PA; [4]Rochester Lifestyle Medicine, Rochester, NY.*

Background: Evidence suggests adoption of a predominately whole food plant-based diet (WFPBD) may be beneficial in both hypertension and CKD. Our pilot trial previously showed that individuals with CKD 3 or 4 who attend an education program emphasizing the benefits of a WFPBD achieved a statistically significant decrease in weight, BMI, total, LDL, and HDL cholesterol levels and trended towards improvement in systolic blood pressure without a statistically significant increase in serum potassium. Here we report the changes in intake of vitamins and minerals during the intervention.

Methods: 40 subjects with CKD 3 or 4, with hypertension but without proteinuria or hyperkalemia, were randomized to attend the education program (known as Jumpstart [JS]) or not. JS is a 15 day educational program designed to foster lifestyle changes including adoption of a WFPBD via a combination of lectures, support systems and food demonstrations. Individuals had food diaries done pre and post JS (or equivalent times for controls). We compared dietary intake of vitamins and minerals both within and between groups at the end of the trial.

Results: Compared to baseline, the intervention group showed significant increases in intake of vitamins A, C, and K, folate, magnesium, manganese, copper and oxalate, and significant decreases in the intake of vitamins B-12, D, and E, niacin. zinc, and selenium. Compared to the control group, the intervention group had significant increases in intake of vitamins A, C, and K, thiamine, folate, magnesium, manganese, and oxalate by the end of the trial. Significant decreases were seen in intake of vitamins B-12, D, and E, pantothenic acid, zinc and selenium. The intervention group also significantly reduced their added sugar consumption, glycemic index, and glycemic load compared to both baseline and with the control group at the end of the trial. Iron intake in the intervention group was not statistically different compared to either baseline values, or controls at the end of the trial.

Conclusions: Subjects with CKD 3 and 4 attending a 15-day education program emphasizing a WFPBD had significant changes in vitamin and mineral intake. Further studies are needed to determine the significance of these changes.

Dietary Intake of ESTEEM (Exercise Study Testing Enhanced Energetics of Muscle Mitochondria in CKD) Participants

Olivia A. Moss, Tae Youn Kim, Baback Roshanravan. *UC Davis Health, Sacramento, CA.*

Background: Diet intake in people with CKD impacts metabolic acidosis and may have downstream effects on physical performance. Potential renal acid load (PRAL) is the acid or base forming potential from food, with greater acid production from protein foods, grains and diary and alkali production from fruits and vegetables. Protein amount and source are of interest for physical performance and plays a role in metabolic acidosis. The following is an analysis of dietary intake in people with CKD enrolled in a randomized exercise control trial.

Methods: Participants were randomized to receive supervised exercise for 12 weeks or to participate in a control group consisting of education on healthy lifestyle. All participants were provided a brochure containing diet recommendations by the NKDEP. No other dietary information was provided to participants. Three 24-hour diet recalls were performed pre and post invention using ASA24 software. Physical performance was measured via 6-minute walk test (6MW). Healthy Eating Index 2020 (HEI), PRAL, and protein intake were calculated. Differences between treatment groups and amongst intervention group were determined, and linear mixed effects models were performed on dietary intake variables and performance on 6MW.

Results: The average age of participants (n=30) was 64 years old, 60% were male, 46.6% had diabetes, and the mean eGFR was 34 mL/min. There were no significant differences in PRAL, HEI score, or protein intake between groups pre and post intervention. HEI and PRAL did not significantly affect changes in 6MW, however protein intake was inversely associated with 6MW in all participants (-60.50, 95%CI: -111.95 – -9.04, p= 0.021) as well as among exercisers (-64.59, 95%CI: -124.36 – -4.82, p=0.034).

Conclusions: PRAL and HEI did not affect 6MW performance. Average protein intake was adherent to KIDGO guidelines (0.6-0.8 g/kg). Further investigation is needed to determine if increased protein intake beyond recommended guidelines in CKD adversely impacts exercise adaptation.

Funding: NIDDK Support, Clinical Revenue Support

Novel Model of Kidney-Cardiovascular-Metabolic Injuries by Unilateral Nephrectomy and an Extreme Western Diet: Beneficial Effects by a Natural Food Additive (FLX)

Bengt C. Fellstrom,[1] Lucas Carvalho,[2] Maria Tydén,[1] Matheus Monteiro,[2] Daniel C. Andersson,[2] Tomas A. Schiffer,[2] Mattias Carlstrom.[2] *[1]Dept Medical Sciences, Nephrology, Uppsala, Sweden; [2]Dept Physiology and Pharmacology, Karolinska Institute, Stockholm, Sweden.*

Background: CV complications are severe in renal failure and patients continue to die from CVD. A novel mouse model with progressive renal, CV and metabolic injuries was developed. Beneficial results from preventive treatment with a food additive were found. We aimed to characterize reno-cardio-metabolic dysfunctions, induced by renal failure and Western diet (WD) rich in sugar, fat and salt, and explore preventive effects by a novel food additive.

Methods: C57BL/6J mice (n=18) were subject to unilateral nephrectomy (UNX), fed a WD rich in fat, carbs and salt and followed for 12 weeks compared with SHAM-operated mice on standard chow. A group of UNX+WD mice (n=8) was fed a food additive (FLEXOVITAL [FLX]: extracts of Rhodiola, beetroot, L-arginine and citrulline). Body weight (BW), blood pressure (BP), endothelial-dep. vasorelaxation (myograph), glucose metabolism (IPGTT), body fat-lean mass (DEXA), adipocyte area, renal function (GFR : FITC-inulin), and mitochondrial function (Highresolution respirometry) were measured plus markers of heart injury (TnI), inflammation (IL6) and histology.

Results: In the UNX+WD group, notable increases in BW were observed along with higher fat/lean-mass ratio (17%) and adipocyte area (31%), all of which were mitigated by FLX. Fasting glucose levels were elevated but decreased with FLX. BP was increased (MAP of 78 to 90 mmHg, p<0.001), substantially attenuated by FLX. Endothelial dysfunction in UNX+WD mice was partially preserved with FLX. GFR decreased by 60%, yet a 75% protective effect by FLX. Glomerular and tubular injuries emerged, but less severe in the FLX group. TnI levels increased 2-3-fold but normalized with FLX. Additionally, FLX reduced IL6 levels. Mitochondrial dysfunction in kidneys and hearts improved with FLX.

Conclusions: Cardiovascular, renal and metabolic dysfunction/injuries emerge in this model and significant protection were demonstrated with the food additive FLEXOVITAL

Altered Gene Expression Profile in the Jejuna and Kidneys of Mice on High-Fructose or High-Fat Diet

Kamyar A. Zahedi,[1,2] Sharon L. Barone,[1,2] Marybeth Brooks,[1,2] Christos Argyropoulos,[1] Manoocher Soleimani.[1,2] Soleimani Lab. *[1]University of New Mexico Health Sciences Center, Albuquerque, NM; [2]Veterans Health Administration, Albuquerque, NM.*

Background: Metabolic syndrome (MetS) is a complex disorder characterized by visceral obesity, hypertension, and insulin resistance. The increased prevalence of MetS correlates with enhanced dietary consumption of refined sugars (i.e. high fructose corn syrup), fat, and salt. To ascertain the molecular pathways critical to the development of MetS (and specifically hypertension), we examined the alterations in the renal and jejunal transcriptomes of mice on high fructose or high fat diet.

Methods: Jejunal and kidney transcriptomes of mice on high fructose or high fat diet for 4 weeks were compared with mice on normal diet. Enrichment analyses were performed to identify the affected biological processes and molecular pathways.

Results: Provision of high fructose or high fat diet led to extensive alterations in gene expression patterns in both jejuna and kidneys. Enrichment analyses identified specific GO-biological process pathways in both groups. Major metabolism-associated pathways specific to carbohydrate and fat metabolism were dominant in jejuna of high fructose and high fat mice, respectively. Similarly, pathways associated with insulin response and reaction to stress were prevalent in both groups. Intriguingly, pathways associated with immune and inflammatory responses (e.g., TNF-a response, cytokine response and production) were detected in both high fructose and high fat groups. The latter pathways were significantly enriched in the jejuna of mice on high fat vs. high fructose diet. Enrichment analysis of kidney RNA-seq data revealed fewer overt derangements in high fat vs. high fructose group, which included significant enrichment in pathways associated with the regulation of inflammatory and stress responses. Comparison of high fat to high fructose enrichment terms in the kidney revealed increased enrichment in alterations associate with salt and sugar absorption, stress, and insulin response pathways.

Conclusions: Our studies demonstrate the induction of gene alterations due to increased consumption fat and fructose. These changes include metabolic alterations as well as derangements in inflammatory and stress responses which can contribute to elevated blood pressure. Increased dietary fat and/or fructose, individually or in tandem, can significantly contribute to the onset of pathologies associated with MetS.

PRDM16 Controls Cellular Senescence and Organ Aging by Promoting Oxidative DNA Damage

Qian Yuan, Yuting Zhu, Chun Zhang. *Wuhan Union Hospital, Huazhong University of Science and Technology Tongji Medical College Union Hospital, Wuhan, China.*

Background: With the increasing lifespan, the burden of aging and age-related diseases has emerged as a global public health concern. The accumulation of senescent cells contributes to accelerated body aging through the secretion of senescence-associated phenotypes. Epigenetic modifications, including DNA methylation, histone methylation, and histone acetylation, play crucial roles in promoting cellular senescence. PRDM proteins interact with various epigenetic-modifying enzymes along with transcription factors, to collectively regulate gene expression. However, the precise involvement of PRDM family members in cellular senescence and aging remains elusive.

Methods: We screened PRDM family in multiple organs from mice at young (2 months) and old (24 months) age by qRT-PCR. Bioinformatics analysis and qRT-PCR were utilized to verify the correlation between PRDM16 and age in humans and mice. Natural aging global and renal tubular specific *PRDM16* knockout mice were obtained to observe multiple organ aging, and kidney aging associated diseases with single-cell RNA sequencing. PRDM16 overexpression lentivirus was applied in old mice. RNA-sequencing, ChIP-seq, ChIP, were used to clarify the mechanism of PRDM16 in senescence.

Results: By detecting the expression of PRDM family members, particular attention was given to PRDM16 due to its significantly altered expression between young and old lung and kidney tissues. The levels of PRDM16 in brain hippocampus, kidney, and lung tissues exhibited a negative correlation with age and p21 expression. Notably, global deletion of PRDM16 in mice at only 3 weeks of age resulted in the accumulation of senescent cells in multiple organs. Renal tubular specific *PRDM16* knockout aggravated ischemia reperfusion injury in aging kidney induced by irradiation. Conversely, overexpression of PRDM16 using lentivirus successfully rescued kidney aging in aged mice as well as senescent tubular cells. Mechanistically, deficiency of PRDM16 promoted oxidative DNA damage through disruption of glutathione metabolism. Specifically, downregulation of PRDM16 led to reduced production of reduced glutathione via transcriptional downregulation GSTM1.

Conclusions: PRDM16 deficiency accelerates cellular senescence and multiple organ aging by promoting oxidative DNA damage in a GSTM1-dependent manner.

Magnesium Deficiency in a Multiethnic Asian Patient Population with CKD

Boon Wee Teo,[1,2] Gek Cher Chan.[2] *[1]National University of Singapore Yong Loo Lin School of Medicine, Singapore, Singapore; [2]National University Hospital, Singapore, Singapore.*

Background: Magnesium homeostasis is primarily regulated by the kidneys. Due to the poor correlation between serum magnesium (mmol/L) and total body magnesium, magnesium deficiency is difficult to diagnose in the chronic kidney disease (CKD) population. We analyzed serum magnesium concentrations, 24-hour urinary magnesium excretion (24UMg, mol), and fractional excretion of magnesium (FEMg) in a multi-ethnic Asian cohort of CKD and healthy participants to determine magnesium deficiency.

Methods: We retrieved data from 232 patients with stable CKD from the Asian Kidney Disease Study, and 103 healthy participants without diabetes, hypertension or urinary abnormalities from the Singapore Kidney Function Study. Participants had 24-hour urine collection followed by blood and spot urine sampling, and measurement of the glomerular filtration rate using Tc99m-DTPA. We analyzed using JMP14 and SPSS with standard statistical tests. Magnesium deficiency is defined as 24UMg <1.9444 and serum magnesium ≦0.75.

Results: There are 19/335 (5.67%) participants with (16/19, 84.21% have diabetes). There are 23/335 (6.87%; 17/23 had CKD) participants with serum magnesium ≦0.75. There is no difference by age (p = 0.244), gender (p =0.162), and ethnicity (p = 0.520). However, participants with serum magnesium ≦0.75 have higher body weight on average 74.74±16.5 kg versus 63.86±11.5 kg, p = 0.009. Serum magnesium is lower in CKD patients (0.86 ± 0.11 vs 0.90 ± 0.68, p <0.001), and positively correlated with declining GFR (p <0.001, r = -0.569). More CKD (89/232, 38.36%) patients compared to healthy individuals (26/103, 25.24%) have 24UMg <1.9444 (p = 0.0196). Older patients are more likely to have 24UMg <1.9444 (p = 0.0253).

Conclusions: A combination of 24-hour urine collection for magnesium and serum magnesium concentrations may identify patients at risk of magnesium deficiency, especially in diabetic and CKD patients.

Effects of Sodium Zirconium Cyclosilicate on Quality of Life in Patients Undergoing Hemodialysis with Hyperkalemia: Design and Rationale of the Y-QOL Study

Hiromichi Wakui, Daisuke Kanai, Shiori Yoshimura, Masaaki Hanaoka, Hiroshi Mitsuhashi, Tomoyuki Kawano, Mari Katsumata, Satoshi Yamaguchi, Nariaki Ogawa, Masato Ohsawa, Naohito Okami, Shinya Taguchi, Sho Kinguchi, Kengo Azushima, Tadashi Kuji, Kouichi Tamura. *Yokohama Shiritsu Daigaku Igakubu Daigakuin Igaku Kenkyuka, Yokohama, Japan.*

Background: Patients undergoing hemodialysis (HD) experience inadequate control of fluid and electrolyte balance through dialysis alone, requiring stringent dietary restrictions. This negatively impacts the quality of life (QOL), which is markedly lower in chronic kidney disease (CKD) patients on dialysis compared to healthy individuals. Moreover, reduced QOL has been linked to poorer prognosis in patients on maintenance dialysis. Hyperkalemia, a common issue in these patients, significantly correlates with increased mortality and necessitates strict dietary potassium restrictions, further diminishing QOL. Traditional potassium binders, like calcium and sodium polystyrene sulfonate, are limited by frequent dosing requirements and adverse effects. Sodium zirconium cyclosilicate (SZC) presents a promising alternative, offering effective potassium removal from the gut with minimal impact on other electrolytes and reduced dosing frequency. This study evaluates whether SZC treatment improves QOL by easing dietary potassium restrictions in patients undergoing HD.

Methods: The Y-QOL study is an 8-week, multicenter, randomized, parallel-group, open-label trial. It plans to enroll 200 hyperkalemic outpatients (potassium levels 5.5 to 6.4 mEq/L after a 2-day inter-dialytic interval) undergoing regular thrice-weekly HD. Participants will be randomized to either receive daily SZC (starting at 5 g on non-dialysis days, with potential adjustments up to 15 g based on serum potassium levels) plus dietary guidance, or to a control group receiving only dietary guidance aimed at maintaining serum potassium levels between 4.0 and 5.4 mEq/L. The primary endpoint is changes in QDIS-7 scores at Week 8 from baseline in the intervention group and control group, respectively.

Results: The recruitment of the first participants commenced on January 24, 2024. As of May 2024, 28 participants have been enrolled. The study is projected to conclude on March 31, 2026.

Conclusions: The Y-QOL study aims to determine the effectiveness of SZC in improving QOL concerning dietary potassium intake restrictions in patients undergoing hemodialysis with hyperkalemia.

Association of Renal Artery Calcium Scoring with Decline in eGFR

Nabeel Aslam,[1] Danielle Mason,[2,1] Ibrahim Khambati,[1] Hiroshi D. Hikida,[1] Christopher L. Trautman,[1] Tambi Jarmi.[1] *[1]Mayo Clinic, Jacksonville, FL; [2]Lincoln memorial DeBusk College of Osteopathic Medicine, Harrogate, TN.*

Background: Coronary artery calcium scoring is associated with adverse cardiovascular events and a lower estimated glomerular filtration rate (eGFR). However, limited data exist on the association of renal artery calcium (RAC) scoring with the rate of decline of eGFR.

Methods: We conducted a single center, retrospective study of adult patients followed in a nephrology clinic with available CT imaging of the abdomen. Data collected included demographics, comorbidities, medications, and eGFR at 3-month intervals for 24 months post-CT scan. Aorta and RAC scoring was calculated using a semiautomated software package designed for quantifying coronary artery calcium by the Agaston method.

Results: A total of 274 patients were included in the analysis: median age 67 years, 65% males, and 90% white. Comorbid conditions included diabetes mellitus 31%, hypertension 82%, hyperlipidemia 68%, and pre-existing chronic kidney disease (CKD) 69%. The cohort was divided into groups based on RAC score: RAC = 0; 1-100; >100. RAC >100 was significantly associated with the decline in eGFR from baseline to 24 months as compared to the RAC 0 group (p=0.03). There was no significant association between RAC 1-100 and RAC 0 with the decline in eGFR from baseline to 24 months (p=0.75). There was no association of aorta calcium scoring with a change in eGFR from baseline to 24 months (p=0.23).

Conclusions: In our cohort, RAC score >100 is associated with a decline in eGFR over the 24 months of follow-up. RAC score may provide prognostic information for eGFR decline in patients with risk factors for developing CKD or pre-existing CKD. Further studies are needed to evaluate the utility of RAC scoring in identifying patients at higher risk of eGFR decline.

Relationships between Physical Activity, Vessel Health, and Kidney Function in CKD: An Observational Study

Mark Davies,[1] Aamer Sandoo,[2] Abdulfattah Alejmi,[3] Jamie H. Macdonald.[2] *[1]NHS Wales Cardiff and Vale University Health Board, Cardiff, United Kingdom; [2]Institute for Applied Human Physiology, Bangor University, Bangor, United Kingdom; [3]NHS Wales Betsi Cadwaladr University Health Board, Bangor, United Kingdom.*

Background: The aims of this prospective, observational study were to determine if i) physical activity and kidney function were independently associated with markers of vessel health in patients with mild-moderate CKD; and ii) physical activity and vessel health exacerbate kidney function decline.

Methods: People with CKD stages 1 to 4 and healthy controls had baseline measurements of physical activity (by accelerometer), vessel health (micro-vessel and large artery endothelial-dependent (EDD) and independent (EID) dilation, and carotid intima-media thickness (cIMT)) and kidney function (estimated glomerular filtration rate (eGFR)). During a longitudinal follow-up period, the rate of decline in eGFR was measured. Multiple linear regression was used: i) in a cross-sectional analysis, to determine if vessel health, in additional to clinical variables (age, blood pressure, insulin resistance) was associated with physical activity or kidney function; and ii) in a longitudinal analysis, to determine if physical activity and vessel health (specifically, micro-vessel EDD), in additional to clinical variables, exacerbated kidney function decline.

Results: Answering aim i), 71 people with CKD and 12 controls were recruited and provided baseline data. Physical activity was independently associated with both large artery (ß=0.32;p=0.03) and micro-vessel EDD (ß=0.26;p<0.01) and cIMT (ß=-0.2;p=0.01). In contrast, kidney function was only independently associated with cIMT (ß=-0.25;p=0.01). Answering aim ii) 60 people with CKD were followed up for median (IQR) 20 (16 to 29) months. Neither micro-vessel EDD (ß=-0.07;p=0.20) nor physical activity (ß=0.04;p=0.69 independently predicted eGFR decline but exploratory analyses suggested large vessel EDD may predict eGFR decline (ß=0.12;p=0.07).

Conclusions: In the first study to combine objectively measured physical activity, vessel health and kidney function in people living with CKD, physical activity was independently associated with vessel function (micro and large vessel EDD), whilst physical activity and kidney function were independently associated with atherosclerosis (cIMT). These findings have implications for CKD cardiovascular risk management. Future research should confirm whether physical activity, via improvements in vessel health, can attenuate kidney function decline.

The Burden of Ventricular Premature Complexes Is an Independent Risk Factor of the Development of Kidney Failure in Patients with CKD

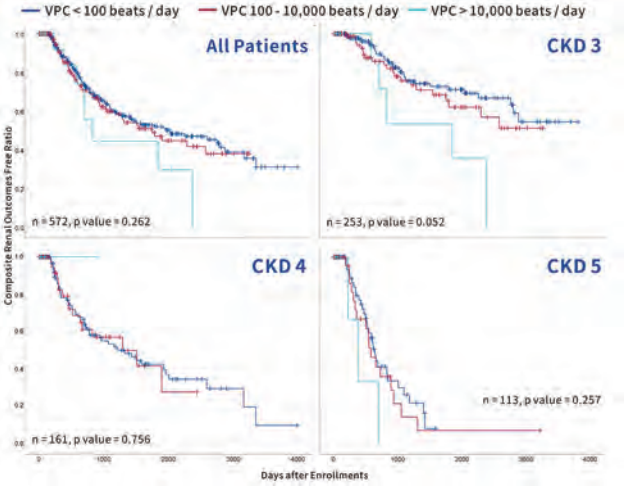
Chih-Hen Yu,[1,2] Chao-Yu Chen,[1,2] Chien-Shien Lee,[1,2] Ting-Chun Huang,[1,2] Po-Tseng Lee,[1,2] Mu-Shiang Huang,[1,2] Ping-Yen Liu,[1,2] An-Bang Wu,[1,2] Chin Chung Tseng,[1,2] Junne-Ming Sung.[1,2] *[1]National Cheng Kung University College of Medicine, Tainan, Taiwan; [2]National Cheng Kung University, Tainan, Taiwan.*

Background: Ventricular premature complexes (VPCs) are strongly linked to heart failure, and a higher VPCs burden independently increases the risk of cardiovascular mortality; however, whether the VPCs lead to renal impairment beyond cardiovascular events remains unknown. The primary objective of the study is to assess whether a high VPCs burden serves as an independent risk factor for the development of kidney failure in CKD patients.

Methods: We conducted a single-center, perspective cohort to clarify the role of VPC burden in composite renal outcome. We follow up the patients with CKD 3b to 5, who's indicated of Holter exam. The composite renal outcome was defined as sustained eGFR decline of at least 40%, sustained GFR<15mL/min/1.73 m^2, maintenance dialysis, or death from kidney failure.

Results: A total of 527 patients was enrolled. The mean follow-up duration was 571 days (Q1:202, Q3:1093). Events shorter than 180 days were excluded. The hazard ratio (HR) for Log VPCs was 1.159 (95%CI, 1.030-1.305, *p*=0.014), adjusted for age (HR 0.986 95%CI, 0.973-0.999, *p*=0.041), diabetes (HR 1.428, 95%CI 1.046-1.950, *p*=0.025), and CKD stages (CKD stage 3: ref, stage 4: HR 2.743 95%CI 1.97-3.945, *p*<0.001, stage 5: HR 5.404 95%CI 3.621-8.063, *p*<0.001). In categories of different VPC burdens, compared to individuals with a VPC burden<100/day, HR of VPC 100-10,000 beats/day and VPC>10,000 beats/day regarding the composite outcome were 1.251(95%CI, 0.868-1.677, *p*=0.353), and 2.42(95%CI, 1.165-5.020, *p* =0.018), respectively.

Conclusions: High burden of VPCs, defined by log VPC, or with cutoff of 100 beats/day and 10,000 beats/day, are independent predictors of composite renal outcome in CKD population.



Kaplan-Meier Analyses for Composite Renal Outcome of VPC Burdens in All Patient and Different CKD Stages

N-terminal Pro B-Type Natriuretic Peptide (NT-proBNP), Troponin T, and Incident Heart Failure: The Chronic Kidney Disease Prognosis Consortium

Nisha Bansal, Markus P. Schneider. CKD Prognosis Consortium. *CKD Prognosis Consortium, New York, NY.*

Background: Recently, the American Heart Association PREVENT equation was developed to predict 10-year risk of incident heart failure (HF) in persons without prevalent atherosclerotic cardiovascular disease (ASCVD), incorporating eGFR and albuminuria. We aimed to determine the added value of NTproBNP and troponin T (TnT) as predictors of HF in the ambulatory setting, across a broad range of cohorts and including participants with prevalent ASCVD.

Methods: We performed individual-participant data meta-analysis of 38,274 individuals without a history of HF. Adjusted Cox models were used to quantify the associations of NT-pro-BNP and troponin T with HF after adjusting for variables in the PREVENT model, and to assess whether the associations varied by age and CKD status.

Results: There were 3,990 incident HF events over a mean of 12 years. In meta-analysis, a 2-fold higher NTproBNP was associated with 1.47-fold (95% CI: 1.37-1.59)

higher risk of HF. The association between NTproBNP and HF was stronger in older age but not different by GFR. The increase in C-statistic was 0.029 (0.018, 0.040) over the base model and was greater among older (0.044, 95% CI: 0.030, 0.059) than younger adults (0.024, 95% CI: 0.010, 0.038). For TnT, a 2-fold higher value was associated with 1.45-fold (95% CI: 1.33-1.57) higher risk of HF, but the increase in C-statistic was smaller (0.009, 95% CI: 0.006, 0.012). Adding TnT to a model with NTproBNP resulted in minimal increment in c-statistic (0.002, 95% CI: 0.001, 0.004).

Conclusions: NTproBNP adds robust information to the PREVENT model for discrimination of HF risk, particularly among older adults.

FR-PO1085

Arterial Stiffness and Cognitive Decline in the Chronic Renal Insufficiency Cohort (CRIC) Study

Renee A. Dreher, Ester Oh, Zhiying You, Michel Chonchol, Kristen L. Nowak. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Kidney function decline is associated with impaired cognitive function, and there is evidence that higher carotid-femoral pulse-wave velocity (PWV), a measure of arterial stiffness, is associated with cognitive impairment in non-chronic kidney disease (CKD) studies. However, it has yet to be investigated if PWV is predictive of incident cognitive impairment in patients with CKD. We hypothesized that higher PWV is associated with a decline in cognitive function over time in adults with CKD who participated in the CRIC study.

Methods: We included 1,864 participants from the observational cohort study, CRIC, with baseline carotid-femoral PWV measurements and no baseline cognitive impairment, defined as Modified Mini-Mental State Examination (MMSE) score >1 SD below the cohort mean at baseline. Cox proportional hazard regression was used to examine the association between PWV and time to cognitive impairment, defined as a decline in MMSE scores of >1.0 SD below the cohort mean (determined from baseline cognitive scores).

Results: Participants were 58±11 years old, 56% (n=1048) were male, baseline estimated glomerular filtration rate (eGFR) was 47±15 ml/min/1.73m^2, baseline carotid-femoral PWV was 10.7±3.7 m/s, and baseline MMSE score was 94.9±4.3. During a follow-up of 9.1±4.6 years, 280 participants (15%) had a clinically significant decline in MMSE score (i.e. incident cognitive impairment). After adjustment for age, sex, race/ethnicity, education, and baseline MMSE there was a significantly greater risk of incident cognitive impairment (Hazard Ratio [HR]: 1.04, 95% CI: 1.00-1.07 per 1 unit increase in PWV). However, this association was attenuated after further adjustment for systolic blood pressure, hypertension, diabetes, cardiovascular disease history, alcohol use, stroke history, smoking status, body-mass index, antihypertensive and anticoagulant usage, eGFR, and 24-hour albuminuria (HR: 1.02 [0.98, 1.06]).

Conclusions: In adults with mild to moderate CKD higher PWV was associated with a greater risk of incident cognitive impairment; however, this association was no longer significant after full adjustment for covariates.

FR-PO1086

Sex Differences in Probable Dementia and Mild Cognitive Impairment in CKD and Non-CKD: The SPRINT MIND Randomized Clinical Trial

Ester Oh, Zhiying You, Vienna E. Brunt, Michel Chonchol, Kristen L. Nowak. *University of Colorado Anschutz Medical Campus School of Medicine, Aurora, CO.*

Background: Females have higher risk of cognitive decline as compared to males in the general population. However, little is known whether this sex-specific risk pattern of cognitive decline translates to individuals with chronic kidney disease (CKD). This study examined sex differences in the risk of cognitive decline in older adults with elevated blood pressure and at high risk of cardiovascular events, who participated in the Systolic Blood Pressure Intervention Trial Memory and Cognition IN Decreased Hypertension (SPRINT MIND) study, both with and without CKD.

Methods: A Cox proportional hazard model was used to compare sex differences in the risk of incident cognitive outcomes (probable dementia [PD], mild cognitive impairment [MCI]; and their composite) in males and females matched for propensity scores (based on age, race, education, randomization arm, smoking status, cardiovascular disease history systolic blood pressure, body-mass index, and estimated glomerular filtration rate [eGFR]), separately for those without and with CKD (defined as eGFR 20-59 ml/min/1.73m^2).

Results: Adults without CKD (n=2,506; 50% F; mean±SD age 68±9 y; eGFR 81±16 ml/min/1.73m^2) and with CKD (n=1,362; 50% F; 70±9 y; eGFR 49±10 ml/min/1.73m^2) were included in the study. The median (IQR) follow-up was 4.6 years (3.6-5.9) and 4.1 years (3.3-5.9) for the non-CKD and CKD groups, respectively. In adults without CKD, there were no sex differences in the risk of MCI/PD composite or PD. Males without CKD had higher MCI risk than females (**Figure A**). Males with CKD had higher risk of MCI/PD composite and PD than females (**Figure B**). Additionally, MCI risk in males with CKD tended to be higher than females.

Conclusions: Males with CKD had a higher risk of PD than females; this sex difference in the risk of dementia was not observed in participants without CKD.

Funding: Private Foundation Support

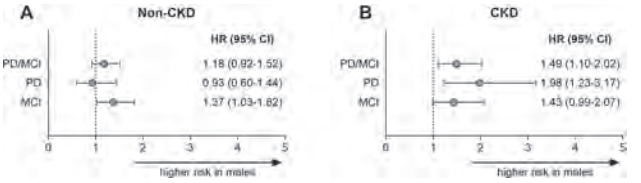

Figure. Sex differences in the risk of PD/MCI composite, PD, and MCI in adults without CKD **(A)** and with CKD **(B)**.

FR-PO1087

Blood Pressure, eGFR, and Kidney Mortality in Mexico: A Prospective Study of 150,000 Adults

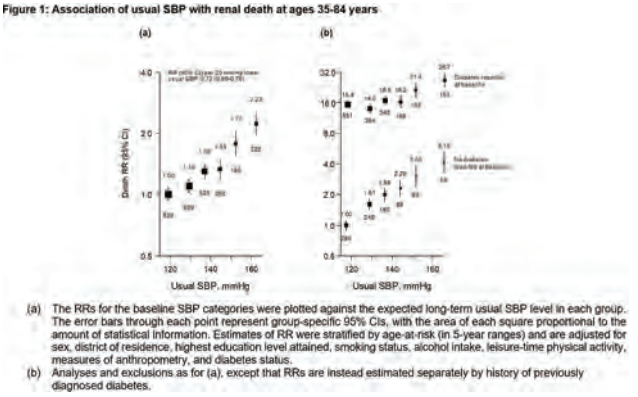
Doreen Zhu,[1] Pablo A. Kuri-Morales,[2] Rachel Wade,[1] Natalie Staplin,[1] Adrian Garcilazo-Avila,[2] Carlos L. Gonzalez-Carballo,[2] Diego J. Aguilar-Ramirez,[1] Fiona Bragg,[1] Louisa G. Friedrichs,[1] William G. Herrington,[1] Lisa E. Holland,[1] Michael R. Hill,[1] Jason M. Torres,[1] Michael P. Turner,[1] Eirini Trichia,[1] Colin Baigent,[1] Richard Peto,[1] Jaime Berumen,[2] Jonathan Emberson,[1] Richard Haynes,[1] Roberto Tapia-Conyer,[2] Jesus A. Alegre-Diaz.[2] Mexico City Prospective Study Group. *[1]University of Oxford Nuffield Department of Population Health, Oxford, United Kingdom; [2]Universidad Nacional Autonoma de Mexico Facultad de Medicina, Ciudad de Mexico, Mexico.*

Background: Chronic kidney disease (CKD) is a leading cause of death and disability in Mexico and blood pressure (BP) may be an important contributor.

Methods: From 1998-2004, 150,000 adults aged ≥35 years from Mexico City were recruited into a blood-based prospective study and followed for cause-specific mortality. A resurvey of 10,000 survivors including urine samples was conducted in 2015-2019. Cox regression related usual BP to risk of death from kidney failure (renal death), excluding those with prior disease (other than diabetes) and adjusted for confounders. Logistic regression related baseline BP to baseline CKD (self-reported and/or eGFR <60 ml/min/1.73m^2) and resurvey BP to resurvey albuminuria (<3, 3-30 and ≥30 mg/mmol).

Results: Systolic BP (SBP) was continuously log-linearly related to renal death risk before age 85 years, with each 20 mmHg lower usual SBP associated with 28% lower risk (RR 0.72, 0.68-0.76) (Fig 1). The association was stronger in those without (RR 0.55, 0.50-0.60) than with diabetes (RR 0.81, 0.76-0.87), but the absolute relevance of SBP to risk was larger in those with diabetes. Overall, the excess renal death risk associated with hypertension (self-reported, treated or measured BP ≥140/90 mmHg) accounted for 27% of all renal deaths. 2% of participants had CKD at baseline and 25% of participants who provided a resurvey urine sample had albuminuria. At baseline, 20 mmHg lower SBP was related to a 31% lower odds of CKD (OR 0.69, 0.66-0.72), while at resurvey 20 mmHg lower SBP was related to a 42% lower odds of albuminuria (OR 0.58, 0.53-0.63).

Conclusions: In this study of Mexican adults, BP was strongly related to the risk of renal death and CKD.



(a) The RRs for the baseline SBP categories were plotted against the expected long-term usual SBP level in each group. The error bars through each point represent group-specific 95% CIs, with the area of each square proportional to the amount of statistical information. Estimates of RR were stratified by age-at-risk (in 5-year ranges) and are adjusted for sex, district of residence, highest education level attained, smoking status, alcohol intake, leisure-time physical activity, measures of anthropometry, and diabetes status.
(b) Analyses and exclusions as for (a), except that RRs are instead estimated separately by history of previously diagnosed diabetes.

FR-PO1088

Ambient Air Pollutant Mixture, Sleep Pattern, and Incident CKD: Results from a Prospective Cohort Study

Feifei Zhang,[1] Chao Yang,[2] Luxia Zhang.[1,2] *[1]Peking University Health Science Center, Beijing, China; [2]Peking University First Hospital Department of Nephrology, Beijing, China.*

Background: The associations of sleep behavior and air pollution with chronic kidney disease (CKD) have been investigated individually, yet the role of their interaction in the incidence of CKD is not well understood.

Methods: This study involved 402,451 participants from the UK Biobank cohort. A composite sleep index was calculated according to five sleep behaviors including sleep duration, chronotype, insomnia symptoms, snoring, and daytime sleepiness. Seven air pollutants, including $PM_{2.5}$, PM_{10}, NO_2, NO_X, SO_2, CO, and benzene, were examined jointly and individually. Cox proportional hazards model was used to calculate associations and to investigate potential modifying effects by assessing the significance of cross-product interaction terms of sleep index and air pollutants.

Results: With a median follow-up duration of 13.6 years, 3.6% of the participants was diagnosed with CKD. Each of the seven air pollutants demonstrated a positive association with the incidence of CKD. Co-exposure to seven air pollutants was associated with an increased risk of CKD incidence (hazard ratio: 1.093, 95% confidence interval: 1.067-1.119, **Figure 1**). There was a significant multiplicative interaction between sleep index and combined air pollutant exposure and the risk of incident CKD (p for interaction: 0.014). Stratified analyses by sleep index showed that the negative effect of air pollution was less pronounced for participants with healthier sleep patterns. Similar interactions existed for individual air pollutants including PM_{10}, NO_2, NO_X, and CO. Subgroup analyses suggested the elderly and females may experience fewer toxic effects from air pollution by adhering to healthy sleep patterns.

Conclusions: Sleep patterns may modify the relationship between air pollution exposure and onset of CKD. Our study highlights the potential of improving sleep as a preventive measure to counteract the detrimental effects of air pollution on incident CKD.

Funding: Government Support - Non-U.S.

Impact of PM2.5 Pollution on Kidney Diseases in São Paulo, Brazil

Iara Da-Silva,[1] Alejandro H. Delgado Peralta,[1] Mario E. Gavidia-Calderón,[1] Edmilson D. De Freitas,[1] Talita R. Sanches,[2] Alessandra Tammaro,[3] Jesper Kers,[3] Maria Andrade,[1] Lucia Andrade.[2] *[1]Department of Atmospheric Sciences, Institute of Astronomy, Geophysics and Atmospheric Sciences, São Paulo, Brazil; [2]Nephrology, University of Sao Paulo School of Medicine, Sao Paulo, Brazil; [3]Amsterdam University Medical Center, Amsterdam, Netherlands.*

Background: Exposure to $PM_{2.5}$ has been associated with a risk of CKD. We have demonstrated that $PM_{2.5}$ aggravates AKI-induced IRI in mice. We evaluated the impact of $PM_{2.5}$ concentration on the incidence of CKD, AKI and glomerulopathy.

Methods: We analyzed meteorological variables, $PM_{2.5}$ concentrations and hospital admissions in São Paulo City during the 2011–2021 period. Admissions were categorized by age group and sex. We performed regression analysis with a generalized additive model and negative binomial distribution of exponential probability, assessing the cumulative medium-term impact of exposure, and a distributed lag non-linear model, which provides the effects of time lags (up to 2,000 days in our study), for AKI, CKD and glomerulopathy.

Results: Of the 37,170 records analyzed, 55% represented male individuals. Exposure to $PM_{2.5}$ was found to increase CKD risk by 1-4 times (95% CI: 1.009-1.18). Long-term exposure to higher $PM_{2.5}$ concentrations (65 $\mu g/m^3$) increases that risk considerably for men and women aged 19-50 years—RR: 1.01 (95% CI: 1.005-1.015) and RR: 1.013 (95% CI: 1.01-1.018), respectively—the risk being ≤ 2.5 times higher in men aged 51-75 years (RR: 1.025; 95% CI: 1.015-1.032). Between genders and among age groups, the risk of AKI after prolonged exposure to high $PM_{2.5}$ concentrations was highest for men aged 19-50 years (RR: 1.04; 95% CI: 1.012-1.07). The risk of glomerulopathy was highest in the < 40-year age group, especially among men, for whom the RR was 1.02 (95% CI: 1.007-1.025) and 1.07 (95% CI: 1.02-1.11) for concentrations of 15 $\mu g/m^3$ and 65 $\mu g/m^3$, respectively.

Conclusions: Our findings underscore the urgency to develop global strategies for air pollution reduction. (FAPESP, NWO, CAPES)

Effects of Environmental Factors on the Progression of CKD in Inhabitants of São Paulo, Brazil

Tiana C. Moreira,[1] Alessandra Tammaro,[2] Thais Mauad,[3] Itamar d. Santos,[4] Maria Andrade,[5] Lucia Andrade,[1] Jesper Kers.[2] *[1]Nephrology, University of São Paulo School of Medicine, São Paulo, Brazil; [2]Amsterdam UMC, Amsterdam Cardiovascular Science, University of Amsterdam, Amsterdam, Netherlands; [3]Pathology, University of São Paulo School of Medicine, São Paulo, Brazil; [4]Internal Medicine, University of São Paulo School of Medicine, São Paulo, Brazil; [5]Institute of Astronomy, Geophysics and Atmospheric Sciences, University of São Paulo, São Paulo, Brazil.*

Background: Epidemiological evidence links air pollution to an increased risk of developing chronic diseases. Exposure to air pollution, especially PM_{10} and $PM_{2.5}$, has received special attention due to its potential associations with cardiovascular disease (CVD), diabetes mellitus, lung cancer and chronic obstructive pulmonary disease, but its relationship with CKD is still poorly established. In Brazil, around 11% of the population suffers from CKD. We aim to evaluate the relationship between the progression of CKD and exposure to environmental factors such as air pollution, green areas, built-up areas, traffic density in the City of São Paulo in a wave of the Brazilian Longitudinal Study of Adult Health.

Methods: For each participant, we assessed demographic data, environmental data, and risk factors. Two different indicators of exposure to green spaces were used: number of street trees and land cover. Land cover classification was based on the random forest algorithm using geometrically corrected aerial photography (orthophotos). Pollutant exposure was evaluated indirectly using the distance-weighted traffic density of the participant residence and from using the annual mean concentration of PM_{10} ($\mu g/m^3$) at the monitoring station closest to the participant residence. Linear regression models were used to evaluate the importance of the environment on CKD progression; the dependent variables were GFR (CKD-EPI), albuminuria (mg/g creatinine) and microalbuminuria (mg/dL), whereas the independent variables were demographic data, environmental data and risk factors.

Results: Cardiac risk according to the American Heart Association, obesity and lower educational level were associated with a higher risk of GFR decline. We also found that traffic density was marginally associated with GFR decline ($\beta = 0.004$; CI: 0.008–0.001; $p = 0.098$). In addition to their associations with CVD and obesity, albuminuria and microalbuminuria were found to correlate inversely with the number of trees ($\beta = 0.03$; CI: 0.06–0.00; $p = 0.04$ and $\beta = 0.002$; CI: 0.004–0.001; $p = 0.05$).

Conclusions: To decrease exposure to air pollution and slow the progression of CKD, large-scale street tree planting should be encouraged.

Correlating Kidney Failure Risk Equation and Kidney Biopsy Chronicity Score as Kidney Failure Predicting Tools

Ana C. Brás, Filipa G. Pereira, Joaquim F. Tinoco, Carolina A. Padrão, Afonso Santos, Patricia S. Carrilho, Rita Theias Manso. *Hospital Professor Doutor Fernando Fonseca EPE, Amadora, Portugal.*

Background: Progression to kidney failure (KF) may be estimated by the Kidney Failure Risk Equation (KFRE), based on age, gender, eGFR and uACR. Kidney biopsy (KB) chronicity score (KBCS), which evaluates the degree of glomerulosclerosis, interstitial fibrosis, tubular atrophy and arteriosclerosis, also predicts progression to KF. We aimed to compare and validate both scores in outcome prediction in a retrospective single-center cohort study.

Methods: Patients who underwent KB from 2017 to 2022 were analyzed. Exclusion criteria were: acute kidney injury, rapidly progressive glomerulonephritis; kidney replacement therapy (KRT) dependence up to 90 days after KB; insufficient histological sample; follow up <2years or death.

Results: From a total of 235 patients, 121 patients were included: 55% (n=68) were male, with a median age of 53 years (IQR 43-65); 78% (n=94) were hypertensive, 63% (n=75) had overweight and 35% (n=42) diabetes. At the time of KB, median eGFR was 43ml/min/1.73m2 (IQR 25-68); median uACR was 2469 mg/g (IQR 964-4490); 74% (n=89) had microscopic hematuria. Median KFRE at 2 years was 2.6% (IQR 0.2-19.3) and at 5 years 9.6% (IQR 0.7-56.5). Median KBCS was 6 (IQR 3-8). At 2 and 5 years of follow-up, 23% (n=28) and 9% (n=11) of patients reached KF, respectively. At 2 and 5 years, KBCS correlated with progression to KF (r=0.543 and r=0.613, p<0.001) as well as KFRE (r=0.553, and r=0.542, p<0.001). Both KBCS and KFRE correlated with each other at 2 and 5 years (r=0.622 and r=0.613, p<0.001). In the subgroup of patients with eGFR>60ml/min/1.73m2 (n=42, 35%) at the time of biopsy, the scores KFRE and KBCS were unable to predict progression to KF (p=0.656 and p=0.084, respectively).

Conclusions: In our cohort, there was a positive correlation between KFRE and KBCS, irrespectively of eGFR. Overall, both KFRE and KBCS were able to estimate progression to KF at 2 and 5 years, showing the usefulness of these tools in clinical practice and in providing timely guidance to patients regarding KRT. In the subgroup of patients with eGFR>60ml/min/1.73m2, however, neither KFRE or KBCS associated with KF, revealing a gap in clinical, laboratory and histological markers that can better define risk progression in this population.

FR-PO1092

Improving the Quality of CKD Care with Risk Prediction and Personalized Recommendations: 1-Year Results from the GEMINI-RAPA Study

Navdeep Tangri,[1,2] Silvia J. Leon Mantilla,[2] Don Watts,[5] Cedric Woo,[5] Samuel T. Fatoba,[3] Pablo E. Pergola.[4] *[1]University of Manitoba Department of Internal Medicine, Winnipeg, MB, Canada; [2]Chronic Disease Innovation Centre, Winnipeg, MB, Canada; [3]Bayer AG, Leverkusen, Germany; [4]Renal Associates PA, San Antonio, TX; [5]Khure Health Inc, Toronto, ON, Canada.*

Background: CKD is associated with cardiovascular disease, progression to kidney failure and early mortality. Clinical guidelines recommend (ACEi, SGLT2i, non-steroidal MRA) to slow CKD progression and prevent heart failure in CKD-T2D patients Unfortunately, most patients are recognized late and use of guideline testing and therapies remain low. We implemented Klinrisk, a highly accurate risk prediction algorithm for CKD progression, with clinical decision support (CDS) to identify patients at risk with the goal of improving quality of CKD care in a large nephrology practice.

Methods: Patients >18 years and not on dialysis were included. Data for estimated glomerular filtration rate, albuminuria, demographics, other laboratory tests and comorbid conditions was extracted from the electronic health record (EHR). Individuals were risk stratified using an externally validated risk prediction equation (Klinrisk[1]), deployed on Khure Health's CDS platform Reports are generated quarterly to inform and educate physicians. One year data on changes in guideline directed care are presented here.

Results: Of 16,099 patients that were risk-stratified, 29% were at high risk of CKD progression. Higher risk individuals were similar in age, but more likely to have diabetes, hypertension and heart failure. At one year, UACR testing increased 3 fold from 12.3 to 38.8 %, and UACR/PCR values were available in 83 % of individuals. Among high risk patients (> 10 % risk of progression over 2 years) there was a 19% increase in prescription of RAASi, 96 % increase in prescription of SGLT2i and an 65 % increase in prescription of ns-MRAs.

Conclusions: Integration of a highly accurate machine model for CKD progression when paired with EHR linked clinical decision support improves guideline-recommended testing and therapy in high -risk patients with CKD. Longer follow up and periodic assessment is planned to observe changes in quality metrics and patient outcomes.

Statewide Impact of CKD Attributable to Dietary Risk Factors in the United States, 1990-2021: Insights from the GBD 2021 Study

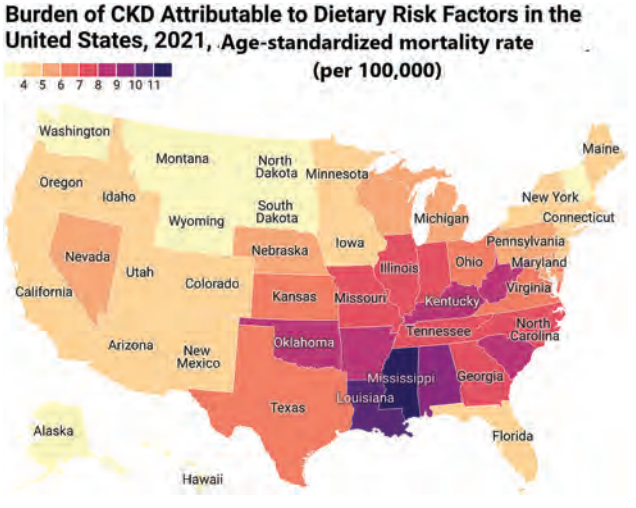
Ashutosh Rangani,[1] Ashwinikumar Shandilya,[4] Mohit Lakkimsetti,[2] Haseeb Madiha,[7] Ram Prasanjith Reddy,[6] Vishrant Amin,[3] Juhi Patel,[3] Hardik Desai,[5] Saif Syed.[8] *[1]Ternopil National Medical University, Ternopil, Ukraine; [2]Mamata Medical College, Khammam, India; [3]Gujarat Medical Education and Research Society Medical College & Hospital Valsad, Valsad, India; [4]Rural Medical College, Pravara Institute of Medical sciences, Ahmednagar, India; [5]Gujarat Adani Institute of Medical Science, Bhuj, India; [6]MediCiti Institute of Medical Sciences, Medchal, India; [7]Jinnah Sindh Medical University, Karachi, Pakistan; [8]Royal College of Surgeons in Ireland, Dublin, Ireland.*

Background: Chronic Kidney Disease (CKD) represents a significant healthcare challenge in the United States, with direct medical costs ranging from $6,592 to $280,727 per person. Among the major modifiable risk factors, dietary habits play a crucial role, yet state-wise comparative assessments remain scarce.

Methods: Using the Global Burden of Disease (GBD) 2021 toolkit, we evaluated the impact of seven dietary risk factors on CKD-related deaths, disability-adjusted life years (DALYs), and years lived with disability (YLDs) across the US from 1990 to 2021, segmented by age, sex, year, and location.

Results: The study observed the highest total percentage change (TPC) in CKD-related deaths due to high consumption of sugar-sweetened beverages (497%), followed by diets high in processed meat (473%), low in vegetables (386%), high in red meat (352%), low in whole grains (332%), and low in fruits (294%) over the studied period. Oklahoma saw the most significant increase in age-standardized mortality rates by 234%, with Alabama experiencing a 43% rise in YLD rates. The age group 80-84 reported the highest number of deaths at 5,468, followed by the 70-74 age group at 13,847 in 2021. Males experienced a higher burden compared to females over the last three decades.

Conclusions: Dietary risk factors accounted for 26.70% of all CKD-related deaths in 2021. Given these findings, enhancing public awareness through targeted e-health and m-health educational campaigns is critical to mitigate the impact of poor dietary habits on CKD.



FR-PO1094

Global Burden of CKD in Individuals 20 Years and Older in 204 Countries and Territories, 1990-2021

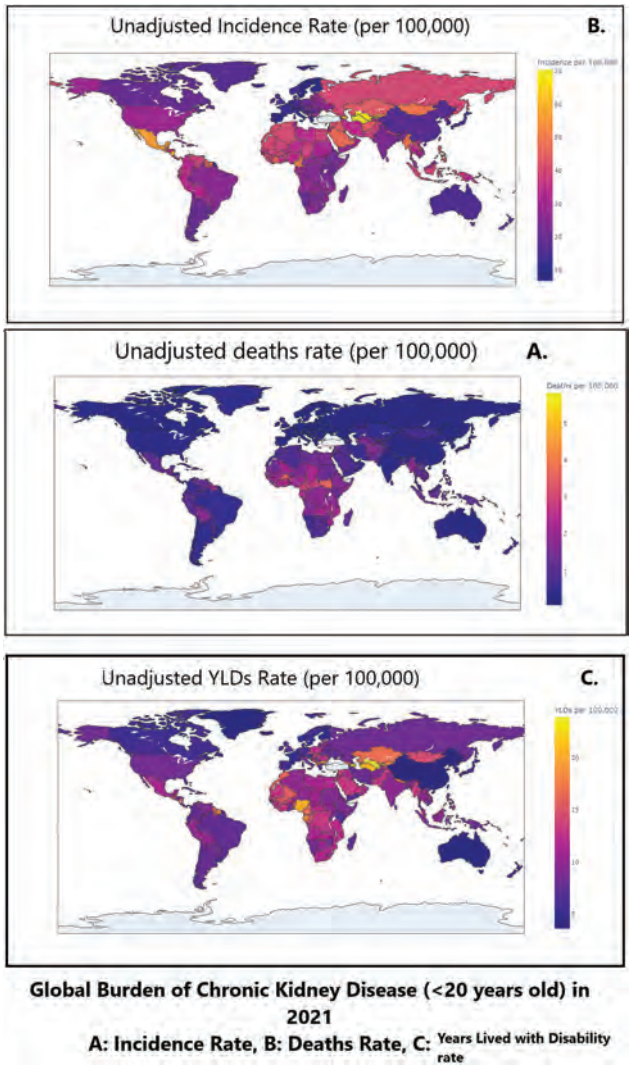
Ishita D. Hirpara,[1] Geethika C. Potluri,[5] Anushka Dekhne,[6] Sashank S. Bollu,[2] Sai Nitya Tejaswi Anne,[2] Asmita Gera,[3] Hardik Desai.[4] *[1]GMERS Medical College Junagadh, Junagadh, India; [2]Gandhi Medical College, Secunderabad-Padmarao Nagar, India; [3]Tianjin Medical University, Tianjin, China; [4]Gujarat Adani Institute of Medical Science, Bhuj, India; [5]Dr YSR University of Health Sciences, Vijaywada, India; [6]American University of Antigua, Coolidge, Antigua and Barbuda.*

Background: The impact of CKD in individuals <20 is profound, affecting their physical health, quality of life, and psychosocial development. The study was aimed at assessing global epidemiological trend of CKD <20 years of age.

Methods: Employing the Global Burden of Disease 2021 framework, we estimated incidence, prevalence, deaths, disability-adjusted life years (DALYs), year lived with disabiliy (YLDs) stratified by age, sex, and year across 204 countries and territories from 1990-2021 for individuals <20 years old.

Results: The total percentage of change (TPC) in prevalence increased by 21% (95%UI: 19-23%), incidence by 20% (14-27%) from 1990-2021. However, there was a decrease in DALYs by 22% and in deaths by 23% over the last three decades. Regionally, the highest TPC in CKD incidence was observed in central Africa by 141%. The Low Sustainable Development Index (SDI) countries exhibited the most significant increases in deaths (32%) and DALYs (33%) from 1990-2021. The unadjusted incidence rate in the 15-19 age group rose by 44%, followed by a 37% increase in 10-14 age group from 1990-2021. Gender disparities were evident in the burden of CKD, with males experiencing a higher overall impact. The TPC in incidence for males increased by 25% compared to 15% for females from 1990-2021.

Conclusions: CKD accounted for 0.43% deaths amongst all casualties in 2021 <20 years old. The study highlights the urgent need for targeted interventions and resources to address the escalating prevalence of CKD in young individuals, particularly in regions with the highest incidence rates and in countries with low SDI countries.



Global Burden of Chronic Kidney Disease (<20 years old) in 2021

Palliative Care and Hospice Utilization in US Veterans Treated with Conservative Management vs. Dialysis

Yoko Narasaki,[1] Connie Rhee,[1] Amy S. You,[1] Man Kit Michael Siu,[1] Csaba P. Kovesdy,[2] Ji Hoon Yoon,[1] Lisa Le,[1] Danh V. Nguyen,[3] Kamyar Kalantar-Zadeh.[4]
[1]University of California Los Angeles, Los Angeles, CA; [2]The University of Tennessee Health Science Center, Memphis, TN; [3]University of California Irvine, Irvine, CA; [4]Harbor-UCLA Medical Center, Torrance, CA.

Background: There is growing need for the role of palliative care in the routine nephrology management of the advanced CKD population given the high physical and psychological symptom burden of these patients, particularly among those who are aging and ailing. However, the utilization of palliative and hospice care services among advanced CKD patients in the US has not been well-studied. We thus sought to examine palliative and hospice care utilization among advanced CKD patients treated with conservative management (CM) vs. dialysis in a national cohort of US Veterans.

Methods: Using national Veterans Affairs (VA) data linked with the USRDS and Medicare databases, we examined advanced CKD patients (≥2 eGFRs <25 separated by ≥90 days) treated with CM vs. dialysis (defined as non-receipt vs. receipt of dialysis within 2-years of 1st eGFR <25) over 2010-19. We compared time to 1st referral to palliative care (primary outcome) or hospice (secondary outcome) among CM vs. dialysis patients who were matched by propensity score (PS) using a 1:1 ratio with a caliper distance of ≤0.2 to address confounding using Cox models.

Results: Baseline characteristics were well-balanced among 13,020 CM patients PS-matched to 13,020 dialysis patients. In PS-matched analyses, patients treated with dialysis had a lower likelihood of both palliative and hospice care referral compared to those treated with CM: HR (95%CI) 0.78 (0.72-0.84) and 0.57 (0.52-0.62), respectively (Figures 1A &1B). We observed similar findings in analyses doubly-adjusted for PS covariates.

Conclusions: In a national cohort of US Veterans with advanced CKD, those who transitioned to dialysis were less likely to be referred to palliative or hospice care than those treated with CM. Further studies are needed to determine factors contributing to differential palliative/hospice care utilization in advanced CKD patients treated with CM vs. dialysis.

Natural Language Processing Artificial Intelligence (AI) Predicts CKD Progression in Medical-Word Virtual Space

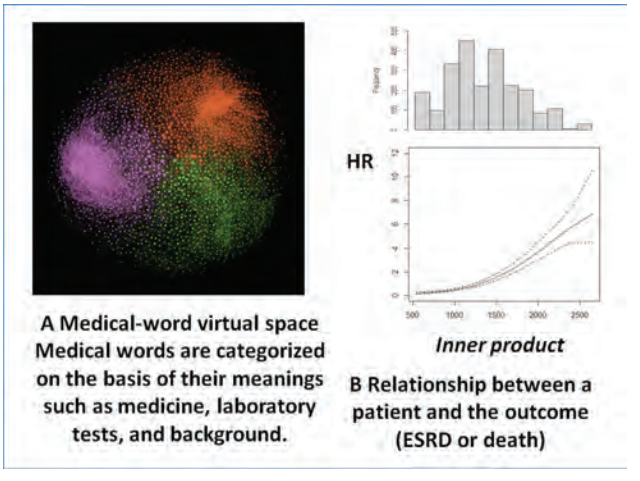
Eiichiro Kanda,[1] Bogdan I. Epureanu,[2] Taiji Adachi,[3] Tamaki Sasaki,[1] Naoki Kashihara.[1] *[1]Kawasaki Ika Daigaku, Kurashiki, Japan; [2]University of Michigan, Ann Arbor, MI; [3]Kyoto Daigaku, Kyoto, Japan.*

Background: Chronic kidney disease (CKD) leads to end-stage renal disease (ESRD) or death. A new surrogate marker reflecting its pathophysiology has been needed for CKD therapy.

Methods: In this study, we developed a virtual space where data in medical words and those of actual CKD patients were unified by natural language processing and category theory.

Results: A virtual space of medical words was constructed from the CKD-related literature (n=165,271) using Word2Vec, in which 106,612 words composed a network. The network satisfied the definition of vector calculations, and retained the meanings of medical words. The data of CKD patients of a cohort study for 3 years (n=26,433) were transformed into the network as medical-word vectors. We let the relationship between vectors of patient data and the outcome (dialysis or death) be a marker (inner product). Then, the inner product accurately predicted the outcomes: C-statistics of 0.911 (95% CI 0.897, 0.924). Cox proportional hazards models showed that the risk of the outcomes in the high-inner-product group was 21.92 (95% CI 14.77, 32.51) times higher than that in the low-inner-product group.

Conclusions: This study showed that CKD patients can be treated as a network of medical words that reflect the pathophysiological condition of CKD and the risks of CKD progression and mortality.



A Medical-word virtual space
Medical words are categorized on the basis of their meanings such as medicine, laboratory tests, and background.

B Relationship between a patient and the outcome (ESRD or death)

Evaluating a Computable Phenotype for CKD Detection in Adult Patients Treated in Primary Care

Joseph D. Nguyen, Lalida Kunaprayoon, Benjamin Silverberg, Indika V. Mallawaarachchi, Jennie Z. Ma, Jason A. Lyman, Julia J. Scialla. *University of Virginia, Charlottesville, VA.*

Background: Chronic kidney disease (CKD) affects about 37 million Americans, particularly those with diabetes and hypertension, and is often detected via laboratory studies prior to symptom onset. This project aims to evaluate the accuracy of a computable phenotype to detect adults with CKD stage 3 or higher. The ultimate goal is to improve CKD recognition and evaluation by launching a best practice advisory (BPA) in patients likely to have CKD.

Methods: We developed an algorithm to identify probable cases of CKD in adult patients seen at a primary care clinic at one academic medical center between October 2023 and February 2024. The algorithm identifies patients with estimated glomerular filtration rate (eGFR)<60 ml/min/1.73m2 during the clinic visit, as well as on a prior date (90 to 730 days prior to the index test). If a patient identified by the algorithm is not yet enrolled into the EPIC CKD registry, the BPA alert is activated for probable CKD. If a patient was alerted multiple times, we analyzed the first alert. For patients flagged for probable CKD, we conducted chart review to collect: (1) laboratory parameters for CKD and (2) data relevant to the clinical impression of CKD that may also consider other elements like markers of kidney damage (e.g. albuminuria) or structural kidney disease (e.g. imaging abnormality).

Results: Of 277 probable CKD cases, 155 individuals were alerted. 133 of these individuals met stringent laboratory criteria for CKD stage 3 or higher (e.g. no intervening normal that disagree). 115 met laboratory criteria and were also deemed to have CKD by the clinical impression of the reviewer (74% of total alerted individuals). The remaining 26% either did not fully meet laboratory criteria (n=22) or were deemed to not clearly have CKD clinically (n=18). Most of these cases were due to either borderline eGFR near 60 ml/min/1.73m2, disagreement between different eGFR equations, recovered eGFR, or oscillating eGFR.

Conclusions: Our computable CKD definition demonstrated a relatively high rate of confirmed CKD, but clinician confirmation is advisable to ensure diagnostic accuracy prior to recommending further evaluation or treatment. Future directions include refining the BPA to include other measures of kidney damage in patients with equivocal eGFR.

FR-PO1098

Validation of Machine Learning-Based Screening Tools for Early Detection of CKD in Patients with Type 2 Diabetes (T2D)

Julian Martinez,[1] Alejandra Perez-Rondon,[1] Jose Zea,[1] Isabella Ilano,[1] Natalia Castano-Villegas,[1] Luong Nguyen Cong,[2] Ahmed Hadaoui.[3] *[1]Arkangel AI, Bogota, Colombia; [2]AstraZeneca, Ho Chi Minh, Viet Nam; [3]AstraZeneca, Algiers, Algeria.*

Background: With the increasing burden of CKD among pts with T2D, early detection is critical. Annual screening is challenging, especially in developing nations. We developed 2 minimal resource models to identify pts at high risk of CKD based on estimated glomerular filtration rate (eGFR) alterations. Our study validated the models on iCaReMe global registry T2D pts.

Methods: Arkangel AI™ software was used to develop 2 algorithms. Machine-learning architectures were used for training and ranking the algorithms. An ensemble learning model was built from the 2 algorithms. A combination of predictions from these algorithms decides whether the pt is positive or negative for CKD. These algorithms were applied to an observational iCaReMe database spanning 6 low-middle-income countries to generate an eGFR-based model. Demographic data including age, duration of T2D, sex, body mass index, and systolic and diastolic blood pressure were extracted for pts with T2D. Pts with eGFR <60 mL/min/1.73m^2 were considered positive cases and those with eGFR ≥60 mL/min/1.73m^2 were negative cases. The study determined the accuracy, sensitivity, specificity, positive predictive values, area under the curve (AUC), and F1 scores of the model.

Results: A total of 4342 pts with validated eGFR measurements were included in training the models. The ensemble learning model reported 85.19% (95% confidence interval [CI]: 82.82 to 87.55) sensitivity, 39.97% (95% CI: 38.34 to 41.59) specificity, and 48.96% (95% CI: 47.48 to 50.45) accuracy. Furthermore, the model has shown a positive predictive value of 26.06% (95% CI: 24.44 to 27.68) indicating a moderate proportion of true positive cases with CKD. The F1 score of the model was 39.91%, presenting a good predictive performance. The AUC was 62.58% showing that the model can distinguish between pts with and without CKD.

Conclusions: The model reported a good sensitivity for identifying CKD risk in the diabetic population with minimal pt information. They can help bridge the unmet need for screening for CKD among at-risk populations in resource-limited, real-world settings.

Age-Specific Estimated Glomerular Filtration Rate for Mortality Prediction in the Korean Population: A Retrospective Kangbuk Samsung Health Cohort Study

Kyu-Beck Lee, Jihyun Yang, Young Youl Hyun. *Kangbuk Samsung Hospital, Jongno-gu, Seoul, Republic of Korea.*

Background: With the advance of the glomerular filtration rate (GFR) formula and the recognition of age-related variations, there is a concern regarding the need to reconsider/adapt a distinct GFR equation for the elderly. We conducted a comparative analysis of the predictive accuracy of CKD-EPI 2009, 2021 (race-free) and the European Kidney Function Consortium (EKFC) equation for mortality prediction across different age groups.

Methods: We analyzed 670,320 participants who underwent a comprehensive health examination, enrolled in Kangbuk Samsung Health Cohort from January 1, 2002 to December 31, 2019 and followed them up for mortality until December 2019. The age group was divided from 18 to 39, 40-64, and over 65 years old (group 1,2,3).

Results: The participants' median follow-up period was 8.8 years, mean age was 39.8 years old (minimum 18, maximum 97), and 53.6% were male. Mean eGFR using 2009 CKD-EPI was 95.1 ml/min/1.73m^2, 100.6 ml/min/1.73m^2 using 2021 CKD-EPI, 94.0 ml/min/1.73m^2 using EKFC. There was no difference between the equations in group 1. Discriminatory power for all-cause mortality prediction was the best when using EKFC in group 2 and group 3. Moreover, the EKFC showed better discriminatory power for CVD mortality in all age groups.

Conclusions: The EKFC equation showed better prediction and explanation in middle age to the elderly.

FR-PO1100

Identification of Rapid Decline of Kidney Function in Older Adults with Different Types of Aging

Mengjing Wang, Jing Chen. *Nephrology, Huashan Hospital, Fudan University, Shanghai, China.*

Background: This study aims to assess the role of glomerular filtration rate (GFR) combined with urine albumin-creatinine ratio (ACR) in predicting rapid kidney function decline (>30% decline in GFR within 2 years) across older adults with three types of aging (healthy aging, aging with comorbidities, aging with nephropathy).

Methods: Categorical analyses were conducted using data from the Rugao Longevity and Aging Study (RLAS) cohort in China (470 older adults with healthy aging and 505 with comorbidities) and healthcare data from Huashan Hospital of Fudan University (315 older adults with nephropathy) between 2011 and 2022. Corrected (age) absolute risk probabilities (aAR) were calculated for different GFR and ACR intervals, stratified by aging category. Finally, the importance of different categories of GFR and ACR in different aging populations for determining rapid decline in kidney function was identified based on random forest (RF) models.

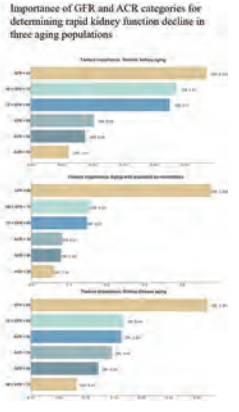
Results: Compared to the healthy group, the risk of rapid decline of kidney function was generally higher in the comorbidity group and highest in the nephropathy group across all GFR combined with ACR categories. The risk thresholds varied among the three populations: for the healthy group, ACR >30 mg/g combined with GFR <75 ml/min/1.73 m2 (moderate risk); for the comorbidity group, ACR >30 mg/g (moderate risk), particularly with GFR <60 ml/min/1.73 m2 (high risk); and for the nephropathy group, at all stages (moderate risk), particularly ACR >30 mg/g combined with GFR <75 ml/min/1.73 m2(high risk). Besides, GFR is of the most importance in distinguishing rapid decline in kidney function, but the discrimination of GFR decreases with the occurrence of comorbidities and kidney diseases, while the discrimination of ACR increases in this two populations.

Conclusions: The thresholds for GFR and ACR to predict rapid decline in kidney function in the elderly population need to be established according to different types of aging.

Funding: Government Support - Non-U.S.

The adjusted absolute risk for GFR and ACR combination in different elderly populations (healthy aging, aging with comorbidities, aging with nephropathy). Colors indicating adjusted absolute risk gradient: green (low risk: 0% - 9.9%), yellow (medium risk : 10% - 19.9%), red (high risk : 20% and above).

Three types	First eGFR and ACR in the baseline	Adjusted absolute risk probability (based on 30% decline in GFR during the 2-year baseline period)			
		GFR > 90	GFR 75 - 90	GFR 60 - 75	GFR < 60
Healthy aging	ACR < 30				
	ACR > 30				
Aging with expected co-morbidities	ACR < 30				
	ACR > 30				
Kidney disease aging	ACR < 30				
	ACR > 30				



FR-PO1101

Impact of Adopting the 2021 CKD-EPI Equation on CKD Detection in a Multiethnic Dutch Population: The HELIUS Study

Brechje Huisman, Taryn G. Vosters, Bert-Jan Van den Born, Irene van Valkengoed, Liffert Vogt. *Amsterdam UMC Locatie AMC, Amsterdam, Netherlands.*

Background: Until recently, the standard method of estimating GFR for the diagnosis of CKD included an ethnicity coefficient for those of African descent. There has been debate whether or not to exclude the coefficient from the CKD-EPI equation, which resulted in the 2021 CKD-EPI equation. We explored the impact of adopting this formula on eGFR and CKD detection in a multi-ethnic Dutch population.

Methods: We analyzed data of 21,617 participants (mean age 44yr, 42% male) of the multi-ethnic HELIUS cohort study (Amsterdam, the Netherlands). Three groups were distinguished: African Surinamese (4,151), Ghanaian (2,339) and Non-corrected (15,127; i.e., those who required no correction for ethnicity. eGFR was calculated using the uncorrected and corrected 2009 and 2021 CKD-EPI equation. CKD prevalence (i.e., eGFR (<60mL/min/1.73m^2) and/or ACR (≥3mg/mmol) was calculated. CKD case detection for all three equations were compared in high risk groups (i.e., diabetes mellitus, hypertension or cardiovascular disease). C-statistics for CKD probability were compared. Inter-rater reliability was measured via Cohen's kappa and consistency calculation.

Results: Compared to the Non-corrected group (mean eGFR 102 mL/min/1.73m^2), age- and sex-adjusted differences (p<0.001) in the mean eGFR(SE) were 4.6±0.2 vs -8.9± 0.2mL/min/1.73m^2 in the African Surinamese and 3.2±0.3 vs -10.4±0.3mL/min/1.73m^2 in the Ghanaian participants for the 2009 and 2021 CKD-EPI equation, respectively. CKD prevalences were similar for both equations overall and in subgroups (e.g., 10.9 vs 11.6% (p=0.33) among African Surinamese). CKD case detection did not differ between equations. The C-index for CKD probabilities was not influenced by the equation. The internal consistency in detecting CKD of the 2009 and 2021 equation was high (Figure 1).

Conclusions: In our cohort, adoption of the 2021 CKD-EPI equation leads to lower eGFR in African Surinamese and Ghanaian participants, but similar overall estimates of CKD prevalence. Our study indicates that discontinuation of the ethnicity-coefficient may have very little impact on CKD detection in a multi-ethnic Dutch population.

Figure 1. Internal consistency between CKD-EPI 2009 and 2021 in detecting CKD (y/n) per group

Consistency (%)	Non-corrected group CKD 2009			African Surinamese CKD 2009			Ghanaian CKD 2009		
	99.7%	y	n	99.3%	y	N	98.9%	y	n
CKD 2021	y	1526	0		452	28		267	28

Insufficient Referral and Monitoring of CKD in Germany: A Nationwide, Retrospective Cohort Study

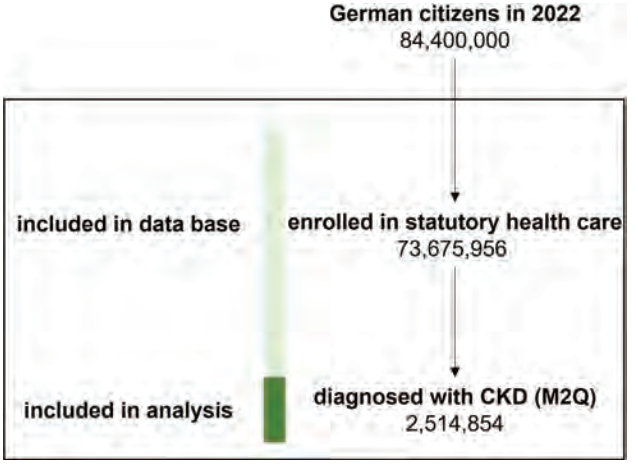
Friedrich A. von Samson-Himmelstjerna,[1] Edgar Steiger,[2] Benedikt Kolbrink,[1] Roland Schmitt,[1] Kevin Schulte.[1] *[1]University Hospital Schleswig-Holstein, Campus Kiel, Department of Nephrology and Hypertension, Kiel, Germany; [2]Central Research Institute of Ambulatory Health Care in Germany, Berlin, Germany.*

Background: Chronic kidney disease (CKD) is one of the most significant drivers of the global disease burden and an increasing public health issue. Adequate referral of high-risk patients to nephrologists is associated with improved management of CKD. Whether this is accomplished in Germany, a country with very high health care expenditure, is unknown.

Methods: We retrospectively analyzed outpatient claims data of 73,675,956 Germans who were covered by statutory health care in 2022.

Results: We identified 2,514,854 patients with prevalent CKD, 207,015 of which had CKD stage 4. Merely 134,132 (64.8%) patients with diagnosed CKD stage 4 received specialist care by a nephrologist in 2022. Failure to refer was associated with insufficient monitoring rates of kidney function and proteinuria. In a mixed logistic regression model, referral to nephrologists was less likely for women (odds ratio [OR] 0.72, 95% confidence interval [CI] 0.71-0.74), for higher age (OR per year 0.97, CI 0.96-0.97) and for nursing home inhabitants (OR 0.62, CI 0.60-0.64). These findings remained steady despite multi-variable adjustment for individual morbidity, population density, urbanization, and nephrologist density.

Conclusions: Our findings suggest serious short comings of the German health care system with inability to provide adequate referral to nephrology services for patients with late-stage CKD, particularly disadvantaging women, the elderly, and nursing home inhabitants. Change of public health policy is needed for better prevention of kidney failure as well as to reduce the CKD-associated burden of disease.



All statutory health care recipients with a diagnosis of CKD in the year 2022 were included. Only reconfirmed cases were included, meaning that a diagnosis of CKD was claimed in at least 1 additional quarter within 1 year after the initial diagnosis (M2Q).

FR-PO1103

Enhancing Access to Nephrology Care: Development of a Telenephrology Dashboard via Human-Centered Design

Melissa L. Swee,[1,2] Diana I. Jalal,[1,2] M. Lee Sanders,[1,2] Mary V. Sarrazin,[1,2] Angie R. Thumann,[1] Kantima Phisitkul,[1] Masaaki Yamada,[1,2] Heather Reisinger,[2,1] Bradley S. Dixon.[1] *[1]VA Iowa City Healthcare System, Iowa City, IA; [2]University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: Chronic kidney disease (CKD) is common and associated with high rates of morbidity and mortality. Despite evidence that early referral to nephrology improves outcomes, it is estimated that less than half of patients with CKD see a nephrologist. We aimed to improve access to nephrology care by developing a user-friendly Telenephrology dashboard for the 40,000 Veterans receiving care through the Iowa City Veterans Affairs Health Care System.

Methods: The development process adhered to the human-centered design framework, encompassing five phases: (1) Empathize, (2) Define, (3) Ideate, (4) Prototype, and (5) Test. We interviewed patients' and providers' regarding perceptions of structural barriers and facilitators for the Telenephrology program, using the Consolidated Framework for Implementation Research (CFIR) as a guide. Data from these interviews were analyzed using directed content analysis. Then, a rapid ideation workshop was convened to generate creative solutions that balance technical requirements with the needs of clinicians and patients.

Results: The iterative design process identified three critical needs: (1) clarity in visualizing data, (2) accuracy of information, and (3) balancing standardization with individualization. The final Telenephrology Dashboard developed through the rapid ideation workshop included: (1) a graph of kidney function over time, (2) tables synthesizing lab data, (3) options to drill down events to specific times, (4) customization of views, and (5) integration of kidney disease progression models. Since the inception of the Telenephrology program in 2018, clinic productivity has increased and wait times have decreased. Key facilitators identified in interviews included increased access to specialist care and convenience for providers and Veterans. Perceived barriers included: concerns of decreased autonomy and increased workload for primary care providers, added complexity, and lack of sustainability.

Conclusions: Telenephrology increases nephrology access and convenience. Nevertheless, future challenges include concerns around primary care autonomy, workload, and system complexity. Ongoing research is needed to validate the impact of Telenephrology on patient outcomes and physician satisfaction and effectiveness.

FR-PO1104

Integrating Clinical Decision Support Tools in CKD Management

Heather Thiessen Philbrook,[1] Dipal M. Patel,[1] Jack Bitzel,[1] Steven Menez,[1] C. E. Cervantes,[1] Bernard G. Jaar,[1] Morgan Grams,[2] Chirag R. Parikh.[1] *[1]Johns Hopkins Medicine, Baltimore, MD; [2]NYU Langone Health, New York, NY.*

Background: Integrating clinical decision support (CDS) tools into nephrology outpatient clinics provides an opportunity to improve patient care by leveraging existing data in electronic medical records (EMR).

Methods: In January 2022, three CDS tools were deployed for use in Johns Hopkins nephrology clinics. A viewer within the EMR system displays Kidney Failure Risk Equation (KFRE) scores, risk of cardiovascular disease and longitudinal graphical

visualizations including prescription status for the top 5 KDIGO-recommended proteinuria-reducing therapies, and laboratory measurements (Figure). Nephrologists can also view the 2-year KFRE on the EMR dashboard and utilize a dotphrase in clinic notes. We examined trends in clinical care practices before (2020-2021) and after (2022-2023) implementation of these CDS tools for patients with advanced kidney disease, and within a subgroup of diabetic patients.

Results: Practice patterns improved with a reduction in the percentage of patients without recent albuminuria measurements (Table). Prescription rates of evidence-based therapies to reduce proteinuria and protect kidney function increased over time.

Conclusions: CDS tools can highlight guideline-based recommendations for clinical care and provide an opportunity to evaluate their impact in real-world clinical settings. More analyses are needed to define mechanisms by which CDS tools impact clinical practices.

CKD Care: Evaluating the Role of Clinical Pharmacists

Masaaki Yamada,[1,2] Qianyi Shi,[1,2] Brian C. Lund,[2] Mary K. Good,[2] Benjamin R. Griffin,[1] Melissa L. Swee,[1,2] Sadaf Akbari,[1] Korey Kennelty,[1] Elissa Z. Faro,[1] Mary V. Sarrazin,[1,2] Diana I. Jalal.[1,2] *[1]University of Iowa Hospitals and Clinics, Iowa City, IA; [2]Iowa City VA Medical Center, Iowa City, IA.*

Background: Clinical pharmacists are proven to lower cardiovascular (CV) risks in chronic disease management. Chronic kidney disease (CKD) increases CV events, yet studies on clinical pharmacist-driven CKD care remain scarce. We evaluated the pharmacist utilization in CKD within the Veterans Health Administration–known for its robust clinical pharmacist workforce.

Methods: We conducted a retrospective cohort study of Veterans with CKD. CKD was defined by an estimated glomerular filtration rate (eGFR) <60 mL/min (measured twice, ≥90 days apart) during 2018 to 2019. Pharmacist users were individuals who had at least 1 clinic visit with a clinical pharmacist. Logistic regression analysis was used to identify factors associated with pharmacist use.

Results: Our cohort (732,003 Veterans with CKD) was predominantly White (72%) and male (96%), with mean age=75 years (yrs) and mean eGFR=46 mL/min; 37% lived in rural areas. 22% were identified as pharmacist users. Compared to pharmacist non-users, pharmacist users were younger (70 vs. 75 years), less likely to live in rural areas (35% vs. 37%) and had a higher prevalence of diabetes mellitus (74% vs. 46%). Logistic regression analysis indicated lower pharmacist utilization among Veterans aged ≥70 yrs (odds ratio [OR] 0.82 for age 70-79 yrs and 0.63 for age ≥80 yrs, p <0.01), particularly in rural areas (p for interaction, <0.05) as shown in Figure. Rurality was associated with underutilization of pharmacist-led care (OR, 0.92, p <0.001). Clinical pharmacist utilization did not differ across varied CKD stages (p >0.05).

Conclusions: Approximately 1 in 5 Veterans with CKD utilize clinical pharmacist care. Older age and rural residence significantly associate with underutilization of pharmacists in CKD care.

Iohexol Plasma Clearance Measurement Protocol Standardization: A Consensus of the European Kidney Function Consortium

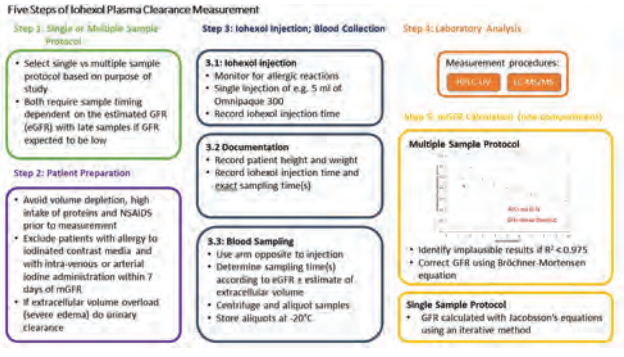
Natalie Ebert,[1] Elke Schaeffner,[1] Tariq Shafi,[3] Bjorn O. Eriksen,[6] Arend Bokenkamp,[8] Marco van Londen,[9] Jesse C. Seegmiller,[10] Runolfur Palsson,[7] Olafur S. Indridason,[7] Pierre Delanaye,[5] Etienne Cavalier,[2] Laurence Dubourg,[11] Christine A. White.[4] European Kidney Function Consortium (EKFC). *[1]Charite Universitatsmedizin Berlin, Berlin, Germany; [2]Universite de Liege, Liege, Belgium; [3]Houston Methodist, Houston, TX; [4]Queen's University, Kingston, ON, Canada; [5]CHU de Liege - Hopital du Sart Tilman, Liege, Belgium; [6]UiT Norges Arktiske Universitet, Tromso, Norway; [7]Landspitali, Reykjavik, Iceland; [8]Amsterdam UMC Locatie AMC, Amsterdam, Netherlands; [9]Rijksuniversiteit Groningen, Groningen, Netherlands; [10]University of Minnesota Twin Cities, Minneapolis, MN; [11]Hospices Civils de Lyon, Lyon, France.*

Background: International consensus and the 2024 KDIGO guidelines supports the development of standardized protocols for measured glomerular filtration rate (mGFR) to facilitate the adoption of mGFR in both clinical and research settings.

Methods: The European Kidney Function Consortium (EKFC) convened an international group of mGFR experts and performed an extensive literature search to inform the development of recommendations for mGFR determination using one-compartment plasma clearance models and iohexol as the exogenous filtration marker. Iohexol was selected as it is non-radiolabeled, safe, inexpensive, widely available, and can be assayed at a central laboratory. Other commonly used non-radio labeled tracers have been (inulin) or are soon to be (iothalamate) discontinued. A plasma clearance model was selected as it does not require timed urine collections. A one-compartment model was preferred to a two-compartment model as it requires fewer samples. The resulting recommendations were based on published evidence complemented by expert opinion.

Results: Recommendations include practical advice for patients and health professionals, preparation, administration and safety aspects of iohexol, laboratory analysis, blood sample collection and sample timing for both multiple and single sample protocols, description of the mGFR mathematical calculations as well as implementation strategies (Figure). The EKFC will provide materials such as patient information sheets, standard operating procedures, a study protocol template, and support for mGFR calculation.

Conclusions: Members of the EKFC have evaluated the evidence and formulated recommendations that include all aspects of iohexol plasma clearance measurement using a one-compartment model. Nephrologist education and widespread dissemination is critical to making mGFR available for patient care and research.



FR-PO1107

Association of Urine-to-Plasma Urea Ratio with the Incidence of Kidney Failure in Patients with CKD

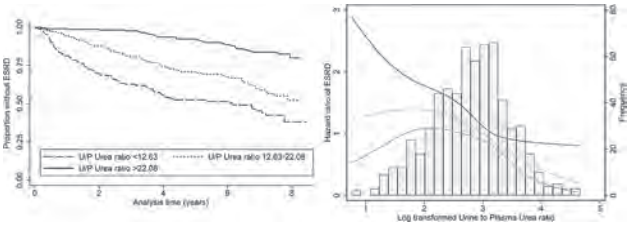
Usha Kumari,[1] Mohamed T. Elkhodary,[1] Keiichi Sumida,[1] Barry M. Wall,[1,2] Csaba P. Kovesdy.[1,2] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]VA Memphis Healthcare System, Memphis, TN.*

Background: Estimated glomerular filtration rate (eGFR) and proteinuria are traditional markers used to assess the risk of kidney outcomes. Measures of tubular function such as the ratio of urine to plasma urea (U/P urea) can offer additional insight on the kidneys' functional capacity, but its association with long term kidney outcomes is unclear.

Methods: In a retrospective cohort of 638 patients with eGFR <60 ml/min/1.73m^2 from a single institution, we measured U/P urea from single spot urine specimens. We examined the association of U/P urea with end-stage kidney disease (ESKD, defined as the initiation of kidney replacement therapy) using the Kaplan Meier method and multivariable adjusted Cox models with adjustment for demographic characteristics, smoking status, comorbidities, eGFR and proteinuria. U/P urea was analyzed both as a natural log-transformed continuous variable and as a categorical variable divided in tertiles.

Results: The mean±SD age was 67±10 years old, 96% were male, 58% were African-American and the mean±SD eGFR was 21±11 mL/min/1.73 m^2. There were 188 ESKD events (event rate, 65.9/1000PY; 95% CI: 57.1-76.1) over a median follow-up of 4.5 years. Lower U/P urea was associated with higher risk of ESKD in unadjusted (hazard ratio and 95%CI for 1 log-unit lower U/P urea: 2.39 [1.95-2.92], p<0.001) and after multivariable adjustment (1.40 [1.06-1.85], p=0.018, Figure).

Conclusions: Lower U/P urea ratio, a marker of impaired renal concentration ability, is associated with higher risk of ESKD independent of known risk factors such as eGFR and proteinuria. U/P urea obtained from spot urine specimens could provide additional information for risk stratification in patients with chronic kidney disease.



FR-PO1108

Large-Scale Proteomics Improve Prediction of CKD in the General Population without Diabetes

Ziliang Ye, Fan Fan Hou, Xianhui Qin. *Southern Medical University Nanfang Hospital, Guangzhou, China.*

Background: To develop a protein risk score (PRS) for predicting chronic kidney disease (CKD) and compare its predictive capability with a validated clinical risk model (CKD Prediction Consortium [CKD-PC]) and CKD genetic risk score (GRS) in the general population without diabetes.

Methods: The development cohort included 36,307 participants from England area in the UK biobank. Participants in the development cohort were randomly divided into a training set and a testing set in a 7:3 ratio. The validation cohort included 4,813 participants from Scotland and Wales area in the UK biobank.

Results: In the training set, a PRS for CKD risk was constructed using 86 out of 2,911 proteins. In the testing set, the CKD PRS was significantly positively associated with incident CKD (per SD increment, HR, 1.88; 95%CI: 1.67, 2.12). The C-index of the CKD PRS in predicting CKD risk was 0.838 (95%CI: 0.814-0.861), which was significantly better than that of CKD GRS (C-index, 0.749; 95%CI, 0.721-0.777). Adding CKD PRS to CKD-PC risk factors significantly increased the C-index (from 0.825 to 0.853; difference, 0.029; 95%CI, 0.018-0.040), the continuous 10-year net reclassification (0.162; 95%CI, 0.074-0.259) and integrated discrimination index (0.009; 95%CI, 0.001-0.026). The C-index for the alternative CKD PRS, compromising only the top 5 proteins (CD59, COL6A3, HRC, ITGB2, and KIM-1), was 0.810 (95%CI: 0.785-0.836), contributing most of the prediction power of original CKD PRS. These results were verified in the validation cohort.

Conclusions: The CKD PRS was a potent predictor for CKD risk in the general population without diabetes. When incorporated into a validated clinical risk model, the CKD PRS significantly improved CKD risk discrimination and reclassification.

A Phenome-Wide Association Study to Investigate the Role of Carbamylation in CKD: Findings from the Chronic Renal Insufficiency Cohort

Aya Awwad,[1,2] Eugene P. Rhee,[2,1] Pranav S. Garimella,[3] Sagar U. Nigwekar,[2,1] Anders H. Berg,[4] James P. Lash,[5] Mengyao Tang,[2,1] Sahir Kalim.[2,1]
[1]Harvard Medical School, Boston, MA; [2]Massachusetts General Hospital, Boston, MA; [3]University of California San Diego Division of Nephrology-Hypertension, San Diego, CA; [4]Cedars-Sinai Medical Center, Los Angeles, CA; [5]Department of Medicine, University of Illinois at Chicago, Chicago, IL.

Background: Protein carbamylation, a urea driven post-translational protein modification, increases in patients with CKD and contributes to the excess morbidity and mortality observed in this population. Given urea's, and thus carbamylation's, ubiquitous nature in the body, we hypothesized carbamylation would associate with a broad range of clinical phenotypes.

Methods: We evaluated the cross-sectional association of carbamylation -assessed by carbamylated albumin (C-Alb)- with 243 phenotypic correlates among 3,111 CKD participants in the Chronic Renal Insufficiency Cohort using a phenome-wide association study (PheWAS). Models were adjusted for demographics, eGFR, and proteinuria, and a conservative Bonferroni adjusted threshold for significance was applied. Results prompted a focused post-PheWAS analysis on the association between C-Alb and coronary artery calcification (CAC) measured by Agatston scores.

Results: C-Alb was significantly associated with hematological abnormalities such as anemia diagnosis (OR: 2.04; 95% CI [1.81, 2.3], adj. pvalue=2.17 × 10-28), cardiovascular abnormalities such as increased left ventricular mass (OR: 1.38; 95% CI [1.19, 1.61], adj. pvalue=5.9 × 10-3), and lipid profile among other phenotypes (Fig.1a). C-Alb's positive association with calcification indices was the largest numerically in standardized magnitude among significant phenotypes (Fig.1b). The association with Agatston score remained significant even after adjusting for traditional atherosclerotic risk factors (β 0.77, 95% CI [0.35-1.19], pvalue <0.001).

Conclusions: Our findings showcase the wide systemic correlates of carbamylation in patients with CKD, particularly in the cardiovascular system. Carbamylation emerged as an independent risk factor for CAC, suggesting its potential as a target for therapeutic intervention to mitigate cardiovascular risk in CKD populations.

Plasma Transcriptome Profile Associated with CKD Progression

Anvesha Srivastava,[1] Mark Maienschein-Cline,[3] Richard L. Amdur,[2] Ana Pabalan,[1] Vaishali I. Parekh,[1] Dominic S. Raj.[1] *[1]The George Washington University, Washington, DC; [2]Northwell Health Feinstein Institutes for Medical Research, Manhasset, NY; [3]University of Illinois System, Urbana, IL.*

Background: Understanding the molecular signals associated with the progression of kidney disease is vital for risk stratification and targeted treatment. Advances in RNA-sequencing technology has enabled us to translate extracellular transcriptome profiles to precision diagnostics.

Methods: We evaluated the plasma mRNA profile of participants exhibiting slow (n=119) and fast (n=119) decline in estimated glomerular filtration rate (eGFR) among the Chronic Renal Insufficiency Cohort (CRIC) in a nested case control study. The two groups were matched for age, sex, race, baseline eGFR, proteinuria and diabetes status. The next generation sequencing data was analyzed edgeR to identify differentially expressed genes (DEGs) and associated pathways. We also compared the top plasma DEGs with gene expression in microdissected human CKD kidney.

Results: We identified fragments from ~28,000 annotated genes, of which 783 transcripts exhibited differential expression between slow and fast CKD progressors. Among 629 protein coding genes, 469 were overexpressed in slow progressors, while 157 showed increased expression in fast progressors. Expression of GLI2, CUX1, NOTCH1 and LRP1 transcripts were amplified in slow progressors. Pathway analysis linked these differentially expressed genes to WNT/β-catenin signaling, IL-12 signaling and production in macrophages, Netrin-1 Signaling and Epithelial-Mesenchymal Transition pathways. Many of the plasma differentially expressed genes were also upregulated in human CKD kidney. A risk score containing transcripts GABA, NEUROG and SHISAL2B was able to predict fast progressors (ROC 0.85 [95% CI= 0.75-0.95]).

Conclusions: Warranting further validation, circulating levels of aberrantly expressed transcripts hold potential to be used as biomarkers for fast CKD progression.

Impact of Bariatric Surgery on Kidney Function: A Prospective Analysis of Short-Term Outcomes

Rolando Claure-Del Granado,[1,2] Verónica N. Carlos-Rodríguez,[1,2] Sergio O. Aparicio-Yuja.[1,3] *[1]Universidad Mayor de San Simon, Cochabamba, Bolivia, Plurinational State of; [2]Department of Medicine, Clinica "Los Olivos", Cochabamba, Bolivia, Plurinational State of; [3]Department of Surgery, Clínica Los Olivos, Cochabamba, Bolivia, Plurinational State of.*

Background: Obesity and diabetes mellitus are leading causes of chronic kidney disease. Patients with obesity are more likely to develop chronic kidney disease and end-stage kidney failure. In the long-term, individuals with a body mass index (BMI) greater than 30 kg/m^2 have a significant higher risk of glomerular filtration rate decline. This study investigated the effects of bariatric surgery on estimated glomerular filtration rate (eGFR) and urinary albumin-to-creatinine ratio (ACR) in morbidly obese patients.

Methods: Clinical variables for patients who underwent bariatric surgery were prospectively analyzed over a 12-month follow-up period between January 15, 2021, and August 14, 2023. eGFR (ml/min/1.73m^2) was calculated using the serum creatinine CKD-EPI formula. Urinary ACR was measured during the follow-up. Body mass index (BMI, kg/m^2), percent weight loss (%WL), systolic blood pressure (SBP), and diastolic blood pressure (DBP) were recorded during the follow-up.

Results: Eighty-two patients were included, 48,8% (n=40) underwent bariatric surgery-laparoscopic Roux-en-Y gastric bypass (LRYGB), 39% (n=32) underwent laparoscopic sleeve gastrectomy (LSG; n = 39) and 12,2% (n=10) underwent intestinal bipartition. Baseline characteristics and follow-up parameters are presented in Table 1. The eGFR of both groups increased at the follow-up outpatient visits (months 1, 3 and 12) ($p < 0.001$) as shown in Table 1. The ACR decreased in the first month and twelve months after the bariatric surgery ($p < 0.0001$). The SBP and DBP decreased after bariatric surgery, with no significant difference between the three groups ($p > 0.05$).

Conclusions: Bariatric surgery is associated with improvements in postoperative renal function 1, 3 and 12 months following surgery, with significant reductions in ACR and better blood pressure control.

	Baseline values	1 month	3 months	6 months	12 months
Systolic Blood Pressure (mmHg)	126.5±12.1	119.2±12.1 (p<0.0001)	115.3±7.9 (p<0.0001)		113.6±10.5 (p<0.0001)
Diastolic Blood Pressure (mmHg)	79.6±5.9	74.2±6.3 (p<0.0001)	72.5±6 (p<0.0001)		72.4±6.2 (p<0.0001)
Glucose levels (mg/dL)	96.6±25.8	85.6±11.8 (p<0.0001)	85.1±11.8 (p<0.0001)		81.3±17.4 (p<0.0001)
HbA1c (%)	5.88±1.3			5.03±0.35 (p=0.001)	5.27±0.6 (p<0.0001)

Overweight/Obesity and Pulse Pressure: Kidney Prognosis in Young and Elderly Patients with ADPKD Regarding Attribute-Based Medicine (ABM) Insights

Hiroshi Kataoka, Toshio Mochizuki, Shun Manabe, Yusuke Ushio, Momoko Seki, Ken Tsuchiya, Kosaku Nitta, Junichi Hoshino. *Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan.*

Background: How aging impacts renal prognosis in autosomal dominant polycystic kidney disease (ADPKD) has yet to be fully undertaken. We sought to explore these distinctions in kidney disease progression among young and elderly ADPKD patients, focusing on the influence of overweight/obesity and pulse pressure, related markers of arteriosclerosis.

Methods: We enrolled 553 ADPKD patients who were not undergoing renal replacement therapy, with a median age of 43 years, an estimated glomerular filtration rate of 55.9 mL/min/1.73 m^2, and a total kidney volume of 1335.4 mL. The renal outcome, defined as a 30% reduction in estimated glomerular filtration rate or initiation of renal replacement therapy, was assessed using Cox regression analysis.

Results: The study followed 236 patients over a median period of 9.1 years to assess renal outcomes. Multivariable Cox analyses identified several significant risk factors for kidney disease progression: female sex (HR=1.82), age (HR=0.76 per 10-year increase), eGFR (HR=0.58 per 10 mL/min/1.73 m^2 increase), urinary protein excretion (HR=1.72), and total kidney volume (HR=1.03 per 100 mL increase). Notably, interactions were observed between age (≥50 years) and urinary protein excretion (P=0.0050), higher pulse pressure (≥50 mmHg) (P=0.0386), and overweight (BMI ≥25 kg/m^2)(P=0.0414). Subgroup analysis revealed that total kidney volume (HR=1.03 per 100 mL increase) and overweight/obesity (HR=2.01) were risk factors in patients under 50, while urinary protein (HR=2.55) and pulse pressure ≥50 mmHg (HR=1.74) were significant in patients over 50.

Conclusions: Poor renal prognosis was associated with increased total kidney volume and obesity in younger patients, but increased protein in the urine and increased pulse pressure in older patients. In recent years, treatments and research that are tailored to patient attributes have been proposed, but in the case of ADPKD patients, it is necessary to change treatment policies depending on age attributes.

FR-PO1113

Long-Term Dynamic Effect of Body Mass Index on Adverse Cardiovascular Outcomes with the Targeted Maximum Likelihood Estimation Method: Results from the KNOW-CKD Study

Yun Jung Oh,[1] Kook-Hwan Oh,[2] Wookyung Chung,[3] Ji Yong Jung.[3] *[1]H Plus Yangji Hospital, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea; [3]Gachon University Gil Medical Center, Incheon, Republic of Korea.*

Background: Unlike the general population, the obesity paradox, referring to the association of high body mass index (BMI) with better survival, has been observed in patients with chronic kidney disease (CKD). However, the impact of long-term BMI changes in CKD patients on the risk of cardiovascular outcomes considering time varying exposure and confounding, has been rarely studied.

Methods: A total of 1,061 patients enrolled as part of The Korean Cohort Study for Outcome in Patients With Chronic Kidney Disease (KNOW-CKD) were analyzed at 3 observational points (baseline, 3-year; early, and 7-year; late) at which BMI was measured. We used longitudinal targeted minimum loss-based estimation (TMLE) and marginal structural models (MSM) to estimate the cumulative incidence of cardiovascular events (CVEs) of dynamic exposure to high BMI (≥23kg/m^2) comparing counterfactuals (BMI <23kg/m^2) adjusted for time varying confounding (systolic blood pressure, estimated glomerular filtration rate) and baseline covariates (age, sex, smoking, diabetes, cardiovascular disease, and proteinuria).

Results: Patients with sustained high BMI throughout 7-year follow-up had significantly reduced risk of CVEs than those with counterfactuals (relative risk [RR], 0.279; 95% confidence interval, 0.143-0.546; P < 0.001). However, the RR were 0.319 (0.001-136.9; P = 0.712) and 0.988 (0.296-3.298; P = 0.985) for early and late change to high BMI comparing sustained low BMI, respectively. In MSM, hazard ratio (HR) of accumulative high BMI frequency were 0.925 (0.663-2.189; P = 0.645) up to 3 years and 0.562 (0.406-0.779; P = 0.001) up to 7 years, respectively.

Conclusions: In CKD patients, higher BMI is associated with better cardiovascular outcome, and the protective effect is observed only in patients who retained high BMI consistently over long-term period.

Muscle Density Changes in CKD and Clinical Outcomes

Sarah J. Schrauben,[1] Babette Zemel,[3] Jin Long,[4] Francis P. Wilson,[2] Michelle Denburg,[3] Sogol Mostoufi-Moab,[3] Joshua F. Baker.[1] *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Yale University School of Medicine, New Haven, CT; [3]The Children's Hospital of Philadelphia, Philadelphia, PA; [4]Stanford University, Stanford, CA.*

Background: Low muscle density associates with muscle impairment and poor outcomes. We measured muscle density annually over 2 years in CKD participants, compared with controls to determine predictors of muscle density decline, and associations with cardiovascular disease (CVD) and death.

Methods: Adults with CKD were recruited as an ancillary to the CRIC Study. Healthy adults, ages 21-78 years were enrolled as controls. Muscle and fat cross-sectional area (CSA, cm^2) in the calf were obtained by peripheral quantitative CT (pQCT). pQCT muscle density (mg/cm^3) was used as a composite index of intra- and extra-myocellular fat content. pQCT measures were converted to age- and sex-specific Z-Scores based on distributions in controls. Linear regression analyses evaluated group differences and changes in muscle density over time in CKD. Cox proportional hazards models evaluated associations of muscle density with CVD and death over mean 8 years.

Results: Included were 501 controls and 277 with CKD. Muscle density was lower in CKD [β: -0.60, 95% CI: -0.75, -0.45]; difference was attenuated when adjusted for BMI. Deficits were most notable among those with sarcopenia (low muscle CSA) (**Figure**). Diabetes and low calf CSA also predicted greater muscle density 2 yr decline [diabetes β: -0.09, 95% CI: -0.18, -0.01, calf CSA Z-score ≤ -1 β -0.17, 95% CI: -0.30, -0.04]. Lower muscle density was associated with a higher risk of death and CVD, but not independently of age, race, sex, diabetes, smoking, CVD, and eGFR [HR per SD: 1.27 (0.92, 1.72); HR: 1.25 (0.97, 1.61), respectively].

Conclusions: Low muscle density was observed among CKD patients with diabetes, greater adiposity, low calf CSA, low BMI, and more advanced CKD. Greater declines in muscle density were associated with baseline diabetes and low muscle mass. These observations suggest loss of muscle density in CKD occurs in the context of metabolic obesity as well as sarcopenia.

Sex Differences in Handgrip Strength in Nondialysis-Dependent CKD

Amy S. Li, Angelina M. Dixon, Zhiying You, Jessica B. Kendrick. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Handgrip strength (HGS) is a simple, reliable measure of skeletal muscle function and a surrogate marker of protein-energy status and functional status in patients with chronic kidney disease (CKD). We assessed HGS using the NIH Toolbox grip strength test in CKD patients.

Methods: We studied 105 individuals (49.5% women) with CKD stage 3b-4 (eGFR 15-44 ml/min/1.73m^2). HGS was measured using the NIH Toolbox grip strength test, a standardized and validated test in the US population, with the Jamar Plus Digital dynamometer.

Results: The mean (SD) age and eGFR were 61 ± 12 years and 34.9 ± 9.8 mL/min/1.73m^2. When compared to the NIH Toolbox reference population, CKD participants scored, on average, below the 50th percentile on HGS in both the dominant and nondominant hand. Women scored in a significantly lower percentile than men, p<0.0001. When adjusted for age, sex, race/ethnicity, and education level, women had a higher dominant mean grip strength score than men but this was not statistically significant. There were no significant differences in HGS between participants with CKD stage 3b or 4.

Conclusions: Participants with CKD have lower HGS when compared to the general population, with women scoring in a significantly lower percentile than men. Women tended to have greater dominant grip strength compared to men, but this was not statistically significant. Further studies are needed to study sex differences in skeletal muscle function in CKD.

Unveiling the Association between Nonalcoholic Fatty Liver Disease and CKD: Insights from NHANES, 1999-2016

Yaerim Kim,[1] Jin hyuk Paek,[1] Woo Yeong Park,[1] Kyubok Jin,[1] Seungyeup Han,[1] Jung Pyo Lee.[2] *[1]Keimyung University School of Medicine, Daegu, Republic of Korea; [2]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea.*

Background: Although non-alcoholic fatty liver disease (NAFLD) increases the risk of kidney dysfunction genetically, the clinical association in different conditions has not been evaluated yet. Herein, we aimed to evaluate the association between NAFLD and chronic kidney disease (CKD) using a fatty liver index (FLI), a useful non-invasive method for assessing the status of NAFLD.

Methods: This study utilized data from the National Health and Nutrition Examination Survey (NHANES) 1999-2016. The participants were categorized into FLI quartiles, with the 1st quartile serving as the reference group. CKD was defined based on the estimated glomerular filtration rates (eGFR) <60 mL/min/1.73 m^2. To evaluate the risk of CKD, we performed multivariate logistic regression model adjusted with age, sex, ethnicity, education, alcohol consumption, smoking status, comorbidities, laboratory parameters, and total calorie intake.

Results: Among 51,688 participants, 9.4% (n=4,843) were defined with CKD. The 4th quartile of FLI significantly increased the risk of CKD with 1.81 times than 1st quartile, and it was maintained after adjustment with such variables (adjusted odds ratio [aOR] 1.35, 95% CI 1.18-1.55). In the subgroup analysis, the significance of FLI was prominent in age ≥60 (aOR 1.38, 95% CI 1.19-1.61). The impact of the highest quartile of FLI was maintained irrespective of sex. In comparing the participants according to the presence of comorbidities, the significance of 4th quartile of FLI was maintained in participants without hypertension (aOR 1.47, 95% CI 1.15-1.87), without diabetes (aOR 1.42, 95% CI 1.21-1.66), or without dyslipidemia (aOR 1.50, 95% CI 1.24-1.82).

Conclusions: NAFLD representing with higher FLI is significantly associated with the risk of incident CKD. The association between FLI and CKD was more prominent in elderly population and without comorbidities such as hypertension, diabetes, or dyslipidemia. FLI could be applied in specific populations as a good predictor of CKD.

FR-PO1117

Gout Prevalence and Management Strategies among Patients with Moderate to Advanced CKD

Deepika Laddu,[1] Dhajanae Sylvertooth,[1] Murilo H. Guedes,[1] Brian Bieber,[1] Roberto Pecoits-Filho,[1] Bradley A. Marder,[2] Brian LaMoreaux,[2] Angelo Karaboyas.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Amgen Inc, Thousand Oaks, CA.*

Background: Gout, a hallmark clinical manifestation of hyperuricemia-induced inflammation in joints and soft tissue, frequently coexists with chronic kidney disease (CKD), potentially exacerbating as kidney function declines. Despite its growing global burden, there is limited data on gout monitoring and treatment practices among CKD patients. This multi-country study describes the prevalence, patient characteristics, and medical management of gout in a cohort of non-dialysis patients with moderate to advanced CKD.

Methods: Cross-sectional data from 3,524 non-dialysis stage 3b-5 CKD patients enrolled in the Chronic Kidney Disease Outcomes and Practice Patterns Study (CKDopps) in Brazil (n=942) and the United States (US; n=2,582) at study enrollment (2013-2022) were analyzed. History of gout (yes/no) was extracted from medical records by study coordinators. Patient characteristics, gout treatment, and uric acid measurement practices were summarized by gout diagnosis and country.

Results: Prevalence of gout was 19% overall – 21% in the US vs. 14% in Brazil – and was higher in stage 4-5 vs. stage 3b CKD in both countries (Figure). Gout patients (versus no gout) were more likely to be male (66% vs. 49%) and have a higher prevalence of cardiovascular comorbidities, despite similar BMI levels across groups. Among gout patients, allopurinol was the most utilized gout treatment in both Brazil (75%) and the US (62%). Colchicine (13%) and Febuxostat (8%) were also used in the US, but rarely in Brazil (<5%). Mean uric acid among gout patients was 7.0 mg/dL in Brazil vs. 6.7 mg/dL in the US; however, only 30% of US gout patients had a uric acid measurement, vs. 70% in Brazil.

Conclusions: Gout affects a substantial proportion of the non-dialysis CKD population, with differing management and monitoring strategies between the US and Brazil. Further examination of the effectiveness of gout diagnosis and treatment practices between countries may provide an important opportunity to improve patient outcomes.

FR-PO1118

Incidence and Risk Factors of Gout in Nondialysis-Dependent Patients with CKD and Asymptomatic Hyperuricemia

Ilia Beberashvili, Elad Nizri, Shai Efrati. *Shamir Medical Center Assaf Harofeh, Tzrifin, Israel.*

Background: The association between asymptomatic hyperuricemia and the development of gout in chronic kidney disease (CKD) patients in stages 3-5 who are not yet on dialysis has not been fully investigated. This study aimed to assess the prevalence of gout in this population and identify risk factors for its development.

Methods: A retrospective analysis of a clinical database of ambulatory CKD patients without dialysis who had asymptomatic hyperuricemia and no prior history of gout was conducted. The study period was from 2010 to the present. Gout diagnoses confirmed during the follow-up period were based on the Rome criteria and were confirmed by the institution's rheumatology clinic.

Results: This study included 771 CKD patients in stages 3-5 without dialysis, with an average age of 72 years, of whom 44% were women. Over a median follow-up period of 47 months, 18% of the patients developed gout. Analysis using a Cox proportional hazards model with backward conditional elimination identified four independent risk factors for gout: age, diuretic use, uric acid levels, and creatinine levels. Cutoff points for continuous variables were determined based on ROC curve analysis, and then these risk factors were combined into a scoring system based on multivariate logistic regression coefficients. This system allowed for the estimation of gout risk and showed a hazard ratio (HR) of 2.25 (95% CI: 1.60-3.16) for CKD patients under 71 years of age who use diuretics regularly, have uric acid levels above 8.3 mg/dL, and creatinine levels below 1.5 mg/dL. This association remained significant even after adjustment for multiple variables, including the Charlson Comorbidity Index and BMI.

Conclusions: Gout prevalence is high among CKD patients with asymptomatic hyperuricemia. Early treatment aimed at lowering blood uric acid levels may be beneficial for high-risk populations. These findings warrant further validation through interventional studies.

FR-PO1119

Association between Alcohol Consumption and the Risk of Incident CKD in Community-Dwelling Older Adults

Ju hwan Oh,[1] In O Sun,[1] Eunjin Bae,[2] Soon hyo Kwon,[3] Byung chul Yu,[4] Jae Won Yang,[5] Won Min Hwang,[6] Yu Ah Hong.[7] *[1]Presbyterian Medical Center, Jeonju, Jeollabuk-do, Republic of Korea; [2]Gyeongsang National University Hospital, Jinju, Republic of Korea; [3]Soonchunhyang University Hospital, Yongsan-gu, Seoul, Republic of Korea; [4]Soonchunhyang University Hospital Bucheon, Bucheon, Gyeonggi-do, Republic of Korea; [5]Wonju Severance Christian Hospital, Wonju, Gangwon-do, Republic of Korea; [6]Konyang University Hospital, Daejeon, Republic of Korea; [7]The Catholic University of Korea Daejeon St Mary's Hospital, Daejeon, Republic of Korea.*

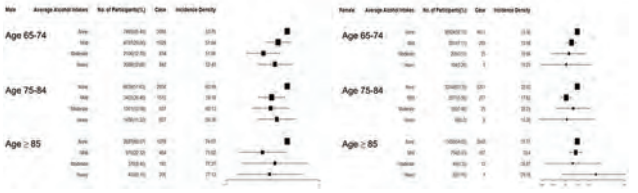
Background: The relationship between alcohol consumption and kidney function decline is not established in older adults. This study aimed to investigate the effects of alcohol consumption on the risk of incident CKD in community-dwelling older adults.

Methods: Adults aged ≥ 65 years with an estimated glomerular filtration rate (eGFR) ≥60 mL/min/1.73 m2 between 2009 and 2010 were recruited and followed through 2018 from a Korean national population-based cohort. Alcohol consumption was categorised into non, mild, moderate, and heavy drinking groups based on self-administered questionnaires. New-onset CKD was defined as an eGFR <60 mL/min/1.73 m2.

Results: Of the total 122,319 subjects, the non, mild, moderate, and heavy drinking groups were 99,091 (81.0%), 14,842 (12.1%), 4,257 (3.5%), and 4,139 (3.4%). During follow-up, 19,796 (20.0%), 4,636 (31.2%), 1,696 (39.8%), and 1,695 (41.0%) developed CKD in the non, mild, moderate, and heavy drinking groups. Univariate Cox regression analyses showed a increased risk of incident CKD in older adults in all drinking groups compared to non-drinkers (all $P < 0.001$). However, hazard ratios for developing CKD were 0.90 (95% CI 0.87–0.94, $P < 0.001$) for mild, 0.89 (95% CI 0.84–0.95, $P < 0.001$) for moderate, and 0.93 (95% CI 0.88–0.99, $P = 0.027$) for heavy drinkers after fully adjusting for confounding variables. This inverse relationship between alcohol consumption and CKD risk was observed in males in all drinking groups, whereas in females it was found in mild drinkers.

Conclusions: In the subgroup analysis, the beneficial effect of alcohol consumption on incident CKD was prominent among moderate drinkers aged 65–75 years, male mild drinkers aged ≥ 75 years, and female mild drinkers aged < 85 years. This study shows that alcohol consumption is inversely associated with the risk of incident CKD in older adults. Further studies are required to elucidate the effects of alcohol on kidney damage in older adults.

