Results: Under the status quo, median wait time was 48.2 months (4.01 years). Under the 10% expansion strategy, wait times increased to 53.1 months (4.43 years; + 5.0 additional months). Under the 50% expansion strategy, median wait times increased substantially to 74.2 months (6.2 years; + 26.1 additional months). 50% waitlist expansion combined with 50% reduction in the kidney nonuse rate attenuated the increase in wait times to 67.5 months (5.6 years; + 19.4 additional months) and resulted in 2,252 additional kidney transplants.

Conclusions: Alternate strategies prolonged the median time to kidney transplant by 5 to 26 additional months depending on the degree of expansion and presence of additional organ supply. Efforts to expand access to transplantation without concomitant increases in organ supply would likely result in longer wait times. Systems-level efforts to increase organ supply and enhance allocation efficiency should be prioritized in conjunction with measures which substantially add to the transplant waitlist.

SA-PO948

Barriers to Obesity Management in Kidney Transplant Candidates

Linda-Marie U. Lavenburg,[1,2] Harry Morford,[2] Sanjana S. Kamat,[3] Michele Molinari,[2] Susan A. Stark,[2] Chethan M. Puttarajappa.[1,2] *[1]University of Pittsburgh, Pittsburgh, PA; [2]UPMC, Pittsburgh, PA; [3]Conemaugh Memorial Medical Center, Johnstown, PA.*

Background: Obesity poses significant barriers to kidney transplantation (KT). Transplant waitlisting is 30-70% lower for candidates with body mass index (BMI; kg/m^2) ≥ 40 compared to BMI ≥18.5 to <25. Although no consensus exists, KT centers often require candidates to have a BMI <35-40 prior to KT. KT candidates are often referred to weight loss programs (WLPs) (e.g., dietitian support, medical weight management, or bariatric surgery) but patients' acceptance for WLP referral and their subsequent follow through are unknown.

Methods: Through a quality improvement project, patients with BMI>43 referred for KT evaluation at our center were offered referral to WLP. A proportion of patients accepting referral and those eventually contacting WLP were evaluated. Differences in patient characteristics among those that accepted vs declined referral and among those that contacted vs did not contact a WLP were evaluated using descriptive statistics and multivariable logistic regression.

Results: Cohort had 59 patients with a median age of 57 years (IQR 49-65), 49% were male, 44% were Black or other race and 56% White, 79% were on dialysis, and 53% were from high social distress areas (area deprivation index ≥80). Of 59 patients, 30 patients (50.8%) accepted referral to a WLP but only 9 contacted WLP. Patients accepting referral had a higher median (IQR) BMI [47 (45-50) vs 45 (41-46); p=0.002] and resided closer to the KT center [20 (3-41) vs 48 (17-67) miles; p=0.010]. In multivariable models, referral acceptance decreased 2% with each mile away from KT center (OR 0.98; 95% CI: 0.96-1.00) and increased by 22% (OR 1.22, 95%CI: 1.03-1.45) with every 1 unit increase in BMI. Among patients accepting referral, every 1 year increase in age reduced odds of contacting WLP by 17% (OR 0.83, 95%CI: 0.74-0.96).

Conclusions: A large share of KT candidates with obesity do not establish care with WLPs. Increasing age and distance to KT center were major barriers. Efforts aimed at obesity management in KT should consider these barriers. WLPs integrated within KT programs may overcome barriers to establishing care with WLPs. Future steps in this study will compare weight trajectories, transplant waitlisting and receipt of a kidney transplant between patients who accepted vs declined WLP referrals.

SA-PO949

Expedited Main Obstacles of Prekidney Transplant Workup: A Quality Improvement Study

Abdelrahman Elsebaie,[1] Natalie Witton,[2] Wilma M. Hopman,[1,2] David C. Holland,[1,2] M. Khaled Shamseddin.[1,2] Kingston Kidney Transplant Program (KKTP). *[1]Queen's University, Kingston, ON, Canada; [2]Kingston Health Sciences Centre, Kingston, ON, Canada.*

Background: Failure to complete a comprehensive pre-kidney transplant workup in a timely fashion results in increased dialysis exposure, poorer post-transplant survival, and higher resource demands. Candidates undergo workup by our transplant program post-referral rather than by their dialysis programs. We aimed to assess quality metrics at our program, focusing on variability in the duration of pre-transplant workup after adopting a more frequent and scheduled chart review process by our newer coordinator to expedite pre-transplant workup.

Methods: This is a retrospective study evaluating the duration and obstacles of the pre-kidney transplant workup of all candidates evaluated at our transplant program between January 1, 2021, and December 31, 2022, after adopting a more regular chart review process by our coordinator, with a follow up until March 1, 2024. Data were also compared with historical candidates' workup evaluated at our program before January 1, 2021.

Results: 101 candidate's files were reviewed [Mean age 55.4±13.1 years, female (42.6%), Caucasian (76.2%)]. By March 1, 2024, 86.1% of candidates were on dialysis, with 79.3% of those on dialysis by the time of assessment. 78 (77.2%) candidates received a transplant decision while 23 patients stayed in workup, including 5 candidates who were referred, after completing their workup, to another center for combined organ transplantation. Median time from assessment to transplant decision was significantly shorter with more regular pre-transplant chart review at 12.8 (7.2-20.4) months, compared with historical candidates' workup of 23.3 (14.3-37.1) months (P <0.001). At the time of transplant decision, 64 (63.4%) patients were on dialysis (12 on dialysis <1 year). Median

time from dialysis to transplant decision was 24.1 (12.3-43.2) months, compared with historical candidates' time of 31.6 (5.9-52.4) months (*P* 0.89). Dialysis vintage can be reduced further with earlier referral to transplant since median time from dialysis to initial assessment was longer in our cohort, 7.9 (2.9-32.1) months, compared with historical candidates' time of 5.6 (-7.0-20.8) months (*P* 0.12).

Conclusions: Frequent and scheduled chart review of pre-transplant candidates results in shorter workup and dialysis vintage.

SA-PO950

"Survival after Listing": A Metric That Helps Transplant Patients Compare Different Transplant Centers

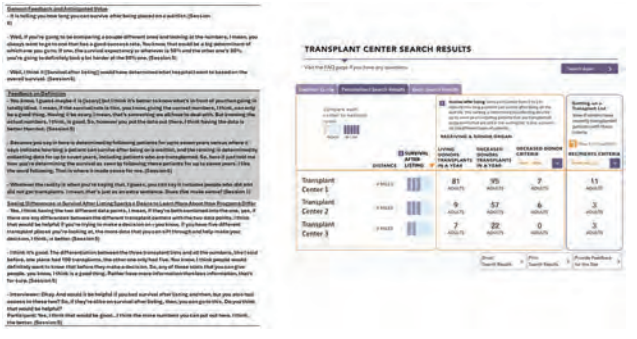
Cinthia Lozano,[1] Warren T. Mckinney,[1] Lucero V. Vazquez Loyola,[1] Cory Schaffhausen,[1] David P. Schladt,[1] Jon J. Snyder,[1] Arthur J. Matas,[2] Ajay K. Israni.[1] *[1]Hennepin Healthcare Research Institute, Minneapolis, MN; [2]University of Minnesota Twin Cities, Minneapolis, MN.*

Background: Previous research has found that using reports to make informed decisions involves processing a large amount of information, which challenges the decision-making process. The Transplant Center Search (TCS) tool was developed to provide patients with comparative information about transplant centers to support decision making on center selection (www.transplantcentersearch.org). To reduce patients' cognitive efforts, we are developing TCS prototypes with a new metric, "survival after listing" which incorporates the current metrics and assesses survival among waitlisted candidates and recipients as provided by the Scientific Registry of Transplant Recipients (SRTR).

Methods: We gathered qualitative data from local kidney transplant candidates. Participants evaluated mockups of the TCS site (Figure 1), including different labels and definitions describing the new metric. Participants were asked to share their impressions of how useful the new metric would be for decision making.

Results: 15 kidney transplant candidates were enrolled in the study with the following characteristics: 60% female, median age 58 (*SD* 7.4), 60% White and 26.7% Black. 13.3% of participants reported needing assistance interpreting printed health materials. Feedback from candidates was generally positive and shows that the new metric supports distinguishing between centers. They also suggested that TCS should continue to provide the current metrics to facilitate decision making (Table 1).

Conclusions: Efforts to reduce the complexity of comparative information on transplant programs are supported by patients. Survival after listing, provides a singular measure of comparative survival among candidates and recipients. We are recruiting national kidney transplant recipients and patients from other solid organ groups to further refine the presentation of the new metric.



SA-PO951

CKD Management and Hemodialysis Planning in Stage 5 Transplant vs. Native CKD Patients

Ricardo A. Macau,[1,2] Afonso V. Ferreira,[2] Joana Gameiro,[1,2] Filipe Marques,[1,2] Fernando Abreu,[1,2] Alice Santana,[1] Jose A. Lopes.[2,1] *[1]Unidade Local de Saude Santa Maria, Lisboa, Portugal; [2]Centro Academico de Medicina de Lisboa, Lisboa, Portugal.*

Background: CKD management and renal replacement therapy (RRT) planning is challenging, especially in patients with graft failure and transitioning to dialysis (dialysis after graft loss), whose complications may not be properly managed, comparing to native CKD patients initiating dialysis.

Methods: We compared patients with native CKD (NKD) and those with graft loss (Tx) initiating hemodialysis (HD) at a Portuguese University Hospital between 2021 and 2023 at a ratio of 3:1. We considered: Age, sex, transplant or native kidney failure, cause of CKD, comorbidities, laboratory at HD start (T0) and three months prior (T3), type of vascular access at HD start and planned start of RRT. We considered as outcomes: type of HD start [outpatient / elective (vs hospitalisation / urgent) and Catheter as vascular access] as well as the patients' status regarding therapeutic levels of haemoglobin and bicarbonate.

Results: The study comprised 112 participants, including 78 (69.6%) NKD and 34 (30.4%) Tx recipients. Participants ranged from 25 to 90 years, (average 65.8 years). Among them, 66 (58.9%) were male. NKD patients demonstrated a higher prevalence of planned RRT initiation (88.5% vs. 47.1%, $p < 0.001$) and elective RRT start (91.0% vs. 32.4%, $p < 0.001$). They were notably younger at RRT initiation than Tx patients (52.1 years vs. 70.2 years, $p < 0.001$). At RRT start, significant differences were observed in bicarbonate levels (21.39 mmol/L in NKD vs. 19.26 mmol/L in Tx, $p = 0.011$) and patients achieving haemoglobin targets (65.4% in NKD vs. 41.2% in Tx, $p = 0.017$). At T3, consistent trends were observed, with differences in bicarbonate and haemoglobin targets.

Conclusions: This retrospective analysis may reveal disparities in CKD management between transplant and native kidney disease patients, notably at the initiation of dialysis. Transplant recipients seem to exhibit a less programmed start, often requiring emergent interventions, while native CKD patients demonstrate better anaemia and metabolic acidosis control. These findings emphasize the impact of transplantation status on CKD management trajectories and highlight the need for further research to understand these differences comprehensively and develop tailored interventions.

SA-PO952

Comparisons of Mortality, Wait-Listing, and Transplantation Outcomes of Young Adults in the United States Renal Data System (USRDS)

Jaya S. Parulekar,[1,2] Marciana Laster,[2,1] Neha D. Pottanat,[2,1] Mengyu Di,[3] Jade Buford,[3] Rachel E. Patzer.[3,1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Riley Hospital for Children at Indiana University Health, Indianapolis, IN; [3]Regenstrief Institute, Indianapolis, IN.*

Background: Young adults are a unique patient population, with the highest incidence of end-stage kidney disease (ESKD) among pediatric subgroups. Despite differences in ESKD cause, comorbidities, and social factors between younger and older adults, young adults are placed in a composite adult category of 18-44 years. Our goal is to better characterize young adults with ESKD (ages 18-25) and compare outcomes with those of older adults (ages 26-44).

Methods: Using data from USRDS, we identified 87,411 incident dialysis patients aged 18-44 starting dialysis from 2015-2020, 9.5% aged 18-25 years and 90.5% aged 26-44 years, following to 2021 for waitlisting and transplant. Multivariable Cox proportional hazards models studied time to mortality, waitlisting, and transplant by age, adjusting for demographics, ESKD cause, comorbidities, pre-ESKD care, transplant awareness, insurance, neighborhood and dialysis-facility variables.

Results: Glomerulonephritis (43%) was the most common cause of ESKD in young adults vs. diabetes (40%) in older adults (Table 1). More older adults had hypertension (86% vs. 76%) and obesity (27% vs. 15%). Younger adults had a 29% lower mortality risk and higher likelihood of waitlisting (33%), transplantation among dialysis-started (32%), and transplantation among waitlisted (18%) (Table 2).

Conclusions: Our analysis provides initial insights into characterizing the broad adult group aged 18-44. Younger adults showed decreased mortality and better transplant outcomes. Future research is needed to define critical age groups with notable outcome differences.

Funding: NIDDK Support

Table 1: Patient comparisons by age group

Variable		Age 18-25 N=8277	Age 26-44 N=79134

Outcomes of Kidney Transplantation from Deceased Diabetic Donors

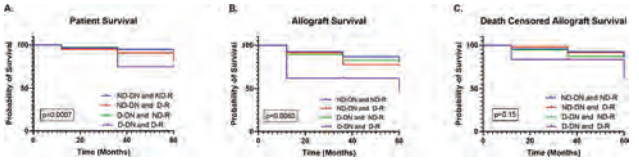
Ahmed Emara,[1] Abigail Hobill,[2] Ria Nagpal,[2] Felix W. Karst,[2] Azhar A. Khan,[2] Maryam Javed,[2] Alice M. Gage,[2] Amy Needleman,[2] Raymond Fernando,[2] Gareth L. Jones,[2] Rhys Evans.[3] *[1]Ain Shams University Faculty of Medicine, Cairo, Egypt; [2]Royal Free London NHS Foundation Trust, London, United Kingdom; [3]University College London, London, United Kingdom.*

Background: Diabetes mellitus (DM) is an increasing comorbidity in the kidney donor population. Utilization of kidneys from donors with DM and subsequent recipient selection is challenging due to limited data on outcomes in this group. To address this gap, we investigated the outcomes of kidney transplantation from deceased diabetic donors over a 10-year period.

Methods: We undertook a retrospective observational study of adult patients who underwent kidney alone transplantation from deceased donors at a single centre between 2012-2022. We stratified patients according to the diabetic status of both donor and recipient. We determined patient and allograft survival at 1-, 3- and 5-years post-transplant.

Results: 985 kidney transplant recipients (KTRs) were included, of whom 64 (6.5%) underwent transplantation from a diabetic donor. Diabetic donors were older, a higher proportion had hypertension, and they had a higher Kidney Donor Profile Index and implant Karpinski score. Recipients of diabetic donor kidneys were also older, and had a higher baseline clinical frailty score. Creatinine levels at 1, 3, and 5 years were higher in KTRs of diabetic donors; rejection rates did not differ according to donor diabetes status. Patient and allograft survival were worst in diabetic recipients of diabetic kidneys (**Figures A-C**). Outcomes were similar in non-diabetic recipients regardless of the diabetic status of the donor. In multivariable analyses, recipient age (HR 1.05, 95% CI 1.03-1.08) and recipient diabetes (HR 2.22, 95% CI 1.32-3.67) increased the hazard of patient mortality but not death censored graft survival and donor diabetes had no effect on any recipient outcomes.

Conclusions: Utilizing kidneys from diabetic donors is associated with acceptable recipient outcomes and offers a potential mechanism to expand the deceased donor pool. Recipient diabetes status should be considered during organ allocation



(**A**) Patient survival, (**B**) Allograft survival (**C**) Allograft survival censored for patient death stratified by donor and recipient diabetes status.
D-DN: Diabetic Donor
D-R: Diabetic recipient
ND-DN : Non-Diabetic Donor
ND-R: Non-diabetic Recipient

SA-PO954

Pilot Randomized Trial to Define the Benefits and Harms of Deceased Donor Kidney Procurement Biopsies

Krista L. Lentine,[1] Vidya Fleetwood,[1] Tiffany Caza,[2] Yasar Caliskan,[1] Gary F. Marklin.[3] *[1]Saint Louis Univ., St. Louis, MO; [2]Arkana, Little Rock, AR; [3]Mid-America Transplant, St. Louis, MO.*

Background: Kidney biopsies obtained during organ procurement are often used in acceptance decisions, but supporting evidence is controversial. We conducted a pilot randomized controlled trial (RCT) to help assess impacts of deferring release of procurement biopsy information at the time of offer (in this design, through permanent processing).

Methods: This pilot, multicenter RCT involved 1 Midwest organ procurement organization (OPO) and 2 local transplant centers (7/2019-7/2022 | *ClinicalTrials.gov* **NCT03837522**). Waitlisted candidates were approached for consent, such that if offered a kidney from an eligible deceased donor (DD), the DD could be randomized (**Fig 1A**). Criteria for routine DD biopsy included KDPI >50% or KDPI components. Eligible DDs for consented recipients were randomized to immediate (frozen) versus delayed (permanent) biopsy processing. Outcomes were assessed in linked SRTR data.

Results: 85 candidates were consented; 25 were disenrolled (**Fig 1B**), most commonly due to receipt of an imported and/or previously biopsied kidney at another OPO, surgeon request for immediate biopsy (25%), or DD not meeting routine biopsy criteria (20%). 12 DDs were randomized for eligible candidates. 2 kidneys from 2 study DDs were not used, both in the frozen group. 12 kidneys from 10 randomized DDs were transplanted in study recipients. Delayed graft function (DGF) occurred in 3/6 (50%) in frozen and 2/6 (33%) in permanent groups. There were no graft failures within 1 y, and 1 death (frozen group).

Conclusions: An RCT of impacts of DD procurement biopsy information on transplant outcomes faces challenges, including effort to consent waitlist candidates and high disenrollment for reasons including rising organ imports. This pilot did not suggest safety concerns for delayed biopsy information.

SA-PO955

Managing the Costs of Kidney Paired Donation: A Survey of Contemporary US Practice and Challenges

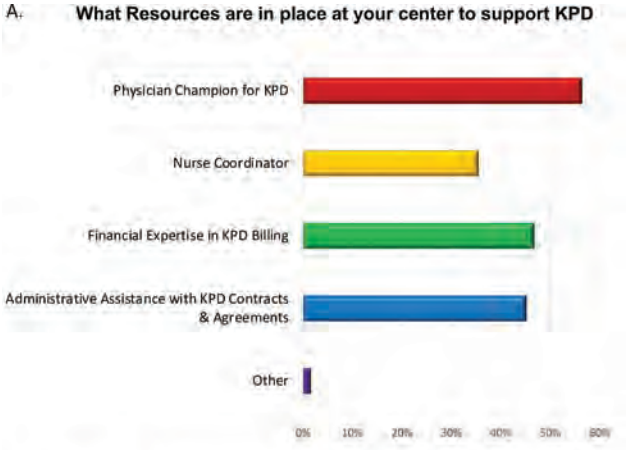
Krista L. Lentine,[1] Geoffrey Gheorghian,[1] Gwen E. McNatt,[2] Robert Howey,[7] Vidya Fleetwood,[1] Didier A. Mandelbrot,[4] Hossein Tabriziani,[6] Cody Wooley,[1] Fawaz Al Ammary,[5] Andrea Tietjen.[3] *[1]Saint Louis Univ., St. Louis, MO; [2]Univ. Iowa, Iowa City, IA; [3]St. Barnabas, Livingston, NJ; [4]Univ. Wisconsin, Madison, WI; [5]UC Irvine, Irvine, CA; [6]Natera, San Carlos, CA; [7]Toyon Assoc., Franklin, TN.*

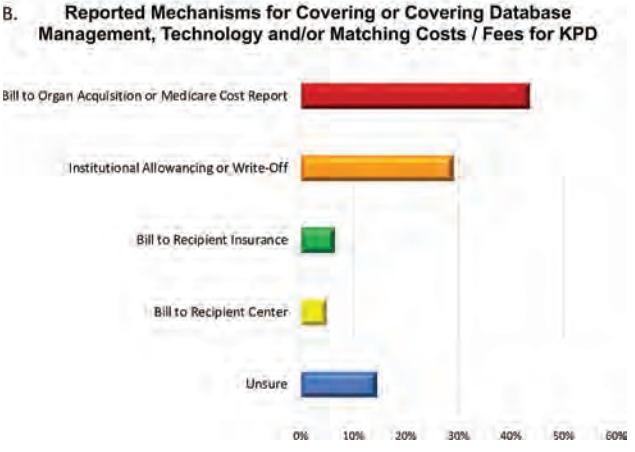
Background: Kidney paired donation (KPD) is increasingly used to provide access to living donor kidney transplantation (LKDT), but concerns related to managing costs pose barriers to transplant center participation. To help inform community discussions of strategies, we surveyed U.S. LDKT program staff on experiences and practices for managing KPD-related costs.

Methods: A survey instrument was designed by a multidisciplinary workgroup of professionals in transplant administration and practice. We distributed the survey to staff at U.S. LDKT transplant programs by email and posting to professional society list-servs in 2024 using the Qualtrics survey platform.

Results: Among 62 programs that participated to date, 95% report KPD participation, with 34% reporting >10 exchanges per year. For external changes, 72% use the National Kidney Registry alone or combined with other programs, and 11% use the Alliance for Paired Donation alone or with other programs. Reported resources for KPD include physician champions (56%), nurse coordinators (35%), financial expertise (47%) and contracting assistance (45%)**(Fig A)**. Heterogenous methods are used to cover database costs (**Fig B**) and other costs including evaluation, nephrectomy, and organ shipping. 42% of centers report standardized policies and procedures for handling KPD costs, while 21% are uncomfortable discussing methods to cover costs of KPD with administration.

Conclusions: Based on a pilot survey of U.S. LDKT programs, a variety of approaches are used to cover costs of KPD practice, and many centers are uncomfortable discussing resource needs with administration. Up-to-date resources on handling KPD finances will be useful to support programs in expanding KPD practice.





SA-PO956

Adjusted Donor-Age (ADA) Score as a Tool for Characterizing Deceased Donor Kidneys: Multicentre Validation Study for a German Eurotransplant Cohort

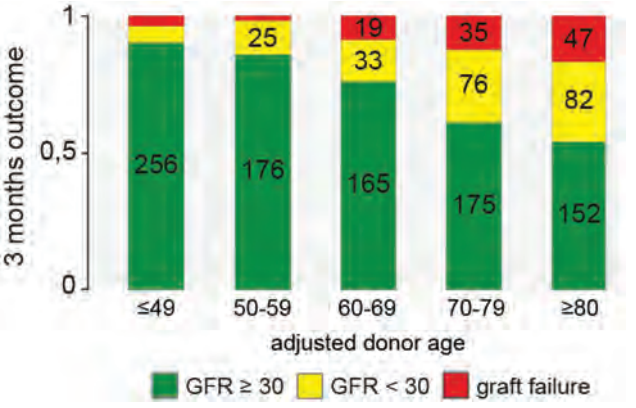
Christoph F. Mahler,[1,2] Felix Friedl,[1] Christian Nusshag,[1] Claudius Speer,[1] Louise Benning,[1] Matthias Schaier,[1] Claudia Sommerer,[1] Markus Mieth,[3] Martin G. Zeier,[1] Can C. Süsal,[4] Vedat Schwenger,[4] Christian Morath,[1] Fabian Echterdiek,[4] Florian Kälble.[1] *[1]Nierenzentrum Heidelberg eV, Heidelberg, Germany; [2]Clinician Scientist Program, Universität Heidelberg, Heidelberg, Germany; [3]Department of General, Visceral and Transplantation Surgery, University Hospital Heidelberg, Heidelberg, Germany; [4]Department of Nephrology, Klinikum Stuttgart, Stuttgart, Germany.*

Background: ADA adjusts the donor age according to risk factors (A: ADA<49, B: 50-59, C: 60-69, D: 70-79, E: >80 years) and stratifies the adjusted age into quintiles (A-C advantageous, D moderate, E unfavorable). The aim of this multicentre study is to explore, whether the ADA score can be validated for a Eurotransplant cohort.

Methods: We conducted a retrospective analysis of all kidney transplants from cadaveric donations at centers in Heidelberg, Stuttgart, and Munich (Technical University) between 2015 and 2021. Donor data were recorded using the Eurotransplant database to calculate the ADA score. The prognostic accuracy was assessed based on graft function after three months.

Results: Out of a total of 1353 transplanted kidneys, 1273 were included in the analysis. After three months, 924 (73%) recipients achieved an eGFR of >30 ml/min/1.75m². In 9% of the cases, graft failure occurred within the first three months. There was a significant correlation between higher ADA quintiles and poor transplant outcome (eGFR < 30 ml/min at 3 months in 10% (A), 14% (B), 24% (C), 39% (D), 46% (E) of patients; p<0.001). For patients with good graft function, the 3-month eGFR was associated with ADA (c-statistic = 0.66) and decreased with higher ADA quintiles (A: 60, B: 49, C: 43, D: 35, and E: 36 ml/min).

Conclusions: The ADA score proves to be a suitable, intuitive method for the evaluation grafts. Our multicentric analysis shows good predictive accuracy for graft function after three months. Although organs with an ADA over 80 years have an increased risk of graft failure, more than 50% of patients in this group show good graft function. Future studies should investigate this group in more detail to adapt the ADA score to the specific characteristics of the Eurotransplant donor pool.



SA-PO957

Perceived Patient Interest in Pursuing Kidney Transplantation: A Qualitative Study

Adam S. Wilk,[1] Jennifer L. Mcdonnell,[1] Megan Urbanski,[1] Stephen O. Pastan,[1] Kimberly Arriola,[1] Cam Escoffery,[1] Rachel E. Patzer.[2] *[1]Emory University, Atlanta, GA; [2]Indiana University School of Medicine, Indianapolis, IN.*

Background: Kidney transplantation improves patient survival and quality of life compared to dialysis for many patients, yet dialysis care teams do not refer all qualified candidates for transplant evaluation. Dialysis professionals often cite "Patient not interested" as a key reason for not providing comprehensive transplant education or completing referrals, yet little is known about how dialysis professionals assess patient interest or use these assessments to guide education and referral practices.

Methods: We conducted 39 in-depth telephone interviews during June-August 2022 with dialysis professionals in Georgia, North Carolina, and South Carolina about their processes leading up to referral decisions. We recruited dialysis social workers, nurse managers, nephrologists, and administrators using purposive sampling to capture diversity by participants' role, years of experience, and county median household income. Interviews were recorded and transcribed and data were managed using MAXQDA software. We used thematic analysis to identify themes, with 3 coders developing the codebook, analyzing, and interpreting data.

Results: Dialysis professionals described assessing patients' interest in transplant as part of transplant education, directly asking patients if they are interested during initial discussions or regularly "checking in" about care options across later care encounters. Most described concurrently assessing and influencing patients' thinking, using distinct approaches. Some encourage nearly all patients to consider transplant given its benefits for most patients. Others are selective, choosing when to bring up transplant and how much transplant education to provide based on assumptions about the patient's interest in transplant and transplant eligibility. These assumptions are based on perceived innate characteristics (e.g.,"really want it") or social constraints (e.g.,"too far to the center," "cannot afford…post-transplant medications") of the patient.

Conclusions: Many dialysis professionals provide transplant education selectively based on how interested they perceive patients are, based on subjective perceptions of patient characteristics and circumstances. Future research should examine whether standardized transplant education practices minimize implicit biases and increase equity in transplant access.

SA-PO958

Organ Donation: A Cross-Sectional, Descriptive Study from an Inner-City Hospital in the Bronx

Htun M. Aung,[1] Juan Diego Rodriguez Salazar,[1,2] Anjali Acharya,[1] Roxanne Todor.[1] *[1]New York City Health and Hospitals Corporation, New York, NY; [2]Albert Einstein College of Medicine, Bronx, NY.*

Background: Renal transplant is the treatment of choice in patients with end-stage renal disease. However, organ donation rates in NYC are relatively low, at approximately 18%, with the Bronx borough having the lowest rate, at around 11%, despite having the highest number of patients on the waiting list. We have been recognized as a high performing donor hospital and are part of the CMS ETCLC initiative. We carried out this retrospective study where we aimed to look at our patients with brain-death diagnosis in a public hospital in the Bronx where health equity and disparities are front and foremost.

Methods: A descriptive cross-sectional study was conducted, during which relevant information was gathered from the electronic medical records of patients diagnosed with brain death between 2020 and 2023. Children under 18 years of age were excluded from the study. The focus was on collecting data related to organ donation, timely referral to our OPO Live On NY, electrolyte and renal function abnormalities, as well as nephrology referral. Data analysis was performed using Excel.

Results: Information was collected from 115 patients, of whom 63.48% were men. LiveOnNY was consulted in more than 95% of cases, and 42.61% of patients diagnosed with brain death ended up being donors. 57.39% were diagnosed with acute kidney injury, of which 20% were classified as KDIGO 3. Additionally, 76.52% and 59.13% of patients exhibited significant alterations in sodium or potassium levels, respectively. Furthermore, 14.78% of the cases required renal replacement therapy. Finally, the nephrology service was consulted in 27.83% of the cases.

Conclusions: Based on the results of our study, we can conclude that despite been an inner-City hospital from the Bronx, the rate of organ donation on death brain patients is encouraging. The rates of AKI and electrolytes disturbances were significant. We would like to encourage the significance of involving nephrology experts in managing the renal complications and increasing the chances of transplantation and decrease organ discard rate.

SA-PO959

A Cross-Sectional, Descriptive Web-Based Survey on Knowledge of the Organ Donation Process among Internal Medicine Residents

Htun M. Aung,[1] Juan Diego Rodriguez Salazar,[1] Roxanne Todor,[1] Anjali Acharya.[1,2] *[1]New York City Health and Hospitals Jacobi, Bronx, NY; [2]Albert Einstein College of Medicine, Bronx, NY.*

Background: Jacobi Medical Center is recognized as a major organ donor hospital by CMS and play a prominent part of the CMS ETCLC initiative. Our resident physicians are on the front lines, taking care of critically ill patients and working with the organ donor network for referrals of potential organ donors. We wanted to improve our understanding of organ donation practices and see how to serve our patients better.

Methods: A cross-sectional, descriptive, web-based 13-item survey was developed. Internal medicine residents at our institution were invited to participate in the survey. All variables were reported descriptively, and free-text responses were summarized.

Results: Out of 102 residents, 25 residents responded to the survey. The survey results are shown in Table 1. Six residents described potential barriers to organ donation as follows: not knowing who to reach out to; hard to work with the organ donor program; resident education; work burden; patients' families and social issues.

Conclusions: Most survey respondents were knowledgeable about the referral process for organ donation. However, there were knowledge gaps regarding electrolyte abnormalities in patients after brain death, renal consult for acute kidney injury or electrolyte abnormalities for these patients, and the First Person Authorization. Subsequently, education sessions were planned to improve the organ donation process.

Table 1: Survey Responses

	Yes	No	Others
1. Do you know the criteria for brain death?	92%	8%	
2. Are you aware of donation after cardiac death?	96%	4%	
3. Do you know when to refer a patient to LiveOnNY?	88%	12%	
4. Do you know the process of referring a patient to LiveOnNY?	80%	20%	
5. Do you know the electrolyte abnormalities that might occur with brain death?	56%	44%	
6. How often do you call renal consult for acute kidney injury in a patient after brain death?	Not applicable	Not applicable	Always (4%), usually (20%), sometimes (20%), rarely (24%), and never (32%)
7. How often do you call renal consult for electrolyte abnormalities in a patient after brain death?	Not applicable	Not applicable	Always (4%), usually (8%), sometimes (24%), rarely (40%), and never (24%)
8. Do you think organ donation is helpful in saving lives?	100%	0%	
9. Have you encountered potential barriers at Jacobi Medical Center to organ donation?	24%	76%	
10. Are you a registered organ donor?	48%	52%	
11. If you are not a registered organ donor, are you interested in becoming one?	20%	36%	I am already registered (44%)
12. Do you know what First Person Authorization (FPA) is?	8%	92%	
13. In your opinion, can First Person Authorization be used for both donation after brain death (DBD) and donation after cardiac death (DCD)?	52%	48%	

SA-PO960

Human Leukocyte Antigen (HLA) Histocompatibility and Kidney Graft Survival

Ada Noemi Chavez. *Hospital General San Juan de Dios, Ciudad de Guatemala, Guatemala.*

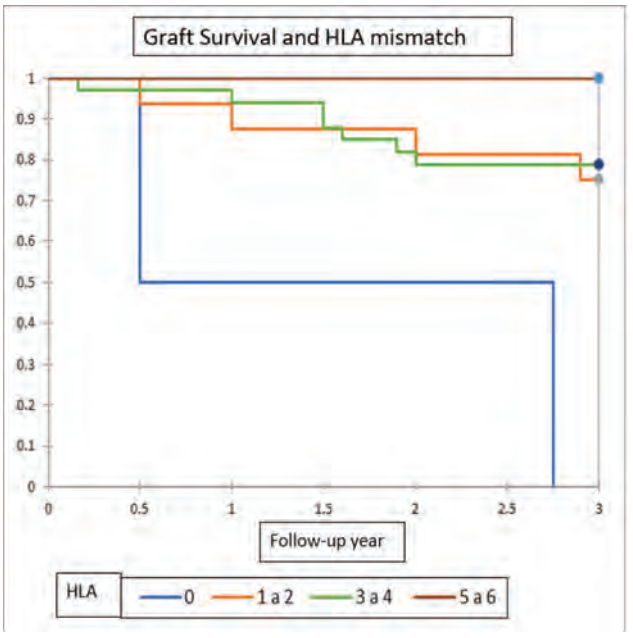
Background: Renal transplantation is the treatment of choice for chronic kidney disease and its survival is known to be related to multiple risk factors. Regarding HLA matching, the number of acute rejection episodes in renal transplantation has been associated with the degree of incompatibility for HLA-DR, as well as a beneficial correlation has been observed between better HLA matching (both HLA-DR and HLA-A and -B) with long-term graft survival.

Methods: Descriptive retrospective, 55 post-renal transplant patients were evaluated during January 1, 2018 to December 31, 2019 and followed up for 3 years.

Results: Graft survival was evaluated at the first year of follow-up 94% of the grafts had survived out of a total of 55 grafts, at the second year, of the 52 grafts that still had survival 6 (12 of the remaining grafts, and at the third year of follow-up 4 more grafts were lost, the patients who presented HLA-DR compatible had a mean graft survival of 2.85 years. (Figure 1) The survival of the graft was also evaluated in relation to the number of compatibilities that the patients presented, dividing the patients into 4 groups according to the number (0, 1- 2, 3- 4 and 5- 6) in which it was evidenced that the patients who presented 0 compatibilities 100% lost the graft, and those who presented compatibility group 5-6, had 100% survival (CI: 95%) at 3 years of follow-up of patients, among patients who were among the groups 1-2 and 3-4, had a graft survival at the end of the study in 78.2% and 80.1% respectively, and very similar data. (Figure 2)

Conclusions: HLA matching was significant for graft survival, mainly HLA-DR. It is important to continue investigating in our population with longer follow-ups as well as the follow-up approach to patients who do not share HLA

Graft Survival	1 year	2 year	3 year	Total
Yes	52 (94%)	46 (83.6%)	42 (76.3%)	42 (76.2%)
No	3 (6%)	6 (16.4%)	4 (23.7%)	13 (23.8%)



SA-PO961

Preemptive Registration in Hispanic Kidney Transplant Candidates: When Is Early Not Early Enough?

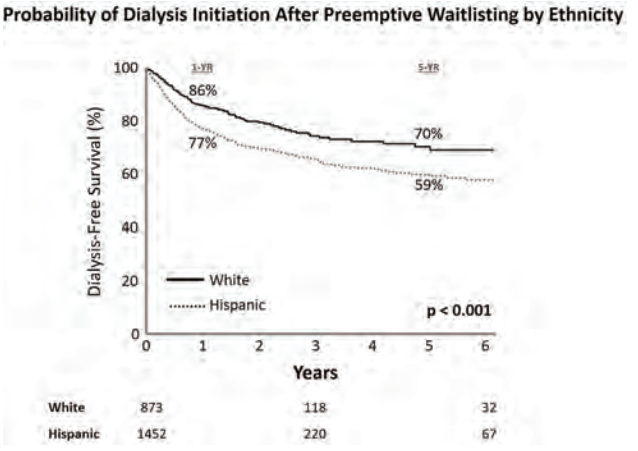
Nassir Thalji, Tamer Shaker, Ranjeeta Chand, Matthias M. Kapturczak.
Methodist Specialty and Transplant Hospital, San Antonio, TX.

Background: Preemptive registration promotes time accrual, waitlist priority, and an opportunity for preemptive kidney transplantation. Hispanic patients with kidney disease enjoy fewer preemptive waitlist registrations. We evaluated the fate of preemptively listed Hispanic kidney transplant candidates.

Methods: We studied adult patients preemptively added to the kidney transplant waitlist at our center between 2003–2022, excluding multiorgan listings. Rates of transplantation, living donor kidney transplant (LDKT), preemptive transplant and dialysis initiation were compared in Hispanic vs. non-Hispanic White patients.

Results: We evaluated 2,624 patients with a median age of 51 years and 58% were male. Hispanic patients accounted for 55% (1,452) and 33% (873) were White. Hispanics had more obesity and diabetes, but were less likely to have higher-level education or paid employment (all p<0.001). Overall 50% of Hispanics and 62% of Whites were transplanted, with Whites 75% more likely to be transplanted preemptively (both p<0.001). Hispanic were 40% less likely to have LDKT (OR 0.61) or preemptive LDKT (OR 0.59) (both p<0.001). Considering dialysis initiation as a time-dependent endpoint, Hispanics were 66% more likely than Whites to start dialysis after preemptive listing (Figure). Accounting for age, sex, diabetes, living donor availability and private insurance, Hispanic ethnicity independently predicted waitlist dialysis initiation (HR 1.34; p=0.009).

Conclusions: Preemptive listings in Hispanic patients yield fewer kidney transplants, LDKTs, or preemptive transplants compared to Whites, and more readily culminate in dialysis initiation. The prognostic value of preemptive registration is thus incompletely realized in Hispanic transplant candidates. Coordinated efforts are needed to bolster capacity for self-advocacy in Hispanic patients while augmenting access to providers able to guide them through early kidney transplant evaluations.



SA-PO962

Disparities in Access to Upstream Steps in the Kidney Transplant Pathway among Young Adults with New-Onset Kidney Failure

Kelsey M. Drewry,[1,2] Jade Buford,[2] Arrey-Takor Ayuk-Arrey,[2] Jaya S. Parulekar,[1] Marciana Laster,[1] Rachel E. Patzer.[2,1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Regenstrief Institute Inc, Indianapolis, IN.*

Background: Despite the benefits of kidney transplantation compared to dialysis, access to transplant remains limited, especially among marginalized populations. Inequities in access to the transplant waitlist persist even among young, otherwise healthy patients with kidney failure who may be best suited for transplant. This study used the only multi-regional referral data to assess whether disparities in access to waitlisting among young patients arise from inequitable access to the pre-waitlisting steps of referral for transplant and evaluation initiation.

Methods: Young adults (age 18-40 years) with new-onset kidney failure in Georgia, North Carolina, and South Carolina (2015-2020) were identified using the United States Renal Data System. Primary outcomes included timely referral for evaluation (within one year of dialysis initiation) and evaluation initiation (within three months of referral among all referred patients), assessed via linkage to the Early Steps to Transplant Access Registry. The odds of timely referral and evaluation were compared using multivariable logistic regression.

Results: Among 13,291 patients (mean [SD] age: 33 [6]; 7528 [57%] male; 1756 [13%] Hispanic, 6535 [49%] Black), 6374 [48%] were referred for evaluation within 1 year of dialysis initiation, and 5448 [41%] began the evaluation within 3 months of referral. In adjusted logistic regression models, White race, full time employment, private health insurance, and longer durations of pre-kidney failure nephrology care were positively associated with timely referral and evaluation. Hispanic ethnicity was associated with lower odds of referral (aOR 0.57 [95% CI 0.49-0.68]), but not evaluation start (aOR 0.80 [95% CI 0.58-1.10]).

Conclusions: This retrospective cohort study found racial, ethnic, and socioeconomic inequities in access to timely referral and evaluation for kidney transplant among young patients likely to be highly suitable for transplant. To improve equity in access to transplantation and subsequent outcomes in this key age group, interventions should focus on increasing the proportion of young patients from underserved populations who are referred for transplant evaluation within the first year of kidney failure diagnosis, and ensuring referred individuals progress to initiating the evaluation.

Does Live Donor and Preemptive Kidney Transplantation Reduce the Impact of Socioeconomic Deprivation on Graft Outcome?

Michael Corr,[1] Jenni Beck,[2] Alexander P. Maxwell,[1] Ciaran O'Neill,[1] Gareth J. McKay.[1] *[1]Queen's University Belfast, Belfast, United Kingdom; [2]Belfast City Hospital, Belfast, United Kingdom.*

Background: Socioeconomic deprivation has been reported to adversely affect transplant outcomes from access to wait listing to post-transplant care. Individuals from lower socioeconomic backgrounds have lower rates of living donor transplants and face significant challenges post-transplant leading to higher rates of graft loss. The aim of this study was to assess the impact of socioeconomic deprivation on transplant outcomes in Northern Ireland, a region with universal healthcare but high socioeconomic deprivation.

Methods: A single-centre retrospective study included all 1,581 kidney transplant recipients from 2000-2020. A national tool allowed determination of socioeconomic deprivation status, using a multi-dimensional deprivation score. Concentration curves were calculated for pre-emptive and living donor transplantation across the study

population ranked by summary deprivation score. For analysis of each individual deprivation score the population was divided into quintiles. Cox regression was used to assess risk of graft failure compared to least deprived quintile. Other variables such as age, live donor and pre-emptive transplantation were investigated for association with graft survival in a regression model.

Results: Concentration curves for pre-emptive and living donor transplantation lie above the line of equality suggesting both are more prevalent in lower socioeconomic groups. Univariate cox proportional hazards failed to identify significant associations between socioeconomic status and graft survival which remained non-significant following adjustment for pre-emptive transplantation (HR 0.64 $p < 0.05$), live donor transplantation (HR 0.79 $p < 0.01$) and increasing recipient age (HR 0.77 $p < 0.05$).

Conclusions: Our results differ from previous reports on impact of socioeconomic deprivation on transplant outcomes. The higher proportion of pre-emptive and live donor transplants in more deprived groups likely represents equitable access to transplantation, despite unequitable burden of end-stage kidney disease. Our region has high pre-emptive (24%) and live donor (42%) rates which may mitigate impact of deprivation on graft survival. These data demonstrate an opportunity to reduce the burden of socioeconomic deprivation on transplant outcomes through expanded access to pre-emptive and live donor transplantation.

SA-PO964

Racial Disparities Exist in the Transplant Process among Hispanic Patients on Dialysis

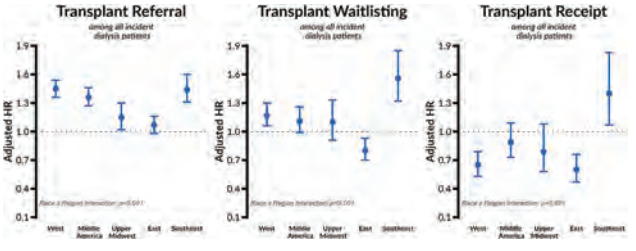
Adam G. Walker,[1] Carey Colson,[1] Danelle Radney,[2] Unini Odama,[2] William D. Maixner,[2] Francesca Tentori,[1] Steven M. Brunelli.[1] *[1]Davita Clinical Research, Minneapolis, MN; [2]DaVita Inc, Denver, CO.*

Background: Kidney transplantation is considered the best long-term treatment for patients with end-stage kidney disease (ESKD). Previous results revealed that African American patients are 54% less likely to receive a kidney transplant than White patients; we sought to examine if any disparities exist for Hispanic patients.

Methods: This retrospective study used electronic health records and county-level indices of socioeconomic deprivation at the time of dialysis initiation at a kidney care organization. Patients included in the study (n=50,102) were those who initiated dialysis between July 2015 and June 2018, were 18-80 years old, either Caucasian or Hispanic, and began care with a kidney care organization within 30 days of first ever dialysis. Patients with prior transplant or transplant evaluation/ listing were excluded. Patients were followed from date of first eligibility until 30 June 2022 or until censoring for death, transfer, withdrawal from dialysis, renal recovery, or loss to follow up. Outcomes included transplant referral, waitlisting, or receipt and were compared using time-to-event models. Models were adjusted for differences in patient demographic factors, comorbidities, laboratory values, and socioeconomic factors across exposure categories.

Results: Results indicate that the progression of Hispanic patients through the transplant process (referral, waitlisting, and receipt) varies by US region. Nearly half (47.1%) of all Hispanic patients on dialysis reside in the West region of the US, where they are ~35% less likely to receive a kidney transplant, primarily driven by a lower rate of conversion from waitlist to transplant. In the East region of the US, Hispanics are 40% less likely to receive a kidney, primarily driven by a lower rate of conversion from referral to waitlist. In all areas of the country, Hispanic patients were more likely to be referred for transplant evaluation.

Conclusions: In this sample, from the period 2015-2022, there were large and systematic biases against Hispanic patients that resulted in a lower likelihood of receiving a kidney transplant despite higher referral rates.



SA-PO965

Kidney Transplantation Outcomes by Dialysis Modality in an Underserved Population

Ali Huzair,[1,2] Jiten Patel,[1,2] Anisha Ganguly,[2] Jaspreet Sian,[1,2] Jillian L. Smartt,[2] Michael Harms,[2] Ramesh Saxena.[1,2] *[1]The University of Texas Southwestern Medical Center, Dallas, TX; [2]Parkland Health, Dallas, TX.*

Background: While in-center hemodialysis (HD) is delivered by trained healthcare providers, peritoneal dialysis (PD) involves active patient-engagement in dialysis treatment. This process of self-care can be associated with a range of potential collateral health benefits that can positively impact clinical and patient-centered outcomes. Kidney transplantation (KT) is the major outcome goal among kidney failure (KF) patients who initiate dialysis. Several studies have shown that PD patients are more likely to receive KT, compared to HD patients. However, baseline differences among HD and PD patient populations such as age, race/ethnicity, education and socioeconomic status, may confound differences in receipt of KT. In this retrospective study, we compared transplant evaluation and listing status among propensity matched incident HD and PD patients initiating dialysis at Parkland Health, a safety net health system caring for underserved populations in Dallas County.

Methods: We included adult patients, who were newly initiated on HD or PD at Parkland Health from January 2012 to December 2022. PD Patients were propensity matched 1:1 with HD patients based on language, race/ethnicity, age and comorbidities. The primary outcome was proportion of patients evaluated for transplantation, while key secondary outcomes included proportion of patients listed for transplantation, reasons for not listing, and proportion transplanted.

Results: During the study period 155 patients were initiated on PD, and were matched with 155 patients initiating on HD. Of patients initiated on PD, 133 (85.8%) were evaluated for KT, compared to 109 (70.3%) patients on HD (p=0.001). Eventually, 78 (50.3%) PD patients and 50 (35.5%) HD patients were listed for transplantation (p=0.001). Of the patients evaluated but not listed, medical ineligibility was the predominant reason in PD group (38/54, 70.3%), while in HD group 36/56 (65%) were not listed due to lack of interest and non-adherence to treatment. Finally, 27 HD patients and 33 PD patients underwent KT (p=0.108).

Conclusions: We observed that more PD patients presented for transplant evaluation compared to HD individuals in a safety net system. This led to higher KT listing of PD versus HD patients. These findings suggest that patient engagement through PD may improve distal KF outcomes, including KT, among underserved population.

SA-PO966

Increasing Transplant Access with a Novel Care Model Employing Transplant Peer Navigators (TPNs)

Eliot C. Heher, Rachel A. Eaton, Katherine E. Norris, Laurie R. White, Jullie Hoggan. *Square Knot Health, Boston, MA.*

Background: Kidney transplantation requires multidisciplinary planning and high levels of patient engagement. Geography, ethnicity, and other social determinants of health impact access to transplantation. We sought to improve access by identifying and removing barriers to transplant.

Methods: A transplant nephrologist (EH) and TPNs (RE, JH, KN, LW) assessed patients with chronic kidney disease (CKD) referred by primary nephrologists. Medical record review, virtual visits, and transplant planning were independent of any one transplant center. TPNs are kidney recipients and donors who received additional formal training. TPNs partnered with patients through the life cycle of transplant, helping them address barriers, search for living donors, and secure care. Outcomes measured included referral, listing, transplant rates, and “net promoter score.”

Results: Patients (Table 1) were referred between Oct 1, 2021 and Sept 30, 2023 from ME, NH, and MA. Results are in Figure 1. 43 (38%) had been referred to a transplant center but never listed, due to high BMI, medical and communication challenges, poor support, failure to complete tasks, and other barriers. We referred 21 of these to a 2nd center, and 5 to a 3rd, resulting in 16 listings and 5 transplants. 6 of 19 transplants occurred at the 2nd or 3rd center. 32 of 34 respondents rated the service a “10” (highly likely to recommend), and 2 others rated it 9 and 8.

Conclusions: Using a novel TPN led, transplant center agnostic, and community-based model, 37% of patients were added to the kidney waitlist after previous denial. Patient satisfaction was high. Further study of our model’s impact on access in other underserved populations is warranted.

SA-PO967

Impact of Victorian Quality Indicator (QI) on Kidney Transplant Wait-Lists for Indigenous and Nonindigenous Australians

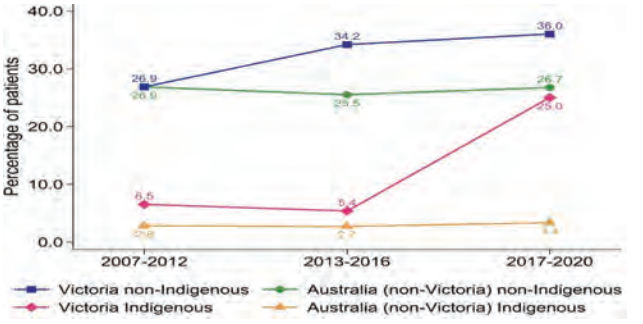
Rebecca Ling,[1] Christopher E. Davies,[2,3] Tia-Maria Mark,[5] Stephen P. McDonald,[2,3] David J. Goodman.[1,4] *[1]Department of Renal Medicine, St Vincent's Hospital, Melbourne, VIC, Australia; [2]Australia and New Zealand Dialysis and Transplant (ANZDATA) Registry, South Australian Health and Medical Research Institute (SAHMRI), Adelaide, SA, Australia; [3]Adelaide Medical School, University of Adelaide, Adelaide, SA, Australia; [4]The University of Melbourne Faculty of Medicine Dentistry and Health Sciences, Melbourne, VIC, Australia; [5]Monash Health Kidney & Pancreas Transplant Unit, Melbourne, VIC, Australia.*

Background: In 2012, Victoria introduced a 6monthly reportable renal QI for proportion of patients waitlisted or pre-emptively transplanted by set time points following start of dialysis. In 2019, renal QI was modified to include patients aged 18-70 at 6 and 12 months after commencing dialysis. We aimed to determine if QI influenced timeliness of placement on kidney transplant waiting list for Victorians, including Indigenous (ATSI; Aboriginal and Torres Strait Islander People) Victorians.

Methods: Dialysis start date, date of waitlisting or pre-emptive transplantation, medical co-morbidities, type of kidney replacement therapy (KRT) for patients aged 18-70 commencing KRT between 2007-2020 was extracted from ANZDATA. Data was divided into three eras and four sub-cohorts. Primary outcome was percentage of patients waitlisted or transplanted at 6, 12 and 24 months from starting dialysis.

Results: Of 25,836 (14.7% ATSI) patients on dialysis, 8,587 (5.7% ATSI) were listed for transplant and 1,103 had pre-emptive transplants by December 2021. A higher proportion of non-ATSI (49%) and ATSI Victorian (31%) patients were waitlisted or had pre-emptive transplants compared to Australians (non-Victorian) (44% and 13% respectively). The proportion of Victorian patients waitlisted or had pre-emptive transplants at all timepoints improved substantially in 2017-2020, compared to 2007-2012. The proportion of Victorian patients waitlisted by 6months improved significantly (aOR 1.85 (1.55-2.21), P<0.001) following QI implementation, but there was no significant change in Australians (non-Victorian). Victorian ATSI patients were three times more likely to be waitlisted or transplanted than ATSI patients in rest of Australia (aOR 3.59 (1.45, 8.87), P = 0.006).

Conclusions: Following introduction of the Victorian QI, the percentage of dialysis patients on waitlist or had pre-emptive transplants at 6 and 12 months increased. Victorian ATSI patients were more likely to be waitlisted than Australian ATSI patients.



SA-PO968

Genetic Evaluation of Living Kidney Donor Candidates: Results from the LDGen Registry

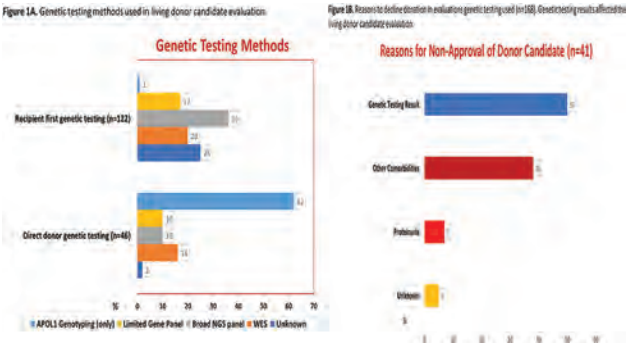
Yasar Caliskan,[1] Ozgur A. Oto,[8] Tarek Alhamad,[2] Halil Yazici,[3] Abdulmecit Yildiz,[11] Arzu Velioglu,[9] Neetika Garg,[12] Karim Soliman,[13] Arksarapuk Jittirat,[14] Ondrej Viklicky,[10] Zeynep Ural,[4] Christina Irene Mejia,[15] Reem Daloul,[5] Danilo Radunovic,[6] Brian Lee,[16] Christie P. Thomas,[17] Hernando Trujillo Cuellar,[18] Roslyn B. Mannon,[7] Krista L. Lentine.[1] LDGen Consortium. *[1]Saint Louis University, St Louis, MO; [2]Washington University in St Louis, St Louis, MO; [3]Istanbul Yeni Yuzyil Universitesi, Istanbul, Turkey; [4]Gazi Universitesi, Ankara, Turkey; [5]Allegheny Health Network, Pittsburgh, PA; [6]Klinicki Centar Crne Gore, Podgorica, Montenegro; [7]University of Nebraska System, Lincoln, NE; [8]Istanbul Universitesi, Fatih, Turkey; [9]Marmara Universitesi, Istanbul, Turkey; [10]Institut Klinicke a Experimentalni Mediciny, Praha, Czechia; [11]Bursa Uludag Universitesi, Nilufer, Turkey; [12]University of Wisconsin-Madison, Madison, WI; [13]Medical University of South Carolina, Charleston, SC; [14]Case Western Reserve University, Cleveland, OH; [15]Johns Hopkins University, Baltimore, MD; [16]Dell Seton Medical Center at The University of Texas, Austin, TX; [17]University of Iowa Hospitals and Clinics, Iowa City, IA; [18]Hospital Universitario 12 de Octubre, Madrid, Spain.*

Background: We describe our preliminary experience with the launch of a novel international Registry – "LDGen" – as a repository to study current and evolving practices in genetic testing as part of living donor (LD) candidate evaluation.

Methods: A cross-sectional, electronic REDCap registry was developed to collect information on LD candidates and their genetic test results. LD candidates who either 1) underwent genetic testing, and/or 2) had a family history of genetic kidney disease, or 3) are looking to donate to a related recipient with kidney disease of unknown etiology were registered. Data reported here were collected between June, 2023 and May, 2024.

Results: Data on 1004 LD evaluations were obtained representing 12 U.S. and 9 international centers. 39% (n=305) of intended recipients had possible genetic kidney disease. Genetic testing was performed in 17% (n=168) of LD evaluations. Testing in recipient candidate was performed before the LD candidate in 73% (n=122) of cases while it was performed only in the donor candidate in 27% (n=46) of evaluations (Fig. 1A). 125 LD candidates underwent genetic testing and 81% of these donors received formal pre-test genetic counseling. Single gene/limited gene panel (42%) and broad kidney disease gene panel (29%) were the most common methods. 33% (n=41) of the LD candidates who underwent genetic testing during evaluation were not accepted, of which 51% (n=21) of declinations were due to the genetic testing result [Pathogenic/Likely pathogenic variant (n=9), renal risk variants (n=2), VUS (n=10)] (Fig.1B).

Conclusions: Our initial experience supports the feasibility of international collaboration in creating a registry of genetic kidney disease testing practices among LD candidates. With more data, the findings of the LDGen registry will provide value information on global LD evaluation practice patterns.



SA-PO969

Increase in Arterial Stiffness in Living Kidney Donors after Kidney Donation

Dennis Kannenkeril,[1] Merve Günes-Altan,[1] Agnes Bosch,[1] Kristina Striepe,[1] Mario Schiffer,[1] Kerstin U. Amann,[2] Roland E. Schmieder.[1] *[1]Department of Nephrology and Hypertension, University Hospital Erlangen, Friedrich-Alexander University Erlangen-Nuremberg (FAU), Erlangen, Germany; [2]Department of Nephropathology, Department of Pathology, University Hospital Erlangen, Erlangen, Germany*.

Background: Low glomerular filtration rate (GFR) is associated with high cardiovascular mortality and morbidity. Living kidney donor's vascular characteristics have been poorly investigated till now. In this analysis, living kidney donors were followed up with respect to vascular parameters for one year after renal donation.

Methods: Blood pressure (BP) and different arterial stiffness parameters were assessed before, 6 months and 1 year after renal donation using a 24-hour blood pressure device (Mobil-o-graph®). Cortical, medullary and total renal perfusion of the donors were assessed using Arterial Spin Labeling MRI before and 6 months after donation. Preimplantation biopsy of the donor kidney was obtained. Biopsies were scored for glomerulosclerosis, interstitial fibrosis, tubular atrophy, and arteriosclerosis.

Results: Twenty-five living kidney donors with mean age of 54±9.4 were followed up for one year. The estimated GFR fell significantly (87.7±15.9 vs. 55.6±10.9 ml/min/1.73m^2; p<0.001) and urinary albumin creatinine ratio remained similar to baseline (19.5±18.4 vs. 19.5±12.2 mg/g creatinine; p=0.204) 1 year after donation. Pulse wave velocity (7.5±1.4 vs. 7.8±1.4; p=0.001), peripheral resistance (1.1±0.19 vs. 1.23±0.19;p=0.003), and augmentation index (heart rate corrected) (24.4±5.5 vs. 26.7±6.1;p=0.025) over 24 hours increased significantly 12 months after donation, while no change was observed in systolic and diastolic BP. A relationship has been found between eGFR at baseline and mean 24-hour pulse wave velocity at 12 months (r=-594, p=0.002). An increase in renal cortex perfusion was found 6 months after donation (351±53.4 vs. 388±40.7; p=0.013). The 24-hour systolic BP (116.6±6.8 vs. 129.1±10.7;p=0.011), -diastolic BP (73.2±4.4 vs. 81.3±5.6;p=0.006) and -central systolic BP (118.6± 8.9 vs. 128.9±7.7;p=0.013) at 12 months post donation was significantly higher in donors with renal histological changes compared to donors without renal histological changes, while no difference in BP was noticed at baseline between these groups.

Conclusions: Our data indicates that arterial stiffness increases after living kidney donation. This can be interpreted as an early change before increase in BP. Living donors with chronic renal histological changes tend to develop high BP after donation.

SA-PO970

Race-Neutral 2021 CKD-EPI Creatinine eGFR and Iohexol-Measured GFR in Living Kidney Donor Candidates

Walaa Dabbas, Ruchi H. Naik, Lorenzo G. Gallon, Ignatius Y. Tang. *University of Illinois Chicago, Chicago, IL*.

Background: The race neutral 2021 CKD EPI creatinine (Cr) eGFR was approved by the OPTN to calculate kidney function for transplant candidates on the national waitlist to address disparities in kidney transplantation. The 2021 CKD EPI Cr equation estimates a lower GFR for Black patients and a higher GFR for non -Black patients for the same creatinine value. Hence the 2021 CKD EPI Cr eGFR may not provide an accurate estimate of kidney function of potential living kidney donors

Methods: single center retrospective review of charts of potential kidney donors who had measured GFR by Iohexol clearance between January 1, 2021 and December 31, 2023. Data collected include demographics, eGFR calculated by race neutral 2021 CKD EPI Cr equation and Iohexol GFR test. Subjects were divided into 2 groups, Black and Non Black.

Results: Iohexol clearance was done in 333 kidney donor candidates, 62.7% were female and 23.7% were black. The average BMI was 30.4 kg/ m 2. There was a positive correlation between 2021 CKD EPI Cr eGFR and Iohexol GFR in both groups. Black donor candidates had lower eGFR calculated by 2021 CKD EPI Cr compared to non black, p=0.002. See table. There was no significant difference between Iohexol clearance between the 2 groups. The race neutral 2021 CKD EPI Cr eGFR overestimated GFR in non black compared to black individuals, p=0.02.

Conclusions: 2021 CKD EPI Cr eGFR correlated with the Iohexol GFR in black kidney donor candidates, however it overestimated GFR in non black kidney donors.

SA-PO971

Postdonation Weight Gain Is Associated with Lower Likelihood of Recovering Predonation eGFR

Rhiannon D. Reed, Marshall C. Mcleod, Paul A. Maclennan, Vineeta Kumar, Jayme E. Locke. *The University of Alabama at Birmingham, Birmingham, AL*.

Background: Living kidney donors with obesity (body mass index (BMI) ≥ 30 kg/m^2) at donation have a lower likelihood of recovery of estimated glomerular filtration rate (eGFR) post-donation. We sought to understand whether early post-donation changes in weight are also associated with the likelihood of eGFR recovery.

Methods: Using data from the Scientific Registry of Transplant Recipients, we examined 91,653 adult living kidney donors (1999-2023) with pre-operative serum creatinine and height/weight measurements and at least one creatinine and weight measurement post-donation. We utilized the 2021 CKD-EPI equation to estimate eGFR, and Cox proportional hazards regression with a time-varying covariate for change in BMI was utilized to estimate the likelihood of recovering at least 60% of pre-donation eGFR, censoring for last creatinine measurement.

Results: Among a cohort that was majority female (63%) and white (85%), donors were median age 43 years (IQR: 33-52) and median BMI 26.6 kg/m^2 (IQR: 24.0-29.6). Median pre-donation serum creatinine was 0.80 mg/dL (IQR: 0.70-0.93), with a median mean arterial pressure of 90 mmHg (IQR: 83.3-96.3). On unadjusted analyses, gaining > 5% BMI (a clinically relevant threshold for risk of cardiovascular and obesity-related complications) was associated with a 7% lower likelihood of recovering 60% of pre-donation eGFR (HR: 0.93, 95% CI: 0.92-0.94, p< 0.001), while losing > 5% BMI was positively associated with recovery (HR: 1.02, 95% CI: 1.00-1.03, p=0.01). After adjusting for relevant baseline factors, gaining > 5% BMI remained significantly associated with a lower likelihood of eGFR recovery (aHR: 0.91, 95% CI: 0.90-0.93, p < 0.001) (Figure).

Conclusions: Weight change in the early post-donation period is a modifiable factor that is associated with recovery of kidney function. These findings highlight the need for a greater commitment to support living donors in maintaining healthy lifestyles post-donation and prospective studies of living donor follow-up.

Using Machine-Learning Techniques to Predict Postdonation Kidney Function in Living Kidney Donors

Junseok Jeon, Kyungho Lee, Jung eun Lee, Wooseong Huh, Hye Ryoun Jang. *Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea*.

Background: Predicting kidney function after kidney donation is critical to properly selecting donors for living kidney donation. We aimed to predict postdonation kidney function after a living kidney donation using machine learning techniques.

Methods: This retrospective cohort study included 823 living kidney donors from 2009 to 2020. The dataset was randomly divided into training (80%) and test (20%) sets. The main outcome was the postdonation estimated glomerular filtration rate (eGFR) at 12 months after kidney donation. We compared the performance of various machine learning techniques, traditional regression models as well as model from previous study. The best-performing model was selected using the mean absolute error (MAE) and root mean square error (RMSE).

Results: The mean age was 45.2 ± 12.3 years, and 48.4% were males. The mean predonation and postdonation eGFRs were 101.3 and 68.8 ± 12.7 mL/min/1.73 m^2, respectively. The XGBoost model showed the best performance with an MAE of 6.23 and RMSE of 8.06 with feature importance, including eGFR, age, serum creatinine, 24-hour urine creatinine, 24-hour urine sodium, creatinine clearance, cystatin C, cystatin C-based eGFR, computed tomography volume of the remaining kidney/body weight, normalized GFR of the remaining kidney measured through a diethylenetriaminepentaacetic acid (DTPA) scan, and sex. An easy-to-use web application titled Kidney Donation with Nephrologic Intelligence (KDNI) was developed.

Conclusions: The prediction model using XGBoost accurately predicted the postdonation eGFR after living kidney donation. This model can be applied in clinical practice using KDNI, the developed web application.

Evaluation of Renal Functional Reserve in Adult Living Kidney Donors

Jose L. Ortega, Mario Alamilla-Sanchez, Enrique F. Morales Lopez, Ydris Z. Rosillo-Salgado, Jose L. Torres Cuevas, Carolina Gonzalez-Fuentes, Victor M. Ulloa Galvan, Jesús O. Rubio, Martin O. Carbajal. *Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico*.

Background: Renal functional reserve (RFR) assessed by renal response to a protein load is considered to reflect functional reserve capacity and is believed to be a tool for screening living donors

Methods: A descriptive, observational and prospective study was carried out in a single center where 22 living kidney donors, over 18 years of age, clinically healthy, were considered between the month of July 2023 to May 2024. RFR was measured with a test of the glomerular stress using an oral protein loading test

Results: Of a total of 22 patients included, the median age was 39 (18-56) years, 77% (17) women. Body mass index was 25.5 (20.2 to 32.7). Median baseline Cr was 0.67 (0.47-1.04) mg/dl, median baseline cystatin was 0.67 (0.40-0.9) mg/dl versus post-cystatin. stress was 0.6 (0.30-0.90) mg/dl. The median values of bGFR and sGFR were statistically different (123.54 [56.38 -250.11] vs. 178.71 [84.88 - 418.43] ml/min/1.73 m2, p = 0. 0017. A difference will be observed between bGFR and sGFR, with an RFR = 45.9% (11.87-132.62) equivalent to an increase in GFR after a protein load of 48.81 ml/min (16.24- 161.56) having a bGFR > 90 ml/min was associated with a risk of presenting borderline FRR < 30). ml/min OR 1.2 95% CI (1.0- 1.05) and a BMI < 30 estimated an OR 0.76 95% CI (0.60-0.96) protective factor to preserve an RFR > 30ml /min.

Conclusions: The results suggest that glomerular renal stress testing by oral protein loading could be useful before transplantation to establish the original global filtration capacity of the donor kidneys. The results provide a previous global renal function of 48 ml/min, a result similar to that reported in the literature, drawing attention to the tendency in obese patients to present a low RFR, as well as the no association in the level of basal normality. creatines and RFR that may represent an inadequate estimate and present the patient's susceptibility to developing kidney injury before it becomes clinically evident

SA-PO974

Long-Term Risk of ESKD in Kidney Donors with Diabetes Mellitus Using eGFR 6 Months after Donation

Lovy Gaur, Manoj K. Singhal. *Max Superspeciality Hospital Vaishali, Ghaziabad, NCR, India*.

Background: Traditionally, diabetes mellitus was considered contraindication for kidney donation. Guidelines now recommend evaluation of such donors on case-to-case basis. Estimated GFR at 6 months post-donation (eGFR6) may be surrogate for long-term risk of ESKD. As per a study, 15-year cumulative incidence of ESKD with eGFR6 >70 ml/min was estimated to be 11.7/10000 donors against 33.7/10000 donors if eGFR6< 50ml/min. We demonstrate potential safety of donors with diabetes using eGFR6.

Methods: Potential kidney donor with diabetes mellitus were evaluated only after exploring other voluntary family members' feasibility to donate. As per KDIGO recommendations, older diabetic candidates with well-controlled glycemia, not requiring insulin & without end-organ damage were considered. Donors were deemed eligible only if pre-donation projected 15-year-risk of ESKD was <1% as estimated by ESRD-Risk tool for living kidney donors(NYU Langone's Center for Surgical & Transplant Applied Research(C-STAR)). Independent assessment of potential donors by Internal Hospital Medical Board was also done.

Results: 345 patients received kidney transplantation from Jan 2019 to Dec 2023. 9 kidney donors with diabetes (mean age-60.7yrs), with follow-up of > 6months were included.8 donors were detected to have diabetes during work-up for donation & 1 had been diabetic for 5 years and 5 had hypertension. Mean HbA1C was 6.7%. Mean pre-donation creatinine was 0.75 mg/dl(eGFR- 92.84 ml/min), urine albumin-creatinine ratio was 20.29. Mean DTPA-GFR of retained kidney was 41.42 ml/min. Mean follow up was 20.6 months (6-48 mon). Average eGFR at 6 months was 59.8 ml/min. Only 1 donor (aged 72 years) had eGFR6 < 50ml/min (38 ml/min). On her last-follow-up at 24 months, she continues to do well (creatinine-1.29,UACR <30). Graft outcomes were good. Only 1 graft was lost to plasma-cell rich rejection at 6 months post-transplant. Another patient who was biopsied 2 weeks after transplant had mild ATN, which recovered gradually. None of these patients had histopathological changes of diabetic nephropathy.

Conclusions: Our study demonstrates safety of diabetic kidney donors using eGFR6 as a surrogate for long-term risk of ESKD. More long-term studies are required to substantiate this risk. In certain exceptional circumstances, donation from diabetic donors may be considered, considering intangible effects of recipient health on donor well-being.

SA-PO975

Relationship between New-Onset Proteinuria and Remnant Kidney Hypertrophy and/or Pre-donated Kidney Volumes

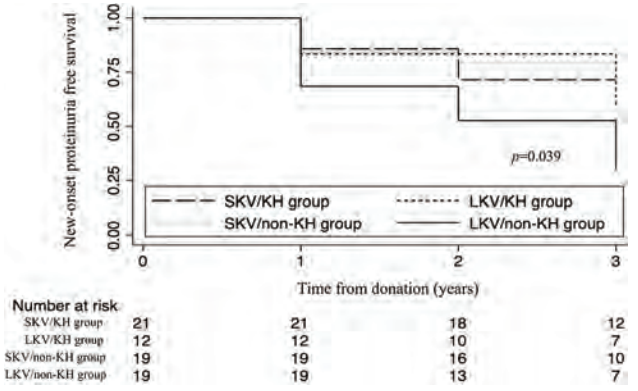
Masatomo Ogata,[1] Takamasa Miyauchi,[1] Kiyomi Osako,[1,2] Naohiko Imai,[1] Yuko Sakurai,[1] Kazunobu Shinoda,[1] Yugo Shibagaki,[1] Masahiko Yazawa.[1] *[1]St. Marianna University School of Medicine, Kawasaki, Japan; [2]Shiraishi hospital, Kagoshima, Japan*.

Background: Some living kidney donors (LKDs) develop proteinuria, which is generally associated with end-stage kidney disease. Previous reports have shown new-onset proteinuria correlates with preoperative preserved kidney volume (PKV) and remnant kidney hypertrophy (%PKV change). We explored the association between the combination of preoperative PKV and %PKV change after donation and new-onset of proteinuria.

Methods: This single-center, retrospective, observational study included eligible LKDs who donated kidneys between January 2008 and July 2022 (N=195). Of these, 71 LKDs who had their PKV calculated via non-contrast computed tomography (CT) volumetry before and 1 year after donation and who were evaluated for proteinuria were included. They were divided into four groups according to the mean body surface area (BSA)-adjusted PKV (large [LKV] and small [SKV]) and mean %PKV change (hypertrophy [KH] and non-hypertrophy[non-KH]), and the association with new-onset proteinuria was investigated. Time-to-event analysis was performed using log-rank tests. Significant factors for event occurrence were calculated using Cox proportional hazards model adjusted by age and sex.

Results: Mean age was 59.7 ± 7.9 years and 71.8% were female (N=51). The mean %PKV change and BSA-adjusted PKV were 20.3 ± 7.0%, and 161.6 ± 24.0 cm^3, respectively. During the 2.3 years follow-up period (mean), the LKV/non-KH group had significantly higher proteinuria events than the other groups (log-rank test, p = 0.039). The LKV/non-KH group had a significantly higher hazard ratio (HR) of new-onset proteinuria than the SKV/KH group (adjusted HR: 2.87, 95% confidence interval: 1.03–8.06).

Conclusions: Post-donated proteinuria is more likely to occur in kidneys already enlarged before donation and is not sufficiently hypertrophic change after donation in LKDs. This imaging study before and shortly after donation might authorize personalized follow-up in LKDs.



SA-PO976

Measurement and Estimation of Kidney Length Using Computed Tomography and Predictor Formulas in Kidney Transplant Donors

Moises Cruz Landino,[1] Diana Laura Muñoz,[1,2] Adriana Banda Lopez,[1,2] Enrique Rojas-Campos,[1] Ricardo Parra Guerra,[1] Salvador Mendoza Cabrera,[1] Luis Alberto Evangelista-Carrillo,[1] Diana N. Sanchez,[1] Maria Santisbais Beas.[1,2]
[1]Instituto Mexicano del Seguro Social Delegacion Jalisco, Guadalajara, Mexico; [2]Universidad de Guadalajara Centro Universitario de Ciencias de la Salud, Guadalajara, Mexico.

Background: Kidney length measurement is fundamental in the diagnosis of chronic kidney disease. The aim of this study is to evaluate the relationship between kidney length measured by computed tomography (CT) and the estimation by three predictive formulas in the Mexican population.

Methods: This was a cross-sectional, analytic study performed in kidney donors who had renal length measured by CT. Age, body height, weight, blood pressure, and serum creatinine concentrations were measured. Based on body height and weight, we calculated kidney length using three distinct formulas. Pearson correlation coefficients were obtained between kidney length measured by CT and the results obtained using the formulas

Results: A total of 212 kidney donors were included. Mean age 39.5 ± 11 years, men 97 (47%), body weight 71.5 ± 6 kg, height 1.65 ± 0.1 m, eGFR 106 ± 12 ml/min. Mean right kidney length: 103 ± 8 mm, left kidney length: 104 ± 8 mm. Right kidney volume 130 ± 33 cm3, left kidney volume 132 ± 34 cm3. Figure 1. There was a significant correlation between CT kidney length, and the estimation by formulas. The strongest correlation significance was observed by using Formula 3 for left kidney (r=.041) and right kidney (r=0.38). Table 1 and Figure 2 resume study findings

Conclusions: The kidney length estimation by formulas show a significant correlation with the measurement by CT. Formula 3 better estimates kidney lenght in Mexican population.

Table 1: Correlation between kidney length by CT and estimation by formulas

		Correlation coefficient	p
Left Kidney	Formula 1	0.4	0.01
	Formula 2	0.34	0.01
	Formula 3	0.41	0.01
Right Kidney	Formula 1	0.36	0.01
	Formula 2	0.28	0.01
	Formula 3	0.38	0.01

	All N=212	Men n=97	Women n=115

Sociodemographic Correlates of Mortality after Living Kidney Donation: Informing the Need for Nondonor Controls

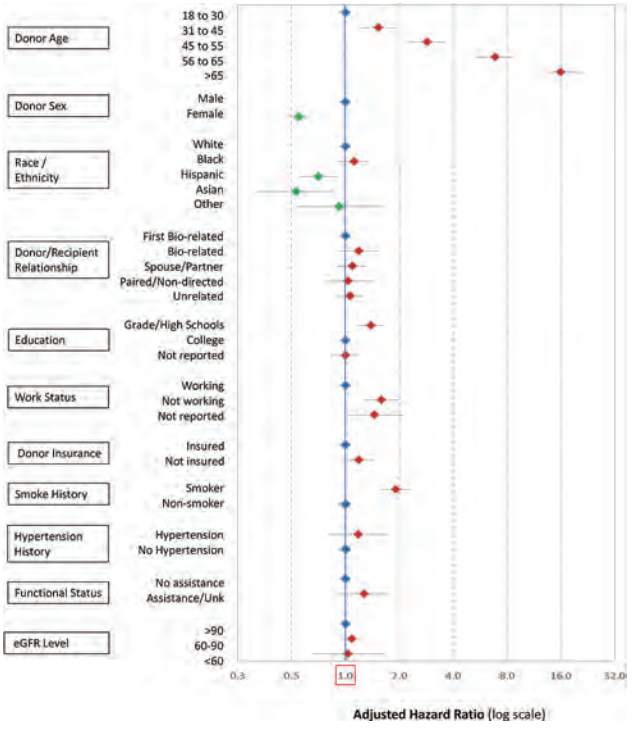
Krista L. Lentine,[1] Yasar Caliskan,[1] Amy D. Waterman,[2] Ajay K. Israni,[3] Jon J. Snyder,[3] Allyson Hart,[3] Vidya Fleetwood.[1] *[1]Saint Louis Univ., St. Louis, MO; [2]Houston Methodist, Houston, TX; [3]Hennepin County, Minneapolis, MN.*

Background: Mandated follow-up of living kidney donors (LKDs) in the U.S. is limited to 2 years postdonation. Recently, an expanded linkage of death records to the national transplant registry was conducted, enabling capture of intermediate-term death events after living donation.

Methods: We examined Scientific Registry of Transplant Recipients (SRTR) data incorporating updated linked national death records to examine the incidence and adjusted correlates of mortality (adjusted hazard ratio, $_{95\%\ LCL}$ aHR $_{95\%\ UCL}$) after donation, censored at 09/02/23. LKDs were registered in 1987-2023.

Results: Among 179,977 LKDs in the registry, overall mortality at 10 years was <1%. 10-year mortality rose with older donor age, up to 4.9% in donors aged >65 years at donation (vs 0.3% in those who donated at age 18-30; aHR; $_{11.5}$ 15.9 $_{21.8}$). Mortality was lower in women (vs men: 0.6% vs 0.9%; aHR, $_{0.48}0.55_{0.63}$), and in Hispanic and Asian (vs White) LKDs, but slightly higher in spousal donors. Mortality trended higher in uninsured LKDs, was higher in those not working, and nearly twice as high in smokers (vs nonsmokers: 0.9% vs 0.7%; aHR, $_{1.57}1.91_{2.31}$). 10-year death risk did not vary significantly according to hypertension history or predonation eGFR.

Conclusions: Intermediate-term mortality after living kidney donation varies with age, sex, race, relationship, education, employment, and smoking status. While trends are similar to general population patterns, comparison to nondonor controls through mechanisms such as the SRTR Living Donor Collective candidate registry are needed for continuous monitoring of donation-attributable risks. Sociodemographic correlates of mortality in LKDs warrant attention for risk mitigation to support optimal long-term outcomes in all donors.



SA-PO978

Racial Disparities in Access to Deceased Donor Kidney Transplantation in the United States, 1999-2023

Fawaz Al Ammary,[1] Krista L. Lentine,[2] Deidra C. Crews,[3] Abimereki Muzaale,[3] Simeon Adeyemo.[1] Living Donor Transplant Outcome Collaborative (LDTOC).
[1]University of California Irvine, Irvine, CA; [2]Saint Louis University, St Louis, MO; [3]Johns Hopkins University, Baltimore, MD.

Background: The Kidney Allocation System was revised in December 2014 to provide priority from start of dialysis rather than listing date to improve equity in access to transplantation. We examined the interplay between race/ethnicity and duration of dialysis in access to deceased donor kidney transplantation over time.

Methods: We used the Scientific Registry of Transplant Recipients of 350,516 adult first-time kidney transplant candidates on dialysis between 1999 and 2018. Outcome was dialysis time to deceased donor kidney transplantation, and exposure was race/ethnicity. We used competing risk survival to estimate the cumulative incidence of the outcome competing with death and multivariable Cox regression models to adjust for confounders. Analyses stratified by era (1999–2003, 2004–2008, 2009–2013, and 2014–2018). Patients were followed for 5 years, ending in December 2023.

Results: Overall, the cumulative incidence of deceased donor kidney transplantation for patients on dialysis varied by race [Figure]. In adjusted models compared to White patients, in the eras 1999–2003, 2004–2008, 2009–2013, and 2014–2018, Black patients were less likely to be transplanted by 45%, 37%, 35%, and 27%; Hispanic patients by 45%, 50%, 43%, and 38%; and Asian patients by 42%, 37%, 31%, and 30%, respectively [Table].

Conclusions: Although there has been increase in deceased donor kidney transplantation in recent years for U.S. dialysis patients, racial disparities remain. Gaps are narrowing for Black and Asian patients but remain unchanged for Hispanic patients on dialysis. Programs are needed to address systemic barriers and enhance policies to support equitable access to transplantation for racial minorities.

Evolution of Biologically Related Living Kidney Donations in the United States over 35 Years

Fawaz Al Ammary,[1] Simeon Adeyemo,[1] Krista L. Lentine,[2] Abimereki Muzaale.[3]
[1]University of California Irvine, Irvine, CA; [2]Saint Louis University, Saint Louis, MO; [3]Johns Hopkins University, Baltimore, MD.

Background: Living kidney donors have declined over the last two decades, mainly driven by biologically related donors with the recipient. We sought to understand the interplay of biological donor-recipient relationship and race to guide future interventions.

Methods: We used the Scientific Registry of Transplant Recipients to examine changes in biologically related living kidney donations over time. *A priori*, we stratified the analyses by era (1988–2004 and 2005–2022) and donor race (Black, Hispanic, and White/others). We used Poisson regression to estimate change in number of donors per 5-year increment (incidence rate ratio, IRR).

Results: Of 106,033 biologically related donors (43% full sibling, 25% offspring, 20% parents, and 12% non-first-degree relative donors) 71% were White, 14% Black, and 15% Hispanic. The rates of biologically related donors between 1988 and 2004 increased across race. For every 5-year increment, White related donors increased by 31% (IRR $_{1.29}1.31_{1.32}$), Black related donors increased by 52% (IRR $_{1.49}1.52_{1.56}$), and Hispanic related donors increased by 55% (IRR $_{1.51}1.55_{1.59}$). Conversely, the rates of biologically related donors between 2005 and 2022 decreased across race. For every 5-year increment, White related donors decreased by 18% (IRR $_{0.82}0.82_{0.83}$), Black related donors decreased by 25% (IRR $_{0.73}0.75_{0.77}$), and Hispanic related donors decreased by 9% (IRR $_{0.89}0.91_{0.93}$).

Conclusions: Our study highlights opportunites to reduce barriers to biologically related donations among racial/ethnic minorities and the socioeconomically disadvantaged healthy adults. Efforts are needed to reduce hurdles for biologically related donors, potentially by providing outreach education, easing access to donor evaluation, offering social and financial support, and assuring post-donation follow-up care.

SA-PO980

Perioperative Donor Nephrectomy Risks in Living Kidney Donors with Obesity: A Systematic Review and Meta-Analysis

Fawaz Al Ammary,[1] Simeon Adeyemo,[1] Abimereki Muzaale,[2] Asad Naveed.[3]
Living Donor Transplant Outcome Collaborative (LDTOC). *[1]University of California Irvine, Irvine, CA; [2]Johns Hopkins University, Baltimore, MD; [3]University of Toronto, Toronto, ON, Canada.*

Background: Obesity is a global public health concern. Given the shortage of living kidney donations, transplant centers have been more willing to accept obese donor candidates in recent years. To better counsel obese donor candidates about donor nephrectomy risks, we aimed to summarize evidence for the perioperative risks for obese living kidney donors compared to non-obese living kidney donors across studies.

Methods: A systematic search of standard databases was conducted to identify studies comparing obese and non-obese living kidney donors. Outcome data were extracted and synthesized. Obesity was defined as BMI ≥ 30. The risk of bias was assessed using Cochrane's risk of bias in non-randomized studies - of interventions (ROBINS-I) tool.

Results: Fifteen cohort studies were included in the final review. Obese patients have significantly longer operative times compared to non-obese patients, with a standardized mean difference of 0.93 (95% CI: 0.21 to 1.65, P=0.01), favoring non-obese donors (Figure 1). Additionally, Obese donors have significantly higher odds of surgical complications compared to non-obese patients, with an odds ratio of 1.22 (95% CI: 1.00 to 1.48, P=0.05), favoring non-obese patients (Figure 2).

Conclusions: Living kidney donors with obesity have increased risks of longer operating time and perioperative complications. These findings highlight the need for interventions to minimize perioperative risk for obese donors and tailored follow-up care to ensure best outcomes for this group of donors, who provide a vital source for living kidney donation.

Racial and Relationship Trends in Living Kidney Donation: A Retrospective Analysis from Miami Transplant Institute

Daniel S. Del Castillo Rix,[1] Veronica A. Ortigosa Serrano,[2] Adriana Medina,[3] Rojin Esmail,[3] Franco H. Cabeza Rivera.[1] *[1]Jackson Memorial Hospital, Miami, FL; [2]University of Miami, Coral Gables, FL; [3]Ross University School of Medicine - Barbados Campus, Bridgetown, Barbados.*

Background: Living kidney donation is pivotal in combating end-stage renal disease, offering superior outcomes and reduced waiting times compared to deceased donor transplants. Understanding the relationship between donors and recipients, particularly across various racial and ethnic groups, is crucial for developing targeted strategies to increase donor recruitment and improve transplant equity, ultimately enhancing patient outcomes in transplant medicine.

Methods: We retrospectively reviewed the clinical data of seven hundred seventy donors who underwent nephrectomy for living donor kidney transplantation at the Miami Transplant Institute from 2011 to 2021. We evaluated the relationships between living kidney donors and recipients and how they varied across racial and ethnic groups over time. We used descriptive statistics to describe the changes in living kidney donors and chi-squared to determine its statistical significance. Logistic regression was used to determine differences in relationships by race over time statistical significance was set at a p-value <0.05, with analyses performed using STATA/BE, version 17.

Results: We included 770 patients, who were categorized into three primary groups: White (266 participants, 34.8%), Black (155 participants, 20.1%), and Latino (347 participants, 45.1%). Within these groups, the total number of related donors varied: 122 (45.5%) in the White group, 107 (69%) in the Black group, and 192 (55.3%) in the Latino group. Logistic regression revealed no significant differences in the trends of kidney donation over time.

Conclusions: This retrospective analysis underscores the complexities of living kidney donation across our different groups. Despite variances in the proportion of related donors among White, Black, and Latino groups, our findings indicate no significant changes in the trends of kidney donation relationships over time. However the proportion of related donors is notably higher in the Black and Latino group compared to white. This suggests underlying social and cultural differences in living kidney donation attitudes that could be addressed by incentivizing culturally sensitive programs. Further studies need to be done to better understand what factors influence differences in relationships.

Quality of Life in Kidney Donors: A Single-Center Experience

Amgad E. El Agroudy. *Arabian Gulf University, Manama, Bahrain.*

Background: Living kidney donation is used to treat ESRD, but it poses risks and decision-making challenges for donors. This study examines kidney donors' long-term quality of life (QOL).

Methods: We conducted a cross-sectional survey on kidney donors between 1982 and 2018. We used the SF-36 (Arabic version) to measure the donors' quality of life (QOL). Out of 60 donors contacted, 44 agreed to participate and responded. Demographic information, donor-recipient relationships, and specific questions about the donation were collected and analyzed.

Results: The mean age of the donors was 50.1 ± 11.7 years at follow-up, and 26 (59.1%) were males. Most donors were siblings and parents, accounting for 36.4% (n=16) each. The time since the donation was 111.5 ± 97.1 months. All donors decided voluntarily to donate and all of them would do it again if given a chance. However, one donor (2.3%) complained that the donation had caused problems in his marriage, while 6 donors (13.4%) experienced clinically relevant distress, and 2 donors (4.5%) experienced financial disadvantages. Donors had high QOL scores, with a mean score of 73.1 and 96.9 (on a scale of 1-100) for the 8 subscales. The highest score was for role social functioning, while the lowest was for Energy/Fatigue. The mean scores for the four fatigue subscales were low, ranging from 61.8 to 86.8. The lowest score was for feeling calm and reassured, while the highest was for feeling frustrated. In social functioning, the highest score was for the effect of mental health on work performance (97.2). We analyzed various demographic factors and their correlation with QOL and found no significant correlation in most domains regarding sociodemographic characteristics.

Conclusions: Our research indicates that most kidney donors have had a positive experience over the past four decades. Both male and female donors of all ages reported good long-term quality of life, further enhanced by recognition and support from their families and friends. These findings provide further support for our current policy on organ donation.

Simultaneous Liver-Kidney Transplant vs. Safety Net Kidney after Liver Transplant: How Has the Policy Change Impacted Graft and Patient Outcomes?

Anjana Murali, Srijan Tandukar, Mary Ann C. Lim. *University of Pennsylvania, Philadelphia, PA.*

Background: The policy governing the eligibility criteria for simultaneous liver-kidney transplant (SLK) was implemented on Aug 10, 2017. After policy change, liver transplant patients can be listed for kidney transplants (KAL) by the safety net criteria between posttransplant days 60 to 365 if they have a qualifying eGFR of ≤20 ml/min. The impact of this policy change for transplant recipients at our center is not known.

Methods: Demographic information for recipients and donors, chronic kidney and liver disease history, transplant characteristics, graft function and patient survival information were collected by chart review for transplants occurring between Aug 10, 2017 and Mar 31, 2023. Rates of primary non function (PNF), death, rejection, and time between waitlisting and transplant were collected for all patients listed for liver and kidney transplant.

Results: There was a total of 49 SLK recipients and 16/37 liver transplant patients who were listed for KAL received a kidney transplant. The proportion of patients on dialysis at the time of listing for SLK and KAL was 57% (N=21) vs 63% (N=23). Hepatorenal syndrome was a cause of kidney disease in 31% (N=15) vs 46% (N=17) patients of SLK vs KAL recipients. 2 SLK recipients developed PNF whereas none of the KAL recipients developed PNF. 14 KAL patients (88%) received the kidney transplant within 2 years of a liver transplant. Among KAL listing, 81% (N=30) occurred within the safety net period. The mean eGFR at 1 year post transplant was 55 and 61 ml/min for SLK vs KAL. Two patients on KAL waitlist recovered kidney function and were removed from the waitlist.

Conclusions: Most patients receiving a liver alone received a kidney transplant within 2 years of the liver transplant, most often through the safety net criteria. The patients receiving KAL had comparable allograft function, rejection and patient survival rates to SLK patients. Some patients on KAL waitlist recovered kidney function and were removed from the waitlist allowing these kidneys to be allocated to patients listed for a kidney transplant alone. Identification of patients that may be able to get KAL transplant may allow for improved access to kidney transplant for others on the deceased donor kidney transplant waitlist.

SA-PO984

Outcomes of Kidney after Liver Transplantation by Induction Type, Stratified by Intertransplant Interval and Immunologic Risk

Gabriel Cojuc,[1] Stalin Canizares,[1] Maria B. Rivera,[1] Ritah R. Chumdermpadetsuk,[1] Kalathil K. Sureshkumar,[2] Devin Eckhoff,[1] Martha Pavlakis,[1] Bhavna Chopra.[1] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Allegheny Health Network, Pittsburgh, PA.*

Background: There is no standard induction immunosuppression (IS) for kidney after liver transplants (KALT). Time from liver engraftment and immunologic risk have been hypothesized as effect modifiers for induction therapy-related outcomes. We aimed to assess outcomes in KALT according to induction type, further stratified by inter-transplant intervals and immunologic risk.

Methods: Retrospective UNOS registry cohort study. We selected KALT between 2010 and 2022 who received mycophenolate- and tacrolimus-based maintenance IS. We compared patient death, graft loss, and death-censored graft failure (DCGF) using Cox proportional hazards models in KALT according to induction type (depleting vs. non-depleting), inter-transplant intervals (<1, 1–3, >3 years), and calculated panel reactive

antibody (cPRA) (<20, 20–49, 50–80, >80) adjusting for gender, age, ethnicity, steroid use, dialysis vintage, HLA mismatch, cold ischemic time, body mass index, kidney donor profile index, diabetes, and donor characteristics.

Results: We included 1640 KALT (31% female, age 58.5±11 yrs), 61% received depleting, and 39% non-depleting induction IS. There were no statistically significant differences between induction IS groups in patient death (HR 1.01, 95% CI 0.79–1.30), graft loss (0.96, 95% CI 0.76–1.22), and DCGF (HR 1.14, 95% CI 0.86–1.52). The results were consistent when stratifying into inter-transplant intervals; no differences were observed in KALT with <1, 1–3, or >3 years between transplants. Similarly, there were no differences in the outcomes categorized by cPRA (Table).

Conclusions: Induction IS therapies did not impact patient death, graft loss, and DCGF in KALT stratified by inter-transplant intervals and cPRA. The selection of induction IS should be individualized based on immunologic and infection risk.

Depleting (D) vs. non-depleting (ND) induction in KALT	Adjusted patient death HR (95% CI); p value	Adjusted graft loss HR (95% CI); p value	Adjusted death censored graft loss HR (95% CI); p value
All KALT (D = 996; ND = 644)	1.01 (0.79–1.30); 0.91	0.96 (0.76–1.22); 0.75	1.14 (0.86–1.52); 0.37
<1 yr post LT (D = 163; ND = 135)	0.70 (0.22–2.23); 0.55	0.49 (0.19–1.25); 0.14	1.09 (0.51–3.81); 0.89

SA-PO985

Comparative Analysis of Infection and Rejection Rates for Recipients of Kidney-after-Liver (KALT) Compared with Simultaneous Liver and Kidney Transplant (SLK)

Sarah Abu Kar, Laura Binari, Scott A. Rega, Irene Feurer, Saed Shawar. *Vanderbilt University Medical Center, Nashville, TN.*

Background: We investigated 1- and 3 year kidney allograft and patient outcomes for recipients of (KALT) compared to (SLK). Analysis of infection and rejection outcomes by induction type and panel reactive antibody (PRA) was performed.

Methods: Data were collected from the records for patients who had SLK or KALT at Vanderbilt University Medical Center between 1983 and 2022. Patients with multiple kidney transplants or insufficient data were excluded. Data were analyzed using summary statistics, chi square, ANOVA, and Kaplan-Meier survival and multivariable logistic regression analysis.

Results: 59 patients, 39 KALT and 20 SLK recipients, were included. Age at kidney transplant was 57±10 years. Among all patients, kidney induction therapy was 44% alemtuzumab, 27% basiliximab, 24% methylprednisolone and 5% thymoglobulin. A higher proportion of KALT received alemtuzumab (62% vs 10% SLK), whereas more SLK patients (60% vs 5% KALT) received methylprednisolone (p<0.05). Maintenance IS did not differ between the two groups. Mean serum creatinine and GFR at 1-year (1.29±0.39 mg/dL, 57.31±19.9 ml/min/1.73m2) and 3-years (1.32±0.37 mg/dL, 54±17.6 ml/min/1.73m2) did not differ between the two groups. Point estimates of 3-year patient and death-censored graft survival were 84.6% (SE= 4.7%) and 93.1% (SE= 3.3%), respectively. Univariate analyses showed no difference in rate of rejection within 1 and 3 years by induction regimen or between SLK and KALT patients. Among person with at least 33 months follow-up after adjusting for induction regimen, the multivariable analysis may suggest that SLK recipients had increased likelihood of rejection within the first 3 years (p=0.051). Rates of infection within 1 and 3 years did not differ by induction regimen or between SLK and KALT. Mean PRA for patients who had alemtuzumab induction (44.7±41.6%) was higher than mean PRA for methylprednisolone induction (11.3±24.6 %) (p =0.045). Mean PRA did not differ significantly among patients experiencing at least one infection or one rejection within 1 and 3 years compared to those who did not.

Conclusions: Infection and rejection rates did not differ between SLK and KALT recipients within 1 year after adjusting for different induction therapies. Additionally, PRA levels were not related to infection or rejection rates.

SA-PO986

Successful Simultaneous Liver-Kidney Transplantation in a Patient with Nonuremic Calciphylaxis (NUC) Secondary to Alcoholic Cirrhosis

Issa R. Haddad, Shawna Lord, Rohan V. Mehta, Alfonso Santos. *Division of Nephrology, Hypertension, and Renal Transplantation, University of Florida College of Medicine, Gainesville, FL.*

Introduction: Calciphylaxis is a rare condition characterized by painful, non-healing skin lesions due to arterial calcification and thrombosis. While typically associated with end-stage renal disease (ESRD), calciphylaxis can also occur in the absence of renal dysfunction, known as non-uremic calciphylaxis (NUC). Common causes include primary hyperparathyroidism, alcoholic liver disease, and malignancy.

Case Description: A 45-year-old male with end-stage liver disease secondary to alcohol (EtOH) cirrhosis presented with worsening bilateral lower extremity necrotic wounds over 6 months. He was initially diagnosed with livedo reticularis. At the time of lesion appearance, renal function was normal (GFR 123 mL/min), but as liver failure progressed, renal dysfunction ensued, necessitating dialysis. Skin biopsy confirmed calciphylaxis, prompting treatment with vitamin K and sodium thiosulfate (STS), along with wound care and prophylactic antibiotics. Significant labs revealed PTH of 68 pg/ml, 25 OH Vit D of 22 ng/ml, calcium of 8.3 mg/dl, PO4 of 5 mg/ml, and albumin of 1.8 g/dl. The patient underwent simultaneous liver and kidney transplantation attaining a baseline creatinine of 0.9 mg/dl. Maintenance Immunosuppression included tacrolimus and mycophenolate. Continuation of STS therapy for 6 weeks post-transplantation led to complete resolution of lesions.

Discussion: We present a case of successful simultaneous liver and kidney transplantation in a patient with active NUC. Although NUC complicates pre-transplant evaluation due to associated high mortality and infection risks, aggressive medical management and continued STS therapy can yield favorable outcomes. While the literature on NUC and transplantation is limited, existing reports suggest favorable outcomes with STS post-transplantation. This case emphasizes that a diagnosis of NUC may not preclude transplantation or immunosuppression.

SA-PO987

Prolonged Cold Ischemia Time in Pancreas Transplantation Yields Similar Outcomes Compared with Standard of Care Outcomes: Single-Center Experience, a Call to Action to Decrease Nonuse Rates

Georges Aboukasm, Mariella O. Goggins, George W. Burke. *Miami Transplant Institute University of Miami School of Medicine Jackson Memorial Hospital, Miami, FL.*

Background: Overall number of deceased donor pancreas transplant have decreased overtime and the rate of nonuse pancreas have reached its highest at 28.6% in 2022. There are many reason for nonuse pancreas, with newer allocation schemes, broader organ sharing, increase ischemia times, decrease risk tolerance and lack of center/surgeon expertise playing a role. We aim to evaluate our single center experience on the use of pancreas with prolonged cold ischemia time(CIT) and outcomes. Standard of care is to place the pancreas within 12 hours(hrs) of CIT. We report our single-center experience in the use of pancreas with over 12hrs of CIT.

Methods: Single center retrospective review of all simultaneous kidney/pancreas(SPK) and pancreas transplant alone(PTA) from January 2014 to September 2023 with at least 6m of follow up. Pancreas graft failure was defined as allograft pancreatectomy or recipients' fully dependency of insulin and/or c-peptide levels <2.0 ng/ml

Results: We had 190 SPK/PTA recipients during the study period, we divided them by less or more than 12hrs of pancreas CIT.Table1. Shortest CIT was 3.5hrs and longest was 23hrs, significantly higher among the groups (p<0.001). Enteric-drained recipients were more likely to have CIT<12hrs and bladder-drained more likely to have >12hr CIT (p<0.00001). Table2: Mean follow-up was longer in the group with >12hrs CIT, 5yrs vs 2.8 yrs (p=0.03). Patient survival was lower among the group with CIT>12hrs (p=0.007). However, there were no difference in pancreas graft survival among the groups. A1c,c-peptide and fasting blood glucose was similar up to 5yrs of follow-up.

Conclusions: In the current environment of high nonuse rate for pancreas transplantation, allowing longer pancreas CIT and total pancreas preservation time, may increase the rates of pancreas transplantation. We are evaluating our outcomes with regards to post-op complications, enteric leak, intra-abdominal abscess and length of stay, between both groups, under and longer than 12hrs CIT.

Table 1 Baseline Characteristics

	Pancreas CIT <12 hours (n = 183)	Pancreas CIT >12 hours (n = 38)	P value
Recipient Mean Age	42	42	0.977

Trends in Discard of Kidneys from Hepatitis C Viremic Donors in the United States, 2020-2023

Krutika P. Chauhan,[1] Su-Hsin Chang,[1] Siobhan Sutcliffe,[1] Massini Merzkani,[1] Krista L. Lentine,[2] Bekir Tanriover,[3] Louai Alrata,[1] Dema Yaseen Alsabbagh,[1] Tarek Alhamad.[1] *[1]Washington University in St Louis, St Louis, MO; [2]Saint Louis University, St Louis, MO; [3]The University of Arizona College of Medicine Tucson, Tucson, AZ.*

Background: With the introduction of direct-acting antiviral (DAA), the discard rate of hepatitis C viremic (HCV) has decreased remarkably. With the continuous shortage of organs and the change in the allocation system, it is not clear if the HCV organs continue to have a higher risk of discard in the new era 2020 – 2023.

Methods: We used the 2020-2023 Organ Procurement and Transplantation Network (OPTN) to identify deceased donor kidneys recovered for transplant. We utilized our inclusion-exclusion criteria (Fig 1) to formulate our analytic cohort. The exposure was donor HCV antibody and viremia status. We did a multivariable logistic regression throughout the years to assess the association of HCV and discard while adjusting for donor characteristics. We also did another model where we adjusted for the COVID status of donors along with donor characteristics.

Results: Among the 101,088 kidneys recovered from 2020-2023, 5,718 (5.7%) were HCV viremic donors (NAT+) and 4,768 (4.7%) were aviremic seropositive (NAT-, Ab+) donors. Compared to HCV aviremic seronegative kidneys (NAT-, Ab-), the odds of HCV viremic kidney discard slightly increased from 27% in 2020 (aOR 1.27, 95% CI, 1.07 to 1.51), to 33% in 2022 (aOR 1.33, 95% CI, 1.31 to 1.57). The results were not significant for 2021 and 2023 (2021, aOR 1.06; 95% CI, 1.31 to 1.57, and 2023, aOR 0.99; 95% CI, 0.83 to 1.18). (Figure 1A). We saw a similar trend when we adjusted for donor COVID status (Figure 1B). Kidneys from aviremic seropositive donors did not carry a higher risk of discard during the entire period.

Conclusions: Discard of HCV viremic kidneys has been fluctuating in the last few years with odds of 30% in 2020 and 2022 while not significant in the other years. With the prevalent organ shortage and safety of DAA, more efforts are needed to eliminate the discard of HCV viremic kidneys.

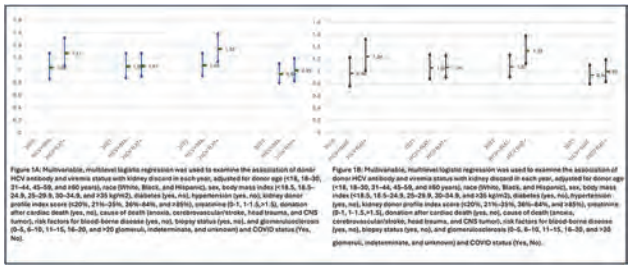

Figure 1A: Multivariable, multilevel logistic regression was used to examine the association of donor HCV antibody and viremia status with kidney discard in each year, adjusted for donor age (<18, 18–30, 31–44, 45–59, and ≥60 years), race (White, Black, and Hispanic), sex, body mass index (<18.5, 18.5–24.9, 25–29.9, 30–34.9, and ≥35 kg/m2), diabetes (yes, no), hypertension (yes, no), kidney donor profile index score (≤20%, 21%–35%, 36%–64%, and ≥65%), creatinine (0–1, 1–1.5,>1.5), donation after cardiac death (yes, no), cause of death (anoxia, cerebrovascular/stroke, head trauma, and CNS tumor), risk factors for blood-borne disease (yes, no), biopsy status (yes, no), and glomerulosclerosis (0–5, 6–10, 11–15, 16–30, and >30 glomeruli, indeterminate, and unknown) and COVID status (Yes, No).

Figure 1B: Multivariable, multilevel logistic regression was used to examine the association of donor HCV antibody and viremia status with kidney discard in each year, adjusted for donor age (<18, 18–30, 31–44, 45–59, and ≥60 years), race (White, Black, and Hispanic), sex, body mass index (<18.5, 18.5–24.9, 25–29.9, 30–34.9, and ≥35 kg/m2), diabetes (yes, no), hypertension (yes, no), kidney donor profile index score (≤20%, 21%–35%, 36%–64%, and ≥65%), creatinine (0–1, 1–1.5,>1.5), donation after cardiac death (yes, no), cause of death (anoxia, cerebrovascular/stroke, head trauma, and CNS tumor), risk factors for blood-borne disease (yes, no), biopsy status (yes, no), and glomerulosclerosis (0–5, 6–10, 11–15, 16–30, and >30 glomeruli, indeterminate, and unknown) and COVID status (Yes, No).

SA-PO989

Simultaneous Heart-Kidney Transplant Is the Best Treatment Option for Patients with CKD and ESKD vs. Heart Transplant Alone

Krutika P. Chauhan, Qingyuan Tan, Siobhan Sutcliffe, Su-Hsin Chang, Tarek Alhamad, Massini Merzkani. *Washington University in St Louis, St Louis, MO.*

Background: Simultaneous heart and kidney transplantation has been considered for patients who had advanced CKD and ESRD who have an indication for heart transplantation. In this study, we analyzed whether there is an increase in patient survival and heart transplant graft survival.

Methods: We analyzed data from the OPTN patients who received heart transplant with CKD/ESRD 1/2020-12/2023. Our inclusion criteria were adults aged >18 years old receiving a solid organ heart transplant with evidence of CKD, defined as eGFR less than 60 or on dialysis for heart transplant alone, and who were ABO compatible. Our outcomes were heart graft loss, defined as receiving another heart transplant or death, and death was defined patient expiring as per UNOS. Multivariable Cox regression was used to evaluate defined patient survival and graft survival while adjusting for recipient, donor, and graft characteristics.

Results: A total of 22,111 transplants were performed, 86.6% of which were HTx and 13.4% of which were SHKTx. The prevalence of graft loss was 40.7% and death was 41.6% overall. We see better patient and graft survival with simultaneous heart-kidney compared to heart alone in all stages of CKD and including the different stages of CKD in graft failure and death as shown in Table 1 and Figure 2 and 3. Our study have the limitation of selection bias as it is unclear why there are patients with CKD/ESRD who did not receive simultaneous heart and kidney transplantation. The other bias the eGFR were calculated by using serum creatinine as a marker and unclear it will be the ideal marker given the patient with end-stage heart failure usually have cachexia with low muscle mass.

Conclusions: SHK transplantation has an increased benefit in patient and heart transplant survival compared to patients who received heart transplantation alone. Prospective studies should be performed to determine the ideal eGFR cutoff for patient listing.

Table 1 Outcomes in Simultaneous Heart Kidney Transplant

	Hazard ratio	Pvy	Low CI	High CI
Graft failure				
All stages	0.540	<0.001	0.493	0.592
Stage 3A	0.617	0.004	0.444	0.859
Stage 3B	0.585	<0.001	0.479	0.715
Stage 4	0.515	<0.001	0.418	0.633
Stage 5	0.126	<0.001	0.041	0.386

Decreased Risk for Rejection in Simultaneous Heart-Kidney Transplant

Krutika P. Chauhan, Qingyuan Tan, Siobhan Sutcliffe, Su-Hsin Chang, Tarek Alhamad, Massini Merzkani. *Washington University in St Louis, St Louis, MO.*

Background: Simultaneous heart and kidney(SHKTx) is one of the best choice for patient with advanced CKD and ESRD. Recent data and basic science research have suggested that kidney transplant has an immunoprotective effect to heart transplant. In this large retrospective cohort study we reviewed the rejection rate in the heart transplant in patient who received a SHK compared with the ones who had heart transplant alone with CKD/ESRD.

Methods: We analyzed the OPTN data that had CKD with heart transplants in the period of 1/1/2020 to 12/31/2023. Our inclusion criteria were adults aged 18 and older who receive solid organ heart transplants with evidence of CKD defined as eGFR being less than 60 or being on chronic dialysis for the HTx and were ABO compatible. Our outcome of interest was Rejection. The aim of this study is to determine in the study population if SHKTx has a better outcome defined as no rejection in all stages of CKD and individual stages of CKD. Multivariable logistic regression was performed to evaluate defined patient survival and heart graft survival while adjusting for recipient, donor, and transplant characteristics.

Results: During the study period, there was a total of 19,141Htx and 2,970 of SHKTx. The prevalence of rejection was 19.2% with 3,078 in heart alone and 170 in simultaneous heart kidney. Highly prevalent CKD stages were Stage 3A Moderate CKD with 49.7%. We see better odds for SHKTx for stages 3A (OR 0.43, CI-0.24 and 0.77), stage 3B (OR 0.49, CI-0.33 and 0.70), stage 4 (OR 0.43, CI-0.27 and 0.67) and ESRD stage (OR 0.31, CI-0.21 and 0.45) with significant values. We see similar results for overall, all stages of CKD and only for Stage 5 of CKD were not a higher risk.

Conclusions: In this we found that Simultaneous heart and kidney was protective for rejection in the heart transplant compared with heart transplant alone. More studies should be done to determine the long-term benefits and pathophysiology of these findings.

Table 1 Logistic Regression Rejection of Simultaneous heart kidney transplant compare with heart transplant alone with CKD/ESRD

Logistic regression	Odds ratio	P>z	[95% conf.	interval]
Simultaneous heart kidney				
Overall	0.3838485	<0.001	0.3191892	0.461606
Stage 3A	0.4304939	0.005	0.2406274	0.7701744

Assessing Kidney Function in Combined Heart-Kidney Transplant Candidates: Challenges and Opportunities

Krishna A. Agarwal, Aman Srivastava, Andrew S. Levey, Lesley A. Inker.
Tufts Medical Center, Boston, MA.

Background: Heart transplant candidates often have concomitant kidney disease, necessitating simultaneous heart-kidney transplantation (SHKT). UNOS outlined GFR cutoffs for allocating heart-kidneys in 2023. A heart transplant (HT) candidate with baseline CKD can qualify for SHKT with GFR<=30 or with sustained AKI if GFR<=25. Unfortunately, there is no guidance for appropriate methods of assessing GFR in these patients with heart failure who can be volume expanded and sarcopenic and hence have inaccurate creatinine based GFR (eGFRcr). While cystatin based GFR (eGFRcys) is an alternative, it is known to have high error rates as well.

Methods: We present 5 cases of HT candidates who were evaluated for SHKT. Only one of them (#2) had peripheral edema on exam. As part of pre-transplant evaluation, eGFRcr, eGFRcys, eGFRcr-cys (CKD-EPI 2021), 24-hour urinary creatinine clearance (mClcr) and measured GFR using plasma iohexol clearance (mGFR) were obtained. For mGFR, blood samples were drawn at 2, 4, 6 and 24 hours after iohexol injection and GFR was determined using a two-compartment model with the Brochner-Mortenson correction.

Results: There was wide discrepancy between eGFRcr and mGFR, with eGFRcr overestimating mGFR for all five patients (Table 1). eGFRcys and eGFRcr-cys were more similar to mGFR. Urine mClcr did not corelate with mGFR.

Conclusions: In HT candidates being evaluated for SHKT, it is essential to have an accurate assessment of GFR. eGFRcr alone is fraught with inaccuracies. Our findings support the use of guideline-recommended eGFRcr-cys (CKD-EPI 2021) with comprehensive evaluation using cystatin C and mGFR. Transplant centers should consider collaborating with laboratory scientists to implement measurement protocols for cystatin C and mGFR for assessing dual organ transplant eligibility.

ID	Creatinine (mg/dL)	eGFRcr (mL/min/1.73m2)	Cystatin C (mg/L)	eGFRcys (mL/min/1.73m2)	eGFRcr-cys (mL/min/1.73m2)	mClcr (mL/min/1.73m2)	mGFR (mL/min/1.73m2)

Lymphocyte Immune Assays for the Management of Immunosuppression of Kidney Transplant Patients in Sepsis

Emiliya Bakhshiyeva,[1] Marie Kranefuß,[2] Mario Schiffer,[1] Carsten Willam,[1] Regine Brox,[2] Johanna T. Kurzhagen.[1] *[1]University Hospital Erlangen Department of Nephrology and Hypertension, Erlangen, Germany; [2]University Hospital Erlangen Department of Transfusion Medicine, Erlangen, Germany.*

Background: Kidney transplanted (KT) patients are on high risk for infections including sepsis. However, by date there is no guideline on the management of immunosuppression in these patients in sepsis and management is based on clinical decision making with little evidence. We therefore aim to study different lymphocyte immune assays as potential biomarkers in septic patients with and without IS.

Methods: T- and B-cell markers were examined in 3 groups of patients: Healthy controls (HC), patients with sepsis without IS and patients with sepsis with IS. Sepsis was diagnosed based on Sequential Organ Failure Assessment (SOFA) Score. Determination of T- and B-cell markers was performed at different time points of sepsis, at day 0, 3 and 7 using flow cytometry.

Results: Study participants were 69.8 (standard deviation, SD: ±18.6) years old in average. Mean SOFA-Score at baseline was 4.5 (±0.7) in patients without IS vs. 4 (±0.0) in patients with IS. CD3+ lymphocytes and CD8+ T-cells were less frequent in both groups compared to HCs. However, patients with IS showed recovery by day 7. CD4+ T-cell frequency was decreased in patients with IS in comparison to patients without IS. In CD4+ T-cells, expression of pro-inflammatory markers such as CD4+TNF-α+, CD4+IFN-γ+ and CD4+IL-17+ was reduced in patients with IS compared to patients without IS. The anti-inflammatory marker CD4+IL-10+ was downregulated in both groups compared to HCs. CD8+IFN-γ+ cells were more upregulated, whereas CD8+IL17+ in patients with IS compared to patients without IS. CD8+IL10+ cells were downregulated and CD8+TNF-α+ showed no differences in both groups compared to HCs. Expression of T-cell activation markers CD25 and CD71 declined over the course of sepsis in both groups compared to HCs. The B-cell activation marker CD86 showed less expression in patients with IS on d0. CFSE revealed no changes in proliferation in different groups.

Conclusions: Preliminary data show differences in T- and B-cell markers between immunosuppressed and non-immunosuppressed patients in different phases of sepsis. This may provide deeper understanding of lymphocyte function and potentially allow a more individualized management of immunosuppression in KT patients in sepsis in future.

SA-PO993

Survival of Kidney Transplantation in People Living with HIV/AIDS: A Systematic Review and Meta-Analysis

Ka chun Leung,[1] Wincy Wing Sze Ng.[2] *[1]Tuen Mun Hospital Department of Medicine and Geriatrics, Hong Kong, Hong Kong; [2]Queen Mary Hospital, Hong Kong, Hong Kong.*

Background: As of 2022, nearly 40 million individuals are affected by HIV/AIDS, with 1.3 million new cases annually. The high effectiveness of antiretroviral therapy (ART) has made kidney transplantation a possibility for people living with HIV/AIDS (PLWHA) who are suffering from chronic kidney disease (CKD). The HIV Organ Policy Equity (HOPE) Act in the US lead to research in different aspects of transplant complexities including drug interactions and co-infections. This review aimed to evaluate kidney transplantation outcomes in PLWHA.

Methods: Databases were searched up to Nov 2023. Prospective and retrospective clinical trials were included. Primary outcomes centered on graft survival(GS), rejection(GR), infections, and patient survival(PS) post-transplantation. Secondary outcomes assessed the impact of ART and co-infections.

Results: 601 potentially eligible studies were identified with 48 included in analysis. No significant survival disadvantage for PLWHA in short term survival despite a higher long term risk (1yr PS 94%, hazard ratio(HR) 1.43, p=0.077; ≥5yr PS 83%, HR 1.91, p=0.005; 1yr GS 90%; ≥5yr GS 71%)(Table1, Figure1). There are positive impact of integrase inhibitor-containing ART regimens on PS and GS.

Conclusions: Kidney transplantation is an effective option for PLWHA, with outcomes comparable to the general population. Research on long-term outcomes, newer ART regimens, and tailored post-transplant monitoring protocols for PLWHA are essential to improve patient outcomes.

Table 1. Primary outcome

	Time Frame (years)	Outcome(%)[95%CI]	Hazard Ratio[95%CI]	I2(%)	p
Patient Survival	1	93.90[92.8–94.9]	1.43[0.96–2.11]	97.04	0.077

Association of 25-Hydroxyvitamin D Levels with BK Viremia and Nephropathy in Kidney Transplant Recipients

Suseela A. Raj, Angela L. Zhou, Ekaterina Fedorova, Zhongyu Yuan, Didier A. Mandelbrot, Brad C. Astor, Sandesh Parajuli. *University of Wisconsin-Madison, Madison, WI.*

Background: In kidney transplant recipients, BK virus reactivation and subsequent viremia (BKV) and nephropathy (BKN) are significant causes of morbidity and mortality. Limited treatment options make these complications particularly detrimental. Vitamin D supports immune function, yet low 25-hydroxyvitamin D [25(OH)D] levels are common in kidney transplant recipients. The association between 25(OH)D and BKV and BKN in kidney transplant recipients remains undefined.

Methods: The relationship between serum 25(OH)D level, measured 61 days to 2 years post-transplant, and BKV and BKN was examined in 3308 kidney transplant recipients. Recipients received kidney transplants from 2010 to 2019. Only recipients with 25(OH)D level measured before BKV were included.

Results: Out of 3308 recipients, 399 (12%) were vitamin D deficient [25(OH)D <20 ng/mL], and 916 (27.7%) were insufficient [25(OH)D 20-29 ng/mL]. 184 recipients had BKV, and 44 recipients had BKN. The incidence rate for BKV/100 person-years was 2.88 in the 25(OH)D sufficient group, 2.22 in the insufficient group, and 2.37 in the deficient group. With reference to sufficient 25(OH)D, there was no significant association for BKV after adjustment for multiple baseline characteristics. Similarly, the incidence rate/100 person-years for BKN was 0.30 in the 25(OH)D sufficient group, 0.75 in the insufficient group, and 1.28 in the deficient group. After adjustment for multiple baseline characteristics, with reference to sufficient 25(OH)D, deficiency (aHR: 3.92; 95% CI: 1.66-9.23) and insufficiency (aHR: 2.22; 95% CI: 1.11-4.45) were significantly associated with increased risk for BKN (Figure 1).

Conclusions: Low serum 25(OH)D is associated with increased risk of BKN but not BKV. Further studies are needed to explore the effects of vitamin D supplements to mitigate complications associated with BKN.

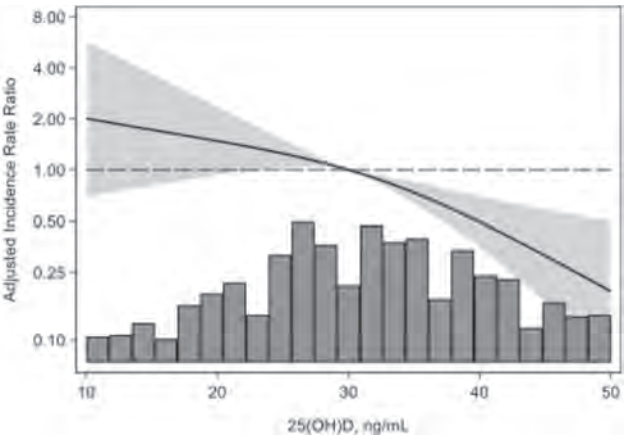

Figure 1. Incidence of BKN decreased with increasing 25(OH)D.

SA-PO995

Association of Post-transplant 25-Hydroxyvitamin D and Infection in Kidney Transplant Recipients

Zhongyu Yuan,[1,2] Michal L. Melamed,[3] Margaret R. Jorgenson,[4] Didier A. Mandelbrot,[2] Sandesh Parajuli,[2] Brad C. Astor.[1,2] *[1]University of Wisconsin-Madison Department of Population Health Sciences, Madison, WI; [2]University of Wisconsin-Madison Department of Medicine, Madison, WI; [3]NYU Langone Health, New York, NY; [4]UW Health, Madison, WI.*

Background: Infection is a leading cause of morbidity and mortality in kidney transplant recipients (KTRs). There is a growing interest in the immunoregulatory effect of vitamin D. While vitamin D inadequacy is common among KTRs, the association of serum 25-hydroxyvitamin D [25(OH)D] and infection remains unclear.

Methods: KTRs with at least one serum 25(OH)D measurement from 5 to13 months after transplant at our center from 2005 to 2020 were included. All 25(OH)D measurements thereafter were included as a time-varying variable. Infections within 365 days of each 25(OH)D measurement were identified. Marginal rates models were fitted to account for multiple infection episodes for each KTR. Models adjusted for recipient age, sex, race, cause of kidney failure, donor status, delayed graft function, prior kidney transplant, human leukocyte antigen-mismatch, immunosuppression, infection and acute rejection history, transplant year, season of 25(OH)D measurement, serum albumin, proteinuria and estimated glomerular filtration rate.

Results: A total of 2251 infection episodes were identified in 2207 KTRs followed for a median of 6.6 years after transplant. 23% and 10% of KTRs had vitamin D insufficiency (21-29ng/ml) and deficiency (≤ 20ng/ml), respectively, at baseline. Vitamin D deficiency was associated with a 1.22-fold (adjusted rate ratio [aRR]=1.22; 95% CI: 1.03-1.43; p=0.02) higher incidence of infection compared with vitamin D sufficiency. The association was strongest for bacterial infection (aRR=1.40; 95%CI: 1.14-1.73; p<0.01), especially urinary tract infection (aRR=1.55; 95%CI: 1.24-1.94; p<0.01).

Conclusions: Vitamin D deficiency is independently associated with a higher incidence of infection in KTRs, especially urinary tract infection. Further research is needed to determine the causal relationship.

Table 1. Clinical characteristics of post-transplant infection episodes.

Characteristics	Frequency, N (%)

Treating Refractory BK Virus Nephropathy with Allogenic BK Virus-Specific T Cells in Kidney Transplant Recipients

Suraj J. Chandwani, Eike Lonnemann, Zhejia Tian, Alena Richter, Sabine Tischer-Zimmermann, Agnes Bonifacius, Astrid Wintering, Rainer Blasczyk, Kai M. Schmidt-Ott, Wilfried Gwinner, Britta Eiz-Vesper, Britta Maecker-Kolhoff, Christian Hinze. *Medizinische Hochschule Hannover, Hannover, Germany*.

Background: Refractory BK virus nephropathy (BKVNP) is a significant risk factor for graft loss in kidney transplant recipients. Currently, there are no targeted therapies available for BKVNP. Given the importance of cellular immunity in viral clearance, we investigated the effects of allogeneic BK virus-specific T cell transfer on graft function, BKV-specific T cell levels, and BKV replication in patients' blood.

Methods: We included three kidney transplant recipients with refractory BKVNP. Refractory BKVNP was defined by persistent BKV replication (>1000 IU/ml), minimum possible immunosuppression, low BKV-specific T cell levels, and histologic evidence of BKVNP. For two patients, donors for virus-specific T cells were selected from the third party T cell donor registry (alloCELL), ensuring the best possible HLA compatibility with the transplanted organ and the recipient. For one patient, the related living organ donor was selected, thus resulting in a haploidentical T cell transfer. BKV-specific T cells were produced from leukapheresis, short-term stimulation with LT and VP1 overlapping peptide pools, followed by cytokine selection and magnetic separation. Patients received at least four T cell transfusions (first fresh, subsequent cryopreserved) every three weeks. BKV load was quantified by qPCR, and BKV-specific T cells were enumerated using interferon-γ Elispot assay.

Results: We observed significant declines in BKV load in all cases (93.16%, 78.10%, 71.11% decrease compared to pre-therapy levels), along with significant increases in BKV-specific T cells in recipients' blood. The most pronounced reduction in BKV load (93.16%) was observed in the haploidentical transplant patient, emphasizing the relevance of HLA compatibility to ensure an adequate T-cell milieu. Graft function remained stable throughout therapy, and no infusion-related adverse events were observed.

Conclusions: Allogeneic BK virus-specific T cell therapy shows promise in treating refractory BKVNP in kidney transplant recipients. Patient selection based on BKV-specific T cell levels, BKV blood levels, graft function, and histology is essential. Further evaluation is needed to determine its clinical efficacy.

SA-PO997

Experience of Utilizing Low-Dosage Belatacept and Cyclosporine in Patients with Refractory BK Polyoma Viremia

Irfan A. Moinuddin, Nouman Akbar, Dhiren Kumar, Akshay Athreya, Gaurav Gupta. *Virginia Commonwealth University Health System, Richmond, VA.*

Background: There are no proven therapeutic options for BK polyoma virus (BKPyV) nephropathy apart from immunosuppression reduction. In-vitro studies have shown that tacrolimus (FK) promotes BKPyV replication through FK binding protein-12 pathyway, while cyclosporine (CsA) inhibits BKPyV replication. Belatacept, CD80/86-CD28 co-stimulation blocker, may have theoretical benefits by avoiding calcineurin inhibitor related nephrotoxicity and FKBP-12 mediated BKPyV replication. We present our experience of CsA and low dose belatacept in refractory BKPyV viremia on FK-based immunosuppression.

Methods: 15 adult kidney transplant patients with refractory BKPyV viremia despite reduction in immunosuppression and IVIg were included. Patients with worsening eGFR were switched to low dose belatacept 2.5mg/kg every 2 weeks for first 5 doses, then monthly (BELA group) and ones with stable eGFR were converted to CsA (CsA group). eGFR and BKPyV PCR between the groups were compared at 3- and 6-months post conversion.

Results: 10/15(67%) patients were in BELA group and 5(33%) were in CsA group. BELA group was transitioned to belatacept at 6±3 months after diagnosis. Mean FK trough was 7.5±2.8ng/ml and median daily dose of mycophenolate(MMF) was 0 mg (range 0-500 mg) at conversion. Mean follow up was 34±19 months. Mean eGFR improved from 24.7±8.3 to 30.4±7.5(p=0.01) at 6 months. BKPyV viral load improved from a median of 87100 COPIES/ml (range 5290-1880000) to 2055 COPIES/ml (range 0-26000;p=0.08). 6/10(60%) patients had resolution of viremia. CsA group were switched to CsA at 21±10 months after diagnosis. Mean FK trough was 6.1±0.6ng/ml and patients were off MMF at the start of CsA. Mean follow up was 13.8±3.3 months. Mean eGFR remained stable, 55±12.5 at conversion vs 54.4±10.7 at 6 months. BKPyV viral load at 6-month improved from a median of 61500 COPIES/ml (range 11500-94800) to 4130 COPIES/ml (range1100-6460;p=0.08). 3/5(60%) patients had resolution of viremia. No rejection was reported in either group.

Conclusions: In our experience, there was a significant reduction in BKPyV viral loads with both strategies. The kidney function improved with belatacept conversion and it remained stable with CsA conversion. Longer follow up is needed to understand the graft outcomes with these strategies. These results provide a framework for prospective studies.

SA-PO998

Effect of Conversion from Tacrolimus to Cyclosporine on BK Viremia among Kidney Transplant Recipients: The TACCsA-SWITCH Study

Shaikha R. Ali,[1,2] Hon Shen Png,[1,2] Abdullah A. A. AlGhamdi,[1,2] Azim S. Gangji.[1,2] *[1]St Joseph's Healthcare Hamilton, Hamilton, ON, Canada; [2]McMaster University, Hamilton, ON, Canada*.

Background: There is no established treatment strategy for BK-polyomavirus (BKPyV) infection among kidney transplant recipients (KTRs) after initial reduction of immunosuppression. In vitro studies suggest an inhibitory role of cyclosporine on replication of BKPyV. We investigated effect of conversion of tacrolimus to cyclosporine (TAC-CsA switch) on BKPyV viral load (VL) among KTRs.

Methods: We conducted a retrospective cohort study with a pre-post study design investigating effect of TAC-CsA switch among KTRs with persistent BKPyV-VL of more than 10,000 IU/ml (equivalent to 4 $\log_{10}$IU/ml) for more than 3 months before TAC-CsA switch. We ensured 6 months of follow up after conversion, between 2020 to 2023. We calculated the slope of change for log-BKPyV-VL in $\log_{10}$IU/ml/month using least-square method and compared the mean results before and after TAC-CsA switch.

Results: 32 patients were included in the analysis. 25 (78.1%) patients had deceased kidney transplantation (KT), and 17 (53.1%) patients received anti-thymocyte globulin. Before TAC-CsA switch, 17 (53.1%) had a change of mycophenolate to leflunomide, 4 (12.5%) and 14 (43.8%) were given cidofovir and intravenous immunoglobulin, respectively. Median time from last immunosuppression adjustment/ therapy given prior to TAC-CsA switch was 112.5 (interquartile range (IQR) 225.75) days. At time of TAC-CsA switch, median BKPyV-VL was $321x10^3$ (IQR $2.49x10^6$) IU/ml, equivalent to median log-BKPyV-VL of 5.50 (IQR 1.39) $\log_{10}$IU/ml. The mean slope of change for log-BKPyV-VL before and after TAC-CsA switch were 0.304 (95% confidence interval (CI) 0.139, 0.469) and -0.279 (95% CI -0.353, -0.204) $\log_{10}$IU/ml/month respectively. Mean difference between the slopes before and after TAC-CsA switch was -0.583 (95% CI -0.807, -0.358) $\log_{10}$IU/ml/month ($p < 0.001$). 21 (65.6%) patients achieved log-BKPyV-VL improvement of at least 0.2 $\log_{10}$IU/ml/month (equivalent to 16 fold VL reduction in 6-month period) after TAC-CsA switch.

Conclusions: TAC-CsA switch is a useful strategy for difficult to treat BKPyV viremia among KTRs.

SA-PO999

Pre- and Post-transplant BK Virus-Specific Enzyme-Linked Immunospot (ELISPot) Assay for Predicting the Outcome of BK Virus Infection in Kidney Transplant Recipients

Do-hyun Na,[1] Eun jeong Ko,[2] Byung ha Chung.[1] *[1]The Catholic University of Korea Seoul St Mary's Hospital, Seocho-gu, Seoul, Republic of Korea; [2]The Catholic University of Korea College of Medicine, Bucheon, Seoul, Republic of Korea*.

Background: It is needed to plan optimal therapeutic strategies for controlling BK viremia. Our previous study showed that BK virus (BKV)-specific T-cell immunity measured by an interferon-γ enzyme-linked immunospot (ELISPOT) are related to outcome of BKV infections. However, there was limitations about difference of time and viremia status.

Methods: We included 84 KTRs who experienced at least one BK viremia at RQ-PCR of BKV-DNA. BKV-ELISPOT were measured in all included recipients at the time of pre-transplant, post- 4 weeks, post- 12 weeks transplant, and when viremia were detected. We divided into two groups Controller and Noncontroller according to sustained duration of BKV infection. We compared BKV-ELISPOT results at each times.

Results: We reduced or stop mycophenolic acid in 88.6% of BK viremia patients and used leflunomide for 48% patients (38.6% and 70% for each group). BKV-ELISPOT results were higher in controller groups at the time of pre-transplant, 4 weeks post-transplant, 12 weeks post-transplant, first viremia detected. When first viremia detected, we analyzed BKV ELISPOT including five BKV peptide mixes. Controller group had higher LT, ST, VP1, VP2 ELISPOT results. Also, those who had no biopsy proven BKVAN had higher LT, ST, VP1, VP3 ELOSPT results.

Conclusions: Pre- and Post- BKV-ELISPOT assay may help to distinguish patients with well controlling BK Viremia from those who have persisting BK Viremia who need more intensive therapy to prevent BKVAN.

SA-PO1000

Burden of BK Virus Infection and BK Virus-Associated Nephropathy in Kidney Transplant Recipients: Scoping Review Reveals Gaps in Patient-Centered Research

Maja Kuharic,[1] Courtney N. Hurt,[1] Kevin J. Fowler,[2,3] Alexander W. Bastian,[2] Juergen Beck,[4] Erik J. van den Berg,[4] John D. Peipert.[1] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Memo Therapeutics Consultant, Schlieren, Switzerland; [3]The Voice of the Patient, Inc., Saint Louis, MO; [4]Memo Therapeutics, Schlieren, Switzerland.*

Background: BK virus (BKV) infection and BKV-associated nephropathy (BKVN) are significant complications affecting kidney transplant recipients, leading to impaired graft function and increased risk of graft loss. This scoping literature review aimed to synthesize the current evidence of the burden of BKV infection and BKVN in kidney transplant recipients.

Methods: A scoping literature search focused on patient-centered research in BKV among kidney transplant recipients was conducted in PubMed and Embase databases from inception to January 2024. Studies were eligible for inclusion if they met the following criteria: (1) included kidney transplant recipients with BK virus infection; (2) reported on clinical, economic, or humanistic burden of BK virus; (3) were published in English; and (4) were original research articles, systematic reviews, or meta-analyses.

Results: Sixty-three studies were included in the review, with most (47%) published within the last five years. No studies examined impacts on quality of life, mental health, and daily functioning. Similarly, no studies reported on economic impact on patients and their families, such as the ability to continue working, opportunity costs of receiving treatment, time off work, and fear of losing jobs. Viruria and viremia were detected in approximately 30% and 12% of kidney transplant recipients, respectively. The incidence of BKVN ranged from 1.4% to 7%. Risk factors for BK virus infection and BKVN included degree of immunosuppression, tacrolimus use, older age, male sex, and donor/recipient ethnic mismatch among others. Graft loss (35% vs. 21%), rejection (42% vs. 25%), and death (18% vs. 13%) were more common in the BKVN group compared to those without BKVN.

Conclusions: This review provides insights into the incidence and risk factors of BK virus infection and BKVN in kidney transplant recipients. However, it also highlights gaps in the literature, particularly regarding the humanistic burden on patients' quality of life, mental health, daily functioning and the economic impact on patients and their families. Future research should prioritize patient-reported outcomes and qualitative studies to better understand the full burden of BK virus infection and BKVN on kidney transplant recipients.

SA-PO1001

An Unusual Suspect: A Case of BK Nephropathy (BKVN)

Gaoyuan Huang,[1] Mabel A. Bodell,[2] Aanand A. Patel,[1] Shreeram Akilesh,[1] Yue-Harn Ng,[1] Karen S. de Wolski.[1] *[1]University of Washington School of Medicine, Seattle, WA; [2]Confluence Health, Wenatchee, WA.*

Introduction: BK viral reactivation is known to occur in non-kidney solid organ transplant (NKSOT) recipients, but patients are not routinely screened for BK viremia/viruria, nor are there studies of the associated long-term kidney prognosis. Importantly, chronic kidney disease (CKD) in Orthotopic Heart-transplant (OHT) patients is often attributed to other causes, such as calcineurin-inhibitor (CNI) toxicity, leading to late or missed diagnosis of BKVN. Here, we report a case of BKVN of native kidneys causing advanced CKD in an OHT recipient.

Case Description: A young male with a history of OHT for viral cardiomyopathy 7 years prior and CKD initially attributed to CNI use (serum creatinine [SCr] 1.3-1.5mg/dl) was referred to nephrology for an increase in SCr to 3.8 over the last year. He had been on immunosuppression (IS) with tacrolimus (goal 8-10ng/ml) and mycophenolate (MMF). Due to concern for CNI toxicity, IS was switched to a CNI minimization regimen with reduction in tacrolimus, continuation of MMF, and addition of sirolimus one year before. However, Scr continued trending up and proteinuria increased to 3g/d, with otherwise bland urine and negative serologic workup, so sirolimus was discontinued. Unfortunately, kidney function continued to decline rapidly, prompting renal biopsy, which showed BKVN (Figure 1) with both chronic and active tubulointerstitial nephritis, 90% globally sclerosed glomeruli, and evidence of mild CNI toxicity. He was concurrently found to have high-titer BK viremia and viruria. MMF was reduced by 50%. He is starting dialysis. OHT has been functioning well without rejection based on routine TTE and endomyocardial biopsies. He will not be a candidate for kidney transplant until resolution of BK viremia.

Discussion: Due to a lack of routine screening, BKVN of native kidneys may be an underreported etiology of CKD in NKSOT patients. Delayed diagnosis of BKVN can result in ESKD and be a barrier for kidney transplant, as is seen here. There may be a role for BK screening in NKSOT patients with kidney dysfunction as a means of early diagnosis of BKVN.

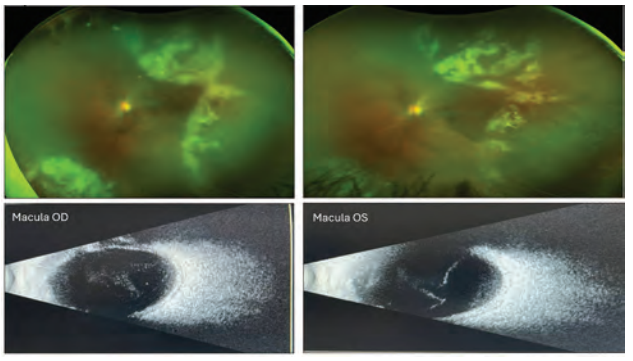
A Complicated Case of Severe Cytomegalovirus (CMV) Retinitis after 2 Decades of Kidney Transplant

Hafsa Habib,[1] Muneeba Sarosh,[2] Shahzad Chaudhry,[2] Beje S. Thomas,[1] Aisha Batool.[1] *[1]Medical College of Wisconsin, Milwaukee, WI; [2]Advocate Aurora Health Inc, Milwaukee, WI.*

Introduction: CMV stands as the primary pathogen following kidney transplantation especially within the initial 6 months post-transplantation, CMV manifests through primo-infection, reactivation of latent infection, or reinfection with a distinct strain. While CMV retinitis is infrequent among kidney transplant recipients compared to its prevalence in HIV-infected individuals.

Case Description: A 44-year-old female with a history of ESRD from type 1 diabetes, who underwent renal transplantation thrice with most recent DDKT in 2002. She was Transitioned from tacrolimus to belatacept 18 years after her DDKT, she has been on belatacept therapy for 40 months. She presented with progressive eye pain and declining vision. Outpatient eye examination revealed retinal infiltrate in the right eye surpassing the left eye, along with subacute posterior vitreous detachment in the right eye. She was admitted with initial CT Head, MRI Brain and CSF were negative for CMV. Serum CMV PCR NAAT revealed 157,000 copies. She started on IV and intravitreal Ganciclovir. She remains admitted inpatient with slight improvement of her visual symptoms. Visual acuity at 20/100 OD and 20/50 OS. OCT reveals no subretinal fluid, while Optos photography shows similar lesion size and distribution overall, with a potential slight increase in the size of an inferior lesion in the right eye. She is planned for IVIGG infusion and transitioning from belatacept to CNI.

Discussion: First-line treatment for CMV retinitis involves systemic and intravitreal ganciclovir, although prolonged therapy may lead to resistance due to mutations in viral genes. Kidney transplant recipients with CMV retinitis have shown multidrug resistance in some cases. The advent of belatacept underscores the importance of identifying potential new side effects of this treatment, particularly considering the cellular-mediated immune response against the virus by CMV-specific T-lymphocytes. The safety of belatacept concerning CMV infection remains inadequately studied.



SA-PO1003

A Patient with Severe Post-transplant Anemia Due to Parvovirus B19 Infection Treated with Hypoxia-Inducible Factor-Prolyl Hydroxylase Inhibitor (HIF-PHI): Desidustat

Arvind Conjeevaram. *Trustwell Hospitals Pvt Ltd, Bangalore, India.*

Introduction: Anemia is a common complication following kidney transplantation, influenced by factors such as immunosuppressive medications, increased susceptibility to infections, hemorrhage, nutritional deficiencies, reduced erythropoietin levels, hyperparathyroidism, and specific post-transplant medications.

Case Description: A 52-year-old male with h/o T2DM, hypertension & ESKD underwent a deceased donor kidney transplant in March, 2023. Postoperatively, the patient developed anemia with an initial Hb level of 9.3 g/dl, with a declining trend. By May 2023, Hb had dropped to 5.8 g/dl, with normocytic normochromic anemia, normal iron/B12 levels & Stool OB -ve. A Bone Marrow Aspiration revealed pure red cell aplasia & giant proerythroblasts with features of "Lantern" cells of Parvovirus B19 infection. Diagnosis was confirmed by detection of B19 DNA through NAAT. Multiple interventions including blood transfusions (x8 units), IVIg at recommended doses, lowering TAC dose, adding everolimus at low dose, reducing steroid/MMF doses, adding erythropoietin inj, were ineffective in sustaining Hb levels (see Fig). In Nov-2023, Desidustat (Oxemia®), an oral hypoxia-inducible factor prolyl hydroxylase inhibitor (HIF-PHI), was started at 100mg 3/wk. Initial improvement in Hb to 8.3 g/dl was observed but was not sustained. The Desidustat dose was subsequently increased to 400mg/wk, resulting in improvement in Hb. By Feb 2024 Hb had increased to 11.1 gm/dl & by Mar 2024, Hb had stabilized at 13 g/dl. The Transplant kidney function remained stable with the serum creatinine of 1.01 mg/dl upon last review in March 2024.

Discussion: This case illustrates the potential efficacy of Desidustat in managing refractory post-transplant anemia, particularly in complex cases involving Parvovirus B19-related anemia and is the first description noted in literature for this particular indication. The observed sustained improvement in Hb with adjusted dosing of Desidustat suggests a promising therapeutic avenue that warrants further research to optimize dosing and ensure long-term efficacy.

SA-PO1004

An Unusual Case of Lymphangioma-Like Kaposi Sarcoma in a Kidney Transplant Patient

Sujay D. Paudel, Syed S. Hasni, Mohammed Javeed Ansari.
Northwestern University Feinberg School of Medicine, Chicago, IL.

Introduction: Lymphangioma-like Kaposi sarcoma (LLKS) is a rare histologic presentation of Kaposi sarcoma (KS). LLKS has been described in acquired immunodeficiency syndrome and in endemic African-type as well as classic indolent KS. Here we present a rare case of transplant-associated iatrogenic immunosuppression–induced LLKS

Case Description: 71 yrs old Caucasian male with PMH of ESRD 2/2 PKD who underwent DDKT, presented with skin lesions at 1 yr post-transplant follow-up. He initially noticed the lesion around the time of transplantation as a bruise-like spot on his right foot and over the past one year gradually developed numerous skin lesions affecting multiple sites. HHV8-pcr was positive. His immunosuppressant at that time comprised of tacrolimus 2mg bid and MMF 1250mg bid. Dermatology referral was done who described the lesion as violaceous discoloration and edema with erythematous patches, ill-defined vascular plaque, purplish-blue papules and nodules, with edema and induration of right foot and lower leg. Skin biopsy revealed grossly dilated and anastomosed vascular channels with prominent hobnail endothelial cells, adjacent stroma showed fibroplasia with a proliferation of atypical spindled-shaped cells, numerous erythrocytes in the adjacent stroma as well as mononuclear cells and plasma cells. Immunohistochemistry was positive for HHV-8 and podoplanin. C-MYC was negative. Tacrolimus was changed to everolimus with improvement and stabilization of the Kaposi's lesions

Discussion: LLKS is a rare histologic presentation of KS which is strongly associated with HHV-8 infection. Incidence of Kaposi sarcoma in renal transplant is 1.5%, however the incidence of LLKS in renal transplant patient is extremely rare. mTOR inhibits the HHV-8 lytic replication cycle and has an antineoplastic and antiangiogenic effects. This case report represents further evidence of the utility of an mTOR inhibitor as a treatment for kidney transplant–associated iatrogenic immunosuppression–induced Kaposi sarcoma

SA-PO1005

The Ticking Time Bomb: A Case of Hemophagocytic Lymphohistiocytosis Triggered by Ehrlichiosis in a Kidney Transplant Recipient

Aung Sitt Naing,[1,2] Sean Bademian,[1,2] Ralph Rogers,[3] Harlan C. Rust,[2,1] Thomas R. McCune.[2,1] *[1]Eastern Virginia Medical School, Norfolk, VA; [2]Nephrology Associates of Tidewater LTD, Norfolk, VA; [3]Sentara Medical Group, Norfolk, VA.*

Introduction: Human Monocytic Ehrlichiosis (HME) is rare in kidney transplant recipients despite immunosuppression and risk of direct transmission from the donor kidney. Disease severity ranges from mild symptoms to life-threatening illness in immunocompromised patients. There are cases of Hemophagocytic Lymphohistiocytosis (HLH) triggered by HME. However, there have been no such reports in adult kidney transplant recipients.

Case Description: A 60-year-old female with a history of living donor kidney transplant 3 years prior presented with a few days of altered mental status and fever. Initial labs showed pancytopenia, elevated liver enzymes, acute kidney injury. Her hospital course was marked by worsening encephalopathy and pancytopenia requiring serial platelet and RBC transfusions. Empirical antibiotic therapy was initiated for meningitis. CSF analysis was unremarkable. Her condition rapidly deteriorated into profound shock requiring intubation and CRRT. She was started on dexamethasone 10 mg Q12 hours for suspected HLH due to ferritin of 44,000, persistent coagulopathy, pancytopenia, hypertriglyceridemia, liver injury and sCD25 of 14856. Despite no known tick bites, further workup was pursued for tickborne disease due to known association of HLH and HME which revealed a positive E. chaffeensis DNA PCR. A 21-day course of doxycycline was initiated and other anti-infectives discontinued. She improved drastically with resolution of pancytopenia, coagulopathy and shock. She was extubated and taken off CRRT.

Discussion: The incidence of HME has risen significantly from 2000-2019 in Southeastern regions of US. While serology tests in an acute phase has poor sensitivity, PCR testing can be diagnostic. HLH is an exceedingly rare but life-threatening condition caused by dysregulated activity of immune system characterized by consumptive coagulopathy and shock. While HME is effectively treated with doxycycline, treating secondary HLH includes moderate-dose dexamethasone and addressing the underlying cause. Etoposide, IVIG and plasma exchange have been used in severe cases. Mortality ranges from 20-88%. Diagnosis of HME and HLH remains very challenging for clinicians. HME-induced HLH can be considered in fever, pancytopenia, coagulopathy and worsening shock when there is no clear cause identified in kidney transplant recipients living in endemic areas.

SA-PO1006

A Double Therapeutic Challenge: Handling Acremonium sp. Hyalohyphomycosis and Atypical Mycobacteriosis in Tandem in a Kidney Transplant Recipient

Felipe Pascoal, Caroline F. Carrera, Jose O. Reusing. *Universidade de Sao Paulo, São Paulo, Brazil.*

Introduction: Acremonium sp. hyalohyphomycosis and Mycobacterium cheloane mycobacteriosis are opportunistic infections, often resistant to medical therapy and requiring prolonged antibiotic treatment. Despite rare, they have become more frequent as imunnosupression efficacy enhances. Herein, we present the first case of succesfully treated concurrent Acremonium sp. hyalohyphomycosis and atypical M. chelonae cutaneous mycobacteriosis in a kidney transplant recipient.

Case Description: A 66-year-old 0% PRA kidney transplant recipient from 2013 with a history of wayward compliance to standard immunossupression and multiple opportunistic infections presented with a one-year history of dorsal right hand erythematous-violaceous, nodular lesions, impaired 2nd to 5th finger flexion and purpuric plaques on abdomen and right thigh (figure 1). Magnetic Resonance Imaging (MRI) of his right hand is also shown (figure 2). Direct examination and culture of his hand and thigh lesions yielded positive for Acremonium sp., while abdominal lesions were biopsied and cultured, revealing Mycobacterium chelonae positivity and chronic inflamation. Oral voriconazole was prescribed to address the fungal infection for twelve months, whereas a combination of Levofloxacin, Linezolid and Azithromycin was initiated for the atypical mycobacteriosis. One year later, marked inflamation control and clinical response was achieved (figure 3), corroborated by follow-up MRI findings (figure 4).

Discussion: To our knowledge, this is the first case of concomitant hyalohyphomycosis and atypical mycobacteriosis in a kidney transplant recipient. While transplantation stands as a top renal replacement choice, suspicion for these rare but highly morbid infections must be raised given their demanding follow-up. When combined, they challenge even experienced nephrologists and infectious disease specialists, but therapy can be effective and optimal response achieved when adequate surveillance and care are provided.

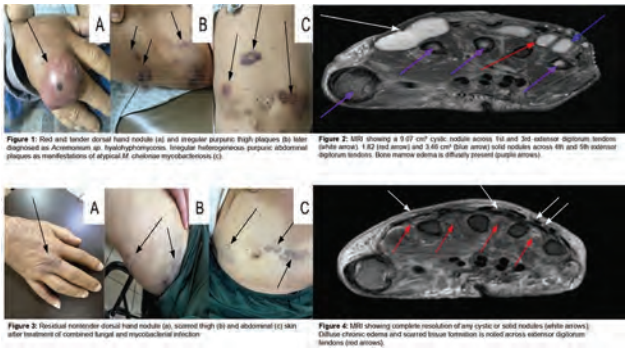


Figure 1: Red and tender dorsal hand nodule (a) and irregular purpuric thigh plaques (b) later diagnosed as *Acremonium sp. hyalohyphomycosis*. Irregular heterogeneous purpuric abdominal plaques as manifestations of atypical *M. chelonae* mycobacteriosis (c).

Figure 2: MRI showing a 0.07 cm² cystic nodule across 1st and 3rd extensor digitorum tendons (white arrow). 1.62 (red arrow) and 3.46 cm² (blue arrow) solid nodules across 4th and 5th extensor digitorum tendons. Bone marrow edema is diffusely present (purple arrows).

Figure 3: Residual noninodular dorsal hand nodule (a), scarred thigh (b) and abdominal (c) skin after treatment of combined fungal and mycobacterial infection

Figure 4: MRI showing complete resolution of any cystic or solid nodules (white arrows). Diffuse chronic edema and scarred tissue formation is noted across extensor digitorum tendons (red arrows).

SA-PO1007

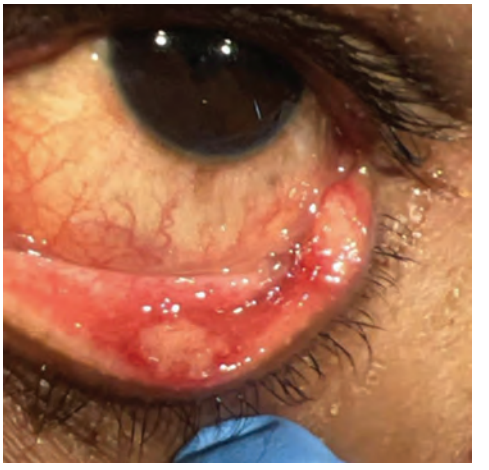
Central Nervous System (CNS) and Ocular Involvement of Systemic Blastomycosis in a Kidney Transplant Recipient

Hanna Larson,[1] Drishti Jain,[2] Ritu Garg.[1] *[1]Loyola University Medical Center, Maywood, IL; [2]Loyola University Chicago Stritch School of Medicine, Maywood, IL.*

Introduction: Blastomycosis dermatitidis is a fungal pathogen primarily affecting lungs. Immunocompromised patients, specifically solid organ transplant recipients, are at increased risk of disseminated blastomycosis. We describe a rare case of disseminated blastomycosis in a kidney transplant recipient with pulmonary, cutaneous, ocular, and CNS manifestations.

Case Description: A man aged 45 status post renal transplant due to post-streptococcal glomerulonephritis presented with fatigue, cough, and fever. Initial workup revealed leukocytosis and pulmonary micronodular lesions, tree-in-bud opacities and ground glass nodules on CT. Post admission the patient developed lower leg painless, flat, red macules that progressed to diffuse painful umbilicated pustules and papules. Skin biopsy showed broad-budding yeast cells, suggesting systemic blastomycosis. IV Amphotericin B was initiated. The patient then developed neck stiffness and encephalopathy. Blastomyces antigen in CSF confirmed leptomeningeal involvement. Palpebral fissure granulomas and culture identified mold, confirming chorioretinitis. During 4-weeks of Amphotericin B, the patient's symptoms improved significantly. Due to high tacrolimus levels, hypovolemia, and Amphotericin B an AKI developed, resolving with tacrolimus reduction and IV fluids. He transitioned to voriconazole for a year of therapy.

Discussion: Disseminated blastomycosis CNS and ocular involvement is rare. It is challenging to diagnose given the range of clinical symptoms, especially in transplant recipients. This case emphasizes early recognition and treatment, specifically for ophthalmologic and neurologic manifestations, to prevent severe complications.



Inferior palpebral conjunctiva with 2 large granulomatous appearing lesions.

SA-PO1008

Nocardia Brain Abscess and Cytomegalovirus Meningoencephalitis in a Kidney Transplant Patient

Irmaris R. Quinones Vargas, Namita Singh, Pablo Garcia, Faye Oakes, Karen S. Santacruz, Laura E. Shevy, Pooja P. Singh. *University of New Mexico Health Sciences Center, Albuquerque, NM.*

Introduction: Nocardia mainly affects immunosuppressed people with 20-50% infections disseminating to the brain. CMV infection can result in meningoencephalitis in the immunocompromised. Both Nocardia and CMV infections can cause significant morbidity for transplant recipients. We present a kidney transplant (KT) recipient with co-existing CMV meningoencephalitis and Nocardia brain abscess.

Case Description: 75 YO woman, 6 months s/p DDKT, presented to the hospital with AMS and fever. Brain MRI demonstrated a 3 cm abscess in the left frontal lobe. LP was performed with detection of CMV by PCR and isolation of *Nocardia veterana* in the CSF. Brain abscess biopsy demonstrated purulent and necrotic debris within brain tissue. GMS stain revealed finely filamentous organisms, and *Nocardia veterana* was isolated in AFB culture. Source of infection was felt to be soil inhalation given pulmonary nodules on chest CT. Her immunosuppression regimen was adjusted. She was treated with IV trimethoprim-sulfamethoxazole and meropenem for the *Nocardia* brain abscess, and with IV ganciclovir for the CMV meningoencephalitis. She had full neurological recovery at 7 weeks and is now 26 weeks out from initial diagnosis with excellent allograft function.

Discussion: A dual diagnosis of CMV meningoencephalitis and *Nocardia* brain abscess post KT is rare; with no other cases reported in the literature. The outcomes of nocardiosis and delayed post-prophylactic CMV disease depend on the site of infection and host immune status. Nocardial CNS infections confer a high mortality rate – up to 85% in immunosuppressed patients. However, early diagnosis and prompt treatment can achieve cure rates up to 50-85%. CMV disease in kidney transplant recipients can increase the risk of mortality by more than 50%. This case demonstrates the importance of early diagnosis and treatment of these virulent infections in transplant recipients so that successful outcomes can be achieved.

SA-PO1009

Fatal Pulmonary Mucormycosis in a Kidney Transplant Patient: Missed "Opportunism"

Tatiana Correa, Barbara A. Greco, Kenneth Brand, Umair Khan, Gregory L. Braden. *Baystate Medical Center, Spring ield, MA*.

Introduction: Pulmonary mucormycosis (PM) has a high mortality rate if not diagnosed promptly. We present a fatal case in a patient presenting seven months post-transplantation whose diagnosis was delayed, and emphasize the need for early diagnosis of opportunistic infections.

Case Description: A 55-year-old man with ESRD and prior failed deceased donor kidney transplant (DDKT) underwent a second DDKT complicated by delayed graft function and antibody-mediated rejection treated with apheresis and IVIG. Seven months post-transplant, he presented with cough, fever, diarrhea, and weight loss. He was on tacrolimus, mycophenolic acid, and prednisone. Imaging revealed diverticulitis and a cavitating thick-walled right lower lung lesion. He was treated with ampicillin/sulbactam but had continued fevers and respiratory distress. Serologic infectious workup was unrevealing; galactomannan test was negative. Bronchoalveolar lavage on hospital day 4 identified Streptococcus species; piperacillin/tazobactam was given for seven days. The patient worsened and required noninvasive ventilation. Repeat imaging demonstrated a pleural effusion with invasion of the RLL mass into the right middle lobe, diaphragm, and liver. Thoracentesis was performed on hospital day 12 and a lung biopsy on day 19. Pleural fluid and tissue histology was consistent with mucor. Amphotericin was started and he was transferred for surgical debridement, but died within 24 hours.

Discussion: Kidney transplant patients are immunosuppressed and at risk for opportunistic infections. Mucormycosis accounts for 2-6% of fungal infections and emerges usually after 6 months post-transplantation as rhinocerebral, PM, skin, or disseminated disease. Concomitant bacterial pneumonia occurs in 30% of PM cases. A negative galactomannan test is expected as mucor lacks this cell wall antigen. Reverse halo sign on imaging is suggestive but histology is necessary for diagnosis. The presence of characteristic non-septate, right-angled branching hyphae confirms diagnosis. Treatment requires intravenous liposomal Amphotericin B and surgical debridement. PM is rapidly progressive, invasive, and carries a 60-70% mortality rate. This case highlights the pitfalls of empiric approaches to infections in immunocompromised hosts and the need for early suspicion for opportunistic infection and tissue diagnosis to optimize outcomes.

SA-PO1010

Hypercalcemia Due to Disseminated Histoplasmosis in a Kidney Transplant Recipient with Negative Histoplasma Antigen Testing

Michael I. Tabet, Lemuel R. Non, M. Lee Sanders. *University of Iowa Hospitals and Clinics, Iowa City, IA.*

Introduction: Histoplasmosis is a fungal infection that can lead to disseminated disease in immunosuppressed patients. Hypercalcemia can occasionally result, as it is a granulomatous disease. We present an interesting case of disseminated histoplasmosis complicated by hypercalcemia but negative histoplasma antigen testing.

Case Description: A 68-year-old male with kidney transplanted in 2002 on sirolimus, mycophenolate mofetil, and prednisone presented to clinic complaining of fevers, night sweats, 35-lb weight loss, fatigue, and intermittent diarrhea. He was found to have enteropathogenic E coli on stool enteric panel and esophagitis on upper endoscopy. With ongoing treatment, his serum calcium rose from normal to 11.0 mg/dL. Initial work-up showed PTH was mildly low, 25-hydroxyvitamin D was normal, but 1,25-dihydroxyvitamin D was elevated. CT imaging showed innumerable miliary lung nodules with multiple cavitary nodules and calcified splenic lesions, consistent with granulomatous infection. An extensive infectious work-up was performed, including bronchoalveolar lavage, and was unremarkable. His hypercalcemia and symptoms improved, and he was discharged home, only to return months later with similar symptoms and a calcium of 13.1 mg/dL. Infectious testing was again unrevealing; therefore, he underwent video-assisted thoracoscopic surgery with pleural fluid sampling and lung wedge resection biopsy. Pleural fluid studies and cultures were unremarkable, but lung biopsy both showed necrotizing granulomas with silver-stained yeast forms and grew Histoplasma capsulatum on culture. He was started on itraconazole. A follow-up CT scan eight months later showed contraction of cavitary lesions to smaller nodules and resolution of his symptoms and hypercalcemia.

Discussion: Histoplasmosis is a concern for immunosuppressed patients in certain geographic areas. While hypercalcemia can occur with disseminated granulomatous disease, it is relatively uncommon. The usual testing performed when histoplasmosis is suspected is checking blood and/or urine for the histoplasma antigen, which is usually positive in disseminated disease. Interestingly, in this case, both blood and urine antigen were negative at two different time points prior to diagnosis, despite dissemination. Persistent testing including tissue biopsy may be needed in such cases to make a diagnosis.

SA-PO1011

Disseminated Histoplasmosis Manifesting as Oral Lesions in a Kidney Transplant Patient

Sebastian Hinojosa,[1] Alexis Nguyen,[2] Piera A. Sosa,[1] Trey H. Richardson,[1] Levan Gakhokidze,[1] Alissa A. Ice,[1] Anthony J. Langone, [1] Heidi M. Schaefer.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Wayne State University School of Medicine, Detroit, MI.*

Introduction: Histoplasmosis, caused by the dimorphic fungus *Histoplasma capsulatum,* is often asymptomatic in immunocompetent individuals. In immunocom-promised hosts, Histoplasmosis can become disseminated and severe. Oral manifestations of histoplasmosis are rare and can pose a diagnostic challenge.

Case Description: A 72-year-old female who had undergone renal transplant 3 years prior presents to the ED with a 1-month history of painful oral lesions and weight loss of 20lbs. Her immunosuppression included tacrolimus, mycophenolate mofetil, and prednisone. Physical examination revealed a painful, irregularly shaped left lateral tongue ulceration with superficial sloughing and similar ulceration over the right buccal mucosa. There was palpable lymphadenopathy of the left anterior cervical chain. Workup was notable for pancytopenia, elevated β-d-glucan, and positive urine histoplasma antigen. CT of the chest revealed ground glass nodular opacities bilaterally and abnormal bone marrow signal. Biopsies were performed revealing budding yeast forms consistent with*Histoplasma capsulatum*.

Discussion: This case illustrates several important points about histoplasmosis in the post-transplant population. Firstly, disseminated histoplasmosis can present with nonspecific symptoms such as mucosal ulcers and weight loss, which can mimic other post-transplant complications like drug reactions, malignancy, or other infections. Secondly, the diagnosis of histoplasmosis should be considered in immunosuppressed patients presenting with unusual lesions or systemic symptoms in endemic areas. In our patient, management included reducing immunosuppression and treatment with amphotericin B followed by oral posaconazole. The patient improved after several weeks of treatment.

SA-PO1012

Feline Footprints in Transplant Realms

Kamil Sardarli,[1] Adolfo Del Bosque-Aguirre,[2] Scott Mullaney.[1] *[1]University of California San Diego, La Jolla, CA; [2]Tecnologico de Monterrey Escuela de Medicina y Ciencias de la Salud, Monterrey, Mexico.*

Introduction: Bartonella henselae is a zoonotic pathogen with clinical presentations influenced by the immune status of the human host. While cat scratch disease is common in immunocompetent hosts, solid organ transplant recipients typically present with a different spectrum of symptoms. Bartonella species are increasingly acknowledged as significant pathogens, but diagnosing Bartonella infection in this population can be challenging due to overlapping clinical manifestations with other conditions, such as malignancy, and the potential risks associated with invasive procedures like biopsies.

Case Description: 35 years old female patient presented with fever and myalgia. She had past medical history of lupus nephritis and atypical HUS complicated by end stage kidney disease and received a deceased donor kidney transplant 6 months prior to presentation, She received thymoglobulin induction and had been taking tacrolimus, mycophenolate, and prednisone for immunosuppression. On initial presentation, she was febrile (103 F), but hemodynamically stable. Initial laboratory work yielded WBC 11.6 cells/mm^6, Hgb 7 g/dl, platelet 74/mm^6, creatinine 1.7 g/dl from baseline 1.2 g/dl, ALP 139 U/L, ALT 39 U/L and AST 47 U/L. Initial imaging revealed an unremarkable transplant kidney but hepatosplenomegaly with multiple hypoechoic lesions throughout the liver and spleen. MRI identifed enhancing lesions in the liver, spleen, and bones with retroperitoneal lymphadenopathy, read as "primarily concerning metastatic disease with atypical infection felt to be less likely." The patient was started on vancomycin, cefepime, metronidazole, micafungin. A broad infectious work up was ordered and interventional radiology consulted for liver biopsy. The biopsy had to be postponed by two days due to scheduling constraints. B. henselae serology returned with a positive IgM titer of 1:32 and IgG > 1:1024. She was started on azithromycin and rifampin. Further history revealed she owned three cats.

Discussion: Bartonella infection should be considered in the differential diagnosis of transplant recipients presenting with fever, lymphadenopathy and hepatosplenic lesions, especially when imaging suggests multifocal involvement. Serology offers a safer alternative to biopsy in confirming the diagnosis. Early recognition and appropriate antimicrobial therapy are crucial in managing Bartonella infection in immunocompromised hosts to prevent complications.

Late Pneumocystis jiroveci Pneumonias in Kidney Transplant Recipients in Central Norway

Marius A. Øvrehus,[1,2] Jakob Lund,[1] Robin K. Kehreman.[1] *[1]Norges Teknisk-Naturvitenskapelige Universitet, Trondheim, Norway; [2]St Olav's Hospital HF, Trondheim, Norway.*

Background: *Pneumocystis jirovecii* pneumonia (PCP) can be life threatening in kidney transplant recipients (KTR). We know little about the course of late onset PCP - occurring later than one year after transplantation - in KTR.

Methods: Retrospective study using electronic patient charts in KTR diagnosed with PCP between 2006 and 2021 in Central Norway, which has a population of 697,000. We collected clinical data (table).

Results: We found 38 kidney transplant recipients with PCP. Median age 60 years, most on standard immunosuppression. Median length of hospitalization was 2 weeks, 32% received organ support treatment. Total mortality 18,4% within 180 days. The incidence was 0,4 cases/100,000 inhabitants.

Conclusions: We found that PCP had a serious course with organ failure, need of organ support, and 180 day mortality of 18%. In spite of the recommendation of life-long prophylaxis after PCP, 30% were not started on TMS at discharge.

Funding: Government Support - Non-U.S.

Risk of Post-transplantation Hepatocellular Carcinoma, Cirrhosis, and Liver Failure in Kidney Recipients with Hepatitis C Infection

Tung-Min Yu, Yu-Nong Kao, Chih Wei Chiu, Shih T. Huang. *Taichung Veterans General Hospital, Taichung, Taiwan.*

Background: Hepatitis C virus (HCV) infection is prevelant in patients with end stage renal disease (ESRD). Compared to ESRD with dialysis, kidney transplantation offers a survival advantage for ESRD patients. To the present, ESRD with HCV infection remains an acceptable candidate for kidney transplantation. However, HCV is the leading cause resulting in hepatic complications after transplantation. Data to elucidate the liver issue in renal transplant patients with HCV infection are scarce. In the present study, we aimed to investigate the hepatic outcomes of renal transplantation with HCV infection.

Methods: Data Source TriNetX is a multicenter federated health research network. Our study population is drawn from 89 Healthcare Organization (HCOs). Patients received kidney transplantation [ICD-10: Z94.0] and those with HCV were case group in this study, while those without HCV were control group. Propensity score matching (PSM) with ratio 1:1 was applied including sex, age at index, and comorbidities.

Results: A total of 6,605 renal recipients with HCV infection and 188.466 renal recipients without HCV infection were enrolled. After PSM, 6,473 were in each group, respectively. In the study population, over 60% of the patients were male and aged between 40-65. After matching, our findings showed that subjects with HCV infecton had significantly higher risk of hepatoma, cirrhosis, hepatic failure, and overall hepatic disease than those without HCV infection. (hepatoma: HR: 8.957; CI: 5.324-15.069; cirrhosis: HR: 5.378; CI: 4.363-6.631; hepatic failure: HR: 3.258; CI: 2.527-4.200; overall hepatic disease: HR: 4.128; CI: 3.428-4.971)

Conclusions: In the present study, our findings show that renal recipients with HCV infection is significantly associated with a remarkably high risk of hepatic complications including hepatoma, cirrosis and liver failure post-kidney transplanttaion and that has been ignored previously. Professionals should pay more attention while taking care of renal recipients with HCV infection. The eradication of HCV therapy by Direct-acting antivirals (DAAs) should be considered.

SA-PO1016

IgG4 Hypogammaglobulinemia Associated with Urinary Tract Infection in Kidney Transplant Recipients at the Centro Médico Nacional de Occidente, Guadalajara, Jalisco, Mexico

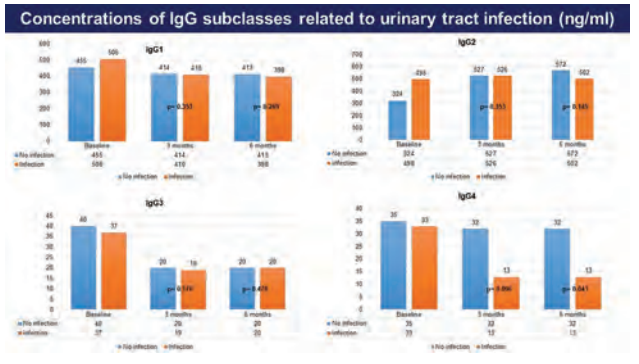
Javier Israel Ruiz, Luis Alberto Evangelista-Carrillo, Adriana Banda Lopez, Caridad A. Leal, Cynthia M. Lujano Navarro. Resident. *Hospital de Especialidades del Centro Medico Nacional de Occidente IMSS, Guadalajara, Mexico.*

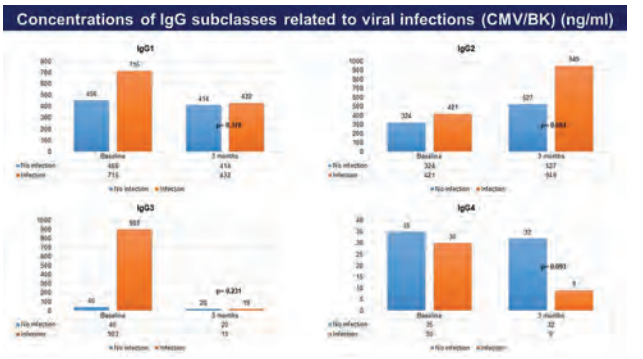
Background: In the era of precision medicine, the evaluation of IgG subclasses represents an attractive tool that could open a new scenario in the personalized pharmacological treatment of the patient. The measurement of immunoglobulins, specifically IgG, has taken importance in recent years as an instrument that allows reducing the risk of complications such as infectious processes in patients with a kidney transplant.

Methods: Single-center, retrospective cohort study. 1-year follow-up. IgG subclasses were quantified using Luminex equipment.

Results: The study included 143 patients diagnosed with chronic kidney disease who underwent kidney transplantation and 20 donors for reference values. Urinary tract infection events at 3 (20.4 ng/ml, p = 0.09) and 6 months (28.4 ng/ml, p = 0.04) were related to low IgG4 concentrations. IgG subclasses concentrations were not related to the presence of viral infections in patients.

Conclusions: IgG4 subclass levels appear to be associated with urinary tract infection events, but not with viral processes. This is the first study, that analyzes the immunoglobulin G subclass profiles of transplant patients and relates them to clinical events (urinary tract infection and viral infections) using magnetic microspheres in Luminex equipment as a measurement technique in the Mexican population. Serum levels of IgG subclasses can be a surrogate in the management of immunosuppression in patients with kidney transplants, since it is not a one-dimensional measurement but rather the final result of a complex interaction of pathways that culminate in their formation.





SA-PO1017

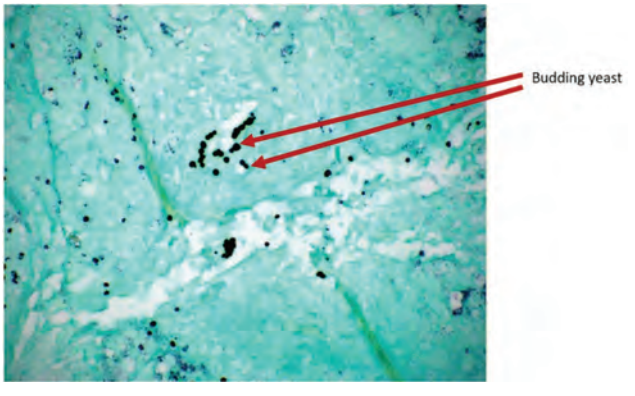
Successful Resolution of Fungal Pyelonephritis in a Kidney Transplant Recipient

Gina G. Suarez,[1,2] Gretchen N. Marrero Lozada,[2] Shawn Alonso,[2] Marco A. Ladino Avellaneda.[2] *[1]Jackson Memorial Hospital, Miami, FL; [2]University of Miami Miller School of Medicine, Miami, FL.*

Introduction: Fungal pyelonephritis in the context of a kidney transplant refers to a renal infection caused by fungi, which can complicate the post-transplant course and potentially lead to delayed graft function. This condition is relatively rare but can be severe, leading to serious consequences such as graft loss and even death if not promptly identified and treated. Various fungi can cause pyelonephritis in kidney transplant recipients. Candida glabrata has been reported to cause emphysematous pyelonephritis, a serious necrotizing infection. Surgical interventions such as graft nephrectomy may be required in severe cases. However, the specific treatment approach, including the choice of antifungal agent and the duration of therapy, should be individualized based on the patient's clinical condition, the causative organism, and the presence of any complications.

Case Description: A 52-year-old male with a history of IgA Nephropathy and a deceased donor kidney transplant presented two months post-transplant with fevers alongside stage II acute kidney injury. Despite isotonic intravenous fluids, his renal function did not improve, necessitating a kidney biopsy to elucidate the underlying cause of his deteriorating condition. He was diagnosed with fungal pyelonephritis from Candida glabrata, and was ultimately treated with fluconazole. The patient did not lose the allograft and has maintained stable renal function with lifelong antifungal therapy.

Discussion: This case represents the first documented instance within the scientific literature of a successful therapeutic resolution of fungal pyelonephritis attributable to Candida glabrata in a kidney transplant recipient. The treatment efficacy delineated in this scenario is particularly noteworthy given the complexity often associated with opportunistic fungal infections in immunocompromised hosts.



The Grocott's Methenamine Silver (GMS) stain revealed the presence of an abundant number of yeast cells.

SA-PO1018

Biopsy-Proven Fungal Pyelonephritis in a Kidney Transplant Recipient

Vikramjeet Kakade, Sri Vibhavari Guntupalli, Sudha Tata, Alton B. Farris, Stephen O. Pastan, Mohammad Kazem Fallahzadeh Abarghouei. Emory University Div of Renal Medicine. *Emory University School of Medicine, Atlanta, GA.*

Introduction: Acute pyelonephritis due to bacterial infections is a common cause of acute kidney injury in kidney transplant recipients but fungal pyelonephritis is rare with only a few cases reported.

Case Description: A sixty-year-old man with a history of end-stage kidney disease attributed to hypertension who had an unrelated living donor kidney transplant in Iraq, with no known complications presented five months after transplantation with fever, and confusion. He was found to have an acute kidney injury. His urine culture was positive for methicillin-susceptible Staphylococcus aureus and his blood culture was positive for Salmonella. He was treated with empiric ceftriaxone therapy. He had two sessions of hemodialysis due to concern for uremic encephalopathy with improvement in his mental status. Due to a lack of improvement in his kidney function, he had a transplant kidney biopsy that showed fungal forms (Figure 1). He had extensive workup including fungal culture and molecular studies of biopsy tissue, but no organism was identified. His immunosuppression regimen was reduced. He received empiric amphotericin followed by oral isavuconazonium resulting in significant improvement in kidney allograft function and no further need for hemodialysis.

Discussion: Fungal pyelonephritis is a rare but serious cause of acute kidney injury in kidney transplant recipients. Observing fungal forms on kidney biopsy is instrumental in the diagnosis. If there is a suspicion of fungal pyelonephritis, for example in patients with systemic fungal infection with acute kidney injury, a kidney biopsy tissue sample should be sent for fungal culture. Our case shows that cases of fungal pyelonephritis in which no specific organism is identified could be successfully treated with empiric amphotericin followed by long-term oral isavuconazonium with close clinical monitoring.

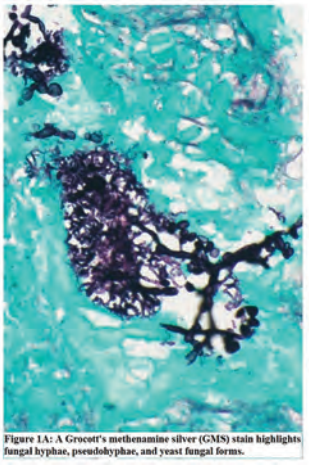


Figure 1A: A Grocott's methenamine silver (GMS) stain highlights fungal hyphae, pseudohyphae, and yeast fungal forms.

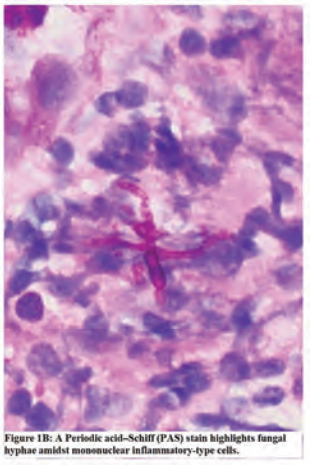

Figure 1B: A Periodic acid–Schiff (PAS) stain highlights fungal hyphae amidst mononuclear inflammatory-type cells.

SA-PO1019

AKI Due to Asymptomatic Pyelonephritis in a Kidney Transplant Recipient

Jae H. Son, Payaswini Vasanth, Mohammad Kazem Fallahzadeh Abarghouei. *Emory University, Atlanta, GA.*

Introduction: Kidney transplant recipients with a positive urine culture but no symptoms of urinary tract infection (UTI) are typically diagnosed with asymptomatic bacteriuria and usually do not receive antibiotic treatment. However, in this report, we describe a case of acute kidney injury (AKI) due to asymptomatic pyelonephritis, which responded to antibiotic therapy.

Case Description: A 62-year-old woman with a history of end-stage kidney disease due to hypertension underwent a deceased donor kidney transplant. Her post-transplant course was complicated by delayed graft function and early borderline acute cellular rejection, which was treated with high-dose oral prednisone. One month post-transplant, she had removal of ureteropelvic stent. Two months post-transplant, she developed a symptomatic urinary tract infection (UTI) caused by multidrug-resistant Klebsiella pneumoniae, accompanied by acute kidney injury (AKI), and was treated with intravenous antibiotics. Three months post-transplant, she presented again with AKI. Although her urine culture was positive for the same organism, she did not exhibit any UTI symptoms and was initially not given antibiotics. A kidney biopsy performed for evaluation of AKI revealed severe tubulointerstitial inflammation with neutrophil casts, indicative of acute pyelonephritis. Consequently, she was treated with intravenous antibiotics, resulting in an improvement in her serum creatinine levels.

Discussion: Monitoring for and treating asymptomatic bacteriuria is typically not recommended beyond two months post-kidney transplant due to a lack of evidence for improved outcomes and concerns about antibiotic resistance. However, our case demonstrates that biopsy-proven acute pyelonephritis, severe enough to cause AKI, can be asymptomatic in kidney transplant recipients. Therefore, acute pyelonephritis should be considered as a potential cause of AKI in patients with asymptomatic bacteriuria when no other clear etiology for AKI is present.

SA-PO1020

Urinary Tract Infections Caused by Carbapenemase-Producing Enterobacteriaceae in Kidney Transplant Patients

Ariane B. Monteiro,[1] Ana Clara E. Perotti,[1] Gisele Meinerz,[1] Elizete Keitel.[1,2] *[1]Universidade Federal de Ciencias da Saude de Porto Alegre, Porto Alegre, Brazil; [2]Santa Casa de Misericordia de Porto Alegre, Porto Alegre, Brazil.*

Background: Patients undergoing kidney transplantation, due to changes in urogenital anatomy and the use of immunosuppressive medications, are more susceptible to infections, with urinary tract infections (UTI) being the most common. The emergence of carbapenemase-producing enterobactéria (CPE) as causes of infectious events in this population is a concern. This study aims to describe kidney transplant patients who presented CPE urinary tract infection and the outcome of these patients in the first year after the procedure. **Objective:** to describe kidney transplant patients who presented CPE urinary tract infection and the outcome of these patients in the first year after the procedure.

Methods: Retrospective observational study of adult and pediatric patients undergoing kidney transplantation between January 2014 and December 2022, in a hospital in southern Brazil, who presented with asymptomatic bacteriuria, simple cystitis and complicated CPE UTI in the first year after the procedure. The project was approved by the Ethics and Research Committee of Santa Casa de Misericórdia de Porto Alegre, CAAE 54930022.9.0000.5335.

Results: During the period, 2119 patients underwent kidney transplantation, 59 (2,8%) presented with asymptomatic bacteriuria and 128 (6,0%) at least one UTI episode due to CPE (figure 1) with a median of 26 days after surgery. Recurrent infection occurred in 62 (48,4%) of UTI patients. The most prevalent microorganism was *Klebsiella pneumoniae* and the resistance mechanism was Klebsiella pneumoniae carpapenemase (KPC). Patient outcomes are detailed in figure 1.

Conclusions: Almost 6% of patients had at least one episode of UTI by CPE. The median time until the first UTI was 26 days. One year graft loss and mortality rate in patients with UTI were 23,4% and 13,3%, respectively. The findings of this cohort highlights the incidence and the negative repercussion of this infection on renal transplant recipients.

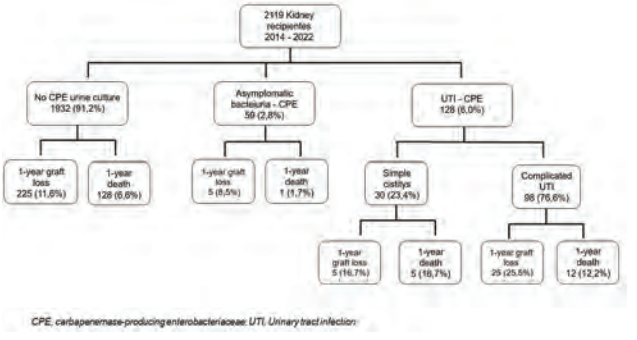

Figure 1. Kidney transplant patients flow during the study.

SA-PO1021

Case Report of Nontyphoidal Salmonella Aortitis in a Kidney Transplant Recipient

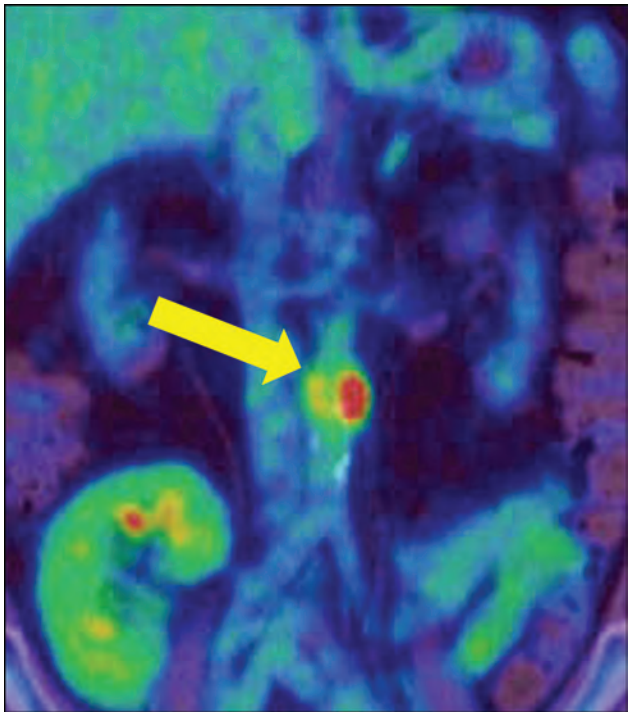
Suguru Muraoka, Yasuhiro Mochida, Kunihiro Ishioka, Machiko Oka, Hidekazu Moriya, Takayasu Ohtake, Sumi Hidaka. Kidney Disease Transplant Center. *Shonan Kamakura Sogo Byoin, Kamakura, Japan.*

Introduction: Immunosuppressive therapy predisposes kidney transplant recipients to various infections. While Salmonella infection after transplantation typically manifests as enteritis or urinary tract infection, there are limited reports of aortitis. We present a case of Salmonella enterica-induced abdominal aortitis.

Case Description: A 49-year-old man with diabetic nephropathy underwent ABO-incompatible living donor kidney transplantation. Five years later, he presented to the emergency department with fever and chills persisting since the previous day. His serum creatinine ranged from 2 to 3 mg/dL. Blood cultures isolated Salmonella enterica, and computed tomography (CT) on day 6 of hospitalization confirmed abdominal aortitis. Conservative management with antibiotics and blood pressure control was initiated, and the aortic diameter was monitored via CT. The maximum aortic diameter reached 27 x 25

mm but subsequently decreased. C-reactive protein (CRP) levels normalized on day 31, and the patient was discharged on day 34.

Discussion: This case highlights infectious aortitis secondary to Salmonella bacteremia post-transplantation. Transplant recipients, particularly those with diabetes, are at heightened risk of Salmonella bacteremia and infectious aortitis due to immunosuppression and atherosclerotic lesions. Given the predominant fecal-oral transmission of Salmonella, dietary counseling for kidney transplant recipients is crucial to mitigate this risk.



PET-CT shows FDG accumulations on a slightly diliated stie of abdominal aorta.

SA-PO1022

Shanghai Fever in Los Angeles: A Solid-Organ Transplant Recipient

Andrea L. Urrutia,[1] Claudia G. Olano,[2] Sami M. Akram.[3] *[1]Universidad de San Carlos de Guatemala Facultad de Ciencias Quimicas y Farmacia, Ciudad de Guatemala, Guatemala; [2]Harbor-UCLA Medical Center, Torrance, CA; [3]Loma Linda University, Loma Linda, CA.*

Introduction: Shanghai fever is a rare presentation of pseudomonas aeruginosa sepsis. The core symptoms are fever, diarrhea and ecthyma gangrenosum (EG) (1). The enteric disease caused by pseudomonas aeruginosa has been reported in pediatric patients (2,3,4); cases in adults are extremely rare (5). To the best of our knowledge this is the first case report of shanghai fever in an adult solid organ transplant (SOT) recipient. EG frequently occurs in immunocompromised and neutropenic patients (6,7). Sixty percent of EG lesions are in the gluteal perineal region (6,8) and can be overlooked if skin is not thoroughly examined

Case Description: This is a 49-y-old female who had simultaneous pancreas kidney transplant 15 months ago. She presents with oral ulcers, severe diarrhea, which progressed to sepsis followed by gastrointestinal bleeding. She required intensive care support and transfusions. She had perirectal pustular and nodular lesions with central necrosis. Histology was consistent with ecthyma gangrenosum. Tissue cultures grew pseudomonas aeruginosa. A clinical diagnosis of pseudomonas sepsis with ecthyma gangrenosum was made, I.e. shanghai fever

Discussion: This is the first case report of shanghai fever in a kidney transplant patient in a suburb of Los Angeles, California. Shanghai fever is a well described enteric disease due to pseudomonas sepsis in pediatric patients. A PubMed search using the terms, [shanghai fever + adults +case report] revealed only one publication (5). While uncommon, shanghai fever or pseudomonas enteric disease (PED) can occur outside of Asia (8). PED can be fatal and in one case series the mortality was 15% (1). The clinical features of PED cases are fever, diarrhea (enteric illness) and ecthyma gangrenosum (1). Our patient had all components of PED. The differential diagnosis of fever in a immunosuppressed patient is challenging because of increased frequency of unusual microbes and other non-infectious mimics. However, our case illustrates that common organisms may have uncommon presentations in immunosuppressed patients. Shanghai fever can occur in Los Angeles. A thorough physical exam and microbiological evaluation is needed for accurate diagnosis. We report the first case of Shanghai fever in an adult kidney-pancreas recipient. We want to inform the clinicians about pseudomonas enteric disease therefore, describe its diagnosis and management

SA-PO1023

Post-transplant Lymphoproliferative Disorders (PTLD) in Kidney Transplant

Mariarosaria Campise,[1] Silvia Malvica,[1] Carlo Alfieri,[1,2] Simona Verdesca,[1] Anna Regalia,[1] Giuseppe Castellano.[1,2] *[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Universita degli Studi di Milano, Milano, Italy.*

Background: PTLD are serious complications in solid organ (SO) and allogeneic hematopoietic stem cell transplants (T), ranging from benign proliferations to malignant lymphomas. PTLD accounts for 21% of cancers in SOT. Risk factors include Epstein-Barr virus (EBV) serostatus, recipient age, organ type, immunosuppression (IS), and genetic predispositions. Most PTLD originate from EBV-infected B cells proliferation due to IS but some 30-40% are not EBV-related. IS reduction (ISR) for immune function restoring, and chemotherapy (CT) is the treatment. We report our single center experience about incidence, risk factors, and treatment outcomes of PTLD in kidney transplant (KT) patients (pts).

Methods: Between January 1, 1969, and August 31, 2023, 3024 adult pts underwent KT. Pts with a confirmed PTLD diagnosis (biopsy/clinical suspicion) were included in the study and PTLD cases classified according to the WHO criteria. KT pts without PTLD transplanted in the same period served as control. All the relevant clinical data before and after PTLD diagnosis were collected. End of follow-up was the last outpatient visit, death, or dialysis. After ISR, chemotherapy was coordinated with hematologists.

Results: Monomorphic PTLD was diagnosed in 26 pts (0.8%):18 B-cell non-Hodgkin Lymphoma (nHL) (68%), 3 T-cell nHL, and 4 multiple myelomas. No early/polymorphic PTLD were detected. PTLD was diagnosed with a median (m) of 121 months (mos) after Tx (IQR 88-165). M-observation time was 187 mos (IQR 93-326). PTLD was EBV-related in 52% of cases. At diagnosis m-plasma creatinine was1.6 mg/dl (IQR 1.2-1.9) and m-proteinuria 0.3 g/24 hours (IQR 0.1-0.5). ISR was done in all but the 3 pts with a smoldering myeloma. In 24% of cases calcineurin inhibitor (CNI) was withdrawn, halved in 16%, discontinued in 8%. mTOR replaced CNI in 24% of pts. Steroid therapy was given at doses prescribed for CT. Pts survival was 44%. Twenty pts (75%) died for PTLD or its complications. Pts m-survival time was 12 mos (IQR 3-145), 77% of pts died with a m-creatinine of 1.9 mg/dl.

Conclusions: In our series PTLD frequency of 0.8% and a mortality of 50% at one year are lower than literature rates. One and 5-year survival rate are 52% and 32% for monomorphic PTLD. Molecular-targeted drugs and immunomodulators may enable international multicenter studies to improve PTLD unfavorable prognosis.

SA-PO1024

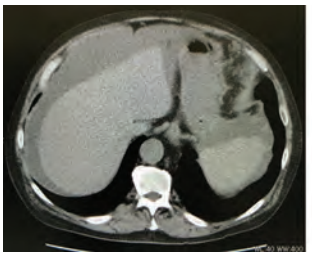
Late-Onset Post-transplant Lymphoproliferative Disorders Presenting with Sudden Massive Abdominal Ascites Effusion: A Case Report

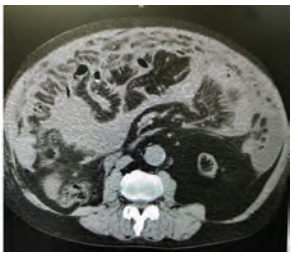
Kana Shirai, Marie Murata, Masatomo Ogata, Takamasa Miyauchi, Kazunobu Shinoda, Yugo Shibagaki, Masahiko Yazawa. *St. Marianna University School of Medicine, Kawasaki, Japan.*

Introduction: Late-onset post-transplant lymphoproliferative disorders (PTLD) are increasingly recognized in recent literature. Late-onset PTLD exhibits distinct characteristics regarding the primary lymphoma lesion, Epstein-Barr virus (EBV) association, and risk factors. Here, we present a case of non-EBV-associated late-onset PTLD marked by sudden massive abdominal ascites, later diagnosed as peritoneal lymphomatosis.

Case Description: A 65-year-old man underwent ABO-compatible living-donor kidney transplantation (KT) 8 years ago for end-stage kidney disease due to nephrosclerosis. Both donor and recipient were EBV-seropositive pre-KT. Post-transplantation, the patient maintained a stable course under a standard immunosuppression with steroids, tacrolimus, and mycophenolate mofetil. Eight years post-KT, however, he presented with anorexia and sudden massive abdominal ascites (Figure). Ascitic fluid cytology revealed diffuse large B-cell lymphoma (DLBCL). Because of negative serum EBV-DNA, non-EBV-associated PTLD was diagnosed. Imaging studies showed diffuse omental and peritoneal thickening without solid organ tumors or lymphadenopathy (Figure), indicating that the primary lesion of PTLD was peritoneal lymphomatosis. Reduced immunosuppression and R-CHOP chemotherapy induced DLBCL remission, resolving ascites without graft function deterioration.

Discussion: Late-onset PTLD often presents with extranodal lesions and involves extra-transplanted organs. Peritoneal lymphomatosis is rare not only as a primary lesion of PTLD but also as a primary lesion of lymphoma in non-transplant patients. Notably, literature of peritoneal lymphomatosis lacks KT case reports, with focus mainly on liver transplantations. Although PTLD with peritoneal lymphomatosis is a rare condition, clinicians should consider it as a differential diagnosis when encountering sudden massive abdominal ascites following kidney transplantation.





SA-PO1025

Recurrent Cutaneous Plasmacytoma: Atypical Presentation of Post-transplant Lymphoproliferative Disorder

Kavindya Wickramasinghe, Sarthak Virmani. *University of Virginia School of Medicine, Charlottesville, VA.*

Introduction: Post Transplant Lymphoproliferative Disorder (PTLD) usually affects the allograft, GI tract or CNS. Plasmacytic PTLD is an unusual variant notable for lack of CD20 expression with limited reports in the literature. We present a complex case of cutaneous plasmacytic PTLD.

Case Description: A 70-year-old lady s/p DDKT for IgAN in 2008 and a 2nd transplant for failing allograft in 2018 presented with multiple skin lesions on her right lower extremity (RLE). There was clinical concern for SCC but a biopsy surprisingly showed plasmacytic PTLD instead. Immunosuppression(IS) reduction & radiotherapy (RT) led to successful treatment. She unfortunately developed new lesions within 3 months of completing RT. An 8-week course of s/c daratumumab infusion was given after which her lesions appeared stable on PET-CT with low-level FDG uptake. Within 6 months, she developed multiple new skin lesions that remained consistent with plasmacytic PTLD. She was then treated with bortezomib but did not tolerate it due to significant GI side effects & weight loss. PET-CT showed more new nodular densities with increased uptake suspicious for recurrent PTLD. She was then transitioned to dara-CyBorD with resolution of all lesions except one small nodule on the RLE after 4 cycles that was surgically excised. A second new lesion appeared approximately one year after discontinuing dara-CyBorD but began to recede on its own. The patient completed 4 doses of rituximab and has had no new lesions as of her last follow-up.

Discussion: Isolated cutaneous PTLD is very rare. Prior cases of plasmacytic PTLD describe responses with a combination of IS reduction & RT. Those with more advanced or relapsed disease have received myeloma-based therapies with varying levels of success. Given the absence of a standard of care for plasmacytic PTLD and our patient's localized disease, we opted to gradually escalate treatment intensity over 4 years as the lesions recurred. To our knowledge, this is the first case report demonstrating successful use of dara-CyBorD in a KTR with cutaneous-limited PTLD.

SA-PO1026

Chylous Ascites in a Patient on Peritoneal Dialysis with Recurrent T Cell Post-transplant Lymphoproliferative Disorder after Transplantation from a Living Unrelated Kidney Donor

Christopher R. Showers, Vishnu S. Potluri, Rebecca K. Seshasai. *Penn Medicine, Philadelphia, PA.*

Introduction: Chylous ascites is a rare manifestation of abdominal lymphatic system disruption; ascites fluid appears cloudy and is characterized by elevated triglyceride levels. Few reports exist of chylous ascites in patients on peritoneal dialysis (PD) or in patients following solid organ transplantation. We report a case of chylous ascites in a patient on peritoneal dialysis with recurrent post-transplant lymphoproliferative disorder (PTLD) following a living unrelated kidney transplant (LUKT).

Case Description: A 54 year old man with ESKD due to IgA nephropathy who received a LUKT in 2018 that was complicated by T-cell mediated rejection in 2022 leading to allograft failure and initiation of peritoneal dialysis (PD) in 2023 presented with cloudy PD fluid and mild abdominal discomfort. Additional history included T-Cell lymphoma characterized as PTLD in 2021 treated to complete metabolic response. Both donor and recipient were EBV seropositive at the time of LUKT. Gross examination revealed cloudy PD fluid; initial PD fluid studies demonstrated 84 total nucleated cells per microliter with 1% neutrophils. PD fluid cultures and smears for acid-fast bacilli were both negative. Ascites fluid triglyceride level was 412 mg/dL (serum 133 mg/dL). A CT abdomen and pelvis demonstrated bulky lymphadenopathy and a PET-CT scan confirmed severe progression of lymphoma. A PD catheter was appropriately positioned. PD was limited by inability to tolerate therapeutic fill volumes and persistent chylous ascites. Hemodialysis was initiated. Following initiation of chemotherapy, the patient developed tumor lysis syndrome and eventually expired.

Discussion: We report chylous ascites as the initial presentation of severe recurrent PTLD following LUKT. Cloudy PD fluid warrants immediate and thorough evaluation and may raise suspicion for PTLD in post-transplant patients. Large volumes of chylous ascites may impair continuation of PD.

SA-PO1027

A Case of Post-transplant Lymphoproliferative Disorder Developed 45 Years after Kidney Transplantation

Nobuaki Nishima, Yoshifumi Hamasaki, Yosuke Hirakawa, Masaomi Nangaku. *The University of Tokyo, Tokyo, Japan.*

Introduction: Post-transplant lymphoproliferative disorder (PTLD) affects 1-3% of renal transplant recipients, with the majority of cases occurring within the first year or around 5 years post-transplant. PTLD presents with a variety of symptoms depending on the affected organs and requires treatment including reduction or discontinuation of immunosuppressive agents. Very late-onset PTLD (VL-PTLD), developing more than 10 years after transplantation, is rare and requires different management strategies from early or late-onset PTLD due to its characteristics.

Case Description: A 61-year-old male pharmacist, who had undergone kidney transplant 45 years ago due to purpura nephritis and was maintained on AZA+PSL, developed fever and shortness of breath. Blood test showed inflammation and worsening kidney function but EBV was negative. Computed tomography showed multiple nodules and masses in lung and liver, and bronchoscopy revealed a tumor exposed in the left bronchus. A lung biopsy confirmed monomorphic PTLD (diffuse large B-cell lymphoma type, stage IVB). Treatment was initiated with change in immunosuppressive agents from AZA to everolimus and chemotherapy (R-CHOP). His symptoms improved and he was discharged on day 45. However, sudden bleeding from his airway led to cardiopulmonary arrest and death on day 66.

Discussion: Three percent of post-kidney transplant patients at our hospital have presented with PTLD, of which this case was the only case of VL-PTLD with the oldest age. It has been reported that VL-PTLD cases are often older and on classical immunosuppressive agents such as AZA, and present monomorphic type pathologically. Previous reports have indicated that the 1- and 5-year survival rates for VL-PTLD are 56% and 29%, respectively, and poor prognostic factors include age 65 or older, male gender, and CyA+AZA maintenance therapy. Continued attention to PTLD should be paid even long after kidney transplantation. Further case collection and research is needed to establish the optimal treatment strategy for VL-PTLD.

SA-PO1028

Long-Term Outcome of a Deceased Donor Kidney Transplant in a Patient with Active Chronic Lymphocytic Leukemia at Time of Transplantation

Nathaniel Leonardi, Brian J. Benes, Clifford D. Miles, Ryan Mullane, Scott G. Westphal. *University of Nebraska Medical Center, Omaha, NE.*

Introduction: While active malignancy is often considered a contraindication to kidney transplantation, certain malignancies have an increased survival with medication advancements. Chronic lymphocytic leukemia (CLL) is such a disease with an 88% 5-year survival and median survival of nearly 10 years. Concerns for organ transplantation in patients with CLL include risk of immunosuppression on disease progression, potential leukemic infiltration of allograft, and increased risk of infection. Transplant experience in patients with CLL is limited. Published experiences report high rates of graft failure and mortality and no long-term follow-up data. We present a patient with CLL treated with a Bruton Tyrosine Kinase inhibitor, ibrutinib, who underwent successful kidney transplant with excellent long-term outcome.

Case Description: A 50-year-old male was diagnosed with CLL/small lymphocytic lymphoma Rai stage 0 with favorable genetics and was initially treated with monitoring approach. Due to CLL progression and kidney function decline, cyclophosphamide and rituximab were initiated. Kidney biopsy revealed IgA Nephropathy with CLL involvement characterized by lymphocytic interstitial infiltrate. He progressed to end-stage kidney disease and completed two years of rituximab followed by maintenance ibrutinib. Prior to transplant, ibrutinib was stopped with concern of increased bleeding

risk. He underwent successful deceased donor kidney transplantation with basiliximab induction and maintenance immunosuppression with tacrolimus, mycophenolate sodium (MPS), and prednisone. Three years post-transplant, progression of CLL developed with worsening lymphadenopathy and lymphocytosis. MPS and tacrolimus doses were reduced. Ibrutinib was resumed and his CLL responded to treatment with improvement in lymphocytosis. Eight years from transplant, serum creatinine is 1.16, without infectious complication or adverse allograft injury related to CLL.

Discussion: While patients with CLL have frequently been excluded from kidney transplant consideration, newer therapies and improved understanding of favorable prognostic markers may allow for safe kidney transplantation in lower risk patients. This case demonstrates potential longevity following transplant with appropriate treatment and immunosuppression adjustments.

SA-PO1029

Renal Whodunit: The Paraprotein Connection

Jessica Boldridge,[1] George P. Bayliss,[1] Anthony Chang.[2] *[1]Brown University, Providence, RI; [2]University of Chicago Division of the Biological Sciences, Chicago, IL.*

Introduction: A monoclonal gammopathy is an abnormal increase in the synthesis of one of the five immunoglobulin (Ig) isotypes. These monoclonal Igs are also referred to as paraproteins which can be nephrotoxic. Manifestations can range from tubulopathies to glomerular disease. Known paraprotein diseases include multiple myeloma, Waldenstrom macroglobulinemia, CLL and malignant lymphoma. All other B cell lymphoproliferative and plasma cell proliferative disorders that result in kidney disease are referred to as monoclonal gammopathy of renal significance.

Case Description: A 68 yo male with a PMH of ESRD secondary to FSGS status post (s/p) living donor kidney transplant in 2020 who was admitted to the hospital for acute kidney injury (AKI). Six weeks prior to presentation, he was diagnosed with IgM paraprotein associated with a low-grade lymphoproliferative disorder most consistent with CD5 positive marginal zone lymphoma. Per hematology/oncology, the initial plan was to not treat unless the patient had systemic involvement. There was no known systemic involvement at that time. Fast forward six weeks and labs are now significant for a creatinine (Cr) of 3.2 mg/dL. Urinalysis positive for 1+ for blood, 30 protein. Tacrolimus level was 6.7. He tested covid positive. Biopsy was pursued which showed no signs of rejection but acute tubular necrosis and ongoing ischemic changes possibly related to tacrolimus. Four of 24 glomeruli were globally sclerosed. There was also severe hyalinosis and moderate IFTA 30%. The plan at that time was to start belatacept and to titrate down tacrolimus. Routinely, immunofluorescence (IF) is not obtained on transplant biopsies. Given new onset AKI and recently diagnosed malignancy, pathology was asked to review the allograft biopsy samples. IF showed evidence of light chain cast nephropathy, kappa light chain restricted.

Discussion: We present a rare case of a light chain cast nephropathy in a renal allograft. As described in this case, the preliminary plan was to hold treatment as he had no known systemic manifestations. The plan changed once AKI developed. Initial result of the biopsy was suggestive of tacrolimus toxicity with plans to alter immunosuppression accordingly. Maintaining monoclonal gammopathy of the allograft as a differential diagnosis is essential in relevant patients as it can alter treatment and important to remain as a differential for all learners.

SA-PO1030

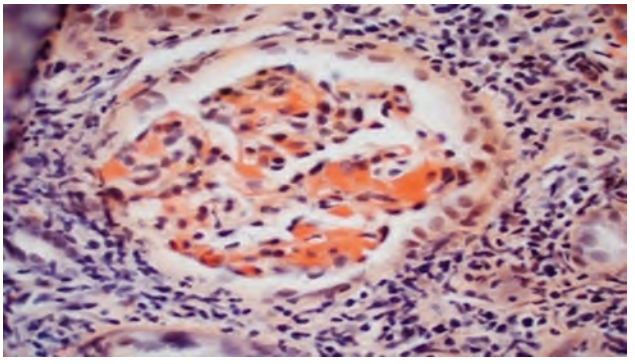
Donor-Derived AA Amyloidosis in a Kidney Allograft

Vamsee K. Chirumamilla, Kiran M. Goli, Sharon E. Maynard, Ravindra Bollu. *Lehigh Valley Health Network, Allentown, PA.*

Introduction: AA amyloidosis in renal allograft is an exceptionally rare occurrence. It typically arises in the context of chronic inflammatory or infectious diseases. We present a distinctive case of AA amyloidosis in a renal allograft.

Case Description: A 62-year-old man with end-stage kidney disease secondary to diabetes mellitus underwent a preemptive deceased donor kidney transplant. Immunosuppresion consisted of thymoglobulin and methylprednisolone, followed by belatacept, mycophenolate mofetil and prednisone. Post-transplant serum creatinine (Cr) improved to 2.5 mg/dl. Urine-protein creatinine ratio (UPCR) improved to 3.97 g/g compared to 6.08 g/g pre-transplant. Five months post-transplant, the Cr increased to 3.95 mg/dl and UPCR increased to 9.36 g/g. Allograft biopsy showed Banff 1A acute cellular rejection (ACR), moderate expansion of mesangium and glomerular capillary walls by an amorphous pink material with apple-green birefringence on Congo red stain, signifying amyloid deposition. Liquid chromatography-tandem mass spectrometry analysis revealed AA type amyloid. The patient had no known chronic inflammation, infection, or autoimmune disorder. The donor had a history of intravenous drug use and died of necrotizing pneumonitis. The mate kidney thrombosed within a week of being implanted and required explantation. Donor kidney biopsy at the time of donation revealed eosinophilic material in the glomeruli, which in hindsight may have represented amyloidosis. The clinical impression was donor-derived AA amyloidosis. His ACR was treated with corticosteroids. Repeat biopsy confirmed resolution of acute rejection but kidney function worsened, and hemodialysis was initiated 7 months after transplantation.

Discussion: Donor-derived AA amyloidosis in a kidney allograft has not been reported. Despite successful treatment of acute rejection, the patient developed graft failure. This complication may be avoidable by thorough pathologic evaluation of donor biopsy prior to transplantation.



Note the deposition of amorphous pink material in the glomerulus

SA-PO1031

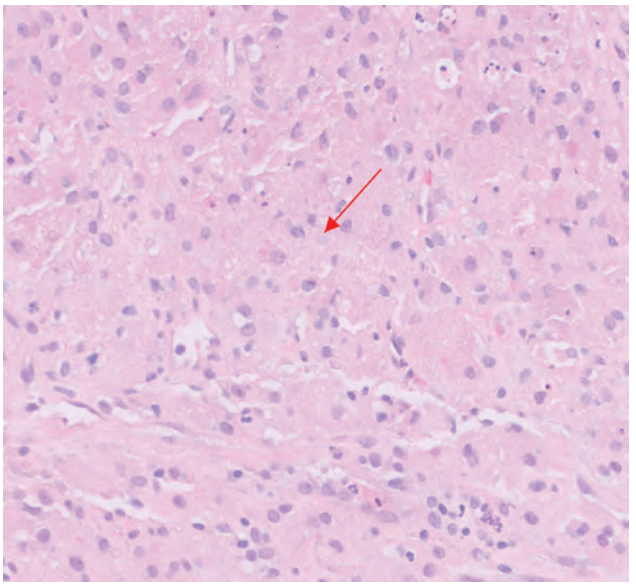
Malakoplakia in a Kidney Transplant Recipient

Samira M. Samant, Camilo Cortesi. *Kaiser Permanente Santa Clara Medical Center, Santa Clara, CA.*

Introduction: Malakoplakia (MK) is a rare inflammatory condition of impaired phagocytosis, often linked to gram-negative infections. It can be devastating in kidney transplant recipients. Presentations vary, from renal dysfunction to extra-renal involvement.

Case Description: A 57-year-old female with end-stage renal disease due to hypertensive nephrosclerosis underwent a kidney transplant five months prior, with recurrent urinary infections post-transplant. She presented with a 50-pound weight loss, three weeks of dysuria, weakness, and hematuria. Labs showed severe acute kidney injury, metabolic acidosis, and elevated lactate. Blood and urine cultures detected E. coli. Ultrasound revealed a hypoechoic focus in the graft, on CT an ill-defined mass suggestive of pyelonephritis or abscess. MRI showed fingerlike masses extending into the cortex, suspicious for post-transplant lymphoproliferative disorder or malignancy. Biopsy showed no malignancy, but identified Michaelis-Gutmann bodies (MGBs). Her immunosuppression was reduced, and long-term antibiotics started. She succumbed to septic shock complications three months later.

Discussion: Malakoplakia is poorly understood due to its rarity. In renal transplant patients, urinary infections, graft dysfunction, or new masses should prompt consideration of MK. Its pathophysiology involves impaired phagocytosis, likely due to inadequate cyclic GMP release, hampering macrophage bactericidal activity and increasing infection risk. Pathognomonic biopsy findings include intracytoplasmic Periodic acid-Schiff positive inclusions (MGBs) and histiocytes with granular cytoplasm (von Hansemann cells). Management includes prolonged antibiotics, reduction of immunosuppression, and occasionally surgical excision. Despite this regimen improving mortality, morbidity remains high due to graft failure. Early recognition and timely biopsy are crucial to optimizing outcomes.



MGBs on biopsy

SA-PO1032

Unmasking Malakoplakia: A Rare Complication in Kidney Transplantation

Alexandra Rosario Aulet,[1] Akash Hazari,[1] Wael A. Hanna,[1,2] Muhammad R. Qureshi.[1,2] *[1]Methodist Dallas Medical Center, Dallas, TX; [2]Dallas Nephrology Associates, Dallas, TX.*

Introduction: Malakoplakia is a rare granulomatous inflammatory disease associated with poor graft and patient survival. Although it frequently involves the bladder, it can also affect transplanted kidneys. Presentation varies from asymptomatic kidney dysfunction to lower urinary tract symptoms or palpable mass.

Case Description: A 38 y/o Puerto Rican male with a history of ESRD secondary to obstructive uropathy from posterior urethral valve, s/p deceased donor kidney transplant. One week post-transplant, his course was complicated with COVID-19 infection and UTI cause by multi-sensitive E. coli. Slow graft function with negative donor-specific antibodies was reported. Serum creatinine did not improve as expected when compared to mate kidney, for which decision was made to proceed with a biopsy of the transplanted kidney. Biopsy reported nuclear inclusion highlighted with Von Kossa stain, known as Michaelis Gutman bodies, supportive of a diagnosis for malakoplakia. As recommended immunosuppression regimen was adjusted, MPA dose was decreased, tacrolimus target level was lowered and started on four weeks of oral antibiotics. A follow up Scr stabilized around 2.4mg/dL, and biopsy was schedule after completion of medical therapy.

Discussion: The risk of malakoplakia increases in immunocompromised states. Treatment includes reduction of immunosuppression and targeted antimicrobial therapy. This pathology must be considered transplanted patient that presents with AKI associated with UTI. If missed can lead to significant morbidity. Kidney biopsy remains the gold standard for diagnosis.

SA-PO1033

Delayed Presentation of Donor-Derived Allograft Squamous-Cell Carcinoma in a Kidney Transplant Recipient

Ricardo A. Pagan, Madhu C. Bhaskaran. *Northwell Health, New Hyde Park, NY.*

Introduction: We present an unusual case of allograft squamous cell carcinoma (SCC) in a kidney transplant recipient, presenting as a mass in the allograft. While kidney transplants notably enhance life expectancy and quality of life, there is a risk of malignancies. Despite SCC of the skin being one of the most common malignancies in transplant recipients it is an rare neoplasm in the allograft.

Case Description: 58 years old male, with history of end stage renal disease related to diabetes, received deceased donor renal transplant. Other comorbidities included hypertension and nephrolithiasis. Post-transplant course included CMV viremia, managed with Valganciclovir. He had a kidney biopsy when due to presentation of persistent generalized weakness, oliguria, elevated creatinine and dark urine. An ultrasound revealed a focal mass lesion of allograft kidney which was followed by a MRI showing a 4.9 cm mass in the transplanted kidney. Biopsy revealed SCC and due to declining GFR and oliguria, patient required hemodialysis. Nephrectomy was performed, immunosuppression discontinued and the patient remains on hemodialysis with oncology follow-up. Interestingly the recipient of the other kidney from the same donor was tracked and was found to be undergoing treatment for metastatic squamous cell carcinoma.

Discussion: Among post-transplant malignancies, SCC of the renal allograft stands out as a rare case. Chronic inflammation and irritation play a crucial role in the development of primary SCC, with the urothelium potentially converting to squamous cells due to irritants like kidney stones and recurrent infections. Additionally, oncogenic viruses like Epstein Barr Virus (EBV) and CMV may contribute to oncogenesis. Immunosuppression is well known to predispose to malignancies. Renal cell carcinoma and papillomas are reported in transplanted kidneys, with donor age, especially over 45, being a significant risk factor for cancer transmission. Even though donor derived malignancies are a known risk in solid organ transplant there are reports of successful outcomes of kidney transplantation with well circumscribed small tumor after they are resected. The atypical presentation of SCC in renal allograft raises questions about donor screening methods prior to organ allocation and reminds the need to keep donor derived malignancies in mind on delayed post-transplant period.

SA-PO1034

An Unusual Case of Late-Onset Profound Granulomatous Interstitial Nephritis Due to Adenovirus in a Kidney Allograft

Syed S. Hasni, Carla L. Ellis, Sujay D. Paudel, Mohammed Javeed Ansari, John J. Friedewald. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Introduction: Adenovirus (AV) is a common infection in transplant recipients with wide clinical presentations, ranging from subclinical and self-limiting to lethal disease. Most often, AV infection occurs within weeks to months after transplantation, suggesting reactivation of a latent AV in the immunosuppressed recipient as the source of infection. This report describes a case of AV infection in the renal allograft 19 years after transplantation.

Case Description: A 71 year old male with analgesic nephropathy, status post DDKT was seen for annual f/u 19 yrs later. Immunosuppression included MMF and Sirolimus. Recently had AKI of unclear etiology and 1g proteinuria which was stable. UA showed hematuria, BK blood/uine and Adenovirus PCR in blood were negative. Urine Adenovirus DNA was barely detected. DSA, non-invasive gene expression profile, and donor-derived cell-free DNA were negative. Kidney biopsy showed granulomatous interstitial nephritis. Adenovirus immunohistochemistry was equivocal. PCR testing for Adenovirus on the paraffin embedded block was positive. Patient's wife was treated for large B cell lymphoma with chemotherapy and had hemorrhagic cystitis 2/2 Adenovirus and was receiving Cidofovir. Given the negative PCR test in the blood and low level of Adenovirus in the urine, no intervention was done. Cr is stable and back to baseline, UA is bland and proteinuria is stable at 6 month follow up.

Discussion: Asymptomatic AV viremia is common in solid organ transplant recipients, estimated at 7.2% of patients and it was estimated that AV is excreted by 11% of patients with renal transplant. Since most AV infections occur during childhood, it is believed to be reactivation of an endogenous latent infection. This late onset of AV infection suggests that this is a de novo infection. In addition, this case highlights the perseverance that may be required to make a definitive diagnosis. Identification of AV contact tracing, prompted us for PCR testing for AV on the paraffin embedded block after immunohistochemical staining for the AV antigen on the biopsy was equivocal. A negative serological test and the absence of diagnostic viral cytopathic changes in a renal biopsy do not rule out AV infection and hence both the clinician and the pathologist need to remain alert to the possibility of this diagnosis.

SA-PO1035

Kaposi Sarcoma Inflammatory Cytokine Syndrome in an HIV-Positive Kidney Transplant Patient

Karishma Iyer, Kaitlin Markoja, Metin Ozdemirli, Nadiesda Costa, Parichi V. Buch. *MedStar Georgetown University Hospital, Washington, DC.*

Introduction: Kaposi sarcoma (KS) is a malignancy that typically appears as skin or mucosal lesions but can develop in other organs. HHV-8 is an oncogenic herpes virus that causes KS. KS is rare but can develop in HIV+ and kidney transplant (KT) patients. A highly fatal presentation is Kaposi Sarcoma Inflammatory Cytokine Syndrome (KICS), which causes multisystem organ failure.

Case Description: A 39 year old male with HIV on ART (CD4 <50 cells/mm3, viral load undetectable) and ESKD status post living donor kidney transplant one year prior (CMV +/+, EBV +/+) presented with febrile illness, acute kidney injury (AKI) and pancytopenia. Prior induction was thymoglobulin and maintenance immunosuppression (IS) was belatacept (due to CNI toxicity), mycophenolate and prednisone; tacrolimus was recently discontinued. Extensive infectious evaluation revealed CMV and EBV viremia, treated with valganciclovir. His condition deteriorated and he developed shock and acute hypoxic respiratory failure requiring mechanical ventilation. Due to persistent cytopenias, bone marrow biopsy was done which showed metastatic KS. HHV-8 returned at 505,000 copies/mL and IL-6 at 183 pg/mL. He was treated with rituximab and liposomal doxorubicin; HHV-8 and IL-6 levels rose, so Tocilizumab was added. IS was changed to sirolimus. AKI required continuous renal replacement therapy. He developed ARDS and died after two months.

Discussion: There is an increased incidence of KS in HIV+ patients as well as KT recipients. There is no consensus guidance regarding HHV-8 screening in the pre or post transplant period in HIV+ KT recipients. Reduction in IS and transition to sirolimus have been associated with KS regression, while the role for antiviral therapy is uncertain. KICS should be considered in at-risk patients with shock, respiratory failure, cytopenias and elevated inflammatory markers. In our patient, this catastrophic syndrome manifested prior to diagnosis of KS becoming evident, as he had no cutaneous lesions and KS was only identified on bone marrow biopsy. Optimal treatment for KICS is uncertain and may include chemotherapeutic and immunomodulatory drugs. It is associated with a high mortality rate, underscoring the importance of consideration of an HHV-8 screening strategy, as well as awareness of this condition among transplant nephrologists.

SA-PO1036

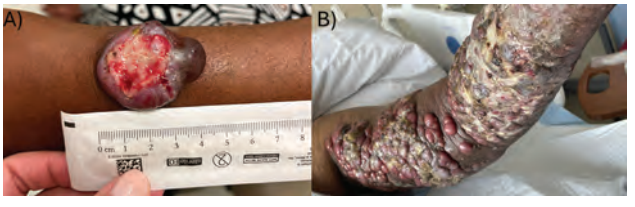
An Unusual Aggressive Skin Cancer in a Kidney Transplant Recipient

Joseph D. Nguyen, Swati Rao, Angie G. Nishio Lucar. *University of Virginia, Charlottesville, VA.*

Introduction: Merkel cell carcinoma (MCC), a rare and aggressive neuroendocrine skin cancer, has a poor prognosis in immunocompromised patients. In advanced stages, radiotherapy, chemotherapy, and immunotherapy have been used with variable success. Immunotherapy is relatively contraindicated in transplant recipients due to the risk of allograft rejection and loss. We report a complex case of aggressive metastatic MCC in a kidney transplant recipient (KTR).

Case Description: A 66-year-old female with ESKD due to hypertension receiving a kidney transplant 4 years prior was diagnosed with stage IIIB MCC of the left wrist (Figure 1A). Her disease progressed rapidly despite undergoing radical local resection and axillary dissection. Within a month post excision, she had developed numerous new MCC lesions on her left arm and axilla which were deemed unresectable and had a suboptimal response to radiotherapy. After deliberation, immunotherapy with pembrolizumab was initiated, but stopped after 4 cycles (of 35 planned) due to extensive disease progression (Figure 1B) and patient progressed to hospice care. Throughout her pembrolizumab course, she remained on prednisone, low dose tacrolimus, and mycophenolate. She had no episodes of rejection and maintained good allograft function.

Discussion: Indications for checkpoint inhibitors in the treatment of malignancies are growing. Pembrolizumab, a PD-1 ligand blocker, enables lymphocytes to target and destroy cancer cells. KTRs are often excluded from checkpoint inhibitor trials due to the risk of allograft loss (40-70% incidence). Despite this risk, KTRs can benefit from immunotherapy to treat aggressive malignancies such as MCC. In our patient, we elected to continue immunosuppression along with pembrolizumab to balance the risk of rejection and anti-cancer effect. Although immunosuppression protected the graft, it may have compromised immune-mediated tumor regression. Our case supports the literature that pembrolizumab can be utilized in certain settings in KTRs without graft loss and highlights the need for additional research for the optimal management of aggressive cancers in KTRs.



SA-PO1037

Immune Checkpoint Inhibitor Therapy Use in Kidney Transplant Recipients: A Single-Center Study

Elena-Bianca Barbir, Ali Ghaffar, Clark Otley, Arkadiusz Z. Dudek, Aleksandra Kukla. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Immune checkpoint inhibitors (ICI) have radically improved cancer outcomes. Due to concerns regarding graft rejection, ICI's were infrequently offered to KTR's despite significant cancer related mortality. We report the cancer and allograft outcomes of patients receiving ICI therapy at our center.

Methods: We retrospectively reviewed all KTR's undergoing ICI therapy at our center that were referred to our transplant clinic for immunosuppression (IS) management from December 1, 2018 to May 1, 2024. All patients continue to be followed, unless deceased. Indication biopsies were performed for acute kidney injuries.

Results: 21 patients met inclusion criteria. Patient characteristics and outcomes are described in Table 1. No acute rejection was noted. 1 patient had biopsy evidence of chronic antibody mediated rejection and recurrent PLA2R positive membranous nephropathy after 11 months of Pembrolizumab. This patient had a complete response with a stable creatinine of 1.5-1.8 mg/dL 2 years post therapy completion. Of 16 evaluable patients, 1 had complete response, 3 had partial response, and 2 had stable disease. Therapy limiting extra-renal immune related adverse events were noted in 1 patient with colitis.

Conclusions: The absence of acute rejection or frequently recurrent native disease in our cohort is encouraging, though objective response is low. Many patients were frail with advanced disease at the time of ICI initiation, likely contributing to the poor objective response, though degree and type of IS may also have influenced outcomes. Additional prospective studies comparing IS regimens while controlling for disease burden are needed.

Table 1

	Total Patients (n=21)
Median Age at ICI Therapy Initiation (years)	65 (range 52-78)
ESRD Secondary to Glomerulopathy (%)	43
Advanced Cutaneous Squamous Cell Carcinoma (%)	57
Metastatic Melanoma (%)	19
Patients on PD1 Inhibitor (%)	95
Maintenance Post ICI (Calcineurin Inhibitor/Pred) (%)	67
Maintenance Post ICI (Mammalian Target of Rapamycin Inhibitor/Pred) (%)	28
Rejection (%)	4.8
Median Follow Up (months)	3 (range 0.25 – 44)
Objective Response in 16 evaluable patients (%)	25
Stable Disease in 16 Evaluable Patients (%)	12.5
Median Overall Survival For Patients with Progressive Disease (months)	3 (range 0.25-8)
Median Time from Transplant to ICI Initiation (years)	8 (range 1-29)

SA-PO1038

Rapid Acute Rejection with Cortical Necrosis after First-Dose Cemiplimab in a Living Donor Kidney Transplant

Ahmed I. Abdelkader, Sakshi Vaishnav, Ahmed Daoud, Karim Soliman, Munsef Barakat, Vishwajeeth Pasham, Maria Aurora C. Posadas, Michael Casey. *Medical University of South Carolina, Charleston, SC.*

Introduction: Transplant recipients (TR) have an increased risk of squamous cell carcinoma (SCC) 65-250 times that of general population. There are few treatment options for advanced SCC in the setting of immunosuppression (IS) which has carcinogenic effect. Cemiplimab (CMP) is a checkpoint inhibitor (CPI) directed at PD-1 which has had promising responses in advanced SCC, but its use has also been associated with acute rejection. However, a recent prospective study using CPM showed safe use in TR with sirolimus (SRL).

Case Description: A 71-year-old male, CKD/V due to IgA nephropathy received a living donor TR. He has a history of BCC treated with Moh's surgery 5 months (Ms) pretransplant. He received basiliximab induction and maintained on a standard IS of tacrolimus (TAC), mycophenolate (MMF), and prednisone. Creatinine (Cr) settled at 1.4 mg/dL. 5 Ms post-transplant (PTx), 15 spots of actinic keratoses were treated with cryotherapy. *A month later*, he had neutropenia, so MMF was changed to everolimus. *By 8 Ms PTx*, he had CMV disease so everolimus was held kept him on prednisone and TAC. He had 2 biopsies at 2 and 9 Ms PTx which showed no rejection. A year PTx, he developed DSA treated with IVIG. Then, he was diagnosed with multiple BCC and SCC involving his face, ear, and hands. He had multiple facial surgeries to control his SCC but the lesions progressed. 19 Ms PTx, CMP was given as salvage therapy for advanced SCC. TAC was switched to SRL while Cr was 1.3 mg/dL. 1 week after the first dose of CMP, he experienced fever and malaise with rise in Cr to 3 mg/dl. He was admitted with oliguria and Cr of 4.7 mg/dL and treated with IV steroid then biopsy showed acute cortical necrosis and vascular inflammation. The patient started on dialysis.

Discussion: Until recently, TR were excluded from CPI's treatment for the risk of organ rejection. A recent prospective study reported favorable outcomes for 12 subjects who used CMP for the treatment for advanced SCC along with SRL with no rejection at 6 months. Our patient suffered from a rapid aggressive acute rejection at 1 week after first dose of CMP that resulted in cortical necrosis and graft loss. This is the first case of rapid renal allograft loss due to acute rejection and cortical necrosis after the CMP reported in literature.

SA-PO1039

Mesenteric Desmoid Tumor in a Transplant Patient

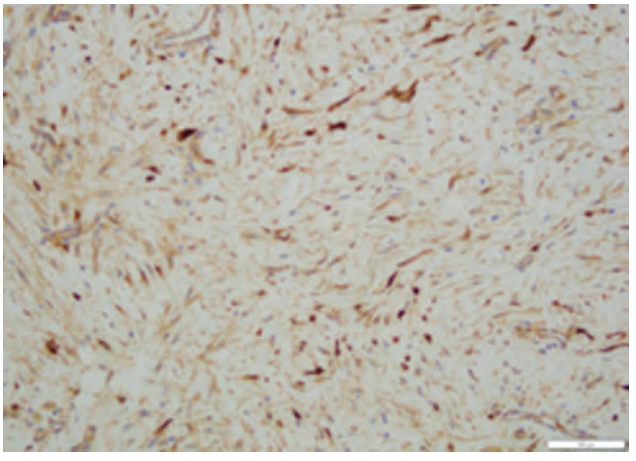
Dominik Thomas, Sarah Gilligan, Suayp Oygen, Duha A. Jweehan, Isaac E. Hall, Miklos Z. Molnar, Divya Raghavan. *University of Utah Health, Salt Lake City, UT.*

Introduction: Desmoid tumors (DTs) are deep, locally aggressive, benign connective tissue neoplasms that originate most commonly in the extremities, intraperitoneal cavity and abdominal and thoracic walls. They are rare with reported incidence of 2–4 per million population per year and account for 0.03% of all neoplasms. DTs have a high rate of local recurrence but do not metastasize. We present an unusual case of a DT found two years after kidney transplant.

Case Description: 61 year-old man with end-stage renal disease due to diabetic nephropathy who underwent a deceased donor kidney transplant presents with abdominal pain starting six months after transplant. He underwent robotic inguinal hernia repair without improvement in pain. He reports night sweats, fatigue, and unintentional weight loss of 15lbs over two months. CT abdomen/pelvis showed a mid-abdomen, mesenteric soft tissue mass measuring 5.4 x 3.5 cm which was mildly hypermetabolic on PET-CT.

Surgical biopsy of the mass revealed a DT. Resection of the mass was not pursued due to areas of fibrosis along the mesentery suggestive of a more diffuse process. Consequently, the oncology team started Pazopanib with good response.

Discussion: The differential diagnosis for an abdominal mass is broad with high concern for post-transplant lymphoproliferative disorder. When suspecting malignancy, tissue diagnosis is always important for diagnosis and guiding treatment. For DT, asymptomatic patients can be managed with active surveillance while symptomatic patients may require surgery, systemic therapy, and/or radiation therapy.



SA-PO1040

Postkidney Transplant Cancer: Incidence, Risk Factors, and Future Perspectives in a Real-World Analysis of a Single Italian Center

Carlo Alfieri,[1,2] Giulia V. Re Sartò,[2] Mariarosaria Campise,[1] Anna Regalia,[1] Simona Verdesca,[1] Paolo Molinari,[1] Margherita Di Naro,[1] Sara Moscardino,[1] Maurizio Gallieni,[2] Giuseppe Castellano.[1,2] *[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Universita degli Studi di Milano, Milano, Italy*.

Background: Our study aims to outline cancer epidemiology post-KTx, examine risk factors, and assess the impact on treatment and survival in a large cohort of kidney transplant patients. We'll analyze the link between changes in immunosuppressive therapy post-cancer diagnosis and survival outcomes.

Methods: Retrospective collection of data in KTx-ps transplanted between January 2004 and December 2021, subjected to outpatient follow-up with a median follow-up of 7 [1-19] years.

Results: Our study included 930 KTx-ps, average age 49yrs. 91% had pre-KTx dialysis for about 52 months. Most received KTx from a deceased donor (84%). 74% had Basiliximab induction therapy, 26% ATG. Maintenance therapy mostly involved steroids (87%), tacrolimus (92%), ciclosporin (8%), and mycophenolate (94.6%). 177 patients (19%) had at least one cancer (CAN+). The mean time from KTx to oncological diagnosis was 83 months. Non-melanoma skin cancers (NMSC) were the most common tumors (55%), while solid tumors were observed in 38.6% of cases. Deceased donor was more represented in CAN+. CAN+ were older and with higher BMI. They had greater presence of vasculitis as basic nephropathy. In the period between 2016 and 2021, induction therapy with ATG was significantly associated with CAN+. In multivariable analysis, ATG emerged as an independent risk factor for CAN+ (p=0.014) and, in survival analyses, ATG was strongly and significantly related to the earlier development of CAN+ (p=0.010). During follow up, cancer-related causes were the second cause of mortality (23%); the average time from cancer diagnosis to death was 23 months. The median survival from Ktx was 148 (CAN+) and 82 months (CAN-). After oncological diagnosis, significant evidence on tumor survival was derived from the shift to mTOR inhibitors compared to the group with definitive drug suspension (p=0.004).

Conclusions: Our study confirms cancer's significance as a KTx complication. ATG is an independent cancer risk factor, emphasizing the need for personalized immunosuppressive therapy at KTx to mitigate neoplastic risk. In KTx-ps, future research should focus on therapeutic strategies with antineoplastic agents and post-malignancy immunosuppression management.

SA-PO1041

Feasibility Study of a Randomized Controlled Trial Investigating Renal Denervation as a Possible Treatment Option in Patients with Loin Pain Hematuria Syndrome

Bhanu Prasad,[1] Aarti Garg,[2] Aditi Sharma.[2] *[1]Regina General Hospital, Regina, SK, Canada; [2]University of Regina, Regina, SK, Canada*.

Background: Loin Pain Hematuria Syndrome (LPHS) is a poorly understood clinical condition characterized by severe pain localized to the kidney but in the absence of identifiable urinary tract disease. Several studies have shown promise in observational studies but have been unable to replicate the results when compared with a sham arm in a randomized controlled trial. To address this gap, we conducted a feasibility study that involved a randomized controlled trial comparing renal denervation (RDN) with a sham arm. The primary objectives were to ensure that 80% of the study patients underwent the procedure (roll-in, treatment or sham) within 6 months and that 80% of the randomized patients (treatment or sham) completed the follow-up measures at 6 weeks, 3 and 6 months.

Methods: We conducted a single-center double-blinded, parallel-group, partial crossover, sham-controlled, randomized feasibility trial. 13 LPHS patients who required >100 mg of morphine milligram equivalent were randomized (treatment or control or roll-in) and they completed the follow-up for 6 months. The participants who received the sham procedure were crossed over into the treatment group and were followed for 6 months. The pain was assessed using Brief Pain Inventory Score (BPI) and quality of life was measured by EuroQol-5D and SF-36.

Results: 100% of patients underwent the procedure within the initial 6-month period. 100% patients in the roll-in and 80% each in the treatment and sham group completed the follow-up assessments throughout the study duration. Improvements in pain severity and interference seem to have continued up to the 3-month follow-up in roll-in, RDN, and crossover. Percentage gain in VAS at 3 months was 100%, 60%, and 60% respectively (Table 1).

Conclusions: This is the first randomized controlled study that shows that RDN is associated with improvement in pain and quality of life. Our results suggest that percutaneous catheter-based radiofrequency energy delivery is a safe, rapid treatment option for all patients with LPHS.

Characteristics	Roll in (n=3)	RDN (n=5)	Sham (n=5)	Cross-over (n=3)
Mean age (years)	43.33±5.5	36±12.5	40±6	39±5.2
Sex (n, female)	3	4	5	3
BPI Percent reduction (baseline to 3 months)	78.8%	34.7%	-17.3%	57%
VAS % gain in scores (baseline to 3 months)	100.2%	60%	21.4%	60%

RDN: renal denervation; BPI: brief pain inventory

SA-PO1042

Quiescent Sex Differences in C57BL/6J Mice

Han Eckenrode, Rohan S. Balkawade, Lisa M. Curtis. *The University of Alabama at Birmingham Heersink School of Medicine, Birmingham, AL*.

Background: Many studies focus on male animals, with fewer studies explicitly studying female animals. Studies have found sex differences in various kidney disease states, such as acute kidney injury and chronic kidney disease, although sex differences in unaltered animals remain underexplored.

Methods: Male and female C57Bl6/J mice were purchased from Jackson labs at 6 weeks of age. Mice had access to standard chow, ad libidum. During the study period, glomerular filtration rate (GFR), plasma creatinine (PCr), and whole blood parameters, including electrolytes, were measured. At 18 weeks of age, mice were euthanized, tissues collected, and complete blood count parameters were measured

Results: Neutrophil count and absolute percent were lower in female mice, although absolute percent of lymphocytes were higher. Male mice had higher red blood cell distribution width, and mean platelet volume, compared to female mice. Hemoglobin and hematocrit did not persistently differ between sexes. Slight differences in electrolyte balance were found, with higher sodium and lower potassium in female mice. Chloride levels did not differ. Although pH and PCO_2 was not different between sexes, HCO_3- levels were higher in male mice, and anion gap was higher in female mice. Direct and indirect measures of renal function, including PCr, GFR, and BUN, did not persistently differ between male and female mice.

Conclusions: Our study provides insight into sex differences at baseline in parameters that directly and indirectly affect kidney function. These quiescent differences may reflect in a sex differential in the capacity to respond to renal insults.

Funding: NIDDK Support

SA-PO1043

Sex Differences in the Impact of Heat Stress on Kidney Function in a Large Taiwanese Population Study

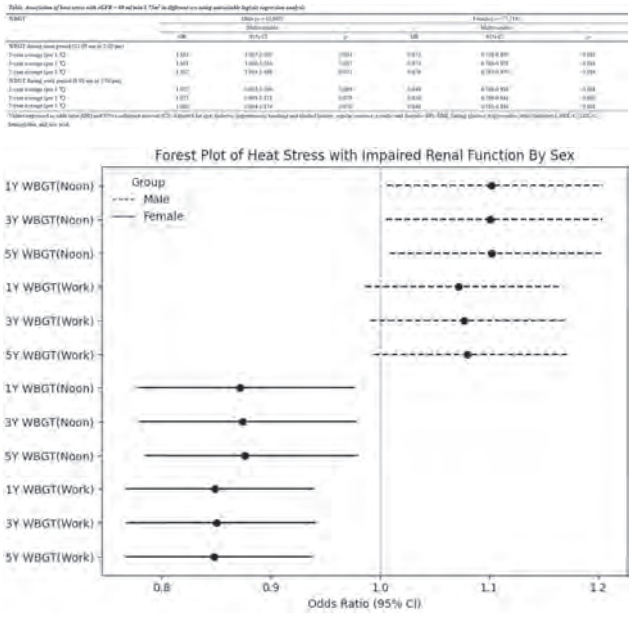
Yi-Kong Chen,[1,2] Yi-Ting Lin,[2,3] Ming-Yen Lin,[2,1] Ping-Hsun Wu,[2,1] Mei-Chuan Kuo,[2,1] Shang-Jyh Hwang,[2,1] Jer-Ming Chang,[2,1] Yi-Wen Chiu,[2,1] Szu-Chia Chen.[2,1] *[1]Division of Nephrology, Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan; [2]Kaohsiung Medical University Chung Ho Memorial Hospital, Kaohsiung, Taiwan; [3]Department of Family Medicine, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan.*

Background: Taiwan, a region with high dialysis incidence and prevalence, prioritizes mitigating chronic kidney disease (CKD) and declining kidney function. Heat stress is a significant CKD risk factor and impairs kidney function. Yet, the impact of heat stress differs between males and females and remains unexplored.

Methods: We conducted this retrospective cross-sectional analysis using data from the Taiwan Biobank (TWB), incorporating records of the wet bulb globe temperature (WBGT) during midday (11 AM - 2 PM) and working hours (8 AM - 5 PM) periods based on the participants' residential address. Average 1-, 3-, and 5-year WBGT values prior to the survey year were calculated and analyzed using a geospatial artificial intelligence-based ensemble mixed spatial model, covering the period from 2010 to 2020.

Results: Our study included 114,483 TWB participants, of whom 35.9% were male and 1,053 showed impaired kidney function (eGFR < 60 ml/min/1.73 m²). Multivariable analysis revealed that for male participants during midday, increases in 1-, 3-, and 5-year average WBGT values were significantly positively linked to impaired kidney function. No significant associations were observed during working hours. For female participants, during both midday and working hours, increases in 1-, 3-, and 5-year average WBGT values were significantly negatively associated with impaired kidney function.

Conclusions: In conclusion, our results revealed that a high WBGT was associated with impaired kidney function in males, whereas a low WGBT was associated with impaired kidney function in females. Further studies are needed to elucidate the exact mechanisms underlying these findings.



SA-PO1044

Reproductive Health and CKD: A Cross-Sectional Survey of Patient Knowledge and Educational Needs

Andrea L. Oliverio,[1] Kelcie Brophy,[1] Corey C. Powell,[2] Michelle A. Hladunewich,[3] Sarah Hawley,[1] Julie A. Wright Nunes.[1] *[1]University of Michigan Medical School, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]Sunnybrook Health Sciences Centre, Toronto, ON, Canada.*

Background: Female reproductive health is affected by kidney disease, but is often not addressed in nephrology care. Our objective was to better understand patient educational needs on this topic to better facilitate family planning care for people with CKD.

Methods: We conducted an online survey of people with CKD assigned female sex at birth, aged 18-45, in English. Survey topics included current knowledge satisfaction, self-ranked education needs, communication preferences, health history, and demographics. Univariate(UV) and multivariable(MV) logistic regression were used to determine associations between individual patient characteristics and overall knowledge satisfaction.

Results: 209 surveys were completed; 77% of participants self-identified as white, 11% Black, 4% Asian; 11% Hispanic. 23% had limited health literacy. Many were dissatisfied with their knowledge of contraception and pregnancy outcomes with CKD (49% and 36%, respectively). Pregnancy planning was associated with lower knowledge satisfaction and glomerular disease with higher knowledge satisfaction. However, after adjustment in MV analysis only health literacy was significantly associated with knowledge satisfaction (β -0.5, 95% CI -0.9 to -0.02) (Table 1). Understanding CKD impact on fetal development and menstruation, and kidney function changes after pregnancy were topics ranked as high priority by participants. The majority were open to receiving a recommendation about contraception (76%; n=159/209) or pregnancy timing (77%; n=161/209) from their nephrologist.

Conclusions: These findings suggest priority topics that should be included in family planning during CKD care. Patients are open to receiving this advice in nephrology clinics. Findings also reinforce the need for education tools to address family planning for all patients, including those with limited health literacy.

Reproductive Planning in Kidney Disease (REPKID): A Survey of Female Patients with CKD

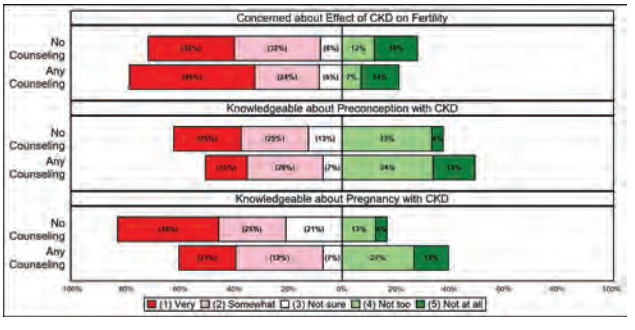
Niloofar Nobakht,[1] Gwendolyn Lee,[2] Maha Al Baghdadi,[1] Yaquelin Arevalo Iraheta,[1] Lorna Kwan,[1] Christina S. Han.[1] *[1]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [2]University of California San Francisco, San Francisco, CA.*

Background: CKD is associated with high rates of maternal, obstetrical & fetal complications in pregnancy. Although preconception counseling (PCC) is recommended by the CDC as primary prevention for pregnancy complications, the frequency of its utilization in CKD is unknown. We hypothesize that PCC in CKD remains suboptimal.

Methods: A cross-sectional survey was distributed to reproductive-aged females at nephrology clinics within a quaternary care health system between 01-05/2024. Data were analyzed using Chi-square (or Fisher's exact tests). Uni- & multi-variable logistic regressions were performed to explore characteristics associated with inadequate PCC.

Results: Of 119 surveys distributed, 98 (82%) were completed. Subjects included those with history of dialysis (54%), transplant (48%), and long duration of disease (32.7%). No PCC was reported in 26% of respondents. In a multivariable logistic regression (Table 1), lack of PCC was more common in individuals who had no college education or did not report loss of libido. Compared to counseling by non-nephrologists, counseling that included a nephrologist were more likely to include discussions on birth control, future childbearing, medication safety, and fetal and maternal complications. Receipt of PCC improved patient's self-reported knowledge about preconception and pregnancy with CKD. (Figure 1)

Conclusions: Preconception counseling for reproductive-aged female patients remains suboptimal in CKD. The underlying causes of this insufficiency and inequity warrants investigation and intervention.



Effect of preconception counseling on concern and self-reported knowledge

Table 1: Crude and adjusted odds ratios for no inclusion of preconception counseling in care

	Crude OR (95% CI)	Adjusted OR (95% CI)
Ethnicity (Not Hispanic as referent)	2.0 (0.8, 5.1)	1.9 (0.6, 5.5)
Education Level (Some College as referent)	**2.9 (1.0, 8.0)**	1.7 (0.5, 5.7)
Insurance (Private or Self-Pay as referent)	2.3 (0.9, 5.8)	1.9 (0.6, 5.6)

Fertility, Sexual Function, and Endothelial Health in Premenopausal Women with Kidney Diseases

Angie S. Lobo,[1] Lisa E. Vaughan,[2] Vesna D. Garovic,[2] Andrea G. Kattah.[2]
[1]University of Minnesota Twin Cities, Minneapolis, MN; [2]Mayo Clinic Minnesota, Rochester, MN.

Background: Women with advanced chronic kidney disease (CKD) face reproductive health challenges, including reduced fertility, sexual dysfunction, and increased pregnancy risks. This study examined changes in sex hormones with CKD progression and their correlation with sexual function.

Methods: This study recruited women aged 18-51 with CKD stages 3b-5 from nephrology clinics and dialysis units. Exclusions included active pregnancy, menopause, prior hysterectomy/bilateral oophorectomy, or hormonal contraceptive/therapy use. Demographics, clinical characteristics, female sexual function index (FSFI) surveys, and hormone levels were collected at enrollment. Comparisons across CKD stages used Kruskal-Wallis or Chi-square tests, and associations between sex hormones and sexual function were evaluated using Spearman's correlation coefficients.

Results: Thirty-eight subjects were enrolled in the trial (8 in CKD stage 3b, 10 in CKD stage 4, and 20 in CKD stage 5/5D). Patient characteristics are detailed in Figure 1. Patients in more advanced CKD stages had significantly higher blood urea nitrogen (BUN) and prolactin levels, and lower hemoglobin levels, compared to those in CKD stage 3b ($p<0.05$ for all). Significant negative correlations existed between prolactin levels and desire, arousal, lubrication, orgasm and total FSFI score ($P<0.05$ for all, data not shown).

Conclusions: This study highlights major reproductive health challenges in women with advanced CKD, including progressive hormonal imbalances. Women in later stages of CKD had higher levels of BUN and prolactin, and lower hemoglobin levels, indicating more severe disease and its impact on reproductive health. Further research is needed to develop effective strategies to improve the quality of life for women with CKD.

The TIMING Study: Patients' and Clinicians' Perspectives on Reproductive Health Care and Autosomal Dominant Polycystic Kidney Disease

Margriet Gosselink,[1] Robin Mooren,[1] Rozemarijn Snoek,[1] Neeltje Crombag,[1] Paul Vos,[2] Mandy G. Keijzer-Veen,[1] Albertien M. van Eerde,[1] Titia Lely.[1]
[1]Universitair Medisch Centrum Utrecht, Utrecht, Netherlands; [2]Haga Ziekenhuis, Den Haag, Netherlands.

Background: Family planning and reproductive care are essential yet complex aspects of lifecycle management for individuals with Autosomal Dominant Polycystic Kidney Disease (ADPKD), given the potential genetic transmission and pregnancy-related complications. This qualitative study studied the experiences and perspectives of ADPKD patients and clinicians to identify areas for potential improvement in reproductive lifecycle care.

Methods: Focus group discussions were conducted in the Netherlands with ADPKD patients, both men and women, who had children through varied reproductive choices, and clinicians, including (pediatric) nephrologists, obstetric gynecologists, geneticists. Thematic analysis, utilizing a grounded theory approach, was performed on verbatim transcriptions of recordings, followed by consensus discussions to finalize themes.

Results: Nine focus groups involving 31 participants (16 patients and 15 physicians) identified six key themes. These included the need for timely and comprehensive information dissemination, understanding patient-specific decision-making factors, improving tailored psychosocial guidance and communication, the need for systematic efforts to take care of missed (minor) at-risk patients, addressing inequities in access to care, and improving multidisciplinary collaboration.

Conclusions: This study represents the first qualitative study of patient and physician perspectives on reproductive lifecycle care for ADPKD. We present valuable insights into factors influencing patients' reproductive decision-making, a comprehensive comparison between the perspectives of patients and clinicians on family planning, and follow-up care of minors at risk for ADPKD, and recommendations for enhancing overall care quality. Incorporating these insights into clinical care could enhance patient-centered care and foster interdisciplinary collaborations to further improve the quality of reproductive healthcare services for individuals with ADPKD.

Unplanned Pregnancy in Women with Lupus Nephritis Is Common and Is Associated with Poor Fetal Outcomes

Hannah K. Beckwith,[1,2] Hannah R. Wilson,[2] Tabitha Turner-Stokes,[2,1] Marlene Pluess,[1,2] Marie B. Condon,[1] Tom Cairns,[1] Philip Webster,[1] Liz Lightstone.[2,1]
[1]Imperial College Healthcare NHS Trust, London, United Kingdom; [2]Imperial College London, London, United Kingdom.

Background: Lupus Nephritis (LN) is a frequent organ manifestation of Systemic Lupus Erythematous among women of childbearing age. Whilst disease activity is known to correlate negatively with pregnancy outcomes(1), the frequency of unplanned pregnancies in people with LN and subsequent maternal-fetal outcomes have not yet been reported.

Methods: All women <35yrs at the time of diagnostic renal biopsy at our centre (01/01/1996-31/12/2016) were included in the study. Our standard practice is to offer pre-pregnancy counselling (PPC). Case notes were manually reviewed and clinical and biochemical data extracted. Pregnancies prior to LN diagnosis were excluded. Pregnancies were considered unplanned when: a. PPC had not occurred or b. teratogenic medication(s) were used peri-conception or c. when pregnancies were reported as unintended.

Results: There were 179 pregnancies in 87/201 women (43%). The median length of follow up was 14.2 years (range 9.4-19.5). 37/179 (21%) pregnancies were unplanned and 128/178 (72%) pregnancies* resulted in a live birth. Unplanned pregnancy resulted in significantly worse fetal outcomes (Table 1) and 50% of unplanned pregnancies did not progress >20 weeks gestation (P=0.0004). 25/201 women (12%) sought help for primary or secondary infertility following a diagnosis of LN and 3 were diagnosed with premature ovarian failure (1.5%).

Conclusions: This study is the largest single centre cohort of LN pregnancies reported to date. Planned pregnancies have excellent outcomes, however 1 in 5 pregnancies are unplanned: these are associated with poor fetal outcomes and high rates of pregnancy loss.

Kidney Disease in Pregnancy and Associated Maternal Outcomes

Cynthia Chalk, Bruce F. Folck, Lue-Yen Tucker, Aida Shirazi, Ali Poyan-Mehr.
Kaiser Permanente, San Francisco, CA.

Background: Maternal hypertension and CKD have increased over the last thirty years. In this study, we evaluate the prevalence of CKD as defined by GFR and proteinuria at the time of pregnancy and its impact on maternal outcomes during pregnancy.

Methods: We identified 353,735 adult female members of an integrated healthcare system who had one or more pregnancies from 1/2011 to 6/2023. We stratified the cohort into KDIGO's CKD subcategories and assessed the risk of maternal and prenatal outcomes of patients with versus without CKD.

Results: We identified a substantial number of patients with CKD. Clinically and statistically significant differences in maternal and prenatal outcomes exist between those with CKD versus those without. (Please see images for results: Cohort Distrubution and Maternal and Prenatal Outcomes)

Conclusions: Understanding individual risks associated with maternal and prenatal outcomes is critical for CKD patients. Additional analysis is being conducted to define risk in individual CKD subgroups and additional predictors of outcome such as comorbidities, age, and ethnicity.

			Proteinuria Categories			
			ACR (mg/g) < 30 mg/g Dipstick negative Or UPCR <0.2 g/g	ACR (mg/g) 30-300 Or dipstick trace to 2+ Or dipstick 30-100 UPCR 0.2-0.5 g/g	ACR (mg/g) > 300 Or dipstick > 2+ Or dipstick >100 Or UPCR >0.5 g/g

Effective Management of Gitelman Syndrome with Amiloride during Pregnancy and Breastfeeding: A Case Report

Abdelrahman Ibrahim, Christof Westenfelder, Aylin R. Rodan, Laith Al-Rabadi.
University of Utah Health, Salt Lake City, UT.

Background: Gitelman Syndrome (GS) is an autosomal-recessive tubulopathy marked by hypokalemia, hypomagnesemia, metabolic alkalosis, hyperreninemic hyperaldosteronism, and normotension. Managing GS during pregnancy and lactation is challenging due to physiological renal changes and concerns about the teratogenicity of conventional treatments.

Methods: We document the case of a 20-year-old pregnant female diagnosed with GS, which was characterized by persistent hypokalemia and hypomagnesemia despite oral supplementation. Genetic testing confirmed GS through the identification of two pathogenic mutations in the SLC12A3 gene. Due to inadequate control with supplementation alone, amiloride was initiated and adjusted during pregnancy and postpartum periods. In this specific instance, the use of amiloride managed the patient's electrolyte imbalances effectively, without observable adverse effects on the neonate.

Results: The patient's treatment comprised the administration of amiloride, along with potassium and magnesium supplements. Initially, amiloride was paused during the first trimester and resumed thereafter. Post-delivery, amiloride was temporarily halted during the initial weeks of breastfeeding and reintroduced due to persistent hypokalemia. Monitoring indicated no significant electrolyte disturbances in the neonate directly attributable to amiloride.

Conclusions: While the extant literature about the use of amiloride during pregnancy is limited, this case highlights amiloride as a potential and viable option, under specific conditions, for managing electrolyte imbalances in GS during pregnancy and breastfeeding. It controlled persistent hypokalemia and hypomagnesemia effectively, with no significant adverse effects observed in the mother or infant. This report supports the consideration for cautious, heavily monitored use of amiloride in similar clinical scenarios. Nevertheless, further studies are recommended to thoroughly evaluate its safety and efficacy during pregnancy and lactation.

SA-PO1051

Assessment of Obstetric and Kidney Outcomes in Women Who Underwent Hemodialysis during Pregnancy in Brazil

Fernanda B. Roberto, Carlos A. Balda, Gianna Mastroianni-Kirsztajn.
Universidade Federal de Sao Paulo Escola Paulista de Medicina, Sao Paulo, Brazil.

Background: Pregnant women with renal disease have worse obstetric outcomes than their healthy pairs, and risks are greater when dialysis is needed. Our main goal is to analyze maternal, fetal and renal outcomes of pregnant women who performed hemodialysis (HD) sessions due to acute kidney injury (AKI) or chronic kidney disease (CKD) during their hospital stay.

Methods: Single center retrospective observational study conducted to assess the features of pregnant women with CKD or AKI who needed HD and were followed by the Nephrology department of UNIFESP-EPM during the years between 2005-2019. These patients were compared between each other and sorted in three groups: AKI, non-dialytic CKD (NDCKD) and end-stage renal disease (ESRD).

Results: Our sample consisted of 36 pregnant women. Overall, 10 (27.8%) women presented with AKI, 14 (38.9%) with NDCKD and 12 (33.3%) with ESRD. Demographic data were similar between the groups, with a mean age of 30,7 years. All of the women in the AKI group dialyzed in the puerperium, while all the women in de NDCKD group started dialysis during pregnancy, with 69.2% starting in the 2nd trimester, and 60% of the ESRD women increased their dialysis schedule in the 1st trimester. Preeclampsia was more common in patients with AKI (50%) comparing to patients with NDCKD (27.3%) or with ESRD (no cases described). Furthermore, 4 patients (40%) in the AKI cohort evolved to death and no patients in the CKD groups. Regarding the live birth rate, we found a 60% rate in the AKI group, 57.1% in the NDCKD group and 58.3% in the ESKD women. Concerning the prematurity, there was a 66.7% frequency in the AKI patients, 87.5% in the NDCKD women and 85.3% in the ESKD group, considering only the live newborns. In the three groups, we did not find any statistical difference concerning the fetal outcomes. In our research, the weekly dialysis time were related only to the birth weight of the newborns, in a way that, the longer the weekly dialysis time, the greater the birth weight ($p = 0.037$).

Conclusions: Pregnant women with AKI needed dialysis later (in the puerperium) and had greater mortality. The negative pregnancy outcomes were similar between the three groups and worse than the general Brazilian population. The longer weekly dialysis schedule was related to greater birth weight.

SA-PO1052

Addressing Hypertensive Disorders of Pregnancy through a Combined Renal-Maternal Fetal Medicine Clinic

Jaya S. Parulekar, Elizabeth Taber-Hight. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Pregnancy marks a thrilling yet precarious time for women with underlying renal disorders, marked by unique physiologic, immunologic, and hemodynamic changes. These changes, complicated by progression of chronic kidney disease (CKD) and development of hypertensive disorders of pregnancy (HDOP), can endanger mother and fetus if left untreated. Establishing interdisciplinary practices through co-management of CKD and HDOP by nephrologists and maternal fetal medicine (MFM) providers, thus, offers great potential. Through collaborative clinic visits with laboratory and blood pressure monitoring, our study aims to better understand and address gaps in maternal and fetal health outcomes when treating CKD and HDOP.

Methods: This retrospective study followed 24 pregnant patients establishing care in our combined Renal-MFM Clinic from September 2022-May 2024. Data encompassed demographics (age, race, zip code, and insurance), obstetric history, estimated gestational age (EGA) at consultation, timing of aspirin initiation, comorbidities, laboratory results, blood pressures, hospitalizations, and delivery outcomes, all cataloged in a Redcap database.

Results: Women aged 17-43 years (mean 31.3, median 32) were studied, of whom 54% were White, 29% Black, 8% Hispanic, and 4% Asian. Referrals spanned gestational ages between 9-36 weeks. Around 67% sought care for HDOP, 29% for CKD, 25% for proteinuria, and 13% for nephrolithiasis. Among HDOP cases, 59% had chronic hypertension, 29% chronic hypertension with superimposed pre-eclampsia, and 11% gestational hypertension. Of those with HDOP, 82% were treated with medications, of whom 29% required 2 or more agents to manage blood pressure. Beta-blockers were more frequently selected (used in 57% of patients, alone and in combination with other agents). Prophylactic low-dose aspirin commenced at 13.1 weeks EGA on average. Of the 18 patients who delivered during the study period, 11% had term deliveries, 44% early term, and 44% pre-term delivery, with 2 cases of fetal demise before 20 weeks EGA.

Conclusions: This initial study outlines baseline characteristics and outcomes for our combined Renal-MFM clinic. Future directions include evaluating optimal medication management for target blood pressure attainment, expanding patient recruitment statewide, and integrating pre-conception counseling into our combined clinic framework.

SA-PO1053

Pregnancy, Peritoneal Dialysis, and a Dive into Some Unchartered Territories

Randall R. Rainwater,[1] Salima Valiani,[1,2] Manisha Singh.[1,2] *[1]University of Arkansas for Medical Sciences, Little Rock, AR; [2]Dialysis Clinic Inc, Little Rock, AR.*

Introduction: Pregnancy with end-stage-kidney disease (ESKD) is challenging at all levels, even more so with peritoneal dialysis (PD). The pregnancy rate on peritoneal dialysis is about half that of patients on hemodialysis, and usually, all such patients are transitioned to hemodialysis to support better outcomes. There are only a few reported cases of pregnancy that were carried beyond 32 weeks' gestation on PD alone. We report such a case in a 41 yo Pacific islander woman with spontaneous conception and continuation on PD through pregnancy and postpartum, using Icodextrin when needed.

Case Description: We present a case of a 41-year-old pacific islander woman with ESKD secondary to ureteral reflux with multiple infections who had been on PD for over two years at the time of natural conception. As the pregnancy progressed, the need for better clearances arose, but the patient was adamant not to transition to hemodialysis due to her fear of blood infections and tunnel catheters. The patient is in the medical profession and would read up on her options. She was aware of the risks and benefits of the alternatives discussed, thus enabling us to carry out a genuinely patient-centered and patient-led plan. With the patient's consent and multiple discussions with our team, division, and the pharmacy medical liaison, at 30 weeks of pregnancy, her PD regimen was modified to include a 1.5-liter Icodextrin to support her adequacy and volume control. This adjustment aided in her pregnancy reaching a higher gestation age of 32w4d when she delivered a viable 1630g female infant with Apgar scores of 1 and 8 at 1 and 5 minutes after birth. Though our patient underwent a cesarean section, she stayed on PD by modifications as appropriate, given her residual renal function, diuretic use, and renal diet, not needing hemodialysis at any time.

Discussion: We present the challenges and report a successful outcome of such a pregnancy, along with the first off-label use of icodextrin in pregnancy. We opine that Icodextrin did not adversely impact the course; it helped carry the pregnancy forward a few more critical weeks. As far as we are aware, this is also the first case report of a pacific islander and only one of two cases of pregnancy on PD in women aged 40 and over.

SA-PO1054

Gestational Changes in eGFR among Patients with CKD

Sharon E. Maynard, Anam Ali, Shae Duka. *Lehigh Valley Health Network, Allentown, PA.*

Background: Chronic kidney disease (CKD) affects ~3% of women of childbearing age and is a risk factor for adverse pregnancy outcomes. In normal pregnancy, glomerular filtration rate (GFR) increases by 40-50%. Pregnant patients with CKD may have a blunted gestational increase in GFR. This study aimed to explore if lower baseline eGFR is associated with a lower gestational increase in eGFR among pregnant patients with CKD.

Methods: This was a single-center retrospective study of pregnant women age ≥18 who received care at a multidisciplinary high-risk obstetric nephrology clinic between 2011-2023. All subjects had CKD, defined as eGFR < 60 ml/min/1.73m2 or urine protein:creatinine ratio (UPCR) >150 mg/mg prior to pregnancy, or UPCR >300 mg/mg prior to 20 weeks gestation. eGFR was calculated using the 2021 CKD-EPI Cr equation. Baseline eGFR was calculated from the last serum Cr prior to and within 2 years of pregnancy. Gestational % change in eGFR was calculated from the baseline eGFR and the peak mid-pregnancy eGFR, measured between 13-28 weeks gestation. Pearson's correlation was used to assess the correlation between baseline eGFR and gestational change in eGFR.

Results: 47 patients were included in the study. 5 (10.6%) had diabetes mellitus, and 15 (31.9%) had chronic hypertension. At the initial prenatal visit, 41 (87.2%) had proteinuria, 13 (37.1%) had eGFR 30-59, and 2 (5.7%) had eGFR 15-29. Median eGFR prior to pregnancy was 91.2 ml/min/1/73 m2 (IQR 58.8-119.0), and median peak eGFR during pregnancy was 105.2 (IQR 59.6-133.9). The median absolute change in eGFR was 11 ml/min/1.73 m2 (IQR 3.9-18.6), and median percent change was +13% (IQR +4-26.9%). There was no correlation between baseline eGFR and gestational change in eGFR (Pearson correlation coefficient -0.065, p=0.6647). 18 patients (39.1%) developed preeclampsia.

Conclusions: We found no correlation between baseline eGFR and gestational change in eGFR in patients with CKD. Limitations included a small number of patients with very low eGFR. Our patients with CKD had a smaller gestational increase in GFR than has been reported in pregnant patients with normal kidney function.

SA-PO1055

Kidney Cortical Necrosis after Placental Abruption

Anthony T. Nguyen, Haiyan Zhang, Margaret Ivanov. *University of California San Diego, La Jolla, CA.*

Introduction: Renal cortical necrosis (RCN) is a rare cause of kidney failure related to obstetric complications such as sepsis, placental abruption, and eclampsia. Incidence of RCN in developed countries is low, accounting for <2% renal failure cases. Prognosis is poor due to abrupt renal function loss, but improving with wider availability of renal replacement therapy (RRT). We present a case of RCN after placental abruption with massive hemorrhage.

Case Description: A 39 year old G5P2122 woman at 32w6d gestation presented for vaginal bleeding. Upon EMS arrival she was found to have placental abruption, with 0.75L of blood loss en route to the OR for emergent C-section. An additional 2L blood loss was reported intraoperatively. Her postoperative course was notable for AKI and anuria. Due to high suspicion for RCN a MRI abdomen/pelvis was obtained showing renal cortical diffusion restriction (Fig 1) suggestive of RCN. Subsequent renal biopsy showed 30% overall patchy cortical infarct and ATN, 10% IFTA, with segmental glomerular TMA-like changes (Fig 2). After 18 days she remained anuric and RRT was initiated; she remains on hemodialysis 2 months later.

Discussion: Obstetric complications account for a majority of RCN cases, possibly attributed to a combination of hypoperfusion, endotoxin-endothelial injury, and vascular thrombosis. There are two histological patterns of RCN: diffuse and patchy. Differing recovery rates are associated with type of injury, with patchy RCN having a more favorable prognosis. Anuria develops in 70-80% of RCN cases. Early RRT initiation in RCN may help reduce hospital length of stay, but further studies are needed on whether it provides a mortality benefit. Prognosis remains poor with 38-56% of patients able to withdraw dialytic support several months after initiation.

T2-weighted MRI abdomen/pelvis comparing early changes in RCN Fig 1(a) versus a normal kidney Fig 1(b).
Fig 1(a) (arrow) showing a dark cortical rim of diffusion restriction and cortex/medullary separation seen in RCN

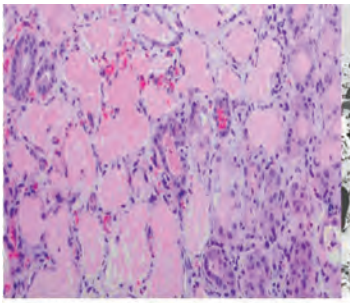

Figure 2(a) H&E staining showing patchy necrosis with areas of necrotic tubules as pink amorphous material

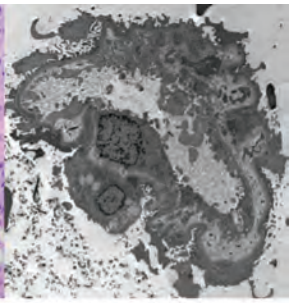

Figure 2(b) Electron microscopy showing glomerular TMA-like changes which can be seen with post-partum related RCN

SA-PO1056

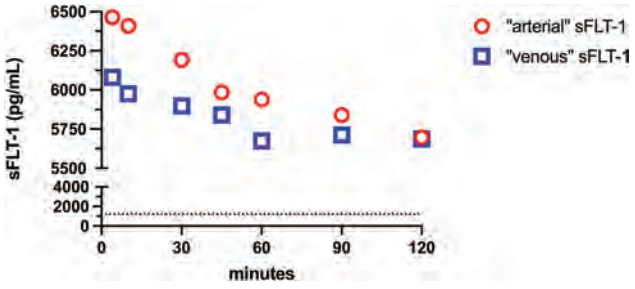
Seraph 100: A New Tool to Decrease Elevated sFlt-1 in Preeclamptic Plasma? An In Vitro Analysis

Amelie Gienapp, Kijanosh Lehmann, Torsten M. Meyer, Jan T. Kielstein. Kielstein Lab. *Stadtisches Klinikum Braunschweig gGmbH, Braunschweig, Germany*.

Introduction: There is an unmet need to treat pre-eclampsia. To reverse endothelial dysfunction caused by elevated soluble fms-like tyrosine kinase -1 (sFlt-1) and therefore antagonizing placental growth factor (PIGF), extracorporeal techniques have been tested including unselective therapeutiic plasma exchange (TPE) and specific adsorprive devices. Since sFlt-1 binds to heparin, we hypothesized that the Seraph® 100, that consists of small polyethylene beads with endpoint attached heparin, lowers sFlT-1.

Case Description: We used the plasma of a 33-year-old woman with severe preeclampsia during her 23rd week of gestation (blood pressure 190/110 mmHg, sFlT1/PIGF ratio 1433, platlets 36.000/µl, ALT 238 U/l). She and her son survived thanks to prolongation of the pregnancy by TPE. For the *in vitro* testing the Seraph® 100 was used in hemoperfusion mode. The Seraph® 100 adsorber clearance (CL) of sFlT-1 as calculated based on the plasma perfusion rate and extraction ratio (C_{pre} - C_{post}) / C_{pre}, using the equation $CL_{sFlT-1} = Q_e * (C_{pre} - C_{post}) / C_{pre}$, where Q_e is the effective plasma flow through the adsorber and C_{pre} and C_{post} are pre and post adsorber concentrations, respectively [Figure].

Discussion: *In vitro* the Seraph® 100 lowered sFlT-1 by roughly 12 % in the plasma of our patient. The median plasma clearance of the Seraph® 100 for sFlT-1 based on seven pre- and post Seraph® 100 plasma levels at a pump speed of 200 mL/min was 8.9 (0.4 – 13.5) mL/min. Interestingly the clearance decreased during the treatment, which could reflect saturation. of the device. A total amount of 3.5 µg sFlT-1 had been removed. Further data are needed to clarify whether the Seraph® 100 decreases sFlT-1 to a clinically relevant degree.