Figure 2



FR-PO1120

Association of Depression and eGFR Decline in World Trade Center Responders

Farrukh M. Koraishy,[1] Sean Clouston,[1] Frank D. Mann,[1] Monika Waszczuk,[2] Benjamin J. Luft,[1] Ruqiyya Bano.[1] *[1]Stony Brook University, Stony Brook, NY; [2]Rosalind Franklin University of Medicine and Science, North Chicago, IL.*

Background: Depression is associated with kidney disease, however if this association is independent of a closely associated condition, posttraumatic disorder (PTSD), is not known. To address this question, we studied the World trade Center (WTC) Responders who have a higher incidence of depression and PTSD compared to the general population.

Methods: Serum creatinine measurements were obtained from 9313 WTC Responders from 2015 to 2022. eGFR was calculated using the CKD-EPI 2021 Equation after excluding individuals with end-stage kidney disease. CKD was defined as an eGFR measurement < 60 ml/min/1.73 m2 or by ICD codes, stratified by mild (eGFR > 45) and moderate/severe (eGFR ≤ 45). eGFR decline was characterized as normal (± 1.0 ml/min/1.73 m2 per year) or rapid (≥5 ml/min/1.73 m2 per year). Depression was defined as a score ≥ 10 on the Patient Health Questionnaire (PHQ)-9 questionnaire administered during annual WTC visits. Stepwise logistic regression (LR) was employed to test the associations.

Results: At baseline, 12% had depression and 3% had CKD. Individuals with baseline CKD had a higher baseline PHQ and were more likely to have depression at the end of their follow-up period, seen mostly in those with moderate/severe CKD. After adjustment for relevant covariates, the association between baseline moderate/severe CKD and final depression was highly significant (OR: 3.76, p = 0.001). Assessing only eGFR decline, 11% had rapid eGFR decline and 41% had normal eGFR decline. Individuals with rapid eGFR decline had a higher proportion of depression diagnosis during their follow-up period. After adjustment for relevant covariates, the association between rapid eGFR decline and depression was significant (OR: 1.37, p = 0.001). 4% developed incident CKD during the observation period. PHQ was higher in those with who developed incident CKD during follow up and PTSD was also more prevalent. Evaluating individuals with only depression and no PTSD at baseline, the association of baseline depression with incident CKD was highly significant (OR: 1.935, p = 0.009) after adjustment.

Conclusions: Moderate to severe CKD at baseline is associated with depressive symptoms, but the prospective prediction of incident CKD by depressive symptoms appears to depend on the relative absence of comorbid PTSD.

FR-PO1121

Dietary Sodium and Potassium Intake and Risk of CKD Progression, ESKD, or Death in the Million Veteran Program

Hannah Angle,[1] Andrew Guide,[2,1] Robert Greevy,[2,1] Otis D. Wilson,[2,1] Jefferson L. Triozzi,[1] Talat Alp Ikizler,[1] Andrew S. Terker,[1] Elvis A. Akwo,[1] Adriana Hung.[2,1] Million Veteran Program; KidPhenGen. *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Nashville VA, Nashville, TN.*

Background: It is established that high sodium (Na) intake and low potassium (K) intake are associated with lower blood pressure and better cardiovascular outcomes. The associations between Na and K intake and chronic kidney disease (CKD) are less clear. This study assessed the relationship between reported Na and K intake and the risk of CKD progression, while accounting for genetic ancestry and other covariates.

Methods: We built a retrospective cohort (n=256,438) from the Million Veteran Program with baseline eGFR >30 ml/min who completed a nutritional survey. The primary outcome was a composite of 40% eGFR decline, ESRD, or death. Stratified Cox proportional hazard models were used to evaluate the individual associations of dietary Na and K intake with the composite outcome, stratified by genetic ancestry. A subgroup analysis by diabetes (DM) was also performed.

Results: In veterans of African (AFR) n=27,896 and European (EUR) ancestry n=219,795, higher Na intake was associated with increased risk for the primary composite (comparing highest to lowest quintile, AFR: aHR 1.06, 95% CI 1.02-1.10, EUR: aHR 1.02, 95% CI 1.00-1.04). Higher K intake was associated with lower risk (AFR: 0.93, 0.90-0.97, EUR: 0.88, 0.87-0.89). Subgroup analyses showed similar effects in patients without DM (AFR: Na aHR 1.09, 1.03-1.15, K aHR 0.89, 0.84-0.94, EUR: Na aHR 1.04, 1.02-1.06, K aHR 0.85, 0.84-0.87). However, in patients with DM the effects were strongly attenuated (AFR: Na aHR 1.01, 0.95-1.08, K aHR 1.00, 0.95-1.07, EUR: Na aHR 0.98, 0.95-1.01, K aHR 0.92, 0.90-0.95).

Conclusions: A diet low in Na and high in K is protective against CKD, though to varying degrees based on ancestry and DM status. Notably, the protective effect of K disappeared in AFR-DM patients. Future nutritional studies accounting for the impact of eGFR, genetics, and DM status are critical.

Impact of Weekend Catch-Up Sleep on CKD and Albuminuria in Adults: Evidence from NHANES, 2017-2020

Seung hyun Han,[1] Ara Ko,[2] Jeonghwan Lee,[1] Dong Ki Kim,[2] Yon Su Kim,[2] Chun Soo Lim,[1] Jung Pyo Lee.[1] *[1]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea; [2]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.*

Background: How weekend catch-up sleep (WCS) influences chronic kidney disease (CKD) risk is unknown. We investigated the association between WCS and CKD prevalence in adults.

Methods: In National Health and Nutrition Examination Survey (NHANES, 2017–2020) participants (n=4,961; age≥40 years), we assessed the relationships of WCS (>1-hr increased sleep duration on weekends) with CKD and albuminuria prevalence via multivariate logistic regression analysis adjusted for potential confounders.

Results: WCS participants exhibited notably lower CKD prevalence than non-WCS participants, even after confounding variable adjustment (adjusted odds ratio [OR]=0.67; 95% confidence interval [CI]=0.45-0.99). Specifically, 1-2 hours of WCS was associated with decreased CKD (OR=0.59; 95% CI=0.38-0.91, p=0.03). Furthermore, 1-2 hours of WCS was also significantly associated with lower albuminuria (OR=0.13; 95% CI=0.06-0.30, p<0.001) prevalence among individuals sleeping <6 hours on weekdays.

Conclusions: WCS is significantly associated with lower CKD and albuminuria prevalence, particularly among adults with restricted weekday sleep. These findings suggest potential preventive effects of WCS against kidney disease. Longitudinal studies are needed to confirm these results.

FR-PO1123

Impact of Treating Metabolic Acidosis in CKD: Consideration of Time-Varying Confounding among Treatment, Kidney Function, and Acidosis through G-formula

Soie Kwon,[1] Jung Pyo Lee.[2] *[1]Chung Ang University Hospital, Seoul, Republic of Korea; [2]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea.*

Background: The debate on whether treating metabolic acidosis decelerates CKD progression persists despite extensive research. Bicarbonate therapy mitigates metabolic acidosis, yet CKD exacerbates it, highlighting the necessity to examine these interactions comprehensively. This study employs G-formula to assess the impact of metabolic acidosis treatment in CKD, considering those intricate interactions.

Methods: A retrospective cohort study was conducted on patients whose eGFR of less than 60 was confirmed at 3-month intervals in two tertiary referral centers. Time-varying Cox analysis and G-formula were used to consider the time-varying effect of metabolic acidosis. In particular, the G-formula was adopted to account for the time-varying confounding between bicarbonate medication, serum total CO2, and creatinine level.

Results: The study included 19,627 participants over a median follow-up of 12 years. 4,127 patients advanced to ESKD and 6,273 patients died. Previous serum TCO2 levels (Coefficient 0.163, 95% CI 0.140–0.186) and bicarbonate treatment (0.898,0.897–0.899) positively influenced the following visit's serum TCO2, whereas previous serum creatinine (-0.398, -0.406– -0.391, <0.001) showed a negative correlation. Time-varying Cox analysis suggested metabolic acidosis treatment heightened risks of ESKD progression (aHR 4.28, 95% CI 3.950–4.637) and mortality (aHR 1.22, 95% CI 1.096–1.353). However, implementing the G-formula revealed treatment significantly reduced ESKD progression (aHR 0.90, 95% CI 0.874–0.927) and mortality rates (aHR 0.94, 95% CI 0.934–0.950). Determining the optimal TCO2 levels for bicarbonate administration, we found that <22 offered the most considerable risk reduction (Table 1).

Conclusions: Properly addressing the time-varying confounding among bicarbonate treatment, metabolic acidosis, and renal function suggests the potential benefit of metabolic acidosis treatment in lowering the rates of ESKD progression and mortality among CKD patients.

Table 1. Impact of metabolic acidosis treatment assessed through G-formula: sensitivity analysis based on initial TCO2 levels

Treatment	ESRD		All-cause mortality	
	Risk ratio	95% CI	Risk ratio	95% CI
Always	0.90	0.874–0.915	0.94	0.934–0.950
TCO2 <18	0.99	0.990–0.993	0.998	0.998–0.998
TCO2 <20	0.98	0.977–0.985	0.994	0.994–0.995
TCO2 <22	0.97	0.959–0.973	0.985	0.985–0.988

Time-fixed covariates: Age, Sex, Comorbidities (diabetes mellitus, hypertension, dyslipidemia, ischemic heart disease, stroke, myocardial infarction, cerebral hemorrhage, cerebral infarction), hospital, body mass index, medication usage (metformin, sulfonylurea, dipeptidyl peptidase inhibitor, sodium-glucose cotransporter2 inhibitor, insulin, meglitinide, thiazolidinedione, a-glucosidase inhibitor, angiotensin 2 receptor blockers, angiotensin-converting enzyme inhibitor, calcium channel blocker, diuretics, beta blocker, statin, ezetimibe, fenofibrate, omega-3, aspirin, clopidogrel, and direct oral anticoagulants) and laboratory findings (white blood cell count, hemoglobin, albumin, total cholesterol, glucose, aspartate aminotransferase)
Time-varying covariate: Serum total CO2 and creatinine level

FR-PO1124

Beta-Blocker Prescriptions in Nondialysis-Dependent Patients with CKD: The French CKD-REIN Study

Margaux Costes-Albrespic,[1] Sophie Liabeuf,[2] Solene M. Laville,[2] Oriane Lambert,[1] Ziad Massy,[1,3] Natalia Alencar de Pinho.[1] *[1]Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; [2]Centre Hospitalier Universitaire Amiens-Picardie, Amiens, France; [3]AURA Paris et Service de Néphrologie Hôpital Ambroise-Paré AP–HP, Boulogne-Billancourt, France.*

Background: Beta-blockers (BB) are a heterogeneous drug class often prescribed to patients with moderate to severe CKD. We aimed at describing real-world BB prescription patterns in these patients.

Methods: We analyzed 2,996 patients with CKD stages 2–5 under nephrology care from the CKD-REIN cohort study. BB prescriptions from any medical doctor were collected by clinical research associates based on anatomical therapeutic chemical (ATC) codes, as were patients' demographic, clinical, and laboratory characteristics. Adverse drug reactions occurring during follow-up were adjudicated by a team of pharmacologists.

Results: Compared with patients with no BB prescription (n=1733, 58%), patients on BB (n=1263, 42%) were older (median age 68 vs. 70 years, respectively), had a higher mean systolic BP (143 vs 140 mm Hg), lower mean heart rate (68 vs 74 bpm), and more comorbidities including diabetes (53% vs 36%), coronary disease (CD, 39% vs 14%), heart failure (HF, 21% vs 7%) and atrial fibrillation (AF, 17% vs 8%). Fourteen different BB agents were prescribed, mostly cardioselective (94%), lipophilic (78%), and non-vasodilatory (71%). Bisoprolol (572, 45.3%), nebivolol (296, 23.5%) and atenolol (179, 14.2%) were the most common agents. Bisoprolol was more often prescribed to patients with history of HF, CD or AF than to patients with no CV history (32.5% vs 56.5%). In contrast, nebivolol exhibited a different pattern, with fewer prescriptions in patients with CV history compared to those without (17.6% vs. 30%). Over the 5 years of follow-up, the rate of adverse drugs reactions attributed to BBs was 7.5 per 1000 person-years (PY), notably bradycardia (4.1 per 1000 PY).

Conclusions: In pre-dialysis CKD patients, BB seems to be well-tolerated and commonly prescribed to high risk CV patients, with a preference for prescribing bisoprolol, nebivolol and atenolol.

Lubiprostone Use and Kidney Outcomes in Patients with CKD and Constipation: A Large, Nationwide, Observational Study of US Veterans

Keiichi Sumida,[1] Yamini Mallisetty,[1] Rida N. Khan,[1] Prabin Shrestha,[1] Fridtjof Thomas,[1] Kamyar Kalantar-Zadeh,[2] Csaba P. Kovesdy.[1,3] *[1]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [2]Harbor-UCLA Medical Center Department of Internal Medicine, Torrance, CA; [3]VA Memphis Medical Center, Memphis, TN.*

Background: Lubiprostone, a chloride channel activator, has been shown to exert renoprotective effects by improving the gut microbiota in animal studies. Little is known about the association of lubiprostone use with kidney outcomes in patients with CKD.

Methods: In a nationwide cohort of 86,157 US veterans with an eGFR <60 mL/min/1.73m^2 and constipation receiving care from the VA healthcare system over 2004-2019, we examined the association of incident chronic use of lubiprostone (*de-novo* prescription with ≥30-day supply) with subsequent risk of a composite kidney outcome (incident ESKD, incident eGFR <15 mL/min/1.73m^2, or 57% reduction in eGFR), using multivariable Cox models and propensity score (PS)-overlap weighted analysis accounting for sociodemographics, comorbidities, vital signs, eGFR, and relevant medications. Untreated patients were enrolled on a randomly assigned date based on the start dates in the treated group to mitigate differential start of follow-up bias.

Results: Patients were 73±10 years old; 96% were male; 16% were African American; and 86% were diabetic. Their baseline eGFR was 49±9 mL/min/1.73m^2. Among 86,157 patients, 945 (1.1%) started lubiprostone therapy. After multivariable adjustment, incident use (vs. non-use) of lubiprostone was significantly associated with a lower risk of a composite kidney outcome (adjusted HR [95% CI], 0.66 [0.55-0.78]). A similar association was observed in the PS-overlap weighted analysis (0.71 [0.59-0.85]) (Table).

Conclusions: Incident use (vs. non-use) of lubiprostone is independently associated with a lower risk of kidney outcomes in patients with CKD and constipation.

Funding: Veterans Affairs Support

Table. Association of incident use (vs. non-use) of lubiprostone with a composite kidney outcome in patients with CKD and constipation

	Incidence rate per 1000 PY (95% CI)	HR (95% CI)	
		Multivariable adjusted (un-weighed) model	PS-overlap weighted model
No Lubiprostone Treatment	55.1 (54.2-55.9)	1 [reference]	1 [reference]
Lubiprostone Treatment	40.1 (33.2-47.1)	0.66 (0.55-0.78)	0.71 (0.59-0.85)

Note: Data were adjusted for age, sex, race, marital status, smoking status, service connectedness, mean per capita income, diabetes, hypertension, myocardial infarction, ischemic heart disease, congestive heart failure, cerebrovascular disease, peripheral artery disease, peptic ulcer disease, rheumatic disease, chronic lung disease, liver disease, malignancy, depression, dementia, HIV/AIDS, bowel disorders (inflammatory bowel disease, irritable bowel syndrome with diarrhea), body mass index, systolic blood pressure, eGFR, and medication use (statins, calcium channel blockers, proton pump inhibitors, renin-angiotensin-aldosterone system inhibitors, thiazide diuretics, loop diuretics, potassium-sparing diuretics, phosphate binders [lanthanum, sevelamer, and calcium acetate], sodium polystyrene sulfonate, oral irons, NSAIDs, opioid analgesics, and non-lubiprostone laxatives

FR-PO1126

Safety Profile of SGLT2 Inhibitor and Glucagon-Like Peptide 1 Receptor Agonist (GLP-1 RA) Use in Patients with CKD

Iqra Nawaz, Sandeep K. Mallipattu. *Stony Brook University, Stony Brook, NY.*

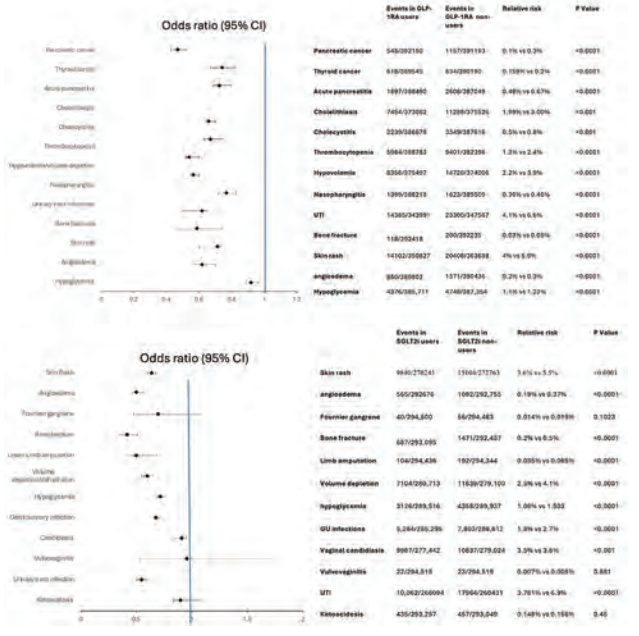
Background: The novel hypoglycemic agents SGLT2i and GLP-1RA have demonstrated combined reno and cardiovascular protective and mortality benefits. Multiple studies have extensively assessed the safety analyses and adverse events

associated with these agents among patients with diabetes and cardiovascular disease. However, there is a paucity of data on the safety analyses of these agents among patients with chronic kidney disease.

Methods: TriNetX database was used to determine patients aged ≥ 18 with CKD (eGFR 30-89) within the USA collaborative network from Jan 1st, 2015, to Dec 31st, 2023. The SGLT2i and GLP-1RA users and nonusers were propensity-scored matched on factors such as Diabetes, HTN, Heart failure, hyperlipidemia, obesity, use of Insulin, sulfonylureas, metformin, ACEi/ARBs, diuretics, and other hypoglycemic agents.

Results: Our results indicate that of 295,798 SGLT2i users and 9885755 non-users, 294567 patients were propensity-scored matched in both groups. The risk of UTI 3.7% (10062) in SGLT2i users, compared to 6.89% (17964) in non-users, genitourinary infections 1.8% (5284) vs. 2.7% (7803), Hypoglycemia 1.08% (3126) vs 1.5% (4358), bone fractures 0.23% (687) vs. 0.5% (1471), limb amputation 0.03% (104) vs 0.06% (192), ketoacidosis 0.14% (435) vs. 0.16 % (457), volume depletion 2.5% (7104) vs. 4% (11639). The risks of Vulvovaginitis are 0.007% (22) vs. 0.008% (23), vaginal candidiasis 3.6% (9978) vs. 3.8% (10837), Fournier gangrene 0.01% (40) vs. 0.019 % (56) were almost similar in both SGLT2I users and nonusers respectively. The results of adverse events comparison of GLP-1RA users with non users is shown in figure 1.

Conclusions: Overall, the results of our study demonstrate that the risks of adverse events in the SGLT2i and GLP-1RA users in patients with chronic kidney disease are relatively lower than in the nonuser groups.



FR-PO1127

Real-World Use of SGLT2 Inhibitors in Patients with CKD with and without Diabetes: A Population-Based Cohort Study

Luis Toro, Josefa Valderrama, Diego Polanco. NephroChile Initiative.
Universidad de Chile Facultad de Medicina, Santiago, Chile.

Background: Several studies have revealed cardiovascular and renal benefits of sodium-glucose cotransporter-2 inhibitors (SGLT2i) in chronic kidney disease (CKD). Recent studies indicate that SGLT2i are underutilized in real-world situations. This study aimed to assess the usage rates in primary care practices regarding SGLT2i use among CKD patients.

Methods: Observational study of CKD patients > 18 years (eGFR < 60 mL/min/1.73m2) in medical control in primary care facilities between January 2022 and December 2023. We included both patients with and without type 2 diabetes. We excluded patients with type 1 diabetes, polycystic kidney disease, and an initial eGFR < 20 mL/min/1.73m2. The study assessed the use of SGLT2i and analyzed variations in their usage through multivariate analysis.

Results: 1,062 patients were included in the study. Age: 61.1±8.3 years. Female: 472 (44.4%). Diabetes: 254 (23.9%). CKD G3a: 504 (47.5%), G3b: 478 (45.0%), G4: 80 (7.5%). 690 (64.9%) had at least one urine albumin-to-creatinine ratio (uACR) measurement. Only 254 (23.9%) were using SGLT2i. Predictors of SGLT2i use included the presence of diabetes (OR: 6.1 [4.5-8.4]), at least one consultation with a nephrologist (OR: 5.0 [3.6-6.9]) or diabetologist (OR: 25.4 [16.9-37.8]), and at least one uACR measurement (OR: 17.1 [11.9-24.7]), regardless of the value (Figure 1). No significant differences were found in age, socioeconomic status, healthcare system, or cardiovascular risk factors.

Conclusions: The utilization rates of SGLT2i are notably low among CKD patients. The results suggest that patients managed by physicians who are more knowledgeable about current CKD guidelines are more likely to receive SGLT2i. These findings highlight significant opportunities to improve the use of SGLT2i, particularly in primary care settings, to prevent future adverse clinical outcomes. Budget Impact Analysis for Empagliflozin in Patients with Nondiabetic CKD

Satabdi Chatterjee,[1] Neda Al Rawashdh,[2] Pablo Anaya,[2] Anastasia Uster,[3] Anna R. Aguirre Mazo,[3] Mafalda Ramos,[4] Laetitia Gerlier,[5] Mark Lamotte.[4]
[1]Boehringer Ingelheim Pharmaceuticals Inc, Ridgefield, CT; [2]IQVIA Inc, Falls Church, VA; [3]Boehringer Ingelheim International GmbH, Ingelheim, Germany; [4]Th(is)2Modeling, Asse, Belgium; [5]IQVIA Belgium, Zaventem, Belgium.

Background: In a wide range of patients with chronic kidney disease (CKD) with and without diabetes enrolled in EMPA-KIDNEY, empagliflozin (EMPA) on top of standard of care (SoC) showed favorable effects on kidney disease progression or cardiovascular death. Our previous research established the cost-effectiveness of adding EMPA to SoC in these patients. This study assessed the budget impact of integrating EMPA into a US commercial payer formulary, and focused on the non-diabetic patients, as they constitute majority of the CKD population.

Methods: In a hypothetical plan covering 1 million lives, data on CKD prevalence, use of angiotensin converting enzyme inhibitors [ACEis] or angiotensin receptor blockers [ARBs] in CKD, and prevalence of diabetes in CKD were used to estimate number of EMPA-eligible patients in non-diabetic CKD. The baseline market utilization was 100% for ACEi/ARB and 0% for dapagliflozin and EMPA. The projected utilization of EMPA and dapagliflozin for years 1-5 were estimated from internal sources (EMPA: 0.17% in year 1 to 19.24% in year 5; dapagliflozin: 2.60% in year 1 to 13.81% in year 5). Drug costs were based on published wholesale acquisition costs; dosing data was obtained from product prescribing information. The annual average costs of treating one patient with EMPA+SoC and comparators were derived from our previous research that included costs of drugs, complications and disease progression management costs. Model results were reported for total budget impact, per member per month (PMPM), and per patient per month (PPPM) costs for each year and cumulatively for years 1-5.

Results: Adding newer therapies such as EMPA to SoC for non-diabetic CKD yielded a net budget impact of -$155,557,417 (-1.83%), -$2.59 in PMPM and -$96.66 PPPM for a commercial payer over five years. This was driven by savings in year 3 and onwards, with $34 million reduction in year 3, $76 million reduction in year 4, and $55 million reduction in year 5, attributable to the reduced expenses for kidney replacement therapies for patients on EMPA compared to SoC alone.

Conclusions: Overall, findings suggest cost savings with adding newer therapies such as EMPA in non-diabetic CKD for commercial payers, and provide evidence on value of EMPA in this high unmet need population.

A Rare Cause of Kidney Failure: Native Kidney BK Polyomavirus Nephropathy after Lung Transplant

Taylor R. Moody, Josephine Abraham, Sydney E. Hartsell, Monica P. Revelo Penafiel, Sarah Gilligan. *University of Utah Health, Salt Lake City, UT.*

Introduction: BK polyomavirus nephropathy (BKVN) is a common complication of kidney transplantation, affecting 1-10% of renal transplant patients. It is rare in the native kidneys and is most often reported following hematopoietic stem cell transplantation. We present a case of native kidney BKVN leading to end-stage kidney disease (ESKD) in a lung transplant recipient.

Case Description: A 71-year-old woman with history of obliterative bronchiolitis who received a bilateral lung transplant in 2021 (on everolimus, mycophenolate mofetil, and prednisone) with course complicated by ischemic stroke, intermittent hypotension, and frequent urinary tract infections was referred to the renal clinic with progressive renal failure in 2023. At the time of referral her serum creatinine had risen from 1 to 2 mg/dl over 12 months. Workup was remarkable for pyuria with positive urine culture. Kidney ultrasound was without obstruction and serologies were negative. She underwent a kidney biopsy which revealed BK polyomavirus nephropathy with 40% interstitial fibrosis and tubular atrophy. Despite minimizing immunosuppression, her kidney function continued to worsen. She was started on cidofovir and, though her BK serum viral load improved, her renal function deteriorated and she developed ESKD. She is now on peritoneal dialysis undergoing evaluation for kidney transplant.

Discussion: BK nephropathy of the native kidneys in non-kidney solid organ transplant recipients is gaining recognition as an important cause of renal failure and progression to ESKD. Patients with unexplained renal failure after non-renal solid organ transplant may benefit from screening for BK virus to facilitate early diagnosis of BK polyomavirus nephropathy.

Insights into Mesoamerican Nephropathy: A Case Report of Environmental and Occupational Influences on CKD

Fnu Shivani,[1] Abhi Lohana,[2] Sejal Neel.[3] *[1]Ascension Saint Joseph - Chicago, Chicago, IL; [2]Camden Clark Medical Center, Parkersburg, WV; [3]Hackensack Meridian Jersey Shore University Medical Center, Neptune, NJ.*

Introduction: In the last 20 years, distinctive forms of chronic kidney disease (CKD) have emerged, unrelated to conventional risk factors like diabetes or hypertension. These diseases, termed as chronic kidney disease of undetermined cause (CKDu), are named after their geographical prevalence, such as Sri Lanka nephropathy or Mesoamerican nephropathy (MeN). Recent studies suggest a combination of environmental and occupational risk factors significantly contribute to the etiology of MeN, including high temperatures, excessive heat stress, agrochemicals, and environmental pollutants.

Case Description: A 40-year-old male from Nicaragua with a past medical history of hypertension presented to the ED with complaints of tingling and numbness in his hands and feet. On arrival, the patient's lab work was remarkable for hyponatremia, hypokalemia, hypocalcemia, hypophosphatemia, hypomagnesemia, elevated creatinine, and BUN. Renal ultrasound showed echogenic kidneys. During the hospital stay, the patient's electrolyte derangements were corrected, but his creatinine consistently stayed around 8.5 mg/dL. The patient's urinalysis was remarkable for nephrotic range proteinuria with normal serum albumin. Extensive workups for renal failure, including autoimmune and infectious markers, were unremarkable. Eventually, a kidney biopsy was done, which showed chronic tubule-interstitial injury being more prominent than glomerular sclerosis, suggesting secondary focal segmental glomerular sclerosis (FSGS), raising suspicion of Mesoamerican nephropathy due to the patient's Nicaraguan origin.

Discussion: Mesoamerican Nephropathy (MeN) is an emerging form of chronic kidney disease prevalent among young males of low socioeconomic status and agricultural workers in hot climates, particularly in Central America. While its exact cause remains unknown, factors such as high temperatures, dehydration, excessive NSAID use, and exposure to pollutants and agrochemicals are associated with MeN development. The chronic tubule-interstitial injury observed in the patient's kidney biopsy aligns with the established understanding of MeN as a condition characterized by tubulointerstitial damage. Studies suggest dehydration-induced acute kidney injury and NSAID overuse contribute to tubulointerstitial nephritis, and disruptions in electrolyte balance worsen MeN progression.

FR-PO1131

Estimating GFR in Young Adults with Cystatin C

Lesley A. Inker. CKD-EPI. *Tufts Medical Center, Boston, MA.*

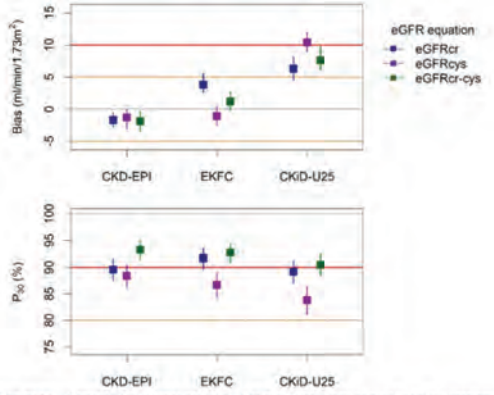
Background: Several research groups have developed eGFR equations for GFR evaluation in young adults. The use of different equations may lead to different eGFR values and uncertainty in GFR-based decision making. We previously showed that creatinine-based eGFR (eGFRcr) using the CKD-EPI 2021 had a small overestimate of measured GFR (mGFR), whereas European Kidney Function Consortium (EKFC) and Children under 25 (CKiD U25) equations had a small to moderate underestimate. We hypothesized that the differences among equation performance were related to populations differences in non-GFR determinants of serum creatinine, such as muscle mass, in the development dataset. Cystatin C is less affected by these non-GFR determinants and therefore cystatin C based eGFR (eGFRcys and eGFRcr-cys) equations may be more similar across populations.

Methods: We compared the CKD-EPI, EKFC and CKiD U25 eGFR equations in young adults (aged 18 to 40 years) in an independent dataset (751 participants from 9 studies). Equation performance compared to measured GFR was assessed as bias (median difference between mGFR and eGFR) and percentage of eGFR within 30% of mGFR (P_{30}).

Results: Mean (SD) age was 31.9 (5.8) years and mGFR was 96.1 (32.2) mL/min/1.73m². There was small bias for the CKD-EPI and EKFC eGFRcys and eGFRcr-cys equations [figure]. In contrast, CKiD-U25 eGFRcys and eGFRcr-cys equations had a moderate underestimation of mGFR. P_{30} was moderate to high for all CKD-EPI, CKiD-U25 and EKFC equations. P_{30} for eGFRcr-cys equations was higher than eGFRcr and eGFRcys for all equations.

Conclusions: Differences in performance between CKiD U25 vs. CKD-EPI and EKFC equations are observed for eGFRcys as well as eGFRcr. This suggests that population differences among the development datasets may vary by factors in addition to muscle mass. Additional research in young adults is needed to understand differences among populations and refine recommendations for use of eGFR equations.

Funding: NIDDK Support



Top panel – Grey line represents zero bias. Estimates between orange lines indicate small bias. Estimates between orange and red lines indicate medium bias. Estimates above red line indicate large bias. Bottom panel – Grey line represents 100% accuracy. P_{30} estimates below orange line indicates low accuracy. Estimates between orange and red lines indicate moderate accuracy. Estimates above red line indicate high accuracy. Equations include CKD-EPI (2021 eGFRcr & eGFRcr-cys, 2012 eGFRcys), EKFC (2021 eGFRcr, 2023 eGFRcys & eGFRcr-cys average) and CKiD U25 (2021 eGFRcr & eGFRcys, eGFRcr-cys average).

FR-PO1132

Association between Median Liver Stiffness and Proteinuria among US Adults: NHANES, 2017-2020

Kamonluk Rodsom,[1] Chutawat Kookanok,[1,2] Sansanee Thotsiri,[3] Methavee Poochanasri,[2] Narathorn Kulthamrongsri,[4] Voramol Rochanaroon,[7] Ariya Mongkolporn,[5] Tulaton Sodsri,[3] Varissara Sinkajarern,[6] Thutpharritchn Phoonakh,[6] Ekamol Tantisattamo.[1] *[1]University of California Irvine School of Medicine, Irvine, CA; [2]Phramongkutklao College of Medicine, Bangkok, Thailand; [3]Mahidol University Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand; [4]Mahidol University Faculty of Medicine Siriraj Hospital, Bangkok, Thailand; [5]Thammasart University Faculty of Science and Technology, Khlong Nueng, Thailand; [6]Vimut Hospital, Bangkok, Thailand; [7]Rayong Hospital, Tha Pradu, Thailand.*

Background: Liver stiffness is linked to CKD and proteinuria. There is limited national-scale evidence on the impact of gender on this relationship. This study explores if gender influences the risk of proteinuria associated with liver stiffness.

Methods: A national study involving 6,525 adults, using NHANES 2017-2020, investigated the relationship between median liver stiffness and ACR. Liver stiffness was categorized into four fibrosis scores with cut-off points at 2-7, 7-11, 11-19, and ≥19 kPa. Three linear regression (LR) models were utilized, considering each gender subgroups [Table 1].

Results: Median liver stiffness was categorized into four fibrosis scores (F1 through F4) among male and female participants. For males, the majority were classified as F1, with 2,620 individuals (84.57%). This was followed by 355 individuals (11.46%) with F2, 99 individuals (3.20%) with F3, and 24 individuals (0.77%) with F4. Similarly, most females were classified as F1, with 3,019 individuals (88.15%). This was followed by 296 individuals (8.64%) with F2, 91 individuals (2.66%) with F3, and 19 individuals (0.55%) with F4. In the final adjusted LR model, the ACR increased significantly for each unit increase in median liver stiffness, by 0.76 (95% CI: 0.13-1.40) in the total group and by 1.74 (95% CI: 0.70-2.79) in female [Table 1].

Conclusions: A significant positive correlation between ACR and median liver stiffness, influenced by gender, was found among US adults. This suggests that monitoring kidney function and proteinuria, especially in women with a history of liver disease, is crucial for the early detection of kidney injury.

	Model 1		Model 2		Model 3	
	β-Coefficients(95% CI)	P-value	β-Coefficients(95% CI)	P-value	β-Coefficients(95% CI)	P-value
Total	1.48 (1.06, 1.91)	<0.001	0.99 (0.36, 1.63)	<0.002	0.76 (0.13, 1.40)	<0.018
Male	1.54 (0.97, 2.11)	<0.001	0.51 (-0.29, 1.31)	0.212	0.28 (-0.52, 1.08)	0.494
Female	1.66 (1.04, 2.29)	<0.001	1.92 (0.87, 2.96)	<0.001	1.74 (0.70, 2.79)	0.001

Fig 1: Table of correlation analysis between Median Liver Stiffness and Albumin Creatinine Ratio (ACR) using three different logistic regression models. The first model included only Median Liver Stiffness, the second model added age, race, smoking, and drinking, and the third model further included dyslipidemia, hypertension, diabetes, coronary artery disease, congestive heart failure, and stroke.

FR-PO1133

Measured GFR Implemented in a US Clinical Practice: Accuracy of eGFR Cannot Be Assumed without Measured GFR

Robert L. Jameson, Jacob Nielsen, Xin Yi, Angelina Edwards, Shane A. Bobart, Tariq Shafi. *Houston Methodist Hospital, Houston, TX.*

Background: In clinical practice, GFR estimated from serum creatinine (eGFR-CR) is often assumed to be accurate for individual patients and eGFR estimated from either serum cystatin C (eGFR-Cys) or both (eGFR-Cr-Cys) is considered the "confirmatory" test. However, without clinical availability of measured GFR (mGFR) these assumptions cannot be verified. We have implemented mGFR (4-hour plasma iohexol clearance; non-radiolabeled) as part of routine clinical care at a large urban academic medical center. The test is orderable in Epic and implemented in our outpatient infusion center. We present case studies to highlight that mGFR is essential for clinical practice and eGFR-Cys is not a universal confirmatory test for GFR.

Methods: We describe three patients that had simultaneous measurement of creatinine, cystatin C, and mGFR by 4-hour plasma iohexol clearance as part of routine clinical care. We defined eGFR to be accurate in assessing mGFR if it was within ± 5 mL/min/1.73m2 of the mGFR.

Results: See Table 1

Conclusions: Availability of mGFR in clinical practice is essential for interpretation of eGFR, when an accurate assessment is needed. Cystatin C eGFR's should not automatically considered to be an mGFR replacement.

Table 1

The clinical and laboratory characteristics of three patients with simultaneous eGFR and mGFR

Characteristic	Patient #1	Patient #2	Patient #3
mGFR indication	Relatively low eGFR in a young male with high muscle mass.	"CKD" in the setting of HIV.	"CKD 3b" in an older female
Age, years	40	45	66
Race/Ethnicity	Black	Asian	Black
Sex	Male	Male	Female
Drugs affecting creatinine secretion	None	Cobicistat (affects tubular creatinine efflux by inhibiting SLC47A1)	None
CVD	No	No	No
Diabetes	No	Yes	No
Hypertension	No	Yes	Yes
Body surface area, m²	2.24	1.61	1.99
BMI, kg/m²	31.2	22.7	31.3
Urine ACR, mg/g	<3	5	<21
Serum Creatinine, mg/dL	1.27	1.72	1.39
Serum Cystatin C, mg/L	0.81	1.1	1.29
Iohexol GFR (4 hr), mL/min/1.73m²	**74**	**77**	**59**
CKD-EPI eGFR mL/min/1.73m²			
Creatinine (Bias*)	**73 (–1)**	49 (-28)	42 (-17)
Creatinine-cystatin C (Bias*)	95 (+21)	62 (-15)	48 (-11)
Cystatin C (Bias*)	111(+37)	**73 (-1)**	50 (-9)
Teaching Points	**eGFR-Cr is accurate**	**eGFR-Cys is accurate, but eGFR-Cr-Cys is inaccurate**	**None of the eGFRs are accurate. CKD stage is incorrectly assumed as "3b"**

* Bias = eGFR – mGFR

FR-PO1134

Performance of eGFR Slope as a Surrogate End Point for Clinical Kidney Events in a Nonglomerular Mechanism of Acute eGFR Change

Alexandra Gallagher,[1,2] Rachel L. O'Connell,[2] George Mangos,[1,4] Brendan Smyth,[1,2] Anthony C. Keech,[5,2] Meg Jardine.[3,2] The FIELD Investigators.
[1]St George Hospital Department of Renal Medicine, Kogarah, NSW, Australia; [2]NHMRC Clinical Trials Centre, Camperdown, NSW, Australia; [3]Concord Repatriation General Hospital, Concord, NSW, Australia; [4]University of New South Wales School of Clinical Medicine, Sydney, NSW, Australia; [5]Department of Cardiology, Royal Prince Alfred Hospital, Camperdown, NSW, Australia.

Background: Glomerular Filtration Rate (GFR) decline is a proposed surrogate kidney endpoint and attractive alternative to the lengthy, expensive, and large sample size requirements to reach "hard" clinical events in trials. Estimated (e)GFR decline has been successfully modelled using eGFR slope, where the correlation between total and chronic eGFR slopes and clinical endpoints was established. To date GFR slope has been tested on agents where acute GFR decline is driven by changes in glomerular haemodynamics. We tested the association of total and chronic eGFR slopes with clinical endpoints for fenofibrate, an agent with an acute eGFR decline mediated by non-glomerular actions.

Methods: The FIELD trial randomised adults to fenofibrate or placebo. Total eGFR slope was calculated using a repeated measures 2-slope linear mixed model for the entire intervention period. Sensitivity analyses were also performed limited to 3 years. Chronic eGFR slope was calculated from month 4. The clinical kidney endpoint was doubling of serum creatinine/eGFR<15ml/min/1.73m^2, renal death or kidney replacement therapy. Frequency of clinical kidney endpoints based on baseline to 8-week washout eGFR was an exploratory subgroup analysis.

Results: 9795 participants were followed for 5 years. A post-washout eGFR was ascertained in 94.3% of the washout sub-study participants. Fenofibrate was associated with a mean acute eGFR decline of -9.05 ml/min/1.73m^2/annum. Fenofibrate slowed rate of chronic eGFR decline by 0.61 ml/min/1.73m^2/annum (95% CI 0.50 to 0.71, P<0.0001), but worsened total eGFR slope (mean diff -1.54, 95% CI -1.65 to -1.44, P<0.0001). Fenofibrate use increased the clinical kidney endpoint 1 (HR 1.48, 95% CI 1.16 to 1.89, P=0.002) (Figure 1). There was no difference for clinical kidney outcomes in washout analyses.

Conclusions: Results generally support use of eGFR slope change as a surrogate for clinical kidney endpoints. Assessment post-wash out should be considered for agents with a large acute eGFR decline.

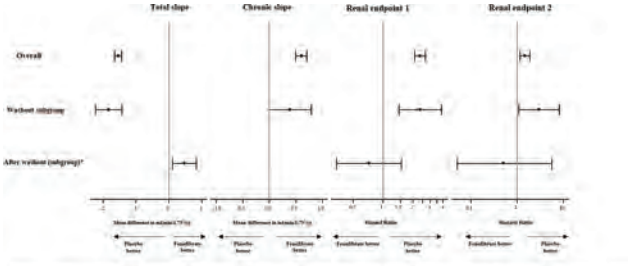


Figure 1: treatment effect on total slope, chronic slope and renal clinical endpoints, overall and in washout subgroup. Renal endpoint 1 is defined as 40% decline in eGFR, eGFR<15, or End Stage Kidney Disease (ESKD). Renal endpoint 2 is defined as doubling of serum creatinine, eGFR<15, or ESKD.
**For washout timepoint treatment effect on total slope is based on a two-sample t-test of each subject's washout-baseline difference over follow-up duration*

FR-PO1135

Assessing Kidney Function Markers and Myocardial Perfusion Imaging with Thallium-201 in Patients with CKD

Wei-Yu Su,[1,2] Yi-Ting Lin,[3,4] Ming-Yen Lin,[1] Mei-Chuan Kuo,[1,4] Yi-Wen Chiu,[1,4] Yi-chun Tsai,[1,4] Jer-Ming Chang,[1,4] Shang-Jyh Hwang,[1,4] Ping-Hsun Wu.[1,4]
[1]Division of Nephrology, Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan; [2]Department of General Medicine, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan; [3]Department of Family Medicine, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan; [4]Faculty of Medicine, College of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan.

Background: Chronic kidney disease (CKD) is a substantial public health challenge worldwide, associated with elevated morbidity and mortality rates. Myocardial perfusion imaging (MPI), a non-invasive diagnostic modality, can detect early-stage cardiovascular disease in patient with CKD. This study aimed to investigate the association between renal function and semi-quantitative parameters of Thallium-201 MPI in CKD patients.

Methods: This retrospective study included 1443 CKD patients who underwent Thallium-201 MPI between August 2008 and December 2021. The risk classification proposed by the Kidney Disease Improving Global Outcomes (KDIGO) guidelines is based on estimated glomerular filtration rate (eGFR) and urine albumin-creatinine ratio (UACR). Semi-quantitative parameters were analyzed using AutoQUANT Version 6.5 software.

Results: Multivariable analysis showed that both lower eGFR and higher UACR stage were significantly associated with worse myocardial perfusion parameters, including higher summed motion scores (SMS), summed motion (SM), summed thickening scores (STS), summed thickening (ST), end-diastolic volume (EDV) and end-systolic volume (ESV), and lower left ventricular ejection fraction (LVEF). Higher CKD stage was significantly associated with increased odds of higher summed difference score (SDS), ST, and SM. Higher UACR stage was significantly associated with increased odds of higher ST. Furthermore, KDIGO category classified as very high risk was significantly associated with higher summed stress score, summed stress percentage, summed rest score, summed rest percentage, SDS, summed difference percentage (SD), stress extent of perfusion defects, stress total perfusion deficit (sTPD), resting extent of perfusion defects, resting total perfusion deficit, SMS, SM, STS, ST, EDV, ESV, lower LVEF, and increased odds of higher lung-to-heart ratio, sTPD, SDS, ST, and SM.

Conclusions: The results suggest that worse kidney function is associated with poorer myocardial perfusion and left ventricular function in participants with CKD, which can inform clinical decision-making, risk stratification, and targeted management strategies for CKD patients, ultimately aiming to improve their cardiovascular outcomes and overall prognosis.

Application of eGFR Thresholds as End Point Components in a Kidney Hierarchical Composite End Point

Niels Jongs,[1] Samvel B. Gasparyan,[2] Lars Frison,[2] Patrick Schloemer,[3] Meike Daniela Brinker,[4] Jerome A. Rossert,[5] Dustin J. Little,[5] Hiddo J. Heerspink.[1,6]
[1]Department of Clinical Pharmacy and Pharmacology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands; [2]Late Stage Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; [3]Pharmaceuticals, Research and Development, Bayer AG, Berlin, Germany; [4]Pharmaceuticals, Research and Development, Bayer AG, Wuppertal, Germany; [5]Late Stage Development, Cardiovascular, Renal and Metabolism (CVRM), Biopharmaceuticals R&D, AstraZeneca, Gaithersburg, MD; [6]The George Institute for Global Health, Sydney, NSW, Australia.

Background: We developed and validated a kidney hierarchical composite endpoint (HCE) combining time-to-event endpoints with the rate of estimated glomerular filtration rate (eGFR) decline (eGFR slope) as a continuous endpoint. An alternative to this continuous endpoint is to apply thresholds on an absolute scale for the pairwise comparisons in the eGFR slope component. We assessed the impact of different thresholds on the treatment effects and statistical power on the kidney HCE analysed using win odds.

Methods: We calculated the win-odds in the DAPA-CKD trial and compared treatment effects for the original HCE versus HCEs with different eGFR thresholds (0.5, 0.75, or 1.0 mL/min/1.73m^2/year eGFR slope difference; **Table**). We estimated the statistical power for these thresholds using a bootstrap sampling procedure and replicated these analyses in the RENAAL, IDNT, ALTITUDE, SONAR, CREDENCE, and FIDELIO-DKD trials.

Results: In DAPA-CKD, the win-odds and statistical power were consistent regardless of which eGFR thresholds were included (**Table**). Results were similar in all the six kidney outcome trials.

Conclusions: Our findings indicate that application of eGFR thresholds in the kidney HCE does not alter treatment effects or compromise statistical power and may facilitate clinical interpretation of trial results.

Funding: Commercial Support - AstraZeneca

Table. Pairwise comparisons per component of the HCE and win-odds

		Dapagliflozin 10 mg	Placebo		Win-odds	Power*

More Accurate eGFR Creatinine Calculation Formula for Japanese Patients Using Insulin Clearance as a Control

Ryoya Tsunoda, Shuhei Nakajima, Kentaro Nakajima, Tatsuya Shimizu, Toshiaki Usui, Hirayasu Kai, Naoki Morito, Joichi Usui, Kaori Mase, Chie Saito, Kunihiro Yamagata. *Tsukuba Daigaku Igaku Iryokei, Tsukuba, Japan.*

Background: There are several formulas to calculate estimated glomerular filtration rate (eGFR), and some formulas devised overseas have been proposed to correct for Japanese patients, but their accuracy has not been sufficiently verified, and a correction method for Japanese patients suitable for the CKD-EPI formula 2021 is unknown.

Methods: eGFR by Cr was calculated using the MDRD formula (corrected for Japanese), the Japanese formula, the CKD-EPI formula 2009 (corrected for Japanese), and the CKD-EPI formula 2021, respectively, in 404 patients whose Cr and inulin clearance were measured at our hospital between 2009 and 2018 and for whom high quality results were obtained. The correlations and errors with the inulin clearance values (C_{inu}) were compared. We also examined the performance of the correction factor for eGFR using the 2021 version of the CKD-EPI formula.

Results: The median Cinu was 62.8 mL/min and the interquartile range was 51.5. The correlation coefficients between eGFR and Cinu were 0.862 for the MDRD formula, 0.871 for the Japanese formula, 0.877 for the CKD-EPI formula 2009, and 0.875 for the CKD-EPI formula 2021, in decreasing order of root mean square of the difference between Cinu and eGFR. The root mean square of the difference between C_{inu} and eGFR was smaller than that of the CKD-EPI 2009, Japanese, MDRD, and CKD-EPI 2021, when the eGFR of the CKD-EPI 2021 was multiplied by 0.824.

Conclusions: Although the Japanese formula was the most accurate of the known Japanese eGFR calculation methods, the CKD-EPI formula 2021 with a novel correction factor may be more accurate.

FR-PO1138

Comparison of Creatinine-Based Glomerular Filtration Rate Equations for Mortality Prediction in Korean Population: A Retrospective Kangbuk Samsung Health Cohort Study

Daseul Huh, Jihyun Yang, Young Youl Hyun, Kyu-Beck Lee. *Kangbuk Samsung Hospital, Jongno-gu, Seoul, Republic of Korea.*

Background: Several creatinine-based equations have been developed for estimating glomerular filtration rate (GFR). However, their relative performance for mortality prediction in Koreans is unclear, thus the creatinine-based equations have been evolving. We aim to compare the CKD-EPI 2009 and 2021 (race-free) equations to the European Kidney Function Consortium (EKFC) equation for mortality prediction in a large Korean cohort.

Methods: We analyzed 670,320 participants who underwent a comprehensive health examination, enrolled in Kangbuk Samsung Health Cohort from January 1, 2002 to December 31, 2019 and followed them up for mortality until December 2019.

Results: The participants' median follow-up period was 8.8 years, mean age was 39.8 years old (minimum 18, maximum 97), and 53.6% were male. Mean eGFR using 2009 CKD-EPI was 95.1 ml/min/1.73m^2, 100.6 ml/min/1.73m^2 using 2021 CKD-EPI, 94.0 ml/min/1.73m^2 using EKFC. The EKFC equation had the highest discriminatory power to predict all-cause mortality (Harrell's C index of EKFC = 0.694 (95% confidence interval 0.687-00.701), 2021 CKD-EPI = 0.665 (95% CI 0.659-0.672), 2009 CKD-EPI = 0.667 (0.636-0.648), p < 0.001) and cardiovascular disease (CVD) mortality (Harrell's C index of EKFC = 0.745 (95% CI 0.728-0.762), 2021 CKD-EPI = 0.716 (95% CI 0.699-0.732), 2009 CKD-EPI = 0.716 (95% CI 0.699-0.732)).

Conclusions: In this large cohort of Koreans, the EKFC equation showed superior discrimination for predicting all-cause and CVD morality versus CKD-EPI equations. These findings support the adoption of the EKFC equation for GFR estimation and mortality risk prediction in this population.

FR-PO1139

Performance of Three Creatinine-Based Equations in Predicting All-Cause Mortality and Cardiovascular Events in a Multiethnic Asian Population: The Singapore Epidemiology of Eye Diseases Study

Zhong Hong Liew,[1] Miao li Chee,[2] Cynthia C. Lim,[1] Ching-Yu Cheng,[2] Charumathi Sabanayagam.[2] *[1]Singapore General Hospital, Singapore, Singapore; [2]Singapore Eye Research Institute, Singapore, Singapore.*

Background: The comparative prediction of novel creatinine-based equations for all-cause mortality and cardiovascular events is not well established. We aimed to compare risk prediction for all-cause mortality and cardiovascular events by estimated glomerular filtration rate (eGFR) using CKD-EPI creatinine equation 2009 (Creat-ASR 2009), CKD-EPI creatinine equation 2021 (Creat-AS 2021) and CKD-EPI creatinine-cystatin equation (Creat-cys 2021) in a multiethnic Asian population.

Methods: In this population-based cohort study, we included Chinese and Indian adults aged 40-80 years who attended baseline visit (2007-2011). Serum cystatin C was measured using particle-enhanced turbidimetric assay. Information on death and cardiovascular events was obtained by data linkage with National Registry of Diseases Office until 31 Mar 2021. Outcomes were all-cause mortality and incident cardiovascular events among those without prior cardiovascular disease. Using Cox proportional hazards model, we conducted multivariate regression analyses to evaluate association of CKD and the outcomes. Net reclassification improvement was performed to compare prediction performance of these 3 equations.

Results: During a mean follow-up of 11.3±2.2 years, all-cause mortality rate was 12.9% (743 of 5738 participants). Using Creat-ASR 2009, Creat-AS 2021, and Creat-cys 2021, mortality rates among those with CKD (eGFR < 60 ml/min/1.73 m^2) were 6.67% vs 5.04% (P <0.001) vs 6.26% (P <0.001), respectively. After excluding those with existing cardiovascular disease, incident cardiovascular event rate was 9.9% (508 of 5120 participants). Reclassification using Creat-AS 2021 compared with Creat-ASR 2009 had poorer prediction performance for all-cause mortality and cardiovascular event (Creat-AS 2021 vs Creat-ASR 2009: NRI= -0.040, p<0.001 and -0.050, p<0.001, respectively). Reclassification using Creat-cys 2021 compared with Creat-ASR 2009 allowed better prediction for all-cause mortality and cardiovascular event (Creat-cys 2021 vs Creat-ASR 2009: NRI = 0.077, p<0.001 and 0.091, p<0.001, respectively).

Conclusions: Creat-cys 2021 was associated with improved risk prediction of all-cause mortality and cardiovascular event, compared with Creat-ASR 2009 and Creat-AS 2021.

FR-PO1140

Systolic Blood Pressure Threshold and Clinical Outcomes in Patients with CKD Stage 4/5

Jiacong Luo,[1] Claire Ryan,[1] Scott Sibbel,[1] Carey Colson,[1] Gilbert Marlowe,[1] Michael H. O'Shea,[2] Francesca Tentori,[1] Steven M. Brunelli.[1] *[1]Davita Clinical Research, Minneapolis, MN; [2]DaVita Inc, Denver, CO.*

Background: KDIGO guidelines suggest a systolic blood pressure (SBP) <120 mmHg for chronic kidney disease (CKD) patients. However, there is a paucity of published evidence directly comparing relevant health outcomes across various SBP targets. We investigated the possible impact of various SBP targets on hospitalizations, mortality, and ESKD transitions among CKD stage 4/5 patients.

Methods: We used the Optum® de-identified Integrated Clinical-Claims Dataset that links administrative claims and clinical data from providers across the continuum of care.[1] We selected patients (n=973) with a first diagnosis of CKD 4/5 following 365+ days insurance coverage, who were prescribed 1+ antihypertensive medication. We excluded patients with SBP <110 mmHg to minimize potential confounding from advanced cardiomyopathy. We used the method of recycled predictions to estimate the effect of time updated SBP aligned to guideline targets (separately for <120 and <140 mmHg) on clinical outcomes accounting for clinical confounders.

Results: SBP <140 mmHg was present during 66% of follow up time. Blood pressures in line with this threshold were not differentially associated with rates of mortality or hospitalization; they were associated with a lower rate of ESKD transition (the anticipated change in transition rate is -2.3 transitions per 100 patient years). SBP <120 mmHg was present during 14% of follow up time. Blood pressures in line with this threshold were not differentially associated with rates of mortality or ESKD transition; they were associated with a higher rate of hospitalization (the anticipated average change in admission rates is +22.4 admissions per 100 patient years).

Conclusions: A SBP target of <120 mmHg in patients with CKD is associated with a higher rate of hospitalization without demonstrable benefits. Conversely, a target of <140 mmHg may reduce ESKD transitions without worsening other outcomes. Current guidelines should be reconsidered.[1] Optum's de-identified Integrated Claims-Clinical dataset (2007-2021)

	Follow-up years	Mortality			Hospitalizations			ESKD Transitions		
		Total Deaths	Deaths per 100 patient years	Anticipated Average Change	Total Admits	Admits per 100 patient years	Anticipated Average Change	Total ESKD Transitions	Transitions per 100 patient years	Anticipated Average Change
≥140 mmHg	577	61	10.6	Ref.	298	51.7	Ref.	60	10.4	Ref.
<140 mmHg	1,154	140	12.3	1.8 (-1.7, 5.3)	600	52.9	0.3 (-6.0, 6.4)	63	5.6	-2.3 (-4.5, -0.3)
≥120 mmHg	647	73	11.3	Ref.	317	49	Ref.	60	9.3	Ref.
<120 mmHg	107	19	17.9	+6.5 (-0.42, 19.3)	82	77	+22.4 (3.2, 45.7)	7	6.6	0.1 (-10.6, 10.1)

FR-PO1141

Systolic Blood Pressure Rhythm Is a Protective Predictor of eGFR in Older Hypertensive Men

Lulu Wang, Han Tian, Lei Jiang. *The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China*.

Background: It is recognized that blood pressure (BP) follows a circadian rhythm, exhibits two peaks during 24 hours. But it is uncertain whether BP has 12 hours rhythm and the influence of this rhythm.

Methods: A total of 200 older hypertensive males without overt cardiovascular or cerebrovascular diseases were recruited in the longitudinal study. 12 patients had less than 20 ambulatory blood pressure readings during 24 hours. Therefore, a total of 188 patients were included in the analyses. The 12 hours circadian rhythmicity of blood pressure was analyzed by ARSER. Blood pressure with 12h rhythmicity was selected by $P < 0.05$. Estimated glomerular filtration rate (eGFR) was calculated using the CKD-EPI formula. The primary outcome was the change of eGFR.

Results: The average age was 64.9±7.2 years, and the eGFR was 83.5±14.7 mL/min/ 1.73m^2. 17 patients had 12 hours rhythmicity in both Systolic blood pressure (SBP) and diastolic blood pressure (DBP). 128 patients had arrhythmicity in either SBP or DBP. At a mean follow-up period of 3 (2.5–3.7) years, 16 patients died, 33 patients were lost to follow-up. The mean eGFR in baseline and follow-up time was 86.4±14.2 and 81.7±16.1 mL/min/ 1.73m^2 (P=0.010). There was no significant difference in the level of urinary protein and creatinine ratio (7.5(3.8-19.4) vs 8.3(7.0-12.7) mg/g, P=0.059). Compared to participants in rhythmic SBP group, the other group had more eGFR decline(P=0.005). But the change of eGFR was similar between DBP rhythmicity group and arrhythmicity group. We defined eGFR decline as the falling difference over 1/2 SD between follow-up and baseline. The risk of eGFR decline in patients with arrhythmic SBP was third that of rhythmic rhythm SBP group after adjusting for confounding factors including age, smoke, alcohol, DM,BMI and albumin(HR = 3.005(1.122-8.048), P=0.029).

Conclusions: The rhythm of systolic blood pressure is a protective predictor of eGFR in older hypertensive males. We need to focus on the rhythm pattern of BP.

FR-PO1142

Time in Target Range of Systolic Blood Pressure and All-Cause Mortality in CKD Population in Korea

Soo-Young Yoon,[1] Dae Kyu Kim,[1] Su Woong Jung,[2] Jin Sug Kim,[1] Ju young Moon,[2] Hyeon Seok Hwang,[1] Kyunghwan Jeong.[1] *[1]Kyung Hee University Hospital, Dongdaemun-gu, Seoul, Republic of Korea; [2]Kyung Hee University Hospital at Gangdong, Gangdong-gu, Seoul, Republic of Korea*.

Background: Time in target range (TTR) of systolic blood pressure (SBP) is the percentage of time that SBP remains within the range of 110–130 mmHg. The TTR metric can be used to express the degree of SBP control over time. The association between SBP-TTR and mortality in patients with chronic kidney disease (CKD) remains unclear, and may depend on the extent of its control. We evaluated the risk of mortality, cardiovascular events, and renal events between SBP-TTR groups in Korea.

Methods: A total of 16,037 patients with CKD who underwent health check-ups at least three times between 2012 and 2015 were recruited from the Korean National Health Insurance Database. The patients were divided into four SBP-TTR categories based on SBP-TTR levels: SBP-TTR 100%, SBP-TTR 51–75%, SBP-TTR 26–50%, and SBP-TTR 0–25%. The primary outcome was the association between SBP-TTR level and mortality by Cox-regression analysis. Secondary outcomes were cardiovascular risk and end-stage kidney disease (ESKD) progression based on SBP-TTR groups.

Results: The median eGFR in the study was 56.08 ml/min per 1.73m^2. The adjusted hazard ratios (HRs) were 1.17 (95% confidence interval [CI], 0.96–1.41), 1.21 (95% CI, 0.998–1.47), and 1.23 (95% CI, 1.02–1.49) for patients with SBP-TTR 51–75%, 26–50%, and 0–25%, respectively. The adjusted HRs for cardiovascular events increased significantly as the SBP-TTR decreased below 50%. For SBP-TTR 26-50%, the adjusted HR was 1.19 (95% CI, 1.01–1.40), and for SBP-TTR 0-25%, the adjusted HR was 1.40 (95% CI, 1.19–1.64). The adjusted HRs for ESKD progression increased gradually: 1.22 (1.01–1.47) for SBP-TTR 51–75%, 1.28 (1.05–1.56) for SBP-TTR 51–75%, and 1.80 (1.50–2.16) for SBP-TTR 0–25%.

Conclusions: Among patients with CKD, those with a low SBP-TTR showed an increased risk of mortality, cardiovascular events, and progression to ESKD.

FR-PO1143

Frequent Premature Atrial Contractions Are Associated with Increased Mortality Risk and Poor Kidney Outcomes in Patients with CKD

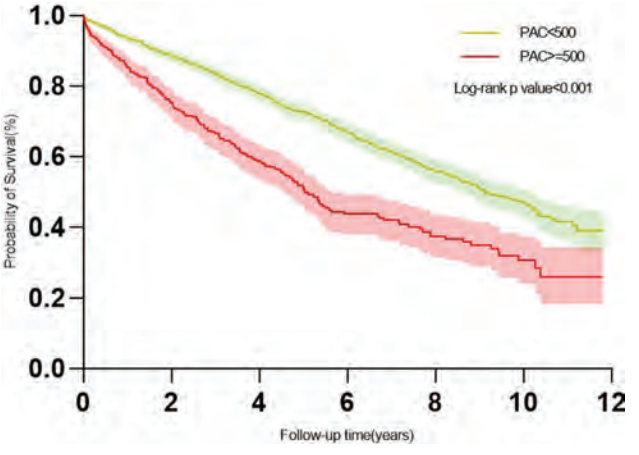
Lu Heng Lu, Ming-Yen Lin, Szu-Chia Chen, Yi-Ting Lin, Yi-chun Tsai, Mei-Chuan Kuo, Yi-Wen Chiu, Jer-Ming Chang, Shang-Jyh Hwang, Ping-Hsun Wu. *Division of Nephrology, Department of Internal Medicine, Kaohsiung, Taiwan*.

Background: Frequent premature atrial contractions (PACs) are associated with atrial fibrillation, cardiovascular events, and death in general population. However, the prognostic significance of PAC burden is not fully elucidated in patients with chronic kidney disease (CKD). This study aims to examine the association between PACs and the risks of all-cause mortality and end-stage kidney disease (ESKD) in non-dialysis CKD patients.

Methods: This retrospective study included 2303 CKD patients receiving 24-hour Holter recording from Kaohsiung Medical University Hospital Health care system between April 2009 and November 2021. Patients were categorized into two groups based on PAC burden, with frequent PACs defined as ≥500 PACs per 24 hours. Cox regression analyses, survival analysis, and subgroup analysis were performed to evaluate the impact of PACs on death and ESKD.

Results: The Kaplan-Meier curve demonstrated a ≥500 PACs group was associated with a higher death risk than < 500 PACs group. In multivariable-adjusted model, frequent PACs were associated with increased all-cause mortality (Hazard Ratio [HR] 1.48, 95% confidence interval [CI] 1.26-1.73, p <0.001) and progression to ESKD (HR 1.37, 95% CI 1.07-1.76, p=0.012). In subgroup analysis, the risk of high PAC burden was consistently higher than in low-burden group across pre-specified subgroups, especially in those with high Kidney Disease Improving Global Outcomes (KDIGO) risk categories.

Conclusions: Frequent PACs were associated with all-cause mortality and poor renal outcomes. Further studies are required to examine the implication of therapeutic strategies in CKD patients with PACs, in order to prevent potential subsequent adverse outcomes.



K-M curve of PACs and survival

FR-PO1144

Prevalence and Burden of CKD-Associated Pruritus in Europe (CENSUS-EU)

James Burton,[1] Amandine Perrin,[2] Despina Ruessmann.[2] *[1]University Hospitals of Leicester NHS Trust, Leicester, United Kingdom; [2]Vifor Pharma Management AG, Glattbrugg, Switzerland.*

Background: Chronic kidney disease-associated pruritus (CKD-aP) is common and can impair health-related quality of life (HRQoL). Despite this, there has been a lack of clarity on its prevalence and impact.

Methods: CENSUS-EU is a real-world, cross-sectional, multicenter study in Europe, which aimed to assess the prevalence of CKD-aP and its impact on HRQoL in adult patients receiving hemodialysis. Patients completed questionnaires on pruritus presence/severity (the Worst Itching Intensity Numerical Rating Scale), and HRQoL (including the 5-D itch scale and the integrated palliative care outcome scale symptom list for end-stage renal disease). Medical records were used to gather information on dialysis, treatment, and healthcare resource use. Data were analyzed by pruritus severity (no, mild, moderate, and severe).

Results: Data were evaluated for 2,963 patients. Patients had a mean age of 66.2 years and 62.7% were male. Overall, the prevalence of CKD-aP was 53.5%; 22.3% of patients experienced mild, 18.0% moderate, and 13.2% severe pruritus. As pruritus severity increased from no pruritus to severe pruritus, patients reported more difficulty sleeping and feelings of depression. 5-D itch disability subscale scores also increased with pruritus severity (**Figure**). Patients with severe pruritus were hospitalized more often than those with mild or moderate pruritus (2.1 versus 1.8 and 2.0 times/patient/year, respectively). The proportion of patients receiving ≥1 ongoing anti-itch treatment increased with pruritus severity but remained low in all subgroups (18.3%, 25.3%, and 39.9% of patients with mild, moderate, and severe pruritus, respectively).

Conclusions: In this study, a third of patients on hemodialysis experienced moderate or severe pruritus, and HRQoL decreased with pruritus severity.

Quantification of Muscle Wasting in CKD by Texture Analysis on 1H-Magnetic Resonance Images

Lisa Hur,[1] Nicole Latman,[2] Alireza Akbari,[2] Justin R. Dorie,[2] Tanya Tamasi,[2] Christopher W. McIntyre.[2,1] *[1]Western University, London, ON, Canada; [2]London Health Sciences Centre, London, ON, Canada.*

Background: Functionally significant muscle wasting is prevalent in chronic kidney disease (CKD). Currently, muscle quality assessment requires biopsy and microscopy. ^{1}H-Magnetic Resonance Imaging (MRI) is non-invasive and can be used to assess changes in skeletal muscle composition. This study aims to utilize ^{1}H-MRI to establish a quantitative metric for muscle heterogeneity, a potential biomarker of muscle quality and composition in patients with CKD, both requiring hemodialysis (HD) and earlier stages.

Methods: ^{1}H T1-weighted axial images (3 Tesla) of the calf were acquired on 43 CKD, 34 HD, and 8 with cardiorenal syndrome (CR). Gastrocnemius and soleus muscles were delineated and the heterogeneity quantification algorithm was applied. The magnitude of pixel intensity gradation between pixel-pair combinations was computed, resulting in a value, zeta, to represent the mean heterogeneity. A one-way ANOVA was performed for significance in heterogeneity between the three cohorts. Combining all participants (n=85), Pearson correlations was completed for blood markers of kidney function in relation to muscle heterogeneity.

Results: Muscle heterogeneity of HD and CR were comparable but significantly more heterogeneous relative to CKD (Figure 1). Negative correlations were seen with albumin and 1,25 Vitamin D with relation to muscle heterogeneity (Figure 2A, B). A positive association was seen with PTH with respect to muscle heterogeneity (Figure 2C).

Conclusions: Muscle heterogeneity of HD and CR may be indicative of fibrosis and wasting that is more pronounced than progressive CKD not on dialysis. Relationship between blood markers of kidney function and muscle heterogeneity suggest texture analysis to be a useful tool for non-invasive evaluation of kidney disease on skeletal muscle structure and function.

Funding: Government Support - Non-U.S.

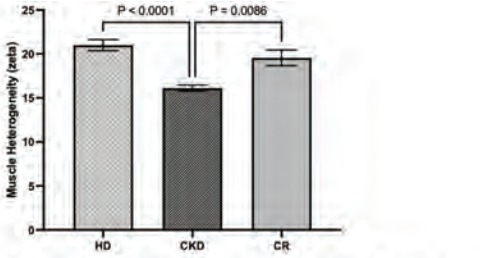

Figure 1. Mean heterogeneity in gastrocnemius and soleus muscles of T1-weighted MR images on hemodialysis (n=34), chronic kidney disease (n=43), and cardiorenal syndrome (n=8) participants. Error bars represent standard error of the mean.

Intramuscular Adipose Tissue (IMAT) Accumulation and Muscle Function in Patients with Moderate to Advanced Kidney Disease

Ragibe Gulsah Dilaver,[1] Mert Demirci,[2] Rachelle Crescenzi,[2] Michael Pridmore,[2] Talat Alp Ikizler,[1] Jorge Gamboa.[1] *[1]Vanderbilt University Medical Center, Department of Medicine, Nashville, TN; [2]Vanderbilt University Medical Center Department of Radiology, Nashville, TN.*

Background: Sarcopenia is common in patients undergoing maintenance hemodialysis (MHD) and is associated with poor physical function. Excessive accumulation of intramuscular adipose tissue (IMAT) is associated with poor physical function in patients with obesity, heart failure, and type 2 diabetes. We examined the extent of IMAT accumulation in MHD patients compared to individuals without kidney disease. We further investigated the factors that are associated with IMAT accumulation.

Methods: We cross-sectionally studied 49 participants (23 controls and 26 patients on MHD). IMAT accumulation in the leg muscle groups was measured using magnetic resonance imaging (MRI) by finding the widest part of the calf. Additional analyses were done for body composition, muscle function (hand grip strength), inflammatory biomarkers, and markers of mitochondrial function (mtDNA).

Results: The controls and patients were matched by age (52±13 versus 56±15 years), gender (%83 male versus %86), and BMI (31.9±4.9 vs 29.7±7.7 kg/m^2). IMAT accumulation was significantly higher in the MHD group compared to the controls (IMAT 0.113 (0.065 – 0.143) for MHD vs 0.063 (0.047 – 0.073) for control; p = 0.0008; **Figure 1A)**. IMAT accumulation was positively associated with BMI ($p < 0.05$, Rho = 0.284) **(Figure 1B)**, IL-6 (p = 0.001, Rho = 0.437) **(Figure 1C)**, and negatively associated with the hand grip test ($p < 0.05$, Rho = -0.361) **(Figure 1D)**.

Conclusions: Patients on MHD display a greater accumulation of IMAT compared to matched controls. IMAT accumulation could be mediated by systemic inflammatory response and might be responsible for decreased muscle function and sarcopenia in patients on MHD.

Assessment of Nutritional Status in Nondialysis-Dependent Patients with CKD Using Handgrip Strength

Minsang Kim,[1] Dha Woon Im,[2] Eunjeong Kang,[1] Kook-Hwan Oh.[1] KNOW-CKD (The KoreaN Cohort Study on the Outcome of Chronic Kidney Disease Patients). *[1]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [2]Eulji University Uijeongbu Eulji Medical Center, Uijeongbu, Gyeonggi-do, Republic of Korea.*

Background: Although handgrip strength (HGS) has been suggested as an indirect assessment of nutritional status in chronic kidney disease (CKD) patients, additional evidences regarding the diagnostic usefulness of HGS for malnutrition in non-dialysis-dependent CKD (NDD-CKD) are warranted.

Methods: A total of 467 patients enrolled in the Phase II KoreaN Cohort Study for Outcome in Patients With CKD who underwent nutritional assessment were included in this study. The exposure was the maximum value of HGS, which was measured twice in each hand. The outcome was a malnutrition status defined as a malnutrition-inflammation score (MIS) of 6 or higher. In this cross-sectional study, the risk of malnutrition was calculated using logistic regression analysis adjusted for age, sex, history of diabetes mellitus (DM), stage of CKD, and income and education status. Predictability of HGS for malnutrition was assessed by area under the curve (AUC) using receiver operating characteristic curve analysis.

Results: Patients with lower HGS, defined as HGS values below sex-specific median values, were older and had a higher proportion of DM. A higher HGS was significantly associated with a lower risk of malnutrition after adjustment (per 1 standard deviation increase, adjusted odds ratio, 0.51 [0.26–0.98]). I]). In the subgroup analyses stratified by age, sex, DM, and CKD stage, these clinical factors did not show significant interaction between HGS and the risk of malnutrition. The tendency of a negative association between HGS and the risk of malnutrition was consistently observed in all subgroups. Furthermore, HGS exhibited fair significance for the prediction of malnutrition in men and women (Figure 1).

Conclusions: HGS is a useful diagnostic indicator of malnutrition in NDD-CKD patients.

FR-PO1148

Feasibility of a Home-Based, Video-Supervised 12-Week Exercise Program in Nondialysis-Dependent CKD: The ESTEEM-VIDA Pilot Randomized Clinical Trial

Gwenaelle Begue,[1] Catherine L. Welsh Osuna,[1] Jesse Gipe,[2] Chenoa R. Vargas,[2] Hiba Hamdan,[2] Tae Youn Kim,[2] Thomas Jue,[2] Jorge Gamboa,[3] Baback Roshanravan.[2] *[1]California State University Sacramento, Sacramento, CA; [2]University of California Davis, Davis, CA; [3]Vanderbilt University, Nashville, TN.*

Background: Sarcopenia is prevalent in CKD and is a central component of the frailty phenotype associated with adverse clinical outcomes. Regular exercise improves muscle function and physical capacity in CKD. There is a critical need for practical, safe, interactive, and personalized exercise program targeting improvements in physical functioning in patients living with CKD.

Methods: The ESTEEM-VIDA CKD pilot randomized clinical trial (NCT02923063) tested the feasibility of a home-based, video-supervised, and personalized exercise program in stage 3-5 non-dialysis CKD. Exercise consisted of 30-40min exercise sessions, thrice a week for 12 weeks. Session 1) high-intensity interval training (HIIT) targeted a hard effort with a rate of perceived exertion (RPE) above 14, session 2) strength training, and session 3) powerwalking both targeted a moderate effort with a RPE of 12-14. One week of video-supervised exercise alternated with one week of self-directed exercise. Each one-week video-supervised session was conducted by exercise trainers using a videoconference tool. Self-directed exercise weeks used pre-recorded exercise videos sent via email to participants. Feasibility was measured via adherence to the exercise dose as well as number of adverse effects and dropouts.

Results: Out of 22 participants randomized to exercise (EX), 21 completed the 12-weeks exercise program with 1 loss to follow-up. EX (n=21) had a mean age of 63±10.3 years (47% male, 47% diabetic) with mean eGFR of 35±12 mL/min/1.73 m^2. Adherence was 90.3% with 32 sessions (range: 14-36) completed out of 36 over 12 weeks. Only 2 (9.5%) exercisers reported less than 75% adherence. Exercisers reported average RPE of 14.3±1.3 compared to targeted RPE of above 14 for HIIT session, and RPEs of 13.9±1.8 for strength and powerwalking sessions compared to targeted RPE of 12-14. No adverse effects due to the exercise protocol were reported.

Conclusions: A 12-weeks home-based video-supervised exercise program is feasible and safe in people with moderate-severe non-dialysis CKD. Future studies should consider exercise protocol that are practical offering various exercise modality to increase participants adherence and physical functioning. **Funding:** R01DK129793, R01DK125794, DCI-4112

FR-PO1149

Home-Based Exercise Improves Skeletal Muscle Mitochondrial Energetics in CKD: Results from the ESTEEM-VIDA Pilot Randomized Clinical Trial

Jennifer E. Norman,[1] Gwenaelle Begue,[2,1] Jesse Gipe,[1] Sarah E. Brashear,[1] Armin Ahmadi,[1] Tae Youn Kim,[1] Jorge Gamboa,[3] Baback Roshanravan.[1]
[1]University of California Davis, Davis, CA; [2]California State University Sacramento, Sacramento, CA; [3]Vanderbilt University Medical Center, Nashville, TN.

Background: Impaired muscle mitochondrial function is mechanistically linked to sarcopenia and frailty in chronic kidney disease (CKD). Loss of electrons from the electron transport chain (ETC) lead to increased reactive oxygen species (ROS) production with mitochondrial dysfunction. Exercise interventions may improve mitochondrial functioning and decrease ROS production.

Methods: ESTEEM-VIDA is a 12-week pilot randomized clinical trial (NCT02923063) of a home-based, personalized, and video-supervised exercise intervention (EX), compared to usual care (UC) in persons with stage 3-5 non-dialysis CKD. We assessed changes in *ex vivo* mitochondrial respiration rates (O_2 consumption) and ROS (H_2O_2) production of vastus lateralis muscle biopsy homogenate using high resolution respirometry (Oroboros O2k-Fluo respirometer). We used linear mixed effects models to test changes in mitochondrial respiration rates and ETC efficiency (H_2O_2 production relative to O_2 consumption) after 12 weeks and at baseline between groups and within each group.

Results: Participants randomized to EX (n=21) had a mean eGFR of 35 ± 12 mL/min/1.73m^2 and mean age of 63 ± 10.3 years, as compared to 31.3 ± 13.5 mL/min/1.73m^2 and 68.1 ± 8.7 years in those randomized to UC (n=7). There were significant ($p<0.05$) between group differences in oxidative phosphorylation (OXPHOS) respiration rates in the presence of succinate and pyruvate and after the addition of rotenone (Figure 1). After 12 weeks, the EX group exhibited significant increases in respiration rates, while ETC efficiency improved (decreased H_2O_2/O_2). No changes were seen in the usual care group.

Conclusions: Twelve weeks of home-based exercise can increase skeletal muscle mitochondrial respiration rates, while improving ETC efficiency. This supports the hypothesis that an exercise intervention improves mitochondrial health and efficiency in persons with CKD.

FR-PO1150

Home-Based Exercise Increases Mitochondrial Respiratory Rates of Quadriceps Muscle Permeabilized Fibers in CKD: Results from the ESTEEM-VIDA Pilot Randomized Clinical Trial

Jennifer E. Norman,[1] Gwenaelle Begue,[3,1] Jesse Gipe,[1] Sarah E. Brashear,[1] Armin Ahmadi,[1] Usman Rehman,[1] Tae Youn Kim,[1] Thomas Jue,[1] Jorge Gamboa,[2] Baback Roshanravan.[1] *[1]University of California Davis, Davis, CA; [2]Vanderbilt University Medical Center, Nashville, TN; [3]California State University Sacramento, Sacramento, CA.*

Background: Impaired mitochondrial function contributes to sarcopenia and frailty in chronic kidney disease (CKD). Exercise interventions may help improve skeletal muscle mitochondrial function, ameliorating sarcopenia and frailty.

Methods: ESTEEM-VIDA is a 12-week pilot randomized clinical trial (NCT02923063) of home-based, personalized, and video-supervised exercise intervention (EX), compared to usual care (UC) in persons with stage 3-5 non-dialysis CKD. We measured *ex vivo* mitochondrial respiration of vastus lateralis permeabilized muscle fibers using high resolution respirometry (Oroboros O2k-Fluo respirometer). Baseline *ex vivo* mitochondrial respiration rates were compared to baseline *in vivo* ^{31}P magnetic resonance spectroscopy (MRS) measurement of skeletal muscle oxidative capacity using Spearman correlations. We used linear mixed effects models to test changes in *ex vivo* mitochondrial respiration rates, comparing 12 week and baseline measurements within each group.

Results: Participants randomized to EX (n=21) had a mean eGFR of 35 ± 12 mL/min/1.73m^2 and mean age of 63 ± 10.3 years, compared to 31.3 ± 13.5 mL/min/1.73m^2 and 68.1 ± 8.7 years in the UC group (n=7). At baseline, maximal OXPHOS and ET capacity rates, with pyruvate, malate, glutamate, and succinate substrates, were positively correlated with MRS measurement of *in vivo* oxidative capacity (R= 0.386, p=0.047 and R=0.435, p=0.023 for maximal OXPHOS and ET capacity, respectively). Sub-saturating and saturating ADP OXPHOS rates with pyruvate and malate as substrates significantly ($p<0.05$) increased after 12 weeks in the EX group (Figure 1). No changes were seen in any of the measured rates after 12 weeks in the UC group.

Conclusions: Twelve weeks of home-based exercise increases pyruvate and malate supported OXPHOS respiration rates in persons with CKD. The mechanisms behind this increase are yet to be determined but may partially proceed through improved pyruvate dehydrogenase functionality.

Exercise Alters Peripheral Blood Mononuclear Cell Mitochondrial Respiratory Rates in Persons with CKD: Results from the ESTEEM-VIDA Pilot Randomized Clinical Trial

Jennifer E. Norman,[1] Armin Ahmadi,[1] Erik R. Gertz,[2] Brian J. Bennett,[2,1] Jesse Gipe,[1] Tae Youn Kim,[1] Gwenaelle Begue,[4,1] Jorge Gamboa,[3] Baback Roshanravan.[1] *[1]University of California Davis, Davis, CA; [2]USDA Agricultural Research Service, Davis, CA; [3]Vanderbilt University Medical Center, Nashville, TN; [4]California State University Sacramento, Sacramento, CA.*

Background: Impaired muscle mitochondrial function is mechanistically linked to sarcopenia and frailty in chronic kidney disease (CKD). Exercise interventions may improve mitochondrial function and preserve physical function in this population. Assessment of mitochondrial respiration in peripheral blood mononuclear cells (PBMCs) may provide insight into the effects of exercise on immunometabolism.

Methods: ESTEEM-VIDA is a 12-week pilot randomized clinical trial (NCT02923063) of a home-based, personalized, and video-supervised exercise intervention (EX), compared to usual care (UC), in persons with stage 3-5 non-dialysis CKD. We assessed changes in *ex vivo* mitochondrial respiration in intact (non-permeabilized) PBMCs. High resolution respirometry (Oroboros O2k-Fluo respirometer) was used to assess routine, leak, ATP-linked, electron transport (ET) capacity, and reserve capacity respiration rates. Linear mixed effects models were used to test changes in these mitochondrial respiration rates, comparing 12 week and baseline measurements within each group.

Results: Participants randomized to EX (n=21) had a mean eGFR of 35 ± 12 mL/min/1.73m^2 and mean age of 63 ± 10.3 years, compared to 32.3 ± 12 mL/min/1.73m^2 and 67.1 ± 8.3 years for those randomized to UC (n=9). While no changes occurred in ATP-linked respiration, significant ($p<0.05$) decreases were seen in routine, leak, ET capacity, and reserve capacity respiratory rates in the EX group after the intervention (Figure 1). No changes were observed in any of the measured respiratory rates in the UC group.

Conclusions: In persons with CKD, a home-based exercise intervention reduced all measured PBMC respiratory rates, with the exception of ATP-linked respiration. It could be hypothesized that ATP-linked respiration does not change due to cellular energy requirements being fixed. Further studies are needed to determine if the changes observed are related to improvements in oxidative stress and inflammation with exercise.

Skeletal Muscle Structural Adaptation to Exercise Training in CKD

Sarah E. Brashear,[1] Vishal Rao,[1,3] Anas Mohamed Sulthan,[1] Denise J. Chan,[1] Gwenaelle Begue,[2] Jorge Gamboa,[4] Baback Roshanravan,[1] Lucas R. Smith.[1] *[1]University of California Davis, Davis, CA; [2]California State University Sacramento, Sacramento, CA; [3]Charles R Drew University of Medicine and Science, Los Angeles, CA; [4]Vanderbilt University Medical Center, Nashville, TN.*

Background: Chronic kidney disease (CKD) is associated with sarcopenia leading to functional impairment. Studies suggest increased muscle fibrosis in CKD with excess extracellular matrix (ECM), particularly collagen. It is not known how exercise in patients with CKD may impact the extent of collagen cross-linking or fibrosis impairing muscle adaptations to exercise.

Methods: We conducted a pilot randomized, controlled trial of 12 weeks home-based, exercise training in CKD. We analyzed vastus lateralis muscle biopsies from patients randomized to exercise (EX, n=19) and usual care (UC, n=6). We tested for collagen content and cross-linked collagen using hydroxyproline assay. Cryosections were stained to study ECM area, satellite cells, vasculature, fibro-adipogenic progenitors (FAPs), and muscle fiber types. We stained for fiber type and vasculature analyzed using semi-automatic muscle analysis using segmentation of histology (SMASH).

Results: The EX group had an mean age of 64 (SD=9.4) years, mean eGFR of 35 (SD=11.69) ml/min/1.73m2 with 52.6% males and 47.4% diabetes compared to 68 (SD=8.85), 35 (SD=6.12), 16.6%, and 66.7% in UC. The amount of collagen and collagen cross-linking were not altered by exercise. No changes in ECM area or collagen packing density were noted with picrosirius red staining in EX vs UC. Minimum feret diameter and percentage of type I (slow twitch) fibers decreased in most patients in the EX group (Fig 1A). Type I and type IIa (fast oxidative) fiber size also significantly decreased, while there was no change in type IIx (fast glycolytic) fiber size. Capillaries (CD31+) increased with exercise in EX vs UC (Fig 1B). There was no change in satellite cells (PAX7+) or FAPs (PDGFRα+) in either the exercise or no exercise groups.

Conclusions: Muscle tissue in CKD patients responded to exercise training, shown by increased capillary density. Exercise induced muscle fiber size and type distribution changes indicate CKD being responsive to an exercise program. This supports exercise as a powerful tool to study muscle plasticity in CKD.

FR-PO1153

Bioimpedance Analysis for the Assessment of Body Composition and Relation with Muscle Strength in Patients with CKD Stage G3 to G5 and Healthy Controls

Elife Ozturk, Amber van Dulmen, Monique Mullens, Jessica Noelmans, Jeroen Kooman, Marc H. Hemmelder. *Maastricht Universitair Medisch Centrum+, Maastricht, Netherlands.*

Background: Bioimpedance analysis (BIA) is an increasingly used method to assess body composition (BC) and the prevalence of sarcopenia in patients with chronic kidney disease (CKD). BIA measurement can be performed at a whole-body level by the Body Composition Monitor (BCM). The InBody S10 Biody Water Analyzer (BWA) enables additional modelling of body segments, extremities and trunk, whereas BCM allows for assessment of overhydration as a separate compartment. This study compares BCM and BWA measurements with respect to assessment of fat free mass (FFM) and its association with handgrip strength (HGS) in patients with CKD stage G3 to G5 and in healthy controls.

Methods: This is a prospective observational study. 50 patients with CKD (23 stage G3 and 27 stage G4-5) and 30 control subjects were included. BC was assessed with the BCM and BWA. HGS was measured to assess muscle strength. BCM and BWA measurements were analyzed with Bland-Altman plots. The relation between BC and HGS in relation to renal function was assessed with multivariable analysis.

Results: FFM of the BCM was 1.4 kg higher than the BWA (95%-CI=0.016 to 2.78, p=0.047, limits of agreement -7.3 to 10.1) for the CKD group and 1.8kg lower for the controls (95%-CI=-3.25 to -0.40, p=0.014, limits of agreement -8.4 to 4.8). Body cell mass (BCMa) of the BCM was 8.1kg lower than the BWA (p=<0.001) for the CKD group and 10.6kg lower for the controls (p=<0.001). HGS was significantly correlated with FFM-BCM (for CKD: B=0.6, 95%-CI=0.4 to 0.9, β=0.59, p=<0.001 and for controls: B=0.7, 95%-CI=0.5 to 0.8, β=0.87, p=<0.001) and with FFM-BWA (for CKD: B=0.8, 95%-CI=0.5 to 1.0, β=0.65, p=<0.001 and for controls: B=0.6, 95%-CI=0.4 to 0.8, β=0.86, p=<0.001).

Conclusions: FFM estimates was significantly different between BCM and BWA for both the CKD group and the healthy controls. The large difference in BCMa might be attributed to differences in expression of BC compartments between the BCM and BWA. Both FFM and BCMa showed high individual variability. FFM assessed by both methods significantly correlated to HGS. Future studies will have to define whether device specific cut-off reference values of BIA estimates are needed to enhance its applicability in clinical care for CKD patients.

FR-PO1154

Inorganic Nitrate for Improving Vascular Endothelial Function in CKD: A Randomized, Placebo-Controlled Clinical Trial

Matthew J. Rossman,[1] Sanna Darvish,[1] Katelyn Ludwig,[1] Akpevweoghene P. Ikoba,[1] Mckinley Coppock,[1] Morgan Berryman-Maciel,[1] Kevin O. Murray,[1] Michel Chonchol,[2] Douglas R. Seals.[1] *[1]University of Colorado Boulder, Boulder, CO; [2]University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Cardiovascular disease (CVD) is the leading cause of death in chronic kidney disease (CKD). A key antecedent to CVD in CKD is vascular endothelial dysfunction mediated by declines in nitric oxide (NO) bioavailability due to excess reactive oxygen species (ROS)-related oxidative stress. Here, we tested the safety and efficacy of targeting the nitrate-nitrite-NO pathway with inorganic nitrate for improving endothelial function in indviduals with mild renal dysfunction through moderate CKD.

Methods: Twenty-six older men and women with mild renal dysfunction to stage III CKD (estimated glomerular filtration rate [eGFR; CKD-EPI]: 40-89 mL/min/1.73m^2) underwent 3 months of supplementation with nitrate-rich beetroot juice (BRJ: 70 mL, 6.45 mmol nitrate/day) (n=13, 7 women; age: 65±2 yrs; eGFR: 68±2 mL/min/1.73m^2) or nitrate-depleted BRJ (placebo) (n=15, 8 women; age: 67±2 yrs; eGFR: 78±3 mL/min/1.73m^2) in a randomized, placebo-controlled, parallel-group design clinical trial. Endothelial function assessed by brachial artery flow-mediated dilation (FMD_{BA}) was the primary outcome. To determine mechanisms of action, acetylcholine-stimulated NO production (DAR-4M-AM) and ROS bioactivity (CellROX) were assessed in human aortic endothelial cells (HAECs) exposed to 10% subject serum collected before/after nitrate-rich BRJ or placebo supplementation.

Results: Nitrate-rich BRJ supplementation was safe, well-tolerated and increased FMD_{BA} by 26% (pre: 4.7±0.7%, post: 5.9±0.8%; p=0.03). FMD_{BA} did not change with placebo (pre: 4.6±0.9%, post: 4.5±0.8%; p>0.05). The improvement in FMD_{BA} with nitrate-rich BRJ was negatively associated with baseline eGFR (r=0.41, p=0.02). Diastolic blood pressure was reduced by ~2 mmHg with nitrate-rich BRJ (P<0.05), but other traditional CVD risk factors were unchanged (p>0.05). NO production was 7% higher (p=0.05) and ROS bioactivity was 25% lower (p=0.02) in HAECs exposed to serum collected after vs. before nitrate-rich BRJ; there were no changes with serum obtained pre-post placebo (P>0.05).

Conclusions: Nitrate-rich BRJ holds promise for improving endothelial function in CKD, in part by inducing changes to the circulating milieu that increase NO production and lower oxidative stress in endothelial cells.

FR-PO1155

Sex Hormones and Vascular Endothelial Function in Men and Women with CKD

Ester Oh,[1] Anna Ostrow,[1] Michel Chonchol,[1] Vienna E. Brunt,[1] Kristen L. Nowak,[1] Anna Jovanovich,[2] Jessica B. Kendrick,[1] Kerrie Moreau.[1] *[1]University of Colorado Anschutz Medical Campus School of Medicine, Aurora, CO; [2]Bozeman Health, Bozeman, MT.*

Background: Vascular endothelial dysfunction is common in chronic kidney disease (CKD) and independently predicts cardiovascular disease events. In older healthy females and males, lower estrogen and testosterone levels contribute to endothelial dysfunction, leading to higher cardiovascular risk. However, limited studies to date have examined the association of sex hormones with endothelial function in patients with CKD. As such, this study investigated if sex hormones are associated with endothelial function in adults with CKD.

Methods: Circulating levels of total testosterone (TT), free testosterone (FT), FT/TT ratio, estrone (E1), estradiol (E2), E1/E2 ratio, and TT/E2 ratio, were measured in males (age 29-81 years) and females (23-80 years) with stage 3-4 CKD, who participated in one of three completed clinical trials (PMID: 28784657 and 37228030; and NCT02209636 [in press]). The association of each sex hormone with brachial artery flow-mediated dilation (FMD_{BA}; a gold-standard measure of conduit artery endothelial function in humans) was assessed via multivariable linear regression.

Results: A total N=187 males (46% white; mean±SD age 61±11 y; eGFR 37±11 mL/min/1.73m²) and N=104 females (49% white; 61±12 y; eGFR 34±10 mL/min/1.73m²) were included. In males, FT/TT was positively associated with FMD_{BA} in the unadjusted model (β=1.59; 95% confidence interval 0.44–2.74). However, this association was attenuated following adjustment for age (**Figure A**). In females, TT, FT, and E2 tended to be associated with lower FMD_{BA} and E1/E2 with higher FMD_{BA} after adjusting for age (**Figure B**).

Conclusions: Sex hormones were not associated with FMD_{BA} in males and females with CKD. Further mechanistic research is needed to better understand sex differences in cardiovascular risk in patients with CKD.

Funding: Private Foundation Support

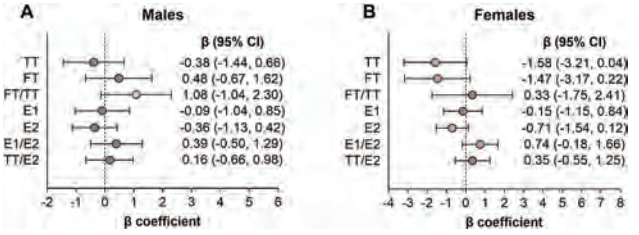

Figure. The association of sex hormones with FMD_{BA} in males **(A)** and females **(B)**, adjusted for age.

FR-PO1156

Phase 3 Clinical Candidate Rilparencel Demonstrates Weak Association with Renal Epithelial Senescence-Associated Secretory Phenotype

Mark A. Rohlfing, Ashley Greenawalt, Brooke Bauer, Andrew T. Bruce, Dominic M. Justewicz. *ProKidney LLC, Morrisville, NC.*

Background: CKD is associated with an enhanced senescence-associated secretory phenotype (SASP) and high inflammation, which can induce senescence. This study evaluated the renal epithelial SASP of rilparencel. Biopsy-derived rilparencel is a first-in-class autologous renal epithelial cell product in Phase 3 clinical trials for patients with T2D and CKD. Data from two Phase 2 clinical trials suggest that cortical administration of rilparencel potentially stabilizes estimated glomerular filtration rate (eGFR).

Methods: rilparencel manufactured from kidney biopsies of each of 5 patients with T2D and CKD (NCT02836574) was submitted for scRNA-seq, and 52 differentially expressed genes (DEGs) were evaluated for this study. Additionally, for each patient, proteins secreted by rilparencel were compared to proteins secreted from a manufacturing precursor to rilparencel (Intelliflex). Fifty-one secreted proteins and 52 DEGs were seeded into the SASP atlas, a proteomic analysis of renal epithelial cells 10 days post-irradiation (PMID:31945054), to determine if any are associated with a renal epithelial SASP. As comparison, IGFBP2 and CXCL8, senescence markers known to be elevated in CKD, were used as positive controls.

Results: Of the secreted proteins and DEGs associated with rilparencel, only PTER (a DEG) was identified as being secreted by renal epithelial cells according to the SASP atlas. The SASP atlas reports that PTER protein expression is approximately 2-fold less than IGFBP2 and CXCL8, which serve as positive SASP controls for comparison (A). Additionally, rilparencel secretes reduced levels of proinflammatory cytokines compared to an earlier stage in the product manufacture (B), which also suggests a reduced senescence phenotype.

Conclusions: Our proprietary manufacturing process generates a renal epithelial cell-based product (rilparencel) from renal cortex tissue with a low SASP, which may in part underlie its therapeutic activity in the clinic.

FR-PO1157

Effect of Glymphatic System Function on Cognitive Function in Patients with CKD

Changmin Heo, Yoo jin Lee, Yang Wook Kim, Bongsoo Park, Sihyung Park, Eul Jo Jeong, Jiyae Yi. *Inje University Haeundae Paik Hospital, Busan, Republic of Korea.*

Background: The aim of this study was to investigate the effects of glymphatic system function on cognitive function in patients with chronic kidney disease (CKD).

Methods: We prospectively enrolled the patients with CKD and healthy controls. We divided the patients with CKD into two groups according to their cognitive function. All of them underwent brain magnetic resonance imaging, which included diffusion tensor imaging (DTI). We calculated the diffusion tensor image analysis along the perivascular space index (DTI-ALPS index) based on the DTI which was the marker for glymphatic system function (Fig1). We compared the DTI-ALPS index between the groups.

Results: DTI-ALPS index in patients with CKD was lower than that in healthy controls (1.436 vs. 1.632, p<0.001). In addition, there were significant differences of the DTI-ALPS index between CKD patients with and without CI. DTI-ALPS index in CKD patients with CI was lower than that in those without CI (1.338 vs. 1.494, p=0.031, Fig 2). Furthermore, DTI-ALPS index was negatively correlated with age (r=-0.326, p=0.014) in the patients with CKD.

Conclusions: This study observed that the DTI-ALPS index was lower in patients with CKD, suggesting glymphatic system dysfunction in patients with CKD. Moreover, within the CKD patient group, those with CI had lower DTI-ALPS index compared to those without CI, indicating a potential link between glymphatic system dysfunction and CI. These findings suggest that glymphatic system dysfunction may contribute to CI in patients with CKD.

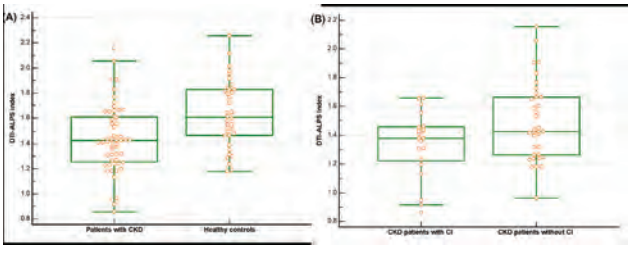

Figure 2. Differences of the DTI-ALPS index between the groups

FR-PO1158

Association between Serum β2-Microglobulin and Executive Function in Patients with Nondialysis-Dependent CKD: The VCOHP Study

Kazuhiko Tsuruya,[1] Hisako Yoshida.[2] [1]*Nara Kenritsu Ika Daigaku, Kashihara, Japan;* [2]*Osaka Koritsu Daigaku, Osaka, Japan.*

Background: Previously, we investigated the association between grey matter (GM) volume ratio (GMR) on brain MRI and the executive function assessed by trail making test (TMT) in 95 patients with non-dialysis chronic kidney disease (ND-CKD). We reported a significant negative correlation between GMR and TMT scores (Tsuruya K, et al. PLoS One 2015;10(12):e0143706). β2-microglobulin (BMG) is a low molecular weight protein composed of 99 amino acids, with a molecular weight of 11,800 and no sugar chains. As the glomerular filtration rate (GFR) decreases, serum BMG levels rise because it is no longer excreted into the urine, thus elevating in cases of kidney dysfunction. Cognitive impairment (CI) and brain atrophy have been reported to progress with declining of GFR. Since BMG levels increase as GFR declines, a possible association between BMG levels and CI has been considered; however, it has not been fully elucidated to date. Therefore, we examined this association in patients with ND-CKD.

Methods: We conducted a cross-sectional study with 95 ND-CKD patients who had no overt CI or history of stroke. The subjects underwent brain MRI scans and completed

TMT part A (TMT-A) and part B (TMT-B). The segmentation algorithm from Statistical Parametric Mapping 8 software was applied to each T1-weighted MRI scan to extract tissue maps corresponding to GM, white matter (WM), and cerebrospinal fluid (CSF). To normalize for head size variability, GMR was calculated as the ratio of GM volume to the total intracranial volume, which is the sum of GM, WM, and CSF volumes.

Results: A linear regression analysis demonstrated significant associations between serum BMG levels and the scores of TMT-A, TMT-B, and ΔTMT (TMT-B – TMT-A) in the univariable analysis. These associations remained robust even after adjusting for confounding factors, including age, sex, body mass index, original kidney disease, history of cardiovascular disease, smoking habits, systolic blood pressure, hemoglobin level, serum levels of albumin, low-density lipoprotein cholesterol, and C-reactive protein, urinary protein-to-creatinine ratio, estimated GFR (eGFR), and GMR.

Conclusions: BMG is an independent factor associated with CI (executive dysfunction) independent of kidney dysfunction and brain atrophy.

FR-PO1159

Kidney Impairment Exacerbates Periventricular White Matter Hyperintensities in Patients with CKD

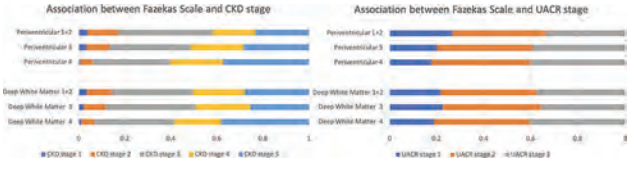
Feng-Ching Shen,[1] Yi-Ting Lin,[3,2] Ming-Yen Lin,[1] Mei-Chuan Kuo,[1,2] Yi-Wen Chiu,[1,2] Jer-Ming Chang,[1,2] Shang-Jyh Hwang,[1,2] Ping-Hsun Wu.[1,2] *[1]Division of Nephrology, Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan; [2]Faculty of Medicine, College of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan; [3]Department of Family Medicine, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan.*

Background: Cognitive impairment is commonly observed in patients with chronic kidney disease (CKD) and tends to worsen as estimated glomerular filtration rate (eGFR) declines and albuminuria increases. Brain magnetic resonance imaging (MRI) scans are valuable in detecting structural brain lesions. Cerebral white matter hyperintensities (WMHs), indicating small vessel diseases, are associated with cognitive decline. The Fazekas scale quantifies WMHs and highlights parenchymal changes in brain MRI. This study investigated the association between kidney function status (eGFR and albuminuria) and WMHs in CKD.

Methods: A cross-sectional study of 1,738 CKD patients was conducted at Kaohsiung Medical University Hospital, Taiwan. Brain MRI scans were utilized to measure WMHs according to the Fazekas scale, separately assessing periventricular WMHs (PWMHs) and deep WMHs (DWMHs). The eGFR was calculated using the MDRD formula. The urinary albumin to creatinine ratio (UACR) was categorized into three stages with cutoff values at 30 mg/g and 300 mg/g. The prognosis of CKD was accessed based on the 2024 KDIGO guidelines, considering both eGFR and albuminuria. Ordinal regression models with potential confounders adjustment were used for the analysis.

Results: Impaired renal functions are associated with increased severity of PWMHs. An increase in eGFR is linked to a decrease in PWMHs with an odds ratio (OR) of 0.987 (95% confidence interval [CI]: 0.979-0.994, $p < 0.001$). UACR stage 3 shows a significant association with increased PWMHs (OR [95% CI]: 1.645 [1.066-2.540], $p = 0.024$) compared with UACR stage 1. Those catagorized as very high-risk group by KDIGO guidelines are associated with increased PWMHs (OR [95% CI]: 1.832 [1.184-2.840], $p = 0.007$), compared to those with low and moderately increased risk. However, impaired renal functions are not associated with DWMHs.

Conclusions: Our findings highlight the impact of renal impairment on brain damage in CKD patients, as evidenced by the increased severity of PWMHs. DWMH shows no significant association with renal function.



Association between Fazekas Scale with CKD stage and UACR stage

FR-PO1160

Posterior Reversible Encephalopathy Syndrome in CKD: A Comprehensive National Analysis, 2016-2019

Mingyue He, Avrum Gillespie. *Temple University Hospital, Philadelphia, PA.*

Background: Posterior Reversible Encephalopathy Syndrome (PRES) is an acute clinical-radiographic neurological syndrome that is potentially reversible with timely treatment. However, if untreated, it may result in severe complications such as intracerebral hemorrhage (ICH). Patients with kidney disease are at an increased risk of developing PRES. It remains unclear whether this is due to concurrent conditions such as hypertension and autoimmune disorders or if renal dysfunction itself is an independent risk factor. Furthermore, the impact of kidney function on the outcomes of PRES is still uncertain. This study aimed to examine the incidence and outcomes of PRES across various stages of chronic kidney disease (CKD), compared to a kidney disease-free group (NKD).

Methods: We conducted a retrospective analysis using the Nationwide Inpatient Sample (NIS) database to identify adult patients non-electively admitted with PRES from 2016 to 2019, categorizing them into CKD stages 3, 4, 5; end-stage kidney disease (ESKD); NKD; and an Others group.

Results: The study included 12,605 patients, representing 0.014% of all admissions. PRES hospitalizations increased significantly from 2016 to 2019. (trend p=0.012). The cohort had a mean age of 57.5 years, with 71.5% female and 72.5% White. Patients with CKD had higher PRES incidence in a dose-response manner as CKD stages advanced from 3 to ESKD. Key risk factors for PRES included gender, hypertension, metastasis, drug use, history of solid organ transplant, carotid artery stenosis, cerebral atherosclerosis, migraine, SLE, and systemic sclerosis. ESKD patients had significantly higher in-hospital mortality (aOR 4.61, 95% CI 1.84-11.57, p= 0.001). Differences in ICH and stroke rates across CKD stages/ESKD and NKD were not statistically significant.

Conclusions: Our findings provide valuable insights into the impact of CKD on the incidence and outcomes of PRES. Our study establishes an association between CKD and PRES, demonstrating a dose-response relationship. ESKD is an independent risk factor for in-hospital mortality. Given these insights, our study emphasizes the need for heightened awareness and targeted management strategies to improve outcomes for this vulnerable group. It also calls for further research to explore the specific mechanisms linking CKD and PRES.

FR-PO1161

Comparative Effectiveness of Roxadustat vs. Erythropoiesis-Stimulating Agents (ESAs) on Anemia and Kidney Outcomes among Patients with CKD: A Retrospective Cohort Study

Jinwei Wang,[1] Luxia Zhang,[1,2] Ming-Hui Zhao.[1] *[1]Peking University First Hospital, Beijing, China; [2]Peking University Health Science Center, Beijing, China.*

Background: Anemia is a common complication of chronic kidney disease (CKD), causing adverse outcomes. Traditional treatments, including iron and erythropoiesis stimulating agents (ESAs), may arouse drug-related adverse events, while the newly developed hypoxia inducible factor prolyl hydroxylase inhibitor (HIF-PHI) demonstrated both efficacy and safety. However, previous evidence largely comes from clinical trials and mainly focused on patients with kidney failure. The “head-to-head” comparison of the effectiveness in real-world setting among patients with CKD regarding HIF-PHI and ESAs is lacking.

Methods: Patients with CKD receiving either intravenous/subcutaneous ESAs or oral Roxadustat capsules (one type of HIF-PHI) were identified from the electronic health records-based CKD registry in Yinzhou district of Ningbo city in China from December of 2018 to December of 2021. The propensity score-based inverse probability of treatment weighting was used to control confounding. The difference regarding hemoglobin (Hb) change between the treatments was evaluated by linear mixed effect model, while association of the treatments with Hb response (Hb>110 g/L with an absolute increase of Hb ≥10 g/L from a baseline of ≥80 g/L or ≥20 g/L from a baseline of <80 g/L) and composite kidney outcomes (initiation of kidney replacement therapy, doubling of serum creatinine or ≥50% reduction of kidney function) by Cox regression model.

Results: Totally, 473 patients receiving ESAs and 189 receiving Roxadustat were identified, with a median follow-up of 8.4 (interquartile range: 6.5-21.8) and 5.8 (3.3-11.3) months, respectively, for Hb response. The Roxadustat group demonstrated a significantly faster Hb increase rate than ESAs group (9.49 [95% confidence interval: 3.66-15.32] g/L/year versus 1.91 [0.83, 2.99] g/L/year, P=0.01). The Roxadustat group also showed a faster achievement of Hb response (weighted hazard ratio=1.496 [95% confidence interval: 1.121-1.652]) during 52 weeks of follow-up. There were 43 and 192 composite kidney outcomes occurred in the Roxadustat and ESAs group, respectively, corresponding to lower risk of composite kidney outcomes (weighted hazard ratio=0.686 [0.489-0.963]).

Conclusions: This study suggests patients with CKD receiving Roxadustat treatment has faster increase of Hb and lower risk of kidney outcomes than ESAs.

FR-PO1162

A Phase 1b, Double-Blind, Placebo-Controlled Study of DISC-0974, an Anti-hemojuvelin Antibody, in Patients with Nondialysis-Dependent CKD and Anemia

Samir Arora,[1] Pablo E. Pergola,[2] Arnold L. Silva,[3] Geoffrey A. Block,[4] Sima Bhatt,[5] Akshay Buch,[5] Olivia Pelletier,[5] Will Savage.[5] *[1]Centricity Research, Columbus, OH; [2]Renal Associates PA, San Antonio, TX; [3]Boise Kidney & Hypertension Institute, Meridian, IN; [4]Rocky Mountain Kidney Care, Lone Tree, CO; [5]Disc Medicine Inc, Watertown, MA.*

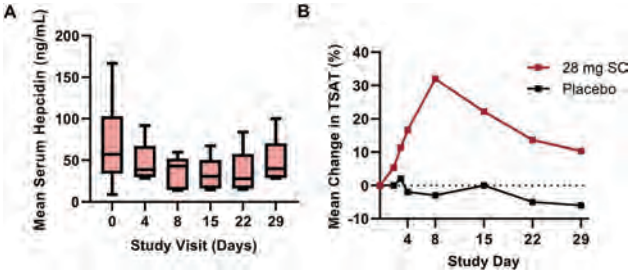
Background: Hepcidin, a key regulator of iron homeostasis, is pathologically elevated in patients with non-dialysis-dependent CKD (NDD-CKD) and contributes to the onset and severity of anemia. DISC-0974 is an investigational, first-in-class, monoclonal

antibody that blocks hemojuvelin (HJV), a co-receptor in the BMP-signaling pathway regulating hepcidin expression. By inhibiting endogenous production of hepcidin and enhancing iron availability, DISC-0974 may provide a novel approach for treatment of anemia.

Methods: DISC-0974-103 is a Phase 1b, double-blind, placebo-controlled, single-ascending dose study (NCT05745883) to assess the safety, PK, and PD of DISC-0974 in patients with NDD-CKD and anemia. On Day 1, participants receive a single dose of DISC-0974 subcutaneously with evaluations through 57 days of follow-up. Dose-escalation is planned across 4 cohorts (n=8), with 3:1 randomization of DISC-0974 (28, 40, 60, and 90 mg) to placebo. Eligible participants include NDD-CKD Stages 2-5, hemoglobin <11 g/dL, serum ferritin ≥75 μg/L, and transferrin saturation (TSAT) ≤35%. Major exclusionary criteria include concomitant treatment with intravenous iron or ESAs.

Results: Initial data in participants (n=8) who received a single dose of 28 mg DISC-0974 showed sustained reductions in serum hepcidin (Figure 1a) with a corresponding doubling of TSAT (Figure 1b) over mean baseline TSAT values of 17%. DISC-0974 was generally well tolerated; 2 subjects treated with DISC-0974 had a TEAE (33%) vs. 2 on placebo (100%); 2 treated subjects had SAEs deemed not related to DISC-0974.

Conclusions: Initial data provide proof-of-concept that DISC-0974 can result in meaningful reductions in hepcidin and improve mobilization of iron. DISC-0974 was generally well tolerated at the evaluated dose level. Additional ascending-dose cohort data will be presented.



a) Serum hepcidin levels and b) change in TSAT over time following single-dose administration of 28 mg DISC-0974 (n=6) or placebo (n=2)

FR-PO1163

Impact of Real-World, Off-Label Dose of Apixaban on Long-Term Clinical Outcomes in Patients with Atrial Fibrillation and CKD

Hark Rim,[1,2] Byeonghwa Bak,[1,2] Ye na Kim,[1,2] Ho Sik Shin,[1,2] Yeonsoon Jung.[1,2] *[1]Kosin University Gospel Hospital, Busan, Republic of Korea; [2]Transplantation Research Institute, Kosin University College of Medicine, Busan, Republic of Korea.*

Background: Apixaban represent one of the cornerstone treatments to prevent cardioembolic events in patients with nonvalvular atrial fibrillation (NVAF). However, the choices of Apixaban dose guided by the decision-making process of the physician, which considers specific according to kidney functions are inconsistent in the real-world practice. The objective of the present study is to evaluate the effects of real-world Off-label dose of Apixaban on long-term clinical outcomes in NVAF patients with chronic kidney disease (CKD)

Methods: Our database of AF patients diagnosed with CKD from 2018 to 2023 was used to obtain laboratory, echocardiography, electrocardiogram (ECG), and clinical outcomes data. Inclusion criteria were all AF patients with CKD using Apixaban. And we compared bleeding, systemic thrombotic events including stroke/systemic embolism and death according to off-label real -world dose of Apixaban.