Serum levels of s-FLT-1 in a life size *in vitro* treatment with 4500 ml pre-eclamptic plasma using the Seraph® 100 on a Multifiltrate® Fresenius Medical Care machine in hemoperfusion mode at a pump speed of 200 mL/min for 120 min. "Arterial" levels refer to the plasma before entering the Seraph® 100 "Venous" levels refer to the plasma leaving the Seraph® 100.

SA-PO1057

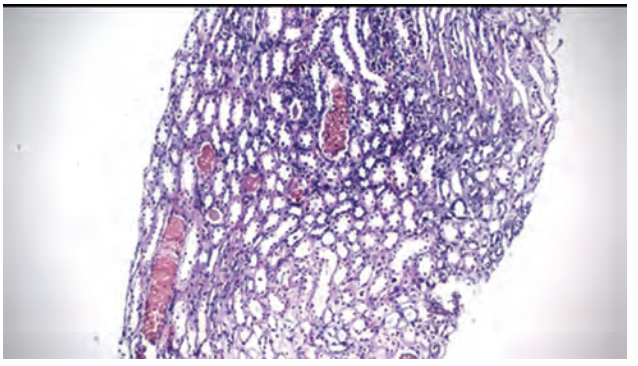
Kidney Involvement in Plasmodium falciparum Infection in a Pregnant Patient

Enzo C. Vasquez Jiménez,[1] Sabrina V. Castillo,[1] Virgilia Soto,[2] Octavio R. Garcia-Flores.[1] *[1]Hospital Juarez de Mexico, Mexico City, Mexico; [2]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico City, Mexico.*

Introduction: In Mexico, cases of malaria are becoming more frequent due to the effects of global warming and the migratory phenomenon. There are various mechanisms that can cause AKI in patients with *P. falciparum* infection: due to a hemodynamic effect associated with parasitemia, parasite sequestration, endothelial dysfunction, intravascular hemolysis, oxidative stress and immunological damage.

Case Description: A 29-year-old pregnant woman from Equatorial Guinea was admitted with abdominal pain, jaundice and fever, anemia (8.9 g/dL), thrombocytopenia ($10x10^9$ /L), hyperbilirubinemia (21 mg/dL), direct bilirubin (15 mg/dL), BUN (21 mg/dl), Cr (0.7 mg/dl). At the time of admission, the patient was 17.5 weeks of pregnancy. Urinalysis showed granular and biliary casts. Diagnosis was confirmed by a thick blood smear and a real-time PCR assay; therefore, antimalarial treatment were started. During stay in the ICU, mechanical ventilation, norepinephrine and CRRT were started due to neurological deterioration, hypotension and severe AKI (creatinine 3.7 mg/dL and anuria). Kidney biopsy was performed due to AKI and a urinary P/C ratio of 4 g/g and revealed an active tubulointerstitial nephritis with acute tubular lesion and pigment tubulopathy with negative IF. Recovery of kidney function was observed and follow-up was carried until the successful resolution of the pregnancy withouth deterioration in kidney function or proteinuria.

Discussion: Malaria is a serious disease in pregnant women. The indications for RRT in pregnant patients with AKI are similar to the general population. However, the thresholds are controversial due to the importance of maintaining an environment without uremia and acidosis to reduce fetal complications. The decision to perform a kidney biopsy in a pregnant patient is less clear and in this case a malaria manifestation was observed. Fortunately, the patient recovered kidney function after specific antimalarial treatment and completed her pregnancy without complications.



SA-PO1058

Lupus Nephritis Masquerading as Preeclampsia: A Treatment Dilemma

Samiya Yasin, Fatima Khalid, Akinwande A. Akinfolarin. *Baylor Scott & White Health, Dallas, TX*.

Introduction: Systemic Lupus Erythematosus (SLE) increases pregnancy related maternal and fetal risk when compared to healthy women. Active disease has been associated with poorer pregnancy outcomes. Differentiating between active lupus nephritis (LN) and preeclampsia is a diagnostic challenge making management difficult.

Case Description: A 21-year-old female was diagnosed with SLE, eight months prior to presentation. She had been on Cellcept which was discontinued at conception. She was admitted at 22 weeks of gestation with abdominal pain, nausea and vomiting. Vital signs were significant for BP of 166/110 mmHg. Physical examination revealed malar rash, mid epigastric tenderness but no peripheral edema. Laboratory data was significant for hemoglobin 9.2 g/dl, platelet count 83 K/uL, Creatinine (Cr) 1.17 mg/dl (baseline 0.6), serum albumin 3.2 g/dl and normal liver enzymes. Urinalysis revealed RBC > 100/hpf, WBC 100/hpf, 3 + proteinuria. A 24-hour urine protein/creatinine ratio was 2.6 g. Serologic work up revealed elevated antinuclear antibody (ANA) titer 1: 1280 and low complement C4 level. Serum Uric acid level was normal. Antineutrophil cytoplasmic antibodies (ANCA), anti-double stranded DNA (dsDNA), anti-Glomerular Basement Membrane Antibody (Anti-GBM), HIV, hepatitis panel, Antibody to SSA-Ro and SSB-were negative. She was initiated on therapy for a LN flare with hydroxychloroquine and prednisone. However, she had clinical and laboratory deterioration with large pleural effusion, pulmonary edema, worsening liver and kidney function and anemia requiring packed RBC transfusions. A kidney biopsy could not be safely done. A suspicion of preeclampsia was entertained and a 24-hour urine calcium collection was 14 mg/d confirming the diagnosis. She was treated with betamethasone, magnesium sulfate and underwent an urgent cesarian section. Subsequently, her renal function and hematologic parameters improved. A subsequent renal biopsy showed mesangial proliferative lupus nephritis class II for which she received Cellcept therapy.

Discussion: Active LN can mask the presentation of preeclampsia making diagnosis challenging due to the similarity of symptoms and laboratory features. A renal biopsy can clarify these differences; however, it is usually avoided during pregnancy. A high index of suspicion can help clarify this diagnostic and treatment dilemma which can otherwise be life threatening.

SA-PO1059

Navigating Recurrent Immune-Mediated Thrombotic Thrombocytopenic Purpura (iTTP) in Pregnancy: A Case Report

Niloufar Ebrahimi, Mohadese Golsorkhi, Sayna Norouzi, Amir Abdi Pour. Postdoctoral Scholar Research Program. *Loma Linda University, Loma Linda, CA.*

Introduction: Thrombotic thrombocytopenic purpura (TTP) is a rare and potentially fatal condition characterized by thrombocytopenia and microangiopathic hemolytic anemia. Primarily affecting women of childbearing age, pregnancy is a significant precipitating factor for TTP. The condition's symptoms often overlap with other pregnancy-related disorders, such as pre-eclampsia or HELLP syndrome, making accurate diagnosis particularly challenging.

Case Description: A 32-year-old woman, gravida 2 para 1, with a body mass index of 39, presented at 11 weeks gestation with a syncopal episode following a blood draw, along with petechiae, bruising, and thrombocytopenia. Her obstetric history includes a similar clinical presentation during her first pregnancy three years earlier, initially diagnosed as HELLP syndrome, necessitating the emergent delivery of a healthy baby at 34 weeks gestation. However, persistent postpartum thrombocytopenia led to further investigation and a definitive immune TTP (iTTP) diagnosis due to anti-ADAMTS-13 antibodies. She was successfully treated with plasma exchange (PLEX) and high-dose steroids at that time. She remained in remission on low-dose steroid, which eventually was tapered off. In her current pregnancy, she experienced a recurrence of iTTP at 11 weeks GA, notably earlier than her previous episode. Laboratory evaluations showed a platelet count of 41,000/μL, anemia (Hb=8.3 g/dL), elevated lactate dehydrogenase (LDH=400 U/L), normal creatinine, and scant schistocytes on the blood smear. Given her medical history, prednisone and PLEX were initiated. Following three PLEX sessions, her thrombocytopenia and clinical signs resolved, and her platelet count increased to 298,000/μL. The patient was subsequently discharged in a stable condition.

Discussion: The incidence and frequency of iTTP increase during pregnancy and can often be misdiagnosed as severe preeclampsia or HELLP syndrome. Plasma-based therapies have significantly improved the prognosis for these patients. Additionally, serial evaluation of ADAMTS-13 activity is recommended both at the preconception stage and throughout pregnancy for women with a history of TTP. This case emphasizes the critical need for heightened awareness and vigilance for TTP relapse during pregnancy.

SA-PO1060

The Proteinuria Puzzle of Pregnancy: Membranous Nephropathy Unmasked

Sandeep Kaur, Ratib T. Mahfouz, Snigdha Reddy. *Henry Ford Hospital, Detroit, MI.*

Introduction: The evaluation of proteinuria in pregnancy can be a challenge. While proteinuria is commonly associated with conditions like pre-eclampsia during pregnancy, it is important to recognize that there can be other underlying causes as well. Membranous nephropathy is one such cause.

Case Description: In this case, a 23-year-old female G5P1031 with a family history of IgA nephropathy presented at 36 weeks of gestation due to oligohydramnios. On admission, she displayed elevated blood pressure (146/82 mmHg) accompanied by headaches, along with facial and leg swelling persisting for several months. Further investigation revealed significant proteinuria, indicating nephrotic syndrome. Tests showed a notably high urine protein to creatinine ratio 11 mg/mg. Diagnosis of pre-eclampsia with severe features was made, necessitating induced labor. Post-delivery, the patient continued to exhibit nephrotic-range proteinuria. Serum albumin level was low 2.5 g/dL, prompting additional tests that revealed elevated phospholipase A2 receptor (PLA2R) level 17 RU/mL with uptrend to 47 RU/mL. Subsequent kidney biopsy showed positive staining for PLA2R in the glomerular deposits (see figure 1), confirming the diagnosis of primary membranous glomerulopathy. Treatment commenced with ACE inhibitor, leading to favorable response characterized by decreasing PLA2R levels to <2 RU/mL and improved proteinuria.

Discussion: This case underscores the intricate relationship between pregnancy-related complications such as pre-eclampsia and underlying renal conditions like primary membranous nephropathy. Effective management requires a comprehensive approach addressing both maternal and fetal health considerations.

Placental Extracellular Vesicles from Preeclampsia Alter the Transcriptome of Murine Renal Proximal Tubule Epithelial Cells

Priyadarshini Pantham,[1,2] Jennifer N. Chousal,[1] Tyler Ostrander,[1,2] Scott A. Lindsay,[1,2] Anushka R. Edlabadkar,[1,2] Willi Cheung,[1,2] Subhashini Bolisetty,[3] Prabhleen Singh.[1,4] *[1]University of California San Diego, La Jolla, CA; [2]Sanford Consortium for Regenerative Medicine, La Jolla, CA; [3]University of Alabama at Birmingham, Birmingham, AL; [4]VA San Diego Healthcare System, San Diego, CA.*

Background: Preeclampsia (PE), a deadly hypertensive disorder of pregnancy, is associated with maternal kidney damage indicated by proteinuria, increased risk of chronic kidney disease, and cardiorenal syndrome. The placenta plays a key role in the etiology of PE and releases extracellular vesicles (EVs) containing RNA cargo into the maternal circulation throughout pregnancy, which can modulate distant organs including the maternal kidney. The role of renal proximal tubule epithelial cells (rPTECs) in the etiology of kidney damage and their interaction with placental EVs in PE has never been studied. We aimed to characterize the effect of human placental EVs isolated from PE pregnancies compared to normal pregnancies on the transcriptome of murine rPTECs.

Methods: Placental EVs (70-100nm) were isolated using size exclusion chromatography following placental explant culture from normal (n=3) or preeclamptic (n=3) pregnancies. Murine rPTECs were isolated from non-pregnant female mouse kidneys (n=2) and treated with normal or PE placental EVs on day 7 at a dose of $1x10^{10}$EVs/mL for 24 hours. RNA was isolated from murine rPTECs, RNA libraries were constructed using the KAPA RNA HyperPrep Kit, and RNA-Seq was performed (Illumina NovaSeq X Plus). Reads were aligned using STAR, gene abundances quantified using RSEM, and differential expression analysis was conducted using DESeq2.

Results: An average of $41x10^6$ reads per sample was obtained, and >5000 transcripts were dysregulated in murine rPTECs treated with EVs from PE compared to normal pregnancies (FDR<0.001, Figure 1). Analysis of molecular pathways using gProfiler showed that these transcripts were significantly enriched for mRNAs involved in oxidative phosphorylation (42 mRNAs, FDR<0.01).

Conclusions: We have shown that placental EVs isolated from PE pregnancies alter the transcriptome of murine rPTECs, particularly in transcripts involved in mitochondrial electron transport. Current efforts are aimed at measuring mitochondrial oxygen consumption in proximal tubules isolated from pregnant mice injected with placental EVs from PE and normal pregnancies, to establish whether increased oxidative stress in rPTECs plays a key role in inducing the kidney damage seen in PE.

Perinatal Outcomes and Risk Factors for Fetal Growth Restriction in Kidney Transplant Recipients: A Retrospective Cohort Study

Nada Alamri,[1] Hatoon Altaifi,[2] Hassan A. Aleid.[3] *[1]Madinah Health Cluster, Ministry of Health, Madinah, Saudi Arabia; [2]Imam Abdulrahman Bin Faisal University, Dammam, Saudi Arabia; [3]King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia.*

Background: Pregnancy outcomes have significantly improved in women with end-stage renal disease following renal transplantation. Despite this, these women still face higher rates of adverse outcomes, including intrauterine growth restriction (IUGR). This study aims to report perinatal outcomes and identify risk factors for IUGR in kidney transplant recipients.

Methods: This retrospective cohort study included 40 women who conceived after receiving a kidney transplant. We compared pregnancies complicated by IUGR with those that had normal fetal growth, focusing on identifying significant risk factors.

Results: IUGR was identified in 8 (21%) cases, with fetal weight below the 10th percentile. Significant risk factors for IUGR included proteinuria (P = 0.03), nulliparity (P = 0.04), and age at the time of transplant (P = 0.03). No significant associations were found with anemia, hypertension, maternal age, or pre-pregnancy creatinine levels. Increased incidences of pre-eclampsia (40%), placental abruption (12.5%), preterm delivery (29%), and cesarean section (66%) were observed.

Conclusions: IUGR is a common adverse outcome among pregnant women post-renal transplantation. Proteinuria, nulliparity, and age at transplant are significant risk factors for IUGR. These findings highlight the importance of targeted monitoring and management in this high-risk population. Future research should include long-term pediatric follow-up to better understand the outcomes for children born to this group of women.

Maternal Kidney Disease and Offspring Neurodevelopmental Outcomes: A Nationwide Population-Based Study

Jeongin Song,[1] Seung hyun Han,[2] Sehoon Park,[3] Hajeong Lee.[3] *[1]Dongguk University Medical Center, Goyang, Gyeonggi, Republic of Korea; [2]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea; [3]Seoul National University Hospital Department of Internal Medicine, Jongno-gu, Seoul, Republic of Korea.*

Background: Maternal immune activation, triggered by both acute and systemic chronic inflammation, is considered a predisposing factor for offspring neurodevelopmental conditions. However, there is no data about the effect of mothers' chronic kidney disease on their offspring's neurodevelopmental diseases.

Methods: We extracted the data on pregnant women from the National Health Information Database from 2008 to 2017 in South Korea. We categorized the subjects into four groups based on their pre-pregnancy kidney function: no CKD, CKD, kidney replacement therapy (KRT), and kidney transplantation (KT). The outcomes are defined as offspring's neurodevelopmental diseases, including motor and cognitive developmental delay, autism spectrum disorders, attention deficit hyperactivity disorder, tics, stereotypic behavior, and seizures based on ICD-10-CM codes.

Results: A total of 3,794,031 children were born to 2,680,092 mothers during the study period. We included 488,208 mothers without kidney diseases, 46,930 mothers with CKD, 49 mothers with ESKD, 187 mothers with KT, and 3,637,903 children after the exclusion of multiple pregnancies. Mothers with CKD, KRT, and KT had older ages and more co-morbidities than those without. They suffered from more adverse pregnancy outcomes, such as preeclampsia, preterm birth, and placenta previa/abruption. Their offspring's neurodevelopmental disease occurred in 8.7%, 10.9%, 31.7%, and 16.3% of the no CKD, CKD, KRT, and KT groups, respectively. Mothers with CKD (adjusted OR [95% CI]: 1.29 [1.26-1.33], p<0.001), KT (1.87 [1.28-2.65], p=0.001), and ESKD (3.73 [2.12-6.37], p<0.001) showed a higher risk of offspring's neurodevelopmental diseases even after adjusting for maternal age, nulliparity, underlying hypertension, smoking history, maternal BMI, gestational diabetes, preeclampsia, neonatal sex, preterm birth, and low birth weight.

Conclusions: In this nationwide cohort study, we first found that maternal pre-pregnancy kidney function was associated with offspring's adverse neurodevelopmental diseases in dose-responsive manners.

SA-PO1064

Association of Marital Status with CKD Progression and Mortality: Analyses from the CRIC Study

Karela B. Herrera-Enriquez,[1,2] Finnian R. McCausland.[1,2] *[1]Brigham and Women's Hospital Department of Medicine, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: Being married is associated with lower mortality among patients with several disease types. Whether marital status is associated with future risk of kidney failure among patients with chronic kidney disease (CKD) is not clear.

Methods: Using data from the Chronic Renal Insufficiency Cohort (CRIC; n=5,625), we explored the association of marital status (never, former, current) with a composite kidney outcome (≥50% decline in estimated glomerular filtration rate [eGFR], eGFR <15, transplant, or dialysis) and mortality. Unadjusted and adjusted Cox models were fit, adjusting for age, race, body mass index, education, income, systolic blood pressure, diabetes, myocardial infarction or revascularization, peripheral vascular disease, heart failure, current smoking status, eGFR, 24-hour urine protein, hemoglobin, serum albumin, and medications (beta-blocker, calcium blocker, ACEi or ARB, aspirin, statin, or diuretic). We also explored if associations differed according to sex.

Results: Mean age was 60 ±11 years; 44% were female; 43% self-reported as Black; baseline eGFR was 49 ±16 ml/min/1.73m2. At baseline 2,994 (53%) reported being married, 1,830 (33%) formerly married, and 801 (14%) never married. Over a median follow-up of 5.1 years, there were 1,501 (27%) kidney composite events and 1,890 (34%) deaths. In adjusted analyses, compared with never married, those currently married had a lower risk of the kidney composite (HR 0.80; 95%CI 0.66, 0.96) and all-cause mortality (HR 0.76; 95%CI 0.63, 0.91). The association of marital status with the kidney composite and death appeared to differ according to sex (P-interaction=0.16 and 0.04, respectively), such that lower risks were observed for males, versus females (Table 1).

Conclusions: Marital status is independently associated with a lower risk for adverse kidney outcomes and death among patients with CKD. These associations appeared to be most potent among male patients.

Table 1 Risk of outcomes according to marital status in sub-groups of females and males

Association between Health Literacy and Body Mass Index among Patients with CKD

You-Chi Chen,[1] Pei-Ni Hsiao,[2] Shang-Jyh Hwang,[1,3] Yi-Wen Chiu,[1,3] Yi-chun Tsai.[1,3] *[1]Division of Nephrology, Department of Internal Medicine, Kaohsiung Medical University Chung-Ho Memorial Hospital, Kaohsiung, Taiwan; [2]Department of Nursing, Kaohsiung Medical University Chung-Ho Memorial Hospital, Kaohsiung, Taiwan; [3]Faculty of Renal Care, Kaohsiung Medical University, Kaohsiung, Taiwan.*

Background: Patients with chronic diseases need to have sufficient health literacy to establish the ability of self-care. Variation of body mass index (BMI) has been related to chronic kidney disease (CKD) progression. Limited studies examined the association between BMI and health literacy in CKD patients. This study aims to explore the relationship between health literacy and BMI in CKD patients.

Methods: The cross-sectional study enrolled CKD patients in Interdisciplinary CKD Care Program conducted at Kaohsiung Medical University Hospital in southern Taiwan. Health literacy was measured at study interview using multidimensional health literacy questionnaire. The proposed scale covers the following five dimensions including accessing, understanding, appraising, applying health information, and communication and interaction. The total scores of health literacy was calculated as (the average scores of the sum of five dimensions -1)*50/3. According to the total scores, health literacy could be graded as inadequate (score range (SR): 0~25), limited/insufficient (SR: 26~33), sufficient (SR: 34-42), and excellent (SR: 43~50).

Results: Among 240 CKD patients, 33.4% had limited and insufficient health literacy. BMI was negatively correlated with total scores and five dimensions of health literacy

in multivariable linear regression (r: -0.25, p=0.02). Late CKD patients with high BMI had lower health literacy scores than early CKD patients with high BMI. CKD patients with high total scores of health literacy and accessing or applying health information had decreased risk of obesity (BMI > 27 kg/m^2).

Conclusions: The significant relationship between BMI and the grade of health literacy was found in CKD patients. Improvement of health literacy may assist in reducing the risk of obesity.

SA-PO1066

Association between Parity and Prevalence of CKD

Haeun Lee, Hee-Chan Moon, Ju hwan Oh, A young Cho, In O Sun.
Presbyterian Medical Center, Jeonju, Jeollabuk-do, Republic of Korea.

Background: Previous studies have demonstrated that women with a history of adverse pregnancy outcomes, such as eclampsia, are at increased risk of developing chronic kidney disease (CKD). However, only a limited number of studies investigated the association between parity and CKD. Under the assumption that physiologic and anatomic changes during pregnancy, such as in glomerular filtration rate, renal plasma flow, renin-angiotensin-aldosterone system and size of kidneys could impact on kidney, we investigated whether the number of parity affects the prevalence of CKD.

Methods: We analyzed the health examinee data from the Korean Genome and Epidemiology Study (KoGES-HEXA), which comprises participants from Korea between 2004 and 2013. After excluding individuals with histories of pre-existing CKD and participants with incomplete records, 100,433 participants were included in this study. CKD was defined as an estimated glomerular filtration rate below 60 mL/min/1.73 m^2, calculated using the CKD-EPI (Epidemiology Collaboration) formula or the presence of proteinuria. We compared the prevalence of CKD across four groups, categorized by the number of parity; 0, 1, 2, and ≥3.

Results: Women with 3 or more parities, compared to those with no parity, were older with more co-morbidities, less likely to smoke or drink, and had higher body mass index, elevated fasting blood sugar and low density lipoprotein cholesterol. CKD prevalence seemed higher in women with three or more parities than in no parity group (5.3% vs. 3.1%, *P*<0.05), but this association disappeared after adjusting for risk factors (**Figure 1**). Among women with a history of eclampsia, 1 and 2 parity groups showed higher risk of CKD compared to 0 parity group (**Figure 1**).

Conclusions: Exposure to eclampsia was associated with higher risk of CKD. On the other hand, parity may not independently affect the prevalence of CKD in Korean women. Further studies are needed to determine whether parity itself increases the prevalence of CKD.

Figure 1. Odds ratios and 95% confidence intervals for CKD based on the number of parity

Prognostic Influence of Physical Activity and Sedentary Behavior in Patients with CKD: The CKD-REIN Study

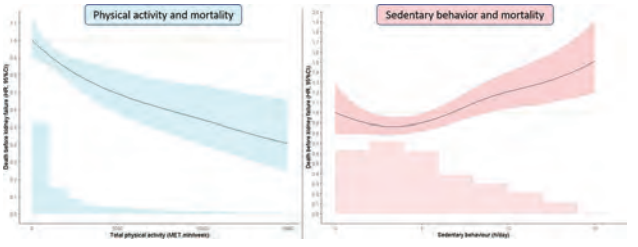
Aghiles Hamroun,[1,2] Raphael Bentegeac,[1,2] Natalia Alencar de Pinho,[3] Celine Lange,[4] Luc Frimat,[5] Denis Fouque,[6] Ziad Massy,[7] Benedicte Stengel,[3] Abdou Omorou.[5] *[1]Centre Hospitalier Universitaire de Lille, Lille, France; [2]Institut Pasteur de Lille, Lille, France; [3]Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; [4]Agence de la biomedecine, La Plaine Saint-Denis, France; [5]Centre Hospitalier Regional Universitaire de Nancy, Nancy, France; [6]Hospices Civils de Lyon, Lyon, France; [7]AURA Paris, Paris, France.*

Background: Although the benefits of adapted physical activity (APA) programs have been demonstrated, including among the population with chronic kidney disease (CKD), there is currently limited data on daily physical activity (DPA) in real life among these patients.

Methods: All patients included in the CKD-REIN prospective cohort (CKD stage 2-5) who completed the Global Physical Activity Questionnaire (GPAQ) at baseline were analyzed. The medical and psychosocial determinants of DPA were studied using a multivariable Poisson regression model. The associations between DPA, sedentary behavior and the risks of kidney failure and all-cause mortality were estimated using cause-specific Cox models adjusted for age, sex, CKD characteristics, medical history, and lifestyle factors. The variables for DPA and sedentary behavior were modeled both continuously (using restricted cubic splines) and categorically, in accordance with recommendations.

Results: Within the 2528 patients included (65% male, median age 69 years, median GFR = 32.8 mL/min/1.73m^2), 48%, 25%, and 27% had low (< 600 MET.min/week), moderate (600-1500), and high (≥ 1500) DPA, respectively, defined by the WHO guidelines. Female sex, advanced age, obesity, and depression were significantly associated with lower DPA. We observed a strong linear association between the level of DPA and the risk of mortality in the fully adjusted models. Conversely, this risk increased non-linearly with the duration of sedentary behaviour per day (Figure 1). For instance, higher DPA was significantly associated with better survival (HR = 0.84 [0.66 to 1.07], HR = 0.63 [0.47 to 0.82] for moderate and high activity, respectively, compared to low activity, p for trend < 0.001), with no association with the risk of kidney failure. Conversely, sedentary behavior (> 9 hours/day) was independently associated with an increased risk of death (HR = 1.39 [1.17 to 1.66], p < 0.001).

Conclusions: Like APA, real-life DPA is associated with better survival among the population of patients with CKD, independantly of sedentary behavior.



SA-PO1068

Snoring and Self-Reported Apnea Are Risk Factors for Albuminuria and CKD: A Retrospective Data Analysis

Shruti Kore, Savneek S. Chugh, Sanjeev Gupta, George N. Coritsidis.
Westchester Medical Center Health Network, Valhalla, NY.

Background: Obstructive sleep apnea is a well-known cause of albuminuria. However, many patients are reluctant to undergo a sleep apnea study due to the time and effort involved, often requiring significant persuasion. It would be beneficial if there is some data to demonstrate to patients that snoring or episodes of sleep apnea are linked to chronic kidney disease. In this study, we present a retrospective data analysis comparing the effects of snoring and self-reported apnea episodes on albuminuria.

Methods: We conducted data analysis of a retrospective survey from 2017-2020 pre-pandemic using National Health and Nutrition Examination Survey (NHANES). We explored variables for sleep disturbance such as self-reporting snoring, and episodes of apena and compared it with Urine albumin and creatinine ratio (UACR). All the demographic variables were included for participants above 20 years of age and data was alanlyzed on 9,232 adults using Stata software.

Results: Episodes of apnea were seen higher in age group of 45-65 years (53.51%). Similarly, episodes of snoring seen higher in the same age group 50.48%, followed by 25.39 % in age group 20-40 years. Snoring and apneic events were higher in males 53.97% and 58.57 % respectively. About 58.42 % of individuals with episodes of apnea and 61.27 % with snoring slept between 7 to 9 hours. Unadjusted logistic regression for episodes of apnea showed 1.34 OR with p value 0.003 for UACR OF 30-299 mg, 1.77OR with p value of 0.002 for UACR of >300 mg/dl. Unadjusted logistic regression for snoring showed 1.19 OR with p value 0.011 for UACR OF 30-299 mg, 1.57 OR with p value of 0.002 for UACR of >300 mg/dl. When adjusted for diabetes and hypertension the results for episodes of apnea showed 1.04 OR for 30-299mg/dl, 1.15 OR for >300mg/dl.

Conclusions: Our study adds to the body of data that sleep disturbances are strongly associated with albuminuria and develpment of chronic kidney disease. We recommemd primary care physicians to check albuminuria in patients with history of snoring and episodes of sleep apnea with timely referral to nephrologist to improve Kidney health.

SA-PO1069

Impact of Smoking Status on Hemoglobin Levels and Progression of CKD in Patients in a Metabolic Disorder Cohort

Hoon Young Choi,[1,2] Hyo Jeong Kim,[1,2] Hyeong cheon Park.[1,2] *[1]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; [2]Gangnam Severance Hospital, Seoul, Republic of Korea.*

Background: Smoking has been known as one of the leading causes of preventable deaths worldwide. Smoking has also known as the risk developing chronic kidney disease (CKD). The hemoglobin level for incident CKD in metabolic patient groups can vary depending on various factors such as age, gender, the specific metabolic disorder, the

stage of CKD, and smoking status. This study investigated the relationship between hemoglobin levels and the progression of CKD depends on smoking status.

Methods: In the data from the medical records database in Gangnam Severance Hospital from 2006 through 2020, a longitudinal analysis included participants with CKD. Progression of CKD was defined by a reduction in the GFR ≥30% of baseline. Logistic regression analyses were used to determine the association between hemoglobin level and progression of CKD according to smoking status by adjusting for the influence of confounders.

Results: The study included 4,176 patients, of whom 986 had smoking status. Mean hemoglobin levels were 13.7 ± 1.9 g/dl (non-smoker) and 14.2 ± 1.9g/dL (smoker) according to smoking status. Among non-smoker, highest and second highest quartiles of hemoglobin levels was decreased with the risk progression of CKD [OR 0.664, OR 0.405, P<0.001] after adjusting for age, sex, hypertension status, diabetes status, and alcohol status. However, the risk progression of CKD was significantly decreased only in the second highest quartile of hemoglobin levels among smoker [OR 0.669, P=0.017].

Conclusions: Our study provides evidence that smoking is associated with elevated hemoglobin levels, and hemoglobin levels may have varying implications for CKD progression depending on smoking status.

SA-PO1070

Baseline and Longitudinal Self-Reported Physical Function and Important Clinical Outcomes in CKD

Sarah J. Schrauben,[1] Vanessa-Giselle Peschard,[2,3] Rebecca T. Brown,[1] Xiaoming Zhang,[1] Michael Shlipak,[2] Navdeep Tangri,[4] Wei Yang.[1]
[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]San Francisco VA Health Care System, San Francisco, CA; [3]UCSF Medical Center, San Francisco, CA; [4]University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada.

Background: Physical function is essential for independent living and good health. However, it's evolution and association with important clinical outcomes is unknown among people with CKD. We aimed to describe self-reported physical function over time and its relationship to heart failure events, incident end-stage kidney disease (ESKD), and death in a CKD cohort.

Methods: Using annual data from the prospective CRIC Study, we calculated the physical composite summary (PCS) score from the SF-12 survey, a validated summary measure of physical health (range, 0-100, higher scores indicate better function). Linear regression models were used to calculate yearly PCS change for each participant using annual PCS scores from baseline to year 3 visits. After the year 3 visit, Cox models were used to examine the association of baseline PCS score and yearly PCS change with incident heart failure, incident ESKD and death. We also assessed effect modification by age, sex, race, and eGFR groups.

Results: Among 5,495 CRIC participants at baseline, mean age was 60 yrs, 42.7% were non-Hispanic Black, 51.5% had diabetes and mean eGFR was 48.1 ml/min/1.73^2. Median (IQR) follow up was 9.4 (7.6-16.8) yrs. Mean (SD) PCS yearly change in the first 3 yrs was -0.17 (3.99). Lower baseline PCS and declining PCS slope were associated with 20-29% increased risk of incident heart failure and death and declining PCS slope was associated with 11% increased risk of incident ESKD (Table). Interactions were found for PCS-12 slope decline between eGFR groups and incident heart failure (HR for eGFR ≥30: 1.21, 95% CI: 1.05-1.39; HR for eGFR <30: 0.82, 95% CI: 0.61-1.09), and between race groups and ESKD (HR for Non-Hispanic White group: 1.09, 95% CI: 0.91-1.31; HR for Non-Hispanic Black group: 0.99, 95% CI: 0.87-1.13; HR for Hispanic group: 1.45, 95% CI: 1.09-1.93).

Conclusions: Baseline and longitudinal changes in self-reported physical function were associated with important clinical outcomes in CKD, highlighting the importance of monitoring self-reported physical function over time in CKD care to identify those at risk and who may benefit from early and targeted interventions.

Funding: NIDDK Support

	Incident Heart Failure	Incident ESKD	Death
	HR (95% CI)	HR (95% CI)	HR (95% CI)
Baseline PCS per 10-unit decrease	1.20 (1.05-1.37)	0.99 (0.92-1.07)	1.29 (1.22-1.36)
PCS yearly change per 1-SD decline	1.20 (1.01-1.44)	1.11 (1.01-1.32)	1.22 (1.13-1.32)
Adjusted for: age, sex, race, smoking, diabetes, cardiovascular disease, systolic blood pressure, body mass index, eGFR, urine protein, baseline PCS, and recruitment site			

SA-PO1071

Metabolic Risk Factors, Genetic Risk Score, and Risk of Incident CKD

Ga Young Heo, Hyung Woo Kim, Jung Tak Park, Tae-Hyun Yoo, Shin-Wook Kang, Seung Hyeok Han. *Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea.*

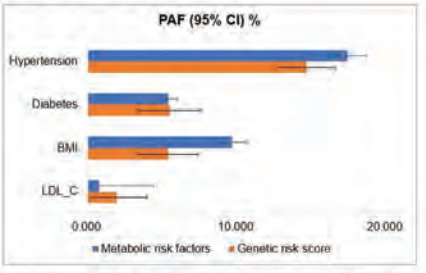
Background: Multiple modifiable risk factors are associated with chronic kidney disease (CKD). However, the combined effect of metabolic risk and genetic risk on CKD remains unexplored.

Methods: This study investigated the association between metabolic risk factors (Obesity, high low-density lipoprotein cholesterol [LDL-C], hypertension, diabetes), genetic risk score and incident CKD, using data from UK Biobank. We used polygenic risk scores (PRS) for hypertension, diabetes, body mass index (BMI), and LDL-C, utilizing PRS data by Genomics PLC as part of UK Biobank project. The primary outcome was the incident CKD. Cox proportional model were used and population attribution fraction (PAF) were analyzed in risk of CKD.

Results: This study included 171,955 participants, with a mean age 55.7 years and 86,153 (50.1%) being men. During the 12.8-year follow-up period, 8,641 incident CKD occurred. Prevalent hypertension exhibited the highest PAF at 17.4% (95% CI, 16.1, 18.7). Regarding the total CKD risk, 5.4% (95% CI, 5.0, 6.0) and 9.6% (95% CI, 8.7-10.7) were attributable to prevalent diabetes or obesity, respectively; while high LDL-C did not show significant attribution to CKD risk. Similar to the metabolic risk factors, PRS_hypertension, PRS_diabetes, and PRS_BMI contributed to CKD risk; PAF 14.7 (95% CI, 12.7-16.6), 5.5 (95% CI, 3.3-7.6), and 5.4 (95% CI,.3.4-7.4), respectively. The risk of CKD was more significantly attributable to hypertension in the high PRS_hypertension and PRS_diabetes group. Prevalent diabetes, and obesity were more significantly attributed to the risk of CKD in the highest quintile of PRS_hypertension.

Conclusions: In this prospective cohort study, both metabolic risk factors and genetic risk were contributed to the development of CKD, except LDL-C. Notably, in the genetically high-risk subgroup, metabolic risk factors showed a more pronounced and significant contribution to CKD risk.

Figure 1. Population attribution fraction of metabolic risk factors and genetic risk score for chronic kidney disease



Abbreviation PAF, population attribution fraction; BMI, body mass index; LDL-C, low-density lipoprotein cholesterol

SA-PO1072

CKD Awareness among US Adults by Kidney Disease: Improving Global Outcomes (KDIGO) Risk Classification

Jennifer L. Bragg-Gresham,[1] Jenna Kiryakos,[1] Michael Heung,[1] Tiffany C. Veinot,[2] Brenda W. Gillespie,[3] Hal Morgenstern,[3] William H. Herman,[1] Yoshihisa Miyamoto,[4] Fang Xu,[4] Rajiv Saran.[1] *[1]University of Michigan Medical School, Ann Arbor, MI; [2]University of Michigan School of Information, Ann Arbor, MI; [3]University of Michigan School of Public Health, Ann Arbor, MI; [4]Centers for Disease Control and Prevention, Atlanta, GA.*

Background: Nearly 1 in 7 U.S. adults have chronic kidney disease (CKD); however, 9 in 10 adults with CKD do not know of their diagnosis. Improving awareness is particularly important because newer therapies are now available that can significantly improve kidney and cardiovascular outcomes in these patients. We sought to quantify awareness of CKD by eGFR and albuminuria categories among adults with a focus on stages G1–G2 with albuminuria (A2–A3), an at-risk population for CKD progression and cardiovascular disease.

Methods: Using the National Health and Nutrition Examination Survey (2017–March 2020), CKD was based on the CKD-EPI 2021 formula and albuminuria testing (urine albumin to creatinine ratio) among U.S. adults aged ≥ 20 years (*N*=7,671). Awareness was defined as a self-reported affirmative response to the question "Have you ever been told by a doctor or other health professional that you had weak or failing kidneys?" Analyses accounted for complex survey design and weights.

Results: Awareness of CKD was markedly lower among adults in the earlier stages of CKD (Table), especially for those with A2 category of albuminuria with eGFR ≥ 60 ml/min/1.73m^2. Extrapolating to the US population, this represents over 18 million U.S. adults with CKD who are unaware of the disease. Adults with CKD G5 had the highest awareness, yet 15-25% (approximately 52,000 adults) were unaware.

Conclusions: While earlier stages of CKD (G1–G3) are more prevalent in the U.S. population than advanced stages (G4–G5), adults with early-stage CKD are much less likely to be aware of their diagnosis. Most adults with albuminuria and eGFR ≥ 60 ml/min/1.73m^2 are unaware of having kidney disease. A limitation is that this analysis uses single measurements of these kidney markers. Raising awareness of CKD in earlier stages of the disease through increase in screening among those with risk factors may help to prompt earlier implementation of preventive strategies and could be studied further.

Funding: Other U.S. Government Support

Awareness of CKD among adults with confirmed CKD based on laboratory testing, National Health and Nutrition Examination Survey 2017—March 2020

GFR categories (ml/min/1.73 m²)				Albuminuria categories		
				A1	A2	A3
				Normal to mildly increased	Moderately increased	Severely increased
				<30 mg/g (<3 mg/mmol)	30–300 mg/g (3–30 mg/mmol)	>300 mg/g (>30 mg/mmol)
	G1	Normal to high	≥90	1.12%	2.26%	4.26%
	G2	Mildly decreased	60–89	2.53%	7.32%	29.42%
	G3a	Mildly to moderately decreased	45–59	15.17%	22.58%	21.36%
	G3b	Moderately to severely decreased	30–44	31.47%	46.94%	41.12%
	G4	Severely decreased	15–29	24.90%	62.86%	83.35%
	G5	Kidney failure	<15	NA	76.23%	84.84%

*Green=Low risk; Yellow=Moderately increased risk; Orange=High risk; Red=Very high risk

SA-PO1073

Screening Programs for Early Detection of CKD: A Systematic Literature Review

Pamela R. Kushner,[1] Christian W. Mende.[2] [1]*University of California Irvine, Irvine, CA;* [2]*University of California San Diego, La Jolla, CA.*

Background: Early detection of chronic kidney disease (CKD) allows intervention to delay progression and other adverse outcomes. Kidney Disease: Improving Global Outcomes (KDIGO) guidelines advise screening high-risk groups with albumin-to-creatinine ratio (ACR) and estimated glomerular filtration rate (eGFR); diagnostic if abnormality in one/both for ≥ 3 months. We investigated CKD screening programs in the US, Canada, Australia, and UK.

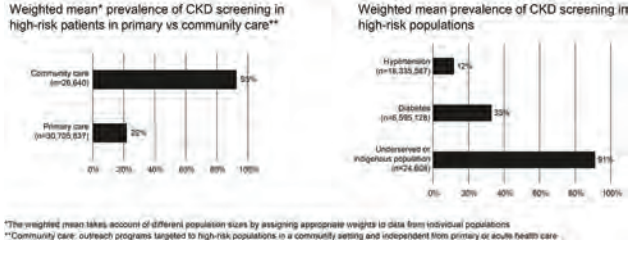
Methods: Systematic literature review (SLR) of CKD screening programs in patients with diabetes and/or hypertension between Jan 2018 – Oct 2023.

Results: Of 2361 records screened, 52 full-text reports were assessed, and 23 publications (of 21 studies) included. In addition to diabetes and/or hypertension (13 studies), high-risk groups included indigenous populations (4 studies), underserved areas (3 studies) and older population (1 study). Of the 21 studies, 5 reported screening prevalence and 16 described screening programs. Also, 7 studies reported 1 test (ACR or eGFR), 9 used ACR + eGFR, 5 used ACR + serum creatinine. Of the 16 screening programs, 9 were in community care and 7 in primary care. Prevalence (mean weighted) of screening in high-risk patients was 4-fold greater in community vs. primary care. Low screening rates were reported for patients with hypertension and diabetes (Fig. 1). Of 10 studies reporting assessment frequency, only 3 repeated ACR within 1 year.

Conclusions: This SLR suggests a low prevalence of CKD screening of high-risk patients, particularly in primary care. Contrary to KDIGO guidelines, approximately one-third of studies performed incomplete screening (only 1 test); follow-up testing was infrequent or not reported. Inadequate testing for CKD and lack of adherence to KDIGO guidelines are delaying CKD diagnosis and appropriate early therapy.

Funding: Commercial Support - Boehringer Ingelheim Pharmaceuticals, Inc. (BIPI) & Lilly, USA LLC

Fig. 1: Prevalence of CKD screening in high-risk patients



*The weighted mean takes account of different population sizes by assigning appropriate weights to data from individual populations
**Community care: outreach programs targeted to high-risk populations in a community setting and independent from primary or acute health care

SA-PO1074

Hypertensive Patients Should be Routinely Screened for CKD

Adi Leiba,[1,2] Avital Angel-Korman.[1,2] [1]*Assuta Ashdod Hospital, Ashdod, Israel;* [2]*Ben-Gurion University of the Negev Faculty of Health Sciences, Beer-Sheva, Israel.*

Background: Hypertension is a well-established risk factor for CKD, but awareness for early detection of CKD especially among non-diabetic hypertensive patients is lacking. Early detection of CKD can promote treatment with novel therapies such as SGLT-2 inhibitors or new MRAs. The aim of this study was to estimate referral rates and the extent of positive screening results for CKD (i.e. reduced eGFR and/or proteinuria), in a large scale community-based registry.

Methods: In this real-life, retrospective, observational study we utilized the Maccabi Healthcare Services (MHS) database. Included in the study, were patients over the age of 18 years, who had entered the MHS HTN registry in the past 10 years before February, 2024, and did not have diabetes or CKD. Early detection of CKD was defined as a PCP referral for blood test (serum creatinine (sCr)) and urine protein quantification (either uACR, uPCR or 24 hour urinary albumin/protein) within 12 months of HTN diagnosis, between 2014 and 2024. CKD diagnosis was defined according to the KDIGO guidelines as eGFR<60ml/min/1.73 square meter and/or urine albumin >30 mg or protein >150 mg per 24 hours or as a ratio to urine creatinine. Only those who had both a sCr test for eGFR estimation and a urine test for protein quantification, were considered as being screened for early detection of CKD.

Results: A total of 1,875,479 MHS members were over 18 years on February 2024, and 121,056 of them had a diagnosis of HTN within the past 10 years (2014-2024). Of those, 76,425 (63.1%) examinees had both urine and blood tests sent within a year after HTN diagnosis. CKD according to the above indices was found in 9958 examinees (13%). Importantly, lifetime prevalence of CKD within all adult MHS members is significantly lower - 5.7%, which indicates the extra burden of disease among those with HTN. Considering a 13% prevalence of CKD in the hypertensive population, early referral of the remaining 36.9% of patients who were not sent for the full blood and urine workup, would be expected to detect an extra 5815 patients with CKD (13% of 44,631 patients), 4.8% of the overall hypertensive cohort.

Conclusions: A one-time referral of every new hypertensive patient, for both urinary sCr and urine protein estimation, is a cost effective and simple tool for early CKD detection and may have a positive impact on CKD progression and cardiovascular complications of both HTN and CKD.

SA-PO1075

Assessment of Public Interest in CKD: A Google Trends Analysis

Cristian A. Milla, Mohammad W. Abushawer, Arfa Amjad, Thin Thin Soe, Dinah Goodman. *SUNY Downstate Health Sciences University, New York City, NY.*

Background: Chronic Kidney Disease (CKD) is a critical global health problem, that affects millions of patients worldwide, leading to severe health complications and increased mortality. Understanding the public interest in CKD is essential for awareness and prevention efforts. Google Trends serves as a valuable tool in this regard, offering insights into the general public's search behaviors and interest patterns, providing a resource for healthcare professionals and policymakers to tailor their strategies more efficiently.

Methods: Google Trends was utilized to analyze searches for the term "chronic kidney disease", from January 2004 to January 2024, focusing on English-Language queries within the United States of America. The gathered data encompassed search frequency over time, location distribution, frequent topic of interest, and related searches. Search frequency is reported on a normalized scale, with a value of 100 representing peak in search popularity.

Results: The number of google searches related to the term chronic kidney disease has significantly increased over time, from a mean of 14% in 2004 to 76% interest in 2024. Regarding interest by subregion in 2024, the state of West Virginia leads the frequency of searches, followed by South Dakota, Alabama, Tennessee and Mississippi. Top searched terms by frequency were the following: chronic kidney disease stage 3, chronic kidney disease treatment, what is kidney disease, assessment of kidney function, and dialysis.

Conclusions: The substantial increase in Google searches for chronic kidney disease over the past two decades reflects a rising public interest and awareness of CKD. This trend, particularly pronounced in some geographic regions, highlights the public's growing concern and need for information about CKD stages, treatments, and kidney function assessment. Physicians should integrate this information to provide better patient care by addressing common concerns, offering targeted education and tailoring prevention strategies.

SA-PO1076

Advancing Nephrology Care Access for Veterans: Implementation and Insights from a Telenephrology Program

Melissa L. Swee,[1,2] Mary V. Sarrazin,[1,2] M. Lee Sanders,[1,2] Heather Reisinger,[2] Kantima Phisitkul,[1] Angie R. Thumann,[1] Bradley S. Dixon,[1] Diana I. Jalal.[1,2] [1]*Iowa City VA Medical Center, Iowa City, IA;* [2]*University of Iowa Health Care, Iowa City, IA.*

Background: Chronic kidney disease (CKD) is a significant health concern among Veterans, often compounded by delayed nephrology referrals. A Telenephrology program was introduced at the Iowa City Veterans Affairs Health Care System (ICVA) in 2018. A dashboard alerted the nephrology service when CKD or acute kidney injury were noted prompting either an e-consult or an outpatient consult to the nephrology service. Here, we evaluated the impact of the program on nephrology encounters.

Methods: We conducted a retrospective cohort study involving Veterans receiving care in Veterans Integrated Service Network (VISN) 23, which consists of 8 medical centers and affiliated clinics. The cohort included patients with at least one eGFR <60 during from 2014 to 2016. Patients with nephrology encounters before 2014 or who died before 2016 were excluded. Annual outpatient virtual and face to face nephrology encounters from 2016 to 2020 were identified. Poisson regression was used to compare nephrology encounters per months alive before and after the intervention to other VISN 23 sites during the same time period, controlling for patient characteristics.

Results: We identified 5161 eligible patients in Iowa City and 44618 in other VISN 23 sites. Veterans in ICVA were older with higher rates of heart failure, peripheral vascular disease, and hypertension. Nephrology encounters rose by ~78% and 114% during 2018-2019 and 2019-2020 compared to the average annual encounters during 2016-2018 [Rate ratios were 1.78 (95% CI, 1.62-1.95; p<.001) and 2.14 (95% CI, 1.97-2.32; p<.001)]. Compared to other sites in VISN23, nephrology encounters per month increased to a lesser extent in ICVA. In the period March 2018-February 2019, the increase in encounters in ICVA was 86% of that observed in other VISN 23 sites (relative rate = 0.86; 95% CI, 0.79-0.95; p<.001). During 2019-2020, the rate of increase in Iowa City was 85% of the increase observed in other VISN 23 sites (relative rate = 0.85; 95% CI, 0.78-0.93; p<.001).

Conclusions: The Telenephrology program in Iowa City improved access to nephrology care but the annual increase in virtual and face-to-face encounters was smaller than seen in other VISN23 facilities. Future studies will explore the impact of the Telenephrology program on clinical outcomes.

SA-PO1077

Prevalence of Albuminuria in US Adults with Obesity and Its Possible Impact on CKD Screening: A Cross-Sectional Analysis of NHANES Data, 2003-2020

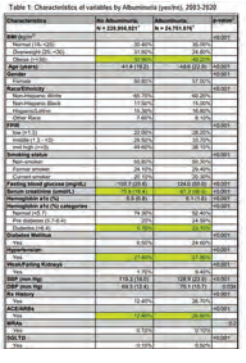
Aisha Batool,[1] Hafsa Habib,[1,2] Shahzad Chaudhry,[3] Ashraf El-Meanawy.[1]
[1]Medical College of Wisconsin, Milwaukee, WI; [2]Nishtar Medical College and Hospital, Multan, Pakistan; [3]Advocate Aurora Health Inc, Milwaukee, WI.

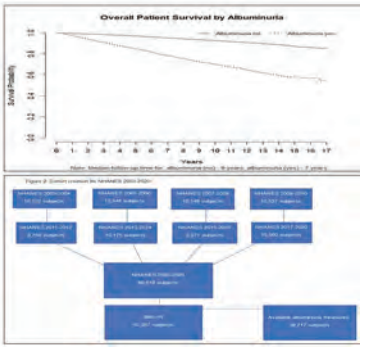
Background: About 37 million US adults are reported to have CKD and those with proteinuric CKD have higher mortality. There's no agreement on whether albuminuria screening is beneficial for the general US population or individuals who are obese. Our study aims to determine a correlation between obesity and albuminuria, and b) relationship of albuminuria with mortality.

Methods: This study utilized data from NHANES 2003-2020 with urine albumin and creatinine ratio>30 (uACR) to identify albuminuria and BMI>30 to identify obesity. The final dataset comprised 59,717 adults. Employing a series of multivariable-adjusted regression models, we assessed the IDR to evaluate the association between uACR and obesity with overall mortality.

Results: The demographic analysis indicated that among those with albuminuria, 40% were obese, 57% women, and 61% were low-middle income category based on FPIR. Within the albuminuria group, 24% were diabetics, with an average A1C level of 6.1%. Additionally, 52% of those with albuminuria were identified as hypertensive and only 26% were utilizing RAAS blockade. Logistic regression model weighted results by albuminuria and obesity when adjusted for socioeconomic risk factors OR of 1.36 with 95% CI 1.23-1.50 p value <.001. The age-adjusted mortality rate exhibited an upward trend across albuminuria group.

Conclusions: In a nationally representative US adult population, we have observed robust, progressively increasing corelation between albuminuria and obesity. We have also observed that individuals with albuminuria have higher likelihood of all-cause mortality within all segments of sex, race or ethnicity, and concurrent health conditions. Our study underscores the underutilization of albuminuria-reducing agents in approximately 75% of individuals with albuminuria. This emphasizes a missed opportunity for screening a potentially at-risk population of obese individuals who could benefit from therapies aimed at reducing albuminuria.





SA-PO1078

Factors Associated with CKD Awareness and Impact on Kidney Prognosis

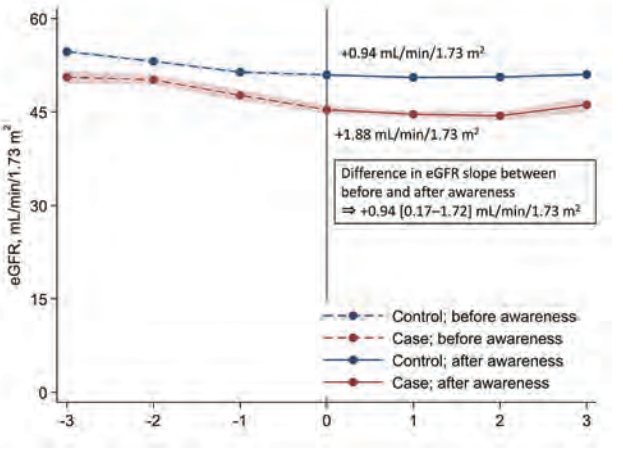
Takahiro Imaizumi, Akiko Hattori, Shoichi Maruyama. *Nagoya Daigaku, Nagoya, Japan.*

Background: Behavioral change and awareness of healthy living are important elements for caring for patients with chronic kidney disease (CKD). Despite the importance of CKD awareness, few patients, even those diagnosed with CKD, are aware of their disease. We aimed to investigate the factors associated with CKD awareness and its impact on renal prognosis. In this study, we focused on urine tests and nutritional guidance, which are typical clinical quality indicators in CKD practice

Methods: The study examined the proportion of participants with CKD who underwent health checkups from 2013 to 2022 and responded that they were aware of CKD in the questionnaire. The outcome was the change from CKD "unaware" to "aware", and multivariable logistic regression analysis was used to examine the association of urine testing or nutritional guidance with CKD awareness. A control group was randomly selected from the unaware group and matched for age, sex, and estimated glomerular filtration rate (eGFR). The change in eGFR slopes before and after the occurrence of awareness was compared using mixed-effects models.

Results: Of the 13,489 participants, 372 (2.8%) were aware of having CKD at baseline, and of the 1,614 participants who had CKD-related diseases in their claims data, only 316 (19.6%) were aware of their CKD status. The odds ratios of urine test or nutritional guidance associated with the occurrence of awareness were 1.72 (95% confidence interval [CI] 1.13–2.62) and 2.91 (95% CI 1.41–6.01), respectively. Compared to the pre-occurrence of awareness, the post-occurrence eGFR slope improved by 0.94 mL/min/1.73 m^2 per year (95% CI 0.17–1.72, P=0.017) (**Figure**).

Conclusions: Our findings suggest that urine tests and nutritional guidance may promote CKD awareness, which may help slow its progression.



SA-PO1079

Development and Validation of a Prediction Model of Early Mortality for Conservative Management vs. Dialysis among US Veterans with Advanced CKD

Connie Rhee,[1] Yoko Narasaki,[1] Amy S. You,[1] Csaba P. Kovesdy,[2] Alejandra Novoa Vargas,[1] Danh V. Nguyen,[3] Kamyar Kalantar-Zadeh.[4] *[1]University of California Los Angeles, Los Angeles, CA; [2]The University of Tennessee Health Science Center, Memphis, TN; [3]University of California Irvine, Irvine, CA; [4]Harbor-UCLA Medical Center, Torrance, CA.*

Background: Given that dialysis may result in greater healthcare utilization, loss of physical function/independence, and high early-mortality in certain subgroups (elderly, multi-morbid), there is growing interest in conservative management (CM) as an alternative patient-centered treatment strategy for advanced CKD. We developed and validated a prediction model to provide individualized predicted probability of survival with CM vs. dialysis transition among a national cohort of advanced stage CKD patients.

Methods: Using the national VA database linked to USRDS and Medicare data, we developed a risk prediction tool for mortality in US Veterans with advanced CKD (≥2 eGFRs <25 separated by ≥90 days) treated with CM vs. dialysis (defined as non-receipt vs. receipt of dialysis within 2-years of 1st eGFR <25) over 2010-19. Patients were divided into a 2/3rds development set and a 1/3rd validation set. Prediction models for 1-year mortality were developed on the basis of survival data up to 2-years after the index eGFR date (1st eGFR <25) using Cox models.

Results: Among a cohort of 61,118 Veterans (43,197 vs. 17,921 receiving CM vs. dialysis), selected characteristics associated with higher overall mortality included older age; higher index eGFR, UACR, and VA frailty index; faster eGFR decline; lower serum albumin and BMI; prior 1-year hospitalization; presence of heart disease, sepsis,

and tobacco use; and dialysis transition. Model discrimination was good with similar C-statistics in the development and validation cohorts: 0.704 (95% CI 0.697-0.708) and 0.704 (95% CI 0.696-0.711), respectively. Model goodness-of-fit tests showed adequate fit in the validation cohort (P=0.65). Risk score and model calibration plots are shown in Fig 1.

Conclusions: In a national cohort of US Veterans with advanced CKD, we developed a clinical prediction tool for survival for CM vs. dialysis to inform individualized treatment and improve the shared decision-making process between clinicians and patients.

Medication Reconciliation at the Time of Admission and Discharge by Pharmacists in the Adult Nephrology Wards of a Referral Hospital in Iran

Iman Karimzadeh.[1,2] *[1]Shiraz University of Medical Sciences, Shiraz, Fars, Islamic Republic of Iran; [2]University of Pittsburgh, Pittsburgh, PA.*

Background: Medication reconciliation is the process of identifying a precise list of drugs taken by a patient and comparing it to his/her current medications. The aim of the present research was investigating the impact of medication reconciliation by pharmacists at both admission and discharge in hospitalized patients with different kidney diseases.

Methods: A prospective, interventional study was conducted in two adult nephrology wards of a teaching, referral hospital in Iran from September 2020 to March 2021. All patients hospitalized in the nephrology ward for at least 1 day received the minimum of one medication during their ward stay within the study period were considered eligible. The best-possible medication history taken from each patient by an educated pharmacist was compared with prescribed medications at the time of ward admission and discharge from the ward. Medications were evaluated for possible intentional as well as non-intentional discrepancies.

Results: At ward admission and discharge, 178 and 134 patients were included. The mean number of un-intentional drug discrepancies per patient at ward admission and discharge was 6.13±4.13 and 1.63±1.94, respectively. The mean ± SD number of prescribed medications for patients before ward admission detected by pharmacist was significantly higher than that by nursing/physician (9.22±4.71 and 6.06±3.53, respectively [P=0.0001]). The number of unintentional medication discrepancies at ward admission has a significant association with the number of comorbidities (P = 0.043) and the number of administered medications (P = 0.023). At the time of ward discharge, only the number of comorbidities was significantly associated with the number of unintentional medication discrepancies (P = 0.031). Drug-drug interactions were observed in 97 (59.49%) of patients. At the time of ward discharge, all 134 subjects were given medication consult.

Conclusions: The rate of reconciliation errors at the time of ward admission and discharge was high in the adult nephrology ward. Implementing medication reconciliation program as a regular practice, preferably by pharmacists, in different phases of patient care in the hospital, especially for patients with numerous comorbidities like kidney diseases, is crucial.

SA-PO1081

Accuracy of Smartphone-Enabled Urinary Albumin-to-Creatinine Ratio (uACR) Testing

Danielle Jeddah,[1] Nicholas J. Bevins,[2] Matan Ronen,[1] Ron Zohar,[1] Navdeep Tangri.[3] *[1]Healthy.io, Boston, MA; [2]Birdrock Laboratories, San Diego, CA; [3]University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada.*

Background: Urinary albumin to creatinine ratio (uACR) testing is crucial for diagnosing, staging, and managing chronic kidney disease (CKD), yet testing rates remain short of guideline recommendations. Guidelines recommend semi-quantitative point-of-care testing (POCT) with ≥85% sensitivity when lab access is limited or when POCT offers advantages like convenience, immediate results, and elimination of sample transportation. We evaluated the accuracy of the Minuteful-Kidney Test (MKT), an FDA-cleared, smartphone-enabled, semi-quantitative test of uACR for home use, improving accessibility to kidney health assessment

Methods: We conducted a diagnostic study comparing the Minuteful-Kidney Test to the Beckman Coulter AU 480 Analyzer, a gold standard laboratory method, in a population at risk for kidney disease. From January to March 2024, we analyzed 615 urine samples in an accredited U.S. laboratory. Inclusion criteria were medical conditions or risk factors for kidney damage based on EMR data. Exclusion criteria were extreme urine pH, diluted samples, and samples with preservatives. Sensitivity, specificity, PPV, and NPV were calculated

Results: Among 615 samples, 60 met exclusion criteria, leaving 555 for analysis. The Minuteful-Kidney Test showed a sensitivity of 96.2% (95% CI 94.2%-98.2%) and specificity of 84.2% (95% CI 80.7%-87.7%), with an NPV of 98.6% (95% CI 97.4%-99.8%) and PPV of 66.8% (95% CI 60.3%-73.3%). Albuminuria was identified in 24.9% (95% CI 21.3-28.5) of the samples based on the quantitative device. The test accurately classified 85.6% of samples into KDIGO albuminuria categories, identifying all 25 (100%) laboratory-confirmed A3 samples as abnormal

Conclusions: The Minuteful-Kidney Test demonstrated high sensitivity (96.2%), exceeding the guideline-required 85%, and robust specificity for detecting albuminuria in high-risk CKD populations. The device can streamline CKD screening and enable early intervention, for patients with or at risk for CKD.

Positivity Rate 24.9%	Specificity 84.2%		Sensitivity 96.2%		

SA-PO1082

Predictive Value of Current KDIGO CKD Screening Criteria in Women and Men across Ethnic Groups: The HELIUS Study

Taryn G. Vosters,[1] Vianda S. Stel,[1] Kitty J. Jager,[1] Liffert Vogt,[1] Frans J. van Ittersum,[2] Bert-Jan Van den Born,[1] Irene van Valkengoed.[1] *[1]Amsterdam UMC Locatie AMC, Amsterdam, Netherlands; [2]Amsterdam UMC Locatie VUmc, Amsterdam, Netherlands.*

Background: Unequal burden of chronic kidney disease (CKD) amongst women and men and amongst ethnic groups poses a public health issue. Early detection of disease enables faster initiation of treatment as well as efficient deceleration of further disease progression. It is unclear whether the current screening guidelines are equally detecting women and men across ethnic groups with CKD.

Methods: Cross-sectional analyses were performed to determine the predictive value of the current available screening criteria recommended by KDIGO 2024, hypertension, diabetes mellitus and cardiovascular disease, in 12384 women and 9046 men from the HELIUS Study (2011-2015, Amsterdam, the Netherlands). Additionally investigating whether the optional variables such as low education, obesity, high risk occupations and genetic risk factors improve detection rates. This was done using Poisson regression analyses, including Likelihood ratio tests and AIC estimations in women and men. Significantly associated variables were added to the base criteria to create a final model. Base- and final model AUC, sensitivity, specificity, positive- and negative predictive values in women and men and across ethnic groups were compared.

Results: Current screening criteria showed higher sensitivity (Sens: 80.4 vs 58.3) and lower AIC (AIC: 3419.6 vs 4273.0) rates in men than women. Both low educational level and obesity in women, but not high risk occupations and genetic risk factors, significantly improved the prediction measures. As was the case for obesity in men. An improvement in predictive measures was observed for the final models (AUC : 0.64 (basemodel women); 0.66 (final model women); 0.75 (base model men); 0.76 (final model men)). These results were consistent across ethnic groups.

Conclusions: Current screening criteria may not be equally detecting women and men across ethnic groups. Different optional criteria, specifically low educational level for women or obesity for men, may improve detection rates in women and men.

Health Care Costs and Utilisation for CKD among Hospitalised Patients in the Republic of Ireland

Leonard Browne,[1] Meera Tandan,[1] Rajiv Saran,[2] Austin G. Stack.[1,3] National Kidney Disease Surveillance System and Quality Assurance Programme. *[1]University of Limerick, Limerick, Ireland; [2]University of Michigan Michigan Medicine, Ann Arbor, MI; [3]Health Service Executive, Dublin, Ireland.*

Background: To facilitate effective healthcare planning and resource allocation, comprehensive knowledge of the frequency, length of stay and costs of inpatient hospitalisation for chronic kidney disease (CKD) is crucial. To fill this deficit, we assesed rates of hospitalisation, length of stay (LOS), and associated costs for all CKD-related hospitalisations in Ireland.

Methods: A retrospective study of the National Hospital In-Patient Enquiry (HIPE) database in 2022. Non-coded hospitalisations and patients aged <1 year were excluded. All ICD-10 coded hospital admissions with a principal or additional CKD diagnoses were included. Age-standardised rates of hospitalisation and inpatient mortality were computed. We assessed hospitalisation, inpatient mortality, length of stay and costs by demographic factors, Charlson comorbidity score and region.

Results: In 2022, 13.1% of all coded hospitalisations in Ireland (n=225,164/1,711,564) recorded CKD as a principal diagnosis and/or additional diagnoses, costing €427 million. CKD-related hospitalisations excluding dialysis and transplantation as principal diagnoses represented 2.1% of all hospitalisations nationally, with 35,409 admissions from 23,261 patients, culminating in a total stay of 422,738 days, costing €320.3 million. The average LOS was 11.9 days and increased from 4.5 to 16.1 days with rising Charlson Comorbidity score. Stratified by comorbidity score, admissions, LOS, and costs rose significantly with increasing comorbidity burden. The leading principal diagnoses in 2022, when CKD was listed as an additional diagnosis included acute kidney failure, sepsis, heart failure, diabetes and pneumonia. CKD hospitalisation rates and inpatient mortality were higher in men and increased with age. Age standardised hospitalisation rates varied significantly across health regions and were lowest in the West and highest in the Midland regions of Ireland, P<0.01).

Conclusions: CKD exerts a substantial impact on healthcare utilisation and cost to the Irish health system. Increasing length of stay, resource utilisation, and in-hospital mortality, are especially common in older patients with higher comorbidity burden. Demographic and regional disparities in CKD hospitalisation rates highlight the need for targeted interventions and healthcare planning to address this public health issue effectively.

Statin Use in Patients with CKD (Nondialysis) in Ambulatory Care: A Quality Improvement Project at a Rural Community Hospital

Waleed Hassan, Vernon Rayford. North Mississippi Medical Center. *North Mississippi Medical Center, Tupelo, MS.*

Background: Chronic kidney disease (CKD) is a known risk factor for cardiovascular disease (CVD). Statins have been shown to reduce CVD risk in CKD (Non-Dialysis) with or without diabetes.

Methods: This is a quality improvement project at North Mississippi Medical Center as a retrospective analysis of 304,575 observations in a total of 178,722 patients. Data were extracted from an office or wellness visit at any Epic clinic between 7/1/2021 and 7/1/2022. CKD diagnosis was made based on an estimated glomerular filtration rate (eGFR) <60 ml/min/1.73 m^2 for > 3 months. The estimated GFR was calculated by the CKD-EPI creatinine equation (2021). The 10-year atherosclerotic cardiovascular (ASCVD) risk was calculated using Pooled Cohort Equations, the risk was categorized as <5%, 5-7.4%, and ≥7.5-10% in patients who met CKD criteria.

Results: Out of the total observations of 119,557 representing 43,557 patients, 8538 patients (20%) met the CKD criteria by eGFR. Demographic characteristics are shown in table 1. For patients with CKD (Non-Dialysis) and diabetes with a 10-year ASCVD risk of ≥7.5-10%, the majority (~75%) were on statins versus 18% being not on statins (figure1). Differently, only 65 % of CKD patients without diabetes with a 10-year ASCVD risk of ≥7.5-10% were found to be taking statins versus 25% not on statins (figure2).

Conclusions: Statin is an underused protective shield in patients with CKD (Non-Dialysis) in the ambulatory setting.

Identifying Barriers to SGLT2 Inhibitor Use in Patients with CKD: A Qualitative Analysis

Rema Elmostafa, Justin A. Dower, Angela M. Victoria Castro, Lisa Chan, Gabriella M. Riwes, Shelli L. Feder, Sherry Mansour. *Yale University, New Haven, CT.*

Background: Despite clearly stated guidelines by KDIGO recommending Sodium-glucose cotransporter-2 inhibitor (SGLT2i) use in CKD, prescription of SGLT2is among providers remains suboptimal. In this study, we aimed to understand the utilization patterns of SGLT2is and to identify barriers hindering their broader implementation.

Methods: We conducted semi-structured interviews with providers from January to April 2024 in a large academic center in New Haven, CT. Participants were asked open-ended questions about their experiences with prescribing SGLT2is, what factors facilitated or limited their use, and ideas on future directions to promote SGLT2i utilization. Each interview was recorded and transcribed. We used a hybrid approach of deductive and inductive content analysis using NVIVO analytic software.

Results: A total of 8 providers participated in the semi-structured interviews. Providers included cardiologists, nephrologists and internal medicine physicians and nurse practioners. The median age of providers was 33 (range: 29-63) years. The cohort consisted of 50% women, with 15% identifying as Black and 29% as Hispanics. Provider comfort level and preference to defer to a specialist were mentioned most frequently as barriers to prescription. Other barriers included side effects, medication costs, and polypharmacy. Most providers believed that SGLT2is were well-tolerated and had significant benefits in slowing CKD progression, but most reported that KDIGO guidelines were not promoted in their workplace. The most common solutions provided by participants to overcome barriers to using SGLT2is were education for providers and patients, EPIC pathways to guide provider decision, and cost assistance for patients.

Conclusions: While most providers agreed that SGLT2is are essential in the treatment of CKD, there exists a need and opportunity to improve education and comfort around their use among providers and patients.

SA-PO1086

Effect of Oral Absorbent Therapy on Kidney Progression According to the Cause of CKD

Hyunjin Cho, Jee Young Lee, Young-Il Jo. *Konkuk University Medical Center, Gwangjin-gu, Seoul, Republic of Korea.*

Background: Oral absorbent therapy with DW-7202 (Renemezin®) and AST-120 (Kremezin®) slows the progression of CKD. The aim of this study is to investigate whether the mitigating effect of oral absorbents on CKD progression varies according to the etiology of CKD.

Methods: This retrospective study included 490 patients at Konkuk University Medical Center who took absorbents for over three months between January 1, 2016, and August 31, 2023. Serum Cr levels were compared annually from the start of treatment until April 30, 2024, or the initiation of renal replacement therapy. The slope of serum Cr was compared among CKD patients with different causes using multilevel mixed-effects linear regression.

Results: The most common cause of CKD was DM (54.9%), followed by HTN (22.7%), GN (7.7%), ADPKD (2.8%), and unknown etiology (11.9%). Baseline Cr levels were not significantly different among the groups (P=0.39), but were significantly different after one year (P=0.02). After drug administration, serum Cr levels significantly increased compared to baseline in all groups (Figure 1, p<0.05), with the highest increase observed in the GN group. Compared to the GN group, the slope of serum Cr increases was significantly lower in the HTN, DM, ADPKD, and unknown etiology groups (Table 1, p<0.01).

Conclusions: These findings suggest that oral absorbent therapy has different effects depending on the cause of CKD. The treatment significantly alleviated CKD progression in patients with HTN, DM, ADPKD, and unknown etiology compared to those with GN.

Funding: Commercial Support - DAEWOONG PHARMACEUTICAL CO.,LTD

Table 1. Comparison of the Slope of Creatinine Increase in Each Etiology Group Following Oral Absorbent Therapy

Cause of CKD	Slope of Creatinine Increase (μmol/L/year) (95% CI)	p Value
HTN	19.3 (4.63 - 33.8)	<0.01
DM	28.3 (18.3 - 38.3)	<0.01
GN	84.4 (62.2 - 106.6)	Reference

SA-PO1087

Hyperuricemia Treatment Reduces ESKD Risk and Mortality in Patients with CKD: A Causal Inference Analysis Using the G-formula Approach

Ara Ko,[1,2] Jeonghwan Lee,[3,2] Chun Soo Lim,[3,2] Jung Pyo Lee.[3,2] *[1]Seoul National University Hospital Department of Internal Medicine, Jongno-gu, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Jongno-gu, Seoul, Republic of Korea; [3]Seoul National University Hospital Boramae Medical Center, Seoul, Republic of Korea.*

Background: Hyperuricemia is recognized as an independent predictor of chronic kidney disease(CKD), but the role of treating it in CKD, especially when asymptomatic, remains under debate. The g-formula, valuable for epidemiological causal inference, allows estimation of effects in complex relationships among time-varying covariates. We used the g-formula to assess the impact of treating hyperuricemia in CKD patients using urate-lowering agents(ULAs).

Methods: Employing the g-formula, we analyzed data from 27,260 CKD patients to build regression models, evaluating relationships among time-varying covariates: serum urate(sUA), creatinine, and ULA prescription status, measured every 6 months. We also adjusted for time-invariant factors like diabetes and hypertension. Our focus was the impact of various strategies for managing hyperuricemia (treating if sUA ≥7, 8, 9, or 10mg/dL, or never treating) on end-stage kidney disease(ESKD) and all-cause mortality, supported by 1,000 bootstrap replicates for 95% confidence intervals(CIs).

Results: Of the cohort, 5,361 patients had been prescribed allopurinol, febuxostat, or benzbromarone. We found that hyperuricemia treatment generally decreased ESKD and all-cause mortality risks compared to never treating. Lower sUA thresholds were linked to dose-responsive decrease in risk, particularly at 7mg/dL [RR of 0.960 for ESKD (95% CI: 0.956 to 0.964), and 0.988 for mortality (0.984 to 0.992) compared to never treating]. Compared to no intervention, initiating treatment ≥9 or 10mg/dL, or never treating, significantly increased ESKD and mortality with a protective effect observed only at the threshold of 8mg/dL or below.

Conclusions: Our study demonstrates that treating hyperuricemia in CKD patients significantly reduces the risk of ESKD and mortality. This suggests potential harm in not treating hyperuricemia at urate levels of 9mg/dL or higher.

Outcome	Intervention	Observed risk*	Risk†	Risk ratio (RR)	95% CIs of RR	
ESRD	No intervention‡†	0.1719	0.1833	1	1	1
	Never treating	-	0.1864	1.0205	1.0158	1.0253
	Treating if sUA ≥10mg/dL	-	0.1851	1.0118	1.0086	1.0144
	Treating if sUA ≥9mg/dL	-	0.1841	1.0052	1.0033	1.0062
	Treating if sUA ≥8mg/dL	-	0.1825	0.9945	0.9926	0.9953
	Treating if sUA ≥7mg/dL	-	0.1502	0.9755	0.975	0.9835

Table 1. Simulated risk estimates using the g-formula under hypothetical interventions on management of hyperuricemia in CKD patients

*1-year cumulative risk calculated based on the observed data
†Risks estimated by the g-formula
‡"No intervention simulation" in the g-formula uses real-world data for time-varying covariates instead of covariate estimations to represent the real-world practice. If the risk under "no intervention simulation" is close to the observed risk, it suggests the absence of model misspecification.

SA-PO1088

Renin-Angiotensin System Blockade Does Not Alter Long-Term Kidney Outcomes in Sickle Cell Disease

Kabir O. Olaniran. *The University of Texas Southwestern Medical Center Department of Internal Medicine, Dallas, TX.*

Background: Sickle disease (SCD) is associated with faster kidney function decline compared to normal hemoglobin phenotypes. The role of renin angiotensin system inhibitors (RASI) in modifying long-term kidney outcomes in SCD is not well described despite several studies showing antiproteinuric effects of RASI in SCD. This study aimed to describe long-term kidney outcomes in adult SCD patients on RASI.

Methods: A single-center observational study of adult patients with SCD on RASI (exposure) and SCD not on RASI (reference) between 2010 and 2021 was performed. Inclusion criteria were patients with a baseline eGFR≥15 ml/min/1.73m^2, ≥3 estimated glomerular filtration rate (eGFR) values, and ≥1 year between first and last eGFR values. The outcomes of interest were the difference in the mean change in eGFR per year (evaluated using linear mixed models), rapid eGFR decline (≥3 ml/min/1.73m^2/year), incident stage 5 chronic kidney disease (CKD), and mortality (described using Cox proportional hazard models). Propensity score matching (1:3) adjusted for 16 baseline characteristics. Time-updated RASI use was utilized in all models. All other covariates (demographics, comorbidities, medications, labs) were baseline values.

Results: In total 1,960 SCD patients (476 RASI, 1,484 reference) were identified. After matching, 442 reference patients were used. Matched cohort median follow-up was 4.6 (IQR 2.5-8.3) years with a median of 24 (IQR 10-60) eGFR values, a mean±SD age of 43±16 years, 59% female, and mean baseline eGFR±SD of 97±29 ml/min/1.73m^2. All results were compared to the matched reference. The adjusted mean eGFR change in RASI users was +0.02 (95% confidence interval [CI] -1.06 to +1.08) ml/min/1.73m^2/year. Rapid eGFR decline (hazard ratio [HR] 0.80; 95% CI 0.51-1.25), incident stage 5 CKD (HR, 0.28; 95% CI 0.06-1.21) and mortality (HR, 0.61; 95% CI 0.30-1.25) were not significantly different. Among RASI users only, the adjusted mean eGFR change pre- vs. during-RASI use was -0.13 (95% CI -0.30 to +0.03) ml/min/1.73m^2/year.

Conclusions: In the largest observational study to date of adult SCD RAS blockade, RASI use was not associated with adverse or improved long-term kidney outcomes compared to no RASI use. Therefore, if RASI are indicated in SCD, adverse long-term kidney outcomes should not be a concern. Conversely, RASI should not be started solely to slow kidney function decline in SCD.

Kidney and Mortality Outcomes on Renin-Angiotensin System Inhibitors in Nonproteinuric CKD: Findings from the CRIC Study

Rachel Shulman, Debbie L. Cohen, Wei Yang, Peter P. Reese, Jordana B. Cohen. *University of Pennsylvania, Philadelphia, PA.*

Background: The kidney benefits of renin angiotensin system inhibitors (RASIs) in patients with absent or minimal proteinuria in CKD is not known. We evaluated the long-term kidney outcomes and survival in those with non-proteinuric CKD treated with RASIs vs. other antihypertensive drugs.

Methods: Among participants with CKD and less than 0.5 g/day of proteinuria in the Chronic Renal Insufficiency Cohort Study, we evaluated baseline RASI use vs other antihypertensive medications (i.e. intention-to-treat approach) with inverse probability of treatment weighting (IPTW) and Cox proportional hazards modeling to determine the association of RASIs with (1) CKD progression (halving of eGFR, dialysis, or transplant) and (2) all-cause mortality. Secondary analyses included censoring with drug discontinuation (i.e. per-protocol) and a new user, time-updated RASI use approach (i.e. cumulative exposure) to evaluate the association of RASI use with CKD progression.

Results: A total of 2664 participants with non-proteinuric CKD met inclusion criteria. In the baseline RASI use approaches, use of RASIs was not significantly associated with CKD progression. The time-updated approach was underpowered but showed a higher risk of CKD progression among low level RASI users (RASI use during 0-25% of follow-up) vs. non-users but no higher risk of CKD progression among higher level RASI users (RASI use during >25% of follow-up) vs. non-users. RASI users had a lower mortality risk vs. non-users in the per-protocol analysis (adjusted HR 0.63, 95% CI 0.49-0.80) and a non-significantly lower mortality risk among higher level RASI users (>25%) vs. non-users.

Conclusions: Among people with non-proteinuric CKD, RASI use is not associated with CKD progression but may be associated with lower mortality risk compared to other antihypertensive medications. For people with non-proteinuric CKD, RASIs may not provide a kidney benefit, but may still confer a mortality benefit for hypertension management.

Kidney Protective Effect of SGLT2 Inhibitors Based on Fractional Excretion of Total Protein

Hideaki Kuno, Go Kanzaki, Saeko Hatanaka, Hirokazu Marumoto, Takaya Sasaki, Kotaro Haruhara, Kei Matsumoto, Kentaro Koike, Hiroyuki Ueda, Nobuo Tsuboi, Takashi Yokoo. *The Jikei University School of Medicine, Tokyo, Japan.*

Background: An initial dipping in eGFR occurs after initiation of SGLT2 inhibitors (SGLT2i), reflecting a decrease in intraglomerular pressure. Changes in proteinuria in response to the initial dipping in eGFR are variable and the impact on renal prognosis is not clear. Fractional excretion of total protein (FETP) which was protein clearance divided by creatinine clearance is an indicator of protein leak that accounts for glomerular filtration rate. This study investigated the association between initial dipping in FETP after initiation of SGLT2i and renal prognosis in CKD.

Methods: This retrospective observational study included 112 CKD patients who received SGLT2i from 2016 to 2022 at our Hospital. The FETP was calculated as follows: FETP = (urinary total protein / serum total protein) / (urinary creatinine / serum creatinine) %. According to the decline in FETP, patients were divided into two groups. The primary outcome was eGFR slope for 2 years (Figure1).

Results: Their median age was 58.0 (interquartile range, 50.0–66.0) years, 69.6 % of which were male. eGFR was 45.0 (33.0–59.9) ml/min/1.73 m^2, and FETP was 0.010 (0.004-0.024) %. The eGFR slope for 2 years was significantly slower in the FETP dipper group than in the non-dipper group (Figure 2). We found that initial dipping in FETP was an independent risk factor for eGFR slope for 2 years in multivariate analysis (P=0.030).

Conclusions: We found that a greater initial dipping in FETP after initiation of SGLT2i was associated with a better renal prognosis. FETP may be a useful and convenient marker that accurately reflects changes in intraglomerular pressure after initiation of SGLT2i.

Changes in Kidney Function Associated with Discontinuation of Lithium Treatment

Gisli Gislason,[1,2] Olafur S. Indridason,[1] Engilbert Sigurdsson,[1,2] Runolfur Palsson.[1,2] *[1]Landspitali, Reykjavik, Iceland; [2]Heilbrigdisvisindasvid - Haskoli Island, Reykjavik, Iceland.*

Background: Lithium treatment for mood disorders has been associated with a decrease in estimated glomerular filtration rate (eGFR) and the development of chronic kidney disease (CKD). It is not clear whether or to which degree discontinuation of lithium improves kidney function. This study examined changes in eGFR when lithium treatment is stopped.

Methods: This was a retrospective study of all persons in Iceland using lithium in the years 2003-2018 for whom serum creatinine (SCr) measurements were available more than a year after their last lithium exposure. Lithium exposure was defined as at least one lithium prescription or at least two serum lithium measurements with detectable levels. CKD stages 3-5 were defined according to the KDIGO GFR criteria. eGFR was calculated using the SCr-based CKD-EPI$_{2009}$ equation. Mean eGFR was calculated for every individual in each year from five years before to five years after lithium discontinuation. Analysis of variance was used to assess the difference in eGFR between time periods.

Results: A total of 682 individuals had SCr measurements performed more than a year after lithium discontinuation, 81 of whom had developed CKD stage 3 or above before cessation of lithium treatment. For all individuals the mean eGFR declined from an initial level of 90.4±20.9 ml/min/1.73 m^2 five years before lithium discontinuation to 84.6±24.8 ml/min/1.73 m^2 in the year of lithium discontinuation (p=0.006), but remained stable in the ensuing years, concluding at 83.4±23.7 ml/min/1.73 m^2 five years after lithium was discontinued (p>0.1). In individuals with CKD stages 3-5 before lithium discontinuation, the mean eGFR was 63.5±19.6 ml/min/1.73 m^2 five years before discontinuation, 50.2±16.3 ml/min/1.73 m^2 at the time of discontinuation (p<0.001) and 48.6±21.0 ml/min/1.73 m^2 five years later (Figure).

Conclusions: Discontinuation of lithium therapy appears to stabilize the decline in kidney function and halt the progression of CKD.

Evaluation of the Effect of Racial Differences on Longitudinal Trajectories of Kidney Function in People with HIV (PWH) on Tenofovir Alafenamide (TAF)-Based Antiretroviral Treatment (ART) Regimens

Myra A. Kleinpeter,[1] Jihad Slim,[2] Sarjita Naik,[3] Xiwen Huang,[3] Amy R. Weinberg,[3] Lauren Temme,[3] Li Tao,[3] Anand Chokkalingam,[3] Samir K. Gupta,[4] Betty Chiang,[3] Robert B. Canada.[5] *[1]Tulane University School of Medicine, New Orleans, LA; [2]Saint Michael's Medical Center, Newark, NJ; [3]Gilead Sciences Inc, Foster City, CA; [4]Indiana University School of Medicine, Indianapolis, IN; [5]The University of Tennessee Health Science Center, Memphis, TN.*

Background: HIV can contribute to chronic kidney disease (CKD), as do some older antiretrovirals. PWH are also subject to traditional risk factors for CKD affecting the general population including but not limited to race, age, and hypertension. Along with variations in prevalence of HIV, racial differences are associated with differences in risk for CKD. We aim to explore the impact of Black race on renal function change in routine clinical practice in a non-CKD population of PWH on TAF-based regimens.

Methods: Individuals with HIV who initiated TAF-based regimens (2015-2023) and had ≥1 estimated glomerular filtration rate (eGFR calculated by CKD-EPI Equation 2021) measurements within 1 year pre- and post-ART initiation were identified using IQVIA Ambulatory EMR-US. Individuals maintained on TAF were followed up until the end of the observation period. eGFR changes were calculated by subtracting post-ART initiation measurements from the pre-initiation 1-year average eGFR and analyzed using a mixed-effects model adjusted for age, sex, and baseline eGFR. Least square means of the adjusted model were plotted.

Results: At baseline, Black (n=1,195) and non-Black PWH (n=1,601) on TAF-based regimens had an average eGFR of 89.9 and 92.4 mL/min. Black PWH were more likely to be female and younger. After adjusting for baseline eGFR and covariates, decline in eGFR at 15 months was -4.5 vs. -2.9 (p>0.05) in Black and non-Black PWH, respectively. The long-term trend became similar between groups at 24 months (Figure). Stratified by baseline eGFR, discrepancies in eGFR changes between groups was mostly driven by baseline eGFR ≥90 mL/min.

Conclusions: Black and non-Black PWH experienced similar changes in eGFR over 24 months of ART including TAF. These results suggest TAF does not increase risk of renal decline in Black PWH.

Funding: Commercial Support - Gilead Sciences

Ketamine Use as a Cause of CKD: A Case Series

Lina Alatta, Bruce S. Spinowitz, Ritesh Raichoudhury, Zainulabdeen S. Al-saedi, Sheng F. Kuo, Mohammed A. Miqdad. *New York Presbyterian Queens, Flushing, NY.*

Background: Use of ketamine has been associated with urinary tract pathology, including contraction of urinary bladder and lower urinary tract obstruction, leading to secondary renal injury. Clinical presentation and image findings include contracted bladder, ureteral stricture, and hydronephrosis. Ketamine is excreted in bile and urine. It has been proposed that tissue damage is related to the duration of exposure and contact with ketamine metabolites in the urinary system, and that bladder wall is usually the first organ to present with lower urinary tract symptoms followed by the lower third of the ureter and renal pelvis. We present a series with history of ketamine abuse resulting in obstructive uropathy and chronic kidney disease.

Methods: Chart review of deidentified patient records with history of ketamine abuse who presented to New York Presbyterian Queens Hospital The following features were extracted: baseline demographic data, serum creatinine, BUN, estimated glomerular filtration rate, and renal imaging.

Results: Seven patients presented to the hospital with abnormal renal function and history of ketamine abuse, all with hydronephrosis on imaging. Six were Asian and one African American. They were predominantly female (5:1). The median age of presentation was 32 (range, 31-56) years. Three patients had hypertension. Serum creatinine, blood urea nitrogen, and estimated glomerular filtration rate were 2.2 mg/dL(range 1.03 to 3.07), 36.2 mg/dL (range 21.4 to 64.3), 34 cc/min (25 to 45), respectively. All had the following abnormalities: elevated liver enzymes (median alanine aminotransferase of 47.5 U/L, aspartate aminotransferase of 65 U/L, and alkaline phosphatase of 1060 U/L; bile duct dilation; bladder wall thickening with moderate to severe hydronephrosis. All required urological intervention (six patients had bilateral ureter stents and one patient had bilateral percutaneous nephrostomy). One patient required transient hemodialysis and one died.

Conclusions: Our experience of Ketamine abuse is consistent with findings in the literature. Image findings of obstructive uropathy are typical and when present, is associated with chronic kidney disease. It is associated with high morbidities and requires frequent hospitalizations and procedures. Cases are likely underreported as most patients may not have symptoms.

SA-PO1094

Potential Reduction of Proteinuria by Oral Care Using Chlorhexidine Gluconate

Taro Misaki,[1,2] Shuhei Naka,[4] Seigo Ito,[5] Yasuyuki Nagasawa,[6] Ryota Nomura,[7] Michiyo Matsumoto-Nakano,[4] Kazuhiko Nakano.[3] *[1]Seirei Hamamatsu Byoin, Hamamatsu, Japan; [2]Seirei Kurisutofa Daigaku, Hamamatsu, Japan; [3]Osaka Daigaku, Suita, Japan; [4]Okayama Daigaku Daigakuin Ishiyakugaku Sogo Kenkyuka, Okayama, Japan; [5]Koku Jieitai Iruma Kichi, Sayama, Japan; [6]Hyogo Ika Daigaku, Nishinomiya, Japan; [7]Hiroshima Daigaku, Higashihiroshima, Japan.*

Background: Chlorhexidine mouthwash is widely used as an antimicrobial agent to reduce bacterial load in the oral cavity. However, its effects on systemic conditions in patients with chronic kidney disease (CKD) are still unknown. In the present study, we examined the relationship between the number of *Streptococcus mutans* in the oral cavity and proteinuria.

Methods: The patients with CKD gargled with chlorhexidine mouthwash three times daily for one year. We investigated the relationship between changes in the number of *S. mutans* and proteinuria.

Results: The *S. mutans* ≥1000 group at 0 month was significantly associated with higher number of *S. mutans*, urinary protein (g/gCr) and higher % urinary protein 2 + or higher in over time. Mean of the number of *S. mutans* in the oral cavity in whole patients decreased significantly over time. Proteinuria also decreased significantly with a delay. Relationship between the degree of decrease in the number of *S. mutans* after 12 months and proteinuria less than 0.3 g/gCr after 12 months remained significantly different in logistic regression analysis adjusted for age, sex, and proteinuria(g/gCr) at baseline (0 month). Additionally, the rate of proteinuria less than 0.3g/gCr at 12 months was significantly higher in the group that achieved S. mutans <1000 at 12 months.

Conclusions: These results suggest that there was a relation between the number of *S. mutans* in the oral cavity and proteinuria in patients with CKD and oral care with chlorhexidine mouthwash may reduce the proteinuria.

SA-PO1095

Association of Changes in Albuminuria with Change in Estimated Glomerular Filtration Rate (eGFR) in Macroalbuminuric CKD (CKD): Post Hoc Analysis of a 5-Year Randomized Trial

Nimrit Goraya,[1] Jan Simoni,[3] Maninder Kahlon,[2] Nazan Aksan,[2] Donald E. Wesson.[2] *[1]Baylor Scott & White Medical Center Temple, Temple, TX; [2]The University of Texas at Austin Dell Medical School, Austin, TX; [3]Texas Tech University System, Lubbock, TX.*

Background: Previous studies show changes in albuminuria associate inversely with the rate of eGFR change in patients with CKD and normoalbuminuria (urine albumin [mg]-to-creatinine [g] ratio [UACR] < 30) or microalbuminuria (UACR 30 to <300). In this post hoc analysis, we hypothesized that this inverse association also holds for patients with macroalbuminuric (UACR ≥ 300) kidney injury and non-diabetic CKD with initially normal eGFR (> 90 ml/min/m2 or stage G1).

Methods: One hundred fifty-three macroalbuminuric, non-diabetic G1 participants on ACEI were randomized to receive F&V (n=51), oral NaHCO3 (HCO3, n=51), or Usual Care, n=51. They were followed annually for 5 years, measuring eGFR (CKD-EPI) and UACR. Mixed linear regressions with random person intercepts tested differential group trajectories, p-values from relevant interaction terms are included below. We conducted preliminary causal mediation analyses examining participant level improvements in eGFR from the first year after randomization until the last study year (time-5) as the outcome. We examined the cumulative impact of change from first year after randomization to year 4 in UACR. In both the mediator and the outcome equations, baseline levels of eGFR and UACR were partialled out.

Results: Baseline eGFR and UACR were not different among groups. The observed mean rate of eGFR decline [mean (SE)] from baseline to year 5 for F&V [-1.08 (0.06) ml/min/1.73m2/ yr] and HCO3 [-1.17 (0.07) ml/min/1.73m2/ yr] were both lower (p<0.001) than UC [-1.94 (0.11) ml/min/1.73m2/yr. Interaction terms indicated that the UACR trajectories for F&V and HCO3 were each lower (consistent with less kidney injury) than UC (p<0.001). Although the direction of the UACR change vs. eGFR change varied among groups, the interaction for the entire sample was inverse (r= -0.41) and significant (p<0.001).

Conclusions: Like in patients with CKD and normoalbuminuria or microalbuminuria, this post hoc analysis showed that directional changes in albuminuria associate inversely with the rate of eGFR changes in patients with CKD and baseline macroalbuminuria. The data support future studies to test if interventions that reduce albuminuria might also be kidney protective in patients with macroalbuminuric level of kidney injury.

SA-PO1096

Association of Calcium-to-Magnesium Intake Ratio with Albuminuria in Community-Dwelling Japanese Adults

Keiko Kabasawa,[1] Michihiro Hosojima,[1] Kazutoshi Nakamura,[1] Ribeka Takachi,[2] Junta Tanaka,[1] Ichiei Narita,[1,3] Yumi Ito.[1] *[1]Niigata University, Niigata, Japan; [2]Nara Women's University, Nara, Japan; [3]Niigata Institute for Health and Sports Medicine, Niigata, Japan.*

Background: Calcium and magnesium both work together and counteract each other. In the kidneys, filtered calcium and magnesium are reabsorbed in consecutive segments from the proximal tubule to the connecting duct, where both are used in albumin handling. Previous studies have suggested that the calcium-to-magnesium intake ratio is associated with chronic health conditions such as cardiovascular disease; however, its relationship with albuminuria is not known.

Methods: This study analyzed data from 6,849 Japanese community-dwelling adults age ≥40 years (51.3% women). We cross-sectionally assessed the calcium-to-magnesium intake ratio and each nutrient using a validated food frequency questionnaire and spot urine albumin-to-creatinine ratio (ACR). Linear regression analyses were performed for the relationships of natural log-transformed intake ratio, calcium intake, and magnesium intake with natural log-transformed ACR, with adjustments for potential confounders.

Results: Median values of the calcium-to-magnesium intake ratio and eGFR were 1.65 and 73.5 mL/min/1.73 m^2, respectively. In the multivariable linear regression analysis, the calcium-to-magnesium intake ratio was inversely associated with log-transformed ACR [β(95%CI), –0.085 (–0.15, –0.021)]. When calcium and magnesium intake were analyzed individually, each nutrient was inversely associated with log-transformed ACR but the relationship with magnesium intake was not independent of calcium intake (Table).

Conclusions: The calcium-to-magnesium intake ratio was inversely associated with albuminuria. The balance of calcium and magnesium intake may be a potential modifiable factor for preventing albuminuria, and calcium intake may be a main contributor to this association.

Funding: Government Support - Non-U.S.

Table: Multivariable linear regression analysis for the relationship of natural logarithms of calcium-to-magnesium intake ratio, calcium intake, and magnesium intake with the natural logarithm of ACR

Note Calcium and magnesium intake were adjusted for energy intake by the residual method. Model 1 was adjusted for age, sex, survey area, no or rarely drinking, current smoking, regular exercise habit, energy intake (quartiles), diabetes, hypertension, history of urinary tract stone, body mass index, and eGFR. Model 2 was further adjusted for magnesium or calcium intake. ACR, urine albumin-to-creatinine ratio.

	Calcium-to-magnesium intake ratio	Calcium intake	Magnesium intake
	β (95%CI)	β (95%CI)	β (95%CI)
Model 1	−0.085 (−0.150, −0.021)	−0.110 (−0.164, −0.057)	−0.172 (−0.270, −0.074)
Model 2		−0.084 (−0.149, −0.019)	−0.085 (−0.204, 0.035)

SA-PO1097

Association of Transthyretin Val122Ile Variant with Kidney Outcomes in Black Participants of REGARDS

Soumya Khanna,[1] Katharine L. Cheung,[2] Mary Cushman,[2] Titilayo O. Ilori,[3] Marguerite Irvin,[1] Orlando M. Gutierrez.[1] *[1]The University of Alabama at Birmingham Heersink School of Medicine, Birmingham, AL; [2]University of Vermont The Robert Larner MD College of Medicine, Burlington, VT; [3]Boston University Chobanian & Avedisian School of Medicine, Boston, MA.*

Background: A *TTR* gene variant (Val122Ile) causes misfolded tetrameric transthyretin protein, accumulating as extracellular amyloid fibrils and causing the most common form of hereditary transthyretin amyloidosis in Black Americans associated with incident heart failure. Whether this variant impacts kidney function through amyloid protein deposition is unclear.

Methods: In 8669 Black participants of the Reasons for Geographic and Racial Differences in Stroke (REGARDS) study with complete data on *TTR* genotyping and kidney function measures, we examined the association of the TTR Val122Ile (rs76992529) genotype with (1) estimated glomerular filtration rate (eGFR) and urine albumin-to-creatinine ratio (ACR) at the baseline visit and (2) risk of incident end-stage kidney disease (ESKD). We used linear regression and Cox proportional hazards models adjusted for genetic ancestry and socio-demographic and clinical factors.

Results: A total of 265 participants carried the *TTR* Val122Ile variant while 8404 participants were non-carriers. There were no significant differences in baseline characteristics between the two groups, including baseline eGFR and ACR (Table). In linear regression adjusted for genetic ancestry, sociodemographic and clinical factors, there were no significant associations of *TTR* Val122Ile carriage with eGFR (1.22±1.48; p=0.41) or ACR (-0.007±.09; p=0.43). After a mean 8±3 years of follow-up, 400 participants developed ESKD. There was no significant association of *TTR* Val122Ile carriage with incident ESKD in fully adjusted analyses (hazard ratio 0.59, 95%CI 0.25,1.44).

Conclusions: Despite an association with left ventricular hypertrophy and heart failure via extracellular amyloid fibril deposition, the *TTR* Val122Ile variant was not associated with kidney function or development of ESKD in a community-based sample of Black Americans.

Short-Term Kidney Function Decline in Patients with Nondiabetic Kidney Disease and Albuminuria with and without APOL1 High-Risk Variants

Carina M. Flaherty, Morgan Grams. On behalf of CRIC and AASK Authors. *New York University, New York, NY.*

Background: Having two *APOL1* high-risk kidney variants has been associated with higher risk of developing end-stage kidney disease (ESKD). Less is known about short-term kidney outcomes in patients with decreased kidney function and albuminuria.

Methods: The study population included participants of recent African Ancestry with CKD, urine protein-creatinine ratios (UPCR) >=0.2 g/g, and no diabetes who were genotyped for *APOL1* kidney risk variants in the African American Study of Kidney Disease and Hypertension (AASK) and the Chronic Renal Insufficiency Cohort (CRIC). Unadjusted GFR slopes were estimated using linear mixed effect models with random intercept and random slope, and change in albuminuria estimated as percent change in UPCR. Outcomes were estimated over the total study follow-up as well as three years.

Results: There were 223 and 273 participants included in AASK and CRIC, respectively, with 35.9% and 33.7% having the high-risk genotype (G1/G1, G1/G2, or G2/G2). In AASK, baseline measured GFR was 39 ml/min/1.73 m^2 and similar by risk status; UPCR was higher among those with the high-risk genotype (median 0.7 g/g vs. 0.5 g/g, p=0.02). Over 12 years, risk of ESKD was higher in high-risk individuals compared with low-risk individuals (77.5% vs. 56.6%, p=0.002), as was eGFR slope (-4.3 vs. -3.7 ml/min/1.73 m^2 per year, p=0.05). Shorter-term eGFR slope and percent change in UPCR were not different by genotype. In CRIC, baseline eGFR was 40 ml/min/1.73 m^2 and similar by genotype; UPCR was also similar between genotypes (median 0.7 g/g vs. 0.6 g/g, p=0.7). Patients in the high-risk genotype were younger and had a lower proportion of cardiovascular disease than patients in the low-risk genotype. Over 18 years, there was a non-significant trend toward higher risk of ESKD in individuals with the high-risk genotype (65% vs. 59%, p=0.3), similar to that for eGFR slope (-3.1 vs. -2.8 ml/min/1.73 m^2 per year, p=0.16). Shorter-term eGFR slope and percent change in UPCR were not different by genotype.

Conclusions: When conditioned on established CKD, UPCR ≥0.2 g/g, as well as the absence of diabetes in two prospective cohorts, short-term eGFR slope and change in UPCR were not meaningfully different by *APOL1* genotype, although long-term ESKD risk appeared to be higher in the high-risk genotype.

Kidney Prognostic Role of a Temporal Relationship between Onset of Diabetes and Hypertension in Patients with Coexisting Diabetes and Hypertension

Seungmin Song,[1] Kyungho Lee,[1,2] Minhyung Kim,[1] Junseok Jeon,[1,2] Jung eun Lee,[1,2] Wooseong Huh,[1,2] Hye Ryoun Jang.[1,2] *[1]Samsung Medical Center, Gangnam-gu, Seoul, Republic of Korea; [2]Sungkyunkwan University School of Medicine, Suwon, Republic of Korea.*

Background: Diabetes and hypertension are well-established risk factors for chronic kidney disease(CKD) and end-stage kidney disease(ESKD). These conditions frequently coexist, potentially due to bidirectional mechanisms. Prognostic differences between hypertension preceding diabetes and diabetes preceding hypertension remain unclear. We aimed to evaluate whether onset of diabetes before or after hypertension differentially influences risk of developing ESKD.

Methods: We identified all adult patients with diabetes and hypertension who participated in national health insurance service(NHIS) in Korea between 2015 and 2016. Patients were categorized into two groups based on order of onset of diabetes and hypertension: those with diabetes preceding hypertension(termed "diabetes first") and hypertension preceding diabetes(termed "hypertension first"). Demographic and laboratory data were obtained from NHIS database. Cox proportional hazards analyses were performed for ESKD.

Results: Among 995,484 patients, 468,072(47%) and 527,412(53%) developed diabetes and hypertension first, respectively. Incidence rates for ESKD were 4.53 in diabetes first group and 1.46 in hypertension first group(1,000 person-years, log-rank p<0.001). In unadjusted analysis, diabetes first group had a 3.10-fold(95%CI 2.99–3.22) higher risk of developing ESKD compared to hypertension first group. After adjusting for multiple covariates, including demographics, lifestyle factors, dyslipidemia, eGFR, blood pressure, blood glucose levels, proteinuria, duration of diabetes and hypertension, adjusted hazard ratio for ESKD was 1.55(95%CI 1.49–1.61) for diabetes first group. Stratified analyses by glucose and blood pressure status consistently showed an increased risk in diabetes first group. Subgroup analyses revealed significant interactions with age, smoking status, and CKD status, with stronger risks in younger patients, current smokers, and non-CKD.

Conclusions: In patients with coexisting hypertension and diabetes, sequence in which these conditions develop plays a significant prognostic role in predicting risk of ESKD. An earlier onset of diabetes than hypertension is associated with a higher risk. Considering order of onset of each condition could be a practical approach to enhance kidney-focused prognostication.

SA-PO1100

Discrepancy between Lifetime Risk of ESKD vs. 3-Year Risk of CKD Progression in US Adults with Diabetes

Yoshitsugu Obi,[1] Xiaoqian Zhu,[1] Maria Clarissa Tio,[1] Timothy E. Yen,[1] Michael E. Hall,[1] Neville R. Dossabhoy,[1] Tariq Shafi.[2] *[1]University of Mississippi School of Medicine, Jackson, MS; [2]Houston Methodist, Houston, TX.*

Background: The CKD Prognosis Consortium developed a model predicting CKD progression (i.e., ≥40% eGFR decline or end-stage kidney disease [ESKD]) in three years (Grams, Diabetes Care 2022). However, the risk of CKD progression is cumulative over time and the lifetime risk of ESKD is also important to assess. We sought to compare the 3-year CKD progression risk with the lifetime ESKD risk using the Swedish prediction model (Østergaard, CJASN 2022).

Methods: Among 5,284 US adults with diabetes who participated in the 1999-2020 NHANES, we estimated the lifetime ESKD risk by calibrating baseline hazards for mortality and ESKD in the Swedish prediction model. Since ESKD incidence was not available, we used the Kidney Failure Risk Equation and obtained the calibration factor for ESKD. We then evaluated their correlation by comparing risk percentiles using spearman's rho and risk quartiles using concordance kappa.

Results: Mean age was 63 years, 47% were women, median HbA1c was 7.0%, and median diabetes duration was 12 years. Mean eGFR was 82 (SD, 21) mL/min/1.73 m^2, with 65% and 32% having moderate and severe albuminuria, respectively. Median [interquartile range] 3-year CKD progression risk was 2.6% [1.5% to 5.2%], and median lifetime ESKD risk was 1.6% [0.9% to 3.0%]. There was only a fair correlation between the two risk estimates (rho=0.49, **Figure**) and only a slight agreement between the risk quartiles (kappa=0.17). The correlation and concordance were poorer among people with eGFR ≥60 mL/min/1.73 m^2 (rho=0.34; kappa=0.11). Additionally, the lifetime ESKD risk percentiles were higher than the 3-year CKD progression risk percentiles among people with longer life expectancies, and vice versa.

Conclusions: Shorter term risk of CKD progression may not be sufficient to identify individuals with high lifetime ESKD risk. Clinicians should consider lifetime ESKD risk in addition to short-term CKD progression risk when counseling people with diabetes.

Trend Analysis of Chronic Kidney Failure-Related Mortality, 1999-2020

Luqman Munir,[1] Ahmed J. Chaudhary,[2] Sara Sohail,[1] Kanwal Fatima,[1] Amna Khalid,[1] Mohammad Ammar ur Rahman,[1] Saleha Azeem.[1] NEURALKEy. *[1]King Edward Medical University, Lahore, Pakistan; [2]Detroit Medical Center, Detroit, MI.*

Background: The hallmark of chronic renal failure, also called chronic kidney disease, is a progressive decline in kidney function over time. Multiple etiologies for the illness may exist, such as glomerulonephritis, diabetes, and hypertension. High risk of heart failure, weak bones, and anemia are just a few of the many complications that may result.

Methods: We reviewed the CRF mortality data obtained from the CDC WONDER (Wide-Ranging Online Data for Epidemiological Research) Database, which spans the years 1999 to 2020. Using 95% confidence intervals, the Joinpoint Regression Program computed annual percent changes (APC) and AAMR per 1,000,000 individuals. For p<0.05, the parallelism test was deemed significant for non-parallel results.

Results: A total of 1,938,505 CRF-related deaths were reported between 1999 and 2020. With an APC of 1.33, AAMR demonstrated an increasing trend. Between 2010 and 2012, there was a noticeable peak, which was followed by a decline. Blacks or African Americans, males, non-metropolitan population, and people 85 years or older showed higher death rates. Disparate trends were found in the tests for parallelism among gender (p=0.0002), Blacks and Whites (p=0.002), Northeast and Midwest (p=0.004), Midwest and South (p=0.02), and Midwest and West (p=0.02). However, the parallelism test between urban and rural areas was not significant (p=0.07).

Conclusions: In the United States, the number of deaths from CRF has increased significantly over the last 20 years, possibly because early-stage CKD is frequently asymptomatic. Certain demographic groups continue to have higher death rates, which emphasizes the need for more research.

SA-PO1102

Albuminuria, eGFR, and Cancer Risk: The Chronic Kidney Disease Prognosis Consortium

Yejin Mok, Jennifer S. Lees. *CKD Prognosis Consortium, New York, NY.*

Background: Studies examining the association of chronic kidney disease (CKD) with cancer risk have demonstrated conflicting results. We quantified the independent associations of albuminuria and estimated glomerular filtration rate (eGFR) with cancer risk overall and among selected site-specific cancers in the CKD Prognosis Consortium (48 cohorts).

Methods: We performed individual-participant data meta-analysis of 715,713 individuals without a history of cancer. Adjusted Cox models were used to quantify the associations of urine albumin-to-creatinine ratio (ACR) and serum creatinine-based eGFR with overall and site-specific cancer risk.

Results: 94,417 incident cancer cases occurred during 17,416,991 person-years of follow-up (incidence rate of 22.2 per 1000 person-years). Higher ACR was positively associated with cancer risk [HR 1.07 (1.05-1.09 per 8-fold increase in ACR], whereas no consistent association of eGFR with cancer risk was seen [HR 1.01 (0.99 - 1.03) per 15 ml

decrease in eGFR]. For the cross-categories of ACR and eGFR, higher ACR was associated with higher risk for overall cancer risk, irrespective of eGFR levels. For site-specific cancer, lower eGFR showed a significant association with urological cancer, multiple myeloma, and prostate cancer, whereas higher ACR was related to many types of cancer (i.e., head/neck, colorectal, liver, pancreas, lung, hemolymphatic, leukemia, and multiple myeloma), in addition to kidney-related cancer. Results were similar after excluding incident cases within 1 year to minimize the possibility of reverse causation.

Conclusions: CKD measures, particularly albuminuria, were independently associated with subsequent risk of cancer. Our result warrant investigation into the pathways from albuminuria to cancer.

Funding: NIDDK Support, Private Foundation Support

Risk Stratification of Delayed Postpolypectomy Bleeding in Patients with and without Kidney Diseases: A Large, High-Dimensional Propensity Score-Matched Cohort Study

Hae-Ryong Yun, Tae-Hyun Yoo. *Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea.*

Background: The assessment of the risk of delayed bleeding following polypectomy in patients with chronic kidney disease (CKD), including those undergoing kidney failure with renal replacement therapy, has not been established. To address this issue, we conducted a high-dimensional propensity score-matched study to investigate whether CKD contributes to an increased risk of delayed post-polypectomy bleeding (PPB).

Methods: A large cohort study and retrospective analysis of 20,052 patients who underwent colonoscopy and polypectomy, between 2005 and 2022 in Korea. Propensity score matching with adjustments for patient-related, polyp-related and procedure-related factors was used to account for differences between patients based on the stage of CKD. The primary end points were the risks of delayed PPB, and the secondary end points were the risks of bleeding depending on the stage of CKD.

Results: A total of 16,895 patients were selected including 2,349 (13.9%) patients with CKD. Based on the estimated glomerular filtration rate (eGFR), 892 (38.0%) patients had CKD at stages 1 and 2, 1163 (49.5%) at stages 3 and 4, and 294 (12.5%) at stages 5 and ESRD. The prevalence of PPB in patient with CKD was 1.3 %. Adjusted propensity matching analysis, the risk of delayed PPB was significantly increased according to the stage of CKD (hazard ratio [HR] = 1.676, 95% confidence interval [CI] 1.100–2.552 for stage 1-2, HR 2.045, 95% CI 1.441–2.901 for stage 3-4, and HR 2.189, 95% CI 1.203–3.982 for stage 5 or ESRD, all $p<0.05$).

Conclusions: CKD is an independent risk factor for delayed PPB, and it showed an association with a substantially increased risk of CKD stage. Consequently, greater caution should be treated when undergoing polypectomy on patients with CKD.

SA-PO1104

Effect of Urolithiasis and Recurrent Urinary Tract Infection on Estimated GFR in CKD

Sameena Iqbal, Song-ah Chai, Celena Scheede-Bergdahl. *McGill University, Montreal, QC, Canada.*

Background: Urolithiasis is a known renal disease cause dependent on stone burden and number of interventions. Urinary tract infections (UTIs) are often associated with urolithiasis given the inflammatory state due to urinary flow obstruction. These two reversible risk factors can further cause progressive Chronic kidney disease (CKD).

Methods: Objective: The primary study objective is to report the association of urolithiasis and urinary tract infection (UTI) with eGFR decline in CKD. Methods: A retrospective cohort study was conducted in a community nephrology clinic in Quebec, Canada that included laboratory and radiologic data collection from April 1, 2015 until June 30, 2022.

Results: Upon review of 310 medical charts, the subjects had a median age of 73 years (IQR 29-99), and 58.1% of the cohort was male. The prevalence of Grade 1 and 2, Grade 3, Grade 4 and Grade 5 CKD was 10.3%, 50%, 32.3%, and 7.4%. The median follow-up time was 1555 days (28-4864). Urolithiasis was seen in 14.5%. The rate of UTIs was 0.107 events per patient-days. The multivariate generalized linear models (GLM) documented the proportionally reverse relationships between more than one UTI and decline in the individual slope of estimated GFR, reaching statistical significance. In the adjusted GLM, for every unit of ml/min/1.73m2/per day of decline in GFR slope, a 2% increase risk that is measured for recurrent UTI event (RR 1.02 (95%CI 1.00-1.04) p=0.0446. A tendency towards urolithiasis diagnosis was associated negatively with the slope of estimated GFR, as the RR for urolithiasis was 1.01 (95% CI 0.99-1.33), p=0.1136. There is an association of urolithiasis and average kidney size on GLM, p=0.0464. Recurrent UTI is associated with CKD grades with on trend analyses, p=0.049. The recurrent UTI proportions were 11%, 9% and 33% in CKD grade 3, 4 and 5, respectively among those with no urolithiasis. Majority of the UTIs were E. coli species (59%).

Conclusions: Our study demonstrated an overall association between urolithiasis, recurrent UTIs and estimated GFR slope. Recurrent UTI is not associated with kidney size. Methods to prevent recurrent urolithiasis and urinary tract infection episodes should be assessed in a prospective manner.

Association between Plasma Alpha 1-Antitrypsin Levels and Kidney Failure in Patients with CKD

Antoine Créon,[1] Julie Klein,[2,3] Sophie Liabeuf,[4,5] Celine Lange,[1,6] Christian Jacquelinet,[1,6] Joost Schanstra,[2,3] Natalia Alencar de Pinho,[1] Ziad Massy.[1,7] Centre for Research in Epidemiology and Population Health. *[1]Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; [2]INSERM 1297, Toulouse, France; [3]Universite Toulouse III-Paul Sabatier, Toulouse, France; [4]Centre Hospitalier Universitaire Amiens-Picardie, Amiens, France; [5]MP3CV Laboratory, Amiens, France; [6]Agence de la Biomedecine, La Plaine Saint-Denis, France; [7]AURA Paris, Paris, France.*

Background: Chronic kidney disease (CKD) is overrepresented in persons with alpha-1-antitrypsin (AAT) deficiency, and previous studies suggest that AAT may play a role in kidney fibrosis. This study assessed the relationship between plasma AAT and kidney failure (KF) in patients with CKD.

Methods: National, prospective cohort of 2263 patients with CKD stage 2-5. Baseline plasma AAT was measured centrally with ELISA (Bio-techne, DY1268, normal ranges from 0.9 g/l to 1.8 g/l). Cause-specific Cox models were used to estimate hazard ratios (HR) for KF, defined as initiation of kidney replacement therapy, adjusted for demographics, eGFR, albuminuria, albumin, hemoglobin, CRP, cardiovascular comorbidities, and use of RAAS, diuretics, MRAs, and corticosteroids.

Results: Patients had a mean age (±SD) of 66 years (±13) and 34% were females. The mean eGFR was 35 (±13) ml/min/1.73 m2 and median AAT (Q1-Q3) was 1.49 g/l (1.23-1.80). Over a median follow-up of 5.8 (5.4-6.3) years, 563 patients experienced KF. The relationship between AAT and KF followed a U-shaped pattern (**figure 1**). The adjusted HR (95% CI) of KF associated with a 0.5 g/l-lower baseline AAT relative to its median value was 1.33 (1.02 -1.73), while that for a 0.5 g/l-higher baseline AAT value was 1.45 (1.10-1.92).

Conclusions: A U-shaped relationship between plasma AAT and KF suggests a relative imbalance between systemic inflammation and anti-inflammatory AAT in patients with low baseline plasma AAT. Clinical studies are needed to clarify whether therapy with AAT, currently indicated only for the treatment of the severe forms of genetic AAT deficiency, may be helpful to correct AAT levels and potentially protect the risk of progression from CKD to KF.

Effect of Ambient Temperature on Renal Colic: A Systematic Review and Meta-Analysis

Csaba P. Kovesdy,[1] Hoimonty Mazumder,[2] Farah Faizah,[2] Naznin Alam,[2] Xichen Mou,[2] Hongmei Zhang,[2] Abu Mohd Naser.[2] *[1]University of Tennessee Health Science Centre, Memphis, TN; [2]The University of Memphis, Memphis, TN.*

Background: Renal colic is a clinical manifestation characterized by spasmodic pain in the lower back, which is commonly caused by kidney stones. Although limited, recent evidence suggests increased risk of kidney outcomes in exposure to elevated ambient temperature. In this meta-analysis, we aimed to elucidate the effect of ambient temperature on renal colic.

Methods: We systematically searched four leading bibliographic databases (PubMed, CINAHL complete, Scopus, and Web of Sciences) and additional sources from the inception of each database to February 12, 2024. Epidemiological studies that met a pre-determined eligibility criteria following PECOS (population, exposure, comparator, outcome, and study design) were included. The effect sizes from individual studies were standardized to Cohen's d and we performed a meta-analysis with a random-effects model to estimate a pooled Cohen's d and constructed a 95% confidence interval. We performed further sub-group analyses by study region, sample size, study design, and mean age of study participants.

Results: Out of 1463 primarily retrieved articles, seven articles representing 758666 study participants underwent meta-analysis. Most of the studies were conducted in the US (3) followed by China (2), Canada (1), and Israel (1). Ambient temperature demonstrated a significant effect on renal colic [Cohen's d: 0.30, 95% CI: 0.18, 0.41, p-value < 0.001, I^2 = 99.08%]. Subgroup analyses for potential explanation of heterogeneity demonstrated statistically significant between-group variance for study region [America- Cohen's d: 0.25, (95% CI: 0.11, 0.39); Asia - Cohen's d: 0.44, (95% CI: 0.42, 0.45)] and study design [Case-crossover- Cohen's d: 0.46, (95% CI: 0.01, 0.93); Retrospective cohort - Cohen's d: 0.44, (95% CI: 0.42, 0.45); Time-series - Cohen's d: 0.21, (95% CI: 0.17, 0.25)].

Conclusions: These findings suggest a moderate effect of ambient temperature on renal colic.

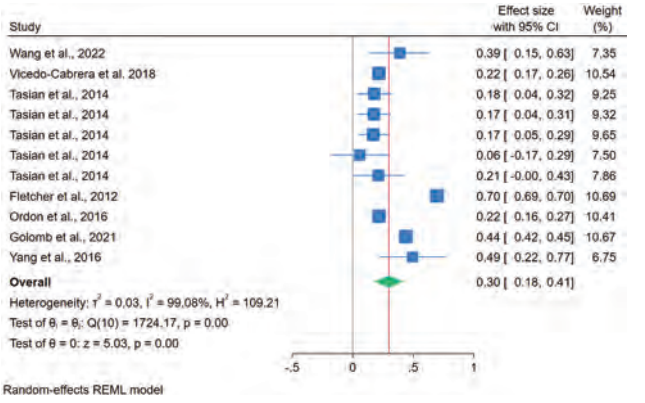

Figure 1: Forest plot showing summary-effect.

SA-PO1107

Deoxycholic Acid and the Risk of Death and Cardiovascular Events among Patients with Advanced CKD

Jun Ha Gu, Michel Chonchol, Cole L. Hoffman, Makoto Miyazaki, Shinobu Miyazaki-anzai, Kristen L. Nowak, Anna Jovanovich. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Circulating levels of the secondary bile acid, deoxycholic acid (DCA), are elevated in chronic kidney disease (CKD) and may contribute to vascular calcification in CKD patients. Whether circulating DCA levels are associated with death and cardiovascular events (CVE) among advanced chronic kidney disease patients is unknown.

Methods: The Homocysteine Study was a randomized double-blind trial evaluating the effects of high doses of folic acid and B vitamins on all-cause mortality (ACM) and CVE in subjects with advanced CKD and elevated serum homocysteine levels. Fasting serum DCA levels were measured in stored serum samples obtained at 3 months in a cohort of 1,054 patients with mainly stage 4 CKD (mean eGFR 18.1± 6.5 mL/min/1.73m^2). The study population was divided into quartiles according to plasma DCA levels. We used Cox proportional-hazards models to examine the association between DCE levels with ACM and a composite of CVE (combining myocardial infarction, stroke, and amputation).

Results: Participants had a mean age of 69±11 years. The median DCA level was 119 [63-232] ng/mL. During a median follow-up of 3.0 years, 445 (42%) patients died from any cause and 210 (20%) had a CVE. Higher DCA levels were not associated with higher risks of death. Compared to the first (lowest) quartile, the HR (95% CI) for death were as follows: second quartile, 0.89 (0.74-1.06); third quartile, 0.98 (0.82-1.18) and fourth quartile, 0.88 (0.73-1.06) after adjustment for potential confounders available in the database. Similar results were obtained when DCA was examined as a continuous variable: 0.97 (0.93-1.02). Compared to the lowest quartile, the two highest quartiles of DCA were also not associated with a significantly elevated risk of CVE (HR 0.98, 95% CI 0.82-1.78) and (HR 0.87, 95%CI 0.73-1.05), respectively after multivariate adjustment.

Conclusions: Among HOST participants, DCA was not associated with death and cardiovascular events in patients with advanced CKD not requiring dialysis.

Funding: Veterans Affairs Support

SA-PO1108

Association of Serum Complement 3 (C3) with Renal Arteriolar Hyalinosis and Blood Pressure-Dependent Proteinuria in Patients with Non-nephrotic CKD

Kentaro Kohagura,[1] Nanako Oshiro,[1,2] Yuki Shinzato,[2] Ryo Zamami,[2] Kenya Kusunose.[2] *[1]Ryukyu Daigaku Igakubu Fuzoku Byoin, Nakagami-gun, Japan; [2]Ryukyu Daigaku Igakubu Daigakuin Igaku Kenkyuka, Nakagami-gun, Japan.*

Background: Renal arteriolar hyalinosis may be associated with proteinuria by disrupting the autoregulatory system in the afferent arteriole. Deposition of complement C3 (C3) is commonly seen in hyaline lesions of arteriolosclerosis. Serum C3 has been suggested to play a pathogenic role as an adipocytokine. However, an association of serum C3 with renal arteriolar hyalinois and blood pressure dependent proteinuria in patients with non-nephrotic chronic kidney disease (CKD) is unknown.

Methods: A total of 174 consecutive patients who underwent renal biopsy at our department were considered for the study. We excluded patients with serum albumin less than 3.0 mg/dl, vasculitis, lupus nephritis, etc. leaving us with 122 patients. Arteriolar hyalinosis was assessed using a semiquantitative grading system. We divided the patients into four subgroups based on the high systolic blood pressure (hSBP) and high serum C3 (hC3), defined as equal or above of their median value. We investigated an association of serum C3 with renal hSBP/hC3 subgroups with proteinuria.

Results: Median age, blood pressure, estimated glomerular filtration rate (eGFR), urine protein, and serum C3 were as follows: 42.0 years, 123/74 mmHg, 71.3 ml/min/1.73 m^2, 0.7 g/gCr and 104.5mg/dl, respectively. Serum C3 was positively associated with body mass index, HbA1c, low-density lipoprotein cholesterol, oxidative stress index, high-sensitivity C-reactive protein (hs-CRP), urine protein, and arteriolar hyalinosis index. In the multiple regression analysis, serum C3, but not C4, was associated with arteriolar hyalinosis index independent of age, sex, and potential confounders (β=0.195, P=0.026). SBP was significantly associated with urinary protein in patients with hC3 but not in those without hC3. In the multiple logistic regression analysis with hC3-/hSBP- as reference, hC3+/hSBP+ was independently associated with high proteinuria, defined as the highest tertile (OR 5.67, 95%CI 1.32-34.29, P=0.02), but its significance disappeared after additional adjustment for the arteriolar hyalinosis index.

Conclusions: These results suggest that serum C3 may be elevated as an adipocytokine and may be associated with increased BP-dependent proteinuria by inducing arteriolar hyalinosis in non-nephrotic CKD patients.

SA-PO1109

Association of Biomarkers of Fibrosis with the Progression of CKD

Jayanta Gupta,[1] Anvesha Srivastava,[2] Richard L. Amdur,[3] Dominic S. Raj.[2]
[1]Florida Gulf Coast University, Fort Myers, FL; [2]The George Washington University School of Medicine and Health Sciences, Washington, DC; [3]Northwell Health Feinstein Institutes for Medical Research, Manhasset, NY.

Background: Fibrosis of the kidney is the hallmark and the final common pathway of chronic kidney disease (CKD) progression, regardless of underlying etiology. Fibrosis is characterized by excessive production and deposition of extracellular matrix (ECM) proteins mainly in the kidney interstitium and results in structural damage, impairment of renal function, and eventually end-stage renal disease (ESRD). The most abundant collagens in the interstitial matrix of the kidney are collagen type I (COL I) and III (COL III). In renal fibrosis, these collagens are upregulated and the activity of the proteases responsible for their remodeling is altered. In this study, we used a sub-cohort of the Chronic Renal Insufficiency Cohort (CRIC) to examine the association of serum PRO-C6, a biomarker for type VI collagen formation and urine C3M, a biomarker for type III collagen degradation with a composite endpoint (ESRD or 50% decline in eGFR).

Methods: Urine C3M was adjusted for 24-hour urinary creatinine excretion. Subjects were categorized into three groups based on tertiles of the biomarker (serum PRO-C6 and urine C3M) levels. The association of biomarkers with the composite outcome was investigated using Kaplan-Meier curves and multivariable Cox proportional hazards regression models after controlling for age, sex, race, income, BMI, diabetes at baseline, hypertension, use of ACEI/ARB, history of CVD, history of smoking, baseline eGFR and UACR.

Results: The number of events in the serum PRO-C6 and urine C3M groups were 426 (out of 998 participants used in the Cox model) and 417 (out of 985 participants used in the Cox model) respectively. The multivariable-adjusted hazard ratios (HRs) comparing the upper to the lower tertiles of serum PRO-C6 and urine C3M for the composite outcome was 1.85 (95% CI: 1.29 - 2.66) and 0.72 (95% CI: 0.56 - 0.94) respectively.

Conclusions: Serum PRO-C6 and urine C3M levels were directly and inversely associated with the composite outcome respectively. These biomarkers may be useful in predicting early events in renal fibrosis.

SA-PO1110

Prognostic Implications of Relative Eosinophil Counts in Nephrosclerosis

Haruki Mae, Go Kanzaki, Kotaro Shimoyama, Hideaki Kuno, Saeko Hatanaka, Hirokazu Marumoto, Takaya Sasaki, Kotaro Haruhara, Nobuo Tsuboi, Takashi Yokoo. The Jikei University School of Medicine. *The Jikei University School of Medicine, Minato-ku, Japan.*

Background: The interplay between atherosclerosis and chronic inflammation has gained considerable recognition, with elevated eosinophil counts identified as a risk factor for cardiovascular diseases. Nonetheless, the effect of eosinophils on the kidney prognosis of patients with nephrosclerosis remains unclear.

Methods: This retrospective observational study was conducted in a single hospital. Patients diagnosed with nephrosclerosis via kidney biopsy between January 2010 and December 2023 were included in the study. Clinical data were extracted from hospital records at the time of biopsy to evaluate the association between blood relative eosinophil count (REC; percentage of eosinophil in WBC) and renal outcomes. Logarithmic transformation was performed for continuous variables to make data conform more closely to the normal distribution. The primary endpoint was dialysis initiation during follow-up. Patients were categorized into three groups based on their REC levels (REC grade 1, lower group [0.7-2.6%]; 2, middle group [2.7-4.0%]; and 3, higher group [4.2-20.5%]), and a log-rank test was performed. Cox regression analysis was conducted and adjusted for REC, age, sex, BMI, and mean arterial pressure.

Results: The cohort comprised 76 patients (median age 54.9 years, 81.6% male, with a median follow-up duration of 68.7 months [interquartile range 21.8-106.8]). Fifteen patients (19.7%) underwent dialysis. Kaplan-Meier curves with the log-rank test for time to events showed no significant difference (Log-rank p = 0.07; Figure 1). However, Cox regression analysis demonstrated that REC, as a continuous variable, was significantly associated with the initiation of dialysis (hazard ratio 1.41, 95% confidence interval 1.21-13.9).

Conclusions: Eosinophil counts may serve as a significant prognostic marker for kidney outcomes in patients with nephrosclerosis.

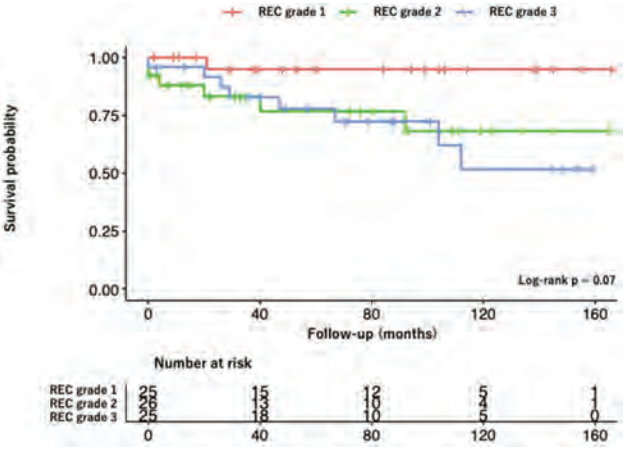

Figure 1

SA-PO1111

Value of Histopathologic Assessment for Nephrosclerosis in Predicting Kidney Function Decline

Haekyung Lee,[1,2] Soon hyo Kwon,[1,2] Hyunjin Noh.[1,2] *[1]Soonchunhyang University Hospital, Seoul, Republic of Korea; [2]Soonchunhyang University Hospital Kidney Center, Seoul, Republic of Korea.*

Background: Accurate prediction of kidney failure risk is crucial for the effective management of kidney diseases. While demographic and laboratory parameters have been utilized to stratify the risk of kidney failure, the potential of histopathologic assessments—specifically evaluating chronic changes such as glomerulosclerosis, interstitial fibrosis, tubular atrophy, and arteriosclerosis—to improve the prediction of kidney function decline remains to be elucidated.

Methods: This study retrospectively analyzed patients who underwent native kidney biopsy from 2014 to 2022 at Soonchunhyang University Seoul Hospital in South Korea. Two kidney pathologists performed semiquantitative visual inspections for glomerulosclerosis, interstitial fibrosis, tubular atrophy, and arteriosclerosis. We evaluated the value of these histopathologic changes in predicting the risk of a decrease in estimated glomerular filtration rate (eGFR) by 30% or more.

Results: Among 491 patients, 183 (37.3%) experienced a decrease in eGFR by 30% or more. Multivariable analyses, which included demographic and laboratory parameters, revealed that severe tubular atrophy (>50%) (hazard ratio [HR] 2.74, 95% CI 1.68–4.46, P < 0.001) and severe interstitial fibrosis (>50%) (HR 2.09, 95% CI 1.31–3.34, P = 0.002) were independently associated with the risk of an eGFR decline of 30% or more. Additionally, incorporating these histopathologic changes into traditional clinical parameters significantly improved the prediction of eGFR decline.

Conclusions: The integration of histopathologic assessments of chronic kidney changes into clinical information significantly improves the prognostic assessment of eGFR decline. This suggests that histopathologic evaluation of chronic kidney changes should be considered to improve risk stratification in patients with kidney diseases.

SA-PO1112

Need and Efficacy of Add-On Opt-Out Strategy to Promote Delivery of Kidney Replacement Therapy (KRT)-Directed Comprehensive Pre-ESKD Education (CoPE) for All Patients with Advanced CKD

Popy Shell,[1] Malea Joyce,[1,2] Grant D. Scheiffele,[1] Shobha Subhash,[1] Teresa A. Lyles,[1] Huanguang Jia,[1] Ashutosh M. Shukla.[1,2] *[1]VA North Florida South Georgia Veterans Health System, Gainesville, FL; [2]University of Florida, Gainesville, FL.*

Background: CoPE is a must for informed KRT selection and use; however, only a minority of advanced CKD patients receive CoPE before KRT. We lack evidence-based estimations for patients' interest for CoPE and effective strategies to facilitate CoPE for all patients with advanced CKD. Mail-inviting eligible patients derived from an electronic health record database can improve advanced CKD identification and aid CoPE dissemination; however, its efficacy has not been tested.

Methods: We conducted secondary analysis of recruitment processes for the ongoing TEACH-VET study aimed to evaluate the benefits of CoPE (vs. usual care) on many patient-level outcomes among Veterans with advanced CKD. TEACH-VET employs a mail-based opt-out strategy; all advanced, stage 4 and 5 CKD patients are extracted from the clinical database, and mail-invited to receive CoPE or usual care (opt-in cohort). Patients not self-responding to study invite within two-week period are actively contacted (opt-out cohort). We examined the rates and efficiency of CoPE interest assessed by enrollment as co-primary outcomes, and successful contact with patients and final randomization as secondary outcomes.

Results: Of the 1130 patients eligible for the opt-in cohort, 90 (8%) enrolled for education with passive, strategy. Significantly higher fraction (n=293, 48%, p<0.001) of the eligible 617 approached through active outreach were enrolled for education. Overall, 77% of all CoPE enrollments required an active outreach. Both, upstream successful contacts (72% vs. 10%, p<0.001) and the downstream randomizations into study (34% vs. 7%, p=0.01) were higher for active outreach group. Subgroup analysis of those successfully contacted with either method showed that enrollments were higher among passive approach (80%), compared to active outreach (66%, p=.02) group. The efficiency of add-on active outreach was significantly better, with time per successful approach 29±8 vs. 169±183 mins, p<.001, per successful enrollment 25.33±11.57 vs. 140.11±157, p<0.001, and randomization 92±34 vs. 319±385, p<0.001, compared to passive strategy.

Conclusions: Adopting a process of active outreach allows higher and more efficient enrollments for the provision of CoPE, necessary for informed KRT decision-making.

SA-PO1113

Longitudinal Study of Conservative Kidney Management by Using Tools to Identify Palliative and End-of-Life Care Needs

Ying-ying Seow,[1] Swee Ping Teh,[1] Ivan Wei Zhen Lee,[1] Koey Cheng,[2] Angelica Lee,[2] Lee Ying Yeoh.[1] *[1]Sengkang General Hospital, Singapore, Singapore; [2]Lee Kong Chian School of Medicine, Singapore, Singapore.*

Background: Trajectory of end-stage kidney disease (ESKD) patients on conservative care varies. The objective of study was assessing the utility of objective assessment tools and mortality outcome.

Methods: This is a single center, prospective study of conservative kidney management patients from April 2021 to February 2024. Palliative trained community nurse performed monthly home visit and assessment. Edmonton symptom assessment system revised (ESASr version 2016), resource utilization groups activities of daily living (RUG-ADL) and palliative performance scale (PPS) were used and monitored longitudinally. SPSS version 27 was used for analysis, $p < 0.05$ is considered significant.

Results: A total of 103 patients with median follow-up of 11.1 months (IQR: 0.4, 15.8). Forty-seven patients passed away during the study. The baseline characteristics including female 64.1%, Chinese 80.6%, mean age 79.6±7.7 years, estimated glomerular filtration rate 10.5±3.4ml/min and Charlson comorbidity index 8.4±1.9. No significant difference between the survived versus demised group. However, those demised patients had higher ESASr (4.4 vs 2.0), RUG-ADL (6.3 vs 4.9) but lower PPS (59 vs 67) at baseline. Mixed model using repeated measurements for ESASr, RUG-ADL and PPS were done. The variance within each time point for RUG-ADL, ESASr and PPS were 1.5, 6.5 and 27.4, whereas covariance between any 2 time-points were 7.2, 11.3 and 136.9 respectively. There was no interaction with PPS model. The CKM patients have relative stable PPS until last few weeks of life (figure1).

Conclusions: This study demonstrated the high degree of symptom burden and functional decline toward the end of life for CKD patients managed conservatively. Optimal community care allow close monitoring of symptoms with optimization of care and timely referral to hospice service to reduce hospitalization for end-of-life care.

Funding: Government Support - Non-U.S.

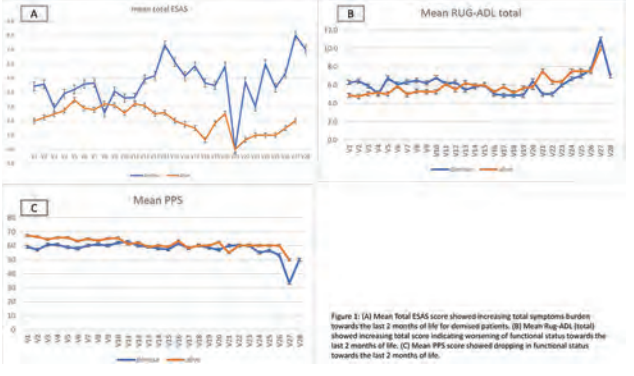

Figure 1: (A) Mean Total ESAS score showed increasing total symptoms burden towards the last 2 months of life for demised patients. (B) Mean Rug-ADL (total) showed increasing total score indicating worsening of functional status towards the last 2 months of life. (C) Mean PPS score showed dropping in functional status towards the last 2 months of life.

SA-PO1114

Age-Stratified Cost of Care in CKD: Real-World Data from a Retrospective Cohort Study

Satabdi Chatterjee,[1] Adrian R. Levy,[2] Sydnie Stackland,[3] Lindsay Bengtson,[1] Bonnie M. Donato.[1] *[1]Boehringer Ingelheim Pharmaceuticals Inc, Ridgefield, CT; [2]Dalhousie University, Halifax, NS, Canada; [3]Panalgo LLC, Boston, MA.*

Background: Chronic kidney disease (CKD) affects an estimated 14% of US adults, and is more common in those aged 65 years or older, than younger age groups. Little is known regarding the costs of CKD by age. In a large cohort of patients with prevalent CKD, this study described the mean total and direct medical costs accrued in the overall and age-stratified cohorts.

Methods: A retrospective longitudinal cohort study was conducted using Optum® Market Clarity electronic health record-linked claims data. The study cohort included adults with 2 estimated glomerular filtration rates <60 ml/min/1.73m^2 (3-12 months apart) followed by an ICD 9/10 code for CKD, and 1-year of continuous enrolment pre- and post-CKD diagnosis. These included patients diagnosed before January 1, 2020 plus new cases arising in 2020 (prevalent cohort); subjects who died or disenrolled in 2020 were excluded upon censoring. Total costs including direct medical costs (inpatient, outpatient, emergency department) as well as medications were calculated for the prevalent CKD cohort for the year 2020. Mean costs per patient were computed for the overall cohort and by age groups.

Results: In 2020, there were 214,631 patients with CKD, consisting of: 7,270 (3.4%) aged 18-49 y; 44,879 (20.9%) aged 50-64 y; 115,070 (53.6%) aged 65-80 y; and 47,412 (22.1%) aged ≥81 y. The mean (SD) total and medical costs were $68,095 (139,099) and $48,379 (104,185), respectively. Cost breakdown by age groups showed annual mean total costs of: $82,958 (203,481), $76,073 (170,039), $69,675 (135,308), and $54,432 (95,669), among the 18-49, 50-64, 65-80, and ≥81 y subgroups, respectively. Total medical costs were $53,388 (139,247), $50,826 (126,435), $49,614 (101,644), and $42,297 (76,868), respectively, ranging from 64% in those aged 18-49 to 78% among those ≥81 y.

Conclusions: In a large cohort of insured patients with prevalent CKD, medical costs accounted for nearly two-thirds of the total costs, and this proportion increased in older age groups. Better understanding of the drivers of medical costs by age along with other sociodemographic and clinical characteristics can provide critical insights on surveillance of CKD, and consequently, informing optimal strategies for reducing the burden of CKD.

SA-PO1115

Timeliness of Documentation and Costs of Care in Adults Newly Diagnosed with CKD

Satabdi Chatterjee,[1] Adrian R. Levy,[2] Sydnie Stackland,[3] Lindsay Bengtson,[1] Bonnie M. Donato.[1] *[1]Boehringer Ingelheim Pharmaceuticals Inc, Ridgefield, CT; [2]Dalhousie University, Halifax, NS, Canada; [3]Panalgo LLC, Boston, MA.*

Background: Among persons with new onset chronic kidney disease (CKD), previous research has found considerable delay between laboratory evidence and documented diagnosis of the condition. However, the consequences of diagnostic delay are not known. Among adults with laboratory evidence (two estimated glomerular filtration rate [eGFR] <60 mL/min/1.73 m^2 measured between 3-12 months apart) and a documented diagnosis of CKD (using ICD 9/10 codes), the study described the mean annual costs, among those with a documentation of the diagnosis within six months ("timely"), and greater than six months ("delayed") of laboratory-based CKD.

Methods: A retrospective longitudinal cohort study was conducted using 2009-2020 Optum® Market Clarity electronic health record-linked claims data among adults with an incident diagnosis of CKD. The study computed the mean total annual costs, which included direct medical (inpatient, outpatient, emergency department) costs and pharmacy costs (in 2022 United States Dollars) between cohorts stratified by the timing of CKD diagnosis. Mean annual costs for each component were calculated by dividing the costs incurred during follow up for each patient divided by the number of years of follow-up that the patient contributed, and represented cost per patient per year.

Results: A total of 193,539 individuals with incident diagnosis of CKD were included; of them, 55,154 (28.5%) had a timely documented diagnosis of CKD, while 138,385 (71.5%) recorded a delayed documentation. The mean (SD) total annual costs were $46,030 (194,293) among those with timely diagnosis, and $50,151 (463,278) among the delayed cohort. Breaking down those totals, the annual mean medical costs were $37,054 (190,103) among those with timely diagnosis, and $41,007 (461,608) with delayed diagnosis. The mean annual pharmacy costs were $8,977 (31,296) and $9,145 (30,035) in timely diagnosed and delayed cohorts, respectively.

Conclusions: In large cohort of US adults with incident CKD, our descriptive analysis found that, less than 30% had a timely documentation, and incurred lower costs than the cohort with delayed documentation. While this could be partially driven by the selection of patients in the timely and delayed groups, our preliminary findings suggest the need for timely documentation of CKD.

SA-PO1116

RevOCE CKD: Revolutionising Outpatient Care for Patients with CKD

Hannah M. O'Keeffe,[1] Saif Al-Chalabi,[1] Ivona Baricevic-Jones,[1] Pierina Kapur,[2] Carlie A. Gardner,[3] Fiona Mendell,[3] Jude Allen,[1] Schanhave Santhirasekaran,[1] Paul W. Robinson,[1] James Ritchie,[1] Philip A. Kalra,[1] Dimitrios J. Poulikakos,[1] Smeeta Sinha.[1] *[1]Northern Care Alliance NHS Foundation Trust, Salford, United Kingdom; [2]Chapel Group Medical Centre, Manchester, United Kingdom; [3]Newbury Green Medical Centre, Manchester, United Kingdom.*

Background: Early detection of chronic kidney disease (CKD) including testing for urine albumin:creatinine ratio (uACR), and risk stratification using tools like the kidney failure risk equation (KFRE) enables proactive management. This facilitates the initiation of renoprotective therapies and earlier identification of patients at risk of progression who should be seen in specialist care. This programme is a multifaceted Quality Improvement intervention to improve CKD management, including the establishment of a virtual multidisciplinary meeting (MDT) to provide specialist advice to General Practitioners (GPs), the creation of a pharmacy medications optimisation pathway, and the utilisation of data to highlight high risk patients.

Methods: Virtual MDTs were established as a pilot with two primary care practices, commencing March 2023. Five MDTs have been carried out in these practices, with an educational component, and approximately 6 patients discussed at each. The virtual MDTs have now been scaled to a third practice, and a primary care network where 8 practices meet together. The MDTs have been iterative, with changes made based on feedback. Patients have been selected by GPs for discussion and data from the practices has been used to identify high risk patients.

Results: Of patients (n=38) discussed at MDT, the majority were managed remotely (n=29, 76.3%) avoiding onward referral. More than 50% of patients discussed had medication changes (e.g. recommendation to commence an SGLT2 inhibitor). The two practices involved in the project since commencement now have CKD coding significantly above average in the region; prevalence of 4.85% and 3.41%, compared to an average of 3.06%. They have uACR screening rates above average; 60.6% and 70.6%, compared to 45.2%. They have SGLT2 inhibitor prescribing rates above average at 35.9/1,000 and 45.8/1,000, versus 29.8/1,000 for the region.

Conclusions: This model has proven acceptable to primary care and can improve patient care, with quicker access to specialist input without the need for patients to be seen in clinic and the associated waiting times. We plan to scale this to additional practices and primary care networks with ongoing assessment of the outcomes and impact.

SA-PO1117

Preemptive Outpatient Clinic Experience: Holistic Approach vs. Standard of Care

Carmen Sivo,[1] Raffaella Guido,[1] Emanuela Cataldo,[2] Ilario Russo,[1] Francesca Annese,[1] Paola M. Acquaviva,[1] Gloria Rana,[1] Gianvito Caggiano,[1] Marco Fiorentino,[1] Adele Mitrotti,[1] Loreto Gesualdo.[1] *[1]Universita degli Studi di Bari Aldo Moro, Bari, Italy; [2]Poliambulatorio Altamura, Altamura, Italy.*

Background: Pre-emptive kidney transplantation (PKT) represents the best option of renal replacement therapy (RRT), but it is still underused.

Methods: We analyzed lab parameters at baseline, at the last follow-up and RRT initiation outcomes in a cohort of 404 chronic kidney disease (CKD) patients with G4-G5 KDIGO-stages, afferent to pre-emptive outpatient clinic at Policlinico of Bari (Apulia, Italy), from January 2017 to January 2024. Inclusion criteria: age within 18 e 80 years, eGFR CKD-EPI < 30 ml/min. We compared different parameters of CKD progression in a group of patients treated with a multidisciplinary holistic approach (that included a nutritional and psychological counseling) and a group of patients managed with standard of-care approach.

Results: Patients (262 M and 142 F) had a mean age of 55 years, with follow-up mean timing of 686,3 days. Of the 404 patients, 139 started hemodialysis, 122 are still in follow-up, 69 chose peritoneal dialysis, 43 underwent PKT, of which 36 from living donors and 7 from deceased donors, while 23 were lost at follow up and 8 died. Patients treated with multidisciplinary holistic approach (N=73) had a lower cumulative probability of initiating RRT (LogRank test: p=0.003) rather than the standard of care group (Fig. 1). Specific nutritional approach was associated with a significative azoturia reduction in the holistic group (15,5 vs 20,3 g/24h); while the use of music- therapy intervention determined a reduction in anxiety and tiredness patients' perception.

Conclusions: Multidisciplinary approach could represent an opportunity to slow CKD progression and increase the number of PKT. These preliminary data lay the foundations for a careful management of advanced CKD patients.

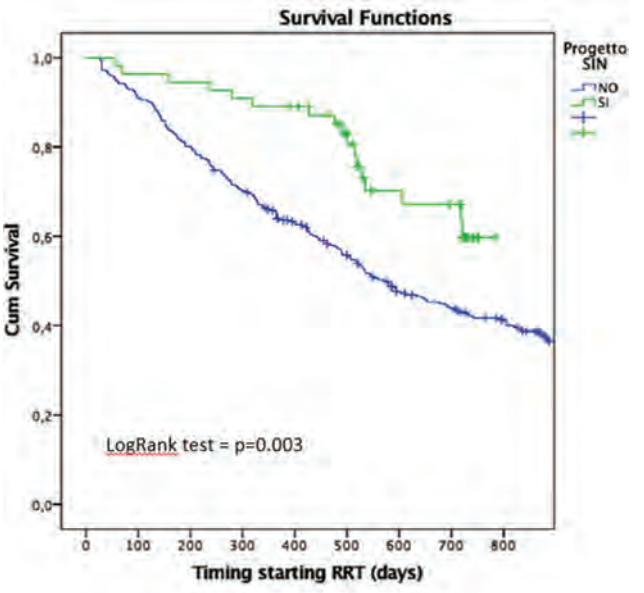

Fig. 1 Cumulative probability of initiating RRT in the holistic and standard- of- care groups.

SA-PO1118

Slicer Dicer as a Potential Tool for Self-Assessment

Richard Hae,[1,2] Sunchit Madan,[1,3] Anita Acai,[1,2] Steven Wong,[1,2] Azim S. Gangji.[1,2] *[1]McMaster University, Hamilton, ON, Canada; [2]St Joseph's Healthcare Hamilton, Hamilton, ON, Canada; [3]William Osler Health System, Brampton, ON, Canada.*

Background: Self-assessment is a crucial competency for physicians, yet the evidence suggests that physicians have limited ability to do so and assessment of competence requires external feedback. Slicer Dicer is a self-service reporting tool on Epic that enables efficient patient data collection, providing a potential tool to self-assess practice patterns. Our study aims to explore whether Slicer Dicer can collect meaningful data for physicians to practise self-assessment. We piloted this question collecting data on prescribing patterns of sodium-glucose co-transporter 2 inhibitors (SGLT2i) in nephrology clinic patients with diabetes mellitus (DM) and chronic kidney disease, aligning with current care standards for this cohort.

Methods: Slicer Dicer was used to collect data from July 1, 2023 to December 31, 2023. Patients were captured using filters by provider, context, visit type, and medical history. "Slices" by medications were created to determine the number of patients on an SGLT2i.

Results: Slicer Dicer captured 1357 patients in the nephrology clinic amongst thirteen nephrologists with a diagnosis of DM who may benefit from an SGLT2i. Of these, 627 (46.2%) of these patients were found to be on an SGLT2i. The percentage of patients on an SGLT2i ranged from 32.9% to 61.4%.

Conclusions: We highlight the potential for Slicer Dicer as an innovative method to collect data using easily accessible EMR tools. Future directions will be aimed at how physicians can use this objective data to self-assess their practice by closer analysis of patients who are not meeting current care standards.

	Patients on SGLT2i	Total number of patients	Percentage (%) of patients on SGLT2i
Nephrologist #1	53	161	32.9
Nephrologist #2	94	225	41.8
Nephrologist #3	55	108	50.9
Nephrologist #4	87	205	42.4
Nephrologist #5	33	63	52.4
Nephrologist #6	62	101	61.4
Nephrologist #7	64	151	42.4
Nephrologist #8	37	91	40.7
Nephrologist #9	77	168	45.8
Nephrologist #10	58	105	55.2
Nephrologist #11	88	166	53.0
Nephrologist #12	54	115	47.0
Nephrologist #13	20	41	48.8
Total	627	1357	46.2

Patients in nephrology clinic with DM from Jul 1-Dec 31, 2023 by nephrologist

SA-PO1119

A LUCID Approach to CKD Care Using Collaborative Primary and Secondary Care Virtual Clinics

Rupert Major,[1,2] James Burton.[1,2] LUCID (Leicester, Leicestershire, and Rutland Chronic Kidney Disease Integrated Care Delivery Project). *[1]University of Leicester, Leicester, United Kingdom; [2]University Hospitals of Leicester NHS Trust, Leicester, United Kingdom.*

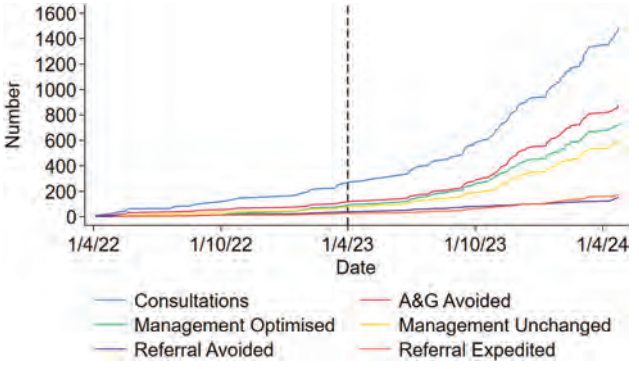
Background: Most people living with CKD are managed in a traditional primary care setting but more collaborative working with secondary care physicians may improve cardiovascular and ESKD outcomes. Standardized systems for CKD screening at a federal level are currently being considered and incentive systems, such Medicaid's merit-based incentive payment system value pathways, may face implementation barriers to improving care.

Methods: We developed and implemented a novel education and virtual CKD service in the UK - "The **L**eicester, Leicestershire, and R**U**tland **C**hronic Kidney Disease **I**ntegrated Care **D**elivery Project" (LUCID) - across an area of ~1.2 million people with ~60,000 people living with CKD. The programme focused on four core LUCID principles for people living with CKD: 1. Identification of cases at a population level 2. Optimisation of guideline directed medical therapy 3. Surveillance of the known CKD population 4. Education for public and professionals

Results: In April 2022 virtual clinics were piloted in an area of ~150,000 people with the focus on the four key principles including education during virtual clinics. Virtual clinics were delivered by an attending nephrologist in collaboration with primary care physicians and pharmacists. The program was expanded in April 2023 to make virtual clinics available to 130 primary care practices with support via an EHR-based CKD dashboard to support the four LUCID principles. Upto 1st April 2024, 1341 consultations have occurred across 102 virtual clinics. 590 episodes of medicines optimisation (Figure 1) have occurred for people living with CKD and often other co-morbidities such as hypertension (75%), diabetes (56%) and heart failure (14%).

Conclusions: LUCID can lead to the delivery of identification, optimization, surveillance and education for people living with CKD and other co-morbidities at a population level. LUCID may represent a clinical model that can promote efficient care, especially in the context of Medicaid's incentive systems and if federal CKD screening were to be implemented.

Funding: Commercial Support - AstraZeneca UK



SA-PO1120

A Collaborative Approach: Pharmacist-Led CKD Clinic in the Primary Care Setting

Erica Reinhardt, Joanna N. Peduzzi, Nathan Jaworsky, Jessica Zuik, Nissreen El Fadawy. *University Hospitals, Cleveland, OH.*

Background: Chronic Kidney Disease (CKD) affects a growing number of US adults every year, with many unaware of their condition. To address this, our ambulatory care pharmacy team has initiated a pharmacist-led CKD clinic in the primary care setting. We aim to identify and provide free Telepharmacy services, treatment, and monitoring for at least 100 patients in the early stages of CKD within our internal medicine practice over the course of a year and measure the impact of our services.

Methods: Patients were selected for pharmacist intervention based on specific criteria, including diagnoses of diabetes, hypertension, and/or CKD, and GFR <90 ml/min and/or urine ACR >30 mg/mmol. Initially, 124 patients were identified candidates for the pilot program, and as of May 2024, 108 patients are participating. Among these patients, 100 have diabetes and 31 have a urine ACR >30 mg/mmol. After identification, patients had a telepharmacy visit with a pharmacist, who completed a medication reconciliation, reviewed lab results, initiated appropriate medications, and provided instructions for lab tests and follow-up visits. The pharmacy team tracked medication adherence, referrals to nephrology, and lab data.

Results: Iinitial findings indicate the pharmacist-led program is impactful. Regarding medication adherence, all patients were prescribed an SGLT2i, and 75% were prescribed an ACE/ARB. Twelve patients were originally under the care of a nephrologist. No new referrals to nephrology were made. Additionally, 59% of patients experienced an increase or no change in their GFR.

Conclusions: The pharmacist led team will continue to follow these patients through July 2024. To this point, the impact of a pharmacist-led CKD clinic has demonstrated increased compliance on medication access and adherence with 100% of patients being treated with an SGLT2i and 75% an ACE/ARB as appropriate. Additionally no new referrals were made to nephrology for these patients throughout the pilot program. And finally, 59% of patients to date have seen a plateau or increase in their GFR indicating preservation of kidney function.

SA-PO1121

Perspectives and Current Practices in the Provision of Sexual Health Support for People with CKD: A Survey of Canadian Health Care Providers

Meghan J. Elliott,[1] Shannan Love,[1] Sabrina Jassemi,[1] Dwight Sparkes,[4] Sandi M. Dumanski,[1] Brenda Hemmelgarn,[2] Clare Mckeaveney,[5] Janine Farragher,[3] Katie B. Ahrenholz,[1] Gillian Crysdale,[1] Nancy Verdin,[4] Maoliosa Donald.[6] *[1]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [2]University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada; [3]University of Toronto, Toronto, ON, Canada; [4]Can-SOLVE CKD Network, Vancouver, BC, Canada; [5]Queen's University Belfast, Belfast, United Kingdom; [6]University of Calgary, Calgary, AB, Canada.*

Background: People living with chronic kidney disease (CKD) have identified sexual health as an important aspect of their wellbeing and kidney care. However, limited information is available to integrate sexual health support within multidisciplinary CKD care. We aimed to explore the perceptions, practices, and needs of healthcare providers in Canadian multidisciplinary CKD clinics related to sexual health support for individuals with non-dialysis CKD.

Methods: We administered an online survey to healthcare providers (i.e., nephrologists, nurses, allied health professionals) from multidisciplinary CKD clinics across Canada. The survey included questions related to providers' understanding of sexual health, current practices, and perceived gaps in how patients' sexual health is addressed in routine CKD care. We conducted semi-structured interviews with interested respondents to expand on survey responses. Data were analyzed descriptively for the survey and using content analysis for the qualitative data.

Results: Thirty nurses, 23 nephrologists, 8 allied health professionals, 5 managers, and 5 other team members (e.g., unit clerk) completed the survey between September and December 2023. Participants most commonly defined sexual health as physical symptoms related to sexual function, prevention of sexually transmitted infections, and pregnancy and fertility care. Most respondents reported not having any formal training in the area (80%) and having discussed sexual health with less than one quarter of their patients (71%). While respondents reported that sexual health was most often discussed when patients introduced the topic (39%), they indicated that less than one quarter of patients raised concerns during clinic visits (89%). Qualitative findings complemented survey results and elaborated on key barriers to integrating sexual health into routine care, including lack of knowledge, inadequate training, and time constraints.

Conclusions: We identified variability in sexual health definitions and care practices among healthcare providers from multidisciplinary CKD clinics. Identified barriers will inform strategies to enhance sexual health supports for individuals with CKD.

SA-PO1122

Patient and Caregiver Perceptions of Health Risks Associated with CKD: A Thematic Synthesis of Qualitative Studies

Meghan J. Elliott,[1] Shannan Love,[1] Kathryn M. King-Shier,[3] Ping Liu,[2] Heather Dumka,[1] Caitrin O'Connor,[1] Pietro Ravani.[1] *[1]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [2]University of Calgary, Calgary, AB, Canada; [3]University of Calgary Faculty of Nursing, Calgary, AB, Canada.*

Background: People with chronic kidney disease follow varying disease trajectories, but it is unclear how they understand and use information about their individual risk of adverse outcomes. We aimed to thematically synthesize the published qualitative literature on how patients with chronic kidney disease not receiving kidney replacement therapy and their care partners perceive their individual risk of disease progression, kidney failure, and death.

Methods: We searched relevant electronic databases for qualitative studies in adults with chronic kidney disease not receiving kidney replacement therapy or their care partners, and that explored perceptions of individual risks of progression to kidney failure or death. Studies were excluded if participants had committed to a kidney replacement therapy or were receiving palliative or end-of-life care. Two research team members screened titles and abstracts and retrieved relevant full-text articles for review. Disagreements were resolved through discussion. We extracted details of included studies and conducted a thematic synthesis of findings captured descriptively or as participant quotes from primary studies.

Results: Of the 7671 citations screened, we included 39 studies. All studies involved patients living with chronic kidney disease, and 5 involved care partners. Only 4 studies addressed perspectives on risk and prognosis as the primary research objective. We characterized 5 themes – Participants conveyed a lack of personalized conversations (*Theme 1*) and limited prognostic understanding (*Theme 2*), which contributed to decisional conflict when choosing between kidney failure treatment options that they perceived as equally unappealing (*Theme 3*). Individuals' readiness and acceptance of information about their individual risks influenced if and how they took action to modify potential outcomes (*Theme 4*) and anticipated implications for life participation (*Theme 5*).

Conclusions: Few qualitative studies have explored the perspectives of patients and their care partners specifically related to their individual risks of kidney failure and death. Our findings highlight a lack of discussions about perceived risk and need for additional supports to facilitate decisions as patients' chronic kidney disease progresses.

SA-PO1123

Comparison of Claims-Based Definitions vs. Measured Frailty in Patients with CKD

Hailey V. Hildebrand,[1,2] Oksana Harasemiw,[1] Ranveer S. Brar,[1,2] Paul Komenda,[1,2] Claudio Rigatto,[1,2] Bhanu Prasad,[3] Clara Bohm,[1,2] Navdeep Tangri.[1,2] *[1]Chronic Disease Innovation Centre, Seven Oaks General Hospital, Winnipeg, MB, Canada; [2]University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; [3]Saskatchewan Health Authority, Saskatoon, SK, Canada.*

Background: Frailty is common in patients with Chronic Kidney Disease (CKD), and those affected by both conditions are at increased risk of adverse outcomes including worsened disability, hospitalization, and death. Collecting data on frailty status as part of routine clinical care could enhance care by identifying patients at high risk of adverse events. Clinical assessment of frailty is time and resource intensive. Frailty definitions based on administrative data might provide a feasible and efficient alternative. The primary objective of this study was to compare agreements between administrative claims-based definitions for frailty versus objectively measured frailty in adults with advanced (Stage G4+), non-dialysis CKD.

Methods: The cohort consisted of Manitoba participants from the Canadian Frailty Observation and Interventions Trial (CanFIT). This multicentre cohort study followed 442 adults with an eGFR < 30mL/min/1.73 m^2 longitudinally. At each visit, an assessment was conducted to determine frailty status using the Fried Frailty Index, Short Physical Performance Battery, and healthcare providers impression. The CanFIT database was linked to several administrative health databases at the Manitoba Centre for Healthy Policy to calculate two claims-based frailty indices, the Segal Frailty Index and the Pre-operative Frailty Index, which have been previously validated in the non-CKD literature.

Results: Of participants included, the mean age was 65.8±13.9 years and 58.4% were male; 87.8% had hypertension, 61.3% dyslipidemia, and 57.5% diabetes. The prevalence of frailty varied from 18.1% to 69.5% depending on definition. Agreement between claims-based frailty indices and objective and subjective measures of frailty was low to modest (κ 0.08–0.31). Individuals considered frail, using both administrative or measured definitions, had an increased risk of all-cause mortality and hospitalization.

Conclusions: This study suggests that claims-based definitions of frailty developed in the general population are poor substitutes for identifying frailty in individuals with advanced, non-dialysis CKD. Efforts to integrate valid and efficient frailty assessments in clinical practice are needed to improve clinical decision making.

SA-PO1124

A Contemporary Economic Model of CKD in the United States

Andrew Briggs,[1] Ciaran Kohli-Lynch,[3] Satabdi Chatterjee,[5] Bonnie M. Donato,[5] Adrian R. Levy,[4] Csaba P. Kovesdy.[2] *[1]London School of Hygiene & Tropical Medicine, London, United Kingdom; [2]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [3]Northwestern University, Evanston, IL; [4]Dalhousie University, Halifax, NS, Canada; [5]Boehringer Ingelheim Pharmaceuticals Inc, Ridgefield, CT.*

Background: Chronic kidney disease (CKD) impacts an estimated 14% of US adults, and is associated with reduced quality of life, progression to kidney failure, and cardiovascular disease (CVD), resulting in high healthcare costs. The recently updated Kidney Disease: Improving Global Outcomes (KDIGO) guidelines have highlighted the importance of CVD management to improve CKD outcomes and including a role for sodium-glucose cotransporter-2 (SGLT2) inhibitors in delaying disease progression and improving CVD outcomes.

Methods: A state transition model was developed (see figure) to follow a hypothetical cohort of US adults with CKD over their lifetime. Progression of CKD was tracked through KDIGO health states defined by estimated glomerular filtration rate (eGFR) and urine albumin creatinine ratio (uACR). Individuals with CKD could transition to kidney failure, major adverse cardiovascular event (myocardial infarction or stroke), heart failure, or death from other causes. Probability of a first event was determined by eGFR, uACR, and diabetes status, with age and sex determining the background mortality risks. Individuals who had a non-fatal first event were followed until death. Resource utilization, costs, transition probabilities, and utilities were derived from peer-reviewed studies.

Results: The model predicted clinical events associated with current management as well as healthcare costs and quality adjusted life years (QALY). Under usual care, the model estimated lifetime outcomes of 6.8 QALYs and $150,386, with time prior to a clinical event contributing most to the QALYs, and dialysis contributing most to the healthcare costs. KDIGO guidelines for optimizing CVD treatment and SGLT2 inhibitor treatment were shown to be cost-effective (cost-per-QALY<$100,000).

Conclusions: The current model can predict clinical events and consequent impacts on healthcare costs and QALYs. This enables estimation of the value of various guideline-recommended strategies designed to treat patients at all stages of CKD.

SA-PO1125

Experience of Patients and Caregivers During the Predialysis Period: A Thematic Analysis

Annie-Claire Nadeau-Fredette,[1,2] Émilie Robitaille,[1] Guylaine Cyr,[1] Karthik K. Tennankore,[3] Kelley Kilpatrick.[4,1] On behalf of the TRANSIT-CARE Study Group. *[1]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [2]Universite de Montreal Faculte de Medecine, Montreal, QC, Canada; [3]Nova Scotia Health Authority, Halifax, NS, Canada; [4]McGill University, Montreal, QC, Canada.*

Background: Patients living with advanced chronic kidney disease (CKD) often plan to initiate dialysis when their kidney function declines. While several studies have explored components associated with dialysis modality choice, little is known as to how patients and their caregivers experience the period preceding dialysis initiation.

Methods: In this qualitative study, semi-structured interviews were performed with patients (n = 9) followed in an advanced multidisciplinary CKD clinic with an eGFR <12 ml/min/1.73 m^2 who had already chosen their dialysis modality and with caregivers (n = 9). Thematic analysis was used to identify patients and caregivers' experiences during the predialysis time.

Results: Patients participants were 69 ±7 years, included 4 women and 5 men. Among them, 5 patients had chosen home dialysis and 4 facility hemodialysis. Caregivers were mostly women (n=7/9) and most were living with the patient with CKD. Four main themes described patients and caregivers experience: ***successive shocks of announcements*** (from CKD diagnosis to imminent need for dialysis), ***minimizing repercussions on lifestyle*** regardless of the choice of dialysis therapy, ***personality type influencing feelings*** linked to dialysis anticipation (optimist versus pessimist, hope versus despair), ***reassurance through support network*** (including loved one and healthcare professionals). Patients and caregiver pairs had mostly concordant experience and overall, emotions toward dialysis were more often positive (hope of better future), although grief was also often identified.

Conclusions: This work highlights the need to individualize care of patients planning to start dialysis, not only at time of modality selection, but also as patients and caregivers near the initiation of dialysis.

Patients' Experiences Receiving a CKD Diagnosis: Opportunities for Clarity, Empowerment, and Support

Leah C. Bush,[1] Eleanor Rivera,[2] Sarah J. Schrauben.[1] *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]University of Illinois Chicago, Chicago, IL.*

Background: Chronic kidney disease (CKD) is a highly prevalent condition, affecting >1 in 7 US adults. Advances in basic science and clinical management of CKD have improved clinical outcomes, but gaps remain in the understanding of patient experiences with the diagnosis of CKD. Such an understanding is crucial to mitigate psychological challenges experienced with receiving a CKD diagnosis and to establish the patient knowledge, agency, and support necessary for optimal patient-driven CKD management.

Methods: We conducted semi-structured interviews with patients with CKD stage 3 or 4 from nephrology clinics using an interview guide related to experiences about being diagnosed with CKD. Interviews were audio recorded, transcribed verbatim, and analyzed inductively using thematic analysis.

Results: We interviewed 30 patients. We identified 5 themes clustered around reactions to receiving a CKD diagnosis: 1) surprise, shock, and fear attributed to the unexpected nature of the diagnosis and the uncertainty about potential need for dialysis or transplant; 2) reluctance to disclose CKD diagnosis to friends and/or family given the lack of overt symptoms and stigma around having a chronic disease; 3) bidirectional relationships between CKD and mental health, in that a CKD diagnosis poses a mental health stress test, and adequate mental health is necessary for optimal CKD management; 4) lack of social support from friends and family; and 5) progression through the stages of grief toward acceptance of the diagnosis (Table).

Conclusions: Our findings describe patients' experiences receiving the diagnosis of CKD, which informs practical recommendations for diagnosis communication, including a focus on patient empowerment and facilitating support services via the CKD care team. Opportunity also exists for greater public understanding of the role of the kidneys for overall health and for greater public familiarization with CKD.

Funding: NIDDK Support

Themes related to Receiving and Coping with CKD Diagnosis

1. Alarming Reaction to Diagnosis	"it was just shock… it was very sudden… It was just kind of like, where did this come from? Like what's going to happen?" -participant #3
2. Reluctance to Disclose Diagnosis	"When you hear the words chronic and disease together – chronic, means I'm going to have this forever, and a disease, something I can't do anything about. Of course, I didn't tell my family. I still haven't told them…they'd probably say, "you have a disease?" -participant #9
3. Linkage of Mental health and CKD	"I'm scared all the time. Am I doing the right thing?" - participant #25 "I get depressed thinking about dialysis." - participant #1
4. Lack of social support	"people I thought were my friends weren't because they were afraid I was gonna ask them for something." - participant #24 "I don't turn to anybody [for support]. I handle everything myself." - participant #6
5. Stages of Grief and Acceptance of Diagnosis	"you start accepting things for what they are. [CKD] is something that has to be managed and you can take control over it." -participant #3

SA-PO1127

Patient-Reported Outcomes and Associations with Clinical Events in a Cohort of People with Nondialysis-Dependent CKD

Dipal M. Patel,[1] Dingfen Han,[1] Chirag R. Parikh,[1] Jung-Im Shin,[2] Kristin Riekert,[1] Deidra C. Crews.[1,2] *[1]The Johns Hopkins University School of Medicine, Baltimore, MD; [2]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.*

Background: People with CKD face substantial disease burden and impairments to quality of life (QOL). The distribution and severity of these patient-reported outcomes (PROs), and whether they are associated with clinical outcomes, is underexplored for people with non-dialysis dependent CKD.

Methods: We quantified general health, QOL, and physical and mental health symptoms, as reported by people with CKD G3-5 who completed an electronic PRO assessment tool prior to Johns Hopkins (JH) nephrology clinic follow-up visits. We performed multivariable regression analyses to investigate the association of PROs with dialysis initiation and 1-year hospitalization.

Results: We collected 2180 PRO assessment tool responses from 1091 individuals with CKD G3-5 (**Figure**). QOL, general health, and some symptoms were worse for people with advanced stages of CKD compared to earlier stages. Among the full cohort, 99 individuals (9%) were hospitalized within 1 year (231 total number of hospitalizations), and 177 (16%) started dialysis. After adjustment for age, sex, comorbidities, and individual measures of socioeconomic status, low self-reported general health was associated with higher risks for hospitalization and dialysis initiation, with every one-point increase in general health scores being associated with a 12% reduction in incidence of hospitalization and a 17% reduction in the risk of dialysis initiation.

Conclusions: People with non-dialysis-dependent CKD experience several symptoms and impairments to QOL and self-perceived general health. Our findings highlight the utility of PRO assessment in identifying people at high risk for adverse outcomes including hospitalization and dialysis initiation.

*Mixed regression models considering the clustering of individual patients was performed after adjustment for age, sex, comorbidities (heart failure, coronary artery disease, hypertension, and diabetes), Charlson comorbidity index, and quartiles of area deprivation index.
**Poisson and ***logistic regression for clinical outcomes were performed after adjustment for the same variables as above, plus eGFR. Point estimates for hospitalization and dialysis are reported for each decile change in physical symptom and mental health scores.

Select PRO assessment tool scores and associations with clinical outcomes. Lower scores represent lower QOL and general health, and more prevalent physical and mental health symptoms.

SA-PO1128

Real-World Utilization of a Patient-Reported Outcome (PRO) Assessment Tool in Nephrology Clinic: Patient and Provider Perspectives

Dipal M. Patel,[1] Mary Ann C. Stephens,[1] Jessica M. Gotay-Lehmer,[1] Kristin Riekert,[1] Deidra C. Crews.[1,2] *[1]The Johns Hopkins University School of Medicine, Baltimore, MD; [2]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.*

Background: Patient-reported outcome (PRO) assessment is a key component of person-centered care; however, approaches for utilizing PRO assessment tools in nephrology clinic are understudied. We integrated a PRO assessment tool into the electronic health record at Johns Hopkins (JH) and distributed it to people with CKD G3-5 prior to nephrology follow-up appointments. We evaluated determinants of patient and provider utilization of the PRO assessment tool.

Methods: We conducted surveys and individual semi-structured interviews of nephrology providers and people with CKD. We quantified questionnaire responses using descriptive statistics and performed thematic analysis of semi-structured interview transcripts.

Results: We surveyed 17 JH nephrology providers and 102 JH CKD patients. Answering Likert-scale questions (1=strongly disagree, 5=strongly agree), patients more strongly agreed with a need for symptom assessment compared to providers (mean ± S.D.: 3.9 ± 0.7 for providers and 4.5 ± 0.5 for patients, $p < 0.01$). Patients also more strongly agreed that PRO assessment tools would make patients "feel heard and understood" (mean ± S.D.: 3.5 ± 0.6 for providers and 4.2 ± 0.7 for patients, $p < 0.01$). Providers were uncertain if they would independently review and discuss PRO assessment tool scores during each clinic visit (mean ± S.D.: 2.6 ± 0.9). From semi-structured interviews of 15 providers and 21 patients, we identified key themes influencing utilization of the PRO assessment tool (Figure).

Conclusions: While the importance of PRO assessment is recognized by people with CKD and nephrology providers, we identified several barriers which should be addressed in order to improve the capability, opportunity, and motivation of care teams to incorporate PRO assessment tools into routine clinical care.

Themes	Exemplary quotations
While symptom assessment is a routine part of CKD care, the role of nephrologists in discussing quality of life (QOL) and mental health is less clear.	"Well, if I needed to talk about it, I feel like I could talk about anything. I just don't really bring it up. Most visits, I'm just so fixated on the numbers and that they remain stable. That's pretty much what I focus on with her. Not really this bigger picture of my everyday health, 'cause I don't hadn't really associated that with the kidney disease." (*Person with CKD*)
Nephrologists may benefit from additional knowledge in symptom and QOL management.	"I think the barrier for me is how do I make them better with those symptoms. And I may not have all the tools necessary to improve those symptoms. And that's where I think we, as nephrologists, may fall short because we are not trained to manage those symptoms necessarily or even to make a good diagnosis of why they have those symptoms." (*Nephrology provider*)
Additional clinical support is needed to optimize utilization of PRO assessment tools in routine care.	"I feel, in terms of quality of life, easier access to allied health professional support, social work support, nutrition, definitely, palliative…having a team to address multiple issues that sometimes it's a little bit hard to be handled by the physician alone, I think, helps." (*Nephrology provider*)

Symptoms and Impacts Experienced by People Living with Nondiabetic CKD (ndCKD) and Diabetic Kidney Disease (DKD): Qualitative Interview Findings

Sara Tadesse Bell,[1] Julia Stein,[2] Lara Ayala-Nunes,[2] Eleanor Scouler,[2] Sophi Tatlock,[2] Patricia Corey-Lisle,[3] Sharan Randhawa.[2] *[1]Genentech Inc, South San Francisco, CA; [2]Adelphi Values Ltd, Bollington, United Kingdom; [3]Formerly Genentech Inc, San Francisco, CA.*

Background: The congruence of the non-diabetic chronic kidney disease (ndCKD) and diabetic kidney disease (DKD) patient experience is not well-known. This study aimed to compare/contrast symptoms and health-related quality-of-life [HRQoL] impacts reported by ndCKD and DKD patients to provide initial insights as to whether a consistent patient-reported outcome (PRO) measurement strategy could be applied across both populations in clinical trials.

Methods: Semi-structured, concept elicitation interviews were conducted to explore patients' experiences of ndCKD/DKD. Interviews were audio recorded and verbatim transcripts were subject to thematic analysis in ATLAS.ti. Concepts identified were compared to explore similarities/differences in the patient experience of ndCKD and DKD.

Results: The sample was racially and ethnically diverse, comprising 24 participants (n=12 ndCKD [83.3% female]; n=12 DKD [66.7% female]), across CKD stages 2-5 and mean age 57 years (range 28-84). Almost all symptoms and impacts elicited were reported across both samples, though frequency of elicitation varied. Most participants (ndCKD n≥10/12; DKD n≥11/12) reported fatigue, low energy or weakness, frequent urination, swelling and nocturia. Erectile dysfunction (ED) was only reported in the DKD sample (n=2/12), which had a higher proportion of males. Restless legs was only reported in the ndCKD sample (n=1/12). Difficulty urinating, weight changes, gastrointestinal symptoms, and vision problems were reported by more DKD participants (n≥3). Muscle cramps were reported more frequently by ndCKD participants (n≥3). HRQoL impact reports were broadly comparable; impacts on diet/drinking were reported by more DKD participants (n≥3). All participants described emotional wellbeing impacts, and most (≥22/24) reported disruptions to daily activities and sleep. Other impacts included physical and social functioning, work and cognition.

Conclusions: Apart from ED and restless legs, all concepts were reported across both samples with small differences in elicitation frequency. Fatigue, frequent urination, swelling and nocturia were most frequently reported across both samples. Patients were also aligned on HRQoL impacts, suggesting that using the same PRO strategy in ndCKD/DKD may be appropriate, depending on the concepts of interest.

SA-PO1130

The National Kidney Foundation's CKD Learning Collaborative: Transforming Care across University Health in Kansas City, Missouri

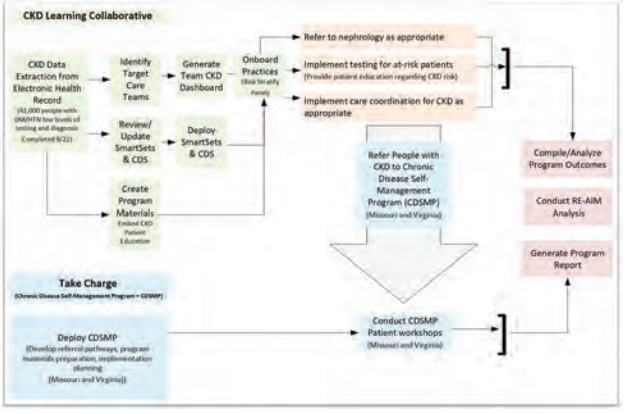
Jignesh Shah,[1,2] Rajib Bhattacharya,[1,2] Megan Schultz.[3] *[1]University of Missouri-Kansas City, Kansas City, MO; [2]University Health Truman Medical Center, Kansas City, MO; [3]National Kidney Foundation Inc, New York, NY.*

Background: National Kidney Foundation (NKF) implemented a CKD intercept project in collaboration with University Health(UH) to improve CKD diagnosis and recognition and clinician confidence and engagement in CKD management. This is done to implement a chronic disease self-management program (CDSMP) tailored for people living with CKD, using primary care outreach as the referral mechanism to Nephrology, and introduce a CKD learning collaborative model to provide integrated care delivery.

Methods: We assessed current CKD testing and diagnosis levels in select clinics at UH. We reviewed existing workflows for diabetes, hypertension, and wellness and worked with the technical team to include EHR data for risk stratification of the initial patient cohort. We determined the individual practices of participating clinicians, provided clinician decision support and workflow-related tools, then utilized them in partnership with clinicians and measured their confidence and engagement throughout interventions.

Results: We improved the identification of proteinuria and eGFR calculation of the at-risk patient population by 62.8%. Identification of patients with eGFR lower than 60, screened, identified, and staged appropriately improved by 60%. ARB and Statin use increased by, 89.9% and 28.5 %, respectively, across all CKD stages. We did not see significant improvements in SGLT2i, GLP-1 agonist, and MRA prescription patterns.

Conclusions: NKF and University Health (UH) partnered to introduce the CKD intercept project in select clinics. The comprehensive interventions covered various aspects of CKD management, improved CKD recognition in primary care, tested eGFR and Urine Albumin Creatinine Ratio, and referral patterns. Clinician confidence and engagement improved regarding CKD identification, self-management, NSAID avoidance ACEI/ARB, and SGLT2i use. We suggest community-level efforts to enhance CKD testing and management.



CKD collaborative model

Real-World Evaluation of Best Practice Patterns in CKD Management

Yan Ting Chua,[1] Clara L. Ngoh,[1] Priyanka Khatri,[4] Shilpa Rastogi,[2] Sky Wei Chee Koh,[5] Valerie Ma,[3] Wui Heng Goh,[3] Horng-Ruey Chua.[1] *[1]National University Hospital, Singapore, Singapore; [2]Ng Teng Fong General Hospital, Singapore, Singapore; [3]National University Health System, Singapore, Singapore; [4]Alexandra Hospital, Singapore, Singapore; [5]National University Polyclinics, Singapore, Singapore.*

Background: The incidence of kidney failure continues to rise amid an evolving landscape in chronic kidney disease(CKD) management, with improved therapeutics that prompted a series of practice guidelines. However, real-world uptake of CKD therapeutics, against a backdrop of polypharmacy, is unclear. We used our information systems to track adoption of best CKD practices in a regional healthcare cluster.

Methods: We performed a multicenter ambi-directional cohort study of patients with CKD, aged≥21, from 7 primary care institutions and 3 acute hospitals. We extracted quarterly anonymized demographics, laboratory and prescription data from electronic health records from March 2022 to March 2024 to evaluate aggregated measures in CKD care. We defined CKD by ICD-10 diagnosis codes and ≥2 estimated glomerular filtration rate(eGFR)≥90 days apart of <60mL/min/1.73m². We excluded patients with kidney failure.

Results: We studied 34,217 patients. Mean age was 72±12years. Clinicians did not monitor 33% of patients for albuminuria or proteinuria. Less than half of diabetic patients aged<80 with CKD G1-3b achieved Hba1c<7%. Of patients aged<80 with eGFR<60, diabetes, ischemic heart disease, stroke or peripheral vascular disease, 71% received statins; 69% had lipids measured, of whom 72% achieved low-density lipoprotein<2.6mmol/L. Use of angiotensin II receptor blockers(ARB) or angiotensin-converting enzyme inhibitors(ACEi) in albuminuric patients was 74%; only 40% received ceiling doses despite 4% prevalence of hyperkalemia and 4% with mean systolic blood pressure<110mmHg. Penetrance of sodium-glucose co-transporter-2 inhibitors(SGLT2i) increased from 21% to 40% among albuminuric patients during the study period. Of patients aged<80 with albuminuric CKD G1-3b, 21% received ACEi/ARB at≥50% ceiling doses, SGLT2i and statins; fewer non-diabetic vs diabetic patients received SGLT2i (12% vs 49%,p<0.01) or statins (65% vs 83%,p<0.01). In contrast, patients with obesity or worse albuminuria were more likely to be on a combination of ACEi/ARB, SGLT2i and statins.

Conclusions: We visualize a disconnect between CKD practice guidelines and their real-world adoption. We will examine a systems approach to scale up population-level CKD management in patients yet to be optimized with evidence-based therapeutics, such as for non-diabetic CKD.

SA-PO1132

Encouraging a Standardized ESKD Transition Pathway in Value-Based Care (VBC) Patients Is Associated with a High Optimal Dialysis Start Rate

Roy G. Marcus, Katherine W. Kwon, Rohit Sharma, Dave M. Miller, Douglas Eckhardt, Nirav Vakharia. *Panoramic Health, Tempe, AZ.*

Background: In 2022, Panoramic Health and several physician leaders from four practice groups developed a standardized ESKD transition pathway (Pathway) as part of a value-based care program. The Pathway led to a substantially higher optimal dialysis start rate, defined as initiation without a central venous catheter. This study aimed to determine if the Pathway could improve optimal start rates in other practice groups participating in the same program.

Methods: The Pathway was taught to all physicians involved. Monthly feedback was provided on ESKD preparation, highlighting patients who were off-track based on Pathway guidelines. Dialysis starts were recorded, and the proportion of optimal starts was determined.

Results: In 2022, the original four practice groups had a historical optimal start rate of 29% prior to Pathway implementation. By Q3, this rate increased to 37%, and by Q4, it reached 53%. In 2023, these groups achieved a 64% optimal start rate. Fourteen other practice groups, with a historical optimal start rate of 28%, reached 53% by the end of 2023. Additionally, two practice groups achieved over 70% optimal starts. One new practice group had a 76% optimal start rate with 50 starts, and one original practice group had a 78% rate with 91 starts. These successful groups shared ESKD preparation data transparently, held each other accountable, celebrated successes, and reviewed non-optimal starts to identify and address local access issues.

Conclusions: The deployment of the Pathway is associated with a large increase in optimal starts. The Pathway can be taught to nephrologists that were not part of the development process with comparable results. and can be effectively taught to nephrologists not involved in its development. Transparent data sharing, peer accountability, and attention to local access processes may further enhance the Pathway's impact. Future efforts will focus on making the Pathway available to all patients.

SA-PO1133

Identifying Key Outcomes for Optimal CKD Management: A UK-Based Delphi Study

Naeema A. Patel, Matthew Graham-Brown, Courtney J. Lightfoot, Alice C. Smith. *University of Leicester College of Life Sciences, Leicester, United Kingdom.*

Background: Effective self-management is crucial for people with chronic kidney disease (CKD). Robust evaluation of resources to support self-management in research and clinical practice settings should be based on outcomes that are meaningful and valued by stakeholders. This study aimed to establish stakeholder consensus on priority outcomes for CKD self-management.

Methods: A 3-round online Delphi survey was conducted. Invited participants included CKD patients, relatives, carers, healthcare professionals and policy-makers. Round 1: Participants were asked to describe in free text their top three most important outcomes for non-dialysis CKD self-management. Responses were analysed using conventional content analysis to generate items for consideration by participants in subsequent rounds. Round 2: Participants rated each item on a 9-point Likert scale. Items scoring ≥70% at 7-9 (critically important) progressed to Round 3. Round 3: Participants ranked items in order of importance to reach a consensus. A ranking-weighted score was used to identify highly ranked outcomes

Results: 64 patients/relatives and 69 kidney professionals contributed to Round 1. 28 outcome items were identified and categorised into 5 themes: 'Clinical', 'Behaviour and self-care', 'Knowledge, skills and confidence to manage own health', 'Healthcare usage' and 'Psychological and social factors'. In Round 2, 44 patients/relatives and 53 kidney professionals participated. Three items did not meet the progression criteria and were subsequently removed (2 items from 'Healthcare usage' category and 1 from 'Psychological and social factors'). In Round 3, 25 patients/relatives and 37 kidney professionals participated. The top three ranked items were: 1) Prevent or slow the decline of kidney function; 2) Feeling more in control of own health and kidney disease, feeling empowered and independent; and 3) Improve life expectancy.

Conclusions: All the items identified as the top three priority outcomes of self-management by patient and professional participants fell into the "Clinical" or "Knowledge, Skills and Confidence" themes. Identification of these key outcomes will be important for future resource design, clinical trials, healthcare service assessment, and strategies to support the commissioning and uptake of self-management resources.

SA-PO1134

Advanced CKD Veterans' Perspectives on Ideal KRT-Targeted Educational Modalities

Darin Ftouni,[1,2] Rebecca Campbell-Montalvo,[1] Shobha Subhash,[1] Popy Shell,[1] Kailyn Pearce,[1] Ashutosh M. Shukla.[1,2] *[1]VA North Florida South Georgia Veterans Health System, Gainesville, FL; [2]University of Florida, Gainesville, FL.*

Background: Awareness of KRT and KRT-targeted kidney disease education (KDE) is a necessity for informed dialysis selection for advanced CKD patients. We currently lack clear understandings of these patients' preferences for receiving such KDE.

Methods: Approaching enrollees for the ongoing mixed-method randomized Trial to evaluate and assess the impact of Comprehensive KRT-directed KDE on home dialysis among Veterans (TEACH-VET), we evaluated advanced CKD Veterans' preferences for the resources and methods for receiving KDE. Qualitative interviews were conducted using a structured interview guide grounded in theoretical domains framework. We oversampled women and individuals from racial/ethnic minorities to ensure broad applicability of findings. In addition to emergent themes related to KDE's influence on lack/gaps in knowledge, thematic analysis also focused on participant views on the preferential forms of future KDE dissemination.

Results: We enrolled 42 Veterans with advanced stage 4 and 5 CKD – 7(17%) women, 13(31%) African Americans, 1 Asian and 2 Latinx individuals. Most (n=32, 79%) had some college education, 60% were married, 26% divorced, and 69% retired; 60% lived with one other person and 24% lived alone. Forty-one provided education modality preferences and engaged in further discussions. Qualitative analysis revealed key social-psychological mechanisms influencing patients' KDE choices. A majority (80%) preferred receiving KDE from the providers. Individual concerns, such as psychological, social anxiety, ease of access, etc., were identified as key factors deterring patients from participating in group sessions, though, 2/3rd (66%) preferring this mode. Peer-Veteran supported KDE was among the least preferred method, with 44% of advanced CKD interviewees rejecting this method. Internet and phone apps were popular with 49% of veterans. Veterans' preferred methods for education provision were audio, podcasts, and video recordings, with an overall 85% interest rate.

Conclusions: This analysis provides a crucial insight into Veterans' preferences for KRT-directed KDE. Veterans have a strong preference for audio, podcasts, and video recordings as well as provider-delivered KDE. These results highlight the need for ongoing efforts to better understand and optimize KRT-directed KDE, guided by patients' own preferences.

Optimizing Patient Outcomes in Advanced CKD: Insights from Predialysis Care in Qatar

Tarek A. Ghonimi,[1] Abdullah I. Hamad,[1] Tarek Ahmed Elsayed Fouda,[1] Hany E. Ismail,[1] Farooq Ahmad,[1] Muhammad A. Baig,[1] Mohamed T. Abdellatif,[2] Heba M. Ateya,[1] Mincy Mathew,[1] Hoda Tolba,[1] Fadwa S. Al-Ali,[1] Hassan A. Al-Malki.[1] *[1]Hamad Medical Corporation, Doha, Qatar; [2]Misr University for Science and Technology College of Medicine, 6th of October City, Egypt.*

Background: A pre-dialysis multidisciplinary clinic (MDC) program improves the quality of care for advanced CKD patients. This study assesses the impact of such a program on the quality of CKD patients outcomes.

Methods: This report outlines the first-year findings of a three-year prospective study initiated on December 5, 2022, at Hamad General Hospital. We enrolled 695 patients with advanced CKD from multidisciplinary Low Clearance Clinics and analyzed demographic and laboratory data retrieved from electronic health records.

Results: Among 695 study patients, initial eGFR was 15.7 ± 5.4 mL/min/1.73m^2, decreasing to 14.9 ± 6.7 mL/min/1.73m^2 at study initiation. 39% had eGFR < 15 mL/min/1.73m^2 at referral. 43.7% received dialysis education, and 43% were referred for transplant evaluation. During follow-up, 24.3% started dialysis (55% acutely, 45% electively). Predictors for acute dialysis were low HB, low eGFR, and high urea (odds 0.662, 1.306, 1.101 respectively). Late referral (eGFR < 15 mL/min/1.73m^2) correlated with shorter time to dialysis (log rank value = 0.004). Mean eGFR at dialysis initiation was 6.3 ± 3.6mL/min/1.73m^2. Hemodialysis (73.3%) was primary, with temporary lines (36.6%) and AVF (28.4%) common. 2.4% had preemptive renal transplant, and mortality rate during follow-up was 1.7%.

Conclusions: Multidisciplinary pre-dialysis care is crucial for advanced CKD management and transitioning to kidney replacement therapy. This report emphasizes its role in enhancing outcomes, stressing early referral for interventions like dialysis education and transplant evaluation to optimize CKD care.

Factors Associated with Decision Change through Shared Decision-Making Process Regarding Kidney Replacement Therapy

Shunsuke Kitamura,[1] Masaru Matsui,[2] Marumi Yamamoto,[1] Kosuke Tansho,[1] Hideo Tsushima,[1] Kazuhiko Tsuruya.[2] *[1]Department of Nephrology, Nara Prefectural General Medical Center, Nara, Japan; [2]Department of Nephrology, Nara Medical University, Nara, Japan.*

Background: In Japan, 97% of patients with end-stage kidney disease (ESKD) choose hemodialysis (HD) as their kidney replacement therapy (KRT), with few patients opting for peritoneal dialysis (PD) or transplantation. Although recent studies have revealed the implementation of shared decision-making (SDM) for KRT increases the number of patients choosing PD and transplantation, decision changes often occur through the SDM process until the development of ESKD. We thus explored the factors associated with decision changes in patients with advanced chronic kidney disease (CKD) who made a decision for KRT.

Methods: We conducted a cohort study involving 317 CKD patients who underwent KRT discussions through SDM process and provided their decisions between 2019 and 2022. The primary endpoint was a time-to-event analysis for changes from the initial decisions made during SDM, and we identified factors associated with decision changes.

Results: The mean age was 73 ± 12 years, with 192 (61%) being male. The baseline eGFR was 15.3 ± 6.4 mL/min/1.73m^2 at the time of SDM. The distribution of the initial decisions was as follows: HD for 124 (39%), PD and transplantation for 118 (37%), conservative kidney management (CKM) for 10 (3%), and 65 patients (21%) remained undecided. Eighty-six patients (27%) changed their initial decisions, with a median of 381 days. In the multivariable logistic regression model, factors associated with decision change (odds ratios [95% confidence intervals]) were male (1.85 [1.01–3.36]), having family support (2.44 [1.24-4.77]) and decisions of PD and transplantation (10.9 [4.27–27.6]) and CKM (7.5 [1.48–38.1]). In fact, approximately 30% of patients who initially decided on PD and transplantation or CKM changed to desire for HD treatment during the study period.

Conclusions: Following the KRT discussion through the SDM process, decisions of PD and transplantation or CKM may be changed to another KRT modality.

Nephrologist Visits Lower Rates of Hospitalization, Mortality, and ESKD Transition in Patients with CKD

Steph Karpinski,[1] Michael H. O'Shea,[2] Steven M. Brunelli.[1] *[1]Davita Clinical Research, Minneapolis, MN; [2]DaVita Inc, Denver, CO.*

Background: Chronic kidney disease (CKD) patients require integrated care from a network of healthcare professionals including primary care physicians (PCP) and nephrologists. While it is hypothesized that increased exposure to nephrology care can slow CKD progression and reduce costs, evidence of the impact of primary care has been mixed. Therefore, we sought to determine if CKD stage 4/5 patients benefit clinically because of nephrologist visits, independent of primary care physician exposure.

Methods: This was a retrospective study of 8,941 adult CKD 4/5 patients. For this analysis, we used Optum's® de-identified Integrated Claims-Clinical Dataset that links administrative claims and clinical data from providers across the continuum of care.[1] The primary exposure (outpatient nephrologist visit: Y/N) was considered over a 6-month period. Outcomes were examined in the subsequent 6 months from exposure and included hospitalizations, mortality, and transition to end-stage kidney disease (ESKD). We modeled the hospitalization outcome using a quasi-Poisson distribution and modeled the ESKD transition and mortality outcomes using binomial distributions, adjusting for age, race, sex, insurance type, baseline CKD state, AKI events, and number of PCP visits (during exposure period). A sensitivity analysis also adjusted for albumin.

Results: After accounting for demographic and clinical factors results indicate that seeing a nephrologist is specifically associated with lower rates of hospitalization [RR (95% CI) 0.81 (0.69, 0.94)], ESKD transitions [OR (95% CI) 0.80 (0.66, 0.98)], and mortality [OR (95% CI) 0.63 (0.48, 0.81)]. The sensitivity analysis yielded similar results.

Conclusions: Among stage 4/5 CKD patients, nephrologist visits over a 6-month period have positive impacts on clinical outcomes.[1] Optum's de-identified Integrated Claims-Clinical dataset (2007-2021)

Outcome	Adjusted Effect
Hospitalization	0.81 (0.69, 0.94)
ESKD Transition	0.80 (0.66, 0.98)
Mortality	0.63 (0.48, 0.81)

Adjusted for number of PCP visits, age, AKI diagnosis, CKD stage (4/5), cohort ID, sex, race, and insurance type.

SA-PO1138

Understanding the Kidney Replacement Therapy Decision-Making Journey

Suma Prakash,[1] Spoorthy Vangala,[1] Kauser S. Razvi,[2] Matthew Taylor,[1] Erika Drury,[1] Marcus D'Alfonso,[1] Igor Oliveira,[1] Peter J. Veazie,[1] Scott Mcintosh.[1] *[1]University of Rochester Medical Center, Rochester, NY; [2]Strategic Urban Solutions Inc., Cleveland, OH.*

Background: This study aimed to better understand kidney replacement therapy (KRT) decision-making. It is unknown whether the KRT decision-making journey is similar across chronic kidney disease (CKD) groups and when interventions would be most helpful.

Methods: A qualitative study was done using journey mapping and focus groups. Journey mapping is a technique in which a visual representation of the process experienced sequentially by the person with their corresponding emotional journey is created. It provides information on what went well and did not at particular points in the journey allowing the participant to point out what and where in the process tailored interventions would be beneficial. Individual journey maps were done in the following CKD groups: stage 4 decided on KRT option, CKD 5 decided, CKD 4/5 undecided, post-transplant CKD 4/5, and patients with underlying stage 3-5 CKD requiring unplanned hospital dialysis start. Individual journey maps were aggregated by group and reviewed in a focus group for accuracy. Two provider focus groups were done to obtain additional perspective and validation. Theme coding was used to aggregate the journey maps and analyze the focus group data.

Results: There were 40 patient participants from a single center (8 per group) and 11 provider participants from multiple institutions. An aggregate map from the post-transplant CKD group is shown in figure 1. A group specific finding from the journey map analysis was the unplanned start group has a different set of steps in their process than the other 4 groups. A common finding across groups was the shock or grief at the time nephrologists suggest the need for KRT.

Conclusions: Journey mapping provides unique information that can be used to tailor the KRT decision-making process to the above CKD groups and may be a useful technique to look at other renal processes.

SA-PO1139

Factors Associated with Major and Minor Complications of Percutaneous Kidney Biopsy: A Quality Improvement Project

Kayla Lett,[1] Lindsay Richels,[1] Ameer Abusada,[1] Shubrandu Sanjoy,[2] Bonnie R. Richardson.[2] *[1]University of Saskatchewan College of Medicine, Regina, SK, Canada; [2]Saskatchewan Health Authority, Regina, SK, Canada.*

Background: Percutaneous kidney biopsies are commonly performed in the evaluation of acute and chronic kidney disease. Due to physiologic, anatomic, and equipment factors, complications are not uncommon. Fortunately, most complications are minor and self-resolving. Life-threatening complications include bleeding requiring blood transfusion, need for angioembolization, and death. Recent literature suggests that these major complications are exceedingly rare. This study aimed to determine the rate of major and minor complications in both outpatient and inpatient kidney biopsies at a tertiary centre and to understand the factors associated with these complications.

Methods: A retrospective chart review of patients who received a kidney biopsy between 2020 and 2023 was conducted. Patients who were at least 15 years of age and underwent a biopsy in the outpatient or inpatient setting were included. Primary endpoints were minor complications (pain, hematoma formation, gross hematuria) and major complications (blood transfusion, admission to hospital, embolization, death). Factors including use of anticoagulation, use of antiplatelet agents, baseline blood pressure, hemoglobin, and platelet count were obtained.

Results: Data from 120 patients were analyzed with 52.5% being male. Median age was 65 years (IQR 50-74) and 70.6% of biopsies were performed in the outpatient setting. All biopsies were performed by interventional radiology staff and the median number of needle passes was 3. Anti-platelet agents were held for a median of 4 days (IQR 1-7). Major complications were observed in 4.2% of patients (n = 5), including blood transfusion (1.67%), need for angiography (1.67%) and death (0.83%).

Conclusions: The rate of major complications at this tertiary centre was higher compared to recently published literature. Significant practitioner variation was observed with respect to the use of anti-platelet medications and blood pressure targets peri-biopsy. Interventions to improve patient safety could include protocols to review all anti-platelet and anti-coagulant medications prior to percutaneous kidney biopsy, practitioner order sets to manage blood pressure, and education surrounding the use of post-procedure imaging when blood products or fluid resuscitation is required.

SA-PO1140

Validation of a Risk Calculator for Predicting Major Bleeding Complications from Percutaneous Kidney Biopsy

Jordan Thorne,[1,2] Keigan More,[1,2] Amanda J. Vinson,[1,2] David Clark,[1,2] Karthik K. Tennankore.[1,2] Kidney Research Institute Nova Scotia. *[1]Nova Scotia Health Authority, Halifax, NS, Canada; [2]Dalhousie University, Halifax, NS, Canada.*

Background: Percutaneous kidney biopsy (PKB) is valuable for the diagnosis of kidney disease but may be associated with adverse events including major bleeding (the most concerning complication of PKB). A prior study developed a risk calculator for the prediction of major bleeding following PKB, however this calculator has not been externally validated.

Methods: We analyzed all adults that received diagnostic PKB at a large, tertiary care center from 2012-2019. Predictors of major bleeding (defined as the need for blood transfusion, surgical intervention/embolization following PKB or death) included age, body mass index (BMI), platelets, hemoglobin, kidney length and transplant versus native kidney biopsy (the same factors included in the "Risk of bleeding complications after kidney biopsy" calculator; https://perioperativerisk.com/kbrc). Similar to the derivation study, continuous variables were converted to cubic splines and the risk of major bleeding complications were analyzed using logistic regression. Discrimination was assessed using the concordance statistic and calibration was analyzed using the Hosmer-Lemeshow test.

Results: Of 714 patients, 568 with complete data for each predictor were included. 82% of biopsies were from native kidneys. Mean age was 56±16 years, mean BMI was 29.3±6.9 and mean kidney length was 11.3±1.5 cm. Mean platelet and hemoglobin count was 248X10^9/L and 109 g/L, respectively. A model incorporating these variables demonstrated excellent discrimination (area under the curve 0.858, figure 1a) and good calibration (P=0.9170, figure 1b).

Conclusions: In this external validation study, a risk calculator for patients receiving diagnostic PKB demonstrated excellent calibration and discrimination emphasizing its utility in predicting the risk of major bleeding following PKB.

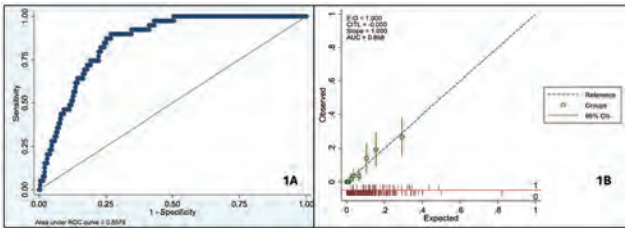

Figure 1: External validation of "Risk of bleeding complications after kidney biopsy calculator" – receiver operating characteristic curve (1A) and calibration plot (1B)

SA-PO1141

Are Waxy Casts in the Urinary Sediment Associated with Advanced Kidney Disease?

Khalid M. Mohammed,[1] Vipin Varghese,[4] Dustin R. Chalmers,[5] Muner Mohamed,[2,3] Juan Carlos Q. Velez.[2,3] Ochsner Nephrology. *[1]Tanta University, Tanta, Egypt; [2]Ochsner Health, New Orleans, LA; [3]The University of Queensland, Brisbane, QLD, Australia; [4]University of Michigan, Ann Arbor, MI; [5]Louisiana State University, Baton Rouge, LA.*

Background: Casts are clusters of urinary sediment elements formed in the kidney tubules, and the contents of the cast indicate the nature of clinical associations. The waxy casts probably represent the last stage of granular or cellular cast degeneration. Such casts thought to be form in chronic kidney disease when there is renal stasis and tubular atrophy.

Methods: We reviewed cases at Ochsner Medical Center who underwent kidney biopsies and have waxy casts in their urinary sediments around the same time of kidney biopsy. The pathology reports were reviewed and we collected the pathological findings of the presence of acute tubular injury (ATI), glomerular diseases (GD) and the pathological markers of chronic kidney disease which includes the percentage of interstitial fibrosis and tubular atrophy (IFTA) and global sclerosis (GS). We used the sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) to assess the significance of clinical association between the presence of waxy casts and different combinations of the above mentioned pathological findings.

Results: We have total 100 patients who underwent kidney biopsy and have microscopic examination of their urinary sediments. In relation to the pathological finding waxy casts seen in 15 of 58 with ATI (sensitivity 26, specificity 21, PPV 63, and NPV 57), in 6 of 26 with ATI/IFTA (sensitivity 18, specificity 27, PPV 33, and NPV 45), in 6 of 23 with GD/IFTA (sensitivity 25, specificity 27, PPV 50, and NPV 53), in 9 of 32 with ATI/GD/IFTA (sensitivity 38, specificity 19, PPV 67, and NPV 43), in 6 of 25 with ATI/GS (sensitivity 17, specificity 26, PPV 17, and NPV 26), in 6 of 23 with GD/GS (sensitivity 20, specificity 28, PPV 17, and NPV 24) and in 9 of 31 with ATI/GD/GS (sensitivity 40, specificity 27, PPV 22, and NPV 14). Serum creatinine levels were

Conclusions: Waxy casts are not specific or pathognomic findings for chronic kidney disease, their presence in urinary sediment should be interpreted carefully in addition to the other clinical findings.

SA-PO1142

Patterns of Low-Frequency Physiological Fluctuations in the Human Kidney Detected by Resting-State Magnetic Resonance Imaging

Edwin Baldelomar,[1] Cihat Eldeniz,[1] Jennifer R. Charlton,[2] Kevin M. Bennett.[1] *[1]Washington University in St Louis School of Medicine, St Louis, MO; [2]University of Virginia School of Medicine, Charlottesville, VA.*

Background: Many mechanisms in the kidney, including autoregulation, act as feedback systems and cause natural fluctuations in perfusion. Detecting these spontaneous hemodynamic fluctuations could provide patient-specific signatures of early disease progression. Non-contrast resting-state magnetic resonance imaging (rsMRI) was

recently developed to detect spontaneous physiological fluctuations in the human kidney, *in vivo*. Here, we examined the spatial patterns and reproducibility of these measured fluctuations.

Methods: We performed rsMRI at 3T over 10 minutes (gradient echo, TE/TR=2.27/4.2ms, resolution=2.5mm^3, temporal resolution = 0.605sec) of the kidneys of two healthy subjects (1 male, 1 female, ages 46-47, no reported history of kidney disease). Individuals were imaged twice on the same day, and again ~16 months later. Imaging and image processing were performed using published protocols.

Results: rsMRI demonstrated spontaneous physiological fluctuations throughout the human kidney (Figure 1A-D). Strong fluctuations at ~0.03Hz occurred in the cortex in 60.5±13.6% of voxels (Figure 1B). Specific fluctuations appeared in other tissue compartments: e.g. vessels, 0.1-0.2Hz; ureter, ~0.05 Hz (Figure 1C-D). rsMRI spectra from cortex and medulla exhibited characteristic peaks in frequency ranges of 0.015-0.026, 0.027-0.038, 0.039-0.05 Hz (Figure 1,E-G). Characteristic spectra were reproducible between scans and over 16 months (77.8% in the male and 88.9% in the female kidney).

Conclusions: rsMRI can be used to map spontaneous hemodynamic fluctuations at frequencies in the healthy human adult kidney. Patterns of these fluctuations are specific to individual subjects and are reproducible over 16 months. rsMRI may detect physiological biomarkers that reflect disease progression or response to therapies.

SA-PO1143

Mild CKD Is Predictive of Higher Mortality in Rural Uganda and Kenya

Anthony N. Muiru,[1] James Ayieko,[2] Jane Kabami,[3] Mucunguzi Atukunda,[3] Gordon O. Orori,[2] Erick M. Wafula,[2] Debbie Adam,[1] Edwin Charlebois,[1] Maya Petersen,[4] Diane Havlir,[1] Moses Kamya,[3] Michelle M. Estrella,[1] Chi-yuan Hsu.[1] *[1]University of California San Francisco, San Francisco, CA; [2]Kenya Medical Research Institute, Nairobi, Kenya; [3]Infectious Diseases Research Collaboration, Kampala, Uganda; [4]University of California Berkeley, Berkeley, CA.*

Background: Few studies have quantified the strength of the association between CKD and death in rural East Africa.

Methods: Within 22 communities of a cluster-randomized HIV trial conducted in Uganda and Kenya (NCT01864603), we randomly selected 100 households with at least one HIV-positive adult and 100 without any HIV-positive adults. We then chose 1 HIV-positive and 1 HIV-negative adult from the respective households to participate in a CKD sub-study. We determined the community-representative prevalence of CKD in 2016–2017 using weighting to account for sampling (PMC7055898). We then ascertained all-cause mortality through interviews with informants in 2023-4. We employed weighted multivariable logistic regression models to evaluate the association of baseline eGFR categories and all-cause mortality.

Results: So far, we have tracked 1,757 participants from 12 of 22 study communities. The population-weighted mean age at baseline was 39 years, and 54% were female. Prevalence of HIV was 9% (95% CI 8-11%), diabetes 5% (95% CI 4-7%), and hypertension 19% (95% CI 16-22%). An estimated 6% (95% CI 4-7%) had dipstick proteinuria, and only 1% (95% CI 0.7-2%) had eGFR<60 ml/min/1.73m^2 (mean 109 ±19 ml/min/1.73m^2). Follow-up visits were carried out after an average of 6.3 (±0.5) years, with 1,419 (81%) consenting to participate, 232 (13%) were deemed lost to follow-up, and 106 (6%) were deceased. Among those with baseline eGFR <60 ml/min/1.73m^2, 38% were deceased, compared with 5% with eGFR ≥90 ml/min/1.73m^2. An eGFR<60 (vs. ≥ 90) ml/min/1.73m^2 was associated with a seven-fold increased risk of death (aOR 7.6 95% CI: 2.2-26.2, P=0.001) after adjusting for geographic region, social demographics, health habits, diabetes, hypertension, HIV, and proteinuria. This effect size surpassed the other modifiable risk factors considered in our model.

Conclusions: CKD is a very strong risk factor for future mortality in rural Uganda and Kenya. The strength of association exceeds that observed between stage 5 CKD and deaths in resource-rich settings. This underscores the urgent need to uncover the specific causes of death related to CKD and to develop effective interventions in resource-poor settings.

Funding: NIDDK Support

SA-PO1144

Clinicopathological Characteristics and Outcomes of Nondiabetic Kidney Disease in Patients with Type 2 Diabetes

Ting Zhou,[1,2] Qiye Liu,[1] Niansong Wang,[1] Ying Fan.[1] *[1]Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China; [2]The First Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: There is limited research on the characteristics and prognosis within the non-diabetic renal disease (NDRD) categories itself. We aim to investigate the clinicopathological characteristics, specific predictors and renal outcomes of various subtypes of NDRD in patients with Type 2 diabetes mellitus (T2D).

Methods: A total of 646 adult T2D patients who underwent renal biopsy were collected from Jan 2008 to Nov 2023. Among which 197 patients were diagnosed NDRD with different types of renal pathology. We conducted analysis on 123 patients with the top three subtypes of NDRD: IgA nephropathy (T2D-IgAN, n=52), membranous nephropathy (T2D-MN, n=48), and podocytopathies (T2D-Podo, n=23). Multivariate Cox regression models were used to analyze the predictors of renal outcomes in NDRD patients. The median follow-up time was 80 months (IQR: 62-102).

Results: Clinically, T2D-MN were older and had higher level of nephrotic proteinuria, total cholesterol as well as lower levels of serum albumin as compared to T2D-IgAN or T2D-Podo. T2D-MN patients were more likely to develop atherosclerotic plaques or unstable plaques in both carotid and lower extremity arteries (LEA), and are more prone to thromboembolism, infections as compared to other two groups. Pathologically, patients in T2D-IgAN group showed more pronounced glomerular sclerosis, interstitial inflammation and C3 deposit. Kaplan-Meier survival curves demonstrated that T2D-MN group had poorer renal survival, although it's not statistically significant. Multivariate Cox regression showed glomerular C3 deposit (HR 2.777, 95%CI 1.008-7.653), estimated glomerular filtration rate (eGFR) more than 60ml/min/1.73m^2 (HR 0.348, 95%CI 0.133-0.909) and T2D duration over 10 years (HR 3.866, 95%CI 1.326-11.275) were independent predictors for renal endpoints.

Conclusions: This is the first study to compare the clinicopathological characteristics of MN, IgAN, and podocytopathies and evaluate the renal outcome in T2D patients, which could help clinicians to initiate early intervention and prevent complications in those NDRD patients with poor prognosis. Novel immunosuppressants and biologics with minimized glucocorticoids strategies might bring more optimized options to NDRD patients.

SA-PO1145

Application of Functional Kidney Magnetic Resonance Imaging to Improve Assessment of CKD: The AFiRM Study

Nicholas M. Selby,[1,2] Mark S. Gilthorpe,[3] Philip A. Kalra,[4] Iosif A. Mendichovszky,[5] Steven Sourbron,[6] Maarten W. Taal,[1,2] Susan Francis.[1] On behalf of the AFiRM Investigators. *[1]University of Nottingham, Nottingham, United Kingdom; [2]University Hospitals of Derby and Burton NHS Foundation Trust, Derby, United Kingdom; [3]Leeds Beckett University, Leeds, United Kingdom; [4]Salford Royal Hospital Manchester Centre for Clinical Neurosciences, Salford, United Kingdom; [5]Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; [6]The University of Sheffield, Sheffield, United Kingdom.*

Background: Current kidney imaging techniques for chronic kidney disease (CKD) are limited. Better methods that can determine cause and prognosis of kidney diseases are required for improved patient stratification, targeting of therapies and new drug development. Renal multiparametric MRI provides whole kidney structural and functional measurements, assessing multiple aspects of kidney pathophysiology including altered tissue microstructure (inflammation/fibrosis), oxygenation and perfusion. The AFiRM study is a UK multi-centre study to evaluate the utility of multiparametric renal MRI to study CKD progression. This abstract describes the study design and baseline study population characteristics.

Methods: AFiRM is a prospective cohort study of people with CKD across 10 UK centres, collecting renal multiparametric MRI (comprising MRI measures of morphology, microstructure, flow and perfusion) at baseline and Year 2. Inclusion criteria include eGFR <60ml/min/1.73m^2, or persistent albuminuria (ACR >30mg/mmol). Annual follow-up visits collect eGFR, albuminuria and change in clinical status until Year 4. Long-term outcomes will be determined with individual patient tracking via the UK Renal Registry to ten years. Cause and effect between the renal MRI measures (alone and in combination) and the progression of CKD will be determined. A mechanistic sub-study is embedded to compare MRI measures to kidney histology.

Results: Between June 2021 and November 2023, 653 patients with CKD were screened for inclusion, of whom 421 were eligible, consented to participate and completed baseline multiparametric MRI. Mean age was 55 ± 13yrs and 64% were male. Mean eGFR was 38 ± 5ml/min/1.73m^2 and distribution across CKD stages was: stage G1/2 14%; stage G3A 22%; stage 3B 34%; and stage G4 30%. Albuminuria was present in 86% (A2/A3). The most common CKD aetiology was IgA nephropathy (21%), 15% had diabetic kidney disease but a large proportion (17%) had CKD of unknown cause.

Conclusions: The AFiRM study is a UK-wide multicentre clinical study of renal multiparametric MRI in people with CKD, which utilises a harmonised renal MRI acquisition, centralised image upload and quality assurance, and analysis.

SA-PO1146

Higher Glycolysis in Circulating Leukocytes in Patients with CKD

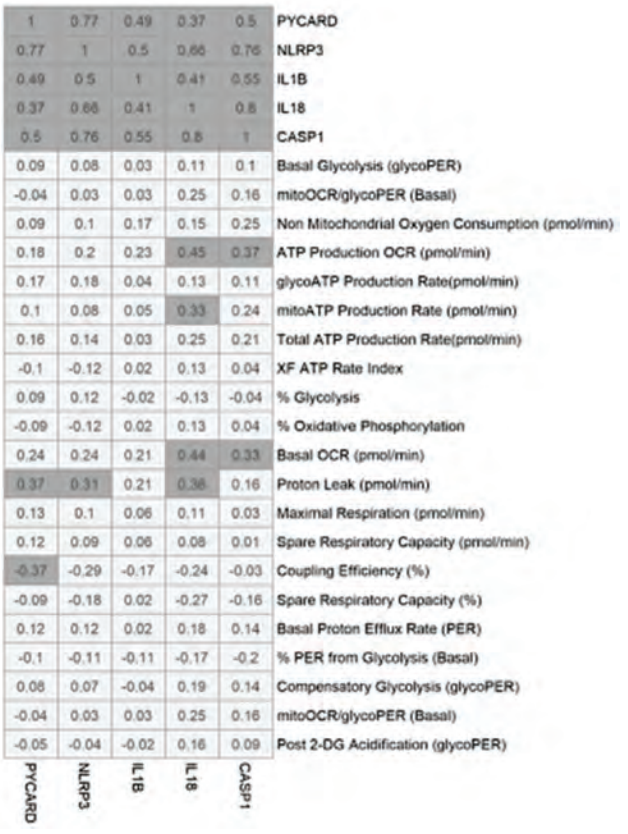
Lucas R. Johnson, Nishank Jain, Yasir Rahmatallah, Jon Coca Juaristi, Rajshekhar A. Kore. *University of Arkansas for Medical Sciences, Little Rock, AR.*

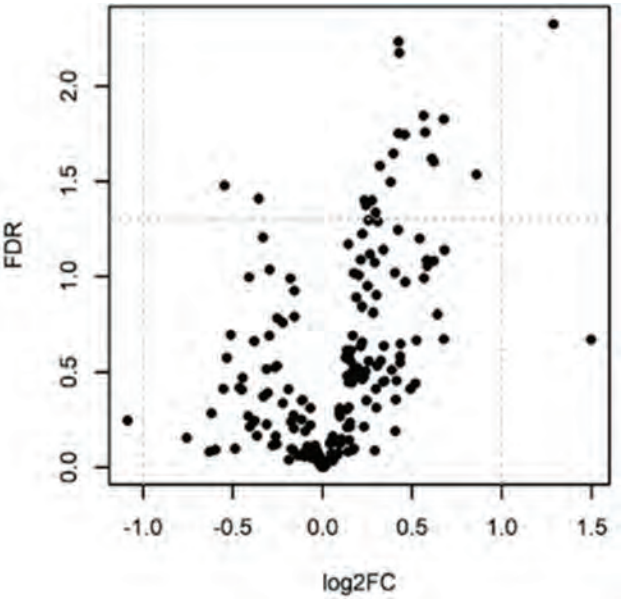
Background: Increased expression of glycolytic enzymes in kidney tissue correlates with CKD progression in the subtotal nephrectomy murine model. There are also higher levels of inflammatory cytokines with worsening CKD. These proinflammatory cytokines promote glycolysis in human endothelial cell lines. It is unknown whether glycolysis is altered in the circulating immune cells of patients with CKD that's associated with the pro-inflammatory phenotype of these patients.

Methods: We collected peripheral blood mononuclear cells from outpatients with CKD with eGFR <30 (n=37) and controls with normal kidney function (n=29) using ficoll high-density gradient leukoseparation. We identified pathways that were significantly different between groups using HALLMARK analysis. We also performed DEseq analysis for differentially expressed genes that met threshold fold change of 1.5 at false discovery rate of 0.1. Seahorse assays measured ATP production from leukocytes via glycolysis and non-glycolytic pathways.

Results: The glycolytic pathway was significantly upregulated in the CKD group in unadjusted analysis; and remained significant even after adjusting for presence of diabetes, age, race and gender. We also found 7 differentially expressed genes in CKD leukocytes - 2 of them from the glycolytic pathways- IDH1 (Isocitrate dehydrogenase 1) and SLC16A3 (Solute carrier). There was higher ATP generation via glycolysis pathways in CKD leukocytes that positively correlated with patients' serum CRP levels.

Conclusions: There is overexpressed glycolytic pathway with differentially overexpressed genes of glycolytic pathways in the immune cells of patients with CKD. In addition, CKD leukocytes rely more on glycolysis for energy production that the controls which positively correlates with their proinflammatory burden.





SA-PO1147

Sarcoidosis Found in the Bone Marrow

Alyssa C. Weyer, Sanjana Bukkapatnam, Arda Akoluk. *The University of Texas Health Science Center at Tyler, Tyler, TX.*

Introduction: 90% of patients who present with hypercalcemia are likely due to primary hyperparathyroidism or malignancy, with the alternative diagnosis of sarcoidosis. Sarcoidosis tends to affect the lung in 95% of cases and about 4% of cases affect the bone marrow. Patients tend to present with vague symptoms of faigue, shortness of breath, arthralgias, and fevers. We present a case of a patient who presented with hypercalcemia and the work-up that it entailed.

Case Description: Patient is a 69-year-old woman with a history of hypertension, microcytic anemia, atrial fibrillation, chronic kidney disease stage 4, proteinuria, and insulin dependent diabetes mellitus type 2 who presented to the Nephrology clinic due

to acute renal failure which was presumed due to acute tubular necrosis and overdiuresis. Patient was undergoing work up with Hematology due to microcytic anemia and was noted to have hypercalcemia. There was concern for multiple myeloma, so extensive work up consisted of negative Serum protein electrophoresis, flow cytometry, and kappa/lambda. Bone marrow biopsy was obtained for further clarification and was found to have granulomas in the bone marrow (Fig. 1). Extensive infectious work up performed including fungal etiologies which was negative. The angiotensin converting enzyme was elevated at 178 U/L. Kidney involvement was highly suspected due to intrinsic pathology consistent with urinalysis. She started on prednisone and her kidney function has normalized, her calcium as well as her angiotensin converting enzyme level is normal currently and prednisone is being weaned. Her fatigue and tiredness have resolved.

Discussion: Sarcoidosis presenting only with bone marrow granulomas and no lung finding is a very rare presentation. Our patient did not have any joint symptoms. Common findings for bone marrow sarcoidosis involve cytopenias, lymphadenopathy, and hypersplenism. Treatment involves steroids, and if not responsive, addition of immunosuppressants. It is important to base decision of obtaining a bone marrow biopsy when sarcoidosis is highly suspected in the setting of hypercalcemia.

SA-PO1148

Bleeding Complications and Insufficient Samples after Percutaneous Native Kidney Biopsy

Hisashi Kamido, Shigekazu Kurihara, Masayuki Yamanouchi, Tatsuya Suwabe, Yoshifumi Ubara, Naoki Sawa. *Toranomon Byoin Bunin, Kawasaki, Japan.*

Introduction: Insufficient samples in kidney biopsies (total number of glomeruli ≤7) significantly impact diagnostic accuracy. Recently, the rate of inadequate kidney biopsy samples in the United States has risen to 14%, posing a substantial issue. This study analyzes the frequency and influencing factors of inadequate samples and bleeding in kidney biopsies at our institution.

Case Description: This retrospective study included 70 cases of kidney biopsies performed between August 2022 and March 2023. Variables analyzed included the presence of insufficient samples, bleeding events, age, gender, height, weight, eGFR, position, laterality, and number of punctures. The results are presented as medians (IQR). Among the patients, 36 were male (52%), with a median age of 56 years (45-68), BMI of 22 kg/m^2 (22-24), and eGFR of 57 ml/min/1.73m^2 (39-72). There were 11 cases (16%) of left kidney biopsies, 2 cases (2.9%) performed in the lateral position, with a median of 5 punctures (4-6), 3 biopsy cores obtained (2-4), and 33 glomeruli collected (22-42). Insufficient samples (total number of glomeruli ≤10) occurred in 3 cases (4.4%), and bleeding events in 5 cases (7.3%). No clear correlation was observed between the number of punctures, hypertension, abdominal circumference, and bleeding events.

Discussion: Since bleeding complications did not increase with the number of punctures, it is recommended that a sufficient number of punctures be performed to collect an adequate volume of specimens for diagnosis.

SA-PO1149

Beyond Anemia of CKD: A Tale of Discovering Post-transplant Lymphoproliferative Disorder by Colonoscopy

Hira Tahir, Farah Daccueil, Katherine Andrade, Henry Yip. *Stony Brook University Hospital, Stony Brook, NY.*

Introduction: In young patients seldom are drops in hemoglobin investigated with colonoscopy. In chronic kidney disease (CKD) patients, anemia is attributed to CKD and further testing is often met with resistance especially in younger population. Our rare case describes how a nephrologists referral for anemia diagnoses post-transplant lymphoproliferative disorder (PTLD) in the form of colon lymphoma. This highlights the important role nephrologist play in caring for transplant patients.

Case Description: A 31-year-old male with congenital nephrotic syndrome (Finnish type) post living related kidney transplant 3/30/2006 is referred by nephrologist for inpatient workup of diarrhea and anemia. Exam revealed pale and toxic appearing young male with admission labs of Na 125, K 5.9, Cl 96, HCO3 16, BUN 73, Cr 3.64 and WBC 12.99, Hb 6.6, Hct 20.8 and PLT 403. Stool pathogen was positive for Yersinia Enterocolitica and E.coli (EPEC). CT imaging revealed pleural effusion and no lymphadenopathy. Although patient responded to transfusion, nephrology team had extensive discussion to pursue endoscopy which gastroenterology finally agreed. EGD/Colonoscopy revealed multiple polypoid non-obstructing medium sized masses in descending colon, transverse colon and ascending colon and multiple superficially ulcerated nodules in recto-sigmoid and sigmoid colon. Pathology diagnosed diffuse large B-cell lymphoma (DLBCL) negative for CD-20. Immunosuppression was reduced and patient was discharged however outpatient PET found mesenteric lymphadenopathy. Even though oncology initiated chemotherapy, the patient suffered septic shock due to enterotoxigenic E.coli after first treatment and expired.

Discussion: Immunosuppressed kidney transplant recipients are at higher risk of developing malignancy including gastroenterology cancer. However current guidelines for testing and screening do not differ between the transplant and general population. Therefore continued sense of awareness and advocacy for screening is important. Evidence based guidelines in this population is needed to improve life expectancy in kidney transplant patients.

SA-PO1150

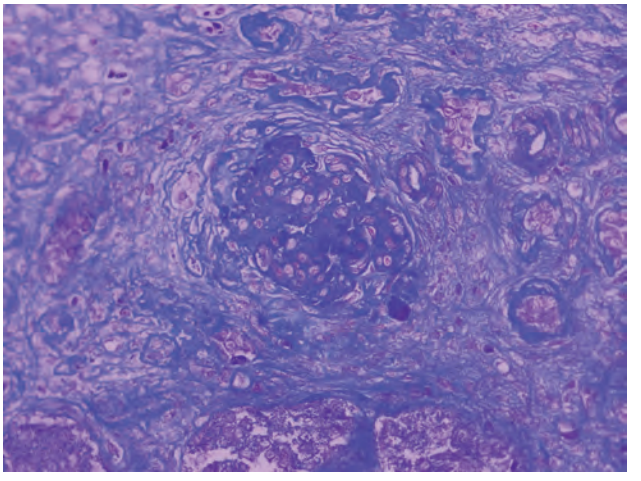
Chronic Organophosphate Intoxication Developed End-Stage Kidney Failure

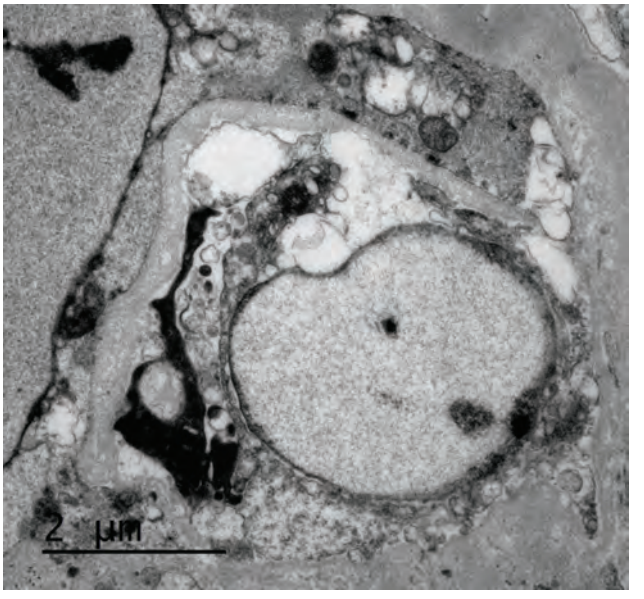
Maite Hurtado Uriarte,[1] Johanna Alvarez.[2] [1]*Baxter Renal Care Services, Bogota, Colombia;* [2]*Fundacion Santa Fe de Bogota, Bogota, Colombia.*

Introduction: Organophosphates, which are commonly used as pesticides, are highly toxic and can enter the body through the skin, lungs, and gastrointestinal tract. They directly affect acetylcholinesterase (AChE), leading to overstimulation of cholinergic neurons. Exposure to organophosphates has been identified as a significant non-traditional cause of chronic renal failure.

Case Description: A nineteen-year-old fumigator with no prior medical history presented with symptoms including headache, cramps, palpitations, fatigue, anorexia, and seizures over the past 20 days. Upon arrival at the emergency room, he was found to have metabolic acidosis and compromised kidney function, requiring ventilator support and immediate renal replacement therapy. Infectious and autoimmune causes were ruled out. A renal biopsy was performed, revealing 66% global sclerosis, 15% segmental sclerosis, retracted basement membrane, cortical infarction, and changes consistent with thrombotic microangiopathy.

Discussion: Chronic kidney disease is a significant global health concern, leading to premature mortality, increased cardiovascular risk, and reduced quality of life. Pesticide exposure, particularly in agriculture, heightens the risk of kidney damage. It is crucial to remain alert about this public health issue.





SA-PO1151

Unknown Disease or Unusual Mesoamerican Nephropathy?

Pooya Zardoost, Sidney Elston, Alexander Prouty, Henry L. Wehrum. *OhioHealth, Columbus, OH.*

Introduction: Mesoamerican Nephropathy (MeN) is a known disease in patients from Central and North America with history in manual labor industries. Aside from ruling out HTN, DM, and AKI, diagnosis requires GFR below 60 ml/min, urine P/C ratio below 2, biopsy showing tubular atrophy, fibrosis, and glomerulosclerosis. We had a patient with nephrotic proteinuria and biopsy consistent with MeN. Whether the proteinuria indicated an unknown disease or an unsual case of MeN is an area of uncertainty.

Case Description: A 31-year-old male with no past medical history was hospitalized after routine labs showed creatinine of 3.9 mg/dL and bicarbonate of 17 mmol/L. He recently moved from Mexico and spent years working in the textile industry. He denied any other symptoms. Vitals were 135/74 mmHg, 72 bpm, 15, 98.6 F and 98%. Exam was non-revealing. CT and ultrasound were negative for obstruction, revealing increased renal cortical echogenicity. Urine studies showed intrinsic disease, and proteinuria with P/C ratio of 3.7. Workup for autoimmune disease, vasculitis, diabetes, and infection were negative. He was initiated on bicarbonate supplementation, and creatinine improved the day after to 3.6 mg/dL; acidosis resolved. He was discharged with renal biopsy scheduled outpatient, which later showed diffuse tubulointerstitial fibrosis with atrophy and global glomerulosclerosis (Figure 1). He was scheduled to see nephrology outpatient.

Discussion: Our patient presented with a picture consistent with MeN despite proteinuria above the maximum level for diagnosis. His history in the textile industry suggests exposure to silica. It is unclear whether this may have resulted in a variant of MeN, or if he had another unknown disease. Atypical presentations of renal disease associated with occupational exposures demand further attention.

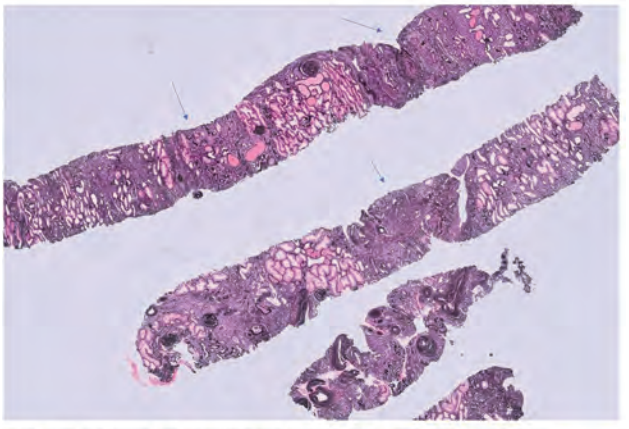


Figure 1 Jones' Methenamine Silver Stain showing zonal areas of interstitial fibrosis and atrophy (blue arrows).

SA-PO1152

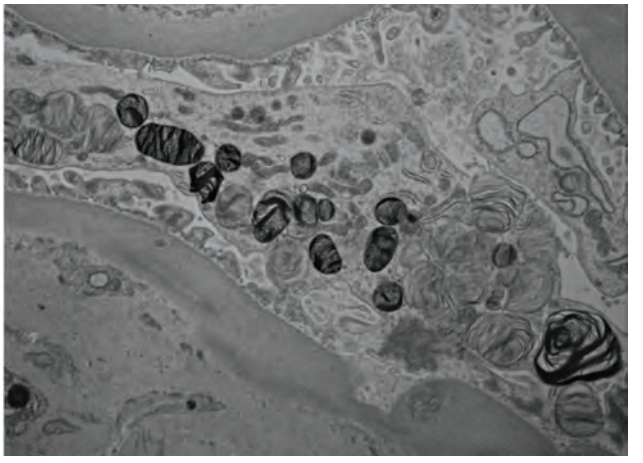
When You Hear Hoofbeats: An Interesting Presentation of Zebra Bodies Associated with Hydroxychloroquine Use

Adileen Sii, Aisha Batool, Carl S. Dernell, Anna R. Gaddy. *Medical College of Wisconsin, Milwaukee, WI.*

Introduction: The presence of zebra bodies in kidney biopsy is a distinctive characteristic of Fabry disease. However, certain medications such as hydroxychloroquine may also induce zebra body formation by mimicking the phospholipidosis of Fabry disease. First developed as antimalarial drugs, chloroquine and hydroxychloroquine are widely used today in management of autoimmune disorders. While both medications have been generally regarded as safe, serious side effects such as retinopathy, myopathy, and cardiomyopathy have been reported. Hydroxychloroquine in particular has been associated with the presence of zebra bodies in the kidney but the clinical significance of this finding is not well-known. We present a case illustrating zebra bodies in a patient with long-term hydroxychloroquine use.

Case Description: A 75 year-old female with history of rheumatoid arthritis was evaluated for proteinuric Stage 3 CKD. Serum electrophoresis revealed a monoclonal band and biopsy was performed. Histologic examination revealed C3 dominant mesangioproliferative glomerulonephritis, but also ultrastructural evidence of podocyte lipid accumulation consistent with Fabry disease. Medication history confirmed that the patient had been on the amphiphilic drug hydroxychloroquine for many years.

Discussion: The prevalence of zebra bodies attributable to hydroxychloroquine has been low and the clinical significance remains unclear. While there is an association of zebra bodies and increased phospholipidosis, the histological difference between drug-induced zebra bodies and those observed in Fabry disease requires further clarification. Understanding these differences will allow for further assessment regarding the implications of long-term usage of drugs such as hydroxychloroquine. Our patient was referred to hematology for bone biopsy due to her C3 disease but hydroxychloroquine was not thought to be causative of her kidney disease and was continued.



SA-PO1153

Chronic Interstitial Nephritis in Agricultural Communities: Two Potential Belgian Cases

Sylvina da Silva Fernandes,[1,2] Isabelle Simon,[5] Karl M. Wissing,[6] Joelle L. Nortier,[4] Eva M. Buhl,[2] Caroline Geers,[6] Cynthia C. Nast,[3] Peter Boor,[2] Marc E. De Broe,[1] Benjamin A. Vervaet.[2,1] *[1]Universiteit Antwerpen, Antwerpen, Belgium; [2]Universitatsklinikum Aachen Institut fur Pathologie, Aachen, Germany; [3]Cedars-Sinai Medical Center, Los Angeles, CA; [4]UVC Brugmann, Brussels, Belgium; [5]Hopital Erasme, Bruxelles, Belgium; [6]Universitair Ziekenhuis Brussel, Brussel, Belgium.*

Introduction: Chronic Interstitial Nephritis in Agricultural Communities (CINAC) is a chronic kidney disease of unknown etiology. Currently, CINAC can be diagnosed when patients are active in a farming context, present no or mild hypertension, have no overt proteinuria, and show light microscopic indication of chronic tubulo-interstitial nephritis on biopsy. A histopathological study of our group discovered enlarged (>1,2 μm) dysmorphic lysosomes containing dispersed round aggregates in proximal tubular cells as a prevalent feature of CINAC. Therefore, we hypothesize that verifying this lesion strengthens the CINAC diagnosis when observed in the aforementioned clinico-epidemiological context and helps uncover new cases.

Case Description: In 2023 two Belgian nephrologists independently admitted CKD patients for renal biopsy who fitted the minimal criteria for CINAC (Table). Patient 1, a 50-year-old male, originated from El Salvador where he assisted and worked in pesticide spraying, without protection, from the age of 10 to 32 before moving to Belgium in 2016 with developing CKD. Patient 2, a 71-year-old male, has been a floriculturist for 50 years with often use of pesticides, although with mask protection. Both patients had features of chronic interstitial nephritis in biopsy with a range of healthy and damaged tubuli, some of which showed the abnormal lysosomal lesions. Electron microscopy confirmed the presence of several enlarged, dysmorphic lysosomes containing moderate- to well-defined electron-dense aggregates.

Discussion: We describe two cases of suspected CINAC, that show the presence of abnormal lysosomal lesions, the first cases identified in Belgium. Albeit rare outside of the typical geographic localization, CINAC should be considered in the differential diagnosis of CKD cases of unknown etiology.

	Patient 1	Patient 2
Creatinine (mg/dl)	2.50	1.91
Proteinuria (g/g creatinine)	0.42	0.06
Hypertension	treated	treated
Kidney size on ultrasound	decreased in size	decreased in size
Histopathology	Chronic Interstitial Nephritis	Chronic Interstitial Nephritis

SA-PO1154

A Rare Case of Nonuremic Calciphylaxis in a Patient with Mild Macroalbuminuric CKD

Michelle N. Keyser, Jyotsana Thakkar. *UPMC, Pittsburgh, PA.*

Introduction: Nonuremic calciphylaxis (NUC) is a rare, poorly understood entity that can occur in patients without end-stage kidney disease (ESKD) and kidney transplantation. Sparse data has shown several risk factors associated with NUC, but these associations are not well understood. We present a case of NUC in a patient with mild macroalbuminuric chronic kidney disease (CKD G2A3).

Case Description: A 61-year-old female with long-standing uncontrolled type 2 diabetes, peripheral vascular disease, hypertension, coronary artery disease, uterine cancer status post total hysterectomy, hypothyroidism, and mild macroalbuminuric chronic kidney disease (CKD G2A3, eGFR 70-80 ml/min/1.73 m2, BUN 18, UACr 749 mg/g) who presented with a painful, ulcerated skin lesion on her right leg following mild trauma. She was evaluated by vascular surgery and underwent angioplasty of the right peroneal artery and anterior tibial arteries. Despite angioplasty, the ulcerated lesion did not improve, and she was referred to a dermatologist. Subsequently, a skin biopsy was performed which showed acute ulceration with necrosis and inflammatory exudate with associated dermal sclerosis and vascular peri-eccrine calcifications concerning for atypical nonuremic calciphylaxis. Calcium, phosphorus, and PTH levels (77 pg/ml) were within normal limits. She was taking vitamin D supplementation for many years and her vitamin D-25-OH was elevated to 72 ng/ml, which was stopped. Serologies were only notable for an elevated rheumatoid factor. She was started on sodium thiosulfate which led to improvement in the skin lesion and pain.

Discussion: Calciphylaxis is typically seen in patients with ESKD and kidney transplantation. However, it has rarely been described in patients with nonuremic causes. It is important to report these cases to better understand the risk factors associated with NUC. Our patient had mild CKD, vitamin D deficiency, uterine cancer, uncontrolled type 2 diabetes, peripheral artery disease, elevated rheumatoid factor, and was on dual anti-platelet therapy. All of these are proposed triggers for NUC. There is currently no standard treatment for NUC, but sodium thiosulfate has shown promise, was trialed in this patient, and led to clinical improvement.

SA-PO1155

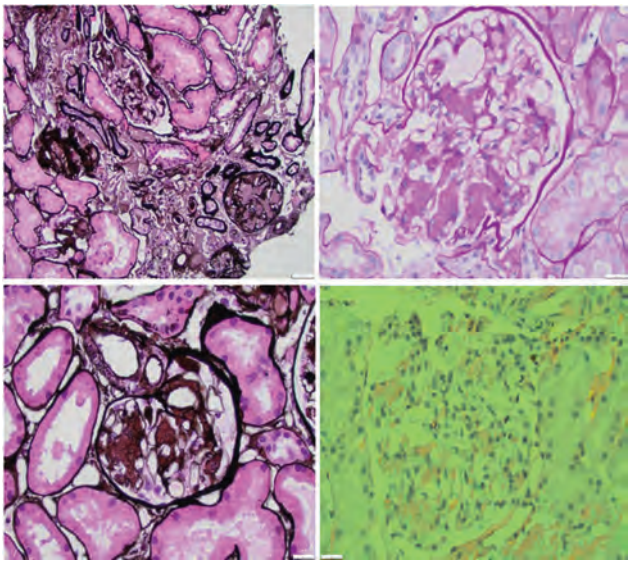
Leukocyte Chemotactic Factor 2-Related Amyloidosis Presenting with a Rash and Unexplained CKD

Zohreh Gholizadeh Ghozloujeh, Yan Chen Wongworawat, Amir Abdi Pour, Niloufar Ebrahimi, Sayna Norouzi. *Loma Linda University, Loma Linda, CA.*

Introduction: Leukocyte chemotactic factor 2 amyloidosis (ALECT2) is a recently described type of amyloidosis predominantly affecting the kidneys. ALECT2 has a relatively benign course, rare cardiac involvement, and a specific ethnic distribution. Recognizing ALECT2 is crucial to avoid unnecessary and potentially harmful treatments intended for more common subtypes like AL or AA amyloidosis. We present a case of ALECT2 with unusual clinical presentation and renal histology.

Case Description: A 60-year-old Hispanic female with a history of prediabetes (HbA1c = 5.7%) and hypertension presented with a pruritic skin rash on her hands. Upon reviewing historical laboratory findings, the patient was found to have elevated serum creatinine (Cr = 1.20 mg/dL) with an estimated glomerular filtration rate of 48 mL/min/1.73m^2 (CKD stage 3) without proteinuria for the past 20 months. Renal ultrasound showed increased echogenicity consistent with CKD. Despite controlling her hypertension, her serum creatinine continued to rise (1.39 mg/dL) over the next 2 months, necessitating a biopsy to investigate the underlying etiology of her CKD. The kidney biopsy revealed LECT2 amyloidosis, predominantly glomerular and less dominant interstitial amyloid deposition, which was Congo red-positive with light green birefringence under polarized light (Image1). No diagnostic features of paraprotein-associated renal deposition disease, immune complex-mediated glomerulonephritis, or interstitial nephritis were observed, and urine protein electrophoresis was negative. The echocardiography did not suggest cardiac involvement with an ejection fraction of 60-65%.

Discussion: We report an unusual case of biopsy proven ALECT2 presenting with skin rashes resembling other autoimmune diseases.



SA-PO1156

Incidental Diagnosis of Lymphoplasmacytic Lymphoma in a Patient with CKD

Muhammad R. Khan, Mauricio Monrroy. *Albany Medical Center, Albany, NY.*

Introduction: Lymphoplasmacytic lymphoma (LPL) is a rare B cell lymphoma, predominantly affecting whites and males, with a median onset age of 65. It mainly targets the bone marrow, and less frequently the spleen and lymph nodes, with kidney involvement being exceptionally rare. LPL often harbors mutations in the MYD88 gene and may not present with typical B symptoms. It is commonly associated with IgM monoclonal gammopathy, known as Waldenström gammaglobulinemia. This report describes an incidental finding of LPL in the kidney of an asymptomatic patient.

Case Description: A 76-year-old male with a history of chronic kidney disease (CKD) stage 3A presented for CKD management. Diagnosed concurrently with hypertension eight years prior, he had no known CKD risk factors. He was a non-smoker without illicit drug use. His medication regimen included irbesartan, hydrochlorothiazide, nifedipine, levothyroxine, atorvastatin, and multivitamins. He had a history of surgically treated prostate cancer and thyroid papillary carcinoma, 11 years ago. No family history of kidney disease was reported. Physical examination showed elevated blood pressure and 1+ lower extremity edema. Labs showed creatinine 1.38 mg/dl and no proteinuria with bland urinalysis. Kidney ultrasound identified bilateral simple renal cysts and a persistent complex cyst in the right kidney. Regular surveillance of the cyst was advised. During subsequent follow-up he reported 9 kg weight loss but no other symptoms. Repeat labs showed creatinine 1.48 mg/dl and normal blood counts. Renal biopsy was done which revealed LPL with a MYD88 mutation. Subsequent diagnoses included Waldenström gammaglobulinemia, with immunoelectrophoresis detecting IgM kappa paraprotein. He was referred to hematology/oncology for further evaluation and treatment, receiving six cycles of Rituximab, Bendamustine, and Neulasta, resulting in normalized IgM levels and creatinine remained stable at 1.46 mg/dl.

Discussion: LPL in the kidney is exceedingly uncommon, with few case reports available. This case emphasizes the significance of renal biopsy in patients with stable renal function and unidentified causes of CKD, highlighting its utility in revealing unusual pathologies even when initial evaluations are inconclusive.

SA-PO1157

CKD Induced by Cholesterol Crystal Embolization (CCE)

Shohan Pervaze, Nirmay Sonar. *Ballad Health, Norton, TN.*

Introduction: CCE typically impacts individuals with widespread erosive atherosclerosis. This occurs when fragments of atherosclerotic plaques detach and travel to distant locations, causing the partial or complete blockage of numerous small arteries, including glomerular arterioles, leading to ischemia in affected tissues or organs.

Case Description: 68-year-old man with CAD post-left heart catheterization with stent placement 4w ago, CKD3, HTN, DM and Afib presented to the ED with fatigue and melena for 3 days. His meds include amlodipine, metformin, aspirin, Plavix and Eliquis. In the ED, he was stable and labs with slight leukocytosis, Cr 3.8, K 5.8, BUN 71, and lactate 2.8. He received 1uPRBC, and a positive FOBT with general surgery consultation for GI bleed workup. Initially, his AKI was thought to be prerenal due to GI bleed from anticoagulation intolerance. However, EGD and colonoscopy were benign. Eliquis was held. He responded well to transfusion and received maintenance IVF. Repeat labs showed improved BUN

but Cr at 5.3 by day 5. A repeat UA on day 3 revealed hyaline and granular casts. Despite good urine output, Cr levels did not improve. Renal US showed a slightly atrophic right kidney. Autoimmune workup and complement levels were normal. A renal biopsy of the right kidney showed light microscopy findings consistent with tubular injury and cholesterol emboli in vessels. Electron microscopy revealed mild thickening of the glomerular basement membrane and focal effacement of podocyte foot processes. The IF study was negative. With a stable chonic renal injury and HPE findings, he was diagnosed with CCE.

Discussion: CCE requires suspicion, especially with AKI, hypereosinophilia, livedo reticularis, or blue toe syndrome in elderly men with atherosclerosis or recent vascular interventions like cardiac cath, with fever, weight loss, anorexia, fatigue, and myalgias. Labs may show elevated WBCs, ESR, CRP, reduced C3/C4, anemia and low Plts. Hypereosinophilia is seen in 80% of cases, mediated by cytokines potentially IL 5 from vascular endothelium. Biopsy, preferably of affected skin or muscles remains the gold standard. Treatment focuses on supportive care for end-organ damage and preventing recurrent cholesterol embolization episodes. Addressing atherosclerosis risk factors like smoking, hypertension, and cholesterol is crucial. Mention on statin, antiplatelets and revascularization therapy is made.

SA-PO1158

Postsurgical Outcomes in Veterans with Advanced CKD vs. ESKD on Chronic Dialysis

Austin L. Mallory, Mary V. Sarrazin, Masaaki Yamada, Diana I. Jalal, Benjamin R. Griffin. *University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: Patients with advanced chronic kidney disease (CKD) have poor post-surgical outcomes, perhaps due in part to negative uremic impacts on immune function, hemostasis, and wound healing. We hypothesized that end stage kidney disease (ESKD) patients on chronic dialysis would have better post-surgical outcomes due to reduced uremic toxin burden compared to patients with advanced CKD, particularly for post-surgical infection and bleeding. We compared outcomes following surgery between patients with advanced CKD not on chronic dialysis to patients with ESKD on chronic dialysis within the Veterans Affairs Health Care System.

Methods: We analyzed data from the VA Surgical Quality Improvement Program (VASQIP) database from 2013 to 2019. Veterans with an eGFR <20 mL/min based on pre-operative creatinine or ESKD on chronic dialysis were included. Exclusion criteria were emergent surgery, pre-operative acute kidney injury, or pre-operative sepsis. Outcomes including mortality, infection, cardiac events, and hematologic and respiratory complications were assessed over a 30-day period from surgery. The two groups were compared using a General Estimating Equation (GEE) model that adjusted for age, comorbidities, frailty, urgent case status, and operative stress score.

Results: A total of 3,097 patients were included, of which 643 had CKD with eGFR <20 mL/min and 2,454 had ESKD. The ESKD patients were younger but had higher frailty and comorbidity scores. After adjustments, CKD patients had 56% increased odds of having a post-surgical complication **(Table)**.

Conclusions: Veterans with advanced CKD had higher rates of post-surgical complications than Veterans with ESKD on chronic dialysis, particularly cardiac and infectious complications. It is possible that uremic burden may contribute to poor post-surgical outcomes in advanced CKD, though additional research is needed to further understand this association.

Outcome (CKD vs ESKD)	Adjusted Odds Ratio	95% Confidence Interval	P-value
30-Day Mortality	1.22	0.74 - 2.03	0.4
30-day Readmission	0.91	0.72 – 1.14	0.4
Any Post-Surgical Complication	1.56	1.23 – 1.97	0.0003
Adverse Cardiac Events	1.67	1.09 – 2.55	0.02
Post-Surgical Infections	1.37	1.00 – 1.86	0.048
Hematologic Complications	0.81	0.27 – 2.40	0.7
Respiratory Complications	0.99	0.58 – 1.70	0.9

SA-PO1159

Mitofusins by Regulating Lung Macrophage-Derived Immune Signals Modulate Monocyte Migration and Interorgan Cross-Talk during Kidney Fibrosis

Divya Bhatia, Edwin Patiño, Eleni Kallinos, Maria Plataki, Augustine M. Choi, Mary E. Choi. *Weill Cornell Medicine, New York, NY.*

Background: Chronic kidney disease (CKD)-associated lung injury is under-recognized. Coexistence of lung dysfunction with CKD increases rates of kidney failure and mortality. We studied alveolar macrophage (AM) and type 2 alveolar epithelial cell (AEC2)-specific roles of mitochondrial fusion proteins, mitofusin (MFN)1 and MFN2 in kidney fibrosis-associated lung injury and interorgan crosstalk.

Methods: Myeloid-(*LysM-Cre*$^{+/-}$) or AEC2 (*Spc-Cre*$^{+/-}$)-specific *Mfn1*$^{+/-}$ and/or *Mfn2*$^{+/-}$ & control mice were subjected to unilateral ureteral obstruction (UUO) or sham surgery (7-days), or adenine or control diet (4 or 8-weeks). Lungs, kidneys, & bronchoalveolar lavage fluid (BALF) were analyzed by western blot, Masson's trichrome staining, & flow cytometry. Blood was assessed for blood urea nitrogen (BUN), creatinine, chemokine analysis (bead array) & flow cytometry. THP-1 cells were treated with TGF-β1 and/or PGC-1α agonist.

Results: CKD-associated monocyte infiltration in the lungs, AM-derived inflammatory (mitochondrial-specific reactive oxygen species (mROS), Ly6C^{high}) & fibrotic (CX3CR1, galectin-3, arginase-I) signals were suppressed in myeloid-specific *Mfn1*$^{+/-}$ and/or *Mfn2*$^{+/-}$ mice. Protection in myeloid-specific *Mfn1*$^{+/-}$ and/or *Mfn2*$^{+/-}$ mice was mediated by AEC2-specific compensatory inductions of MFN1/MFN2 during CKD. AEC2-specific *Mfn1*$^{+/-}$ and/or *Mfn2*$^{+/-}$ mice after UUO had increased monocytes in the lungs and BALF. After UUO, interstitial, monocyte-derived, and tissue-resident alveolar macrophages from lungs and BALF of AEC2-specific *Mfn1*$^{+/-}$ and/or *Mfn2*$^{+/-}$ mice displayed increased mROS & galectin-3. AEC2-specific *Mfn1*$^{+/-}$ and/or *Mfn2*$^{+/-}$ mice after UUO had increased levels of i) BUN & creatinine, ii) circulating CCL-17, 22, TGF-β1, IL-12p40, & iii) CCR2+, Ly6C^{high}, mROS+ monocytes. TGF-β1 promoted, while PGC-1α agonist suppressed migratory, inflammatory, and profibrotic functions of THP-1 monocytes.

Conclusions: Myeloid lineage-specific *Mfn1*/*Mfn2* ablation attenuated CKD-associated lung injury via a compensatory induction of MFN1/MFN2 in AEC2. AEC2-specific loss of *Mfn1*/*Mfn2* accelerated kidney fibrosis-associated lung macrophage-derived local and circulating inflammatory signals. Circulating immune signals by promoting monocytes' infiltration into the kidney, can exaggerate kidney inflammation and fibrosis.

Nano Delivery of Sinomenine Targeting Mitochondria to Improve Mitochondrial Autophagy against Kidney Fibrosis through PINK1/Parkin Pathway

Hong Dong Huang.[1,2] [1]*Capital Medical University, Beijing, China;* [2]*Capital Medical University Affiliated Beijing Friendship Hospital, Beijing, China.*

Background: Mitophagy plays a key role in maintaining kidney function and impaired in pathologic states. This study investigated the protective effect of mitochondria-targeted nano sinomenine on renal fibrosis and its molecular mechanism.

Methods: Synthesis mitochondria-targeting nanomaterials. Cell fibrosis cell and animal model were established. Different concentrations of nano sinomenine were used to interfere with cell fibrosis and animal model. Western blot/ flow cytometry were used to detect the expression of LC3, CollagenI, α-SMA and ROS. The expression of PINK1/Parkin were analyzed by RNA-SEQ. The mitochondria and autophagosomes of mitochondria-like organelles were observed by electron microscope. Western blot and immunofluorescence were used to compare the expressions of fibrotic proteins CollagenI, α-SMA, Fibronectin, and mitochondrial autophagy in renal tissues of mice in each group. The renal tubule boundary destruction, atrophy and collagen deposition were observed by PAS and Masson staining.

Results: Nanometer sinomenine targeting mitochondria was successfully established. Cell experiments induced by TGF-β1 and animal experiments on adenine and UUO surgical models confirmed that mitochondrial autophagy was enhanced and TGF-β1 was decreased in the group treated with nano sinomenine. Nano sinomenine decreased the expression of CollagenI, α-SMA, Fibronectin proteins. PINK1 was highly enriched, and the expression level of LC3B decreased after silencing PINK1. The levels of urea nitrogen and creatinine of mice with Nanometer sinomenine treatment were lower than those of control group. The ROS, fibrotic proteins CollagenI, α-SMA, Fibronectin were significantly lower than that of control group, and the expression level of mitochondrial autophagy protein was significantly increased. Renal tubule boundary destruction, atrophy and collagen deposition were significantly lower than those in the control group.

Conclusions: Mitochondria-targeted nano sinomenine had a strong mitochondrial targeting effect on renal tubules, significantly enhances mitochondrial autophagy, inhibits ROS, CollagenI, α-SM production, and against renal fibrosis. It provides a new idea for the treatment of renal fibrosis and the transformation of basic experimental results.

Knockout of Integrin αvβ6 Protects against Kidney Inflammation in CKD by Reduction of Proinflammatory Macrophages

Chang-Jian Zhu,[1,2] Ruilin Zheng,[1,2] Zhou Liang,[1,2] Yi Zhou.[1,2] [1]*Department of Nephrology, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China;* [2]*NHC Key Laboratory of Clinical Nephrology (Sun Yat-sen University) and Guangdong Provincial Key Laboratory of Nephrology, Guangzhou, China.*

Background: Integrin αvβ6 holds promise as a target for organ fibrosis, yet targeted therapies are hampered by concerns of inflammatory-related side effects. The role of αvβ6 in renal inflammation remains unknown, and clarifying this issue is crucial for αvβ6-targeted treatment of chronic kidney disease (CKD).

Methods: The correlation between αvβ6 and renal inflammation was investigated in CKD patients and mouse fibrotic models. *Itgb6* systemic or proximal tubular cells (PTCs)-specific conditional knockout mice were established to explore the effect of αvβ6 on the renal inflammation during fibrosis. *In vitro*, PTCs transfected with si-NC or si-*Itgb6* were co-cultured with macrophages to elucidate the mechanism of crosstalk.

Results: A positive correlation was revealed between overexpressed αvβ6 in PTCs and renal inflammation in CKD patients and mouse models. Notably, knockout of αvβ6

not only alleviated renal fibrosis but also reduced inflammatory responses in mice, especially the infiltration of pro-inflammatory macrophages. Conditional knockout of αvβ6 in PTCs *in vivo* and co-culture of PTCs with macrophages *in vitro* showed that depleting αvβ6 in PTCs suppressed the migration and pro-inflammatory differentiation of macrophages. Screening of macrophage activators showed that αvβ6 in PTCs activates macrophages via secreting IL-34. IL-34 produced by PTCs was significantly diminished by αvβ6 silencing, and reintroduction of IL-34 restored macrophage activities, while anti-IL-34 antibody restrained macrophage activities enhanced by αvβ6 overexpression. Moreover, RNA-sequencing of PTCs and verification experiments demonstrated that silencing αvβ6 in PTCs blocked hypoxia-stimulated IL-34 upregulation and secretion by inhibiting YAP expression, dephosphorylation, and nuclear translocation, which resulted in the activation of Hippo signaling. While application of a YAP agonist recurred IL-34 production by PTCs, enhancing the subsequent macrophage migration and activation. Besides, reduced IL-34 expression and YAP activation were also observed in global or PTCs-specific αvβ6-deficient injured kidneys.

Conclusions: Our research elucidates the pro-inflammatory function and YAP/IL-34/macrophage axis-mediated mechanism of αvβ6 in renal inflammation, providing a solid rationale for the use of αvβ6 inhibition to treat kidney inflammation and fibrosis.

Myeloid Ferritin Heavy Chain Regulates Macrophage Differentiation towards Iron Recycling Phenotype in CKD

Tanima Chatterjee, Sarah E. Machado, Kellen A. Cowen, Abolfazl Zarjou. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: Chronic kidney disease (CKD) is a worldwide public health problem affecting ~850 million people. Dysregulation in iron metabolism is a hallmark of advanced CKD. Myeloid cells, particularly macrophages (MΦ), play a crucial role in establishing the delicate balance of iron homeostasis. Ferritin, a spherical shell composed of heavy (FtH) and light (FtL) chains, is paramount in maintenance of this process. Our overarching hypothesis is that myeloid FtH orchestrates iron distribution and regulates MΦ plasticity under injurious/inflammatory conditions through controlling Spic expression.

Methods: To investigate the role of myeloid FtH in relation to kidney iron metabolism, mice deficient in FtH in the myeloid compartment ($FtH^{LysmΔ/Δ}$) were generated. Experiments were carried out using bulk RNA sequencing, single cell RNA sequencing, real-time PCR, western blot, flow cytometry, immunohistochemistry.

Results: Using unbiased transcriptome analysis, significant upregulation of Spic, a transcription factor that selectively controls the development of iron recycling MΦ (Fe-MΦ) was observed in kidneys of $FtH^{LysmΔ/Δ}$ mice following iron administration. This observation was further validated by other markers expressed by this subset of MΦ and was accompanied by higher degree of tubular iron deposition when compared to their wild-type counterparts ($FtH^{fl/fl}$). Moreover, we observed marked induction of Spic in different kidney injury models including ischemia-reperfusion, aristolochic acid, and sepsis mediated kidney injury. Notably, Fe-MΦ are responsible for the resolution stage of the injury and inflammation. Functional significance of myeloid FtH was validated by worse kidney outcomes as evidenced by higher serum creatinine, increased fibrosis, and leukocyte expansion.

Conclusions: Our findings suggest a potential contribution of myeloid FtH to calibrate the iron recycling MΦ phenotype during kidney injury and resolution however, the functional significance of spic in the context of CKD remain to be elucidated.

Macrophage Iron Dyshomeostasis Promotes Aging-Related Kidney Fibrosis

Lingzhi Wu, Hongchun Lin, Hui Peng. *The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.*

Background: Renal aging, marked by the accumulation of senescent cells and chronic low-grade inflammation, leads to renal interstitial fibrosis and impaired function. However, the mechanism of macrophages in renal aging remains unclear. Here, by analyzing single-cell RNA sequencing data and constructing aging models in vivo and in vitro, we further explore the role and mechanism of macrophages in promoting kidney aging.

Methods: We analyzed kidney single-cell RNA sequencing data (GSE198832) of C57BL/6J mice aged 8 weeks to 24 months to describe the dynamic changes in the proportion and function of kidney cell types during kidney aging. CellChat analysis uncovered changes in the intercellular communications between macrophages and tubular cells. SCENIC analysis revealed key regulons in a network of aging-related genes within kidney macrophages. Molecular docking and virtual screening revealed potential anti-aging agents.

Results: Our findings elucidate the dynamic changes in the proportion of kidney cell types during renal aging and reveal that increased macrophage infiltration contributes to chronic low-grade inflammation, with these macrophages exhibiting senescence and activation of ferroptosis signaling. CellChat analysis indicates enhanced communications between macrophages and tubular cells during aging. Suppressing ferroptosis alleviates macrophage-mediated tubular partial epithelial-mesenchymal transition in vitro. Using SCENIC analysis, we infer Stat1 as a key age-related transcription factor promoting iron dyshomeostasis and ferroptosis in macrophages by repressing the expression of Pcbp1, an iron chaperone protein that inhibits ferroptosis. Knockdown of Pcbp1 aggravated the drug-induced macrophage senescence phenotypes, whereas overexpression of Pcbp1 alleviated macrophage senescence phenotypes. Through virtual screening and molecular docking from a library of anti-aging compounds, we construct a docking model targeting Pcbp1, which indicates that the natural small molecule compound Rutin can suppress macrophage senescence and ferroptosis by preserving Pcbp1.

Conclusions: Our study underscores the crucial role of macrophage iron dyshomeostasis and ferroptosis in renal aging. Our results also suggest Stat1 and Pcbp1 as intervention targets in aging-related renal fibrosis, and highlight Rutin as a potential therapeutic agent in mitigating age-related renal chronic low-grade inflammation and fibrosis.

Role of Nephrotoxic Serum-Driven Ferroptosis in Ncf1-p.R90H KI Female Mice

Mariia Stefanenko,[1] Lei Wang,[1] Mykhailo Fedoriuk,[1] Alena Cherezova,[2] Daria Ilatovskaya,[2] Sun-sang J. Sung,[3] Betty Tsao,[1] Oleg Palygin.[1] *[1]Medical University of South Carolina, Charleston, SC; [2]Augusta University, Augusta, GA; [3]University of Virginia, Charlottesville, VA.*

Background: Systemic Lupus Erythematosus (SLE) is an autoimmune disorder characterized by deposition of autoantibodies and immune complex formation, leading to inflammation and impaired organ function. The activation of NOX2, facilitated by efferocytosis, is disrupted by the substitution of arginine (R) for histidine (H) in the NCF1/p47phoxprotein, which reduces NOX2's ability to produce reactive oxygen species, exacerbating autoimmune responses and affecting redox balance in SLE pathogenesis in humans and mouse models on the C57BL/6 background. This study explores the mechanisms of ferroptosis in the renal proximal tubules (PT) of the H90.B6 knock in (KI) mice and examines potential sexual dimorphism in nephrotoxic serum (NTS)-driven tubulointerstitial disease.

Methods: The R90.B6 wild-type (WT) and H90.B6 KI female littermates were injected with either sheep (control) or NTS and kidneys were harvested after two weeks. Prussian blue histochemical staining was performed on fixed tissue to detect ferroptosis and PT damage. Freshly isolated PT was obtained by vibrodissociation, and *ex vivo* confocal imaging with fluorescent indicators was performed to assess ferrous ion (Fe^{2+}) presence (Mito-FerroGreen) and mitochondrial membrane potential (ΔΨm, JC1) in PT cells, respectively.

Results: Histochemical staining revealed elevated ferroptosis in NTS-treated H90.B6 compared to the NTS-treated R90.B6 littermates ($P<0.05$) but not in control-treated groups. The confocal microscopy confirmed a high prevalence of mitochondrial ferrous ion in PT of female H90.B6 NTS- treated group that control-treated and NTS-treated WT and KI were 4±3, 2±1, 4±2, 17±4 % of PT ferroptosis (n≥74 tubule/ group, $P<0.05$). The accumulation of mitochondrial ferrous iron in PT was also confirmed by acute ammonium iron (II) sulfate applications. Compared to control serum treatment, the NTS-treated R90.B6 and H90.B6 groups showed a reduced ΔΨm.

Conclusions: The human SLE causal variant NCF1-H90 variant promotes ferroptosis in PT of non-autoimmune mice. These findings underscore the importance of understanding the role of redox mechanisms in linking ferroptosis, nitrosative stress, and lipid peroxidation in NCF1-p.R90H (H90) variant, highlighting the need to better understanding of tubulointerstitial disease in SLE.

Single-Cell RNA Sequencing Identifies a Unique Population of Macrophages in the Aristolochic Acid-Induced AKI-to-CKD Transition Murine Model

Xiangchen Gu, Yaodong Gu, Lin Xie, Ye Cheng, Yi Wang, Min Chen. *Shanghai University of Traditional Chinese Medicine Yueyang Hospital of Integrated Traditional Chinese and Western Medicine, Shanghai, China.*

Background: The transition from acute kidney injury (AKI) to chronic kidney disease (CKD) is a significant contributor to kidney injury progression, and effective treatments to prevent or slow this transition are lacking. Macrophages are known to play a pivotal role in this process, but the specific subtypes involved and their interactions with other cell types remain unclear.

Methods: We induced AKI in mice via intraperitoneal injections of Aristolochic Acid I (AAI) every 3 days for 2 weeks, followed by a 2 week remodeling phase without injections. Single-cell RNA sequencing (scRNA-seq) was then performed on kidney samples from control, AKI, and CKD phases using 10x Genomics. Following stringent quality control and feature selection using Scanpy, SoupX, and scDblFinder, we harmonized gene symbols and integrated the data using deep generative modeling (scVI). We identified cell subclusters, cell-to-cell communication, and cellular trajectories

using Scanpy, LIANA, and scVelo. Differentially expressed genes (DEGs) and enriched pathways were determined using edgeR. Immunofluorescence of the unique population of macrophages was confirmed in both human CKD kidney samples and the murine AAI-induced AKI to CKD model.

Results: We profiled 56,325 single cells representing 30 major cell types across three time points. Significant changes in immune cell clusters, particularly macrophages, were observed during the AKI to CKD transition. Enriched pathways in the CKD phase included mitochondrial ATP synthesis and electron transport, while the AKI phase was characterized by inflammatory and innate immune responses. A unique population of Ctsk+ and Mmp9+ macrophages was identified in the CKD phase. These macrophages interacted with T cells (via Lgals1/Ptprc and Calr/Itgav), injured proximal tubules and fibroblasts (via Apoe/Lrp2), and dendritic cells and basophils (via Vim/Cd44). Increased expression of CTSK and MMP9-positive macrophages was confirmed by immunofluorescence staining in both the CKD phase of the murine model and human CKD samples.

Conclusions: ScRNA-seq of the murine AAI model identified a unique population of CTSK and MMP9-positive macrophages as critical responders in the AKI to CKD transition. Targeting these macrophages may present a valuable therapeutic strategy for preventing the progression from AKI to CKD.

Involvement of Protein-Tyrosine Phosphatase ζ Receptor on the Progression of Kidney Fibrosis in Mice with Unilateral Ureteral Obstruction

Tetsuya Abe, Yukihiro Wada, Masashi Satoh, Takayuki Imanishi, Makoto Otsu, Tadahiro Suenaga, Yasuo Takeuchi. *Kitasato Daigaku Igakubu, Sagamihara, Japan.*

Background: Intrarenal expressions of protein-tyrosine phosphatase ζ receptor (PTP-ζ), the second receptor of interleukin (IL)-34 for macrophage (Mø) proliferation, have been demonstrated in several experimental renal disease models. However, role of PTP-ζ on the progression of renal diseases remains elusive. We investigated the influence of PTP-ζ on renal fibrosis caused by unilateral ureteral obstruction (UUO).

Methods: 10-week-old male wild type (WT) C57BL/6 (B6) mice (WT, n = 14) and age-matched male PTP-ζ knockout (KO) B6 mice (KO, n = 16) were induced UUO. Four age-matched male B6 mice received sham operation as control. All mice were sacrificed on day 14. *In vitro*, mouse Mø cell line (RAW 264.7) or mouse bone marrow-isolated Møs (BMMøs) were stimulated with TGF-β (5 ng/mL), and then treated with or without recombinant IL-34 (r-IL-34) (500 pg/mL) for the effects of PTP-ζ analyses.

Results: Compared to the sham-operated control, the UUO kidneys of WT mice exhibited remarkable intrarenal IL-34 and PTP-ζ expressions. Meanwhile, the KO mice showed deficiency of intrarenal PTP-ζ expression despite comparable IL-34 expression to the WT mice. Compared to the WT mice, tubular injury and sirius red-stained fibrosis area were significantly attenuated in the KO mice kidney (9.0% ± 0.7 vs. 4.8% ± 0.7/HPF, $p<0.001$). The KO mice significantly suppressed the number of $F4/80^+$ Mø, $PDGF\text{-}\beta^+$ fibroblasts, and $\alpha\text{-}SMA^+$ myofibroblast in damaged kidneys of UUO by immunofluorescence (IF) analysis. Intrarenal mRNA levels for TGF-β, COL-1, fibronectin, Yim1/Chil3, and Timp-1 were lower in the KO mice. IF revealed significant suppression of intrarenal $F4/80^+CD206^+$ Mø infiltration in the KO mice. Flow cytometry analysis showed that the ratio of CD206/CD11c in the population of intrarenal $CD11b^+F4/80^+$ Mø was higher in the KO mice. *In vitro*, expressions of PTP-ζ were confirmed in TGF-β stimulated RAW264.7 cells and BMMs. Administration with TGF-β and rIL-34 significantly up-regulated the mRNA level for Timp-1 in RAW264.7 cells compared to TGF-β- and vehicle-treated group.

Conclusions: Up-regulation of PTP-ζ in the damaged kidneys is involved in the progression of renal fibrosis. IL-34/PTP-ζ pathway on Mø might skew Mø into M2-like Mø, contributing to renal fibrosis via enhancing profibrotic response.

SA-PO1167

Single-Cell Spatial Transcriptomics Unveil Platelet-Fueled Cycling Macrophages for Kidney Fibrosis

Jun Liu. *Children's Hospital of Soochow University, Suzhou, China.*

Background: With the increasing incidence of kidney diseases, there is an urgent need to develop therapeutic strategies to combat post-injury fibrosis. Immune cells, including platelet, play a pivotal role in this repair process. However, the specific role of platelet in kidney injury and subsequent repair remains underexplored.

Methods: The surgery of bilateral I/R-induced kidney injury was performed on Wild-type and *Thbs1* knock-out mice to induce kidney injury and fibrosis. Single-cell and spatial transcriptomics and Magnetic Resonance Imaging (MRI) scanning were applied.

Results: We show that depleting platelet accelerates injury resolution and significantly reduces fibrosis. We identify a novel subset of macrophages, termed "cycling M2", which exhibit an M2 phenotype combined with enhanced proliferative activity. This subset emerges in the injured kidney during the resolution phase and is modulated by platelet-derived THBS1 signaling, acquiring profibrotic characteristics. Targeted inhibition of THBS1 reduces the cycling M2 macrophage, thereby mitigating fibrotic progression.

Conclusions: Our findings highlight the adverse role of platelet THBS1-boosted cycling M2 macrophages in renal injury repair and suggest platelet THBS1 as a promising therapeutic target for alleviating kidney fibrosis.

Platelet Transcriptome Analysis in CKD Provides Insight into Cardiovascular Events

Avantika Israni, Matthew Muller, David M. Charytan, Jeffrey S. Berger.
New York University, New York, NY.

Background: Platelet dysfunction is common in patients with CKD and contributes to hemorrhagic tendencies as well as CVD, but to our knowledge effects of CKD on the platelet transcriptome have not been analyzed.

Methods: We compared the platelet transcriptome from prospectively recruited patients with peripheral artery disease according to eGFR and CKD class: moderate CKD (eGFR of 30-<60 mL/min/1.73m²), severe CKD (eGFR of < 30 mL/min/1.73,2), or chronic dialysis. Results were adjusted for age, sex, ethnicity and race.

Results: 54 participants had CKD (28% male, mean age 72, and 12% Black) and 81 had preserved kidney function (62% male, mean age 69, and 15% Black). After adjusting for age, sex, race, ethnicity, and multiple comparisons, we identified 17 differentially expressed genes in moderate CKD (13 upregulated, 4 downregulated), & 344 in severe CKD (188 upregulated, 156 downregulated), and 560 in chronic dialysis (274 upregulated, 286 downregulated) compared with preserved kidney function. We defined a transcriptomic signature of 13 genes differentially expressed in CKD, and showed that this signature associated with CKD severity in a test cohort (N=40). This signature was correlated with epinephrine and ADP induced platelet aggregation and was significantly associated with mortality and major adverse cardiovascular events in adjusted analyses. In additional analyses multiple genes were significantly correlated with eGFR. Mitochondrial function and RNA function processes were particularly impacted (Figure)

Conclusions: These findings demonstrate a unique platelet transcriptomic signature in CKD that is associated with future risk of cardiovascular events.

Cardiac Dysfunction in C57Bl/6J Mice with CKD: Comparison of Dietary Adenine and 5/6 Nephrectomy Models

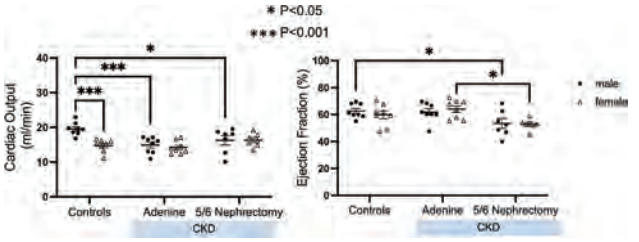
Yitong Zhao,[1] Karen Yang,[2] Hongmei Wu,[1] Han Liu,[1] Leandro Velez,[3] Jin Kyung Kim,[4] Marcus Seldin,[3] Wei Ling Lau.[1] *[1]Division of Nephrology, Department of Medicine, University of California-Irvine, Irvine, CA; [2]University of California Riverside School of Medicine, Riverside, CA; [3]University of California Irvine Department of Biological Chemistry, Irvine, CA; [4]Division of Cardiology, Department of Medicine, University of California-Irvine, Irvine, CA.*

Background: Cardiovascular disease (CVD) is the leading cause of death among patients with chronic kidney disease (CKD). Gut-derived uremic toxins contribute to vascular injury and cardiomyopathy in CKD. In this study, we compared echocardiogram parameters between dietary adenine and 5/6 nephrectomy CKD models and examined associations with gut-derived uremic toxins stratified by sex.

Methods: Male and female adult C57Bl/6J mice were randomly assigned to control, adenine-induced CKD and 5/6 nephrectomy CKD groups. Echocardiography was performed on all mice at 5 weeks after CKD induction. Serum creatinine, cystatin C and gut-derived uremic toxins (trimethylamine N-oxide, TMAO; indoxyl sulfate, IS; and p-cresyl sulfate, pCS) were analyzed at study termination. Data was analyzed using two-way ANOVA and Spearman correlation analysis.

Results: Serum markers of kidney dysfunction (creatinine and cystatin C) were significantly elevated in both CKD models. TMAO was significantly increased in adenine CKD mice, IS was elevated in both CKD models, and pCS was increased in the nephrectomy group. Left ventricular volume was increased in nephrectomy animals. Cardiac output (CO) was decreased in male CKD animals from both models compared to male controls, and ejection fraction (EF) was decreased in male 5/6 nephrectomy mice (figure). Female controls had lower CO than male counterparts, and female CKD animals were not significantly different from female controls in terms of CO and EF. In female animals, higher serum pCS and IS were positively correlated with increased left ventricular volume; higher pCS were inversely correlated with EF ($r = -0.501$, $P<0.05$). These associations were not seen in male animals.

Conclusions: Our work highlights sex differences in cardiac function and serum toxin levels in two established preclinical CKD models. Gut-derived uremic toxins may impact cardiorenal pathophysiology in female but not male CKD animals.



SA-PO1170

Gut Microbiota Drives Kidney Damage and Cardiac Remodeling in Experimental CKD

Wibke Anders, Alex Yarritu, Istvan A. Szijarto, Arne Thiele, Sara A. Hassan, Carina Hoffmann, Ariana Rauch, Franziska Fuckert, Natnael Gebremedhin, Paul Moritz Bonnekoh, Olena Potapenko, Johannes Holle, Hendrik Bartolomaeus, Nicola Wilck. *Charite Universitatsmedizin Berlin, Berlin, Germany.*

Background: Chronic kidney disease (CKD) represents a major, often overlooked cardiovascular (CV) risk factor. CV disease (CVD) is the leading cause of mortality in CKD. Alterations in gut microbiome composition and function are evident in CKD, leading to increased production of detrimental metabolites of bacterial origin, impacting inflammation and end-organ damage. We hypothesize that CV remodeling and preservation of kidney function are influenced by the microbiome.

Methods: Experimental CKD was induced in *129/Sv* mice by subtotal nephrectomy (STNx). To suppress the microbiome mice received antibiotics (Abx) orally over the course of 13 weeks. CV damage was quantified by echocardiography, histological and gene expression analysis, as well as radiotelemetry blood pressure measurements and analysis of endothelial function.

Results: Compared to STNx, STNx+Abx mice exhibited a significantly improved kidney function quantified by plasma cystatin c (0.66±0.41 mg/l vs. 1.14±0.54 mg/l; p = 0.012). This was confirmed by the expression of renal damage markers (e.g. *Ngal, Tgfb, Ctgf*) and histological analyses. We observed an increase in heart weight/tibia length in STNx (10.1±0.5 g/m) that was attenuated by Abx (7.0±0.2 g/m; p < 0.001). Hearts of STNx+Abx mice displayed significantly less remodeling, independent of similarly elevated blood pressures in both groups. Cardiac expression of hypertrophy and pro-fibrotic markers were reduced in STNx+Abx (e.g. *Nppb, Myh7, Ctgf*). Histological analysis of the left ventricle by picrosirius red revealed STNx-induced cardiac fibrosis (PSR-positive area 12.0±1.5%), that was ameliorated by Abx (5.8±1.8%; p=0.008). Vascular function, as assessed by wire myography of mesenteric arteries, indicated an impaired endothelium-dependent relaxation in STNx that was improved in STNx+Abx. In addition, we performed functional analysis by echocardiography, organ-specific immune phenotyping, and bulk RNA sequencing of the heart.

Conclusions: In experimental CKD, kidney function and cardiac remodeling depend on the dysbiotic microbiome, highlighting the interplay between the microbiome, CKD progression, and the development of CV complications in CKD.

SA-PO1171

Associations of Urine Epidermal Growth Factor with Kidney and Cardiovascular Outcomes in Individuals with CKD in SPRINT

Merve Postalcioglu,[1] Ronit Katz,[2] Simon Ascher,[4] Pranav S. Garimella,[3] Stein I. Hallan,[5] Joachim H. Ix,[3] Michael Shlipak.[1] *[1]UCSF Medical Center, San Francisco, CA; [2]University of Washington, Seattle, WA; [3]University of California San Diego, La Jolla, CA; [4]University of California Davis, Davis, CA; [5]St Olav's Hospital HF, Trondheim, Norway.*

Background: Urine epidermal growth factor (uEGF) marks kidney tubule function and lower urine concentrations are associated with faster kidney function loss. Its associations with cardiovascular disease (CVD) and mortality are unknown.

Methods: We measured uEGF among 2,346 Systolic Blood Pressure Intervention Trial (SPRINT) participants with an eGFR<60 ml/min/1.73m^2. Linear mixed-effects models were used to investigate associations with the annual eGFR change, and Cox models evaluated associations with the ≥30% eGFR decline, cardiovascular disease (CVD), and mortality. To account for the competing risk of death, Fine and Gray method was utilized for acute kidney injury (AKI) and end-stage kidney disease (ESKD) outcomes.

Results: Mean (SD) age was 73±9 years, mean eGFR was 46±11 ml/min/1.73m^2 and median UACR of 15 mg/g (interquartile range: 7-49). In analyses adjusting for baseline albuminuria and eGFR, each 50% lower uEGF concentration was associated with 0.74% (95% confidence interval:1.19, 0.29) per year faster decline in eGFR. **(Table)** During 3.1 (median) years of follow-up, lower uEGF was also associated with higher risk of ≥30% eGFR decline. Lower uEGF concentrations were associated with ESKD, AKI, incident CVD, and mortality in initial models, but associations were substantially attenuated by adjustment for albuminuria and eGFR. **(Table)**

Conclusions: Among hypertensive adults with CKD, lower uEGF is associated with faster eGFR decline independent of baseline albuminuria and eGFR; but not with ESKD, AKI, CVD, or mortality.

Funding: NIDDK Support

Table. Associations of baseline uEGF concentrations with kidney outcomes, CVD and all-cause mortality among SPRINT participants with prevalent CKD

Outcome (N=2346) (per 50% lower uEGF concentration)	Multivariable adjusted model*	Multivariable adjusted model +UACR+eGFR*
Annualized percent change in eGFR (% year)	β (95% CI)	β (95% CI)
	-1.41 (-1.76, -1.06)	-0.74 (-1.19, -0.29)
≥30% eGFR Decline (N=418)	HR (95% CI)	HR (95% CI)
	1.39 (1.23, 1.56)	1.17 (1.00, 1.36)
Acute kidney injury (N=183)	SHR (95% CI)	SHR (95% CI)
	1.63 (1.35, 1.98)	1.11 (0.85, 1.45)
End-stage kidney disease (N=73)	SHR (95% CI)	SHR (95% CI)
	4.14 (3.06, 5.61)	1.24 (0.81, 1.89)
Cardiovascular disease[1] (N=180)	HR (95% CI)	HR (95% CI)
	1.32 (1.09, 1.59)	0.98 (0.76, 1.27)
All-cause mortality (N=158)	HR (95% CI)	HR (95% CI)
	1.61 (1.31, 1.99)	1.08 (0.82, 1.43)

[1]CVD composite outcome includes myocardial infarction, acute coronary syndrome not resulting in myocardial infarction, stroke, acute decompensated heart failure, or death from cardiovascular causes.
* Adjusted for age, sex, race, randomized treatment arm, urine creatinine, smoking status, body mass index, history of cardiovascular disease, systolic blood pressure, diastolic blood pressure, total cholesterol, high density lipoprotein, angiotensin converting enzyme inhibitors, angiotensin receptor blockers, beta blocker, calcium channel blockers, and diuretics.
†Additionally adjusted for baseline urine albumin and eGFR.

Indoxyl Sulfate Dysregulates Choline Acetyltransferase-Mediated Cognitive Impairment in Patients with ESKD by Extrinsic Apoptosis in the Neuronal Cells during the Differentiating Process

Yi-Chou Hou. *Cardinal Tien Hospital, New Taipei City, Taiwan.*

Background: This study investigates the correlation between indoxyl sulfate (IS) levels and cognitive impairment in end-stage renal disease (ESRD) patients from human study, in vivo and in vitro study.

Methods: A CKD animal model induced renal impairment in adenine-fed C57BL/6 mice, assessing memory loss and behavioral changes. Immunohistochemistry evaluated choline acetyltransferase. Differentiating SH-SY5Y cells were treated with IS to assessing cell viability. Reactive oxidized species generation was measured using DCFCA fluorescence.

Results: IS levels were significantly higher compared to healthy controls, along with older age. CKD mice exhibited renal impairment and memory loss, accompanied by altered choline acetyltransferase. IS treatment induced early apoptosis in SH-SY5Y cells, associated with increased cleaved caspase 3 levels and Fas/Fas-ligand activity, altered Bax/Bcl2 ratio, and reactive oxidized species generation.

Conclusions: IS levels was associated with cognitive impairment and neuronal apoptosis with choline transferase dysfunction. IS could be a therapeutic target for cognitive dysfunction in CKD.

Figure 1. (A) The impairment in NOR test in adenine-fed mice; (B)The decrease of Choline transferasein CA1 of hippocampus and cortex in adenine fed mice.

Klotho Mitigates Indoxyl Sulfate-Induced Oxidative Stress through Modulation of the AKT/Nrf2 Pathway

Chien Yao Sun,[1,2] Chia-Ter Chao,[3] Yu T. Chang.[1] *[1]National Cheng Kung University Hospital, Tainan, Taiwan; [2]University of California San Francisco Department of Medicine, San Francisco, CA; [3]National Taiwan University Hospital, Taipei, Taiwan.*

Background: Chronic kidney disease (CKD) is a progressive condition with significant global prevalence. The uremic toxin indoxyl sulfate (IS) induces tubulotoxicity and oxidative stress in CKD patients. It has been shown that IS downregulates the expression of the anti-aging protein klotho in proximal tubule cells and kidneys. The detailed mechanism of reduced klotho's role in nephropathy and oxidative stress is unclear.

Methods: We treated renal proximal tubule epithelial cells (HK-2 cells) with 500μM IS to induce oxidative stress. Antioxidant gene expression was studied by real-time PCR, and ROS levels were investigated by DCF-DA.

Results: Our results showed that the mRNA expression levels of HO-1 and NQO1 were suppressed in IS-treated cells, but administration of klotho counteracted this effect. Blocking AKT/Nrf2 signaling with an AKT inhibitor (LY2780301) or silencing Nrf2 impeded klotho's rescue effect on HO-1 and NQO1 expression, suggesting that IS inhibits HO-1 and NQO1 via the klotho/AKT/Nrf2 axis. We also examined superoxide dismutase (SOD) expression and found that IS treatment reduced SOD levels, which were restored by recombinant klotho. Inhibition of AKT/Nrf2 signaling negated Klotho's beneficial effect on SOD concentration. IS-stimulated cells showed elevated ROS formation, while recombinant klotho hindered this upregulation. Suppression of AKT/Nrf2 signaling restrained Klotho's protective effect against IS-induced ROS production.

Conclusions: Our findings suggest that IS increases oxidative stress in HK-2 cells by elevating ROS and inhibiting antioxidant capacity, as evidenced by lower expression of HO-1, NQO1, and SOD via the Klotho/AKT/Nrf2 signaling pathway.

ARNTL Regulates Endoplasmic Reticulum Stress and Mitochondrial Apoptosis through NRF2 and Plays a Crucial Role in the Development of CKD

Li He, Aili Cao, Niansong Wang. *Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China.*

Background: The core molecular clock protein, ARNTL, contributes to kidney tubular injury and fibrosis. Endoplasmic reticulum (ER) stress is implicated in the pathogenesis of chronic kidney disease (CKD), yet the interaction between ER stress and circadian clock pathways in kidney tubular cells remains unclear.

Methods: In this study, we observed ARNTL expression and ER stress markers in both CKD patients and CKD rats. In vitro experiments involved treating HK2 cells with the ER stress activator tunicamycin (Tm) and the ER stress inhibitor Tauroursodeoxycholic acid (TUDCA). Additionally, ARNTL was silenced using siRNA to assess the effects on ER stress markers and mitochondria-related apoptosis. The regulation of NRF2 by ARNTL was studied through direct E-box binding to the Nrf2 promoter.

Results: We found a decrease in ARNTL expression and a significant increase in ER stress markers in both CKD patients and CKD rats. In vitro experiments showed that the ER stress activator tunicamycin (Tm) markedly reduced ARNTL expression, while treatment with Tauroursodeoxycholic acid (TUDCA), an effective ER stress inhibitor, significantly increased ARNTL protein levels and reduced ER stress markers. Silencing ARNTL with siRNA in HK2 cells resulted in the upregulation of ER stress markers and activation of mitochondria-related apoptosis. NRF2, crucial in the innate immune response and apoptosis regulation, is shown to be regulated by ARNTL through direct E-box binding to the Nrf2 promoter. Loss of ARNTL diminished NRF2's response to ER stress, leading to increased production of the proinflammatory cytokine IL-1β and subsequent mitochondria-related apoptosis in HK2 cells.

Conclusions: These findings underscore the pivotal role of ARNTL in modulating NRF2 activity and the ER stress response in HK2 cells, providing insights into the mechanisms underlying CKD. Our study highlights the importance of ARNTL, ER stress, and NRF2 in the apoptosis and injury of renal tubular cells, contributing to the pathology of CKD.

Empagliflozin Attenuates CKD-Induced Cognitive Impairment by Improving Blood Brain Barrier Integrity in Mice and Endothelial Cells

Lung-Chih Li,[1,2] Chia-An Chou,[1] Chiang-chi Huang,[1] Jenq-Lin Yang.[2] *[1]Division of Nephrology, Department of Internal Medicine, Kaohsiung Chang Gung Memorial Hospital and Chang Gung University College of Medicine, Kaohsiung, Taiwan; [2]Institute for Translational Research in Biomedicine; Kaohsiung Chang Gung Memorial Hospital and Chang Gung University College of Medicine, Kaohsiung, Taiwan.*

Background: Chronic kidney disease (CKD) is characterized by progressive loss of renal function and complicated with varies comorbidities, including cardiovascular disorders (CVD) and neurological dysfunction. The evidence of our previous study has suggested that uremic toxins, including indoxyl sulfate (IS) and p-cresyl sulfate (PCS), could pass blood brain barrier (BBB) promoting neuroinflammation that eventually contributes to CKD-induced cognitive dysfunction. Empagliflozin (EMPA), a sodium-glucose cotransporter 2 (SGLT2) inhibitor, has emerged as a novel therapeutic approach for CVD and neurodegenerative disorders. This study aims to investigate pathogenic mechanisms of CKD-induced cognitive impairment, furthermore, to determine whether EMPA improves CKD-induced neurological dysfunction.

Methods: Eight-week-old male C57B6 wide type mice received sham and 5/6 nephrectomy to mimic CKD status. EMPA was given orally for 12 weeks. The Morris water maze (MWM) testes was applied to evaluate cognitive function, including the short-term and long-term memory in shame, CKD, and EMPA-treated CKD mice. Fe^3O^4 Brain MRI and Evans blue were used to evaluate the permeability of BBB in mouse brain. Trans-well assay was used to evaluate the permeability of in vitro BBB model, constructed by bEnd3 cell, an endothelial cell from mouse brain. Western blot was used to identify the protein expression of target molecules in the brain tissue and endothelial cells.

Results: The results of *in vitro* study revealed that 20 μM IS, but not PCS, dysregulated permeability of brain endothelial cells (bEnd3) via disruption of tight-junction integrity. The brains of 5/6-nephrectomy-induced CKD mice also showed BBB leakage by Fe^3O^4 tail vein-injected magnetic resonant images (MRI). In addition, MWM tests indicated the impaired learning capability and long-term memory in CKD mice. The treatment of EMPA restored permeability of bEnd3 cells as well as ameliorated CKD-induced cognitive impairment that were consequences of EMPA maintaining BBB integrity of CKD mice. The evidence was demonstrated by Evans blue brain perfusion, brain MRI, MWM, and transwell permeability assay.

Conclusions: EMPA effectively improved BBB integrity and attenuated CKD-induced cognitive impairment in brains of CKD mice.

Empagliflozin Reduces Progressive Proteinuria by Potentially Reprogramming Energy Metabolism in Proximal Tubules in Young, Nondiabetic, Obese, Dahl Salt-Sensitive Rats

Sautan Mandal, Anukool A. Bhopatkar, Ubong S. Ekperikpe, Ngoc Hoang, Karen Brooks, Kristin Edwards, Jan M. Williams. *The University of Mississippi Medical Center, Jackson, MS.*

Background: Prepubertal obesity has become a major health problem and has been associated with early signs of proteinuria. Recently, we reported that the non-diabetic obese Dahl salt-sensitive leptin receptor mutant (SS^{LepR}mutant) rat develops proteinuria prior to puberty. Renal proximal tubules (PTs) are highly energy demanding primarily

relying on fatty acid oxidation (FAO) for energy production. Previous studies have demonstrated that PT energy metabolism shifts to glycolysis during the development of diabetic renal injury. We recently observed the expression of SGLT2 was upregulated in the PTs of SS^{LepR}mutant rats before puberty. This suggests there may be energy metabolic alterations in the PTs of young SS^{LepR}mutant rats contributing to proteinuria. Therefore, the current study examined whether treatment with the SGLT2i, empagliflozin (EMPA), shifts energy metabolism in the PT and reduces the early proteinuria in SS^{LepR}mutant rats.

Methods: Four-week-old SS and SS^{LepR}mutant rats were treated with either vehicle (orally) or EMPA (30mg/kg/day) for 4 weeks. Proteinuria was measured every two-weeks. At the end of the protocol, one kidney was used to measure mitochondrial bioenergetics, and PTs were isolated from the other kidney to measure glycolysis.

Results: Proteinuria was significantly higher in SS^{LepR}mutant vs SS rats (401±51 vs. 27±4 mg/day; $p<0.05$), and treatment with EMPA reduced proteinuria in SS^{LepR}mutant rats (252±23 mg/day; $p<0.05$). We observed a 3-fold increase in GFR in SS^{LepR}mutant rats compared to SS rats, and EMPA markedly decreased GFR in SS^{LepR}mutant rats by 50%. Renal cortical FAO was reduced and PT glycolysis was increased in SS^{LepR}mutant rats when compared to SS rats suggesting a shift in the source of energy metabolism in PTs. Chronic treatment with EMPA significantly increased FAO in the renal cortex and markedly decreased glycolysis in the PTs in SS^{LepR}mutant rats.

Conclusions: Overall, these data indicate that the early proteinuria observed in SS^{LepR}mutant rats during PPO is associated with an energy metabolic shift in PTs that may involve increased SGLT2 activity. Moreover, these results also suggest that SGLT2 inhibition could be of great potential in non-diabetic obese children with early signs of proteinuria.

Neuropilin 1 Expressed in Resident Fibroblasts Protects Kidneys from Development of Fibrosis

Yunzhu Shen, Christos Chatziantoniou, Amelie Calmont. *Inserm UMR-S 1155 Common and Rare Kidney Disease, Paris, France.*

Background: Renal fibrosis is the common end point of Chronic Kidney Disease (CKD), the hallmark of which is the deposition of pathological extracellular matrix by myofibroblasts. Experiments with lineage tracing in mice and single-cell RNAseq in humans revealed that resident fibroblasts/pericytes are the major sources of myofibroblasts during CKD progression. Neuropilin 1 (NRP1) is a membrane-bound coreceptor for class 3 semaphorins and for specific isoforms of vascular endothelial growth factor. Importantly, NRP1 plays a critical role in fibrosis progression in various pathophysiological conditions such as liver cirrhosis and tumor proliferation and metastasis. In the kidney, NRP1 is expressed in resident fibroblasts/pericytes of the renal interstitium. We therefore tested the possibility that NRP1 could participate in a cell-autonomous manner in the development of renal fibrosis

Methods: We used the myelin protein zero-Cre (*P0-Cre*) strain of mice to invalidate the expression of *Nrp1* constitutively in resident fibroblasts of the kidney. *Nrp1-ko* mutants (P0-Cre, $Nrp1^{flox/flox}$, $Rosa^{YFP}$) and wildtype littermates were subjected to two well-characterized models of renal fibrosis: the folic acid (FA) nephrotoxicity model and the unilateral ureteral obstruction (UUO) model. In separate experiments, we used angiotensin II (Ang II) administration through an osmotic minipump to generate cardiac fibrosis.

Results: We found that *Nrp1-ko* displayed proliferative defects that affected renal recovery after acute kidney injury. Accordingly, the renal function and structure of *Nrp1-ko* were significantly more impaired than those of their wildtype littermates in FA-induced renal disease. Similar observations were done in *Nrp1-ko* subjected to UUO. Our lineage tracing experiments showed that renal and cardiac interstitial cells derived from the same P0-Cre positive progenitors. This observation led us to investigate the role of NRP1 in the progression of cardiac fibrosis. We found that after continuous Ang II infusion, the fibrotic lesions are more pronounced in the hearts of *Nrp1-ko* mice compared to those of their wildtype littermates.

Conclusions: Our data suggest that NRP1 expressed in resident fibroblasts is a protective mechanism against the progression of fibrosis, and this mechanism appears to be common in the kidney and heart.

Targeting Neuropilin-1 in Distal Tubules Improves Kidney Injury and Fibrosis

Yinzheng Li, Rui Zeng, Gang Xu, Ying Yao. *Huazhong University of Science and Technology Tongji Medical College Tongji Hospital, Wuhan, China.*

Background: Transforming growth factor-beta (TGF-β) is a critical driver of organ fibrosis, but current strategies to target it are clinically ineffective. One reason for this inefficiency is due to co-receptor surrogacy. Notably, Neuropilin-1 (NRP1), a broad-spectrum co-receptor for various cytokines, has been identified as a potential therapeutic target for liver and pulmonary fibrosis in recent years. However, its role in renal injury and renal fibrosis is still unclear. Therefore, this study aimed to investigate the role of NRP1 in kidney injury and fibrosis and its specific mechanisms.

Methods: Renal puncture specimens from patients with transplant renal insufficiency and kidney samples from ischemia-reperfusion (IR) mice were analyzed. Additionally, multi-omics analyses including single-cell RNA sequencing (scRNA-seq), transcriptomics, proteomics, and post-translational modified proteomics were conducted to investigate the role of NRP1 in renal injury and fibrosis.

Results: NRP1 expression was found to been upregulated in DT of patients with transplant renal insufficiency and mice with IR injury. Knockdown of NRP1 in DT reduced IR-induced kidney injury and fibrosis in mice. Increased TNF-α after renal injury promoted NFKB1 expression by promoting the binding of NRP1 to TNR1A (TNF-α receptor), thereby inhibiting its downstream target protein ACOX3. The downregulation of ACOX3 lead to a decrease in lysine crotonylation modification level of cytochrome c oxidase subunit COX4, which consequently resulted in mitochondrial damage and a decrease in oxidative phosphorylation level. This lead to increased cell death in DT, ultimately exacerbating renal injury. Meanwhile, NRP1-positive DT secrete collagen and communicate with myofibroblasts, exacerbating renal fibrosis by activating TGF-β-dependent/independent SMAD3 signaling in renal DT.

Conclusions: NRP1 worsens renal injury and fibrosis by inhibiting the lysine crotonylation modification level of cytochrome c oxidase subunit COX4 and bi-activation of TGF-β-dependent and -independent SMAD3 signaling. Intervention against NRP1 represents a promising strategy for the treatment of chronic kidney diseases.

Fibroblast-Selective Smoothened Sensing of the Fibrotic Microenvironment by Controlling Energy Metabolism

Yuan Gui, Yuanyuan Wang, Saiya Zhu, Dong Zhou. *University of Connecticut School of Medicine, Farmington, CT.*

Background: Smoothened (Smo) is a serpentine transmembrane protein that regulates hedgehog signaling through an intracellular conformational switch controlled by electrostatic interactions and multiple phosphorylations. Our previous study found that the loss of fibroblast-Smo decreased tyrosine phosphorylation on GSK-3β, activating the Wnt signaling pathway to mitigate acute kidney injury. However, the role of fibroblast-selective Smo in kidney fibrosis remains unclear.

Methods: We generated two strains of inducible fibroblast-specific Smo conditional knockout (cKO) mice using Gli1-Cre and Pdgfrβ-Cre drivers. These mice underwent unilateral renal ischemic reperfusion injury combined with nephrectomy (UIRI [10 days] + Nx [7 days]) or unilateral ureter obstruction (UUO [7 days]) to induce kidney fibrosis. Global, phospho-, and spatial-proteomics were employed to analyze the results.

Results: Following UIRI + Nx or UUO, both strains of fibroblast-Smo cKO mice showed improved renal function and reduced kidney fibrosis. Global proteomics identified 5,945 differential candidates out of 8,024 proteins in fibrotic kidneys. Among these, 67 significant core-matrisome proteins were highlighted, with fibulin-2 being the most notably altered. Phosphoproteomics identified 10,740 phospho-sites corresponding to 3,351 non-redundant phosphoproteins. KEGG enrichment analysis indicated that the epidermal growth factor (EGF) signaling pathway was inactivated in cKO mice compared to controls. Notably, the phosphorylation of most EGF downstream proteins was substantially reduced at multiple serine and tyrosine sites. Mechanistically, fibroblast-released fibulin-2 directly interacted with tubular EGFR, causing EGFR phosphorylation and mitochondrial translocation. This suborganelle translocation induced acetyl-CoA acetyltransferase 1 (ACAT1), as confirmed by spatial proteome analysis. Consistent with Gene Ontology analysis of the global- and phospho-proteome showed upregulated fatty acid β-oxidation and amino acid metabolism in cKO kidneys, as a mitochondrially localized enzyme, ACAT1 indeed processed amino acids and fatty acids in energy metabolism, facilitating the alleviation of kidney fibrosis in fibroblast-Smo cKO mice.

Conclusions: Fibroblast-specific deletion of Smo reduced EGFR phosphorylation and its mitochondrial translocation, improving the fibrotic kidney microenvironment.

Deciphering Endoplasmic Reticulum Stress Activation and Its Role in Kidney Disease Progression via the STING Pathway

Magaiver A. Silva, Andrea Sanchez Navarro, Dhanunjay Mukhi, Kolligundla L. Prasanna, Jonathan Levinsohn, Katalin Susztak. Susztak Lab. *University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

Background: Endoplasmic reticulum (ER) stress is crucial in the pathogenesis of kidney disease, yet the mechanisms initiating ER stress remain largely unexplored. Viruses are known to manipulate ER-related processes, potentially aiding their replication and pathogenesis. The adaptor molecule STING, which detects double-strand DNA in viral and bacterial infections, has also been implicated in sterile chronic kidney inflammation and may influence ER stress. Given these insights, we investigated the relationship between STING, ER stress, and the development of kidney disease.

Methods: We utilized STING N153S mice, which exhibit constitutive STING activation, and mice with conditional STING deletion in kidney tubules. In vitro

experiments included silencing of STING or ER stress pathways, and molecular events were analyzed through immunofluorescence, qPCR, Western blotting, and immunoprecipitation techniques. Gene expression data were scrutinized through RNA sequencing from human control and diseased samples, as well as mouse kidney disease models

Results: In both cisplatin and UUO models, we observed consistent activation of STING and the ER stress–activated eIF2α kinase (PERK) pathway. STING was found to physically interact with and activate PERK in tubule cell, leading to ER stress and subsequent renal fibroinflammation. Conversely, deletion of STING or inhibition of PERK provided protection against disease development. sc-RNA-Seq and spatial transcriptomic analysis of human CKD patients and mouse kidney injury models reinforced the association between renal dysfunction and activation of the ER stress pathway.

Conclusions: Our findings reveal a novel mechanism whereby STING activation triggers ER stress via the PERK pathway, resulting in kidney tubule injury and fibrosis. This breakthrough offers promising avenues for developing strategies to modulate ER stress and create effective therapies for fibroinflammatory kidney diseases.

Autophagy Attenuation-Induced LSD1 Enrichment Promotes Renal Tubular Cell Senescence and Kidney Aging

Yingying Zhang, Xiaoyan Li, Chen Yu, Xiaogang Li. *Mayo Clinic Minnesota, Rochester, MN.*

Background: The process of population aging will inevitably lead to an increase in age-related comorbidities, including CKD. Alterations of epigenetic modifications are associated with aging at various levels, making them promising targets for interventions against age-related CKD. Lysine-specific demethylase 1 (LSD1) as the first identified histone demethylase plays a critical role in a variety of diseases. However, the role of LSD1 in senescence and kidney aging remains unknown.

Methods: To explore the role and mechanisms of LSD1 in renal tubular senescence and kidney aging, we treated renal tubular epithelial cells with oxidative stress injury agent D-Gal and DNA damaging agent etoposide (ETO) and wild type mice with ionizing radiation (IR) plus an LSD1 specific inhibitor, ORY1001.

Results: The protein level of LSD1, but not its mRNA, was increased in 22-month-old mouse kidneys compared to that in 2-month-old mouse kidneys. The expression of LSD1 protein was also increased in mouse IMCD cells treated with D-gal or ETO. Inhibition of autophagy with its inhibitor Lys05 resulted in a dose-depedent increase of LSD1 protein. We found that LSD1 interacted with autophagy proteins, LC3 and Beclin1, and these interactions subjected to autophagy mediated LSD1 degradation, suggesting a mechanism of that the downregulation of autophagy contributes to the upregulation of LSD1 in senescent cells and aged kidneys. We further found that LSD1 bound to the promoters of $p16^{ink4a}$ and $p21^{cip-2}$, two senescence markers, in renal tubular epithelial cells and targeting LSD1 with its specific inhibitor, ORY100, or siRNA decreased their expression in those cells induced by ETO, supporting a promoting role of LSD1 in senescence. Irradiation(IR) induces high levels of DNA damage which often leads to cellular senescence in vivo. We found that treatment with IR increased LSD1 protein in IR treated kidneys, and administration of ORY-100 demonstrated a protection from IR-induced gray hairs seen in vehicle treated wild type mice and decreased IR-induced accumulation of senescent cells in kidneys.

Conclusions: This study indicates a role of LSD1 in promoting senescence and kidney aging, and a mechanism of that the upregulation of LSD1 is subjected to impaired autophagy in these processes. Our study places an emphasis that LSD1 has potential as a therapeutic target for the delay of kidney aging.

Distal Convoluted Tubule (DCT)-Specific Disruption of the COP9 Signalosome Induces Autophagy Leading to Kidney Injury and DCT Atrophy

Ryan J. Cornelius,[1] Xiao-Tong Su,[1] Jonathan W. Nelson,[2] David H. Ellison,[1] Chao-Ling Yang.[1] *[1]Oregon Health & Science University, Portland, OR; [2]University of Southern California Keck School of Medicine, Los Angeles, CA.*

Background: Regulated maintenance of protein degradation is accomplished by two main systems: the ubiquitin-proteasome system and autophagy-lysosome system. Proteasomal degradation selectively ubiquitinates substrates via E3 ubiquitin ligases, the largest family of which are Cullin-RING ligases (CRLs). All CRLs are regulated by the COP9 signalosome (CSN), which interacts with the CRL to turn off ubiquitin ligase activity. To investigate the role of impaired CSN dysfunction in the kidney, we inactivated the CSN by deleting *Jab1* (the key CSN catalytic subunit) along the entire nephron (KS-*Jab1*$^{-/-}$). The mice developed progressive kidney injury with specific atrophy of the distal convoluted tubule (DCT) that culminated in chronic kidney disease (CKD). Autophagy is known to be associated with exacerbating CKD and can be activated due to cellular stress. We hypothesized that CSN dysfunction activates autophagy leading to atrophy of the DCT and CKD.

Methods: Inducible DCT-specific NCC-Cre-ERT2 mice were bred to INTACT (Isolation of Nuclei TAgged in specific Cell Types, which fluorescently labels nuclei) and *Jab1* floxed mice to generate DCT-INTACT-*Jab1*$^{-/-}$ mice. At six-weeks nuclei from kidney cortex was isolated and the DCT was enriched using Fluorescence-Activated Nuclei Sorting (FANS). GFP-positive nuclei were used for single-nucleus RNA-sequencing (snRNA-seq). Additionally, we impaired the autophagy pathway utilizing *Atg5* floxed mice to generate JAB1 and ATG5 double knock out mice (DCT-*Jab1*$^{-/-}$/*Atg5*$^{-/-}$).

Results: snRNA-seq of DCT enriched cells from DCT-INTACT-*Jab1*$^{-/-}$ mice showed four distinct populations: DCT1, DCT2, damaged DCT1 (dDCT1), and damaged DCT2 (dDCT2) cells. The damaged DCT cells showed downregulation of Differentially Expressed Genes (DEGs) associated with ion transport and metabolic processes and upregulation of DEGs associated with apoptosis, which is known to activate autophagy. Like KS-*Jab1*$^{-/-}$ mice, DCT-*Jab1*$^{-/-}$ mice developed tubule injury and atrophy of the DCT. Inhibition of autophagy in DCT-*Jab1*$^{-/-}$/*Atg5*$^{-/-}$ mice attenuated kidney injury and reduced DCT atrophy.

Conclusions: DCT-specific CSN disruption causes activation of apoptosis and autophagy pathways leading to tubule injury and atrophy of the DCT.

KLF5 Is Upregulated via NFkB to Promote Maladaptive Kidney Repair after Ischemia-Reperfusion Injury

Zhengwei Ma,[1] Zheng Dong.[1,2] *[1]Augusta University Medical College of Georgia, Augusta, GA; [2]Charlie Norwood Department of Veterans Affairs Medical Center, Augusta, GA.*

Background: Kruppel Like Factor 5 (KLF5) is a transcriptional factor that has been implicated in the pathogenesis of diabetic kidney disease and lupus nephritis. However, its role and regulation in acute kidney injury (AKI) and post-AKI kidney repair are unknown.

Methods: KLF5 expression was analyzed in C57BL/6 mice after renal ischemia-reperfusion injury (IRI) in vivo and TGFβ-treated kidney proximal tubule cells in vitro. A proximal tubule-specific *Klf5* knockout (PT-Klf5-KO*)* mouse model was established to examine the role of KLF5 in AKI and post-AKI repair. In vitro, the effect of *klf5* knockdown was investigated in TGFβ-treated proximal tubular cells.

Results: KLF5 was induced by IRI in the kidney and the induction was mainly in proximal tubule cells in immunohistochemistry staining. Renal IRI was more severe in PT-Klf5-KO mice than in wild-type mice as shown by BUN and creatinine levels and the percentage of injured tubules, suggesting a protective role of KLF5 at the acute injury phase. However, PT-Klf5-KO mice showed a significantly better kidney repair after renal IRI. At 2 weeks after renal IRI, PT-Klf5-KO mice had higher eGFR, lower BUN and serum creatinine, and markedly less renal fibrosis. K*lf5* KO mice also showed less senescence as indicated by less β-Gal staining and P16 expression. In addition, PT-*Klf5* KO decreased TNFα and Cxcl2 mRNA expression and macrophage infiltration in the kidneys. KLF5 was also induced in TGFβ-treated proximal tubular cells, and knockdown of *Klf5* decreased the induction of fibronectin and profibrotic cytokines in these cells. The induction of KLF5 during renal IRI was attenuated in proximal tubule-specific NF-kB/P65 knockout mice. It was also suppressed by the pharmacological inhibitor of NF-kB, JSH23. Chromatin immunoprecipitation (ChIP) assay further showed that KLF5 was a direct transcriptional target of NF-kB.

Conclusions: KLF5 is upregulated via NF-kB during renal IRI and post-injury kidney repair. While KLF5 may play a protective role against acute injury, it promotes maladaptive kidney repair by inducing renal inflammation, senescence, fibrosis, and deterioration of kidney function.

SA-PO1184

A Cost-Effective, High-Throughput, Three-Dimensional Coculture Model of Kidney Fibrosis for Drug Discovery

Long T. Nguyen,[1,2] Sonia Saad,[1,2] Carol A. Pollock.[1,2] Renal Research Group. *[1]Kolling Institute of Medical Research, St Leonards, NSW, Australia; [2]The University of Sydney Faculty of Medicine and Health, Sydney, NSW, Australia.*

Background: Acute kidney injury (AKI) can cause permanent damage to the kidneys, leading to chronic kidney disease (CKD). Recent advances in system biology revealed thousands of novel molecules involved in the transition of AKI to CKD. Nevertheless, there is a lack of efficient and reliable platforms to validate their biological functions and therapeutic potentials. Stem cell-derived kidney organoids and three-dimensional (3D) tissue culture have been shown to be able to capture key characteristics in kidney development and pathology. However, most of these models are not suitable for studying fibrosis, the common hallmark in CKD. The aim of this study is to develop a cost-effective and high throughput 3D coculture model of kidney fibrosis for drug screening.

Methods: Renal proximal tubular epithelial cells, fibroblasts and endothelial cells were seeded on polymerised Matrigel at a specific ratio to form a 3D network of vascularised tubules with interspersed fibroblasts. The 3D coculture was treated with Transforming

Growth Factor beta (TGFb) and Cyclosporin A (CsA) simultaneously to induce AKI and fibrosis. Telmisartan was used as the standard therapy to attenuate these effects.

Results: The 3D coculture produced a stable tubular network that is rich in Collagen type 1A (COL1A), which was otherwise not expressed in 2D and 3D monocellular culture even when being stimulated by TGFb, suggesting that the addition of fibroblasts was essential for fibrotic responses. TGFb and CsA treatment for 48 hours induced cell death to the tubular cells while stimulated cell growth of fibroblasts. In association, the expression of inflammatory markers MCP-1 and TNFa as well as fibrotic markers Fibronectin and COL1A were significantly increased. Such effects were partially attenuated by treatment of telmisartan, suggesting that the 3D coculture mimics pathology and drug responses in patients with kidney diseases.

Conclusions: In conclusion, We have successfully developed a 3D coculture model of tubulointerstitial fibrosis to be used as a low-cost, high throughput fibrotic assay for studying intercellular interaction and drug effects.

SA-PO1185

Multiplexed Imaging of Senescent Chromatin State in Single Cells in the Kidneys

Hannah S. Perry, Benjamin C. Mustonen, Madeline K. Wong, Stuart J. Shankland, Joshua C. Vaughan. *University of Washington, Seattle, WA.*

Background: The gradual loss of kidney function with age and disease can be linked to changes in physiology and single cell epigenetics. As cells become stressed or damaged from these conditions, they undergo the process of becoming senescent, a state of permanent cell cycle arrest associated with massive chromatin rearrangement and telomere shortening, as a way to mitigate further damage. The order of events and extent of epigenetic changes within single cells and their correlation to physiological alterations as the kidney ages or becomes diseased and senescence forms are not fully understood.

Methods: Super-resolution optical microscopy techniques were used with advanced chemical labeling methods to concurrently study epigenetic states and nanoscale physiology in mouse kidney slices. We used multiplexed imaging to simultaneously study histone marks, telomeres, and tissue morphology at the single cell level.

Results: The use of optical super-resolution techniques allows for ~70 nm spatial resolution. Multiple histone modifications have been detected and quantified throughout the nucleus and at locations of repetitive DNA sequences (telomeres and major satellites) in single cells with a high degree of accuracy. In the same sample, these single cell epigenetic signatures were correlated with nanoscale features within glomeruli and proximal tubules. Telomeres in aging samples have been shown to shorten using imaging techniques. The quantification of these nanoscale features includes the glomerular basement membrane thickness, width of individual podocyte foot processes, and the size of endothelial fenestrations.

Conclusions: The combination of these advanced labeling methods and super-resolution optical microscopy techniques allows for an unprecedented view and correlation of single cell epigenetic states and nanoscale physiology in kidney tissue at many age points. Our approach has implications for identifying specific epigenetic changes in the kidney that precede the development of senescence and related diseases and their physiological markers. Understanding the sequence of events may assist in predicting disease formation along with studying the effectiveness of various treatments.

Targeted Pulsed Ultrasound of the Spleen Protects against AKI and CKD and Permits Kidney Regeneration

Eibhlin S. Goggins,[1] Yanjun Xie,[2] Yi Huang,[2] Carson A. Brantley,[1] Junlan Yao,[1] William Nash,[1] Sylvia Cechova,[1] John Hossack,[2] Mark D. Okusa.[1]
[1]Division of Nephrology, Center for Immunity, Inflammation, and Regenerative Medicine, University of Virginia, Charlottesville, VA; [2]University of Virginia Department of Biomedical Engineering, Charlottesville, VA.

Background: Our group has demonstrated that unfocused pulsed ultrasound (pUS) protects against ischemic AKI. The efficacy of pUS targeted directly to the mouse spleen and in kidney injury caused by other insults is unknown. Here, we aimed to 1) Develop an effective and reproducible pUS protocol specifically targeting the mouse spleen to block inflammation and prevent ischemia induced AKI 2) To test the hypothesis that pUS can prevent toxin induced AKI and the transition to CKD and that 3) pUS permits regeneration in the kidney microenvironment.

Methods: The US configuration consists of a power amplifier and waveform generator paired with a 1 MHz single element transducer with a stand-off of 1mm. The optimized stimulation parameters used were tonebursts of 150 cycles, pulse repetition frequency of 2kHz, and a peak-negative pressure of 280kPA. 4 min of pUS was delivered to the spleen 24h prior to folic acid (FA, 250mg/kg IP), lipopolysaccharide (LPS, 3.5mg/kg IP), or bilateral kidney ischemia reperfusion injury (bIRI, 25min).

Results: Mice that received spleen targeted pUS demonstrated significantly reduced plasma TNFα 1h after LPS. The increase in plasma creatinine (Cr) and BUN 24h after bIRI was significantly reduced in splenic pUS mice. In the FA model, the increase in Cr (Sham: 1.14±0.25, pUS: 0.32±0.04 mg/dL) and BUN (Sham: 155.8±23.2, pUS: 45.9±4.6 mg/dL) on day 2 was reduced in pUS mice. Analysis of H&E and PAS stained kidney sections demonstrated reduced injury in pUS treated mice. 23% of sham treated mice died over the 14d study period. On day 14, kidney mRNA levels of the fibrotic markers, *Col1α1*, *Col3α1*, and *Fn-1* and proinflammatory cytokines, *IL-1β*, *IL-6*, and *Ccl2* were decreased in pUS treated mice. pUS mice displayed reduced kidney tubulointerstitial fibrosis and collagen deposition by blinded assessment of Masson trichrome sections. Kidney mRNA expression of *Wnt2*, *Wnt4* and the acute epithelial stress response gene, *Sox9* remained persistently elevated in sham treated mice compared to pUS mice.

Conclusions: We developed a spleen targeted pUS protocol that reduces inflammation and prevents AKI/CKD in multiple mouse models. Future work is focused on understanding the mechanism by which pUS may promote a microenvironment conducive to kidney regeneration.

Low-Intensity Pulsed Ultrasound Stimulation to Treat Kidney Fibrosis through Inhibition of Tubular IL-1R

Zhimin Huang, Jiaxin Dong, Ziqi Fu, Jiafa Ren, Huijuan Mao. *The First Affiliated Hospital with Nanjing Medical University, Nanjing, China.*

Background: Low intensity pulsed ultrasound (LIPUS) has become increasingly appreciated for kidney diseases. However, its mechanisms for chronic kidney disease (CKD) remain poorly defined.

Methods: Under different parameters of LIPUS, histological tests and molecular biology were determined. We detected IL-1β/IL-1R and its downstream in unilateral renal ischemia/reperfusion (IR) induced renal fibrosis and IL-1β-induced tubular partial epithelial-to-mesenchymal transition with or without LIPUS treatment. In addition, we evaluated the IL-1R dependence of LIPUS in treating IR-induced CKD models using tubular IL-1R$^{-/-}$ mice.

Results: Daily LIPUS treatment at 315 mW/cm^2 reduced the IR-induced tubular injury and fibrosis, accompanied by the remarkable amelioration in IL-1β and IL-1R[Fig.1A-D]. Transcriptome sequencing showed a significant reduction of IL-1R and its downstream(p-NF-κB, Myc) in the LIPUS-treated IR-injured plus IL-1β stimulation, compared to the untreated diseased group[Fig.1E-G]. LIPUS treatment reversed IL-1β induced tubular injury and profibrotic cytokines by reducing IL-1R in vivo and in vitro. Knockout mice lacking tubular IL-1R expression exhibited less renal tubular injury and retained a more preserved renal function after IR injury. However, LIPUS treatment showed no more improvement in tubular IL-1R Knockout mice after IR injury[Fig.1H-J].

Conclusions: Daily LIPUS treatment at 315 mW/cm^2 could reduce IR-induced tubular injury and fibrosis by ameliorating tubular IL-1R[Fig.2].

Funding: Government Support - Non-U.S.

Optimized Protocol for the Multiomics Processing of Cryopreserved Human Kidney Tissue

Sydney Elisabeth Gies,[1,3] Sonja Haenzelmann,[1,2] Dominik Kylies,[1,4] Moritz Lassé,[1,3] Nikolay Zolotarev,[1,3] Robin Khatri,[3,2] Manuela Poets,[1,2] Shun Lu,[1,3] Shuya Liu,[1,3] Fabian Hausmann,[2,3] Jan Czogalla,[1,3] Fabian Braun,[1,3] Markus M. Rinschen,[1,3] Victor G. Puelles,[1,3] Stefan Bonn,[2,3] Maja Lindenmeyer,[1,3] Tobias B. Huber.[1,3] *[1]Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Institute of Medical Systems Biology, Center for Biomedical AI (bAIome), Center for Translational Immunology (HCTI), Center for Molecular Neurobiology (ZMNH), University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [3]Hamburg Center for Kidney Health, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [4]Massachusetts Institute of Technology Picower Institute for Learning and Memory, Cambridge, MA.*

Background: Immediate processing of fresh kidney tissue obtained from needle biopsies is challenging in clinical routines. To address this, tissue samples can be harvested in (cryo-) preservative agents such as RNA*later* (Rl) or CellCover (CC), that rapidly preserve the integrity of cellular molecules already at room temperature. In this study, we examined the effects of *Rl* and CC on the single nucleus transcriptome, on tissue architecture and immunofluorescence stainings and on the proteome.

Methods: Biopsy cores from pig kidneys received from a slaughterhouse were either snapfrozen (sf) or put into Rl or CC. For human kidney tissue, the second core of a kidney needle biopsy and healthy kidney tissue from tumor nephrectomies were either sf or put in Rl. For single nucleus RNA sequencing (snRNAseq) with the Chromium 10X platform, 3-4 mm of a thawed kidney biopsy core was dissociated. For proteomic analysis, 2-3 mm sections of biopsies were analyzed by mass spectrometry. For immunohistochemical analysis, samples were thawed and subjected to fluorescent immunolabeling (IF).

Results: Each data set from sf, Rl and CC stored pig kidney tissue contributed to 31 clusters of both common and rare kidney cell types. Enrichment analysis detected a similar activation of the stress response pathways in all preservation methods. Applying snRNAseq to human kidney tissue stored in Rl resulted in diverse cell type clustering. Proteome analysis of pig kidney tissues showed the highest correlation between Rl and sf tissues. Classical histology with OCT-embedded kidney tissue as control indicated better preservation in Rl stored kidney compared to CC. IF-staining signal quality in Rl and CC preserved tissue was comparable to OCT-embedded kidney tissue.

Conclusions: Our study demonstrates that Rl can facilitate the collection and storage of kidney tissue without the need for snap freezing, supporting snRNAseq, proteome and histopathological analysis. As our optimized protocol requires only 3-4 mm of a biopsy core for high-throughput snRNAseq, the remaining part of a biopsy core can be utilized to generate other omics data.

SA-PO1189

Regulation of NLRP3 Inflammasome Expression through Inhibition of Podocyte-Specific Lysyl Oxidase-Like 2 as a New Therapeutic Target for AKI on CKD

Hoon Young Choi,[1,2] Nara Jeon,[1,2] Beom Jin Lim.[1,2] *[1]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; [2]Gangnam Severance Hospital, Seoul, Republic of Korea.*

Background: The NLRP3 inflammasome activation has been suggested a potential role in renal inflammation and thus contribute to the progression of kidney disease. Lysyl oxidase-like 2 (LOXL2) has been known to play an important role in target organ fibrosis including heart, liver and lung. In this study, we investigated the expression of LOXL2 in human kidney and podocyte, and its contribution to the NLRP3 inflammasome expression in the progression of acute kidney injury (AKI) on chronic kidney disease (CKD).

Methods: A podocyte cell line that suppresses LOXL2 expression was generated to investigate the role of LOXL2 in podocytes. And also, the podocyte-specific LOXL2-inhibiting mice (Nphs2-Cre:Loxl2-/-) was constructed to determine the role of LOXL2 in renal podocytes mice to determine the role of LOXL2 in renal podocytes in an animal model of AKI on CKD progression using lipopolysaccharide (LPS) and streptozotocin injection.

Results: Gene silencing of LOXL2 significantly reduced NLRP3 mRNA and protein expression in human podocytes (1.19±0.16 vs. 1.87±0.16, P<0.05). In hyperglycemic mice treated with LPS, podocyte-specific LOXL2 deficiency significantly reduced NLRP3 mRNA and protein expression in human kidney glomerulus. Western blot analysis also showed that TGF-beta 1, collagen I and phosphorylated Smad2 protein expression were significantly decreased in podocyte-specific LOXL2 deficiency mice.

Conclusions: Our results demonstrated that the genetic manipulation of podocyte-specific LOXL2 expression on NLRP3 inflammasome expression in AKI on CKD, suggesting its potential as a new therapeutic target for the mechanism of AKI on CKD.

The Early Renal Profibrotic Phenotype Caused by 5/6 Nephrectomy in Mice Depends on CD11c+ Antigen-Presenting Cells Population

Javier I. Reyes Osorio,[1] Patricio A. Araos,[2] Stefanny M. Figueroa,[1] Javiera Saez,[1] Maria J. Fuenzalida,[3,1] Rodrigo Pacheco,[3,1] Cristián A. Amador.[1] Laboratory of Renal Physiopathology. *[1]Universidad San Sebastian Facultad de Medicina y Ciencia, Santiago, Chile; [2]Universidad Autonoma de Chile - Campus El Llano Subercaseaux, Santiago, Chile; [3]Fundacion Ciencia & Vida, Santiago, Chile.*

Background: The recruitment and activation of antigen-presenting cells (APC) represent key mechanisms for the pro-inflammatory stages that lead to fibrosis in the progression of chronic kidney disease (CKD). Our revious experimental studies indicate that dendritic cells-like APC (APC-CD11c$^+$) are essential for inflammation, renal dysfunction, and heart fibrosis in mice with hypertensive nephropathy. Although that we have previously demonstrated that APC-CD11c$^+$ would not contribute to the inflammatory processes in the experimental unilateral ureteral obstruction, it is still unknown whether these cells contribute to the renal pro-fibrotic status in a model of CKD with reduction of renal function. Our objective was to determine whether the depletion of APC-CD11c$^+$ prevents the early renal pro-fibrotic status in a 5/6 nephrectomy model ($Nx_{5/6}$).

Methods: Male CD11c.DOG mice (8-12 wo, n=3-7), which can be depleted of APC-CD11c$^+$ by using diphtheria toxin (DT), underwent to the $Nx_{5/6}$ or Sham surgery (control) for 5-days. These groups received vehicle (Vh) or DT (8ng/g/d, ip) from the beginning of the experiment, where those animals-DT+ with a reduction >60% of APC-CD11c$^+$ were selected. Biochemical, histological and molecular analyses were performed.

Results: $Nx_{5/6}$ caused a trend increase in plasma creatinine (p=0.16 vs Sham-Vh), and in blood urea nitrogen (p=0.08 vs Sham-Vh). In addition, $Nx_{5/6}$ caused a significant increase in renal fibrotic area and was associated with the overexpression in the mRNA for the following pro-fibrotic markers: Collagen (COL)1A1, COL3A1 and Fn-I (p<0.05 vs Sham-Vh), and the pro-inflammatory mediators: Interleukin (IL)-6 and Lipocalin-2 (NGAL). Depletion of APC-CD11c$^+$ in $Nx_{5/6}$ animals did not alter the plasma parameters analyzed for determining renal function, but it did prevent renal fibrosis (3.79% vs 5.80% $Nx_{5/6}$-Vh; p<0.05), and the increase of mRNA for COL3A1 (p<0.05). In addition, the use of DT was associated with a lower abundance of COL1A1 and Fn I (p=0.07 and p=0.12, vs $Nx_{5/6}$-Vh, respectively), without affecting any pro-inflammatory mediator.

Conclusions: APC-CD11c$^+$ depletion prevents the early renal profibrotic phenotype in the $Nx_{5/6}$ model, providing new background related to the importance of APCs in the early progression of CKD.

Genetic Ablation of SLC6A19 Is Protective against Kidney Damage in Mouse Models of CKD

Laura Sanman, Richa Sarwaikar, Amelia Joslin, Sheela Crasta, Lisa Pang, Perryn Wong, Terry Satterfield, Nina Oberbeck, Yonghong Xiao, Yannan Xi, Maarten Hoek, Julie Ullman. *Maze Therapeutics Inc, South San Francisco, CA.*

Background: SLC6A19 is a sodium-dependent neutral amino acid transporter expressed in the small intestine and proximal tubule of the kidney. SLC6A19 has emerged as a novel target for the treatment of CKD based on analyses of large human data sets that have identified a link between loss of function gene variants with protection from CKD, and that individuals carrying heterozygous putative loss-of-function (LOF) variants in SLC6A19 have improved eGFR while gain of function variants carriers have diminished eGFR. In agreement with the protection from CKD observed in humans, ablation of SLC6A19 in mice has been shown to protect animals from renal injury induced by the proximal tubule toxin aristolochic acid (AAI).

Methods: Maze Therapeutics has developed a new SLC6A19 KO mouse model to further investigate published findings. These mice were tested in the AAI model of CKD

and biomarkers of kidney injury were assessed. In order to understand mechanistically how SLC6A19 LOF protects from renal injury samples were evaluated using transcriptomic, metabolomic, and immunostaining assays.

Results: When tested in the AAI CKD model the SLC6A19 KO mice were protected from chronic renal injury with evidence of normalization of kidney injury markers KIM1 and NGAL, as well as attenuation of UACR. Metabolomics from KO and WT animals reveals distinct redistribution of metabolic pathways consistent with SLC6A19's role as an amino acid transporter. Transcriptomic analysis of kidney samples from the AAI study suggest KO protection is mediated through alterations in metabolic pathways including downregulation of glycolysis and upregulation of oxidative phosphorylation.

Conclusions: Though the exact mechanism by which SLC6A19 LOF protects the kidney is not completely understood, we hypothesize this could be through a combination of decreasing workload on the proximal tubule, decreasing proximal tubule mTOR activity mediated by amino acid uptake, and decreasing intraglomerular pressure by restoring tubule-glomerular feedback via increased sodium delivery to distal regions of the nephron. In addition to direct effects on the kidney, reduction of SLC6A19 activity in the gut may lead to reduction of whole-body amino acid and metabolite intake that benefits multi-system physiology.

Urea Suppresses the Alternative Activation of Murine Macrophages

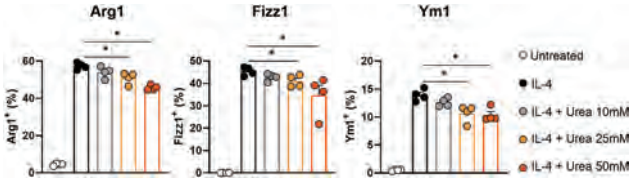
Seung Yun Chae,[1,2] Kyoung Il Min,[1,2] You-Me Kim.[2] *[1]The Catholic University of Korea Seoul St Mary's Hospital, Seoul, Seocho-gu, Republic of Korea; [2]Korea Advanced Institute of Science and Technology, Daejeon, Republic of Korea.*

Background: Although urea is generally considered harmless, it has been documented to obstruct the intracellular transport of arginine in vascular endothelial cells and inhibit glycolysis in pancreatic beta cells. This study aims to determine whether elevated extracellular urea concentrations impact macrophage functions.

Methods: Peritoneal macrophages and bone marrow-derived macrophages (BMDMs) were exposed to LPS and IL-4 to induce M1 and M2 polarization, respectively, in the presence of varying urea concentrations. Flow cytometry was utilized to examine the expression of markers of macrophage polarization including arginase-1 and iNOS. Additionally, M2 marker gene expression was analyzed using qPCR. Bulk RNA sequencing was performed to elucidate the transcriptomic changes induced by urea in BMDMs. The Seahorse real-time cell metabolic analysis was conducted to measure the oxygen consumption rate (OCR) and extracellular acidification rate (ECAR) in IL-4-treated BMDMs.

Results: Our study discovered that physiologically high urea concentrations reduce IL-4-induced upregulation of arginase-1 in murine macrophages in a dose-dependent manner at both mRNA and protein levels. Urea also significantly decreased the expression of other M2 macrophage markers, such as Fizz1 and Ym1. However, urea had minimal impact on LPS-induced M1 polarization. RNA sequencing of M2-polarized BMDMs indicated that urea downregulates genes associated with mTOR signaling, glycolysis, and oxidative phosphorylation. Correspondingly, urea treatment reduced phosphorylation of S6 protein and AKT, targets of mTORC1 and mTORC2, respectively. Additionally, ECAR and OCR were lower in urea-treated M2 BMDMs. The attenuation of M2 polarization by urea was not evident in the presence of Torin, a pan mTOR inhibitor, indicating that urea's inhibitory effect is mediated through downregulation of mTOR signaling.

Conclusions: Based on these findings, we propose that, contrary to the traditional view of urea as an inert molecule, urea suppresses M2 polarization in murine macrophages, likely through the attenuation of mTOR signaling.



Flow cytometry analysis of M2 marker expression in BMDMs

SA-PO1193

Microbes Regulate Glomerular Filtration Rate in Health and Disease in Mice

Jiaojiao Xu, Eesha Verma, Jason Sanchez, Sepideh Gharaie, Mahta F. Gooya, Kunal Gupta, Hamid Rabb, Jennifer L. Pluznick. *The Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: We hypothesized that the microbiome modulates glomerular filtration rate (GFR).

Methods: Microbiota were depleted using antibiotics in drinking water (ABX: ampicillin, neomycin, vancomycin). Germ-free (GF) mice were born in the Johns Hopkins GF Facility. GFR was measured by transcutaneous detection of FITC-sinistrin clearance. Mice were treated with adenine to model chronic kidney disease (CKD).

Results: GFR was significantly increased after microbiota depletion (ABX) in both sexes (Table 1, Study I). GFR was also significantly elevated in GF as compared to both control (ctrl) and conventionalized GF (CGF) mice in both sexes (Table 1, Study II). To determine if ABX increases GFR in CKD, mice were given adenine or adenine+ABX (simultaneously). Adenine decreased GFR. In females, adenine+ABX improved GFR (vs adenine) on weeks 4 and 6. In males, GFR improvement was seen on week 2 (Table 1, Study III). Plasma creatinine was significantly increased on adenine but normalized by ABX treatment in females (chow 0.19 mg/dl ±0.03 vs adenine 0.31±0.02, p=0.04; adenine vs adenine+ABX 0.15±0.03, p=0.005, n=7-9) and males (chow 0.17±0.03 vs adenine 0.65±0.07, p<0.0001; adenine vs adenine+ABX 0.40±0.04, p=0.005, n=7-9). Histological studies revealed that adenine increased collagen; ABX suppressed this increase in both females (chow 2.9±2.1 collagen area% vs adenine 7.2±7.4, p=0.0008; adenine vs adenine+ABX 4.5±4.0, p=0.02) and males (chow 2.2±2.1 vs adenine 8.7±6.6, p<0.0001; adenine vs adenine+ABX 6.2±4.6, p=0.02). 16S rRNA analysis on female feces indicated that *Akkermansia muciniphila* was elevated in adenine than chow diet, but adenine+ABX treatment decreased it.

Conclusions: Both the absence (GF) and suppression (ABX) of gut microbes increased GFR in healthy females and males. Moreover, ABX partially improved kidney function in an adenine-induced CKD model.

Investigating the Kidney-Gut-Brain Axis in CKD: Effects of Choline Trimethylamine Lyase and SGLT2 Inhibitors

Su mi Lee,[1,2] Yitong Zhao,[1] Tiffany Tran,[1] Nikitha M. Vancheeswaran,[1] Lily Tran-Phung,[1] Joshua J. Jung,[1] Stanley L. Hazen,[3] Mark Fisher,[4,5] Wei Ling Lau.[1] *[1]Division of Nephrology, Department of Medicine, University of California-Irvine, Irvine, CA; [2]Department of Internal Medicine, College of Medicine, Dong-A University, Busan, Republic of Korea; [3]Cardiovascular Medicine, Cleveland Clinic, Cleveland, OH; [4]Department of Neurology, University of California-Irvine, Irvine, CA; [5]Department of Pathology & Laboratory Medicine, University of California-Irvine, Irvine, CA.*

Background: Gut dysbiosis in CKD leads to increased uremic toxins including indoxyl sulfate (IS), p-cresyl sulfate (pCS) and trimethylamine N-oxide (TMAO). These toxins are associated with vascular injury and cognitive dysfunction. Choline trimethylamine lyase inhibitors such as iodomethylcholine (IMC) selectively block TMAO generation, while sodium-glucose cotransporter 2 (SGLT2) inhibitors such as canagliflozin have been shown to alter gut microbial composition. In this project, effects of IMC and canagliflozin therapy on the kidney-gut-brain axis were studied in CKD mice.

Methods: CKD was induced in male and female C57Bl/6J mice using dietary adenine. Controls (10-16 mice per group) and CKD animals (31-33 mice per group) were randomized to IMC, canagliflozin or IMC+canagliflozin treatment. Open field behavior test, serum levels of uremic toxins and brain microhemorrhage histology were analyzed.

Results: In CKD mice, serum creatinine was increased 4.5-fold while IS, pCS and TMAO levels were increased 6-fold compared to controls. On open field testing, CKD mice demonstrated decreased locomotor activity; higher serum creatinine, IS and pCS correlated with lower distance traveled. When stratified by sex, these findings remained significant in male mice only. Brain microhemorrhages were increased in CKD mice and correlated with decreased locomotor activity. IMC effectively reduced TMAO levels in CKD mice, but was noted to increase pCS in female CKD animals. Canagliflozin decreased serum TMAO and pCS, and decreased brain microhemorrhages (figure). The drug therapies did not improve locomotor scores.

Conclusions: Oral treatment with IMC or canagliflozin modified levels of gut-derived uremic toxins. The SGLT2 inhibitor decreased brain microhemorrhages but

did not improve behavior scores. Further studies are needed to elucidate the role of the kidney-gut-brain axis in CKD-associated cognitive dysfunction.

Novel Single-Cell Sequencing Methods for Detection of Mosaic Chromosomal Alterations in the Kidneys

Gary Wang,[1] Xinyi E. Chen,[2] Amit Verma,[1] Nancy Zhang,[2] Parker C. Wilson.[1]
[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]University of Pennsylvania Wharton School, Philadelphia, PA.

Background: Mosaic chromosomal alterations (mCA) are a type of somatic mosaicism characterized by large chromosomal gains or losses. We previously reported that mosaic loss of Y chromosome (LOY) increases with age and is enriched in an injured population of proximal tubule cells. However, the majority of these cells do not have LOY, which raises the possibility there are additional mCA we cannot detect. Here, we jointly profile genomic DNA and RNA by single-cell sequencing to unpack inaccessible chromatin regions and improve sensitivity for detection of mCA in the kidney.

Methods: We performed DEFND-seq (Olsen et al., bioRxiv 2023) and single cell multiome ATAC + gene expression (10X Genomics) on nuclei isolated from male rat kidney cortex aged 16 to 82 weeks. Split samples were subject to either standard nuclei processing (10X Multiome) or pretreatment with lithium diiodosalicylate to deplete nucleosomes. We generated 8 droplet-based single-cell libraries (DEFND = 4; Multiome = 4) and called mCA using a negative binomial model adjusting for cell-specific factors. We validated sex chromosome mCA using a 3-color digital PCR assay.

Results: A total of 40,031 cells passed filters and the number was similar between DEFND and Multiome libraries. DEFND had a 25-50% increase in genome-wide coverage compared to Multiomes, indicating we were able to "open" inaccessible regions for mCA analysis. We estimated mCA abundance for cell types and observed an increase in chromosome X (chrX) mCA compared to other chromosomes. The proportion of cells with a chrX mCA was higher in DEFND libraries, suggesting increased sensitivity in the DEFND assay. In contrast, chromosome 1 had a low probability of mCA and the proportion of cells was unchanged (Figure 1A). Approximately 8% of proximal tubule had a chrX mCA and enrichment analysis shows upregulation of oxidative phosphorylation and epithelial migration pathways (Figure 1B).

Conclusions: We hypothesize that sex chromosome mCA are enriched in the proximal tubule and are associated with increased oxidative stress. Our approach can be used to study the role of mCA as biomarkers of aging and kidney disease progression.

Inducible Deletion of MicroRNA Activity in Kidney Mesenchymal Cells Exacerbates Kidney Fibrosis

Hirofumi Sakuma, Naoki Nakagawa. *Asahikawa Medical University, Department of Internal Medicine, Division of Cardiology and Nephrology, Asahikawa, Japan.*

Background: Renal interstitial mesenchymal cell-specific deletion of Dicer results in hypoplastic kidneys with abnormal differentiation of nephron tubules and vasculature (Kidney International, 2015); however, the role of Dicer in these cells in adult kidney diseases remains unexplored. We developed a new mouse model and investigated the role of Dicer and Dicer-dependent miRNA activity in renal interstitial mesenchymal cells.

Methods: We generated Dicer conditional knockout (cKO) mice by crossing hemizygous *Pdgfr-β-CreER^{T2}* mice with homozygous Dicer floxed (*Dicer$^{FL/FL}$*) mice. *Dicer$^{FL/FL}$* mice without *CreER^{T2}* were used as controls. After administering oral tamoxifen, these mice underwent unilateral ureter obstruction (UUO) or intraperitoneal injection of folic acid (FA, 250 mg/kg). Fibrosis in the renal interstitium was assessed using immunofluorescent staining and real-time PCR (RT-PCR). RNA sequencing was performed using total RNA from Sham- or UUO-kidneys. Primary renal fibroblasts were transfected with miR-9-5p inhibitors (20 nM) and treated with 5 ng/mL TGF-β1 for 48 hours. RT-PCR was performed to evaluate *Pdgfrb* and *Acta2* expression in vitro assay.

Results: Compared with control mice, cKO mice significantly increased expression of PDGFR-β in injured kidneys by immunofluorescence staining and RT-PCR. The percentage of Sirius red staining in injured kidneys was also significantly elevated in cKO mice compared with that in control mice. Microarray analysis indicated decreased expression of *miR-9-5p*, *miR-344g-3p*, and *miR-7074-3p* in cKO mice. The major transcriptional changes in cKO mice were related to smooth muscle cell differentiation, actin cytoskeleton, and fibroblast proliferation. In vitro assays demonstrated significant upregulation of *Pdgfrb* and *Acta2* in primary renal fibroblasts transfected with miR-9-5p inhibitor following TGF-β1 treatment.

Conclusions: This study revealed that renal interstitial mesenchymal cell-specific deletion of Dicer increased activation of PDGFR-β and exacerbated renal fibrosis by decreasing levels of *miR-9-5p*, *miR-344g-3p*, and *miR-7074-3p*. Activation of PDGFR-β was sufficient to drive renal fibrosis, and these miRNAs are potential therapeutic targets for renal fibrosis.

Unveiling the Role of Transgelin as a Prognostic and Therapeutic Target of Kidney Fibrosis via a Proteomic Approach

Kyu hong Kim,[1] Soie Kwon,[3] Eunjin Bae,[4] Kyung Don Yoo,[5] Seong Min Lee,[2] Seong Joon Park,[2] Jae Wook Lee,[6] Dong Ki Kim,[2] Yon Su Kim,[2] Seung Hee Yang.[2]
[1]Seoul National University College of Medicine, Jongno-gu, Seoul, Republic of Korea; [2]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [3]Chung Ang University Hospital, Seoul, Seoul, Republic of Korea; [4]Gyeongsang National University Changwon Hospital, Changwon, Gyeongsangnam-do, Republic of Korea; [5]Ulsan University Hospital, Ulsan, Republic of Korea; [6]National Cancer Center, Goyang, Gyeonggi-do, Republic of Korea.

Background: This study investigated the effects of kidney fibrosis and identified potential biomarkers based on the proteomic profile of human derived primary cell and animal models.

Methods: Mass spectrometry-based proteomic analysis of transforming growth factor β-induced human-derived tubular epithelial cells and kidney tissue of a 5/6 nephrectomy rat model were performed.

Results: 351 differentially expressed proteins showing concurrent changes were identified. Among these, 69 proteins associated with the extracellular matrix, aging, and mitochondria were selected for gene set enrichment analysis. Network analysis of the selected proteins revealed five crucial proteins, of which transgelin showed the highest interactions with known fibrosis-related proteins. Consistent with the proteomics results, transgelin mRNA expression in the kidney tissue of the 5/6 nephrectomy model was elevated. Transgelin expression on kidney tissue gradually increased from intermediate to final fibrosis in the 5/6 Nx and unilateral ureteral obstruction mouse models. Subsequent validation in the kidney tissue and urine samples of patients with chronic kidney disease confirmed the upregulation of transgelin, particularly in the advanced stages of chronic kidney disease. Moreover, blocking transgelin in a cellular model of kidney fibrosis demonstrated its therapeutic potential.

Conclusions: In conclusion, transgelin is a promising biomarker and therapeutic target for kidney fibrosis in patients with chronic kidney disease. This study suggests transgelin as a potential noninvasive diagnostic biomarker and therapeutic intervention target for patients with chronic kidney disease. Further studies are warranted to elucidate the precise role of transgelin and its clinical utility in larger patient cohorts.

SA-PO1198

CD11b Deficiency Ameliorates AKI-to-CKD Progress via Promoting Alternative Activation of Macrophages

Yiqin Shi. *Department of Nephrology, Zhongshan Hospital, Fudan University, Shanghai, China.*

Background: Acute kidney injury (AKI), even if followed by renal recovery, is a risk factor for the future development of chronic kidney disease (CKD). Persistent chronic inflammation has been proposed to contribute to the progress of AKI-to-CKD. Macrophages are a heterogeneous cell group implicated in injury, repair, and fibrosis during AKI-to-CKD process. However, the underlying mechanism of how macrophages participate in the progress of disease is largely unclear. CD11b/CD18, a leukocyte adhesion molecule, expressed on neutrophils, eosinophils and macrophages, has been shown to mediate several adhesion-dependent processes. CD11b/CD18 also contributes to the polarization of macrophages.

Methods: To determine the underlying mechanism of how CD11b/CD18 participates in AKI-to-CKD, we use a long-term ischemia/reperfusion (I/R) model in $CD11b^{-/-}$ mice on C57BL/6 background. Wild-type (WT) and $CD11b^{-/-}$ mice with unilateral renal IRI were euthanized at day 3,7,14 after disease induction. Organ damage was histologically analyzed and flow cytometric analysis, real-time PCR were performed for the evaluation of leukocyte infiltration in kidney. *In vitro*, we used murine bone marrow-derived macrophage (BMDM) from WT and $CD11b^{-/-}$ mice to determine IL-4 induced alternatively activated (M2) macrophage associated gene expression.

Results: The extent of inflammation and fibrosis was alleviated in $CD11b^{-/-}$ mice, accompanied by an early increase of M2 macrophages in renal and higher activity of p-STAT6. We demonstrated both in vitro and in vivo that enhanced alternative activation in CD11b-knockout macrophages is regulated by the IL-4/STAT6 axis, which is mediated by the inactivation of the Src kinase family member Lyn. Importantly, the therapeutical administration of CD11b-neutralizing mAbs can effectively prevent AKI-to-CKD progression.

Conclusions: CD11b plays a critical role in limiting the alternative activation of macrophages and may be a potential therapeutic target during the AKI-to-CKD process.

SA-PO1199

APOE-Activating Noncoding RNA (AANCR) Regulates APOE in Kidney Cell Types

Lillian B. Elkin, Ma Wan, Ryan J. Snyder, Jason A. Watts. *National Institute of Environmental Health Sciences, Durham, NC.*

Background: Apolipoprotein E (*APOE*) is a lipid carrier protein and polymorphisms of the gene are predictive of the development of chronic kidney disease (CKD). In line with its role in kidney function, *APOE* knockout mice develop renal disease, indicating that *APOE* is necessary to maintain normal renal function. However, some studies have suggested it is *APOE* dysregulation in macrophages or changes in lipid profiles that lead to kidney disease. Hence, the question remains whether *APOE* function in renal epithelial cells contributes to CKD risk. Recently, we identified a non-coding RNA, *APOE*-Activating Noncoding RNA (AANCR), that regulates *APOE* in human cells through a novel mechanism involving R-loop mediated RNA polymerase pausing. In this project, we asked whether AANCR regulates *APOE* expression in renal cell types.

Methods: To quantify AANCR-mediated *APOE* expression and its effect on renal cell types, we measured gene expression in cultured human proximal tubule cells (HK-2) and murine inner medullary collecting duct cells (IMCD) and performed apoptosis assays in HK-2 cells.

Results: First, we measured AANCR and *APOE* expression in renal cells by RT-qPCR and found that both are expressed in proximal tubule and collecting duct cells. Next, to test if AANCR regulates *APOE*, we performed siRNA knockdown of AANCR and found a significant reduction in the expression of *APOE* in renal proximal tubule cells. RNA polymerase pausing is common at stress responsive genes, so we asked if AANCR-*APOE* are stress responsive in renal cells. We found AANCR is induced in response to both osmotic stress and heavy metal exposure. To explore whether AANCR induction has functional consequences for renal cell types, we asked if APOE has a cytoprotective role in the kidney. APOE is a secreted protein, so we treated cells with osmotic stress to induce APOE expression and then collected the conditioned media. We fractioned the media to have either high or low APOE protein. We found that cells treated with conditioned media with abundant APOE were more resistant to apoptosis induced by osmotic stress, whereas conditioned media without APOE was not protective.

Conclusions: We show that the non-coding RNA AANCR regulates *APOE* expression in renal cell types and plays a cytoprotective role in response to stress. Future work will address whether targeted modulation of *APOE* expression is protective in CKD.

Serum Amyloid A1 Damages the Peritubular Capillary Network and Promotes Kidney Fibrosis

Yadie Xiang, Haiyan Fu. *State Key Laboratory of Organ Failure Research, National Clinical Research Center of Kidney Disease, Renal Division, Nanfang Hospital, Southern Medical University, Guangzhou, Guangdong, China, Guangzhou, China.*

Background: The deterioration of the peritubular capillary network causes renal tissue ischemia and hypoxia, accelerating chronic kidney disease (CKD). Finding ways to mitigate endothelial cell injury and restore capillary density has been a persistent challenge. This project examines the pathological role and molecular mechanisms of serum amyloid A1 (SAA1), identified by our team as a kidney injury-associated molecule. Using multi-omics analysis and traditional biological experiments, we study SAA1 in CKD patients, mouse models, and in vitro endothelial cell injury models. Our goal is to deepen understanding of CKD pathogenesis, identify therapeutic targets, and develop effective prevention and treatment strategies.

Methods: Proteomic analysis of renal tissue post-ischemia/reperfusion injury (IRI) in mice identified molecules driving renal fibrosis, validated in CKD mouse models and patient biopsy specimens. Gene knockout mice were used in CKD models induced by IRI or unilateral ureteral obstruction (UUO). We employed histology, pathology, immunology, biochemistry, and molecular biology to study expression characteristics and damage effects. In vitro, transcriptome sequencing and traditional experiments elucidated molecular mechanisms in an endothelial cell injury model.

Results: Proteomic analysis of renal tissue post-ischemia/reperfusion injury (IRI) in mice identified molecules driving renal fibrosis, validated in CKD mouse models and patient biopsy specimens. Gene knockout mice were used in CKD models induced by IRI or unilateral ureteral obstruction (UUO). We employed histology, pathology, immunology, biochemistry, and molecular biology to study expression characteristics and damage effects. In vitro, transcriptome sequencing and traditional experiments elucidated molecular mechanisms in an endothelial cell injury model.

Conclusions: SAA1 is critical in renal fibrosis development, causing endothelial cell damage, increasing vascular permeability, disrupting capillary integrity, exacerbating renal ischemia and hypoxia, and accelerating fibrosis via the CD36/JNK pathway. Targeting SAA1 significantly improves renal microcirculation and delays CKD progression. SAA1 vaccination shows promise as an innovative CKD therapy.

Hematopoietic Mosaic Loss of Y Chromosome Promotes Renal Cell Senescence and Kidney Diseases

Yohei Arai,[1] Nicholas W. Chavkin,[1] Yuka Arai,[1] Jonatan Halvardson,[2] Josefin Bjurling,[2] Heather Doviak,[1] Lars A. Forsberg,[2] Kenneth Walsh.[1] *[1]University of Virginia School of Medicine, Charlottesville, VA; [2]Uppsala Universitet, Uppsala, Sweden.*

Background: Aging leads to the accumulation of senescent cells that, in turn, promote morbidity and mortality. Hematopoietic mosaic loss of Y chromosome (mLOY) with age is the most frequently acquired somatic mutation in males, and this condition has been associated with various age-associated diseases and reduced lifespan. The pathogenesis of kidney diseases is associated with the infiltration of immune cells in response to the kidney injury, and senescent cells accumulate in kidney in response to injury or advance age. However, the roles of hematopoietic mLOY in renal disease progression and senescent cell accumulation are unknown.

Methods: We investigated the association between the LOY percentage in leukocytes and the incidence of kidney diseases using male dataset derived from a prospective cohort study of a half million individuals with paired genetic and phenotype information. To assess the specific transcriptional signatures associated with hematopoietic mLOY, cross-sectional analyses were performed on a single-cell RNA sequencing dataset of renal biopsies from healthy control males and male patients with kidney diseases. A mouse model of hematopoietic mLOY was employed to examine whether hematopoietic mLOY is causally link to kidney diseases.

Results: A prospective cohort study (n=216,608) revealed an association between mLOY in blood and the incidence of kidney diseases during the follow-up period (median 14.8 years). The analysis of transcriptional signatures in human kidneys identified associations between disease progression, immune cell LOY and the accumulation of senescent cells. Hematopoietic mLOY causally led to renal dysfunction that was accompanied by senescent cell accumulation in murine models of advanced age and kidney injury. In aged mLOY mice, treatment with a senolytic agent suppressed the progression of renal dysfunction and prolonged lifespan.

Conclusions: Hematopoietic mLOY promotes renal cell senescence, contributing to the development of kidney disease. Senolysis could be a promising therapeutic strategy for hematopoietic mLOY.

Suppressing Exocytosis of Mast Cells and Its Therapeutic Efficacy for Peritoneal Fibrosis in Rats with Chronic Kidney Failure

Itsuro Kazama. *Miyagi Daigaku Kango Gakugun Daigakuin Kangogaku Kenkyuka, Kurokawa-gun, Japan.*

Background: In addition to their exocytotic release of chemical mediators, mast cells produce fibroblast-activating factors to facilitate the progression of organ fibrosis in chronic inflammatory diseases. The process of exocytosis in mast cells can be monitored electro-physiologically by the changes in the membrane capacitance (Cm).

Methods: Employing the standard patch-clamp whole-cell recording technique in rat peritoneal mast cells, we examined the effects of anti-allergic drugs on the changes in the Cm. Additionally, using rat models with chronic renal failure (CRF) induced by 5/6 nephrectomy, we actually examined the therapeutic efficacy of these drugs for peritoneal fibrosis complicated with CRF.

Results: Among anti-allergic drugs, second-generation antihistamines, such as olopatadine, loratadine and ketotifen, markedly suppressed the increase in the Cm and directly inhibited the exocytotic process, suggesting their potency as mast cell stabilizers. Of note, tranilast, a potent anti-allergic drug, most effectively and strongly suppressed the increase in the Cm. Therefore, using rat models with CRF, we examined the effects of tranilast (200 mg/kg) on the histop**a**thological features of CRF rat peritoneum. In the fibrotic areas of CRF rat peritoneum, mast cells proliferated *in situ* and increased their activity by producing fibroblast growth factors. Therapeutic intervention with tranilast actually slowed the progression of peritoneal fibrosis.

Conclusions: From these results, the activation of mast cells was considered to be responsible for the progression of peritoneal fibrosis in uremic condition. Additionally, the results suggested the therapeutic potency of mast cell stabilizers in the treatment of peritoneal fibrosis in CRF.

PUB001

Epidemiology of Patients with CKD from Eastern North Carolina (ENC) Hospitalized with COVID-19

Cameron T. Lawson. *East Carolina University, Greenville, NC.*

Background: Early meta-analysis by Jdiaa et al showed that patients with CKD were more likely to have worse outcomes from COVID–19 compared to patients with normal renal function. To our knowledge, a similar retrospective analysis of COVID-19 positive patients hospitalized in Eastern North Carolina has not been replicated. Our study aimed to describe demographics and compare outcomes of COVID-19 positive patients with and without baseline CKD hospitalized within the ECU Health System.

Methods: This retrospective, observational study involved a review of data from electronic health records of patients aged ≥ 18 years with laboratory-confirmed COVID-19 admitted to one of the ECU Health Systems from March to October 2020. We described patients' demographics, comorbidities, length of stay, disposition, and mortality. We further subcategorized patients into two groups: those with glomerular filtration rate (GFR) > 60 ml/min/1.73 m^2 and a second group with GFR < 60 ml/min/1.73 m^2. Categorical variables were compared by Chi-squared while continuous variables were compared by Mann-Whitney U Test and reported as medians with interquartile ranges (IQR). The Institutional Review Board of ECU Health approved the study protocol before the study began.

Results: Of the 446 hospitalized COVID-19 positive patients, the median age was 64.5 years, 49% were African American, followed by 30% Caucasians. 43% of the patients had underlying CKD at least stage IIIa and 6% had end-stage renal disease (ESRD) as per Kidney Disease Improving Global Outcomes (KDIGO) guidelines. The median BMI was 30 kg/m^2 and 40% had tobacco exposure. Patients with GFR < 60 ml/min/1.73 m^2 were mostly older > 70 years old, African-American (p-value <0.001), had underlying DM, HTN, and were more likely to be discharged to a skilled nursing facility (p-value <0.001). Patients who had GFR < 60 ml/min/1.73 m^2 had a higher risk of in-hospital death compared to those with GFR> 60 ml/min/1.73 m^2 (p-value <0.001).

Conclusions: Our data demonstrated higher mortality rates in COVID-19 positive African-American patients with GFR < 60 ml/min/1.73 m^2. It has been previously shown that ENC has a higher concentration of lower socioeconomic counties and an overall higher comorbidity index. Further data analysis is needed to determine if a GFR < 60 ml/min/1.73 m^2 conveys an additional mortality risk outside the lower socioeconomic status.

PUB002

Risk Factors and Clinical Outcomes of Hyponatremia in Patients with COVID-19 Admitted to St. Luke's Medical Center-Global City (SLMC-GC) from January 1, 2021, to December 31, 2021: A Case-Control Study

Jill Therese U. Au. *St Luke's Medical Center - Global City, Taguig, Philippines.*

Background: Studies have found that hyponatremia in COVID-19 can result from inflammation-induced non-osmotic release of antidiuretic hormone. This study was conducted to identify the risk factors associated with hyponatremia (Na < 135mmol/L) in COVID-19 patients. The clinical outcomes of COVID-19 patients with and without hyponatremia were also compared.

Methods: This case-control study included a total of 384 patients (192 patients each for the hyponatremic and normonatremic groups) aged 18 years old and above diagnosed with COVID-19 infection, who were admitted at SLMC-GC from January 1, 2021 to December 31, 2021. Data pertaining to the patients' demographic characteristics, comorbid conditions, drug exposure, and laboratory results upon admission were collected and analyzed. The clinical outcomes analyzed include in-hospital mortality, need for ICU admission, need for ventilator support, acute kidney injury, and length of hospital stay.

Results: Patients with hyponatremia were found to be significantly older with male predominance. The presence of acute kidney injury had a significant association with hyponatremia. As compared to the normonatremic group, patients with hyponatremia had higher creatinine levels upon admission as well as higher white blood cell count, neutrophil-to-lymphocyte ratio, absolute neutrophil count and inflammatory markers (ferritin, CRP, IL-6, procalcitonin) but lower absolute lymphocyte count. Hyponatremia in COVID-19 patients had also been found to carry about two to three times the risk for adverse outcomes, with a significantly higher proportion of prolonged hospitalization, acute kidney injury, in-hospital mortality, need for ICU admission and need for intubation. Binary logistic regression showed that the significant predictors of hyponatremia include age, presence of acute kidney injury, absolute lymphocyte count, and ferritin level.

Conclusions: Hyponatremia in COVID-19 patients is significantly associated with adverse clinical outcomes. Determination of serum sodium is rapid, inexpensive and widely available. It may be used in the local setting to identify COVID-19 patients at high risk for poor clinical outcomes who may benefit from more intensive monitoring and allow proper interventions to be put in place in a timely fashion.

PUB003

Dynamic Evolution of Renal Markers and Mortality Prediction in Hospitalized Hispanic Patients with COVID-19

Andrew Banuelos,[1] Rajdeep S. Gadh,[1] Wayne R. Kotzker,[1] Ivan Delgado-Enciso,[2] Martha A. Mendoza Hernandez,[3] Gustavo A. Hernandez-Fuentes,[2] Jose G. Esquivel,[2] Janet Diaz Martinez.[1] Hispanic Kidney Researchers. *[1]Florida Kidney Physicians, Coral Springs, FL; [2]Universidad de Colima, Colima, Mexico; [3]Mexican Institute of Social Security, Colima, Mexico.*

Background: Kidney dysfunction is common in hospitalized COVID-19 patients and is linked to higher in-hospital mortality. Mortality prediction studies often use renal function markers (BUN, eGFR, AKI) from admission or the first 48 hours. Few studies analyze the evolution of these parameters during hospitalization and their predictive capacity for survival or death. **Objective**: To assess the predictive power of BUN and eGFR for mortality at different time points during hospitalization in a cohort of hospitalized Hispanic COVID-19 patients.

Methods: Clinical data were collected at admission and at 2, 4, 6, and 8 days into hospitalization from a cohort of 515 COVID-19 patients at the General Hospital of the Mexican Social Security Institute, Mexico (February 2021 to December 2022). Using time-dependent ROC curve analysis, we calculated the area under the curve (AUC), sensitivity, specificity, and predictive values for BUN and eGFR(ml/min/1.73m2. Patients were stratified based on eGFR was ≥60 or<60 at admission. Values equal to or above the cutoff point were predictive of mortality for BUN and survival for eGFR. Predictive capacity was classified as 0.50-0.60 (failed), 0.61-0.70 (worthless), 0.71-0.80 (poor), 0.81-0.90 (good), and >0.90 (excellent).

Results: Mean age was 63.3±16.1 years, 61.9% being male. The median length of hospital stay was 7.0 days. BUN and eGFR predictive capacities were more relevant on days 6 [AUC, 0.775 and 0.672] and 8 [AUC, 0.790 and 0.659], respectively. BUN ≥ 25.5 on day 8 predicts death in patients with GFR ≥60 at admission, while patients with GFR< 60 require a BUN ≥ 57 for this parameter to predict mortality.

Conclusions: BUN had better predictive capacity for mortality than eGFR. A BUN value of 25.5 or higher on day 8 predicts death in patients with adequate renal function at admission, while patients with impaired renal function require a BUN level above 57 to predict mortality.

PUB004

Trend Analysis of Kidney Disease and COVID-19-Related Mortality, 1999-2020

Mohammad Gul Yousaf Khan,[2] Mohammad Ammar ur Rahman,[1] Luqman Munir,[1] Amna Khalid,[1] Ahsan Zil-E-Ali,[2] Umar Farooq.[2] NEURALKEy. *[1]King Edward Medical University, Lahore, Pakistan; [2]Penn State College of Medicine, Hershey, PA.*

Background: The interaction of kidney diseases and COVID-19 may present in various forms and may pose various challenges. Individuals with pre-existing kidney pathologies may face increased complications and risks if infected. On the other hand, some of the infected individuals with previously normal renal function have also been seen to develop AKI. The mortality due to COVID related kidney diseases is on the rise in the United States. In this study we explored these trends from 1999-2020, using age adjusted mortality rates (AAMR) to pinpoint incongruities between epidemiological groups.

Methods: Our study conducted an in-depth search of the CDC Wonder database, based on the incidence of sequalae of stroke-related Age-Adjusted Mortality Rate (AAMR) per 100,000 individuals. Employing Join point Regression Analysis, we assessed Parallelism and computed Annual Percent Changes (APC) with a 95% Confidence Interval. For a $p<0.05$, the test of parallelism was considered significant for unparallel.

Results: From 1999-2020, a total of 4778965 deaths were reported due to COVID related kidney diseases. The overall AAMR showed a rise from 1999-2011, with an APC of 0.38. Following this, the AAMR started to decline from 2011-2014, with an APC of -11.94. The AAMR then showed a rise again from 2014-2020, with an APC of 1.50. The highest mortality populations were males and African Americans. The geographical hotspots for mortality were rural and Midwest. Tests for parallelism revealed disparate trends across gender (p=0.0002), Black and White races (p=0.0089), urban versus rural demographics (p=0.001). However, the parallelism test in Midwest versus South (p=0.25) was not significant.

Conclusions: The recent rise in the mortality due to COVID related kidney diseases is concerning. Furthermore, the disparity among the demographic variables warrants more investigation, and the planning of targeted interventions.

PUB005

Dialysis Initiation Practices during the COVID-19 Pandemic among US Veterans in Veterans Affairs (VA) and Non-VA Settings

Virginia Wang,[1,2] Cynthia Coffman,[1,2] Cassie L. Meyer,[1] Lan Jiang,[3] Kaitlyn B. Goodwin,[1] Clarissa J. Diamantidis,[4] Ann M. O'Hare,[6,7] Vincent Mor,[3,5] Matthew L. Maciejewski,[1,2] Amal Trivedi.[3,5] *[1]Durham VA Health Care System, Durham, NC; [2]Duke University, Durham, NC; [3]Providence VA Medical Center, Providence, RI; [4]Wake Forest University School of Medicine, Winston-Salem, NC; [5]Brown University, Providence, RI; [6]VA Puget Sound Health Care System Seattle Division, Seattle, WA; [7]University of Washington, Seattle, WA.*

Background: Veterans undergoing dialysis are susceptible to fragmented care in both VA and non-VA settings and their initiation of dialysis may be particularly affected by disruptions in care during the COVID-19 pandemic.

Methods: In this retrospective cohort study, we compared dialysis initiation practices among Veterans initiating dialysis through the Veterans Affairs (VA) in VA or VA community care (VACC) (i.e., non-VA) settings in 2018-2022. Changes in dialysis initiation were assessed across COVID eras (January 2018-February 2020 [pre], March 2020-December 2020 [acute], January 2021-January 2022 [recovery]) and dialysis settings (VA and non-VA). Dialysis initiation outcomes included nephrology visit ≤12 months prior to dialysis onset, estimated glomerular filtration rate (eGFR) ≤90 days of dialysis onset, and receipt of arterio-ventricular (AV) access placement. Linear and logistic models were fit with inverse probability of treatment weights that adjusted for Veterans' demographic, clinical, and healthcare utilization characteristics, and area-level COVID infection and vaccination rates.

Results: In adjusted analyses, the 17,780 Veterans in the cohort initiated VA dialysis during the study period (58% pre, 19% acute, and 24% recovery COVID eras) and most (77%) received dialysis in VA community care settings. Overall, there was a diminishing mean rate of pre-dialysis nephrology visits across COVID eras (67% pre, 66% acute, 60% recovery; p-value <0.0001) that was present in both VA and non-VA settings. Across all COVID eras, mean eGFR was higher in VA (14.3 vs. 13.4 in VACC; $p<0.01$), indicating lower kidney function at dialysis initiation, and mean rate of AV placement was also slightly higher in VA (13% vs. 10% in VACC; $p<0.01$).

Conclusions: Among US Veterans, COVID-19 was associated with overall decrease in nephrology consultation prior to dialysis initiation. There were no observed changes in kidney function or AV placement at dialysis onset over time. However, differences in conditions of dialysis initiation among Veterans in VA and non-VA settings persisted throughout the pandemic. Future analysis should further examine pandemic-related outcomes in this vulnerable population.

PUB006

Evaluating Tubulopathy and Podocytopathy in COVID-19 Patients with Proteinuria Using Urinary NGAL and Podocalyxin Levels

Zeynep Ural. *Kirikkale Yüksek Ihtisas Hospital, Kirikkale, Turkey.*

Background: Clinical observations have shown that renal dysfunction is frequently seen in hospitalized COVID-19 patients. The mechanisms and pathways of kidney involvement in COVID-19 patients are not yet fully understood. Podocalyxin is an anionic transmembrane protein localized on the apical surface of glomerular podocytes. Podocalyxinuria indicates glomerular level damage to podocytes and/or the presence of apoptotic and necrotic podocytes in the urine. NGAL protein is freely filtered by the glomeruli and mostly reabsorbed by the proximal tubules. NGAL expression is rapidly induced in response to renal tubular epithelial cell damage and inflammation, and it is thought to be a marker of both acute and chronic kidney damage.

Methods: Our study includes patients with proteinuria and hypoalbuminemia who were hospitalized and followed up with a diagnosis of COVID-19 at Gazi University Faculty of Medicine Hospital (n=72) and a control group (n=48). Urinary podocalyxin and NGAL levels were measured in these patients.

Results: Podocalyxin and NGAL levels were significantly higher in proteinuric patients. NGAL levels were significantly associated with COVID-19 severity and disease mortality.(both p value <0.05= Correlation analysis of podocalyxin showed significantly higher levels in patients with proteinuria greater than 1000 mg/day.

Conclusions: Current literature does not provide studies showing whether the kidney damage seen in COVID-19 patients with proteinuria, hematuria, and GFR loss is due to direct viral damage to the kidney glomeruli and podocytes or related to the septic and hemodynamic condition. Therefore, assessing the impact on glomeruli and predicting patient and renal prognosis non-invasively without kidney biopsy by measuring urinary podocalyxin and NGAL in COVID-19 patients with proteinuria, hematuria, and renal dysfunction will be possible. This study is the first to investigate the presence of podocyturia in COVID-19 patients.

Cefepime's Neurotic Nexus: Complexities of Antibiotic-Induced Neurotoxicity

Daniela Carralero Somoza, Graciela M. Luna, Umair S. Ahmed, Kaitlyn Cariaga. *Lakeland Regional Medical Center Inc, Lakeland, FL.*

Introduction: Cefepime is a widely used fourth generation cephalosporin. It is primarily renally excreted, requiring dose adjustment in patients with deranged renal function. Cefepime-induced neurotoxicity, though rare, presents with neurological symptoms such as confusion, hallucinations and seizures. This case delves into the development of status epilepticus in a patient with renal insuffiency treated with cefepime.

Case Description: 68-year-old female with pertinent right nephrectomy presented with generalized weakness, vomiting and diarrhea to the emergency department. Investigations revealed a urinary tract infection and acute kidney injury. Serum creatinine was 7.51 mg/dl (baseline 1.10 three months prior, and 3.68 one month before). Intravenous (IV) cefepime was started. Three days after starting IV cefepime, patient developed progressively worsening encephalopathy, leading to airway compromise and subsequent intubation. CT and MRI brain showed no acute abnormalities, while EEG revealed epileptiform discharges. Neurology was consulted and diagnosed status epilepticus and patient was started on anti-seizure medication. As dose of IV cefepime was not renally adjusted, there was concern about cefepime neurotoxicity. IV cefepime was stopped and patient was started on hemodialysis. Mental status improved and no further seizures were noted.

Discussion: Cefepime has an elimination half life of 2.5 hours in patients with normal kidney function. This is increased with deranged kidney function. Risk factors for cefepime neurotoxicity include high dose, decreased renal clearance and increased penetration into the central nervous sytem as a result of dysfunction of the blood-brain barrier. Discontinuation of cefepime is the most important intervention. Sometimes dialysis is needed for rapid drug removal if symptoms persist. The low molecular weight and low protein binding facilitate its removal with dialysis. This case reinforces the importance of renally adjusting medications. A high index of suspicion is needed especially in patients with risk factors as the prognosis of cefepime neurotoxicity depends on early recognition and management. The diagnosis was cefepime neurotoxicity rather than uremia as patient's mental status improved after initial management and remained good despite worse renal parameters on her dyalisis days later on the stay.

PUB008

Cryptogenic Liver Cirrhosis and Hepatorenal Syndrome (HRS) Management in Developing Countries

Marcelo R. Bacci,[1,2] Fernanda R. Ranieri,[1] João Victor D. Ferreira.[1] *[1]Faculdade de Medicina do ABC, Santo Andre, Brazil; [2]Praxis Clinical Research, Santo Andre, Brazil.*

Introduction: HRS is a renal dysfunction secondary to liver failure and portal hypertension. Increased vasodilator circulation causes reduced effective blood volume, activation of the renin angiotensin-aldosterone system. This hormone storm has engulfed the kidneys, necessitating the exclusion of other potential causes of their failure. In the past few decades, HRS definition has changed, which has contributed to the difficulty in understanding a correct diagnosis. In this case report, we describe a HRS female patient with a late referral to the nephrologist after hospital discharge.

Case Description: A 62-year-old female presented with jaundice, ascitis and confusion, requiring hospitalization. She had a history of liver disease with no proper investigation and 15 years of evolution. A nephrologist was called upon admission due to kidney failure. She had no history of drug abuse, alcohol consumption, sepsis or viral infection. There was no answer with volume expansion. The medical team performed a liver biopsy but kidney biopsy was not considered. The medical team did not classify the HRS properly as no data of previous creatinine was available. The patient evolved to permanent conventional dialysis. Following discharge, the patient visited an outpatient

nephrologist which classified as HRS non-acute kidney injury(NAKI) due to acute kidney disease(AKD). The liver biopsy revealed cryptogenic liver cirrhosis.

Discussion: There has been a recent change in the classification of HRS. What used to be HRS1 became HRS-AKI.HRS2 transitioned to HRS-NAKI, which further categorizes into AKD or CKD. We still have a thorough understanding of HRS new acronyms. It is common practice in developing countries to categorize HRS patients without considering their specific causes due to lack of resources. Brazil is a developing country with a universal health system, however there are few hospitals with proper liver-kidney support and integrated electronic medical records. Kidney and liver biopsies are not easy to get at the most of these hospitals. Liver dialysis is not available and usually these patients need to wait for an outpatient nephrologist for adequate treatment. In summary, knowledge about the new HRS classification still requires attention. A better educational training with a robust differential diagnosis and better access to the patient's medical history are keys to success.

PUB009

Incidence of AKI after Cardiac Surgery

Varisha Shahzad, Dabhóg Boyle, Orlaith Corcoran, Denise M. Sadlier.
Mater Misericordiae University Hospital, Dublin, Ireland.

Background: Cardiac surgery is a life-saving intervention, however, the development of cardiac surgery–associated acute kidney injury (CS-AKI) is associated with longer hospital stay, higher hospitalization costs and increased postoperative mortality. Here, the incidence of CS-AKI is described in patients undergoing cardiac surgery over a 1-year period examining the major risk factors in this patient population.

Methods: Local databases were used to collect data. 429 patients underwent cardiac surgery between the 1st January 2023 and 1st January 2024. For all patients, demographic data was collected including age, gender, past medical history and type of cardiac surgery. Serum creatinine was recorded on day 0, 1, 3, 5 and on discharge. Patients with end stage kidney disease requiring dialysis were excluded (n = 4). AKI was defined by AKIN criteria.

Results: Majority of patients had normal renal function pre-operatively (n = 380/425), of these 32% (n = 138) developed CS-AKI. Over 80% of these patients developed an acute kidney injury (AKI) on the first postoperative day. Out of these, 23 were female, 115 were male and 77 people were aged above 65 years. Around 81% (n=112) developed stage 1, 8% (n=11) stage 2 and 11% (n=15) stage 3 AKI. A total of 56 patients were active smokers of these only 25% (n = 14) developed CS-AKI. Breakdown of risk factors for the 138 patients with CS-AKI were as follows; hypertension (n=99), dyslipidaemia (n=75), heart disease (n=61), diabetes mellitus (n=41), obesity (n=14), smoking (n=14), structural abnormality (n=8), one patient had previously required RRT for a contrast-induced AKI. A large proportion of patients with stage 3 AKI (n=11) had undergone a cardiac bypass. The average duration of renal replacement therapy (RRT) for those requiring it (n=13) with stage 3 AKI was 17.4 days, of these 5 patients recovered renal function to be dialysis independent. While 6 other patients requiring RRT died from complications of surgery. The mean serum on discharge was 117.7 umol/L (range = 54 – 493 umol/L).

Conclusions: A post-operative AKI can have short- and long-term complications. Even if the renal function initially recovers patients are still at risk of developing premature chronic kidney disease. Studies are required to develop a system for AKI risk prediction in the setting cardiac surgery.

PUB010

Filtration Fiasco: A Case of Tenofovir-Alafenamide False Creatinine Elevation

Jeshanah Johnson, Jacob A. Nysather. *University of Cincinnati, Cincinnati, OH.*

Introduction: Human Immunodeficiency Virus (HIV) is a viral infection most transmitted by sexual contact and injection drug use. The development of anti-retroviral therapy has positively impacted life expectancy and reduced the progression of disease.[1] HIV treatment is composed of an integrase inhibitor and reverse transcriptase inhibitor.[2] Commonly used Biktarvy includes Tenofovir alafenamide (TAF), a reverse transcriptase inhibitor. This case explores the effect of TAF on the interpretation and monitoring of renal function.

Case Description: We report a case of a 50-year-old male with TAF false serum creatinine (SCr) elevation. He was diagnosed with HIV on a screening test (HIV-1 viral load 10,100 copies/mL) and started on Biktarvy. Pre-therapy SCr was 1.3 mg/dL and rose to a peak of 2.3 mg/dL six months later. Evaluation for acute kidney injury was unrevealing and other historical tenofovir nephrotoxicity including proximal tubulopathy and Fanconi Syndrome were ruled out. No signs of chronic kidney disease associated abnormalities were seen. A Cystatin-C (CysC) of 1.04 mg/L (SCr 1.77 mg/dL) showing a discordance. A 24-hr creatinine clearance of 46 and 24-hr urea nitrogen of 25 for a mean GFR of 35 (3 liters of volume), aligning with SCr estimation. A Tc-99m nuclear GFR scan showing a GFR 113 mL/min/1.73sq.m aligning with the CysC eGFR. The patient's SCr stabilized around 1.7 mg/dL. Of note, the patient remained TAF throughout evaluation and remains on treatment given disease control (HIV-1 viral load <20 copies/mL).

Discussion: TAF therapy has largely replaced previously used tenofovir disoproxil fumarate (TDF) which is associated with proximal tubular toxicity at the mitochondria. In this case, the presumed cause of SCr and CysC discordance is inhibition of creatinine secretion by unclear mechanism (e.g. trimethoprim). A small elevation in SCr of 0.1mg/dL was noted on initial clinical trials.[3] Our case demonstrates the need for individualized evaluation of SCr changes in those taking TAF due to the potential clinical impact on management of HIV.

PUB011

Incidence of Cardiac Surgery-Associated AKI in a Third-Level Hospital

Ydris Z. Rosillo-Salgado, Mario Alamilla-Sanchez, Jose L. Torres Cuevas.
Instituto de Seguridad y Servicios Sociales de los Trabajadores del Estado, Mexico City, Mexico.

Background: Acute kidney injury (AKI) is a common complication in cardiac surgery patients, the incidence of cardiac surgery-associated AKI is still around 40% increasing mortality, development of chronic kidney disease and has a significant impact on global health care costs. Identication risk factors that can prevent AKI

Methods: Prospective cohort included 51 patients who had cardiac surgery

Results: The mean preoperative eGFR was 75 ml/min/1.73 m2. The 37 of 51 participants (72%) developed AKI as defined by the KDIGO until 3 days after surgery. Stage 1 occurred in 26 (50.9%); stage 2 happened in 8 (15.6%) and stage 3 was in 3 (5.88%) patients of which 1 (1.9%) required hemodialysis. Day 1 after surgery AKI was present in 4 (10.8%), day 2 AKI occurs in 25 (67.5%) and day 3 AKI happened in 8 (21.6%) patients. All surgeries were elective and cardiopulmonary bypass (CPB) was utilized in 100%, and CPB mean time was 96.4min and aortic clamping mean time was 73.6min. The most frequent cardiac surgery was coronary artery bypass graft (CABG) 25 (49%), valvular surgery 24 (47.1%) and combined 2 (3.9%) in which AKI was present in 36%, 75% and 100% respectively according to the type of surgery. Patients with AKI had an average postoperative fluid balance of 3.7L vs 2.4L without AKI. Venous congestion with portal flow pulsatility >30% and abnormal morphology of renal intraparenchymal venous flow arises in 12 (32.4%) of 37 patients with AKI. On the 1st postoperative day, 9 (56%), on 2nd day 3 (50%) and on 3rd day 1 (33%) related to venous congestion. Overall mortality was 13.7% (n= 7), while for AKI mortality rate was 21% (n=7).

Conclusions: AKI was present in 70% of patients undergoing multifactorial cardiac surgery including type of surgery, drug use, cardiac dysfunction and venous congestion.

Comparative Outcomes and Risk Analysis of Kidney Replacement Therapy in Adult Patients with AKI

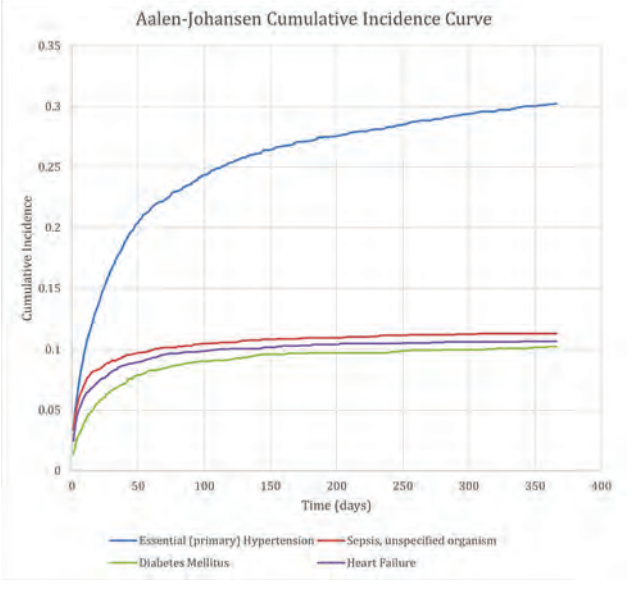
Sanat Subhash, Rupesh Raina, Prakash S. Gudsoorkar. *Akron Nephrology Associates/ Cleveland Clinic Akron General Medical Center, Akron, OH.*

Background: Acute kidney injury (AKI) is a condition present in nearly 7% of hospital admissions and 30% of ICU admissions with significant mortality and is linked to several major comorbidities including diabetes, sepsis, and heart failure. We utilized aggregated electronic healthcare patient data to analyze the incidence of AKI comorbidities, characterize epidemiological data, and compare patient outcomes between those on IHD (Intermittent Hemodialysis) and CKRT (Continuous Kidney Replacement Therapy).

Methods: A retrospective cohort assessment was performed using the TrinetX database. We studied the incidence rates of diabetes mellitus, primary hypertension, heart failure, and sepsis in ICU HD AKI patients at a 365-day period preceding AKI onset. Additionally, we evaluated clinical outcomes among ICU AKI HD patients compared to CKRT patients by measuring rehospitalization rates, intensive care unit (ICU) readmission, mechanical intubation/ventilation, and all-cause mortality risk at 30, 90, 180, and 365-days post-treatment.

Results: Hypertension (20.2%), sepsis (9.23%), and diabetes mellitus (7.28%) were the most common comorbidities in the AKI patient cohort. Comparative outcomes analysis showed increased mortality and ICU readmission in the CKRT AKI patient cohort and higher rehospitalizations in the HD AKI patient cohort. Both groups demonstrated similar ventilation/intubation rates.

Conclusions: Our ICU CKRT and HD cohort comparison indicates a significant increase in mortality and ICU readmission rates among CKRT patients. HD patients reported higher rehospitalization rates, while ventilation/intubation rates were similar between cohorts. The competing risks analysis for our HD AKI cohort demonstrated strong links between comorbidities and patients needing HD treatment.



PUB013

Valacyclovir-Induced Crystal Kidney Failure: An Underestimated Adverse Effect of a Well-Known Drug

Abraham Bell,[1] Stefan Milutinovic,[1] Gautam Maddineni,[1] Isaac Bell,[2] Meloney Oliveira.[1] *[1]Florida State University, Tallahassee, FL; [2]Nova Southeastern University, Fort Lauderdale, FL.*

Introduction: Valacyclovir is an oral antiviral drug used to treat herpetic infections. Valacyclovir related acute kidney injury (AKI) is described as a rare side effect. The mechanism of nephrotoxicity includes crystal deposition in the renal tubules resulting in intratubular obstruction and local interstitial inflammation. The risk of AKI increases with other risk factors for AKI are present such as chronic kidney disease, hypovolemic, overdose of the medication or concomitant use of known nephrotoxic medications. We used the FDA Adverse Events Reporting System (FAERS) to quantify the reported incidence of valacyclovir induced AKI.

Case Description: A 60 yo lady with a past medical history of hypothyroidism and hypertension presented to the ER with new visual hallucinations. Her symptoms were associated with new onset nausea, vomiting and generalized weakness. Five days prior to her acute presentation, she had been prescribed a 7-day course of valacyclovir to treat an acute herpes zoster lesion. Labs revealed a serum creatinine of 7 mg/dL (2 weeks prior serum creatinine was 0.8 mg/dL), UA with brown granular casts. Urine eosinophils were negative. She received IV fluids in the emergency department that were continued on admission and her renal function started to improve.

Discussion: Data published in FAERS suggests that the rate of AKI with concomitant valacyclovir is greater than 7.49% in over 1,434 cases since 1995. It is the second most common side effect associated with the drug reported in FAERS. The rate of AKI with concomitant acyclovir is 8.63% in reported cases since 1995, which is not significantly more in comparison to valacyclovir.

PUB014

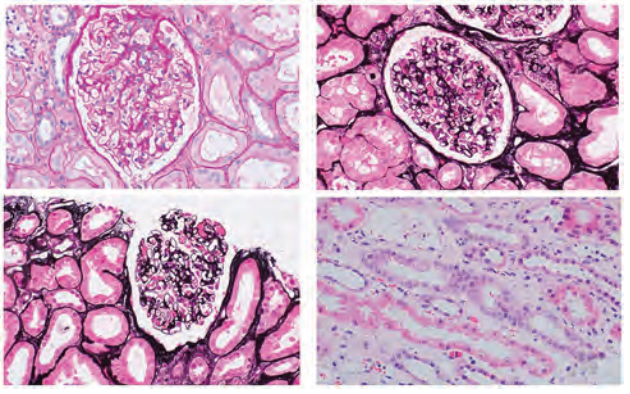
Vaping-Induced Acute Tubular Necrosis

Indira Tata, Victor A. Canela-Samaniego. Dallas Nephrology Associates. *Medical City Denton, Denton, TX.*

Introduction: E-cigarettes have gained popularity as a smoking cessation tool and perceived as a safer alternative to traditional cigarettes. These devices contain harmful compounds such as nicotine, heavy metals, and carcinogens. Recognizing their potential to cause direct lung injury and kidney damage is crucial for nephrologists and clinicians. This case report highlights AKI in a patient using e-cigarettes daily.

Case Description: A 60-year-old male with history of Hypertension presented with one-week of headache, and shortness of breath. His BP medications included amlodipine, Hydrochlorothiazide, and losartan. On exam, he was hypertensive with a BP of 240/130, appeared volume overloaded, and was progressively hypoxic. An echocardiogram revealed normal cardiac function. Initial lab tests showed a BUN of 39 mg/dl and creatinine of 2.29 mg/dl, normal electrolytes; LFTs; and CK. Complement levels, ANCA, anti-GBM titers, and infectious serologies were negative. Urinalysis showed no WBCs, eosinophils, granular casts, RBCs, protein, or crystals. Utox was negative, and a renal US showed normal kidneys with no hydronephrosis. Despite adequate diuresis, his oxygenation worsened. He reported increased daily use of e-cigarettes. Steroids were started, and his hypoxia quickly improved. A bronchoscopy with bronchoalveolar lavage (BAL) suggested Diffuse Alevolar Hemorrhage. Despite holding diuretics, his renal function continued to decline, leading to oliguria and necessitating urgent dialysis. A kidney biopsy revealed Acute Tubular Necrosis with 20% tubular atrophy, no immune component, and no microthrombi. While his uremic symptoms improved, he remains dialysis-dependent to this day.

Discussion: This case highlights severe acute kidney injury associated with vaping. Proposed mechanisms include oxidative stress and direct toxic cellular injury. Compounds in e-cigarettes, such as nicotine, propylene glycol, glycerol, and flavorings like diacetyl, have been implicated in cellular damage and inflammation. Healthcare providers should be aware of the risks associated with e-cigarettes, including potential kidney injury.



PUB015

From Tubular Injury to Membranoproliferative Glomerulonephritis: A Complex Case of AKI

Adrian Llama,[1] Alejandro S. Garcia.[2] *[1]Yale University School of Medicine, New Haven, CT; [2]Yale New Haven Health System, New Haven, CT.*

Introduction: Acute kidney injury (AKI) is a common complication in hospitalized patients, with intrinsic causes like acute tubular injury (ATI), interstitial nephritis (IN), and glomerular injury accounting for 30% of cases. Rarely, aminoglycosides in antibiotic-loaded spacers for prosthetic joint infections can cause ATI and glomerular toxicity. IN is often drug-related, with penicillins strongly associated. Membranoproliferative glomerulonephritis (MPGN), a type of glomerular injury, can be triggered by infections.

Case Description: We present a 71-year-old woman with comorbidities including RA on prednisone and bilateral knee replacements who developed septic shock from a prosthetic joint infection. Despite surgery and tobramycin-vancomycin spacers, she had poor wound healing. Further debridement, spacer placement, and flap surgery were performed. Prednisone was reduced due to poor healing. Renal failure developed 14 days post-op without hemodynamic insults. Urine showed granular and RBC casts. Biopsy revealed severe ATI from tobramycin induced tubular injury, AIN, and MPGN. This case highlights the importance of multifactorial AKI. ATI was likely the main driver due to high-dose tobramycin spacers, but IN and MPGN suggest roles for drug exposure, and infection.

Discussion: Renal biopsy is crucial for rapidly progressive AKI with RBC casts, identifying pathological processes for targeted treatment. High suspicion for multifactorial AKI is needed. The patient's ATI was linked to prolonged exposure to tobramycin spacers, with higher doses and longer duration increasing AKI risk. IN treatment is usually corticosteroids, but evidence is limited and was deferred to avoid poor wound healing and recurrent infection. Prednisone reduction may have contributed by unmasking doormant AIN. MPGN was also present with immunoglobulin and complement deposits. Ampicillin was stopped, infection treated, steroids deferred, and spacer remained to avoid surgical risks. She made a full recovery.

PUB016

Sex-Based Differences in Cisplatin-Induced Nephrotoxicity

Dianet Sanchez Vega, Dana Hammouri, Barbara O'Steen, Leah J. Siskind, Levi J. Beverly. *University of Louisville School of Medicine, Louisville, KY.*

Background: Cisplatin is a potent chemotherapeutic agent, but its efficacy is limited by dose-dependent nephrotoxicity, with 30% of patients developing kidney injury, subsequently increasing the risk of chronic kidney disease. Sex-based differences are implicated as a biological variable of cisplatin-induced nephrotoxicity (CIN) and in immunological responses, but are greatly understudied. Given the crucial role of the immune system in mediating CIN, we hypothesize that sex-based immunological variations contribute to differential susceptibility to CIN.

Methods: Male and female B6:129 mice were administered weekly doses of vehicle or cisplatin (5 or 7 mg/kg) for four weeks. Kidney function (transdermal GFR measurements), and immunological differences in the kidney (flow cytometry) were assessed.

Results: Males treated with cisplatin exhibited a significant increase in kidney leukocytes, specifically resident macrophages. Transdermal GFR measurements showed a trending decrease in treated male mice. Conversely, treated female immune response was not statistically different than vehicle treated. Transdermal GFR measurements showed no significant difference between vehicle treated females and cisplatin treated females.

Conclusions: Data indicate sex differences in a repeated low dose cisplatin model. Data suggest that kidney function in females, but not males was preserved in this model and that this could be in part be due to differences in immunological responses to cisplatin. This study highlights the importance of considering sex as a biological variable in CIN and advocates for sex-specific strategies to mitigate its adverse effects. Further studies will aid in gaining mechanistic insight for these sex specific differences for the development of more effective treatments.

PUB017

Levothyroxine as an Unusual Cause of Acute Interstitial Nephritis

Hassan H. Allahrakha, Roberto L. Collazo-Maldonado. *Methodist Dallas Medical Center, Dallas, TX.*

Introduction: Acute interstitial nephritis (AIN), a common cause of acute kidney injury (AKI), is accompanied by histologic findings of interstitial inflammation, edema, and tubulitis. We report a patient who presented with AIN after starting levothyroxine, a medication used to treat hypothyroidism.

Case Description: A 79-year-old male with a history of hypothyroidism and chronic kidney disease (CKD) presented with a two-week history of a painless, urticarial rash and intermittent diarrhea after starting levothyroxine. Laboratory findings were significant for a serum creatinine of 3.57 mg/dL, potassium of 5.6 mmol/L, CO_2 of 11 mmol/L, and peripheral eosinophilia (eosinophils 12%). Serologic work-up showed normal levels of C3, C4, antinuclear antibodies, antineutrophil cytoplasmic antibodies, rheumatoid factor, and anti-glomerular basement membrane antibodies. Serum and urine protein electrophoresis was normal; however, urinalysis showed trace proteinuria. Renal ultrasound revealed echogenic kidneys consistent with CKD. The patient was diagnosed with AIN, and started on treatment for the AIN with IV Solu-Medrol (500 mg) for three days. He was discharged on a prednisone taper. The patient's AKI, metabolic acidosis, and rash improved following IV steroids. He was switched from Mylan Levothyroxine to Armor Thyroid for thyroid supplementation at discharge.

Discussion: Levothyroxine is a rare cause of AIN. AIN should be considered in cases of unexplained AKI, especially after new medication administrations. This case emphasizes the importance of considering levothyroxine as a cause of AKI and AIN. In addition, the offending agent should be discontinued upon a diagnosis of drug-induced AIN.

PUB018

The Role of Terlipressin in AKI Secondary to Hepatorenal Syndrome (AKI-HRS)

Syeda S. Bukhari, Subodh J. Saggi, Susan Grossman. *SUNY Downstate Health Sciences University, New York City, NY.*

Introduction: Terlipressin is the most common vasoconstrictor used worldwide. It can be administered as a first-line agent for treatment of Acute Kidney injury secondary to Hepatorenal Syndrome. The pathophysiology includes increased intrahepatic resistance and vascular tone. Activation of the vasodilatory response leads to both splanchnic and systemic vasodilation. Progressive vasodilation leads to vasoconstrictive system activation, resulting in decreased blood flow to kidneys and the development of Acute kidney injury.

Case Description: We represent a case of a 74-year-old male with a past medical history of decompensated cirrhosis secondary to alcohol use disorder and HCV infection, HTN, OSA, Atrial flutter, and COPD presented to the Emergency Department with a three-day history of abdominal pain, distension and shortness of breath. On presentation vitals were B.P 108/61, HR>110. Physical examination showed a distended abdomen with ascites. Labs included serum creatinine>2.8 (baseline serum creat>0.9) and cystatin C 2.68. Abdominal sonogram normal. The patient was admitted to MICU for Decompensated Cirrhosis complicated with Hepatorenal syndrome and hepatic encephalopathy. The patient was given albumin challenge 25gm q6H, midodrine and octreotide for 2 days, and Terlipressin for 3 days. Lactulose and rifaximin was also started. Renal function markedly improved from serum creat 2.8 to serum creat 1.2. after the terlipressin was initiated. The patient got clinically better and was downgraded to floors.

Discussion: In one of the large randomized controlled trials, the efficacy of terlipressin was proven with some additional side effects of pulmonary edema. Therefore, caution should be taken before using terlipressin in patients with volume overload like anasarca, jugular venous distention, hypoxemia secondary to pulmonary congestion, and elevated right ventricular systolic pressures. Other possible options for treatment of AKI-HRS include placement of Trans jugular intrahepatic portosystemic shunt to decrease portal hypertension and Liver transplantation with kidney transplantation if there was prolonged damage to the kidneys. AKI-HRS prevention includes preventing volume depletion through careful use of diuretics, and lactulose, prevention of variceal bleeding, and discontinuation of nephrotoxic medications such as Ace/Arbs, Nsaids, contrast, and certain antibiotics.

PUB019

Prevalence of AKI in Patients Treated with Cisplatin

Jose L. Ortega, Enrique F. Morales Lopez, Mario Alamilla-Sanchez, Ydris Z. Rosillo-Salgado, Jose L. Torres Cuevas, Carolina Gonzalez-Fuentes, Victor M. Ulloa Galvan, Martin B. Yama Estrella, Jorge D. Salazar Hurtado, Jesús O. Rubio. *Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico.*

Background: Cisplatin is a potent chemotherapy used in a wide spectrum of malignant tumors, however it has been associated to nephrotoxicity manifested by acute kidney injury and electrolyte disorders. The main objective of this study is to describe the frequency and the outcomes in patients with nephrotoxicity induced by cisplatin.

Methods: Retrospective cohort of 30 patients treated with cisplatin in a single Mexican third level healthcare center, data were collected from electronic clinical records. Descriptive analysis was performed with central tendency characteristics. Univariate logistic regression (odds ratios [OR], 95% CI) was used to evaluate renal outcomes and mortality

Results: Of the 30 participants, 21 (70%) were men, the more frequent comorbidity was arterial hypertension, 7 patients (23.3%) and only one patient had the diagnosis of chronic kidney disease. The median of glomerular filtration rate was 67 (55-77), 15 (50%) had acute kidney injury and 8 (26.7%) progressed to acute kidney disease, the mortality in the follow up was 10%. The more frequent electrolyte disorder was hypomagnesemia recorded in 16 (53.3%) of the participants, 14 (46.7%) was moderate (0.9-1.6 mg/dl), no severe hypomagnesemia (<0.9 mg/dl) was identified. Acute kidney injury was not associated to mortality but patients who had progression to acute kidney disease had a significant risk of mortality with a OR= 1.42, 95% CI, (1.11-1.81).

Conclusions: Nephrotoxicity induced by cisplatin is mainly manifested by acute kidney injury and hypomagnesemia, identified in 50% and 53.3% respectively. Patients with no recovery and progression to acute kidney disease had a significant risk to mortality, the limitation to aggressors of kidney function after nephrotoxicity induced by cisplatin could influence in the patient's prognostic.

PUB020

A Case of Allopurinol-Induced Toxic Epidermal Necrolysis Complicated by Kidney Failure

Steven Pham,[1] Gabriel C. Graham,[1] Kayla Nguyen.[2] *[1]Unity Health, Searcy, AR; [2]Kaiser Permanente, Bakersfield, CA.*

Introduction: Toxic epidermal necrolysis (TEN) is a life-threatening condition marked by extensive blistering, rapidly developing exanthema, and mucosal involvement, with mortality exceeding 30%. Acute kidney injury (AKI) is defined by a sudden decline in kidney function, characterized by elevated creatinine level or reduced urine output. AKI is associated with a high incidence in TEN cases, but the full manifestation remains unclear. We report a case of allopurinol-induced TEN leading to severe oliguria and AKI.

Case Description: An 89-year-old female presented with a full-body rash. Two weeks prior, she was hospitalized, during which she received rocephin, and was discharged with a prednisone taper and diphenhydramine as needed. Skin biopsy at that time showed lichenoid dermatitis secondary to allopurinol that was started two weeks earlier. Upon rehospitalization, she had a diffuse, painful macular rash covering 65-75% of her body. Her dermatological symptoms worsened daily and there was positive Nikolsky's sign along with numerous bullae. Skin sloughing affected her torso and mucous membranes. Repeat skin biopsy confirmed TEN. Her creatinine rose from 2.3 mg/dL to 5.3 mg/dL, with inadequate urine output despite adequate fluid resuscitation and oral intake given through a nasogastric tube. Transfer to any nearby tertiary burn centers was not feasible due to the unavailability of a skin biopsy result at that time. After discussing with her family, a decision was made to move towards comfort-directed care due to a significantly poor prognosis. She expired shortly after care withdrawal.

Discussion: Managing TEN is challenging due to invasive skin exfoliation, with current protocols primarily providing supportive care. Extensive fluid loss from wounds can decrease renal blood flow if not promptly resuscitated. The loss of extracellular fluid and albumin, compounded by oliguria, disrupts protective barriers and facilitates bacterial translocation. Infections, due to the compromised skin barrier, can precipitate renal dysfunction. Additionally, stress-induced vasoconstriction from skin exfoliation exacerbates renal impairment. Consequently, AKI in TEN is associated with a high risk of sepsis and multi-organ failures, indicating a poor prognosis.

PUB021

Atypical Case of Hemolytic Uremic Syndrome Caused by Shiga Toxin-Producing Aeromonas Species

Soloman Kreik.[2,1] *[1]University of Michigan, Ann Arbor, MI; [2]San Ysidro Health, San Diego, CA.*

Introduction: Hemolytic uremic syndrome (HUS) is a leading cause of acute kidney injury in infants and young children, rarely effecting adults. It is defined as a triad of renal insufficiency, hemolytic anemia, and thrombocytopenia associated with shiga-like toxin (SLT). SLT is an antigen associated with diarrhea and plays a role in the pathogenesis of HUS. Commonly, the toxin is produced by E. Coli or Shigella species; however, recent studies show active SLT produced by Aeromonas spp. We present an atypical case of HUS caused by SLT producing A. hydrophila.

Case Description: A 77 year old female with past medical history of hypertension presented with one day of worsening lethargy. The patient complained of bloody diarrhea and diffuse abdominal pain. She endorsed eating raw oysters a day prior. On examination her abdomen was diffusely tender to palpation. Initial labs revealed a creatinine of 3.1 hemoglobin of 10.1 and a platelet count of 102. CBC and CMP were otherwise unremarkable. The patient was bolused with normal saline and started on maintenance fluids. Peripheral blood smear returned with schistocytes, LDH was elevated at 346 and haptoglobin was low at 28. The patient's stool antigens returned positive for Shiga toxin and blood culture showed Aeromonas Hydrophila bacteremia. At day 9 the patient's renal function subsequently returned to baseline.

Discussion: HUS is a microvascular occlusive disease that damages the glomeruli due to accumulation of platelets and sheared red blood cells. Isolation of A. hydrophila producing SLTs is concerning, as these toxins are associated with HUS. Aeromonas spp. producing SLTs could be an emergent pathogen in the pathophysiology fo HUS. This was a rare phenomenon, which is now proven by PCR amplification of the stx1 and stx2 gene in many similar cases. Our patient's HUS diagnosis demonstrated a prodromal illness of diarrhea, development of renal failure, thrombocytopenia and anemia. Early identification will allow prompt management and the prevention of long-standing renal failure.

Lab results on admission

Test	Patient	Reference range
Creatinine	3.1 mg/dL	0.6 – 1.1 mg/dL
Hemoglobin	10.1 g/dL	11.6 – 15 g/dL
Platelet count	102,000 µL	150,000 – 450,000 µL
LDH	346 U/L	140 – 280 U/L
Haptoglobin	28 mg/dL	41 – 165 mg/dL

PUB022

An Unusual Case of Retroperitoneal Fibrosis Masking Severe Hydronephrosis

Garo Kalfayan,[1] Arian Gower,[1,2] Jasprit Takher.[1] *[1]Los Robles Regional Medical Center, Thousand Oaks, CA; [2]Renal Consultants Medical Group, Thousand Oaks, CA.*

Introduction: Acute kidney injury (AKI) increases morbidity and mortality. Hydronephrosis is dilatation and distension of the renal collecting system of one or both kidneys due to obstruction of urine outflow distal to the renal pelvis. This a unique case as the degree of hydronephrosis is being undervalued due to the retroperitoneal fibrosis.

Case Description: A 75 year old female presented with progressively worsening abdominal pain. Initial laboratory evaluation demonstrated blood urea nitrogen (BUN) of 19 mg/dL and creatinine of 1.09 mg/dL. Lab values approximately 2 years prior were 10 mg/dl and 0.60 mg/dl. Computed Tomography showed extensive inflammatory changes in the lower pelvis, centered mostly around the cervix and extending into bilateral lower retroperitoneum. Ultrasound demonstrated very mild bilateral hydronephrosis. Nuclear medicine renal with Lasix showed significant renal impairment with an element of renal obstruction that cannot be excluded. Creatinine worsened to 6.46 mg/dl and BUN 48 mg/dL. It was hypothesized that imaging was incorrectly portraying the degree of hydronephrosis, and potentially it may be worse than a mild degree. Right sided percutaneous nephrostomy tube was placed with 2,175 mL output in 24 hour period. Creatinine improved to 3.76 mg/dL and BUN 46 mg/dL. Ultrasound six days later confirmed resolution of hydronephrosis, and return of creatinine to 0.48 mg/dL and BUN to 14 mg/dL.

Discussion: The resolution of hydronephrosis and AKI after percutaneous nephrostomy tube placement with significant output confirmed the hypothesis that imaging was potentially inaccurately portraying the degree of hydronephrosis. This can help guide future treatment when considering whether retroperitoneal fibrosis may be masking the degree of hydronephrosis.

Retroperitoneal fibrosis appreciated on Coronal CT Abdomen (red arrow)

PUB023

Interstitial Nephritis with Tenofovir-Containing Pre-exposure Prophylaxis (PrEP)

Matthias Bergmann,[1] Mark E. Williams,[2,1] Nathan H. Raines.[1] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Joslin Diabetes Center, Boston, MA.*

Introduction: Use of pre-exposure prophylaxis (PrEP) for people at high risk of HIV infection has increased worldwide. Emtricitabine/tenofovir disoproxil (TDF) has been most used but is known to rarely cause tubular dysfunction and tubular necrosis (TN) through drug accumulation and mitochondrial damage. Emtricitabine/tenofovir alafenamide (TAF) has been approved for PrEP as an alternative agent with less nephrotoxicity, attributed to better plasma stability and lower plasma levels of the active agent. We present the case of a 51-year-old man using TDF-based PrEP who developed acute kidney injury (AKI) from interstitial nephritis (IN).

Case Description: A 51-year-old man with type 1 diabetes mellitus on insulin injections, hypertension on amlodipine, and HIV-PrEP with emtricitabine/tenofovir underwent urgent renal biopsy for AKI. Creatinine was elevated to 3.9 from 1.6 mg/dL at a 3-months follow-up visit and increased further to 4.6 mg/dL within one week. Urine albumin to creatinine ratio (UACR) had increased from 233 to 826 mg/g. A1c was stable at 6.7%, chemistry was without any significant abnormalities, and renal ultrasound was unremarkable. Complement levels were normal and serum protein electrophoresis showed no monoclonal abnormalities. HBsAg, HCV-Ab, and HIV screen were negative. Urine sediment showed only few fine granular casts. Renal biopsy showed IN. He was initiated on 60 mg prednisone daily for two weeks followed by a slow taper. Tenofovir-containing PrEP was discontinued. Within two months, creatinine decreased to 2.24 from 4.67 mg/dL and UACR decreased to 172 from 826 mg/g.

Discussion: We report the case of a 51-year-old man using tenofovir-containing HIV-PrEP who presented with AKI and underwent renal biopsy showing IN. TDF has been described to cause TN while TAF is thought to be less nephrotoxic. Our patient was initially considered for conversion to TAF due to suspected tenofovir toxicity. However, renal biopsy showed IN. Creatinine and UACR decreased within two months of initiation of high-dose prednisone and discontinuation of all tenofovir-containing agents. This case emphasizes the importance of a renal biopsy for AKI with PrEP to avoid missed treatment opportunities. Our patient would likely have been continued on an alternative tenofovir-containing agent and would not have been treated with glucocorticoids without the histopathologic diagnosis of IN.

PUB024

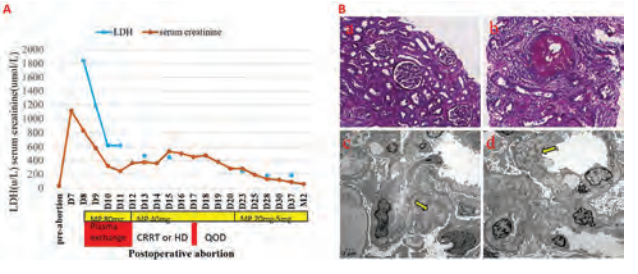
Complete Recovery from AKI: A Rare Case of Postpartum Atypical Hemolytic Uremic Syndrome

Ling Hong, Zhihua Zheng. *The Seventh Affiliated Hospital Sun Yat-sen University, Shenzhen, China.*

Introduction: As a critical disease in pregnancy, atypical hemolytic uremic syndrome (aHUS) features thrombocytopenia, acute kidney injury and the non-immune microangiopathy degeneration of hemolytic anemia. Its clinical course is disruptive and progressive. Pregnancy-related aHUS mostly progresses to end-stage renal disease (ESRD) with a high incidence. Here, a pregnant woman who developed hemolytic anemia and acute renal failure after induced abortion was reported.

Case Description: During her third month of pregnancy, a female aged 45 underwent an artificial abortion one month ago. One week after the abortion, she developed increased vaginal bleeding, abdominal pain and oliguria. Serum creatinine (Scr) increased from 36 to 1,114 umol/L. Laboratory examination showed hemolytic changes: increased proportions of helmet cells in peripheral blood (11%), significantly increased lactate dehydrogenase (LDH, 1,845 U/L), decreased haptoglobin (< 0.0706 g/L) and decreased platelets (38*10^9/L). The Coombs test was negative. She was diagnosed with thrombotic microangiopathy (TMA). Renal biopsy showed that renal tubule epithelial cells were granular denaturated and shed to form a bare basement membrane under a light microscope. In addition, electron microscopy showed endothelial cell swelling with loss of fenestrae and subendothelial electron-lucent widening. C5b-9 exhibited a significant increase by the quantitative detection of complement-related indicators, which was classified as aHUS. Corticosteroid impulse therapy combined with plasma exchange, the transfusion of fresh frozen plasma, hemodialysis and other treatments were given successively. Consequently, urine volume completely recovered, and Scr decreased from 1,184 to 78 umol/L. The patient was off dialysis, and hematological indicators were in complete remission.

Discussion: Postpartum acute kidney injury can be caused by a variety of reasons, of which the rare cause of aHUS can be life-threatening. The outcome of complete renal function recovery in this case confirmed that timely identification and early treatment can save patients' lives, preserve renal function, and avoid dialysis.



PUB025

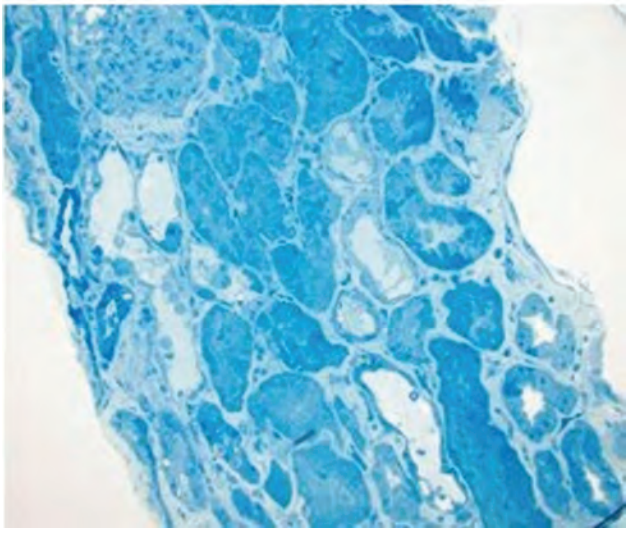
Toxic Attack: Organophosphate-Induced Acute Tubular Necrosis

Garo Kalfayan,[1] Arian Gower,[1,2] Jasprit Takher.[1] *[1]Los Robles Regional Medical Center, Thousand Oaks, CA; [2]Renal Consultants Medical Group, Thousand Oaks, CA.*

Introduction: Although organophosphate (OP) induced renal injury has been documented sporadically, there has not been an identified pathophysiology. The biopsy proven acute tubular necrosis due to organophosphate poisoning is unique as it may provide information into the pathophysiology of the disease process.

Case Description: A 73-year-old male presented to the emergency department after ingesting approximately 240 ml of a glyphosate-based herbicide as a suicide attempt. He was found to have elevated creatinine of 3.9 mg/dL and BUN of 40 mg/dL. Urine studies revealed urine sodium of 38 mmol/L and urine creatinine of 101 mg/dL, FENa of 1.1%, consistent with intrinsic etiology. Conservative management with lactated ringers 100 ml/hr was started initially. The patient's creatinine continued to trend upwards to 5.60 mg/dL, and a renal biopsy was performed. Due to worsening renal failure, the patient was placed on hemodialysis. The patient subsequently developed acute respiratory failure secondary to aspiration and required intubation. As his condition deteriorated the patient's family elected for hospice care, and patient later expired. Biopsy was found to report acute tubular necrosis due to toxic exposure to organophosphate.

Discussion: Organophosphate poisoning occurs in nearly three million people worldwide per year with symptoms involving the autonomic nervous system, neuromuscular junction, and central nervous system. Sporadically OP poisoning can cause AKI, with patients potentially developing ATN. This case illustrates organophosphates ability to perhaps cause direct damage to renal tubules. The biopsy results demonstrated acute injury and necrosis of the proximal tubules with focally prominent cytoplasmic swelling and near circumferential shedding of necrotic epithelial cells. This case illustrates OP ability to cause direct injury as the pathophysiology behind the disease process.



Acute Tubular Necrosis

PUB026

In a Bind

Zachary S. Grissom, Tyler Sims, Eun Y. Lee. *University of Kentucky College of Medicine, Lexington, KY.*

Introduction: A 55-year-old woman with suspected Sevelamer-induced colonic ulcer after admission for acute on chronic respiratory failure and an acute kidney injury (AKI).

Case Description: A 55-year-old female was admitted for acute respiratory failure and an oliguric AKI due to acute tubular necrosis (ATN) in setting of influenza A infection. She developed hyperphosphatemia (peak phosphorus level of 7.5 mg/dL) which was treated with 1,600mg oral Sevelamer carbonate 3x daily. She was placed on mechanical ventilation and subsequently transferred to an academic center. Within 24 hours of Sevelamer initiation and transfer, the patient experienced multiple episodes of hematochezia. Sigmoidoscopy demonstrated a 15 mm cratered linear ulcer in the cecum opposite the Ileocecal valve. Biopsy showed a single crystalloid structure with a tree-bark appearance and rusty color, consistent with a Sevelamer-induced ulcer. Sevelamer was promptly discontinued, and kidney function improved with supportive measures.

Discussion: This case demonstrates the rare finding of a Sevelamer-induced colonic ulcer in the setting of an AKI. Sevelamer is a non-metal hydrogel polymer that binds phosphorus in the GI tract and is widely used to treat hyperphosphatemia; it is generally preferred over calcium-based binders due to reduced risk of hypercalcemia (1). Injury to the gastrointestinal mucosa by direct deposition of Sevelamer crystals is a rare cause of hematochezia and should be considered in any patient taking Sevelamer who presents with intestinal hemorrhage (2). 1. Zeng Q, Zhong Y, Yu X. Meta-analysis of the efficacy and safety of sevelamer as hyperphosphatemia therapy for hemodialysis patients. Vol. 45, Renal Failure. Taylor and Francis Ltd.; 2023. 2. PUB027

Use of Vasopressors in Patients with AKI on Continuous Kidney Replacement Therapy

Ambika Ramesh,[1] Akshith Doddi,[1] Aisha Abbasi,[1] Mohammad A. Al-Mamun,[3] Ankit Sakhuja,[1,2] Khaled Shawwa.[1] *[1]West Virginia University, Morgantown, WV; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]West Virginia University School of Pharmacy, Morgantown, WV.*

Background: To investigate whether use of any specific vasopressor is associated with increased mortality or adverse outcomes (kidney recovery and hypervolemia) in patients with acute kidney injury (AKI) receiving continuous kidney replacement therapy (CKRT).

Methods: Patients were included if they had AKI and underwent CKRT between 1/1/2012-1/1/2021 at a tertiary academic hospital. Cox proportional hazard model was used to assess the relationship between time-dependent vasopressors and in-hospital mortality. The relationship between vasopressors and daily fluid balance was assessed using Generalized Estimation Equation.

Results: There were 641 patients with AKI that required CKRT. In-hospital mortality occurred in 318 (49.6%) patients. Those who died were older (63 vs 57 years), required mechanical ventilation at time of CKRT (80% vs 63%), had higher SOFA score (10.6 vs 9) and lactate (6 vs 3.3 mmol/L). In multivariable model, increasing doses of norepinephrine (NE) [HR 4.4 (95% CI: 2.3-7, p<0.001)] per 0.02 mcg/min/kg and vasopressin [HR 2.6 (95% CI: 1.9-3.2, p=0.01)] per 0.02 unit/min during CKRT were associated with in-hospital mortality. Dobutamine, epinephrine and phenylephrine were not associated with in-hospital mortality. Baseline vasopressor values measured at CKRT initiation were not associated with in-hospital mortality. The model was adjusted for vasopressor doses and fluid balance prior to CKRT initiation, time-dependent daily fluid balance and vasopressor doses, SOFA score, septic shock, age, sex, Charlson comorbidity index, mechanical ventilation and baseline lactate. NE was the most commonly used vasopressor (18% of the time). All vasopressors, except dobutamine, were associated with positive daily fluid balance. Phenylephrine had the lowest coefficient 0.6 (0.45-0.73) liters per 1 mcg/kg/min increase, whereas the other vasopressors ranged between 2.4-4.3 L per 1-unit increase. Mean values of individual vasopressors were not associated with doubling of creatinine or persistent need of dialysis at day 30.

Conclusions: The associations between norepinephrine and vasopressin with in-hospital mortality could be related to their common use in this cohort.

PUB028

Renal Sarcoidosis Presenting as an Isolated Manifestation: A Rare Clinical Entity

Aseel Zghayer, Maria M. Picken, David J. Leehey. *Loyola University Chicago Stritch School of Medicine, Chicago, IL.*

Introduction: Sarcoidosis is a multisystem disorder with accumulation of non-necrotizing granulomas in the lungs and other organs. Renal involvement in sarcoidosis is rare, and its exact incidence remains uncertain. When present, it may manifest as interstitial nephritis, with or without granulomas, nephrocalcinosis, or hypercalciuria. Here, we describe a rare presentation of sarcoidosis with renal involvement as the only manifestation.

Case Description: A 65-year-old man with a history of chronic lymphocytic leukemia (CLL) in remission presented with lethargy, weight loss and anorexia. He was found to have acute kidney injury (AKI) on chronic kidney disease (CKD) of unclear etiology and hypercalcemia (total calcium 14.2 mg/dL). Urinalysis revealed +1 protein without hematuria or pyuria. 24-h urine protein was 1.2 g. Further workup showed low parathyroid hormone (PTH), normal PTH-related peptide (PTHrP), low 25-hydoxy vitamin D_3 (7 ng/mL) and normal 1,25-dihydroxy vitamin D_3 (43 pg/mL), and high angiotensin-converting enzyme (ACE) levels. Bone marrow biopsy showed no evidence of plasma cell neoplasm or a lymphoproliferative disorder and CT chest abdomen pelvis showed no acute abnormality. Kidney biopsy revealed interstitial nephritis with noncaseating granulomas consistent with sarcoidosis (Figure 1). He was treated with prednisone with improvement of hypercalcemia and renal function.

Discussion: The diagnosis of renal sarcoidosis is challenging in the absence of involvement of other organs with sarcoidosis. In our case, the normal level of 1,25-dihydroxy vitamin D_3 ($1,25(OH)_2D_3$) despite low 25-hydroxy vitamin D_3 ($25(OH)D_3$) levels with an elevated $1,25(OH)_2D_3/25(OH)D_3$ ratio suggested calcitriol production due to granulomatous processes (Rohmer et al., Ocul Immunol Inflamm 2020;28:341-7). In such instances, renal sarcoidosis should be considered in the differential diagnosis, particularly when encountering cases of acute or chronic renal failure with uncertain causes. Early identification and treatment can facilitate renal function recovery and reduce the risk of interstitial fibrosis.

Tobramycin Nephrotoxicity after Intra-articular Instillation

Kunal Bailoor,[1,2] Zeenat Y. Bhat.[1] [1]*University of Michigan, Ann Arbor, MI;* [2]*University of Michigan Center for Bioethics and Social Sciences in Medicine, Ann Arbor, MI.*

Introduction: Tobramycin powder is often instilled intra-articularly during operative management of septic arthritis with purportedly reduced risk of toxicity relative to systemic therapy. We present a case of tobramycin nephrotoxicity resulting in AKI requiring hemodialysis.

Case Description: A 70-year-old man who had a history of CKD3 with a baseline serum creatinine of 1.2 as well as osteoarthritis with history of right prosthetic knee replacement was hospitalized for lower extremity cellulitis. He had a complex medical history, most notable for prior bilateral lung transplant in 10/2011 for end stage COPD, atrial fibrillation, and type 2 diabetes mellitus. He initially presented with severe right lower leg pain and swelling; he was noted to have a new DVT. He was started on anticoagulation and IV cefepime. On evaluation, he was noted to have significant right knee effusion; joint aspiration reveled WBC count of 81,000 and synovial fluid culture growing Citrobacter koseri. He was taken to the OR and after joint washout, had 4 grams of vancomycin powder and 3 bottles of tobramycin powder (approximately 3.6 grams) instilled into the joint. There was no significant blood loss or intra-operative hypotension. His pre-operative serum creatinine was 1.2; approximately 12 hours after returning from the OR, his SCr had risen to 1.63 with hyperkalemia to 6.1. Despite attempts at medical management, the patient became rapidly oliguric with persistent hyperkalemia requiring initiation of hemodialysis. Serum tobramycin levels checked 48 hours after the patient returned from the OR were notable for a serum tobramycin level of 36.8 micrograms per milliliter, and a serum vancomycin level of 19.5 micrograms per milliliter. The patient received daily hemodialysis treatments until serum tobramycin levels dropped to below 1 microgram per milliliter. He had renal recovery and was able to stop hemodialysis approximately one month after his operation.

Discussion: Intra-articular antibiotic administration is often felt to be a safer alternative to systemic therapy with reduced risk of systemic toxicity; however, e present a case were there was significant systemic absorption of an intra-articular aminoglycoside resulting in nephrotoxicity. Aminoglycoside toxicity from intra-articular administration should be considered on the differential diagnosis of post-operative AKI for patients with septic arthritis who undergo this procedure.

PUB030

Association between Net Ultrafiltration Intensity and Mortality in Patients with AKI Undergoing Low-Dose Continuous Kidney Replacement Therapy

Keisuke Okamoto, Hidetada Fukushima, Masahiko Kawaguchi, Kazuhiko Tsuruya. *Nara Kenritsu Ika Daigaku, Kashihara, Japan.*

Background: Continuous kidney replacement therapy (CKRT) is a preferred dialysis modality for hemodynamically unstable acute kidney injury (AKI) patients in the intensive care unit (ICU). Several retrospective studies have reported that a higher net ultrafiltration (UF) intensity is associated with better patient survival, under the standard KDIGO-recommended delivered CKRT dose of 20 to 25 mL/kg/h. In Japan, however, the CKRT doses are usually below the KDIGO recommendation due to government health insurance system restrictions, and the association between the net UF and the mortality under lower than the KDIGO-recommended delivered CKRT dose has remained unknown.

Methods: We consecutively evaluated 603 patients who required CKRT in the ICU at Nara Medical University Hospital between January 1, 2012, and December 31, 2021. The following patients were excluded: those with end-stage kidney disease, deceased within 24 hours of ICU admission, CKRT for nonrenal indications, or CKRT duration exceeding 28 days. We categorized patients into four groups by median net UF intensity and delivered CKRT dose, and assessed ICU mortality using multivariable logistic regression.

Results: Of the 603 patients, 494 were included in this study. The median net UF intensity was 3.7 mL/kg/day, and the delivered CKRT dose was 13.2 mL/kg/h. We categorized 494 patients into four groups based on median net UF intensity and delivered CKRT dose: 129 in low net UF intensity-low delivered CKRT dose, 118 in low-high, 118 in high-low, and 129 in high-high groups. The adjusted odds ratios (95% confidence intervals) for ICU mortality via multivariable logistic regression were as follows: low-low 1.54 (0.76–3.12); low-high 0.52 (0.23–1.20); high-low, reference; high-high 0.41 (0.19–0.90).

Conclusions: In this cohort of AKI patients who underwent low-dose CKRT, higher net UF intensity with above-median delivered CKRT dose was independently associated with decreased ICU mortality, compared to higher net UF intensity with below-median delivered CKRT dose. These findings underscore the importance of optimizing CKRT dosing strategies in improving outcomes for AKI patients in the ICU.

PUB031

Recovery from Kidney Failure Associated with Pulmonary Hypertension following Use of Vasodilators

Batoul Dekmak, Emmanuel A. Aydin-Ghormoz, Swati Mehta, Geovani Faddoul. *Albany Med Health System, Albany, NY.*

Introduction: Pulmonary hypertension (PH) and kidney dysfunction are co-morbidities affecting patient outcomes. Chronic kidney disease (CKD) contributes to WHO group IV PH, while kidney injury frequently occurs in PH patients, indicating poor prognosis. The mechanisms involve cardiorenal syndrome and neurohormonal activation. Targeted therapies for PH may offer renal protective benefits, suggesting a beneficial approach for these conditions. We report a case of decompensated heart failure due to severe PH, resulting in acute kidney injury (AKI) from cardiorenal syndrome (CRS). The patient required continuous renal replacement therapy (CRRT) and experienced renal function normalization after vasodilator therapy.

Case Description: A female in her 60s with severe tricuspid regurgitation and right-sided heart failure due to pulmonary hypertension presented with a two-week history of bilateral lower extremity edema and increased abdominal girth, indicating an acute exacerbation of right-sided heart failure. Initial intravenous diuretics led to suboptimal response and kidney injury from CRS. The patient developed shock, necessitating the cessation of diuretics. CRRT was started, followed by hemodialysis (HD). Concurrently, intravenous epoprostenol, oral sildenafil, and ambrisentan were administered, leading to the resolution of kidney failure.

Discussion: The pathogenesis of CKD involves hemodynamic changes, inflammation, and oxidative stress, leading to glomerulosclerosis and kidney atrophy. PH-targeted therapies, including endothelin receptor antagonists (ERAs), phosphodiesterase type 5 inhibitors (PDE5Is), and prostacyclin analogues, influence kidney function due to their vasoactive properties. Sildenafil, a PDE5I, offers nephroprotective effects such as lowering blood pressure and reducing ischemia-reperfusion injury. The endothelin system, with its ET-A and ET-B receptors, plays a crucial role in vascular tone regulation. Selective ET-A blockade shows superior renal protection compared to dual ET-A/ET-B

antagonism, as evidenced by preclinical and clinical studies. Prostanoids like epoprostenol demonstrate renal protective effects, improving outcomes in various kidney dysfunction contexts. Overall, these targeted therapies offer promising renal benefits in patients with PH and CKD.

PUB032

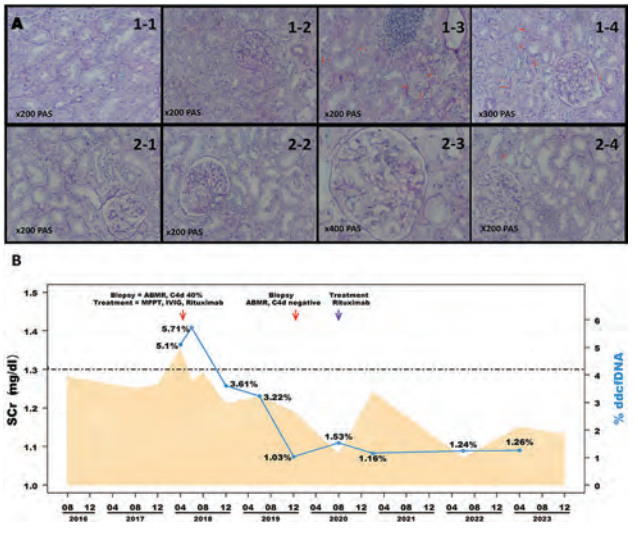
Continuous Routine Detection of Donor-Derived Cell-Free DNA Guides the Diagnosis and Treatment of Subclinical Rejection

Dongrui Cheng,[1] Haider Cuello Garcia,[2,3] Tingya Jiang.[3] *[1]Nanjing General Hospital of Nanjing Military Command Research Institute of Nephrology, Nanjing, China; [2]Jiangsu University, Zhenjiang, China; [3]AlloDx Biotech, Shanghai, China.*

Introduction: Donor-derived cell-free DNA (ddcfDNA) has been closely associated with antibody-mediated rejection (ABMR), however, there are few reports on using ddcfDNA to diagnose and treament evaluation for subclinical ABMR (subABMR). This study imployed a serial ddcfDNA testing in one KTx with subABMR.

Case Description: A 64-year-old man experience subclinical ABMR (subABMR) with devolpment DSA (A11, MFI=1530), and increase ddcfDNA (5.1%) after 4 years of transplantation. The result of biopsy shows 40% of peritubular capillaries with C4d positivity (Fig 1A, 1-4). The patient was treated with a combination of 200 mg of Rituximab and Intravenous Immunoglobulin. During follow-up, ddcfDNA levels were assessed in the first month post-treatment and subsequently every 6 months. DdcfDNA levels were decreased over time, at 24 months post-treatment, the ddcfDNA % value decreased to 1.03%. At this point, a repeat biopsy of the transplanted kidney revealed decrease pathological features of rejection with resolution of tubulitis. C4d staining changed from being positive in 40% ptc to negative; however, Glomerulonephritis (g=1) and ptc (>10%) remained positive (**Fig. 1A, 2-2, 2-3, 2-4**). Following a total surveillance duration of 28 months, it was found that the value increased by 48.5% during the fifth examination of the ddcfDNA. And considering the second biopsy showed ABMR, we promptly administered 200 mg of RIX, resulting in a subsequent decrease in ddcfDNA values. The patient has been followed up for nearly 5 years since then, with stable ddcfDNA levels and negative antibody status (**Fig. 1B**).

Discussion: This study highlights the utility of ddcfDNA as a biomarker for detecting subABMR. Monitoring ddcfDNA levels allowed for precise evaluation of treatment response and adjustment of therapy dosage. The study suggests that ddcfDNA may be is a reliable biomarker for subABMR.



PUB033

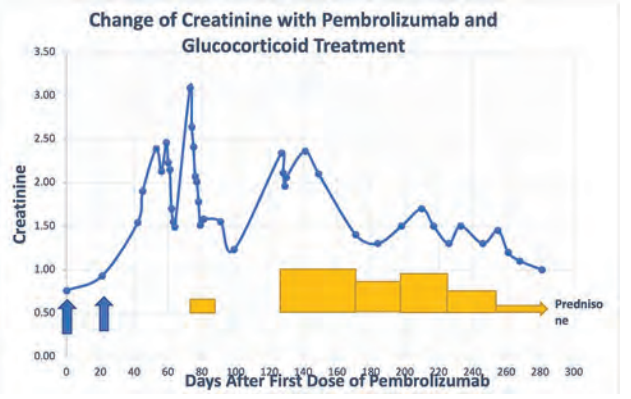
Pembrolizumab-Induced AKI

Abhi Lohana, Buse Eglenen Polat, Neeharika Muddana. *Camden Clark Medical Center, Parkersburg, WV.*

Introduction: Pembrolizumab, a monoclonal antibody targeting the programmed death 1 (PD-1) receptor, has revolutionized cancer therapy by enhancing T-cell-mediated anti-tumor immune responses. Despite its efficacy, Pembrolizumab is associated with immune-related adverse events (irAEs), including acute kidney injury (AKI), a rare but serious complication.

Case Description: An 86-year-old female with hypertension and type 2 diabetes mellitus was diagnosed with stage IV squamous cell lung cancer and initiated Pembrolizumab treatment. Within weeks, her renal function deteriorated, evidenced by declining glomerular filtration rate and rising creatinine levels. Pembrolizumab was discontinued after the second cycle due to significant creatinine elevation. Despite kidney protective measures, renal function did not improve. Urinalysis revealed an elevated urine protein/creatinine ratio, suggestive of AIN. Treatment with slow prednisone taper led to gradual improvement, with creatinine normalization and establishment of a new baseline glomerular filtration rate.

Discussion: The incidence of immune checkpoint-induced acute kidney injury (ICI-AKI) is estimated to range between 2-3%. Acute interstitial nephritis (ATIN) is the most common pathology in this context. Diagnosis is challenging due to multiple AKI risk factors in cancer patients. Clinical features such as sterile pyuria, white blood cell casts, and sub-nephrotic range proteinuria, commonly associated with ICPI-AKI, lack sensitivity and specificity and may manifest in other causes of ATIN. Increased vulnerability to ICPI-AKI is observed in patients experiencing other immune-related adverse effects (irAEs) linked to ICIs and PPIs. Current guidelines recommend initiating empirical treatment for ICPI-AKI without awaiting tissue diagnosis unless a three-fold increase in creatinine or suspicion of alternative causes for AKI arises. Prednisone, coupled with the discontinuation of the immune checkpoint inhibitor, constitutes the recommended therapeutic approach in the management of ICPI-AKI.



PUB034

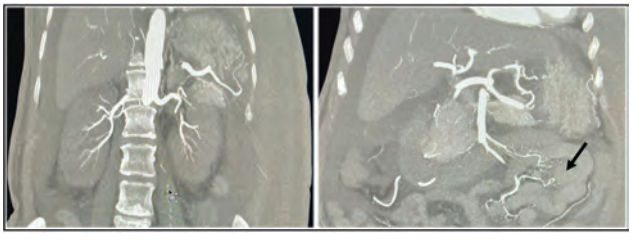
Polyarteritis Nodosa with Bilateral Renal Ischemia Masking as Nephrotic Syndrome in a Diabetic Patient: A Case Report

Stephanie Joyce R. Liao. *Chong Hua Hospital, Cebu City, Philippines.*

Introduction: Polyarteritis nodosa (PAN) is a necrotizing vasculitis primarily affecting medium-sized arteries. While PAN may present with mild proteinuria and microhematuria, signs of glomerulonephritis are rare. We report a complex case of PAN in which bilateral renal ischemia accelerated the underlying diabetic kidney disease, hence presenting with nephrotic syndrome and obscuring the diagnosis of PAN.

Case Description: A 72-year-old Filipino diabetic female with a four-month history of bilateral pitting edema and worsening hypertension presented to our institution with oliguria and increasing creatinine from 3.2 mg/dL to 4.3 mg/dL (eGFR of 10 mL/min/1.73m2). She was previously managed as rapidly progressive glomerulonephritis at another institution. Workup revealed negative results for ANA, ANCA, hepatitis, and anti-GBM. Abnormal findings include low C3, elevated LDH, nephrotic range proteinuria with UACR of 4744 ug/mg, and hypoalbuminemia. The initial impression was immune complex glomerulonephritis. However, kidney biopsy results were consistent only with those for diabetic kidney disease. She was readmitted for hematochezia, and endoscopy only revealed multiple gastric ulcers. The persistence of gastrointestinal (GI) bleeding prompted CT angiography, which showed irregular narrowing of the distal branches of both renal and superior mesenteric arteries with a beading appearance. Patient developed seizures, and a CT scan of the brain showed acute frontal lobe infarct. With the clinical presentation and angiographic findings, PAN was now highly considered. Repeat MPPT and intravenous cyclophosphamide infusion were given. However, massive GI bleeding persisted, and the patient eventually died.

Discussion: The differential diagnosis of PAN is broad, and diagnosis is often delayed due to the wide range of conditions that resemble and complicate the clinical signs. Risk factors for early mortality included older age, renal, CNS, and GI involvement. This case highlights the importance of considering PAN as a possible cause of progressive renal failure, even in patients with nephrotic features, and the potential implications of delayed diagnosis and treatment.



PUB035

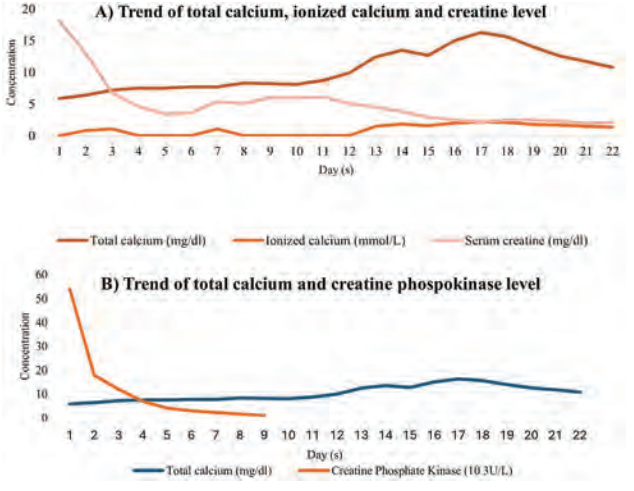
Hypercalcemia in the Recovery Phase of Pigment-Induced Acute Tubular Necrosis

Usha Kumari,[1] Sanjana K. Maheshwari,[2] Syed M. Raza.[1] [1]*The University of Tennessee Health Science Center, Memphis, TN;* [2]*Dow University of Health Sciences, Karachi, Pakistan.*

Introduction: Acute tubular necrosis (ATN) is a common intrinsic cause of renal failure. Common etiologies are severe hypovolemia, nephrotoxins, or sepsis. Rhabdomyolysis or skeletal muscle injury leads to pigment induced ATN. Hypercalcemia has been described in cases of rhabdomyolysis. However, in this case, hypercalcemia occurred well after a decline in creatine phosphokinase (CPK) levels, possibly related to post ATN diuresis and prolonged immobility.

Case Description: We describe a case of a 23-year-old Hispanic male with a history of travel through the desert who presented with abdominal discomfort, myalgias, and respiratory distress. He initially developed an oliguric acute kidney injury due to rhabdomyolysis, followed by recovery by the end of the second week, marked by polyuria. He then developed symptoms of nausea and headaches, besides polyuria. Laboratory values showed increasing total calcium, as shown in figure (A) The trend of serum calcium and CPK levels is shown in figure (B). The vitamin D 25-OH level was low, and the parathyroid gland was appropriately suppressed. The electrocardiogram was unremarkable. Hypercalcemia was initially unresponsive to increasing volume replacement and calcitonin. Patients eventually received pamidronate with a gradual decline in calcium to a normal level. The alkaline phosphate was normal initially and peaked at 145 U/L when calcium started to trend down. Hypercalcemia was presumed to be related to dehydration during the polyuric phase of ATN. On the 22nd day of stay, the polyuria and hypercalcemia had resolved, and the patient was discharged. Lab values were normal on the 2-week follow-up post-hospital discharge.

Discussion: ATN is a very common acute illness in hospitalized patients. This case highlights that life-threatening hypercalcemia can present late with a prolonged course in the setting of acute kidney injury. It is crucial to closely monitor patients with ATN following their discharge.



PUB036

Obstructive Nephropathy Unmasking a Suicide Attempt with Ethylene Glycol Poisoning

Katherine Andrade, Hira Tahir, Henry Yip, Farah Daccueil, Louisette Soussan. *Stony Brook University, Stony Brook, NY.*

Introduction: Ethylene glycol (EG) poisoning is a life-threatening condition that requires early diagnosis to prevent complications and death. This is a patient with obstructive nephropathy from EG poisoning who successfully recovered after fomepizole and renal replacement therapy.

Case Description: 67-year-old male presented with acute encephalopathy. Vitals showed blood pressure 180/74 mmHg, respirations 22, and temperature 35.5 °C. Laboratory included K 5.8 mg/dL, bicarbonate <6 mmol/L, serum creatinine 2.2 mg/dL, BUN 22 mg/dL, lactic acid 12.7 mmol/L, urine toxicology, and ethanol normal. CT head non-revealing and CT abdomen and pelvis bilateral obstructing calculus resulting in hydronephrosis. He was taken for urgent bilateral stent placement by urology and admitted to MICU for urosepsis. Nephrology was consulted for persistent acidosis, acute kidney injury, and electrolyte derangements. Nephrology investigation showed anion gap 35 mmol/L, osmolar gap 100, ethylene glycol level 293 mg/dL, pH 7.1. Formal ethylene glycol toxicity was made, and oxalate monohydrate stones found; He was treated with IV fluids, vasopressors, IV antibiotics, fomepizole, and continuous renal replacement therapy. He fully recovered and was discharged to inpatient psychiatry after confessing suicidal attempt.

Discussion: EG is a dangerous sweet-tasting, colorless, and odorless liquid used as an industrial compound. It causes significant morbidity and mortality if left untreated. More than 5,000 cases of intentional or unintentional toxicity are reported in the United States yearly, affecting mostly adult men. EG is broken down into glycolic acid, oxalic acid, glyoxylic acid, and glycolaldehyde causing kidney injury, central nervous system, and cardiopulmonary compromise. The glycolic acid is known to cause severe high anion gap metabolic acidosis, high osmolar gap, and oxalate precipitation causing kidney injury. In our case, he had acute encephalopathy, severe acidosis, high osmolar gap, and obstructive nephropathy with bilateral oxalate monohydrate stones unmasking an unknown suicide attempt. EG poisoning is challenging to diagnose and manage due to non-specific symptoms, limitations on direct EG quantification methods, and the shortened duration of an elevated osmolar gap in chronic alcohol abusers. High suspicion can prevent irreversible, and life-threatening complications.

PUB037

Postdischarge Follow-Up of Patients with Liver Disease and AKI

Varsha Swamy, Jay L. Koyner, Matthew T. Cerasale. *The University of Chicago Medicine, Chicago, IL.*

Background: Acute Kidney Injury (AKI) in the setting of liver disease is complicated and associated with adverse outcomes, but much of the data is from the Intensive Care Unit. We sought to better understand the outcomes for ward-based patients with cirrhosis and AKI.

Methods: We conducted quality initiative via a retrospective chart review of all patient encounters on the Liver Hospitalist Service from January 1st – June 31st, 2023 with at least 2 serum creatinines (SCr). Baseline SCr function was defined as the mean SCr within 6 months to 1 year prior to admission. Diagnosis and staging of AKI was based on KDIGO SCr-criteria. Diagnosis of liver cirrhosis and of source of AKI was determined via chart review. The outcomes of interest were around incidence and severity of AKI, inpatient nephrology consultation, and post-discharge follow up.

Results: Of 141 admissions, 23 patients had multiple encounters during the study period. The final cohort consisted of 103 patients, 59 (57%) who had cirrhosis, 34 (33%) who had history of liver transplant, 5 (5%) with acute liver injury, and 5 (5%) with other. Of those with cirrhosis, 24 (41%) had AKI on admission or developed AKI during their hospitalization (Table). The etiologies of AKI included: Volume-responsive (11), Hepatorenal Syndrome (6), Acute Tubular Necrosis (1), Sepsis (1), and Multifactorial (5). Nephrology was consulted on 7 patients with AKI, 6 with Stage 3 and 1 patient with Stage 1. Outpatient Nephrology follow up, readmission rates, and other long-term outcomes are in the table. All patients with Nephrology follow up were readmitted within 90-days, but there was more mortality in the No AKI group.

Conclusions: Among ward based (non-ICU) patients with liver dysfunction, patients scheduled for Nephrology follow up were more likely to be readmitted. Future interventions should look to prevent readmissions while ensuring more follow-up for patients with cirrhosis and AKI.

Patients with Cirrhosis with AKI status and post-discharge outcomes

	Length of Stay	90-day Readmission	Liver Transplant within 6 months	Mortality
No AKI (n=35)	7.1 (9.2)	15 (43%)	7 (9%)	2 (6%)
Stage I Follow up (n=1)	4	1 (100%)	0	0
Stage I No follow up (n=9)	6.6 (3.2)	5 (55%)	3 (33%)	0
Stage II Follow up (n=1)	4	1 (100%)	0	0
Stage II No follow up (n=6)	8.8 (5.6)	4 (67%)	1 (17%)	0
Stage III Follow up (n=3)	19 (11)	3 (100%)	0	0
No follow up (n=4)	13 (9)	0	0	0

Syphilis-Associated Membranous Nephropathy

Patrick J. Jenkinson,[1] Hafsa K. Tareen,[2] Benjamin R. Wagner.[1] [1]*University of Michigan, Ann Arbor, MI;* [2]*Aga Khan University Hospital Clinical Laboratories, Karachi, Pakistan.*

Introduction: Syphilis, known as "The Great Masquerader," can present with a myriad of systemic manifestations. Renal sequelae have been documented, though rarely. Here, we report a case of biopsy-proven syphilis-associated membranous nephropathy.

Case Description: A 35-year-old man with a history of well-controlled HIV presented with six weeks of fatigue, arthralgias, headache, neck stiffness, lower extremity edema, and a diffuse maculopapular rash – including over the palms and soles. He was ultimately diagnosed with secondary syphilis, complicated by aseptic meningitis, for which IV penicillin G was initiated. Upon presentation, he was found to have new onset nephrotic-range proteinuria with urine protein/creatinine ratio 4.49. Creatinine was normal and at the patient's baseline. Kidney biopsy was performed to investigate his heavy proteinuria. Light microscopy of the glomerular basement membranes revealed pinhole defects on silver stain. Immunofluorescence demonstrated an IgG and C1q dominant

membranous glomerulopathy that was negative for PLA2R. Electron microscopy showed scattered, subendothelial electron dense deposits along with diffuse podocyte foot process effacement. There was no evidence of HIVAN. After a two-week course of penicillin G, the patient achieved complete remission, with urine protein/creatinine ratio 0.28.

Discussion: According to the CDC, the incidence of syphilis is at its highest rate since 1950, and continues to rise. Despite this, renal sequelae of syphilis may be under-recognized due to a lack of awareness among clinicians. Syphilis-associated membranous nephropathy is due to immune complex-mediated podocyte injury. Treponemal antigens – among others – have been identified as causative. Prompt initiation of penicillin G can lead to reversal of kidney injury, including complete resolution of nephrotic-range proteinuria.

PUB039

AKI in a Young Pregnant Woman with Hypertriglyceridemia-Induced Severe Acute Pancreatitis Treated with Urgent Plasma Exchange

Diana Yusim, Jyotsana Thakkar. *UPMC, Pittsburgh, PA.*

Introduction: Acute kidney injury (AKI) is a common complication of severe acute pancreatitis in critically ill patients. It is associated with substantial risk of mortality, especially when kidney replacement therapy (KRT) is needed. We present a case of a pregnant patient who developed AKI secondary to hypertriglyceridemia (HTG) induced severe acute pancreatitis requiring plasma exchange and KRT.

Case Description: A 34-year-old female G1P0 at 34 weeks gestation presented with diffuse abdominal pain. Lipase level was 7,686 U/L and triglyceride level was >10,000 mg/dl. CT abdomen showed severe edematous pancreatitis with extensive intra-abdominal fluid involving the omentum and retroperitoneum with diffuse gastric and bowel wall thickening. She required urgent C-section due to fetal distress. She received insulin drip and one session of plasma exchange with nadir of triglycerides to 514 mg/dl. Her baseline creatinine was 0.7mg/dl, peaked at 4.5 mg/dl, associated with oliguria necessitating CKRT initiation. She was subsequently transitioned to hemodialysis for two weeks followed by complete resolution of acute tubular necrosis and renal recovery.

Discussion: Pancreatitis is a risk factor for AKI. The release of activated pancreatic enzymes and free radicals into the bloodstream in acute pancreatitis triggers an inflammatory cascade that impairs renal perfusion leading to AKI. Patients frequently develop hypovolemia, sepsis, tubular necrosis, and abdominal compartment syndrome. Hypertriglyceridemia has been hypothesized as an independent risk factor for AKI in pancreatitis. One proposed mechanism is accumulation of free fatty acids (FFA) in renal parenchyma induced by breakdown of triglycerides by pancreatic lipase. The FFA accumulation damages renal parenchyma. Our case is unique as our patient had no prior history of hyperlipidemia and presented in the third trimester with severe HTG induced pancreatitis and AKI requiring CKRT and plasmapheresis with recovery of renal function. Management should focus on volume resuscitation, monitoring compartment pressures, and kidney replacement therapy when indicated.

PUB040

Implementing the AKI in Care Transitions Program: A Mixed-Methods Study

Heather P. May,[1] Caroline B. Ledet,[1] Joan M. Griffin,[1] Kianoush Kashani,[1] Andrea G. Kattah,[1] Rozalina G. Mccoy,[2] Andrew D. Rule,[1] Angeliki G. Tinaglia,[1] Erin F. Barreto.[1] ACT Study Group. *[1]Mayo Clinic Minnesota, Rochester, MN; [2]University of Maryland School of Medicine, Baltimore, MD.*

Background: The AKI in Care Transitions (ACT) Program was designed to address barriers to post-AKI care delivery by promoting follow-up with primary care. In a clinical trial comparing ACT to usual care, mixed methods were used to assess the feasibility and acceptability of ACT implementation among health care staff and trial participants.

Methods: The study included health care staff who delivered ACT and trial participants who were adults with stage 3 AKI during hospitalization and discharged home without dialysis needs. Patients randomized to the ACT group received kidney health education before discharge and coordination of post-discharge laboratory and clinician (primary care physician, pharmacist) follow-up within 14 days. ACT implementation was evaluated using surveys and interviews, which were coded to identify themes.

Results: Feasibility and acceptability of ACT were high among all participants (Figure 1). However, qualitative data revealed implementation considerations that could threaten future scale and spread. Scheduling was complex, requiring coordinated efforts from care team members from multiple departments. Clinicians perceived that engaging more frequently with ACT patients improved their comfort level with the workflow and opinions on sustainability and reduced the perceived burden of ACT. Many patients and clinicians felt ACT was more valuable in the presence of chronic kidney disease or incomplete AKI recovery at discharge, relative to other patients.

Conclusions: Primary care-based transitions of care for AKI survivors represents a feasible solution to the gaps identified in post-AKI care. Post-AKI care delivery models are likely to meet implementation challenges related to the diffusivity of AKI across practice settings and patients' and clinicians' knowledge and perceived value of post-AKI care.

Usability Testing of Discharge Summary Template for AKI

Jia Hwei Ng,[1,2] Katherine L. Dauber-Decker,[1] Fatima Malik,[1] Richard L. Amdur,[1] Michael A. Diefenbach.[1] *[1]Northwell Health Feinstein Institutes for Medical Research, Manhasset, NY; [2]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

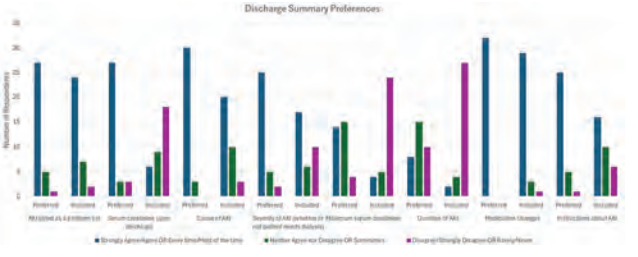
Background: Acute kidney injury (AKI) survivors experience suboptimal transitions post-hospitalization due to inadequate communication between inpatient and outpatient providers. We aimed to design a discharge summary template that improves AKI information sharing in the electronic health record (EHR).

Methods: First, we conducted a preliminary survey among clinicians to guide the AKI content. Second, we designed an EHR mockup of the AKI template and conducted think aloud usability testing, where participants verbalized their though process as they interacted with the mockup.

Results: We surveyed 47 clinicians: 45% worked inpatient, 15% outpatient, and 40% in both. Specialties included 78% internal medicine, 8% nephrology, and 13% others, with roles as 28% resident/fellow, 57% attendings, and 15% nurse practitioners. The median years practicing was 10 (range 3-18). A notable discrepancy existed between the AKI information clinicians wanted and what they typically included in discharge summaries (Figure 1). During usability testing, key themes identified were in categories of content, usefulness, visibility, workflow, and navigation (Figure 2).

Conclusions: Usability testing of the AKI template showed the need for improved content and functionality. Future iterations will incorporate clinician and patient feedback.

Funding: NIDDK Support



Clinician preferences versus actual inclusion of AKI-related information in discharge summaries.

Code Category	Theme	Illustrative Quotes	Planned Changes to the Discharge Summary
Content	The need for more detailed serum Creatinine levels	*I would want the serum creatinine on admission, peak, and discharge*	We will pull the serum creatinine levels from the time of admission, peak, and time of discharge.
	Fluid intake recommendation	*Fluid recs are so individualized. May want to say "as per your doctor's instructions".*	We will remove the standardized recommendation for fluid intake, and allow the recommendation to be individualized.
	The use of plain language makes the content clear to the patient.	*I like the wording. This is more plain English*	We will keep future iterations of the discharge instructions at a 4th grade reading level. We will also perform separate usability testing among patients to test the language of the content.
	The need to add details about dialysis-related information	*If patient is on dialysis... [want to know] if they have dialysis access and when they started it...Small percentage of patients but that kind of information is helpful*	Although the AKI template was originally designed for those with AKI Stage 2 and AKI 3 who do not require dialysis, the providers noted that they do not want multiple versions of an AKI template. Thus, we will include a section related to dialysis in the next iteration.
	The need for the AKI instruction template to be congruent with the overall message to prevent conflicting information	*It has to be congruent with overall message and instructions. Especially, if it's filled out by different providers- they should look at overall message and avoid conflicting messages.*	We will remove specific fluid and dietary recommendation from the standardized template.
Usefulness	The presence of an AKI template is deemed as useful for both the provider and the patient.	*It would make my life easier but also better equipped to take care of patients post discharge*	N/A
Visibility	Some information needs to be placed at certain locations for better visibility.	*Cause of AKI should be on top of screen*	We will place the "Cause of AKI" text box at the top of the screen.
Workflow	Pre-populated information makes the workflow smooth.	*I like the fact you can click through the buttons, and it can generate the text for you. It's standardized and pulls the numbers for you.*	N/A
	Redundancy of work	*It's potentially redundant- at least some sections in it and will probably make the provider of the discharge summary spend more time filling it out*	We will remove sections in the AKI template that are already in the general discharge instruction section.
Navigation	The purpose of the checkboxes was unclear.	*So, by clicking these checkboxes this is going to populate the education and care plan?*	We will add instructions to explain that the checkboxes should be used to provide patient-facing information and discharge instructions.

Usability feedback on the AKI discharge summary template, showing thematic categories, illustrative quotes, and subsequent planned changes to enhance the template.

PUB042

Dengue Virus-Induced Acute Interstitial Nephritis

Nolan Interial, Aanusha Ghouri, Eman Alshaikh, Ali I. Gardezi. *University of Wiscosnin School of Medicine and Public Health, Madison, WI.*

Introduction: Acute Interstitial Nephritis (AIN) is a common cause of acute kidney injury, manifests as inflammation within the kidney's interstitial tissue. While AIN is often attributed to medications, infections can also be causal factors. This case presents a rare instance of AIN induced by Dengue fever.

Case Description: A 57-year-old male with history of hypertension and hyperlipidemia presented with myalgias and dark urine after recent travel to Europe and Africa. Home medications were Amlodipine, Atorvastatin and Sildenafil. Vital signs were unremarkable. Blood work revealed creatinine (Cr) 2.93 mg/dL (baseline 1.2 since 2022), BUN 33 mg/dL, potassium 5.3 mmol/L, bicarbonate 18 mmol/L, phosphorus 6.9 mg/dL, creatine kinase (CK) 1,088,400 U/L, ALT 608 U/L and AST 3,494 U/L. Urinalysis showed brown urine, 3+ blood and 2+ protein but no RBCs. Imaging studies were unremarkable. Upon holding Atorvastatin and administering fluids, CK level gradually improved. Autoimmune and infectious work up revealed positive Dengue virus IgM and IgG. The rest of the work up was negative. Creatinine levels peaked at 4.0 mg/dl on hospital day 3, subsequently decreased to 3.5 mg/dl. However, over the following 9 days, there was no further improvement, which prompted a kidney biopsy revealing AIN with mild to moderate acute tubular necrosis (ATN). The patient was discharged on Prednisone taper for two weeks. Two weeks post-discharge, creatinine levels decreased to 2.4 mg/dl.

Discussion: AIN is an immune-mediated syndrome characterized by the presence of inflammatory cell infiltration in glomerular interstitial space. This histological finding can be elicited by several mechanisms, while commonly triggered by medication allergies, systemic infections, including viral ones like CMV, EBV, HBV, and HIV, can also induce AIN. Limited literature exists regarding the histological etiology of kidney injury in Dengue fever. There have been reports of ATN secondary to severe rhabdomyolysis in dengue fever but there has not been any reported case of AIN. Even though amlodipine has been reported to cause interstitial nephritis, the patient had been taking it for more than a year before the presentation, without any worsening of his renal functions.

PUB043

Postacute AKI Follow-Up Reduces 30-Day Readmission Rate

Desiree Mytych, Christina M. Cruz, Jeffrey S. Stoff, Kenneth M. Ralto. *UMass Memorial Medical Center, Worcester, MA.*

Background: Acute kidney injury (AKI) is a frequent hospital complication which is associated with high rates of rehospitalization, mortality, and increased healthcare cost (estimated at $9,230* per readmission after AKI). Furthermore, guideline-directed medical therapies and diuretics are often stopped or reduced during an episode of AKI which has been shown to worsen patient outcomes. We developed an AKI follow-up clinic to provide post-acute care to this vulnerable population which historically has received little nephrology care after discharge.

Methods: Education regarding the AKI follow-up clinic was provided to the hospital medicine providers, and referrals were made via the electronic medical record approximately 24-48 hours prior to discharge. Patients were scheduled within 7-21 days of discharge, depending on their clinical status and anticipated needs. The focus for this clinic was to assess the degree of renal recovery after AKI, coordinate ongoing nephrology care if indicated, and reinitiate nephroprotective medications and diuretics as appropriate.

Results: The 30-day readmission rate for patients with AKI was reduced from a historical average of 19.4% to 10.0% in those patients who attended the AKI follow-up clinic. Over 99% of AKI clinic patients underwent a clinic intervention, including diagnostic testing and/or medication changes. We identified a sub-group of AKI survivors who were particularly high-risk for readmission: patients who were over 65 years-old and had either congestive heart failure or cirrhosis.

Conclusions: Providing prompt subspecialty follow-up care for AKI survivors reduced the risk of 30-day readmission in this population. The AKI clinic provided an opportunity to resume diuretics and guideline-directed medical therapy in a timely manner.

PUB044

Semaglutide-Induced Severe AKI Requiring Hemodialysis

Boris Livitz, Jagraj Singh, Lia Sepanek, Elnaz Mahbub, Frances E. Mccarthy, Louis R. Spiegel. *Stony Brook Southampton Hospital, Southampton, NY.*

Introduction: Glucagon-like peptide-1 (GLP-1) receptor agonists, notable for their cardio and nephroprotective effects, are growing in popularity for the management of type 2 diabetes and obesity. We present a rare case of a patient with normal baseline renal function who developed severe acute kidney injury (AKI) with uremia requiring emergent dialysis shortly after starting semaglutide.

Case Description: A 61-year-old female with type 2 diabetes, hypertension, and hyperlipidemia presents with a four week history of nausea, vomiting, diarrhea, and poor oral intake. Patient began semaglutide three months prior; other medications were unchanged. She has no known kidney disease. On arrival, she was lethargic and tremulous, but hemodynamically stable. Initial labs notable for sodium 129 mmol/L, potassium 2.9 mmol/L, bicarbonate 13 mmol/L, chloride 82 mmol/L, BUN 135 mg dL, creatinine 14.2 mg/dL, eGFR 3 mL/min/1.73m^2, magnesium 0.6 mmol/L, uric acid 26.8 mg/dL, and positive serum ketones. Imaging showed no acute pathology. Nephrology was consulted, recommending emergent hemodialysis (HD) and ICU admission. She was started on IV fluids, electrolyte repletion, and rasburicase. Nephrotoxic medications were held and she received DDAVP for bleeding at an IV site. After HD, labs trended towards optimal levels. Once improved she was transferred to the general floor and later discharged with nephrology follow-up.

Discussion: GLP-1 receptor agonists enhance insulin secretion, reduce glucagon levels, and slow gastric emptying. Originally developed for diabetes, some have been recently approved for obesity. With the rise in use, closer examination of adverse effects is needed. While gastrointestinal effects are common, AKI remains rare, typically linked to dehydration. A post hoc analysis of the STEP 1, 2, and 3 trials revealed that semaglutide did not worsen renal outcomes regardless of patients' baseline renal function.[1] A meta-analysis of FDA data indicated liraglutide had the highest risk of AKI, followed by semaglutide.[2] Our patient developed AKI with uremia without existing renal disease. Extensive workup ruled out other causes such as immunologic, obstruction, etc., suggesting the presentation was due to semaglutide.

PUB045

Renal Oxalosis from Excess Dietary Intake: A Guide to Improve Kidney Function

Muhammed Khalfan, Hong Yang, Yinelka G. Silverio De Castro, Jerin Karingattil, James Drakakis. *NYU Langone Hospital - Long Island, Mineola, NY.*

Introduction: Hyperoxaluria may be due to hereditary defects of key enzymes of oxalate metabolism or from excess intake or increased enteric absorption. High dietary intake is related to ingestion of vitamin C, spinach, rhubarb, or beets. Acute kidney injury (AKI) is due to calcium oxalate crystals desposited within tubules causing acute tubular injury. Renal recovery is possible with correction of the underlying cause. However, the insult may also be severe enough to require dialysis and can even lead to end stage renal disease. We present a case of oxalate nephropathy (intake related) whereby kidney function improved significantly with strict dietary oxalate restriction.

Case Description: 69 year old female with no past history was found with serum creatinine 2.4 mg/dL. Baseline one year prior 0.9 mg/dL. UA without blood or RBC and urine protein quantification 144 mg/g. Renal ultrasound with increased echogenicity and non obstructing kidney stones. Kidney biopsy showed acute tubular injury with multifocal tubular oxalate crystal deposition (renal oxalosis); 30% tubular atrophy and interstitial fibrosis. This was not primary oxalosis related to inherited enzyme defect (genetic testing negative). Nor prior surgeries or predisposing conditions to suggest enteric form. History was elucidated that she was on a diet rich in oxalate. With very tight restriction of 50-100 mg oxalate per day (ingesting foods <5 mg oxalate per serving), creatinine improved to 1.26 mg/dL (10 months after initial diagnosis).

Discussion: The prognosis of acute oxalate nephropathy is variable, with insult severe enough to warrant renal replacement in at least one half of paitents. Treatment depends on underlying cause but generally includes hydration, oral calcium supplementation, correction of hyperoxalauria causing conditions and as in our case, low oxalate diet. Literature review reveals most patients do not make a complete recovery in terms of renal function. Our patient bolstered her urine output to upward of 3 liters per day, and lowered oxalate intake to <100 mg per day. Serum creatinine improved in less than 1 year from diagnnosis to 1.26 from 2.4 mg/dL. This cause illustrates the importance of dietary modification in renal oxalosis from excess intake and the potential for significant renal recovery, otherwise described as being unlikely.

PUB046

Lacosamide-Induced Thrombotic Microangiopathy

Khaled Al-Baqain, Said Sharawi, Zeid Khitan. *Marshall University, Huntington, WV.*

Introduction: Drug-induced thrombotic microangiopathy is a life-threatening condition that is characterized by anemia, thrombocytopenia, and acute kidney failure without ADAMTS13 deficiency. Many drugs have been identified to cause TMA including quinine, antimicrobials, and cancer therapies. In this case we will describe a rare case of lacosamide induced TMA

Case Description: An 84-year-old female who presented to the hospital with intracranial hemorrhage. She then underwent craniotomy and was intubated for seizure. The patient was then started on lacosamide and valproic acid for her seizures. On admission hemoglobin was 13 and platelets were 250. 6 days into her admission, schistocytes started appearing on automated differential. Also, her hemoglobin dropped to 7.5 and platelets count gradually dropped until they reached a nadir of 54. Peripheral smear showed schistocytes, D-Dimer was positive, RPI was low, LDH was mildly elevated, but she had normal pt/INR, fibrinogen. Creatinine increased from 0.7 to 1.4 and the patient remained non oliguric. Nephrology team was consulted for AKI and MAHA. ADAMTS13 level was collected, lacosamide was held and valproic acid was continued. The patient was started on 60 IV methyl prednisone every eight hours. She also received 2 units of fresh frozen plasma. Three sessions of plasma exchange were performed. ADAMTs 13 came back at 50% making the diagnosis of drug induced thrombotic microangiopathy (DITMA) more likely. Patient platelets improved back to baseline. She was then stable and was discharged home.

Discussion: The patient in this case started having signs of TMA 6 days after starting lacosamide, which improved after discontinuation of the medication. ADAMTS13 of 50% differentiated between drug induced TMA and TTP. DITMA can sometimes be challenging to diagnose, especially in the ICU setting. Although literature on lacosamide induced TMA is scarce, this case sheds the importance of keeping TMA as a differential in the setting of new onset thrombocytopenia and anemia after starting new medications.

PUB047

A Long Road to Diagnosis: A Case with Unexpected Twists

Klement Yeung, Tushar S. Malavade. *University of Toronto, Toronto, ON, Canada.*

Introduction: It is often thought that cases of obstructive acute kidney injury (AKI) are straightforward to diagnose and manage. The following case report explores how experienced physicians navigated an unusual case and the convoluted path taken to arrive at the eventual diagnosis.

Case Description: A 74 year-old previously healthy male presented to the hospital with syncope in the context of six weeks of nausea, vomiting, anorexia and one year of nocturia. Labwork showed potassium of 8.1mmol/L and creatinine (Cr) of 14.97mg/dL (baseline of 1.07mg/dL). EKG showed peaked T-waves. After management of hyperkalemia, significant arrhythmias persisted so dialysis was initiated. A renal ultrasound showed bilateral hydronephrosis and ascites. Presuming prostactomegaly as the case of the obstruction, a foley catheter was placed and drained 445mL of urine, but he became oligoanuric. Urine microscopy showed one heme-granular cast. Urine albumin to creatinine ratio was 101mg/g. A serologic work-up was negative and kidney biopsy was consistent with acute tubular necrosis (ATN). However, a repeat ultrasound showed no improvement in bilateral hydronephrosis and ascites. A paracentesis revealed malignant cells on cytology. Discussions were held regarding pursuing a contrast-enhanced CT for work-up of malignancy. However, in the context of severe AKI, a shared decision was made to delay the CT as it can impede renal recovery. Serum tumor markers revealed elevated Ca19-9, CA125, and CEA. A colonoscopy showed two colonic masses. We obtained a contrast-enhanced CT as we felt the potential information we would gain outweighed the risks, which showed metastatic malignancy with retroperitoneal masses causing bilateral ureteric obstruction and hydronephrosis. Nephrostomy tubes were inserted and the patient experienced significant renal recovery. He was discharged with a Cr of 1.4 mg/dL (eGFR of 53mL/min/1.73m2).

Discussion: From this case, we learned it is imperative to re-evaluate initial assumptions when an element of the case is unusual, such as why he became oligoanuric after a foley was placed if the obstruction was relieved and why he had new-onset ascites. Persistent anomalies prompted additional studies, which led to the uncovering of the previously unknown metastatic malignancy, the true cause of the patient's AKI. This case highlighted the dangers of early diagnostic closure and the importance of thorough investigation.

PUB048

HIV-Associated Immune Complex Kidney Disease in a Patient with Normal Complement Levels

Kaitlin Markoja, Karishma Iyer, Lukman Cheraghvandi, Donghyang Kwon, Negiin Pourafshar. *MedStar Georgetown University Hospital, Washington, DC.*

Introduction: HIV infection is frequently complicated by renal dysfunction. There is a variety of renal pathology associated with HIV.

Case Description: A 35-year-old male with a medical history including HIV (CD4 257 cells/mm^3, viral load 36 copies/mL) not on antiretroviral therapy (ART) and schizophrenia presented with shortness of breath. He was treated for community acquired pneumonia at another facility three months prior, where his serum creatinine (SCr) was 4.5-5 mg/dL. At our institution, he was afebrile, not hypoxic, and hypertensive with systolic blood pressure 160-180 mmHg. Laboratory results showed elevated blood urea nitrogen at 84 mg/dL and SCr at 10.76 mg/dL. Urinalysis had moderate proteinuria and 5 red blood cells per high-power field, with a urine protein to creatinine ratio of 2.0 g/g. CT of the chest, abdomen, and pelvis revealed dense left lower lobe pneumonia, and blood cultures later confirmed Streptococcus pneumoniae infection. He was treated with ceftriaxone, yet SCr remained elevated. Serologic investigation was unremarkable. Renal biopsy revealed interstitial edema with a lymphoplasmacytic infiltrate with occasional eosinophils in the interstitium. Tubules showed epithelial flattening and cellular debris, tubular loss, interstitial fibrosis, and vascular wall thickening. Immunofluorescence revealed 1+ IgG granular positivity, while electron microscopy detected occasional immune-complex deposits in the mesangium, accompanied by mesangial matrix expansion, concerning for HIV-associated immune complex kidney disease (HIVICK). With blood pressure reduction and treatment for infection, SCr decreased to 6 mg/dL. SCr remained stable two months later and after ART initiation.

Discussion: HIVICK involves immune complex deposition, which can occur in situ or via secondary deposition. Proposed viral antigens include p24 and gp120. Previous studies suggest that HIVICK is more prevalent in patients with higher viral loads, hepatitis co-infection, and low complement levels. However, our patient had low HIV viremia, no hepatitis, and normal complement levels. Renal biopsy is crucial to discern HIV-associated renal pathologies accurately. Treatment strategies for HIVICK warrant further exploration, particularly considering the overall higher risk for immunosuppression in this population and each patient's unique clinical profile.

PUB049

A PerPLEXing Case of Refractory Thrombotic Thrombocytopenic Purpura

Katharine Goebel, Barbara Garay Nontol, Ibrahim Mohsin, Srimathi Manickaratnam. *University of Connecticut, Farmington, CT.*

Introduction: Thrombotic thrombocytopenic purpura (TTP) typically presents with thrombocytopenia, microangiopathic hemolytic anemia, and renal dysfunction. Fever, fatigue and other neurological symptoms can be associated with it. Plasmapheresis (PLEX), often combined with corticosteroids, is the gold standard treatment for TTP. Recent trials have shown that caplacizumab improves platelet levels and reduces mortality, exacerbations, hospital stays and PLEX procedures. We present a unique case of refractory TTP complicated by FFP-induced anaphylaxis managed successfully with caplacizumab and PLEX.

Case Description: A 35-year-old female presented with petechiae, dark urine, and bruising for 3 days. Initial workup revealed platelets of 9000, Hgb 11.2 g/dL, creatinine 1.6 mg/dL (baseline 0.6 mg/dL), hematuria on urinalysis, and positive hemolysis labs, indicative of TTP. Treatment included steroids and daily PLEX with FFP. However, during the fifth PLEX session, she developed anaphylaxis, requiring intubation. PLEX was resumed the next day due to worsening thrombocytopenia and creatinine levels. She underwent 19 PLEX sessions, escalated to twice daily for five days. Caplacizumab was administered from day 9 for 17 days. Additionally, she received one dose of bortezomib while awaiting caplacizumab. Her clinical course was complicated by multiple thromboembolic events, necessitating anticoagulation therapy. Due to bleeding risks, caplacizumab was discontinued. She was discharged home with a low dose of steroid taper with normal platelet count and renal functions.

Discussion: TTP is a life-threatening hematologic disorder with high mortality if untreated. Standard treatment involves PLEX with FFP due to bleeding risk. Body weight influences the FFP volumes used in PLEX. High volume and multiple treatments increase FFP-related anaphylaxis risk, as seen in our case. Despite anaphylaxis, PLEX with FFP was resumed. Caplacizumab, later administered, significantly improved platelet count and reduced PLEX sessions, decreasing FFP usage. Despite challenges, favorable outcomes with caplacizumab mirror trial results, affirming its efficacy. Early caplacizumab initiation may expedite platelet count recovery and decrease PLEX sessions, mitigating FFP-related risks.

PUB050

Spontaneous Tumor Hemorrhage: A Case of AKI

Ramandeep Kaur,[1] Thomas S. Truglio,[2] Brian D. Remillard,[2] Clay A. Block.[2] *[1]Dartmouth Health, Lebanon, NH; [2]Dartmouth Hitchcock Medical Center, Lebanon, NH.*

Introduction: We present a case of spontaneous hemorrhage in a yolk sac tumor resulting in hemorrhagic ascites causing intra-abdominal hypertension, hydronephrosis and acute kidney injury (AKI).

Case Description: A 22-year-old man with previous medical history of asthma presented with abdominal distention and loss of appetite for 3 weeks. The serum creatinine (SCr) at presentation was 0.8 mg/dL (reference range 0.8-1.5 mg/dL) and hemoglobin (Hgb) 7.8 g/dL (reference range - 13.7 -16.5 g/dL). Computed tomographic (CT) imaging demonstrated multiple lesions in the liver, omental and paralumbar masses, a retroperitoneal (RP) hematoma and ascites. Alpha fetoprotein was 18,158 ng/mL (reference range - < 8.3 ng/mL). Biopsy of a liver lesion identified non-seminomatous yolk sac tumor. Chemotherapy with bleomycin, etoposide and cisplatin was initiated, but abdominal distention progressed. By day 5, Hgb had fallen to 5.7 g/dL. SCr rose to 2.4 mg/dL. The worsening ascites was refractory to diuretics. Tumor lysis syndrome was excluded on the basis of normal uric acid and potassium. Ultrasound-guided paracentesis demonstrated intraabdominal hypertension (IAH) with direct pressure measurement of 20 mmHg; mild right-sided hydronephrosis was also observed. The hematocrit of the ascitic fluid was 26.8% suggesting hemorrhagic ascites. CT angiography and the tagged red blood cell scintigraphy failed to identify an actively bleeding vessel. Tumor neovascularity in the large omental and paralumbar mass fed by the right and left gastroepiploic arteries and lumbar arteries without an active extravasation was noted. IAH was resolved with recurrent large volume paracentesis leading to normalization of kidney function. Multiple red blood cell transfusions stabilized the hemoglobin.

Discussion: Spontaneous hemorrhage in yolk sac tumor as a cause of hemorrhagic ascites resulting in IAH and AKI is not well studied, but incidence of 15% in hepatocellular carcinoma has been reported. The etiology likely involves rapid tumor growth and spontaneous and/or chemotherapy related necrosis. Our patient had bleeding prior to the presentation since he came with RP hematoma; suggesting spontaneous necrosis had occurred. IAH results in high renal vein and parenchymal pressure, thereby reducing renal perfusion pressure. Ascites, particularly with IAH, can cause hydronephrosis and AKI.

PUB051

AKI Compared between Critically Ill Patients with Cirrhosis, Neoplasm, and Heart Failure

Kelly Silva,[1] Maria E. Juliao,[2] Stephanie E. Leoni,[2] Ana C. Marchesini,[2] Carolina S. Garcia,[3] Cecília Amaral Peixoto Rabelo,[2] Victor Arthur Ohannesian,[2,1] Miguel Angelo Goes.[2,3] *[1]Sociedade Beneficente Israelita Brasileira Albert Einstein, Sao Paulo, Brazil; [2]Faculdade Israelita Ciências de Saúde Albert Einstein, São Paulo, Brazil; [3]Universidade Federal de Sao Paulo Escola Paulista de Medicina, Sao Paulo, Brazil.*

Background: Acute kidney injury (AKI) might occur in critically ill patients in the ICU with cirrhosis (Cirrh), neoplasms (Neopl), and heart failure (HF). Thus, we studied and evaluated the frequency of AKI in these three conditions, and we also compared a subset of patients with AKI and without AKI in the HF group.

Methods: Our study, a retrospective analysis, meticulously examined 76 patients in the HF group, 27 in the Cirrh group, and 56 in the Neopl group admitted to the ICU. We compared demographic and clinical data, AKI development, and the need for kidney replacement therapy (KRT), mechanical ventilation, inotropes, and vasoactive drugs. Subsequently, we compared the subgroups with and without AKI from the HF group. Multivariate analysis was also performed, ensuring the robustness of our findings.

Results: The Cirrh group had higher total bilirubin levels and lower platelets. The HF group had higher serum urea and creatinine levels and a higher CKD frequency on admission. There also were higher inotrope requirements, development of AKI, and the need for KRT within 28 days of hospitalization. The subgroup of patients with HF and AKI had lower mean arterial pressure (MAP) and ejection fraction (34.6±2.1%, 51.8±2.2%; p<0.001) at hospital admission. While MAP, serum urea levels (OR 1.036; CI, 95% 1.006-1.067; p=0.02), and ejection fraction at hospital admission had an independent association with AKI in the HF group.

Conclusions: Our study's findings underscore the significant frequency of AKI in patients with HF. Moreover, we discovered that ejection fraction, MAP, and urea levels on admission were independently associated with AKI in critically ill patients with HF. These insights are crucial for understanding and managing AKI in this patient population.

PUB052

Light at the End of the Tunnel: A Case of Eculizumab in Gemcitabine-Induced Thrombotic Microangiopathy

Katherine Andrade, Hira Tahir, Henry Yip, Fatima D. Sheikh, Randolph A. Hennigar. *Stony Brook University, Stony Brook, NY.*

Introduction: Gemcitabine-induced thrombotic microangiopathy (G-TMA) is a rare life-threatening condition that is underrecognized, underdiagnosed, and underreported. We report a case of a patient with the classic triad of microangiopathic hemolytic anemia, thrombocytopenia, and kidney failure due to G-TMA treated with Eculizumab.

Case Description: 50-year-old female with metastatic Mullerian adenocarcinoma on Gemcitabine presented with shortness of breath and leg edema. Vitals included a blood pressure 170/78 mmHg, temperature 37.2°C, respiration 18, and heart rate 96 bpm. Labs were significant for serum creatinine (Scr) 1.9 mg/dL on initial presentation which peaked at 4.3 mg/dL, BUN 53 mg/dL, K 5.9 mmol/L, hemoglobin 7.7 g/dL, platelets 82 K/uL, LDH 514 IU/L, haptoglobin 17 mg/dL, reticulocyte count 4% and urinalysis with small blood and protein 100+. Full paraproteinemia and glomerulonephritis workup was non-revealing, and ADAMTS13 was 89% ruling out thrombotic thrombocytopenic purpura. Although Gemcitabine was discontinued, the acute kidney injury, anemia, and thrombocytopenia continued to worsen. A kidney biopsy confirmed TMA likely due to Gemcitabine therapy which prompted initiation of weekly Eculizumab. She had renal recovery with improved Scr to 2.8mg/dL, hemoglobin to 9.4 g/dL, and platelets to 334 K/uL.

Discussion: TMA is classified as primary or secondary. Secondary causes can be due to infection, autoimmune disorder, cancer, or drugs like Gemcitabine. Adverse effects include edema, new onset/exacerbated hypertension, thrombocytopenia, and TMA. The first case of G-TMA was reported in 1994 and its incidence is estimated between 0.02% and 2.2%. It is associated with increased mortality up to 60% and renal injury resulting in end-stage kidney disease. The mechanism is unknown and limited data is available regarding optimal management. Treatment options can include plasma exchange and Eculizumab- a monoclonal anti-C5 antibody that inhibits complement indicated in treating atypical hemolytic uremic syndrome. In our case, she was treated with Eculizumab for G-TMA with partial renal recovery. G-TMA is a challenging diagnosis with unknown recurrence rates and high morbidity-mortality rates in need of therapy guidelines for better outcomes.

PUB053

Severe Rhabdomyolysis-Induced AKI Requiring Hemodialysis in an Adolescent with Influenza A

Sura Alsaffar, Anil K. Mongia. *SUNY Downstate Health Sciences University, New York City, NY.*

Introduction: Viral infections like Influenza A and Covid -19 related infection can cause rhabdomyolysis and subsequent AKI. Most of these AKI resolve with conservative management. We here in report an adoloscent with Influenza A with severe rhabdomyolysis induced AKI requiring hemodilaysis.

Case Description: A 15-year-old male presented with a history of fever, cough, running nose, headache, phonophobia, sore throat, dysphonia, and decreased appetite. He had no known history of liver, kidney, or muscle disorders. He denied any recent history of trauma, immobility (travel, surgery), seizures, new medications, or drug abuse. Physical examination revealed bilateral thigh tenderness and abnormal gait. Laboratory tests were positive for Influenza A, elevated AST/ ALT and elevated BUN/creatinine. Aggressive intravenous fluid resuscitation was initiated. His creatine kinase (CK) levels (>900,000 U/L) started to rise rapidly along with worsening urine output and renal funnction. He developed complete anuria on Day 5 requiring hemodialysis which was done daily initially and then switched to every other day. The patient's urine output and renal function started to improve around Day 8. His CK levels decreased, and urine output returned to normal. Renal function upon discharge showed a creatinine level of 1.6 mg/dL, which further improved to 0.8 mg/dL on subsequent follow up.

Discussion: Monitoring musculoskeletal and renal involvement is important when treating patients with severe acute influenza infection. This case highlights the critical nature of rhabdomyolysis induced acute kidney injury post influenza A infection which in some cases may need renal replacement therapy like hemodialysis.

lab results

Masquerading IgG4 Disease or a Disease Caught in Evolution

Sobia N. Khan,[1] Monica P. Revelo Penafiel.[2] *[1]Stony Brook University, Stony Brook, NY; [2]University of Utah Health, Salt Lake City, UT.*

Introduction: IgG4-related disease (IgG4-RD), a systemic disease characterized by IgG4-positive plasma cells, storiform fibrosis, and tissue eosinophilia. We present a unique case of IgG4 disease which initially has acute interstitial nephritis on kidney biopsy.

Case Description: 64-year-old male with hypertension presented for acute kidney injury. Vitals stable, takes bisoprolol-HCTZ daily. Na 129, K 3.2, BUN 41, SCr 3.2, +ANA, C3/C4 normal. Last known creatinine ~0.9. History revealed has completed Bactrim DS, 2 weeks ago, NSAIDs in past 2 months. Urinalysis: no hematuria, urine-protein to creatinine ratio ~500. SPEP/UPEP with M-spike. Immunofixation with IgG kappa monoclonal antibody. Bone marrow biopsy: 10-15% CD138 positive plasma cells, diagnosed with smoldering multiple myeloma. Native kidney biopsy revealed acute interstitial nephritis with mild interstitial fibrosis and tubular atrophy, diagnosis of acute interstitial nephritis was made with co-trimoxazole or NSAIDs being possible drug culprits. He was treated with Prednisone, acute kidney injury improved but developed residual chronic kidney disease with creatinine of 1.74. MM labs remained stable with no treatment planned. Eight months later, readmitted with AKI and weight loss, repeat kidney biopsy: acute tubular damage, mixed interstitial inflammatory infiltrate with IgG4 positive plasma cell and obliterative arteriopathy consistent with IgG 4 mediated interstitial nephritis. Immunohistochemical stains for IgG4: aggregates of >10 IgG4 positive plasma cells. Serum Immunoglobulin: IgA 148, IgM 35, IgE 110, IgG 2530, normal complement level. CT/MRI of spine, lumbar region, and pelvis negative for cancer. Treated with prednisone and Rituximab.

Discussion: IgG4-RD, a fibroid inflammatory disorder. Pathogenesis unclear, thought to involve a persistent antigenic stimulus possibly from chronic infection triggering polyclonal expansion of B cells. These signals promote IgG 4 class switching, plasma cell expansion and local fibrotic response. Our case is atypical as the general manifestations of IgG4-RD include lymphadenopathy and weight loss. Weight loss is a prominent symptom in patients with exocrine pancreatic insufficiency, but our patient only had kidney involvement. This case highlights the importance of including IgG4 disease in the differential diagnosis of acute kidney injury.

PUB055

Oliguria in Leptospirosis-Associated AKI Is Associated with Worse Outcomes: A Study Based on Novel Prognostic Score System

Renan G. Diniz,[1,2] Luiz P. Neto,[2] Raoni d. Domingues da Silva,[2] Leticia M. De Araujo,[2] Gdayllon C. Meneses,[2] Gabriela Galdino,[2] Geraldo B. Silva Junior,[3] Alice C. Martins,[2] Elizabeth D. Daher.[2] *[1]Universidade de Sao Paulo, Sao Paulo, Brazil; [2]Universidade Federal do Ceara, Fortaleza, Brazil; [3]Universidade de Fortaleza, Fortaleza, Brazil.*

Background: Leptospirosis (LPT) is a neglected tropical zoonosis, with high incidence in some regions of the world. Its severe forms manifest with acute kidney injury (AKI) and lung hemorrhage, associated with systemic inflammatory response and high mortality rates. Prognostic scores and early identification of AKI and endothelial biomarkers have been the subject of recent studies. This study aimed to evaluate the association between oliguric and non-oliguric LPT with clinical scores and endothelial and AKI biomarkers.

Methods: This prospective study incçuded patients with LPT admitted in three hospitals in Brazil. Patients were divided into two groups: those with oliguria (O), and without oliguria (NO). Clinical data, blood, and urine samples were obtained and clinical scores applied. A specific prognostic score system for leptospirosis prognosis was used (QUICK-LEPTO - a new validated score that involves age, lethargy, tachypnea, blood pressure and hematocrit), as well as SOFA (sequential organ failure assessment) score.

Results: Among the total of 44 patients, 81.8% were male. Average age was 40.8 years. Creatinine level was 3.9mg/dL in O vs 2.1mg/dL in NO (p=0.2). Mortality rate was 18% in O and 6.1% in NO (p=0.3). Hemoptysis was more prevalent in O (27% vs. 3%; p-0.043). The QUICK-LEPTO score was worse in O patients (median score 3 vs. 2; p=0.03), while the QUICK-SOFA surprisingly showed no significant difference between the groups. Biomarkers V-CAM, I-CAM, FGF23, Ang1, MCP-1 did not differ significantly between the groups. Syndecan, was higher in O group (774 ± 424 ng/mL vs. 419 ± 380 ng/mL, p = 0.037). NGAL was higher in QLEPTO scores 2 to 6 in O group (472±21 vs. 370±93; p=0,03).

Conclusions: This study indicates that oliguric LPT patients had more hemoptysis and worse results in QLEPTO, despite no differences in QSOFA. QLEPTO is emerging as a new valuable score also for association with some organ injury biomarkers. Further studies with larger samples can help to elucidate more valuable parameters and biomarkers associated with oliguric AKI in LPT aiming to identify early cases with poor prognosis, aiding the early introduction of clinical management.

PUB056

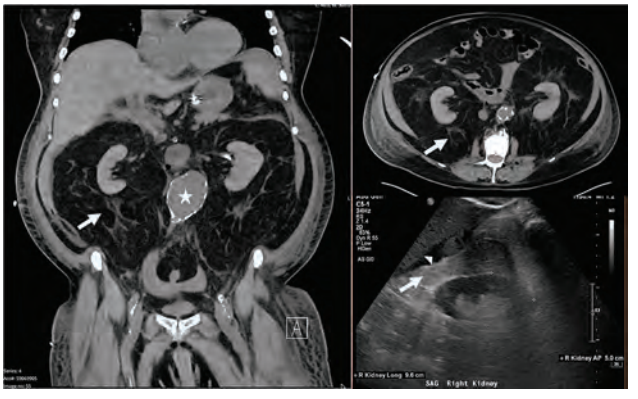
Incidental Finding of Retroperitoneal Lipomatosis

Kristen N. Tillquist,[1] Nadia Al Haddad,[1] Abhilash Koratala,[2] Nathaniel Reisinger.[1] *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Medical College of Wisconsin, Milwaukee, WI.*

Introduction: Knowledge of imaging findings is key to the appropriate diagnosis and treatment of AKI. Here we present a rare incidental finding.

Case Description: A 70-year-old man with hypertension and diabetes presented with complaints of abdominal pain found to be in septic shock due to ascending cholangitis with mixed bacteremia. He was treated with fluids, antibiotics, and percutaneous cholecystostomy with course complicated by acute dyspnea due to pulmonary edema and pulseless cardiac arrest further complicated by AKI for which we were consulted. Exam revealed increased work of breathing and abdominal distention. Urine sediment examination revealed pigmented granular casts. Serum creatinine was 3.33 mg/dL rising from a baseline of 1.03. Echocardiography revealed severe biventricular failure. Right heart catheterization showed right atrial pressure of 8 mmHg with pulmonary capillary wedge pressure of 8 mmHg. Imaging findings in caption.

Discussion: Retroperitoneal liposmatosis is a rare diagnosis consisting of symmetric lipomatous hyperplasia of perinephric adipose tissue. Presentation is usually asymptomatic and incidental, found on imaging obtained for other indications as in our case. Pathology has been described with symptomatic abdominal distention and rarely urinary obstruction. On CT, this appears as marbling of hypoattenuating and hyperattenuating tissue in the retroperitoneal space surrounding the kidneys. On ultrasound, this entity appears as hyperechoic tissue in the hepatorenal and splenorenal recess which can easily be mistaken for hemorrhage. We also considered retroperitoneal fibrosis leading to obstruction without hydronephrosis, but the CT showed fat characteristics that did not affect the collecting system area and urine sediment findings were consistent with ATN.



Left: coronal CT with retroperitoneal lipomatosis (arrow), aortic aneurysm (star)
Right top: transverese CT with retroperitoneal lipomatosis (arrow)
Right lower: sagittal ultrasound with retroperitoneal lipomatosis (arrow), liver subcapsular hematoma (arrowhead)

PUB057

Improving Outcomes for Kidney Patients by Increasing Patient Activation

Lee A. Fleisher,[1] Judith H. Hibbard.[2] *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]University of Oregon, Eugene, OR.*

Background: Effective self-management is essential for patients who have chronic conditions, including kidney disease. Studies show that patient activation (PA), an individual's knowledge, skills and confidence to manage their health is a critical factor in influencing outcomes in kidney patients. Using the Patient Activation Measure (PAM), a 13-item survey, kidney patients who score higher are more likely to follow treatment regimens and achieve better clinical outcomes. This presentation addresses: 1) How much difference can clinical teams make in helping patients gain self-management capabilities? 2) Does incentivizing clinicians make a difference in achieving greater gains in PAM scores, 3) Is it possible for patients who are sicker, older, and economically disadvantaged to make gains in their PAM scores?

Methods: Two populations were compared, a population receiving kidney care and whose patient care plans were designed to support greater PA, and a general population of patients who received ambulatory care, with no special intervention to increase PA. We examine gains in PAM scores over time in both populations and look specifically at gains among patients disadvantaged in some way.

Results: In the general care population, without tailored-interventions and no clinician incentive, PAM scores increased, but score improvement rarely reaches a 3-point threshold considered clinically meaningful. Findings from a forthcoming Lewin report will be discussed, showing gains in activation when clinicians are incentivized to support activation in patients with kidney disease (including dialysis and transplant patients).

Average score change in the report [not publicly released yet] will be shared and compared to the average score change in general care population.

Conclusions: These findings highlight the important role that incentives play in directing the clinical team to help patients gain in PA, especially compared to those who are not incentivized. Findings indicate that patient characteristics were not key determinants of gains in activation: even those who are older, sicker, and economically-disadvantaged, made dramatic gains when clinicians are incentivized to support activation. Speakers will discuss the importance for insurers to provide financial incentives for clinicians to devote time and resources to activate chronic kidney disease patients, resulting in improved care and increasing equity in care

PUB058

Seizures as an Uncommon Presentation of Cisplatin-Induced Nephrotoxicity

Taniya Thomas,[1] Omar Ali,[2] Aman Pal,[2] Swati Mehta,[2] Krishnakumar D. Hongalgi.[2] *[1]Albany Medical College, Albany, NY; [2]Albany Medical Center, Albany, NY.*

Introduction: Cisplatin is a platinum-based chemotherapeutic agent which is commonly used for the treatment of solid tumors. Nephrotoxicity is a well-known complication of this medication and thought to occur due to tubular cell injury and death. We report a case of seizures due to cisplatin induced electrolyte derangements in a patient with osteosarcoma.

Case Description: A 21-year-old female presented with a one week history of poor oral intake and muscle weakness followed by a witnessed tonic-clonic seizure, on a pertinent background of osteosarcoma currently being treated with cisplatin and doxorubicin. She was found to have new-onset electrolyte disturbances with serum potassium 2.3 mmol/L, magnesium 0.7 mg/dL, phosphate <1.0 mg/dL, and calcium 6.8 mg/dL. Urine electrolytes revealed elevated potassium and magnesium. There was no evidence of metabolic acidosis (bicarbonate 25mmol/L) or acute kidney injury (AKI) with a creatinine of 0.74mg/dL and urine output of 2L/day. Urine studies were consistent with magnesium and potassium wasting. CT head was unremarkable for gross changes. Cisplatin was discontinued, electrolytes were repleted daily to maintain certain goals, and amiloride was initiated to decrease magnesium and potassium wasting. Over the course of her hospitalization, her oral intake and electrolytes continued to improve, eventually only requiring magnesium supplementation upon discharge after a week.

Discussion: Nephrotoxicity is a well-established side effect of cisplatin chemotherapy, commonly manifesting with AKI and hypomagnesemia. Persistent hypomagnesemia has been shown to inhibit the sodium-potassium pump and inhibit the release of parathyroid hormone (PTH), resulting in hypokalemia, hypophosphatemia and hypocalcemia, respectively. Our case emphasizes routine electrolyte monitoring and prompt medical management of electrolyte disturbances in patients receiving platinum-based chemotherapy to prevent complications.

PUB059

From Health to Harm: Acute Oxalate Nephropathy in a Weightlifter

Sandeep Kaur, Ryann Sohaney. *Henry Ford Hospital, Detroit, MI.*

Introduction: Oxalate nephropathy is a rare condition characterized by deposition of calcium oxalate within the kidney tubules, typically associated with acute tubular injury. This phenomenon arises from an excess of urinary calcium oxalate, leading to the precipitation of insoluble calcium oxalate crystals within the kidney tubules.

Case Description: A healthy 33-year-old male presented with four days of nausea and vomiting. Laboratory work up showed his serum creatinine (SCr) was 5.4 mg/dL and BUN was 53 mg/dL, compared to a SCr of 1 mg/dL four years prior. Urinalysis revealed 27 RBC/hpf and no protein; with imaging showing no hydronephrosis. A kidney biopsy demonstrated diffuse acute tubular injury with associated calcium oxalate deposition in tubular lumens (see figure 1), consistent with acute oxalate nephropathy. SCr improved modestly to 4.8 mg/dL after 48 hours of aggressive hydration. The patient reported no prior abdominal surgeries, diarrhea, or vitamin C supplements. Upon further questioning, the patient disclosed a rigorous weight training regimen, along with the use of several supplements including a pre-workout and creatine. He was eating a high protein diet and juicing with an abundance of spinach. He was instructed to discontinue juicing and all supplements. Subsequent investigation post-discharge revealed normal vitamin B6 levels, SCr 3.8 mg/dL, 24-hour urine oxalate 76 mg/day (normal <45 mg/day), urine sodium 528 mmol/volume, urine calcium 216 mg/volume, uric acid 954 mg/volume, creatinine clearance 68 mL/min, and total urine volume 6L/day.

Discussion: Secondary hyperoxaluria from excessive ingestion of high oxalate foods is uncommon. Juicing of green leafy vegetables provides large oxalate loads (spinach: ~650mg oxalate/cup). Exercise supplementation, widely used by amateur and professional athletes, is believed to enhance athletic performance yet is largely unregulated. With the escalating popularity of juicing and exercise supplementation, consulting healthcare professionals can help individuals navigate risks and benefits.

PUB060

Non-ICU Administration of Norepinephrine for HRS

Akash Hazari, Alexandra Rosario Aulet, Roberto L. Collazo-Maldonado. *Methodist Dallas Medical Center, Dallas, TX.*

Introduction: Addition of vasoconstrictor is the standard of care for treatment of patients with HRS-AKI. Terlipressin is the only FDA approved vasoconstrictor but it is not available in all hospitals. Norepinephrine is equally effective but it requires the patient to be transferred to the ICU for administration. However ICU beds are in high demand and here we present a case for norepinephrine use for HRS in a specialized liver floor outside of the ICU.

Case Description: 67 yo Caucasian female was admitted with decompensated alcoholic cirrhosis with MELD score of 37, and ascites. Nephrology was consulted for creatinine of 1.98mg/dL elevated from baseline of <1 mg/dL. After 48 hours, the diagnosis of HRS-AKI was done using the ICA 2024 criteria. The patient creatinine went up to 2.1 mg/dL and patient was started on non-ICU specialized liver unit protocol for norepinephrine administration for HRS via central line with a goal to increase the MAP up to 15 mmHg from the baseline of 61 without exceeding the dose of 10mg/min. Therapy was continued for 7 days with the highest dose administered of 6 mcg/min and creatinine improved back to baseline. The patient did not develop any complication throughout the course of norepinephrine administration and was started on midodrine after completion of therapy.

Discussion: Treatment of HRS-AKI with norepinephrine is a safe and cost effective choice for treatment of HRS-AKI without the need for the patient to be transferred to the intensive care unit using a protocol in a specialized non-ICU liver unit barring other indications for ICU transfer.

PUB061

Validation of the Spanish Translation for "Standardized Clinical Assessment and Management Plan" (SCAMP) for the Evaluation of Patients with AKI

Enrique J. Robiou Vivero, L. M. Perez-Navarro, Rafael Valdez-Ortiz. NefrologíaHGM. *Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico.*

Background: Acute Kidney Injury (AKI), a syndrome characterized by the sudden renal excretory function loss defined by changes in urine volume and serum creatinine, affects 10-15% of hospitalized patients, particularly those in ICU, conferring an elevated mortality rate. Currently, timing to start and stop renal replacement therapy (RRT) consider multiple biomarkers and resources, not available everywhere. We must count on different, simple, available tools to facilitate clinicians' decision-making.

Methods: With the authorization of SCAMPs original author, we developed the validation process of it's Spanish Translation following Ortíz-Gutierrez guidelines. We applied the translated format to 68 doctors and fellows of Internal Medicine, Nephrology, and Intensive Care for validation through a standardized clinical vignette that allowed evaluating all the items.

Results: We conducted the analyses on each item conforming "SCAMP", dividing them into 5 domains. First domain identifies risk factors and probable causes of AKI; second domain examines patient's actual state and mortality risk; third domain evaluates RRT classical indications; fourth domain recommends starting or not RRT, while the last domain recommends continuing or discontinuing RRT. We identified several aspects to improve about SCAMP with an overall Cronbach's alpha between 0.6-0.75 on 4 of 5 domains and 0 on the last one. The average time of fulfilling the process was 9.48 ± 1.86 minutes, perceived by the applicants as adequate, considering the translation to be simple, clear in most of the domains except for the ones in which SCAMP asks reasons to overlook the recommendations. SCAMP Spanish Translation was considered a useful and practical tool for the assessment of patients with AKI.

Conclusions: SCAMP is a useful, practical, simple, clear and accurate tool to decide whether to start or not RRT in patients with AKI, based on the clinical assessment. Complementing the findings of the original authors of SCAMP.

PUB062

Two Cases of Interstitial Cystitis and Nephrology Consultation

Gwendolyn R. Derk, Rob Rope. *Oregon Health & Science University, Portland, OR.*

Introduction: Interstitial cystitis is a poorly understood disorder that is primarily managed by urology. There is not a standard of practice regarding the interdisciplinary management and the necessity of nephrology involvement. We present two cases of nephrological consultation for management of interstitial cystitis.

Case Description: Case #1: A 61-year-old Hispanic female with seropositive rheumatoid arthritis and fibromyalgia developed interstitial cystitis 2 years ago managed by urogynecology and rheumatology. She had a normal GFR, sterile urine with microscopic hematuria, no proteinuria nor leukocoria, negative ANA and normal inflammatory markers. She was started on amitriptyline, gabapentin, duloxetine and multimodal pain medications without any response. She was started on hydroxychloroquine with no response after 3 months then switched to methotrexate without any reduction in bladder pain. Cystoscopy revealed Hunner's lesions which did not respond to triamcinolone kenalog nor botulinum toxin injections. She underwent hydrodistention procedures, implantation of a sacral neuromodulator device, pelvic floor physical therapy, and behavioural therapy without improvement. At this point, nephrology was consulted for a trial of off-label cyclosporine therapy prior to offering cystectomy. Case #2: A 39-year-old Chinese male developed ulcerating eosinophilic interstitial cystitis with hematuria and pyuria from ketamine use vs primary cystitis. Final workup was consistent with interstitial cystitis. The patient was treated with trials of antibiotics, fesoterodine, oxybutynin, trospium chloride, and mirabegron over the course of 3 years. He underwent cystectomy and ileal conduit urostomy. He subsequently developed bilateral narrowing of his ureters and moderate to severe bilateral hydronephrosis, chronic kidney disease, and recurrent acute kidney injuries requiring bilateral nephrostomy tubes. He subsequently developed bilateral narrowing of his ureters and moderate to severe bilateral hydronephrosis, chronic kidney disease, and recurrent acute kidney injuries requiring bilateral nephrostomy tubes.

Discussion: Multidisciplinary management and early involvement of nephrology may result in improved outcomes in patients suffering from interstitial cystitis. Given the complex and potentially intransigent nature of the disease, nephrologists should be aware of potential standard and off-label treatments for these patients.

PUB063

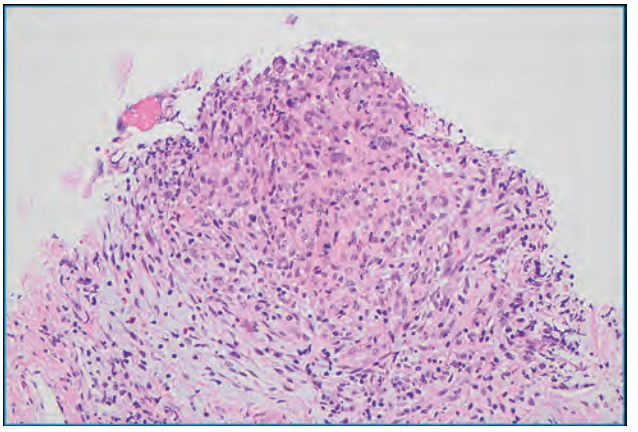
Granulomatous Interstitial Nephritis Secondary to Levetiracetam

Romela Petrosyan, Sujal I. Shah. *Brigham and Women's Hospital, Boston, MA.*

Introduction: Granulomatous interstitial nephritis is detected in approximately 0.5-0.9% of kidney biopsies. Retrospective studies and clinical experience suggest that removal of the offending agent and prompt treatment with corticosteroids result in improvement of renal function. Levetiracetam has not been typically implicated to cause renal toxicity. Here, we report a case of non-necrotizing granulomatous interstitial nephritis secondary to levetiracetam in a patient with APOL1 G1 homozygocity.

Case Description: 53-year-old male with epilepsy and chronic pain presented with severe acute interstitial nephritis after taking omeprazole prescribed by his primary care physician for gastritis with serum creatinine rising from a baseline of 1mg/dL to 4mg/dL. Proton pump inhibitors were added to patient's allergy list and the patient was treated with prednisone taper. Renal function initially improved and subsequently worsened, potentially implicating another culprit. Patient had 312mg of mostly tubular proteinuria which remained unchanged, but his serum creatinine worsened from 2mg/dL to 4mg/dL prompting a repeat kidney biopsy. Kidney biopsy demonstrated a drug-related, active severe granulomatous interstitial nephritis. At the time, patient also experienced a breakthrough seizure and his levetiracetam dose was increased.

Discussion: This case highlights association between levetiracetam, a common and essential anti-seizure therapy, in inducing granulomatous interstitial nephritis in a patient with a background of APOL1 nephropathy. This comes following repeat kidney biopsy after initial corticosteroid treatment for acute interstitial nephritis thought to be secondary to proton pump inhibitors. This case also enforces the significance of repeat kidney biopsy following insufficient response to corticosteroids and removal of a commonly implicated offending agent.



PUB064

Successful Treatment of Human Immunodeficiency Virus-Associated Thrombotic Microangiopathy with Eculizumab

Natasha Freeman, Pietro A. Canetta. *Columbia University Irving Medical Center, New York, NY.*

Introduction: In the era of highly active antiretroviral therapy (HAART), thrombotic microangiopathy (TMA) is a rare manifestation of advanced human immunodeficiency virus (HIV) infection. Management of infection-associated TMA has traditionally included supportive care and antimicrobial agents, rather than anti-complement therapy such as eculizumab.

Case Description: A 62-yo man with advanced HIV and chronic kidney disease stage 3B presented with 3 days of abdominal pain, vomiting, and diarrhea. Laboratory workup revealed severe thrombocytopenia, hemolytic anemia (with schistocytes on peripheral smear), acute kidney injury (AKI), ADAMTS13 activity of 72%, uncontrolled HIV (CD4 count 61 cells/ml, HIV viral load > 10 million copies/ml) (Table 1). A broad infectious workup revealed norovirus GI/GII and influenza A H3 infections and was otherwise negative including for Shiga-toxin producing *Escherichia coli*. Complement factor H autoantibody testing was negative, and he declined genetic testing for complement-mediated TMA risk genes. On day 3, he was started on eculizumab and hemodialysis. On day 8, HAART was resumed. All laboratory parameters improved dramatically by day 10, and hemodialysis was stopped on day 26. He received 5 doses of eculizumab while hospitalized and was discharged on day 31 with resolution of AKI and hemolysis. He was transitioned to maintenance ravulizumab post-discharge, and kidney function remained stable at least 2 weeks after original presentation.

Discussion: HIV-associated TMA is well-recognized but only rarely reported to be successfully treated with eculizumab, as our case illustrates. The underlying pathophysiology and optimal duration of anti-complement therapy for this indication is unknown and warrants further investigation.

Table 1. Laboratory values throughout clinical course

	Day 1 (admission)	Day 3 (prior to HD and eculizumab)	Day 10 (1 week after eculizumab, on HD)	Day 31 (hospital discharge, off HD)	Day 55 (two weeks post-discharge, off HD)
Hemoglobin (g/dl)	12.1	5.7	7.3	8.3	9.4
Platelets (x103/ul)	5	11	90	129	152

Demystifying the Atypical Presentation of Complement-Mediated Thrombotic Microangiopathy

Allysha Yasuda,[1] Chelsea Takamatsu,[2] Meleesa Nocera.[3] *[1]Banner - University Medical Center Tucson, Tucson, AZ; [2]The University of Arizona, Tucson, AZ; [3]The University of Arizona College of Medicine Tucson, Tucson, AZ.*

Introduction: Complement-mediated thrombotic microangiopathy (CM-TMA), also known as atypical hemolytic uremic syndrome (aHUS), is a rare disease characterized by diffuse endothelial blood vessel damage secondary to overactivation of the complement immune system. The classic presentation includes the triad of hemolytic anemia, thrombocytopenia, and acute kidney injury. CM-TMA occurs more commonly in children, but when it occurs in adults, identifying both the diagnosis and underlying etiology requires extensive workup via multi-disciplinary collaboration.

Case Description: We present a male veteran with a complex medical history notable for Crohn's disease treated with increasing doses of his biologic agent, presenting with new-onset liver cirrhosis, splenomegaly, pulmonary hypertension, and the triad of CM-TMA. Our patient's presentation of CM-TMA posed a diagnostic dilemma with overlapping multiorgan dysfunction. However, while awaiting definitive diagnostic confirmation for CM-TMA with genetic complement screening results pending for weeks, ruling out other infectious, hematologic, rheumatologic, autoimmune, and iatrogenic explanations for our patient's condition led us to diagnose CM-TMA and begin urgent treatment. Our patient received infusions of a novel monoclonal complement C5 inhibitor, Ravulizumab, prior to esoteric tests resulting to prevent further, irreversible organ damage.

Discussion: In highlighting the diagnostic workup for and the evolving management of this rare disease, we intend to guide clinicians managing similar patients with confounding pathologies in a clear algorithmic approach to minimize the devastation of CM-TMA.

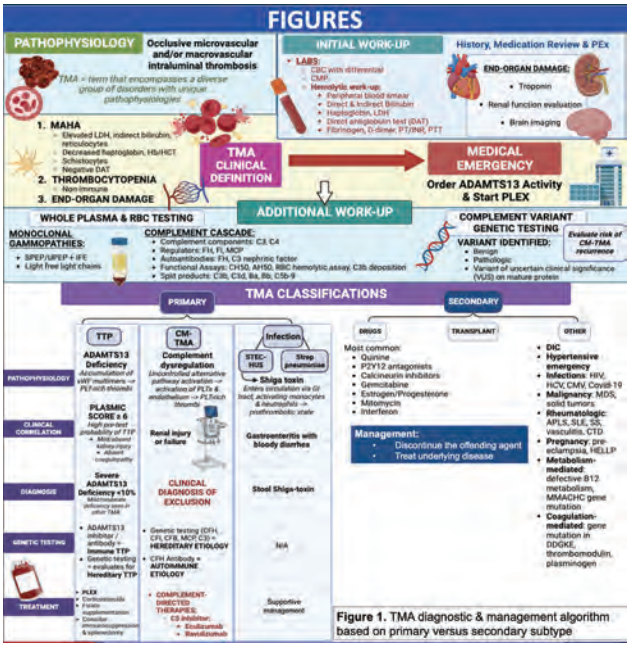

Figure 1. TMA diagnostic & management algorithm based on primary versus secondary subtype

Squeeze the Kidneys Tight Enough: Acute Can Look like Chronic

Ashish Gummadi. *The University of Mississippi Medical Center, Jackson, MS.*

Introduction: Looking at the serum creatinine - physicians can guess on the timeframe of kidney insult. We report an extremely rare example of clinical diagnosis of acute tubular injury where the serum creatinine has increased from 0.8 mg/dL to 5 mg/dL in less than 24 hours while patient had the kidney insult during the hospital stay.

Case Description: 36-year-old female with multiple prior pregnancies complicated with abortions and fetal demise was admitted to OBGYN service for management of right Bartholin's abscess after she failed prior incision and drainage attempts in the ED. she was getting treated with Bactrim for the abscess and underwent Marsupialization of Bartholin's cyst abscess under general anesthesia with propofol along with intraop 30 mg IV Toradol. She spent nearly 15 minutes of her intraoperative time with mild hypotension and inappropriately normal heart rate in 70s. Post operatively she became oliguric during the 1st 24 hours post procedure and put out only 300 mL of urine. Her creatinine went up from 0.8 mg/dL to 5 mg/dL. Increased echogenicity of kidneys was noted on the kidney ultrasound. PTH levels became abnormal within 48 hours-168 pg/mL and then remained elevated even at 2 weeks-201 pg per mL. Clinical diagnosis of acute tubular injury based on her urine electrolytes and clinical course. Her serum creatinine went up by nearly 1 point every 24 hours and reached the peak value of 7.5 mg /dl. Her creatinine recovered to 1.9 mg/dL at 2 weeks mark and she was lost to follow up.

Discussion: When there is increased echogenicity of the kidneys along with elevated iPTH it is often thought to be secondary to chronic kidney disease. Cr of 5 mg/dl in a patient with baseline Cr of 0.8mg/dl would make one look for the kidney insult in the prior 3-5 days range. This is a very rare example of clinical diagnosis of dense acute tubular injury in native kidneys where ultrasound and iPTH values loose their specificity with respect to CKD diagnosis. We know the rate of rise of Serum Creatinine usually falls in the range of 0.8-1.2 mg/dl per day in cases of Acute tubular injury but can Kidneys leak Creatinine stored in the organ itself is a question that remains unanswered. The initial rise in Cr of 0.8 to 5 mg / dl was out of proportion to the expected changes. Eventually her Cr rate of rise from D3 to D4 of hospitalisation started to follow usual expected changes.

PUB067

Improved Kidney Function in Anticoagulant-Related Nephropathy Using N-acetylcysteine

Madeline S. Chung, Brad H. Rovin, Sergey V. Brodsky. *The Ohio State University Wexner Medical Center, Columbus, OH.*

Introduction: Anticoagulant-related nephropathy (ARN) is a recognized condition marked by unexplained acute kidney injury (AKI) accompanied by hematuria while under anticoagulant therapy. Initially associated with warfarin, ARN now encompasses direct oral anticoagulants and antiplatelet agents. Its pathogenesis involves several factors, including tubular obstruction by red blood cell (RBC) casts and cytotoxicity of tubular cells due to intracellular accumulation of hemoglobin degradation products, notably free iron. Clinical outcomes are generally poor, with most patients failing to regain kidney function, leading to progressive kidney failure. Studies show a one-year mortality rate of 39%. Research in mice indicates that treatment with N-acetylcysteine (NAC) improves interstitial fibrosis and tubular atrophy (IFTA) in ARN by reducing oxidative stress. Here, we present a case of a 54-year-old woman diagnosed with biopsy-proven ARN, whose kidney function stabilized after initiating oral NAC.

Case Description: Our patient was noted to have a significant increase in her serum creatinine (sCr) to 5.2 mg/dL from a baseline of 1.09 mg/dL a year earlier. Further evaluation revealed elevated anti-myeloperoxidase (MPO) antibody levels, active urine sediment with RBC casts, and subnephrotic-range proteinuria. Kidney biopsy confirmed ARN, ruling out the suspected ANCA-associated vasculitis but showing moderate mesangial IgA staining suggestive of a form of IgA nephropathy. Additionally, Prussian Blue staining revealed iron deposition in tubular epithelial cells. Her serum creatinine remained elevated, prompting a second biopsy five months later, which showed increased IFTA and more tubules with iron deposition. The patient received a six-month course of glucocorticoids and started oral NAC twice daily at this time, maintaining dialysis independence with improvements in sCr and proteinuria after 15 months.

Discussion: Early recognition and intervention in ARN are crucial due to its association with accelerated chronic kidney disease progression and increased mortality rates. While treatment options remain limited, antioxidant therapy with NAC shows promise in mitigating oxidative stress-induced damage, particularly in patients requiring ongoing anticoagulation. This is significant for individuals like ours with mechanical aortic valves, where discontinuing anticoagulants is not feasible.

PUB068

Apixaban-Related Acute Interstitial Nephritis: A Rare Adverse Effect

Vipin Varghese, Amro Abdelghani, Zeenat Y. Bhat. University of Michigan. *University of Michigan Division of Nephrology, Ann Arbor, MI.*

Introduction: Apixaban is widely prescribed for the prevention of stroke and systemic embolism in atrial fibrillation and the management of venous thromboembolism. Its favorable efficacy and safety profile has escalated its use. However, emerging evidence suggests that apixaban may be associated with adverse renal effects. Here we report a case of apixaban related acute interstitial nephritis.

Case Description: A 62-year-old female with atrial fibrillation, hypertension, hyperlipidemia initially presented to hospital after elevated creatinine on outpatient labs. Patient denied any symptoms apart from fatigue and continued to make urine. She reported the initiation of apixaban 1 month prior to admission. She reported no proton pump inhibitor or antibiotic use. Patient was afebrile and normotensive on admission. She appeared euvolemic and had no rashes or skin changes. Initial laboratory findings were notable for sCr 4.5 mg/dL, serum sodium 137 mmol/L, serum potassium 3.7 mmol/L, serum bicarbonate 20 mmol/L, blood urea nitrogen 50 mg/dL, white blood cell count 8.8 x109/L with 5.3% eosinophils on differential. Urinalysis was noted to have positive leukocyte esterase, 30 mg/dL protein, 50 red blood cells per high power field, and 26 white blood cells per high power field with few eosinophils. Urine protein creatinine ratio with 1.69 g/g protein. Urine culture was found to have no growth. Serologic work up was unremarkable. Serum creatinine peaked at 4.6 mg/dL. A renal biopsy was completed and notable for diffuse interstitial infiltrate enriched in eosinophils and mononuclear inflammatory cells. Immunofluorescence and electron microscopy were unremarkable.

A diagnosis of acute interstitial nephritis was made. Apixaban was discontinued and transitioned to warfarin. Patient was started on prednisone 1 mg/kg (80 mg daily). Serum creatinine improved to 3.5 mg/dL at the time of discharge. Patient was continued on steroid taper. Two weeks after discharge, sCr had improved to 1.54 mg/dL.

Discussion: This case report highlights the importance of vigilance regarding apixaban-induced AIN, particularly as the use of apixaban continues to rise. While AIN remains a relatively rare side effect of apixaban therapy, clinicians should maintain a high index of suspicion when evaluating patients with unexplained renal dysfunction and be prepared to promptly diagnose and manage this potentially reversible condition.

PUB069

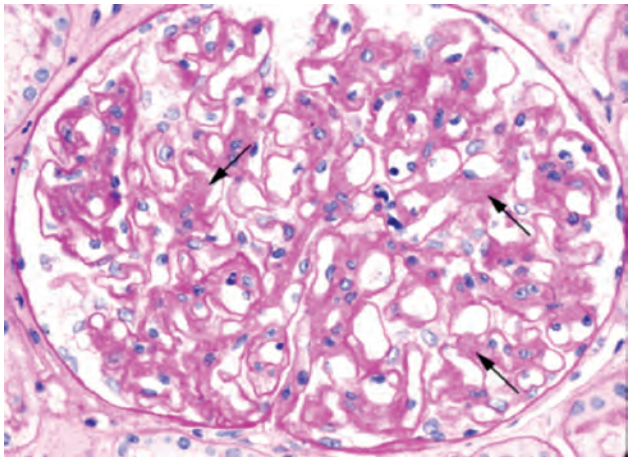
Fibrillary Glomerulonephritis

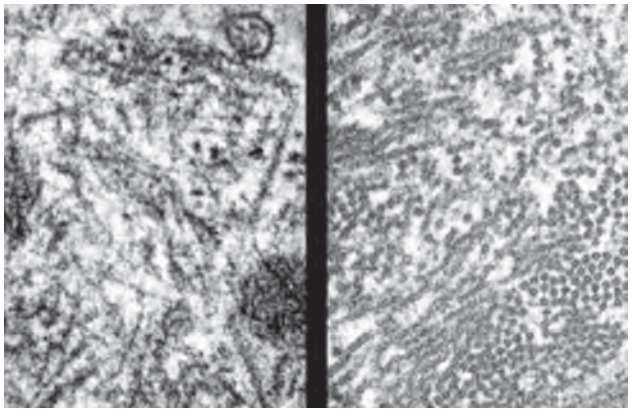
Abdulkader Farran. *Ascension Michigan, Warren, MI.*

Introduction: AGE: 68 GENDER: Female ALLERGIES: None BP at Home: SBP 140-150s. PMH: HTN,OSA,COPD,CHpEF. Review of labs shows evidence of volume depletion in the past, hyaline casts. SH: tobacco use Current Meds: Losartan, Diltiazam, Lasix, Metolazon Worsening renal disease. Physical exam: Bilateral Pitting edema, Irregular rhythm 5.6 bun31 Cr 2.87 glucose113 GFR 18ml/min, CL 101 uric acid 4.4 Ca 8.4 phos 3.3, includes holding ARB therapy, renal ultrasound, UACR

Case Description: Next follow up visit: The patient's lab results show a worsening anemia and a need for an urgent kidney biopsy. Kidney ultrasound showed no hydronephrosis with R 9.5 cm, L 9 cm kidney. The cause of the condition remains unknown. Hospital course: The patient was prescribed IV steroid pulse for three days and received two units of PRBC. Urgent biopsy was held, and GI consultation was conducted. EGD/ colonoscopy showed only polyp which was removed with no malignancy, serology work up was negative. EGD/ colonoscopy showed was negative, serology work up was negative.

Discussion: Fibrillary glomerulonephritis is a condition characterized by hematuria, proteinuria, kidney function impairment, hypertension, and monoclonal gammopathy. Diagnosis involves kidney biopsy, electrophoresis, immunofixation, serum free light chain levels, and other tests. Patients without known cancer should undergo age and risk appropriate cancer screening, while those with imamunotactoid glomerulopathy should be screened for monoclonal gammopathy. Management approach: Addressing underlying causes, immunosuppressive therapy, and supportive care.





PUB070

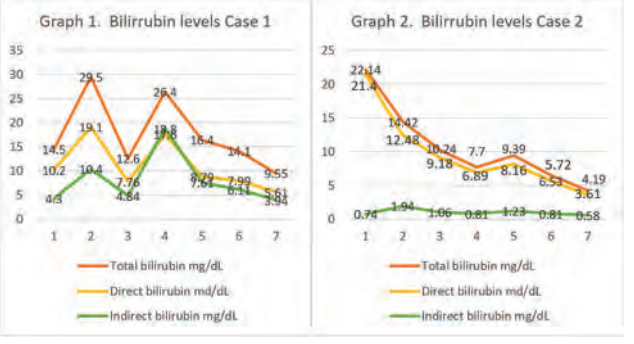
Double Plasma Molecular Adsorption System as Treatment of Liver Failure: A Case Series

Mariana N. Zavala, Rodrigo Lopez, Ricardo A. Garza Treviño, Diana Carolina Sanchez Guerrero, Daniel Alvarez Lara, Carlos Cortez Hernandez, Lilia M. Rizo Topete. *Christus Muguerza Sistemas Hospitalarios SA de CV, Monterrey, Mexico.*

Introduction: The use of extracorporeal liver support systems (ECLS) as a bridge to liver transplantation or recovery has improved in recent years. We present two cases in which double plasma molecular adsorption system (DPMAS) was applied, resulting in progressive improvements in clinical condition and laboratory values of bilirubin and inflammatory markers.

Case Description: Case 1 - A 55-year-old female with AIH for 4 years, in treatment with immunosuppressants. She began one week before with jaundice, Grade I hepatic encephalopathy, and ascites. Laboratory test: Hb 8.9 g/dL, platelets 54,000, INR 2.84, aPTT 55.9 s; Cr 0.73 mg/dL; urea 72.8 mg/dL; BT 14.5 mg/dL, BD 10.2 mg/dL, BI.3 mg/dL; AST 97 U/L; ALT 60 U/L; GGT 43 UI/dL. MELD score of 28 points and Child-Pugh C. On the fifth day laboratory values: Cr 1.71 mg/dL, BUN 61.7 mg/dL, BT 21.9 mg/dL, BD 15.7 mg/dL; we performed 3 sessions of DPMAS, on alternate days, with TPE2000 filter cartridge HA330 II and BS 330. Each session lasted 6 hrs with a plasma volume of 1.5 for DPMAS and 1 time for TPE. The Qb was 130-150 ml/min and Qr post 1300 -1400 ml. RRT technique was CVVHDF. IL-6 decreased from 2707 pg/mL to 993 pg/mL. **Case 2 -** A 51-year-old male with Chronic Hepatitis C, who began 12 hours before admission with Grade II hepatic encephalopathy and mucocutaneous jaundice. On admission, the laboratory tests were: Hb 12.4 g/dL, platelets 219,000, INR 1.94, aPTT 46.9 s; Cr 2.38 mg/dL; urea 38 mg/dL; BT 22.14 mg/dL, BD 0.74 mg/dL, BI 21.4 mg/dL; AST 297 U/L; ALT 402 U/L; GGT 169 UI/dL, ALP 135 U/L. On the third day with worsening of his clinical condition, it was decided to start MARS for two sessions and later two DPMAS sessions.

Discussion: The DPMAS is a blood purification method that is safe and effective for reducing bilirubin levels and inflammatory markers, making it an important option for bridging to transplant or recovery. This could be observed in our patients, in whom the bilirubin and IL-6 levels decreased significantly after treatment with DPMAS.



PUB071

AKI and Hyponatremia in a Patient with Crohn Disease: A Case Report

Ritu Chandra Prakash Tated. *New York Medical College, Valhalla, NY.*

Introduction: Crohn's disease (CD) and ulcerative colitis are examples of inflammatory bowel disease (IBD), which frequently has systemic symptoms that extend outside of the digestive tract. Although they are less frequent, renal and urologic problems can present serious treatment difficulties. Glomerulonephritis is an uncommon but serious extraintestinal manifestation. This case report demonstrates an uncommon correlation between immunoglobulin A nephropathy (IgAN), the most common glomerulonephritis worldwide and Crohn's disease.

Case Description: A week-long history of malaise, flu-like symptoms, and myalgias brought this 47-year-old White female patient to the emergency room. She had a history of Crohn's disease following ileostomy. Severe electrolyte abnormalities and acute kidney damage (AKI) with a creatinine level of 10.7 mg/dL were discovered during laboratory examinations. Renal ultrasonography revealed modest bilateral renal enlargement without hydronephrosis or calculi, despite stable vitals and an unremarkable physical examination. Urine culture came back negative, but urinalysis revealed severe hematuria, pigmented granular casts, and proteinuria. The patient's sodium and creatinine levels gradually improved subsequent to fluid restriction, desmopressin and hypertonic saline. Subsequently, a kidney biopsy demonstrated IgAN. Notably, at the time of the development of renal failure, the patient was not receiving immunosuppressive medicine and was not going through an aggressive flare-up of Crohn's disease.

Discussion: This case emphasizes the need of keeping an eye out for renal involvement in individuals with IBD. The patient's abrupt renal failure and biopsy-proven IgAN demonstrate the intricate interactions between systemic immune responses and renal pathology in inflammatory bowel disease. Although uncommon, IgAN requires regular renal function monitoring in individuals with inflammatory bowel disease (IBD) in order to facilitate the early identification and treatment of any renal consequences. This report supports the use of an integrated strategy to patient management that takes into account both extraintestinal and gastrointestinal IBD symptoms. It is critical to research the pathogenic processes that connect IgAN and IBD and to ascertain if the two conditions are coincidental or suggest that they share common etiopathogenic pathways.

PUB072

Acute Kidney Injury following Ingestion of Topical Minoxidil

Santoshi M. Kandalam, Sean P. Mahoney, Doree Morison. *Tulane University, New Orleans, LA.*

Introduction: Our case presents the dangers of ingesting a 5% topical minoxidil solution as well as the factors that may have contributed to the accidental ingestion.

Case Description: A 24-year-old, spanish-speaking male with no past medical history presented with altered mental status. The patient was not able to participate in the interview. The patient was reportedly agitated and confused, which prompted his family to call EMS. They denied drug use. He was distressed about hair loss and drank approximately one ounce of 5% topical minoxidil. The patient did not realize the minoxidil was meant to be applied topically, likely due to a language barrier. The exam was remarkable for tachycardia to 130, tachypnea, forceful movements of extremities against restraints, and difficulty to arouse. Patient was normotensive, afebrile, and denied abdominal pain. Labs were notable for sodium 119, chloride 73, bicarb 28 with an anion gap of 18, and creatinine of 3.81 with an unknown baseline. UDS was negative for ethanol. UA wnl. VBG with a pH of 7.38. EKG showed sinus tachycardia. Imaging, including a CXR and CT head, showed no abnormalities. Patient was given IV fluids with significant improvement in his Cr and was discharged without requiring any hemodialysis during hospitalization.

Discussion: The maximum recommended dose of oral Minoxidil is 100mg/day. Our patient consumed approximately 1500mg. Minoxidil has been known to cause transient increases in creatinine and blood urea nitrogen, generally resolved with supportive care. Long term studies have shown that minoxidil can cause irreversible kidney damage. There have been a select few case reports discussing severe poisoning after ingestion of topical minoxidil solution, with the most prevalent symptom being profound hypotension. Co-ingestion with alcohol or underlying hepatic disease are considerations in many other toxic alcohol poisonings and may have had a factor in our case. These medications and other cosmetics products are becoming increasingly available over the counter and often do not have black box warnings. This case highlights the importance of obtaining a thorough history and workup, especially in patients who may have a language barrier. Though minoxidil poisonings are rare, understanding the pathophysiology of Minoxidil and the impact on the renal system may lead to better understanding of toxic alcohols such as propylene glycol.

PUB073

A Case of Refractory Anemia from Symptomatic Aluminum Toxicity

Sahil Patel,[1] Alison Nguyen,[1] Renu Regunathan-Shenk.[1,2] *[1]Inova Fairfax Hospital, Falls Church, VA; [2]Virginia Nephrology Group, Falls Church, VA.*

Introduction: Aluminum toxicity is an uncommon disorder seen in patients on hemodialysis (HD) and chronic kidney disease (CKD) because of the availability of non-aluminum containing phosphate binders and removal of aluminum from dialysis fluid.

Case Description: 65-year-old-female Nepali immigrant with a history of end-stage-renal-disease (ESRD) due to unclear etiology on HD who was admitted for subacute confusion, weakness, diffuse pain and fatigue. She started HD in Nepal about 3 months prior to immigrating to the United States (US), and had missed dialysis for 3 weeks because she was unable to establish care here. Her laboratory workup was consistent with ESRD, hyperphosphatemia, hypocalcemia, and severe anemia. She was treated with HD and received supportive care with transfusions, iron, erythropoietin stimulating agents, activated vitamin D, and phosphate binders. Despite these measures, when she started outpatient dialysis she was found to have severe anemia, hypercalcemia, hypophosphatemia and hypoparathyroidism on the initial outpatient tests. An aluminum level was checked that revealed a value of 110 ug/L. This number was confirmed with the Deferoxamine stimulation testing. She started Deferoxamine 5 mg/kg weekly as chelation therapy. As the aluminum levels decreased, her symptoms and laboratory values improved (Table 1).

Discussion: Aluminum toxicity, now rarely reported in developed countries, occurs mainly from ingestion of aluminum containing phosphate binders, exposure to aluminum containing dialysis fluid, or environmental exposures. It is not routinely screened in all dialysis centers in the US given elimination of aluminum from the water supply and from phosphate binders. Our patient likely had aluminum exposure while in Nepal prior to her arrival in the US. Her treatment refractory anemia and poorly controlled hyperparathyroidism were emblematic of aluminum toxicity. This case report highlights the importance of screening for aluminum levels among immigrants with ESRD.

Laboratory values as the patient was treated with Deferoxamine.

Date	Aluminum (ug/L)	Hemoglobin (g/dL)	Parathyroid (pg/mL)	Calcium (mg/dL)	Phosphorus (mg/dL)
5/18/23	-	3.9	-	6.5	9.7
5/25/23	-	8.0	-	7.7	3.2
6/6/23	110	6.5	<7	11.6	2.2
7/1/23	92	6.9	60	10.8	2.1

PUB074

Increase in Hemoglobin Levels in Patients with Advanced CKD with Severe Anemia and Major Adverse Kidney Events

Jonathan Chavez,[1,2] Guillermo Garcia-Garcia,[1] Ramon Medina,[1,2] Karla Hernandez Morales,[1] Jahir R. Camacho,[1] Edgar J. Carmona,[1] Alexa N. Oseguera Gonzalez,[1] César Murguía Soto,[1] Maria de la Luz Alcantar Vallin,[1] Alejandro Martínez Gallardo González,[2] Guillermo Navarro Blackaller.[1] *[1]Universidad de Guadalajara, Guadalajara, Mexico; [2]Hospital Civil de Guadalajara, Guadalajara, Mexico.*

Background: In advanced CKD the worse the hemoglobin (Hb) values, the higher the risk of major adverse kidney events (MAKE). The existing evidence regarding this relationship is scarce. We carried out a retrospective cohort in patients with advanced CKD and severe anemia, who had increases in Hb level during follow-up, we looked for the association with MAKE.

Methods: In a retrospective cohort study, we included patients with CKD G3b-G5 without dialysis and severe anemia at baseline (Hb <8.0 gr/dL). Our objectives were to analyze whether there was an association between reach Hb >10gr/dL or >12gr/dL and the risk of MAKE, defined as the start of KRT and death, also analyzed the individual components of MAKE

Results: Between 2018 and 2023, a total of 174 patients with CKD G3b-5 and severe anemia (median Hb 7.05 g/dL) were included; the age was 38.5 years, 64% were male. During follow, 32 and 11 patients elevated the Hb >10 g/dl and >12 g/dl, 88.5% used erythropoietin. Patients who achieved an Hb >10 g/dL had an associated reduction in the risk of MAKE (HR 0.46, p = 0.002), especially in reducing the risk of KRT (HR 0.463, p = 0.002), but not for mortality (HR 0.88, p = 0.834), interestingly, use of EPO were associated with increasing this risk (HR 7.78, p = 0.03). We found no benefit in MAKE or its components in patients who achieved Hb >12 g/dL, nor in granular changes in the Hb level.

Conclusions: In our cohort of patients with advanced CKD and severe anemia, we found that those who during their follow-up increased their Hb value >10 g/dL had an association with a reduced risk of MAKE, mainly due to the KRT component.

PUB075

Single-Center, 1-Year Experience of the Hypoxia-Inducible Factor-Prolyl Hydroxylase Inhibitor (HIF-PHI) Desidustat in Dialysis-Dependent Patients with CKD-Related Anemia

Rajeev Bhatia, Ajay Marwaha, Sonali Raheja. *Shriman Superspeciality Hospital, Jalandhar, India.*

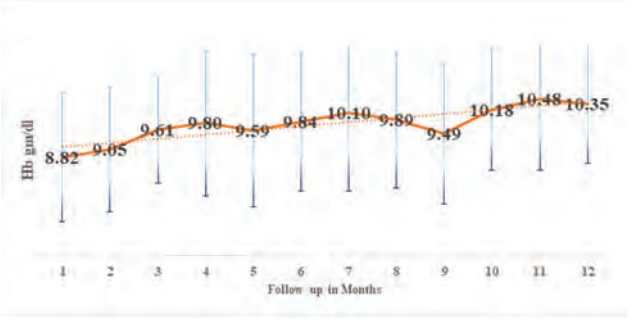
Background: Chronic kidney disease-induced anemia is due to relative deficiency of Erythropoietin from kidneys. In the dialysis-dependent category, patient become dependent on erythrocyte-stimulating agents. Newer HIF PHIs showed promise of correcting anemia in dialysis-dependent CKD anemia patients. Our study is a retrospective analysis of usage of HIF PHI in dialysis-dependent patients.

Methods: This is a single center retrospective analysis of one year experience at Shrimann hospital, Jalandhar. We enrolled patient who are diagnosed with CKD – Anemia and dialysis dependent at our center. These patients were started on Treatment of Desidustat 100 mg and 50 mg thrice in a week and every monthly their Hemoglobin monitored.