Results: Among 635 patients with AF and CKD (76.9±10.4 years), 335 (52.8%) patients took off-label underdosed Apixaban. Difference in the baseline characteristics was not observed among patients including CHA2DS2 VASc score and HASBLED score. During the median 18-month follow-up, a lower incidence of bleeding events (P=0.001) was observed in the off-label underdosed Apixaban group compared to those with standard dose or off-label overdosed Apixaban. However, there was no significant difference of systemic thrombotic events including stroke/systemic embolism and death according to off-label real-world dose of Apixaban (off-label underdose vs. standard dose, P=1.000; off-label overdose vs. standard dose, P=1.000; off-label underdose vs. off-label overdose, P=0.609). In multivariate analysis, HASBLED score was independent risk factors for bleeding events (OR 9.650; CI 1.998- 46.622; P=0.005).

Conclusions: Compared with standard or off-label overdose of Apixaban, off-label underdose of Apixaban was associated with a lower risk of bleeding in patients with AF and CKD, with no difference in the risk of stroke/systemic embolism or death, supporting the apixaban dosing tailored to specific clinical features and drug pharmacokinetics of the Asian patients.

FR-PO1164

Plasma Ceramides and CKD Progression in Type 2 Diabetes

Augustine Takyi, Amara Sarwal, Robert E. Boucher, Sydney E. Hartsell, Niharika Katkam, Farahnaz A. Moghaddam, Akhil Ramanujam Chakravartula, Scott Summers, Tom Greene, Marcus G. Pezzolesi, Srinivasan Beddhu. *University of Utah Health, Salt Lake City, UT.*

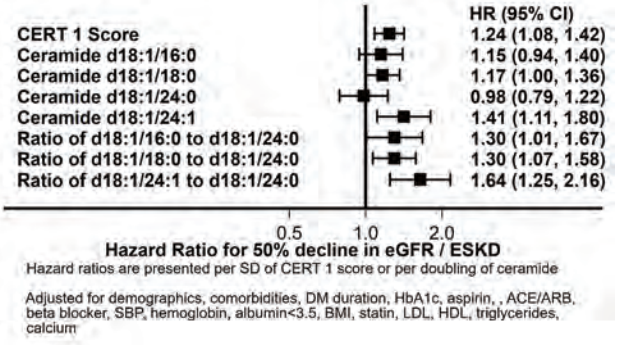
Background: The Cardiovascular Event Risk Test (CERT) 1 score is used in general population to predict atherosclerotic CV events; however, whether altered plasma ceramides (CER) and CERT1 scores predict the progression of CKD is unknown.

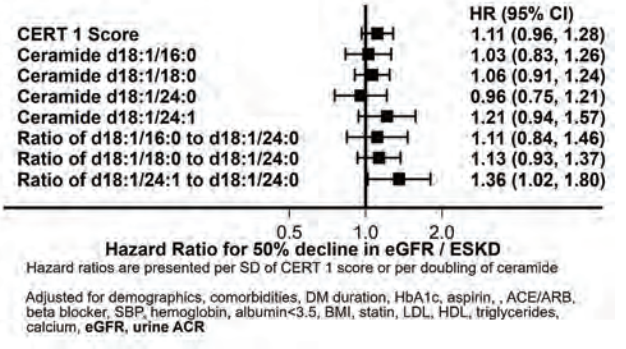
Methods: We measured plasma CER with targeted lipidomics in year 1 visit samples of 1054 Chronic Renal Insufficiency Cohort (CRIC) participants with T2D. Based on plasma CER 16:0, 18:0, 24:1 and their ratios to 24:0, CERT1 scores were calculated (2 points for concentrations/ratios in the 4th quartile and 1 point for concentrations/ratios in the 3rd quartile of reference population). In separate multivariate Cox regression models, we related CERT1 scores (Model 1) and individual CER and their ratios (Model 2) with a composite kidney outcome defined as a 50% decline in eGFR or the onset of ESKD.

Results: Baseline mean age was 61 ± 9 years and eGFR 46 ± 13, respectively. 57% were male, 49% were Black, CERT1 score median (IQR) was 4 (2,7). There were 377 kidney events/6127 years of follow-up. CERT1 score was associated with higher risk of kidney events. In a separate Cox model of its components, CER 18:0, CER 24:1 and the ratios were associated higher risk of kidney events (Figure 1). However, with further adjustment for baseline eGFR and UACR, only CER ratio 24:1/24:0 associated with the kidney outcome (Figure 2).

Conclusions: CER ratio 24:1/24:0 but not CERT1 score predicted CKD progression, independent of baseline eGFR and UACR. Interventions targeting plasma CER, in particular CER ratio 24:1/24:0 might slow CKD progression in T2D.

Funding: NIDDK Support





FR-PO1165

Plasma Ceramides and Risk of Cardiovascular Events in CKD

Farahnaz A. Moghaddam,[1,2] Marcus G. Pezzolesi,[1,2] Amara Sarwal,[1,2] Robert E. Boucher,[1,2] Augustine Takyi,[1,2] Sydney E. Hartsell,[1,2] Akhil Ramanujam Chakravartula,[1,2] Niharika Katkam,[1,2] Guo Wei,[1,2] Jincheng Shen,[1,2] Scott Summers,[1,2] Srinivasan Beddhu.[1,2] *[1]University of Utah Health, Salt Lake City, UT; [2]VA Salt Lake City Health Care System, Salt Lake City, UT.*

Background: Ceramide (CER) accumulation in tissues is implicated in platelet dysfunction, inflammation, insulin resistance, and atherosclerosis. As altered plasma CER predicts CV events, a Cardiovascular Event Risk Test (CERT)1 score based on plasma CER has been developed in the general population. It is unknown whether plasma CER and CERT1 scores predict CV events in CKD.

Methods: We measured plasma CER with targeted lipidomics in year 1 visit samples of 1054 Chronic Renal Insufficiency Cohort (CRIC) participants with T2D. Based on plasma levels of CER 16:0, 18:0, 24:1 and their ratios to CER 24:0, CERT1 scores were calculated as 2 points for concentrations or ratios in the 4th quartile and 1 point for concentrations or ratios in the 3rd quartile of the reference population. In separate multivariate Cox regression models adjusted for variables listed in Figure, we related individual CER, ratios, and CERT1 scores with a composite of adjudicated MI, HF, stroke or CV death.

Results: The mean age was 61 ± 9 years, 57% were male, 49% were African American, baseline eGFR was 46 ± 13 ml/min/1.73 m^2 and mean CERT1 score was 4.4 ± 3.4. There were 454 CV events/8654 patient years of follow-up. While CER 16:0, 18:0, and 24:1 were not associated with CV events (Figure), CER 24:0 had a lower risk and the ratios of CER 16:0, 18:0, and 24:1 to CER 24:0 were significantly associated with higher CV risk. Each standard deviation increase in CERT1 score (3.4 points) was associated with CV events(HR 1.16, 95% CI 1.04 to 1.30).

Conclusions: CER 24:0 and the ratios of CER 16:0, 18:0, 24:1 to CER 24:0 predict CV events in CKD independent of BMI, serum lipids and statin use. CERT1 score but not all of its components were associated with CV events in CKD suggesting that calibration and discrimination of CERT1 score in CKD could be improved with a CKD specific score.

FR-PO1166

Propensity Score Matching in CKD: Evaluating Guca2b as a Biomarker for Diagnosis and Treatment Monitoring

Aaron L. Carrithers,[1] Luke E. Morrison,[1] Ryan Ott,[2] Stephen L. Carrithers.[1]
[1]PrognostX Health, LaGrange, KY; [2]Ethos Biosciences, Newtown Square, PA.

Background: Limitations of early diagnosis of CKD with standard of care have been well documented. Guanylate cyclase activator 2B (Guca2b), a prohormone that delivers the bioactive hormone moiety uroguanylin to its receptors lining the nephron, has recently been shown to significantly increase in the circulation during increased severity of renal impairment and early chronic kidney damage. Guca2b exhibits a dual paracrine-endocrine secretion mechanism, being released into the tubular lumen and arterioles, where protease activation in the glomerulus enables immediate nephroprotective effects on the proximal tubule (PT) by maintaining salt and fluid homeostasis and conserving energetic expenditure. Guca2b mediates natriuresis and kaliuretic actions through cGMP-dependent and -independent pathways. These include downregulation of the PT Na^+-pump, inhibition of Na^+/H^+ exchanger (akin to SGLT2i's) and $Na^+/K^+/2Cl^-$ in the mTAL (site of action for loop diuretics), and distal ClC-K2 chloride channels (mitigating activation by AII and emulating renoprotective properties of ACEI/ARBs).

Methods: To account for potential differential treatment effects on circulating Guca2b levels as an early biomarker for CKD and balance covariates between CKD stages and controls, nearest neighbor propensity score matching with caliper width 0.2x±SD of the logit was conducted on age, race, gender, and eGFR in a 426-patient case-control observational study. Median treatment effect on circulating Guca2b levels (ng/ml) was calculated for cases and controls treated with therapeutic agents that act on tubular salt transport channels.

Results: Mild reductions in Guca2b levels were observed across all treatment groups within the nested G3a/G3b subgroups, yet none were statistically significant: loop diuretics (3.57 vs 3.81; MTE, -0.54; n=18), thiazide diuretics (3.10 vs 3.16; MTE, -0.06; n=18), all diuretics (3.41 vs 4.02; MTE, -0.61; n=28), and ACEI/ARBs (3.06 vs 3.51; MTE, -0.45; n=32). Baseline characteristics and eGFR's were matched in stage A1/A2 CKD patients to healthy controls, demonstrating significantly higher mean Guca2b levels (2.70 vs 1.20, n=43, p<0.05) yet lower than matched G3a/G3b (2.55 vs 3.94, n=37, p<0.05).

Conclusions: This study suggests a multifactorial mechanism of early renal pathogenesis independent of GFR and potential biomarker for early CKD detection.

FR-PO1167

Association between Irisin and Cardiovascular Structure and Function in Patients with Advanced CKD

Hannah E. Wilson, Nikita F. Samanani, Gayatri Narayanan, Neal X. Chen, Heather Burney, Sharon M. Moe, Kenneth Lim. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Emerging evidence suggests that irisin, a myokine released from muscle during exercise, could exert cardiovascular (CV) protective effects. Circulating irisin is reduced as CKD progresses, and low irisin has been associated with increased risk of vascular calcification and CV mortality in patients on hemodialysis. However, to-date no studies have comprehensively studied its role in regulating CV structure and function in advanced CKD.

Methods: We performed a cross-sectional analysis of 149 patients from the Cardiopulmonary Exercise Testing in Renal Failure and After Kidney Transplantation (CAPER) cohort. All patients underwent cardiopulmonary exercise testing to assess CV functional capacity, echocardiography, and applanation tonometry. Patients were stratified by sex (M/F) and dialysis status (pre-dialysis (P), dialysis (D)) (n=16 P/F, n=41 D/F, n=23 M/P, n=69 M/D). Wilcoxon rank-sum tests were performed to assess differences in irisin levels. Multiple linear regression models were performed to examine associations between irisin and outcomes. Plasma irisin (ng/mL) was assessed via ELISA (Phoenix Pharmaceuticals, EK-067-29).

Results: The mean age of the dialysis group was higher than the pre-dialysis group among males but not females (M: 50.8±13.9, p=0.0055, vs F: 41.3±13.7 yr, p=0.3). Additionally, there was no difference in BMI among all strata groups (p>0.05). Interestingly, irisin was higher in male dialysis compared to pre-dialysis patients (n=92, 8.8 vs 5.4 ng/mL, p=0.0003) but not in females (n=57, 8.3 vs 8.6 ng/mL, p=0.67). Multiple linear regression demonstrated that plasma irisin was not associated with VO_2Max, left ventricular mass index, pulse pressure or augmentation index after adjusting for age, sex, BMI, dialysis status and phosphate levels. However, irisin concentration was negatively associated with maximum workload after the same adjustment (β=-1.8, p=0.04).

Conclusions: This study suggests that irisin is dysregulated in kidney failure and may target the musculoskeletal system, rather than CV structure in advanced CKD patients. Additionally, the lack of a validated blood irisin assay is a current limitation in clinical studies. Future studies will assess the association of irisin with physical performance and quantitative musculoskeletal metrics (i.e. DXA) in CKD patients.

FR-PO1168

Association of Plasma Uromodulin with Kidney Outcomes in the SPRINT Trial

Jesse C. Ikeme,[1] Rebecca Scherzer,[1] Pranav S. Garimella,[2] Stein I. Hallan,[3] Ronit Katz,[4] Michelle M. Estrella,[1] Joachim H. Ix,[2] Michael Shlipak.[1]
[1]University of California San Francisco, San Francisco, CA; [2]University of California San Diego, La Jolla, CA; [3]Norges Teknisk-Naturvitenskapelige Universitet, Trondheim, Norway; [4]University of Washington, Seattle, WA.

Background: Uromodulin (UMOD) is a kidney tubule biomarker that may help identify persons at greater risk of eGFR decline. We evaluated the associations of plasma UMOD with kidney outcomes in persons with CKD and hypertension.

Methods: This was a secondary analysis of the Systolic Blood Pressure Intervention Trial, in which an intensive SBP target reduced risk of CV events and mortality. Plasma UMOD was measured at baseline in 2,302 participants with eGFR <60 ml/min/1.73m^2. Acute kidney injury (AKI) was determined based on serious adverse event reporting during the trial. Quarterly labs were used to determine 30% and annual % eGFR decline from baseline. Cox proportional hazards (AKI, 30% eGFR decline and ESKD) and linear mixed models (annual % eGFR decline) were adjusted for baseline characteristics, including eGFR and albuminuria.

Results: Plasma UMOD and eGFR had a Spearman correlation of 0.47. In fully adjusted models, each standard deviation higher plasma UMOD was associated with lower risk of 30% eGFR decline and slower annual eGFR decline **(Table)**. There were no independent associations with risk of future AKI or ESKD. The association with lower risk of 30% eGFR decline appeared stronger in those randomized to a usual SBP target (HR 0.73, 95% CI 0.62-0.87) than in those randomized to an intensive SBP target (HR 0.90, 0.79-1.02; p-interaction = 0.03). Associations with other outcomes appeared similar across randomized treatment arms (p-interaction >0.10).

Conclusions: Higher plasma UMOD levels are independently associated with lower risk of 30% eGFR decline and slower decline in eGFR among hypertensive persons with nondiabetic CKD.

Funding: NIDDK Support

Adjusted associations of baseline plasma uromodulin (per SD higher) with kidney outcomes in 2,302 SPRINT participants with CKD

Outcome	n	Hazard Ratio (95% CI)	p
Acute kidney injury	179	0.84 (0.70, 1.01)	0.06
30% eGFR decline	461	0.84 (0.75, 0.94)	0.002
ESKD	72	0.91 (0.70, 1.19)	0.51
		% estimate (95% CI)	p
Annual % eGFR change		+0.58 (+0.22, +0.94)	0.002

Models adjusted for randomized SBP target, age, sex and race; baseline eGFR, log urine albumin, log urine creatinine, smoking, BMI, SBP, anti-hypertensive medications number and class, cardiovascular disease, heart failure, high-density lipoprotein, total cholesterol, and statin use.

FR-PO1169

Association of Kidney Length with Clinical Outcomes among Individuals with CKD

Cassianne Robinson-Cohen, Rashedeh Roshani, Roy Zent, Jennifer E. Below. *Vanderbilt University Medical Center, Nashville, TN.*

Background: The assessment of kidney health is typically limited to estimates of glomerular filtration (eGFR) and glomerular integrity (albuminuria). These are insufficient, given the complexity and heterogeneity of renal pathology, and disease misclassification using these biomarkers is a well-known problem in clinical and research settings. Measuring and evaluating kidney size may provide a complementary understanding of kidney function and structure, particularly among individuals with chronic kidney disease (CKD).

Methods: We studied 3,585 non-dialysis requiring CKD patients from Vanderbilt University Medical Center's electronic health record (EHR) databank, BioVU. We ascertained kidney length using computational free text mining techniques within abdominal MRI radiology report notes. We examined associations of kidney length with time to end-stage kidney disease or death, using Cox proportional hazards regression models stratified by diabetes status. Secondarily, a phenome-wide association study was conducted to explore associations of kidney length with other phenotypes in the EHR.

Results: During a median follow-up of 2.5 years, 138 patients had an incident ESKD event and 643 died (incidence rate for composite endpoint: 6.0 events per 100 person-years). After adjustment, among non-diabetic patients (n=2,515), shorter kidneys were associated with risk of the combined endpoint (hazard ratio (HR), 1.08 (1.02, 1.15) for each cm increment in kidney length, p=0.012). In contrast, kidney length was not associated with risk of ESKD or death among diabetic patients (HR 1.04 (0.92, 1.18)). PheWAS signaled additional associations of kidney length with subclinical and clinical cardiovascular outcomes, acute kidney injury and liver diseases.

Conclusions: Shorter kidney length was associated with an increased risk of ESKD and mortality among CKD patients without diabetes. Efforts to establish the broader clinical significance of kidney size are underway.

FR-PO1170

Advancement in CKD Stages Leads to Increased Levels of Soluble PD-L1 in Serum

Ayaka Hayashi, Izumi Yamamoto, Mayuko Kawabe, Akio Nakashima, Takashi Yokoo, Mitsuyoshi Urashima. *Tokyo Jikeikai Ika Daigaku, Minato-ku, Japan.*

Background: Programmed death-ligand 1 (PD-L1) and its receptor, programmed death-1 (PD-1), play crucial roles in immune tolerance through their interactions. PD-L1, expressed on antigen-presenting cells, cancer cells, placental tissue, vascular endothelial cells, and tubular epithelial cells, suppresses T-cell activation when it binds to PD-1 on T cells. Recent studies indicate that soluble PD-L1 (sPD-L1) also induces immunotolerance, with levels varying in clinical conditions such as cancer and pregnancy. However, data on sPD-L1 levels in chronic kidney disease (CKD), including hemodialysis (HD) patients, are lacking. This study aims to compare serum sPD-L1 levels among individuals without CKD and patients with CKD stages 1 to 5.

Methods: Serum sPD-L1 levels were measured using ELISA in samples from three cohorts (n=2,816): healthy individuals who received the SARS-CoV-2 mRNA vaccine (n=1,781) with or without underlying conditions such as hypertension and diabetes; cancer patients without CKD and with CKD stages 1 to 4 (n=402); and HD patients (n=633).

Results: sPD-L1 levels increased with worsening CKD stages. Median sPD-L1 levels were higher in HD patients compared to those with stage 4 CKD. In a 1:1 matched case-control study of 394 HD patients with age- and sex-matched healthy controls, HD patients exhibited significantly higher median sPD-L1 levels than non-HD individuals (231.7 pg/mL vs. 85.0 pg/mL, p<0.0001). This finding remained consistent after excluding and re-matching patients with hypertension, diabetes, and cancer. Furthermore, longer HD vintage was associated with higher sPD-L1 levels.

Conclusions: Serum sPD-L1 levels increase with CKD progression, reaching the highest levels in HD patients, particularly those with longer treatment duration. Future research will focus on elucidating the mechanisms behind the increase in sPD-L1 levels due to declining renal function and investigating whether elevated sPD-L1 levels heighten the risk of cancer or infections in dialysis patients.

Exploring the Effects of Low-Energy Diets on Risk Factors and Markers of Kidney Disease: Findings from the Slowing Kidney Disease with Weight-Loss Feasibility Study

Marguerite M. Conley,[1,2] Kirsten S. Hepburn,[3,4] Hannah L. Mayr,[1,4] David W. Mudge,[5,4] Justin J. Holland,[2] Andrea K. Viecelli,[5,4] David W. Johnson,[5,4] Helen L. MacLaughlin.[6,2] *[1]Department of Nutrition and Dietetics, Princess Alexandra Hospital, Brisbane, QLD, Australia; [2]Queensland University of Technology Faculty of Health, Kelvin Grove, QLD, Australia; [3]Kidney Health Service, Royal Brisbane and Women's Hospital, Brisbane, QLD, Australia; [4]Faculty of Medicine, The University of Queensland, Brisbane, QLD, Australia; [5]Department of Kidney and Transplant Services, Princess Alexandra Hospital, Brisbane, QLD, Australia; [6]Dietetics & Food Services, Royal Brisbane and Women's Hospital, Brisbane, QLD, Australia.*

Background: Whether weight loss can delay or prevent the progression of obesity-associated CKD, and the amount of weight loss that may confer such benefit have not been well-established. This feasibility study explored kidney disease risk factors and markers of kidney function in a six-month randomised controlled trial (RCT).

Methods: Forty-nine adults with stages 1-3b CKD, body mass index (BMI) ≥30kg/m^2, and proteinuria (urinary protein to creatinine ratio (uPCR) >3mg/mmol) were randomised 1:1. The low energy diet (LED) group followed a 3-month LED (800-1000 kcal/day) with dietitian support; followed by a 3-month exercise and nutrition program. Usual care offered standard weight loss support. Changes in CKD risk factors and kidney markers were examined.

Results: Thirty-eight adults (78%) with a median age of 56 years, eGFR 57 mL/min/1.73m^2 and BMI 39kg/m^2 completed the study. At 6 months, significant intervention effects were observed for weight (WT) and waist circumference (WC) but not for uPCR, systolic blood pressure (SBP), diastolic blood pressure (DBP) or estimated glomerular filtration rate (eGFR) measures (Table 1). There was large variability across eGFR measures.

Conclusions: Low energy diets can significantly reduce body weight and waist circumference and may lead to improvements in eGFR, proteinuria and systolic blood pressure. Interpreting estimates of kidney function remains problematic when coupled with changes in body mass. Longer and larger trials exploring the use of LEDs on risk factors and measures of CKD progression are warranted.

Funding: Private Foundation Support

Table 1. Changes in risk factors and markers of kidney function, following six-month weight loss program.

	Change score 0-6 month Median (interquartile range)		
Variable	LED (n=16)	Usual Care (n=22)	p-value
WT (kg)	-9 (-12, -7)	0 (-4, 2)	<.001

Plasma Potassium Negatively Correlates with Sodium-Chloride Cotransporter (NCC) Abundance and Phosphorylation in Urinary Extracellular Vesicles (uEVs) from Patients with CKD

Aihua Wu,[1,3] Paul A. Welling,[2] Andrew S. Terker.[1] Leudcq Network Potassium in Hypertension. *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Johns Hopkins Medicine, Baltimore, MD; [3]Princess Alexandra Hospital, Woolloongabba, QLD, Australia.*

Background: Hypertension is a leading cause of CKD. Low potassium diet is often advised in moderate to severe CKD. Emerging data now suggest that higher dietary potassium may be beneficial in these patients, but the underlying mechanism is unclear. Using uEVs we recently demonstrated that dietary potassium interventions can regulate distal sodium and potassium handling via the "renal-K switch" mechanism (the WNKs-SPAK/OSR1-NCC pathway) in both healthy adults and those with primary aldosteronism

(PA). The close relationship between blood pressure and CKD has led to the hypothesis that blood pressure-lowering effects of high potassium intake may also be reno-protective through the same mechanism. This study is to use uEVs to evaluate if plasma potassium negatively correlates with NCC and its phosphorylation in patients with CKD.

Methods: Morning blood and 2nd morning urine were collected on a single occasion between 8-11 am from patients with CKD at all stages. Clinical and biochemical features were assessed by Pathology Queensland. uEVs were obtained by progressive ultracentrifugation and analysed by Western blot. Those taking SGLT2 inhibitors or K binders were excluded

Results: Analysis of 20 participants demonstrates plasma potassium negatively correlates with uEV abundance of NCC (R^2=0.41, P=0.003) and its phosphorylation (R^2=0.22, P=0.04). These correlations persisted even patients with a low level of uEV. (Figure 1).

Conclusions: Plasma potassium measurements showed a strong negative correlation with the abundance of NCC and its phosphorylation state in uEVs from 20 patients with CKD. If the "renal-K switch" mechanism in CKD functions in the same way as has previously been demonstrated in patients without CKD, then increasing dietary potassium may assist in natriuresis, providing a renoprotective effect via reductions in blood pressure.

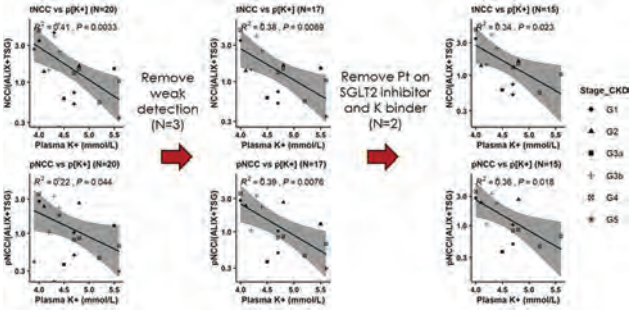

Figure 1. Correlations of plasma K^+ with uEV levels of NCC and pNCC.

Assessing the Selectivity of Urinary Proteins Using Albumin as an Alternative to Transferrin

Masayoshi Kukida, Shingo Kinnami, Fumikazu Kondo, Satoru Shichijo, Ken-ichi Miyoshi, Osamu Yamaguchi. *Ehime Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Toon, Japan.*

Background: Since the 1960s, the utility of urinary protein selectivity in diagnosing and predicting the prognosis of glomerular diseases has been reported. Urinary protein selectivity has traditionally been assessed using the Selectivity Index (S.I.), which compares the clearance of high molecular weight protein IgG to that of medium molecular weight protein transferrin. Although albumin is a major medium molecular weight urinary protein, its measurement accuracy was initially low, leading to the use of transferrin in calculating the S.I. However, recent improvements in the measurement accuracy of albumin have been noted. At our institution, serum albumin is measured using the modified bromocresol purple (BCP) method, while urinary albumin is measured using an immunoturbidimetric assay.

Methods: In this study, we analyzed data from 224 patients, comprising both outpatients and inpatients at our institution, whose concentrations of IgG, transferrin, and albumin in serum and urine were measured simultaneously between January 2014 and December 2023.

Results: Firstly, we calculated the S.I. using albumin (S.I. (Alb)) and S.I. using transferrin (S.I. (Tf)) and then analyzed their correlation. The results of linear regression analysis revealed a significant correlation, with S.I. (Alb) = S.I. (Tf) × 1.077 + 0.00295 ($p < 0.0001$, R2 = 0.7077) in patients with trace albuminuria or more, and S.I. (Alb) = S.I. (Tf) × 0.9570 + 0.0360 ($p < 0.0001$, R2 = 0.7516) in those with massive proteinuria equivalent to nephrotic syndrome (3.5g or more). Subsequently, we performed the receiver operating characteristics (ROC) analysis to examine the utility of the S.I. for the diagnosis of minimal change disease, characterized by its high selectivity for urinary protein. According to the ROC analysis, the AUC of S.I. (Tf) was 0.85 (95% CI, 0.74 – 0.95), and the AUC of S.I. (Alb) was 0.85 (95% CI, 0.74 – 0.96).

Conclusions: The findings suggest that the versatile S.I. (Alb) may be as useful as S.I. (Tf) in diagnosing glomerular diseases.

FR-PO1174

Analysis of In-Hospital Mortality Risk Factors and Establishment of a Nomogram Prediction Model for Patients with Stage 5 CKD in the Intensive Care Unit (ICU)

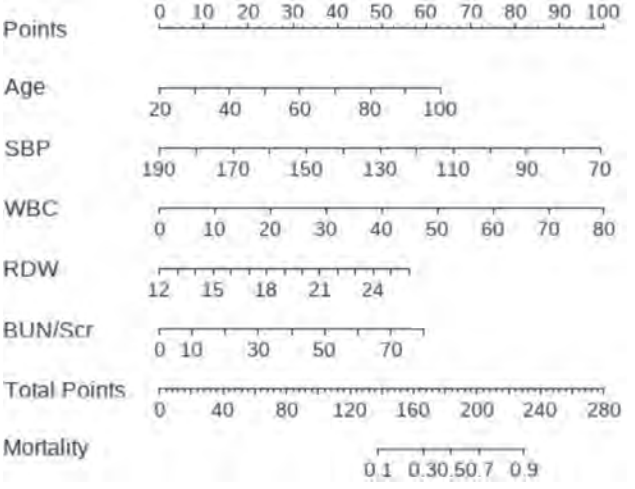
Fanna Liu. *The First Affiliated Hospital of Jinan University, Guangzhou, China.*

Background: Patients with stage 5 chronic kidney disease (CKD5) have a high risk of mortality. ICU patients have lots of abnormal results. Defining the risk factors for in-hospital mortality in ICU CKD5 patients will help doctors pay more attention to the most important factors and intervene in a timely manner. In this study, we analyzed the risk factors related to in-hospital mortality and drew the nomogram to predict in-hospital mortality in CKD5 non-dialysis (CKD 5ND) patients.

Methods: According to the diagnosis code, 495 CKD 5ND patients were selected from the MIMIC-IV database. The differences between the survival group and the death group were analyzed by two independent samples t-test, rank-sum test, or chi-square test. The nomograms to predict the risk of in-hospital mortality in CKD 5ND patients were established respectively. In order to evaluate the nomogram, ROC curve, calibration curve, and DCA curve were used. Boostrap-resampling was used for internal verification. eICU patients were used for external verification. And the predictive performance of the nomogram was compared with commonly scores.

Results: There were 1439 CKD5 patients in the MIMIC-IV database, including 495 non-dialysis patients. There were 425 CKD5 ND patients in the survival group and 70 patients in the death group. Age, SBP, WBC, RDW, and BUN/Scr were the correlation factors for in-hospital mortality in CKD5 ND patients. Internal and external validation showed that the CKD5 ND patients nomogram prediction model had good calibration, clinical benefit, and discrimination (training set AUC=0.832, validation set AUC=0.770). The predictive ability of nomogram was better than the three commonly used scores.

Conclusions: The nomogram prediction model predicting in-hospital mortality of CKD5 ND patients has good discrimination, calibration, and clinical value, which are established by Age, SBP, WBC, RDW, and BUN/Scr.



FR-PO1175

Development of a Comprehensive Human Urine Single-Cell RNA Sequencing (scRNA-seq) Atlas for Enhanced Diagnostic Accuracy of Kidney Diseases

Amin Abedini,[1] Konstantin A. Kloetzer,[2] Katalin Susztak.[3] *[1]University of Maryland Medical Center, Baltimore, MD; [2]Medizinische Universitat Graz, Graz, Austria; [3]University of Pennsylvania, Philadelphia, PA.*

Background: Understanding the cellular composition of human urine is crucial for advancing diagnostic and therapeutic strategies for kidney and urinary tract diseases. Previous studies have provided insights into individual conditions, but a comprehensive, spatially resolved single-cell RNA-sequencing (scRNA-seq) atlas of human urine has been lacking.

Methods: We generated a human urine scRNA-seq atlas by integrating various published datasets. Deep generating modeling (scVI) was used for the data integration. Identified cell types were validated using kidney spatial transcriptomics. Additionally, we utilized the largest human kidney scRNA-seq atlas and MetaNeighbor analysis to further confirm our findings. Differentially expressed genes (DEGs) were identified and used to develop gene panels for the diagnosis of various conditions. We trained a logistic regression model with the gene expression data to evaluate the diagnostic performance of gene panels.

Results: Our integration of 86 samples yielded a comprehensive urine scRNA-seq atlas comprising 133,208 cells from various kidney conditions. This atlas captures a broad spectrum of cell types, including all kidney cell types, immune cells, and uroepithelial cells. The identified cell types were validated using kidney spatial transcriptomics. Importantly, identified cell types were successfully integrated and validated against the largest human kidney scRNA-seq data. The gene panels derived from DEGs demonstrated high sensitivity and specificity in diagnosing different conditions, supported by validation against a large human kidney scRNA-seq atlas.

Conclusions: The establishment of a spatially resolved human urine scRNA-seq atlas marks a significant advance in the non-invasive monitoring and diagnosis of kidney and urinary tract diseases. The validated gene panels offer promising tools for precise condition diagnosis, potentially changing current diagnostic practices and reduce our reliance on kidney biopsy.

FR-PO1176

Single-Cell and Spatial Transcriptome Profiling Identifies a Tenascin C-Enriched Niche Promoting Kidney Inflammation

Li Li, Jinlin Liao, Yuxi Zhang, Haiyan Fu, Youhua Liu. *Division of Nephrology, Nanfang Hospital, Southern Medical University, Guangzhou, China*.

Background: Kidney fibrosis is often accompanied by inflammatory cell infiltration and interstitial inflammation. Among all inflammatory cells, macrophage infiltration plays an important role in the occurrence and development of renal fibrosis. However, the mechanism by which macrophages promote renal fibrosis remain to be elucidated. In this study, we demonstrate that tenascin-C-enriched microenvironment promotes the development of renal inflammation and fibrosis by activating macrophages.

Methods: Unilateral ischemic-reperfusion injury (UIRI) and unilateral ureteral obstruction (UUO) were used as models of kidney fibrosis. Single-cell RNA sequencing (scRNA-Seq) and spatial transcriptome (ST) sequencing techniques were used to characterize various cell subpopulations after kidney injury. Decellularized kidney tissue scaffold (dKTS) was prepared. The role of tenascin-C (TNC) in macrophage activation and proliferation was investigated in vitro. TLR4-KO mice and TLR4 inhibitor were used in vivo. A bone marrow chimera model was established by transplanting the bone marrow from TLR4 KO to WT mice.

Results: Single-cell and spatial transcriptome profiles of normal and UIRI kidney showed a significant increase of macrophages in the injured site, which was closely associated with TNC expression. Compared with the TNC-low region, the TNC-high region was associated with an increased infiltration of macrophages and activation of proinflammatory and profibrotic signaling. TNC-enriched dKTS from fibrotic kidney induced macrophage activation and proliferation, characterized by an increased expression of TNF-α, c-Fos, PCNA, c-Myc, TLR4, p-P65 and P65. Furthermore, TNC induced the activation, proliferation, migration and phagocytosis of macrophages via activating TLR4/NF-κB signaling in vitro. Inhibition or knockout of TLR4 and knockdown of TNC alleviated renal inflammation and fibrosis by inhibiting the activation, proliferation and migration of macrophages.

Conclusions: This study showed that TNC-enriched microenvironment promotes the development of renal inflammation and fibrosis by activating macrophages via TLR4/NF-κB signaling. Targeted inhibition of TNC and TLR4 could be novel therapeutic strategies for protecting kidney against inflammation in CKD.

FR-PO1177

RNA Sequencing (RNA-seq)-Based Machine-Learning Models for Kidney Injury Genes in Patients with CKD

Feifei Sun, Jiahui Cai, Yunbo Sun, Qiaoyun Pan, Shasha Zhao, Danshu Wang, Runyan Tan, Feng Yang, Yanling Yan. *Yanshan University, Qinhuangdao, China*.

Background: Chronic kidney diseases (CKD) are prevalent and cause high patient mortality and healthcare costs. However, mechanisms have not been well characterized. We hypothesized that machine learning (ML) would provide new insights into the exploration of RNAseq assessment to identify gene networks driving disease for early diagnosis of CKD.

Methods: We retrieved CKD datasets from the Gene Expression Omnibus (GEO) database. GSE180394 and GSE47184 were randomly split for training and GSE37455 for testing. Differentially expressed genes (DEGs) were screened to differentiate CKD from healthy controls. Weighted Gene Co-expression Network Analysis (WGCNA) further selected Modules and critical genes related to CKD as potential candidates. Characteristic hub genes were identified following being trained independently with ML model algorithms, including Support Vector Machine - Recursive Feature Elimination (SVM-RFE) and Least Absolute Shrinkage and Selection Operator (LASSO). Several ML models were created to predict CKD. The relationship between the potential targets and traditional renal function parameters was also examined.

Results: WGCNA and ML algorithms identified five central Hub genes, namely COL10A1, DUSP1, GADD45A, TSC22D3, and ZFAND5. Those genes could be instrumental in diagnosing CKD through multivariate logistic regression analysis. Four ML models were established, as shown in Figure 1. The model performed robustly evidenced by the area under the curve (AUC) of the receiver operating characteristic (ROC) curve (93.6%, 90.7%, 93.8%, and 95.0%, respectively) in the validation cohort. The Nephroseq database was utilized to reveal a positive correlation between hub-genes GADD45A (R=0.55, p=0.0084) & TSC22D3 (R=0.53, p=0.011) and GFR, as well as a negative correlation between the above two hub-genes and SCr (R=-0.61, p=0.0096; R=-0.87, p=0.011, respectively), ensuring the predicted accuracy for CKD. In addition, immunological infiltration analysis showed that these hub genes affected the recruitment and infiltration levels of immune cells in CKD.

Conclusions: ML approaches endow RNAseq analysis with promising potential for diagnosing renal injuries. Implementation of the ML model can help identify the CKD patients who would benefit from early intervention to delay CKD progression and reduce healthcare costs.

Causal Effects from Kidney Function to Plasma Proteome: Integrated Observational and Mendelian Randomization Analysis with More than 50,000 UK Biobank Participants

Jeongmin Cho,[1,2] Minsang Kim,[3] Semin Cho,[2] Soojin Lee,[4] Dong Ki Kim,[3] Sehoon Park.[3] *[1]Seoul National University College of Medicine, Jongno-gu, Seoul, Republic of Korea; [2]Chung-Ang University Gwangmyeong Hospital, Gwangmyeong, Gyeonggi-do, Republic of Korea; [3]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [4]Eulji University Uijeongbu Eulji Medical Center, Uijeongbu, Gyeonggi-do, Republic of Korea*.

Background: Chronic kidney disease (CKD) causes detrimental systemic consequences leading to substantial morbidity and mortality. However, the causal effect of reduced kidney function on systemic proteomic signatures is incompletely understood. The plasma proteome is a phenotype of dynamic molecular changes within cells and tissues, providing insights into the underlying disease mechanisms and potential drug targets.

Methods: We performed an integrated Mendelian randomization (MR) and observational analysis to identify the causal association between kidney function and plasma protein levels, based on 1,815 plasma protein profiles in 50,407 UK Biobank participants and the CKDGen phase 4 GWAS meta-analysis for the genetic instruments of eGFR.

Results: The MR analysis revealed 383 plasma proteins causally associated with eGFR. Reduced kidney function was found to be causally associated with an increase in the plasma levels of 381 proteins, among which FABP1, TNF, and IGFBP4 were included, while the level of 2 proteins, NPHS1 and SPOCK1, decreased. Apoptosis-related pathway was significantly enriched in the gene-set enrichment analysis. Through the network analysis, TNF was identified as a hub protein with multiple linkages to molecules included in the TNF-signaling pathways, involved in inflammation, fibrosis, and apoptosis. In addition, the eGFR-associated proteins were annotated to molecular function GO term related to insulin-like growth factor binding.

Conclusions: In this proteo-genomic analysis, we identified 383 plasma proteins causally associated with eGFR, highlighting TNF-associated pathways as pathologically relevant processes in kidney disease progression, systemic inflammation, and organ fibrosis, warranting further investigation.

Differences in Plasma Proteomic Profiles between Patients with and without Type 2 Diabetes and CKD: New insights from DAPA-CKD

Mark A. De la Rambelje,[1] Niels Jongs,[1] Peter J. Greasley,[2] Rasmus Ågren,[2] Ann Hammarstedt,[2] David Sjostrom,[2] Adriaan A. Voors,[3] Hiddo J. Heerspink.[1] DAPA-CKD Biomarker Committee. *[1]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [2]AstraZeneca, Gothenburg, Sweden; [3]Universitair Medisch Centrum Groningen Afdeling Cardiologie, Groningen, Netherlands.*

Background: The pathophysiology of chronic kidney disease (CKD) in patients with and without type 2 diabetes (T2D) may share common and distinct pathways. To better understand potential pathophysiological differences between patients with CKD with or without T2D, we compared circulating protein profiles between these two groups.

Methods: We used baseline plasma samples and clinical data from 2485 patients with CKD with and without T2D from the phase 3, randomized, placebo-controlled DAPA-CKD trial. We used the Olink® Explore 3072 panel with 2941 unique proteins for obtaining biomarker profiles of patients with CKD. We cross-sectionally compared patients with vs. without T2D. Differentially abundance testing was performed using Wilcoxon rank-sum test. Pathway analysis was performed with ingenuity pathway analysis (IPA).

Results: The 2485 included patients had a similar eGFR, UACR, and diabetes distribution compared with the overall clinical trial population. Patients with T2D compared with those without T2D were older (64.8 vs. 56.8 years), had a higher eGFR (44.4 vs 41.8 mL/min/1.73m^2), and a higher UACR (median 990 vs. 870 mg/g). Patients with T2D compared to those without had higher levels of adhesion G protein-coupled receptor G1, keratin 8, kidney injury marker-1, natriuretic peptide B and interleukin 6 with respectively significant (Bonferroni adjusted p-value < 0.05) fold changes of 2.39, 1.97, 1.74, 1.56, and 1.39. These differentially expressed proteins, along with others, were associated with atherosclerosis signaling and increased inflammation and immune system activity in those with vs without T2D and CKD.

Conclusions: Plasma proteomic profiles of patients with CKD and T2D were revealed to be related to atherosclerosis and increased inflammation and immune system activity compared to CKD patients without T2D. These findings may aid in identifying new treatment targets for patients with diabetic and non-diabetic CKD.

FR-PO1180

Elucidating Metabolic Microenvironment of Tertiary Lymphoid Structures in the Kidney

Hiroyuki Arai,[1] Yuki Sugiura,[2] Motoko Yanagita.[1,3] *[1]Kyoto Daigaku Daigakuin Igaku Kenkyuka Igakubu, Kyoto, Japan; [2]Center for Cancer Immunotherapy and Immunobiology, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [3]Kyoto Daigaku Hito Seibutsu Koto Kenkyu Kyoten, Kyoto, Japan.*

Background: Tertiary lymphoid structure (TLS) is an ectopic lymphoid structure induced in non-lymphoid organs by chronic inflammation. Functionally, TLSs serve as local sites for adaptive immune responses and are characterized by robust lymphocyte proliferation and cytokine production. During TLS formation, ectopic recruitment of a considerable number of cells to non-lymphoid organs implies a propensity for dramatic metabolic remodeling in both immune and parenchymal cells. However, the mechanism underlying metabolic remodeling required for TLS formation remains to be elucidated.

Methods: Imaging mass spectrometry and metabolomics were used to investigate the metabolic pathways that characterize TLSs. We also performed *in situ* hybridization combined with immunofluorescence and pharmacological inhibition to explore the expression and function of the key molecules that govern the pivotal metabolic pathways of TLSs. Furthermore, we analyzed urine samples from both mice and humans to explore the metabolites that predict the presence of TLSs.

Results: Significant accumulation of glutathione was observed specifically within TLSs and the kidneys with TLSs exhibited higher glutathione concentrations than healthy kidneys. Compared to other organs, the kidney contained more cysteine/cystine, the crucial substrates for glutathione synthesis. TLSs also displayed significant accumulation of 4-HNE and 8-OHdG, prominent markers of oxidative stress. Dendritic cells and fibroblasts within TLSs selectively express xCT, an inducible cystine transporter that governs the rate limiting step of glutathione synthesis. Pharmacological inhibition of xCT prevented TLS formation with enhanced cell death and oxidized lipid accumulation that promotes ferroptosis. Furthermore, urinary metabolite profiles significantly differed depending on the presence of TLSs both in mice and humans. In patients with IgA nephropathy, urinary metabolite profiles effectively detected TLSs in the kidney by multivariate logistic regression analysis.

Conclusions: Glutathione accumulation is a distinctive metabolic signature of TLSs in the kidney. Glutathione synthesis plays a pivotal role in TLS formation, acting as a resilience mechanism to oxidative stress and ferroptosis. Urinary metabolite profiles hold important clinical promise to identify TLSs in the kidney.

FR-PO1181

Absence of Lymphoid Cells May Aggravate Macrophage-Mediated Kidney Injury but Improve Repair in Immunodeficient Mouse Model of Adenine-Induced CKD

Federica Petrillo,[1] Shrikant R. Mulay,[1] Kevin Woollard,[1] Lorraine Miller,[1] Tajana Tesan Tomic,[2] Magnus Soderberg,[2] Aurelie Thomas,[1] Pernille B. Laerkegaard Hansen,[2] Matthew S. Dearman,[1] Stephanie Ling.[1] Early CVRM Renal Bioscience, AstraZeneca R&D. *[1]AstraZeneca R&D Cambridge, Cambridge, United Kingdom; [2]AstraZeneca R&D Gothenburg, Molndal, Sweden.*

Background: Myeloid and lymphoid subpopulations have shown to be both protective and mediators of kidney injury. Mechanisms of crosstalk between pro- and anti-inflammatory actions of these effector cells is still unclear.

Methods: NSG mice *(NOD.Cg-Prkdc^{scid}Il2rg^{tm1Wjl}/SzJ)* are deficient in mature lymphocytes, in natural killer cell cytotoxic activity and in cytokine signalling. In the current study we established a novel NSG mouse model of kidney injury by inducing renal failure through dietary delivery of 0.15% adenine for 7 days, compared to C57BL/6N mice and examined response to recovery by removing adenine diet for 14 days. We used Image Mass Cytometry to label 34 markers of immune cell kidney network and kidney injury pattern in adenine versus controls in NSG mice.

Results: CKD was induced in NSG and C57BL/6N mice by feeding 0.15% adenine diet. NSG-CKD mice showed 12% and 17% weight-loss (WL) after 3 and 6 days, respectively, while C57BL/6N-CKD mice showed 10% WL after 7 days. Blood Urea Nitrogen (BUN) and plasma Creatinine were increased 2-fold in NSG-CKD than C57BL/6N-CKD mice with a considerable amount of urinary excreted kidney injury markers, KIM-1 and NGAL after 4 days of treatment. NSG-CKD mice showed downregulation of epithelial markers (Megalin, SGLT2, GLUT-1, NKCC2, E-Cadherin) and upregulated markers of fibrosis (αSMA, Collagen I, Vimentin) that was not seen in C57BL/6N-CKD mice. Immune profile of NSG-CKD mice revealed increased macrophage-based inflammation with upregulated F4/80, CD45, CD11b, CD206, and loss of innate and adaptive lymphocytes immune response, CD4 and MHCII. This suggests that lack of lymphoid cells in NSG mice leads to a perpetual recruitment of macrophage cells and a worsening damage to the kidney in CKD. Interestingly, unlike C57BL/6N-CKD mice, removing adenine diet after 4 days in NSG-CKD mice completely recovered kidney function (BUN, NGAL, KIM-1) at 14 days. More work is underway to phenotype lymphoid subpopulations which may aggravate injury but boost repair during recovery in adenine-induced CKD.

Conclusions: This data highlights the need to unravel the dichotomy of inflammatory actions of lymphoid subpopulations, as T-regulatory and cytotoxic T-cells in CKD.

FR-PO1182

LYVE1 Ectodomain Shedding Promotes Renal Interstitial Retention of Macrophages Cleared by Lymphatic Vessels and Kidney Fibrosis

Jing Liu, Chen Yu. *Tongji Hospital Affiliated to Tongji University, Shanghai, China.*

Background: Macrophage accumulation has been associated with the progression of renal fibrosis. However, most previous studies have focused on the recruitment of macrophages while neglecting their efflux. Lymphatic vessel endothelial hyaluronan receptor 1 (LYVE1) has a macrophage-binding domain at the extracellular site, which mediates macrophage adhesion and subsequent translocation in lymphatic vessels (LVs). However, it is unknown whether LYVE1 is altered in renal disease and whether it thereby mediates changes in macrophage trafficking.

Methods: Models of ureteral obstruction (UUO), ischemia/reperfusion (I/R), folic acid (FA)-induced renal fibrosis models were created for in vivo experiments and human lymphatic endothelial cell (hLEC) line was used for in vitro experiments.

Results: First, we found that macrophages were significantly recruited and clustered around LVs in the mouse fibrosis models. We further showed that in renal fibrosis models and TGF-β1-cultured hLECs, LYVE1 shed its extracellular domain on LECs and therefore lost its macrophage-binding domain, thus hindering macrophage adhesion to LECs. Meanwhile, LYVE1 shedding fragments were shown to mediate macrophage-to-myofibroblast transition (MMT) to promote fibrosis. Mechanistically, elevated MMP9 mediated LYVE1 ectodomain shedding, resulting in the loss of sites for macrophage binding. The use of chemical shedding inhibitors or MMP9 targeting siRNA attenuated LYVE1 shedding, restored macrophages trafficking and alleviated renal fibrosis.

Conclusions: LYVE1 shedding is tightly associated with progression of renal fibrosis, whereas inhibition of LYVE1 shedding is capable of ameliorating macrophage aggregation and MMT to attenuate disease progression.

Identification the Classification and Heterogeneity of Lymphatic Endothelial Cells, and Their Role in Mice with Kidney Fibrosis via Single-Cell RNA Sequencing Analysis

Zheng Wang, Rui Zeng, Gang Xu, Ying Yao. *Huazhong University of Science and Technology Tongji Medical College Tongji Hospital, Wuhan, China.*

Background: We previously found that knockdown of lymphatic endothelial cells (LECs) delayed the progression of chronic kidney disease. However, due to the relatively low abundance of LECs, little is known about their classification and the heterogeneity in renal inflammation and subsequent fibrosis.

Methods: We established a unilateral ureteral obstruction (UUO) model of mouse and isolated CD31+LYVE-1+ cells using CD31 magnetic bead enrichment and LYVE-1 flow sorting. We employed single-cell RNA sequencing to analyze the heterogeneity of LECs in mice with renal fibrosis. In order to selectively suppress proliferating lymphatic vessels, LYVE-1-TK transgenic mice were constructed.

Results: LECs are classified into three types, including capillary lymphatic endothelial cells (Cap.LECs), pre-collecting lymphatic endothelial cells (Pre-col.LECs) and collecting lymphatic endothelial cells (Col.LECs). Single-cell sequencing analysis showed that Cap.LECs are characterized to participate in cell adhesion, angiogenesis and metal ion transport. Pre-col.LECs are primarily associated with ERK and WNT signaling as well as anion transport. Col.LECs are mainly focused on the regulation of antigen presentation, lipid transport, and immune cell migration. After UUO, all three types of renal LECs shows significant proliferation, and the activity of lymphangiogenesis related transcription factors, proliferation related genes, and lymphangiogenesis related receptors were upregulated. Pseudotime trajectory analysis showed that Pre-col.LECs had strong stem cell characteristics, and both Cap.LECs and Col.LECs were directly derived from the Pre-col.LECs. In the UUO group, the expression of the APP protein, secreted specifically by Pre-col.LECs and Col.LECs, was found to be upregulated. This protein interacts with the CD74 receptor expressed by NK cells and T cells, chemotactically attracting these cells and influencing their function. Knockdown of proliferative lymphatic vessels significantly reduced the number of Pre-col.LECs and Col.LECs in the UUO kidney, resulting in a significant decrease in the populations of T cells and NK T cells, thereby improving the inflammatory microenvironment and fibrosis.

Conclusions: These findings provide a theoretical basis for future interventions targeting lymphangiogenesis in kidney diseases.

PCK1 Plays a Central Role in the Control of Metabolic and Mitochondrial Activities in Renal Tubular Cells

Delal Dalga,[1] Thomas Verissimo,[1] Anna Faivre,[1,2] Sophie M. De Seigneux.[1,2] *[1]Universite de Geneve Faculte de Medecine, Geneve, Switzerland; [2]Hopitaux Universitaires Geneve, Geneve, Switzerland.*

Background: During chronic kidney disease (CKD), renal gluconeogenesis is impaired, leading to metabolic dysfunction. Among the enzymes involved in gluconeogenesis, Phosphoenolpyruvate Carboxykinase 1 (PCK1), which facilitates the conversion of oxaloacetate to phosphoenolpyruvate, is rate-limiting. In this study, we hypothesize that the alteration of PCK1 expression in kidney proximal cells contributes to metabolic alterations during CKD and renal dysfunction, through modifications of acid-base balance and cataplerosis.

Methods: Using kidney tubular-specific knockout (KO) and knockin (KI) PCK1 mice models, we assessed the influence of PCK1 expression changes on renal function and kidney metabolism under physiological and pathological conditions. We utilized models of AKI (ischemia) and CKD (proteinuria and platinum toxicity).

Results: Under physiological conditions, PCK1 deletion leads to a loss of renal function and hyperchloremic metabolic acidosis. PCK1 inhibition also induces significant alterations in mitochondrial structure and function, as evidenced by Seahorse analysis and electron microscopy. Additionally, metabolomic analysis revealed that the loss of PCK1 results in decreased cataplerosis, leading to the accumulation of TCA cycle intermediates such as fumarate and malate in the kidney, thereby impeding the TCA cycle. In models of AKI and non-diabetic CKD, PCK1 deletion exacerbated renal dysfunction and mortality. Conversely, in two models of non-diabetic CKD, restoration of PCK1 in kidney tubular cells improved renal function, reduced tubular injury, and slowed fibrosis progression. Similarly, PCK1 restoration mitigated mitochondrial damage by promoting TCA cataplerosis.

Conclusions: PCK1 is essential for maintaining renal tubular acid-base balance, mitochondrial energy production, and TCA cataplerosis. Restoring PCK1 could be a crucial target for preventing mitochondrial dysfunction and the progression of kidney disease during CKD.

FR-PO1185

Knockdown of Translocator Protein (TSPO) Slows AKI to CKD Transition through Regulating Mitochondrial Dysfunction

Yuchen Feng, Wai Han Yiu, Jingyuan Ma, Kar Neng Lai, Sydney Tang. *The University of Hong Kong, Hong Kong, Hong Kong.*

Background: Acute kidney injury (AKI) has been widely recognized as an important risk factor for the occurrence and development of chronic kidney disease (CKD). Emerging studies suggest that mitochondrial dysfunction is a pivotal contributor to the transition from AKI to CKD. Translocator protein (TSPO), located on the outer mitochondrial membrane, is associated with kidney tubular cell death and regeneration in AKI. However, the role of TSPO in AKI to CKD transition remains unknown.

Methods: Kidney tubule-specific TSPO knockout (Tubule-TSPO-/-) mice were created by crossing TSPO floxed (TSPOflox/flox) mice on a C57BL/6J background with tamoxifen inducible Ksp-CreERT2 mice. Unilateral ischemia-reperfusion injury (uIRI) for different timepoints was performed on both Tubule-TSPO-/- and TSPOflox/flox wildtype mice to establish AKI to CKD transition. Kidneys were harvested for histology, inflammation, fibrosis and mitochondrial function measurements.

Results: Both TSPO mRNA and protein levels were increased at day 1 and lasted for at least 14 days after uIRI. Histopathologically, uIRI-induced tubular damage was reversed by knockdown of TSPO at day 7 and day 14. Induction of fibronectin, Col-1, TNF-α, CCL-2 and IL-1β mRNA in the uIRI kidney was reduced in knockout mice compared to control. In 14 day-uIRI mice, immunohistochemical analysis further confirmed significant reduction of Col-1 and Col-3 expression by TSPO depletion. Furthermore, PGC1-α, the master regulator of mitochondrial function, was significantly increased after knockdown of TSPO. Electron microscopy demonstrated a higher number of mitochondria and improved mitochondrial morphology with TSPO depletion. Reduction of mitochondrial DNA copy number by uIRI was also reversed by knockdown of TSPO.

Conclusions: Knockdown of TSPO in tubular cells could alleviate kidney inflammation and fibrosis in murine uIRI models, increase mitochondrial number and restore mitochondrial structure. The results suggested that TSPO could play an important role in regulating mitochondrial function during AKI to CKD transition progress. Metabolic Landscape of Naturally Occurring CKD in Cats: An Integrated Multiomics Study

Qinghong Li,[1] Ornella Cominetti,[3] Eugenia Migliavacca,[3] James Holzwarth,[3] Sonia Karaz,[3] Mathieu Membrez,[3] Charlotte Macron,[3] Marie-Claude Courtet-Compondu,[3] Stacie Summers,[2] Vincenzo Sorrentino,[4] Loïc Dayon.[3] *[1]Nestle Purina PetCare Co, Saint Louis, MO; [2]Oregon State University, Corvallis, OR; [3]Nestle Research, Lausanne, Swaziland; [4]National University of Singapore, Singapore, Singapore.*

Background: Human and feline CKD shares similar pathophysiology, including chronic tubulointerstitial inflammation and fibrosis. The underlying mechanisms for both diseases are incompletely understood. This study outlined our first step towards creating a metabolic atlas of feline CKD.

Methods: Cats diagnosed with CKD were staged according to the International Renal Interest Society guidelines. Targeted and untargeted metabolomics was performed on serum samples. Transcriptomics and proteomics were performed on cortical and medullar tissues from cats euthanized for humane reasons unrelated to the study. Linear model was applied for data analysis with false discovery rate (FDR)<0.05 for differential metabolites and genes, and FDR<0.15 for differential proteins between groups.

Results: Serum concentrations of free fatty acids, 3-hydroxy fatty acids, and acylcarnitines were elevated, while renal RNA and protein expressions of enzymes for fatty acid transport and oxidation were downregulated in CKD cats compared to control cats. Tissue protein expressions of several glycolytic enzymes were increased but decreased for gluconeogenic enzymes in CKD cats. While the levels of oxidized glutathione, glutamine and several Krebs cycle intermediates accumulated in the circulation, tissue RNA and protein expressions of enzymes involved in glutathione biosynthesis, glutaminolysis, Krebs cycle, ketolysis, and NAD+ biosynthesis were reduced in CKD cats compared to control cats. Further, tissue gene expressions of profibrotic (TGFβ1, CTGF, GAL3, α-SMA, FN1, LOX) and proinflammatory (IL11, IL16, TNF) markers, and hypoxia inducible factor HIF1A were upregulated, while gene expressions of anti-fibrotic klotho and hypoxia inhibitors (FIH1, PHD2) were downregulated in CKD cats vs control cats. Finally, targeted metabolomics revealed elevated circulating uremic toxins, including TMAO, indoxyl sulfate, p-cresol sulfate, phenol sulfate, while RNA expressions of renal tubular transporters OAT1, OATP4C1 and ABCC2 were downregulated in cats with CKD.

Conclusions: Our study unveiled extensive abnormalities and readaptations in bioenergetics, impaired redox homeostasis and uremic toxin excretion, and increased inflammation, fibrosis, and hypoxia in cats with CKD.

FR-PO1187

Plasma Calciprotein Particles and Calcification Propensity in Cats with CKD Stabilized on a Phosphate-Restricted Diet

Pak Kan Tang,[1] Makoto Kuro-o,[2] Miki Tsuchida,[2] Rebecca Geddes,[3] Rosanne E. Jepson,[3] Yu-Mei Chang,[1] Jonathan Elliott.[1] *[1]The Royal Veterinary College Department of Comparative Biomedical Sciences, London, United Kingdom; [2]Jichi Medical University Center for Molecular Medicine, Shimotsuke, Japan; [3]The Royal Veterinary College Department of Clinical Science and Services, Hatfield, United Kingdom.*

Background: Fetuin-A aggregates with calcium and phosphate ions to form calciprotein monomers, preventing precipitation (low-density calciprotein particles [L-CPP]). Consolidation of L-CPP with further protein leads to amorphous CPP which transform spontaneously into pro-inflammatory crystalline CPP over time (high-density CPP [H-CPP]). The transition time (T50) from amorphous to crystalline CPP indicates the calcification propensity. This study evaluated relationships between CPP levels, T50 and CKD-MBD parameters in cats with azotemic CKD.

Methods: Cross-sectional study: Frozen heparinized fasted plasma samples from cats with naturally occurring CKD stabilized on a phosphate-restricted diet (forming ≥50% of diet consumed) were retrospectively identified for CPP and calcification propensity (T50) assessment. Total CPP (T-CPP), L-CPP and H-CPP were measured by an infrared fluorescent bisphosphonate (OsteoSense), in conjunction with gel filtration. Associations between CPP, T50 and CKD-MBD parameters were evaluated by Spearman or Pearson correlations and linear regression models.

Results: 38 euthyroid client-owned cats with International Renal Interest Society (IRIS) stage 2–3 azotemic CKD were enrolled. Moderate negative correlations were found between T-CPP, L-CPP and H-CPP with T50 (**Table 1**). FGF-23 correlated positively with T-CPP, L-CPP (**Table 1**) and total calcium (r=0.41; *P*=0.011), and negatively with T50 (r=-0.44; *P*=0.006) and total magnesium (r=-0.42; *P*=0.011). FGF-23 was a significant predictor of T-CPP and L-CPP.

Conclusions: Plasma FGF-23 was a major determinant of T-CPP and L-CPP in fasted samples obtained from CKD cats stabilized on restricted phosphate diets. Comparable findings were reported in human patients with CKD, suggesting a similar relationship between FGF-23 and CPP in both species. Like humans, cats spontaneously develop CKD and FGF-23 is predictive of progression, therefore, studying cats could provide additional insights into the pathophysiology underlying CPP and CKD progression for humans.

Sirtuin 3 Promotes Renal Gluconeogenesis in Fibrotic Kidneys

Pinglan Lin, Ming Wu. *Department of Nephrology, Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicine, Shanghai, China.*

Background: Decreased renal gluconeogenesis is currently identified as a hallmark of chronic kidney disease, which may contribute to renal fibrosis. Sirt3 is a crucial metabolic sensor that regulates ATP generation, mitochondrial adaptive response to stress, and glucose metabolism. Sirt3 is renal protective in fibrotic kidneys, however its underlying mechanisms is not completely known.

Methods: Sirt3 inhibitor (3-TYP) was used to evaluate the effect of Sirt3 on renal fibrosis and renal gluconeogenesis in UUO mice. The effect of Sirt3 on proximal tubular cells was evaluated in *in vitro*, *ex vivo* and *in vivo* models of renal fibrosis. Mechanistically, the effect of Sirt3 on metabolic transcription factors FOXO1 was evaluated. Finally, pharmaceutical activation of Sirt3 by its agonist HKL on renal gluconeogenesis and systemic glucose metabolism was assessed in *in vivo* model.

Results: Decreased sirt3 expression was accompanied by reduced expression of gluconeogenesis rate-limiting enzymes (PCK1, FBP1) in UUO kidneys. Sirt3 is co-localized with PCK1 and FBP1 expression in proximal tubular cells of fibrotic kidneys. Sirt3 adenovirus alleviated renal fibrosis and improved the glucose homeostasis *in vitro*, *ex vivo* and *in vivo* models of renal fibrosis. Furthermore, Sirt3 agonist or overexpressed of sirt3 by adenovirus improved gluconeogenesis through activation of metabolic transcription factor FOXO1 and PGC-1α in *in vitro* and *ex vivo* models. A direct

interaction between FOXO1 and Sirt3 was revealed through co-immunoprecipitation experiment by using primary kidney tubular cells. FOXO1 inhibitor abolished the pro-gluconeogenic effect of Sirt3 agonist in fibrotic renal cells. Pharmaceutical activation of Sirt3 improved renal gluconeogenesis and systemic glucose metabolism in UUO mice.

Conclusions: Sirt 3 promotes renal gluconeogenesis in proximal tubular cells of fibrotic kidneys through direct interaction and up-regulation of FOXO1. Pharmaceutical activation of Sirt3 could be a new strategy to improve glucose metabolism in chronic kidney disease patients.

Less Is More: Protective Effects of Caloric Restriction on Acute and Chronic Kidney Injury

Paolo Molinari,[1,2] Alberto Verlato,[2] Johan Noble,[2] Sara Alibrandi,[2] Carlo Alfieri,[1] Giuseppe Castellano,[1] Paolo Cravedi.[2] *[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Acute kidney injury (AKI) leads to an high risk of progression to chronic kidney disease (CKD). Monocytes are crucial in renal injury pathogenesis, and caloric restriction appears to inhibit the CCL2/CCR2 axis and monocyte recruitment. Thus, we hypothesized that caloric restriction via a fasting-mimicking diet (FMD) reduces both acute and chronic kidney injury.

Methods: We compared the effects of FMD (5 days of caloric restriction and 2 days of ad libitum (*ad lib*)) vs. *ad lib* diet on the severity of aristolochic acid (AA)-induced AKI and kidney recovery in BALB/c male mice. Samples were collected after 2 days of normal diet in FMD mice.

Results: At 14 (AKI phase) and 35 (CKD phase) days post-injury, serum creatinine levels were significantly lower in mice on FMD **(Figure 1A)**. Importantly, the protective effects of FMD on CKD were present also when FMD was started at the peak of AKI severity (14 days). Overall, kidney infiltrating monocytes were reduced in FMD mice both at 14 and 35 days. Especially during transition from AKI to CKD (35 days), kidney monocyte infiltrates were markedly reduced by FMD, showing a clear shift towards Ly6c^{low} anti-inflammatory monocytes **(Figure 1B)**. FMD markedly inhibited CCL2/CCR2 axis, leading to lower serum CCL2 levels and lower monocyte recruitment throughout kidney damage progression **(Figure 1C)**. In the presence of a selective CCR2 inhibitor, FMD had no additional effects on kidney function, monocyte recruitment and infiltrating kidney monocytes indicating the key involvement of CCL2/CCR2 signaling in FMD's mechanism of action **(Figure 1D)**.

Conclusions: FMD appears to mitigate acute and chronic kidney injury by decreasing CCL2-mediated recruitment of pro-inflammatory monocytes in the kidney.

Effects of Bariatric Weight Loss on Inflammatory Protein Signatures and Shear Elastographic Evidence of Kidney Injury in Obesity

Clara L. Ngoh,[1,2] Boon Wee Teo,[1,2] Asim Shabbir,[1,2] Jorming Goh,[2] Horng-Ruey Chua.[1,2] The ELASTO Study Group. *[1]National University Hospital, Singapore, Singapore; [2]National University of Singapore, Singapore, Singapore.*

Background: Bariatric surgery represents a unique human model of accelerated metabolic optimization. Preclinical models have demonstrated improvements in inflammatory correlates of kidney injury after weight loss, although mechanisms in humans are poorly elucidated without kidney biopsies. We detected substantive improvements in estimated glomerular filtration rate (eGFR) in obese patients with CKD, following bariatric surgery. While this suggests attenuated kidney injury with reduced adiposity, creatinine-based eGFR is confounded by lean muscle loss. Novel kidney imaging by shear wave elastography bridges these gaps by quantifying kidney parenchymal stiffness non-invasively.

Methods: We studied 50 CKD patients with obesity planned for bariatric surgery. Shear wave elastography (Axiplorer, Hologic) and inflammatory biomarkers (Olink proteomic assays) were sampled at baseline and 6 months post-surgery. Kidney shear wave scans were performed by 2 independent investigators. The average of 12 measurements was taken.

Results: Absolute GFR demonstrated resolution of hyperfiltration 6 months after bariatric surgery (139 versus 103 ml/min, P =0.005). Despite initial high glomerular filtration rates, baseline kidney stiffness by shear wave elastography pre-surgery was 26.1 ± 6.2 kPa, levels of which based on our previous work, should correlate with CKD stage 3. Kidney stiffness improved 1 year-post surgery to 13.1 ± 6.2 kPa (P =0.008). This correlated with improvements in body mass indices from 40.2 ± 11.2 kg/m^2 (baseline) to 26.8 ± 12.5 kg/m^2 (post-surgery). 276 plasma proteins were sampled. At 1-year post-surgery, 17 protein biomarkers showed decreased expression, in particular CUB-domain containing protein (CDCP1) and Delta/notch-Like EGF repeat (DNER) (All P <0.0001). Conversely, 3 proteins: Fibroblast growth factor-19 (FGF-19), Chemokine ligand-9 (CXCL9), Chemokine ligand-23 (CCL23) showed increased expression (All P <0.05).

Conclusions: By demonstrating kidney stiffness reversal in parallel with reduction in systemic inflammation following bariatric surgery-induced weight loss, this study advocates for intensive weight loss as a means of attenuating CKD progression. Novel serum and elastographic imaging biomarkers hold potential to surpass traditional eGFR in assessment of metabolic kidney disease.

Alleviating Obesity-Related Kidney Injury with Polyethylene Glycol-Capped Ceria-Zirconia Nanoparticles by Enhancing Autophagy Flux

Eun Kyung Kim, YunSeok Choi, Daun Song, Won Min Hwang, Sung-Ro Yun, Yohan Park, Se-Hee Yoon. Div of Nephrology and Dept of Internal Medicine, Myunggok Medical Research Institute. *Konyang University College of Medicine, Daejeon, Republic of Korea*.

Background: Obesity poses a significant contemporary health challenge, contributing to a range of complications. The underlying mechanisms remain incompletely understood, with obesity often triggering various pathological signals, such as lipotoxicity. Despite the considerable efforts by individuals to lose weight, achieving this goal is challenging. Polyethylene glycol-capped ceria-zirconia nanoparticles (PEG-CZNPs) have garnered attention for their antioxidant properties and their ability to restore autophagy flux. In this study, we investigated the protective effect of PEG-CZNPs against obesity-induced kidney injury.

Methods: An in vitro model of obesity was established using palmitate in HK-2 cells. The change in lipid droplet deposition, reactive oxygen species (ROS), inflammation, and autophagy flux were evaluated using the oil-red O assay, western blotting, polymerase chain reaction, and immunofluorescence assays. An in vivo model of obesity was induced in mice through a high-fat diet. Biochemical analysis, histological stains, and immunohistochemistry were performed on the liver, kidney, and adipose tissue of the obese mice at 12 weeks after initiating the high-fat diet.

Results: PEG-CZNPs successfully reduced lipid droplet deposition in HK-2 cells exposed to palmitate by restoring autophagy flux dysfunction. ROS, inflammation, and fibrotic change caused by palmitate were also improved by PEG-CZNPs treatment. PEG-CZNPs attenuated glucose intolerance and serum cholesterol levels in animal models of obesity. Additionally, PEG-CZNPs notably decreased cellular lipid droplet deposition.

Conclusions: PEG-CZNPs alleviated obesity-induced kidney injury by reducing inflammation and oxidative stress and by decreasing organ lipid deposition through the restoration of autophagy flux function.

Six Months of High-Fat Diet and Physical Inactivity in Thermoneutrality Are Insufficient to Cause CKD in Mice

Precious C. Opurum, Stephen Decker, Deborah Stuart, Alek D. Peterlin, Venisia L. Paula, Alejandro Sanchez, Nirupama Ramkumar, Katsuhiko Funai. *University of Utah Health, Salt Lake City, UT*.

Background: Chronic kidney disease (CKD) is a progressive disorder marked by a decline in kidney function. The process by which obesity and sedentary behavior contribute to the development of CKD is poorly understood. Studies suggest a decline in mitochondrial function likely contributes to the pathogenesis of CKD, but the detailed mechanisms remain unclear. This knowledge gap is contributed to by a lack of a murine CKD model that does not rely on injury, toxin, or gene deletion to induce reduced kidney function.

Methods: Here, we employed a recently published model of sedentariness developed in our lab, which phenocopies many of the systemic metabolic adaptations that occur in human sedentary behavior. Wildtype C57BL/6J male mice housed under ambient (22°C) or thermoneutral conditions (29°C) were fed standard chow or Western high-fat diet (HFD) with or without small mice cage (SMC) intervention for 6 months.

Results: However, while HFD or SMC tended to increase the glomerular filtration rate (GFR), these interventions were insufficient to cause CKD. Histological and gene expression data suggested a potential early onset of fibrosis programming, but the magnitudes of these changes were minor. High-resolution respirometry and fluorometry experiments showed increases in mitochondrial respiration and ATP synthesis capacities, also likely demonstrating early adaptive responses to heightened kidney burden.

Conclusions: Given the long duration of the intervention, these data reinforce the technical challenge associated with modeling CKD in mice. They also suggest that metabolic pressures caused by obesogenic diet and/or sedentariness may be insufficient to robustly negatively influence kidney function.

The Golgi Apparatus-Hosted ATP7A-Fibulin-4 Complex Mediates Activation of LOX to Promote Kidney Fibrosis

Wenqian Zhou, Chen Yu. *Tongji Hospital Affiliated to Tongji University, Shanghai, China*.

Background: Lysyl oxidase (LOX) is a copper-dependent monoamine oxidase whose primary function is the covalent cross-linking of collagen and elastin in extracellular matrix (ECM), however, the regulation of LOX activity in renal fibrosis is not well understood.

Methods: To explore the relationship between cellular copper overload and LOX activity, we employed copper chelator tetrathiomolybdate and implemented specific knockdown of copper transporter1 (CTR1) both in vivo and in vitro. Subsequently, we evaluated LOX activity and activated LOX expression by LOX assay kit and western blot. The specific regulatory mechanism of LOX activity was elucidated by knocking-down expression of ATPase copper transporting alpha (ATP7A) and Fibulin-4 (FBLN4) in vitro or in vivo.

Results: 1) Expression of LOX and extracellular matrix (ECM) cross-linking were markedly increased in fibrotic kidneys of ischemia/reperfusion (IR) induced renal fibrosis model. Treatment with tetrathiomolybdate or the knockdown of CTR1 resulted in a reduction in copper levels, leading to decrease LOX activity and ameliorated renal fibrosis. 2) The upregulation of ATP7A expression increased copper levels in the Golgi apparatus of renal tubular epithelial cells, resulting in enhanced LOX activity and ECM crosslinking, thereby promoting the progression of renal fibrosis. 3) FBLN4 was essential for ATP7A-transfering copper to LOX and formed a ternary complex of ATP7A-FBLN4-LOX in renal tubular epithelial cells.

Conclusions: Our results suggest that the ATP7A-FBLN4 complex facilitates the aberrant accmulation of copper in the Golgi apparatuses, thereby promoting the activation of LOX to catalyze ECM cross-linking and contribute to the progression of renal fibrosis.

FR-PO1194

Trim21 Alleviates Renal Tubulointerstitial Fibrosis by Mediating Loxl2 Ubiquitination Modification and Degradation

Hanlu Jiang, Chunsun Dai. *The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China*.

Background: Extracellular matrix (ECM) accumulation is closely associated with renal interstitial fibrosis. However, its mechanisms is largely unknown. Tripartite motif 21 (Trim21), as a member of the TRIM family, has been demonstrated to be an E3 ubiquitin ligase. The involvement of Trim21 in immunity, inflammation, antiviral response and tumorigenesis has been documented. However, whether Trim21 involved the occurrence and development of renal interstitial fibrosis is unclear. This study aimed to investigate the role and mechanism of Trim21 in renal tubulointerstitial fibrosis.

Methods: Renal tubule-specific knockout Trim21 mice were constructed, and unilateral ureteral obstruction (UUO) and ischemic reperfusion injury (IRI) were conducted to induce renal interstitial fibrosis. In vitro Trim21 overexpression plasmid or siRNA were used to disrupt Trim21 expression in cultured primary renal tubular epithelial cells, and then treated with transforming growth factor β1 (TGFβ1) for induce ECM production.

Results: We first found that Trim21 mRNA and protein levels were elevated in kidney of CKD patients and UUO and IRI-induced renal interstitial fibrosis model. Moreover, knockout of Trim21 in tubular cell significantly exacerbated renal interstitial fibrosis induced by UUO and IRI. In primary renal tubular epithelial cells, silencing Trim21 upregulated lysyl oxidase-like protein 2 (Loxl2) and extracellular matrix deposition by inhibiting ubiquitination modification and degradation of Loxl2, while overexpression was the opposite. Immunoprecipitation experiments showed that PRY/SPRY domain of Trim21 interacted with amino-terminal of Loxl2.

Conclusions: In summary, Trim21 directly interacts with Loxl2 through the PRY/SPRY domain, promotes ubiquitination modification and degradation of Loxl2, inhibits extracellular matrix production and attenuates renal fibrosis. Therefore, Trim21 plays an essential role in Loxl2 regulated ECM deposition and may be a viable target for treating chronic kidney diseases.

FR-PO1195

Dietary Sodium Modulates mTORC1-Dependent Trained Immunity in Macrophages to Accelerate AKI to CKD Transition

Guochun Chen, Jie Song, Li Zeng. *The Second Xiangya Hospital of Central South University, Changsha, China*.

Background: Chronic Kidney Disease (CKD) constitutes a substantial global health concern, with its etiology closely associated with dietary patterns, particularly elevated salt consumption, and recurrent infections that precipitate the transition from Acute Kidney Injury (AKI) to CKD. However, the mechanistic pathways underpinning this progression have yet to be fully elucidated.

Methods: Flow cytometry,RT PCR,ELISA,Western blot analysis, renal histological analysis, immunofluorescent and immunohistochemical staining were performed to measure the inflammatory response of macrophages in AKI to CKD and how high-salt diet aggravates this response by modulating mTORC1 pathway.

Results: Analysis shows elevated CD45+F4/80+ macrophage infiltration and inflammatory cytokine production under high-salt conditions. Distinct responses were observed between circulating and resident renal macrophages to a high-salt diet, with a notable upsurge in the migration of pro-inflammatory macrophages, driven by CCL2-CCR2 signaling and aberrant mTORC1 pathway activation. Treatment with

rapamycin-liposome effectively reduced this inflammatory cascade by mitigating mTORC1 signaling. Transplantation of monocytes from CKD mice with a high-salt diet significantly exacerbates renal inflammatory damage in the host mice, showing increased migratory tendency and inflammatory activity. The cell co-culture experiment further confirmed that macrophages derived from CKD mice, particularly those under conditions of high salt exposure, significantly induced apoptosis and inflammatory responses in renal tubular cells.

Conclusions: Recurrent exposure to LPS elicits the activation of trained immunity, consequently augmenting inflammatory response of monocytes/macrophages in the involved kidneys. The high-salt diet exacerbates this phenomenon, attributable at least in part to the overactivation of the mTORC1 pathway.

Lysine-Specific Demethylase 1A Is a Targetable Kidney Disease Causal Gene

Kolligundla L. Prasanna,[1] Dhanunjay Mukhi,[1] Hongbo Liu,[1,2] Katalin Susztak.[1] Katalin Susztak Group. *[1]University of Pennsylvania, Philadelphia, PA; [2]University of Rochester Medical Center, Rochester, NY.*

Background: Large scale chronic kidney disease genome-wide association study (GWAS) identified more than eight hundred genetic risk loci for kidney dysfunction, however, causal genes, cell types, and targetable pathways remain elusive. In our research, we leveraged human kidney expression and methylation quantitative trait loci (eQTL, meQTL), and single cell open chromatin and gene expression information to prioritized KDM1A (Lysine specific demethylase 1A) on chromosome 1 as a likely causal gene. KDM1A controls genes expression by demethylating histone 3 lysine 4 di-or mono methylation residues.

Methods: We generated kidney-specific KDM1A knockout mice by breeding with KDM1A floxed mice with Six2 cre or Ksp cre mice. We analysed these mice at baseline and following kidney injury by cisplatin or unilateral ureteral obstruction. Kidney function was analyzed by measuring serum creatinine, and blood urea nitrogen, and cystatin C levels, and gene expression by real-time PCR and protein levels by western blotting, and immunohistochemistry. In addition, primary tubule cells were employed and treated with TGFβ1 or ORY-1001, an inhibitor of KDM1A, and analyzed fibrosis markers. Chromatin immunoprecipitation sequencing, single nuclear RNA-seq, and ATAC-seq were applied to find the molecular mechanism.

Results: By applying a comprehensive gene prioritization strategy, we identified that genetic variants on chromosome 1 regulate KDM1A gene expression. RNA and protein expression studies revealed that KDM1A levels were higher in kidney disease patients and animal models. Tubule-specific KDM1A knockout mice were healthy at baseline but showed lower kidney injury in models of acute kidney injury by cisplatin, and chronic fibrosis by UUO. In vitro studies with TGFβ1 treatment showed lower fibrosis markers expression in the presence of ORY-1001 or in KDM1A knockout tubule cells. Inhibition of KDM1A with ORY-1001 in mice also showed protection against UUO-induced kidney fibrosis. Our future studies will investigate the mechanistic role of KDM1A in kidney disease development.

Conclusions: Our studies propose that lysine specific demethylase 1A could be a therapeutic option to combat kidney disease.

Critical Role of Lysine-Specific Histone Demethylase 1 in Kidney Inflammation and Fibrosis

Baihai Jiao,[1] Hao Du,[1] Melanie Tran,[1] Yanlin Wang.[1,2] *[1]University of Connecticut School of Medicine, Farmington, CT; [2]VA Connecticut Healthcare System, West Haven, CT.*

Background: Chronic kidney disease is characterized by inflammation and fibrosis. Inflammation often triggers fibrosis, and fibrosis is the end result of chronic inflammatory reactions. Kidney inflammation is characterized by inflammatory cell infiltration and activation leading to inflammatory and fibrotic molecule production. However, there is a critical knowledge gap on molecular mechanisms underlying kidney inflammation and fibrosis. In this study, we evaluated the impact of lysine-specific histone demethylase 1 (LSD1) on kidney inflammation and fibrosis.

Methods: To explore the role of LSD1 in kidney inflammation and fibrosis in vivo, we generated mice with tamoxifen inducible deletion of LSD1 using Cre-LoxP strategy. Unilateral ureteral obstruction (UUO) and ischemia-reperfusion injury (IRI) models were used to induce kidney inflammation and fibrosis. Cultured macrophages were used to examine the role of LSD1 in the regulation of macrophage activation in vitro.

Results: LSD1 expression markedly increased in the kidneys following obstructive or ischemic injury. Mice with a tamoxifen-inducible deletion of LSD1 exhibited no significant morphological abnormalities in the kidney. Compared with Cre negative, floxed LSD1 mice, mice with tamoxifen-induced deletion of LSD1 exhibited fewer α-SMA$^+$ myofibroblasts and expressed less α-SMA protein in the kidneys following UUO or IRI. Inducible deletion of LSD1 significantly ameliorated total collagen deposition and ECM protein production in the kidneys in response to UUO or IRI. Real-time RT-PCR showed that the mRNA expression levels of proinflammatory and profibrotic molecules were significantly increased after UUO or IRI, which were significantly reduced in LSD1 deficient mice. Furthermore, the activity of NF-κB signaling was significantly decreased in LSD1-deficient mice following UUO or IRI. In cultured macrophages, inhibition of LSD1 reduced NF-κB signaling activation and proinflammatory and profibrotic molecule expression.

Conclusions: Our study demonstrates that LSD1 is a key regulator of inflammation and renal fibrosis in chronic kidney disease. Targeting LSD1 could provide a novel therapeutic approach to mitigate kidney inflammation and fibrosis and ameliorate the progression of chronic kidney disease.

The Micropeptide LSMEM1 Attenuates Renal Tubulointerstitial Fibrosis by Reducing Lipid Droplet Accumulation

Peimin Liu, Xiaoyan Bai. *Guangdong Provincial People's Hospital, Guangzhou, China.*

Background: Chronic Kidney Disease (CKD) is a syndrome defined by persistent changes in kidney structure, function, or both, and today the global burden of CKD is increasing. Regardless of the starting injury or disease, the most common pathological manifestation of CKD is some form of renal fibrosis that eventually progresses to end-stage renal disease (ESRD). Micropeptides are commonly defined as polypeptides with arelatively arbitrary length of less than 100–150 amino acids (aa) in length. Evolving evidence suggests that micropeptides regulate a variety of biological processes, and more and more micro-molecule peptides being discovered as technology develops. In recent years a variety of diseases have detected up-regulation of LSMEM1 which is a micropeptide enriched with 133 amino acids.

Methods: Analysis of renal expression levels of LSMEM1 in CKD patients compared to normal controls using the GEO database and nephroseq database. Though the immunohistochemical staining, the level of LSMEM1 was examined in patients with CKD caused by different diseases. In the vivo, We constructed the LSMEM1-knockout mice followed by unilateral ureteral ligation (UUO) surgery and executed the mice 7 days later. In the vitro, lentivirus was used to silence or over-expression LSMEM1 in HK-2 cells under the TGF-β stimulation. Other testing methods include RNA-seq, ELISA, Colorimetric Assay, Western Bloting, Masson staining, Sirius Red Staining and et al.

Results: Compared to normal controls, LSMEM1 expression is upregulated in CKD kidneys. Animal and cellular experiments showed that LSMEM1 expression levels increased with increasing degrees of fibrosis. Animal experiments showed that renal fibrosis was aggravated in UUO mice after LSMEM1 knockdown compared with the SHAM group. Cellular experiments showed that silencing LSMEM1 elevated the level of fibrosis induced by TGF-β in HK-2 cells and, conversely, overexpression reduced. RNA-seq analysis shows lipid metabolism-related pathways are significantly enriched in the kidney of LSMEM1-KO mice. Knockdown of LSMEM1 caused more severe lipid accumulation in mice and cell, conversely, overexpression attenuated.

Conclusions: Current study suggests the micropeptide LSMEM1 could attenuates renal tubulointerstitial fibrosis by reducing lipid droplet accumulation and may be a therapeutic target in CKD.

FR-PO1199

Characterizing Lipid Metabolism in Diseased Kidneys and Understanding the Impact of Blood Contamination

Kimberly L. Steen, Zhongyuan Sun, Srinath Jagarlapudi, Rose A. Keenan, Simone Romoli, Denis Feliers, Justin Crane. Internal Medicine Research Unit. *Pfizer Inc, Cambridge, MA*.

Background: The kidney exhibits a high bioenergetic flux owing to constitutive filtration and absorption. Dysfunction of proximal tubule metabolism, specifically reduced mitochondrial fatty acid oxidation and increased lipid synthesis, are considered key drivers of chronic kidney disease (CKD) and are recapitulated in CKD mouse models. There are numerous ways to characterize these processes, including lipid profiling, enzyme activities and flux tracing of energy substrates. However, the kidney is enriched by blood, which itself contains lipids and may influence the measurement of endogenous lipids or synthesis byproducts.

Methods: We characterized lipid abundance, mitochondrial markers and kidney functional readouts in two renal disease models: 1) AAV-renin, uninephrectomized db/db mice and 2) mice fed a 0.15% adenine diet for 6 weeks. Lipids were measured by HPLC, mtDNA by qPCR, and mitochondrial enzymes by absorbance kinetic assays. To isolate endogenous kidney lipids from the blood, we compared kidneys from C57BL6 mice with and without systemic PBS perfusion prior to collection. We also compared the effects of perfusion on de novo lipogenesis (DNL) by tracing D2O incorporation into tissue palmitate. All procedures performed on animals were in accordance with regulations and established guidelines and were reviewed and approved by an Institutional Animal Care and Use Committee or through an ethical review process.

Results: In the db/db Unx Renin mice, we found reduced GFR and mitochondrial content and a significant elevation of plasma cholesterol and cholesterol esters relative to controls. However, we observed no impact on kidney cholesterol or triglyceride levels. Similarly, in the adenine model, we found reduced GFR, mitochondrial content, and kidney cholesterol content. There were no effects of perfusion on kidney triglyceride levels or rates of DNL, yet there was higher free cholesterol in perfused vs. non-perfused kidney.

Conclusions: In two renal disease models we found reduced mitochondrial oxidative capacity, but no elevation in kidney lipids. Moreover, the lack of lipid changes in diseased kidney is unlikely to be due to contamination of kidney lipids by the blood, but further studies are warranted.

ECT2-PLXNB2 Signaling Inhibits Ribosome Biogenesis Leading to Kidney Fibrosis

Kaixin Song, Hua Su. *Huazhong University of Science and Technology Tongji Medical College First Clinical College Union Hospital Department of Nephrology, Wuhan, China*.

Background: During kidney fibrosis, the G2/M arrest and senescence of Tubular Epithelial Cells (TECs) are key pathogenic events. Ribosome Biogenesis (RiBi) refers to the assembling of ribosome complex, and RNA Pol1 catalyzing rDNA transcription is essential in RiBi. When RiBi is inhibited, ribosomal proteins RPL5 and RPL11 combine with HDM2 to form an Impaired Ribosome Biogenesis Checkpoint (IRBC) complex, which subsequently results in p53 upregulation. Formerly, it is reported RiBi partakes in senescence, however, whether RiBi is involved in kidney fibrosis is uncovered. It is reported that ECT2 plays important roles in G2/M arrest, aging and fibrosis, however whether ECT2 could regulate RiBi is unknown. Currently, we aim to investigate whether and how ECT2 regulate RiBi during renal fibrosis.

Methods: The UUO and in vitro TGF-β stimuli were utilized to setup fibrosis models. CX5461 was administrated to inhibit rDNA transcription. EU staining was used to detect the synthesis of nascent RNA. Cell proliferation and senescence were observed by CCK8 and SA-β-Gal staining respectively. Besides, RT-qPCR, WB, Masson, IF and multiple IF, Flow cytometry, Co-IP and transcriptome sequencing were used in this study.

Results: In vitro and in vivo, multiple IF and EU staining revealed a significant reduction of nascent RNA during fibrosis, and which was reconfirmed by the decline of 47S rRNA level tested via RT-qPCR. Above findings indicated that RiBi was depressed in fibrotic status. Moreover, using CX5461 successfully disrupted RiBi along with kidney fibrosis, G2/M arrest and cell senescence. Interestingly, CX5461 treatment increased the binding of HDM2 to RPL5 and RPL11. Next, we found ECT2 induced RiBi failure, contrarily, blocking ECT2 mitigated the inhibition of RiBi and kidney fibrosis caused by CX5461. Furthermore, transcriptome sequencing indicated that PLXNB2 was one of the down-regulated genes of ECT2. Knocking down PLXNB2 inhibited RiBi and promoted fibrosis, however, this effect could be partially abolished by co-transfection with ECT2 siRNA. These data implied that the elevated ECT2 depressed PLXNB2, and which consequently led to the failure of RiBi and kidney fibrosis.

Conclusions: Collectively, our findings indicated that blocking RiBi initiated G2/M arrest and senescence of TECs as well as kidney fibrosis. ECT2 mediated PLXNB2 decline was a potential mechanism accounting for the impaired RiBi in fibrosis.

Rolling-Translation of circVMP1 Promotes Proteinuric Nephropathy by Inhibiting Autophagy in Tubular Epithelial Cells

Peng Wang,[1] Tongtong Ma.[2] *[1]Department of Nephrology, and Guangdong Provincial Key Laboratory of Autophagy and Major Chronic Non-communicable Diseases, Affiliated Hospital of Guangdong Medical University, Zhanjiang, China; [2]The Department of Anesthesiology, Affiliated Hospital of Guangdong Medical University, Zhanjiang, China*.

Background: Proteinuria promotes the progression of chronic kidney disease (CKD) to end-stage renal disease by impairing tubular epithelial cells (TECs). Recent studies have found that autophagy and circRNAs play important roles in injured TECs. However, the functions and molecular mechanisms of circRNAs in autophagy and CKD progression is largely unclear. Our previous work revealed a novel mechanism, by which circBNC2 regulated cell cycle progression through encoding a previously unidentified protein, BNC2-681aa. However, whether circRNA mediates autophagy by translation remained to be elucidated.

Methods: High-throughput sequencing was carried out to identify differentially expressed circRNA in albumin-stimulated HK2 cells. The expression level of one candidate circRNA, circVMP1, was analyzed using Northern blot, FISH and real-time PCR. The effects of circVMP1 on autophagy was evaluated using TEM, RFP-GFP-LC3 cells. The encoding capacity of circVMP1 was proved through LC/MS and IRES reporter assay. After the validation of VMP1-143aa with a customized monoclonal antibody, the proteins that interact with VMP1-143aa was identified by LC/MS and Co-IP assays. Tubule-specific circVMP1 knockout mice were generated by crossing circVMP1$^{f/f}$ mice with Ksp-Cre mice.

Results: The expression level of circVMP1 in albumin-stimulated HK2 cells and biopsy samples from CKD patients with proteinuria was elevated. Knocking out circVMP1 in TECs alleviated renal inflammatory injury by promoting TECs autophagy in mouse adriamycin nephropathy model. Mechanistically, circVMP1 was found to inhibited TECs autophagy by translating a novel protein VMP1-143aa to function as a molecular decoy by interacting with BECN1 and TP53INP2, thereby inhibiting the function of VMP1 protein.

Conclusions: Collectively, circVMP1 promotes renal inflammatory injury in proteinuric nephropathy by hindering autophagy flux in a translation-dependent manner. Therefore, targeting circVMP1 or it's translation product, VMP1-143aa, might provide a potential angle for proteinuric nephropathy by restoring TECs autophagy.

Dysregulated Renal Microcirculation in Human Obesity Detected by Urinary Extracellular Vesicles (uEVs)

Mina H. Al Saeedi, Xiang yang Zhu, Aleksandar Denic, Andrew D. Rule, Hui Tang, Kyra L. Jordan, Amir Lerman, Aleksandra Kukla, Lilach O. Lerman. Nephrology and Hypertension. *Mayo Foundation for Medical Education and Research, Rochester, MN*.

Background: Obesity may dysregulate angiogenesis, and renal inflammation may induce microvascular proliferation. Plasmalemmal vesicle-associated protein (PLVAP) is a peritubular capillaries (PTC) marker, and the notch ligand pathway delta-like ligand-4 (DLL4) is a microvascular metabolic sensor that regulates angiogenesis, but their role in the kidney in obesity is undetermined. We hypothesized that human obesity dysregulates the renal microcirculation, detectable by elevated urinary levels of renal endothelial cell-derived PLVAP+/DLL4+ uEVs

Methods: Blood and urine samples were prospectively collected from obese patients (OB, n=22) and lean kidney donors (n=11). uEVs were quantified and characterized for CD31, PLVAP, CD144, and DLL4 expression and their relationship with body mass index (BMI), insulin, and plasma angiopoietin levels. PTCs were also counted in time-0 biopsies of OB (n=20) and lean (n=17) kidney donors

Results: OB patients had preserved renal function and elevated insulin levels(Table). The total uEV number was similar, but the fraction of CD31-/PLVAP+/CD144-/DLL4+ uEVs was higher in OB and directly correlated with BMI, plasma angiopoietin, and insulin levels (Fig1). Congruently, PTC density and count/tubule were higher in OBs than lean(Fig2)

Conclusions: Obese patients show elevated urinary markers of renal PTC proliferation that correlate with obesity severity. These may aim to support tubular enlargement and indicate the development of early microvascular kidney injury that might be useful in the risk stratification of obese patients

RNA-Binding Protein Hu Antigen R (HuR) Mediates Kidney Fibrosis in Mice with CKD Induced by Deoxycorticosterone Acetate-Salt and Angiotensin II Infusion

Lili Zhuang, Zhou Wang, Yufeng Huang. *University of Utah Health, Salt Lake City, UT.*

Background: The RNA-binding protein Hu antigen R (HuR) is pivotal in modulating mRNA turnover and translation of genes implicated in immune response and inflammation. Elevated HuR levels have been observed in patients with chronic kidney disease (CKD), yet its specific role in CKD pathogenesis remains elusive. This study aims to investigate the involvement of HuR in progressive renal injury resulting from deoxycorticosterone acetate-salt (DOCA) and angiotensin II (AII) infusion in mice, utilizing the HuR inhibitor KH3.

Methods: Male mice at age of 12 weeks were subjected to DOCA+AII infusion along with 1% NaCl in drinking water. Subsequently, they were treated either with or without the HuR inhibitor, KH3 (administered at 40mg/kg-BW daily via intraperitoneal injection) (DOCA+AII+KH3) for a duration of 3 weeks. Control mice (NC) received saline injections without any infusion.

Results: DOCA+AII infusion significantly increased HuR expression by 2.67 folds in the kidneys, a response effectively mitigated by KH3 treatment. Notably, KH3-treated mice exhibited a partial reduction in blood pressure compared to untreated DOCA+AII mice (SBP, 137.7±7.58 vs. 158.1±3.97 mmHg, P<0.05 vs. DOCA+AII). Additionally, KH3 treatment arrested the progression of albuminuria and led to a significant reduction in impaired renal function, kidney hypertrophy, and glomerular and tubulointerstitial fibrosis by 47.5%, 39.9%, 47.5% and 88.8% respectively (P<0.01), compared to untreated DOCA+AII mice. These improvements were accompanied by ameliorated podocyte injury, evidenced by reduced podocyte foot process effacement; and alleviated tubular injury, indicated by decreased mRNA and protein expression of KIM-1, NGAL and OPN in tubular cells, compared with untreated DOCA+AII mice. Furthermore, KH3 treatment significantly attenuated renal macrophage infiltration and the production of NF-kB-p65, Nox2, TGFß1 and Wisp1, markers of inflammation, oxidative stress and major profibrotic modulators induced by DOCA+AII infusion.

Conclusions: Our findings suggest that HuR is upregulated in DOCA+AII induced kidney injury in mice and contributes to hypertensive, oxidative stress, inflammatory, and fibrotic pathways associated with CKD. Inhibition of HuR holds promise as a potential therapeutic strategy for CKD treatment.

Single-Cell Detection of Somatic Copy Number Alterations in Human Kidney by Chromatin Accessibility Profiling

Xinyi E. Chen,[1] Nancy Zhang,[1] Parker C. Wilson.[2] [1]*University of Pennsylvania Wharton School, Philadelphia, PA;* [2]*University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

Background: Loss of Y chromosome (LOY) is the most common somatic chromosomal alteration (mCA) in men. Until recently, it was thought that LOY was unique to hematopoietic tissue, but it also occurs in the kidney and is enriched in injured proximal tubule (PT) cells – a cell state defined by a pro-inflammatory signature that predicts kidney function decline (Wilson et al. Genome Biology 2023). We hypothesize LOY is an indicator of genomic instability, however, LOY is not a perfect marker because the majority of injured PT cells do not have LOY and it is unclear if similar mCA occur in female cells.

Methods: We realigned and preprocessed single-cell multiome or single-cell ATAC (snATAC) datasets using SnapATAC2, integrated them with scvi-tools and annotated cell barcodes using established markers. To detect mCA, we modeled ATAC fragment coverage as a proxy of single-cell copy number. For our model, let X_{ci} be the fragment coverage of region i (which can be a chromosome arm) and cell c. We assume a negative-binomial model for the fragment coverage, $X_{ci} \sim NB(\alpha_c \beta_i \gamma_{ci}, \Phi_{ci})$ where α_c is the cell-specific library size, β_i is a region-specific background bias, and Φ_{ci} is a cell- and region-specific dispersion, to be estimated by the observed variance-mean relationship in the data. The parameter γ_{ci}, which captures the cell-specific fold enrichment/depletion of fragment coverage for region i, is an estimate of copy number state.

Results: We analyzed 526,903 kidney cells from 99 male or female donors with or without CKD. Injured PT (PT_VCAM1, PT_PROM1), endothelial cells (ENDO), fibroblasts (FIB_VSMC_MC) and mononuclear cells (MONO) had approximately two-fold higher proportion of LOY than other cell types (Figure 1A). mCA involving the X chromosome were enriched in some of the same cell types in women, but at a lower proportion than LOY (Figure 1B). Both LOY and X chromosome mCA were associated with an increased autosomal mCA burden.

Conclusions: Somatic mCA are enriched in specific kidney cell types and may provide insight into factors that drive CKD progression.

FR-PO1205

Evaluation of Glucocorticoid Metabolism in CKD as a Therapeutic Target against Sarcopenia

Michael S. Sagmeister,[1,2] Ana Crastin,[1] Angela E. Taylor,[1] Simon W. Jones,[1] Lorraine Harper,[1,2] Rowan S. Hardy.[1] [1]*University of Birmingham College of Medical and Dental Sciences, Birmingham, United Kingdom;* [2]*Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom.*

Background: Skeletal muscle loss and weakness, termed sarcopenia, has been linked to dysregulation of glucocorticoid hormones in CKD. Glucocorticoid excess is favoured by loss of the renal enzyme 11β-hydroxysteroid dehydrogenase (11βHSD) type 2 that inactivates cortisol to cortisone. The cortisol-activating counterpart, 11βHSD type 1, which is upregulated in skeletal muscle in response to inflammation, has not yet been investigated in this context. This study tests whether raised glucocorticoid activation by 11βHSD1 in skeletal muscle contributes to sarcopenia in CKD and represents a novel therapeutic target.

Methods: An observational study recruited 17 patients with pre-dialysis CKD (eGFR <30) and 14 healthy volunteers aged 60-80 years. Muscle phenotype was assessed by bio-impedance body composition, grip strength and short physical performance battery. Steroid hormones were measured in early morning serum and 24-hour urine by liquid

chromatography/mass spectrometry. The rate of enzymatic cortisol activation by 11βHSD1 in muscle was determined in vastus lateralis biopsies *ex vivo*. Using the adenine mouse model of renal impairment, an animal experiment examined the therapeutic potential of 11βHSD1 suppression to protect against muscle atrophy.

Results: Serum cortisol is similar in CKD, while serum cortisone is reduced relative to healthy controls ($p<0.0001$). Serum cortisol or 24-hour urinary glucocorticoid excretion are not associated with skeletal muscle mass or strength. In contrast, 11βHSD1 enzymatic activity in skeletal muscle correlates negatively with muscle strength independent of age and gender ($p=0.002$). Despite its association with muscle strength, 11βHSD1 activity is not significantly different between patients with CKD and healthy volunteers. In the mouse model of renal impairment, genetic silencing of 11βHSD1 fails to improve skeletal muscle atrophy.

Conclusions: Low muscle strength correlates with cortisol activation by 11βHSD1 in skeletal muscle. However, renal impairment by itself does not alter 11βHSD1 function in muscle, and 11βHSD1 suppression does not prevent muscle atrophy in a mouse model of CKD. Future studies may explore to what extent glucocorticoids contribute to sarcopenia in human CKD through alternative mechanisms, or whether 11βHSD1 is significant for sarcopenia development in settings unrelated to CKD.

FR-PO1206

Role and Mechanism of PCK2 in Regulating Fatty Acid Oxidation during Kidney Interstitial Fibrosis

Wei Xiong, Chun Zhang. *Huazhong University of Science and Technology, Wuhan, China.*

Background: Renal interstitial fibrosis is the final stage of the progression of chronic kidney disease. Currently, the means to restore or prevent the renal fibrosis process are still very limited. Abnormal metabolism is an important concomitant feature of renal fibrosis, in which the sharp reduction of fatty acid oxidation capacity is the key factor of tubulointerstitial energy metabolism failure. Phosphoenolpyruvate carboxyl kinase 2 (PCK2) is a mitochondrial subtype of phosphoenolpyruvate carboxyl kinase (PEPCK), widely involved in cell metabolism and plays an important role in maintaining cell homeostasis. However, the role and mechanism of PCK2 in renal interstitial fibrosis have not yet been revealed.

Methods: Western blot, immunoblot analysis and immunohistochemistry were used to detect the expression of PCK2. PCK2 over expression lentivirus in HK2 cells and proximal tubule-specific transgenic mice were used to upregulate PCK2. EMT related markers, collagen I, fibronectin, and Hippo signal pathway related makers were detected by western blot and immunofluorescence. Lipid metabolism-related product kits such as triglyceride kits, fatty acid kits, fatty acid synthase kits, and cholesterol detection kits were applied to measure the specific content changes of various lipid components.

Results: PCK2 expression is significantly decreased in renal interstitial fibrosis and is highly correlated with the severity of fibrosis. Overexpression of PCK2 can reduce renal interstitial fibrosis. Further research reveals that PCK2 is enriched with multiple lipid metabolism pathways. PCK2 increases the level of renal tubular fatty acid oxidation and activate the Hippo pathway.

Conclusions: PCK2/Hippo axis is involved in the progression of renal interstitial fibrosis by regulating fatty acid oxidation.

Dapagliflozin Ameliorates High-Fat, Diet-Induced, Megalin-Mediated Autolysosomal Disorders in Mouse Proximal Tubules

Kazuya Takemoto, Michihiro Hosojima, Hideyuki Kabasawa, Ichiei Narita, Akihiko Saito. *Niigata University, Niigata City, Japan.*

Background: Megalin is a multi-ligand endocytic receptor located in the apical membrane of proximal tubules (PTs). Our prior study (*JASN* 2016) elucidated that megalin-mediated endocytosis of glomerular-filtered lipotoxic substances drives tubulo-glomerular alterations in mice fed a high-fat diet (HFD). In this model, pathological vacuolation appears particularly in segment 2 (S2) of PTs due to megalin-dependent autolysosomal disorders. Receptor-mediated endocytosis (RME) is the primary pathway for substance uptake in S1 (greater than S2), while fluid-phase endocytosis (FPE) prevails in S2, which is vulnerable to metabolic overload due to its less advanced endolysosomal systems. This investigation aims to explore the impact of dapagliflozin, an SGLT2 inhibitor, on autolysosomal disorders in PTs of HFD-fed mice and its underlying mechanism.

Methods: Nine-week-old male C57BL/6J mice were fed an HFD with oral administration of dapagliflozin (1mg/kg body weight/day) or vehicle for 28 days (n=10 each). Kidney sections underwent PAS staining, and Image-Pro Plus ver. 7.0 evaluated the vacuolar area/cortical tubular area. Urinary C-megalin, a marker for lysosomal overload in PTs (*Diabetes* 2017), was also measured. Renal megalin expression was gauged via immunoblotting, qPCR, and immunohistochemistry. Megalin's endocytic function was assessed by measuring the urinary excretion of α_1-microglobulin, an endocytic ligand of megalin. RME and FPE were scrutinized on kidney sections post intravenous injection of fluorescent lysozyme and dextran, respectively, in 9-week-old male kidney-specific conditional megalin KO mice and littermate controls, and C57BL/6J mice receiving dapagliflozin or vehicle for 5 days.

Results: Dapagliflozin administration significantly reduced the vacuolar area/cortical tubular area and urinary C-megalin excretion in HFD-fed mice. While renal megalin expression remained unaltered, urinary α_1-microglobulin excretion increased with dapagliflozin administration. In megalin KO mice, the uptake of fluorescent lysozyme and dextran in PTs decreased. Similarly, the administration of dapagliflozin to mice diminished the uptake of both tracers in PTs.

Conclusions: Dapagliflozin ameliorates HFD-induced, megalin-mediated autolysosomal disorders particularly in S2 of PTs by suppressing both RME and FPE dependent on megalin.

Evaluating the Role of Urinary Volatile Organic Compounds in CKD

Henry Wu,[1,2] Malcolm Possell,[5] Long T. Nguyen,[1,3] Wenbo Peng,[4] Carol A. Pollock,[1,3] Sonia Saad.[1,3] *[1]Kolling Institute of Medical Research, St Leonards, NSW, Australia; [2]University of New South Wales, Sydney, NSW, Australia; [3]Royal North Shore Hospital, St Leonards, NSW, Australia; [4]University of Technology Sydney, Sydney, NSW, Australia; [5]The University of Sydney, Sydney, NSW, Australia.*

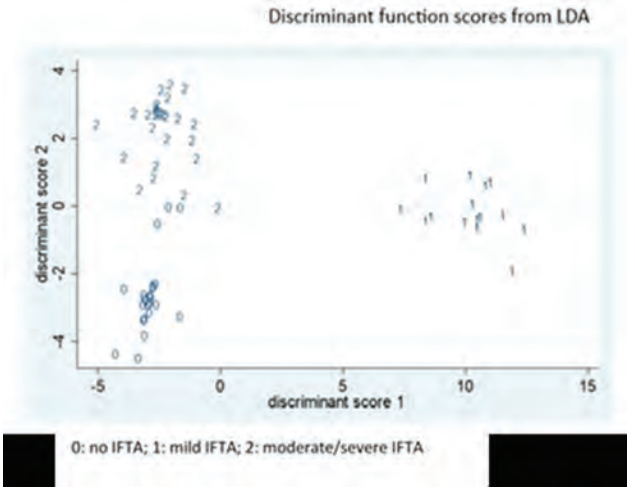
Background: Volatile organic compounds (VOCs) are gaseous products of metabolic processes in organisms which are conventionally released with greater abundance in disease. Whether urinary VOCs are valuable as a non-invasive source in reflecting CKD status is unclear.

Methods: Adults aged 18-75 years with kidney biopsy performed were included. All biopsy samples had an interstitial fibrosis and tubular atrophy (IFTA) grade scored by standardized assessment. Pre-biopsy urine were collected. Urine supernatant was extracted from residue and sampled for stir bar sorptive extraction, followed by gas chromatography–mass spectrometry (GC-MS). Post-processing of GC-MS data involved measuring mass-to-charge ratios and fragment patterns for identification and quantification of individual VOCs. Linear discriminant analysis (LDA) assessed the ability of urinary VOCs in discriminating between no IFTA, ≤25% (mild) IFTA and >25% (moderate/severe) IFTA. Linear regression analysis adjusting for age, sex, eGFR and diabetes mellitus status was conducted to determine significantly upregulated urinary VOCs with IFTA progression.

Results: 64 study participants were included (22 individuals no IFTA, 15 individuals mild IFTA, 27 individuals moderate/severe IFTA). LDA demonstrated individuals with no IFTA, mild, and moderate/severe IFTA could easily be separated by their urinary VOCs profile (see figure). 34 VOCs were identified to be helpful in correctly classifying between the IFTA groups, of which 7 VOCs were significantly upregulated in the mild IFTA compared to the no IFTA group and 3 VOCs were significantly upregulated in the moderate/severe IFTA compared to the mild IFTA group ($p<0.05$). 'Benzaldehyde, 4-methyl' is positively associated with IFTA progression across all stages ($p<0.05$).

Conclusions: We report novel links between urinary VOCs and tubulointerstitial histopathology. Urinary VOCs may have a clinical diagnostic role in CKD going forward.

Funding: Government Support - Non-U.S.



FR-PO1209

Aryl Hydrocarbon Receptor Promotes Kidney Fibrosis via Accelerating Cell Senescence in Tubular Epithelial Cells

Qian Ren, Hui Li, Liang Ma, Ping Fu. *Department of Nephrology, Kidney Research Institute, West China Hospital of Sichuan University, Chengdu, China*.

Background: Chronic kidney disease (CKD) has a high prevalence worldwide and tubulointerstitial fibrosis is considered the final convergent pathway of progressive CKD regardless of etiology. However, mechanisms underlying kidney injury-induced fibrosis largely remain unknown. The aryl hydrocarbon receptor (AhR) is a well-known ligand-activated cytoplasmic transcription factor that contributes to cellular responses against environmental toxins and carcinogens. AhR activity is strongly implicated throughout the course of CKD but its certain role and underlying mechanism remains unknown.

Methods: AhR expression was examined in the kidney specimens of CKD patients as well as in the kidneys of mouse models with experimental kidney fibrosis (unilateral ureteral obstruction [UUO], adenine nephropathy [Aden], and aristolochic acid-induced nephrotoxicity [AA]). The potential role of AhR in renal fibrosis was further validated by AhR conditional knock out in mice or AhR siRNA in TCMK-1 cells. ATAC-seq combined with RNA-seq was employed to explore the underlying mechanisms.

Results: Increased AhR expression was observed in the kidneys of both CKD patients of various etiology and three mouse models with kidney fibrosis. The elevated AhR expression was mainly located within tubualr cells and was associated with the levels of Scr and eGFR in CKD patients. Tubule-specific knock out of AhR in mice alleviated UUO- and Aden-induced renal fibrosis. Mechanistically, in tubular epithelial cells, AhR exerted a profibrotic role via a NF-κB-dependent signaling. AhR promoted the activation of NF-κB by regulating the transcription of IκBα and thus accelerating tubular senescence. Pharmacological inhibition of AhR ameliorated tubular senescence and renal fibrosis in both animal models and TCMK-1 cells.

Conclusions: Tubular AhR plays an important role in kidney fibrosis by suppressing profibrotic NF-κB signaling. Hence, our findings suggest that modulating the activity of tubular AhR may be a new therapeutic option for treating tubulointerstitial fibrosis and subsequent CKD.

Quinolinic Acid Excess May Promote Kidney Fibrosis

Marie Christelle Saade, Amanda J. Clark, Valerie Etzrodt, Kyle Q. Vu, Samir M. Parikh. Parikh Lab. *The University of Texas Southwestern Medical Center, Dallas, TX*.

Background: Acute kidney injury (AKI) and chronic kidney disease (CKD) are characterized by decreased NAD+ biosynthesis. The de novo NAD+ pathway, one of the three pathways for NAD+ biosynthesis, involves quinolinic acid, a metabolite catalyzed by quinolinate phosphoribosyl transferase (QPRT) and converted into NAD+. Primarily recognized as a neurotoxin acting through the NMDA receptor, little is known about quinolinic acid's kidney effects. We hypothesized that sustained accumulation of quinolinic acid might worsen renal health and favor fibrosis.

Methods: We used 8-week-old wild-type C57BL/6 male mice. Two injury models were employed: an acute injury with cisplatin 25 mg/kg harvested on day 3 and a CKD model with folic acid (FA) 250 mg/kg harvested on day 14. We primarily measured fibrosis and kidney injury markers using qPCR, serum BUN, and creatinine. We compared 8 to 72-week-old wild-type (WT) mice. We generated conditional inducible mice that overexpress QPRT with doxycycline 0.2 mg/mL. FA model WT mice were harvested at 0, 36 hours, day 7, and day 14 for metabolomics analysis. Quinolinic acid 0.5 g/L was administered for 14 days, and for 28 days with the FA model starting at day 14. Cell cultures assessed the profibrotic effect of quinolinic acid (1 μM). Memantine 250 nM was applied to pericytes +/- quinolinic acid.