Results: In present study, we have enrolled total 58 patients. Out of this 36 (62%) were male and 22 (38%) were female. All patient received dialysis for 3 times in a

week. Patient received IV iron according to iron profile. Out of 57 patients, majority had diabetic Kidney Disease (n=42, 73.6%), Hypertension (45, 78.9%), CAD (4, 7%), ADPKD (2, 3.5%) and one case of post-transplant (1, 1.7%), Multiple Myeloma (1,1.7%), IgAN (1,1.7%), Majority of our patient received treatment of Desidustat 100 mg (n=32, 55.2%) and 50 mg (n= 26, 44.8%) for CKD anemia thrice a week. Mena Serum creatinine 7.56 ± 3 mg/ dl and eGFR 8.72 ± 5.7 mL/min/1.73m^2. Mean Serum Iron 29.74 ± 46.5 mcg/dl. Baseline Hb at the start of treatment was 8.82 ± 1.8 gm/dl at the end of study Hb was 10.35 ± 1.7 gm/dl (p= 0.002, One way ANOVA) test) showed in Figure 1. Mean difference from baseline observed was 1.53 gm/dl in dialysis dependent patients. In present study al patients maintained good compliance with the treatment of Desidustat. Out of 58 patients, we have not observed any thrombosis of AV fistula or Fistula failure, treatment failure, or hyperkalemia with HIF-PHI treatment.

Conclusions: Desidustat showed a promising outcome in terms of improvement of Hb in CKD-anemia. Long-term, one year data showed desidustat is a safe alternative to erythropoietin analogue.



PUB076

Hematuria Rescues Urothelium

Jonathan M. Barasch,[1] Katherine Xu,[1] Tian Shen,[1] Aryan S. Ghotra,[1] Kivanc Nesanir,[2] Rachel Sturley.[1] *[1]Columbia University, New York, NY; [2]University of Richmond, Richmond, VA.*

Background: Hematuria is a frightening complication of urinary diseases. Hematuria may be pathogenic because heme carries lipophilic Fe^{2+} which damages cells. In addition, iron is limiting for bacterial growth, but bacteria express heme transporters and siderophore receptors. Hence, hematuria may accelerate UTI and tissue damage.

Methods: We loaded the urinary system with ferric iron or with heme by phenylhydrazine (PHZ) hemolysis. UTI was titrated in male-females (20uL of 10^7 UTI89 CFU) and tissue damage monitored by $CK20^+$ superficial shedding versus preserved $CK5^+$ basal cells. RNA was captured by (1) physical isolation of urothelia from bladder mucosa (2) and by 4-thiouracil pulse labeling of nascent RNA in vivo in Upk2Cre;$Uprt^{f/f}$ urothelia. RNAscope probed anatomical expression of induced genes.

Results: UTI induced detachment and shedding of superficial cells (6-12hrs post infection). Ferric iron worsened and ferric iron deficiency suppressed bacterial growth and shedding. In contrast, hematuria did not affect bacterial growth but surprisingly prevented shedding (n=75 mice). Retention of superficial cells and suppression of erythema were grossly visibile even after bacterial invasion. Urothelial RNA demonstrated that pyroptosis genes mediate heme sensitive cell death. Indeed, GsdmD KO mice suppressed urothelial shedding and accordingly hematuria suppressed GsdmD RNA expression. Upstream regulators of GsdmD, such as Nlrp3 and cleaved casp1 and 11 proteins were depressed by hematuria in superficial and intermediate cells. Pyroptosis associated cytokines, chemokines, neutrophil chemoattractants, interleukins and inflammatory cell death regulators were quantitatively downregulated. In accordance, neutrophil invasion of the infected bladder was suppressed. Heme is captured in urothelia by HRG1, which in turn transports heme into the cytoplasm where upregulated BMAL, NPAS2, and HMOX1 metabolize heme to Carbon Monoxide (detectable with our Palladium-based fluorescence quenched probes) and iron (detectable by Perls and Turnbull's staining). However, HRG1 KO and HMOX KO still demonstrated rescue by hematuria. Rather, multiple TLR components mediate heme's activity since KO prevented urothelial rescue.

Conclusions: Hematuria, a frightening sign of urological disease, is surprisingly anti-inflammatory and cell protective in UTI-Cystitis.

Funding: NIDDK Support

PUB077

Dapsone-Induced Methemoglobinemia

Ariella Rubel, Alan Araiza, Raphael J. Rosen. *The Stamford Hospital, Stamford, CT.*

Introduction: Methemoglobinemia is a state in which hemoglobin-associated iron is oxidized to Fe3+, resulting in allosteric changes to hemoglobin that inhibit oxygen release to peripheral tissues. It is often secondary to oxidizing substances like benzocaine, nitrates, and dapsone, a sulfa derived antibiotic that can be used for pneumocystis jiroveci (PCP) prophylaxis. Methemoglobinemia presents with nonspecific headache, weakness, and fatigue along with unexplained hypoxemia and cyanosis that do not improve with supplemental oxygen. The saturation gap, or the difference between a depressed pulse oximetry reading (SpO2) and a normal oxygen saturation (SaO2) on arterial blood gas (ABG), is characteristic. This is an artifact of pulse oximetry technology, which measures SpO2 by calculating the difference between absorption of distinct light wavelengths for hemoglobin and oxy-hemoglobin. As oxyhemoglobin falls, SpO2 drops, plateauing around 85%. In contrast, ABG measures oxygen partial pressure directly to estimate SaO2, neither of which change in methemoglobinemia.

Case Description: An 84-year-old woman presented with rapidly progressive glomerulonephritis and, after kidney biopsy showed diffuse cellular crescents, was diagnosed with PR-3 ANCA vasculitis. She had no pulmonary manifestations. She was treated with pulse-dose steroids, cyclophosphamide, and plasma exchange. G6PD level was normal and she was given dapsone for PCP prophylaxis. Despite kidney recovery and decreasing PR-3 ANCA titer, she developed worsening hypoxia. Hemoptysis and cough were absent. Chest X-ray was clear and chest computed tomography (CT) showed no evidence of pneumonia or diffuse alveolar hemorrhage. VQ scan excluded pulmonary embolism. Echocardiogram with bubble study was normal. A trial of furosemide did not improve oxygenation. Pulse oximeter measured oxygen saturation of 88% with no improvement after administration of 6 liters oxygen by nasal cannula. ABG demonstrated oxygen partial pressure of 100 mmHg. Serum methemoglobin level was elevated to 7.6%. With withdrawal of dapsone therapy and addition of high dose oral ascorbic acid, hypoxia resolved.

Discussion: Glucocorticoids are the basis of ANCA vasculitis treatment, causing iatrogenic immunocompromise and necessitating PCP prophylaxis. While hypoxemia has many potential culprits in syndromes that include pulmonary manifestations, dapsone use should prompt consideration of methemoglobinemia.

PUB078

Safety and Efficacy of Hypoxia-Inducible Factor-Prolyl Hydroxylase Inhibitors Compared with Erythropoiesis-Stimulating Agents in Patients with Nondialysis-Dependent CKD: Analysis of Real-World Data

Masayuki Yamanouchi,[1] Tatsuya Suwabe,[1] Kengo Furuichi,[3] Takashi Wada.[2] *[1]Toranomon Hospital, Minato-ku, Japan; [2]Kanazawa University, Kanazawa, Japan; [3]Kanazawa Medical University, Kahoku-gun, Japan.*

Background: Hypoxia-Inducible Factor Prolyl Hydroxylase Inhibitors (HIF-PHIs) are expected to be an alternative to erythropoietin stimulating agents (ESAs) due to their ease of administration. However, evidence for the safety and efficacy of HIF-PHIs compared to ESAs is limited in the real-world clinical settings.

Methods: We emulated a target trial, using a 1:1 propensity score matching, to compare the safety and efficacy of outcomes in patients with non-dialysis dependent chronic kidney disease and renal anemia who initiated HIF-PHIs with those initiated ESAs. The primary safety outcomes were the first occurrence of MACE; composite of cardiovascular death, myocardial infarction, or stroke, expanded MACE; MACE plus hospitalization for either heart failure or a thromboembolic event, MAKE; composite of initiating kidney replacement therapy, experiencing over a 40 % eGFR decline from baseline, and all-cause mortality. The primary efficacy outcome was the mean changes in Hb level from baseline to month 21 through 24 (non-inferiority margin, -0.75 g/dL).

Results: During a median follow-up of 14 (IQR, 10-24) months, compared with patients initiating ESAs (n = 269), those initiating HIF-PHIs (n = 263) had a similar risk of MACE (Hazard ratio (HR) 0.80; [95% confidence interval (CI), 0.31-2.10]), expanded MACE (HR 0.81 [0.40-1.63]), MAKE (HR 1.01 [0.72-1.42]), and all-cause mortality (HR 1.41 [0.50-3.99]). The mean (±SE) changes in Hb level from baseline to month 21 through 24 were 1.62±0.16 g/dL in the HIF-PHIs group and 1.38±0.08 g/dL in the ESAs group.

Conclusions: There were no statistically significant differences in safety and efficacy between HIF-PHIs and ESAs. The results may help guide the choice of treatment of renal anemia.

PUB079

Alignment of ChatGPT with Expert Opinion in Nephrology Polls

Justin Pham, Charat Thongprayoon, Jing Miao, Iasmina Craici, Wisit Cheungpasitporn. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Healthcare professionals often face complex clinical scenarios that do not have straightforward solutions, necessitating professional collaboration. This is common in nephrology, where soliciting peer insight is crucial for informed decision making. ChatGPT, a sophisticated language model, has demonstrated its problem-solving utility in several fields. However, its alignment with prevailing medical opinions in the context of intricate clinical scenarios remains unexplored. This study seeks to evaluate how closely ChatGPT's responses align with the nephrology community's prevailing opinions by comparing responses to real-world clinical questions.

Methods: Nephrology polls were collected from the social media site X using the hashtag #AskRenal, resulting in 271 questions. These were presented to ChatGPT-4, which generated answers without prior knowledge of the poll outcomes. This was

repeated one week later using the same questions presented in a randomized order to assess internal consistency. The responses given by ChatGPT-4 during the two rounds of inquiry were compared to the poll results (inter-rater) and between each other (intra-rater) using Cohen's kappa statistic (κ). The questions were also grouped into seven categories based on subject matter, and subgroup analysis was performed.

Results: 60.2% of responses from ChatGPT matched the poll results in the first round of inquiry (κ=0.42) and 63.1% matched in the second (κ=0.46). The two rounds had an internal agreement rate of 90.4% (κ=0.86). The included table presents subgroup data.

Conclusions: ChatGPT-4 demonstrates moderate capability in replicating prevailing professional opinion in nephrology polls, with varying performance levels between question categories and high internal consistency. While AI-based language models have potential to assist with decision making in complex clinical scenarios, their reliability has yet to be fully proven and they should be integrated cautiously.

Agreement by question category

	Round 1	Round 2	Intra-rater
CKD, ESRD, dialysis, & transplant	62% (κ=0.4)	64% (κ=0.5)	90% (κ=0.9)
Electrolyte & acid-base disorders	62% (κ=0.5)	54% (κ=0.4)	92% (κ=0.9)
Glomerular disease, AKI, & critical care	51% (κ=0.3)	58% (κ=0.4)	87% (κ=0.8)
Mineral, bone, & stone diseases	78% (κ=0.7)	89% (κ=0.8)	89% (κ=0.8)
Pharmacology	65% (κ=0.5)	65% (κ=0.5)	100% (κ=1.0)
Tubular, interstitial, & cystic disorders	50% (κ=0.1)	25% (κ=-0.1)	75% (κ=0.6)
Other	73% (κ=0.6)	80% (κ=0.7)	93% (κ=0.9)

PUB080

Examining Global and Regional Interest in Kidney Transplantation Awareness

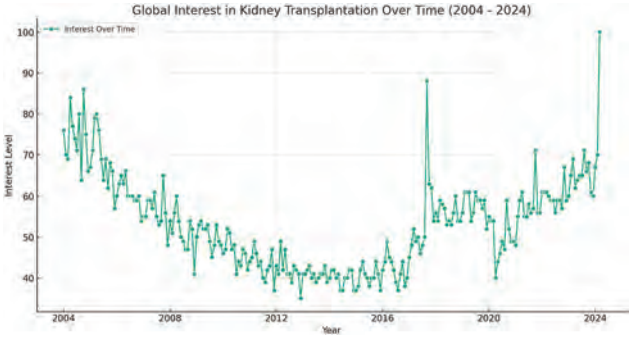
Oscar A. Garcia Valencia,[1] Charat Thongprayoon,[1] Jing Miao,[1] Napat Leeaphorn,[2] Pooja Budhiraja,[3] Supawadee Suppadungsuk,[1] Iasmina Craici,[1] Wisit Cheungpasitporn.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Mayo Clinic in Florida, Jacksonville, FL; [3]Mayo Clinic Arizona, Scottsdale, AZ.*

Background: Kidney transplantation is a vital treatment for end-stage kidney disease, offering enhanced quality of life and survival rates. Given the increasing use of the internet for health-related information, analyzing online search trends can provide insights into public engagement and awareness. This study used Google Trends™ to examine global and regional interest in kidney transplantation.

Methods: A comprehensive investigation using the phrase "kidney transplantation" was conducted on Google Trends, covering the period from its creation in January 2004 until March 2024. The analysis was centered on global engagement, with a detailed examination of patterns across regions and nations. The interest was assessed using Google Trends indices, with each data point reflecting a monthly search volume score

Results: Across the two decades, a dynamic fluctuation in global interest was observed, marked by significant peaks and valleys. The highest interest occurred in March 2024, reaching an index score of 100, while the lowest was recorded in December 2012 with a score of 35. A pronounced increase in interest was seen in March 2024 when compared to the same period in 2023 (escalating from 69 to 100) suggesting an increase in global attention towards kidney transplantation. Regional analysis highlighted distinct variations with South Dakota, Missouri, and Maryland leading in the United States. Globally, Sudan, Nepal, and Pakistan emerged as the countries with the highest interest with the US ranking sixth.

Conclusions: The study reveals a significant global and regional interest in kidney transplantation, highlighted by recent peaks in search volume. The variations in interest levels may reflect differences in healthcare needs, awareness, and resource availability. This study provides valuable insights into the global and regional landscape of kidney transplantation interest, emphasizing the importance of harnessing online platforms to enhance public awareness, education, and engagement.



PUB081

Identification of Kidney Cell Types in Single-Cell RNA Sequencing and Single-Nucleus RNA Sequencing Data Using Machine-Learning Algorithms

Siddharth S. Madapoosi,[1] Adam Tisch,[1] Stephen A. Blough,[1] Jan S. Rosa,[1] Sean Eddy,[1] Abhijit S. Naik,[1] Christine P. Limonte,[2] Phillip J. McCown,[1] Rajasree Menon,[1] Sylvia E. Rosas,[3] Chirag R. Parikh,[4] Laura H. Mariani,[1] Matthias Kretzler,[1] Ahmed Mahfouz,[5] Fadhl Alakwaa.[1] Kidney Precision Medicine Project (KPMP). *[1]University of Michigan, Ann Arbor, MI; [2]University of Washington, Seattle, WA; [3]Joslin Diabetes and Endocrinology Research Center, Boston, MA; [4]Johns Hopkins University, Baltimore, MD; [5]Leids Universitair Medisch Centrum, Leiden, Netherlands.*

Background: Single-cell RNA (scRNA) and single-nucleus RNA (snRNA) sequencing offer researchers valuable insight into the biological states of kidney cells. Manual cell-type annotation requires extensive domain expertise, is time-consuming, and limits broad scalability.

Methods: We compared the ability of different machine learning (ML) algorithms including support vector machines, random forests (RF), multilayer perceptrons (MLP), k-nearest neighbors (KNN), and XGBoost to predict kidney cell types from scRNA/snRNA-seq data. We used publicly available human kidney datasets comprised of 62,120 cells from 40 donor biopsies included in 5 expert-annotated sc/snRNA-seq studies. We integrated all 5 studies using the Seurat rPCA integration protocol and used inter-dataset combinations of 4 training datasets and the fifth for performance testing. We compared the performance of the different ML algorithms using F1 scores and percentage of unknown cells.

Results: Upon integration of all 5 datasets, we identified a total of 16 harmonized cell types. All 5 algorithms predicted these cell types with high accuracy (median F1=0.94 and 1.8% unknown cells). No algorithm was superior to the others overall (p>0.05) and all algorithms successfully rejected cell types naive to training data, in particular RF, MLP, and KNN models. F1 scores were lower across ML algorithms when using snRNA-seq data for testing, particularly for proximal tubule and fibroblast cells.

Conclusions: ML algorithms were able to accurately annotate adult kidney cell types from scRNA-seq, and to a lesser extent, snRNA-seq data. Our study methodology may be applied across other validation cohorts with the expectation that prediction accuracy improves over time.

Evaluating the Acceptability and Feasibility of a Low-Sodium Educational Program Using Immersive Virtual Reality in Patients on Hemodialysis: A Study Protocol

Milad Hasankhani,[1] Geovana Martin-Alemañy,[1] Kaitlyn Pawelczyk,[2] Kenneth R. Wilund.[1] *[1]The University of Arizona, Tucson, AZ; [2]University of Illinois Urbana-Champaign, Urbana, IL.*

Background: About 80% of hemodialysis (HD) patients in the U.S. have uncontrolled hypertension, primarily due to chronic volume overload. HD patients are often prescribed low-sodium diets to prevent thirst and fluid accumulation. However, the poor compliance highlights the pressing need for innovative strategies to reduce sodium intake to minimize cardiovascular risks associated with HD.

Methods: This study employs an exploratory, non-randomized, open-label trial using a mixed-methods approach. Twenty patients who meet the inclusion criteria will be provided access to the VR program during their regular dialysis sessions. The program includes five educational modules, each approximately thirty minutes, and incorporating interactive games and other knowledge building activities in an engaging environment to help patients learn low-sodium meal planning and shopping. Oculus Quest 2 headsets will be used to deliver the VR experience, ensuring patient safety and comfort. Quantitative and qualitative data will be collected through surveys measuring engagement, satisfaction, VR content quality, and sodium-related knowledge.

Results: Results will focus on the acceptability and feasibility of the low-sodium educational program delivered through immersive virtual reality. The target rates for recruitment, retention, and adherence are set at or above 75%. The study anticipates a positive impact on participants' dietary sodium knowledge post-intervention.

Conclusions: This program has the potential to advance HD patient's knowledge on better management of their dietary sodium intake and related health conditions, with implications for broader applications of VR in health education and patient engagement.

The Kidney Mobile Health Registry: A Digital Research Approach

Eloise Salmon,[1] Ashley E. Rahimi,[1] Rebecca Scherr,[1] Michael Arbit,[1] Tina Creguer,[1] Hailey Desmond,[1] Abigail R. Smith,[2] Susan F. Massengill,[3] Zubin J. Modi.[1,4] *[1]University of Michigan Michigan Medicine, Ann Arbor, MI; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]Levine Children's Hospital, Charlotte, NC; [4]University of Michigan Susan B Meister Child Health Evaluation and Research Center, Ann Arbor, MI.*

Background: Mobile health (mHealth) technologies offer a novel approach to research and data collection. Despite mHealth use in other chronic disease states, kidney focused initiatives are limited. The Kidney Mobile Health Registry is designed to assess the feasibility of mHealth use in targeted kidney disease study populations.

Methods: Three observational cohort studies were selected as pilots for the mobile registry (Figure 1). The registry was built in collaboration with CareEvolution (*Ann Arbor, MI*) and is offered via the MyDataHelps (MDH) application. Individuals are invited to participate or can enroll independently, consenting electronically within MDH. Enrollment is uncapped and includes both children and adults.

Results: The studies were moved to production following beta testing in a phased approach. All studies have launched as of March 2024, with recruitment to date detailed in Figure 2.

Conclusions: MHealth offers a novel research and disease management approach. Further exploration of recruitment, retention, and engagement strategies specific to kidney disease populations are needed.

Cardiovascular Risk Stratification Using Predicted Coronary Artery Calcium Score from a Machine-Learning Model

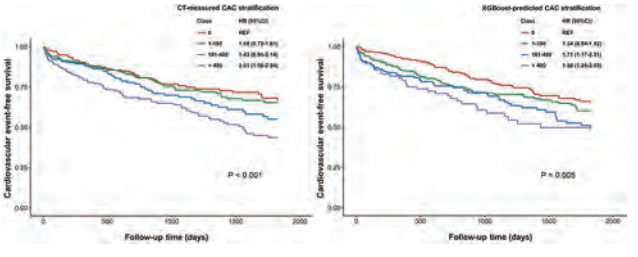
Kullaya Takkavatakarn,[1,2] Pooja Anand Gownivaripally,[1] Girish N. Nadkarni,[1] Lili Chan.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]King Chulalongkorn Memorial Hospital, Bangkok, Thailand.*

Background: Cardiovascular disease (CVD) is a common complication in patients with chronic kidney disease (CKD). Coronary artery calcium (CAC) score is a clinically validated marker of CVD risk but not readily accessible for many patients. We aimed to develop and validate machine learning (ML) models to predict CAC groups and assessed the use for risk stratification of CVD events.

Methods: We obtained electronic health record (EHR) data from patients with non-dialysis CKD stages 3-5, defined by an eGFR of less than 60 mL/min/1.73 m2 for at least 3 months, and without a history of CVD at the Mount Sinai Health System who underwent a CAC scan. CAC scores were categorized into 4 groups (0, 1-100, 101-400, and > 400). We divided the cohort into a training and test dataset (70/30) then developed and validated four models, decision tree (DT), random forest (RF), XGBoost, and deep neural network (DNN), to predict CAC score groups. Area under the receiver operating characteristic curve (AUROC) was used to evaluate model performances. We utilized Cox regression to assess the association between CAC group and the best-performing ML model-predicted CAC group with CVD events within 5 years. Risk discrimination was measured using C-statistics.

Results: We included 648 patients; the median age was 70 (IQR 63-77) and the median CAC score was 64 (IQR 0-306). XGBoost yielded the best AUROC (0.72; 95%CI 0.63 to 0.79), followed by RF (0.71; 95%CI 0.63 to 0.78), DNN (0.64; 95%CI 0.53 to 0.71), and DT (0.61; 95%CI 0.52 to 0.68). 210 (32%) had CVD events during the 5-year follow-up. CT scan-measured CAC and the XGBoost-predicted CAC risk stratification were significantly associated with CVD events (Figure1). The C-statistics were 0.67 and 0.66 respectively.

Conclusions: ML-derived CAC risk stratification is comparable to CT scan-measured CAC risk stratification in predicting CVD events. Implementing ML techniques on EHR data can serve as an alternative approach for assessing CAC and improving CVD risk prediction, particularly in settings with limited resources.



PUB085

Exploring the Connection between Serum Lead Levels and Kidney Function among the Obese Population: Analysis of NHANES, 2017-2020

Chutawat Kookanok,[1,2] Sansanee Thotsiri,[3] Methavee Poochanasri,[2] Kamonluk Rodsom,[1] Narathorn Kulthamrongsri,[4] Ariya Mongkolporn,[5] Varissara Sinkajarern,[6] Thutpharritchn Phoonakh,[6] Wanprapit Noree,[7] Urairat Chuenchaem,[8] Ekamol Tantisattamo.[1] *[1]University of California Irvine School of Medicine, Irvine, CA; [2]Phramongkutklao Hospital, Bangkok, Thailand; [3]Mahidol University Ramathibodi Hospital, Bangkok, Thailand; [4]Mahidol University Faculty of Medicine Siriraj Hospital, Bangkok, Thailand; [5]Thammasart University Faculty of Science and Technology, Khlong Nueng, Thailand; [6]Vimut Hospital, Bangkok, Thailand; [7]University of Illinois Chicago, Chicago, IL; [8]Bumrungrad International Hospital, Bangkok, Thailand.*

Background: Lead, a common toxic substance found in air pollution and consumer products, is known for its association with renal damage, notably lead nephropathy. National-scale evidence on how obesity influences this link is limited and uncertain. This study investigates whether obesity exacerbates the risk of kidney damage from lead toxicity.

Methods: A national study of 6,789 adults, using NHANES 2017-2020 data, analyzed the correlation between serum lead levels (Pb-S) and eGFR. Participants were categorized into non-obesity and obesity groups based on BMI, with three linear regression models employed (Table 1). Receiver operating characteristic (ROC) curve analysis was also conducted for each BMI category to predict advanced kidney disease (eGFR < 60) based on Pb-S levels.

Results: The study population had an average BMI of 29.9±7.3 kg/m^2, with 41.5% classified as obese. The average Pb-S level was 1.04±0.68 μg/dL, and average eGFR was 96.1±19.8 mL/min/1.73 m^2. In the final adjusted model, eGFR declined significantly in the total group by 0.96 (95% CI: -1.81 to -0.11) and in the obese group by 1.97 (95% CI: -3.41 to -0.54) per unit increase in Pb-S (Table 1). Pb-S demonstrated a notable predictive ability for advanced kidney disease, with obesity achieving a sensitivity of 63%, specificity of 68%, and an ROC-AUC of 0.77.

Conclusions: A significant negative correlation between Pb-S and eGFR, amplified by obesity was founded among US adult, suggest the kidney function monitoring among those with history of lead exposure especially those with obesity in order to early detection of kidney injury.

	Model 1		Model 2		Model 3	
	β-Coefficients (95% CI)	P-value	β-Coefficients (95% CI)	P-value	β-Coefficients (95% CI)	P-value
Total	-8.35 (-9.02,-7.67)	**<0.001**	-1.08 (-1.92,-0.23)	**0.013**	-0.96 (-1.81,-0.11)	**0.027**
Non-obesity	-7.60 (-8.43,-6.76)	**<0.001**	-0.89 (-1.95,0.17)	0.099	-0.70 (-1.76,0.37)	0.200
Obesity	-10.46 (-11.63,-9.29)	**<0.001**	-2.13 (-3.56,-0.71)	**0.003**	-1.97 (-3.41,-0.54)	**0.007**

Table 1: Table of correlation analysis between serum lead levels (Pb-S) and estimated glomerular filtration rate (eGFR) using three different logistic regression models. The first model included only Pb-S, the second model added age, race, smoking, and drinking, and the third model further included dyslipidemia, hypertension, diabetes, coronary artery disease, congestive heart failure, and stroke.

PUB086

Role of Artificial Intelligence (AI) in Renal Diet

Harshil Fichadiya,[1] Vraj Patel,[2] Iasmina Craici.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Canton Medical Education Foundation, Canton, OH.*

Background: Patients with advanced CKD and ESRD experience hypertension, hyperkalemia and hyperphosphatemia and frequently struggle with maintaining a low sodium, potassium and phosphorous diet. Part of this struggle is from lack of understanding of foods containing higher amount of these electrolytes and lack of an organized diet plan. Consultation with a renal dietician may help them create a dietary plan, however the high CKD patients to renal dieticians ratio and subesequent difficulty with frequent monitoring of dietary plans make this option less feasible for many patients. An AI tool that can monitor daily dietary electrolyte intake and suggest dietary plans per patient preference may be more affordable and accessible to majority of patients.

Methods: We used ChatGBT- 4 to i) Assess electrolyte content of various foods and suggest a renal friendly alternate ii) Devise a daily renal dietary plan for vegan, vegeterian and meat based diet (K<60 Meq, Na <2g, Phos <1g/kg/day) for 70 kg patient iii) Assesed if Chat-GBT was able to modify the dietary plan based on patient preference for episodic food craving while maintaining compliance with renal diet.

Results: Chat GBT 4 devise a wonderful vegan, vegeterian and meat based dietary plan (including breakfast, lunch and dinner) with renal electrolyte restriction as mentioned above. It was able to accomodate a small serving of high potassium food high phosphorous food (orange & cookie), when asked to modify diet to include episodic cravings that our patients may feel. It was also able to suggest alternates to high potassium foods, eg apple juice, cranberry juice or grape as an alternate to orange juice.

Conclusions: Though simple, this intervention has the potential to be highly effective in helping advanced CKD and ESRD patients maintain compliance with a renal friendly diet. While daily access to a renal dietician may be difficult, this intervention will allow patients to devise daily renal friendly dietary plan based on their food preference while accomodationing for episodic non-renal friendly food craving in real time. Long term effective compliance with a renal friendly diet will translate into better bone health, slower CKD progression and reduction in episodes of dangerous hyperkalemia between dialysis sessions. In summary AI will complement the role of a renal dietician by facilitating effective implementation of dietary goals set by the dietician.

PUB087

Real-World Data Acquisition Methodology for Studying Cardiovascular Functional Capacity in CKD

Nolan Groninger,[1] Nikita F. Samanani,[1] Cody A. Altherr,[2] Gayatri Narayanan,[1] Sharon M. Moe,[1] Kenneth Lim.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Indiana Center for Musculoskeletal Health, Indianapolis, IN.*

Background: Cardiopulmonary exercise testing (CPET) is a diagnostic tool that generates hundreds of data points from ventilatory, cardiac and hemodynamic assessments during graded exercise. Unfortunately, there currently exists a paucity of epidemiologic datasets incorporating CPET data in patients with chronic kidney disease (CKD). Translational bottlenecks also exist to obtain and process the data for research purposes. Herein, we developed a methodology to create a novel centralized "CPET data hub" for capturing, automating data transfer and creating data linkages with important clinical information.

Methods: At Indiana University Health, CPET data is acquired by a specialized software (Breeze) that pushes a summary image report onto our electronic medical record system. To address this, we created a unique CPET data hub—a centralized data acquisition and processing hub enabling real-time capture of CPET output (linked to our hospital SQL server). The CPET data hub houses a digital platform (involving the development of algorithms via data mining methods and query modules) to process and calculate computed variables uniformly. CPET data on the hub is then linked to clinical information obtained through the Regenstrief Institute Informatics and the Indiana Network for Patient Care. CPET data is merged with clinical information including demographics, comorbidities, imaging, laboratory data and longitudinal outcome data.

Results: To date, our CPET data hub has captured comprehensive CPET data from n=1,953 adult ambulatory referral patients who underwent CPET testing. The cohort includes n=773 males and n=712 females. Approximately 37% have CKD stage 3; 4% have CKD stage 4; and 3% have end-stage renal disease or a history of kidney transplantation. The CPET data hub and linkage to important clinical outcomes (ongoing work) has led to the development of the "Cardiorespiratory Fitness in Patients with Chronic Kidney Disease in Indiana (FIT-INDY) cohort".

Conclusions: As automation processes becomes readily available through the integration of computer science into medical research, it is necessary that we incorporate data acquisition methodologies into nephrology to assess real-world health outcomes for patients with CKD. The feasibility of epidemiologic studies incorporating CPET data is enabled by the CPET data hub.

Pilot Study of a Remote Blood Self-Collection Device in Cure Glomerulonephropathy (CureGN)

Taylor A. Hill-Horowitz,[1] Suzanne Vento,[1] Lawrence B. Holzman,[3] Christine B. Sethna.[1,2] On behalf of CureGN Investigators. *[1]Cohen Children's Medical Center, Queens, NY; [2]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; [3]Penn Medicine, Philadelphia, PA.*

Background: Long-term biospecimen collection is a challenge in longitudinal cohort studies, especially for participants not actively followed clinically. TAP Micro Select is an FDA 510(k) cleared device that uses microneedles and a vacuum mechanism for self-collection of blood, allowing participants to provide biosamples remotely. This study aimed to determine the feasibility, reliability, and tolerability of the TAP device for remote blood collection for routine labs in the longitudinal CureGN study of primary glomerular disease.

Methods: Active participants at select CureGN sites were eligible. Participants were mailed materials for using the TAP device for at-home blood collection. Participants returned biosamples in a pre-paid shipper. Blood was processed for serum creatinine, albumin, and cystatin-C. In addition, samples from healthy controls were drawn both by venipuncture and TAP device. Control TAP samples were held at ambient temperatures for 24-72 hours (h) to simulate participant shipping. Outcomes were percent enrolled of those approached, time to receive samples, lab completion rate, participant satisfaction, and concordance of TAP samples with venipuncture.

Results: Of 47 participants approached, 39 (ages 14-85 years, 69% male) consented to the study (83% recruitment). The primary reason for declining was "dislike of handling blood." Of the 22 who completed the blood draw, participants shipped their collected samples a median of 4.4 days [IQR 0.2-15.6] after receiving materials. Median time in transit was 27h [IQR 24-29]. Labs were successfully resulted for 91% (N=20/22) of samples (2 QNS). Satisfaction surveys show that 20/22 rated discomfort 1-2 of 10, 13/18

would choose TAP over venipuncture, and 12/16 said the option of TAP would increase their likelihood of research participation. Main participant concerns were the force needed to push the activation lever and difficulty obtaining enough blood. For 17 healthy controls, analyses comparing samples obtained by TAP vs venipuncture did not vary by assay or time (ICC ≥0.98).

Conclusions: Self-collection of blood with the TAP device was well-tolerated and strongly correlated with venipuncture under study conditions. Thus, remote blood collection with the TAP device is a feasible alternative to venipuncture and may improve collection of biosamples in longitudinal studies.

In Vitro Evaluation of a Continuous Potassium Monitoring System in Simulated Dialysis Conditions

Jean-Baptiste Valsamis,[1] Rita Roshni,[1] Citsabehsan Devendran,[1] Fenge Lin,[1] Kaixuan Wang,[1] Cody J. Lensing,[2] Sahan Ranamukha,[1,2] Victor J Cadarso.[1]
[1]Proton Intelligence Australia, Pty Ltd., Melbourne, VIC, Australia; [2]Proton Intelligence, Inc., Vancouver, BC, Canada.

Background: Potassium (K+) dysregulation is a life-threatening condition. During a dialysis session, a patient's K+ levels often begin above the normal range and end below the normal range, before rebounding after the session. We have developed a continuous K+ monitor (CKM) capable of measuring dynamic K+ levels in real-time. In this report, we mimic dialysis conditions in vitro to characterize the sensors' ability to measure rapidly shifting K+ levels.

Methods: The potentiometric sensor probes consist of a working electrode (WE) that measures K+ directly, selectively, and sensitively and a reference electrode (RE). Eight sensors were immersed in fluid controlled by a pump system able to control K+ levels. We simulated dialysis conditions over 5 hours by changing K+ concentration from 7 mmol/L to 4.5 mmol/L and back to 6 mmol/L. The electrical potential was recorded every 30 seconds, and analyzed by retrofitting to the K+ concentration using a 3 parameters function to account for sensitivity, offset, and drift. Parameters were estimated for each sensor individually using least square fit method.

Results: All sensors responded rapidly during K+ changes (Figure). One sensor showed a faulty RE and one showed a time lag of 15 minutes, and were excluded. With the 6 remaining sensors, the average sensitivity was 48 ± 3.5 mV/dec, the drift was 0.84 ± 0.24 mV/h, and the offset was 2.87 ± 14.2 mV. Compared to the programed K+ profile, MARD was <1% and average accuracy was <0.1 mmol/L (defined as the standard deviation of the difference between estimated K+ and reference K+).

Conclusions: The CKM sensors responded accurately to changing K+ levels across the physiological range during a simulated dialysis session. In vivo testing is needed to further support these results.

Funding: Commercial Support - Proton Intelligence, Inc.

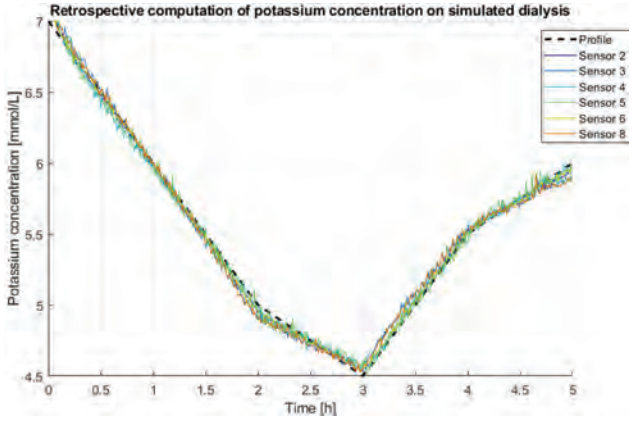

Figure: CKM sensor probes tested in a simulated in vitro dialysis session. Profile represents the programmed K+ concentrations.

Optimizing Microfluidic Gradient Generating Surface Plasmon Resonance (SPR) Chips for High-Throughput Biochemical Reaction Kinetics in Renal Physiology

Daniela Molnar, Kiley Kuykendall, Jonathan M. Berman. *New York Institute of Technology College of Osteopathic Medicine at Arkansas State University, Jonesboro, AR.*

Background: Motivated by the desire to study the activity of proteases, and protease inhibitors and activators in urine, we are developing a novel surface plasmon resonance technique which enables monitoring of these reactions over a wide range of simultaneous substrate concentrations, facilitating high-throughput measurement of proteolysis against peptides from protease-regulated macromolecules such as Epithelial Sodium Channel (ENaC).

Methods: This study focuses on optimizing microfluidic chips for channel design, polydimethylsiloxane (PDMS) adhesion to glass, and gold-thin film sputter coating parameters while fabricating sensor chips. We developed a gradient generator chip design, which was cast from 3D-printed resin molds. BK7 glass slides were sputter coated with a gold thin-film. Both glass and PDMS were functionalized using oxygen plasma from a high voltage-high frequency generator to form covalent bonds.

Results: We systematically examined effects of gold coaching thickness, and deposition time on sensor chip functionality. Our results demonstrate successful gradient generation, and assembly of biomolecule monolayers on the gold surface.

Conclusions: Future work will integrate with the SPR design to measure real-world reaction kinetics, advancing our understanding of protease-substrate interaction and regulation in the kidney.

PUB091

Impact of Type 2 Diabetes Mellitus and CKD on Bone Mineral Density in Elderly Patients with Hip Fractures

Debajyoti M. Roy,[1] Chee Yong Ng,[1] Vyjayanti Vasudevan,[2] Sreekanth Koduri,[1] Wenxiang Yeon.[1] *[1]Changi General Hospital, Singapore, Singapore; [2]Singapore American School, Singapore, Singapore.*

Background: Diabetes mellitus (T2DM) and chronic kidney disease (CKD) are common medical conditions in the elderly and have been associated with increased risk of bone fractures due to their negative impact on bone quality. When DM and CKD occur in combination, the negative impact on BMD may be greater due to the complex interplay between the two conditions. This study investigates potential differences in the impact of T2DM and CKD on BMD in elderly patients with fragility hip fracture when these conditions occur alone versus when in combination. We also investigate the relationship of worsening HBA1c to BMD in the groups with and without CKD.

Methods: A cross-sectional study was conducted on 715 elderly patients (age ≥65 years) with fragility hip fracture admitted to a hospital between Jan 2018 and Dec 2020. The study population was divided into four groups: Group 1 - No CKD or Diabetes (n=201), group 2 - No CKD with diabetes present (n=188), group 3 - CKD present with no diabetes (n=166), group 4 - Both CKD and diabetes present (n=160). BMD was measured using dual-energy X-ray absorptiometry (DXA) at the femoral neck. The data were analyzed using analysis of variance (ANOVA) and post-hoc testing with Bonferroni correction.

Results: The mean age of the study population was 75.6±6.8 years, and 62.5% were female. The mean body mass index (BMI) was 25.1+/-3.7 kg/m2. Of the cohort 326 had CKD & 160 T2DM. Table 1 depicts patient groups and variables

Conclusions: 1.In elderly patients with hip fracture, Group 2(T2DM+/CKD-) T score was higher as compared to Group 1 (T2DM-/CKD-). 2.There is a positive linear association between higher HBA1C and T score in Group 2 (T2DM+/CKD-). This association is however lost in the presence of CKD. 3.The post operative LOS was longer in Group 4 (CKD+/T2DM+), 10.4 days compared to Group 1 (T2DM-/CKD-), 8.6 days (P-0.04).

A Difficult Case of Calciphylaxis: Continuous Warfarin Use in a Patient with Calciphylaxis

Rupinder Kaur, Sindhu Yarrabelli, Saikiran Mandyam, Bhoomi Shah, Nowoghomwenma C. Ibie. *Southeast Health, Dothan, AL.*

Introduction: Calciphylaxis, or calcific uremic arteriolopathy (CUA), is a poorly understood, challenging complication of end-stage renal disease (ESRD) whose incidence has been increasing in the United States. Several risk factors have been associated with CUA, including warfarin. This article presents a difficult case of calciphylaxis that requires continued warfarin use in a patient with a history of antiphospholipid antibody syndrome with 50-60 episodes of deep venous thrombosis (DVTs), given unsuccessful trials with other anticoagulants in this patient.

Case Description: A 46-year-old male with PMH of ESRD on peritoneal dialysis for 4 months, p-ANCA vasculitis, antiphospholipid syndrome with recurrent DVTs on warfarin, and hypertension presented with violaceous plaques and central eschar-like necrosis in bilateral distal upper inner thighs associated with significant tenderness. The clinical presentation raised suspicions of Calciphylaxis; treatment was initiated with sodium thiosulfate and sevelamer while continuing peritoneal dialysis. A skin biopsy revealed patchy, mild small-vessel vasculitis with calcification and epidermal ischemic necrosis, consistent with CUA. Initially, warfarin was temporarily halted. However, given the patient's unsuccessful trials with Eliquis in the past and his extensive history of venous thromboembolism, ongoing warfarin therapy was deemed necessary, particularly considering his history of heparin-induced thrombocytopenia and allergy to rivaroxaban. Following education on the risks and benefits associated with calciphylaxis and warfarin, the decision was made to continue warfarin. The patient was recommended to follow up with hematology at a tertiary facility for further recommendations on anticoagulation.

Discussion: Once thought to be an uncommon condition, calciphylaxis has increased in frequency as more people require hemodialysis or peritoneal dialysis for ESRD. Given the poorer prognosis of CUA, which includes over 80% mortality in cases of severe CUA, prompt identification and treatment initiation are crucial. As anticoagulants, especially warfarin, have been linked with calciphylaxis, more research is required to understand the pathophysiology and to develop substitute interventions in a complex scenario such as this one where the risk of stopping warfarin outweighs the benefit.

PUB093

Metastatic Pulmonary Calcification in CKD

Ashley Golbus,[1] Natalie T. Freidin.[2] *[1]Medical University of South Carolina College of Medicine, Charleston, SC; [2]Medical University of South Carolina Department of Medicine, Charleston, SC.*

Introduction: Metastatic calcification, that outside of the cardiovascular system, is observed in 0.5-3% of living dialysis patients. In patients with CKD, the mechanism can involve elevated calcium phosphate product, secondary, or tertiary, hyperparathyroidism. Sites of calcification can include the lung tissue (metastatic pulmonary calcification or MPC).

Case Description: We present a case of a 75-year-old male with a history of ESRD on hemodialysis, hypertension, hyperlipidemia, two vessel coronary artery disease s/p recent PCI, severe aortic stenosis, and chronic heart failure, presenting with hypoxemic respiratory failure. Pertinent labs included: PTH 666.8 pg/mL, phosphorous 7.9 mg/dL, and calcium 9.1 mg/dL. Chest X-ray (CXR) demonstrated bilateral multifocal patchy and confluent airspace opacities, favored to represent pulmonary edema. Non-contrast chest CT showed diffuse bilateral ground glass opacities and centrilobular groundglass nodularity (note subpleural sparing) with upper lobe predominant patchy, hyperdense parenchymal consolidations and calcifications (Figure 1). These findings were determined to represent MPC. After a complicated hospital course, valve replacement was not a feasible option and he was transitioned to hospice care and died.

Discussion: MPC is apparent on CXR as confluent or patchy airspace opacities and on CT as diffuse calcified nodules, diffuse or patchy areas of ground glass opacities or consolidation, and confluent high attenuation parenchymal consolidation. In rare cases, this can cause acute respiratory failure with a rapidly progressive chest shadow that mimics pneumonia or pulmonary edema. These imaging findings in patients with chronic kidney disease or on dialysis should lead to consideration of MPC as a differential diagnosis.

PUB094

Efficacy of Peridialytic Cinacalcet in Controlling Hyperparathyroidism in Non-observant Patients on Chronic Hemodialysis in Western French Guiana

Arriel Makembi,[1,2] Florence Fermigier.[2] *[1]Universite de Kinshasa Faculte de Medecine, Kinshasa, Congo (the Democratic Republic of the); [2]Centre Hospitalier de l'Ouest Guyanais Franck Joly, Saint-Laurent-du-Maroni, French Guiana.*

Background: Secondary hyperparathyroidism (HPT) is one of the most common complications in chronic kidney disease and hemodialysis (HD). The side-effects of these drugs have been shown to affect compliance with therapy and the lack of control of HPT, hence the interest of this study, which aims to measure the effectiveness of daily administration of calcimimetic drugs on the control of HPT through compliance with therapy.

Methods: Prospective and interventional study over 6 months evaluating the efficacy of administering Cinacalcet in dialysis session to treat hyperparathyroidism. 60% of the patients were identified with 9N PTH. We compared three groups. G1: Patients on intravenous Etelcalcetide at the end of the dialysis session three times a week, G2: Patients on non-observing Cinacalcet that we put on Cinacalcet 3 times a week at the end of the dialysis session and 4 times at home and G3: Patients on Cinacalcet observing that we kept under a daily dose at home. For therapeutic adjustment, biological monitoring was performed once per month. The primary outcome was the reduction of plasma PTH at 6 months stratified as follows: 25%, 50%, and normalization. Secondary and tertiary outcomes were improvement in serum calcium and reduction in alkaline phosphatase. Significance threshold: $p<0.005$

Results: 32% of the patients were non-compliant with nausea and vomiting as the main reason and were treated with an anti-emetic drug. All patients were on calcium and vitamin D supplementation. The distribution of patients in the department was as follows: G1: 43%, G2: 32%, and G3: 6%. 19% were not treated as enrolled. In terms of general characteristics, the groups were comparable. In groups 2 and 3, the mean PTH rate was higher. The PTH rate decreased in the first 2 groups as follows 25% in 25% of the patients in the first group and 30% in the second group, 50% in 16% of the patients in the first group and 20% in the second group, it normalized in 4.2% of the patients in the first group and in 18% in the second group. The mean level of serum calcium was higher in the second group. Alkaline phosphatase levels also decreased significantly in the first two groups.

Conclusions: The perdialytic administration of Cinacalcet seems to be an interesting alternative in the control of hyperparathyroidism in non-compliant chronic hemodialysis patients.

PUB095

A Diagnostic (Non)Dilemma

Ann R. Finke, Cortney Lee, Juan-Carlos Aycinena, Madhumathi Rao, Muhammad Qasim. *University of Kentucky, Lexington, KY.*

Introduction: Primary Hyperparathyroidism (pHPT) is a very common disease and should be thought of anytime persistent hypercalcemia is found. Having a normal range PTH level does not rule out pPHT and one should always obtain a 24hr urine Ca and evaluate end organ effects. A high bone turnover state is expected in pHPT with an elevated ALP.

Case Description: 51 y/o M with PMHx of HIV on ART, CKD3, left knee avascular necrosis, and CHF presented for evaluation of hypercalcemia noted since 2017. Initially intermittent, serum calcium became persistently elevated to 11.2-11.8mg/dL (ionized Ca 5.8 mg/dL) over two years. He had no history of kidney stones or medications associated with hypercalcemia. Laboratory workup was notable for hypercalciuria (792mg/day), normal PTHrP, vitamin D 25 levels (35-68ng/mL), vitamin D 1,25 levels (48-69pg mL) and persistently normal PTH (26-34pg/mL) and alkaline phosphatase (54 u/L) levels. Other workup included a DEXA scan with osteopenia, and a bone scan without focal uptake. Sestamibi parathyroid scan was negative, but neck ultrasound revealed a potential target lesion. Given the atypical presentation further validation was sought with undecalcified bone biopsy after double tetracycline labelling. Histology showed elevated bone turnover consistent with increased parathyroid activity, supporting the diagnosis of Normohormonal Primary Hyperparathyroidism (NHpHPT).

Discussion: Classically, pHPT is recognized by the combination of hypercalcemia, with elevated or non-suppressed PTH levels. An absence of PTH elevation in our patient prompted a search for other causes of hypercalcemia including Familial Hypocalciuric Hypercalcemia (FHH), excessive dietary Ca intake, medications and Calcitriol mediated diseases, that were differentiated by elevated urinary calcium and normal vitamin D25 and vitamin D1, 25 levels. NHpHPT is defined by PTH level of 21-65pg/mL in patients with hypercalcemia. The most accepted hypotheses explaining the lower PTH levels is a lower physiological PTH setpoint. Accordingly, intraoperative PTH drop during parathyroidectomy (PTX) remains a 50% decrease to ensure sufficient resection of glandular tissue. Diagnosis can further be aided by assessing the end organ effects, specifically on the bones and kidneys. A lack of ALP elevation prompted a bone biopsy that showed high bone turnover consistent with pHPT. Ultimately, the patient underwent a parathyroidectomy.

PUB096

A Rare Case of Oncologic Osteomalacia

Sunayna Gurnani, Maham Ali. University of Michigan Fellowship. *University of Michigan, Ann Arbor, MI.*

Introduction: Oncogenic osteomalacia is a paraneoplastic syndrome characterized by hypophosphatemia due to FGF-23 secreting tumors. FGF 23 acts on the proximal tubules to reduce α hydroxylation of Vitamin D2 and reduce phosphate reabsorption. The secreting tumors must be identified swiftly as the treatment lies in complete excision of the tumor.

Case Description: A 52 year old male with Stage IV prostatic adenocarcinoma with known metastasis to ribs, humerus and pelvis who presented with severe fatigue and diffuse myalgias. Laboratory evaluation revealed serum Phosphate 0.5 mg/dl (2.7-4.6 mg/dL), Corrected serum calcium 7.2 (8.6-10.3 mg/dl), Alkaline phosphatase 765 (40-116 U/L), PTH 55 (10-65 pg/mL). Further evaluation revealed FePhos 62% with FGF 23 level of 3481 pg/ml (< 59 pg/ml). The patient was treated with IV Calcitriol along with judicious phosphate repletion however, the patient remained hypophosphatemic to < 2 mg/dL.

Discussion: Oncogenic osteomalacia is generally associated with mesenchymal tumors found in bone and soft tissue. It is rarely associated with malignant or metastatic disease. In the systematic review completed by Bosman et al of 895 cases of TIO, 10% of cases were reported malignant per histology. In this review, 98% of patients were noted to have hypophosphatemia and low Vitamin D levels, and FGF 23 levels were found to be related to tumor size ($r = 0.344$, $P < 0.001$). In 2020, the FDA approved the use of Burosumab for hypophosphatemic hyperphosphaturic TIO in patients whose lesions are not amenable to excision. Novel therapies such as FGF Receptor tyrosine kinase inhibitor Infigratinib are underway.

PUB097

PTH Variability Is Associated with Increased Risk of Mortality in Patients on Hemodialysis

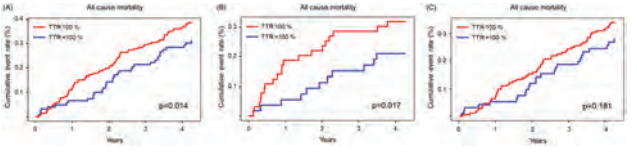
Tadashi Kato,[1] Kiryu Yoshida,[2] Tomohiro Saito,[1] Noriyuki Kato,[3] Masahide Mizobuchi,[1] Hiroaki Ogata,[2,5] Fumihiko Koiwa,[4] Hirokazu Honda.[1]
[1]Division of Nephrology, Department of Medicine, Showa University School of Medicine, Shinagawa, Japan; [2]Division of Nephrology, Department of Internal Medicine, Showa University Northern Yokohama Hospital, Yokohama, Japan; [3]Saiyu Clinic, Koshigaya, Japan; [4]Division of Nephrology, Department of Internal Medicine, Showa University Fujigaoka Hospital, Yokohama, Japan; [5]Department of Medical Education, Showa University School of Medicine, Shinagawa, Japan.

Background: Elevated parathyroid hormone (PTH) levels are associated with cardiovascular events, bone disease, and mortality in patients undergoing maintenance hemodialysis. PTH levels widely vary in hemodialysis patients, but it is unclear PTH variability would affect mortality.

Methods: A total of 331 maintenance hemodialysis patients at Saiyu Clinic who had measured PTH at least twice a year were included in the study. The association between all-cause mortality, cardiovascular events, and fractures was evaluated in patients with PTH concentrations always between 60 and 240 (Time in Terget range (TTR) 100%) and those without PTH concentrations (TTR < 100%).

Results: There were 122 patients with TTR 100% and 209 patients with TTR < 100%; over the 4-year observation period, patients with TTR 100% had significantly decreased all-cause mortality than those with TTR < 100% (HR 1.68, 95% CI 1.11-2.53) (Figure A). Subgroup analysis by the presence or absence of pharmacological intervention showed no difference in all-cause mortality in the ntreatment group (HR 2.73, 95% CI 1.20-6.24) (Figure B), but showed significant difference in no-tratment group (HR 1.39, 95% CI 0.86-2.24) (Figure C).

Conclusions: Even one deviation of PTH concentrations from the optimal range during a one-year period was associated with an increase in all-cause mortality. However, this effect was not seen when patients were receiving pharmacological intervention. The results suggest that early intervention is desirable when PTH levels vary from the optimal range in patients with secondary hyperparathyroidism.



PUB098

Penile Calciphylaxis: A Rare Complication in a Patient with ESKD

Jee H. Kim, Stela Teferici, Hyun Joon Cho, Nitzy N. Munoz Casablanca. *NYC Health and Hospitals Elmhurst, Elmhurst, NY.*

Introduction: Calciphylaxis, a rare but potentially devastating complication, predominantly affects patients with end-stage kidney disease (ESKD) undergoing dialysis, with a reported prevalence of 1-4%. Penile calciphylaxis is an even rarer manifestation, with limited data on its prevalence due to the scarcity of reported cases. This case further highlights the rarity of this presentation.

Case Description: A 61-year-old male with a history of ESKD on hemodialysis since 2020, HTN, DM, and PAD s/p bilateral below-knee amputation presented with week-long urinary retention. Despite initial drainage of 800cc of urine with catheter placement, he developed phimosis, balanitis, and purulent discharge. A 14-day course of antibiotics for a urinary tract infection was completed, but symptoms persisted. A penile incision was performed, yet he continued to have penile pain and developed new-onset black discoloration of the glans penis. Computed tomography of the abdomen/pelvis showed surrounding soft tissue calcifications and gas within the corpora cavernosa and scrotum. Penectomy and urethrostomy were performed. Histopathological examination revealed extensive tissue necrosis, acute inflammatory infiltrates with abscess formation, and multifocal calcification involving medium-sized arteries. Laboratory evaluation showed parathyroid hormone at 372 pg/mL, with calcium levels in the 7-8 mg/dL range and phosphorus levels in the 3-4 mg/dL range. Albumin was 2.9 g/dL. No medications linked to calciphylaxis (phosphate binders, calcium supplements, warfarin, iron) were in use. Based on the findings suggestive of penile calciphylaxis, two doses of sodium thiosulfate 25g were administered. However, the treatment was discontinued due to concerns about prolonged QTc interval. Fortunately, on six-month follow-up, no new lesions or associated pain suggestive of calciphylaxis have developed.

Discussion: This case highlights the diagnostic challenge of penile calciphylaxis in ESKD. Initial symptoms, such as those seen here, can mimic a UTI or represent superimposed infection, potentially delaying diagnosis of calciphylaxis. Maintaining high suspicion for calciphylaxis is crucial in ESKD patients with unexplained skin lesions and persistent pain despite treatment for other causes due to the high morbidity and mortality associated with the condition.

PUB099

Severe Hypercalcemia by PTH-independent Extrarenal Production of 1,25-Hydroxyvitamin D

Ravi S. Patel,[1] Roberto L. Collazo-Maldonado,[1] Avani R. Patel,[2] Alexandra Rosario Aulet.[1] *[1]Methodist Dallas Medical Center, Dallas, TX; [2]Meharry Medical College School of Medicine, Nashville, TN.*

Introduction: Humoral hypercalcemia of malignancy is a condition characterized by elevated serum calcium levels due to exogenous production of parathyroid hormone-related protein (PTHrP). However, in rare cases, PTHrP may be normal and elevated serum calcium can be secondary to increased 1,25 hydroxy vitamin D production. Hypercalcemia of malignancy due to increased 1,25 hydroxy Vitamin D production can be challenging to diagnose due to its infrequency, but it may help discern the underlying cause of hypercalcemia.

Case Description: An 82 yo Hispanic woman presented to the ED due to confusion and generalized weakness. A clinical diagnosis of severe hypercalcemia with acute metabolic encephalopathy was made as her serum calcium levels were >14 mg/dl and creatinine 1.29 mg/dl on admission. She was recently diagnosed with Non-Hodgkin lymphoma (NHL) with metastasis to her liver and lungs. Her parathyroid hormone level was 12.4 pg/ml and parathyroid hormone-related protein level was <2.0 pmol/L. The patient's 1,25 hydroxy vitamin D levels, which resulted later, were markedly elevated at 186. The patient was treated with aggressive volume expansion, calcitonin, zoledronic acid, and steroids resulting in a quick improvement in her calcium levels and mentation. The patient was discharged in stable condition with a calcium level of 10.8 mg/dl with an improvement in kidney function with follow up with oncology.

Discussion: In patients with NHL, the most common cause of hypercalcemia (accounting for up to 80%) is the secretion of PTHrP, known as humoral hypercalcemia of malignancy. However, in rare cases, elevated levels of 1,25 hydroxy vitamin D can also cause hypercalcemia of malignancy despite normal PTHrP levels due to increased a1 hydroxylase activity by macrophages and lymphocytes.

PUB100

Hungry Bone Syndrome (HBS) as an Outcome of Parathyroidectomy for Treatment of Hyperparathyroidism in a Third-Level Hospital in a Medium-Income Country

Nicte Alaide R. García, Carolina Gonzalez-Fuentes, Karen Hopf, Jorge D. Salazar Hurtado, Manuel Camacho Luna, Michelle Sánchez, Mario Alamilla-Sanchez, Martin O. Carbajal. *Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico.*

Background: Hyperparathyroidism is a common disorder of mineral metabolism that is due to excessive secretion of PTH from one or more of the four parathyroid glands. It can be classified as primary, secondary and tertiary. In ESRD the definitive treatment in severe disease is parathyroidectomy. HBS is one complication after the surgery.

Methods: Retrospective cohort study with information (Jan 2023 and Jan 2024) in a third level hospital "Centro Médico Nacional 20 de Noviembre". The goal was to describe and analyze the incidence of HBS on patients with hyperpharatidoidism primary, secondary and tertiary treated with parathyroidectomy. We made a Principal Component Analysis (PCA) to observe the factors that have more impact.

Results: 51 cases were included. There were 16 patients with primary, 29 patients with secondary and 5 with tertiary hyperparathyroidism. Patients with ERSRD with secondary and tertiary hyperparathyroidism were mainly in Hemodialysis (71%) as Kidney Replacement Therapy (n=25). The mean value of PTH before surgery was 728 pg/ml among all patients. 80% patients (n=41) have AP >100 mg/dl as a parameter of high bone replacement. 30% patients (n=15) develop hungry bone syndrome. 86% of patients (n=13) that developed HBS have 3 ½ surgery. We made a PCA we observed that the principal components that predict to developed HBS in our population were AP, PTH and the surgery 3 ½ and patients have more risk if they have the three of them together.

Conclusions: The principal components observed that predict the developed HBS in our population were AP, PTH and the surgery 3 ½ and patients have more risk to develop HBS if they have them together.

Bibliometric Analysis of Renal Osteoporosis in Nondialysis-Dependent CKD

Liangmei Chen, Chaoying Kuang, Fanna Liu. *nephrology, Guangzhou, China.*

Background: Chronic kidney disease (CKD) can cause abnormalities in biochemical markers, particularly affecting bone mineral metabolism, leading to deterioration of bone health. To date, many CKD osteoporosis (OP) studies have focused primarily on dialysis patients. Skeletal health in non-dialysis CKD patients has not received sufficient attention, and only a limited number of studies have found a correlation between reduced BMD and poor renal prognosis in non-dialysis patients. Bibliometric analyses help us to take control of the history and current status of this research field, explore its hot trends, and provide some basis for future research on CKD OP.

Methods: All research-based articles and reviews in the field of CKD OP from 2000 to 2023 were searched in the Web of Science database through a developed search strategy. Information from different countries, institutions, journals and scholars was analysed and their contributions compared using CiteSpace and VOSviewer software. Analyse the frequency and prominence of keywords to fully present the current state of research and trajectory of the field.

Results: A bibliometric study of studies related to CKD OP in CKD between 2000 and 2023 reveals that the attention received by this field is increasing year by year. The leading countries, institutions and authors in this field are from Europe and the United States. Disorders of bone metabolism have been the focus of research into CKD OP since 2000. Future trends in CKD OP research may focus on the study of the effect of vitamin D dosage and treatment regimen on improving CKD OP Relationship between bone metabolism-related indicators such as intact Parathyroid hormone and FGF23 and CKD OP and fracture risk in CKD patients. A prospective study of new calcium mimetics in the field of CKD OP. Mechanistic studies on the mechanisms regulating indolyl sulfate-induced oxidative stress in osteoblasts and the exploration of Nrf2 as a target for the prevention of bone loss in CKD patients.

Conclusions: CKD OP has received increasing attention, and research hotspots in recent years have focused on the exploration of risk factors, drug development and clinical treatment. For the risk of developing CKD OP in non-dialysis patients, age, advanced stage of renal failure (G5), and NBAP are risk factors, and overweight or obesity, 25-(OH)-vitamin D, and iPTH are protective factors.

PUB102

Current and Future State of Hyperphosphatemia Management

Stephen Regan. *Spherix Global Insights, Exton, PA.*

Background: The hyperphosphatemia treatment landscape is evolving with the FDA's recent approval of tenapanor, the pending availability of generic iron-based phosphate binders, and the prospect of oral-only ESRD medications entering the Prospective Payment System (PPS), also known as the "dialysis bundle," starting January 1, 2025. As nephrologists continue to adjust their hyperphosphatemia treatment approach, they aim to expand the proportion of patients who maintain an optimal phosphorus level and to reduce their medication burden.

Methods: Data were collected via independent online surveys of 228 US nephrologists in February and May 2024.

Results: While nephrologists report that their use of calcium-based phosphate binders in their hemodialysis patients is declining, treatment rates with sevelamer (46%) and iron-based phosphate binders (16%) are holding steady. With the eventual availability of a generic ferric citrate product, nephrologists project that their use of calcium-based binders and sevelamer will decline, while their use of ferric citrate products and tenapanor will expand. However, the potential for oral-only medications to eventually enter the dialysis bundle is likely to alter their treatment approach further. As nephrologists have become more familiar with tenapanor, the proportion of those who view the agent as a substantial advance in hyperphosphatemia treatment (75%) has expanded over time. Tenapanor's user base among nephrologists (61%) has continued to increase month-over-month since its launch, as physicians have been prescribing the agent to a higher volume of their dialysis patients. Among the pipeline agents in development for hyperphosphatemia, oxylanthanum carbonate (OLC) has advanced to late-stage clinical development, with most nephrologists expressing interest in the product due to its bioequivalence to lanthanum carbonate, reduced pill burden, and smaller pill size. A substantial proportion of nephrologists (44%) project that OLC will have a definite role in the treatment of hyperphosphatemia.

Conclusions: Pending adequate medication access, nephrologists expect to have more treatment options available to them to help reduce the proportion of patients who do not reach their target phosphorus range, along with the potential added benefit of improving quality of life for their hyperphosphatemia patients.

PUB103

Clinical Manifestations of Pseudo-clubbing and Management in the Setting of Severe Secondary/Tertiary Hyperparathyroidism with ESKD

Adarsh S. Jones, Alyssa C. Weyer, Arda Akoluk. *The University of Texas at Tyler, Tyler, TX.*

Introduction: Secondary hyperparathyroidism frequently complicates chronic kidney disease (CKD) and can evolve into tertiary hyperparathyroidism due to prolonged parathyroid gland stimulation. This progression significantly impacts bone metabolism and overall health. We report a case of a 27-year-old male patient with severe long-standing secondary/tertiary hyperparathyroidism and end-stage renal disease (ESRD), presenting with pseudoclubbing of the fingers and thumbs.

Case Description: Patient is a 27 year old man with a history of bilateral congenital renal hypoplasia on peritoneal dialysis at six months of age, cadaveric kidney transplant recipient at 6 years old, which failed in October 2020, leading to a transition to hemodialysis. Currently, he undergoes hemodialysis four times per week, for 18 to 20 hours weekly, with excellent clearance. Recent lab findings have been significant for elevated blood urea nitrogen, creatinine, Phosphorous, PTH (1409-1846 pg/mL), and a normal calcium consistent with severe tertiary hyperparathyroidism. Patient noted to have pseudoclubbing on physical exam, which is indicative of significant systemic effects. The patient's current hemodialysis regimen has led to excellent clearance, although severe hyperparathyroidism and pseudo clubbing persist, necessitating ongoing comprehensive management. The patient is on calcimimetics and active vitamin D analogs to suppress PTH secretion and manage mineral metabolism. Given the severity of hyperparathyroidism and presence of pseudoclubbing, surgical intervention (parathyroidectomy) is currently being considered.

Discussion: This case underscores the complexity of managing severe secondary/tertiary hyperparathyroidism in ESRD patients. Pseudoclubbing, although rare, requires meticulous clinical attention and intervention. A multidisciplinary approach involving nephrologists, endocrinologists, and surgeons is crucial for optimizing outcomes. Continuous monitoring of labs, individualized treatment plans, and proactive management of complications are vital for improving quality of life and prognosis in patients with advanced renal disease and associated endocrine disorders. Further research is needed to explore optimal management practices for patients with similar presentations, including rare manifestations like pseudoclubbing.

PUB104

Investigating the Immunomodulatory Impact of Wharton's Jelly Mesenchymal Stem Cells (WJ-MSCs) on Cobalt Chloride (CoCl2)-Induced Damage to HK-2 Cells

Zih Han Liao, Ming Ling Kuo. *Chang Gung University Graduate Institute of Biomedical Sciences, Taoyuan, Taiwan.*

Background: End stage renal diseases (ESRD) are usually caused by chronic kidney diseases (CKD) and renal dysfunction. Hypoxia, induced by reduced oxygen delivery, plays a crucial role in kidney damage by triggering inflammation, oxidative stress, mitochondrial dysfunction, and DNA damage. Studies indicate that hypoxia-inducible factor 1α (HIF-1α) regulates metabolic remodeling in renal tubular epithelial cells (RTECs) and promotes interstitial fibrosis. Promising results have been shown with the use of mesenchymal stem cells (MSCs) in CKD models, such as reducing oxidative stress, improving mitochondrial function, and decreasing inflammation. Interferon-gamma (IFN-γ) has been found to enhance MSCs' therapeutic effects on renal fibrosis, which is closely related to renal hypoxia, though the mechanisms remain unclear. This study aims to investigate whether IFN-γ primed Wharton's Jelly-MSCs (IFNγ-MSCs) can protect HK-2 cells, human proximal tubule epithelial cells, from hypoxia-induced damage. We generated a hypoxic environment with $CoCl_2$ and treated HK-2 cells with IFNγ-MSCs to explore their potential protective effects against kidney injury.

Methods: The differentiation ability and cell surface marker profile of WJ-MSCs were confirmed. We mimicked hypoxia in HK-2 cells using $CoCl_2$ and pretreated them with conditioned media from IFNγ-MSCs to assess the efficacy of MSCs against cell injury. Cell viability was measured using Cell Counting Kit-8. Gene and protein expressions related to hypoxia, oxidative stress, and apoptosis were evaluated via RT-qPCR and western blot. Mitochondrial ROS production and membrane potential were detected using MitoSOX and MitoTracker, respectively.

Results: Our findings indicated that $CoCl_2$ effectively induced cytotoxicity in HK-2 cells and upregulated genes and proteins associated with hypoxia, oxidative stress, and apoptosis. IFNγ-MSCs alleviated $CoCl_2$-induced apoptosis in HK-2 cells by suppressing the Bax/Bcl-2 ratio. Additionally, IFNγ-MSCs downregulated the gene expressions of *BNIP3*, *NIX*, *NRF2*, *HO1*, and *iNOS*, as well as the protein expressions of HIF-1α, Nrf-2, and HO-1. These results suggest that IFNγ-MSCs might reverse hypoxia and reduce oxidative stress, thereby protecting HK-2 cells from apoptosis.

Conclusions: In summary, our findings suggest that IFNγ-MSCs can alleviate $CoCl_2$-induced HK-2 cells injury by reducing oxidative stress and reversing hypoxia.

PUB105

First-in-Class Phase 3 Clinical Trial Candidate Rilparencel Expresses Nephron Markers and Acquires Glomerular Epithelial and Tubular Features

Prakash Narayan,[1] Brooke Bauer,[1] Howard Trachtman,[2] Guido Filler,[3] Benjamin S. Freedman,[4] Joseph Stavas,[1] Emily L. Butler,[1] Andrew T. Bruce.[1] *[1]ProKidney, Winston-Salem, NC; [2]Renal Strategies LLC, New York, NY; [3]Western University, London, ON, Canada; [4]University of Washington, Seattle, WA.*

Background: Kidney cortical administration of rilparencel, a biopsy-derived autologous kidney epithelial cell platform, improves glomerular, tubular and urine concentrating profiles in chronic kidney disease (CKD) models & may support kidney function in type 2 diabetes (T2D)&CKD patients. We tested the hypothesis that rilparencel expresses markers spanning the nephron & acquires glomerular epithelial & tubular features.

Methods: Banked rilparencel samples from 5 T2D&CKD patients (NCT02836574) were analyzed with scRNAseq & kidney cell types & states identified with unsupervised clustering & projection on to the KPMP single cell CKD atlas. Organoids from rilparencel were grown for up to 17 d, sectioned & stained with periodic acid Schiff. Human rilparencel (discarded kidneys, NDRI) organoids in 3D culture were immunofluorescent antibody stained for nephron & glomerular epithelial precursors, HOXA11 & PTPRO (GUDMAP ATLAS-D2K), respectively, tubular epithelial markers, LTL & CD13 & the cycling cell marker, CDC6.

Results: KPMP-anchored molecularly profiled cell types constituting rilparencel include glomerular parietal epithelial cells (PECs), adaptive proximal tubules (PTs), ascending thin limb (ATL) & adaptive thick ascending limb-2 (TAL-2), distal convoluted tubule (DCT), connecting tubule (CNT) & intermediate collecting duct (IMCD). Proportions of each cell type were consistent amongst samples. Immunoflourescent antibody staining confirmed nephron & glomerular epithelial precursors, tubular epithelium & cycling cells. Sectioning of rilparencel organoids revealed morphologic features consistent with glomerular epithelium & tubules.

Conclusions: An integrated, cross-validating approach indicates that rilparencel expresses markers spanning the nephron & acquires glomerular epithelial & tubular features in culture. Increased nephron mass with both functional compartments may underlie beneficial effects of cortical delivery of rilparencel.

Effect of a High-Fat Diet on the Progression of Diabetic Nephropathy and End-Organ Damage

Melissa Lowe,[1] Ruslan Bohovyk,[1] Vladislav Levchenko,[1] Christine A. Klemens,[1,3] Alexander Staruschenko.[1,2] *[1]University of South Florida Morsani College of Medicine, Tampa, FL; [2]The James A. Haley Veterans Hospital, Tampa, FL; [3]University of South Florida Hypertension and Kidney Research Center, Tampa, FL.*

Background: The high-fat Western diet (HFD) is a key contributor to the growing rate of obesity, which is a global health concern. Obesity increases the risk of metabolic syndrome leading to chronic illnesses like diabetes. Diabetic Nephropathy (DN) is a complication prevalent in Type 2 Diabetes (T2D), which eventually leads to end-stage renal disease or kidney failure. This study aimed to assess how HFD impacts diabetic severity and the progression of kidney, heart, and liver injury in T2D.

Methods: Young (12 weeks old) and aged (>38 weeks old) male and female Type 2 Diabetic Nephropathy (T2DN) rats, a non-obese T2D model, were placed on either normal (NFD) or HFD calorically balanced diets for 12 weeks. Glucose tolerance testing was performed every three weeks and total body weight (TBW), and 24-hour urine sampling were measured weekly. Kidney, heart, and liver functions were analyzed at the end of the study. RNA-Seq, lipidomic, and microbiome analyses were also performed.

Results: HFD males' glucose intolerance and fasting blood glucose levels increased progressively and became significant by week 9 (aged rats) and week 6 (young rats). In contrast, glucose tolerance and fasting blood glucose were not affected in the females. The HFD did not affect 2-kidney/TBW ratios in all groups except young females. Heart weight/TBW ratios in females were significantly reduced on the HFD in both age groups. Studies are ongoing in young animals; however, old animals revealed a significant increase in albuminuria, KIM-1 staining, and medullary protein casts in the aged HFD female group, while there was no further progression of renal damage in the males. There was a significant increase in glucosuria in male HFD animals, and the HFD also increased lipid deposits in the liver for both sexes. No changes in cardiac fibrosis were observed. Microbiome analysis revealed a significant decrease in gut microbiota alpha diversity in males on HFD, while no significant changes were observed in females.

Conclusions: In conclusion, the HFD appears to have a more deleterious effect on glucose handling in both old and young T2DN males than in female rats. More profound renal effects in the aged female group are most likely due to already severe kidney injury in male T2DN rats, as we have previously reported.

PUB107

Mitochondrial AKT1 Signaling and Kidney Injury: Unraveling Mechanistic Insights into Metabolic Syndrome-Induced Kidney Dysfunction

Hugo Y. Lin,[1,2] Yu-Min Ko,[4] Ming-Yu Yang.[3] *[1]Kaohsiung Medical University Chung Ho Memorial Hospital, Kaohsiung, Taiwan; [2]Kaohsiung Municipal Ta-Tung Hospital, Kaohsiung, Taiwan; [3]Chang Gung University, Taoyuan, Taiwan; [4]Kaohsiung Medical University, Kaohsiung, Taiwan.*

Background: Metabolic syndrome (MetS) is associated with kidney diseases, but the etiology is inconclusive. We hypothesized that renal tubular mitochondrial AKT1 (mito-AKT1) signaling plays a mechanistic role in the pathogenesis of kidney injuries in MetS.

Methods: We executed the study with 8-week C57BL/6 male mice fed a high-fat diet for four months, compared with mice fed a standard chow diet. To examine the role of mito-AKT1 translocation, the cell viability of HK-2 cells treated with heat shock protein 90 (Hsp90) was examined.

Results: In our murine MetS model, body weight significantly increased. The kidney size as a percentage of body weight remained similar between the groups. For the glucose tolerance test, fasting glucose levels were significantly higher in MetS mice than those on a regular diet ($p<0.05$). From 15 to 120 minutes, glucose levels were consistently elevated. The intraperitoneal glucose tolerance test curve differed between three and six months, with the area under the curve (AUC) value being higher at six months ($p=0.013$). Fasting hyperinsulinemia and insulin resistance, as measured by the Homeostatic Model Assessment for Insulin Resistance, were also elevated. Regarding renal function, serum BUN and creatinine levels in MetS mice did not change significantly. However, proteinuria and urine KIM-1 levels were elevated, which indicated renal tubular injuries. Histological examination revealed significant increases in glomerulosclerosis index, tubulointerstitial fibrosis, tubular dilatation, and tubular vacuolation score. To further investigate the role of mito-AKT1 signaling during MetS in renal tubules, we examined the mito-AKT1 protein. We observed an increased accumulation of phosphorylated AKT1 ($p=0.030$) in the mitochondria of proximal tubules after MetS. This AKT1 translocation was confirmed using immunohistochemistry staining and western blot analysis of mitochondrial proteins. Cell viability significantly decreased in the group treated with palmitic acid and the Hsp90 inhibitor, compared to the vehicle-treated group ($p<0.01$).

Conclusions: These findings shed new light on the mechanistic role of renal tubular mito-AKT1 in MetS-induced kidney injuries and may be used to develop new strategies for preventing and treating kidney diseases.

PUB108

Spatial-omic Profiling of Human Kidney Tissues Using SeqStain Stratifies Disease Pathology

Anirudh Vattikota,[1] Mohamed Youssef,[1] Sowmya Gurusamy Kamaraj,[1] Ishwarya Venkatesh,[2] Ameera M. Shaw,[2] David J. Cimbaluk,[2] Vineet Gupta.[1] Internal Medicine. *[1]The University of Texas Medical Branch at Galveston, Galveston, TX; [2]Rush University Medical Center, Chicago, IL.*

Background: A deep understanding of the pathophysiology of the tissue microenvironment is crucial for scientific advancements. Newer multiplex imaging-based methods are providing important details about the histoarchitecture of tissue. We previously developed a novel user-friendly tissue imaging method, called SeqStain, allows rapid immunofluorescence based multiplexed tissue imaging and analyses. Here, we utilize this approach to understand the complex spatial organization of cells and their relationships with each other with both healthy subjects, and patients with diabetic nephropathy and lupus nephritis.

Methods: We generated antibodies conjugated with fluorescently-labelled-DNA oligonucleotides for analyzing multiple kidney-specific antigens using sequential cycles of staining and de-staining on each tissue section. We probed different areas of histologically relevant to the kidney and used conventional fluorescence microscopy for imaging the tissues and HALO software for image analyses.

Results: We analyzed both paraffin-fixed and frozen tissue sections using commercially available reagents and a confocal microscope. This allowed us to precisely image up to 20 antigens on single tissue specimens for healthy subjects, as well as from patients with lupus nephritis (LN) and diabetic nephropathy (DN). Analysis of various cellular biomarkers indicated enrichment of specific cellular clusters into distinct neighborhoods.

Conclusions: SeqStain is a versatile, gentle, and easy to use method for multiplex imaging making it highly effective in mapping the spatial relationship of cells within the kidney. The spatial relationship maps generated by this method will offer valuable new insights into disease pathophysiology and enhance future diagnostics and treatments for LN and DN.

Modulation of Kidney Disorders in Type 2 Diabetes: Evaluating the Role of Probiotics in a Rat Model of Diabetic Kidney Disease

Eloiza O. Silva,[1,2] Luciana Soares C. Santos,[1,2] Maria De Fatima Vattimo,[2] Giulia T. Cabreira,[1] Julia F. Santos,[1] Monique M. Pinheiro,[1] Vitória C. Costa.[1] *[1]Faculty of Medical Sciences of Santa Casa de São Paulo, Sao Paulo, Brazil; [2]Universidade de Sao Paulo, Sao Paulo, Brazil.*

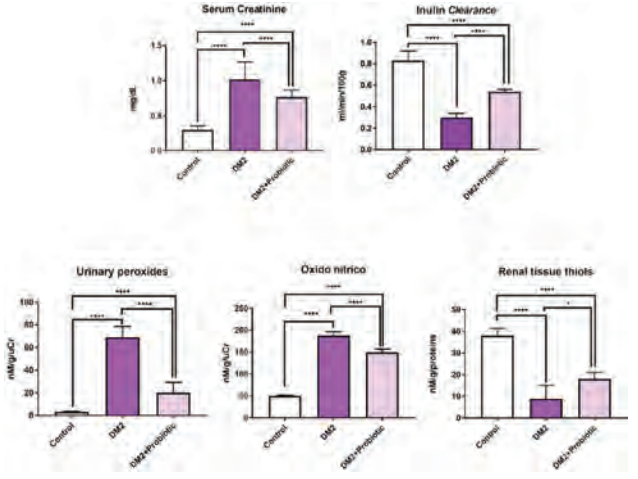
Background: To prevent the progression of Diabetic Kidney Disease (DRD), some strategies have been used. Currently there is Investigated the use of foods enriched with probiotics which, through their effects on microflora modulation, can contribute to glycemic control and mitigate complications of DM2 such as DRD. The objective of our study is to evaluate the effects of probiotics on the function, oxidative profile and renal histology of rats with DM2 and DRD.

Methods: Male Wistar rats were randomized into the following groups: Control (CT n=5) animals that received 0.9% saline solution (SF) (nicotinamide diluent (NA), 0.4 ml i.p. single dose) and after 15 min buffer citrate (streptozotocin diluent (STZ) at pH 4.2 and, i.p., single dose); Type 2 Diabetes Mellitus (DM2 n=5): animals received (NA; 100 mg/kg), i.p., single dose, in 0.9% SF after 15 minutes they received (STZ; 60 mg/kg), i.p., single dose ; Type 2 Diabetes Mellitus + Probiotic (DM2+P n=5): DM2

animals that received probiotic strains (bifidabacterium longum, bifidabacterium bifidum and lactobacillus rhamnosus, dose 10 10 CFU/mL); by gavage, 6 weeks. Renal function (serum creatine-CrS and inulin clearance-Clin) and redox profile were evaluated.

Results: The DM2 group demonstrated a reduction in inulin clearance, an increase in CrS and redox disorders. On the other hand, diabetic animals that received probiotics demonstrated attenuation in the deterioration of renal function perceived by an increase in Clin, a reduction in CrS and redox disorders.

Conclusions: The probiotic confirmed its renoprotective effect, providing a relevant positive effect on the morbidity of DKD in DM2 rats.



PUB110

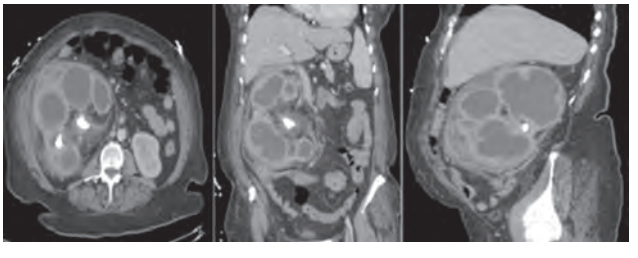
A Rare Case of Xanthogranulomatous Pyelonephritis

Cameron T. Lawson. *East Carolina University, Greenville, NC.*

Introduction: Xanthogranulomatous pyelonephritis (XPN) is a rare variant of chronic pyelonephritis occurring in the setting of obstructive uropathy and recurrent urinary tract infections (UTIs). It accounts for less than 1% of all cases of pyelonephritis. Diabetes is a known systemic risk factor. Localized symptoms such as flank pain and dysuria may be attributed to nephrolithiasis or UTI without prompting a need for further workup. We present a case of XPN which resulted in kidney loss and dialysis dependence.

Case Description: A 54-year-old Hispanic female with a history of HTN, type 2 DM, kidney stones and recurrent UTIs presented with two years duration of intermittent right flank pain that acutely worsened one week prior to hospital admission. Most recent antibiotic use was one month prior. On physical exam patient appeared clinically stable, blood work was notable for a creatinine of 1.26 mg/dL, WBC of 11k/uL, and a urine culture growing Proteus Mirabilis. Renal ultrasound showed a 4 cm stone chronically obstructing the right ureteropelvic junction. CT scan demonstrated right-sided staghorn calculus with perinephric inflammation and a pathognomonic bear paw sign. Patient subsequently underwent right-sided nephrectomy. Postoperative hospital course was complicated by hemorrhagic shock, IVC thrombus, and persistent kidney failure. Patient remained dialysis dependent.

Discussion: XPN is a difficult diagnosis given that there are no specific symptoms until late stage. Exact etiology remains largely unknown. Malek et al proposed a three-stage classification of XPN, with stage II or diffuse type being the most common type and characterized by destruction of renal parenchyma (higher attenuation on CT) and dilated calyces (lower attenuation), mimicking a bear's paw. Our case highlights the importance of high clinical suspicion of XPN in diabetic patients with recurrent UTIs and kidney stones. Perinephric inflammatory changes are known predictors of poor outcomes. Early clinical and radiologic suspicion along with awareness of risk factors play an important role in preventing disease progression and avoiding late-stage complications including ESRD.



Bear paw sign

Background: In clinical trials, finerenone reduced risks of cardiovascular and renal complications among patients with chronic kidney disease (CKD) and type 2 diabetes (T2D). Evidence regarding finerenone use in real-world clinical settings is limited. This study aims to describe clinical characteristics, outcomes, and safety of new users of finerenone in Japan.

Methods: A retrospective observational cohort study using electronic health records and claims data from Japanese hospital-based databases provided by Real-World Data, Co. was conducted. Persons initiating finerenone from July 2021 to August 2023 with prior CKD and T2D were included. Prevalence of comorbidities and use of concomitant medication during the previous 365 and 180 days were calculated. Occurrence of kidney failure, a composite cardiovascular outcome, and hyperkalemia was assessed during follow-up.

Results: A total of 92 new users of finerenone were identified during the study period. Patient characteristics are described in Table 1. Median follow-up was 49 days. We observed no case of kidney failure and only one of a composite cardiovascular outcome. No patients showed serum potassium >5.5mmom/l or fatal hyperkalemia/hospitalization associated with hyperkalemia during follow-up. Results from ongoing analysis of several hundred finerenone users in one additional database will be presented at the conference presentation.

Conclusions: Early evidence from clinical practice in Japan suggests that finerenone is used for patients across risk stages and comedications. This study is the first database study conducted on evaluation of finerenone use in Japan.

MRI-Based Kidney Volume and Resistive Index in Patients with Progressive vs. Stable Diabetic Kidney Disease (DKD)

Paul Hockings,[1,3] Kianoush Makvandi,[4] Robert J. Unwin,[2] Johannes Hulthe,[1] Seema Baid-Agrawal.[4] *[1]Antaros Medical, Molndal, Sweden; [2]University College London, London, United Kingdom; [3]Chalmers Tekniska Hogskola AB, Goteborg, Sweden; [4]Sahlgrenska universitetssjukhuset, Goteborg, Sweden.*

Background: Multiparametric Magnetic Resonance Imaging (MRI) can non-invasively assess kidney structure and function but there are few longitudinal studies.

Methods: In this prospective study: - 38 DKD subjects aged 18–79 years and 20 age- and gender-matched healthy volunteers (HV) were included at baseline - 31 DKD subjects (2 stage 2, 13 stage 3, 14 stage 4, and 2 stage 5) and 17 HV were re-examined at 2 years ± 6 months Measured glomerular filtration rate (mGFR) was obtained using iohexol clearance. Kidney volume and renal artery resistive index (RARI) were measured by MRI. Subjects were classed as stable (S) or as progressors (P) if they met at least one of the following criteria at 2 years: - decrease in mGFR slope of >5 mL/year/1.73m^2 - worsening UACR category - any major adverse kidney event defined as: >sustained decrease in eGFR of >40% >doubling of serum creatinine from baseline >development of kidney failure with mGFR <15 ml/min/1.73m^2 >death from renal cause

Results: 8/31 (26%) DKD subjects and 4/17 (24%) HVs progressed. Mean 2-year mGFR decline in DKD patients was 2.7±5.4 and in HV 1.9±10.7 (ml/min/1.73m^2). Figure 1 shows correlation between both baseline and 2-year kidney volumes and RARI (R^2 0.91 and 0.78, respectively). Figure 2 shows changes in kidney volume and RARI for HV and DKD subjects who were either stable (S) or progressors (P).

Conclusions: Baseline vs 2-year follow up for both kidney volumes and RARI are highly correlated. Progressors tend to have larger decreases in kidney volume than stable subjects. Subjects with DKD tend to have larger increases in RARI than HV subjects. Larger studies are needed to confirm these results.

Funding: Commercial Support - Antaros Medical; AstraZeneca

CKD Testing among Patients with Diabetes in the US Military Health System

Robert Nee,[2,1] James D. Oliver,[1] Hava Marneweck,[3] Amanda Banaag,[3] Fang Xu,[4] Alain K. Koyama,[4] Yoshihisa Miyamoto,[4] Meda E. Pavkov,[4] Tracey L. Koehlmoos.[1] *[1]Uniformed Services University of the Health Sciences, Bethesda, MD; [2]Walter Reed National Military Medical Center, Bethesda, MD; [3]Henry M Jackson Foundation for the Advancement of Military Medicine Inc, Bethesda, MD; [4]Centers for Disease Control and Prevention, Atlanta, GA.*

Background: Despite guideline recommendations, annual chronic kidney disease (CKD) testing that includes both urine albumin-creatinine ratio (uACR) and estimated glomerular filtration rate (eGFR) remains low (<50%) among U.S. adults with diabetes mellitus (DM). As an integrated health care system with universal coverage, we hypothesized that CKD testing rates among DM adults in the Military Health System (MHS) would be higher than the overall national trend.

Methods: Using the MHS Data Repository (2016–2019), we analyzed the annual prevalence of non-pregnant DM adults with and without CKD based on ICD-10 codes who were tested for urine protein only (urine albumin, uACR, urine protein, urine protein-creatinine ratio [uPCR]); eGFR only; or both urine protein and eGFR. We also assessed race stratification and specialties of ordering providers.

Results: For 2019, 186,616 (6.2%) of 2,989,368 adults had DM (median age 60 [IQR 53–64] years; male 52.4%; White 32.3%, Black 17.4%, Asian American/Pacific Islander 4.9%, Native American/Alaskan Native 0.5%, Missing 30.3%; median eGFR = 79 [IQR 58–97] ml/min/1.73m^2, median uACR = 16.9 [IQR 6.6–56.6] mg/g). Sixty-one percent (61%) of DM+/CKD- and 70% of DM+/CKD+ were tested for both urine protein/eGFR (Fig). Racial categories were significantly associated with both urine protein/eGFR testing in the two cohorts in 2019 (p<0.0001). Among DM+/CKD- patients, 66% of urine protein and 55% of eGFR labs were ordered by primary care providers.

Conclusions: CKD testing rates among DM adults in the MHS were higher than other national-level data. However, there is a substantial opportunity to improve early detection of CKD in this high-risk population. *The views expressed in this abstract are those of the authors and do not necessarily reflect the official policy of the Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc., the Department of Defense, the Department of Health and Human Services, or the U.S. government.*

Impact of Gasdermin Gene on CKD in Iraqi Persons with Diabetes

Riyadh M. Alsaegh,[1,2] Ameer F. Al-Tu'ma,[1] Ameer R. Al-Saegh.[2] Al-Nahrain Medical College, Clinical Biochemistry Team for DSDMD-PhD Research Project-2024. *[1]University of Kerbala, Kerbala, Iraq; [2]Saegh Center for Nephrology and Kidney Transplantation, Karbala, Iraq.*

Background: Pyroptosis links diabetes and DN via GSDMD. Study examines SNP rs59118283's impact on this process.

Methods: This case-control study included 160 participants. Biochemical parameters, GSDMD, and IL-18 levels were measured. GSDMD (rs59118283) was genotyped using PCR and Sanger sequencing.

Results: The rs59118283 SNP in the GSDMD gene was successfully amplified (476 bp product) and confirmed by sequencing. Genotype distribution showed no significant differences in odds ratios for diabetic nephropathy (DN) and type 2 diabetes mellitus (T2DM) patients compared to healthy controls (0.4 and 0.8, respectively). This aligns with studies suggesting genetic markers like GSDMD influence disease susceptibility, modulated by other factors. Significant differences in HbA1c levels, particularly in DN patients with the insertion genotype, indicate its impact on glycemic control. The genetic impact on CKD progression in T2DM is independent of demographic factors, highlighting the need for further research into genetic and environmental interactions.

Conclusions: The GSDMD gene polymorphism (rs59118283) showed no significant association with CKD stages 2 and 3 in T2DM patients versus healthy controls. Significant biochemical variations suggest genetic factors in disease progression, warranting further research.

Funding: Government Support - Non-U.S.

Effect of SGLT2 Inhibitor Therapy on Urinary Podocyte Markers in Diabetic Kidney Disease

Chuanlei Li,[1,2] Cheuk-Chun Szeto.[1,2] *[1]Departments of Medicine & Therapeutics, Prince of Wales Hospital, Hong Kong, Hong Kong; [2]Li Ka Shing Institute of Health Sciences (LiHS), Faculty of Medicine, The Chinese University of Hong Kong, Hong Kong, Hong Kong.*

Background: Sodium glucose cotransporter 2 inhibitor (SGLT2i) is a standard treatment for kidney and cardiovascular protection in diabetic kidney disease (DKD). Previous studies suggested that urinary level of podocyte-associated molecules may predict the progression of DKD. We determined the effect of SGLT2i on the urinary podocyte-associated molecules levels in patients with DKD.

Methods: We studied 24 DKD patients who were started on SGLT2i treatment and 25 patients who were not treated (control group). Urinary levels of podocyte-associated molecules, their corresponding mRNA levels in urinary sediment, estimated glomerular filtration rate (eGFR), and urine albumin-creatinine ratio (UACR) were measured at baseline and then again at 3 months.

Results: Urinary levels of podocin, podocalyxin, nephrin and synaptopodin did not change from baseline to 3 months in the SGLT2i treatment group. However, in the control group, urinary podocin, podocalyxin, and synaptopodin levels increased from (4.63 ± 4.84 to 18.49 ± 22.22 ng/μmol-Cr, 489.75 ± 480.62 to 1399.53 ± 1265.27 ng/mmol-Cr, and 38.61 ± 42.56 to 78.50 ± 85.61 ng/μmol-Cr, p = 0.0006, 0.0002, and 0.03, respetively) over 3 months, while unriary nephrin level did not change significantly. Urinary sediment podocin, podocalyxin, nephrin and synaptopodin mRNA levels did not change from baseline to 3 months in control and SGLT2i treatment groups. There were no significant correlations between urinary podocyte-associated marker levels and eGFR and UACR at baseline, and there was no significant correlation between urinary sediment mRNA levels of nephrin, podocin, podocalyxin, synaptopodin and eGFR or UACR at baseline. After 3-month treatment, podocalyxin mRNA level had a significant inverse correlation with eGFR (r = -0.392, p = 0.009) but not UACR. In the control group, the change in podocalyxin (r = -0.389, p = 0.017) and nephrin (r = -0.471, p = 0.010) mRNA level had significant inverse correlations with the change in eGFR and UACR, respectively.

Conclusions: SGLT2i has a small but significant effect on preventing the progressive rise in urinary podocyte-associated molecule levels but not sediment mRNA level. Our result suggests that SGLT2i therapy may affect podocyte function in DKD.

PUB116

Decrease of Hemoglobin A1c (HbA1c) in Patients with Type 2 Diabetes, Suboptimal Glycemic Control, in Advanced CKD, and Major Adverse Kidney Events

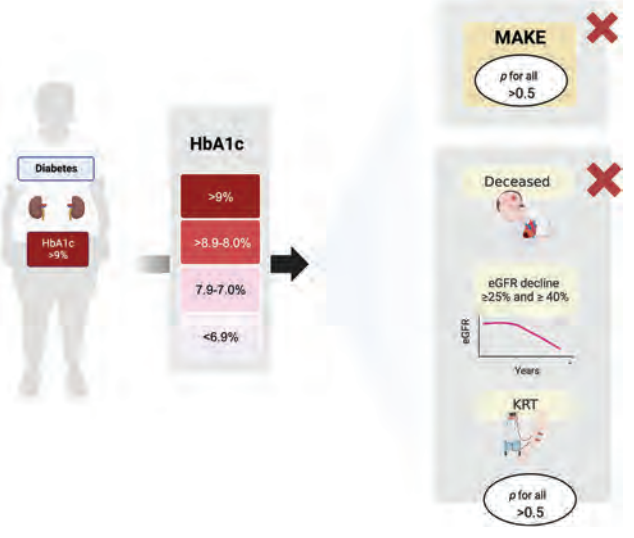
Jonathan Chavez,[1,2] Guillermo Garcia-Garcia,[1] Ramon Medina,[1,2] Zarahi Andrade,[1] Juárez Correa de León,[1] Eduardo M. Hernández,[1] Jorge L. Padilla Armas,[1] Rebeca L. Ornelas Ruvalcaba,[1] Jose S. Cabrera Aguilar,[1] Guillermo Navarro Blackaller,[1] Maria de la Luz Alcantar Vallin,[1] Alejandro Martínez Gallardo González.[2] *[1]Universidad de Guadalajara, Guadalajara, Mexico; [2]Hospital Civil de Guadalajara, Guadalajara, Mexico.*

Background: In subjects with type 2 diabetes (DM), poor glycemic control, and advanced chronic kidney disease (CKD), the kidney benefit of the reduction of glycated hemoglobin (HbA1c) is not well established.

Methods: In a retrospective cohort, we included patients with DM, CKD grade 3b-5, and HbA1c >9%, to evaluate the risk of developing major adverse kidney events (MAKE) defined as the start of kidney replacement therapy (KRT), ≥ 25% or ≥ 40% decline in the glomerular filtration rate (eGFR) from baseline, and death; according to the HbA1c groups at the end of the follow-up, divided by >75 mmol/mol (≥9.0%), 74-64 mmol/mol (8.9-8.0%), 64-53 mmol/mol (7.9-7.0%) and <52 mmol/mol (<7.0%). We described their characteristics and analyzed their risks adjusting for confounding variables.

Results: During 2015 to 2023, 111 patients were included. In 46 (41.4%) the HbA1c at the end of follow-up (60 months) was still >75 mmol/mol (≥9%), each patient had a mean of 4.9 HbA1c measurements. The mean age was 59 years and 46% were male, baseline eGFR was 25 ml/min/1.73m^2. MAKE occurred in 67% of cases. In a multivariate analysis, the risk of MAKE was not associated with the HbA1c groups. Nor was it associated with any of the MAKE components individually, nor in certain subgroups. When evaluating the magnitude of percentage changes in HbA1 with the initiation of KRT, we did not find any association.

Conclusions: With advanced CKD and poor glycemic control, changes in HbA1c during long follow-up are not associated with MAKE or its individual components.



PUB117

Modifying Effect of Albuminuria on the Association between Joslin Kidney Panel Biomarkers and Kidney Failure among Patients with Diabetes: Findings from the ACCORD/ACCORDION Trial

Balamurugan Tangiisuran,[1,2] Hetal Shah,[1,2] Andrzej Galecki,[4,3] James P. Lash,[5] Andrzej S. Krolewski,[1,2] Alessandro Doria.[1,2] *[1]Joslin Diabetes Center, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]University of Michigan Medical School, Ann Arbor, MI; [4]University of Michigan, Department of Biostatistics, School of Public Health, Ann Arbour, MI; [5]University of Illinois Chicago College of Medicine, Chicago, IL.*

Background: The Joslin Kidney Panel (JKP) includes 21 serum proteins identified as predictors of risk of kidney failure (KF) in patients with diabetes. Our goal was to evaluate the association with KF and the predictive performance of JKP biomarkers in patients with type 2 diabetes with and without albuminuria at baseline.

Methods: A case-cohort analysis of the ACCORD/ ACCORDION cohort was carried out by selecting a 15% random sub-cohort plus all KF cases outside the sub-cohort. JKP biomarkers were measured in baseline serum samples using a custom multiplex Olink® assay. Weighted Cox models (adjusted by clinical KF predictors and trial treatment assignments) were used to assess the association between baseline JKP biomarkers and KF during follow-up by baseline albuminuria status.

Results: A total of 1,393 subjects were included in the study: 432 with albuminuria (urinary ACR >30 mg/g) and 961 with normoalbuminuria at baseline. There were 129 and 127 KF events in the albuminuric and normoalbuminuric strata, respectively, during a median follow-up of 6.1 years (IQR 4.0-9.4). Fifteen JKP markers showed a significant association with KF in the albuminuria stratum, with the axon-guidance protein EFNA4 showing the strongest effect (HR 3.96, 95% CI 2.05 – 7.67). By contrast, only six biomarkers were associated with KF in normoalbuminuric participants and with smaller HRs than in albuminuric participants. In an interaction analysis, 13 biomarkers showed significant differences in their effect on KF risk between albuminuria and normoalbuminuria strata. Addition of the JKP biomarkers to clinical predictors increased the C-index from 0.70 to 0.76 ($p<0.0001$) in the albuminuria stratum and from 0.58 to 0.67 ($p<0.0001$) in the normoalbuminuria stratum.

Conclusions: Currently available biomarkers of increased KF risk are more strongly associated with KF in albuminuric than in normoalbuminuric subjects with type 2 diabetes. While these proteins improve KF risk discrimination in both groups, the combined performance of clinical and biomarker predictors is lower among normoalbuminuric subjects. Studies are needed to identify novel biomarkers allowing better KF risk prediction in normoalbuminuria.

PUB118

Superimposed Focal Segmental Glomerulosclerosis Lesions Worsen Kidney Prognosis in Diabetic Nephropathy (DN)

Maria Jose Vargas-Brochero,[1] Miriam Machado,[1] Nancy Daniela Valencia-Morales,[1] Marta I. Casal Moura,[1] Sana Abouzahir,[1] Sanjeev Sethi,[1] Maria Jose Soler.[2] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Hospital Universitari Vall d'Hebron, Barcelona, Spain.*

Background: Patients with biopsy-proven DN may have superimposed focal and segmental glomerulosclerosis(FSGS), and its implications for kidney prognosis have been scarcely assessed. This study aims to assess how the presence of FSGS in patients with DN affects kidney prognosis

Methods: Historical cohort study of biopsy-proven DN from 2010 to 2022. Exclusion criteria included ESKD at diagnosis, primary glomerulopathies, metastatic cancer, pregnancy, transplant of any organ, or lack of follow-up. Primary outcome was comparing the progression to ESKD (defined as an estimated glomerular filtration rate(eGFR)<15 mL/min/1.73m2, kidney transplant, or renal replacement therapy need. Time-to-event analysis was conducted using the Kaplan-Meier (ESKD as the event of interest). Cox proportional hazard regression was used to determine predictive factors associated with ESKD

Results: 67 patients; mean age 61.6y, 38(56.7%) male, and 56(83.6%) white. 37 (55.2%) had FSGS lesions. FSGS cohort had a higher presence of non-white ethnicity n=10 (27%)(p=0.009), higher Albumin/creatinine ratio (ACR) (***p=0.014***), higher IFTA ***(p=0.009)***, and percentage of class IV (***p=0.037)***, there were no differences regarding the body mass index. 26 (38.8%) reached ESKD during follow-up; the median follow-up was 3.3 years, and the median survival was 4.13 years. Estimated kidney survival was 86.6 % (78.7-95.1%) at one year, with a significant difference in the FSGS group (long-rank p=0.04). In the multivariate Cox regression model, FSGS (HR, 2.9; 95% CI 1.04 to 8.10), stroke (HR, 5.6; 95% CI 1.8 to 17.7), and albumin (HR, 0.2; 95% CI 0.94 to 0.43), were independently associated with progression to ESKD

Conclusions: Our study characterizes a population with DN and demonstrates how superimposed FSGS is related to a higher risk of progression to ESKD

Neurotuberculosis in a Patient with CKD: A Rare Case Report of the Lethal Duo

Abhijit S. Chavan, Prabhakar Yadav, Himanshu Shekhar. *Tata Main Hospital, Jamshedpur, India.*

Introduction: One of the leading causes of deaths worlwide has been infections with Mycobacterium tuberculosis (TB), which is endemic in certain nations where also prevalance of CKD has been on an rising trend. In patients with CKD, the incidence of TB has been 10–15 times greater than that in the general population, considering the immunocompromised state associated with CKD. The clinical presentation of TB in CKD patients is often insidious and atypical. Patients frequently present with symptoms like fever, anorexia, and weight loss which may mimic uremia and mask diagnosis of Nuero-tuberculosis.

Case Description: A 66 year old gentlemen, a known case of CKD stage V due to underlying diabetic Nephropathy, presented with complains of easy fatigabilty since a month. He was found to have a right sided plueral effusion and a serum creatinine of 5.6 mg/dl. Subsequently patient underwent a diagnostic tap which favoured diagnosis of extra-pulmonary TB (pleural fluid: cells- 550/cumm lymphocytes-90%, ADA- 54 IU/L, lights criteria ratio-1.2). Patient was started on Anti-tubercular drug therapy as per National TB guidelines including Isoniazid, Rifampicin, ethambutol and Pyrazinamide as per weight based dosing and dose adjusted for CKD staging. Two weeks later patient complained of uremic symptoms and drowsiness. On further investigations, he had urea of 157 mg/dl, creatinine of 8.4 mg/dl demanding initiation of hemodialysis. After initial 3 sessions of hemodialysis patient did not show any improvement and underwent an MRI Brain with diffusion imaging suggestive of a T2 heterointense lesion measuring 1.20 x 1.28 cm is seen in left posterior frontal lobe showing mild perilesional edema and heterogeneous diffusion restriction on DWI images. On the context of an established extra-pulmonary TB and the intra-parenchymal CNS lesion a diagnosis of Tuberculoma was made.

Discussion: Tuberculomas, occur secondary to a primary infection, the focus being lungs or lymph nodes, occuring in the background of CKD is a very rare extrapulmonary manifestation of TB. The performance of TB screening and diagnostic tests is suboptimal in the CKD population, making a timely diagnosis a challenging task. Considering the high prevalance of CKD in TB endemic areas, a missed diagnosis of TB in CKD population could have significant public health implications and poor patient outcomes.

PUB120

Unveiling the Continuum: Tracking Urinary Transforming Growth Factor (TGF)-β1 in Diabetic Nephropathy Follow-Up

Akshay R. Kulkarni, Atul Sajgure, Charan B. Bale, Pavan Wakhare, Nilesh Shinde, Abhijit S. Chavan, Debapriya Saha, Anuja P. Makan, Shreeharsh Godbole, Chetan U. Phadke, Abhishek S. Borle, Gaurav Singh, Tushar A. Dighe. *Dr. D. Y. Patil Medical College, Hospital & Research centre, Pimpri, Pune, Pune, India.*

Background: Diabetic nephropathy (DN) is a leading cause of end-stage kidney disease (ESKD). Accumulating evidence points to transforming growth factor beta-1(TGF-β1), a potent profibrotic mediator, as a significant mediator in the development of DN.

Methods: It was a prospective observational study including 10 cases of diabetic Nephropathy in group A and 10 healthy controls in group B, age ≥ 18 years. Patients with

urinary tract infection, pregnancy, CKD stage Vd patients on maintenance hemodialysis and post renal transplant cases were excluded. Patients clinical characteristics and examination findings were recorded at visit 1 and follow up after 3 months (visit 2). Patients received standard of care treatment during the follow up. Urinary TGF-β1 levels were determined in a 24 hours urine sample using Miltenyi-MACSQuant-10 flowcytometer, each sample run in triplicates and average of the three taken. The biochemical tests were performed using dimension ExL clinical chemistry system (SIEMENS). Quality of life was assessed using Karnofsky performance status scale.

Results: In group A, the mean value of urinary TGF-β1 on visit 1 was 88.33 ± 12.44 ng/24 hours and on visit 2 was 69.25 ± 13.56 ng/24 hours. The reduction in the TGF-β1 levels on follow up in group A was statistically significant (p< 0.001). The mean value in the group B was 29.03± 3.23 ng/24 hours, significantly low compared to group A (p<0.001). In group A there was no significant correlation between urinary TGF β1 levels and 24 hours urine protein, on visit 1 and 2(r = 0.341 and r=0.505) or UPCR on visit 1 and 2 (r = 0.154,p = 0.672 and r= 0.120,p= 0.742). Also, the change in urinary TGF-β1 levels(between visit 1 & 2) didn't correlate with change in 24 hours urine protein (r=0.258, p=0.472), UPCR(r=0.240, p=0.505) or eGFR(r=-0.268, p=0.455). The median Karnofsky performance status was 80 on visit 1 and 90 on visit 2 in group A, while it was 100 in group B.

Conclusions: Urinary TGF- β1 levels reduced significantly on follow up after 3 months amongst diabetic nephropathy patients but that change didn't correlate with the change in proteinuria and eGFR. There was no significant correlation between urinary TGF- β1 levels and proteinuria, serum creatinine level or eGFR.

PUB121

Tirzepatide Improves Glycemic Control Better than Dulagutide in Patients Undergoing Hemodialysis

Emiko Otsuka,[1] Mineaki Kitamura,[1] Shinichi Abe,[2] Satoshi Funakoshi,[2] Tomoya Nishino.[1] *[1]Nagasaki Daigaku Daigakuin Ishiyakugaku Sogo Kenkyuka, Nagasaki, Japan; [2]Nagasaki Kidney Center, Nagasaki, Japan.*

Background: Glycemic control is crucial to reduce cardiovascular events and mortality in patients with type 2 diabetes undergoing hemodialysis. On the other hand, some anti-diabetic drugs are of limited use or contraindicated in patients undergoing hemodialysis. Tirzepatide is a novel dual glucagon-like peptide-1 (GLP-1) and glucose-dependent insulinotropic peptide (GIP) agonist that can be used in patients undergoing hemodialysis. However, the safety and efficacy of tirzepatide in patients undergoing hemodialysis remain unclear. We aimed to compare the glycemic control between dulaglutide and tirzepatide in patients undergoing hemodialysis.

Methods: This study is a retrospective single-center study. We included patients with type 2 diabetes undergoing hemodialysis whose prescriptions for diabetes were transitioned from dulaglutide to tirzepatide at the Nagasaki Renal Center between June 2023 and August 2023. Blood glucose levels were evaluated using continuous glucose monitoring (CGM) for 7 days in both periods before and after switching from dulaglutide to tirzepatide. Time in range (TIR), time above range (TAR), time below range (TBR), and mean blood glucose levels, were analyzed using the Wilcoxon signed-rank test.

Results: We analyzed 14 patients (61.9 ± 9.9 years, male: female =11:3). After switching to tirzepatide, TIR increased to 50.8% from 42.7% (p=0.02), TAR decreased to 37.8% from 48.4% (p=0.02), and mean glucose levels decreased to 137.4 mg/dL from 156.6 mg/dL (p=0.006). However, TBR did not show significant change before and after switching to tirzepatide (11.3% and 8.9%) (p=0.75). Furthermore, there were obvious improvements in glycemic control on hemodialysis days; TIR increased from 44.8% to 52.2% (p=0.02), TAR decreased from 40.9% to 32.6% (p=0.07), and TBR did not increase (13.7% and 14.3%) (p=0.76). In contrast, there were no significant changes in TIR (47.9% and 51.7%) (p=0.25), and mean glucose levels (157.9 mg/dL and 141.3 mg/dL) (p=0.08), on non-hemodialysis days.

Conclusions: Tirzepatide improves glycemic control without increasing hypoglycemia compared to dulagutide in patients with type 2 diabetes undergoing hemodialysis.

PUB122

Impact of Once-Weekly Semaglutide on eGFR and Hemoglobin A1c (HbA1c) among Patients with Type 2 Diabetes and CKD: An Observational Study

James J. Amamoo,[1] Sunny T. Sheth,[1] Brenna L. Brady,[2] Anh Thu Tran,[2] Lin Xie,[1] Josh Noone,[1] Sherif Mehanna,[1] George L. Bakris.[3] *[1]Novo Nordisk Inc., Plainsboro, NJ; [2]Merative, Cambridge, MA; [3]University of Chicago Medical Center, Chicago, IL.*

Background: Of ~35 million patients living with type 2 diabetes (T2D) in the US, 30–40% also have CKD, which is associated with increased morbidity and mortality. Therefore, managing comorbidities is of utmost importance. This real-world study assessed the changes in eGFR and HbA_{1c} in adults with T2D and CKD following initiation of once-weekly (OW) semaglutide subcutaneous injection.

Methods: This exploratory non-interventional, longitudinal, retrospective cohort study included patients aged ≥18 years with evidence of T2D and CKD (eGFR <60 mL/min/1.73 m^2) pre-index, newly initiating OW semaglutide (index selection period: January 2018–September 2022) from the Merative™ MarketScan® Laboratory Database. Other key inclusion criteria included persistence to OW semaglutide of ≥6 months, and no evidence of dialysis or kidney transplant at baseline. The first prescription fill for OW semaglutide served as the index date. Patients were followed over a variable post-period, the end of which was the first of OW semaglutide discontinuation, end of continuous eligibility or end of study data. Change in eGFR and HbA_{1c} from the last value taken prior to index date were assessed over a variable period for all patients with ≥6 months' of follow-up and over a fixed 12-month follow-up.

Results: A total of 254 patients qualified for the analyses. Mean (SD) baseline eGFR and HbA_{1c} were 45.1 (10.5) mL/min/1.73 m^2 and 7.8 (1.6)%, respectively. The mean (SD) changes in eGFR and HbA_{1c} values from baseline to post-index were 2.0 (10.9) mL/min/1.73 m^2 and –1.1 (1.6)%, respectively. In a subgroup of patients with 12 months' follow-up (n=99), mean (SD) eGFR and HbA_{1c} at baseline were 45.2 (10.8) mL/min/1.73 m^2 and 7.5 (1.7)%, respectively. The mean (SD) changes in eGFR and HbA_{1c} values from baseline to 12 months post-index were 4.5 (12.8) mL/min/1.73 m^2 and –1.2 (1.5)%, respectively.

Conclusions: In this exploratory real-world study, initiation of OW semaglutide was associated with improvements in both eGFR and HbA_{1c} in adults with T2D and CKD over 12 months, demonstrating its potential utility in this patient population.

A Randomized Controlled Clinical Trial to Evaluate the Efficacy and Safety of FX CorAL Dialyzers during Hemodialysis Treatment in Chinese Patients on Maintenance Hemodialysis: Study Protocol

Liangying Gan,[1] Bingbin Zhao,[2] Lily Zhang,[2] Yuanying Guo,[3] Qing Lin,[2] Bettina Griesshaber,[4] Kakiu Ho,[5] Manuela Stauss-Grabo,[4] Li Zuo.[1] *[1]Peking University People's Hospital, Beijing, China; [2]Fresenius Medical Care, Beijing, China; [3]Fresenius Medical Care, Shanghai, China; [4]Fresenius Medical Care, Bad Homburg, Germany; [5]Fresenius Medical Care, Hong Kong, China.*

Background: Dialyzers are designed to eliminate uremic toxins during dialysis treatment, this is especially important as the accumulation of small and middle molecular weight uremic solutes is associated with increased morbidity and mortality. The FX CorAL dialyzers are a series of high flux hemodialyzers with a modified membrane surface, resulting in improved clearance performance and hemocompatibility. This study tests the hypothesis of non-inferiority of efficacy and safety comparing FX CorAL to WEGO dialyzer.

Methods: In the two-stage, prospective, multicenter, randomized, parallel controlled, open, non-inferior study, a total of 238 adult Chinese maintenance hemodialysis patients will be enrolled and randomized in a 1:1 fashion to the investigational group (FX CorAL, Fresenius Medical Care AG) and the control group (WEGO HF, Shandong Weigao Blood Purification Products, China). Each patient will undergo regular thrice weekly HD treatment. The study consists of two mid-week HD treatments in sequence for study dialyzer evaluations (Stage I with surface area 1.4 m^2: FX CorAL 60 vs. WEGO HF14; Stage II with surface area 1.8 m^2: FX CorAL 80 vs. WEGO HF18), and a washout period including two HD treatments between Stage I and II (figure 1). The primary endpoints are clearance of creatinine and urea nitrogen at 60 min after start of dialysis, and reduction ratio of β2-microglobulin during HD treatment. The secondary endpoints include removing performance of other uremic solutes, inflammatory markers, and safety.

Results: The study is ongoing and will be completed in 2027.

Conclusions: This study will add insights to the efficacy and safety profiles for FX CorAL dialyzer. It is hypothesized that the uremic toxin clearance performance of FX CorAL is non-inferior (and potentially superior) to the comparator dialyzer.

PUB124

A Case of Multidrug Intoxication Including Calcium Channel Blocker Treated with Plasmapheresis

Alissa A. Ice, Edward Gould. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Amlodipine, a dihydropyridine calcium channel blocker (CCB), has a large volume of distribution and is primarily hepatically metabolized with an extended half-life. Despite amlodipine being highly protein bound, there is a paucity of evidence for the potential role of plasmapheresis (PLEX) in toxicity management. We present an overdose case with refractory shock necessitating both ECMO and PLEX treatment.

Case Description: A 47 year old male with HTN, DMII, prostate cancer, gout, and PTSD presented following an intentional overdose of 900mg of amlodipine and a large quantity of an unknown medication, reportedly either triamterene-hydrochlorothiazide or amitriptyline. He presented with profound distributive shock and acute hypoxemic respiratory requiring several vasopressors and eventually intubation. Labs were notable for potassium 1.7, phosphorous <0.7, bicarb 9, Cr 2.32, glucose 597, anion gap 18, lactic acid 6.6 (peaked at 15.3), AST 57, ALT 71, WBC 29.4, VBG 7.26/30/40/13, CPK 6718, troponin 0.33 (peaked at 1.59). EKG demonstrated anterolateral ST depressions but no evidence of QT prolongation and TTE without wall motion abnormalities and EF >70%. He was seen by toxicology and started on insulin, glucagon, calcium chloride, sodium bicarb, lipid, and methylene blue infusions. In addition to electrolyte supplementation, he was started on VA-ECMO and underwent one session of PLEX followed by CRRT given persistent oliguric AKI and severe metabolic derangements. His course was further complicated by lower limb ischemia and ARDS, and the family elected for comfort measures.

Discussion: Although dihydropiridine CCBs have affinity for the L-type calcium channels within the vascular smooth muscle, this pharmacological selectivity can be altered in the setting of toxicity. In addition to the profound cardiovascular repercussions, CCB also inhibit beta islet cells, leading to hyperglycemia. This finding has been described to associate with the severity of the intoxication. Conventional treatment includes hemodynamic support and calcium administration. Given CCBs are highly protein bound, hemodialysis is not recommended, but there may be some utility in PLEX in select cases. Previous case studies have demonstrated a reduction in amlodipine plasma concentrations of approximately 36%. In the setting of profound CCB overdose and associated vasoplegia, PLEX should be considered.

PUB125

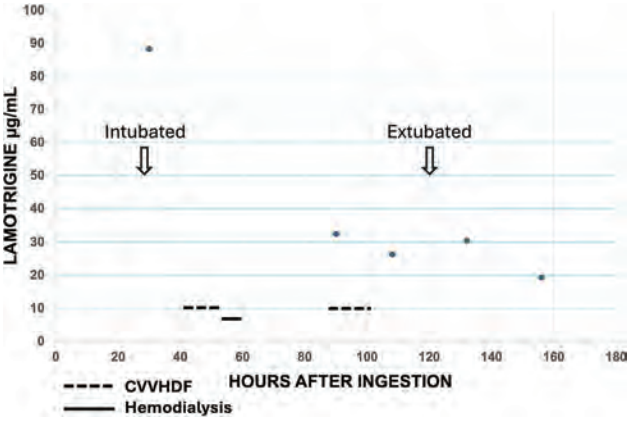
Dialysis for Lamotrigine Intoxication in a Teenager

Elliott Huang, Hilda E. Fernandez. *Columbia University, New York, NY.*

Introduction: Lamotrigine (LTG) is a rare cause of acute intoxication. A 1993 pharmocokinetic study of a dose of LTG was conducted in healthy volunteers, patients w CKD and ESRD on iHD. The elimination half-life of LTG was approximately 25 h in subjects w normal renal function and 50 h in uremic patients. iHD shortened the elimination half-life from 59.6 +/- 28.1 h during the interdialysis period to 12.2 +/- 6.4 h during the dialysis period; 17% of the dose was extracted by HD. Clinical reports of 2 to 5 iHD treatments have been associated w neurologic improvement. LTG levels > 25 µg/mL have been associated w severe toxicity in adults. Ingestions > 4.5gm of LTG have been associated w severe morbidity and mortality.

Case Description: 16 yo F w h/o depression intentionally ingested a total of 6 g of LTG and unknown small amounts of lurasidone and fluoxetine. She was taken to ER for headache and dizziness 3 h post ingestion. At 27 h after ingestion, she developed hypotension requiring pressor support and had a GTC seizure requiring intubation for airway protection. There was no AKI. Poison Control recommended hemodialysis to clear LTG. CVVHDF was initiated 41 h after ingestion and continued until 55 h after ingestion. She was switched to 4 h iHD when she was stable off pressors. CVVHDF was resumed at 89 h after ingestion for 12 h, then discontinued w Poison Control advice. She had improvements to her mental status and was extubated at 120 h. LTG levels were sent daily but results were not available until dialysis was discontinued (Figure). She was transferred to inpatient psychiatry on day 8.

Discussion: Sixty-three percent of LTG was cleared after a combination of CVVHDF and iHD within 48 hours. Subsequent CVVHDF for 12 hours cleared an additional 19% of LTG. A rebound in LTG level was seen the next day off dialysis; however, patient already had recovery from AMS. Due to the severity of clinical presentation and delay in LTG levels resulting, we performed dialysis for 3 consecutive days in this patient w clinical improvement.



Lamotrigine intoxication

PUB126

Relative Change in Itch Intensity Determines Treatment Satisfaction of Patients with CKD-Associated Pruritus

Joerg Latus,[1] Thilo Schaufler,[2] Isabelle Morin,[2] Warren Wen,[3] Joel M. Topf.[4] *[1]Robert-Bosch-Krankenhaus GmbH, Stuttgart, Germany; [2]CSL Vifor, Glattbrugg, Switzerland; [3]Cara Therapeutics Inc, Stamford, CT; [4]Oakland University William Beaumont School of Medicine, Rochester, MI.*

Background: Four in ten patients on hemodialysis (HD) report suffering from moderate or severe CKD-associated pruritus (CKD-aP) and associated conditions such as: sleep problems, fatigue, depressive symptoms, and reduced quality of life. Burden of itch and itch relief are highly subjective.

Methods: HD patients in KALM-1 and -2 (NCT03422653 and NCT03636269) trials received either difelikefalin or placebo 3 times per week for 12 weeks. Itch intensity was assessed with the weekly mean of the Worst Itching Intensity Numerical Rating Scale (WI-NRS; range 0 [no itch] to 10 [worst itch imaginable]) as moderate (KALM-1: >4 to <7; KALM-2 ≥5 to <7) or severe (≥7) at baseline. Patient Global Impression of Change (PGIC) asked patients after 12 weeks how their itch changed (1 [very much improved] to 7 [very much worse]). This exploratory analysis reports absolute and relative change in WI-NRS relative to PGIC-assessed treatment satisfaction stratified by baseline itch severity independent of treatment exposure.

Results: Patients with moderate or severe CKD-aP at baseline reporting their itch to be "much improved" had a mean reduction of ≥3 WI-NRS points. Those "very much improved" had a mean reduction of ≥4 WI-NRS points (see Figure 1a). Relative improvement by PGIC category was highly consistent across baseline severity groups, independent of treatment received, with patients reporting their itch having "much improved" seeing a 50% reduction from their baseline WI-NRS value. Those "very much improved" saw a reduction of ~ 70% from baseline (see Figure 1b). Spearman correlation (95% confidence interval) between the PGIC and relative change in WI-NRS in patients with moderate CKD-aP was 0.63 (0.55 – 0.69) and 0.71 (0.66 – 0.76) in patients with severe CKD-aP at baseline, respectively.

Conclusions: While patient-reported treatment satisfaction should be the main goal in subjective conditions such as CKD-aP, this analysis demonstrates that the relative change on the validated WI-NRS scale can offer valuable decision support for nephrology professionals assessing treatment benefit.

Improving Dialysis Initiation in Stage 5 CKD: A Quality Improvement Project at a Safety Net Hospital

Elaine J. Oldford,[1,2] Annika K. Khine.[1] *[1]Los Angeles General Medical Center, Los Angeles, CA; [2]Keck Medicine of USC, Los Angeles, CA.*

Background: At Los Angeles General Medical Center (LAGMC), a large safety net training institution, residents and fellows rotate through specialty clinics, serving a primarily Hispanic and underserved population. In LAGMC renal clinic, we implemented a quality improvement project in patients with eGFR <20 ml/min/1.73m2, by scheduling them in an attending-directed CKD clinic rather than with resident trainees for follow-up visits. This study evaluates the impact of this intervention on inpatient and outpatient dialysis initiation and the use of permanent dialysis access.

Methods: In this retrospective observational study, medical records of 244 CKD Stage V patients at LAGMC renal clinic from January to July 2022 were reviewed. We determined the endpoint for each patient as dialysis initiation (inpatient or outpatient) or the end point date of February 2024 if not yet on dialysis. The intervention began in October 2022, transferring patients from resident panels to attending panels for follow-up visits, with a 3-month run-in period.

Results: 167 of patients initiated dialysis, with 105 (63%) as inpatient and 62 (37%) as outpatient. There was a decreasing trend in inpatient initiations and an increasing trend in outpatient initiations over time. Inpatient dialysis initiations resulted in an average hospital stay of 7 days, with 22% of patients requiring temporary dialysis catheters. There was also an increase in permanent vascular access (AVF/AVG) over time of CKD Stage V patients at the endpoint.

Conclusions: Quality improvement that have CKD Stage V patients seen directly by attending nephrologists can decrease the rates of inpatient "crash" start dialysis and increase vascular access.

Midodrine-Induced Ischemic Vascular Injury: A Case Report in Patients on Hemodialysis

Hillary Vo,[1,3] Shehpar Khan,[1] Samir Nangia.[1,2] *[1]Dallas Renal Group, Dallas, TX; [2]Burnett School of Medicine, Fort Worth, TX; [3]Arkansas College of Osteopathic Medicine, Fort Smith, AR.*

Introduction: Midodrine is an alpha-agonist that increases blood pressure by inducing vasoconstriction. It is widely prescribed due to its efficacy in managing hemodialysis-associated hypotension in ESRD patients. Midodrine is generally well-tolerated by most patients. However, despite its rarity, we present a case highlighting an adverse effect of midodrine.

Case Description: We present the case of a 68-year-old male with ESRD on hemodialysis, with a history of type 2 diabetes-associated nephropathy, CAD, and CHF with EF 20-25%. The patient was initiated on Midodrine 10mg three times a day for hypotension. He presented after 3 weeks with numbness, discoloration of digits, and gangrenous lesions. He denied any specific injury or use of calcium-based phosphorus binders. ABI of the left lower extremity was as low as 0.5. ANCA and ANA tests were negative, and cryoglobulin was absent, ruling out autoimmune systemic vasculitis. Initial lab results indicated well-controlled levels of calcium, iPTH, and phosphorus. A punch biopsy was performed to rule out calciphylaxis, which showed no calcium deposits, thrombi, or evidence of vasculitis.

Discussion: While current literature generally indicates the safety of midodrine, this case appears to be one of the few documented instances of midodrine-induced ischemic vascular injury observed in hemodialysis patients. Further research should prioritize discontinuing the medication to evaluate the persistence of symptoms. The primary aim of this report is to increase awareness of ischemic vascular injury as a potential side effect of midodrine and to encourage heightened vigilance among physicians.

Determination of Fracture Risk in a Hemodialysis Unit in Ecuador Using the FRAX Tool without Bone Mineral Density (BMD)

Ana Y. Navarro,[1] Ailiyomar Perez,[2] Ricardo J. Lino.[3] *[1]Fresenius Medical Care, Quito, Ecuador; [2]Menydial, Ambato, Ecuador; [3]Baxter Ecuador SA, Quito, Ecuador.*

Background: Patients with chronic kidney disease (CKD) present mineral bone disease which is developing from earlier stages, producing osteoporotic fractures that aggravate their morbidity and mortality during the treatment, so prevention plays a fundamental role in preserving the quality of life of patients.

Methods: cross-sectional, correlational and descriptive study. It included 209 patients. As inclusion criterion: patients between 40 and 90 years old, on hemodialysis. Excluded were: patients with malignant disease, bedridden patients and patients receiving antiresorptive treatments. Demographic variables and serum levels of biochemical markers that guide the diagnosis of bone mineral disease were evaluated. cross-sectional, correlational and descriptive study. It included 209 patients. As inclusion criterion: patients between 40 and 90 years old, on hemodialysis. Excluded were: patients with malignant disease, bedridden patients and patients receiving antiresorptive treatments. Demographic variables and serum levels of biochemical markers that guide the diagnosis of bone mineral disease were evaluated.

Results: 60.28% men and 39.71% women, with an average age of 61.85±10.75. 77.55% were at risk of major osteoporotic fracture, of which 43.75% were women and 56.24% men, with an average age of 64.78±9.88. Differentiating the higher risk group vs. the lowest risk was recorded: BMI 24.53vs 25.98; calcium 8.26 vs 8.4; Pth 385.91 vs 359.2; in albumin and phosphorus there were no significant differences. The variables resulted with sensitivity and specificity of 95% confidence. In hip fracture, 27.27% of patients were at risk, of which 49.12% were women and 58.87% were men, with an average age of 71.73±8.89; BMI, calcium and albumin were lower than in those patients without significant risk of hip fracture, respectively, 23.64 vs 25.30; 8 vs 8.25; 3.72 vs 3.88; the opposite occurred with Pth 434 vs 358.92; which is expected, again the phosphorus without relevant meanings and the confidence index for the significant variables was 95% for sensitivity and specificity

Conclusions: The risk of major osteoporotic fracture and hip fracture in the hemodialysis unit was high. The frax tool proved to be assertive for patients on hemodialysis, even without the use of BMD, the results show the association of variables that allow diagnosing mineral disease.

PUB130

Prevalence of the Chronic Inflammatory State and Relationship with Prealbumin and Morbimortality in Patients with CKD

Ana Y. Navarro,[1] Ailiyomar Perez,[2] Ricardo J. Lino.[3] *[1]Fresenius Medical Care Ecuador, Quito, Ecuador; [2]Menydial, Riobamba, Ecuador; [3]Baxter Ecuador SA, Quito, Ecuador.*

Background: The chronic inflammatory state is common in patients on hemodialysis (HD), the evaluation of the clinical and nutritional status of patients on HD is essential. High mortality in HD may be associated with protein wasting síndrome energy (PEW), decreased levels of prealbumins, the objective of this work is to determine the prevalence of c-reactive protein (CRP) ≥ 9mg/L and its relationship with prealbumins <30 mg/dl, morbidity and mortality in a dialysis unit, Ecuador

Methods: cross-sectional, prospective study, 334 patients on HD, over 18 years old, with more than 3 months on dialysis, without active infectious processes at the time of sample collection, which included determination of serum levels of prealbumin and c-reactive protein, morbidities and mortalities were recorded during a period of 6 months (November 2022-April 2023), averages, percentages were determined, the Statistical analysis was performed analysis of variance and chi square

Results: 55.9% men, Women 44.01%, most common etiologies DM2 43.71%, HTN 38.92%, others 17.37%. Patients with CRP ≥ 9 mg/L 40.11%, CRP <9 mg/L 59.88%. In the distribution of CRP <9 with prealbumin < 30, 87 patients were found, of these, 32% presented comorbidities, died 1%. CRP < 9 with prealbumin ≥ 30 occurred in 113 patients, 19% with comorbidities, 3 % deaths. CRP ≥ 9 and prealbumin < 30 evidence in 73 patients, 63% with comorbidities, 18 % deceased. CRP ≥ 9 and prealbumin ≥ 30 were evident in 61 patients, 30% with comorbidities, 2% deceased. A greater number of cases with comorbidities is evident in the group with CRP ≥ 9 mg/L and prealbumin <30 mg/dl with chi square 35.535 and statistical significance p= 0.0000, CI 95.0%; with a greater number of deaths in this group of patients chi square 28.258 and statistical significance p= 0.0000, CI 95.0%

Conclusions: CRP is present in the patients of our center in more than a 1/4 of the cases, are closely related to nutritional status, using prealbumin as indicator, the high incidence of morbidity and mortality in these patients is demonstrated, which imposes the need to establish early detection measures for these factors in order to carry out preventive and therapeutic management to improve the quality of life of patients and their clinical conditions.

PUB131

Serum Transferrin Levels Predict Hemodialysis (HD) Adequacy and Mortality in Patients on Maintenance Hemodialysis

Sonoo Mizuiri,[1] Yoshiko Nishizawa,[1] Toshiki Doi,[1,2] Aiko Okubo,[1,2] Kenichi Morii,[1,2] Kazuomi Yamashita,[1] Kenichiro Shigemoto,[1] Kazuyoshi Karasuda,[1] Takao Masaki.[2] *[1]Iryo Hojin Ichiyokai Harada Byoin, Hiroshima, Japan; [2]Hiroshima Daigaku Byoin, Hiroshima, Japan.*

Background: Tarantino et al. reported that transferrin levels can be used to evaluate 3 important factors (Kt/Vurea, geriatric nutritional index [GNRI], and C-reactive protein [CRP]) in 78 hemodialysis (HD) patients. We investigated if transferrin levels can predict HD adequacy and mortality.

Methods: Subjects were 454 HD patients. Clinical data including serum transferrin, transferrin saturation (TSAT), ferritin, Kt/Vurea, predialysis β2-microglobulin (β2MG), serum albumin, GNRI, CRP, Agatston coronary artery calcium score (CACS), and postdialysis body composition using bioelectrical impedance were assessed at baseline. The patients were followed up for 400 days.

Results: Age, the dialysis duration, and the prevalence of diabetes in all patients were 72±13 years, 66 (35–134) months, and 44.7%, respectively. Patients with transferrin levels ≥200 mg/dL (n=152) had a significantly lower age (69±13 vs. 73±13 years), TSAT (19 [13–27] vs. 24 [18–31] %), ferritin (73±78 vs. 170±145 ng/mL), CRP (0.11 [0.04–0.34] vs. 0.19 [0.06–0.63] mg/dL), β2MG (26.7 [22.9–31.3] vs. 28.1 [24.8–31.8] mg/L), and extracellular water/total body water, but higher serum albumin levels (3.7 [3.4–3.9] vs. 3.4 [3.1–3.7] g/dL), GNRI (93±7 vs. 88±9), and lean tissue index (12.2 [10.7–14.2] vs. 11.1 [9.7–13.0] kg/m^2) than patients with transferrin levels <200 mg/dL (n=302) (P <0.05). Sex, dialysis duration, prevalence of diabetes, Kt/Vurea, and CACS were not significantly different between the 2 groups. Multiple linear regression showed that serum albumin levels, CRP levels, and Kt/Vurea were significant determinants for transferrin levels (P <0.001). Kaplan–Meier analysis showed a better 1-year survival rate in patients with transferrin levels ≥200 mg/dL than patients with transferrin levels <200 mg/dL (P <0.01). After adjusting for age, sex, dialysis duration, diabetes, serum albumin and CRP, transferrin levels were a significant predictor for 1-year all-cause mortality in HD patients (hazard ratio: 0.99, P <0.05).

Conclusions: In patients on maintenance HD, measurement of serum transferrin levels can be used to evaluate Kt/Vurea, albumin, and CRP. Patients with transferrin levels ≥200 mg/dL had higher 1-year survival rate than patients with transferrin levels <200 mg/dL, despite the presence of iron deficiency.

Clinical Performance of the New Plasma Filter PX2 in Therapeutic Plasma Exchange

Jana Schmitt,[1] Christine Gillen,[2] Ansgar Erlenkoetter,[1] Lena Rauber,[1] Anja Derlet-Savoia,[1] Manuela Stauss-Grabo.[1] *[1]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [2]Fresenius Medical Care Adsorber Tec GmbH, Krems, Austria.*

Background: Therapeutic plasma exchange (TPE) belongs to field of therapeutic apheresis and therefore the recommendations of the American Society for Apheresis (ASFA) are applied. TPE is a method for extracorporeal blood treatment designed to remove high molecular weight substances, such as immunoglobulins and pro-inflammatory factors. TPE is indicated for diseases which are associated with increased concentrations of plasma components and where a rapid depletion of these molecules mitigates or stops a pathogenic process. The usual dose of TPE is equivalent to 1.0-1.5 times the plasma volume (PV), which corresponds to removal of 63–72% of the plasma constituents. Treatment dose, defined as the plasma volume to be exchanged to achieve the desired clinical outcome for various diseases, are determined by the ASFA Guidelines.

Methods: The study (NCT06382675) is an interventional, single arm study assessing the clinical performance and safety of the new plasma filter PX2 (Fresenius Medical Care, Bad Homburg, Germany), applied for extracorporeal blood purification during plasmapheresis therapy. In preclinical studies, the filter showed excellent hemocompatibility. 272 TPE treatments, performed according to the clinical practice, will be evaluated, by assessing e.g., the delivered treatment dose, sieving coefficients of plasma constituents, and the incidence of hemolysis, clotting or clogging of the filter. Blood and filtrate samples are drawn before, after every 0.5 PV treated and at the end of the treatment. The performance benchmark – defined as achieved absolute plasma separation volume in comparison to planned plasma separation volume – will be used to analyze if the new filter will be able to deliver the treatment dose and thus the expected clinical outcome.

Results: The study is designed to clinically evaluate the PX2 plasma filter regarding sieving coefficients and safety. In addition, the influence of patients factors on TPE treatment success (delivery of treatment dose) will be assessed through subgroups analysis. The results of the subgroup analysis will be presented as descriptive analysis.

Conclusions: The study aims to evaluate the clinical performance and safety of a newly developed plasma filter. Moreover, the study aims to broaden the knowledge about patient factors influencing the treatment success.

PUB133

Optimizing Intracranial Pressure Management in AKI: A Novel Approach Using Enhanced Sodium Concentration in Continuous Kidney Replacement Therapy

Zeinab A. Abdulrahman,[1] Harry J. Dounis,[1] Avais Masud,[1] Sion Kim,[2] Supreet Kaur,[1] Sushil Mehandru.[1] *[1]Jersey Shore University Medical Center, Neptune TWP, NJ; [2]St. Mary Medical Center, Langhorne, PA.*

Introduction: Hypertonic saline treats elevated intracranial pressure (ICP) and cerebral edema by causing osmotic dehydration, avoiding complications like acute kidney injury and pulmonary edema. Maintaining therapeutic hypernatremia in patients needing renal replacement therapy is challenging as dialysis dilutes serum sodium, reducing hypertonic saline efficacy.

Case Description: A 25-year-old male with a history of polysubstance abuse presented in cardiac arrest and was resuscitated after 25 minutes. The patient was comatose with no response to stimuli, non-reactive pupils, and absent corneal and oculocephalic reflexes. A CT scan showed diffuse cerebral edema with potential herniations. Laboratory results revealed acute kidney injury with serum sodium of 142 mmol/L, necessitating continuous venovenous hemodiafiltration (CVVHDF). For cerebral edema, 3% hypertonic saline was administered. To maintain a serum sodium of 150-155 mEq/L, dialysis bath solution adjustments were made. This involved infusing 10 ml of a 23.4% hypertonic saline solution into a 2.5-liter bag of dialysis solution. Each ml of the 23.4% solution contained 4 mEq of sodium, adding a total of 40 mEq to the bag. This resulted in 40 mEq sodium/2.5 liters = 16 mEq/L added to the 140 mEq/L in the dialysis solution, reaching 156 mEq/L. Adjustments maintained serum sodium between 146-153 mEq/L during hospitalization. Despite efforts, the patient's neurological status did not improve, leading to hospice care.

Discussion: This case highlights the complexity of managing patients with anoxic brain injury and cerebral edema undergoing dialysis. Conventional intermittent hemodialysis can exacerbate ICP; thus, CVVHDF is preferable due to its continuous nature and lesser impact on systemic and cerebral hemodynamics. Increasing dialysis bath sodium concentration can effectively maintain a desired hyperosmolar state. For patients with increased ICP undergoing renal replacement therapy, a dialysis bath sodium concentration of 150-160 mEq/L, achieved by augmenting standard solutions with hypertonic saline, is crucial for managing cerebral edema. This strategy stabilizes patients in critical care settings.

PUB134

Using Ecological Momentary Assessment to Redefine Postdialysis Fatigue

Cramer J. Kallem,[1] Maria-Eleni Roumelioti,[2] Jennifer L. Steel,[1] Sarah J. Erickson,[2] Alaa A. Alghwiri,[1] Jonathan G. Yabes,[1] Mark L. Unruh,[2] Manisha Jhamb.[1]
[1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]University of New Mexico School of Medicine, Albuquerque, NM.

Background: Patients with ESKD have a high symptom burden and many report an acute exacerbation of symptoms immediately following hemodialysis (HD). While post-dialysis fatigue has been studied, very few studies have used ecological momentary assessment (EMA) to examine post-HD symptom experiences.

Methods: Participants in the Technology Assisted Collaborative Care (TACcare) trial completed an automated telephone-administered version of the Daytime Insomnia Symptom Scale (DISS) at 4 timepoints daily for 7 consecutive days. The DISS yields 4 symptom domain scores: Positive mood (PM), negative mood (NM), alert cognition (AC), and sleepiness/fatigue (SF). Post-HD symptom scores were compared to the corresponding timepoints on non-HD days via mixed models adjusting for age, race, sex, and Charlson Comorbidity Index. Demographic, psychosocial, and disease-specific characteristics were compared between patients who did versus did not show a post-HD increase of ≥1 point in the sum of SF and NM.

Results: 160 HD patients were enrolled [mean age=58±14 years, 55% men, 52% White]. In the post-HD period, patients reported significantly lower PM [mean difference (MD)= -0.22, 95% CI (-0.29, -0.14), p<0.001] and AC [MD= -0.13, 95% CI (-0.18, -0.08), p<0.001] and significantly higher NM [MD=0.12, 95% CI (0.05, 0.19), p<0.001] and SF [MD=0.51, 95% CI (0.42, 0.61), p<0.001] symptoms, compared to non-HD days. Patients who endorsed an increase in symptoms (NM or SF ≥1 point) in the post-HD period reported lower baseline fatigue (on FACIT-F) than those who did not (p=0.02); no other between-group differences were observed.

Conclusions: Patients with ESKD tend to experience worsening of both fatigue and mood symptoms after HD treatments. Our findings align with recent critiques that the post-dialysis fatigue label does not fully describe the post-HD symptom burden patients experience. Future studies should utilize EMA to assess a broader range of potential post-HD symptoms.

PUB135

Effect of Dialysis Dose on Nutritional Status of Patients on Hemodialysis

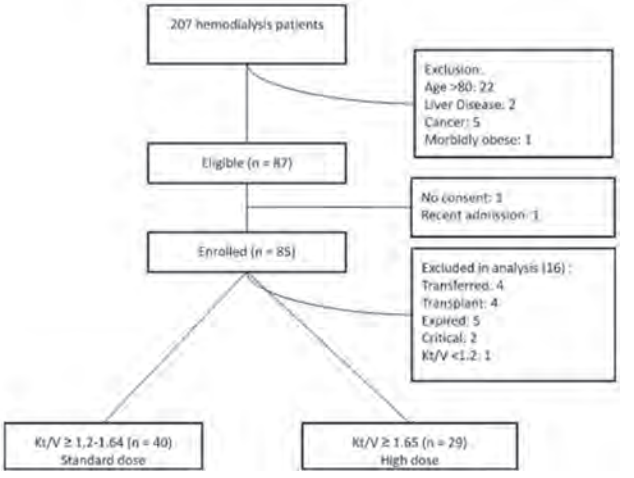
Kiara Marie H. Padua, Antonio V. Cayco, Mary Rose Bisquera. *Makati Medical Center, Makati City, Philippines.*

Background: Malnutrition is common among dialysis patients and impacts morbidity and mortality. Underdialysis causes malnutrition, but it is not known if high dialysis doses (Kt/V ≥1.65) lead to greater intradialytic nutrient loss, inflammation and protein catabolism. This study challenged the hypothesis that a higher dialysis dose increases the risk of malnutrition.

Methods: This is a pilot, single-center, prospective cohort. Aidamea online Kt/V was averaged for 6 months and compared with the change in dry weight, body mass index (BMI), mid-upper arm circumference (MUAC) for anthropometrics, modified SGA score, albumin, blood urea nitrogen (BUN), creatinine, and total lymphocyte count (TLC) as laboratory parameters.

Results: There is an inverse correlation between high Kt/V and anthropometric parameters and BUN. As Kt/V increases, it is more likely to have a BMI <18.5 (OR 2.6), SGA B (OR 1.19) and TLC <1500 (OR 1.07), and less likely to have albumin <3.4 (OR 0.25), though associations were not statistically significant.

Conclusions: The discordant results may be due to the high sieving coefficient for albumin, adequate protein repletion, and use of a single-use dialyzer in the center. A longer observation period may be needed. Thus, it is essential to individualize the approach when interpreting each parameter.



Patient Flow Diagram

Parameters	Correlation coefficient	P-value
Dry weight	-0.5615	**<0.001**
BMI	-0.3598	**0.002**
MUAC	-0.3339	**0.005**
End SGA score	0.1046	0.393
Albumin	0.0663	0.588
Crea	-0.0945	0.440
BUN	-0.2695	**0.025**
TLC	-0.0821	0.502

Correlation of HD doses to Nutritional Parameters

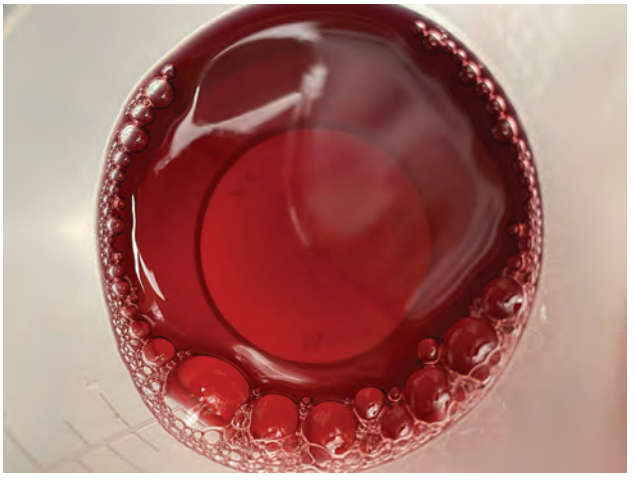
Vitamin B12 as an Obstacle to Hemodialysis in the Intensive Care Unit (ICU)

Varsha Suresh, Sungsoo Kim, Phoenix Xu, Noor Shahin, Michael Chang, Martin Sedlacek. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: Normally total body stores of vitamin B12 are between 1 and 5mg. Log scales higher 5-10g amounts of hydroxocobalamin are used as antidote for cyanide, forming cyanocobalamine in equimolar proportion. Because of a catecholamine independent hypertensive effect such high doses are also used in vasoplegic shock, similar to methylene blue. Dialysis clearance of vitamin B12 has been used to estimate middle molecule clearance. Here we present a case where a 5g dose of hydroxocobalamine impeded hemodialysis by triggering blood leak alarms.

Case Description: A 91 year old woman with metastatic breast cancer underwent surgery for a pathologic facture of her left femor. Her postoperative course was complicated by vasoplegic shock with AKI which was treated with three vasopressors and hydroxocobalamine. A drop in Hb and red colored urine (picture) raised concern for hemolysis but haptoglobin was normal and the urine sediment showed only rare RBC and calcium oxalate crystals. The patient developed oligoanuria and a family decision was made for a trial of dialysis support. However, the patient could not be dialyzed because of intractable blood leak alarms, despite several dialyzer sets used and the dialysate consistently testing negative for heme. The patient then was started on CVVH which was well tolerated. Red effluent was noted. The patient did not recover and passed away.

Discussion: Very high doses of hydroxocobalamine cause urine to be colored red for weeks. Hydroxocobalamine is cleared by dialysis but interferes with the blood leak alarm on hemodialysis machines, effectively rendering hemodialysis impossible. As in our patient, CVVH is not impeded but red effluent is usually noted. This side effect is important to consider if hemodialysis is needed for the treatment of toxic alcohol ingestion or drug toxicity. As there was no autopsy we do not know if the patient had oxalate nephropathy, a reported side effect of hydroxocobalamine with unclear pathophysiology.



PUB137

Intradialytic Heartbeat Irregularities (IR) Predict Increased Mortality in Patients on Chronic Hemodialysis (HD)

Dan Sapoznikov, Michal Dranitzki Elhalel, Rebecca Backenroth, Dvora Rubinger. *Hadassah University Medical Center, Jerusalem, Israel.*

Background: The pressent study was undertaken to define the significance of asymptomatic IR during HD.

Methods: Beat to beat systolic blood pressure (SBP) and interbeat interval (IBI) were monitored duriing HD in 96 age-matched HD patients (Pt). IR were defined as ≥5 irregular beats over 10 min during HD. Hemodynamic variability indices were assessed using Finometer device and beatscope software.

Results: IR were detected im 29 Pt (IR(+)). The representative clinical data in IR (+) and in Pt with regular beats (IR (-) n=67) are listed in Table 1. There were no marked differences between groups regarding the proportion of diabetes (DM), hypertension, ischemic heart disease, history of previous arrhrythmia. biochemical measurements or anthypertensive medication. Kaplan Meier showed a significant decreased survival at 2 to 5, but not at 7 years (y) or later in IR (+) (Figure 1).

Conclusions: Intradialytic IR were more frequent in Pt with a background of smoking and LV systolic dysfunction. In these Pt, decreased SBP at the end of HD and increased variabilities of CO and TPR might have contributed to hemodynamic instability. IR were associated with significntly enhanced mortality in HD.

Table 1.

	IR (-) (n=67, age 66±9 y)	IR (+) (n=29, age 65±12 y)	p

Predictors of Intradialytic Hypotension in Critically Ill Patients Undergoing Kidney Replacement Therapy: A Systematic Review

Rafaella Maria da Cunha Lyrio,[1] Tess M. Calcagno,[5] Estevão F. Sampaio,[3] Rafael Hennemann Sassi,[2] Rogerio Passos.[4] *[1]Universidade Salvador, Salvador, Brazil; [2]Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil; [3]Hospital Geral Ernesto Simões Filho, Salvador, Brazil; [4]Sociedade Beneficente Israelita Brasileira Albert Einstein, São Paulo, Brazil; [5]Cleveland Clinic, Cleveland, OH.*

Background: This systematic review aims to identify predictors of intradialytic hypotension (IDH) in critically ill patients undergoing renal replacement therapy (RRT) for acute kidney injury (AKI).

Methods: A comprehensive search of PubMed was conducted from 2002 to April 2024. Inclusion criteria comprised studies involving critically ill adults undergoing RRT for AKI. Exclusion criteria included pediatric patients, non-critically ill individuals, those with chronic kidney disease, and those not undergoing RRT. The primary outcome was identifying predictive tools for hypotensive episodes during RRT sessions.

Results: The review analyzed data from 8 studies involving 2,873 patients. Various machine learning models were assessed for their predictive accuracy. The Extreme Gradient Boosting Machine (XGB) model emerged as the top performer, achieving an area under the receiver operating characteristic curve (AUROC) value of 0.828 (95% CI: 0.796–0.861). It was closely followed by the deep neural network (DNN) with an AUROC of 0.822 (95% CI: 0.789–0.856). Notably, all AUROC values from machine learning models surpassed those of other predictors. The SOCRATE score, incorporating cardiovascular SOFA score, index capillary refill, and lactate level, showed increasing IDH incidence rates with the number of parameters, yielding an AUROC of 0.79 (95% CI: 0.69–0.89, $P < 0.0001$), indicating robust predictive accuracy. Peripheral perfusion index (PPI) and heart rate variability (HRV) exhibited AUROCs of 0.721 (95% CI: 0.547–0.857) and 0.761 (95% CI: 0.59–0.887), respectively. Additionally, pulmonary vascular permeability index (PVPI) and mechanical ventilation displayed significant diagnostic performance, with an area under the curve (AUC) of 0.68 (95% CI: 0.53–0.83) and 0.69 (95% CI: 0.54–0.85), respectively. A PVPI ≥ 1.6 at the onset of intermittent hemodialysis (IHD) sessions predicted IDH associated with preload dependence with a sensitivity of 91% (95% CI: 59–100%) and specificity of 53% (95% CI: 42–63%).

Conclusions: Machine learning models and clinical parameters offer promise in predicting IDH in critically ill AKI patients undergoing RRT. Further research is needed to manage hypotensive episodes effectively and improve patient outcomes.

PUB139

Association of Monocyte-Lymphocyte Ratio with Cardiovascular Events and All-Cause Mortality in Patients with ESKD

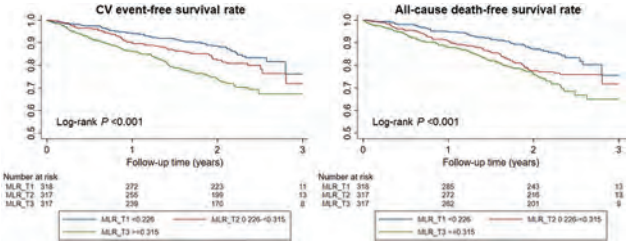
Ahmed Kabeil,[1] Cameron J. Bergeron,[1] Yamini Mallisetty,[1] Zhongji Han,[1] Chi-Yang Chiu,[1] Csaba P. Kovesdy,[1,2] Keiichi Sumida.[1] *[1]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [2]VA Memphis Medical Center, Memphis, TN.*

Background: Monocyte to lymphocyte ratio (MLR) represents a pro-inflammatory immune microenvironment and has been associated with adverse clinical outcomes, including cardiovascular disease (CVD). However, little is known about its association with clinical outcomes in patients with end-stage kidney disease (ESKD).

Methods: In a nationwide prospective cohort of 952 patients receiving maintenance hemodialysis from 2011-2013, we examined the association of baseline MLR with subsequent risk of CV events (CV-related hospitalization and CV death) and all-cause mortality, using the Kaplan-Meier method and Cox proportional hazards models with adjustment for age, sex, dialysis vintage, vascular access type, BMI, systolic blood pressure, Charlson Comorbidity Index, ischemic heart disease, diabetes mellitus, serum albumin, hemoglobin, infectious hospitalization, culture-positive bacteremia, and antibiotic or antifungal use. MLR was categorized into tertiles (<0.226, 0.226-<0.315, and ≥0.315).

Results: Overall, patients were 60±13 years old; 53% were male; 40% were African American; and 57% were diabetic. The mean dialysis vintage was 4.3±3.8 years. During a median follow-up of 2.2 years, 184 and 207 cases experienced CV events and death, respectively. The rates of CV events and all-cause death were higher in those with higher MLR (log-rank *P* <0.001, Figure). The adjusted hazard ratios (HRs) [95% CI] of CV events and all-cause mortality for the highest (vs. lowest) tertile was 1.88 [1.29-2.74] and 1.47 [1.02-2.11], respectively. Similar associations were seen when MLR was treated as a continuous variable (1.18 [1.06-1.31] and 1.19 [1.07-1.31], per 0.1 higher MLR, respectively).

Conclusions: A higher MLR was independently associated with higher risk of CV events and all-cause mortality in patients with ESKD, suggesting the potential of MLR as a simple, cost-effective prognostic biomarker in ESKD.



PUB140

Accuracy of Inferior Vena Cava (IVC) and Lung Point-of-Care Ultrasonography (POCUS) as an Adjunct in the Evaluation of Hypervolemia among Patients on Maintenance Hemodialysis

Denise C. De Los Reyes, Annabelle S. Lim, Vonn Velasco. *Saint Luke's Medical Center, Quezon City, Philippines.*

Background: Fluid overload is a burdensome problem among maintenance hemodialysis patients that is associated with morbidity and mortality.[1] There is no gold standard to predict or estimate dry weight.[2] It is traditionally determined clinically but can be complex, varied, and confounded by several factors. Incorporating a simple, quick, and more objective method using point-of-care ultrasound (POCUS) gives a more accurate evaluation of fluid volume status.[3]

Methods: This is an observational, cross-sectional study involving 45 examinations among 29 adults on maintenance hemodialysis. A primary investigator performed IVC and lung POCUS before and after dialysis using a handheld ultrasound device. Results were recorded and validated by a nephrologist trained in POCUS. Another fellow who is blinded to the POCUS findings performed the clinical volume status assessment.

Results: Using the cut-off scores for lung B-lines, IVC diameter, and IVC-CI examinations, there were 37.78%, 33.33%, and 68.89%, respectively, which had hypervolemia at pre-dialysis, and 24.44%, 15.56%, and 71.11%, respectively which had hypervolemia at post-dialysis. The sensitivity of lung B-lines, IVC diameter, and IVC-CI were 61.5%, 53.8%, and 61.5%, respectively, and specificity of 65.6%, 75%, and 28.1%, respectively. The AUC-ROC of all three parameters, 0.636, 0.644, and 0.448, did not reach AUC > 0.7. Post-hemodialysis, there were 27.27% by lung B-lines, 15.91% by IVC diameter, and 70.45% by IVC collapsibility index who already had negative hypervolemia by clinical assessment. This finding is consistent with the fact that physical examination (crackles and peripheral edema) is helpful when signs of congestion are present, but their absence does not exclude congestion. The interrater reliability and agreement of lung and IVC POCUS were also similar to that of the nephrology fellow and the nephrologist trained in POCUS.

Conclusions: This study cannot strongly conclude IVC and lung POCUS as a single method to accurately identify hypervolemia among adult hemodialysis patients but the real-time changes can help assess a patient's physiologic response to fluid volume changes. Integrating insonation into clinical assessment can be used as an adjunct in objectively estimating fluid status and guiding clinicians in their day-to-day practice.

PUB141

Can Post-Dilution Online Hemodiafiltration Provide a Valid Means of Preserving the Global Environment?

Kenji Sakurai,[1] Yoshitaka Kurihara,[1] Hiromi Hosoya,[1] Fumi Yamauchi,[1] Takeshi Saito,[1] Daisuke Ishii,[3] Toru Hyodo,[2] Kenichi Kokubo.[4] *[1]Hashimoto Clinic, Sagamihara, Japan; [2]Fureai Clinic IZUMI, Yokohama, Kanagawa, Japan; [3]Dept. of Urology Kitasato Univ. Hospital, Sagamihara, Japan; [4]Kitasato Univ. School of Allied Health Sciences, Sagamihara, Japan.*

Background: There are numerous open issues with dialysis therapy related to reducing climate change and preserving the global environment that need to be urgently addressed. Hemodiafiltration (HDF) has become common due to its excellent removal performance. In Japan, in-end 2022, 55.1% of dialysis patients underwent HDF, and 69% were receiving pre-dilution on-line HDF (pre-HDF). Reducing dialysate usage is a readily applicable method of preserving water resources and reducing the burden of waste fluid disposal. We switched from pre-HDF to post-HDF with high-flux hemodiafilter, which allowed the total dialysate flow rate (t-Qd) to be reduced by 20% and 30%, and evaluated the removal efficiency of each mode.

Methods: A study involved 14 patients who received pre-HDF (t-Qd 500 mL/min) using FIX-210Seco (Nipro) at our institution. While keeping the Qb and dialysis time unchanged, we performed post-HDF with t-Qd of 400 mL/min and evaluated the removal efficiency. The substitution fluid volume (Vs) was then adjusted to avoid excessive albumin loss so that an optimal convection volume (CV) (the sum of Vs and the net ultrafiltration volume) could be set for each patient. Next, the effect of this method in reducing the volume of dialysate and raw water required was evaluated using the volume data after the settings had been modified. Finally, the removal efficiency at this CV was evaluated again with t-Qd of 350 mL/min.

Results: The removal efficiency results obtained for each mode are shown in Figure. Even during the first month after modification of the settings, the dialysiate amount and the raw water volume required could be reduced by 4368L and 6720L, respectively.

Conclusions: Post-HDF using high-flux hemodiafilter at lower t-Qd exhibited favorable solute-removal efficiency. This type of post-HDF should be more widely used as a means of reducing climate change and preserving the global environment.

Mortality Trends of Patients with Systemic Lupus Erythematosus on Dialysis in the Japanese Society for Dialysis Therapy (JSDT) Registry: Web-Based Analysis of Dialysis Data Archives (WADDA) System

Nanako Oshiro,[1] Kentaro Kohagura,[1] Kenya Kusunose,[2] Kunitoshi Iseki.[3] *[1]Dialysis Unit, University of the Ryukyus Hospital, Nishihara-cho, Japan; [2]Department of Cardiovascular Medicine, Nephrology and Neurology, Graduate School of Medicine, University of the Ryukyus, Nishihara-cho, Japan; [3]Nakamura Clinic, Urasoe-city, Japan.*

Background: There are few reports about the gender-specific prognosis of the dialysis patients with systemic lupus erythematosus (SLE), particularly in recent years since 2015 when treatment with multitarget regimen for lupus nephritis became widely practiced in Japan. We examined the prognosis of SLE on dialysis by gender.

Methods: We used the JSDT annual data of dialysis patients from 2017 to 2022 obtained from the WADDA system. Relative risks (RRs) with 95% confidence intervals (CIs) were obtained from 2017 to 2022 in reference to non-SLE dialysis patients. We examined those with age less than 60 years.

Results: The average of annual number of patients was total 20,087/SLE 437 (female) and total 50,927/SLE 152 (male). The crude mortality rate of all dialysis patients was around 2.5%, and for females, it was around 2.3%, both remaining relatively stable. On the other hand, among patients with SLE, the crude mortality rate of both the overall patient population and females has increased year by year. In female patients with SLE, there was no significant increase in all-cause mortality from 2017 to 2019; 2017 (RR: 1.14, 95% CI: 0.66-1.97, p=0.6188), 2018 (RR: 1.26, 95% CI: 0.73-2.18, p=0.3923), and 2019 (RR:1.51, 95% CI: 0.92-2.47, p=0.0950), respectively. However, continuously since 2020 to 2022: 2020 (RR: 1.76, 95% CI: 1.11-2.80, p=0.0151), 2021(RR 1.91, 95% CI:1.22-3.00, p=0.0042), and 2022 (RR 2.50, 95% CI: 1.69-3.70, p<0.001). In male patients, there was no consistent changes observed: 2017 (RR 0.69, 95% CI: 0.22-2.12, p=0.5183), 2018 (RR 2.21, 95% CI:1.21-4.04, p=0.0091), 2019 (RR 0.73, 95%CI: 0.23-2.24, p=0.5801), 2020 (RR 2.59, 95% CI :1.46-4.60, p=0.0009), 2021 (RR 0.67, 95% CI: 0.21-2.05, p=0.4794). and 2022 (RR 2.15, 95% CI: 1.18-3.93, P=0.0118).

Conclusions: This study revealed an increased risk of all-cause mortality among female dialysis patients with SLE under 60 years old since 2020.

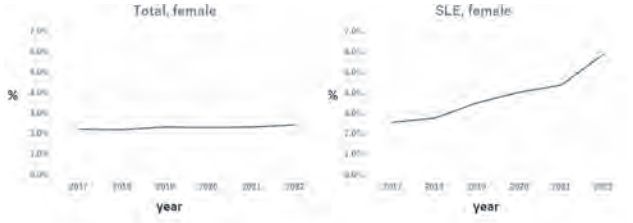

Figure1. The crude mortality among all female dialysis patients under 60, and among dialysis patients under 60 with SLE. SLE=systemic lupus erythematosus.

Impact of Hemodialysis Center Accreditation on Patient Mortality: Korean Nationwide Cohort Study

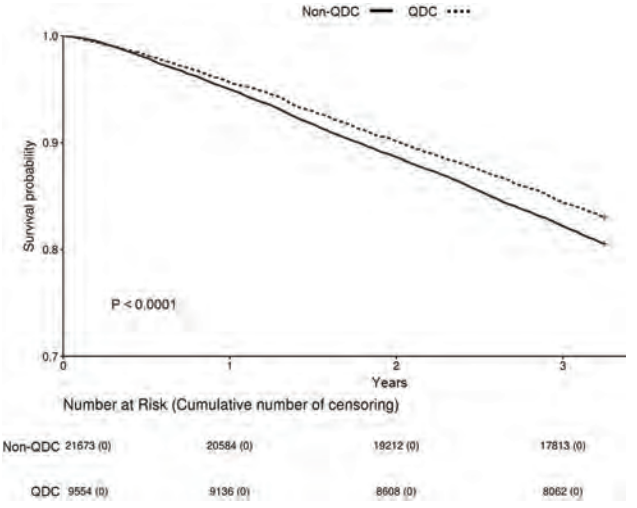
Hayne C. Park, Do Hyoung Kim, Ajin Cho, Young-Ki Lee. *Hallym University Kangnam Sacred Heart Hospital, Seoul, Republic of Korea.*

Background: Since hemodialysis (HD) patients are prone to various complications and high mortality, they need to be treated in HD units with professional personnel, proper equipment, and facilities. The Korean Society of Nephrology has been conducting HD unit accreditation program since 2016. This study was performed to evaluate whether qualified dialysis center (QDC) reduced mortality of HD patients.

Methods: This longitudinal, observational cohort study included 31,227 HD from 832 facilities. HD units were classified into two groups: the hospitals that have been certified as QDC between 2016 and 2018 (n = 219) and hospitals that have never been certified as QDC (non-QDC, n = 613). Baseline characteristics and patient mortality were compared between QDC vs. non-QDC groups using Korean HD quality assessment data from 2018. Multivariate logistic regression and Cox proportional hazards model was used to compare patient mortality between two groups.

Results: Among study subjects, 30.6% of patients were treated at QDC and 69.4% were treated at non-QDC. The patients in the QDC were younger, had a longer dialysis duration, lower serum phosphorus and calcium levels, and higher hemoglobin and single-pool Kt/V levels compared to the patients from non-QDC group. After adjusting for demographic and clinical parameters, QCD independently reduced mortality risk (hazard ratio, 0.897; 95% confidence interval, 0.847–0.950; $P < 0.001$).

Conclusions: HD unit accreditation program may reduce the risk of death among patients undergoing HD.



A total of 5848 deaths occurred during 35.6 ± 8.5 months. After censoring 3515 (10.1%) cases who received kidney transplantation during follow-up, QDC group showed better survival compared to non-QDC group ($P < 0.001$). Abbreviations: QDC, qualified dialysis center.

PUB144

Fatigue Has the Highest Diurnal Symptom Variability in Patients on Dialysis

Elife Ozturk,[1] Aidan W. Smith,[1] Jessica Noelmans,[1] Martijn A. Spruit,[2] Jeroen Kooman,[1] Marc H. Hemmelder.[1] *[1]Maastricht Universitair Medisch Centrum+, Maastricht, Netherlands; [2]Ciro-Horn, Horn, Netherlands.*

Background: Patients treated with dialysis (hemodialysis (HD) and peritoneal dialysis (PD) have a high burden of disease. The amount of and the burden of symptoms experienced by dialysis patients is often underestimated. Limited data are available regarding the diurnal variability of symptoms. We therefore analyzed the diurnal variability of symptoms in HD and PD patients.

Methods: This prospective study was performed as a single center study. Patients completed baseline questionnaires on quality of life (SF-12), symptom burden (DSI), anxiety and depression (HADS), general level of daytime sleepiness and patient activation measurement(self-efficacy). After installing of a mobile application (Your Research®) on the patients' smartphone, patients received 8 times a day during 7 consecutive days a questionnaire on symptom burden. Symptoms were scored on a scale from 1 (no symptoms) to 7 (most severe intensity). The diurnal variability of 4 frequently occurring symptoms (fatigue, anxiety, muscle soreness and headache) was assessed with the with-in subject standard deviation (WS-SD). In case of HD, WS-SDw was also calculated on HD days and non-HD days.

Results: 25 dialysis patients were included (15 HD and 10 PD). Ten patients answered <50% of the questionnaires by mobile app and were excluded from the analyses. The remaining 15 patients (53% male, age 59 years) had an overall median symptom score of 4 for fatigue and 1 for anxiety, muscle soreness and headache. Median fatigue scores were not different between HD days versus non-HD days or between both dialysis modalities. Median WS-SD for fatigue was 1,01 (IQR 0,34). Median WS-SD was 0 for anxiety (IQR 0,44), 0,44 for muscle soreness (IQR:0,83) and 0,32 for headache (IQR: 0,50).

Conclusions: Fatigue is clearly the most intense symptom for HD and PD patients compared to anxiety, muscle soreness and headache. Fatigue does not exacerbate on HD versus non-HD days in HD patients. The expected symptom variability within and between days seems lower than expected. This may suggest that a simple spot check of symptom burden may sufficient to understand the symptoms throughout the day.

PUB145

Early Monitoring of Arrhythmias in Patients on Hemodialysis with Wearable Devices: A Multicenter, Cross-Sectional Observational Study

Yu Shaobin, Zeng Xiaoxi. *West China Hospital of Sichuan University, Chengdu, China.*

Background: To further test the applicability of wearable devices for arrhythmia monitoring and early warning in HD patients

Methods: This study was a multicenter cross-sectional investigation involving five tertiary general hospitals from March 2022 to December 2023. This portion of the study mainly involved validating the reliability and feasibility of the use of wearable devices with long-term ECG monitoring capabilities (Lepu ER1 single-lead ambulatory ECG recorders and ECG chest belts) for the real-time dynamic detection of arrhythmia and heart rate variability, with ambulatory ECG recorders (CT-086S) that are used in clinical practice taken as the gold standard.

Results: A total of 538 maintenance HD patients from 5 tertiary general hospitals, were included in the study. 1. Reliability assessment: In the feasibility analysis of monitoring arrhythmia, a total of 185 patients with HD were included in the study. This study revealed that the heart rate variability metric measured by the Lpepu ER1 was positively correlated with others measured by ct-086S. 1.3 The sensitivity, specificity, and accuracy of diagnosing atrial fibrillation in HD patients were 88.9%, 93.8%, and 93.5%, respectively. The positive predictive value was 42.1%, and the negative predictive value was 99.4%. 2. Feasibility Assessment: A total of 353 HD patients from 4 medical centers wore Lepu ER1 single-lead dynamic electrocardiogram recorders. 72.5% of HD patients were monitored by Lepu ER1 single-lead dynamic electrocardiographic recorder with arrhythmia during dialysis. It is worth noting that among the 47 patients with clinical symptoms, 91.5% of them were also monitored by wearable devices for the occurrence of arrhythmia, and only 8.5% of patients were not monitored for arrhythmia when clinical symptoms appeared. However, among patients without clinical symptoms, 69.6% were still monitored with arrhythmia. There was a statistically significant difference in the correlation between the occurrence of clinical symptoms and arrhythmia monitored by wearable devices in the two groups.

Conclusions: Wearable devices equipped have the ability to continuously and dynamically monitor arrhythmias in patients with heart disease, particularly for the detection of atrial fibrillation. Heart rate variability parameters show a positive correlation with dynamic electrocardiogram assessments.

Post-dilution High-Volume Online-Hemodiafiltration Versus High-Flux Hemodialysis Mortality Outcome in Patients with End-Stage Kidney Disease

Alkhateeb K. Alkemary,[1,2] Ayman S. Fadlallah,[1] Imed Helal,[1] Mohammed A. Alhomrany,[1] Saeed Al-Ghamdi,[1] Dujanah H. Mousa,[1] Ali Alharbi.[1]
[1]Diaverum Holding AB branch, Riyadh, Saudi Arabia; [2]Cairo University Kasr Alainy Faculty of Medicine, Cairo, Egypt.

Background: Several studies showed improved survival with high volume online hemodiafiltration (OL-HDF) over high-flux hemodialysis (HF-HD), but still with some limitations.

Methods: A retrospective multicentre cohort study with the main predictor high-volume post-dilution OL-HDF with convective volume ≥ 22 Litres/ session versus HF-HD. The primary endpoint was all-cause mortality during the 48-month follow-up period. 8006 patients were screened; 480 (6%) were excluded due to a change of dialysis modality, 790 (9.8%) were excluded for not being capable of achieving convective volume ≥ 22 Litres/ session, 6736 patients were analysed; 2324 (34.5%) were on high-volume OL-HDF & 4412 (65.5%) were on HF-HD.

Results: Online HDF group included significantly younger patients than HF-HD group with the age (mean±SD) (57.7±16.9) & (51.9±15.1) years, respectively, (p-value <0.001). And a significantly lower proportion of diabetic patients in the OL-HDF group (41.3%) than in the HF-HD group (52.4%), (p-value <0.001), with a significantly lower proportion of patients with a high Charlson comorbidity index > 6, (29.5%) versus (47.1%). And a significantly higher proportion of patients with arteriovenous fistula (95.7%) versus (71.1%). Patients on OL-HDF showed significantly lower overall mortality in comparison to HF-HD n(%) 304(13%) & 842(19.1%) respectively, (p-value <0.001), with a lower cardiovascular and cerebrovascular mortality rate of 171 (7.4%) & 484(11%) (p-value <0.001), and lower infection-related mortality 92(4%) & 268(6.1%) (p-value <0.001). Multivariate Cox-regression analysis showed survival advantage of OL-HDF versus HF-HD (HR, 0.72: 95% CI [0.63-0.83]) (p-value <0.001).

Conclusions: Patients with kidney failure who received high-volume OL-HDF had a lower risk of all cause mortality, cardiovascular mortality, and infection-related mortality than those who received HF-HD.

	patient at risk	All cause mortality events n(%)	Cardiovascular mortality events n(%)	Infection related mortality events n(%)

Detrimental Effects of Diet Selection in Hospitalized Patients with ESKD

Hanna Larson,[1] Drishti Jain,[2] Karen A. Griffin,[1] Kavitha Vellanki.[1] *[1]Loyola University Medical Center, Maywood, IL; [2]Loyola University Chicago Stritch School of Medicine, Maywood, IL.*

Background: End-Stage Renal Disease (ESRD) patients are at increased risk of emergent dialysis and mortality with hyperkalemia (K ≥5.5 mmol/l). There is limited data on outcomes from prescribed diets for hospitalized ESRD patients. Our study aims to evaluate outcomes of medically prescribed diets in hospitalized ESRD patients on maintenance hemodialysis.

Methods: Our study is a single-institution retrospective cohort study (1/2020-12/2023). Exclusion criteria comprised patients with critical illness requiring ICU care, rhabdomyolysis, hyperkalemia or NPO on admission, and receiving bone marrow/ stem cell transplant or chemotherapy (associated with cell lysis/K release). Cohort patients were defined by diet prescribed on admission: renal or non-renal diets. Primary outcomes included arrhythmias and additional dialysis for hyperkalemia. Secondary outcomes included additional medications or labs to manage hyperkalemia, and 30-day readmissions.

Results: The 195 study patients had 842 admissions. After applying exclusion criteria, 489 admissions were analyzed. Primary and secondary outcomes are outlined in Table 1. On admission, non-renal diets were prescribed more frequently (Table 1). Hyperkalemia occurred less on renal diets, as did episodes of additional dialysis, and the need for extra medications and labs to manage hyperkalemia. Readmissions within 30 days were less if on a renal diet (Table 1).

Conclusions: Preliminary analysis reveals more interventions occur to manage hyperkalemia in hospitalized ESRD patients prescribed a non-renal diet and readmissions are more frequent. Further studies are needed to understand the risks and outcomes of diet prescription practices in hospitalized ESRD patients to determine steps to improve outcomes.

Table 1: Demographics, Incidences and Outcomes of Hyperkalemia (K+ ≥ 5.5 mmol/L)

Cohort: Hospitalizations meeting inclusion criteria	N=195 N=489		
Age (yrs)	63.24 (± 15.0)

Quality of Life in Patients on Hemodialysis vs. Peritoneal Dialysis

Amgad E. El Agroudy. *Arabian Gulf University, Manama, Bahrain.*

Background: Chronic diseases, including chronic kidney disease, affect patients' quality of life. Hemodialysis and peritoneal dialysis are renal replacement methods in these patients. This work aimed to study the relationship between Quality of Life (QOL) scores in patients with end-stage renal disease (ESRD) on hemodialysis and peritoneal dialysis.

Methods: This study was done at one center in Bahrain from May to July 2023. A standard QOL Index score instrument in Arabic form was used on 76 hemodialysis (HD) and 38 peritoneal dialysis (PD) patients. The inclusion criteria included dialysis for at least 3 months and an age of more than 18 years with no severe morbidities or psychological diseases.

Results: The mean age of HD and PD patients was 58.7 ± 11.2 and 55.9 ± 12.1 years, respectively. Thirty-five (46.1%) of HD patients and seventeen (44.7%) of PD patients were females. In most dimensions, the QOL score of patients treated with PD was better than that of the HD group. The number of hospital admissions was statistically significantly higher in the HD group (p = 0.007); however, there was no significant difference in the causes of admissions (p = 0.131). In this study, we observed the highest QOL score in the family subscale (93.2 ± 9.2 and 98.6 ± 4.7), followed by the psychological/spiritual subscale (81.1 ± 16.7 and 97.6 ± 3.9) in HD and PD groups, respectively), but it was statistically significantly higher in the PD group (p <0.001).

Conclusions: Our findings show that patients starting PD had better QOL scores in all domains than patients starting HD. Moreover, patients on PD maintained more active social support and ultimately felt better emotional well-being and physical health than those undergoing HD.

PUB149

Effects of Repetitive Transcranial Magnetic Stimulation on Cognitive Function and Intestinal Flora in Patients on Maintenance Hemodialysis

Hua Liu. *The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China.*

Background: To investigate the effects of repetitive transcranial magnetic stimulation (rTMS) on cognitive function and intestinal microflora in maintenance hemodialysis (MHD) patients with subjective cognitive decline (SCD).

Methods: One-way blind design was used, thirty-three MHD patients with MMSE score ≥24, SCD-Q9 score ≥5 and SCD were enrolled in this study, the intervention group (rTMS Group) and the Sham group (Sham group) were randomly assigned 1:1 according to the random number method. The cognitive function was measured at baseline and at the end of the experiment, before and after intervention, the changes of each index were compared between the two groups.

Results: MMSE score in rTMS group was significantly higher than that in Sham group after intervention (27.94 ± 1.25 VS 26.94 ± 1.39, P = 0.037). In the 5 parts of MMSE score, there was only a significant difference in the memory ability (P = 0.039). After intervention, the SCD-Q9 score in rTMS group were significantly lower than those in Sham group (6.09 ± 1.06 vs 7.09 ± 1.25, P = 0.018), only the ability of daily activity memory was significantly different between the two groups (P = 0.037). After intervention, there was no significant difference in α-diversity (Fig.1) and β-diversity (Fig.2) between the two groups. The results showed that the composition of intestinal flora was similar between the two groups at family level and genus level after intervention (Fig.3). Lefse analysis was used to screen the flora with statistical difference between the two groups after intervention (Fig.4, Table.1), there were 5 distinct microbial communities at the family level, Marinifilaceae, Flavobacteriaceae, RF39, Carnobacteriacea were the most abundant in rTMS group, while Wohlfahrtiimonadaceae was the most abundant in Sham group. At the level of 17 genera, the abundance of Faecalibacterium, Alistipes and Odoribacter in rTMS group was higher than that of Erysipelatoclostridium in Sham group (Fig.5).

Conclusions: rTMS therapy may alter the cognitive function of MHD patients with SCD, improve their memory, and affect the abundance of some intestinal flora, which may modulate the differential flora associated with SCD, it is suggested that the therapy may affect cognitive function during SCD by regulating the flora.

Removal of Middle Molecules with Hemodiafiltration plus Hemoadsorption in Patients with Kidney Failure

Thiago A. Reis,[1,2] Bruno P. Biluca,[1] Maria G. Guimaraes,[4] Jessica L. Andrade,[1,3] Miguel Angelo Goes,[3] Andreia Watanabe,[6] Gonzalo Ramirez Guerrero,[5] Claudio Ronco,[5] Francisco R. Neves,[2] Antônio Luiz J. Almeida.[1] *[1]Fenix Nephrology, São Paulo, Brazil; [2]Laboratory of Molecular Pharmacology, University of Brasília, Brasília, Brazil; [3]Discipline of Nephrology, Federal University of São Paulo, São Paulo, Brazil; [4]Nephrology Department, Hospital Ana Nery, Salvador, Brazil; [5]International Renal Research Institute of Vicenza, Vicenza, Italy; [6]Department of Pediatrics, Pediatric Nephrology Unit, Instituto da Criança e do Adolescente, University of São Paulo School of Medicine, São Paulo, Brazil.*

Background: Hemodiafiltration (HDF) promotes a higher clearance of middle molecules compared to hemodialysis for patients with kidney failure. Whether the association of HDF plus hemoadsorption (Fig. 1a) using cartridges with styrene-divinylbenzene resin further enhances the removal of middle molecules is yet to be defined. We prospectively analyzed the removal of middle molecules in four patients undergoing simultaneous hemoadsorption in series with HDF.

Methods: Patients underwent 3-hour sessions of online HDF with post-filter replacement plus hemoadsorption. We measured the pre- and post-session concentrations of five middle molecules and albumin.

Results: Four patients performed a total of 23 sessions. Dialysis characteristics are presented in Table 1. In the sum of the 23 session, blood flow was 400 mL/min (IQR 350-400 mL/min), convective post-filter flow was 115 mL/min (IQR 105-115 mL/min), and dialysate flow was 500 mL/min (IQR 500-800 mL/min). The reduction ratio [i.e.,1 - (pre-session/post-session)] of parathormone (9.4 kDa), ß2-microglobulin (12 kDa), myoglobin (17 kDa), Prolactin (25 kDa), and lipase (33 kDa) are depicted in (Fig. 1b). There was a statistically significant increase in albumin (66 kDa) concentration between pre- and post-session (38.3 vs 40.0 g/L, p = 0.002).

Conclusions: Compared to previous results in HDF trials, where patients carried out 4-hour HDF stand-alone sessions, 3-hour HDF plus hemoadsorption sessions provide an equivalent or superior reduction ratio of five middle molecules.

Hemodiafiltration prescription

Patients	Number of sessions	Blood flow (mL/min)	Dialysate flow (mL/min)	Post-filter replacement flow (mL/min)	Vascular Access	Filter type/area
Patient 1	8	350	500	115	AVF - 15 G	Fx CorDiax 1000/2.3 m2

Is a Bioimpedance Assay an Effective Tool for Evaluating Cardiac Parameters in Patients with ESKD Undergoing Hemodialysis? A Cross-Sectional Study from North India

Dinesh Khullar, Vandana Prasad, Rahul Grover, Sahil Bagai, Kulwant Singh, Prof Narinder P. Singh, Deepak Kumar, Abhishek Singh, Anish K. Gupta. *Max Super Speciality Hospital, Saket, Delhi, India.*

Background: Hemodynamic stress caused by either fluid overload or depletion is a major contributor to cardiac complications in dialysis. Study aimed to investigate the role of BIA in assessing fluid status and its correlation with cardiac parameters in hemodialysis patients.

Methods: In cross-sectional study, 39 patients with ESKD undergoing hemodialysis at least three times a week for three months and had a preserved ejection fraction (EF>40%) were enrolled. Exclusion criteria included patients undergoing diuretics those with sepsis, limb amputations, pacemakers, metallic intravascular devices, malignancies, or pregnancy. The study investigated the levels of N-terminal pro-b-type natriuretic peptide (NT-pro BNP) and performed echocardiography (ECHO-2D) before and after hemodialysis. Hydration status of patients was assessed using 4-electrode BIA device (Fresenius Medical Care, Germany). This was done before dialysis, 30 minutes after dialysis, and before subsequent dialysis. Patients categorized into two groups based on hydration status: Group-A had overhydration (OH/ECW ratio ≥15%), while Group-B had normal hydration (OH/ECW ratio<15%).

Results: Among 39 patients, 69.2% were in Group A, while remaining 30.8% were in Group B. Mean age was 57.3±11.4 years for Group A and 54.0±16.3 years for Group B. Both groups matched for age, sex, BMI, biochemical, hemodynamic, and echocardiographic parameters. Before and after dialysis, no significant differences observed in various cardiac parameters between two groups, except for changes in aortic root diameter, left atrial diameter, and A wave velocity in Group A. NT-proBNP levels showed a significant decline after dialysis in groups A and B (p0.001). Hydration status (OH/ECW) before dialysis exhibited a negative correlation with left ventricular ejection fraction (LVEF)(r-0.434,p0.006) and NT-proBNP levels (r-0.708,p0.001). Post-dialysis OH/ECW displayed a negative correlation with LVEF(r-0.744,p0.001), and peak late transmitral filling wave velocity (A)(r-0.342,p0.033).

Conclusions: BIA-evaluated hydration levels were correlated with LVEF. By controlling OH/ECW during BIA-guided dialysis, we can potentially reduce the risk of cardiac morbidity.

PUB152

High Ultrafiltration Rate and Mortality among Patients Undergoing Hemodiafiltration at St. Luke's Medical Center-Global City: A Retrospective Cohort Study

Andrew Solomon R. Echavez. *St. Luke's Medical Center Global City, Taguig, Philippines.*

Background: Effective hemodiafiltration (HDF) and volume clearance over shorter treatment times were made possible by the development of hydrostatic ultrafiltration and other technical advancements. Ultrafiltration is commonly used to treat fluid overload; however, it is uncertain if its rate influences outcomes. The study therefore aims to determine the association between high UFR and mortality; and the predictors of mortality in end-stage renal failure patients receiving hemodiafiltration.

Methods: This was a retrospective analytical cohort study of the medical data of all patients >18 years old undergoing maintenance hemodiafiltration at the St. Luke's Medical Center-Global City from January 2018 to December 2022. Records review was done to gather data on clinical and demographic variables, laboratory findings, UFR values, and mortality.

Results: A total of 296 patients were included in the study and 93 (31.4%) were observed to have high UFR. The mean age was significantly higher among those without high UFR (67.3 years) than those with high UFR (61.4 years) (p-value = 0.002). Among those with high UFR, the mortality rate was 34.4% with median follow-up time of 4 years. Among those without high UFR, the mortality rate was 27.6% with median follow-up time of 4 years. High UFR was not seen to be significantly associated with mortality (HR=1.3, 95%CI=0.7 to 2.4, p-value = 0.443). Increasing age was significantly associated with higher risk for mortality (HR=1.03, 95% CI=1.02 to 1.05, p-value <0.0001).

Conclusions: High UFR was not associated with increased risk of mortality in end-stage renal failure patients receiving hemodiafiltration. Only increasing age significantly predicts risk for mortality in this group of patients. Future prospective studies conducted in multiple centers are needed to validate the findings of the current study.

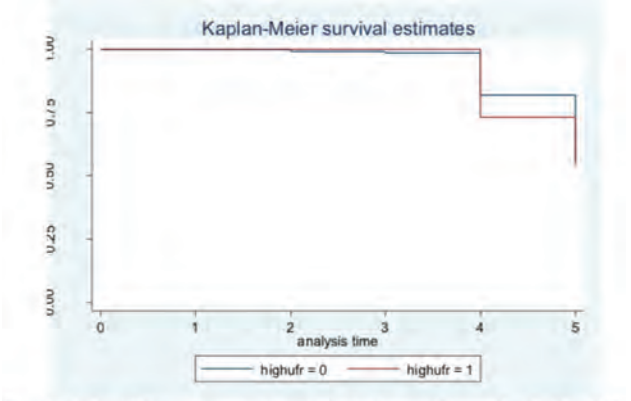

Figure 1. Kaplan Meier curve comparing survival rates between those with and without high UFR.

PUB153

Self-Efficacy Predicts Patient-Reported Outcomes Measurement Information System (PROMIS) Health-Related Quality of Life Outcomes in Turkish Patients on Dialysis Better than the 36-Item Short Form Health Survey (SF-36)

Krister Cromm,[1,2] Ngoc Pham,[1] Özlem K. Tunçel,[3] Mirja Humpert,[1] Tatiana De los Ríos,[1] Manuela Stauss-Grabo,[1] Gulay Asci,[3] Ercan Ok,[3] Hayriye Elbi.[3] *[1]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [2]Charite Universitatsmedizin Berlin, Berlin, Germany; [3]Ege Universitesi, Izmir, Turkey.*

Background: Recent research has emphasized the importance of psychosocial factors on health-related quality of life (HRQL). Self-efficacy (SE) and social support (SS) emerged as particularly relevant. The purpose of this study was to understand the degree to which these two variables are also useful in predicting HRQL in Turkish patients using standard SF-36 and new PROMIS-29 measures.

Methods: 177 patients (mean age: 55.5±13.4) on in-center or home hemodialysis in Izmir, Turkey filled out electronic surveys. A series of ANCOVA models was employed to examine the relationship between HRQL scores and domains as dependent variables, and SE and SS as predictor variables. HRQL was measured by SF-36 mental (MCS) and physical composite scores (PCS), PROMIS mental (MHS) and physical health (PHS) composite scores as well as 7 PROMIS-29 domain scores. SE and SS were measured with the MOS-SSS and GSE scales. Covariates included demographic characteristics and disease impact (KDQOL-36 burden, symptoms, and effects of kidney disease scales).

Results: SE was a significant predictor for MHS ($F(1,138)=19.57$, $p<.0001$; $R^2=.60$ for whole MHS model) as well as MCS ($F(1,138)=5.84$, $p=0.02$; $R^2=.47$ for whole MCS model) over and above the covariates. SE was related to PHS ($F(1,138)=5.52$, $p=0.02$; $R^2=.43$ for whole PHS model) but not to PCS. SS was not significantly related to any composite scores. SE was a significant predictor for all PROMIS-29 domains except for Physical Function and Pain Intensity. The Tangible Support domain of SS was a significant predictor for Sleep Disturbance only ($F(1,138)=4.27$, $p=0.04$; $R^2=.42$ for whole Sleep Disturbance model).

Conclusions: In line with previous research, our results show that SE is a significant predictor for mental health. PROMIS includes a broader range of HRQL subdomains than SF-36, leading to more explained variance of SE on physical health. This suggests that PROMIS may provide a more sensitive assessment of HRQL. The Social Support domains appear to be less useful for predicting HRQL, though the Tangible Support domain does show a relationship with the PROMIS-29 Sleep Disturbance domain.

PUB154

Salicylate Intoxication: When Bicarbonate Is Not Enough

Alexis F. Mena,[1] Jose D. Mena.[2] *[1]Universidad UTE Facultad de Ciencias de la Salud Eugenio Espejo, Quito, Ecuador; [2]Nephrology Associates of the Carolinas, PA, Shelby, NC.*

Introduction: Accidental or intentional overdose of salicylates is a medical emergency that can precipitate severe metabolic derangements and in some cases death. In 2014 more than 24,700 salicylate intoxication cases were documented in the US. We present a case of acute aspirin overdose with emphasis in the indications of renal replacement therapy.

Case Description: A 47-year-old male with a past medical history of polysubstance abuse, depression and CKD presented to the emergency department after being found unresponsive. On arrival, vital signs showed a heart rate of 120 bpm, respiratory rate of 35, SpO2 97% on room air and blood pressure of 130/80. On physical exam he was tachypneic, lethargic and non responsive to voice commands. Breath sounds were clear bilaterally. Labs showed a creatinine 1.46 mg/dl (baseline), sodium 138 mmol/L, potassium 4.1 mmol/L, CO2 13 mmol/L. Blood gas: pH 7.42, pO2 63 mmHg, pCO2 20.1 mmHg. Urine toxicology was positive for cocaine. Salicylate level was 96.8 mg/dL. He was started on sodium bicarbonate infusion and poison control was contacted. Despite initial management, salicylate levels didn't improve. He was started on intermittent hemodialysis (iHD) and was continued for 6 hours with improvement in salicylate levels from 89.6 mg/dL pre iHD to 14.7 mg/dL post iHD.

Discussion: The history of substance abuse in a patient with encephalopathy and anion gap metabolic acidosis should raise the concern for salicylate toxicity. Initial treatment includes discussion with poison control, fluid resuscitation and bicarbonate administration. The goal of bicarbonate is to generate alkalemia to minimize the passage of salicylate to the central nervous system and to increase the excretion of salicylate alkalinizing the urine. The low volume of distribution, absence of tissue binding and the small size of salicylate, make iHD the best way to remove this drug. Dialysis is recommended when salicylate levels are above >100 mg/dl or >90 mg/dl with impaired kidney function. It is also recommended in the presence of encephalopathy or new hypoxemia and if standard therapy fails. In this case, iHD was continued for 6 hours with improvement in salicylate levels and improvement in his symptoms. Guidelines recommend to stop dialysis when clinical improvement is apparent and when salicylate levels are below 19 mg/dL. If salicylate levels are not available, iHD should be performed for at least 4 to 6 hours.

PUB155

Effectiveness of Dialysis Transition Unit to Improve Patients' Decision-Making and Self-Management Skills

Warda Munawar, Veronica Hammer, Chel Lee, Danielle E. Fox, Meghan J. Elliott, Jennifer M. MacRae. *University of Calgary Cumming School of Medicine, Calgary, AB, Canada.*

Background: Dialysis initiation is a stressful time for people living with kidney failure. As a quality improvement initiative, we created a dialysis transition unit (DTU) in Calgary, Alberta with the goal of providing person-focused dialysis care for patients starting hemodialysis. Objectives:To compare patient's perception of participation in self-management and receipt of dialysis transition/chronic care counseling using PACIC-20, (Patient Assessment of Chronic Illness Care) between patients starting hemodialysis in the DTU and in a traditional facility-based HD unit (HDU).

Methods: PACIC-20, anxiety (GAD-7) and depression (PHQ-9) scores were captured prospectively (June 1, 2021-June 30, 2022) on patients starting hemodialysis on the DTU and the HDU at dialysis initiation and two weeks later. Our primary outcome of interest was between-group differences in PACIC-20 scores at 2 weeks after dialysis initiation.

Secondary outcomes included between-group differences in PACIC-20 subcategories and between-group differences for the change in patient-reported outcome measures of GAD-7 and PHQ-9 at 2 weeks.

Results: A total of 26 DTU and 26 HDU participants completed data collection (mean age 62.6 ± 17.7 years; 42.3% females). The PACIC-20 scores at two weeks were similar (DTU 3.60 ± 0.6 and HDU 3.26 ± 0.95, P = 0.21). All PACIC-20 subcategories were similar between groups except for problem solving, which trended higher in DTU (4.09 ± 0.9 vs 3.39± 1.36, p=0.06). The subcategory, patient activation was associated with improved anxiety in DTU (p= 0.02) but not HDU (p= 0.35). The between-group difference was significant for PHQ-9 for DTU (p= 0.007) but non-significant for GAD-7 (p=0.05).

Conclusions: While we did not find a significant difference in the overall patient perception of self management (PACIC-20) when transitioning to a specialized DTU (vs HDU), we did find improved problem-solving scores and lower depression scores for DTU. Further research on the role of a DTU to optimize patient care is needed.

PUB156

COVID-19 Pandemic in Dialysis: Urban and Suburban Outcomes in a Small Dialysis Organization

Shruti Kore,[1,2] George N. Coritsidis,[2] Steven Weiss.[3] *[1]New York Medical College, Valhalla, NY; [2]Westchester Medical Center, Valhalla, NY; [3]Atlantic Dialysis Management Services, New York, NY.*

Background: The COVID-19 pandemic was devastating to the ESRD population, contributing to a decrease in prevalence of dialysis patients. Atlantic Dialysis Management Services (ADMS), a small dialysis organization, provides dialysis to the NYC and Long Island areas. We reported early findings, in 2020, describing increased mortality, and reviewed the progression of these findings into 2021.

Methods: A retrospective EMR review of 13 ADMS facilities comprising 4 boroughs of NYC and Long Island from February 1, 2020 to August 31, 2020 Wave (W1) and September 1, 2020 to February 28, 2021 Wave (W2). Aggregate data was used to calculate values for combined wave categories. We reviewed the demographic characteristics, COVID-19 status, years on dialysis (vintage), mortality (overall and COVID-19 related), presence/absence of a social security number, insurance, and comorbidities. Adjusted odds ratio analysis was performed.

Results: There were 2147 patients in Wv1 and 1658 in Wv2. The total ADMS population decreased by 22.8% by Wv2 with a total of 911 deaths, despite admissions. *215* or 31% were covid related deaths in W1, decreasing to 11% in W2. Living in NYC and being Hispanic had significantly higher odds ratio for infectivity and COVID related mortality in W1 but not in W2. COVID-19 related mortality was significantly associated with age, vintage, ethnicity, and dialyzing in a NYC borough. Patient infection, overall deaths, and COVID-19 related deaths on Long Island more than doubled from W1 to W2. Overall mortality was significantly associated with age, vintage, diabetes, but not ethnicity, and only with NYC boroughs with nursing home patients.

Conclusions: Ethnicity and urban dwelling was associated with increased COVID-19 mortality in W1, but not overall mortality, likely due to housing differences. These factors likely lost significance in W2 due to COVID-19's spread into other communities. As the pandemic expanded into suburbia, mortality increased, likely due to rapid spread/novelty of the infection, and unique safety challenges. Overall COVID-19 mortality decreased by W2, possibly due to an increased knowledge of infection control and treatment. Mortality's association with age, diabetes, vintage and entities with nursing home patients represents strain on the healthcare system that may be repeated in future pandemics.

PUB157

Incidence and Predictive Factors of Intradialytic Hypertension in Patients Undergoing Hemodialysis? An Observational Study from North India

Dinesh Khullar, Harleen Singh, Rahul Grover, Sahil Bagai, Kulwant Singh, Prof Narinder P. Singh, Deepak Kumar, Abhishek Singh, Anish K. Gupta. *Max Super Speciality Hospital Saket, New Delhi, India.*

Background: Cardiovascular issue associated with hemodialysis is intradialytic hypertension (IDH), affecting approximately 15% of patients. To enhance our comprehension of IDH, study sought to ascertain its incidence and identify factors that predict its development in hemodialysis patients.

Methods: An observational study was carried out in 174 patients over the age of 18 years, undergoing hemodialysis at least twice a week for at least three months. IDH was defined as systolic BP increase of ≥10 mm Hg occurring during dialysis, starting after the first hour and continuing for at least 30 minutes after the session's completion, observed in at least 4 out of 6 successive dialysis sessions. Blood tests including CBC, and KFT were performed before dialysis. ECHO-2D was conducted at baseline. BP, pulse rate, and Mean Arterial Pressure were monitored hourly and 30 minutes post-dialysis. Four-electrode BIA device (Fresenius, Germany) utilized for assessment of hydration status. Patients were categorized into two groups - IDH-group A and non-IDH group B.

Results: The incidence of IDH was 34.5%, with half of patients being male and average age was 55.4±15 years. The non-IDH group B (65.5%) consisted of 58.7% males, with mean age of 57.3±12.8 years. The most common cause of ESKD in both groups was chronic glomerulonephritis, accounting for 55% of group A and 44.7% of group B. Hypertension (86.7%) and diabetes (48.8%) were prevalent in both groups. A negative correlation was found between IDH and BMI (r-0.16,p0.037), and hemoglobin levels (r-0.21,p0.006). IDH was positively correlated with Hydration status(r0.19,p0.011), left ventricular hypertrophy (LVH) (r0.16,p0.034), and number of antihypertensive medications (r0.3,p0.01), particularly ACE/ARB use (r0.39,p0.01). The multivariate analysis revealed that hydration status (p0.037), LVH (p0.04), and ACE/ARB use (p0.02) were independent predictors of IDH.

Conclusions: Almost one-third of patients with hemodialysis experience IDH, which is a clinically relevant phenomenon. The risk factors associated with IDH include hydration status, LVH, and the use of ACEi/ARB.

PUB158

ESKD Is Often Not Identified as a Cause of Death in Death Certificates

Nicholas S. Kowalczyk, Anthony Chang. *The University of Chicago Medicine, Chicago, IL.*

Background: Many studies have found high error rates in death certificates, as most healthcare professionals have minimal to no training regarding how to complete this important task. A recent multicenter study demonstrated that most pathologists did not recognize end-stage kidney disease (ESKD) as either an underlying or contributing cause of death (COD) in autopsy reports of ESKD patients. Therefore, we conducted this study to determine whether a similar omission could be observed in the death certificates of ESKD patients.

Methods: We identified 60 deceased patients with ESKD in our electronic medical record (EMR) between August 1, 2022 and January 30, 2024. Inclusion criteria were a diagnosis of ESKD, being on dialysis for at least 1 year, and a viewable death certificate in the EMR. Patients that were 18 years or younger or had any history of kidney transplant or malignancy were excluded.

Results: The average age of patients was 62 years with sex equally split. Time on dialysis ranged from 1 to 20 years with a mean of at least 5.6 years. The common co-morbidities were hypertension (28/60, 47%), diabetes (28/60, 47%), heart disease including coronary artery disease, heart failure, and arrhythmias (35/60, 58%), and other cardiovascular disease including cerebrovascular disease and peripheral vascular disease (16/60, 27%). Cardiovascular causes were the most common immediate COD (27/60, 45%) followed by infection (13/60, 22%), ESKD (10/60, 17%), and hemorrhage (6/60, 10%). ESKD was listed as an immediate or proximate COD in 22 (37%) of 60 death certificates. The majority (41/60, 68%) of death certificates were completed by trainees, and the remaining 27% (16/60) were hospitalists, physician assistants, advanced practice nurses, or primary care physicians. Of the trainees, 29% (12/41) identified ESKD as a COD. Non-trainees identified ESKD as a COD in 8/19 (42%) of cases.

Conclusions: The majority (63%) of providers failed to recognize ESKD as a cause of death in death certificates. The failure to identify ESKD as an underlying or contributing COD emphasizes the decreasing sense of urgency that is commonplace among healthcare providers ever since the advent of dialysis. This study identifies an important practice gap regarding the inaccurate completion of death certificates in the setting of ESKD, which shortchanges the nephrology community and their ESKD patients.

PUB159

Rare Case of Enteropathogenic Escherichia coli Causing Hemolytic Uremic Syndrome

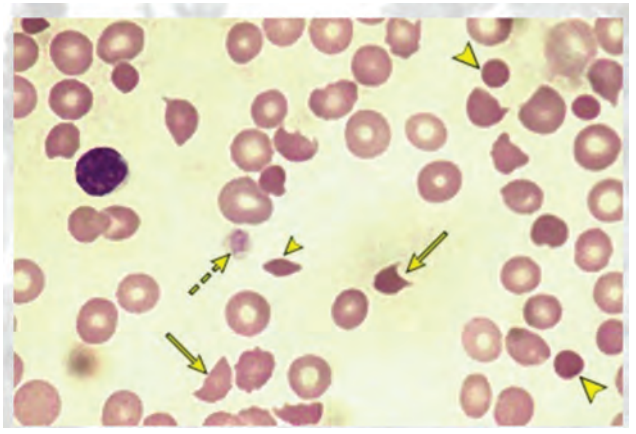
Bhoomi Shah, Nabeel Siddiqui, Rupinder Kaur, Greeshma A. Thomas, Karen Terry, Sagar Kulkarni. *Southeast Health, Dothan, AL.*

Introduction: Association of Shigella and EnteroHemorrhagic E.Coli strain O157:H71 causing HUS has long been established and is known as typical HUS. Atypical HUS is caused by mutation causing abnormal complement activation. EPEC is a rare cause of diarrhea in adults and people who live in developed countries.

Case Description: A 40-year-old female with no significant medical history presented with complaints of nausea, vomiting, and diarrhea for 3 days. She also had blood in her urine and decreased urine output. Her diarrhea was watery in nature with few streaks of blood. She also reported a fever spike of 100.5 F. She had associated decreased appetite and abdominal pain. She denied any blood in vomitus, recent travel, or eating outside food. Her vital signs were revealing of tachycardia and fever. Her abdomen was diffusely tender to palpation. Her labs showed decreased hemoglobin, elevated creatinine 6.27, platelets 14000, troponin 9888, bilirubin 3.29, and CK 1122. Her ADAMTS-13 levels were low. Peripheral smear showed schistocytes. She also had elevated LDH, ferritin, and low haptoglobin. She was transfused with 8 units of PRBCs. She underwent plasma exchange due to concerns of TTP-HUS from STEC, but the stool studies were positive for EPEC. Therefore, she was started on steroids and later transitioned to supportive treatment. She also required dialysis and aggressive management of her hypertension.

Discussion: Though most cases of HUS are associated with Shigella and EHEC O157:H71, thorough work up is required to rule out causes including genetic causes, atypical HUS to provide appropraite treatment to the patient. EPEC causes watery diarrhea

and EHEC causes bloody diarrhea. Appropriate management depends on the underlying cause of the microangiopathy whcich is not always established and includes a wide range of treatment options from supportive care to RBC transfusion, plasma exchange, dialysis and anti-complement therapy.



PUB160

Hemodiafiltration: Impact of Private Health Insurance on Mortality

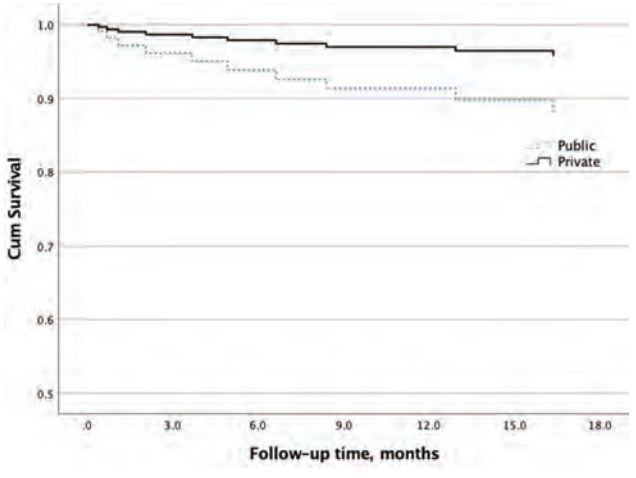
Eduardo D. Luciano,[1] Érica P. Rocha,[4] Cynthia M. Borges,[3] Christiane Kojima,[4] Sandra Reis,[6] Maria G. Rosa,[3] Aline Cordeiro,[5] Whelington F. Rocha,[1] Adolfo M. Silva,[1] Andréa O. Magalhães,[1] Rosilene M. Elias.[2] Nefrostar. *[1]Universidade Federal de Sao Paulo Escola Paulista de Medicina, Sao Paulo, Brazil; [2]Universidade de Sao Paulo, Sao Paulo, Brazil; [3]Universidade Estadual de Campinas, Campinas, Brazil; [4]Universidade Estadual Paulista Julio de Mesquita Filho, Sao Paulo, Brazil; [5]Universidade de Taubate, Taubate, Brazil; [6]Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil.*

Background: High-volume hemodialfiltration (HDF) is associated with an improved survival. However, in Brazil, HDF is allowed only for patients with private insurance (approximately 20% of population). It is not known whether the better survival rate observed in patients with private health insurance is related to the dialysis therapy or to the global care associated with a better economic situation. We had the opportunity to evaluate the impact of HDF on mortality rate in patients with private and public health insurance.

Methods: all patients who received HDF in both clinics were included (private, N=83, 35.3% with diabetes, age 53± 17 years) and public (N=40, 51.2% with diabetes, age 61± 2 years). Patients were followed until death, withdraw from dialysis or end of the study (May-9-2024). The nephrology team was the same in both facilities.

Results: during a median follow-up of 16.9 months there were 11 deaths (5 from the public and 6 from the private facility). In a Cox survival analysis revealed a not significant difference between public and private facilities (p=0.099, HR=0.336) after adjustments for age (p=0.047, HR=1.065) and diabetes (p=0.775, HR=1.202)

Conclusions: Despite the differences in global care and economic status, HDF confers similar survival rate for patients with private and public insurance. Whether this benefit will be confirmed in a larger population deserves further evaluation.



PUB161

ESKD with Renal Artery Stenosis

Christian J. Wiscombe, Lark Steafo, Sami S. Zarouk. *Corewell Health Beaumont Hospital, Royal Oak, MI.*

Introduction: Atherosclerosis is the leading cause of renal artery stenosis accounting for 90% of all renovascular lesions. Complications that arise secondary to renal artery stenosis can include hypertension, ischemic nephropathy, and destabilizing cardiac syndrome. In patients with a single functioning kidney, these complications can lead to rapidly declining kidney function. Patients can present from a spectrum of hypertension, acute kidney injury, or worsening chronic kidney disease.

Case Description: A 71-year-old Caucasian woman with history of hypertension, atrophic right kidney, and chronic kidney disease stage IIIb A1 was evaluated for uncontrolled hypertension. She presented for second opinion regarding hypertension and kidney disease. Her blood pressure was 190/90 and eGFR at 36 cc/min which appeared to be her baseline for several years. Workup for primary hyperaldosteronism was negative and doppler of the renal arteries was negative. Five months later the patient was admitted through the emergency room with a creatinine of 13 mg/dL on routine screening. She was hypotensive and had melena. Renal angiography revealed total occlusion of the renal arteries bilaterally and she was initiated on hemodialysis. Over time she became nonoliguric, requiring less dialysis time and ultrafiltration. She was referred to a vascular surgeon to re-evaluate her left renal artery. Repeat aortogram revealed >90% left ostial stenosis with a greater than 70% proximal renal artery stenosis. She underwent renal artery angioplasty and stenting. She was able to discontinue dialysis 11 months after her start date. She has remained dialysis free for the last 7 months with eGFR at 33 cc/min and tolerating the use of Valsartan.

Discussion: Multiple studies have been designed to evaluate the role of renal artery stent placement in chronic kidney disease patients with renal artery stenosis. Limited small retrospective studies have been performed to evaluate the role of renal stenting in dialysis patients. We believe the patient had acute tubular necrosis with a single partially functioning left kidney with renal artery stenosis that recovered over time. The initial angiogram failed to demonstrate the patency of the left renal artery. We would like to bring attention to the importance of evaluating the urine output as a marker for renal flow in spite of a false reporting of occlusion of the renal artery on angiogram.

PUB162

Topical Oxygen Therapy Use in Patients with ESKD in Qatar: A Case Series

Ali Mahgoub, Robert A. Menzies, Talal K. Al Enizi, Abdullah I. Hamad, Hassan A. Al-Malki. *Hamad Medical Corporation, Doha, Qatar.*

Background: End-stage kidney disease (ESKD) is an increasing healthcare concern. The major etiology is attributed to diabetes worldwide. Diabetic foot disease (DFD) is a serious complication as its the major cause of non-traumatic lower extremity amputations. ESKD is a known independent risk factor for foot ulcers in patients with diabetes, furthermore they are predisposed to other ulcerating conditions such as calcific uremic arteriolopathy (CUA). Topical oxygen therapy (TOT) has emerged as one of the modalities to improve wound healing in patients with DFD. It can be provided as an in-center treatment during hemodialysis (HD) thus bypassing some of the difficulties encountered with hyperbaric oxygen therapy. In this case series we aimed to evaluate the use of TOT in patients with ESKD.

Methods: 6 patients receiving HD were identified, 5 patients diagnosed with DFD and 1 with CUA. All patients received standard of care which included thrice weekly wound examination, debridement as needed, dressing, wound swab and antibiotics if signs of infection were found. TOT was started thrice weekly during HD for 1.5 hours at 40–50 millibars of pressure and was continued till wound closure or for a total of 20 sessions. Wound dimensions were obtained before initiation of TOT and when an outcome is met.

Results: All patients included received standard of care alone for at least 2 months prior to TOT without significant improvement. All patients had hypertension and diabetes. One patient was excluded as he travelled abroad. All patients tolerated the treatment without reported side effects. 3/5 patients improved with topical oxygen therapy on completion of 20 sessions. Patient 1 had complete wound closure. Patient 2 and 3 achieved significant improvement; their wounds dimensions has improved to 0.6x.0.4 cm from 1.1x0.8 cm and 0.7x0.5 cm from 4x2.2 cm respectively. Patient 4 and 5 did not complete treatment as they developed infections requiring hospitalization.

Conclusions: Topical oxygen therapy is a well-tolerated adjuvant therapy that was associated with higher rates of wound healing amongst patients with end-stage kidney disease. it can be provided as an in-center treatment therefore improving patient's adherence and convenience. Prospective trials are needed to further evaluate safety and efficacy of TOT in patients with end-stage kidney disease.

PUB163

Changes of Arterial Oxygen Saturation during Hemodialysis

Lin-Chun Wang,[1] Andrea Nandorine Ban,[1] Vincent Filardi,[1] Xiaoling Ye,[1] Peter Kotanko,[1,2] Hanjie Zhang.[1] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: The study of intradialytic arterial oxygen saturation (SaO_2) in hemodialysis (HD) patients is an under-explored area. We aim to describe the dynamics of SaO_2 in HD patients with arteriovenous (AV) access during HD.

Methods: SaO_2 levels during HD were measured using the Crit-Line monitor (CLM; Fresenius Medical Care, Waltham, MA). CLM measurements were recorded at 10-second intervals and transmitted into Amazon Web Services (AWS) via Apache KAFKA, a real time streaming software. We extracted CLM data between January 2021 and July 2023. CLM values with the following characteristics were deemed implausible and excluded: $SaO_2 \leq$ 0 or ≥99.9; hematocrit <15% or >60%. We then excluded the sessions with the standard deviation of SO_2<0.1%, an SaO_2 interquartile range of zero, and sessions less than 60 total minutes of recordings. SaO_2 at HD start was calculated as the mean SaO2 between minutes 5 and 20. SaO_2 at the HD end was calculated as the mean SaO_2 in the last 5-20 minutes. The sessions with less than 5 minutes of measurements either at the start or at the end of the session were filtered.

Results: SaO_2 from over 3 million HD sessions from 49,580 patients with AV access are analyzed. The mean SO_2 at the start was 96.42±3.6% and 96.45±3.75% at the end, indicating an average intradialytic SO_2 increase of 0.03% [95% CI: 0.0289 - 0.0325] (**Figure 1**).

Conclusions: Our results showed that SaO_2 during HD remain similar at the start and end of HD. These data provide a rich source for future research into SaO_2 and its clinical outcome associations. Exploring intradialytic SaO_2 in depth will offer valuable insights to improve patient care and optimize treatment procedures.

SaO_2, arterial oxygen saturation.

PUB164

Predictive Factors of Catheter-Related Bloodstream Infection among Patients on Hemodialysis

Sandra L. Diaz, Mary Anne C. Lu. *Cotabato Regional and Medical Center, Cotabato City, Philippines.*

Background: Catheter-related bloodstream infection (CRBSI) is a one of the major cause of morbidity and mortality among end stage renal disease patients undergoing hemodialysis using central venous catheter (CVC). The study aimed to investigate the predictors of catheter-related bloodstream infections (CRBSI) with end-stage renal disease (ESRD) patients on hemodialysis through a central venous catheter.

Methods: We conducted a retrospective analytical study to investigate the predictive factors and associated outcome of CRBSI among ESRD patients undergoing hemodialysis at Cotabato Regional and Medical Center. A total of 42 patients who have central venous access(CVC) were included in this study from January 1, 2020 to December 31, 2022. We obtained the patient's demographic data, laboratory results at admission, information regarding catheter infections, culture results, and other information from electronic medical records.

Results: The study involved patients with a mean age of 48±15 years, with more females (59.5%, 25 patients) than males (40.5%, 17 patients). The primary causes of hemodialysis were diabetes mellitus (38.1%) and hypertension (35.7%), which were also the most common co-morbidities. Non-tunneled catheters were the majority of the central venous access used in the study. Sepsis is a significantly associated outcome of CRBSI among hemodialysis using central venous catheter with p value of 0.05. According to logistic regression analysis, the development of CRBSI was predicted by ages greater than 71 with a p-value of 0.023.

Conclusions: We conclude that ESRD patients undergoing hemodialysis with venous catheters, who are 71 years of age or older, are at an increased risk of developing CRBSI and sepsis is a significantly associated outcome.

Surveillance of Patients on Dialysis in a Large Polysomnography Database in Okinawa, Japan

Kunitoshi Iseki.[1,2] *[1]Nakamura Clinic, Urasoe, Japan; [2]Okinawa Heart and Reanal Assocation, Naha, Japan.*

Background: Sleep disturbance is a major cause of lowering quality of life (QOL) and may contribute to high mortality rate of chronic dialysis patients. Overnight polysomnography (PSG) is the precise method to diagnose sleep disturbance such as obstructive sleep apnea (OSA). However, there is a few reports on characteristics of OSA among dialysis patients based on PSG database.

Methods: Since September 1990, we have a large PSG database: the Okinawa Nakamura Clinic Sleep (ONSLEEP) registry (Nakamura K, et al. J Clin Sleep Med 2021). By reviewing medical records, we surveyed hemodialysis (HD) patients by the end of March, 2024. Baseline data at the first PSG such as age, body mass index (BMI), and apnea hypopnea index (AHI) were obtained. Also, we collected dialysis-related date such as the start date of chronic dialysis therapy and primary cause of end-stage renal disease. To compare those not-on dialysis, we used data of the previous report (N=6,483).

Results: There were 374 dialysis patients (men 302, women 72). The median (interquartile range, IQR) age, BMI and AHI at PSG were 57.0 (49.0-67.0) years, 27.2 (23.6-30.8) kg/m^{2}and 32.3 (13.9-66.4) per hour. PSG was performed before starting dialysis in 204 patients (54.5%). Demographics at the PSG were compared between after and before starting dialysis therapy (Table 1). Those who tested PSG before starting dialysis were significantly higher BMI and AHI.

Conclusions: Results support the notion that continuous positive airway pressure (CPAP) therapy may lowered the death risk, and they survived until start dialysis therapy. Whether the use of CPAP is effective to retard the progression of CKD remained to be studied.

Baseline characteristics at the time of PSG. Data are presented as median (IQR) for continuous measures, and n (%) for categorical measures.

PSG Timing	Total	After start of HD	Before start of HD	P-value
N of patients	374	170 (45.5%)	204 (54.5%)	
Age, years	57.0 (49.0-67.0)	58.5 (50.0-69.0)	56.5 (47.0-65.0)	0.008

Prevalence of Protein-Energy Wasting in Patients with CKD on Hemodialysis in Mexico

Gabriela Luna,[1] Edgar Solis,[1] Geovana Martin-Alemañy,[2] Karla Davalos,[1] Alondra Muñoz,[1] María Escobar,[1] Laura Lagunes,[1] Tania Sepúlveda,[1] Diana Flores,[1] Luz Piña,[1] Ingrid Diez,[1] Ludwig Romero,[1] Jorge Navarro,[1] Juan M. Ardavin Ituarte,[1] Sergio Hernández-Estrada.[1] *[1]Médica Santa Carmen, Querétaro, Mexico; [2]University of Arizona, Nutritional Sciences and Wellness, Tucson, AZ.*

Background: The protein energy wasting (PEW) contributes to increasing the high rates of morbidity and mortality known in patients with chronic kidney disease. The objective of the study was to know the prevalence of PEW using the Malnutrition Inflammation Score (MIS).

Methods: In this multicenter cross-sectional study in adults hemodialysis (HD) patients the prevalence of PEW was calculated using the MIS tool for its diagnosis, its clinical and nutritional characteristics were described. Generalized linear model analysis was applied to evaluate the associations with different risk factors.

Results: 3347 adult HD patients were evaluated from September 2020 to December 2023 from 11 kidney health facilities in Mexico. Prevalence of PEW was 35.5% (95% CI: 33.9% to 37.2%). It was observed that an increase in the triceps skinfold (OR: 0.95 95% CI 0.93-0.96), in the mid-arm muscle circumference (OR: 0.98 CI 95% 0.98-0.99) and serum creatinine (OR: 0.90 95% CI 0.87-0.93) were associated with a decrease in the probability of being diagnosed with PEW (p= 0.000).

Conclusions: We found a prevalence of PEW of 35.5% in patients on HD, these results are in line with what is reported in the literature where a worldwide prevalence has been calculated 28-54%.

Temperature Regulation to Counter Inflammation Associated with Hemodialysis (TRIAD) Study

Srikanth Bathini.[1,2] [1]*Asian Institute of Nephrology and Urology, Hyderabad, India;* [2]*Krishna Institute of Medical Sciences Hospital Group, Secunderabad, India.*

Background: CKD is a chronic inflammatory state. Inflammatory markers (IL-6, TNF- α) have been associated with adverse outcomes in CKD. The role of cool dialysate over standard temperature dialysate in preventing intra-dialytic hypotension is well known. The effect of a cool dialysate over inflammation is not known. We studied the effect of a cooled dialysate on inflammatory markers.

Methods: This is a prospective, randomised, open label study, with 13 patients in each group. Two groups with standard dialysate (36.5^{0}C) and cooler dialysate (one degree lesser than the core body temperature, never going below 35^{0}C) were studied. The inflammatory markers IL-6 and TNF-α were noted at baseline and at 8 months post randomization.

Results: The mean change in dialysate temperature from core body temperature was 0.90 ^{0}C in the cooled dialysate group. Cooled dialysate group had significantly lower intra-dialytic hypotension($p = 0.041$). There was a statistically higher level of IL-6 ($p < 0.05$) at baseline in the control group. However, at 8 months, the difference was insignificant($p>0.05$). There was no difference in TNF-α levels between both the groups at baseline and at 8 months post intervention($p>0.05$).

Conclusions: The use of a cooled dialysate did not significantly lower inflammatory marker level in ESKD patients, but was was significantly associated with lower intradialytic hypotension. We recommend a larger trial to confirm the effect of cooled dialysate on the inflammatory milieu.

Distractions as Anxiolytics during Hemodialysis: A Pilot Study

Yash A. Patel, Sundus Sardar, Nasrollah Ghahramani. *Penn State College of Medicine, Hershey, PA.*

Background: In-center hemodialysis is an emotional burden for patients. While its correlation with fatigue and depression is well-documented, little research exists on its correlation with anxiety and on anxiolytic interventions. This study aims to determine how to better analyze the anxiolytic effects of distractions during hemodialysis.

Methods: Subjects were recruited at the Penn State Hershey Medical Center's Outpatient Dialysis Unit. After an hour of a self-selected activity during treatment, subjects completed the State-Trait Anxiety Inventory (STAI) to determine their state (situational) and trait (personal) anxiety levels. The STAI-provided norm table was used to assign percentiles to each subject. Subjects were then grouped by activity and a two-tailed analysis was performed to compare mean state and trait anxiety percentiles for each group.

Results: 14 out of 30 eligible individuals consented to the study. The average age was 57, and 2 subjects were older than the oldest age group (50-69) on the STAI norm table. 79% of subjects participated in a hobby. Average enjoyment was above 7/10 across all groups. No significant difference was found between mean state (s) and trait (t) anxiety percentiles in any of the 5 groups: TV/Radio (n=8, s=27.4%, t=36.6%, p=0.40), Social Media/Communication (n=2, s=48.5%, t=65.5%, p=0.70), Sleeping (n=2, 67.5%, t=53%, p=0.82), Games (n=1, s=33%, t=59%, N/A), or Reading (n=1, s=55%, t=59%, N/A).

Conclusions: This pilot study did not find significant changes to subjects' anxiety during hemodialysis with any of the above distractions but does elucidate considerations for future studies through its limitations. A multi-center interventional design would be more powerful and allow for analysis of less common distractions like reading. However, assigning interventions may blunt their anxiolytic effect, as subjects may perform activities they do not enjoy. Additionally, the STAI norm table excludes individuals older than 69, preventing accurate analysis for those patients. High school graduates struggled with the STAI vocabulary, and completion of a lengthy survey may alter anxiety levels and mask anxiolytic effects. Use of a custom inventory may therefore be preferable to the STAI. Through this study, it is evident a carefully tailored method is necessary to better understand anxiety and the anxiolytic effects of distractions during hemodialysis.

Investigation of Core Symptoms during Hemodialysis Period in Chinese Middle-Aged and Young Patients on Maintenance Hemodialysis: A Network Analysis

Nina Zhang. *Department of Nursing, Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China.*

Background: Recent epidemiological studies have found that the population of young and middle-aged maintenance hemodialysis (MHD) survivors has gradually increased. MHD is one of the most important treatments for patients withend-stage renal disease. Due to renal dysfunction and long-term dialysis treatment, MHD patients are prone to various physiological and emotional symptoms, which seriously affect their quality of life. Network analysis is a new method for estimating and visualizing the structure and interaction of various symptoms of diseases. By identifying core and bridging symptoms, it helps to determine the key mechanisms of symptom occurrence and implement precise interventions for some key symptoms.

Methods: A convenience sampling method was used to collect information from 197 young and middle-aged patients at Shanghai Sixth People's Hospital between November 2023 and February 2024. Dialysis symptom index was used to investigate the prevalence and severity of 30 symptoms in MHD patients,and a symptom network model based on Fruchterman—Reingold algorithm was constructed to analyze the central indicators and deternfine the core symptoms and bridge symptoms.

Results: The top five commonly occurring symptoms were dry skin (73.92%), fatigue (70.6%), dry mouth (68.37%), waking up easily (67.82%) and difficulty in falling asleep (66.16%). The most severe symptoms were dry skin,followed by pruritus, fatigue, dry mouth and waking up easily. The symptom network analysis showed that dry skin was most strongly associated with pruritus (weight=0.67) among physiological symptoms,irritability was most strongly associated with anxiety (weight=0.32) among mood symptoms. The centrality index showed that the intensity of sadness was the most centrality (r_s=1.65) and was identified as the core symptom; fatigue had the highest mediation centrality (r_b=2.76) and irritability had the highest close centrality (r_c=1.45). Irritability,sadness,and inattention were identified as bridge symptoms,and their bridge centrality was 0.34,0.21,and 0.20.

Conclusions: Dry skin and sadness are respectively the most severe symptom and core symptom in Chinese middle-aged and young MHD patients,while irritability, sadness and in attention are the bridge symptoms. Medical staff can formulate precise interventions based on core symptoms and bridge symptoms to improve the level of symptom management.

PUB171

Association between Blood Pressure Variability and Prognosis in Diabetic Patients on Maintenance Haemodialysis

Siqi Peng, Shuangxin Liu. *Guangdong Provincial People's Hospital, Guangzhou, China.*

Background: Patients receiving dialysis who also have diabetes mellitus have high mortality. This study aimed to explore blood pressure variability (BPV) in diabetic patients treated with hemodialysis and analysis of prognosis.

Methods: This study retrospectively colected pre-dialysis and intra-dialysis blood pressure (BP) of maintenance hemodialysis (MHD) patients in the haemodialysis centre of Guangdong Provincial People's Hospital in March 2020. The patients were divided into diabetic and non-diabetic groups, and the differences in mean pre-dialysis and dialysis BP and BPV were compared between the two groups. They were also grouped according to whether they had diabetic kidney disease (DKD), whether they were taking antihypertensive drugs, and the absolute value of BP for subgroup analysis.BPV was expressed as the standard deviation (SD) and coeffi cient of variatioil (CV) of multiple BP readings and the average real variability (ARV). Survival analysis was performed using the multivariate Cox proportional hazard model, and Kaplan-Meyer survival analyses with log-rank tests were performed to show differences between groups.

Results: A total of 208 patients were included, of whom 81 had diabetes mellitus. Compared with the non-diabetic group, the diabetic group showed a non-significant difference in absolute BP levels, and greater SBP variability in both pre-dialysis and intra-dialysis. According to the Kaplan-Meier estimator, high SBP SD and CV in dialysis were associated with high all-cause mortality (log-rank 7.12, p = 0.008). Cox multivariate analysis also showed a significant association between diabetes combined with high SBP variability and all-cause mortality (HR 2.259; 95% CI 1.017 -5.018).

Conclusions: Compared with nondiabetic patients, SBP variability is higher in diabetic patients with MHD, both pre-dialysis and intra-dialysis. Diabetes mellitus combined with high dialysis BPV is independently associated with increased all-cause mortality.

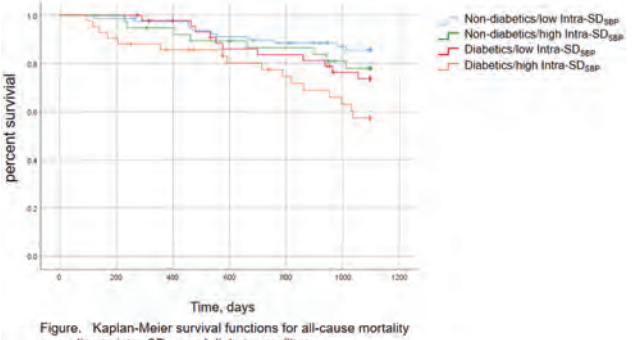

Figure. Kaplan-Meier survival functions for all-cause mortality according to intra-SD$_{SBP}$ and diabetes mellitus

PUB172

Prevalence of Hepatitis B Virus Antibody Levels Seroconversion in Patients on Hemodialysis: Mexican Cohort at Medica Santa Carmen

Sergio Hernández-Estrada, Alicia Pineirua, Edgar Solis, Juan M. Ardavin Ituarte. Medica Santa Carmen. *Médica Santa Carmen, Mexico City, Mexico.*

Background: Chronic Hemodialysis (HD) patients (px) are immunocompromised and hepatitis B virus (HBV) infection is a major concern due to increased susceptibility and poor vaccine response. Current recommendation related to HBV is to give vaccines during stage 5 in order to reach immunization and generate protective antibody levels of HBV (HbsAb). In Mexico, international HBV vaccination schedules for HD px are not necessarily accomplished (three double doses of 20 mcg/1ml for 6 months) and HbsAb are below what is desirable.

Methods: We reviewed 1,967 HD px in Medica Santa Carmen kidney network and the main objective was to analyze seroconversion status with HbsAb over 10 mUI/ml. Vaccination status was uncertain for most px. Median, interquartile range and proportions were estimated. We compared groups with Man-Whitney U-test and chi square test. A regression model adjusted for significant variables was performed.

Results: Seroconversion with HbsAb over 10 mUI/ml and 100 mUI/ml were 39% (760px) and 25% (487px) respectively. Comparative results by dividing HbsAb ≥10 vs HbsAb <10 mUI/ml groups are shown in the table. Significant differences were found in the HbsAb ≥10 mUI/ml group related to lower percentage of diabetes, hypertension, smoking and ischemic cardiopathy. In a multivariate analysis, age (OR 0.977, IC 0.970-0.984) and HD vintage (OR 1.004, IC 1.004-1.009) were statistically significant for seroconvertion status.

Conclusions: In Mexico, individuals with protective levels of HbsAb is scarce. Immunized against the HBV group had lower weight, BMI and higher Kt/v. Younger patients and vintage in HD are related to better chances of being immunized.

Joint Modeling of Longitudinal Ferritin Trajectories and COVID-19 Infections in Native American, Hispanic, and White Patients on Hemodialysis

Mingzhao Hu,[1] Talia Quandelacy,[3] Yuedong Wang,[2] Peter Kotanko,[5] Baqiyyah Conway.[3,4] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]University of California Santa Barbara, Santa Barbara, CA; [3]University of Colorado Anschutz Medical Campus, Aurora, CO; [4]The American Academy of Epidemiology, Inc., Tyler, TX; [5]Renal Research Institute, New York, NY.*

Background: American Indians/Alaska Natives (AIAN) and Hispanic individuals in the U.S. are overrepresented in the hemodialysis (HD) population and were hardest hit by COVID-19. Early in the pandemic, hyperferritinemia was linked to COVID-19 infections. Joint modeling learns from both longitudinal and time-to-event data for predictive accuracy and dynamic estimation. We investigated the predictive utility of ferritin w/ COVID-19 infection in a cohort of AIAN, Hispanic and White HD patients.

Methods: We followed 2,242 HD patients from 1/2020 to 3/2022. Baseline ferritin was the average between days 365 and 14 till COVID-19 diagnosis (day 0). In non-infected control, a random date matching the distribution of diagnosis dates was chosen as the "test date". Longitudinal ferritin trajectories were modeled with a linear mixed effects model and COVID-19 infection with a Cox model. A joint model linked these to measure the association between COVID-19 infection and ferritin.

Results: Cumulative COVID-19 incidence was 36%. In exploring ferritin's link with potential confounders, the longitudinal submodel coefficients highlighted age had a strong positive link while albumin, creatinine, hemoglobin and WBCs were not linked. The joint model revealed a marginal association between ferritin and infection risk (HR = 1.001, $p < 0.001$). Males had lower COVID-19 risks while diabetes was not linked. AIAN patients had almost twice the risk of White patients (HR = 1.948, $p < 0.001$) while Hispanics also had higher risk than White (HR = 1.328, $p < 0.001$). Vaccination greatly reduced the risk (HR < 0.001, $p < 0.001$).

Conclusions: Joint modeling indicated a weak link of ferritin with COVID-19 infection, however, dynamic predictions via joint models did not strongly support early detection via ferritin alone. AIAN and Hispanic patients had higher infection risk than White patients, while vaccination nearly eliminated the risk.

User-Friendly Features of Moda-flx Show High Usability Success Rates

Stephanie Wall, Nicholas Hyun, Vitas B, Emiline Victoria Hernandez, Clayton Poppe, Osman Khawar. *Diality, Inc., Irvine, CA.*

Background: The Moda-flx Hemodialysis System™ prioritizes user-friendliness, safety, and connectivity, aiming to enhance the dialysis experience for users. By incorporating features such as automatic priming, Bluetooth connectivity for blood pressure monitoring, and automatic saline bolus delivery during treatment and rinseback, Diality aims to enhance usability and patient outcomes, thereby affirming the company's dedication to patient-centric innovation in renal care.

Methods: Three simulated-use formative usability studies and a summative usability study involving Certified Clinical Hemodialysis Technicians and Nephrology Nurses as representative users were used for data collection. Tasks were tailored to match the operational requirements of the Moda-flx Hemodialysis System™, prioritizing scenario-driven interactions to provide users with genuine, real-world experiences.

Results: Nine Nephrology nurses and six Certified Clinical Hemodialysis Technicians from diverse backgrounds participated in a simulated-use summative usability study. They received three hours of training in small groups, including presentations and hands-on sessions, with a minimum 1-hour decay period before evaluation. The study showed a remarkable 98.33% success rate across 285 tasks related to the discussed user-friendly features, affirming their ease of use.

Conclusions: The Moda-flx Hemodialysis System, designed with a focus on user-friendliness, represents a significant advancement in renal care. By incorporating features such as automatic priming, Bluetooth-enabled blood pressure connectivity and monitoring, automatic saline bolus delivery during treatment and at rinseback features, Diality aims to enhance patient comfort and treatment adherence. The study's impressive 98.33% success rate across 285 tasks validates the effectiveness of these user-friendly enhancementsand reinforces Diality's commitment to patient-centric innovation in dialysis device design.

Prolonged Intermittent Kidney Replacement Therapy in the Intensive Care Unit: A Single-Center Experience

Deepak Chandramohan,[1] Calvin C. Baker,[1] Katrina Eggleston,[2] Javier A. Neyra,[1] Ashita J. Tolwani,[1] Yan Lu.[1] *[1]The University of Alabama at Birmingham, Birmingham, AL; [2]DaVita Inc, Denver, CO.*

Background: Prolonged intermittent renal replacement therapy (PIRRT) is a viable RRT option for critically ill hemodynamically unstable patients. Herein, we report a single-center experience of PIRRT delivery to critically ill adults in the ICU.

Methods: This retrospective observational case-series study included non-surgical critically ill adults admitted to the ICU at an acute care hospital affiliated with the University of Alabama at Birmingham. This hospital offers only PIRRT (not CRRT) through the Tablo® Hemodialysis System to ICU patients. We analyzed 38 PIRRT treatments from 15 patients between August 2022 and January 2024. Treatments were administered with a blood flow rate of 150-300 ml/min and a dialysate flow rate of 100 ml/min. No protocol anticoagulation was utilized, but systemic anticoagulation was used if medically indicated. The primary process endpoint was premature filter clotting, defined as clotting of the filter before completion of treatment, and the secondary endpoint was the full treatment completion rate without interruptions.

Results: The median age was 55 years(IQ1-IQ3: 43-79); 46.7% were men, 66.6% Black and 73.3% had AKI. 93.3% were on vasopressors, 66.6% on mechanical ventilation, and 53.3% had septic shock. The median Sequential Organ Failure Assessment (SOFA) score was 12 (10-13), and the median Acute Physiology and Chronic Health Evaluation II (APACHE II) score was 25 (22-29). The dialysis catheter was placed in the internal jugular vein in 66.6% of instances and the femoral vein in 33.3%. The median blood flow rate was 250 ml/min (233.2-250), and the dialysate flow rate was 100ml/min for all treatments. Patients received a median of 2 (1-3) treatments. The median individual treatment duration was 8 hours(6-10). Premature filter clotting occurred in 9 out of 38 treatments (23.6%), and the time to filter clotting was 5.4 hours (3.5-7.6). The treatment completion rate was 94.5% (77-100). The mortality rate was 33.3%; and 40% of patients were transferred to an academic quaternary center for medical and surgical procedures, while 13.3% were transferred to be started on CRRT.

Conclusions: While the provision of PIRRT without protocol anticoagulation to critically ill adults requiring RRT is safe and feasible, about one of four treatments had premature clotting.

PUB176

Outcome of Peripheral Arterial Disease in Patients with ESKD on Hemodialysis

Ashraf O. Oweis,[1] Sameeha A. Alshelleh.[2] *[1]Jordan University of Science and Technology Faculty of Medicine, Irbid, Jordan; [2]The University of Jordan, Amman, Jordan.*

Background: Patients on hemodialysis are at higher risk for cardiovascular complications due to increased risk of atherosclerosis. This has been associated with higher morbidity and mortality rates. Peripheral arterial disease (PAD) is an important complication of atherosclerosis that is manifested significantly in these patients. However, it has not been extensively studied in our region.

Methods: A retrospective analysis was performed from the years 2010- 2021. ESRD patients that were diagnosed with PAD during this period were studied, diagnosis was done through CT- Angiography. Predefined end points were death and amputation

Results: The mean age for the patients was 65.9 (SD± 12.96). Most patients were either with DM (84.6%) or HTN (91%). The prevalence of amputation was 44.7%, using univariate analysis DM was a strong predictor for amputation (P=0.001) as long as coronary artery disease (P=0.001). On multivariate analysis only DM (P=0.003) was associated with higher prevalence of amputation Time to death was 16.9 months (SD±25.6), 11.3 months (SD±9.1) for patients with amputation vs. 21.1 (SD±32.7) for those without amputation

Conclusions: End stage renal disease patients with PVD especially with PVD have higher mortality and majority are diabetic which necessitate earlier recognition of PVD and modified risk factors like better control of DM and its complications in addition to other risk factors like HTN, dyslipidemia and metabolic disorders of CKD.

Factors Associated with Adherence to Antihypertensive Treatment and Complications Due to Inadequate Adherence in Patients Undergoing Hemodialysis at the Hospital Regional Puebla ISSSTE

Sergio V. Pérez Reyes, Alexis Perez Reyes, Maria J. Gonzalez Farris, Kriscia M. Hernandez, José L. Gálvez-Romero, Brenda Lima. *Instituto de Seguridad y Servicios Sociales de los Trabajadores del Estado, Mexico City, Mexico.*

Background: Poor medication adherence hampers hypertension control and increases the risk of adverse health outcomes. Medication adherence can be measured with direct and indirect methods. In México not exist any study to evaluate the medication adherence in patiens under hemodialysis. For this is important to assess Mexican hypertensive patients' adherence rate to hypertension therapeutic regimen and to identify the strongest predictors of adherence rate among such patients.

Methods: A descriptive comparison design and convenience sampling were used. The sample comprised 113 participants who came to their regular sessions at hemodialysis in a ISSSTE hospital. The Hill-Bone Compliance to High Blood Pressure Therapy Scale indirectly assesses adherence to hypertension therapy in three behavioral domains: appointment keeping, diet and medication adherence. Secondary objectives to evaluate if there is a relationship between adherence to treatment and years on hemodialysis, levels of urea, potassium, creatinine, albumin and ferritin.

Results: 113 patients were evaluated, of which 54 were women and 59 men. The length of stay on hemodialysis was from 1 to 12 years. 89.4% have been on hemodialysis for less than 6 years.85.8% of patients obtained a good adherence result.14.2% of patients have moderate-poor adherence to antihypertensive treatment. We found that albumin levels above 3.5 g/dl were correlated with better adherence to pharmacological treatment ($p \leq .0405$). During the time of patient evaluation, 5 deaths were reported, all belonging to the group with poor adherence to pharmacological treatment.

Conclusions: This is the first study to be include hemodialysis patients in Mexico. Adherence to taking antihypertensive medications was good overall among the study participants; these participants, however, they agreed to have a high consumption of table salt and forget to take their medication at least once a week. The HBCHBPT Scale has high versatility globally and has been used in various settings by various healthcare worker cadres and researchers. The scale has several strengths, including high adherence phenotyping capabilities, contributing to the paradigm shift toward personalized health care.

Electrocardiographic (ECG) Changes and Asymptomatic Cardiac Arrhythmias in Patients with Chronic Kidney Failure on Hemodialysis

Alondra J. Quesnel Samperio,[1] Paola Gomez-Aviles,[1] Armando Castillo García,[1] Aranza García,[2] Marianela Rodney,[3] Ivana A. Rosales Stevenson,[1] Marco E. Bello,[2] Mario Jimenez Hernandez.[2,1] *[1]Universidad de las Americas Puebla, Cholula, Mexico; [2]Unidad de Nefrologia, Hospital Universitario, BUAP, Puebla, Mexico; [3]Instituto Cardiorenal de Puebla, Puebla, Mexico.*

Background: Chronic kidney disease (CKD) is a current public health problem that has increased over the years. In Mexico, the incidence and prevalence of types of arrhythmias in CKD patients undergoing hemodialysis have not been studied, nor have risk factors associated with their development been identified. The objective of this study was to determine the frequency of arrhythmias in patients with CKD undergoing hemodialysis and to evaluate their overall health status to identify risk factors associated with the development of these electrocardiographic changes both before and after hemodialysis.

Methods: A descriptive, observational, prospective study was conducted at Hospital Universitario Puebla from May 2023 to April 2024. A systematic search identified 58 CKD patients undergoing hemodialysis. Clinical, laboratory, and pre- and post-hemodialysis electrocardiogram data were collected.

Results: The analysis included 58 patients with a mean age of 63.75 years; 51.72% were male. The most common arrhythmias were atrioventricular block (10.3%), bundle branch block (9.5%), prolonged QT interval (9.5%), and sinus bradycardia (8.6%). Older age groups were more predisposed to prolonged QT interval, while younger age groups had a higher prevalence of atrioventricular block. A history of heart disease and kidney disease secondary to diabetic nephropathy were associated as risk factors (p=0.03). The presence of arterial hypertension was not identified as a risk factor (p=0.65).

Conclusions: Atrioventricular block was the most common arrhythmia in hemodialysis patients. The types of arrhythmias observed in our CKD population were not as prevalent as reported in other populations.

AGE	First degree atriovent ricular Block	Prolonged QT interval	Sinus Bradycardia	Right Bundle Branch Block	Extrasystoles	Atrial Fibrillation	Sinus Tachycardia

An Underrecognized Cause of Unexplained High Anion Gap Metabolic Acidosis on Continuous Kidney Replacement Therapy: A Case Series of Euglycemic Ketoacidosis

Htun M. Aung,[1] Aye M. Thida,[2] Anjali Acharya.[1,3] *[1]New York City Health and Hospitals Jacobi, Bronx, NY; [2]SUNY Downstate Health Sciences University, Brooklyn, NY; [3]Albert Einstein College of Medicine, Bronx, NY.*

Introduction: Euglycemic ketoacidosis (EKA) on continuous renal replacement therapy (CRRT) first appeared in the literature in 2018 after Coutrot et al. described 18 patients (15%) who developed EKA on CRRT using a glucose-free solution. Subsequently, in 2020, Sriperumbuduri et al. proposed pathophysiologic mechanisms of EKA on CRRT as 1) glucose losses from CRRT with glucose-free solutions; 2) compromised caloric intake; and 3) stress of critical illness. These conditions create a state of low-insulin, high-glucagon levels, leading to increased lipolysis and ketogenesis causing ketoacidosis, while on the other hand, causing increased glycogenolysis and gluconeogenesis to maintain euglycemia. However, the EKA on CRRT is still under-recognized at the provider level.

Case Description: We present the clinical characteristics of 3 patients who developed euglycemic ketoacidosis on continuous renal replacement therapy (Table 1). Case 1: A 79-year-old female had a history of chronic kidney disease (CKD) stage 3A, hypertension (HTN), diabetes mellitus type 2 (DM-2), and heart failure with reduced ejection fraction (HFrEF). Case 2: An 82-year-old male had a history of CKD stage 2, HTN, DM-2, adenocarcinoma of colon, and HFrEF. Case 3: A 73-year-old male had a history of CKD stage 5, HTN, DM-2, and HFrEF.

Discussion: Providers should consider EKA as one of the differential diagnoses of high anion-gap metabolic acidosis when evaluating a patient on CRRT, especially using a glucose-free solution. The beta-hydroxybutyrate test is easily available in most laboratories, and once the diagnosis of EKA is made, management is feasible and could potentially avoid catastrophic complications.

Table 1: Clinical Characteristics of Patients

	Case 1	Case 2	Case 3
Age (years) and sex	79. Female	82. Male	73. Male

Recanalization of Filter-Bearing Inferior Vena Cava Occlusion: Management Conundrum

Ivana Boktor,[1] Ahmed E. Ali,[2] Rakesh K. Varma,[3] Ammar Almehmi.[4] *[1]George Walton Comprehensive High School, Marietta, GA; [2]Mayo Foundation for Medical Education and Research, Rochester, MN; [3]The University of Texas Southwestern Medical Center, Dallas, TX; [4]The University of Alabama at Birmingham, Birmingham, AL.*

Introduction: Central venous occlusion is a common complication of long-term hemodialysis catheters that is detrimental to vascular access survival. Occlusion of filter-bearing inferior vena cava (IVC) in dialysis population is life-threatening and often challenging to treat. We report unusual case of a patient with complicated dialysis access history who became catheter-dependent via right femoral vein and presented with total occlusion of IVC below the filter level.

Case Description: A 47-year-old female on chronic hemodialysis presented with poor functioning of her right femoral dialysis permanent catheter. Past medical history was remarkable for end-stage kidney disease 1996 due to pre-eclampsia, systemic lupus erythematosus, multiple deep venous thromboses that required IVC filter placement and chronic oral anticoagulation. After failing peritoneal dialysis and multiple dialysis accesses, she became catheter-dependent via right femoral vein. Notably, she was off dialysis 2009-2015 after receiving kidney transplant. During this admission, a venogram through the existing catheter demonstrated complete occlusion of IVC accompanied by extensive collateralization (Fig 1-a). After removing the catheter over the wire, supra-renal IVC was recanalized using stiff guidewire and Kumpe catheter under fluoroscopy guidance. This was followed by sequential balloon angioplasty of the occluded IVC and stent deployment extending from the inferior cavoatrial junction to the superior margin of the IVC filter. Final angiogram demonstrated a wide patent IVC with brisk blood flow into the right atrium (Fig1-b). Dialysis therapy was resumed immediately after intervention and the catheter remains functioning up till now.

Discussion: Treatment of filter-bearing IVC occlusions in dialysis population poses specific technical challenges. Recanalization of these occlusions, such as in our case, is vital, especially among those who exhausted dialysis access options and are not candidates for other treatment modalities such as transplant and peritoneal dialysis.

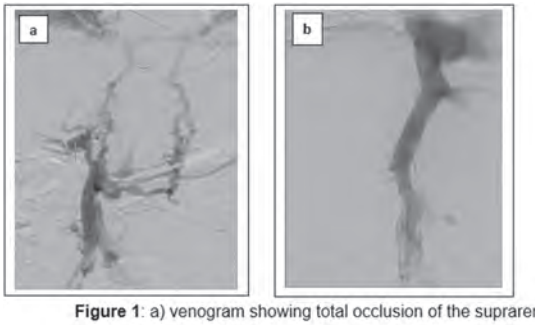

Figure 1: a) venogram showing total occlusion of the suprarenal IVC vein. b) venogram showing patent IVC after stenting and angioplasty.

PUB181

Successful Use of Droxidopa to Treat Intractable Hypotension Attributed to Vasodilatory Shock Due to Autonomic Failure in a Patient with ESKD Who Is Dependent on Continuous Kidney Replacement Therapy

Ramanath B. Dukkipati, Yasemin B. Balin, Anuja P. Shah, Tiane Dai. *Harbor-UCLA Medical Center, Torrance, CA.*

Introduction: Droxidopa is a synthetic amino acid precursor, which acts as a prodrug to the neurotransmitter norepinephrine. It is used to treat neurogenic orthostatic hypotension caused by primary autonomic failure. The goal of our use of Droxidopa is to remove dependence on vasopressors in a patient who was receiving CRRT, as he was deemed unstable to transition to intermittent hemodialysis (iHD).

Case Description: 61-year-old male patient, who has End Stage Kidney Disease, was admitted with hypotension(blood pressure 84/64 mmHg) and no cause of hypotension could be detected after extensive work-up. Primary autonomic failure (vasodilatory shock) was diagnosed based on exclusion of other causes of shock and therefore as receiving vasopressors and CRRT (continuous renal replacement therapy) as a renal replacement therapy. Many attempts and interventions (including midodrine 20 mg three times a day use) to wean off vasopressors and transition to intermittent hemodialysis were not successful over two months. We initiated Droxidopa at 100 mg three times a day in this patient and titrated the dose. We saw that once Droxidopa was initiated in our patient, vasopressors could be weaned off in 48 hours and we could transition to intermittent hemodialysis (as blood pressure improved to 109/75 mmHg) with no requirement of any vasopressors. During the period of initiation and use of Droxidopa no other interventions were made which led us to firmly believe that Droxidopa was the intervention that

treated our patient. No adverse reactions were observed. Droxidopa use (vs. non-use) was associated with successful weaning of vasopressors and transition to Hemodialysis from CRRT.

Discussion: In a patient with intractable hypotension who therefore required being in the ICU to receive CRRT for many months, initiation and titration of Droxidopa successfully made the transition from CRRT to iHD with no further dependence on vasopressors. Droxidopa can be used to treat severe vasoppressors requiring neurogenic orthostatic hypotension caused by primary autonomic failure in Dialysis patients.

PUB182

High Prevalence of Obstructive Sleep Apnoea among Patients with ESKD on Haemodialysis in India

Arghya Majumdar. *Manipal Hospital, Dhakuria, Kolkata, India.*

Background: Patients with end- stage kidney disease (ESKD) may be affected with sleep disorders like insomnia, obstructive sleep apnoea (OSA), hypoventilation, central sleep apnoea, central disorders of hypersomnolence, circadian rhythm sleep–wake disorders, parasomnias and restless legs syndrome. OSA needs special mention as CKD is a comorbidity of OSA and contributes to the course of OSA. The objective of this study was to delineate the prevalence of OSA in ESKD patients on hemodialysis (HD) in India and to document the comorbidities in these patients, which might have an association with OSA.

Methods: The study was a descriptive study with cross- sectional design conducted on 75 patients more than 18 years of age, with CKD stage 5 on MHD attending the Haemodialysis center of a tertiary care hospital in Kolkata, India. Stratified sampling was used and a pre-designed and pre-tested semi-structured schedule was used to collect data. The statistical software SPSS 20 was used for the analysis

Results: The mean age of the 75 patients studied, was 62 years, of whom 57% were male. The prevalence of OSA was 65.3%, of whom 42.7% had moderate and 22.6 % had mild disease. The median Apnoea Hypopnoea Index (AHI) was 15. A statistically significant association was observed between AHI score and Body Mass Index (BMI), alcoholism, hypertension, chronic liver disease, frequency of dialysis per week**,** magnesium levels and ejection fraction. Binary logistic regression of factors showed a statistically significant association with BMI (p=0.000, 95% CI=1.304-2.067) and reduced ejection fraction (p=0.017, 95% CI=0.019-0.682).

Conclusions: A high prevalence of OSA was noted in ESKD patients on maintenance hemodialysis in India. The patients tended to be obese. A high level of awareness and regular screening is mandated in this patient population to diagnose these cases early so that the quality of life, morbidity and mortality can be improved with CPAP therapy.

PUB183

A Curious Case of Dialysis-Associated Reaction

Omar Dodin, Sreelakshmi Ravula, Nadia M. Alqurini. *University of Arkansas for Medical Sciences, Little Rock, AR.*

Introduction: Hemodialysis is a renal replacement therapy where the patient's blood comes in contact with different membranes. This may trigger a cascade of inflammatory responses leading to dialyzer reactions, broadly classified into types A (IgE mediated) and B (complement mediated). Symptoms range from mild itching to dyspnea, hypotension and cardiac arrest.

Case Description: Our case is a 53 years old female with Hx of ESRD from DM. She was switched from peritoneal dialysis due to delayed abdominal wound healing. She was tolerating her treatments well without complications. She presented with low back pain and fever and was found to have Tunneled dialysis catheter associated Staph epidermidis bacteremia and was admitted to ICU for septic shock. CRRT was provided (NXstage machine/gamma sterilized polyether sulfone membrane). As she became hemodynamically stable, dialysis was attempted using Optiflux F160NR single use dialyzer (an ebeam sterilized polysulfone membrane). Within the first few minutes, she developed dyspnea and hypotension requiring prompt cessation of hemodialysis. Dialyzer reaction was suspected. For her second session the filter was prerinsed using sterile normal saline. She tolerated well for the first hour but then developed the same symptoms again. Ultrafiltration was attempted at a rate of 2.5ml/kg/hr which was lower than 10ml/kg/hr ultrafiltration while on CRRT. Her workup showed normal cardiac function, no pericardial effusion and no pulmonary embolism. For her third session, we premedicated her with methyl prednisone, diphenhydramine, and famotidine one hour prior to dialysis. She did not develop symptoms. She received 9 hemodialysis sessions during her hospital course which she tolerated well without complaints. No similar events were recorded in other patients in the unit. We couldn't reuse filters or obtain a different type per institution policy.

Discussion: Our patient's recurring symptoms of dyspnea and hemodynamic instability while receiving intermittent hemodialysis were suggestive of allergic reaction. Cardiac, volume, sepsis, Medication side effects and related etiologies were ruled out. Resolution of her symptoms only after premedicating her with steroids, H1 and H2 antagonists confirmed our suspicions. Dialysis reactions are rare but can cause life-threatening complications and nephrologists need to have a high index of clinical suspicion for timely diagnosis and treatment.

PUB184

Triglyceride and Glucose Index as a Predictor of Adverse Cardiovascular Events in Patients on Hemodialysis

Dae Kyu Kim,[1] Seok hui Kang,[3] Hyun Kyu Kim,[1] Jeong-Yeun Lee,[1] Soo-Young Yoon,[1] Jin Sug Kim,[1] Yang Gyun Kim,[2] Ju young Moon,[2] Kyunghwan Jeong,[1] Sangho Lee,[2] Hyeon Seok Hwang.[1] K-cohort Study Group. *[1]Kyung Hee University Medical Center, Seoul, Republic of Korea; [2]Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea; [3]Yeungnam University Medical Center, Daegu, Republic of Korea.*

Background: The triglyceride and glucose (TyG) index have recently been established as an indicator of insulin resistance, which has the predictive values for cardiovascular (CV) disease. However, the clinical significance of the TyG index in hemodialysis (HD) patients remains unknown.

Methods: A total of 759 patients were enrolled in a prospective multicenter K-cohort from June 2016 to December 2023. The TyG index and echocardiographic parameters were examined at baseline. Circulating endostatin and VAP-1 were measured as vascular injury markers. The primary endpoint was defined as atherosclerotic CV events, cardiac events, and all-cause death.

Results: TyG index were positively correlated with circulating endostatin ($\rho = 0.134$, $P = 0.025$) and vascular adhesion protein-1 level ($\rho = 0.130$, $P = 0.012$). However, TyG index was not significantly correlated with left ventricular systolic and diastolic function, and left ventricular mass index. Patients in tertile 3 of the TyG index showed the highest cumulative event rate of CV events ($P < 0.001$) and cardiac events ($P = 0.001$). In multivariate Cox regression analysis, patients in tertile 3 of the TyG index were significantly associated with a 2.43-fold increased risk of CV events [95% confidence interval (CI) 1.32 – 4.47] and a 2.14-fold increased risk of cardiac events (95% CI 1.27 – 3.61) compared to patients in tertile 1 of the TyG index. However, patient mortality rate did not differ between the TyG index tertiles.

Conclusions: The TyG index was positively correlate with vascular injury markers, and significantly associated with increased risk of atherosclerotic CV events in HD patients. Our study suggests that the TyG index is useful to identify HD patients at high risk of atherosclerotic CV events.

PUB185

Falls in Hemodialysis Centers

Elhadi A. Eltayeb.[1,2] *[1]North Riyadh Hemodialysis Center, Riyadh, Saudi Arabia; [2]King Abdelaziz Medical City, Riyadh, Saudi Arabia.*

Background: 25% of dialysis population fall every year; the outpatient HD center is a particularly high risk- location for falls this is attributed to high prevalence of old age and comorbidities, HD treatment related complications, and frailty. Falls remain a significant cause of morbidity and mortality and contribute to a substantial burden to annual health care costs. A serious fall injury can precipitate functional decline, loss of independence, nursing home placement, and death.

Methods: North Riyadh hemodialysis center is outpatient dialysis facility which looks after 300 hemodialysis patient. We noted on our hemodialysis patients increasing number of falls occurred at the community level. We extended our routine falls screening tool to assess the frequency and outcomes of out of center falls over twelve months' period. Our falls screening tools document type of injuries sustained, hospital admission and also include measures to reduce impact and risk of falls.

Results: The majority of reported falls occurred at out of center (**Fig 1**). Out of center falls are common in males (**64%**), elderly patients (**47%**), patients with multiple comorbidities, frailty, hemodialysis vintage >5 yrs. (**50%**), previous falls, and polypharmacy. Majority of patients sustained soft tissue injuries (**45%**), fractures (**14%),** and head injuries (**14%**). 21 of patients required hospital admission. On further follow up **12%** of patients died of other medical causes.

Conclusions: Falls among prevalent hemodialysis population are under reported, On our HD population the majority of falls taking place at the community level. Identifying patient with high risk of falls may result in measures to reduce the impact on this vulnerable hemodialysis population. We recommend outpatient falls screen tools to record falls at the community level and have protocols on falls prevention including mulitargeted multidisciplinary approach, staffand patient education are important in prevention and reducing impact of falls

PUB186

Five-Year Mortality Outcomes of High-Volume Hemodiafiltration in Mexico: Insights from Real-World Data

Salvador L. Gil, Alfredo Fuentes Mercado, Erika E. Jaime Borja, Victor H. Gomez Johnson, Magdalena Madero. *Instituto Nacional de Cardiologia Ignacio Chavez, Mexico City, Mexico*.

Background: High volume hemodiafiltration (HDF) offers significant benefits for patients undergoing renal replacement therapy. The objective of this study is to evaluate real world data and assess mortality between pre and post dilutional HDF modalities.

Methods: In this observational, cross-sectional, retrospective study we analyzed all prescribed sessions over a 5-year period in our HDF clinic to evaluate overall mortality rates and assess mortality differences between pre- and post-dilutional HDF modalities. The statistical analysis was made using mortality rates and Mantel-Cox test.

Results: 89 patients of whom 66.3% were female were included with a total of 26,047 HDF sessions over the past five years. During the study period, outcomes included 16 deaths, 23 kidney transplants, 5 peritoneal dialysis transition, 1 loss to follow-up, and 2 cases of kidney function recovery. The distribution of vascular access types revealed 59 tunneled catheters, 10 non-tunneled catheters, and 20 arteriovenous fistulas. Patients were further categorized based on HDF modality (table 1.) Mortality rates demonstrated no significant differences between the two HDF modalities, yielding an overall mortality rate of 0.8 per 1,000 population—0.7 for pre-dilution HDF and 0.8 for post-dilution HDF (*logrank*: 0.9785).

Conclusions: No mortality differences were found between pre and post dilutional OL- HDF. Larger studies are warranted to confirm our findings.

Misleading Dialysate Discoloration after Vitamin B12 Infusion: A Case Report

Niloufar Ebrahimi, Sayna Norouzi, Amir Abdi Pour. *Loma Linda University Medical Center, Loma Linda, CA.*

Introduction: Hemodialysis (HD) blood leaks through the dialyzer, may lead to hemolysis, and blood loss and potentially cause hemorrhagic shock in patients undergoing HD. A semipermeable membrane separates blood from the dialysate in the HD machine circuit. An alarm is triggered when blood leaks through the dialyzer membrane and blood flow ceases. Vitamin B12 is easily removed by HD and may appear in the dialysate, causing a red discoloration. Consequently, the dialysate color change can falsely trigger the dialysis machine's blood leak alarm.

Case Description: A 75-year-old Hispanic male with a history of type 2 diabetes mellitus, hypertension, chronic kidney disease stage 3, and chronic systolic heart failure was admitted with acute respiratory failure due to fluid overload. His hospitalization course was complicated by cardiac tamponade, cardiogenic shock, upper gastrointestinal bleeding, and oliguric acute kidney injury requiring dialysis. The patient was initially started on continuous renal replacement therapy (CRRT) and, upon hemodynamic status improvement, was transitioned to intermittent HD. The patient had received a vitamin B12 infusion while in shock, which triggered a false blood leak alarm on the HD machine in two separate sessions. HD was terminated, and a dialysate test confirmed no evidence of blood. The serum vitamin B12 was measured > 2000 pg/mL. The patient remained in kidney failure, necessitating dialysis; therefore, CRRT was resumed with red-color effluent (Figure 1).

Discussion: The dialysate outflow line sensors on HD machines are designed to detect blood, reducing the risk of potential complications from a blood leak. False blood alarms may occur due to non-blood contaminants. Administering high doses of vitamin B12 can trigger blood leak alarms, leading to dialysis treatment termination.

CRRT red-colored effluent

PUB188

Exploring Adequacy Parameters and Survival Patterns in a Brazilian Cohort Undergoing Hemodiafiltration

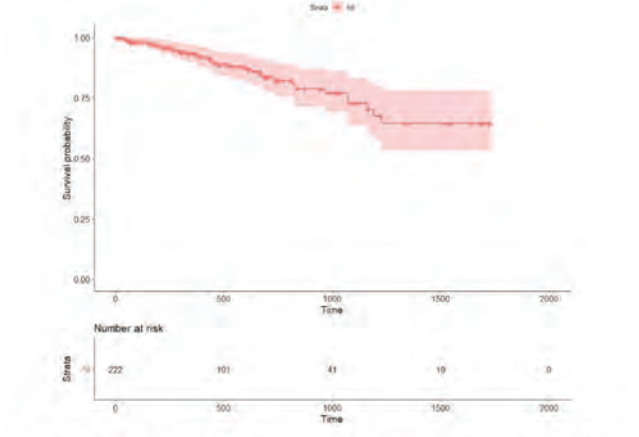
Érica P. Rocha, Christiane Kojima, Daniel M. Costa, Andréa O. Magalhães, Tales D. Vieira, Luis Gustavo Modelli de Andrade, Carolina S. Martins. Nefrostar Kidney Care. *Universidade Estadual Paulista Julio de Mesquita Filho, Botucatu, Brazil.*

Background: Recent evidence suggests a survival benefit of hemodiafiltration compared to conventional hemodialysis. We aimed to analyze the baseline characteristics and survival patterns among patients undergoing hemodiafiltration in a real-world scenario.

Methods: We included a cohort of patients undergoing hemodiafiltration therapy at the NefroStar clinics, ranging from October 2018 to May 2023. We retrieved baseline patient characteristics, the dialysis access method, monthly biochemical exams classified in Kidney Disease Outcomes Quality Initiative (KDOQI) bundles, hospitalization rate, and the follow-up data.

Results: We analyzed a cohort of 223 patients who exclusively underwent hemodiafiltration. The mean convective volume was 67±30 liters per week. The majority of patients achieved the KDOQI-recommended bundles, ranging from 70% for phosphorus to 87% for potassium. The majority of hospitalizations were attributed to vascular access complications, ranging from 2.4% to 15.9%, followed by cardiovascular issues (5.3% to 9.9%) and clinical hospitalization (1.4% to 8.4%). The incidence of catheter-related bloodstream infectious density ranged from 0.02 to 0.1 per 1000 catheters per day. Univariate Kaplan-Meier analysis revealed survival rates for hemodiafiltration at 180 days, with a rate of 93% (90 – 97%), at 730 days, a rate of 83% (77-90%), and at 1095 days, a rate of 73% (63-83%).

Conclusions: We showed significantly lower rates of hospitalization, fewer catheter-related bloodstream infections, and reduced mortality in a real-world cohort of hemodiafiltration patients. These factors warrant further in-depth investigation, particularly with the aim of mitigating mortality rates in the Brazilian dialysis population.



Kaplan-Meier Survival Analysis in a Cohort of Patients exclusively Treated with Hemodiafiltration in Brazil.

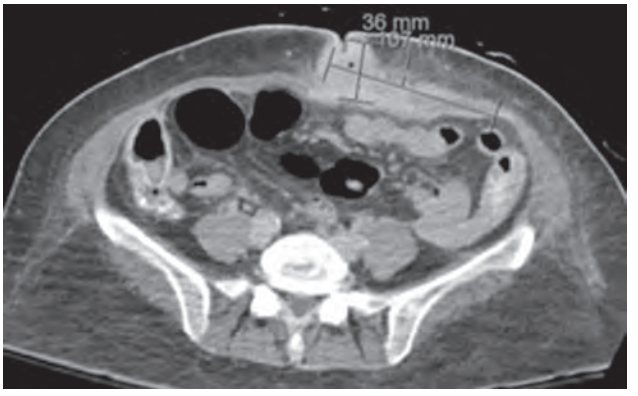
Cat-Induced Pasteurella Peritonitis in a Patient on Peritoneal Dialysis

Matthew Knapp, Shivangi Patel. *Morristown Medical Center, Morristown, NJ.*

Introduction: *Pasteurella multocida* remains a rare, but established cause of peritonitis in peritoneal dialysis (PD) patients.

Case Description: Here we present a 79-year-old female with a medical history of coronary artery disease and end stage renal disease secondary to diabetes mellitus and hypertension, on chronic PD. She presented to her nephrology clinic with fevers and chills and reported that her kitten had chewed through her PD catheter during her overnight PD session. Intraperitoneal ceftazidime was initiated and peritoneal fluid cultures were drawn, which would later reveal *Pasteurella multocida*. Initial CT imaging was unremarkable. Oral levofloxacin was added to her antibiotic regimen. Her symptoms developed into pain and induration around the catheter site. She was hospitalized for IV ceftriaxone and PD catheter removal, and then transitioned to oral cefdinir. Despite this therapy, interval CT findings [Figure] suggested abscess formation along the catheter tract. IV ceftriaxone was restarted and a percutaneous drainage catheter was placed with successful evacuation of the collection. Blood and peritoneal cultures remained negative. She was discharged on 10 days of oral cefixime, recovered well and has since had a new PD catheter placed.

Discussion: *Pasteurella* is a gram-negative coccobacilli that is a common inhabitant of the upper airways of healthy pets, such as cats and dogs. Transmission occurs through biting, scratching, or other contact with nasopharyngeal secretions. Pasteurellosis generally features soft tissue or lower respiratory tract infections, both of which may progress to abscess formation. Given that Pasteurella is isolated from approximately 75% of cat-inflicted wounds, and the bacterium's prevalence in household pets, this case underscores the duty of the clinician to inform the patient of risk factors and adequate preventative measures, such as catheter site protection. Additionally, our case suggests that prolonged IV antibiotics may be necessary when intraabdominal pathology is identified to prevent abscess formation.



PUB190

Influence of Variable Inflow Volume, Dwell Duration, and Dialysate Glucose Concentration on Ultrafiltration Volume in Patients on Automated Peritoneal Dialysis: pPD Study

Tatiana De los Ríos,[1] Isabel Garcia,[2] Jana Schmitt,[1] Manuela Stauss-Grabo,[1] Saynab Atiye.[1] *[1]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [2]Hospital Universitario Son Espases, Palma, Spain.*

Background: In current practice, optimization of peritoneal dialysis (PD) prescription relies heavily on clinical techniques and a trial-and-error process, as prescription must be tailored to achieve a number of outcome goals, given the peritoneal membrane transport characteristics of the patient. So far, developments in practice have made important contributions to the notion of precision PD (pPD). Given the many demands of a PD prescription, ultimately, pPD refers to the process of finding the optimal profile of PD treatment that fits the patient's lifestyle while maintaining homeostasis. The pPD study is designed to investigate the influence of 'dialysis dose variables' (dwell duration, glucose concentration, inflow volume) on ultrafiltration volume per defined dwells in automated peritoneal dialysis (APD) patients.