Results: Our results verified the age-related decline in QPRT and the progressive accumulation of quinolinic acid with CKD development. Renal tubular induction of the QPRT enzyme reduced excess quinolinic acid and protected renal function in mice induced with cisplatin. Excessive quinolinic acid administration achieved serum levels comparable to CKD and was sufficient to worsen baseline renal function. Introducing quinolinic acid in the FA model exacerbated kidney damage. Application of quinolinic acid to various cell types revealed a specific profibrotic response exclusively in pericytes, a population of cells responsible for fibrosis. Memantine, a NMDA receptor antagonist, protected pericytes from the fibrotic effects of quinolinic acid.

Conclusions: Quinolinic acid accumulation may contribute directly to CKD progression. As CKD progresses, the QPRT enzyme expression decreases, and quinolinic acid accumulates. This metabolite may act through NMDA receptors on pericytes to promote a fibrogenic program. Further studies may unveil new ways to target renal fibrosis.

Glutamine Metabolism Inhibition Alleviates Kidney Fibrosis through the Immunometabolic Axis

Huang-Yu Yang,[1,2] Chung Ying Tsai,[1] Kuan-Hsing Chen,[1] Chih-Wei Yang.[1,2] *[1]Chang Gung Memorial Hospital Linkou, Taoyuan, Taiwan; [2]Chang Gung University, Taoyuan, Taiwan.*

Background: Chronic kidney disease manifests as a gradual loss of kidney function, which is partly attributed to fibrosis. An inflammatory response is elicited in a unilateral ureteral obstruction (UUO) model and contributes to kidney fibrosis. A glutamine antagonist, 6-diazo-5-oxonorleucine (DON), acts as an immune modulator. However, the role of glutamine metabolism in kidney fibrosis remains unclear.

Methods: Fibrosis induced by UUO is reduced in DON-treated mice than that in untreated mice. Single-cell RNA sequencing is used to characterize the effects of DON on immune and proximal tubule (PT) cells following UUO.

Results: DON induces oxidative stress in T cells infiltrating the kidney and skews the T cells toward regulatory phenotype via HIF-1α-KDM4C-ROS axis. Hypomethylation of the FOXP3 promoter occurred under glutamine deprivation with elevated levels of reactive oxygen species, a result of fatty acid β-oxidation and attenuated intracellular glutathione levels. Moreover, infiltrating macrophages show an Mmp12+ reparative phenotype. Patrolling monocytes decrease upon DON treatment. The percentage of aged neutrophils also increases, showing an apoptotic phenotype. DON alleviates UUO-induced hypoxia and increases oxidative phosphorylation in PT cells. DON-treated kidneys show reduced collagen and CD52 levels and upregulated the macrophage migration inhibitory factor communication pathway.

Conclusions: Hence, the inhibition of the glutamine pathway reduces kidney fibrosis after injury and can be exploited as a therapeutic strategy for chronic kidney fibrosis.

FR-PO1212

Glutamine Reprograms Metabolism in CKD-Induced Pathological Cardiac Remodeling via the GLS1/GLUD1 Axis

Linnan Bai,[1] Yi Wang,[2] Minchao Kang,[1] Qiu-yu Li,[3] Junnan Wu.[1] *[1]Zhejiang University School of Medicine Sir Run Run Shaw Hospital, Hangzhou, China; [2]The First Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou, China; [3]Zhejiang University School of Medicine Children's Hospital, Hangzhou, China*.

Background: CKD-induced cardiac remodeling is characterized by myocardial hypertrophy, however, available therapeutic options are limited. Here, we employed a multi-omics approach to analyze a total of 36 mice hearts to detect cardiac structural changes.

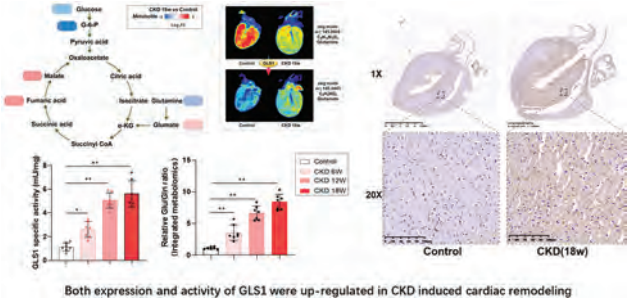
Methods: We performed 5/6 nephrectomy surgery on mice and collected samples at multiple time points during disease progression (6, 12, and 18 weeks post-surgery). Initially, we performed snRNA-seq and a comprehensive metabolomics strategy including in situ metabolomic was conducted to obtain the in situ metabolic profiles. We screened out the most significantly changed metabolic pathway and corresponding rate-limiting enzymes. Using targeted metabolomics and Western blotting, we validated metabolic reprogramming signatures. We further created CKD mice with conditional knockout of the rate-limiting enzyme in cardiomyocytes and monitored the degree of cardiac tissue damage.

Results: Our findings illustrate the time course of changing gene expression patterns for multiple CKD stages. The TCA cycle was defective in the chronic phase but was transiently activated in the very early stages of CKD. The glutaminolysis pathway, however, was persistently activated throughout the time course and reached a peak at

18 weeks post-surgery, especially in left ventricle and interventricular septum region. Our gene-metabolite interaction network showed that glutaminase 1 (GLS1), the rate-limiting enzyme in glutaminolysis, and its target gene glutamate dehydrogenase 1 (GLUD1) were activated and up-regulated in CKD cardiomyocytes. Cardiac-specific deletion of GLS1 was achieved, and this ameliorated cardiac dysfunction and cardiomyocyte hypertrophy in response to CKD. At the mechanistic level, GLS1 controls the epigenetic expression of pro-hypertrophic genes. Moreover, GLS1 and GLUD1 are both transaminases, leading to the accumulation of ammonia in mitochondria.

Conclusions: These findings suggested the GLS1/GLUD1 axis plays an essential role in maintaining a homeostatic metabolic response in cardiomyocytes under CKD.

Funding: Government Support - Non-U.S.



Both expression and activity of GLS1 were up-regulated in CKD induced cardiac remodeling

Effects of the Preservative Sodium Benzoate and a High-Fat Diet on Kidneys

Anna Lipinski, Alayna R. Wells, Adam E. Gaweda, Michael Merchant, Loretta L. Jophlin, Michelle T. Barati. *University of Louisville, Louisville, KY.*

Background: Sodium Benzoate (SB) is used as a food preservative and generally recognized as safe by the Food and Drug Administration (FDA). Reports suggest altered kidney function and oxidative stress in kidneys of mice exposed to SB. However, effects of dietary SB exposure on renal structures are unclear. Given the rising prevalence of obesity and increased risk of kidney disease with intake of ultraprocessed foods, effects of SB at dosages relevant to human dietary exposures coupled to a high fat diet, remain to be determined. This study addressed the hypothesis that SB with a high fat diet alters kidney histology and anti-oxidative mechanisms.

Methods: 5-week-old male and female mice were assigned to either control diet (CD; 13% Kcal fat) or high fat diet (HFD; 42% Kcal fat). After 6 weeks, animals continued on their diet and assigned to groups gavaged with distilled water or distilled water containing SB (99mg/kg bw) daily for 28 days. Based on intake, this exposure approximated a highly processed diet where all food contained 0.1% added SB (FDA limit). Kidney sections were PAS-stained for histologic analysis of tubulo-interstitium and glomeruli. Protein abundance of superoxide dismutase (SOD-1), fibronectin, and glutamyl-cysteine synthetase (GCS) analyzed by western blot. Three-way ANOVA used to compare diet and SB effects between female and male. Two-way ANOVA used to compare diet and SB effects within either sex group.

Results: Male mice had higher body weight than female mice in and all groups. Increased body weight from HFD was not altered by SB in male mice. Kidneys of mice in HFD, SB, and HFD+SB groups had focal areas of interstitial cell proliferation and fibrosis. Male mice on HFD had increased tubule vacuolization and a trend for increased glomerular mesangial matrix. Focal tubule injury/necrosis detected in kidneys of mice in HFD+SB groups. Abundance of SOD-1 was unaltered in all diet/treatments, while GCS was lower in kidneys of male mice.

Conclusions: In conclusion, HFD and SB increased kidney tubule-interstitial fibrotic foci and tubule injury, suggesting that long term dietary intake of highly processed foods may cause kidney fibrosis, a hallmark of chronic kidney disease. Additionally, these findings suggest that HFD and SB may reduce protective measures against oxidative stress, a characteristic consistent with kidney disease.

Blockade of Tubule-Specific Mitochondrial Calcium Uniporter (MCU) Augments Renal Fatty Acid Oxidation in High-Fat Diet-Induced Obese Mice

Soumya Maity, Pragya Singh, Ian M. Tamayo, Afaf Saliba, Hak Joo Lee, Richard Montellano, Kumar Sharma. *The University of Texas Health Science Center at San Antonio, San Antonio, TX.*

Background: Impaired fatty acid oxidation (FAO) is a consequence of obesity-induced chronic kidney disease. Proximal tubular cells depend on FAO to fulfill their high energy demand. The mitochondrial Ca^{2+} uniporter (MCU) complex mediates acute mitochondrial Ca^{2+} influx to drive mitochondrial bioenergetics. However, loss of *Mcu* is reported to enhance muscle performance with a preferential shift toward fatty acid metabolism. Here, we examined the role of MCU in renal fatty acid metabolism in a high-fat diet (HFD)-induced obese model.

Methods: 8-12 weeks wildtype (WT) and tubule-specific *Mcu* knock-out (*Mcu*$^{fl/fl}$ X *Pax*8-Cre$^{+/-}$; *Mcu* KO) male mice were fed with HFD for six months. MALDI-MSI followed by untargeted analysis using MetaboAnalyst 6.0 was carried out to evaluate the distribution of lipid species in the kidney cortex. The mitochondrial oxygen consumption rate (OCR) was used as a functional readout of mitochondrial bioenergetics. Histological staining, western blots, and biochemical assays were employed to establish the mechanism.

Results: Loss of MCU did not affect kidney growth and maturation. Histological staining showed a significant decrease in the size and number of lipid droplets in renal tubules of *Mcu* KO compared to WT mice under HFD stress. Lipid droplet-associated protein perilipin 2 was decreased in HFD *Mcu* KO mouse kidneys. MSI data demonstrated that kidneys from HFD group accumulated several lipid species, notably different subtypes of phosphatidylcholine and ceramides, in WT tubules. These lipid species were significantly reduced in *Mcu* KO tubules. Palmitic acid treatment in MCU knockdown human proximal tubular (HK2) cells showed a higher OCR and less lipid accumulation. The upregulation of CPT1 in HFD *Mcu* KO mice's kidneys suggests that MCU loss facilitates FAO in renal tubules. Moreover, increased L-carnitine and phosphorylation of pyruvate dehydrogenase α1 at ser-293 in kidneys of *Mcu* KO mice with regular diet indicate that renal tubules undergo metabolic reprogramming towards favorable FAO in absence of MCU to combat lipid stress.

Conclusions: Loss of MCU promotes fatty acid oxidation in kidney tubules and reduces renal lipid accumulation in high-fat diet stress. These findings open possibilities for treating obesity-induced lipotoxicity in the kidney by tubule-specific MCU inhibition.

Dysregulated Intestinal Group 3 Innate Lymphoid Cell (ILC3) Fatty Acid Uptake Mediates Susceptibility to Colitis in Kidney Injury

Ziwen Tang, Zhou Liang, Chang-Jian Zhu, Yi Zhou. *The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.*

Background: Renal injury is commonly accompanied by systematic disorder and remote organ dysfunction. Patients with renal injury often display gastrointestinal symptoms and increased risk of colitis. However, the role and underlying mechanisms of intestinal immunity in mediating renal injury-associated colitis susceptibility have not yet been elucidated.

Methods: Mice that have undergone sham surgery or unilateral ureteral obstruction (UUO) were exposed to dextran sodium sulfate (DSS) to induce experimental colitis. To clarify the contribution of group 3 innate lymphoid cells (ILC3s) in renal injury-associated colitis, ILC3s-deficient mice (*Rorc*$^{GFP/GFP}$ mice) or ILC3s-reconstruction mice were exposed to DSS, and then severity of colitis was measured. Single-cell RNA sequencing of intestinal ILC3s was performed to identify their functions and molecular regulatory mechanisms. And flow cytometry was used to detect the corresponding changes in intestinal ILC3s. ILC3s were stained with BODIPY C16 and BODIPY 493/503 to assess their capacity of fatty acid uptake and storage. IL-22 secretion from intestinal ILC3s and the severity of colitis were measured in sham or UUO mice after administration of SSO, a fatty acid uptake inhibitor.

Results: Compared to sham-DSS controls, UUO-DSS mice exhibited exacerbated colitis, faster weight loss, shorter colon length, and higher DAI and histological scores. The exacerbation of colitis also existed in ILC3-complete *Rorc*$^{GFP/+}$-UUO mice, which was abolished in ILC3-deficient *Rorc*$^{GFP/GFP}$ mice. In contrast, colitis in UUO-intestinal-ILC3s-reconstituted mice was more severe than in mice receiving sham-intestinal ILC3s. Further analysis revealed that UUO-ILC3s had significantly reduced IL-22 secretion and markedly upregulated fat digestion and absorption pathways, which was confirmed by higher MFI of BODIPY C16 and BODIPY 493/503 than sham-ILC3s. SSO inhibition of UUO-ILC3s fatty acid uptake restored IL-22 expression and prevented UUO-induced colitis exacerbation.

Conclusions: Our data demonstrate that ILC3s are required and sufficient to mediate the susceptibility to colitis associated with renal injury. Mechanistically, upregulation of fatty acid absorption and storage in UUO-ILC3s leads to impaired IL-22 secretion and loss of intestinal barrier protective function.

Astragaloside Ameliorates Kidney Fibrosis by Inhibiting the Sonic Hedgehog Signaling Pathway

Long Mei, Weijian Xiong, Fan Li. *Chongqing Traditional Chinese Medicine Hospital, Chongqing, China.*

Background: Sonic hedgehog (SHH) signaling plays a critical role in promoting renal fibrosis.*Astragalosid* (*As-IV*) is the main integrete of the traditional Chinese medicine(TCM) *Astragalus membranaceus*(*Huangqi*). Our preliminary researches indicated that intervention with some TCM formulas containing *Huangqi* led to a

significant amelioration of renal interstitial fibrosis. This study aims to explore the mechanism by which *As-IV* mitigates renal interstitial fibrosis in mice model of unilateral ureteral obstruction(UUO) through the modulation of the SHH signaling pathway.

Methods: Thirty male mice were randomly assigned into five groups: a control group, a UUO model group, and three *As-IV* treatment groups with low, medium, and high doses. Except for the control group, the other four groups underwent ligation of a single ureter to establish an animal model of renal interstitial fibrosis. The *As-IV* groups was administered *As-IV* via daily gavage for 14 days. Then Scr and BUN were measured in all groups. Renal tissue morphology was observed using HE staining, and Masson's trichrome staining was employed to assess the deposition of extracellular matrix(ECM) in the renal tissue. The expression of SHH and its downstream signaling molecules Gli1 and Snail was detected using Western blot analysis.

Results: Compared with the control group, the UUO model group exhibited elevated levels of Scr and BUN, increased expression of ECM, and heightened levels of SHH. The protein expression of Gli1 and Snail were markedly upregulated ($P < 0.05$). In contrast to the UUO model group, *As-IV* groups significantly reduced Scr and BUN levels, diminished ECM deposition, and downregulated the levels of SHH as well as the protein expression levels of Gli1 and Snail(figure 1).

Conclusions: *As-IV* has been shown to improve renal function and inhibit renal interstitial fibrosis in mice model of UUO, with its effects potentially being associated with the blockade of the SHH signaling pathway.

Omega-3 Fatty Acid Mitigates Mitochondrial Dysfunction and Modifies Renal Myostatin Expression in Adenine-Induced Uremic Rats

Binna Park, Dongeun Yang, Soy Kang, Won Suk An. *Dong-A University, Busan, Republic of Korea.*

Background: Mitochondrial dysfunction and inflammation play a central role in the progression of chronic kidney disease. Myostatin may be related to inflammation but expression of renal myostatin remains unclear. We aimed to investigate whether omega-3 fatty acids (FA) regulate mitochondrial dysfunction in adenine-induced uremic rats. We also tried to elucidate whether omega-3 FA affects renal myostatin expression and renal mitochondrial morphology.

Methods: Male Sprague-Dawley rats were fed diets containing 0.75% adenine and 2.5% protein for three weeks. Rats were randomly divided into four groups that were fed diets containing 2.5% protein and saline with cholecalciferol (3000 IU/kg/week) or omega-3 FA (300 mg/kg/day) with cholecalciferol by gastric gavage for two weeks: normal control, adenine control sacrificed at 3weeks, adenine control sacrificed at 5weeks, and omega-3 FA group sacrificed at 5weeks. The renal expression of myostatin and mitochondrial mediators was examined by western blot analysis. Renal mitochondrial morphology was evaluated using transmission electron microscopy.

Results: Compared to normal, serum creatinine in adenine control was increased and improved in the omega-3 FA group. Compared with normal, PGC-1α, SIRT1/3, and Nrf2 were down-regulated in adenine control. DRP-1 was up-regulated in adenine control and recovered with omega-3 FA supplementation for 2 weeks. PINK1, BNIP3, and NIX were down-regulated in adenine control and recovered in the omega-3 FA group. Compared to normal, renal myostatin expression was continuously downregulated at 3 weeks and 5 weeks and recovered with omega-3 FA. The size and number of tubular mitochondria were decreased at 5 weeks and mitigated with omega-3 FA supplementation for 2 weeks.

Conclusions: Omega-3 FA is beneficial for mitochondrial dysfunction and morphology in uremic rats. Further studies are necessary to find the pathogenic mechanism for decreased renal myostatin expression in uremia.

FR-PO1218

Urinary Clearances of Indoxyl Sulfate and P-cresol Are Directly Correlated with the Functional Stress Response of the Proximal Tubule

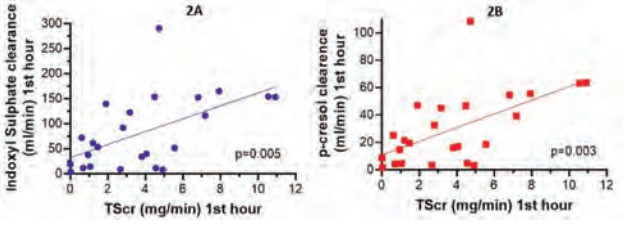
Magdalena Madero,[1] Ana K. Fernandez Yepez,[1] Jesse C. Seegmiller,[3] Guadalupe M. Montesinos Ojeda,[1] Alan J. Guzmán Portillo,[1] Aurora I. Estrada Escamilla,[1] Bernardo Rodriguez-Iturbe.[1,2] *[1]Instituto Nacional de Cardiologia Ignacio Chavez, Ciudad de Mexico, Mexico; [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [3]University of Minnesota Twin Cities, Minneapolis, MN.*

Background: Urinary clearance of cardiotoxic and nephrotoxic indoxyl sulfate (IS) and p-cresol (pC) largely depends on the function of organic anionic (OAT) and cationic (OCT) transporters of the proximal tubule. Therefore, we examined the relationship between the clearance of IS and pC and the functional stress response of OAT and OCT in normal individuals and in patients with reduced glomerular filtration rate (GFR)

Methods: Studies were performed in 24 patients (GFR range 14 -129 ml/min/1.73m^2). Serum and urine IS and pC were determined by mass spectrometry for clearance determinations (UV/P). GFR (iohexol), serum and urinary creatinine (autoanalyzer) and urinary furosemide (HPLC), were assayed to determine the tubular secretion of creatinine (TScr) and furosemide (TSfr), hourly for 4 hours after the oral administration of 5g of creatinine and 1-1.5 mg of furosemide intravenously. This was intended to induce maximal stimulation of OCT and OAT, respectively. Studies were performed with induced water diuresis. Complete bladder emptying was assured via ultrasound evaluation.

Results: TScr and TSfr (mg/min, mean±SD) were higher in the first hour (KDIGO 1: TScr = 4.1±2.44, TSfr =0.4±0.15; KDIGO 2: TScr= 6.8±4.37, TSfr= 0.4±0.29; KDIGO 3: TScr= 3.2±1.88, TSfr= 0.3±0.15; KDIGO 4: TScr= 2.3±2.08, TSfr= 0.2±0.13) and became stable and similar after the second hour. There was no significant correlation between GFR and TScr or TSfr (Figure 1A-1B). The TScr and TSfr of the first hour correlated significantly with the clearances of IS and pC. The significant correlation was observed between stimulated TScr and IS clearance (p=0.005) and pC clearance (p=0.003 (Figure 2A - 2B)

Conclusions: The urinary clearance of IS and pC is associated and directly correlated with the secretory response of the organic transporters of the proximal tubule



FR-PO1219

Type 1 Interferon Signaling Inhibition Blocks Effects of Indoxyl Sulphate Exacerbation of Glomerular Endothelial Cell Injury In Vitro

Asha Seth,[1] Heena S. Stone,[1] Sambit K. Nanda,[2] Catharina Lindholm,[3] Nicola Ferrari,[1] Kevin Woollard.[1] *[1]AstraZeneca PLC, Cambridge, United Kingdom; [2]AstraZeneca US, Gaithersburg, MD; [3]AstraZeneca Swe, Gothenburg, Sweden.*

Background: High levels of uremic toxins, including indoxyl sulphate (IS), are associated with poor outcomes in chronic kidney disease. Previous work by us has shown anifrolumab, a type I IFN receptor mAb approved for the treatment of moderate to severe systemic lupus erythematosus (SLE), reduces the levels of IS in patients with lupus nephritis (LN). To explore the mechanisms through which anifrolumab treatment and IS reduction may provide benefit in kidney disease we examined if IS has direct damaging effects on renal cells and explored whether interferon signalling is mediating these effects.

Methods: We used an in vitro model of human primary glomerular endothelial cells (HGECs) to investigate the effects of IS treatment on the activation of inflammatory signaling and markers of endothelial dysfunction (IL-1A, IL-6, IL-8 VCAM1, ICAM1) and on the induction of an interferon response (IFI27, RASD2). We first challenged the

cells with LPS to prime the cells and mimic the increased vascular permeability that is seen in kidney disease. In further studies cells were treated with anifrolumab or human IgG1 isotype control, prior to the LPS and IS treatment. Cell lysates and supernatants were then collected for RNA and protein analysis respectively.

Results: Treatment of HGECs with IS significantly exacerbated the induction of the inflammatory markers IL-6, IL1A, and CXCL8 and the vascular dysfunction markers VCAM1 and ICAM1 caused by LPS priming. The treatment of the cells with IS alone had no effect on the markers assessed. The expression of type I IFN-responsive IFI27 and RASD2 genes following treatment with LPS was increased and no additional effects were seen when IS was added. The addition of anifrolumab prior to stimulation reduced IS mediated increases in injury and inflammation markers. In addition, anifrolumab prevented the increase in the type I IFN-response genes IFI27 and RASD2 in response to LPS treatment.

Conclusions: This study shows IS has a direct damaging effect on glomerular endothelial cells and this is mediated by type I IFN signalling. This mechanism may in part account for the link observed between increased IS levels and poor prognosis in CKD.

FR-PO1220

Nr1d1 Deficiency in Renal Proximal Tubular Cells Aggravates Kidney Fibrosis by Increasing Lipid Accumulation

Cheng Jia, Xiaolan Wang, Chun Zhang. *Huazhong University of Science and Technology Tongji Medical College Union Hospital, Wuhan, China.*

Background: Renal functions are closely associated with circadian rhythms. However, the specific role and mechanism of clock genes in kidney pathophysiology remain unclear. Here, we aim to investigate the function of core clock molecular-nuclear receptor subfamily 1, group D member 1 (Nr1d1) in the development of chronic kidney diseases (CKD) and how it works.

Methods: CKD mouse model was established by unilateral ureteral obstruction. Renal proximal tubular cell-specific Nr1d1 knockout mice were generated. The effect of Nr1d1 was further evaluated by injection of the agonist SR9009 in CKD mice. The downstream of Nr1d1 was examined through chromatin immunoprecipitation.

Results: 1. Down-regulation of Nr1d1 exacerbated renal fibrosis in UUO-induced CKD mice. 2. Nr1d1 deficiency increased lipid accumulation in renal proximal tubular cells through targeting nuclear factor interleukin 3-regulated (NFIL3). 3. The Nr1d1 agonist SR9009 alleviated renal fibrosis and lipid deposition in CKD mice.

Conclusions: Our findings suggest that Nr1d1 deficiency aggravates renal fibrosis via targeting Nfil3 to increase lipid accumulation in renal proximal tubular cells in CKD mice.

FR-PO1221

PM2.5 Induces Epithelial-to-Mesenchymal Transition by Oxidative Stress in Renal Tubular Kidney Cells

Duk-Hee Kang, Chor ho Jo, Dal-Ah Kim. *Ewha Womans University College of Medicine, Seoul, Republic of Korea.*

Background: The incidence and prevalence of chronic kidney disease (CKD) are increasing worldwide. Recently, the exposure to air pollution, especially particulate matter$_{2.5}$ ($PM_{2.5}$) was newly identified to be a potential risk factor for CKD, however there are no studies on whether exposure to $PM_{2.5}$ is a direct cause of CKD ccurrence and exacerbation. Epithelial-to-mesenchymal transition (EMT) of tubular cells is one of the early mechanisms of progression of renal disease. Therefore, the identification of association between fine dust and EMT may allow to reveal the casualty toward CKD.

Methods: Fine dust collected by $PM_{2.5}$ filter (Ulaanbaatar, Mongolia) was dissolved in DMSO by sonication. Renal tubular kidney cells (NRK) were treated with dissolved $PM_{2.5}$ (2 & 5 μL/mL). EMT was evaluated by morphological changes of NRK cells and the expressions of E-cadherin, α-SMA, and vimentin after the stimulation with $PM_{2.5}$ and TGF-β (5 ng/mL) by WB and immunostaining. ROS generation was assessed by DCF-DA and MitoSox staining. RNA-seq analysis (Ebiogen, Korea) was performed to investigate which upregulated/downregulated-genes are associated with $PM_{2.5}$-induced phenotype transition in NRK cells.

Results: $PM_{2.5}$ at the concentrations of 2 and 5 μL/mL did not alter LDH release and cell proliferation up to 48 hours of exposure. $PM_{2.5}$ induced EMT of NRK cells assessed by morphologic changes associated with a decreased E-cadherin expression and de-novo expression of α-SMA and vimentin. $PM_{2.5}$ also increased DCF-DA and Mito-Sox staining. RNA-seq analysis demonstrated the differences in gene expression related to EMT (16.7%), adipokine (15.9%), apoptotic process (13.7%), and oxidative stress (12.8%). Among them, lipocalin 2 (LCN2), Interleukin-11 (IL-11), and hyaluronan synthase 2 (HAS2) expression showed the highest fold difference (2.7-folds, 2.5-folds, and 2.0-folds, respectively) between control and $PM_{2.5}$-treated NRK cells.

Conclusions: This data suggest that exposure to $PM_{2.5}$ induces EMT and oxidative stress in NRK cells, which may be one of the possible mechanisms for the association between fine dust exposure and the development of renal disease.

A High-Content and High-Throughput Imaging Screen to Identify a Small Molecule Inhibitor for the Lipid Uptake Function of KIM-1

Amrendra K. Ajay,[1,2] Yutaro Mori,[3] Joseph V. Bonventre.[1,2] Bonventre Laboratory. *[1]Brigham and Women's Hospital Department of Medicine, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Rikagaku Kenkyujo, Wako, Japan.*

Background: Kidney Injury Molecule-1 (KIM-1) is a glycosylated protein upregulated following proximal tubular injury in humans and mice. KIM-1 mediates the uptake of oxidized lipids and long-chain fatty acids bound to albumen by the proximal tubule. Overexpression of KIM-1 causes inflammation and fibrosis in mice.

Methods: We developed a cell-based high throughput functional assay for KIM-1-mediated uptake of DiI-labeled ox-LDL and screened 14,414 unique compounds of known bioactive library (FDA approved (Biomol 4, and Selleck) and Non-FDA approved including Cayman, MedChemExpress, and Tocris), using 769-P cells that express high levels of KIM-1. After setting up a score based on each compound's potential to inhibit cellular ox-LDL uptake, we selected 240 potential hits and cherry-picked them from the primary screening. We performed secondary assays to confirm whether TW-37 quenches the fluorophore or cleaves the extracellular domain of KIM-1. Cell-based binding assays, competitive inhibition assays, and Raman spectroscopy were employed to investigate the binding of recombinant human KIM-1 to the compound that showed the highest level of inhibition of ox-LDL uptake, TW-37.

Results: Out of a number of compounds with varying degrees of inhibition, we identified TW-37 as the top hit. TW-37 is known to have Bcl2 inhibitory activity; however, this activity is likely not related to the inhibition of uptake since another specific Bcl-2 inhibitor, ABT-263, did not block ox-LDL uptake. TW-37 is not toxic to epithelial cells at concentrations up to 11 μM. Our results from fluorescence quenching and KIM-1 cleavage assays confirmed that TW-37 does not quench the DiI-fluorophore used for the uptake experiments, nor does it cleave KIM-1. Our *in silico* docking experiments showed a putative TW-37 binding pocket spanning residues from 37 to 52 of human KIM-1. Raman spectroscopy revealed that TW-37 specifically binds in a dose-dependent manner to recombinant human KIM-1 and not to the BSA.

Conclusions: TW-37 inhibits the oxidized lipid uptake after binding to the KIM-1 protein. Thus, TW-37 is a promising therapeutic agent for blocking lipid uptake by KIM-1 in fibrotic kidney disease.

Nephrology Tools: Using Chatbots for Image Interpretation and Answering Questions

Oscar A. Garcia Valencia, Charat Thongprayoon, Pajaree Krisanapan, Supawadee Suppadungsuk, Wisit Cheungpasitporn, Jing Miao. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Effective medical diagnosis and treatment planning rely heavily on clinical imaging. As of September 2023, ChatGPT-4 had broadened its functionality to allow image interpretation, providing comprehensive explanations and problem-solving insights. However, the effectiveness of chatbots in image interpretation remains understudied. We aimed to evaluate the performance of leading chatbots (i.e GPT-4, Bard AI, and Bing Chat), in interpreting nephrology images and addressing related test questions.

Methods: We assessed 57 nephrology test questions with their associated images from the Nephrology Self-Assessment Program and Kidney Self-Assessment Program tests. This group included 19 kidney histopathological images, 28 radiological images, and 10 images from miscellaneous categories. We ommited the image descriptions to focus only on the chatbots' interpretative abilities. Each question was analyzed two times through GPT-4, Bing Chat, and Bard AI. We then calculated and compared the accuracy and concordance rates for both image interpretation and question answering by these AI models.

Results: Regarding image interpretation, GPT-4 showed a 79% total accuracy, outperforming Bard AI's 51% and Bing Chat's 35% ($p<0.001$). All chatbots displayed a similar performance across image types ($p=0.57$, 0.39, and 0.38 for GPT-4, Bard AI and Bing Chat, respectively). On image-related questions, GPT-4, Bard, and Bing Chat yielded comparable results, with total accuracy rates of 60%, 53%, and 61% ($p>0.05$) and concordance rates of 75%, 68%, and 74% ($p>0.05$), respectively. Notably, GPT-4 and Bard AI were likely to provide correct answer when their image interpretation was accurate (correct response 60% vs 37%, $p=0.01$ for GPT-4; 60% vs 27%, $p<0.001$ for Bard AI when image interpretation was correct and incorrect respectively), while Bing Chat's accuracy on answering questions did not differ based on its accuracy of image interpretation (58% vs 51%, $p=0.50$).

Conclusions: These results highlight the challenges in developing AI-driven chatbots for medical image interpretation in nephrology, with GPT-4 showeing remarkable potential. The study provides valuable insights for further refinement of AI models, emphasizing the importance of accuracy, especially in scenarios where medical decisions rely on precise image interpretations.

SA-PO002

The Role of Artificial Intelligence (AI) Chatbots in Educating Patients with CKD on Intermittent Fasting

Joel N. Shah,[1] Adeel Ahmad,[1] Charat Thongprayoon,[2] Wisit Cheungpasitporn,[2] Prakrati C. Acharya.[1] *[1]Texas Tech University Health Sciences Center El Paso, El Paso, TX; [2]Mayo Foundation for Medical Education and Research, Rochester, MN.*

Background: Intermittent fasting (IF) is a growing nutritional intervention trend that may provide health and weight loss benefits in patients. However, research is limited regarding the effects of IF in CKD patients. AI Chatbots hold enormous potential in patient education regarding various lifestyle modifications. This study aims to provide an analysis of the effectiveness of AI Chatbots on patient education regarding the effects of IF in CKD patients.

Methods: A Nephrologist generated 25 questions related to IF and CKD. Responses were generated from three AI-based Chatbots, Chat GPT 3.5, Chat GPT 4.0, and Claude 3 Sonnet. Responses for each question were generated twice across all three Chatbots with >24 hours between each. Responses were evaluated and compared to the current literature regarding IF and CKD for accuracy.

Results: The 3 AI Chatbots each generated accurate responses though the vocabulary, use of paraphrasing, and formatting differed. Each chatbot's individual responses were roughly similar though some key differences were noted. Chat GPT 4.0 noted "[Patients] should be fully informed about...the lack of extensive research specifically in CKD populations." in response number 2 for a question, an answer absent from the 1st response. Claude 3 Sonnet was noted to have large variations between its responses, including one question in which electrolyte imbalances were categorized in the 1st response but replaced by a discussion of proteinuria in the 2nd. Chat GPT 4.0, Chat GPT 3.5, and Claude 3 Sonnet referenced limited literature or the need for more extensive research in 32%, 42%, and 40% of the responses generated respectively.

Conclusions: AI Chatbots provide a novel way to educate patients with CKD on lifestyle modifications including IF. Chat GPT 3.5, Chat GPT 4.0, and Claude 3 Sonnet provided mostly accurate responses with evidence of active learning between the 2 responses for each. Chat GPT 3.5, despite being the free version of Chat GPT, provided a greater percentage of responses correctly addressing the limited literature or the need for more research regarding IF and CKD. AI Chatbots require additional technological modifications and advancements to improve patient education regarding lifestyle interventions. Additionally, further research is necessary to establish the effects of IF in CKD patients.

SA-PO003

Enhancing Large Language Models (LLM) Performance in Nephrology through Prompt Engineering: A Comparative Analysis of ChatGPT-4 Responses in Answering AKI and Critical Care Nephrology Questions

M. Salman Sheikh, Charat Thongprayoon, Fawad Qureshi, Yasir Abdelgadir, Iasmina Craici, Kianoush Kashani, Wisit Cheungpasitporn. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Large Language Models (LLMs) have significantly advanced the field of artificial intelligence (AI). The effectiveness of LLMs is substantially influenced by the structure and formulation of input queries, a process known as prompt engineering. Prompt engineering techniques, such as the chain of thought approach, which involves thinking through problems step by step, have shown promising accuracy compared to regular prompts. This study investigates the impact of the chain of thought approach on the accuracy of ChatGPT-4 in addressing acute kidney injury (AKI) and critical care nephrology questions.

Methods: We presented ChatGPT-4 with 101 questions from the Kidney Self-Assessment Program (KSAP) and Nephrology Self-Assessment Program (NephSAP). We employed two prompting methods: one using the original question and the other utilizing the chain of thought approach. The McNemar test was used to assess differences in accuracy, while Cohen's kappa was employed to evaluate agreement between the two prompting methods.

Results: ChatGPT-4 demonstrated an accuracy of 87.1% with chain of thought prompting, outperforming the 81.2% accuracy achieved with regular prompting (P=0.15). The kappa statistic for the responses provided by the two prompts is 0.80. Consistency between the two methods was observed in 84.2% of the questions, with 78.2% being correctly answered by both methods. Chain of thought prompting correctly answered nine questions that were missed under regular prompting. Among the thirteen questions missed under chain of thought prompting, a notable 76.9% were repeated errors from regular prompting. Only three questions incorrectly answered with the chain of thought prompting were correct under regular prompting.

Conclusions: The chain of thought approach improves ChatGPT-4's accuracy in addressing nephrology-related questions compared to regular prompting, although the difference is not statistically significant. These findings emphasize the importance of developing effective prompting strategies to optimize the application of LLMs in clinical decision support. Future research should aim to generalize these findings across different medical specialties to maximize the benefits of LLMs in clinical decision-making.

SA-PO004

Self-Captured Images Recognition by Artificial Intelligence (AI) in Common Nephrology Medications: A Comparative Analysis of ChatGPT-4 and Claude 3 Opus

M. Salman Sheikh, Benjamin Dreesman, Erin F. Barreto, Jing Miao, Charat Thongprayoon, Fawad Qureshi, Iasmina Craici, Kianoush Kashani, Wisit Cheungpasitporn. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Accurate medication identification is crucial in nephrology, where patients with kidney diseases often require complex regimens. Artificial intelligence (AI) shows the potential to assist medication management, particularly when patients cannot remember medication names or labels are unavailable. Self-captured image recognition by AI could enhance medication safety and reduce errors for these patients by streamlining medication reconciliation, improving adherence, and supporting clinical decision-making. This study evaluates ChatGPT-4 and Claude 3 Opus in identifying common medications in nephrology from self-captured images.

Methods: Twenty-five medications commonly encountered in nephrology were randomly selected and systematically photographed using an iPhone 13 Pro Max, capturing both front and back views. The images were analyzed by ChatGPT-4 and Claude Opus with the inquiry, "What is this medication?" The percentage of correct identifications determined the accuracy of each model, and a two-tailed Fisher's exact test was used to compare the accuracy rates between the two models, with a P-value < 0.05 considered statistically significant.

Results: ChatGPT-4 showed a robust performance, correctly identifying twenty-two out of twenty-five medications, with an accuracy rate of 88%. Errors occurred in identifying hydrochlorothiazide, nifedipine, and spironolactone due to challenging imprints. Conversely, Claude 3 Opus only accurately identified one medication – trazodone. It misidentified the remaining twenty-four medications, achieving a notably lower accuracy rate of 4%, even though it correctly read the imprint of eighteen of these. ChatGPT-4 significantly outperformed Claude 3 Opus ($P<0.001$).

Conclusions: The study highlights the superiority of ChatGPT-4 over Claude 3 Opus in the task of identifying common medications from self-captured pictures. While ChatGPT-4 demonstrated high accuracy, Claude 3 Opus showed significant limitations, underscoring its inadequacy for clinical application in this context. These findings advocate for further development and integration of robust image recognition technology to support accurate medication management in nephrology.

SA-PO005

Data Preprocessing: A Key Factor in Large Language Models' Performance in Critical Care Nephrology

M. Salman Sheikh, Charat Thongprayoon, Fawad Qureshi, Jing Miao, Iasmina Craici, Kianoush Kashani, Wisit Cheungpasitporn. *Mayo Clinic Minnesota, Rochester, MN.*

Background: In clinical evaluations, data is often encountered in the form of tables from outside sources. These tables can be processed as images or reformatted into text before being input into multimodal large language models (LLMs). The use of LLMs in medical education and decision-making is gaining traction. However, their accuracy in interpreting complex clinical data, particularly when presented as images rather than reformatted text, remains a concern. This study evaluates the impact of data formatting on the performance of ChatGPT-4 and Claude 3 Opus in answering critical care nephrology questions from the Kidney Self-Assessment Program (KSAP).

Methods: Fifty-six AKI and critical care nephrology questions from KSAP were reviewed, focusing on 46 questions that included tables with pertinent information such as laboratory values and diagnostic results. Initially, tables were inputted in an image-encoded format (screenshots), and the models' responses were recorded. Subsequently, the tables were reformatted into pure-text format, and the models were reassessed using the same questions. McNemar test assessed the statistical significance of the improvement in accuracy, and Cohen's Kappa test evaluated the agreement between pre-formatting and post-formatting answers for each model.

Results: In the initial run with tables in image-encoded format, ChatGPT-4 and Claude 3 Opus achieved accuracies of 50% and 43.5%, respectively. After reformatting from image-encoded format to pure-text based format, ChatGPT-4 and Claude 3 Opus' accuracies improved significantly to 73.9% and 60.87% ($p<0.001$), respectively. The Cohen's Kappa score for the agreement between GPT-4's pre-formatting and post-formatting answers is approximately 0.141, while the Cohen's Kappa score for the agreement between Claude 3 Opus's pre-formatting and post-formatting answers, after aligning the data for the same set of questions, is 0.350.

Conclusions: Data formatting significantly impacts the performance of LLMs in interpreting complex clinical data in critical care nephrology. Reformatting tables from image-encoded to pure-text format significantly improves the accuracy of ChatGPT-4 and Claude 3 Opus in answering KSAP questions. This highlights the importance of data preprocessing in optimizing LLM performance for clinical decision support.

SA-PO006

Integrating Artificial Intelligence (AI) in Nephrology Workflows: Evaluating ChatGPT's Performance in Triaging Patients to Nephrology Subspecialty Clinics

Priscilla Koirala, Charat Thongprayoon, Jing Miao, Oscar A. Garcia Valencia, M. Salman Sheikh, Iasmina Craici, Wisit Cheungpasitporn. *Mayo Clinic Minnesota, Rochester, MN.*

Background: The rising prevalence of kidney-related conditions and aging global populations pose challenges for the healthcare sector, particularly nephrology. Efficient patient referral and treatment processes are crucial, and artificial intelligence offers promise in revolutionizing medical triage. This study evaluates ChatGPT's utility in triaging nephrology cases through simulated real-world scenarios, aiming to enhance decision-making efficiency and accuracy in clinical settings.

Methods: Two nephrologists created 100 simulated cases, encompassing a variety of aspects within nephrology and its intersecting subspecialties, to test ChatGPT 4.0. We assessed ChatGPT's performance in two separate evaluation attempts in March and April 2024. The evaluation focused on two main areas: the appropriateness of nephrology consultations and the accuracy in identifying suitable nephrology subspecialties.

Results: ChatGPT demonstrated high overall accuracy (98.5%) in identifying the need for nephrology consultations across two rounds, achieving 99% on the first attempt and 98% on the second. However, some misreferrals occurred to nephrology subspecialty clinics, such as recommending an Electrolyte Disorders clinic instead of Onconephrology for a cancer patient with worsening renal failure. While ChatGPT's suggestions were reasonable and safe, they sometimes lacked the depth needed to fully prioritize the intertwined oncological impacts. The AI's triage suggestions showed a reasonable level of clinical appropriateness by identifying related nephrological issues, even when the optimal subspecialty choice was missed. The output was grounded in logical clinical reasoning but could better integrate multidisciplinary care approaches for complex, intersecting medical conditions.

Conclusions: ChatGPT demonstrated high accuracy in triaging nephrology cases, providing safe and clinically appropriate recommendations. However, the AI could be enhanced to better integrate multidisciplinary care approaches for patients with complex, intersecting medical conditions. This study highlights the potential of AI in improving medical triage efficiency and accuracy while identifying areas for refinement.

SA-PO007

Optimizing Triage of Emergency, Urgent, and Elective Inbox Messages in Nephrology Using Artificial Intelligence (AI)

Justin Pham,[1,2] Charat Thongprayoon,[2] Jing Miao,[2] Iasmina Craici,[2] Wisit Cheungpasitporn.[2] *[1]Mayo Clinic College of Medicine and Science, Rochester, MN; [2]Mayo Clinic Minnesota, Rochester, MN.*

Background: In nephrology clinics, the workload burden associated with responding to patient inbox messages is significant. Some cases require emergent attention, such as those with severe electrolyte disorders or significant acute kidney injury. Efficient triage of these messages is crucial for ensuring timely medical attention based on urgency, reducing workload, and ultimately improving patient care. The integration of large language models like ChatGPT-4 into clinical practice has the potential to enhance operational efficiency by automating the triage process. This study aims to evaluate the accuracy of ChatGPT-4 in categorizing patient inbox messages in a nephrology clinic setting.

Methods: Two nephrologists wrote 150 patient inbox messages based on cases encountered in everyday practice at a nephrology outpatient clinic. 50 were written to simulate emergencies, 50 were urgent, and 50 were non-urgent. They were then submitted to ChatGPT-4 for independent triage into the same categories. The process was repeated after two weeks. ChatGPT responses were graded as correct, overestimation (higher priority), or underestimation (lower priority). Cohen's kappa statistic (κ) was calculated to quantify inter-rater and internal agreement.

Results: ChatGPT correctly triaged 140/150 messages (93.3%; κ = 0.9) in each trial, with an intra-rater agreement rate of 92% (κ = 0.88) across trials. It had the highest accuracy for emergent messages, followed by non-urgent, then urgent ones. There were more instances of overestimation than to underestimation. Subcategorical results are included in **table 1**.

Conclusions: ChatGPT-4 demonstrated near-perfect inter-rater agreement with nephrologists and high internal consistency in triaging 150 simulated patient inbox messages based on cases encountered in an outpatient clinic. The study highlights the potential for AI-driven triage systems to enhance operational efficiency and improve care for patients with kidney diseases. More research with larger datasets across medical specialties is needed to validate the generalizability of these findings.

Table 1

		ChatGPT Trial 1			ChatGPT Trial 2		
Category	Number	Correct	Overestimate	Underestimate	Correct	Overestimate	Underestimate
Nonurgent	50	49	1	0	46	4	0
Urgent	50	45	3	2	45	5	0
Emergency	50	46	0	4	49	0	1
All	150	140	4	6	140	9	1

SA-PO008

Artificial Intelligence (AI) and Green Nephrology: Assessing the Commitment of ChatGPT Models to Environmental Sustainability

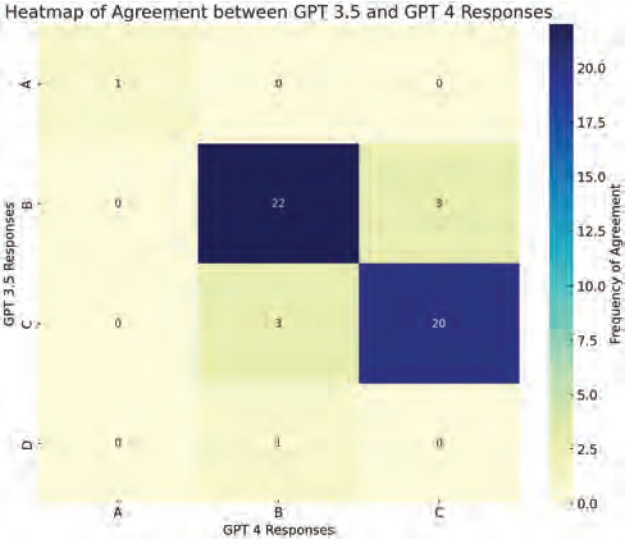
Suryanarayanan Balakrishnan,[1] Charat Thongprayoon,[2] Jing Miao,[2] Iasmina Craici,[1] Wisit Cheungpasitporn.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Mayo Clinic Health System, Mankato, MN.*

Background: With increasing use of AI and large language models in healthcare, including nephrology, there is growing concern about their potential impact on the environment and sustainable medical practices. Green nephrology has been increasingly emphasized in recent years due to climate change and environmental concerns. However, the commitment of AI models to green nephrology remains unclear.

Methods: Between March and May 2024, a set of 50 simulated questions, reviewed by two nephrologists, were created to assess the commitment of ChatGPT 3.5 and 4.0 to green nephrology practices. The questions were scored on a scale of 0 to 3, with 0 indicating no support for green nephrology and 3 indicating strong support. The total scores for GPT 3.5 and GPT 4 were calculated and compared. The Cohen's kappa coefficient was used to measure the agreement between the answers of GPT 3.5 and GPT 4.

Results: The total scores for GPT 3.5 and GPT 4 were 142/150 and 144/150, respectively. Both had the same score on 88% of the questions, with GPT 4 outperforming GPT 3.5 on 8% of the questions. The Cohen's kappa coefficient for the agreement between the answers of GPT 3.5 and GPT 4 was approximately 0.74. Both identified key barriers, such as high energy consumption, waste management challenges and limited awareness. They suggested strategies like implementing energy-efficient technologies, developing recycling programs and integrating sustainability into education and training to address these barriers.

Conclusions: GPT 3.5 and GPT 4 demonstrated commitment to green nephrology practices, providing valuable insights into the barriers to sustainable nephrology and potential solutions. The high agreement between them suggests that AI can be developed to support sustainable medical practices. Further research is needed on AI's environmental impact in healthcare.



SA-PO009

Harnessing Artificial Intelligence (AI): Evaluating Models for Social Discourse Analysis among Patients with Kidney Disease in Online Communities

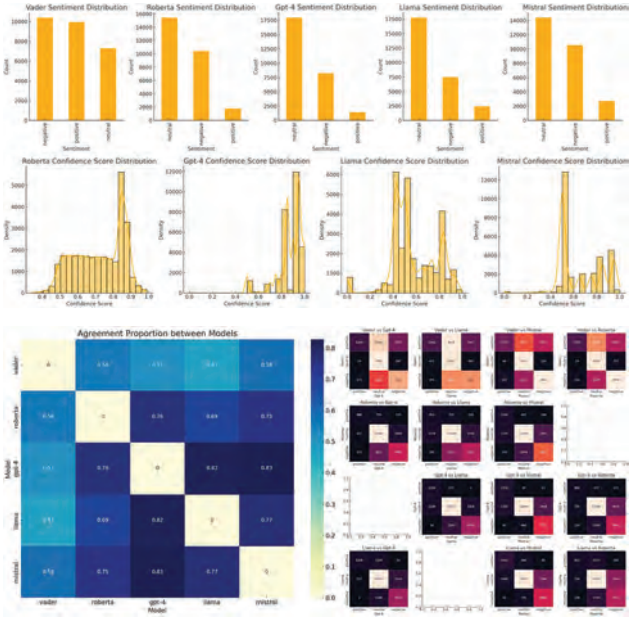
Rajesh Anumolu,[1,2] Aaron Delory,[3] Anil K. Chandraker.[1,2] *[1]University of Massachusetts Chan Medical School, Worcester, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]IO Design Team LLC, Danvers, MA.*

Background: The rapid exchange of information through technology has transformed healthcare communication. Online patient communities generate data too quickly for traditional methods, offering opportunities for sentiment analysis to guide research and inform pharmaceutical development. While many researchers use OpenAI's Chat-GPT, the variability and nuances of different large language models (LLMs) are under-assessed. Understanding these differences is crucial for selecting the appropriate model for specific applications. This study compares four LLMs to evaluate their strengths and weaknesses in sentiment analysis.

Methods: The study analyzed 39,637 Reddit posts and 283,326 comments from 2011 to 2022 across subforums related to dialysis, kidney disease, kidney stones, and transplants. The following LLMs were used: **VADER**: Rule-based model for social media sentiment analysis **RoBERTa**: Transformer-based model optimized for sentiment analysis tasks **Chat-GPT 4o**: Fine-tuned version of OpenAI's GPT-4 **LLaMA 3 8b-instruct and Mistral 283k**: Transformer-based models Each model analyzed the text for sentiment (positive/negative/neutral) and provided confidence scores. The results were compared to assess agreement and model-specific biases.

Results: Visualized results on graphs. Models' Biases: -VADER: Tends to overestimate positive sentiment due to sensitivity to positive keywords. **-RoBERTa**: Classifies more posts as neutral, possibly underrepresenting emotional extremes. **-GPT-4**: Balanced sentiment with a slight positive bias, capturing nuanced positivity. **-LLaMA**: Frequently predicts neutral sentiment, ensuring conservative interpretation. **-Mistral**: Higher count of negative predictions, emphasizing detection of negative expressions.

Conclusions: Recognizing the variability among LLMs is crucial for selecting the right tool, as even this analysis of four models showed different emphases and nuances. In the best of circumstances, these models may provide insights into patient experiences, highlight health disparities, guide equitable interventions, and amplify marginalized voices. However, without proper evaluation, we may miss the mark. Future research should explore diverse datasets to enhance our understanding of these platforms.



SA-PO010

Role of Artificial Intelligence (AI) in Clinical Interpretation of 24-Hour Ambulatory Blood Pressure Monitoring

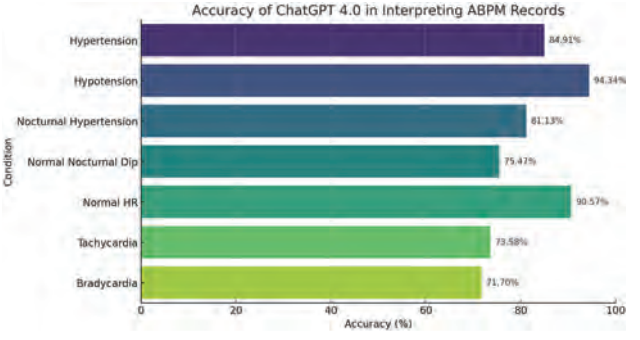
Sreyoshi F. Alam, Maria Lourdes Gonzalez Suarez, Charat Thongprayoon, Jing Miao, M. Salman Sheikh, Oscar A. Garcia Valencia, Gary L. Schwartz, Iasmina Craici, Wisit Cheungpasitporn. *Mayo Clinic Minnesota, Rochester, MN.*

Background: The utility of AI in interpreting ambulatory blood pressure monitoring (ABPM) data is increasingly recognized. Evaluating the accuracy of AI models, like ChatGPT 4.0, in clinical settings can inform their integration into healthcare processes. However, limited research has been conducted to validate the performance of such models against expert interpretations in real clinical scenarios.

Methods: This study assessed the performance of ChatGPT 4.0 in interpreting 24-hour ABPM records from 54 cases at Mayo Clinic, Minnesota, in March 2024. The AI's interpretations were compared with results confirmed by two nephrologists, who reached a consensus on the presence or absence of specific conditions based on the American College of Cardiology/American Heart Association (ACC/AHA) guidelines.

Results: ChatGPT 4.0 demonstrated varied accuracy across different conditions: Hypertension (84.91%), Hypotension (94.34%), Nocturnal Hypertension (81.13%), Normal Nocturnal Dip (75.47%), Normal Heart Rate (90.57%), Tachycardia (73.58%), and Bradycardia (71.70%). These outcomes highlight the model's capability to reliably interpret complex clinical data with considerable accuracy. The model's performance in identifying tachycardia and bradycardia, however, was comparatively lower, suggesting room for improvement in these areas.

Conclusions: The findings suggest that ChatGPT 4.0 has the potential to assist in the clinical interpretation of 24-hour ABPM. However, the model's current performance indicates that further improvements in accuracy are necessary before it can be effectively incorporated into clinical practice. Ongoing advancements and training on diverse datasets could enhance the model's diagnostic precision, making AI a promising tool for the routine analysis of ABPM data. While the results are encouraging, further research is needed to refine the model's performance and validate its utility across larger, more diverse patient populations.



SA-PO011

Natural Language Processing for Extracting Kidney Biopsy Pathology Diagnoses: The Houston Methodist Hospital Kidney Biopsy Registry

Shane A. Bobart, Enshuo Hsu, Luan D. Truong, Amy D. Waterman, Stephen L. Jones, Tariq Shafi. *Houston Methodist Hospital, Houston, TX.*

Background: Kidney biopsy reports provide detailed description of kidney pathology, but the diagnosis is not captured as searchable, discrete data in electronic health records (EHR) requiring labor-intensive manual review and abstraction. We sought to use Natural Language Processing (NLP) to extract kidney biopsy pathology diagnoses as an initial step to create an automatically updated Houston Methodist Hospital Kidney Biopsy Registry (HM-KBR).

Methods: We identified 3,087 native kidney biopsies (2,700 patients) from June 2016 to December 2023. We extracted 1000 native kidney biopsy reports in PDF format from the Epic EHR. A domain expert (SAB) manually annotated the primary diagnosis in the 1000 reports and a renal pathologist (LT) validated 20% (n=200). We processed the PDFs into machine-readable free text with SQL server (database management software) and Python (programming language). We split the biopsy reports into a training set (80%) and used the bidirectional encoder representations from transformers (BERT) NLP model to extract primary diagnoses. We evaluated the NLP model performance in a stand-alone test set (20%). The evaluation metrics included precision (false positive rate), recall (false negative rate), F1 score (harmonic mean of precision and recall, ranging 0 to 1, with 1 implying perfect model performance) and AUROC (overall performance, 1.0 is best). Due to the preliminary size of the training set, we limited the diagnosis types to those present in at least 20 reports for the evaluation metrics.

Results: The median age was 57 years, 50% were female, 28% Black and 23% Hispanic. The agreement between the two reviewers in the validation sample was assessed by Cohen's kappa statistic (0.76; excellent). The NLP extracted diagnoses showed an F1 score of 0.66 and AUROC of 0.93 (Table 1).

Conclusions: Our preliminary data shows an accurate and scalable NLP based model to extract the primary diagnosis from free text kidney biopsy pathology reports.

Table 1: Standard Evaluation Metrics of the NLP model

Biopsy Diagnosis	Total (N=1000)	Training set (N=800)	Test set (N=200)	Precision	Recall	F1	AUROC
Diabetic Kidney Disease	235	191	44	0.917	1.000	0.957	0.997
Arterionephrosclerosis	228	171	57	0.830	0.684	0.750	0.921

SA-PO012

Use of Natural Language Processing and Deep Learning to Analyze Kidney Ultrasound Reports and Their Correlation with CKD Diagnosis

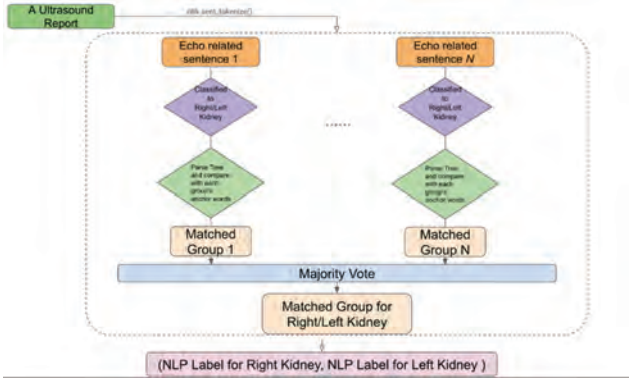
Farrukh M. Koraishy, Chenlu Wang, Ritwik Banerjee, Harry Kuperstein, Hamza Malick, Hira Tahir, Ruqiyya Bano, Priyal Sakhuja, Janos G. Hajagos. *Stony Brook University, Stony Brook, NY.*

Background: Natural language processing (NLP) can analyze unstructured data in imaging reports for clinical correlation, but this has not been reported in the context of kidney ultrasound reports and chronic kidney disease (CKD).

Methods: From the set of 1,068 patient ultrasound reports, NLP models were developed for kidney echogenicity and length. Kidney echogenicity was divided into 'normal', 'echogenic' or 'others' categories using NLP Toolkit to isolate sentences pertinent to echogenicity and Parse Tree Method and BioBERT to determine the word-level and sentence-level echogenicity classification respectively. Embeddings from Language Models was used to extract kidney size data and length classified as 'normal' or 'small' based on percentiles.100 reports were randomly selected for annotation by nephrologists to develop ground-truth ultrasound labels that were initially tested on the model. Subsequently the model was used to analyze the association of kidney ultrasound features with CKD diagnosis using logistic regression (LR) models.

Results: The word-level NLP method (Figure 1) demonstrated higher accuracy and precision for the classification of increased echogenicity compared to the sentence-level method. Subsequently only the word -level NLP model was used for further analyses with clinical correlations. Based on the 10% percentile, kidneys measuring under 8.5 cm in females and under 9.0 cm in males were categorized as "small". On multivariable LR, in addition to traditional factors like age, sex, diabetes, hypertension, heart failure and AKI; the presence of bilaterally echogenic kidneys was a strong predictor of CKD (OR = 5.49 [3.44, 8.75]; p<0.0001). The presence of bilaterally small kidneys was also a significant predictor (OR = 3.77 [1.25, 13.87)]; p=0.046).

Conclusions: Advanced NLP models with detailed text analysis can accurately detect CKD features in kidney ultrasound reports.



SA-PO013

Identifying Peripheral Artery Disease in Persons with and without CKD from Electronic Health Records

Georgia Parsons, Gomathy Parvathinathan, Margaret R. Stedman, Tara I. Chang. *Stanford University School of Medicine, Stanford, CA.*

Background: Peripheral artery disease (PAD) may be more difficult to identify in CKD due to altered pathophysiology. We aimed to develop a model to identify PAD in persons with and without CKD from electronic health records (EHR) to facilitate future studies.

Methods: We used the Stanford Medicine Research Repository (STARR) EHR mapped to the OMOP Common Data Model to identify adults with ≥1 PAD encounter 1/2020 to 9/2022. We randomly selected 993 patients for chart review for ground truth PAD status. Potential variables included PAD billing codes, demographics, comorbidities, diagnostic testing, and specialist visits. We built logistic regression models using age, diabetes and the top 10 percentile of variables selected by random forest. We assessed sensitivity, specificity, positive predicted value (PPV), negative predicted value (NPV), and accuracy overall and by CKD status (defined using ≥2 codes/labs). We chose the threshold probability to maximize Youden's index with specificity>sensitivity. We calculated 95% confidence intervals [CI] by bootstrapping 1,000 samples.

Results: In our cohort (**Table**), 222 (22%) had PAD (130 with CKD, 92 without). Our model had high sensitivity, specificity, NPV and accuracy but low PPV (**Figure**). Results were similar by CKD status.

Conclusions: Our study is among the first to focus on PAD ascertainment in CKD. Using discrete EHR data elements, our model generally performed well regardless of CKD status, but due to the lower prevalence of PAD, the PPV was relatively low. Future approaches will use natural language processing to incorporate clinical notes and diagnostic reports to improve model performance.

Funding: Other NIH Support - NHLBI

	Overall (n = 993)	CKD (n = 498)	Non-CKD (n = 495)
Age, y, mean (SD)	73.6 (12.7)	76.2 (12.3)	70.9 (12.5)
Women	484 (48.7%)	232 (46.6%)	252 (50.9%)
White race	620 (62.4%)	300 (60.2%)	320 (64.6%)

Validation of an Electronic Phenotyping Algorithm for Nephrolithiasis

Nicholas B. Larson,[1] Shannon K. McDonnell,[1] Jun Ma,[1] Jacob A. Frank,[1] Alexander R. Chang,[2] Ion D. Bucaloiu,[2] Steven J. Scheinman,[2] Peter C. Harris,[1] John C. Lieske.[1] *[1]Mayo Foundation for Medical Education and Research, Rochester, MN; [2]Geisinger Commonwealth School of Medicine, Scranton, PA.*

Background: Computable phenotypes using electronic health record (EHR) data are highly useful for facilitating research for various disease conditions, including history of kidney stones (KS). However, evaluating the performance and limitations of phenotyping algorithms is essential.

Methods: We defined a KS phenotyping algorithm using ICD-9/10 and CPT codes. To assess its performance, we designed a phenotyping validation study using EHR data from Mayo Clinic Biobank (MCBB) participants. Gold standard chart abstraction was performed by two readers blinded to the predicted KS status. A random sample of 150 predicted KS cases and 150 predicted controls were abstracted, with phenotyping performance assessed by sensitivity, specificity, PPV, and NPV, with 95% confidence intervals (CIs), adjusted for verification bias. Inter-reader reliability was assessed on 80 participants evaluated by both readers via Cohen's k. Finally, external validation was performed on a random sample from the Geisinger MyCode/DiscovEHR participants.

Results: Among 46,207 MCBB participants eligible for our study, 3917 (7.9%) were screen positive using the KS algorithm. For the 80 MCBB participants abstracted by both readers, 75/80 (93.8%) matched abstracted KS status (k = 0.88; 95% CI: [0.77,0.98]). Estimated performance measures are reported in Table 1. Overall, we observed very high specificity of 0.992, but sensitivity was moderate at 0.456. These estimates suggest a true MCBB KS prevalence of ~15.6%. Similar performance was observed in the MyCode/DiscovEHR participants.

Conclusions: Our code-based KS electronic phenotyping algorithm demonstrated excellent specificity but moderate sensitivity. Additional sensitivity may be possible through inclusion of natural language processing, similar AI-based clinical note interpretation, and/or inclusion of patient questionnaire data.

Funding: NIDDK Support, Private Foundation Support

Performance Measures

Measure	MCBB: Estimate [95% CI]	MyCode/DiscovEHR: Estimate [95% CI]
PPV	0.913 [0.857, 0.949]	0.923 [0.832, 0.967]
NPV	0.905 [0.848, 0.843]	0.827 [0.767, 0.873]
Sens	0.456 [0.416, 0.496]	0.348 [0.315, 0.381]
Spec	0.992 [0.990, 0.993]	0.991 [0.988, 0.993]

Phenotyping algorithm performance measures and 95% confidence intervals. PPV = positive predictive value, NPV = negative predictive value, CI = confidence interval, Sens = sensitivity, Spec = specificity

SA-PO015

Comparative Accuracy of Self-Reported vs. Electronic Health Record (EHR)-Derived Charlson Comorbidity Index among Veterans with Advanced CKD

Nandita Senthil,[1,2] Grant D. Scheiffele,[2] Cydney E. Parmar,[1,2] Popy Shell,[2] Huanguang Jia,[2] Ashutosh M. Shukla.[1,2] *[1]University of Florida, Gainesville, FL; [2]VA North Florida South Georgia Veterans Health System, Gainesville, FL.*

Background: Inaccurate or missing diagnosis codes limit the prognostic power of EHR-derived comorbidity indices, such as, Charlson Comorbidity Index (EHR-CCI). CCI calculated by patients self-reporting individual comorbidities (SR-CCI) can address these errors but are subject to patient awareness and recollection bias. The relative accuracy of SR-CCI vs. EHR-CCI has not been examined, especially among the US Veterans with CKD.

Methods: Using the baseline data of the ongoing randomized Trial to Evaluate and Assess the impact of Comprehensive pre-kidney failure education on Home dialysis among Veterans (TEACH-VET) on variety of patient outcomes, this study aimed to assess the concordance and accuracy of SR-CCI and EHR-CCI among veterans with advanced CKD. In addition to the detailed data for demographic and socioeconomic variables, all enrollees were self-queried for the individual comorbidities by trained study staff to collect their CCI at the enrollment. SR-CCI was compared against EHR-CCI, extracted from VA database, anchoring for each patient's enrollment date.

Results: Of the 551 Veterans with advanced CKD enrolled in TEACH-VET, 338 participants with complete baseline data, including SR-CCI were included for this analysis. The primary outcome, the aggregate CCI score did not differ significantly between the SR-CCI and EHR-CCI (p=0.1), however, there were significant differences in individual comorbidities composing CCI. Of the 17 comorbidities comprising CCI, 13 (76.5%), notably, CKD-related comorbidities, e.g., moderate to severe CKD and liver disease, diabetes with or without complications, and myocardial infarction, etc., had substantial disagreements (p<0.0001) between the two methods, whereas peripheral vascular disease, mild liver disease, hemiplegia, and AIDS had no significant difference between the two methods. There were no significant differences in the demographic characteristics across the score patterns.

Conclusions: Most comorbidities used for CCI are either over or under accounted for by EHR-CCI, raising concerns for its routine use in clinical and epidemiological research. Future qualitative studies comparing SR-, and EHR-CCI comparison are needed to determine optimal method for reporting CCI and similar comorbidity indices.

SA-PO016

Real-World Data in an Observational Medical Outcomes Partnership/ Common Data Model (OMOP/CDM) Platform: Assessing the Impact of Statins on Reducing the Need for Dialysis of Diabetic Patients Treated with ARBs/ACE Inhibitors

Cesar A. Truyts, Rogerio Passos, Maria T. Abrahao, Uri P. Flato, Amanda G. Rabelo, Mateus d. Freitas, Diogo F. Patrão, Edson Amaro Junior, Adriano José Pereira. *Sociedade Beneficente Israelita Brasileira Albert Einstein, Sao Paulo, Brazil.*

Background: Diabetics are at high risk of developing kidney dysfunction. Angiotensin receptor blockers (ARBs) or angiotensin-converting enzyme inhibitors (ACEIs) are often employed to mitigate the risk of kidney disease progression. Statins also show promise in reducing the risk of chronic kidney disease (CKD) progression. This study examines the impact of statins on reducing the need for dialysis among diabetic patients treated with ACEIs or ARBs, utilizing the OMOP CDM framework within the Hospital Israelita Albert Einstein in São Paulo/Brazil.

Methods: This retrospective, observational cohort study at a single hospital used the OMOP CDM framework to analyze electronic health records of diabetic patients treated with ACEIs/ARBs, from 2017 to 2023. Adult Type 2 Diabetes Mellitus patients receiving ACEIs/ARBs, and possibly statins were included. Statistical analyses using Python involved Chi-square and Mann-Whitney U tests, and multivariate logistic regression, ensuring significance with p-values less than 0.05.

Results: Out of 55,764 diabetic patients using ACEIs or ARBs, 36,378 (65.2%) were taking statins. Statin users were older (median [range], 65 years [53–75] vs. 45 years [35–59]; P < 0.01) and predominantly male (56% vs. 44%; P < 0.001). Logistic regression adjusted for age and sex showed that statin users had a lower dialysis rate (0.20% vs. 2.88%; P < 0.001 - Table 1)

Conclusions: The data suggest that statin therapy was associated with a reduced need for dialysis in high-risk diabetic patients with ACEIs/ARBs. The OMOP CDM framework was an easy way to simplify and accelerate analysis of large amount of data, in an integrated and protected environment, highlighting its value in advanced medical research.

Baseline demographics

Variables	Statin Users (n = 36,378)	Nonstatin users (n = 19,386)	P Value
Age, years median [IQR]	65 [53;75]	45 [35;59]	< 0.01
Sex (Male) n(%)	20,311 (56%)	8,574 (44%)	< 0.001
Dialysis n(%)	73 (0,20%)	559 (2,88%)	< 0.001

SA-PO017

A Randomized Controlled Trial of Video-Assisted Electronic Consent vs. Standard Consent for Percutaneous Kidney Biopsy (eConsent Bx)

Pedro H. Gois,[1,2] Vera Y. Miao,[4] Rebecca Saunderson,[4] Marina Wainstein,[2] Kylie-Ann Mallitt,[6] Shaun P. Chandler,[5] Belinda Elford,[5] Rebecca Hudson,[7] Julia Jefferis,[5] Helen G. Healy,[5,2] Ann Bonner.[3] *[1]John Hunter Hospital, New Lambton Heights, NSW, Australia; [2]The University of Queensland, Brisbane, QLD, Australia; [3]Griffith University Griffith Sciences, Southport, QLD, Australia; [4]Northern Sydney Local Health District, St Leonards, NSW, Australia; [5]Royal Brisbane and Women's Hospital, Herston, QLD, Australia; [6]The University of Sydney, Sydney, NSW, Australia; [7]Fiona Stanley Hospital, Murdoch, WA, Australia.*

Background: Video-assisted electronic consent (eConsent) enhances understanding, reduces anxiety, and boosts satisfaction in medical procedures. Yet, its impact on percutaneous kidney biopsies (PKB) remains unexplored. We aimed to assess patient-reported benefits of eConsent versus conventional consent for PKB.

Methods: In a single-center, open-label, RCT, consecutive patients undergoing PKB were randomized (1:1) to either video-assisted eConsent (intervention) or conventional consent (control). The intervention group accessed an online platform featuring an 8-minute explanatory animation before providing eConsent, while the control group was consented by clinicians and signed a paper form. The primary outcome was questionnaire-based patient comprehension, with secondary outcomes including patient-reported experience (KidneyPREM), anxiety, and satisfaction with consent.

Results: Median participant age was 52 years (IQR [34-65]), 30.7% had ≤ year 12 education and 69.3% post-secondary qualifications. Baseline characteristics were similar between groups. PKB comprehension was significantly higher in the intervention group compared to control (3 more questions correct/9; p<0.001), regardless of education level. Moreover, the intervention group demonstrated better understanding of critical information related to pre- and post-PKB care and when to seek medical attention for complications. There were no statistically significant differences in KidneyPREM, anxiety, or satisfaction between groups.

Conclusions: Video-assisted eConsent enhances PKB comprehension without affecting KidneyPREM, anxiety or satisfaction. These benefits extend to patients with lower education levels. Its implementation could standardize and streamline consent processes in PKB, with potential application in other nephrology domains.

Health 360x Registry (H360xR): Artificial Intelligence (AI)-Enabled Equitable Access to Point-of-Care Decentralized Clinical Trials

Chamberlain I. Obialo,[1,2] Eva Lee,[1] Elizabeth O. Ofili.[2,1] *[1]Accuhealth Technologies Inc, Atlanta, GA; [2]Morehouse School of Medicine, Atlanta, GA.*

Background: The lack of diversity in clinical trial population and non-involvement of community physicians are major barriers to recruitment and retention of representative populations in industry sponsored and National Institute of Health [NIH] research studies.

Methods: AH received an NIH Fast Track Small Business Innovation Research (SBIR) Award to implement a scalable access to point of care decentralized clinical trials (DCT), by systematically addressing gaps in the practice infrastructure of resource limited small-medium practices. The conceptual model is the Practical, Robust Implementation and Sustainability (PRISM) that targets barriers at the patient, provider and practice levels. We developed H360x Clinical Research Platform and Registry as an artificial Intelligence [AI] enabled digital health platform (DHT) that uses machine learning to analyze electronic health records [EHR] and identify suitable clinical trial participants. Primary outcome: Adoption and implementation progress, with performance indicators based on the H360xR protocol; IRB/informed consent; PhenX surveys for social determinants; Recruitment and Retention rates. Method of measurement: surveys; observation; key informant interviews; focus groups.

Results: H360xR includes data from 35 community-based practices, who have conducted 3 NIH and 1 industry sponsored study. Over a 3- year period, H360xR had 7513 participants. Median age 70 yr., 90% black, 7% white, 58% female, 15% rural residents while 51% have annual income <$25,000. H360xR supplements patient clinical and EMR data with surveys and questionnaires on social determinants. Qualitative analysis demonstrated that EMR AI/ML recruitment resource and Training of site teams are dominant themes; 75% references to H360x patient engagement, 85% references to training of site teams and research workflows (p<0.02 compared to baseline). H360x system usability scale was 95%.

Conclusions: H360xR resource support of trusted healthcare providers, who are research naïve, enabled successful participation in NIH and industry sponsored studies. The DCT/DHT model can effectively scale the participation of underserved populations in clinical trials. Ongoing analysis will generate a full representation of multi-dimensional patient characteristics, with human-in-the-loop AI/ML, and adapted to practice workflows.

SA-PO019

Point-of-Care Atrial Fibrillation Screening Using Mobile Electrocardiography in a CKD Patient Population

Ajay Mittal, Mansi Patel, Victor A. Savu, Mark S. Segal. *University of Florida, Gainesville, FL.*

Background: Recent metadata analysis suggests chronic kidney disease (CKD) patients have an increased incidence of atrial fibrillation (AF). Mobile electrocardiograms (ECGs) provide a low-cost, scalable technology for simple and efficient AF screening. In this study, we aim to use the KardiaMobile (AliveCor), a single-lead mobileECG, to examine the detection of subclinical AF amongst CKD patients in an outpatient nephrology setting.

Methods: From October 2020 to April 2024, 353 University of Florida Shands Nephrology patients filled out an informed consent form and one-page survey regarding heart and kidney health. A 30-second ECG rhythm strip was obtained by a trained research assistant using the Kardia Mobile ECG. The subsequent ECG reading provided by the device, along with the survey results were: flagged for abnormalities, applied to a CHA2DS2-VASc score to stratify the risk of stroke, and assessed by an electrophysiologist ordering a 12-lead ECG to confirm previously undetected AF in CKD Stage III-IV patients.

Results: The ECG readings determined 281 (79.6%) of patients had a normal single-lead rhythm strip, 72 (20.4%) had an irregular strip with possible arrhythmia indication of which 51 (14.4%) patients were confirmed to have AF. Of the previous undetected AF in CKD patient population the average CHA2DS2-VASc score was 3.2, indicating an elevated risk for stroke and oral anticoagulant therapy being recommended regardless of sex. The sample population was 51.03% female and 48.46% male with 0.51% of patients not answering. The mean age of participants was 65.25 with a standard deviation of 13.69.

Conclusions: The KardiaMobile device allowed for a primary screening tool to be applied in an outpatient clinic setting enabling CKD patients to gain insight about cardiovascular health through a 30-second single lead rhythm strip. Early detection and appropriate medical management of AF reduces risk of stroke, providing the nephrologist valuable information to optimize patient care. Further testing in larger, more diverse patient populations could help establish more direct connections between kidney disease and AF.

SA-PO020

Can Automated Digital Counseling Enhance Mental Health in Patients with Chronic Heart Failure or Kidney Disease? The ODYSSEE-vCHAT Study

Bourne L. Auguste,[1,2] Janice Montbriand,[3] Christopher T. Chan,[3,1] Robert Nolan.[3] ODYSEE-vCHAT Investigators. *[1]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; [2]Sunnybrook Health Sciences Centre, Toronto, ON, Canada; [3]University Health Network, Toronto, ON, Canada*.

Background: Chronic Kidney Disease (CKD) and Chronic Heart Failure (CHF) significantly impact morbidity, mortality, and quality of life. We evaluated the ODYSSEE-vCHAT automated digital counseling program, including social network support, to enhance mental health and quality of life in patients with CHF and CKD. The primary aim was to assess the effect of ODYSSEE-vCHAT on Mental Component Summary (MCS) of the SF-36 health survey.

Methods: This 11-month, multicenter, open-label trial evaluated adults with CHF (reduced EF) or CKD (2-year KFRE≥ 10%), focusing on self-care skills (medication adherence, exercise, diet, smoke-free living) via a digital platform. The primary outcome was achieving a minimal clinically important difference in MCS (ΔMCS ≥ 3.8 or MCS ≥ 65).

Results: Of 215 enrolled participants, 174 completed the study, with a mean age of 54.4 years; 61% (n=106) had CKD. Significant improvements in MCS scores were noted for both CKD and CHF patients. However, no statistically significant changes were found in KDQOL or MCS scores for CKD patients alone, though small-to-moderate effect sizes were observed: Vitality (0.40, p=0.16), Emotional Well-Being (-0.11, p=0.70), Social Functioning (-0.37, p=0.19), Role Limitations (0.43, p=0.12), aggregate MCS (0.15, p=0.60), and KDQOL Subscale CKD Burden (0.36, p=0.12). These suggest meaningful small-to-moderate improvements (Fig 1). Participants experienced reduced CKD burden and enhanced quality of life.

Conclusions: The ODYSSEE-vCHAT program showed potential in enhancing mental health and quality of life among CKD patients, indicating value in digital health interventions in managing chronic diseases. These findings underscore the need for further trials to establish the efficacy of digital counseling in CKD patient care.

Funding: Other NIH Support - Canadian Institutes of Health Research-MS2 173076 - Type of funding sources: Public grant(s) – National budget only

SA-PO021

Technology in Education of Patients with CKD in Singapore

Ying-ying Seow, Hui Boon Tay, Lee Ying Yeoh. *Sengkang General Hospital, Singapore, Singapore*.

Background: With high penetration of technology and a shrinking workforce in Singapore, healthcare is turning increasingly to the former to improve patients' knowledge and self-management skills. However, for it to be effective, patients need to have adequate health literacy skills. In this study, we aim to evaluate current technology use, electronic health literacy and receptiveness of education via electronics means among our CKD patients.

Methods: This is a cross-sectional survey of 200 CKD patients attending renal clinics at Sengkang General Hospital, Singapore between Feb-Jun 2022. The survey consisted of questions on technology use, the validated eHealth Literacy Scale (eHEALS), and patient preference of modality for CKD education.

Results: We sampled 100 men and 100 women, median age was 56.5y (IQR 44.5-68). 51% of patients was CKD stages 1-3. 22.5% were on dialysis at the time of the study. 38.5% were not aware of their diagnosis of CKD. 37.5% had >10years of formal education. 53% were employed, 61.3% of whom were professionals. The median eHEALS score was 29 (IQR 24-32). 194 (97%) participants had mobile phones, with 158 (79%) using the internet on them. The top modality preferred for CKD education was for in person education by a renal coordinator (66.5%). Overall, 94 (47%) participants were receptive to education by electronic means (website or mobile application), though only 19.5% chose it as their top choice. Older participants were less likely to be receptive to education by electronic means (OR=0.95, CI 0.91-0.98, p=0.003), while those with a higher eHealth literacy were more likely (OR=1.14, CI 1.05-1.23, p=0.001). Education level and internet use on phone were not associated.

Conclusions: Access to technology was high among our Singapore CKD patients but electronic health literacy scores lower than CKD counterparts in the US. Receptiveness to education by electronic means was associated with younger age and higher eHEALS scores. Face-to face education was still much preferred.

Funding: Government Support - Non-U.S.

Regression analysis for receptiveness of education via electronic means

	Univariate analysis			Multivariate analysis		
	OR	95% CI	p-value	OR	95% CI	p-value
Age	0.95	0.93-0.97	<0.001	0.95	0.93-0.98	0.002
Education	2.15	1.43-3.27	<0.001	1.31	0.70-2.46	0.394

Internet use on phone	5.80	2.43-13.87	<0.001	1.05	0.30-3.72	0.935

SA-PO022

Bridging the Future: Perspectives of a Multinational Group of Nephrologists on Artificial Intelligence (AI) in CKD Management

Eliana Silva, Carla Santos, Carlos Lucas, Luis Rodrigues, Jesus Garrido, Lidia Santos, Fernando Jose Gordinho R. Macario. *Diaverum AB, Malmo, Sweden*.

Background: Artificial intelligence (AI) techniques, particularly machine learning (ML) and deep learning, have made significant strides in predicting and diagnosing chronic kidney disease. This study aims to explore the perceptions of a multinational group of nephrologists regarding the application of AI in clinical practice. Understanding their views is crucial for the integration of AI in nephrology.

Methods: A prospective, observational study was conducted in March 2024, involving nephrologists from 17 countries across four continents, all affiliated with a large hemodialysis provider. The survey, validated by 6 nephrologists, comprised 8 technical questions using a 5-point Likert scale, with 1 corresponding to "totally disagree" and 5 to "totally agree." Demographic data were also collected. Results presented as mean±standard deviation or proportions, as appropriate. T-test was used for statistical analysis, with a p-value below 0.05 considered statistically significant.

Results: Among the 196 valid responses, 80% of nephrologists recognized the term "AI," and 65% were familiar with "ML." Nephrologists acknowledge the potential of AI in the future but currently rely more on traditional tools to support the clinical decision-making process (3.74±1.14 vs. 3.12±1.07, p<0.05). This reliance on traditional tools is more evident among nephrologists not familiar with the term "ML" (3.90±0.93 vs. 3.09±1.01, p<0.05). When asked about the advantages of AI and ML in supporting clinical decision-making, the highest score was attributed to "simplification of decision algorithms" (3.82±1.10). Interestingly, nephrologists without previous contact with AI-supported decision-making tools considered the role of AI less significant in "assisting in making decisions, allowing concentration on high-value activities", compared to those with previous experience in this area (3.38±1.22 vs. 3.88±0.97, p<0.05).

Conclusions: Enhancing the understanding of AI can facilitate the integration of these technologies into nephrology practice, benefiting patient care. Given the perceived potential of AI in managing different types of CKD patients, efforts to promote AI literacy in the nephrology community may be fundamental for the adoption of these tools in regular clinical practice.

SA-PO023

Clinical and Cost-Effectiveness of a 6-Month Digital Health Intervention to Improve Physical Activity and Mental Health-Related Quality of Life in People with CKD (Kidney BEAM)

Sharlene A. Greenwood,[1,2] Jackie Campbell,[4] Nicola Cooper,[3] Christy G. Walklin,[1] Hannah M. Young,[3] Ellen M. Castle,[6] Roseanne E. Billany,[3] Jamie H. Macdonald.[5] Kidney Beam. *[1]King's College Hospital, London, United Kingdom; [2]King's College London, London, United Kingdom; [3]University of Leicester, Leicester, United Kingdom; [4]University of Northampton, Northampton, United Kingdom; [5]Bangor University, Bangor, United Kingdom; [6]Curtin University, Perth, WA, Australia*.

Background: There is inequity in provision of physical rehabilitation services for people living with chronic kidney disease (CKD). The Kidney BEAM trial evaluated the clinical value and cost effectiveness of a physical activity digital health intervention in CKD. We hypothesised that the Kidney Beam intervention would be a cost-effective solution to improve mental health-related quality of life (HRQOL) for people with CKD.

Methods: In a single-blind, 11 centre, randomised controlled trial, 340 adult participants with CKD were randomly assigned to either the Kidney BEAM physical activity digital health intervention or a waitlist control. This study assesses the difference

in the Kidney Disease Quality of Life Short Form 1.3 Mental Component Summary (KDQoL-SF1.3 MCS) between intervention and control groups at 6 months, and cost-effectiveness of the intervention.

Results: At 6 months there was a significant difference in mean adjusted change in KDQoL MCS score between Kidney BEAM and waitlist control (intention-to-treat adjusted mean: 5.9 {95% confidence interval: 4.4 to 7.5} arbitrary units, p<0.0001), and a significant increment in quality-adjusted life years (QALYs) of 0.027 {95% confidence interval: 0.013 to 0.040} years per participant, resulting in a cost per QALY of £3,446 for the Kidney BEAM intervention, and a 93% and 98% probability of the intervention being cost-effective at a willingness to pay threshold of £20,000 and £30,000 per quality-adjusted life year gained.

Conclusions: The Kidney BEAM physical activity digital health intervention is a clinically valuable and cost-effective means to improve mental health related quality of life in people with CKD.

SA-PO024

Targets for Improvement of Care for Hospitalized Patients with AKI

Dion G. de Martines,[1] Gozewijn D. Laverman,[2] Aaltje Y. Adema,[3] Peter T. Luik,[4] Ernst C. Hagen,[4] Aernoud Fiolet,[1] Christina M. Gant.[1] AKI PATROL Consortium. *[1]Universiteit Utrecht, Utrecht, Netherlands; [2]Ziekenhuisgroep Twente, Almelo, Netherlands; [3]Medisch Centrum Leeuwarden, Leeuwarden, Netherlands; [4]Stichting Meander Medisch Centrum, Amersfoort, Netherlands.*

Background: Acute Kidney Injury (AKI) complicates 20% of hospital admissions and is associated with prolonged hospital stay, increased mortality and end stage renal disease. Timely guideline based management can prevent further deterioration of kidney function and improve AKI-associated outcomes. Prior research has shown low adherence to these recommendations. Large scale data regarding quality of care are currently lacking. To enhance guideline adherence, understanding the quality of care is of the utmost importance to formulate targeted interventions such as e-alerts or tailored management advice for physicians.

Methods: We conducted a retrospective cohort study in three large teaching hospitals in The Netherlands. Hospitalized patients that developed AKI were included over a period of one year, between January 2022 to October 2023. AKI was identified using an algorithm using KDIGO criteria for serum creatinine (>50%/week or >26µmol/l/48h increase compared to baseline). We logged the occurrence of interventions recommended by the guideline.

Results: 2367 episodes of AKI were included. Mean age of patients at AKI was 72 years, 45% were female. AKI was documented in the electronic health record in 70% of cases. Urine tests were performed in 58%, renal imaging conducted in 31%. In 47% of cases, intravenous fluids were started, in 60% nephrotoxic medication was ceased and in 17% a nephrologist was consulted. Anti-hypertensives were ceased in 57%. In 14% of cases patients received iodine contrast during AKI. A follow-up appointment with a nephrologist was made in 10% of patients. Lower adherence rates to KDIGO guideline recommendations were found in surgery wards (such as performing urine diagnostics in 22%, documenting AKI in 65% of cases).

Conclusions: Quality of care for patients with AKI in Dutch hospitals is suboptimal. The most promising targets for improvement of quality of care for patients with AKI are timely recognition of AKI, cessation of antihypertensives and nephrotoxic medication, consultation of a nephrologist, and initiation of fluid therapy. Guideline adherence differed depending on the ward of admission. Tools like an AKI alert may aid in guideline adherence rates.

SA-PO025

Seven-Day AKI Nursing Team Leads to Secondary Care Transformation

Gemma Highway, Riaz V. Bavakunji, Liz Grace. *Walsall Manor Hospital, Walsall, United Kingdom.*

Background: Our district general hospital, reported high mortality rates for AKI admissions of 33.2% vs UK average of 26.61%, with an adjusted standardized mortality ratio 1.09. We noted high incidence of chronic kidney disease at 5.2% (stages G3a-5), in a 36% ethnic minority population. Our median length of stay (LoS) for all Acute Kidney Injury (AKI) stages was 13 days median while UK was 12. Getting It Right First Time report showed over 75% patients are transferred to hub for dialysis later than 24 hours. This delay has led to harm in 100% of patients. We implemented a 3-member, 7-day AKI nursing service and aim to evaluate the new nursing service and its impact.

Methods: We appointed 3-AKI nurses, for a 7-day service in 2022 Prospective data was collected between April 1, 2023, to March 31, 2024. Outcome data was collected on timely intervention, dialysis transfer times, number of ICU days after patient stabilised, LoS data and 90-day major adverse kidney events (MAKE90: death, renal replacement therapy).

Results: The nursing team reviewed 891 patients during the study period. We noted that 78% of patients presented with community-acquired AKI (CA-AKI) and 22% had Hospital-acquired AKI. There were 54% male and 31% of the total have preexisting CKD. The mortality was 50% in G4 and G5 patients. Patients reviewed same day (within 6 hours) were 16% for AKI stage 1 and 72% for AKI stages 2/3 with MAKE 90 outcomes showing 28% mortality and 8.9% required ICU haemofiltration. The mean transfer time for dialysis was 20.19 hours, aligning with GIRFT recommendations. Patients remained in the ICU for an average of 4.92 hours post-stabilization before transfer to the dialysis unit, reducing ICU bed pressure. The mean AKI LoS was decreased to 6.99 days, with a median of 5 days (IQR 2, 9). We conclude this reduction in LoS was due to nursing input as this was the only new intervention implemented.

Conclusions: The 7-day AKI nursing team has significantly improved the timeliness of renal replacement therapy decisions, reduced ICU bed utilization, and streamlined the transfer process to the regional hub. The service introduction estimates a cost-saving, assuming the entire costs associated with a bed day can be removed, the reduction in LoS can contribute £1.8 million in avoided costs. We plan to implement a community PILOT GP AKI stage reporting, with rapid review protocols potentially preventing hospital admissions.

SA-PO026

Low Baseline Creatinine Reduces the Likelihood of Nephrology Consultation in Stage 3 AKI

Casey G. Hardin, Mary V. Sarrazin, Jason Misurac, Diana I. Jalal, Benjamin R. Griffin. *University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: Acute kidney injury (AKI) is common among hospitalized patients and significantly affects clinical outcomes. Previous studies suggest that inpatient nephrology consultation improves outcomes in patients with AKI. We analyzed consult rates for Kidney Disease: Improving Global Outcomes (KDIGO) stage 3 AKI to determine nephrology consult rates and to explore reasons for lack of consultation.

Methods: This single-center, retrospective cohort study included adults admitted in 2019 with in-hospital KDIGO stage 3 AKI. Baseline creatinine was defined as the lowest creatinine within six months of admission. High nephrotoxin exposure was determined based on the current Nephrotoxic Injury Negated by Just-in-Time Action (NINJA) definition as ≥3 nephrotoxins on one day or ≥3 days of intravenous vancomycin or aminoglycoside. Patients were stratified into high and low baseline creatinine, and Chi-squared analysis was used to investigate rates of renal consultation, nephrotoxin exposure, and in-hospital mortality.

Results: Among 634 patients with stage 3 AKI, the nephrology consultation rate was 54%. The most significant factor influencing consult rates was peak creatinine; 81% of patients with peak creatinine greater than the median of 3.25 mg/dL had a nephrology consultation compared to 27% of patients below the median (p<0.001). Similarly, 74% of patients with a baseline creatinine above the median of 0.7 mg/dL had a nephrology consult versus 38% less than the median (p<0.001). Females, elderly, and patients with a history of malignancy were statistically more likely to have baseline creatinine below the median. Neither rates of in-hospital mortality (25% vs. 23%, p=NS) nor high nephrotoxin exposure (32% vs. 35%, p=NS) were different in patients above and below median baseline creatinine.

Conclusions: Rates of renal consultation were low among patients with stage 3 AKI (54%), and this was exacerbated in patients with a baseline creatinine of 0.7 mg/dL or below (38%), who were more likely to be elderly females. There was no significant difference between those above and below median baseline creatinine for in-hospital mortality or nephrotoxin exposure, suggesting that patients with low baseline creatinine and stage 3 AKI are an underrecognized patient subset with equally poor outcomes and equal need for nephrology consultation.

SA-PO027

Nephrology Follow-Up and Mortality of Critically Ill Patients with AKI

Rachel Jeong,[1] Alix Clarke,[1] Pietro Ravani,[1] Robert R. Quinn,[1] Matthew T. James,[1] Sean M. Bagshaw,[2] Henry T. Stelfox,[2] Tyrone Harrison,[1] Neesh I. Pannu,[2] Daniel Niven,[1] Ngan Lam.[1] *[1]University of Calgary, Calgary, AB, Canada; [2]University of Alberta, Edmonton, AB, Canada.*

Background: Acute kidney injury (AKI) is common in the intensive care unit (ICU) and associated with adverse outcomes. We sought to estimate the association between nephrology follow-up within 3 months post-discharge and mortality in survivors of critical illness and moderate-to-severe AKI, compared to family physician-only follow-up.

Methods: In this retrospective cohort study in Alberta, Canada, we identified adult patients admitted to ICU with KDIGO stage 2-3 AKI from 2005-2020 who survived to 3 months post-discharge without kidney replacement therapy or eGFR <15 mL/min/1.73 m^2. Patients with nephrology follow-up were matched 1:1 on their propensity scores for nephrology vs. family physician-only follow-up within 3 months post-discharge. The primary outcome was death from 3 months post-discharge, reported as the cumulative incidence at 12, 24 and 50 months and hazard ratios (HR [95% confidence interval, CI]).

Results: Of 8979 survivors of critical illness and stage 2-3 AKI at 3 months post-discharge, 500 (6%) received nephrology and 7455 (83%) received family physician-only follow-up. Outcome analysis included 437 patient pairs. Risks at 12, 24, and 50 months in patients with nephrology follow-up were 7%, 13%, and 26%, respectively, compared to 14%, 21%, and 36%, in patients with family physician-only follow-up (Figure 1).

Nephrology follow-up was associated with lower mortality risk compared to family physician-only follow-up (HR 0.58 [95% CI: 0.44, 0.77] in the first 35 months and 1.09 [95% CI: 0.83, 1.42] after 35 months).

Conclusions: In survivors of critical illness and stage 2-3 AKI, nephrology follow-up was associated with lower mortality, with potential benefits up to 3 years.

Funding: Private Foundation Support

Nephrology Follow-Up Care Patterns for Survivors of Neonatal Intensive Care Unit AKI

Anna E. Williams,[1] Clarissa J. Diamantidis,[2] Rasheed A. Gbadegesin.[1]
[1]Duke University School of Medicine, Durham, NC; [2]Wake Forest University School of Medicine, Winston-Salem, NC.

Background: Acute kidney injury (AKI) is the sudden loss of kidney function and complicates nearly 25% of neonatal intensive care unit (NICU) hospitalizations. Neonates who survive AKI events are at increased risk of long term adverse outcomes such as the development of chronic kidney disease, however few guidelines exist to promote nephrology follow-up at discharge for this high-risk group. We investigated patterns of neonatal AKI survivor nephrology follow-up to determine patient- and provider-level factors associated with receipt of AKI follow-up at discharge.

Methods: Retrospective review of 100 neonates at a single academic center NICU with diagnosis of AKI during the first month of life identified via ICD-10 diagnostic codes and confirmed by laboratory findings concordant with KDIGO neonatal AKI diagnosis. Data collected included patient-level characteristics—sex, gestational age, AKI stage, and AKI etiology—and provider-level characteristics—discharging provider type. The primary outcome was outpatient nephrology follow-up care as defined by a scheduled follow-up visit at time of discharge. Data were compared by Fisher's exact test.

Results: From January 2017-December 2020, 85 neonates with diagnosis of AKI survived to discharge. The population was male predominant (66%) with a median gestational age of 26 weeks. About three quarters (75%) experienced Stage 2 or Stage 3 AKI. Etiology of AKI was predominantly due to nephrotoxic medication exposure such as indomethacin, gentamicin and vancomycin (82%). Inpatient nephrology involvement in NICU care was limited (10%). Most neonates were discharged home by neonatal nurse practitioners (92%). Few neonates (3%) had scheduled nephrology follow-up care recorded at discharge. AKI stage, AKI etiology or receipt of inpatient nephrology consultation did not correlate with receipt of outpatient nephrology follow-up care at discharge.

Conclusions: Post-AKI nephrology follow-up is lacking in survivors of neonatal AKI regardless of AKI severity or etiology. Though not clinically significant, infrequent pediatric nephrology consultation in the hospital likely influenced lack of outpatient nephrology follow-up. This provides opportunity for provider education and collaboration with pediatric nephrologists to unify follow-up practices and mitigate adverse AKI-related outcomes in this population.

SA-PO029

Health Care Provider Awareness of AKI in Patients with Advanced CKD Undergoing Surgery: A Descriptive Study of Preoperative Notes

Jonah Buckstein,[1,2] Sarah M. Hammond,[1,2] Tyrone Harrison,[3] Samuel A. Silver.[1,2] *[1]Kingston Health Sciences Centre, Kingston, ON, Canada; [2]Queen's University, Kingston, ON, Canada; [3]University of Calgary, Calgary, AB, Canada.*

Background: Postoperative acute kidney injury (AKI) is a frequent complication of surgery, with an incidence of 18-47%. The KDIGO guidelines offer a bundle of preventative strategies to mitigate AKI risk. Our study examined how often the risk of AKI and elements of the KDIGO bundle were mentioned by healthcare providers in their preoperative notes.

Methods: We retrospectively identified patients ≥ 18 years followed in a tertiary care advanced chronic kidney disease (CKD) clinic who underwent elective surgery with a preoperative anesthesia assessment between January 1, 2017 and December 31, 2022. We extracted data on provider awareness of AKI, inclusion of KDIGO bundle elements in preoperative assessments, and qualitative comments on AKI risk assessment. We analyzed the quantitative data descriptively, stratifying our findings by preoperative healthcare provider awareness of AKI. We used a constant comparison technique and consensus to analyze qualitative comments.

Results: Of 91 patients, the mean age was 76 (±13) years, 75% were male, and 96% had category 4 or 5 CKD. Postoperative AKI and dialysis frequencies were 13% and 1%, respectively. Few anesthesia providers (n=22/91, 24%) mentioned the risk of postoperative AKI. The most commonly documented KDIGO recommendations included holding ACEi/ARB medications (n=15/21, 80%), obtaining a preoperative creatinine measure (n=66/91, 73%), and considering hemodynamic monitoring (n=28/91, 31%). The least mentioned KDIGO recommendations included avoiding radiocontrast media (n=0/91, 0%), controlling hyperglycemia (n=2/91, 2%), and documenting the need for a postoperative creatinine (n=2/91, 2%). There was no difference in the inclusion of KDIGO bundle elements when stratifying preoperative awareness of AKI. In qualitative comments, providers who recognized postoperative AKI risk frequently mentioned the potential for dialysis (n=12/22, 55%), rarely utilized risk scores (n=1/22, 5%), and did not provide any actionable postoperative orders (n=0/22, 0%).

Conclusions: Among patients with advanced CKD, only 24% of anesthesia providers mentioned the risk of AKI in their pre-operative assessments. Opportunities may exist to improve the perioperative care of patients with advanced CKD by increasing awareness of AKI risk and the KDIGO bundle elements.

SA-PO030

Validation of AKI Prediction Model as Clinical Decision Supporting System

Eun Mi You,[1] Jinyeong Yi,[2] Sangyub Han,[3] Sejoong Kim,[1,4] Giae Yun.[4,5]
[1]Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [2]Seoul National University Graduate School of Convergence Science and Technology, Gwanak-gu, Seoul, Republic of Korea; [3]Seoul National University College of Medicine, Jongno-gu, Seoul, Republic of Korea; [4]Seoul National University College of Medicine Department of Internal Medicine, Seoul, Republic of Korea; [5]Hallym University Dongtan Sacred Heart Hospital, Hwaseong, Gyeonggi, Republic of Korea.

Background: Acute kidney injury (AKI) is a critical clinical syndrome requiring immediate intervention. Our previous research developed a 'PRIME solution' AI model for AKI. This study aims to evaluate the usefulness of this AI model in improving the predictive capabilities of AKI prediction.

Methods: We utilized convolutional neural networks with a residual block to predict AKI in hospitalized patients. The training set comprised data from 183,221 patients at Seoul National University Hospital (2013-2017). At Seoul National University Bundang Hospital (2020-2021), we randomly selected 74 patients from departments with high AKI rates, including 15% AKI cases. We assessed the impact of an AI model on clinical decisions by comparing evaluations with and without AI assistance.

Results: Accuracy was highest for physicians, with students and the AI model were similar (physician: 0.797, student: 0.574, AI: 0.568). AI assistance improved recall and F1 scores for all almost individuals (recall: 52.4% to 71.4%, F1: 37.7% to 46.1%). In the AKI predicted group, recall increased while F1 decreased for physicians (recall: 36.4% to 60%, F1: 43.2% to 33.3%) and students (recall: 54.5% to 80%, F1: 44.4% to 36.9%). For the non-AKI predicted group, both saw significant gains in recall and F1 with AI (physicians: recall 16.7% to 87.5%, F1: 18.2% to 66.7%; students: recall 44.4% to 75%, F1: 21.1% to 40%). Review times decreased for all with AI (median: 69.0 to 52.0 seconds, p=0.032), especially in the non-AKI predicted group (68.5 to 46.0 seconds, p<0.001; AKI predicted group 71.0 to 57 seconds, p<0.001).

Conclusions: AI notably improved physician performance, especially in the non-AKI predicted group with significant time savings and higher F1 scores. However, its impact was less marked in the AKI-predicted group. Alongside enhancing AI, studies on its application and target groups are essential.

The bars represent the average performance of each group, with error bars reflecting the 95% confidence interval (CI).

SA-PO031

Risk vs. Reward: Impact of Kidney Biopsies on the Management of Critically Ill Patients

Adrian Llama, Sagar S. Sadarangani, Dennis G. Moledina, Randy L. Luciano. *Yale University School of Medicine, New Haven, CT.*

Background: Kidney biopsy is the gold standard for diagnosing many renal diseases, providing crucial information that guides treatment decisions and potentially improves patient outcomes. However, these benefits must be balanced against the risks, particularly in critically ill patients, who are at higher risk of complications due to unstable hemodynamics and coagulation abnormalities. Here we examine the safety and benefit of kidney biopsies in critically ill patients compared to others.

Methods: In participants enrolled in the Yale Kidney biobank, we compared the safety and benefit of kidney biopsies between those in the ICU, inpatient wards, and outpatients. The benefit was changes in management, defined as the initiation of steroids, immunosuppressive agents, pheresis, or drug discontinuation post-biopsy. Secondary outcomes included changes in diagnosis, the need for short-term hemodialysis, and chronic hemodialysis dependence. We also assessed safety outcomes using a composite measure of medium/large hematomas, drops in hemoglobin, the need for additional imaging, and interventional radiology procedures.

Results: Of the 748 participants, 30 were in the ICU, 202 were inpatient, and 516 were outpatients (Table). Kidney biopsies in the ICU group had a significant impact on management, with 18/30 (60%) of the biopsy results leading to changes in or avoidance of immunosuppressive therapy relative to what would have been the standard of care based on the pre-biopsy diagnosis. The remaining biopsies either confirmed the pre-biopsy diagnosis or resulted in a change between two non-treatment-requiring processes. Safety events were observed in all groups, with the highest rate in the critically ill.

Conclusions: Kidney biopsies in the critically ill can significantly impact management but may carry a higher risk of safety events. This risk needs to be compared to the potential benefit and should not be a barrier to a biopsy in select patients.

Table. Comparison of kidney biopsy safety and adequacy outcomes amongst biopsies performed in patients in different admission/outpatient settings

Characteristic	Outpatient	Inpatient	ICU	P value
Composite safety outcome	115 (22.3%)	66 (32.7%)	15 (50.0%)	<0.001
Transfusions due to complication, n (%)	5 (1.0%)	11 (5.7%)	1 (3.4%)	0.001
Medium/large hematoma found after biopsy n (%)	11 (2.2%)	10 (5.2%)	3 (10.0%)	0.014
Immediately after biopsy	7 (1.4%)	4 (2.3%)	0	0.569
Within 30 days of biopsy	6 (2.4%)	7 (5.8%)	3 (18.8%)	0.003
Hemoglobin drop	1.10 (0.60, 1.75)	1.20 (0.60, 2)	1.50 (1, 2.80)	0.016
Hb drop ≥1 but <2 g/dl	180 (36.3%)	66 (33.8%)	11 (36.7%)	0.827
Hb drop ≥2 g/dl	103 (20.8%)	51 (26.2%)	12 (40.0%)	0.025
IR intervention	8 (1.6%)	11 (5.6%)	2 (7.1%)	0.007
Additional Imaging, n (%)	53 (10.5%)	53 (27.2%)	13 (43.3%)	<0.001
For drop in Hb	4 (0.8%)	3 (1.5%)	2 (6.7%)	0.017
For flank/back pain	17 (3.4%)	10 (5.1%)	0	0.300
For concern for bleeding	8 (1.6%)	16 (8.2%)	4 (13.3%)	<0.001
For hypotension	2 (0.4%)	3 (1.5%)	1 (3.3%)	0.098
Reason not specified	22 (4.4%)	21 (10.8%)	6 (20.0%)	<0.001

SA-PO032

Low-Sodium Diet and Mortality in Patients with Heart Failure with Worsening Kidney Function during Hospitalization

Minhyung Kim, Seungmin Song, Kyungho Lee, Jung eun Lee, Wooseong Huh, Hye Ryoun Jang, Junseok Jeon. *Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.*

Background: Sodium restriction can help prevent and alleviate congestion in patients with heart failure (HF), but the benefits of sodium restriction are controversial. Patients with worsening renal function (WRF) during treatment of heart failure have worse outcomes and may benefit from more strict volume control. We investigated the prognostic impact of sodium restriction in patients hospitalized with HF focusing on WRF.

Methods: This retrospective cohort study included patients hospitalized for HF from 2000 to 2019. WRF was defined as a decrease in estimated glomerular filtration rate (eGFR) >20% from admission at any point during hospitalization. The difference in weight from admission to discharge was used to estimate the degree of decongestion. Low-sodium diet status was estimated from the diet prescription at the time of discharge. The primary outcome was all-cause mortality.

Results: In a total of 1,079 patients, 566 (52.5%) developed WRF and 325 (30.1%) consumed a low-sodium diet. There was no difference in baseline characteristics between the low-sodium diet and control groups, except for eGFR (low-sodium diet vs control: 58 vs 66 mL/min/1.73 m^2; p=0.001). The proportion of low-sodium diets did not differ between the WRF and no-WRF groups (31% vs 29%; p=0.548). The low-sodium diet group lost more weight than the control group (-2.2 vs -1.9 kg; p=0.015) during hospitalization. During a median follow-up of 33.1 months (IQR 4.7–64.5), 229 (21.2%) patients died. Low-sodium diet was associated with lower mortality in the WRF group (HR 0.563, 95% CI 0.385–0.822, p=0.003), but not in the no-WRF group (HR 0.922, 95% CI 0.563–1.510, p=0.747). Low-sodium diet showed association with lower mortality after multivariable adjustment in the WRF group (adjusted HR 0.668, 95% CI 0.452-0.987, p=0.043).

Conclusions: Low-sodium diet could be beneficial for patient with HF requiring hospitalization, especially with WRF.

SA-PO033

Intravenous Contrast-Induced Nephropathy Risk in Acute Kidney Disease: Nationwide Taiwanese Cohort Study

Li-Chun Lin, Vincent Wu. NSARF (National Taiwan University Hospital Study Group of ARF). *National Taiwan University Hospital, Taipei, Taiwan.*

Background: Current debate surrounds the clinical relevance of nephropathy post-iodinated contrast media (ICM) administration. Limited research exists on the specific impact of intravenous ICM on renal outcomes in acute kidney disease (AKD) patients.

Methods: We conducted a nationwide retrospective cohort study in Taiwan from January 2015 to September 2022, identifying adult patients transitioning from acute dialysis to AKD status. Propensity score weighting and entropy balancing were used to minimize heterogeneity between contrast-enhanced computed tomography (CT) and non-contrast exposure groups. Primary outcome was redialysis, with MAKE as secondary outcomes, defined as redialysis or a ≥50% increase in serum creatinine from baseline AKD value. Follow-up extended up to one year.

Results: A total of 19,505 AKD patients were included (mean age: 68.70 years, male 58.80%). Among them, 14.9% underwent intravenous ICM. Following propensity score weighting and entropy balancing adjustment, the ICM-exposed group did not exhibit a significantly elevated risk of redialysis compared to the non-contrast group (odds ratio (OR) 0.88, 95% confidence interval (CI) 0.74–1.05) and entropy balancing adjustment (OR 0.81, 95% CI 0.69–0.94). Similarly, the risk of MAKE was not significantly different between the ICM and non-contrast groups (propensity score weighting: OR 1.00, 95% CI 0.88–1.12; entropy balancing: OR 0.94, 95% CI 0.84–1.05). Subgroup analysis for patients with an estimated glomerular filtration rate (eGFR) either ≥ 30 or <30 ml/min 1.73 m2 yielded similar results; for the patients with eGFR of ≥ 30 ml/min 1.73 m2, the OR of redialysis and MAKE were 0.93 (95% CI: 0.74-1.16) and 1.04 (95% CI: 0.92-1.18), respectively; for those with eGFR < 30 ml/min 1.73 m2, the OR of redialysis and MAKE were 1.15 (95% CI: 0.96-1.37) and 1.10 (95% CI: 0.95-1.30), respectively.

Conclusions: In patients with AKD, intravenous administration of ICM for contrast-enhanced CT scans did not significantly increase the risk of redialysis or MAKE within one year

SA-PO034

Breaking the Myth: Does Albumin before the Furosemide Test Work?

Nayeli N. López Villa, Ricardo A. Garza Treviño, Juan P. Gomez Villarreal, Mara C. Olivo Gutierrez, Sofia Lopez-Guzman, Lilia M. Rizo Topete. *Hospital Universitario Dr Jose Eleuterio Gonzalez, Monterrey, Mexico.*

Background: Acute kidney injury is a common complication in patients in the intensive care unit. It has multiple etiologies and risk factors that lead to adverse clinical outcomes, chronic kidney disease or death. Patients undergoing the furosemide stress

test are classified as responders or non-responders based on whether their urine output is greater than 200 ml or not within 2 hours after the administration of furosemide. We consider that hypoalbuminemia could be an important factor for the diuretic response, as 95% of furosemide binds to plasma proteins. Therefore, we sought to evaluate the effectiveness of the Furosemide Stress Test in patients with hypoalbuminemia.

Methods: This is a prospective quasi-experimental study. Informed consent was obtained, with prior authorization from the ethics committee. Patients were obtained from the intensive care unit of the Dr.José Eleuterio González University Hospital with KDIGO 1 and 2 AKI and serum albumin less than 3 g/dL. A bolus of furosemide was administered at a dose calculated to be 1-1.5 mg/kg in a single dose to patients without a prior diagnosis of kidney disease and without clinical signs of hypovolemia.

Results: A total of 37 patients were enrolled, aged between 19 and 77 years, of which 45% had diabetes mellitus, 40% had hypertension, 51% were on at least one nephrotoxic medication, and 40% had sepsis as the cause of AKI. The mean albumin level was 1.8 g/dL. To evaluate the relationship between albumin levels and the use of furosemide, a correlation analysis was performed between albumin levels and the response to the furosemide stress test, which found no decrease in urinary response in patients with hypoalbuminemia.

Conclusions: According to the population evaluated in our study, we determined that hypoalbuminemia does not decrease the response to the furosemide stress test. Therefore, we conclude that intravenous albumin should not be administered before furosemide.

Hemofiltrate Reinfusion (HFR)-Supra during Sepsis-Associated (SA)-AKI Treats Inflammation and Improves Patient Outcomes

Giuseppe Gernone. *ASL Bari, Bari, Italy.*

Background: Sepsis is life-threatening organ dysfunction caused by dysregulated response to an infection leading to systemic inflammation (SI). AKI is final common pathway of this immune dysregulation. KRT is often required in SA-AKI. HFR-Supra (HFR) trought is adsorbing resin cartridge that remove myoglobin, cytokines and pro-inflammatory mediators, have been used anecdotally. Aim of this study is to test HFR on outcome of SA-AKI in critically ill patients (pts).