Methods: This is a prospective, multicenter, interventional pilot study. Ten patients with total weekly Kt/V ≥ 1.7 and treated with the sleep safe or sleep safe harmony PD-cycler (Fresenius Medical Care, Bad Homburg, Germany) will be included. After a training phase and a run-in period of up to 6 weeks, depending on the PD cycler used prior to the study, the interventional phase will be initiated. The interventional phase has 3 subphases; in each of them, one of three 'dialysis dose variables' will be varied: dwell duration (phase A), glucose concentration (phase B), and inflow volume (phase C). This will be followed by a follow-up period of 4 weeks (see figure).

Results: Due to the small sample size, statistical analyses will comprise descriptive statistics and hypothesis testing using non-parametric tests where appropriate.

Conclusions: In this study, dose variables will be evaluated over a wide range, to become part of the clinical toolbox not only for delivering optimal treatment but as a method for peritoneal membrane function assessment. This study aims to collect additional diagnostic information while making repeated observations in the same patient during which the PD prescription undergoes systematic adaptations.

Systolic Blood Pressure (SBP) and Risk of Mortality in Patients on Maintenance Peritoneal Dialysis (PD): A Systematic Review and Meta-Analysis

Viangkaeo Lee,[1] Haleh Siami,[1,2] Vanessa-Giselle Peschard,[1] Mohsen Malekinejad,[1] Emily X. Huang,[1,3] Peggy Tahir,[1] Chi-yuan Hsu.[1] *[1]University of California San Francisco, San Francisco, CA; [2]Islamic Azad University, Tehran, Islamic Republic of Iran; [3]Bates College, Lewiston, ME.*

Background: A great deal of uncertainty exists regarding management of hypertension among maintenance PD patients. The International Society for Peritoneal Dialysis (ISPD) recommends targeting SBP <140 mmHg based on "very low" quality evidence. Recognizing the lack of randomized controlled trials, we conducted a systematic review of observational studies to examine the association between SBP and all-cause mortality.

Methods: We searched PubMed, Web of Science, Embase, CINAHL and Cochrane Library databases up to April 2023 and abstracts from the 2019-2023 ASN, ISN, and NKF meetings followed by dual study screening and data extraction. We included patients on any non-acute PD types regardless of kidney failure cause. We defined SBP 100-140 mmHg as reference, pre-specified decision rules to group data for pooling, and combined data to estimate pooled risk ratios (RR) using random-effects models.

Results: Of 3,546 peer-reviewed records, 28 full-text studies and 1 abstract were eligible (and 1 conference abstract). Out of eight assessed bias domains, most studies had issues with comparability of the BP groups and the incomplete capture of prognostic factors. Based on one-time baseline measurement (i.e. not time-updated), SBP >140 (vs. 100-140) mmHg was associated with a 15% increase in risk of all-cause mortality (RR=1.15; 95%CI: 0.99-1.34) (Figure). SBP <100 (vs. 100-140) mmHg was associated with even higher risk (RR=1.79; 1.38-2.32). Similar results were seen in sensitivity analyses. There was high degree of heterogeneity across all meta-analyses (I^2 range: 54-88%).

Conclusions: The existing epidemiologic literature provides limited guidance due to a high degree of heterogeneity and concerns regarding bias. But it does lend some support to the current ISPD guideline targeting SBP <140 mmHg. SBP <100 mmHg is associated with highest risk of death, but that is not a plausible consideration as a treatment target.

PUB192

The "Silent" Threat: Group G Streptococcus Peritonitis in Peritoneal Dialysis

Lucinda Lau,[1] Stefano Benincasa,[1] Rachel S. Nash.[1,2] *[1]Rowan University Cooper Medical School, Camden, NJ; [2]Cooper University Health Care, Camden, NJ.*

Introduction: Peritoneal dialysis (PD) is a therapy for patients with end-stage renal disease (ESRD). PD carries an increased risk of peritonitis, often secondary to poor technique. A small subset of patients may present with "silent" peritonitis, or peritonitis in the absence of fever and abdominal pain, making diagnosis and treatment challenging. Identification of a causative organism can be an added barrier further delaying care.

Case Description: A 95-year-old female with a history of ESRD on PD presented with two days of progressive fatigue, confusion, and lower leg pain and swelling. On exam, a shallow, ulcerated wound with purulent drainage was found on the left lateral leg. Laboratory testing was significant for leukocytosis and group G streptococcus (GGS) grown on blood cultures. Treatment with vancomycin and ceftriaxone did not yield significant improvement, prompting investigation of PD dialysate as a potential source. The patient was afebrile with persistent leukocytosis and no clinical signs of peritonitis. Peritoneal fluid analysis revealed increased cellularity with neutrophilic predominance suggesting peritonitis despite negative cultures. Intraperitoneal ceftriaxone and prophylactic fluconazole were added to the patient's nightly PD dwell. Repeat blood and PD fluid cultures were negative. However, the patient was ultimately transitioned to comfort measures before passing shortly thereafter.

Discussion: Commonly, PD peritonitis is caused by gram positive organisms, such as Staphylococcus and Streptococcus species, with the ability to create biofilms on nonbiologic surfaces. GGS is a rare cause of peritonitis, more commonly present on the skin and in the urogenital and gastrointestinal tracts. Still, research investigating its effect on the presentation of peritonitis is sparse. It is important to remain cognizant of PD peritonitis in patients receiving PD therapy even in the absence of classic symptomatology. Risk factors such as advanced age, dementia, altered mentation from sepsis, or uncommon organisms may create an atypical presentation, delaying diagnosis and treatment. High rates of morbidity in peritonitis with concomitant bacteremia make early treatment even more crucial.

PUB193

Report of Laparoscopic Findings of PD Catheter Replacement after Catheter Removal Due to Refractory Peritonitis in Patients on PD

Hiroaki Io,[1] Hiroyuki Iwasaki,[1] Toshiki Kano,[1] Kunimi Maeda,[1] Yusuke Suzuki.[2] *[1]Juntendo University Nerima Hospital, Nephrology & Blood Purification Center, Tokyo, Japan; [2]Juntendo University Faculty of Medicine, Tokyo, Japan.*

Introduction: There are no reports of laparoscopic findings in peritoneal dialysis (PD)-related peritonitis. We have previously reported laparoscopic imaging findings at the end of PD (KI Reports 2016, Nephrology 2023), and repeated peritonitis is a risk factor for peritoneal degeneration (Semin Dial 2020).

Case Description: We investigated laparoscopic findings observed during catheter removal and re-placement for intractable peritonitis at our hospital. Intraperitoneal findings were variable. In cases of Mycobacterium/MRSA, strong pseudo membrane formation and adhesions were observed, and differences in localization and severity were observed. In all cases several years had passed without complications of encysted peritoneal sclerosis. In the case of Corynebacterium, there was almost no evidence of inflammatory changes in the abdominal cavity, and PD was reintroduced 2 months later. In the case of Pseudomonas aeruginosa, there were strong signs of intraperitoneal adhesions and fibrin occlusion, which led to the removal of the PD catheter. Three years later, due to the patient's strong desire to restart PD, laparoscopic observation showed that the adhesions were improving over time and were easy to remove with forceps, so PD was reintroduced. However, due to insufficient water removal, the patient was used in PD+HD combination therapy.

Discussion: Although it is difficult to infer the intraperitoneal cavity from clinical findings, we believe that the decision to re-place a PD catheter should be made carefully in cases of peritonitis that exhibit strong inflammatory changes, especially Pseudomonas aeruginosa. Laparoscopic findings at the time of PD catheter removal in patients with refractory peritonitis may be helpful in evaluating the possibility of restarting PD.

PUB194

Peritoneal Dialysis in Developmental Disability

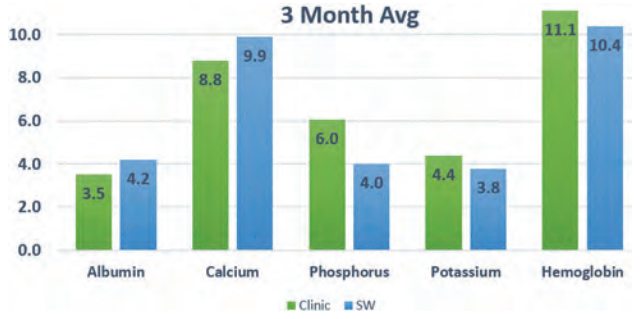
Stacey Rall, Amy Peregord, Catherine M. Poslaiko, Tracey A. Doss-Simmons, Rachel L. Perlman. Canton PD Unit. *University of Michigan Michigan Medicine, Ann Arbor, MI.*

Introduction: Although not well described, peritoneal dialysis (PD) should be considered for adults patients who cannot participate in their own care. SW is a 30 yo with renal dysplasia and significant developmental disabilities (dd) due to cerebral palsy. We present our experiences as an interdisciplinary team managing SW's care with the goal of increasing provider confidence in providing PD to patients with significant dd.

Case Description: Social Work: SW is minimally verbal, requires a wheelchair and is totally dependent on her parents. Her cognitive disability impacts her ability to express what she is feeling or experiencing, even to her parents. MD: We were concerned about how SW would tolerate PD and how we would assess her well-being. Catheter was placed in the OR with careful attention to exit site location based on her kyphoscoliosis, incontinence, and need to avoid her pulling on it. SW typically sleeps well and we use a cycler program for safety and simplicity. She has had no peritonitis over 3 years. RN: Visits require parent involvement and 2-3 staff for blood draws. Care has become routine and works smoothly at home and clinic. We had initial concerns but have seen her thrive and travel with family. Dietitian: Nutrition challenges have included selective eating and

meeting calorie needs. Interventions include a focused, liberalized diet and powdered phosphate binders. SW has stable weight and routine labs are favorable compared to our clinic and KDOQI guidelines (see table). Parents: We were responsible for making decisions for our daughter, we could not engage her in the process, and we could not agree on a course of action. We were paralyzed with fear because it seemed like PD required specialized training. We found a clinic that was warm, welcoming and had a very "can do" attitude. Our daughter has now been on PD for 3 years. At every turn, we have felt supported by the clinic staff.

Discussion: Take aways: Interdisciplinary collaboration, including with parents, has enabled successful PD. We modified some practices to meet SW's needs, but caring for her is not disruptive to our clinic.



PUB195

Clinical Performance of the Therapy Option FlexPoint (Flexible Volume and Dwell Time Management) of the PD Cycler Sleep Safe Harmony

Jana Schmitt,[1] Maite Rivera Gorrin,[2] Tatiana De los Ríos,[1] Manuela Stauss-Grabo.[1]
[1]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [2]Hospital Universitario Ramon y Cajal, Madrid, Spain.

Background: While adequate removal of fluid, uremic toxins and sodium may be regarded as cornerstones of clinical homeostasis, modern peritoneal dialysis (PD) therapy should ideally deliver also on a number of other fronts that relate to lifestyle and quality of life. FlexPoint therapy option – flexible volume and dwell time management – of the Fresenius PD cycler sleep safe harmony allows to shorten cycle phases where no effective dialysis takes place without compromising patient's comfort and dialysis targets. The prescribed therapy is automatically adjusted within defined, medically acceptable limits for residual volume, inflow volume, dwell duration, as part of flexible management, without triggering alarms. In addition to medically reasonable default values, physicians can adapt the limit values for the individual options to the patient.

Methods: The study (NCT06390592) is an interventional, randomized, crossover trial designed to evaluate whether usage of the therapy option FlexPoint influences the efficacy of APD treatments, by assessing total Kt/V, mean daily ultrafiltration, as well as the hydration status of PD patients. During the six-week clinical phase 24 patients are continuously treated with the sleep safe harmony PD-cycler according to their prescription. The clinical phase is divided into 3 study phases of 2 weeks each which only differ in the FlexPoint settings. The patient's treatment during the clinical phase will follow a randomized scheme of treatment sequences using a Williams 6*3 cross-over design. To evaluate patient perspectives, questionnaires on quality of life and sleep are completed. Patient-reported outcomes and clinical data are recorded at baseline and the end of the second treatment week during the clinical phase.

Results: For primary analysis, three pairwise comparisons between the treatment settings will be performed to assess equivalence with respect to total Kt/V. All secondary efficacy and safety variables are summarized descriptively by treatment setting and where appropriate also for pairwise treatment differences.

Conclusions: The study aims to demonstrate that individualized volume and dwell time management during the treatment does not influence the PD treatment efficacy but improves the patient's well-being.

PUB196

Gastrointestinal Manifestations of Long-Term Effects after COVID-19 Infection in Patients on Peritoneal Dialysis: A Single-Center Observational Study

Zhen Zhuang, Yuehong Li, Mingxia Cao, Wen Wen. *Beijing Tsinghua Changgung Hospital, Beijing, China.*

Background: Long-term symptoms of peritoneal dialysis patients after COVID-19 infection, especially gastrointestinal (GI) symptoms, may be a potential risk factor for long-term prognosis of peritoneal dialysis patients.

Methods: A retrospective analysis was conducted on peritoneal dialysis patients who were regularly followed up at the peritoneal dialysis center from January 2020 to July 2023. Clinical and laboratory examination data were collected for analysis. The occurrence and severity of gastrointestinal symptoms after COVID-19 infection were evaluated by questionnaires using the gastrointestinal symptom rating scale (GSRS). A total of 20 patients underwent gastroscopy.

Results: 1. A total of 67 patients were included. 59 patients (88.1%) were found to be positive for the COVID-19 virus. Gastrointestinal symptoms were observed in 81.4% of cases (Fig 2). Gastrointestinal symptoms were noted to appear later but had a longer duration (Fig 1). 2. It was summarized that 10 patients in each of group (before and after the epidemic, time node 2022/12/01) completed gastroscopy. None of them had serious complications such as bleeding and peritonitis. Pations in the post-epidemic group had more gastrointestinal symptoms and more positive findings under gastroscopy (Chart 1 and 2). There were more complex and higher-grade lesions under gastroscopy in this group (Tab 1) (Fig 3). 3. It was found that Pations in the post-epidemic group had a higher history of taking hormones or NSAIDs drugs, lower plasma albumin and serum sodium levels, and higher CRP (Tab 2).

Conclusions: The gastrointestinal symptoms are more common in patients with peritoneal dialysis after COVID-19 infection, including reflux esophagitis and peptic ulcer. The symptoms of long COVID after the epidemic are related to the nutritional and inflammatory status of patients. Gastroscopy is of great significance in diagnosing gastrointestinal diseases in PD patients.

PUB197

Concordance between Dialysate-to-Plasma (D/P) Ratios for Urea and Creatinine in Peritoneal Equilibration Testing: A Retrospective Observational Cohort Study

Lohith S. Chatragadda,[1] Susie L. Hu,[2] Ankur Shah.[2] *[1]University of Rhode Island, Kingston, RI; [2]Brown University Warren Alpert Medical School, Providence, RI.*

Background: Peritoneal equilibration testing (PET) is a crucial tool for assessing peritoneal membrane function in patients undergoing peritoneal dialysis (PD). The dialysate-to-plasma (D/P) ratios of urea and creatinine are commonly used to evaluate peritoneal transport characteristics. This study aimed to assess the concordance between D/P Glucose and D/P creatinine in PET and identify factors associated with discordance.

Methods: A retrospective observational cohort study was conducted using data from PD patients who underwent PET between 1/1/2015 and 12/31/2021 at a single PD center. Demographic, clinical, and PET data were collected from electronic medical records. Concordance between D/P urea and D/P creatinine was assessed using the spearman rank correlation coefficient.

Results: A total of 67 PD patients (mean age: 54.5±2.1 years; 40.3% male) were included in the study. The mean 4 hour D/P glucose and D/P creatinine were 0.78±0.02 and 0.37±0.05, respectively. Spearmans rho between 2h and 4h Glucose was .9058 and Spearmans rho between 2h and 4h Creatinine was .8713. Discordance between 4h glucose and 4h creatinine was observed in 20 (29.8%) patients. Spearmans rho between D/P glucose and D/P creatinine was 0.79. In discordant pairs, 4h creatinine was better correlated than 4h glucose with 4h UF (rho .23 vs .19).

Conclusions: In this retrospective observational cohort study, we found a strong correlation between D/P glucose and D/P creatinine in peritoneal equilibration testing (PET) among peritoneal dialysis (PD) patients. The high Spearman's rho values between the 2-hour and 4-hour measurements for both glucose and creatinine suggest that these markers provide consistent information about peritoneal transport characteristics over time. However, discordance between 4-hour D/P glucose and 4-hour D/P creatinine was observed in nearly 30% of patients. This finding highlights the potential limitations of relying on a single marker to assess peritoneal membrane function. In cases of discordance, 4-hour D/P creatinine showed a slightly stronger correlation with 4-hour ultrafiltration compared to 4-hour D/P glucose, suggesting that creatinine may be a more reliable indicator of peritoneal transport when the two markers are discordant.

PUB198

Refined Management of Serum Potassium Is Necessary in Patients on Peritoneal Dialysis

Mingxia Cao, Yuehong Li, Zhen Zhuang. *Beijing Tsinghua Changgung Hospital, Beijing, China.*

Background: Chronic renal failure is a high risk factor for hyperkalemia but is generally considered to be rare in peritoneal dialysis patients.

Methods: 86 patients with peritoneal dialysis who were followed up regularly every month in the outpatient clinic from January 2022 to February 2023 were selected as the research subjects and followed up for one year. Collect general data such as gender, age, dialysis age, primary disease, weight, blood pressure, urine output, etc. Dialysis data: peritoneal dialysis method, whether the abdomen is persistent, treatment volume, ultrafiltration volume, Kt/v, Ccr, etc; biochemical indicators : Hemoglobin, parathyroid hormone, NT-proBNP, albumin, blood sugar, calcium, phosphorus, potassium, sodium, chlorine, carbon dioxide, etc.

Results: 1. There were 48 patients with CAPD and 38 patients with APD. There were no statistics on weight, age, kt/v, diastolic blood pressure, hemoglobin, parathyroid hormone, BNP, albumin, blood sugar, calcium, potassium, chloride, and carbon dioxide between the two groups (Tab1). 2. The incidence of hyperkalemia was 12.98%, if the threshold for diagnosing hyperkalemia defined as K>5.0 mmol/l (2.33% K≥5.5mmol/L) (Fig1). 62.5% of patients with hyperkalemia relapse within one year (Fig2). 3. There were 50 patients dwell abdomen. The occurrence of hyperkalemia was related to dry abdomen (P=0.031). (Tab2)

Conclusions: The study found that peritoneal dialysis patients are also a high-risk group for hyperkalemia, especially those with poor residual renal function or dry abdomen. The threshold for diagnosing hyperkalemia defined as K>5.0 mmol/l, which significantly improves the diagnostic efficiency of hyperkalemia. We can detect the risk of hyperkalemia early, avoid recurrence of hyperkalemia, and reduce the risk of cardiovascular mortality in patients with peritoneal dialysis.

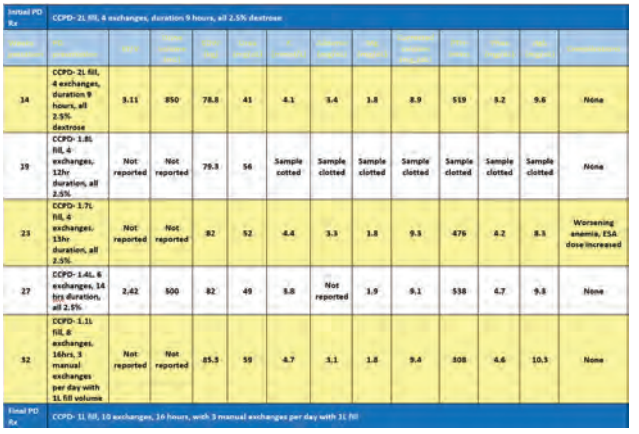
A Case of Persevering on Peritoneal Dialysis through Pregnancy

Farah Abifaraj,[1] Elias C. Ghandour,[2,3] Bernard G. Jaar.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]MedStar Good Samaritan Hospital, Baltimore, MD; [3]MedStar Union Memorial Hospital, Baltimore, MD.*

Introduction: Hemodialysis (HD) is often the preferred modality in pregnancy as patients undergoing PD have been found to be less likely to deliver successfully, historically. There have also been concerns over difficulty achieving necessary clearance with peritoneal dialysis as a pregnancy progresses, resulting in various possible maternal and/or fetal complications.

Case Description: We present a case of a patient with end stage renal disease due to biopsy proven class IV lupus nephritis on continuous cyclic peritoneal dialysis (CCPD) who was maintained on PD throughout her pregnancy. She required careful lab monitoring and frequent prescription adjustment to maintain adequate clearance throughout her pregnancy. She went into labor spontaneously at 33 weeks and had an uncomplicated vaginal delivery.

Discussion: With close monitoring, and careful adjustment of the dialysis prescription and a patient's willingness to adjust to the changing and intensifying prescription, PD can be safely maintained throughout a pregnancy.



PUB200

Frequency of Routine Blood Work among Patients on Chronic Dialysis: A Narrative Review

Alessandro Cau,[1] Rajinder SIngh,[1,2] Adeera Levin.[1,3] British Columbia Renal Agency. *[1]The University of British Columbia, Vancouver, BC, Canada; [2]Vancouver General Hospital, Vancouver, BC, Canada; [3]Saint Paul's Hospital, Vancouver, BC, Canada.*

Background: Home dialysis patients, including both those on hemodialysis and peritoneal dialysis, undergo monthly blood testing to identify and correct harmful laboratory abnormalities such as hyperkalemia and assess for dialysis adequacy. The frequency and utility of testing, however, is not supported by available evidence and is largely based on historical practice and expert consensus. While early identification and correction of critical laboratory values may theoretically lead to improved clinical outcomes, unnecessary testing has implications on patient quality of life, practitioner workload, use of healthcare resources and the environment. Frequent monitoring of a highly variable laboratory value (i.e., phosphate) will lead to over- or under-treatment where no outcome data exists.

Methods: PubMed search identified literature on blood work frequency amongst dialysis patients of any modality. Search strategy included keywords related to blood work, lab work, frequency, and dialysis modalities. Separate searches were also performed to identify studies addressing a similar question in patients with other chronic diseases such as kidney transplant recipients and diabetes. Reference lists of relevant studies were also screened. Studies were included if they were relevant to our population of interest and addressed either the evidence behind or consequences of routine monthly blood work.

Results: Overall, there are no randomized controlled studies on this topic to date. There were four observational studies comparing outcomes between in-centre hemodialysis patients undergoing monthly blood work and those receiving less frequent blood work. Of those four studies, two were conducted in Canada, one in Lebanon and one in Korea. There were no studies of patients on home dialysis including peritoneal dialysis or hemodialysis.

Conclusions: There is a paucity of evidence underpinning monthly routine lab testing among home dialysis patients. Furthermore, there is little available evidence to suggest that it is unsafe to undergo less frequent testing. More high-level evidence is needed to inform an appropriate testing frequency in these patients which in turn, has the potential to transform care at the patient, provider, system, and planetary levels.

PUB201

Analysis of Anemia Management Protocol in Home Dialysis

Paul W. Davis, David Ramirez, Elsa Olson, Andrea G. Kattah. *Mayo Clinic Minnesota, Rochester, MN*.

Background: Anemia is a common complication of chronic kidney disease with multiple possible etiologies and management options. Given the prevalence of anemia within patients on dialysis, diagnosis and management can be burdensome with a significant impact to quality of care. To provide safe and effective care for patients on dialysis, many in-center dialysis units utilize nursing protocols for managing anemia with success. The objective was to assess the effectiveness of a similar protocol for home dialysis patients.

Methods: An anemia management protocol outlining decisions for identifying home dialysis patients with anemia and assessing for need of intravenous iron repletion and/or erythrocyte stimulating agents (ESA) was implemented on 5/1/2022. Patient data were assessed for effects on hemoglobin, ferritin, and transferrin saturation (TSAT) before and after the date of implementation. ESA drugs were mailed from a central pharmacy and iron was repletion was given either at home or at an infusion center for peritoneal dialysis (PD).

Results: A cohort of 133 home dialysis patients, encompassing both PD and home hemodialysis (HHD), was analyzed from 5/1/2022 to 5/31/2023. The median hemoglobin levels were 10.5 g/dL (IQR: 9.7-11.3) prior to protocol implementation and 10.5 g/dL (IQR: 9.7-11.5) post-implementation; p-value 0.56. Median ferritin levels increased from 405 ng/mL (IQR: 237-610) pre-implementation to 424 ng/mL (IQR: 263-737) post-implementation; p-value 0.19. Median transferrin saturation (TSAT) rose from 28% (IQR: 20.5-36) to 30% (IQR: 24-38); p-value 0.11. Among patients receiving erythropoiesis-stimulating agents (ESAs), the incidence of hemoglobin values exceeding 12 g/dL decreased from 28 cases pre-implementation to 12 cases post-implementation.

Conclusions: Overall, it appears that implementation of anemia management protocol was at least as effective as solely provider directed management. There was a trend toward fewer episodes of Hb > 12 mg/dL which could represent lower exposure to ESAs. Other potential benefits of such a protocol include reduced provider burden and reduced unit cost and improved patient safety with lower ESA exposure and fewer blood transfusions; however, further analysis and studies are needed to elucidate statistically significant results and other impacts, including implementation of newer agents such as hypoxia-inducible factor prolyl hydroxylase Inhibitors.

PUB202

The Impact of Urgent-Start Peritoneal Dialysis on Related Peritonitis, Mechanical Complications, and Hospitalization Rate in Qatar

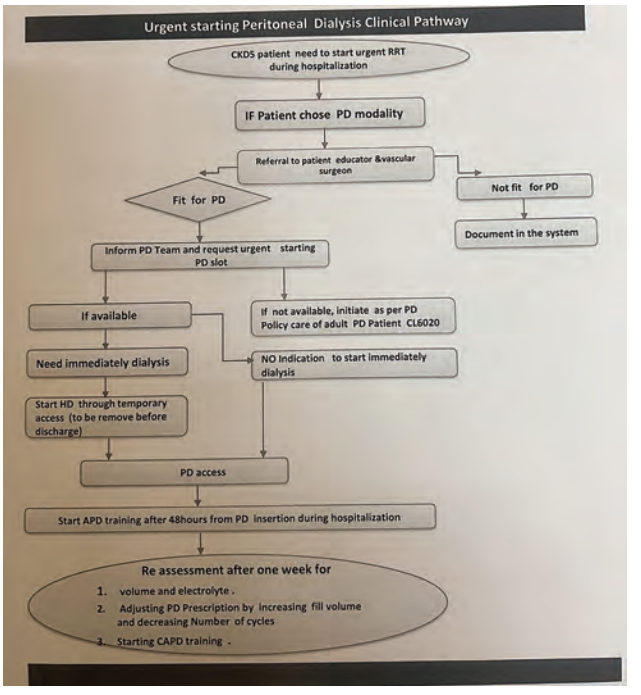
Mohammed E. Hussain, Mohamad M. Alkadi, Hanaa Ahmed, Sahar Aly, Reyrita Katrina P. Tariga, Michelle cruz Futotana, Thoraya A. Alabdulla, Abdullah I. Hamad, Hassan A. Al-Malki. *Hamad Medical Corporation, Doha, Qatar*.

Background: Urgent start Peritoneal dialysis by starting PD 48 hrs. after catheter insertions is a safe, efficient with a significant reduction in bacteremia comparing to HD in acute unplanned dialysis settings.

Methods: We identified CKD-5 patients during ED visits as either having an earlier plan for PD as a dialysis modality or having no plan. Emergency and urgency need to start dailysis was evaluated. We created an Urgent Start PD pathway for those patients without the emergency need to start or who had an emergency need and became stable after starting HD through a temporary dialysis catheter (review attached Clinical pathway). We enrolled twenty-four patients (14 % of all PD patients) from October 2022 till April 2024, all of them were started on APD as the PD model, the final PD model was decided after completing both APD and CAPD training. Body surface area was the main factor that affected APD Prescription (duration, number of cycles, fill volume). PD-related peritonitis, mechanical complications and hospitalization rates were estimated till April 2024.

Results: PD-related peritonitis rate is significantly reduced (Zero episodes) compared with Conventional starting PD (0.26 episodes/patient/year) with no ED visit related to PD complications. One patient developed a small inguinal hernia that was conservatively managed without surgical intervention.

Conclusions: In this limited observation, Urgent start PD seems to be associated with decreased PD-related peritonitis rate and hospitalization rate with minor resolved incidence of mechanical complications. A larger number of patients and a longer duration are needed to generalize the findings of these observations.



PUB203

Serum Potassium Behavior in Patients on Peritoneal Dialysis: A National Cohort Study from the Dominican Republic Health System

Sergio O. Hernandez-Ordonez,[1,2] Erwin I. Campos,[1,3] Elianny Polanco,[1] Zulma Lara,[1] Miguel A. Cuevas Budhart,[4] Alfonso Ramos.[1] *[1]Macrotech, Santo Domingo, Dominican Republic; [2]Universidad Nacional Autonoma de Mexico Departamento de Educacion Medica, Tlalnepantla, Mexico; [3]Hospital Salvador B. Gautier, Santo Domingo, Dominican Republic; [4]Instituto Mexicano del Seguro Social Coordinacion de Investigacion en Salud, Ciudad de Mexico, Mexico*.

Background: Dyskalemia in peritoneal dialysis (PD) patients is clinically important due to its association with increased morbidity and mortality. The aim of this study is to describe the alterations in serum potassium (K^+) values in a national cohort of PD patients within the National Health System (SNS) of the Dominican Republic.

Methods: This is a cross-sectional cohort study of 1,080 prevalent PD patients. Biochemical, demographic, and clinical variables were recorded. Simple frequencies were evaluated, with measures of central tendency and dispersion. For differences between groups and due to their heterogeneity, the non-parametric Kruskal-Wallis test was used. To identify differences in means, the X^2 test was used for categorical variables. The population was stratified into three groups based on the following K^+ cut-off points: hypokalemia <3.5 mmol/L, hyperkalemia >5.1 mmol/L, and normokalemia for values between these margins.

Results: The cohort mean age was 56yo, 59% where male, 91% hypertensive, 48% DM, 67 use diuretics and 82% CAPD. The mean K^+ level was 4.7±0.83 mmol/L. The variables with significant differences according to K+ levels were weight (p=0.017), phosphorus (P) (p<0.001), and albumin (p=0.004). The correlation betwen K^+ with albumin and time on dialysis (r=-0.026, p=0.391) was not significant. However, a positive correlation was found between P and K^+ levels (r=0.253, p<0.001). The variables that best explain hypokalemia (regression model) are P (β=0.603, p<0.001, 95% CI:0.492-0.740), albumin (β=0.595, p=0.016, 95% CI:0.389-0.909), diuretics (β=0.512, p=0.009, 95% CI:0.309-0.847), and PD modality (β=1.866, p=0.029, 95% CI:1.067-3.264). The variables that best explain hyperkalemia were age (β=1.024, p<0.001, 95% CI:1.024-1.035), P (β=1.361, p<0.001, 95% CI:1.242-1.492), and type of therapy (β=2.367, p<0.001, 95% CI:1.446-3.875)

Conclusions: In our cohort, hyperkalemia is the most common disorder and is associated with higher albumin levels and hyperphosphatemia, indicating a link to greater food intake and better nutritional status. Hypokalemia was observed with hypophosphatemia and hypoalbuminemia. Since diuretic use is associated with hypokalemia, we recommend closer monitoring of potassium levels in patients with residual renal function who use diuretics.

Effusion Confusion: The Tale of a Pleuro-Peritoneal Fistula

Fiona Murphy,[1,2] Luke Harris,[2] Bradley R. Salonen.[1] [1]*Mayo Clinic Minnesota, Rochester, MN;* [2]*University of Galway, Galway, Ireland.*

Introduction: Pleural effusions are common in patients on peritoneal dialysis (PD). A pleuroperitoneal fistula (PPF) is an important cause. Delays in diagnosis can lead to worsening of pleural effusions, particularly if a mistaken suspicion of fluid overload leads to the escalating use of high osmolar peritoneal dialysate fluids and volumes with the aim to achieve better ultrafiltration.

Case Description: A 78-year-old female presented with 10 days of dyspnoea. She had autosomal dominant polycystic kidney disease (PCKD) on PD. She was commenced on PD 12 weeks prior. She has right sided stage IIIA lung cancer in remission. On examination she was tachypneic, with absent breath sounds on the right and volume overloaded. Blood workup was unremarkable. Chest X-ray (CXR) showed a right pleural effusion. Pleural tap was performed. She was diagnosed with a PPF, given that pleural glucose was significantly higher than serum, in addition to her unilateral effusion. (Table 1) A dialysis catheter was placed and she transitioned to hemodialysis.

Discussion: In a patient undergoing peritoneal dialysis with a unilateral pleural effusion, special consideration must be given to a possible PPF. The estimated incidence is less than 2%. A risk factor for PPF is PCKD. PCKD leads to high intra-abdominal pressure could lead to an increased pleuroperitoneal pressure gradient. For diagnostics a pleural glucose concentration higher than serum is highly suggestive of a PPF. The long-term management of a PPF depends on its severity and patient preference.

Pleural Fluid Analysis

PUB205

A Retrospective Analysis of Peritoneal Dialysis Catheter Reinsertion over 11 Years

Emma C. Morganti, Bhrigu Raj Sood. *Epsom and Saint Helier University Hospitals NHS Trust, Carshalton, United Kingdom.*

Background: Increasing peritoneal dialysis uptake is limited by the shortened treatment time on PD compared with in-centre HD. A transition from PD to HD is costly, and associated with morbidity and impaired quality of life. There are numerous reasons why a PD catheter may need to be removed, and there is significant variability in patients having opportunity to return to PD. We retrospectively analysed a sample of PD catheter insertions to assess impact of our practice to reduce permanent transfer to HD over 11 years in our renal unit.

Methods: A sample of 583 of 1061 PD catheter insertions from 01/01/2013 to 31/12/2023 in a renal unit were reviewed. Electronic databases were reviewed for catheter duration, removal reason, whether reinserted, interim management and duration of management where available.

Results: The 583 catheters reviewed related to 448 distinct patients. 21.4% remained in situ at the completion of follow up (31/12/2023). Of the removed, 45% were removed for reasons which would not warrant consideration of reinsertion (transplantation 14.4%, death 11.5%, failure of PD 9.4%, patient preference 9.4%, regain of native renal function 0.7%). Of the 55% which were removed for reasons which could allow for potential reinsertion (infection, malposition, accidental removal, hernias or leak), 53.8% were reinserted. The percentage of patients having reinsertion of catheters varied across years from 43.5 to 72.7%. Interim management for 83 of the reinserted catheters showed 8.4% had a catheter reinserted on the same day, 49% had no interim renal replacement therapy, and 42.2% had interim haemodialysis.

Conclusions: PD is often the preferred form of renal replacement therapy for many patients, but a significant proportion transfer to HD within 2 years of starting PD. Supporting appropriate patients to return to PD varies amongst units. In this sample 54% of catheters removed for an indication which did not preclude reinsertion were reinserted, allowing ongoing access for PD. There is little information available to compare this with practices from other units. This study is limited as it is only sample of the data, and it was difficult to delineate decisions processes around whether reinsertion was appropriate from the available records. Going forward, we would aim to review all PD catheter insertions and removals for the time period and analyse what variables impacted outcomes.

PUB206

A Rare Case of Stenotrophomonas maltophilia-Refractory Peritonitis in a Patient on Automated Peritoneal Dialysis

Laurene M. Asare, Aisha Abbasi, Jade M. Teakell. *The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX.*

Introduction: *Stenotrophomonas maltophilia* is a multidrug-resistant gram-negative bacillus common among the severely immunocompromised population and is associated with a high morbidity and mortality. Additionally, *S. maltophilia* in peritoneal dialysis (PD) population is also associated with loss of PD catheter and poor prognosis. We present a case of *S. maltophilia* refractory peritonitis in a PD patient.

Case Description: An 85 year-old woman with end stage kidney disease on peritoneal dialysis was admitted for refractory peritonitis and PD catheter dysfunction. Four weeks prior, the patient was diagnosed with *S. maltophilia* peritonitis. Initial effluent cell count was 800/uL (51% neutrophils, 38% monocytes). Treated with empiric intra-peritoneal vancomycin and cefepime followed by cefpodoxime for 4-weeks. Despite symptomatic improvement, repeat peritoneal effluent analysis showed greater than 600 WBC/uL (74% neutrophils, 25% monocytes) suggestive of refractory peritonitis. Antibiotics were changed to trimethoprim/sulfamethoxazole and levofloxacin, and PD catheter was removed. She transitioned to temporary thrice weekly hemodialysis with plan to return to PD.

Discussion: *S. maltophilia* is an emerging multidrug-resistant opportunistic pathogen; it can be found in water, soils, and on rhizomatous plants. *S. maltophilia* peritonitis is a rare finding in patients on peritoneal dialysis. Its presence poses a therapeutic challenge and is often associated with poor prognosis. We present here a case of an elderly patient found to have refractory *S. maltophilia* peritonitis. *S. maltophila* infections commonly present in patients who are immunocompromised although our patient was immunocompetent. Interestingly, this patient is an avid vegetable gardener, and thus touch-contamination may have been the source. International guidelines recommend dual antibiotic coverage for environmental gram-negative bacteria such as *Pseudomonas* and *Stenotrophomonas*; special attention was paid to treatment of Stenotrophomonas in most recent guideline update. This case highlights the importance of considering this organism in patients with PD peritonitis regardless of their immunocompetence, the importance of hand hygiene, and also spotlights the resistant nature of the organism prompting us to be more vigilant when presented with such case.

PUB207

Urgent Bedside PD Catheter

Tushar S. Malavade,[1,2] Naeim G. Salah.[1,2] [1]*University Health Network, Toronto, ON, Canada;* [2]*University of Toronto, Toronto, ON, Canada.*

Introduction: PD catheter for ESRD is an elective procedure is done by surgeons, interventional radiologists (IR), or nephrologists. We describe a successful bedside PD catheter insertion and immediate initiation of PD in a uremic patient, with hypoxia, and hyperkalemia with no bowel preparation.

Case Description: A 38-year-old patient with diabetic nephropathy was on 5/week HD for 5 years. He had failed multiple accesses for HD including temporary and tunneled catheters, AV grafts, trans-lumbar dialysis catheter. The accesses were complicated with CRBSIs, and central venous stenosis needing multiple interventions including angioplasties, and thrombolytics. He had inefficient HD and persistent pruritus, leading

to the pulling of the HD catheter on multiple occasions. He was recently admitted with infective endocarditis, mitral regurgitation, and heart failure. His tunnelled internal jugular catheter was again dislodged. While waiting 2 days for a new HD catheter placement by IR, he developed uremia in the form of myoclonus, orthopnea, hypoxia needing Oxygen and refractory hyperkalemia. IR staff evaluated all the vascular accesses and concluded that no further HD CVC could be placed. A decision was taken to place a bedside PD catheter on an urgent basis. The bowel prep was given 3 hours before the procedure. The patient was hypoxic needing 6 lits of O2 and with 30° head elevation. Under mild sedation, using ultrasound, a midline supraumbilical coiled double-cuffed Tenchkoff PD catheter was inserted at the bedside by the nephrology team. After confirming good inflow and outflow, we were able to start the PD on the table itself with 4.25% dextrose PD solution and continued with low volume, supine, cycler PD with 4.25% solution. His UF was 1.3 lits in 24 hours. There were no complications like leak, bleeding or perforation. After a week, the patient was on room air, with no uremic features and electrolyte imbalances. His PD was continued with low volume cycler, supine PD.

Discussion: Bedside PD catheter placement for the immediate start of PD is not commonly done. Our patient did not have any vascular access for HD and we had to do urgent PD catheter insertion and start PD immediately as life life-saving measure as he was getting uremic, hypoxic and hyperkalemic and with no bowel preparation. Fortunately, there was no PD leak in short-term follow-up.

PUB208

Optimizing Renin Angiotensin-Aldosterone System Inhibition (RAASi) for Kidney Function Preservation in Peritoneal Dialysis (PD): A Quality Improvement (QI) Project

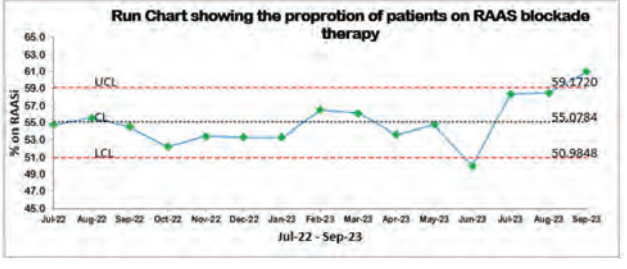
Mona Aflaki, Wen Qing Wendy Ye, Fatema Zaidi, Arifuddin Saad Mohammed, Joshua Shapiro, May Alabdulaaly, Bourne L. Auguste. *University of Toronto, Toronto, ON, Canada.*

Background: Preserving residual kidney function is crucial for improving outcomes in PD. RAASi helps preserve kidney function, protect cardiovascular health, and regulate blood pressure (BP). However, it is often discontinued due to concerns about hyperkalemia, and hypotension. Using QI methodology, we explored reasons for discontinuation and developed solutions to improve RAASi in PD patients. We aimed to develop and implement solutions using QI methods to increase the proportion of patients on RAASi.

Methods: We reviewed charts of 54 PD patients at Sunnybrook Health Sciences Centre between July 2022-Sept 2023. Data on RAASi usage, baseline potassium (K), and residual urine output were collected. Root-cause analyses, using surveys and Pareto charts, identified gaps in RAASi usage.

Results: Our analysis revealed only 55% of patients were prescribed a RAASi (Figure 1). The median residual urine volume was 861.8 ± 72.3 mL, and the average serum K was 4.4 ± 0.1 mmol/L. The root-cause analysis identified two reasons for the low prescription: cessation of RAASi before PD initiation and failure to restart therapy. We implemented the PD Passport in electronic medical records to identify patients not on RAASi to ensure monitoring of urine output, serum K, and BP every six months, with initiation of RAASi if appropriate. There was a slight increase in patients on RAASi after the project was announced between July-Sept 2023, suggestive of a possible Hawthorne effect prior to initiation of formal interventions.

Conclusions: The PD Passport, launched in May, aims to increase RAASi use by 20%. We will evaluate its impact on prescription rates, residual urine volume, hyperkalemia, and BP. We demonstrate the feasibility of using QI principles in PD to enhance care. With the PD Passport, we aim to preserve residual kidney function with RAASi, while monitoring patients to maximize benefits and minimize side effects. This initiative promises improved patient outcomes and PD management.



PUB209

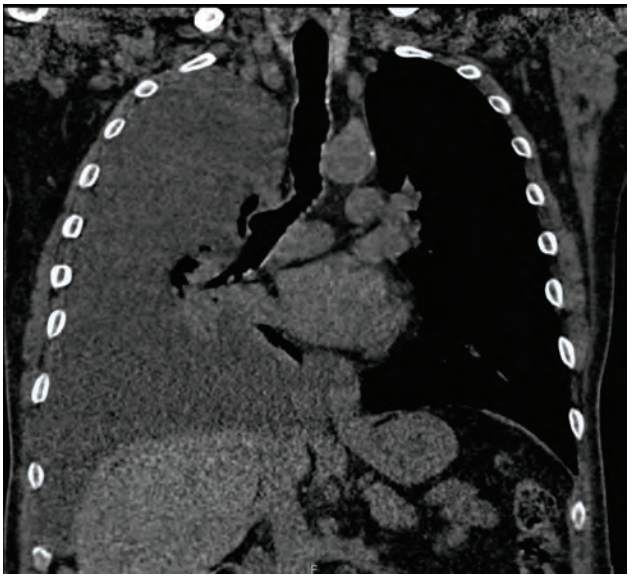
Pleuroperitoneal Communication: A Rare Complication of Peritoneal Dialysis Observed in an Ecuadorian Hospital

Jorge A. Valdivieso,[1] Wilson S. Penafiel,[1] Andrés R. Monge,[1] Michella Dirani,[3] Michael I. Anstead,[4] Carina V. Coronel,[2] Monica G. Fernandez.[2] *[1]Universidad de Las Americas Facultad de Ciencias de la Salud, Quito, Ecuador; [2]Universidad Central del Ecuador, Quito, Ecuador; [3]Universidad San Francisco de Quito, Quito, Ecuador; [4]University of Kentucky, Lexington, KY.*

Introduction: Pleuroperitoneal communication (PPC) is a rare complication seen in approximately 1.6% of patients with end-stage renal disease who undergo peritoneal dialysis. Although there have been several reports where its diagnosis and management have followed a straightforward path, we encounter a case in which the accessibility to some of the diagnostic tools has become a limitation for its final treatment. The gold standard for diagnosis is Tc-99m scintigraphy, which is noninvasive, low in radiation, simple, safe, and cost-effective. The treatment of choice is video-assisted thoracic surgery (VATS).

Case Description: A 65-year-old male with a history of end-stage renal disease treated with peritoneal dialysis presented to the emergency department with a productive cough, fever, inferior limb edema, and dyspnea. A Computed Tomography (CT) Scan revealed a right unilateral pleural effusion. A cytology analysis of the pleural fluid showed an elevated glucose concentration. TC-99m scintigraphy was not available to confirm the diagnosis. The ultimate decision was to discontinue peritoneal dialysis and initiate hemodialysis instead. One month after follow-up the patient did not reveal any signs of hydrothorax.

Discussion: PPC represents a rare complication in patients undergoing peritoneal dialysis. While TC-99m scintigraphy and VATS are the gold standards for diagnosing and treating this condition, their advanced and complex nature renders them unavailable at every healthcare center. Consequently, alternative treatment strategies, such as discontinuing peritoneal dialysis and transitioning to hemodialysis, may need to be considered, despite potential compromises to patient well-being.



Chest CT. Coronal view shows right hydrothorax.

PUB210

Early Fusariosis after Peritoneal Dialysis Drain Placement

Bibi Maryam, Adolfo Diaz-Barba. *The University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Introduction: Fusarium peritonitis has been reported in people with long-standing peritoneal dialysis (PD) catheters and usually occurs on average of 48 months after peritoneal drain placement. We present a case of invasive fusariosis manifested by *Fusarium* peritonitis within one week of peritoneal drain placement.

Case Description: A 40-year-old man with chronic alcohol use was admitted to our intensive care unit with one-month history of vague abdominal pain. CT abdomen and pelvis revealed free intraperitoneal air in pelvis near the proximal rectosigmoid colon suggestive of ruptured diverticulitis with a potential loculated fluid collection as well as large volume ascites with a markedly enlarged cirrhotic liver. Paracentesis was performed and peritoneal fluid was sent for culture which was sterile. IR placed a peritoneal drain on day 11 and peritoneal fluid cultures were collected which showed growth of ampicillin susceptible E. faecium and *Candida lusitaniae*. On day 20, peritoneal cultures collected from day 15 showed growth of mold, and he was started on empiric liposomal amphotericin B. The mold was later identified as *Fusarium* and antifungal was switched to voriconazole. The family opted for comfort care and patient passed away on day 25 of the hospitalization.

Discussion: One of the risk factors for developing *Fusarium* peritonitis is indwelling PD catheter as well as long-retained peritoneal drains for chronic dialysis. The optimal treatment of *Fusarium* remains unclear, but voriconazole, itraconazole or polyenes have been reported with some treatment success. Usually, it takes several months for the *Fusarium* infections to develop after a catheter placement, but in our patient, he developed *fusarium* peritonitis within 5 days of peritoneal drain placement. This early growth during hospitalization and lack of growth first sampling of peritoneal fluid suggests that the patient might have acquired it from the inpatient hospital setting. *Fusarium* should be on the differential for early peritonitis especially in patients with risk factors such as ESLD, chronic ascites and presence of a peritoneal catheter and empiric antifungals with activity against molds should be considered. Aggressive management of *Fusarium* peritonitis is essential to prevent disseminated disease.

PUB211

Prevalence of Metabolically Associated Fatty Liver Disease in Patients Undergoing Peritoneal Dialysis

Jose A. Solis Rojas, Gloria G. García Villalobos, L. M. Perez-Navarro. *Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico*.

Background: Metabolically Associated Fatty Liver Disease (MAFLD) in Chronic Kidney Disease (CKD) patients undergoing renal replacement therapy (RRT) has been reported to have a prevalence of up to 58%. Patients on peritoneal dialysis (PD) have an increased risk for MAFLD due to prolonged exposure to high concentrations of glucosa. The aim of this study is to determine the prevalence of MAFLD in PD patients evaluated using elastography.

Methods: Cross-sectional study conducted in adults with CKD on PD, from April to May 2024. Data were collected from medical records and elastography was performed. Data are presented as absolute and relative frequencies, means±SD. Student's t-test and Spearman correlation were performed, with a 95%CI and p-value ≤0.05.

Results: 22 patients were included. 82% of the patients exhibited MAFLD, of which 23% showed suggestive data of chronic hepatopathy. No association was found between MAFLD, the use of dialysis solutions, and RRT duration. An association was identified between GGT levels and MAFLD (r=0.51 p= 0.008), with a negative correlation observed with albumin concentrations (r=-0.448 p= 0.01). Daily glucose load was associated with total bilirubin levels (r=0.486 p=0.01), TP (r=0.418 p=0.03), and INR (r=0.408 p=0.03).

Conclusions: A high prevalence of MAFLD was identified, higher than reported in other studies, with the presence of advanced fibrosis in a significant percentage of patients, along with the absence of elevation in most serum biomarkers. Therefore, it is necessary to promote screening for MAFLD, supported by imaging studies such as elastography.

Comprehensive Evaluation of Clinical Consequences in Diverse Fistula Elevation Procedures

Masayoshi Nanami, Yasuyuki Mimura, Akihiro Kuma, Yukiko Hasuike, Takahiro Kuragano. *Department of Cardiovascular and Renal Medicine, Hyogo Medical University, Nishinomiya, Japan*.

Background: Arteriovenous fistula (AVF) superficialization is a recommended alternative autologous vascular access (VA) in patients for whom conventional AVF creation is not possible because of insufficient superficial veins. This procedure utilizes a deeply located vein as an outflow conduit in AVF creation and makes the vein accessible for cannulation. Tunnel transposition (TT) is employed in a standard manner as a superficialization technique. However, TT tends to be exclusively applied to the basilic vein in the upper arm because of anatomical considerations and inherent procedural limitations. We recently reported that elevation transposition can serve as a simplified minimally invasive substitute for TT (Contrib Nephrol. 2019;198:1-11). In AVF superficialization employing elevation transposition (i.e., fistula elevation procedure [FEP]), three potential outflow veins are available in the upper arm: the cephalic, basilic, and brachial veins. This study was performed to comprehensively evaluate the clinical consequences of three valid FEP techniques, ascertain whether they are reasonable alternatives to autologous VA, and determine which, if any, have superior performance.

Methods: The demographic and outcome data of 111 patients who underwent the FEP were retrospectively collected and analyzed. The outcomes of the three fistula techniques were assessed and compared in terms of patency rates, requirements for VA intervention therapy (VAIVT), and complication rates.

Results: The basilic, cephalic, and brachial vein-based FEP was performed in 63.1%, 23.4%, and 13.5% of cases, respectively. The overall cumulative primary and secondary patency rates were 76.2% and 98.2% at 1 year and 70.7% and 97.0% at 2 years, respectively. VAIVT was required in 32.4% of cases, and the patency rates at 1 and 2 years after VAIVT were 65.3% and 62.0%, respectively. There were no significant differences in these patency rates among the three FEP types. Minor complications occurred in only 4.5% of cases.

Conclusions: Our results suggest that the FEP provides three equivalently reliable options to accommodate the deeply located venous anatomy of the upper arm on individual-patient basis. The diversity of the FEP may help to expand the applicability of autologous VA.

PUB213

Effect of Transdermal Nitroglycerin (NTG) Cream on Postdialysis Parameters on Brescia-Cimino Arteriovenous Fistula (AVF)

Tanmay P. Vagh. *Mahatma Gandhi University of Medical Sciences & Technology, Jaipur, India.*

Background: Important factor in AVF failure is inadequate blood flow through access.NTG cream[made up of 25mg Injection NTG+5gm NIVEA cream(as the base is same in NTG ointment & nivea cream & this decision of making this combination has been made because of unavailability of NTG ointment in the market)] at the point of vascular access at wrist on AVF to increase blood flow by vasodilation & prevent thrombosis by inhibiting platelet aggregation. Aim is to evaluate the changes in post dialysis parameters after application of NTG cream on AVF.

Methods: 86 patients came to the Nephrology Department at Mahtma Gandhi University of Medical Sciences & Technology, Jaipur, India between October 2023 to March 2024, whom had fistula as the initial vascular access for hemodialysis were placed into 2 groups;study group(n=43) & control group(n=43). Study group received NTG cream application 24 hour prior to dialysis at 8 hourly(such 3 application) & also 1 hour prior coming for dialysis, & advised to continue the same for 4 weeks. The control group received no application. In both groups the blood flow rate(Qb), ultrafiltrate rate(UFR), blood output at the drainage vein, urea reduction ratio(URR) measured after 4 weeks.

Results: The distribution were according to age, gender, duration of dialysis & native disease was almost similar in both groups(Table 1). All fistulas were functioning well immediately after operation. During the study no patient had any reaction to the NTG including nausea, hypotension, or headache. In the study group, Qb[from 150ml/min to 250ml/min maximum 300ml/min], UFR, and blood output at the drainage vein, URR(increased from 0.55 to maximum 0.67) were significantly increased after 4 weeks of NTG cream application. In control group, all parametes were unchanged.

Conclusions: The most important factors in performing AVF are good surgical technique & patent central veins. However adequate blood flow cannot be established even in the presence of these factors so, in this study of NTG cream application showen significant improvement in study group, whereas there was no change in control group.

Patients age, gender, duration of hemodialysis, native diseases, post dialysis parameters.

Thoughts on the Integrated Management of Vascular Access in Elderly Patients with Maintenance Hemodialysis (MHD)

Hua Liu. *The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China.*

Background: Although the use of arteriovenous fistulas (AVFs) has better clinical outcomes in the general hemodialysis population, the use of AVFs is uniquely challenging due to the high rate of immature vascular access and limited life expectancy in older hemodialysis patients.

Methods: This article reviews the vascular access development plan and clinical data of 6 elderly patients, and summarizes the integrated vascular access management strategies of elderly patients with MHD based on literature review and guideline recommendations.

Results: Case 1: Male patient with renal transplantation failure 10 years after kidney transplantation, who had previously had right AVF occlusion and the left side could not meet the establishment conditions, established the ulnar AVF of the right forearm after comprehensive evaluation, and started using it one month after surgery, and had good function. Case 2: Male patient with stage 5 CKD, diabetes, hepertension, coronary heart disease and gastric cancer, his left forearm catheter over 1 month, the right internal jugular vein TCC + left forearm ulnar AVF was established, and the AVF was started 3 months after surgery and the TCC was removed. Case 3: Male patient with CKD stage 5 stage and diabetes mellitus, in order to establish AVF in advance, and the left forearm blood vessel did not meet the surgical conditions, and the right cephalic vein branch was multiple and relatively tortuous, and the right radial artery-cephalic vein AVF was established in the first stage, and the fistula began to be used normally within 1 month after the re-examination was reconstructed and repaired after the tortuous cephalic vein was reconstructed and repaired. Case 4: Female patient with CKD stage 5 who underwent regular hemodialysis with TCC for 2 months were required to be admitted to the hospital with AVG, evaluated that the left radial artery, especially the cephalic vein, did not meet the surgical conditions, and the right vascular condition was acceptable.

Conclusions: We believe that it is necessary to comprehensively consider the basic conditions of elderly patients. Individualized planning and implementation of designated vascular access and standardized postoperative follow-up. Regardless of whether the catheter is started for hemodialysis, the possibility of AVF or AVG should be comprehensively evaluated. Standardize the clinical pathway for the use of arteriovenous fistula.

PUB215

Vascular Access Outcomes among Patients on Maintenance Hemodialysis in Perpetual Succour Hospital: A 3-Year Cross-Sectional Analysis

Joel John C. Mejos, Grecia Darunday, Eratosthenes S. Polito, Ruben A. Maguad. *Perpetual Succour Hospital, Cebu City, Philippines.*

Background: Vascular access is the key in successful management of chronic hemodialysis (HD) patients. Though native arteriovenous fistula (AVF) is considered the access of choice, many patients in our country initiate HD through central venous catheter (CVC). The ideal vascular access should have specific characteristics among which the most important are the following: ease of placement; delivery of adequate blood flow for effective HD; good primary patency rates; low rates of complications; long-lasting life; and low economic costs. Hence, successful HD depends on creation and maintenance of adequate vascular access.

Methods: This is a single center, cross-sectional study of ESRD patients on maintenance hemodialysis enrolled in Perpetual Succour Hospital Hemodialysis Unit from April 1, 2021, to November 30, 2023.

Results: There were 260 hemodialysis patients included, with successful vascular access outcome (73.13%) and were younger (57.2 ± 14.1). Those with failed vascular access were females (54.2%), unemployed (61.4%) and had diabetes mellitus (DM) (50.6%) as the primary etiology of their ESRD. Those with failed vascular access were hypertensive (86.7%), with concomitant CAD, MI (57.8%) and DM (56.6%). Proportion of those with failed and successful vascular access significantly differ among hypertensives (p=0.012), diabetics (p=0.039), with chronic glomerulonephritis (p=0.011), and among those with malignancy (p=0.003). And the association of clinical outcomes (death or not) and failure or success of vascular access is statistically significant, p= <0.001.

Conclusions: Our study showed that failed vascular access were more associated with female gender, DM as the primary etiology of ESRD and with other co-morbid conditions such as hypertension and CAD or MI. Successful vascular outcome were among those of younger age group compared to those whose vascular access failed, probably due to better vascular condition and fewer co-morbidities. Lastly, 87% of patients on AVF were alive however, most of those who died also had AVF (59.1%) and CVC (36.4%), and proportion of those who were alive and dead with different vascular access significantly differ, p<0.001.

Clinical Outcomes of Different Vascular Access

Access	All HD Patients n = 260	Clinical Outcomes		p-value
		Alive n = 194	Dead n = 66	
AV Graft	3 (1.2)	2 (1.0)	1 (1.5)	<.001
AVF	209 (80.4)	170 (87.6)	39 (59.1)	
CVC	42 (16.2)	18 (9.3)	24 (36.4)

PUB216

A Single-Center Descriptive Study on the Catheter Salvage Rate of Catheter-Related Bloodstream Infection Treated with Antibiotic Lock Therapy among Patients on Hemodialysis

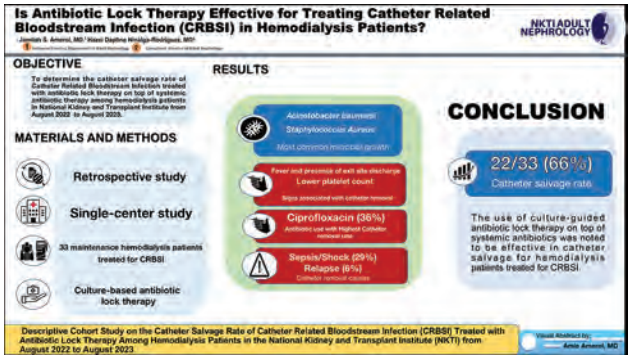
Jamilah S. Amerol. *National Kidney and Transplant Institute, Quezon City, Philippines.*

Background: Catheter Related Bloodstream Infection is a common complication of hemodialysis patients with tunneled catheter as route of access for renal replacement therapy. Antibiotic lock therapy along with systemic antibiotics has been one of the treatments offered for CRBSI with aim of catheter salvage especially for patients with multiple access failure however no local studies has been published yet to determine the catheter salvage rate against catheter removal rate using antibiotic lock therapy.

Methods: A retrospective and descriptive design to identify ESRD patients treated with antibiotic lock treatment in a single-center for bloodstream infections due to catheter use for 1 year study period. The demographic and clinical characteristics of the subjects were then compiled using Univariate Descriptive statistics.

Results: Out of the 33 patients included in the study, 23 patients (66%) had catheter salvage while the remaining 11 (33%) had catheter removal. Findings revealed that there were no significant differences between the two groups in terms of age, sex distribution, comorbidities, or etiology of ESRD. Most prevalent microbial growths were Staph aureus and A. Baumanii. The presence of fever and discharge were significantly higher among catheter removal group. A trend towards lower mean platelet count was likewise seen. Catheter removal was significantly higher among patients given with Ciprofloxacin lock therapy.

Conclusions: The collective understanding of the significant factors influencing catheter removal and salvage may help tailor more targeted interventions and better patient care. This study assessed the catheter salvage rate of patients receiving hemodialysis who have a catheter-related bloodstream infection treated with antibiotic lock treatment. This study sought to serve as a foundation for future research projects, policy proposals as well as plans to improve services to ESRD patients on hemodialysis with central line bloodstream infection.



PUB217

Reimaging Patient Safety for Dialysis

Sobia N. Khan, Mansoor Ahmed, Navdeep Kaur, Sandeep K. Mallipattu.
Stony Brook University, Stony Brook, NY.

Introduction: Arteriovenous fistula/graft (AVF/AVG) are commonly used for dialysis. Vascular access related morbidity accounts for 20% of hospitalization. Blood vessel rupture, a serious complications of AVF.

Case Description: 79-year-old male with End Stage Kidney disease on hemodialysis through Left AVF was admitted. Nephrology was consulted for hemodialysis. Patient was initially evaluated by a nephrology fellow and the case was discussed with the attending physician. Hemodialysis was initiated through the AVF. Physical examination of the fistula was described as a thrill and a bruit without any signs or concerns for erythema, even though the attending physician noted the presence of scabs on the patient's access, prompting consideration for vascular evaluation. Despite this observation, the patient underwent dialysis again during which bleeding from AVF was observed at the conclusion of treatment. The vascular team was immediately notified, he was taken to the operating room where AVF was ligated.

Discussion: We have implemented follow-up strategy to prevent similar catastrophes in the future. Nephrology team received dedicated lectures with strong emphasis on physical examination skills. They were instructed to include images of AVF/AVG after obtaining patient consent, which heightened their awareness of the importance of thorough physical examination. They were encouraged to promptly consult the vascular surgery team if any concerns arose. In the hemodialysis unit nurses received more frequent dialysis education sessions to accommodate the increased turnover rate among them. Significant improvements were observed. Almost all charts now include images of dialysis access. Additionally, fellows are more aware of the patient access conditions. We have also noticed an increase in phone calls from dialysis unit nurses ensuring better communication and patient care.

PUB218

Effect of Glycemic Control in Outcomes of Dialysis Vascular Access Surgery

Jin Huang,[1] Jimmy Pak,[2] Bradley R. Cohn,[2] Aida Shirazi,[1] Sijie Zheng.[2]
[1]Kaiser Permanente San Francisco Medical Center, San Francisco, CA; [2]The Permanente Medical Group Inc, Oakland, CA.

Background: Arteriovenous fistula (AVF) and arteriovenous graft (AVG) are the preferred dialysis accesses and one of the quality measurements. Hyperglycemia is recognized to be an independent risk factor of adverse surgical outcomes. However, it is unclear the optimal pre-surgery diabetic control and the underlying patient characteristic that are associated with adverse outcomes of AVF/AVG surgery. Currently there are no specific guidelines regarding acceptable preoperative glucose thresholds for AVF/AVG surgery nationally or regionally at Kaiser Permanente Northern California (KP NCAL).

Methods: We are conducting a retrospective cohort study of adult KP NCAL members with advanced chronic kidney disease, who underwent AVF/AVG surgery between January 1, 2013 and December 31, 2023. Pre-surgery diabetic control was measured by HgA1c, glucose or fructosamine. Patient characteristics including demographics, eGFR, comorbidity, and medications were obtained. The adverse clinical outcomes considered are operative complications (infection, hematoma, occlusion, maturation issue, open wound, steal), re-operation, all-cause ER visits, readmissions, MI and death within 30 days postop. We have designed logistic regression models to assess association between pre-surgery diabetic control and adverse clinical outcome of AVF/AVG surgery.

Results: A total of 9,981 patients with advanced CKD underwent AVF/AVG surgery. The mean age (±SD) was 65.6 (±13.4) years old, 40.4% were females, 31.9% were White, 16.1% were Asian, 11.0% Black, and 22.6% were Hispanic. Majority of patients (83.0%) had AVF surgery. The average preoperative HgA1c was 6.8 (SD 1.49, range 3.6-16.2). Our model estimates the odds ratio of adverse outcomes of AVF/AVG surgery with worsening glycemic control adjusting for patient's demographics, eGFR, comorbidity, and medications.

Conclusions: Our study examines the surgical risks associated with hyperglycemia and aims to provide guidance regarding preoperative glucose management to improve surgical outcomes and avoid unnecessary delay of lifeline creation for patients with kidney failure requiring maintenance hemodialysis.

PUB219

Mortality within 12 Months following Bacteraemia in Patients Dialysing through Tunnelled Lines: Effect of the Organism Isolated

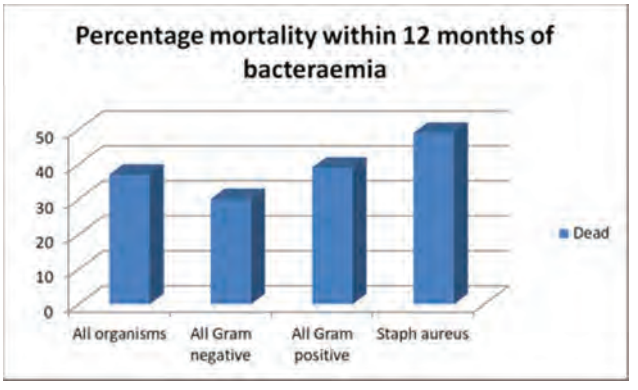
Takudzwa J. Dhlandhlara, David Makanjuola. *St Helier Hospital, Carshalton, United Kingdom.*

Background: Haemodialysis (HD) patients are at risk of dialysis access-associated infections. The risk is more in patients dialysing with lines. The most commonly implicated organism is Staph aureus (SA), accounting for 27-39% of bacteraemias. SA has a tendency to cause metastatic infections e.g. endocarditis, septic emboli, and discitis. We looked at bacteraemias in patients dialysing with lines to see if there was a difference in the mortality related to the kind of organism isolated.

Methods: This retrospective cohort study was on HD patients who had positive blood cultures between 2019 –2022. Data on blood cultures and survival were collected from an electronic database and statistical analysis was done with Microsoft Excel.

Results: There were 506 bacteraemias in 275 patients. 168 were male. Median age at time of bacteraemia was 67 years (range 19-91). Organisms responsible for the bacteraemias were: Gram negatives 93 (23.8%), Gram positives 296 (75.7%), of which staphylococcus aureus SA species were 85 (85.7%). The percentage of patients who died within 12 months of a bacteraemia was 37% in the whole population. For those with Gram negative bacteraemia, it was 30% and for those with Gram positive bacteraemia, it was 39%. In those with SA bacteraemia, the mortality rate was 49%.

Conclusions: While the causes of death within 1 year of the infection are varied it is intriguing that the lowest survival of patients was in the group of those who had had SA bacteremia. Our data suggest that the type of organism causing the bacteraemia is important, as the mortality in those with SA appears worse compared with other Gram positive and with Gram negative organisms. This might be due to the difficulty eradicating SA as it causes a biofilm on the line, and can cause metastatic infections.



PUB220

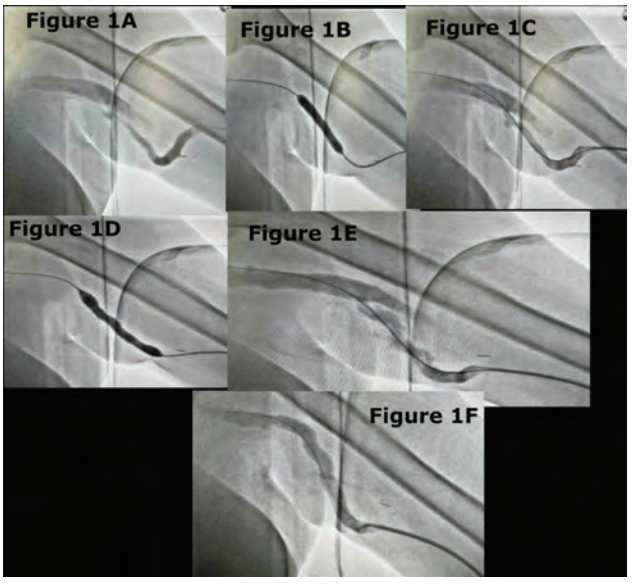
Treatment of Severe Outflow Stenosis Leading to Steal Syndrome

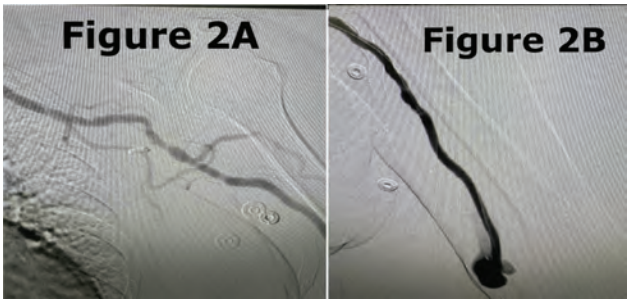
Sylvester Barnes IV, Ahmet E. Yassa. *Loyola University Medical Center Department of Nephrology, Maywood, IL.*

Introduction: 67-year-old F with ESRD on dialysis via a left brachiobasilic AV fistula created several years ago with multiple previous interventions was referred to interventional nephrology for venous pressures of 300 mmHg on 400 ml/min pump flow.

Case Description: Access was obtained and angiogram showed an extremely hypoplastic basilic vein draining to the brachial system via a perforator vein. Balloon angioplasty was performed incrementally with 4x40, 6x40, and 8x40 compliant Powerflex balloons. Due to the high recurrence likelihood and the severe stenosis, an 8x60 drug-eluting Lutonix balloon was deployed. Patient had significant discomfort and arm swelling upon balloon deflation, with angiogram showing extravasation. Immediate balloon occlusion was done, but due to continued swelling and extravasation, an 8x100 Viabahn stent was deployed. Post-procedure, fistula had excellent flow(Fig. 1). Later, patient developed left-hand numbness and pain during dialysis concerning for steal syndrome. Vascular surgery performed angiogram showing significant stenosis in the axillary/brachial artery junction with subsequent angioplasty and symptom improvement(Fig. 2).

Discussion: Extravasation can occur in dialysis access interventions with covered stents used as bailout procedures. In this case, despite successful angioplasty of the significantly diseased segment of the basilic vein, there was enough flow resistance to prevent steal syndrome. The stent deployment increased flow, reducing resistance and unmasked arterial stenosis in the upper brachial artery leading to successful treatment and resolution of steal syndrome.





PUB221

Safety of the Placement of Tunneled Catheters for Hemodialysis Inserted under Ultrasound Guidance without Fluoroscopy

Javier Rivera Flores,[1] Mauricio Arvizu Hernández.[2] *[1]Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico; [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico.*

Background: The installation of a tunneled access for hemodialysis traditionally requires fluoroscopy; however, in Mexico, the availability of this instrument is limited. The objective of the study is to determine if the placement of tunneled catheters for hemodialysis without fluoroscopy is safe using ultrasound guidance and calculating the intravascular portion based on the patient's height.

Methods: This is a retrospective, observational, and descriptive study conducted at the National Institute of Medical Sciences and Nutrition Salvador Zubirán. Patients who received a tunneled vascular access without the use of fluoroscopy, only using real-time ultrasound guidance. The intravascular portion of the catheter was calculated by considering the patient's height in centimeters and dividing it by 10. A chest X-ray was performed to corroborate the appropriate path and position of the catheter tip, distinguishing four locations: cavo-atrial junction, right atrium, deep portion of the right atrium, right ventricle, and any other location.

Results: A total of 317 tunneled access placements without fluoroscopy were performed between january 2018 to december 2023 ;in 99% the indication was chronic hemodialysis. 167 were women (52.6%) and 150 were men (47.4%). In 291 patients (91.8%), the right jugular vein was used, in 25 patients (7.9%) the left jugular vein was used, and only 1 femoral access (0.3%). No vascular or pleuropulmonary injuries were reported. The catheter tip was located at the cavo-atrial junction in 59 patients (18.6%), in the right atrium in 231 patients (72.9%); in 20 patients (6.3%) the tip was observed in the deep portion of the right atrium or right ventricle and was retracted to locate it in the right atrium. The tip was located in another anatomical region in 7 patients (2.2%), in which cases replacement by the Interventional Radiology team was necessary. All accesses showed immediate adequate functionality.

Conclusions: The placement of tunneled catheters for hemodialysis with ultrasound guidance without fluoroscopy is safe and cost-effective. The calculation of the intravascular portion considering height allowed the tip to be located in the right atrium in 72.9% of the catheters. The placement was considered successful based on the tip location and AV functionality in more than 98% of cases.

PUB222

Impact of Prepared Vascular Access on Mortality and Medical Expenses in Elderly and Nonelderly Japanese Patients with CKD Stage G5: A Retrospective Cohort Study

Yuji Kamijo, Takayuki Nimura, Yuki Nakayama, Daiki Aomura, Kosuke Yamaka, Koji Hashimoto, Makoto Harada. *Shinshu University School of Medicine, Matsumoto, Japan.*

Background: Patients with chronic kidney disease (CKD) stage 5 (CKDG5) have greater dialysis requirements that increase the risk of cardiovascular disease and mortality. The elevated costs associated with CKDG5 are a serious concern. The impact of prepared vascular access (VA) through planned VA creation on mortality and medical expenses remains unclear in Japanese patients with CKDG5.

Methods: We conducted a retrospective cohort study of 157 patients with CKD who started hemodialysis (HD) at Shinshu University Hospital from April 2016 to March 2021 and analyzed the relationship between the presence of a prepared VA and mortality and hospitalization expenses in elderly and non-elderly patients with CKDG5.

Results: The presence of a prepared VA was associated with lower mortality in non-elderly patients but not in elderly patients. Medical expenses, emergency HD, and hospitalization duration were significantly lower in patients with a prepared VA in both age groups. The contribution of a prepared VA to mortality and medical expenses remained consistent after adjusting for sex, performance status, comorbidities, and nutritional status.

Conclusions: A prepared VA has several benefits; however, the prognostic benefit was not observed in elderly patients with CKDG5. From a prognostic perspective, we should consider patient's general condition and predicted prognosis in proactive decision-making regarding the selection of renal replacement therapy and VA preparation in elderly patients.

PUB223

Bacteraemia in Patients on Kidney Replacement Therapy: A 4-Year Single-Centre Experience

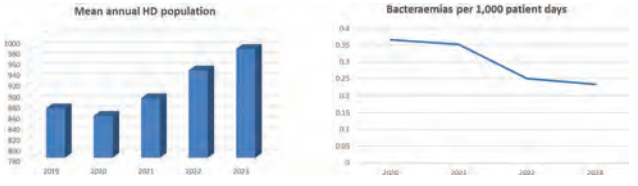
David Makanjuola, Christy R. Ratnakumar, Jahanzaib Chatha, Takudzwa J. Dhlandhlara, Olusegun O. Olalowo. *Epsom and Saint Helier University Hospitals NHS Trust, Carshalton, United Kingdom.*

Background: Infection is a common cause of morbidity and mortality in patients on renal replacement therapy (RRT). The majority of bacteraemias in haemodialysis (HD) patients are related to the vascular access. We decided to look at our dialysis cohort to see whether there was a difference in the incidence and types of bacteraemias based on the type of HD access and what the annual trends were over the last 4 years.

Methods: Retrospective review of patients on RRT who had bacteraemias between May 2019 to March 2024. Data collected included RRT type, blood culture results and dialysis access. Statistical analysis was done with Microsoft Excel.

Results: There were 501 bacteraemias, 435 (87%) were from patients undergoing HD. Median age was 67 years (range 19-91). The HD population rose from 872 to 982 between 2019 and 2023. The bacteraemias fell over this period from 0.36 to 0.23 bacteraemias per 1,000 patient days (figure 1). Micro-organisms isolated from HD patients were gram positive 336 (77%), and Gram negative 88(20%). Of the Gram positive organisms, 28(6.4%) were Enterococci; 275 (63%), were staphylococci [MSSA - 105 (24%) MRSA - 8 (1.8%) coagulase negative - 161 (37%)]. Dialysis access related bacteraemias were as follows: AV fistula/graft 58(13%), Tunnelled dialysis lines 332 (76 %), non-tunnelled dialysis lines 35 (8%).

Conclusions: In this cohort of patients, bacteremias were more common in HD patients. The predominant organisms isolated were Gram positive and the majority of these were coagulase negative staphylococci. The incidence of MRSA was one tenth that of MSSA. Bacteraemias were much more likely to occur in patients dialysing through lines as compared with AV fistulae or grafts. This lends weight to the drive to increase the proportion of patients dialysing through AVFs or AVGs.



PUB224

In a Heartbeat: Rapid Assessment of Cardiac Output after Arteriovenous Fistula Creation Using Point-of-Care Ultrasonography

Nasir A. Shah,[1,2] Blake Cochran,[3] Zoltan Endre,[1,2] Tracie Barber,[4] Jonathan H. Erlich.[1,2] *[1]University of New South Wales School of Clinical Medicine, Sydney, NSW, Australia; [2]Prince of Wales Hospital and Community Health Services, Randwick, NSW, Australia; [3]University of New South Wales School of Biomedical Sciences, Sydney, NSW, Australia; [4]University of New South Wales School of Mechanical and Manufacturing Engineering, Sydney, NSW, Australia.*

Background: Up to 44% of patients treated with haemodialysis develop heart failure. Though numerous observational studies have found associations between arteriovenous fistula (AVF) flow and cardiac function, the exact contribution of AVF flow on the incidence of heart failure remains unclear. The aim of this pilot study was to use point-of-care ultrasound (POCUS) to assess cardiac output (CO) after arteriovenous fistula creation.

Methods: POCUS was used to assess left ventricular outflow tract (LVOT) diameter and LVOT velocity time integral before and after AVF creation. These values were used to calculate CO. Measurements were taken preoperatively, within 1 hour of AVF creation, and after AVF maturation.

Results: Nine patients were included in the study. In all patients, there was no significant difference in CO between measurements performed prior to AVF creation and those taken immediately post-operatively. Six patients had repeat CO measurements after AVF maturation. Four patients had an increase in CO and 2 had a decrease. Overall, there was no significant between-group difference when comparing pre-operative CO to measurements taken after AVF maturation ($p = 0.77$).

Conclusions: This small study using POCUS to assess CO showed some patients increase and others decrease their CO after AVF creation. Individual patient data suggests the possibility of a functional difference where some patients are unable to increase their CO after AVF creation. Whether this inability to mount a compensatory change in CO is associated with additional changes to cardiac imaging, biochemical markers of heart failure, or clinical outcomes such as incident heart failure and all-cause morbidity/mortality needs to be examined further.

PUB225

Hyperkalaemia: Problem or Epi-phenomenon following Thrombectomy for Arteriovenous Fistulae and AV Grafts

Amy J. Forrester, Florence Coath, Stephen Henihan, Mikel Suarez, Benjamin R. Hawthorn, Karanam Munige Randika C. Wijerathne, Subash Somalanka, David Makanjuola. *Epsom and Saint Helier University Hospitals NHS Trust, Carshalton, United Kingdom.*

Background: Arteriovenous fistulae/grafts (AVF/G) are felt to be superior to haemodialysis catheters (HDC). Their Achilles' heel is thrombosis. This often requires intervention to 'rescue' the AVF/G, including percutaneous mechanical thrombectomy with thrombolysis [PMT] or venoplasty and stent insertion. Clot disruption by PMT carries a risk of hyperkalaemia. Some centres have protocols which do not allow PMT to be carried out if potassium (K) is > 5.0 mmol/l prior. Hyperkalaemia is less of a concern when performing thrombectomy by suction/Fogarty balloon. In our centre we perform PMT using Angiojet, a rheolytic thrombectomy device. Hence we decided to find out the magnitude of potassium rise following PMT.

Methods: Data were prospectively collected from electronic records for patients who underwent PMT for thrombosed AVF/G between November 2021 – January 2024. Demographic characteristics, K pre and post-PMT, need for dialysis prior to procedure and complications associated with HDC insertion were recorded.

Results: 15 procedures were performed in 32 patients. AVF:AVG = 19:13. M:F=20:12. Median age was 61 years (range 40-83). Mean time interval between thrombosis and thrombectomy was 3.02 days (range 1-7). Mean K at time of thrombosis was 5.34mmol/l (range 4 - 7.1). 28 patients had a HDC inserted pre-procedure, of which 21 patients had K > 5.0mmol/l. One non-functioning HDC needed re-insertion. Mean pre-PMT K was 4.54mmol/l (range 4.2 - 5.3). Mean post-PMT K was 4.72mmol/l (range 3.7-5.7); samples were obtained between 1 - 26 hours (mean 7.44) after the procedure. Mean change in K pre and post procedure ('delta K') was +0.19mmol/L (range -0.9 to +1.3).

Conclusions: We report the outcomes of PMT in AVF/G with focus on change in K pre and post-procedure. The average potassium change was +0.19 mmol/L. None of the patients had severe or life-threatening hyperkalaemia following PMT. Some protocols mandate measures to reduce the K prior to PMT, in some cases this means performing dialysis through a new HDC. The rise in potassium following the procedure in our patients is quite small and suggests that the threshold for instituting potassium lowering measures prior to PMT could be raised without necessarily causing severe or life-threatening hyperkalaemia following the procedure.

PUB226

Bloodstream Infections in the Context of Hemodialysis Care: Experience in a Wide Mexican Renal Health Network

Alicia Pineirua, Edgar Solis, Sergio Hernández-Estrada, Juan M. Ardavin Ituarte. Medica Santa Carmen. *Medica Santa Carmen, Mexico City, Mexico.*

Background: Infections are the 2nd cause of morbidity and mortality among hemodyalisis (HD) patients with chronic kidney disease (CKD). Preventing blood stream infections (BSIs) is challenging due to several factors. In our cohort, about 60% of patients use catheters, which is below the national average. Here we detail the experience and trends in BSI rates at our centers from 2019 to 2023, considering the interventions implemented.

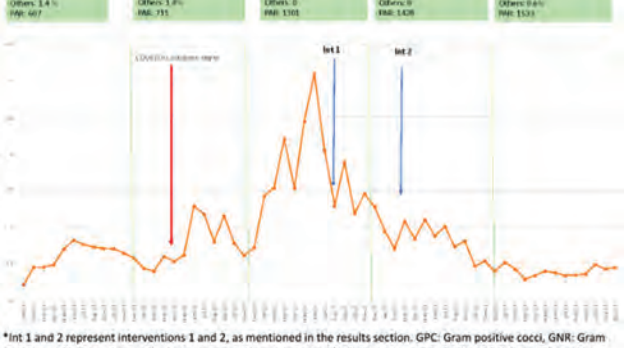
Methods: Data on BSI rates and isolated microorganisms were extracted from our electronic records. Catheter-days BSI rates were calculated. Through a chronological timeline, we described the interventions implemented in accordance with our protocols.

Results: By the end of 2023, around 2,300 individuals were receiving HD at our centers. The annual infection rates from 2019 to 2023 were 0.73, 0.81, 1.24, 0.42, and 0.50, respectively. COVID-19 lockdown in Mexico started on Apr 2020. By 2021, we started taking care of over 1,000 individuals from a new HD clinic, lacking established BSI prevention protocols, which led to a spike in BSI rates. We implemented these measures: Formed small teams within large centers (over 500 patients) to better assess BSI risk (Int 1). Developed an emergency alert and used gentamycin preventive locks when an outbreak was detected (Int 2). The strategies resulted in a 66% reduction in BSIs, sustained during follow-up. The most frequently isolated gram-positive cocci (GPC) and gram-negative rods (GNR) were S. aureus and Enterobacter sp., respectively. We did not observe increased antibiotic resistance with the use of gentamycin locks.

Conclusions: The enhancement of surveillance for individuals at higher risk of BSIs through the establishment of specialized teams within large HD centers, and the use of gentamicin preventive locks has proven effective in reducing BSI rates.

Funding: Clinical Revenue Support

Figure 1.- BSI rates per month, from 2019 to 2023.



*Int 1 and 2 represent interventions 1 and 2, as mentioned in the results section. GPC: Gram positive cocci, GNR: Gram negative rods. Proportion in the box represents the percentage of infections caused by GPC or GNR during the entire year. PAR: Patients at risk during the year (mean).

PUB227

Identifying Global Awareness of SGLT2 Inhibitors through Google Search Trend Analysis

Harshil Fichadiya,[1] Vraj Patel,[2] Wisit Cheungpasitporn,[1] Iasmina Craici.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Canton Medical Education Foundation, Canton, OH.*

Background: SGLT-2i has been identified as therapy with profound benefit in disease involving multiple organs. Initially introduced as anti-hyperglycemic drugs, they are now used for heart failure, proteinuric and early stages of non-proteinuric CKD, hyponatremia, hypomagnesemia. We performed a google trend analysis of SGLT2i related google search since 2004 and assessed the trend of this search overtime in different areas of the World. This may be an indirect measure of public awareness, availability, and utility of these medicines in different regions globally

Methods: A retrospective analysis of Google Trends was conducted for the term "SGLT-2 inhibitors" from 2004 until April 30, 2024. Search trends were assessed over time as well as per nation.

Results: A sustained rise is seen in the search trends for SGLT2i since Jan 2017 with this trend continuing to rise exponentially due to recent trials determining its benefit. The number of google searches per region have been distributed in different shades of blue with the darkest shade representing region with the highest number of searches and the lightest shade representing region with the lowest number in Fig 1. Grey represents areas with lack of enough data for the term. Highest search rates were seen in Japan, Taiwan, Hong Kong and lowest search rates were seen in Russia, China, some eastern European and South American countries. Certain areas in Central Asia, Africa, Middle east and South America did not have enough data to compute a search number.

Conclusions: Google trends are an indirect indicator of public awareness and use of SGLT-2i, given the recently identified multisystem benefit of SGLT-2i, it is important to assess the discrepancy in awareness and distribution of these drugs. Areas with lower awareness can be identified with the distribution map in Fig 1 and targeted efforts to increase awareness about kidney disease and benefit of SGLT-2i should be focused on these areas from a global health perspective. Major contributing factors to low awarness are socioeconomic disparities, unequal market distribution & lack of internet and medical literature access & efforts to mitigate these should be made to ensure equity in global health.

PUB228

Incident CKD among Canadian Immigrants: A Population-Based Cohort Study

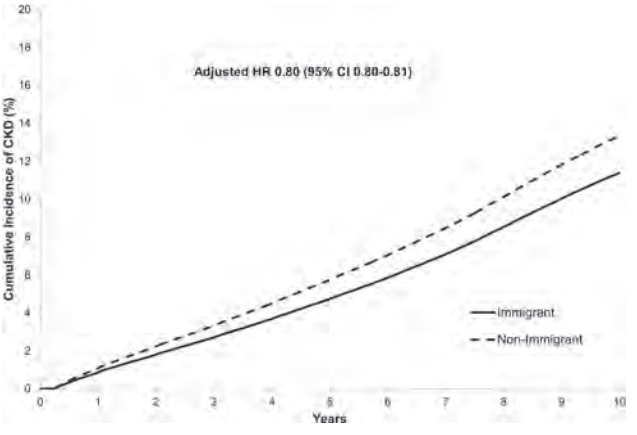
Gregory L. Hundemer,[1] Ida-Ehosa I. Olaye,[2] Ayub Akbari,[1] Manish M. Sood.[1] *[1]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [2]University of Ottawa, Ottawa, ON, Canada.*

Background: A "healthy immigrant effect" has been demonstrated for a number of chronic health conditions including cardiovascular disease, diabetes, and dementia; however, the link between immigrant status and chronic kidney disease (CKD) remains uncertain. We sought to compare the risk for incident CKD among Canadian immigrants and non-immigrants.

Methods: We conducted a population level, observational cohort study of adult Ontario residents, including foreign-born immigrant Canadian citizens and non-immigrant Canadian citizens by birth, with normal baseline kidney function (outpatient estimated glomerular filtration rate [eGFR] ≥70 mL/min/1.73m^2) between 2007-2020 utilizing provincial health administrative data. We used multivariable Cox proportional hazard regression modeling to evaluate the relationship between immigrant status and incident CKD (outpatient eGFR <60 mL/min/1.73m^2).

Results: The study cohort included 10,440,210 Ontario residents, consisting of 22% immigrants and 78% non-immigrants. The mean (SD) age and eGFR were 45 (17) years and 102 (16) mL/min/1.73m^2, respectively, and 54% of individuals were female. A total of 117,028 immigrants (5%, 7 events per 1000 person years) and 984,277 non-immigrants (12%, 16 events per 1000 person years) developed incident CKD during follow-up. Immigrants experienced a 20% lower adjusted risk for incident CKD compared to non-immigrants (adjusted hazard ratio [HR] 0.80 [95% confidence interval [CI] 0.80-0.81]) - see **Figure**. Both refugee immigrants (adjusted HR 0.87 [95% CI 0.86-0.89]) and non-refugee immigrants (adjusted HR 0.79 [95% CI 0.79-0.80]) experienced a lower risk for incident CKD compared to non-immigrants.

Conclusions: Immigrants experience a lower risk for incident CKD compared to non-immigrants. These findings provide evidence of a "healthy immigrant effect" in relation to kidney health.



Adjusted Cumulative Incidence Curves for Chronic Kidney Disease among Immigrants Versus Non-Immigrants.

PUB229

Call to Address Diabetes and CKD Disparities Leveraging the Project ECHO Model

Nicolas Cuttriss. EDAN Diabetes and CKD Disparities Learning Collaborative. *ECHO Diabetes Action Network, Chevy Chase, MD.*

Background: Racial, ethnic and socioeconomic disparities in diabetes and CKD outcomes are disheartening. Due to the shortage of specialists, the majority of adults with complex diabetes and CKD will be treated by primary care professionals (PCPs). From a health equity and population health level perspective, approaches to improving the care of diabetes and CKD must target this care setting and population. The Project ECHO® (Extension for Community Healthcare Outcomes) model is a proven tele-education and mentoring model that is designed to explicitly target frontline PCPs to address health disparities and improve patient outcomes.

Methods: To address the urgent need to offer diabetes-related ECHO programs with CKD program content, the ECHO Diabetes Action Network (EDAN) facilitated a learning collaborative to implement ECHO programing to address Diabetes Disparities & CKD in primary care. Selected "hubs" were ECHO Colorado, Rutgers, and University of Washington. Shared guiding principles drove programing. Topics, case presentation materials and evaluation tools were share. Hubs included multidisciplinary and interprofessional faculty (nephrologist, endocrinologist, behavioral health specialist, primary care clinician, pharmacist, diabetes educator, community health worker and patient advocate). Participant recruitment prioritized PCPs in safety-net/community-focused settings such as FQHCs.

Results: ECHO programs were completed within 5 months (Sep2022–Jan2023). 582 total learners participated from 70 community clinics across the country. 33% (+/- 19%) of learners participated in ≥50% of the teleECHO sessions across programs. Average weekly participation (31 +/-11) varied across hub sites. Learner evaluations demonstrated low baseline confidence in managing diabetes-related CKD. Post-program evaluation, including learner confidence and knowledge surveys. The collaborative created a replication toolkit to support additional organizations launch diabetes and CKD-related programming.

Conclusions: The care of people with diabetes and CKD falls on PCPs and community health centers due to limited access to specialists. This is compounded for minorities, the underserved and those with disparities. Implementation of the ECHO model is a strategy to explicitly address disparities in CKD through education, mentoring and collaboration among all stakeholders in the healthcare system while improving clinician satisfaction.

A Decade of Diversity: Exploring Ethnic Disparities in Kidney Donation in the Northeast United States

Oscar Y. Pena Zapata.[1,2] *[1]St Vincent's Medical Center, Bridgeport, CT; [2]Quinnipiac University Frank H Netter MD School of Medicine, North Haven, CT.*

Background: Over the past decade, substantial changes have affected the landscape of kidney transplantation in the Northeastern United States (Region I), comprising Connecticut, Maine, Massachusetts, New Hampshire, and Rhode Island. This region has seen a steady increase in kidney transplants, reflecting the growing trend nationwide. Still, disparities remain in kidney donation across ethnic groups. We aim to explore these disparities, utilizing data from the United Network for Organ Sharing (UNOS).

Methods: We included the UNOS database from 2013 to 2023 within Region I. Total kidney transplants, waiting lists, deceased kidney donors, and living kidney donors, categorized by ethnicity were obtained.

Results: Kidney transplants increased from 678 in 2013 to 1,004 in 2023. In 2023, 5,085 patients were on the kidney waiting list, with distribution: White 57.8%, Black 19.45%, Hispanic 15.05%, and Asian 6.6%. White patients received in 2023, 58.0% of kidney transplants, followed by Black 21.4%, Hispanic 13.0%, and Asian 6.6%. Compare to 2012, where white patients: 69.6%, Black 18.1%, Hispanic 9.1%, and Asian 2.8% In 2023, White donors constituted most deceased organ donors at 73.9%, down from 81.6% in 2013. Black deceased donors were in 2023 6.1%, up from 2013 5.1%. Both Hispanic and Asian deceased donors increased. In 2023, 81.9% of living donors were White, 8.1% Hispanic, 4.7% Black, and 4.1% Asian. Black living donors decreased from 6.1% in 2013 to 4.7% in 2023. Blacks received a lower proportion of kidney transplants compared to their waiting list representation, with similar disparities in both deceased and living kidney donations.

Conclusions: The ethnic disparity persists within Region I. To ensure everyone has access to life-saving treatments, it is imperative to promote equity, diversity, and inclusion in organ donation and transplantation. Collaborative initiatives involving healthcare providers, policymakers, and community organizations are essential to address these disparities and foster a supportive transplantation system.

Table 1. Comparison of UNOS Kidney transplant data from 2013 to 2023

Category	2023 (%)	2013 (%)
Kidney Deceased Donor by Ethnicity		
White	73.9	81.6
Black	6.1	5.1
Hispanic	16.3	9.0
Asian	1.3	0.4
Living Donor by Ethnicity		
White	81.9	82.7
Black	4.7	6.1
Hispanic	8.1	7.3
Asian	4.1	1.0

PUB231

Identifying Global Awareness of Glucagon-Like Peptide 1 Receptor Agonists (GLP-1 RAs) through Google Search Trend Analysis

Harshil Fichadiya,[1] Vraj Patel,[2] Wisit Cheungpasitporn,[1] Iasmina Craici.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Canton Medical Education Foundation, Canton, OH.*

Background: GLP-1 RA initially introduced as anti-glycemic agents are now found beneficial in HF, ASCVD & CKD and most popularly in treatment of Obesity. This has made GLP1RA a popular choice among patients with a higher BMI and diabetes requiring a kidney transplant. We performed a google trend analysis of GLP1RA related google search since 2004 and assessed the trend of this search overtime and in different areas of the World. This may be an indirect measure of public awareness, availability, and utility of these drugs in different regions globally.

Methods: A retrospective analysis of Google Trends was conducted for the term "GLP-1 Receptor Agonist" from its inception in 2004 until May 21, 2024. Search trends were assessed over time as well as per nation.

Results: Search started trending up from 2020 & increased exponentially from September 2023. The number of google searches per region have been distributed in different shades of blue in Fig 1 with the darkest shade representing region with the highest number of searches and the lightest shade representing region with the lowest number. Grey represents areas with lack of enough data for the term. Highest search rates were seen in Denmark, USA, South Korea and lowest search rates were seen in Russia, Vietnam and Turkey. Many African, some Eastern European and some central Asian countries did not have enough data to compute a search number. Search trends more or less corelated with search trends of obesity and to a lesser extent to diabetes and CKD.

Conclusions: GLP1RA are found to be beneficial in treatment of multiple disorders like HF, obesity, diabetes and CKD which are major contributors to morbidity and mortality in the current time. Equal awarness, distribution and access to these drugs is essential from a global health perspective. Map in Fig 1 helps us identify area with low awarness (as indicated indirectly by low google search trend) such that targeted efforts can be channeled to these areas to improve access and awareness. Some common causes of low awarness maybe socioeconomic disparities, high cost & lack of medical literature access and efforts should be made to mitigate these

PUB232

STARx Health Care Transition Readiness Scores among Arabic-Speaking Youth with Chronic Conditions

Yara Abumohsen, Peter Said, Maria E. Ferris. *The University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: We assessed Healthcare transition (HCT) readiness among Arabic-speaking youth with chronic conditions—an often-underrepresented group in HCT literature. Using the STARx Questionnaire our study examined 107 youths (mean age 13.3 years) with diverse chronic conditions, such as kidney issues, thalassemia, and diabetes mellitus.

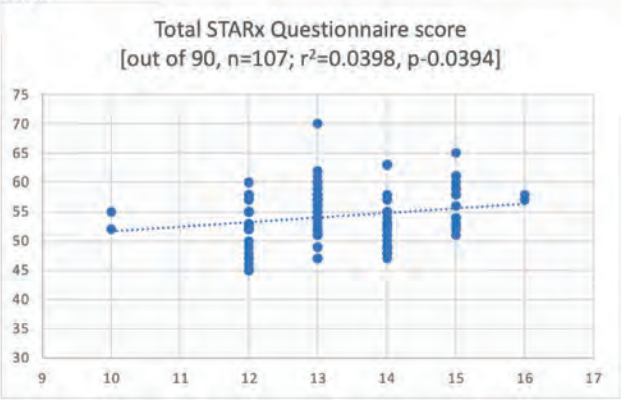
Methods: The 18-item self-administered STARx Questionnaire has been utilized in 15 countries to determine HCT. After Arabic translation/back translation from and to English, the questionnaire was administered at Zagazig Hospital in Egypt.

Results: The HCT readiness assessment revealed an overall score of 54.30 out of 90, with a weak positive correlation between age and the STARx Questionnaire score (Linear regression line: r^2=0.0398, p-0.0394, Figure 1). Further analysis using the STARx Questionnaire showed that the scores for the disease knowledge, self-management,

and provider communication subdomains were 15±1/20, 15±2/25, and 12±2/20, respectively with a significant positive correlation with age. The percentages of possible maximum score in each domain were 75±6, 61±7, and 62±10, respectively. Significant sex differences emerged, with males having significantly lower scores in the following questions: "How easy or hard is it to take care of yourself?" (p=0.0364), "How often do you forget to take your medication?" (p=0.0025), "how often did you need someone to remind you to take your medicines?" (p=0.0032), and "how often did you take your medicines on your own?" (p=0.0316).

Conclusions: In this Arabic-speaking cohort of youth with chronic conditions, the average HCT readiness score was 54/90 with the best domain in disease knowledge. As in other countries, we observed significant sex differences in self-management and medication adherence which require attention to improve long-term outcomes. Providers need to develop strategies to augment HCT readiness.

Figure 1: Relationship between youth age and total STARx Questionnaire score



PUB233

Planning for Locally Provided Haemodialysis Care in Badu Island in the Torres Strait: Kikirrui dan Walmai Project

Jaquelyne T. Hughes, Candice M. Liddy-Stokes, Katie Cundale, Karla J. Canuto. *Flinders University College of Medicine and Public Health, Adelaide, SA, Australia.*

Background: Diabetes is a very common cause of morbidity in the Torres Strait, the remote island region of Australia that has been inhabited for many thousands of years by Torres Strait Islander people. Morbidity and mortality related to diabetes and kidney disease emerged post-colonisation, and in the 1990s, Tribal leaders across all Island clusters endorsed the Torres Strait Health Strategy. This strategy identified that investment in health infrastructure – including buildings, staffing needs, and care models – are critical to ensure locally provided, culturally safe care was available for adults living with diabetes-related kidney failure. Tribal Elders from the main island of the Western Cluster of the Torres Strait, Badu Island, prioritised locally available haemodialysis as key health infrastructure. Here, we describe the community-defined infrastructure needs for safe and quality haemodialysis care on Badu Island.

Methods: Badu Island Tribal elders sought to establish a culturally knowledgeable, Torres Strait Islander-led team to engage community members on Badu, Mabuiag, and Moa Islands, as well as community members living in Cairns. The research and its conduct was approval by Maluilgal Tribal Governance, and supported by an Australian National Health and Medical Research Council Fellowship.

Results: The team met with communities in the Torres Strait in October 2023 and in Cairns in December. At each meeting, the attendees supported the pursuit of a dialysis unit on Badu Island. The need to also pursue funding to support community-led restorative health initiatives was also discussed. A report consolidating those engagement visits was relied upon to make a Commonwealth Government Grant, approximating $3.5million to support a new build of 4-chair haemodialysis unit.

Conclusions: Tribal governance was the persisting attribute in bringing together a report that summarised a health plan for locally delivered haemodialysis. The zageth will continue with the award of funds to commence building, and parallel zageth to identify a clinical training pathway for Torres Strait Islander clinicians to provide dialysis care and related health care.

Funding: Government Support - Non-U.S.

PUB234

Conducting a Patient Panel Discussion to Highlight the Intersection of Humanism and Health Equity

Asheen Zariat, Andrea Bilger, Mlka Mengesha, Lawrence B. Holzman, Yuvaram N. Reddy. *University of Pennsylvania, Philadelphia, PA.*

Background: Medical humanism is defined as "attitudes and actions that demonstrate interest in and respect for the patient that addresses the patient's concerns and values." While research shows physicians' implicit biases about minority patients affects their care, there is less research on the possibility of an "empathy gap" for these patients. Encouraging humanism in medicine could be one way of countering bias which may exacerbate disparities in outcomes for Black patients experiencing Chronic Kidney Disease (CKD). Patients as teachers is a pedagogical technique that has been noted to be impactful in changing attitudes of clinicians. In honor of Dr. Sidney Kobrin, a highly esteemed nephrologist and humanist who unexpectedly died in 2023, we conducted a panel discussion which aims to honor his legacy of humanism while furthering our understanding of how to practice humanism in a way that incorporates an understanding of health disparities and social determinants that drive these disparities

Methods: We conducted a panel discussion of 2 patients and 1 staff member who worked extensively with Dr. Kobrin, including self-identified Black individuals with CKD and women. This 60-minute panel discussion ocurred during a larger Humanism symposium with an audience of 200+ people. Questions explored panelist perspectives on aspects of humanism embodied by Dr. Kobrin, how these aspects of humanism address power differentials, medical mistrust, and barriers to care, and how can clinicians incorporate these principles into their daily practice. Afterwards, a 20 minute reflection session was conducted with 3 audience members.

Results: Recordings of the panel discussion and reflection session will by analyzed and coded by two independent coders who will generate a summary of broad themes regarding humanism's role in medicine and in addressing health disparities. We will assess whether this panel discussion might lead to new ideas on how to provide more humanistic, equitable care.

Conclusions: This project will bring together people from different racial and socioeconomic groups and different power structures to identify broad themes of humanism that have the potential to address health inequities. This experience could be especially empowering for patients of marginalized backgrounds who may not see themselves represented in their providers.

PUB235

Ethics of Dialysis in People with Advanced Kidney Disease Who Inject Drugs

Rachel E. Brobst, Jean Lee, Alexandra Green, Suzanne Boyle. *Temple University Hospital, Philadelphia, PA.*

Background: Barriers such as unstable housing, lack of insurance, and social stigma make it challenging to secure outpatient dialysis for people who inject drugs (PWID) with advanced kidney disease. We describe four cases from our center and propose a bioethical framework for guiding clinicians in dialysis planning.

Methods: Cases were obtained through review of medical records from 2022-2024. Inclusion criteria were: PWID, chronic xylazine wounds, CKD stage 5 or end-stage kidney disease, and life-prolonging goals of care. We described their baseline characteristics, time of initial presentation (each presented for nonhealing leg wounds), management decisions regarding dialysis, and long-term outcomes.

Results: See Image 1

Conclusions: These are challenging cases as there are no established guidelines for determining outpatient dialysis candidacy. Decisions are often driven by unfounded stereotypes which typically default to declaring the patient unfit. We propose evaluating patients through the lens of four bioethical principles: autonomy, beneficence, nonmaleficence, and justice. This strategy permits evaluation of the risks and benefits to the individual, system, and society. In each of the outlined cases, the patients' goal is life prolongation (autonomy), and 3 have begun dialysis (beneficence). Nonmaleficence is often cited when discussing long-term dialysis candidacy, due to concern patients may inject into catheters, increase risk of infection, and hasten death. Two patients have tunneled catheters and have not used their catheters to inject drugs. Justice is the most nuanced of the principles, given the systemic barriers to placing high-risk patients in dialysis units and the psychosocial barriers to accessing appropriate dialysis care, as evidenced by the 120 hospital visits for these patients since time of identification. In summary, PWID with concomitant advanced kidney disease present a unique challenge. Patients and clinicians can implement a systematic framework with these four bioethics principles to evaluate outpatient dialysis candidacy.

Patient	Age	Sex	Housing Status	Initial Presentation	Decision	Long-term Outcomes	# hospitalizations since presentation
#1	37	Male	Housed	11/2023	HD started 01/2024 for hyperkalemia; HD unit assigned, left AMA, lost unit	Presents every ~2 weeks to ED needing emergent HD. No unit assigned	24
#2	41	Male	Unhoused	01/2024	Managed conservatively	Remains off HD. Attended 1 follow up appointment	9
#3	56	Male	Unhoused	05/2022	Attended follow up appointments, managed conservatively	Started HD 11/2023 for hyperkalemia. Assigned HD unit 04/2024	53

Using Social Media/Mainstream Media Surrounding Transplantation Education: Perspective on CKD

Shahid N. Muhammad. *Coventry University, Coventry, United Kingdom.*

Background: The use of social media (SM) today provides unparalleled opportunities to provide and receive education, access to communication and engagement. SM/ mainstream media (MM) such as television, newspapers, magazines, and radio stations are also being used to prompt education surrounding specific Long-Term Conditions (LTCs). Certainly, use of SM is not limited by constraints of time and geography. Three questions being proposed here: 1) Is there a Faith stance on using SM/ MM to prompt organ donation/ transplantation education? 2) Can those who follow Faith donate organs? and 3) Does the Healthcare Scientist have a role providing the public education surrounding organ donation/ transplantation? Chronic Kidney Disease (CKD) will be used to provide a LTC example.

Methods: There is a need for multi-channel approaches so that the issue is a more widely known social norm in primary care, where healthcare scientists will know underlying pathologies. If those with Faith decide to donate an organ, they must do so out of free will without being morally or socially forced and without economic pressures. If the deceased indicated during life (in a will) that they do not want to donate organs, then no one is authorized to do this on the deceased person's behalf.

Results: More educational campaigns via SM/ MM involving healthcare scientists and Faith communities are required. Bridging gaps in health literacy (HL) is also important. This is where healthcare scientists have an important role, to provide health science transparency where other health professionals are challenged. Clarity of terminology to help increase HL on topics relating to organ donation/ transplantation is now especially required owing to more time being spent online.

Conclusions: 1) The Faith stance on use of social media to prompt organ donation/ education has not been investigated. 2) Those who follow Faith can donate organs, and 3) More research is required to shed light on what is the most effective approach for healthcare scientists in above context.

PUB237

Exploring the Educational Implications of Declining Nephrology Fellowship Interest: A Comparative Analysis of Internal Medicine Specialties Using GPT-4

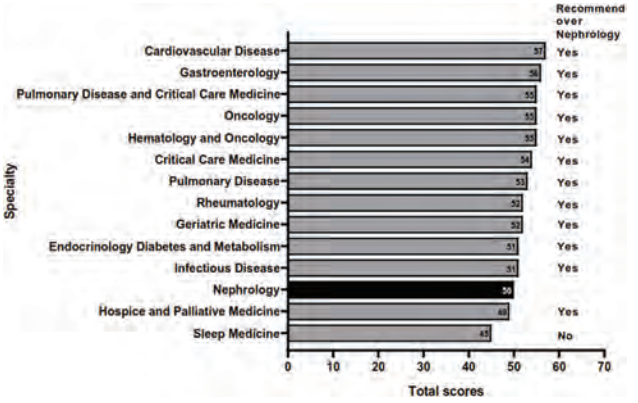
Oscar A. Garcia Valencia, Charat Thongprayoon, Iasmina Craici, Wisit Cheungpasitporn, Jing Miao. *Mayo Clinic Minnesota, Rochester, MN.*

Background: The 2024 US fellowship match shows a concerning decline in interest in Nephrology with an 11% drop in candidates and only 66% of positions filled. We used Chat GPT to discern the factors affecting this trend and devise educational strategies to attract more trainees.

Methods: Using GPT-4, we compared Nephrology to 13 Internal Medicine specialties based on factors such as intellectual complexity, work-life balance, procedures, research, patient interactions, career demand, and remuneration. The model assigned scores (1-10) based on how well each specialty performed. The cumulative score determined ranking. To mitigate bias, we instructed GPT-4 to prioritize other specialties over Nephrology in hypothetical reverse scenarios.

Results: In GPT-4's evaluations Nephrology ranked only above Sleep Medicine. It lagged in crucial aspects such as a healthy work-life balance, strong patient relationships, and meeting career demands. While the match fill rate was 66%, slightly higher than Geriatric Medicine's 45%, there was a decline ranging from 4% to 14% across five critical criteria, encompassing intellectual challenge, procedural engagement, career prospects, research and academic opportunities, and financial compensation.

Conclusions: Nephrology's attractiveness is declining compared to other Internal Medicine specialties. This trend is concerning and calls for a reassessment of the factors influencing specialty choices among medical residents. The insights provided by AI can be used to redesign nephrology training programs, curriculum, and mentorship initiatives and apply them to improve medical education and career guidance. Further educational research and interventions are needed to comprehensively reassess nephrology education and training, and specific areas for future research and educational initiatives should be proposed to address the declining interest in the specialty.



PUB238

Awareness of Nephrology Fellows regarding Hepatitis B Vaccination in Patients with CKD Approaching Dialysis

Sobia N. Khan. *Stony Brook University, Stony Brook, NY.*

Background: Dialysis patients face a heightened risk of hepatitis B infection due to their immunocompromised state and frequent exposure to body fluids. Vaccinating these patients is cost effective than monthly monitoring of antigen/ antibody titers. Due to immunosuppression, they are prone to becoming chronic carriers. Our goal is to raise awareness, enhance knowledge and improve the hepatitis B vaccination rate among chronic kidney disease (CKD) patients.

Methods: We developed a tool including questionnaire to evaluate Nephrology fellows' perception of the importance of Hepatitis B vaccination in CKD patients, followed by one-on-one discussion with a nephrology attending. This study was conducted over a year.

Results: In the year prior to the educational intervention, 34 new patients were admitted to our outpatient dialysis unit, of these 10 patients (29%) were vaccinated meaning 24 patients (71%) were unvaccinated before starting dialysis. After implementing the educational program, a follow-up questionnaire revealed that the fellows' proficiency in hepatitis B vaccination knowledge increased from 70% to 90% following the lecture. This indicated a significant improvement in awareness and understanding which we hope will translate into higher vaccination rate among CKD patients. We reviewed new ESRD admissions a year later to assess the impact of improved awareness among fellow physicians. Charts of newly admitted patients revealed that 46 patients started chronic dialysis. Among them 15 (32%) needed vaccination at the initiation of dialysis while 31 (67%) were vaccinated beforehand. Table 1

Conclusions: The data indicated that although fellows' clinical knowledge improved after the educational intervention, their effectiveness in ensuring patients received the vaccination did not show significant improvement. To enhance the fellows' efficiency in vaccination, the next step could be to ensure standardizing the process of Hepatitis B vaccination in CKD patients, which can be implemented by order bundle set for chronic kidney disease in the electronic medical records (EMR).

Table 1: Analysis pre and post intervention

	Pre	Post
New patients	34	46
Vaccinated before dialysis	24	31
Received vaccination after Dialysis	10	15

PUB239

Importance of the Nephrologist in Teaching AKI

Juan P. Gomez Villarreal, Paola Borbolla-Flores, Ricardo A. Garza Treviño, Mara C. Olivo Gutierrez, Lilia M. Rizo Topete. *Hospital Universitario Dr Jose Eleuterio Gonzalez, Monterrey, Mexico.*

Background: Acute Kidney Injury (AKI) is associated with high mortality and morbidity, and the cost of treating patients with AKI is substantial. However, there are currently several challenges in early recognition. One of them is the concepts that should

be taught from basic science to postgraduate medical students. The use of new tools to teach AKI definition and early recognition is important for improving healthcare and medical practice.

Methods: We conducted a survey in 321 participants, that included medical students, general practitioners, and those with different specialties. This survey was able through google forms we evaluated the knowledge of AKI with the next questions. Which of the following classifications is correct for defining acute kidney injury? How is acute kidney injury defined? What is considered the first cause of acute kidney injury? Which of the following parameters tells us about acute deterioration of renal function? What is considered to be the first cause of acute kidney injury? Which of the following parameters tells us about acute deterioration of renal function? Do you consider urinary sediment to be a diagnostic tool for acute kidney injury? Do you consider this a risk factor for the development of acute kidney injury?

Results: The most relevant findings were in risk factors, in which the poll had more opportunities to grow because they did not associate premature birth and preeclampsia with 64% and 46.7%, respectively, 30.8% did not think that urine sediment is a diagnostic tool, about the classification the poll uses KDIGO in the 69.1%, AKIN in 18.6%, and RIFLE in 5.9%.

Conclusions: There has been a growth in the knowledge of AKI, but there is still work to be done in teaching the risk factors and diagnostic tools. We must also reinforce correct classification using technology and educational meetings or conferences.

PUB240

Decoding the Renal Puzzle: Idiopathic Distal Renal Tubular Acidosis in a 23-Year-Old Woman with Nephrocalcinosis and Metabolic Acidosis

Graciela M. Luna, Daniela Carralero Somoza, Umair S. Ahmed, Kaitlyn Cariaga. *Lakeland Regional Medical Center Inc, Lakeland, FL.*

Introduction: Distal Renal Tubular Acidosis (dRTA) is a cause of normal anion gap metabolic acidosis. Its etiology encompasses various factors, including autoimmune diseases, genetic mutations affecting chloride-bicarbonate exchanger genes, and drug-induced occurrences, such as with lithium, amphotericin B and Toluene inhalation due to glue sniffing. dRTA can also manifest as an idiopathic disorder.

Case Description: A 23-year-old female with an unremarkable medical history presented to the emergency department with nausea, vomiting, bilateral flank pain and fever. Prior to seeking emergency care, the patient had visited an urgent care facility where she was provisionally diagnosed with a urinary tract infection and treated with Bactrim. Upon admission, her creatinine level was 1.14 mg/dL, serum potassium was 2.9 mmol/L), serum bicarbonate 10 mmol/L, and an anion gap of 12. Urine pH was 6.0. CT abdomen/pelvis disclosed severe bilateral nephrocalcinosis in the renal pyramids and the presence of calculi. Urine anion gap was positive. Subsequent investigations ruled out rheumatoid arthritis, Sjogren's disease, lupus and multiple myeloma. Patient was discharged on PO sodium bicarbonate and potassium chloride which was switched as an outpatient to potassium citrate. 24 hour urine collection recommended as an outpatient prior to starting potassium citrate to evaluate for hypocitraturia could not be done due to financial constraints.

Discussion: Distal RTA is an uncommon disorder. Pathophysiology of distal RTA involves damage to alpha-intercalated cells in the distal tubule, impairing the secretion on hydrogen ions, consequently raising the urine pH and causing metabolic acidosis. Hypokalemia occurs due to the failure of H/K ATPase. This case highlights the importance of checking a urine anion gap in patients with normal anion gap metabolic acidosis and the need to consider distal RTA in patients who have nephrocalcinosis. Timely diagnosis of distal RTA is crucial to preventing long-term complications such as nephrocalcinosis and nephrolithiasis, allowing early initiation of alkali and potassium supplementation. Furthermore, distal RTA can sometimes be the first manifestation of an underlying autoimmune condition and once it is diagnosed, attempts should be made to identify the cause of the distal RTA.

PUB241

A Case of Multifactorial Severe Hypophosphatemia

Andrew Murphy, Matthew Sangoi, Toni Sabbouh. *Pennsylvania Hospital, Philadelphia, PA.*

Introduction: Hypophosphatemia is defined as serum phosphate < 2.5 mg/dL. It is induced by internal redistribution, decreased intestinal absorption, or urinary wasting. We present a case of multifactorial severe hypophosphatemia in the setting of chronic alcoholism and presumed refeeding syndrome.

Case Description: A 69 year old male with a history of alcohol use disorder presented to the ED with generalized muscle weakness, recurrent falls and confusion. He reported consuming 2 bottles of wine daily for several years, with his last drink 24 hours prior to presentation. He reported a history of caloric restriction with intentional weight loss followed by a recent increase in caloric intake in the preceding week. His initial presentation was consistent with sepsis from contained sigmoid perforation due to foreign body ingestion, likely a chicken bone. Labs revealed phosphorus < 1, potassium 2.0, magnesium 1.4, lactate 8.5, WBC 6.1 with 34% band neutrophils, mild alkalosis (venous pH 7.43), pCO_2 42, HCO_3 24. He was admitted to the ICU and received volume resuscitation, IV antibiotics, management of alcohol withdrawal, intravenous phosphate, potassium and magnesium. Repeat labs showed improved phosphorus to 1.9, however serum corrected calcium decreased from 9.5 to 7.5 mg/dL. He continued to receive further repletion of electrolytes with eventual normalization.

Discussion: The etiology of this patient's severe hypophosphatemia was multifactorial from chronic alcoholism and refeeding syndrome. Refeeding syndrome was likely present in this case given the patient's malnutrition and weight loss with recent significantly increased caloric intake resulting in severe hypophosphatemia, hypokalemia and hypomagnesemia. His generalized muscle weakness can be explained by alcoholism and severe electrolyte derangements. Fortunately, he did not develop respiratory failure which is a complication of severe hypophosphatemia as a result of decreased intracellular ATP. For patients with severe hypophosphatemia (< 1 mg/dL), IV phosphate repletion is recommended with level monitoring every six hours. This patient developed hypocalcemia in the setting of phosphate repletion, which is a known complication and should be monitored closely.

PUB242

A Case of Hyponatremia Due to Unilateral Renal Hypoperfusion from a Type B Aortic Dissection

Andrew A. Lin,[1] Nadia Al Haddad,[2] Kristen N. Tillquist,[2] Jordana B. Cohen,[1] Nathaniel Reisinger.[1] *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Penn Medicine, Philadelphia, PA.*

Introduction: Hypoosmolar hyponatremia in euvolemic patients has a broad differential diagnosis and significant potential morbidity. Much of the underlying pathophysiology in hypoosmolar, euvolemic hyponatremia stems from ADH secretion, whether from ectopic overproduction or the body attempting to regulate perceived osmolar and volume status. Here, we present a case of severe symptomatic hyponatremia due to unilateral renal hypoperfusion.

Case Description: A 64-year-old male with a past medical history of hypertension and type A aortic dissection presented with a new type B aortic dissection. Blood pressure was elevated to the 170s/90s and was quickly controlled with carvedilol, hydralazine, and clonidine. On admission, the patient's sodium was 137. Late on hospital day 2, the patient became confused and unable to follow commands. The sodium was now 120 with urine sodium 30, urine osmolality 786, and serum osmolality 259. On physical exam, he was euvolemic with a blood pressure of 121/89. Jugular venous distention, pulmonary rales, and edema were absent. Repeat urine sodium was 10 and urine osmolality was 521. The patient received multiple 3% hypertonic saline boluses which stabilized his sodium at 128 on day 4. Review of the patient's imaging demonstrated the right renal artery arising from the false lumen of his dissection with decreased contrast uptake, versus the left renal artery which arose from the true aortic lumen. We hypothesized that the patient's hyponatremia was due to unilateral renal hypoperfusion causing increased renin secretion by the right kidney, leading to stimulation of sodium resorption by angiotensin II, and ultimately increased ADH secretion leading to hyponatremia. The patient was placed on fluid restriction and his sodium stabilized at 133; he was discharged with instructions for close nephrology follow-up.

Discussion: While renal hypoperfusion such as in unilateral renal artery stenosis can cause hyponatremia, this is usually accompanied by hypertension (hyponatremic hypertensive syndrome). Here, the patient's euvolemia and initial urine studies suggested SIADH until revisiting his abdominal imaging. A high degree of clinical suspicion is thus required for alternative anatomic causes of hyponatremia and ADH secretion in response to perceived hypovolemia.

PUB243

A Unique Case of Hypokalemic Periodic Paralysis with Resolution after Successful Surgery for Cervical Stenosis

Ahmed A. Zaher, Matthew D. Nguyen, Ramy M. Hanna. *University of California Irvine Nephrology Hypertension & Kidney Transplantation, Orange, CA.*

Introduction: Hypokalemic periodic paralysis is a rare neuromuscular condition that presents with episodic severe muscle weakness, often triggered by strenuous exercise or high carbohydrate diets, that can be further divided into two major types, primary and secondary. The primary type could be genetically inherited or sporadic. The most common mutation causing this condition is CACNA1S gene mutation and the SCN4A gene mutation. The secondary type could be caused by any renal or gastrointestinal pathology causing loss of potassium, along with certain drugs like loop diuretics, thiazide diuretics, laxatives, corticosteroids, beta adrenergic agonists, insulin, and glucose. Here we present a unique case of a 29-year-old white male patient who presented with periodic paralysis attributed to his hypokalemic status.

Case Description: This previously healthy patient did not have any of the secondary causes or any other known condition to cause his periodic paralysis. His serum potassium was between 3.6 to 3.8 mmol/L, and genetic analysis proved that he has a mutation in his CACNA1S gene. Moreover, he has a mutation in 11B-HSD gene causing him to have aberrant mineralocorticoid excess. He reported several episodes of loss of consciousness which is atypical of primary hypokalemic periodic paralysis. Later, after he was treated for cervical stenosis as he was investigated for symptoms of cervical radiculopathy, he reported complete resolution of his symptoms and declines any further episodes of loss of consciousness. At this time, potassium supplements were stopped, given no indication to continue them. However, he was advised to continue to take amiloride if his serum potassium levels dropped below 4 mmol/L.

Discussion: The patient's clinical presentation is believed to be attributed to his cervical spine lesion instead of his hypokalemic periodic paralysis. More research is required to determine the level of genetic penetrance in each case to customize the treatment accordingly with precision medicine, improving outcomes and minimizing potential adverse effects.

PUB244

Chronic Hypokalemia Secondary to Distal Renal Tubular Acidosis Induced by Sodium Valproate

Abhi Lohana, Usman Akbar, Neeharika Muddana. *Camden Clark Medical Center, Parkersburg, WV.*

Introduction: Sodium Valproate is a commonly prescribed medication for the treatment of various conditions, including mood disorders and epilepsy. However, it can lead to rare adverse effects, such as valproate-induced distal renal tubular acidosis (dRTA), which results in a non-anion-gap metabolic acidosis with associated hypokalemia. We report a case of dRTA in a patient with a history of chronic hypokalemia attributed to long-term sodium valproic acid therapy.

Case Description: A 61 y.o. female with a past medical history of hypertension, anxiety, depression, and tobacco dependence with half a pack per day, was admitted to the hospital for concern of bilateral lower extremity muscle pain and weakness for the last 5 days which worsened to numbness and led to difficulty ambulating. She mentioned that she has been told on multiple outpatient visits that she had low potassium for the last 1-2 years and no workup was done in the past. She does not recall any family history of hypokalemia. Her home medications include sodium valproate, lisinopril, olanzapine, and ondansetron. On arrival at ED the patient was found to have a Potassium level of 1.8 was a significant drop from her previous labs. On further evaluations, the patient had non-anion gap metabolic acidosis in the blood. Urine studies showed an alkalotic pH of 7.0, potassium of 44, sodium of 93 and chloride of 116 concerning of urine anion gap of 21 suggesting renal tubular acidosis. Other labs like thyroid function tests and renin aldosterone studies were within normal limits.

Discussion: Valproate-induced dRTA is a rare and idiosyncratic side effect of long-term valproic acid therapy. DRTA is characterized by impaired acid secretion in the distal renal tubules, leading to metabolic acidosis and hypokalemia. In this case, the patient's chronic hypokalemia was likely exacerbated by valproate use, which prompted the development of dRTA. This case emphasizes the importance of recognizing valproate-induced distal renal tubular acidosis as a rare but potentially serious complication of long-term valproic acid therapy. Prompt diagnosis and appropriate management are vital for the patient's well-being.

PUB245

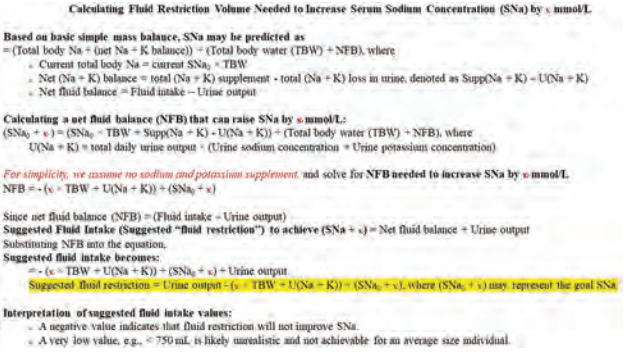
Fluid Restriction in Hyponatremia

Phuong-Chi T. Pham,[1] P.M. T. Pham,[3] Phuong-Thu T. Pham.[2] *[1]UCLA Medical Center Olive View, Sylmar, CA; [2]Ronald Reagan UCLA Medical Center, Los Angeles, CA; [3]VA Greater Los Angeles Healthcare System, Los Angeles, CA.*

Introduction: Fluid restriction (advised as fluid intake of 500 mL below average daily urine output, Hyponatremia Expert Panel 2007) to correct hyponatremia for euvolemic/hypervolemic hyponatremia is often minimally effective or ineffective. We present a case illustrating how failure of fluid restriction can be mathematically predicted.

Case Description: A 48-year-old male with non-ischemic heart failure with ejection fraction of 30%, presents for volume overload. Nephrology is consulted for persistent hyponatremia ranging from 122-126 mmol/L despite fluid restriction in the setting of loop diuretic use. On the day of consult, serum sodium (SNa) is 126 mmol/L. Chart review reveals daily fluid restriction of 1.8L/d with urine output averages 4L/d. Urine studies: sodium 66-95 (average 80.5) mmol/L, potassium 35-39 (average 37) mmol/L. Urine electrolyte free water clearance (EFWC) = Urine volume*(1-[urine Na + urine K]/serum Na) = 4*(1-(80.5+37)/126)=0.3L/d. Fluid "restriction" of 1.8L/d, albeit much less than urine output of 4L/d, exceeds daily EFWC of 0.3L/d. Fluid intake greater than EFWC cannot correct hyponatremia.

Discussion: As illustrated, fluid restriction to a volume below urine output in this case (i.e., 1.8L << 4L/d) exceeds the daily EFWC (i.e., 1.8L/d fluid intake > 0.3L/d electrolyte-free water lost in urine) and can never correct SNa. The suggestion to reduce fluid intake to 500 mL less than average daily urine output should be revised to be lower than daily EFWC. Alternatively, fluid restriction may be suggested to be [Urine output - $(x \times TBW + U(Na + K)) \div (SNa_0 + x)$], where x is the change in SNa desired. A negative value predicts that fluid restriction is ineffective. See figure for equation derivation and definitions of terms. Alternatively, for stable patients with euvolemic hyponatremia who are at goal SNa, advice to not exceed a predicted fluid intake volume may be given. In this case, x is set at zero. The fluid intake volume that would not worsen hyponatremia is [Urine output - $(U(Na + K)) \div (SNa_0)$].



PUB246

A Clinical Roadmap to Managing a Patient with Gitelman Syndrome

Jerin Karingattil, Yinelka G. Silverio De Castro, Eliot Sachsenmeier, James Drakakis. *NYU Langone Hospital - Long Island, Mineola, NY.*

Introduction: Gitelman syndrome is a salt wasting tubulopathy whereby the classic findings are hypokalemia, metabolic alkalosis, hypomagnesemia and hypocalciuria. The cause is an inactivating mutation in the SLC12A3 gene which encodes the thiazide sensitive sodium-chloride cotransporter on the apical membrane of the distal convulted tubule. There is significant variability in the phenotypic manifestatons of the disease. In any case, management includes liberal salt intake and supplementation of potassium and magnesium as the hallmarks. However, literature providing specific guidance and dosing in this arena is lacking.

Case Description: 44 year old male initially presented to the ER with palpitations and near syncope. He was found to have a serum potassium of 2.3 mmol/L and serum magnesium of 1.2 mg/dL. Both were supplemented intravenously and he was discharged with outpatient follow up. Renal magnesium loss was confirmed with 24 hour urine magnesium of 220 mg and fractional excretion of magnesium of 11%. Urine calcium was low at 60 mg per day. Genetic testing was pursued given the high suspicion for Gitelman syndrome, revealing compound heterozygous mutations in SLC12A3. As his electrolytes were in disarray and blood pressure low (~90/50 mm Hg) a treatment regimen was sought. The goal being a strategy that would be both effective, well tolerated and safe.

Discussion: Specific management of Gitelman syndrome with a prevalence of only 1-10 per 40,000 is not precisely outlined or defined. Much additional information is needed to understand the appropriate options, as supportive evidence is lacking. In this particular case, we settled upon the following: potassium chloride 40 mEq per day, magnesium chloride to provide 640 mg elemental magnesium per day, and sodium chloride tablets 2 grams three times per day. Adjustements were made along the way to

arrive at an overall stable electrolyte panel. On a recent visit, BP measured 116/80 mm Hg with serum magnesium 1.4 mg/dL and potassium 3.7 mmol/L. He has not had any additional hospitalizations for related metabolic disturbances. Future practice may be guided by this framework with the realization that goal electrolyte values may be lower than the expected range. Long term outcomes in such patients are also potential areas for further investigation.

PUB247

Unmasking the Enigma: A Case Report on Hyponatremia and Chimeric Antigen Receptor T Cell (CAR-T) Therapy in Mantle-Cell Lymphoma

Ahmad Matarneh, Sundus Sardar, Rafael Portela, Muhammad Abdulbasit, Navin Verma, Naman Trivedi, Nasrollah Ghahramani. *Penn State College of Medicine, Hershey, PA.*

Introduction: Chimeric Antigen Receptor T-cell (CAR-T) therapy is a new treatment for relapsed and refractory hematologic cancers. CAR-T cells are modified T-cells that express receptors targeting specific antigens on cancer cells, leading to their apoptosis and destruction. CAR-T therapy is associated with a unique adverse effects, such as cytokine release syndrome (CRS) and neurotoxicity. It can also cause electrolyte abnormalities, such as hyponatremia, hypophosphatemia, and hypokalemia. Here, we present a challenging case of hyponatremia following CAR-T therapy.

Case Description: A 66-year-old male, known to have a history of Mantle cell lymphoma, diagnosed 8 months prior to presentation. Initially treated with R-CHOP, then underwent CAR-T therapy. Two months ago, he underwent Tecartus CAR-T therapy, which was complicated by grade 2 CRS. This was managed with tocilizumab, anakinra, and dexamethasone. He was noted with hyponatremia on outpatient labs, sodium levels at 119 meq/l. Upon presentation, he was completely asymptomatic. Exam showed orthostatic hypotension; treated with normal saline 0.9%, but sodium levels remained low. His serum osmolality was low(258mosm/kg), urine sodium was high(53meq/l), and urine osmolality was high(463mosm/l), suggesting syndrome of inappropriate antidiuretic hormone secretion. He was initiated on urea powder. Despite that, his sodium levels remained around 128meq/l. Considering the orthostatic vitals, bedside ultrasound findings revealed features consistent with a hypovolemic state, including an inferior vena cava diameter of 2.1cm and respiratory collapse exceeding 50%. Given these findings, he was given intravenous fluids which resulted in improvement in his levels, discharged with instructions to maintain a liberal intake of oral fluids. Follow-up labs showed sodium increase.

Discussion: Hyponatremia, can complicate CAR-T treatment, and is frequently associated with CRS. The prompt identification and management of hyponatremia are crucial to ensure optimal outcomes for patients undergoing CAR-T therapy. CRS can be treated with immunosuppression. Treating hyponatremia in CAR-T-related cases poses challenges as one of the pathophysologies is volume depletion. Supportive measures with hydration, coupled with addressing potential underlying CRS, can aid in management.

PUB248

Inhalation Burn from a Fire Extinguisher: A Rare Cause of Acute Phosphate Toxicity

Madhab Ray, Brian Y. Young, Hiba Hamdan, Lindsey R. Goetz. *University of California Davis, Davis, CA.*

Introduction: Dry chemical fire extinguishers often contain monoammonium phosphate (MAP). Inhalation of MAP can cause upper and lower airway damage leading to acute respiratory distress syndrome. It is also a rare cause of acute phosphate toxicity, leading to a potentially fatal constellation of metabolic derangements including hyperphosphatemia, hypocalcemia, and high anion gap metabolic acidosis in addition to acute kidney injury.

Case Description: A 44-year-old male with psychiatric illness and no known kidney disease presented in cardiac arrest after intentionally expelling a fire extinguisher containing MAP into his mouth. He had a prolonged resuscitation and was admitted with acute respiratory failure, non-oliguric AKI, severe, mixed metabolic and respiratory acidosis, hyperkalemia, and marked hyperphosphatemia. Initial chemistry showed: Na 146, K 6.8, Cl 104, C02 9, Ca 11.7, Phos 40, BUN 24, Cr 1.29, anion gap 41, lactic acid 4.8. Arterial blood gas showed: pH 6.77, pCO2 100, pO2 12. The patient was treated initially with inotropes and mechanical ventilation along with bicarbonate infusion. As there was no clinical improvement despite robust urine output, sustained low-efficiency dialysis was started. His metabolic derangements resolved within 24 hours and his creatinine stabilized near 1.3 off dialysis. Unfortunately, the patient died of severe hypoxic brain injury. His family donated his kidneys for transplantation. One of the allografts (for which data are available) functioned well without evidence of acute phosphate nephropathy on subsequent biopsy.

Discussion: Organophosphorus poisoning often results from use of pesticides. However, poisoning from inorganic phosphate like MAP is rare. MAP is used as a fertilizer, stabilizing agent to reduce cadmium mobility in soil, and fire retardant or extinguisher. It is recognized to cause respiratory compromise, yet its metabolic consequences are infrequently reported. MAP inhalation and ingestion lead to very high phosphorus levels and a high anion gap metabolic acidosis, due in part to the contribution from the inorganic phosphate anion. It is important to remain aware of this rare poisoning. There is no antidote available. Treatment is supportive and the outcome is often fatal. In this case rapid initiation of dialysis resolved the metabolic abnormalities and prevented long term damage to the kidneys.

PUB249

Unusual Presentation of Sjogren Disease with Proximal Renal Tubular Acidosis

Jee Hoon Kim, Eric Siddall. *Columbia University, New York, NY.*

Introduction: Sjogren's disease (SD) has many renal manifestations. We present a case of type 2 (proximal) renal tubular acidosis (pRTA) with Fanconi syndrome and tubulointerstitial nephritis (TN) treated with maintenance mycophenolate mofetil (MMF), tacrolimus (TAC) and low dose steroids in a SD patient.

Case Description: 69-year-old female with history of SD presented for evaluation of elevated creatinine (Cr). The patient's SD symptoms were bone pain, stiffness in her lower extremities eventually leading to a wheelchair bound state and dry mucous membranes. She denied any family history of kidney disease. Labs showed a Cr 1.36 mg/dl, bicarbonate 18 mmol/L, potassium 3.2 mmol/L, glucose 96 mg/dl, phosphate 1.7 mg/dl, uric acid 1.6 mg/dl, vitamin D 25 OH 19 ng/ml, vitamin D 1, 25 OH 15 pg/ml. Urinalysis was significant for pH 6, sterile pyuria and glucosuria. Her fractional excretion of phosphate was 34.6%. Lab work was consistent for pRTA. Due to the sterile pyuria, a renal biopsy was done which showed acute on chronic TIN with severe activity. The patient started 50 mg of prednisone daily. Metabolic derangements were treated orally. Unfortunately, her TIN quickly relapsed when steroids were tapered prompting initiation of MMF with another steroid taper. She again relapsed when steroids were weaned. At this point, a multitargeted immunosuppression regimen was initiated with prednisone 10 mg/day, MMF 1000 mg twice daily, and TAC with a trough goal 4-7. On this regimen, the patient's Cr has remained stable at 1.2 mg/dl with no additional flares for the last 9 years. Her prednisone was also tapered down to 5 mg. Clinically, the patient's bone pain and wheelchair bound state improved after treatment with active vitamin D and oral phosphate.

Discussion: TIN is the most common kidney manifestation in SD. Most patients are treated with 1 mg/kg of prednisone with a taper. Maintenance therapy usually involves MMF or azathioprine. TAC is rarely used for TIN in SD. In this patient's biopsy, the TIN appeared similar to acute cellular rejection and thus was treated with transplant immunosuppressive medications. PRTA occurs in around 3% of patients with SD. PRTA can lead to Fanconi's syndrome resulting in a normal anion gap metabolic acidosis, phosphaturia, glycosuria and aminoaciduria. Treatment usually involves supplementation of bicarbonate and electrolytes such as potassium and phosphate.

PUB250

Exploring Therapeutic Effects of Continuous Kidney Replacement Therapy in Patients with Severe Acidosis Using Deep Learning-Based Causal Inference

Min Woo Kang, Sehoon Park, Yong Chul Kim, Kook-Hwan Oh, Dong Ki Kim. *Seoul National University College of Medicine, Jongno-gu, Seoul, Republic of Korea.*

Background: Continuous kidney replacement therapy (CKRT) is an essential treatment for uncontrolled severe metabolic acidosis. However, CKRT can increase workload and lead to complications, thus necessitating its selective application to patients who stand to benefit significantly. This study aims to investigate the therapeutic effect of CKRT in patients with severe acidosis by utilizing a deep learning-based causal inference model to assess its potential impact on in-hospital mortality.

Methods: The Medical Information Mart for Intensive Care III (MIMIC-III) dataset was utilized, and patients with data available within the first 48 hours after intensive care unit (ICU) admission were selected. Patients experiencing severe acidosis with a pH <7.2 within the initial 48 hours were selected. Treatment was defined as the application of CKRT within 48 hours of ICU admission, and the outcome was defined as in-hospital mortality. The dataset was randomly divided into an 85:15 ratio for train and test data. The Generative Adversarial Nets for Inference of Individualized Treatment Effects (GANITE) model was applied on training the model, and its performance was evaluated in the test data.

Results: In the train data, the model demonstrated an accuracy and Area Under Receiver Operating Characteristic Curve (AUROC) of 0.883 and 0.887 (0.880–0.893), respectively, while in the test data, it showed 0.841 and 0.824 (0.804–0.843). The model was well calibrated. The probability change of average in-hospital mortality with CKRT treatment for all severe acidosis patients was +15% and +14% in the train and test data, respectively. However, in the patient who underwent CKRT, the application of CKRT resulted in an average reduction of in-hospital mortality probability by 13% in both the train and test data.

Conclusions: Developing a model that strategically represents the therapeutic effects of CKRT for individual patients could be expected to aid decision-making in the future application of CKRT treatment.

PUB251

Primary Aldosteronism with Hypercortisolism in a 47-Year-Old Man

Tamar Mosulishvili,[1] Dylan M. Ofri,[2] Charles W. Hopley.[2] *[1]Dartmouth College Geisel School of Medicine, Hanover, NH; [2]Dartmouth Hitchcock Medical Center, Lebanon, NH.*

Introduction: Despite its high prevalence, PA remains underdiagnosed and undertreated. There is a need for clinicians to be well-versed in additional features that PA can present with, to initiate appropriate and timely diagnostic workup.

Case Description: A 47-year-old man with extensive CV history, including persistent HTN (on several medications) and hypokalemia, presented with diaphoresis, lethargy, nausea, abdominal cramps, and muscle aches. Chart review revealed multiple admissions with HTN and hypokalemia. On admission, he was mildly ill-appearing, VSS and WNL, Weight 121.9kg, BMI 37. PE: unremarbakle with negative Cushingoid signs. Labs notable for K 2.5, Cl 83, HCO3- 36, AG 16. BUN 37 with creatinine 1.57. Glucose was 326, with Hgb A1c at 14.3%. A CT abdomen showed a 12mm left adrenal nodule. Empirical treatment for PA was initiated with potassium, IV fluids and insulin. Aldosterone was 16ng/dl and renin activity was 1.3ng/ml/hr. Adrenal venous sampling revealed unilateral left aldosterone hypersecretion with cortisol-corrected aldosterone ratio > 4 at 17, further supported by non-dominant adrenal vein cortisol corrected aldosterone (0.4) to IVC (2.3) (R/IVC) ratio of less than one at 0.17. Notably, left adrenal gland cortisol was significantly higher at 1117 (right at 172), suggestive of adrenal adenoma producing concomitant high levels of cortisol and aldosterone. The shared decision for left laparoscopic adrenalectomy was made.

Discussion: This case demonstrates an interesting and rare presentation of primary aldosteronism with additional features. Since laparoscopic adrenalectomy can be curative for unilateral adenomas, adrenal venous sampling to determine lateralization is recommended. In the case of this patient, secondary hyperaldosteronism and hypertension likely due to primary hyperaldosteronism with elevated cortisol levels are potentially suggestive of aldosterone and cortisol co-producing adenoma (A/CPA). About 10% of patients with PA also have A/CPA, and in patients with PA and single adenoma, the prevalence of A/CPA is 9.7 – 20%. Patients with A/CPA are more prone to metabolic abnormalities and have higher risk of cardiovascular events. Characterization of A/CPAs prior to surgery is critical since the removal of A/CPAs can result in post-op adrenal crisis and required management with hydrocortisone replacement therapy.

PUB252

Hyponatremia, mg vs. mEq Gone Terribly Wrong: A Cautionary Tale

Shubha Ananthakrishnan, Andrea Broka, Niti Madan. *UC Davis Health, Sacramento, CA.*

Introduction: We present a case of a rapid hyponatremia correction due to an improper medication dose conversion calculation. Hyponatremia, a common electrolyte disorder, remains a nephrologist nightmare as it can lead to osmotic demyelination syndrome (ODS). Management of hyponatremia remains challenging and involves an understanding of the relationship between, weight, osmolality, tonicity, and different unit measures.

Case Description: 59-year-old female > 50% total body surface area burns complicated by tracheoesophageal fistula s/p complex repair, recurrent aspiration pneumonia, severe malnourishment, chronic hyponatremia, thought due to SIADH managed with salt tabs, presented due to malfunction NG tube, and was found to be hyponatremic at 119 mmol/L. After endoscopic NG tube placement, she was restarted on diet and Salt tabs, 3 tabs q 8 hours (EMR order Thermotabs/chloride 287 mg Sodium 180 mg, Potassium 15mg (540 mg of sodium equal to 72 mEq in 24 hour) with slow improvement on her serum sodium. However, given NG tube clogging issues, the night team changed her tablets into a liquid formulation 540 mEq q8 hr (EMR order liquid sodium chloride 4 mEq/ml). The[SA1] conversion unfortunately was done assuming milligrams and mEq were the same with the patient mistakenly getting **23 times** the intended amount of sodium through the NG tube in liquid form, that caused a sodium correction[SA2] from 123 to 145 mmol/L in the next few hours. CT brain showing subarachnoid hemorrhage. MRI brain the next day also showed T2/FLAIR hyperintensity in the pons concerning for myelinolysis.

Discussion: Electrolytes dosing errors are well-known and associated with high morbidity and mortality. In general, when a system fails to prevent an adverse outcome, poor communication is almost always a contributing factor. We also identified that a non-standardized sodium formulation's units in EMR orders (tablets registered in milligrams, while liquid formulations with their concentration mEq/ml) contributed to the adverse event. Our systems heavily rely on the provider's knowledge, increasing the risk of human error. We hope that standardizing EMR listing of electrolytes replacements to include the mEq content for each formulation and automatically calculate the total prescribed dose will aid in avoiding future errors.

PUB253

Analysis of the Impact of the Rate of Severe Hyponatremia Correction on Clinical Outcomes

Ana Gabriela J. T. Melo, Marcia Fernanda Arantes de Oliveira, Lucia Andrade, Jose M. Vieira Jr. *Hospital das Clinicas da Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil.*

Background: Hyponatremia correction is well known associated with a extremely rare, albeit severe event, osmotic demyelination. Guidelines therefore strongly recommend a rate of correction no faster than 6 mEq/L/24h. Here, we sought to investigate whether faster correction of severe hyponatremia is associated with longer length of hospital stay (LOS) and mortality.

Methods: We reviewed medical records for hospitalized patient who had severe hiponatremia (Na< 125 mEq/L) during a year. Variables related to hyponatremia diagnosis and other clinical characteristics were assessed. Then we analyzed through regression analysis whether the rate of Na correction within 24h above 6 mEq/L was independently associated with either prolonged LOS (defined as above the median duration time) or mortality.

Results: We evaluated N=304 hyponatremic (Na<125 mEq/L) patients. Overall, age was 60 IQR 47-69; 86% had chronic (>48h) hyponatremia, 37% were admitted in the ICU, and 18% were under dialysis. Out of 304, 129 patients (42.5%) had Na correction rate higher than 6 mEq/L/d (rapid correction, RC). RC group had lower baseline Na levels (122 IQR 116-124 vs 123 IQR 120-125 mEq/L, P=0.001), but compared to controls had similar age, baseline sCr, heart failure, cirrhosis, cancer, AKI and CKD diagnosis, but less hypertension and diabetes cases. The hospital LOS was significantly higher for RC group (23 IQR 11-52 vs 19 IQR 10-33 days, p=0.012), but after regression analysis the model found other variables associated with prolonged LOS (> 20d): admission in the ward, type of hyponatremia and ICU admission. Overall mortality was 20% and did not differ between groups. Besides the Na correction rate cutoff of 6 mEq/L/d, sensitivity analysis showed that neither 10 mEq/L/d nor the rate of Na correction (as a continuous variable) remained as predictor of hospital LOS or mortality. Lactate, vasopressor use and heart failure were independent variables associated with mortality in this cohort.

Conclusions: Our study strongly suggest that the rate of correction of a severe hyponatremia above the limits defined by current guidelines does not impact on LOS and mortality, and appears to be safe regarding these outcomes.

PUB254

Peripartum Hyponatremia: A Case Report of Complications in Preeclampsia

Khushleen Jaggi. *San Mateo Medical Center, San Mateo, CA.*

Introduction: Preeclampsia, characterized by new-onset hypertension and end-organ dysfunction after 20 weeks of gestation, carries the potential for severe complications such as eclampsia and HELLP syndrome. Peripartum hyponatremia, associated with adverse outcomes, presents a serious concern when coupled with preeclampsia.

Case Description: 39 year old with hypothyroidism, obesity (BMI 38.1), IVF pregnancy and gestational hypertension was admitted at 36 weeks for labor induction due to severe preeclampsia. At 35 weeks, she developed headaches, proteinuria (urine protein to creatinine ratio 1.1), and elevated AST levels (66 U/L). Estimated GFR and platelets were normal. Upon admission, she received misoprostol, oxytocin, and artificial rupture of membranes for labor induction. Her serum sodium decreased from 131-134 mmol/L three weeks before admission to 129 mmol/L on admission, reaching a nadir of 122 mmol/L the next day. Patient was euvolemic, with low serum osmolality (262 mOsm/kg), high urine osmolality (290 mOsm/kg), urine sodium of 29 mmol/L, normal TSH (1.44), and low morning cortisol (1.3, likely due to antenatal betamethasone). Fetal intolerance prompted a C-section. Postpartum hemorrhage from uterine atony prompted ICU transfer for hemorrhagic shock. Fluid restriction and sodium chloride tablets improved serum sodium. Treatment was continued until delivery, after which serum sodium promptly normalized. Follow-up labs at 6 weeks and 5 months postpartum showed normal electrolytes.

Discussion: While rare, severe hyponatremia in preeclampsia patients can lead to maternal symptoms like nausea, headache, confusion, and seizures, with fetal

manifestations including jaundice, seizures, and tachypnea. It is associated with adverse outcomes, including stillbirth and postpartum ICU admissions. Treatment in this population is challenging due to limited medication options, with fluid restriction and sodium chloride tablets typically used. Delivery of the fetus is often necessary for definitive treatment, especially in cases of moderate to severe hyponatremia. While pregnant women may have physiological alterations in sodium homeostasis causing mild hyponatremia, the exact etiology of severe hyponatremia in preeclampsia patients remains unclear. Close monitoring and timely intervention are needed to avoid adverse outcomes. Further research is needed to understand the underlying physiology contributing to hyponatremia.

PUB255

Unveiling the Effects: The Influence of Trimethoprim Sulfamethoxazole (TMP-SMX) on Electrolyte and Acid-Base Disturbances

Emily Vazquez Morales, Juan J. Adams Chahin, Adriel Gonzalez Rivera, Ileana E. Ocasio Melendez. *Universidad de Puerto Rico Recinto de Ciencias Medicas, San Juan, Puerto Rico.*

Introduction: Trimethoprim sulfamethoxazole (TMP-SMX) is an antibiotic commonly used as treatment and prophylaxis for infectious processes including Pneumocystis jirovecii pneumonia (PCP) in HIV patients, but it has been associated with various metabolic disturbances including renal tubular acidosis. This case will describe the chronology of a patient's metabolic derangements after medication was started.

Case Description: A 53-year-old woman with alcohol and drug abuse was brought to the ED due to loss of consciousness requiring intubation upon arrival due to alcohol withdrawal symptoms. On initial laboratory tests, patient tested positive to HIV and days later she developed respiratory distress. Chest CT scan was performed and demonstrated right lower lobe necrotizing pneumonia. HIV viral load was elevated at 5,920 with an associated low CD4 count of 31. Opportunistic infections were high on the differential which included PCP and prophylactic treatment with TMP-SMX was began. Nephrology service was consulted approximately 5 days after initiation of therapy due to increasing trend in serum creatinine levels, hyperkalemia, normal anion gap metabolic acidosis and hyponatremia. Urine spots yielded a urine anion gap of 44.6. Alkali therapy was initiated, and hyperkalemia management was provided, and type 4 renal tubular acidosis was highly suspected due to temporal association with TMP-SMX administration. The offending agent was discontinued after discussion with ID and Pulmonology services. Patient's serum creatinine, hyponatremia, hyperkalemia, and non-anion gap metabolic acidosis resolved afterwards.

Discussion: Our case represents a patient who developed several metabolic disturbances TMP-SMX may cause. There are no accepted treatments for TMP-SMX induced RTA and literature has demonstrated that patients improve after withdrawal of medication. Although patients often show improvement after discontinuing treatment, it may sometimes be delayed and can increase the patient's morbidity. Therefore, it is crucial to consistently evaluate for hyperkalemia, hyponatremia, metabolic acidosis and increases in serum creatinine levels after initiating medication.

PUB256

Hyperkalemia: Room for Improvement?

Juan Rodríguez Mansilla, Claudia Diez, Alba Santos, Sandra L. Castro Molano, Natalia R. Romero, Mario Colomer, Elisabeth M. Martí, Javier Perez-Contreras. *Hospital General Universitario Dr Balmis Servicio de Nefrologia, Alicante, Spain.*

Background: Patiromer and sodium zirconium ciclosilicate mitigate the risk of RASi-associated hyperkalemia, avoiding decreasing or stopping its dose. Our aim was to evaluate how physicians from different specialties treat hyperkalemia.

Methods: A survey with different items related to the prevalence of hyperkalemia, severity assessment, and acute and chronic treatment was coducted among physicians in one hospital.

Results: 68 surveys were included: 51.5% women, age 37.1±10.6 years. Medical specialties enrolled were 38.2% Nephrologists, 14.3% internal medicine, 14.3% GPs, and 33.2% other. Among all the surveys, 43.2% assess 5 or more patients per month with hyperkalemia, of which 17.6±8.3% are moderate and 8.1±6.1% are severe. Although 92.6% of the surveyed identify peaked T waves as a sign of severity, 26.5% acknowledge not requesting an ECG in all patients. In acute hyperkalemia:100% adjust treatment according to the patient's blood glucose and 96.6% to the acid-base status; 86.2% prescribe diuretics and 69% use new binders, although 51% are unaware of their financing conditions in Spain. The use of new binders has reduced the use of diuretics in 31% of respondents. After correcting a mild hyperkalemia, only 50% of physicians recommend analytical review, within a time frame of 30(15-90) days. After correcting a moderate hyperkalemia, 88.2% recommend review and within a time: 30(15-30) days, p=0.006. After severe hyperkalemia is corrected, 98.5% recommend analytical review, significantly earlier, within 10(4-30) days (p<0.001). In chronic hyperkalemia, 16.2% of physicians discontinue treatment with RASi and 52.9% reduce their dose. Although 42.6% always recommend a low-potassium diet and 47.1% do so sometimes, 26.5% of surveyed are unaware of culinary techniques to reduce potassium and 33.8% are unaware of hidden potassium sources (such as sodium-free salt) When starting a RASi/MRA in a patient with normal renal function, 67.6% recommend analytical review to assess potassium and it is recommended within 30(15-90) days. If initiated in a patient with renal disease, 88.2% recommend review, significantly earlier within 30(15-30) days, (p=0.004).

Conclusions: The management of hyperkalemia is adequate in our area although there is room for improvement. Strategies to improve the maintenance of cardio-nephro-protective treatment are essential.

PUB257

Recurrent Cerebral Salt Wasting in Subarachnoid Hemorrhage

Jamie R. Greathouse, Sukhman Dhaliwal, Evelyn C. Aldana Barrientos, Salma Yasin. *Temecula Valley Hospital, Temecula, CA.*

Introduction: Hyponatremia occurs in over 50% of patients with subarachnoid hemorrhage (SAH) due to various etiologies such as diuretic therapy, SIADH, and cerebral salt wasting (CSWS) (Nakajami, 2017). Differentiating between SIADH and CSWS is challenging due to similar diagnostic results. SIADH and CSWS present with increased urinary sodium and volume but differ in management. This case highlights the diagnostic difficulties and management of CSWS.

Case Description: 49-year-old male presented with a severe headache. Imaging showed a SAH. A ventricular drain was placed, and the patient was put on a sodium goal, nimodipine, and intra-arterial verapamil for vasospasm. During admission, the patient developed high urinary output and hyponatremia. Initial treatment with fluids and desmopressin failed. Hypertonic fluids and fludrocortisone were started. Despite this, sodium levels dropped, necessitating increased hypertonic fluid rates and NaCl tablets. Recurrence of high urinary output with hyponatremia called for monitoring of hypertonic fluids and overall fluid balance until complete resolution.

Discussion: Hyponatremia in CNS disease is often due to SIADH; however, CSWS can be on the differentials, especially in SAH. Proposed CSWS mechanisms include impaired sympathetic input to the kidneys and elevated levels of brain natriuretic peptide (BNP). Disruption of neural input and BNP release decreases sodium reabsorption and inhibits renin release, leading to hyponatremia without potassium wasting (Sherlock, 2006). CSWS is uncommon but significant in acute brain injuries like SAH. Characterized by renal sodium excretion leading to hyponatremia, CSWS poses diagnostic challenges due to its overlap with SIADH. Prompt differentiation is critical as CSWS requires salt replacement and volume repletion, whereas SIADH is managed with fluid restriction (Luo & Wang, 2022).

Respiratory Acidosis in Salicylate Toxicity: An Unusual Initial Presentation

Hoon Chang,[1] Jonas Kwok,[1] Christina H. Brotman.[1,2] *[1]Renal, Electrolyte and Hypertension Division, University of Pennsylvania, Philadelphia, PA; [2]Center for Clinical Epidemiology and Biostatistics, University of Pennsylvania, Philadelphia, PA.*

Introduction: Salicylate toxicity is classically associated with mixed respiratory alkalosis and increased anion-gap metabolic acidosis. We present a case of primary respiratory acidosis in a patient with severe salicylate toxicity.

Case Description: A 59-year-old female with major depressive disorder on sertraline and quetiapine presented to the emergency room after being found unconscious next to an empty bottle of aspirin. Upon arrival, she was hypotensive with blood pressure of 83/71 mmHg and tachycardic with a heart rate of 115 bpm, and had a Glasgow Coma

Score of 7. Initial laboratory data were notable for creatinine of 0.76 mg/dL, serum bicarbonate of 14 mmol/L, and phosphorus of 6.7 mg/dL. Venous blood gas showed a pH of 7.26 and pCO2 of 49 mmHg. Salicylate level was 115 mg/dL, with the urine toxicology screen otherwise negative. Due to a witnessed seizure, she was intubated for airway protection. Subsequent arterial blood gas revealed a pH of 7.15, pCO2 of 85 mmHg, bicarbonate of 21.4 mmol/L, and a lactic acid level of 1.7 mmol/L. She was initiated on a continuous bicarbonate infusion, underwent placement of a non-tunneled dialysis catheter, and started on intermittent hemodialysis. The repeat salicylate level was 38.1 mg/dL, and she was transitioned to continuous kidney replacement therapy due to worsening vasodilatory shock and concerns for early cerebral edema based on head imaging.

Discussion: The traditional acid-base disturbance associated with salicylate toxicity is the co-occurrence of metabolic acidosis from increased anaerobic metabolism and respiratory alkalosis from hyperventilation due to direct stimulation of the respiratory centers within the cerebral medulla. Respiratory acidosis is typically considered in cases of co-ingestion and is a rare presentation of isolated salicylate ingestion. However, it is important to recognize that hypoventilation is a late or severe manifestation of salicylate toxicity and is a harbinger of respiratory failure. In this case, the patient developed severe cardio-pulmonary collapse, acute kidney failure, and cerebral edema within the first 12 hours of presentation. This highlights the importance of early recognition and prompt management of primary respiratory acidosis in severe salicylate toxicity.

PUB259

A Case of Graves Disease Presenting as Hypokalemic Periodic Paralysis

Krishna Mohita Kuruvada, Milagros Yunes. *Montefiore Medical Center, New York, NY.*

Introduction: Thyrotoxic periodic paralysis(TPP) is a rare complication of hyperthyroidism and is a treatable form of hypokalemic periodic paralysis(HPP). While hereditary channelopathies primarily underlie HPP, acquired cases are seen with hyperthyroidism and tend to affect males more frequently. We describe a case of thyrotoxicosis that presented with severe hypokalemia and sudden onset paralysis.

Case Description: 37-year-old male with no medical history presented with acute paralysis of upper and lower extremities. He had experienced severe muscle weakness and painful cramps intermittently over the past few months, worsened by exercise. He also noted weight loss, heat intolerance, and dry skin. Examination revealed thyromegaly, mild proptosis, power of 0/5 in upper and lower limbs, and hyporeflexia. Laboratory tests showed severe hypokalemia (< 2 mEq/L) and mild metabolic acidosis (pH 7.25, bicarbonate 16 mEq/L). The possibility of distal RTA was considered with the combination of hypokalemia and metabolic acidosis, however, thyroid studies were pursued as his exam findings were concerning for hyperthyroidism. Thyroid studies revealed low TSH (<0.05 μIU/mL), elevated free T4 (3 ng/dL), free T3 (>20 pg/mL), thyroid-stimulating immunoglobulin (326%), thyroid-binding inhibitor (34 IU/L), and thyroid peroxidase antibody (>1000 IU/mL). Ultrasound showed an enlarged, hypervascular and heterogeneous thyroid gland. These findings were consistent with Graves' thyrotoxicosis. The patient was started on potassium supplementation, methimazole 20 mg daily, and atenolol 50 mg twice daily with which his weakness improved. The resolution of symptoms with potassium replacement and treatment for Graves' disease suggests that severe hypokalemia in this patient represents a case of hypokalemic periodic paralysis caused by thyrotoxicosis.

Discussion: Thyroid hormone increases Na+/K+-ATPase activity on muscle membranes leading to intracellular potassium influx. Patients experience sudden, painless episodes of muscle weakness during periods of stress. Bulbar and respiratory muscles are minimally involved. Acute episodes are managed with potassium supplementation and treatment of hyperthyroidism. Beta blockers inhibit the Na+/K+-ATPase and can be used for symptom control. This case illustrates the importance of checking thyroid studies in patients with HPP as restoration of euthyroidism eliminates episodes.

PUB260

Licorice: Treat or Poison?

Anita Kamarzarian, Tuan Nguyen, Sharona Hariri, Hoang Anh Nguyen, Sapna Gopal, Phuong-Chi T. Pham, Golriz Jafari. *UCLA Medical Center Olive View, Sylmar, CA.*

Introduction: Patients take many supplements considering them to be safe. Licorice has been used as a sweetener in candies and treats. Furthermore it is used in complimentary medicine for treatment of variety of conditions.

Case Description: 64 year old woman with diagnosis of stage 1**B** HR+ Her2- Left breast IDC, DCIS s/p lumpectomy, completed adjuvant radiation 6 months ago who was recommended by onclology to take anastrozole for 5 years as adjuvant therapy which she refused and instead saw a Chinese traditional practitioner and was started on supplements that included licorice 6 grams/day. She presented to the ED with complaints of L flank pain for one day. Workup of the L flank pain including CT Abd/pelvis, urinalysis, and urine culture did not reveal any abnormalities. However, incidentally found to have severe hypokalemia, K of 1.9 mmol/L,ABG: PH of 7.49 PCO2 of 38mmHg, Bicarbonate of 29 mmol/L, severe HTN and prolonged QTC 509 mS. Serum aldostrone and renin were depressed, her 24 hour urine potassium was 185 mmol/24 HR. She requried admission and recieved total of 700 meq of KCL over 48 hours.

Discussion: Pseudo-hyperaldosteronism is a condition that clinically mimics hyperaldosteronism with suppression of plasma renin activity and aldosterone levels. Hypokalemia, metabolic alkalosis, and HTN can be seen in this condition. Dietary causes include prolonged overconsumption of licorice. 11Bhdryoxysteroid dehydrogenase type 2 enzyme is responsible for conversion of cortisol to inactive cortisone. Licorice, specifically glycyrrhizic acid and its hydrolytic product Glycyrrhetinic acid are potent competitive inhibitors of 11-BHSD2 and lead to excess cortisol which avidly binds to the mineralocorticoid receptor resulting in cortisol-induced mineralocorticoid effect of sodium retention and urinary potassium waisting. Glycyrrhizic acid onsumption in excess of 100 to 200 mg daily has been noted to cause clinically significant complications. In addition to electrolyte abnormalities, licorice induced HTN and hypertensive encephalopathy, hypokalemic myopathy manifesting as flaccid paralysis, and QT prolongation and possible torsade de pointes with fatal arrhythmias can be seen. Our patient was asymptomatic, which in fact put her at higher risk of cardiac complications and sudden death given her prolonged QT findings. Presenting to the ED with non related flank pain potentially saved her life.

PUB261

A Matter of Fluid: Managing a Rare Case of Diabetes Insipidus and Multiple Sclerosis-Driven Hypernatremia

Henry Yip,[1] Claire Kim,[1,2] Katherine Andrade,[1] Rula A. Abdulrahman.[1]
[1]Stony Brook University Hospital, Stony Brook, NY; [2]Stony Brook University Renaissance School of Medicine, Stony Brook, NY.

Introduction: Transient central diabetes insipidus (CDI) is a rare condition which may result in hypernatremia and is rarely associated with multiple sclerosis (MS). Here we report a case of new onset hypernatremia, likely secondary to CDI in a patient with MS after exhibiting mental status changes.

Case Description: A 55-year-old female with MS and neurogenic bladder with suprapubic catheter was admitted for urosepsis. On initial labs, she had an acute kidney injury (AKI), bland urinalysis with concentrated urine and she produced normal range urine output (UOP). Following AKI resolution, she developed stroke like symptoms followed by polyuria up to 6L/24h resulting in hypernatremia of 167mmol/L and urine osmolarity 140mmol/L. Non-contrast stroke imaging showed no acute cerebral vascular accidents. She was started on intravenous fluid (IVF) repletion, which was unable to keep up with UOP, and was treated with intranasal desmopressin. Following desmopressin administration her urine output decreased to 1.2-1.8L/24h, which she reports to be closer to her baseline and her hypernatremia was ultimately resolved with continued IVF.

Discussion: CDI is a polyuric, hypotonic state typically due to injury to the hypothalamic track and inability to release vasopressin. MS produces demyelinated plaques which have a broad range of symptoms, and rarely has been seen to cause CDI. Although multiple cases describe transient CDI following cerebral vascular accidents, trauma and acute MS flairs there is limited data regarding overall incidence or mechanism of this injury. This makes management of hypernatremia difficult as in addition to supportive management with fluid repletion, the underlying cause must also be addressed. In our case we believed her hypernatremia was driven by transient CDI and her MS as noted with her mental status change and negative stroke work up. Given the relative lack of data, she was started on IVF, and empirically treated with desmopressin. Managing both hypernatremia, and new onset CDI in MS, this unique patient presented a unique challenge and highlights a relatively under explored topic. To date, there are only a few prior cases reporting CDI presenting in a patient with MS, and our report aims to highlight the association and areas of future research.

PUB262

Beyond the Bottle: Lactic Acidosis as a Consequence of Alcoholic Ketoacidosis

Graciela M. Luna, Daniela Carralero Somoza, Kaitlyn Cariaga, Umair S. Ahmed. *Lakeland Regional Medical Center Inc, Lakeland, FL.*

Introduction: Alcoholic ketoacidosis (AKA), a consequence of chronic alcohol use disorder in malnourished individuals. Ketoacidosis is caused by accumulation of ketone bodies when glucose availability is limited for metabolic energy. Lactic acidosis (LA) is classically type A acidosis due localized or systemic hypoperfusion. LA in the absence of evidence of hypoperfusion is type B acidosis.

Case Description: A 60-year-old male with a past medical history significant for alcohol abuse presented to the emergency department after a fall. No abdominal pain, fever, dizziness, lightheadedness, or loss of consciousness reported. On admission, vital signs were stable. Physical exam was unremarkable. Investigations revealed leukocytosis and metabolic acidosis. Serum lactic acid was elevated at 21.8 mmol/L on admission. Urinalysis showed presence of 3+ ketones. Liver function tests were unremarkable except for marginally elevated AST peaking at 109 u/l. Blood alcohol level was 179 on presentation. Beta-hydroxybutyrate was checked due to concerns for AKA and was 45.70

on presentation. HIV screen was negative. Patient was started on D5 water to help with ketoacidosis. Urine ketones and serum beta-hydroxybutyrate normalized 48 hours after admission with subsequent resolution of lactic acidosis.

Discussion: Type B LA causes include medications such as Metformin, malignancy, HIV infection, thiamine deficiency and mitochondrial dysfunction. Patients with chronic alcohol use disorder and malnutrition are at risk for developing AKA. Ketoacidosis usually presents after alcohol ingestion has ceased and after a binge episode. When ethanol levels start to decrease, catecholamines and cortisol rise, increasing lipolysis, accelerating the production of ketones. During the metabolism of ethanol, high amounts of NADH are generated. The reduction of NAD+ and consequential accumulation and imbalance of NADH in the metabolism of ethanol has several important consequences including an inhibition of the citric acid cycle and hepatic gluconeogenesis. The LA seen in AKA is due to an abnormal redox state. This case highlights the need to assess for unusual causes of LA when there is no evidence of either systemic or local hypoperfusion. This can help identify any underlying problem such as AKA, thiamine deficiency or HIV when there may sometimes be no other clues about these diagnoses.

PUB263

A Case of Unresolving Hypokalemia

Omar Dodin, Sreelakshmi Ravula, Nadia M. Alqurini. *University of Arkansas for Medical Sciences, Little Rock, AR.*

Introduction: Renal Tubular acidosis are a group of disorders that occur in the tubules of nephrons. They have multiple causes and all result in acidosis and electrolyte defects. Type 1 RTA is caused by a defect of H+ secretion in distal tubules, due to multiple drugs, autoimmune or genetic disorders causing: acidosis, Urine pH>5.5 and hypokalemia.

Case Description: Our case is a 35 years old female with Hx of SCD s/p splenectomy and allo SCT complicated by steroid refractory GVHD, for which she is currently on belumosudil. She also has acyclovir resistant HSV rectal lesions for which she was on cidofovir-stopped 08/13, restarted on 1/2024 then stopped again on 2/17/2024. Pt has long Hx of hypokalemia since 2014. On her last admission for sickle cell crisis, she was found to have a serum potassium of **2.1**. She was placed on maximum oral and IV potassium of total around **160 Meq** with amiloride which only raised potassium to **3.4.** On follow up after discharge, she was found to have serum potassium of around 3. She states that her chronic hypokalemia has become more severe and persistent over the last year, since her BMT. She has been getting regular IV potassium infusions in addition to taking PO supplementation. Although Pt had always denied any emesis/diarrhea or Poor PO intake some of her labs are suggestive of malnutrition including her urine potassium which was **18.6** and **25.4** on 2 consecutive days, with **urine pH of 6-7 during inpatient stay**. She was discharged with following admissions for IV potassium needed to maintain serum potassium above 3.

Discussion: We conclude that Pt has a mixed etiology of potassium malabsorption, cidofovir use and RTA 1, as she has low urine potassium which goes against RTA 1 but at the same time still doesn't achieve full compensation even with IV replacement and observed oral compliance and high potassium diet. A final solution would be bilateral Nephrectomy with at least 3 times/week HD with IV potassium supplementation if needed to improve potassium control and decrease risk of sudden death. Literature previously reported hypokalemia post BMT, SCT but by themselves they are amenable to oral and may need temporary IV management. Antiretroviral induced Fanconi has been rarely noted previously. This case shows that: 1-Hypokalemia can be refractory when multifactorial and certain pathologies have additive effects. 2-Full treatment is sometimes difficult as therapy ends up being too radical for Pt.

PUB264

Hypermagnesemia Caused by Laxatives in a Patient with Colitis and AKI

Nazia Habib, Omar Ali, Muhammad R. Khan, Swati Mehta, Krishnakumar D. Hongalgi. *Albany Medical College, Albany, NY.*

Introduction: Hypermagnesemia is uncommon but can be a potentially serious clinical condition with high morbidity and mortality. Magnesium (Mg) containing products are widely used by the general population. Although generally well tolerated in patients with normal renal function, their use in the elderly can result in severe hypermagnesemia particularly with concomitant renal failure and bowel disorders. We report a case of symptomatic hypermagnesemia with laxative use in the setting of acute kidney injury (AKI) and colitis

Case Description: 62 y/o male with history of COPD, hypertension, and chronic back pain, on chronic opioid was transferred from community hospital with severe colitis leading to shock. Patient is chronically constipated due to his opioid use. He initially presented with acute abdominal pain and nausea. CT abdomen showed severe colitis with significant stool burden but no obstruction and was given magnesium citrate. Labs revealed Cr of 2.3 mg/dl, WBC 16, Hemoglobin of 15 Mg 8.7 and lactic acid (LA) of 3.1. Patient respiratory status declined and was intubated. At our facility, Mg was 7.9, creatinine 2.9, and BUN of 62. Repeat CT Abd /pelvis shows interval worsening of bowel thickening. He was started on loop diuretics and isotonic fluids for hypermagnesemia, and his Mg level improved gradually. However, the patient's condition declined over the next few days with worsening shock, AKI and respiratory failure. As per family wishes, the patient was placed on comfort care and no other interventions pursued.

Discussion: Magnesium is an important intracellular cation in several enzymatic pathways. Serum magnesium level is affected by magnesium intake, absorption and excretion. In this case, impaired excretion and increased absorption of Mg due to colitis lead to hypermagnesemia and related complications. It is important to monitor for hypermagnesemia with laxative use in a patient with AKI, and colitis. Initial treatment consists of cessation of magnesium-containing medications and therapy with intravenous isotonic fluids plus a loop diuretic. Renal replacement treatment is often required in patients with severe or symptomatic hypermagnesemia in patients with moderate to severe AKI. Early recognition and treatment of hypermagnesemia can be highly effective to prevent significant morbidity and mortality.

PUB265

Mineralocorticoid-Responsive Hyponatremia in Elderly Patients

Matthew Ray,[1,2] Rakin Solaiman.[3] *[1]MultiCare Health System, Spokane, WA; [2]University of Washington, Seattle, WA; [3]Providence Sacred Heart Medical Center, Spokane, WA.*

Introduction: Hyponatremia is a common electrolyte disturbance. We present the case of a 69-year old female after recent surgery who presented with profound, symptomatic hypotonic hyponatremia. She was unresponsive to initial treatments of hypertonic saline and DDAVP, but received fludrocortisone with improvement in her symptoms and hyponatremia. This case highlights the importance of considering mineralocorticoid deficiency in the differential diagnosis of hyponatremia.

Case Description: This is the case of a 69-year old female who underwent right hip arthroplasty and subsequently presented to the hospital with acute encephalopathy, with initial serum sodium 104. Despite large volume of 3% saline with DDAVP and fluid restriction, she demonstrated minimal improvement in her serum sodium. Subsequently based on her lab findings with high volume urine output and elevated urine sodium levels, mineralocorticoid deficiency was suspected. Sshe was started on fludrocortisone with appropriate initial improvement, and she was discharged with follow-up with outpatient nephrology.

Discussion: Euvolemic hyponatremia has a broad differential diagnosis, and is a more misunderstood of the dysnatremias. Potential etiologies include various medications, inappropriate antidiuresis, severe hypothyroidism, and glucocorticoid deficiency, as well as low solute intake. However this patient did not have other secondary findings. The syndrome of mineralocorticoid responsive hyponatremia of the elderly has been reported in several cases and a case series, mainly from Japan. These share several key features: lack of volume depletion, no overt hormonal cause of hyponatremia, response to mineralocorticoids, or no improvement with fluid restriction alone. Our case bears concern given her marked urine output with urine sodium wasting with normal hemodynamic parameters. Few cases share this magnitude of hyponatremia and do not demonstrate the lack of response to hypertonic saline. This patient's profound hyponatremia was suspected to be multifactorial however did not begin to improve until administrtion of mineralocorticoid Mineralocorticoid deficiency is a rare but treatable cause of hyponatremia. Clinicians should consider this on the differential, especially in cases of refractory hyponatremia. Early recognition and treatment of mineralocorticoid deficiency can lead to a favorable outcome and prevent serious complications associated with hyponatremia

PUB266

A Rare Case of Sjogren Syndrome Associated with Acquired Gitelman Syndrome

Leonardo R. Ramirez Botana. *LSU Health Shreveport, Shreveport, LA.*

Introduction: Acquired renal tubular disorder has been detected in various disease processes, specifically autoimmune diseases. Gitelman syndrome is an autosomal recessive disease characterized by hypokalemic metabolic alkalosis, hypomagnesemia, and hypocalciuria. This case reported an acquired Gitelman syndrome associated with Sjögren's syndrome.

Case Description: A 61-year-old female with past medical history of Sjögren's syndrome, bronchiectasis, hypothyroidism was admitted due to right hip pain after a fall. She has been presenting with muscle weakness and cramping of lower extremities for several weeks. On phhysical examination was found low blood pressure, right lower hip pain, decreased range of motion and externally rotate right lower extremity. Initial laboratory results was found elevated white blood cell count, severe hypokalemia and metabolic alkalosis, hypocalcemia and hypomagnesemia. Urine spot chloride was reported 26 mEq/L, greater than 20 mEq/L, having with this value a differential diagnostic with intermittent diuretic use, and urine calcium excretion and maganesium are low as well. Renal magnesium wasting and hypomagnesemia are found in Gitelman syndrome, as well as, spot urine calcium/creatinine ratio of less than 44 mg/g, as our patient. This urine labs are explained due to the sodium chloride cotransporter (NCC) in Gitelman syndrome are shed into the urine in nanovesicles called urine exosomes and reducing the NCC activity in urine exosomes has been described in patients with Gitelman syndrome

Discussion: Our patients who was found with an unexplained hypokalemia, metabolic alkalosis and persistently elevated urine chloride for a Gitelman syndrome. It was reviewed other more common etiologies to excluded, and her home medications side effects was revised. In other cases, that has been reported a phenotype resembling Gitelman syndrome that can result from autoimmune diseases, most commonly in patients with Sjögren's disease–associated interstitial nephritis, for that reason, renal biopsy and genetic studies were ordered and will be follow up the results. The diagnosis of acquired Gitelman syndrome in our cases was based upon the clinical and laboratory findings. The hip was surgical repair and treated her electrolyte abnormalities and hypovolemia. Oral supplementation with substantial doses of sodium, potassium chloride and magnesium salts was ordered as fisrt line of therapy

PUB267

Amphotericin-Induced Apparent Mineralocorticoid Excess (AME)

Aldo E. Torres Ortiz. Tulane Nephrology and Hypertension. *Tulane University, New Orleans, LA.*

Introduction: AME is a syndrome characterized by a genetic or acquired deficiency in 11 beta-Hydroxysteroid dehydrogenase type 2 (11 beta-HSD2), which results in overactivation of the mineralocorticoid receptor. Licorice and certain medications such as azoles are known to induce AME. Amphotericin has a different mechanism of action, and to our knowledge, there are no prior case reports of AME induced by amphotericin.

Case Description: 64 year-old female with newly diagnosed acute myeloid leukemia, was admitted to the hospital for induction chemotherapy. Hospital course was complicated by neutropenic fever, secondary to mucormycosis of the abdomen, for which she was started on amphotericin B. Three days after the initiation of this medication, patient developed persistent hypokalemia, metabolic alkalosis and difficult to control hypertension for which Nephrology was consulted. Upon chart review, patient's blood pressure in office visits and on the first 25 days of admission had been <120/80 mm/Hg. Work-up for secondary hypertension revealed increased Cortisol/cortisone ratio on 24 hour urine collection of 0.6. Rest of work-up, including renal artery dopplers and metanephrines was unremarkable. Aldosterone and renin were low at 1.9 ng/dL and 1.1 ng/mL/hr respectively. Creatinine remained unchanged at her baseline of 0.5-0.7 mg/dL. Patient's blood pressure was controlled with maximum doses of Nifedipine and Lisinopril, showing a dramatic improvement after addition of spironolactone. Blood pressure, potassium and bicarbonate levels normalized after completion of amphotericin therapy.

Discussion: After review of all medications given in the Hospital, the only one with a clear temporal relation with the onset of hypertension was amphotericin B. This medication has a different mechanism of action than azoles, and to our knowledge, this is the first case report of amphotericin-induced apparent mineralocorticoid excess syndrome. Hypokalemia is a known side effect of hypokalemia secondary to amphotericin B, which is known to be secondary to tubular toxicity causing concentration gradients between the cytoplasm of distal tubule cells and the tubular lumen. This case can potentially explain a different mechanism of hypokalemia.

PUB268

Ominous Hyponatremia

Golriz Jafari, Hoang Anh Nguyen, Phuong-Chi T. Pham, Sapna Gopal, Anita Kamarzarian. *UCLA Medical Center Olive View, Sylmar, CA.*

Introduction: Hyponatremia is the most common electrolyte disorder in hospitalized patients and a signal for an underlying disorder. The differential diagnosis is broad and often times multifactorial in etiology. It is important to note that some less common causes may be overlooked in the initial evaluation.

Case Description: A 52-year-old man presents to the emergency room for right upper abdominal pain and found to have severe asymptomatic hyponatremia of 112 mmol/L. He had poor po intake, 30 lb. weight loss over the last months and drinks about 1.5L water daily. He has no known significant medical problems except vitreous hemorrhage, 30 pack year tobacco use and is originally from El Salvador. Initially he was thought to have hyponatremia due to hypovolemia vs. low solute state and initially treated with NS. His initial Uosm 495 and urine Na 89 mmol/L were consistent with hypovolemia. Na corrected to124 mmol/L, but then plateaued and relowered to 119 mmol/L. He was thought to have underlying SIADH from pain, lung lesion found on CXR and new diagnosis of TB. Despite fluid restricted and salt tabs, Na did not improve and renal was consulted. Repeat Uosm was 588 and urine Na 98 remained elevated and patient was noted to have hyperkalemia of K 6.1 mmol/L on admit without evidence of AKI. Patient was not hypotensive or orthostatic; AM Cortisol was low normal 5.4 mcg/dL however cosyntropin stimulation test was abnormal suggesting adrenal insufficiency. Further work up of lung lesion with CT revealed that patient had primary lung cancer with diffuse metastasis to brain, peritoneum, pericardium, liver, kidneys and adrenal glands. Patient was treated with hydrocortisone and fludrocortisone with improvement in Na to 129 mmol/L on discharge.

Discussion: Hyponatremia can be the first sign of an underlying malignancy. Often in malignancy patients, the etiology can be multifactorial including hypovolemia, low solute intake, SIADH, renal salt wasting or adrenal insufficiency. A thorough and detailed evaluation should be done to consider all possible etiologies and provide the optimal treatment.

PUB269

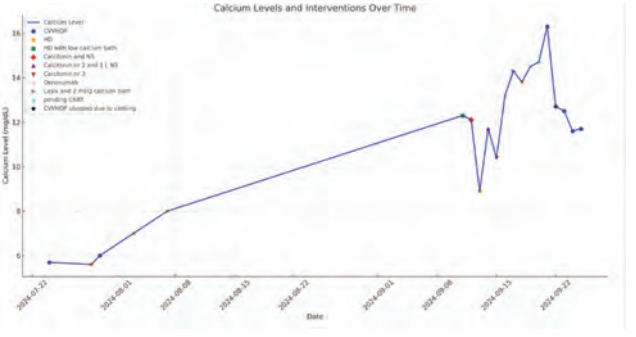
Hypercalcemia: Immobility's Insidious Impact and Navigating Rhabdomyolysis

Stela Teferici,[1] Nitzy N. Munoz Casablanca,[1] Hameeda T. Khan.[1,2] *[1]NYC Health and Hospitals Elmhurst Department of Emergency Medicine and Urgent Care, Queens, NY; [2]Mount Sinai Health System, New York, NY.*

Introduction: Hypercalcemia is a well-recognized complication. This case report explores less frequent etiologies: hypercalcemia occurring during the recovery phase of rhabdomyolysis and hypercalcemia due to immobilization.

Case Description: A 33-year-old man was found intoxicated on the street. On presentation, he displayed dilated pupils, tachypnea, and altered mental status, necessitating endotracheal intubation. Drug screen showed cocaine, benzodiazepines, and opioids. Additionally, he reported ingesting a banned weight-loss substance, raising concern for serotonin syndrome. He developed renal failure from rhabdomyolysis (creatine kinase level of 69,020 U/L), requiring renal replacement. Hospital course was further complicated by bacterial pneumonia with superimposed fungal infection, requiring eventual tracheostomy and percutaneous endoscopic gastrostomy tube placement. Despite kidney recovery and normal urine output, hypercalcemia recurred (12 mg/dl) and was unresponsive to several interventions (see Diagram 1). Work up showed low Vitamin D levels, low Parathyroid hormone level (PTH 7 pg/ml, phosphorus relatively normal, and mildly elevated Alkaline phosphatase (160 IU/L). Elevated collagen telopeptide 2369 pg/ml indicated PTH-independent hypercalcemia. Imaging revealed no abdominal or pelvic mass making malignancy unlikely. Normocalcemia was eventually achieved with calcium-free hemodialysis. Diagram 1.

Discussion: Rhabdomyolysis, though initially often causing hypocalcemia from muscle uptake, can lead to rebound hypercalcemia in up to a third of patients during recovery, due to the release of deposited calcium. However, our patient developed severe hypercalcemia despite resolution of rhabdomyolysis with workup indicating hypercalcemia of immobilization. Prolonged immobilization can cause bone resorption and hypercalcemia, especially in critically ill patients with high bone turnover. Fluid administration, pamidronate, and calcium-free dialysis are some methods used to correct severe hypercalcemia. Our case highlights one of the less common causes of hypercalcemia



PUB270

Electrolytes and Maintenance Intravenous (IV) Fluids

Jaicy Pottokaran, Mark S. Segal, Larry T. Patterson. *University of Florida, Gainesville, FL.*

Background: Isotonic saline is the recommended standard treatment of choice for maintenance intravenous (IV) infusion in pediatric population (NEJM, Oct 2015) since the recognition of hyponatremia as a complication following hypotonic IV fluids. We studied the change in incidence of electrolyte abnormalities before and after the 2015 publication. We also determined the risk factors for the development of abnormal electrolytes and their associated morbidity and mortality.

Methods: Data from the Integrated Data Repository (IDR) over a 10-yr period. Inclusion criteria: Children 2 months to 19 yrs who received IV fluids 24 hrs after admission from January 2012 to January 2022. Those with abnormal sodium levels on admission, patients with head trauma or stroke for whom hypernatremia was indicated, were excluded. SAS 9.4 version was used for statistical analysis.

Results: We examined data from 104,911 patient hospital days in 5916 patients from two time periods 2012 to 2016 and 2017 to 2021. See Table on Demographics for more details. Sodium levels were done in 5,915 patients and the incidence of hypernatremia fell from 9% in 2012 to 16 to 7% in 2017 to 2021 (Chi Squared 115, P value <0.0001). The incidence of hyponatremia was the same in both year time periods (10%). The incidence of hyperkalemia was the same in both time periods (1%), but the incidence of significant hyperchloremia increased from 7% from 2012 to 2016 to 16% from 2017 to 2021 (p value <0.0001). The incidence of hypochloremia events fell from 5% from 2012 to 2016 to 3% from 2017 to 2021 (p value <0.0001). The incidence of both alkalosis and acidosis increased from the period of 2012-16 to 2017-21 from 8% to 11% (p value <0.0001) and 5% to 7% (p value <0.0001), respectively.

Conclusions: Isotonic fluid use has not significantly changed the incidence of hyponatremia, but the incidence of hypernatremia has significantly decreased. We will discuss the incidence of a number of complications of maintenance IVF along with associated morbidity and mortality.

PUB271

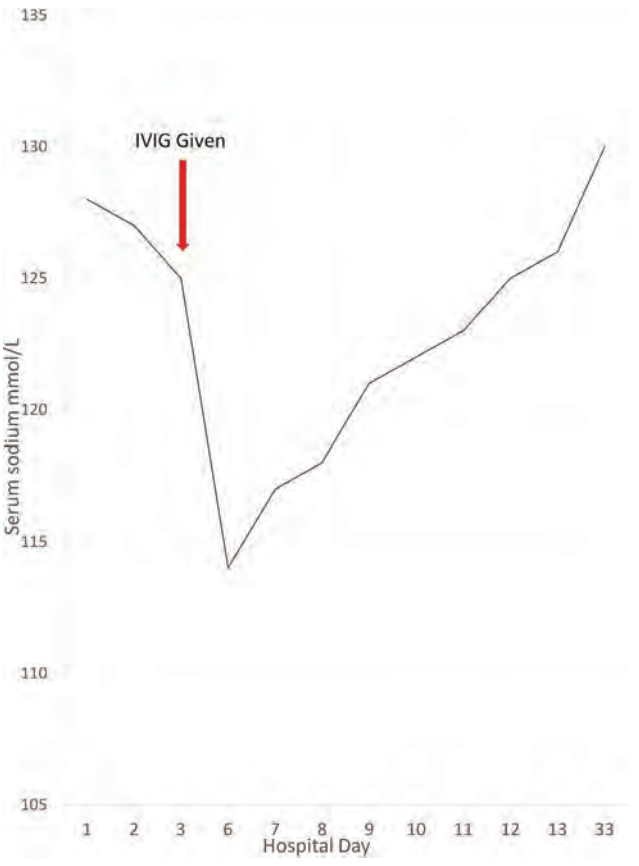
True Hyponatremia Secondary to Intravenous Immunoglobulin Infusion

Neepa Shah, Claudia Waters, Siddhartha Kattamanchi, Rebecca Blonsky.
Marshfield Clinic Health System, Marshfield, WI.

Introduction: Intravenous immunoglobulin infusion (IVIG) is used to treat a number of autoimmune disorders. However, IVIG can cause sodium disorders. Here we present a case of hyponatremia due to IVIG.

Case Description: The patient is a 96 year old female with history significant for chronic hyponatremia and ITP presented following a fall complicated by a displaced femoral neck fracture requiring surgical intervention. Serum sodium at baseline is approximately 130 to 132 mmol/L and at the time of admission sodium was 128 mmol/L. The patient was thrombocytopenic due to underlying ITP, thus was given platelets and IVIG due to need for surgical intervention. Following IVIG her serum sodium fell to a nadir of 113 mmoL/L. Nephrology was consulted for hyponatremia. Based on workup, the patient was diagnosed with true hyponatremia due to increased extracellular water concentrations as a result of the IVIG. The patient was treated with high protein diet, oral sodium chloride 2 grams PO TID, fluid restriction and diuretics. With treatment the patient's sodium improved and was 126 mmoL/L by discharge.

Discussion: Plasma comprises approximately 93% plasma water and 7% proteins and lipids. Any medical condition causing increased proteins and lipids in the blood will cause automated chemistry to interpret this as a low serum sodium. IVIG can cause post-infusion hyperprotenemia leading to pseudohyponatremia. However, the sucrose used as a carrier in commercial IVIG is osmotically active and can lead to the movement of water from the intracellular compartment to the extracellular compartment causing a true hyponatremia. Patients with impaired free water excretion, such as those with kidney disease can lead to further worsening of this hyponatremia.



PUB272

An Unusual Case of CKD and Kidney Cysts: It's All in the Family

Daniel A. Moreno, Meloney Oliveira, Roger A. Rodby, Stephen M. Korbet.
Rush University Medical Center, Chicago, IL.

Introduction: Autosomal dominant kidney disease with renal cysts and family history of progressive kidney disease suggests diagnoses such as polycystic kidney disease, tuberous sclerosis or von Hipple-Lindau syndrome. We present a rare and unusual case in which genetic testing was essential in establishing the diagnosis.

Case Description: A 55 yo woman with HTN was referred for evaluation of chronic kidney disease (CKD). The kidney function had been normal (SCr of 0.7 mg/dl) but over the next few yrs the SCr increased to 1.9 mg/dl. There was no history of NSAID abuse. The urinalysis was normal and the UAC and UPC ratios were normal at 30 and 140 mg/g, respectively. Uric acid and magnesium levels were normal. Serologic evaluation (ANA, Scl 70 Ab, SSA/SSB, RF, SIEP and UIEP) was negative. CT imaging revealed bilateral renal cysts (Image). The pt's father and paternal grandfather had HTN and ESRD of unknown etiology requiring dialysis at ages 50 and 70, respectively. The pt underwent a renal biopsy which demonstrated non-diagnostic moderate tubule-interstitial fibrosis and global sclerosis and severe arterial sclerosis (Image). Genetic testing revealed a heterozygous whole gene deletion of hepatocyte nuclear factor1 β (HNF1β).

Discussion: HNF1β is expressed in the kidney and regulates tubular transport and architecture. It is autosomal dominant and mutations exhibit incomplete penetrance with variable expressivity and result in progressive tubule-interstitial kidney disease and renal cysts. Mutations in HNF1β are an addition to the differential of autosomal dominant tubule-interstitial kidney disease (ADTKD) which previously included mutations in ADTKD-UMOD, -MUC1 and -REN. This case demonstrates the vital role genetic testing can play in making a diagnosis in a patient with CKD of unknown origin.

PUB273

Assessing Global and National Trends in Public Awareness and Interest in Polycystic Kidney Disease, 2004-2024

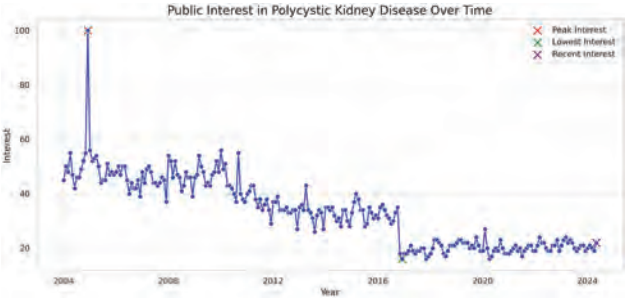
Justin Pham,[1,2] Charat Thongprayoon,[2] Jing Miao,[2] Iasmina Craici,[2] Wisit Cheungpasitporn.[2] *[1]Mayo Clinic College of Medicine and Science, Rochester, MN; [2]Mayo Clinic Minnesota, Rochester, MN.*

Background: Polycystic kidney disease (PKD) is a genetic disorder characterized by the growth of numerous renal cysts that can lead to worsening kidney function and varios sequelae. Recent advancements in treatment options have made it possible to slow disease progression. In this context, public interest and awareness of PKD play a crucial role in early diagnosis, timely management, and support for affected individuals and their families. This study aims to analyze the trends in global and national public interest and awareness of PKD.

Methods: We conducted a comprehensive analysis of Google Trends data for the search term “polycystic kidney disease” over a period of 245 months, from January 2004 to May 2024. The worldwide trend was examined, along with specific data from the United States. The relative search volume was used as a measure of public interest, with the peak interest assigned a score of 100.

Results: The global highest public interest in PKD was observed in December 2004 (score: 100), while the lowest interest occurred in December 2016 (score: 16). As of May 2024, the interest score was 22, slightly lower than the previous year. Among the top 10 regions with the highest relative search volume, Poland ranked first, followed by the United States and Pakistan. In the United States, the peak interest in PKD was recorded in September 2010 (score: 100), and the lowest interest was observed in May 2020 (score: 28). The most recent data from May 2024 showed an interest score of 44. Missouri, Vermont, and Kansas were the top three states with the highest relative search volume for PKD.

Conclusions: There has been a decrease in online interest and awareness of PKD over the past two decades. The findings underscore the need for targeted interventions and campaigns to raise awareness about PKD, its symptoms, and the importance of early diagnosis and management. Nephrologists, patient advocacy groups, and policymakers should collaborate to develop strategies that effectively reach and educate the public about this disorder.



PUB274

A Family with Variants in Multiple ADPKD Genes

Hisae Tanaka,[1] Takehiko Wada,[2] Michio Nakamura,[3] Yuko Ohnuki,[4] Akinari Sekine,[2] Takuya Fujimaru,[5] Takayasu Mori,[5] Eisei Sohara,[5] Shinichi Uchida,[5] Masafumi Fukagawa,[1] Hirotaka Komaba.[1] *[1]Division of Nephrology, Endocrinology and Metabolism, Tokai University School of Medicine, Isehara, Japan; [2]Nephrology Center, Toranomon Hospital, Tokyo, Japan; [3]Department of Transplant Surgery, Tokai University School of Medicine, Isehara, Japan; [4]Department of Medical Ethics, Tokai University School of Medicine, Isehara, Japan; [5]Department of Nephrology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University, Tokyo, Japan.*

Introduction: Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited kidney disease characterized by progressive cyst formation and enlargement of the kidneys, often leading to end-stage kidney disease (ESKD). ADPKD is thought to be caused by mutations in one of two genes (*PKD1* or *PKD2*). Recent advances in genetic technologies have enabled the identification of new variants of the ADPKD genes and revealed the complexity of the genetic inheritance of this disease.

Case Description: A 30-year-old female was referred to our hospital for evaluation of progressively worsening kidney function and potential living donor kidney transplantation. She was diagnosed with multicystic dysplastic kidney of the right kidney in her fetal period. At the age of 4, a renal cyst developed in the left kidney and the number of cysts increased with age. Later, her kidney function gradually declined and she developed ESKD in her late 20s. Laboratory tests showed a serum creatinine of 3.75 mg/dL, an eGFR of 13 mL/min/1.73m^2, and a urine protein/creatinine ratio of 2.6. Abdominal CT showed multiple kidney cysts in both kidneys with only one small hepatic cyst. It was later recognized that her biological father had been clinically diagnosed with ADPKD and had been on hemodialysis since the age of 50. Next-generation sequencing revealed a heterozygous *PKD2* pathogenic variant, accompanied by *PKD1* and *IFT140* variants of uncertain clinical significance, in both the patient and her father, but not in her mother. The patient eventually received a kidney transplant from her mother.

Discussion: Genetic testing could help identify the cause of ESKD in this patient and exclude genetic risk in her mother, a kidney donor candidate. The lack of genetic difference between this patient and her father does not support the possibility that digenic effects of *PKD1* and/or *IFT140* variants led to the atypical ADPKD manifestations in this patient. Further studies are required to investigate the putative impact of these variants on the development of ADPKD.

PUB275

Innovative Approaches for Increasing Community Engagement in ADPKD

Priya Deshpande. *Mount Sinai Health System, New York, NY.*

Background: The purpose of this project is to increase community engagement and awareness by creating podcasts that address important topics for patients with ADPKD using a culturally sensitive approach in both English and Spanish. This study is sponsored by the PKD Cure Foundation.

Methods: Podcasts in both English and Spanish were created with a patient stakeholder (a native Spanish speaker), two nutritionists, one of whom is a native Spanish speaker and a physician (fluent in both English and Spanish). To date 6 episodes (3 in English and 3 in Spanish) of the podcast series were created. Topics include: Nutrition in ADPKD, “I was diagnosed with ADPKD, what do I do next?,” and Transplantation in ADPKD (to be published). The podcasts were recorded on Zoom, edited, and then published on Spotify platform. Analytics were collected using Spotify analytics. The podcasts were promoted on Facebook (Meta), X and Instagram. An optional “yes” or “no” one question survey in both English and Spanish was administered (“Did this podcast increase your knowledge about this topic?”). The podcast series was also promoted by word of mouth to our patients in our PKD Clinic.

Results: A total of 14 individuals, primarily male with a median age of 43, followed this podcast series. Followers were primarily from the US (76%) and 10% of the followers were from Spanish speaking regions/countries. The most listened to podcasts in both English (52%) and Spanish (23%) were about nutrition and lifestyle. Three audience

members who listened to the English version of the nutrition episode and three voters who listened to the Spanish version of the nutrition episode felt that the episode improved their overall understanding of nutrition in ADPKD.

Conclusions: This study supports the feasbility of using to help disseminate information and promote patient engagement about ADPKD. The results show that the podcasts are reaching the Spanish speaking population. The most popular episode was about nutrition and lifestyle in ADPKD. These results support the further development of patient facing podcasts in both ADPKD and other conditions.

PUB276

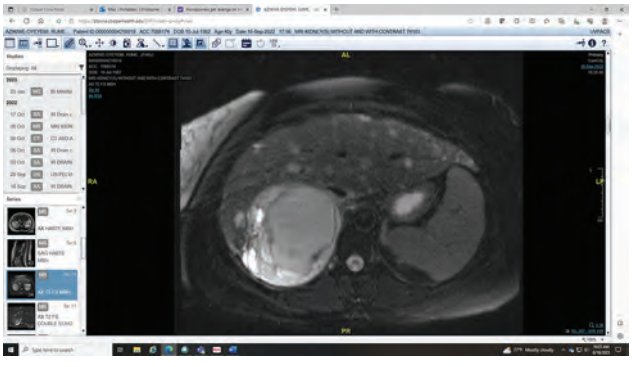
Use of Gadolinium-Enhanced MRI in a Patient with ADPKD and a Cyst Infection

Karen Cohen, Elizabeth Ives, Christopher B. McFadden. *Rowan University Cooper Medical School, Camden, NJ.*

Introduction: Autosomal dominant polycystic kidney disease presents significant complications to patients. One such complication is infection of a cyst. Identification of the infected cyst has proven challenging with imaging techniques including ultrasound and computer tomography (CT). Localization of the infected cyst is required with cysts larger than 5 cm for source control.

Case Description: A 40-year-old woman with PMH of ADPKD and CKD 3a presented with flank pain and fever. Creatinine was 2.17 mg/dl and white blood cell count 13.8 x109/l. A urinalysis revealed 2+ blood; blood and urine cultures remained negative. Computer tomography (CT) of the abdomen and pelvis without contrast revealed innumerable cysts with no signs of infection. On hospital day three, antibiotics were broadened from ceftriaxone to ertapenem. Renal bladder ultrasound revealed enlarged bilateral kidneys (R 9.0 x 7.7 x 2.7 cm and L 8.1 x 7.4 x 17.1 cm) with innumerable simple and hemorrhagic cysts. No cyst wall thickening or hyperemia was detected. She continued to have fevers with a maximum temperature of 103.1 °F. On hospital day seven, a pre and post gadolinium MRI was completed and revealed a right upper pole cyst with inflammatory changes consistent with a large (8 cm) infected cyst. Following drainage of the cyst, her pain improved and fever resolved.

Discussion: The accuracy of MRI in detecting infected renal cysts in ADPKD patients with abnormal kidney function is largely unknown due to previous contraindication of gadolinium-based contrast media (GBCM) in patients with an eGFR <30 mL/min per 1.73 m^2. Recent guidelines no longer advise against use of type 2 GBCM contrast in patients with eGFR <30. This case adds to the body of research that gadolinium enhanced MRI is an effective and safe method of localizing renal cyst infections. Importantly, it may be the best method to localize infected cysts in patients at risk for radiocontrast nephropathy.



Axial T2 fat saturated showing decreased T2 hyperintensity of the large inflamed cyst (large arrow) relative to the surrounding cysts (small arrow).

PUB277

Evaluating Physician Confidence and Barriers in Prescribing Tolvaptan for ADPKD Management

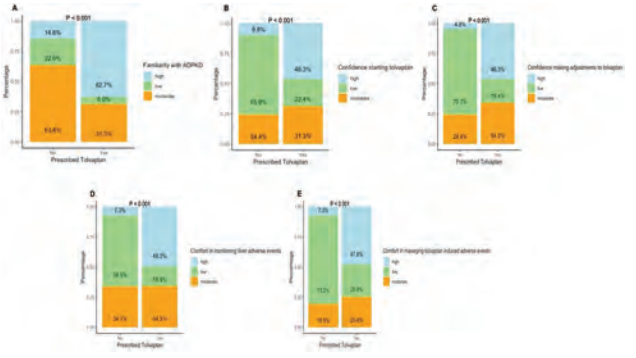
Niloufar Ebrahimi, Mehrbod Vakhshoori, Amir Abdi Pour, Sayna Norouzi. *Loma Linda University Medical Center, Loma Linda, CA.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the leading genetic cause of end-stage kidney disease in adults. The FDA approved tolvaptan in 2018 as the first treatment for ADPKD patients at risk of rapid disease progression. This study evaluates physicians' confidence and identifies barriers to prescribing tolvaptan for ADPKD management.

Methods: A survey assessed physicians' backgrounds, ADPKD management experience, familiarity with and use of tolvaptan, confidence in prescribing, barriers to prescribing, and needs for support and education. Distributed online via LinkedIn and X, the survey received 110 responses; 108 respondents who had managed at least one ADPKD patient in the past five years met the study's criteria. Data normality was tested with the Shapiro-Wilk test. Categorical and continuous variables were described using frequency (percentage) and median (IQR). Group differences were analyzed using chi-square, t-tests, or Mann-Whitney tests as appropriate. Statistical analyses were conducted in RStudio, with P-values < 0.05 considered significant.

Results: Participants were predominantly male (80.6%) with a median of 12 (7-20) years in practice. The median number of ADPKD patients seen in the past five years was 10 (7.5-22.5). Of the respondents, 62.0% had prescribed tolvaptan. Prescribers were mainly nephrologists, handling significantly more ADPKD patients than non-prescribers (98.5% vs. 80.45%, P<0.001 and 15 [10-30] vs. 9 [5-18.75], P=0.001, respectively). Tolvaptan prescribers exhibited higher level of familiarity with ADPKD (62.7% vs. 14.6%), confidence in starting (46.3% vs. 9.8%), adjusting tolvaptan (46.3% vs. 4.9%), comfort in monitoring liver adverse events (49.3% vs. 7.3%), and managing side effects (47.8% vs. 7.3%) compared to non-prescribers (Figure 1).

Conclusions: Addressing barriers to tolvaptan prescription is an essential step toward optimizing patient care.



Comparison of tolvaptan prescribers vs. non-prescribers

PUB278

Cystic Autosomal Dominant Alport Syndrome Masquerading as Polycystic Kidney Disease: Implications for Family Screening and Transplantation

Janewit Wongboonsin,[1,2] Anna Verwillow,[1,4] Judith A. Savige,[3] Ana C. Onuchic-Whitford.[1,5] *[1]Brigham and Women's Hospital, Boston, MA; [2]Mahidol University Faculty of Medicine Siriraj Hospital, Bangkok, Thailand; [3]The University of Melbourne, Melbourne, VIC, Australia; [4]Massachusetts General Hospital, Boston, MA; [5]Boston Children's Hospital, Boston, MA.*

Introduction: Autosomal dominant polycystic kidney disease (ADPKD) and Alport syndrome (AS) are two common monogenic kidney diseases. While their phenotypes are typically distinct, renal cysts may occur in autosomal dominant AS (ADAS), potentially leading to diagnostic confusion. Herein, we describe a family where a prior diagnosis of ADPKD was corrected to ADAS, resulting in implications for family screening and transplantation.

Case Description: A 61-year-old woman presented to our clinic for evaluation as a kidney donor for her brother with ADPKD. She had persistent microscopic hematuria since age 38, negative cystoscopy, normal kidney function and one kidney cyst. Review of her brother's case revealed that 4 months prior, at age 72 and after years without medical follow-up, he presented to another hospital in renal failure and was started on hemodialysis. He was reportedly diagnosed with ADPKD after an ultrasound demonstrated bilateral kidney cysts and genetic testing found a variant in *PKD1*. We further evaluated him in our clinic with an MRI that showed small, atrophic kidneys (~8cm) with scattered small (<1.5cm) bilateral cysts. Review of his genetic panel revealed a heterozygous variant of uncertain significance in *PKD1* (p.Asn2353Ser) and a heterozygous likely pathogenic variant in *COL4A4* (p.Gly481Val – a glycine substitution in Gly-X-Y motif). His sister's genetic test identified the same 2 variants, and the *PKD1* variant was deemed Benign. His diagnosis was thus reverted and both siblings were diagnosed with ADAS. Audiologic screening revealed mild (sister) and moderate (brother) bilateral sensorineural hearing loss. Another sibling tested negative for the *COL4A4* variant and became a kidney donor for the brother, who was transplanted successfully.

Discussion: The phenotypic heterogeneity of AS may pose a challenge for its clinical diagnosis. The identification of kidney cysts in AS further complicates this, adding AS as a differential diagnosis for cystic diseases. Thorough family history, review of clinical course, and careful visual inspection of renal imaging become important steps to avoid misdiagnosis. This case also highlights the key role of genetic testing, especially in the setting of atypical imaging, advanced chronic kidney disease, and assessment of family members as kidney donors.

PUB279

Coexistence of Alport Syndrome and Autosomal Dominant Polycystic Kidney Disease: A Case Report

Abdelrahman Ibrahim, Zena Altawallbeh, Laith Al-Rabadi. *University of Utah Health, Salt Lake City, UT.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) and Alport Syndrome (AS) are genetic kidney disorders, which affect individuals in different ways. ADPKD, which usually appears in adulthood, is marked by multiple fluid-filled cysts in the kidneys. However, ADPKD can also be diagnosed early in life, when based on family history, with advanced imaging such as MRI. Meanwhile, AS affects renal glomeruli, the inner ears and eyes. Histologically, AS shows segmental thinning and thickening of the glomerular basement membrane (GBM), which can occur just with the thinning of the GBM in an early stage of the disease. Both of these conditions lead to end-stage renal disease (ESRD). While ADPKD arises from gene mutations influencing kidney development and function, AS is linked to mutations in collagen genes essential for kidney structure and function. We present a case of a 34-year-old woman with early-onset ADPKD, exhibiting proteinuria of 1.5 grams, which is atypical for ADPKD, that has subsequently resolved. Additionally, she reported hearing loss. Along with a subsequent biopsy, genetic testing identified an autosomal recessive AS gene mutation. Patient's functions are stable, with normal creatinine and glomerular filtration rates. Maternal ADPKD history with renal failure requiring transplantation is noted, but two siblings also are asymptomatic.

Methods: Genetic analysis was conducted with next-generation sequencing (NGS), in conjunction with copy number variation (CNV) analysis. Mutations were confirmed through polymerase chain reaction (PCR) and Sanger sequencing. Renal ultrasound and biopsy were carried out, and audiological and ophthalmological examinations were ordered.

Results: Genetic analysis revealed a pathogenic deletion in COL4A3 c.4265-4273 del (p.Ser1422_Gly1424del), as well as a pathogenic mutation in PKD1 gene, consistent with ADPKD. Renal ultrasound showed enlarged kidneys, consistent with polycystic kidney disease while renal biopsy indicated borderline-thin GBM.

Conclusions: This case emphasizes an extremely rare concurrence of AS and ADPKD, underscoring the importance of considering the factor of overlapping inherited kidney diseases. Therefore, comprehensive genetic and familial evaluations in such cases should be requested for accurate diagnosis and management, particularly in cases with atypical overlapping disease symptoms.

PUB280

Progressive CKD Is Associated with Multiple Kidney Cyst Formation in Adult and Elderly Patients with Genetic Variations of Kidney Disease

Joseph C. Mihindu.[1,2] *[1]Saratoga Hospital, Saratoga Springs, NY; [2]Glens Falls Hospital, Glens Falls, NY.*

Introduction: CKD affects about 10 % of the global population. Common etiologies including Diabetes, Hypertension(HTN), Glomerulonephritis etc. are well known; a large number of patients however have CKD of unknown etiology. Genome wide association studies have revealed multiple genetic variations associated with CKD renal phenotype. This abstract documents 2 patients with autosomal recessive (AR) and 2 patients with Autosomal dominant(AD) genetic variations associated with progressive CKD and multiple cyst formation (MRC) in adult and elderly population. Some of the AR variations in homozygous state would have caused severe CKD in early infancy associated with cystic renal changes. None of these patients had evidence of Autosomal Dominant or Resessive Polycystic Kidney Disease Gene variation.

Case Description: Initials Age Race Sex [Presenting Phenotype] [Genetic variation] [Phenotype in Homozygous disease]: JBL 89 W F [CKDG4,HTN,MRC] [AR INPP5E] [Joubert's Syndrome, Nephronophthisis,CKD, Hepatic fibrosis] GW 74 W F [CKDG2,HTN,MRC] [AR CC2D2A] [COACH syndrome, Nephronophthisis, CKD, Hepatic fibrosis] AEP 80 WM [CKDG5,HTN,MRC] [AR or AD NMNA] [Lipodystrophy, Insulin resitance, Proteinuria, Premature CVD] BJF 65 W F [CKDG5, MRC] [ADTKD-UMO] [Chronic Tunbulointerstitial Nephritis, Progressive CKD]

Discussion: These case studies are in agreement with recent studies showing the association of genetic variations with progressive CKD. Two patients (JBL and GW) have specific AR variations. The AD state of these variations is associated with severe CKD and Nephronophthisis in early infancy. In conclusion, the following hypothesis is set forth: the Autosomal Dominant gene which protected these 2 patients from the development of severe disease in early life may lose its dominant function with advancing years. This may result in the resurgence of the Ressessive varient leading to the development of Cystic disease and CKD in later years. These case studies show the importance of genetic variants in the development of CKD.

PUB281

Suspected Hepatocyte Nuclear Factor 1-beta (HNF1B) Glomerulocystic Kidney Disease: A Case Report of Recurrent Hypomagnesemia and Kidney Cysts in a 30-Year-Old Woman

Syed Salman Hamid Hashmi,[1,2] George C. Bonifant.[1,2] *[1]Staten Island University Hospital, Staten Island, NY; [2]Northwell Health Feinstein Institutes for Medical Research, Manhasset, NY.*

Introduction: Hepatocyte Nuclear Factor 1-beta (HNF1B) glomerulocystic kidney disease (GCKD) is a rare genetic disorder characterized by renal cysts, renal dysfunction, and extrarenal manifestations like hypomagnesemia, diabetes, and liver abnormalities. This case report presents a 30-year-old female with polycystic kidney disease (PCKD) and chronic hypomagnesemia, whose clinical presentation raises the suspicion of HNF1B GCKD.

Case Description: A 30-year-old female with a history of polycystic kidney disease (PCKD), transaminitis, chronic hypomagnesemia, and recurrent urinary tract infections presented with abdominal pain, nausea, and vomiting. These symptoms typically coincided with low magnesium levels. Her vital signs were stable. Laboratory tests revealed a magnesium level of 0.8 mg/dL. A CT scan showed multiple cortical and parapelvic cysts in both kidneys and multiple kidney stones over 6 mm. Urinalysis indicated small leukocyte esterase. Despite taking 2 grams of magnesium daily, her levels remained low, suggesting a genetic cause. Urinary fractional excretion of magnesium was elevated. The presence of renal cysts, hypomagnesemia, bicornuate uterus, kidney stones, and transaminitis suggested a potential diagnosis of HNF1B-related genetic kidney cystic disease (GCKD). She was discharged with high-dose oral magnesium lactate, amiloride, and is receiving weekly magnesium infusions. She was referred for genetic testing for HNF1B mutations and the results are pending.

Discussion: HNF1B GCKD is often underdiagnosed due to its phenotypic variability. The diagnosis is considered in patients with renal cysts and systemic features like hypomagnesemia and hyperglycemia. This patient's recurrent hypomagnesemia despite supplementation, transaminitis, renal cysts, and bicornuate uterus align with HNF1B GCKD. Management focuses on symptom relief, electrolyte balance, and renal function monitoring. Magnesium supplementation is crucial, and genetic testing is recommended. Amiloride blocks ENaC channels in the distal nephron, creating an electrical gradient favoring magnesium absorption via transient receptor potential melastatin channels. This case underscores the importance of considering HNF1B GCKD in patients with PCKD and chronic hypomagnesemia.

PUB282

Lessons Learned from Patient Engagement in the Polycystic Kidney Disease Research Resource Consortium (PKD RRC)

Vinamratha Rao,[1] Susan Gleason,[3] Jullie Hoggan,[3] Sarit Neter,[3] Taslima Rahman,[3] Terry J. Watnick,[4] Lisa M. Guay-Woodford,[2] Reem Mustafa.[1] *[1]The University of Kansas Medical Center, Kansas City, KS; [2]The Children's Hospital of Philadelphia, Philadelphia, PA; [3]Polycystic Kidney Disease Research Resource Consortium, Bethesda, MD; [4]University of Maryland School of Medicine, Baltimore, MD.*

Background: Polycystic Kidney Disease (PKD) is a prevalent inherited kidney disease that often leads to renal failure and profoundly impacts patient quality of life. The Polycystic Kidney Disease Research Resource Consortium (PKD RRC) aims to advance PKD research through resource development and sharing. The Patient Engagement Group (PEG) was established to integrate patient and stakeholder voices into PKD research resource development, aiming for a patient-driven agenda in PKD research.

Methods: Expert and participant input from various research initiatives, patient organizations, and literature reviews established the PEG framework. Structured recruitment, introductory webinars, and nominations yielded a diverse group of 10 participants, including individuals with PKD, caregivers, and patient advocates. Monthly virtual meetings with educational sessions familiarized members with objectives and projects undertaken by PKD RRC subcommittees. PEG members served as subcommittee liaisons, integrating patient perspectives into research resource development processes.

Results: Patient engagement in the PKD RRC included sharing experiences, learning opportunities, and continuous feedback to refine engagement strategies. While participant input did not routinely alter resource development plans, inclusion of patient perspectives added a patient voice dimension to subcommittee decision-making. For PEG members, involvement fostered personal growth and empowerment, enhancing their understanding of the disease and the research landscape. In particular, PEG members highlighted the importance of balancing data security with research efficiency to maintain trust and participation in clinical trials. Proposed future steps include ongoing innovation in engagement methods and inclusive recruitment. Achieving diversity in the PEG remains challenging but essential for representing the spectrum of patient experiences and needs.

Conclusions: This novel patient engagement initiative in a research resource consortium demonstrates the potential of involving patients in research resource development and establishing patient perspectives as a valuable research resource. The lessons learned highlight the need for effective communication, continuous education, and inclusive practices for effective patient engagement.

Genetic Testing in Nephrology and Kidney Transplant Clinics in an Academic Center with a Predominant Minority Population

Luis N. Madera Marin, Pablo Garcia, Christos Argyropoulos, Namita Singh. *University of New Mexico School of Medicine, Albuquerque, NM.*

Background: Chronic kidney disease (CKD) affects about 14% of the adults in the US. Accurate diagnosis of any clinical condition is key to appropriate and successful management. A recent multi-center study showed that genetic testing with a CKD-focused 385 gene panel called Renasight® substantially refined clinical diagnoses and had widespread implications for treatment strategies. We aimed to review the diagnostic yield of Renasight® in our patient population as well as the impact of test results on management decisions.

Methods: We conducted a retrospective chart review on all adult patients who underwent Renasight® testing through nephrology and/or kidney transplant clinics. Hospital EMR and Natera® organ health portal (clinical genetic testing company providing Renasight® testing) were utilized as sources.

Results: A total of 28 individuals underwent Renasight® testing between 7/1/2020 and 4/15/2024. Of the entire cohort: mean age was 43 years, 57% males, and 57% identified their ethnicity as Hispanic or Latino. The majority of the patients (75%) were referred from transplant clinics. Mean serum creatinine at initial visit for non-ESKD patients (n=17) was 2.34 mg/dL (S.D. 2.07). Family history of kidney disease was found to be positive in about 36 percent. FSGS was noted to be the most common reason for test order. Renasight® test reported positive significant gene abnormality in 4 (14%), with an additional 17 people (60%) with a variable of undetermined significance (VUS) or carrier mutation. Negative result aided in decision making for all 3 potential living donors to proceed. Out of the 4 positive results, 2 positive APOL1 mutations confirmed the suspected FSGS diagnosis. Both these patients self-identified as African Americans. One patient previously diagnosed as CKD, unspecified was found to have likely pathogenic CFI gene, associated with aHUS and C3G, which is postulated to significantly impact treatment strategies in future.

Conclusions: In our primarily Hispanic/ Latino population, we noted a diagnostic yield of 14% for significant gene abnormalities. Positive results impacted management in 3 out of 4 cases, and negative report supported decision to proceed with living donor evaluation in all tested for this indication.

PUB284

A Young Woman with Autosomal Dominant Polycystic Kidney Disease and Recurrent Kidney Stones Coexisting with Gitelman Syndrome

Ang Lu, Chien-Chou Chen, Shih-Hua P. Lin. *Tri-Service General Hospital, Taipei, Taiwan.*

Introduction: Autosomal dominant polycystic kidney disease (ADPKD), the leading genetic cause of end-stage kidney disease, is characterized by bilateral renal cysts, chronic kidney disease, and recurrent urinary tract infections (UTIs). Gitelman syndrome (GS), the most common inherited tubulopathy, involves a salt-losing nephropathy featured by hypokalemia, metabolic alkalosis, magnesium wasting, and hypocalciuria. The coexistence of ADPKD and GS is rarely reported. We present a case of a young female with recurrent UTIs, renal stones, cystic kidney disease, and hypokalemia, diagnosed through genetic analysis.

Case Description: A 26-year-old female with history of cystic kidney disease, recurrent UTIs and chronic hypokalemia (3.1 mmol/L) presented with fever, and dysuria for days. Her family history included a mother with ADPKD and an aunt on hemodialysis after bilateral nephrectomy. On admission, she had UTI with bilateral renal stones, hypokalemia, and hypomagnesemia (2.8 and 0.8 mmol/L) and received ureteroscopy with laser lithotripsy. Urine biochemistry showed renal potassium and magnesium wasting and hypocalciuria. Her recurrent renal stones, electrolyte imbalances, and cystic kidney disease, along with family history, raised suspicion of genetic disorder. The molecular sequencing revealed possible PKD1 and NHF1B mutations. Following treatment with oral magnesium and potassium supplements, no recurrent episodes occurred.

Discussion: This is the first case demonstrating the coexistence of ADPKD and GS diagnosed via whole exome sequencing. The PKD1 gene is releated with ADPKD, causing to renal cysts and stone formation. Hepatocyte nuclear factor-1β is a DNA-binding transcription factor essential for kidney development, and its mutations cause tubulointerstitial abnormalities and GS. This case highlights the importance of genetic analysis for early diagnosis and management to prevent complications and improve outcomes.

PUB285

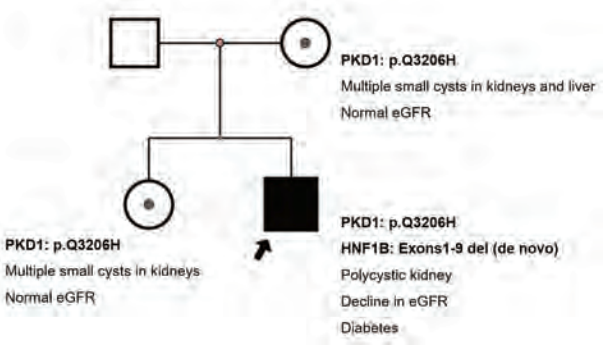
Atypical ADPKD Due to Complex Genotypes of Both PKD1 and HNF1B Pathogenic Variants: An Educational Case Report

Mengshi Li, Ruilian You, Zhiying Liu, Jiayi Zhang, Yang Li, Xu-jie Zhou, Hong Zhang. *Peking University First Hospital, Beijing, China.*

Introduction: ADPKD is the most common genetic cause of renal failure in adults. Advances in next-generation sequencing have revealed complex genotypes, including mosaicism, digenic inheritance, diallelic variants, and genetic modifiers. Understanding the phenotypes associated with variants is crucial for clinicians, as genetic variability significantly influences the severity of ADPKD.

Case Description: A 33-year-old Han Chinese male presented with enlarged kidneys, numerous small cysts, deteriorating renal function, early-onset diabetes mellitus, proteinuria, and a family history of CKD and renal cysts. His mother and sister had multiple renal cysts consistent with ADPKD but only moderately enlarged kidneys and normal renal function. This suggested an atypical ADPKD form, with rapid cyst development, renal decline, and early-onset diabetes, lacking common ADPKD-associated extra-renal manifestations. Whole-exome sequencing identified a heterozygous PKD1 variant (c.9618G>T, p.Q3206H), inherited from his mother and confirmed in his sister, classified as likely pathogenic. Additionally, a heterozygous deletion of exons 1-9 in the HNF1B gene, absent in his pedigree, was confirmed by real-time quantitative PCR. A comprehensive treatment strategy was implemented, including insulin therapy, blood pressure control, and symptom management. At latest follow-up, proteinuria had decreased, but renal function continued to decline slowly.

Discussion: Distinguishing HNF1B-related cystic kidney disease from PKD1/PKD2 variants is crucial. HNF1B-related disease typically features small cysts, normal kidney size, progressive CKD, and early-onset diabetes, overlapping with ADTKD. However, its presentation, prognosis, and pathogenesis differ significantly from PKD1/PKD2-related ADPKD. Genetic testing is recommended for patients with atypical ADPKD features, which is important for diagnosis, genetic counseling, and prognosis. Further research on ADTKD variants in unexplained ADPKD cases is valuable.



PUB286

Clinical Overlap and Diagnostic Challenges: Differentiating HNF1B Mutation Disease from Gitelman Syndrome

Mariem Borcheni, Hanna Ghanayem, Nilofar Behbahani-Nejad, Joel M. Topf. Ascension St. John Team. *Ascension St John Hospital, Detroit, MI.*

Introduction: Hepatocyte nuclear factor 1 beta (HNF1B) mutation disease, is a rare genetic disorder characterized by a range of clinical manifestations, such as development of renal cysts, chronic kidney disease, electrolyte imbalances, and early-onset diabetes mellitus. HNF1B mutations are relatively rare, with an estimated prevalence of less than 1 in 100,000 individuals. One of the significant challenges in diagnosing this disease is its

clinical overlap with other disorders, such as Gitelman's syndrome. Both conditions can exhibit similar symptoms, including chronic hypomagnesemia and hypokalemia, making differentiation between them difficult.

Case Description: A middle-aged female with no significant past medical history, has been evaluated for chronic hypomagnesemia and hypokalemia, initially assumed to be due to Gitelman's syndrome. She was hospitalized for labor induction. Physical exam and vitals were normal. Laboratory findings showed a magnesium level of 1.2mEq/L and a potassium level of 3.5mmol/L, despite daily supplements. Other electrolytes and creatinine were normal. Of note, prior abdominal imaging showed bilateral renal cysts. The patient was given Intravenous magnesium sulfate which failed to improve magnesium level. She had a successful delivery with no complications and was then discharged home. On follow-up visit at the nephrology clinic, a full workup showed a potassium level of 4.1 mmol/L, magnesium level of 1.3mEq/L, fractional excretion of magnesium of 12%, normal kidney function and calcium level. Therefore, a genetic testing was ordered and came back positive for a single heterozygous mutation of HNF1B consistent with a deletion in a whole gene. Given the association between HNF1B mutation and Maturity Onset Diabetes of the Young (MODY), diabetes screening was performed and results were normal. The patient and her daughter, who also had bilateral renal cysts, were then referred for genetic counseling.

Discussion: This case highlights the importance of the diagnostic complexities of HNF1B mutation disease, particularly due to its symptomatic overlap with conditions like Gitelman's syndrome. Genetic testing plays a crucial role in differentiating these disorders, enabling more precise treatment and better patient outcomes.

PUB287

HNF1B Mutation Misdiagnosed as Polycystic Kidney Disease

Trang D. Tran, Alyssa C. Weyer, Arda Akoluk. *The University of Texas at Tyler, Tyler, TX.*

Introduction: HNF1b-related kidney disease, also known as autosomal dominant tubulointerstitial kidney disease (ADTKD) with renal cysts, is a rare genetic disorder caused by mutations in the HNF1b gene. It is characterized by the development of kidney cysts, tubulointerstitial fibrosis, and progressive renal dysfunction, and extrarenal manifestations that can be found in these patients are pancreatic failure, transaminitis, and genital tract abnormalities. Patients often present with features similar to Polycystic Kidney Disease (PKD), including hypertension, proteinuria, and renal insufficiency.

Case Description: A 40 year old woman was evaluated by a Nephrologist after being informed that she had PKD based on magnetic resonance imaging. These images were captured during her pregnancy, for which she was noted to have fetal loss due to unknown causes. Pertinent laboratory results were random blood glucose level of 734 mg/dL, glycated hemoglobin 13%, erythrocyte sedimentation rate level was elevated at 26 mm/hr, urinalysis showed ketone bodies and sugar >1000 mg/dL. The results showed that her fasting glucose level was 398 mg/dL and serum C-peptide was 0.78 ngl/mL. Serum creatinine and eGFR were 0.6 mg/dL and 110, respectively. She was informed during a pregnancy that the fetus was presumed to have autosomal dominant PKD as evidenced by several small cysts in the maternal kidneys on magnetic resonance imaging. There was also a previous ultrasound that indicated a large cyst. Patient denied any family history of PKD. Patient reported that she was diagnosed with type 1 diabetes mellitus, which was misdiagnosed. It was deemed that the patient has Maturity-onset diabetes of the young, type 5 (MODY-5) due to testing negative for Anti-GAD, anti-IAA and anti-ICA antibodies, which is unique to type 1 diabetes.

Discussion: Considering the patient had a cyst in the left kidney, negative for diabetes related antibodies, bicornuate uterus, pancreatic insufficiency, the patient was presumed to have MODY5 with the HNF1B score of 20. Upon further investigation to establish a working diagnosis, DNA sequencing revealed whole gene deletion of 17q12 deletion consistent with HNF1B mutation. Genetic testing plays a role in identifying specific mutations that can guide clinical management and counseling, particularly in cases where invasive procedures such as kidney biopsies are contraindicated, such as in pregnant individuals.

PUB288

Patient-Centered Insights on Treatment Adherence and Social Determinants of Health in Autosomal Dominant Polycystic Kidney Disease

Vanessa Holliday, Savanna Moore, Elise Hoover. *PKD Foundation, Kansas City, MO.*

Background: The Polycystic Kidney Disease Foundation (PKDF) advocates, educates, and funds research for PKD, the most common genetic kidney disease in the United States (U.S.), estimated to affect around 600,000 individuals. This study explores patient treatment adherence among patients within the Autosomal Dominant Polycystic Kidney Disease (ADPKD) population, examining the influence of social determinants of health (SDOH). Understanding these factors is essential for effective treatment strategies, aligning with Healthy People 2030's recognition of social determinants' impact on health outcomes. PKDF is uniquely positioned to address this issue, thereby empowering clinicians, researchers, and patients towards improved healthcare approaches and overall health outcomes.

Methods: The study, conducted via an online survey and the ADPKD Registry, adopted a SDOH framework to investigate factors affecting treatment adherence among individuals diagnosed with ADPKD. Approved by an Institutional Review Board, this study includes U.S. individuals who reported partaking in various treatment or management strategies for ADPKD such as diet and lifestyle interventions, non-kidney related medications, kidney related medications, dialysis, and others.

Results: Among 489 participants, 95% are non-Hispanic, 92% white, 69% female, and 71% pre-transplant. Of 487 participants identified as partaking in a treatment(s), 62% reported diet and lifestyle interventions, 54% kidney-related medications, and 40% non-kidney related medications. Of those who encountered treatment barriers, unclear clinician guidance, nephrologist transitions, and financial constraints were cited.

Conclusions: The study, encompassing primarily non-Hispanic, white, female, and pre-transplant participants, identified key treatments such as diet and lifestyle interventions, and medications for kidney and non-kidney related conditions. Although a non-significant number of participants reported barriers to treatment, such as unclear guidance, nephrologist transitions, and financial constraints, these underline areas for improved patient care. The findings emphasize the importance of specialized intervention and improved affordable access to enhance care for individuals diagnosed with ADPKD.

PUB289

Symptom Burden and Health Care Resource Utilization in Patients with Polycystic Kidney Disease

Maham Ali,[1] Michael Heung,[1] Gauri Bhutani,[2] Elise Hoover,[3] Savanna Moore,[3] Areeba Jawed.[1] *[1]University of Michigan Michigan Medicine, Ann Arbor, MI; [2]University of Wisconsin-Madison, Madison, WI; [3]PKD Foundation, Madison, WI.*

Background: Patients with PKD experience a variety of renal and extrarenal symptoms; however, there is limited data on prevalence of symptom burden in this population. We assessed the frequency of patient reported symptoms in PKD and impact on healthcare resource utilization.

Methods: Single center retrospective study of all patients with a diagnosis of PKD (N:355) seen between 7/1/20 and 6/30/23. Patients with ESKD and those lost to follow up were excluded (n:130). Of 225 patients who met inclusion criteria, 112 (49.8%) symptom related encounters were further analyzed.

Results: Study population mean age was 48±15 yrs, and 60% were female. Mean eGFR closest to encounter was 50±29 ml/min with mean duration of clinic follow up 4±3.3 yrs to the time of encounter. Most reported symptoms were cardiovascular (30%), flank pain (16%), and urinary symptoms other than hematuria (8%) whereas 17.8% of encounters were related to non-PKD symptoms. Most common PKD related diagnosis were medication side effects (25%, of which 6% were related to Tolvaptan), hypertension (22%), urinary tract infections (9.8%), and suspected cyst rupture (7.1%). In 20.5% of encounters, the final diagnosis attributed to presenting symptoms were non-PKD related. Providers managed most symptoms with either medication change (30%) or further testing (21.4%) and referred only 6.2% of patients to the emergency department (ED).

Conclusions: Patients with PKD experience diverse symptoms affecting different organ systems. A sizable percentage of encounters were related to non-PKD associated concerns and nephrologists managed most of these without additional referrals to specialty physicians or the ED, suggesting limited additional resource utilization. The substantial proportion of non-PKD related queries may reflect the close relationship PKD patients share with their providers and the comprehensive medical care provided by nephrologists.

Chief Complaint	N:112

Variable Clinical Presentation of DNAJB11-Related Kidney Disease in a Large Family Cluster

Federico Yandian,[1,2] Lucia Facal,[1,2] Lucia Spangenberg,[3] Víctor E. Raggio,[4] Paula Parnizari,[2] Jose Boggia,[2] Oscar A. Noboa.[2] *[1]Médica Uruguaya, Montevideo, Uruguay; [2]Hospital de Clinicas Doctor Manuel Quintela, Montevideo, Uruguay; [3]Institut Pasteur, Montevideo, Montevideo, Uruguay; [4]Departamento de Genetica, Facultad de Medicina UDELAR, Montevideo, Uruguay.*

Introduction: We report a case of DNAJB11-kidney diseaseand its phenotype variability within the family.

Case Description: A 28-year-old woman with histopathologic diagnosis of chronic tubular interstitial nephritis presented to our clinic with a history of kidney insufficiency that progressed to ESRD in the following 3 years. She did not show microhematuria or proteinuria. CT scan without evidence of kidney or hepatic cysts at the time of kidney biopsy. She had a family history of renal disease. Her mother developed kidney failure requiring initiation of RRT at 45 years. Several of her mother's cousins developed kidney failure. The patient's cousin, a 35-year-old female with renal cysts but with preserved kidney function and normal urinalysis has a diagnosis of Autosomal Dominant Polycystic Kidney Disease (ADPKD) and has a 4 year-old daughter with renal cysts. Another cousin, a 40-year-old male has a diagnosis of ADPKD that developed kidney failure at 40 years. His deceased father, paternal grandma and paternal uncle developed kidney failure and also had a diagnosis of ADPKD with hepatic involvement. A presumptive diagnosis of Autosomal Dominant Tubulointerstitial Kidney Disease was made in the index case. Exome sequencing (100x, 100 paired/end) revealed a non-coding novel DNAJB11 mutation (chr3:186295418, -/T, hg19) in the index case and her two cousins.

Discussion: Renal disease associated with DNAJB11 mutations is an emerging field in nephrology that requires attention due to its clinical impact. This genetic entity has a variety of presentations, including renal cystic disease and tubulointerstitial nephropathy. Renal cystic disease related to DNAJB11 manifests with the formation of multiple kidney cysts, which can result in progressive renal dysfunction and eventual kidney failure. These cysts can be simple or complex and are often associated with arterial hypertension and hematuria. On the other hand, tubulointerstitial nephropathy associated with DNAJB11 is characterized by inflammation and fibrosis of the renal tissue, leading to tubular dysfunction and loss of renal function. In summary, DNAJB11-kidney diseaseencompasses a wide range of clinical presentations, from renal cyst formation to tubulointerstitial nephropathy, underscoring the importance of its early recognition and proper management in clinical practice.

PUB291

Mosaicism in a Patient with ADPKD: A Case Report

Nenzi Marzano,[1] Carlotta Caprara,[1,2] Thiago A. Reis,[3] Diego Pomare' Montin,[1,4] Sofia M. Pretto,[1] Matteo Rigato,[1,2] Fiorella Gastaldon,[2] Claudio Ronco,[1] Monica Zanella,[1,2] Valentina Corradi.[1,2] *[1]International Renal Research Institute (IRRIV) Foundation, Vicenza, Italy; [2]UOC Nefrology, ULSS 8 Berica, San Bortolo Hospital, Vicenza, Italy; [3]Laboratory of Molecular Pharmacology, University of Brasilia, Brasilia, Brazil; [4]Universita degli Studi di Firenze, Firenze, Italy.*

Introduction: Autosomal Dominant Polycystic Kidney Disease (ADPKD), considered the most frequent genetic renal disease, is characterized by renal involvement with progressive bilateral development of renal cysts and volumetric increase of kidneys, causing loss of renal function leading to chronic kidney disease (CKD). ADPKD has a complex inheritance and a wide phenotypic variability. In some cases, it is necessary to perform genetic testing to achieve a definitive diagnosis. The occurrence of mosaicism, described by a few cell populations with different genomes, may modify the presentation of the disease, modulate its clinical course, and better define an ADPKD population.

Case Description: The case describes a 47-year-old woman presenting typical ultrasound and computed tomography features of ADPKD. She had CKD stage 3b and hypertension. There was no family history of ADPKD, prompting an investigation with a genetic test. Next Generation Sequencing (NGS, nephropathies solution gene panel) did not detect the presence of any genomic variants. The CGH array negative result confirmed the NGS analysis. Multiple Ligation-dependent Probe Amplification (MLPA) for the investigation of large rearrangement of PKD1 and PKD2 genes showed a large deletion (PKD1 gene, exons 3-33) present in heterozygosis with a percentage of cells close to the resolution limits of the used technique (<25-30%). The MLPA analysis was repeated after a revision of the used kit, making it possible to better define the border of the deletion. The new result showed a deletion in heterozygosis of exons 2-34 in PKD1: NC_000016.10: g. (2136179_2119520) (2097184_2094247) del, chr16:2094247: 2136179: del.

Discussion: We concluded that the mutation is present as mosaic, a genetic condition of difficult detection since there are no election methods for its molecular identification. The deletion present in mosaic may have contributed to the attenuated reduction in kidney function compared to PKD1 protein-truncating mutations. The variant is not reported, but due to the type of mutation and the patient's clinical picture, it is to be considered as likely pathogenic. This case highlights how a stepwise genetic approach might be useful when standard methods do not allow to reach a definitive diagnosis.

PUB292

A Possible Correlation between Nephronophthisis and Glaucoma

Harini K. Venkatesh, Mina El-Kateb, Ali Hussain. *Henry Ford Macomb Hospital, Clinton Township, MI.*

Introduction: Cilia perceive extracellular signals like growth factors, chemicals and light for normal kidney development and maintenance. 'Ciliopathies' are autosomal recessive genetic diseases caused by their dysfunction. Most commonly affected are the kidneys causing Nephronophthisis (NPH), but the brain, eye, face, liver, heart and skeleton are also involved. Several associations between NPH and other conditions have been discovered. This case report describes an unusual combination of glaucoma and NPH leading to profound visual and renal function loss.

Case Description: A 20-year-old African American male presented with progressive vision loss after undergoing retinal cryotherapy and laser at the age of 4 for an unknown retinopathy. He had end-stage renal disease (ESRD) secondary to infantile NPH confirmed by genetic testing, having already failed transplantation twice. Eye examination noted decreased visual acuity bilaterally with only preserved light perception; he also had horizontal nystagmus, elevated intraocular pressure, retinal dystrophy and optic atrophy. Despite the discontinuation of steroids after the failure of his second allograft, tonometry continued to suggest open-angle glaucoma, concerning for a different disease process.

Discussion: Over 90 gene mutations are involved in ciliopathies, of which more than 20 give rise to NPH. NPH has 3 forms – infantile, juvenile and adult; while the latter two produce tubulointerstitial fibrosis, infantile NPH causes a more severe medullary cystic kidney disease that quickly progresses to ESRD. Retinopathy in conjunction with NPH, is a rare autosomal recessive disease affecting 1 in a million, called Senior-Loken syndrome that presents with childhood-onset hyperopia, photophobia and nystagmus. Glaucoma has been recognized in other ciliopathies. In this case, despite the estimated 3% risk of permanent glaucoma following steroid cessation, dysfunctional cilia impairing aqueous humor outflow in the anterior segment of the eye may be responsible. Life expectancy with NPH may vary depending on the onset of ESRD. Although renal transplantation is the only solution currently, specific signaling pathways like cAMP/PKA, mTOR and Hedgehog are potential sites for therapy. Identification of patients with NPH and new associations adds to the literature and maximizes pathological discoveries, thus paving the way for better treatment.

PUB293

Inferior Vena Cava (IVC) Compression Secondary to ADPKD: A Diagnostic Dilemma

Abdel-Rauof M. Akkari, Ahmad Matarneh, Sundus Sardar, Fnu Varnika, Umar Farooq, Nasrollah Ghahramani. *Penn State College of Medicine, Hershey, PA.*

Introduction: Adult polycystic kidney disease (ADPKD) is one of the most common life-threatening genetic diseases. It is an inherited condition where fluid-filled cysts develop and enlarge in both kidneys and multiple other organs. It is the fourth leading cause of kidney failure, with over 50% of ADPKD patients developing kidney failure by age 50. Interestingly, cysts can enlarge and become symptomatic, with variable symptoms ranging from non-specifiC to mass effect. We present an interesting case of a patient who had symptoms of inferior vena cava (IVC) compression that improved with bilateral nephrectomies.

Case Description: A 51-year-old female with a history of ESRD secondary to ADPKD had been receiving hemodialysis (HD) for several years. She was relatively stable on hemodialysis; however, she was usually noted to have bilateral lower limb edema despite having clear chest sounds. The usual thought process was that her target EDW needed to be changed, and more ultrafiltrate needed to be removed. However, every time we tried, her edema persisted. On abdominal examination, we found a distended abdomen. There was suspicion that this might be related to IVC compression. A bedside ultrasound showed large kidneys, leading to the decision to proceed with a CT scan of the abdomen. The CT scan revealed bilateral enlarged kidneys (left: 22x22x12 cm, right:29x19x12 cm) with evidence of IVC compression secondary to mass effect. She was referred to the urology team, who performed bilateral nephrectomies. Her symptoms improved tremendously postoperatively, and she is currently undergoing HD with no active complaints.

Discussion: ADPKD remains one of the leading causes of kidney failure. If the kidneys are large enough, they can cause symptoms related to the mass effect. Symptoms related to mass effect compression against surrounding organs are not uncommon. It can compress vascular structures, leading to symptoms of ischemia if compressing the aorta, or symptoms of IVC distention. IVC compression symptoms are mainly related to lower circulatory venous congestion, which can cause edema, congestion, and discomfort. A point of interest is when it causes these symptoms in patients who are in ESRD, making it difficult to judge their volume status. The incidence of IVC compression in ADPKD is not well established, but removal of kidneys appears to result in symptomatic relief.

PUB294

Cystinosis Presenting with Complications in an Adult: A Difficult Case

Abdullah Masood, Andrew Polyak, Aryeh Moskovits, Geronimo E. Banayat. *Trinitas Regional Medical Center, Elizabeth, NJ.*

Introduction: Cystinosis is a rare autosomal recessive disease caused by a defect in lysosomal transport protein causing accumulation of cysteine in lysosomes which causes multiple deleterious effects in body organs, especially the kidneys and eyes. It is the most common cause of Fanconi syndrome in children. It is caused by mutations in the *CTNS* gene, which encodes the lysosomal cystine carrier protein *cystinosin*. Incidence is generally 1:200000 but up to 1:3000 in certain consanguineous populations. Herein we present a case of a 21 y/o M with cystinosis presenting with status epilepticus and AKI on CKD requiring haemodialysis.

Case Description: A 21 y/o M with PMH of cystinosis with CKD, HTN and seizures came to the ED with bradypnea and status epilepticus. Vitals were: Temp 98.3, Pulse 106, RR 10, BP 132/67. Labs were Na 137, K 3.4, Cl 97, HCO3 19, AGAP 21, Cr 4.42, BUN 20 Urine pH 5.5, Urine Cl 31.8, Urine K 39, Urine Na 33 UAG 27.6. US kidney was normal, MRI brain showed no acute changes. Patient was on levocarnitine and cysteamine at home and had not required haemodialysis yet. At this admission, he had COVID-19 and aspiration pneumonia secondary to the seizures leading to VDRF. He was started on Keppra and Meropenem. Patient developed severe hyperchloremic, hypokalaemic metabolic acidosis with polyuria and was started on dialysis. Amiloride was started as well. Patient improved, electrolytes became stable and was extubated to trach, PEG tube placed for feeding and discharged to LTAC.

Discussion: Cystinosis was first described in 1903 in Switzerland but evidence of the mutation is nearly 2000 years old. It can be divided into infant, juvenile, and ophthalmopathy type. Our patient had the infant type which kidney disease is the most common. This patient had a preexisting diagnosis but generally spectrometric detection of cysteine in WBC, slit lamp and gene studies can be used to diagnose. Cysteine depleting therapy like cysteamine bitartrate delays the progression to ESRD as seen in this patient. Carnitine supplementation has not really shown much improvement in outcomes. Kidney transplant however shows an excellent prognosis in this disease. Cysteinosis remains an enigmatic disease with few case reports and epidemiological studies in adults. Much more study is needed to truly tackle the new adult population living with this disease with monitoring and treatment.

PUB295

Kidney Failure in Familial Mediterranean Fever: Heller Revisited

Jan V. Meulen. *Albert Schweitzer Ziekenhuis, Dordrecht, Netherlands.*

Introduction: In 1955 Heller introduced the term Familial Mediterranean Fever (FMF) for a hereditary syndrome, manifesting itself in infancy or adolescence. The syndrome was already known as periodic disease and found in Jews, Arabs, and Armenians. Heller chose the adjective Mediterranean because 45 of his 74 patients (pts) were Sephardic Jews i.e. coming from Egypt, Libya, Tunis, Algeria and Morocco (SJ). Twenty pts had marked proteinuria and 3 pts died of chronic renal failure (CRF) due to amyloidosis. None of his 74 pts were Ashkenazi Jews i.e. from Central and Eastern Europe (AJ). Heller's explanation was that AJ have another ethnicity than SJ. A study of 100 Armenians with FMF in California (AC) found no marked proteinuria or amyloidosis. The explanation: AC had different mutations as compared to SJ. Colchicine, introduced as a prophylactic in 1972, prevents CRF. The pathogenetic gene, the MEFV, was found in 1997. Almost 75% of all FMF pts have the mutants M694V, M694I, V726A and M680I. Homozygosity for M694V is significantly associated with a severe form of FMF and CRF.

Case Description: After the earthquake in 1988, "Doctors without Borders" from the Netherlands set up a hemodialysis (HD) unit in Armenia. Nine pts started HD because of acute renal failure and 47 pts because of CRF. Eleven CRF pts had periodic disease (table). The term FMF and colchicine as prophylactic were unknown in Armenia at that time.

Discussion: The finding that Armenians with FMF in Armenia (AA) develop CRF, suggests that they have similar mutants as SJ. Most likely, the presence of these mutants is due to the fact that SJ and AA have not been exposed to genocide. Whereas at present the highest prevalence of FMF is in the non-Mediterranean part of Turkey and neighbouring Armenia, one may question the adjective "Mediterranean". However, from a historical point of view, the adjective should remain. It reflects that the Jewish community in these Arabic countries lived in harmony with the Muslims.

Table. Diagnoses of 47 CRF patients starting HD.

Uncovering the Hidden Genetic Causes of Kidney Diseases: A Whole-Genome Sequencing (WGS) Study

Silvia Giovanella,[1] Alessandra Terracciano,[3] Francesco Emma,[3] Angela Ferrulli,[2] Francesca Testa,[4] Maria Ferri,[1,4] Gabriele Donati,[1,4] Michele Rossini,[5] Giovanna Valenti,[2] Antonio Pisani,[6] Laura Massella,[3] Riccardo Magistroni.[1,4]
[1]Universita degli Studi di Modena e Reggio Emilia, Modena, Italy; [2]University of Bari, Department of Biosciences, Biotechnologies and Environment, Bari, Italy; [3]Bambin Gesù Children Hospital, Rome, Italy; [4]Azienda Ospedaliero-Universitaria di Modena, Modena, Italy; [5]University Hospital Bari, Bari, Italy; [6]Azienda Ospedaliera Universitaria Federico II, Napoli, Italy.

Background: Employing a genomic approach holds promise in elucidating the etiology of CKD. Our prior study ('DECIDE') demonstrated a yield of 36% in a select population (n=692) undergoing gene panel, with an additional 12% diagnostic rate upon further investigation. This study showed that a large proportion of our patients lacked a final diagnosis despite a high suspicion of genetic disease. This spurred the creation of an Italian consortium comprising 4 clinical centers specialized in genetic kidney diseases. We propose to assess the diagnostic yield of Whole Genome Sequencing (WGS) in unresolved cases.

Methods: The consortium will conduct WGS analysis on 300 patients (100 index cases in trios) with suspected genetic kidney disease who tested negative in initial genetic analyses. Collaboration with AIRP (Italian Patients' Association for Kidney Diseases) will ensure that our protocols align with patient expectations. During recruitment, clinical data will be centralized in RedCAP, with emphasis on family history, age of onset, and lacking diagnosis despite thorough diagnostic evaluation, to prioritize patients with a high suspicion of a genetic condition. The genomic analysis will utilize Illumina's NovaSeq 6000 sequencing platforms. Variants will be classified following ACMG guidelines. The clinical impact of new genomic diagnoses will be assessed by determining whether they will guide tailored therapies, prevent futile treatments, and facilitate cascade testing. In a subset of patients with cystic manifestations, identified variants will undergo evaluation through functional studies focusing on renal concentrating ability alterations.

Results: Our goal is to identify new pathogenic variants that may have been missed by previous analyses. Integration of genetic results with functional assessment could allow evaluation of the potential of personalized medicine in rare cystic conditions other than ADPKD.

Conclusions: A genetic diagnosis may hold direct clinical implications. By leveraging WGS and advanced bioinformatics, we aim to unearth novel insights contributing to our comprehension of the mechanisms underlying renal diseases. PUB297

A Rare Find of Glucocorticoid-Remediable Aldosteronism

Elizabeth Cho, Jie Tang. *Brown University Warren Alpert Medical School, Providence, RI.*

Introduction: Glucocorticoid remediable aldosteronism (GRA), is a rare genetic form of hyperaldosteronism caused by an unequal cross-over of steroid 11β-hydroxylase (*CYP11B1*) and aldosterone synthase (*CYP11B2*) genes, leading to an increased aldosterone synthesis driven by ACTH. Here, we present a case of GRA diagnosed by ACTH stimulated adrenal vein sampling (AVS) and confirmed by genetic testing.

Case Description: A 24-year-old female was referred for hypertension. She was found to have elevated blood pressure (BP) at age 16 after falling from a horse ride. At age 20, she was again hypertensive and developed mild hypokalemia. Since then, her BP has not been controlled on maximum doses of amlodipine, chlorthalidone, and lisinopril. She has no other medical history, is a nonsmoker, rarely drinks alcohol, never used illicit drugs. She was adopted. Her only compliant was involuntary 80 lbs weight gain over the past three years. Vitals: BP 150/98, heart rate 88 bpm; physical exam was unremarkable. Laboratory tests showed normal renal and liver functions, normal thyroid function, normal electrolytes except potassium 3.1 mEq/L, plasma renin activity was <0.1 ng/mL/hr, serum aldosterone was19.4 ng/dL; CT showed normal adrenal glands. Shortly after, ACTH-stimulated adrenal vein sampling (AVS) was performed which showed dramatic aldosterone responses to ACTH without lateralization (see Table). Genetic test confirmed pathogenic CYP11B1 and CYP11B2 fusion. She responded to low dose prednisone and spironolactone 50 mg twice a day.

Discussion: GRA diagnosis is often overlooked due to fluid clinical presentations. Work up starts by confirming hyperaldosteronism. In this case, AVS was very helpful in securing the diagnosis with dramatic aldosterone response to ACTH. A prompt diagnosis of GRA is crucial to establish an effective treatment regimen.

ACTH-stimulated adrenal vein sampling result

	Pre-ACTH			Post-ACTH		
	IVC	R Adrenal Vein	L Adrenal Vein	IVC	R Adrenal Vein	L Adrenal Vein

Fumarate Hydratase-Deficient Renal Cell Carcinoma

Emad S. Khater. *SehaKidney Care, Abu Dhabi, United Arab Emirates.*

Introduction: Fumarate hydratase FH deficiency is very rare disorder. characterized by educed FH enzyme activity. Fumarate hydratase-deficient renal cell carcinoma RCC is a rare pathological subtype.

Case Description: We reported a 33 years old male know to have diabetes and hypertension well controlled presented with complains of right side loin pain. and visible haematuria. no family history or renal disease.renal function normal. Urine showed RBC. Clinical examination unremarkable. CT showed large infiltrating tumour in the right kidney. biopsy of renal mass showed renal RCC. However, as the patient is young. translocation related tumours considered hence immunohistochemistry performed it showed diagnosis of a fumarate hydratase-deficient RCC. plan was to start the patient on immunotherapy in the form bevacizumab and erlotinib and to repeat the CT if CT improved then to do nephrectomy.

Discussion: Fumarate catalysed to malet by fumarate FH enzyme in Krebs cycles. deficiency of FH enzyme due to Genetic disorder lead to accumulation fumarate intracellularly and extracellularly. Its rare disorder. mode of transmission is autosomal recessive. accumulation of fumarate may function as an oncometabolite in homozygous FH deficiency causes sever neonatal neurological defect, dysmorphic feature and brain abnormalities. prognosis is poor most of severely affected child do not survive. The heterozygotes form majority of cases are healthy. however, they may develop tumours like cutaneous leiomyomata uterine fibroids and uterine myomas also may develop RCC known as Hereditary Leiomyomatosis with Renal Cell carcinoma HLRCC. In regards to RCC associated with FH deficiency defined as a rare pathological subtype (WHO 5th edition 2022) due to mutations in the FH gene. Diagnosed based on a molecular and immunohistochemical biomarkers. The incidence is very rare and only a few hundreds of cases reported. average age onset between 20 -25. Unfortunately its highly metastasize and very invasive. main treatment is nephrectomy. immunotherapy considered new hope in these patients treatment. Family member of high risk needs early genetic counselling and testing also renal surveillance. Conclusion, FH deficiency is an autosomal recessive disease due to accumulation of fumarate. It may associated with RCC FH deficient. Its rare disease very invasive in young age with RCC advised to investigate for FH deficiency as possible cause.

Gordon, You're Bananas! A Case of Resistant Hyperkalemia

Ashley Tang, Huy Truong, Shonit Nandakumar, Rajesh Gulati. *Riverside Community Hospital, Riverside, CA.*

Introduction: Gordon syndrome, also known as familial hyperkalemic hypertension or pseudohypoaldosteronism type II, is a type IV renal tubular acidosis (RTA) and presents during adolescence or young adulthood. Its pathology is due to gene mutations that affect electrolyte transporters in the renal distal tubules and can be difficult to clinically identify from other common diagnoses. In this case, we highlight Gordon syndrome as an alternative diagnosis for a patient with suspected acute heart failure exacerbation nonresponsive to standard treatments.

Case Description: A 30-year-old male with a history of hypertension presents for worsening dyspnea and leg edema. His family history was significant for early onset hypertension. On exam, he was tachycardic, hypertensive, and had diffuse lung crackles and severe edema. Labs indicated hyperkalemia, NAGMA, and elevated BNP. A transthoracic echocardiogram and renal ultrasound were unremarkable. Repeated furosemide and potassium binder doses had inadequate responses, triggering other renal workup. Loop diuretics were discontinued in favor of thiazide diuretics, and he improved, discharging home with instructions to obtain outpatient genetic testing for Gordon syndrome. Labs were significant for an elevated renin, low aldosterone, and normal metanephrine and normetanephrine. Two months later, he was re-evaluated for intermittent edema after being compliant with a thiazide, and his symptoms and laboratory abnormalities were primarily resolved.

Discussion: Gordon syndrome, although rare, can resemble more prevalent disorders like heart failure, but can be differentiated by distinct lab results and early onset hypertension. This patient's volume status and hyperkalemia were also unresponsive to standard heart failure treatments, and in the setting of unremarkable renal and adrenal workup, his ongoing NAGMA, hyperkalemia promoted investigation into a type 4 RTA. His renin was elevated, likely from furosemide administration and its activation of the renin-angiotensin-aldosterone system. His aldosterone however remained suppressed, and he responded well once transitioned to thiazides, which coincides with Gordon syndrome's pseudohypoaldosterone nature and its sensitivity to that drug class. Recognizing these diagnostic hallmarks in the early stages can expedite accurate diagnosis and the initiation of appropriate treatment, thereby improving patient care outcomes.

PUB300

Answering the Call for Genetic Testing: Recurrent Hypomagnesemia Secondary to the Gitelman-Like ADTKD-HNF1

Andrew Yanik, Taylor R. Moody, Anne Cioletti, Sarah Gilligan. *University of Utah Health, Salt Lake City, UT.*

Introduction: Autosomal dominant tubulointerstitial kidney disease (ADTKD) is a group of inherited kidney disorders characterized by early onset chronic kidney disease. Mutations to the transcription factor hepatocyte nuclear factor 1B (HNF1B) are associated with renal cysts, diabetes, and tubular dysfunction. We report the case of a patient with recurrent hypomagnesemia and hypokalemia secondary to *HNF1B* mutation.

Case Description: A 22-year-old female with history of non-diabetic gastroparesis requiring tube feeds and total parenteral nutrition was seen by nephrology for refractory hypomagnesemia and hypokalemia. Since early adolescence she had recurrent hypomagnesemia and hypokalemia as low as 0.9 and 2.4, respectively. She was managed with thrice daily oral magnesium and potassium and daily IV magnesium through indwelling catheters. Due to frequent hospital admissions for central line-associated bloodstream infections, her long-term IV access was discontinued. A formal workup for hypomagnesemia showed an elevated 24-hour urinary magnesium of 578 mg/d and an elevated fractional excretion of magnesium of 17% with serum magnesium of 1.1 mg/dL. Interestingly, her genetic testing years prior revealed no pathogenic mutations causing Gitelman syndrome but instead showed a heterozygous whole gene deletion of HNF1B. She is currently managed with magnesium oxide thrice daily, IV mag thrice weekly, and amiloride. She was recently started on SGLT2 inhibition with improvement in her magnesium levels.

Discussion: HNF1B is a transcription factor encoded by the *HNF1B* gene on chromosome 17q12, mutations in which can present as tubular dysfunction similar to Gitelman syndrome. HNF1B has downstream targets that regulate the Na-K-ATPase pump in the basolateral membrane of the distal convoluted tubule (DCT). Loss of HNF1B limits active transcellular magnesium reabsorption and disrupts potassium handling, resulting in hypomagnesemia and hypokalemia. Several case reports demonstrated improvement in hypomagnesemia in patients with HNFB1 mutation when SGLT2 inhibitors are used as treatment for associated diabetes, but to our knowledge they have not been used for this indication in a non-diabetic patient. This case demonstrates the value of genetic testing, gives insight into the presentation of ADTKD-HNF1B, and suggests yet another indication for SGLT2 inhibitors.

PUB301

Mitochondrial Nephropathy with m.5538G>A Mutation within the tRNA-Trp Region Treated with Imeglimin: A Case Report

Mari Ikeda,[1] Toshiyuki Imasawa,[2] Tomohiko Inoue,[3] Mamiko Ohara,[1] Tomo Suzuki.[1] *[1]Kameda Medical Center, Kamogawa, Japan; [2]Chiba-East National Hospital, Chiba, Japan; [3]St. Marianna University School of Medicine Hospital, Kawasaki, Japan.*

Introduction: Mitochondrial nephropathy (MN) is a genetic disease characterized by a defect in oxidative phosphorylation, with a diverse clinical presentation, urinary protein in more than 90% of cases, and decreased kidney function reported in about 70% of cases. Although CoQ10 and taurine have been reported to be effective in improving kidney function in some cases, most cases are difficult to treat. We report the first case of mitochondrial nephropathy treated with imeglimin after genetic and mitochondrial function analysis.

Case Description: This case is a 25-year-old male with mild proteinuria who was diagnosed with minor glomerular abnormalities in his first kidney biopsy at age 15. Due to increased urinary protein (urine protein creatinine ratio 2.2 g/gCr) and decreased kidney function (serum creatine 1.24 mg/dL), we performed second kidney biopsy at age 22. Light microscopy showed segmental glomerulosclerosis lesions. Electron microscopy revealed many abnormal mitochondria in the podocytes. Serum lactate was 27.8 mg/dL and cerebrospinal fluid lactate was 35.5 mg/dL after admission. Therefore, we considered mitochondrial disease (MD). We further suspected MD when cultured dermal fibroblasts showed decreased oxygen consumption and decreased respiratory chain enzyme activity complex III and complex IV, leading us to perform genetic testing. Genetic analysis of frozen sections of kidney tissue confirmed with m.5538G>A mutation in the tRNA-Trp region. Similarly, we detected the same genetic mutations in blood, urine, and skin fibroblasts. The rate of urine, blood, and skin fibroblast of heteroplasmy were 64.0%, 32.4%, and 73.3%, respectively. We treated him on olmesartan and dapagliflozin for chronic kidney disease with severe persistent urinary protein. In addition, we added imeglimin in the hope of improving new-onset diabetes and reducing complex III activity. Approximately one year after the start of imeglimin treatment, renal function declined at a faster rate, but proteinuria and lactate/pyruvate ratio decreased, suggesting that mitochondrial function may have improved.

Discussion: Imeglimin may be effective in MN with reduced complex III activity, but the long-term effects need to be verified.

PUB302

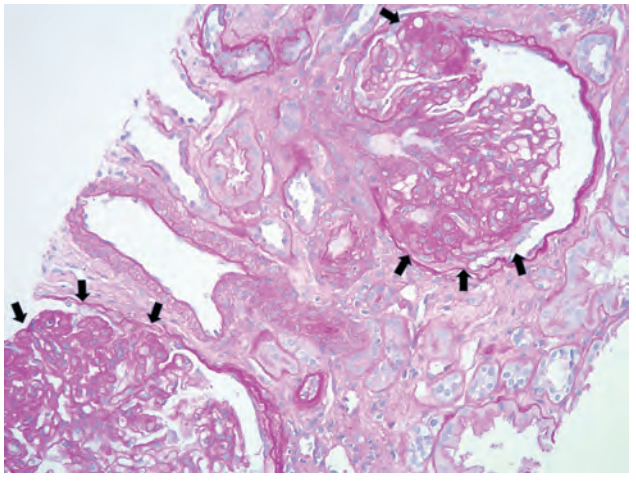
PAX2 Mutation Associated with Focal Segmental Glomerulosclerosis

Manuel A. Santos Carrasquillo,[1] Leal C. Herlitz,[2] Surafel K. Gebreselassie,[1] Scott D. Cohen.[1] *[1]Cleveland Clinic Florida, Weston, FL; [2]Cleveland Clinic, Cleveland, OH.*

Introduction: FSGS is a heterogenous disorder with a variety of causes including immunologic factors, genetics, medications, and infections. Recognizing the potential pathogenic etiology is essential in the appropriate management of patients. Knowledge of genetic etiologies will avoid unnecessary patient exposure to the toxic effects of immunosuppression.

Case Description: A 19-year-old male presented with abnormal kidney function, eGFR 42 ml/min/1.73m2, serum creatinine of 2.2 mg/dl along with a nephrotic range proteinuria of 4.1 g/g on a random urine sample. Serum albumin was 4.5 g/dl. On physical examination, the patient had a blood pressure of 125/78, examination was remarkable for 1+ peripheral edema. A kidney biopsy was performed which showed FSGS with mild to moderate tubular atrophy and interstitial fibrosis. 6 out of 28 glomeruli were globally sclerotic with 7 FSGS lesions, some of which were perihilar in location, there was also moderate foot process effacement. Genetic testing was ordered and returned with a PAX2 gene mutation. The patient was referred for genetic counseling as well as ophthalmology and audiology evaluations. He was started on Losartan 25 mg once daily; on 3 month follow up the proteinuria decreased to 1.4 g/g with a serum creatinine of 2.4 mg/dl, eGFR 40 ml/min/1.73m2.

Discussion: Mutations in PAX2 are associated with autosomal dominant adult-onset FSGS. PAX2 is a transcription factor that plays an essential role in kidney development and was previously found to be associated with congenital abnormalities of the kidney and urinary tract (CAKUT) including reduced nephron mass. The reduction in nephron mass can lead to glomerular hyperfiltration and adaptive FSGS. PAX2 may also have a direct effect on the podocyte as it suppresses the expression of WT1, a nuclear protein expressed in these cells. Genetic testing can play an integral role in the diagnostic evaluation and treatment of patients with FSGS.



PUB303

ABCC6/MRP6 Gene Mutation with Associated Membranous Nephropathy

Samir D. Patel, Ryan E. Fekrat, Gayathri Dileep, Matthew D. Nguyen, Ramy M. Hanna. *University of California Irvine Nephrology Hypertension & Kidney Transplantation, Orange, CA.*

Introduction: Multidrug resistant associated protein 6 (ABCC6/MRP6) is found in the liver and kidneys and functions in ATP-dependent export for systemic delivery related to modulators of calcification. Mutation of ABCC6 results in ectopic mineralization characterized in cases of pseudoxanthoma elasticum (PXE) and dystrophic cardiac malfunction (DCC). Neural epidermal growth factor-like 1 protein (NELL-1) has been associated with a rare form of membranous nephropathy (MN) with little proposed mechanistic link. Here we present a 54-year-old female with known ABCC6/MRP6 and NELL1 positive MN with no evidence of serological factor, rheumatoid factor, cryoglobulin, or M-protein abnormality, implying a possible link between ABCC6 mutation and NELL1 positive MN.

Case Description: Our patient is a 54-year-old female with a known ABCC6/MRP6 gene mutation on outside testing presented with initially normal renal function (BUN 6 mg/dl, sCr 0.5 md/dl). However, 24-hour urine collection shows 1.1 grams of protein with findings of an increase in urine protein to 4.4 grams (within nephrotic level range) with a peak UPCR of 7 grams at an outside hospital. Serological testing was negative with exception of isolated low C4. There was no evidence of rheumatoid factor, cryoglobulin, or M-protein abnormalities. Renal biopsy reflects membranous nephropathy, NELL1 positive. glomerulomegaly, mesangial IgM deposits, and mild to moderate arteriosclerosis. She was advised cancer screening for secondary MGN/NELL membranous nephropathy. She currently is on a RAAS inhibitor for blood pressure control. Her proteinuria decreases when on steroids to less than 350 mg.

Discussion: Our case presents as NELL1 positive MN in an adult female with negative findings of most common associations of secondary MN such as sarcoidosis, hematopoietic stem cell therapy (HSCT), autoimmune disease, infection, or malignancy with the additional presentation of ABCC6 mutation and low complement activation and no cancer as of report timing. Negative lipoid acid supplementation and target antigens in cases of secondary MN additionally are not always associated with identifiable causes. In our case, we propose the association of NELL1 positive finding with mutant or aberrant ABCC6-MN in conjunction with negative cancer findings. Supplemental ABCC6/MRP6 therapy may improve prognosis in patients with NELL1-MN.

PUB304

Fabry Disease Baseline Phenotype in Migalastat-Treated Patients: A Single-Centre Experience

Elena-Emanuela Rusu,[1,2] Gener Ismail.[1,2] *[1]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania; [2]Nephrology Department, Fundeni Clinical Institute, Bucharest, Romania.*

Background: Fabry disease (FD) is a rare lysosomal storage disease causing progressive kidney, heart and nervous system disorders. Migalastat is an oral FD specific treatment that provides a suitable alternative in patients with amenable genetic variants. The aim of our retrospective study is to present the clinical phenotype of FD amenable patients evaluated and initiated on migalastat in the Expert Center for Rare Diseases of the Reno-Urinary System between 2020 – 2024.

Methods: All patients had comprehensive assessment for target organ manifestations of FD. Renal function was assessed using eGFR, albumin creatinine ratio and proteinuria. Also, 7 patients underwent kidney biopsy (KB).

Results: Our study included 12 adult (6M/6F) patients with confirmed diagnosis of FD by the genetic test and amenable GLA variants. Seven patients presented classic FD phenotype, while five patients presented late-onset FD phenotype. Seven patients started "de novo" migalastat and 5 were switched from enzyme replacement therapy (ERT). In naïve patients, the main indications were: heart disease (5 cases), kidney damage (1 case), neurological involvement (2 cases). In patients switched from ERT, the most frequent indication was the patient decision. At baseline, average age of the patients was 47.5 +/- 16.1 years old (range 24-75). Alfa-GLA activity was reduced in 10 patients, mean 1.6 +/- 1.8 mol/L/h. Overall baseline mean eGFR was 79.6 26.7 mL/min/1.73 m2. Five patients presented CKD stage 3, three patients presented kidney transplantation, 2 patients were in CKD stage 2, one patient with CKD stage 1, and 1 patient without clinical kidney involvement. Six patients presented normal UACR, four patients showed microalbuminuria, and 2 patients presented macroalbuminuria. KB was performed before ERT in 3 cases, before switch in 1 case, and in 3 naïve patients before migalastat treatment. Eight patients presented left ventricular hypertrophy. There was a statistically significant difference in eGFR in the males versus females (p=0.048), but no difference between classic versus late-onset phenotype. Left ventricular mass index were significantly high in late onset phenotypes.

Conclusions: Migalastat has been successfully initiated in this cohort of disease-specific naïve and previously treated patients with amenable mutations, after a complete patient evaluation by a multidisciplinary FD team.

PUB305

Genetics in Thrombotic Microangiopathy

Yaman Kouatli, Krista L. Lentine, Thanh-Mai N. Vo, Aliza Anwar Memon. *Saint Louis University, St Louis, MO.*

Introduction: The underlying molecular mechanisms in complement mediated Thrombotic Microangiopathy (C-TMA) tend to overlap but unify at the common end-point of endothelial injury. Literature has shown that complement activation is triggered at the endothelial surface. Some triggers like infection is the first presentation of TMA even in the genetically susceptible individuals. In this case, we discuss the unmasking of C-TMA after an infection.

Case Description: A 30-year-old African American male presented with acute pancreatitis and acute kidney injury (AKI). Workup was significant for creatinine 5.4 mg/dl, hemoglobin 10.3g/dl, platelets 21x10*3/uL, 2+ Schistocytes, reticulocyte 1.7%, bilirubin 1, Fibrinogen 365mg/dL, D-dimer >20, PT 1.5, APTT 28, C3 102, C4 23, and direct Coombs test negative. The ADAMTS13 activity at 67%. A genetic panel for C-TMA was sent and decision was made to start the patient on complement inhibitor therapy until genetic study was pending. Unfortunately, the patient left hospital against medical advice and two days later presented at an outside hospital. There he was started on hemodialysis for worsening renal failure and underwent a kidney biopsy which showed chronic TMA. Genetic results were positive for C-TMA due to the presence of a splice variant in CFHR1 in combination with large CFHR1-3 deletion which makes the patient in effect CFHR1-null.

Discussion: C-TMA is caused by the dysregulation of alternate pathway (AP), perpetuating the downstream effects of the complement pathway. Only 50-60% of cases of C-TMA are caused by genetic variants and the absence of the gene does not exclude the diagnosis. C-TMA is not a monogenic disease and familial forms are only reported in 20% of patients. More genetic variants are emerging as genetic testing is becoming frequent and patient registries continue to expand. Due to the variable penetrance in familial cases of C-TMA, most patients present at an advanced age and often require a second hit such as an infection, pregnancy, and vaccination to unmask the TMA. The studies done so far to compare the enrichment of the variant frequency have been geographically limited and the issue of race has not been addressed in the field of TMA genetics. The data on the incidence of C-TMA and complement genetics is lacking in black individuals. Further studies are needed to explore the frequency of genetic variants in the African American population.

PUB306

Hereditary Angiopathy with Nephropathy, Aneurysms, and Muscle Cramp (HANAC) Syndrome: There Is More to Explore!

Nahida Baigam, Rajesh Mohandas, Siddhartha D. Bajracharya. *LSU Health New Orleans, New Orleans, LA.*

Introduction: Structural integrity of the glomerular basement membrane (GBM) is essential to maintain the selectivity of the slit diaphragm and filtration barrier. One of the key components of the GBM is Collagen Type 4. Mutations in Collagen Type 4 underlie the well-known hereditary disorder, Alport's syndrome. We report a more uncommon hereditary disorder affecting the kidneys due to mutations in Collagen Type 4

Case Description: A 30-year-old man with bilateral congenital cataracts and cerebral palsy (CP) was referred for asymptomatic microscopic hematuria. He did not report muscle pain or cramps, neurological symptoms, gross hematuria, hearing issues, polydipsia, or polyuria. He had hypertension but was not on medications. His estimated Glomerular filtration has declined from 66 to 57 mL/min/1.73m^2. Otherwise, his lab work was within normal limits. He did not have a family history of CKD, but his mother and sister had CP. We performed a renal biopsy, which showed Thin Glomerular Basement Membrane Disease (TBMN) and genetic test was performed, which revealed a pathogenic mutation in COL4α1.

Discussion: The glomerular basement membrane in humans contains two separate networks of type 4 collagen. The sub-endothelial GBM comprised of α1/α2 networks, while the thicker sub-epithelial layer comprised of α3/α4/α5 networks. Defects in α3/α4/α5 cause Alport's syndrome, while mutations in COL4α1 mutations can cause diverse clinical presentations hereditary angiopathy with nephropathy, aneurysms, and muscle cramps, the HANAC syndrome, and non-syndromic congenital cataracts. Renal involvement can cause thin basement membrane with microscopic hematuria and renal cysts and less often CKD. Earlier genetic testing could have avoided the need for a biopsy in this patient. Worldwide, 13.4% of the population has CKD; among the causes, Primary glomerular disease is more than 8% and familial 10%. COL4 A disorders have significant similarities. All patients with suspected Alport syndrome or TBMN disease should receive genetic testing for the COL4 variants because up to 27% of cases are caused by a de novo pathogenic variant. The penetrance of COL4A1-related disorders is close to 100%, with the clinical presentation differing widely. Genetic testing allows for the early detection of exceptionally rare kidney diseases like HANAC syndrome.

PUB307

Apparent Steroid Sensitivity in Congenital Nephrotic Syndrome Type 1 (NPHS1)

Mohammad S. Al-Awad, Essa Abuhelaiqa, Awais Nauman. *Hamad Medical Corporation, Doha, Qatar.*

Introduction: Congenital Nephrotic Syndrome (CNS) Type1 is an autosomal recessive disease caused by mutation in NPHS1 gene. NPHS1 encodes for Nephrin which is essential for maintaining slit diaphragm integrity. Herein we report a case of CNS Type1 that was treated with multiple Immunosuppressants with numerous relapses and remission giving an apparent impression of steroid sensitivity

Case Description: A 21 y.o male, diagnosed with Nephrotic Syndrome at age of 20 months, Received Steroids initially with partial response. Later, The patient continued to exhibit low grade proteinuria less than 1 g/24hr with sharp interval increases reminiscent of relapses. Despite treatment with Cyclophosphamide, Mycophenolate Mofetil and Cyclosporin, his relapses persisted Kidney Biopsy at age of 10 years when he was in partial remission revealed no Glomerular Proliferative changes or Segmental Sclerosing lesions with minimal IFTA, Negative IF. EM Showed moderate and non-global foot process effacement and was decided to have Minimal Change Disease in partial remission. He was maintained on Cyclosporine and Prednisone and continued to have frequent relapses. Therefore, he was given Rituximab, other therapies were tapered off as there was partial improvement of proteinuria. The patient had preserved GFR through all clinical course. and noted that the patient had fluctuation of proteinuria with no particular relationship with Immunosuppression therapy which led to the suspicion of CNS type1. He was referred to Genetic Testing which revealed NPHS1-related disorder with Homozygous mutation of (TTC>GTC): c.2617 T>G in exon 19 of the NPHS1 gene

Discussion: CNS type1 (NPHS1) Classically is characterized by prenatal onset of massive proteinuria followed by severe steroid-resistant nephrotic syndrome apparent at birth with rapid progression to end-stage renal failure. When NPHS1 patients are on therapy partial improvement in proteinuria can give an apparent impression of steroid sensitivity resulting in continued use of various immunosuppressive which are potentially toxic. Genetic testing can confirm the diagnosis thereby avoiding pernicious side effects of immunosuppression. Our patient had relapsing-remitting Nephrotic syndrome with no relation to therapy. It is therefore imperative to maintain high index of suspicion and low threshold for considering genetic testing in childhood Nephrotic Syndrome

PUB308

Duplication Syndrome and Its Association with Kidney Disease

Mercedes Malone. *University of Florida, Jacksonville, FL.*

Introduction: Williams-Beuren Syndrome (WS) refers to a segment on chromosome 7 that, when absent, is associated with WS. Conversely, duplicating this segment can lead to Duplication 7 Syndrome (Dup 7). Duplication syndrome is a rare genetic disorder characterized by developmental delay, impairment of the kidneys, and behavioral abnormalities. Here, we describe a case of 7q11.23 duplication exhibiting such features. Duplication syndrome follows an autosomal dominant inheritance pattern and is characterized by an extra copy of a region on the long (q) arm of chromosome 7. Due to its rarity, duplication syndrome may be misinterpreted as a psychological disorder due to the limited information available about the condition and also remains a critical etiology for kidney disease. In the current case, the 7q11.23 duplication was identified many years after the initial presentation.

Case Description: A 19-year-old male with a solitary kidney presented to our nephrology clinic for persistent chronic kidney disease of unknown etiology. His medical history included autism absence seizures, chronic kidney disease stage 3a, and developmental disorder. During infancy, he faced unexplained growth issues and episodes of pneumonia, prompting negative tests for cystic fibrosis. His family history revealed a father with epilepsy. On examination, he was afebrile with no notable physical abnormalities except for agitation. Initial laboratory tests returned unremarkable results with a creatinine of 1.45 mg/dl. Neurological evaluations showed no abnormalities to explain his persistent behavioral symptoms. A psychiatric assessment highlighted speech and behavariol issues. Despite multiple medication trials yielding no improvement, consultation with a geneticist was pursued, considering a potential genetic association due to his solitary kidney. A breakthrough occurred when the geneticist identified a 7q11.23 duplication, shedding light on the underlying cause of his complex medical presentation.

Discussion: Diagnosing rare genetic conditions like 7q11.23 duplication syndrome requires teamwork and thorough exploration of family medical history. Early identification and intervention are vital for managing kidney disease and seizures, offering clarity and psychological relief. While treatment options may be limited, understanding the illness's cause brings psychological benefits and encourages further learning.

PUB309

A Rare Case of HNF1B and NR3C1 Genetic Mutations Leading to Severe Electrolyte Derangements and Impaired Glucose Control

Saeed Razaq, Khudija Nayab, Eric L. Wallace, Arun Rajasekaran. *The University of Alabama at Birmingham, Birmingham, AL.*

Introduction: HNF1B plays a crucial role in the development the kidney/liver/pancreas by regulating gene expression. HNF1B gene mutations cause structural kidney defects and electrolyte abnormalities. Non-renal consequences, notably MODY type 5, are also noted. Our case describes a patient incorrectly diagnosed with type 1 diabetes but was found to have a pathogenic HNF1B mutation and a likely pathogenic NR3C1 mutation, both contributing to her hyperglycemia, as well as hallmark features of ADTKD.

Case Description: 37-year-old female with insulin-dependent diabetes, autonomic neuropathy, hypomagnesemia, hypokalemia, hypophosphatemia, and cachexia presented with worsening fatigue and CKD. She was wheelchair bound, hypotensive, and cachectic. She denied PPI/laxative/diuretic use; denied family history of kidney disease. K 2.6 mmol/L, Cl 93 mmol/L, CO2 37 mmol/L, BUN 12 mg/dL, Cr 0.7 mg/dL, eGFR 114 mL/min/1.73m^2 [CKD Epi 2021; likely an overestimate of actual GFR given cachexia], Mg 1.1 mg/dL, Phos 1.9 mg/dL, Albumin 3.1 g/dL, HbA1c 15.9. Urinalysis - pH 6.3 and absent dipstick proteinuria. UACR 321 mg/g and UPCR 1987 mg/g [tubular proteinuria]. Kidney USG: B/L kidneys 10.5 cm, normal echogenicity, and no kidney cysts. Targeted gene panel of blood revealed a pathogenic HNF1B whole gene deletion [heterozygous, AD inheritence] at chromosome 17q12 and likely pathogenic NR3C1 mutation at chromosome 5 [heterozygous, AD inheritence]. She requires frequent IV crystalloids, magnesium, and potassium replacement therapy. Genetic counselling was provided and she is being followed at the Rare Genetic Kidney Disease Clinic at UAB.

Discussion: The case report explores the intricate relationship between HNF1 Beta mutation, potential tubulointerstitial nephritis, and MODY5 phenotype. HNF1B gene shows significant variability in mutation carriers, often without family history due to spontaneous mutations. Kidney involvement is common, with early manifestation and diverse phenotypes including electrolyte abnormalities. Pancreatic involvement is also notable. Our patient has a HNF1B 17q12 genetic variant that has been observed at a frequency of < 0.014% of the general population. Not much is known regarding NR3C1 mutations. We highlight the importance of genetic testing and counselling in tailoring individualized treatment.

PUB310

Alport Syndrome in a Woman with Proteinuria and Familial Hematuria

Jordan Hartman. *The University of Texas at Tyler, Tyler, TX.*

Introduction: Approximately 80% of Alport cases are due to X-linked gene mutations in COL4A5, although homozygous variants exist in people with autosomal recessive disease. The best screening tool for Alport syndrome is urinalysis with evidence of hematuria[1]. The diagnosis should be considered in patients with persistent microscopic hematuria or gross hematuria, although definitive diagnosis is by genetic testing[3].

Case Description: A 27-year-old female with a history of major depressive disorder presented to the clinic as a referral due to profound proteinuria on screening urinalysis by OBGYN for first trimester screening. Family history revealed persistent hematuria in the patient, her mother and brother. Autoimmune workup including Lupus was unremarkable with negative ANA. No signs of systemic inflammation were present, and inflammatory markers were within normal limits. We decided to perform genetic testing with NATERA Renasight Kidney Gene panels to determine if there is any hereditary explanation for her hematuria, ultimately avoiding a very high-risk kidney biopsy procedure during pregnancy. Her genetic testing came back positive c.2452G>A (p.Gly818Arg) mutation for COL43A gene. We have decided that Alport syndrome is the most likely explanation for her benign hematuria. We plan to obtain kidney biopsy following the delivery of her baby for confirmation of the diagnosis. However, with family history of multiple family members, genetic testing showing mutation the mutation above, and negative extensive work up, her most likely diagnosis is currently Alport Syndrome.

Discussion: algorithm for diagnosing CKD. Genetic testing is emerging as a valuable component for the evaluation of CKD cause. The prevalence of genetic causes of CKD is expected to increase in future years as our screening methods and diagnostic tools become more available and cost effective[3]. In our case, it helped prevent possible complications that can arise with kidney biopsy during pregnancy, and gave us more information for reproductive counseling. We believe that genetic testing should be considered as an initial diagnostic tool in CKD diagnosis.

PUB311

Adult Kwashiorkor Presenting with Extreme Hypernatremia and Edematous State: A Therapeutic Challenge

Jose F. Bernardo,[1] Marco A. Dominguez,[2] Carlos R. Valenzuela.[2] [1]*Clinica Medica Cayetano Heredia, Lima, Peru;* [2]*Hospital Nacional Cayetano Heredia, Lima, Peru.*

Introduction: Children with severe chronic malnutrition often present with either Marasmus or Kwashiorkor (an edematus state) and dysnatremia. There is a paucity of data on the effects that chronic malnutrition can have on sodium metabolism in the adult population. We present the case of an elderly female whose initial chief complaint was progressive weakness, decreased oral intake and weight loss. At time of her hospital admission, she had an edematous state and extreme hypernatremia.

Case Description: 72 years old female with history of depression on treatment with mirtazapaine. She had history of decreased apetite and weight loss for the past 6 months. In the past month she presented to the ER for up to three occasions complaining of progressive weakness and confusion and agitation and was found to be hypoglycemic. In this admission he was brought with a hstory of an episode of tonic-clonic seizure followed by loss of consciousness. On admission his BP was 100-60, HR 56, afebrile, looked older than stated age, her skin was dry and had areas of desquamation, severely decreased muscle mass, bilateral, peripheral edema up to thigh area, lungs were clear, heart no gallop, neurologic: slow response to painful stimuli and no focal motor deficit. All other systems were negative. Her Hb/Hct 15, Glucosa 46 mg/dl, Urea/Cr 102/2.2 mg/dl. Electrolytes showed: Na 193 mEq/L, K 5.24 mEq/L, Cl 117 mEq/L, Alb 3.9 g/dl, Total protein 7.2 3.9 g/dl. Total Cholesterol 102 mg/dl, Triglycerides 75 mg/dl. ABGs pH 7.32, HCO3 16, pCO2 32. PO2 86, lactate 1.6

Discussion: This case illustrates the concomitnt presence of an edematous state along with severe dehydration and hypernatremia. The combination of anemia, hypogycemia and hypocolesterolemia corroborated the presence of severe malnutrition, Kwashiorkor type. She has underlying severe chronic kidney disease, on admission she was not hypotensive but she had bradycardia. Her serum K levels wele slightly elevated potassium level and had a compensated metabolic acidosis both premonitory signs of a bad outcome. Her volumen status was deemed expanded because of the presence of moderate edema. She was then prescribed IV albumin and IV furosemide and subsequently evolved with a fatal cardiac arrest. The combination of severe edema and severe hypernatremia in adult patients with Kwashiorkor constitutes a therapeutic challenge.

PUB312

Kidney Biopsy in Elderly Patients: Is It Really the Case to Desist?

Adele Mitrotti, Francesca Digennaro, Eleni Ioannou, Donatella Cappiello, Marica Giliberti, Vincenzo Di leo, E. D. Stea, Adriano Montinaro, Paola Pontrelli, Michele Rossini, Loreto Gesualdo. *Universita degli Studi di Bari Aldo Moro, Bari, Italy.*

Introduction: Italy is the second country in the world for elderly population, after Japan, with an estimated population over 75 years of 11,7% while 7,18% are those over 80s. Of those, 42,3% have three or more chronic diseases (ISTAT data 2019). We investigated our kidney biopsy (KB) database from 2002 to 2024, looking at all the KB performed in patients over 80s, in our nephrology unit.

Case Description: We performed a KB in a 84 female with acute kidney injury and nephrotic syndrome, approaching dialysis. We diagnosed a “Light Chain Cast Nephropathy” in the setting of Multiple Myeloma with multiple osteolytic lesions. She rapidly started steroids and Bortezomib showing rapid and stable improvement of clinical symptoms and laboratory tests. We wondered if age still represent a limit to perform KB. From 2002 to 2024 we performed 7150 KB; 1,8% were performed in patients with an age over 80. Of the 131 patients, 54 were females and 77 were males, with a median age of 82 (range 80 to 96). Figure 1 shows renal biopsy diagnoses. The most frequent diagnoses were Membranous Nephropathy (19%), Vasculitis (15,2%), Amyloidosis (12,2%), followed by Light chain Cast Nephropathy (8,3 %), Minimal Change Disease and Focal Segmental Glomerulosclerosis (7,6% respectively).

Discussion: These diagnoses may represent a challenge, particularly in elderly patients with comorbidities. Personalized therapy can help in slow the progression of renal damage, improving their outcome even in vulnerable patients, as occurred in our case report. We will investigate the outcomes of each patient related to clinical presentation, diagnose, comorbidities and treatment. Our preliminary data show the importance of histological diagnosis, confirming the power of renal biopsy even in advanced ages, in order to identify the underlying pathology and evaluate which is the most appropriate personalized treatment option.

Project on Geriatric Assessment in Nephrology Unit: Evaluation of Frailty and Vulnerability, Physical Capacity, and Kidney Function

Francisco Javier Lavilla. *Clinica Universidad de Navarra, Pamplona, Spain.*

Background: Improve geriatric assessment in Nephrology Unit.

Methods: Phase 1: Evaluation of subjective well-being (SWB) (1 to 10) and experience on diet, exercise, sleep, self-care, medication adherence, daily activity, socio-familial environment, and emotional state (1 to 3). **P 2:** Evaluation anthropometric (AM) (BMI, circumference upper extremity relaxed-contracted), grip strength (GS). **P 3:** Study orthostatic hypotension (OH) (diastolic DBP, systolic SBP) in supine (SUP), orthostatic (ORT), and late orthostatic (ORT LATE). **P 4:** Evaluation frailty index (FI) (FRAIL, Clinical Frailty Scale, VIG FRAIL), SPPB, Get Up and Go Test (GUGT). **P 5:** Study analytical variables (SAV). **P 6:** Follow-up vulnerable elderly (VE)

Results: 506 consultations : ages 65-74y (A) 166, 75-84 (MA) 268, over 85 (L) 70, and under 65 (C) 332. 67% male In elderly **SWB:** SWB by groups: C 7.47, A 7.46, MA 7.13, L 7.71. Influencing factors >65 y: emotional state (t 4.351 p<0.001) and exercise (t 2.312 p 0.021). In elderly with CKD, socio-familial environment (t 2.723 p 0.007). Social vulnerability: 27.7% without CKD, 29.9% with CKD (p=0.737). **AM - GS:** Age associated with strength (r -0.297 p<0.001), better with CKD (r -0.405 p<0.001). Lower strength in CKD (24.8 vs 28.3 p=0.071). **OH:** In CKD where DBP decreases (DBP SUP to DBP ORT 5.7 vs -2.32 p<0.001) and DBP SUP to DBP ORT LATE 6.1 to -1.36 p=0.003). **FI:** Age associated with SPPB (r -0.471 p=0.001), FRAIL (r=0.419 p<0.001), Clinical Frailty Scale (r=0.476 p<0.001), VIG FRAIL (r=0.490 p=0.003), GUGT (r=0.406 p=0.013). In CKD, age associated with SPPB (r -0.470 p=0.008), FRAIL (r=0.363 p=0.005), Clinical Frailty Scale (r=0.375 p=0.004), VIG FRAIL (r=0.524 p=0.009), GUGT (r=0.512 p=0.006). **SAV:** Age associated with eGFR CREAT (r -0.165 p=0.026), eGFR CYS (r=-0.363 p=0.006), eGFR CREATCYS (r=-0.347 p<0.001), and Hb (r=-0.250 p<0.001). **VE:** Social vulnerability: 27.7% without CKD, 29.9% with CKD (p=0.737). SWB worse in negative environments (6.31 vs 7.51 p=0.002), especially in CKD (5.63 vs 7.69 p=0.025).

Conclusions: In elderly age correlates with grip strength and frailty, especially in CKD. Elderly with CKD exhibit greater diastolic OH. eGFR by cystatin better associated with age and Hb. Significant vulnerability, slightly higher in CKD, affects SWB. CKD impacts elderly patients' emotional, physical, hemodynamic status, and vulnerability.

PUB314

Implementation of the "Life-Sustaining Treatment Decision-Making Act" in Decisions Regarding Dialysis: A 5-Year Single-Center Experience

Seokjin Hwang, Soyoung Lee, Sua Lee, Bo Sun Park. *Daejeon Eulji University Hospital, Daejeon, Daejeon, Republic of Korea.*

Background: The legislation on life-sustaining treatment decisions was enacted in 2016 and has been in effect since February 2018 in South Korea due to social resistance to the implementation of life-sustaining treatment (LST) in patients with end-of-life care. Since then, patients at the end-of-life have been able to decide to receive or discontinue LST. These include cardiopulmonary resuscitation (CPR), mechanical ventilation (MV), hemodialysis (HD), and chemotherapy (CTX).

Methods: This was a retrospective chart review of patients who discontinued LST from August 2018 to May 2023 under the law on life-sustaining treatment decisions at single-center. We classified each patient based on underlying diseases, whether to implement existing LST, and whether to self-determine life-sustaining treatment.

Results: A total of 105 patients included in the study. Group 1 include patients previously had no dialysis treatment. Group 2 include patient with previous hemodialysis. This table shows the baseline characteristics of those patients (Table 1). The implementation of withdrawing LST was investigated for each group (Figure 1).

Conclusions: Our data shows the composition of patients' implementation of LST termination decisions in a single center in Korea over 5 years. Comparing the dialysis and non-dialysis groups, there is a significant statistical difference in decision not to undergo MV (p=0.024). Patients' decisions not to undergo CPR, HD, or CTX do not show a statistical difference between those two groups.

	Total (n=105)	Goup 1 (Non HD) (n=94)	Group 2 (HD) (n=11)	P value

PUB315

Glomerular Injury and Differences in Colocalization of Glomerular IgA, IgG, and Complement C3 in Patients with IgA Vasculitis with Nephritis

Lea Novak,[1] Stacy D. Hall,[1] Dana V. Rizk,[1] Bruce A. Julian,[1] Mark Haas,[2] Jan Novak.[1] *[1]The University of Alabama at Birmingham, Birmingham, AL; [2]Cedars-Sinai Medical Center, Los Angeles, CA.*

Background: IgA vasculitis is usually a self-limited disease but some children and adults with nephritis (IgAVN) progress to kidney failure. Routine immunofluorescence of kidney-biopsy specimens from IgAVN patients show glomerular immunodeposits with IgA as dominant or co-dominant immunoglobulin with variable staining for IgG and complement C3 (C3). The goal of this study was to assess pairwise colocalization of IgA, IgG, and C3 and correlate the data with kidney histologic findings.

Methods: Remnant frozen kidney biopsies from 23 IgAVN patients (age range 5-67 yr, mean 20.2 yr) were stained for IgA, IgG, C3, and nuclei. Using confocal microscopy, four-fluorochrome images of glomeruli in multiple optical planes were acquired for each slide. Sixty regions of interest were selected and Pearson correlation coefficient (PCC) colocalization data were generated for each IgA-C3, IgA-IgG, and IgG-C3 pairwise comparison. Mean value of PCC for each pairwise comparison for each slide was calculated and the colocalization of the pairs was evaluated. To correlate results with Oxford MEST-C scores, biopsies were divided into paired groups: M0/M1, E0/E1, S0/S1, T0/(T1+T2), and C0/(C1+C2). Differences in PCC in IgA-C3, IgA-IgG, and IgG-C3 colocalization for these paired groups were evaluated.

Results: Glomerular staining for IgA, IgG, and C3 was identified in all 23 biopsies including those without IgG on routine immunofluorescence (n=16). Immune complexes exhibited higher PCC for IgA-C3 or IgA-IgG than for IgG-C3 (P=0.002 and P=0.023,

respectively). Comparison of colocalization data with MEST-C scores showed higher IgA-C3 colocalization in biopsies with endocapillary hypercellularity (E1) compared to biopsies without (E0; P=0.034). In contrast, biopsies with segmental glomerulosclerosis (S1) showed lower IgA-IgG colocalization compared to biopsies without (S0; P=0.044).

Conclusions: IgG was detected in all biopsies, including those without IgG on routine immunofluorescence. IgA, IgG, and C3 components of glomerular immunodeposits showed pairwise colocalization. Colocalization studies suggested that complement likely contributes to the kidney injury in IgAVN biopsies with endocapillary hypercellularity. In contrast, segmental glomerulosclerosis showed differences only in IgA-IgG colocalization.

PUB316

Clinical Implications of Appropriate Molecular and Glomerular Models

Robert L. Luke. *Maine Medical Center, Portland, ME.*

Background: Proteinuria is associated with deposition of immunoglobulin and complement because these proteins initiate damage to the glomerular capillary wall, particularly basement membrane, long considered the definitive layer because dextran accumulated before, but not after the lamina densa. Only a small percent of animals developed proteinuria after antigen/adjuvant challenge, however, and dextran had been unrealistically represented as impervious rigid spheres. In this study partial draining malleable dextran defines inherent glomerular dysfunction in two diseases that are devoid of immunoglobulin or complement, minimal change disease and diabetic nephropathy.

Methods: A flow dependent fiber formulation separates podocyte from basement membrane and a cylindrical glomerular tuft separates filtering basement membrane bordered by capillaries from non-filtering basement membrane bordered by mesangium. These models are introduced with the permeability of $a_1$acidglycoprotein, albumin, transferrin, IgG, and $a_2$macroglobulin in newly reported patients with primary glomerular disease and completed using hydrostatic pressures, vascular dimensions, and permeability of dextran, albumin, and IgG in similar patients obtained from the literature. Linear regression yields fiber density from slope and trans-epithelial shunt from intercept; glomerular volume is concomitantly apportioned between vascular and mesangial regions.

Results: Fiber density was similar in controls and patients; urinary protein was proportional to trans-epithelial shunts and mesangial volume. Dextran does not accumulate beneath slit pore because flow reduces its effective size. Most albumin is blocked by lamina densa, but significant amounts leak, is blocked by slit diaphragm, and must return locally to circulation to explain low proximal tubular albumin. Lower fiber densities revealed by proteins and large dextran are compatible with retrieval route that begins in lamina rara externa and continues back across lamina densa into mesangial channels that are indistinct in minimal change disease, but prominent in diabetic nephropathy, a flow path driven by periodic reversed hydraulic pressure.

Conclusions: Realistic macromolecular models trace a loop through glomerulus that is critical to protein homeostasis. Tubular reabsorption is overwhelmed if podocyte seal is compromised in minimal change disease or if mesangial recovery is compromised in diabetic nephropathy.

PUB317

Double Trouble: A Rare Case of Cephalosporin-Induced Myeloperoxidase Glomerulonephritis with Acute Interstitial Nephritis

Mario Mekhail, Sabrina Bulancea, Jonathan London, Shemrine Mark, Jorgio Auguste, Papiya Begum, Neeru Kumar. *Long Island Community Hospital, Patchogue, NY.*

Introduction: Myeloperoxidase (MPO) glomerulonephritis and acute interstitial nephritis (AIN) are distinct pathological entities that have rarely been reported to occur concurrently.

Case Description: A 76-year-old female with PMH HTN and HLD presented to the ED with worsening bilateral lower extremity edema and a non-pruritic rash which started on her arms and spread to the trunk, back and groin. Of note, she was hospitalized 12 days prior for a UTI and received ceftriaxone and later cefpodoxime. On exam, vitals were stable and she was afebrile; she had bilateral lower extremity pitting edema and a maculopapular rash on the upper extremities, torso, and groin. Labs revealed WBC 31.7, Hb 9.9, absolute eosinophil count 1.4, BUN 49, and Cr 3.5. She was admitted for acute kidney injury due to possible AIN given diffuse rash, elevated eosinophils, and recent cephalosporin use. Further studies revealed positive MPO-ANCA antibodies, negative PR3-ANCA antibodies, low C4, positive ANA, positive RF, and negative GBM. A subsequent renal biopsy demonstrated MPO-positive, pauci-immune type, subacute crescentic glomerulonephritis, active necrotizing vasculitis involving two small arteries and global glomerulosclerosis, and active interstitial inflammation. Her clinical condition improved with hemodialysis, steroids, and rituximab.

Discussion: MPO glomerulonephritis is a form of anti-neutrophil cytoplasmic antibody-associated glomerulonephritis, characterized by immune complex deposition and inflammation within the glomeruli [1]. AIN is an immune-mediated renal injury primarily affecting the renal interstitium, often induced by medications such as antibiotics [2]. To date, there have been four cases in medical literature reporting concurrent MPO glomerulonephritis and drug-induced AIN [3-6]. The pathophysiological mechanisms underlying this dual renal insult from cephalosporin use remain unclear but may involve a combination of immune-mediated processes and drug-induced hypersensitivity reactions. The simultaneous manifestation of both conditions poses diagnostic and therapeutic challenges that require further research regarding the optimal management strategy.

PUB318

Urine Proteomics of Primary vs. Secondary Focal Segmental Glomerulosclerosis: Is There a Potential Noninvasive Urine Biomarker?

Ilario Russo,[1,2] Shane A. Bobart,[4] Poemlarp Mekraksakit,[1] Maria Jose Vargas-Brochero,[1] Pajaree Krisanapan,[1,3] Coraima C. Nava Chavez,[1,6] Cristine Charlesworth,[7] Benjamin J. Madden,[7] Sanjeev Sethi,[5] Fernando C. Fervenza.[1]
[1]Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN; [2]Universita degli Studi di Bari Aldo Moro Dipartimento di Medicina di Precisione e Rigenerativa e Area Jonica, Bari, Italy; [3]Thammasat University Hospital, Khlong Nueng, Thailand; [4]Houston Methodist, Houston, TX; [5]Mayo Clinic Department of Laboratory Medicine and Pathology, Rochester, MN; [6]Hospital General Universitario Gregorio Maranon, Madrid, Spain; [7]Mayo Clinic Minnesota, Rochester, MN.

Background: Focal Segmental Glomerulosclerosis (FSGS) is a histological pattern of glomerular injury. It is classified into primary, secondary and genetic, each requiring distinct management. No reliable biomarkers can distinguish among them. We evaluated urine protein profile among a cohort of patients phenotyped as presumed primary, genetic or secondary FSGS to see if this could further differentiate these patients.

Methods: 21 patients with an FSGS lesion were classified as primary, secondary, or genetic FSGS using a clinico-pathological approach (De Vriese 2017). Primary was defined as serum albumin (SA) <3.5 g/dL, proteinuria >3.5g/24h, and diffuse foot process effacement (FPE; >80%). Secondary FSGS was defined as SA >3.5 g/dL, and segmental FPE, regardless of proteinuria. Genetic was defined by the presence of a disease-causing mutation (NPHS2, n= 3, COL4A, n=3, both MYO1E and ITGB4 mutation, n=1). Each group included 7 patients. Total protein concentration for each sample was determined by bicinchoninic acid assay, and 9 ug of protein from each sample was separated by SDS-PAGE. Baseline characteristics are shown in Table 1.

Results: SDS page gel urinary proteomics showed proteins with MW from 250 to 10 (kDa) with the majority of protein running as a 66.5 kDa band compatible with albumin. However, there were no observable differences in any molecular fraction that could help to differentiate patients with primary, secondary or genetic forms of FSGS.

Conclusions: Our analysis indicates that the urine proteomic profile does not provide additional information regarding the underlying cause of the FSGS lesion nor has the ability to differentiate different forms of FSGS.

Analysis of Clinicopathological Characteristics of Patients with Malignancy and Membranous Nephropathy: A Literature Review

Hong Cheng,[1] Guo-qin Wang,[1] Xiaoying Hu,[1] Nan Ye,[1] Xiao-yi Xu,[1] Weiyi Guo,[1] Li-jun Sun,[1] Hong-rui Dong,[1] Xiaoyi Zhao.[2] [1]*Beijing Anzhen Hospital Affiliated to Capital Medical University, Chaoyang-qu, China;* [2]*Affiliated Hospital of Chifeng University, Neimenggu, China*.

Background: The incidence of malignancy patients with membranous nephropathy (MN) has gradually increased, but the clinical and pathological characteristics of these patients are still unclear.

Methods: Patients diagnosed with renal biopsy-proven MN and comorbid malignancy detected within 5 years before and after MN diagnosis were included. The control group were diagnosed with renal biopsy-proven IMN with 5 years of follow-up data. We present a comprehensive analysis of MN with concomitant malignancy in our cohort and literature review.

Results: A total of 19 MN patients with concomitant malignancy were evaluated at our center; among them, 68.4% were male, and the median age was 57.0 (45.0, 69.0) years, with digestive system malignancy (36.8%) ranking as the predominant type. IHC showed that the highest percentage for PLA2R-only positivity (68.4%) followed by THSD7A-only positivity (15.8%). Only 2 of 5 patients expressed the same specific MN antigen on kidney and tumor. Screening 17 articles encompassing 21 patients in whom MN-specific antigen staining was performed on both renal and tumor tissues simultaneously. Among these patients, 71.4% were male, and the median age was 61.0 years (56.3, 72.8), with 33.3% digestive system malignancy. Notably, THSD7A accounted for the highest proportion of MN antigens (66.7%); among these patients, 78.6% also exhibited positive tumor THSD7A staining. The clinicopathological data of the above two cohorts were pooled and compared with IMN patients at our center. MN patients with malignancy were older at the time of renal biopsy (P=0.017), had a lower eGFR (P=0.035) and demonstrated a lower rate of CR/PR after treatment (P<0.001). The rate of PLA2R positivity in the glomeruli was significantly lower (P<0.001), while the rate of THSD7A positivity was significantly higher (P<0.001). Renal tissue IgG subclass staining showed that the rate of IgG4 positivity was significantly decreased (P<0.001), with the increased rate of IgG2 (P=0.033).

Conclusions: Malignancy screening should be more actively performed for MN patients with the above characteristics.

PUB320

Nogo-B May Mediate the Glomerular Endothelial Cell Injury of Hypertensive Nephropathy by Enhancing the Inflammatory Phenotype

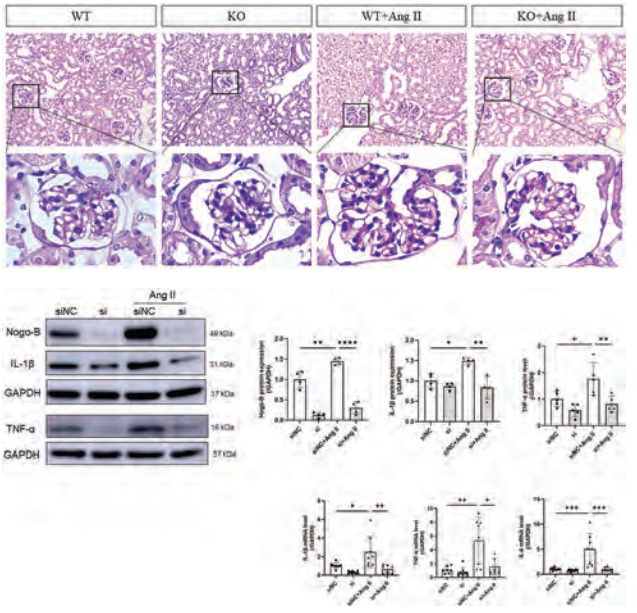
Haosen Xu, Ting Zhang, Huan Jiang, Peimin Liu, Xiaoyan Bai. *Guangdong Provincial People's Hospital, Guangzhou, China*.

Background: Nogo-B is an endoplasmic reticulum resident protein, which is mostly expressed in vascularendothelial cells and smooth muscle cells. Previous studies have elucidated the relationship betweenhypertension and Nogo-B in endothelial cells, but whether Nogo-B is involved in glomerularendothelial cell injury in hypertensive nephropathy and its mechanism is not clear.

Methods: The localization of Noao-B was proved by immunohistochemistry lHC) and immunofluorescence lFstaining in renal tissue of hypertensive patients, and the relationship between it and systolic bloodpressure (SBP) and UACR was analyzed. In animal experiments, lHC, IF, PAS, gRT-PCR andWestern blot were employed to prove the localization of Nogo-B and analyze the relationship betweenits expression level and the degree of renal injury in Ang ll-induced Nogo-B KO and control mice. inthe vitro, the level of Nogo-B in endothelial cells (Ea.hy926) was knocked down by small interferingRNA (siRNA), and the correlation between Nogo-B expression and cell phenotypes were explored.

Results: Nogo-B is expressed in glomerular endothelial cells and increased in hypertensive nephropathy. lt ispositively correlated with the patients' SBP and UACR, n animal experiments, the renal pathologicadamage of Noao-B KO mice treated with hypertension was mild. The level of Nogo-B in endothelialcells is up-regulated in hypertensive environment and inflammatory markers including TNF-a, lL-1Band lL-6 were up-regulated. Knockdown of Nogo-B by siRNA reduces the inflammatory phenotype ofendothelial cells in hypertensive environment.

Conclusions: Nogo-B may mediate the glomerular endothelial cell injury of hypertensive nephropathy by enhancingthe inflammatory phenotype.



PUB321

Contribution of the p38MAPK Signaling Pathway and the Egr-1 Transcription Factor in Glomerulosclerosis

Heitor M. Braz, Maria Oliveira-Souza, Guilherme G. Lopes, Juliana M. Pessoa. *Universidade de Sao Paulo Instituto de Ciencias Biomedicas, Sao Paulo, Brazil*.

Background: Chronic kidney disease (CKD), characterized by the progressive loss of kidney function, is one of the most serious public health problems. Its progression is followed by focal and segmental glomerulosclerosis (FSGS). This study aims to look at how ERK/p38MAPK and Egr-1 pathways interact in the signaling of Adriamycin (ADR)-induced FSGS.

Methods: 8-week-old BALB/c mice received a single dose of ADR via the tail vein (10 mg/kg) and the control (CTL) group received 0.9% NaCl solution. Both groups were monitored for 28 days and then euthanized. Kidney function, morphology and protein expression were evaluated. Immortalized mouse podocytes were treated by ADR [10^{-6} M] for 15 min and 24 h followed by protein expression Statistical analyses were done using *t* test with Welch correction.

Results: The ADR treatment did not change the creatinine and urea plasmatic levels when compared with the CTL group. [Creatinine,mg/dL: (CTL: 0.23±0.05 vs. ADR:0.25±0.12, p= 0.7427), Urea, mg/dL: (CTL: 59.60±4.97 vs. ADR: 70.76±60.39, p=0.6181). ADR showed a higher urinary flow rate than the CTL animals [µL/min (CTL: 0.11±0.06 vs. ADR: 0.91±0.38, p=0.0005). The ADR treatment induced a body weight loss when compared to the CTL group. [g (CTL: 2.00±1.05 vs. -2.75±2.71, p=0.0013). Food and water intake were not different between the groups. [Food intake, g/24h (CTL: 5.60±1.50 vs. ADR: 6.25±1.66, p=0.4054), (Water intake, ml/24h (CTL: 2.40±0.84 vs. ADR: 3.62±1.50, p=0.0655). About podocyte protein expression, the p38MAPK was increased after ADR treatment for 15 min or 24h [arbitrary units, 15 min: (CTL: 0.5130±0.13 vs. ADR: 3.16±1.35, p= 0.0289), (arbitrary units, 24h: (CTL: 0.30±0.12 vs. ADR: 1.61±0.54, p=0.0142). However, the Egr-1 was significantly increased after 24 h of treatment with ADR [10^{-6}M] [AU, 24h: (CTL: 0.13±0.06 vs. ADR: 0.93±0.16, p= 0,0009, n=4). About the glomeruloesclerosis index (GSI), there were significant differences between the groups. [GSI: (CTL: 0,04±0,05 vs. 2,39±0,81, p=0,0101)].

Conclusions: Our results indicate that the activation of p38MAPK by an insult corroborates the activation of the nuclear transcription factor Egr-1 and thus the development of FSGS as shown in the treated animals with ADR.

PUB322

Comparison of Histopathologic Findings with Patterns of Immunofluorescence Staining in Native Kidney Biopsies Diagnostic for IgA Nephropathy

Selin Kurt, Lanny T. DiFranza. *Montefiore Medical Center, New York, NY.*

Background: Although IgA nephropathy (IgAN) is the most common type of primary glomerulonephritis worldwide, there is still much to be understood about the relationship of glomerular complement deposition to disease activity and prognosis. Prior studies suggest the degree of C3 deposition may represent an important pathogenetic and clinical prognostic factor. Our study aims to investigate the relationship between morphologic pathologic features observed by light microscopy (and documented using the Oxford scoring system) with results of immunofluorescent staining techniques for examining IgA and C3 deposition.

Methods: A total of 57 cases (n = 57) of IgAN, each representing a unique patient, and diagnosed by 3 different renal pathologists, are included in this study. Case data are collected retrospectively, and correlation matrix analysis is used to examine the relationship between intensity of C3 and IgA staining and the rendered Oxford scores for each biopsy.

Results: Cases with C3 staining show higher total scores by the Oxford scoring system [r= 0.22, CI: 90%; p = 0.05]. Significant positive correlations between the intensity of C3 and IgA staining [r= 0.59, CI: 90%; p = <0.001], and between C3 staining intensity and mesangial cellularity score (M) [r= 0.19, CI: 90%; p = 0.06] are found. Although not reaching the level of statistical significance, a positive correlation is demonstrated between C3 staining intensity and endocapillary hypercellularity (E), interstitial fibrosis/tubular atrophy (T), and crescent (C) scores, but C3 staining intensity, and segmental sclerosis (S) score show a negative correlation. Interestingly, correlation analyses resulted in quite disparate findings when comparing series of cases diagnosed by separate pathologists, suggesting there may be a high degree of interobserver variability in assessment of these pathologic findings.

Conclusions: C3 deposition may play an important role in IgAN pathogenesis, and with the advent of complement inhibiting drugs, updates to the diagnostic approach and clinical management of IgAN are necessary. Further higher-powered studies examining the molecular, clinical, and histopathologic relationships of complement activity in IgAN should help elucidate the utility of these novel complement-inhibiting therapies in the management of IgAN.

PUB323

Post-COVID-19 Vaccine Activation of IgA Vasculitis

Yasameen Fardi, Niraj Desai, Meghan Kapp. *University Hospitals, Cleveland, OH.*

Background: A 69 year old female with hypertension and longstanding microscopic hematuria received Pfizer BioTech SARS-COV-2 vaccine. Three weeks post vaccination, the patient developed diffuse abdominal pain and a palpable, right lower extremity purpuric rash.

Methods: Skin biopsy was consistent with leukocytoclastic vasculitis. Serologic workup was negative. Kidney function was normal, but there was newly identified proteinuria on urinalysis and redemonstrated microscopic hematuria. Urine protein/creatinine ratio was 1.6 g/g. Histopathologic examination revealed mild mesangial hypercellularity and immunofluorescense showed IgA dominant mesangial staining (Fig 1). Electron microscopy showed mesangial deposits. The constellation of symptoms and biopsy findings were consistent with an IgA Vasculitis, suspected to be associated with recent SARS-CoV-2 vaccination. The patient was treated with ace inhibition and sglt2 inhibition, resulting in reduction in proteinuria to less than 200 mg/g and preservation of renal function. The rash resolved with no additional intervention.

Results: Development of abdominal pain, purpuric rash and sub-nephrotic proteinuria after vaccination raises possibility that SARS-CoV-2 vaccination may have triggered a de-novo IgA vasculitis or, given the longstanding, unexplained microscopic hematuria, may have exacerbated a pre-existing, otherwise quiescent IgA nephropathy.

Conclusions: In susceptible individuals, an aberrant immune response triggered by vaccination may result in production and deposition of galactose deficient-IgA1 in glomeruli, activating an inflammatory cascade leading to glomerular injury and possibly a systemic vasculitis. However, despite the temporal association, both a causative link between, and pathogenic mechanisms underlying SARS-CoV-2 vaccination and IgA vasculitis remain incompletely elucidated.

Chronic Limited Renal Thrombotic Microangiopathy and Podocytopathy Secondary to Cabozantinib

Sanjana Bukkapatnam, Alyssa C. Weyer, Arda Akoluk. *The University of Texas at Tyler, Tyler, TX.*

Introduction: Thrombotic microangiopathy (TMA) is a condition characterized by thrombi in the microcirculation, often leading to kidney dysfunction. Podocytopathy is caused by damage to podocytes which are essential cells in the kidney's filtration barrier. Cabozantinib, a tyrosine kinase inhibitor, is linked to such renal complications. This case report presents such a case of chronic limited renal TMA and podocytopathy secondary to cabozantinib.

Case Description: Patient is a 79 year old male with a history of hepatocellular carcinoma (HCC), type 2 diabetes mellitus, and a history of hepatitis C, cirrhosis who presented to the Nephrology clinic for nephrotic syndrome. Briefly, he was diagnosed with HCC based on MRI imaging and elevated alpha-fetoprotein. He underwent treatment with Y-90 with some benefit, and was subsequently started on atezolizumab and bevacizumab. His course was complicated upon interval development of lung adenocarcinoma, and he had disease progression of his HCC. Both malignancies were thought to be covered on this regimen, though the patient developed proteinuria and hypoalbuminemia so bevacizumab was held and cabozantinib was added to atezolizumab. However, his proteinuria was noted to worsen. Workup included normal complement levels, kappa/lambda light chains, serum protein electrophoresis, negative double stranded DNA, but positive ANA. This prompted a kidney biopsy, which revealed changes consistent with chronic phase of TMA, and ultrastructural features of podocytopathy (Figure 1). It was determined that cabozantinib was causing his worsening proteinuria and TMA with podocytopathy, and thus his treatment regimen has changed to lenvatinib and pembrolizumab.

Discussion: Cabozantinib is a TKI used in a variety of malignancies, and chronic limited renal TMA and podocytopathy are significant but rarely documented complications of this chemotherapeutic agent [1]. Cabozantinib inhibits angiogenesis, and in this manner, may disrupt vascular integrity in the kidneys, thus inducing TMA and podocyte injury [2]. Podocytopathy compromises the glomerular filtration barrier, causing a nephrotic syndrome type presentation in [3]. This case thus illustrates the importance of vigilant monitoring for renal side effects in patients initiated on cabozantinib so this medication can be dose-adjusted or discontinued so as to prevent irreversible renal impairment.

PUB325

High Serum Vascular Endothelial Growth Factor (VEGF) Level Is Associated with Vascular Lesions in Glomerular Diseases

Gessica Sabrine Braga Barbosa, Renata D. Zen, Wagner Dominguez, Viktoria Woronik, Cristiane B. Dias. *Universidade de Sao Paulo, Sao Paulo, Brazil.*

Background: Vascular endothelial growth factor (VEGF) is a pro-angiogenic factor essential for vascular homeostasis. However, it has been pathogenically involved in tumor growth and diabetic retinopathy, which can be treated with VEGF inhibitors (VEGFi). The implication of VEGFi and kidney damage is well described, but the association between serum VEGF level (sVEGF) and histological vascular lesions in glomerular diseases is limited.

Methods: We evaluated sVEGF in patients with primary glomerular disease, including IgA nephropathy, focal segmental glomerulosclerosis, minimal change disease and membranous nephropathy at the time of kidney biopsy. We then analyzed the sVEGF in two comparative groups regarding the presence or absence of vascular lesions (VL) on renal histology. Patients under 50 years of age were included and those with diabetes, systemic autoimmune diseases and chronic infections were excluded.

Results: Of all patients with glomerular diseases (N=20), the median age was 31.5 years [27.2;43.5], with a predominance of females (55%) and white ethnicity (75%). Most patients had vascular lesions at the time of kidney biopsy (85%). The arterial intimal fibrosis/thickening was the most common lesion (88.2%), followed by arteriolar hyalinosis (29.4%) and thrombotic microangiopathy (5.8%). A higher sVEGF was detected in the group with VL (568.8 ± 97.0 vs 77.4 ± 13.8, p = 0.0001). Other laboratory findings at the time of kidney biopsy were as follows: proteinuria level 4.8g/g or g/24h [1.9;6.0], albumin level 2.4g/dL [1.7;3.2], serum creatinine level 1.24 mg/dL [0.88;2.6], hemoglobin level 11.8 g/dL [10.7;13.7], C3 level 125.5mg/dL [100.3;136.3], and C4 level 29.1mg/dL [22.3;40.2], no difference between the groups, except for the platelet level, which was higher in the VL group (337,000/mm^3 vs 190,000/mm^3, p = 0.019). There was no difference in the sVEGF or in the presence of VL between patients with a history of hypertension and those without.

Conclusions: Serum VEGF level is higher in glomerular diseases with histologic vascular lesions. More studies are needed to define the mechanisms of this increase and the relationship with glomerulopathies, whether it is a reparative effect, secondary or involved in the development of vascular lesion.

Effects of Anti-GBM Serum on Kidney Function and Glomerulosclerosis in Mice

Alex Frias Hernandez, Frederikke E. Sembach, Maria K. Ougaard, Ditte M. Jensen, Michael Christensen. *Gubra AS, Horsholm, Denmark.*

Background: Antibody-induced glomerulonephritis (GN) is a condition characterized by an inappropriate autoimmune response to renal antigens, such as glomerular basement membrane (GBM), leading to progressive glomerulosclerosis and rapidly declining renal failure, for which few treatment options exist. Understanding the underlying mechanisms of GN is crucial for developing effective therapeutic strategies. In this study, our objective was to investigate the induction of antibody-induced GN using anti-GBM serum on kidney biomarkers, histology and transcriptome signatures.

Methods: Male C57BL/6J mice (n=12) were randomly assigned to three groups (n=4 per group) and received an injection of vehicle, 100, or 200 µl of anti-GBM serum. We measured urinary albumin-creatinine ratio (ACR) as an indicator of kidney function. Renal endpoints included urinary albumin-creatinine ratio (ACR), AI-assisted glomerulosclerosis score, histology analysis of fibrosis (Collagen type 3, Col3), and RNA sequencing (RNA-seq) analysis.

Results: Compared with vehicle controls, both doses of anti-GBM serum significantly increased urinary ACR, suggesting renal insufficiency and glomerular damage. AI-based histopathological scoring confirmed significant glomerulosclerosis increase in the anti-GBM serum-treated groups. Furthermore, IHC image analysis indicated renal fibrotic damage as shown by the increase of Col3. Consistent with this, RNA-seq analysis revealed upregulated gene expression programs indicative of kidney extracellular matrix remodelling (eg, Col1a1, Col3a1, Col4a1) and inflammation (eg, CD68, Ccl2, Il1b).

Conclusions: Anti-GBM serum induces the rapid onset of renal failure, glomerulosclerosis, and fibrosis in the murine model of antibody-induced GN. The antibody-induced GN model in mice is very useful for testing test compounds with potential nephroprotective effects in autoimmune GN.

PUB327

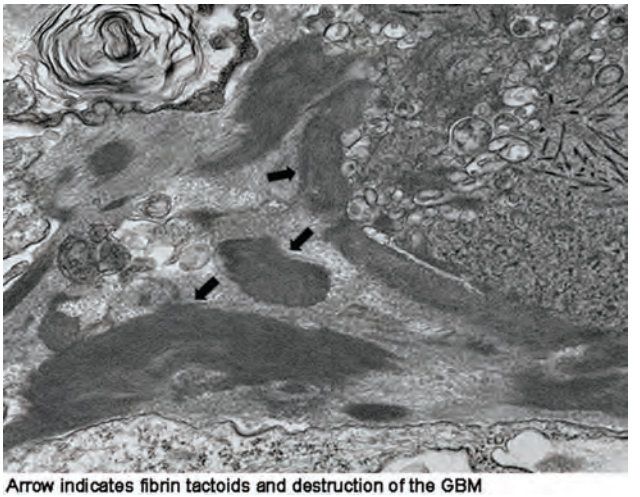
A Case of ANCA-Associated Vasculitis with Glomerulonephritis Unmasked by Electron Microscopy

Priscilla Koirala, Alessia Buglioni, Charat Thongprayoon, Wisit Cheungpasitporn, Jing Miao. *Mayo Clinic Minnesota, Rochester, MN.*

Introduction: Risk of progression to ESKD remains high in ANCA vasculitis with glomerulonephritis (AAV GN). Early diagnosis is critical for enhancing renal outcomes, yet it proves to be a challenge because active AAV GN lesions may not always be visible under light microscopy (LM), attributed to the focal nature of these lesions. We present a case where electron microscopy (EM) played a key role in identifying active necrotizing AAV GN.

Case Description: A 63-year-old healthy female presented with hypertensive emergency. Creatinine was elevated to 2.1 mg/dL from 0.8 mg/dL 1.5 years prior and 1.15 mg/dL 8 months earlier. UA showed microscopic hematuria and mild proteinuria. Serologic testing showed high levels of MPO (>8 U), positive p-ANCA, equivocal PR3 and negative c-ANCA. ANA, dsDNA, GBM ab, cryoglobulin, SPEP and immunofixation, were unremarkable. After addressing hypertension, persistent hematuria and AKI indicated potential glomerular disease. A subsequent kidney biopsy revealed FSGS (10%), global glomerulosclerosis (50%) and moderate interstitial fibrosis with tubular atrophy (40-50%) under LM, suggesting a prior occurrence of AAV GN. Although LM did not identify current AAV GN lesions, the presence of high MPO antibodies and ongoing AKI led to the administration of pulse dose steroids and rituximab, which resulted in reduced creatinine levels. EM further confirmed the AAV GN diagnosis by revealing crescent formation and fibrinoid necrosis.

Discussion: The case highlights the difficulties in diagnosing AAV GN accurately, emphasizing the risk of misdiagnosis resulting from the localized nature of the lesions. Recent study suggests that kidneys may continue to function adequately, even when only a small fraction of glomeruli remained unaffected in AAV GN. Precise diagnosis and prompt treatment is needed to maintain normal glomerular function and enhance renal prognosis.



Arrow indicates fibrin tactoids and destruction of the GBM

AAV GN on EM

PUB328

A Rare Case of "No Change Disease" Presenting as an Unexplained Nephrotic Syndrome

Jusong Choi,[1] Sherif Badra,[2] Jeongheun Kim.[1] [1]*Georgia Nephrology, Lawrenceville, GA;* [2]*Florida Kidney Physicians, Riverview, FL.*

Introduction: "Nephrotic syndrome" delineates a unique set of clinical and laboratory manifestations of kidney disease. It is precisely characterized by pronounced proteinuria (> 3.5 g/24 hours), hypoalbuminemia (< 3.5 g/dL), and peripheral edema. Here, we present a case illustrating nephrotic syndrome in the absence of distinct histologic evidence substantiating the pathological process.

Case Description: 60 year-old female with history of hypertension and a previous tuberculosis infection treated. Referred by PCP due to albuminuria on urinalysis after contracting COVID-19 in September 2023. Her sole symptom post-COVID-19 was foamy urine, prompting to obtain an ACR which showed 1.8 g/g, and a subsequent test in following month revealed 2.6 g/g. She maintains a preserved eGFR with a baseline creatinine level of 0.6 mg/dL. No prior history of albuminuria from the previous lab. The initial workup results were as follows: Creatinine: 0.59 mg/dl Albumin: 3.6 g/dl UA: Positive for occult blood and 3+ protein, but negative for red and white cells C3 and C4 within normal limits Negative results for Anti-GBM, ANA, PR3, MPO, parvovirus B19,

RPR, hepatitis, HIV, PLA2R antibodies Without further delay, a biopsy was performed, and the results showed it to be unremarkable except for arteriosclerosis. Post-biopsy, a 24-hour urine protein of 5.2g was collected, and both UPEP and SPEP with IFE, urine cytology were unremarkable. Subsequently, her proteinuria worsened up to 7.7 g/g along with worsening hypoalbuminemia to 2.2 g/dL, resulting in nephrotic syndrome. The decision was made to start Prednisone 50 mg daily. With the initiation of prednisone, both proteinuria and hypoalbuminemia improved within 4 weeks and continue to be in remission with 24-hour urine protein at 120 mg at week 7 of treatment.

Discussion: Likely diagnosis for this case is post-COVID Minimal Change Nephrotic Syndrome. This case underscores the importance for clinicians to recognize that podocyte foot process effacement does not always correlate with proteinuria. Variances in podocyte effacement observed between MCNS and other types of nephrotic range proteinuria disorders may suggest diverse mechanisms of podocyte injury in these conditions. Extensive foot process effacement is typically associated with the presence of a full nephrotic syndrome, characterized by concurrent nephrotic range proteinuria and hypoalbuminemia.

PUB329

A Patient with Minimal Change Disease with AKI

Ashok A. Varughese,[1] Abdallah Sassine Geara,[2] Tammy Yu.[2] [1]*Lower Bucks Hospital, Bristol, PA;* [2]*University of Pennsylvania, Philadelphia, PA.*

Introduction: Minimal change disease (MCD) accounts for about 10% of nephrotic syndrome in adults. While MCD typically presents with a rapid onset of nephrotic syndrome, it can also be associated with acute kidney injury in about 18% of cases. Most cases of MCD are considered idiopathic; it has been associated with a variety of secondary causes though no clear association with an underlying disease or event has been established.

Case Description: A 68-year-old male presents to the emergency department for progressive leg swelling, abdominal distension, dark urine, and shortness of breath for two weeks. Medical history was notable for hypertension treated with lisinopril, hyperlipidemia, type II diabetes mellitus, osteoarthritis managed with Ibuprofen daily for the past 1 year. Laboratory tests revealed serum creatinine of 5.32 mg/dL, blood urea nitrogen of 52 mg/dL. The patient become anuric within 24 hours of admission and required one session of hemodialysis. The differential diagnosis was broad and was favoring acute tubular necrosis possibly due to NSAIDs use. Since the etiology was not clear, without a clear hypovolemic or hypoperfusion event, the patient underwent a kidney biopsy which demonstrated on light microscopy focal acute tubular necrosis acute, the immunofluorescence stainings were found to be negative, electron microscopy revealed global podocyte foot process effacement, consistent with minimal change disease associated with acute tubular necrosis.

Discussion: Identifying the etiology of MCD can be challenging. In this case, multiple causes were plausible, but the exact cause remains unclear. Rapid progression into nephrotic syndrome and anuric AKI are uncommon in MCD. The patient had a history of using Ibuprofen daily for arthritis, which has been associated with MCD in rare cases, though there was no concurrent interstitial nephritis seen on kidney biopsy a common accompanying finding in NSAIDs-induced MCD.

PUB330

Atypical Even for Atypical Hemolytic Uremic Syndrome (aHUS)

Sunny R. Parmar, Melissa Baker, Jagmeet S. Dhingra, Leal C. Herlitz, Ali Mehdi. *Cleveland Clinic, Cleveland, OH.*

Introduction: Atypical hemolytic uremic syndrome (aHUS) involves overactivation of the alternative complement pathway leading to complement-mediated acute kidney injury (AKI). This dysregulation occurs in the presence of a genetic predisposition or an acquired loss of regulation, usually resulting in an elevated serum membrane attack complex (sMAC) level. Here we present a case of aHUS where fluid phase levels were normal with indirect evidence of complement activation on the kidney biopsy.

Case Description: A 28 year old male with hematuria and flu-like symptoms presented with an AKI (Cr peak 4.4; baseline 1.1), anemia and thrombocytopenia. Thrombotic microangiopathy (TMA) was suspected given low haptoglobin, high lactate dehydrogenase, and schistocytes on peripheral smear. Interestingly, the patient had a similar presentation a year prior following a COVID-19 infection. Empiric plasmapheresis was initiated until ADAMTS13 resulted back normal. Stool Shiga toxin was negative. Empiric terminal complement blockade with eculizumab was started for presumed aHUS. Serologic complement assays including factors I, B, H, factor H antibody, and sMAC were all normal. Only factor Bb level was elevated. After the platelet count improved, a kidney biopsy was obtained demonstrating acute TMA of glomeruli and arterioles. IgG kappa deposition was noted in the vessels, consistent with tissue deposition of eculizumab. Six weeks following hospitalization, Cr was down to 1.4 with normal complete blood count. Genetic testing is pending.

Discussion: This patient's case highlights a severe AKI from TMA due to aHUS and emphasizes that evidence of complement pathway overactivation in aHUS may not always be present in the fluid phase. Despite normal fluid phase assays, the IgG kappa kidney deposition (indicating eculizumab deposition) indirectly reflected tissue level alternative complement activation which was being modulated by the drug. Tissue deposition of eculizumab in this context has been well described previously in the renal pathology literature *(Herlitz et al, JASN, 2012, PMID: 22677550)*. Continued improvement of the patient's renal and hematologic parameters with eculizumab therapy supports this interpretation. Learning Points: AHUS should remain in the differential even with normal serologic complement assays. Empiric eculizumab therapy is key and its deposition in kidney tissue can provide further diagnostic certainty.

PUB331

Diabetic Kidney Disease in a Patient without Diabetes? A Case of Myeloproliferative Neoplasm (MPN)-Associated Glomerulopathy

Kavita Mistry, Leigh-Anne Dale, Seymour Rosen, Stewart H. Lecker. *Beth Israel Deaconess Medical Center, Boston, MA.*

Introduction: Myeloproliferative neoplasms (MPNs) are now recognized to cause a wide spectrum of renal disease, including thrombotic complications, extramedullary hematopoiesis, vascular nephrosclerosis, and glomerulopathy. The biological basis for vascular nephrosclerosis and glomerulopathy in MPNs remains to be elucidated, although has been presumed to result from increased cytokine levels.

Case Description: A 66-year-old man recently diagnosed with primary myelofibrosis (PMF) was referred to onconephrology clinic for acute kidney injury. He had initially presented 4 months prior with several weeks of night sweats and weight loss. Bone marrow biopsy was performed for evaluation of severe anemia and revealed JAK2 V617F and exon 12 mutated PMF. At the time of ruxolitinib initiation, his creatinine was noted to have risen to 2.06 mg/dL from 1.5 mg/dL, prompting nephrology referral. In onconephrology clinic, vital signs were remarkable for hypertension to 185/96 with no abnormalities on physical exam. Creatinine was 1.9 mg/dL with albumin of 3.9 g dL and 9.5 g/g proteinuria with spot urine albumin to creatinine ratio 7123 mg/g. SPEP and UPEP revealed no M spike. Renal biopsy was performed and revealed glomerular, tubulointerstitial and vascular changes compatible with diabetic nephropathy, including mesangial matrical increase and mild thickening of the glomerular basement membrane, as well as fibrotic and hyaline changes of the arterioles. The patient denied any history of diabetes. Fructosamine test was sent to evaluate for diabetes mellitus in the setting of frequent blood transfusions and was normal at 257 umol/L. In the absence of the appropriate clinical context for diabetes, his biopsy findings were ultimately attributed to MPN-associated glomerulopathy, which closely resembles the glomerular changes of diabetes.

Discussion: This report adds to a growing literature describing cases of MPN-associated glomerulopathy, an entity whose pathologic description resembles that of diabetic glomerulosclerosis. Given the lack of clinical association between diabetes and MPN, the close pathologic parallels between diabetic nephropathy and MPN-associated glomerulopathy could suggest common causal mechanisms for both diseases and a possible role for cytokine-mediated glomerular damage in diabetic kidney disease.

PUB332

Renal Riddles: Decoding a Case of Lupus Nephritis

Karteek Chennupati, Russell Vo, Leonel Abarca Jr, Morgan G. Fairweather. *Texas Health Harris Methodist Hospital Fort Worth, Fort Worth, TX.*

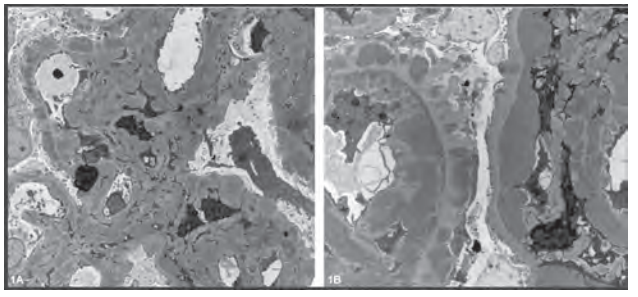
Introduction: Systemic lupus erythematosus (SLE) is characterized by the production of autoantibodies resulting in immune-mediated injury often involving multiple organs. Current literature suggests that anti-dsDNA antibodies facilitate the pathogenesis of the disease process. However, the absence of anti-dsDNA antibodies cannot exclude the diagnosis of lupus as up to 15 to 35% of individuals with lupus test negative.

Case Description: 24-year-old male presented with diffuse swelling and hypertensive urgency refractory to recent initiation of anti-hypertensives. Physical exam revealed a discoid, hypopigmented rash on both shoulders, non-scarring alopecia areata, and anasarca. Work-up revealed nephrotic range proteinuria, elevated Scr, and hypoalbuminemia. ANA 1:160, low C3 and C4, negative anti-dsDNA antibodies, and positive anti-Smith antibodies. Renal biopsy showed an abundance of immune complex deposits on electron microscopy consistent with class V lupus nephritis. The patient was initiated on high-dose steroids, mycophenolate mofetil, hydroxychloroquine, and atovaquone and discharged with outpatient follow-up.

Discussion: Lupus nephritis is a secondary membranous nephropathy caused by the deposition of immune complexes derived from anti-dsDNA antibodies throughout the glomeruli. Depending on the test used, the specificity for anti-dsDNA antibodies ranges from 80 to 97%. Studies suggest that the presence of anti-Smith antibodies correlates with younger age of onset, higher rates of alopecia, and transaminitis. Male gender is associated with higher mortality rates as compared with female patients with similar baseline features and treatment. Renal involvement in SLE patients poses a higher mortality rate in cases presenting with acute kidney injury and those that fail to achieve remission at 1 year.

Physical Exam Findings in Lupus Nephritis Patients (N=300)

Lupus Specific Findings:	
Malar rash	80%
Photosensitive dermatitis	50%
Generalized maculopapular rash	26.67%
Discoid rash	20%
Lupus non-specific findings	
Non-scarring alopecia	86.67%
Oral ulcers	56.67%
Vasculitic lesions	33.34%
Raynauds phenomenon	6.67%



Renal Biopsy
1A: EM, 1800X with multiple immune complex deposits
1B: EM, 4400X uranyl acetate staining multiple immune complex deposits and effacement of podocytes.

PUB333

Clinical and Pathological Characteristics of Lupus Nephritis in Elderly Patients

Tatsuaki Kosaka, Shinya Yamamoto, Hideki Yokoi, Motoko Yanagita.
Kyoto Daigaku Igakubu Fuzoku Byoin, Kyoto, Japan.

Background: Systemic lupus erythematosus (SLE) predominantly affects young women and is frequently complicated by lupus nephritis. Less than 10% of SLE cases manifest after the age of 65 years and lupus nephritis is less prevalent in elderly SLE patients. The prognosis of lupus nephritis in the elderly could be poor owing to numerous complications. Despite its clinical significance, the clinical and pathological characteristics of lupus nephritis in the elderly population remain unclear, and we investigated the data from our institution.

Methods: We retrospectively collected data from 40 patients diagnosed with lupus nephritis by renal biopsy between 2017 and 2023 at our hospital. We obtained data at the time of renal biopsy and after treatment, and the patients were divided into two age groups: younger (< 65 years) and older (≥ 65 years) patients. Statistical analyses were conducted using *t*-tests and chi-squared tests. Additionally, the outcomes were assessed in these patients.

Results: There were 8 patients (5 women and 3 men) in the elderly group and 32 patients (29 women and 3 men) in the younger group. Compared to the younger group, the elderly group exhibited significantly lower levels of eGFR, anti-DNA antibody, and anti-Sm antibodies. There were no significant differences in BMI, blood pressure, serum albumin, C3, C4, CH50, urinary RBC score, urinary protein or the frequency of rapid progressive glomerulonephritis. The most common renal histologic type in the elderly patients was ISN/RPS Class IV (± V) (3 patients). 75 percent of the elderly patients underwent treatment with steroids, and 83.3% of them additionally received immunosuppressive drugs. The complete or partial remission rate of lupus nephritis among the treated elderly patients was 83.3%. Two patients died from infection (within 2 months of starting treatment) and CO_2 narcosis, respectively.

Conclusions: We revealed the clinical and pathological characteristics of lupus nephritis in elderly patients. Lower eGFR and titers of specific antibodies were observed in the elderly patients than in the younger patients. Although the remission rate with treatment was favorable, mortality due to infection, which was likely associated with immunosuppression, was noted. Management strategies for lupus nephritis in elderly patients should carefully consider the risk of infection.

PUB334

A Unique Disease of C1q Nephropathy and Lymphadenopathy: Coincidence or Not?

Ipek Burkut Sarioguz, Justin D. Merszei. *Greater Houston Kidney Specialists, Houston, TX.*

Introduction: C1q nephropathy, characterized by mesangial immunoglobulin and complement deposition with a predominance of C1q, represents a rare renal disease with a very low prevalence world wide varying from 0.2 to 2.5%. We present a case of a patient with a seven-year history of widespread lymphadenopathy who was referred for evaluation of Chronic Kidney Disease Stage 3. Renal biopsy unexpectedly revealed C1q nephropathy coexisting with diabetic nephropathy.

Case Description: A 59-year-old African American female, with a medical history of widespread lymphadenopathy, congestive heart failure, hypertension and type 2 diabetes mellitus, presented with CKD Stage 3.Despite, more than 10 years of follow-up by oncology for a possible B cell disorder, diagnostic workup, including bone marrow showed polyclonal B cell proliferation without definitive evidence of malignancy. Previous biopsy of lymph nodes demonstrated atypical lymphoid infiltrate. On first presentation, PR3 was positive without vasculitis symptoms. She had proteinuria 2694mg/gr with GFR 37ml/min and elevated sedimentation rate 86mm/h.ANA and RF were negative and C3,C4 were normal. A kidney biopsy showed immune complex mediated glomerulonephritis with strong C1q immunofluorescence with background of diabetic nephropathy.

Discussion: C1q complement deposition in the glomeruli suggests an immune complex mechanism underlying the disease process.However, the exact mechanism by which immune complexes selectively target renal mesangial cells remains uncertain. Given the common occurrence of false positive results for PR3 and the lack of clinical evidence supporting its significance in isolation, we chose not to rely solely on PR3 testing for diagnosis.B-cell activation may have resulted in glomerular immunoglobulin deposition and lympadenopathy, which allows binding of C1q to the Fc portion of the IgG antibodies;therefore rituximab, a monoclonal antibody targeting CD20 on B cells, was administered as a first-line treatment. Recent studies reported complete remission for patients with C1q nephropathy by using a single dose or two doses of rituximab. While rituximab is a well-established treatment for various autoimmune conditions, C1q nephropathy still presents a significant clinical challenge. Further research is needed to elucidate the mechanisms driving immune complex formation in such cases and to optimize therapeutic strategies for improved patient outcomes.

PUB335

Hydralazine-Induced Vasculitis: A Case Report with Negative Kidney Biopsy

Nabeel Siddiqui, Abdelrahman N. Shehata, Mohamad N. Jajeh, Courtney Syfrett, Maria F. Kewish, Omer Farooq, Nowoghomwenma C. Ibie. *Southeast Health, Dothan, AL.*

Introduction: Hydralazine, a commonly used vasodilator for hypertension, can rarely induce vasculitis, a serious adverse effect. This condition is characterized by the formation of autoantibodies that attack blood vessels, leading to inflammation and tissue damage. In severe cases, such as pulmonary-renal syndrome, it can be rapidly progressive and life-threatening. Here, we present a case of hydralazine-induced p-ANCA vasculitis with a negative renal biopsy.

Case Description: 62yoM with CHF, HTN, CVA, T2DM, and PVD presents w/ hemoptysis, SOB, 30lb unintentional weight loss in 6 wks. Also: decr. appetite, nocturnal dyspnea, weakness, joint pain, and night sweats. He initially went to his PCP, who diagnosed him with pneumonia and prescribed Levaquin and Bactrim. He reported stopping his Plavix 3 days before presentation due to worsening hemoptysis. He was admitted for non-life-threatening hemoptysis, AKI, and acute blood loss anemia. Temp: 97.9F, HR: 69, RR: 20, BP: 182/75, O2 sat: 95% on 2L O2. Labs: BUN: 45, Cr: 4.43 (baseline 1.06), UA: 3+ blood, >100 RBC's, Hg: 6.8. CXR: bilateral diffuse pulmonary opacities, upper lobe predom. CT: scattered ground-glass, consolidative opacities. Rx: Vancomycin, Zosyn, pulse dose steroids, and 1 unit PRBC's. Bronchoscopy showed diffuse alveolar hemorrhage. Elevated: Myeloperoxidase, p-ANCA, ANA, dsDNA, MPO antigen, anti-histone antibodies. Hydralazine, which he was taking for greater than 10 years was held. Renal biopsy: no obvious vasculitis. His hemoptysis and kidney function improved and he was discharged on a steriod taper.

Discussion: Hydralazine-induced vasculitis, potentially dose-dependent, occurs in a minority of patients, with increased risk associated with higher doses and longer duration of use. While commonly affecting the kidneys and skin, our patient lacked skin manifestations. Management involves discontinuation of the drug, with severe cases requiring immunosuppressive therapy. Our patient responded well to steroids alone, underscoring the need for further research to guide treatment strategies for similar cases.

PUB336

A Challenging Clinical Scenario of ANCA-Associated Vasculitis Featuring Rapidly Progressive Crescentic Glomerulonephritis, Neutropenic Colitis, and Pancytopenia

David Pagan Maldonado, Andres Aranda, Linda G. Ruiz Fabian, Erick I. Marrero Santiago, Fatima D. Flores Arevalo, Cristian X. Rivera Benitez, Faviola M. Negrón, Valeria E. López Martínez, Zulmarie Rodriguez Cruz, Jorge C. Collazo Meléndez, Sarah Diaz Gonzalez, Valeria Mora, David A. Maldonado-Ruiz, Juan A. Morciego, Javier A. Morciego. *Universidad Autonoma de Guadalajara, Zapopan, Mexico.*

Introduction: With a peak incidence between 65 and 75 years, though it can occur at any age, ANCA-associated vasculitis (AAV) exhibits a slight male predominance. AAV shows geographical and race/ethnic differences in prevalence and encompasses various clinicopathologic phenotypes, including granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA), eosinophilic GPA (EGPA), and renal-limited necrotizing and crescentic glomerulonephritis (NCGN). It primarily affects small vessels (arteries, arterioles, venules, and veins) in any organ. The activity in the bone marrow is typically diagnosed through a biopsy with the presence of granulomas, accompanied by serum antibodies and systemic symptoms.

Case Description: We present a 58-year-old with ANCA GPA vasculitis diagnosed 3 years ago. Initial symptoms included episcleritis, blurred vision, rhinitis, sinusitis, headaches, and migraines. Treatment included methotrexate, prednisone, and folic acid. In late August 2023, polyarthralgia, polyarthritis, and macroscopic hematuria emerged. Creatinine rose to 6.0, urea to 250, with neutropenic colitis due to Clostridium difficile. Suspected acute kidney injury or vasculitis activity required renal replacement therapy. A bone marrow biopsy showed no vasculitis response. Tests for ANA, SSA/Ro, HIV, HCV, HBV were negative. Kidney biopsy revealed small vessel pauciimmune vasculitis. Improvement followed rituximab induction. Glomerular filtration rate is 30 ml/min, and the patient is hemodialysis free

Discussion: This case underscores the significance of performing biopsies to diagnose AAV in patients with systemic activity. Even though the patient's bone marrow biopsy showed no evidence of granulomas and they were exposed to methotrexate despite prophylactic treatment, it is possible that systemic vasculitis activity affected the bone marrow, which went undiagnosed in the sample obtained. These cases emphasize the need for a comprehensive clinical evaluation and interdisciplinary management.

PUB337

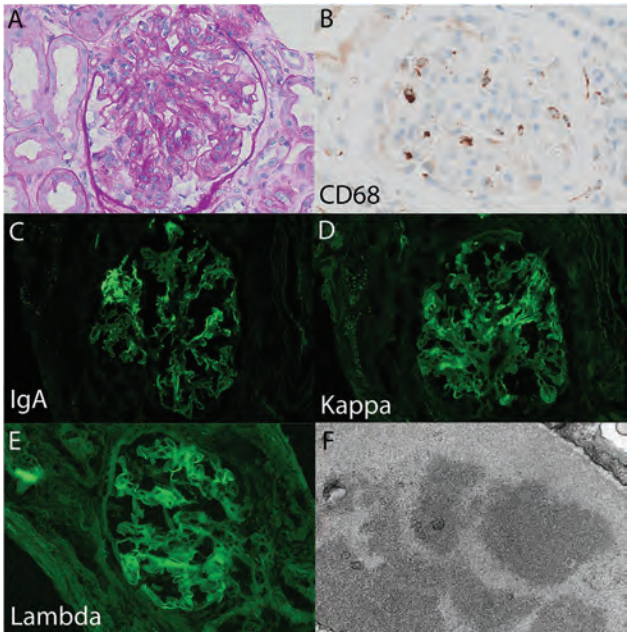
Untargeted Therapy: A Case of Proliferative Glomerulonephritis with Monoclonal Immunoglobulin A Kappa Deposits

Victor D. Hoang,[1,2] Javier F. Sevilla Rodriguez,[2] Sarwat Gilani,[2] John L. Musa.[3] *[1]Brooke Army Medical Center, Fort Sam Houston, TX; [2]The University of Texas Health Science Center at San Antonio, San Antonio, TX; [3]Audie L Murphy Memorial Veterans' Hospital, San Antonio, TX.*

Introduction: Proliferative glomerulonephritis with monoclonal immunoglobulin deposits (PGNMID) is a rare disorder, and the majority of affected patients do not have a detectable plasma/B-cell clone. This complicates management, and current therapy is based on data from small cohorts.

Case Description: A 77-year-old male presented with 2 weeks of melena and new bilateral lower extremity pitting edema. His labs were notable for serum creatinine of 1.5 mg/dL from a baseline of 1.2 mg/dL, and hemoglobin of 8.7 g/dL. Urinalysis was notable for 3+ protein and moderate blood with no cellular casts. Urine protein-creatinine ratio was 8.3. Extensive serologic workup was unremarkable. SPEP noted possible monoclonal spike in gamma region, which may be free kappa light chain measuring 0.1 g/dL. Renal biopsy demonstrated focal endocapillary proliferative and crescentic glomerulonephritis with IgA kappa restricted deposits (Figure 1). Hematology was consulted. Bone marrow biopsy noted no abnormal lymphocyte population and 0.6% polyclonal plasma cells. After inter-disciplinary discussion and risk/benefit discussion with the patient, therapy was initiated with bortezomib, cyclophosphamide, and dexamethasone.

Discussion: This case demonstrates the multi-disciplinary approach required to effectively treat cases of PGNMID. Specifically in cases where no plasma cell clone is found, there is still debate on ideal therapy.



Focal endocapillary proliferative glomerulonephritis (A) with infiltrating mononuclear cells of histiocytic lineage highlighted by CD68 stain (B). Frozen immunofluorescence studies show IgA (C) and kappa light chain (D) restricted deposits that are negative for lambda light chain (E). Electron micrograph shows mesangial deposits with no substructures (F).

PUB338

Kidney Involvement in Systemic Lupus Erythematosus (SLE): Beyond Lupus Nephritis

Keren Cohen-Hagai,[1,2] Sydney Benchetrit,[1,2] Dorin Bar-Ziv,[1,2] Mohamad Kabaha,[1,2] Moshe Shashar,[3] Oshrat Tayer Shifman.[1,2] *[1]Meir Medical Center, Kfar Saba, Israel; [2]Tel Aviv University Faculty of Medicine, Tel Aviv, Israel; [3]Laniado Hospital, Netanya, Israel.*

Background: Systemic lupus erythematosus (SLE) frequently involves the kidneys, contributing to morbidity among this population and may result in chronic kidney disease (CKD). While CKD diagnosis has significant clinical and therapeutic implications, it is still underdiagnosed even in high-risk population for CKD such as SLE. We aimed to detect prevalence and long-term clinical outcomes of non-dialysis dependent CKD among SLE patients

Methods: A retrospective study, conducted between 2014–2023 and included adults with a diagnosis of SLE for at least 1 year. CKD was defined as either eGFR<60 ml/min/1.73m^2 or albuminuria persisting in ≥2 consecutive tests spaced at least 3 months apart

Results: A total of 162 SLE patients were included, of them 57 had albuminuria, 43 had eGFR<60, and 23 patients had both. Out of the CKD patients, 61.1% never had a diagnosis of LN. Odds ratio for having CKD was 2.6 (95%CI 1.3-5.2, p=0.01) in patients with LN as cpmpared to patients without LN. CKD was associated with higher rates of diabetes, hypertension and heart disease (p=0.03, <0.01, <0.01 respectively). Rates of severe SLE exacerbations and severe infections were higher among CKD patients (p<0.01;<0.01). Despite comparable follow-up time, CKD patients had significantly higher mortality rates vs. non-CKD (23.4% vs 0, p<0.001 on univariate and multivariate analysis (Figure 2, p<0.01)

Conclusions: CKD is prevalent among SLE patients, including those without diagnosed LN, and is associated with elevated rates of morbidities, disease exacerbations, and mortality. These findings underscore the importance of proactive monitoring and intervention to alleviate the substantial morbidity and mortality burden associated with CKD in SLE.

Complete Response in a Patient with New-Onset Lupus Nephritis following COVID-19 Vaccination

Won-Hee Cho. *SahmYook Medical Center, Dongdaemun-gu, Seoul, Republic of Korea.*

Introduction: Recent studies have suggested a potential association between the coronavirus disease 2019 (COVID-19) vaccination and the development or exacerbation of LN. Here, we present a case of a patient who was diagnosed with LN class IV after receiving the COVID-19 vaccine and achieved a complete response through immunosuppressive therapy.

Case Description: A woman in her 50s presented with nephrotic syndrome, deteriorating kidney function 1 month after receiving a Pfizer-BioNTech COVID-19 vaccine. Her creatinine level was normal prior to vaccination, but she developed edema 1 week after receiving the vaccine. All serologic tests were negative, but the patient showed positive results for both anti-nuclear antibodies (ANA) and anti-double stranded (ds) DNA, as well as low complement C3 levels. An emergency kidney biopsy confirmed diffuse proliferative crescentic LN class IV. Induction therapy involved intravenous methylprednisolone and cyclophosphamide, followed by maintenance therapy with prednisolone and mycophenolate mofetil. At the 18-month follow-up, the patient achieved a complete response, experiencing full recovery of kidney function, improvement in proteinuria, and even seroconversion to negative for both ANA and anti-dsDNA. In the repeat biopsy conducted two years later, the activity index significantly decreased compared to the initial biopsy. However, persistent disease activity was evident, accompanied by a slight increase in the chronicity index.

Discussion: Timely diagnosis and prompt immunosuppressive therapy are crucial for achieving favorable outcomes, even in severe cases of LN that occur after COVID-19 vaccination. Additionally, a repeat biopsy may contribute to assessing disease activity at the tissue level and predicting prognosis.

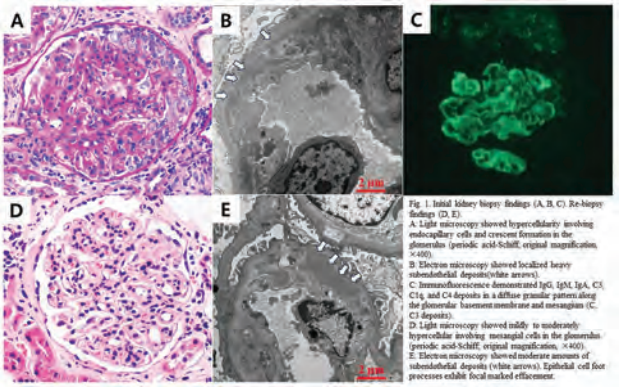

Fig. 1. Initial kidney biopsy findings (A, B, C). Re-biopsy findings (D, E).
A. Light microscopy showed hypercellularity involving endocapillary cells and crescent formation in the glomerulus (periodic acid-Schiff, original magnification, ×400).
B. Electron microscopy showed localized heavy subendothelial deposits(white arrows).
C. Immunofluorescence demonstrated IgG, IgM, IgA, C3, C1q, and C4 deposits in a diffuse granular pattern along the glomerular basement membrane and mesangium (C, C3 deposits).
D. Light microscopy showed mildly to moderately hypercellular involving mesangial cells in the glomerulus (periodic acid-Schiff, original magnification, ×400).
E. Electron microscopy showed moderate amounts of subendothelial deposits (white arrows). Epithelial cell foot processes exhibit focal marked effacement.

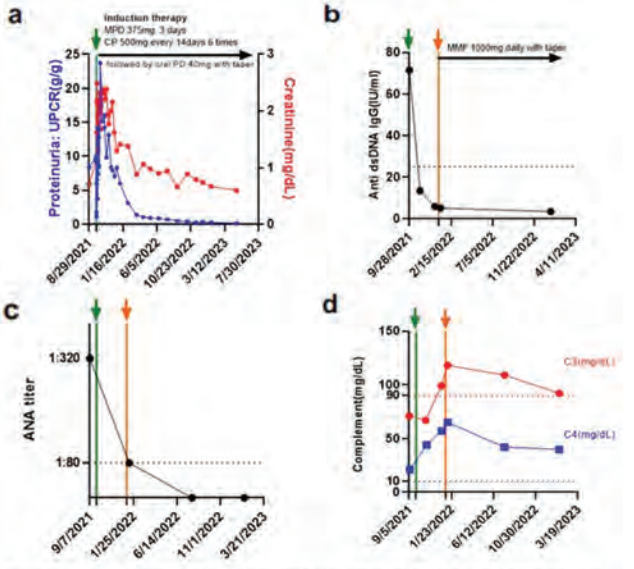

Figure2: (a) Time course of urine protein creatinine ratio(UPCR) and serum creatinine with end of induction therapy(green arrow), followed by maintenance therapy of prednisolone and mycophenolate mofetil(orange arrow). Serological parameters (b) anti-ds DNA-IgG, (c) antinuclear antibody(ANA), and (d) complement C3 and C4 are plotted in relation to induction therapy. Dotted lines represent normal limits. MPD, methylprednisolone; CP, cyclophosphamide; PD, prednisolone; MMF, mycophenolate mofetil.

PUB340

Lithium-Induced Nephrotic Syndrome: A Rare Complication of a Known Kidney Offender

Megha E. Pendyala,[1] Reshub R. Pendyala,[2] Prashant Pendyala.[3]
[1]Williamsville Central School District, East Amherst, NY; [2]Nichols School, Buffalo, NY; [3]Buffalo General Medical Center, Buffalo, NY.

Introduction: Lithium is commonly used effective medication for treatment of bipolar and unipolar disorders. A variety of renal complications have been well described with Lithium usage. Nephrogenic diabetes insipidus, chronic interstitial nephropathy and renal tubular acidosis being the common ones. Nephrotic syndrome is a rare but known complication.

Case Description: A 34 yr old lady presented to the emergency room with complaints of generalized edema and weight gain of 25 lbs in a 3-day period. She has known history of severe depression and suicidal ideation. She has been taking Lurasidone, Clonazepam, Desvenlafaxine and Mydayis. She was started on Lithium Carbonate 4 months prior. No NSAID intake. She was found to have anasarca. The Lithium level was normal (1.14 mmol/l). She had 17gm of urine protien. The total cholesterol was 405 mg/dl, serum albumin of 1.5gm/dl. Creatinine was mildly elevated at 1.32gm/dl. Serology for Hepatitis and HIV were negative. Rheumatoid Factor, Antinuclear and anti DNA antibodies were also negative. Lithium was discontinued. Two weeks later the urine protein had decreased to 12.5 gm and serum albumin was 1.7gm/dl. Four weeks later her edema had resolved. Her proteinuria had completely resolved and serum albumin 2.9gm/dl with a normal creatinine. In a six month follow up she did not have any proteinuria; her serum albumin and cholesterol were normal. She did not get a kidney biopsy and was not started on steroids

Discussion: Lithium induced nephrotic syndrome is a rare occurrence. Only around 30 cases have been reported. Our patient was on Lithium for 4 months prior to the onset of symptoms. Usual duration described was 1 to 12 months. These patients respond well to discontinuation of lithium with most of them recovering within few weeks. The Lithium

levels in our patient were therapeutic showing that it is likely an idiosyncratic reaction and not a result of toxicity. Review of literature shows that usually these patients do not need treatment with steroids and there is no need for kidney biopsy. However, if the symptoms persist beyond 6 weeks, a kidney biopsy to exclude other causes and treatment with prednisone have been done in the case reports. Kidney biopsy usually shows minimal change disease. This case provides an example of a rare renal side effect of Lithium that occurs after relative short duration of treatment.

PUB341

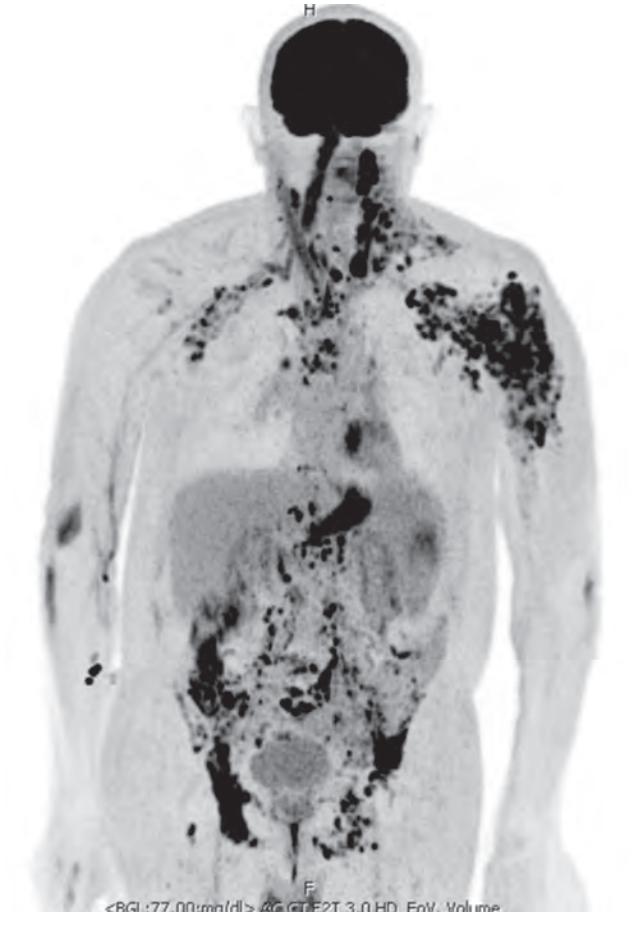
Nephrotic Syndrome Secondary to Renal AA Amyloidosis Predating Hodgkin Lymphoma Diagnosis: A Case Report

Sherida Edding, Jennifer A. Tuazon. *Northwestern Memorial Hospital, Chicago, IL.*

Introduction: AA amyloidosis is the most prevalent form of systemic amyloidosis. Common causes are chronic bacterial infections, inflammatory and autoimmune conditions. Association with solid and hematologic malignancies are uncommon. The kidneys are the most affected organ with nephrotic syndrome phenotype, though incidence is less than 1%. We present a rare case of a patient with nephrotic syndrome from AA amyloidosis with initially unknown etiology and later on proven to be from Hodgkin's Lymphoma.

Case Description: Patient is a 72M of Bosnian origin with no known medical history presenting 1 year prior with lower extremity and scrotal edema with creatinine 1.7, low albumin and proteinuria of 7g. Renal biopsy showed amorphous material and immunoperoxidase stain positive for AA amyloidosis. Infectious and autoimmune workup were unrevealing. Imaging showed retroperitoneal lymph nodes though biopsy negative for malignancy. Multiple myeloma workup negative. Patient seen by Oncology and advised treatment but was lost to follow. He presents again one year later with hemiplegia and aphasia, severe AKI on CKD (Creatinine ~10), proteinuria (~15g with 7g albumin), and a new neck mass. Workup revealed acute stroke concerning for hypercoagulable state. Patient initially resistant to invasive measures but eventually agreed on dialysis initiation. Biopsy of neck mass was pursued and was consistent with classical Hodgkin's lymphoma. PET-CT showed metastatic disease. Treatment options discussed though decision made to defer for now. Patient maintained on chronic dialysis.

Discussion: Though rare, undiagnosed malignancy should always be considered in patients with nephrotic syndrome from biopsy-proved AA amyloidosis. This case highlights the importance of thorough investigation including a complete malignancy workup in such patients.



PUB342

Characterization of Screening Patterns and Identification of Patients with Lupus Nephritis in a Community Rheumatology Setting

Nehad Soloman,[1] Jawad Bilal,[1] Romy Cabacungan,[1] Scott Milligan,[2] Andrew Sharobeem,[1] John Tesser,[1] Henry Leher.[3] *[1]Arizona Arthritis & Rheumatology Associates, P.C., Phoenix, AZ; [2]Trio Health Analytics, Louisville, CO; [3]Aurinia Pharmaceuticals Inc, Victoria, BC, Canada.*

Background: Lupus nephritis (LN) is a serious but common complication of systemic lupus erythematosus (SLE) characterized by proteinuria and decreased renal function. As delays in LN diagnosis may lead to nephron loss and delayed administration of disease-modifying therapies, current treatment recommendations suggest regular screening of patients with SLE for kidney involvement. Given the importance of early identification and treatment of LN, we assessed screening patterns for kidney involvement in patients with SLE in care of community rheumatologists in the United States.

Methods: Patient selection criteria: ≥2 diagnosis codes for SLE separated by >30 days, in care of the American Rheumatology Network (ARN) between July 2018 and June 2023, and >365 days observation. Individual patient observation windows were calculated from the first date of observation by ARN (index date) to the last encounter date, up to June 30, 2023. Patients were suspected of having probable LN if they had any of the following qualifying events during their observation window: an ICD-10 code for LN, an ICD-10 code suggestive of LN (e.g., kidney issues or related testing), or laboratory results indicative of proteinuria or reduction in estimated glomerular filtration rate (eGFR >20% less than observed at earliest observation and where lower eGFR measure is <72 mL/min/1.73 m^2 and not already categorized by ICD-10 code).

Results: 8631 of >540,000 patients with data in the ARN database met all study criteria. Of these, 5314 (62%) had at least one qualifying event during their observation window; 24% of patients had a diagnosis of LN by ICD-10 code, whereas an additional 38% had laboratory values or other ICD-10 coding suggestive of LN. Of the 62% of patients with probable LN, 97% had record of an eGFR assessment compared to 66% and 62% of patients, respectively, who had record of protein assessment by urine test strip or urine protein.

Conclusions: This study suggests that most patients with SLE will develop renal involvement over the course of their disease. These data support increased routine screening of SLE patients for LN via regular utilization of urine protein testing, consistent with the LN treatment guidelines.

PUB343

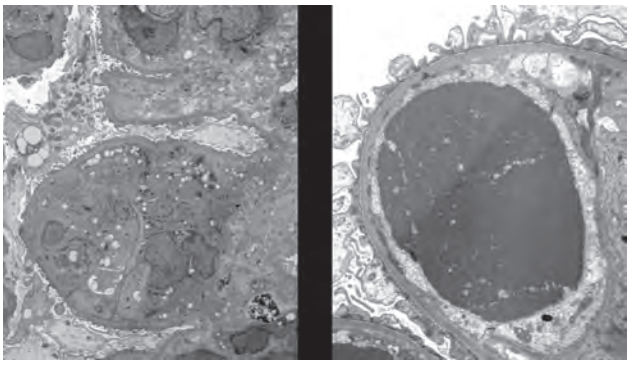
A Muddy Brown Presentation: A Case of Monoclonal Gammopathy of Renal Significance Associated with IgM Kappa Proliferative Glomerulonephritis with Monoclonal Immune Deposits and Leukocytoclastic Rash

Cindy Le, Alex Y. Ge, Hima B. Doppalapudi, Vijay K. Vanguri, Konstantin Abramov. *University of Massachusetts Chan Medical School, Worcester, MA.*

Introduction: Monoclonal gammopathy of renal significance (MGRS) is a diagnostic term, first introduced in 2012, used to describe patients who have renal disorders secondary to monoclonal gammopathies but who do not otherwise meet criteria for a hematologic malignancy. This case illustrates a unique presentation of proliferative glomerulonephritis (PGNMID) with IgM kappa immune deposits that presented with a leukocytoclastic rash.

Case Description: A 75-year-old man presented with hematuria, vomiting, and hematochezia. His serum creatinine was 3.78 mg/dL. Urine sediment showed muddy brown and granular casts initially attributed to acute tubular necrosis secondary to hypovolemia. He developed a leukocytoclastic rash. His renal function continued to decline requiring dialysis. Renal biopsy showed proliferative glomerulonephritis with monoclonal immune deposits. Hematologic workup identified an IgM kappa-producing B-cell clone, confirming a diagnosis of MGRS. He was treated with cyclophosphamide, bortezomib, dexamethasone, and rituximab, with resolution of his monoclonal paraprotein and recovery of his kidney function.

Discussion: Although not well studied, about 40-45% of patients with MGUS who underwent kidney biopsy also had MGRS-related disease. Furthermore, IgM kappa is a rare immunoglobulin class in PGNMID. The leukocytoclastic rash this patient presented with appears to be uncommon. It is unclear if there is a direct relation between this patient's rash and MGRS. When association is suspected between monoclonal gammopathies and cutaneous manifestations, it would be expected that the immune complex deposits in the skin would be the same as the monoclonal gammopathy. However, the skin biopsy was positive for IgG but his kidney biopsy was positive for IgM. It is possible that clonal antigens from the patient's B-cell clone triggered formation of immune deposits, which then deposited in the skin.



PUB344

Sparsentan (SPAR) in Combination with a SGLT2 Inhibitor (SGLT2i) and Steroid as First-Line Treatment for IgA Nephropathy (IgAN): A Case Report

Ray R. Goshtaseb,[1] Agness Pelts Block,[2] Christopher Gisler.[2] *[1]UCLA, Department of Medicine, Nephrology Division, Los Angeles, CA; [2]Travere Therapeutics, Inc., San Diego, CA.*

Introduction: SPAR is a nonimmunosuppressive, dual endothelin angiotensin receptor antagonist (DEARA) approved in the US and EU for the treatment of adults with IgAN at risk of rapid disease progression. Early clinical experience from a limited number of patients suggests that an SGLT2i added to SPAR is generally well tolerated and may have additive benefit on proteinuria reduction in IgAN. However, the use of SPAR in combination with an SGLT2i in the first-line setting has not been evaluated in a clinical trial. We present a case of SPAR + SGLT2i + steroid combination therapy as a first-line treatment for IgAN.

Case Description: A 51-year-old Asian woman with biopsy-proven IgAN presented with substantial proteinuria (24-h urine protein excretion [UPE] of 10.9 g/d), gross hematuria, an estimated glomerular filtration rate (eGFR) of 61 mL/min/1.73 m^2, and slightly elevated blood pressure (BP) at diagnosis. She is receiving SPAR (400 mg/d; dose increased after 2 weeks at 200 mg/d) in combination with the SGLT2i dapagliflozin (10 mg/d) and a tapering dose of prednisone (60 to 5 mg). All medications were initiated simultaneously following diagnosis. After 6 mo, proteinuria was markedly reduced (UPE of <0.5 g/d), eGFR and BP improved, and hematuria resolved (**Table**). The combination treatment was well tolerated, with no safety concerns; liver function tests were stable and within normal limits.

Discussion: This case supports the efficacy and safety of SPAR in combination with an SGLT2i and steroid in the first-line setting, highlighting a rapid reduction in proteinuria despite high levels at treatment initiation, together with improvement in kidney function and resolution of hematuria with the combination treatment.

PUB345

An Unanticipated Case of C1Q Nephropathy Diagnosed after Re-biopsy

Shan Pandya, Tamara R. Batarseh, Ashwin R. Shetty. *Swedish Hospital, Chicago, IL.*

Introduction: C1q nephropathy is a rare, poorly understood glomerulonephropathy that typically occurs in older children or younger adults. It is characterized by C1q protein deposition in the mesangium without features of Systemic Lupus Erythematosus (SLE). Treatment generally consists of immunosuppressants however specific regimens are not well established. We present a case of a patient with new onset edema and proteinuria with initial renal biopsy suggesting Minimal Change Disease (MCD) vs Focal Sclerosing Glomerulonephritis (FSGS) and repeat biopsy confirming C1Q nephropathy.

Case Description: A 39 y/o Hispanic female presented to the hospital for 5 days of bilateral edema from her ankles to her abdomen. Creatinine was 0.5 mg/dL. Urinalysis showed 4+ protein and trace blood without RBCs. A spot urine Protein:Cr was 8.9 g/g and albumin was 2.2 g/dL. Secondary workup for autoimmune and infectious glomerular etiologies revealed high SS-A and SS-B. Renal biopsy showed one glomerulus with segmental sclerosis, diffuse podocyte effacement, and prominent mesangial/paramesangial deposits with no glomeruli on immunofluorescence. Her proteinuria improved to 1.3 g/g after a 4 week prednisone taper for presumed MCD vs FSGS, but increased to 5.3 g/g off steroids. Rheumatology follow-up determined she did not have SLE. An 8 week steroid taper improved her proteinuria to 0.35 g/g, but worsened to 7.6 g/g after several months off steroids. A repeat renal biopsy revealed FSGS with likely C1q nephropathy variant with 2+ granular staining with C1q. Steroids were resumed. Rituximab and mycophenolate were considered, however lack of insurance delayed treatment. Despite continued steroids, her proteinuria increased to 6.7 g/g and she eventually started mycophenolate. She is currently improving with 5mg prednisone, mycophenolate, and tacrolimus. Her most recent proteinuria was 0.89 g/g and Cr was 0.55 mg/dL.

Discussion: This case highlights the importance of considering C1Q nephropathy as part of the differential with presentations similar to MCD and FSGS as well as the value of considering a second biopsy with recurrent relapses. Moreover, the events of this case span over four years due to difficulties in obtaining specialty appointments, affordable medications, and consistent care. This case also highlights the detriments of inaccessibility to healthcare when attempting to treat nephropathies in a timely manner.

PUB346

Granulomatosis with Polyangiitis: Role of Nephrologist in Management of a Rare Systemic Disease

Usha Kumari, Dhirisha Bhatt, Omer M. Asif Siddiqui, Margaret C. Hastings. *The University of Tennessee Health Science Center, Memphis, TN.*

Introduction: Granulomatosis with polyangiitis (GPA) is a rare form of systemic vasculitis primarily affecting the upper respiratory tract, lungs, and kidneys and associated with antineutrophil cytoplasmic antibodies (ANCA). This case highlights the importance of the nephrologist in the interdisciplinary management of GPA with a multisystemic presentation.

Case Description: A 39-year-old African American female presented with a saddle nose deformity and chest pain. A computed tomography (CT) scan revealed mediastinal lymphadenopathy, numerous lung masses, and total obstruction of the nares. A nasal biopsy showed pyogenic granuloma. Serum creatinine (SCr) was 0.59 mg/dl. Anti-proteinase 3 titers were positive (1:160). Urine studies showed microhematuria and low-grade proteinuria with a urine protein:creatinine ratio (UPC) of 0.85. A kidney biopsy showed pauci-immune focal necrotizing glomerulonephritis, consistent with ANCA-associated vasculitis. Corticosteroids and rituximab were initiated by nephrology. A month later, SCr increased to 2.86 mg/dl. She developed severe headaches, periorbital edema, and vision changes, leading to the diagnosis of dacryocystitis. A lacrimal gland biopsy showed marked acute inflammation due to histiocytosis, plasma cells, and lymphocytes. Pulse steroids and rituximab were re-administered, followed by steroid tapering per the PEXIVAS protocol and the addition of avacopan. Though renal function improved, she had worsening orbital symptoms. She received another cycle of pulse-dose steroids and two doses of cyclophosphamide, with improvement in eye and nasal symptoms. At her most recent visit, SCr was 0.86 mg/dl and UPC was 0.45. Continued immunosuppression with rituximab for 18–24 months, along with avacopan, was planned.

Discussion: A multidisciplinary team including nephrology, rheumatology, pulmonology, and ophthalmology managed the patient. The nephrologist played a crucial role in diagnosing the disease with a renal biopsy (performed when normal renal function and only mild abnormalities in urine were present) and initiating immunosuppression. Successful management of this complex case exemplifies the invaluable contribution of the nephrologist as part of the interdisciplinary team navigating the challenges posed by systemic GPA.

PUB347

Thrombotic Microangiopathy in Scleroderma: Is It Always a Crisis?

Loai Dweik,[1] Leal C. Herlitz,[2] Kristen Tomaszewski,[2] Corey J. Cavanaugh.[2] *[1]Cleveland Clinic Akron General, Akron, OH; [2]Cleveland Clinic, Cleveland, OH.*

Introduction: Thrombotic microangiopathy (TMA) is a pathological lesion seen across many diseases, initiated by endothelial injury and/or dysfunction. In systemic sclerosis (SS), the presentation has classically been described as a rapid onset of hypertension with declining kidney function and RNA polymerase III (RNApolIII) positivity. Prompt initiation of Angiotensin Converting Enzyme inhibitor (ACEi) is crucial for treatment. Here we describe an atypical case of TMA in SS and the use of complement targeted therapy.

Case Description: This case describes a 66-year-old female with a medical history of hypothyroidism, SS and myositis overlap who presented with muscle weakness and acute renal failure. Physical examination revealed blood pressure (BP) of 143/75, wheezing, decreased breath sounds on auscultation, purple discoloration of fingertips with ulceration and calcinosis of second and third right fingertips. Creatinine was 1.4mg/dl from a baseline of 0.8-0.9 mg/dl and platelets 145 k/uL, electrolytes and blood counts were otherwise normal. The patient had positive ANA and Anti-SSA titers. RNApolIII, C3, C4 were normal. Despite her BP, she was started on captopril. Kidney biopsy was pursued and revealed acute thrombotic angiopathy and microangiopathy, as evidenced by widespread fibrin thromboses, and intimal edema within arteries and arterioles with accumulation of schistocytes. There was no adventitial fibrosis or onion skinning, reflective of a relatively acute onset.

Discussion: The findings of an unexpected amount of thromboses, normal BP readings on ACEi, and lack of RNAPolIII, cued pathology and nephrology to consider a complement mediated injury. Thus, as the patient exhibited deterioration in renal function, with creatinine rising to 1.95 mg/dl and worsening thrombocytopenia to 99 k/uL, the decision was made to start eculizumab. ADAMTS13, Factor B, H, and I testing were normal. Genetic testing is currently pending. After 1 month follow-up, creatinine remains stable at a level of 1.8mg/dl. It is important to consider TMA in patients with SS and acute renal failure, even in the absence of elevated BP. The report highlights the diverse nature of TMA even within a single disease entity like SS. TMA in SS should be classified as ACEi responsive or non-responsive. The use of complement targeting therapy should be considered in atypical cases, and those not responding to ACEi.

PUB348

A Unique Presentation of Fabry Disease with Progressive Bilateral Hearing Loss

Iskandar Berbari, Fayaz A. Khan, Amit K. Rajput. *TriHealth Inc, Cincinnati, OH.*

Introduction: Fabry disease is the second most prevalent lysosomal storage disease and can affect multiple organs, including the kidneys and the vertebrobasilar system. Fabry Nephropathy presents with proteinuria and progressive renal failure. We present a case of a patient who presented with nephrotic range proteinuria and progressive hearing loss, who was found to have Fabry disease.

Case Description: A 32-year-old male with a past medical history of progressive bilateral hearing loss, initially presented for evaluation of nephrotic range proteinuria. He attributed his hearing loss to a traumatic ear injury and reports "compensating with his other ear". He also reports a history of acroparasthesias in his hands triggered by cold weather, generalized fatigue, and a single episode of self-limiting hematuria which occurred a year prior. The patient was referred for a UACR of 3.2g with Creatinine within normal range and GFR>60. Given the concern for Alport disease, a renal biopsy was performed. The biopsy demonstrated numerous podocyte inclusions concerning for Fabry disease. There was also evidence of glomerulomegaly, thickened GBM, and segmental sclerosis likely due to hyperfiltration/proteinuria. Genetic testing done was positive for GLA mutation and enzyme testing showed deficiency in alpha galactosidase, confirming the diagnosis of Fabry disease. The patient was started on Fabrazyme infusions. Proteinuria (UPCR of 0.5g), paresthesia, and fatigue all improved significantly after starting enzyme replacement therapy. The patient reported improvement in hearing loss, but still required the use of hearing aids.

Discussion: This is a case of Fabry disease with an atypical presenting symptom. Fabry disease is an X-linked disorder and results in accumulation of globotriaosylceramide (Gb3) within lysosomes in a wide variety of cells. Multiple organs, including the kidneys, can be affected. Proteinuria and progressive renal decline occur secondary to accumulation of Gb3 in the glomeruli, distal tubule, and vascular smooth muscle cells. It is essential to keep a high index of suspicion of unexplained nephrotic range proteinuria accompanied by paresthesia in patients. Our case demonstrated the importance of early diagnosis with kidney biopsy leading to resolution of proteinuria and symptoms after initiation of enzyme replacement.

PUB349

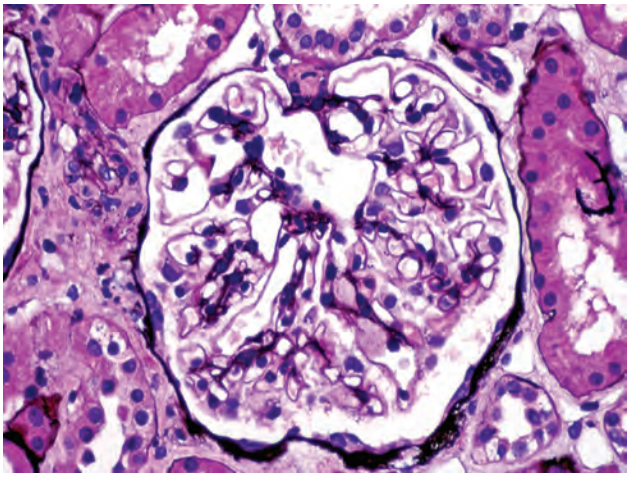
NELL-1-Positive Membranous Nephropathy

Alejandro Valdesuso,[1] Sobia Mansoor,[1] Satoru Kudose,[2] Larissa Kruger Gomes.[1,3] *[1]Landmark Medical Center, Woonsocket, RI; [2]Columbia University, New York, NY; [3]Kent Hospital, Warwick, RI.*

Introduction: Membranous nephropathy (MN) is a common cause of nephrotic syndrome in adults with over 20 novel target antigens discovered. NELL-1 is the second most common after PLA2R.

Case Description: 57-year-old male with PMHx of HTN and obesity was referred to the nephrology clinic for proteinuria. Patient was well until 3 months prior when he presented to the ED with lower extremity edema and shortness of breath and was diagnosed with a right lower extremity DVT and PE. BMP showed normal serum creatine. He was started on Eliquis. Persistent lower extremity edema led to a 24-hour urine protein test which showed 12 g of protein. A previous UA 7 months earlier showed no proteinuria. Nephrological work up was negative for glomerular basement membrane, c-ANCA, p-ANCA and PLA2R antibodies, with normal C3 and C4 levels. Kidney biopsy revealed segmental membranous nephropathy, mild tubular atrophy and interstitial fibrosis, severe arteriosclerosis and mild arteriolosclerosis. Immunohistochemical staining for NELL-1 was positive. Patient's lisinopril was increased to highest tolerated dose, and vitamin supplements he was taking were stopped. However, high-grade proteinuria persisted prompting the initiation of rituximab.

Discussion: NELL-1 MN, while mostly seen in adults like PLA2R MN, typically has a higher age of onset. Mercury-containing indigenous remedies and lipoic acid supplements have been associated with NELL-1 MN, with discontinuation resulting in remission. Unfortunately, the patient's supplements did not contain these agents. Compared to PLA2R MN, NELL-1 MN has a more robust association with malignancy with as many as 10-33% of cases. In the case, age-appropriate cancer screening as well as PAN CT scan was done; however, no malignancy was found. Still, close follow up is recommended. Finally, NELL-1 MN is more resistant to treatment and more likely to recur. Patient's proteinuria has decreased to 2.7 mg/mg after two sessions of rituximab, but he has not achieved remission yet.



PUB350

A Case of AL Amyloidosis: A Common Cause of Nephrotic Syndrome without the Damage

Ashley Tang, Hira H. Al-adroos, Arthur Galoustian. *Riverside Community Hospital, Riverside, CA.*

Introduction: AL amyloidosis, the most common subtype of systemic amyloidosis, is characterized by the overproliferation of immunoglobulin-associated proteins by plasma cells. These unstable proteins misfold into amyloid fibrils and deposit into various tissues. Approximately two-thirds of patients will develop nephrotic syndrome from amyloid deposition in the glomeruli, leading to progressive renal dysfunction and failure. We present a unique case of AL amyloidosis with nephrotic syndrome in the absence of renal impairment.

Case Description: A 79-year old male, with a history of dyslipidemia and paroxysmal atrial fibrillation, presents for worsening edema and dyspnea on exertion non-responsive to loop diuretics. On outpatient echocardiogram, he had new aortic regurgitation, pleural effusion, and spot urinalysis with albuminuria 3000mg. Metabolic panel showed BUN 20, creatinine 1.0, and eGFR 77. Urine studies revealed a protein/creatinine ratio 13.6. An echocardiogram revealed left ventricular hypertrophy with speckling suspicious for amyloidosis infiltration. A renal ultrasound showed a simple cyst but otherwise unremarkable. His renal biopsy was Congo red positive AL amyloidosis associated with lambda-light changes and acute tubular injury. A bone marrow biopsy confirmed increased abnormal plasma cells and amyloid deposition within vessels. He was discharged home with diuretics and angiotensin-converting enzyme inhibitors for his nephrotic syndrome and plans to enroll in a clinical trial for his AL amyloidosis.

Discussion: The kidney glomeruli are the most frequent site of AL amyloid accumulation, leading to proteinuria. Notably, >5g/day and reduced eGFR <50 are closely associated with the development of end-stage renal disease. Existing criteria measure the severity of the nephrotic syndrome with progression to ESRD as an inverse correlation of proteinuria to eGFR. In this patient, his protein/creatinine ratio can be approximated as proteinuria around 13.6g/day but with a normal eGFR. There is no evidence of that relationship, nor did his acute tubular injury seen on the renal biopsy manifest on labs. While an unusual case without renal damage, it solidifies the use of proteinuria not only for the detection of AL amyloidosis and its organ involvement but also reaffirms the ongoing significance as a biomarker of damage or response to therapy further down the line.

PUB351

Idiopathic Nodular Glomerulosclerosis in a New Uncontrolled Hypertensive and Passive Smoker: A Case Report

Mehrbod Vakhshoori, Amir Abdi Pour, Yan Chen Wongworawat, Sayna Norouzi. Post-doctoral Scholar Research Program. *Loma Linda University Medical Center, Loma Linda, CA.*

Introduction: Idiopathic nodular glomerulosclerosis (ING) is a rare disease characterized by mesangial expansion with increased nodularity in absence of diabetes or other specific diseases. Despite its unknown pathogenesis, the presence of longstanding hypertension (HTN) and active smoking are associated with this disease leading to a new term "smoking-modified HTN-associated nodular glomerulosclerosis (SHaNGS)". Herein we report a case of ING in a passive smoker with uncontrolled HTN.

Case Description: A 60-year-old female with history of polyneuropathy, monoclonal gammopathy of undetermined significance (MGUS), hypothyroidism, onychomycosis (POEMS syndrome), and HTN was referred due to increased creatinine level (1.4 mg/dl). She denied active smoking but reported long-standing exposure to cigarette smoking being surrounded by heavy smoker family members and then working as a bartender. Further workups showed hematuria (50 RBC/high power field), proteinuria (urine-protein-creatinine ratio: 2.4 g/g, increased to 2.9 g/g) with normal renal ultrasound (Table 1). Kidney biopsy results showed evidence of diffuse and focal nodular mesangial expansion without hypercellularity, negative staining for amyloid, fibrillary glomerulonephritis and immunoglobulins (both direct and pronase digested immunofluorescence), finally diagnosed as ING (Figure 1 A&B).

Discussion: This case highlights a rare case of ING secondary to heavy passive smoking and uncontrolled HTN.

Table 1. Laboratory data of the patient on first and most recent visit

Laboratory data	First visit	Most recent visit	Reference range (unit)
White blood cell	4.60	4.27	4.80-11.80 (*10³/l)
Red blood cell	2.97	2.63	3.80-5.30 (*10^12/l)
Hemoglobin	8.9	8.1	11-16 (g/dl)
Platelets	192	136	140-340 (*10³/l)
Sodium	138	139	134-147 (mMol/l)
Potassium	4.6	5.4	3.5-5 (mMol/l)
Blood urea nitrogen	53	35	7-20 (mg/dl)
Creatinine	1.8	1.7	0.7-1.3 (mg/dl)
HbA1C	5.4	-	%
Total protein	7.5	6.7	6.3-8.2 (g/dl)
Albumin	3.6	3.4	3.2-4.6 (g/dl)
Aspartate aminotransferase	17	18	0-35 (U/l)
Alanine aminotransferase	11	12	7-45 (U/l)
Alkaline phosphatase	72	64	37-132 (U/l)

PUB352

An Unexpected Case of C3 Glomerulopathy in the Setting of Monoclonal Gammopathy and Cryoglobulinemic Vasculitis

Kelly V. Liang, Kimberly P. Liang, Al-Ola Abdallah, Timothy A. Fields. *The University of Kansas Medical Center, Kansas City, KS.*

Introduction: Membranoproliferative glomerulonephritis (MPGN) can be associated with cryoglobulinemia, monoclonal gammopathy of renal significance (MGRS), C3 glomerulonephritis (C3GN), and vasculitis. MGRS has rarely been associated with C3GN via monoclonal immunoglobulin impairment of regulation of the complement alternative pathway (CAP). We present a case of C3GN due to MGRS in a patient with Type I cryoglobulinemia, monoclonal gammopathy of undetermined significance (MGUS), and granulomatosis with polyangiitis (GPA).

Case Description: A 57-year-old female with history of Type 1 cryoglobulinemic vasculitis (livedo on bilateral legs, ulcers, fatigue in 2022), IgG lambda MGUS, recurrent ulcerative chronic sinusitis and nasal septal perforation suggestive of GPA, was referred to Nephrology in April 2023 for proteinuria and microscopic hematuria. She was on methotrexate and intermittent prednisone for vasculitis. Hepatitis B and C were negative. Bone marrow biopsy (BMBx) in 2019 showed normocellular bone marrow (30-40%), 2% blasts and <5% monoclonal lambda plasma cells (PC). In July 2022, Kappa/Lambda ratio: 0.36, M protein: 1.2, urine M-protein: detectable but not measurable. In April 2023, urine protein/Cr ratio (UPCR) was 1.6. Kidney biopsy showed MPGN with C3-dominant deposits consistent with C3GN (Congo red negative). In May 2023, CAP functional assay confirmed overactivity, and genetic test for CAP mutations was negative, confirming acquired dysregulation of CAP from monoclonal gammopathy. Repeat BMBx in June 2023 showed 12% monoclonal PC. She was started on bortezomib (Velcade) and dexamethasone (Vd), then switched to daratumumab in Oct 2023 due to neuropathy from Velcade. Creatinine is preserved and UPCR <0.5 since July 2023.

Discussion: This case illustrates a rare and distinct subtype of C3GN associated with monoclonal IgG lambda, which can cause dysregulation of the CAP via enhancement of C3 convertase by acting as anti-complement factor H (CFH) autoantibody, thus interfering with normal CFH regulation of C3 convertase. Although MPGN is commonly associated with cryoglobulinemia and vasculitis, this case highlights the role of monoclonal gammopathy as a potential etiology of C3GN and MGRS. Recognition of this entity is important as clone-directed treatment may improve outcomes and differs greatly from treatment for vasculitis.

PUB353

Urine IgG4 May Be a Specific Biomarker to Monitor the Progression of Phospholipase A2 Receptor (PLA2R)-Positive Primary Membranous Glomerulopathy (pMGN)

Ping L. Zhang,[1] Gabriel N. Maine,[1] Devin Young,[2] Atul Singh,[1] Dilip Samarapungavan.[1] *[1]Corewell Health, Royal Oak, MI; [2]Oakland University, Rochester, MI.*

Introduction: PLA2R is known to be closely related to IgG4 in the serum of patients with pMGN. Our recent study indicated that PLA2R staining in the glomeruli of renal biopsies remained positive in different stages of pMGN (usually graded as stage 1 to 4, subepithelial to resolving deposits by electron microscopy [EM]). IgG4 staining was positive in stage 1-2 p-MGN. In contrast, its staining faded away in glomerular basement membranes (GBM) due to its low affinity to GBM in stage 3-4 pMGN. This pilot study was to determine if urine IgG4 was reduced in stage 3- 4 pMGN when compared to stage 1-2 pMGN.

Case Description: Patient #1 had nephrotic range proteinuria. His transplant renal biopsy showed De Novo pMGN with positive stains for both PLA2R and IgG4, and stage 1 subepithelial deposits by EM. Patient #2 also had nephrotic range proteinuria and his transplant renal biopsy showed recurrent pMGN with positive PLA2R but focal/weak IgG4 staining. The EM for patient #2 showed stage 3-4 intramembranous vacuoles. Urine IgG4 levels were measured in both transplant patients with pMGN. Relative urine IgG4 concentrations were comapred against measurements from normal urine (< 0.03 mg/dl, negative control) and a positive control (peak IgG4 of 6.64 mg/dl). Patient #1 had a urine IgG4 level at 3.13 mg/dl and urine protein/creatinine ratio (UPCR) at 7.55 mg/mg, thus producing 0.415 mg/dl IgG4 per unit urine protein by dividing two indices (see Table below). Similarly, patient #2 had urine IgG4 level at 2.10 mg/dl and UPCR at 4.96 mg/mg, thus generating 0.423 mg/dl IgG4 per unit urine protein by dividing two indices. There was no significant difference in urine IgG4 levels between them.

Discussion: Our pilot study suggests that IgG4 immuno-staining may only reflect stages of immune complex deposits seen by EM but cannot correlate with the urine level of IgG4. However the urine IgG4 measurement may serve as a non-invasive biomarker to monitor progression of pMGN. Additional studies are required to further validate this claim.

Table 1. Two patients with primary membranous glomerulopathy

Patients	Serum Creatinine (mg/dl)	Urine Pro/Cr Ratio (mg/mg)	Urine IgG4 (mg/dl)	Urine IgG per unit protein
Pt #1 44 male with de novo pMGN	1.50	7.55	3.13	0.415
Pt #2 46 male with recurrent pMGN	1.35	4.96	2.10	0.423

PUB354

Beyond the Virus: A Case Report on Tip Lesion Variant of FSGS after COVID-19 Infection

Manpreet Chahil,[1] Larissa Kruger Gomes,[1] Michael B. Stokes.[2] [1]*Kent Hospital, Warwick, RI;* [2]*Columbia University, New York, NY.*

Introduction: Focal segmental glomerulosclerosis (FSGS) is one of the most common causes of nephrotic syndrome and has been seen associated with COVID-19 infection and vaccination. FSGS is a pattern of glomerular injury seen at the glomerular visceral epithelial cell (the podocyte) level and defined as the presence of sclerosis in parts of some glomeruli. Appropriate therapy is based on the classification of the FSGS lesion into either primary, secondary, genetic, or undeterminate forms.

Case Description: A 72-year-old male with history of DVT and PE (on Xarelto) presented to the hospital with progressively worsening diffuse body swelling, dyspnea, and fatigue developing over the course of one month in the setting of prior COVID-19 infection 4 weeks ago. Initial vital signs on arrival revealed elevated BP 172/103 but otherwise the patient was hemodynamically stable. Initial chest x-ray revealed trace right and left small pleural effusions. Initial BMP was notable for creatinine elevated at 1.84, BUN 66, and K 5.9. Urinalysis revealed >500 protein, 2+ blood. Initial urine studies were suspicious for nephrotic syndrome given total urine protein >4000 g/dL and urine creatinine 376.6 mg/dL. Further work-up during admission revealed negative SPEP and UPEP, normal C2 and C3, negative p-ANCA and c-ANCA, and nonreactive hepatitis A, B, and C antibodies. Renal ultrasound was negative. Kidney biopsy revealed FSGS tip variant; patchy acute tubular injury; minimal tubular atrophy and interstitial fibrosis; mild arterio- and arteriosclerosis. Following results of kidney biopsy, the patient was started on high dose steroids.

Discussion: It is important to recognize post-COVID Renal Syndrome to raise awareness for conditions such as FSGS which are steroid responsive to further assist in diagnosing renal complications earlier in patients who present with nephrotic range proteinuria post COVID infection. Literature review has revealed cases on tip-variant FSGS being one of the most frequent FSGS variants associated with COVID vaccination and post-COVID infection. By understanding the pathophysiological mechanisms underlying renal involvement post-COVID, including direct viral invasion, immune-mediated injury, and endothelial dysfunction, this report highlights the complexity of renal manifestations in the context of viral infections.

PUB355

A Multicenter Study on the Related Factors of Pathological Classification in Patients with Primary IgA Nephropathy

Sijie Yang, Zhu Zhou. *First Affiliated Hospital of Kunming Medical University, Kunming, China.*

Background: The aim of this study is to analyze the correlation between pathological staging and clinical data of patients with primary IgA nephropathy. To find the influencing factors of pathologic staging in patients with IgA nephropathy. It is expected to intervene these factors at an early stage to provide clinical ideas for controlling renal pathological damage.

Methods: Pathological typing and clinical data of a total of 204 patients diagnosed with IgA nephropathy by renal puncture biopsy and meeting the inclusion and exclusion criteria were collected from eight centers, including the First Affiliated Hospital of Kunming Medical University, Dali Prefecture People's Hospital, Baoshan City People's Hospital, Wulumu People's Hospital, Pu'er People's Hospital, the First People's Hospital of Anning City, Yuxi City People's Hospital, and the Armed Police Force General Hospital of Yunnan Province. The correlation between the pathologic typing and clinical data of these patients was analyzed.

Results: 1.High urinary PH (P=0.040), high 24-hour urinary protein (P=0.013), and history of alcohol consumption (P=0.016) are independent risk factors for endocapillary hypercellularity (E) lesions. 2.High blood total bilirubin (P=0.013) and high blood C4 (P=0.004) are protective factors for segmental glomerulosclerosis (S) lesions. High blood urea nitrogen (P=0.006) is an independent risk factor for them. 3.High blood urea nitrogen (P=0.044) and high blood creatinine (P<0.001) are independent risk factors for tubular atrophy/interstitial fibrosis (T) lesions. 4.High blood total bilirubin (P=0.046) is a protective factor for cellular or fibrocellular crescents (C) lesions.

Conclusions: 1.High urinary PH, high 24-hour urinary protein, and history of alcohol consumption are independent risk factors in the typing of intracapillary hyperplasia (E). 2.High blood total bilirubin and high blood C4 are protective factors in the typing of segmental glomerulosclerosis(S). High blood urea nitrogen is an independent risk factor for it. 4.High blood urea nitrogen and high blood creatinine are independent risk factors in the typing of tubular atrophy/interstitial fibrosis (T). 5.High blood total bilirubin is a protective factor in the typing of cellular or fibrocellular crescents (C) lesions.

PUB356

A Case of Secondary Membranous Nephropathy Caused by Rheumatoid Arthritis Accompanied by Double Positive for Anti-GBM Antibodies and Proteinase 3 (PR3)-ANCA

Saki Kawamori,[1] Hitoshi Suzuki,[1,2] Mingfeng Lee,[1] Yukako Umezawa,[1] Yuya Sasatsuki,[1] Masahiro Muto,[1] Hisatsugu Takahara,[1] Shigeki Tomita,[1] Yusuke Suzuki.[2] [1]*Juntendo Daigaku Igakubu Fuzoku Urayasu Byoin, Urayasu, Japan;* [2]*Juntendo Daigaku Igakubu Daigakuin Igaku Kenkyuka, Bunkyo-ku, Japan.*

Introduction: The underlying mechanism of double positive for ANCA and anti-GBM antibody is unclear. Up to a third of patients with anti-GBM disease are positive for ANCA, mainly with specificity to myeloperoxidase. It is postulated that GBM damage from ANCA-associated vasculitis exposes the antigens which leads to the production of GBM autoantibodies. However, there are no literature that describe the association between membranous nephropathy and dual positive for ANCA and anti-GBM antibody.

Case Description: 71-year-old man was diagnosed with rheumatoid arthritis (RA) due to the appearance of polyarthral pain, synovitis, and a positive anti-CCP antibody at two months ago. Disease modifying anti-rheumatic drugs (DMARDs) and low dose steroid were initiated. Recently, he was referred to our hospital by pointing out of proteinuria. Laboratory data was as follows: eGFR, 29 mL/min/1.73 m^2, anti-GBM antibodies, 143 U/mL, PR3-ANCA, 4.2 U/mL and C-reactive protein, 2.4 mg/dL. Examination of anti-nuclear antibody and anti-double stranded DNA IgG antibody were negative. Urinalysis showed mild proteinuria (0.7 g/gCr) and no microscopic hematuria. No pulmonary lesions were observed. Antiglomerular basement membrane nephritis or ANCA-associated nephritis were suspected, however, pathological analysis of kidney biopsy specimens indicated no crescentic formation and peritubular capillaritis. Meanwhile, spike formation was observed in the glomerular basement membrane by PAM staining, and the fluorescent analysis showed the deposition of granular IgG (IgG1 dominant) and complement 3 on the basement membrane. Electron microscopy showed a wide range of subepithelial electron dense deposits. Glomerular PLA2R1 and THSD7A were negative. Thus, he was diagnosed as secondary membranous nephropathy caused by RA. Intensified treatment of RA resulted in remission of proteinuria.

Discussion: This is the first case of membranous nephropathy with double positive for anti-GBM antibody and PR3-ANCA in patients with RA. Several reports indicated that membranous nephropathy complicated by anti-GBM antibody or PR3-ANCA often progresses renal dysfunction rapidly. Careful observation is necessary for the appearance of vasculitis and pulmonary lesions.

PUB357

Retrospective Analysis of a Large Brazilian Center on Systemic Vasculitis and Evaluation of C3 Levels Behavior

Liliana M. Kassar, Felipe Carvalho Barros Sousa, Karoline W. Silva, José Guilherme R. Gonçalves, Vinícius S. Silveira, Viktoria Woronik, Luis Yu, Cristiane B. Dias, Lectícia Jorge. *Hospital das Clinicas da Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil.*

Background: Systemic small vessel vasculitis are characterized by necrotizing inflammation with little or no deposition of immune complexes. Activation of the alternative complement pathway is part of the disease's pathophysiological mechanism. This study aims to identify the profile of these vasculitis in a large Brazilian center and the behavior of complement levels over time.

Methods: Patients diagnosed with vasculitis between February 2012 and September 2023 were included. The evaluated data included age, sex, creatinine, estimated glomerular filtration rate by CKD-EPI, proteinuria, hematuria, ANCA positivity, serum C3 levels at diagnosis, and the average C3 levels after 6-12 months of follow-up.

Results: 48 patients were diagnosed with vasculitis through biopsies during this period, with 60% being women. The median age was 60 years (14-83), serum creatinine 3.7 mg/dL (SD ± 1.7), eGFR 17 mL/min (7-79), proteinuria 1.43g (0.05-8.4), 96% had hematuria, admissional C3 was 107 (41-174), 38% c-ANCA positive and 43% p-ANCA positive. Chi-square test was conducted to assess the association between serum C3 and the intensity of C3 in renal biopsy (p 0.56). Tukey and Bonferroni tests were performed to evaluate C3 variation during treatment, no statistically significant difference was found (p 0.29).

Conclusions: We couldn't identify changes in the behavior of C3 levels in the present study. The local activation of the alternative complement pathway is well established in ANCA-associated vasculitis, however this could be difficult to identify in the usual laboratory assays. Therefore, identifying patterns of mild changes on systemic C3 levels in patients with vasculitis might be feasible utilizing larger samples.

PUB358

Exostosin-Associated Membranous Nephropathy Secondary to Lupus with Castleman-Like Features

Abdullah Jalal, Atinuke O. Aluko, Dilan A. Patel, Ying M. Chen.
Washington University in St Louis, St Louis, MO.

Introduction: Membranous Nephropathy (MN), an immune-mediated kidney disease characterized by subepithelial immune complex deposition, is caused by circulating autoantibodies targeting podocyte surface antigens. The landmark identification of the M-type phospholipase A2 receptor (PLA2R) as the major podocyte autoantigen has led to a paradigm shift in the diagnosis and management of MN in the past two decades. By utilizing laser microdissection of glomeruli followed by mass spectrometry, more putative podocyte autoantigens have been identified recently. Herein we present a case of MN secondary to systemic lupus erythematosus (SLE) with Castleman Disease (CD)-like features diagnosed on the basis of positive exostosin (EXT) staining on kidney biopsy.

Case Description: 42 year old female with history of PLA2R-negative MN noticed increased foamy urine without other systemic manifestations, including skin rash. Prior secondary MN evaluation was unremarkable except for positive ANA (1:1280). Over 6 months her urine protein to creatinine ratio rose from 1.42 g/g to 4.6 g/g with new hypocomplementemia prompting repeat renal biopsy. Pathology unchanged from previous with exception of scattered mesangial deposits and positive EXT2 staining. Amidst her proteinuria evaluation she developed new right subpectoral lymphadenopathy. PET/CT revealed multiple hypermetabolic lymph nodes (LNs) above and below the diaphragm. Excisional LN biopsy showed reactive follicular hyperplasia with partial vascular proliferation of nodes and onion skinning of follicles concerning for CD, a rare lymphoproliferative disorder. Although high levels of interleukin 2 receptor and vascular endothelial grow factor support the diagnosis of CD, she does not have any clinical manifestations of CD.

Discussion: Our patient received a preliminary diagnosis of CD; however, autoimmune conditions like SLE can resemble CD and must be excluded for precise diagnosis. Adding complexity to the case, the patient's renal pathology was atypical for lupus MN given the lack of full-house immunofluorescence staining, numerous subepithelial electron dense deposits with scattered mesangial deposits. The advent of novel autoantigens like EXT1/2 will aid in accurate and specific MN diagnosis, with significant implications for patient management and targeted treatment.

PUB359

Tip Variant of Focal Segmental Glomerulosclerosis in a Patient with COVID-19

Haya H. Al Suradi,[1,2] Larissa Kruger Gomes,[2] Michael B. Stokes.[3]
[1]Kent Hospital, Warwick, RI; [2]Brown University, Providence, RI; [3]Columbia University, New York, NY.

Introduction: Focal segmental glomerulosclerosis (FSGS) is a clinicopathological syndrome with nephrotic range proteinuria, histology with focal and segmental glomerular sclerosis, and diffuse podocytopathy. FSGS can be classified based on histologic variants into 5 categories, important to recognize for prognostication and treatment options. We present a case of tip variant FSGS with preceding COVID infection.

Case Description: A 72-year-old male with history of provoked DVT and recent COVID infection, he presented with gradually worsening lower limb swelling over the past month. Patient also had bilateral upper limb and abdominal swelling, and exertional dyspnea. On presentation, patient is hypertensive at 172/103, and otherwise hemodynamically stable. Physical examination is notable for bilateral lower and upper limb pitting edema with normal cardiopulmonary exam. CBC is unremarkable. Notable labs showed elevated creatinine at 1.83 mg/dL up from normal baseline 0.98, BUN 66 mg/dL, K 5.9 mmol/L, albumin of 2.1. Due to concern of nephrotic syndrome, urine studies were completed with UPCR 11.07. Additional work-up requested by nephrology included Hba1c, ANCA, HIV, viral hepatitis, SPEP/UPEP & immunofixation, and PLA2R Ab with unremarkable results. Ultimately, the patient underwent renal biopsy showing tip variant FSGS. The patient was started on prednisone 1 mg/kg with improvement in UPCR to 2.71. He has ongoing improvement of proteinuria and symptoms.

Discussion: Tip variant portends the most favorable prognosis with complete remission of FSGS. Our case shows nephrotic range proteinuria after COVID infection that has been described in the literature, although no clear etiology has been found, genetic predisposition has been postulated with viral infections being a second hit. Fortunately, our patient had a favorable response to steroids.

PUB360

A Rare Case of Atypical IgA-Mediated Anti-GBM Disease with ANCA-Associated Glomerulonephritis

Kristina K. Nasr, Sean Pickthorn, Nattawat Klomjit. *University of Minnesota Twin Cities, Minneapolis, MN.*

Introduction: Atypical anti-GBM has been used to describe seronegative cases of anti-GBM disease and constitutes up to 10% of anti-GBM cases. Patients can have milder symptoms and atypical pathological findings, such as linear deposition of IgA or IgM. Current conventional assays are unable to detect these classes of immunoglobulin. Approximately 30% of anti-GBM glomerulonephritis (GN) cases have concomitant ANCA GN. However, coexisting atypical anti-GBM and ANCA GN is very rare. We present the first case of seronegative atypical IgA-mediated anti-GM with MPO-ANCA GN.

Case Description: The patient is a 64-year-old male with a history of well-controlled type 2 diabetes. Two months prior, he developed myalgias and unintentional weight loss after a COVID-19 infection. He was diagnosed with polymyalgia rheumatica and treated with prednisone 20 mg/day. Initially, myalgias improved but symptoms recurred when the dose was reduced to 5 mg/day. At a subsequent visit, he endorsed a new cough, and his BP was elevated at 164/94 mmHg. Laboratories showed creatinine (Cr) 2.01 mg/dl, CRP 64.0 mg/l, normal C3 and C4 complement, P-ANCA 1:320, MPO >134.0 U/ml and negative anti-GBM. Monoclonal protein was negative with normal kappa/lambda ratio. Urinalysis showed RBC 17/hpf without RBC casts, UACR 142 mg/g and UPCR 0.39 g/g. Kidney biopsy showed focal necrotizing and crescentic glomerulonephritis in 23% of glomeruli with a vasculitis lesion in one artery and no significant fibrosis. Immunofluorescence showed linear GBM staining for IgA (3+), kappa (1+) and lambda (2+). Overall results were consistent with atypical anti-GBM and ANCA-GN. He was started on methylprednisolone 500 mg x 3 days and plasmapheresis (PLEX) for 5 days until Cr improved (as serologic levels of IgA anti-GBM were unavailable to guide the duration of PLEX). He then started oral cyclophosphamide. At 3-month follow-up, he felt better with improved energy. Cr improved to 1.45 mg/dl. MPO titer decreased to 2.0 U/ml with normal ESR and CRP. UA showed resolution of hematuria.

Discussion: Atypical anti-GBM may present with ANCA-GN. Treatment with cyclophosphamide and PLEX can improve kidney outcomes in these patients.

PUB361

A Curious Case of C3 Glomerulonephritis

Zoheb Backer, Omar H. Maarouf. *Thomas Jefferson University, Philadelphia, PA.*

Introduction: C3 Glomerulopathy(C3G) is a group of rare kidney diseases that is caused by genetic or acquired dysregulation of the alternate complement pathway resulting in predominant C3 deposition in the glomeruli. C3G encompasses two disorders, C3 glomerulonephritis(C3GN) and dense deposit disease. It is a histopathological diagnosis supplemented by low C3 levels. A kidney biopsy is necessary to confirm diagnosis. Currently, there is no high-quality evidence to guide therapy. Here, we present a case of C3GN with normal complements and high ANA titers.

Case Description: A previously healthy 32-year-old presented with dyspnea. Initial physical exam revealed hypertension, hypoxia and peripheral edema. Initial labs showed serum creatinine (SCr) of 1.96 mg/dL, albumin 2.1 g/dL, UA with 3+ protein, 32 RBC/HPF, 66 WBC/HPF. His spot urine protein creatinine ratio (UPCR) was elevated at 5.86 g/g with 24-hour collection yielding 5.4g of protein. Paraproteins were negative. Urine toxicology was negative. Imaging was significant for CXR showing diffuse bilateral

opacities, ECHO with EF of 40%. A renal US showed abnormal echogenicity. Infectious workup was negative for Hepatitis B, Hepatitis C, HIV, COVID-19 and flu. Autoimmune workup was remarkable for positive ANA at a titer of 1:1280 with negative ds-DNA antibody. His C3, C4 levels were normal and ANCA antibodies were negative. A kidney biopsy was obtained that showed C3GN without any crescents. He was placed on a steroid taper following a pulse dose, in addition to mycophenolate mofetil at 500 mg twice daily and uptitrated to 2g daily after one week. SCr trended down to 1 mg/dL, repeat UPCR showed a rapid improvement in proteinuria to 2.3 g/g. He was discharged for outpatient C3 dysregulation workup and follow up.

Discussion: C3G is a rare disease with an incidence of about one in a million. It affects children or young adults. C3 level is typically low, although it can be normal as in our case. ANA was strongly positive signifying possible underlying autoimmune condition triggering his C3GN. C3G is likely more than a single disease entity. With multiple trials ongoing for proximal complement activation blockade, a better understanding of its various presentations and associations along with newer drugs available may help us personalize care to patients and improve outcomes.

PUB362

A Rare Case of Anti-GBM Disease Complicated by Thrombotic Microangiopathy

Samantha J. Itchon, Mehdi Yavari, Yasser Ellaicy, Mirjana Dimitrijevic, Raghavendra Kamath. *Ascension Michigan, Detroit, MI.*

Introduction: Anti-glomerular basement membrane (GBM) disease is a small vessel vasculitis marked by antibodies targeting type IV collagen in the glomerular and alveolar basement membranes. This leads to rapidly progressive glomerulonephritis and/or alveolar hemorrhage. Pulmonary involvement often occurs in patients with factors like smoking, infection, or hydrocarbon exposure. Kidney manifestations typically present as acute injury with proteinuria, nephritic sediment, and hematuria. Thrombotic microangiopathy (TMA) involves thrombocytopenia, microangiopathic hemolytic anemia (MAHA), and organ damage. We present a case of anti-GBM disease complicated by TMA in a patient with hydrocarbon exposure.

Case Description: A 59-year-old female with chronic obstructive pulmonary disease, hypertension, and cystic kidney disease presented with a two-week history of hematuria, diarrhea, and fatigue. Labs revealed a creatinine level of 10.36, nephrotic range proteinuria, and elevated anti-GBM IgG antibodies. Kidney biopsy showed crescentic glomerulonephritis. The patient developed TMA, requiring multiple blood and platelet transfusions, managed with steroids and plasma exchange. Respiratory distress and hemoptysis necessitated intubation, and bronchoscopy confirmed alveolar hemorrhage. She began immunotherapy with rituximab. Post-extubation, outpatient treatment included plasma exchange, hemodialysis, and steroid tapering.

Discussion: This case highlights the rare occurrence of anti-GBM disease complicated by TMA in a patient with hydrocarbon exposure. Literature indicates TMA often arises during anti-GBM treatment, with poor renal outcomes despite ADAMTS-13 activity above 10% in most cases [1]. Initially presenting with diarrhea, Shiga toxin-induced hemolytic uremic syndrome was unlikely. Clinical improvement with rituximab, steroids, and plasma exchange suggests TMA was a complication of anti-GBM disease, emphasizing the disease's complex immune dysregulation. Works Cited: 1. Nakamura, Yoshihiro, et al. "Clinical Characteristics of Anti-GBM Disease with Thrombotic Microangiopathy: A Case Report and Literature Review." PUB363

A Case of Spontaneous Remission of Idiopathic Minimal Change Disease in an Adult

Seshma Ramsawak,[1] Andrea R. Linares,[2] Jagmeet S. Dhingra.[1]
[1]Cleveland Clinic, Cleveland, OH; [2]Cleveland Clinic Florida, Weston, FL.

Introduction: Spontaneous early remission of primary minimal change disease (MCD) in adults is rare (5-10%). To mitigate risks of nephrotic syndrome such as thromboembolic events and infections, early initiation of treatment in adults is recommended. We present a case of complete spontaneous remission of MCD in an elderly adult with conservative management.

Case Description: A 73-year-old female with recently diagnosed hypertension, presented with dyspnea, lower extremity edema and an 8-pound weight gain. Evaluation revealed a serum creatinine of 1.5mg/dL (baseline 0.8 mg/dL) and hypoalbuminemia. Spot urine protein creatinine ratio (UPCR) was 7.28 mg/mg. Initial serological work up including ANA, ANCA, HIV, hepatitis, monoclonal screen and primary membranous testing were negative. No inciting factors including medications or recent illness were identified. A kidney biopsy was performed and showed findings of MCD. Due to the age at diagnosis, an evaluation to exclude underlying malignancy was performed. CT chest abdomen pelvis was unremarkable. Mammogram and gynecologic evaluation were normal and colonoscopy 9 months prior was also normal. The patient was managed with a combination of olmesartan, spironolactone and dapagliflozin, with plan to initiate steroid therapy if she remained nephrotic as patient expressed concerns over side effects associated with steroid use. She was monitored clinically and over the ensuing three months, UPCR improved with conservative therapy and she had complete remission 4 months post- biopsy. Her most recent UPCR was 0.1 mg/mg and creatinine stable at 1.2 mg/dl.

Discussion: The majority of MCD cases achieving spontaneous remission are due to secondary causes. The mainstay of therapy for patients diagnosed with MCD, in addition to supportive measures, is immunosuppressive therapy. The goal is to induce remission thereby minimizing adverse outcomes associated with nephrotic syndrome. Glucocorticoid monotherapy is first line but alternative glucocorticoid sparing options are also available. Treatment with these agents have inherent risk. This case highlights a rare occurrence of spontaneous complete remission of idiopathic MCD in an adult patient. Physicians should be cognizant of the risk versus benefit ratio of immunosuppressive agents, especially in an elderly population.

PUB364

Focal Segmental Glomerulosclerosis after COVID-19 Vaccine: A Case Report and Literature Review

Mehrbod Vakhshoori, Sayna Norouzi, Yan Chen Wongworawat, Amir Abdi Pour. Post-doctoral Scholar Research Program. *Loma Linda University Medical Center, Loma Linda, CA.*

Introduction: We present a case of de novo focal segmental glomerulosclerosis (FSGS) occurring approximately two months after receiving the Moderna COVID-19 vaccine.

Case Description: A 77-year-old man with no personal or family history of kidney disease was admitted with dizziness, anasarca and acute kidney injury. On Admission, blood pressure was high (150/86 mmHg) and lab tests showed elevated serum creatinine (Cr) (1.8 mg/dl with normal baseline Cr), low albumin (2.3 g/dl), and significant proteinuria (urine-protein-to-creatinine ratio of 13.37 g/g). Kidney biopsy revealed complete effacement of podocytes and early-stage FSGS (Figure 1 A&B). Detailed history and workups were negative except for report of receiving Moderna COVID-19 vaccine approximately two months prior. Treatment with prednisone (60 mg/day) was started, leading to complete resolution of proteinuria, normalization of Cr levels and overall symptoms (Figure 1 C&D).

Discussion: This case highlights the significance of maintaining a high level of clinical suspicion for FSGS as a potential complication of COVID-19 vaccines (Table 1). Further studies are still needed to establish causality.

Table 1. Summary of case report studies reported *de novo* FSGS post COVID-19 vaccination

A Case of Hydralazine-Induced ANCA-Associated Vasculitis

Iskandar Berbari, Mohammad Amin Eshghabadi, Amit K. Rajput. *TriHealth Inc, Cincinnati, OH.*

Introduction: ANCA vasculitis is a systemic autoimmune disease that results in small-vessel inflammation caused by pathogenic autoantibodies directed against proteinase-3 or myeloperoxidase. Hydralazine is a commonly used antihypertensive which is known to precipitate drug-induced lupus. However, it can also cause a drug induced ANCA vasculitis, which presents with a necrotizing and crescentic glomerulonephritis. We present a case of hydralazine induced ANCA vasculitis.

Case Description: A 69-year old female with chronic sinusitis and CKD 3B attributed to HTN, presented for a 3-week history of nausea, vomiting, and poor PO intake. Work up revealed an AKI (Cr 7.8mg/dL from a baseline of 1.6mg/dL), with new onset hematuria, non-nephrotic range proteinuria (UPCR 0.5g), and an elevated ESR. Her antihypertensive regimen included hydralazine, hydrochlorothiazide, and nifedipine. Given concerns for an underlying glomerulonephritis, she underwent a renal biopsy, which showed pauci-immune (ANCA) focal necrotizing and crescentic GN. Anti-histone Ab levels were elevated at 6.1 units and there was dual ANCA positivity (pANCA >1:1280; MPO 254;SP3 49). The patient was started on solumedrol IV for 3 days and transitioned to PO prednisone with a four-month taper. She was also given rituximab 1000mg weekly for two doses, followed by 500mg every four months for maintenance therapy. She initially had improvement in her renal function (Cr 5mg/dL), but unfortunately was re-admitted due to worsening renal function and required initiation of hemodialysis.

Discussion: As clinicians, we should always be cognizant of the potential harms of the medications we prescribe. Hydralazine can cause a drug-induced ANCA vasculitis associated with elevated ANA, anti-histone antibodies, and dual ANCA positivity (MPO-ANCA and anti-PR3 antibodies) in one third of patients. Patients who develop these complications should immediately stop the offending agent and receive immunosuppressive therapy. Unfortunately, a literature review shows that 27% of patients progress to ESRD despite treatment, demonstrating the importance of early diagnosis. Nephrologists should keep a high level of suspicion when patients on these medications present with worsening renal function and a nephritic syndrome.

PUB366

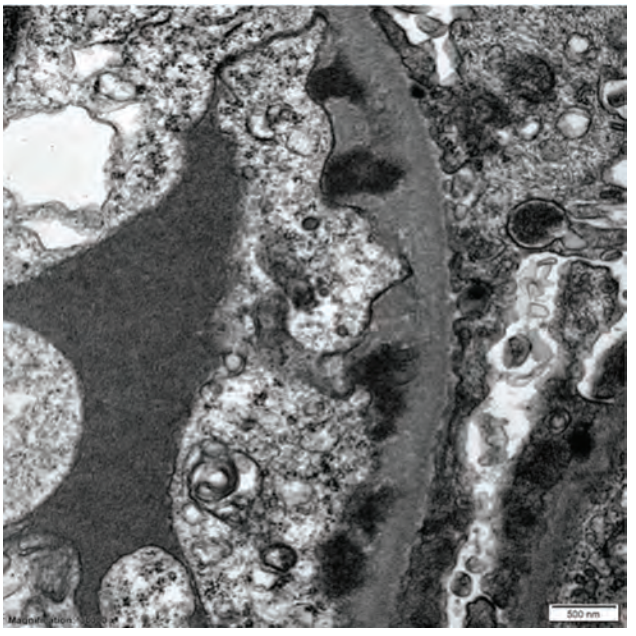
C3 Glomerulonephritis in Intravenous (IV) Drug Use

Divya Ravi. *Unity Hospital, Rochester, NY.*

Introduction: C3 glomerulopathy includes a group of disorders where there is dysregulation and overactive stimulation of the alternative pathway of the complement system. The common triggers are monoclonal antibodies, autoimmune diseases and infections. We present a case of C3 glomerulonephritis in a patient with IV drug use.

Case Description: A 30 year old male patient with past medical history of asthma, GERD, anxiety and IV fentanyl and cocaine use presented with complaints of intermittent fever, chills and dark urine since 3 months. He was found to be febrile with mild left sided CVA tenderness. He had AKI with creatinine elevated to 2.4 from baseline of 1.0-1.2. Urinalysis showed RBC casts along with moderate proteinuria. Patient was started on vancomycin and cefepime while awaiting cultures. Glomerulonephritis workup was sent and revealed elevated C3 and CRP but negative auto-immune panel. Protein-creatinine ratio was 9310 mg/day. Blood cultures were negative and TEE was negative for vegetations. He was started on suboxone for opiate use disorder. Patient underwent a kidney biopsy which showed diffuse active intracapillary proliferation glomerulonephritis with C3 containing immune complex deposits. The patient was started on lisinopril and offered immunosuppressive therapy but wanted to complete COVID19 vaccination first. On follow up, he was found to have improvement of proteinuria (97 mg/day) and creatinine returned back to his baseline (1.0-1.2)

Discussion: Previous cases of C3 glomerunephritis have been associated in other pro-inflammatory states like auto-immune flares and infections. In our patient, while infection and autoimmune disease was ruled out, we found presence of C3 deposits and glomerular disease which improved with cessation of IV drug use. This raises an important question of whether transient bacteremia or an inflammatory state brought on by IV drug use can induce C3 glomerulopathy.



PUB367

Clinical Utility of the International Risk-Prediction Tool in Japanese Patients with IgA Nephropathy

Sayumi Kawamura, Yukihiro Wada, Keiichi Matsuzaki, Tetsuya Abe, Akizumi Tsutsumi, Yasuo Takeuchi. *Kitasato Daigaku Igakubu, Sagamihara, Japan.*

Background: Recently, International Risk-Prediction Tool (IRPT) in IgA nephropathy (IgAN) has been reported. However, the utility of IRPT remains completely unelucidated. We attempted to validate the value of IRPT in Japanese patients with IgAN.

Methods: We retrospectively reviewed 145 patients (male 51.0%) with IgAN in our hospital since 2014. We collected clinical indicators, pathology, and treatment options during the observation period (mean 37 months). According to IRPT score, patients were divided into quartiles from prognostic score (PS) I to IV group. The study outcomes were end-stage kidney disease (ESKD) and estimated glomerular filtration rate (eGFR) 30% reduction.

Results: At baseline, mean proteinuria and eGFR were 1.5 g/gCr and 60.0 ml/min/1.73 m^2, respectively. 40.0% of patients received corticosteroid, and 36.6% underwent tonsillectomy plus corticosteroid pulse therapy (TSP). Baseline proteinuria and eGFR reduction were remarkable as IRPT-score increased (Proteinuria: PS I/II/III/IV, 0.5/1.1/1.6/3.0 g/gCr, $p<0.001$; eGFR: PS I/II/III/IV, 81.7/63.9/55.1/38.6 ml/min/1.73 m^2, $p<0.001$). Degree of M1, E1, S1, and C1-2 lesions in the Oxford classification were comparable among the study groups, whereas tubulointerstitial (T1-2) lesions were significant in PS-III or PS-IV compared to PS-I or PS-II groups. Rate of patients receiving steroid therapy or TSP were comparable between the study groups. The proportion of patients who were treated with RAS inhibitor is significantly higher in PS-III or IV than in PS-I or II group. During a follow-up period, 5.6% and 15.9% of patients progressed to the ESKD and eGFR 30% reduction. Incidence of high and super high risk for dialysis proposed from Japanese Society of Nephrology (JSN) was significantly higher in PS-III or IV group compared to PS-I or II group (PS-I/II/III/IV, 2.7/33.3/61.0/83.2%, $p<0.001$). On Kaplan-Meier analysis, the cumulative renal survival rate to developing the ESKD or eGFR 30% reduction was significantly higher in group PS-IV than in group PS-I to II ($p<0.001$). However, there was no significant difference in the renal outcomes between PS I to III groups.

Conclusions: IRPT is useful to assess disease severity and predict renal prognosis as well as JSN-classification. Especially, IRPT might be helpful to evaluate mid stage or advanced Japanese patients with IgAN.

PUB368

A Novel Therapeutic Approach to ANCA-Negative Crescentic IgA Nephropathy

Maximillian Bzdula, Jordan L. Barry, Marco Khiella, Mohammed Sadique Hussain, Mohammed S. Hammad, Tauseef A. Sarguroh. *Franciscan Health Inc, Mishawaka, IN.*

Introduction: IgA nephropathy is an autoimmune disorder caused by dysregulation of mucosal IgA immunoglobulins that results in deposition within the renal mesangium with variable presentations. Rarely, IgA nephropathy may lead to rapidly progressive glomerulonephritis(RPGN), characterized by gross hematuria, edema, hypertension, and acute kidney injury.

Case Description: A 48 year old male with a past medical history of hypertension and type 2 diabetes mellitus presented with two days of painless, gross hematuria. Initial labs showed creatinine(Cr) 2.5mg/dl, eGFR 31ml/min, INR 1.3, platelets 253, and a urinalysis significant for moderate blood, >100 urine RBCs, and urine protein to creatinine ratio(UPCR) of 6.7. During hospitalization, the patient's Cr peaked at 3.0, ASO >2,100, negative ANCA, and Kappa/Lambda ratio of 2.01. Kidney biopsy revealed IgA nephropathy with focal crescents. The Oxford classification score was M0 E1 S0 T1 C2. In the hospital, the patient was treated with 1g IV methylprednisolone for 3 days, followed by oral prednisone for 1 week and losartan upon discharge. On follow-up, the patient was transitioned to empagliflozin, budesonide, and sparsentan with improvement of Cr to 1.9mg/dl and UPCR of 0.5.

Discussion: IgA nephropathy may lead to RPGN with poor prognosis and a 5-year progression to renal failure of 70%. The case presented as an IgA nephropathy with RPGN and negative ANCA titers. While standard treatment includes steroids and cyclophosphamide or mycophenolate mofetil, the prognosis remains poor. There is sparse research on alternative modalities. We desribe a positive outcome with the triad of novel therapies of sparsentan, budesonide and empagliflozin.

Pauci-Immune Glomerulonephritis (GN) in a Patient with Scleroderma: Importance of Urine Sediment and Kidney Biopsy

Stephanie S. Pavlovich, Nina Mehta, Vanessa Moreno, Shannon L. Murphy. *The University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Introduction: Up to 10% of patients with systemic sclerosis can develop scleroderma renal crisis (SRC), a syndrome of malignant hypertension, microangiopathic hemolytic anemia, and progressive AKI. Kidney biopsy is not typically done in patients who have classic symptoms, especially with anti-RNA Polymerase III antibodies; however, biopsy can be critical in establishing a diagnosis in patients who have unusual disease features. We present a case of pauci-immune ANCA-associated GN in a patient with systemic sclerosis and a high pre-test probability for SRC.

Case Description: A 49-year-old man with untreated scleroderma presented with hemoptysis, fatigue, one week of right upper quadrant abdominal pain, and mild unintentional weight loss over three months. On physical exam, he was afebrile, with a blood pressure of 147/84 mmHg, and had bilateral sclerodactyly, skin tightness, and clear lung fields. Laboratory data showed creatinine of 2.9 mg/dL (from 0.62 mg/dL three months prior), urine protein creatinine ratio of 3.5 g/g, and hemoglobin of 5.1 g/dL with iron deficiency. A CT chest showed extensive bilateral lower lobe airspace opacities with air bronchograms. Bronchoscopy was not consistent with diffuse alveolar hemorrhage. Given worsening renal function (peak creatinine of 4.24 mg/dL) and a positive RNA Polymerase III antibody, a presumptive diagnosis of SRC with superimposed pneumonia was made and he was treated with enalapril and antibiotics. However, his clinic course worsened with recurrent, severe hemoptysis. Urine sediment showed dysmorphic red blood cells, red blood cell casts, and granular casts, prompting kidney biopsy, which showed diffuse pauci-immune crescentic GN. MPO-ANCA titer was positive. Enalapril was stopped and he was treated with IV solumedrol, cyclophosphamide, and plasma exchange with resolution of hemoptysis and improvement of creatinine to 2.33 mg/dL on discharge.

Discussion: This case illustrates the importance of examining urine sediment to guide biopsy in patients with suspected SRC, particularly if atypical features are present, and if an alternate diagnosis may require steroid therapy. We add to a body of cases reporting MPO-ANCA vasculitis in patients with systemic sclerosis, potentially identifying an association between scleroderma and small vessel vasculitis.

PUB370

A Case of Spontaneous Resolution of Secondary Membranous Nephropathy

Nimrah H. Imam, Joseph Tasch. *Fairfield Medical Center, Lancaster, OH.*

Introduction: Membranous nephropathy (MN) is the most common cause of adult-onset nephropathy. Primary MN is characterized by the presence of antibodies to the M-type phospholipase A2 receptor (PLA 2R). The most common causes of secondary MN are infectious, autoimmune disorders, or neoplasms. Here we present a unique case of secondary MN that spontaneously resolved despite progressive primary colon malignancy.

Case Description: An 82-year-old gentleman with no known history of kidney diseases presented to clinic with proteinuria. The patient's only complaints included leg swelling and unintentional weight loss of 15-20 pounds over the previous 3 years. He was noted to have a microalbumin to creatinine ratio of 5000 mg/g. One year prior, his urine microalbumin to creatinine ratio was 57 mg/g. His serum creatinine had been 0.9 mg/dL. Work up for his proteinuria included an SPEP with immunofixation, serum free light chains, hepatitis B/C serologies, anti-PLA 2R antibody, and rheumatoid factor which were all unremarkable. Kidney biopsy revealed membranous glomerulonephritis with several globally sclerosed glomeruli. IgG subclass staining showed IgG1 predominance and absent IgG4 and PLA 2R, suggestive of secondary membranous glomerulonephritis. On electron microscopy, the immune type deposits showed a mixture of electron dance and loosened deposits suggestive of prolonged disease course. Approximately 40 to 50% of the glomeruli in the biopsy were already sclerosed globally. The patient was later evaluated for several malignancies with a CT chest/abdomen/pelvis with IV contrast and a PSA screen. Patient had been recommended to undergo a screening colonoscopy but refused. He was found to have a large right sided pulmonary nodule. Patient had undergone a bronchoscopy in 2022 with pathology showing no evidence of malignant cells. A follow up PET scan showed low level activity. Patient remained on therapy with losartan, HCTZ, and spironolactone. Several months later, the patient's microalbumin to creatinine ratio trended to 361 mg/g, which persisted for months. He was later diagnosed via repeat colonoscopy to have primary colon cancer but proteinuria had already resolved at that time.

Discussion: Resolution of secondary membranous nephropathy is not known to resolve without treatment of the suspected cause.

PUB371

Crescentic Glomerulonephritis with Dual Autoantibody Positivity in the Setting of Polycystic Kidney Disease

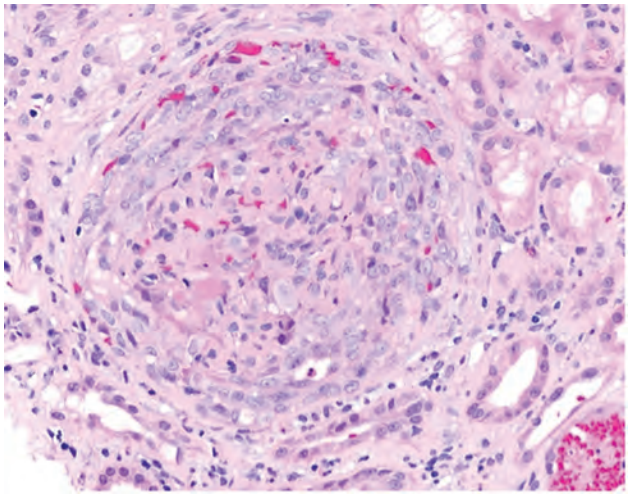
Lonnie Luu, Laura C. Luu, Yogesh Sanghvi, Guruswamy Ramamurthy. *HCA Healthcare Inc, Nashville, TN.*

Introduction: This is the sole documented case of a patient with PCKD diagnosed with dual seropositive glomerulonephritis for anti-GBM and ANCA.

Case Description: 71 yo M with PMH of PCKD, CKD3A, BPH, DM2, HTN, HLD, and PAD presented to the ED with bilateral leg edema, SOB, lightheadedness, fatigue, decreased urine production, flank pain and cough with hemoptysis. UA revealed elevated urine protein and a large amount of urine blood. Renal US showed multiple bilateral renal cysts. Chest CT showed bilateral infiltrates and pleural effusions. Pt developed anuria and metabolic acidosis and was started on HD. Pt was also dyspneic and hypoxic necessitating Bipap. Immunology was positivite for p-ANCA. Pt was started on IV methylprednisone

1g/day x 3 days then prednisone 40mg PO/day, rituximab 1g/day with plasmapheresis and MWF HD. Additional serology results were also positive for anti-GBM ab. Following a confirmatory renal biopsy, the patient was switched to cyclophosphamide 100mg/day. Anti-GBM ab levels began to downtrend from 8.0 to 5.1 with Rituximab treatment. Anti-GBM levels further decreased to 2.7 on Cyclophosphamide. During admission, he developed hemoptysis and hypoxia 2/2 to alveolar hemorrhage which required intubation. Pt suffered from multiple episodes of pulmonary effusions and hemothorax secondary to recurrent alveolar hemorrhage. Finally, he contracted COVID pneumonia during his admission. Ultimately, his POA decided to withdraw care due to poor prognosis, and unfortunately, pt expired shortly after extubation.

Discussion: This case presents a unique diagnositic challenge as pt's baseline CKD3A 2/2 PCKD along with his initial clinical presentation was consistent with AKI leading to volume overload and pulmonary edema. Furthermore, GN rarely presents with PCKD with only 3 cases seen based on a literature review which may lead to cases such as this being easily overlooked.



PUB372

Type B Insulin Resistance Syndrome Associated with Lupus Nephritis

Muhammad Qasim,[1] Kanza Mustafa,[2] Ann R. Finke,[1] Tyler Sims,[1] Sayee Sundar Alagusundaramoorthy,[1] Taha Ayach,[1] Virgilius Cornea.[1] *[1]University of Kentucky College of Medicine, Lexington, KY; [2]Yusra Medical and Dental College, Islamabad, Pakistan.*

Introduction: Type B insulin resistance(TBIR) syndrome is a rare disease entity caused by IgG polyclonal Ab that antagonize the insulin receptor. Systematic review in 2020, 119 cases described in literature. 50% have coexisting autoimmune disorder. 35% associated with systematic lupus erythematosus (SLE).

Case Description: 33 yo M with no past medical history presented with 1 week of hematuria, fatigue, polyuria, polydipsia admitted for new onset diabetes. Progressed to DKA with uncontrolled hyperglycemia. Labs C3 34, C4 7, CRP 15.5 mg/L, ANA Speckled 1:1280. RF <10. Anti DNA Screen 1:80, Smith Ab IgG 61, SmRNP Ab IgG 143. Glutamate Decarboxylase Ab <5. Insulin Ab 0.4 [0-0.4 U/mL]. HgbA1c 8.6%. Developed AKI Stage III; Cr 0.74 mg/dL on admit, peaked at 2.49 mg/dL. Renal biopsy (Fig 1):mesangial proliferative lupus nephritis(LN). Revised lupus classification, Class II. NIH protocol initiated, 40mg dexamethasone. Required up to 215,000 U Insulin/day, then dexamethasone held for hyperglycemia. Initiated cyclophosphamide(CYC)15 mg/kg. Plasmapheresis(PLEX) initiated as per NIH recommendations. Rituximab administered with PLEX session 3 and 6. 11 days of PO CYC + 2nd pulse dose dexamethasone. Relapsed 1 month after PLEX with persistent hyperglycemia and required 5 more PLEX sessions. He had 2 more courses of dexamethasone. 5 months post diagnosis remains stable on outpatient management: U500 Insulin 1400 U 3x daily.

Discussion: We present the complexity of managing a rare case of TBIR syndrome coalesced with overlapping SLE/LN and the challenges related to pulse dose steroids, plasmapheresis and immunosuppressants. Renal biopsy of LN strengthened our suspicion for TBIRS. Inability to tolerate glucocorticoids due to hyperglycemia. Treatment also consisted of CYC, PLEX, Rituximab. AKI resolved with CYC, PLEX x 6, 1 dose of Rituximab and dexamethasone pulse.

PUB373

Glucocorticoid Monotherapy as Induction Therapy for Class 1/2 Lupus Nephritis Is Associated with Higher Renal Relapse and Poorer Kidney Outcomes

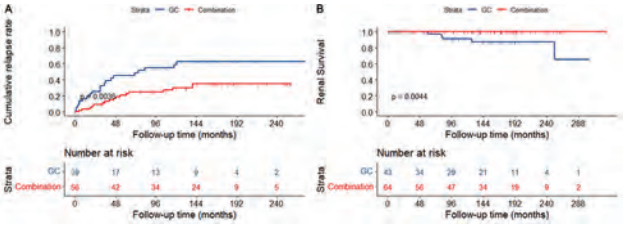
Xiuzhi Jia, Huajing Peng, Rui H. Tang, Xi Xia, Wei Chen. *The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.*

Background: For class I/II lupus nephritis (LN), the efficacy of immunosuppressive therapy is less clear.

Methods: A total of 128 patients with first biopsy-proven class I/II LN were included and divided into glucocorticoid alone induction therapy (GC monotherapy) group and GC in combination with other immunosuppressant induction therapy (combination therapy) group according to treatment regimens for induction therapy. The rates of remission, relapse, end-stage renal disease (ESRD), and risk factors related to the outcomes were analyzed.

Results: During the median follow-up of 94 (IQR 30–169) months, all the 96 patients achieved remission. Renal relapse occurred in 37 cases (38.9%), of which 20 (51.3%) were in GC monotherapy group and 17 (30.4%) were in combination therapy group. Kaplan-Meier curve showed that the cumulative renal relapse rate in the GC monotherapy group was much higher than that in the combination group (p = 0.0036). GC monotherapy was significantly associated with higher renal relapse (hazard ratio (HR) = 2.526, 95% confidence interval (CI) 1.211–5.267, p = 0.013). Multivariate cox regression analyses showed that partial remission (HR = 4.073, 95% CI 1.760–9.425, p = 0.001) and GC monotherapy (HR = 2.502, 95% CI 1.145–5.466, p = 0.021) were independent risk factors for class I/II LN renal relapse. The median follow-up time with ESRD as the endpoint was 151 (IQR 76–193) months. At the end of follow-up, 5 (4.7%) patients developed ESRD, all of whom were in GC monotherapy group. The 10-year, 15-year, 20-year and 25-year renal survival rates for class I/II lupus nephritis were 99%, 95%, 95%, and 90%, respectively, with GC monotherapy group had significantly poorer long-term renal outcomes (91.7% vs 100%, 87% vs 100%, 87% vs 100%, 65% vs 100%, P=0.010).

Conclusions: Patients with class I/II LN treated with glucocorticoid induction therapy alone have higher renal relapse rate and poor long-term renal prognosis. Prospective randomized controlled trial studies with large samples are necessary to further explore the clinical benefits of combination therapy in the treatment of class I/II LN.



PUB374

Complement 3 Glomerulopathy and Subsequent Atypical Hemolytic Uremic Syndrome

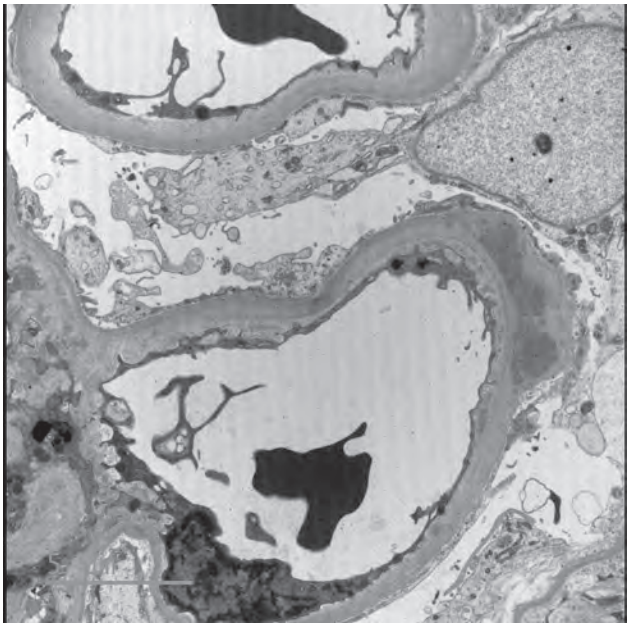
Christian Nguyen,[1] Brendan Schmidt,[1] Ramyashree R. Nyalakonda,[2] Morgan G. Fairweather,[1] Ihsan Housini,[1] Obiajulu Kanu.[3] *[1]Texas Health Harris Methodist Hospital Fort Worth, Fort Worth, TX; [2]University of North Texas Health Science Center, Fort Worth, TX; [3]UNC Health, Chapel Hill, NC.*

Introduction: Complement 3 glomerulopathy (C3G) is a collection of rare renal diseases that can be driven by genetic anomalies or, more commonly, acquired protein dysfunction that results in C3 deposition into the renal tissues. We present the case of an

80-year-old female with prior concerns of renal cell carcinoma that developed rapidly progressive renal dysfunction, progressing to dialysis and subsequently diagnosed with C3 glomerulonephritis (C3GN). Treatment was initiated with pulse-dose methylprednisolone, mycophenolate mofetil (MMF), and eculizumab – a novel treatment regimen relying on the augmentation of steroid and MMF treatment with eculizumab rather than transitioning therapy to eculizumab alone as previously described in severe cases of C3G. Interestingly, our patient later developed atypical hemolytic uremic syndrome (aHUS).

Case Description: An 80-year-old female with a medical history of diastolic heart failure and chronic kidney disease stage 3a returned to the emergency room after a previous admission for a complicated UTI. Her new complaints were shortness of breath, 20lbs of weight gain and productive cough.

Discussion: C3G is characterized by the deposition of C3 complement within the renal tissues due to a dysregulation of the C3 complement activation pathway. Another recently described phenomenon, aHUS, is also posited to be due to dysfunction of the alternate pathway of complement activation. While individually each syndrome is considered rare, the lack of literature may be due to limited reporting as opposed to non-occurrence coinciding with the novelty and relatively recent characterization of each disease process. This report adds to the growing literature describing the clinical course, diagnosis and treatment of C3G as well as C3G in relation to aHUS.



Ultrastructural study shows subepithelial and rare subendothelial deposits.

Impact of SARS-CoV-2 Vaccination and/or COVID-19 in the Clinical Course of Patients with IgA Nephropathy

Sophia Lionaki,[1,2] Angeliki Sardeli,[1] Smaragdi Marinaki,[2,5] Dimitra Gkalitsiou,[3] Kriki Pelagia,[4] Minas Karagiannis,[1] Konstantia Kantartzi,[4] Georgios Moustakas,[3] Marios Papasotiriou,[6] Eirini Grapsa,[2] Stylianos A. Panagoutsos.[4]
[1]Panepistemiako Geniko Nosokomeio Attikon, Athens, Greece; [2]Ethniko kai Kapodistriako Panepistemio Athenon, Athens, Greece; [3]Geniko Nosokomeio Athenon Giorgos Gennematas, Athens, Greece; [4]Demokriteio Panepistemio Thrakes, Komotini, Greece; [5]Laiko General Hospital, Athens, Greece; [6]Panepistemio Patron, Patra, Greece.

Background: To explore the impact, if any, of SARS-CoV-2 vaccination and/or COVID-19 in the disease course of patients with IgA nephropathy (IgAN).

Methods: This is a multicenter, retrospective study of patients with biopsy-proven IgAN, who were vaccinated against SARS-CoV-2 or were infected or both. Patients with ESKD prior to vaccination or infection were excluded. Adverse effects of vaccination, doses administered, immunosuppressive therapy and outcome of glomerular disease, clinical picture of infection, need for hospitalization and outcome of infection were recorded.

Results: Included patients (N=51) with IgAN were 46.5(±16.58) years old and 30 (58.8%) were males. The time interval from IgAN diagnosis was 80.27 (±71.5) and 41(80.4%) were vaccinated within 65.9 (±77.7) months from the diagnostic kidney biopsy with 3 (±0.75) doses while 19.8% of patients were on immunosuppressive therapy at the time of vaccination. 14.6% of patients reported systemic and 26.8% local side effects from vaccination. In total, 37(72.5%) patients were infected of whom 72.9% had been vaccinated. 85.3% of patients had symptoms at the time of testing for SARS-CoV-2. One patient was hospitalized and all had complete recovery. One patient (2.7%) experienced recurrence of IgAN within 3.5 months after infection.

Conclusions: In this study, SARS-CoV-2 vaccination was shown safe for patients with IgAN while it was associated with an uncomplicated outcome of the related infection.

PUB376

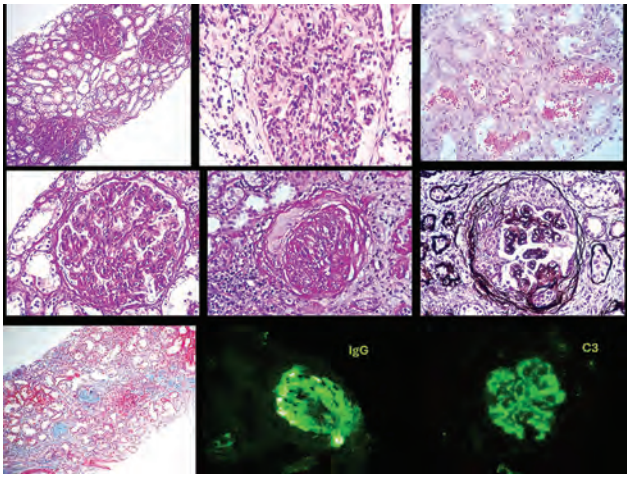
Postinfectious Glomerulonephritis Secondary to Pathological Puerperium

Guillermo Navarro Blackaller,[1,2] Rebeca L. Ornelas Ruvalcaba,[1,2] Jonathan Chavez,[1,2] Guillermo Garcia-Garcia,[1,2] Jose S. Cabrera Aguilar,[1,2] Jenifer M. Langarica López,[1,2] Ramon Medina,[1,2] Maria de la Luz Alcantar Vallin,[1,2] Jorge L. Padilla Armas,[1,2] Alexa N. Oseguera Gonzalez,[1,2] César Murguía Soto.[1,2]
[1]Universidad de Guadalajara, Guadalajara, Mexico; [2]Hospital Civil de Guadalajara, Guadalajara, Mexico.

Introduction: Post-infectious glomerulonephritis (PIGN) is a disease with nephritic syndrome with decreased complement usually secondary to an infection of the skin or throat by beta-hemolytic streptococcus, histopathologically with endocapillary proliferation, C3 deposits at the level of the capillary and mesangial wall, IgG-positive IF and subepithelial immune complex deposits.

Case Description: A 22-year-old woman, with type 1 diabetes mellitus for 12 years, with a pregnancy of 38 weeks gestation, presented an infection of the site of cesarean section infection at 3 weeks, with previous treatment with clindamycin and cephalotin. Blood cultures with S. epidermidis and acute kidney injury KDIGO 3 (Cr 5.1mg/dl), hematuria (80% acanthocytes), proteinuria (580mg/day) and hypertension. Complement 15 mg/dL (normal 79 – 152) and normal C4, ANAs, ANCAs, HIV-HCV-HBV negative, albumin 2.78 g/dl., Procalcitonin 5 ng/ml (<0.5 ng/ml), requiring vasopressor amines, hemodialysis, and antibiotic therapy was escalated to meropenem. Renal biopsy: Postinfectious glomerulonephritis (23 glomeruli with cell crescents, pattern with extracapillary proliferation, mesangial proliferation, endocapillary hypercellularity, double contours. IF: IgG (+++), C3 (++), diffuse granular pattern). At one month with a 50% decrease in proteinuria, normal complement, no hematuria, Cr.s 1.9mg/dl, no hemodialysis required.

Discussion: Treatment is based on treating the infection with antibiotics and the current evidence in RCTs shows no benefit from steroid use, however no persistently low C3 rule out C3 glomerulopathy



PUB377

Syphilis as a Cause of Secondary Membranous Nephropathy

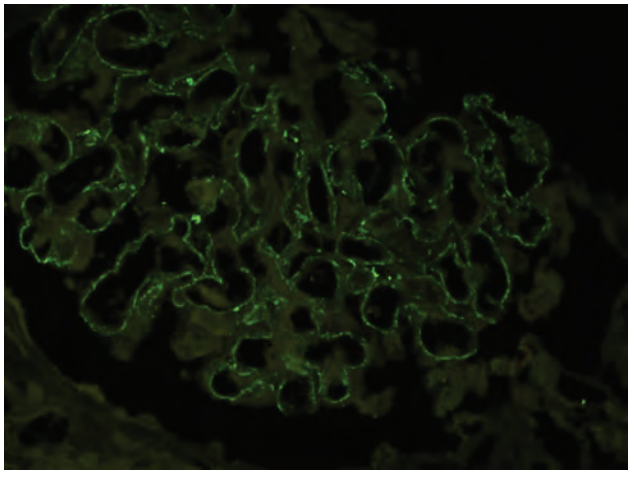
Rogelio Maya-Quinta,[1] Adolfo Del Bosque-Aguirre,[1] Fanny Y. Henriquez,[1] Mariana G. Garcia Zubizar,[1] Kamil Sardarli.[2] *[1]Tecnologico de Monterrey Escuela de Medicina y Ciencias de la Salud, Monterrey, Mexico; [2]University of California San Diego, La Jolla, CA.*

Introduction: Membranous nephropathy (MN) can arise from secondary and congenital syphilis. In these cases, immunofluorescence microscopy demonstrates the presence of treponemal antigens within the glomeruli, indicating direct antigen involvement and a immunological response against these within the kidney. Effective treatment of syphilis can lead to the resolution of MN without commonly used immunosuppressive medications.

Case Description: 50-year-old male with no medical history presents with progressive lower extremity and genital edema for 4 weeks. Labs reported creatinine 0.8 mg/dl, albumin 1.1 mg/dl, cholesterol 282 mg/dl, UA with 3+ protein, and a 24-hour urine protein of 43.92 g. He was given single 500 mg dose of methylprednisolone IV due to suspicion of a primary MN. Subsequently, the patient presented a rash characterized by erythematous macules on the palms and soles, as well as non-painful ulcers with

erythematous base and irregular borders in the genitalia. Additional labs showed normal complement levels, negative ANCA panel, negative ANAs, negative anti-PLA2R, negative HBsAg and anti-HCv, negative HIV, negative QuantiFERON and a positive VDRL (1:16) with reactive FTA-ABS. A renal biopsy was performed and reported histopathologic characteristics of MN with sclerosing scarring segmental lesions and treponemal antigen deposits. Benzathine penicillin G was given once a week for three consecutive weeks. The patient had a favorable response with partial reduction of the edema and proteinuria; therefore, he was discharged. However, due to persisting residual edema an additional course with dicloxacillin was given, resulting in complete resolution of symptoms and illness remission.

Discussion: In patients with unexplained glomerulonephritis or proteinuria, syphilis should be considered as a possible cause. Accurate diagnosis and prompt treatment can resolve kidney issues without immunosuppressants.



Glomerulus with treponemal antigen deposits

PUB378

A Rare Coexistence: Minimal Change Disease and Guillain-Barre Syndrome in a Patient with Polysubstance Abuse

Adam W. Tsen. *The University of Texas Medical Branch at Galveston, Galveston, TX.*

Introduction: Minimal Change Disease (MCD) and Guillain-Barre Syndrome (GBS) are distinct clinical entities with unique pathophysiological mechanisms. MCD, characterized by nephrotic syndrome and podocyte effacement on renal biopsy, is commonly associated with autoimmune disorders and certain medications. GBS, on the other hand, is an acute autoimmune neuropathy leading to ascending motor weakness and areflexia. Here, we present a rare case of concurrent MCD and GBS in a patient with a history of polysubstance abuse.

Case Description: A 50-year-old female with a past medical history of heart failure with reduced ejection fraction (HFrEF), polysubstance abuse, and untreated hypothyroidism presented with worsening shortness of breath, vomiting, and hyperbilirubinemia. Evaluation revealed acute kidney injury, likely exacerbated by congestive heart failure, and bilateral tibial axonal motor neuropathy consistent with GBS. Further investigations confirmed a diagnosis of MCD based on renal biopsy findings.

Discussion: The coexistence of MCD and GBS in this patient highlights the importance of considering multiple etiologies in individuals with complex medical histories, particularly those with a history of polysubstance abuse. The underlying mechanisms linking these two conditions remain unclear but warrant further investigation. Management requires a multidisciplinary approach, addressing both renal and neurological manifestations to optimize patient outcomes.

PUB379

A Decade of Biopsy-Proven Kidney Diseases: Temporal Trends and Clinical Correlates from a Single Tertiary Center in Saudi Arabia, 2013-2022

Sultan Al Dalbhi,[1] Manal E. Alotaibi.[2] *[1]Prince Sultan Military Medical City, Riyadh, Saudi Arabia; [2]Umm Al-Qura University, Makkah, Saudi Arabia.*

Background: Kidney biopsy is the gold standard for diagnosing glomerular diseases. Large-scale epidemiologic studies describing the prevalence of kidney diseases are limited. This study aims to determine the spectrum of biopsy-proven kidney disease at a tertiary center; Prince Sultan Military Center in Saudi Arabia over ten years

Methods: This cross-sectional observational study analyzed data from 1027 patients who underwent kidney biopsies from 2013 to 2022. We included all patients with native kidney biopsies, excluding transplant and donor biopsies. The data included demographic and clinical characteristics stratified by year, age, sex, and diagnosis to determine epidemiologic trends. Temporal trends in biopsy diagnoses were analyzed using time-series methods to determine changes in diagnosis frequencies over the past decade. Associations between biopsy diagnoses and clinical characteristics (age, gender, BMI, co-morbidities, transplant status) were evaluated using multivariate logistic regression models. Outcomes and treatment responses for the most common biopsy diagnoses were assessed, focusing on diseases with significant prevalence changes over time.

Results: The study included 1027 patients. The median age was 55 years with a nearly equal distribution of male and female patients. The most common biopsy diagnoses were focal segmental glomerulonephritis (FSGS) 14.6% and diabetic nephropathy 13.6%, followed by IgA nephropathy 9.7% and lupus nephritis 8.8%. The COVID-19 pandemic led to a reduction in the number of biopsies performed, but the distribution of diagnoses remained relatively stable.

Conclusions: This study catalogs the spectrum of biopsy-proven kidney diseases over ten years. These findings highlight the need for a standardized national kidney biopsy registry to enhance glomerular disease research.

C3 Glomerulonephritis, Rare Association with Multiple Myeloma: A Case Report

Leonel P. Román López,[1] Virgilia Soto,[2] Octavio R. Garcia-Flores.[1] *[1]Hospital Juarez de Mexico, Mexico City, Mexico; [2]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico.*

Introduction: In C3 glomerulonephritis, a monoclonal protein can cause kidney damage indirectly. Acting as an autoantibody, the protein cannot be detected in kidney biopsy, which promotes deregulation of the alternative pathway of the complement system.

Case Description: 43-year-old male with a history of abused substances. Beginning current condition of bromuria for 8 years, with remission and exacerbation. The presence of bromuria increases, during realitation of laboratory evidence of deteriorating function kidney and proteinuria in subnephrotic rank, electrophoresis urine presence of predominant kapa chains and igg, as well as a bone marrow aspiration is carried out with a predominance of >20% plasma cells, diagnostic multiple myeloma, renal biopsy diagnosis of C3 nephropathy.

Discussion: There are few cases of C3 nephropathy associated with multiple myeloma. The pathophysiology remains unknown, however, in the presence of C3 nephropathy it is required to search intentionally for multiple myeloma. More studies are required to denote whether treatment directed at the neoplasia reduces kidney injury. In this case it was not a satisfactory answer.

A Case of Rapidly Progressive Nephrotic-Range Proteinuria in a Patient with Purpuric Rash

Dean Mellas, Xueguang (Gary) Chen. *Southern Illinois University School of Medicine, Springfield, IL.*

Introduction: IgA Vasculitis (IgAV) [formerly known as Henoch-Schonlein Purpura] is a systemic vasculitis involving IgA deposition in small vessels within various tissue types including the skin, joints, GI tract, and kidneys. It is often accompanied by a tetrad of signs/symptoms including palpable purpura, arthralgia, abdominal pain, and kidney disease.

Case Description: A 77-year-old male with purpuric skin rash and skin biopsy-proven IgA vasculitis was referred by his dermatologist to the nephrology clinic after having found an acute kidney injury (serum creatinine: 1.5) along with hematuria and rapidly progressing proteinuria. Random total protein/creatinine ratio was 3.11 g/g, and 24-hour urine collection showed total protein 4.4 g. Renal biopsy was obtained showing Crescentic IgA Nephropathy. The patient was urgently admitted to the hospital and treated with pulse dose Methylprednisolone along with Cyclophosphamide. His kidney disease and proteinuria during his hospital stay stabilized on the immunosuppressive treatment, and he was discharged home one week later. Follow up in the nephrology clinic after 3 months of oral steroids showed stabilization of kidney function and proteinuria with creatinine level 1.4 mg/dL and urine protein/creatinine ratio 0.66 g/g.

Discussion: IgA Vasculitis is not common among the adult population. The kidney involvement in IgA Vasculitis (termed IgAV nephritis) is more prevalent among adults than children, and long-term kidney prognosis tends to be worse in adults. Many patients present with only mild hematuria and proteinuria that is self-limited, but some patients may present with nephrotic range proteinuria. This case demonstrated the importance of close nephrology follow up in adults with new diagnosis of IgA Vasculitic rash as the initiation of immunosuppression can prevent the progression of nephrotic range proteinuria.

PUB382

Crescentic IgA Nephropathy: Levamisole-Induced?

Zeyad J. Rifai, Heather Rowe, Nirali B. Ramani. *Southern Illinois University School of Medicine, Springfield, IL.*

Introduction: Immunoglobulin A (IgA) nephropathy is the most common primary glomerulonephritis (GN) worldwide and results from galactose- deficient IgA1 deposition within mesangial cells triggering an autoimmune response. Less than 10% of cases present as rapidly progressive GN. Levamisole is a cocaine adulterant, classically associated with ANCA vasculitis, that has a variable pattern of immunologic disturbance of renal significance.

Case Description: A 58-year- old female with a history of IV drug-use induced hepatitis C, with a negative viral load for two years following glecaprevir-pibrentasvir therapy, presented to the hospital with one month of intermittent hematuria, vague abdominal discomfort, malaise, and bilateral lower extremity worsening large violaceous plaques with early signs of ulceration. She admitted to frequent cocaine use and heavy NSAID usage for her abdominal discomfort and malaise but was unable to quantify either substance. Serum creatinine was at her baseline of 1.0 mg/dL, however, her urine protein creatinine ratio was 25 mg/mg with 219 RBC/HPF. Serologic, antiphospholipid, celiac and hepatitis workup were completely unremarkable. There was significant concern for ANCA negative levamisole induced vasculitis in the setting of cocaine usage versus NSAID induced glomerulonephritis. A renal biopsy was obtained revealing mesangial staining for IgA, IgM, C3 with diffuse mesangial hypercellularity, with 77% of glomeruli with fibrocellular crescents. This represented an Oxford classification of M1, E0, S0, T0, C2. The patient was discharged on losartan, moderate dose prednisone and cyclophosphamide. Outpatient follow-up with notable improvement in proteinuria and hematuria, she currently has preserved renal function with a creatinine of 1.0 mg/dL.

Discussion: This unusual presentation of possible levamisole induced crescentic IgA nephropathy (cIgAN) is confounded by the possibility of superimposed ANCA negative levamisole induced vasculitis as the underlying mechanism for the crescentic glomerular injury. There is no literature on levamisole induced cIgAN, we aim to share the first potential association between levamisole and development of cIgAN based on histologic findings. Alternatively, the cIgAN may be the outcome of hepatotoxicity resu from the resolved hepatitis C infection, however the patient's presentation and the timeline is more suggestive of a levamisole induced process.

PUB383

ANCA-Associated Vasculitis with Atypical Findings of Renal Medullary Angiitis

Heather Rowe, Zeyad J. Rifai, Nirali B. Ramani. *Southern Illinois University School of Medicine, Springfield, IL.*

Introduction: Renal medullary angiitis is a poorly understood marker of systemic vasculitis that is frequently mistaken for acute interstitial nephritis due to the presence of neutrophils on microscopy. Medullary angiitis and the associated systemic vasculitis are rarely documented in the literature.

Case Description: A 71-year-old male presented with constitutional symptoms of malaise, unintentional weight loss, decreased appetite, and worsening renal function. Urinalysis revealed 310 RBCs/high-powered field and a serum creatinine of 3.7 mg/dL. Comprehensive serologic workup revealed an antineutrophil complement antibody titer of 1:640 and proteinase-3 antibody positivity. Given the severity of his constitutional symptoms and the overt suspicion for ANCA vasculitis, the patient was started on prednisone 60mg daily and underwent renal biopsy. Light microscopy showed pauci-immune focal necrotizing crescentic glomerulonephritis with severe medullary angiitis characterized by lymphocytic inflammation and scattered eosinophils surrounding the vasa recta and mild interstitial fibrosis and tubular atrophy. Immunofluorescence confirmed the pauci immune ANCA associated type, while electron microscopy revealed nonspecific mild podocyte effacement. The patient underwent induction with rituximab and was discharged with scheduled maintenance doses of rituximab. The patient continues to follow up with nephrology for his chronic kidney disease (new baseline serum creatinine 1.96 mg/dL).

Discussion: The impressive serologic findings despite vague constitutional symptoms without a rash are an exceedingly rare presentation of this poorly understood diagnosis. We emphasize the necessity of achieving complete immunologic resolution, evidenced by negative serologic markers, via rituximab, to prevent further neutrophil-induced endothelial cell activation and vascular damage. Establishing a standardized guideline for this subset of ANCA vasculitis cases concentrated on serial titer monitoring is an area of interest.

PUB384

Crystalline Nephropathy: A Hidden Complication of Bariatric Surgery

Aakash Padodara, Katelyn Kaufman, Carlos A. Fernandez Bojanini, Gabriel A. Valle. *University of Miami Health System, Miami, FL.*

Introduction: Oxalate nephropathy (ON) is an uncommon etiology of kidney disease characterized by the accumulation of calcium oxalate crystals in the renal parenchyma. It is a pleomorphic disorder which can present as Acute or Chronic Kidney injury and frequently progresses to end stage renal disease. Although the exact prevalence of this condition is unknown, ON was identified in 1% of 2265 consecutive kidney biopsies and it is often associated with specific conditions such as primary and enteric hyperoxalurias or ethylene glycol toxicity.

Case Description: A 74-year-old male with type 2 diabetes, heart failure with preserved exection fraction, atrial fibrillation, CVA, and chronic kidney disease 3b and morbid obesity s/p remote Roux-en-Y gastric bypass (RNYGB) was noted to develop rapidly progressive deterioration of his kidney function following an episode of Herpes Zoster infection treated with Valacyclovir. After 6 weeks of conservative management his eGFR declined to 8 mL/min/1.73m^2 and was associated with insidious uremic symptoms necessitating hospitalization for initiation of dialysis. A kidney biopsy showed diffuse severe epithelial cell injury with features consistent with ON, diabetic glomerulosclerosis, Class IIa, moderate interstitial fibrosis, 18% global glomerular sclerosis and arteriosclerosis.

Discussion: The mechanism of ON in gastric bypass surgery, specifically jejunoileal bypass and RYGB surgery, encompasses increased dietary oxalate availability as undigested fatty acids bind to intraluminal calcium in the small intestine leaving a large load of unbound oxalate to be absorbed in the colon. Subsequent hyperoxaluria and the formation of calcium oxalate crystals within the tubules and renal parenchyma cause tubular obstruction, interstitial inflammation and scarring. ON remains largely an unsuspected diagnosis, is progressive in nature and has a poor prognosis. Clinicians should recognize the potential risks of this hyper absorptive complication of RYGB in patients who develop renal dysfunction and institute measures to forestall the progression of this disorder.

PUB385

Unveiling the Hidden Culprit: Glomerulonephritis and Hand Lesions Leading to Infective Endocarditis

Mohammed Alshehri,[1,2] Ali A. Abdi,[3] Hussain M. Al mosa.[2] *[1]King Khalid University College of Medicine, Abha, Saudi Arabia; [2]Aseer Central Hospital, Abha, Saudi Arabia; [3]Fakeeh Care, Jeddah, Saudi Arabia.*

Introduction: We present a case of Rapidly Progressive Glomerulonephritis associated with Staphylococcus aureus mitral valve infective endocarditis (IE). The patient developed lesions on the palms and soles, which led to the discovery of a large vegetation.

Case Description: A 31-year-old woman with hypertension was advised to go to the ER for high serum creatinine (2.3 mg/dl). Blood pressure was 199/153 mmHg, heart rate 94 bpm, oxygen saturation 99%, and temperature 36.8°C. Urine dipstick showed +3 blood and +2 protein. CBC was unremarkable, but creatinine rose to 4 mg/dl with sub-nephrotic range proteinuria and 10-20 RBCs in urine. Steroid was started, and kidney biopsy was arranged. Immunological workup revealed low C3, with negative ANA, ANCA, hepatitis, and HIV. The biopsy showed significant atrophy, leading to tapering of steroid and dialysis/transplant discussion. Two weeks later, she presented with sepsis, anuria, lethargy, and serum creatinine of 6.2 mg/dl. Exam of her palms and soles revealed Osler's nodes, Janeway lesions, and splinter hemorrhages. She had thrombocytopenia without hemolysis. Blood cultures were positive for MSSA. Echocardiograms showed a sub-mitral vegetation (2.6x1.2 cm). A CT angiogram ruled out renal artery stenosis but detected splenic infarction. The patient remained on dialysis and underwent surgical removal of the vegetation and mitral valve replacement.

Discussion: Subacute IE can present with an indolent course, causing delayed diagnosis. We present a case initially showing nephritis and low C3. Classical signs of microemboli and positive blood cultures led to the diagnosis. Consistently low C3 level suggests clinicians should consider an echocardiogram in cases of unexplained glomerulonephritis.

Summary of kidney biopsy findings

LM	IF	EM
The specimen contains 15 glomeruli; 2 (~13%) are globally sclerosed. +Glomerular ischemia, marked corrigation, focal fibrous obliteration, and thickened Bowman	Staining shows granular nonspecific mesangial C3 (1+), focal segmental IgM (1+), and trace Kappa and Lambda light chains in a sclerotic tuft.	Mesangium shows segmental expansion with increased matrix and segmental capillary obliteration. The GBM is corrugated and thickened, without attenuation, double contouring, or lamellation. The foot processes are effaced over a long segment, and focal microvillous transformation of podocyte cytoplasm is noted. No definite immune/complement dense deposits are identified.

PUB386

Beyond the Bowel: A Case of Ulcerative Colitis-Associated Membranous Nephropathy

Nathan Aleger. *Tulane University School of Medicine, New Orleans, LA.*

Introduction: Glomerulonephritis is a rare extraintestinal manifestation of Ulcerative Colitis (UC) and presents clinical challenges in management. We present a case of glomerulonephritis in a 68-year-old male with a history of UC, highlighting the importance of vigilance for extraintestinal manifestations in inflammatory bowel diseases.

Case Description: A 68-year-old male with UC on adalimumab presented with worsening lower extremity edema, dyspnea on exertion, and hematochezia. Laboratory investigations revealed anemia, elevated serum creatinine, and nephrotic range proteinuria. Immunological workup demonstrated positive Anti-Phospholipase A2 receptor IgG. Renal biopsy confirmed Membranous Nephropathy. Treatment initially involved corticosteroids, adalimumab, and lisinopril, with subsequent adjustments including infliximab, losartan, azathioprine, and empagliflozin due to UC flares and renal deterioration. Transition to Ustekinumab led to improved UC symptoms and reduced proteinuria.

Discussion: The association between UC and glomerulonephritis underscores the need for comprehensive screening and monitoring of renal function in UC patients. The positive response to corticosteroid therapy suggests an autoimmune component, necessitating further research into underlying immunological pathways. This case emphasizes the challenges in managing UC-related glomerulonephritis and highlights the importance of multidisciplinary care. Early recognition of extraintestinal manifestations is crucial for optimizing patient outcomes, warranting further studies for better therapeutic strategies.

PUB387

C3 Glomerulopathies: Navigating Diagnostic and Therapeutic Challenges in Anticoagulated Patients

Atousa Jahanshahi, Mauricio A. Pedroza. *Jefferson Einstein Philadelphia Hospital, Philadelphia, PA.*

Introduction: C3 glomerulopathies are rare kidney disorders marked by dysregulated complement pathways, leading to C3 deposition in the glomeruli. They're classified into Dense Deposit Disease (DDD) and C3 glomerulonephritis (C3GN).

Case Description: A 56-year-old male with history of hypertension, mechanical aortic valve replacement on anticoagulation and autoimmune hemolytic anemia, seen initially for elevated creatinine at 2.4, in January 2023, attributed to pigment nephropathy or Coumadin-associated nephropathy given presence of microscopic hematuria; despite

considering glomerular issues, a biopsy was not pursued given overall stable kidney function and anticoagulation. A year later he experienced worsening kidney function, with serum creatinine of 4.1 mg/dL, leading to hospitalization. Laboratory tests revealed persistent proteinuria, hematuria, and low C3 and C4 level. Kidney biopsy showed mesangial and capillary loop C3 deposition, ultrastructural examination showed very rare electro-dense deposits within the mesangium, no deposits within the glomerular basement membrane. Biopsy was complicated by perinephric hematoma requiring transfusion. Treatment with Prednisone and mycophenolate mofetil (MMF) was initiated, and the patient was referred to a glomerular disease center.

Discussion: This case underscores the challenges in treating glomerular diseases, particularly in anticoagulated patients, requiring a thorough, individualized approach. Symptoms include varying degrees of proteinuria, hematuria, low C3 levels, and kidney dysfunction with hypertension. Diagnosis relies on kidney biopsy, with immunofluorescence and electron microscopy aiding differentiation. Further tests may be needed for causative factors and tailor treatment. Treatment, often comprising MMF and glucocorticoids, alongside supportive care.

PUB388

A Case of Membranous-Like Glomerulopathy with Masked IgG-kappa Deposits (MGMID) in an Otherwise Healthy Young Man without Autoimmune Disease

Stephen R. Sammons, Laith Al-Rabadi, Monica P. Revelo Penafiel, Siddhartha Kakani. *University of Utah Health, Salt Lake City, UT.*

Introduction: MGMID is characterized histologically by immunoglobulin deposits that are absent on routine frozen immunofluorescence (IF) but show strong staining for IgG and Kappa when IF is performed on formalin-fixed, paraffin embedded tissue. MGMID is largely seen in young patients with a female predominance and is associated with nonspecific autoimmune serologies and monotypic immunoglobulin deposition without underlying hematologic malignancy.

Case Description: A 27 y/o man with no known past medical history was evaluated for subnephrotic proteinuria found on routine labs. He takes no medications and denies any symptoms. Labs were notable for normal serum creatinine, absence of hematuria, and unrevealing serological workup. Renal biopsy revealed a membranous glomerulopathy pattern with IF showing weak IgM & C3 staining in glomeruli, however IF was performed on a paraffin embedded sample which revealed IgG, Kappa, C3, and C1q staining in glomerular capillary walls, consistent with MGMID pattern.

Discussion: This case of MGMID is unique as the patient is male and lacks features commonly seen in other MGMID patients including hematuria and positive autoimmune serologies. It is vital to consider MGMID when examining cases of glomerular disease with membranous pattern and particularly when only weak C3 staining is detected on IF.

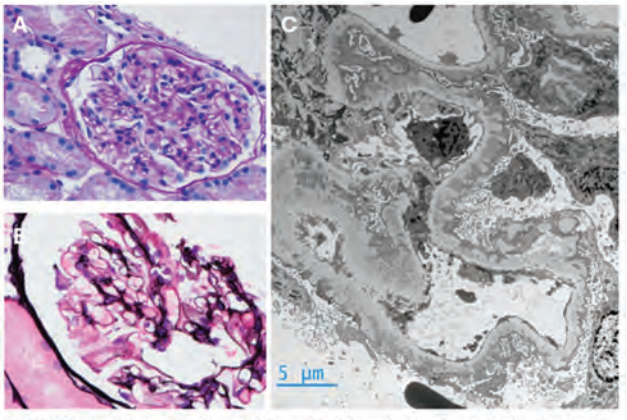

Figure 1. Representative images from renal biopsy showing membranous glomerulopathy changes with A) H&E staining on light microscopy, B) Jones silver stain on light microscopy, and C) electron microscopy

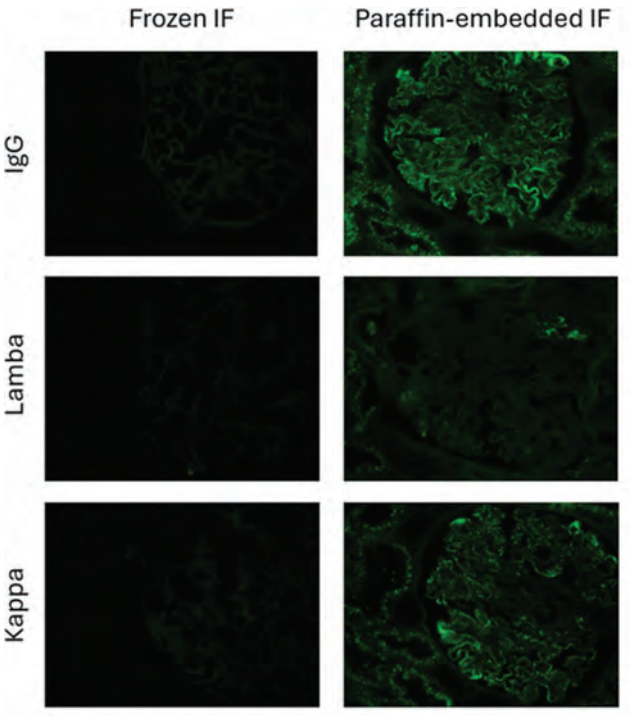

Figure 2. IF images from renal biopsy showing staining of IgG, Lamba, and Kappa on routine frozen IF and on paraffin-embedded IF following Pronase digestion.

PUB389

A Young Woman with Sick Kidney in Biopsy

Giuliani T. Oliveras Maldonado, Fabiola Feliciano Bonilla, Carlos Cortes. *VA Caribbean Healthcare System, San Juan, Puerto Rico.*

Introduction: Rapidly progressive glomerulonephritis is characterized by a rapid decline in renal function over days to weeks with U/A with proteinuria, hematuria, dysmorphic RBC's, and RBC casts. Incidence in the United States is 7 cases per 1 million persons, while in the United Kingdom it is 2 cases per 1 million. Common etiologies include immune complex-mediated RPGN, such as lupus, IgA vasculitis, or C3 glomerulonephritis. Here we present a difficult to treat case of a young woman with rapidly progressive glomerulonephritis.

Case Description: This is a case of a 27-y/o female without medical history, who presented to the emergency room with nausea, vomiting, and diarrhea over two days. Vital signs revealed high blood pressure, tachycardia, hgb 6 g/dL. Labs revealed serum creatinine: 17, BUN: 116, Na:126, K: 5.5, CO2: 13. U/A with protein >500 mg/dL, large blood, microhematuria and urine protein/creatinine 6.6 g/day. After, patient developed pleuritic chest pain, with pericardial effusion and pericardial friction rub. Emergent hemodialysis was started with improvement after 4 days of HD and pulse steroids. Other labs revealed (+) Coombs test, high ferritin and LDH levels, (+) ANA/Ro pattern, low C3, (-) C4, (-) scleroderma AB, (-) anti-RNP AB, (-) anti-Sm AB, (+) anti-Ro AB, (-) anti-dsDNA AB, and (+) lupus anticoagulant. Kidney biopsy confirmed Diffuse Proliferative Lupus Nephritis Class IV. Treatment begun with Hydroxychloroquine, Mycophenolate and high dose steroids. After treatment patient remained dependent on HD.

Discussion: Kidney biopsy is required for LN diagnosis, prognosis, and adequate management. Prognosis of disease worsens with advancing WHO histopathology classes, particularly in LN Class 4, where early initiation of therapy significantly improves disease outcomes. Treatment involves pulse steroids with methylprednisolone for 1-3 days followed by oral prednisone along with either cyclophosphamide (500 mg IV every two weeks for 3 months) or mycophenolate mofetil (2-3 g/day for 6 months). Monitoring disease includes assessments of blood pressure, renal function, proteinuria, urinary sediment, C3/C4 levels, and anti-dsDNA AB measured at least biannually. Earlier disease detection is vital as achieving complete kidney response during treatment provides a 5-year patient and kidney survival of more than 90% vs 69% (patient) and 45% (kidney) for those not achieving complete remission.

PUB390

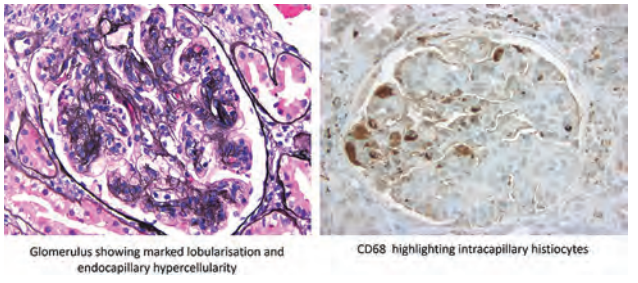
A Rare Case of Histiocytic Glomerulopathy

Ujjwala Murari,[1] Prathap Simhadri,[2] Md. Shahrier Amin,[1] Anthony J. Parravani.[1]
[1]West Virginia University Health Sciences Center, Morgantown, WV; [2]AdventHealth Centra Care, Altamonte Springs, FL.

Introduction: Histiocytic glomerulopathy is a rare kidney disorder characterized by presence of histiocytes within glomeruli leading to damage and dysfunction.

Case Description: 38 year old white female with history of Hypertension and hypothyroidism referred to the CKD Clinic for worsening generalised swelling. Labs showed creatinine of 1.24mg/dl (baseline creatinine a month ago <1) with GFR 56, Electrolytes within normal limit, Hemoglobin 11.6g/dl, platelets 301 K. Urine studies showed nephrotic range proteinuria (10 grams), albumin 4g/dl which prompted to check serological work up include C3-68 and C4-21, rheumatoid factor is <15, ANA, dsDNA and hepatitis B/C were negative. Kappa and lambda chain ratio 1.5 with no M protein. In view of nephrotic proteinuria shared decision was taken to proceed with kidney biopsy. Light microscopy: The glomeruli enlarged, marked endocapillary, mesangial hypercellularity. Many foamy histiocytes are noted within the capillary loops, confirmed by a CD68 immunostaining. Immunofluorescence: There is granular capillary wall staining in the glomeruli for C3 (2+). Electron Microscopy :The loops are distended by lipid laden cells and swollen endothelial cells. No crystals are seen Since the biopsy showed histiocytic glomerulopathy further work up ordered like EBV, Parvovirus, Cytomegalovirus and EBV Ig M and Ig G antibody positive and PCR negative. Ferritin levels were 155, Fibrin 564. Plan is to start on steroids.

Discussion: Histiocytic glomerulopathy is multifactorial disorder with complex interplay of genetics, immunological and environmental factors contributing to its pathogenesis. Further research is needed to elucidate the precise mechanisms underlying the development and progression of this condition. In the above case the possible factor could be EBV (Epstein bar virus) stimulating an immune response leading to accumulation of histiocytes in the kidney



Glomerulus showing marked lobularisation and endocapillary hypercellularity

Decoding the Kidney Conundrum: Dive into the Glomerulonephritis Mystery!

Sonakshi Mirchandani,[1,2] Ana Chavez Velasquez,[1,2] Rahul Paryani.[2] *[1]Texas Health Resources, HEB/Denton, TX; [2]Texas Christian University, Fort Worth, TX.*

Introduction: ANCA-associated glomerulonephritis (GN) comprises over half of RPGN cases, Typically, patients present with acute kidney injury (AKI) and active urinary sediment. Kidney biopsies often reveal necrotizing and crescentic glomerulonephritis with minimal (pauci immune) complex deposits and normal serum complements. Here, we describe a rare case of myeloperoxidase (MPO)-ANCA glomerulonephritis with concurrent immune complex deposition and low complement levels.

Case Description: A 77-year-old female with a medical history of OA, gout, hypertension, and type 2 diabetes presented in 2019 with AKI Cr 2.34 Baseline(0.9-1.1), hematuria (65 RBC), and significant proteinuria (Urine Protein Creatinine UP/C 3g). Biopsy indicated IgA nephropathy with acute crescentic changes. Serology showed MPO pANCA positivity and low C4. Treatment involved IV Solumedrol and cyclophosphamide which were later transitioned to oral immunosuppressants once creatinine stabilised. In 2021, she experienced an intestinal angioedema due to ACE inhibitor(c1 esterase), leading to treatment discontinuation. A relapse occurred in 2022, necessitating oral immunosuppressants. In August 2023, she had another AKI episode(Cr 3.1 UP/C 6g) and underwent a second biopsy, revealing MPO-ANCA mediated focal necrotizing and focal sclerosing glomerulonephritis with concurrent immune complex and crescent formation, IF with granular capillary wall staining for IgG, IgA, IgM, C3, C1Q, kappa and lambda chains and electron Microscopy (EM) with immune complex dense deposits with 90% epithelial foot process effacement. Serology -MPO ANCA positive 1:40. low C4 <2.9, normal complement C3 at 95, Anti ds DNA negative, ANA negative, HIV negative. Treatment involved IV Rituximab and steroids with significant improvement for Cr to 1.7 She developed facial angioedema and AKI, prompting a third biopsy(April 2024) pending results showing improvement with Rituximab and planned avacopan therapy.

Discussion: Immune complex deposition in ANCA-associated vasculitis (AAV) GN is atypical, as AAV is typically "pauci-immune." Recent studies classify AAV/GN into "pauci-immune" (PI) and "immune complex" (IC) groups, with IC deposits potentially exacerbating ANCA effects and role of complement activation causing worsened proteinuria. Early recognition is crucial for preserving renal function, with rituximab and avacopan showing promise in treatment.

PUB392

Hesitating on Receiving Treatment for Rapidly Proliferative Glomerulonephritis

Fabiola Feliciano Bonilla, Gabriel J. Torres-Rivera, Carlos Cortes.
VA Caribbean Healthcare System, San Juan, PR.

Introduction: ANCA vasculitis, is an inflammatory condition affecting small arteries and causing tissue damage in various organs. Renal involvement can lead to ESRD with a high mortality rate. Prevalence ranges from 4.6 to 21.8 cases per 1 million person-years globally. RPGN is a severe renal manifestation, such as nephrotic proteinuria, hypertension, and azotemia. Diagnosis involves serological testing for ANCAs and kidney biopsy. This is a case of RPGN with ANCA(+) in a patient hesitant to receive therapy.

Case Description: A 73 y/o female with PMHx of active smoking, breast cancer, and HTN who was referred to nephrology clinic due to elevated serum creatinine, hematuria, and foamy urine for 4 months. Vital signs with 152/94 mmHg, 78 bpm, and 96% oxygen. Laboratory revealed UPCR of 4.6 grams/day and a creatinine of 2.12 mg/dL from 0.88. Biomarkers showed an ANA titer 1:2560, RF 22, p-ANCA (+), ESR 95; CRP 31.7. Started Solumedrol 500 mg IV every 12 hours for 3 days and a kidney biopsy was done. Differential diagnoses of ANCA vasculitis, lupus nephritis, and C3GN considered. Workup showed MPO (+), C3 138, C4 12, anti-dsDNA(-), anti-Smith (-), and anti-GBM (-). Despite steroid induction, renal function and HTN worsened. Rituximab initiated and she developed sudden headache and blurry vision. MRI revealed an acute ischemic left occipital stroke and an old lacunar infarct. Final biopsy showed immune complex-mediated necrotizing glomerulonephritis with epithelial crescents and interstitial fibrosis. Despite advice to continue therapy, she refused due to perceived association with her acute stroke. Also, denied cyclophosphamide and agreed to receive azathioprine and prednisone. On follow-up, she continued to have severe proteinuria and de novo CHF due to poor compliance with regimen.

Discussion: ANCA glomerulonephritis requires induction and maintenance therapy. Severe cases may require treatment such as methylprednisolone, cyclophosphamide, and plasmapheresis with prednisone. Maintenance therapy, rituximab or azathioprine with prednisone, this is crucial for preventing relapse. Patient involvement in treatment and education is essential for achieving goals and ensuring compliance. Despite advancements, relapse rates remain significant. Close monitoring for treatment resistance and lack of remission enables healthcare providers to optimize outcomes for ANCA GN patients.

PUB393

"A" Is for Adult: Nonclassic Presentation of IgA Vasculitis

Hannah Freibert,[1] Tyler Sims.[2] *[1]University of Kentucky College of Medicine, Lexington, KY; [2]University of Kentucky, Lexington, KY.*

Introduction: IgA vasculitis (IgAV), formerly Henoch-Schönlein purpura, is an immune-mediated disease which most commonly affects children but also occurs in adults. Here we discuss the diagnosis and treatment of an IgAV patient with a history of multiple chronic immune-mediated disorders.

Case Description: A 46-year-old woman was evaluated by nephrology due to proteinuria in the setting of newly diagnosed leukocytoclastic vasculitis (LCV) on skin biopsy. Patient with history of T2DM, autoimmune hemolytic anemia, eosinophilic asthma on mepolizumab, and chronic sinusitis. The patient presented with one month of pruritic rash with blistering on all extremities and polyarthralgia. Skin punch biopsy revealed small-vessel LCV. Steroid taper initially helped, but symptom regression occurred on decreased steroid dose. She was readmitted and noted to have leukocytosis, eosinopenia, 24-hour urine protein 1528 mg/day. Workup including complement levels, ANA, Anti Beta 2 Glycoprotein, cryoglobulins, ANCA and kappa lambda light chain ratio were all negative. A kidney biopsy showed significant 2-3+ IgA granular staining, minimal IgG staining, minimal c3, normal cellularity, minimal tubular atrophy consistent with IgA vasculitis. A 2nd skin biopsy with immunofluorescence also confirmed the diagnosis. She was started on high dose steroid taper and mycophenolate, alongside lisinopril and empagliflozin in the setting of her proteinuria.

Discussion: IgA vasculitis (IgAV) is an immune-mediated disease which most commonly affects children. It is characterized by IgA and complement deposition along with subsequent leukocyte inflammation, forming immune complexes within affected organs. IgAV may result from an immune reaction to infectious triggers. Patients often have a tetrad of findings: palpable purpura without underlying thrombocytopenia or coagulopathy, arthralgias, abdominal pain, and kidney disease. Biopsy of the dermis or kidney is indicated in unusual presentations or with concern for renal involvement. Pursuing a tissue biopsy to make the diagnosis of IgAV in adults is of notable consequence as adults are at increased risk of recurrent disease and IgAV-associated end stage kidney disease.

PUB394

A 30-Year-Old Caucasian Man with Phospholipase A2 Receptor-Associated Primary Membranous Nephropathy

Htun M. Aung,[1] Nidhi Varma.[1,2] *[1]New York City Health and Hospitals Jacobi, Bronx, NY; [2]Albert Einstein College of Medicine, Bronx, NY.*

Introduction: Primary membranous nephropathy (MN) is more commonly seen in Caucasian males over the age of 40 years. We present a unique case of anti-phospholipase A2 receptor (PLA2R)-associated primary MN in a 30-year-old Caucasian male who presented with end-stage kidney disease (ESKD).

Case Description: A 30-year-old Caucasian male patient with a history of chronic kidney disease stage 3B and obesity presented to the emergency department with fatigue, dizziness, and shortness of breath. History was notable for NSAID use a year ago that he had stopped. He denied illicit drug use or contrast exposure. He was not taking any medications at the time of presentation. A chart review revealed that he was evaluated for serum creatinine (sCr) of 2.5 mg/dl and 1.5-gram proteinuria at a different hospital a year ago. Serologies with antinuclear antibody (Ab) and anti-double-stranded DNA Ab were negative. His CKD was thought to be secondary to NSAID use. But, he was lost to follow-up and presented to our hospital a year later with renal failure. He was anuric with a blood pressure of 193/99 mmHg, sCr of 17.4 g/dL, bicarbonate 9.6 mEq/L, venous pH of 7.1, serum albumin of 4.2 g/dL, and creatine phosphokinase of 205 U/L. There was no urinary retention. He was emergently started on hemodialysis for uremic symptoms. Urinalysis showed 4+ protein and RBCs of 13.6 per high-power field. The urine protein-creatinine ratio was 3,960 mg/gm. The right kidney was 12.8 cm, and the left was 13.9 cm on ultrasound. Renal artery stenosis was ruled out. Serological workup was negative except for the PLA2R Ab of 37. He underwent a kidney biopsy which revealed advanced membranous glomerulopathy stage 3 (PLA2R-positive), with extensive global and focal segmental sclerosing features, severe tubular atrophy and interstitial fibrosis with focal acute tubular injury, and severe arteriosclerosis and hyalinosis with focal intimal fibrin. He was not a candidate for immunosuppressive therapy due to his poor renal prognosis. He was continued intermittent hemodialysis on discharge.

Discussion: Anti-PLA2R Ab is highly specific for the diagnosis of primary MN. In a young person with decreased GFR and proteinuria, PLA2R Ab should be considered to help with the diagnosis. Adding PLA2R Ab at the time of his first evaluation could have elucidated the cause of his chronic kidney disease and possibly prevented ESKD.

PUB395

A Rare Late Presentation of Galloway Mowat Syndrome (GAMOS) with Membranous Nephropathy

Sandeep R. Sasidharan, Tahir A. Jatoi, Eugene K. Yeboah, Subodh J. Saggi. *SUNY Downstate Health Sciences University, New York City, NY.*

Introduction: GAMOS is a rare autosomal recessive disorder initially described in 1968. It is characterized by various neurological and renal abnormalities, with heterogeneous clinical and histopathological phenotypes reported. Renal presentations range from asymptomatic proteinuria to SRNS. Here, we present a unique case of GAMOS diagnosed in an elderly black male with a WDR73 gene deletion.

Case Description: A 64-year-old male with recurrent DVT on AC, UC, HTN, and CKD. He presented with worsening proteinuria due to membranous nephropathy despite being on Tacrolimus and low-dose steroids along with enalapril. He complained of increased urinary frequency with frothing. He was vitally stable and exam unremarkable. Labs were creat of 1.0, alb 3.5, UPCR 2.8, C3 127, C4 41, urinalysis showed protein >500 and rest were negative. The genetic test was negative for APOL1 and positive for WDR73 gene deletion. Biopsy showed 5/25 globally sclerosed glomeruli, with 20% mild to moderate interstitial fibrosis. IF had a granular pattern along capillary walls for 3+ IgG, 1+C3, 2+ kappa, and 2+ lambda light chains, rest negative, including M-type PLA2R. EM showed a markedly irregular contour of BM with subepithelial and intramembranous electron-dense deposits. Diagnosed as membranous glomerulonephritis stage 2-3, PLA2R negative. THSD7A and NELL-1 antigens are pending. Patient was advised Rituximab infusion and will follow up with his nephrologist in Barbados.

Discussion: Homozygous mutations in WDR73 were first implicated in patients with GAMOS in 2014. Recently, via whole exon sequencing and high-throughput exon sequencing, mutations were identified in the Kinase, Endopeptidase, and Other Proteins of Small Size (KEOPS) complex genes responsible for GAMOS. The complex comprises four subunits: LAGE3, OSGEP, TP53RK, and TPRKB. A fifth member of the complex, C14ORF142, has been identified recently. Our patient has a deletion of the WDR73 gene and presents late in life with only proteinuria. The reported life expectancy was between 0.3 to 28 years of age, with most individuals not surviving beyond their teenage years, with the commonest causes of death being nephrotic syndrome or seizures. We aim to contribute to the existing knowledge base by presenting the first known case of GAMOS in an elderly male.

PUB396

Focal Segmental Glomerulosclerosis Associated with Mitochondrial Disease

Jessica M. Segarra, Federico Yandian, Lucia Facal, Jose Boggia, Víctor E. Raggio, Lucia Spangenberg. *Universidad de la Republica Uruguay, Montevideo, Uruguay.*

Introduction: Mitochondrial diseases include myopathy, neurological diseases, and multisystem diseases. The most frequent mutation is DNAt.3243 >G and is associated in 80% with mitochondrial encephalomyopathy syndrome, lactic acidosis and MELAS-like stroke episodes.

Case Description: SF 32 years old, with short stature, HT, DM, hearing loss, dyslipidemia, hypertrophic cardiomyopathy and ESRD-HD, a renal biopsy was performed that describes a FSGS pattern and in the ME 100% pedicellar fusion. With the suggestion of mitochondrial disease, a genetic study is requested that reports the m.3243A>G mutation in the mitochondrial gene MT-TL1 related to MELAS. Exome sequencing detected 2 variants of uncertain significance in the Gene: MYH9. Later he had a similar stroke and maintains prophylaxis with arginine. Family history mother with DM and hearing loss

Discussion: For MELAS there are clinical criteria available at https://www.ncbi.nlm.nih.gov/sites/books/NBK1233/ The case described presents seizures, acute focal lesions on neuroimaging, elevated plasma lactate and a pathogenic variant. The MYH9 gene mutation is related to macrothrombocytopenia and sensorineural deafness, no definitive functional mutation has been identified in this gene. A better clinicopathological approach is needed for an accurate differential diagnosis, allowing clinicians to perform a comprehensive evaluation of the pattern of FSGS injury for the development of appropriate treatments

Management of Cardiovascular Risk Factors in Lupus Nephritis

Zohreh Gholizadeh Ghozloujeh, Roy O. Mathew, Amir Abdi Pour, Sayna Norouzi. *Loma Linda University, Loma Linda, CA.*

Background: Patients with Lupus Nephritis (LN) show a higher prevalence of subclinical atherosclerosis and an elevated risk of cardiovascular disease (CVD) compared with healthy individuals. This study aims to examine the differences in the management of hypertension and hyperlipidemia to assess how these variations in treatment impact the prevalence of CVD in patients with LN.

Methods: A retrospective data review of 128 patients over 14 years was performed. Cardiovascular risk factors were defined as the presence of at least one of the following: hyperlipidemia, diabetes, and hypertension. Treatment management was characterized by administering antihypertensive, antidiabetic, and lipid-lowering therapies. The rates of myocardial infarction, stroke, and new diagnoses of peripheral vascular disease were compared between patients with and without cardiovascular risk factors.

Results: Patients with a cardiovascular risk factor (Group A) were older (Median age = 41 vs. 35 years, $p = 0.038$) and had a significantly longer duration of disease (Median = 65 vs. 50 months, $p = 0.025$) than patients without a risk factor (Group B). However, the gender distribution was similar in both groups (Male: 14% vs. 20%, $p = 0.420$). A higher number of patients in Group A received treatment (54.8% vs. 11.4%, $p<0.001$). The comparison between mean systolic blood pressure and laboratory data is shown in Table 1. Myocardial infarction and stroke were observed in 1.1% and 9.7% of patients in Group A, respectively, while no incidents were observed in Group B. Additionally, during management, 6.5% of patients in Group A were newly diagnosed with peripheral vascular disease, whereas no cases were diagnosed in Group B. However, none of these differences in the rate of CVD incidences were statistically significant.

Conclusions: Our results suggest that despite effective management of cardiovascular risk factors in patients with LN, there was a higher rate of cardiovascular events. These findings might be due to the higher age and longer disease duration in our population, although more studies with larger sample sizes are needed to confirm these results.

Median/IQR (25%-75%)	Group A (n=93)	Group B (n=35)	P value
HbA1c (%)	5.65 (5.2-5.9)	5.3 (4.9-5.8)	0.087
LDL (mg/dL)	103 (82-128.6)	103 (82-128.6)	0.503
Systolic BP (mmHg)	117 (107.5-132.6)	115.17 (107.4-126)	0.168

PUB398

Burden of Acute Glomerulonephritis in 204 Countries and Territories, 1990-2021: A Global Benchmarking Analysis

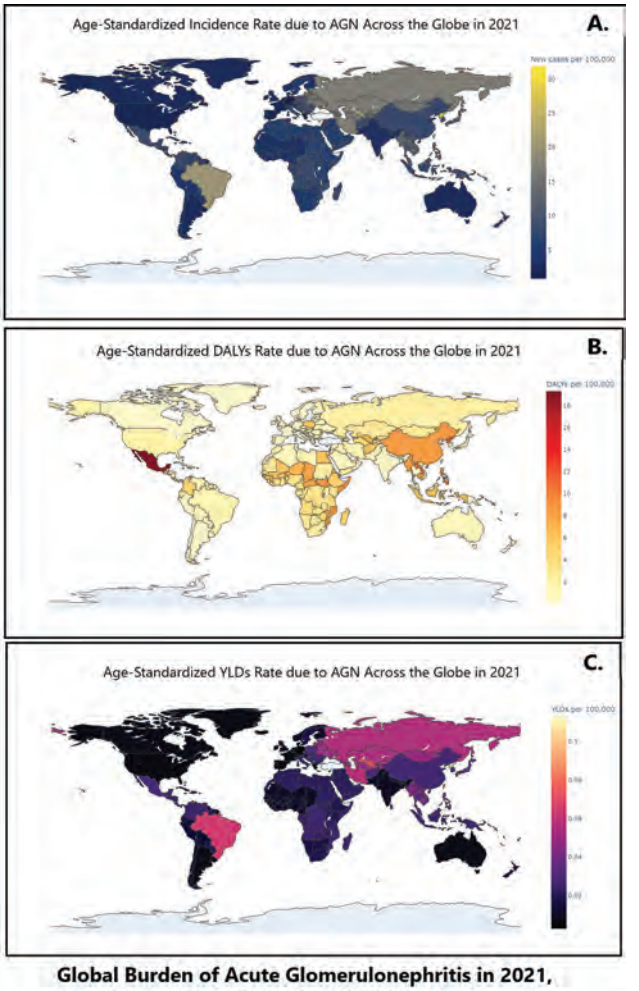
Muhammad Waqas,[1] Adan Irfan,[8] Kushagrita Singh,[2] Shruthi Katam,[3] Ashwinikumar Shandilya,[5] Mohit Lakkimsetti,[4] Vishrant Amin,[6] Juhi Patel,[6] Hardik Desai.[7] *[1]Jinnah Sindh Medical University, Karachi, Pakistan; [2]Government Medical College and Hospital, Chandigarh, Chandigarh, India; [3]Sri Venkateswara Medical College, Tirupati, India; [4]Mamata Medical College, Khammam, India; [5]Rural Medical College, Pravara Institute of Medical Sciences, Ahmednagar, India; [6]Gujarat Medical Education and Research Society Medical College & Hospital Valsad, Valsad, India; [7]Gujarat Adani Institute of Medical Science, Bhuj, India; [8]Shalimar Medical and Dental College, Lahore, Pakistan.*

Background: Acute Glomerulonephritis (AGN) poses an escalating threat to global health, significantly influencing morbidity and mortality rates. This study is the first of its kind to estimate the worldwide burden of AGN over three decades, inclusive of the initial two years of the COVID-19 pandemic, which significantly complicated the management of non-COVID cases.

Methods: Utilizing the GBD 2021 framework, we assessed the incidence, prevalence, mortality, disability-adjusted life years (DALYs), and years lived with disability (YLDs) of AGN globally, stratified by age, sex, year, and location.

Results: The total percentage change (TPC) in prevalence of AGN increased by 2% (95% UI: 2-3%) from 2019-2021. The highest unadjusted incidence rate (IR) was observed in Eastern Europe at 18.21 per 100,000 (95% UI: 15.39-21.43) in 2021, followed by the highest mortality rate (MR) in Central Latin America at 0.44 per 100,000 (95% UI: 0.38-0.51). Nationally, the highest IR was observed in North Korea at 33.51 per 100,000, while the highest MR was recorded in Mexico at 0.74 cases per 100,000 in 2021. The highest incidence count occurred in individuals aged 10-14 years with 52,933 cases, while the highest number of deaths was in those aged 75-79 years at 1,201 in 2021. Males continued to experience a higher burden of AGN over the last three decades.

Conclusions: In 2021, AGN led to 10,760 global deaths, underscoring the need for targeted strategies. Collaboration among public stakeholders, policymakers, and clinicians is essential to enhance detection, management, and reduce its global impact.



Global Burden of Acute Glomerulonephritis in 2021, Age-Standardized Rate (Per 100,000 person years). A: Incidence Rate, B: DALYs Rate, C: YLDs Rate

PUB399

A Rare Presentation of Primary Systemic Lupus Erythematosus (SLE) Tubulointerstitial Nephritis (TIN)

Sandeep R. Sasidharan,[1] Tahir A. Jatoi,[1] Fnu Pariya,[1] Susan Grossman,[2] Marie-Alex Michel.[2] *[1]SUNY Downstate Health Sciences University, New York City, NY; [2]VA New York Harbor Healthcare System, New York, NY.*

Introduction: SLE is an inflammatory disease with systemic effects, and 50% of them present with signs of nephropathy, which involve the parenchyma's glomerular, vascular, and tubular aspects.TIN is a well-recognized feature of lupus nephritis (LN) in 66% of SLE kidney biopsies (KB). SLE TIN is recognized in two forms, i.e., secondary, coexisting with lupus glomerulonephritis, and primary: develops with no or mild glomerular or vascular involvement. We present a rare case of primary SLE TIN in an elderly male.

Case Description: A 76-year-old male with a history of MI with PCI, HTN, COPD, h/o CVA, resolved DM2, h/o AKI d/t prerenal/over diuresis, and BPH. He presented with 3 days of intense red rash on his face and bilateral hands associated with pruritis and facial puffiness. No h/o NSAID use, beta lactams. Hydrochlorothiazide was stopped as a source. However, he continued to have persistent proteinuria > 2 g/d. The lab was positive for ANA 1:320, EBV IgG>600, EBV nuclear antigen 544, ESR 74, Beta2microglobulin 2.7, and IgG 544, but IgG subclasses normal, SPEP showed the faint band in the gamma region, kappa 27.2, lambda 20.4, ratio 1.33, rest of nephritic panel was normal. UPCR started at 1.2g/d and trended up to 4.5g/d. KB showed mild mesangial hypercellularity, moderate foot process effacement, and chronic interstitial nephritis with associated tubular atrophy. Before a skin biopsy, he had another rash episode in sun-exposed areas of bilateral shin with persistent proteinuria. He was started on prednisone with a diagnosis of SLE TIN, with improvement in his renal function and proteinuria.

Discussion: Primary SLE TIN is rare, with only 16 reported cases in the literature. In our patient, the diagnosis was challenging, with differential including AIN, Schnitzler syndrome, dermourticariopathy with renal dysfunction, and IgG4 nephropathy. Finally diagnosed with SLE after fulfilling 4 out of 11 criteria per ACR. To our knowledge, our

patient is the first to have nephrotic range proteinuria, with KB showing both foot process effacement and mesangial hypertrophy. As seen with our patient, primary SLE TIN is known to have a good response to steroids with a good prognosis as seen with our patient. We report this case to increase awareness of this unique diagnosis.

PUB400

Avacopan as Adjuvant Therapy for ANCA-Associated Vasculitis: A Case Report

Sanjeev Gupta,[1,2] Anastasios Papanagnou,[3] Amol Mittal,[1,2] Savneek S. Chugh.[1,2] *[1]Westchester Medical Center Health Network, Valhalla, NY; [2]New York Medical College, Valhalla, NY; [3]NewYork-Presbyterian Hudson Valley Hospital, Cortlandt Manor, NY.*

Introduction: The anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis are severe systemic disorders marked by small-vessel vasculitis. This involve autoantibodies against neutrophil proteins, particularly leukocyte proteinase 3 (PR3) or myeloperoxidase (MPO). Standard treatment for ANCA vasculitis often includes high-dose steroids, rituximab, or cyclophosphamide. Rituximab is the preferred option, but patients who do not respond sufficiently might be switched to cyclophosphamide. However, cyclophosphamide's significant side effects necessitate its limited use. We present a case of partial response to rituximab, who, instead of increasing steroids or using cyclophosphamide, was treated with avacopan, resulting in a favorable outcome.

Case Description: A 48-year-old male with hyperlipidemia presented with rash on palms and soles, and shortness of breath. Initial workup showed hemoglobin of 11.8 g/dl, platelet count of 437k/mm, BUN of 16mg/dl, and creatinine of 1.34mg/dl. Urinalysis indicated 3+ protein and 136 RBCs. Further tests revealed a urine protein-to-creatinine ratio of 1.3, negative hepatitis panel, negative ANA, and normal C3 and C4. Anti-MPO antibodies were 109 units, anti-PR3 antibodies were 2.35 units, and anti-GBM ab was negative. Kidney biopsy confirmed ANCA-associated renal disease with focal glomerular fibrinoid necrosis and crescents. The patient received 60 mg prednisone and 1 g Rituximab. He returned with worsening creatinine and shortness of breath within a week, was diagnosed with cardiac tamponade, and underwent a pericardial window. Despite moderate increased prednisone, his creatinine continued to rise with active sediments in urine. Avacopan was initiated. Within a week, his creatinine improved to baseline, and urine analysis normalized. He completed 4 rituximab doses and 52 weeks of avacopan. Eighteen months later, his creatinine remains stable at 1.3mg/dl.

Discussion: Avacopan, used as an induction therapy alongside rituximab and steroids, provides an alternative to high-dose steroids, typically tapered within a month to reduce toxicity. Despite the lack of case reports on avacopan as adjuvant therapy for partial responders to standard ANCA vasculitis treatment, our patient's positive outcome highlights its potential benefit. To date, the patient's kidney function remains stable, emphasizing avacopan's role in vasculitis management

PUB401

Light Deposited All Over (Lighted All Over)

Fnu Pariya,[1] Sandeep R. Sasidharan,[1] Tahir A. Jatoi,[1] Susan Grossman,[2] Marie-Alex Michel.[2] *[1]SUNY Downstate Health Sciences University, New York City, NY; [2]VA New York Harbor Healthcare System, New York, NY.*

Introduction: Light-chain deposition disease (LCDD) is the deposition of monoclonal light chains in multiple organs. It is a rare disease characterized by deposition of nonamyloid immunoglobulin light chains, which do not stain with Congo red and do not exhibit a fibrillar structure when examined ultra structurally. The incidence of LCDD is unknown.

Case Description: 76-year-old man with history of HTN, HLD, CVA, CKD prostate cancer s/p radical prostatectomy, and severe IPF with light smoking history. He came to ED for raised creatinine thought due to chlorthalidone use. Systemic review revealed nocturia, four times a night, more than usual. Vitals were normal. Labs showed BUN/Cr of 41/2.7, no electrolyte abnormality, ALP 499, AST 151, ALT 232, GGT 770, CBC normal except eosinophils at 9%, ANA positive 1: 80, negative for Hepatitis A, B, C, AMA, AntiSm, Urine protein initially 30. He was discharged with outpatient follow ups. GI considered DILI but with worsening LFT requested liver biopsy. Biopsy showed mild hepatitis with biliary ductal inflammation, sclerosing cholangitis with portal and peri portal fibrosis. Other labs showed Bence Jones proteins on UPEP, k/l ratio of 19, no monoclonal spike. UPCR 197g/day. Renal ultrasound was normal. MRCP showed no liver or biliary pathology but slight prominence of pancreatic duct in the head of pancreas. Fat pad biopsy was negative for amyloid. Renal labs and LFT continued to be elevated hence tried on ursodiol. Rheumatology followed for eosinophilia without asthma or allergy. Autoimmune work up including ACE, Vitamin D ratio, lysozyme, SSA, SSB, centromere, Scl70, C3, C4, dsDNA was negative. Extensive infectious work up was negative. A bone marrow biopsy showed 15% plasma cell with kappa restriction. Heme started him on high dose steroids and Bortezomib with prophylaxis. LFT Down trended with chemotherapy however, the kidney function continued to worsen, and patient had to be initiated on hemodialysis.

Discussion: Symptomatic extrarenal LCDD is rare. We present a case with involvement of multiple organ systems. Liver with biliary ductal involvement with fibrosis. Pulmonary with interstitial fibrosis. Cardiac with diastolic dysfunction. Other systems likely involved include pancreas with a ductal prominence, and possible peripheral neuropathy. To our knowledge, this is the first ever case involving so many organ systems.

PUB402

Diagnostic Challenges and Multidisciplinary Management in Atypical Lupus Nephritis

Israr Baloch, Sharon E. Maynard. *Lehigh Valley Health Network, Allentown, PA.*

Introduction: SLE is a complex autoimmune disorder affecting multiple organs, with LN being one of its most severe complications, potentially leading to significant morbidity due to renal impairment and progression to ESRD. Diagnosing LN is challenging, especially in patients not fully meeting SLE criteria. This case report discusses a 40-year-old male with LN, highlighting diagnostic challenges and the importance of multidisciplinary management.

Case Description: 40M with PMH significant for migraines, tobacco, and NSAID use presented with bilateral hand swelling, pain, and poor dentition. Denies dry mouth, fever, diarrhea, rash, and weight loss. Found to have positive ANA and AKI. Initial labs showed serum creatinine of 1.58, 200 mg proteinuria, no hematuria or pyuria. Diagnosis of LN was initially considered, but pt did not meet full criteria for SLE, and AKI was attributed to NSAID use. AKI resolved after discontinuing NSAIDs, and pt was sent home for a 5-month follow-up. However, at the follow-up visit, serum creatinine increased, along with worsening proteinuria. Repeat labs showed serum creatinine of 1.38 and UPCR of 2 g. Repeat serological workup now remarkable for +ANA, low C3 and C4, and elevated ESR, platelets, and CRP. New cardiac murmur noted on PE. Given rapidly worsening renal function and proteinuria, pt started on prednisone 60 mg daily and MMF 500 mg BID, with renal biopsy planned due to concerns for RPGN. A new murmur raised concerns for SBE, prompting an Echo and BCx. TEE revealed MV vegetations, but BCx remained -ve. Further serologic workup revealed positive APLA. Hem recommended warfarin, with Lovenox bridging for NBTE. Renal Bx revealed findings consistent with LN; however, limited sampling prevented precise classification within LN, and activity/chronicity indices could not be calculated. Pt was also started on atovaquone for PJP ppx with plans for close outpatient follow-up.

Discussion: This case underscores the importance of considering LN in patients with suggestive clinical and laboratory findings, even if they do not meet full SLE criteria. Careful medication management and a multidisciplinary approach are essential in managing complex cases like this one. The patient's outcome highlights the potential for successful treatment with a coordinated, patient-centered approach.

PUB403

Treatment of ANCA-Associated Glomerulonephritis in a Patient with Bacteremia and Vertebral Osteomyelitis: A Challenging Clinical Dilemma

Bahjat Azrieh, Melissa L. Swee, Abdullah Thayyil. *University of Iowa Hospitals and Clinics, Iowa City, IA.*

Introduction: ANCA-associated vasculitis (AAV) involves an autoimmune response that produces antibodies targeting neutrophil antigens, leading to necrotizing and crescentic glomerulonephritis. While modern immunosuppressive therapies have improved outcomes, infections remain a significant risk. Older age and high disease activity at diagnosis are critical prognostic factors. This case highlights the challenge of balancing immunosuppression with infection management.

Case Description: A 77-year-old man with a history of anti-glomerular basement membrane disease leading to chronic kidney disease (CKD) stage 3a was admitted for a burn injury, which worsened his kidney function. He was readmitted with acute kidney injury (AKI) and diagnosed with microscopic polyangiitis and crescentic glomerulonephritis with IgA deposits. Despite treatment with Rituximab and high-dose corticosteroids, he developed Enterobacter Cloacae bacteremia and vertebral osteomyelitis. His condition further complicated with disseminated Herpes Zoster infection and progression to end-stage kidney disease (ESKD), requiring dialysis. He ultimately succumbed to refractory septic shock three months after diagnosis.

Discussion: The treatment of ANCA-associated small vessel vasculitis and glomerulonephritis primarily involves high-dose corticosteroids and cyclophosphamide. However, balancing immunosuppression with infection risk is challenging, especially in elderly patients. Despite remission in the majority of patients, relapse is common, particularly in those with anti-PR3 positivity. This case underscores the need for accurate prognostic tools and strategies to mitigate infection risks while managing AAV. Lower dose steroid regimens and new agents like Avacopan may offer safer alternatives without compromising efficacy.

Rituximab to the Rescue in Refractory Anti-GBM Disease

Pratap Kumar Upadrista,[1,2] Purva D. Sharma,[1,2] Prashant N. Bhenswala.[1,2]
[1]Northwell Health, New Hyde Park, NY; [2]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.

Introduction: Anti GBM antibody disease is an aggressive disease that presents with rapidly progressive glomerulonephritis and pulmonary involvement with diffuse alveolar hemorrhage. The standard treatment includes steroids, PLEX and Cytoxan until anti-GBM Ab titers become negative. However, some cases are refractory to this conventional therapy. We present here such a case of anti GBM disease with severe lung and kidney involvement that did not respond to PLEX, cyclophosphamide and steroids with persistently high anti GBM Ab titers treated successfully with Rituximab.

Case Description: A 65 y/o M with Hx of DM, HLD, MVR and CABG presented with dyspnea, fatigue, hemoptysis and oliguria for a week. He had a baseline serum creatinine of 0.84 mg/dL. He was a non-smoker and did not use any illicit drugs. At presentation, he was anemic (7.1 g%) from his baseline of 10 g% and had anuric AKI with a Scr of 3.6 mg/dL which peaked at 6.3 mg/dL and was started on HD. He had 2.9g proteinuria and hematuria. CT chest GGOs suggestive of hemorrhage vs pulmonary edema. Work up showed anti GBM antibodies >8.0. The pt was initiated on daily PLEX (1 Plasma volume with 5% albumin + Plasma) pulse followed by oral steroids and oral cyclophosphamide. Renal biopsy showed anti-GBM glomerulonephritis with segmental glomerular necrosis and cellular crescents (88%). As his Anti-GBM antibodies titers were still >8, even after 14 sessions of PLEX, Cytoxan and Steroids. Rituxan was started for refractory anti GBM abs with pulmonary symptoms. The patient continued to be on hemodialysis. Within 2 months, his anti GBM ab titers slowly improved to negative, with improved pulmonary symptoms. Kidney transplant eval is underway.

Discussion: Management of refractory anti GBM disease with dialysis dependent AKI and lung hemorrhage with persistently high Ab titers even after PLEX, Cytoxan and steroids is challenging. There is limited literature on use of Rituximab to achieve remission. Rituxan removes CD 20 positive B cells by inducing apoptosis, antibody and complement mediated cytotoxicity resulting in lowered anti GBM ab production. Our patient was successfully managed with Rituximab with improvement in lung hemorrhage and enabling him to get kidney transplant evaluation.

PUB405

A Case Report of C3 Glomerulonephritis: A Rare and Poorly Understood Disease

Alexandra Conforti. *St. Luke's University Health Network, Bethlehem, PA.*

Introduction: Cases of C3 Glomerulopathies are rare, with an incidence of one to three cases per million. The pathogenesis is caused by excessive activation of the alternative complement pathway that leads to dense deposit formation leading GN. The disease is often caused by autoantibodies that target C3 or C5 convertase, although the pathophysiology remains poorly understood. Currently, there are no disease-specific treatments available. Immunosuppressive agents can be helpful but are not universally curative or effective. The progression to end-stage-renal disease occurs in 50% of adults in 10 years. This is a case of a middle-aged female without significant medical history who presented after a mechanical fall with uremic symptoms and was diagnosed with rapidly progressive C3GN.

Case Description: 64-year-old female presented to the hospital after have a mechanical fall one week prior, complaining of visual hallucinations, nausea, and decreased appetite. She had a prior history notable for schizoaffective disorder, bipolar, and prior DVT. Lab work on presentation was significant for severe AKI (Cr of 7.1 from a baseline of 1.0), normochromic normocytic anemia, severe metabolic acidosis, and hypoalbuminemia. Initial UA with 3+ proteinuria, innumerable RBCs, 20-30 WBCs with multiple hyaline case. Serologies for glomerulonephritis work up were significant for low C3 (56) and reactive hepatitis B core total antibody Patient underwent a renal biopsy that showed diffuse crescenteric GN with severe activity and moderate chronicity concerning C3 glomerulopathy. She subsequently underwent bone marrow biopsy that ruled out monoclonal gammopathy of renal significance. She underwent an unremarkable genetic renal panel that tested 13 genes implicated in C3GN. The patient was initiated on solumedrol and mycophenolate but unfortunately did not have renal recovery and became dialysis dependent.

Discussion: C3GN are extremely rare conditions from underlying complement dysregulation. The diagnosis merely relies on renal biopsy immunofluorescence, light microscopy, and complement biomarker findings. Autoantibodies and monoclonal gammopathy are most associated with complement dysregulation, however genetic variants are a potential cause. An imperative need remains for studying the history of C3GN to better understand pathophysiology and genetic biomarkers to establish an optimal treatment through clinical trails.

PUB406

Clinical Characteristics and Laboratory Findings in Primary vs. Secondary Membranous Nephropathy in Western Mexico

Milagros M. Flores Fonseca,[1] Alejandro Garcia-Rivera,[1] Omar H. Sanchez-Vazquez,[1] Sandra F. Velasco,[2] Samantha I. Verdugo.[1] *[1]Instituto Mexicano del Seguro Social Delegacion Jalisco, Guadalajara, Mexico; [2]Universidad de Guadalajara Centro Universitario de Ciencias Exactas e Ingenieria, Guadalajara, Mexico.*

Background: Membranous nephropathy (MN), a major cause of nephrotic syndrome in adults, occurs in primary and secondary forms. Accurate differentiation between these forms is essential for effective treatment and prognosis.

Methods: Retrospective observational, single-center study, in a third-level hospital in Western Mexico. We collected demographic, laboratory and kidney pathology data from patients biopsied and diagnosed with MN from January 2022-January 2023, and registered in the center's Glomerular Disease Registry.

Results: Overall, 81 participants were included in the study. The mean age was 35.4 y (SD ±16.3), 41 were female (50.6%), 61 patients (75.3%) presented with nephrotic syndrome and 30 patients (37%) had AKI at presentation. Table 1 shows primary and secondary MN's clinical, laboratory, and pathology characteristics. The most common cause of secondary MN was lupus nephritis.

Conclusions: Primary MN is associated with higher degree of proteinuria and a higher prevalence of nephrotic syndrome at presentation compared to secondary MN. AKI at presentation was more common in primary MN, and serum albumin levels were lower. Only 30.3% of those classified as primary MN had positivity for PLA2r antigen on biopsy, a lower prevalence compared to other cohorts.

Characteristic	Primary MN n=33	Secondary MN n=48	p value
Age	49.36 (± 11.2)	25.8 (11.8%)	0.550
Sex (female, %)	8 (24.2%)	33 (68.7%)	0.001
NS at presentation (n, %)	30 (90.9%)	31 (64.5%)	0.014
AKI at presentation (n, %)	16 (48.4%)	14 (29.1%)	0.077
Serum creatinine (mg/dL) *	1.74 (± 1.31)	1.13 (± 1.04)	0.122
eGFR at presentation (ml/min) *	66.37 (± 39.9)	103.6 (± 48.6)	0.083
Proteinuria (g/day) *	13.1 (± 7.9)	6.4 (± 4.9)	0.001
Serum albumin (g/dL) *	2.35 (± 0.8)	2.76 (± 0.76)	0.593
PLA2r antigen on biopsy (n, %)	10 (30.3%)	0 (0%)	0.001
Extracapillary proliferation (n, %)	1 (3.03%)	11 (22.9%)	0.013
Endocapillary proliferation (n, %)	1 (3.03%)	28 (58.3%)	0.001
Mesangial expansion (n, %)	4 (12.1%)	23 (47.9%)	0.044

Podocytopathy Associated with IgA Nephropathy: Is It Really a Prognostic Factor?

Belén Gallegos, Angela M. Cordoba Hurtado, L. M. Perez-Navarro, Rafael Valdez-Ortiz, Virgilia Soto. *Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico.*

Background: In IgA nephropathy(IgAN) podocyte hypertrophy and tip- lesions are markers of podocyte damage, which tend to be treated with immunosuppression, so they have a better kidney prognosis. In Latin America there are no cohorts that evaluate the clinical course of these lesions.

Methods: Cases and controls.

Results: 37 patients with IgAN were evaluated, 27% presented podocytopathy(IgAN-P) and 73% IgAN without histological data in the optical microscopy of podocytopathy(IgAN-NP), with a mean follow-up of 41±32months. Clinically, IgA-P, independent of treatment prior to biopsy, is associated with higher baseline proteinuria, (ß of .044, p=0.01) mean of 3.9±3.0gr/gr vs 1.6±1.5gr/gr in the group with IgAN-NP). Kidney function in IgAP was slightly lower with a mean eGFR of 65.9±45ml/min/1.73m2 vs 80.2±36.4 ml/min/1.73m2 p=0.23, associated granular casts in podocytopathy (92% vs 80% p=0.02) describing probable associated acute tubular injury. Histologically, patients with podocytopathy presented 80% of podocyte hypertrophy and 20% of tip-type FSGS. MEST-C score had no differences between the groups, except for mesangial proliferation that was present in 96.3% of subjects with podocytopathy compared to 70% of subjects without podocytopathy, p=0.02. The prognosis based on the international SCORE was not statistically significant between the groups p=0.59. Association was found between immunosuppressive treatment prior to biopsy and the presence of podocytopathy (OR=8, 95% CI 1.4-44.9, p=0.018), in 50% vs 37% in the group without podocytopathy p=0.01, however once the histological diagnosis was obtained it was more common to decide to continue with

immunosuppressants in subjects with podocytopathy with 90% vs 63% (p=0.11). Finally, when evaluating MAKE outcomes, there were no differences between groups.

Conclusions: In previous reports the presence of podocytopathy reported as podocyte hypertrophy and tip-lesions was 16%. In our population this finding was more frequent (27%), with podocyte hypertrophy being more prevalent. Greater proteinuria and worse kidney function were observed compared to IgAN-NP, justifying a greater frequency of immunosuppressive therapy, impacting the kidney outcome being the same as that reported in patients without podocytopathy. Similar result to that observed in previous cohorts.

PUB408

Atypical Anti-glomerular Basement Membrane Disease: An Emerging Clinical Dilemma

George Vasquez-Rios,[1] Karla G. Carias Martinez,[2] Ravi K. Thimmisetty,[2] Pablo Garcia.[3] *[1]Glomerular Disease Center, Renal Medicine Associates, Albuquerque, NM; [2]Renal Medicine Associates, Albuquerque, NM; [3]University of New Mexico Health Sciences Center, Albuquerque, NM.*

Introduction: Atypical anti-glomerular basement membrane (anti-GBM) disease is a rare subtype of vasculitis that has been described as indolent and relatively benign at times. However, aggressive presentations might pose significant challenge specially in young individuals.

Case Description: We present a 35-year-old female with no relevant past medical history who presented to the hospital with anasarca, fatigue, and nausea. She was recently seen by her primary care provider, who recommended evaluation in the ED due to progressive functional deterioration. On examination, she was hypertensive (BP 150/90s), with HR of 80s, RR: 16, and T: 37°C. Additionally, she had evident anasarca and mild paleness. Laboratory markers revealed a serum Cr: 7 mg/dL (baseline: 0.7 mg/dL 3 months prior), BUN of 85 mg/dL, bicarbonate of 17 mmol/L, and hypoalbuminemia at 2 mg/dL. Urinalysis showed hematuria, RBC casts, and proteinuria, which was later quantified to be 8 gr in a 24-hour collection. An extensive GN and MGRS workup was pursued, which showed positive ANCA levels (MPO: 5.1 IU/mL, UNL>0.9 IU/mL) and negative serum anti-GBM antibodies. Imaging studies and comprehensive evaluation did not reveal significant pulmonary, bronchial, or extra-renal compromise.

Discussion: She received a pulse of steroids and started on hemodialysis due to oliguria, anasarca, and high BUN prior to kidney biopsy. Kidney biopsy demonstrated diffuse fibrotic crescents with extensive interstitial fibrosis and tubular atrophy (IFTA >70%). IF studies revealed moderate IgG dominance with no evidence of MPO or PR3 signals. Our team was concerned about kidney-limited atypical anti-GBM. After a careful multidisciplinary discussion considering marked IFTA, medication side-effect profile, and prognosis, the patient was treated with Rituximab. Three weeks later, we continue to monitor for potential kidney response, though we explained that the chances of significant improvement are low. Atypical anti-GBM disease is an emerging and obscure vasculitis presentation that is yet to be understood. Linear deposition with IgG on IF should also warrant careful evaluation for MGRS in the appropriate age group. Our case calls for caution within the nephrology community given the miriad of questions regarding prognosis, treatment, and recurrence risk after tranplant.

PUB409

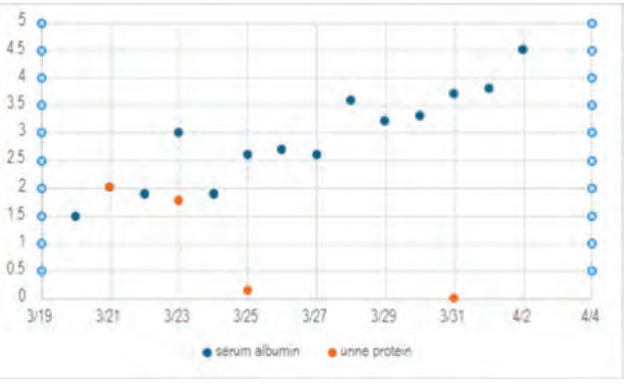
Relapsing Steroid-Resistant Primary FSGS Treated with Plasmapheresis

Dinah Goodman, Cristian A. Milla, Fnu Pariya, Arfa Amjad, Thin Thin Soe, Subodh J. Saggi, Sandeep Sasidharan, Mohammad W. Abushawer, Tahir A. Jatoi, Ao Wang, Fausto R. Cabezas, Moro O. Salifu, Okwudili Nnaji. *SUNY Downstate Health Sciences University, New York City, NY.*

Introduction: Focal Segmental Glomerulosclerosis (FSGS) constitutes 35% of Nephrotic Syndrome (NS) cases in the US, being the primary glomerular disease in End-Stage Kidney Disease (ESKD). Primary FSGS (pFSGS) presents with acute onset of NS, hematuria (50%), and hypertension (20%). Treatment focuses on reducing proteinuria, typically with Immunosuppression. This case report explores the use of plasmapheresis, a less common treatment, in a young man with relapsing steroid resistant (RSR) FSGS and severe NS.

Case Description: A 22 year old male with history of RSR pFSGS, and atrial fibrillation, presented with worsening edema. He had been treated with multiple immunosuppressive agents including cyclosporine, cyclophosphamide, rituximab, IvIG and was currently on MMF, Tacrolimus and prednisone. Vital signs were stable. On examination he had 3+ bilateral lower extremity edema. Labs showed proteinuria of >50g/d and creatinine at baseline of 0.6. He was initiated on high dose steroids and 5 sessions of plasmapheresis were given on Days 1,2,3,5,&7. After plasmapheresis, serum albumin decreased from <1.5 to 4.5, urine protein went from >2000 mg/dl to <4 mg/dl. The patient was discharged on a steroid taper with continued MMF/tacrolimus.

Discussion: pFSGS is thought to be secondary to a putative circulating permeability factor that causes podocyte dysfunction manifested by widespread foot process effacement. Proposed factors include suPar, CLCF1, microRNA, PAI-1, AT1R, DG, MMPs, POXp3, PARP1, anti-nephrin antibodies, and CD40. In this patient, the circulating factor is hypothesized to be an antibody released by plasma cells. This hypothesis is supported by the patient's dramatic response to plasmapheresis. This case provides an example of the benefit of plasmapheresis in patients with steroid resistant recurrent nephrotic syndrome due to pFSGS.



PUB410

A Rare Coexistence: Minimal Change Disease and Guillain-Barre Syndrome in a Patient with Polysubstance Abuse

Adam W. Tsen, Divya Monga. *The University of Texas Medical Branch at Galveston, Galveston, TX.*

Introduction: Minimal Change Disease (MCD) and Guillain-Barre Syndrome (GBS) are distinct clinical entities with unique pathophysiological mechanisms. MCD, characterized by nephrotic syndrome and podocyte effacement on renal biopsy, is commonly associated with autoimmune disorders and certain medications. GBS, on the other hand, is an acute autoimmune neuropathy leading to ascending motor weakness and areflexia. Here, we present a rare case of concurrent MCD and GBS in a patient with a history of polysubstance abuse.

Case Description: A 50-year-old female with a past medical history of heart failure with reduced ejection fraction (HFrEF), polysubstance abuse, and untreated hypothyroidism presented with worsening shortness of breath, vomiting, and hyperbilirubinemia. Evaluation revealed acute kidney injury, likely exacerbated by congestive heart failure, and bilateral tibial axonal motor neuropathy consistent with GBS. Further investigations confirmed a diagnosis of MCD based on renal biopsy findings.

Discussion: The coexistence of MCD and GBS in this patient highlights the importance of considering multiple etiologies in individuals with complex medical histories, particularly those with a history of polysubstance abuse. The underlying mechanisms linking these two conditions remain unclear but warrant further investigation. Management requires a multidisciplinary approach, addressing both renal and neurological manifestations to optimize patient outcomes.

PUB411

Patient Perspectives on Social Support-Related Facilitators and Barriers to Kidney Diet Adherence: A Photovoice Study

Bengucan Gunen,[1] Dahlia Stott,[2] Brandy-Joe Milliron,[2] Meghan Butryn,[4] Meera N. Harhay,[3] Ann C. Klassen.[1] *[1]Drexel University Dornsife School of Public Health, Philadelphia, PA; [2]Drexel University College of Nursing and Health Professions, Philadelphia, PA; [3]Drexel University College of Medicine, Philadelphia, PA; [4]Drexel University College of Arts and Sciences, Philadelphia, PA.*

Background: In the United States, 40% of adults with end stage kidney disease (ESKD) have obesity (body mass index, BMI, ≥30 kg/m^2). Most ESKD patients with obesity report a desire to lose weight, whether to improve transplant eligibility or quality of life. Weight loss attempts may be complicated by requirements to limit intakes of fluid, sodium, potassium, and phosphorus, while ensuring adequate protein and fiber intake. Poor renal diet adherence (RDA) increases the risk of hospitalization and mortality. Understanding family and community support for weight loss strategies and RDA among ESKD patients with obesity can help healthcare providers better assist patients and empower individuals to meet health goals.

Methods: Using a participatory Photovoice activity (Figure), we will qualitatively examine the relationship between received and provided social support, and RDA within an ongoing prospective cohort of adults with ESKD and obesity. Photovoice is a unique qualitative methodology in which participants photograph their home and community environment and, in collaboration with the research team, interpret the images. In June-September 2024, Photovoice participants will capture prompt-based photos of meals, snacks, food preparation methods, and food consumption settings; then discuss images in individual and group interviews. Images and interview content will be coded and analyzed using MAXQDA software and interpreted with 12-month clinical data.

Results: The study will enroll 10 ESKD patients with obesity. Among participants in the parent study who are eligible for the Photovoice substudy, median age is 58, median BMI is 35.2 kg/m², 45% are female, 94% are Black/African American. We will describe patients' attitudes towards renal dietary guidelines and how social support influences strategies used to maintain or improve RDA. Images will be interpreted and curated with input from the participants.

Conclusions: This study will produce participant-generated visuals and qualitative findings on diet-related sociobehavioral challenges experienced by ESKD patients with co-existing obesity in an urban setting, to inform obesity management and clinical nutrition care.

PUB412

Recurrent Priapism after Initiation of Oral Minoxidil

James Mcgee, Jordan L. Rosenstock, Maria V. DeVita. *Lenox Hill Hospital, New York, NY.*

Introduction: We present the case of a patient with end stage renal disease on dialysis and sickle cell trait presenting with multiple recurrent priapism episodes over four weeks which were associated with the initiation of minoxidil for hypertension. Priapism is considered a urological emergency which requires prompt medical attention to prevent adverse sequelae such as erectile dysfunction. While priapism has been associated with sickle cell trait and hemodialysis likely in the setting of occlusive events, minoxidil is not readily identified as a potential trigger in patients predisposed to this condition.

Case Description: This is a 46 year old male with a past medical history of end stage renal disease on thrice weekly hemodialysis for four years, hypertension, type 2 diabetes mellitus, and sickle cell trait. The patient presented to the emergency department with a painful erection which had lasted for 5-6 hours after hemodialysis. He had one prior episode approximately 3 years ago. He underwent cavernosal aspiration and injection of phenylephrine with resolution of the episode and the patient was discharged. Over the next four weeks, the patient presented twice more with similar episodes despite having started finasteride to prevent recurrence, and was treated similarly. Upon further questioning, the patient had been started on oral minoxidil 5mg daily for uncontrolled hypertension, two weeks prior to the first event. Once minoxidil was stopped, no further episodes of priapism have occurred in the following two months.

Discussion: Priapism is a urological emergency and requires prompt diagnosis and treatment. Here we present a case in which recurrent episodes of priapism appeared to be temporally associated with the initiation of minoxidil and resolved following its discontinuation. While topical minoxidil has been proposed as a treatment for erectile dysfunction, we are unaware of any previous reports of an association with priapism. Minoxidil and potentially other vasodilatory agents should be considered as a potential cause of priapism, particularly in patients with other predisposing factors.