Methods: A retrospective observational study evaluated 16 SA-AKI pts. No ESKD pts in chronic dialysis. SA-AKI were treated with daily HFR-S. Given the laboratory operating standards they were assessed: urea, creatinine, C-reactive protein (CRP), procalcitonin (PCT), WBC, platelets (PLT), myoglobin, albumin, mean arterial pressure (MAP), need for vasopressor and outcome. The values have been reported as mean±SD or median and interquartile range. AKI was defined according to KDIGO. Statistical analyzes by Wilcoxon Test

Results: Among 16 pts 10 had AKI III stage. Age was 73.1±11.1 y, 90% are hypertensive, some with heart disease, 60% with CKD, 60% obese or with diabetes. All received mechanical ventilation, 80% received amines. They underwent to 5.5±3.4 HFR treatments (range 2-13); Qb= 238±29.6 ml/m', TT 233.2±45.8 m'. UF 477.9±185.5ml/h. HFR show significant abatement of CRP, PCT and myoglobin. Albumin remain stable. The effect on WBC and PLT reflect the trend of sepsis. Cardiovascular instability decreased allowing suspension of vasoactive amines given significant increase in MAP. (Tab. 1) 7 pts did not survive within follow four weeks, 5 pts had renal recovery, 2 pts had chronic dialysis.

Conclusions: HFR represent a new strategy to decrease SI and support renal recovery in SA-AKI pts. The adsorbing resin is able to remove myoglobin, proinflammatory cytokines and many other mediators that improve MAP and reduce critical illness scores. HFR is safe and cheapest for SA-AKI in comparison to the CRRT, Cytosorb and others. Has excellent cost-effectiveness-sustainability ratio regarding treatment times and staff-sparing. Our evidence gradually help to build a new scientific evidence.

Tab. 1- Median and interquartile range (IQR)	*Baseline*	*After*	*p value < 0,05*
CRP mg/L	222.5 (180.5 - 292)	50,1 (26.5-80.9)	*p < 0,01*
PCT ng/ml	23.7 (13.5 - 75)	2.2 (0,9 - 5)	*p < 0,01*
WBC mm³	17.7 (6.2 - 27)	9.6 (7.8 – 17.4)	*p = 0,23*
Myoglobin ug/L	1666 (907.5 – 6749.5)	453 (219.5 - 557)	*p = 0,01*

MAP mmHg	70,5 (68,2 - 88,7)	87.8 (78,5 - 96,2)	*p = 0,02*
PLT mm³	198.5 (105,7-262,5)	187 (148-258.5)	*p = 0,43*

SA-PO036

UNI-494 Phase 1 Safety, Tolerability, and Pharmacokinetics

Guru Reddy, Sanjay S. Mourya, Steve Hasal, Shalabh Gupta.
Unicycive Therapeutics Inc, Los Altos, CA.

Background: Currently, there are no effective treatments approved for acute kidney injury (AKI). Inflammation and reactive oxygen species driven mitochondrial permeability transition pore (mPTP) opening causes mitochondrial dysfunction/swelling and cell death. This is implicated in acute diseases originating from ischemia reperfusion injury or delayed graft function (DGF). Furthermore, unresolved inflammation exacerbates sustained mPTP opening, evident in chronic kidney diseases. UNI-494 is a selective mitochondrial ATP-sensitive potassium channel activator that binds to ATP-sensitive potassium channels which reverses mitochondrial dysfunction by closing mPTP. We present results from a study evaluating safety, tolerability, and pharmacokinetics (PK) of UNI-494 capsules administered to healthy subjects.

Methods: This was a single-center, double-blind, placebo-controlled, randomized single ascending dose (SAD) (Part 1) and multiple ascending dose (MAD) (Part 2) study in healthy males and females of non-childbearing potential. Part 1 enrolled up to 40 subjects in 5 cohorts of 8 subjects each (6 active/2 placebo per cohort). There was an interim decision meeting after each dose cohort, to review the safety, tolerability, and PK data up to 48 h post-dose to decide the dose level for the subsequent cohort. Part 2 enrolled up to 20 subjects in 2 cohorts of 10 subjects each (8 active/2 placebo per cohort) dosed for 5 days. The dose level for the Part 2 Cohort 1 was selected based on the safety, tolerability, and PK data from Part 1.

Results: Following single and multiple oral administration of 10, 20, 40, 80, and 160 mg UNI-494 capsules there were no serious or severe adverse events, and no subjects were withdrawn for adverse events. In the SAD cohorts, mean UNI-494 C_{max} was 14.9, 52.8, and 80.3 ng/mL and mean $AUC_{(0\text{-last})}$ was 44.6, 154, and 308 hour*ng/mL for the 40, 80, and 160 mg UNI-494 dose groups, respectively.

Conclusions: Single and multiple doses of UNI-494 capsules were safe and well-tolerated in healthy volunteers. Exposure to UNI-494 increased in a dose-proportional manner. Therapeutic levels of nicorandil in SAD dosing were achieved at 160 mg UNI-494. UNI-494 is a potential candidate for the prevention of DGF and other AKI clinical conditions. Future studies should evaluate this promising treatment in the target population of patients with AKI.

Trace Element Intake and Major Adverse Kidney Outcomes in Critically Ill Patients with Severe Sepsis

Tsai-Jung Wang,[1,2] Cheng-Hsu Chen.[1] *[1]Taichung Veterans General Hospital, Taichung, Taiwan; [2]Chung Shan Medical University, Taichung, Taiwan.*

Background: Acute Kidney Injury (AKI) is common in ICU and can lead to poor renal outcomes. The balance of trace elements (e.g., selenium, zinc, and copper) in AKI patients is often disrupted. This study aims to investigate the relationship between trace element intake and renal outcomes in critically ill patients with severe sepsis.

Methods: In this prospective cross-sectional and follow-up study, ICU patients with severe sepsis, older than 20 years, and who stayed in the ICU for >48 hours, excluding those with end-stage renal disease, were included. Major adverse kidney events (MAKE-28) were determined by one or more criteria (e.g., dialysis, sustained Cr doubling from baseline, or death) on the 28th day after ICU admission. The patients' data were collected on the 1st day of ICU admission, and the mean 7-day nutrient intake from both enteral and parenteral nutrition was recorded.

Results: Of 80 patients, the mean age was 69.5 ± 14.2 years and 53 (66.25%) patients developed AKI on ICU admission. During follow-up, 28 (35%) patients experienced MAKE-28. After adjusting for age, gender, and APACHE II score, we found significant associations between nutritional intake and MAKE-28. Specifically, among patients who were admitted with AKI, there were significant correlations between various nutritional intake parameters and MAKE-28, including mean energy intake, mean carbohydrate intake, mean protein intake, and mean selenium/zinc/copper intake. However, for non-AKI patients, nutritional intake was not significantly associated with renal outcomes.

Conclusions: Our findings suggest that nutritional intake, including not only macronutrients but also trace elements plays a critical role in renal outcomes in critically ill patients, particularly those admitted with AKI.

Funding: Government Support - Non-U.S.

Hepatorenal Syndrome-AKI Reversal and Liver Transplant Rates in Patients Treated with Terlipressin

Justin M. Belcher,[1] Kevin R. Regner,[2] Ram Subramanian,[3] Muhammad A. Mujtaba,[4] Andrew S. Allegretti,[5] Sanaz Cardoza,[6] Hani Wadei.[7] *[1]Yale University School of Medicine, New Haven, CT; [2]Medical College of Wisconsin, Milwaukee, WI; [3]Emory University, Atlanta, GA; [4]The University of Texas Medical Branch at Galveston, Galveston, TX; [5]Massachusetts General Hospital, Harvard Medical School, Boston, MA; [6]Mallinckrodt LLC, Bridgewater, NJ; [7]Mayo Clinic in Florida, Jacksonville, FL.*

Background: Hepatorenal syndrome-acute kidney injury (HRS-AKI) occurs in patients (pts) with advanced cirrhosis and ascites. Liver transplantation (LT) is the definitive treatment for the underlying disease, while pre-LT renal replacement therapy (RRT) is associated with poorer post-LT outcomes. Terlipressin (terli) reverses HRS-AKI, which is associated with a reduced need for RRT and improved LT outcomes. However, there are concerns that HRS-AKI reversal and the consequent decrease in serum creatinine (SCr) may reduce the MELD score and thereby negatively affect LT prioritization. The FDA recommends using terli in pts with SCr <5 mg/dL, ACLF grade 0–2, and MELD score <35 (if transplant listed).

Methods: Pts LT-listed at baseline who met the FDA criteria from 2 Phase III, randomized, placebo (pbo)-controlled studies of terli in pts with HRS-AKI (CONFIRM and REVERSE) were pooled for analysis.

Results: In LT-listed pts (terli: n=53; pbo: n=35), the rate of HRS-AKI reversal was significantly higher in the terli group vs pbo (terli: 43% vs pbo: 20%, *P*=.023) (**Figure**). The RRT rate in the terli group vs pbo was 28% vs 46% (*P*=.094) by Day 30; 32% vs 54% (*P*=.038) by Day 60; and 36% vs 54% (*P*=.087) by Day 90. However, the LT rate was similar in the terli and pbo groups: 53% vs 51% (*P*=.90) by Day 30; 66% vs 57% (*P*=.40) by Day 60; and 66% vs 63% (*P*=.76) by Day 90 (**Figure**).

Conclusions: Terli increased the rate of HRS-AKI reversal and reduced the need for RRT vs pbo. Importantly, the increase in HRS-AKI reversal in the terli group (vs pbo) did not negatively impact the LT rate in pts listed for LT at baseline in the population meeting the FDA criteria for terli treatment.

Novel Predictors of Hepatorenal Syndrome Response to Terlipressin: Biomarker Analysis from the CONFIRM Trial

Andrew S. Allegretti,[1] Josh Levitsky,[4] Pratima Sharma,[2] Tianqi Ouyang,[1] Scott Silvey,[3] Jasmohan S. Bajaj.[3] *[1]Massachusetts General Hospital, Boston, MA; [2]University of Michigan, Ann Arbor, MI; [3]Virginia Commonwealth University, Richmond, VA; [4]Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Terlipressin is the only FDA approved vasoconstrictor for hepatorenal syndrome (HRS). The CONFIRM study is the largest trial of terlipressin vs. placebo (HRS response as primary outcome). Novel predictors of HRS response are required to enrich patient selection and optimize outcomes.

Methods: Samples at initiation were tested using (a) LC-MS of 1594 plasma/1420 urine metabolites (Metabolon Inc), (b) aptamer-based array of 7289 plasma proteins (SomaScan), and (c) 14 serum/urine ELISA assays. The CONFIRM trial's original definition of HRS response was used (2 creatinine [SCr] <1.5 mg/dL).

Results: 116 patients (79 terlipressin-treated [TT] and 36 placebo-treated [PT]) provided samples. Baseline characteristics, outcomes, and 2:1 TT:PT allocation were preserved from the original 300 patient trial. 36/116 (31.0%) patients achieved HRS reversal. Demographics were similar by HRS response (**Table**). In metabolite analysis, PT had the most significant differences in HRS responders (n=26 plasma, n=50 urine), with fewer in TT (n=1 plasma, n=2 urine), and in all patients (n=3 plasma, n=7 urine). There were no significant aptamers associated with HRS response after false-discovery correction. HRS responders had lower SCr (p = 0.001), cystatin C (p = 0.005), angiopoietin-2 (p = 0.04), and B2 microglobulin (p = 0.006), while osteopontin, VEGF, and NGAL were similar.

Conclusions: SCr, Cystatin C, angiopoietin-2, and B2 microglobulin, were associated with HRS response. Further study of predictors of HRS response may enrich for better candidates for terlipressin.

Funding: Commercial Support - This work was supported by an investigator-initiated research grant from Mallinckrodt Pharmaceuticals.

Demographics and Analytes by HRS Response

	HRS Response (n = 36)	No Response (n = 79)	P value

Comparison of Conventional and High-Dose Continuous Kidney Replacement Therapy in Critically Ill Patients with Septic AKI

Chan-Young Jung,[1] Jiyun Jung,[3] Jeong-Hoon Lim,[4] Jin hyuk Paek,[6] Kipyo Kim,[5] Yong Chul Kim,[2] Jae Yoon Park,[3] Hyosang Kim,[1] Chung Hee Baek.[1] RENERGY. *[1]Asan Medical Center, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea; [3]Dongguk University Ilsan Hospital, Seoul, Gyeonggi-do, Republic of Korea; [4]Kyungpook National University Chilgok Hospital, Daegu, Republic of Korea; [5]Inha University Hospital, Incheon, Republic of Korea; [6]Keimyung University School of Medicine, Daegu, Republic of Korea.*

Background: Although prospective studies have suggested no differences in patient outcomes between high-dose and conventional-dose continuous kidney replacement therapy (CKRT) in critically ill patients undergoing CKRT, real world data are lacking. This study aimed to compare patient outcomes between conventional and high-dose CKRT in critically ill patients with septic acute kidney injury (AKI).

Methods: This multi-center, retrospective, observational cohort study included 1,390 critically ill patients with septic AKI treated with either conventional (<35 mL/kg/h; *n* =552) or high-dose (≥35 mL/kg/h; *n* = 838) CKRT. The primary outcome was 28-day mortality. Secondary outcomes included 90-day mortality, CKRT duration, kidney replacement therapy (KRT) dependence at discharge, and intensive care unit (ICU) and hospital stays.

Results: No significant differences were observed for both 28- (52.2% vs. 52.4%, *P*=0.938) and 90-day (59.8% vs. 61.7%, *P*=0.475) mortality rates among the conventional and high-dose groups. Compared to the conventional-dose group, the adjusted hazard ratios (95% confidence interval [CI]) for 28- and 90-day mortality were 0.91 (95% CI, 0.78-1.06, *P*=0.213) and 0.94(95% CI, 0.81-1.08, *P*=0.383), respectively. The conventional-dose group was associated with both a higher rate of KRT dependence at discharge (17.6% vs. 9.0%, *P* <0.001) and longer length of ICU stay (median 9.5 vs. 7.0 days, *P*=0.010), compared to the high-dose group.

Conclusions: While mortality rates did not significantly differ, when compared to conventional-dose CKRT, high-dose CKRT appeared to have lower rates of KRT dependence at discharge and shorter lengths of ICU stays.

Bioelectrical Impedance Analysis to Assess Fluid Balance in Children Undergoing Continuous Kidney Replacement Therapy

Shruthi Mohan,[1] Ryan W. Schablein,[1] Kelli A. Krallman,[1] Stuart Goldstein,[1,2] Natalja L. Stanski.[1,2] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]University of Cincinnati, Cincinnati, OH.*

Background: Acute kidney injury (AKI) is common in critically ill children and may require continuous renal replacement therapy (CRRT). Accurate fluid balance (FB) assessment during CRRT is important but challenging as traditional methods show limited agreement and variation. BIA has been studied in adults on CRRT, but no data exist in children. We aimed to (1) assess the feasibility of BIA to evaluate FB in pediatric CRRT, and (2) compare it to traditional methods. We hypothesized that bedside and BIA assessments of FB would be discrepant.

Methods: Ongoing single-centered, prospective, observational study of patients 3-25 years (Y) receiving CRRT. We performed BIA (InBody BWA 2.0) at several timepoints (prior to CRRT, Day 2, 4, and 7 *or* prior to CRRT discontinuation) to measure total body water (mTBW). These values were compared to calculated TBW (cTBW) using the Morgenstern equation, weight (kg), cumulative FB (L), and clinician assessment of FB (nephrology/ICU).

Results: Five included patients (60% males, mean age 15.8Y) contributed 11 BIA measurements. Seven (64%) demonstrated >10% difference between mTBW and cTBW, with an absolute mean difference of 17.5% (SD 14.1%). Temporal trends in mTBW, weight and FB for patients with complete data are shown in Figure1. Concordance of FB assessment was 50% or less for all possible combinations of BIA/nephrology/ICU (Table1).

Conclusions: BIA for assessment of FB in critically ill children receiving CRRT is feasible and discrepant with traditional methods, highlighting its possible role in guiding fluid removal on CRRT.

Funding: NIDDK Support

SA-PO042

Characteristics of Antimicrobial Administration in Patients Receiving CRRT

Danica Quickfall, Jay L. Koyner. *University of Chicago Division of the Biological Sciences, Chicago, IL.*

Background: Antimicrobials are given frequently to patients requiring renal replacement therapy (RRT) in the intensive care unit (ICU). Antibiotic overuse is associated with increasing antimicrobial resistance, which comes with individual, public health, and socioeconomic consequences. While early antimicrobial therapy crucial for surviving sepsis, there are no studies that characterize the incidence of confirmed infection and antimicrobial resistance in patients receiving continuous RRT (CRRT).

Methods: A retrospective chart review identified 954 ICU patients admitted to University of Chicago Medicine between May 2016 and April 2020 who received an antimicrobial of interest and continuous veno-venous hemodialysis (CVVHD). Antimicrobial administration, specimen cultures and sensitivities were recorded. Patients were grouped according to the antimicrobial received, culture type, microbe present and sensitivities.

Results: In 954 patients receiving antimicrobials on CVVHD, vancomycin was the most administered (941, 99%), followed by cefepime (824, 86%). Of the patients receiving antibiotics, 175 (18.3%) had a confirmed infection identified with culture data. A total of 13,960 cultures were sent, with 4022 (28.8%) returned positive. The most common infections were respiratory (36.7%), blood stream (31.3%) and skin and soft tissue infections (12.8%). The most common bacteria were *Pseudomonas aeruginosa* identified in 10.3% of positive cultures (Table 1). In patients with positive cultures 132 (75.4%) died compared to 557 (71.1%) in culture negative patients (p = 0.24).

Conclusions: The incidence of positive cultures in ICU patients receiving CVVHD was low, but when present was most often a respiratory or blood stream infection. Vancomycin is administered in nearly every patient despite the high incidence of vancomycin resistant pathogens. Additionally, positive cultures are not associated with increased mortality.

Antimicrobial	n (% total patients)	Culture	n (% positive cultures)	Pathogen	n (% positive cultures)	Sensitivities	Percentage of Resistant Isolates (%)
Cefepime	824 (86)	Respiratory	1140 (36.7)	Candida sp.	910 (22.6)	Vancomycin resistance	76.6
Meropenem	124 (13)	Blood stream	972 (31.3)	P. aeruginosa	428 (10.6)	Carbapenem resistance	17.8
Piperacillin-Tazobactam	223 (23)	Urine	365 (11.3)	E. coli	193 (4.8)	Cefepime resistance	34.1
Vancomycin	941 (99)	Skin and soft	398 (12.8)	S. aureus	310 (7.6)		

Table 1 – Summary of most administered antibiotics confirmed source of infection and causative pathogens in ICU patients on CVVHD.

Anticoagulation in Extended Kidney Replacement Therapy (EKRT) for Critically Ill Patients with AKI: Efficacy and Safety of Citrate vs. Saline

Lucas B. Mota,[1] Etienne Macedo,[2] Renato A. Caires,[1] Ligia C. Battaini,[1] Elerson Costalonga,[1] Maristela C. Costa,[1] Emmanuel A. Burdmann,[1] Veronica T. Costa e Silva.[1] *[1]Hospital das Clinicas da Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil; [2]University of California San Diego, La Jolla, CA.*

Background: Regional citrate anticoagulation (RCA) is becoming a popular alternative to heparin for EKRT in acute kidney injury (AKI) patients in the intensive care unit (ICU). Single-pass batch dialysis (SBD) is well suited for EKRT, yet there is limited data with RCA. This study compares efficacy and safety of RCA vs. saline for SBD-EKRT in ICU patients with AKI.

Methods: We conducted a prospective cohort using SBD-EKRT in critically ill adults with AKI from January 2015 through February 2020 at a tertiary university hospital in Brazil. Patients were divided in two groups, RCA and normal saline (NS). RCA used either citrate 4% or acid citrate dextrose (ACD) 2.2%, initial dose of 3 mmol/L. Calcium levels were measured every 2 hours for adjustment. The saline infusion rate (mL/h) matched the blood flow (mL/min). The primary outcome was filter clotting.

Results: The RCA group included 25 patients, and 39 EKRT sessions, while the NS group included 17 patients, and 31 EKRT sessions. All 42 patients were 63y (47-67), 59% male, main AKI cause was sepsis (60%), 20% on vasopressors, and 7% on mechanical ventilation. RCA had longer therapies, lower median blood flow, and higher ultrafiltration (UF) targets, compared to NS. Clotting interruption occurred in 3 (7.9%) RCA sessions and in 5 (16.1%) NS therapies (p=0.28). Hypotension (mean blood pressure <65 mmHg) frequency was similar (p=0.60) in both groups. A good metabolic control was achieved by RCA-SBD, post KRT laboratory disclosed creatinine 2.19 mg/dL (1.6-3.0), urea 55 mg/dL (29-105), potassium 3.9 mEq/L (3.5-4.2), and ionized calcium 4.1 mg/dL (3.9-4.4). During RCA-SPB, frequency of severe hypocalcemia (≤ 4 mg/dL) and bicarbonate ≥ 29 mEq/L were 35% and 8%, respectively.

Conclusions: This is the largest series of ICU patients with AKI with RCA in SBD-EKRT, showing safety and efficacy.

Funding: Government Support - Non-U.S.

Extracorporeal Treatment with Hemoperfusion in the Management of Acute Poisoning

Enzo C. Vasquez Jiménez, Mayra Aviles, Octavio R. Garcia-Flores. *Hospital Juarez de Mexico, Mexico City, Mexico.*

Background: Acute poisonings are a major cause of morbidity and mortality in the world, especially in developing countries like Mexico. Hemoperfusion (HP) is a technique for clearing medium and large molecular weight, lipophilic and highly protein-binding molecules, based on the principle of adsorption through a sorbent. It can be used alone or combined with other renal replacement techniques. Hemoperfusion removes toxins from the blood or plasma by attaching to a surface incorporated into a cartridge or resin where the toxin is adsorbed. The advantage of adsorption when compared to diffusion is that it is not limited by the molecular weight or protein binding of the toxin. In this study, we present the experience of using hemoperfusion in acute poisoning by different poisons.

Methods: Eight poisoned patients were treated with Hemoperfusion.

Results: Results are shown in Table 1

Conclusions: Extracorporeal treatment of poisoning is considered in serious situations in which immediate elimination of the poison is indicated. Also in situations where there are no antidotes available or when toxicity is expected to be prolonged despite treatments to eliminate toxins. To make the decision to use ECT, some properties of the venom must be considered: molecular weight, protein binding, volume of distribution, and clearance pathway. Some of the indications where hemoperfusion has been used are in acute poisoning; in poisoning by drugs (valproate, carbamazepine, quetiapine), chemicals (paraquat, organophosphates) or natural toxic products (fungi, snake bite).

Safety and Efficiency Evaluation of Carbon Dioxide Removal in Combination with Continuous Veno-Venous Hemodialysis/ Hemodiafiltration Therapy: Baseline Characteristics of the multiECCO2R Study

Anna P. Wammi,[1] Stefan Kluge,[2] Dominik Jarczak,[2] Carsten Willam,[3] Stefan H. Blaas,[4] Bertram Ottillinger,[5] Natalia Korolev,[1] Jennifer Braun,[1] Manuela Stauss-Grabo.[1] *[1]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [2]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany; [3]Universitatsklinikum Erlangen, Erlangen, Germany; [4]Klinik Donaustauf, Donaustauf, Germany; [5]Ottillinger Life Sciences, Brunnthal, Germany.*

Background: Extracorporeal carbon dioxide removal ($ECCO_2R$) was introduced to reduce the level of blood CO_2 in patients with acute respiratory distress syndrome (ARDS) and to limit the risk of ventilator-induced lung injury. The use of CO_2 removal gas exchangers could allow non-invasive ventilation techniques or the adoption of protective invasive mechanical ventilation reducing pulmonary stress. The CO_2 blood gas exchanger multiECCO2R with a surface of 1,35 m^2 can be integrated into a CRRT platform downstream of the dialyzer, allowing simultaneous treatment of adult patients with ARDS and acute kidney injury.

Methods: The open, interventional post-market clinical follow-up study plans to enroll 40 patients overall in Germany, it is currently in the recruitment phase. Patients with combined renal failure and hypercapnia due to acute lung failure in COVID-19 and other forms of respiratory insufficiency (e.g. ARDS) are being recruited and will be treated on the multiFiltrate MFT/MFT PRO (Fresenius Medical Care) with the multiECCO$_2$R gas exchanger (EUROSETS) for up to 72 hours.

Results: 17 patients (12 males) with a mean age of 66.8±11.3 years and a baseline paCO2 value of 59.2±8.3 mmHg treated with best possible protective ventilation setting have been recruited. The leading cause for renal disease was sepsis (42.1%), and the leading cause for lung disease was pneumonia (50%). All included patients were treated in a CVVHD setting, with a mean blood flow of 186.5±75.3 ml/h and anticoagulation with heparin (47.1%) or citrate (52.9%).

Conclusions: The multiECCO$_2$R study will evaluate safety and efficiency of CO_2 removal in combination with CRRT treatment. Trial results are planned to be reported in 2025.

Funding: Commercial Support - Fresenius Medical Care Deutschland GmbH

Impact of Statins on Mortality and Length of Hospital Stay among Patients with AKI: A Systematic Review and Meta-Analysis

Abdulmueti Alshareef,[1,2] Mutaz Bellah Abudrea,[3] Abdulmohimen A. Elkhadar,[3,2] Ibrahim Ben Shady.[3,2] *[1]Zawia Teaching Hospital, Zawia, Libya; [2]Preventive Medicine Hospital, Tarabulus, Libya; [3]Tripoli Medical Center, Tripoli, Libya.*

Background: Acute kidney injury (AKI) is a frequent complication in critically ill patients, with very high mortality rates. Several studies have suggested that statin therapy, beyond its effects on cholesterol, may have impacts on the course of AKI and its complications. However, we conduct a systematic review and meta-analysis to assess the impact of statin on mortality and the length of hospital stay in hospitalized AKI patients

Methods: We conducted a systematic review and meta-analysis to investigate the impact of Statin on the Length of hospital stay in AKI patients, A literature search was performed using electronic databases and engines including; PubMed, Google Scholar, Scopus, and Web of Science, from inception to May 2024. We included all Original studies that investigate the mortality and length of hospital stay among hospitalized AKI patients.

Results: Nine studies were included in our meta-analysis, the pooled analysis showed a statistically significant reduction in the length of hospital stay for patients using statins compared to those not using statins. The overall standardized mean difference (SMD) was -0.21 (95% CI: -0.32, -0.08), indicating a moderate effect size favoring statin use. In terms of mortality, the pooled analysis of three studies showed a significant reduction of mortality with statin therapy OR (95% CI), 0.728 (0.68, 0.77) ($p < 0.001$)

Conclusions: Our current meta-analysis shows that important beneficial association between statin use and reduction of the overall mortality and reduction of hospital stay length among hospitalized AKI patients, Highlighting the potential benefits of statins beyond their lipid-lowering effects. Even with a limited number of studies that investigate the association, these findings should be further explored in ongoing international, randomized clinical trials.

Effect of Cessation of Renin-Angiotensin System Inhibitors on Clinical Outcomes in AKI

Amrita Makhijani, Farah Yasmin, Dennis G. Moledina, Yu Yamamoto, Francis P. Wilson. *Yale University School of Medicine, New Haven, CT.*

Background: In the ELAIA-2 trial, we investigated whether an automated clinical decision support system affects discontinuation rates of potentially nephrotoxic medications and improves clinical outcomes in patients with AKI. One of the findings of the ELAIA-2 trial was that the proportion of RAASi prescribed were significantly altered due to the best practice alerts the providers received. We conducted a subgroup analysis to evaluate the differences in clinical outcomes between patients with RAASi inhibitors discontinued vs. cessation and clinical outcomes using an instrumental variable regression. A secondary objective was to evaluate the existence of a causal relationship between ACE/ARB inhibition and clinical outcomes and to evaluate if the effect of the drugs is influenced by potential patient characteristics using an instrumental variable regression.

Methods: All statistical analysis was conducted on STATA (Stata, v.18., College Station, TX).

Results: There was a significantly higher proportion of in-patient mortality, dialysis, AKI progression and composite outcomes at 14-days follow-up in the group that had their ACE/ARB discontinued. However, we observed no causal relationship of cessation of RAASi on clinical outcomes upon instrumental variable regression. This was the case amongst all examined subgroups including congestive heart failure, chronic kidney disease, pulmonary disease, hypertension, depression, malignancy and liver disease (Table 1).

Conclusions: There is minimal causal relationship between RAASi cessation and outcomes among hospitalized patients with AKI.

Table 1: Regression of RAASi on Clinical Outcomes

	Composite Outcome	AKI Progression	Mortality	Dialysis
Unadjusted Cohort	2.49 (1.96-3.16)	2.08 (1.62-2.67)	4.88 (3.24-7.33)	4.34 (2.31-8.16)

SGLT2 Inhibitor Treatment during AKI and Its Association with Major Adverse Kidney Events

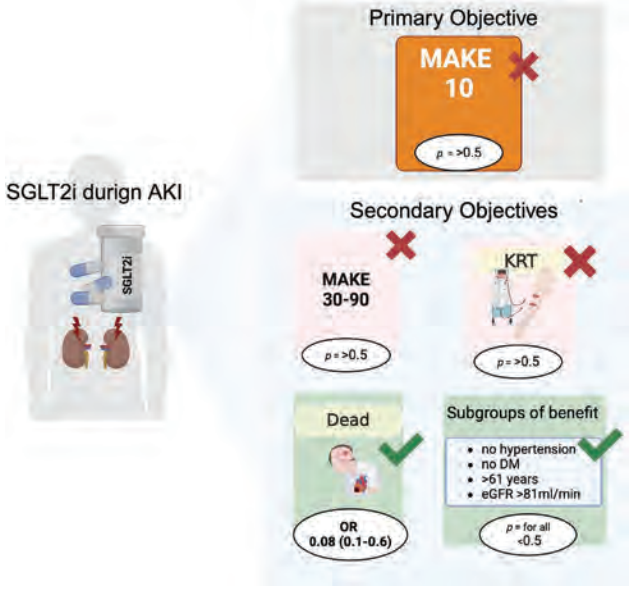
Jonathan Chavez,[1,2] Guillermo Garcia-Garcia,[1] Ramon Medina,[1,2] Francisco O. Ruiz Ochoa,[1] Yulene Navarro Viramontes,[1] Narda C. Ramírez,[1] Jose G. De la Rosa Medina,[1] Ixchel De la Torre De la Vega,[1] Jenifer M. Langarica López,[1] Fernando Cruz Aragon,[1] Guillermo Navarro Blackaller,[1] Maria de la Luz Alcantar Vallin.[1] *[1]Universidad de Guadalajara, Guadalajara, Mexico; [2]Hospital Civil de Guadalajara, Guadalajara, Mexico.*

Background: The association between the administration of sodium–glucose cotransporter 2 inhibitors (SGLT2i) during acute kidney injury (AKI) and the incidence of major adverse kidney events (MAKEs) is not known.

Methods: This retrospective cohort study included patients with AKI and compared outcomes for those who were treated with SGLT2i during hospitalization and those without SGLT2i treatment. The associations of SGLT2i use with MAKEs at 10 and 30-90 days, each individual MAKE component and the prespecified patient subgroups were analyzed.

Results: From 2021 to 2023, 374 patients were included—316 without SGLT2i use and 58 with SGLT2i use. Patients who were treated with SGLT2i were older; had a greater prevalence of diabetes, hypertension, chronic heart failure and chronic kidney disease; required hemodialysis less often; and presented stage 3 AKI less frequently than those who were not treated with SGLT2i. Logistic regression analysis with nearest-neighbor matching revealed that SGLT2i use was not associated with the risk of MAKE10 (OR 1.08 [0.45-2.56]) or with MAKE30-90 (OR 0.76 [0.42-1.36]). For death, the stepwise approach demonstrated that SGLT2i use was associated with a reduced risk (OR 0.08; 0.01-0.64), and no effect was found for kidney replacement therapy (KRT). The subgroups of patients who experienced a reduction in the risk of MAKE in patients with AKI treated with SGLT2i were those older than 61 years, those with an eGFR >81, and those without a history of hypertension or DM ($p \leq 0.05$ for all).

Conclusions: The use of SGLT2i during AKI had no effect on short- or medium-term MAKE, but some subgroups of patients may have experienced benefits from SGLT2i treatment.



SA-PO049

Impact of SGLT2 Inhibitors on the Risk of Postoperative AKI

Seungmin Song,[1] Minhyung Kim,[1] Kyungho Lee,[1,2] Junseok Jeon,[1,2] Hye Ryoun Jang,[1,2] Wooseong Huh,[1,2] Jung eun Lee.[1,2] *[1]Samsung Medical Center, Gangnam-gu, Seoul, Republic of Korea; [2]Sungkyunkwan University School of Medicine, Suwon, Republic of Korea.*

Background: Sodium-glucose cotransporter-2 inhibitors (SGLT-2i), recognized for the cardiovascular and renal benefits, impact intraglomerular pressure through tubuloglomerular feedback restoration, potentially altering the risk of acute kidney injury (AKI). This is supported by increased AKI occurrences in patients receiving Renin-Angiotensin-Aldosterone system inhibitors. We aimed to assess the real-world preventive effects of SGLT-2i on risk of postoperative AKI.

Methods: We conducted a retrospective study on diabetic patients who underwent a major surgery at a tertiary hospital in Korea from 2013 to 2023 (n=5902). We compared patients taking SGLT-2i with those taking dipeptidyl peptidase-4 inhibitors (DPP4i) before surgery to evaluate the development of AKI within seven days after surgery. Due to substantial differences in baseline characteristics between the two groups, we performed 1:3 propensity score matching to adjust for 11 potential confounders.

Results: Before matching, the mean age was 67.4 years, with males comprising 66.5% of the cohort. In the unmatched cohort, the incidence of AKI was 14.4% in the SGLT2i group (n=1006) and 14.9% in the DPP-4i group (n=4896), showing no difference between the two groups. Following matching, the incidence of postoperative AKI was 12.9% in patients with SGLT-2i and 16.0% in those with DPP-4i (p=0.030). This difference persisted even after adjusting for patient and operation-related factors (odds ratio 0.742; 95% confidence interval 0.565-0.968; p=0.029). Moreover, the development of severe AKI, defined as a serum creatinine increase of three times or more, was 0.1% in the SGLT-2i group and 1.0% in the DPP-4i group (p=0.014).

Conclusions: The use of SGLT-2i were independently associated with a lower risk of postoperative AKI than the use of DPP-4i in type 2 diabetes. SGLT-2i could potentially become the first-line medication for preventive use in high-risk groups for postoperative AKI.

A. Any-stage of AKI	OR (95% CI)	p value
Overall	0.779 (0.622-0.968)	0.026
Adjusted for patient related factors	0.783 (0.610-1.000)	0.052
Adjusted for patient & operation related factors	0.742 (0.565-0.968)	0.029
B. Stage 3 AKI		
Overall	0.106 (0.006-0.503)	0.028
Adjusted for patient related factors	0.173 (0.009-0.955)	0.102
Adjusted for patient & operation related factors	0.204 (0.012-1.416)	0.194

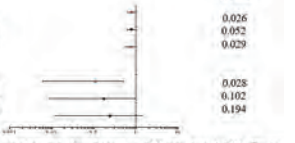


Figure 1. Univariate and multivariate logistic regression model assessing development of postoperative AKI and stage 3 AKI after 1:3 propensity score matching
Analyses were adjusted for patient related factors, including sex, age, body mass index, comorbidities (hypertension, coronary artery disease, and heart failure), medication taking before surgery (Renin-Angiotensin-Aldosterone system inhibitors, diuretics, and nonsteroidal anti-inflammatory drugs), baseline estimated glomerular filtration rate, proteinuria, hyponatremia, hypoalbuminemia, anemia, hemoglobin A1c and operation related factors, including operation time, type of operation (cardiovascular surgery vs. noncardiovascular surgery), use of intraoperative cardiopulmonary bypass, emergent operation and estimated blood loss.

Bleeding Complications after Native Kidney Biopsy Associated with Aspirin Use

Steven Menez,[1] David Hu,[1] Heather Thiessen Philbrook,[1] Jack Bitzel,[1] Yumeng Wen,[1] Mohamed G. Atta,[1] Nityasree Srialluri,[1] John Sperati,[1] Bernard G. Jaar,[1] Celia P. Corona Villalobos,[1] Kyra A. Shelton,[2] Amrita Makhijani,[2] Dennis G. Moledina,[2] Chirag R. Parikh.[1] *[1]The Johns Hopkins University School of Medicine, Baltimore, MD; [2]Yale University School of Medicine, New Haven, CT.*

Background: Bleeding complications following native kidney biopsy include a drop in hemoglobin (Hgb) and the need for blood transfusion. Anti-platelet agents such as aspirin are often discontinued for 7 days pre-biopsy, and this washout period can lead to delays in diagnosis and clinical decision-making. We explored the association of aspirin exposure pre-biopsy with post-biopsy bleeding complications.

Methods: Among adult patients receiving native kidney biopsies at the Johns Hopkins Hospital (JHH) between 2019-2022, and at Yale University Hospital between 2015-2018, aspirin exposure was categorized by last documented use pre-biopsy. Outcomes included a Hgb drop within 3 days and packed red blood cell (pRBC) transfusion within 7 days post-biopsy. Logistic regression was used to determine the odds of these complications by aspirin use, adjusting for pre-biopsy Hgb and platelet count. We adjudicated relatedness of pRBC transfusion to kidney biopsy in a subset of patients.

Results: At JHH, last aspirin use within 3 days pre-biopsy was not significantly associated with higher risk of Hgb drop ≥ 1 g/dL (aOR 1.51; 95% CI: 0.90-2.51) compared to patients with no prior aspirin use within a year. The overall incidence rates of pRBC transfusion were 126/711 (18%) and 33/166 (20%) at JHH and Yale respectively. There was no significant increase in the odds of pRBC transfusion by timing of aspirin discontinuation. In a sub-cohort of 166 patients at JHH, after adjudication, only 8 (4.8%) were deemed to be biopsy-related. Similar results were seen at Yale.

Conclusions: Aspirin exposure pre-biopsy was not associated with increased odds of significant bleeding complications, with biopsy-related pRBC transfusion between 5-8%. These risks should be discussed when consenting patients where urgent biopsy diagnosis is necessary for timely therapeutic decision-making.

Table 1. Bleeding complications following percutaneous kidney biopsy

Overall native kidney biopsy cohorts					
Outcome	Aspirin Use Before Biopsy	n (%)		Odds Ratio* (95 % CI)	
		Yale (N=166)	JHH (N=711)	Unadjusted	Adjusted*
Hgb Drop ≥ 2 g/dL within 3 days	No History	9/122 (7%)	25/418 (6%)	reference	
	Within 3 days	2/18 (11%)	9/86 (10%)	1.76 (0.75, 3.78)	1.69 (0.70, 3.76)

Grading and Follow-Up of T Lymphocyte-Mediated Acute Interstitial Nephritis following Checkpoint Inhibitor Therapy

Ping L. Zhang, Wei Li, Hassan D. Kanaan. *Corewell Health, Royal Oak, MI.*

Background: Immuno-check point inhibitors (CPI) such as PD-1/PD-L1 inhibitors have been used to treat a variety of metastatic carcinoma with positive effects. However, there are complications such as gastrointestinal symptoms and/or kidney dysfunction. This study was determine what dominant inflamatory cells were involved in the CPI-associated acute interstitial nephritis (AIN) and if the AIN can be gradred using a modified Banff criteria for the cellular rejection of renal transplants.

Methods: Totally 20 renal biopsies from 18 patients were performed to evaluate renal pathology due to acute kidney injury following CPI treatment for various metastatic carcinomas. Infiltrating lymphocytes were stained for CD3 to highlight T lymphocytes and for CD20 to identify B lymphocytes. Then the AIN was graded by modifying the popular Banff criteria for borderline changes and acute cellular rejection (ACR) (see Table below).

Results: The identified cases represented 0.7 % of all our renal biopsies. In 15 biopsies, typical AIN was dominated by CD3-positive T lymphocytes and a small percent of B lymphocytes with minimal eosinophils or plasma cells; there were 1 grade 3 AIN, 4 grade 2 AIN and 10 grade 1 AIN. No vasculitis was seen. Five patients' biopsies without AIN had either chromic thrombotic microangiopathy (TMA, n = 1) or acute tubular injury (ATN, n = 4). Following renal biopsies with a diagnosis of AIN, 10 out of 15 patients (66.7 %) with AIN had clinical improvement with steroid treatment. Four patients were found deceased during the recent follow-up check.

Conclusions: Our study indicate that the nephrotoxicity due to CPI treatment is characterized by T lymphocyte mediated AIN as CPI mainly activates T lymphocytes for attaching tumor cells and incidentally attacking normal targets such as renal tubular epithelium. Therefore, using the popular Banff criteria for borderline changes and ACR can be easily adapted for grading AIN due to CPI (the majority was grade 1 AIN). Most patients had some renal functional recovery in response to steroid treatment.

Funding: Clinical Revenue Support

Table 1. Modified Banff Criteria for Grading Acute Interstitial Nephritis (AIN) Induced by CPI

Morphologic changes	CPI associated AIN	Banff criteria for ACR
Lymphocytic infiltration less than 25% of parenchyma with rare tubulitis	AIN 1	Borderline changes
Lymphocytic infiltration more than 25 % parenchyma with mild tubulitis (>4 lymphocytes per cross tubular section).	AIN 2	Grade 1a
Lymphocytic infiltration more 50% parenchyma with moderate or severe tubulitis (>10 lymphocytes per cross tubular section)	AIN 3	Grade 1b

SA-PO052

AKI after Percutaneous Cryoablation of Kidney Tumors: A Retrospective Cohort Study

Shirley Botros, Aman Pal, Krishnakumar D. Hongalgi, Swati Mehta. *Albany Medical Center, Albany, NY.*

Background: Preservation of renal function is an important consideration in the management of renal tumors as decreased renal function is associated with a higher number of cardiovascular events, length-of-stay and overall mortality. Techniques for localized tumor management consist of radical or partial nephrectomy, and thermal ablation, which is considered the least invasive. To further assess the safety of thermal ablation, we evaluated the incidence of acute kidney injury (AKI) and need for hemodialysis after percutaneous renal cryoablation (PRC).

Methods: This multicentric retrospective study involved two tertiary care centers between 2016 and 2022. Subjects were identified through a filter search of electronic medical records for any patient who underwent PRC for a renal tumor. A total of 311 patients were identified and the following data was collected: demographics, comorbidities, use of anticoagulation, laboratory data, tumor characteristics, and procedural data. AKI was identified by KDIGO definition of an absolute increase in serum creatinine (SCr), at least 0.3 mg/dL within 48 hours or by a 50% increase in SCr from baseline within 7 days. Baseline was defined as the lowest SCr within 1 year or most recent SCr if there was evidence of new baseline. Patients were excluded if there was no SCr recorded within 1 year prior to cryoablation or no SCr was obtained within 7 days post-cryoablation.

Results: Among the cohort of 311 patients, only 44 met the inclusion criteria. 14 patients (32%) developed AKI, and 30 patients (68%) did not have AKI. Additionally, there were no patients who required hemodialysis following PRC. Of the patients that developed AKI at the primary center, all 8 of them had resolution of AKI within one month.

Conclusions: PRC is a relatively safe and effective way to treat renal tumors while preserving kidney function. A major limitation of this study is the small number of patients with labs available pre- and post-cryoablation, which may be attributed to clinical stability of the patient precluding the need to obtain labs. Other limitations include lack of control group, short follow-up interval, and retrospective nature of study. These results are promising and warrant larger, randomized controlled trials to be conducted to validate the safety profile of PRC from a renal perspective.

SA-PO053

A Rare Case of Severe Myositis with Microsporidia Invasion of the Kidneys

Sheeraz G. Abro,[1] Paras A. Abro,[2] Javier A. Neyra,[1] Huma Fatima,[1] Emmy K. Bell.[1] *[1]The University of Alabama at Birmingham Division of Nephrology, Birmingham, AL; [2]Liaquat University of Medical and Health Sciences, Jamshoro, Pakistan.*

Introduction: Anncaliia algerae is an obligate intracellular microsporidian parasite known to cause severe myositis among immunocompromised patients. The majority of reported cases are limited to renal transplant patients. We present a case of native renal parenchymal microorganism invasion in a patient with disseminated microsporidia.

Case Description: A 59-year-old man presented with a six-month history of progressive muscle weakness and pain. His condition deteriorated to the point he could no longer ambulate or care for himself. Medical history included Crohn's disease and arthritis, diagnosed in his early twenties and managed with long-term steroid use. Prior to his current illness, he was receiving methotrexate for 6 months and infliximab for 3 months. He only received 3 doses of infliximab before discontinuation due to presumed anti-TNF-induced myositis. Despite administration of intravenous immunoglobulin and pulse-dose steroids, his condition continued to deteriorate. A muscle biopsy revealed necrotizing myositis. Extensive work-up revealed no autoimmune causes for myositis. Urinalysis showed 3+ blood and 2+ protein, along with RBC casts on microscopy. The urine protein-to-creatinine ratio was 1.9 g/g. Renal biopsy **(Figure 1)** revealed uniform-sized, oval-shaped intratubular microorganisms without inflammation, highly suspicious for microsporidia invasion. A tongue biopsy **(Figure 2)** supported this diagnosis, which was confirmed by cell-free DNA testing identifying Anncaliia algerae. Treatment with albendazole was initiated, and immunosuppressants were tapered off. Due to persistent parasitemia complicated with septic shock and multiorgan failure including acute kidney injury requiring dialysis, fumagillin -a mycotoxin from Aspergillus- was administered. Subsequently, his clinical condition improved significantly, with marked recovery of multiorgan function including kidney function.

Discussion: This complex case underscores the importance of comprehensive investigations to uncover rare infectious etiologies and highlights the challenges of managing disseminated microsporidia.

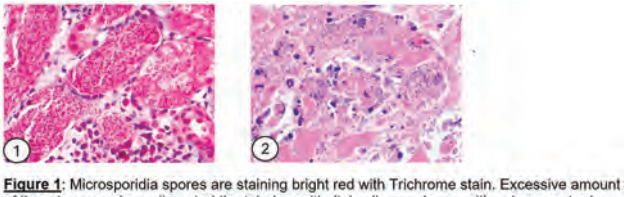

Figure 1: Microsporidia spores are staining bright red with Trichrome stain. Excessive amount of the microorganisms disrupted the tubular epithelial cells membrane with subsequent release of spores into the lumen. Trichrome x 40. **Figure 2:** Tongue biopsy showing microsporidia myositis. Necrotizing myositis with prominent karyorrhexis and spores within the necrotic cytoplasm of the myocytes. Hematoxylin and Eosin, x60.

Epstein-Barr Virus-Associated Acute Interstitial Nephritis in an Adult Presenting with Chronic Osteomyelitis

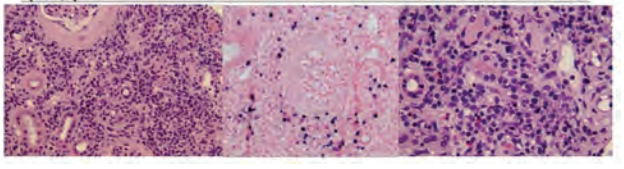
Simran Dhillon,[1,2] Amin Abedini,[2] Songul Onder.[1,2] *[1]University of Maryland School of Medicine, Baltimore, MD; [2]University of Maryland Medical System, Baltimore, MD.*

Introduction: Epstein Barr Virus (EBV) is a rare cause of acute interstitial nephritis (AIN) in adults. It is primarily reported in children and young adults. The use of steroids and duration of the steroid use in viral intertitial nephritis is controvertial.

Case Description: 45 Year old female with chronic osteomyelitis and open wound presented with fever, hypotension, fatigue, flank/abdominal pain and sore throat. Her past medical history was significant for chronic kidney disease stage 3b due to diabetic nephropathy, with baseline serum creatinine at 2.0 mg/dl. Initial labs revealed acute on chronic kidney failure, with serum creatinine at 4.4 mg/dl, cholestatic hepatitis, leukopenia and anemia. She was started on intravenous vancomycin and piperacillin-tazobactam. EBV IgM was positive with elevated viral load. Bilateral flank pain, AKI and cholestatic liver injury worsened despite discontinuing antibiotics. She was started on hemodialysis (HD). Kidney biopsy revealed extensive interstitial inflammatory infiltrates, Epstein-Barr encoding region (EBER) in situ hybridization positive consistent with EBV associated AIN. She was started on Prednisone 60 mg/day and valganciclovir due to worsening symptoms and renal/liver indices. Her symptoms and renal and liver parameters improved to baseline after 10 days course of Prednisone.

Discussion: We here report fast recovery of EBV-associated AIN with short course of prednisone and valganciclovir. Case reports and retrospective cohorts support the use of corticosteroids and antivirals in addition to supportive care in severe complicated EBV-associated AIN. The use of corticosteroid for renal recovery had to be balanced against infectious concerns with osteomyeltis, and thus corticosteroid course was discontinued at ten days after greatly improved renal/liver indices, improved clinical symptoms and liberation from HD. Early recognition and timely initiation of corticosteroid treatment may be crucial for favorable outcomes in EBV-AIN requiring HD.

Labs	Initial	Peak	Post-Treatment
Creatinine (mg/dl)	4.36	7.32	2.4
Bilirubin (mg/dl)	1.0	18.7	1.8
Alkaline phosphatase (units/L)	375	1930	415



Lab results and renal biopsy

Hemopure Therapy in Postpartum Hemorrhagic Shock: Challenges in Laboratory Interference and Kidney Assessment

Issa R. Haddad, Chintan V. Shah, Sheena Pramod. *Division of Nephrology, Hypertension, and Renal Transplantation, University of Florida College of Medicine, Gainesville, FL.*

Introduction: HBOC-201 (Hemopure) is a second-generation hemoglobin-based oxygen carrier (HBOC) derived from bovine (cow) hemoglobin. It is intended to be used as an alternative when human blood is unavailable or unsuitable, such as in emergencies or when a patient refuses blood transfusion for religious or personal reasons. Challenges arise with its interference in laboratory tests, particularly in assessing renal function.

Case Description: We describe the case of a previously healthy 35-year-old pregnant Jehovah's Witness who presented at 38 weeks gestation with placental abruption necessitating emergent cesarean section, leading to postpartum hemorrhagic shock with acute hemoglobin drop to 2.5 g/dL. Due to religious beliefs, she declined human blood products, prompting her transfer to a tertiary center for participation in a clinical trial of Hemopure therapy. The hospital course was further complicated by peripartum cardiomyopathy, ventilator-dependent respiratory failure, and non-oliguric acute kidney injury with refractory hyperkalemia, necessitating intermittent hemodialysis followed by continuous venovenous hemodiafiltration. However, despite regional anticoagulation, circuit clots resulted in further blood loss. Hemopure administration, erythropoiesis-stimulating agents, and intravenous iron were initiated. Hemopure use was complicated by inaccurate laboratory results, including creatinine, blood urea nitrogen, and potassium, due to interference with ion selective electrode, making the interpretation of laboratory parameters unreliable. Due to lack of accurate laboratory parameters, further decisions for renal replacement therapy remained solely on clinical grounds and indirect parameters (altered mental status, electrocardiogram, etc.). The patient's condition eventually improved, leading to extubation, improvement in kidney function, and rise in hemoglobin up to 10 g/dL, allowing discharge from the hospital.

Discussion: This case highlights the complexity of managing postpartum hemorrhagic shock in Jehovah's Witness patients, necessitating alternative therapies like Hemopure. Its interference with laboratory tests poses significant challenges critical for guiding therapy, especially for nephrologists. Further research is imperative to elucidate Hemopure's impact on metabolic panel accuracy, aiding nephrologists in clinical decision-making.

SA-PO056

What to Do When It RAINs?

Pratap Kumar Upadrista,[1,2] Purva D. Sharma.[1,2] *[1]Northwell Health, New Hyde Park, NY; [2]Donald and Barbara Zucker School of Medicine at Hofstra/ Northwell, Hempstead, NY.*

Introduction: Recurrent Acute Interstitial Nephritis (RAIN) is a poorly studied condition, associated with adverse kidney outcomes. Treatment options for RAIN are not well established, making management more challenging. Systematic approach for ruling out underlying causes and prompt diagnosis and treatment are of paramount importance to salvage kidneys. However, no precise cause can be identified in many cases. Here, we present a case of idiopathic RAIN that was successfully treated with MMF.

Case Description: A 70 Y/O F with Hx of DM, HTN, HLD came to ED with fever of ~ 2 weeks, low back ache, chills, and malaise. She was on Metformin, Losartan, HCTZ and Omeprazole. Physical examination was unremarkable. On presentation, she had anemia (Hb 9.8 gm/dL), AKI with a Scr of 4.0 mg/dL (baseline Scr 6 weeks ago was 0.9 mg/dl) and BUN of 40mg/dL. UPCR was 0.6 g/g. Blood & urine cultures were negative. Hepatitis B & C serologies were negative and SPEP was normal. A kidney biopsy was suggestive of AIN, presumed to be due to PPI. Omeprazole was stopped and she was started on prednisone 1mg/kg/day (80mg/d), her creatinine started to improve with a nadir of 1.6 mg/dl and prednisone was slowly tapered off over 2 months. Off prednisone, for a month, her creatinine worsened to 2.75 mg/dL. Other causes of AKI were ruled out, and she was restarted on prednisone at 0.75mg/kg/d for AIN recurrence. Creatinine improved to 1.25mg/dL and prednisone tapered off. However, 3 weeks later, she again developed AKI (Scr 1.6mg/dL). Due to 2nd recurrence of AIN, we looked for systemic disorders. IgG, ANA, ENA profile & ANCA were negative. CT chest and abdomen was negative for malignancy. Repeat protein electrophoresis, FLC ratio were normal. PET-CT ruled out any inflammation. She was started on MMF 500mg BID as steroid sparing agent for idiopathic recurrent AIN. Her creatinine stabilized at 1.26 mg/dL and repeat UA was negative for proteinuria and hematuria. She has remained stable for the last 9 months on this regimen.

Discussion: RAIN needs thorough work up. Its management options are not standardized. MMF, Azathioprine, CNI and Rituximab have been tried with some success. Biomarkers to diagnose and prognosticate AIN like CXCL-9, TNF-α, IL-9 are under consideration. We aim to highlight the management of idiopathic RAIN with MMF as steroid sparing agent with good outcome. We need more studies to establish guidelines to effectively manage this entity.

SA-PO057

Tacrolimus as a Treatment of Immunotherapy-Induced Minimal Change Disease

Richard Odle, Hsu pheen Chong, William G. Petchey. *West Suffolk NHS Foundation Trust, Bury Saint Edmunds, United Kingdom.*

Introduction: Immune-related adverse reactions affecting the kidneys are a well-recognised complication of immune-checkpoint inhibitors (ICIs). Causatively suspected with temporarily related acute kidney injuries (AKI), acute interstitial nephritis (AIN) is believed to represent the most common pathology for ICI-induced kidney injury. ESMO guidelines currently recommend consideration of a renal biopsy on a case-by-case basis. However, glomerulonephritis is an increasingly recognised manifestation of ICI-induced kidney injury.

Case Description: We outline the case of a 76 year-old male who developed an AKI one week after receiving combination ipilimumab-nivolumab, with baseline creatinine of 86 umol/L which peaked at 529 umol/L. Urinalysis demonstrated 1+ protein and 3+ blood, and ICI-induced AIN was presumed. He received IV methylprednisolone 1 g x 3 doses, and weaned off steroids completely in Jan 2024 as his renal function returned back to baseline. Within 3 weeks of stopping steroids he then sustained a further AKI, with an albumin: creatinine ratio of 814 mg/mmol – 4 months after last receiving immunotherapy. After a normal ultrasound, renal biopsy confirmed minimal change disease. He was initiated on IV methylprednisolone, followed by a weaning course of prednisolone with tacrolimus 1 mg BD and switch thereafter to tacrolimus monotherapy - his renal recovery has so far been maintained with a normalised urinary ACR and creatinine.

Discussion: This case highlights a case of minimal change disease which was steroid responsive and now remains in remission with a single steroid sparing agent (Tacrolimus). It has been suggested that approximately 8% of immunotherapy- induced AKI have glomerular involvement. Identifying proteinuria early is therefore of vital importance to raise diagnostic suspicion, and to aid with decisions around whether to perform a renal biopsy. Identification of minimal change disease also enables the utilisation of the steroid-sparing agent tacrolimus, which has been suggested to be non-inferior to steroids. This case demonstrates no relapse despite completion of a steroid reducing regime whilst on tacrolimus therapy at time of writing.

SA-PO058

AKI Due to Idiopathic Tubulointerstitial Nephritis with Uveitis Syndrome

Krishna Mohita Kuruvada,[1] Moazam M. Cheema,[1] Lanny T. DiFranza,[2] Maureen Brogan,[1] Deep Sharma,[1] Kettia N. Guillite.[1] *[1]Department of Nephrology, Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY; [2]Department of Pathology, Montefiore Medical Center/ Albert Einstein College of Medicine, Bronx, NY.*

Introduction: Tubulointerstitial nephritis with uveitis(TINU) syndrome is a rare oculorenal inflammatory disorder. It generally affects younger individuals and is more prevalent in females. Uveitis is often bilateral and develops simultaneously with renal disease. We report a case of TINU syndrome presenting with uveitis.

Case Description: 27-year-old man with a history of GERD presented with left temporal headache and ocular symptoms including pain, foreign body sensation, photophobia, and redness, without preceding ocular trauma. He was taking aspirin for headaches and omeprazole 20mg for gastritis. Physical examination revealed no skin rash or peripheral edema. He was evaluated by ophthalmology and diagnosed with bilateral nongranulomatous anterior uveitis. Laboratory tests showed an elevated creatinine level of 2.76 mg/dl compared to a recent baseline of 1.3 mg/dl. Urinalysis revealed 6-10 WBCs, no RBCs, and a spot UPCR of 433 mg. ESR was elevated to 59mm/hr, and CRP was elevated to 5.1mg/dl. Urine beta 2 microglobulin was elevated to 19.55mg/L. Kidney ultrasound was unremarkable. Our differentials included Sjögren syndrome, SLE, granulomatosis with polyangiitis and infectious causes such as leptospirosis which were excluded based on serologies. Kidney biopsy showed acute and chronic interstitial nephritis with light microscopic findings of neutrophilic, eosinophilic, and lymphocytic tubulitis and a moderate degree of tubular atrophy and interstitial fibrosis. The simultaneous onset of bilateral acute anterior uveitis and biopsy-proven tubulointerstitial nephritis confirmed a diagnosis of TINU syndrome. The patient was started on systemic steroids and eventually kidney function returned to baseline.

Discussion: TINU syndrome is generally considered an autoimmune disease, with medications(such as NSAIDs and antibiotics) and infections acting as acquired risk factors. Serum beta-2 microglobulin is a sensitive biomarker of interstitial nephritis that is helpful in the diagnosis of TINU although a biopsy is confirmatory. Mainstay of treatment involves the use of corticosteroids which reduces oculorenal inflammation in the active phase. Our case highlights the importance of using a high index of suspicion when dealing with a patient with both uveitis and kidney dysfunction as early treatment reduces the risk of progression to CKD.

SA-PO059

Treating TAFRO Syndrome: A Case Study of Castleman Disease Kidney Complications

Jennifer A. Schoonmaker, Paavana Varanasi, Evamaria Anvari. *Mayo Clinic Arizona, Scottsdale, AZ.*

Introduction: TAFRO syndrome, a rare variant of idiopathic multicentric Castleman disease, presents with Thrombocytopenia, Anasarca, Fever, Reticulin fibrosis on bone marrow biopsy, and Organomegaly (TAFRO). This case details successful treatment of a young male with siltuximab, steroids and eculizumab.

Case Description: A previously healthy 19-year-old male presented to an outside hospital with respiratory symptoms. Imaging exposed pleural and pericardial effusions requiring drainage, antibiotics, antifungals, and steroids. At that time, he had Cr 1.3 mg/dL, low-grade proteinuria, and negative serologic workup for glomerulonephritis (GN). He presented 3 weeks later with worsening fatigue, edema, nausea, vomiting and diarrhea with Cr 2.5 mg/dL and thrombocytopenia. Renal function rapidly declined, requiring dialysis. Renal biopsy showed features of thrombotic microangiopathy (TMA). He was transferred for higher level of care. Another extensive GN and infectious workup was negative. Imaging showed lymphadenopathy and splenomegaly. Initial lymph node biopsy was inconclusive. Bone marrow biopsy was negative. Patient continued to deteriorate despite steroids to treat suspected Castleman's disease. A second renal biopsy again showed TMA. Eculizumab was started with improvement in renal function, but not thrombocytopenia. A second lymph node biopsy confirmed a plasma cell variant of Castleman's disease diagnosing TAFRO. He was started on siltuximab and thrombocytopenia improved after 6 doses. Renal function improved, dialysis was weaned off, and eculizumab was stopped after Castleman's disease was controlled.

Discussion: TAFRO syndrome involves systemic inflammation and is a subtype of multicentric Castleman's disease (MCD). Lymph node biopsy findings in MCD are crucial for TAFRO diagnosis. Thrombocytopenia, always found in TAFRO, is not always present in MCD. The renal pathology in TAFRO is unclear, but TAFRO may trigger the complement cascade, leading to TMA. Eculizumab can be stopped once TAFRO is controlled. As in other complement mediated diseases, Eculizumab can also be weaned off once the triggering disease is controlled. Further research is needed to understand renal involvement, optimal treatment, and long-term outcomes in TAFRO.

SA-PO060

AKI in IgG4-Related Retroperitoneal Fibrosis: A Case Report

Saman Rashid,[1] Bharath Duraisamy Swami Kannan,[2] Faizan Babar.[3] *[1]Karachi Medical and Dental College, Karachi, Pakistan; [2]Government Sivagangai Medical College and Hospital, Sivagangai, India; [3]Nephrology Associates of Lexington, Lexington, KY.*

Introduction: IgG4 related disease is a chronic fibro-inflammatory disease with multiorgan involvement. Although a multisystem disease, renal involvement is the most common presentation, exhibiting the features of tubulointerstitial nephritis. The pathological hallmark of the disease is dense lymphoplasmacytic infiltrate with elevated IgG4 positive plasma cells. First line treatment for IgG4-RKD is steroids and any delay in the treatment can lead to irreversible kidney damage, necessitating early diagnosis and prompt treatment.

Case Description: A 35 year old male presented with weight loss, unexplained anemia, and generalized lymphadenopathy. On admission, laboratory investigations revealed :BUN/Cr 72/12 and K+5.9. Urinalysis was unremarkable and Renal Ultrasonogram revealed moderate to severe hydronephrosis bilaterally. CT scan revealed new proliferative abnormal soft tissue in the lower retroperitoneum and bilateral iliac regions, suggesting retroperitoneal fibrosis with bilateral ureteral obstruction which was not present in the previous scans two months prior to presentation. Initial diagnosis of post-renal AKI was managed with nephrostomy tube placement and a single dialysis session. Anemia evaluation showed positive ANA (1:80) and elevated total protein (9.0 mg/dL), IgG (3107 mg/dL) and IgA (492 mg/dL) with no M spike on SPEP. Further IgG subtyping showed mildly elevated IgG4 (101 mg/dL). A diagnosis of idiopathic retroperitoneal fibrosis was made after all other differentials were ruled out.

Discussion: IgG4-RD has a rare incidenceof less than 1 per 100,000 population. Renal damage in IgG4-RD can be attributed to direct parenchymal damage or retroperitoneal fibrosis around the ureters resulting in hydronephrosis and post renal AKI, as seen in our patient. A comparative analysis from past CT scan showed diffuse retroperitoneal fibrosis around the external, common and internal iliac arteries and mesenteric arteries, indicating the severity and rapidly progressive nature of the disease. Following a treatment plan with high dose steroids, there was no significant response as evidenced by a repeat CT scan showing fibrosis in multiple areas throughout the body. As per treatment protocol, the patient was started on four week Rituximab therapy with tapering steroid and weekly Methotrexate. The patient currantly has stable disease based on repeat imaging and levels of inflammatory markers.

SA-PO061

Successful Management of Membranoproliferative Glomerulonephritis with Repository Corticotropin Injection

Muhammad R. Khan, Kelly H. Beers. *Albany Medical Center, Albany, NY.*

Introduction: Membranoproliferative glomerulonephritis (MPGN) is a pattern of glomerular injury subdivided by light microscopy into immune complex/monoclonal immunoglobulin-mediated, complement-mediated, and MPGN without immunoglobulin or complement deposition. Treating underlying causes is ideal, but idiopathic immune complex MPGN is often managed with immunosuppressive medications. Repository corticotropin injection shows promise in hard-to-treat cases, as illustrated in a successful treatment involving significant psychiatric side effects from steroids.

Case Description: A 30-year-old female with MPGN diagnosed at age 16, presented to hospital with lower extremity edema and AKI. Before the presentation she was treated with prednisone 20 mg daily for many years and any attempt to taper prednisone resulted in MPGN flares. She was previously also trialed on mycophenolate with lower dose prednisone, but gastrointestinal side effects led to discontinuation of mycophenolate. She was then treated with repository corticotropin injection with prednisone 5 mg and was stable for two years until she had another flare with urine protein creatinine ratio (UPCR) rising to 3.2 g/g. Increasing prednisone to 50 mg/day temporarily improved UPCR, but severe depression with suicidal ideation prompted cessation of steroids. Subsequently, her renal function declined, with creatinine rising and UPCR reaching 4 g/g. After discontinuing all her medications for six months, severe deterioration ensued, with creatinine at 3.19 and UPCR at 12 g/g. She was admitted to hospital and renal biopsy was done which showed MPGN immune complex. Despite induction therapy with cyclophosphamide and rituximab her UPCR remained at 8.5 g/g after three months. Repository corticotropin injection was initiated at 80 mg biweekly, reducing UPCR to 4.35 g/g in a month and further to 0.75 g/g over three months.

Discussion: Our case of difficult-to-treat idiopathic immune complex MPGN responded only to high steroid doses, which were discontinued due to steroid-induced suicidal ideation. Repository corticotropin injection, which stimulates endogenous steroid production, offered lower steroid exposure and fewer side effects. This may be a good option to avoid systemic side effects of steroids in other hard to treat cases.

SA-PO062

Iptacopan in C5 Blockade for Refractory Atypical Hemolytic Uremic Syndrome

Minh-Ha Tran,[1] Stefan O. Ciurea,[2] Sheetal Desai,[3] Arash Rezazadeh Kalebasty,[4] Matthew D. Nguyen,[5] Vu Q. Nguyen,[5] Samir D. Patel,[5] Umut Selamet,[6] Ramy M. Hanna.[5] *[1]University of California Irvine - Department of Pathology - Division of Transfusion Medicine, Irvine, CA; [2]University of California Irvine - Department of Medicine - Division of Hematology/Oncology-Bone Marrow Transplant Unit, Irvine, CA; [3]University of California Irvine - Department of Medicine - Division of Rheumatology, Irvine, CA; [4]University of California - Irvine - Department of Medicine - Division of Hematology/Oncology, Irvine, CA; [5]University of California Irvine Nephrology Hypertension & Kidney Transplantation, Orange, CA; [6]Harvard - Dana Farber Cancer Institute - Department of Medicine-Division of Oncology, Boston, MA.*

Introduction: Atypical Hemolytic Uremic Syndrome (aHUS) is a life-threatening disease related to mutations in the complement system resulting in overactivation and dysregulation of the alternate pathway. Currently, there are only two United States Food and Drug Administration (FDA) approved treatments for aHUS, eculizumab and ravulizumab, which target complement factor 5 (C5) and prevent the formation of C5b-9. Iptacopan (Fabhalta) is a small-molecule inhibitor of complement factor B (FB) that binds to FB and prevents the formation of the alternative pathway (AP) C3-convertase (C3bBb). This limits the cleavage of C3 to the active fragment C3b and can prevent C3b-mediated extravascular hemolysis. We report the first known case of the factor B inhibition with Iptacopan in treatment of aHUS.

Case Description: 21-year-old Pakastani male with heterozygous complement factor related protein 4 mutation and aHUS, had an initial partial response to eculizumab and then complete response to ravulizumab, which resulted in the patient coming off dialysis. Patient had a sudden and unexpected flare 2 years after his initial presentation. The treatment failure was not abated by redosing with ravulizumab, leading to the use of multiple advanced diagnostics (including artificial intelligence algorithms) to look for a possible differential. No malignancy or other aggravating factor was found even after bone marrow biopsy. Recent data on Iptacopan's use in C5 refractory Paroxysmal Nocturnal Hemoglobinuria provided a therapeutic rationale. An application for the compassionate use of Iptacopan was filed and approved by the FDA. Patient's blood counts completely recovered, his microangiopathic hemolytic anemia ceased, his acute kidney injury completely resolved thus permitting discontinuation of renal replacement therapy was discontinued. Human Anti-murine anti-drug antibodies were suspected as the cause of C5-blockade failure but could not be confirmed.

Discussion: To our knowledge this is the first report of using Iptacopan in treatment of aHUS in the United States. Larger clinical trials involving diverse patient populations are needed to validate these initial findings, assess safety, and establish Iptacopan as a potential treatment for the management of aHUS.

SA-PO063

Acute Tubular Necrosis (ATN) after Hemopure in a Patient with Sickle Cell Disease (SCD)

Sabiha M. Khan, Syeda B. Ahmad. *UPMC, Pittsburgh, PA.*

Introduction: Hemopure (HBOC-201) is a bovine hemoglobin-based oxygen carrier (HBOC), classified as a semi-synthetic, cell-free, purified hemoglobin product. It effectively binds and delivers oxygen to tissues, mimicking the function of red blood cells. This is the first case report, to our knowledge, which details the clinical trajectory of a patient who developed ATN after hemopure administration.

Case Description: A 57-year-old female Jehovah's Witness with SCD and vaso-occlusive crisis was intubated for mixed respiratory failure. She had influenza pneumonia and pulmonary edema attributed to high output failure from severe anemia. Her blood pressure (BP) was normal. Her laboratory results showed a hemoglobin (Hgb) of 6.0 g/dL and a creatinine (Cr) of 1.1 mg/dL. Her ferritin was 1365 ng/mL. She was given Epogen 20,000 IU daily and was diuresed with robust urinary response (3L/24hr). Her Cr remained 1.0-1.3 mg/dL over the following days; however, her Hgb decreased 5.3 to 4.9 g/dL, and she was given 2 units (32.5 g/unit) of IV Hemopure. The day after infusion, her Cr increased to 1.8 mg/dL and her systolic BP rose to 200 mmHg. A urine sediment showed muddy brown casts suggestive of ATN. A renal ultrasound with doppler showed no renal papillary necrosis or obstruction. She became progressively volume overloaded and started urgent peritoneal dialysis. Further doses of Hemopure were held, her volume status improved, and she was extubated. One month later, she demonstrated renal recovery to baseline kidney function.

Discussion: Hemopure has been approved for use by the FDA's Expanded Access Program since 2013 for patients with life-threatening anemia who are unable to receive blood transfusions. HBOCs offer several unique advantages such as reduced risk of alloimmunization and infection. They have been hypothesized to reverse the sickling process in SCD. As a bloodless medicine, they can be utilized in patients who decline blood transfusions for religious reasons like Jehovahs' Witness. Hemopure trials in surgical patients resulted in increased mean arterial pressure, serum urea (N_2), bicarbonate, and base extract. Renal side effects include hypertension attributed to heme scavenging of endothelial nitric oxide, and nephrotoxicity possibly from renal oxidative stress and vasoconstriction. This case seeks to contribute to the growing body of literature on the safety and risks associated with HBOCs.

SA-PO064

BRASH Syndrome: Familiar Yet Difficult to Manage, a Case Series

Hong Hieu Truong,[1] Pabitra Adhikari,[1] Laith S. Sorour,[1] Muhammad Albanna,[1] Sopiko Gogia,[1] Le Y Nhi Vo,[2] Valiko Begiashvili.[1] *[1]Ascension Saint Francis, Evanston, IL; [2]University of Medicine and Pharmacy at Ho Chi Minh City, Ho Chi Minh City, Viet Nam.*

Introduction: BRASH syndrome is characterized by the combined effects of AV nodal blockers and Renal dysfunction, leading to Hyperkalemia, severe Bradycardia, and Shock. Although the connection between these medications and renal failure has been known for years, managing the syndrome remains challenging.

Case Description: Case 1: A 78-year-old woman with atrial fibrillation and severe mitral valve stenosis (MVS) presented with fatigue. She was taking metoprolol, diltiazem. Upon arrival at the emergency department (ED), her heart rate (HR) of 50 beats per minute (bpm), blood pressure (BP) of 65/30 mmHg, and a potassium (K+) level of 8.3 mEq/L, and creatinine level of 5.17 mg/dl from a baseline of 1.23 mg/dl. She was given norepinephrine, home medications were stopped, and hyperkalemia treatment was initiated, resulting in lowering her K+ level to 4.8 mEq/L and an increase in HR to 77 bpm. Echocardiography later revealed pulmonary hypertension from MVS, which was identified as the underlying cause of her AKI. Kidney function gradually improved with furosemide within the context of cardiorenal syndrome stemming from MVS. Upon discharge, her creatinine level was 1.9 mg/dl **Case 2:** An 84-year-old male with hypertension (HTN), chronic kidney disease (CKD), and benign prostatic hypertrophy (BPH) was on carvedilol. In the ED, his HR was 18 bpm, BP was 92/43 mmHg, K+ level was 8.1 mEq/L, and creatinine was 2.7 mg/dL (baseline 1.96 mg/dL). A bladder scan showed significant urinary retention. Foley catheter placement helped resolve the obstruction. He was also hypothermic, with rectal temperature of 90.9°F, and passive warming methods were employed. He received hyperkalemia treatment without response. Both pacing attempts and atropine administration were unsuccessful. IV dobutamine was also started for hypotension. His HR increased to 40 bpm. Immediate dialysis was performed for life-threatening hyperkalemia, reducing K+ level to 5.2 mEq/L. His HR improved slowly to 50 bpm. Cardiology was consulted and diagnosed BRASH syndrome on top of sick sinus syndrome

Discussion: BRASH syndrome affects patients with various levels of kidney function, from normal eGFR to ESRD on dialysis. It can involve multiple etiologies or just a single cause. Most patients improve with supportive care, but standard hyperkalemia and bradycardia treatment protocols should be followed.

SA-PO065

Atypical Presentation of IgG4-Negative Idiopathic Retroperitoneal Fibrosis

Kyra Colston, Margaret Spolnik. *Indiana University School of Medicine, Indianapolis, IN.*

Introduction: Retroperitoneal fibrosis (RPF) is a rare condition in which fibro-inflammatory tissue surrounds the iliac arteries and abdominal aorta. Ureteral obstruction is common, resulting in acute or chronic renal failure. Most cases are idiopathic and often develop alongside autoimmune conditions or IgG4-related disease. Clinical manifestations include fever, anorexia, and weight loss with back or flank pain.

Case Description: A 53-year-old African American male presented to the emergency room with extreme fatigue, worsening anorexia, and weight loss. Past medical history included hypertension, type 2 diabetes mellitus, obstructive sleep apnea, depression, and medication noncompliance. Physical exam was unremarkable and blood testing revealed serum creatinine of 5.28 (baseline 1.2), eGFR of 12.2 (68.6), and BUN of 35 (17). He denied flank pain, urinary symptoms, and history of kidney disease. Ultrasound showed moderate to severe bilateral hydronephrosis. CT scan of the abdomen and pelvis revealed no stones within the urinary tract but identified a retroperitoneal mass at the level of the aortic bifurcation. Following admission, bilateral upper pole percutaneous nephrostomy tubes and lower pole nephroureteral stents were placed. CT scan of the chest showed no evidence of malignancy. Two weeks later, diuretic renal scintigraphy determined renal function to be 68% (left) and 32% (right). Repeat CT abdomen/pelvis revealed improved hydronephrosis. Biopsy of the retroperitoneal mass showed myofibroblastic proliferation with thick collagen and inflammatory cells but rare IgG4-positive plasma cells. Treatment of idiopathic RPF was initiated with high dose corticosteroids. Serum creatinine has since decreased to 1.89, eGFR increased to 41.9, and BUN decreased to 22.

Discussion: This case illustrates the importance of maintaining a broad differential in the setting of AKI and considering rare causes for hydronephrosis. Idiopathic RPF can have a varied clinical presentation as seen in our patient lacking back or flank pain despite extensive fibrosis causing hydronephrosis. Prompt recognition of idiopathic RPF is vital to early intervention and preservation of renal function.

SA-PO066

Thrombotic Microangiopathy Treated with Eculizumab in a Patient with Known Immune Thrombocytopenic Purpura

Ali R. Koksal, Golnaz Vahdani, Hasan T. Ozpolat, Erika R. Bracamonte, Iyad S. Mansour, Bijin Thajudeen. *Banner - University Medical Center Tucson, Tucson, AZ.*

Introduction: Thrombotic Microangiopathy (TMA) is rare but part of a broad spectrum of syndromes that can cause severe kidney failure. Here, we present a TMA case that was previously followed by hematology with a diagnosis of immune thrombocytopenic purpura (ITP), which was proven by a kidney biopsy despite severe thrombocytopenia.

Case Description: A 64-year-old female with traumatic fever, mitral stenosis post mechanical valve replacement, and thrombocytopenia due to ITP presented to ED with severe headache, dizziness, and double vision for 3 days. Cranial CT scan showed subdural hemorrhages, along with trans tentorial herniation. She underwent successful suboccipital craniotomy and and was transferred to the ICU. Hematology was consulted for worsening thrombocytopenia measuring 49 K, down from 102 K on admission, prompting the initiation of 1 mg/kilogram/day prednisone. The patient experienced episodes of hypotension resulting in acute kidney injury. On admission creatinine was 0.7 mg/dL and increased to 4.8 mg/dL in one week. Urine sediment microscopy showed multiple granular casts WBCs and rare isomorphic RBCs, UACR 78 mg, UPCR 800 mg, and urine NGAL:492. Renal ultrasound showed no signs of obstruction or chronicity. Subsequently, her thrombocytopenia continued to worsen along with increasing creatinine, but on peripheral smear there was no evidence of schistocytes, ADAMTS13 activity was normal, and GN panel was negative. She required intermittent HD for clearance and ultrafiltration. Kidney biopsy was performed due to delayed kidney recovery, and revealed thrombotic microangiopathy with predominant chronic lesions, with patchy moderate interstitial fibrosis 40%. Complement- targeted therapy was started with diagnosis of chronic TMA/ atypical Hemolytic Uremic Syndrome (HUS) vs. renal limited TMA. She received an induction of Eculizumab 900 mg weekly for one month and continued with maintenance thereafter. The patient creatinine improved, and hemodialysis was discontinued. Long-term creatinine was stable at 2.5 mg/dL on third month follow-up visit.

Discussion: Severely progressive AKI with thrombocytopenia can be related to TMA with a component of atypical HUS. Eculizumab is a good option for maintaining immunosuppression when there is a concern of atypical HUS.

SA-PO067

A Unique and Successful Story of Atypical Hemolytic Uremic Syndrome (aHUS)

Beshoy Abdalla, Jia Yi, Nahomie I. Veguilla Rivera, Naveen Punchayil Narayanankutty. University of South Florida, Dept of Nephrology and Hypertension. *University of South Florida, Tampa, FL.*

Introduction: Microangiopathic hemolytic anemia, thrombocytopenia & end organ damage is a clinical scenario that can present in a plethora of similar conditions including TTP, HUS, aHUS & HELLP syndrome. The caveat being that establishing the correct diagnosis & starting treatment early is critical for good outcomes.

Case Description: In this case, a 62-year-old female with a history of HTN & CKD3a with a recent COVID associated hospitalization a few months prior to presentation. The patient presented with progressive fatigue & headaches. She reported an associated unintentional 20 lb weight loss over 2 months & occasional foamy urine. Noted to be hypertensive with elevated Cr 5.4 (baseline of 1.7) & lab evidence of microangiopathic hemolytic anemia. The presence of schistocytes on peripheral smear was inconsistent. The majority of the workup was negative including Coombs, infectious & ADAMTS13 levels. Renal imaging was unremarkable. Patient underwent renal biopsy which revealed 15% globally sclerotic glomeruli w/ acute tubular injury without necrosis, interstitial fibrosis & edema involving 40-50% of cortical parenchyma, focal intimal thickening & hyalinosis. Immunofluorescence was unremarkable. Electron microscopy showed some ischemia with some podocyte foot process effacement. The patient was started alternating days of intermittent hemodialysis & plasmapheresis for 4 doses each without much improvement prior to being transferred for further treatment. Repeat testing showed continued mild hemolysis. After much review of the case & extensive discussions about the risks & possible benefits of using monoclonal C5 inhibitors & the possibility of renal recovery. Treatment of Eculizumab was started in the inpatient setting & discharged to continue treatment in the outpatient setting. On discharge, although the patient had some residual renal function, she was still dependent on hemodialysis. Genetic testing eventually returned with variant of Complement F associated with aHUS.

Discussion: It is improtant to consider the totality of the case, not just limited to age while maintaing a broad differential & evaluate treatment response. In this case, based on the previous findings, presentation after transfer & renal biopsy results, the decision to treat for aHUS was made. Eventually, the patient was taken off dialysis & has continued treatment with Ravulizumab.

SA-PO068

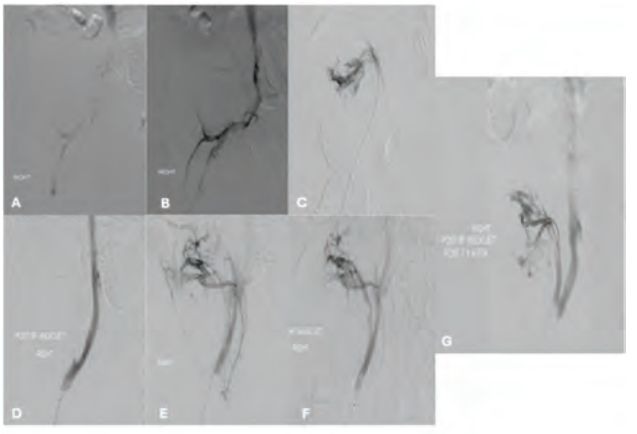
Thrombosis Turnaround: Successful Endovascular Rescue in Common Iliac Vein Thrombosis of Kidney Allograft

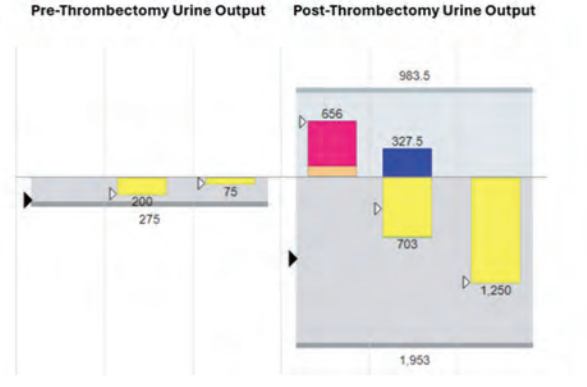
Sabita Budhathoki, Deena Chihade, Kriti Devkota, Michael Lioudis, Ankur Chawla. *SUNY Upstate Medical University, Syracuse, NY.*

Introduction: This is a case of kidney transplant dysfunction due to right common iliac vein (civ) thrombosis that occurred 4 years after kidney transplantation. Late venous thrombotic events in kidney transplant patients are rare compared to early arterial or venous thrombosis or stenosis (1).

Case Description: A 78-year-old male with history of ESKD status post brain death donor kidney transplant on 3/6/2020 came with abdominal pain. He had an acute kidney injury (AKI) with serum creatinine (SCr) 3.66 mg/dL that had increased from his baseline of 0.77 mg/dL. He was hypotensive. Clinical exam was benign. The doppler ultrasound revealed diminished flow within the renal and iliac veins along with heterogenous echogenic material within iliac vein concerning for occlusion. Nephrostomy tube was deferred due to concern of civ thrombosis and started on a heparin drip. Renal angiogram confirmed right civ and external iliac vein thrombosis extended into both the donor renal vein and inferior venacava. He underwent AngioJet Tissue plasminogen activator and right civ thrombectomy. Urine output (UO) improved immediately post op. SCr started decreasing the next day. The patient was discharged 5 days post op.

Discussion: Kidney transplantation is the goal for ESKD patients. Transplanted patients have a better quality of life and improved long term survival. Vascular thrombosis is a rare complication that can result in loss of the allograft. Patients present with AKI and abrupt decrease in UO. There is limited evidence that prophylactic low dose aspirin is beneficial in decreasing the incidence of vascular thrombosis (2). Individuals with high-risk of thrombosis may benefit from anticoagulation (AC) after kidney transplantation (2). Endovascular intervention is the best approach if AC fails (3).





SA-PO069

Regional Citrate Anticoagulation: Going around in Circles!

Sara Jane Chan,[1] Ruzita Ghani,[2] Manish Kaushik.[2] *[1]Ministry of Health Holdings Pte Ltd, Singapore, Singapore; [2]Singapore General Hospital Department of Renal Medicine, Singapore, Singapore*.

Introduction: Regional Citrate Anticoagulation (RCA) is widely used during Continuous Kidney Replacement Therapy (CKRT). Adequacy of RCA and efficacy of RCA-CKRT are monitored by post-filter ionized calcium (iCa) and systemic total calcium (TCa), iCa, metabolic and acid-base parameters, respectively.

Case Description: An elderly lady with end stage kidney disease on peritoneal dialysis and endometrial carcinoma with previous hysterectomy was admitted for septic shock secondary to buccal abscess. She commenced RCA-CKRT as per institutional protocol. Her circuit clotted in 15 minutes due to catheter flow issue. On her second circuit, without catheter port reversal, laboratory tests were significant for extremely low post-filter iCa (<0.10 mmol/L: target 0.25-0.40 mmol/L). Systemic TCa and iCa showed a gradual increase over 12 hours, necessitating a progressive reduction in her systemic intravenous Ca replacement to 25% of initial rate. Also, her metabolic acidosis persisted despite uninterrupted CKRT. Access recirculation was suspected, and confirmed (>85% recirculation) with simultaneous measurements of systemic, access, pre-filter and post-filter: urea, TCa, iCa and bicarbonate. Abdominal CT scan revealed tip of left femoral dialysis catheter in the external iliac vein but no vein thrombus or external catheter compression. A longer catheter was inserted in right femoral vein and RCA-CKRT continued uneventfully. The removed catheter demonstrated luminal blood clots.

Discussion: The observations were explained by access recirculation and consequent high citrate accumulation locally (low post-filter iCa; filter acidosis) but without adequate systemic buffer contribution (systemic acidosis). In patients on RCA-CKRT, unexpected extremely low post-filter iCa or increasing systemic TCa and iCa requiring decreasing intravenous calcium replacement, should raise suspicion of access recirculation. Improper catheter size and tip position increase risk of recirculation, compromising dialysis delivery despite well anticoagulated functioning filter.

All values in mmol/L and IV Ca in mmol/hour	Pre RCA-CKRT	1 hour	3 hour	6 hour	12 hour	18 hour
Systemic						
Urea	6.6	8.0		7.7	7.9	7.8
Total Ca	2.06	2.32		2.49	2.24	2.03

Clearance of Plasma Free Hemoglobin by Therapeutic Plasma Exchange for Mechanical Hemolysis-Related Pigment-Induced AKI

Clarkson Crane,[1] Alexander H. Song,[2] Dinna Cruz.[1] *[1]University of California San Diego, La Jolla, CA; [2]Stanford University School of Medicine, Stanford, CA.*

Introduction: Intravascular hemolysis is a complication of extracorporeal membrane oxygenation (ECMO) and associated with pigment-induced AKI and increased mortality. Elevated plasma-free hemoglobin (PFH) can promote thrombosis in an acquired thrombotic thrombocytopenic purpura (TTP) process by inhibiting von Willebrand factor (VWF) cleavage by ADAMTS13. We report use of therapeutic plasma exchange (TPE) in an attempt to reduce ECMO circuit clotting and promote AKI recovery.

Case Description: A 42-year-old woman admitted for COVID-19 respiratory failure required cannulation to ECMO. She developed thrombocytopenia and microangiopathic hemolytic anemia with LDH >2,500 U/L, elevated total bilirubin, undetectable haptoglobin, and schistocytes, attributed to ECMO-induced hemolysis. PFH was elevated 398.0 mg/dL and it was hypothesized this caused an acquired TTP-like presentation. She subsequently developed anuric AKI attributed to pigment nephropathy. CRRT was initiated and in-line TPE started to remove PFH to stop the cycle of thrombolysis/hemolysis to potentially allow for AKI recovery. Four sessions of TPE were performed with supernatant transitioning from dark red (from PFH) to a lighter color as PFH level decreased to 4.1 mg/dL (Figure 1). LDH decreased and haptoglobin became detectable. Given these, TPE was considered successful. However, before an improvement in urine output could be demonstrated, she developed refractory septic shock and expired.

Discussion: We describe a case where PFH due to ECMO-related hemolysis was successfully removed with TPE, resulting in improved hematologic parameters and the potential for continuation of mechanical circulatory support and recovery of AKI. In similar clinical settings, this therapy has potential to provide clinical benefit and merits ongoing study.

Hemoperfusion in the Treatment of Doxylamine-Induced Rhabdomyolysis

Vincent Anthony S. Tang, Elizabeth Montemayor. *Division of Adult Nephrology, Department of Medicine, University of the Philippines - Philippine General Hospital, Manila, Philippines*.

Introduction: Rhabdomyolysis is characterized by myocyte necrosis and release of intracellular contents into the circulation. It may manifest as myalgia, acute kidney injury (AKI), electrolyte abnormalities, and arrhythmia. Doxylamine succinate is a 1st generation antihistamine, and an active ingredient in many over-the-counter decongestant products. Doxylamine overdose has been reported to cause severe rhabdomyolysis. Cornerstones of management include prompt recognition, adequate hydration, and close monitoring of electrolytes. Literature on drug intoxication have explored the role of hemoperfusion as an adjunct to facilitate rapid clearance of drugs from the circulation. To date, however, the use of hemoperfusion for doxylamine-induced rhabdomyolysis has not been previously reported.

Case Description: A 23-year old female presented with decreased sensorium, generalized myalgia, and oliguria five hours after consuming 190 tablets of doxylamine succinate. Her past medical, family, and personal-social histories were non-contributory. On admission, her vital signs were normal and the systemic physical exam was unremarkable. She was lethargic, but without any focal neurologic deficits. Initial laboratory tests showed elevated creatine kinase (CK) levels, azotemia, myoglobinuria, hyperkalemia, hyperphosphatemia, and metabolic acidosis. She was managed as a case of severe rhabdomyolysis complicated by AKI secondary to doxylamine intoxication. Despite aggressive volume expansion and supportive therapy, she remained oliguric with intractable hyperkalemia and metabolic acidosis. Hence, she underwent emergency, combined hemoperfusion (HP) and hemodialysis (HD) on the 1st three hospital days. Serial monitoring of urine output, CK, creatinine, and electrolyte levels on succeeding days showed resolution of the rhabdomyolysis. The patient was eventually weaned off HP-HD and discharged improved on the 7th hospital day.

Discussion: Doxylamine overdose is posited to cause rhabdomyolysis through direct myocyte injury. In cases of impaired renal clearance, plasma concentrations of said drug remains elevated for an extended duration, allowing for persistent muscle injury. Due to its lipophilic nature and relatively high molecular weight, systemic clearance of doxylamine in patients with severe AKI can be facilitated by hemoperfusion, leading to faster recovery and shorter length of hospital stay.

SA-PO072

Unraveling a Case of Oxalate Nephropathy: A Complex Presentation

Rafael E. Cardenas, Salil Mangi. *Doctor at Renaissance (DHR), McAllen, TX.*

Introduction: Hyperoxaluria, a rare condition, elevates calcium oxalate levels in the body, leading to deposition in various organs, particularly the kidneys. This can result in progressive renal function decline or kidney failure, known as oxalate nephropathy. Primary hyperoxaluria, a rare inborn error in glyoxylate metabolism, involves excessive oxalate production. Secondary hyperoxaluria is associated with either increased intake of oxalate rich food or increased absorption of oxalate from the gut in patient who have undergone intestinal surgeries, including gastric bypass. We will present a case of AKI associated with oxalate nephropathy in a patient with a history of uric acid stones

Case Description: Patient, a 62-year-old female with longstanding type 2 diabetes mellitus, hypertension, asthma, morbid obesity, and obstructive sleep apnea managed with CPAP at home, has a history of surgical interventions including hysterectomy, cholecystectomy, and gastric bypass surgery in 2015. She experiences intermittent diarrhea managed by gastroenterologists. Previous nephrolithiasis episodes led to extracorporeal shockwave lithotripsy in 2012 and percutaneous nephrolithotomy in 2013 for left staghorn stones. Stone analysis revealed 100% uric acid composition. Multiple other episodes in 2014 were resolved via extracorporeal shockwave lithotripsy and fluoroscopic imaging. She has been followed by a nephrologist for gradual kidney function decline. In 2023, she presented with severe fatigue, weakness, and mild respiratory distress, found to have acute kidney injury (AKI) superimposed on chronic kidney disease. Initial labs showed elevated BUN, creatinine, and proteinuria. Kidney biopsy revealed oxalate nephropathy and diabetic glomerulopathy with interstitial fibrosis. Serum oxalate was markedly elevated at 52. She required hemodialysis and blood transfusions followed by placement of a Permcath for outpatient hemodialysis. The patient was discharged stable to continue care as an outpatient

Discussion: This case sheds light on the persistent challenges of diagnosing and managing oxalate nephropathy in a rapidly progressive kidney failure in a patient with a complex medical history. It important to keep this entity in mind, especially in patients who are likely to develop secondary hyperoxaluria even though they may have had a different category of kidney stones in the past prior to their gastric bypass surgery

SA-PO073

From Marathon to Miracles: Managing Dialysis-Dependent Oxalate Nephropathy with Ethylenediamine Tetra Acetic Acid (EDTA)

Paavana Varanasi, Srekar N. Ravi, Leslie F. Thomas. *Mayo Clinic Arizona, Scottsdale, AZ.*

Introduction: Oxalate nephropathy is a rare cause of kidney injury due to oxalate crystal deposition within tubules, causing direct tubular injury and obstruction. Excessive vitamin C intake can cause secondary hyperoxaluria and acute kidney injury (AKI). Early diagnosis and management are crucial to prevent ESRD, but there is no known cure. We present a case of stage 3 AKI due to biopsy-proven oxalate nephropathy requiring dialysis that was successfully treated.

Case Description: A 31-year-old female without known medical problems presented with intractable nausea, vomiting, back pain, and minimal urine output after running a marathon. One week prior, she took 400-600 mg of ibuprofen daily for migraine headaches and oral vitamin C supplements. Immediately following the race, she received a total of 3.5 L of IV fluids and one IV vitamin C infusion at mobile hydration units. Labs showed Cr 8.42 mg/dL, BUN 64 mg/dL, and CK 2400 U/L. Urinalysis had pyuria without hemoglobinuria. On hospital presentation, she was oliguric (200-300cc/day) and renal function continued to worsen despite aggressive IV fluid resuscitation. Dialysis was started on hospital day 3 and a kidney biopsy revealed acute tubular injury with abundant calcium oxalate deposits consistent with oxalate nephropathy. Given limited interstitial fibrosis and tubular atrophy (10-15%), she was trialed on IV EDTA 250 mg infusion for 3 consecutive days. She had increased urine output with each subsequent dose and return of kidney function with discontinuation of dialysis.

Discussion: This case demonstrates a novel treatment for oxalate nephropathy with IV EDTA infusion. The patient's recovery from dialysis-dependence is rare. 24-hour urine studies before and after EDTA showed increased oxalate, presumably from renal excretion of soluble oxalate after calcium chelation with EDTA in the tubules. This underscores the consideration of oxalate nephropathy in AKI patients with high vitamin C intake and suggests a potential therapy for further study.

Paradoxical Role of Myeloid Cell PD-L1 Expression in AKI

Oliver B. Pelletier, Franklin J. Herbert, Vikram Sabapathy, Bushra Mehkri, Rahul Sharma. *University of Virginia School of Medicine, Charlottesville, VA.*

Background: Blocking of immune checkpoint molecules Programmed Death-1 (PD-1) and its ligands PD-L1 and PD-L2 have revolutionized cancer therapy via activation of anti-tumor immunity. However, this checkpoint inhibitor therapy also led to increase in immune check-point inhibitor (ICPI)-associated inflammatory diseases including acute kidney injury (AKI) suggesting a protective role of PD-1 and its ligands in AKI. While PD-1 is mainly expressed on T-cells, PD-L1 and PD-L2 are expressed on tumor, stromal, and immune cells including myeloid cells. Treatment of mice with antibodies to PD-1, PD-L1 and PD-L2 worsens ischemia reperfusion injury (IRI). Expression of PD-1 on the T-regulatory cells (Tregs) is important for protection from IRI (ASN Kidney week 2020, PO-0152). However, the role of PD-L1 expression on myeloid cells, as related to AKI remains a knowledge gap.

Methods: To investigate the role of PD-L1 expression on myeloid cells, we generated mice with deletion of PD-L1 in myeloid cells using lysozyme-driven Cre (*LysM-Cre*) to generate *PD-L1$^{fl/fl}$.LysM-Cre* mice. Mice were subjected to unilateral IRI and euthanized on day 14 after nephrectomy of contralateral kidney on day 13 or subjected to Cisplatin-induced renal injury. Blood, spleen and kidneys were analyzed for immunophenotype, and kidneys were analyzed for inflammation and injury by flow cytometry, histopathology and quantitative PCR.

Results: Deletion of PD-L1 in myeloid cells resulted in an overall inflammatory phenotype in mice as represented by lymphadenopathy and splenomegaly with greater accumulation of activated and memory T-cells that produced more proinflammatory cytokines. However, despite the inflammatory conditions, *PD-L1$^{fl/fl}$.LysM-Cre* mice displayed lower levels of injury and kidney dysfunction as compared to PD-L1 sufficient mice with IRI or cisplatin. While the infiltration of neutrophils in the PD-L1 deficient mice was lower, the infiltration of monocytes was significantly higher. Interestingly, the dendritic cells in the spleen and kidneys of PD-L1 deficient mice expressed lower levels of co-stimulatory molecules suggesting of lower activation status.

Conclusions: The data reveals a paradoxical role of PD-L1 expression in myeloid cells in promoting ischemic and cisplatin AKI, such that myeloid-cell specific deletion of PD-L1 was protective in AKI via promoting a tolerogenic milieu.

Myeloid Cells Alleviate Kidney Fibrosis after Folic Acid-Induced AKI via Vascular Endothelial Growth Factor (VEGF)-A Signaling

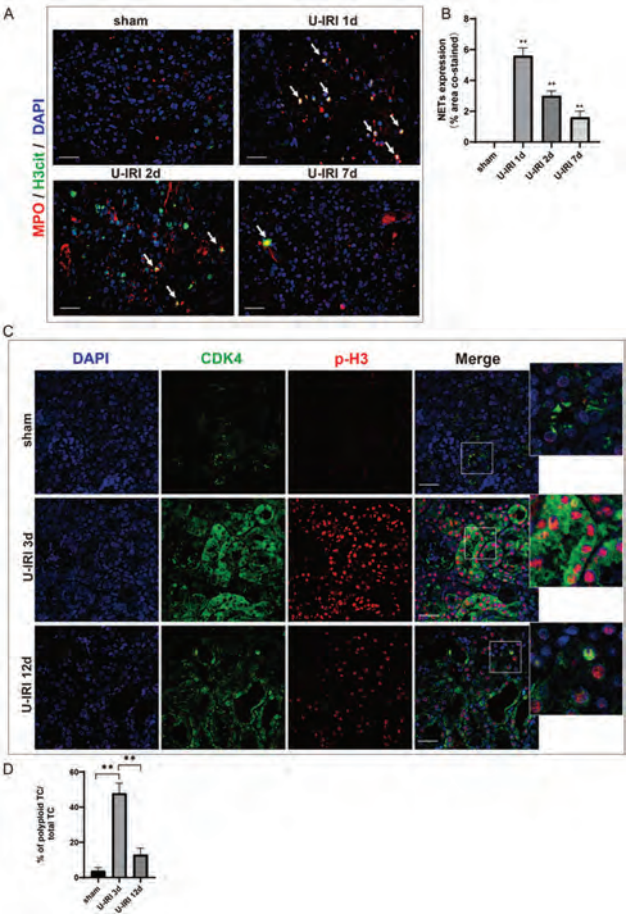
Kazutoshi Ono,[1] Takayuki Isagawa,[1] Daisuke Nagata,[1] Norihiko Takeda.[1,2]
[1]*Jichi Ika Daigaku, Shimotsuke, Japan;* [2]*Tokyo Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Bunkyo-ku, Japan.*

Background: Tubular epithelial cells (TEC) consume oxygen and nutrients to maintain its physiological function. Peritubular capillaries (PTC) maintain oxygen environment in kidney tissues, and its density is correlated with renal function and its prognosis. In healthy kidney, TEC act as a predominant source of vascular endothelial growth factor-A (VEGF-A) a major angiogenic cytokine which is required for the maintenance of PTC. However, how do angiogenesis and subsequent tissue repair take place in acute kidney injury (AKI) or its transition to chronic kidney disease (CKD) are largely unknown.

Methods: The mouse folic acid acute kidney injury (FA-AKI) model was used as an AKI model. We first performed histological and gene expression analysis of the kidneys of the wild-type mice over time after FA-AKI. Next, we performed single-cell RNA-sequencing (scRNA-seq) on kidneys of the wild-type mice 7 days after FA-AKI to detect VEGF-A-producing cells where TEC decreased.

Results: Histological analysis showed that proximal TEC and PTC gradually decreased until day 14 after FA-AKI. The mRNA expression levels of kidney *Vegfa* and *Megalin* (proximal TEC specific gene) were significantly lower on day 2 compared to baseline. *Megalin* was still lower on days 7 and 14, whereas *Vegfa* increased on days 7 and 14. ScRNA-seq revealed that the major source of *Vegfa* was macrophages (MΦ) among the leukocytes accumulated in the kidney 7 days after FA-AKI. In addition, fluorescence-activated cell sorting showed that F4/80^{lo} MΦ and F4/80^{hi} MΦ subpopulations accumulated biphasically in the kidney after FA-AKI, and F4/80^{lo} MΦ expressed higher levels of *Vegfa* than F4/80^{hi} MΦ. Finally, we generated myeloid cell-specific VEGF-A conditional knockout mice (mVEGFA CKO: *LysM*-Cre *Vegfa*$^{flox/flox}$) and controls (Control: *Vegfa*$^{flox/flox}$). PTC formation and TEC regeneration were significantly suppressed and tissue fibrosis was more pronounced in mVEGF-CKO compared to Control 14 days after FA-AKI.

Conclusions: Our data suggest that kidney macrophages substitute VEGF-A production in AKI where TEC derived VEGF-A secretion is impaired. Kidney macrophages have a potential as a therapeutic target in the management of AKI. Further study regarding how macrophages accumulate and produce VEGF-A in kidney tissues will help us to understand the pathological process of AKI to CKD transition.



Expression of NETs and polyploid tubular cells in IRI model

SA-PO076

Neutrophil Extracellular Traps Promote Polyploidization of Tubular Epithelial Cells after Kidney Injury

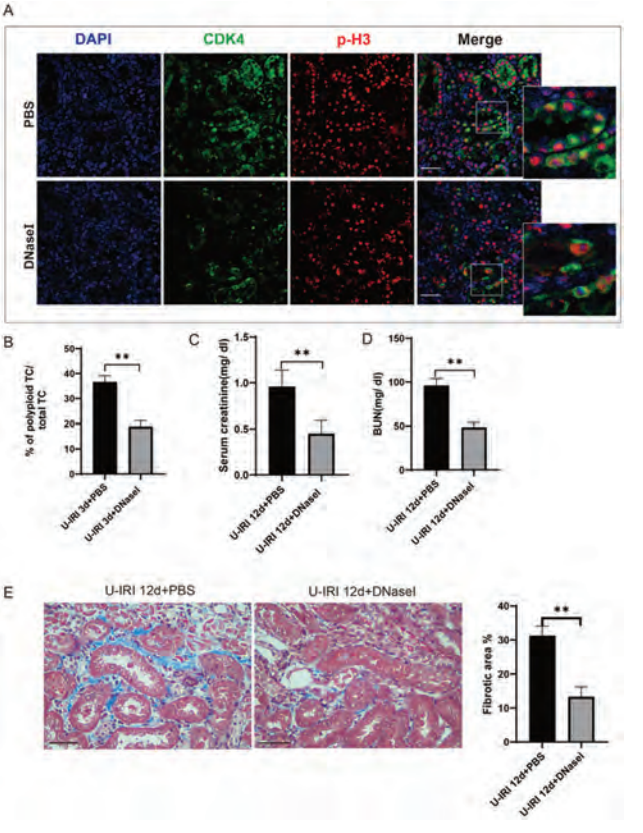
Wenchao Li, Li Hao, Yangang Gan, Jiajia Li, Hao Yu, Qianqian Han, Weicong Zeng, Qiongqiong Yang. *Sun Yat-Sen Memorial Hospital, Guangzhou, China.*

Background: Renal tubular epithelial cells undergo polyploidization after acute kidney injury (AKI), which promotes tubular cell senescence and renal fibrosis, the underlying mechanism remains unclear. Neutrophil extracellular traps (NETs) play a crucial role in tubular injury after AKI, but whether NETs promote tubular cell polyploidization is uncear.

Methods: The expression of NETs and polyploid tubules were analysed in renal ischemia-reperfusion (IRI) model. DNase I was emplayed as inhibitor of NETs, and the effects of tubular cell polyploidization and renal fibrosis was detected.

Results: The expression of NETS and polyploid tubular cells were upregulated after AKI. Clearing NETs decreased the amount of polyploid tubules and ameliorated renal fibrosis.

Conclusions: NETs regulate the transition from AKI to CKD by promoting polyploidization of renal tubular cells.



Removal of NETs decreased polyploid tubular cell formation in IRI model

SA-PO077

AKI Induces Neutrophil Swarms in Lung Alveolar Capillaries That Cause Perfusion Deficits and Hypoxemia

Yohei Komaru,[1] Rupal Ojha,[1] Liang Ning,[1] Anusha Suresh,[1] Carine Lama,[1] Eirini Kefalogianni,[1] Mark J. Miller,[1] Andreas Herrlich.[1,2] *[1]Washington University in St Louis School of Medicine, St Louis, MO; [2]Veterans Administration Health Care System, St. Louis, MO.*

Background: Acute kidney injury (AKI) complicated by respiratory failure is common among critically ill patients and associated with high mortality. We recently showed that circulating osteopontin released from the injured kidney causes remote lung inflammation with hypoxemia (Sci Adv 2022). However, mechanisms that rapidly establish remote lung inflammation after AKI and the underlying cause of hypoxemia remain incompletely understood.

Methods: Single-cell RNA-seq analysis with cell-cell communication analysis was employed to investigate remote lung inflammation 24 hours after bilateral renal ischemia-reperfusion injury (IRI). Intravital imaging of the lung conducted by two-photon microscopy, was performed 1.5-2 hours after IRI, with capillary flow assessment by iv injection of 1-μm beads. Intracellular F-actin in circulating neutrophils was visualized using phalloidin staining. Fibrinogen and CD41 were used as markers for thrombosis in immunofluorescent staining.

Results: AKI induces rapid intravascular "neutrophil train" formation in lung capillaries, a novel form of neutrophil swarming. Neutrophils are rapidly captured in lung capillaries due to AKI-induced actin cytoskeleton rearrangement leading to reduced deformability that impedes neutrophil lung capillary passage. Unlike in direct lung injury where neutrophils extravasate driven by the concerted action of non-classical monocytes and alveolar macrophages, in remote lung inflammation after AKI neutrophils do not extravasate and are retained and assembled into lung capillary neutrophil trains by CXCL2 released by lung classical monocytes; this occurs independent of non-classical monocytes or alveolar macrophages. Lung capillary neutrophil trains significantly impede perfusion and cause thrombosis in a significant part of the lung capillary network.

Conclusions: We thus discovered a novel feature of kidney-lung crosstalk after AKI, capillary perfusion deficits that lead to reduced oxygenation despite proper alveolar function and ventilation, unlike in infectious inflammatory lung processes, such as bacterial pneumonia, where alveolar ventilation is typically compromised by inflammatory exudates. Our findings highlight potential therapeutic targets in post-AKI remote organ inflammation, which cannot be addressed by existing therapies including dialysis.

SA-PO078

Single-Cell RNA Sequencing and Spatial Transcriptomics Reveal Unique Subpopulations of Infiltrating Macrophages and Dendritic Cells following AKI

Arin Melkonian, Matthew D. Cheung, Elise Erman, Yanlin Jiang, Anupam Agarwal, James F. George. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: Kidney infiltrating macrophages (KIMs) and kidney dendritic cells (KDCs) have been strongly associated with inflammation and fibrosis in acute kidney injury (AKI). Contrary to kidney resident macrophages (KRMs), which are self-renewing and present in the kidney prior to injury, KIMs are bone-marrow derived F4/80^{int}, CD11b^{high} macrophages. Here, we combined single-cell RNA sequencing (scRNAseq) and spatial transcriptomics to elucidate temporal, spatial, and transcriptional characteristics of unique subpopulations of KIMs and KDCs in AKI.

Methods: CD11b^{high} KIMs and KDCs from C57BL/6J mice were sorted using fluorescence activated cell sorting (FACS). We collected macrophages before injury and at days 1, 6, and 28 following 19 minutes of bilateral ischemia reperfusion injury (BIRI). Cells were subjected to scRNAseq using the 10X Genomics Chromium platform. Gene ontology was conducted to elucidate the functional roles of differentially expressed genes. Spatial transcriptomics were evaluated using the 10X Visium Spatial Gene platform. Data from all timepoints were integrated and analyzed using Seurat 5.0.

Results: scRNAseq results revealed 3 unique KIM and 2 KDC subpopulations. All 5 clusters were localized in unique microenvironments in untreated mice, and their locations were dynamically regulated following BIRI. We have shown that a specific KIM cluster, identified by its Arginase 1 expression, infiltrates the kidney medulla at day 1 and migrates to the cortex at day 6 post-injury. We have also identified a macrophage precursor cell population that expresses genes specific to cell proliferation and regeneration (e.g., *Stmn1* and *Top2a*) that are predicted to reside in the medulla in uninjured states. Gene ontology analysis revealed distinctive functional characteristics that set apart each KIM and KDC population.

Conclusions: We have identified distinct subpopulations of KIMs and KDCs within the kidney, each of which infiltrates at different times (i.e., 1 and 6 days) and occupies specific microenvironments after AKI. Because KIMs and KDCs are involved in inflammation and AKI, it is paramount we understand their dynamics—temporally and spatially—to develop macrophage-specific therapeutics aimed towards targeting kidney disease and promoting tissue repair.

Macrophage Infusion Rescues Cisplatin (CP)-Induced AKI

Xiaojia Guo,[1] Leyuan Xu,[1] Heino Velazquez,[1,2] Tian-Min Chen,[1] Robert L. Safirstein,[1,2] Gary V. Desir.[1,2] *[1]Yale University School of Medicine, New Haven, CT; [2]VA CT Healthcare System, West Haven, CT.*

Background: CP induces AKI, and repeated doses leads to chronic kidney disease (CKD) in humans. Previously, we produced a mouse model using two doses of CP two weeks apart that recapitulates the features of CP-AKI and CP-CKD in humans. Here, we employ 13 different KO mouse models to identify genes that play a critical role in kidney injury.

Methods: Single-cell RNA sequencing (scRNAseq) was performed on kidneys of wild-type (WT) mice 0, 1, 3, and 5 days (D) after 15 mg/Kg CP to identify the transcriptional response changes in major cell types during the induction of injury. These findings were confirmed by immunohistochemistry and quantitative reverse transcription polymerase chain reaction (RTqPCR). The course of AKI and CKD was then followed in KO mice. Bone marrow-derived macrophages (BMDM) were isolated from either WT or KO mice and injected into KO mice treated with cisplatin to identify protective genes.

Results: Plasma creatinine at D0, D1, D3, and D5 was 0.07±0.01, 0.08±0.09, 0.42±0.05, and 0.16±0.09 mg/dL, respectively, n=3, ($p<0.005$ for D3 by one way ANOVA). The % of injured proximal tubule cells (PT) of D0, D1, D3, and D5 were 0.15, 0.44, 4.36, and 2.93 respectively; Neutrophils increased from 0.04% at D0 to 0.89% at D3 and reduced to 0.31% at D5. Macrophage and T cell plateaued at D3. ScRNAseq and whole kidney RTqPCR showed CP increased Cxcl1, p21, Tlr2, Sox9 in injured PT; Apobec1, Tlr4, Tlr2, RIPK3, Ccl2, Ccr2, Cxcl1, p21 in macrophages; and Ppif, Lcn2 in neutrophils and reduced RNLS in whole kidney. Of 13 KOs of these 12 genes plus double KO of Tlr2 and Tlr4, only Apobec1 and RNLS showed profound effects on the course of AKI/CKD as none of the Apobec1 KOs survived the initial dose of CP, and Rnls KOs developed more severe CKD. As Apobec1 and Rnls were expressed by macrophages, we injected undifferentiated WT BMDM in each KO mouse. WT macrophage infusion reduced kidney injury in Apobec1 KO (BUN 53.81±3.52 vs 72.74±1.4 mg/dL, n=4, $p<0.01$) and Rnls KO mice (49.16±4.39 vs 68.57±2.89 mg/dL, n=4, $p<0.01$) as compared to mice infused with KO BMDM and reduced the expression of KIM-1 and Ccl2 in the kidneys of these mice.