PUB413

Intraperitoneal Nutrition Associated with Improved Albumin Levels in Malnourished Patients on Peritoneal Dialysis

Maiya Slusser. *Patient Care America, Pompano Beach, FL.*

Background: Malnutrition and hypoalbuminemia occur in 30%-50% of people receiving peritoneal dialysis (PD) which is associated with poor quality of life and poor health outcomes including increased risk of peritonitis and increased hospitalizations. Evidence suggests improving albumin levels by 0.1g/dL to 0.2g/dL can reduce the frequency of malnutrition-related challenges. Intraperitoneal nutrition (IPN) is a unique form of PD solution designed to help correct malnutrition. IPN is a combination of amino acids and dextrose that provides ultrafiltration while allowing amino acids to infuse during the dwell time to improve protein synthesis and replace protein lost during PD. IPN is commonly provided as a once daily, one-for-one replacement of a standard dialysis solution in the patients PD regimen.

Methods: Thirteen patients on automated PD who started on IPN therapy in 2021 were randomly selected and albumin was compared from baseline to measurements at month 3 and month 6 of IPN therapy.

Results: A t-test was run and found the results to be statistically significant at both 3 and 6 months, 0.002 and 0.0004 respectively.

Conclusions: PD results in varying protein losses and has common side effects resulting in diminished appetite and poor oral protein intake leading to malnutrition. Malnutrition contributes to poor quality of life and costly adverse health outcomes for patients. IPN provides a non-invasive, low burden option to help correct malnutrition.

PUB414

Recurrent Exertional Rhabdomyolysis

Jinhua Zhao.[1,2] [1]*Case Western Reserve University School of Medicine, Cleveland, OH;* [2]*Louis Stokes Cleveland VA Medical Center, Cleveland, OH.*

Introduction: Rhabdomyolysis (Rhabdo) was first described by Larrey in 1812. The original "crush injury syndrome" was described by Bywater et al in 1941. Myoglobin was identified as the offending agent for AKI by Bywater et al in 1943. The prevalence of exertional rhabdo is ~12,000 cases annually in US. It is well described among athletes and military personnel, but may occur in anybody after unaccustomed exercise.

Case Description: 32 year-old male, a runner has "dark red urine" after each marathon or training. His urine (Fig. 1) appears to be heme loaded, it clears up in one day. It's a problem of 2 years. He also has sports related mild proteinuria. No myalgia. No family history. Meds: lisinopril 2.5mg, loratadine 10mg, omeprozole 20mg daily AM labs after the morning run: UA: dark brown color, protein 100mg/dL, Heme >1.0 mg/dL, RBC <1/hpf. Renal panel: Na 135, K 4.2, Cr 1.0. Myoglobin-Urine 3574 H Ng/Ml (ref 0 - 13) Myoglobin-Serum 72 Ng/Ml (ref 28 - 72) CK 484 H U/L (ref 46 – 171)

Discussion: Fig.2 showed the common cause of rhabdomyolysis (Ref 1): Diagnosis of rhabdo does not dependent on the presence of myoglobinemia and myoglobinuria as they are quickly cleared. CK >1,000 U/L is concerning for rhabdo without exercise, but has been frequently observed without apparent health consequences (Ref 2) with exercise. Exertional rhabdo may be the first manifestation of a genetic muscle disease that lowers the exercise threshold for developing muscle breakdown. The genetic testings for this patient are ordered and will be shared when available.

Table 1. Major Categories and Commonly Reported Causes of Rhabdomyolysis.

Category	Commonly Reported Cause
Trauma	Crush syndrome
Exertion	Strenuous exercise, seizures, alcohol withdrawal syndrome
Muscle hypoxia	Limb compression by head or torso during prolonged immobilization or loss of consciousness,* major artery occlusion
Genetic defects	Disorders of glycolysis or glycogenolysis, including myophosphorylase (glycogenosis type V), phosphofructokinase (glycogenosis type VII), phosphorylase kinase (glycogenosis type VIII), phosphoglycerate kinase (glycogenosis type IX), phosphoglycerate mutase (glycogenosis type X), lactate dehydrogenase (glycogenosis type XI) Disorders of lipid metabolism, including carnitine palmitoyl transferase II, long-chain acyl-CoA dehydrogenase, short-chain L-3-hydroxyacyl-CoA dehydrogenase, medium-chain acyl-CoA dehydrogenase, very-long-chain acyl-CoA dehydrogenase, medium-chain 3-ketoacyl-CoA, thiolase† Mitochondrial disorders, including succinate dehydrogenase, cytochrome *c* oxidase, coenzyme Q10 Pentose phosphate pathway; glucose-6-phosphate dehydrogenase Purine nucleotide cycle; myoadenylate deaminase
Infections‡	Influenza A and B, coxsackievirus, Epstein–Barr virus, primary human immunodeficiency virus, legionella species *Streptococcus pyogenes, Staphylococcus aureus* (pyomyositis); clostridium
Body-temperature changes	Heat stroke, malignant hyperthermia, malignant neuroleptic syndrome, hypothermia
Metabolic and electrolyte disorders	Hypokalemia, hypophosphatemia, hypocalcemia, nonketotic hyperosmotic conditions, diabetic ketoacidosis
Drugs and toxins	Lipid-lowering drugs (fibrates, statins), alcohol, heroin, cocaine
Idiopathic (sometimes recurrent)

Protein-Energy Wasting: Correlation between Geriatric Nutritional Risk Index and Malnutrition-Inflammation Index

L. M. Perez-Navarro, Juan J. Molina Garcia, Rafael Valdez-Ortiz, Gloria G. García Villalobos. *Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico*.

Background: Protein-energy wasting (PEW) in patients with chronic kidney disease (CKD) is common and can be detected using the Malnutrition-Inflammation Score (MIS) and the Geriatric Nutritional Risk Index (GNRI). The latter is easy to estimate; however, its performance in patients with stage 3-4 CKD has not been evaluated. Our aim was to determine the correlation between the GNRI and MIS scales in patients with CKD 3-4.

Methods: Cross-sectional study evaluated 44 patients with CKD stages 3-4. The GNRI and MIS scales were applied to classify nutritional risk (MIS: Normal 0-2 points, Mild Malnutrition 3-5, Moderate Malnutrition 6-8, Severe Malnutrition ≥9); GNRI: absent, mild, moderate, severe. Averages ±SD were estimated, and absolute and relative frequencies. The correlation between GNRI and MIS scores was estimated, and the nutritional status was compared using both instruments. A 95% CI was used, with a value of p <0.05.

Results: 44 patients were evaluated, with 27% in KDIGO 3a, 27% in KDIGO 3b, and 46% in KDIGO 4. 59% women. The mean BMI was 27.06±5.57. Through electrical bioimpedance, the phase angle was of 5.76±1.42. According to the GNRI scale, 23% of the patients had PEW vs 52% with MIS. The latter classified the patients as: 47% normal, 34% mild PEW, 7% moderate PEW, and 21% severe PEW vs 77% patients as normal, 14% with mild wasting, 7% moderate, and one with severe malnutrition according to GNRI. 57% of the patients had a BMI >25, of which 40% had PEW by MIS vs 20% by GNRI. The correlation between the MIS and GNRI scales was r2= 0.643 (p <0.001), and between BMI <25 and MIS-GNRI was 0.91 (p<0.001).

Conclusions: The correlation between MIS and GNRI in this population was moderate due to the high prevalence of obesity; GNRI, by using albumin and weight as main variables, has limited applicability and proper interpretation in obese patients. The correlation between MIS and GNRI increases when these tools are used in patients with a BMI <25.

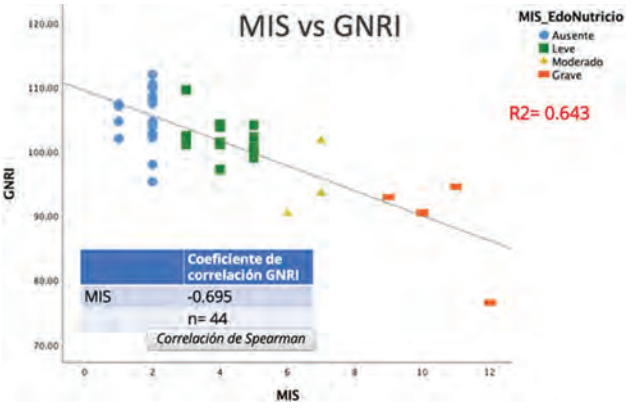

Fig. 1 Correlation between MIS and GNRI

PUB416

Public Awareness and Interest in Hypertension: An Analysis from 2004-2024

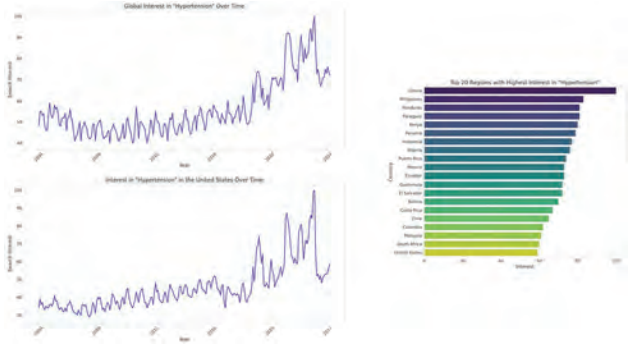
Sreyoshi F. Alam, Charat Thongprayoon, Jing Miao, Supawadee Suppadungsuk, Maria Lourdes Gonzalez Suarez, Iasmina Craici, Wisit Cheungpasitporn. *Mayo Clinic Minnesota, Rochester, MN*.

Background: Hypertension is a leading global health challenge, associated with an increased risk of cardiovascular diseases. The Internet serves as a vital resource for individuals seeking health-related information. This study aimed to analyze global and regional Internet search interest in hypertension using Google Trends™, providing insights into public awareness and interest over time.

Methods: We conducted a comprehensive Google Trends™ analysis for the search term “Hypertension” and “blood pressure” from January 2004 to March 2024. The investigation included worldwide trends and detailed analyses by country and region within the US. Google Trends™ indices were examined to identify patterns of interest and awareness, with a focus on peak and the lowest points of interest.

Results: The analysis demonstrated a statistically significant uptrend in public engagement and awareness concerning “Hypertension” and “Blood Pressure” globally and within the US, as evidenced by the slope analysis (p trends <0.05). February 2023 marked the zenith of global interest, registering a search interest score of 100. The trough of interest was in December 2008, with a score of 40. As of March 2024, the latest interest level was noted at 72. On a regional scale, Ghana, Trinidad & Tobago, Jamaica, Barbados, and Nigeria emerged as the top five countries with most pronounced interest. In the US, Arkansas, Mississippi, Alabama, West Virginia, and Louisiana were the regions with the highest interest.

Conclusions: The findings of our study underscore a significant increase in global and regional public interest regarding hypertension. The findings reveal pivotal insights into public health engagement dynamics, demonstrating an overarching trend towards heightened digital information-seeking behavior. The analysis illuminates significant regional disparities in search interest. These regional variations may reflect differing levels of awareness, prevalence, access to information, and the impact of health initiatives.



PUB417

Impact of Renal Macrophages on Blood Pressure Regulation via the Neuroimmune System

Norito Washimine,[1,2] Ryusuke Umene,[1,2] Chia-Hsien Wu,[1] Yasuna Nakamura,[1] Sayumi Matsuo,[1,2] Tomoya Nishino,[1,2] Tsuyoshi Inoue.[1] *[1]Nagasaki Daigaku Daigakuin Ishiyakugaku Sogo Kenkyuka, Nagasaki, Japan; [2]Department of Nephrology, Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan.*

Background: Hypertension affects over a billion people globally and is a risk factor for many diseases. Research shows that macrophages infiltrate various organs and regulate blood pressure. Previous studies noted increased macrophages and phenotype changes in hypertension, but the specific role of kidney macrophage infiltration remains unclear. Additionally, the nervous system influences immune cell dynamics through their neurotransmitter receptors, suggesting a neuro-immune interaction in blood pressure regulation. The precise mechanisms and their connection to the kidney remain unclear. This study aims to explore renal macrophage dynamics in hypertension development and the effects of different neural stimuli on macrophage function.

Methods: Hypertension was induced in mice using subcutaneous angiotensin II administration and oral saline intake. Immune cell subsets in the spleen and kidney were analyzed via flow cytometry. Hypertensive mice lacking macrophages or specific macrophage receptors were also created to assess blood pressure and immune cell changes. The effects of salt loading and pharmacological autonomic stimulation under angiotensin II administration on hypertension development were evaluated. A comprehensive genetic analysis of renal macrophages from hypertensive mice was conducted to identify factors related to hypertension suppression.

Results: The hypertensive group showed an increased number of renal macrophages compared to the control group. Hypertension was suppressed in mice without macrophages or macrophage-specific autonomic receptors. In angiotensin II-induced hypertensive mice, salt loading and pharmacological autonomic stimulation appeared to contribute to hypertension development. Renal macrophages were successfully isolated from hypertensive mice, and genetic analysis is underway to identify related factors.

Conclusions: Macrophages significantly contribute to hypertension pathogenesis through their kidney accumulation. Autonomic stimulation may regulate blood pressure via macrophages. Identifying factors linked to hypertension development from renal macrophages in hypertensive mice could offer new therapeutic targets for hypertension treatment. Stimulating the autonomic nervous system might help uncover underlying mechanisms.

PUB418

Renal ACE 2, Inflammation, and Oxidative Stress Cross-Talk in Diet-Induced, Salt-Sensitive Hypertension in Mice with Obesity

Jiahui Cai,[1] Feifei Sun,[1] Shasha Zhao,[1] Yunbo Sun,[1] Qiaoyun Pan,[1] Feng Yang,[1] Runyan Tan,[1] Danshu Wang,[1] Sandrine V. Pierre,[2] Yanling Yan.[1] *[1]Yanshan University, Qinhuangdao, China; [2]Marshall Institute for Interdisciplinary Research, Marshall University, Huntington, WV.*

Background: Obesity-induced salt-sensitive hypertension (ssHTN) is associated with inflammation and oxidative stress. Angiotensin Converting Enzyme type 2 (ACE2) is crucial in regulating blood pressure. This study aims to identify how renal ACE2, inflammation, and oxidative stress orchestrate to modulate blood pressure.

Methods: High-fat (HF)- induced obese C57BL/6J (B6) male mice were established as a model of ssHTN. Western blot was performed to monitor the effects of oxidative stress, inflammation, and Na/K-ATPase signaling pathway activation on ACE2 expression in the kidney. The related mechanisms affecting ACE2 expression were further verified *in vitro*.

Results: In the kidney of B6 mice, high salt (HS) stimulated signal transducer and activator of transcription 3 (Stat3), Extracellular Signal-Regulated Kinase 1/2 (Erk1/2) phosphorylation levels, and ACE2 expression. In our model of ssHTN caused by obesity, HF up-regulated phosphorylation of Stat3 and Erk1/2, as well as Heme Oxygenase-1 (HO-1) expression, but downregulated ACE2 expression compared with normal diet mice. These findings suggested that obese-mediated ssHTN was accompanied by inflammation and oxidative stress. The short-term activation of p-Stat3 and p-Erk1/2 by HS triggered a "defense response," contributing to significant upregulation of ACE2, which has the endogenous function of negative regulation of the renin-angiotensin system (RAS). However, persistent signaling activation caused by HF would disrupt the "defense response," leading to a dysfunctional ACE2 expression, which might ultimately contribute to the development of ssHTN. *In vitro* studies evidenced that Co(III) Protoporphyrin IX chloride (CoPP)-induced HO-1 attenuated IL-6-mediated p-Stat3 and p-Erk1/2 in porcine proximal tubular LLC-PK1 cells, suggesting the role of HO-1 in modulating the balance of "defense response."

Conclusions: Our studies reveal a novel association between ACE2 expression in the kidney and the activation of p-Erk1/2 and p-Stat3, which not only provides a theoretical basis for the role of ACE2 targets in ssHTN but also offers promising avenues for its clinical treatment.

PUB419

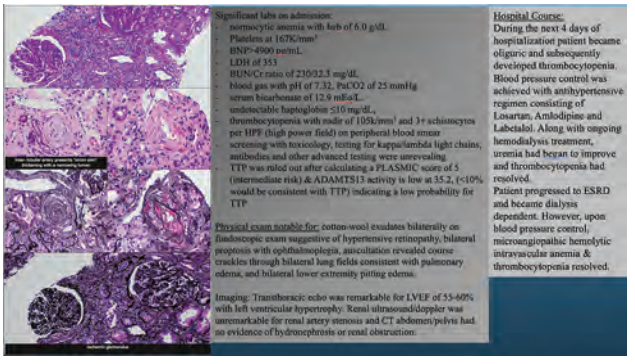
A Shearing Sensation: An Uncommon Cause of Thrombotic Microangiopathy

Angeli Patel, Craig Herrforth, Abhinav K. Rao, Matthew B. Madden. *Trident Medical Center, Charleston, SC.*

Introduction: Malignant Hypertension (MH) defined as a type of hypertensive emergency with severe increase in blood pressure often >200/120 mm Hg, hypertensive retinopathy (flame hemorrhages, cotton wool spots, papilledema) and renal damage (6). Thrombotic microangiopathy (TMA) is a coagulation system disorder resulting in extensive clot formation within small blood vessels. MH has a low prevalence and incident rate of 5/100,000 within the Caucasian population (7) & a prevalence of about 3.2% in the African American (AA) population (8). There is a paucity of reported cases of biopsy proven MH-TMA. Publications have reported a prevalence of up 25%, but variations exist due to results based on lab tests without confirmatory renal biopsy (7).

Case Description: A 43 y/o AA male with medical history of Tobacco Abuse, EtoH abuse & HTN presented with 1 week of abdominal discomfort & BP of 232/118mmhg. Notable initial findings & management found in figure 1. Extensive workup confirmed presence of TMA with renal biopsy findings showed inter- lobular artery "onion skin" thickening with a narrowing lumen, intimal fibrosis, ischemic glomerulus and thrombi within glomerular arteriole with features of chronic tubulointerstitial nephropathy.

Discussion: Microangiopathic hemolytic anemia (MAHA) defined as an intrinsic mechanical destruction of erythrocytes; underlying etiologies are grouped into primary TMA (TTP,HUS,aHUS) & secondary TMA (MH,DIC,Drug induced). The exact mechanism MH-TMA is unclear but the proposed theory consists of hypertension induced shearing & endothelial damage of arterioles and glomerular capillaries which advances to TMA (3). The challenge to swiftly identify MAHA is due to overlapping symptomatic presentations of TTP, HUS, atypical HUS/CM-TMA & MH-TMA. Ultimately, when presenting symptoms consist of severe hypertension, anemia, thrombocytopenia and progressive renal dysfunction should raise suspicion for MH induced TMA. Renal biopsy is the gold standard to assist in diagnostic confirmation of MH induced TMA & management entails aggressive blood pressure control.



PUB420

Prevalence of CKD and Its Relationship with Cardiovascular Risk: An Experience from Calcutta School Teachers' Cardiovascular Health Study Using Atherosclerotic Cardiovascular Disease (ASCVD) Model

Madhab Ray.[1,2] Healthy Heart Initiative Study Group. *[1]UC Davis Health, Sacramento, CA; [2]Tufts Medical Center, Boston, MA.*

Background: Cardiovascular disease (CVD) is the number one cause of death in high-income nations. Chronic kidney disease (CKD) shares most of the traditional risk factors with CVD. CVD event rates are much higher when CKD is a comorbidity. This study aimed to assess the relationship of CKD with CVD risk estimated by ASCVD model.

Methods: Cardiovascular risk factors and kidney function were evaluated in 4,140 schoolteachers in Calcutta, India in the summer of 2019 with joint approval of Tufts University IRB, Boston, and the local Ethics Committee, Calcutta. CVD risk was evaluated using the American College of Cardiology ASCVD risk calculator and stratified as mild (<5), moderate (>5 and <10) and high (>10). Kidney function was evaluated using serum creatinine level and eGFR calculated with CKD-Epi equation. Two-way Anova was used to evaluate the relationship between estimated GFR and ASCVD risk categories.

Results: The mean age of the participants was 44 years and 41% were male. Most participants (86%) were categorized as low risk for CVD, while 12% and 2% of the participants had moderate and high risk, respectively. Most participants had CKD G2 (n = 125, 52%) followed by G1 and G3 (n = 53, 22% each). Six participants had CKD G3B while number of participants in G4 and G5 were one in each category. There were no significant differences in the GFR among the different ASCVD risk categories (p-value > 0.05).

Conclusions: Our study failed to demonstrate any significant difference in GFR among the different CVD risk categories. In a randomized sample stratified by the CVD risk a high proportion of participants were found to be diabetic, previously not diagnosed. This discrepancy possibly led to under estimation of the CVD risk of the participants while their GFR was overestimated because of their underlying hyperglycemia. Further studies are necessary to ascertain the community burden of CKD and to explore the complex relationship between CKD and different traditional and nontraditional cardiovascular risk factors.

Cardiovascular risk categories and their relationship with estimated GFR

ASCVD Risk Category	Male	Female	Combined	GFR (mean) +/-SD
Low	78	114	192 (86%)	74.92 +/- 20.76
Moderate	21	7	28 (12%)	72.32 +/- 17.43
High	17	3	20 (2%)	76.95 +/27.29

Two-way Anova p value not statistically significant

PUB421

Hydralazine-Induced ANCA-Associated Vasculitis with Pulmonary Involvement

Shemrine Mark,[1] Jonathan London,[1] Mario Mekhail,[1] Olena Bolotova,[2,1] Ayse S. Durgun,[3,1] Mohammed S. Rahman.[2,1] *[1]Long Island Community Hospital, Patchogue, NY; [2]Brookhaven Nephrology Associates, Patchogue, NY; [3]NYU Langone Pulmonary Associates, East Patchogue, Patchogue, NY.*

Introduction: Hydralazine is a frequently used antihypertensive associated with ANCA vasculitis. Clinical symptoms range from benign to multiorgan involvement like alveolar hemorrhage and glomerulonephritis which can be fatal if not treated in a timely manner. It is important to be aware of this association for timely treatment and management.

Case Description: A 64-year-old male with a pmh of ESRD on hemodialysis for 5 years due to hypertensive nephropathy, Coronary artery disease presented to the emergency department for low hemoglobin. The patient complained of chronic fatigue, cough and denied any other complaints. Vitals were stable with conjunctival pallor on exam. The patient has had frequent hospital visits for weekly blood transfusions. Laboratory results showed hemoglobin of 6.2(13.7-17.5 g/dL). CT chest showed bilateral ground glass opacities. Evaluation of anemia included endoscopy, colonoscopy and bone marrow biopsy which were negative. Treatment included iron, darbepoetin alfa, weekly blood transfusion and pantoprazole. Due to recurrent transfusions and inflammatory changes on imaging autoimmune workup was done. Results showed ESR 51(0-15mm/hr), CRP 28.8(0-3mg/L), positive ANA, MPO ANCA >8(<1AI), anti-histone antibodies 2.1(0-0.9 units), low complement level and normal thyroid function. Hydralazine was discontinued and the patient was treated with pulse steroids. Patient had a lung biopsy which showed bronchiolar fibrosis with hemosiderin laden macrophages, perivascular chronic inflammation with necrosis consistent with treated granulomatosis with polyangiitis. Patient was reported to be on hydralazine for at least 2.5 years maximum dose 100 mg three times daily. Patient reported improvement in symptoms with stabilization of hemoglobin on follow up appointment.

Discussion: ANCA vasculitis is a rare disease with an incidence of 10-20 cases per million people. Of the patients with hydralazine induced vasculitis only 18% had pulmonary involvement. Mechanism is unclear. However, risk factors include thyroid disease, increased dose and duration of drug use, female sex and slow acetylators. Diagnosis is made through history, serology for anti-histone antibodies, ANCA, low complement and biopsy of affected organs. Treatment includes discontinuation of hydralazine and immunosuppressive therapy with pulse steroids, rituximab and or cyclophosphamide.

PUB422

Prehypertension and Hypertension among University Students in Bahrain: Study of Prevalence and Associated Risk Factors

Amgad E. El Agroudy. *Arabian Gulf University, Manama, Bahrain.*

Background: In the last twenty years, hypertension has become more common among younger age groups. Based on a global meta-analysis, the combined prevalence of hypertension and prehypertension were 4.0% and 9.7%, respectively. This study aimed to evaluate the prevalence of prehypertension and hypertension among university students and their associated risk factors.

Methods: Four hundred and eleven students aged between 18 and 25 (196 males and 215 females) were randomly selected to participate from College of Medicine and Medical Sciences (CMMS) and the College of Business Administration. The data was collected through a structured questionnaire, which gathered information about lifestyle habits. Trained students measured the participant's blood pressure and body mass index (BMI) according to standardized settings. All risk factors were studied according to the studying field and their gender.

Results: The mean age of the participants was 16.4±0.9 years. Of the total participants, 61.3% (n= 252) were normotensive, 30.7% (n= 126) were pre-hypertensive, and 8% (n= 33) were hypertensive. The prevalence of hypertension and prehypertension was higher in male students, 13.8% (n=27) and 44.9% (n= 88), compared to female students, 2.8% (n=6) and 17.7% (n=38), respectively. The results of the univariate analysis showed an association of hypertension with the field of study, gender, age, BMI, exercise frequency, frequency of eating junk food, and family history of hypertension ($p < 0.05$). Multivariate logistic regression analysis found a significant association between hypertension and pre-hypertension with gender, the field of study, and BMI.

Conclusions: The findings of the study revealed that hypertension and prehypertension are common among university students in Bahrain. The risk factors for these conditions include studying medicine, being male and being obese.

PUB423

Therapeutic Inertia of Hypertension and Physician Logic

Benjamin Strickland, Talar Markossian, Grant T. Hiura, Holly J. Kramer. *Loyola University Chicago, Chicago, IL.*

Background: Therapeutic Inertia (TI), the lack of escalation or initiation of blood pressure (BP) lowering medications during clinic visits with BP ≥ 140/90 mmHg occurs in majority of clinic visits among older adults. It remains a major barrier for achieving BP control. We reviewed a random selection of university affiliated outpatient primary care clinics with documented TI to elucidate reasons for not escalating treatment.

Methods: The source population included 7215 patients aged ≥65 with ICD-10 diagnosis of hypertension and ≥1 visit with uncontrolled BP at a university-affiliated clinic from January 2019 to December 2020. Uncontrolled BP was defined as a clinic systolic BP ≥140 mmHg and/or diastolic BP ≥ 90 mmHg confirmed with blood pressure measured 3 times in 1-minute intervals and averaged. Two investigators reviewed 101 unique patient outpatient clinic visits with documented TI in source population. A priori, reasons for TI were categorized as acute symptoms/illness, stress/pain, noncompliance, patient refusal, side effects and documentation of home BP < 140/90 mmHg. If more than one reason was present in a note, all reasons were included.

Results: The mean age of the 101 patients was 76.2 years (Standard Deviation [SD] 8.7) during the clinic visist. Comorbidities included diabetes mellitus in 35%, chronic kidney disease in 13% and cardiovascular diseases in 35%; 90% were covered by Medicare insurance. The mean total number of BP lowering medications was 1.8 (SD 0.92). Overall, 38% of charts lacked documentation justifying the TI; 51% overall had uncontrolled blood pressure at the subsequent clinic visit. Figure 1 shows the documented reasons for TI. Acute medical illness was the most common justification found(17%). No encounter had documentation of orthostatic hypotension. Overall 38% of encounters lacked documentation justifying the TI.

Conclusions: TI is common among older adults and may be due to clinician attention to acute illnesses, pain and stress. However, a substantial proportion of TI may not be justified.

PUB424

Prospective Study on the Analysis of High-Sensitivity Troponin T in Patients with Hemodialysis: Cutoff Points and Cardiovascular Outcomes

Renato E. Eick,[1] Priscila Werner,[1] Gabriel Sartori Pacini,[2,1] Milton Kalil,[1] Mauricio L. André,[1] Renata A. Schuchmann,[2] Luiz Nasi,[1] Carlos A. Ferreira,[1] Anna C. Stein,[1] Camila M. Melere,[1] David Saitovich.[1] *[1]Hospital Moinhos de Vento, Porto Alegre, Brazil; [2]Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil.*

Background: Patients with chronic kidney disease on dialysis may present troponin levels above the normal value even outside the context of suspected acute myocardial infarction. Even so, there is no clear established cutoff value in this population. Our aim was to evaluate and determine the basal troponin levels of each patient with CKD dialysis in a reference dialysis center in addition to assess cardiovascular outcomes.

Methods: We prospectively included consecutive patients with CKD on dialysis at a tertiary center in Southern Brazil. Mean, median and standard deviations of high-sensitive troponin T were assessed. Also, we correlated these values with other variables such as age, sex, hemoglobin levels, and iron measures to predicte an increased risk of cardiovascular mortality and mortality for other causes. The Receiver Operating Characteristic (ROC) curve was used to estimate the best cutoff point for pre-dialysis troponin levels to predict death within 24 months.

Results: During two-year follow-up, 88 dialytic patients were included. Mean age was 67 years, and most participants were male (62%). The troponin value using the pre-hemodialysis median was 64.7ng/L. In patients with previous ischemic heart disease and/or diabetes, this value is statistically higher. When we relate troponin to chest pain during dialysis or need to emergency room visits due to chest pain and death, the probability of death within 24 months is significantly higher in patients with troponin levels equal to or above 83.3 (p<0.001). The cut off value of 83.3 ng/L has a sensitivity of 75%, specificity of 80.9%, positive predictive value of 53.9% and negative predictive value of 91%, with accuracy of 79.5% to predict long-term mortality.

Conclusions: In our sample a cut off level of hS-TnT greater than 83.3 ng/L was associated with cardiovascular mortality and for other causes. Determining the median troponin value of a hemodialysis service and the basal troponin value of patients can improve the management of care by reducing the time to diagnose AMI and to avoid unnecessary measures, if the value remains constant at the patient's baseline.

PUB425

Feasibility of Near-Infrared Spectroscopy and Peripheral Arterial Disease Risk in CKD

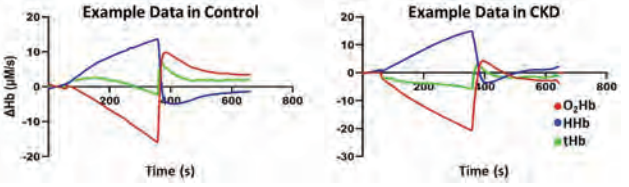
Stephanie E. Thompson, Ilhae Bok, Natasha Wiebe, Aminu K. Bello, Michael K. Stickland. *University of Alberta, Edmonton, AB, Canada.*

Background: Peripheral arterial disease (PAD) is common in chronic kidney disease (CKD). The role of microvasculature (MV) in the development and progression of PAD is recognized. Near-infrared spectroscopy (NIRS) tests muscle oxygen utilization (mVO2) and reactive hyperemia (MV function) non-invasively but its role in CKD and PAD is unknown. We evaluated NIRS feasibility and compared parameters in severe CKD with healthy controls. We explored its reliability and correlation with a MV referent test, velocity time integral (VTI).

Methods: A priori, feasibility was ≤10% of tests with i. discomfort and test termination ii. incomplete ischemic occlusion or iii. uninterpretable data. Participants completed baseline tests, Doppler US with reactive hyperemia from brachial and popliteal arteries for VTI and NIRS from the tibialis anterior muscle. An ischemic occlusion 50 mmHg above systolic BP for 5 minutes was used. The CKD group had repeat testing <14 days. Diagnostic accuracy testing was planned for NIRS and VTI correlations >0.7 and intraclass correlation coefficients (ICC) > 0.7.

Results: 39 CKD 5/5D and 20 controls participated. CKD participants were older with higher median systolic BP 135 mmHg [125,150] vs 109 [102,118], ABI 1.12 [1.03,1.20] vs 1.02 [0.89,1.06] and TBI 0.82 [0.77,0.92] vs 0.98 [0.93,1.03]. In CKD, 9 tests (23%) were terminated due to discomfort from the ischemic provocation vs none in controls. In CKD, 20% of tests had incomplete occlusions vs 10% in controls and 13% were uninterpretable vs 0% in controls. In CKD, brachial artery peak VTI was 55.8 cm [42.7, 71.3] vs 82.8 cm [76.2,97.3] in controls (P<0.001). Popliteal peak VTI results were similar. Median mVO2 was higher in CKD: 0.25 %/second [0.23,0.28] vs 0.20 [0.18,0.24] (P=0.007) and reactive hyperemic response was lower in CKD oxyhemoglobin recovery slope 0.61 μM/sec [0.50,0.93] vs 0.93 [0.69,1.21] (P=0.007) (Figure). No NIRS tests had correlations >0.7 and ICCs >0.7.

Conclusions: Ischemic provocation limited feasibility. mVO2 and reactive hyperemia from NIRS in CKD was consistent with muscle adaptations in PAD. Applications of NIRS in PAD should be evaluated in larger studies using alternative provocation tests.



PUB426

Examining Circadian Blood Pressure Patterns: Investigating the Interplay between Dipper Status and Arterial Stiffness Metrics

Chanwoo Nam, Negiin Pourafshar. *MedStar Georgetown University Hospital Nephrology Services, Washington, DC.*

Background: Compared with dippers, hypertensive individuals with a nondipping nocturnal blood pressure (BP) pattern, often present with heightened target organ damage and a bleaker cardiovascular prognosis, influenced by arterial stiffness. Tonometric pulse wave velocity (PWV) and Augmentation index (AI) have been confirmed as a non-invasive method for arterial stiffness evaluation. The purpose of this study was to assess the relationship between nocturnal blood pressure dipping and arterial stiffness in the hypertensive subjects.

Methods: This was a retrospective study of patients underwent ambulatory blood pressure monitoring (ABPM) between April 2021 and April 2022 at our institution. 41 subjects with essential hypertension were included, mean age 55.6 (42% female, 58% male). BP measured by ambulatory monitoring every 20 min between 07:00 am and 23:00 pm and every 30 min at night, throughout 48 hours with a Mobil-o-graph device. Carotid-femoral PWV and AI also measured as an index of aortic stiffness, by using the Mobil-o-graph which uses a validated transfer function. Dipping was defined as a 10-20% fall in nocturnal BP; extreme dipping as greater than 20%, nondipping as less than 10%, and reverse-dipping as 0% at most fall in nocturnal BP.

Results: The relationship between PWV and percent of fall in nocturnal SBP (percent of dipping) had negatively related with univariate generalized linear model (coefficient = -0.148, p-value = 0.007). Following multivariate adjustment for age, gender, mean arterial pressure and AI, percent of dipping becomes a variable without significant effect to model (coefficient = -0.408, p-value = 0.110). Age and percent of dipping has significant negative relationship (coefficient = -0.145, p-value = 0.0247) and age is strongly positively related with PWV (coefficient = 0.134, p-value = 0.000001). When multivariate adjustment is made for gender, mean arterial pressure and AI, percent of dipping remains significant variable to model (coefficient = -0.126, p-value = 0.009)

Conclusions: Percent of fall in nocturnal SBP has significant negative correlation with PWV. When adjusted with age, percent of fall in nocturnal SBP becomes insignificant variable. This is because age is a confounding variable to multivariate model. Elderly patients have less percent of fall in nocturnal SBP which leads to higher PWV.

PUB427

A System-Based Initiative to Improve Screening for Primary Aldosteronism (PA) in Patients with Resistant Hypertension

Medha Airy,[1] Michael Fordis,[1] Tresa Mcneal,[2] Derek Meeks,[1] Jacob S. Minor,[2] Daniel R. Murphy,[1] Michael J. Mcneal,[2] Jason E. King,[1] Michael O'Connor,[1] Abraham Mendoza,[1] Mohanram Narayanan,[2] Sara Bedrose,[1] Arindam Sarkar,[1] Jason D. Ramm,[1] Rory R. Laubscher,[1] Penny M. Coots,[2] Hania Janek,[2] Ashok Balasubramanyam,[1] F David D. Winter.[2] *[1]Baylor College of Medicine, Houston, TX; [2]Baylor Scott & White Medical Center Temple, Temple, TX.*

Background: PA is increasingly recognized as an under-screened etiology of resistant hypertension for all patients including those with chronic kidney disease. The specific aim was to increase the screening rates for PA by 25% over baseline.

Methods: The study aimed to change PA screening and referral practices of primary care clinicians operating in two diverse health systems: a health science university [HSU]

and a large health system [HS]. Customized interventions, adapted to each system's workflow, included live meetings; online modules in an indexed library to support just-in-time education, and point-of care education delivered via the EHR using a best practice advisory (BPA) to identify patients at risk for PA. Each health system collected data on three targeted metrics measured pre- and post-intervention: overall screening rates for PA [primary metric], referrals of patients with positive screening results to appropriate subspecialty department (i.e., nephrology, endocrinology, cardiology), and total diagnoses of PA after controlling for patient populations [secondary metrics].

Results: For the primary metric, baseline screening rates of 1.4% (HSU) and 0.015% (HS) of patients improved at post intervention to 7.1% (~5-fold increase) and 0.117% (~8-fold increase), respectively. A *z* test for independent proportions applied to each dataset indicated statistical significance ($p < 0.001$ for each analysis). Use of statistical control charts with special cause analysis allowed us to track for each of the three metrics whether intervention effects emerged, and if so, whether higher levels of performance continued and stabilized over time or degraded. Enhanced screening rates following the intervention were evident in the control charts, which continued during the 16-month post period. Regarding secondary metrics, rates of referral and diagnosis evidenced similar trends in meeting the conditions for detecting special cause, with elevated gains sustained longitudinally.

Conclusions: PA is an important cause of resistant hypertension. Increasing awareness of this diagnosis amongst clinicians can improve diagnosis and outcomes in patients.

PUB428

Study of Pulmonary Hypertension in Patients with CKD in a Teaching Hospital

Geetika Gorrepati. *Tulane University, New Orleans, LA.*

Background: Pulmonary hypertension is defined as a mean artery pressure >25 mm Hg and is a serious and progressive complication of chronic kidney disease and end-stage renal disease. Identifying pulmonary arterial hypertension (PAH) can be challenging but is important in this population since management strategizes differ from those for patients with ESKD who donot have PH.

Methods: This was an observational cross section study conducted on 85 patients of CKD stage 4 and 5 (based on KDIGO 2012 criteria) admitted to the medicine wards in Mamata academy of medical sciences, bachupally Hyderabad from the year 2022-2023

Results: In our study 35.2 % cases showed no PAH. Mild PAH noted in 23.5% cases, Moderate PAH noted in 36.4% cases and 4.7% showed severe PAH. systolic and diastolic blood pressure with PH showed significant association. Presence of haemodialysis significantly associated with PH. Significant association was seen with age and BMI. Low haemoglobin was also significantly associated with PH.

Conclusions: CKD patients have a higher prevalence of pulmonary hypertension. The prevalence of pulmonary hypertension is high in stage 5 CKD patients, and it is also higher in dialysis patients.

Racial and Ethnic Disparities in the Association of Sleep-Disordered Breathing Diagnosis with Hypertension Severity at Baseline in Youth Referred for Hypertension Disorders

Elizabeth A. Onugha,[1,2] Andrew M. South,[3] Sahar Siddiqui,[2,1] Ashna Pudupakkam,[2,1] Carol Vincent,[3] Fallon Campbell,[1,2] Giya Harry.[3] *[1]Texas Children's Hospital, Houston, TX; [2]Baylor College of Medicine, Houston, TX; [3]Atrium Health Wake Forest Baptist Medical Center, Winston-Salem, NC.*

Background: Sleep-disordered breathing (SDB) is associated with a higher risk of hypertension (HTN). Black/African Americans with SDB have more severe disease and are more susceptible to uncontrolled HTN compared with White adults. While Black/African American youth have a higher prevalence of SDB compared to White youth, racial and ethnic disparities in the association of SDB with HTN severity remain unknown. We set out to describe racial/ethnic differences in the association of SDB with baseline HTN severity in youth.

Methods: Retrospective cross-sectional analysis of baseline data from the Study of the Epidemiology of Pediatric HTN (SUPERHERO), a multisite Registry of youth referred to subspecialty care for HTN disorders using electronic health record data. Inclusion criteria were an initial subspecialty clinic visit for HTN disorders identified by ICD-10 codes from 1/1/2016–12/31/2023 and age <19 years. Exclusion criteria were youth on dialysis, kidney transplantation, or pregnancy by ICD-10 codes, as well as missing race or ethnicity data and blood pressure not in the HTN range. The exposure was SDB identified by ICD-10 codes. The outcome was stage 2 vs. stage 1 HTN based on age, sex, and height-based U.S. guidelines. We conceptualized race/ethnicity as a social construct and defined it as an effect modifier. We estimated the associations with unadjusted generalized linear models with an interaction term and stratified models.

Results: Of our cohort of 5,562 participants, mean age was 13.3 years (SD 4.1), 38% were male, 58% were White, 22% were African Americans and 19% were Hispanic/Latino. 39% had stage 2 HTN and 6% (n=549) had a diagnosis of SDB. Overall stage 2 HTN risk by SDB was 0.9 (95% CL 0.9–1.0). There was no significant effect modification, and stratified analyses showed no significant association in any group.

Conclusions: In our large cohort of youth referred for hypertension disorders, we did not observe racial or ethnic differences in the association of SDB with HTN severity at baseline. Equitable screening for and management of SDB in all populations is imperative.

PUB430

Effect of Early Spironolactone Treatment on Albuminuria in Patients with CKD and Hypertension: A Randomized Controlled Trial

Nattakarn Anantasamit, Kamolwan Pakchotanon. *Bhumibol Adulyadej Hospital, Bangkok, Thailand.*

Background: Recent research emphasizes non-steroidal mineralocorticoid receptor antagonists (MRAs) for slowing chronic kidney disease (CKD) progression and reducing albuminuria. However, there is limited research on the efficacy of spironolactone, a more accessible and low-cost steroidal MRA.

Methods: This randomized controlled trial was conducted at Bhumibol Adulyadej Hospital, Bangkok, Thailand, from October 2023 to February 2024. Participants had hypertension and CKD stage 2-3 (eGFR 30-89 ml/min/1.73 m2) and were already receiving ACEI or ARB medication. Eleven patients were enrolled: five received spironolactone, and six did not. Both groups received standard hypertension care. Follow-up evaluations were conducted at 3 months.

Results: Patients receiving spironolactone showed a mean decrease in urinary albumin-to-creatinine ratio (UACR) of 655.00 ± 621.82 mg/g, compared to 320.50 ± 504.87 mg/g in the control group, resulting in a difference of 295.92 mg/g (95% CI: -942.33 to 350.49; p = 0.370). The change in eGFR was -8.64 ± 9.12 ml/min/1.73 m2 in the spironolactone group and -3.38 ± 14.62 ml/min/1.73 m2 in the control group, with a difference of -5.26 ml/min/1.73 m2 (95% CI: -16.77 to 6.69; p = 0.400). The change in systolic blood pressure (SBP) was -21.80 ± 20.64 mmHg vs. -22.00 ± 24.79 mmHg (difference: 0.20 mmHg, 95% CI: -39.74 to 10.49; p = 0.254). The mean serum creatinine levels were 1.61 ± 0.90 mg/dL in the spironolactone group and 1.10 ± 0.14 mg/dL in the control group, differing by 0.51 mg/dL (95% CI: 0.07 to 0.95; p = 0.009). The mean potassium levels were 4.90 ± 0.43 mmol/L and 4.23 ± 0.41 mmol/L, respectively, differing by 0.67 mmol/L (95% CI: 0.22 to 1.08; p = 0.003).

Conclusions: Spironolactone did not significantly decrease albuminuria in hypertensive CKD patients already on ACEI or ARB therapy but was associated with increased potassium and creatinine levels. The study's findings are limited by the small sample size and short duration.

PUB431

The Persistent Challenge of Resistant Hypertension in CKD

Jennifer Lafave, Meghan Weiss. *Spherix Global Insights, Exton, PA.*

Background: Many nephrology and cardiology patients suffer from both hypertension and chronic kidney disease (CKD). These patients are burdened with complicated treatment regimens that are difficult to follow, which makes it challenging to achieve target blood pressure goals.

Methods: Data from 156 US physicians (76 nephrologists and 80 cardiologists) was collected via an online survey conducted in March 2024.

Results: Physicians report that half (54%) of their CKD Stage 1 and 2 patients have hypertension as a comorbidity and as these patients advance in their CKD, the prevalence of hypertension increases substantially. Approximately one-third (36%) of CKD patients with hypertension are estimated to be poorly controlled on their current treatment regimen and 14% are classified as having "resistant" hypertension, which occurs when blood pressure levels remain elevated despite treatment with maximum tolerated doses of at least three antihypertensive drugs. Both nephrologists and cardiologists rank resistant hypertension as one of the most challenging cardiorenal conditions to manage and consider it to have a high unmet need for new treatment options. Physicians report that they struggle with optimizing and simplifying medication regimens that make it feasible for patients to adhere to treatment regimens. Nephrologists and cardiologists express strong interest in newly approved and pipeline agents for hypertension. They are eager to begin prescribing aprocintentan once it is available and report that more than one-quarter of their hypertensive CKD patients are candidates for treatment. Baxdrostat (an aldosterone synthase inhibitor) also garners high interest from specialists to treat uncontrolled hypertension. As new agents become available, physicians will primarily seek information related to their respective clinical trial data, degree of advancement over other available therapies, the ability to address multiple indications, and cost implications to help them determine appropriate candidates for treatment.

Conclusions: New pipeline products for hypertension, especially those tested in the CKD patient population, will offer nephrologists and cardiologists alternative treatment options to more effectively address one of the most challenging conditions that they face.

PUB432

Body Mass Index and Hypertension Risk among a Coptic Adolescent Population

Ivana Boktor,[1] Ahmed E. Ali,[2] Ammar Almehmi.[3] *[1]George Walton Comprehensive High School, Marietta, GA; [2]Mayo Foundation for Medical Education and Research, Rochester, MN; [3]The University of Alabama at Birmingham, Birmingham, AL.*

Background: Elevated Body Mass Index (BMI) is a significant risk factor for developing hypertension (HTN). Other factors, including family history, smoking, and energy drink consumption, can potentially increase risk for HTN. Limited data are available on the risk factors for HTN in Coptic adolescent population. This study sought to investigate association between these risk factors and HTN in Coptic adolescents.

Methods: A screening survey was conducted on 140 high school students who attended church services. After signing a consent form, each participant was interviewed and asked to answer the survey questions. The blood pressure was measured twice after 15 minutes of rest using Omron device. Both weight and height were measured, and BMI was calculated using CDC BMI calculator. Descriptive statistics, univariate, and multivariable logistic regression analyses were used to explore the relationship between the HTN and other potential variables.

Results: The cohort included 70 females (50%) and 70 males (50%) aged 16-21 years old. The overall prevalence of HTN was 45.7% (73% in males and 18.6% in females). Participants were categorized by BMI into normal (n=78), overweight (n=44), and obese (n=18) groups. Compared to normal weight group, the odds ratio (OR) for HTN in overweight and obesity groups was 7.2 (95% C.I. 3.1 – 16.6, p<0.001) and 1.9 (95% C.I. 0.67 – 5.5, p=0.27), respectively. After adjustment for potential confounders such as age, sex, family history of HTN, and consumption of energy drinks, the adjusted ORs were 4.9 (p=0.001) and 1.1 (p=0.9) in overweight and obesity groups, respectively. Among total cohort, hypertensive individuals exhibited significantly higher BMI compared to normotensive individuals (26.3 [23.5, 28.3] vs. 22.5 [20.6, 25.7], p=0.001). However, there was no association between HTN and other covariates (p>0.05). In multivariable logistic regression, the association between HTN and elevated BMI remains significant (adjusted OR 3.7, 95% C.I. 1.5 – 8.7; p=0.003).

Conclusions: Our findings are consistent with accumulative evidence about positive relationship between BMI and HTN, which is a part of the metabolic syndrome. Moreover, this is the first study to investigate risk factor profile for HTN in Coptic adolescents. Larger scale epidemiologic studies are needed to assess prevalence of HTN in this population and the best approach to manage these modifiable risk factors.

PUB433

Impact of Systemic Lupus Erythematosus on Cardiovascular Morphologic and Functional Phenotypes

Zishan Lin,[1] Wenfeng Wang,[1] Bingjing Jiang,[1] Jian He,[2] Yanfang Xu.[1] *[1]The First Affiliated Hospital of Fujian Medical University, Fuzhou, China; [2]Southern Medical University Nanfang Hospital, Guangzhou, China.*

Background: Previous studies have established a correlation between systemic lupus erythematosus (SLE) and the cardiovascular system, but the potential causal implications of SLE on the cardiac and aortic morphology remain unclear. Cardiovascular magnetic resonance (CMR) imaging, a novel and non-invasive modality, uniquely assesses cardiovascular structure and function, serving as risk biomarkers. In this study, we conducted a Mendelian randomization (MR) analysis to ascertain the causal connection between SLE and CMR traits.

Methods: Genetic variants independently linked to SLE were selected from a genome-wide association study (GWAS) containing 5,201 cases and 9,066 controls as instrumental variables. A set of 82 CMR traits was obtained from a recent GWAS, serving as preclinical indicators to provide preliminary insights into the morphology and function of the four cardiac chambers and two aortic segments. Primary analysis employed a two-sample MR study using the inverse-variance weighted method. Heterogeneity testing, sensitivity analyses, and instrumental variable strength assessments confirmed the robustness of the findings.

Results: SLE exhibited a correlation with increased stroke volume (β=0.007, P=0.045), regional peak circumferential strain (β=0.013, 0.009, 0.013; P=0.002, 0.043, 0.006), and global peak circumferential strain of the left ventricle (β=0.010, P=0.022), as well as decreased left ventricular regional radial strain (β=-0.010, P=0.017) (Figure.).

Conclusions: This research presents evidence of a potentially causal association between traits of SLE and alterations in the structure and function of the cardiac and aortic systems, offering guidance for cardiac examinations and disease prevention in lupus patients.

Funding: Government Support - Non-U.S.

Multiple Office Blood Pressure Measurement for Hypertension Diagnosis in Children

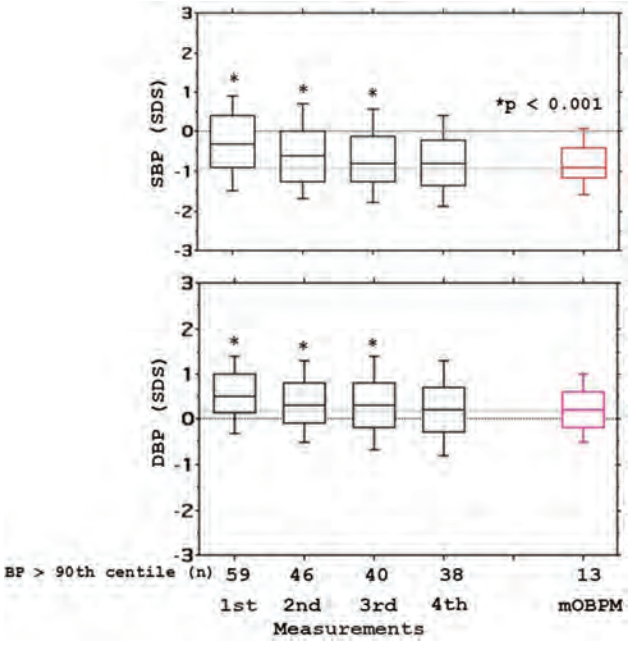
Letizia Dato,[1] Maria Cristina Mancuso,[2] Laura Viola,[3] Giacomo Tamburini,[2] Daniele Rossetti,[2] Andrea Gualtieri,[4] Gianluigi Ardissino.[2] *[1]Università del Piemonte Orientale, Division of Pediatrics, Department of Health Sciences, Novara, Italy; [2]Fondazione IRCCS Ca'Granda Ospedale Maggiore Policlinico, Pediatric Nephrology, Dialysis and Transplantation Unit, Milan, Italy; [3]Ospedale di Stato, ISS San Marino, Pediatric Unit, San Marino, San Marino; [4]ISS San Marino, Health Authority, San Marino, San Marino.*

Background: Blood pressure (BP) measurement (M) in children may be challenging. International guidelines suggest measuring BP 3 times. In a previous study, we reported that the first 3 readings are unreliable. At our Centre, multiple Office BPM (mOBPM) is the standard practice for hypertension diagnosis in children since 2010. It consists of 10 serial readings taken at 3-minute intervals using a validated automated oscillometric device. After discarding outlier readings (<5th and >95th centile), the coefficient of variation (CV) and the remaining systolic (S) and diastolic (D) BP means are calculated by a software. This contribution is aimed at testing mOBPM in a children cohort to bolster its use as a practical tool to assess BP in children.

Methods: School children underwent mOBPM at baseline and after 12 months. After excluding series with a CV>15%, the mean SBP and DBP values obtained by mOBPM were compared with each of the first 4 M (t test for paired data). The number of children with BP>90th centile within those M was also determined.

Results: One hundred and seventy-five children (93 females, 53%) with a mean age of 8.6±0.3 and a mean BMI of 17.5±2.9 (BMI>20 n=34; 19%) were enrolled. Thirteen mOBPM were excluded for a CV>15% in SBP or DBP. As represented in **Figure 1**, the remaining 328 mOBPM showed that the mean of the first 3 SBP and DBP values were higher (p<0.001) than those obtained with mOBPM. The same held true for the mean of the 2nd and 3rd M, whereas the 4th was the first one not significantly different from mOBPM. The number of children with BP>90th centile by each reading and by mOBPM is also provided.

Conclusions: Relying on the first 3 M overestimates the number of hypertensive subjects, prompting unnecessary diagnostic and therapeutic pathways. The 4th is more reliable but mOBPM provides a better evaluation of BP particularly when initial readings show higher than normal values.



PUB435

Onconephrology's Public Awareness and Interest Landscape, 2020-2024: Trends Underscore Need for Enhanced Engagement

Priscilla Koirala, Charat Thongprayoon, Oscar A. Garcia Valencia, M. Salman Sheikh, Jing Miao, Iasmina Craici, Maria Lourdes Gonzalez Suarez, Swetha Rani Kanduri, Sandra Herrmann, Wisit Cheungpasitporn. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Onconephrology, a specialized field at the intersection of oncology and nephrology, addresses the complex kidney-related issues in cancer patients and survivors. With the Internet increasingly becoming a vital resource for healthcare information, this study aims to explore the global and United States-specific Internet search interest in onconephrology from 2020 to March 30, 2024, utilizing Google TrendsTM as an analytical tool.

Methods: This investigation utilized Google TrendsTM to analyze search queries for "Onconephrology" globally and within the United States. The period of study extended from January 2020 to March 2024. We examined the search interest over time, identifying peak interest points, the lowest interest, and trends in recent interest compared to the previous year. These indices were contextualized against the backdrop of onconephrology's evolving role in healthcare.

Results: Throughout the five-year study period, the peak global search interest for onconephrology was observed on October 6, 2019, with a value of 100, denoting its highest popularity. Conversely, the lowest interest was recurrently observed at several points, starting from March 31, 2019, each reflecting minimal search activity. In the USA, the peak interest was on January 9, 2022, with the lowest and most recent interests mirroring the global pattern. Both global and USA-specific analyses revealed minimal seasonal effects on search interest, suggesting that fluctuations were likely influenced by non-seasonal factors, possibly including significant academic or clinical developments within the field.

Conclusions: This analysis underscores a generally ascending yet fluctuating interest in onconephrology, manifest both globally and within the United States. Despite periods characterized by intermittent peaks of interest, this trend highlights the necessity of amplifying public and professional interaction with onconephrology through tailored information campaigns and enhanced digital platform education. Future endeavors should focus on improving the accessibility and comprehension of online onconephrology resources, addressing the evolving informational needs of both the general public and healthcare professionals.

PUB436

From Remedy to Etiology: Pauci-Immune Necrotizing and Crescentic Glomerulonephritis following Immune Checkpoint Inhibitor Therapy

Gagan Aulakh, William P. Ott, Arshdeep Singh. *Jersey City Medical Center, Jersey City, NJ.*

Introduction: Immune checkpoint inhibitors (ICI) block inspections before attacking foreign cells widely used in various cancers. Renal IRAEs (Immune-Related Adverse Events), observed in 2-5% of patients, encompass pathologies like acute interstitial nephritis (AIN) and different glomerulonephritides. Prompt steroid commencement should be done before kidney biopsy following suspected renal IRAEs

Case Description: 82-year-old Filipino male was evaluated for experiencing fatigue, lethargy, and nausea persisting for one week. The patient has medical history of non-small cell lung carcinoma, undergoing ICI therapy (nivolumab and ipilimumab). The patient had desquamating generalized painful black skin lesions two months before and showed perivascular dermatitis with eosinophils, raising concerns about a potential drug reaction. Vital signs were within normal limits and examination was unremarkable except for lethargy and skin lesions. The initial laboratory results indicated non-anion gap metabolic acidosis with BUN 149 mg/dL (7-30) and creatinine 8.94 mg/dL (0.7-1.2). His renal functions were within the normal range during baseline assessments conducted three weeks ago. As a result, a diagnosis of acute renal failure was established. Tests were negative for relevant antibodies and infections. Our differential diagnosis included considerations for AIN, immune complex glomerulonephritis, or thrombotic microangiopathy, likely associated with immunotherapy. Patient was initiated on high-dose steroids i.e. methylprednisolone 125 mg daily. The patient exhibited an improvement in next 3 days in urine output and creatinine level to 4.38 mg/dL. Ultimately, a renal biopsy was performed for definative diagnosis, revealing pauci-immune necrotizing and crescentic glomerulonephritis with granulomatous interstitial nephritis and eosinophils. Then he was discharged on oral prednisone 50 mg daily. Hemodialysis was not required throughout the entire hospitalization period.

Discussion: Renal IRAE could manifest following the co-administration of drugs such as Proton Pump Inhibitors, NSAIDs, or other nephrotoxic medications. Managing renal IRAEs involves halting ICI therapy and steroids. If no improvement then Mycophenolate Mofetil or monoclonal antibodies like Infliximab may be given.

PUB437

Fatal Case of Crystalglobulin-Induced Nephropathy with Cardiac Nonamyloid Immunoglobulin Deposition Disease

Yusuke Ushio, Shun Manabe, Anna Nakai, Momoko Seki, Hiroshi Kataoka, Junichi Hoshino. *Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan.*

Introduction: Crystalglobulin-induced nephropathy (CIN) is a rare renal disorder associated with multiple myeloma(MM). Crystal-induced organ damage occurs in various organs, and the diagnosis is based on the presence of crystals in the affected tissues. In the context of cardiac deposition of monoclonal immunoglobulin, AL amyloidosis and monoclonal immunoglobulin deposition disease (MIDD) can be differentiated. When amyloidosis is excluded and light and/or heavy chain immunostaining is positive, the cardiac variant of MIDD, cardiac non-amyloid immunoglobulin deposition disease (CIDD), is diagnosed. There has never been a report of CIN combined with CIDD. Here, we report a case of severe acute kidney injury with gradually reduced cardiac function diagnosed as CIN combined with CIDD.

Case Description: A 55-year-old Asian woman presented with leg edema two weeks after COVID-19 infection. She exhibited renal dysfunction with Cr of 1.89 mg/dL, urinary protein 3+, and urinary occult blood 2+, and presented to our hospital. At the time of admission, her Cr was 2.4 mg/dL, IgG-λ M-protein was positive, and cryoglobulin was negative. Despite the initiation of hemodialysis due to anuria shortly after admission, her condition progressively deteriorated. Renal biopsy revealed a MPGN-like pattern of injury with proteinaceous thrombi in the glomeruli, arterioles, and interlobular arteries. Immunofluorescence staining was positive for IgG1 and λ light chains, consistent with monoclonal proteinaceous thrombi. Electron microscopy showed crystal-like structures in the glomeruli and arteries. Myocardial biopsy revealed λ light chain deposition, confirmed by immunoelectron microscopy. Bone marrow biopsy showed 10% plasma cells. The patient was treated with dexamethasone, daratumumab, and bortezomib as for MM. However, her renal function didn't recover. With a gradual decline in cardiac function, lactic acidosis and hypotension persisted, and she passed away.

Discussion: Both CIN and CIDD are rare diseases associated with monoclonal protein. CIN might involve the cardiac system as infarction. However, in this case, the same monoclonal protein affected the kidneys as crystals but directly damaged cardiomyocytes as intact light chains. Evaluation of each affected organ might benefit the patient for accurate diagnosis and appropriate treatment.

PUB438

The Final Hit: A Case of IgA Nephropathy with Pembrolizumab

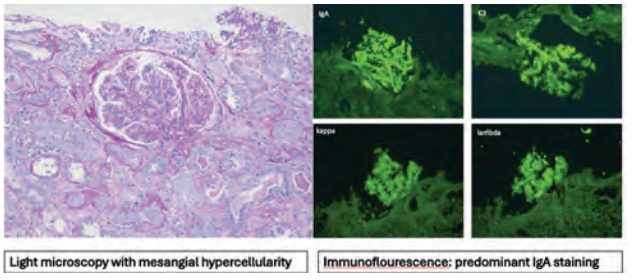
Sandipan Shringi,[1,2] Reginald Y. Gohh.[1,2] [1]*Rhode Island Hospital, Providence, RI;* [2]*Brown University Warren Alpert Medical School, Providence, RI.*

Introduction: Immune checkpoint inhibitors (ICI) have been implicated in the development of IgA Nephropathy (IgAN) and may not always respond to steroids leading to poor outcomes. We present a case of IgAN in a patient with lung cancer treated with pembrolizumab.

Case Description: A 73-year-old male presented with dark urine and dyspnea for a feew days and developed progressive AKI. He had a history of CAD, hypertension, DVT, tonsillectomy, soft palate invasive squamous cell carcinoma in 2012 treated with radiation, chronic dysphagia, and recently diagnosed bilateral lung squamous cell carcinoma in

2022 for which he was on carboplatin, paclitaxel and pembrolizumab for 3 months with latest dose 1 month ago. Physical exam was remarkable for tachypnea, bibasilar crackles without edema. Presentation labs were BUN 45 mg/dl, creatinine 2.77 mg/dl, Urinalysis with 3+ blood, >180 RBC, 51 WBC, 300 protein, urine culture had Enterococcus faecalis. UA 12 years ago had 6 RBC and one month ago had 3 RBCs. A chest radiograph showed multifocal interstitial and airspace opacities. Urine sediment had muddy brown casts, many isomorphic RBCs. C3 150 mg/dl, C4 28 mg/dl, ANCA, MPO, PR3, anti GBM were all negative, kappa chains 519 mg/L, lambda chains 216 mg/L, K/L ratio 2.4, serum IFE with 2 equivocal IgG kappa bands, urine IFE with equivocal IgG band. Renal biopsy had mesangial hypercellularity, focal endocapillary neutrophilic hypercellularity without crescents, several RBC casts, mild IFTA with predominant IgA staining on IF without C1q, fibrinogen or albumin and mesangial immune type electron dense deposits with partial foot process effacement on EM. He was treated with ceftriaxone but sCr did not improve and peaked at 9.4 mg/dl. He did not respond to pulse steroids which were then tapered. Due to poor overall health, he was not a candidate for chemotherapy or immunosuppression and transitioned to hospice. He died shortly after.

Discussion: IgAN occurs after four hits and our case was likely dormant for >10 years. It possibly got activated upon exposure to ICI but did not respond to steroids.



Light microscopy and Immunoflourescence

PUB439

Renal Thrombotic Microangiopathy Caused by Bevacizumab Treated with Eculizumab

Yasameen Fardi, Arash Rashidi, Daniel Grosser. *University Hospitals, Cleveland, OH.*

Background: 76 year old female diagnosed with hepatocellular carcinoma started Atezolizumab and Bevacizumab in March, 2023 and completed eight cycles in October, 2023. Prior to treatment her serum creatinine was 0.7mg/dL, urine albumin/creatinine 15mg/g. In November, she presented with creatinine 3.56 mg/dL, 3+ proteinuria on urine analysis.

Methods: Renal biopsy obtained revealed thrombotic microangiopathy with glomeruli showing double contours (Fig 1A), arterioles with mild to moderate subendothelial swelling (Fig 1B). Given these findings, she was started on Eculizumab, 900mg weekly for total of 4 doses. Eculizumab is a monoclonal antibody that targets complement protein C5, preventing cleavage of C5a and C5b and the formation of the terminal complement.

Results: When starting Eculizumab she required hemodialysis however after receiving three doses, she did not require further dialysis with signs of renal recovery.

Conclusions: Bevacizumab is a VEGF-A targeting monoclonal antibody that is associated with hypertension, proteinuria and renal TMA. VEGF-A increases endothelial cell survival and maintains vascular permeability. Inhibition of VEGF-A can cause damage of the glomerular filtration barrier and change in vascular tone. Initial treatment is drug discontinuation however our patient had no recovery after Bevacizumab was stopped. For this reason, Eculizumab was started with improvement of urine output and stabilization of serum creatinine off of dialysis. This case suggests further therapeutic role of Eculizumab for Bevacizumab associated TMA.

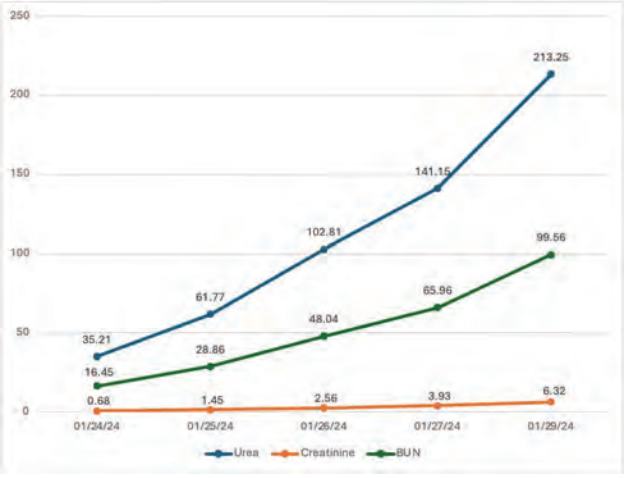
An Unusual Outcome after Hyperthermic Intraperitoneal Chemotherapy (HIPEC): AKI in a Patient Treated with HIPEC with Cisplatin

Jorge J. Font, Jorge E. Arch, Jose P. Castro, Fabiola Cassani, Javier Torres Figueroa. *Tecnologico de Monterrey - Campus Guadalajara, Zapopan, Mexico.*

Introduction: HIPEC stands at the forefront of innovative therapeutic approaches for managing select abdominal malignancies, revolutionizing the landscape of cancer treatment by combining an aggressive cytoreductive surgery with localized delivery of heated chemotherapy agents directly into the peritoneal cavity. Concerns regarding nephrotoxicity, particularly associated with the use of cisplatin, warrant attention. HIPEC has gained challenges such as excessive cost and the need for highly qualified personnel. In presenting this case, we exemplify the complexities of HIPEC-induced nephrotoxicity, highlighting the need for its timely recognition and management and the importance to consider and investigate post HIPEC CKD

Case Description: A 57-year-old Mexican female was hospitalized at the ICU after undergoing cytoreductive surgery and cisplatin-based HIPEC for peritoneal recurrence of ovarian cancer. Follow-up labs performed the next day revealed increased CR, urea, and BUN, suggesting impaired kidney function. Pre-op lab results did not indicate any type of risk factors or kidney injury before surgery. Renal function and diuresis continued to deteriorate over the following days. On the 4th day after surgery, presenting with anuria and unable to reverse her condition, the patient underwent an initial session of hemodialysis and has been dependent ever since with more than 5 months after surgery

Discussion: To our knowledge post HIPEC CKD information is scarce. AKI Post HIPEC has been noted as an important challenge due to the nephrotoxic properties of cisplatin but progression to CKD remains unclear. Nevertheless, the development of HIPEC-induced AKI with the possibility of CKD should not deter its use but rather emphasize the importance of raising awareness of searching for preventive strategies in aims of enhancing its effectiveness in improving patient clinical outcomes



PUB441

Prevalence of CKD Based on Estimated Glomerular Filtration Rate Using Creatinine and Cystatin C in Patients with Cancer Exposed to Conventional Chemotherapy: A Prospective Study

Renato A. Caires,[1] Lesley A. Inker,[2] Emmanuel A. Burdmann,[3] Veronica T. Costa e Silva.[1] *[1]Universidade de Sao Paulo, Sao Paulo, Brazil; [2]Tufts Medical Center, Boston, MA; [3]Universidade de Sao Paulo Laboratorios de Investigacao Medica, Sao Paulo, Brazil.*

Background: Data on the impact of conventional chemotherapy (chemo) on development of chronic kidney disease (CKD) are largely based on retrospective surveys and rely on serum creatinine (SCr) to estimate the glomerular filtration rate (eGFR). We assessed the prevalence of CKD during chemo using eGFR equations based on SCr and cystatin C (SCysC)

Methods: This is a prospective cohort of patients with solid tumors exposed to chemo at São Paulo State Cancer Institute. eGFR was calculated through race-free CKD-EPI equations based on SCr (eGFRcr); SCysC (eGFRcys); or the combined version (eGFRcrcys) in three moments: before initiation of chemo (T0), during treatment (TM) and after end of chemo (TF). SCr and SCysC were measured through certified reference materials at the University of Minnesota. CKD was defined as eGFR<60mL/min/1.73m^2

Results: 485 adults with solid tumors were recruited between Oct2017 and Jan2019. Patients were 53±15y, 62.3% female. Most prescribed drugs were platinum-compounds (cisplatin, carboplatin, oxaliplatin) (53.7%), paclitaxel (39.8%), and doxorubicin (27.4%). Patients received a median of 4(3-6) cycles during 105(63-148) days of chemo. Median follow-up was 28(21-32) months. TM was collected 98(84-119) days after T0, and TF was collected 124(44-204) days after end of chemo. At this point, increased prevalence of CKD was observed in elderly, worse performance status, metastasis, or treated with cisplatin (Table)

Conclusions: In this cohort of adults with solid tumors, CKD developed more frequently in patients at higher risk. eGFRcr appeared to underestimate CKD prevalence compared to eGFRcys and eGFRcrcys in overall population and in most important subgroups

Antineoplastic Agents Associated with Hyponatremia and Modifiable Factors for the Associations

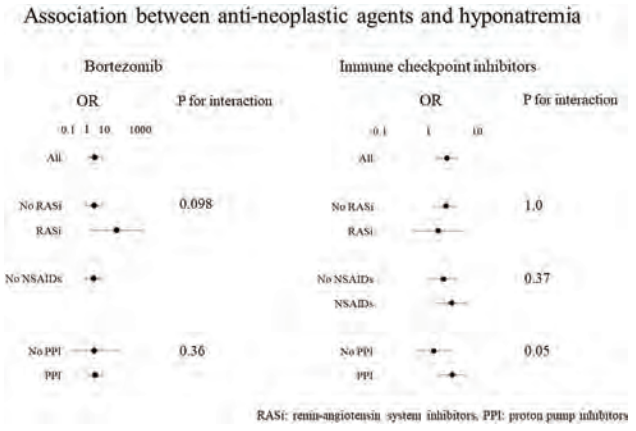
Yuki Miyaguchi,[1,2] Miho Murashima,[1] Kodai Suzuki,[1] Takahisa Kasugai,[1] Tatsuya Tomonari,[1] Masashi Mizuno,[1] Takayuki Hamano.[1] *[1]Nagoya Shiritsu Daigaku, Nagoya, Japan; [2]Nagoya Shiritsu Daigaku Igakubu Fuzoku Seibu Iryo Center, Nagoya, Japan.*

Background: Hyponatremia is associated with worse outcomes among patients with malignancy. In our previous study, we found that bortezomib (BOR), and immune checkpoint inhibitors (ICI) were significantly associated with hyponatremia. We aimed to identify modifiable factors for the associations.

Methods: This is a retrospective cohort study on patients with malignancy on anti-neoplastic agents at Nagoya City University Hospital from 2018 to 2020. We utilized logistic regression analyses using data at the time of each patient's lowest serum sodium concentration to examine the association of BOR and ICI with hyponatremia (Na ≤130 mmol/L) and effect modifications by rening-angiotensin system inhibitors (RASi), non-steroidal anti-inflammatory agents (NSAIDs) and proton pump inhibitors (PPI), as these factors are potentially modifiable.

Results: We included 2644 patients. Median age was 69 (58-75) years and median eGFR was 72.9 (58.1-88.1) mL/min/1.73m^2. Of these, 657(24.9%) developed hyponatremia and the lowest serum sodium concentration was 104 mmol/L. The use of BOR and ICI was associated with hyponatremia (OR 2.95 [1.25-6.97] and 2.40 [1.53-3.76], respectively) The incidence of hyponatremia was particularly high with simultaneous use of RASi and BOR (OR 48.6 [1.79-1330.70]), and with the use of PPI and ICI (OR 3.05 [1.69-5.49]) (p for interaction 0.098 and 0.05, respectively). No effect modifications were observed by NSAIDs. A sensitivity analysis using a mixed effects logistic regression showed similar associations and effect modifications.

Conclusions: Hyponatremia was common among those with malignancy. The concomitant use of BOR with RASi and ICI with PPI was especially associated with higher incidence of hyponatremia. Avoiding the contamitant use of RASi with BOR and use of PPI with ICI might reduce the incidence of hyponatremia.



PUB443

Acute Kidney Disease in Patients with COVID-19 and Cancer in Intensive Care: A Clinical and Retrospective Study

Germana A. Brito,[1] Joubert A. Alves,[1] Alexandre R. Fernandes,[1] Aline L. Baptista,[1] Marina H. Imanishe,[1] Benedito J. Pereira.[1,2] *[1]A C Camargo Cancer Center Centro Internacional de Pesquisa, Sao Paulo, Brazil; [2]Hospital das Clinicas da Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil.*

Background: As cancer patients are a high-risk group for COVID-19, it is important to understand the potential complications they may experience, such as acute kidney disease (AKD). This study aimed to investigate the clinical characteristics and risk factors associated with AKD in cancer patients with COVID-19

Methods: The study was conducted retrospectively, using data from patients who were hospitalized with SARS-CoV2 infection. Demographic, clinical, and laboratory data were collected, and statistical analysis was performed using SPSS 29.0.

Results: In total, 143 patients were evaluated, of which 59.4% were male and aged 65.5±12.8 years. The majority (81.1%) had a solid tumor. During their hospital stay, 43.3% of patients developed AKD, with 25.8% requiring renal replacement therapy (RRT). Patients with AKD were more likely to have hypertension (64.5%) and cardiovascular diseases (32.3%). They also required more mechanical ventilation (MV) (71.7%), prone position (18.0%), and vasoactive drugs (VAD) (75.8%) (Table). The mortality rate was significantly higher in patients with AKD (72.6%) compared to those without AKD (39.5%). After 12 months, 44 patients were followed up, of which 84% did not have AKD and 16% developed AKD due to COVID-19 while in the ICU.

Conclusions: AKD in cancer patients with COVID-19 admitted to the ICU was more common in older patients with underlying hypertension or cardiovascular diseases. These patients required more invasive procedures such as MV, prone position, and VAD. The mortality rate was high even after discharge from the ICU.

A Rare Case of Proliferative Glomerular Nephritis with Monoclonal Immunoglobulin Deposits

Justin D. Tse, Kiran Suryadevara, Jackson Wang. *Sutter Health, Roseville, CA.*

Introduction: Monoclonal gammopathies are an important cause of renal deposition diseases, known as monoclonal gammopathy of renal significance (MGRS). MGRS involves non-malignant or premalignant B-cells or plasma cells secreting monoclonal immunoglobulins that damage the kidneys. PGNMID, a new MGRS pathology, affects 1/4 of patients with detectable monoclonal gammopathy and presents with nephrotic syndrome, impaired kidney function, and hematuria. Here, we present a patient with PGNMID and diabetic glomerular sclerosis.

Case Description: We present a 78-year-old male with a history of depression, type 2 diabetes, peripheral vascular disease, HTN, HLD, and peripheral neuropathy who presented with abnormal labs: creatinine: 5.27mg/dL (baseline 1.10mg/dL), albumin: 1.1g/dL, and potassium: 5.6mmol/L. He had lower extremity bilateral edema. Urinalysis showed trace ketones, 3+ blood, and 500 protein. A comprehensive workup revealed UPC: 16g, kappa/lambda ratio of 2.04, beta 2 microglobulin level of 16.88 with SPEP beta 2 globulins increased relative to the beta 1 globulins. Renal biopsy indicated PGNMID (IgG3 kappa deposits) with diabetic changes. Hematological workup and bone marrow biopsy confirmed kappa-restricted plasma cell neoplasm. Due to progressive renal failure, he was started on hemodialysis with chemotherapy for continued management of his novel diagnosis.

Discussion: PGNMID and MGRS represent significant diagnostic challenges due to their specificity and complexity. Treatment depends on the type of kidney injury, guided by bone marrow biopsy to determine the clonal cell type. Clone-directed therapy could include rituximab, cyclophosphamide, bortezomib, and glucocorticoids. Daratumumab, a monoclonal anti-CD-38 antibody, can also be used if associated with multiple myeloma. If no clone or monoclonal protein is found, conservative therapy with anti-proteinuric agents and blood pressure control is recommended. When common causes like multiple myeloma or lymphoproliferative disorders are excluded, examining the secreted proteins helps distinguish between MGUS and MGRS pathology. Prompt diagnosis with a renal biopsy is essential, followed by a bone marrow biopsy to guide treatment. PGNMID is a rare and complex kidney disease requiring an interdisciplinary treatment approach. Its unique overlap with hematological disorders makes it a compelling subject for ongoing research.

PUB445

Long-Term Kidney Prognosis in Patients with Urologic Cancer after Nephrectomy

Sewon Oh, Yookyung Jang, Young Eun Choi, Tai yeon Koo, Myung-Gyu Kim, Sang-Kyung Jo. *Korea University, Seongbuk-gu, Republic of Korea.*

Background: Recent advances in medical technology have contributed to improved survival rates among cancer patients. Long-term outcomes are important for cancer survivors, and renal function plays a significant role in determining these outcome. We investigate the long-term renal functions in patients with urology cancers following surgery.

Methods: We analyzed the medical records of 1,661 patients with kidney, ureter and bladder cancer who underwent surgery without receiving chemotherapy at Korea university Anam Hospital and Guro Hospital from November 1999 to February 2019.

Results: Out of the total patients, 356 (21.4%) and 396 (23.8%) patients underwent partial nephrectomy(PN) and radical nephrectomy(RN), respectively. The average eGFR was 82.5±18.6 mL/min/1.73m^2 in the non-nephrectomy(NN) group, in the PN group it was 88.7±19.4 mL/min/1.73m^2, and in the RN group, it was 80.1±21.9 mL/min/1.73m^2. There was an average annual decrease of 4.4±17.3 mL/min/1.73m^2 in eGFR in patients who did not undergo nephrectomy adjusted by multiple factors. PN group exhibited a greater decline in eGFR compared to the NN (5.5±11.2 mL/min/1.73m^2,*P*=0.010). Furthermore, there was a greater decrease in eGFR in the RN group compared to the PN group (8.3±31.9 mL/min/1.73m^2,*P*=0.024). The risk of a 20% and 30% decline in eGFR showed no significant difference between NN and PN group (RR, 0.69, 95% CI, 0.45-1.07; RR, 0.72, 95% CI, 0.40-1.29). However, there was a significant increase in the risk of a 20% and 30% decline in eGFR observed in the RN group compared to NN group (RR, 1.58, 95% CI, 1.09-2.29, *P*=0.015 and RR, 2.00, 95% CI, 1.24-3.25,*P*=0.005).

Conclusions: The annual decline in eGFR was significantly different among patients who underwent PN, RN, and those who did not undergo nephrectomy. Preserving renal tissue is crucial for determining renal prognosis when undergoing nephrectomy.

Relevance of Measured GFR in the Onconephrological Panorama: An Essential Tool to Apply Precision Medicine

Francesco Trevisani,[1] Fabiana Laurenti,[2] Mariadelina Simeoni,[3] Alessandra Cinque,[1] Arianna Bettiga,[1] Umberto Capitanio,[1] Andrea Salonia,[1] Massimo Locatelli,[1] Giorgio Pizzagalli,[1] Francesco Montorsi.[1] *[1]IRCCS Ospedale San Raffaele, Milano, Italy; [2]Universita degli Studi di Verona Dipartimento di Neuroscienze Biomedicina e Movimento, Verona, Italy; [3]Universita degli Studi della Campania Luigi Vanvitelli Dipartimento di Scienze Mediche Traslazionali, Napoli, Italy.*

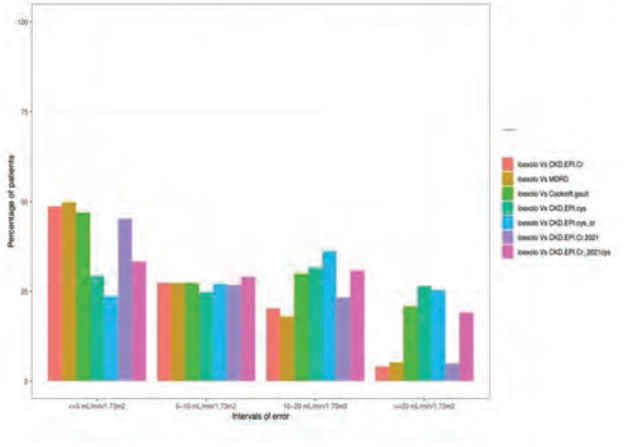
Background: An accurate assessment of renal function is fundamental in several categories of patients where the adequate medical or surgical treatment depends on the values of glomerular filtration rate (GFR). In particular, in the onco-nephrological scenario the determination of the "real" GFR can dramatically change the clinical algorithm and therefore the lifespan of patients. Unfortunately, the most used method to define the GFR is represented by eGFR which harbours a significant error in comparison to gold standards methods (mGFR). Aim of this study was to determine the extent of the error of eGFR compared to the mGFR in a consecutive cohort of patients affected by urological malignancies.

Methods: A consecutive cohort of 500 oncological patients affected by urological cancers enrolled in a single tertiary institution between 2018-2024 was collected in order to compare the most common eGFR formulas (Cockroft-Gault, MDRD, CKD-EPI 2012 and 2021, CKD-EPI cystatin, CKD-EPI creatinine and cystatin 2012 and 2021) with mGFR using Iohexol Plasma Clearance. True positives and False positives were classified in CKD stages based on eGFR and mGFR. Comparisons between groups were performed using Wilcoxon ranks sum test for numerical variables and Pearson's Chi square test for categorical ones.

Results: Clinical data: overall median age was 66 years, median BMI 25, Male:536, F:165, Diabetes: 10.9%, Hypertension: 53.8%, CKD stage I: 3.7%, II: 25.5%, IIIA: 28%, IIIB: 27.5%, IV: 13.4%, V: 1.74%, mean Creatinine: 1,44 mg/dl, cystatin: 1,24. We reported a huge discrepancy between the eGFR formulas and mGFR values, suggesting the essential role of mGFR in the clinical decision making algorithm (Figure 1 and 2).

Conclusions: In onco-nephrological scenario the use of eGFR remain debatable and misleading. mGFR is a crucial tool for a correct clinical decision based on precision medicine.

Figure 1: Overall population (oncological and non-oncological patients) percentages of patients with four different intervals of error in term of ml/min/1.73 m2



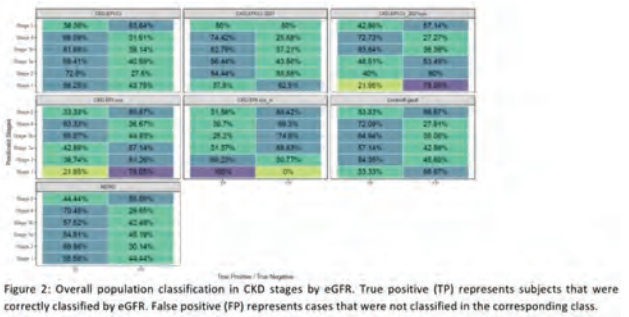


Figure 2: Overall population classification in CKD stages by eGFR. True positive (TP) represents subjects that were correctly classified by eGFR. False positive (FP) represents cases that were not classified in the corresponding class.

PUB447

Ectopic Cushing Syndrome: A Diagnostic Anomaly of Malignancy

Elizabeth F. Oguntuwase,[1] Carlos D. Flombaum,[2] Ilya Glezerman,[2] Victoria Gutgarts.[2] *[1]Weill Cornell Medicine, New York, NY; [2]Memorial Sloan Kettering Cancer Center, New York, NY.*

Introduction: Ectopic Cushing syndrome (ECS) occurs when Adrenocorticotropic hormone (ACTH) is produced outside the pituitary gland. This rare phenomenon increases mortality risk and may be a presenting sign of new or recurrent malignancy. We describe a patient with a history of breast cancer who presents with new metastatic cancer with hypertension, edema, hypokalemia and hypernatremia.

Case Description: 58-year-old female with history of breast cancer treated 9 years ago (on tamoxifen), Crohn's disease and nephrolithiasis was referred to the hospital for hypokalemia and concern for cord compression. She had a fall prior to admission with now pathological cervical and T12 fracture managed with dexamethasone and kyphoplasty. Her blood pressure was 161/87, Pulse 100bpm and oxygen saturation 90% on room air. Physical examination was notable for edema up to the thighs. Laboratory values; included potassium 2.7 (3.3-4.9)mEq/L, sodium 148 (133-143)mEq/L, carbon dioxide 24 (18-29)mEq/L, creatinine 0.7 (0.6-1.1) mg/dL. Fractional Excretion of potassium was 30.8% consistent with renal potassium wasting. PET scan showed metastasis involving the liver, lungs, adrenal, and osseous structures initially concerning for recurrent breast cancer based on prior history. Further work up showed cortisol level of 80.1 (5-25) mcg/dL, 24 hr cortisol 1428 (3.5-45) mcg/24h and ACTH of 610 (7.4-64.3) pg/mL consistent with ECS. Serum aldosterone of <4 (< 21) ng/dl, renin activity of 1.1 (0.6-3.0) ng/ml/hr. She was started on spironolactone 25mg twice daily and metyrapone 250mg every 8 hours. Ketoconazole was avoided due to transaminitis. Her potassium requirements declined, and she was no longer hypertensive. The biopsy from bone lesion was consistent with new small cell lung carcinoma with elevated Chromogranin A levels 2036 (<93) ng/ml.

Discussion: This case highlights the importance of recognizing ECS as a rare paraneoplastic phenomenon. Cortisol and ACTH levels should always be checked in a patient with malignancy, hypertension, and hypokalemia, despite exogenous steroids. Once the diagnosis of ECS is made, treatment is aimed at the cancer as well as steroidogenesis inhibitors (ketoconazole or metyrapone) and mineralocorticoid antagonists (spironolactone). Biopsy in new metastatic disease is key for appropriate diagnosis to avoid anchoring bias and assume that metastases are from prior malignancy.

PUB448

Atypical Acute Myeloid Leukemia Presentation: Spinal Metastasis and Neurogenic Bladder

Katie Gallagher, Prakash S. Gudsoorkar. *University of Cincinnati College of Medicine, Cincinnati, OH.*

Introduction: Central nervous system (CNS) involvement in acute myeloid leukemia (AML) is rare, with symptomatic involvement is much less common, only about 1-5% of cases. We present a case of AML, with a neurogenic bladder resulting from spinal metastasis.

Case Description: A 60-year-old male with AML complicated by renal dysfunction with baseline serum creatinine (SCr) 1.9-2.1 mg/dL presented with urinary retention. Diagnosed to have AML In (16) (FLT3-TKD mutation) 10 months before current presentation, treated with azacitidine & venetoclax. Admission labs were: Scr: 2.9 mg/dL, hemoglobin 9.4 g/dL, WBC count 9,300, and normal platelet count. Ultrasound: no urinary obstruction. Contrast MRI (Fig.1) showed multiple areas of white matter enhancement in the brain & diffuse T1 signal abnormalities with intramedullary lesions throughout the cervical and thoracic spine. Findings were suggestive of metastatic disease, with concern for an acute demyelinating process. Lumbar puncture results are in Tab.1 & Fig.2. A Foley catheter was placed & IV dexamethasone was started with intrathecal cytarabine, methotrexate and hydrocortisone. His urine output was 4-6 L/day, likely due to post-obstructive diuresis. Multiple voiding trials failed. Despite chemotherapy, he developed neurogenic bowel, causing diarrhea. SCr peaked at 5.6 mg/dL with acidosis. As symptoms progressed, he chose hospice care.

Discussion: CNS involvement in adults with AML is rare but more common in pediatric cases, affecting 1.1% of patients. Symptoms include encephalopathy, seizures, & cranial nerve palsies. Only 1-4% present with paraspinal or intracranial granulocytic sarcoma. Risk factors include hyperleukocytosis (>10^5/mcL), age <2 years, elevated LDH, prominent monocytic/myelomonocytic/monoblastic characteristics, APL/PML::RARA in relapse, and molecular/cytogenetic abnormalities like FLT3-ITD, inv(16) & chromosome 11 abnormalities. Acute urinary retention in our patient is rare and not reported in adults due to intraspinal involvement by AML.

Unveiling the Dual Threat: Glofitamab-Induced AKI via Tumor Lysis and Cytokine Release Syndromes

Akaljot Singh, Mragank Gaur, Prakash S. Gudsoorkar. *University of Cincinnati College of Medicine, Cincinnati, OH.*

Introduction: Glofitamab, a monoclonal CD20-directed CD3 T-cell engager, treats refractory diffuse large B-cell lymphoma (DLBCL) but can induce acute kidney injury (AKI) via tumor lysis syndrome (TLS) and cytokine release syndrome (CRS). We report a case of a patient who developed AKI secondary to glofitamab infusion through both mechanisms simultaneously.

Case Description: A 78-year-old male with DLBCL presented with AKI. His baseline serum creatinine (SCr) was 1.6-1.8 mg/dL. Treated with 6 rounds of R-CHOP regimen, with some improvement 6 months ago. 6 weeks before admission, he developed spontaneous TLS, treated with rasburicase and IV fluids & was found to have metastatic recurrence of DLBCL. His tumor was treated with gemcitabine and oxaliplatin to no avail. Glofitamab was then started for DLBCL treatment. Due to CRS risk, the patient received obinutuzumab pretreatment. 30 minutes into the test dose, he experienced nausea, lethargy, and hypotension, leading to hospitalization. After stabilization, he tolerated the therapeutic dose of obintutuzumab 5 days later. Later, he received his first glofitamab infusion. Within 12 hours, he developed symptoms of CRS (fever, tachycardia, and hypotension) and was sent to ICU, received IV fluids, dexamethasone, and tocilizumab, which assisted with stabilizing his vitals. Key lab tests of CRS and TLS are in Table 1. For TLS, he was treated with IV fluids, sodium zirconium cyclosilicate, and sevelamer. His CRS resolved first, allowing him to be transferred back to the floor from the ICU. He continues to be treated for TLS, is recovering well, and is currently preparing for a 2nd dose of glofitamab.

Discussion: Glofitamab is a novel immunotherapy for DLBCL that can induce both CRS and TLS. While reports exist of these syndromes occurring simultaneously in response to other therapies, to our knowledge, glofitamab has not been previously reported to do so. As both CRS and TLS can cause AKI, albeit through different mechanisms, nephrologists should closely monitor patients receiving glofitamab for both syndromes.

Table: Key lab values pre-and post-glofitamab transfusion

Labs	Pre Glofitamab	Post Glofitamab	Reference interval
Sodium	151	145	133-146 mmol/L
Potassium	3.7	5.6	3.5-5.3 mmol/L
Chloride	110	117	98-110 mmol/L
Bicarbonate	24	15	21-33 mmol/L
BUN	29	107	7-25 mg/dL
Creatinine	1.8	3.52	0.60-1.30 mg/dL

AKI after Chimeric Antigen Receptor T Cell Therapy in Patients with Relapsed Hematological Malignancies: Experience of a Brazilian Cancer Center

Germana A. Brito, Benedito J. Pereira, Vanessa D. Bovolenta, Marjorie V. Batista, Jayr Schmidt Filho. *A C Camargo Cancer Center, Sao Paulo, Brazil.*

Background: Cytokine release syndrome (CRS) is the most frequent adverse event after chimeric antigen receptor T cell (CAR-T) therapy and can lead to multiple organ dysfunction. Acute kidney injury (AKI) is common, but usually mild. We aimed to assess the incidence of AKI, electrolyte disturbances, CRS, and mortality in a Brazilian cancer center.

Methods: We retrospectively evaluated patients with relapsed hematological malignancies treated with CAR-T therapy targeting CD-19 at the A.C. Camargo Cancer Center between November 2022 and April 2024.AKI was defined using KDIGO (Kidney Disease: Improving Global Outcomes) criteria. Laboratory test parameters, including serum creatinine and electrolytes collected daily in the pre and post-infusion period were retrospectively registered during hospital stay.

Results: Sixteen patients were included for analysis, age was 60,2 (36,4-67,1) years, 62,5% male. Fourteen (87,5%) had relapsed lymphoma and 12,5% acute lymphoid leukemia. CRS occurred in 87,5% of patients in a median of 3 (2-4,7) days after infusion; 81,2% of them were treated with tocilizumab and 62,5% with corticosteroids. CRS was similar in patients with and without AKI (Table). AKI occurred in 37,5% of patients 5 (3.2-15.2) days after infusion, stage 1,2, and 3 in 50%,33,3% and 16,7%% of cases, respectively. Only one patient required kidney replacement therapy.AKI recovery occurred in 83% of cases, 6 (4,5-11) days after AKI diagnosis. Most common electrolyte abnormalities were:hypokalemia(25%), hyponatremia(18,7%), and hypomagnesemia(18,7%). Mortality at 90 days post-infusion was 18,7%, occurring in 16,7% AKI patients and 20% without AKI (p=0,87).

Conclusions: This is the first study assessing AKI in patients treated with CAR-T therapy in Brazil, which included patients with relapsed hematological malignancies. CRS and AKI were frequently observed, AKI was usually mild and transitory.

Table. Baseline Characteristics of Patients with and without AKI

	All (n=16)	No AKI (n=10)	AKI (n=6)	p
Male, n (%)	10 (62,5%)	8 (80%)	2 (33,3%)	0,06
Age, median	60,2 (36,4-67,1)	60,2 (53,5-66,9)	52(29,1-66,6)	1,00
CAR T therapy, n(%)				0,69
Axicabtagene	2 (12,5%)	2 (20%)	0	
Tisagenlecleucel	14 (87,5%)	8 (80%)	6 (100%)	
Baseline Scr, mg/dL	0,85 (0,7-1,0)	0,8 (0,72-0,9)	0,95 (0,75-1,2)	0,41
Time until CRS	3 (2 – 4,75)	3 (2-3)	4 (2-5)	0,78
CRS, n (%)	14 (87,5%)	9 (90%)	5 (83,3%)	0,69

Outcomes following Treatment with Bortezomib in Patients with Multiple Myeloma Who Required Haemodialysis: A Single-Centre Experience

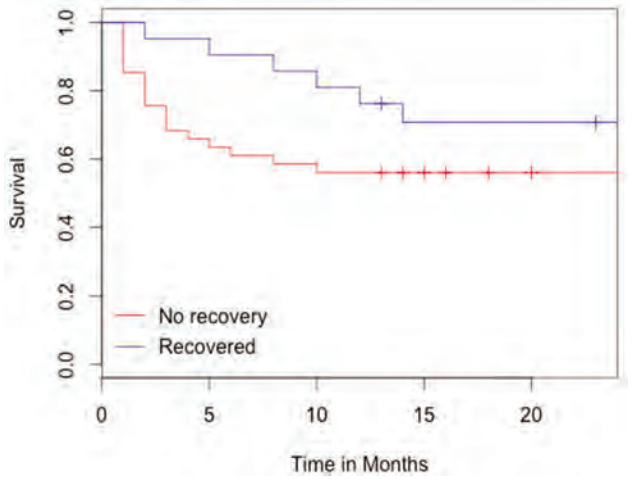
Mohammad Rabiul Islam Rony, Omaisa Mushtaq, Aoife Dervin, Simon C. Stern, James Croft, David Makanjuola. *St Helier Hospital, Carshalton, United Kingdom.*

Background: Renal impairment is a common complication of multiple myeloma (MM). About 10% present with acute kidney injury (AKI) needing haemodialysis (HD). Renal impairment is associated with increased morbidity and mortality. Bortezomib has resulted in a significant improvement in survival in comparison to other treatments. We looked at the survival and outcome of myeloma patients treated with Bortezomib, who also required HD during their treatment.

Methods: We analysed data from our electronic database on patients diagnosed with MM with associated renal impairment between 2010 to 2024. Patients who had HD at presentation, or after diagnosis of myeloma were included. Analyses were performed using Microsoft Excel and R.

Results: There were 116 patients. 68 (58.62 %) had HD. 62 (92%) received Bortezomib. Median age at diagnosis was 70 years (range 49-89 years), male to female ratio was 2.4:1. Median creatinine at initiation of HD was 645.5μmol/l. 20 (33%) recovered renal function. Median creatinine at stopping HD was 418μmol/L. Median duration on HD among patients who recovered function was 22.5 days. Survival at 3, 6 and 12 months was 90.4%, 90.4% and 70% respectively in patients who recovered renal function. In those who did not recover function, the 3, 6 and 12 month survival was 68%, 60.9% and 53.6% respectively. Survival in both groups is shown in the Kaplan Meier curve below.

Conclusions: In our patients, a significant proportion of those who had Bortezomib regained kidney function. Recovery occurred in most patients within 4 weeks, and was associated with improved survival at 3, 6 and 12 months. Newer agents available to patients with myeloma and severe kidney disease are likely to improve outcomes.



Survival of patients with recovered or non-recovered Renal function

PUB452

Incidence of AKI in Patients Admitted to Intensive Care Unit after Outpatient Chimeric Antigen Receptor T Cell Therapy: A Retrospective Single-Center Analysis

Adolfo Diaz-Barba, Noha Soror, Bibi Maryam, Taha Al-Juhaishi. *The University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: Chimeric antigen receptor T-cell (CAR-T) therapy represents a new therapeutic option for patients with refractory hematological malignancies. New paradigms are being implemented to perform them in the outpatient setting. However, the multiple side effects often require hospital admission in different levels of care, including intensive care unit (ICU). We performed a retrospective analysis of ICU utilization, development of acute kidney injury (AKI) and need for renal replacement therapy (RRT), in patients who underwent outpatient CAR-T therapy in a National Cancer Institutes (NCI)-designated cancer center.

Methods: After obtaining IRB approval, we performed a retrospective chart review of 79 adult patients who underwent outpatient infusion of CAR-T therapy at Stephenson Cancer Center, Oklahoma City, between September 2019 and November 2023. We included patient whose indication for CAR-T was a hematological malignancy. We determined rates of ICU admission within 45 days after infusion, ICU admission diagnosis, development of AKI, need for RRT, length of stay and in-ICU mortality.

Results: We identified 79 patients who underwent ambulatory, FDA-approved CAR-T therapy infusion during the study period. Within 45 days of CAR-T infusion, 12.6% (10/79) of patients required ICU admission (one patient was excluded due to inability to obtain medical records during ICU stay). ICU admission diagnosis included (with some patients with more than one): distributive shock secondary to CRS grade 3-4 (4/9), sepsis (2/9), encephalopathy secondary to ICANS (2/9), acute hypoxic respiratory failure (2/10), hypovolemic shock (1/9). Among patients admitted to ICU, 11% (1/9) developed AKI. Of note, this patient who developed AKI required RRT for a total of 12 days (until date of death). Mean ICU length of stay was 4.8 days (1-16), and in-ICU mortality rate was 11% (1/9).

Conclusions: In this study, we found a lower rate of ICU admission compared to rates reported in similar studies. In majority of cases, ICU admission was due to CAR-T toxicities. Among patients admitted to ICU, one case developed AKI, and, notably, this case derived in fatal outcome. Kidney-specific toxicities are common with the advent of newer cancer therapies, which represents novel research pathways in nephrology.

PUB453

Percutaneous Kidney Biopsy in Patients with Metastatic Solid Malignancy and AKI on Systemic Anticancer Therapy

Tomaz Milanez,[1] Vinay Srinivasan,[2] Janja Ocvirk,[1] Edgar A. Jaimes.[3] *[1]Onkoloski Institut Ljubljana, Ljubljana, Slovenia; [2]Cooper University Health Care, Camden, NJ; [3]Memorial Sloan Kettering Cancer Center, New York, NY.*

Background: Percutaneous renal biopsy (PRB) is the gold standard for assessing renal parenchymal disease and renal toxicity of systemic anticancer therapy (SAT). In pateints with solitary kidney (SK), PRBs are often deferred due to the perceived risk for major bleeding complications that may result in permanent loss of renal function. In this study we assessed the safety of PB and findings in patients receiving SAT including those with SK.

Methods: We retrospectively analyzed pathological findings of PRBs and the incidence of major complications of PRBs performed on native kidneys for the evaluation of AKI in patients with metastatic solid malignancy who received SAT and who underwent PRB between 2018 and 2023 at the Institute of Oncology Ljubljana, the University Medical Centre Ljubljana, and at Cooper University Hospital in Camden, NJ. All PRBs were performed under ultrasound guidance by a nephrologist.

Results: A total of 19 PRBs were performed in 18 patients and of these 11 PRBs where performed in patients with a SK. At the time of acute kdiney injury (AKI) 15 patients were being treated with immune check point inhibitors (ICIs) and 4 with a tyrosine kinase inhibitor (TKI). Five patients who developed AKI stage 3 during ICI therapy experienced at least one Grade 3 concomitant immune-related adverse event. Pathologic analysis revealed TMA in 5 patients exposed to TKIs, and acute interstitial nephritis in two, Acute tubular injury (ATI) in 5, and severe necrotizing granulomatous vasculitis in one patient exposed to ICIs. In a patient with severe ATI, the pathologic analysis also revealed IgA nephropathy. Based on pathological findings, SAT was changed in twelve patients after PRBs. One patient with TMA had progressive loss of renal function after discontinuation of TKI, while the other 3 had stable or improved renal function. After PRB, one patient experienced a large perinephric hematoma. In another patient, who had a SK, a follow-up ultrasound revealed an A-V fistula and 7 days after PRB. Both patients fully recovered.

Conclusions: Our results indicate that PRB in patients with AKI and receiving SAT are safe and informative even in patients with SK. Importantly, the observed pathological findings can have a significant impact in the cancer treatment plan for these patients. Major PRB complications were manageable even in patients with a SK.

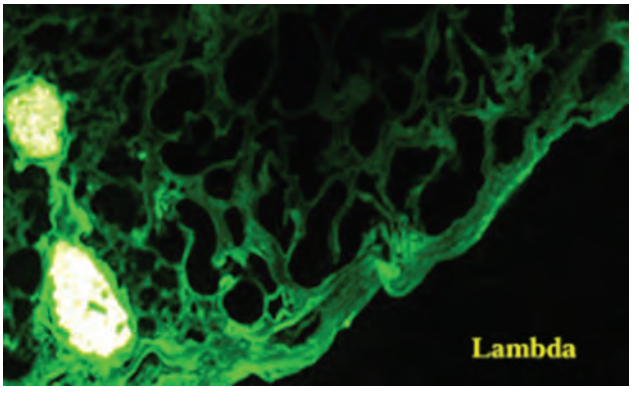
Complex Renal Involvement in Multiple Myeloma and Extramedullary Plasmacytoma: A Clinical Perspective

Carlos B. Gonzalez,[1] Mara C. Olivo Gutierrez,[1] Virgilia Soto,[2] Monica Sanchez Cardenas.[1] *[1]Hospital Universitario Dr Jose Eleuterio Gonzalez, Monterrey, Mexico; [2]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico.*

Introduction: This case involves a 43-year-old male patient with no prior comorbidities who was admitted to our unit with rapid deterioration of renal function and uremic syndrome. During evaluation, a left lung mass was detected. The objective of this report is to present a clinical case featuring a large plasmacytoma and severe renal function impairment as the initial manifestation of Multiple Myeloma (MM) in a young and healthy man.

Case Description: A 43-year-old previously healthy man experienced symptoms of asthenia, adynamia, emesis, and wasting syndrome during the two weeks prior to hospital admission. Initial laboratory tests revealed severe renal impairment, with creatinine at 20.1 mg/dL and BUN at 107 mg/dL, with no significant abnormalities in blood cell count. During evaluation, a 24-hour urine protein test showed 630 mg/dL. Incidentally, a large pulmonary mass (8.4 x 13.1 x 10 cm) was detected in the left apex. A renal biopsy (image 1) revealed active tubulointerstitial nephritis with intratubular lambda (+) casts, as well as minimal glomerular and vascular amyloidosis. A biopsy of the pulmonary mass confirmed the histological diagnosis of plasmacytoma associated with multiple myeloma.

Discussion: Amyloidosis is a heterogeneous disease characterized by the deposition of insoluble and toxic fibrillar protein aggregates in various tissues. Renal involvement is a common complication of hematologic malignancies, with monoclonal gammopathy of undetermined significance (MGUS) being the most common form. The incidence of solitary plasmacytomas affecting only soft tissues ranges from 1.4-4.5%, with 34% located as paraeskeletal tumors. The evaluation of new renal injury events in the context of newly appearing malignancies requires consideration of monoclonal disorders within the differential diagnosis; this is particularly true even in the context of solid tumors as the initial manifestation of the condition without significant abnormalities in blood cell counts.



PUB455

Characterization of Myoglobin Endocytic Function in Primary Human Proximal Tubular Epithelial Cells

Yoshio Funahashi,[1,2] Michael Hutchens.[1,3] *[1]Oregon Health & Science University, Portland, OR; [2]Nagoya University Graduate School of Medicine, Nagoya, Japan; [3]Portland VA Medical Center, Portland, OR.*

Background: The endocytic function of proximal tubular epithelial cells (PTEC) has important role in health and disease. Megalin is a multi-ligand endocytic receptor which mediates myoglobin uptake. We generated primary culture of PTEC from human kidneys (hPTEC), and characterized response to injury and myoglobin endocytic function.

Methods: Research-designated human donor kidneys were used to generate hPTEC. After dissection and digestion, hPTEC was isolated using cell strainers and fluorescence-activated cell sorting (FACS). After serum starvation or gentamicin treatment, cells were subjected to survival assay (MTT assay and FACS/DAPI), and injury assay (FACS/KIM-1). Megalin expression in hPTEC and HK2 were evaluated by western blotting (WB), quantitative polymerase chain reaction (qPCR), and immunofluorescence (IF). Cells were incubated with FITC conjugated myoglobin (FITC-Mgb) up to 120min, then FITC-Mgb uptake was evaluated by IF or intracellular FITC intensity using a plate reader. Megalin knockdown or inhibition was performed using siRNA or cilastatin (Cil). Dynamin inhibition was performed using dynasore (Dyn) and prochlorperazine (PCP).

Results: After FACS, hPTEC culture was 95% CD10/CD13 positive. hPTEC from 4 different kidneys with various cold ischemia time (16-26h) did not express KIM-1. hPTEC strongly expressed megalin by WB, qPCR and IF while HK2 did not. Serum starved cells demonstrated reduced viability and increased KIM-1 expression compared with control (MTT, DAPI, KIM-1, $p<0.05$ by One-way ANOVA). Compared with HK2, hPTEC demonstrated higher flux of FITC-Mgb uptake in first 20 min ($p=0.004$ by non-linear regression), which resulted in more FITC-Mgb uptake in hPTEC up to 120min. Megalin knockdown by siRNA caused reduced FITC-Mgb uptake in hPTEC ($p<0.0001$ by non-linear regression). Mgb uptake along a wide range of concentrations was reduced by Cil dose-dependently (Mgb:0 to 160ug/mL, Cil: 0 to 200mg/mL, $p<0.0001$ by non-linear regression). Dynamin inhibition by Dyn or PCP also reduced FITC-Mgb uptake.

Conclusions: hPTEC demonstrated healthy epithelial phenotype, high megalin expression, and megalin-mediated, dynamin-dependent endocytosis. They expressed KIM-1 in response to injury. hPTEC are a feasible platform for studies of endocytosis.

PUB456

Cellular Indices in Relation to D-dimer and Thrombin Levels in Patients with ESKD

Hamzah Hussain,[1,2] Fakiha Siddiqui,[1,3] Debra Hoppensteadt,[1] Emma Abulencia,[1] Elyse Fairand,[1] Jawed Fareed,[1] Vinod K. Bansal.[1] *[1]Loyola University Medical Center, Chicago, IL; [2]Hurley Medical Center, Flint, MI; [3]Universidad Catolica San Antonio de Murcia, Murcia, Spain.*

Background: End-stage renal disease (ESRD) is often associated with thromboinflamatory complications. Besides the biomarkers of thrombin generation such as D-Dimer (DD) and peak thrombin (PT) levels, cellular indicies (CI's) have been reported to change with the severity of ESRD. Such CI's as neutrophil to lymphocyte ratio (NLR), platelet to lymphocyte ratio (PLR), systemic immune-inflammation index (SII), lymphocyte to monocyte ratio (LMR), neutrophil to monocyte ratio (NMR) and their relevance with biomarkers such as DD and PT were profiled in ESRD patients.

Methods: Citrated plasma samples from patients with confirmed ESRD were collected in the Hemodialysis Clinic at Loyola University Medical Center. 50 healthy plasma samples served as control. Commercially available sandwich ELISA methods were used for DD levels, and PT was quantified by using a fluorogenic method. Blood CI's were extracted from complete blood counts. Applicable statistical methods were performed and $p<0.05$ were considered significant.

Results: The ESRD group comprised 56.9% males and 43.1% females, with a median age of 66 years. Comparing controls to ESRD cohort, DD increased significantly from 7.1 to 905.8ng/mL ($p<0.05$) while PT levels decreased from 138.4 to 109.9nM ($p<0.05$). NLR increased from 1.6 to 3.4, SII increased from 444.5 to 583.2, and LMR decreased from 4.1 to 2.4 ($p<0.05$). PLR and NMR showed no significant difference. Table 1 represents the composite results. There was no correlation between DD and PT. There were varying degrees of correlation between cellular indicies.

Conclusions: These studies suggest that beside thromboinflmatory biomarkers, CI's may provide additional prognostic parameters in the risk stratification of ESRD. All of the CI's included in this study are increased except for LMR. CI's represent an emerging tool to risk stratify ESRD patients.

Table 1

Biomarker or CI	Controls Median (Range)	ESRD Median (Range)	p-value
DD (ng/ml)	7.1 (7.1-696.5)	905.8 (79.3-6385.1)	<0.05
PT (nM)	138.4 (81.3-224.3)	109.9 (0.0-245.4)	<0.05
NLR	1.6 (0.8-13.3)	3.4 (1.3-9.0)	<0.05
PLR	131.6 (58.8-1966.7)	138.3 (2.2-344.0)	0.51
SII	444.5 (186.7-1573.3)	583.2 (10.5-2424.0)	<0.05
LMR	4.1 (1.0-14.5)	2.4 (0.4-19.0)	<0.05
NMR	7.0 (2.3-39.0)	7.1 (2.8-48.0)	1.00

Comparison of Spot Creatinine Estimation by StatSensor Creatinine Meter and Serum Creatinine Estimation by Conventional Enzymatic Method

Manoj Chandrasekar,[1] Manjunath S. Shetty,[1] Basavanagowdappa Hathur,[1] Prashant Vishwanath,[1] Akila Prashant,[1] Praveen Kulkarni,[1] Kiran K K,[1] Naman Chandra,[1] Abhijith Devaraju,[1] Dennis Begos,[2] John O. Oyelakin-Ogunbileje,[4] Vishakantha Murthy.[3] *[1]JSS Medical College, Mysore, India; [2]Nova Biomedical, Waltham, MA; [3]JSS Reasearch Foundation, Gaithersburg, MD; [4]Indiana University School of Medicine, Indianapolis, IN.*

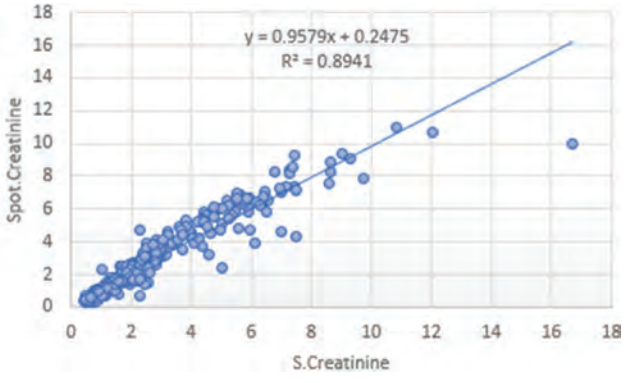
Background: The objective was to compare and validate creatinine measured by Nova StatSensor Creatinine meter against S.Creatinine measured by conventional enzymatic assay

Methods: Patients with renal dysfunction and age/sex matched healthy volunteers underwent Spot.creatinine measurement by Nova StatSensor Creatinine meter using capillary blood (finger prick) and Serum creatinine measurement by conventional enzymatic assay

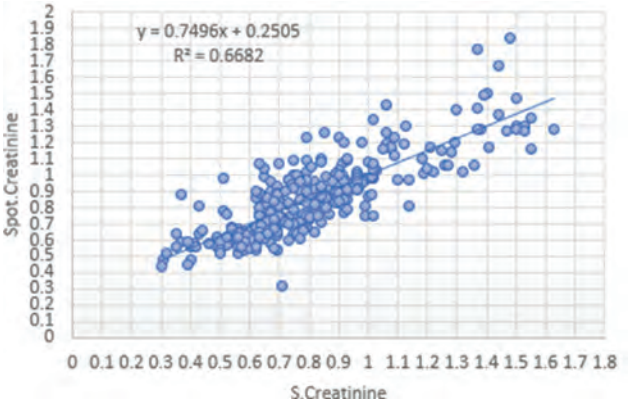
Results: A total of 618 (320 patients and 298 healthy volunteers) were included in the study. The baseline characteristics were similar Mean (±SD) Spot. Creatinine & S.Creatinine in the overall population was 1.9 (±1.9) & 1.8 (±1.8); 2.9 (± 2.2) & 2.8 (± 2.2) in patients; 0.86 (± 0.2) & 0.81 (± 0.2) in healthy volunteers A Pearson coefficient depicted a positive linear correlation between Spot. Creatinine and S.Creatinine, r (df)= 1, $p < 0.001$. The sensitivity and specificity of Spot. Creatinine was 91.2% and 96% respectively; PPV and NPV of 94.5% and 93.6% and an accuracy of 94.1%

Conclusions: Spot. Creatinine measurement using StatSensor Creatinine meter with capillary blood is simple, rapid, reliable and provides a good estimate of creatinine

Funding: Commercial Support - Nova Biomedical Corporation, Waltham, MA, USA



A positive, linear and strong relationship between Spot. Creatinine and S. Creatinine in patient population (r=0.89)



A positive, linear relationship of moderate strength between Spot. Creatinine and S.Creatinine in healthy population (r=0.66)

Comprehensive Analysis of Glomerular Antigens in Membranous Nephropathy

Isohata Rina,[1] Hitoshi Suzuki,[1,2] Kenichiro Abe,[1] Mingfeng Lee,[1] Yukako Umezawa,[1] Yuya Sasatsuki,[1] Masahiro Muto,[1] Hiroaki Io,[2] Hisatsugu Takahara,[1] Shigeki Tomita,[1] Yusuke Suzuki.[2] *[1]Juntendo Daigaku Igakubu Fuzoku Urayasu Byoin, Urayasu, Japan; [2]Juntendo Daigaku Igakubu Daigakuin Igaku Kenkyuka, Bunkyo-ku, Japan.*

Background: For the diagnosis and treatment of membranous nephropathy (MN), it is essential to determine idiopathic or secondary onset. The phospholipase A2 receptor (PLA2R), thrombospondin type-1 domain-containing 7A (THSD7A), and neural epidermal growth factor-like 1 (NELL-1) have been reported as antigens for MN. Recently, EXT1/EXT2 reported as responsible antigens for secondary membranous nephropathy, however, their significance in diagnosis of each disease type is not clarified.

Methods: We recruited twenty four patients with MN diagnosed at our hospital from 2021 to 2023. We comprehensively analyzed the IgG subclasses on the glomeruli, PLA2R, THSD7A, NELL1, and EXT/EXT2, and verified their significance in the differential diagnosis of idiopathic or secondary MN.

Results: Of the idiopathic MN, 63% were positive for glomerular PLA2R and 16% for THSD7A, and all were negative for NELL-1. Glomerular IgG4 was dominant in 74% of idiopathic MN. On the other hand, in secondary MN, THSD7A was positive in 60% of patients, NELL-1 was positive in all cases, and PLA2R was negative in all cases. Half of the secondary MN caused by autoimmune diseases were positive for EXT1.

Conclusions: Regarding the differential diagnosis between idiopathic and secondary MN, staining with IgG subclass and PLA2R is useful for the diagnosis of idiopathic MN. NELL-1 and EXT1/EXT2 may be useful as markers of secondary MN, however, the further validation of caused antigens of positive for NELL-1 and EXT1/EXT2 is desired.

PUB459

Association between Thromboinflammatory Biomarkers and Cellular Indices in Patients with ESKD

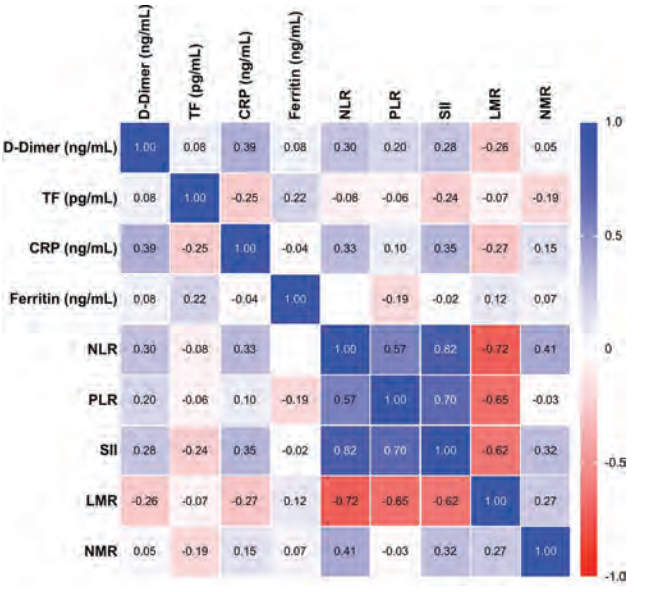
Hamzah Hussain,[1,2] Fakiha Siddiqui,[1,3] Debra Hoppensteadt,[1] Emma Abulencia,[1] Elyse Fairand,[1] Jawed Fareed,[1] Vinod K. Bansal.[1] *[1]Loyola University Medical Center, Chicago, IL; [2]Hurley Medical Center, Flint, MI; [3]Universidad Catolica San Antonio de Murcia, Murcia, Spain.*

Background: End-stage renal disease (ESRD) is often associated with chronic inflammation and hypercoaguable state. This results in the alteration of cellular indicies (CI's) like neutrophil to lymphocyte ratio (NLR), platelet to lymphocyte ratio (PLR), systemic immune-inflammation index (SII), lymphocyte to monocyte ratio (LMR), and neutrophil to monocyte ratio (NMR). Thromboinflammatory biomarkers (TIB's), like D-Dimer (DD), Tissue Factor (TF), Ferritin, and C-Reactive Protein (CRP), have also been observed to be abnormal in ESRD patients. This study was designed to find a possible relevance between these CI's and TIB's.

Methods: 79 citrated plasma samples from patients with confirmed ESRD were collected in the Hemodialysis Clinic. Patient complete blood counts and ferritin levels were collected from chart review and blood CI's were calculated. Sandwich ELISA methods were used to determine DD, TF, and CRP concentrations. A correlation analysis was performed and a correlation matrix was generated.

Results: The following figure depicts the composite data. DD showed correlation with CRP along with NLR, PLR, SII and is inversely related to LMR. Interestingly, TF showed inverse relationship with CRP, SII, and NMR. CRP showed a relationship with DD, NLR, and SII where-as it showed inverse relationships between TF and LMR. Ferritin showed positive relationship with TF and inverse relationship with PLR. Among the CI's, varying degrees of strong correlation were observed.

Conclusions: This data demonstrates that there is a complex interdependence between the CI's and TIB's in the pathogenesis of ESRD. Furthermore, this study shows that an integrated profiling of CI's and TIB's may have a prognostic role which will be helpful in the management and risk stratification of this complex syndrome.



PUB460

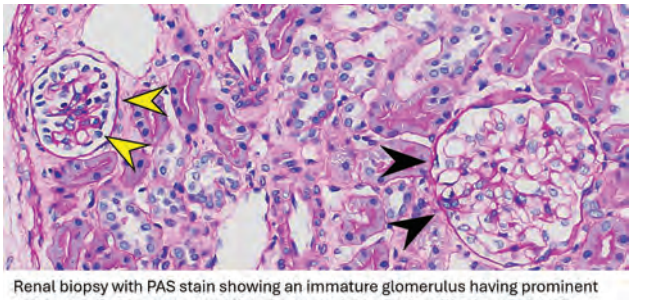
Intriguing Presentation of Proteinuria Associated with Immature Glomeruli in a Child with Horseshoe Kidney

Ganesh Prasanna,[1] Wesley Hiser,[2] Abhijeet Pal.[1] *[1]The University of Oklahoma Health Sciences Center, Oklahoma City, OK; [2]Pathologists Bio-Medical Laboratories, Coppell, TX.*

Introduction: Horseshoe kidney, a congenital anomaly resulting from the fusion of the lower poles of both kidneys, affects about 1 in 500 children. While horseshoe kidney has been associated with various glomerulopathies, we report the first instance where evaluation for persistent proteinuria revealed immature glomeruli with segmental sclerosis on renal biopsy.

Case Description: A four-year-old boy presented in 2021 with incidental proteinuria with no other symptoms. He was born at term with no familial history of kidney disease. His blood pressure was normal, and his physical examination was unremarkable. Urinalysis showed proteinuria with urine protein creatinine ratio (UPCR) of 1.1 mg/mg (normal range <0.2 mg/mg), albumin creatinine ratio (ACR) of 0.6 mg/mg, and no hematuria. Serum creatinine was 0.3 mg/dL. Blood counts were within normal limits. Renal ultrasound revealed a horseshoe kidney. Renal biopsy showed forty-six glomeruli, of which six (13%) were immature, which is unusually high for his age. Four immature glomeruli also had segmental sclerosis. Six glomeruli (13%) were globally sclerosed. Remaining were normal with insiginificant foot process effacement. Initially, he was monitored with no therapy. However, due to persisting proteinuria (UPCR 1.11 mg/mg) over a two-year follow-up, losartan was started in January 2024. By April 2024, UPCR had reduced (0.8 mg/mg). The patient remains on follow-up.

Discussion: This is the first report of horseshoe kidney concomitant with proteinuria and immature glomeruli. At first, we opted to survey without treatment, hypothesizing that the proteinuria was due to developmentally abnormal nephrons, whose further scarring may resolve the proteinuria. Moreover, we were reassured by the non-severe degree of proteinuria and the absence of symptoms. But the persisting proteinuria prompted us to start therapy with losartan, which reduced the proteinuria. This case suggests that immature glomeruli might be a benign cause of proteinuria, while also indicating a developmental correlation with the horseshoe kidney.



Renal biopsy with PAS stain showing an immature glomerulus having prominent podocytes (Yellow arrowheads) and a normal glomerulus (Black arrowheads)

PUB461

Severe Hypertension in a Female Adolescent with Severe Chronic Obstructive Unilateral Hydronephrosis

Asma B. Shaoba, Oluwatoyin F. Bamgbola. *SUNY Downstate Health Sciences University, New York City, NY.*

Introduction: Hypertension is rare in patients with a unilateral ureteral obstruction (UUO) due to a functional compensation from the contralateral kidney. We describe an adolescent who had severe hypertension and an incidental finding of a congenital UUO. We postulated the mechanisms of hypertension and highlighted the decision-making dilemma on therapeutic intervention.

Case Description: A 15-year-old African American female was admitted for shortness of breath, pharyngitis, and fever. BMI was 29.3 kg/m2, T 102.7 F, HR 118/min, RR 26/min, and BP 158/101 mmHg. CT angiogram did not reveal pulmonary embolism. Instead, she had severe right-sided hydroureteronephrosis with extreme cortical thinning (Fig 1A). On renal US, right kidney measured 22.1 x 9.6 x 10.7 cm while left kidney was 11.4 x 6.0 x 6.0 cm. The washout times of the LK and RK on diuretic renogram were 7 (30%) and 46 (70%) minutes respectively (Fig 1B). Plasma renin activity, serum creatinine and aldosterone were normal. Her BP was controlled with labetalol and thereafter angiotensin-receptor blocker. A pediatric urologist contemplated a right-sided nephrectomy.

Discussion: Studies showed elevation of plasma renin in hypertensive acute UUO but it is often normal in chronic UUO. Plausible mechanisms for intrarenal generation of renin in the latter may include renal ischemia, ureterorenal reflex [prostaglandins], and distension of renal capsule with its sympathetic innervation. Given the rapid control of the BP, and absence of a prior acute pyelonephritis, we recommend supportive care rather than nephrectomy.

Figure 1: A contrast-enhanced CT scan imaging showing a severe obstructive right-sided hydronephrosis (blue arrow).

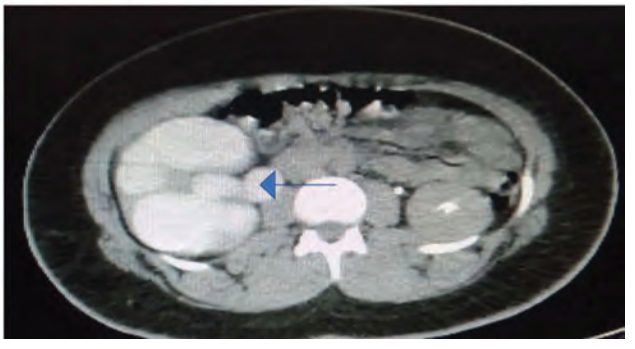


Figure 1 B: A diuretic MAG 3 renal scan showed a reduced renal uptake, and delayed excretion of radioisotope from the obstructed right kidney (broken green line).

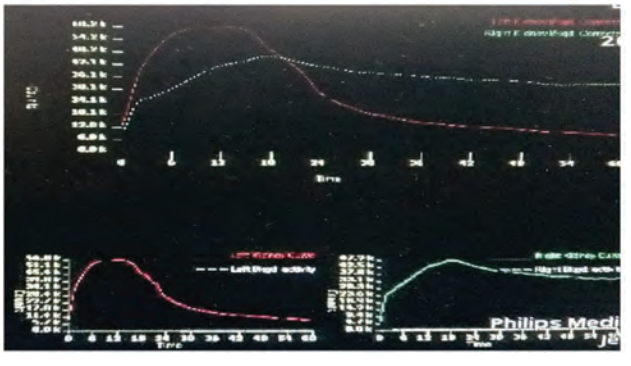


PUB462

General Pediatrician Confidence in Managing First-Time Microscopic Hematuria or Proteinuria

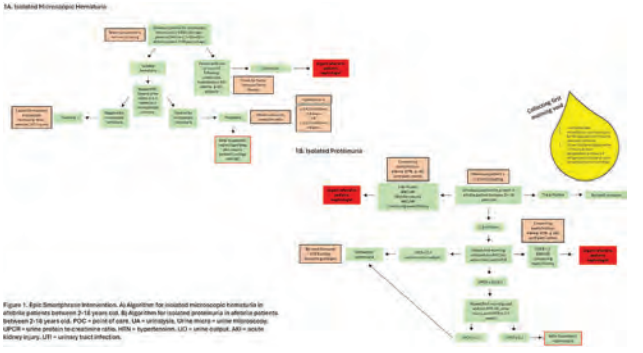
Kayla J. Erspamer, Kelsey L. Richardson, Abbie R. Bauer. *Oregon Health & Science University, Portland, OR.*

Background: Microscopic hematuria and proteinuria are frequently detected in the pediatric population and are often referred to pediatric nephrology. While both can signify renal disease, if either is detected in isolation without other symptoms it is more likely benign. Many articles include algorithms to help pediatricians in the initial workup of hematuria and proteinuria, but there have not been any studies analyzing if providing algorithms or electronic health care record tools improve management confidence. The purpose of this study is to determine pediatrician confidence in management of first-time microscopic hematuria and proteinuria with and without an algorithm.

Methods: Pre-intervention surveys (11 questions) were distributed to general pediatric and adolescent medicine clinicians via email with a link to the Qualtrics survey. Epic Smartphrases with the algorithm for isolated microscopic hematuria and isolated proteinuria in afebrile patients between 2-18 years old were made available in Epic to those surveyed with an email announcement in March 2024 (Figure 1). Post-intervention surveys (12 questions) will be distributed after at least six months of intervention.

Results: Forty-seven clinicians completed the pre-intervention survey (55%). Clinicians are more confident in interpreting rather than managing microscopic hematuria and proteinuria. For microscopic hematuria, 28%, 49%, and 23% marked confident, some confidence, and little confidence respectively for interpretation compared to 17%, 30%, and 47% for management. For proteinuria, 17%, 60%, and 23% marked confident, some confidence, and little confidence respectively for interpretation compared to 17%, 38%, and 40% for management. Ninety percent of respondents said yes when asked if they would use an Epic Smartphrase algorithm.

Conclusions: General pediatricians are more confident in interpreting rather than managing first-time microscopic hematuria and proteinuria. The majority of those surveyed would use an Epic Smartphrase algorithm and this type of intervention warrants further study.



PUB463

A Case of Proximal Renal Tubular Acidosis without Fanconi Syndrome

Isaac Esplin, Morgan E. Beebe, O. N. Ray Bignall. *Nationwide Children's Hospital, Columbus, OH.*

Introduction: Proximal renal tubular acidosis (pRTA) is characterized by impaired resorption of bicarbonate in the proximal tubule. This occurs most commonly with Fanconi syndrome, as isolated pRTA is rare. The most common inherited form is an autosomal recessive mutation in the Na/HCO3 transporter; infants with a sporadic form tend to spontaneously improve over time. We present a case of isolated pRTA confounded by a history of diarrhea in a neonate.

Case Description: A 4-week-old term baby girl presented with poor weight gain (+160 g from birth) and fussiness, found to have metabolic acidosis. Initial labs showed hypokalemia, hyperchloremia and anion gap metabolic acidosis (AGMA) with a gap of 15. After fluid resuscitation, subsequent labs showed a non-AGMA. Urine pH was 5.0 with no protein or glucose; urine chloride level was <15mmol/L. Mom reported persistent diarrhea, which was favored to be the cause of her acidosis. She began supplementation with potassium citrate during admission with improvement in labs. Two weeks later, she returned with recurrence of diarrhea, non-AGMA, and hypernatremia in the setting of adenovirus infection and overconcentrated formula due to improper preparation. Her acidosis improved with fluids and increase of potassium citrate. After two more weeks she was readmitted from Nephrology Clinic with persistent non-AGMA. The urine pH was 6.0 with a gap of -24.9. Mom reported persistent diarrhea, but inpatient stools were observed to be normal. A clinical diagnosis of isolated pRTA was then made; the family refused genetic testing. Magnesium citrate was added to regimen, with improvement in hypokalemia and bicarbonate levels prior to discharge. She continues to grow well in follow up.

Discussion: This case highlights pRTA without Fanconi syndrome as the cause of poor growth and non-AGMA in a neonate. It also demonstrates the difficulty in recognizing an isolated pRTA if more common etiologies are reported, especially when patients have confounding historical factors or lab results. An accurate history is paramount in making the diagnosis when genetic testing is unavailable to help distinguish between stool or renal bicarbonate losses, and a pRTA diagnosis should not be discounted in the absence of Fanconi syndrome.

PUB464

Factors Associated with Successful Transition from Pediatric to Adult Nephrology

Laura Nishi,[1,2] Jay H. Kang,[2] Cybele Ghossein.[1] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Northwestern Memorial HealthCare, Chicago, IL.*

Background: Young adults (YA) aged 18-26 with chronic kidney disease face challenges when transitioning from pediatric to adult care. To improve successful transition (ST) rates, Northwestern Medicine (NM) partnered with Lurie Children's Hospital to implement a transition of care program. To better understand risk factors for failure to transition, we retrospectively reviewed our 8-year clinic data.

Methods: YA seen in the transition clinic between 2014-2022 were included in the analysis. ST was defined as one visit to NM. We compared baseline kidney function, insurance, distance from clinic, average household income, and pediatric no-show rate for those YA who ST to those who did not.

Results: 166 total patients were seen, with 154 patients being eligible to transition. 92% of patients ST and 8% were lost to follow up (Table 1). YA who ST had lower baseline kidney function and were more likely to have private insurance. Those who did not ST were more likely to have no insurance. The other factors were not significantly correlated with ST.

Conclusions: Based on our retrospective study, baseline kidney function and insurance status are associated with ST in YA with kidney disease. Further prospective studies are needed to confirm our findings in this high-risk population.

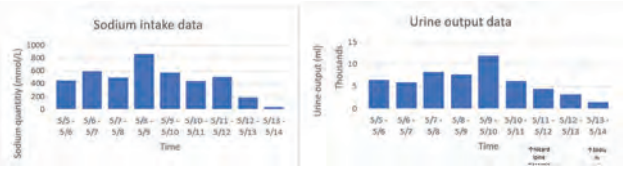
An Unusual Case of Renovascular Hypertension in a Pediatric Patient Associated with Hyponatremia and Polyuria Responding to Angioplasty and Losartan

Ayodele Obigbesan, Matthew Oelstrom, Omar N. Al Masri. *Marshfield Clinic Health System, Marshfield, WI.*

Introduction: Renovascular abnormalities are an important cause of secondary hypertension in pediatric population. Hyponatremia and polyuria are uncommon complications.

Case Description: This is a report of a 13-year-old female who developed hypertensive emergency secondary to unilateral renal artery stenosis. She presented with a two-week history of severe headaches, nausea, vomiting, polyuria and enuresis. Initial Blood Pressure (BP) was 196/132mmHg. It was safely lowered over 48 hours to 115-130mmHg range using Nicardipine infusion. Laboratory tests on admission showed Sodium 128 mmol/L, Potassium 2.1 mmol/L, Plasma Renin Activity (220ng/ml/hr, normal limit<2.4), and Aldosterone levels (45ng/dL, normal<21). Echocardiography revealed mild concentric left ventricular hypertrophy, with normal aorta. Computerized Tomography Angiography (CTA) showed delayed enhancement of the relatively small size right kidney with stenosis of the ostium of its main artery. Digital Subtraction Angiography done on hospital day #5, confirmed CTA findings and demonstrated presence of collateral flow through a hypertrophied right adrenal artery which explains kidney viability despite severe stenosis. Balloon angioplasty was successful in restoring blood flow with 15-20% residual stenosis. Post-procedure, she required less Nicardipine infusion and subsequently transitioned to oral Amlodipine. Polyuria and hyponatremia were observed upon admission and persisted despite achieving BP target early during hospitalization, after angioplasty it started to improve. Losartan 12.5mg was commenced on day 7 with further improvement in polyuria and no further need for salt supplementation (figure 1 and 2).

Discussion: Renovascular disease can lead to life threatening hypertensive emergencies. Excessive diuresis and hyponatremia have complicated the management of our case. It required efforts to replace losses using large volumes of fluids and sodium chloride to maintain homeostasis. Hyperfiltration due to Angiotensin II excess is the plausible underlying mechanism; this explains why It started to improve gradually following angioplasty and the addition of Losartan.



PUB466

Association of Maternal Hypertensive Disorders in Pregnancy and Offspring Kidney Function from Adolescence into Young Adulthood

Jo A. Kelly, Andrew M. South. *Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: Maternal hypertension (HTN) during pregnancy is associated with significant health complications for the mother and offspring. Little research exists on its effect on offspring kidney function into young adulthood. Our aim is to estimate the association of maternal HTN during pregnancy with offspring kidney function in adolescence and young adulthood.

Methods: This is a secondary longitudinal analysis of data collected in a prospective cohort study of individuals born with very low or extremely low birth weight (birth weight <1500 g). Participants were assessed at 14–15 and 19–23 years old. Blood and first-morning urine samples were collected. We estimated the glomerular filtration rate (eGFR) using the original creatinine-based Schwartz equation in adolescents and the CKD-EPI 2021 creatinine-cystatin C equation in young adults. We calculated the albumin-to-creatinine ratio at both time points. We estimated the relationships with multivariable generalized linear models informed by directed acyclic graphs.

Results: Of the 213 included participants, 113 (53%) were female, 89 (42%) were Black, and 79 (37%) were exposed to maternal HTN. The mean eGFR was 130.2 mL/min/1.73 m2 in adolescence (n=124) and 168.7 mL/min/1.73 m2 in young adulthood (n=159). The median ACR was 5.3 mg/g in adolescence and 3.1 mg/g in young adulthood. Kidney function in adolescence was associated with kidney function in young adulthood (eGFR adjusted β 0.48 mL/min/1.73 m2, 95% CL 0.21–0.75; ACR adjusted β 0.19 mg/g, 95% CL 0.15–0.24). There was no significant association between maternal HTN and kidney function in both adolescence and young adulthood.

Conclusions: We found no significant association between maternal HTN in pregnancy and offspring kidney function in adolescence and young adulthood. The next step for this project is to perform a causal mediation analysis to estimate the direct effect of maternal HTN in pregnancy on young adult kidney function and the indirect effect mediated by adolescent kidney function.

A Rare Presentation: Male Neonate with Severe Bilateral Hydronephrosis and Normokalemic Acute Renal Tubular Acidosis

Victoria Gutierrez-Lorea,[1] Carol E. Perez Mena,[1,2] Jose A. Rodriguez.[2] *[1]Ponce Health Sciences University, Ponce, PR; [2]Hospital Episcopal San Lucas, Ponce, PR.*

Introduction: Among the most common causes of hydronephrosis in neonates are birth defects that lead to Ureteropelvic Junction obstruction (UPJ) and Vesicoureteral Reflux (VUR). If the obstructive uropathy is chronic, renal tubules lose their function leading to Renal Tubular Acidosis (RTA). Here we present a male neonate who presented with severe bilateral hydronephrosis which caused acute RTA.

Case Description: A male newborn patient born at 37 weeks gestational age with perinatal diagnosis of bilateral hydronephrosis and unremarkable physical exam was admitted for evaluation. Protocole laboratories, showed abnormal BUN (16 mg/dl), creatinine level (1.71 mg/dl) and normal values of potassium. The patient started exhibiting progressive decline in Carbon dioxide (CO2) levels despite adequate feeding and intravenous fluids. Acute RTA was suspected. ABG showing mild metabolic acidosis (PH 7.29, HCO3 21, CO2 44), ammonia levels at 40 mg/dl and unremarkable urine analysis. Patient was started on Sodium Citrate at 2mEq/kgdose every 8 hours. Result of Voiding Cysto-Urethrogram (VCUG) is seen on Figure 1. Patient was transferred to another facility for further evaluation.

Discussion: Severe bilateral hydronephrosis caused by UPJ and VUR which consequently leads to acute RTA is extremely rare in a neonate. We believe chronic obstructive nephropathy led to RTA with severe renal impairment. Although one hallmark of RTA is hypokalemia, the hypokalemic levels were likely masked by the administration of Sodium Citrate. Healthcare providers should be aware of unreliable potassium values in RTA patients taking sodium citrate.

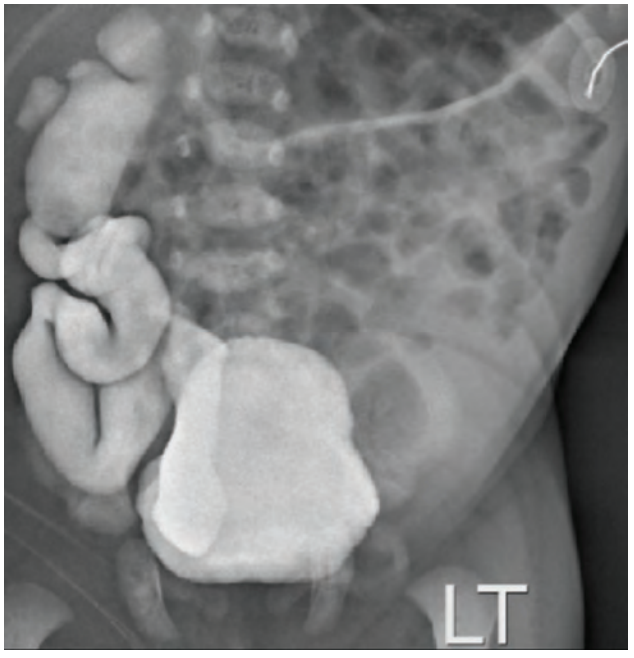

Figure 1: VCUG shows severe reflux from the right-sided ureter and significant dilation of the renal pelvic, calyces and infundibulum. No reflux is evident on the left.

PUB468

Establishment of Reference Values for Estimated Kidney Volume Using Ultrasonography in Japanese Pediatric Patients

Hideki Matsumura, Yuko Fujii, Tomoko Tanaka, Akihiko Shirasu, Akira Ashida. *Osaka Ika Yakka Daigaku, Takatsuki, Japan.*

Background: Ultrasonography serves as a noninvasive and effective screening modality for renal evaluation. Assessing renal dimensions is crucial, given the established correlation between renal function and kidney size. In pediatric populations, renal size varies with growth, necessitating the establishment of growth-specific reference values. Renal length reference values derived from ultrasonography are widely utilized in clinical practice due to their ease of measurement. However, we believe that renal length alone is inadequate for a comprehensive assessment of kidney size due to the variability in renal morphology. Consequently, we hypothesize that renal volume provides a more precise metric for evaluating kidney size and have investigated the reference values for renal volume in Japanese children with normal renal function.

Methods: We measured serum creatinine levels, body height and weight, and renal long and short diameters and depths via ultrasonography in pediatric patients under 18 years of age without renal disease. We included patients with eGFR within the reference range and excluded those with body height and weight significantly deviating from the reference values. We calculated kidney volume using the average of two ultrasound measurements of kidney size, approximated as an ellipsoid: long diameter × short diameter × thickness × π / 6.

Results: Out of 42 candidates, 29 patients meeting the criteria for body height, weight, and eGFR were included in the study. The median age of participants was 12 years. The strongest correlation was found between renal volume and body surface area ($r^2 = 0.852$), followed by age, body height, weight, or body mass index. Total kidney volume, defined as the sum of bilateral kidney volumes divided by body surface area, increased with growth, with multivariate analysis identifying age as the primary influencing factor. Thus, the reference value for total kidney volume can be expressed as total kidney volume/body surface area (mL/m^2) = 140 + age × 2. This reference value for renal volume showed a stronger correlation with the previously reported reference value for renal length diameter in Japanese children. Furthermore, renal volume correlates more strongly with eGFR than renal length diameter.

Conclusions: Renal volume is the more precise method for evaluating renal size.

PUB469

Posterior Urethral Valve Masquerading as Failure to Thrive

Staney A. John, Nikhila Aimalla, Omar N. Al Masri. *Marshfield Clinic Health System, Marshfield, WI.*

Introduction: Only half the cases of posterior urethral valves (PUV) are diagnosed antenatally with dilated kidneys and ureters. The rest, present later in life with failure to thrive (FTT), recurrent urinary tract infections (UTI) and nocturnal enuresis in older boys. Undiagnosed PUVs can have sequelae such as progression to chronic kidney disease, vesicoureteral reflux (VUR) and overactive bladder which can be prevented if picked up early.

Case Description: Patient is a 6 month old male, ex-35 weeker born small-for-gestational age with an otherwise normal prenatal course who presented with FTT. Since birth, his weight has been tracking below the 3rd centile. He had been tried from breast milk to various formulae over a period of time with minimal weight gain. He was having frequent spit-ups and took frequent small volume feeds; so was started on a proton pump inhibitor for possible gastroesophaegal reflux. There was also concerns of crying during voiding and stooling. He was admitted to the hospital and was started on scheduled feeds. His labs were unremarkable except for mild hyponatremia (132 mEq/L), 3+ red blood cells and 3+ leukocyte esterase in the urine. His C-reactive protein was moderately elevated. So a catheterized urine sample was obtained which also revealed the same findings and was sent for culture. The next day, his serum sodium dropped further (128 mEq/L) with a 4x rise in serum creatinine (0.8 mg/dL). Physical exam disclosed a new mass in the right iliac fossa. Ultrasonography revealed a massively distended urinary bladder with bilateral moderate-to-severe hydroureteronephrosis. A voiding cystourethrogram revealed dilatation and elongation of the posterior urethra, grade 5 VUR on the left and severe bladder trabeculation concerning for a PUV. An indweling Foley's catheter was placed and his serum sodium and creatinine normalized within the next few hours. Urine culture was sterile, but he was started on prophylactic antbiotics given his severe VUR and was referred to a higher facility for surgical correction.

Discussion: PUV is a rare yet serious cause of FTT in male children. This case was a reminder of how PUVs can be present even in babies who did not have oligohydramnios in-utero and have been voiding well. Chronic struggling to void against a tight urethra, fighting recurrent UTIs and a distended bladder which limits food intake can all contribute to poor weight gain in babies.

PUB470

Vacation in Egypt as Major Risk for Shiga Toxin Escherichia coli Infection in Children during 2023: Data from the ItalKid-HUS Network

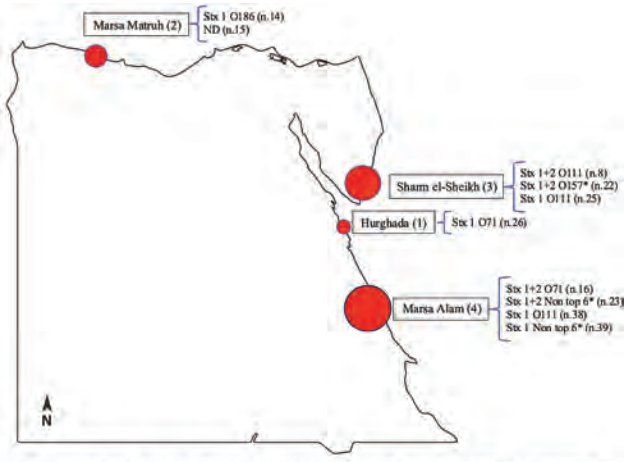
Thomas Ria,[1] Gianluigi Ardissino,[1] Maria Cristina Mancuso,[1] Laura Daprai,[5] Alessandra Gazzola,[2] Sara Arnaboldi,[6] Mario V. Luini,[3] Dario Consonni.[4] *[1]Centro per la Cura e lo Studio della Sindrome Emolitica Uremica, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Istituto Zooprofilattico Sperimentale della Lombardia e dell'Emilia Romagna, Lodi, Italy; [3]Institute of Agricultural Biology and Biotechnology, National Research Council, Lodi, Italy; [4]Epidemiology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [5]SC Patologia Clinica, Laboratorio di Microbiologia, Fondazione IRCCS CA' Granda, Ospedale Maggiore Policlinico, Milan, Italy; [6]Department of Food Safety, Istituto Zooprofilattico Sperimentale della Lombardia e dell'Emilia-Romagna "Bruno Ubertini" (IZSLER), Brescia, Italy.*

Background: Hemolytic uremic syndrome (HUS) is a severe thrombotic microangiopathy that may develop as a complication of Shiga toxin-producing *Escherichia coli* (STEC) infection. Although environmental sources of STEC are known, in individual cases the source of infection usually remains unknown. During 2023 we observed several cases of infection in children returning from vacations, thus we evaluated the association between the infection and travel patterns.

Methods: We analyzed all Shiga toxin genes-positive children with bloody diarrhea identified during 2023 by the ItalKid-HUS Network surveillance system in Northern Italy. Families of infected children were contacted and a short questionnaire regarding recent travels abroad was administered. The exposure time was considered since the 3rd day after the arrival abroad until the 5th day after the return home. A self-controlled case series (SCCS) design was used to calculate relative risk.

Results: Of 43 cases with STEC infection, 32 had uncomplicated infection while 11 developed HUS. Twenty-three subjects did not travel abroad, while 20 had travelled to several destinations. For 12 subjects (10 travelled to Egypt, 1 to Kosovo and 1 to Albania), we identified an association between infection and travelling. The relative risk associated to travelling to Egypt was 88-fold. Serotype analysis excluded the possibility of an epidemic given the variability of the strains found. Exposures analysis didn't provide evidence of a single potential source of the infection.

Conclusions: There is an elevated risk of acquiring STEC infection (thus of HUS) associated with travelling to Egypt. Specific investigations to identify the source are needed to develop effective preventive measures.



ND: not determined; Non Top 6: STEC whose serotype is not O157, O26, O103, O111, O104 or O145; *: Determined in stools by Real Time PCR only.

Ophthalmologic Symptoms and Practice Patterns in Children and Young Adults in the NAPRTCS Cystinosis Registry

Sara A. Boynton,[1] Bradley A. Warady,[2] Larry A. Greenbaum,[3] Paul C. Grimm,[4] Alicia Neu,[1] Jodi M. Smith.[5] *[1]Johns Hopkins University, Baltimore, MD; [2]Children's Mercy Kansas City, Kansas City, MO; [3]Emory University, Atlanta, GA; [4]Stanford University, Stanford, CA; [5]Seattle Children's Hospital, Seattle, WA.*

Background: Launched in 2018, the NAPRTCS Cystinosis Registry is a prospective cohort study of children & young adults with cystinosis whose objective is to describe the clinical features of cystinosis and practice patterns of providers. The NAPRTCS Cystinosis Registry includes detailed information on ophthalmologic clinical outcomes and related care practices.

Methods: Children and young adults <25 years of age at a participating NAPRTCS center are eligible for inclusion in the NAPRTCS Cystinosis Registry. Data are collected from time of diagnosis, at time of registry entry, and every 6 months thereafter.

Results: The NAPRTCS Cystinosis Registry has collected clinical information on children & young adults with cystinosis since 2018 and includes information on 104 patients from 30 centers who were diagnosed from 12/1999 to 8/2023. Participants are primarily male (52.9%), majority White (77.9%), and over a quarter (28.8%) live ≥ 50 miles from the treating center. Median age is 16.5 months at diagnosis and 9 years at registry entry. At time of diagnosis corneal deposits were reported in 32.3% of participants and cysteamine eye drops were prescribed to 34.4%. At time of registry entry, a visit with an ophthalmologist was reported for 28.4% of participants and an ophthalmologic exam for 26.3%, 26.6% reported photophobia and 24.3% wore glasses. Of those participants with an exam, 72% had corneal crystals and 12% retinal changes. Throughout the follow up period, the majority of participants of were on cysteamine eye drops (73.7% at registry entry; 82.4% at 12 months; 84.2% at 24 months).

Conclusions: The NAPRTCS Cystinosis Registry provides a unique opportunity to gain insight into the pediatric cystinosis population and to further our understanding of the complex care needs of pediatric cystinosis patients. Children and young adults with cystinosis have significant ophthalmological clinical features necessitating treatment with cysteamine eye drops and close follow up.

Blue in the Face: Dapsone-Induced Methemoglobinemia in a Woman with Minimal Change Disease

Nicholas W. Salupo, James F. Simon. *Cleveland Clinic, Cleveland, OH.*

Introduction: Dapsone is a sulfone antibiotic effective for Pneumocystis jiroveci pneumonia (PJP) prophylaxis. It can induce methemoglobinemia, a potentially life-threatening condition marked by impaired oxygen delivery. While glucose-6-phosphate dehydrogenase (G-6-PD) deficiency is a risk factor for developing methemoglobinemia, this complication can develop in its absence.

Case Description: A 23-year-old female with minimal change disease flare and a previous allergic reaction to trimethoprim-sulfamethoxazole was placed on prednisone 30 mg daily with concurrent dapsone for PJP prophylaxis. G-6-PD level measured prior to starting therapy was elevated at 15.8U/g Hb (9.8-15.5 U/g Hb). She immediately developed progressively worsening perioral cyanosis, burning sensation of her lips and face and difficulty concentrating. On evaluation 4 days later, pulse oximetry revealed 92% on room air. PaO2 was 93 mm Hg. There was no "saturation gap," however arterial methemoglobin was 7.3%. Dapsone was discontinued, and intravenous methylene blue administered, leading to rapid clinical improvement and resolution of methemoglobinemia.

Discussion: This case emphasizes the potential for dapsone-induced methemoglobinemia even in young individuals without classic risk factors, like G-6-PD deficiency or underlying respiratory disease. Early recognition of clinical features is crucial for prompt diagnosis and treatment. Methylene blue remains the first-line therapy for symptomatic methemoglobinemia. This case underscores the need to vigilantly monitor patients taking dapsone, regardless of age or traditional risk factors. A high index of suspicion for methemoglobinemia in the setting of unexplained cyanosis or hypoxia can potentially prevent more serious complications.

PUB473

Transthyretin (ATTR) Cardiac Amyloidosis with Kidney Involvement

Nihal Bashir. *Seha Kidney Care, AlAin, United Arab Emirates.*

Introduction: Amyloidosis refers to the extracellular deposition of fibrils arising from a variety of serum proteins. These fibrils adopt a beta-pleated sheet configuration that leads to characteristic histologic changes. Amyloid deposits can occur in a variety of organs, but morbidity and mortality from amyloid deposition most commonly occur when the heart, kidney, liver, or autonomic nervous system are affected. ATTR-CA (transthyretin) leads to a progressive restrictive physiology with reduced stroke volume, decreased compliance, and compromised cardiac output. Studies directly addressing the benefit of traditional heart failure (HF) medical therapy for ATTR-CA remain limited.

Case Description: 77 years old male known to have history of hypertension, dyslipidaemia, chronic kidney disease stage 3, he was following with cardiology in 2022 for symptoms of shortness of breath and chest pain and his ECHO showed sever aortic regurgitation and mild left ventricle global systolic dysfunction with restrictive filling pattern but no aortic stenosis. Two years later he was admitted with worsening renal function, anasarca and right arm cellulitis with Methicillin sensitive staphylococcus aureus (MSSA) bacteraemia. His ECHO showed sever aortic stenosis this time. His urine protein was negative during the 2 years follow up period. He was started on haemodialysis and underwent Cardiac scintigraphy which was strongly suggestive of Transthyretin amyloidosis. The patient was started on Tafamidis which prevents cleavage of transthyretin tetramers and may reduce deposition of amyloid. The patient currently on twice per week haemodialysis and his creatinine 150-200 micromole/L and on watchful followup for his renal function recovery.

Discussion: ATTR AMYLOIDOSIS In patients with ATTR cardiac amyloidosis and New York Heart Association (NYHA) functional class I to III HF symptoms, treatment with tafamidis is recommended rather than no disease-specific therapy. Tafamidis is given as tafamidis meglumine 80 mg daily or as tafamidis 61 mg daily. Tafamidis (either formulation) does not require specific monitoring and is continued indefinitely. The high cost of tafamidis is a major barrier to therapy. Tafamidis reduced the rate of mortality compared with placebo and reduced the rate of cardiovascular-related hospitalizations, it also reduced the rate of decline in six-minute walk distance and Kansas City Cardiomyopathy Questionnaire-Overall Summary.

PUB474

Unexplained Severe and Recurrent Hypoglycemia in a Patient with History of Miliary Tuberculosis, Systemic Lupus Erythematosus (SLE), and ESKD on Chronic Hemodialysis

Jose F. Bernardo,[1] Marco A. Dominguez,[2] Carlos R. Valenzuela.[2] *[1]Clinica Medica Cayetano Heredia, Lima, Peru; [2]Hospital Nacional Cayetano Heredia, Lima, Peru.*

Introduction: Hypoglycemia is defined by a plasma glucose below 70 mg/dl, with symptoms usually manifest whenever the levels are less than 55 mg/L. The brain needs continuous supply of glucose as a fuel. During fasting state, the serum glucose level is maintained as a result of the gluconeogenesis and glycogenolysis by theliver. Coma is usually the most common presentation of severe hypoglycemia. We describe a patient

on chronic hemodialysis with adequate oral intake presenting with recurrent episodes of agitation and seizures related to hypoglycemic attacks

Case Description: 34 years old male with history of ESRD on HD, hypertension, had a recent diagnosis of miliary tuberculosis (on standard dose reatment with isoniazid, rifampim, ethambutol and pirazinamide. He also a diagnosis of Systemic Erythematous Lupus, on maintenance with hydroxycloroquine. He was admitted on April 2024 for an episode of severe hypoglycemia. A month later he was admitted with 1 week of progressive weakness, dyspnea on exertion, agitation and confusion. On admission blood glucose was reported at 55 mg/dl atributed to poor oral intake. The patient presented to the ER with an episode of clonic-tonic seizures with loss of consciousnes for one hour. There was no history of decreased oral intake, nausea or vomiting and he was compliant with HD sessions. On admission: had a BP 122/68 mmHg, HR 110 bpm, afebrile, POx 94% on room air. Oral mucosa hydrated, no significant edema. Neurological exam: stupurous, no focal motor deficits. Imaging studies were non revealing. Blood glucose level was 65 mg-dl. He was managed with Dx10% for several hours with a persistent blood glucose of less than 100 mg/dl. An ACTH level was 26.87 pg/ml (7.20-63.30 pg/ml.

Discussion: Our patient was compliant with his chronic HD and medication, There was no history of depression. His food intake was closely observed while in the hospital. During his hospital stay, had repeated episodes of severe hypoglycemia. Diagnostic studies did not suggest the presence of an adrenal infarction and(or the presence of an insulinoma. His prescription of hydroxycloroquine was discontinued with marked and rapid improvement of his glucose levels. Hypoglycemia as a side effect of hydroxycloroquine has been previously described, the incidence however has not been well established.

PUB475

Rifampin as Rescue Therapy for Paxlovid-Associated Calcineurin Inhibitor Toxicity

Shejuti Paul, Sandeep Aggarwal. *University of Pennsylvania, Philadelphia, PA.*

Introduction: Ritonavir-nirmatrelvir (Paxlovid) is effective in treating COVID-19 but is a strong CYP inhibitor that can provoke life threatening calcineurin inhibitor toxicity (CNI). We present a novel case of treating severe CNI intoxication 2/2 to Paxlovid using rifampin as rescue therapy in a heart transplant recipient.

Case Description: The patient was a 40YO male with history of heart transplant in 2003 on tacrolimus and rapamycin, hypertension, and type II diabetes. He contracted covid-19 and was prescribed Paxlovid. Patient presented 3 days later with severe headache, tremors, tachycardia, and hypertension. Found to have acute kidney injury (AKI) with creatinine (Cr) 3.15 from baseline Cr 1.0. Tacrolimus level 53 and rapamycin 23. Tacrolimus and rapamycin held with no improvement. Treated with CYP inducer rifampin 300mg BID for 1 day and IV hydration for 3 days. Patient's symptom resolved. AKI improved with Cr near baseline. Subsequent troughs improved until no longer supratherapeutic. Restarted on rapamycin and tacrolimus day 4 of hospitalization.

Discussion: Paxlovid is a strong inhibitor of cytochrome P450 activity which when used with CNIs can provoke supra-therapeutic levels. Toxicity is associated with AKI, neurotoxicity, and HTN. The use of rifampin for CYP induction therapy resulted in resolution of symptoms, rapid reduction of CNI trough concentrations, and full renal recovery. As Paxlovid becomes more widely used for covid-19 treatment, we can expect more incidence of CNI toxicity. Rifampin is a potent CYP inducer and can be an effective rescue therapy for severe CNI toxicity. More studies are needed to understand drug-drug interactions and treatment of CNI toxicity.

Valacyclovir Toxicity in Patients with ESKD: A Case Series

Nahom Eyasu,[1] Sonali Poobalasingham,[3] Danielle Feldman,[3] Ajai S. Rajabalan,[2,4] Jason Cobb.[1] *[1]Emory University, Atlanta, GA; [2]Wellstar Health System Inc, Marietta, GA; [3]Emory University Emory College of Arts and Sciences, Atlanta, GA; [4]Augusta University, Augusta, GA.*

Background: Valacyclovir (VCV), a cornerstone in managing herpes virus infections, poses unique challenges in ESRD patients. There is sparse literature on VCV toxicity in this population. More data is available regarding acyclovir toxicity, however, VCV has a longer duration of action and is becoming more commonly used.

Methods: We present two cases and a review of literature of VCV toxicity in ESRD patients.

Results: Case 1: A 33-year-old female with ESRD on peritoneal dialysis (PD) with a right-sided rash suspicious for zoster was prescribed oral VCV 1 g TID at an urgent care. Within 24 hours, she exhibited new-onset confusion and involuntary movements. Suspecting VCV toxicity, the medication was discontinued, and continuous PD provided symptom relief. Case 2: A 54-year-old man with ESRD on hemodialysis (HD) was started on oral VCV 1 g TID for zoster at an urgent care and presented to us with visual and auditory hallucinations. Suspecting VCV neurotoxicity, emergent HD was performed, resulting in symptom resolution after one treatment. Review: 19 total patients on different dialysis modalities: PD (9) and HD (10). Average age 61.6 years. 50% female (7), some case reports did not report gender. All HD patients appeared to respond to a single HD treatment. We were unable to determine specific treatment regimens for PD patients.

Conclusions: The literature on VCV toxicity in ESRD patients has been confined to only case reports and we are the first to present a literature review. VCV's longer duration makes it the treatment of choice for herpes zoster, however, the occurrence of VCV toxicity in ESRD patients is likely to rise if not dosed correctly. PD patients comprise 11-12% of ESRD patients but are involved in 47% of VCV toxicity cases. We suspect that PD patients are more susceptible to VCV toxicity, which raises questions about the differential impact of dialysis modalities on its clearance. In addition, the older age of patients may play a role as well. The critical clinical presentation of our patients underscores the importance of both vigilant monitoring and the need to inform primary and urgent care physicians about the dosing of VCV in the setting of renal dysfunction – 1 g oral daily for ESRD patients.

PUB477

Mind Matters: Muscle Relaxants and Kidney Health, a Case of Baclofen Neurotoxicity

Daniela Carralero Somoza, Graciela M. Luna, Umair S. Ahmed, Kaitlyn Cariaga. *Lakeland Regional Medical Center Inc, Lakeland, FL.*

Introduction: Drug adjustment in the setting of chronic kidney disease is something as physicians we stay vigilant. When prescribing muscle relaxants, the rule does not change. Although baclofen neurotoxicity in presence of CKD is rare, a few reported cases have been evaluated and we present one below.

Case Description: 75-year-old female with hypertension, Type 2 diabetes, hyperlipidemia, and CKD stage IV presented with altered mental status from an assisted living facility. Two days prior, the patient had been prescribed baclofen 10mg tid and was taking it as directed. CT scan of the head revealed no acute intracranial issues. Nephrology was consulted due to elevated creatinine (3.0) and BUN (49), with positive protein in urine analysis. Metabolic encephalopathy was deemed less likely due to uremia given renal parameters, while baclofen neurotoxicity was considered more probable given underlying kidney disease and recent baclofen use in the setting of low GFR. Hemodialysis was initiated due to progressing encephalopathy, leading to improved alertness following the first session.

Discussion: Approximately 10 to 15% of baclofen undergoes hepatic metabolism, while the remaining 85 to 90% is excreted by the kidneys. Baclofen penetrates CNS by directly crossing the blood brain barrier. Baclofen elimination is heavily dependent on renal clearance and patients with reduced kidney function are at higher risk for intoxication. While studies have examined the relationship between dosage and encephalopathy development with the use of baclofen, further data are required to comprehensively assess the safety profile and prescribing guidelines for this medication in CKD patients. This case emphasizes the ongoing quest to refine dose adjustments based on GFR and will serve as a gateway to explore the broader effects of baclofen in CKD. Nevertheless, it's imperative for clinicians to exercise caution, recognizing that even muscle relaxants such as baclofen can pose risks in individuals with compromised renal function.

PUB478

An Unusual Case of Recurrence of Crescentic IgA Nephropathy in Kidney Allograft

Syed S. Hasni, Carla L. Ellis, Sujay D. Paudel, Mohammed Javeed Ansari, Sookhyeon Park. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Introduction: IgA nephropathy (IgAN) is the most common cause of primary glomerular disease worldwide. Recurrence rates have been reported at around 20-30%. Long term graft survival was significantly lower in patients with recurrent IgAN. We describe a case of recurrent IgAN after kidney transplant with crescents.

Case Description: A 35-year-old female with past medical history of ESKD due to biopsy proven IgAN underwent deceased donor kidney transplant with six antigen mismatches. Immunosuppression consisted of Alemtuzumab with Methylprednisolone, followed by long-acting tacrolimus and Mycophenolate mofetil. The patient experienced multiple urinary tract infections (UTI) and was maintained at low immunosuppression. The patients' creatinine (cr) began to rise from 1.0 to 1.58 with hematuria and elevated urine UPCR of 0.39 g/g at 2.5 year follow up. Her DSA, non-invasive gene expression profile, and donor-derived cell-free DNA were all negative. A biopsy showed recurrent IgAN with focal crescents and glomerular fibrin (Image-1). The patient was started on Prednisone 20mg daily for 2 weeks and then 10mg daily along with Losartan 12.5 mg daily for proteinuria. Her cr became stable at 1.23 and UPCR decreased to 0.2 g/g without hematuria.

Discussion: Recurrent IgAN is common but recurrent crescentic IgAN is rare. Many factors can contribute to the recurrence of IgAN, such as lowering immunosuppression due to recurrent UTIs and steroid withdrawal. Nephrologists must be aware that IgAN can recur after renal transplantation with aggressive features. Close monitoring should be performed on urine sediment abnormalities, serum creatine, and proteinuria followed by prompt kidney allograft biopsy. Maintaining low dose of prednisone and ACEi or ARB may help to prevent recurrence of IgAN in a renal allograft.

Acceptance of Opt-Out Organ Donation in Saudi Arabia: Insights from a Cross-Sectional Study

Sami A. Alobaidi. *University of Jeddah, Jeddah, Saudi Arabia.*

Background: Existing research reveals varied attitudes towards organ donation in the Middle East. This study specifically investigates public opinion on opt-out organ donation registration in Saudi Arabia, addressing a research gap identified through comparative studies in Qatar and Saudi Arabia.

Methods: This study analyzed data from a cross-sectional survey conducted among 1,397 residents of Saudi Arabia. The questionnaire, adapted from a previous study in Qatar, included three sections to gather socio-demographic information, assess general awareness about organ donation, and explore participants' agreement with opt-out consent along with their beliefs related to organ donation using the Theory of Planned Behaviour (TPB) model. Statistical methods were employed to determine significant associations and trends.

Results: Among the participants, nearly half (44.4%) supported opt-out consent, with women and Saudi citizens showing considerable support at 25.7% and 39.1% respectively. Women and individuals with diploma/graduation-level education were significantly more likely to support opt-out ($p<0.001$ and $p=0.012$, respectively). Of the opt-out supporters, a vast majority were familiar with organ donation (98.06%), willing to promote it (93.05%), and believed that registration saves lives (98.38%). Furthermore, 86.75% expressed readiness to support with more information, and 85.78% if informed about their religion's perspective on donation. A large proportion believed that both living and posthumous donations positively impact life after death (92.25%). However, concerns were raised about inadequate care (33.44%) and bodily disfigurement (28.43%) post-mortem. Most felt healthy enough to donate (45.56%) and appropriate in age (57.67%).

Conclusions: The study reveals considerable openness among Saudis toward an opt-out organ donation system, suggesting a potential avenue for significantly increasing organ donation rates. While acknowledging cultural and familial influences, targeted interventions are vital to address specific barriers such as concerns about post-mortem care and bodily integrity. Implementing informed policies based on these insights could facilitate the successful adoption of an opt-out policy, enhancing organ donation rates in the region.

PUB480

Cystinuria following Successful Kidney Transplantation in a Small Child: A Rare but Serious Complication

Rainer Büscher, Anja K. Büscher. *University of Duisburg-Essen, Pediatrics II, Essen, Germany.*

Introduction: Cystinuria, an autosomal recessive hereditary renal-tubular disorder is the most common genetic cause of nephrolithiasis in children and characterized by the impaired reabsorption of the amnio acids cystine, ornithine, lysine and arginine. Mutations in the genes *SLC3A1* and *SLC7A9*, encoding defective cystine transporter subunits have been identified as being responsible for most cases.

Case Description: We describe the case of a seven year old girl with autosomal recessive polycysic kidney disease and *PKHD1*-mutaion who received peritoneal dialysis for 16 months. Kidney transplantation from a deceased donor was successfully performed at the age of 4 years and 10 months. The kidney donor died from brain damage at the age of 14 months (10 kg, 80 cm). Pre-existing medical conditions of the donor were excluded, blood chemistry was normal and both kidneys showed no abnormalities in ultrasound and CT scan. Creatinine normalized within 3 days following renal transplantation (RTx) and the girl showed an uncomplicated clinical course. Nine months after RTx she was admitted with acute post-renal kidney failure with renal pelvic dilatation caused by obstruction with kidney stones in the transplanted kidney. Kidney function normalized quickly after insertion of an ureteral double-J cathether. Cystine stones were diagnosed and two compound heterozygous, pathological mutations in the donor *SLC3A1*-gene (c.647C>T, o.T216M and c.1400T>C, p.M467T) were deteced later on. The second donor kidney could not be transplanted and did not show concrements. The clinical course of our patient was complicated by 5 ureterorenoscopic stone displacements, repeated insertions of ureteral double-J catheters and three episodes of pyelonephritis. The girl presents now a stable renal function for the past 20 months (GFR 65 ml/min/1.73m^2) after repeated surgery, urine alkalization and reduction of the tubular cystine-reabsorption.

Discussion: Teaching point: Deceased young donor clinical factors may have a major impact on patient and/or kidney allograft survival. Cystinuria of the donor in this case was not diagnosed in advance because of the young donor age and missing early clinical symptoms. In the context of time-pressured decision-making and despite the good clinical outcomes of RTx with young donors, one has to consider that rare inherited diseases can be transferred accidentally.

PUB481

Main Obstacles of Pre-kidney Transplant Work-Up: A Quality Assessment/ Process Improvement Program

Abdelrahman Elsebaie,[1,2] Natalie Witton,[2] Wilma M. Hopman,[1,2] David C. Holland,[1,2] M. Khaled Shamseddin.[1,2] Kingston Kidney Transplant Program (KKTP). *[1]Queen's University, Kingston, ON, Canada; [2]Kingston Health Sciences Centre, Kingston, ON, Canada.*

Background: Failure to complete a comprehensive pre-kidney transplant workup results in increased dialysis exposure and poorer post-transplant survivals. Failure also puts stress on transplant centers' resources, as referrals continue to come, patients who are in 'pending activation limbo' are either neglected or detract from new patients' evaluation. Candidates are worked-up by our transplant program after referral rather than by the

dialysis programs where candidates are universally referred to transplant centres after finalizing workup. We are aiming to assess metrics of quality at our program focusing on variability in the time taken for completion of pre-transplant workup among different coordinators, processes, and populations.

Methods: This is a single center retrospective study evaluating the duration and obstacles of pre-kidney transplant workup of all in limbo candidates who were evaluated at our program prior to January 1, 2021. Data will be compared with candidates' workup during a later period, when a more regular chart review was adopted by our newer coordinator to expedite workup.

Results: 112 candidate's files were reviewed by January 1, 2021. 54 (48.2%) candidates were in limbo [Age 54.5±10.7 years, female (44.4%), Caucasian (74.1%)], 38 files were closed due to patients' wishes or nonadherence and 20 others had expired. By March 1, 2024, 47 (87%) in limbo candidates received a transplant decision while 7 patients stayed in workup. Median time from assessment to transplant decision was 23.3 (14.3-37.1) months, while time from chart review to transplant decision was 7.7 (3-16) months. Patients who are still in workup live further away from our center, were assessed once (*P* 0.035), and have a longer median workup to date 44.6 (42.4-55.7) months. The median time to transplant decision of candidates with more frequent pre-transplant assessments compared with those with less frequent assessments was shorter (20.2 vs 27.1 months, *P* 0.037). Finally, at the time of transplant decision, 38 (81%) patients were on dialysis (24 on dialysis > 24 months, 9 (24%) on dialysis < 1 year).

Conclusions: Regular chart review and frequent assessments of pre-transplant candidates result in shorter workup and dialysis vintage.

PUB482

Does Size Matter?

Mansoor Khalid, Payaswini Vasanth. *Emory University, Atlanta, GA.*

Introduction: Acute cellular rejection secondary to de novo Focal segmental glomerulosclorsis after pediatric en bloc renal transplant to a 48 year old female receptient with absence of focal segmental glomerulosclerosis in donor on renal biopsy prior to transplant.

Case Description: 48 year old female status post pediatric en bloc renal transplant. She had history of Hypertension, end stage renal disease on hemodialysis. Renal biopsy showed global sclerosis, moderate interstitial fibrosis and thrombotic microangiopathy. Donor : DBD, CPRA 70%, KDPI74%, CIT 12 hours, Terminal Cr 0.25, positive B cell cross match. Induction with thymoglobulin and immunosuppression with Belatacept, tacrolimus, prednsione and mycophenolate motefil. Weaned off tacrolimus 9 months per protocol. 12 months post transplant she had new Class 2 DSA at 5000 MFI and 12 grams proteinuria. Renal biopsy showed moderate tubulitis, extensive effacement and blunting of foot process, C4D negative. Treated with pulse dose steroids, plasma exchange, tacrolimus and prolonged steroid taper. Proteinuria decreased to 3 grams and serum creatinine stable at 0.85.

Discussion: Incidence of post transplant proteinuria is higher in adults who received pediatric kidneys compared to those who received adult kidney. Body surface area disparity of > 1.3 $m^{2,}$ recepient weight > 30 kg compared to donor, kidney/ recepient weight ratio <2g/kg is associated with higher risk of graft loss.(Transplantation 2020;104;1695-1702)

Mycotic Aneurysm of Transplant Renal Artery

Trey H. Richardson, Anthony J. Langone, Saed Shawar. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Kidney transplant recipients are at risk for infectious complications of surgery during the first three months after transplantation. Fungal infections, though rare, affect 0.1% to 5% of kidney transplant recipients. Herein, we present a case of a transplant recipient who developed a ruptured mycotic aneurysm that led to a transplant nephrectomy.

Case Description: A 72-year-old man with end-stage kidney disease from hypertension and type two diabetes underwent a deceased donor kidney transplant. He presented to the emergency department 22 days after transplantation with a fall. His hemoglobin was 6.1 mg/dl from a baseline of 8.0 mg/dl. A CT of his abdomen revealed a hematoma surrounding the allograft. The hematoma was evacuated and attributed anastomotic dehiscence. The allograft was resected in order to obtain hemostasis, and a patch angioplasty from a saphenous vein was performed. The vessel had a mycotic appearance, prompting the collection of cultures from perinephric fluid and the allograft. The allograft cultures grew Staphylococcus epidermidis, Staphylococcus capitis, Candida tropicalis, and Candida albicans [Figure 1]. Perinephric fluid cultures grew Candida tropicalis and Candida albicans. He was treated with vancomycin and micafungin. Micafungin was switched to fluconazole, which he continued for 4 months due to positive perinephric fluid cultures. His immunosuppressive medications were stopped. Prophylactic trimethoprim-sulfamethoxazole and valacyclovir were continued.

Discussion: Mycotic arteritis is a rare complication that leads to graft loss and should prompt an investigation for the source of infection. This patient likely developed the infection de novo, as there were no reports in UNOS of infections in the other organs procured from the donor. Donor organs can be contaminated during procurement, preservation, and intra-operative organ handling. Treatment involves antifungals and allograft nephrectomy.

Understanding What Patients and Families Living with Kidney Failure Want and Need to Know about Xenotransplantation: A Kidney Transplant Research Possibility

Tandrea Hilliard-Boone, Holly DePatie. *American Institutes for Research, Chicago, IL.*

Background: Advances in xenotransplantation offer great promise for an alternative supply of organs to meet the needs of people with life-threatening illnesses like kidney failure. However, this kidney transplant possibility has not yet been tested in clinical trials with humans, only early testing. The American Society of Nephrology (ASN) Kidney Health Initiative (KHI) formed a project team to assess perspectives about xenotransplantation and identify information needed to help ensure that future first-in-human (FIH) clinical studies are patient-centered and reflect the perspectives of those most affected by the research.

Methods: To understand what is most important for patients and families living with kidney failure to know about xenotransplantation and future clinical trials, the American Institutes of Research (AIR) conducted 39 virtual individual interviews with patients, care partners, and nephrologists between April 1, 2022 and May 14, 2022. We used qualitative thematic analysis to synthesize and cross-validate the data.

Results: Patients, care partners, and nephrologists shared perceived benefits of xenotransplantation, including expanding the supply of organs available, reducing long waiting times, and improving quality of life. Perceived risks included organ rejection, infection, or other complications. Nephrologists identified potential risks associated with a lack of available data related to short-and long-term health outcomes and safety. All participants expressed a need for information about xenotransplantation that is transparent, accessible, and understandable for diverse audiences and recommended strategies to help prepare clinicians to have conversations with patients and families about future clinical trials.

Conclusions: Breakthroughs in xenotransplantation offer great promise for addressing the critical organ donor shortage, particularly for those living with kidney failure. Our discussions with patients, care partners, and nephrologists underscore the need to prepare both clinicians and families for discussions about potential participation in a clinical trial for xenotransplantation.

PUB485

Catch It or Lose It: Timely Recognition and Conservative Management of Thrombotic Microangiopathy in a Kidney Transplant Recipient

Ahmad Matarneh, Sundus Sardar, Rafael Portela, Nasrollah Ghahramani, Gurwant Kaur. *Penn State Health Milton S Hershey Medical Center, Hershey, PA.*

Introduction: Thrombotic microangiopathy (TMA) is rare and potentially lethal complication in kidney transplant recipients, characterized by hemolytic anemia, thrombocytopenia, and kidney failure. TMA can be triggered by multiple factors including medications. Calcineurin inhibitors (CNIs) are associated with TMA. Prompt recognition and management are crucial to prevent severe outcomes, such as graft loss. This case highlights early TMA occurring two weeks after a kidney biopsy-proven chronic acute antibody-mediated rejection, where timely intervention led to a favorable prognosis and graft salvage.

Case Description: A 41-year-old man with end-stage kidney disease from adult polycystic kidney disease who received deceased donor kidney transplant six years ago. His immunosuppression included mycophenolate mofetil (1000mg twice daily) and extended-release tacrolimus (5mg daily). His kidney function declined over time, with creatinine rising from 2.2mg/dl to 3.5mg/dl, prompting a kidney biopsy. The biopsy showed acute T-cell-mediated rejection (grade 1A) and chronic active antibody-mediated rejection, treated with pulse steroids, IV immunoglobulin, and a tapering course of oral steroids. He presented to the hospital with bruising, abdominal pain, nausea, and diarrhea for 3 days. Labs revealed thrombocytopenia (35K/μL from 130K/μL), anemia (7.1g/dL from 8.9g/dL), and elevated creatinine (5.25 mg/dL, baseline 2.2mg/dL). Suspecting TMA, especially with recent supratherapeutic tacrolimus level. Workup showed high LDH (572 U/L), low haptoglobin (<10mg/dL), normal bilirubin (0.5mg/dL), and rare schistocytes on a peripheral smear. ADAMTS13 and Coombs tests were negative. Tacrolimus was replaced with belatacept. Platelet count, Hb, and kidney function improved with stopping tacrolimus. Early inclusion of TMA in the differential diagnosis enabled prompt treatment and favorable outcomes.

Discussion: The timely diagnosis of TMA in a kidney transplant recipient is critical and delay in diagnosis can lead to severe complications including graft loss. TMA in transplant recipients can be triggered by medications such as CNIs and mTOR inhibitors, antibody mediated rejection, viral infections (Hepatits C, HIV, BK Virus), genetic abnormalities in complement cascade. Prompt recognition and management of TMA can reduce graft loss and improve outcomes.

PUB486

Noninvasive Bladder Cancer Treated with Bacillus Calmette-Guérin in Kidney Transplant Recipients

Jessenia A. Contreras, Rana Sandhu. *Kaiser Permanente Northern California Region, San Francisco, CA.*

Introduction: Bacillus Calmette-Guérin (BCG) is best known as one of the discoveries for the protection against tuberculosis, which also was noted to have other benefits, such as a therapy for non-muscle invasive bladder cancer (NMIBC). In immunosuppressed patients, the use of BCG developed concerns because the creation was derived from being a re-culture of Mycobacterium bovis. The few cases found during literature review discussed the complications of intravesical BCG therapy in kidney transplant patients, such as subacute interstitial pneumonitis and disseminated Mycobacterium bovis infection. We have four cases of kidney transplant recipients who were treated with intravesical BCG therapy for NMIBC with no post-treatment complications.

Case Description: A 67-year-old man with history of pre-emptive kidney transplant due to autosomal dominant polycystic kidney disease (ADPKD) in 2022 and high-grade noninvasive papillary urothelial carcinoma (PUC) in 1988 status post (s/p) transurethral resection of bladder tumor (TURBT) in 1998 treated with intravesical BCG in 2019 due to recurrence. A 49-year-old man with history of renal transplant due to end-stage kidney disease (ESKD) caused by autosomal 17q12 microdeletion syndrome in 2005 and high-grade noninvasive PUC s/p TURBT in 2019 treated with intravesical BCG in late 2019. A 67-year-old man with history of kidney transplant due to ESKD from type one diabetes mellitus and hypertension early 2017 (previously on dialysis) and low-grade noninvasive PUC s/p TURBT in late 2017 treated with intravesical BCG therapy in 2019 due to recurrence. A 66-year-old man with history of renal transplant due to ESKD from focal segmental glomerulosclerosis (FSGS) in 1995 and high-grade noninvasive PUC s/p TURBT in 2017 treated with intravesical BCG in late 2017.

Discussion: All four cases did not exhibit post-treatment complications and are currently doing well. These cases depict that use of intravesical BCG may be safe for patients taking immunosuppression.

PUB487

Vanishing Kidney Allograft

Laura A. Imarhiagbe, Aimen Liaqat, Vasanthi Balaraman, Barry M. Wall. *The University of Tennessee Health Science Center College of Medicine, Memphis, TN.*

Introduction: Emphysematous pyelonephritis is a severe infection of the kidney characterized by necrosis and gas accumulation in kidney parenchyma, adjacent tissues and urinary collecting system. We present a case of severe emphysematous pyelonephritis with a very rapid evolution to complete destruction and a sonographically vanishing kidney allograft.

Case Description: 60-year-old female with a history of end stage renal disease from diabetic nephropathy received a deceased donor kidney transplant. Her immediate post operative course was complicated by early ureteral stricture and revision of ureteral anastomosis resulting in good allograft function with average creatinine of 2-2.5mg/dl on quadruple immunosuppression. She had two admissions for uncontrolled hyperglycemia and Escherichia coli (E. coli) urinary tract infection (UTI) at 3 months and Klebsiella UTI at 5 months post-transplant. At month 8, she presented with sepsis secondary to E. Coli UTI with bacteremia, diabetic ketoacidosis, and AKI requiring dialysis initiation. CT of the abdomen and pelvis at admission had normal findings of transplanted kidney. Ultrasound on day 3, performed due to worsening clinical condition and graft function was reported as no visible kidney allograft. Repeat CT showed complete liquefaction of

her transplant kidney replaced by pockets of air and abscess formation. She underwent transplant nephrectomy following unsuccessful abscess drainage. Surgical cultures were positive for E. Coli and Vancomycin resistant enterococcus faecium. Eventually, targeted antibiotic therapy resulted in complete resolution of her infection.

Discussion: Vanishing kidney is an advanced presentation of emphysematous pyelonephritis where a kidney previously visible sonographically disappears as layers of encasing gas pockets block penetration of ultrasonographic waves. While uncommon, it is a life-threatening disease with major risk factors including poorly controlled diabetes, immunosuppression, and urinary obstruction. E. Coli is the causative pathogen in 70% of cases. Emphysematous pyelonephritis frequently requires nephrectomy. High index of suspicion upon non visualization of kidney allograft on ultrasound warrants immediate confirmation with CT imaging, as early diagnosis and timely intervention are essential in this life-threatening condition.

PUB488

Postkidney Transplant May-Thurner Syndrome Causing Ipsilateral Left Lower-Extremity Edema and Left Lower-Quadrant Kidney Allograft Dysfunction

Macaulay A. Onuigbo, Marios Prikis, Erin Berg, Rachel Preston, Andrew Myhre, Selena Patterson, Ema Allen, Jaime Pineda. *The University of Vermont Medical Center, Burlington, VT.*

Introduction: May-Thurner syndrome (MTS) results from extrinsic venous compression of the iliocaval veins. We report progressive MTS post-DDK with ipsilateral left LE edema and DDK dysfunction.

Case Description: A 43-yo male with ESRD from ADPKD, on hemodialysis for 7 years received a DDK in 2024. 9 weeks later, he developed unilateral painless left LE swelling (Figure 1). Dopplers ruled out LE DVT but showed extrinsic 75%-90% narrowing of the left external iliac vein from compression by the large left ADPKD kidney and the left LQ DDK, consistent with MTS (Figure 2). DDK ultrasound and Duplex showed no hydronephrosis, and no renal artery stenosis. Serum creatinine that had promptly progressively declined to 1.60 mg/dL has since partially reversed this trend. An open left nephrectomy is planned.

Discussion: Our patient has May-Thurner syndrome with symptomatic ipsilateral LE edema and further complicated by new evidence of renal allograft dysfunction. To avoid further renal allograft compromise and to mitigate the lower extremity swelling, the patient will undergo an urgent open native left nephrectomy.

New left LE swelling 9 weeks post-DDK

Large ADPKD kidneys on prior CT

PUB489

Pretransplant Hypoalbuminemia Is Not Associated with Worse Outcomes among Simultaneous Pancreas and Kidney Transplant Recipients

Ekaterina Fedorova, Sofia Nehring Firmino, Brad C. Astor, Didier A. Mandelbrot, Dixon Kaufman, Jon S. Odorico, Sandesh Parajuli. *University of Wisconsin-Madison, Madison, WI.*

Background: Hypoalbuminemia is a well-known independent risk factor predictive of worse outcomes in surgical patients. Nonetheless, the role of pre-transplant hypoalbuminemia and its impact on post-transplant outcomes in patients undergoing simultaneous kidney-pancreas (SPK) transplantation remains unclear.

Methods: We retrospectively analyzed all SPK recipients at our center from 2001-2022, who had at least 2 weeks of pancreatic graft survival. Serum albumin levels measured within 6 weeks or closer to transplant were included. Recipients were categorized based on pretransplant albumin level normal (≥ 4.0 g/dl, N = 222), mild (≥3.5 - < 4.0 g/dl, N = 190), moderate (< 3.5 g/dl, N = 120). Multivariable logistic regression and Cox proportional hazard models were used to analyze associations with the length of stay (LOS), kidney delayed graft function (DGF), re-hospitalization within 30 days after discharge, and need for return to the operating room (OR) related to transplant surgical complications, along with acute rejection and uncensored and death-censored graft failure, within the first-year post-transplant.

Results: A total of 532 SPK recipients were included, 42% had normal serum albumin; 36% had mild and 23% had moderate hypoalbuminemia. The mean pre-transplant albumin level was 4.3 g/dl in normal, 3.7 g/dl in the mild, and 3.0 in the moderate group. After adjustment for multiple variables, with reference to normal pre-transplant albumin level, mild or moderate hypoalbuminemia was not associated with either increased or decreased risk for LOS, DGF, re-hospitalization or return to the OR. Also, mild, or moderate hypoalbuminemia was not associated with risk for either graft rejection or graft failure.

Conclusions: Among SPK recipients, pre-transplant hypoalbuminemia is not associated with worse outcomes. Pre-transplant albumin level should not be the determining factor in offering or rejecting these life-saving organs.

PUB490

BK Viremia in Kidney Transplantation

Rakhi Khanna, Andrea Pabon. Rush Nephrology. *Rush University Medical Center, Chicago, IL.*

Background: BK polyomavirus can cause BK nephropathy resulting in allograft dysfunction or premature allograft loss. Reducing immunosuppression has been the cornerstone of management, effectively treating BK viremia and BK virus associated nephropathy (BKVAN), which poses a challenge for clinicians, as it involves balancing and risking rejection. The optimal post-transplant screening approach for BK has not been determined and varies among transplant centers.

Methods: We examined the association of allograft function in kidney transplant recipients who had reduced immunosuppressive regimens from 3 to 2 agents due to BK viremia. We defined BK viremia as any patient with a positive result rather than a specific number of copies in the serum. This retrospective single-center analysis of 16 patients who received a kidney transplant and developed BK viremia post-transplant looked at changes in serum creatinine one month post-transplant and up to 10 years post-transplant.

Results: BK viremia onset ranged from 1-35 months post-transplant with an average onset of 10 months. All 16 had dose reduction or discontinuation of the antimetabolite agent. 7 of the 16 (44%) were with sustained BK viremia at last check within 3 months. 9 (56%) tested negative for BK viremia at last check within 3 months. Serum creatinine increased by 9 - 49%. Mean sCr increase was 22%. 0 of the 16 were challenged with reintroduction of the previously discontinued antimetabolite. Post-transplant complications included Crohn's exacerbation, bacteremia, pyelonephritis, antibody-mediated rejection, and urothelial tract carcinoma.

Conclusions: Our retrospective review of 16 patients followed for 10+ years aligns with the current KDIGO BK viremia screening recommendation. Of the total 16 patients this study included, >80 % had elimination of the antimetabolite agent; however, despite this regimen 44% of patients continue to have BK viremia. Over 22% had some rise and worsening of kidney function from one month baseline. We recommend that further attention be given to the patient population with BK viremia and further reduction of immunosuppression be considered, especially of the calcineurin inhibitor (CNI) along with bimonthly evaluation of BK viremia until its resolution, and evaluation by a kidney biopsy if the viremia persists.

PUB491

Use of the Monocyte-to-Lymphocyte Ratio to Predict Delayed Graft Function in Patients after Kidney Transplantation

Irin Jariyayothin. *Police General Hospital, Bangkok, Thailand.*

Background: Delayed graft function (DGF) is a significant complication following kidney transplantation, affecting graft survival. The monocyte-to-lymphocyte ratio (MLR) is being explored as a potential predictor of DGF, reflecting inflammatory and immune responses. Evaluating MLR's utility in predicting DGF could improve patient management post-transplantation.

Methods: Medical records of patients undergoing kidney transplantation at Police General Hospital from January 1989 to December 2023 were reviewed. DGF was defined as a temporary impairment of kidney function immediately after transplantation, requiring dialysis within the first week post-transplant. Clinical data and laboratory were collected. The optimal cut-off value for MLR was determined using receiver operating characteristic (ROC) curve analysis. Univariate and multivariate logistic regression models were performed to investigate the risk factors associated with DGF.

Results: A retrospective cohort study was conducted on 162 kidney transplant patients, of which 58 had DGF, while 104 did not. Clinical outcomes focused on DGF, with MLR investigated as a potential biomarker. In the receiver-operating characteristic (ROC) curve analysis, MLR, with an optimal cut-off value of 0.255 (AUC of 0.686; 95% CI 0.603, 0.769; P < 0.001), predicted the DGF with a sensitivity of 81.0% and specificity of 55.8%. The multivariate logistic regression analysis confirmed that MLR was an independent factor of DGF (MLR) >0.255 (Adj. OR 3.74 [95% CI 1.55, 9.02], P=0.003).

Conclusions: This study suggested that high MLR may associated with DGF. The MLR is an inexpensive and straightforward indicator to reflect systemic inflammation status to help clinicians improve kidney transplant care.

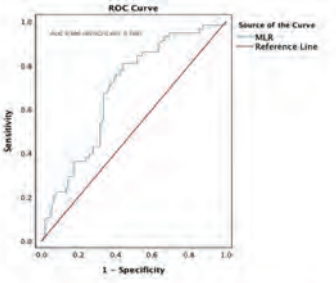

Figure 1 The ROC curve of the monocyte-to-lymphocyte ratio (MLR) for predicting delayed graft function showed statistically significant difference from the reference line (P<0.05)

Table 4 Area under the receiver operating characteristic curve of the monocyte-to-lymphocyte ratio (MLR) in predicted delayed graft function

	AUC	95%CI	P-value	Optimal cutoff point	Maximum of Youden index
MLR	0.686	0.603, 0.769	<0.001*	0.255	0.368

*Statistically significant at the 0.05 level (α=0.05)

PUB492

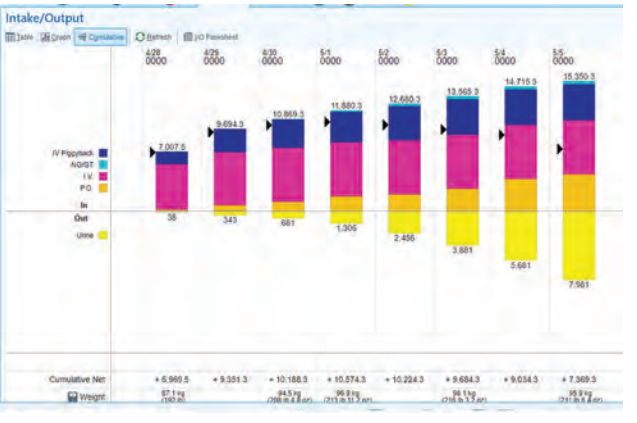
Can Post-transplant Congestive Nephropathy from Hypervolemia Cause Slow Graft Function?

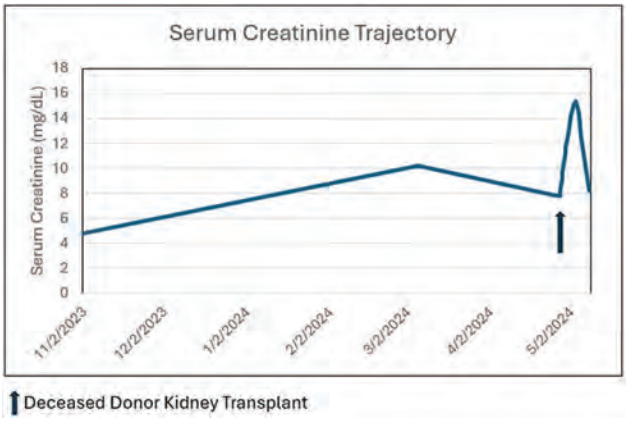
Macaulay A. Onuigbo, Marios Prikis, Rachel Preston, Erin Berg, Joshua Hsu, Jamie Vanvught, Jaime Pineda. *The University of Vermont Medical Center, Burlington, VT.*

Introduction: Low cardiac output alone does not define renal dysfunction in cardiorenal syndrome (CRS). Congestive nephropathy (CN) depicts the role of renal venous hypertension in CRS. Our understanding of CN is evolving. Furthermore, we do not have any known reports of CN in renal allografts.

Case Description: A 48-yo female with ESRD from Fabry's disease, who started hemodialysis in February 2020 was on Midodrine to sustain hemodialysis due to hypotension. She made about a cup of urine. She received a deceased donor kidney transplant in late April 2024. Due to peri-operative hypotension with systolic blood pressure in the 70s, she received multiple liters of IVF therapy perioperatively and post-operatively (Figure). She received IV albumin boluses and was restarted on oral Midodrine post-operatively. There was evidence of hypervolemia and fluid retention. She had slow graft function and subsequently responded well to combination IV Furosemide + IV Chlorothiazide infusions and subsequent switch to oral Torsemide 100 mg daily + oral Metolazone 5 mg daily with later fall in serum creatinine. She was discharged on post-op day #8 for outpatient management and monitoring of improving renal allograft function (Figure).

Discussion: To our knowledge, this is the first report of CN in a new renal allograft. The serum creatinine trajectory supports the speculation that both native kidneys and the newly transplanted renal allograft were simultaneously impacted by CN. The subsequent falling creatinine with decongestive diuresis supports this hypothesis. Further investigation is warranted.





PUB493

Validation of Donor-Derived Cell-Free DNA as a Biomarker for Antibody-Mediated Rejection in Kidney Transplant Recipients Late Post Transplantation

Grace K. Lee,[1] Anantharaman Vathsala,[2,3] Hersharan Sran,[2,3] Matthew D'Costa,[2] Zi Yun Chang,[2] Emmett Tsz Yeung Wong.[2,3] *[1]Department of Medicine National University Hospital, Singapore, Singapore; [2]National University Centre for Organ Transplantation, National University Hospital, Singapore, Singapore; [3]Department of Medicine National University of Singapore, Singapore, Singapore.*

Background: Antibody-mediated rejection (ABMR) is a leading cause of late allograft failure in kidney transplant recipients (KTRs). Plasma donor-derived cell-free DNA (dd-cfDNA) is a non-invasive diagnostic biomarker for ABMR early post-transplant. As most studies evaluated KTRs at <3 years post-transplant, it is unclear if dd-cfDNA is useful in distinguishing ABMR from other findings in allografts >3 years post-transplant when superimposed on chronic inflammation and fibrosis. We hypothesise that dd-cfDNA is sensitive and specific for diagnosing late ABMR.

Methods: We conducted a single-centre, prospective, observational, pilot study. We recruited 27 KTRs with allograft dysfunction at >3 years post-transplant in whom a biopsy was planned. Plasma dd-cfDNA (AlloSeq®, CareDx, Brisbane, CA) was sent at the time of biopsy. Diagnostic characteristics were performed for dd-cfDNA and DSA, and dd-cfDNA correlated with Banff lesion scores.

Results: The median age of KTRs was 53 years (IQR 40, 55); 14 (52%) were living donor KTRs. Eighteen (67%) were Chinese and 7 (26%) were Malays. The median time post-transplant was 7.8 years (4.9, 11.7). Four (15%) KTRs had ABMR. Median dd-cfDNA was higher in KTRs with ABMR (1.95% vs 0.24%, p=0.004). Using a cut off of 1%, the AUROC for dd-cfDNA was 0.97. Its sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) to diagnose ABMR were 100%, 96%, 80%, 100%, vs. 100%, 91%, 67%, 100% for DSA. Combining dd-cfDNA with DSA achieved 100% sensitivity, specificity, PPV and NPV. Dd-cfDNA correlated positively with peritubular capillaritis (ptc, p=0.002) but not glomerulitis (g, p=0.070) scores when evaluated as continuous variables. Other than interstitial fibrosis (ci) scores (negative correlation, p=0.038), there was no significant correlation between dd-cfDNA and Banff chronicity scores.

Conclusions: In this pilot study, dd-cfDNA showed good diagnostic characteristics for ABMR late post-transplant and correlated positively with ptc scores. A lack of correlation between dd-cfDNA and chronicity scores suggests its utility as a predictor of late ABMR. This provides preliminary data for larger studies.

PUB494

Eco-friendly Innovation in Kidney Transplants: Outcomes from a Collaborative Artificial Intelligence (AI) Feedback Loop

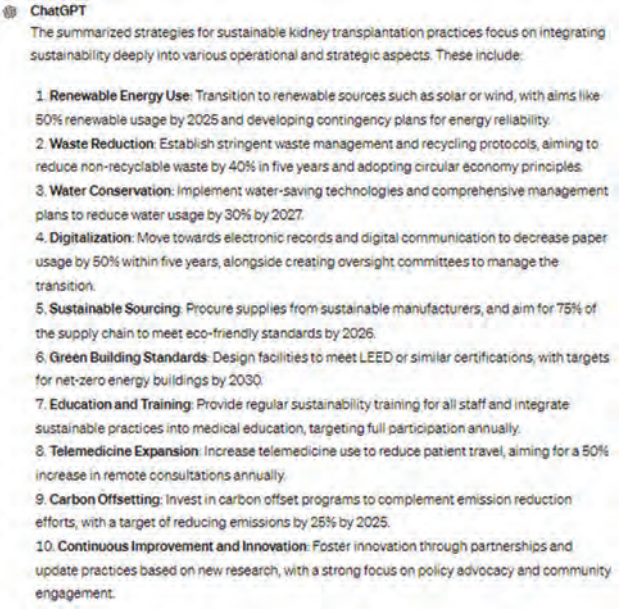
Suryanarayanan Balakrishnan,[1] Oscar A. Garcia Valencia,[1] Yasir Abdelgadir,[1] Charat Thongprayoon,[2] Jing Miao,[2] Napat Leeaphorn,[3] Iasmina Craici,[1] Wisit Cheungpasitporn.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Mayo Clinic Health System, Mankato, MN; [3]Mayo Clinic in Florida, Jacksonville, FL.*

Background: Negative environmental impact of kidney transplant is significant. Sustainable practices are crucial for reducing the environmental burden while ensuring optimal patient outcomes. ChatGPT-4.0 developed ten key strategies, which were further enhanced through a collaborative feedback process involving three other cutting-edge AI agents: Claude 3.0 Opus, Gemini Advanced, and Meta AI with Llama-3.

Methods: In April 2024, a multi-stage feedback loop approach was conducted, involving GPT-4.0 and three other AI agents (Claude 3.0 Opus, Gemini Advanced, and Meta AI with Llama 3), utilized a series of feedback loops to refine and improve ten critical strategies for establishing sustainable transplants. The feedback loops continued until all agents were satisfied with the final set of strategies, at which point the strategies were executed.

Results: The refinement process included six rounds and 29 communications encompassing initial feedback, subsequent revisions and final approvals. This iterative review led to a robust set of strategies, significantly enhancing the initial proposals. The strategies achieved specific targets (see Fig. 1), such as 50% renewable energy use by 2025, and a comprehensive sustainability plan included transitioning to renewable energy, water conservation, digital transformation and carbon offsets.

Conclusions: Our study demonstrated the potential of AI collaboration in creating sustainable medical practices for 'green' kidney transplants which can guide healthcare organizations. This model highlights the effectiveness of collaborative AI in developing sophisticated solutions to complex problems, potentially serving as a blueprint for future sustainability initiatives.



ChatGPT

The summarized strategies for sustainable kidney transplantation practices focus on integrating sustainability deeply into various operational and strategic aspects. These include:

1. **Renewable Energy Use**: Transition to renewable sources such as solar or wind, with aims like 50% renewable usage by 2025 and developing contingency plans for energy reliability.
2. **Waste Reduction**: Establish stringent waste management and recycling protocols, aiming to reduce non-recyclable waste by 40% in five years and adopting circular economy principles.
3. **Water Conservation**: Implement water-saving technologies and comprehensive management plans to reduce water usage by 30% by 2027.
4. **Digitalization**: Move towards electronic records and digital communication to decrease paper usage by 50% within five years, alongside creating oversight committees to manage the transition.
5. **Sustainable Sourcing**: Procure supplies from sustainable manufacturers, and aim for 75% of the supply chain to meet eco-friendly standards by 2026.
6. **Green Building Standards**: Design facilities to meet LEED or similar certifications, with targets for net-zero energy buildings by 2030.
7. **Education and Training**: Provide regular sustainability training for all staff and integrate sustainable practices into medical education, targeting full participation annually.
8. **Telemedicine Expansion**: Increase telemedicine use to reduce patient travel, aiming for a 50% increase in remote consultations annually.
9. **Carbon Offsetting**: Invest in carbon offset programs to complement emission reduction efforts, with a target of reducing emissions by 25% by 2025.
10. **Continuous Improvement and Innovation**: Foster innovation through partnerships and update practices based on new research, with a strong focus on policy advocacy and community engagement.

PUB495

Nonsteroidal Anti-inflammatory Drug (NSAID) Prescriptions in Living Kidney Donors

Mikayla Laube,[1] Robert R. Quinn,[1] Pietro Ravani,[1] Krista L. Lentine,[2] Rachel Jeong,[1] Ngan Lam.[1] *[1]University of Calgary, Calgary, AB, Canada; [2]Saint Louis University, St Louis, MO.*

Background: Current guidelines recommend that living kidney donors should avoid non-steroidal anti-inflammatory drugs (NSAIDs) due to their potential nephrotoxic effects. It is unclear if physicians are adhering to this guideline recommendation.

Methods: We conducted a population-based, retrospective cohort study of adult living kidney donors in Alberta, Canada, who donated between 2002 and 2019. We identified the proportion of living kidney donors who filled an NSAID prescription at least 1-year beyond date of donation. Of those donors who were prescribed an NSAID, we assessed how many underwent post-prescription laboratory testing for kidney function and potassium within 14 days.

Results: Of 759 living kidney donors in the study cohort, 273 (36%) had at least one NSAID prescription over a median follow up of 7.2 years (IQR 3.5-11.5). Donors with at least one NSAID prescription were more likely to be from lower socio-economic status, have an earlier donation date, have higher pre-donation eGFR, and have co-morbid gout and osteoarthritis at the index date. The proportion of donors with at least one prescription in follow-up remained stable over time (~10% per year). Family physicians accounted for 66% of all NSAID prescriptions. Of the donors with an NSAID prescription, 30% also filled at least one prescription for an opioid. Approximately, 10% of donors had measurements of serum creatinine or potassium within 14 days of the first NSAID prescription. The risk of acute kidney injury or hyperkalemia was uncommon in those that underwent laboratory testing (6% and 3% respectively).

Conclusions: Over one-third of living kidney donors are prescribed NSAIDs despite current guideline recommendations. Few donors had evidence of post-prescription laboratory testing, but adverse outcomes were uncommon in those who were tested. Further research assessing outcomes following NSAID use is recommended to better inform guidelines for living kidney donors.

PUB496

A Home Hospital Program Offers Versatility in Treating Cytomegalovirus (CMV) Viremia in a Kidney Transplant Recipient

Yinelka G. Silverio De Castro, Jerin Karingattil, Eliot Sachsenmeier, James Drakakis. *NYU Langone Hospital - Long Island, Mineola, NY.*

Introduction: Hospital at home (HaH) health care was initially driven by the COVID-19 pandemic as a way to administer comprehensive care to patients in the comfort of their own homes. NYU Langone's Home Hospital Program screens patients either in the emergency department or after they have already been admitted for inpatient stay. After transport home, they receive care through in-person and virtual visits with their team. Literature pertaining to involvement of kidney transplant (KT) patients in HaH initiative is limited. Publications describe it as a potential first line strategy for KT recipients with COVID-19. But what about application to those transplant recipients with other complications (provided they stable enough to be monitored at home)?

Case Description: 73 year old female with past history of Hodgkin's lymphoma (status post chemotherapy + radiation + autologous stem cell transplant) in 1996, end-stage-renal-disease with preemptive deceased donor KT in 2022. She presented to the ER at NYU Hospital Long Island after outpatient testing revealed whole blood CMV DNA PCR of 77426 IU/mL. Infectious disease consultation called for renally dosed standard induction Ganciclovir (2.5 mg every 24 hours for creatinine clearance 40 mL/min). After three days in the hospital, she was transferred to the HaH program. In her home, she received IV Ganciclovir via midline catheter for an additional 8 days. Ultimately, viral load (plasma) improved to 1570 IU/mL from plasma peak of 11900 IU/mL. At that point she was discharged on oral Valgancyclovir.

Discussion: The choice of CMV therapy is determined by several factors, one of which is inital viral load. While there is no established cut off for high viral load, usually >10,000 copies/mL is considered high. The duration of therapy may vary but is typically 21 days. Our otherwise asymptomatic patient received IV Ganciclovir while at home for the desired duration, administered by a registered nurse. In addition, immunosuppressants were administered, blood work (including daily Tacrolimus levels and weekly CMV viral loads) completed. Per day, she received at least two nurse visits, a hospitalist and nephrologist visit and vital sign monitoring. This case is one example whereby a HaH program offers a unique opportunity to manage a stable KT patient who requires a potentially long hospitalization.

PUB497

Characterization of Cytomegalovirus (CMV) Viremia and Disease in CMV High-Risk Kidney Transplant Recipients: A Single-Center Experience

Shanmugha Vigneshwar Padmanabhan, Martha Pavlakis, Barbra M. Blair, Bhavna Chopra. *Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Cytomegalovirus (CMV) infection in Kidney Transplant Recipients (KTRs) is associated with significant morbidity particularly in the high risk (HR) [donor positive (D+) and recipient negative (R-)] KTRs. We compared severity of CMV infection in CMV HR KTRs at our center after 6 months (mo) of valganciclovir prophylaxis (ppx) where post ppx, CMV PCR monitoring is NOT performed vs. published data where post ppx CMV PCR surveillance was done.

Methods: We reviewed records of CMV HR KTRs at our center from 2019-2022, to identify the frequency and severity of CMV viremia, disease burden, hospitalizations, and mortality. We then compared our outcomes to published literature in a similar setting (IS and ppx) where CMV PCR monitoring is performed post ppx for 3 mo (PMID: 27423138).

Results: Of the 71 CMV HR KTRs, induction was with Anti Thymocyte Globulin in 81%, Basiliximab in 15%, no induction in 4%. Maintenance IS consisted of Tacrolimus (T) / Mycophenolate (M) /Prednisone (P) in 52%, T/M in 38% and Belatacept (B) in 4%. 87% completed 6 months of valganciclovir. CMV viremia/infection was seen in 42%. Mean time to viremia was 224±181 days. Mean viral load was 4.43 ±1.3 log. Of those with CMV, 30% had a prior rejection episode, 90% were symptomatic, 70% required hospitalization, 17% required multiple hospitalizations and 13% had resistant CMV. All 3 KTRs on belatacept had CMV. Average length of stay per hospitalization was 12.8±10 days (total 361 hospital days). Eventually 2(6.7%) died. Treated with reduction in IS, ganciclovir or valganciclovir. Alternate therapies as Maribavir or Foscarnet was needed in 27%. Comparison with published data as shown in Table 1.

Conclusions: CMV infection is associated with increased morbidity among CMV HR KTRs. Post ppx CMV PCR monitoring may help with early detection of CMV viremia which may reduce disease burden and hospitalizations. More studies are needed to establish benefit and cost effectiveness.

	Study	Comparison group
Incidence of CMV (%)	42	40
CMV resistance rate (%)	13	15.8
Hospitalization rate in CMV (%)	70	47
Alternate therapies other than Valganciclovir/ Ganciclovir	27	5

PUB498

Collapsing Focal Segmental Glomerulosclerosis 5 Years after Transplant: Diagnosis, Treatment, and Outcome

Ulises Rodriguez Medina,[1] Claudia N. Aragon,[1] Kingsley I. Onuoha,[1] Paul B. Avila,[1] Namita Singh,[1] Pooja P. Singh,[1] Danniele G. Holanda,[2] Pablo Garcia.[1] *[1]University of New Mexico School of Medicine, Albuquerque, NM; [2]Arkana Laboratories, Little Rock, AR.*

Introduction: Collapsing FSGS involves segmental and global collapse of glomerular capillaries. Its etiology is often unclear; risk factors include genetic predisposition, immune abnormalities, and environmental exposure. Predominantly affects AA and rapidly progresses to ESKD. Recurrence rate after KT is about 20-50%, often leading to allograft loss. We present a case of recurrent FSGS after KT.

Case Description: A 39-yo Hispanic KT recipient with ESKD secondary to FSGS developed nephrotic syndrome five years post-transplant. Urine protein-creatinine was 8.8 g/g with eGFR of 105 ml/min. KT biopsy revealed collapsing FSGS with rare tubular cells showing weak nuclear staining for SV40. Tests for CMV, parvovirus, and HIV were negative. Genetic testing for APOL1 was negative in both patient and donor. Given the presence of SV40, JC virus PCR was checked and was positive. Patient was treated with 9 PLEX sessions and a prednisone taper, reducing proteinuria to 3.7 g/g. One month later, proteinuria increased to 5 g/g. Given the persistent positive JC virus, we discussed potential risks/benefits and treated him with rituximab 1g. Proteinuria declined significantly to 0.6 g/g after two months, and eGFR has remained stable at 110 ml/min.

Discussion: This case highlights the recurrence of FSGS five years after KT, relatively late for post-KT recurrent FSGS. Efficacy of treatment modalities in post-transplant FSGS, especially collapsing FSGS, remains challenging. However, our case suggests that combining PLEX, steroids, and rituximab is effective. JC virus infection can potentially lead to PML. Further studies are warranted to understand this population's risk-benefit profile with rituximab.

PUB499

Prevalence and Trends of Quantitative Bone Anomalies in Kidney Transplant Patients: A Single-Center Experience

Carlo Alfieri,[1,2] Margherita Di Naro,[1] Anna Regalia,[1] Simona Verdesca,[1] Mariarosaria Campise,[1] Paolo Molinari,[1] Chiara De liso,[1] Giuseppe Castellano.[1,2] *[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Universita degli Studi di Milano, Milano, Italy.*

Background: Quantitative bone disorders are relevant in kidney transplanted patients (KTxps) especially during the first year of transplantation (KTx). We aim to report the preliminary data about our single center experience concerning the prevalence and the trend of quantitative bone anomalies in a cohort of KTxps.

Methods: We studied 469 kidney transplant patients (M=271, age 49±11 yrs) from 2004-2023. Post-KTx data at baseline (T0) and 12 months post-transplant (T12) were analyzed. Each patient had a DEXA at T0 and T12. BMD was given as g/cm2. BMD reduction of >5% in the first year of KTx was significant. T and Z-scores were calculated. Patients with T-score -1>T>-2.5 were osteopenic (OPN), and those with T-score<-2.5 were osteoporotic (OPS).

Results: Most patients had glomerulonephritis or autosomal dominant polycystic kidney disease (21% each). 82% received deceased donor transplants, and 68% underwent hemodialysis pre-transplant. 21% received anti-human thymocyte immunoglobulin

induction, and most were maintained on tacrolimus (91%) and mycophenolate (85%). 90% received steroids (mean cumulative dosage at T12: 2887±926 mg). 33% had Vitamin D supplementation, with mean levels of 17±4 ng/dL in the first year post-transplant. Femoral and vertebral BMD remained stable. F-OPN and V-OPN were present at T0 and T12 in 57% and 38% of patients, whereas F-OPS and V-OPS in 17% and 26% of patients. 14% showed significant femoral BMD worsening, associated with older age, higher BMI, and urinary protein excretion. 16% showed significant vertebral BMD worsening, also associated with higher urinary protein excretion. Multivariate analysis identified baseline BMD, age at transplant, and Prot U at T0 as significant factors for BMD worsening.

Conclusions: Our data shows prevalent bone anomalies in kidney transplant patients from the beginning. Despite vitamin D supplementation, levels remained low in the first year post-transplant, indicating a need for intervention to improve bone health. While BMD was generally stable, many patients showed osteopenia or osteoporosis, with some worsening. Older age at transplant and higher urinary protein excretion were linked to BMD worsening. Ongoing BMD monitoring can help track bone health and personalize interventions.

PUB500

International Survey of Nephrologists about Referral of Patients with Advanced CKD for Kidney Transplantation

Somaya Zahran,[1] Shaifali Sandal,[1] Jolanta Malyszko,[4] Gopal Basu,[2,3] Mohd Ghnaimat,[5] Maria cristina R. Castro,[6] Vivekanand Jha,[7] Marcelo Cantarovich.[1] ISN-TTS Working Group on Referral for Kidney Transplantation. *[1]McGill University, Montreal, QC, Canada; [2]The Alfred, Melbourne, VIC, Australia; [3]Monash University, Melbourne, VIC, Australia; [4]Uniwersytet w Bialymstoku, Bialystok, Poland; [5]The Specialty Hospital, Amman, Jordan; [6]Universidade de Sao Paulo, Sao Paulo, Brazil; [7]The George Institute for Global Health, Delhi, India.*

Background: Kidney transplantation (KTx) is the treatment of choice for patients with kidney failure and could be lifesaving in countries with limited access to dialysis. However, studies have shown low rates of referrals from high-income countries (HIC); 17-33% within the first year of chronic dialysis initiation, while data is lacking in low-income countries (LIC).

Methods: An ISN-TTS working group created a Knowledge, Attitude and Practice (KAP) survey, sent to nephrologists globally via the ISN mailing list. Responses are collected anonymously and sorted per respondents' countries income level. HIC and middle-high were combined into HIC and LIC and middle-low were combined into LIC. The survey is currently being administered. We report preliminary analysis of the first 100 responses to 9 compiled questions across KAP pillars.

Results: Respondents from 55 countries are 62% males, 60% 30-50 years, and 85% work at academic centers. Living and/or deceased donor KTx is available in 92.5% and HIC comprise 52%. Knowledge questions were answered similarly in both cohorts, except for referral of elderly patients (P=0.01), patients with nonadherence (P=0.014), or financial hurdles (P=0.027). Responses to attitude questions are shown in Fig 1. Based on participants' practice, patients in LIC vs. HIC were referred as follows: elderly <15% vs. 45% (P<0.0001), preemptively 70% vs. 90% (P<0.004), combined Tx 8% vs. 30% (P=0.0002); patients with cancer in remission 25% vs. 55% (P=0.007); financial difficulties 22% vs. 65% (P<0.0001).

Conclusions: Our results highlight KTx referral pattern differences between LIC and HIC. Educational activities should address practitioners' needs and optimize KTx referral for patients worldwide.

Case scenario questions, responses are based on comfort level (Likert scale:1 uncomfortable–5 very comfortable)

PUB501

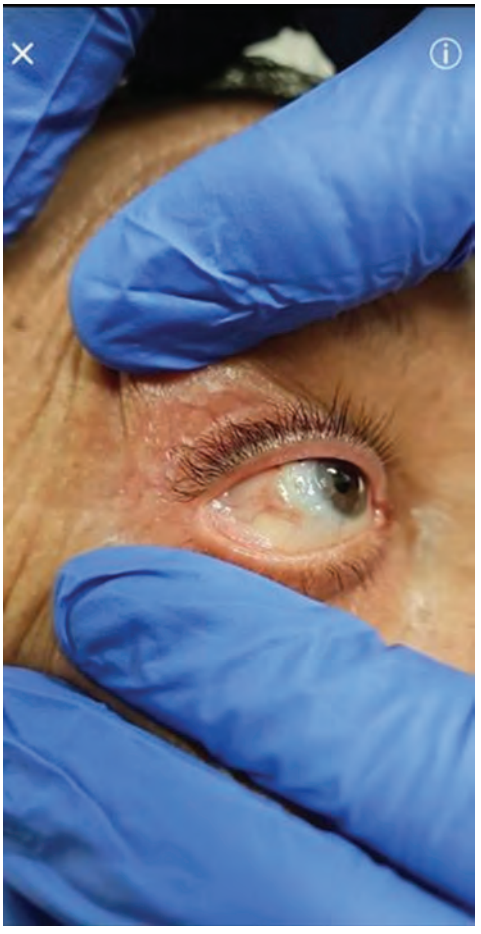
Conjunctival Squamous-Cell Carcinoma after Kidney Transplant

Muna Alnimri. *University of California Davis, Sacramento, CA.*

Introduction: Conjunctival squamous cell cancer (SCC) is rare affecting HIV patients and elderly exposed to extra UV light, the incidence increases post kidney transplant due to immunosuppression, treatemnt with wide excision, cryotherapy, local chemotherapy and radiation had been successful Prognosis depends on local invasion of the tumor to the orbit and the presence of distal metastasis. Our patient developed SCC 13 years post transplant

Case Description: 64 year old Hispanic male farm worker diagnosed with Hypertensive Nephrosclerosis on Hemodialysis received a kidney transplant in 2011 baseline creatinine 1mg/dl was maintained on Tacrolimus 2 mg bid imuran 50 mg as he did not tolerate Mycophenolate Mofetil and prednisone 5 mg. Presented in 2/24 with a right eye mass, tearing and eye discharge, followed by headach (figure 1) Orbital and head MRI showed fungating mass involving the temporal conjunctiva without invasion to the cornea. Biopsy of the lesion showed SCC. He underwent excision/debulking of the mass and pathology confirmed SCC with positive margins, Oncology consult suggested cryotherapy, local chemotherapy or radiation therapy The patient agreed to local chemptherapy with eye drops. Immunosuppression had been reduced with discontinuing imuran and lowering tacrolimus to a level of 3-5 with 5 mg prednisone.

Discussion: The risk of SCC increases with the duration of immunosuppression, 7% of transplant patients develop SCC after 10 years and 35% after 25 years, conjuctival SCC is rare with incidence of 0.02-2.8/100000, It usually grows slowly on the epithelial surface of the eye and rarely invades the orbit and spreads distally, treatment is wide excision of the conjunctive with reconstructive flaps, cryotherapy, topical chemotherapeutic eye drops like mytomycin, 5FU and interferon, prognosis is not bad if dicovered early, 5 years survival 85%.



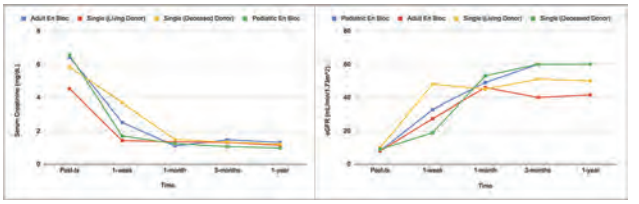


Figure 1. (left) Serum creatinine levels of en bloc vs. single kidney transplantation adult recipients post-transplant, 1-week, 1-month, 3-months, and 1-year post-op. (right) eGFR levels of en bloc vs. single kidney transplantation adult recipients post-transplant, 1-week, 1-month, 3-months, and 1-year post-op.

PUB502

Single-Center Experience of En Bloc vs. Single Kidney Transplantation: A Case Series

Yoon-Jung Chang.[1,2] *[1]The University of Toledo College of Medicine and Life Sciences, Toledo, OH; [2]The University of Toledo Medical Center, Toledo, OH.*

Introduction: Pediatric en bloc kidney recipients have been shown to demonstrate comparable outcomes with reduced potential risk for complications despite the reduced size and mass. This case series is focused on comparing the post-operative outcomes between recipients of en bloc kidneys from deceased donors and recipients of single kidneys from living or deceased donors.

Case Description: This case series includes a total of 61 patients - 12 pediatric en bloc recipients, 5 adult en bloc (horseshoe) recipients, and 11 per single kidney recipient groups. Living and deceased donor single kidneys had EPTS values ranging from 67 to 83 and a KDPI value of less than 50, whereas the EPTS and KDPI values of en bloc kidneys varied to a greater degree. The most prevalent primary renal disease among en bloc and single kidney recipients were hypertensive nephrosclerosis and diabetes mellitus type II, respectively. Not only did we see an increase in eGFR values and a decrease in serum creatinine values in the pediatric donors' recipients, but the rate of delayed graft function was also lower in pediatric en bloc kidney recipients (16.67%) compared to that of single kidney recipients from living (18.18%) or deceased donors (54.55%).

Discussion: The results from this institution, along with the literature published, support the notion that en bloc renal transplantations from pediatric donors result in superior outcomes. Though receiving organs from pediatric donors has been previously neglected due to technical complications, the continuous advancement in surgical techniques and increased demand for transplantations have allowed for further exploration in en bloc renal transplantations. As evidenced by the data, it may be crucial to take into account the positive outlook on long-term renal functions of the pediatric en bloc kidneys to decrease the wait time and increase the quality of life of the patients.

PUB503

A Case of Disseminated Histoplasmosis in Transplant Patient

Tahir A. Jatoi, Sandeep R. Sasidharan, Andrea Roche-Recinos, Mariana S. Markell. *SUNY Downstate Health Sciences University, New York City, NY.*

Introduction: Histoplasma(HP) capsulatum is a dimorphic fungus with a worldwide distribution. In a study from a hyperendemic area, 24% of the solid organ transplant(SOT) candidates had evidence of prior exposure to HP. In immunocompetent patients, HC is usually mild, but in immunocompromised patients like SOT recipients it develops into severe infection with dissemination to extrapulmonary organs. We present a case of disseminated histoplasmosis in a kidney transplant recipient

Case Description: 35 y.o. M with HTN, recurrent UTI, failed LDKT from 2006 and DDKT in 2022, presented for fever, melena, and diarrhea for a day with exposure to farm animals in a recent trip to Trinidad. Vital signs, system review and PE were otherwise unremarkable. Labs showed BUN/Creat of 78/3.2, from baseline of 2.6, HGB 6.2, K 6.6. He was transfused with 4u of PRBCs, and hyperkalemia was treated medically. Endo-Colonoscopy was delayed due to history of fever. He was on Tac 3mg BID and MMF 1gm BID. The patient was empirically started on treatment for C-Diff and UTI, blood and urine cultures were negative. Respiratory panel detected Rhinovirus/Enterovirus. CT abdomen and pelvis showed bilateral pulmonary nodules and multiple enlarged retroperitoneal and mesenteric lymph nodes. BAL was positive for fungal infection (FI). HP Urine Ag was positive (6.4 ng/mL). He improved Voriconazole and was switched to Itraconazole to cover broadly for 1 year. He became afebrile after 48 hours of antifungal treatment. Tacrolimus was reduced to 1mg bid, level on the day of discharge 9.3

Discussion: HP accounts for <5% of all invasive FI in SOT recipients, the infections can be devastating. Transplant-associated HP can occur as a de-novo infection from an environmental exposure which was most likely in our patient, or as the reactivation of a latent infection or donor-derived (DD) transmission. DD HP is seen in 1:10,000 transplants and occurs in the early post-transplant period. The agent of choice and duration of therapy depends on the severity of disease but all SOT with HP require therapy. Our patient initially came with a GI complaint and the disseminated infection was discovered incidentally. With rising incidence of FI due to climate change, clinicians must have a high index of suspicion in all diagnose infections among SOT recipients especially in those who visited endemic area's

PUB504

Investigation of Proteinuria in a Simultaneous Heart-Kidney Transplant Recipient with AL Amyloidosis

Brittany Samberg, Sunny R. Parmar, Yuan Huang, Itunu O. Owoyemi. *Cleveland Clinic, Cleveland, OH.*

Introduction: Although they are two of the most affected organs by AL amyloidosis, simultaneous heart and kidney transplants (SHK) are rarely performed regardless of the underlying disease process. Diagnostic work up for proteinuria requires a comprehensive work up and multidisciplinary shared decision making with management.

Case Description: A 57-year old male presents with worsening proteinuria. Notable history includes SHK 4 years prior for severe cardiac AL amyloidosis with chronic kidney disease stage 4. Initially he suffered delayed graft function requiring dialysis for 3 weeks post-transplant. Surveillance biopsy after 3 months showed cortical necrosis and renal MAG3 scan showed about 23% of the split differential function. Bortezomib and daratumumab were discontinued for recurrent CMV viremia. He was switched to sirolimus for tacrolimus toxicity sparing. Creatinine (Cr) improved to baseline of 1.8-2 mg/dL with urine protein-creatinine ratio (UPCR) average of 0.2 mg/mg. Relevant labs on presentation included Cr of 2 mg/dL, UPCR 2.98 mg/mg, HbA1c of 9.2%, and normal kappa/lambda free light chain ratio albeit elevation of the lambda light chain to 32.5. A repeat MAG3 scan showed 82% of native kidney function and 17% allograft kidney function. With these findings, he had biopsies of both native and transplant kidneys. The former revealed AL amyloidosis and the latter revealed subclinical Banff 2A acute cellular rejection in allograft without amyloid deposition.

Sirolimus was switched to tacrolimus, and he was treated with pulse steroids for subclinical rejection. Kidney function remains at baseline and UPCR has improved to 1mg/mg at most recent follow up.

Discussion: The patient's progressive proteinuria presented a diagnostic dilemma. The repeat MAG3 scan findings guided the decision to biopsy both native and allograft kidneys. Presumably native kidney amyloidosis was present pre-transplant, and this was less likely the culprit in the absence of allograft deposition or serologic evidence of recurrence. However, subclinical rejection in the allograft was notable and treated in addition to switching sirolimus to tacrolimus causing reduced proteinuria. The value of MAG3 studies and kidney biopsies in this case remain evident and may guide future diagnostic decisions.

PUB505

Increasing Transplant Awareness and Addressing Barriers to Transplantation among Patients on Dialysis

Sobia N. Khan, Sandeep K. Mallipattu. *Stony Brook University, Stony Brook, NY.*

Background: End Stage Kidney Disease patients require dialysis or kidney transplant to maintain life. Kidney transplant has been recognized as their best option. Our aim was to identify barriers for transplant among dialysis patients.

Methods: Patients were recruited from chronic dialysis unit requiring hemodialysis and age over 18. Patient with acute kidney injury on dialysis, dementia or hospice were excluded.

Results: 126 were screened, 40 recruited. Mean age 60 ± 16 years, male (57.5%). Comorbidities: HTN (85%), DM (32.5%), CAD (25%). Table 1 14 patients were identified, who have either refused or lost to follow up. They were interviewed to explore the reason for refusal. It was concerning to realize that the patients had several pschosocial barriers and lacked proper transplant education. Table 2

Conclusions: Our study data has indicated a crucial need for enhanced awareness and kidney transplant education. Building upon these findings, we have launched an educational initiative aimed at providing nephrology trainees with the necessary skills to recognize and address the psycho- social barriers for referral. The multifaceted project entails 2 components: Enhancing the communication abilities of nephrology fellows to navigate challenging interactions with patients and integrating transplant education into patient encounters. We expect to contribute to nephrology field by having defined a feasible means to identify and create more enrollment.

Table 1: Patient Characteristics

Age	60 ± 16
Gender, n	
Male	23
Female	17
Race/ Ethnicity	
Black	7
White	27

Table 2: Reasons for Transplant refusal

Patient 1	Has failed transplant, so no desire to pursue it again
Patient 2	Content with hemodialysis
Patient 3	Was delisted due to medical comorbidities due to EF~14%, underwent vascularization, EF improved t0 30%, he was supposed to consider re-activation, but patient never followed up
Patient 4	BMI ~64, never saw the transplant team
Patient 5	Failed transplant, told us the transplant work up is too cumbersome
Patient 6	Last saw transplant team in 2015
Patient 7 & 8	Never saw the transplant team

PUB506

Terminal Effector Memory (TEMRA) CD8+ T Cell: The Key Lymphocyte Subset in BK Virus Infection Early after Kidney Transplantation

Lilin Liu, Jing Luo, Min Gu, Chunsun Dai, Hongdi Cao. *The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: BK virus associated nephropathy (BKVAN) is an important cause of early allograft failure after renal transplantation. Low immune status of renal recipients leads to the reactivation of BKV in renal tubular epithelial cells, and BK viruria is the early phase of BKV infection. Timely intervention of BK viruria could prevent the development of BKVN. Meanwhile, measurements of lymphocyte subsets can display the recipient's real-time lymphocyte subpopulations and functional status. Therefore, this study aimed to analyze the lymphocyte subsets of patients with BK viruria early after kidney transplantation to explore the key lymphocyte subsets of BKV infection and provide potential monitoring and targeting methods for clinical intervention.

Methods: Patients who received renal transplantation at the Kidney Disease Center of the Second Hospital of Nanjing Medical University from April 2022 to October 2022 were included in the study. The patients' lymphocyte subsets were analyzed using the BD FACS CantoII cytometer. The clinical characteristics and distribution differences of lymphocyte subsets were compared between BK viruria and BKV negative patients. Binary logistic regression method was used to analyze the lymphocyte subsets of BK viruria.

Results: A total of 67 renal recipients were included in the study, including 23 cases (34.2%) of BK viruria. There were statistical differences in terminal effector CD8+T cell ($CD8^+$ Temra) subsets and central memory $CD8^+$ T cell ($CD8^+$ TCM) subsets between the two groups ($p<0.05$), while no differences were found in other lymphocyte subsets. Binary logistic regression analysis suggested that high ratio of $CD8^+$ Temra and $CD8^+$ TCM is an independent risk factor for BK viruria ($p=0.039$, *95%CI:* 0.02-0.907).

Conclusions: High ratio of $CD8^+$ Temra and $CD8^+$ TCM is an independent risk factor for BK viruria early after renal transplantation. Abnormal differentiation of memory $CD8^+$ T cells might be a promising target for monitoring and treatment of BKV infection early after kidney transplantation.

Postkidney Transplant Thrombotic Microangiopathy Effectively Treated with Eculizumab in a Tertiary Care Center

Joyita Bharati, Jean M. Francis, Justine E. Dickson. *Boston Medical Center, Boston, MA.*

Background: Post-transplant thrombotic microangiopathy (PT-TMA) after kidney transplant is associated with a high risk of graft loss. Terminal complement pathway inhibition by anti-complement C5 antibody (eculizumab) effectively treats post-transplant TMA after kidney transplant related to complement disorders. Initial evaluation of PT-TMA is limited by the lack of availability of complement pathway analysis, including genetic tests.

Methods: We reviewed the charts of patients with PT-TMA treated with eculizumab at our center. Ten patients were identified. PT-TMA was defined as hemolytic anemia, schistocytes on peripheral smear, thrombocytopenia, and acute allograft dysfunction. Renal response was defined as eGFR>15 ml/min/1.73m^2 and dialysis independence. Complete renal response was defined as eGFR>45 ml/min/1.73 m^2.

Results: PT-TMA was diagnosed within a week (median 2.75 days) of kidney transplant in 7 out of 10 patients. Kidney biopsy was performed on 9 patients; 8 patients showed signs of acute TMA without evidence of active rejection. Genetic analysis was done in 5 patients. One patient had a pathogenetic variant in the CFHR1 gene. Eculizumab was started within 1-3 days after diagnosis in all patients. After a median of 9 days from diagnosis, platelets persistently improved to >150 X 10^9/L in all patients. Haptoglobin and lactate dehydrogenase levels improved after a median of 2 weeks. After a median last follow up of 35.2 months, renal response was noted in 8 out of 10 patients. Four patients had complete renal response. Six patients were started on belatacept after discontinuing tacrolimus, considering it as a potential trigger of PT-TMA.

Conclusions: Patients with early de-novo PT-TMA treated with eculizumab within 1-3 days of diagnosis had prompt hematological remission. All but two patients with late PT-TMA had improved kidney allograft function. PT-TMA after kidney transplant develops from different triggers in predisposed individuals, which are often indiscernible on immediate evaluation. Prompt eculizumab therapy may benefit PT-TMA irrespective of etiology, especially those developing early post-transplant, suggesting the role of complement activation. A prospective study on the effectiveness of eculizumab in treating PT-TMA from different etiologies is important to inform further practice.

PUB508

Transplant Renal Artery Stenosis

Brian Min, Sara Hashemi, Muhammad Haseeb Aslam, Sabita Budhathoki. Upstate Nephrology Dept. *SUNY Upstate Medical University Hospital, Syracuse, NY.*

Introduction: Transplant renal artery stenosis is a rare vascular complication that arises in approximately 1 to 26% of patients after receiving kidney transplant. It should raise awareness for prompt diagnosis as it can lead to volume overload, hypertension, worsening graft function, and allograft loss. We describe a case of transplant renal artery stenosis that was successfully revascularized and was able to maintain a stable allograft function thereafter.

Case Description: A 60 year old male with history of hypertension, diabetes, CKD stage 4 underwent deceased donor transplant with immediate graft function. During surgery, doppler ultrasound of artery and veins, including upper, middle, lower pole, and external iliac artery below and above anastomosis were within normal ranges. Post-operative course was uneventful other than a complication with bleeding from a small perihilar arterial branch, which was controlled by surgical reopening of the incision and by using hemostatic clips. Due to worsening hypertension during a follow-up visit 3 months post-transplantation, doppler ultrasound of transplant kidney was performed, which revealed increasing velocities of renal artery. This was remeasured 1 month after with worsening parameters. The renal artery waveform showed a sharp upstroke, without evidence for a parvus tardus waveform. Patient underwent a arteriography of the renal artery and was found to have stenosis at the anastomoses of the superior and inferior transplant renal arteries with the external iliac artery. Stenosis improved after balloon angioplasty with improvement of pressures of the superior and inferior transplant renal arteries, and thereby improving his worsening hypertension. Patient's kidney function has been stable without any evidence of loss of graft function.

Discussion: Transplant renal artery stenosis (TRAS) is a complication that should be sought out with doppler ultrasound. Symptoms that can arise are worsening hypertension, worsening graft function, volume overload, pulmonary edema. Our patient was promptly investigated for TRAS due to his worsening hypertension despite having stable allograft function, and was found to have stenosis of renal arteries at anastomosis sites. The pathophysiology for TRAS varies, and mainly is due to turbulent blood flow at anastomosis. Treatment is either angioplasty alone or angioplasty with stents, and generally have success rates of 90%.

PUB509

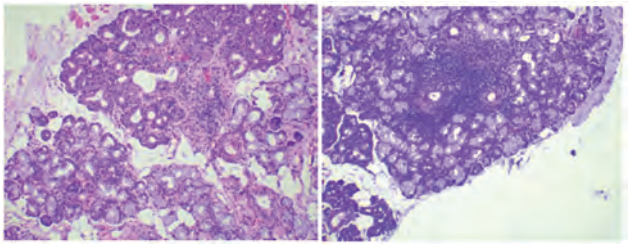
Cryoglobulinemia Secondary to Sjögren Syndrome after Kidney Transplant

Ada Noemi Chavez. *Hospital General San Juan de Dios, Ciudad de Guatemala, Guatemala.*

Introduction: The most frequent autoimmune disease that underlies non HCV-induced cryoglobulinaemia is Sjögren syndrome. Among the most common findings of Sjögren's syndrome from a hematological point of view are cytopenias: anemia, leukopenia, thrombocytopenia and also cryoglobulinemia and lymphoma. In post-kidney transplant patients, it is less common to find Sjögren's syndrome. Monoclonal gammopathy of undetermined significance (MGUS) has been observed in 20% of Sjogren's patients when serum immunoelectrophoresis is routinely performed. About 5% of patients with this abnormality may progress to develop lymphoma or another hematologic malignancy

Case Description: A 23-year-old female patient received a kidney transplant from a related living donor in July 2023. In September 2023, patient presented with difficult pancytopenia management, so autoimmune tests are performed and AntiRo >200 is evident, Sjögren's syndrome is diagnosed and a biopsy of minor salivary glands is performed where periductal lymphocytic sialadenitis is observed (Figure 1), patient persists with leukocyte count as follows: WBC 3060 Neutrophils 84 %, Hemoglobin in 9.16 g/dL, platelets in 126,000, peripheral blood smear was performed within normal limits, patient with refractory cytopenias for which cryoglobulins were performed which in 18%, rheumatoid factor 12.5 (normal), IgG 848.05, electrophoresis and negative protein immunofixation, creatinine at 1.87mg/dl, 24-hour urine protein at 186, refractory cytopenia is considered a manifestation of cryoglobulinemia type I secondary to Sjögren's syndrome, so it was decided to admit the patient to start treatment with plasmapheresis (5 sessions) and rituximab (1gr) for refractory presentation of cytopenias.

Discussion: Our patient presented refractory cytopenias secondary to cryoglobulinemia due to Sjögren's syndrome, which is a common cause not associated with HCV but a common cause of autoimmune disease. However, it is not common in post-transplant patients and currently our patient has no renal manifestations of the disease, there is no evidence of glomerulonephritis and the graft is functioning properly.



PUB510

Association of Postdonation Kidney Function and Risk of CKD in Living Kidney Donors at the Civil Hospital of Guadalajara, Mexico

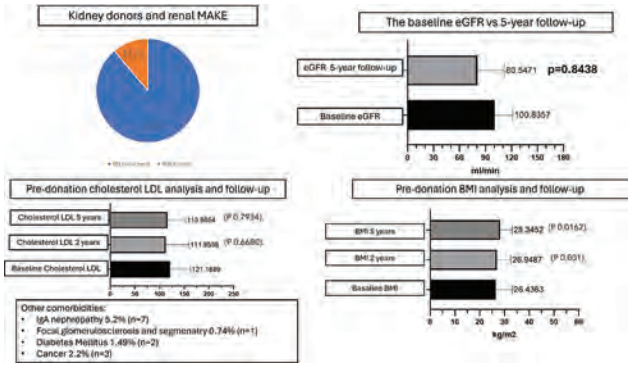
Jahir R. Camacho,[1,2] Guillermo Navarro Blackaller,[1,2] Edgar J. Carmona,[1,2] Ixchel De la Torre De la Vega,[1,2] Jonathan Chavez,[1,2] Ramon Medina,[1,2] Juárez Correa de León,[1,2] Fernando Cruz Aragon,[1,2] Maria de la Luz Alcantar Vallin.[1,2] *[1]Universidad de Guadalajara, Guadalajara, Mexico; [2]Hospital Civil de Guadalajara, Guadalajara, Mexico.*

Background: In Mexico, according to figures from the National Transplant Center Registry, more than 90% of transplants are from living donors. This makes it difficult to estimate the risk attributable to donation. The outcome of donors in our country is unknown, in terms of risk of progression to CKD and comorbidities. In previous studies, some of which do not confer a higher risk, mainly in the first-world population.

Methods: Cross-sectional cohort study without retrospective intervention, Unicentro, of kidney donor patients from the program of the Civil Hospital of Guadalajara. In the period from January 2019 to December 2022, at the 5-year follow-up. Objective: Association of post-donation renal function from the year of donation and risk of chronic kidney disease with a 30% loss of GFR, renal replacement therapy.

Results: found with an average age of 39 years in total. The 93.2% (124) of donors do not have social or private security. The eGFR before donation was 102.21 ml/min/1.73 m2. (DE +/ 7.65ml/min/1.73m2). Only 11.1% achieved renal MAKE. + The estimated glomerular filtration rate was compared with the CKD-EPI formula with serum creatinine, baseline eGFR with a mean of 102.21 ml/min/1.73m2 SD +/- 7.65 ml/min/1.73m2 and at follow-up at the fifth year with a mean 80.5ml/min/1.73m2 SD +/- 9.78 ml/min/1.73m2 with a decrease in eGFR with a non-significant value of p=0.8438. + Kidney donors were analyzed, comparing their baseline pre-kidney donation BMI (26.4 kg/m2 SD +/- 1.78 kg/m2), at follow-up BMI 27.3 kg/m2 SD +/- 9.3 kg/m2 with a significant difference of p=0.0162Conclusion

Conclusions: In this study, we observed that although there was a significant difference in renal function at 5 years post-transplant, but 11.2% of our population had it MAKE RENAL..



PUB511

Impact of Genetic Testing on the Outcome of Kidney Transplant Recipient Evaluation

Yasar Caliskan, Fadee Abu Al Rub, Vidya Fleetwood, Bahar Bastani, Mustafa Nazzal, Chintalapati Varma, Henry B. Randall, Kate Rabideau, Dzuy Truong, Ava DeLonais-Dick, Rengin Elsurer Afsar, Baris Afsar, Krista L. Lentine. *Saint Louis University, St Louis, MO.*

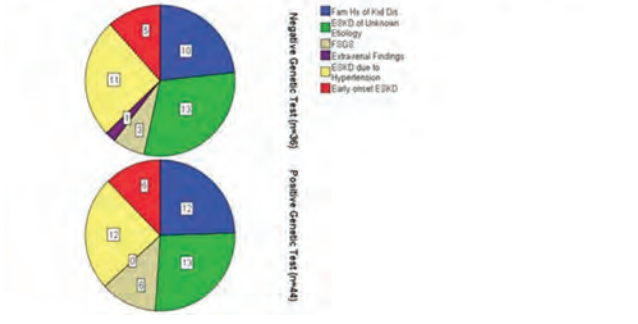
Background: Identifying a genetic etiology during evaluation of kidney transplant (KT) candidates can inform the risk of disease recurrence, guide KT management, and enable the assessment of living related donors. Despite these benefits, there is limited literature on the impact of genetic testing on recipient candidate outcomes.

Methods: Eighty patients who underwent KT evaluation in January 2021 to November 2022 were assessed. Patients with positive genetic test results were compared with patients without any identified kidney disease related genetic variants. The primary outcomes were waitlisting, KT and delayed graft function (DGF).

Results: Positive genetic test results were found in 44 (55%) patients, with *APOL1* high risk genotypes (20, 45%), *PKD1/2* (6, 14%) and *COL4A3-4* variants (4, 9%) being the most common. There were no significant differences between patients with positive and negative test results in terms of age, sex, self-identified race and cause of kidney disease. The criteria for testing are shown in Figure 1. During a median follow up of 2 yrs (IQR,1.75-2.58), 63% of the patients were waitlisted and 45% underwent KT. Waitlisting, deceased (DDKT) and living donor KT (LDKT) rates did not differ significantly between patients with positive and negative genetic results (Waitlisting: 28 (64%) vs 22 (61%), p=0.82; DDKT: 16 (36%) vs 14 (39%) and LDKT: 2 (5%) vs 3 (8%), p=0.58). DGF rates were similar between patients with positive and negative results (3 (7%) vs 3 (8%), p=0.59). Four patients with positive genetic test results developed biopsy confirmed rejection while no rejection episodes were recorded in patients with negative genetic results (p=0.039).

Conclusions: In this pilot study, genetic testing with positive findings in KT evaluations did not significantly impact waitlisting, transplant and DGF risk of recipient candidates. Higher rate of rejection in patients with positive genetic test results needs further studies.

Figure 1. Number of patients met each criteria for genetic testing according to positive (n=36) and negative genetic test results (n=44)



PUB512

Urinary Tract Infections in Kidney Transplant Recipients: A Single-Centre Experience

Nicholas Evans,[1] Rosa M. Montero.[2,1] *[1]St George's University of London, London, United Kingdom; [2]St George's University Hospitals NHS Foundation Trust, London, United Kingdom.*

Background: Urinary tract infections(UTIs) occur in 25% of kidney transplant recipients (KTR) within one year post-transplant(PTx) accounting for 45% of infective complications. Few reports are on the timeframe of recurrent UTIs >1yrs PTx. Recurrent UTIs are associated with bacteraemias, impaired allograft function, allograft loss, acute T-cell mediated rejection causing increased morbidity and mortality. We looked to determine the frequency, organisms and influencing factors for UTIs in our cohort.

Methods: A cross-sectional retrospective observational study of all KTR at our centre with a UTI from April 2022- April 2023. Clinical data was extracted from electronic patient records and microbiology electronic system. Recurrent UTIs was defined: 2 episodes of symptomatic acute bacterial cystitis in 6 months or 3 episodes within a year. Data on organism and sensitivities, immunosuppression(IS) regimens, deprivation scores 1 most deprived, 10 least deprived) were collected. Paired t-tests and ANOVA were used to perform statistical analysis with a $p<0.05$ significant level.

Results: 167 of 516 KTR had a UTI between 2022-2023 with a total of 294 UTIs in 167 KTR. 58 Male, 109 Female. Median age 59yrs(range 18-92yrs). 24% White, 20% Black, 16% Asian, 1% Chinese, 8% Other, 31% unknown. Number of UTIs in KTR: x1 65% (109), x2 20.4%(34), x3 6.6%(11), x4 3%(5), x5 0.6%(1), x6 1.2%(2), x7 0.6%(1), x8 0.6%(1), x10 1.8%(3). UTIs median 31 weeks (range 9 days to 16.4 years) PTx. Deprivation scores were insignificant (p=0.08). 20 different organisms were grown 54% Escherichia coli, 15.5% Enterococcus, 8.8% Klebsiella pneumonia, 7.7% staphylococcus organisms, 4.7% proteus, 3% pseudomonas, 6.3% combination of different organisms. Tacrolimus based IS regimens had more UTIs ($p<0.05$) compared to non-tacrolimus regimens. 24% UTIs were fully sensitive with 60% of all UTIs resistant to Amoxicillin, 16% other antibiotic resistant micro-organisms.

Conclusions: UTIs continue to be problematic up to 16yrs PTx. 32% of KTR had UTI between 2022-2023 with 35% of KTR having >2. Consistent with previous results females had more UTI and were predominantly gram-negative. Tacrolimus based regimens increased risk of UTIs. Up to 10 recurrent UTIs occurred PTx. Deprivation scores did not influence UTI occurence. We recommend reviewing IS regimens in KTR with recurrent UTIs to avoid allograft dysfunction, morbidity and mortality.

PUB513

Comprehensive Approach to Kidney Education and Support: Transplant Outcomes

Danielle Wentworth, Brendan T. Bowman, Theresa "Thessa" Churillo, Jessica Jenkins, Rebecca P. Peters, Sana F. Khan. *UVA Health, Charlottesville, VA.*

Background: The 2019 Advancing American Kidney Health Executive Order set a goal to increase the number of End-Stage Renal Disease (ESRD) patients receiving a kidney transplant. Per the USRDS 2023 Annual Data Report, only 7.9% of incident dialysis patients were preemptively transplanted or waitlisted prior to starting dialysis and 12.3% of prevalent dialysis patients were waitlisted. To help achieve high rates of preemptive transplant and waitlisting prior to dialysis, we designed a quality improvement (QI) project that provided comprehensive patient-centered nephrology care for patients at high risk of progression to ESRD.

Methods: Our prospective QI project began January 2021 with analysis performed through May 2024. Patients at high risk of developing ESRD were identified via EMR registry. Inclusion criteria were GFR < 30 mL/min and 2-year KFRE score >20%. Patients were offered enhanced education and support regarding all possible ESRD modality treatment choices. Patients were seen sequentially by an experienced nephrology nurse practitioner (NP), social worker, dietician, and home dialysis nurse. Patients received an additional NP visit for ESRD decision planning and to address outstanding educational needs. Patient modality choices were documented in the EMR and communicated to the primary nephrologist. Patient progress and coordination gaps were discussed during quarterly list management meetings.

Results: Our cohort included 42 patients (average age 65 years, GFR 16 ml/min, KFRE 53%), and 30 progressed to ESRD (71%). 11 ESRD patients were waitlisted (37%) with an average GFR of 16.3 mL/min at time of transplant referral. 4 waitlisted ESRD patients were transplanted (36%). Of our incident ESRD patients, 10 received a preemptive transplant or were waitlisted prior to starting dialysis (33%). Average time to transplant was 1.13 years after starting dialysis.

Conclusions: Development of a multidisciplinary high-risk nephrology care clinic at our institution helped us surpass national rates of kidney transplant waitlisting, both preemptively and for patients on dialysis. By maintaining a high percentage of our high-risk patients on the waitlist, we hope to improve access to transplantation and decrease the duration of dialysis dependence.

PUB514

A Case of Recovery of Native Kidney Function Years after Simultaneous Liver-Kidney Transplant

Stephen R. Sammons, Miklos Z. Molnar, Duha A. Jweehan, Isaac E. Hall, Suayp Oygen, Divya Raghavan. *University of Utah Health, Salt Lake City, UT.*

Introduction: Simultaneous Liver-Kidney (SLK) transplantation is often considered in End Stage Liver Disease (ESLD) patients with significant renal dysfunction. Prior to the implementation of the Organ Procurement and Transplantation Network's (OPTN) 2017 policy on SLK allocation, criteria were variable and of particular concern was the potential recovery of native renal function following SLK. Here we describe a case of a patient who underwent an SLK transplant and was found to have native renal recovery eight years later.

Case Description: A 45-year-old female with ESLD due to autoimmune hepatitis who underwent liver transplant in 2009 with subsequent failure and resulting hepatorenal syndrome (HRS) followed by SLK in 2015 presented to the hospital after unintentional acetaminophen overdose complicated by acute kidney injury (AKI). Ultrasound of her kidney graft showed severe atrophy with a lack of renal cortex blood flow despite patent vessels. She briefly required dialysis for uremia followed by rapid renal recovery. A nuclear medicine (NM) study using Tc99m MAG3 was later performed which found functioning native kidneys with minimal activity in the kidney graft. Immunosuppression decisions were deferred to the liver transplant service in the setting of kidney graft loss.

Discussion: Native renal recovery following SLK is a known phenomenon particularly in patients with HRS. NM studies are more commonly done in the post-SLK period and are not usually considered years after SLK. This case features a patient who received an SLK prior to the 2017 SLK policy updates and who was found eight years later to have renal graft loss with recovery of native renal function. Reviewing this patient's pre-transplant data shows she would not have been an SLK candidate under current criteria. This case illustrates the importance of careful policy decisions regarding SLK allocation.

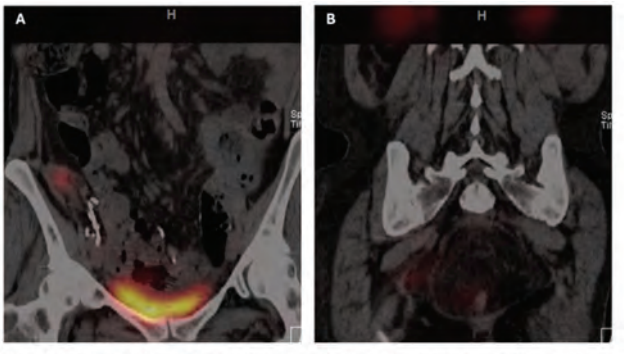


Figure 1. NM renal study with coronal images showing A) minimal radiotracer uptake in the kidney graft parenchyma with no apparent activity in the collecting system and B) partially visualized native kidneys with activity throughout all phases of exam

PUB515

A Comparison of Close Family Members and Other Relationships in Live Kidney Donor Evaluation

Ritah R. Chumdermpadetsuk, Adriana Montalvan, Stalin Canizares, Maria B. Rivera, Amy Evenson, Devin Eckhoff, Martha Pavlakis, Bhavna Chopra. *Beth Israel Deaconess Medical Center, Boston, MA.*

Background: While initially live kidney donations (LKD) were largely restricted to biological relatives, there is currently more variety in the types of donor-recipient relationships. We examined the LKD evaluation process to compare behaviors and characteristics of close family members (CFM) versus other relationships.

Methods: Single institution retrospective chart review of referrals for LKD between 1/2009-12/2022. Referrals were identified using the Organ Transplant Tracking Record database and cross referenced with billing data. Elimination at each stage of evaluation was compared between CFM (spouses, parents, siblings, and children) and non-CFM using Chi square test.

Results: In sum, 1861 referrals were reviewed, including 477 (25.6%) CFM and 1384 (74.4%) non-CFM, resulting in 146 approvals and 125 donations. CFM were more likely to complete medical (med) and psychosocial (psych) workup (WU). Among those who completed WU, CFM were less likely to have med and psych contraindications (CI). Overall, CFM were more likely to be approved and to donate. However, once approved, there was no difference in donation between the 2 groups ($p = 0.61$). The top med CI for both was obesity, eliminating 60/124 (48.3%) CFM and 203/399 (50.9%) non-CFM, followed by hypertension (HTN) and malignancy concerns for CFM; nephrolithiasis and HTN for non-CFM. The top psych CI was substance use disorder (SUD) for CFM; young donor age for non-CFM.

Conclusions: We saw a high proportion of non-CFM referrals, suggesting increased awareness and acceptance to be considered as donors. Non-CFM were more often eliminated due to med or psych CI. CFM showed greater commitment to complete LKD evaluation, but once approved, both groups were equally likely to follow through with donation.

	Close family member (n = 477)	Other (n = 1384)	p value
Positive crossmatch (%)	3 (1.4)	7 (1.8)	0.75
Begin medical workup (%)	248 (52.0)	503 (36.3)	< 0.01

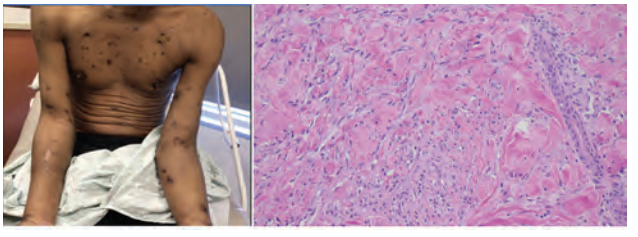
Kaposi Sarcoma in a Nonadherent Transplant Patient

Dominik Thomas, Sarah Gilligan, Suayp Oygen, Duha A. Jweehan, Isaac E. Hall, Miklos Z. Molnar, Divya Raghavan. *University of Utah Health, Salt Lake City, UT.*

Introduction: Kaposi Sarcoma (KS) is an angioproliferative cancer caused by human herpesvirus 8 (HHV-8). Most cases of post-transplant KS arise after HHV-8 reactivation triggered by immunosuppression with 60-times higher risk of KS in solid organ transplant recipients than the general population. We present a kidney transplant patient who develops KS shortly after transplant.

Case Description: 53-year-old Somali man with end-stage renal disease due to diabetic nephropathy underwent kidney transplant with induction with thymoglobulin, and maintained on belatacept, mycophenolate sodium (MPS), and prednisone. Acute antibody-mediated rejection and Banff IIA acute cellular rejection is found four months after transplant due to non-adherence with belatacept infusions and treated with thymoglobulin, steroids, intravenous immunoglobulin, and therapeutic plasma exchange. Belatacept was subsequently switched to tacrolimus. He develops lymphadenopathy and a core biopsy of his axillary lymph nodes shows reactive lymphoid tissue. He has worsening disseminated rash two months later with initial rash noticed one month post-transplant. Biopsy of skin lesions shows KS. HHV-8 was checked and found to be 162,000 copies/ml. HIV was negative. Prior lymph node biopsy was found without features of KS and negative staining for HHV-8. MPS was switched to everolimus, a mammalian target of rapamycin inhibitor (mTORi), with regression of KS skin lesions. His graft function remained stable with serum creatinine around 1.5 mg/dL.

Discussion: This patient developed progression KS despite nonadherence to immunosuppression which then worsened after treatment for rejection. Management of post-transplant KS focuses on reducing immunosuppression, switching to mTORi, and/or chemotherapy. In one study, conversion to mTORi and reducing immunosuppression induced response in over 80% of patients. Chemotherapy is usually reserved for cases of extensive KS and best understood in AIDS-related KS. We were able to control KS by switching to an mTORi.



PUB517

Rare Vascular Complications in a Kidney Allograft

Arpita Joshi, Raul F. Garcia Maya, Raviprasenna K. Parasuraman. *University of Michigan, Ann Arbor, MI.*

Introduction: The occurrence of vascular complications in kidney transplant ranges 6-30% and has a significant impact on allograft and patient outcomes.

Case Description: Case 1: A 54-year-old male with ESKD from hypertension received a DDKT. He developed an AKI 5 weeks later. Ultrasound showed a 3 cm large extrarenal pseudoaneurysm (EPSA) at the site of anastomosis of the renal artery to the right external iliac artery. Endovascular intervention with occlusion of the pseudoaneurysm and intentional exclusion of transplant renal arteries was performed to prevent rupture and leak with eventual allograft failure. Case 2: A 25-year-old with ESKD from Alport's syndrome and LUKT had an AKI, proteinuria, microscopic hematuria with ipsilateral leg edema 3 weeks later. Biopsy negative. External compression of the right common iliac vein by a 6 cm hilar lymphocele causing renal vein congestion was seen on imaging. Aspiration of the lymphocele resolved the findings.

Discussion: EPSAs occur in 1% of transplants. Infections commonly cause EPSAs and can cause irreversible arterial damage. EPSA in our case was due to complex vasculature with 3 renal arteries on 2 aortic patches. Infected ESPAs or larger than 2.5 cm are at high risk for rupture and need intervention, usually allograft nephrectomy. Iliac vein stenosis is a rare, reversible cause of allograft AKI, ipsilateral leg edema, proteinuria and microscopic hematuria. This can be due to perihilar fluid collections or hematomas, surgical clamp injury and faulty suturing. In our case, a lymphocele led to a nutcracker-like phenomenon and renal vein congestion. Evolution and standardization of surgical techniques may have contributed to a decrease in vascular complications but the incidence remains substantial.

An Atypical Case of Post-transplant Lymphoproliferative Disorder of the Bladder in a Kidney Transplant Recipient

Gurbir S. Sehmbey, Dominik Thomas, Sarah Gilligan, Suayp Oygen, Duha A. Jweehan, Isaac E. Hall, Miklos Z. Molnar, Divya Raghavan. *University of Utah Health, Salt Lake City, UT.*

Introduction: Post-transplant lymphoproliferative disorder (PTLDs) represents a spectrum of abnormal lymphoid or plasma cell proliferations that arise in individuals receiving chronic immunosuppression for solid organ transplantation. PTLD encompasses a spectrum of manifestations from benign polyclonal lymphoproliferation to fully developed lymphomas.

Case Description: We present a case of a 50-year-old female with ESRD and history of two kidney transplants. The first transplant was from a living unrelated donor in 2003; graft loss occurred five years later due to pulmonary renal syndrome caused by p-ANCA microscopic polyangiitis. The second transplant in 2012 was from a deceased donor. Both transplants were complicated by recurrent ESBL E. coli UTIs requiring IV ertapenem and bilateral native nephrectomies in 2014. Her kidney function remained stable while on Azathioprine 100 mg, prednisone 5mg and tacrolimus 3mg twice daily for immunosuppression after the second transplant for 8 years. In April 2020, she presents with gross hematuria. Renal ultrasound reveals an irregular hypoechoic mass with vascularity within the bladder. She subsequently underwent a cystoscopy showing 3 masses: 8cm, 5cm and 6cm – the 5cm mass was resected. Pathology revealed PTLD (monomorphic subtype, EBV-, DLBCL GCB). The MIB1=70%. cMYC was expressed on 30-40% of cells and BCL2 and BCL6 were expressed in most tumor cells. The sample also stained strongly for CD10 and CD20. Therefore, she did not have a double expressor or double hit lymphoma. She was treated with weekly rituximab for 4 weeks and 4 cycles of rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP). Immunosuppression was decreased. A repeat cystoscopy and CT abdomen showed resolution of lesions in the bladder.

Discussion: PTLD is a serious complication after solid organ transplantation. Risk factors for developing PTLD include Epstein-Barr virus (EBV) infection, recipient age, transplanted organ, type of immunosuppression, and genetics. PTLD has a reported incidence of 1-5% in kidney transplant recipients. Outcomes following a diagnosis of PTLD can vary, with 5- and 10-year survival rates of 53% and 45% respectively. Although PTLD can happen in almost every organ system in the body, occurrence in urinary bladder is very rare.

PUB519

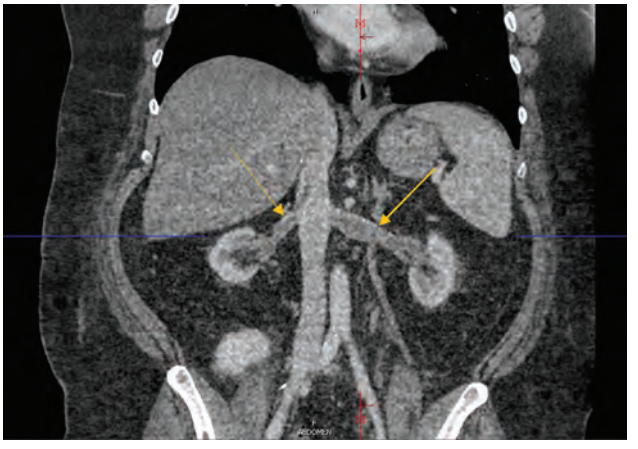
Bilateral Native Renal Vein Thrombosis in a Liver and Kidney Transplant Recipient

Andrew Slater, Alfonso Santos, Rohan V. Mehta, Amer A. Belal, Kawther Alquadan. *University of Florida, Gainesville, FL.*

Introduction: Renal vein thrombosis (RVT) is a rare condition predominantly linked to nephrotic syndrome, hereditary hypercoagulable disorders, malignancies, and sepsis in adults. The incidence of native RVT after simultaneous liver and kidney transplantation (SLKT) is unknown. In this case, we present an incidental finding of bilateral native kidney vein thrombosis in a liver and kidney transplant recipient.

Case Description: A 44-year-old male received SLKT. Thirteen months post-transplant, bilateral native renal vein thrombosis extending into the inferior vena cava (IVC) below the diaphragm appeared on a CT scan during a preop workup for incisional hernia repair. The renal allograft was free of venous thrombosis based on the CT scan and a Doppler study. A focused investigation for the underlying cause of thrombosis ensued. The family history of thromboembolism was negative. Tests including Lupus anti-coagulant; anti-cardiolipin IgG and IgM; anti-beta-2 Glycoprotein IgG and IgM; factor V Leiden and prothrombin (20210G>A) mutations yielded negative results. Genetic mutations implicated in myeloproliferative neoplasm including JAK2 (V617F), Calreticulin (CALR Exon 9), and MPL mutations were not detected. Similarly, paroxysmal nocturnal hemoglobinuria was ruled out by flow cytometry. The function of the renal and liver allografts remained stable, and proteinuria was not detected. With apixaban treatment, a CT scan showed complete resolution of the bilateral native renal vein thrombosis after 3 months.

Discussion: This case highlights the incidental finding of native RVT after SLKT, a pathology with an unknown clinical incidence. When found, it warrants a complete comprehensive workup for an underlying etiology. The most efficacious type and duration of anticoagualation is unknown, and this decision should be multi-disciplinary and collaborative with the patient.



Bilateral RVT extending into the IVC with renal vein dilation (yellow arrows).

PUB520

Safety of SGLT2 Inhibitors in Kidney Transplant Recipients with Type 2 Diabetes Mellitus (T2DM) or New-Onset Diabetes after Transplant (NODAT): A Single-Centre Experience

Wigdan Hamza, Komal Moqeem, Aisha Riaz, Natasha A. Moore, Elham Asgari, Caroline Dudreuilh. *Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom.*

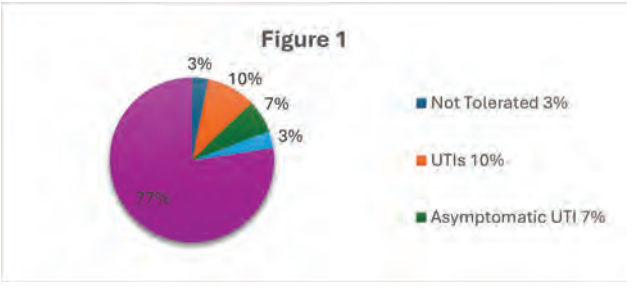
Background: Sodium/Glucose Transporter 2 inhibitors (SGLT2i) have demonstrated significant renoprotective effects in native kidney disease. However, evidence of their safety in kidney transplant recipients (KTRs) is lacking. Attention was drawn to the potential increased risk of urinary tract infections (UTIs) in the setting of immunosuppression. We aim to present our local experience on the safety of SGLT2i in KTRs with pre-existing type 2 diabetes mellitus (T2DM) or new-onset diabetes after transplant (NODAT).

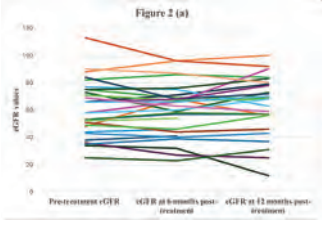
Methods: A retrospective analysis of 31 KTRs with either pre-existing T2DM or NODAT, who were commenced on SGLT2i, was conducted. Pre-treatment eGFR (estimated glomerular filtration rate) was recorded (using CKD-EPI equation) and further assessed at 6 and 12 months following initiation of SGLT2i. Treatment complications and adverse events were reviewed during the follow-up period.

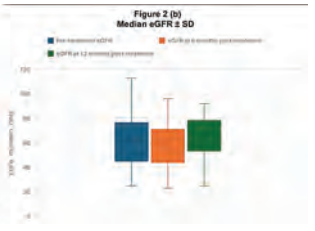
Results: SGLT2i were started for 21/31 (67.7%) KTRs diagnosed with NODAT and 9/31 (29%) with pre-existing T2DM. The median duration of SGLT2i treatment was 23 months (± 12.9). Among 31 KTRs, 5 patients developed uncomplicated UTIs (16%) (Figure 1). eGFR remained stable following SGLT2i initiation with a median value of

62ml/min/1.73m² (±22.8) pre-treatment and 68 ml/min/1.73m² (±18.6) 12 months post treatment (Figure 2). One patient developed acute rejection due to non-compliance with immunosuppression. No patient developed euglyceamic diabetic ketoacidosis or genital fungal infections.

Conclusions: Our data suggests that SGLT2i are not associated with significant adverse effects. UTIs were the most frequent complications. The incidence, however, is similar to KTRs who were not on SGLT2i as reported in the literature. One of the limitations of our study is the small sample size, however, we conclude that SGLT2i can be safely prescribed in diabetic KTRs.