Conclusions: Our results indicate that Apobec1 and RNLS are key cargo components within the macrophages and are crucial to the outcome of the injury and suggest that macrophages can be a potent delivery system of these molecules.

Kidney Macrophage IL-1 Receptor Limits Endoplasmic Reticulum Stress and Nephrotoxic Serum Nephritis

Yanting Chen,[1] Yu Li,[1] Jiafa Ren,[2] Chia-Chun Wu,[3,1] Xiaohan Lu,[1] Steven D. Crowley,[1,4] Jamie R. Privratsky.[1] *[1]Duke University, Durham, NC; [2]Nanjing First Hospital, Nanjing, China; [3]Chi Mei Medical Center, Tainan, Taiwan; [4]Durham VA Health Care System, Durham, NC.*

Background: Acute kidney injury (AKI) often leads to chronic kidney disease. Macrophages play divergent roles in kidney injury and repair. Previously, we demonstrated a protective role of IL-1R1 in CD11c-expressing kidney myeloid cells in early AKI. This study aims to determine the role of IL-1R1 in myeloid cells in chronic kidney injury. We hypothesized that myeloid cell IL-1R1 signaling would limit chronic inflammation after AKI.

Methods: Mice with CD11b-expressing myeloid cells-specific deletion of IL-1R1 (*LysMCre*(+) / *Il1r1fl/fl* - MKO) and littermate wildtype controls (*LysMCre*(-) / *Il1r1fl/fl* - MWT) were subjected to nephrotoxic serum nephritis (NTS) and chronic ischemia/reperfusion (I/R) models. Kidney and glomerular injury were assessed by albuminuria, histologic injury scoring, and kidney injury biomarkers kidney injury molecular (KIM)-1 and neutrophil gelatinase-associated lipocalin (NGAL). Fluorescent cell-sorting and single cell RNA sequencing were used to profile gene expression and identify cell-specific ligand-receptor interactions. Renal HK-2 cells were co-cultured with bone marrow-derived macrophages (BMDM) from MKO and MWT mice.

Results: Compared to MWT mice, MKO mice demonstrated worsened nephritis as indicated by increased albuminuria (mean ± SD: MWT 24,638 ± 4,262 vs MKO 30,826 ± 3,237 μg/mg urinary creatinine, $p=0.02$), elevated KIM-1 mRNA and exacerbated histologic injury scoring. MKO mice also displayed evidence of increased tubular injury following chronic I/R. We found increased endoplasmic reticulum stress

(ER stress)-mediated apoptosis and pro-inflammatory polarization in macrophages from NTS injured MKO kidneys, which was associated with elevated renal expression of type I interferons (IFNs). Nichenet analysis revealed that high mobility group protein B1 (HMGB1) is a prioritized ligand from macrophages that could induce type I IFNs in damaged tubular cells. In co-culture studies, we confirmed the increased ER stress and pro-inflammatory cytokines in MKO macrophages, which led to heightened cellular injury and elevated type I IFNs in HK-2 tubular cells. In turn, anti-IFNR1 therapy ameliorated these detrimental effects in vivo.

Conclusions: IL-1R1 signaling on macrophages constrains ER stress-mediated pro-inflammatory polarization and ameliorates type I IFNs-induced tubular injury and NTS injury.

Major Vault Protein Promotes Kidney Inflammation and Macrophage Recruitment in a Murine Model of AKI

Cheuk Yin Wong, Susan Yung, Tak Mao D. Chan. *The University of Hong Kong Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong.*

Background: Acute kidney injury (AKI) is characterized by deterioration of kidney function and increased risk of developing chronic kidney disease (CKD). AKI-to-CKD transition following acute injury results from maladaptive repair leading to renal tubular loss, chronic inflammation and kidney fibrosis. We previously demonstrated that major vault protein (MVP) contributed to kidney inflammation and fibrosis in murine models of CKD. This study investigated the role of MVP in AKI and AKI-to-CKD transition.

Methods: MVP expression was assessed using immunocytochemical staining in kidney biopsies from patients with active proliferative lupus nephritis, acute tubular injury, pauci-immune ANCA-associated renal vasculitis or kidney allograft dysfunction. AKI was induced in wild-type (WT) and MVP-knockout (KO) mice by a single dose of folic acid (250 mg/ kg) in 0.3 M sodium bicarbonate administered by intra-peritoneal injection. Mice were sacrificed after 7 days and kidneys harvested for investigation of histopathology and expression of mediators relating to tubular injury and inflammation. Mice administered 0.3 M sodium bicarbonate served as non-AKI Control.

Results: MVP was weakly expressed in normal human kidney specimens, but its expression was markedly increased in proximal renal tubular epithelial cells in kidney biopsies of patients with AKI. In WT AKI mice, MVP gene expression was increased by 5.85±1.22-fold compared to WT non-AKI Control mice ($p<0.0001$), and was accompanied by increased serum urea level, tubular atrophy, macrophage recruitment and increased expression of mediators of tubular injury and inflammation including KIM-1, NGAL, TNF-α, IL-1β, CCL2 and CCL5 *($p<0.01$, for all)*. MVP KO mice subjected to induction of AKI showed less severe kidney histopathological features with reduced macrophage infiltration and serum urea level and decreased expression of mediators of tubular injury and inflammation ($p<0.05$, for all).

Conclusions: Our data suggest that MVP contributes to tubulo-interstitial inflammation and tubular injury in murine folic acid-induced AKI, which may modulate AKI-to-CKD transition.

TREM2 Macrophages Ameliorate the Transition of AKI-CKD via a PI3K/AKT Signaling Pathway

Yiming Zhou,[1] Yating Zhang,[1] Siweier Luo,[1] Yufei Du,[1] Le Wang,[1] Hanzhi Liang.[2] *[1]Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China; [2]The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China.*

Background: Macrophages have been shown to contribute to renal injury and fibrosis as well as repair. Their multiple phenotypes may explain the diverse functions of macrophages in acute kidney injury (AKI) and subsequent chronic kidney disease (CKD). TREM2 macrophages have recently been shown to play an important role in regulating tissue inflammation and repair. But their role in the AKI-CKD transition remains unclear.

Methods: A unilateral ischemia-reperfusion injury (UIRI) mouse model was used to generate the transition of AKI-CKD. After operation, sham and UIRI mice were sacrificed on day 14. Serum urine, and kidney samples of each mouse were collected. Serum creatinine and urea nitrogen levels were determined by ELISA. Urinal albumin levels were determined by a CBB gel staining method. qPCR and WB were used to determine the expression levels of genes and proteins in kidney samples. H&E, PAS, Masson and Sirus Red staining were used to evaluate the renal histology. Bone marrow-derived macrophages from WT and TREM2 knockout mice were harvested and treated with the hypoxia and reoxygenation (HR) condition. Stable TREM2 overexpression macrophages were used to investigate the renal protective effect in UIRI mice.

Results: In this study, we found that TREM2 macrophages play a strong protective role in the transition from AKI to CKD. The population of TREM2 macrophages was significantly increased in the UIRI-induced AKI-CKD transition mice. Knockout of Trem2 resulted in increased renal inflammation, exacerbated renal injury and fibrosis. In addition, we found that TREM2 expression enhanced macrophage phagocytosis but reduced the expression of pro-inflammatory cytokines, resulting in lower levels of tubular cell apoptosis and fibrosis. RNA-seq analysis revealed that these effects of TREM2 were controlled by PI3K/AKT pathway. Notably, the kidney injury and fibrosis in the UIRI mice was effectively attenuated by cell therapy with TREM2-overexpressing macrophages.

Conclusions: Our study demonstrates that TREM2 macrophages play a protective role in the transition of AKI-CKD and targeting TREM2 may be a therapeutic strategy for this disease.

SA-PO083

Myofibroblast-Macrophage Cross-Talk Supports Proliferative Tubule Repair after Kidney Injury

Bhavya Bharathan, Leyuan Xu, Jiankan Guo, Lloyd G. Cantley. *Yale University School of Medicine, New Haven, CT.*

Background: After ischemia-reperfusion injury (IRI), macrophages expressing arginase 1 (Arg1) exclusively localize to the outer medulla adjacent to injured and dying S3 proximal tubule cells. Genetic deletion of macrophage Arg1 leads to less tubular proliferation and decreased mouse survival after IRI. Arg1 is known to be required for protein translation, and we speculate that upregulation of Arg1 leads to macrophage secretion of unidentified factor(s) that are required for downstream tubular cell proliferation.

Methods: Unilateral IRI with contralateral nephrectomy (IRI/CL-NX) was used to induce ischemic kidney injury in mice. Cultured macrophages were induced to express Arg1 by co-culture with renal tubular cells + GM-CSF. We performed bulk RNA sequencing and quantitative PCR (qPCR) of primary cultured renal cells and single cell RNA sequencing of mouse kidneys 3 days after IRI or sham to identify relevant growth factors and cell types after IRI. PDGFRβ± cells were isolated from injured and control kidneys using Magnetic-Activated Cell Sorting, and RNA was isolated to analyze relevant growth factors by qPCR.

Results: scRNAseq from day 3 injured kidneys demonstrated that Insulin-like Growth Factor-1 (Igf1) is upregulated in myofibroblasts (PDGFRβ+ cells), and Igf1 Receptor (Igf1R) is upregulated on proximal tubule cells. Conditioned medium from Arg1 expressing macrophages induced an 8.95-fold increase in expression of Igf1 in cultured PCRC (containing a mix of ~94% tubular cells and ~5% PDGFRβ+ myofibroblasts). Isolation of PDGFRβ+ cells from the kidney on day 2 after IRI revealed a 14.83±0.14-fold increase in Igf1 in these myofibroblast-enriched cells as compared to PDGFRβ- cells ($p<0.0001$), with a 7.51±0.14 fold increase compared to PDGFRβ+ cells from uninjured kidneys ($p<0.0002$)

Conclusions: Arg1-expressing macrophages secrete a yet unidentified factor(s) that can induce Igf1 expression by primary cultured renal cells, likely myofibroblasts, with concomitant upregulation of Igf1R on tubular cells. We hypothesize that this macrophage-myofibroblast crosstalk underlies Igf1-induced proliferative tubule repair by surviving proximal tubule cells.

Immunomodulation and T Cell Infiltration in AKI Caused by Ischemia-Reperfusion (IR): Role of Sex Difference and Angiotensin II Type 2 Receptor (AT2R)

Tahmid Faisal,[1] Riyasat Ali,[1,2] Tahir Hussain.[1] *[1]University of Houston, Houston, TX; [2]The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: A greater renoprotection against injury in females compared to males has been suggested. However, the mechanism and factors responsible for this difference are unknown. Recently, we have reported that angiotensin AT2R activation (by its agonist compound C21) attenuates immune cells infiltration in the kidney and increases protective/reparatory regulatory T cells ($CD4^+$-$FoxP3^+$ Treg) accumulation in the IR kidney in male rats. Present study is designed to evaluate sex difference in immune cell infiltration and T cells profiles in the IR kidney and the signaling mechanism by which AT2R promotes Treg modulation.

Methods: Male, female (ovary intact, Ovi) and ovariectomized (Ovx) SD rats were divided into 3 groups- sham, IR, and IR+C21 (daily 0.3 mg/kg, i.p). After 30 mins ischemia and 3 days of reperfusion, kidneys were incised and digested to make kidney cell suspension for flow cytometry of immune cells. To understand the signaling pathway(s) associated with AT2R mediated modulation of CD4 T cells into Treg cells, primary splenic CD4 T cells were cultured, induced Treg formation with pharmacological agents.

Results: Flow cytometry revealed that CD45 cells accumulation was increased in the IR kidney, being 2-fold higher in males than Ovi. The AT2R agonist C21 treatment reduced CD45 in both males and females equally. Preliminary studies show Ovx did not affect CD45 compared with Ovi but attenuated the response of the AT2R activation on CD45 cell reduction. Like CD45, basal CD3 and CD4 were higher in males than in Ovi, but these cells were similar in the IR groups and reduced by C21 treatment. Treg cells were higher in male than Ovi in IR and C21. There is an increasing pattern of AT2+Tregs cells in IR rats of all groups with 50% cells with AT2R expression. Normal blood CD3, CD4, CD4+AT2+T and Tregs cells did not show sex difference. Kidney injury markers

showed less injury in IR Ovi females than males. Ex vivo studies show AT2R activation by C21 in splenic T cells modulation to Tregs is inhibited totally by the PP2A inhibitor okadaic acid and only partially by NO synthase inhibitor L-NAME.

Conclusions: Under AKI, there are fewer immune cells, including T cells accumulation in females compared to males and AT2R function is reduced by Ovx in females, suggesting a sex difference. AT2R modulates Tregs via PP2A pathway.

Interferon Regulatory Factor 4 (IRF4)-Dependent Type 2 Conventional Dendritic Cells (cDC2s) Promote Kidney Inflammation and Injury in Ischemia-Reperfusion Injury (IRI)-Induced AKI/AKD

Hao Long,[1,2] Kristina O. Borisova,[1] Hans J. Anders,[1] Julia Lichtnekert.[1]
[1]Division of Nephrology, Department of Medicine IV, University Hospital, Ludwig-Maximilians-University, Munich, Germany; [2]Department of Urology, The Affiliated Hospital of Southwest Medical University, Luzhou, China; Sichuan Clinical Research Center for Nephropathy, Luzhou, China.

Background: Ischemia-reperfusion injury(IRI) is a frequent cause of AKI/AKD. cDCs play pivotal immunoregulatory roles in kidney injury and repair. Previous research had indicated that cDC1s and cDC2s may have opposing roles. We demonstrated a protective function of cDC1s in the IRI-induced AKI/AKD model. In our study, we investigated the functions of cDC2s in AKI/AKD.

Methods: *In vivo*, we did unilateral IRI on IRF4$^{fl/fl}$Clec9a^{cre} and WT mice.IRF4 deletion on DC lineage led to a diminished proportion of the cDC2s. We analyzed kidney function, kidney immune cells, i.e., DC subsets, neutrophil infiltration, T cell differentiation, inflammatory responses. We differentiated *in vitro* bone-marrow-derived DCs from IRF8$^{fl/fl}$Clec9a^{cre} and WT mice using an in-house produced FLT3L supernatant and a recombinant GM-CSF. We compared the phenotype of the generated cells based on the surface markers and essential genes. With different TLR stimulants, we analyzed cytokine secretion, DC activation, migration, and phagocytosis (IHC, IF, ELISA, flow cytometry, transwell migration assay, qPCR).

Results: IRF4 ko mice had a lower proportion of cDC2s in kidney than WT mice. After uIRI, IRF4 ko mice showed reduced renal tubular cell injury, improvement of kidney function and recovery than WT mice. This was associated with increased expression of anti-inflammatory, decreased pro-inflammatory cytokines and acute tubular cell death, reduced recruitment of neutrophils, and differentiation of Th2 and Th17 cells. *In vitro*, WT DCs exhibited a cDC1 phenotype, but IRF8 ko cells resulted in the evolution to cDC2. With LPS and CpG stimulations, these cDC2-like cells displayed elevated activation, phagocytic and migration capabilities. Additionally, they exhibited a higher proinflammatory roles, with increased levels of CXCL2 than WT cells.

Conclusions: Our data demonstrated that IRF4 was essential for the differentiation of kidney cDC2s. The reduction of cDC2s ameliorated kidney inflammation, reduced kidney injury, and promoted kidney recovery. In-vitro IRF4^{high} cDC2-like cells could be generated by IRF8 deletion in DC lineage cells, which led to a shift in cell fate and an increased proinflammatory phenotype. Together, cDC2s had an immunoregulatory role in AKI/AKD and could serve as a potential therapeutic target for improving kidney injury and inflammation.

Spatial Transcriptomics Enables Generation of a Complement Atlas of Mouse AKI

Vikram Sabapathy,[1] Daniel Chauss,[2] Shuqiu Zheng,[1] Resmi Raju,[3] Jeremie O. Piña,[3] Rahul Sharma,[1] Tilo Freiwald,[4] Behdad Afzali,[2] Didier Portilla.[1]
[1]University of Virginia, Charlottesville, VA; [2]NIH/NIDDK, Bethesda, MD; [3]NICHD/NIH, Bethesda, MD; [4]University Med Ctr, Hamburg, Germany.

Background: Kidney tubulointerstitial fibrosis plays an essential role in progressive kidney disease. Our previous studies suggest that increased expression of intracellular complement (C') components contribute to the pathogenesis of kidney fibrosis. The identity of the C' components that participate in this process and cellular mechanisms involved in their activation remain under-explored. We hypothesized that increased local expression of C' and its receptors directly in kidney tissue is compartmentalized and that local interactions involving this system impact fibrosis.

Methods: We used Spatial Transcriptomics (ST) by 10X Xenium, and formalin-fixed paraffin embedded (FFPE) kidney tissue from mice subjected to IRI and UUO to map all C' components and their receptors (n=100 genes) in tandem with a multi-tissue atlasing panel (n=380 genes). Computational analyses included Seurat, integration by Harmony and clustering by UMAP.

Results: We generated a high-resolution map of C' components and their receptors in control kidneys (Ctrl), UUO and IRI. Key C' components were clearly differentially induced in AKI models compared to Ctrls. These included *C3*, factor B (*CFB*), factor H (*CFH*) and properdin (*CFP*). *C3* and *CFB* were localized to failed to repair (FTR) PTs in AKI. CFH was highly induced in stromal cells, which were more than 3-fold expanded following AKI and UUO. CFP was localized to interstitial immune cells. We noted that infiltrating immune cells coalesced around FTR PTs and expressed the C3AR1 as well as receptors for C5a. The majority of immune cells were macrophages expressing high levels of F480, IL-1b and TNF, suggesting that they were proinflammatory macrophages. RNAscope, RT-PCR and confocal microscopy confirmed the changes seen by ST. The proximity of inflammatory immune cells expressing C3AR1 to PTs expressing their cognate ligand suggests bi-directional signaling between FTR PTs and immune cells. Ongoing work will functionally explore these observations and determine the local roles of CFH and CFP in AKI and fibrosis.

Conclusions: Compartmentalized induction of C' components and receptors occurs following AKI and may modulate inflammation and subsequent fibrosis through interactions with local immune and stromal cells.

The Human Sepsis Blood Transcriptome Correlates with Molecular Signatures of Murine Sepsis-Associated AKI

Danielle Janosevic, Sean D. Mccabe, Thomas De Luca, Michael T. Eadon, Takashi Hato, Pierre C. Dagher. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Sepsis is a common cause of acute kidney injury for which we lack predictive biomarkers. In murine models of sAKI, renal tissue injury progresses through precise tissue gene expression stages that are mirrored in the blood transcriptome. We hypothesize that blood-based murine sAKI biomarkers can help diagnose and stratify human subjects with sepsis.

Methods: Whole blood RNAseq (25-30 million read depth/sample, mm10 transcriptome) was performed in a murine model of sAKI at 0 and 1,16 hr after endotoxin injection. Counts were TMM normalized and log-transformed (counts-per-million, EdgeR). Human data was derived from GSE 65682 (Scicluna et al., MARS consortium) and "abdominal-sepsis" (sepsis) and "control-GI" (non-sepsis) groups of blood RNA were compared. A within-species analysis was used to calculate gene log fold changes (LFC). Spearman correlations were calculated using a filtered gene set (> +/- 0.25, human, > +/- 1.5, murine samples) to determine sample relatedness.

Results: Murine blood-based sAKI biomarkers were able to discriminate between septic and non-septic patients. Correlations of gene changes between human non-sepsis with murine controls (0 hr) were as high as 0.43 and as high as 0.44 between human sepsis and murine late sAKI samples (16 hr, Figure). Correlated genes upregulated in sepsis were related to immune function (Bcl11b, Hvcn1, Cx3cr1) and metabolism (Pask).

Conclusions: Correlation of blood-based RNA biomarkers between human and murine sepsis data revealed shared alterations in critical processes related to sepsis-immune system regulation and metabolism. Defining such biomarkers may aid in the identification of subjects at risk for sAKI and afford early interventions to attenuate or reverse sAKI.

Funding: NIDDK Support, Private Foundation Support

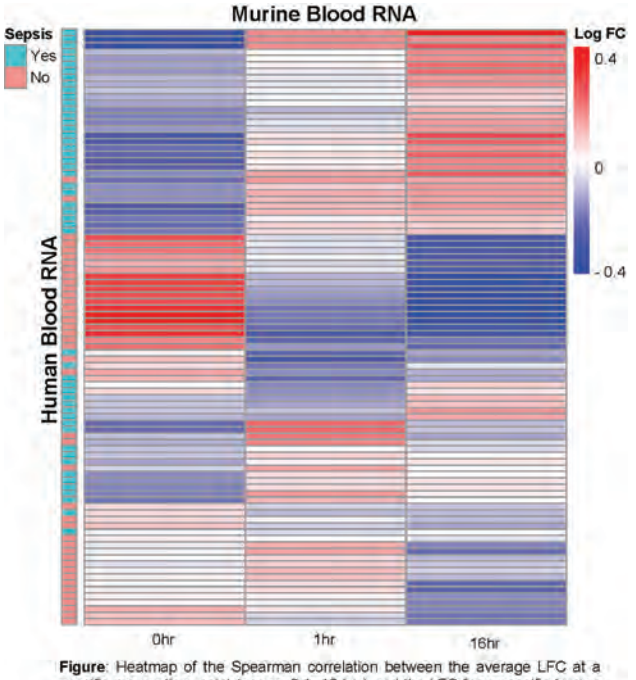

Figure: Heatmap of the Spearman correlation between the average LFC at a specific mouse time point (across 0,1, 16 hrs) and the LFC for a specific human sample (sepsis vs non-sepsis). Only genes with the LFC greater than 0.25 for the human sample and greater than 1.5 for the mouse sample were included.

Unraveling Autoimmunity and Tissue Residency in a Model of CD8 T Cell-Driven Nephritis

Frederic Arnold,[1,2] Laurence Kupferschmid,[2] Philipp Weissenborn,[2] Sagar -,[4] Manuel Rogg,[3] Christoph Schell,[3] Yakup Tanriver.[1,2] AG Tanriver.
[1]Department of Internal Medicine IV, University Medical Center Freiburg, Freiburg im Breisgau, Germany; [2]Institute for Microbiology and Hygiene, University Medical Center Freiburg, Freiburg im Breisgau, Germany; [3]Institute for Pathology, University Medical Center Freiburg, Freiburg, Germany; [4]Department of Internal Medicine II, University Medical Center Freiburg, Freiburg, Germany.

Background: There is strong evidence, that autoreactive cytotoxic T cells (CTLs) play a crucial role in different forms of autoimmune nephritis (*e.g.*, acute interstitial nephritis or immune checkpoint inhibitor-related nephritis). Yet, mechanisms of differentiation and memory formation of autoreactive CTLs in the kidney are poorly understood. Distinct tissue-resident memory T cells (T_{RM}) providing localized immunity have been identified in the kidney. However, their role in context of renal autoimmunity remains elusive.

Methods: A murine model of CTL-driven nephritis was established to dissect the role of autoreactive CTLs. It is based on NOH mice, that express ovalbumin (OVA) on podocytes. CTL-driven autoreactivity was induced by adoptive transfer of OVA-specific CTLs (OT-1 cells) into NOH hosts and activation through infection with OVA-expressing pathogens. The transcriptome and T cell phenotype was analyzed applying scRNASeq and multi-dimensinal flow cytometry on circulating and renal CTLs. Additional histopathological analysis was performed on kidneys of NOH mice and patients with interstitial nephritis.

Results: Autoreactive CTLs induced a robust renal phenotype in NOH mice. Despite the phenotype, peripheral OT-1 counts declined more rapidly in NOH *vs.* wildtype mice. In line with that, scRNASeq and cytometry analysis of OT-1 cells revealed a distinct peripheral T memory phenotype. It was characterized by higher expression of markers associated with T cell dysfunction (*e.g.*, Tox, Ctla4, Lag3), indicating functional restriction of autoreactive CTLs. While peripheral immunity appeared curtailed, robust accumulation of OT-1 cells was detected in kidneys of NOH mice. Within OT-1 infiltrates a subpopulation of autoreactive renal T_{RM} cells ($CD103^+CD69^+$), most likely required for maintaining the phenotype, could be identified. Histopathological analysis of human samples revealed a comparable T_{RM} subpopulation in interstitial nephritis.

Conclusions: CTLs show a distinct transcriptome and immune phenotype in a model of CTL-driven nephritis. While the systemic immune response is curtailed, CTLs persistently accumulate at the site of autoantigen cross-presentation. Differentiation of T_{RM} cells within infiltrates of mice and nephritis patients indicate a crucial role of renal T_{RM} cells in context of sustained renal autoimmunity.

SA-PO089

Tertiary Lymphoid Structures and Late-Stage Lymphangiogenesis at Very-Late Time Points following Ischemic Kidney Injury

Gelare Ghajar-Rahimi,[1] Arin Melkonian,[1] Daria Barwinska,[2] Grace Whipple,[1] Malgorzata Kamocka,[2] Seth Winfree,[3] James F. George,[1] Timmy C. Lee,[1] Tarek M. El-Achkar,[2] Anupam Agarwal.[1] *[1]The University of Alabama at Birmingham, Birmingham, AL; [2]Indiana University School of Medicine, Indianapolis, IN; [3]University of Nebraska Medical Center, Omaha, NE.*

Background: The role of the lymphatic system in the transition from AKI to CKD is unknown. In several AKI models, kidney lymphatics undergo expansion or lymphangiogenesis (LA), which is considered acutely protective, but long-term changes post-injury have not been assessed. This study aimed to determine if long-term alterations in kidney lymphatics persist and their relationship to inflammation and injury.

Methods: C57BL/6J mice underwent bilateral ischemia-reperfusion injury (BIRI) and were followed for 9 months. Kidney function was assessed using serial glomerular filtration rate (GFR) measurements. The abundance and spatial distribution of LYVE-1+ lymphatic vessels were determined using quantitative three-dimensional tissue cytometry (3DTC). Lymphangiogenesis (LA) was evaluated by quantitative real-time PCR for lymphangiogenic markers. Single-cell and single-nucleus transcriptomic datasets of murine and human endothelial cells were analyzed to identify additional target genes. Sequential immunofluorescence characterized tertiary lymphoid structures in the kidney.

Results: BIRI induced AKI within 24 hours. While GFR recovered, BIRI mice showed progressive histological signs of CKD overtime, including fibrosis and CCR7+ lymphoid aggregates. Sham-operated mice did not display these phenotypes. 3DTC revealed an increase in cortical LYVE-1+ vessels in BIRI compared to sham groups at 3 days and 6 months post-surgery, with no significant difference at intermediate time points. Expression of lymphatic marker gene *Flt4* and *Lyve1* increased acutely, while *Flt4*, *Lyve1*, and *Pdpn* were elevated later. Increased *Ccl21a* expression was detected in kidneys collected 6 months after BIRI. Single-cell/nucleus transcriptomics suggest the source of *Ccl21a* is likely a subpopulation of lymphatic endothelial cells.

Conclusions: Three distinct phases of kidney lymphatic responses occur after BIRI: acute LA, an intermediate regression to a basal phenotype, and late-stage LA coinciding with increased *Ccl21a* expression and tertiary lymphoid tissue formation. Future studies will aim to examine the precise spatial and functional relationship between injury-associated lymphatics, tertiary lymphoid structures and kidney function.

Single-Cell RNA Sequencing of Kidney-Gut Axis during Microbiome Manipulation of Severe AKI to CKD Progression

Jiahui Yao, Shishir K. Patel, Sanjeev Noel, Patrick Cahan, Hamid Rabb.
Johns Hopkins University, Baltimore, MD.

Background: The gut microbiome modifies experimental acute kidney injury (AKI) outcomes. The antibiotic drug amoxicillin, accelerates kidney repair and decreases fibrosis after severe AKI, likely through CD8 T cells (Kidney International, 2023). The goal of this study was to uncover specific genes and pathways that mediate T cell response to amoxicillin and regulate recovery and repair from severe AKI.

Methods: 8-10 week old male C57BL6 mice underwent unilateral ischemia reperfusion injury (UIRI) to kidney (n=10/group). Mice were given vehicle (1% glucose) or amoxicillin (50 mg/ml) in drinking water starting soon after UIRI and kidney and colon tissues collected after 15 days. Non surgery mice treated with vehicle and amoxicillin were used as controls. CD3+ cells were flow sorted for 10X Chromium 5-prime single cell RNA sequencing (scRNA-seq). Cells were annotated using machine learning classification and manual annotation using established cell markers. Differential gene expression and Gene Set Enrichment Analysis (GSEA) was performed to identify specific genes and pathways that differed between corresponding cell types across conditions.

Results: After quality control, we recovered 22,260 cells from the kidney and 14,669 cells from the colon. Nine cell types were annotated, including Th1, Th2, Th17, regulatory T cells, effector and memory CD8+ cells, and naive CD4+, CD8+, double negative and double positive T cells. Amoxicillin treatment after UIRI increased the proportion of CD8+ T cells and reduced that of CD4+ T cells in kidney, while the colon decreased the fraction of CD8+ T cells. GSEA revealed aldosterone-regulated sodium reabsorption (downregulated Prkcb, Insr, Nedd4l, etc) and JAK-STAT signaling pathway in kidney (downregulated Jak1, Ccnd3, and Socs1, etc), as well as estrogen signaling pathway (downregulation was repaired after Amoxicillin, marked by Jun, Fos, Hsp90aa1, etc) and renin secretion (downregulated Gnai2, Adrb1, Gnas, etc) in the colon.

Conclusions: These scRNA-seq results show shifts in T cell populations in gut-kidney axis during severe AKI and corroborated our prior flow cytometry observations. Our scRNA-seq data and analyses promise to yield novel mechanisms, markers, therapeutic options for severe AKI and gut microbiome-kidney cross talk.

Pathological Effects of IL-17A on Renal Leukocyte Infiltration in Murine Septic AKI (SAKI)

Yoshitaka Naito, Tomoyuki Fujikura, Akihiko Kato, Hideo Yasuda. *Hamamatsu Ika Daigaku, Hamamatsu, Japan.*

Background: There are no specific treatments for SAKI. Hyperinflammation in kidney leads to renal leukocyte infiltration, which contributes to SAKI. In non-septic AKI, neutrophils and NK cells are first recruited to kidney, followed by inflammatory monocytes. However, the course of renal leukocyte infiltration in SAKI has not been clarified. We have shown that knockout of IL-17A improved survival and SAKI after cecal ligation and puncture (CLP) surgery. We next focused on the downstream of IL-17A. It is well known that IL-17A stimulates non-myeloid cells, such as epithelial cells, to produce chemokines that promotes leukocyte recruitment to inflammatory site. We hypothesized that IL-17A contributes to the pathogenesis of SAKI by promoting leukocyte infiltration into kidney.

Methods: IL-17A knockout (IL-17AKO) or wild type mice (WT) were subjected to CLP to induce polymicrobial sepsis or sham surgery. We assessed leukocyte (neutrophil, macrophage, NK cell, B cell, and T cell) infiltration into kidney by flow cytometry and IL-17A, CXCL-1, and -2 concentration in kidney tissue by ELISA at 3, 6, and 18 h after CLP. We also assessed whether recombinant human IL-17A can promote production of human IL-8, a functional homolog of murine CXCL-1 and -2 and a potent promoter of neutrophil recruitment, in HK-2 (human kidney 2) cells in vitro.

Results: In WT, CLP upregulated neutrophil and B cell infiltration into kidney at 3 h; neutrophil, NK cell, and T cell infiltration at 6 and 18 h after CLP. IL-17AKO attenuated neutrophil and macrophage infiltration at 3 h and neutrophil, macrophage, and NK cell infiltration at 18 h after CLP. CLP upregulated IL-17A, CXCL-1, and -2 production in kidney tissue at 18 h after CLP, which is significantly decreased by IL-17AKO. Recombinant IL-17A promoted human IL-8 production in HK-2 cells.

Conclusions: We have shown that in SAKI, first neutrophils and B cells infiltrated into kidney, followed by NK cells and T cells; IL-17A contributed to neutrophil, NK cell, and macrophage infiltration. IL-17A promoted CXCL-1 and -2 production in kidney. These findings indicates that IL-17A promotes neutrophil infiltration via CXCL-1 and -2 production in kidney after CLP. We are planning further studies to determine how IL-17A promotes NK cell or macrophage infiltration into kidney after CLP.

SA-PO092

Viral Priming Enhances Kidney Injury at Early Time Points in Lipopolysaccharide (LPS)-Induced Sepsis-Associated AKI

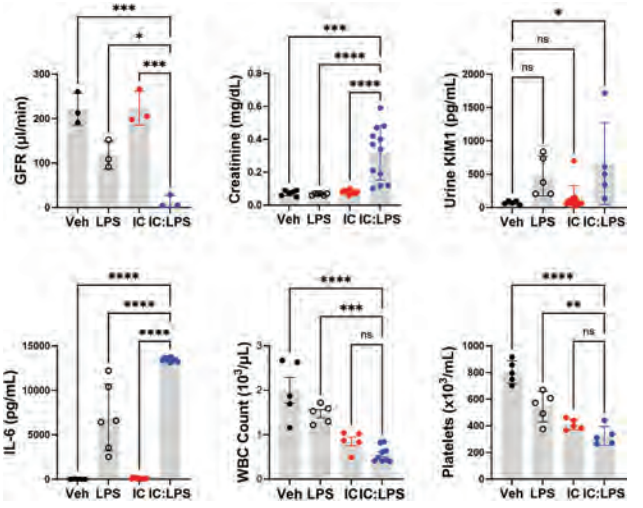
James D. Odum, Giacynta A. Vollmer, Juheb Akhter, Subhashini Bolisetty. *The University of Alabama at Birmingham Heersink School of Medicine, Birmingham, AL.*

Background: Sepsis-associated acute kidney injury (SA-AKI) is a heterogenous syndrome inflicted by the sepsis inflammatory cascade and phenotype-specific mechanisms. Viral priming followed by bacterial sepsis causes exaggerated inflammation and is associated with higher mortality than bacterial sepsis alone. We generated a novel murine SA-AKI model that recapitulates the viral primed bacterial sepsis phenotype using polyinosinic-polycytidylic (poly(IC)) acid, a synthetic viral double-stranded DNA analog, followed by low-dose lipopolysaccharide (LPS).

Methods: Using 8-week-old male C57BL/6J mice, we induced viral priming at 0h via poly(IC) intraperitoneal (IP) injection (10 mg/kg) vs. saline control. At 24h post-poly(IC), we administered low-dose LPS (0.5 mg/kg via) by IP injection vs. PBS control. We measured glomerular filtration rate (GFR) at 28h via FITC-sinistrin and sacrificed mice at 32h for collection of blood and urine. Analysis employed 2-way ANOVA; $p<0.05$ deemed significant.

Results: GFR was significantly reduced by 28h in poly(IC)+LPS (IC:LPS, 12.9± 8.0 uL/min) mice compared to poly(IC)+PBS (IC, 223.3± 7.9 uL/min, $p<0.001$), saline+LPS (LPS, 117.4±31.4 uL/min, $p=0.014$) or control (Veh, 221.3±35.8 ml/min, $p<0.001$) mice. This corresponded to increased serum creatinine in IC:LPS mice at 32h compared to normal creatinine in other cohorts. At 32h, IC:LPS mice had significantly increased IL6 along with leukopenia and thrombocytopenia compared to LPS or Veh mice. Urine kidney injury molecule-1 was elevated in IC:LPS mice, but not in IC mice.

Conclusions: We generated a novel murine model to study mechanisms of viral primed SA-AKI. Poly(IC) alone does not cause kidney injury. Poly(IC)+LPS leads to early and significant kidney injury despite low dose LPS that has modest reduction in GFR with no changes in creatinine. Viral priming imparts a synergistic injurious response and warrants further investigation.



SA-PO093

The Initiating Effect of Acute-Phase Serum Amyloid A (A-SAA) on AKI

Dier Li, Haiyan Fu. *State Key Laboratory of Organ Failure Research, National Clinical Research Center of Kidney Disease, Renal Division, Nanfang Hospital, Southern Medical University, Guangzhou, China.*

Background: Acute kidney injury (AKI) is a common and rapidly progressing condition lacking effective therapies. Understanding key molecular events during AKI initiation and progression is crucial. This project aims to identify factors that trigger AKI. Integrating biological experiments, bioinformatics, and mathematical modeling, we identified acute-phase serum amyloid A (A-SAA) as a key initiating molecule.

Methods: We constructed ischemia/reperfusion injury (IRI)-induced AKI model in mice and analyzed renal tissue proteome changes at various post-surgery time points using mass spectrometry. Bioinformatics and mathematical modeling identified AKI initiating factors. A-SAA knockout mice were used to create IRI- or cisplatin-induced AKI models. We assessed kidney injury severity through histological, immunological, and molecular biology techniques. In vitro, hypoxia/reoxygenation-induced and cisplatin-induced models were used to study A-SAA's mechanisms. Primary cells and cell lines were used to examine A-SAA's function and tubule-macrophage interactions. A recombinant protein vaccine against A-SAA was designed and tested in mice for therapeutic potential. Additionally, serum A-SAA levels were measured in patients undergoing cardiac surgery to assess its predictive value for AKI.

Results: A-SAA levels surged in serum and kidney tissue within 4 hours post-IRI. Initially expressed in tubule epithelial cells, A-SAA later appeared in various kidney cells. Proteomic data analysis using the Hopfield model highlighted A-SAA as a critical AKI driver, significantly influencing other protein expressions. A-SAA knockout reduced IRI- or cisplatin-induced AKI in male mice, evidenced by decreased tubule cell injury and inflammation. Mechanistically, A-SAA bound to CD36 and TLR4, aggravating cell injury, apoptosis, and inflammatory response, creating a harmful inflammatory microenvironment. A-SAA also recruited and activated macrophages, further worsening the microenvironment. The A-SAA vaccine induced antibodies in mice and showed reno-protective effects against AKI. Serum A-SAA levels in cardiac surgery patients correlated with AKI severity.

Conclusions: A-SAA is a critical driver in early AKI stages. By binding CD36 and TLR4, A-SAA damages tubule cells and recruits activated macrophages, creating a detrimental inflammatory microenvironment that exacerbates AKI. Targeting A-SAA could mitigate kidney injury and serve as an early AKI warning signal.

HDAC1 Modulates Cell Cycle and Proliferation of Myofibroblasts in the Kidneys

Huy Nguyen, Kelly A. Hyndman, Luciano D. Mendoza. *The University of Alabama at Birmingham Division of Nephrology, Birmingham, AL.*

Background: Ischemia-reperfusion injury (IRI) can cause acute kidney injury (AKI) leading to renal interstitial fibrosis. Histone deacetylase 1 (HDAC1), a regulator of transcription, is implicated in mediating renal injury and fibrosis post-IRI. Understanding its role post-IRI may lead to novel therapeutic approaches for improving health outcomes. We hypothesized that fibroblast HDAC1 activation after IRI leads to fibrosis by promoting cell cycle progression and proliferation of myofibroblasts.

Methods: Male, floxed HDAC1 (control), and floxed HDAC1 mice with hemizygous Col1A2-CreER (iFibHDAC1KO mice, littermates) received tamoxifen i.p. in adulthood and this resulted in fibroblast HDAC1 knockdown in Cre+ mice. Mice underwent 18-min kidney bilateral IRI or sham surgery. AKI was confirmed 24 h post-surgery by serum creatinine levels and glomerular filtration rate (GFR). Interstitial fibrosis was evaluated after four weeks of recovery using picrosirius red. Normal rat kidney fibroblasts (NRK49F) were transfected with empty vector control or HDAC1 and cell cycle was determined by flow cytometry. Cells were also treated for 24 h with 2 ng/ml TGFβ1 to induce myofibroblast transition. Cells were collected for bulk RNA-seq to assess gene expression profiles.

Results: All IRI mice experienced a 50% reduction in GFR 24 h post-surgery compared to shams. iFibHDAC1KO IRI mice had significantly lower renal fibrosis compared to control IRI mice (0.47 ± 0.1% vs/ 1.16±0.2, p = 0.0011, n=5-7). HDAC1 overexpression in NRK49F cells led to a shift in the cell cycle with greater percentage of cells in the S (11 ± 0.2 vs 4 ±0.2, p< 0.001, n=3) and G2 phases (19 ± 0.4 vs 7 ± 0.1, p< 0.001). These cells also had increased expression of 44 cell cycle, and 65 proliferation related genes compared to control cells (adjusted P < 0.05). Although TGFβ1 treatment for 24 h didn't lead to a further shift in cell cycle, there were 2 additional cell cycle and 7 proliferation-related genes increased. HDAC1 overexpression lead to the cyclin gene *Ccna2* and proliferation marker *Mki67* upregulation in both conditions.

Conclusions: HDAC1 may be profibrotic through shifting the cell cycle and increasing fibroblast/myofibroblast proliferation. Targeting HDAC1-mediated pathways could offer a therapeutic solution for mitigating renal fibrosis progression.

Mechanisms of Injury and Protection in Ischemic AKI

Jillian R. Campbell,[1] Jesus H. Dominguez,[2] Meagan R. Troyer,[2] Katherine J. Kelly.[2,1] *[1]Richard L Roudebush VA Medical Center, Indianapolis, IN; [2]Indiana University School of Medicine, Indianapolis, IN.*

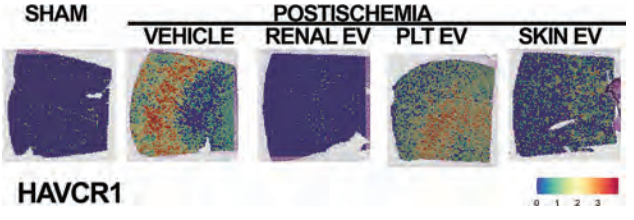
Background: AKI is frequent and deadly. Effective therapy is an unmet need. In experimental ischemia, we have shown rapid improvement in renal function and structure after therapy with extracellular vesicles (EV, exosomes) derived from kidney, when given 24 hours postischemia. We hypothesized that EV from platelets, a rich and readily available source, or from skin epithelia would be beneficial. Our hypothesis was not true, but the difference between therapeutic and ineffective EV allows exploration of injury/protection mechanisms in an unbiased manner.

Methods: Using an established model of ischemia/reperfusion, mechanism was examined using spatial transcriptomics.

Results: As in previous studies, serum creatinine and histological evidence of injury were improved within 24 hours of delivery of EV from tubular cells. Renal EV improved multiple pathways of injury with ~68% of transcripts altered postischemia improved with renal EV, including known markers of injury, such as HAVCR1 (KIM1, figure). Spatial analyses showed multiple alterations in all tubular segments, leukocytes, endothelia, glomeruli and regions of the kidney. Multiple pathways of immune and oxidant-mediated injury, including neutrophil extracellular trap formation and complement, were significantly altered with ischemia and improved with renal, but not platelet or skin, EV. In addition, only renal EV corrected alterations in mRNA involved in the programatic steps of peptide synthesis, cellular senescence and renal cytochrome p450. The latter is relevant because, as in liver, renal cytochrome enzymes may serve to preserve endothelial function and renal perfusion following ischemia.

Conclusions: The specific restoration by renal EV is consistent with the hypothesis that renal EV upload new sets of renal molecular instructions that reset the injured kidney towards rapid restoration of function and structure.

Funding: NIDDK Support, Veterans Affairs Support



Spatial distribution of KIM1 in postischemic kidneys. Expression levels of HAVCR1 (KIM1) overlaid upon hematoxylin and eosin stained sections are presented. Significantly less expression is seen with renal extracellular vesicle (EV, exosome) treatment as compared to EV from platelets (plt) or skin.

Inhibition of PTP1b via Milk Exosome-Mediated Small Interfering RNA (siRNA) Delivery Is a Novel Therapeutic Approach for AKI

Myung-Gyu Kim, Yookyung Jang, Young Eun Choi, Ko Yoon Sook, Lee Hee Young, Sewon Oh, Sang-Kyung Jo. *Korea University Anam Hospital, Seoul, Republic of Korea.*

Background: Protein tyrosine phosphatase-1B (PTP1b) plays a crucial role in regulating insulin, leptin sensitivity, and inflammatory responses, rendering it a promising therapeutic target for diseases like diabetes, obesity, and neuroinflammation. Despite its well-established significance in various conditions, its involvement in kidney disease remains largely unexplored.

Methods: In this study, we developed an innovative siRNA delivery system using exosomes derived from milk to encapsulate PTP1b siRNA (PTP1b siR@mExo), with the aim of investigating its impact on acute kidney injury (AKI). C57BL/6 mice were subjected to bilateral ischemia reperfusion injury (IRI), and PTP1b siR@mExo was pretreated at -6, -4, and -2 hrs.

Results: In vitro studies demonstrated better cellular uptake of Cy3-labeled PTP1b siR@mExo by human proximal tubule cells (HK2) with superior stability compared to treatment with PTP1b siRNA alone. Moreover, in mice, PTP1b siR@mExo exhibited highly efficient kidney delivery, reaching maximum absorption at 2 hours, sustaining elevated levels up to 48 hours, followed by accumulation in the liver and spleen, indicating milk exosomes as a novel siRNA delivery system. PTP1b expression was notably observed on tubules and glomeruli, and pre-treatment with PTP1b siR@mExo in IRI effectively reduced PTP1b levels in the kidney. This reduction was accompanied by decreased expression of inflammatory cytokines (TNF-α, IL-6, IL-1β), alleviated endoplasmic reticulum stress (CHOP), diminished DMAP signal (HMGB1), and a significant improvement in renal function.

Conclusions: In conclusion, our study demonstrated that milk-derived exosomes, with superior structural stability, serve as efficient carriers for siRNA, and showed the efficacy of milk-derived exosomes carrying PTP1b siRNA in treating IRI. The inhibition of PTP1b emerges a promising novel therapeutic target for AKI, providing valuable avenues for further exploration and intervention strategies in kidney disease.

Circulating Extracellular Vesicles Exert Age-Dependent Immunomodulation in Acute Hypoxic Kidney Tubular Injury

Chia-Te Liao, Dora Livkisa, Tsung Lin Lee, David J. Lundy. *Taipei Medical University, Taipei, Taiwan.*

Background: Aging and paracrine secreted factors would affect systemic immune responses, and circulating extracellular vesicles (EVs) potentially play a role in these processes. This study aims to investigate the interaction of plasma EVs and bone marrow-derived macrophages (BMDMs) isolated from young and aged mice in the context of acute hypoxic renal tubular injury.

Methods: Plasma EVs from young (Y_EV) and aged (O_EV) C57BL/6 mice were first isolated by precipitation, then characterized by nanoparticle tracking analysis. EV miRNA were extracted and profiled, then miRNA targets were predicted using ingenuity pathway analysis. EVs stimulated BMDMs from young (Y_BMDM) and aged (O_BMDM) mice, both in naïve conditions and following hypoxic renal tubular injury. Macrophage M1/M2-related secretomes were assessed by quantitative PCR for comparison.

Results: Our results revealed distinct differences in the immunomodulatory effects of Y_EVs and O_EVs, and the corresponding responses of Y_BMDMs and O_BMDMs. Y_EVs tended to induce less pro-inflammatory cytokines, whereas O_EVs had a more varied impact, inciting both pro- and anti-inflammatory responses. However, neither EV population induced a distinct 'M1' or 'M2' phenotype. Notably, plasma EVs and whole plasma induced very different responses in BMDMs; plasma from aged mice was profoundly pro-inflammatory, whereas O_EVs were not. We further characterized and compared Y_EV and O_EV miRNA cargo, surprisingly finding only a very limited difference. In the context of hypoxic renal injury, Y_EVs suppressed inflammatory cytokine expression, but O_EVs were able to induce higher anti-inflammatory cytokine expression. However, both Y_EVs and O_EVs did not directly affect the degree of protection offered by macrophage secretomes following hypoxic renal tubular injury (Figure).

Conclusions: This study showed some age-related differences in the effects of EVs on macrophage function. In hypoxic renal injury, young EVs were able to reduce macrophage pro-inflammatory gene expression and increase anti-inflammatory gene expression. Further *in vivo* studies are warranted to decipher the exact role of circulating EVs in kidney diseases.

Nuclear-Localized Complement Factor B (CFB) Is a DNA-Binding Enzyme Regulating Histone Degradation

Md Tajmul,[1] Tilo Freiwald,[2,4] Jorge L. Trujillo-Ochoa,[1] Daniel Chauss,[1] Dhaneshwar Kumar,[1] Baktiar O. Karim,[3] Maja Gunkel,[2,4] Yubing Guo,[2,4] Julius F. Jäger,[2,4] Claudia Kemper,[5] Tobias B. Huber,[2,4] Thorsten Wiech,[6] Martin Kolev,[7] Scott D. Briggs,[8] Majid Kazemian,[8] Didier Portilla,[9] Behdad Afzali.[1] *[1]Immunoregulation Section, Kidney Diseases Branch, National Institute of Diabetes and Digestive and Kidney Diseases, NIH, Bethesda, MD; [2]Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [3]Leidos Inc, Reston, VA; [4]Hamburg Center for Kidney Health (HCKH), University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [5]Complement and Inflammation Research Section, National Heart Lung and Blood Institute, NIH, Bethesda, MD; [6]Institute of Pathology, Section for Renal Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [7]Apellis Pharmaceuticals Inc, Waltham, MA; [8]Department of Biochemistry, Purdue University, West Lafayette, IN; [9]Division of Nephrology and Center for Immunity, Inflammation, and Regenerative Medicine, University of Virginia, Charlottesville, VA.*

Background: The complement (C') system is essential for innate immunity and pivotal to lytic pathogen destruction, recognition of danger signals, and orchestration of inflammatory responses. Although traditionally viewed as an extracellular, serum-based defense mechanism, recent insights have revealed critically important intracellular functions of C' components, suggesting roles beyond classical immune responses. Despite extensive studies on circulating factor B (CFB), its intracellular functions remain under-explored. We have observed inducible CFB expression in injured kidney epithelial cells, leading us to hypothesize that intracellular CFB also regulates cellular processes.

Methods: We studied mouse proximal tubular epithelial cells using primary cells, TKPTS cell lines, confocal imaging, a small molecule CFB inhibitor, CUT&Tag, electrophoretic mobility shift assay (EMSA), computational predictions with AlphaFold2 and GraphSite and protein assays with wild-type and mutated CFB.

Results: Confocal microscopy revealed significant nuclear accumulation of CFB in kidney epithelial cells. To explore potential DNA-binding by CFB, we employed CUT&Tag, identifying a consensus motif enriched at CFB binding sites within the genome. EMSA confirmed the binding of CFB to this motif, with a Kd of 0.71uM, indicating a meaningful interaction. *In silico* modeling suggested a DNA-binding pocket with 11 DNA-contacting residues, supported *in vitro* with CFB mutants showing reduced DNA binding. Considering the serine protease activity of CFB, we proposed that CFB targets and degrades DNA-associated proteins, such as histones, within its vicinity. *In vitro* experiments, including those with a CFB inhibitor, confirmed this hypothesis, showing the ability of CFB to degrade nucleosomal histones. Ongoing experiments aim to map specific histone cleavage sites to guide future functional studies

Conclusions: These findings expand understanding of intracellular C' functions and highlight a potential role for CFB in modulating transcriptional outcomes, with potential implications for therapeutic strategies targeting CFB in the intracellular or extracellular space in patients.

Examining the Anti-inflammatory and Renoprotective Effects Resulting from Parasympathetic Nerve Stimulation after Inflammation

Sayumi Matsuo, Chia-Hsien Wu, Yasuna Nakamura, Norito Washimine, Ryusuke Umene, Tomoya Nishino, Tsuyoshi Inoue. *Nagasaki Daigaku Daigakuin Ishiyakugaku Sogo Kenkyuka, Nagasaki, Japan.*

Background: Recent reports have indicated that pre-injury stimulation of the parasympathetic nervous system, activating the cholinergic anti-inflammatory pathway (CAP), yields anti-inflammatory and renoprotective effects. However, it is unclear whether similar effects can be achieved with post-injury stimulation of the parasympathetic nervous system. This study aims to confirm whether post-inflammatory stimulation of the parasympathetic nervous system can indeed lead to anti-inflammatory and renoprotective effects, as well as to elucidate the underlying mechanisms.

Methods: The animal model employed in this study involved inducing acute kidney injury/sepsis using lipopolysaccharide (LPS). Due to concerns about the highly invasive nature of direct vagus nerve stimulation, we chose to activate the parasympathetic nervous system by administering 3-(2,4-Dimethoxybenzylidene)-anabaseine dihydrochloride (GTS-21), a selective α7 nicotinic acetylcholine receptor agonist. After inducing inflammation in wild-type C57BL/6 mice by administering LPS, we subsequently administered GTS-21 to evaluate its anti-inflammatory and renal protective effects. Furthermore, we induced inflammation in RAW 264 (mouse macrophages) and U937 (human macrophages) using LPS, followed by parasympathetic nerve stimulation, to evaluate their anti-inflammatory effects similarly. Furthermore, we conducted RNA-seq analyses on each cell type to elucidate the underlying molecular mechanisms.

Results: We confirmed that administering the selective α7 nicotinic acetylcholine receptor agonist, GTS-21, in the mouse model of acute kidney injury/sepsis induced by LPS, resulted in anti-inflammatory and renal protective effects. Moreover, based on the findings from RNA-Seq analysis, we elucidated that the expression of CCL2, a chemokine, in splenic macrophages is involved in mediating these effects.

Conclusions: Even after inflammation induction, stimulation of the parasympathetic nervous system yielded anti-inflammatory and renoprotective effects. This discovery holds significant promise for the development of novel treatments for sepsis and AKI.

Inhibition of Plk1 Attenuates Cisplatin-Induced AKI via Upregulation of PERK/P-eIF2α Pathway

Yang Du, Xiuli Lin, Yaqiong Shang, Shuang Chen, Yan Guo, Weidong Cao, Zhanjun Jia, Yue Zhang. *Nanjing Medical University, Nanjing, China.*

Background: Acute kidney injury(AKI) is a common and serious clinical complication and lacks effective treatment except renal replacement therapy. PLK1 is an important cell cycle regulator with no study reported in AKI. In current study, we investigated the effect of Plk1 inhibition by BI6727 or knock down of Plk1 by siRNA in cisplatin induced AKI in mice or in cultured renal tubular epithelial cells.

Methods: AKI was induced in C57BL/6J mice by administration of cisplatin at dose of 25mg/kg(i.p.). Plk1 inhibitor BI6727 (7.5mg/kg) was given 6hrs prior to cisplatin injection. All Mice were executed 72hrs after cisplatin injection. Mice blood and kidney tissues were collected for histology or protein anaylsis. Renal proximal tubular epithelial cell line TKPT was pretreated with BI6727 or transfected with Plk1-shRNA, then cisplatin was added for 24hrs and cells were collected for apoptosis detection by flow cytometry.

Results: In BI6727 treated mice, increased serum creatinine caused by cisplatin was reduced by 65%. PAS staining showed tubular injury score was about 47% less. Protein expression of Kim1 and NGAL were reduced by 56% and 81%. mRNA of TNF-α and IL-6 were reduced by 85% and 77%. Tunnel staining showed about 46.1% less apoptotic cells. In cultured TKPT cells, BI6727 treatment reduced the apoptotic cells by 58% and knock-down of Plk1 reduced the apoptotic cells by 46.8% compared to cisplatin treated cells. Further, we found BI6727 upregulated PERK/P-eIF2α pathway, which is the central mechanism of the integrated stress response(ISR). Under conditions of stress, activation of the ISR inhibits protein translation and preserves energy for essential functions to support cell survival.

Conclusions: Inhibition of Plk1 by BI6727 protects against cisplatin-induced acute kidney injury. This effect is mediated by upregulation of PERK/P-eIF2α pathway. Our research suggests a pathogenic role of Plk1 in promoting AKI. Plk1 may be a potential target for AKI treatment.

PDZD8, a Tethering Protein of Endoplasmic Reticulum (ER)-Lysosome Interaction, Alters Tubular Inflammation in Mice with Cisplatin-Induced AKI

Yuto Takenaka,[1] Sho Hasegawa,[1] Yu Ah Hong,[1] Qi Li,[1] Hiroshi Maekawa,[2] Masaomi Nangaku,[1] Reiko Inagi.[1] *[1]Tokyo Daigaku Daigakuin Igakukei Kenkyuka Igakubu Seirigaku, Bunkyo-ku, Japan; [2]Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: The pathophysiological importance of organelle crosstalk in maintaining cellular homeostasis is a prominent trend. PDZD8, a tethering protein located on the ER lumen, facilitates interactions with other organelles and promotes homeostasis at organelle contact sites. We thus aim to elucidate the role of organelle crosstalk, specifically through PDZD8, in the context of AKI.

Methods: In vivo studies: 8-10 week-old male PDZD8 knockout (KO) and wild-type (WT) mice were administered 20mg/kg cisplatin and euthanized 48 hr later. Kidney injury was assessed by BUN, Cre, PAS, IHC for inflammatory molecules and RT-PCR. In vitro studies: human proximal tubular cell line (HK-2) was treated with 20mM cisplatin and assessed changes in organelle homeostasis and their effect on inflammatory response (TLR9-NFkB axis) using mass spectrometry-based immuno-precipitation proteomics and immunofluorescence microscopy for organelle function.

Results: PDZD8 KO mice improved cisplatin-induced kidney injury compared to WT mice, as indicated by lower BUN and Cre levels and less severe tubular damage. This was accompanied by a diminished activation of the NFkB inflammatory pathway and decreased NFkB-downstream inflammatory gene expression (IL6, CXCL10). In vitro studies revealed that cisplatin-induced inflammation was also reduced in PDZD8-knockdown (KD) HK-2 cells, while cisplatin damage, estimated by mitochondrial DNA leakage, was identical between WT and KD cells. Interestingly, such PDZD8-mediated tubular inflammatory signal was closely correlated with the TLR9 activation level: 1) cisplatin-exposed HK-2 cells induced the intracellular translocation of TLR9 (to the lysosome), which activates NFkB inflammatory signaling, 2) PDZD8-KD significantly impaired the TLR9 translocation/activation, leading to the reduction of NFkB-mediated tubular inflammation. Further, PDZD8-KD significantly affected the lysosomal functions, characterized by insufficient lysosomal pH, which hindered TLR9 activation. These findings suggested the critical role of PDZD8-TLR9-NFkB axis as a novel pathway for regulating tubular inflammation.

Conclusions: Tubular PDZD8 regulates TLR9-NFkB inflammatory pathway through its regulation of lysosomal function via ER-lysosome interaction.

SA-PO102

FBF1 Deficiency Protects against Chronic Progression of Cisplatin-Induced AKI

Jielu H. Robichaud,[1] Chuan Chen,[1] Kai He,[1] Xiaobo Sun,[1] Zheng Dong,[2] Jinghua Hu.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Augusta University, Augusta, GA.*

Background: Cisplatin-induced nephrotoxicity exhibits hallmarks of acute kidney injury (AKI), yest its long-term exposure results in chronic kidney disease (CKD). Recent evidence shows that senescence of renal epithelial cells contributes to chronic progression after injury. However, how senescence is initiated in the injured kidneys remains poorly defined.

Methods: C57BL/6 mice were exposed to repeated low-dose cisplatin (RLDC) treatment consisting of 4 weekly injections of 8 mg/kg cisplatin. Mouse proximal tubular (BUMPT) cells were exposed to 4 cycles of 2 μM cisplatin treatment, with 7-hour cisplatin exposure followed by 17-hour cisplatin-free culture medium incubation. The level of cellular senescence was determined by measuring Senescent Associated (SA)-b-Gal staining, and levels of senescence markers as well as inflammatory Senescence-Associated Secretory Phenotype (SASP) markers. *Fbf1* deficiency in mice were established by homozygous *Fbf1*$^{tm1a/tm1a}$ mutant using the ''knockout first strategy''. *FBF1* knockdown BUMPT cell lines were generated by using *shRNA*. Western blotting, confocal imaging were used to determine the expression and subcellular localization of key components. Histological/immunofluorescent stain, serum BUN, and creatinine level were detected to investigate the progression of kidney injury. Immunoprecipitation or chromatin immunoprecipitation assay were performed to analyze protein-protein or protein-DNA interaction.

Results: We discover that RLDC treatment of C57BL/6 mice induced FBF1 upregulation in injured kidney tubules, which develop characteristics of cellular senescence. RLDC prompted FBF1 nuclear translocation to initiate senescence in Cisplatin-exposed BUMPT cells. FBF1 depletion effectively reduce senescent burden of BUMPT cells, reversed the profibrotic phenotype, and increased regenerative capacity following RLDC treatment. Consistently, deficiency of FBF1 *in vivo* suppressed senescence initiation, attenuated renal fibrosis and improved tubular repair. Mechanistically, we discovered that nuclear-translocated FBF1 triggered the recruitment of transcriptional factor HNF-1β to promyelocytic leukemia nuclear bodies (PML-NBs) to regulate senescence responses in damaged cells.

Conclusions: Suppression of the FBF1 pathway ameliorates adverse senescence-associated impacts and prevents AKI-CKD transition in cisplatin-treated kidneys.

Secretory Leukocyte Protease Inhibitor as an Early Protective Protein and Potential Biomarker in Ischemia-Reperfusion-Induced AKI

Fei Chen,[1,3] Yuanyuan Wu,[3] Bin Yang.[1,2] *[1]Affiliated Hospital of Nantong University, Nantong, China; [2]University of Leicester, Leicester, United Kingdom; [3]Nantong University School of Medicine, Nantong, China.*

Background: Ischemia reperfusion (IR) injury is one of main causes of acute kidney injury (AKI) that is a common syndrome characterized by a sudden decline of renal function and lacking early diagnosis and effective intervention. Secretory leukocyte protease inhibitor (SLPI) is an acute response protein that is associated with IR-induced AKI and repair, but its dynamic change, exact roles and underlying mechanisms remain unknown.

Methods: C57BL/6 mice was used to establish a time-course model of IR-AKI. Bilateral kidney pedicles were clamped for 30 minutes (min) followed by reperfusion for 6 hours (h) to 4 weeks (w), the expression and localization of SLPI were monitored. *In vitro*, a mouse kidney epithelial cell line TCMK-1 was treated with hydrogen peroxide (H_2O_2) to mimic IR injury. The effects of erythropoietin-derived helix B surface peptide (HBSP) or targeted siRNA on SLPI expression were further observed. The downstream cellular apoptosis and injury markers, as well as the phagocytic ability of TCMK-1 cells through uptaking fluorescent-labeled *E. Coli* were then assessed.

Results: The increase of serum SLPI in IR group mice was at 12 h earlier than that of serum creatinine. The renal expression of SLPI was also up-regulated as early as 12 h post IR injury, as well as in TCMK-1 cells, prior to the changes of inflammation and apoptosis related indicators. SLPI was mainly located in tubular epithelial cells of IR kidney. HBSP significantly increased SLPI expression in a dose-dependent manner. Moreover, SLPI siRNA further increased cellular apoptosis, cleaved-caspase3, HMGB1, IL-6 and TNF-α in TCMK-1 cells treated with H_2O_2, but inhibited the phagocytosis of TCMK-1 cells.

Conclusions: SLPI was increased early upon IR-induced kidney injury, acting as a protective factor to regulate apoptosis, inflammation and phagocytosis. The up-regulation of SLPI may be one of the mechanisms that HBSP protects IR-AKI. In summary, SLPI not only serves as a potential biomarker, but also a protector against AKI.

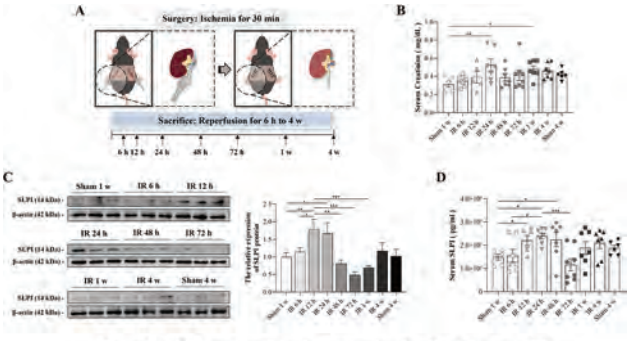

Figure 1. SLPI was significantly up-regulated at 12 h after renal IR.

MG53 in Kidney Injury and Fibrosis

Min Zhang, Zhongguang Li, Pu Duann, Haichang Li, Sethu M. Madhavan, Brad H. Rovin, Pei-Hui Lin. Lin Lab. *The Ohio State University, Columbus, OH.*

Background: MG53 (TRIM72) is a muscle-predominant protein and functions as a circulating myokine that appears to confer tissue protection during ischemia-reperfusion (I/R) acute kidney injury and UUO-mediated kidney fibrosis. We discovered the functional duality of MG53 in kidney protection serving as a membrane repair protein and modulating the immune response during kidney inflammation. To further identify whether elevated level of either circulating MG53 or kidney proximal tubule-specific MG53 over-expression impact on kidney injury and fibrosis, we generated transgenic ctPA-MG53 mouse strain for conditional circulation and kidney MG53 over-expression to facilitate studying the role of MG53 in kidney disease and its impact on AKI-to-CKD transition.

Methods: We generated mouse strain "TRE-STOP^{flox}-tPA-MG53" ("ctPA-MG53") as conditional MG53 over-expression in kidney PTE cells and circulation. This mouse strain was bred to PEPCKcre (kidney PTE expression) mice. We examined and confirmed the doxycycline (DOX) induction of the ctPA-MG53 of kidney overexpression. We characterized these mouse strains – Control: "X/Y, ctPA-MG53" and the conditional overexpression "PEPCKcre/Y, ctPAMG53" on a DOX time-dependent MG53 expression. We established a kidney bilateral (bIRI) mouse model to study AKI-to-CKD transition. Additionally, using Lenti-viral gene transduction system, we successfully engineered in human PTE HKC8 cells with scramble knockdown, MG53 knockdown and MG53 overexpressing HKC8 cells as an *in vitro* system to study the cellular mechanisms.

Results: The transgenic "PEPCKcre/Y, ctPAMG53" mice follow a DOX-dependent and PTE specific MG53 induction. One week of DOX will induce a greater than 20-fold increase in kidney MG53 (protein) levels in proximal tubule cells and simultaneously high level of circulating MG53. Initial characterization of tissue expression of MG53 indicated an elevation in liver as well. We also did initial kidney functional characterization on these transgenic mice on DOX time-dependent induction. We subjected engineered HKC8 cells to various oxidative stress inducers and showed that MG53 over-expression confers better cell survival upon ROS stimulation.

Conclusions: We have established an *in vivo* animal system to study the impact of MG53 in AKI-to-CKD progression. We also established an *in vitro* system to investigate MG53 in ROS protection and its cellular mechanism.

Inflammatory Pathway in Crystalline Nephropathy: Modulation by Uromodulin and Its Potential Renoprotective Role

Larissa de Araujo,[1,2] Tarek M. El-Achkar,[2] Maria Oliveira-Souza.[1]
[1]Universidade de Sao Paulo Instituto de Ciencias Biomedicas, Sao Paulo, Brazil; [2]Indiana University School of Medicine, Indianapolis, IN.

Background: Uromodulin (UMOD) plays a crucial immunomodulatory role in the kidney. We hypothesize that this function is impaired in acute kidney injury (AKI) caused by crystalline nephropathy and that exogenous administration of UMOD may offer a renoprotective effect in this condition.

Methods: 8-week-old C57BL/6J mice were randomly allocated into four groups: 1. Control (saline 0.9%,i.p); 2. UMOD (exogenous UMOD–5µg/animal, single injection i.p); 3. NaOx (sodium oxalate–9mg/100g of body weight, single injection i.p); 4. NaOx administration and UMOD treatment. The animals were placed in metabolic cages for 24 hours before euthanasia and organ harvest. The results presented as mean ± S.D. were analyzed by two-way ANOVA and a Bonferroni post hoc test using GraphPad Prism software. p<0.05 was considered statistically significant.

Results: Crystal-positive medullary and cortical areas were increased in NaOx group. Co-treatment with exogenous UMOD prevented medullary crystal formation [NaOx+UMOD:1.3±0.8vsNaOx:5.0±1.6,p=<0.0001. Interaction p=<0.0001], but not cortical. Protein-positive medullary and cortical areas were increased in NaOx group. The co-treatment with exogenous UMOD prevented these changes [Medullary=NaOx+UMOD:2.0±2.2 vs NaOx:17.1±17.5,p=0.0250. Interaction p=0.0554/ Cortical =NaOx+UMOD:0.8±0.4 vs NaOx:2.7±2.2,p=0.0397. Interaction p=0.0717]. Treatment with NaOx significantly increased mRNA expression for KIM-1, NGAL, Ki67, MCP-1, TNFα, IL-1β, IL-6, CXCL1, and CXCL10, consistent with kidney injury. The mRNA expression for CCL19 significantly decreased in NaOx group. Co-treatment with exogenous UMOD prevented these changes (Fold change from control for NaOx+UMOD vs. NaOx, respectively):KIM-1 [95.2±121.7 vs. 730.0±182.5,p=<0.0001. Interaction p=0.0001],NGAL [2.5±2.1 vs. 86.4±19.3,p=<0.0001. Interaction p=0.0001],Ki67[2.0±1.0 vs. 5.7±1.7,p=0.0001. Interaction p=0.0006],MCP-1[1.9±1.8 vs. 8.2±3.8,p=0.0008. Interaction p=0.0030],TNFα[1.3±0.7 vs. 4.0±2.2, p=0.0087. Interaction p=0.0216],IL-6[5.4±7.5 vs. 84.4±46.2,p=0.0002. Interaction p=0.0010], CXCL1[8.4±15.9 vs. 1.2±0.4,p=0.0001. Interaction p= 0.0003],CXCL10[1.0±0.5 vs. 6.5±3.2,p=0.0005. Interaction p= 0.0030],CCL19[1.0±0.4 vs.0.1±0.1,p= 0.0066. Interaction p=0.0014].

Conclusions: The exogenous UMOD may have a renoprotective effect on nephropathy crystalline-induced AKI by modulating kidney inflammation.

Funding: Government Support - Non-U.S.

SA-PO106

The Tubular Epithelial Role of SMOC2 in Aristolochic Acid Nephropathy

Peng Gao,[1,2] Jonatan Barrera-Chimal,[2] Nathalie Henley,[2] Casimiro Gerarduzzi.[1,2]
[1]Universite de Montreal Departement de Pharmacologie et Physiologie, Montreal, QC, Canada; [2]Hopital Maisonneuve-Rosemont Centre de Recherche, Montreal, QC, Canada.

Background: Acute kidney injury (AKI) is a prevalent clinical condition with a rising incidence, posing an increased risk of chronic kidney disease (CKD) development characterized by interstitial fibrosis. Our lab has previously shown the effects of the matricellular protein SMOC2 on fibroblasts in regard to renal fibrosis present within CKD patients and in vivo kidney models. However, its involvement in tubular epithelial cell injury during AKI and its transition into CKD has not been previously examined.

Methods: Wild-type and SMOC2 knock-out (KO) mice were subjected to aristolochic acid I (AAI) injection to induce nephrotoxic AKI (known as aristolochic acid nephropathy, AAN). To evaluate the underlying mechanism, bulk RNAseq analysis of WT and KO kidneys 3 days after AAI injection was performed. Primary mouse tubular epithelial cells (mTECs) and human proximal tubular epithelial cells (HK-2) were exposed to recombinant SMOC2 (rSMOC2) protein alone or in combination with AAI.

Results: SMOC2 expression was increased in AAI-treated mTECs and renal tubules in AAI-injected mice, which was accompanied with tubular injury. On day 3 after injection, SMOC2 KO kidneys had increased tubular necrosis and histological damage scores compared to WT AAI-injected mice. Bulk RNAseq analysis revealed an increased expression of proliferation-related genes (CCND1 and Mki67) in SMOC2 KO AKI mice. In vitro studies showed that rSMOC2 treatment alone did not affect the proliferation of HK-2 cells; however, when combined with AAI treatment, it induced complete cell cycle arrest.

Conclusions: In contrast to the proliferative role of SMOC2 in fibroblasts during renal fibrosis, we unexpectedly discovered a cell cycle arrest role of SMOC2 on TECs. SMOC2 deficiency accelerates tubular cell proliferation after AKI, which renders them vulnerable to cell death signals. Therefore, SMOC2 may be a novel and important modulator of cellular injury after AKI by assisting in cell cycle arrest, which allows more time for DNA damage to be repaired, thus preventing the proliferation of cells with genotoxic insults and potentially avoiding maladaptive epithelial responses to injury.

Ischemic AKI Modifies Expression of Immune Checkpoint Inhibitor TIGIT Ligands and Co-signaling Partners

Radhika Kapoor, Shishir K. Patel, Qisen Guo, Mahta F. Gooya, Hamid Rabb, Sanjeev Noel. Hamid Rabb's Group. *Johns Hopkins University, Baltimore, MD.*

Background: T cell immunoreceptor with Ig and ITIM domains (TIGIT) increases in kidney T cells following ischemic AKI and participates in the pathogenesis of AKI in mice. To explore how TIGIT mediates AKI, we investigated the effects of ischemic AKI on TIGIT interacting ligands (CD155, CD112, CD113) and co-signaling molecules (CD226, CD96, CD127, PD1)

Methods: C57BL6 mice underwent bilateral ischemia reperfusion (IR) injury. TIGIT ligand/co-signaling molecule expression was initially measured with western blotting at 24h and 18 days post-AKI. Flow cytometry was performed to identify the cell types that express TIGIT ligands and co-signaling partners at baseline and 24h post-IR. TIGIT positive (TIGIT+) and TIGIT negative (TIGIT-) cells were analyzed to examine TIGIT relationship with these molecules

Results: Western blotting showed enhanced expression of CD155 (5.6±0.5 fold; P<0.001) and CD112 (2.4±0.5 fold; P<0.01) 24h after AKI. At 18 days, CD155 expression returned to normal levels however, CD112 remained elevated (2.7-fold). CD113 expression was reduced 24h after AKI (0.7±0.2 fold; P=0.04) with normalization at 18 days. CD155 expression by FACS increased significantly in CD11b+ cells at 24h (26.7±4.7 vs 1.5±0.3% P<0.0001) compared to control. Conversely, TIGIT co-stimulatory counterpart CD226 decreased in CD4 (67.1±19.0 vs 46.0±10.3%; P<0.05), double negative (DN) (92.1±5.1 vs 61.4±10.8%; P<0.001) and NKT (91.2±3.5 vs 71.2±5.9%; P<0.001) cells at 24h. CD96 expression was not affected by IR injury. Analysis of TIGIT+ cells showed significant decrease in CD155 (22.4±19.7 vs 6.8±8.6%, P<0.05) and CD127 (42.6±20.3 vs 10.7±6.5%, P<0.05) in NK cells from post-IR kidneys. TIGIT+ cells expressed PD1 both at baseline and after IR injury in CD4 (52.1±12.6 and 66.7±7.1%), CD8 (76.3±18.2 and 84.1±8.5%) and DN T (42.9±17.7 and 47.4±15.3%) cells. PD1 significantly increased at 24h in TIGIT+ CD4 (66.7±7.1 vs 16.5± 4.6%; P<0.001), CD8 (84.10±8.5 vs 12.3± 6.0%, P<0.01) and DN T cells (47.4±15.4 vs 16.6±7.4%; P<0.01) compared to TIGIT- cells.

Conclusions: Ischemic AKI leads to increased TIGIT ligands CD155 and CD112, and modulates TIGIT co-signaling molecules CD226 and CD127. TIGIT and PD1 are co-expressed by a subset of kidney T cells at baseline and during AKI. TIGIT ligand/ signaling molecule interactions likely underlie TIGIT effects on AKI

Membrane Tumor Necrosis Factor (TNF) Drives Progression to Fibrosis after Kidney Injury via TNFR1 Activation

Charikleia Katsouridi, Andreas Herrlich, Eirini Kefalogianni.
Washington University in St Louis, St Louis, MO.

Background: Global TNF blockade reduces AKI-to-CKD transition, but the underlying mechanisms are unclear. TNF signaling is complex as it involves soluble and membrane-bound forms of TNF (sTNF and mTNF respectively) and of its two receptors, TNFR1 and TNFR2. As a result, TNF controls multiple signaling pathways with overlapping, separate, or even opposite functions. We hypothesized that targeting individual components of TNF signaling would increase our understanding of kidney disease progression and point to more specific targets for therapies.

Methods: We used mouse models of kidney injury and progression to fibrosis, wild-type mice, knockout mice, or mice with TNF or TNFR1 mutations that prevent cleavage and release of their soluble forms, and single-cell/nuclei RNAseq data analysis.

Results: Using pharmacological and genetic approaches, we show that mTNF, rather than sTNF, drives progression to fibrosis after kidney injury. In addition, mice that cannot cleave TNFR1, therefore cannot terminate its signaling, show increased fibrosis after injury. The latter phenotype is also mTNF-dependent. Serum creatinine and BUN levels on day 1 post-injury were not different between groups, suggesting that the observed outcomes are not the result of initial injury susceptibility differences. Kidney accumulation of macrophages, a key TNF-expressing cell type, accompanies mTNF-TNFR1-driven progression to fibrosis. Single-cell/nuclei RNAseq analysis showed that, during the transition to fibrosis, TNFR1 gene signature is enriched in endothelial and tubular cell subpopulations, suggesting that these cells potentially receive the profibrotic mTNF-TNFR1 signals.

Conclusions: Our results identify that the mTNF-TNFR1 signaling axis drives AKI-to-CKD transition and represents a potential target for therapeutic interventions.

Establishment of a New Detection Method for Senescent Cells in Injured Kidneys and Proof of Their Relationship to Failed-Repair Proximal Tubules

Ryo Yamada,[1] Yohei Iwashige,[1] Takuya Morinishi,[1] Koji Muro,[1] Shigenori Yamamoto,[1] Toshio Kitamura,[2] Motoko Yanagita.[1] Cell Cycle & Cellular Senescence Group. *[1]Kyoto Daigaku Daigakuin Igaku Kenkyuka Igakubu, Kyoto, Japan; [2]Foundation of Biomedical Research and Innovation at Kobe, Kobe, Japan.*

Background: Cellular senescence occurs in response to repeated passages, persistent DNA damage, and oxidative stress and is characterized by permanent growth arrest. Recently, accumulation of senescent cells in vivo and their correlation with organ dysfunction has been reported; however, a highly sensitive method to identify senescent cells *in vivo* has not yet been established.

Methods: The cell cycle of the proximal tubular cells was evaluated in mice expressing the proximal tubule-specific G0 marker (*Ndrg1CreER^{T2} $^{/+}$: R26-mVenus-p27K$^{-/+}$*). The G0 marker is mVenus-p27K^{-} and is usually used to identify cells in the quiescent phase (G0 phase). We also performed spatial transcriptomics of G0 marker-positive cells using photo-isolation chemistry (PIC) based system.

Results: Using adult G0 marker mice, almost all proximal tubular cells (PTCs) were stayed at G0 phase under physiological conditions. In the chronic phase of kidney injury models, most PTCs became G0^{+}, but some G0^{+} cells exhibited nuclear abnormalities with Cyclin D1 positivity (G0 double positive cells: G0^{DP} cells). G0^{DP} cells exhibited various features of cellular senescence in tissue. In addition, G0^{DP} cells were included within the VCAM1^{+} failed-repair PTCs (FR-PTCs), which were recently attracted attention for their inflammatory features. After injury, most FR-PTCs were G0^{+} (≥ 90%), and Cyclin D1 positivity rate gradually increased up to 20-30% depending on the injury type. The PIC-based RNA-seq study also revealed that G0^{DP} cells exhibited features not only of FR-PTC but also of cellular senescence compared to G0^{+} cells in the vehicle group and Cyclin D1^{-} G0^{+} cells (G0 single positive cells: G0^{SP} cells) within FR-PTCs. Timelapse imaging of primary PTCs from G0 marker mice, treated with doxorubicin (DOXO), continuously expressed the G0 marker, and their cell cycle was permanently arrested. DOXO-treated primary PTCs further obtained Cyclin D1 positivity with senescent phenotypes.

Conclusions: G0 marker with Cyclin D1 expression can be a useful tool for identifying senescent proximal tubular cells under DNA damage conditions, both *in vivo* and *in vitro*.

Deficiency of Hedgehog Interacting Protein (Hhip) in Endothelial Cells Prevents Kidney Ischemia-Reperfusion-Mediated Renal Tubular Cell Senescence

Yuchao Pang,[1,2] Junzheng Peng,[1] Xin-Ping Zhao,[1] Shiao-Ying Chang,[1] Min-Chun Liao,[1] Alain Rivard,[2] Julie R. Ingelfinger,[3] John S. Chan,[1,2] Shao-Ling Zhang.[1,2] *[1]Centre de Recherche du Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [2]Universite de Montreal, Montreal, QC, Canada; [3]Harvard Medical School, Boston, MA.*

Background: Acute kidney injury (AKI) caused by renal ischemia/reperfusion (R I/R) injury is a major clinical issue lacking viable therapies, and with incompletely delineated underlying mechanisms. Given the important roles of hedgehog interacting protein (Hhip) in glomerular endothelial cells (ECs), we asked whether Hhip knockout (KO) in ECs prevents R I/R-induced kidney injury *in vivo* and *in vitro*.

Methods: Both male Hhip^{EC} KO and control Hhip$^{fl/fl}$ mice at 10-weeks of age were subjected to 45 minutes of unilateral R I/R or sham surgery along with contralateral nephrectomy. The time course of AKI was followed at Days 1, 3 and 7. We also studied naïve renal proximal tubular cells (IRPTCs) exposed to the conditioned media harvested from mouse endothelial cell (mECs) with or without Hhip (siRNA) ± cisplatin (20μM) treatment.

Results: Compared to the respective sham controls, R I/R mice (Hhip^{EC} KO and Hhip$^{fl/fl}$) lost body weight starting from Day 1 to Day 7. In line with the AKI time course, Hhip$^{fl/fl}$-R I/R mice had higher mortality with significant kidney apoptosis documented by IVISense™ Annexin-V 750 fluorescent imaging probe; increased urinary albumin-to-creatinine ratio; and displayed renal dysmorphology (PAS, Masson's trichrome and Sirius red) with enhanced Cystatin C- and kidney injury molecule-1 immunoexpression in their kidneys. Notably, renal tubular cell senescence (SA-β-galactosidase, p21, p16, MCP-1 staining) was significantly increased in Hhip$^{fl/fl}$-R I/R mice. In contrast, those changes were significantly ameliorated in the kidneys of Hhip^{EC} KO -R I/R mice. *In vitro*, naïve IRPTCs exposed to the conditioned media harvested from mECs treated with cisplatin exhibited higher cellular senescent activity with enlargment of nuclear size with both mono- or multi-nuclei and increased cytoskeleton destabilization as evidenced by dysmorphic patterns of α-tubulin and F-actin staining. Those changes were largely prevented in naïve IRPTCs exposed to the conditioned media from Hhip KO mECs treated with cisplatin.

Conclusions: Our data suggest that Hhip KO in ECs prevented or ameliorated AKI-induced renal tubular injury. This potential protection may be mediated, at least in part, by the inhibition of Hhip-mediated tubular cell senescence.

SA-PO111

Glutathione S-transferase Mu-1 (GSTM1) Deficiency Exaggerates Cisplatin Nephrotoxicity

Luojing Chen. *University of Rochester Medical Center, Rochester, NY.*

Background: Cisplatin is the first line chemotherapeutic agent for several cancers. However, its use is limited by significant toxicity, including acute kidney injury (AKI) in up to 30% of patients. Increased reactive oxygen species (ROS) generation plays a key role in cisplatin nephrotoxicity (CN). Glutathione-S-transferase Mu-1 (*GSTM1*) gene encodes GSTM1 enzyme that functions in the detoxification of electrophilic compounds. We previously reported that *Gstm1* knockout (KO) mice have increased oxidative stress and susceptibility to kidney injury in chronic kidney disease (CKD) models, and CKD patients carrying the highly common null variant of *GSTM1* gene are more susceptible to CKD progression. Here, we investigate the effect of GSTM1 in a chronic CN mouse model of AKI and in a human HK2 proximal tubular epithelial cell (PTEC) line model.

Methods: Wild-type (WT) and *Gstm1* KO male mice (12 weeks old) on FVB background were treated with cisplatin (9mg/kg) once per week for 4 weeks via IP injection. HK2 PTEC line deficient in *GSTM1* was used to generate a stable *GSTM1* overexpressing cell line (HK2-Tg). Cells were treated with cisplatin (60uM) for 24 hrs. Intracellular ROS was measured using ROS Assay Kit, and mitochondrial superoxide was measured by MitoSox. The color intensity of the images (three random fields of each image) was quantitated with Image J. Live cell numbers were counted with Trypan blue.

Results: After 4 weeks cisplatin treatment, *Gstm1* KO mice had a significant increase in serum creatinine measured by mass spec (0.13±0.157mg/ml), compared to WT mice (0.06±0.006 mg/ml) (n = 6 each, p=0.0043). There was a trend toward increase in BUN level (22.16 vs 14.77, p=0.309) in KO mice. Compared to HK2-Tg cells expressing *GSTM1*, HK2 cells deficient in *GSTM1* displayed fewer % of live cells: HK2 39±2.95 vs HK2-Tg 54±2.37; p=0.003. Compared to vehicle, cisplatin treatment resulted in a higher fold of intracellular ROS production in HK2 compared to HK2-Tg PTECs (6.6 vs 3.9; p=0.03). Similarly, HK2 PTECs showed a larger fold increase in mitochondrial ROS level compared to HK2-Tg PTECs (23.5 vs 17.6; p=0.01).

Conclusions: GSTM1 deficiency increases susceptibility to CN, which can be attributable to increased intracellular and mitochondrial ROS generation. Understanding how GSTM1 regulates ROS signaling pathway may lead to a novel therapeutic target in CN.

Depletion of Salvage NAD+ Biosynthesis Exerts Opposing Effects in Inflamed Proximal Tubule vs. Microvascular Endothelium

Valerie Etzrodt, Liping Chen, Amanda J. Clark, Kyle Q. Vu, Marie Christelle Saade, Samir M. Parikh. *The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Nicotinamide phosphoribosyl transferase (NAMPT) is the rate-limiting enzyme of the nicotinamide adenine dinucleotide (NAD+) synthesizing salvage pathway. NAMPT's roles in the kidney, particularly in proximal tubule cells and adjacent microvascular endothelial cells, are of significant interest due to their vital functions in maintaining renal homeostasis. We hypothesized that NAMPT enzymatic function is necessary for renal tubular resilience to injury whereas its effects in the endothelium may be dispensable given the low metabolic activity of the latter.

Methods: In vivo disease models: LPS 17.5 mg/kgBW; in vitro models: human proximal tubule kidney cells (HK2), human umbilical vein EC (HUVECs), transendothelial electrical resistance, NAD(H) biochemical assessments.

Results: In a murine model of systemic inflammation, total kidney NAMPT was upregulated. This effect appeared to localize to ECs. HUVECs treated with inflammatory stimuli confirmed dose-dependent induction of NAMPT expression along with canonical markers of vascular inflammation such as intercellular adhesion molecular 1 (ICAM-1). In contrast, HK2 cells exhibited no induction of NAMPT following exposure to inflammatory stimuli. As expected, knockdown or pharmacological inhibition of NAMPT in HK2 cells depleted intracellular NAD+ and exacerbated the expression of kidney injury markers following inflammation. In contrast, knockdown or pharmacological inhibition of NAMPT in inflamed HUVECs significantly attenuated expression of ICAM-1. Interestingly, reintroduction of β-nicotinamide mononucleotide, in NAMPT deficient HUVECs abrogated the anti-inflammatory effect.

Conclusions: Kidney endothelial NAMPT may be markedly induced during systemic inflammation. Whereas NAMPT's major role in the renal tubule may be promote NAD+ homeostasis, NAMPT in the endothelium may be a potent regulator of vascular inflammation. Future studies have to clarify how NAMPT can be cell-specifically targeted in acute inflammation.

PDK4/SMAD3/HIF-1α Circle Enhances AKI Susceptibility in Diabetic Kidney Disease (DKD) through Fibrosis

Jianbo Guo,[1,2] Haidi Li,[3] Yifan Wang,[1,2] Baoyi Shao,[1,2] Jianan Wang,[3] Hai-Yong Chen.[1,2] *[1]School of Chinese Medicine, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, China; [2]Department of Chinese Medicine, The University of Hong Kong-Shenzhen Hospital, Hong Kong, China; [3]Anhui Medical University, Hefei, China.*

Background: AKI poses significant risks of mortality and organ dysfunction, especially in DKD. Excessive accumulation of ROS is implicated in AKI pathogenesis. Pyruvate dehydrogenase complex is phosphorylated by pyruvate dehydrogenase kinase 4 (PDK4), leading to increased ROS. Previous studies have revealed that TGF-β/SMAD3 signaling activation promotes fibrosis in DKD, while HIF-1α could be activated by phosphorylated SMAD3. However, the regulatory relationship among PDK4, SMAD3, and HIF-1α in AKI susceptibility in DKD remains unclear.

Methods: The ischemia/reperfusion (I/R) induced AKI models were conducted in db/m and db/db mice. Kidney epithelial cells were treated high glucose with/without the hypoxia and reoxygenation (HG + H/R) conditions. Chromatin immunoprecipitation (ChIP)-qPCR were utilized to identify the promoter binding site at gene transcriptional level. Gain to loss-function of inter-players were used to further confirm the results.

Results: Oxidative stress levels were significantly increased in *vivo* and in *vitro* models, including increased SOD and GSH levels and decreased MDA levels. I/R-induced AKI in db/db mice and the HG + H/R model exhibited significant elevations in PDK4, p-SMAD3, HIF-1α, fibronectin and KIM-1. Inhibition of PDK4 by using PDK4-IN-1 hydrochloride down-regulated the expressions of p-SMAD3, HIF-1α, fibronectin and KIM-1. Inhibition of p-SMAD3 by using SIS3 down-regulated the expressions of PDK4, HIF-1α, fibronectin and KIM-1. Inhibition of HIF-1α by using YC-1 down-regulated the expressions of PDK4, p-SMAD3, Fibronectin and KIM-1. Besides, overexpressed PDK4, p-SMAD3, or HIF-1α by constructing plasmids up-regulated the expressions of other genes. ChIP results showed that p-SMAD3 protein could bind to HIF-1α promoter and up-regulate HIF-1α transcription.

Conclusions: PDK4, mediated by SMAD3, increases HIF-1α transcription and further up-regulate the PDK4 expression. The circular pathway increases the level of fibrosis and enhances AKI susceptibility in DKD.

SA-PO114

Effect of Semaglutide in an Ischemic AKI Model

Juliana V. Silva, Guilherme H. Ferreira Vieira, Eloiza O. Silva, Maria De Fatima Vattimo, Camila Lima, Jessica P. García, Maikol L. Gonçalves, Carla D. Victoria, Alessandra Oliveira Maia. *Universidade de Sao Paulo, Sao Paulo, Brazil.*

Background: Semaglutide is an antidiabetic drug analogous to human GLP-1, the scarcity of data on its effects on chronic and acute cardiovascular and kidney diseases limits its use by the general public. Acute kidney injury affects approximately 49% of patients undergoing major cardiovascular surgery, in addition to a mortality rate of over 50%, which justifies the possibilities of seeking to prevent AKI. Objectives: To evaluate the effect of oral semaglutide on the renal function of rats subjected to an animal model of ischemia/reperfusion

Methods: This is an experimental study with adult male Wistar rats, weighing 250-300g, planned in groups: SHAM(control, with simulated clamping of the renal pedicle); GLP-1(semaglutide, oral;3mg/day;5 days); Ischemia and Reperfusion (IR) (clamping of bilateral renal pedicles for 30 minutes, followed by reperfusion) and GLP-1+IR(semaglutide followed by IR). Renal function was assessed by inulin clearance, serum creatinine and urinary flow rate and oxidative profile was assessed by urinary peroxides FOX, lipid peroxides(TBARS) and nitric oxide(NO)

Results: The I/R group showed an increase in serum creatinine and urinary NGAL, a decrease in urinary flow, and a reduction in Clin, while the GLP-1+IR group showed an increase in Clin compared to the I/R group. Furthermore, the GLP-1+IR group showed an increase in oxidative metabolites(FOX, TBARS and NO) when compared to IR.

Conclusions: Semaglutide showed a renoprotective effect associated with its antioxidant role that prevented the reduction in renal function caused by ischemic AKI.

Funding: Government Support - Non-U.S.

Table 1 Renal Function

Groups	n	Urinary Flow (ml/min)	Serum creatinine (mg/dl)	Inulin *Clearance* (ml/min)	Urinary NGAL (ng/mL)

Enhancing Glutathione Pathway Activity for Improved Resilience to Kidney Injury

Shun-Yang Cheng, Kari A. Koppitch, Andrew P. McMahon. *University of Southern California, Los Angeles, CA.*

Background: Males are more susceptible to AKI than females. What underlies superior resilience and increased tolerance to kidney injury in female? Our lab's analysis identified 984 genes with sex-biased expression: proximal tubule (PT), key target in many injury scenarios emerging as source of this sex-specific variability. Excessive ROS contribute to PT damage. Female-biased genes include glutathione pathway members, Gsts, that could potentially neutralize ROS. We hypothesize that female-enriched gene expression in glutathione pathway components may enhance resilience of female PT to IRI-induced oxidative stress. If so, activating these genes in male proximal tubules is predicted to increase resilience to IRI

Methods: To generate appropriate genetic tools, we identified and verified enhancers driving PT-restricted expression of HNF4a. Transgenic mice were generated that drive Gst transgene to PT and examined for effect on IRI response in male mice

Results: Identifying proximal tubule-specific enhancers ensures that overexpression is from target cell type. Using ATAC-seq, we identified conserved open chromatin, 5' and 3' of HNF4a promoter, in mouse and human PT cells that showed strong enhancer predictions in ENCODE datasets. Transgenic lacZ reporter studies using knock-in at a safe harbor locus demonstrated PT-restricted reporter activity of human enhancers in mouse kidney. Next, we generated a transgenic line in which Gst gene that shows marked female-enriched expression in PT cells is expressed under control of human HNF4A enhancer. To examine potential protective effects of elevated Gst levels in male mice, severe IRI was performed following unilateral nephrectomy, and serum creatinine levels and GFR determined to evaluate kidney function 2 and 28 days post IRI, respectively. Preliminary data suggests protective effect of ectopic Gst expression in male kidney: despite similar level of injury as measured by creatine levels 2 days after IRI, transgenics show improved post IRI survival and higher GFR at 28 days

Conclusions: Our research identified human HNF4A enhancers that will have broad utility for targeting gene expression to proximal tubule cells. Initial data addressing potential renal protective role for Gst, in male PT cells, are encouraging. Future studies will focus on earlier responses and rigorously assessing injury outcomes in transgenic and control male mouse kidneys

Metabolomics Assessment Reveals Amino Acid Depletion in Skeletal Muscle after Ischemic AKI in Mice

Amy S. Li, Zhibin He, Kayo Okamura, Colin C. Anderson, Julie Haines, Sarah Faubel. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Acute kidney injury (AKI) is a systemic disease that affects energy metabolism in various remote organs, including heart, lungs, and liver, in murine models of AKI. However, AKI-mediated effects on skeletal muscle have not been comprehensively assessed.

Methods: Ischemic AKI was induced in 8-10-week-old male C57BL/6J mice via bilateral pedicle clamping for 25 minutes. Untargeted mass spectrometry metabolomics was performed on gastrocnemius samples at 24-hrs and 72-hrs after AKI with a targeted analysis on energy & redox metabolism. MetaboAnalyst 6.0 was utilized for normalization of the data via autoscaling and statistical analysis.

Results: Univariate ANOVA revealed that 166 of 175 (95%) named metabolites were significantly different among the 5 experimental groups (unmanipulated, 24-hr sham & AKI, 72-hr sham & AKI). The 24-hr AKI group exhibited the most distinct phenotype as demonstrated by principal component analysis (Fig. 1). 30% (50/166) and 16% (27/166) of analytes were significantly different at 24-hrs and 72-hrs after AKI, respectively, compared to sham controls. Hierarchical clustering analysis of the 50 analytes in the 24-hr AKI vs. sham group reveal that 66% (33/50) are reduced (Fig. 2), majority of which are amino acids and their derivatives, which was further supported by pathway analysis.

Conclusions: This is the first study to describe changes of the skeletal muscle metabolome after AKI in a murine model. The metabolome of murine gastrocnemius exhibits significant change after ischemic AKI, particularly at 24 hours. Multiple amino acids and their derivatives are significantly reduced, consistent with the notion that AKI is a hypercatabolic disease, which may lend insight into the mechanistic underpinnings of adverse sequelae associated with AKI in patients.

Funding: NIDDK Support

Fig 2. HCA heat map of top 50 analytes in murine gastrocnemius that are significantly different 24-hrs after AKI vs sham.

SA-PO117

Mitochondria Functional Study in Cisplatin-Induced AKI

Fnu Vikky, Rihab Bouchareb. *Temple University, Philadelphia, PA.*

Background: Acute kidney injury (AKI) results from a generalized or localized impairment of oxygen and nutrient delivery to the kidney. As a result of this imbalance, the tubular epithelial cells undergo injury, which manifests as cell death by apoptosis and necrosis, with reduced kidney function, impaired water and electrolyte homeostasis, and reduced excretion of waste products of metabolism. Administration of the chemotherapeutic agent cisplatin leads to acute kidney injury (AKI). Cisplatin-induced AKI (CIAKI) has a complex pathophysiological map, which has been linked to apoptosis, oxidative and stress. objective:Since the pathophysiology of AKI is reflected in mitochondrial function dysregulation, we aim to examine the role of mitochondria in the Cisplatin model of AKI in kidney tubular cells at different time points

Methods: We isolated tubular cells from *Pham* mice. The cell's mitochondria are tagged with Dendra2 (mito-Dendra2), a photo-convertible fluorescent protein, which enables us to examine the fission-fusion events in response to stimuli

Results: The confocal microscopy shows that upon treatment of the cells with cis-platin, mitochondria were more fragmented and profoundly affected photobleaching. The mitochondrial movement was significantly reduced as compared to untreated control, and the stress was delayed. The genes corresponding to mitochondrial function were analyzed by qPCR. It was interesting to find that the genes related to mitochondrial functionalities (COXI) and biogenesis (PGC1a) were upregulated in 12hr treatment with cisplatin; however, cells treated with cisplatin for 24hrs had increased oxidative stress (~2 folds). It was observed that the mitochondria biogenesis genes were drastically reduced in 24-hour treatment. Further, ALCLAT-1, a gene that promotes autophagy, was upregulated, indicating that the cells try to negate the stress due to cisplatin treatment; however, prolonged treatment reduces the transcriptional activity.

Conclusions: Our preliminary results suggest that cisplatin treatment leads to compromised mitochondrial functions and increased oxidative stress.

SA-PO118

Glucose-Pyruvate Metabolism in Sepsis-Associated AKI

Prabhleen Singh.[1,2] [1]*University of California San Diego, La Jolla, CA;* [2]*VA San Diego Healthcare System, San Diego, CA.*

Background: *Metabolic reprograming* from oxidative to glycolytic in proximal tubules (PT) in AKI has been proposed. However, in the cecal ligation and puncture (CLP) model of sepsis-AKI (sAKI), we found dynamic changes with reduced oxidative metabolism (OXPHOS), increased glycolytic enzymes, but decreased functional glycolysis in PTs. Pyruvate, from glucose via glycolysis, can convert to lactate or fuel OXPHOS and is regulated by pyruvate dehydrogenase (PDH) and inhibited by PDH kinase (PDK). We examined the PDH-PDK axis, which is key in the control of OXPHOS and glycolysis, in sAKI.

Methods: Kidneys from sham or CLP mice were harvested at 24 hours. Protein and mRNA expression of key components of glucose and pyruvate metabolism were examined. *Seahorse Substrate Oxidation Stress kits were used* to interrogate substrates that fuel OXPHOS real-time with specific inhibitors- etomoxir (ETO) for fatty acids (FA) and UK5099 for pyruvate in fresh isolated PTs. RNA sequencing and metabolomics were also performed.

Results: PDH E1, E2, E3 were reduced, phospho-PDH and PDK4 were increased in CLP. PDP, which activates PDH, and PDH enzyme activity were decreased in CLP. Glucose transporters (GLUT2, SGLT1), gluconeogenic enzymes (FBP and G6pc) were decreased, but pentose phosphate pathway enzymes (G6pdx and Pgd) were increased in CLP. PTs from shams showed no change with ETO or UK5099 but in CLP PTs ATP-linked and maximal respiration were lower with UK5099 showing reliance on pyruvate. RNA sequencing showed differential regulation of OXPHOS, TCA, and glucose metabolism in CLP kidneys with gene expression changes consistent with above for pyruvate and glucose metabolism. Targeted metabolomics showed pyruvic acid as among the top 25 metabolites altered in CLP kidneys.

Conclusions: Our results advance the findings of dynamic and complex metabolic changes in CLP kidneys. Inactivation of PDH by increased PDK4 diverts pyruvate away from OXPHOS, which can lead to less ATP and more tubular injury, given the reliance of OXPHOS on pyruvate in CLP PTs. Therapeutics targeted to tubular metabolism via PDH-PDK axis can impact sAKI.

Protective Effects of Pemafibrate against Ischemia-Reperfusion-Induced AKI in Mice

Yuki Nakayama, Takayuki Nimura, Kosuke Yamaka, Daiki Aomura, Koji Hashimoto, Yuji Kamijo. *Shinshu Daigaku, Matsumoto, Japan.*

Background: The effect of peroxisome proliferator-activated receptor alpha (PPARα) on acute kidney injury (AKI) is unknown due to the limited literature investigating the renoprotective effect of PPARα in AKI using fenofibrate. Pemafibrate, a novel PPARα modulator, is characterized by high selectivity for PPARα. In this study, we aimed to explore the function of PPARα using pemafibrate in renal ischemic injury.

Methods: Twelve-week-old male C57BL/6J mice were divided into two groups: the pemafibrate group, which received mixed pemafibrate in their diet for 1 week before surgery, and the normal diet group. Bilateral 35-minute ischemia-reperfusion (I/R) was performed on the mice to produce an ischemic AKI model (n=9 in both groups). A sham

operation was also performed for control (n=3 in each group). All mice were sacrificed 24 hours after I/R or sham operation. Renal function, histology, and tissue gene expression were evaluated.

Results: Serum creatinine levels were significantly lower in the pemafibrate group than in the normal diet group. Pathological findings showed mild expansion of the urinary tubule lumen and slight loss of the brush border in the pemafibrate group compared to the normal diet group. RNA analyses revealed decreased expressions of urinary tubule injury markers and inflammatory genes. The renal PPARα expression was not significantly different between groups. However, oil red O staining showed less fat droplet accumulation, and the gene expressions of enzymes involved in fatty acid oxidation and anti-oxidative stress, which are target genes of PPARα, were up-regulated in the pemafibrate group.

Conclusions: Pemafibrate treatment attenuated ischemic AKI by activating fatty acid metabolism and reducing oxidative stress.

Ablation of Type 2 IP3R, a Calcium Channel Located on the Organelle Contact Site, Improves the Repairment of Cell Survival and Endoplasmic Reticulum-Mitochondria Function in Tubular Cells

Qi Li, Sho Hasegawa, Yuto Takenaka, Masaomi Nangaku, Reiko Inagi.
Tokyo Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Bunkyo-ku, Japan.

Background: The renal proximal tubules (PT) are susceptible to ischemia-reperfusion injury (IRI). The Inositol trisphosphate receptors (IP3Rs) are calcium-release channels located on endoplasmic reticulum (ER). IP3Rs, composed of 3 isoforms, mediate calcium flux from the ER to the mitochondria via mitochondria-associated ER membrane (MAM) and multiple cellular functions. However, isoform-specific IP3R function in PT cells still remains unknown.

Methods: To assess the isoform-specific IP3R function in kidney tubules, the isoforms were separately knocked down in the human proximal tubular cell line, HK-2 cells. As a mimic of IRI, HK-2 cells were exposed to 24h anoxia followed by 4h reperfusion (AR) and assessed the cell fate and organelle function by corresponding assays and fluorescent probes.

Results: Among 3 isoforms, knocking down IP3R2 in HK-2 cells decreased the cell number stacked in the cell cycle G1 phase and improved the cell proliferation rate under the AR conditions. In contrast, knocking down IP3R1 or IP3R3 did not protect the cells from G1 arrest. Interestingly, IP3R2 knockdown did not alter the AR-induced calcium flux after AR, a major MAM function in ER-mitochondrial interaction. Mechanistically, IP3R2 knockdown reduced the AR-induced p27 upregulation, which promotes the CDK2 activity, leading to the cell's entry to an efficient S phase. It was consistent with that induction of senescence-associated secretory phenotype (SASP: TGF-b1 and IL-6) by AR was significantly ameliorated by IP3R2 knockdown. Importantly, the IP3R2 knockdown ameliorated organelle stress caused by AR: ER stress and mitochondrial stress (depolarization and dynamics) were ameliorated by IP3R2 knockdown, but not IP3R1 and IP3R3.

Conclusions: IP3R2 knockdown improved cell cycle status and ER-mitochondria function in PT cells with AR injury, suggesting the novel pathophysiological significance for IP3R2 on cell fate and ER-mitochondrial homeostasis under IRI by a calcium flux-independent pathway.

Slc25a21 in Cisplatin-Induced AKI: A New Target for Renal Tubular Epithelial Protection by Regulating Mitochondrial Metabolic Homeostasis

Huimei Chen,[1] Aihua Zhang,[2,3] Xin Su.[2,3] *[1]Duke-NUS Medical School Cardiovascular & Metabolic Disorders Programme, Singapore, Singapore; [2]Nanjing Medical University, Nanjing, China; [3]Children's Hospital of Nanjing Medical University, Nanjing, China.*

Background: Acute kidney injury (AKI) is a global health issue frequently induced by cisplatin therapy. Dysfunctional mitochondria in tubular epithelial cells are key drivers of kidney injury, and the regulation of mitochondrial metabolites is proposed to be beneficial in kidney protection. Here, we highlighted that maintaining a mitochondrial 2-oxodicarboxylate carrier, Slc25a21 in cisplatin-induced AKI protected against tubular apoptosis and inflammation by restoring mitochondrial metabolic homeostasis.

Methods: Kidney samples from AKI patients and cisplatin-induced mice models were to evaluate the association of renal Slc25a21 expression and AKI progression. Slc25a21 expression was upregulated using AAV9 system via in situ injection and plasmid transfection in kidney proximal tubular epithelial cells. AKI severity was evaluated through histological assessments and kidney function tests. Cellular apoptosis and inflammatory response were assessed using TUNEL assays, flow cytometry, and ELISA for cytokines (e.g., IL-18 and TNFα). Additionally, mitochondrial function and metabolic alterations were examined through Seahorse assays and metabolomics analysis.

Results: It was observed that renal Slc25a21 is highly expressed in proximal tubular epithelial cells and showed a negative correlation with kidney function in both AKI patients and cisplatin-induced murine models. Maintaining renal Slc25a21 expression alleviated cisplatin-induced tubular injury by reducing cellular apoptosis and inflammatory responses. It also helped restore respiratory ATP production, mitochondrial biogenesis, and integrity in acutely injured tubular epithelial cells. Mechanistically, reduced Slc25a21 levels in AKI disrupted mitochondrial 2-oxoadipate transport, altering the influx of related metabolites, and particularly affecting the tricarboxylic acid cycle, while restoration of Slc25a21 reversed these effects in mitochondrial metabolic homeostasis.

Conclusions: Our findings suggest that suppression Slc25a21 contributes to AKI and sustaining Slc25a21 expression could prevent the progress of AKI via fuel metabolite transport and the restoration of mitochondrial homeostasis in tubular epithelial cells. We believe our findings will contribute to the advancement of mechanistic insights and potential therapeutic strategies to treat AKI.

Metabolic Alterations in Organs and Biofluids following Unilateral Ischemia-Reperfusion Kidney Injury in Pigs

Oliver Hahn,[1] Maria Chrysopoulou,[1] Johannes Jaegers,[1,3] Christoffer Laustsen,[4] Markus M. Rinschen.[1,2] Kidney Omics Group. *[1]Department of Biomedicine, Aarhus University, Aarhus, Denmark; [2]Department of Medicine, University Medical Center Hamburg Eppendorf, Hamburg, Germany; [3]Childrens Hospital, Pediatrics II, Pediatric Nephrology, University of Essen, Essen, Germany; [4]MR Research Centre, Aarhus University, Aarhus, Denmark.*

Background: The kidneys play a crucial role in eliminating metabolic waste products and regulating various metabolites. However, metabolic alterations in renal injury sometimes remain un-interpretable, since multiple organ systems may be affected.

Methods: We employed stable isotopes 13-Carbon glucose and 15-Nitrogen ammonium chloride to track metabolites across pig organs subjected to unilateral ischemia-reperfusion kidney injury for 2 hours and either one or four days of recovery. Utilizing ultra-high-pressure liquid chromatography-triple quadrupole tandem mass spectrometry, we accurately measured both labeled and unlabeled metabolites, enabling precise quantification of metabolite fluxes and fates. Additionally, we assessed changes in the proteome to correlate with metabolite fluxes.

Results: Using functional MRI, we accurately phenotyped the pigs and observed a significant decrease in the single kidney GFR of the injured kidney. Ammonia flux in the kidney medulla increased after 1 and 4 days of recovery in both the ipsilateral and contralateral kidneys compared to the kidneys of the control pigs. In contrast, ammonia flux remained unchanged in other organs, including the liver, heart, muscle, and brain. Additionally, measurements of metabolites from the citric acid cycle, urea cycle, and glycolysis indicated a strong metabolic rewiring to ischemia reperfusion injury. Proteome changes correlated with the observed findings, but subtle changes were also observed in the non-injured, contralateral kidney.

Conclusions: The metabolic epicenter of acute injury is the injured kidney, but distinct metabolic alterations are observed in the other kidney and, partly, other organs. These metabolic alterations are sequelae of renal injury and provide a first window into initial metabolic mechanisms conveying cardiovascular risk in renal injury.

Increased Severity of AKI in Obese Mice

Chathri Ratnayake,[1,2] Kurt Gleich,[2,3] Marina Katerelos,[2,3] Geoffrey Harley,[1,2] Mardiana Lee,[1,3] David A. Power,[1,3] Peter F. Mount.[1,3] *[1]The University of Melbourne Austin Clinical School, Heidelberg, VIC, Australia; [2]Kidney Laboratory, The Institute for Breathing and Sleep (IBAS), Austin Health, Heidelberg, VIC, Australia; [3]Department of Nephrology, Austin Health, Heidelberg, VIC, Australia.*

Background: Obesity is a lipotoxic state of abnormal and excessive fat accumulation. Although obesity is a well-known risk factor for chronic kidney disease, its role in acute kidney injury (AKI) is not well understood. We conducted this study to investigate the impact of obesity from a high fat diet (HFD) on AKI using the folic acid nephropathy (FAN) model.

Methods: Male mice aged 6-8-week-old received either HFD or control diet (CD) for 6 weeks. AKI was induced using FAN, in which intraperitoneal folic acid is given at 240 ug/g. Control mice were administered vehicle. Kidneys and bloods were collected 48 hours post FAN.

Results: HFD mice demonstrated more severe AKI compared to CD mice post FAN as evidenced by worse serum urea (HFD 48.9±4.9 mmol/L vs CD 32.3±19.8 mmol/L, P=0.035) (Fig 1A), worse creatinine (HFD 0.09±0.08 mmol/L vs CD 0.03±0.014 mmol/L, P=0.022), increased NGAL expression by Western blot (HFD 10.8±4.8-fold vs CD 2.1±1.3-fold) (Fig 1B) and RT-PCR (HFD 303.2±117.5-fold vs CD 184±77.6-fold, P=0.004). RT-PCR found that HFD increased the expression of inflammatory markers after FAN with increased IL-6 (HFD 214.6± 23.3-fold vs CD 108±87.8-fold, P = 0.014) and increased MCP-1 (HFD 32.3± 15.9-fold vs CD 12.8±8.5-fold, P<0.001). HFD mice showed worse histological injury score after FAN (HFD 3.43±0.6 vs CD 2.27±0.9, P<0.001). Notably, HFD increased tubular vacuolation in both FAN (HFD 3.5±0.6 vs CD 2.34±0.6, P<0.001) and vehicle treated (HFD 3.25±0.8 vs CD 1.93±0.4, P< 0.001) consistent with lipid accumulation in tubular epithelial cells (TEC).

Conclusions: Our data indicate that obese mice accumulate lipid in tubular epithelal cells and develop more severe AKI and inflammation following FAN. Strategies to reduce obesity may improve outcomes in AKI.

Adiponectin Alleviates AKI-Related Pyroptosis and Inflammation by Accelerating NLRP3 Degradation

Baoyi Shao,[1] Jianan Wang,[2] Haidi Li,[2] Jianbo Guo,[1] Yifan Wang,[1] Hai-Yong Chen.[1,3] School of Chinese Medicine. *[1]School of Chinese Medicine, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, China; [2]Anhui Medical University, Hefei, China; [3]Department of Chinese Medicine, The University of Hong Kong-Shenzhen Hospital, Shen Zhen, China.*

Background: Adiponectin (APN), an adipose tissue-derived hormone, exhibits multifaceted effects on various tissues. The role of adiponectin in acute kidney injury (AKI) remains largely unclear. This study investigated whether adiponectin mitigates AKI by inhibiting pyroptosis and inflammation through the NLRP3/GSDMD-mediated pathway.

Methods: The levels of APN were tested in AKI-induced mouse models. Adiponectin knockout (KO) and wild-type (WT) mice were induced into AKI by injection of cisplatin, lipopolysaccharide, or folic acid. The effects of AdipoRon, an APN receptor agonist, were observed in three AKI models *in vivo* and in cisplatin-induced mouse tubular epithelial cells (mTECs). The role of AMPK in the renoprotective effects of APN was investigated and the relationship between AMPK and NLRP3 was researched.

Results: APN decreased in different AKI models. APN deletion exacerbated AKI-induced nephrotoxicity and inflammation as indicated by increased kidney injury scores and related inflammatory factors. APN deletion promoted the activation of pyroptosis-related NLRP3/GSDMD pathway across three AKI models rather than apoptosis, necroptosis or ferroptosis as expressed by relevant executioners *in vivo*. AdipoRon protected against AKI-induced nephrotoxicity and inflammation by directly activating AMPK and ameliorating pyroptosis-related pathways *in vivo* and *in vitro*. The renoprotective role of AdipoRon/APN was reversed by Compound C, an AMPK inhibitor. AICAR, an activator of AMPK, reduced the protein levels of NLRP3 without significantly affecting its mRNA levels, indicating NLRP3 undergoes post-translational modifications upon AMPK activation. AICAR-mediated NLRP3 reduction was prevented by MG-132 but not chloroquine, which suggested NLRP3 might be degraded through the ubiquitin-proteasome system. Indeed, AICAR enhanced NLRP3 ubiquitination as demonstrated by western blots in ubiquitin-transfected mTECs. Co-Immunoprecipitation followed by liquid chromatography–mass spectrometry identified several potential E3 ubiquitin ligases that could interact with NLRP3 and function as downstream transcription factors of AMPK.

Conclusions: APN mitigates AKI by inhibiting pyroptosis and inflammation via AMPK/NLRP3 pathways. Targeting APN/AMPK/NLRP3 represents a novel therapeutic strategy for addressing AKI-induced nephrotoxicity and inflammation.

Nicotinamide Phosphoribosyltransferase (NAMPT) Improves Kidney Injury and Promotes Kidney Regeneration of Adult Zebrafish

Young Sun Kang. *Korea University Ansan Hospital, Ansan, Gyeonggi-do, Republic of Korea.*

Background: NAMPT is a known adipokine which improves insulin resistance in obesity and have an anti-diabetic effect. However, its role remains uncertain in kidney injury and regeneration. In this study, we investigated the role of NAMPT on puromycin-induced kidney injury and regeneration of adult zebrafish model.

Methods: We injected 100ug of puromycin or/and 500ng of NAMPT via intraperitoneal injection into adult wild zebrafish, which were sacrificed at 1, 3, 5, 7, and 14 dpi. To investigate the role of NAMPT in kidney regeneration, we generated NAMPT knock-out zebrafish, then observed nephron injury and regeneration.

Results: Larva kidney showed only *namptb* gene expression and adult kidney presented both *nampta* and *namptb* gene expressions. Puromycin increased both *nampta* and *namptb* gene expressions. And puromycin also increased NAMPT protein expression of adult kidney. Compared to controls, puromycin-induced NAMPT protein synthesis was increased from 1 dpi until 7 dpi. NAMPT was not expressed on podocytes of glomeruli, but identified on interstitial and tubular cells of kidney in adult zebrafish. Especially, IF staining showed NAMPT expression on the apical area of tubular cells and intranuclear area of interstitial cells between 7 dpi and 14 dpi. NAMPT treatment recovered puromycin-induced nephron loss and tubular regeneration of adult zebrafish at 7 dpi and 14 dpi. This result also was identified by *in situ* hybridization of *lhx1a* as a regeneration marker. Finally, NAMPT knock-out zebrafish showed smaller number of nephrons in puromycin-induced kidney regeneration than that of puromycin-treated wild zebrafish.

Conclusions: From these results, NAMPT improved puromycin-induced kidney injury and enhanced kidney regeneration in adult zebrafish. Moreover, NAMPT showed the key role in nephron regeneration.

Humanin, a Mitochondrial-Derived Peptide, Mitigates the Progression of Acute Kidney Disease

Yung-Ho Hsu.[1,2] *[1]Taipei Medical University, Taipei, Taiwan; [2]Hsin Kuo Min Hospital, Taipei Medical University, Taoyuan, Taiwan.*

Background: Acute kidney disease (AKD) represents a critical period following acute kidney injury (AKI), during which preventing the onset of chronic kidney disease (CKD) becomes crucial. In this study, we investigated the impact of humanin, a mitochondrial-derived peptide, on AKD through both in vivo and in vitro experiments.

Methods: We analyzed the protective effect of humanin-G, a humanin analog, on rat renal tubular cells (NRK-52E) subjected to hypoxia/reoxygenation (H/R). We also established an AKD mouse model by performing right nephrectomy and inducing transient ischemic injury to the left kidney. One week after the operation, we administered 4 mg/Kg/week of humanin-G to AKD mice for 4 weeks.

Results: We found that H/R impaired mitochondrial function and triggered inflammatory and apoptotic responses, which were reversed by humanin treatment. Humanin treatment also reduced H/R led ROS levels. Humanin also upregulated PI3K III, downregulated phosphor-mTOR, and increased LC3 expression, all of which contribute to mitophagy. In hypoxic NRK-52E cells, humanin increased the levels of mitochondrial Complex I, which plays a crucial role in energy production within the mitochondria. Over a one-month period, humanin led to reduced serum creatinine and blood urea nitrogen levels in AKD mice. Additionally, renal fibrosis was mitigated in AKD mice treated with humanin.

Conclusions: Humanin shows promise as a potential intervention to prevent the transition from AKI to CKD. By enhancing mitochondrial function, it may play a crucial role in minimizing AKD progression.

Funding: Government Support - Non-U.S.

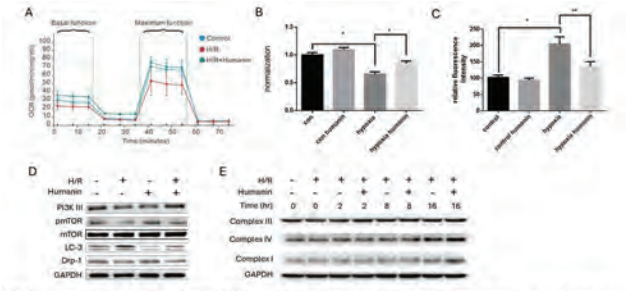

Figure 1. Humanin upregulated mitochondrial function in NRK-52E cells. (A) Oxygen consumption rate (OCR) curves. OCRs were measured 16 h after the humanin treatment (10 μM). Results are presented as the mean ± SD (n = 3). (B) The cell proliferation of hypoxic NRK-52E cells. The cells were treated with the hypoxia treatment overnight, cultured under normal conditions for 30 minutes, and then added 10 μM humanin for 24 hours. (C) The ROS in NRK-52E cells. We used DCFHDA staining for ROS detection and measured the fluorescence value by an ELISA reader. ROS in the hypoxia cells increased significantly compared to that in the control cells. ROS in the cells added humanin after hypoxia significant decreased. Results are presented as the mean ± SD (n = 3). *, P<0.05. (D) The Western blots of mitophagy-related signals in hypoxic cells. Humanin promoted the expression of PI3K III and LC-3, and reduced phospho-mTOR and Drp-1 expression. (E) The Western blots of mitochondrial complexes in hypoxic cells. The mitochondrial complexes were monitored 2, 8, or 16 h after the humanin treatment.

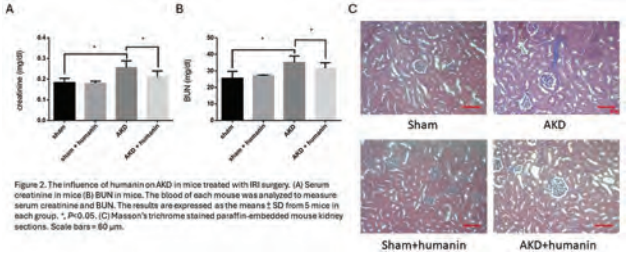

Figure 2. The influence of humanin on AKD in mice treated with IRI surgery. (A) Serum creatinine in mice (B) BUN in mice. The blood of each mouse was analyzed to measure serum creatinine and BUN. The results are expressed as the means ± SD from 5 mice in each group. *, P<0.05. (C) Masson's trichrome stained paraffin-embedded mouse kidney sections. Scale bars = 60 μm.

SA-PO127

Loss of Vascular Endothelial Growth Factor Receptor 2 (VEGF-R2) in the Renal Stroma Regulates Lipid Metabolism to Halt AKI-to-CKD Transition

Akira Oda, Sunder Sims-Lucas, Takuto Chiba. *University of Pittsburgh, Pittsburgh, PA.*

Background: A dire consequence of acute kidney injury (AKI) is a dramatically increased risk of developing chronic kidney disease (CKD). Understanding the mechanisms by which AKI progresses to CKD is essential for the development of therapies, for which none currently exist. The renal microvasculature, including pericytes and endothelial cells, is damaged in AKI, leading to recruitment of inflammatory cells that contribute to progression to CKD. Pericytes are a heterogeneous mesenchymal population and have been identified as a major source of myofibroblasts that drive CKD. Interestingly, VEGF-R2 (known as the master regulator of angiogenesis for endothelium) acts as a negative regulator of pericytes limiting angiogenesis *in vitro*. Understanding the molecular mechanisms that mediate maladaptive endothelial-pericyte crosstalk leading to exacerbated and prolonged inflammation may facilitate therapeutic exploitation of this phenomenon.

Methods: We generated genetic mouse models for renal stromal cell (RSC)-specific loss-of-function of VegfR2 with Foxd1-Cre (*VegfR2*$^{RSC-/-}$) to interrogate the role of *VegfR2* in the renal stroma, which includes pericytes, in the AKI-to-CKD transition. Mice were subjected to three CKD models induced by either renal ischemia/reperfusion injury (IRI), low/repeated cisplatin treatment, or unilateral urethral obstruction (UUO).

Results: Our RNA-seq analysis of isolated renal stroma with or without renal IRI revealed that injured renal RSCs decreased the expression of genes associated with lipid metabolism. We found that *VegfR2*$^{RSC-/-}$ mice consistently mitigated AKI-to-CKD transition in all three CKD models (IRI, UUO, and cisplatin). *VegfR2*$^{RSC-/-}$ mice have reduced inflammation, oxidative stress as well as reduced interstitial lipid deposition after renal IRI. Mechanistically, *VegfR2*$^{RSC-/-}$ kidneys have increased expression of a lipid metabolism associated genes, Bnip3 and Pyruvate dehydrogenase kinase1 (PDK1), contributing to the enhanced protection.

Conclusions: These data suggest that loss of VEGF-R2 in the renal stroma reduces oxidative stress and lipid metabolism to attenuate inflammation to halt CKD.

SA-PO128

GATM Ameliorates the Acute-to-Chronic Kidney Disease Transition through Enhancing Endogenous Creatine-Mediated Lipophagy

Xu Guan, Fan Li, Weijian Xiong. *Chongqing Hospital of Traditional Chinese Medicine, Chongqing, China.*

Background: Acute kidney injury (AKI), characterized by a rapid decline of kidney function in the short term, is a common clinical syndrome with complex pathogenesis. The incomplete recovery from AKI increases the risk of progression to chronic kidney disease (CKD). GATM, highly expressed in the mitochondria of renal tubular epithelial cells (RTECs), is a key rate-limiting enzyme in the endogenous creatine biosynthesis. Previous studies have found mutations in GATM gene in the kidney of patients with CKD contribute to the ROS production, mitochondrial damage and cell death in RTECs. Moreover, GATM mutations also upregulate the expression of the fibrotic cytokine IL-18 and accelerate CKD progression, indicating that GATM may play an important role in the pathogenesis of kidney diseases. However, the role of GATM in AKI-to-CKD transition remains unknown.

Methods: In this study, GATM adenovirus-overexpressed mice and cultured RTECs were used as subjects. Renal ischemia-reperfusion (IRI) mouse model, RNA sequencing, Immunofluorescence, Western blot and qRT-PCR were employed to reveal the crucial role and mechanisms of GATM in AKI-to-CKD transition.

Results: GATM was significantly reduced in the kidneys AKI patients and IRI mice. The analysis indicated GATM expression was positively correlated with kidney function. In vivo, GATM overexpression by adenovirus improved the transition from AKI to CKD. Primary RTECs were employed to RNA-seq analysis that GATM overexpression upregulated the expression of fatty acid degradation and autophagy-related genes while downregulated lipid droplet-related gene in RTECs through KEGG analysis. Transmission electron microscopy revealed that a large amount of lipid droplets were accumulated in RTECs after IRI, which could be reversed by GATM overexpression, accompanied by an increased autophagosomes enveloping-lipid droplets and reduced kidney injury. GATM promoted endogenous creatine synthesis and enhanced the lipophagy of RTECs. Collectively, our findings demonstrate that GATM deficiency contributes to AKI-to-CKD transition and GATM ameliorates AKI-to-CKD transition though enhancing endogenous creatine-mediated lipophagy.

Conclusions: GATM plays an important role in the transition of AKI to CKD and targeting GATM-lipophagy axis could serve as a promising therapeutic approach for retarding AKI-to-CKD transition.

SA-PO129

Reactivation of Pax2 in Proximal Tubular Epithelial Cells May Be Involved in the Directivity of Programmed Cell Death in Acute Tubular Necrosis

Kasumi Ohno, Keisuke Sako, Kiyoaki Ito, Shinji Kitajima, Ichiro Mizushima, Norihiko Sakai, Miho Shimizu, Yasunori Iwata. *Kanazawa university, Kanazawa, Japan.*

Background: Acute Tubular Necrosis (ATN) is a severe kidney injury, posing a critical issue due to its high mortality rate and the risk of progression to chronic kidney disease (CKD). In ATN, Paired box 2 (Pax2) reactivation in injured tubular epithelial cells has been known to occur. Pax2 is a transcription factor essential for kidney development and is reactivated in proximal tubular epithelial cells during recovery from injury. Previously, we reported that Pax2 reactivation is necessary to regenerate cells via cyclin-dependent kinase 4 (CDK4) in injured proximal tubules using a unilateral renal ischemia-reperfusion injury model. However, it is unclear whether the reactivation of Pax2 is an essential factor in the biological defense against ATN. Therefore, we hypothesized that inadequate Pax2 reactivation leads to exacerbating kidney injury and mortality.

Methods: To test our hypothesis, we conducted experiments using 8-week-old male mice with proximal tubule-specific Pax2 knockout (Pax2 KO mice) under endogenous androgen control. We administered aristolochic acid (AA) at a dose of 5 mg/kg intraperitoneally for three consecutive days. As a control group, we used C57BL/6 mice. Mice were sacrificed on days 1, 4, 7, and 42 after the end of AA administration. To evaluate the impact on mortality, we administered a single intraperitoneal dose of AA at 15 mg/kg.

Results: On the first and fourth days, the two groups showed no significant difference in kidney function. However, on the seventh day, serum creatinine levels increased in the Pax2 KO group (p=0.025). Kidney histological analysis revealed a clear obstruction of the Henle loop in the Pax2 KO group. In addition, TUNEL-positive cells were observed in both groups, while the number of Cleaved caspase 3-positive cells decreased in the cKO group (p=0.001). Instead, the number of p-Mlkl-positive cells increased (p=0.001). The experiment evaluating mortality showed a significant exacerbation in the Pax2 KO group (p=0.01).

Conclusions: Pax2 reactivation was shown to be protective against kidney injury and mortality. Our results suggest that non-apoptotic cell death is increased in tubular epithelial cells with inadequate Pax2 reactivation and may affect mortality and kidney function by inducing maladaptive cell death.

Nicotinamide N-methyltransferase (NNMT) Induction during AKI Reduces NAD+ and Durably Alters Global Gene Expression

Amanda J. Clark,[1,2] Kyle Q. Vu,[1] Samir M. Parikh.[1] *[1]The University of Texas Southwestern Medical Center, Dallas, TX; [2]Children's Medical Center Dallas, Dallas, TX.*

Background: NAD+ is a critical cofactor in cellular metabolism and is required for kidney tubular cell function. Reduced NAD+ abundance is a pathologic feature of both acute (AKI) and chronic kidney diseases (CKD). While NAD+ biosynthesis is suppressed

in AKI, multiple studies demonstrate an upregulation of nicotinamide N-methyltransferse (NNMT) during injury. NNMT catalyzes the methylation of nicotinamide (NAM), the most significant NAD+ precursor. Methyl-NAM is permanently removed from NAD circulation. Further, via production of methyl-NAM, NNMT permanently removes circulating methyl groups. Thus, NNMT induction during AKI may represent an actionable target to increase NAD+ to reduce AKI severity and also a mechanism where AKI induces long-term changes in gene expression that could underly the AKI to CKD transition.

Methods: NNMT expression was measured using qPCR of mouse kidneys after AKI induced by cisplatin, folic acid, ischemic reperfusion injury (IRI), and lipopolysaccharide (LPS). A novel, inducible renal tubule specific NNMT overexpression mouse (iNephNNMT) was created - Pax8rtTA, tetOCre, fl-STOP-fl-NNMT. iNephNNMT mice had kidney function (GFR) estimated via measurement of serum creatinine after 4 weeks of overexpression followed by IRI or sham. Wild type mice induced with IRI were treated with NNMT inhibitors methyl-NAM and JBSNF followed by GFR estimation. RNASeq and ATACSeq were performed on kidneys from iNephNNMT mice and littermate controls.

Results: NNMT induction was a conserved feature across 4 distinct AKI mouse models: cisplatin, folic acid, IRI, and LPS. iNephNNMT mice exhibited reduced GFR at baseline as well as more severe injury after IRI compared to littermate controls. Two structurally unrelated NNMT inhibitors increased kidney NAD+ and protected against IRI. RNASeq and ATACSeq data from iNephNNMT kidneys demonstrated that NNMT overexpression increased chromatin accessibility at the native NNMT locus and led to sustained NNMT overexpression.

Conclusions: NNMT induction during AKI may be a conserved, maladaptive feature. Transient NNMT induction during periods of stress can lead to persistently increased NNMT expression, which in turn could perturb kidney metabolism towards greater injury susceptibility and fibrosis. Finally, NNMT may be an attractive therapeutic target in the AKI-to-CKD transition.

SA-PO131

Role of Lactate Dehydrogenase A (LDHA)-Mediated Glycolytic Switch in AKI

Yan Lu, Anna A. Zmijewska, Anupam Agarwal. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: Acute kidney injury (AKI) is a detrimental and frequently irreversible loss of renal function that affects millions of individuals worldwide. Despite effective biomarkers, treatment options are limited, and outcomes from AKI remain poor. Proximal tubule cells (PTCs) are among the key functional renal cell populations significantly affected by AKI. In particular, the bioenergetics of PTCs are diminished during AKI, followed by maladaptive responses accompanied by hypoxia or endotoxin-induced inflammation. In this setting, lactate dehydrogenase A (LDHA), an enzyme involved in glycolysis, is activated in PTCs, although the impact of this activation and therapeutic potential of LDHA in AKI remain to be determined.

Methods: Nephron-specific LDHA knockout mice were generated by crossbreeding Pax8-rtTA/tetO Cre and LDHAfl/fl mice. Western blot, real-time PCR, and immunofluorescence analyses were used to determine LDHA levels in wild-type and LDHA-deficient mice. For an AKI model, ($LDHA^{Whole\ Nephron-/-}$) and LDHA wild-type ($LDHA^{Whole\ Nephron+/+}$) mice were subjected to Cisplatin (20 mg/kg; i.p., once) -induced injury. The severity of AKI, including serum creatinine levels, glomerular filtration rate (GFR), and Neutrophil gelatinase-associated lipocalin (NGAL) expression, was determined 4 days post-injection of Cisplatin.

Results: Both LDHA expression and protein levels were diminished in the whole nephron of LDHA knockout mice, while LDHB remained unchanged. Control groups of ($LDHA^{Whole\ Nephron-/-}$) mice showed no phenotype changes in proximal tubules. However, these mice developed more severe injury upon Cisplatin-induced AKI compared to wild-type counterparts. The severity of injury included increased serum creatinine levels, reduced glomerular filtration rate, and increased NGAL expression in ($LDHA^{Whole\ Nephron-/-}$) compared to wild-type mice.

Conclusions: Collectively, our findings indicate that LDHA deficiency increases the severity of Cisplatin-induced AKI, predominantly due to more significant dysfunction of proximal tubule cells. These results suggest that the accumulation of endogenous LDHA has a protective effect in AKI.

Alternative Splicing of Uromodulin Enhances Mitochondrial Metabolism for Adaptation to Stress in Kidney Epithelial Cells

Azuma Nanamatsu, George Rhodes, Kaice A. LaFavers, Radmila Micanovic, Virginie Lazar, Daria Barwinska, Malgorzata Kamocka, Carrie L. Phillips, Katherine J. Kelly, Robert L. Bacallao, Pierre C. Dagher, Takashi Hato, Tarek M. El-Achkar. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Cells of thick ascending limb of the loop of Henle (TAL) are resistant to ischemic injury, despite high energy demands in a relatively hypoxic medullary milieu. This adaptive metabolic response is not fully understood even though the integrity of TAL cells is essential for recovery from acute kidney injury (AKI). TAL cells uniquely express uromodulin (UMOD), the most abundant protein secreted in healthy urine. The role of UMOD in this adaptation mechanism and the involvement of alternative splicing have not been previously described.

Methods: To explore alternative splice variants of UMOD, we assessed long-read RNA sequencing data of human and mouse kidneys. The expression of the spliced variant after AKI was evaluated using a renal ischemia-reperfusion injury (IRI) mouse model. To test the localization and function of the splice variant, its cDNA was overexpressed in Madin-Darby canine kidney (MDCK) cells. To evaluate its role during AKI, we designed splice-switching antisense oligonucleotides (SSOs) to induce this alternative splicing, and their efficacy was tested in immortalized mouse kidney TAL cells and IRI mice. We isolated primary TAL cells from IRI mice to confirm the cytoprotective effect of the splice variant.

Results: Long-read RNA sequencing showed the existence of alternatively-spliced UMOD (AS-UMOD) which skips exon 10 both in humans and in mice. AS-UMOD expression was induced by mild IRI, but not by severe IRI. This variant lacks a GPI-anchoring site and was localized intracellularly in mouse kidneys and MDCK cells. AS-UMOD was targeted to the mitochondria, interacted with SLC25 carriers, increased NAD^+ and ATP levels, and improved cell viability after hypoxic injury in MDCK cells. We identified SSOs that enhance AS-UMOD expression *in vitro* and *in vivo*. Augmentation of AS-UMOD using the SSO after severe IRI improved the course of injury by protecting TAL cells.

Conclusions: Alternative splicing generates a conserved intracellular isoform of uromodulin, which contributes to the metabolic adaptation of TAL cells to ischemic injury. Enhancing this protective splice variant in TAL cells might become a novel therapeutic intervention for AKI.

Stearyl-Coenzyme A Desaturase 1 Regulates Tubular Cells Mitochondrial Homeostasis Exacerbates AKI

Han Wu, Ying Li, Mengru Gu, Chunsun Dai. *The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: Acute kidney injury is a common clinical acute and critical condition, which is associated with increased mortality, prolonged hospital stay, and the risk of chronic kidney disease (CKD). Numerous studies have shown that renal tubular cell injury and death are the core events of AKI. The kidney is a high energy-consuming organ, and fatty acids become the preferred energy source for renal tubular cells due to their high performance, so mitochondrial dysfunction may be the main cause of renal tubular cell injury during AKI. SCD1 is a key enzyme in lipogenesis, mainly catalyzing production of monounsaturated fatty acids (MUFAs). Previous studies found that SCD1 may play an important role in maintaining mitochondrial homeostasis by participating in lipid metabolism, so we aimed to study whether SCD1 can participate in AKI by regulating mitochondrial homeostasis in tubular cells.

Methods: *In vivo*, we used SCD1 global knockout mice to construct ischemia-reperfusion-induced acute kidney injury model to study the role of SCD1 in AKI. *In vitro*, We primarily used primary tubular epithelial cells extracted from SCD1 knockout mice with H_2O_2 treatment and the role of SCD1 in AKI by metabolomics, proteomics, and transcriptomic methods.

Results: Firstly, we found that SCD1 mainly was expressed in the S3 tubular epithelial cells increased significantly during acute kidney injury. Further research showed that SCD1 knockout or inhibiting SCD1 significantly alleviated ischemia-reperfusion-induced acute kidney injury and H_2O_2-induced tubular cell death. Secondly, the results of electron microscopy showed that after H_2O_2 treatment, mitochondrial crest in SCD1 -/- tubular cells was more intensive and the mitochondrial structure was more complete. Thirdly, the metabolomics data demonstrated that SCD1 knockout significantly altered the tubular cells metabolic profile, in which the TCA cycle equivalent significantly increased. The data from transcriptomics and proteomics suggested that knocking out SCD1 significantly upregulated the mitochondrial oxidative phosphorylation proteins relative mRNA and protein expression.

Conclusions: Stearyl-Coenzyme A desaturase SCD1 aggravates acute kidney injury by regulating mitochondrial structure and function.

Mitochondrial Treatment Mitigates Hypoxia-Induced Renal Cell Injury

Edgar Maquigussa,[1,2] Bruno S. Bronel,[1] Mirian A. Boim.[1]
[1]Universidade Federal de Sao Paulo, Sao Paulo, Brazil; [2]Universidade Nove de Julho, Sao Paulo, Brazil.

Background: Renal ischemia promotes renal hypoperfusion and hypoxia, leading to tubular epithelial damage, infiltration of inflammatory cells, and activation of pro-fibrotic pathways. Mitochondrial dysfunction plays a central role in cellular alterations induced by hypoxia. Mitochondria and their components can be secreted by cells and are found in the extracellular fluid in various forms: functional mitochondria, mitochondrial DNA, and mitochondrial vesicles. These mitochondrial components regulate cell metabolism, inflammation, and oxidative stress. Therefore, this study aimed to evaluate the role of mitochondria in an in vitro model of renal hypoxia.

Methods: Proximal tubular epithelial cells (mm55K) were cultured in normoxia (95% atmosphere air and 5% CO2) or hypoxia (94% N2, 5% CO2 and 1% O2) environment. The hypoxic stimulus length was previously determined using lactate levels by ELISA. Mitochondria were isolated from mm55K cells cultured in normoxia and hypoxia conditions and evaluated by flow cytometry and mitotracker-labeled. The mm55K cells cultured in normoxia or hypoxia were treated with either mitochondria isolated from normoxia or hypoxia conditions. The ability of mm55K cells to incorporate mitotracker-labeled mitochondria was evaluated by fluorescence microscopy. The gene expression of extracellular matrix markers (fibronectin, collagen IV, vimentin, and TGF-β), inflammation (p50 and p65), oxidative stress (NOX4, SOD-1, and UCP2), and apoptosis (caspase-3 and caspase-9) was assessed by RT-PCR.

Results: Hypoxia increased lactate concentration at 24, 48, and 72 hours in mm55K cells. There were no differences in the quantity of isolated mitochondria between the groups. Mitochondria stained with mitotracker were observed in the cytoplasm of mm55K cells, demonstrating the internalization of the isolated mitochondria by these cells. Under hypoxic stimulation, the gene expression of extracellular matrix markers, inflammation, oxidative stress, and apoptosis significantly increased. However, the effects on gene expression were attenuated with mitochondria treatment from both normoxia and hypoxia conditions.

Conclusions: Isolated mitochondria have a potential therapeutic role in reversing key markers in an in vitro model of cell injury caused by hypoxia.

SA-PO135

Effect of Ischemia-Reperfusion Injury on Mitochondrial Malondialdehyde Levels in Kidney Cortex and Medulla of Aged Rats

Marianna J. Zamlauski-Tucker, Bingwei Ye. *Ball State University, Muncie, IN.*

Background: The present study was undertaken to determine the effect of ischemia-reperfusion injury (IRI) on mitochondrial malondialdehyde (MDA) levels in kidneys from aged rats. MDA is a product of lipid peroxidation of cell and organelle membranes by free radiacals and is used as an indicator of oxidative stress. Kidney dysfunction in ischemia is associated with tissue damage caused by free radicals generated in IRI.

Methods: Anesthetized female Lewis rats (22 months of age) were used. Both renal pedicles were clamped for 60 min, followed by 60 min of reperfusion in the Experimental Group (n = 6). The kidneys were then harvested, separated into cortex and medulla, and homogenized. Kidneys in the Control Sham Group (n = 6) were not subjected to IRI before being harvested. The mitochondrial fractions were isolated by differential centrifugation and MDA levels were measured using a spectrophotometric assay. The water content of the cortex and medulla were determined to allow MDA levels to be expressed as nmol/g kidney dry weight. A Student's T Test was used to compare groups, and statistical significance was determined at $p< 0.05$. All data reported as X ± SEM.

Results: MDA levels were not changed in the kidney cortex of the Experimental Group.when compared to the Control Group. Mitochondrial MDA levels in the kidney cortex of the Experimental Group were 19.0 ± 1.8 nmol/ g kidney dry weight and 16.0 ± 1.6 nmol/g kidney dry weight in the Control Group. Mitochondrial MDA levels significantly decreased by 25% in the kidney medulla of the Experimental Group.when compared to the Control Group. Mitochondrial MDA levels of the kidney medulla were 30.5 ± 1.5 nmol/g kidney dry weight in the Experimental Group and 44.5 ± 2.6 nmol/g kidney dry weight in the Control Group.

Conclusions: The results suggest that in IRI the mitochondria in both kidney cortex and medulla may not be experiencing increased oxidative stress and damage, as indicated by no change or a decrease in MDA levels, respectively, after 60 min of ischemia.

SA-PO136

The FDA-Approved Drug Lasmiditan Augments Primary Mouse Renal Peritubular Endothelial Cell Wound Healing and Angiogenic Capacity

Austin D. Thompson,[1,2] Jaroslav Janda,[1] Rick G. Schnellmann.[1,3]
[1]The University of Arizona College of Pharmacy, Tucson, AZ; [2]Southwestern Environmental Health Sciences Center, Tucson, AZ; [3]Southern Arizona VA Health Care System, Tucson, AZ.

Background: Acute kidney injury (AKI) remains a significant public health concern with no FDA-approved treatments. AKI often involves mitochondrial dysfunction, tubular injury/necrosis, and microvascular damage/rarefaction, all of which exacerbate renal injury and increase the risk of developing chronic kidney disease. Pharmacological stimulation of mitochondrial biogenesis (MB) has been shown to enhance mitochondrial function and renal vascular recovery post-AKI; however, its role in relation to renal peritubular endothelial cell repair mechanisms remains unknown. To address this gap in knowledge, we conducted wound healing and tube formation assays using primary mouse renal peritubular endothelial cells (MRPEC) exposed to tumor necrosis factor-alpha (TNFα) in the presence/absence of lasmiditan, a HTR1F agonist known to induce MB in the renal cortices of mice.

Methods: Primary MRPEC were isolated as previously described by Thompson et al. (2023). For wound healing assays, MRPEC were seeded onto fibronectin-coated Ibidi wound healing dishes ($7x10^4$ cells/well) and incubated overnight in microvascular media (EGM-MV2). MRPEC were then treated with TNFα [100ng/mL] or vehicle [saline+0.1%DMSO], with/without lasmiditan [100nM], and chamber inserts were removed. Dishes were imaged 24h post-treatment. For tube formation assays, MRPEC were treated for 24h, as described above, and seeded onto growth factor reduced Matrigel-coated Ibidi 3D-angiogenesis μ-Slides ($1.5x10^4$ cells/well). Cells were incubated overnight in EGM-MV2 and imaged the following day. All images were analyzed via Ibidi FastTrackAI software.

Results: Lasmiditan-treated MRPEC exhibited 1.15- and 1.10-fold increases in wound closure and 2.40- and 7.21-fold increases in tubular branch formation, compared to vehicle- and TNFα-treated controls, respectively. Cells treated with both TNFα and lasmiditan exhibited 1.22- and 1.16-fold increases in wound closure compared to vehicle- and TNFα-treated controls, and a 2.98-fold increase in tubular branch formation compared to TNFα-treated cells.

Conclusions: Together, these data reveal that lasmiditan augments MRPEC wound healing and angiogenic capacity, independently and in response to TNFα-induced cellular injury, suggesting a potential role for lasmiditan treatment in promoting vascular recovery post-kidney injury.

Role of Sulfotransferase 1C2 in Vitamin D Signaling in Ischemic AKI Associated with Vitamin D Deficiency in Rats

Ana Carolina de Braganca,[1] Desiree R. Bernardo,[2] Mariana M. Nascimento,[2] Vitor A. dos Santos,[2] Maria H. Shimizu,[2] Antonio C. Seguro,[1] Daniele Canale,[2] Rildo A. Volpini,[1,3] Robert L. Bacallao,[4] David P. Basile,[4] Ana Carolina R. Viotto.[2]
[1]Hospital das Clinicas da Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil; [2]Universidade de Sao Paulo Faculdade de Medicina, Sao Paulo, Brazil; [3]Universidade de Sao Paulo Faculdade de Medicina de Ribeirao Preto, Ribeirao Preto, Brazil; [4]Indiana University School of Medicine, Indianapolis, IN.

Background: Cytosolic sulfotransferase enzymes (SULTs) facilitate inactivation/elimination of compounds from the body. SULTs expression is regulated by lipid-/xenobiotic-sensitive receptors, including vitamin D receptor (VDR). SULT1C2 seems to be regulated by vitamin D (VD) status via VDR, and may be an action pathway of VD in mitigating the renal disease progression. Our aim was to study the role of SULT1C2 in VD signaling in ischemic-AKI associated with VD deficiency in rats.

Methods: Male *Wistar* rats received a VD-depleted diet for 32 days (*protocol [P]1-48 h*), 37 days (*P2–7 days*) and 45 days (*P3–15 days*). Four groups of rats were assigned to each follow-up *P*: Sham; Renal ischemia/reperfusion (IR); IR with VD deficiency (d+IR); IR with VD replacement (R+IR). During the first 30 days of all *P*, only the rats in the Sham and IR groups received 40 IU/day of VD (maintenance dose [MD]) orally. On the 30th day of all *P*, the rats were submitted to sham or renal ischemia-reperfusion surgeries. On days 30th and 31st, VD was administered orally (80 IU/day attack dose) in the Sham, IR and R+IR groups of all *P*. Once *P1* was concluded, the VD MD was offered from the 32rd day until the end of *P2* and *3*. We evaluated plasma levels of 25(OH)D, creatinine and cystatin C as well as renal total tissue levels of VDR, immunoblotted for SULT1C2, and kinetic metabolite utilization rates (Biolog assay kit) in mouse S3 proximal tubule cells plus PAPS and SULT1C2 treated with VD.

Results: See figure 1. In vitro studies showed that VD treatment (125 pM-24 h) increased the utilization kinetics of malate, isocitrate, alpha-ketoglutarate, fumarate, and cis-aconitate.

Conclusions: Our study suggests that vitamin D status, via temporal modulation of VDR, regulated the expression of SULT1C2 in the progression of kidney disease after renal ischemia injury. Grants: FAPESP 2022/05519-3, 2022/07409-0, 2019/20840-0.

SA-PO138

The Nicotinic Acid Receptor HCA2 Regulates Progression of AKI and Development of CKD in Mouse Models of Sepsis and Postischemic Kidney Injury

Kambiz Zandi-Nejad,[1] Samir M. Parikh,[2] Ayumi Takakura.[3] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]The University of Texas Southwestern Medical Center, Dallas, TX; [3]Brigham and Women's Hospital, Boston, MA.*

Background: Patients with sepsis-associated AKI (SA-AKI) have longer ICU stay compared to patients with sepsis alone, higher mortality rate and higher requirement for renal replacement therapy. SA-AKI is also a risk factor for development and progression of CKD. However, pathophysiological mechanisms of SA-AKI remain poorly understood. We have previously shown that hydrocarboxylic acid receptor 2 (HCA2) is expressed in SA-AKI kidneys and in activated macrophages and that *Hca2* KO male mice have higher mortality than wild type mice in response to low-grade cecal ligation and puncture-induced sepsis (CLP-IS). We have also shown that renal tubular cell expression of the mitochondrial biogenesis factor PGC1α increases the local abundance of HCA2 ligand beta-hydroxybutyrate (β-OH B) and protects mice from experimental AKI. Thus, we hypothesized that activation of HCA2 may have a protective role in SA-AKI.

Methods: We used well-established models CLP (generate sepsis and SA-AKI), and ischemia reperfusion (IR).

Results: Here we show 100% of female *Hca2* KO mice died within 3 days after severe CLP whereas 77% of WT female mice were alive at 3 days after surgery and nearly 40% of the female WT mice were alive at 2 weeks. Conversely, activation of HCA2 by nicotinic acid or β-OH B improved survival in both male and female mice after severe CLP-IS by more than 40%. Deficiency of *Hca2* resulted in greater kidney interstitial fibrosis and pro-inflammatory cytokine production such as TNF-α after CLP-induced sepsis. Renal tubule specific overexpression of PGC1α (Pax8rtTA; tetO-PGC1α) improved survival and renal function during sepsis. However, deficiency of *Hca2* abolished the reno-protective effects of PGC1α during SA-AKI, suggesting that HCA2 may be required for PGC1α-induced renoprotection. Finally, we further investigated the role of HCA2 on AKI-to-CKD transition. In bilateral IR (a model of AKI) and in unilateral IR (a model of CKD), *Hca2*$^{-/-}$ mice exhibited greater renal damage (assessed by pathology and BUN) and increased pro-inflammatory cytokine production compared with wild-type mice.

Conclusions: Considered together, we propose that a positive feedback loop of HCA2 activation through PGC1α signaling may thwart maladaptive repair, thereby delaying or inhibiting transition from AKI to CKD.

SA-PO140

A Novel Pharmacological Agent, MARY1, Induces Mitochondrial Biogenesis and Restores Kidney Recovery in a Mouse Model of AKI

Paul Victor Santiago Raj, Jaroslav Janda, Rick G. Schnellmann. *R Ken Coit College of Pharmacy, University of Arizona, Tucson, AZ.*

Background: Acute kidney injury (AKI) is a rapid decline in renal function that can increase mortality and morbidity. Ischemia reperfusion (I/R) injury, hypovolemia and drug induced nephrotoxicity are common initiators of AKI. As there is no FDA-approved drug for the treatment of AKI, we have studied chemicals that induce mitochondrial biogenesis (MB), generation of new functional mitochondria, and restore renal function and recovery following AKI. A novel small molecule, MARY1, was tested *in vitro* and *in vivo* for MB, and restoration of vascular integrity and renal function following I/R induced AKI in mice.

Methods: Male ~7-8-week-old C57B/6NCrl mice were administered either MARY1 (0.3mg/kg) or vehicle daily, beginning 24h after I/R-induced AKI and continuing for 6 days (n=4-6/group). Kidneys were harvested, and gene and protein expression were analyzed using q-RT-PCR and immunoblot analysis. One way ANOVA followed by TUKEY multiple comparison test was used to determine statistical significance between treatment groups. A p-value of $p \leq 0.05$ was used to identify statistical changes and correct for multiple comparisons.

Results: MARY1 induced MB in primary cultured renal proximal tubule cells and in naive mice. Following bilateral I/R induced AKI, serum creatinine, kidney injury molecule 1 (KIM1) and Lipocalin 2 (LCN2) were maximally elevated at 24h. Daily administration of MARY1 for 6 days post AKI decreased serum creatinine, KIM1, LCN2, microvascular leakage and mitochondrial damage score compared to vehicle group. qRT-PCR and immunoblot analysis revealed restoration of PGC1α, mitochondrial proteins (OXPHOS, NDUFB8, TFAM), mitochondrial copy number and total ATP in kidney cortex. In addition, treatment with MARY1 for 6 days restored beta oxidation proteins (AMPKα, ACSM2A, ACADM), tight junction proteins (CLDN1, CLDN2, CD9) and cell senescence (p21) in kidney cortex in mice. Interestingly, administration of MARY1 for 6 days post I/R injury had no effect on inflammation markers such as NF-κB and its downstream pro-inflammatory cytokines and eNOS in kidney cortex in mice.

Conclusions: MARY1 restored mitochondrial, vascular, renal function and recovery through the induction of MB. However, MARY1 had no effect on inflammation. Future experiments will determine the efficacy of MARY1 in other kidney diseases (CKD, DN).

Ischemia Precondition Attenuates Ischemia-Reperfusion (I/R)-Induced AKI by Activating CLpP

Wenjia Xie, Chunsun Dai, Lei Jiang. *The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: Ischemic preconditioning (IPC) activates endogenous defense mechanisms to protect the kidney from ischemia-reperfusion (I/R) injury, but its protective mechanism is still unclear. The imbalance of mitochondrial protein homeostasis is closely related to the development of acute kidney injury (AKI). Casein hydrolytic protease P (CLPP) is a protease that maintains mitochondrial protein homeostasis by degrading unfolded proteins. In addition, the activation of mitochondrial unfolded protein response (UPR^{mt}) leads to the initiation of integrated stress response (ISR). Various stress factors promote phosphorylation of eukaryotic translation initiation factor 2α (eIF2α), inhibiting overall protein synthesis, and initiating stress response gene expression. However, it remains unclear whether activated eIF2α phosphorylation is involved in renal ischemic tolerance induced by IPC via upregulation of CLPP expression.

Methods: In vivo, I/R was used to induce AKI. To investigate the potential effects and mechanisms of different degrees of ischemia on renal injury, C57BL/6J mice underwent bilateral renal artery clamping for 5, 10, and 15 minutes followed by 6 hours of reperfusion to simulate mild, moderate, and severe renal injury. Subsequently, the protective effect of IPC on I/R was studied using ISRIB (ISR inhibitor), or systemic CLPP gene knockout.

Results: Moderate IPC significantly alleviates AKI induced by IRI in mice, as evidenced by decreased levels of BUN, Scr, KIM-1, and NGAL mRNA. In addition, IPC notably mitigates the morphological alterations induced by IRI, including loss of brush border, tubular formation, and reduced cell apoptosis. Mechanistically, we propose that IPC activates the ISR, thereby promoting upregulation of CLPP expression and reducing accumulation of unfolded proteins in mitochondria. Inhibition of the eIF2α activity, which is involved in the ISR, abolishes the protective effect of IPC on I/R-induced renal injury. Systemic CLPP gene knockout counteracts the protective effect of IPC on renal injury.

Conclusions: Phosphorylation of eIF2α and upregulation of CLPP contribute to the protective effect of IPC on I/R injury. This could offer more possibilities for clinical treatment, thereby improving patient prognosis and quality of life.

Effect of Renal Ceramidase on AKI

Xinling Liang, Yingwen Chen, Yuanhan Chen, Zhilian Li, Li Zhang, Jieyi Luo. *Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China.*

Background: This study was designed to explore the changes of renal metabolic enzymes related to sphingolipids in AKI and to clarify the important role of ceramidase, the metabolic enzymes of sphingolipids in AKI.

Methods: renal tissue of C57BL/6 mouse was taken on bilateral renal ischemia reperfusion injury (Bi-IRI) 2nd day and 28day for quantitative proteomic. Renal tissue ceramide and expression of renal tissue acid ceramidase and neutral ceramidase were performed at 6 hours, 12 hours, 18 hours, 24 hours, and 48 hours. Acid ceramidase inhibitor ARN14974, neutral ceramidase inhibitor C6-urea-ceramide, and ceramidase broad-spectrum agonist adiporon were administrated to IRI mice.

Results: Among the enzymes related to ceramide synthesis, serine palmitoyltransferase 1, serine palmitoyltransferase 2, and glucose ceramidase were elevated at both IRI 2d group and IRI 28d group, and ceramide synthase 2 was mildly elevated at IRI 2d group but the change was not statistically different at IRI 28d group. β-Hexosaminidase α-subunit was mildly elevated at IRI 2d group and markedly elevated. Among the ceramide-degrading enzymes, acid ceramidase was slightly elevated at IRI 2d group and significantly elevated at IRI 28d group, and neutral ceramidase was decreased at both IRI 2d group and at IRI 28d group. In the renal tissues of ischemia-reperfusion AKI mice, both total Cer(d18:1) and Cer(d18:1/16:0) levels were significantly elevated at 6 hours after IRI, but the levels gradually began to decline thereafter, and basically decreased to the level of the sham-operated group at 48 hours after IRI. The expression of renal acid ceramidase increased at IRI 48h group compared to the sham group, while the expression of neutral ceramidase decreased at IRI 48h group. Intervention with acid ceramidase inhibitor ARN14974 and neutral ceramidase inhibitor C6-urea-ceramide did not alleviate nor aggravate AKI. Ceramidase activator adiporon could significantly alleviate renal tubular injury, and improve renal function.

Conclusions: Renal ceramidase plays a protective role in AKI, activating ceramidase could promote renal function in AKI.

SA-PO143

Spatially Resolved Metabolomics to Discover Metabolic Alterations in PHF14-Associated Kidney Protection after Acute Kidney Injury

Jiaxin Chen, Cheng Xue, Zhiguo Mao. *Shanghai Changzheng Hospital, Shanghai, China.*

Background: Acute kidney injury (AKI) is a severe clinical syndrome,and a considerable part of AKI patients underwent maladaptive repair, resulting in renal fibrosis and chronic kidney disease. The epigenetic regulatory plant homologous domain Zinc finger protein-14 (PHF14) was proved to play a key role in inhibiting renal fibrosis after AKI, and its specific mechanism needs to be further clarified. This study aims to explore the mechanism of PHF14 inhibiting maladaptive repair after AKI from the metabolic level, so as to discover new therapeutic targets.

Methods: In this study, wild type (WT) and PHF14 knockout (PHF14-/-) mice were treated with folic acid (FA) to induce acute kidney injury. The renal function and histopathological were detected. Air-flow-assisted desorption electrospray ionization (AFADESI) was employed for metabolite analysis in cortical and medulla areas of mice kidney. Then the differential metabolites (DEMs) were identified respectively and KEGG enrichment was performed to identify the metabolic changes, and the DEMs were selected for mass spectrometry imaging analysis to determine their spatial distribution in the kidney.

Results: After 14 days of folic acid induction, renal function decreased, obvious inflammatory cell infiltration and fibrosis in kidney interstitial; while in PHF14-/- mice, were more serious. Compared with WT, different metabolites in the renal cortex and medulla of WT and PHF14-/- mice treated with FA were mainly concentrated in lipid metabolism, polyamine biosynthesis and TCA cycle, metabolites such as carnitine, glycerophospholipids, fatty acids, arginine, spermidine, succinic acid, malic acid and L-aspartic acid had significant changes in the kidney.

Conclusions: Spatial metabolomics was applied to investigate the changes of renal tissue metabolism after AKI, and the finding revealed the effect of PHF14 on renal metabolism after AKI, which proposed potential targets for the prevention and treatment of AKI.

Transcription Factor BACH1 in Promoting Mitochondrial Dysfunction of Kidney Ischemia-Reperfusion Injury via Mitochondrial Glutathione Depletion

Jun Li,[1,2] Xiaolin Li,[2] Hui Zhang,[2] Jingyao Lu.[2] *[1]Affiliated Hospital of Jiangnan University, Wuxi, China; [2]Jiangnan University Wuxi School of Medicine, Wuxi, China.*

Background: The hypothesis is that BACH1 induce mitochondrial glutathione(mtGSH) depletion through inhibiting SLC25A39 expression. The study aims to clarify the novel molecular pathogenesis of BACH1 on the renal ischemia-reperfusion induced-mitochondrial dysfunction, and provide a new intervention target for acute renal ischemia-reperfusion injury.

Methods: In vivo renal ischemia-reperfusion injury model(I/R) was established using C57BL/6J wild-type mice and BACH1 gene-knockout mice (BACH1-/-) respectively. Invitro anoxia-reoxygenation injury model(H/R) was established using human proximal tubular cells (HK-2) strain. BACH1 gene was silenced or overexpressed respectively, and SLC25A39 gene was also silenced. The effect of BACH1 on the transcriptional activity of SLC25A39 was detected by the luciferase reporter gene and Electrophoretic mobility shift assay (EMSA). The oxidative stress and mitochondrial function indexes were also measured.

Results: The renal expression of BACH1 increased, yet the renal expressions of SLC25A39 and mtGSH contents decreased significantly in patients with acute ischemic tubular injury and renal ischemia-reperfusion injury mice models. BACH1 deletion up-regulated renal expression of SLC25A39 and mtGSH contents, yet decreased mitochondrial oxidative stress index, leading to improved mitochondrial function in $BACH1^{-/-}$ mice following renal ischemia-reperfusion injury. In HK-2 cells subject to anoxia-reoxygenation injury, BACH1 gene overexpression down-regulated the expression of SLC25A39 and mtGSH contents, increased mitochondrial oxidative stress, leading to mitochondrial dysfunction. And BACH1siRNA up-regulated the expression of SLC25A39 and mtGSH contents, yet decreased mitochondrial oxidative stress, leading to improved mitochondrial function. Intriguingly, BACH1siRNA increased mtGSH contents and improved mitochondrial function in anoxia-reoxygenation HK-2 cells pretreated with GSH ethyl-ester. Luciferase reporter gene detection and EMSA confirmed the binding site between BACH1 and SLC25A39 promoter region.

Conclusions: BACH1 induced mitochondrial glutathione depletion through inhibition of SLC25A39 expression, leading to mitochondrial dysfunction of renal ischemia-reperfusion injury.

Protective Effect of Methylthioadenosine Phosphorylase (MTAP) Inhibition in AKI

Afaf Saliba, William B. Reeves, Kumar Sharma. Laboratory of Kumar Sharma, Center for Precision Medicine. *The University of Texas Health Science Center at San Antonio, San Antonio, TX*.

Background: Acute kidney injury (AKI) is sudden kidney failure, ranging from minor to severe, with multiple etiolgies. We identified adenine as a factor in diabetic kidney disease pathology, but its role in AKI is unknown. This study explores AKI metabolic mechanisms, focusing on adenine and the protective effects of inhibiting MTAP, the enzyme responsible for its production.

Methods: Male mice with ischemia-reperfusion injury (IRI) were prophylactically treated with dapaglifozin (10mg/kg) or MT-DADMe-ImmA (MTDIA 20 mg/kg) or vehicles with sham-operated mice as controls. For cisplatin-induced AKI, mice received MTDIA or vehicle before cisplatin (20 mg/kg), with saline controls. Plasma and kidney metabolomics were performed using capillary electrophoresis and liquid chromatography-mass spectrometry.

Results: Experimental IRI increased plasma metabolites, with adenine as the only nephrotoxic factor. Gene expression showed elevated inflammation and *Mtap*. Dapagliflozin modestly reduced kidney injury markers during ischemia, while MTAP inhibition significantly protected against AKI from IRI and cisplatin-induced models. MTAP inhibition normalized BUN, plasma creatinine levels and reduced kidney injury markers Kim-1 and Lcn2. PAS staining showed decreased necrotic tubules in MTDIA treated mice. MTAP inhibition reduced plasma LABA and pipecolate but not leucine and tyrosine. Kidney cortex adenine, pipecolate, GABA, and LABA were reduced, with increased MTA in MTDIA-treated mice. In cisplatin-induced AKI, MTDIA normalized BUN, Kim-1, and Lcn2 levels, and prevented tubular necrosis (Figure 1).

Conclusions: This study highlights the metabolic changes from IRI and identifies MTAP inhibition as a protective strategy against AKI. MTAP inhibition mitigates metabolic changes and improves cellular stress responses, suggesting its potential as a therapeutic target.

The IDH1-R132H Mutation Aggravates Cisplatin-Induced AKI by Promoting Ferroptosis through the Induction of NDUFA1 Methylation

Yanfang Xu. *Department of Nephrology, Blood Purification Research Center, the First Affiliated Hospital, Fujian Medical University, Fuzhou, China*.

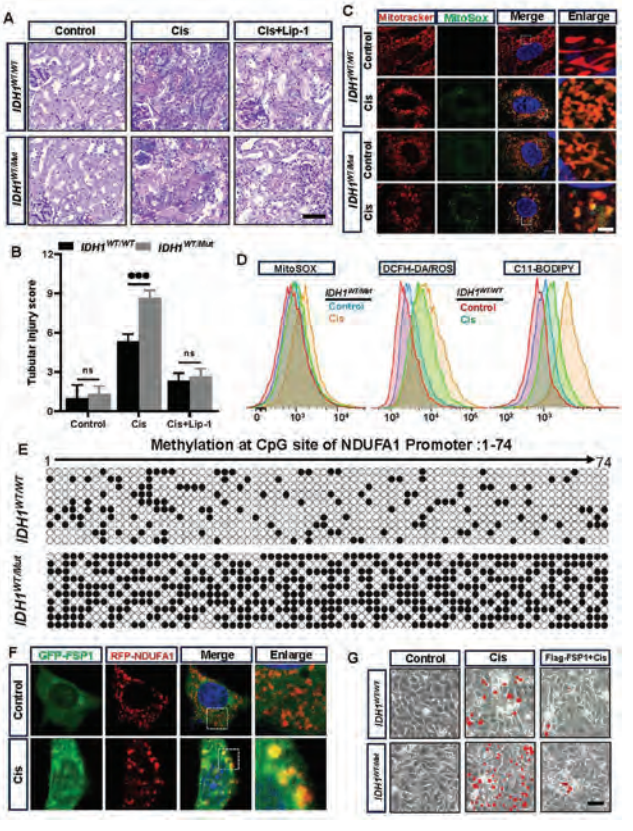
Background: The IDH1-R132H mutation is implicated in the development of various tumors. Whether cisplatin, a common chemotherapeutic agent, induces more significant renal toxicity in individuals with the IDH1-R132H mutation remains unclear.

Methods: We constructed a mouse model with the IDH1-R132H mutation to evaluate renal injury induced by cisplatin exposure. We explored key genes affected by the IDH1-R132H mutation using ferroptosis inhibitors, Reduced Representation Bisulfite Sequencing **(**RBBS) sequencing, and flow cytometry. Furthermore, we investigated the deeper mechanisms through overexpression and knockout of Ndufa1 and Fsp1.

Results: We revealed that the IDH1-R132H mutation exacerbates mitochondrial lipid peroxidation and dysfunction in renal tubules, rendering the kidneys more susceptible to cisplatin-induced ferroptosis. Further mechanistic investigations revealed that the IDH1-R132H mutation upregulates the methylation level of the NDUFA1, leading to the suppression of NDUFA1, disrupting the interaction between NDUFA1 and FSP1, resulting in the accumulation of lipid peroxidation and ferroptosis, thereby promoting AKI.

Conclusions: This study elucidates a novel mechanism underlying cisplatin-induced nephrotoxicity and provides valuable insights for the development of personalized treatment strategies for tumor patients carrying the IDH1-R132H mutation.

Funding: Government Support - Non-U.S.



IDH1-R132H mutation aggravates cisplatin-Induced AKI

(A, B) The IDH1-R132H mutation exacerbates kidney injury, which can be partially reversed by the ferroptosis inhibitor Lip-1. (C, D) IDH1-R132H mutation increases mitochondrial lipid peroxidation. (E) IDH1-R132H mutation leads to an upregulation of NDUFA1 methylation levels. (F) There is a direct interaction between NDUFA1 and FSP1. (G) Overexpression of FSP1 exerts a protective effect.

Sex-Specific Differences in Branched Chain Amino Acid (BCAA) Catabolism and Mitochondrial Respiration in Healthy and Injured Kidneys

Samaneh DiMartino, Sandeep K. Mallipattu, Sian E. Piret. *Stony Brook University Renaissance School of Medicine, Stony Brook, NY.*

Background: Proximal tubule (PT) cells are highly susceptible to acute kidney injury (AKI) and undergo significant changes in cellular metabolism, directly contributing to injury. PT cells use fatty acid oxidation (FAO) and branched chain amino acid (BCAA) catabolism to generate ATP, however during AKI, both pathways are downregulated. Women and female mice are protected from AKI versus men and male mice. Our aim was to investigate BCAA catabolism in male and female human subjects and mice PT cells.

Methods: Publicly available RNA-sequencing data from kidney cortex of males and female subjects with and without AKI (three per group) were used for differential gene expression and pathway enrichment analysis using Seurat and EnrichR. Primary PT cells from *Bckdhb*$^{fl/fl}$ male and female mice were infected with adenoviral GFP (control) or CRE to excise *Bckdhb*, which encodes a crucial subunit of BCKDH, the rate-limiting enzyme in BCAA catabolism, followed by qRT-PCR. Wildtype (WT) primary PT cells were treated with aristolochic acid I to induce injury, and BT2 to activate BCKDH and increase BCAA catabolism. All primary PT cells underwent live cell metabolic assays using a Seahorse bioanalyzer.

Results: The BCAA catabolism pathway was significantly downregulated in males and females with AKI compared to healthy controls. However, more genes in the pathway were downregulated in males than females, and the downregulated genes were different between males and females. For example, *BCKDHB* was significantly downregulated in males but not females. To determine the specific role of *Bckdhb*, CRE recombination was undertaken in *Bckdhb*$^{fl/fl}$ primary PT cells, resulting in *Bckdhb* mRNA knockdown of 60% and 80% in male and female cells, respectively. Seahorse assays showed significant downregulation of basal respiration and mitochondrial ATP production rate in male cells but not in female cells upon *Bckdhb* knockdown, with no significant differences in glycolytic ATP production rate. BT2 treatment protected mitochondrial function in WT male primary PT cells treated with AAI but not female primary PT cells.

Conclusions: These findings suggest that BCKDH may play a more important role in males versus females, both in healthy and injured kidneys, which may have implications for targeted therapeutic strategies for AKI.

MicroRNA-mRNA Interactions in Cisplatin-Induced AKI to CKD

Hisakatsu Sone, Tae Jin Lee, Byung Rho Lee, Dan Heo, Sang-Ho Kwon. *Augusta University Medical College of Georgia, Augusta, GA.*

Background: Chemotherapy with cisplatin can lead to chronic kidney disease, complicating cancer prognosis. Understanding the interactions between microRNAs (miRNAs) and their target messenger RNAs (mRNAs) can shed light on the biological processes involved in cisplatin-induced kidney injury.

Methods: We used small and total RNA sequencing, and chimeric-eCLIP sequencing to identify pairs of miRNAs and their target mRNAs in the kidneys of cisplatin-injured male mice. These interactions were confirmed using various methods, including database searches, RNAscope, RT-qPCR, immunofluorescence, and immunoblotting.

Results: We identified 55,794 direct miRNA-mRNA interactions in the kidneys. Among the interactions, a group of cisplatin-induced miRNAs enriched with select mRNAs affects mitochondrial metabolic pathways. Specifically, the cisplatin-induced miRNAs, miR-429-3p and miR-21a-5p, suppress the pathway that breaks down branched-chain amino acids (BCAAs) in the proximal tubule, leading to ferroptotic cell death. In contrast, stimulating BCAA catabolism in the injured kidneys reduced ferroptosis and inflammation.

Conclusions: In vivo renal miRNA-mRNA interaction mapping identifies the role of branched-chain amino acid catabolism in ferroptotic proximal tubular cell death. Our findings suggest potential therapeutic benefits in modulating the branched-chain amino acid pathway to alleviate nephrotoxicity.

Controlling p53 Responses in AKI

Shin-ichi Makino, Amy Zollman, Pierre C. Dagher, Takashi Hato. *Indiana University School of Medicine, Indianapolis, IN.*

Background: The guardian of the genome p53 is essential for controlling the cell cycle, genome integrity, and tissue repair. p53 is also an important determinant of AKI outcomes. However, limited strategies are available to control the p53 expression and facilitate tissue recovery.

Methods: Multiple models of AKI were used in our study. The full-length cDNA from endotoxin-treated mouse kidneys was sequenced using Nanopore long-read sequencing. CRISPR knock-out strategy was used to produce a cryptic exon knock-out mouse. For *in vitro* experiments, several antisense nucleotides targeting the short isoform were synthesized and transfected into HEK cells. CRISPR knock-in strategy was also used to generate p53 mutant human cell lines.

Results: We identified a previously uncharacterized short transcript consisting of the first p53 canonical exon and a cryptic exon embedded in the first p53 intronic region. We found that this short transcript emerges under various stress conditions. To determine the role of this transcript, we generated a mouse model in which the cryptic exon is genetically removed. We found that the lack of the cryptic exon heightens the expression of the canonical p53 upon stress challenges. Notably, mice lacking the short transcript were protected against ischemia-reperfusion injury with a significant increase in the expression of the canonical p53 in various cell types. Next, we designed and screened splice-switching antisense oligonucleotides. Our screening revealed specific antisense targeting sites that enabled us to differentially control the expression of the short transcript and canonical p53. Specifically, we found that targeting the transcription termination site results in the upregulation of the short transcript, linking transcription control and p53-mediated stress responses.

Conclusions: We have identified a strategy to control the expression of p53 in the kidney. This strategy involves targeting the stress-responsive cryptic exon, opening the door for finetuning p53 responses in AKI.

DHHC6-Mediated SDHB Palmitoylation Protects against Tubular Cell Death and AKI

Qing Hou, Chunsun Dai. *The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: Acute kidney injury (AKI), a syndrome characterized by an abrupt of loss of kidney function, is associated with considerable morbidity and mortality. The tubular cell injury and death contributes to the initiation and progression of AKI. Palmitoylation, a reversible post-translational modification, is involved in the development of renal fibrosis. However, the role of palmitoylation in tubular cell survival and AKI remains unclear. We aimed to investigate the role and mechanism of palmitoylation in tubular cell survival and AKI.

Methods: 1.Acyl–biotin exchange,ABE; 2.Blue native polyacrylamide gel electrophoresis,BN-PAGE.

Results: 1. The level of protein palmitoylation was markedly downregulated in the kidney of mice after UNx+IRI surgery. Analysis of the transcription levels of DHHCx in the GSE98622 database revealed significant downregulation of *Zdhhc6* in the murine renal tissue of AKI. The expression of DHHC6 was reduced in tubular cells of AKI mice and patients. 2. To elucidate the role of DHHC6 in tubular cell survival and AKI, we generated DHHC6-deleted tubular cells mice by Cre/Loxp system and DHHC6 overexpressing mice by renal in situ injection of adeno-associated virus. We found that DHHC6 deficiency could exacerbate IRI induced renal injury, while overexpression of DHHC6 exerted renal protective effects. DHHC6 deficiency in vitro promoted tubular cell mitochondrial dysfunction and cell death, and significantly downregulated SDHB abundance. SDHB knockdown also promoted tubular cell death. 3. ABE assays showed that SDHB could be palmitoylated, and DHHC6 deficiency reduced, while DHHC6 overexpression elevated the palmitoylation level of SDHB. Immunoprecipitation and immunofluorescent analyses revealed the interaction of DHHC6 and SDHB. Furthermore, DHHC6 deficiency promoted the degradation of SDHB and reduced the activity of mitochondrial complex II. Based on the proteomics of palmitoylation modification and CSS/GPS-palm prediction results, the Cys115 site of SDHB was identified as its palmitoylation modification site. The palmitoylation of Cys115 was also associated with SDHB degradation and tubular cell death.

Conclusions: In summary, this study revealed that the palmitoyltransferase DHHC6 protects against UNx+IRI induced AKI and tubular cell death by catalyzing SDHB palmitoylation.

Dapagliflozin Attenuates Tubular Injury and Ferroptosis after AKI in Diabetic and Nondiabetic Mice

Tetta Sato,[1] Shintaro Ide,[1] Kana Ide,[1] Ayano Yamaguchi,[1] Naoya Teramoto,[1] Yoshiro Maezawa,[1] Koutaro Yokote.[2] *[1]Chiba Daigaku Daigakuin Igaku Kenkyuin Igakubu, Chiba, Japan; [2]Chiba Daigaku, Chiba, Japan.*

Background: Diabetes Kidney disease (DKD) is the most common cause of chronic kidney disease (CKD) and end-stage renal disease. Diabetic patients are at a higher risk of acute kidney injury (AKI), which can lead to the rapid deterioration of kidney function, suggesting that AKI is a potential risk factor for DKD without albuminuria. Although several studies have shown sodium-glucose cotransporter 2 (SGLT2) inhibitors have a renoprotective effect in both diabetic and non-diabetic patients, it remains unclear whether SGLT2 inhibitors are protective in AKI and its transition to CKD, with or without diabetes.

Methods: To clarify the effect of an SGLT2 inhibitor in AKI and its mechanism, we performed unilateral ischemia-reperfusion injury (uIRI) in type 2 diabetic mice (db/db). We then divided these mice into two groups: one treated with Dapagliflozin (DAPA), an SGLT2 inhibitor, and the other treated with vehicle. We also performed uIRI on C57B6J (WT) mice and compared kidney phenotypes between the DAPA and vehicle groups to reveal this effect independently of glycemic control. We used histological analysis, immunofluorescence, and quantitative PCR to evaluate kidney injury.

Results: Db/db uIRI kidneys with vehicle showed severe tubular injury (ex. *Vcam1, Havcr1*), accumulation of inflammatory cells, and fibrosis. In contrast, treatment with DAPA significantly reduced tubular injury in db/db uIRI kidneys, indicating a protective effect of DAPA against AKI and AKI to CKD transition. This protective effect was also seen in WT uIRI kidneys. To understand the mechanism, we focused on ferroptosis, a non-apoptotic cell death process that plays a key role in diseases, such as DKD, AKI, and AKI to CKD transition. Db/db uIRI kidneys and WT uIRI kidneys with the vehicle showed increased ferroptosis, characterized by 4-Hydroxynonenal (4HNE) and TUNEL positivity. However, treatment with DAPA reduced these markers in both groups.

Conclusions: Our data demonstrate that Dapagliflozin attenuates kidney tubular injury and reduces ferroptosis, thereby mitigating AKI to CKD transition after AKI. The renoprotective effect of SGLT2 inhibitors appears to be mediated through suppressing ferroptosis. These findings would provide new insights into the potential treatment of AKI in patients with diabetes.

Sex Differences in Dynamics of Necroptosis in Ischemia-Reperfusion-Induced AKI

Minh H. Tran. *University of South Florida, Tampa, FL.*

Background: Ischemia reperfusion induced injury (IRI) is an important cause of acute kidney injury (AKI). Interruption of the arterial blood supply to a donor kidney leads to renal hypoxic injury and cell death, but blood flow restoration also result in reperfusion injury and organ dysfunction. Necroptosis has been recently identified as an essential factor in the pathogenesis of IR-AKI. However, sex differences in the dynamics of necroptosis in kidney IRI have not been a focus of study until now.

Methods: Male and female C57BL/6J mice (n=3-5 male or female mice/ group) were induced AKI via bilateral renal pedicle clamping for 18 minutes at 37 degrees Celsius. Plasma, urine and kidney tissue were collected at 0, 3, 6, 12, 24, 48, and 72 hours post reperfusion and plasma creatine, BUN and morphological damage were assessed by PAS staining and TUNEL staining. Necroptosis activation was equantified by the phosphorylation status of the necroptosis factors RIPk1, RIPk3, MLKL, and inflammatory factors (IL-6, IL-10 and TNF-α) post I/R injury. The effects of different sex hormone on the dynamic of necroptotic activation was assessed by ovariectomy to the female mice followed by IR-AKI. Kidney injury and function were evaluated and compared.

Results: Activation of necroptosis started at 3 hours post reperfusion in male mice, and around 6 hours after reperfusion in the female mice. The male mice exhibited a stronger and longer activated necroptosis status than females based on the phosphorylation measurement by western blotting. This sexual dimorphism closely correlated with sex differences in kidney injury dynamics. The plasma creatinine was 0.35±0.04 and 0.32±0.06 mg/dL for male and females, respectively, at 3 hours of reperfusion. Which dramatically increased to 2.05±0.18 at 48 hours of reperfusion for the males and gradually increased to 0.94±0.13 mg/dL. Deficiency in sex hormone mitigated the sex difference in the dynamic of the necroptotic activation and consequently in kidney injury.

Conclusions: Our study is the first to describe the sex differences in the dynamics of necroptosis and necroinflammation in a mouse model of IRI-AKI. Our findings provide a different time frame in monitoring kidney injury in males and females and suggest that although treatments targeting necroptosis may be effective even if given 3 hours after reperfusion, the treatment in male should start earlier than females.

SA-PO153

Tryptophan Breakdown Product 3-Hydroxyanthranillic Acid Promotes AKI Recovery under Hypoxic Conditions

James O'Sullivan, Gabriella Borkowski, Rajni Sharma, Ratnakar Tiwari, Pinelopi P. Kapitsinou. Kapitsinou Lab. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: We and others have demonstrated that hypoxic preconditioning is an effective strategy to protect against renal ischemia reperfusion injury (IRI). While more clinically relevant, however, the effect of hypoxia exposure after IRI remains undefined. Here, by profiling the effects of systemic hypoxia exposure on kidney repair after IRI, we identified the tryptophan metabolite 3-hydroxyanthranillic acid (3HAA) as a metabolite promoting adaptive repair. Beneficial effects of 3HAA reported include oxidative stress reduction via NRF2 activation, anti-ferroptosis, ROS-scavenging and enhanced longevity.

Methods: Male C57/BL6 mice were subjected to unilateral IRI and 6 hours later were placed in hypoxic chamber at 8% O_2 or normoxia for 72 hours post-IRI. Kidneys and serum collected for RNA-seq and HPLC metabolite profiling. HK2 cells were maintained under defined growth medium, treated with 3HAA (100μM or 200μM) and/or IL1β (10ng/mL) for 24 hours.

Results: 72 hours post-IRI, Hx mice had significantly lower injury scores histologically (2.2±0.4 Hx vs 3.3±0.5 Nx, P=0.02) and significantly lower KIM1 mRNA (0.8±0.2 Hx vs 2±0.5 Nx, P=0.0002). RNA-seq analysis followed by KEGG pathway analysis showed significant upregulation of tryptophan metabolism and glutathione metabolism, while inflammatory response was the top downregulated pathway. TRRUST implicated NRF2 as a key TF (P=3e-8), regulating many highly upregulated genes such as glutathione S-transferase alpha (GSTA) genes. Metabolite profiles indicated 3HAA as a key metabolite increased by hypoxia in serum (8.6-fold, P=0.02) and kidney (2.2-fold, P=0.005) compared to normoxia. In HK2 cells, 24-hour treatment with 3HAA 100μM increased GSTA1 expression by 3.1-fold (P=6e-4 vs untreated). Under IL1β-stimulation, 3HAA 100μM or 200μM reduced CCL2 expression by 4.3-fold (P=0.03) and 17.6-fold (P=0.01), respectively, compared to IL1β-stimulation alone.

Conclusions: Systemic hypoxia after IRI promotes adaptive kidney repair and reduces inflammation, a response that is associated with increased 3HAA and NRF2 activation. In vitro work indicated 3HAA alone counteracts inflammation in tubular epithelial cells and promotes anti-oxidative defense. Our findings identify a hypoxia/3HAA axis that can be exploited as therapeutic strategy in AKI, warranting further mechanistic investigation.

Mechanism of Nicotinamide N-methyltransferase (NNMT) Regulating Heterogeneous Nuclear Ribonucleoprotein (HnRNP) D Promoting Ferroptosis in Renal Tubular Epithelial Cells and Aggravating Acute Kidney Injury

Yuebo Huang, Hui Peng. *Sun Yat-sen University, Guangzhou, China.*

Background: The study has shown that AKI is a significant risk factor for CKD and ESRD, seriously endangering human health. Exploring the mechanisms of AKI and finding effective treatment and intervention measures is of great clinical significance. Recently, Xu et al. used single-cell mRNA sequencing (scRNA-seq) to show that the ferroptosis pathway was significantly activated in proximal renal tubular epithelial cells (PTCs) of AKI mouse models. Therefore, ferroptosis could be a potential therapeutic target, which can provide new strategies for the treatment of AKI.

Methods: First, we screened the human GEO AKI database GSE30718, and enrichment analysis based on differential genes revealed significant enrichment of the ferroptosis pathway. Further screening of candidate gene nicotinamide N-methyltransferase (NNMT) in the ferroptosis pathway through machine learning for further research. Through combined human and mouse AKI scRNA-seq analysis, we found that NNMT is highly expressed in renal tubular epithelial cells of AKI renal tissue. Then, we overexpressed or silenced NNMT protein in HK-2 cells, changes in cell ferroptosis markers and release of inflammatory factors were detected by Western blot, real-time PCR, ELISA, immunofluorescence, and flow cytometry. Next, we used LC-MS/MS to detect potential binding proteins of NNMT and then validated it by using CO-IP and immunofluorescence.

Results: Silencing or overexpression NNMT can improve or exacerbates H/R and Cis-induced ferroptosis and inflammatory cytokine release in HK-2 cells. By using LC-MS/MS analysis, it was found that there is a potential interaction between HnRNPD and NNMT. Further validation of the binding between NNMT and HnRNPD was conducted through CO-IP and immunofluorescence, and NNMT increased the expression of HnRNPD protein by inhibiting the degradation of HnRNPD ubiquitinated proteasomes. RIP experiments confirmed that HnRNPD can stabilize the expression of ATF3 protein expression and lead to ferroptosis.

Conclusions: Our findings indicate an upregulation of NNMT expression in renal tubular epithelial cells during AKI. NNMT serves to stabilize ATF3 protein expression by impeding the ubiquitination and proteasome-mediated degradation of HnRNPD. This mechanism leads to lipid peroxidation and ferroptosis in renal tubular epithelial cells, thereby fostering the onset and progression of AKI

Hydrogen Sulfide Alleviates Cisplatin-Induced AKI by Targeting Pyroptosis

Zhenyuan Han,[1,2] Yutao Jia,[1,2] Tianyu Deng,[1,2] Zhiyun Ren,[1,2] Weiwan Wang,[1,2] Xiaoyan Wang.[1,2] *[1]Department of Nephrology, Nanjing BenQ Medical Center, The Affiliated BenQ Hospital of Nanjing Medical University, Nanjing, China; [2]The Core Laboratory, Nanjing BenQ Medical Center, The Affiliated BenQ Hospital of Nanjing Medical University, Nanjing, China.*

Background: Our previous studies have demonstrated that GYY4137, a long-acting hydrogen sulfide(H_2S) donor, exerts a remarkable protective effect on diabetic renal damage by affecting multiple ROS-associated enzymes. According to animal experimental research reports, exogenous H_2S donors alleviate the renal toxicity caused by cisplatin, mainly through anti-inflammatory, antioxidant, autophagy, etc. However, the effect of H_2S on pyroptosis in cisplatin-induced AKI(cis-AKI) is currently unclear.

Methods: Male C57BL/6J mice (7-8 weeks old), were randomly divided into 3 groups (n=7/group). Cisplatin (20 mg/kg) was given by a single intraperitoneal injection to both cisplatin group and cisplatin+GYY group, the latter was given GYY4137(100mg/kg) by daily intraperitoneal injection for 4 times, a day before cisplatin. The control mice were given 0.9% saline. Blood and kidney samples were collected after the mice were sacrificed on day 3 of cisplatin. Data was shown as mean±SE, while significance($P<0.05$) was achieved by one-way ANOVA, and Holm-Sidak posthoc test.

Results: Compared to the control group, cis-mice showed an increase in serum creatinine (82.22±6.05 vs 57.3±2.4, umol/L) and urea nitrogen (23.3±1.1 vs 6.5± 0.3, mmol/L). Histological analysis also revealed severe damage to the renal cortex, characterized by vacuole-like degeneration of tubular epithelial cells, loss of brush border, and tubular cell necrosis. There were increases of NLRP3 (121.9±5.2) and GSDMD (127.3±1.7) in cis-group, indicating an activation of classical pyroptosis. In the non-classical pyroptosis pathway, caspase3 (132.9±2.1) and GSDME (209.1±8.2) were significantly elevated in response to cisplatin treatment. Treatment with GYY4137 mitigated serum creatinine levels (63.6±4.6) and blood urea nitrogen (18.1±1.7) and reduced histological damage to the renal cortex in cis-mice. Moreover, it normalized or reduced the cis-mediated increases in pyroptosis-related proteins, including caspase3 (106.9±5.9), GSDME (173.8±11.2), NLRP3 (88.3±4.3), and GSDMD (97.1±6.4).

Conclusions: Exogenous hydrogen sulfide may alleviate cis-AKI via inhibiting caspase3-dependent or independent pyroptosis.

NINJ1 Has a Pathogenic Role in Kidney Ischemia-Reperfusion Injury

Jianyong Yin, Niansong Wang. *Department of Nephrology, Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China.*

Background: Programmed cell death (PCD) plays a pivotal role in the pathogenesis of AKI. It has been proved that various PCDS such as pyroptosis, necroptosis and ferroptsis can induce plasma membrane rupture (PMR) and release of damage associated molecular patterns (DAMPs), further activating inflammatory responses, and lead to kidney tissue damage. PMR is the common ultimate event in a variety of lytic cell death. Nerve injury-induced protein 1 (NINJ1) is a cell adhesion molecule highly expressed in immune cells and kidney. Recent studies indicate that NINJ1 is a key executive protein of PMR during various PCD. Therefore, we speculate that NINJ1 mediates PMR in tubule cells during PCD and subsequently activates inflammation, which may be the primary molecular mechanism of its pathogenic role in AKI.

Methods: We examined renal NINJ1 oligomerization in patients with AKI and AKI mice model. Male C57BL/6J were subjected to bilateral renal ischemia-reperfusion to induce AKI. Tubule cell-specific NINJ1 knockout mice was utilized to determine the pathogenic role of NINJ1 in AKI. Renal function, tubular cell death, release of HMGB1 and pro-inflammatory cytokines was assessed. Besides, we determined the role of NINJ1 in cell damage induced by hypoxia reoxygenation in primary renal tubular epithelial cells.

Results: The expression of NINJ1 was significantly increased in AKI model and kidney specimens of AKI patients. Tubular cell-specific knockout of NINJ1 remarkably ameliorated ischemia-reperfusion induced renal dysfunction and pathological injury. Moreover, tubular cell death and the levels of HMGB1, IL-1β were significantly blunted in NINJ1 knockout mice compared with WT mice. Additionally, hypoxia and reoxygenation induced NINJ1 oligomerization in renal tubular cells, while knockout of NINJ1 significantly decreased the LDH, which is the standard marker of PMR.

Conclusions: NINJ1 mediated PMR and subsequent release of DAMPs is critically involved in the pathogenesis of AKI and blockade of NINJ1 may be a novel therapeutic strategy for the treatment of AKI.

SA-PO157

Estrogens Protect against AKI by Regulating Ferroptosis Sensitivity

Wulf Tonnus. Linkermann Lab. *Technische Universitat Dresden, Dresden, Germany*.

Background: Epidemiological studies demonstrated that premenopausal women experience less episodes of acute kidney injury (AKI) than males, and that estrogen supplementation protects concomitantly in menopause. This falls in line with the known phenomenon that female mice are protected against ischemia/reperfusion injury. However, molecular mechanisms of this phenomenon remain ill-defined. As ferroptosis, an iron-dependent form of regulated necrosis, plays a crucial role in the pathogenesis of AKI, we hypothesized that estrogens modulate sensitivity to ferroptosis.

Methods: The effects of estrogens on ferroptosis sensitivity were investigated in various cell culture assays. Mechanistic insights were derived from western blots, and confirmed by CRISRP-mediated knock-outs. Radical trapping mechanisms were tested in cell free systems, whereas translational relevance was established via isolated renal tubules of various species. Complex murine studies tested proposed mechanisms in AKI models.

Results: 17-beta-estradiol (E2) protected against ferroptosis and associated lipid peroxidation in cell culture. Mechanistically, E2 quinone derivates 2OH and 4OH were identified as potent lipophilic radical trapping antioxidants, which were regenerated by the oxidoreductase FSP1 (AIFM2). Interestingly, inhibition of FSP1 sensitized female cells to ferroptosis and increased the E2 doses required for protection. Furthermore, E2 induced several antiferroptotic programs via genomic functions, including increased expression of FSP1, generation of hydropersulfides, and downregulation of ether lipids via reduced AGPS expression. Knock-out studies confirmed the functional relevance of these mechanisms in cell culture, whereas isolated tubuli from several mammalian species demonstrated the conservation of these mechanisms. Studies utilizing the murine IRI model proved the functional relevance of these mechanisms upon AKI.

Conclusions: In summary, we describe the molecular underpinnings of ferroptosis resistance in female mammals. These findings may explain epidemiological data on female resistance to AKI, and could lead the path to sex-specific interventions in prevention and treatment of human AKI.

KRT20 Protects against Ferroptosis of Renal Tubular Cells by Inhibiting Extracellular Secretion of PRDX2 in AKI

Lijun Yin, Anqun Chen. *The Second Xiangya Hospital of Central South University, Changsha, China.*

Background: Acute kidney injury (AKI) exhibits high incidence and morbidity. Ferroptosis of renal tubular cells is a key event driving tubular injury in AKI, but the mechanism of which is unclear. Cytokeratin 20 (KRT20), a biomarker of tubular injury, is an intermediate filament protein whose role in renal tubular injury remain elusive. Intracellular peroxiredoxin2(PRDX2) is closely related to ferroptosis, but the relationship between KRT20 and PRDX2 has not been reported in any studies.

Methods: Bulk RNA-seq and snRNA-seq of kidneys from the AKI mouse model in public databases, were used to analyze transcript levels of KRT20 in AKI, which was validated in two AKI mouse models (cisplatin-induced AKI and ischemia-reperfusion(IR) AKI) and clinical kidney biopsy specimens. Renal proximal tubule-specific *Krt20* knockout mice in vivo, knockdown and overexpression of KRT20 in vitro, were used to construct two AKI models to assess the role of KRT20 in AKI. Luciferase reporter assays, CHIP-PCR and IP-MS were used to explore the transcription factors and the downstream candidates target of KRT20, respectively. CO-IP and truncating mutation were used to explore the binding domain between KRT20 and candidate targets. Whether urinary PRDX2 could be used as a promising predictor for AKI was investigated in a patient cohort.

Results: KRT20 was dramatically increased in renal tubules upon injury in the AKI mouse model and AKI patients, which might be regulated by the transcription factor Fosb. The renal tubular specific knockout of *Krt20* aggravated cisplatin- and IR-induced AKI in mice. The intervention of KRT20 affected ferroptosis of tubular cells in vitro. Mechanistically, KRT20 bound with PRDX2, whose secretion was dependent on ALG-2-interacting protein X(Alix), to retain its intracellular location to prevent renal tubular cell ferroptosis and attenuate AKI. KRT20 and Alix competitively bind to the NTD domain of PRDX2, thus affecting the secretion of PRDX2. Urinary concentrations of PRDX2 significantly increased in patients who underwent partial nephrectomy, which positively correlated with the renal tubular injury biomarker, such as KIM-1 and NGAL.

Conclusions: This study discovered a Fosb-KRT20-PRDX2 axis in the progression of AKI, which warrants future exploration as a therapeutic targets. In addition, PRDX2 may be a noninvasive biomarker for renal tubular injury.

Heat Acclimation Attenuates Ferroptosis and Prevents Heat Stress-Induced AKI by Enhancing Mitophagy

Yongwei Song,[1] Wenting Chen,[1] Wang Ling,[1] Yang Xuesen,[2,3] Dai H. Zi.[1] *[1]Department of Rheumatology and Clinical Immunology, Daping Hospital, Army Military Medical University, Chongqing, China; [2]Department of Tropical Medicine, Army Military Medical University, Chongqing, China; [3]Key Laboratory of Extreme Environmental Medicine, Ministry of Education of China, Army Military Medical University, Chongqing, China.*

Background: Exposure to a intense heat stress environment can lead to acute kidney injury (AKI), while heat acclimation(HA) can prevents the kidney against ischemic injury induced by intense heat stress. However, the mechanism underlying of the nephroprotective effect of HA remains unclear. It has been reported that ferroptosis is involved in heat stress-induced AKI. But,It is still unclear whether heat acclimation can exert renal protective effects by reducing ferroptosis. Furthermore, Mitophagy may influence the development of AKI through regulating intracellular iron metabolism, but it has not been reported in heat stress-induced AKI.

Methods: C57BL / 6 mice were divided into control group (CON), heat acclimation group (HA), heat stroke group (HS), heat stroke + heat acclimation group (HS+HA), and

heat stroke+heat acclimation+3-MA group (HS+HA+3-MA). Among them, the mice in the HS group were kept in a high-temperature environment to establish the HS model. The mice in the HS+HA group were kept in low-temperature environment for 30 days to establish the HA model, followed by inducing the HS model. Mice in the HS+HA+3-MA group were subjected to high heat stress after consecutive intraperitoneal injection of 3-MA (20 mg/kg/day) for the last 7 days of the constructed HA model. The levels of mitophagy and ferroptosis were assessed in each group of mice.

Results: In the HS group, there was a significant increase ferroptosis. Moreover, heat acclimation significantly enhanced mitophagy and alleviated HS-induced ferroptosis. In contrast, Inhibiting mitophagy exacerbated ferroptosis and reversed the renoprotective effect of the heat acclimation.

Conclusions: Heat acclimation may prevent heat stress-induced acute kidney injury by alleviating ferroptosis through enhanced mitophagy.

Remote Ischemia Precondition Protects against Kidney Ischemia-Reperfusion Injury (IRI) through Apoptosis-Associated Vesicles Carrying MIF Protein

Nieke Zhang,[1,2] Yi Xia,[1,2] Ming Chen,[1,2] Guangyuan Zhang.[1,2] [1]*Southeast University, Nanjing, China;* [2]*Southeast University Zhongda Hospital Department of Urology, Nanjing, China*.

Background: Previous study showed remote ischemia precondition (rIPC) protected against kidney ischemia-reperfusion injury (IRI) through extracellular vesicles (EVs) delivering, however the mechanism remains unknown. It's showed apoptosis-induced compensatory proliferation signaling related vesicles (ACPSVs) could transmit proliferation signal to surrounding cells. In this study, we aim to investigate the role of ACPSVs in renal IRI after rIPC and its underlying mechanism.

Methods: We established a bilateral hind limb IPC followed by unilateral renal IRI rat model and a serum-starved apoptotic cell model. ACPSVs were isolated from rat plasma or cellular supernatant using differential centrifugation, ACPSVs size was analyzed by electron microscopy and nanoparticle tracking analysis and their contents were analyzed by ELISA and Western blot. Observing the effects on renal IRI by HE staining, Ki67 and serum creatinine tests after allogeneic injection of ACPSVs or plasma post-IPC. Using CCK8 and flow cytometry analysis to investigate ACPSVs impact on cell proliferation and apoptosis after co-culture with HK2 cell. Applying GO and KEGG analysis to explore the potential downstream molecular mechanisms.

Results: A stable rat model was established. The characterization of ACPSVs was confirmed, and plasma or ACPSVs after rIPC can alleviate kidney damage, the protective effect was diminished when ACPSVs were removed from plasma. A tenfold increase in plasma macrophage migration inhibitory factor (MIF) expression after rIPC was observed, mainly concentrated in ACPSVs. A HeLa cell model was established, the optimal condition for ACPSVs generation was to culture cell in EBSS containing 0.1% BSA and 0.1g/L $MgCl_2$ for 24 hours. HK2 cells can uptake ACPSVs, with peak uptake at 12h post co-culture. EVs of approximately 460.6 nm in size were obtained, its ACPSV marker (CrkI) was confirmed. Compared to the sham group, apoptosis rates reduced and cell viability increased in the ACPSVs+HK2 group. Analysis of ACPSV contents highlighted the significance of MIF. GO and KEGG analysis showed that proteins contained in ACPSVs were enriched in molecular complexes related to macrophages and cell proliferation pathways.

Conclusions: rIPC not only exerts cytoprotective effects but also confers protection against renal IRI through ACPSVs carrying MIF protein.

Fibroblast Growth Factor 23 (FGF-23) Inhibits Gasdermin E (GSDME)-Mediated Pyroptosis via Autophagy in Folic Acid-Induced AKI

Lina Zhang,[1,2] Limeng Wang,[1] Fengmin Shao,[1] Wei Qin.[2] [1]*Henan Provincial People's Hospital, Zhengzhou, China;* [2]*Sichuan University West China Medical Center, Chengdu, China*.

Background: Fibroblast growth factor 23 (FGF23) increases rapidly after acute kidney injure (AKI); however, the precise role of FGF23 in AKI remains unclear.

Methods: In vitro and in vivo folic acid (FA)-induced AKI models were utilized to investigate the role of FGF23, via inhibition with FGFR inhibitors or enhancement with recombinant human FGF23 (rhFGF23) protein.

Results: Serum FGF3 and renal FGF23 protein levels were significantly increased in mice with FA-AKI (Fig. 1 A and B). In vitro, FGF23 levels were observed to rise progressively with higher FA concentrations and extended stimulation periods (Fig. 1 C). Transmission electron microscopy (TEM) strongly suggests the occurrence of pyroptosis in FA-AKI characterized by balloon-like bubbles on the cell membrane and membrane rupture (Fig. 1 D). The expression levels of GSDME-NT and cleaved-caspase 3 experienced an increase with higher concentrations of FA or extended stimulation periods (Fig. 1 E). Similarly, significant increases in GSDME-NT and cleaved-caspase 3 levels were detected in the kidney tissues of the mice with FA-AKI (Fig. 1 F). Furthermore, the presence of autophagy in FA-AKI was confirmed by the observation of autophagosomes and autolysosomes in the FA group, as well as the upregulation of LC3B-II proteins in both in vivo and in vitro FA-AKI models. The addition of the FGFR pan-inhibitor PD173074 led to reduced cell viability and increased LDH levels compared to the FA group. Additionally, the levels of LC3B-II were significantly reduced, while the levels of cleaved-caspase 3 and GSDME-NT were significantly elevated. The FGFR4 specific inhibitor BLU9931 showed similar results. In contrast, administration of rhFGF23 resulted in opposite results (Fig. 1G, H, and I). In summary, FGF23 can facilitate autophagy then inhibit caspase-3/GSDME-mediated pyroptosis in FA-AKI.

Conclusions: Our study elucidated the protective role of FGF23 in AKI and clarified its underlying mechanism by targeting GSDME-mediated pyroptosis through autophagy.

KLF4/Galectin3 Signaling Axis Promotes Tubular Cell Death and AKI

Lishan Liu,[1] Kang Liu,[1] Juanjuan Jiang,[1] Jiafa Ren.[1,2] [1]*The First Affiliated Hospital of Nanjing Medical University, Nanjing, China;* [2]*Nanjing Medical University, Nanjing, China*.

Background: Acute kidney injury (AKI) is a serious clinical condition characterized by a rapid deterioration in renal function. Among the various components of the kidney, renal tubular cells are particularly vulnerable and often sustain the most significant damage during AKI. In clinical practice, AKI can stem from a diverse array of causes including ischemia, exposure to nephrotoxic agents, or sepsis. This diversity raises the question of whether there exists a common pathophysiological mechanism or pathway in renal tubular cells that underlies the development of AKI. Given the lack of effective therapies for the different etiologies of AKI, uncovering its common underlying molecular mechanisms across different causes could have a significant impact on human health.

Methods: We reanalyzed the single-cell RNA-sequencing atlas from four mouse AKI models to identify Galectin3 as a commonly expressed candidate in injured tubular cells. We then confirmed expression of Galectin3 protein in injured mouse and human tissues by immunofluorescence or western blotting. Furthermore, to determine the molecular

mechanisms regulating the galectin3 pathway, we utilized the "Cre-loxp" system, conducted bulk RNA-sequencing assays, and employed pharmacological interventions in a mouse model of AKI. Additionally, we examined the molecular mechanisms in an in vitro culture of the human kidney tubular cell line (HK2).

Results: We observed that Galectin3 is significantly up-regulated in all four AKI mouse models and shows a positive correlation with tissue injury in human kidneys affected by AKI. Our ChIP-PCR and luciferase-reporter experiments confirmed the direct binding of the transcription factor KLF4 to a specific sequence of the galectin3 gene promoter, supporting the predictions of the JASPAR database. Furthermore, mice with tubular-specific deletion of KLF4 displayed reduced kidney injury and inflammation, along with lower levels of galectin3 expression in both cisplatin and ischemia-reperfusion-induced AKI. Targeting the KLF4/Galectin3 axis with Kenpaullone and GB1107 demonstrated protective effects against cisplatin-induced cell death and acute kidney injury, respectively.

Conclusions: Our study highlights the critical role of KLF4/Galectin3 axis in the pathogenesis of AKI. Disrupting KLF4/Galectin3 signaling pathway may offer a promising therapeutic approach for the treatment of AKI.

Exposure of Viable Proximal Tubular Epithelial Cells (PTEC) to Apoptotic Cells Enhances Activation of Mixed-Lineage Kinase-3 (MLK-3) in PTEC

Sunho Park,[1,2] Saket Jha,[1,2] Sandeep Kumar,[1,2] Sowdhamini Mahendiran,[1,2] Sunil K. Singh,[1,2] Piush Srivastava,[1,2] Ajay Rana,[1,2] Jerrold S. Levine.[1,2]
[1]University of Illinois Chicago, Chicago, IL; [2]Jesse Brown VA Chicago Healthcare System, Chicago, IL.

Background: We have previously shown that receptor-mediated recognition of apoptotic targets by viable PTEC induces caspase 8- and BID-dependent apoptotic death of the PTEC. The signaling intermediates between target recognition and caspase-8 activation remain unknown. Separate studies have shown that MLK-3 mediates the death of kidney epithelial cells in response to a variety of toxic and inflammatory stimuli. We therefore hypothesized that MLK-3 may play a role in target-dependent death of PTEC.

Methods: BU.MPT cells, a conditionally immortalized PTEC line, were used as both viable responding cells and apoptotic targets. Responder cells were exposed to targets for 30 mins, followed by washing. Responder cells were then treated with vehicle, TNF-a, LPS, or both for 15 mins, either immediately after washing or after overnight incubation.

Results: Exposure to apoptotic targets led to increased activity of MLK-3, as shown by increased phosphorylation of MLK-3 and its downstream target JNK, on both Western blotting and immunofluorescence microscopy. The degree of MLK-3 activation was equal to or exceeded that induced by TNF-a and/or LPS. Activation by apoptotic targets alone occurred immediately after target exposure and persisted despite overnight exposure in the absence of targets.

Conclusions: We have shown that exposure of viable PTEC to apoptotic targets leads to activation of MLK-3, a kinase known to enhance the death of PTEC to a variety of injurious stimuli. Additional studies involving the overexpression or inhibition of MLK-3 are planned to determine whether MLK-3 is a key signaling intermediate connecting receptor mediated recognition of apoptotic targets and caspase 8-dependent apoptotic death. As most therapies for acute kidney injury (AKI) fail because efficacy depends on their administration before injury, activation of MLK-3 by apoptotic targets offers great promise because this mechanism of PTEC death is initiated *after* injury occurs.

Effect of PD-1 Blockade on Neonatal Sepsis and Septic Kidney Injury in Mice

Dong Li, Huiling Wu. *The First Affiliated Hospital of Dalian Medical University, Dalian, China.*

Background: Blocking the Programmedcelldeath-1 (PD-1) pathway can improve the prognosis and survival of patients with sepsis, and affect the occurrence of kidney injury in sepsis, but the mechanisms are still unclear. In this study we explored the effects of PD-1 blocking on neonatal sepsis and sepsis kidney injury, and aim to explore whether the kidney changes are mediated by glycolysis pathway.

Methods: C57BL/6 newborn mice at 7 days post birth (P7) were selected and randomly divided into four groups: Anti- PD-1-LPS group, neonatal mice were i.p. injected with anti PD-1 antibody (10mg/kg), 24 hours later followed i.p. injected with lipopolysaccharides(LPS) (15mg/kg); Anti-PD-1-NS group; NS-LPS group; and control group (NS-NS group). After injecting LPS or physiological saline, all mice were subdivided into 6 hour group, 12 hour group, and 24 hour group. Blood and renal tissue were collected separately. ELISA was performed to determine the soluble PD-1 (sPD-1) and IL-6 in serum. Renal tissue morpholog by HE, and the expression of PD-1 and PFKFB3 in renal tissue by IHC.

Results: The serum IL-6 levels in the NS-LPS group were significantly higher than those in the NS-NS group, while the serum IL-6 levels in the Anti-PD-1-LPS group were also significantly higher than those in the NS-LPS group. The proximal tubule epithelial cells in the Anti-PD-1-NS group showed mild edema changes, and the proximal tubule epithelial cells in the NS-LPS group showed serious damage, while the proximal tubule damage in the Anti-PD-1-LPS group was reduced. The expression of PD-1 in the kidneys of the NS-LPS group was significantly increased, the expression of PFKFB3 was not significantly different. The expression of PD-1 in Anti-PD-1-LPS group was decreased, while PFKFB3 expression was significantly increased (Fig 1).

Conclusions: Serum sPD-1 may involved in the neonatal sepsis. PD- 1 blockade can significantly increase the expression level of IL-6. PD-1 blockade can alleviate renal tubular injury in neonatal sepsis, which may be mediated by changes in glycolysis.

Funding: Government Support - Non-U.S.

Inhibition of ZC3H13 Attenuates G2/M Arrest and Apoptosis by Alleviating NABP1 m6A Modification in AKI

Zhimei Lv, Qinghao Sheng, Qun Yu, Jinxiu Hu, Yating Lang, Rong Wang.
Shandong Provincial Hospital, Jinan, China.

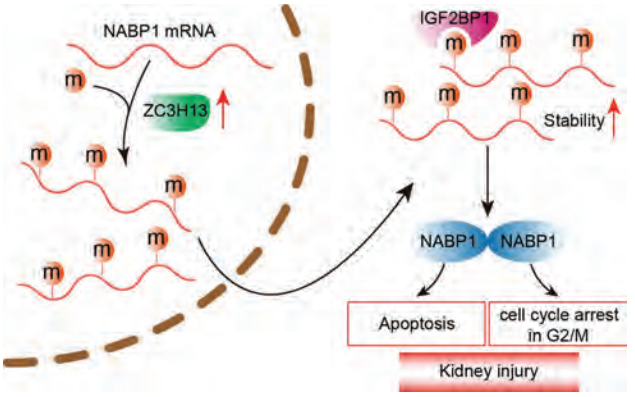
Background: Acute kidney injury (AKI) refers to a clinical syndrome caused by various etiologies, leading to rapid decline in renal function in a short period of time. M6A modification, which is the most common internal modification of mRNA, have been reported to play a vital role in AKI. ZC3H13, a kind of m6A methyltransferases, plays vital roles in canceer. However, the biological roles of ZC3H13 in the pathogenesis of AKI is still unknown.

Methods: Dot blot assay, and m6A ELISA were performed to detect the m6A modification in cisplatin-induced AKI mice and cisplatin-treated HK2 cells. Hematoxylin and eosin (H&E) and Periodic acid Schiff (PAS) were used to evaluate the histological and immunohistochemical change of the kidney. Flow cytometry and TUNEL staining were used to assess cell apoptosis rate in HK2 cells. Actinomycin was used to measure the stability of NABP1 mRNA. MeRIP-qPCR was used to detect the enrichment of NABP1 mRNA. RNA immunoprecipitation was performed to verify the binding of IGF2BP1 protein to NABP1 mRNA.

Results: We observed that m6A modification and the expression of ZC3H13 were substantially elevated in cisplatin-induced AKI mice and cisplatin-treated HK2 cells. Gain- and loss-of-function experiments showed silence of ZC3H13 attenuated G2/M cell cycle arrest and apoptosis both *in vivo* and *in vitro*. Mechanistically, we demonstrated that ZC3H13 mediated cisplatin-induced cell cycle arrest, apoptosis, and renal injury by regulating NABP1. Moreover, we confirmed that m6A modification mediated by ZC3H13 stabilized NABP1 mRNA and was discriminated by IGF2BP1.

Conclusions: In conclusion, ZC3H13 promoted the m6A modification of NABP1 and further enhanced its mRNA stability through IGF2BP1-dependent mechanism. The inhibition of ZC3H13 alleviated G2/M cell cycle arrest, apoptosis and kidney injury through regulating NABP1, showing that ZC3H13/NABP1 axis is a promising AKI treatment target.

Funding: Government Support - Non-U.S.



A simplified schematic diagram showing the effect of ZC3H13 in AKI.

Dapagliflozin Protects against Cisplatin-Induced AKI on Primary Human Renal Proximal Tubular Epithelial Cells (hRPTECs)

Yuta Sekiguchi, Yutaro Mori, Makiko Mori, Yuki Nakao, Shintaro Mandai, Hiroaki Kikuchi, Fumiaki Ando, Koichiro Susa, Takayasu Mori, Eisei Sohara, Shinichi Uchida. *Tokyo Ika Shika Daigaku, Bunkyo-ku, Japan.*

Background: The renal protective effects of SGLT2 inhibitors are widely known. However, the mechanism is not fully clear yet, although reduction of glomerular intraglomerular pressure and other factors are believed to be involved. We hypothesized that the direct actions of SGLT2 inhibitors on the tubular epithelium takes on a significant role to their renal protective effects, and we investigated them in unimmortalized human renal tubular epithelial cells (hRPTECs) in cisplatin induced acute kidney injury.

Methods: Our hRPTECs were obtained from the non-tumor kidneys removed from patients with malignancies with written informed concent. Renal cortex was diced and digested. Tubules were seeded on plates. And we obtained human primary renal proximal tubular cells. Then we administered cisplatin with or without dapagliflozin. We evaluated the expression of renal damage marker KIM-1 and other markers. To check the myofibroblast activation, potentially leading to tissue fibrosis through the secretion of paracrine factors from injured hRPTECs, we performed fibrosis bioassay, using culture supernatants with no cisplatin left over, and fibroblasts established from mouse renal cortex.

Results: Our hRPTECs express SGLT2 well unlike immortalized RPTEC (RPTEC/TERT). Tubular epithelial cells had increased expression of KIM-1 after cisplatin administration. Culture supernatants from these cells induced fibrosis, indicating injured hRPTECs excretes pro-fibrotic factors. When dapagliflozin administered simultaneously with cisplatin, KIM-1 expression was drastically suppressed, and the fibrosis-inducing effect of the culture supernatant was attenuated. Cisplatin treatment also increased the expression of the immune checkpoint ligand PD-L1, which induces immune tolerance against injured hRPTEC, and dapagliflozin suppressed it.

Conclusions: Dapagliflozin relieved cisplatin-induced acute kidney injury and attenuated myofibroblast activation through reducing the secretion of paracrine factors. Our findings demonstrate that dapagliflozin inhibits the progression from AKI to CKD. Immune tolerance may also be involved in these mechanisms.

The Importance of Kidney Response over Hematologic Response in Predicting Kidney Outcomes in AL Amyloidosis

Sungmi Kim, Kyungho Lee, Junseok Jeon, Jung eun Lee. *Samsung Medical Center, Gangnam-gu, Seoul, Republic of Korea.*

Background: Light chain amyloidosis is a clonal plasma cell disorder characterized by amyloid fibril deposition in multiple organs. Kidney involvement of amyloidosis often leads to progression to end-stage kidney disease. This study aimed to identify predictors of kidney survival in patients with kidney amyloidosis, focusing on hematologic and kidney response.

Methods: This retrospective study included 138 patients diagnosed with kidney amyloidosis between 2011 and 2019. Palladini et al.'s criteria were applied for kidney stage and response, and the 2012 International Society of Amyloidosis criteria for hematologic response. Kidney and hematologic response were assessed at 6 months after treatment initiation. Deep hematologic response was defined as the achievement of at least very good partial response.

Results: Overall, 17 (12.3%) progressed to end-stage kidney disease. In multivariable analysis, kidney stage 2 was independently associated with an increased risk of end-stage kidney disease compared to stage 1 (hazard ratio [HR] 3.75; 95% confidence interval [CI] 1.38–10.15; P = 0.01). Compared to kidney response, the risk of end-stage kidney disease increased by 8.42 times (95% CI 1.71–41.35; P = 0.01) in stable disease and 7.36 times (95% CI 1.25–43.33; P = 0.03) in kidney progression. However, neither deep hematologic response nor the difference between involved and uninvolved free light chain, one component of hematologic response, showed an association with kidney outcome. Kidney survival was longer in patients with both deep hematologic response and kidney response than in those with only hematologic response (P = 0.004).

Conclusions: The study underscores the importance of kidney response over hematologic response in predicting end-stage kidney disease and emphasizes the need to establish treatment endpoints, considering organ response alongside hematologic response.

An Atypical Cause of Kidney Amyloidosis: Combined Heavy and Light-Chain Amyloidosis

Dina R. Gonzalez Hernandez,[1] C. E. Cervantes.[2] *[1]MedStar Health, Baltimore, MD; [2]Johns Hopkins University, Baltimore, MD.*

Introduction: The kidney is the second most commonly affected organ in systemic amyloidosis. The International Society of Amyloidosis identifies 14 types of kidney-related amyloidosis, with most studies indicating that immunoglobulin (Ig) light chain (AL) amyloidosis is the predominant cause in over half of the cases. Heavy chain (AH) amyloidosis has been reported in 0.1 % to 2.3 % of kidney amyloidosis cases. However, combined heavy and light chain (AHL) amyloidosis is extremely rare.

Case Description: A 78-year-old man presented to the hospital with lower and upper extremities edema, dyspnea, and pulmonary edema. Workup revealed a serum creatinine of 1.25 mg/dL, and serum albumin of 2.7 g/dL. Urinalysis showed 3+ proteinuria with 22 g of proteinuria in a 24-hour collection. Serologic workup revealed high lambda light chains at 3,800 mg/L with kappa/lambda ratio of 0.01 and elevated IgM levels at 3,500 mg/L. A kidney biopsy showed mesangial expansion with negative periodic-acid-Schiff (Fig 1A) and positive Congo Red Stain (Fig 1B) with apple-green birefringence under polarized light. Immunofluorescence revealed diffuse mesangial staining for IgM (3+) (fig 1C), C3 (2+) and lambda light chains (2+). Mass spectrometry confirmed lambda light chain and mu heavy chain amyloidosis. The patient was diagnosed with AHL amyloidosis and initiated treatment with bendamustine and rituximab; however, his kidney disease progressed rapidly, necessitating dialysis initiation approximately 10 months after his initial presentation.

Discussion: AHL amyloidosis is extremely rare. Diagnosis requires a kidney biopsy and mass spectrometry to type the amyloidogenic protein given the highest sensitivity and specificity of this technique and the limitations of immunofluorescence. Compared to AL, AHL patients have a higher prevalence of IgM monoclonal gammopathy, longer overall survival (5-year survival rate of 66%), and less advanced disease. Although data are limited, our case underscores the potential rapid progression to dialysis in AHL patients with high proteinuria at diagnosis.

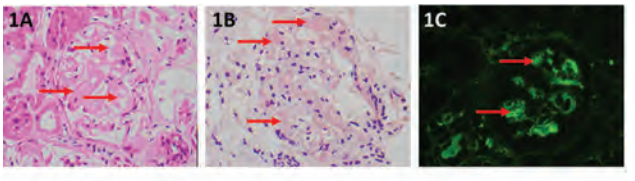

Figure 1A shows mesangial expansion, which is periodic-acid-Schiff (PAS) negative.
Figure 1B demonstrates a positive Congo Red Stain in the mesangium (salmon pink color).
Figure 1C reveals diffuse mesangial staining for IgM (3+) on immunofluorescence.

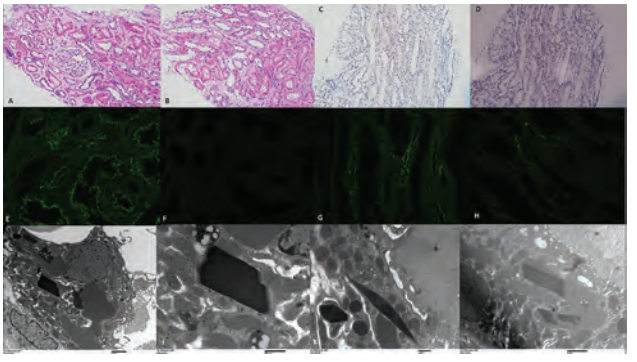
Monoclonal Gammopathy Manifested as Renal Interstitial Amyloidosis

Muhammad Qasim,[1] Kanza Mustafa,[2] Ann R. Finke,[1] Virgilius Cornea,[1] Taha Ayach.[1] *[1]University of Kentucky College of Medicine, Lexington, KY; [2]Yusra Medical and Dental College, Islamabad, Pakistan.*

Introduction: Amyloidosis is a disorder caused by deposition of insoluble misfolding proteins as fibrils leading to organ dysfunction. Incidence of AL Amyloidosis is 9 cases per million. Monoclonal gammopathy manifested as renal interstitial amyloidosis is a rare disorder.

Case Description: 54 yo F with history of hypothyroidism, covid 19 presents to primary care provider (PCP) with fatigue. Cr was noted to be 1.28 mg/dl, eGFR 50ml/min. Urinalysis was bland, and urine protein to creatinine ratio was 0.2 g/g. Renal U/S: Normal. SPEP: Normal. Serum free light chains (LC) K 249.23 mg/L[3.3-19.4], λ 10.90 mg/L [5.71-26.3], elevated K/λ LC ratio of 22.87[0.26-1.65]. Bone marrow biopsy(BMBx): plasma cell dyscrasia, 15% of the population of K-restricted plasma cells, negative Congo Red stain. Skeletal survey: negative. Renal Biopsy: proximal tubulopathy, monoclonal kappa light chain related and Interstitial renal amyloid deposition.

Discussion: Isolated K related monoclonal gammopathy manifested as renal interstitial amyloid is a rare disease entity scarcely reported in literature. We report a case of this patient with mild symptoms and minimal serum Cr elevation, no significant proteinuria with elevated K/λ LC ratio. BMBx: K-related plasma cell abnormality. Renal biopsy: K LC proximal tubulopathy along with interstitial amyloid deposits. Treated with lenalidomide, bortezomib, dexamethasone[6 cycles]. Achieved remission confirmed on BMBx. Had autologous hematopoietic stem cell transplant. Remains in remission on lenalidomide maintenance dose 20 months post auto-HCL. Renal function stable with serum Cr ~ 1-1.2 mg/dL with bland urine.



A&B- H&E. Proximal Tubulopathy, Acute Tubular Damage. C&D-Amyloid interstitial deposits- Congo Red. D:Apple-green; Polarized Light. E-H:(IF) E-Tubules, 2+ cytoplasmic staining after pronase digestion for K-LC. F-Tubules, no cytoplasmic staining after pronase digestion for λ-LC. G&H, interstitial staining for Kappa(G) and lambda(H) after pronase digestion. I-J:EM, enlarged atypical shaped lysosomes (J) and IC rhomboid and needle shaped crystals (I-L).

Subphenotypes of Tumor Lysis Syndrome with AKI

Ming-Jen Chan, Yi-Jiun Su, Chih-Hsiang Chang. *Chang Gung Memorial Hospital Linkou, Taoyuan, Taiwan.*

Background: The diverse clinical outcomes observed in tumor lysis syndrome (TLS) patients with acute kidney injury (AKI) suggest underlying heterogeneity within TLS. We aimed to elucidate the subphenotypes of TLS with latent class analysis (LCA) to better understand their clinical characteristics and outcomes.

Methods: A cohort of 1,377 patients presenting with TLS-related AKI between 2005 and 2019 was enrolled. Analysis of total forty clinical variables, including baseline characteristics, malignancy type, metastatic site, AKI stage, and laboratory measurements, was conducted using LCA to identify distinct subphenotypes. All-cause death, cancer-specific death, non-recovery of renal function, and progression to dialysis requiring AKI, were compared among the identified subphenotypes.

Results: LCA revealed four distinct subphenotypes of TLS patients. Subphenotype 1 exhibited the lowest all-cause mortality (hazard ratio [HR] 0.27, 95% confidence interval [CI] 0.22-0.34), while subphenotype 4 had the highest mortality rate. Similar trend was observed in cancer-specific mortality with subphenotype 1 displaying the lowest risk (HR 0.28, 95% CI 0.22-0.35). Additionally, subphenotype 1 exhibited significantly lower risks of non-recovery of renal function (OR 0.30, 95% CI 0.19-0.47) and progression to dialysis-requiring AKI (OR 0.36, 95% CI 0.17-0.77) compared to the other subphenotypes.

Conclusions: Our study identifies four novel subphenotypes, with subphenotype 1 associated with the most favorable outcomes, while subphenotype 4 exhibits the worst prognosis. This subphenotyping approach holds promise in guiding future research.

Impact of Hematopoietic Cell Transplantation Associated Thrombotic Microangiopathy on Kidney Failure Requiring Dialysis in Patients Aged 40 Years and Older Characterized by Pretransplant Kidney Health

Udit Nangia,[1] Deepak Chandramohan,[2] Hari Naga Garapati,[4] Prathap Simhadri.[3] *[1]UH Parma Medical Center, Parma, OH; [2]The University of Alabama at Birmingham, Birmingham, AL; [3]AdventHealth East Florida, Daytona Beach, FL; [4]Baptist Medical Center South, Montgomery, AL.*

Background: Allogeneic hematopoietic cell transplantation (all-HCT) associated thrombotic microangiopathy (TA-TMA) and pre-transplant renal dysfunction are recognized risk factors for mortality after all-HCT. In a recent observational study (Farhadfar et al, 2021), patients with pre-transplant decreased kidney function had higher risks of renal failure requiring dialysis (RFD). Using the same data from the Center for International Blood and Marrow Transplant Research (CIBMTR), we investigated the association between onset of TA-TMA and pre-HCT renal dysfunction on RFD.

Methods: All-HCT recipients of age ≥40 years between 2008-2016 were included in this secondary analysis. We evaluated TA-TMA as a time-dependent covariate, while pre-transplant renal health and other risk factors were included as fixed covariates in a multivariate Cox regression model for RFD. Cumulative hazards of RFD in patients with and without onset of TA-TMA were estimated.

Results: The incidence of TA-TMA was not significantly different between the renal function groups. As expected, renal dysfunction was a significant risk factor for RFD when compared to eGFR ≥60 mL/min group. TA-TMA was significantly associated with increased risk (5.9-fold compared to No TA-TMA) for RFD, the highest of all the significant risk factors (Table 1). Estimated cumulative hazard for patients with TA-TMA in the two pre-HCT renal function groups were significantly elevated when compared to similar patients with No TA-TMA (52% vs 9% for eGFR <60 mL/min and 22% vs 4% for eGFR ≥60 mL/min group, respectively) at 12 months post-HCT.

Conclusions: Our results demonstrate that the adjusted hazard ratio of renal failures requiring dialysis and cumulative hazard were much higher in patients with onset of TA-TMA vs No TA-TMA, emphasizing the need for therapies for preventing and addressing TA-TMA.

Table 1. Incidence of TA-TMA, Renal Failure Requiring Dialysis and Adjusted Risk Factors for Renal Failure Requiring Dialysis Post-Hematopoietic Cell Transplantation

Characteristic	Pre-HCT eGFR (mL/min)		
	<60 (n=1151)	≥ 60 (n=12025)	P-value
Incidence of TA-TMA	3.4%	2.8%	0.300
Incidence of Renal Failure Requiring Dialysis	12.2%	5.8%	<0.001
With No TA-TMA	11.8% (131/1112)	5.4% (627/11682)	<0.001
With TA-TMA	23.1% (9/39)	21.0% (72/343)	
[a]Significant Risk Factors for Renal Failure Requiring Dialysis Post-Hematopoietic Cell Transplantation			
Risk Factors		HR (95% CI)	P-value
TMA vs No TA-TMA		5.92 (4.23, 8.28)	<0.001
Renal Function Group eGFR <60 mL/min vs eGFR ≥60 mL/min		2.31 (1.89, 2.82)	<0.001
Hematopoietic cell transplantation-comorbidity index 2 vs 0		1.31 (1.01, 1.71)	0.045
Hematopoietic Cell Transplantation-Comorbidity Index 3 vs 0		1.49 (1.22, 1.82)	<0.001
Donor Age 40-49 (ref: identical sibling or other relative)		1.39 (1.04, 1.86)	0.027
Donor Age N/A - Cord Blood (ref: identical sibling or other relative)		1.54 (1.14, 2.08)	0.005
Donor Type: Unrelated vs Related		1.43 (1.11, 1.82)	0.005
Anti-thymocyte globulin and/or alemtuzumab: Yes vs No		0.77 (0.64, 0.92)	0.004
Chronic GVHD: Yes vs No		0.33 (0.28, 0.40)	<0.001
Conditioning Regimen: Bu-Cy (ref: Cy/TBI)		0.70 (0.51, 0.96)	0.027
Conditioning Regimen: Bu-Flu (ref: Cy/TBI)		0.49 (0.37, 0.66)	<0.001
Conditioning Regimen intensity: NMA vs Myeloablative		0.61 (0.46, 0.82)	<0.001
Disease Group: Lymphoma vs AML		1.56 (1.21, 2.01)	<0.001
Disease Group: MDS vs AML		1.25 (1.02, 1.53)	0.029
Disease Group: Other malignant hematologic disease vs AML		1.89 (1.43, 2.49)	<0.001
Veno-occlusive disease: Yes vs No		4.41 (3.30, 5.87)	<0.001
Idiopathic pneumonia syndrome: Yes vs No		2.19 (1.75, 2.75)	<0.001

SA-PO172

Kidney Recovery Prognosis after Allogeneic Hematopoietic Stem-Cell Transplantation

Ping-Chi Tsai,[1] Bor-Sheng Ko,[2,3] Jenq-wen Huang,[1,2] Chi-Ting Su.[2,3]
[1]National Taiwan University Hospital, Taipei, Taiwan; [2]National Taiwan University College of Medicine, Taipei, Taiwan; [3]National Taiwan University Cancer Center, Taipei, Taiwan.

Background: Predictors of renal dysfunction should be thoroughly investigated to prevent compromising the success of HSCT in treating malignant and non-malignant hematological diseases. We aimed to determine the factors and effects of acute kidney injury (AKI), acute kidney disease (AKD), and chronic kidney disease (CKD) in patients receiving HSCT and investigate the impacts of the trajectory of renal recovery on outcomes.

Methods: We conducted a retrospective study of adult patients receiving allo-HSCT between 2015 and 2023. We identified incident AKI, AKD, and CKD as defined by changes in serum creatinine (sCr) levels based on the KDIGO criteria and ADQI consensus. Severe AKI and AKD were defined as a 100% increase in sCr within 7 and 90 days, respectively. Kidney recovery was based on the AKI resolution and subsequent sCr measurements below 1.5× the baseline at different timeframe. Multivariate Cox regression was used to assess known risk factors.

Results: The participants were 805 patients (mean age; 50.3 years; men; 53.3%; and median follow-up; 2.3 years). The incidence rates of AKI and AKD after 100 days of treatment were 53.8% and 65.3%, respectively. The cumulative incidence of CKD was 23.4%, whereas the non-relapse mortality was 11.8%. Severe AKI was independently associated with higher non-relapse mortality (hazard ratio [HR]; 2.01) and recovery after 3, 7, and 90 days of AKD were similar (HR; 2.90, p=0.004; HR; 2.39, p=0.01; and HR; 3.41, p=0.001, respectively). Non-recovery of AKI by 90 days was a risk factor for CKD (HR; 5.65/5.32, p<0.001), whereas AKI recovery by 3 and 7 days were not risk factors. Male sex, diabetes mellitus, hemorrhagic cystitis (HR; 2.40), and acute dialysis after HSCT (HR; 8.89) conferred higher risk of CKD incidence. Exposure to various nephrotoxic agents (HR; 1.76, p<0.001) increased risk of AKI. Cyclosporine levels was associated with AKI (HR for 1 standard deviation (SD) increase; 1.27, p<0.001) and exerted negative effect on recovery at 3 days (odds ratio for 1 SD increase; 1.52, p<0.001).

Conclusions: Recovery patterns of AKI stratify the risk of CKD and mortality. Moreover, the results highlighted cyclosporine levels, nephrotoxic agents, and hemorrhagic cystitis for further monitoring of the AKI-CKD continuum. Thus, transition from post-AKI to post-AKD and CKD should be prevented for patients receiving HSCT.

SA-PO173

Impact of Kidney Impairment Recovery on Survival of Patients with Newly Diagnosed Multiple Myeloma

Fernando L. Strufaldi, Luciana G. Lutf, Renato A. Caires, Francisco Z. Mattedi, Elerson Costalonga, Fernanda S. Seguro, Gracia A. Martinez, Veronica T. Costa e Silva. *Universidade de Sao Paulo Instituto do Cancer do Estado de Sao Paulo, Sao Paulo, Brazil.*

Background: It has recently been suggested that recovery of Renal Impairment(RI) after treatment(AT) of patients(pts) with multiple myeloma (MM) is a better predictor of overall survival(OS) than RI at diagnosis(AD). Our aim is to assess the impact of RI recovery on the OS of pts with newly diagnosed(NDMM)

Methods: We screened adult pts with NDMM admitted for treatment at the Sao Paulo State Cancer Institute between January 2009 and September 2018. Estimated glomerular filtration rate(eGFR) was determined by the 2021 CKD-EPI creatinine(Cr) equation in ml/min/1.73m^2. RI was defined as eGFR<40 or serum Cr>2.0mg/dL. Chronic Kidney Disease (CKD) criteria was eGFR<60ml/min/1.73m^2, considering Cr in the previous three months before MM diagnosis. Acute Kidney Injury (AKI) was stratified according to the KDIGO criteria. Patients were classified into 3 groups: (1) no RI at diagnosis, (2)RI AD with recovery AT, (3)RI AD without recovery AT

Results: We enrolled 429 pts. Median age was 61.7(54.1–69.5)y, 58.1% male. Median Charlson comorbidity index was 4.0(3.0–5.0). International staging system III was found in 37.9%. Novel agents(bortezomib or thalidomide) were used in 70.8% pts. eGFR AD and AT were 70.9(40.7–98.7) and 93.2(62.7-104.1)ml/min/1.73m^2, respectively. AD, CKD, RI, and AKI stage 3 were observed in 26.3, 24.0, and 12.1% of patients, respectively. In the adjusted Cox regression models, among kidney variables, only the lowest eGFR AT was associated with worse OS(Table).

Conclusions: The lowest eGFR AT might be a better predictor of OS than RI AD in pts with NDMM

Variables	p value	Hazard Ratio (95% Confidence interval)
Renal impairment at diagnosis	0.54	1.11 (0.79 – 1.56)
eGFR at admission	0.88	1.0 (0.99 – 1.05)
Acute Kidney Injury stage 3	0.46	0.67 (0.51 – 0.89)
Chronic kidney disease	0.67	0.94 (0.70 – 1.26)
Renal recovery groups No Renal Impairment Renal impairment at diagnosis, recovery after treatment Renal impairment at diagnosis, no recovery after treatment	0.29 0.83 0.42	 1.04 (0.74 – 1.45) 1.62 (0.88 – 2.96)
Lowest eGFR in 6 months	0.004	0.99 (0.98 – 0.99)

Each model was adjusted for age, Charlson index, international staging system stage 3, body mass index categorization, and usage of novel chemotherapy agent(thalidomide or bortezomib).eGFR: estimated glomerular filtration rate

SA-PO174

Effects of Primer on Episodes of Hypotension during Therapeutic Plasma Exchange

Madhab Ray, Anna G. Macadam, Grace Monis. *University of California Davis, Davis, CA.*

Background: Plasma pheresis instruments are primed (pre-filled with a fluid) before Therapeutic Plasma Exchange (TPE) with saline solution or 5% albumin to prevent air embolism and hypovolemia from extracorporeal fluid shift. Changes in blood composition during TPE can cause various side effects, including hypotension through the involvement of the autonomic nervous system. No published study compares effect on hypotension when an albumin solution is used instead of normal saline. The purpose of this study was to characterize the blood pressure response during TPE when albumin is used for priming compared to normal saline.

Methods: Data was retrospectively collected from 118 TPE records of 26 patients who had one or more TPEs in the last two years at UC Davis Medical Center, California. TPE was done according to Spectra Optia System guidelines, and no patient had more than one exchange on a particular day. Five percent human albumin was used as the preferred replacement fluid, and the dose was calculated based on the body weight, height, sex, and age of the patients. Patients were closely monitored during the procedure. Changes in mean arterial blood pressures were compared to their respective baseline using unpaired two-tailed t-test. Episodes of hypotension (SBP <90 mm Hg or DBP <60 mmHg) during TPE were analyzed using Anova.

Results: The mean age of patients was 51 years and 42% were male. Hypotension was noted more frequently and with increased severity when 5% human albumin was used for priming the plasma apheresis system. Significant increase was noted both in severity (p-value < 0.01) and frequency of hypotensive episodes (p-value <0.001) when 5% human albumin was used for priming the plasma apheresis system (figure 1).

Conclusions: Episodes of hypotension were less frequent and less severe during therapeutic plasma exchange when the plasma apheresis system was primed with saline compared to 5% human albumin. Results may reflect the heterogenous pathophysiology of our study population. Further studies will be necessary to generalize these observations.

Drug (Carfilzomib)-Induced Atypical Hemolytic Uremic Syndrome (aHUS)

Fnu Pariya,[1] Sandeep R. Sasidharan,[1] Tahir A. Jatoi,[1] Muhammad Azhar,[2] Isha Puri,[2] Mary C. Mallappallil,[2] Mohammad W. Abushawer.[1] *[1]SUNY Downstate Health Sciences University, New York City, NY; [2]Kings County Hospital Center, Brooklyn, NY.*

Introduction: MM, the second most common hematologic malignancy, accounts for 2.1% of all cancer deaths (1). TMA is a potentially organ and life-threatening condition affecting patients with MM. Risk for TMA in MM is from both the disease and drug used to treat (2). We present an elderly man with refractory MM on Carfilzomib who developed aHUS.

Case Description: 60-year-old male with history of prostate cancer in remission, refractory IgG Lambda chain associated MM, and was receiving chemotherapy with Carfilzomib presented with yellow productive cough for 3 days with fever and chills. On exam, Pt was febrile to 102 F, HR >100, and has rhonchi on lung fields. Labs showed Creatinine at 3.38 mg/dL (baseline 1.1mg/dl), WBC 10.57 K/uL with bands, Platelets 51K/uL and influenza A positive. CXR showed bibasilar opacities. The peripheral smear showed schistocytes with elevated LDH 795 U/L. ADAMS13 was negative and pt was diagnosed with aHUS. Patient was initiated on plasmapheresis followed by intermittent HD as the patient became oliguric with worsening renal functions. He was started on eculizumab after appropriate vaccinations. He had improvement in hematology labs but renal functions did not improve and remained dependent on iHD.

Discussion: TMAs in MM patients incur a high mortality risk with long-term morbidity like kidney failure as seen in our patient. MM- related TMA is poorly understood but thought to be due to VWF dysfunction mediates thrombotic thrombocytopenic purpura (TTP) (3), and uncontrolled complement activation mediates atypical hemolytic uremic syndrome (aHUS)(4). So Eculizumab, a complement inhibitor, is used with good results as in our patient but has not been studied as well. Influenza-associated TMA has been reported (5) which could be a trigger in our patient like other Carfilzomib TMAs (6, 7). It may be prudent to investigate if these patients need more frequent influenza vaccination. We report this case of TMA in MM especially with proteasome inhibitors to increase awareness for early detection and treatment thus can prevent morbidity and mortality.

SA-PO176

When Bad Becomes Worse: A Complex Case of Hypophysitis Causing Severe Hyponatremia in the Setting of Immune Checkpoint Inhibitor Therapy and Pituitary Metastasis

Rafael Portela, Ahmad Matarneh, Sundus Sardar, Aidaliz Llorens, Naman Trivedi. *Penn State Health Milton S Hershey Medical Center, Hershey, PA.*

Introduction: Immune checkpoint inhibitors (CPI) are immunotherapy drugs that have revolutionized cancer therapy by enhancing the immune response against tumor cells. However, their use is associated with life threatening complications such as hypophysitis, pituitary gland inflammation. Unrecognized secondary adrenal insufficiency in these cases could result in hyponatremia. We present a case of severe hyponatremia caused by CPI use and pituitary metastasis.

Case Description: 76-year-old woman with papillary thyroid cancer treated with thyroidectomy and metastasized angiosarcoma of the breast, presented with asymptomatic hyponatremia of 118 mmol/L. She had been receiving nivolumab and ipilimumab for 2 months prior to presentation. She was hemodynamically stable. Physical exam was unremarkable; patient was euvolemic. Chemistry showed a sodium 118 mmol/L with normal renal function. Other electrolytes were normal. Nephrology was consulted for management of hyponatremia. Further workup revealed urine sodium 123 mmol/l, urine osmolality 415 mmol/l and serum osmolality 255 mosm/kg; findings consistent with Syndrome of Inappropriate Antidiuretic Hormone (SIADH). Interestingly, morning cortisol was 2.4 mcg/dL with a suppressed ACTH of <0.1 pg/mL consistent with SIADH caused by secondary adrenal insufficiency most likely due to CPI use. Brain MRI revealed an enlarged pituitary gland. She was started on hydrocortisone 25 mg twice daily which resulted in improvement of her sodium level from 118 mmol/L to 127 mmo/L in 24 hours. In 48 hours, sodium was 134 mmol/L and remained stable thereafter. Patient was discharged on hydrocortisone 15 mg in the am and 5 mg at 2 pm.

Discussion: We have portrayed a very interesting presentation of isolated hyponatremia due to central adrenal insufficiency due to CPI use. Understanding the mechanisms underlying CPI-induced hypophysitis is crucial for early detection and management. The current theory is that T-cell activation leads to immune-mediated destruction of pituitary cells, hence affecting synthesis of pituitary hormones. Severe hyponatremia could prompt a nephrology consult as a first approach by primary teams and therefore, recognizing this etiology for hyponatremia in the setting of CPI use could be essential in assertive treatment.

SA-PO177

A Rare Manifestation of Myeloma in a Kidney

Saieda Alleyne, Dhara Dave, Maryam Gondal. *Yale University, New Haven, CT.*

Introduction: Proteinuria and renal insufficiency are among the most common renal manifestations of Multiple Myeloma [MM] with cast nephropathy being the most common pathophysiology. There have been few case reports of plasma cell infiltration into the kidney resulting in renal dysfunction and proteinuria. Here we describe a case of nephrotic syndrome without deranged creatinine in a patient with long standing MM.

Case Description: 64-year-old female with history of anal cancer status post chemoradiation and Ig G multiple myeloma, diagnosed in 2016 refractory to numerous lines of treatment, including CAR-T and stem cell boost, currently on Blenrep and Pomalyst was found to have new onset nephrotic range proteinuria. Urine protein to creatinine ratio 3.74 mg/mg and urine albumin to creatinine ratio 16.1 mg/mg. Serum albumin 1 g/dl, creatinine 1.07 mg/dl [Baseline 0.8-1] and hemoglobin 8.2. Serum protein electrophoresis showed discrete abnormal band measuring 1.7g/dl in the gamma region and serum free kappa/lambda ration >665 unchanged from prior. Renal biopsy revealed diffuse and expansile plasma rich interstitial infiltration distorting the kidney architecture suggestive of infiltrative myeloma in the kidney. Unfortunately, due to the refractory nature and overall decline in her health she was made hospice.

Discussion: Renal involvement in multiple myeloma varies widely and there is a wide spectrum of pathologies noted on biopsy. Plasma cell infiltration of the kidney is a rare presentation of MM that showed itself as only proteinuria and no renal function impairment. It is, however, one that is usually associated with advanced myeloma and like in other reported cases, our patient succumbed to complications of advanced myeloma. With this case we emphasize the point that despite marked histologic changes one may not have significant renal dysfunction. It is important to note and recognize this advanced presentation that may otherwise disguise itself as a benign kidney involvement of MM.

SA-PO178

Membranoproliferative Glomerulopathy with Masked Monoclonal Deposit: A Case Report

Saieda Alleyne, Maryam Gondal. *Yale University, New Haven, CT.*

Introduction: Membranoproliferative glomerulonephritis [MPGN] is diagnosed on immunofluorescence. Some cases are influenced by the dysregulation of the alternative complement pathway. Larsen et al. have described the unmasking of immunoglobulin deposits when tissue is treated with paraffin and hence exposing immunoglobulin previously staining negative on immunofluorescence. Here, we describe a case of monoclonal gammopathy of renal significance presenting as MPGN with masked monoclonal deposit.

Case Description: 42-year-old male with history of intravenous drug use on methadone who presented with elevated creatinine and lower extremity swelling. No prior history of kidney disease or family history of kidney disease. Labs notable for creatinine 1.81, hemoglobin 7.9 [83.7] and albumin 3. Urine analysis showed +3 protein, RBC and WBC. Spot urine protein/creatinine ration showed 10 mg/mg with >4,400 mg/g albumin to creatinine ratio. Hepatitis B, C, Cryoglobulin, C3 and HIV were unremarkable. Serum kappa/lambda light chain ratio 1.91 and immunofixation positive for Monoclonal component detected in the gamma region in serum and characterized as IgM lambda. Renal biopsy revealed MPGN with masked monoclonal deposit with subsequent bone marrow aspirate showing findings are of a moderately hypocellular marrow with 10% lambda monoclonal plasma cells consistent with involvement by a plasmocytic neoplasm. CYBORD (Cyclophosphamide + Bortezomib + Dexamethasone) and lisinopril was started with improvement in protein/creatinine ratio to 3.42 mg/mg in 1 month and recent creatinine improvement to 1.2.

Discussion: This case is unique as it signifies the importance of Monoclonal gammopathy of Renal Significance. Early detection with renal biopsy and initiation of treatment was instrumental in preserving renal function

SA-PO179

Cast Nephropathy from Gamma Heavy-Chain Disease

Sai Prasad Desikan,[1] Raman Desikan.[2] *[1]The Ohio State University Wexner Medical Center, Columbus, OH; [2]White River Health System Inc, Batesville, AR.*

Introduction: In heavy chain disease, frame shift, point mutations, or somatic hypermutations result in the loss of portions of the heavy chain responsible for binding light chains. Gamma heavy chain disease in particular is uncommon. Here we present a patient with gamma heavy chain disease with nephrotic range proteinuria and heavy chain cast nephropathy.

Case Description: A 70-year old male presented with pancytopenia and declining renal function. CBC consisted of WBC of 1.6 x 10^3 /μL, Hgb 10.2 g/dL, and PLT of 90 x 10^3 / μL. Cr was 2.1 mg/dL. IgG was elevated at 2784 mg/dl. IgM and IgA were both low. 24 hour urine protein was elevated 8g/24 hours. Ig heavy chain made up 7.5g/24hr period. Bone marrow aspirate and biopsy evaluation was notable for 40% plasma cells on immunohistochemistry. Flow cytometry revealed 14.7% plasma cells, cytoplasmic

lambda light chain restricted CD38 bright plasma cells. FISH revealed loss of IgH and *FGFR3* genes. Renal biopsy revealed cast nephropathy with IgH and severe arteriolar nephrosclerosis. He received the VDT-ACE, Daratumumab protocol. Autologous SCT was performed. On follow up, proteinuria was significantly diminished at 150mg/24 hours and. Monoclonal protein was absent. Bone marrow biopsy revealed normocellular bone marrow 1% plasma cells observed in aspirate and 5-10% plasma cells in core biopsy. Minimal residual disease assessed by flow cytometric analysis was positive. He received velcade, revlimid and dexamethasone as well as stem cell infusion. Course complicated by pancytopenia. Upon recovery he received further consolidation with daratumumab and dexamethasone. He achieved MRD negativity. Cr continues to be elevated at 1.9 mg/dL.

Discussion: Our patient presented with the rare combination of gamma heavy chain disease, nephrotic range proteinuria, and cast nephropathy. Cast nephropathy is usually a result of light chains binding uromodulin; however, this is the first reported case of heavy chains resulting in cast nephropathy. This patient was successfully treated with induction, autologous transplant, and post transplant consolidation. To date, this is the first patient with gamma heavy chain disease managed with autologous transplant.

SA-PO180

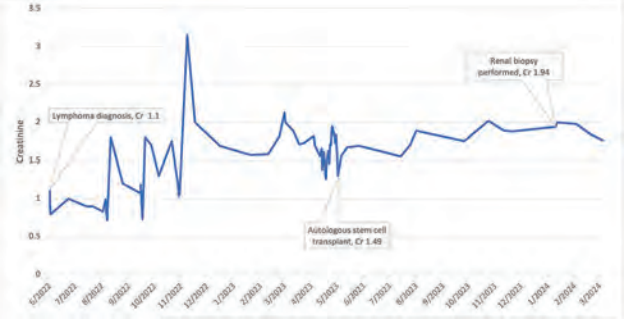
Unveiling the Link: Exploring the Association between Cancer and Leukocyte Chemotactic Factor 2 (ALECT2)-Associated Amyloidosis

Veena Ganesan, Rahul Maheshwari, Priya Deshpande, Matthew Abramson.
Icahn School of Medicine at Mount Sinai, New York, NY.

Introduction: We present a case of a 53-year-old Hispanic male diagnosed with mantle cell lymphoma with subsequent decline in glomerular filtration rate (GFR) found to have LECT2 amyloidosis on renal biopsy. Notably, following treatment of the lymphoma, his GFR stabilized. Given the correlation between his GFR and lymphoma course, we hypothesize that his lymphoma, possibly via dysregulated Wnt/β-catenin signaling, served as a trigger for ALECT2 amyloidosis.

Case Description: The patient was diagnosed with mantle cell lymphoma in June 2022 and underwent alternating R-CHOP and R-DHAP until December 2022. In May 2023, he had an autologous stem cell transplant with BEAM induction, followed by rituximab maintenance. Despite a normal baseline creatinine, his creatinine worsened to 1.5 mg/dL by May 2023. Post-transplant, creatinine continued to rise to 1.89 mg/dL by the time of initial nephrology consultation in December 2023. Urinalysis, urinary microalbumin and protein-to-creatinine ratio, monoclonal gammopathy screening, and renal sonogram were all unremarkable. Due to the unclear cause of worsening renal function, he had a renal biopsy in January 2024 showing tubulointerstitial amyloid deposition. Mass spectrometry was consistent with the ALECT2 type. As of March 2024, his creatinine was stable at 1.76 mg/dL

Discussion: ALECT2 amyloidosis is characterized by LECT2 protein accumulation, a molecule involved in neutrophil chemotaxis and implicated in multiple inflammatory conditions. Our patient's course and Hispanic origin align with other documented ALECT2 cases in the literature. However, no cases describe an association with lymphoma nor hypothesized treatment. Given the patient's course and the pathophysiology of ALECT2 amyloidosis, we suggest that a surge in LECT2 possibly occurred due to dysregulated Wnt/β-catenin signaling, a pathway implicated in carcinogenesis. We highlight the potential interplay between cancer and ALECT2 amyloidosis, with treatment addressing the underlying cause of amyloid accumulation.



SA-PO181

BK Nephropathy in a Patient with Multiple Myeloma Receiving Bispecific Antibody Therapy

Douglas R. Farrell, Matthew Abramson, Isaac E. Stillman, Daniel Stalbow.
Icahn School of Medicine at Mount Sinai, New York, NY.

Introduction: Human Polyomavirus BK (BKV) is typically a benign virus with seroprevalence in the adult population of 50-90%, but has been associated with interstitial nephritis (nephropathy) in kidney transplant and hemorrhagic cystitis in hematopoietic stem cell transplant (HSCT) recipients. While rare, BKV nephropathy has been described in native kidneys, though mostly in solid organ transplant and HSCT recipients. We describe a case of native kidney BKV nephropathy in a patient receiving the T-cell redirecting bispecific antibody (BsAb), talquetamab, for multiple myeloma (MM).

Case Description: A 66 yo woman with a history of relapsed/refractory IgG Kappa MM was admitted to our hospital for progressive kidney disease. Two months prior to her current admission, she had been started on talquetamab, a BsAb, for her 13th line of therapy for MM. Her creatinine at initiation of therapy was 2.45 mg/dL with a calculated eGFR of 22cc/hr/1.73m3. Her kidney function initially improved to a nadir of 1.89 mg/dL, but then over the duration of 2 months slowly increased to 4.47 mg/dL on day of admission. Her workup included well controlled light chains including a free kappa light chain 1.2mg/l and free lambda light chain1.6mg/l. Her Igs were low, despite treatment 1 month prior with IVIG, with undetectable IgA+IgM, and IgG of 699 mg/dL. She had bland UA, UPCR of 600mg/g, and urine immunofixation with faint monoclonal IgG protein. Kidney biopsy was performed and revealed marked IFTA with remaining tubular cells showing foci of viral cytopathy changes with >10% positive for SV40 Ag, diagnosed as polyomavirus nephritis Banff class 3. No evidence of myeloma kidney was seen. Urine BKV PCR after showed >100,000,000 iu/mL, confirmed the diagnosis of BKV nephropathy. Talquetamab was stopped and she as treated with monthly IVIG, but unfortunately never recovered kidney function.

Discussion: BsAbs are a novel therapy with two different binding domains, which bind one domain to a T-cell antigen (Ag) and another to a B-cell maturation Ag, thus allowing for T-cell destruction of MM cells. BsAbs have significant risk for infection, and some providers utilize prophylactic anti-virals and antibiotics with therapy. While infectious complications of BsAbs are common, BKV nephropathy has not be described, and thus this is the first description to our knowledge.

SA-PO182

Rare Glomerulopathy Associated with Renal Extramedullary Hematopoiesisin a Patient with Primary Myelofibrosis

Sami Mesgun,[1] Daniel Grosser,[1] Kwadwo A. Oduro,[2] Jing Wang,[1] Adily N. Elmi,[1] Richard Y. Chang,[1] Arash Rashidi.[1] *[1]University Hospitals, Cleveland, OH; [2]University of Wisconsin-Madison School of Medicine and Public Health, Madison, WI.*

Introduction: Primary myelofibrosis (PMF) is a rare form of myeloproliferative neoplasm (MPN) that results in increased megakaryocytes and granulocytes, leading to marrow fibrosis, cytopenia, and splenomegaly due to extramedullary hematopoiesis (EMH). Glomerular involvement is rare and characterized by renal injury and proteinuria. MPN-related glomerulopathy is an underrecognized late complication of MPN.

Case Description: A 75-year-old woman with PMF and CKD presented with AKI and proteinuria. She was previously diagnosed with CALR type-1 myelofibrosis for which she began darbepoetin alfa. She was monitored without immune-modulation therapy. A kidney biopsy revealed EMH, notably present with atypical megakaryocytes on light microscopy. Interstitial fibrosis was also noted throughout most of the sampled cortex. She was diagnosed with PMF-related glomerulopathy with EMH.

Discussion: PMF findings vary by the phase of the neoplastic process from hypercellular marrow with myeloid predominance to hypocellular marrow with fibrosis and atypical megakaryocytes. Glomerular changes in MPN are sparsely described, with observed lesions possibly linked to the overproduction of cytokines and growth factors by clonal hematopoietic cells. Generally, the presence of EMH within glomerular capillaries, namely megakaryocytes, distinguishes MPN-related glomerulopathy from other glomerulopathies. EMH found in our case argues for direct involvement of the kidney by the neoplastic process. In sum, patients with PMF should be screened for proteinuria and kidney injury as early as possible, for the presence of renal dysfunction should be concerning for renal EMH and MPN-related glomerular disease.

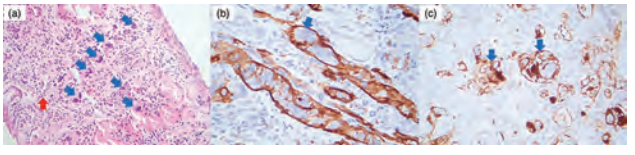


Figure 1. Kidney biopsy findings: (a) Renal interstitium is prominently infiltrated by hematopoietic elements, including erythroid precursors (red arrow on illustrative cluster), characterized by round hyperchromatic nuclei and eosinophilic to basophilic cytoplasm, and atypical megakaryocytes (blue arrows), characterized by clustering and bulbous hyperchromatic nuclei. Renal proximal tubules are visible at the top and bottom of the image. (b) Megakaryocytes are also found in vascular spaces, highlighted by CD34. (c) Megakaryocytes stain with Factor 8.

SA-PO183

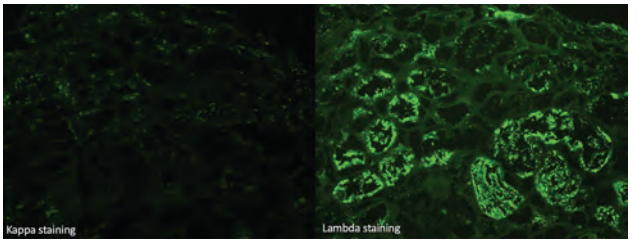
Where's Walden? Rare Manifestation of Waldenström Macroglobulinemia as Proximal Tubulopathy

Ethan N. Downes, Selvaraj Muthusamy, Jason M. Kidd. *Virginia Commonwealth University, Richmond, VA.*

Introduction: Waldenström's macroglobulinemia (WM) is an IgM monoclonal gammopathy that rarely effects the kidneys. We present a patient with WM with proximal tubulopathy that responded to treatment with Rituximab and Zanubrutinib.

Case Description: A 67-year-old man with CLL and mixed connective tissue disease manifested with Raynaud's phenomenon was seen for evaluation of proteinuria. Physical exam was significant for blood pressure of 127/85 and a vasculitic lower extremity rash. Serum creatinine was 1.2 mg/dl and spot urine protein/creatinine ratio (UPCR) was 1.4 g/g. Urinalysis was significant only for proteinuria and he was noted to have a positive urine immunofixation with elevated lambda light chains. A kidney biopsy was performed which showed findings consistent with a proximal tubulopathy and interstitial and perivascular clusters of mononuclear cells with a predominance of lambda staining on immunofluorescence (Figure 1). A bone marrow biopsy was significant for 5-10% CLL/SLL cells and 4% lambda monoclonal plasma cells. Further serologic testing revealed an elevated IgM level of 1493 mg/dl and type I cryoglobulins. A diagnosis of Waldenström's macroglobulinemia was made and treatment with rituximab was initiated. Two months later, proteinuria had decreased to 0.7 g/g but serum IgM failed to improve, and he developed acrocyanosis. He was started on the Bruton Tyrosine Kinase inhibitor (BTK), Zanubrutinib. Seven months after the initial presentation, UPCR decreased to 0.2g/g with stable kidney function.

Discussion: Kidney involvement in WM is rare and most often manifests as amyloidosis or cryoglobulinemic glomerulonephritis. Our patient presented with a light chain proximal tubulopathy without evidence of Fanconi syndrome. Proteinuria resolved by treating his WM with Rituximab and Zanubrutinib, before a hematologic response occurred.



Immunofluorescence staining of proximal tubular cells

SA-PO184

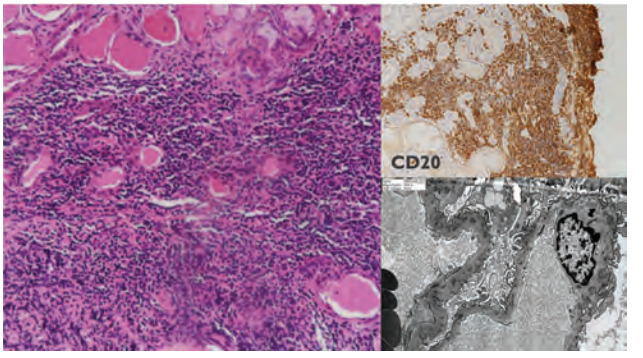
Acute Tubulointerstitial Nephritis with Membranous Nephropathy in a Patient with Newly Diagnosed Waldenstrom Macroglobulinemia

Napat Wongmat, Nitcha Suphatheerawatr, Oraphan Kongpanvijit, Solos Jaturapisanukul. *Navamindradhiraj University, Bangkok, Thailand.*

Introduction: Waldenstrom's macroglobulinemia (WM) is a rare B-cell lymphoproliferative neoplasm characterized by monoclonal immunoglobulin M (IgM) production. Renal involvement in WM is uncommon, often presenting as monoclonal-related kidney diseases like amyloidosis and cryoglobulinemia. Here, we report a rare case of WM associated with acute tubulointerstitial nephritis (ATIN) and membranous nephropathy (MN).

Case Description: A 62-year-old Thai woman was referred for rapid declining kidney function. 1 month prior to presentation, she had generalized edema, fatigue, and foamy urine. She had no prior medical history and was previously active. Physical examination revealed anemia, hepatosplenomegaly, and signs of volume overload. Laboratory results showed a serum creatinine level of 10.9 mg/dL and urine protein of 6 g/day without active urine sediment. Serum protein electrophoresis demonstrated IgM kappa monoclonal gammopathy. A bone marrow biopsy was consistent with lymphoplasmacytic lymphoma. Kidney biopsy findings included ATIN with B-cell lymphoma infiltration. Immunohistochemistry showed heavy interstitial staining for CD20+ and kappa light chain restriction. Electron microscopy revealed numerous subepithelial electron-dense deposits consistent with membranous nephropathy. The patient received a CHOP regimen, which improved the anemia; however, kidney function did not recover.

Discussion: In this case report, we describe a previously healthy woman presenting with rapidly progressive kidney function decline as the initial manifestation of her WM. Kidney pathology revealed ATIN due to lymphomatous infiltration and MN.



Light microscopy, immunohistochemistry for CD20+ shwoed acute tubulointerstitial nepritis from lymphomatous infiltration and electron microscopy show numberous subepithelial electron deposit.

SA-PO185

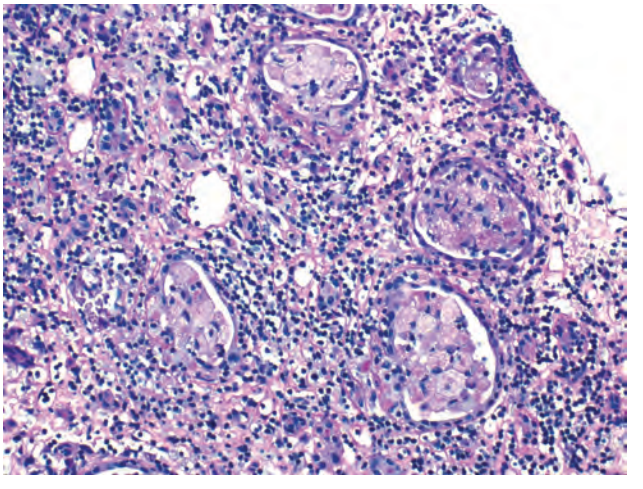
Unique Dystrophic Xanthomatous Reaction in Renal Parenchyma Due to T Cell Lymphoma

Sharmilee Vuyyuru, Rajib K. Gupta, Nasim Wiegley, Hiba Hamdan. *University of California Davis, Sacramento, CA.*

Introduction: While B-lymphocyte and plasma cell-associated kidney involvement have been described extensively in literature, kidney involvement by T-cell lymphoma remains a rare phenomenon. Rare case reports have described an interstitial nephritis-like picture in association with peripheral T cell lymphoma. We describe a unique dystrophic xanthomatous reaction in the kidney parenchyma in association with interstitial involvement with a CD8+ve T cell lymphoma.

Case Description: A 23-year-old woman with autoimmune encephalitis, seizure disorder hypogammaglobulinemia due to Common Variable Immune Deficiency (CVID), and CD3+/CD8+ T cell lymphoproliferative involvement of the liver and bone marrow, was admitted for seizures, and found to have non-oliguric acute kidney injury (Creatinine (Cr) of 4.42 mg/dL (baseline 1) with severe metabolic acidosis (serum bicarbonate of 9 mmol/L). Urine showed hematuria and proteinuria of 1.6g/g. Kidney ultrasound showed bilateral enlarged kidneys measuring 14.8cm and 16cm with diffuse infiltrative process. Kidney biopsy showed unremarkable glomeruli and an abnormal-appearing tubulointerstitium in the form of diffuse interstitial sheets and intra-tubular collections of foam cells/histiocytes, along with a patchy infiltrate of atypical T-lymphoid cells of CD3/CD8-lineage. (image 1) She was started on methotrexate 5mg/m2 weekly and prednisone 1mg/kg by her oncologist. On follow up, kidney function had improved with most recent Cr of 1.98mg/dL.

Discussion: We describe a unique histologic reaction (dystrophic xanthoma cells in the interstitium and within dilated kidney tubules) in association with interstitial involvement by a T-cell lymphoma, which has not been described before in the kidney, although such xanthomatous reaction has been described for cutaneous T-cell lymphomas. Awareness is vital in identifying such rare kidney histomorphology in association with T-cell lymphomas.



SA-PO186

Granulomatous Interstitial Nephritis Due to Small Lymphocytic Leukemia: A Management Conundrum

Ivette Gomez, Daniele Rios Leite, Sheena Pramod. *University of Florida, Gainesville, FL.*

Introduction: Granulomatous interstitial nephritis (GIN) is a rare morphological variant of interstitial nephritis defined histologically by the presence of interstitial inflammation and 1 or more interstitial granulomas, with a low incidence of 0.5% -5.9% of biopsies of acute interstitial nephritis. Small lymphocytic leukemia (SLL) can cause infiltration of kidneys in 60–90% of patients, however, renal dysfunction is uncommon

Case Description: We describe a 70-year-old male with history of hypertension, A. fib and BPH referred for declining renal function and hypercalcemia for 8-months, associated with weight loss and fatigue. Initial Creatinine was 3.57 mg/dL (baseline creatinine 0.57 mg/dl) and calcium level of 13 mg/dL with suppressed PTH. Patient's proteinuria was 1.2 grams per day with albuminuria of 50 mg per day. His SPEP was normal with k/l ratio of 2. Bone marrow biopsy showed small lymphocytic leukemia. Kidney biopsy showed B-cell infiltrates, few plasma cells, T cells and eosinophils and discrete noncaseating granulomas consistent with granulomatosis interstitial nephritis with Interstitial fibrosis and tubular atrophy (IFTA) of 70%. His presentation was consistent with GIN which is rarely associated with SLL. Patient was a started-on prednisone 60 Mg daily, with improvement of renal function to creatinine of 1.9 mg/dL. As soon as prednisone was discontinued, renal function worsened with creatinine increase to 3.2mg/dl, proving steroid sensitive GIN. Patient was started on Acalabrutinib for SLL along with prednisone and continued on prednisone 10mg with creatinine 1.7 to 1.9 mg/dL 14 months since presentation.

Discussion: GIN is suspected to be a local hypersensitivity reaction, which would explain its adequate response to steroids with or without SLL directed chemotherapy. There are no established management guidelines for these cases. Here we highlight the possibility of using low dose prednisone following a taper as an option for this uncommon entity to stabilize renal dysfunction. Another aspect of our case is the degree of response to steroids in spite of severe IFTA which is clinically important. GIN associated with SLL is a rare manifestation with overall poor outcomes.

SA-PO187

Worsening Proteinuria Reveals Lymphoplasmacytic Lymphoma

Iskandar Berbari, Fayaz A. Khan, Moarij A. Qazi, Madelyn Durhman. *TriHealth Inc, Cincinnati, OH.*

Introduction: A patient presented with worsening proteinuria diagnosed as Lymphoplasmacytic Lymphoma (LPL). Chemotherapy treatment was effective, significantly improving proteinuria and IgM levels

Case Description: A 59-year-old male with chronic lymphocytic lymphoma (CLL), Diabetes presented with new nephrotic range proteinuria of 3172 mg/g microalbumin/creatinine ratio from baseline of around 600, new foamy urine and creatinine elevation from 0.8 to 1 mg/dL. Further tests revealed elevated IgM (1243), kappa/lambda free light chain ratio (9.35), hypercalcemia, and IgM kappa spike (0.61 g/dL). Bone marrow biopsy showed a 30-40% cellular infiltrate of small lymphocytes. Kidney biopsy was pursued due to unexplained worsening proteinuria which revealed mild mesangial expansion with patchy dense mononuclear inflammatory infiltrates predominantly small lymphocytes (CD20+ve) with scattered plasma cells (figure 1), consistent with LPL. After 2 cycles of Rituximab-bendamustine, urine protein/creatinine ratio improved from 1.23 to 0.62; IgM level decreased to 327, M spike to 0.13 g/dL, creatinine back to baseline and urine appearance normalized.

Discussion: This case highlights the importance of proteinuria surveillance, especially in patients with CLL. Any changes in proteinuria should be aggressively investigated while other management strategies are pursued. A low threshold for kidney biopsy is crucial, as timely intervention can help preserve kidney function. Further research is essential to deepen our understanding of the pathogenesis and potential connections between CLL and LPL. While these conditions are distinct entities, cases of their co-occurrence have been documented. Investigating these associations more thoroughly could offer valuable insights into the mechanisms of disease and therapeutic strategies.

SA-PO188

Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits Is Not Only a Disease in Elderly Patients but Also a Disease in Young Patients

Neeharik Mareedu, Hassaan Rasheed. *UPMC Western Maryland, Cumberland, MD.*

Introduction: Proliferative glomerulonephritis with monoclonal immunoglobulin deposits (PGNMID) is a special category of disease within the group of disorders, monoclonal gammopathy of renal significance (MGRS). Though it is an uncommon disorder, PGNMID is increasingly recognized in the recent times. Though PGNMID can occur at any age, the average age of onset is usually around 55 years.

Case Description: We report a young 31 year old female patient with history of resistant hypertension, type 2 diabetes mellitus and morbid obesity admitted to the hopsital with acute kidney injury and and noted to be having nephrotic syndrome with urine protein of 21 gm/24 hour, from biopsy-proven PGNMID with IgG3 kappa light chain deposistion. The patient failed treatments with Bortezomib, Lenalidomide, Dexamethasone (VRd) and daratumumab, bortezomib and dexamethasone. She had partial response to cyclophosphamide, bortezomib and dexamethasone (CyBorD) along with daratumamab with eventual worsening of proteinuria again. During the course of her disease, she continued to have significant problems with resistant hypertension as well as cardiac problems including coronary artery disease requiring 4-vessel bypass grafting. Unfortunately, despite multiple lines of chemoterapeutic/immunosuppressive agents the patient eventually progressed to end stage renal disease requiring initiation of hemodialysis.

Discussion: Though MGRS/PGNMID are rare causes of renal dysfunction, early recognition and early initiation of proper management of these patients is of utmost importance for improved renal outcomes. Unfortunately, due to unclear pathogenic mechanisms effective treatment options remains limited and usually treatment regimens are aimed at clone-directed therapies in patients with detectable clones as well as without detectable clones where the treatment is directed at potential hypotehtical clones. Moreover, our case also demonstrates that PGNMID can happen even in younger patients and may be associated with more aggressive disease with limited response to the traditional chemotherapeutic agents.

SA-PO189

Lysozyme Is No Lie! AKI in a Patient with Acute Myeloid Leukemia

David Lyu, Renuka Tolani, Shane A. Bobart, Lawrence Rice, Angelina Edwards, Ethan A. Burns, Tariq Shafi. HMH Nephrology. *Houston Methodist, Houston, TX.*

Introduction: In patients with leukemia who develop acute kidney injury (AKI) we often suspect tumor lysis syndrome and other common etiologies such as cytokine release syndrome. Lysozyme-induced nephropathy (LyN) is a less recognized cause of AKI. When monocytic cells release lysozyme, a small cation, it is filtered by the glomerulus and reabsorbed by the proximal tubule, resulting in toxic tubular injury. We present a case of a patient who was diagnosed with acute myelomonocytic leukemia (AMML) and had AKI with elevated lysozyme level in the blood that improved with treatment of the underlying leukemia.

Case Description: A 77 year old male with PMH of myelodysplastic syndrome (MDS) was noted to have 0.5 grams of proteinuria and AKI with serum creatinine of 1.9mg/dL from a prior baseline of 1.1 mg/dL. Serological studies and work up for paraproteinemia and thrombotic microangiopathy was negative. CBC showed worsening anemia, increasing leukocytosis (29.4 k/uL) with 18% monocytes and Pelger-Huët neutrophils, as well as thrombocytopenia and the patient was admitted for suspected acute leukemia. Bone marrow biopsy showed AMML, 28% blasts, hypercellular marrow (50%) with trilineage hematopoiesis and monocytosis. Given the severe thrombocytopenia, kidney biopsy was unable to be safely attempted. Given the new diagnosis of AMML, a lysozyme enzyme assay was ordered and the level was greater than 10 ug/mL (normal range < 4.5 ug/mL). Treatment with decitabine infusions commenced and one month after initiation, lysozyme levels decreased to 4.37 ug/mL and creatinine improved to near the patient's baseline (1.1 mg/dL). The clinical course was consistent with a diagnosis of lysozyme-induced AKI in the setting of AMML.

Discussion: While kidney biopsy remains the gold standard for diagnosis of AKI in the setting of acute leukemia, when unable to be safely performed, clinicians should be aware of the clinical entity of lysozyme-associated AKI. Checking and trending lysozyme enzyme levels can also be a useful tool to guide management of AKI in this setting. In our case, once treatment for AMML was started both lysozyme levels and serum creatinine improved.

SA-PO190

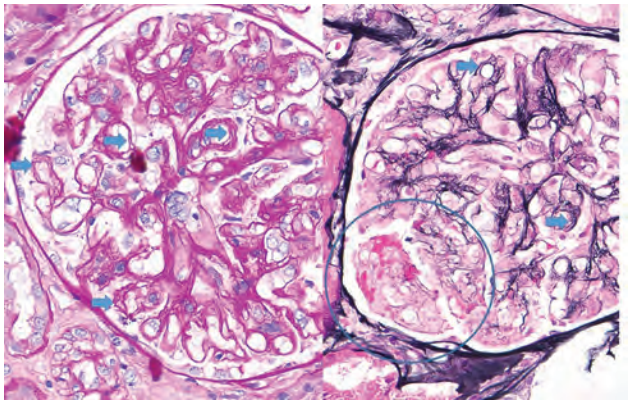
A Diagnostic Dilemma: Renal Limited Thrombotic Microangiopathy in a Stem-Cell Transplant Recipient

Virender S. Mahabir, Meghan Kapp, Arash Rashidi. *University Hospitals, Cleveland, OH.*

Introduction: Kidney disease following hematopoietic stem cell transplantation is attributed to a variety of etiologies

Case Description: A 59 year old male with history of diffuse large B cell lymphoma was seen in consultation for an elevated serum creatinine (SCr) of 1.8 mg/dL. He had previously failed therapy with multiple treatments, initially Rituximab, Etoposide phosphate, Prednisone, Vincristine sulfate, Cyclophosphamide, Doxorubicin hydrochloride (R-EPOCH), followed by CAR-T therapy, and most recently allogenic stem cell transplant. He was being treated with Epcoritamab (anti-CD20 agent) at time of consultation. He was not on a Calcineurin inhibitor. Urinalysis and imaging studies were unremarkable. Urine total protein creatinine ratio was mildly elevated at 0.32 mg/mg, with no monoclonal protein on urine electrophoresis. There were no schistocytes on peripheral smear and no thrombocytopenia on complete blood count. LDH was mildly elevated to 340. A renal biopsy was performed given no clear etiology of SCr elevation. Renal biopsy showed diffuse double contouring of glomerular basement membranes (arrows), focal segmental mesangiolysis with red cell fragmentation and microaneurysm formation (circle) and focal segmental endocapillary hypercellularity. There were no immune complexes by immunofluorescence. These findings were indicative of chronic endothelial injury (so-called Chronic Thrombotic Microangiopathy [TMA]).

Discussion: Early detection of transplant associated TMA is critical given potential for multiple organ dysfunction syndrome and death. Management options include Rituximab, Defibrotide and Eculizumab but evidence is limited to small cohorts and observational data. The patient was planned to start Eculizumab, and renal function remained stable at follow up visit. This case highlights the importance of renal biopsy in making this diagnosis since there were no obvious clues to suggest TMA from history and lab investigations.



SA-PO191

Battle Beyond the Bone Marrow! Case Report of Extramedullary Plasmacytoma with Multiple Myeloma

Aashvi R. Dalal, Michael Liben, Sein Y. See. *NewYork-Presbyterian Brooklyn Methodist Hospital, Brooklyn, NY.*

Introduction: Plasma cell neoplasms includes monoclonal gammopathy of undetermined significance, multiple myeloma (MM), and solitary plasmacytomas. Extramedullary plasmacytomas (EMPs), found in soft tissues, are rare, with mediastinal involvement even rarer. Only 5% of EMPs coexist with MM. We present a rare case of MM and concurrent mediastinal extramedullary plasmacytoma in a patient who presented with AKI.

Case Description: A 62 year old male patient with medical history of hypertension, hyperlipidemia with baseline creatinine of 1.1 mg/dl presented to the hospital, asymptomatic with abnormal labs of elevated creatinine to 6.9 mg/dl and anemia of 8.9 g/dl. Kidney injury was initially considered prerenal due to recent NSAID use. Incidental finding of anterior mediastinal mass on imaging was noted. Workup included elevated UPCR (7.56 gram), positive SPEP with monoclonal lambda light chain, elevated free Lambda light chains (13136.56 mg/L) and K/L Ratio of <0.01. Kidney biopsy confirmed monoclonal immunoglobulin deposition disease, monoclonal lambda light chains with light chain cast nephropathy and chronic tubulointerstitial disease without amyloid positivity. Bone marrow biopsy was notable for MM coexpressing lambda light chain. Mediastinal mass biopsy confirmed plasmacytoma. Due to worsening renal function, hemodialysis was initiated. Chemotherapy (bortezomib, cyclophosphamide, dexamethasone and daratumumab) led to significant reduction in lambda light chain allowing discontinuation of dialysis.

Discussion: Solitary osseous plasmacytomas are known to progress to MM, the likelihood of soft tissue EMPs (particularly involving anterior mediastinal) evolving into systemic disease is rare. In our case it is unclear which condition developed first, this case underscores the importance of considering a broad differential diagnoses in patients with acute kidney injury and associated mass. Renal complications like light chain cast nephropathy significantly impact morbidity and mortality. Treatment involves stem cell transplantation for eligible patients, radiation or chemotherapy. Early recognition and intervention, by nephrologists and oncologists, is crucial for improving survival.

SA-PO192

A Rare Case of Myelomatous Ascites with ESKD

Berk Celik, Unnati Bhatia, Sami S. Zarouk. *Corewell Health Beaumont Hospital, Royal Oak, MI.*

Introduction: Ascites is seen in less than 1% of patients with multiple myeloma (MM) and can be difficult to manage in the setting of concomitant kidney disease. Literature review revealed that myelomatous ascites has never been described concomitantly with end-stage kidney disease (ESKD). Here we describe an ESKD patient with relapsing MM presenting with refractory ascites.

Case Description: A 63-year-old African American male presented in February 2023 with acute kidney injury. He was initiated on hemodialysis (HD). Bone marrow biopsy showed more than 90% plasma cells. Flow cytometry showed lambda-restricted plasma cell myeloma. He was treated with CyBorD regimen (cyclophosphamide, bortezomib, dexamethasone). An autologous bone marrow transplant was done in November 2023 and showed relapse proven by bone marrow biopsy in January 2024. He presented with ascites in April 2024. Laboratory tests revealed decreased total protein but normal levels of albumin, ALT, AST, ALP, and total bilirubin. CT abdomen/pelvis showed a large amount of ascites with infiltration of the omentum. Paracentesis was done multiple times. Peritoneal cytology and flow cytometry showed CD138-positive plasma cells. Serum ascites albumin gradient (SAAG) was 1.4 g/dL, total nucleated cell count of 2742, and 2.8 g/dL total protein. Persistent hypotension prevented ascites control in spite of albumin use with hemodialysis.

Discussion: Myelomatous ascites is present in less than 1% of non-dialysis patients and significantly reduce the life expectancy. Rare cases of myelomatous ascites with acute kidney injury were previously described. ESKD patients dependent on HD have never been reported to have myelomatous ascites. It should be considered as a cause of ascites after other etiologies are excluded. Multiple studies showed SAAG is being helpful in diagnosing ascites with more than 90% sensitivity and specificity. A SAAG of less than 1.1 g/dL is expected in myelomatous ascites. However, in our case, SAAG was 1.4 g/dL on two different measurements. The presence of ascites makes dialysis ultrafiltration challenging without much benefit. In our case, abdominal paracentesis was helpful for immediate relief.

SA-PO193

No More Wandering To and Fro: Shedding Light on TAFRO

Nisarg Gandhi,[1] Xixi Zhao.[2] *[1]Stanford Medicine, Stanford, CA; [2]VA Palo Alto Health Care System, Palo Alto, CA.*

Introduction: TAFRO syndrome is a systemic inflammatory disease characterized by thrombocytopenia (T), anasarca (A), fever (F), reticulin fibrosis (R), and organomegaly (O), often accompanied by AKI. Recently described in 2010 through a case series of Japanese patients, TAFRO is now recognized as a subtype of human-herpesvirus 8 (HHV8) negative idiopathic multicentric Castleman disease (iMCD). Herein, we present a rare case of TAFRO syndrome with AKI requiring dialysis, who was successfully treated with rituximab-based chemotherapy.

Case Description: A 45-year-old previously healthy male presented with anasarca and was found to have new thrombocytopenia, leukocytosis, anemia, and extensive abdominal and axillary lymphadenopathy. After undergoing an excisional lymph node biopsy and a bone marrow biopsy, he was diagnosed with HHV8-negative iMCD, TAFRO subtype, and started on dexamethasone and siltuximab. Despite treatment, creatinine rose from 0.8 mg/dL to 3.11 mg/dL with hyperkalemia requiring hemodialysis. Labs were notable for IL-6 of 35.6 pg/mL (ref: <5 pg/mL) and VEGF of 446 pg/mL (ref: 31-86 pg/mL). UA was negative for proteinuria and hematuria. Renal biopsy showed intact glomerulus with mesangiolysis, glomerular basement membrane double contouring, and scattered fragmented RBCs consistent with thrombotic microangiopathy (TMA). Given severe features of the disease without improvement in renal function, he was initiated on a rituximab-based chemotherapy regimen (R-CHOP) with immediate response. His kidney function returned to its previous baseline two weeks later.

Discussion: TAFRO syndrome is an underrecognized condition that can result in AKI requiring dialysis. Despite the majority of TAFRO cases describing AKI as a central feature, descriptions of renal histology and treatment regimens have been limited in the literature. Prior kidney biopsies have commonly reported MPGN and TMA, which led to the postulated mechanism of injury to occur via IL-6 and VEGF leading to glomerular microangiopathy. Our patient was refractory to IL-6 blockade with siltuximab, suggesting the pleomorphic cytokine profile of iMCD and that IL-6 may not be the primary driver of inflammation. Due to the rarity of the condition and paucity of data guiding treatment, our case adds to the otherwise limited clinical description, renal histology, and treatment of TAFRO syndrome.

SA-PO194

A Rare Incidental Finding of Erdheim-Chester Disease

Maria A. Chilo Bejarano, Sonya D. Shah, Rohin Gurumurthy, Jeanine Hernandez, Celia P. Corona Villalobos, Nityasree Srialluri. *Johns Hopkins Medicine, Baltimore, MD.*

Introduction: Erdheim–Chester Disease (ECD) is a rare non-Langerhans histiocytic disorder marked by histocyte overproduction and tissue infiltration affecting the retroperitoneum, large vessels, heart, lung and central nervous system. Clinical presentation is nonspecific and varies depending on the organ involved. Here we report an incidental case of ECD in a patient with acute kidney injury (AKI).

Case Description: A 77-year-old white male with coronary artery disease, heart failure, and tobacco use presented for facial and shoulder burns after cardiac syncope and fall onto a space heater. He was found to have enterococcus faecalis bacteremia with right aortic valve vegetation, AKI and pulmonary embolism. Incidentally, CT abdomen pelvis showed irregular symmetric soft tissue infiltration of bilateral perirenal spaces, known as “hairy kidney” appearance, modest bilateral pelviectasis and soft tissue thickening surrounding the thoracic and intra-abdominal aorta (Fig. 1). Initial creatinine was 1.79 mg/dl which increased to 5.32 mg/dl in 24 hours. Biopsy of the lesion was deferred due to anticoagulant requirements and rapid clinical decline with volume overload and mental status changes. He was on hemodialysis briefly and transitioned to hospice per family wishes. Radiological features in this case, including the “hairy kidney” appearance, periaortic soft tissue, sparing of the vena cava and ureters, interlobular septal thickening and pleural effusion, are characteristic for ECD and support the diagnosis.

Discussion: ECD is a multiorgan disorder marked by sclerotic lesions of the long bones and perirenal infiltration. Less than 10% of cases occur without bone lesions, necessitating the consideration of histopathology and radiological characteristics for diagnosis. Given the nonspecific nature of ECD, early recognition of the radiological presentations as in our patient is crucial for timely diagnosis and management. Recent discoveries of underlying mutations, like the common BRAFV600E mutation, have shaped the use of targeted therapies such as BRAF inhibitors to prevent disease progression.

Figure 1 Axial contrast-enhanced CT images of the chest. (a) Soft tissue encasement of the thoracic aorta(yellow arrowheads) and presence of pleural effusion (*). (b) axial and (c) coronal contrast-enhanced CT images of the abdomen depict soft tissue encasement of the kidney (arrows) secondary to retroperitoneal infiltration with dilation of renal pelvis.

SA-PO195

The Case of the Hairy Kidneys

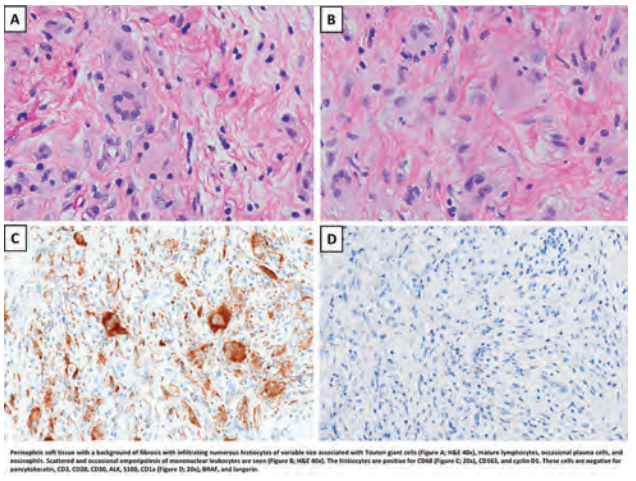
Nazish Khan, Vimal K. Derebail, Ryan Bonner, Vanessa Moreno. *The University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Introduction: Erdheim-Chester disease (ECD) is a multi-organ infiltrative disease due to to non-Langerhans histiocytosis, causing mostly bone and skin lesions. Kidney involvement occurs in 30% of patients.

Case Description: A 54-year-old male with hypertension experienced flank pain and was diagnosed with kidney stones 4 years prior. He had sclerotic bone lesions on imaging and biopsies demonstrated non-specific myelofibrosis. More recently, he had worsening flank pain and renal insufficiency. By computed tomography, extensive bilateral perinephric edema and fat stranding was seen, identified as “hairy kidney sign”, a finding pathognomonic for ECD. Kidney biopsy was performed to establish diagnosis and perform genetic sequencing and demonstrated macrophage-predominant histiocytic infiltrate. Tissue was BRAF negative by immunohistochemistry, but BRAF positive by molecular analysis. The patient was diagnosed with ECD based on his clinical, imaging, and biopsy findings and began MAPK/extracellular signal regulated kinase (MEK) inhibitor therapy.

Discussion: Fewer than 1,000 cases of ECD are reported. Somatic mutations of BRAF or other MAPK signaling pathway components result in myeloid progenitor cell proliferation. Kidney involvement presents as reduced glomerular filtration rate, perinephric stranding, hydronephrosis, renovascular hypertension, or flank pain with infiltration and enlarged kidneys. Tissue biopsy (often skin or kidney) establishes diagnosis and identifies mutations for targeted therapy.

CT scan with extensive bilateral perinephric stranding



Perinephric soft tissue with a background of fibrosis with infiltrating numerous histiocytes of variable size associated with Touton giant cells (Figure A; H&E 40x), mature lymphocytes, occasional plasma cells, and eosinophils. Scattered and occasional emperipolesis of mononuclear leukocytes are seen (Figure B; H&E 40x). The histiocytes are positive for CD68 (Figure C; 20x), CD163, and cyclin D1. These cells are negative for pancytokeratin, CD1, CD30, CD30, ALK, S100, CD1a (Figure D; 20x), BRAF, and langerin.

SA-PO196

Isosorbide Mononitrate (IMN) for Anti-vascular Endothelial Growth Factor (VEGF)-Induced Kidney Injury

Jaya Kala, Kevin W. Finkel. *The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX.*

Background: Antiangiogenic drugs that target VEGF and its receptors are standard treatment for several cancers. Their action on VEGF expression has been associated with acute kidney injury(AKI), proteinuria and hypertension(HTN) which result in delay, interruption or reduction of effective dose in cancer patients. These effects have been attributed to the downregulation of nitric oxide(NO). Current recommendations for treatment of anti-VEGF induced HTN include use of ACE inhibitors and non-dihydropyridine calcium channel blockers but strategies to prevent proteinuria or AKI are lacking. NOdonors normalize blood pressure in anti-VEGF induced HTN. Studies have shown pre-treatment with long lasting NOdonors protect against development of anti-VEGF induced HTN. Paucity of large clinical studies using NOdonors for proteinuria, AKI and HTN prompted us to investigate this modality of treatment

Methods: Study-Population: Adult patients with AKI(≥ 25%decrease in eGFR)), HTN (systolicBP≥140mmHg and/or diastolicBP≥90 mmHg) and/or proteinuria(UPC of >500mg/g) while on anti-VEGF therapy. **Treatment:** Patients were randomized to treatment(IMN 60mg/d with dose escalation to 120mg/d in 4weeks if no response) or placebo arm. Criteria for Response(≥1) included improved eGFR≥25%; reduction in UPC by >500 mg/day;reduction in SBP≥10mm Hg and/or DBP≥5mmHg. **Follow-up:** UPC and eGFR were monitored monthly and blood pressure weekly. **PrimaryEndPoint:** Reduction in UPC by >500mg/day. **SecondaryEndPoints:** Improved eGFR≥25%;reduction in SBPof ≥10mmHg and/or DBP≥5mmHg

Results: 42 patients were screened and 9 were enrolled. Seven were randomized to treatment and two to placebo. In treatment arm, two patients showed proteinuria response but none showed eGFR response. Four showed responses in their SBP. The two patients who showed improvement in proteinuria had preceding improvement in HTN. Neither patient in placebo arm showed response in UPC or eGFR, but unexpectedly showed improved systolicBP. Unfortunately, COVID-19 pandemic precluded further recruitment and study was terminated

Conclusions: Treatment with NOdonors could be considered when ACEinhibition and non-dihydropyridine calcium channel blockers fail to control proteinuria in anti-VEGF treated patients. Larger population-based studies are needed to evaluate the use of NOdonors to improve renal prognosis in patients while allowing them to continue anti-VEGF treatment

Funding: Government Support - Non-U.S.

SA-PO197

Renal Adverse Events Associated with Atezolizumab Plus Bevacizumab, Carboplatin, and Paclitaxel (ABCP) Therapy in Patients with Non-small Cell Lung Cancer

Yusuke Watanabe, Koji Tomori, Tsutomu Inoue, Hirokazu Okada. *Saitama Ika Daigaku, Iruma-gun, Japan.*

Background: In recent years, the combination therapy comprising immune checkpoint inhibitors (ICIs), VEGF inhibitors, and cytotoxic anticancer drugs has gained prominence in treating various advanced cancers. ICIs, notably, can induce immune-related adverse events (irAEs) like acute interstitial nephritis (AIN), while VEGF inhibitors are associated with proteinuria, occasionally manifesting as nephrotic syndrome (NS). A novel regimen, ABCP therapy (atezolizumab + bevacizumab + carboplatin + paclitaxel), has emerged for non-small cell lung cancer. In the global phase III IMpower150 study of ABCP, renal adverse events included NS in 2.5%, severe AKI in 0.3%, and AIN due to irAE in 0.8%. This study aims to assess renal adverse events in such patients treated with ABCP at our institution, examining their clinical characteristics and risk factors.

Methods: We conducted a study involving 73 non-small cell lung cancer patients treated with ABCP therapy (up to 4 cycles of ABCP, followed by continuation of atezolizumab + bevacizumab combination therapy). We evaluated the incidence of nephrotic-level proteinuria and AKI.

Results: At the initiation of ABCP therapy, the median age was 70 years (IQR 64.5 - 73), UPCR was 0.11 g/gCr (IQR 0.07 - 0.16), and eGFR was 73.1 ml/min/1.73m2 (IQR 58.4 - 87). Patients underwent a median of 6 cycles of ABCP (IQR 2.3 - 11), with a median observation period of 10 months (IQR 5.5 - 15). Notably, 4 patients (5.5%) exhibited UPCR ≥3.5 g/gCr, and 1 patient (1.4%) experienced AKI due to irAE, necessitating steroid treatment. Patients with nephrotic-level proteinuria tended to have higher UPCR at treatment onset (0.24; 0.1- 0.38) vs (0.11; 0.07 - 0.15), lower BMI (18;17.3 - 20.1) vs (21.2; 19.2 - 24.2), and more frequent ABCP therapy sessions (10; 8.3 - 26.8) vs (6; 2 - 10.8) compared to those without.

Conclusions: The incidence of massive proteinuria may be higher during ABCP therapy in real-world clinical practice compared to the phase III trial. Possible contributing factors include patients with elevated UPCR prior to treatment initiation, potential excessive bevacizumab doses in patients with progressive emaciation, and the prolonged duration of ABCP treatment.

Drug-Induced Thrombotic Microangiopathy from Cancer Therapies: A Clinicopathologic Series

Wai Lun Will Pak,[1,2] Andrea Knezevic,[3] Steven Salvatore,[4] Surya V. Seshan,[4] Ilya Glezerman,[1,4] Edgar A. Jaimes,[1,4] Insara Jaffer Sathick.[1,4] *[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]United Christian Hospital, Hong Kong, Hong Kong; [3]Memorial Sloan Kettering Cancer Center Department of Epidemiology & Biostatistics, New York, NY; [4]Weill Cornell Medicine, New York, NY.*

Background: Drug-induced thrombotic microangiopathy (di-TMA) is a major sequela of cancer therapies. The diagnosis of di-TMA is often presumptive, making accurate clinical characterization difficult. Herein we present our experience of biopsy-proven renal di-TMA due to cancer therapies.

Methods: We retrospectively reviewed kidney biopsies performed in a cancer center between 2001 and 2023. We included patients with biopsy-proven di-TMA and presentation consistent with a drug-induced process. We describe their clinical, laboratory, pathologic characteristics, and outcomes.

Results: We identified 53 patients with biopsy-proven di-TMA. Median age of this predominantly female (72%) cohort was 64 (range 44-81) years. Primary malignancies were pancreatic (19%), breast (15%), ovarian (15%) and lung (15%) cancers. Primary causative drugs were gemcitabine (49%), bevacizumab (25%), tyrosine kinase inhibitors (19%), and doxorubicin (15%). A secondary drug exposure was implicated in 28% patients. Hypertension was the commonest symptom (81%), followed by edema (53%). Hematological signs were anemia (77%), thrombocytopenia (29%), elevated LDH (67%), and low haptoglobin (46%). AKI occurred in 41 patients (77%), of which 53% was KDIGO stage 1, 20% was stage 2, and 27% was stage 3. Proteinuria occurred in 59% patients, nephrotic range proteinuria in 20% patients. Median creatinine at presentation was 2.0 (1.7-3.1) mg/dL and median eGFR was 29.2 (16.7-37.3) mL/min/1.73m^2. Majority (84%) had chronic TMA on biopsy, 36% with acute and 13% with subacute features. Cessation of offending drug was the mainstay management in 96%, other treatment included steroids (15%) and eculizumab (8%). Of patients with cessation of drug alone (40, 75%) who experienced AKI (30, 77%), renal recovery was observed in 47% after one year. One out of 9 patients requiring dialysis was weaned off.

Conclusions: We present the largest single institution cohort of patients with biopsy-proven di-TMA from cancer treatment. Though limited by its retrospective nature, our experience suggests that doxorubicin is an underrecognized cause of di-TMA. Many patients had chronic changes on biopsy indicating mild, ongoing endothelial injury before overt TMA develops. Clinical vigilance with early cessation of offending drug may allow for higher rates of renal recovery.

Gamma-Secretase Inhibitor-Associated Hypophosphatemia in Patients with Desmoid Tumors

Wai Lun Will Pak,[1,2] Edgar A. Jaimes,[1,3] Andrea Knezevic,[5] Jordyn Agins,[1] Kenar D. Jhaveri,[4] Aisha Shaikh.[1,3] *[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]United Christian Hospital, Hong Kong, Hong Kong; [3]Weill Cornell Medicine, New York, NY; [4]Northwell Health, New Hyde Park, NY; [5]Memorial Sloan Kettering Cancer Center Department of Epidemiology & Biostatistics, New York, NY.*

Background: Nirogacestat, a γ-secretase inhibitor (GSI), improved progression-free survival in adults with desmoid tumors (*DeFi trial, Gounder et al., NEJM, 2023*). Hypophosphatemia (HP), a class effect of GSI therapy, occurred in 42% of trial subjects. The mechanism of GSI-associated hypophosphatemia (GSI-HP) is unknown. The objective of the study was to elucidate the mechanism of GSI-HP.

Methods: We used our institute's electronic medical record system to conduct a retrospective cohort analysis of the subjects in the DeFi trial, the RINGSIDE trial (an ongoing trial of AL102, another GSI), and those on compassionate use of nirogacestat at a single large cancer center. Clinical and laboratory data on all patients on a GSI were collected and analyzed.

Results: We identified seventeen patients who received nirogacestat or AL102 and had at least one episode of HP between 2020 and 2023 (Figure 1). Twelve patients had GSI-HP; nine of them had diarrhea. Urine fractional phosphate excretion (FePO4) was available in four patients with diarrhea and two without diarrhea. All six patients had a high urine FePO4 and a normal serum fibroblast growth factor 23 (FGF23), and two patients had high serum parathyroid hormone (PTH). 25-OH vitamin D level was low in one patient with a high PTH. In most patients, the hypophosphatemia was not severe (median serum phosphate 2.2, IQR: 1.9-2.2), and treatment with phosphate supplements and anti-diarrheal medications allowed the continuation of GSI therapy.

Conclusions: We conclude that the primary mechanism of GSI-HP is gastrointestinal loss due to diarrhea. High urine FePO4 may also contribute to GSI-HP in some patients, but FGF23 does not mediate it. This is the first study to describe the mechanism of GSI-HP. These findings will equip clinicians with the knowledge to assess the cause of GSI-HP and implement effective therapies to manage GSI-HP, ensuring better patient outcomes.

Funding: NIDDK Support, Other NIH Support - MSK Cancer Center Support Grant/Core Grant P30CA008748

AKI and Perioperative Complications Based on Modality of Nephrectomy for Treatment of Kidney Cancer

Maulinkumar N. Patel,[1] Edgar A. Jaimes.[2] *[1]The University of Texas Health Science Center at Houston, Houston, TX; [2]Memorial Sloan Kettering Cancer Center, New York, NY.*

Background: Historically radical nephrectomy (RN) has been the standard of care for renal masses. However, the use of partial nephrectomy (PN) as a therapeutic modality has become more common. Laparoscopic (LAP) and robotic assisted (RAS) approaches are often used for either RN or PN. In this study we determined the rates of acute kidney injury (AKI) and peri-operative complications based on surgical approach

Methods: We used the National Inpatient Sample NIS 2020-2021 to identify kidney cancer patients who underwent PN or RN. Patients were stratified based on type of surgical approach, (open, LAP or RAS). Bivariate analysis was done using Kruskal Wallis test (for age and length of stay), chi-square test, and Fischer's exact test. Multivariable logistic and negative binomial regression models were used to assess the outcome rates. Multivariable models were adjusted for age, gender, race, hospital teaching status, and hospital region.

Results: Overall, 4,572 had PN, and 8,104 had RN. Median age was 63 years, 64% were male and 72% were whithe. In PN patients 21% had open, 9% had LAP, and 70% had RAS. In RN patients, 32% had open, 25% had LAP, and 43% had RAS. RN had greater risk of AKI (OR 1.73) as compared to PN. In PN patients, open approach had greater risk of AKI (OR 2.41), cardiac complications (OR 1.40), pulmonary complications (OR 2.34), and increased length of stay [rate ratio (RR) 1.81] as compared to RAS. A LAP approach had greater rsik of AKI (OR 1.61) and increased length of stay (RR 1.19,), as compared to RAS. In RN patients, compared to RAS, open approach had greater risk of AKI (OR 1.44), cardiac complications (OR 1.25), intraoperative complications (OR 2.26), pulmonary complications (OR 1.93), vascular complications (OR 3.41), postoperative bleeding (OR 2.6), and increased length of stay (RR 1.72). In RN patients length of stay (RR 1.08) was higher in LAP as compared to RAS.

Conclusions: Our results show a higher risk for AKI among patients undergoing RN as compared to PN. The use of LAP or RAS was associated with a lower risk for AKI and peri-operative complications as compared to open surgery. RAS was linked to a lower risk for AKI and peri-operative complications as compared to LAP. This study underlines the importance of surgical approach on the risk for AKI and perioperative complications in patients undergoing a nephrectomy for cancer.

Impact of Ischemia Time on Kidney Function in Patients with Microcirculation Impairment during Partial Nephrectomy (PN) for Kidney Cancer

Francesco Trevisani, Francesco Cei, Daniele Cignoli, Federico Belladelli, Chiara Re, Giacomo Musso, Arianna Bettiga, Isaline Rowe, Roberta Lucianò, Giuseppe Rosiello, Daniela Canibus, Francesco Fiorio, Roberto Bertini, Andrea Salonia, Francesco Montorsi, Umberto Capitanio. *IRCCS Ospedale San Raffaele, Milano, Italy.*

Background: The role of onco-nephrologists in renal cancer patients (RCC) is crucial due to the risk of surgical AKI and CKD. Despite the benefits of partial nephrectomy (PN) in preserving renal function, arterial clamping during surgery could lead to AKI and CKD, especially in RCC patients with comorbidities like hypertension, diabetes, or vascular diseases. This study aims to investigate the impact of PN on RCC patients with microcirculation impairment (MI)

Methods: Data are from 186 patients with microcirculation impairment undergoing elective partial nephrectomy (PN) for cT1-2 cN0 cM0 RCC. Impairments included hypertension, diabetes, peripheral vasculopathy, or vascular nephropathy. Ischemia time was the duration of clamping the renal artery without refrigeration. Primary outcome was the effect of warm ischemia time (WIT) on renal function postoperatively, at 6 months, and long term. Secondary outcome was hemorrhagic risk, defined as estimated blood loss (EBL) or peri-operative transfusions. Multivariable regression analyses were used

Results: A total of 139 patients (75%) underwent PN with WIT and 47 (25%) without. The baseline median eGFR was 71 mL/min/1.73m^2 for the on-clamp population and 61.4 mL/min/1.73m^2 for the off-clamp population. At multivariable analyses predicting renal function, longer WIT was associated with decreased postoperative eGFR (Est:−0.23, [P<0.001]). Conversely, no association between WIT and eGFR was recorded at 6-month or long-term follow-up (all P>0.1). At multivariable analyses predicting hemorrhagic risk, clampless resection with no ischemia time and PN with short WIT was associated with an increased EBL (Est:−25.77, [P=0.03]) and peri-operative transfusion rate (Est:−0.017, [P=0.04])

Conclusions: Patients and clinicians should know that performing partial nephrectomy (PN) with limited or zero warm ischemia time (WIT) in patients with microcirculation impairment does not improve long-term renal function and increases bleeding and transfusion risk. Our findings support hilum clamping even in these patients

Figure 1: Estimated blood loos and transfusion risk according to the duration of ischemia time in 186 patients with microcirculation impairment.

Trend Analysis of Kidney Neoplasms-Related Mortality, 1999-2020

Mohammad Gul Yousaf Khan,[1] Mohammad Ammar ur Rahman,[2] Saleha Azeem,[2] Luqman Munir,[2] Amna Khalid,[2] Muhammad Talha Shaukat,[2] Ahsan Zil-E-Ali,[1] Umar Farooq,[1] Wania Rehman.[2] NEURALKEy.
[1]Penn State College of Medicine, Hershey, PA; [2]King Edward Medical University, Lahore, Pakistan.

Background: Renal neoplasms represent conditions with prognoses of varying severity depending on the tumor subtype. These neoplasms entail the abnormal proliferation of cells within kidney tissues, characterized by hematuria, localized flank or lumbar mass, extended pyretic episodes, weight reduction and edema in lower extremities. Early detection is critical to intervention, as renal neoplasms are amenable to treatment in their initial stages but may pose an imminent risk in advanced phases. This study aims to evaluate the incidence and mortality rates of kidney neoplasms from 1999 to 2020.

Methods: We examined mortality data for kidney neoplasms from 1999 to 2020 acquired from CDC Wonder Database. The AAMR per 100,000 people and annual percentage change (APC) with 95% confidence intervals were computed. We looked for substantial tests of parallelism that revealed different trends. To determine overall trends and variations in main demographic groupings (gender, race, age, and urban/rural), the Joinpoint Regression Programme was used.

Results: Between the years 1999 and 2020, a total of 275,905 fatalities linked to Kidney neoplasms were documented. An observed pattern of decreasing trend in the AAMR was significant throughout this period. Specifically, there was an APC of 2.34 from 1999 to 2001 followed by a decrease to -1.91 from 2001 to 2020. The analysis additionally demonstrated elevated rates of mortality in subpopulations characterized by male gender, African American and White ethnicities, as well as individuals residing in urban areas.

Conclusions: Between 1999-2020, the United States has witnessed a decline in mortality rates associated with kidney neoplasms, a trend ostensibly due to advancements in medical care and the deployment of comprehensive vaccination programs. Nevertheless, the persistently elevated mortality rates within certain demographic cohorts underscore a critical need for further research to address these disparities. It is imperative that future endeavors focus not only on the general population but also on those subgroups disproportionately affected by kidney neoplasms.

SA-PO203

Extent of Screening for CKD Development and Monitoring for CKD Complications in Childhood Cancer Survivors: A Single-Centre Retrospective Cohort Study

Carolyn Sun,[1,2] David A. Rubenstein,[1,2] Mahmudul Mannan,[1,2] Paul Nathan,[1,2] Tal Schechter,[1,2] Brandon Yip,[1] Anisa Mata,[1] Sham Haddad,[1] Yasmine Hejri-Rad,[1] Vedran Cockovski,[1] Stella Q. Wang,[1] Michael Zappitelli.[1,2]
[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada.

Background: Childhood cancer survivors (CCS) are at risk for CKD. The extent to which CCS are screened for CKD, or monitored for CKD complications is unknown. We evaluated: 1) the extent of screening for CKD in CCS ≥6 months post-cancer therapy; 2) in patients attaining CKD criteria, the extent of monitoring for CKD complications and of nephrology referral; and 3) the association of patient and cancer characteristics with CKD screening.

Methods: Retrospective cohort study of CCS, ≤18 years at cancer diagnosis from 2016–2020 at a quaternary care referral institution. Outcomes: 1) CKD screening (serum creatinine [SCr] or proteinuria); 2) CKD complications monitoring (i.e., repeat SCr/proteinuria; nephrology referral; vitamin D; PTH; hemoglobin; frequency per KDIGO guideline/CKD severity). CKD defined as: a) *"non-strict"*: any abnormal result; b) *"strict"*: ≥2 abnormal results (eGFR or proteinuria); ≥3 months apart; no normal results in between. Associations between characteristics and CKD screening were evaluated using distribution-appropriate univariable analyses.

Results: Of 443 CCS, only 240 (54.2%) and 132 (29.8%) were screened for non-strict and strict CKD, respectively; 41 (17.1%) and 15 (11.4%) attained criteria for non-strict and strict CKD, respectively. In CCS with non-strict and strict CKD respectively, percentages with complications monitoring: SCr measured (92.7%; 100.0%); urine protein measured (76.9%; 86.7%); nephrology referral (54.1%; 61.5%); vitamin D (36.8%; 61.5%); PTH (31.6%; 38.5%); hemoglobin (90.2%; 93.3%). Table: several variables were associated with CKD screening; many are recognized kidney risk factors.

Conclusions: Screening for CKD and monitoring for CKD complications in CCS are not ideal. Kidney guidelines and follow-up in CCS should be improved to reduce CKD and complications.

Funding: Government Support - Non-U.S.

Table. Comparison of characteristics for CCS who were vs. who were ***not*** screened for CKD, using the "non-strict" CKD definition (left) and "strict" CKD definition (right).

	Non-strict CKD		Strict CKD	
Characteristic	CKD screened (N=240)	CKD not screened (N=203)	CKD screened (N=132)	CKD not screened (N=311)

Late Kidney and Blood Pressure Outcomes after Pediatric Hematopoietic Stem-Cell Transplant: A Systematic Review and Meta-Analysis

Carolyn Sun,[1,2] Sahrish Masood,[1] Jenan-Jill Kiyingi,[1] Salma Abrahim,[1] Tal Schechter,[1,2] Victoria E. Lui,[1] Stella Q. Wang,[1] Michael Zappitelli.[1,2]
[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada.

Background: Pediatric hematopoietic stem cell transplant (HSCT) recipients are at risk for late kidney and blood pressure (BP) outcomes, but existing literature on their prevalence is unclear and outcome assessments differ widely. We evaluated 1) the proportion of patients with late kidney and BP outcomes after pediatric HSCT; 2) the proportion of studies that assess AKI in the first 100-days post-HSCT; 3) kidney and BP outcome definition methods reported.

Methods: Searched MEDLINE, Embase, CINAHL, Web of Science, and Scopus (January 2000–November 2022) for observational studies or clinical trials reporting kidney or BP outcomes, ≥6 months post-pediatric HSCT (excluded: N<20; conference abstracts; non-English/French). Categorical (e.g., CKD) and continuous (e.g., GFR) outcome measures were collected. Two reviewers independently reviewed articles, extracted data, and evaluated study quality; a third reviewer resolved disagreements. Stratified meta-analyses of pooled proportions were performed by HSCT indication (malignancy; non-malignancy; both) using a random-effects model. Heterogeneity was assessed; multiple sensitivity analyses were performed.

Results: 12,333 references identified, 45 selected: 36/45(80.0%) and 20/45(44.4%) evaluated late kidney and BP outcomes, respectively; 18/45(40.0%) assessed AKI. Pooled proportions of patients with late kidney and BP outcomes: 15.0% [95% CI 0.11–0.20, I^2=87.2%] and 9.0% [95% CI 0.06–0.13, I^2=92.2%], respectively. Sensitivity analyses (removing different studies) showed similar estimates. Highest proportions were observed for the malignancy HSCT indication. There was significant heterogeneity in pooled estimates (all, p<0.05). GFR, albuminuria, and proteinuria were used to assess kidney function in 26(72.2%), 4(11.1%) and 4(11.1%) studies, respectively. Definitions for late kidney and BP outcomes were at times undefined and varied greatly.

Conclusions: Late kidney and BP outcomes are common after pediatric HSCT, especially in malignancies, but the literature is exceedingly difficult to interpret. Future research should use well-defined kidney and BP outcome definitions with a goal to study data-driven interventions to reduce long-term kidney health burden.

SA-PO205

Association between AKI during Cisplatin Therapy in Children with CKD and Hypertension at 12 and 36 Months after Therapy End

Salma Abrahim,[1] Asaf Lebel,[2,3] Kelly McMahon,[4] Vedran Cockovski,[1] Stella Q. Wang,[1] Jasmine Lee,[1] Michael Zappitelli,[1,2] Able Study Group.[1]
[1]The Hospital for Sick Children Child Health Evaluative Sciences, Toronto, ON, Canada; [2]The Hospital for Sick Children Department of Paediatrics, Toronto, ON, Canada; [3]Emek Medical Center, Afula, Israel; [4]McGill University Health Centre, Montreal, QC, Canada.

Background: Cisplatin (CisP) may cause acute kidney injury (AKI) in children treated for cancer. Predicting post-CisP chronic kidney disease (CKD) or elevated blood pressure or hypertension (≥eBP) remains elusive. We determined: 1) adjusted associations of AKI during CisP therapy with CKD and ≥eBP at 12 and 36 months(M) post-therapy end; 2) whether CKD and ≥eBP at 3M are associated with CKD and ≥eBP at 12 and 36M after CisP therapy end.

Methods: Multicenter prospective study of children treated with CisP followed throughout therapy and for 36M post-therapy end. Exclusion: pre-existing kidney conditions. Urine, blood, BP collected at 3, 12, and 36M post-CisP therapy. Exposures: a) serum creatinine (SCr)-AKI any time during CisP therapy, per KDIGO; b) severe

electrolyte-defined AKI (eAKI) during CisP therapy per National Cancer Institute (NCI) v4.0 criteria; c) composite AKI (SCr-AKI *and* severe eAKI); d) presence of CKD or ≥eBP at 3M post-CisP therapy end. Outcomes at 12 and 36M post-CisP therapy: a) CKD (per KDIGO); b)≥eBP (per AAP guidelines); c) composite of CKD *or* ≥eBP. Analysis: 1) multiple logistic regression (MLR) to evaluate AKI – outcome association (stepwise covariate selection); 2) MLR to evaluate association between 3M and 12M/36M outcomes (for AKI interaction).

Results: Table shows prevalence of CKD and ≥eBP at 12 and 36M. Patients with SCr-AKI, eAKI and composite AKI were more likely to have ≥eBP at 12M. CKD or ≥eBP at 3M did not predict outcome presence at 12 and 36M (Table 1). However, patients with vs. without CKD at 12M were 4.8 times more likely to have CKD at 36M (Table 1).

Conclusions: HTN and CKD were common at 12 and 36M post-CisP therapy. AKI during therapy was associated with ≥eBP at 12M, but the presence of kidney or BP outcomes at 3M did not predict later CKD or HTN. Novel methods to predict kidney health outcomes and interventions to reduce AKI during therapy should be investigated.

Table 1. Adjusted Odds Ratios for Relationship Between SCr-AKI, Severe eAKI and Composite AKI with 12 and 36 Month Outcomes

	12 Month Outcomes	
	CKD[B] n= 119: *48 (40.3%) CKD* Adj OR (95% CI)	≥eBP[C] n=127: *34 (26.8%) ≥eBP* Adj OR (95% CI)
SCr-AKI[A]	1.24 [0.56-2.75]	3.37 [1.39-8.19]
Severe eAKI	0.98 [0.42-2.27]	5.45 [2.09-14.23]
Composite AKI	0.91 [0.32-2.60]	5.18 [1.76-15.24]
3M CKD[D]	1.14 [0.48-2.68]	*NA*
3M ≥eBP	*NA*	0.54 [0.10-2.97]**
36 Month Outcomes		
	CKD[F] n= 81: *27 (33.3%) CKD*	≥eBP[G] n= 88: *26 (29.5%) ≥eBP*
SCr-AKI	0.58 [0.19-1.75]	1.74 [0.65-4.70]
Severe eAKI	1.11 [0.34-3.65]	0.91 [0.27-3.11]
Composite AKI	1.24 [0.27-5.62]	1.37 [0.32-5.86]
3M CKD	0.21 [0.35-1.22]**	*NA*
3M ≥eBP	*NA*	1.11 [0.32-3.83]
12M CKD	4.79 [1.62-14.18]	*NA*
12M ≥eBP	*NA*	2.94 [0.96-9.01]

Legend:

SCr-AKI: AKI defined based on KDIGO guidelines (peak SCr during cisplatin therapy over pre-cisplatin baseline SCr concentration).

eAKI: presence of low magnesium, phosphate or potassium during therapy. The presence of electrolyte abnormalities is common with cisplatin therapy, therefore severe eAKI was defined as NCI-CTCAE v4.0 ≥grade 3.

[A]All models evaluating relationship of 3M or 12M CKD or ≥eBP with 12M and 36M CKD or ≥eBP were adjusted for age and sex; models also included interaction term with SCr-AKI (and SCr-AKI) if the interaction term was statistically significant.

[A]All MLR were adjusted with age <3 at start of therapy and sex in addition to specific variables per outcome and follow up time.

[B]Adjusted with history of nephrotoxic medications 2 weeks before 12 months visit, history of veno-occlusive Disease.

[C]Adjusted with cancer diagnosis of Medulloblastoma; received vancomycin 1 month before visit.

[D]Adjusted with history of nephrotoxic medications 2 weeks before 36 months visit.

[E]Adjusted with baseline eGFR.

**AKI interaction term is significant ($p<0.05$).

SA-PO206

Psychiatric Disorders in Onconephrology Patients: Prevalence, Impact on Survival, and Quality of Life

Jorge I. Zamora Carrillo,[1] Sheila Bermejo Garcia,[2] Ana Callejo,[1] Marina López-Martínez,[1,2] Juan C. León-Román,[1] Marc Patricio-Liébana,[1] Maria Jose Soler.[1,2] *[1]Hospital Universitari Vall d'Hebron, Barcelona, Spain; [2]Vall D'hebron Institut de Recerca (VHIR), Barcelona, Spain.*

Background: Onconephrology has emerged as a crucial subspecialty. Psychiatric disorders are common in cancer and kidney patients, but their impact in Onconephrology patients is not known. The aims of study are to investigate the prevalence and impact of psychiatric disorders on survival and quality of life in Onconephrology patients.

Methods: This prospective study included patients from the Onconephrology Unit (Nov-2021 to Feb-2023). Questionnaires assessed sleep disorders (Epworth scale), depression (GDS, PHQ), cognition (Montreal scale), and anxiety (GAD) at the first visit, 6 months, and 12 months. Clinical and analytical characteristics were collected.

Results: 182 patients were included (mean age 68(±11) years, 70(38.5%) women). 18(9.9%) lived alone, 152(83.5%) lived accompanied and 4(2.2%) in residence. At the first visit, (81)44.5% had sleep disorders, 52(32.7%) depression, 72(39.6%) cognitive impairment, and 14(7.7%) anxiety. Depression was more prevalent in people who lived in residence (p=0.013). Patients with cognitive impairment had a higher prevalence of DM(p=0.003), worse kidney function and were older(p<0.001). Sleep disorders were more prevalent in older patients(p=0.01), and anxiety in women(p<0.001). At six months, anxiety was higher in women(p=0.03) and those with progressive oncological disease(p<0.001). Living alone was linked to more depression(p=0.002). At twelve months, depression correlated with oncological progression(p=0.034). Multivariate analysis identified age as a risk factor for cognitive impairment(OR: 1.1; p<0.001) and female sex for depression(OR: 3.39; p=0.001). At 6 months, female sex was a risk factor for anxiety(OR: 8.6; p=0.01) and living alone for depression(OR: 10.8; p<0.001). 30(16.5%) patients died during follow-up. Kaplan-Meier analysis showed higher mortality in patients with sleep disorders(p=0.039), worse kidney function(p=0.003), and progressive disease(p=0.028)

Conclusions: Onconephrology patients had high rates of depression and anxiety, especially females and people living alone. Comprehensive approaches and early detection tools are essential to improve their survival and quality of life.

Statewide Burden and Trend of Kidney Cancer in the United States, 1990-2021: A Benchmarking Secondary Analysis

Abrisham Akbariansaravi,[1] Pragathi Munnangi,[2] Venkata Ramana Katikala,[3] Mankarn Hara,[5] Hardik Desai.[4] *[1]American University of Antigua, Coolidge, Antigua and Barbuda; [2]N.R.I Medical College, Guntur, India; [3]Konaseema Institute of Medical Sciences and Research Foundation Hospital, Amalapuram, India; [4]Gujarat Adani Institute of Medical Science, Bhuj, India; [5]Sri Guru Ram Das Institute of Medical Sciences and Research, Amritsar, India.*

Background: In 2020, national expenditures for kidney cancer (KC) care in the United States were reported at $9.4 billion. This study is the first to assess the state-wide burden of KC over the past three decades, which includes the challenging first two years of the COVID-19 pandemic that impacted cancer management.

Methods: Using the Global Burden of Disease 2021 methodology, we analyzed the incidence, prevalence, deaths, disability-adjusted life years (DALYs), and years lived with disability (YLDs) related to KC by age, sex, year, and location across the United States from 1990-2021. Using the Global Burden of Disease 2021 methodology, we analyzed the incidence, prevalence, deaths, disability-adjusted life years (DALYs), and years lived with disability (YLDs) related to KC by age, sex, year, and location across the United States from 1990-2021.

Results: Over this period, the total percentage change (TPC) showed a 90% increase in KC prevalence (95% UI: 83-96%), a 61% rise in mortality (53-66%), and an 83% increase in YLDs (75-91%). The age-standardized incidence rate (ASIR) rose by 2%, and YLDs by 1%. Mississippi experienced the highest increase in ASIR by 26%, while Massachusetts saw a decrease of 27%. Regarding mortality rates, Mississippi saw an 11% increase, whereas the District of Columbia saw the greatest decrease at 38%. Among age groups, the highest number of deaths was observed in the 70-74 age group, totaling 2,863 (95% CI: 2,684-2,980), and the highest DALYs were recorded in the 65-69 age group, totaling 63,803 (95% CI: 60,635-66,470) in 2021. Males showed a higher burden compared to females, with a 3% increase in incidence rates, while females saw a 7% decrease from 1990-2021.

Conclusions: Kidney cancer accounted for 2.52% of all cancer-related deaths. These findings highlight the urgent need for focused efforts to manage the increasing burden of kidney cancer. Public health strategies should focus on improving early detection, optimizing treatment approaches, and ensuring widespread access to care to reduce the impact of this disease.

Burden of Kidney Cancer Attributable to Smoking in 38 Organisation for Economic Cooperation and Development (OECD) Countries, 1990-2021: Insights from the Global Burden of Disease Study 2021

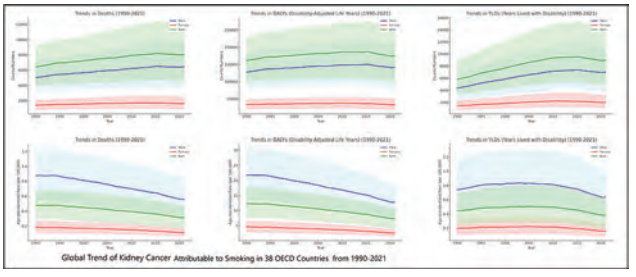
Harsha Choudary Pudhota,[1] Sree Abhilekha Purohit,[2] Sravani Bhavanam,[8,9] Ashwinikumar Shandilya,[4] Saif Syed,[7] Mohit Lakkimsetti,[5] Juhi Patel,[3] Hardik Desai,[6] Vishrant Amin.[3] *[1]Guntur Medical College, Guntur, India; [2]Shadan Institute of Medical Sciences College of Nursing, Hyderabad, India; [3]Gujarat Medical Education and Research Society Medical College & Hospital Valsad, Valsad, India; [4]Rural Medical College, Pravara Institute of Medical Sciences, Ahmednagar, India; [5]Mamata Medical College, Khammam, India; [6]Gujarat Adani Institute of Medical Science, Bhuj, India; [7]Royal College of Surgeons in Ireland, Dublin, Ireland; [8]Sri Devaraj Urs Medical College, Karnataka, India; [9]Brookdale University Hospital and Medical Center, New York, NY.*

Background: Kidney cancer (KC) is on the rise globally, presenting significant concerns. Among modifiable risk factors, this study focuses on the impact of smoking on KC across 38 Organization for Economic Cooperation and Development (OECD) countries over the past three decades. This study is pioneering in its assessment of the burden during the initial two years of the COVID-19 pandemic, a period that significantly challenged cancer management.

Methods: Utilizing the Global Burden of Disease (GBD) 2021 tool, we estimated the deaths, disability-adjusted life years (DALYs), and years lived with disability (YLDs) attributed to KC attributable to smoking by age, sex, year, and location across these countries from 1990-2021.

Results: The total percentage change (TPC) in death counts increased by 26% (95% UI: 10-41%), DALYs by 9% (2-20%), and YLDs by 56% (39-71%) from 1990-2021. The highest number of age-standardized mortality rates (ASMR) was observed in Czechia at 0.69 cases, followed by Poland at 0.55, and while the US at 0.36 cases per 100,000 in 2021. Individuals aged 70-74 years recorded the highest number of deaths at 1,423 (821-2,122), while those aged 65-69 years showed the highest DALYs at 30,932 (18,383-45,164). In terms of gender differences over the last three decades, males experienced a higher burden compared to females, with TPC in deaths at 29% versus 15%, DALYs increased by 11% for males while decreasing by 1% for females, and YLDs at 61% versus 39%.

Conclusions: KC attributable to smoking accounted for 10.24% of all KC-related deaths in 2021. From the perspective of public stakeholders and policymakers, it is crucial to encourage smoking cessation and implement e-health or m-health education initiatives to reduce this burden.



Global Trend of Kidney Cancer Attributable to Smoking in 38 OECD Countries from 1990-2021

SA-PO209

Global Burden of Kidney Cancer Attributable to High Body Mass Index in 204 Countries and Territories, 1990-2021: Insights from the GBD 2021 Study

Ashwinikumar Shandilya,[1] Shruthi Katam,[3] Muhammad Waqas,[5] Sravani Bhavanam,[9,10] Shrey Goel,[6] Saif Syed,[8] Mohit Lakkimsetti,[7] Vishrant Amin,[2] Juhi Patel,[2] Hardik Desai.[4] *[1]Rural Medical College, Pravara Institute of Medical Sciences, Ahmednagar, India; [2]Gujarat Medical Education and Research Society Medical College & Hospital Valsad, Valsad, India; [3]Sri Venkateswara Medical College, Tirupati, India; [4]Gujarat Adani Institute of Medical Science, Bhuj, India; [5]Jinnah Sindh Medical University, Karachi, Pakistan; [6]Government Medical College and Hospital Chandigarh, Chandigarh, India; [7]Mamata Medical College, Khammam, India; [8]Royal College of Surgeons in Ireland, Dublin, Ireland; [9]Sri Devaraj Urs Medical College, Karnataka, India; [10]Brookdale University Hospital and Medical Center, New York, NY.*

Background: The burden of kidney cancer (KC) has escalated over the past three decades, alongside modifiable risk factors such as high body mass index (H-BMI). This pioneering study evaluates the burden of KC due to H-BMI over the last three decades, including the initial two years of the pandemic where non-COVID related excess mortality surged, and cancer patients faced challenges in accessing care.

Methods: Utilizing the GBD 2021 framework, we estimated the deaths, disability-adjusted life years (DALYs), years lived with disability (YLDs), and years of life lost (YLLs) due to KC attributable to H-BMI by age, sex, year, across 204 countries and territories from 1990-2021.

Results: The annual percentage change (APC) in age-standardized mortality rate (ASMR) increased by 20% (95% UI: 13-27%), with DALYs rate rising by 15% (9-22%) from 1990-2021. Regionally, the highest ASMR was observed in Southern Latin America at 1.18 per 100,000 population. High-income countries recorded the highest ASMR at 0.71 deaths per 100,000 in 2021. Czechia had the highest unadjusted mortality rate at 3.27 cases per 100,000. Among age groups, the highest number of deaths was observed in the 70-74 age group with 4,857 deaths, followed by the highest DALYs in the 65-69 age group with 119,593 in 2021. Males experienced a greater increase in deaths and DALY rates compared to females (96% vs 59% for deaths, 79% vs 46% for DALYs) from 1990-2021.

Conclusions: KC attributable to H-BMI accounted for 20.01% of all KC-related deaths in 2021. There is a pressing need to implement public health policies focused on managing BMI and to enhance awareness and education about the risks through health news media and public influencers.

Neuroendocrine Nephrotoxicity: A Case of Chromogranin A Tubulopathy

Madison B. Calder, Omar A. Ayah, Samin Sharma, Sarwat Gilani.
The University of Texas Health Science Center at San Antonio, San Antonio, TX.

Introduction: Neuroendocrine neoplasms (NENs) are capable of secreting functional peptides such as chromogranin A (CgA), an acidic glycoprotein that serves as a NEN biomarker. Although CgA is normally present at basal levels and is easily filtered, reabsorbed, and metabolized within the nephron, when filtered into the urinary space in large amounts, increased resorption can engorge proximal tubular epithelial cells beyond capacity causing cellular damage. We present a case of progressive renal insufficiency in the setting of metastatic NEN consistent with CgA tubulopathy.

Case Description: A 78-year-old female with known metastatic NEN maintained on somatostatin analog therapy was referred for progressive renal dysfunction. Urine microscopy was negative for hematuria or pyuria, and ultrasonography revealed structurally normal kidneys. Total proteinuria was elevated out of proportion to microalbuminuria in the setting of normal serum and urine protein electrophoresis but a rising serum CgA. Due to persistent renal function decline, kidney biopsy was performed, which demonstrated acute tubular injury with proximal tubular epithelial cell resorption granules identified as CgA by immunohistochemistry; these granules demonstrated neither light chain restriction on frozen or paraffin-based immunofluorescence nor evidence of Congo red staining (**Figure 1**).

Discussion: CgA tubulopathy has been described histologically as acute tubular injury resulting from intracellular CgA resorption granules or intratubular cast formation, both of which lead to direct epithelial cytotoxicity. Management centers on early detection and targeted NEN therapy; plasma exchange has been attempted without demonstrated effectiveness. Although rare, a keen awareness of the clinicopathologic consequences of CgA tubulopathy must be shared by oncologists and nephrologists to facilitate early and optimal diagnosis and management.

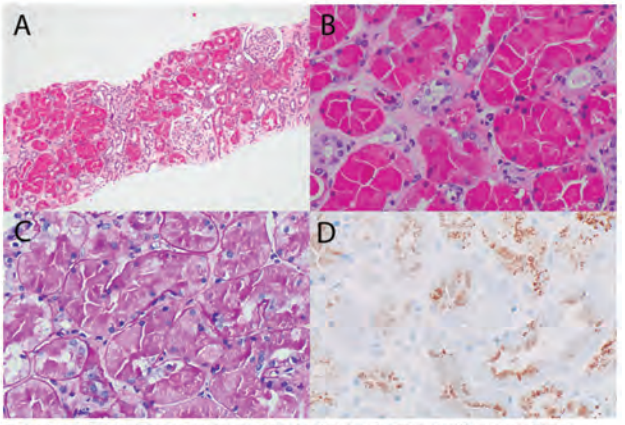

Figure 1. Histologic sections show proximal tubular epithelial cells engorged with intracytoplasmic eosinophilic (H&E stain, A. x200, B. x400) and PAS weak to negative (PAS section, C. x400) granules. The granules showed positivity with chromogranin A immunohistochemical stain (D. x400).

Sarcoid-Like Reaction Causing Hypercalcemia and AKI in a Patient Treated with Dabrafenib and Trametinib

Stefanie Worwa,[1] Mayssaa Hoteit,[2] Sahar Koubar.[1] [1]*University of Minnesota Twin Cities, Minneapolis, MN;* [2]*Yale New Haven Health System, New Haven, CT.*

Introduction: Protein kinase B-raf (BRAF) and mitogen-activated protein kinase (MEK) inhibitors are pivotal in treating melanoma. Despite efficacy, they can induce adverse events. This case presents a unique instance of hypercalcemia-induced AKI due to a sarcoid-like reaction in a melanoma patient taking dabrafenib and trametinib. Two prior cases of sarcoid-like reactions with these drugs exist, but this is the first symptomatic case.

Case Description: A 53-year-old female was diagnosed with BRAF-positive metastatic melanoma. She started therapy with immune checkpoint blockade (ipilimumab/nivolumab) and later shifted to BRAF/MEK inhibition (dabrafenib/trametinib) with nivolumab. She developed fevers, fatigue, hypercalcemia, and AKI. A lung granuloma and hilar lymph nodes were seen on chest CT. The urinalysis was bland, and the renal ultrasound was normal. Nivolumab was stopped with concern for AIN; dabrafenib and trametinib were continued. She was placed on steroids with recovery, but with any taper, her AKI and calcium would worsen (figure 1). She eventually ended therapy and tapered off steroids as her creatinine and calcium stabilized.

Discussion: AKI recurred with steroid tapers despite the absence of nivolumab. Concomitant severe hypercalcemia and a bland urinalysis suggest the AKI was hypercalcemia-induced. Other etiologies of hypercalcemia were excluded (figure 2). The hilar lymph nodes and lung granuloma likely represented a granulomatous reaction, caused by dabrafenib/trametinib, and led to hypercalcemia. Calcitriol was normal, but hypercalcemia can occur in sarcoidosis despite this. In such cases, steroids decrease levels as they slow production of 1-25 $(OH)_2$ vitamin D. Her calcitriol level was markedly reduced with steroids.

Hypercalcemia Differential Diagnoses	
Bone metastasis	Alk phosphatase isoenzymes 611 U/L (NL 40-120 U/L) Liver 556 U/L (91%) Bone 55 U/L (9%)
Primary hyperparathyroidism	PTH 15 pg/mL (NL 10-65 pg/mL)
Hypercalcemia of malignancy	PTHrP 2.8 pmol/L (NL 0-3.4 pmol/L)
Hypervitaminosis D	25 OH Vitamin D 36 (NL 20-75 ug/L)
Medications	No history of lithium, thiazides, calcium supplements
Calcitriol-mediated	Before steroids: Calcitriol 48.5 (NL 19.9-79.3 pg/mL) With steroids: Calcitriol 15.7

Acute Interstitial Nephritis Associated with Dabrafenib-Related Pyrexia: A Case Report

Yi-Ting Ong,[1] Ya Hwee Tan,[2] Hui Zhuan Tan.[1] [1]*Singapore General Hospital, Singapore, Singapore;* [2]*National Cancer Centre Singapore, Singapore, Singapore.*

Introduction: Acute kidney injury is common in patients receiving proto-oncogene B-Raf (BRAF) and mitogen-activated protein kinase (MEK) inhibitors, with a subset occurring in conjunction with BRAF/MEK-related pyrexia (Seethapathy *et al.* Nephrol Dial Transplant, 2022). We report a rare case of biopsy-proven acute tubulo-interstitial nephritis (ATIN) diagnosed in the setting of Dabrafenib-related pyrexia.

Case Description: A 69-year-old Chinese female with metastatic melanoma was referred for KDIGO Stage 3, non-oliguric acute kidney injury (AKI) [baseline sCr 54 μmol/L, peak sCr 195 μmol/L], occurring in the setting of Dabrafenib-induced pyrexia. She was reinitiated on Dabrafenib alone at a reduced dose of 75mg 3 weeks prior to presentation, after developing drug-induced liver injury to Dabrafenib/Trametinib (DT). Notably, she last received Nivolumab, an immune checkpoint inhibitor (ICI) 4 months prior, but had no recent exposure to proton pump inhibitors, non-steroidal anti-inflammatory drugs or antibiotics. Evaluation showed pyuria (urinary WBC 15/μL) and sub-nephrotic range proteinuria (uPCR 1.34g/g). Serum C-reactive protein was elevated at 17.8 mg/L. Autoimmune markers and virologies were negative. AKI was slow to improve despite supportive therapy and fever lysis. Kidney biopsy showed severe ATIN, with a small non-necrotising granuloma. There were no other clinical features suggestive of a systemic sarcoid-like reaction. She was started on prednisolone 60mg (1mg/kg), which was tapered over 7 weeks. Partial renal recovery was observed (sCr 76μmol/L). Dose-reduced DT was resumed 8 weeks later without prophylactic steroids. No recurrence of AKI was observed during 3 months of follow-up.

Discussion: AKI occurring with BRAF/MEK-related pyrexia can result from multiple etiologies. Cytokine release and NSAID use are common causes, but ATIN is an important differential. We postulate that previous ICI exposure could have contributed to the development of ATIN given their potential for longer-term modulation of immune tolerance. Diagnostic kidney biopsy should be strongly considered if AKI persists despite fever lysis and supportive therapy, especially in patients with past ICI exposure. Our case suggests that same-drug rechallenge is feasible, with or without prophylactic steroids, together with close monitoring for AKI recurrence.

SA-PO213

Hypophosphatemia in Midostaurin-Treated FLT3 Acute Myeloid Leukemia

Timothy M. Chow, Nityasree Srialluri. *Johns Hopkins Medicine, Baltimore, MD.*

Introduction: Midostaurin is a first in class, multiple protein kinase inhibitor approved in 2017 for treatment of FLT3-mutated acute myeloid leukemia with conventional therapy. It has activity against multiple protein receptors including the mutated and wild type FMS-related tyrosine kinases. Other kinase inhibitors have been previously described to contribute to hypophosphatemia and 5% of patients were found to have hypophosphatemia in a phase 3 trial of midostaurin. There have been no cases describing the course or nature of hypophosphatemia in midostaurin use. We present the first case of hypophosphatemia attributed to midostaurin use with resolution after discontinuation.

Case Description: A 51-year-old female with hypertension presented with encephalopathy and fevers and was found to have acute myeloid leukemia positive for the FLT3 IDT mutation. She underwent cytoreduction with hydrea and induction with