PUB521

Clinical and Histopathological Features of Anti-AT1 Receptor Antibody-Mediated Acute Rejection in Kidney Transplant Recipients: A Case Series

Claudia G. Olano,[1] Andrea L. Urrutia,[1] Sami M. Akram.[2] *[1]Harbor UCLA Medical Center, Torrance, CA; [2]Loma Linda University, Loma Linda, CA.*

Introduction: According to US renal Data System (USRDS), one in five patients will lose their kidney allograft within 5 years of transplantation, and over half will experience allograft loss by 10 years (**1**). Allograft loss is associated with a high burden of psychologic and medical morbidity, with patients faring poorly across many traditional measures of quality of care, including anemia management and phosphate control (**2**, 3). The most common cause of graft loss during life is alloimmunity (5).

Case Description: Patients: There were four kidney transplant recipients between the ages 34 – 60 (table 1). There were two males and two females. Blood groups are shown in Table 1. The causes of primary renal disease and the comorbidities recorded in Table 1. One patient had biopsy proven TMA as the cause of renal failure. There was one case of second renal transplant. One patient had Living unrelated donor kidney transplant (case 1) and the three others had deceased donor kidney transplant. The case number 2 received donation after cardiac death (DCD). No patient had zero mismatch organ (table 1). In all cases, complement-dependent T-cell and B-cell cross match were negative prior to the operation. T cell antibody and B cell antibody cross match was done with pronase tested donor cells. In case #1 of living unrelated donor, cross match was performed using multiple techniques, automated flow, and serology. Case one and four had zero panel reactive antibodies (PRA), while cases two and three were severe and moderately sensitized respectively (case 2 PRA 85/75, case 3 PRA 45/62). In case number two there were both Class I DSA and Anti AT1R. Relapse of her underlying TMA was reason. This patient was prescribed Ultimiris resulting in stabilizing of serum creatinine.

Discussion: In conclusion, testing for anti AT1R antibody should be done early if not prior to kidney transplantation. Injury in Acute Rejection mediated by anti AT1R antibodies may be due to mitochondrial dysfunction. Repertoire to treat Acute rejection by inhibiting ERK ½ signaling pathway is about to grow explosively. There is an opportunity to influence the therapy of acute rejection and improve graft as well as patient survival

PUB522

Sepsis-Induced Thrombotic Microangiopathy (TMA) in Simultaneous Pancreas-Kidney (SPK) Transplantation: Diagnosis and Treatment Dilemmas

Atousa Jahanshahi, Ananthalaxmi Vangapalli, Sudhindra Pydimarri, Richard Gargiulo. *Jefferson Einstein Philadelphia Hospital, Philadelphia, PA.*

Introduction: TMA is an acute life-threatening condition characterized by the formation of microscopic blood clots in capillaries and small arteries, causing microangiopathic hemolytic anemia (MAHA), thrombocytopenia, and organ damage.

Case Description: 50-year-old female, with end-stage-renal-disease from diabetes, SPK transplantation in 2018, with baseline creatinine of 1.3mg/dl presented with a week-long history of diarrhea, dysuria, weakness, oliguria, and bilateral flank pain. Found to have acute kidney injury, neutropenia, elevated tacrolimus level (see Table 1). Due to severe neutropenia, mycophenolate was held, and G-CSF initiated. Tacrolimus dose was adjusted for goal level 4 – 6ng/ml. As she was afebrile and initial cultures were negative, patient was monitored off antibiotics. On day four, hemoglobin dropped to 5.8gm/dL with negative hemolytic workup. By day eight, platelet count decreased to 18 x10^3/mcL, with signs of MAHA (see Table 1). Despite daily plasma exchanges and reduced tacrolimus levels, her condition worsened, developing hypotension, and altered mental status. After extensive negative workup, repeat blood cultures revealed ESBL Klebsiella pneumonia bacteremia. She was started on vancomycin and meropenem with clinical improvement. At discharge, creatinine improved to baseline and blood counts and hemolysis stabilized.

Discussion: This case highlights the challenge of diagnosing sepsis-induced TMA in the transplant population, with many potential etiologies to consider including Shiga toxin-mediated hemolytic uremic syndrome (ST-HUS), thrombotic thrombocytopenic purpura, complement-mediated TMA (CM-TMA), and drug-induced TMA (DITMA). Antibiotics were vital in her clinical improvement. When managing TMA syndromes in transplant and other immunosuppressed patients, consideration of sepsis in the differential diagnosis is crucial, particularly if standard treatments fail.

Donor Sex Disparities in CKD Progression: A UNOS Analysis

Fausto R. Cabezas, Andrea Roche-Recinos, Subodh J. Saggi, Angelika C. Gruessner. *SUNY Downstate Health Sciences University, New York City, NY.*

Background: Living donor kidney transplantation (LDKT) remains the gold standard for the treatment of ESRD. However, there is scarce prospective data on long term outcomes for kidney donors. Retrospective studies with follow-up time of 10 years or more have shown a modest risk increase in all-cause mortality, hypertension and ESRD. As a higher proportion of living donors are female, we aim to assess sex disparities amongst kidney donors requiting listing for kidney transplantation (KT).

Methods: We queried the UNOS/OPTN database for all adults listed for a primary KT between 1/1/2014 and 12/31/23. Probabilistic linkage was used to link the donor record to the waitlist information. Comprehensive statistical methods were applied to assess the development over time and to describe possible sex differences.

Results: 51,700 primary LDKTs performed during the study period, 64% of donors were female (p=0.007). In contrast, of 519 donors (1%) who were listed for KT, 64% were male (p<0.0001) (fig 1). Baseline characteristics were similar in between the groups (table 1). Only males were more likely to have hypertension and diabetes at the time of listing. There was no significant difference in time from donation to listing between the groups.

Conclusions: Male kidney donors are more likely to progress to require kidney transplant listing. Higher rates of diabetes and hypertension are likely associated with faster decline in kidney function amongst males. Prospective research assessing long term outcomes in donors is warranted.

Safety and Diagnostic Yield of Kidney Transplant Biopsies in an Interventional Nephrology Program: A Retrospective Single-Center Study

Kingsley I. Onuoha, J. Pedro Teixeira, Pablo Garcia, Jonathan G. Owen. *University of New Mexico Health Sciences Center, Albuquerque, NM.*

Background: Kidney transplant (KT) biopsy remains the gold standard in diagnosing rejection. However, biopsy carries risk of complications which must be weighed against the diagnostic yield, and variability exists between providers and centers in aggressiveness of pursuing transplant biopsy. We created a renal biopsy registry at our center for both research and quality improvement purposes. We reviewed all transplant biopsies performed to determine the rate of complications and diagnostic yield.

Methods: We performed a retrospective chart review of all KT biopsies performed by our Interventional Nephrology program between 11/27/2017 and 4/9/2024. Data collected included pathological diagnosis and complications. Major bleeding was defined as the need for secondary interventional procedure, need for blood transfusion, need for surgery, hospitalization, hematoma >5 cm, or death. Minor bleeding was defined as hemoglobin drop of >1.5 g/dL, hematoma <5 cm, or uncomplicated gross hematuria. Diagnoses of rejection included all forms of rejection, including borderline cases.

Results: A total of 282 biopsies were performed, of which 154 (54.6%) were KT biopsies. Major bleeding events occurred in 3 KT patients (1.95%). All 3 patients presented with gross hematuria. The first patient was found to have an arteriovenous fistula and died of an unrelated cardiac event before planned IR embolization. The second patient developed urinary obstruction secondary to bleeding and required a nephrostomy tube for 51 days. The third patient required 1 unit of blood and was observed in the hospital until the hematuria resolved. Minor bleeding occurred in 2 additional patients (1.3%), manifest in both as hemoglobin drop >1.5 g/dL. Of the KT biopsies, 65/154 (42%) revealed evidence of rejection.

Conclusions: In our center, major bleeding after KT biopsy was uncommon relative to the frequency of transplant rejection diagnoses. Our findings support the consideration of an aggressive approach to KT biopsy for detection of rejection. Further analyses of our registry are planned to determine factors most likely associated with rejection (e.g., donor-specific antibodies, time since transplant, cell-free DNA levels) to improve the screening process for biopsy referral and help personalize the decision-making process for individual patients.

PUB525

An Unusual Case of Transplant Kidney Emphysematous Pyelitis and Cystitis

Taylor R. Moody, Sarah Gilligan, Isaac E. Hall, Duha A. Jweehan, Miklos Z. Molnar, Suayp Oygen, Divya Raghavan. *University of Utah Health, Salt Lake City, UT.*

Introduction: Emphysematous cystitis, pyelitis, and pyelonephritis are rare but serious complications of urinary tract infections (UTIs) with gas-producing bacteria. We present a case of emphysematous UTI in a kidney transplant recipient concomitant with rejection.

Case Description: A 36-year-old woman with history of end-stage kidney disease of unclear etiology who underwent a living related kidney transplant in 2001 complicated by cellular and antibody-mediated rejection in 2017 and recurrent UTIs presented with worsening kidney function and allograft pain. She initially presented a month prior with allograft pain and dysuria and was treated for *Escherichia coli* (*E. coli*) UTI. Computed tomography (CT) and urinalysis 10 days prior to admission were unremarkable. Testing revealed a persistently positive class II donor specific antibody. Kidney biopsy showed chronic active antibody mediated rejection and she was started on high-dose intravenous steroids with plan for therapeutic plasma exchange (TPE). She continued to report significant allograft pain and repeat CT scan demonstrated emphysematous transplant pyelitis and emphysematous cystitis. Antibiotics were started and surgical intervention was not recommended. Repeat urine culture grew *E. coli*. Further rejection treatment was deferred and she was discharged home with clinical improvement. Her serum creatinine was down to 1.73 mg/dl on discharge from a peak of 2.35 mg/dl during hospitalization.

Discussion: This case demonstrates the importance of thorough evaluation prior to initiating treatment for allograft rejection. If this patient had received potent immunosuppression as planned, her emphysematous pyelitis may have progressed to emphysematous pyelonephritis which is associated with increased risk of allograft loss and mortality.

Influence of Anemia Prior to Kidney Transplant in Early Graft Function

Jose L. Torres Cuevas, Manuel Camacho Luna, Victor M. Ulloa Galvan, Martin B. Yama Estrella, Ydris Z. Rosillo-Salgado, Francisco Velasco Garcia Lascurain, Christian P. Flores, Citlali Fernandez Vivar, Mayra M. Matias Carmona, Jose H. Cano Cervantes. *Instituto de Seguridad y Servicios Sociales de los Trabajadores del Estado, Mexico City, Mexico.*

Background: Modifiable factors associated to better allograft function are relevant to de success of the kidney transplant. Anemia, complication associated to chronic kidney disease could influence in allograft function.

Methods: Retrospective, cross-sectional study, included transplant kidney receptors of a single Mexican third level healthcare center performed in 2017-2019. Univariate logistic regression (odds ratios [OR], 95% CI) were used to evaluate allograft function associations, spearman correlation coefficient (SCC) was also performed to continuous variables.

Results: A total of 97 participants were included (52% from living kidney donors), the median age was 33 (25-48), 61 (62.9%) were women and 51 (52.6%) were living kidney donors, mean hemoglobin (Hb) pre-transplant was 11.53 ± 2.18, median transferrin saturation (TS) was 28.2 (17-35). Anemia (Hb < 11 g/dl) prevalence was 77.3% and iron deficiency (TS <20 %) in 34%. Inmediate graft function (IGF) defined as serum

creatinine decrease of at least 70% of preoperative value in the first week was recorded in 75 participants (77.3%), delayed graft function (DGF), defined by requirement of dialytic therapy in the first week after kidney transplantation, was identified in 11 participants (11.3%). The OR for IGF by anemia and iron deficiency were OR= 0.74, 95% CI, (0.28- 1.93) and OR=0.87, 95% IC, (0.32- 2.36) respectively. SCC between hemoglobin previous transplant and the glomerular filtration rate after 3 months was 0.13, *p:* 0.19.

Conclusions: Anemia previous a kidney transplant doesn't influence in the early kidney function. Kidney transplantation in living kidney donors shouldn't be delayed by a specific hemoglobin target. Therapeutic interventions to increase hemoglobin previous kidney transplant in receptors of a cadaveric donor could be avoided.

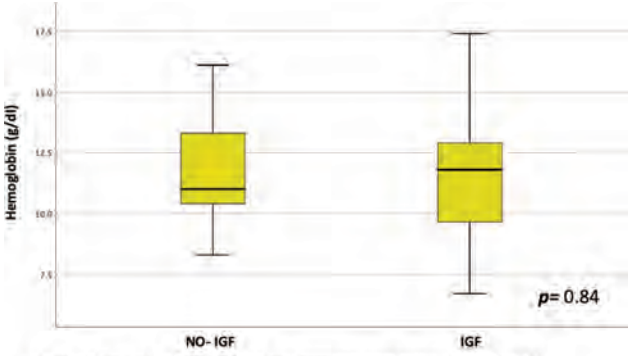

Figure 1. Comparation of hemoglobin pre-transplant in patients with IGF vs No-IGF.

PUB527

Graft Kidney Artery Stenosis in a Deceased Donor Kidney Transplant Recipient with Autosomal Dominant Polycystic Kidney Disease: A Case Report

Byung Min Ye, Seo Rin Kim, Il Young Kim, Soo Bong Lee, Dong Won Lee.
Pusan National University School of Medicine, Yangsan, Republic of Korea.

Introduction: This paper presents a case study of a rare instance of transplant renal artery stenosis caused by mechanical compression from the native polycystic kidney in a recipient with ADPKD who received a kidney from a deceased donor.

Case Description: A 53-year-old man received a kidney transplant from a deceased donor. On the fourth day post-surgery, underwent color Doppler ultrasound (Fig 1-A) and CT angiography (Fig 1-B) to assess vascular issues, revealing renal artery stenosis in the transplanted kidney. The patient underwent reoperation to correct TRAS, we confirmed that the right native polycystic kidney compressed the transplanted kidney, causing it to rotate medially, resulting in the stenosis of the renal artery. (Fig 2-A) Right nephrectomy of the native polycystic kidney, and straightening of the renal artery of the transplanted kidney to relieve compression. (Fig 2-B) After the surgical resection, renal function and urine output were well-maintained, and the blood pressure remained stable.

Discussion: Our focus on TRAS is due to its classification as one of the reversible complications linked to hypertension, as well as its association with the dysfunction of transplanted kidneys. This perspective underscores the importance of early detection and management of TRAS to ensure successful outcomes for the transplant recipients. We hope that by introducing this case, we can gain some insights for dealing with similar patients who develop renal artery stenosis.

Comparison of Anti-human T-lymphocyte Immunoglobulin (r-ATLG) vs. Anti-thymocyte Globulin (r-ATG) as Induction Agents in Kidney Transplantation: A 5-Year Retrospective, Single-Center, Observational Study

Vijay Kumar Sinha, Amit Devra, Ravi K. Singh, Prashant Pandey.
Jaypee Hospital, Noida, India.

Background: T cell depletion agents, Anti-Thymocyte Globulin (r-ATG) and Anti-Human T-Lymphocyte Immunoglobulin (r-ATLG), are routinely employed as induction therapies in kidney transplantation. This study systematically evaluates the short-term and long-term outcomes of kidney transplants at our center, focusing on the comparative efficacy and safety profiles of these agents.

Methods: This retrospective cohort study analyzed data from kidney transplant recipients treated at a tertiary care hospital in India between 2017 and 2024. A total of 603 patients were included, with 381 receiving ATG and 222 receiving ATLG as induction therapy. All patients were maintained on a standard regimen of triple immunosuppressive therapy. Follow-up assessments included evaluations for graft rejection, infections, development of de novo diseases, and overall graft survival

Results: The mean follow-up duration was 60 months. The mean doses administered were 5.4 ± 1.4 mg/kg for ATLG and 2.37 ± 1.2 mg/kg for ATG. Baseline demographic and clinical characteristics were well-matched between the two groups. HLA matching showed <3/6 in 95 patients (42.7%) with ATLG and in 318 patients (83.4%) with ATG, while >3/6 HLA matching was found in 127 patients (57.2%) with ATLG and 63 patients (16.5%) with ATG. Serum creatinine levels at discharge and during follow-up intervals were comparable between groups. The incidence of de novo diseases was higher in the ATG group (12 cases, 3.1%) compared to the ATLG group (3 cases, 1.3%). However, the incidence of infections was similar between the two groups.

Conclusions: Both ATG and ATLG demonstrated similar efficacy in terms of short-term and long-term graft rejection rates in kidney transplant recipients.

	ATG(n=381) (n=38, Rejection 10%)	ATLG (n=222) (n=24, Rejection 10.7%)

Malakoplakia in the Transplanted Kidney

Edward Mwarangu,[1] Ramya Krishna Velagapudi,[1] Prathap Simhadri,[2] Mohammad Atari,[1] Pradeep Vaitla.[1] *[1]The University of Mississippi Medical Center, Jackson, MS; [2]AdventHealth, Ormond Beach, FL.*

Introduction: Malakoplakia is a rare chronic granulomatous disease associated with gram-negative infection especially Escherichia coli. This disease is induced by defective phagolysosomal activity of the macrophages and mainly affects the urinary bladder but has been shown to affect any solid organ, however isolated malakoplakia of the renal allograft is rare.

Case Description: **Case 1** - A 66-year-old male with a deceased donor kidney transplant (DDKT), course complicated with transplant pyelonephritis. He acknowledged adherence to his medication. Six months post-transplant he developed urinary tract infection (UTI) secondary to E.Coli. A routine allograft ultrasound showed a mass which

was biopsied and negative for rejection. A follow up MRI showed masses within the renal transplant and a repeat biopsy showed malakoplakia. He was started on Bactrim and a repeat MRI four months later showed unchanged malakoplakia and his antibiotics switched to cefuroxime **Case 2** - A 39-year-old female patient with a simultaneous pancreas and kidney transplant course complicated by disseminated nocardia. Developed acute pyelonephritis 1.5 years post-transplant. An allograft US showed a mass which was biopsied showing acute rejection and malakoplakia. The patient was treated for rejection and antibiotics for urinary tract infection, malakoplakia and discharged with plans to stop upon resolution. A repeat MRI six months later showed resolution of Malakoplakia. **Case 3** - A 62-year-old male with DDKT, course complicated by transplant pyelonephritis at eight weeks post-transplant. He presented few weeks later with an acute kidney injury (Creatinine 3.01, baseline 1.5-.18), CT imaging showed a nodular mass on the allograft, which was biopsied revealing malakoplakia. Malakoplakia resolved within 6 months after treatment of UTI.

Discussion: Malakoplakia can present as granulomatous renal mass and should be considered as a differential diagnosis while evaluating renal masses in transplant recipients.

Paradoxical Association of Predonation Urine Protein with Kidney Function in Living Kidney Donors without Obesity

Ekamol Tantisattamo,[1,2] Chutawat Kookanok,[1,3] Kamonluk Rodsom,[1,4] Voramol Rochanaroon,[1] Tatchaya Kanthajan,[1] Vitchapong Prasitsumrit,[1] Tulaton Sodsri,[1] Adivitch Sripusanapan,[1] Smuch Siramongkholkarn,[1,5] Phuuwadith Wattanachayakul.[1,6] *[1]University of California Irvine School of Medicine, Orange, CA; [2]VA Long Beach Healthcare System, Long Beach, CA; [3]Phramongkutklao College of Medicine, Bangkok, Thailand; [4]Mahidol University Faculty of Medicine Siriraj Hospital, Bangkok, Thailand; [5]Mahidol University Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand; [6]Jefferson Einstein Philadelphia Hospital, Philadelphia, PA.*

Background: Clinical significance of pre-donation proteinuria in living kidney donors (LKD) is unknown. We aim to examine the association between pre-donation urinary protein:creatinine ratio (UPCR) and the risk of kidney function decline in LKD.

Methods: A retrospective cohort study using OPTN/SRTR included adult LKD undergoing donation between 6/1972 and 9/2022. The association between pre-donation UPCR and time-to-event of ≥35% decline in post-donation eGFR from pre-donation eGFR was examined by multiple Cox regression.

Results: Of 174,311 adult LKD, the mean±SD age was 41±12 years and 60% were female. Mean pre-donation UPCR was 2.12 ±9.23 mg/g of Cr and UPCR at immediate post-donation, 6-, 12-, and 24-months post-donation were 1.23±6.54, 1.44±8.26, 1.72±9.26, and 1.37±7.96 mg/g of Cr, respectively. The median (IQR) pre-donation eGFR was 91 (75, 111) mL/min/1.73 m^2. Median eGFR at immediate post-donation, 6-, 12-, and 24-months post-donation were 50 (40, 62), 54 (44, 67), 55 (45, 68), and 57 (47, 70) mL/min/1.73 m^2, respectively. Out of 38,780 LKD with post-donation eGFR data at 6, 12, or 24 months, 31,054 LKD had the event of ≥35% decline in post-donation eGFR from pre-donation eGFR with a median time to follow-up of 6.77 months (IQR 5.93, 12.67). The incidence rate of the event was 0.08 person-months. After adjusting for age, race/ethnicity, U.S. citizenship, education level, history of pre-donation BMI, hypertension, diabetes, and pre-donation SBP and DBP, every 1 mg/g of Cr increase in pre-donation UPCR was associated with a 0.8% lower risk for the event (HR 0.992, 95%CI 0.985, 0.998). Obesity status was an effect measured modifier with a decreased risk of a decline in eGFR ≥35% observed in LKD with pre-donation normal weight and overweight, but not obesity ($HR_{normal\ weight}$ 0.988, 95%CI 0.977, 0.999; $HR_{overweight}$ 0.989, 95%CI 0.978, 0.999; and $HR_{obesity}$ 1.003, 95%CI 0.991, 1.014).

Conclusions: Pre-donation UPCR is inversely associated with the risk for a significant decline in post-donation eGFR in LKD with normal weight and overweight. Relatively less glomerular hyperfiltration in non-obese LKD may contribute to a reno-protective effect regardless of the degree of pre-donation proteinuria.

PUB531

Don't Get Burned Twice by the Same Post-transplant Lymphoproliferative Disorder (PTLD): A Case Highlighting the Progression and Advancement in PTLD Management in One Transplant Patient

Rania Salam, Farah Daccueil, Heesuck Suh, Henry Yip, Katherine Andrade. *Stony Brook University Hospital, Stony Brook, NY.*

Introduction: PTLD, incidence is reported at 2-20% in solid organ transplant and throughout the decades carried a high risk of allograft lost as well as other hematologic and systemic complication. Management of immunosuppressant of transplanted patient with PTLD and management of PTLD itself has evolved over the years. Our case illustrated how far we have come in management of transplant patients with PLTD and the importance of surveillance.

Case Description: 29 year old female with ESRD secondary to C1q nephropathy diagnosed in 1999 who received DDRT 2002 complicated by acute rejection in 2005 from immunosuppression reduction and eventual hold of immunosuppression for PTLD diagnosis in 2003 (mesenteric LN and appendix). She subsequently received another DDRT in 2006. She had a stable graft function and was followed closely by nephrology and oncology with regular PET scans. Eventually in 2023, had rising EBV titers, fatigue and high fever. She was referred to inpatient by nephrologist for further workup. Exam revealed fever 39.5 C, tachycardia, and normotensive. Labs marked for WBC 3.43, Hb 8.1, Ht 27.0 ESR 56, EBV plasma 44,900. CT scan showed large right-sided mediastinal mass measuring 7.8 cm. Bronchoscopy and mediastinal node biopsy, possible lymphoma. Cytology diagnosed PTLD Hodgkin type. Hematology recommended 6 cycles of A+AVD (Brentuximab vedotin, Doxorubicin, Vinblastine, Dacarbazine). Tacrolimus dose slight reduced with trough in range and MMF also reduced. Tumor burden significantly reduced and patient is reported to be doing well.

Discussion: PTLD often managed by reducing immunosuppression risking graft loss. However with advancement in treatment, patients are allowed to receive targeted treatment, maintain adequate transplant immunosuppression; with higher chances of graft preservation and improved quality of life. Our patient's presentation showcases this progression, where her first transplant complicated by rejection after immunosuppression was reduced/held. Second transplant was preserved by timely diagnosis and targeted treatment of PTLD with chemotherapy.

PUB532

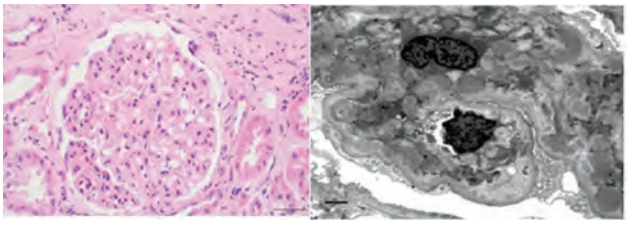
Recurrent Lupus Nephritis in a Kidney Transplant Patient

Ahsan Sajjad,[1] Rida Amer,[1] Amanda Tchakarov,[2] Sreedhar A. Mandayam,[3,1] Muhammad Daoud Butt.[4] *[1]Prolato Clinical Research Center, Houston, TX; [2]The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX; [3]The University of Texas MD Anderson Cancer Center Anne C Brooks Brain and Spine Center, Houston, TX; [4]Universiti Malaya Faculty of Medicine, Kuala Lumpur, Malaysia.*

Introduction: Lupus nephritis (LN) is a severe manifestation of SLE. The recurrence of LN post-renal transplantation is an uncommon event, particularly in patients without a prior diagnosis of SLE.

Case Description: A 60-year-old female with a history of CKD due to IgA nephritis underwent renal transplantation in 1999. In 2023, she presented with worsening proteinuria, lacrimal gland enlargement, Jaccoud's arthropathy, and b/l lower extremities pitting edema. Renal allograft biopsy revealed diffuse lupus nephritis ISN/RPS Class IV, 19% global sclerosis of glomeruli, and 20% interstitial fibrosis with tubular atrophy. CKD onset followed a miscarriage in 1997, progressing to end-stage renal failure during a subsequent pregnancy in 1998, necessitating transplantation. Absence of prior SLE diagnosis and prolonged immunosuppression (Cellcept and Cyclosporine) suggest undiagnosed chronic SLE, possibly reactivated or newly manifested as LN in the allograft. Biopsy shows immune complex-mediated glomerulonephritis with endocapillary hypercellularity, neutrophils and a few wire-loops/hyaline thrombi. By immunofluorescence, there is positivity for IgA, IgG, IgM C3, C1q, kappa and lambd. Corresponding mesangial and subendothelial electron-dense deposit are present ultrastructurally. **Diagnosis:** Immune complex-mediated glomerulonephritis, Findings consistent with borderline changes of T-Cell mediated rejection per Banff criteria. Severe Interstitial inflammation(i3) and Mild tubulitis(t1). Peritubular capillaries were focally positive for C4d by immunohistochemistry. Moderate arterial and hyaline arteriolar sclerosis. Global sclerosis of 19%(3/16) of glomeruli and approximately 20% interstitial fibrosis with tubular atrophy

Discussion: Lupus nephritis is found in approximately 30-50% of SLE patients, with recurrence post-transplantation being rare, occurring in about 1-2% of cases. This case underscores the diagnostic challenge and the necessity of considering SLE in patients with renal allografts presenting with proteinuria. The long-term immunosuppressive therapy may have masked the underlying SLE, delaying the diagnosis until the renal allograft biopsy revealed lupus nephritis.



PUB533

10-Year Kidney Allograft Survival in Patients from a Safety Net Transplant Program Introduction

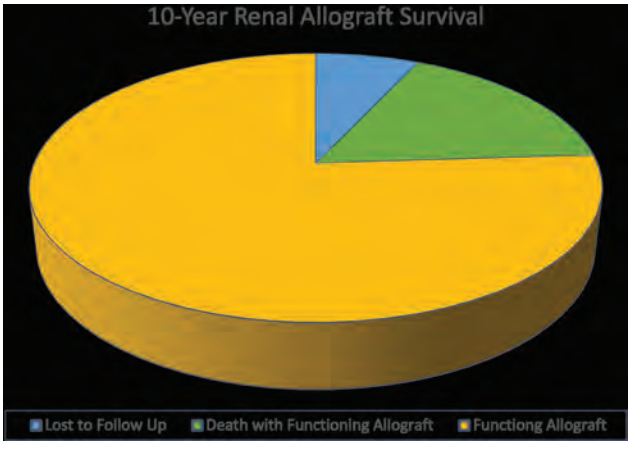
Anuja P. Shah,[1,2] Ibrahim Elali,[1,2] Ramanath B. Dukkipati,[1,2] Kamyar Kalantar-Zadeh,[1,2] Lilly M. Barba.[1,2] *[1]Harbor-UCLA Medical Center, Torrance, CA; [2]The Lundquist Institute, Torrance, CA.*

Background: Data regarding 1-year and 5-year renal allograft survival is readily available from transplant databases. The 10-year allograft function rates data particularly in a safety net hospital in an underserved metropolitan area is scarce. Lower socioeconomic status (SES) is a barrier to transplantation. Patients on Medicaid have lower rates of transplantation than those with commercial insurance. Long term allograft survival rates of lower SES renal transplant recipients are not known.

Methods: In order to shed light on the long-term allograft survival, we reviewed the outcomes of transplants performed in 2014, the most recent 10 year allograft survival available, from a single center safety net hospital transplant program.

Results: 29 renal transplants were performed in the year 2014. 14 % of recipients were African American, 21% were Asian, 3% Caucasian, and 62% were Hispanic. All patients were participants in the Medicaid program. 2 patients were lost to follow up. Of the 27 other patients, 22 (81%) continue to have functioning allografts; 5 patients died with functioning allografts. No patients lost allograft function and returned to chronic renal replacement therapy

Conclusions: Patients from an underserved population can achieve long term excellent renal allograft function. Socioeconomic barriers to transplantation do not necessarily carry forward as barriers to long term allograft survival. The care structure of these patients being followed long term in renal transplant clinic may have had a positive impact on the long-term allograft function observed in this population. Safety net transplant programs are important to maintain access to positive renal outcomes in low SES patients with ESRD.



PUB534

Anuria in Transplant Renal Artery Stenosis (TRAS) with Pseudoaneurysm: A Rare Presentation of an Uncommon Co-occurrence

Joy Kumar,[1,2] Tanisha Mishra,[1,2] Shankar Prasad Nagaraju,[1,2] Attur R. Prabhu,[1,2] Dharshan Rangaswamy.[1,2] *[1]Kasturba Medical College Manipal, Manipal, India; [2]Manipal Academy of Higher Education, Manipal, India.*

Introduction: TRAS and pseudoaneurysm are notorious post-transplant vascular complications with reported incidence of 1-23% and 1% respectively. Decline in graft function, worsening or resistant hypertension with volume overload and flash pulmonary edema in severe cases due to RAAS activation is commonly seen. However, anuria is a rare but alarming manifestation.

Case Description: A 54-year-old male was evaluated for acute onset dyspnea and anuria. Hypoxia with bilateral coarse crepitations due to pulmonary edema was evident on CXR. BP was elevated to 210/110 mmHg. Acute increase in Cr to 4.26 mg/dl as compared to his post-transplant baseline Cr range of 0.7-0.9 mg/dl signaled graft dysfunction. Post cadaveric renal transplantation, he had achieved good graft function and urine output with nadir Cr of 0.67 mg/dl and received induction anti-thymocyte globulin along with triple immunosuppression maintenance. No improvement in urine output was seen after initial stabilization in the ED with O2, intravenous diuretics and nitroglycerin infusion support. Hemodialysis was started while transplant renal artery doppler was suggestive of TRAS with low velocity (30cm/sec) parvus tardus waveform at the hilum. A graft renal artery angiography diagnosed TRAS with pseudoaneurysm. Therapeutic angioplasty with stenting led to improvement in renal function, urine output and blood pressure recordings. Dialysis was stopped. The patient was discharged with serum Cr of 0.97 mg/dl.

Discussion: Acute onset anuria is an uncommon yet emergent sign in post transplant patients requiring urgent investigation and management to prevent graft loss and mortality. While post-renal obstruction is the usual etiology, evaluation for renal and prerenal vascular compromise causing anuria is important. A high index of suspicion is crucial to evaluate for TRAS in the background of graft dysfunction and worsening hypertension post transplantation while ruling out graft rejection, post transplant infections, calcineurin nephrotoxicity and post renal obstruction. Stenting has shown improved outcomes in management of TRAS and pseudoaneurysm.

PUB535

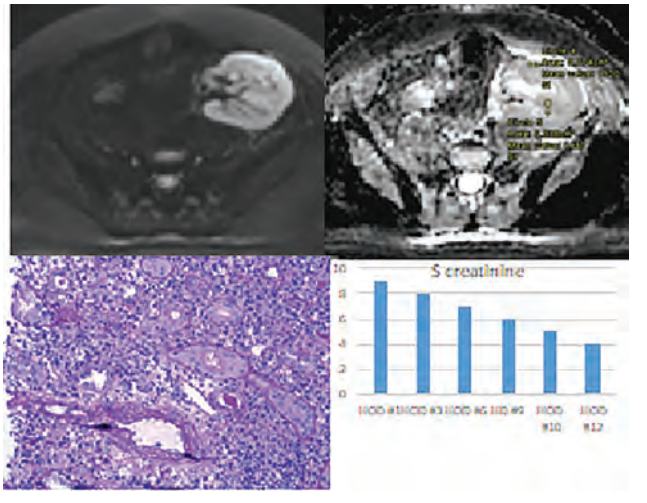
Evaluation of Allograft Rejection with MRI, Attenuation Diffusion Coefficient (ADC) Mapping: A Case Report

Sami M. Akram,[1] Michael A. Staton,[1] Lilly M. Barba,[2] Rafael Villicana.[1] Transplant Nephrology and Radiology. *[1]Loma Linda University, Loma Linda, CA; [2]Harbor-UCLA Medical Center, Torrance, CA.*

Introduction: The movement of water is the essence of life, and is central to kidney function. The kidney moves water by filtration, reabsorption, excretion, and secretion via aquaporin channels. Therefore, Diffusion-Weighted MRI Imaging with attenuation diffusion coefficient (ADC) maps can assess renal pathology but seldom utilized. Therefore, we report a case of allograft rejection evaluated by ADC map.

Case Description: A 26-year-old male with end stage kidney disease (ESKD) due to congenital kidney disease, had 0-mismatch diseased donor kidney transplant (DDKT), two years ago with thymoglobulin induction. He presented with oliguria of one week duration. He was non-complaint with therapy. Vital signs were within normal limits. Physical exam was remarkable for pitting leg edema. Laboratory exam showed serum creatinine of 9mg/dL; WBC 6.7 k/mcL; Hemoglobin, 8.3mg/dL; potassium 5.3mMol/L. Donor specific antibodies (DSA) were present. Allograft ultrasound showed mildly increased cortical echogenicity with mild pelviectasis. Renal indices were normal. MRI with ADC mapping showed uniformly low values in upper, mid and low consistent with restricted diffusion. Histology revealed acute Antibody mediated Rejection (AMR). Had good clinical respoonse to therapy.

Discussion: Diffusion-weighted imaging measures the Brownian motion of water molecules within a voxel by acquiring phase information of moving water molecules between the first and the second gradient MRI pulse sequence. Computer software generates ADC map. ADC is affected by the number of cells, the integrity of the cell membranes, and the amount of fibrosis, all of which restrict diffusion of water molecules. Ghar and Djasty et al described heterogeneity of ADC map in kidneys with acute tubular necrosis (ATN) when compared to kidneys with acute rejection (AR). T-cell and antibody mediated rejctions are high cellularity states, therefore ADC maps can be a useful tool in the initial evaluation and longitudinal follow-up transplant recipients. Further study of this modality is needed.



PUB536

Financial Toxicity in Kidney Failure

Lindsey Maclay,[1] Anne M. Huml,[2] Kyle J. Woodward,[1] Miko Yu,[1] Sumit Mohan,[1] Syed A. Husain.[1] *[1]Columbia University Irving Medical Center, New York, NY; [2]Cleveland Clinic, Cleveland, OH.*

Background: Financial toxicity (FT), defined as the combined objective (oFT) and subjective (sFT) economic burden of medical care, has not been explored in end-stage kidney disease (ESKD). We sought to describe the prevalence of FT experienced by patients with ESKD.

Methods: Cross-sectional survey of patients with ESKD undergoing inpatient dialysis, kidney transplant evaluation, or transplant follow-up at our center. The survey, derived from prior studies, measured sFT via the validated Comprehensive Score for Financial Toxicity (CoST) tool, and oFT via patient-reported changes in employment, spending, or maladaptive financial coping mechanisms. Based on prior literature, sFT was defined as CoST <26 (44-26 none, 14-25 moderate, 0-13 severe).

Results: Among 24 respondents, 19 (79%) were on dialysis and 5 (19%) had a functioning kidney transplant after prior dialysis. Median time since incident kidney failure was 2.5 years (IQR 1.6-6.4). Median age was 55 years (IQR 40-69), 38% were female, 39% self-reported Hispanic/Latino ethnicity, 46% had Black/African American race, and 21% had White race. 14 (58%) had Medicaid primary or dual coverage, while 6 (25%) had private insurance. Median CoST was 14 (IQR 12-22), with 20 respondents (83%) reporting any sFT (COST<26) and 8 (33%) reporting severe sFT (Fig. 1A). 14 reported (58%) household income decrease after dialysis start, with 8 (33%) experiencing >50% reduction. Measures of oFT were common, including 16 (67%) respondents with job loss/reduction and 11 (46%) with maladaptive financial coping mechanisms including withdrawal of emergency savings or utilization of credit card debt (Fig. 1B).

Conclusions: Most patients with ESKD experience FT. Further research is needed to understand risk factors for and consequences of financial toxicity in this population.

Funding: NIDDK Support

BK Nephropathy Treatments in Kidney Transplant Recipients

Vanessa M. Ogungbesan,[1] Nisha Gurung,[1] Dewanshi Maniar,[1] Rosa M. Montero.[2,1] *[1]St George's University of London, London, United Kingdom; [2]St George's University Hospitals NHS Foundation Trust, London, United Kingdom.*

Background: BK virus is a polyoma virus(BKPyV) and an important cause of allograft loss in kidney transplant recipients(KTR). Currently there are no effective treatments for BKPyV with centres using combination therapies strategies. It is unclear whether the increase in BK viraemia is due to immunosuppression(IS), assays or screening. We looked to determine the treatments used for management of BK in our centre.

Methods: An observational retrospective single centre experience looking at BKPyV. All KTR 2001-2023 with detectable BK(plasma/urine) were identified from the electronic renal database(cv5). Maintenance IS regimens were recorded: Tacrolimus(Tac), Mycophenolate Mofetil(MMF), Prednisolone(P), Sirolimus(Sir) and Azathioprine(Aza). BKpyV erradication treatments included; reduction of MMF(1), cessation of MMF(2) reduction in Tac(3), introduction of Ciprofloxacin(Cip)(4), Leflunomide(5), P(6) and cessation of Aza(7).

Results: 7%(37/525) KTR were found to have BKPyV(34 viraemia, 3 viuria) between 2001-2023. 10 female, 27 male. Median age 59yrs(26-84yrs). 9 White, 10 Asian, 7 Black, 4 Chinese, 4 Other, 3 Unknown. Primary kidney disease: IgA 8, CKD 7, FSGS 4, Renovascular 2, T2DM 2, Congenital kidney disease 1, Glomerulonephritis 3, Malignant hypertension 1, APKD 3, SLE 2, Unknown 4. BK occurred following treatment for rejectionx2, 1xdrain removal and 1xureteric stent removal. 3 KTR had biopsy proven BK nephropathy. Peak BKPyV viraemia 2.9 million copies/ml, peak viruria 1.28E+10 copies/ml. BKPyV viraemia median 3mths post-transplant(1mth-8yrs), viuria median 4 months(1mth-12yrs). Treatments included; 2 KTR (1,3), 1 KTR (1,3,4), 7 KTR (1,3,6), 3 KTR (1,3,4,6), 1 KTR (1,3,5,6), 1 KTR (2,3,4), 2 KTR (2,3,6), 8 KTR with (2,3,4,6), 7 KTR (2,3,4,5,6), 1 KTR (2,3,5,6), 1 KTR (2,3,6,7),1 KTR (3), 1 KTR (3,4,6), 1 KTR (3,6) and 1 KTR no changes. Commonest treatment was cessation of MMF, reduction in Tac, Cip ranging from 2-12wks and P with maintenance therapy of Tac+P. 5 KTR had 1 recurrence of BKPyV viraemia, 4 KTR had 2 episodes of recurrence with prolonged treatment with Cip. Remission of BKPyV was between 1mth-12yrs (median 2yrs).

Conclusions: Over 22 yrs our centre has used a variety of treatments for BKPyV. Remission was seen in 28 KTR. The commonest intervention was to stop MMF however, despite these interventions 4 KTR lost their allografts highlighting the ineffective treatments for BK.

PUB538

A Formidable Foe: BK Virus, an Association with Early Cancer Development: A Case Report

Zeeshan Azeem, Prince M. Anand, Adrian Carlson. *Medical University of South Carolina, Lancaster, SC.*

Introduction: Urothelial cancer of the bladder is the most common malignant neoplasm of the urinary system. Kidney transplant recipients have a significantly higher risk of urothelial malignancy compared to the general population; it typically presents about 8.5 years after transplantation. BK-polyoma virus (BKPyV) is a well-established cause of urothelial malignancy in kidney transplant recipients. We present a rare case of urothelial carcinoma of the urinary bladder diagnosed three months after kidney transplantation.

Case Description: A 71-year-old woman underwent a deceased donor kidney transplant (DDKT) due to end-stage renal disease secondary to diabetes mellitus. The intraoperative cystoscopy for ureteral anastomosis showed no evidence of growth in the urinary bladder. However, one month later, at the time of the ureteral stent removal, a papillomatous growth was noted near the site of ureteral anastomosis. Subsequently, a repeat cystoscopy and excisional biopsy revealed urothelial cancer. Concurrently, elevated levels of plasma BKPyV were noted, which continued to rise despite the reduction in immunosuppression. The tumor tissue was positive for SV40 stain, suggesting a possible causal correlation with BKPyV identified in the cancer tissue.

Discussion: Despite the widely known presentation of BKPyV viremia in kidney transplant patients, the presentation of malignancy is typically delayed. This case highlights the need for a high index of suspicion for any bladder lesion in post-transplant patients with elevated levels of BKPyV. Early diagnosis with biopsy and SV 40 immunostaining is crucial for improved patient outcomes.

PUB539

Post-transplant Hospitalization Rates in a Safety Net Hospital

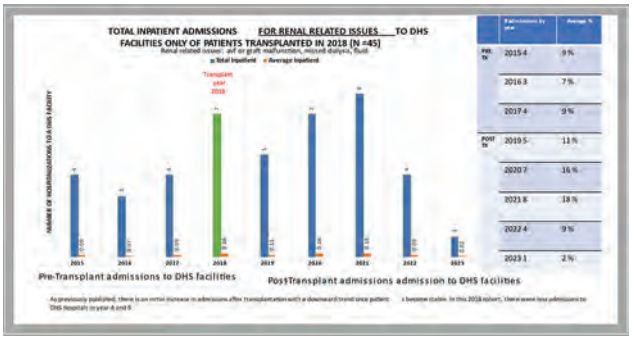
Anuja P. Shah, Ibrahim Elali, Kamyar Kalantar-Zadeh, Lilly M. Barba. *Harbor-UCLA Medical Center, Torrance, CA.*

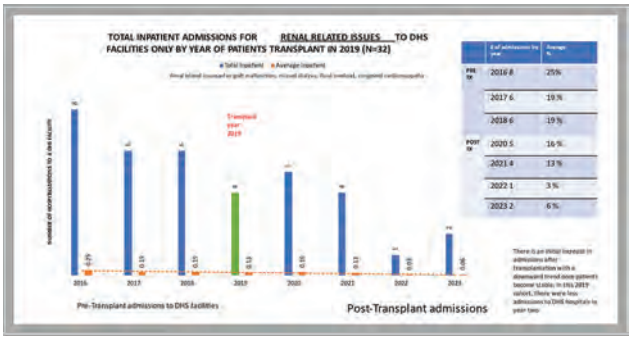
Background: USRDS reports hospitalization rates in ESRD patients in the Medicare population. Post transplantation, admission rates increase and then decrease to below pretransplant levels. It is not known if these trends are consistent in the Medicaid population. Less is known about hospitalization related to dialysis and renal disease.

Methods: Analysis: We retrospectively reviewed the medical records of patients that received a kidney transplant during 2018 and 2019. For 2018 transplants, data collected 3 yrs pre and 5 years post-transplant on 45 patients. For patients transplanted in 2019, data collected 3 yrs pre and 4 years post-transplant on 32 patients. Data was collected on ER visits and hospital admissions for related to their kidney disease only. Non-kidney related admissions were censored as this time overlapped with the COVID pandemic. Censoring COVID related admissions would make this data more comparable to historical data. Only admissions to the County of Los Angeles Hospitals were captured

Results: Both Groups showed an increase in hospitalization rates post-transplant years 1 and 2. For patients transplanted in 2018, hospitalizations decreased by year 4 post-transplantation. For patients transplanted in 2019, hospitalizations decreased by year 3 post-transplant.

Conclusions: Rates of hospitalization post-transplant in patients with lower socioeconomic status mirror hospitalization trends in the Medicare population. This cohort uniquely confirms the trend toward lower hospitalization after the initial years post-transplant in the same group of patients. Only hospitalizations at the safety-net system were captured; these patients were followed closely by the transplant center, and outside hospitalizations were not reported.





PUB540

Anti-human Leukocyte Antigen (HLA) Antibodies in Patients with ESKD on Kidney Transplantation Protocol

Victor M. Xulú Díaz, Elio Perez, Karla Escobar Castro, Ada Noemi Chavez.
Hospital General San Juan de Dios, Guatemala, Guatemala.

Background: Renal transplant is the chosen treatment for the ESRD (End-Stage Renal Disease), so identifying factors possibly associated with complications such as rejection helps to improve renal graft survival.

Methods: Retrospective cross-sectional observational study, 150 files were selected; sex, age, medical records, type of renal transplant protocol, record of infectious processes, as well as records of exposure to sensitization factors were reviewed.

Results: The average age of the parties was 30 years old, the youngest was 13 years old and the oldest was 75 years old; 46.7% were female and 53.3% were male. 71.3% of patients had transfusion exposure, 30% of patients had previous pregnancy exposure and 8% of the parties had a previous transplant record; 5.3% had diabetes mellitus, and 31.3% of the patients had infections. The 64% of patients were on cadaveric transplant protocols, 36% were on living-donor transplant protocols.

Conclusions: The prevalence of anti-HLA antibodies in patients with chronic renal disease undergoing renal transplant protocol at the Hospital General San Juand de Dios was found to be 33.3%. Previous transplant record was associates with anti-HLA antibodies generation in renal transplant protocol patients.

Accuracy of Donor-Derived Cell-Free DNA (Dd-cfDNA) Compared with Kidney Allograft Biopsy in the Diagnosis of Allograft Rejection among Adult Filipino Patients in a Tertiary Medical Center

Mae Madeleine N. Ang, Brian Michael I. Cabral, Angel Joaquin M. Amante.
St. Luke's Medical Center - Global City, Taguig, Philippines.

Background: In the Philippines, transplant surveillance primarily involves monitoring common laboratory parameters (creatinine, proteinuria). Allograft biopsy, the gold standard for diagnosing allograft rejection, is not part of surveillance protocols. Donor-derived cell-free DNA (dd-cfDNA) quantifies fragmented DNA that rises in allograft injury. It is non-invasive, has short turnaround time and has been shown to rise prior to laboratory indicators. No study has been done yet among Filipinos involving dd-cfDNA in the diagnosis of allograft rejection since the test became available locally in April 2023.

Methods: This is a cross-sectional descriptive study in a tertiary medical center in the Philippines. All data were obtained from electronic medical records. Rejection discrimination was analyzed through area under the curve (AUC), sensitivity (SN), specificity (SP), predictive values, and likelihood ratios. Histologic changes associated with dd-cfDNA levels of >1% were analyzed similarly. Box and Whisker Plots were used to determine differences in dd-cfDNA mean levels in those with and without rejection and between classes of rejection (ABMR and TCMR).

Results: Dd-cfDNA significantly discriminates allograft rejection vs no rejection (AUC 0.86, SN 72.73%, SP 100%) and ABMR from non-rejection (AUC 0.94, SN 88.89% SP 100%). It did not discriminate TCMR from non-rejection (AUC 0.55, SN 50, SP 40%). dd-cfDNA level of >1% occurred significantly in: Acute, active ABMR rejection; moderate microvascular inflammation; donor specific antibodies; any microvascular inflammation; chronic active ABMR; and severe peritubular capillary multilayering. Mean dd-cfDNA scores for ABMR is significantly higher (p=0.0394***)*** than those without ABMR. There was no difference in mean levels between rejection and non-rejection (p=0.1790) and TCMR versus non-rejection.

Conclusions: Accuracy of dd-cfDNA in diagnosing allograft rejection cannot definitively be concluded based on this study alone. However, findings trend similarly to the DART Cohort and ADMIRAL Study. Dd-cfDNA accuracy values in identifying allograft rejection trend comparably. Mean dd-cfDNA levels in ABMR is significantly higher than in TCMR and in no rejection. Histologic findings associated with dd-cfDNA level of >1% are similar.

PUB542

Kidney Transplant Candidacy in a Patient with Recurrent Infection: Balancing Improved Quality of Life vs. Potential Infection Risk

Marrey Ruby L. Quizon, Ekamol Tantisattamo. *UCI Health, Orange, CA.*

Introduction: In the field of kidney replacement therapy, the definitive management is kidney transplant (KT). While recurrent infection is generally a contraindication for KT, a balance between improved quality of life from KT and increased risk of post-transplant infection can be justified. We report a case of man with recurrent soft tissue infections above the arteriovenous fistula (AVF) site who underwent KT and subsequent AVF removal for infection source control.

Case Description: A 57-year-old man with ESKD who underwent a deceased donor kidney transplant (DDKT) 2 months prior was admitted for management of purulent cellulitis on his left arm AVF. For the past few years, he had chronic issues with this fistula including thrombosis requiring stent placement. He also had episodes of nonpurulent cellulitis over an area of the AVF, managed by vancomycin courses during his dialysis sessions. These episodes had occurred every 3-4 months for the past year. He was originally planned for AVF revision to eliminate infection source, but he received a kidney offer and underwent DDKT. The AVF revision was postponed with a plan to be addressed six months post-transplant. However, around two months post-transplant, he again developed cellulitis over the AVF, but now with purulence. Given the severity of infection in the setting of immunosuppressed state, AVF ligation and removal of the underlying infected stent was performed. He had no systemic symptoms and blood cultures were negative. He recovered well and was discharged with intravenous antibiotics.

Discussion: Our patient had recurrent soft tissue infections over his AVF, suggesting bacterial seeding of the stent or refractory skin infection and failed antimicrobial treatment. While KT improved his survival and quality of life, post-transplant immunosuppressed state contributed to a more severe purulent form of his usual cellulitis overlying a high-flow vascular access, which, while fortunately did not occur for him, may increase the risk of bacteremia and associated systemic sequelae. Patients with a history of prior infection should receive close monitoring and definitive treatment to get rid of the source of recurrent infections ideally prior to KT. However, KT while the infection is controlled and then followed by infection source elimination can be considered in selected patients.

PUB543

Emphysematous Pyelonephritis as a Presentation of Delayed Venous Allograft Thrombosis

Marrey Ruby L. Quizon, Nyein Nyein Htun, Ekamol Tantisattamo.
University of California Irvine, Irvine, CA.

Introduction: While transplant allograft thrombosis commonly manifests during the immediate post-transplant period, a delayed onset may occur and lead to allograft loss. We present a case of a kidney transplant (KT) recipient who presented with anuric acute kidney injury and emphysematous pyelonephritis.

Case Description: A 45-year-old woman with ESKD who underwent a deceased donor kidney transplant 1 month prior presented with nausea and vomiting for two days. She had been doing well post-KT with a serum creatinine of 1.3 mg/dL 1 week prior. She had anuric AKI over 24 hours prior to admission with a creatinine of 5 mg/dL. An abdomen and pelvic CT scan showed severe emphysematous pyelonephritis of the transplant kidney and a 7 cm air-fluid collection in the abdomen, contiguous with the transplant kidney. Within hours after admission, she progressed to septic shock. Allograft function remained unimproved despite initial management of antibiotics and fluids. Therefore, transplant allograft nephrectomy was performed to eliminate the infection source. Pathology showed liquefactive necrosis and emphysematous changes of the transplant kidney, and thrombosis of the transplant renal vein. Hypercoagulable work-up is pending and she reinitiated hemodialysis and is referred for pretransplant evaluation for the second KT.

Discussion: Vascular complication is a major concern during the acute post-transplant period. But a late onset of the venous allograft thrombosis may occur and lead to allograft loss complicated by severe life-threatening infections like emphysematous pyelonephritis. Early diagnosis by imaging and transplant allograft nephrectomy are warranted to reverse immunosuppressed status and avoid mortality.

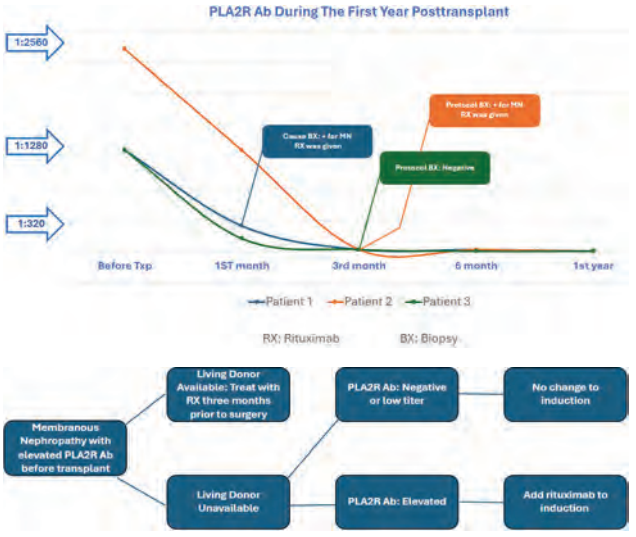
Management of Primary Membranous Nephropathy (PMN) after Transplant

Fadee Abu Al Rub,[1] Sana J. Shaikh,[2] Krista L. Lentine.[1] [1]*Saint Louis University, St Louis, MO;* [2]*University of California Davis, Davis, CA.*

Introduction: PLA2R Ab were identified as the underlying cause in about 70% of PMN cases. After transplant (TXP), PMN recurrence rate is about 31%. A more aggressive disease and a higher level of PLA2R Ab in native kidneys can predict recurrence.

Case Description: We reviewed records of 6 kidney TXP patients with biopsy (Bx) proven MN, 3 of them had negative PLA2R Ab at the time of surgery, and had no complications. We followed the other three for one-year and here we report their course: All patients received Thymo for induction, and their maintenance regimen consisted of: Tacrolimus, MMF +/- and prednisone. One patient had a 3-month protocol biopsy which showed PLA2R-positive MN despite intact renal function and negative serum PLA2R titers. He received Rituximab (RX) 1 gm x 2 doses 14 days apart. Another patient had a cause biopsy for elevated cell free DNA at the end of the first month, and it showed MN recurrence. He had high PLA2R titers and mild proteinuria. He was treated with RX as above. The third patient had a protocol biopsy which was negative, and no alteration in immunosuppression needed to be made.

Discussion: Since It was observed that patients with positive anti-PLA2R Ab testing before TXP, who continued to have high titers despite induction and maintenance immunosuppression, were likely to develop an early recurrence of MN. It is reasonable to consider pre-emptive Rituximab: First, at the time of TXP in those with high titers of anti-PLA2R Ab, and in the first month post-transplant if the titers of anti-PLA2R ab remain elevated. We also suggest treating a living donor recipient candidate before surgery, if his PLA2R level is elevated, to avoid recurrence. It is noted here too that cell-free DNA technology was helpful in detecting MN recurrence, as it triggered the biopsy decision. More studies are needed to evaluate its sensitivity in screening for glomerulonephritis recurrence in an allograft.



PUB545

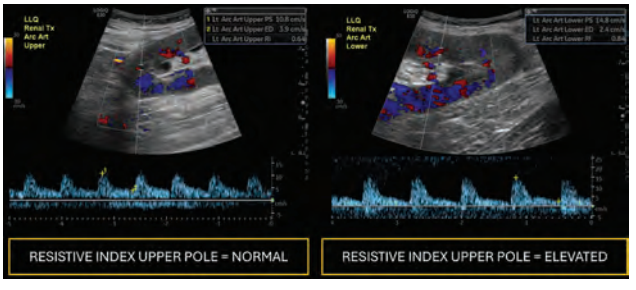
Value of Mercaptoacetyltriglycine (MAG3) Scintigraphy in Functional Assessment of Kidney Transplant: A Case Study

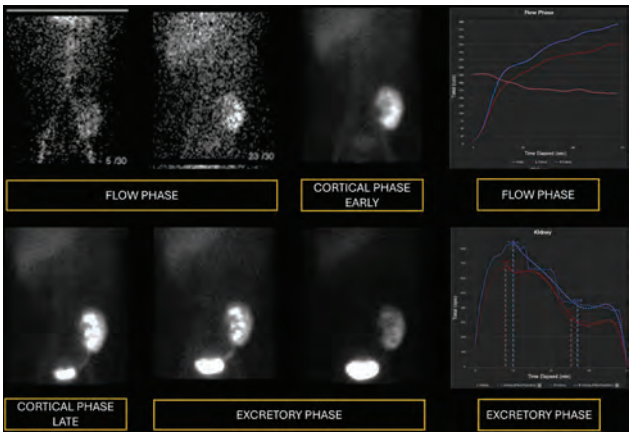
Gaelle Haddad, Akash Sharma. *Mayo Clinic in Florida, Jacksonville, FL.*

Introduction: Post-renal transplant malfunctions, such as acute tubular necrosis (ATN), graft rejection, infection, and ischemic damage can be challenging to differentiate due to overlapping symptoms. Accurate diagnosis and management typically require multiple imaging modalities and biopsies. MAG-3 renal scintigraphy may offer complementary renal parenchymal function assessment. We present a case of a 33-year-old woman with a transplanted kidney with complications. MAG-3 scintigraphy provided meaningful functional corroboration of inferred ultrasound findings, with limited CT assessment.

Case Description: A 33-year-old woman with a donor kidney transplant experienced recurrent urinary tract infections after transplant. During routine follow-ups, a renal biopsy showed borderline cellular rejection, treated with steroids. Progressive creatinine level increase warranted a full work up; imaging revealed mild hydronephrosis, and cystoscopy was suggestive of vesicoureteral reflux. A renal biopsy showed mesangial expansion without recurrent rejection. Functional assessment with MAG-3 scintigraphy revealed regional abnormality in the lower half of the kidney, suggesting regional dysfunction. A contemporaneous ultrasound demonstrated elevated regional resistive index in the lower pole, corroborating the regional dysfunction.

Discussion: This case shows value of MAG-3 scintigraphy in functional assessment of kidney transplants. A regional abnormality such as in this case is atypical, and can point to uncommon underlying pathology, such as infection or traumatic/iatrogenic vascular insult and not ATN. Scintigraphy can yield a more expansive differential diagnosis and is complementary to other modalities such as US.





PUB546

The Silent Invader, Cytomegalovirus Nephritis: A Rare Presentation in Early Post-transplant Period

Abinaya Srikanthan, Arjun L. Kalaria, Rajil B. Mehta. *UPMC, Pittsburgh, PA.*

Introduction: Cytomegalovirus (CMV) is a formidable pathogen and an important cause of morbidity and mortality among transplant recipients. Among its deleterious manifestations, CMV nephritis emerges as a significant complication, with profound implications on allograft function and outcomes. This is particularly true in those who are CMV seronegative and receive an allograft kidney from a CMV seropositive donor are particularly high risk (HR). We present a case of a 33-year-old kidney transplant recipient with an unusual early presentation of CMV nephritis.

Case Description: A 33-year-old M with end stage kidney disease (ESKD) secondary to presumed hypertension, status post deceased donor kidney transplant (37 yo donor, CMV HR, EBV R+) in 09/2023, presented with an allograft acute kidney injury (AKI) 3 months post-transplant. His immediate post-transplant course was uncomplicated. He was maintained on valgancyclovir prophylaxis dosed per eGFR for CMV HR. In January 2024 he presented with an allograft AKI, labs were relevant for a serum creatinine (Cr) of 7.1 (baseline Cr 2 mg/dl) and a CMV PCR level of 414 IU/mL. A kidney biopsy performed revealed glomerulitis and interstitial nephritis with positive CMV immunostaining, and borderline acute T cell mediated rejection. As per infectious disease recommendations, he was treated with Maribavir 400mg BID x 8 weeks for refractory CMV nephritis and immunosuppression was lowered. Response to treatment was monitored by weekly CMV PCR levels. CMV viremia resolved on treatment, but he represented with nephrotic range proteinuria (persistent protein excretion >3.5 gm/day). A repeat biopsy performed in April 2024 revealed acute antibody mediated rejection (ABMR) with no evidence of CMV nephritis. He was found to have new donor specific antibodies and is currently undergoing treatment with plasmapheresis and remains on Maribavir with no indication for dialysis.

Discussion: CMV nephritis is a serious complication in renal transplant recipients. This is a rare presentation of CMV nephritis as he presented with low copies of CMV. Nephrotic range proteinuria in the setting of CMV nephritis is also a rare presentation. His ABMR was likely an unintended consequence of decreasing immunosuppression during treatment of CMV nephritis. Appropriate prophylaxis and early detection of CMV infection is particularly important in CMV HR transplant patients.

Comparison of Estimated Glomerular Filtration Rate in Mexican Kidney Transplant Recipients

Samantha I. Verdugo,[1] Milagros M. Flores Fonseca,[1] Alejandro Garcia-Rivera,[1] Omar H. Sanchez-Vazquez,[1] Luis A. Camacho-Murillo,[1] Sandra F. Velasco.[2] *[1]Instituto Mexicano del Seguro Social Delegacion Jalisco, Guadalajara, Mexico; [2]Universidad de Guadalajara Centro Universitario de Ciencias Exactas e Ingenieria, Guadalajara, Mexico.*

Background: Assessment of glomerular filtration rate (GFR) is important in the follow-up of patients after receiving a kidney transplant (KT). Several studies have evaluated the performance of based creatinine eGFR-equations in KT. The purpose of our study was to compare the two current main eGFR-equations, MDRD and the CKD-EPI 2021, in Mexican KT recipients (KTR).

Methods: For each kidney transplant recipient, we collected data on age, gender, serum creatinine, eGFR (mL/min/1.73m2), maintenance immunosuppression who were under follow up between June 2023 and May 2024 from the HGRl 110 Oblatos, IMSS. For all patients, race was chosen “not African-American” and eGFR was calculated using the MDRD and CKD–EPI formulas.

Results: Overall, 98 participants were included in the study, in whom 294 eGFR values were measured and estimated. Mean age 37.33 SD ± 10.59, 68% male and a mean time from transplantation to GFR evaluation was 10.43 years ± 6.43 years. The mean MDRD eGFR was 61.78 ± 22.57 mL/min/1.73 m^2 and mean CKD EPI eGFR was 71.47 ± 24.52 mL/min/1.73 m^2. When analyzed according to gender or age groups none significant were observed in terms of age, creatinine or eGFR. When correlation analysis was performed, there was a negative low correlation between the MDRD and gender (R=-0.21, p = 0.038) and a strong positive correlation between eGFR equations (R= 0.975, p<0.01). The combined CKD-EPI and MDRD equation are in a Bland Altman plot (Figure 1A), with the bias and its 95% CI.

Conclusions: Although there is a strong association between these creatinine-based equations in estimating GFR in Mexican kidney transplant patients. We need to confirm in our population, if the rise of creatinine provides outcome prediction in KT or if our attention should move forward to other markers in the reinforcement of eGFR power.

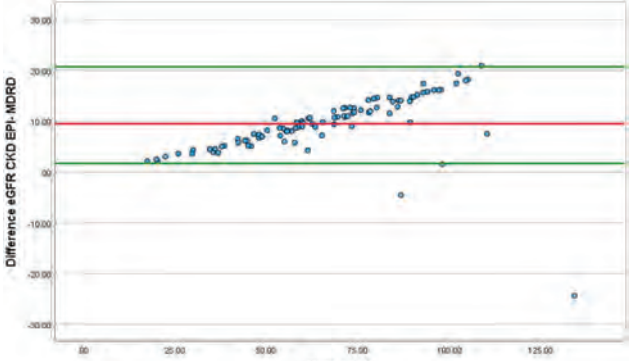

Figure 1. Bland- Altman plot with absolute bias (CI) between eGFR for CKD-EPI and MDRD equations

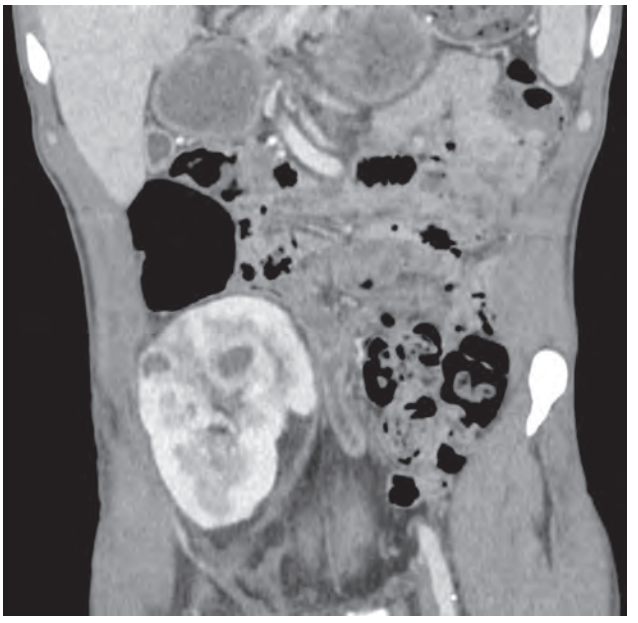
Multiple Embolic Strokes in Kidney Transplant Recipient Due to Kidney Allograft Abscesses after Urinary Tract Infection (UTI)

Dinah Goodman, Ao Wang, Mary C. Mallappallil, Muhammad Azhar, Isha Puri. *New York City Health and Hospitals Corporation, New York, NY.*

Introduction: Intrarenal and perinephric abscess formations are infrequent infectious complications in kidney allograft recipients. There have been reported cases of abscesses within the allograft but no reported cases of ischemic embolic strokes from such abscesses

Case Description: 63 year old male post deceased donor kidney transplant presented with altered mental status, fever and leukocytosis. He tested positive for COVID-19 at an outside hospital 2 days prior. Because of febrile illness blood cultures and urine cultures were drawn which both resulted positive for Enterococcus faecalis. He was initially emperically treated for bacterial/viral meningitis but therapy was de-escalated after results from a lumbar puncture were negative and urine and blood cultures were positive for E. Faecalis. After 5 days of appropriate antibiotic therapy he was afebrile with improving leukocytosis however continued to have altered mentation, hence, a brain MRI was done which showed multiple bilateral ischemic strokes in anterior left pons, medial right occipital lobe and medial temporal lobes bilaterally likely embolic in nature. A transesophageal echocardiogram did not show any vegetations. A kidney allograft ultrasound was done which showed a 3.0x1.3x3.1 cm complex fluid collection within the right lower quadrant of kidney midpole, the findings were suspicious for abscess. He then underwent a CT Abdomen and pelvis which showed multiple rim-emhancing fluid collections measuring up to 3.6 cm concerning for pyelonephritis with renal abscess. Due to lack of a tranplant surgeon at our facility he was then transferred out to his transplant center for drainage of the abscess

Discussion: A renal allograft abscess is a relatively rare condition. Embolic CVA from bacterial emboli of renal abscess source has not been reported so far to the best of our kowledge. Appropriate antimicrobial therapy and drainage are recommended for treating renal abscesses



PUB549

The First Case in Uzbekistan of Successful Pregnancy and Natural Birth in a Patient on Dialysis

Olimkhon N. Sharapov,[1,2] Botir Daminov,[2,1] Sabit Azizov.[1] *[1]Republican Specialized Scientific Practical Medical Center of Nephrology and Kidney transplantation, Tashkent, Uzbekistan; [2]Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan.*

Introduction: Improvement of hemodialysis services in Uzbekistan, in particular the transition to single use of disposable dialyzers from reusable ones in 2019, has significantly improved the quality of life of dialysis patients. The reproductive system in these patients also improved as a result of this; one such patient experienced pregnancy and subsequent natural childbirth for the first time in the history of Uzbekistan.

Case Description: Patient A. 39 years old, with ESRD and a detected pregnancy of 18 weeks. History: 17 years ago, she fell ill with glomerulonephritis, has been receiving HD for 9 years. Obstetric history-has 1 normal birth and 1 abortion at 11 weeks. After experiencing nausea, vomiting, malaise and abdominal discomfort, she was sent for screening to determine if she was pregnant. Based on the results of two consecutive screenings, pregnancy was detected, 18 weeks, without pathologies and with progression. At 29-30 weeks of pregnancy, she was hospitalized. During the examination: BP-100/60 mmHg, HR-80 beats per minute, daily diuresis 2.0-2.5 liters. CBC: Hb-81, erythrocytes-2.7, leukocytes-8.5, platelets-192, ESR-63. Proteinuria-0.3. Blood: urea-6.9, creatinine-284, total protein-63, ferritin-2826.2, calcium-2.01, phosphorus 0.75, cholesterol-6.3, glucose-4.2, PTH-445.8 pg/ml, Vitamin D - 10.2 ng/ml. Hormones: Chorionic gonadotropin - 263240 mlU/ml, free estriol - 2.82. Tests for HIV, hepatitis B, C, and TORCH infections showed negative results. Ultrasound revealed moderate hepatomegaly, chronic cholecystitis, bile stagnation and bilateral shrinkage of both kidneys. On 09/07/2022, after hemodialysis session at 14:45 the patient was transferred to the maternity ward, at 16:50, a live premature boy was born, weighing 1554 g, length 42 cm, with an Apgar score of 5/7 points. A premature newborn corresponds to a gestational age of 29 weeks. After 5 days, she was discharged home. The child stayed in the neonatal pathology department. Incubator nursing, respiratory therapy NCPAP, treatment - Curasurf, antibacterial therapy (ampisul, merkacin) were carried out. After his condition improved, he was safely discharged home. Now, the health of mother and child is satisfactory. The child grows and develops.

Discussion: This case indicates that improving the quality of dialysis services improves the reproductive system of dialysis patients.

PUB550

Global Trends in Endothelin A Receptor Antagonist Research for Kidney Disease Management

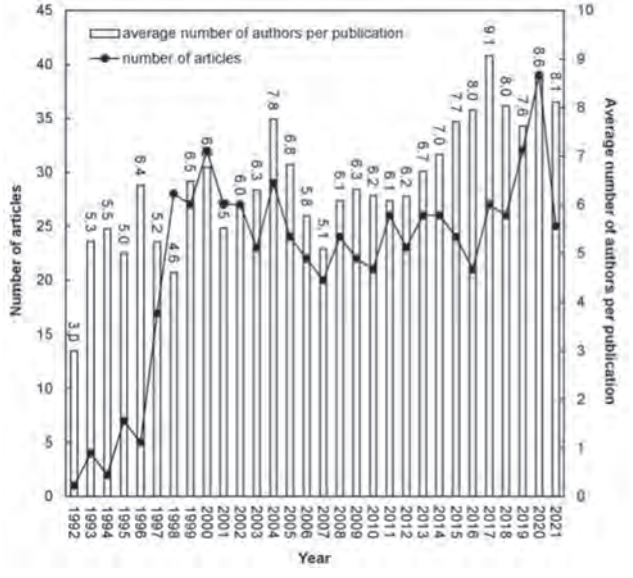
Pajaree Krisanapan,[1,2] Supawadee Suppadungsuk,[2] Charat Thongprayoon,[2] Tibor Fulop,[4,3] Karim Soliman,[3] Jing Miao,[2] Wisit Cheungpasitporn.[2]
[1]Thammasat University Hospital, Khlong Nueng, Thailand; [2]Mayo Clinic Minnesota, Rochester, MN; [3]Medical University of South Carolina, Charleston, SC; [4]Ralph H Johnson VA Health Care System, Charleston, SC.

Background: Chronic kidney disease (CKD) is a growing global health concern, with millions of people affected worldwide. Endothelin A (ETA) receptor antagonists have shown promise in slowing CKD progression by reducing proteinuria. This study examines the evolution of ETA receptor antagonist research in CKD over the past 30 years, including collaboration patterns, author contributions, and publication trends.

Methods: We conducted a bibliometric analysis of research papers published from 1992 to 2023, focusing on kidney diseases and ETA receptor antagonists. We used specific keywords to identify relevant articles and assessed author contributions using the Y-index, which combines publication numbers and impact.

Results: The findings show a significant increase in collaborative research efforts for ETA Receptor antagonist research in kidney diseases, as evidenced by a rise in the average number of authors per article. The United States emerged as a leading contributor to this research area, with the University of Groningen standing out as a major hub for collaborative projects. Among researchers, H.J.L. Heerspink was recognized for his extensive contributions. Of note, there has been a steady increase in the annual publication rate, culminating in a significant peak in the most recent period.

Conclusions: ETA receptor antagonist research in CKD is characterized by growing global collaboration and a strong focus on understanding and treating this disease. With leading authors and institutions driving research, the future of ETA receptor antagonist therapy for CKD looks promising. Further studies are needed to fully explore the potential of ETA receptor antagonists in slowing CKD progression and improving patient outcomes.



PUB551

Vascular Aging (VA) Analyzed by Dermal Autofluorescence (DA) on the Risk of Initiating Renal Replacement Therapy (RRT) and Mortality in Patients with Nondialysis-Dependent CKD Stages 1 to 5

Secundino Cigarran,[1] Ana Maria Sanjurjo Amado,[2] Amaia Santidrián Novo,[1] Raquel Vázquez Rodríguez,[1] Jose Rios,[3] Miguel Perez Fontan,[4] Guillermina Barril.[5] *[1]Hospital Ribera Polusa, Lugo, Spain; [2]Hospital Publico da Mariña, Burela, Spain; [3]Hospital Clinic de Barcelona, Barcelona, Spain; [4]Complexo Hospitalario Universitario A Coruna, A Coruna, Spain; [5]Fundacion Investigaciones Biomedicas, Madrid, Spain.*

Background: CKD is age-related disease that displays multiple features of accelerated ageing and considered as an early aging process measured through VA. Aim is to examine VA as risk for RRT and mortality in CKD stage 1-5ND.

Methods: Oservational, prospective, longitudinal study, 1064 pts followed 14 years, 59.8% male, 40.2% female.X age 72.07±14.13 yr. Markers of nutrition, inflammation, and cardiovascular risk evaluated. Kidney Failure Risk Equation (KFRE) for CKD progression. Mortality was considered for all causes. Frailty by Clinical Frailty Scale. VA from advanced glycation end products (AGEs) by AGEs Reader (Diagnoptics Technologies BV, Groningen, the Netherlands). Koetsier formula. (Vascular Age = AFD - 0.83/0.024). Tertil low (<73 yrs, 594 pts), medium (73-107 yrs, 509 pts), and high (>107 yrs, 501 pts). Lowest tertile was reference.

Results: VA 20.05±31.85 years over chronological. Significance with Charlson comorbidity, Frailty, higher 5-year mortality, KFRE, FRAX for osteoporotic fracture, and risk of hip fracture. VA > 15.6 yrs was independent risk for RRT or death as competitive event (Log Rank; p < 0.001), mean time to RRT 15.08 yrs (50% 15.33 years). Conversely, VA<15.6 yrs mean time to RRT 21.30 years (50% 28 years) Figure 1. Mortality low tertile 9.6% i16.3% medium and 30.6% high (Log Rank; p < 0.001, HR 2.70; 95% CI 1.669-4.399; p < 0.001) Figure 2.

Conclusions: VA>15.6 years start RRT 13 years earlier and 50% higher mortality than <15.6 yrs.VA is a predictor of RRT and mortality. DA is a useful tool for risk RRT & mortality in CKD.

Funding: Private Foundation Support

Frequency of CKD Patient Referrals to Nephrology Clinics Using the Kidney Failure Risk Equation at Kaiser Permanente Northern California

Jessenia A. Contreras, Jessica B. Lapasia. *Kaiser Permanente Northern California Region, San Francisco, CA.*

Background: Early detection of chronic kidney disease (CKD) is a fundamental goal in caring for patients with kidney disease. Timely implementation of a CKD care plan for patients, and regular follow up with a nephrology care team, can help delay the onset of end-stage kidney disease (ESKD). Referrals to a nephrologist for CKD care are often placed by primary care providers (PCPs), prompted by certain lab abnormalities. The Kidney Disease: Improving Global Outcomes (KDIGO) guidelines recommend that patients with CKD stage 3B through 5 be referred to a nephrologist. Although early education about healthy lifestyle habits and ESKD treatment options has been shown to improve patient outcomes, a subset of patients continues to have delayed detection of CKD. The kidney failure risk equation (KFRE), which is a four-variable risk equation, is an added tool to help identify patients at risk for CKD progression. In 2021, the KFRE was incorporated into PCP referral guidelines at Kaiser Permanente Northern California (KPNC). This study aims to evaluate the frequency of CKD referrals in the three years before and after the incorporation of KFRE.

Methods: A KPNC statistical analyst will help collect data using the following inclusion criteria: patients ≥18 years old, with at least one estimated Glomerular Filtration Rate (eGFR) < 45 ml/min/1.73m2 prior to the initial referral to KPNC Nephrologist, and at least two eGFR < 60 ml/min/1.73m2 three months apart in the 3 years prior to referral. Data will be collected over a 6-year period, 3 years before and after KFRE incorporation. Statistical analysis will be performed by the analyst.

Results: This is an ongoing study, currently in the data collection phase. Projected completion of data collection and evaluation will be by August/September 2024.

Conclusions: There is wide variability in the referral of patients with CKD to a nephrologist. The KFRE is an important tool that can help identify patients at higher risk for progression of CKD. By incorporating the KFRE into PCP referral guidelines at KPNC, the number of appropriate CKD referrals to nephrology was enhanced. These patients can then have access to available treatments to help slow their progression to ESKD.

PUB553

Association between Multimorbidity and the Risk of Major Adverse Cardiovascular Events and Mortality in Patients with Nondialysis-Dependent CKD

Kazuhiro Okamura,[1] Shigeru Tanaka,[1] Hiromasa Kitamura,[2] Kazuhiko Tsuruya,[3] Takanari Kitazono,[1] Toshiaki Nakano.[1] *[1]Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [2]Department of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan; [3]Department of Nephrology, Nara Medical University, Kashihara, Japan.*

Background: Multimorbidity, defined as the coexistence of two or more comorbidities, is associated with poor life prognosis and the onset of cardiovascular disease among the general population. It remains unclear whether the accumulation of comorbidities, including non-cardiovascular comorbidities, is associated with poor prognosis in patients with chronic kidney disease (CKD), a high-risk group for cardiovascular risk.

Methods: We investigated 4,420 patients with non-dialysis CKD who participated in the Fukuoka Kidney disease Registry (FKR) study and had confirmed comorbidities at the time of research registration. We defined 23 comorbidities, including hypertension, diabetes, and dyslipidemia. Patients were divided into three groups based on the number of comorbidities: one or fewer (1265 patients), two (1205 patients), and three or more (1,950 patients). We assessed the association between the number of comorbidities and the incidence of major adverse cardiovascular events (MACE) (cardiovascular death, non-fatal myocardial infarction, or non-fatal stroke) and all-cause mortality using the Cox proportional hazards model.

Results: During the five-year observation period, 229 patients developed MACE, and 456 died. The multivariable-adjusted hazard ratios for MACE and all-cause mortality were significantly higher (2.90 and 2.20, respectively) in the group with three or more comorbidities compared to the group with one or fewer comorbidities.

Conclusions: In non-dailysis CKD patients, the multimorbidity is associated with an increased risk of MACE and all-cause mortality. The accumulation of all types of comorbidities, not just cardiovascular comorbidities, was found to be associated with poor outcomes in CKD patients as their number increased.

PUB554

SGLT2 Inhibitor Prescribing Practices in a Large Health System

Robert Kosalka, Fitsum T. Hailemariam. *Thomas Jefferson University Sidney Kimmel Medical College, Philadelphia, PA.*

Background: Sodium-glucose transport protein 2 (SGLT2) inhibitors are a class of medication that act on the renal proximal convoluted tubules to reduce the reabsorption of glucose. They were primarily used in diabetics to assist with glucose control and are now approved for the treatment of heart failure and chronic kidney disease (CKD). Once started on SGLT2 inhibitors, patients must be monitored for a decline in renal function especially if they are also put on angiotensin-converting enzyme inhibitors (ACEi), angiotensin receptor blockers (ARB), and/or diuretics, as they can lead to decreases in kidney function and dehydration/hypotension.

Methods: This is a retrospective cohort study of patients who were prescribed SGLT2 inhibitors in the Jefferson Health System. Data was sourced from the electronic medical record (EMR) using a customized query that returned the most recent 3 glomerular filtration rate (GFR) measurements, diagnostic codes, prescribed ACEi or ARB therapy, and prescribed diuretics.

Results: Eleven thousand and eighteen adults with SGLT2 inhibitors in their medication lists were analyzed. Of these, 5956 (54.1%) patients had no GFR on record, 8744 (79.4%) were diagnosed with diabetes, 7152 (64.9%) were on concurrent ACEi/ARB therapy and 3579 (32.5%) were on diuretics.

Conclusions: SGLT2 inhibitors have become the standard of care in patients with diabetes, CKD, cardiovascular disease, and heart failure. However, the proportion of patients in our study with CKD and heart failure was lower than expected, 6.9% and 1.9%, respectively. The concurrent use of ACEi/ARB medications and diuretics can be safe provided there is adequate monitoring of the fluid status and renal function. A substantial proportion (54.1%) of these patients do not have kidney function recorded in the EMR. This analysis highlights the need for improved clinical practices to ensure all patients are being safely monitored.

GFR > 60mL/min	GFR <. 60mL/min	No GFR on record	Diagnosed with heart failure	Diagnosed with diabetes mellitus	Prescribed ACEi/ARB	Prescribed diuretic
4300 (39.0%)	762 (6.9%)	5956 (54.1%)	213 (1.9%)	8744 (79.4%)	7152 (64.9%)	3579 (32.5%)

PUB555

Impact of Smoking Intensity and Initiation Age on Cardio-Cerebrovascular Disease and Mortality Risk in Patients with CKD: A Nationwide Population-Based Cohort Study

Sehyun Jung,[1] Seong Geun Kim,[6] Semin Cho,[4] Hyuk Huh,[8] Jung Hun Koh,[3] Jeongmin Cho,[4] Minsang Kim,[3] Min Woo Kang,[3] Eunjeong Kang,[3] Sehoon Park,[3] Yaerim Kim,[5] Dong Ki Kim,[3] Kyungdo Han,[7] Soojin Lee.[2] *[1]Gyeongsang National University Hospital, Jinju, Republic of Korea; [2]Eulji University Uijeongbu Eulji Medical Center, Uijeongbu, Gyeonggi-do, Republic of Korea; [3]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [4]Chung-Ang University Gwangmyeong Hospital, Gwangmyeong, Gyeonggi-do, Republic of Korea; [5]Keimyung University Daegu Dongsan Hospital, Daegu, Republic of Korea; [6]Inje University Sanggye Paik Hospital, Nowon-gu, Seoul, Republic of Korea; [7]Soongsil University Department of Statistics and Actuarial Science, Dongjak-gu, Seoul, Republic of Korea; [8]Inje University Busan Paik Hospital, Busan, Busan, Republic of Korea.*

Background: Tobacco use is a significant modifiable risk factor for numerous diseases. While previous research had shown the adverse health outcomes related to smoking, the impact of smoking initiation age and intensity on chronic kidney disease (CKD) patients remains further investigation.

Methods: We conducted a retrospective cohort study with National Health Insurance Database of South Korea, encompassing 652,223 adults aged 20 and above, who underwent national health screening in 2009. Participants with CKD were identified, and their smoking status, smoking initiation age, pack-years, and clinical outcomes were assessed. Cox regression analysis was employed to investigate the association between smoking parameters and the risk of cardio-cerebrovascular diseases (CCVDs) and all-cause mortality, adjusting for potential confounders.

Results: The risks of CCVDs and all-cause deaths according to the smoking initiation age and pack years were assessed. Among CKD patients, higher pack-years and younger smoking initiation ages were associated with elevated risks of CCVDs and all-cause mortality. Participants with pack years < 20 and smoking initiation age below 20 exhibited an increased risk of all-cause death (HR 1.83; 95% CI 1.67-2.00). Among high-risk groups (with 30, 40, and 50 pack years), those with smoking initiation age below 20 showed elevated risk of CCVDs and all-cause death (Figure 1).

Conclusions: Our findings highlight the importance of smoking cessation in CKD patients, as early initiation and higher intensity of smoking are associated with heightened risks of CCVDs and all-cause mortality. Encouraging smoking cessation, particularly in younger individuals, may mitigate the burden of cardiovascular diseases and mortality among CKD population.

An Application Study of the Simple Insulin Sensitivity Index for the Assessment of the Level of Insulin Resistance in People with Different Kidney Function

Guang Yang,[1,2] Xin Shen,[1,2] Bokai Cheng,[1,2] Qingli Cheng.[1,2] *[1]Department of Geriatric Nephrology, The Second Medical Centre, Chinese PLA General Hospital, Beijing, China; [2]National Clinical Research Centre for Geriatric Diseases, Beijing, China.*

Background: Chronic Kidney Disease (CKD) has become an important global public health issue, and with the increasing prevalence of metabolic risk factors, the risk of developing CKD also increases. Insulin resistance (IR) is a core pathogenic mechanism of many related risk factors of CKD, making it crucial in the prevention and control of CKD. Therefore, we need to better assess the level of IR in the CKD population.

Methods: The M-value of HECT test was applied to accurately assess the IR level of the subjects and analyse the differences of IR level in people with different blood creatinine levels. Simple insulin sensitivity index (ISI) was calculated based on fasting glucose, insulin, and OGTT results to analyse the test efficacy of ISI for IR level assessment in people with different renal functions.

Results: The subjects exhibited a progressive decline in IR levels (M-values) as their blood creatinine levels increased, and this difference was found to be statistically significant (P=0.016). A correlation regression analysis was conducted to assess the relationship between ISI and M-value. The results indicated that 1/FIN, HOMA-IR, FINS/FBG, QUICKI, McAuley, Matsuda, Gutt, Disposition, Stumvoll, and Avignon were significantly correlated with M-value, with correlation coefficients (r) ranging from 0.325 to 0.577 ($p<0.01$). However, Insulinogenic and Belfiore showed no significant correlation with M-values (p=0.948, 0.831 respectively). The effectiveness of each ISI was evaluated based on renal function grouping, and ANOVA analysis revealed that Matsuda ($p<0.01$), INS/GLU, McAuley, Gutt, and Stumvoll ($p<0.05$) indices could effectively differentiate between groups in terms of IR levels. Among these, McAuley, Matsuda, and Stumvoll indices were particularly responsive to changes in IR levels across different groups.

Conclusions: As kidney function decreases, the level of insulin resistance in subjects increases. The simple ISI-McAuley, Matsuda, and Stumvoll indices show better testing efficiency in identifying trends of insulin resistance compared to the gold standard M value in populations with varying levels of kidney function.

PUB557

Prevalence of CKD in Sahuayo, Michoacán, Mexico and Its Associated Risk Factors

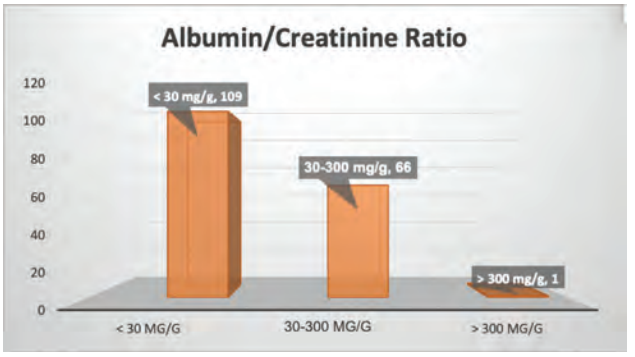
Alberto Corona.[1,2] *[1]Hospital Santa Maria de Sahuayo, Sahuayo, Mexico; [2]Instituto de Seguridad y Servicios Sociales de los Trabajadores del Estado, Sahuayo, Mexico.*

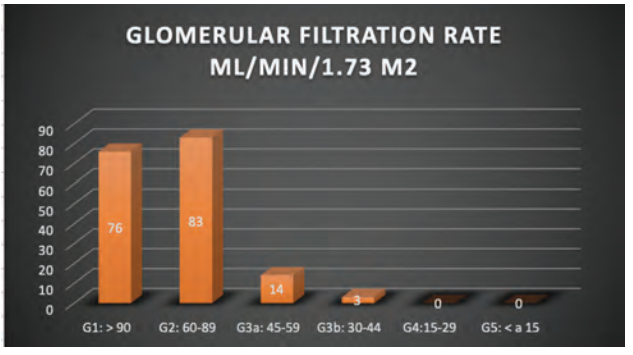
Background: Chronic Kidney Disease (CKD) has been described as the most neglected chronic disease; However, it represents a serious public health problem in Mexico and the world. Between 8 and 10% of the adult population have some form of kidney damage, and every year millions die prematurely of complications related to CKD.

Methods: A Kidney Disease detection campaign was carried out at the ISSSTE Sahuayo facilities on World Kidney Day 2024. Attendees were given information about kidney health; They were questioned for background and glucose, blood pressure, anthropometry as well as serum creatinine and microalbuminuria (Mission Urinalysis Reagent Strips (Urine)) were taken. 176 subjects were evaluated, including a population of all ages. The GFR was estimated with the CKD-EPI formula and CKD was defined according to the KDIGO guidelines. The data were analyzed using descriptive and inferential statistics with logistic regression analysis.

Results: The CKD classification, by glomerular filtration rate, was: G1: 76, G2: 83, G3A: 14, G3B: 3, G4: 0 and G5: 0; with established prevalence (GFR <60 ml/min 1.73 m2) of 9.6%. Regarding the albumin/creatinine ratio in urine, it was: A1: 109, A2: 66, A3: 1; with prevalence of ratio greater than 30 mg/gr: 38%

Conclusions: In the population of Sahuayo, there is a significant percentage of patients with CKD, similar to that observed worldwide, there is a direct relationship with chronic-degenerative diseases such as diabetes, hypertension, dyslipidemia, hyperuricemia, as well as habits such as smoking and alcoholism; Most of the patients captured were not found in advanced stages of kidney damage, which is why it is important to provide preventive measures to reduce its progression.





PUB558

Copper Accumulations as a Uremic Toxin in CKD

Tomofumi Moriyama, Kensei Taguchi, Yuya Yamashita, Kei Fukami. *Division of Nephrology, Department of Medicine, Kurume University School of Medicine, Kurume, Japan.*

Background: 95% of copper (Cu) in the body is excreted into the bile; meanwhile, the rest is excreted by the kidney. Excess Cu accumulation is known to produce reactive oxygen species in Wilson's disease, and the higher level of serum Cu, the more likely to develop kidney injury. However, it remains unknown whether the relationship between Cu accumulation and kidney injury. We demonstrated that serum Cu level was negatively correlated with serum creatinine level in diabetic rats; thus, we hypothesize that Cu might be accumulated as a uremic toxin with progression of kidney injury. In the present study, we investigated serum Cu levels in patients with CKD and explored how Cu accumulation occurs in CKD and induces kidney injury.

Methods: 115 patients with CKD who admitted to our hospital were enrolled to conduct a retrospective clinical study to investigate the relationship between serum Cu and CKD. Low-dose cisplatin (5 mg/kg per week x 4 weeks) was injected into wild-type mice to induce CKD. Serum and urinary levels of Cu, gene expressions of Cu transporters in liver and kidney, and expression pattern of Cu transporters in the liver and kidney were analyzed. LLC-PK1 cells, cultured proximal tubular cells (PTC) were co-incubated with Cu to investigate if Cu accumulation causes PTC damages.

Results: Serum Cu level was increased in CKD stage 4 and 5 when compared to earlier stages. Under 65-year-old and female showed higher level of serum Cu. ATP7B and CTR1 gene expressions in the livers were reduced and serum Cu levels were increased in CKD rodents. The increased level of serum Cu was associated with the increase in its urinary excretion. CTR1, a transporter responsible for Cu intake into PTC, was expressed on basolateral plasma membrane of PTC under basal condition, but CTR1 was translocated into nucleus in the CKD rodents. Co-incubation with Cu increased α-SMA, TGF-β, and cleaved caspase3, suggesting that high level of cooper causes PTC injury and fibrosis.

Conclusions: We identified that Cu was accumulated with progression of kidney impairment in patients with CKD and high amount of Cu induced PTC apoptosis and profibrotic reaction, indicating that Cu can be considered a uremic toxin. Liver metabolism and excretion of Cu is suppressed with the decrease in liver ATP7B and CTR1 in the context of CKD, which leads to increase urinary Cu levels that induces PTC damages and renal fibrosis.

PUB559

Effects of Irisin Secretion on the Development of Kidney Injury in a Mouse Model of Uremic Sarcopenia

Teruyuki Okuma,[1,2] Seiji Ueda,[1] Hajime Nagasawa,[1] Yusuke Suzuki.[2] *[1]Shimane Daigaku Igakubu Fuzoku Byoin, Izumo, Japan; [2]Juntendo Daigaku, Bunkyo-ku, Japan.*

Background: The prevalence of sarcopenia is high in patients with chronic kidney disease (CKD). Sarcopenia is known to be closely associated with reduced physical activity and mortality. Recently, it has been reported that skeletal muscles after exercise secrete bioactive substances called myokines, which are associated with metabolic improvement and muscle mass increase. Irisin, one of myokines has been found to play an important role in maintaining endothelial function and is believed to be a factor for the development of atherosclerotic vascular diseases in patients with sarcopenia. In CKD condition, Irisin is reported to be decreased and its levels are associated with the severity of atherosclerosis. We investigated the impacts of exercise on Irisin kinetics and the role of Irisin in the development of renal injury in a mouse model of uremic sarcopenia.

Methods: We performed 5/6 nephrectomy on C57BL/6J mice as a model of uremic sarcopenia and treated them with or without exercise intervention for 8 weeks. And kaempferia parviflora (KP) which is an activator of SIRT1 was also tested to investigate the involvements of SIRT1-PCG1α-Irisin axis in uremic sarcopenic condition. We measured serum Irisin, the expression levels of FNDC5 (a precursor of Irisin), SIRT1-PCG1α expressions in skeletal muscle, muscle mass, grip strength, renal function, pathological changes, and especially endothelial damage.

Results: The expression levels of SIRT1, PGC1α and FNDC5 in the skeletal muscles of CKD model mice were significantly decreased. In addition, glomerular endothelial damage assessed by glycocalyx staining were observed in the CKD model mice along with a decrease in serum Irisin levels. Exercise intervention not only improved FNDC5 expression and serum Irisin levels but also halted progressive renal function loss by promoting eNOS activation and improving glomerular endothelial injury. Further, KP administration ameliorated the decreased levels of SIRT1-PGC1α in CKD model mice and subsequently enhanced FNDC5 expression and Irisin release, thus contributing to the prevention of endothelial injury and renal damage.

Conclusions: Exercise intervention and KP administration may activate the SIRT1-PGC1α axis and promote Irisin secretion, and thereby contributing to the prevention of endothelial dysfunction and halting the progression of renal damage in CKD.

PUB560

Bioelectrical Impedance Markers as Predictors of CKD Progression

Timothy E. Yen,[1] Xiaoqian Zhu,[1] Maria Clarissa Tio,[1] Yoshitsugu Obi,[1] Michael E. Hall,[1] Neville R. Dossabhoy,[1] Tariq Shafi.[2] *[1]The University of Mississippi Medical Center, Jackson, MS; [2]Houston Methodist Hospital, Houston, TX.*

Background: Bioelectric Impedance Analysis (BIA) objectively quantifies body composition metrics which change during CKD progression. The predictive utility of BIA metrics for outcomes in CKD, especially in advanced disease, is unknown.

Methods: We analyzed 3,632 participants from the Chronic Renal Insufficiency Cohort (total-CRIC) (data provided by NIDDK CR) and a sub-group of 1771 participants with advanced CKD (<30 eGFR, mL/min/1.73 m^2) which was comprised of individuals who started with or progressed to advanced CKD during the study. We analyzed BIA metrics—total body water (TBW, kg), vector length (VL, Ω), phase angle (PA, °), and fat free mass (FFM, kg) as continuous variables. We used multivariable Cox proportional hazard models to examine the associations of each BIA metric with incident CKD progression (≥50% eGFR decline or ESKD) in total-CRIC, and with incident ESKD in the advanced CKD group. We calculated three risks scores--the 2-year and 5-year Kidney Failure Risk Equation (KFRE), and CKD Prognosis Consortium (CKD-PC) 3-year risk score for 40% eGFR decline or ESKD--and evaluated if BIA metrics improved prediction of CKD progression or ESRD compared to using these risk scores alone (Harrel's C).

Results: In the total population, mean age was 58 years, 46% were women, 42% were Black persons, and mean eGFR was 42. In unadjusted models, TBW, VL and FFM were associated with CKD progression in total-CRIC, while VL and FFM were associated with ESKD in advanced CKD. Associations were statistically insignificant after multivariable adjustment (Table). Addition of the BIA parameters did not significantly improve prediction of CKD progression or ESRD (Harrel's C) compared to models using KFRE or CKD-PC risk alone in either group.

Conclusions: BIA, although widely available and easily implementable, did not improve prediction of CKD progression beyond existing risk factors. Our study highlights the limitations of existing technologies and the need for innovation to advance precision medicine for individuals with CKD.

Table. BIA Metrics associations with ESKD / CKD Progression

Study Population	Survival Event	BIA metrics	Unadjusted	Fully Adjusted
			HR (95% CI)	HR (95% CI)
Total-CRIC	CKD Progression	Total Body Water	**1.004 (1.001, 1.007)**	1.002 (0.998, 1.006)
		Vector Length	**0.692 (0.566, 0.845)**	1.054 (0.945, 1.175)
		Fat Free Mass	**1.011 (1.004, 1.019)**	0.996 (0.991, 1.001)
		Phase Angle	0.995 (0.980, 1.011)	0.993 (0.975, 1.011)
Advanced CKD	ESKD	Total Body Water	1.006 (1.000, 1.011)	1.002 (0.997, 1.007)
		Vector Length	**0.658 (0.575, 0.753)**	1.033 (0.901, 1.184)
		Fat Free Mass	**1.013 (1.007, 1.018)**	0.996 (0.988, 1.005)
		Phase Angle	1.002 (0.996, 1.008)	0.998 (0.987, 1.010)

*Fully adjusted models included age, sex, race, systolic blood pressure, diabetes, cardiovascular disease, smoking, statins, ACE/ARB, diuretics, beta blockers, eGFR (CKD-EPI 2021), and urine protein/creatinine as adjusters

** sex variable was excluded in TBW analysis as it is used in TBW calculation

PUB561

Prevalence of Albuminuria and Risk Factors for CKD in a Screening Program in Mexico

Juan M. Ardavin Ituarte,[1,2] Alicia Pineirua,[1] Edgar Solis,[1] Sergio Hernández-Estrada.[1] Medica Santa Carmen. *[1]Medica Santa Carmen, Mexico City, Mexico; [2]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.*

Background: "Check Your Kidney" (CYK) is a screening program to assess for risk factors of CKD in a Renal Health Network in Mexico. The present study reports the prevalence of albuminuria and CKD risk factors in CYK participants.

Methods: In 2023, 8 CYK campaigns took place in 5 HD clinics across Puebla, Mexico City, Jalisco, and Guanajuato. Evaluation included a risk factor questionnaire, anthropometric measurements, BPM, glucometer, and urine albumin/creatinine ratio tests. Chi-square, Student's t-test, and Mann-Whitney U test were used for analysis where applicable, along with multiple logistic regression, to assess the risk of albuminuria.

Results: A total of 1089 participants were evaluated, with a mean age of 47 years ± 15); 61% were women. The most common CKD risk factor was obesity, with 76% of participants having a BMI ≥ 25 and 35% > 30. This was followed by chronic use of potentially nephrotoxic medications in 26%, known hypertension (HTN) in 23%, and known diabetes mellitus (DM2) in 15%. Capillary glucometry identified 20 additional participants with probable undiagnosed DM2 (random capillary glucose > 200 mg/dL) for a total prevalence of 17%, and blood pressure measurement (SBP ≥ 160 or DBP ≥ 100) identified 44 more with probable HTN for a total prevalence of 27%. Albuminuria > 30 mg/g was detected in 25% and ≥ 300 mg/g in 2% of all participants; in 39% ($p < 0.001$) and 7% ($p < 0.001$) respectively of participants with DM2; and in 36% ($p > 0.001$) and 3% ($p=0.16$) of participants with HTN. The risk association remained significant only for DM2 in the logistic regression analysis after adjusting for age, sex, and other reported risk factors, with an OR = 1.72 (CI 1.19 - 2.49, $p = 0.004$) for albuminuria > 30 mg/g and OR = 6.17 (CI 2.36 - 16.1, $p < 0.001$) for albuminuria ≥ 300 mg/g. Four percent of the patients had all three risk factors (DM2, HTN, and obesity); however, no interaction effect was found between these covariates for the risk of albuminuria.

Conclusions: The prevalence of albuminuria was higher than reported in other populations, but there may be measurement and selection bias. The prevalence of obesity, DM2, and HTN is consistent with that reported in the Mexican population. The most relevant risk factor for albuminuria, as expected, was DM2.

Predictors of CKD Progression in Dogs: Results from a Real-World Animal Health Study

James Jackson, Dean A. Taylor, Sophie Barlow, Mollie Lowe. *Adelphi Real World, Bollington, United Kingdom.*

Background: Real world evidence is used to substantiate the benefit of medical intervention in human healthcare, but is less commonly employed in animal healthcare research. We aimed to understand the predictors of canine chronic kidney disease (CKD) progression using a real-world dataset.

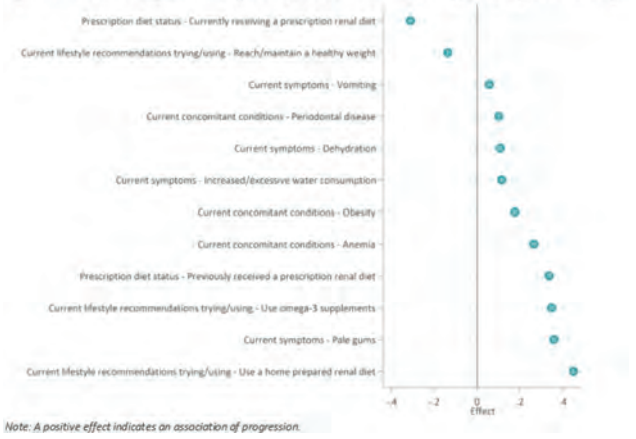
Methods: Data were drawn from the Adelphi Real World Canine CKD Disease Specific Programme™, a cross-sectional survey of veterinarians in the United States from Dec 22 – Jan 24. Vets reported demographics, international renal interest society (IRIS) stage, time since diagnosis, symptoms, comorbidities, lifestyle and treatment goals, for dogs with CKD. A ten-fold elastic net regression (ENR) analysis was conducted.

Results: Overall, 100 vets provided data on 308 dogs. Mean [SD] dog age was 11.4 [3.4] years, 53% were at ideal weight and mean [SD] time since CKD diagnosis was 11.8 [15.6] months. In total, 21% of dogs were at IRIS stage 1, 49% stage 2, 21% stage 3, and 8% stage 4. Overall, 21% had progressed to a higher IRIS stage, from stage at diagnosis to current classification. ENR analysis showed that using a home prepared renal diet was most strongly associated with disease progression. Presence of pale gums, obesity and

anemia were also associated with disease progression. Receiving a prescription renal diet and maintaining a healthy weight were associated with no disease progression (Figure 1).

Conclusions: This real-world data demonstrated the importance of using a prescription renal diet over a home prepared diet, and the need for owner vigilance with their dog's weight and gum colour. Vets should prioritise owners' understanding of the importance of optimal CKD management to help slow disease progression.

Figure 1: Elastic net regression coefficient plot to show predictors of CKD progression in dogs.



PUB563

Hyperkalemia and CKD

L. M. Perez-Navarro, Enrique J. Robiou Vivero, Rafael Valdez-Ortiz.
Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico.

Background: Hyperkalemia (HK) is a frequent complication of chronic kidney disease (CKD), with a prevalence of between 14-20%, which is associated with different factors, such as the use of some antihypertensives (ARA's, IECAS), age, gender, Diabetes Mellitus (DM), cancer. Our aim was to determine the prevalence and factors associated with HK in patients with CKD.

Methods: Transversal study. Patients with CKD who attended the nephrology service of the Hospital General de México during the period Feb 2019 to August 2022 were included. The prevalence and factors associated with HK (K>5) by CKD stage were estimated using regression logistics (95% CI).

Results: 1249 patients were included, with an average age of 55±16 years; 52% of the population female. The prevalence of HK was 26% (321). The standardized B coefficient for the relationship between serum levels and GFR was -0.334, (p<0.0001). Figure 1 shows the prevalence of HK by severity grade across CKD stages. The factors associated with HK are presented in Figure 2.

Conclusions: An association between HK and the use of commonly prescribed medications, such as oral hypoglycemics and loop diuretics, was identified from the early stages of CKD, along with the presence of diabetes mellitus. It is necessary to intentionally screen for HK from the early stages of CKD and to implement pharmacological treatment with the aim of reducing the risk of CKD progression, death, and cardiovascular events.

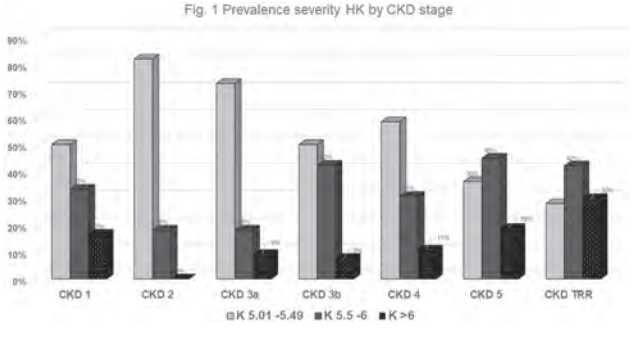


Figure 1. Prevalence of HK by severity grade across CKD stages

PUB564

Evaluation of Serum Beta-2 Microglobulin (B2M) in Patients with CKD and People Living with HIV (PLHIV) and CKD

Andrea Torres Rojas,[1,2] Monserrat Álvarez Zavala,[2,4] Karina Sánchez Reyes,[2,4] Jonathan Chavez,[5] Pedro Martínez Ayala,[3] Adriana Valle Rodriguez,[3] Jaime Federico Andrade Villanueva,[3,2] Vida V. Ruiz Herrera,[3] Luz A. González Hernández.[3,2] Estudio Inmunológico de la Infección por VIH e Inmunodeficiencias Humanas. *[1]Doctorado en Biología Molecular en Medicina, Dpto Biología Molecular y Genómica, CUCS-UDG, Guadalajara, Mexico; [2]Instituto de Investigación en Inmunodeficiencias y VIH (InIVIH), CUCS-UDG., Guadalajara, Mexico; [3]Hospital Civil de Guadalajara Unidad Hospitalaria Fray Antonio Alcalde, Unidad de VIH., Guadalajara, Mexico; [4]Universidad de Guadalajara Centro Universitario de Ciencias de la Salud, Guadalajara, Mexico; [5]Hospital Civil de Guadalajara Unidad Hospitalaria Fray Antonio Alcalde, Servicio de Nefrología., Guadalajara, Mexico.*

Background: Chronic kidney disease (CKD) is one of the main co-morbidities in people living with HIV (PLHIV). In CKD, Cystatin C (CC) and creatinine are the most sensitive markers of renal function. However in HIV, these decrease after the use of antirretroviral therapy (ART), so renal function is underestimated. Beta-2 Microglobulin (B2M) has gained importance as a marker of glomerular and/or tubular damage in CKD. So, we determined and compared serum B2M levels in both groups of patients and correlated with estimated glomerular filtration rate (eGFR) with CKD-EPI equation with creatinine and B2M in order to find a reliable renal function marker for PLHIV.

Methods: Analytical cross-sectional study, in which we included 163 patients with CKD and 102 PLHIV with CKD under ART with undetectable viral loads from the Hospital Civil de Guadalajara. Clinical assessment, laboratory studies and measurement of serum B2M by ELISA were performed.

Results: Comparisons between the groups were significant for B2M, with an increase by stage. There is also a negative correlation between eGFR and B2M in both groups. A ROC curve was performed to define a cut-off point for early renal damage in PLHIV (>2.37 µg/mL (AUC 0.9622, SE 91%, SP 95%)). In PLHIV, using CKD-EPI B2M equation (133 x $B2M^{-0.852}$) eGFR was estimated and compared to CKD-EPI creatinine equation (median: 27.4 vs 52.24 mL/min *p* 0.0001) and there is a redestribution by stage. Bland & Altman analysis revealed a bias of -15.69±17.99 with a 95% CI (-50.95,+19.58).

Conclusions: CKD stratification in PLHIV has been a challange due to the impact of ART, inflammation and immune reconstitution over CC and creatinine. Since B2M is less variable, it is a promising marker for correct classification and follow-up of CKD in PLHIV.

Funding: Government Support - Non-U.S.

Mortality Outcomes of Patients with CKD Underdoing Transcatheter Aortic Valve Replacement at Cooper University Hospital

Michael Chau,[1,2] Krystal Hunter,[2] Christopher B. McFadden.[1,2] *[1]Rowan University Cooper Medical School, Camden, NJ; [2]Cooper University Health Care, Camden, NJ.*

Background: Chronic kidney disease (CKD) is a major risk factor for valvular heart disease, specifically aortic valve calcification. The prevalence and progression of aortic stenosis is higher and faster in patients with CKD thus many of these patients undergo transcatheter aortic valve replacement (TAVR) in their respective lifetimes. Many studies have reported that in-hospital morbidity and mortality are significantly higher in CKD patients when compared to non-CKD patients. However, there are few studies that further distinguish CKD into its different stages and categorize patients on their risk relative to their CKD category. The purpose of this study is to elucidate the mortality outcomes in patients with different stages of CKD following TAVR surgery.

Methods: An IRB approved retrospective study was conducted on patients who underwent TAVR at Cooper University Hospital between 02/2020 and 12/2022. The primary outcome was the 1-year mortality rate after TAVR surgery. Patients with CKD were stratified by their estimated glomerular filtration rate (eGFR) calculated with the CKD-EPI Creatinine Equation (2021). Statistical analyses were performed on this dataset to compare outcomes at different stages of CKD on patients who underwent TAVR.

Results: When compared to patients with CKD3a, patients with CKD3b or worse have greater odds of mortality at the 1-year and 3-year mark after undergoing TAVR. When compared to patients with CKD3b, patients with CKD4 did not have a significant difference in mortality at the 1-year and 3-year mark but patients with CKD1, 2, and CKD3a had lower odds of mortality.

Conclusions: Despite advances in technology and increased in operative experience, patients with CKD who undergo TAVR experience a higher risk of morbidity and mortality. Studies have noted that patients who have advanced CKD such as in dialysis patients are at an even higher risk compared with CKD patients not on dialysis. Our retrospective study shows that the increased risk of mortality after TAVR in CKD patients begins at CKD3b or at an eGFR of 45 mL/min. These results emphasize the importance of risk stratifying these patients prior to obtaining a TAVR surgery, paying particularly special attention to those who have CKD3b.

PUB566

Level of Proteinuria before and after Spironolactone in Combination with ACE Inhibitor or ARB in Filipino Patients with CKD: A Retrospective Cohort Study

Ellani Louise A. Huilar, Brian Michael I. Cabral, Monica Therese Cating-Cabral. *St. Luke's Medical Center - Global City, Taguig City, Philippines.*

Background: In the Philippines, prevalence of chronic kidney disease has been increasing due to comorbidities such as diabetes mellitus and hypertension. Proteinuria has been associated with progression of chronic kidney disease and its reduction shows renoprotective effects to CKD patients. Standard treatments to block the renin angiotensin aldosterone system such as angiotensin-converting enzyme inhibitors or angiotensin II receptor blockers are not enough to halt or slow the progression due to *aldosterone breakthrough*. Hence, blocking the aldosterone by mineralocorticoid receptor antagonist could benefit patients with CKD. Spironolactone, a steroidal MRA, specifically works by competitively blocking aldosterone, decreases inflammation, and improves proteinuria.

Methods: The study was a non-interventional, retrospective or historical cohort investigation using clinical data from chart review of patients from July 2020 to July 2023 in outpatient clinics. Laboratory results were obtained through electronic medical records and were compared in patients who used spironolactone (n=49).

Results: In a population of 49 chronic kidney disease patients on spironolactone dosed at 12.5mg to 50mg per day, random urine protein creatinine ratio decreased from 2.53±2.3 at baseline to 1.78±1.6 with a p-value of 0.005 (p=0.005). The serum creatinine, sodium and estimated glomerular filtration rate showed no statistical significance. Potassium showed statistical significance but has clinically insignificant results.

Conclusions: Reduction of proteinuria by blocking aldosterone breakthrough using mineralocorticoid receptor antagonists such as spironolactone, plays an important part in slowing the progression of CKD. In the Philippines, the use of spironolactone as well as monitoring of proteinuria by RUPCR has not been a common practice. Therefore, further studies are needed to transform the standard of care in treating blood pressure and cardiovascular disease in ESRD.

Clinical Variables	Median, Range (minimum, maximum)		Z	P
	Baseline	Spironolactone		
RUPCr (mg/mg)	1.89 (0.33-12.70)	1.29 (0.13-7.10)	-5.148	<0.001
Creatinine (µmol/L)	1.79 (1.14-4.23)	1.76 (1.05-4.84)	-0.344	0.731
eGFR (mL/min/1.73m^2)	36 (15-65)	37 (15-77)	-0.728	0.467
Serum sodium (mmol/L)	140 (132-149)	142 (134-148)	-1.452	0.146
Serum potassium (mmol/L)	4.2 (2.50-5.00)	4.4 (3.60-6.10)	-3.290	0.001

PUB567

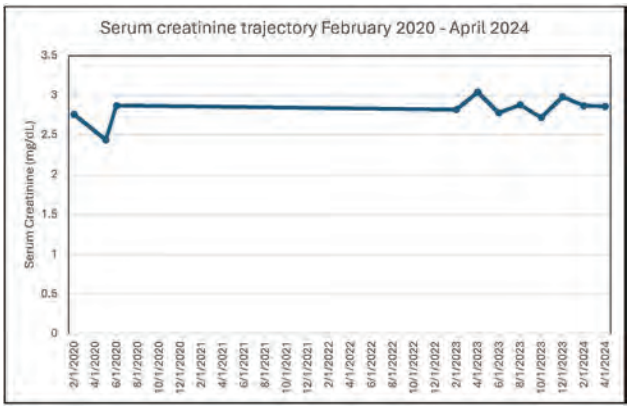
CKD Nonprogressors: A Commonly Underrecognized Syndrome?

Lynn Do, Macaulay A. Onuigbo. *The University of Vermont Medical Center, Burlington, VT.*

Introduction: NKF-KDOQI 2002/KDIGO 2005 guidelines established CKD stages 1-5 to optimize CKD care. Is CKD progression inevitable, unless of course managed properly? A population-based cohort study of 129,486 CKD patients found that with advancing age, CKD regression and death were more likely than CKD progression or kidney failure. We describe nonprogression over several years in CKD III and CKD IV, respectively.

Case Description: Case 1 - A male liver transplant recipient (July 2018, then aged 49 years), developed post-transplant AKI needing hemodialysis for a week. Pre-transplant creatinine was 0.81 mg/dL, peaked at 7.41 mg/dL, and subsequently stabilized (Figure). It was 1.79 mg/dL (eGFR=44) in May 2024. He was hypertensive in October 2018, and was on Losartan 25 mg daily for 17 months, which was discontinued during a hospitalization with sepsis in March 2020. He has since then not received any CKD-modifying agent. **Case 2 -** A now 75-yo male patient has a history of AKI on CKD in February 2020 from pyelonephritis, with peak serum creatinine of 5.39 mg/dL, that subsequently improved to 2.76 mg/dL (eGFR=23), 12 days later, hypertension, BPH, morbid obesity (BMI 33.13 kg/m^2), and known bilateral renal cysts completed his recent annual Nephrology review in April 2024. Latest creatinine was 2.86 mg/dL (eGFR=22) from April 2024 (Figure). Current medications include Carvedilol, Amlodipine, Torsemide, Baby ASA, Ezetimibe, Finasteride, Tamsulosin and Rosuvastatin. He was never on any other CKD-modifying agent.

Discussion: Clearly, there are patients with later stage CKD who remain stable over several years, the so-called CKD non-progressors. Determinants of such CKD stability call for further investigation; the role of pharmacologic agents in such stabilization, in our opinion, remains to be fully truly elucidated.



PUB568

Male Sex and Anemia Are the Most Pivotal Risk Factors for Progression of Kidney Dysfunction and All-Cause Mortality, Especially in Elderly Patients with CKD

Yuta Kimura, Takahito Moriyama, Yoshitaka Miyaoka, Yoshihiko Kanno, Rie Suzuki. Dept of Nephrology, Tokyo Medical University. *Department of Nephrology, Tokyo medical University, Tokyo, Japan.*

Background: Two decades have been passed since the definition of chronic kidney disease(CKD) was advocated in 2003. Hypertension and the diabetes have been recognized as the most important risk factors for progression of CKD, cardio-vascular events, and mortality. However, the recent therapeutic strategies and managements might change those risks. This study analyzed about the renal survival and all-cause mortality and risk factors for them in elderly patients and non-elderly patients in recent data.

Methods: The 311 out-patients with CKD on January 2017 were divided into two groups according to their age over and under 65 [elderly patient group (EPG: ≥ 65 years old, n=193), non-elderly patient group (NEPG: < 65 years old, n=118)]. The clinical and laboratory findings, treatments, and the survival rate until progression to end stage kidney disease (ESKD) and all-cause mortality were compared between both groups. The risk factors were analyzed by Cox regression analysis in each group.

Results: The mean arterial pressure (MAP) was significantly lower and the diabetes patients were significantly higher in EPG (EPG vs. NEPG; MAP:92.0 vs. 96.4 mmHg, p=0.006, diabetes: 42.0 vs. 26.3 %, p=0.005). The hemoglobin (Hb) (12.1 vs. 13.2 g/dL, p<0.001), and eGFR(31.2 VS.38.0mL/min/1.73m', p<0.001) were significantly lower, and the blood urea nitrogen (27.7 vs. 22.4 mg/dL, p<0.001) and uric acid (6.66 vs. 6.27 mg/dL, p=0.01) were significantly higher in EPG. The survival rates were similar between both groups (EPG vs. NEPG:58.1 vs. 66.7 %, p=0.093). The univariate and multivariate analysis indicated that CKD stage and amount of proteinuria were significant risk factors in both groups. Moreover, the male and lower Hb were significant risk factors in EPG [male: hazard ratio (HR) 2.56, 95% confidence interest (CI) 1.27-5.17, p=0.009, Hb: HR 1.46, 95% CI 1.27-5.17, p=0.009], but not in NEPG.

Conclusions: CKD stage and proteinuria were the significant risk factors for progression of CKD and all-cause mortality in both elderly and non-elderly CKD patients rather than hypertension and diabetes. Moreover, the male and anemia were also the significant risk factors in especially elderly CKD patients. These results indicated that the risk factors of CKD and all-cause mortality have changed in these two decades.

PUB569

Impact of Dapagliflozin on Anemia Status of Patients with CKD

Ioannis Griveas.[1,2] *[1]Noseleutiko Idryma Metochikou Tameiou Stratou, Athens, Greece; [2]Athens-Nephrology Private Clinic, Athens, Greece.*

Background: Sodium-glucose cotransporter 2 inhibitors (SGLT2i) have demonstrated cardiovascular and renal benefits in patients with type 2 Diabetes Mellitus, Heart Failure, or Chronic Kidney Disease (CKD). At the same time, there are scattered data which support the hypothesis that SGLT2i may increase hematocrit (Hct) and hemoglobin (Hb). The increase in hemoglobin was strongly associated with the cardiorenal benefits of these drugs. Aim of our study was to investigate the impact of a SGLT2i representative such as Dapagliflozin on anemia status of patients with CKD.

Methods: 22 stable CKD patients, that were receiving Dapagliflozin, were enrolled in our study for a period of one year. 72 years was the mean age of our patients. 16 patients were diabetic, one had FSGS, one had ischemic nephropathy, one had IgA nephropathy, 2 patients had membranous nephropathy and one patient with unknown primary cause of CKD. None of our patients was receiving erythropoietin or Fe supplementations. For a period of one year we measured Hct, Hb, GFR, proteinuria in our study group.

Results: After one year period, Hct was significantly increased from 42.06±4.85 to 44.34±4.74 (p<0.05). Hb was also increased from 13.8±1.63 to 14.36.34±1.50, p=0.63. The above notice was combined with decrease of GFR after one year of giving Dapagliflozin (from 38.66±13.92 mils/min to 34.38±11.59 mils/min, p<0.05). At the same time, proteinuria remained stable over the study period (936.28±1371.10 to 864.47±1256.83, p=NS).

Conclusions: Dapagliflozin use was associated with higher Hct levels in patients with CKD. Our study group is small, but represents the whole spectrum of CKD aetiology. More studies with larger populations are needed to confirm our first impression that SGLT2 inhibitors may be considered as an adjunct therapy to reduce anemia incidence in patients with CKD.

PUB570

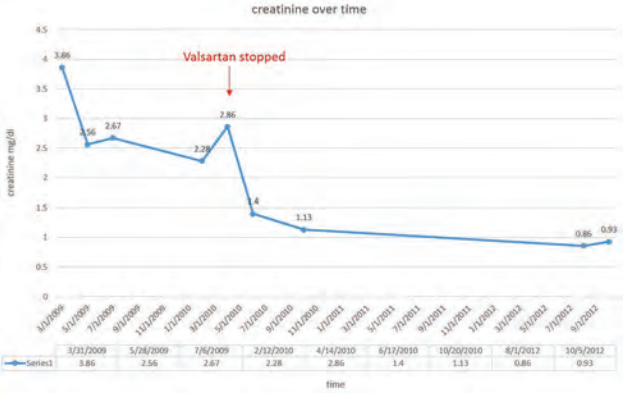
A Case of CKD Mimicry

Martin Sedlacek,[1] Martha L. Graber.[2] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Dartmouth College, Hanover, NH.*

Introduction: CKD is treated with medications to delay disease progression, resulting in an increase in serum creatinine that is expected and beneficiel. Here we present the case of a patient who complained of lightheadedness and palpitations while he was treated for CKD. After stopping valsartan and fenofibrate his kidney function returned to normal with no sign of kidney disease for several years.

Case Description: A 56 y/o man was referred for stage 4 CKD since about 9 months in the context of type 2 diabetes mellitus, HTN, dyslipidemia and a history of colonic polyps and hand surgery. His diabetes was diet controlled with his last HbA1c 6.1%. He was treated with valsartan 320mg daily for years. His other medications were fenofibrate 145mg daily, rosuvastatin 10mg daily and ASA 325mg daily. There was no history of severe illness, radiocontrast studies or NSAID use. BP was 131/81 and he was overweight. Urinalysis and urine sediment were normal and there was no microalbuminuria. Laboratory tests were negative for complications of CKD. Renal ultrasound and Duplex were normal. The patient complained of dizziness and palpitations and underwent a cardiology evaluation which was negative. The patient stopped Valsartan himself and his symptoms resolved. HTN was treated with Atenolol. His serum creatinine improved and for the next years he had no more evidence of kidney disease with normal blood and urine testing (figure 1).

Discussion: The clinical diagnosis of CKD depends on blood and urine tests which can be affected by medications. The patient had a lasting but reversible creatinine increase by valsartan (hemodynamic effect) and fenofibrate (increased creatinine generation). Rosuvastatin has been associated with hematuria and albuminuria (not in this patient). Patient complaints of medication side effects are statistically non significant in most CKD studies, often implying that they might not be relevant for treatment decisions. This case shows that in the individual patient, ignoring symptoms of medication side effects can lead to morbidity and even iatrogenic disease.



PUB571

Effects of Prebiotic on Metagenome and Lipid Metabolism in Patients with CKD: Findings from the TarGut CKD Study

Anvesha Srivastava, Dominic S. Raj. TarGut-CKD Study Group. *The George Washington University, Washington, DC.*

Background: Patients with chronic kidney disease (CKD) have dysbiosis and dysmetabolism. Dysbiosis in CKD could promote progression of CKD through alterations in immune response, blood pressure regulation and metabolic changes. The aim of the study is to define the impact of p-inulin supplementation on gut microbiota-related metabolites, as well as the plasma lipid metabolism.

Methods: In a non-randomized, open-label, 3-phase pilot trial, we examined the effect of oligofructose-enriched inulin (p-inulin) on functional metagenome and alterations in plasma, urine and stool metabolites in 15 patients with CKD (TarGut CKD). The study consisted of a pre-treatment phase (8 weeks), a p-inulin treatment phase (12 weeks), and a post-treatment phase (8 weeks).

Results: Abundance of *Bifidobacterium adolescentis*, *Bifidobacterium longum* and *Lachnospiraceae* species were increased during the treatment phase. Microbial pathways related to carbohydrate, lipid, amino acid and purine metabolism were altered during the treatment phase. Differential enrichment in microbiota generated metabolites and lipids metabolites was evident between study phases. Specifically, levels of secondary bile acids were reduced significantly in plasma, urine and stool during the treatment phase. Despite an increase in abundance of short chain fatty acid (SCFA)-producing bacteria during p-inulin consumption, there was no parallel increase in SCFA. Several polar and non-polar lipids were altered during the study phases, which was associated with specific microbiota.

Conclusions: This study indicates that prebiotics alters functional metagenome, metabolic pathways and metabolites that transcends carbohydrate metabolism in patients with CKD. The clinical significance of our findings needs to be confirmed in an adequately powered clinical trial.

Perspectives of Patients and Care Partners on Prognostic Discussions in CKD: A Qualitative Study

Shivani S. Tauh,[1] Pietro Ravani,[1] Shannan Love,[1] Kathryn M. King-Shier,[3] Robert R. Quinn,[1] Ngan Lam,[1] Ping Liu,[2] Maoliosa Donald,[2] Meghan J. Elliott.[1] *[1]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [2]University of Calgary, Calgary, AB, Canada; [3]University of Calgary Faculty of Nursing, Calgary, AB, Canada.*

Background: The incidence and prevalence of chronic kidney disease (CKD) is expected to rise over the next decade. Adults with severe CKD must navigate difficult decisions related to kidney replacement therapy and the competing risk of death without kidney failure. In this qualitative study, we sought to explore the experiences of patients with CKD and their care partners related to discussions about kidney failure risks and mortality, and to elicit their preferences for discussing and using prognostic information.

Methods: We purposively sampled patients with non-dialysis-dependent CKD (eGFR <30 mL/min/1.73m^2) followed in multi-disciplinary CKD clinics and their care partners in Alberta, Canada. We conducted online or telephone-based, semi-structured interviews that centered around eliciting personal experiences and responses to clinical vignettes that included risk estimates for kidney failure and mortality. Interviews were audio recorded and transcribed verbatim. Data were coded iteratively and in duplicate and analyzed through reflexive thematic analysis.

Results: We conducted interviews with 22 patients and 7 care partners. Participants emphasized the quality of communication and interactions with their healthcare team as the greatest influences on their prognostic understanding. Participants' experiences and preferences related to prognostic discussions are elaborated across the following themes: 1) Alignment of discussion context with informational readiness (*appropriate timing, setting, roles*), 2) Level of directness in conveying individual risk (*sensitivity, frankness, professional obligation*), 3) Quality of personal and therapeutic relationships impacting preferences (*reliance on trust and support structures*), and 4) Perceived value and applicability of prognostic information (*personalized information, utility in care planning*).

Conclusions: The perceived quality of prognostic discussions among patients with CKD and their care partners was influenced by contextual factors, individual preferences, and communication styles. Strategies tailored to individuals' readiness and the collaborative CKD care setting may improve understanding of clinical outcomes of severe CKD and use of prognostic information in treatment planning.

PUB573

A Phase 2b Dose-Finding Study to Evaluate Effects of Balcinrenone/Dapagliflozin vs. Dapagliflozin in Patients with CKD and Albuminuria

Patrick B. Mark,[1] Anna Eriksson,[6] Nicolas J. Guzman,[3] Erika De Sousa Amorin,[6] Maria Leonsson Zachrisson,[6] Samvel B. Gasparyan,[5] Yunyun Jiang,[4] Hiddo J. Heerspink.[2] *[1]School of Cardiovascular and Metabolic Health, University of Glasgow, Glasgow, United Kingdom; [2]Department of Clinical Pharmacy and Pharmacology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [3]Late-Stage Development, Cardiovascular, Renal, and Metabolism, BioPharmaceuticals R&D, AstraZeneca, Gaithersburg, MD; [4]Biometrics, Late Cardiovascular, Renal, and Metabolism, BioPharmaceuticals R&D, AstraZeneca, Gaithersburg, MD; [5]Biometrics, Late Cardiovascular, Renal, and Metabolism, BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; [6]Late-stage Development, Cardiovascular, Renal, and Metabolism, BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden.*

Background: Despite current standard of care with SGLT2i being recommended for the treatment of chronic kidney disease (CKD), there is still an unmet need for managing residual risk of disease progression. Balcinrenone is a novel selective mineralocorticoid receptor (MR) modulator, expected to maintain the cardio-renal treatment benefits of MR antagonists with a reduced risk of hyperkalaemia. The combined usage of balcinrenone and dapagliflozin is therefore expected to provide complementary and additive kidney and cardiovascular protection. MIRACLE Phase II study (NCT04595370) in heart failure (HF) and CKD suggested potential for reduced albuminuria and low risk of hyperkalaemia with balcinrenone/dapagliflozin.

Methods: This Phase IIb, international, randomized, double-blind, parallel-group trial is enrolling adult patients with CKD, albuminuria and potassium 3.5 to ≤5mmol/L (NCT06350123; Figure). Participants will be randomised 1:1:1 to three treatment arms: balcinrenone/dapagliflozin 15/10mg, balcinrenone/dapagliflozin 40/10mg and dapagliflozin 10mg for 12 weeks followed by an 8-week wash-out period to assess off-drug effects. This study will evaluate the effect of balcinrenone/dapagliflozin on urinary albumin-to-creatinine ratio (UACR), compared with dapagliflozin, as well as safety and tolerability. eGFR will be monitored throughout the study, to assess any acute changes and its reversibility.

Results: The primary endpoint is the relative change in UACR from baseline to week 12. Safety and tolerability will be assessed from adverse events (including AEs of special interest; hyperkalaemia, adverse renal events and hypotension), vital signs and safety laboratory parameters throughout the study.

Conclusions: The MIRO-CKD study will assess efficacy, safety and tolerability of the combination of balcinrenone and dapagliflozin with the aim to identify an optimal dose for a future Phase III study in patients with CKD.

PUB574

Effects of Coronary Artery Bypass Grafting on Kidney Function and Associated Risk Factors in Patients with CKD: A 12-Month Prospective Study

Mohammad Rahmanian,[1] Shiva Samavat,[3] Reza Ghotbein,[5] Nasrin Borumandnia,[4] Behrang Nooralishahi.[2] *[1]Student Research Committee, School of Medicine, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran; [2]Tehran Heart Center, Cardiovascular Diseases Research Institute, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran; [3]Chronic Kidney Disease Research Center (CKDRC), Shahid Labbafinejad Medical Center, Shahid Beheshti University of Medical Sciences (SBMU), Tehran, Islamic Republic of Iran; [4]Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran; [5]Shahid Beheshti University of Medical Sciences School of Medicine, Tehran, Islamic Republic of Iran.*

Background: This study aims to investigate the impact of coronary artery bypass grafting (CABG) on the 12-month glomerular filtration rate (GFR) in Iranian patients with chronic kidney disease (CKD) and to identify the factors associated with changes in GFR.

Methods: One hundred patients undergoing CABG were enrolled in the study. GFRs were assessed at 3-, 6-, and 12-months post-surgery. Analyses were conducted to obtain the trend of GFR. Additionally, a linear regression analysis using the Generalized Estimating Equations (GEE) approach was conducted to explore the effect of various predictors on the trend of GFR. The B coefficient was reported for each parameter to measure the estimated change in GFR for each unit increase in the parameter, holding all other parameters constant.

Results: Prior to surgery, the mean GFR was 62.5. At 3-, 6-, and 12-months post-surgery, the mean GFRs were 58.1, 58.4, and 56.8, respectively, showing a decreasing trend (P value<0.05). Among various possible predictors, gender, age, pre-op hemoglobin, AKI during admission, intra-aortic balloon pump (IABP), and renal replacement therapy (RRT) showed a statistically significant effect on the trend of GFR (P < 0.05). However, no significant correlations were found between the GFR trend and factors such as body surface area (BSA), smoking, ejection fraction (EF), type of surgery, hypertension, diabetes, cerebrovascular accident (CVA), and anemia (P > 0.05).

Conclusions: The declining trend of GFR and its predictive factors, including gender, age, pre-operation hemoglobin, AKI during admission, IABP, and RRT, should be considered when CKD patients undergo CABG. .

GFR Recovery in a Patient with Stage 4 CKD and Chronic Uncontrolled Gout after Treatment with Intravenous (IV) Pegloticase

Eddie M. Rodriguez,[1,2] Sergio F. Santiago Calderon,[2] Hector Quintero Alvarez.[2]
[1]Bayamon Medical Center, Bayamon, Puerto Rico; [2]Universidad Central de Bayamon, Bayamon, Puerto Rico.

Introduction: Gout has been associated as an important comorbidity for cardiovascular disease, Diabetes Mellitus type 2, increase risk of death, and chronic kidney disease. Kidney biopsies have shown urate deposition in kidney tissue and there is a chronic inflammatory component that may be contributing to GFR loss in CKD patients with uncontrolled gout. But a correlating between chronic gout stabilization and renal protection outcomes has not been established, in part due to lack of effective therapies to significantly impact urate tissue in chronic uncontrolled gout.

Case Description: A 59 y/o male with past medical history of coronary artery disease, Diabetes Mellitus Type 2, chronic kidney disease stage 4 and uncontrolled Gout with Tophi and recurrent flares. Patient usually treated flares with prednisone and avoided colchicine and NSAIDS due to CKD status. Due to failure of conventional therapies of uric acid lowering therapy he was started on Pegloticase infusion IV every 2 weeks. After 6 months of treatment in addition of controlling flares and tophi dissolution he has shown a consistent improvement in eGFR which has increased after each visit. Initial eGFR prior initiation of treatment was 28 ml/min. After 6 months of treatment latest eGFR is 70 ml/min which shows dramatic improvement after stabilizing uncontrolled gout and the removal of the urate burden from tissues.

Discussion: Improvement of GFR with by controlling inflamation and reducing urate burden in CKD patient with chronic gout is a promising treatment alternative. At the moment Pegloticase is indicated for treatment of patients with uncontrolled gout regardless of GFR since it does not require dose adjustments related to GFR, but the indication is to reduce flares and tophi disolution. So far there is only anecdotal data that patients may present benefits in term of GFR recovery after treatment with Pegloticase. The findings of his case proposes that treatment with pegloticase IV could be beneficial for patients with uncontrolled gout in terms of eGFR recovery and also reduction in CKD progression by stabilizing chronic uncontrolled gout. Potentially this may leed to future controlled trials which may further evaluate pegloticase as a treatment for GFR recovery and GFR protection in patients with CKD and chronic gout.

PUB576

Modulating Branched-Chain Amino Acid Catabolism: A New Approach to Ameliorate Cisplatin- and Unilateral Ureteral Obstruction (UUO)-Induced Kidney Injury

Hisakatsu Sone, Byung Rho Lee, Samuel V. Vitale, Dan Heo, Sang-Ho Kwon.
Augusta University Medical College of Georgia, Augusta, GA.

Background: Cisplatin chemotherapy can lead to chronic kidney disease in cancer patients. We have identified that endogenous renal microRNA-messenger RNA (miRNA-mRNA) interactions mediate attenuation of branched-chain amino acid catabolism in cisplatin-induced kidney injury. This study examines the roles of branched-chain amino acid catabolism in maladaptive cellular processes associated with cisplatin nephrotoxicity and unilateral ureter obstruction (UUO) injury.

Methods: To understand the role of BCAA catabolism in the murine models of kidney injury, we conducted marker analyses for renal fibrosis and ferroptosis.

Results: Enhancing branched-chain amino acid catabolism reduces renal ferroptosis and fibrosis in cisplatin- and UUO-induced kidney injury.

Conclusions: Our study reveals a novel regulatory interaction between BCAA catabolism and ferroptosis in proximal tubule cells, as well as fibrosis in chronically injured kidneys. Modulating the BCAA pathway could offer therapeutic potential for alleviating kidney injury caused by cisplatin and UUO.

PUB577

Cyclo-glycylproline (cGP) Ameliorates Kidney Failure in Mice with Adenine-Induced Kidney Failure and db/db Mice

Koichi Kikuchi, Shun Watanabe, Takafumi Toyohara, Takehiro Suzuki, Tetsuhiro Tanaka, Takaaki Abe. *Tohoku Daigaku, Sendai, Japan.*

Background: Chronic kidney disease (CKD) is a worldwide public health problem with increasing prevalence, poor outcomes and high cost. Progression of CKD leads to accumulation of uremic toxins such as indoxyl sulfate (IS), trimethlyamine-N-oxide (TMAO), and phenyl sulfate (PS), which further accelerates the progression of CKD and is involved in a variety of CKD-related complications. Therefore, the reduction of the accumulated uremic toxins is important for the protection against CKD.

Methods: Cyclo-glycylproline (cGP) is a cyclic dipeptide containing a condensation bond between glycine and proline. C57BL6 mice were fed a diet containing 0.2% adenine for 6 weeks to create a renal failure model. After the mice were created, they were switched to a normal diet and a diet containing 0.001% cGP for 2 weeks. Blood, urine, and organ samples were collected after administration. Similarly, db/db mice, a diabetic model mouse, were administered a diet containing 0.0031% cGP for 6 weeks, and blood, urine, and organ samples were collected. Plasma creatinine levels and urinary toxins were measured using LCMS/MS. Fibrosis of the renal cortex was also analyzed using Image J.

Results: In mice with adenine-induced renal failure, serum creatinine levels were significantly ($p<0.05$) lower in the renal failure (RF) + cGP-treated group than in the RF group, suggesting improved renal function. In addition, a comparison of the residual tubular area of the kidneys showed that the residual tubular area was significantly increased in the cGP-treated group (RF group: 43%, RF + cGP group: 62%). No reduction in urinary toxins was observed. Next, db/db mice treated with cGP for 6 weeks also had significantly lower plasma creatinine levels compared to the control group. In addition, a comparison between before and after cGP treatment showed that plasma PS levels were significantly reduced in addition to plasma creatinine levels after cGP treatment, suggesting that cGP may be a novel therapeutic agent for DKD, as we have reported PS as an aggravating factor in the onset and progression of diabetic kidney disease (DKD) in a previous study.

Conclusions: It is suggested that oral administration of cGP may improve renal function in renal failure model mice and diabetes model mice.

PUB578

Nephroprotective Effects of Dapagliflozin in the Adenine-Diet Induced Mouse Model of CKD

Maria K. Ougaard, Alex Frias Hernandez, Michael Christensen.
Gubra, Hørsholm, Denmark.

Background: Translational models are essential to identify improved treatment options for chronic kidney disease (CKD). However, most preclinical CKD models do not demonstrate reduced glomerular filtration rate (GFR) or improvement by standard of care, including sodium-glucose cotransporter type 2 inhibitor (SGLT2i) therapy. Here, we evaluated the SGLT2i dapagliflozin in the adenine diet-induced (ADI) mouse model of CKD.

Methods: Male C57BL/6J mice (11 weeks old) were randomised into study groups based on body weight. From day 1, mice received control diet (CTRL mice) or 0.2% adenine-supplemented diet (ADI mice). ADI mice were administered with vehicle or dapagliflozin (10 mg/kg, PO, BID) for 3 weeks. Transdermal GFR (tGFR), urine albumin-to-creatinine ratio (uACR), and urine cystatin C (uCYC) was measured at termination.

Plasma was collected for evaluation of urea, creatinine, and cystatin C levels. The left kidney was weighed and processed for histomorphometric assessment of fibrosis (Col1a1 and Col3a1), tubular injury (KIM-1) and macrophage infiltration (F4/80).

Results: Compared to vehicle-dosed ADI mice, dapagliflozin significantly improved tGFR (520 vs 278 μL/min/100 g body weight ± SEM, p<0.01), uACR (146 vs 279 μg/mg± SEM, p<0.001) and uCYC (122.9 vs 518.2 ng/mL ± SEM, p<0.001). Furthermore, dapagliflozin significantly improved plasma levels of CYC (885.1 vs 1884.2 ng/mL ± SEM, p<0.001), creatinine (10.4 ± SEM vs 29.1 mmol/l ± SEM, p<0.001) and urea (11.6 ± SEM vs 22.7 mmol/l ± SEM, p<0.001). Renal benefits of dapagliflozin therapy were supported by reductions in %-area of Col1a1, Col3a1, KIM-1 and F4/80 IHC.

Conclusions: Dapagliflozin improves functional, biochemical, and histological hallmarks of CKD. These findings support nephroprotective effects of dapagliflozin in CKD and clinical translatability of the ADI mouse model of CKD.

Dose-Dependent Nephroprotective Effects of an ALK5 Inhibitor in the Unilateral Ureteral Obstruction (UUO) Mouse Model of Kidney Fibrosis

Ditte M. Jensen, Alex Frias Hernandez, Maria K. Ougaard, Michael Christensen, Frederikke E. Sembach. *Gubra, Hørsholm, Denmark.*

Background: Development of renal fibrosis is a hallmark of chronic kidney disease (CKD) and an essential factor for progressive loss of kidney function and development of end-stage kidney disease. The unilateral ureteral obstruction (UUO) mouse is a widely used surgery-induced model of CKD with rapid induction of renal inflammation and fibrosis. Here, we characterized the effect of an anti-fibrotic TGF-β type 1 receptor kinase inhibitor (ALK5 inhibitor, ALK5i) on renal outcomes in the UUO mouse.

Methods: Male C57BL/6J mice (9 weeks old) were randomised into study groups based on body weight and were either sham-operated or underwent UUO surgery. UUO mice received vehicle or ALK5i (3, 10 or 30 mg/kg, PO, BID) for 8 days. Vehicle-dosed sham-operated mice served as controls. At termination, both kidneys were weighed, and the obstructed left kidney was processed kidney hydroxy proline (HP) and for quantitative histological assessment of macrophage infiltration (F4/80), fibrosis (Col1a1, Col3a1), myofibroblast activation (α-SMA) and tubular injury (KIM-1). Plasma was sampled for measurement of KIM-1 levels.

Results: UUO mice displayed marked kidney tubular injury, macrophage infiltration, myofibroblast activation, and fibrosis as compared to sham-operated animals. ALK5i dose-dependently improved kidney histology, plasma KIM-1 levels, and kidney HP (0.148 vs 0.214 μg/mg).

Conclusions: ALK5i exerted dose-dependent nephroprotective effects in the UUO mouse. Given the rapid induction of fibrosis and inflammation, the UUO mouse is optimal for screening of compounds with potential anti-inflammatory and anti-fibrotic effects.

PUB580

Effect of Lisinopril on Glomerular and Tubular Injury in a Surgical Rat Model of Progressive CKD and Kidney Failure

Ditte M. Jensen, Alex Frias Hernandez, Maria K. Ougaard, Michael Christensen. *Gubra, Hørsholm, Denmark.*

Background: Development of renal fibrosis is a hallmark of chronic kidney disease (CKD), underlying the progressive loss of kidney function and progression to end-stage kidney disease. The 5/6 nephrectomy (Nx) rat model of CKD displays progressive albuminuria, glomerulosclerosis, tubulointerstitial fibrosis, and loss of kidney function. Here, we characterised the effect of lisinopril, a standard ACE inhibitor, on kidney histopathology, renal biochemical markers, and kidney function in 5/6 Nx rats.

Methods: Male Wistar rats (9 weeks old) underwent either sham operation or 2/3 nephrectomy of the right kidney at week -4 and full nephrectomy of left kidney at week -2. Rats were randomised into study groups at week -1 based on plasma urea, creatinine, and body weight. Sham rats received vehicle and 5/6 Nx rats received either vehicle or Lisinopril (20 mg/kg, PO, QD), for a total of 8 weeks, starting on day 1. Urine was sampled for analysis of albumin-to-creatinine ratio (ACR) (week 7) and the glomerular filtration rate (GFR) (week 8). Terminal plasma was sampled for analysis of urea albumin and creatinine. The remaining right kidney was harvested for quantitative histological assessment of glomerulosclerosis (PAS staining), macrophage infiltration (CD68), tubular injury (KIM-1), and fibrosis (Col1a1).

Results: The 5/6 Nx rat model displayed significant increase of renal biomarkers, GFR decline, glomerulosclerosis, tubular injury, renal macrophage infiltration and fibrosis as compared to sham-operated rats. Treatment with lisinopril significantly reduced albumin-to-creatinine ratio and significantly reduced tubular injury. The 5/6 Nx rat model is applicable for probing preclinical drug candidate for CKD.

Conclusions: 5/6 Nx rats displayed loss of kidney function including declined GFR and increased albuminuria as well as key histopathological features of chronic kidney disease. Treatment with Lisinopril significantly reduced ACR and tubular injury.

Finerenone and Kidney Outcomes in Patients with Heart Failure: The FINEARTS-HF Trial

Finnian R. McCausland,[1] Muthiah Vaduganathan,[1] Brian Claggett,[1] Ian J. Kulac,[1] Akshay Desai,[1] Pardeep Jhund,[6] Alasdair D. Henderson,[6] Meike Daniela Brinker,[2] Robert M. Perkins,[2] Markus Scheerer,[2] Patrick Schloemer,[2] Carolyn S.P. Lam,[8] Michele Senni,[9] Sanjiv Shah,[3] Adriaan A. Voors,[7] Faiez Zannad,[4] Bertram Pitt,[5] John McMurray,[6] Scott D. Solomon.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]Bayer AG, Leverkusen, Germany; [3]Northwestern University Feinberg School of Medicine, Chicago, IL; [4]INSERM, Paris, France; [5]University of Michigan, Ann Arbor, MI; [6]University of Glasgow, Glasgow, United Kingdom; [7]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [8]National Heart Centre Singapore, Singapore, Singapore; [9]Aziende Socio Sanitarie Territoriale Papa Giovanni XXIII, Bergamo, Italy.*

Background: Finerenone has kidney protective effects in patients with chronic kidney disease (CKD) with type 2 diabetes, but effects on kidney outcomes in patients with heart failure (HF) with and without diabetes and/or CKD are not known.

Methods: FINEARTS-HF was a global, randomized clinical trial of finerenone vs. placebo among patients with HF with mildly reduced or preserved ejection fraction. A secondary outcome was a sustained ≥50% eGFR decline or kidney failure (sustained eGFR decline <15 mL/min/1.73m^2; initiation of chronic dialysis; renal transplant). In this prespecified analysis, we also report effects of finerenone on: 1) sustained ≥57% eGFR decline or kidney failure; 2) changes in UACR.

Results: Among 6,001 participants, mean eGFR was 62±20mL/min/1.73m^2; 48% had eGFR<60mL/min/1.73m^2. Overall, 5,797 had baseline UACR data (median 18 [7, 67]mg/g; UACR<30mg/g: 61%; 30-<300mg/g: 30%; ≥300mg/g: 10%). Over 2.6 years median follow-up, the incidence of the composite kidney outcome (≥50% eGFR decline or kidney failure) was low and not affected by finerenone (75 vs. 55 events; HR 1.33; 95%CI 0.94,1.89). Similar results were observed for ≥57% eGFR decline or kidney failure (41 vs. 31 events; HR 1.28; 95%CI 0.80, 2.05). Finerenone reduced UACR by 30% (95%CI 25%, 34%) by 6 months vs. placebo, an effect that persisted throughout follow-up (**Fig.**), irrespective of diabetes ($P_{interaction}$=0.48). Among those with baseline UACR<300mg/g, finerenone reduced the risk of new-onset of macroalbuminuria by 38% (HR 0.62; 95%CI 0.53, 0.73), irrespective of diabetes ($P_{interaction}$=0.96).

Conclusions: Finerenone did not modify eGFR-based kidney outcomes but led to early and sustained reductions in albuminuria and reduced the risk of new-onset of macroalbuminuria, among patients in FINEARTS-HF at low risk of adverse kidney outcomes.

Personalized Recommendations for AKI Using a Kidney Action Team: A Multicenter Randomized Controlled Trial

Abinet M. Aklilu,[1] Steven Menez,[2] Yu Yamamoto,[1] Jack Bitzel,[2] Celia P. Corona Villalobos,[2] Kyle D. O'Connor,[1] Kyra A. Shelton,[1] Sophia Faulkner,[1] Amrita Makhijani,[1] Bashar A. Kadhim,[1] Chirag R. Parikh,[2] Francis P. Wilson.[1] *[1]Internal Medicine, Yale University School of Medicine, New Haven, CT; [2]Internal Medicine, Johns Hopkins University, Baltimore, MD.*

Background: AKI alerts have not improved patient outcomes but AKI care bundles have. We investigated if timely personalized recommendations for AKI are more effective at improving patient outcomes.

Methods: KAT-AKI was a 1:1 randomized investigator-blinded trial conducted at 2 large US hospital systems, Yale and Johns Hopkins, evaluating the effectiveness of rapid, expert-led diagnosis and management recommendations at creatinine-based AKI diagnosis. A physician and pharmacist "Kidney Action Team" (KAT) screened patients with new AKI at the time of an automated AKI alert that was not visible to clinicians. For patients who passed screening, the KAT remotely reviewed their chart and provided structured recommendations in 5 major categories (general diagnostics, volume, potassium, acidosis, medications). Patients were then randomized to either receive a KAT Recommendation Note in their chart or no KAT Note. The primary clinical outcome was a composite of AKI progression, dialysis or mortality within 14 days. The primary process outcome was proportion of recommendations implemented within 24h of randomization.

Results: The trial included 4003 patients 786(20%) of whom were in an ICU. The median(IQR) age was 72(61-81)yrs, 47% were female and 41% had CKD. The median(IQR) time from automated AKI detection to randomization was 56(33-83)min. Nearly all (96%) had at least one general recommendation and 55% had at least one medication-specific recommendation. The process outcome was significantly higher in the intervention arm (0.25[0-0.50] vs 0[0-0.33], p<0.001). The intervention particularly improved ordering of urinalysis, orthostatic vitals, creatine kinase, obstruction evaluation, AKI documentation and medication changes.(Figure) However, there was no difference in the primary clinical outcome, individual components or post-AKI hospital LOS.(Table)

Conclusions: Personalized early recommendations improved AKI documentation and process outcomes but did not change clinical outcomes.(NCT04040296)

Funding: Other U.S. Government Support

14-day Outcomes	Control	Intervention	p-value
Primary composite outcome, n (%)	329 (16.5%)	344 (17.3%)	0.554
AKI progression, n (%)	261 (13.1%)	270 (13.6%)	0.722
Dialysis, n (%)	30 (1.5%)	31 (1.6%)	0.987
Mortality, n (%)	185 (9.2%)	191 (9.6%)	0.762
Length of stay, days, median (IQR)	5.2 (2.2, 9.4)	5.1 (2.1, 10.0)	0.760

Effects of Semaglutide on Kidney Parameters in Patients with Obesity and Nondiabetic CKD

Hiddo J. Heerspink,[1] Ellen M. Apperloo,[1] Niels Jongs,[1] Secundino Cigarran,[2] Maria Jose Soler,[3] Josep M. Cruzado,[4] Annemarie B. van der Aart,[11] Gozewijn D. Laverman,[5] Jacobien Verhave,[12] Sofia B. Ahmed,[6] Roland E. Schmieder,[7] Christoph Wanner,[8] David Cherney,[9] Jose L. Gorriz.[10] *[1]Clinical Pharmacy and Pharmacology, Universiteit Groningen Faculteit Medische Wetenschappen, Groningen, Netherlands; [2]Nephrology Service, Hospital Ruber Internacional, Madrid, Spain; [3]Hospital Universitari Vall d'Hebron, Barcelona, Spain; [4]Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, Spain; [5]Ziekenhuisgroep Twente, Almelo, Netherlands; [6]University of Alberta, Edmonton, AB, Canada; [7]Friedrich-Alexander-Universitat Erlangen-Nurnberg, Erlangen, Germany; [8]Universitatsklinikum Wurzburg Deutsches Zentrum fur Herzinsuffizienz, Wurzburg, Germany; [9]University of Toronto, Toronto, ON, Canada; [10]Universitat de Valencia, Valencia, Spain; [11]Martini Ziekenhuis, Groningen, Netherlands; [12]Rijnstate, Arnhem, Netherlands.*

Background: Semaglutide is a glucagon like peptide 1 receptor agonist which reduces albuminuria and the risk of kidney failure in patients with type 2 diabetes and chronic kidney disease (CKD). We assessed the effects of semaglutide in patients with overweight/obesity and albuminuric CKD without diabetes.

Methods: We conducted a multicenter randomized placebo-controlled clinical trial in adults with CKD (eGFR ≥25 mL/min/1.73m^2, urine albumin-to-creatinine ratio [UACR] ≥30 and <3500 mg/g), body mass index ≥27 kg/m^2 and HbA1c <6.5% without use of hypoglycemic agents. Participants were randomized to 24 weeks treatment with subcutaneous semaglutide 2.4 mg/week or placebo adjunctive to renin-angiotensin-system inhibition when indicated. The primary endpoint was percentage change from baseline in UACR at week 24. Secondary endpoints included change in iohexol measured GFR, estimated GFR, body weight, and systolic blood pressure (BP). Safety was monitored throughout.

Results: Of 125 screened participants, 101 were randomized to semaglutide or placebo. Mean age was 55.8 (SD 12) years, 40 (39.6%) were female, median UACR was 251 mg/g (IQR 100, 584), eGFR 65.0 (SD 25) mL/min/1.73m^2. Chronic glomerulonephritis (N=25) and hypertensive CKD (N=27) were the most common CKD etiologies. At week 24, the placebo-corrected geometric mean change from baseline in UACR with semaglutide was -52.1% (95%CI -65.2, -34.1; p<0.0001). Compared to placebo, mGFR was changed at week 24 with semaglutide by -1.9 mL/min/1.73m^2 (95%CI -8.0, 4.3). Corresponding changes in eGFR-creatinine and eGFR-cystatin C were -1.1 (95%CI -4.8, 2.6) and +2.1 mL/min/1.73m^2 (95%CI -1.7, 5.9), respectively. Semaglutide compared to placebo changed body weight by -9.1 kg (95%CI -11.1, -7.1) and systolic BP by -6.3 mmHg (95%CI -11.1, -1.5). Gastrointestinal adverse events were more often reported in the semaglutide (N=30) versus placebo group (N=15).

Conclusions: Treatment with semaglutide for 24 weeks in patients with overweight/obesity and CKD without diabetes resulted in a robust and clinically meaningful reduction in UACR. These results support further trials to assess long-term efficacy and safety of semaglutide in these patients.

Funding: Commercial Support - Novo Nordisk provided a grant to the University Medical Center Groningen to conduct this investigator initiated clinical trial

Long-Term Effects of Empagliflozin in CKD

William G. Herrington, Natalie Staplin, Nikita Agrawal, Richard Haynes. EMPA-KIDNEY Collaborative Group. *Renal Studies Group, CTSU, NDPH, University of Oxford, Oxford, United Kingdom*.

Background: We observed the cardiorenal effects of ~2 years of empagliflozin within EMPA-KIDNEY for an additional ~2 years of post-trial follow-up (PTFU).

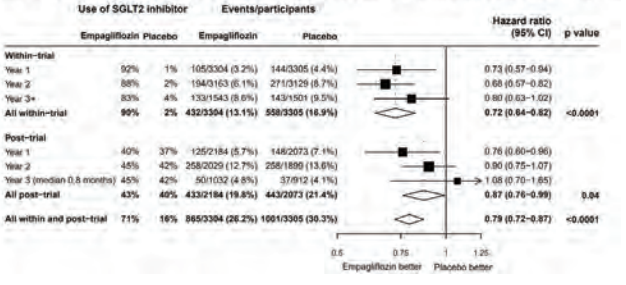
Methods: Patients with an eGFR 20-<45; or 45-<90 and urine ACR of ≥200 mg/g were randomized to empagliflozin versus placebo and provided with allocated treatment for a median of 2 years. Post-trial, participants were then prospectively observed off study treatment. Local doctors were free to commence an open-label SGLT2 inhbitor (blinding to original allocation was maintained). The primary composite outcome was kidney disease progression or CV death for the entire follow-up period (i.e. within-trial + PTFU periods combined).

Results: Of 6609 randomized participants, 4895 entered PTFU and were followed for a median of 2 years. During the post-trial period, any SGLT2 inhibitor use was similar between groups (average use empagliflozin 43% vs placebo 40%). Over the entirety of follow-up a primary outcome occurred in 865/3304 participants (26.2%) in the empagliflozin group and in 1001/3305 (30.3%) in the placebo group (HR=0.79, 95%CI 0.72-0.87). Relative effects on the primary outcome were similar across the key subgroups (by diabetes, eGFR & uACR). There was a 13% (0.87, 0.76-0.99) reduction in risk of the primary outcome post-trial (Figure). This meant the absolute differences in the primary outcome were 57 (SE14) per 1000 at the end of the within-trial period and still 45 (14) at the end of PTFU. Allocation to empagliflozin reduced risk of kidney disease progression (23.5% vs 27.1%), the composite of death or end-stage kidney disease (16.9% vs 19.6%), and CV death (3.8% vs 4.9%).

Conclusions: EMPA-KIDNEY PTFU quantifies more completely the total effects of the short period of 2 years of empagliflozin. Study empagliflozin continued to exert benefit on cardiorenal outcomes for a period after its discontinuation. The post-trial benefit was smaller than the benefit when taking study treatment and appeared to be temporary. To maximize the cardiorenal clinical benefits of SGLT2 inhibitors therefore requires long-term treatment of patients with CKD.

Funding: Commercial Support - Boehringer Ingelheim

Effect of allocation to empagliflozin on progression of kidney disease or CV death



FR-OR104

Efficacy and Safety of HSK21542 for Moderate-to-Severe CKD-Associated Pruritus: A Phase 3 Trial in Hemodialysis Patients

Bi-Cheng Liu,[1] Jianghua Chen,[2] Aimin Zhong,[3] Yaling Bai,[8] Yan Xu,[4] Bi hu Gao,[5] Yanlin Li,[6] Yu Wang.[7] *[1]Zhongda Hospital Southeast University, Nanjing, China; [2]The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China; [3]Jiangxi Provincial People's Hospital, Nanchang, China; [4]The Affiliated Hospital of Qingdao University, Qingdao, China; [5]The Affiliated Zhong-Shan Hospital of DaLian University, Dalian, China; [6]Zhongshan hospital of Traditional Chinese Medicine, Zhongshan, China; [7]The First Affiliated Hospital of Nanchang University, Nanchang, China; [8]The Fourth Hospital of Hebei Medical University and Hebei Tumor Hospital, Shijiangzhuang, China*.

Background: Chronic kidney disease-associated pruritus (CKD-aP) is a common and distressing condition that often presents in patients on hemodialysis(HD), which reduced quality of life and an increased risk of death.HSK21542 is a peripherally restricted and selective agonist of kappa opioid receptors that are considered to be important in treating CKD-aP. Here we reported the results from the phase 3 trial of HSK21542 in HD pts with CKD-aP (21542-302; NCT05135390).

Methods: In this double-blind, placebo-controlled, phase 3 trial, we randomly assigned patients undergoing hemodialysis who had moderate-to-severe pruritus to receive either intravenous HSK21542 (at a dose of 0.3 μg per kilogram of body weight) or placebo three times per week for 12 weeks. The primary outcome was the percentage of patients with an improvement (decrease) of at least 4 points from baseline at week 12 in the weekly mean score on the 24-hour Worst Itching Intensity Numerical Rating Scale (WI-NRS). The secondary outcomes included the percentage of patients with an improvement of at least 3 points in the WI-NRS score at week 12, the change from baseline in itch-related quality-of-life measures, and safety.

Results: A total of 545 patients underwent randomization. The percentage of patients with a decrease of at least 4 points in the WI-NRS score at week 12 was significantly greater in the HSK21542 group than in the placebo group (37.2% vs. 15.0%, P<0.001). The imputed percentage of patients with a decrease of at least 3 points in the WI-NRS score was 51.0% in the HSK21542 group, as compared with 24.2% in the placebo group (P<0.001). HSK21542 also resulted in a significant improvement from baseline to week 12 in itch-related quality of life as measured by the 5-D itch scale and the Skindex-10 scale. HSK21542 was generally safe and well tolerated throughout. Dizziness and hypotension were more common in the HSK21542 group than in the placebo group.

Conclusions: Patients treated with HSK21542 had a significant reduction in itch intensity and improved itch-related quality of life as compared with those who received placebo.

FR-OR105

Efficacy and Safety of Tac or MMF for Children with Steroid-Sensitive but Frequent Relapse or Steroid-Dependent Nephrotic Syndrome: A Nationwide, Multicentre Randomized Study

Fei Liu,[1] Jingjing Wang,[1] Weili Yan,[3] Jianhua Zhou,[4] Xiaoyun Jiang,[5] Fei Zhao,[6] Xiaochuan Wu,[15] Shuzhen Sun,[7] Mo Wang,[8] Hong Xu,[9] Jing Chen,[9] Cuihua Liu,[10] Shipin Feng,[11] Xuhui Zhong,[2] Haidong Fu,[1] Lingfei Huang,[1] Daqing Ma,[12,13] Jie Ding,[2] Qing Ye,[14] Jianhua Mao.[1] *[1]Children's Hospital, Zhejiang University School of Medicine, National Clinical Research Center for Child Health, Hang Zhou, China; [2]Department of Pediatric Nephrology, Peking University First Hospital, Beijing, China; [3]Department of Clinical Epidemiology and Clinical Trial Unit, Children's Hospital of Fudan University, National Children's Medical Center, Shanghai, China; [4]Department of Pediatrics, Tongji Hospital, Tongji Medical College, Huazhong University of Science & Technology, Wuhan, China; [5]Department of Pediatric Nephrology and Rheumatology, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China; [6]Department of Pediatric Nephrology, Children Hospital of Nanjing Medical University, Nanjing, China; [7]Department of Pediatric Nephrology and Rheumatism and Immunology, Shandong Provincial Hospital, Cheeloo College of Medicine, Shandong University, Jinan, China; [8]Department of Nephrology, Children Hospital of Chongqing Medical University, National Clinical Research Center for Child Health and Disorders, Ministry of Education Key Laboratory, Chongqing, China; [9]Department of Nephrology, Children's Hospital of Fudan University, Shanghai, China; [10]Department of Nephrology and Rheumatology, Zhengzhou Key Laboratory of Pediatric Kidney Disease Research, Children Hospital Affiliated to Zhengzhou University, Zhengzhou, China; [11]The Affiliated Women's and Children's Hospital, School of Medicine, UESTC; Chengdu Women's and Children's Central Hospital, Chengdu, China; [12]Perioperative and Systems Medicine Laboratory, Children's Hospital, Zhejiang University School of Medicine, National Clinical Research Center for Child Health, Hangzhou, China; [13]Division of Anaesthetics, Pain Medicine & Intensive Care, Department of Surgery and Cancer, Faculty of Medicine, Imperial College London, Chelsea and Westminster Hospital, London, United Kingdom; [14]Department of Laboratory Medicine, Children Hospital, Zhejiang University School of Medicine, National Clinical Research Center for Child Health, Hangzhou, China; [15]Department of Pediatrics, The Second Xiangya Hospital of Central South University, Hunan, China*.

Background: Both tacrolimus (TAC) and mycophenolate mofetil (MMF) are recommended for children with frequently relapsing nephrotic syndrome (FRNS) and steroid-dependent nephrotic syndrome (SDNS). However, their comparative effectiveness and safety have not been evaluated through randomized controlled studies.

Methods: In this multicenter, randomized, open-label, controlled trial, 270 children aged 2-18 years with FRNS/SDNS were allocated at a 1:1 ratio to receive either TAC (0.025-0.05 mg/kg, orally twice daily) or MMF (10-15 mg/kg, orally twice daily) for one year, along with a tapering regimen of steroids. The primary endpoint was 1-year relapse-free survival. Relapse frequency, cumulative steroid dosage and safety profiles were also evaluated. The trial was prospectively registered at ClinicalTrials.gov (NCT04048161).

Results: A total of 243 out of 270 patients completed the trial, and their data were analyzed and reported. Compared with MMF, TAC significantly reduced the risk of relapse by 65% (HR = 0.35, 95% CI: 0.21–0.56, P <0.0001) in the intention-to-treat analysis. This difference was also significant after adjusting for the per-protocol analysis

(HR = 0.36, 95% CI: 0.22–0.58, P <0.0001). Among the relapsed patients, the median time to first relapse was 225.5 days in the TAC group and 165.5 days in the MMF group. The TAC group had fewer annual relapses (mean [SD], 0.319 [0.936] vs. 0.778 [1.274]) and a reduced cumulative dose of steroid (0.221 [0.103] vs. 0.337 [0.222] mg/kg/d) than did the MMF group. The safety profile was similar in both groups, with infections being the most common adverse event.

Conclusions: In children with FRNS/SDNS, a 1-year course of TAC therapy significantly extended the period of relapse-free survival in comparison to MMF treatment.

Funding: Commercial Support - The STAMP trial was sponsored by Hangzhou Zhongmei Huadong Pharmaceutical Co., Ltd., Hangzhou, Zhejiang, China, Government Support - Non-U.S.

Deferoxamine for the Prevention of Cardiac Surgery-Associated AKI: The DEFEAT-AKI Randomized Clinical Trial

David E. Leaf,[1,2] Megan L. Krajewski,[3,2] Edy Y. Kim,[4,2] Jochen D. Muehlschlegel,[5] Aranya Bagchi,[6,2] Shahzad Shaefi.[3,2] *[1]Division of Renal Medicine, Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Beth Israel Deaconess Medical Center, Boston, MA; [4]Division of Pulmonary and Critical Care Medicine, Brigham and Women's Hospital, Boston, MA; [5]Johns Hopkins University, Baltimore, MD; [6]Massachusetts General Hospital, Boston, MA.*

Background: Multiple lines of evidence support a central role of free iron in the pathogenesis of acute kidney injury (AKI). Patients undergoing cardiac surgery may be particularly susceptible to iron-mediated AKI due to the profound hemolysis that occurs from cardiopulmonary bypass and intraoperative transfusion of red blood cells.

Methods: In an NIH-funded, phase II, multicenter, double-blind trial, we randomly assigned adult patients undergoing coronary artery bypass graft and/or valve surgery with cardiopulmonary bypass considered to be at high-risk of AKI to receive a 12-hour IV infusion of deferoxamine (30 mg/kg) or an equal volume of saline placebo beginning immediately after induction of anesthesia. The primary outcome was the occurrence of AKI within 7 days, defined according to the KDIGO consensus criteria, incorporating changes in serum creatinine, urine output, and kidney replacement therapy. Secondary outcomes included AKI stage, receipt of kidney replacement therapy, atrial fibrillation, prolonged receipt of invasive mechanical ventilation, sepsis, and time to liberation from IV vasoactive medications.

Results: We enrolled 301 patients from 3 large academic medical centers in Boston, MA and assigned 151 to deferoxamine and 150 to placebo. AKI occurred in 99 patients (65.6%) in the deferoxamine group and in 108 (72.0%) in the placebo group (relative risk, 0.91; 95% CI, 0.78–1.06). Rates of secondary outcomes were similar between groups (**Table**), as were rates of adverse events.

Conclusions: Among adult patients undergoing cardiac surgery, prophylactic administration of IV deferoxamine did not reduce the occurrence of AKI.

Funding: NIDDK Support

Outcome*	Deferoxamine (n=151)	Placebo (n=150)	Relative Risk (95% CI)

Prolonged (>24h) IMV	31 (20.5)	27 (18.0)	1.14 (0.72–1.81)
Sepsis	7 (4.6)	2 (1.3)	3.48 (0.73–16.48)
Time (h) to liberation from IV vasoactive medications – median (IQR)	29 (20–59)	30 (15–50)	N/A

Data are shown as no. (%) unless otherwise specified.
Abbreviations: h, hours; IMV, invasive mechanical ventilation.
*All outcomes were assessed within the first 7 days postoperatively unless otherwise specified
**For atrial fibrillation, only patients without atrial fibrillation at baseline were included (102 deferoxamine-treated patients at 90 placebo-treated patients)

FR-OR107

Effect of a Perioperative Hypotension Avoidance Strategy vs. a Hypertension Avoidance Strategy on the Risk of AKI

Amit X. Garg.[1,2] Maura Marcucci,[3,4] Meaghan S. Cuerden,[5] Jessica M. Sontrop,[5] PJ Devereaux.[3] Perioperative Ischemic Evaluation-3 (POISE-3) Investigators. *[1]Medicine, Western University, London, ON, Canada; [2]Population Health Research Institute, Hamilton, ON, Canada; [3]McMaster University, Hamilton, ON, Canada; [4]Humanitas University, Milan, Italy; [5]London Health Sciences Centre, London, ON, Canada.*

Background: Acute kidney injury (AKI) is a common complication of the over 200 million noncardiac surgeries performed worldwide each year. We conducted a pre-specified substudy of the POISE-3 trial to determine whether a peri-operative hypotension-avoidance strategy versus a hypertension-avoidance strategy alters the risk of postoperative AKI (substudy protocol publication: PMID 35024154).

Methods: This was a two-group, open-label, randomized trial of 7307 high-risk patients from 110 hospitals in 22 countries undergoing noncardiac surgery. Patients were ≥ 45 years old and took at least one antihypertensive medication. hypotension-avoidance strategy ... target intraopertive mean arterial pressure (MAP) ≥80 mmHg ... on day of surgery and for 2 days after, aim to hold renin-angiotensin-aldosterone system inhibitors ... stepwise use other long-term antihypertensive medications if SBP ≥130 mmHg hypertension-avoidance strategy ... target intraoperative MAP ≥60 mmHg ... continue all antihypertensive medications before and after surgery. The primary outcome was postoperative AKI, defined as an increase in serum creatinine concentration of either ≥26.5 μmol/L (≥0.3 mg/dL) within 48 hours of randomization or ≥50% within 7 days of randomization.

Results: The hypotension-avoidance group (n=3654) vs. the hypertension-avoidance group (n=3653), ... used fewer antihypertensive medications .....specifically, 6% vs. 38% of patients used an ACEi or ARB on the day of surgery, ...6% vs. 47% one day after surgery, ... 7% vs. 50% two days after surgery. ... spent less intraoperative time with a MAP < 80 mmHg (average 28% vs. 45% of the time) ... had no difference in mean SBP/DBP/MAP outside the operation (day of surgery and two days after surgery) ... had no difference in the risk of AKI ..... (15.1% vs. 14.4%; relative risk 1.05 [95% CI, 0.93 to 1.19]). Results were consistent with multiple alternate continuous and categorical definitions of AKI and in the subgroup with baseline chronic kidney disease.

Conclusions: In this trial of patients undergoing noncardiac surgery, the risk of postoperative AKI did not differ between patients randomized to receive a hypotension-avoidance strategy versus a hypertension-avoidance strategy. Trial registration: NCT03505723.

Impact of Semaglutide on Infections and COVID-19: Data from the FLOW Trial

Brian Rayner,[1] Kenneth W. Mahaffey,[2] Johannes F. Mann,[3,4] Richard E. Pratley,[5] Katherine R. Tuttle,[6,7] Nicolas Belmar,[8] Heidrun Bosch-Traberg,[8] Ole K. Jeppesen,[8] Minh Chau Tran,[8] Gil Chernin,[9] Peter Rossing.[10,11] *[1]Groote Schuur Hospital and University of Cape Town, Cape Town, South Africa; [2]Stanford Center for Clinical Research, Department of Medicine, Stanford School of Medicine, Palo Alto, CA; [3]KfH Kidney Centre, München, Germany; [4]University Hospital, Friedrich-Alexander University, Erlangen, Germany; [5]Translational Research Institute, AdventHealth Research Institute, Orlando, FL; [6]Division of Nephrology, University of Washington School of Medicine, Seattle, WA; [7]Providence Medical Research Center, Providence Inland Northwest Health, Spokane, WA; [8]Novo Nordisk A/S, Søborg, Denmark; [9]Hebrew University of Jerusalem, Kaplan Medical Center, Rehovot, Israel; [10]Steno Diabetes Center Copenhagen, Herlev, Denmark; [11]Department of Clinical Medicine, Kobenhavns Universitet, Copenhagen, Denmark.*

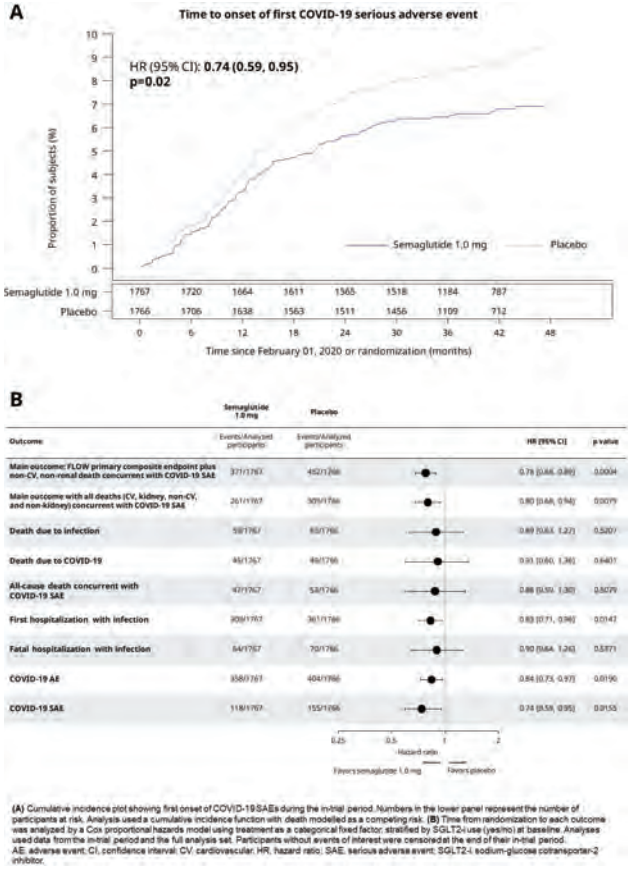
Background: In the FLOW trial, once-weekly subcutaneous semaglutide 1.0 mg reduced the risk of major kidney and cardiovascular (CV) events in people with type 2 diabetes (T2D) and chronic kidney disease (CKD). This analysis assessed the impact of semaglutide on the incidence of infection adverse events (AEs) and COVID-19 AEs in people with T2D and CKD.

Methods: The main outcome of this analysis was time from randomization to the primary FLOW study outcome (composite of onset of kidney failure, sustained reduction in eGFR, kidney death, or CV death, regardless of COVID-19) including non-CV, non-kidney death concurrent with a COVID-19 serious AE (SAE). A pre-defined MedDRA search was applied for COVID-19 events. Other infection SAEs were collected by standard AE reporting.

Results: Participants (N=3533) had a mean (SD) age of 66.6 (9.0) years, and HbA_{1c} of 7.8% (1.3) at baseline. 73.6% received a COVID-19 vaccine during the trial. Semaglutide reduced the risk of the main outcome compared to placebo (hazard ratio [HR] [95% CI] 0.78 [0.68, 0.89]; p=0.0004). The semaglutide group also had a lower incidence of infection SAEs (17.9% vs 21.3%; p=0.01), and COVID-19 SAEs (6.7% vs 8.8%; p=0.02). Semaglutide also reduced the risk of an additional endpoint comprising the primary composite outcome including all-cause death concurrent with a COVID-19 SAE (HR [95%CI] 0.80 [0.68, 0.94]; p=0.0079). Semaglutide reduced the risk of a COVID-19 AE or SAE, and risk of hospitalization with an infection (**Figure**).

Conclusions: In the FLOW trial, semaglutide was associated with lower rates of infection SAEs, COVID-19 AEs and COVID-19 SAEs, in people with T2D and CKD.

Funding: Commercial Support - Novo Nordisk A/S



(A) Cumulative incidence plot showing first onset of COVID-19 SAEs during the in-trial period. Numbers in the lower panel represent the number of participants at risk. Analysis used a cumulative incidence function with death modelled as a competing risk. (B) Time from randomization to each outcome was analyzed by a Cox proportional hazards model using treatment as a categorical fixed factor, stratified by SGLT2-i use (yes/no) at baseline. Analyses used data from the in-trial period and the full analysis set. Participants without events of interest were censored at the end of their in-trial period.
AE, adverse event; CI, confidence interval; CV, cardiovascular; HR, hazard ratio; SAE, serious adverse event; SGLT2-i, sodium-glucose cotransporter-2 inhibitor.

Effect of Semaglutide on Mortality Outcomes in the FLOW Trial

Richard E. Pratley,[1] Kenneth W. Mahaffey,[2] Johannes F. Mann,[7,8] Katherine R. Tuttle,[3,4] Peter Rossing,[5,6] Thomas Idorn,[9] Jens-Peter David,[9] Heidrun Bosch-Traberg,[9] Ole K. Jeppesen,[9] Willem A. Bax,[10] Pieter Gillard,[11] Mustafa Arici,[12] Minara Shamkhalova,[13] Vlado Perkovic.[14] FLOW Trial Committees and Investigators. *[1]AdventHealth Translational Research Institute, Orlando, FL; [2]Department of Medicine, Stanford Center for Clinical Research, Stanford University School of Medicine, Palo Alto, CA; [3]Division of Nephrology, University of Washington School of Medicine, Seattle, WA; [4]Providence Medical Research Center, Providence Inland Northwest Health, Spokane, WA; [5]Steno Diabetes Center Copenhagen, Herlev, Denmark; [6]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; [7]KfH Kidney Centre, Munich, Germany; [8]University Hospital, Friedrich-Alexander University, Erlangen, Germany; [9]Novo Nordisk A/S, Søborg, Denmark; [10]Medical Centre Alkmaar, Alkmaar, Netherlands; [11]Department of Endocrinology, University Hospitals Leuven - KU Leuven, Leuven, Belgium; [12]Faculty of Medicine, Hacettepe University, Ankara, Turkey; [13]Department of Diabetic Kidney Disease, Endocrinology Research Centre, Moscow, Russian Federation; [14]University of New South Wales, Sydney, NSW, Australia.*

Background: In FLOW, semaglutide 1.0 mg (sema) reduced the risk of major kidney and cardiovascular (CV) events. Here, we assess the effect of sema on mortality outcomes.

Methods: Participants (≥18 years with T2D and CKD) were randomized 1:1 to receive once-weekly subcutaneous sema or placebo. Cause of death was confirmed by an event adjudication committee.

Results: Compared with placebo, sema reduced the risk of all-cause death (HR [95% CI] 0.80 [0.67, 0.95]), CV death (0.71 [0.56, 0.89]), and death of undetermined cause (0.62 [0.42, 0.91]; **Figures 1, 2**). The most common causes of CV death were sudden cardiac death (2.8% sema vs 3.8%) placebo and heart failure (0.3% vs 0.7%). Sema had no effect on non-CV/non-kidney or kidney death. The most common causes of non-CV/non-kidney death were infection (3.3% vs 3.7%) and malignancy (1.4% vs 1.2%; **Figure 2**).

Conclusions: In FLOW, sema reduced the risk of all-cause and CV death by 20% and 29%, and death of undetermined cause by 38%, relative to placebo.

Funding: Commercial Support - Novo Nordisk

Effects of 3.0 mEq/L [K+] Dialysate with Sodium Zirconium Cyclosilicate (SZC) vs. 2.0 mEq/L [K+] Dialysate without SZC on Cardiac Arrhythmia Rates

Wolfgang C. Winkelmayer,[1] David M. Charytan,[2] Christopher B. Granger,[3] John P. Middleton,[4] Charles A. Herzog,[5,6] Glenn M. Chertow,[7] James M. Eudicone,[8] James A. Tumlin.[9] ADAPT Investigators. *[1]Baylor College of Medicine, Houston, TX; [2]New York University Grossman School of Medicine, New York, NY; [3]Duke University Duke Clinical Research Institute, Durham, NC; [4]Duke University Medical Center, Durham, NC; [5]Hennepin Healthcare System Inc, Minneapolis, MN; [6]University of Minnesota Medical School, Minneapolis, MN; [7]Stanford University School of Medicine, Stanford, CA; [8]AstraZeneca Pharmaceuticals LP, Wilmington, DE; [9]NephroNet, Inc., Atlanta, GA.*

Background: K^+ homeostasis may be a modifiable risk factor for atrial fibrillation (AF) and clinically significant cardiac arrhythmias (CSCA) in patients receiving hemodialysis (HD). The optimal approach to managing serum K^+ (sK^+) and dialysate K^+ (dK^+) is uncertain.

Methods: ADAPT was a prospective, randomized, open-label 2×2 crossover trial. Adults receiving HD 3 d/wk for ≥3 mo with hyperkalemia (two predialysis sK^+ measurements 5.1–6.5 mEq/L) underwent placement of an implantable cardiac loop recorder and were randomized 1:1 to one of two crossover sequences: A) $2.0K^+/2.5Ca^{2+}$ mEq/L dialysate bath without SZC ($2.0K^+$/noSZC) for 8 wks followed by $3.0K^+/2.5Ca^{2+}$ mEq/L dialysate bath with SZC on non-HD days ($3.0K^+$/SZC) for 8 wks, or B) vice versa. SZC starting dose (on non-HD days) was 5 g, up titrated weekly to 15 g to maintain predialysis sK^+ 4.0–5.5 mEq/L. sK+ was measured pre-HD and <30 min prior to rinse back once weekly. The primary outcome was the rate of AF episodes >2 min duration. Key secondary outcomes included rate of CSCA and proportion of sK^+ values within an 'ideal' window of 4.0-5.5 mEq/L.

Results: Overall, 88 pts (mean age 57.1 yrs, 51.1% male, mean sK^+ 5.5 mmol/L) were randomized. Over 25.5 person yrs (PY), 296 AF episodes were recorded among 9 (10.2%) patients. The crude AF rate was lower with $3.0K^+$/SZC (9.7/PY) vs $2.0K^+$/noSZC (13.4/PY); modelled rate ratio (RR): 0.52; 95% CI 0.41; 0.65; *P*<0 001. The rate of CSCA was lower with $3.0K^+$/SZC (6.8/PY) than $2.0K^+$/noSZC (10.2/PY); RR: 0.47; 95% CI 0.38; 0.58; *P*<0.001. The mean proportion of monitoring time spent in AF (0.22% vs 0.53%; RD: -0.30%; 95% CI -1.11%; 0.45%) did not differ significantly between exposure groups. Pts with $3.0K^+$/SZC had lower odds of sK+ being outside the ideal window; OR: 0.27; 95% CI 0.12; 0.35. Hypokalemia occurred in 33 pts with $3.0K^+$/SZC vs 58 patients with $2.0K^+$/noSZC. Hyperkalemia occurred in 3 pts with $3.0K^+$/SZC vs 1 pt with $2.0K^+$/noSZC. Adverse events occurred in 37 vs 28 pts with $3.0K^+$/SZC vs $2.0K^+$/noSZC.

Conclusions: Among patients receiving maintenance HD with a history of hyperkalemia, a combination of dK^+ 3.0 mEq/L and SZC on non-HD days reduced the rates of AF, CSCA, and post-HD hypokalemia compared with dK^+ 2.0 mEq/L and no SZC.

Haemodiafiltration or Haemodialysis for Kidney Failure: Totality of Evidence Based on Individual Patient Data Meta-Analysis from Randomised Controlled Trials

Peter J. Blankestijn,[1] Robin W. Vernooij,[1,2] Michiel L. Bots.[2] The CONVINCE Scientific Committee and the HDF Pooling Project Investigators. *[1]Department of Nephrology and Hypertension, Universitair Medisch Centrum Utrecht, Utrecht, Netherlands; [2]Julius Center for Health Sciences and Primary Care, Universitair Medisch Centrum Utrecht, Utrecht, Netherlands.*

Background: Recently a 23% lower mortality risk was reported in patients with kidney failure treated with high-dose haemodiafiltration compared to conventional high-flux haemodialysis (NEJM 2023). Nevertheless, it remains unclear whether treatment effects differ across subgroups, whether there is a dose-response relationship with convection volume, and the effects on cause-specific mortality. The goal of this individual patient data meta-analysis was to analyse the effect of haemodiafiltration on death from any cause compared with standard haemodialysis.

Methods: We searched MEDLINE, Embase, and CENTRAL from inception to until July 2024 for all randomised controlled trials, comparing online haemodiafiltration with haemodialysis, that were designed to measure mortality outcomes. The primary outcome was all-cause mortality. Hazard ratios were generated using Cox proportional hazards regression models reporting hazard ratios (HR) and 95% confidence intervals (95% CI). Subgroup analyses on predefined patient characteristics and dose-response analyses, using natural splines, on convection volume were performed (PROSPERO registration: CRD42024511514).

Results: Five trials (CONTRAST, ESHOL, Turkish HDF study, French HDF study, CONVINCE, n=4153 patients; 2070 receiving haemodialysis, 2083 receiving haemodiafiltration) proved eligible. After a median follow-up of 30 months (Q1-Q3: 24-36), all-cause mortality occurred in 477 patients (23.3%) treated with haemodiafiltration compared with in 558 patients (27.2%) treated with haemodialysis (HR: 0.84; 95%CI: 0.74 to 0.95). There was no evidence for a differential effect across subgroups. A graded relationship between convection volume and mortality risk was apparent: as the convection volume increases, the mortality risk decreases.

Conclusions: Online haemodiafiltration reduces all-cause mortality and cardiovascular mortality compared with haemodialysis in patients with kidney failure. Results do not differ across patient and treatment characteristics and the risk reduction appears dose-dependent.

Funding: Government Support - Non-U.S.

FR-OR112

Exploratory Post Hoc Analysis of the CONVINCE Randomized Controlled Trial: Differential Treatment Effects of Hemodiafiltration (HDF) and Hemodialysis (HD) on Quality of Life

Krister Cromm,[1] Felix Fischer,[2] Claudia M. Barth,[3] Bernard J. Canaud,[4] Jorgen B. Hegbrant,[5] Giovanni Strippoli,[6] Mark Woodward,[7] Michiel L. Bots,[8] Peter J. Blankestijn,[8] Matthias Rose.[2] The CONVINCE Scientific Committee and CONVINCE Investigators. *[1]Fresenius Medical Care AG, Bad Homburg, Germany; [2]Center for Patient-Centered Outcomes Research, Charite - Universitatsmedizin Berlin, Berlin, Germany; [3]B. Braun Avitum AG, Melsungen, Germany; [4]Universite de Montpellier, Montpellier, France; [5]Lunds Universitet, Lund, Sweden; [6]Universita degli Studi di Bari Aldo Moro, Bari, Italy; [7]The George Institute for Global Health, Sydney, NSW, Australia; [8]Universitair Medisch Centrum Utrecht, Utrecht, Netherlands.*

Background: The CONVINCE trial provided compelling evidence that high-dose HDF is associated with a reduction in all-cause mortality when compared to standard high-flux HD. On average, participants receiving HDF also reported a slower decline in their self-reported health status. So far, it is unclear whether there are specific patient groups for whom HDF is particularly effective in maintaining quality of life.

Methods: Out of 1360 participants of the multicenter, randomized controlled CONVINCE trial comparing HDF with HD, 1211 (89%) provided data on eight domains of self-reported health status (Physical Function, Fatigue, Pain Interference, Sleep Disturbance, Anxiety, Cognitive Function, Depression, Ability to Participate in Social Roles and Activities). These were assessed every 3 months over the course of the trial. We investigated differential treatment effects of HDF compared to HD by age group (<50 yrs (n = 240), 50-65 yrs (514), >65 yrs (606)), biological sex (male (856), female (504)), history of cardiovascular disease (yes (612), no (748)), diabetes at baseline (yes (481), no (879)) and dialysis vintage (<2 yrs (548), 2-5 yrs (414), >5 yrs (395)) by testing the significance of interaction terms between treatment and respective subgroup in a longitudinal linear mixed model.

Results: We observed significant differential treatment effects for dialysis vintage on physical function (p = 0.028), for age on pain interference (p = 0.044) and for history of cardiovascular disease on cognitive function (p = 0.048).

Conclusions: High-dose HDF has overall benefits on quality of life. These benefits may vary slightly between patient subgroups, but these differences appear to be small. Findings should be weighed carefully due to multiple statistical comparisons.

FR-OR113

Varoglutamstat Increases Glomerular Filtration in Elderly Patients without Signs of Proteinuria and Potentially Offers a New Approach to Treat Diabetic Kidney Disease (DKD)

Frank T. Weber,[1] Christine Wenzkowski,[1] Michael Karl Schaeffer,[1] Sylvia Schell-Mader,[1] Antje Meyer,[1] Stefan Tasler,[1] Katharina Fuchs,[1] Asger R. Bihlet,[2] Kevin Carroll,[5] Tobias B. Huber.[3,4] *[1]Vivoryon Therapeutics N.V., Halle (Saale), Germany; [2]NBCD A/S, Herlev, Denmark; [3]Department of Medicine, Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany; [4]Hamburg Center for Kidney Health, Hamburg, Germany; [5]KJC Statistics Ltd, Dublin, Ireland.*

Background: Varoglutamstat is an oral, small molecule inhibitor of glutaminyl cyclases (QPCT/L) designed to target Alzheimers disease pathology. In the phase 2b VIVIAD study, effects on kidney function as judged by a significant and clinical meaningful improvement of the estimated glomerular filtration rate (eGFR) were observed over time by slope analysis.

Methods: VIVIAD (NCT04498650) is a multicenter, randomized, placebo-controlled, double-blind, parallel group dose-finding Phase 2b study in 259 patients with Mild Cognitive Impairment (MCI) and early Alzheimers disease (AD) with a treatment duration between 48 and 96 weeks. Participants received 300 mg or 600 mg varoglutamstat, or placebo, twice-daily.

Results: A significant increase of 3.4 mL/min/1.73m2/year ($p<0.001$) the annualized rate of change of eGFR vs placebo was found in the overall study population. Further investigations in patients with diabetes (N=32) showed an increase of > 8 mL/min/1.73m2/year (p=0.02). Additional effects in the diabetes subgroup included a reduction in liver transaminases (AST/ALT) of 6 units average, a mild weight loss (- 4 kg), and a reduction in mean arterial pressure (- 5 mmHg) at week 48. Semi quantitative urine dip-stick evaluation did not reveal signs of sustained proteinuria. The safety assessment showed that varoglutamstat was safe and well-tolerated. There were no meaningful differences in adverse events observed in renal and metabolic system organ classes versus placebo or the total population. Earlier preclinical data suggest beneficial effects for varoglutamstat on inflammation and fibrosis. However, the specific functional improvement of the kidney was unexpected and additional mechanistic studies are ongoing.

Conclusions: The significant increase in eGFR and several findings of the VIVIAD study support a further development in a new indication like diabetic kidney disease. The precise molecular mechanism of action of varoglutamstat is under investigation. Importantly, a clinical study in a relevant population and with additional endpoints like measures of albuminuria/proteinuria (UACR/UPCR), inflammation and fibrosis-related biomarkers, in addition to eGFR slope analysis, is in planning.

FR-OR114

Replacing Mycophenolate Mofetil by Everolimus in Kidney Transplant Recipients to Increase Vaccine Immunogenicity: The PREPARE-iVAC Trial

A. Lianne Messchendorp, Jan-Stephan Sanders. The RECOVAC Consortium. *Nephrology, Universitair Medisch Centrum Groningen, Groningen, Netherlands.*

Background: Vaccine immunogenicity is diminished in kidney transplant recipients (KTR) due to the use of immunosuppressive agents. Patients on long-term everolimus (EVR) elicit a higher immune response after vaccination compared to patients on mycophenolate mofetil (MMF). Whether short-term replacement of MMF by EVR improves vaccine immunogenicity needs yet to be established.

Methods: In this multicenter, open-label randomized controlled trial, KTR were randomized 1:1 to continue MMF or replace MMF by EVR (ClinicalTrials.gov:NCT05924685). After randomization, patients received a COVID-19 vaccination (mRNA Omicron XBB.1.5) at 6 weeks and two herpes zoster (HZ) vaccinations (Recombinant Zoster Vaccine) at 10 and 14 weeks. Primary objective was to investigate whether vaccine immunogenicity was superior in the EVR group by comparing neutralizing antibody titers 28 days after COVID-19 vaccination, for which a minimum sample size of 88 patients was calculated. Secondary objectives were to evaluate antibody responses 28 days after COVID-19 and HZ vaccination and safety of replacing MMF by EVR.

Results: A total of 110 KTR from 7 UMCs across the Netherlands were randomized, 55 to MMF and 55 to EVR. Neutralizing Omicron XBB.1.5 titers (PRNT50) after COVID-19 vaccination were comparable between the MMF and EVR group (log10 difference -0.07 [-0.37-0.22], p=0.62). Results were supported by SARS-CoV-2 S1-specific IgG levels (4280 (1425-14250) vs. 3870 (1018-9535) BAU/mL, p=0.38). After second HZ vaccination however, the VZV gE-specific IgG titer was higher in the EVR group (1101 (440-2078) vs. 2192 (888-4523) 50% endpoint titer, p=0.004). Next to usual side effects of EVR (edema, oral ulcers, thrombocytopenia), more bacterial infections were observed with EVR (11.1 vs. 27.3%, p=0.03), which were in general easily manageable. There were no cases of acute rejection.

Conclusions: Short-term replacement of MMF by EVR does not improve COVID-19 vaccine immunogenicity but may enhance HZ vaccine immunogenicity in KTR. This discrepancy may be explained as patient have received multiple prior COVID-19 vaccinations, whereas this was a primary HZ vaccination. These data indicate that replacing MMF by EVR may be a valuable strategy to improve vaccine immunogenicity in case of novel viral threats and contribute to pandemic preparedness.

Impact of Targeted Hyponatremia Correction on 30-Day Mortality and Rehospitalization Rate

Julie Refardt,[1,2] Laura Potasso,[2] Anissa Pelouto,[3] Claudia Gregoriano,[8] Markus Koster,[6] Ivana Dora Vodanovic,[10] Dario Norello,[4] Svenja Ravioli,[5] Sadrija Cukoski,[5] Lana Sambula,[10] Nikola Rapsch,[5] Sophie Monnerat,[2] Julia Beck,[2] Deborah R. Vogt,[2] Martina L. Bontognali,[6] Philipp Schuetz,[8] Adrienne A. Zandbergen,[3] Alessandro Peri,[4] Darko Kastelan,[10] Gregor Lindner,[7] Jörg D. Leuppi,[9] Beat Mueller,[8] Volker R. Burst,[5] Ewout J. Hoorn,[3] Mirjam Christ-Crain.[2] The HIT Study Group. *[1]Endocrinology, Erasmus MC, Rotterdam, Netherlands; [2]Endocrinology, Universitatsspital Basel, Basel, Switzerland; [3]Nephrology, Erasmus MC, Rotterdam, Netherlands; [4]Endocrinology, Careggi University Hospital, Florence, Italy; [5]Nephrology, Universitatsklinikum Koln, Cologne, Germany; [6]Endocrinology, Kantonsspital St Gallen, Sankt Gallen, Switzerland; [7]Endocrinology, Kantonsspital Solothurn, Solothurn, Switzerland; [8]Endocrinology, University Hospital Aarau, Aarau, Switzerland; [9]Endocrinology, Kantonsspital Baselland, Liestal, Switzerland; [10]Klinicki Bolnicki Centar Zagreb, Zagreb, Croatia.*

Background: Chronic hyponatremia is associated with increased mortality and rehospitalization rates, but it is unclear whether this relationship is causal. This leads to uncertainties in correction, which is therefore often slow or non-existent. The aim of this study was therefore to evaluate the direct effects of targeted hyponatremia correction versus routine care on mortality and rehospitalization rates.

Methods: Randomized controlled, superiority, parallel-group, international multi-center trial with blinded outcome assessment. Hospitalized participants with hyponatremia <130 mmol/L from nine tertiary centers across Europe were assigned to undergo either targeted correction of plasma sodium levels according to guidelines (intervention) or routine care for hyponatremia (control). The primary outcome was the combined risk of death or rehospitalization within 30 days of study inclusion.

Results: 2174 patients were included in the primary analysis of which 1079 (49.6%) were randomized to the intervention and 1095 (50.4%) to the control group. Through the intervention, 641 (60.4%) patients reached normonatremia, compared to 493 (46.2%) patients in the control group. Within 30 days, death or rehospitalization occurred in 93 (8.6%) and 138 (13.0%) patients in the intervention group, compared to 93 (8.5%) and 151 (14.0%) patients in the control group, leading to a combined event rate of 21.0% (224/1079 patients) in the intervention group and 22.2% (239/1095 patients) in the control group, estimated absolute difference in proportions [95% CI] -1.2% [-4.7, 2.3], p=0.50. This result was robust in the per protocol analysis and in subgroup analyses considering hyponatremia etiology, severity or correction rate.

Conclusions: In this large hyponatremia intervention trial, targeted plasma sodium correction did not reduce 30-day mortality and rehospitalization rates. This suggests that in hospitalized patients, chronic hyponatremia is a marker of disease severity rather than a cause of worse outcome.

Background: VALIANT (NCT05067127) is a double-blind, PBO-controlled trial investigating the efficacy/safety of pegcetacoplan (PEG), a C3/C3b inhibitor, in adolescents (≥12 yrs) and adults with native or post-transplant recurrent C3G or primary IC-MPGN.

Methods: Patients (pts) received PEG (SC infusion 2x/wk) or PBO (randomized 1:1) for 26 wks. The primary endpoint was log-transformed ratio of uPCR at wk 26 vs. baseline to measure proteinuria reduction vs. PBO.

Results: 124 pts were randomized to PEG (n=63) or PBO (n=61). The primary endpoint was met:68.3% (95% CI –76.3, –57.7) uPCR reduction in PEG vs. PBO arms at wk 26 (p<0.0001; **Table**). Results were consistent across all subgroups (disease type, age, and transplant status). Robust reductions in C3c staining and clinically meaningful eGFR stabilization were observed with PEG vs. PBO (**Table**). Treatment-emergent AE frequency and severity were similar between arms. None of the 4 serious infections (3 PEG; 1 PBO) were attributed to encapsulated bacteria. 1 death occurred in the PEG arm due to COVID-19 pneumonia (unrelated to PEG).

Conclusions: PEG, a C3/C3b inhibitor, is the first therapy to achieve significant and clinically meaningful reductions in proteinuria (68.3% vs. PBO) and C3c staining and eGFR stabilization, compared with PBO in pts ≥12 yrs with C3G or primary IC-MPGN and was well tolerated.

Table. VALIANT disposition and primary and key secondary efficacy outcomes (wk 26 vs. BL, unless otherwise specified)

	PEG (N=63) --- C3G (n=51) Primary IC-MPGN (n=12) --- Adolescents (n=28) Adults (n=35) --- Native (n=58) Posttransplant (n=5)	PBO (N=61) --- C3G (n=45) Primary IC-MPGN (n=16) --- Adolescents (n=27) Adults (n=34) --- Native (n=57) Posttransplant (n=4)	Difference in PEG vs. PBO arms	P-value for PEG vs. PBO arms
Primary Endpoint (Overall Population)				
uPCR change, LS mean log-transformed ratio (95% CI)	–67.3% (–74.9, –57.5%)	3.2% (–8.3, 16.2%)	Relative reduction (95% CI): 68.3% (–76.3, –57.7)	p<0.0001[a]
Key Secondary Endpoints (Overall Population)				
Composite renal endpoint (≥50% uPCR and ≤15% eGFR reductions) at wk 26, n (%)	32 (50.8)	2 (3.3)	OR (95% CI): 29.4 (6.5, 132.2)	p<0.0001[a]
≥50% uPCR reduction, n (%)	39 (61.9)	3 (4.9)	OR (95% CI): 32.1 (8.8, 116.9)	p<0.0001[a]
C3G histologic index activity score change, adjusted LS mean change (95% CI)[b]	n=35 –3.5 (–4.7, –2.2)	n=34 –2.5 (–3.8, –1.2)	Adjusted LS mean difference (95% CI): –1.0 (–2.8, 0.8)	p=0.2753[a]
Reduced C3c renal biopsy staining of ≥2 OOM, n (%)[b]	n=35 26 (74.3)	n=34 4 (11.8)	OR (95% CI): 27.4 (6.5, 115.9)	Nominal p<0.0001
eGFR change, LS mean change (95% CI), mL/min/1.73m²	–1.6 (–6.0, 2.8)	–7.9 (–11.7, –4.2)	Adjusted LS mean difference (95% CI): 6.3 (0.5, 12.1)	Nominal p=0.0322

BL, baseline; C3G, C3 glomerulopathy; CI, confidence interval; eGFR, estimated glomerular filtration rate; IC-MPGN, immune complex membranoproliferative glomerulonephritis; LS, least squares; OOM, orders of magnitude; OR, odds ratio; PBO, placebo; PEG, pegcetacoplan; pts, patients; SE, standard error; uPCR, urine protein to creatinine ratio; wk, week.
Data cut-off date: June 20, 2024. Includes all randomized pts. Endpoints listed in order of hierarchical testing. [a]2-sided p value. [b]In adults with evaluable BL and wk 26 renal biopsies.

Background: Semaglutide reduced risks of major kidney outcomes, cardiovascular (CV) events, and death from any cause in participants with type 2 diabetes (T2D) and chronic kidney disease (CKD) in the FLOW trial. The aim of this analysis was to assess kidney outcomes by baseline CKD severity.

Methods: Participants had T2D with eGFR 50–75 mL/min/1.73m² and urine albumin–creatinine ratio (UACR) >300–<5000 mg/g, or eGFR 25–<50 mL/min/1.73m² and UACR >100–<5000 mg/g. They were randomized to subcutaneous semaglutide 1 mg once weekly or placebo. The FLOW primary outcome was a composite of kidney failure (initiation of chronic kidney replacement therapy, eGFR <15 ml/min/1.73m²), ≥50% eGFR decline, or death due to kidney or CV causes. Participants were categorized by baseline eGFR and UACR.

Results: Among 3533 participants, 30% (n=1069) were women. At baseline, their mean age was 67 years, mean eGFR was 47 mL/min/1.73 m^2, and median UACR was 568 mg/g. The hazard ratio for the primary outcome was 0.76 (95% CI 0.66–0.88) for semaglutide versus placebo over a median of 3.4 years. Consistent results were observed across eGFR and UACR categories (**Figure**).

Conclusions: Semaglutide safely reduced risks of major kidney outcomes irrespective of CKD severity defined by baseline eGFR or UACR in participants with T2D and CKD in the FLOW trial.

Pain Coping Skills Training for Patients Receiving Hemodialysis: The HOPE Consortium Randomized Clinical Trial

Laura M. Dember,[1] Jesse Y. Hsu,[1] Rajnish Mehrotra,[2] Kerri L. Cavanaugh,[3] Sahir Kalim,[4] David M. Charytan,[5] Michael J. Fischer,[6] Manisha Jhamb,[7] Kirsten L. Johansen,[8] William Becker,[9] Francis J. Keefe,[10] David M. White,[11] Paul L. Kimmel,[12] Daniel Cukor.[5] HOPE Consortium. *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]University of Washington, Seattle, WA; [3]Vanderbilt University Medical Center, Nashville, TN; [4]Massachusetts General Hospital, Boston, MA; [5]New York University Grossman School of Medicine, New York, NY; [6]University of Illinois Hospital & Health Sciences System, Chicago, IL; [7]University of Pittsburgh School of Medicine, Pittsburgh, PA; [8]Hennepin Healthcare System Inc, Minneapolis, MN; [9]Yale University School of Medicine, New Haven, CT; [10]Duke University School of Medicine, Durham, NC; [11]American Association of Kidney Patients, Tampa, FL; [12]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.*

Background: Chronic pain is common among individuals undergoing maintenance hemodialysis and contributes to poor quality of life, depression, and anxiety. Pharmacologic management of pain is challenging in this patient population.

Methods: In this multicenter randomized controlled trial, patients undergoing hemodialysis and experiencing chronic moderate or severe pain were randomly assigned 1:1 to a cognitive behavioral intervention called pain coping skills training or to usual care. The intervention consisted of 12 weeks of remotely delivered coach-led sessions followed by 12 weeks of daily telephone-based interactive voice response sessions. The primary outcome was pain interference measured by the Brief Pain Inventory (BPI) Interference subscale at 12, 24, and 36 weeks, with change from baseline to 12 weeks serving as the primary endpoint. Secondary outcomes included pain intensity, pain catastrophizing, quality of life, depression, and anxiety.

Results: 643 patients enrolled at 16 centers and 103 affiliated dialysis facilities were randomized to pain coping skills training (319 participants) or usual care (324 participants), yielding a cohort with 44.8% female, 45.9% Black, and 18.5% Hispanic participants. At Week 12 (primary endpoint), the pain coping skills training group had a larger reduction in the BPI Interference score compared with usual care [between-group difference (95% CI) -0.49 (-0.85, -0.12); p=0.009]. The effect persisted at Week 24 [difference -0.48 (-0.86, -0.11)] but was diminished at Week 36 [difference -0.34 (-0.72, 0.04)]. A decrease in BPI Interference ≥1 point (minimal clinically important difference) occurred in 50.9% of those in pain coping skills training vs 36.6% in usual care at 12 weeks [OR (95% CI) 1.79 (1.28, 2.49)], and 55.0% vs 42.8% at 24 weeks [OR 1.59 (1.13, 2.24)]. Favorable changes with the intervention were also apparent for secondary outcomes of pain intensity, quality of life, depression, and anxiety at Weeks 12 and/or 24, and for pain catastrophizing at Weeks 24 and 36.

Conclusions: Among patients undergoing maintenance hemodialysis, pain coping skills training had benefits on pain interference and other pain-associated outcomes. Clinicaltrials.gov NCT04571619

Prospective Randomized Trial of Humacyte's Acellular Tissue Engineered Vessel vs. Autologous Arteriovenous Fistula for Hemodialysis Access

Mohamad A. Hussain,[1] Charles K. Ozaki,[1] Ernest E. Moore,[3] Zakaria Khondker,[2] Shamik J. Parikh,[2] Laura E. Niklason.[2] *[1]Vascular and Endovascular Surgery, Brigham and Women's Hospital, Boston, MA; [2]Humacyte Global Inc, Durham, NC; [3]Ernest E Moore Shock Trauma Center, Denver Health Main Campus, Denver, CO.*

Background: Arteriovenous fistulas (AVFs) are a preferred method for initial vascular access in patients requiring hemodialysis (HD). Failure of AVF maturation can drive increased catheter use and associated increased morbidity/mortality. An alternative vascular access option that offers the benefits of AVFs, including a low infection rate, without the associated maturation failure, is needed.

Methods: We conducted a phase 3, prospective, multicenter, two-arm, randomized controlled trial in 242 subjects with HD undergoing surgical vascular access creation. Receipt of the Acellular Tissue Engineered Vessel (ATEV) or autologous AVF was randomized. Co-primary outcomes were 6-month functional patency and 12-month secondary patency after access creation. Secondary outcomes included comparisons of access usability and infection rates.

Results: Mean participant age was 58.6 years; 29% were female. ATEV recipients had higher rates of 6-month functional patency (81% vs 68% for AVF) and 12-month secondary patency (68% vs 62% for AVF) (p=0.0071; joint test for co-primary endpoints). Mean duration of ATEV use was also significantly higher than AVF (7.5 vs 6.1 months, p=0.0162). Female ATEV subjects experienced higher rates of 6-month functional patency (89% vs. 55% for AVF) and 12-month secondary patency (81% vs. 49% for AVF) (p<0.0001; joint test). Access-related infection rates were comparable (ATEV 5.8% vs AVF 4.1%). No unexpected safety events were observed.

Conclusions: Humacyte ATEV had better access functional patency and usability versus AVFs at one year. Female subjects experienced improved outcomes, supporting ATEV consideration as a novel access option for subjects at high risk for AVF non-maturation. (CLN-PRO-V007; ClinicalTrials.gov, NCT03183245).

Efficacy and Safety of Dapagliflozin in Patients with CKD Stages 4-5

Chi-Chih Hung, Yi-Wen Chiu, Shang-Jyh Hwang. DAPA advKD Trial Investigators. *Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan.*

Background: Importance: Dapagliflozin improves renal outcome in patients with chronic kidney disease (CKD), but the effect of late initiating dapagliflozin when estimated glomerular filtration rate (eGFR) <25 mL/min/1.73m^2 remains uncertain. Objective: To evaluate the efficacy and safety of dapagliflozin in patients with CKD stage 4 and 5.

Methods: Design: Dapagliflozin and Renal Surrogate Outcomes in Advanced Chronic Kidney Disease (DAPA advKD) trial (NCT05196347) was an investigator-led, randomized, open-label, trial designed to recruit 180 patients with eGFR 10-30 mL/min/1.73m^2 and eGFR decline ≥2.5 mL/min/1.73m^2/yr. Interventions: Patients were randomized 2:1 to dapagliflozin (5-10 mg/d) + integrated CKD care or integrated CKD care alone. Main outcomes: The primary outcome was a preservation of eGFR decline ≥0.75 ml/min/1.73m^2/yr. The 1st secondary outcome (renal endpoint) was a composite of renal replacement therapy, eGFR <5 mL/min/1.73m^2, renal or cardiovascular (CV) death, or a >50% decline in eGFR. The 2nd secondary outcome (renal and CV endpoint) was a composite of renal outcome as above, acute kidney injury (AKI) and heart failure. Predefined safety outcomes were measured.

Results: Over a median of 1.62 years, total eGFR slope (mL/min/1.73m^2/yr) were -2.24 (-4.70 to -0.62) and -3.67 (-7.16 to -1.25) in the dapagliflozin and control groups, respectively; the primary outcome of eGFR slope difference was 1.06 (0.10 to 2.32) (p=0.019, linear mixed model). The secondary (renal) outcome occurred in 24/120 (20%) and 21/60 (35%) participants in the dapagliflozin and control groups, respectively (hazard ratio, 0.50 (0.28 to 0.89), p=0.019). The secondary (renal and CV) outcome occurred in 25/120 (21%) and 21/60 (35.0%) participants in the dapagliflozin and control groups, respectively (hazard ratio, 0.52 (0.29 to 0.93), p=0.028). There were higher incidence of AKI and heart failure in the control group, but higher incidence of eGFR dip in the dapagliflozin group. There was no difference of 5p- major adverse CV event and electrolyte imbalance.

Conclusions: Among patients with eGFR 10-30 mL/min/1.73m^2, the risks of eGFR decline and composite renal outcomes were lower with dapagliflozin than with control group.

Safety and Efficacy of Bardoxolone Methyl in Patients with Autosomal Dominant Polycystic Kidney Disease

Shuchi Anand,[1] Suneeta Chimalapati,[6] Maria E. Montez-Rath,[1] Angie Goldsberry,[5] Melanie Chin,[5] Colin J. Meyer,[5] Samina Khan,[5] Rafael José Esteban de la Rosa,[4] Arlene B. Chapman,[2] Bradley A. Warady,[3] Glenn M. Chertow.[1] *[1]Stanford University, Stanford, CA; [2]University of Chicago Pritzker School of Medicine, Chicago, IL; [3]Children's Mercy Kansas City, Kansas City, MO; [4]Universidad de Granada, Granada, Spain; [5]Reata, Boston, MA; [6]Biogen Inc, Cambridge, MA.*

Background: Interstitial fibrosis is a universal finding in nephrectomy samples from patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD). Bardoxolone methyl (BARD) activates the nuclear-factor-related factor 2 pathway, hypothesized to attenuate inflammation and fibrosis.

Methods: A phase 3, randomized 1:1, placebo-controlled clinical trial (NCT03918447) was designed to test the efficacy of BARD among patients with ADPKD and reduced eGFR (30-90ml/min/1.73 m^2 for patients 12-55 years, 30-44ml/min/1.73 m^2 for patients 56-70 years) and evidence of rapid eGFR decline (≥ 2.0ml/min/year for 2 years). The primary endpoint was off-treatment change from baseline eGFR at week 108 and the secondary endpoint was change from baseline at end of treatment (week 100). The trial was stopped prematurely by the sponsor, prior to meeting target enrollment.

Results: A total of 667 patients were enrolled, and eGFR (mean [SD]) at baseline were similar between randomized groups (BARD 51.6 [15.5] vs placebo 51.2 [16.8] mL/min/1.73m^2, respectively). 79 and 70 patients randomized to the placebo and Bard group had week 108 eGFR. There was no difference in the off-treatment (week 108) change from baseline (0.97 [95% CI –1.25, 3.19] mL/min/1.73m^2), although end of treatment (week 100) eGFR was higher among patients randomized to the BARD group (7.9 [95% CI 6.41, 9.47] mL/min/1.73m^2; **Fig 1**)). A majority of patients (89% placebo, 94% BARD) had treatment-emergent adverse events (TEAEs). The most common AEs in the group randomized to BARD were muscle spasms, aminotransferase elevations, and nausea. No one experienced serious cardiac events; one death occurred in the study (avalanche accident).

Conclusions: Among the subset of patients with available data on the primary endpoint in the FALCON trial, there was no evidence for preservation of eGFR among patients randomized to BARD at the end of 100 weeks of treatment and an 8-week washout period.

Small Molecule Premature Termination Codon Readthrough Therapy: A Phase 2 Pediatric and Adult Trial in Nonsense Mutation Alport Syndrome

Daniel P. Gale,[1,2] Detlef Bockenhauer,[1,8] Melanie M. Chan,[1,6] Katie Wong,[2,1] Johannes Pospiech,[3] Tobias Bohnenpoll,[3] Philipp Skroblin,[3] Olivier Radresa,[3] Uwe Andag,[3] Nicole Endlich,[4] Behzad Najafian,[5] Sumit Aggarwal.[7] *[1]Renal Medicine, University College London, London, United Kingdom; [2]UK National Registry of Rare Kidney Diseases (RaDaR), Bristol, United Kingdom; [3]Evotec International GmbH, Gottingen, Germany; [4]Nipoka GmbH, Greifswald, Germany; [5]Department of Laboratory Medicine and Pathology, University of Washington, Seattle, WA; [6]Imperial College London, London, United Kingdom; [7]Eloxx Pharmaceuticals Inc, Watertown, MA; [8]Department of Paediatrics, Katholieke Universiteit Leuven, Leuven, Belgium.*

Background: Alport syndrome is the second commonest Mendelian kidney disease and shows strong correlation between severity and mutation type, with Nonsense Mutation Alport Syndrome usually associated with kidney failure by late adolescence. ELX-02 is a small molecule that induces readthrough of premature (but not native) stop codons and is efficiently taken up by cells expressing megalin, allowing full length protein to be made by podocytes or tubular cells in the presence of a nonsense mutation.

Methods: An open label study was performed in 3 patients with autosomal recessive Alport syndrome, aged 13, 13 and 19, who each had the stop codon *COL4A4*:p.(Ser969Ter) *in trans* with another pathogenic *COL4A4* variant. Participants required eGFR >60ml/min/1.73m^2 and >0.5g per day proteinuria. Each received 0.75mg/kg subcutaneous ELX-02 daily for 8 weeks with follow-up for a further 12 weeks. Proteinuria was assessed before, during and after treatment. Filtration Slit Density (FSD), with automated 3D-SIM (structured illumination microscopy), and Foot Process Width (FPW), with stereology in a masked fashion, were assessed in pre- and post-treatment kidney biopsies.

Results: No significant safety signals were observed. Immunostaining for Collagen IV alpha 5 chain was globally (2 patients) or partially (1 patient) absent before treatment and detectable segmentally following treatment in all 3 patients. FSD improved in all patients after 2 months' treatment: pre-treatment 1.0 (48.5% of the mean (±standard deviation) of 2.06 (±0.12) in healthy individuals), 1.54 (74.8%) and 0.8 (38.8%); post-treatment: 1.5 (72.8%), 1.75 (85.0%) and 1.73 (80.6%), p=0.06, paired t-test. FPW was significantly reduced in 2 patients, changing by -19%, +6% and -45% respectively. Proteinuria was variable but reduced in 2 of the 3 patients during or following treatment.

Conclusions: This first evidence of efficacy of a gene-targeted therapy in a podocyte-based Mendelian disease justifies a follow-on randomised-controlled study to quantify the potential for clinical benefit. Therapeutic readthrough of premature termination codons in Alport Syndrome suggests other genes expressed by megalin-expressing kidney cells may be targetable with this approach.

Associations of APOL1 Biallelic and Monoallelic Kidney Disease Variants with CKDs in West Africans: H3Africa KDRN Study

Rasheed A. Gbadegesin,[1] Ifeoma I. Ulasi,[5] Yemi R. Raji,[2] Manmak Mamven,[3] Adebowale A. Adeyemo,[4] Titilayo O. Ilori,[7] Adaobi Solarin,[6] Paul L. Kimmel,[8] Frank C. Brosius,[9] Matthias Kretzler,[10] Jeffrey B. Hodgin,[10] Martin Pollak,[11] Barry I. Freedman,[12] Winfred W. Williams,[13] Rulan S. Parekh,[14] Dwomoa Adu,[15] Akinlolu Ojo.[16] *[1]Pediatrics, Duke University School of Medicine, Durham, NC; [2]University of Ibadan, Ibadan, Oyo, Nigeria; [3]University of Abuja, Abuja, Federal Capital Territory, Nigeria; [4]National Human Genome Research Institute, Bethesda, MD; [5]Boston University Chobanian & Avedisian School of Medicine, Boston, MA; [6]Lagos State University, Ojo, Lagos, Nigeria; [7]Boston University, Boston, MA; [8]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [9]University of Arizona, Tucson, AZ; [10]University of Michigan, Ann Arbor, MI; [11]Beth Israel Deaconess Medical Center, Boston, MA; [12]Wake Forest University School of Medicine, Winston-Salem, NC; [13]Massachusetts General Hospital, Boston, MA; [14]Women's College Hospital, Toronto, ON, Canada; [15]University of Ghana Medical School, Accra, Greater Accra, Ghana; [16]The University of Kansas Medical Center, Kansas City, KS.*

Background: Background: Apolipoprotein L1 gene (*APOL1*) variants are risk factors for chronic kidney disease (CKD) among African Americans (AA). Data are sparse on the genetic epidemiology and clinical association of *APOL1* variants with CKD in West Africans, a major group among the AA population.

Methods: The Human Health and Heredity in Africa (H3Africa) Kidney Disease Research Network studied 8,355 participants from Ghana and Nigeria: 4,712 participants with CKD stages 2-5, 866 participants with biopsy proven glomerular diseases, and 2777 controls (eGFR ≥90 ml/min/1.73m2 and no proteinuria). The association of CKD with high-risk carriers (two *APOL1* alleles) and low-risk carriers (<2 *APOL1* alleles) was determined by fitting logistic regression models controlling for covariates, including clinical site, age, and sex.

Results: Monoallelic and biallelic *APOL1* variant prevalence were 43.0% and 29.7%, respectively. Compared with low-risk carriers, the adjusted odds of CKD and focal segmental glomerulosclerosis (FSGS) among high-risk carriers were 1.25 (95%CI: 1.11-1.40) and 1.84 (95%CI 1.30-2.61), respectively. Compared with those with no *APOL1* variant (G0/G0), persons with one APOL1 variant (G0/G1, G0/G2) had higher odds of CKD (OR 1.18, 95% CI 1.04-1.33) and FSGS (adjusted OR 1.61; 95% CI 1.04-2.48). Covariates did not modify the association of 1-2 *APOL1* variants with CKD or FSGS.

Conclusions: Both monoallelic (G1/G0, G2/G0) and biallelic (G1/G1, G2/G2, G1/G2) risk variants have 18% and 25% higher odds of CKD, and 61% and 84% higher odds of FSGS, respectively. Individuals with monoallelic *APOL1* variant should be classified as being at high risk for CKD and FSGS.

Safety and Efficacy of Low-Dose CD19-Targeted CAR T Cells in Refractory Pediatric Systemic Lupus Erythematosus (SLE)

Xue He,[1] Yingzi Zhang,[2] Fei Liu,[1] Qiu-yu Li,[1] Jingjing Wang,[1] Jianhua Mao.[1]
[1]Nephrology, Children's Hospital of Zhejiang University School of Medicine, Hangzhou, China; [2]Chongqing Precision Biotech Co., Ltd., Chongqing, China.

Background: Recent advancements indicate that CAR T cell therapy shows promise for treating SLE, there remains a significant lack of data in pediatrics. This study evaluates the safety and efficacy of CAR T-cell therapy in pediatric SLE by utilizing autologous CD19-targeted CAR T cells (MC-1-50) to treat refractory pediatric SLE.

Methods: In this Phase I/II study (NCT06222853), MC-1-50 CAR T cells were manufactured by the PRIMCAR manufacturing platform. Most patients(pts) were preconditioned with fludarabine (30 mg/m^2) and cyclophosphamide (300 mg/m^2) daily for 3 days, while some received dosage reduction due to infections or intolerance. Toxicity was graded by CTCAE V5.0, CRS and ICANS were graded by ASTCT criteria.

Results: AS of August 2024, 11 pts were infused with MC-1-50 (Table). 9 pts (81.8%) experienced CRS, all at grade 1. 2 pts (18.2%) experienced grade 1 ICANS. There were no unexpected adverse events (AE) or seriou AE reported. 5 pts were followed for over 3 months (3M), with 4 achieving SRI-4 response. Notably, for Pt 5, though there was persistent proteinuria at 3M, all other active indicators had normalized, and her scr levels had declined from a peak of 786 to 169μmol/L, accompanied by a urine output from 50-100ml/day to 1000mL/day. The other pts exhibited varying degrees of improvement. CAR T cells expansion was observed in all dose levels, and B cells were rapidly eliminated within 7 days after infusion while its reconstitution was observed in most pts by 2M. It was noted that the majority of these B cells were predominantly naive B cells.

Conclusions: The treatment of refractory pediatric SLE with a low dose of CD19-targeted CAR-T Cells (MC-1-50) demonstrated an excellent safety profile while exhibiting high efficacy.

Felzartamab for IgA Nephropathy: Final Results of the IGNAZ Study

Jonathan Barratt,[1] Jürgen Floege,[2] Richard A. Lafayette,[3] Brian M. Schwartz,[4] Uptal D. Patel,[4] Paul Manser,[4] Lisa Kivman,[4] Stefan Haertle,[5] Nicola Faulhaber,[5] Anjali G. Thakur,[5] Sean Barbour.[6] *[1]University of Leicester, Leicester, United Kingdom; [2]Div. Nephrology and Cardiology, RWTH Aachen University, Aachen, Germany; [3]Glomerular Disease Center, Stanford Medicine, Palo Alto, CA; [4]Human Immunology Biosciences, Inc., a Biogen Company, South San Francisco, CA; [5]MorphoSys AG, Planegg, Germany; [6]Division of Nephrology, The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada.*

Background: Felzartamab is a monoclonal antibody that binds to CD38 on plasma cells–the likely source of pathogenic Gd-IgA1 and autoantibodies in IgA nephropathy (IgAN). The randomized, double-blind, placebo-controlled phase 2a IGNAZ study assessed the efficacy and safety of felzartamab vs placebo (PBO) in patients with IgAN. Final 24-month data are reported.

Methods: Patients aged 18–80 years with biopsy-confirmed IgAN, proteinuria ≥1.0 g/d (≥0.5 g/d for Japanese patients), and eGFR ≥30 mL/min per 1.73m2 using renin-angiotensin inhibitors ≥3 months were randomized 1:1:1:1 in Part 1 to PBO (n=12) or felzartamab in 1 of 3 arms: 2 doses in 15 days (M1; n=12), 5 doses in 2 months (M2; n=11), and 9 doses in 5 months (M3; n=13). In Part 2, 6 Japanese patients received open-label M3.

Results: Patients were 67% men, with a mean age of 41.6 years, UPCR of 1.7 g/g, and eGFR of 74.6 mL/min per 1.73m2. In Part 1, 40/48 patients completed treatment. Treatment with felzartamab led to rapid, clinically meaningful reductions in UPCR vs PBO, with the greatest effect in the M3 arm (Fig A). Mean eGFR declined less in the felzartamab arms vs PBO (Fig B). Among felzartamab arms, IgA reductions were rapid and durable (lasting 19 months after the last dose); IgG recovered by 6–9 months. Efficacy in Part 2 was similar to that of the Part 1 M3 arm. Treatment-emergent AEs were typically grade 1 or 2 and were not dose-dependent. The most common treatment-related AE was infusion-related reaction (IRR), usually on dose one. There was one treatment-related serious AE of IRR. Five patients discontinued felzartamab for IRR/hypersensitivity. The infection incidence was similar across felzartamab arms; all were grade 1 or 2 and non-serious.

Conclusions: Felzartamab was generally well tolerated and led to sustained proteinuria reduction and reduced eGFR decline vs PBO, indicating potential disease modification in patients with IgAN. Investigation of felzartamab in patients at high risk for loss of kidney function is warranted.

Long-Term Results from the ORIGIN Phase 2b Study of Atacicept for the Treatment of IgA Nephropathy (IgAN)

Jonathan Barratt,[1] Sean Barbour,[2] Robert M. Brenner,[3] Kerry Cooper,[3] Xuelian Wei,[3] Necmi Eren,[4] Jürgen Floege,[5] Vivekanand Jha,[6] Sung Gyun Kim,[7] Bart D. Maes,[8] Richard K. Phoon,[9] Harmeet Singh,[10] Vladimir Tesar,[11] Richard A. Lafayette.[12] ORIGIN Phase 2b Study Team. *[1]University of Leicester, Leicester, United Kingdom; [2]The University of British Columbia, Vancouver, BC, Canada; [3]Vera Therapeutics, Inc., Brisbane, CA; [4]Kocaeli Universitesi, Kocaeli, Turkey; [5]Rheinisch-Westfalische Technische Hochschule Aachen, Aachen, Germany; [6]The George Institute for Global Health India, New Delhi, India; [7]Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea; [8]AZ Delta vzw, Roeselare, Belgium; [9]The University of Sydney, Sydney, NSW, Australia; [10]Western Nephrology, Arvada, CO; [11]Univerzita Karlova, Praha, Czechia; [12]Stanford University, Stanford, CA.*

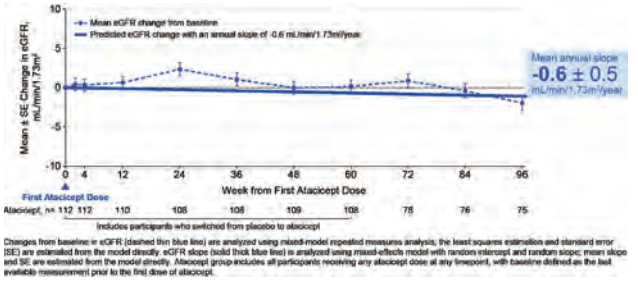
Background: B-cell activating factor (BAFF) and A proliferation-inducing ligand (APRIL) play key roles in IgAN pathogenesis. Atacicept is a humanized TACI-Fc fusion protein that inhibits both BAFF and APRIL and is self-administered at home by subcutaneous injection. The ORIGIN Phase 2b study met the primary endpoint with a statistically significant and clinically meaningful UPCR reduction compared to placebo at 24 weeks, with a further reduction and eGFR stabilization through 36 weeks. This analysis reports 96-week results from the open-label extension (OLE).

Methods: Participants with IgAN who received atacicept or placebo in the 36-week Phase 2b, randomized, blinded study period were enrolled in an OLE and received atacicept 150 mg for an additional 60 weeks. Key efficacy outcomes were changes in galactose-deficient IgA1 (Gd-IgA1), percentage of participants with hematuria, UPCR, and eGFR over 96 weeks. Long-term safety data were also evaluated.

Results: There were 113 participants who received ≥1 atacicept dose. Over 96 weeks, there were sustained reductions (mean ±SE) in Gd-IgA1 (-65.9% ±1.7%), the percentage of participants with hematuria (-75.0%, 95% CI -87.3, -58.8; in participants with baseline hematuria), and UPCR (-52.2% ±4.7%). Importantly, long-term eGFR was maintained near baseline levels with a mean annualized slope of -0.6 ±0.5 mL/min/1.73m^2/year at 96 weeks (Figure). Safety data showed atacicept was generally well tolerated.

Conclusions: Gd-IgA1, hematuria, and UPCR reductions with eGFR stabilization through 96 weeks demonstrate that atacicept offers a potentially safe, long-term, disease-modifying treatment for IgAN. Specifically, the conversion of an eGFR profile in patients with IgAN from one of steady decline to one representative of the general population without kidney disease[1] supports the potential of atacicept to decrease the high lifetime risk of kidney failure in patients with IgAN. 1. Baba M. PLoS One 2015.

Funding: Commercial Support - Vera Therapeutics, Inc.



Changes from baseline in eGFR (dashed thin blue line) are analyzed using mixed-model repeated measures analysis, the least squares estimates and standard error (SE) are estimated from the model directly. eGFR slope (solid thick blue line) is analyzed using mixed-effects model with random intercept and random slope; mean slope and SE are estimated from the model directly. Atacicept group includes all participants receiving any atacicept dose at any timepoint, with baseline defined as the last available measurement prior to the first dose of atacicept.

Background: Endothelin-1 upregulation and endothelin receptor type A (ETA) activation causes proteinuria, kidney inflammation and fibrosis in patients with IgA nephropathy (IgAN). A phase 2 trial was designed to characterize the efficacy, safety and optimal doses of SC0062 in patients with IgAN (2-SUCCEED, NCT05687890).

Methods: We conducted a randomized placebo-controlled double-blind trial in adults with biopsy proven IgAN and eGFR ≥30 mL/min/1.73m^2 with urinary protein: creatinine ratio (UPCR) ≥0.75 g/g or proteinuria ≥1 g/24h despite using maximum tolerated doses of ACEIs or ARBs. Patients were randomized 1:1:1:1 to SC0062 5, 10, 20 mg or matching placebo once daily. The primary efficacy outcome was percent change from baseline in UPCR in 24h urine samples after 12 weeks of treatment. Secondary endpoints included changes in eGFR over time. Safety outcomes including treatment emerging adverse events (TEAE) and serious adverse events (SAE) were recorded throughout the trial.

Results: A total of 131 patients (mean age 42 years [standard deviation (SD) 11]; mean eGFR 72 mL/min/1.73 m^2 [SD 24] and median 24h UPCR 1.2 g/g [Q1-Q3 0.90-1.53]) were randomized to placebo (n=34) or SC0062 5 mg (n=33), 10 mg (n=32), or 20 mg (n=32). SC0062 reduced UPCR versus placebo throughout the treatment period. At Week 12, placebo-corrected geometric mean changes (95% confidence interval) from baseline in UPCR with SC0062 5, 10, and 20 mg were −27.8% (−42.9, −8.6), −20.4% (−37.2, 0.8), and −38.1% (−51.3, −21.3), respectively. The proportion of participants with a reduction in UPCR ≥ 30% from baseline in the placebo, SC0062 5, 10 and 20 mg dose groups were 33.3%, 48.5%, 62.5%, and 71.0%, respectively. No differences in eGFR were observed among treatment groups. The proportion of participants with TEAEs or SAEs was balanced among treatment groups. The rates of peripheral edema were lower in the SC0062 5, 10 and 20 mg groups, at 3%, 0% and 0%, respectively, compared to 14.7% in the placebo group.

Conclusions: In patients with IgA nephropathy and significant proteinuria, the novel ETA selective antagonist SC0062 showed a clinically meaningful reduction in proteinuria and a favorable safety profile with no risk of peripheral edema.

Out-of-Sequence Placement of Deceased Donor Kidneys Is Exacerbating Inequities

Miko Yu,[1] Syed A. Husain,[1] Joel T. Adler,[2] Lindsey Maclay,[1] Jesse D. Schold,[3] Sumit Mohan.[1] *[1]New York-Presbyterian/Columbia University Irving Medical Center, New York, NY; [2]Dell Seton Medical Center at The University of Texas, Austin, TX; [3]University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Deceased donor kidney allocation in the US follows an objective algorithm that is designed to balance equity & utility. Organ procurement organizations (OPOs) have the ability to circumvent this system & are increasingly turning to out-of-sequence (OOS) allocation of organs, allowing them to allocate at their own discretion.

Methods: Using SRTR transplant registry & offer data from 2020-23, we identified all organ offers for deceased donor kidneys, including those placed OOS. We examined the prevalence of OOS allocation, using Gini coefficients as a measure of inequality at the center level.

Results: From 2020 to 2023, OOS allocation increased nearly 9-fold, from 342 to 2,882 kidneys, representing 1 in 7 deceased donor kidney transplants – including kidneys across the quality spectrum (**Figure 1**). By 2023, 91% of OPOs were using OOS allocation. Only 14 transplant centers accounted for a third of all OOS transplants, creating a system-wide inequity that is reflected in the persistently high Gini coefficient despite the rapid OOS increase (**Table 1**). OOS recipients include a greater proportion of older, white & male recipients as well as those with private insurance & preemptive patients.

Conclusions: There has been a sharp increase in OOS allocation of deceased donor kidneys across the spectrum of organ quality. Most of these kidneys are being placed at a small number of transplant centers, creating preferential access to transplantation for a subset of patients & exacerbating patient & system-level inequities in access to transplantation.

Funding: NIDDK Support, Other NIH Support - NIH grants DK114893, DK116066, DK126739 and DK130058, Private Foundation Support

Gini coefficients for all OPOs and transplant centers, ranging from 0 (perfect equality) to 1 (perfect inequality)

Center Type	Year	In-sequence Gini	Out-of-sequence Gini
OPO	2020	0.31	0.89
	2021	0.31	0.65
	2022	0.32	0.53
	2023	0.32	0.47
Transplant center	2020	0.49	0.93
	2021	0.50	0.82
	2022	0.48	0.78
	2023	0.48	0.72

Xenotransplantation and Physiologic Homeostasis: Case Report of a First Living Human Recipient

Sul A Lee,[1] Marie-Camille Lafargue,[1] Winfred W. Williams,[1] Hannah M. Gilligan,[1] Kassem Safa,[1] Abraham Cohen Bucay,[1] Pitchaphon Nissaisorakarn,[1] Ayman Al Jurdi,[1] Harald Jüppner,[1] Susan Low,[2] Michael Curtis,[2] Leonardo V. Riella.[1] Mass General Kidney Transplant Team and eGenesis Team.
[1]Massachusetts General Hospital, Boston, MA; [2]eGenesis Inc, Cambridge, MA.

Background: Although kidney transplantation is the preferred treatment for ESKD, organ shortages severely limit timely access to transplants. Pig-to-human xenotransplantation has been proposed to address this issue, but concerns remain about meeting the physiologic needs of a living human and the potential incompatibility between humans and pigs. Here, we present several physiologic aspects of a gene-edited porcine xenograft in the first living human recipient during 51 days of follow-up.

Methods: A 62-year-old male with ESKD due to diabetes on hemodialysis, who was facing ongoing vascular access challenges, had no living donor options and an expected wait time for a deceased donor kidney exceeding 5 years, was selected for xenotransplantation with a 69-gene-edited porcine kidney donor.

Results: Kidney excretory function was assessed by BSA-adjusted 24-hour urine creatinine clearance (CrCl), Cr-based estimated GFR (eGFR), and cystatin C-based eGFR. The xenograft eGFR was 45-55 ml/min/1.73m^2 with a strong correlation among Cr- and Cystatin C-based eGFR (r=0.9). The 24-hour urine CrCl was generally higher than Cr-based eGFR by 7-14 ml/min/1.73m^2. Despite concerns about inefficient human angiotensinogen activation by pig renin, the recipient maintained hemodynamic stability post-transplantation. To gauge human anti-diuretic hormone compatibility on porcine kidneys, the osmoregulatory function of the xenograft was evaluated. The electrolyte-free water excretion was 0.5-1.5 L/day with fluctuating serum sodium levels within the normal range. The urine osmolality ranged between 220-670 mOsm/kg H_2O. No albuminuria or hematuria was observed post-transplantation. The recipient developed hypocalcemia (8.0±0.5 mg/dL) and hyperphosphatemia (6.7±0.7 mg/dL) post-transplantation, possibly in part related to iatrogenic hypoparathyroidism from prior parathyroidectomy (PTH undetectable). Fractional excretion of phosphorus stayed low (<10%) despite elevated intact fibroblast growth factor 23 (FGF-23).

Conclusions: This case report suggests that the xenograft maintained excretory function, hemodynamic stability, and urinary concentrating capacity during follow-up. While lack of PTH may have contributed to hypocalcemia and reduced phosphate excretion, further investigation into the potential incompatibility of human FGF23 on porcine kidneys is needed.

Remote Ischemic Preconditioning Can Prevent Contrast-Induced AKI (CIAKI) by Reducing Neutrophil Extracellular Traps (NETs)

Mengqing Ma,[1] Xin Wan,[1] Changchun Cao.[2,1] *[1]Nanjing First Hospital, Nanjing, China; [2]Sir Run Run Hospital Nanjing Medical University, Nanjing, China.*

Background: To explore the protective effect of remote ischemic preconditioning (RIPC) in CIAKI by reducing NETs.

Methods: A prospective randomized controlled trial was conducted. Patients who underwent coronary angiography (CAG) in Sir Run Run Hospital, Nanjing Medical University from October 2021 to December 2022 were enrolled in the RIPC group and the control group at a 1:1 ratio. Patients in the RIPC group were inflated/deflated with a sphygmomanometer cuff to cause unilateral upper limb ischemia and reperfusion. During inflation, the pressure was 50 mmHg higher than the patient's systolic blood pressure. The Doppler probe showed that the brachial artery blood flow was completely blocked. At the same time, the fingertip oxygen saturation of the upper limb on the test side could not be measured and the radial artery pulsation disappeared; the inflation/deflation time was 5 min/5 min, 4 cycles. Serum samples were collected from each group of patients before, 2 hours after and 12 hours after CAG, and the levels of MPO, NE and IL-33 were detected.

Results: A total of 100 eligible CAG patients were included in this study, and the incidence of CIAKI was 11%. The incidence of CIAKI in the RIPC group and the control group was (6% vs 16%, P<0.001). There were significant differences in MPO, NE and IL-33 before and after angiography, and their expression gradually increased 2h and 12h after CAG. The levels of MPO, NE and IL-33 in the RIPC group after surgery were significantly lower than those in the control group. The levels of MPO, NE and IL-33 in CIAKI patients at 2h and 12h after surgery were significantly higher than those in non-CIAKI patients. The results of AUC showed that the performance of the clinical model in predicting CIAKI was 0.767. NE (0.873, 95% CI 0.803-0.943, P<0.001), MPO (0.882, 95% CI 0.813-0.951, P<0.001) and IL-33 (0.844, 0.766-0.921, P<0.001) at 12 hours after surgery had better prediction of CIAKI. After combining with clinical indicators, the AUC was 0.909 (0.829-0.989, P<0.001), which significantly improved the prediction performance of CIAKI.

Conclusions: RIPC before angiography can reduce the level of NETs, reducing the incidence of CIAKI. Serum MPO, NE and IL-33 12 hours after CAG can better predict the occurrence of CIAKI and improve the predictive effect of the CIAKI clinical model.

TH-PO1166

Advancing Community Care and Access to Follow-Up after AKI Hospitalization: The AFTER AKI Randomized Controlled Trial

Neesh I. Pannu,[1] Kerry Mcbrien,[2] Coralea Bignell,[2] Eleanor C. Benterud,[2] Taylor Palechuk,[1] Tyrone Harrison,[2] Braden J. Manns,[2] Matthew T. James.[2] *[1]Medicine, University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada; [2]University of Calgary, Calgary, AB, Canada.*

Background: Acute kidney injury (AKI) is associated with development and progression of chronic kidney disease (CKD). Gaps in guideline recommended care for CKD are common after AKI.

Methods: In this randomized controlled trial conducted in Alberta, Canada, hospitalized adults with Kidney Disease Improving Global Outcomes (KDIGO) stage 2 or greater AKI were randomized to a risk-guided, transition of care intervention versus usual discharge practices at hospital discharge. For people in the intervention group, we used a validated risk index to predict risk of severe CKD after AKI to risk stratify patients. People at low risk (<1%) received patient education alone. People at medium risk received additional clinical guidance, provided to their primary care physician. People at high risk (>10%) were referred to Nephrology. The primary outcome was the proportion of patients with CKD who were receiving guideline-concordant care at 90 days after discharge based on use of ACE inhibitors or ARBs, statins, and nephrology specialist follow-up. Processes of care and safety were also evaulated.

Results: We recruited 155 patients into the trial; mean (SD) age 60 (15) years, 91 (60%) were male. 90 days after discharge, 99 (64%) participants had CKD defined by estimated glomerular filtration rate (eGFR) <60 mL/min/1.73m^2 or albumin to creatinine ratio (ACR) >30 mg/g. The proportion of participants with CKD after hospitalization with AKI who received guideline-concordant care was 59% in the intervention group versus 24% in the usual-care group (absolute risk difference [RD] 35 %, 95% CI, 17 to 53%; P < 0.001; risk ratio 2.47, 95% CI, 1.43 to 4.25). ACE inhibitor or ARB use was higher with the intervention (67 versus 46%, RD 21%, 95% CI, 2-40] %), as was statin use (78 versus 58%, RD 20%, 95% CI, 2 to 38 %). Among 18 (12%) participants with eGFR <30 mL/min/1.73m^2 at 90 days, the proportion who received nephrology follow-up was also greater with the intervention (73 versus 29%, RD 44, 95% CI, 2 to 87%). The risk of adverse events was similar in the groups, except for hyperkalemia, which was more frequent in the intervention group (15% versus 5%).

Conclusions: A risk-guided intervention for patients with AKI increased CKD-guideline concordant care early after hospital discharge.

Acute Kidney Disease Detection in an Outpatient Setting: A Pragmatic Randomized Controlled Trial

David R. Chang,[1,2] Hsiu-Yin Chiang,[4,3] Yu-Ting Lin,[4,3] Zi-Han Lin,[4] Hung chieh Yeh,[1] Chin-Chi Kuo.[4,1] *[1]Division of Nephrology, China Medical University Hospital Department of Internal Medicine, Taichung, Taiwan; [2]Department of Biomedical Informatics, Harvard Medical School, Boston, MA; [3]Department of BioMedical Informatics, China Medical University, Taichung, Taiwan; [4]Big Data Center, China Medical University Hospital, Taichung, Taiwan.*

Background: Outpatient acute kidney injury or disease (AKD_{OPT}) is underrecognized due to fragmented data. No randomized controlled trials (RCTs) of AKD_{OPT} alert system have been reported.

Methods: Taiwan's National Health Insurance MediCloud enables integration of serum creatinine (S-Cre) data across institutions within 180 days before a visit. We developed an AKI Detection System (AKIDS) to screen for AKD_{OPT} and suggest nephrology referrals (**Fig 1**). This pragmatic RCT assessed AKIDS's effectiveness in reducing the 1-year risk of composite kidney outcome (CKO) — including ESKD, S-Cre doubling, and a 40% eGFR decline — in cancer-free adult outpatients. CKO risks were estimated using Cox proportional hazard models.

Results: Among 9,907 AKD_{OPT} patients, the adjusted hazard ratio (aHR) for 1-year CKO with AKIDS was 0.91 (95% CI: 0.81, 1.03), with an adjusted absolute risk reduction (aARR) of 11 per 1,000 patients (95% CI: 10, 13). Among 213 high-risk patients who adhered to nephrology follow-up in 3 months, AKIDS was associated with a 39% reduced risk of 1-year CKO (0.61; 95% CI: 0.42, 0.89) and an aARR of 160 per 1,000 patients (95% CI: 122, 198), with a number needed to treat of 6 (95% CI: 5, 8). The AKIDS's time-to-event curve for 1-year CKO was consistently lower (**Fig 2**).

Conclusions: This RCT demonstrates the effectiveness and resource efficiency of AKIDS in AKD_{OPT} care by targeting high-risk outpatients for nephrology referral. Studies are needed to evaluate its generalizability in healthcare systems with varying levels of data interoperability.

Funding: Government Support - Non-U.S.

Figure 1. The design of Acute Kidney Injury Detection System (AKIDS) developed by Big Data Center at CMUH. Targeting on the appointed outpatient visits, the AKIDS automatically integrate the S-Cre and eGFR measurements from the Taiwan's NHI and local EMRs and screen for AKD_{OPT} based on a prespecified S-Cre and eGFR fluctuation criteria within a 180-day period prior to the index outpatient clinic. Patients with AKD_{OPT} are further classified into stable (>0.3 mg/dL increase) and deteriorating (otherwise) subgroups based on the last two S-Cre. Cases A, B, and C illustrate the S-Cre dynamics of AKD_{OPT}, with A and B being stable subtypes and C representing the deteriorating subtype. AKIDS provide suggestions of nephrology referral based on the latest eGFR and AKD_{OPT} deteriorating status. ***Abbreviations***: AKD_{OPT}, acute kidney disease in outpatient setting; CMUH, China Medical University Hospital; eGFR, estimated glomerular filtration rate; EMRs, electronic medical records; NHI, National Health Insurance; OPT, outpatient; S-Cre, serum creatinine.

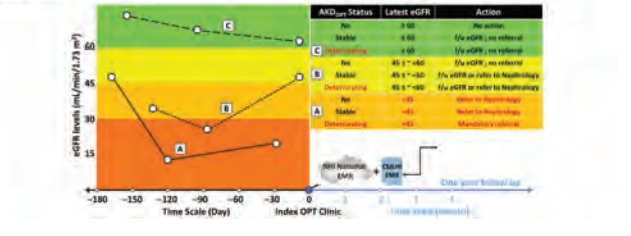

Figure 2. Adjusted time to event curves for 1-year CKOs of patients requiring referral who adhered to the nephrology follow-up care within 3 months.

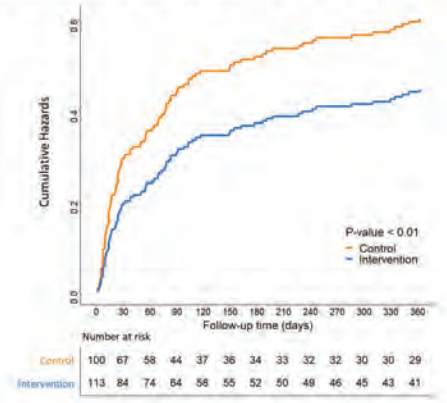

TH-PO1168

Validation of a Combined Biomarker Including FGF-23, Erythropoietin, and Klotho for Development AKI and Clinical Outcomes in Patients in the Intensive Care Unit (ICU)

Luis Michea,[1] Luis Toro,[1] Veronica Rojas,[1] Daniela Ponce,[1] Carlos Irarrazabal,[2] Danilo Fischer,[2] Carlos Romero,[1] Julia Guerrero.[3] *[1]Hospital Clinico Universidad de Chile, Santiago, Chile; [2]Universidad de los Andes, Santiago, Chile; [3]Clinica Alemana de Santiago, Santiago, Chile.*

Background: Acute kidney injury (AKI) is a common complication in patients in critical care units (CCUs) associated with increased morbidity and mortality. The development of AKI is associated with increased plasma levels of Fibroblast Growth Factor 23 and Erythropoietin, with a reduction in Klotho. Previously, our group evaluated a combined biomarker using these molecules (named FEK) in a single-center clinical study, observing that critically ill patients with high levels of the FEK biomarker had a higher rate of AKI and worse clinical outcomes. Our objective was to evaluate in a multicenter study whether this combined biomarker predicts the development of AKI and clinical outcomes in critically ill patients.

Methods: Prospective multicenter cohort of 3 critical care units in Chile. Adult patients admitted to the Critical Care Unit with serum creatinine levels in normal ranges were recruited between 2019 and 2022. The diagnostic accuracy of the FEK biomarker in predicting AKI during the first 48 hours after admission was determined by ROC analysis. Secondary outcomes were life support therapy requirements and mortality in the first 28 days of hospitalization. The combined biomarker was compared against serum creatinine, NGAL, and TIMP-2*IGFBP7.

Results: 280 patients were recruited, age: 61.3 ± 15.7 years, female: 47%, serum creatinine at admission: 0.71 ± 0.16 mg/dL. During follow-up, 50% developed AKI, 27% required vasoactive drugs, 11% required emergency dialysis, and 10% died. When evaluating the diagnostic capacity of AKI, it was observed that plasma levels of the combined FEK biomarker were significantly higher in patients who developed AKI compared to those who did not. The area under the curve to predict AKI was 0.83 [0.78-0.88]. Finally, patients with high levels of the FEK biomarker had a higher rate of life support therapy requirements and mortality at 28 days of hospitalization (OR: 4.3 [1.6-13.5]).

Conclusions: Our results show that the combined biomarker FEK has a high diagnostic capacity for the development of AKI in critically ill patients and is associated with worse short-term clinical outcomes. Our results suggest that this combined biomarker could be helpful for decision-making in patients admitted to critical care units.

TH-PO1169

Evaluation of the Anticoagulant Effect of Effluent Ionized Calcium iCa to Measure Regional Citrate Anticoagulation (RCA) Performance vs. Post-filter Ionized Calcium iCa: A Single-Center Non-inferiority Randomized Controlled Trial (RCT)

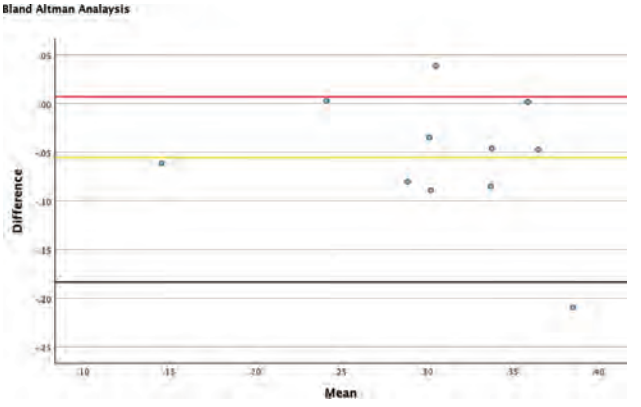
Niroj Mali, Ping Fu. *Nephrology, West China Hospital of Sichuan University, Chengdu, China.*

Background: This study aimed to evaluate the feasibility of using effluent fluid instead of postfilter ionized calcium (iCa) measurements for assessing anticoagulation in continuous renal replacement therapy (CRRT) with regional citrate anticoagulation in critically ill patients. Using citrate in CRRT is to prevent clotting within the circuit by chelating calcium, which is essential for the coagulation cascade.

Methods: A two-arm, parallel, placebo-controlled, single-center RCT was conducted to assess and compare the efficacy and safety of different target ranges of effluent fluid ionized calcium and post-filter ionized calcium in continuous renal replacement therapy (CRRT) with regional citrate anticoagulation

Results: In total, 11 critically ill patients with 91 paired samples of CVVHDF with a mean age of 57.7 and a male-to-female ratio of 7:4. The mean post-filter ionized calcium was 0.28 ± 0.12 mmol/L, and the mean ionized calcium level of effluent fluid was 0.33 ± 0.11 mmol/L. r = 0.631, P value = 0.03, which is statistically significant, i.e., P<0.05. Bland-Altman analysis showed that the mean difference of ionized calcium between two sampling sites in continuous renal replacement therapy patients was -0.06 mmol/L with a 95% confidence interval ranging from -0.18 to 0.007 mmol/L.

Conclusions: Our results suggested there was a significant correlation between the two sampling points, and we explored the possibility of using effluent fluid for iCa measurements instead of postfilter iCa.



Bland-Altman analysis

Sodium Zirconium Cyclosilicate (SZC) to Enable Renin Angiotensin-Aldosterone System Inhibitor (RAASi) Use for Diabetic Kidney Disease: The CRYSTAL Study

Weiming Wang,[1] Leyi Gu,[2] Xiujuan Zang,[3] Na Liu,[4] Yangbin Pan,[11] Chunming Jiang,[5] Ying Li,[6] Gengru Jiang,[7] Zhiguo Mao,[8] Jun Xue,[9] Rong Zhou,[10] Hao Xu,[1] Jian Liu.[1] *[1]Shanghai Jiao Tong University Medical School Affiliated Ruijin Hospital, Shanghai, China; [2]Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital, Shanghai, China; [3]Songjiang Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China; [4]Tongji University Dongfang Hospital, Shanghai, China; [5]Nanjing University Medical School Affiliated Nanjing Drum Tower Hospital, Nanjing, China; [6]Jiading District Central Hospital Affiliated Shanghai University of Medicine & Health Sciences, Shanghai, China; [7]Shanghai Jiaotong University School of Medicine Xinhua Hospital, Shanghai, China; [8]Shanghai Changzheng Hospital, Shanghai, China; [9]Huashan Hospital Fudan University, Shanghai, China; [10]Yangpu Hospital Affiliated to Tongji University School of Medicine, Shanghai, China; [11]Shanghai Pudong Hospital, Shanghai, China.*

Background: RAASi, the preferred treatment for Diabetic Kidney Disease (DKD), can induce hyperkalemia, and reduction/discontinuation of RAASi will affect its cardio-renal benefits. This study evaluated the efficacy of SZC in maintaining RAASi use in stage 3–4 DKD patients.

Methods: This multicenter, open-label, randomized controlled, phase IV trial enrolled stage 3–4 DKD patients with hyperkalemia (sK >5.0 mmol/L) within 90 days prior to enrollment and randomized them 1:1 to SZC (SZC + RAASi) or control (RAASi-only) groups, with a 24-week follow-up (12-week RAASi titration + 12-week maintenance). The primary endpoint was the proportion of patients with increased RAASi dose by week 12.

Results: By June 28, 2024, this study included 86 patients in the intention-to-treat (ITT) set, and 56 adhered to study protocol (per-protocol, PP). The mean age of the ITT set was 58.7 years old, and 59.3% were male. Both ITT and PP analyses showed a significantly higher proportion of patients in the SZC group achieved increased dose of angiotensin-converting enzyme inhibitor (ACEi)/angiotensin II receptor blocker (ARB) than control at week 12 (ITT: 55.8% vs. 27.9%, p<0.05; PP: 71.4% vs. 28.6%, p<0.05; **Figure 1**). In the PP set, a higher proportion of the SZC group received ≥50% of the labeled maximum dose than control at weeks 12 (60.7% vs. 42.9%) and 24 (53.6% vs. 35.7%). From baseline to week 24, the SZC group had decreased mean UACR (-63.5 mg/g), whereas that in the control group increased (+316.9 mg/g). Adverse events occurred in 62.8% of the SZC group and 72.1% of the control group.

Conclusions: This study showed that using SZC to manage hyperkalemia can help optimize RAASi treatment for Chinese stage 3–4 CKD patients with diabetes and hyperkalemia. This can facilitate the use of RAASi at higher, guideline-recommended doses to achieve its cardio-renal benefits for DKD pts experiencing hyperkalemia.

TH-PO1171

Can Exogenous Ketones Prevent the Effects of High Salt on Renal Vascular Resistance during Sympathoexcitation?

Soolim Jeong,[1,2] Nina L. Stute,[2] Sofia O. Sanchez,[1] Orlando M. Gutierrez,[3] Zachary Schlader,[1] Austin Robinson.[1] *[1]Indiana University Bloomington, Bloomington, IN; [2]Auburn University, Auburn, AL; [3]The University of Alabama at Birmingham, Birmingham, AL.*

Background: Renal vascular resistance (RVR) is the opposition to blood flow by renal arteries. At the population level, dietary salt increases RVR and subsequently blood pressure (BP), which is associated with cardiovascular disease risk. However, recent data indicate exogenous ketones may offset adverse cardiorenal effects of salt. Therefore, we investigated whether dietary ketone and salt supplementation influences RVR and BP during sympathoexcitation (cold pressor test).

Methods: Thirteen participants were included in this analysis (10 M/3 F, age 30 ± 9 years. BMI: 26 ± 3 kg/m^2; mean ± SD). In this registered clinical trial (NCT05545501) participants were randomized to three 10-day conditions: A) control; B) high salt; C) high salt and ketone supplementation. Renal blood velocity (RBV) in the renal artery was measured in the decubitus position using Doppler ultrasound during a 3-minute baseline, 3-minute cold pressor test, and 2-minute recovery. We measured brachial BP with a validated oscillometric BP monitor. We calculated RVR as mean BP divided by RBV. We also calculated renal vascular conductance (RVC), the ease of blood flow through the renal arteries, as RBV divided by mean BP. Statistical analyses included ANOVA with α set at ≤ 0.05.

Results: Baseline BP did not differ between conditions for systolic (control: 107 ± 10, salt: 109 ± 14, ketone and salt: 107 ± 8 mmHg, p=0.91) or diastolic BP (control: 64 ± 6, salt: 63 ± 7, ketone and salt: 64 ± 5, p=0.90). Further, there were no differences for baseline RVR (control: 1.9 ± 0.6, salt: 2.1 ± 1.0, ketone and salt: 2.0 ± 0.8 mmHg/cm/s, p=0.86) or RVC (control: 0.6 ± 0.2, salt: 0.6 ± 0.2, ketone and salt: 0.6 ± 0.2 cm/s/mmHg, p=0.99). There were no effects of diet during CPT and REC for delta MAP (p=0.99), RVR (p=0.89), or RVC (p=0.58).

Conclusions: We observed no changes in blood pressure, renal vascular resistance, or renal vascular conductance between the three diets in our preliminary dataset; however, additional data is needed.

TH-PO1172

Immunosuppression Minimization In Kidney Transplant Recipients with Transplant Excellence Based on the TruGraf Test

Venkat Ram Peddi, Parul S. Patel, Allison Gourley, Jalyn R. Vickroy. *California Pacific Medical Center, San Francisco, CA.*

Background: We prospectively evaluated the utility of serial TruGraf testing to guide immunosuppression (IS) management following Kidney Transplant (KT).

Methods: Pts undergoing KT and meeting inclusion (primary txp; cPRA <50; no DSA; non-African American recipients) and exclusion (multi-organ and HLA-identical living related recipients) criteria are consented at the time of KT. Pts who consent enter Part I of the study, receive Thymo induction (≥3 mg/kg), have steroids withdrawn at 30 d post-txp, and maintained on MMF and Tacro IS. Pts are followed with weekly labs. Pts qualifying for Part II of the study (eGFR >45 mL/min; BK viremia <10,000 copies/mL; no acute rejection episodes) are randomized 2:1 to study group : standard of care at 3mos post-txp. All pts also receive serial TruGraf testing monthly for mos 3-9, and at 12 mos post-txp. Study group receive TruGraf results in real time and used to guide IS reduction. If result is Transplant eXcellence (TX), first step in IS minimization is to decrease MMF dose followed by decrease in Tac target trough to between 3 & 6 ng/mL. Control group are managed per center standard of care & TruGraf samples will be analyzed at end of the study.

Results: Enrollment is completed and IS minimization is ongoing. 82 pts were enrolled. 73 pts completed 3 mos posttxp follow-up & qualified to be randomized into Part II of the study (52 to study arm and 21 to control arm); 57 pts completed the study; 40 pts in the study arm and 17 in the control arm. Renal function and IS results are shown in the Table below. To date, DSA was checked in 30 pts who completed the study. 25/30 (83.3%) had no DSA; 3/30 (10%) had de novo Class I DSA; and 2/30 (6.7%) had de novo Class II DSA. One study arm pt with elevated serum creat level and TruGraf TX had borderline acute rejection on biopsy (1/52 or 2%).

Conclusions: Results of this study are anticipated to provide helpful information necessary for IS minimization and have the potential to individualize pt care and improve outcomes by reducing infections and malignancies while maintaining good graft function.

Social Network Interventions to Reduce Racial/Ethnic Living Donor Kidney Transplants (LDKT) Disparities: Preliminary Results from the Friends and Family of Kidney Transplant Patients Study

Jonathan Daw,[1] Jennifer M. Kirk,[1] Ashton Verdery,[1] Selena E. Ortiz,[4] Rhiannon D. Reed,[5] Jayme E. Locke,[5] David Kloda,[5] Brian A. Mccauley,[3] Deirdre L. Sawinski,[2] Peter P. Reese.[3] *[1]Department of Sociology & Criminology, The Pennsylvania State University, University Park, PA; [2]Department of Medicine, Weill Cornell Medicine, New York, NY; [3]Department of Medicine, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [4]Department of Health Policy & Administration, The Pennsylvania State University, University Park, PA; [5]Department of Surgery, University of Alabama at Birmingham, Birmingham, AL.*

Background: Kidney transplants are often the optimal therapy for those w/ end-stage kidney disease; LDKT are particularly beneficial. Yet, LDKT rates are low & substantial racial/ethnic disparities in LDKT are a key driver of disparities in outcomes. Hence, more research is needed to boost LDKT & reduce racial/ethnic disparities.

Methods: This 2x2 factorial clinical trial in 2 transplant centers randomized 158 transplant candidates to the following groups: 1) the Script intervention: sets of advice & an example script on how to initiate LDKT discussions w/ potential living donors; 2) the Search intervention: advice on which friends/family members were least likely to have LDKT contraindications; 3) the Combined Intervention; or 4) No Intervention controls.

Results: Gender, age, & race/ethnicity did not differ by intervention group at baseline. At a median of 11 months post-enrollment, 17% of participants remained active on the waitlist, 3.8% died, 52% became/remained waitlist inactive. Only 11% of participants received LDKT, including 15% of controls, while 27% of the Search group received a deceased donor kidney transplant. Results indicate that neither intervention significantly increased the likelihood of LDKT (*See Table*). Notably, Non-Hispanic (NH) Black participants remained significantly (p=.01) less likely to receive LDKT.

Conclusions: We aimed to increase LDKT & ameliorate racial/ethnic disparities through the implementation of Script & Search interventions. Findings indicate neither intervention alone nor in combination significantly influenced LDKT. These results underscore the need for further investigation into alternative strategies to increase LDKT, particularly among racial/ethnic minorities.

VIRENO Study: A Novel Approach for Early Outcome Prediction after Kidney Transplantation

Patrick Affeldt,[1] Katharina Burkert,[1] Rabi R. Datta,[1] Franziska Grundmann,[1] Martin Kann,[1] Florian Klein,[1] Christine E. Kurschat,[1] Dirk L. Stippel,[1] Michael N. Thomas,[1] Katharina Tuschen,[2] Alexander Weidemann,[2] Benjamin Wilde,[3] Veronica Di Cristanziano,[1] Roman-Ulrich Mueller.[1] The VIRENO Study Group. *[1]Universitatsklinikum Koln, Koln, Germany; [2]Krankenhaus Koln-Merheim, Koln, Germany; [3]Universitat Duisburg-Essen, Duisburg, Germany*.

Background: Achieving balanced immunosuppression remains a significant challenge following kidney transplantation (KTx). VIRENO is a prospective multicenter study designed to examine the combination of clinical and viro-immunological parameters as predictors of major complications after KTx.

Methods: Viro-immunological monitoring was conducted before KTx, 3 weeks and 6 months after KTx. This monitoring included measurements such as the humoral response to BK polyomavirus (BKPyV) and cytomegalovirus (CMV), T-cell reactivity against CMV, and the viral load of torque teno virus (TTV). Clinical outcomes were tracked for 12 months post-transplantation, with clinically relevant infection- and rejection-related events as outcomeparamter. Clinical and viro-immunological parameters were used to develop predictive models for infectious and immunological events through logistic regression. The best models were then integrated for predicting infections and immunological events to create the VIRENO-score, to stratify patients by adverse event risk after KTx.

Results: A total of 196 patients were followed for the first year post-KTx. Relevant infectious events occurred in 95 patients, while 36 patients experienced at least one immunological event (biopsy-proven rejection / de novo donor-specific antibodies). The best predictive model for significant infections included variables such as baseline plasma TTV-DNA load, CMV serostatus of the donor and recipient, recipient's blood type, type of donation (deceased vs. living), recipient's ethnicity, and differences in HLA alleles between donor and recipient (Area under the curve (AUC) 0.781). For immunological events, the predictive model included nine variables, including baseline CMV-IgG levels, presence of underlying genetic renal diseases, recipient's body mass index, and the number of HLA mismatches and different HLA constellations (AUC 0.799).

Conclusions: The combination of viro-immunological and clinical parameters is a promising tool for predicting major adverse events after KTx. Validation in further cohorts and a prospective trial using the models to guide immunosuppression will now be the crucial steps towards implementation in clinical practice.

Funding: Other NIH Support - The present study was supported by the Koeln Fortune Program of the Faculty of Medicine of the University of Cologne (Germany) and by the Clinical Leave Program of DZIF (Deutsches Zentrum für Infektionsforschung)

TH-PO1175

Phase I/IIa Trial of Autologous Regulatory T Cell Therapy Together with Donor Bone Marrow Infusion in Kidney Transplantation

Rainer Oberbauer,[1] Moritz Muckenhuber,[2] Jasmin Mucha,[2] Roman Reindl-Schwaighofer,[1] Andreas Heinzel,[1] Anna M. Weijler,[2] Gabriela Berlakovich,[2] Nina Worel,[5] Michael Wolzt,[3] Thomas Lion,[5] Matthias Edinger,[4] Thomas Wekerle.[2] *[1]Nephrology, Medizinische Universitat Wien, Vienna, Austria; [2]Surgery, Medizinische Universitat Wien, Wien, Austria; [3]Clinical Pharmacology, Medizinische Universitat Wien, Wien, Austria; [4]Hematology, Krankenhaus Barmherzige Bruder Regensburg, Regensburg, Germany; [5]CCRI, Medizinische Universitat Wien, Wien, Austria*.

Background: In preclinical models combining Treg therapy with donor bone marrow transplantation leads to mixed hematopoietic chimerism and tolerance without myelosuppressive recipient conditioning.

Methods: A single center, controlled, first-in-human phase I/IIa trial is conducted in HLA-mismatched living donor kidney transplant recipients. In vitro expanded polyclonal recipient Tregs and MNC-separated donor bone marrow cells are administered within 3 days after transplant. No irradiation or cytotoxic drugs are given. IS consists of thymoglobulin, belatacept, sirolimus and steroids. Starting at 6 months, sirolimus and steroids are gradually withdrawn in study group patients. A parallel control group receives the same IS, but no Tregs & bone marrow. Total leukocyte donor chimerism and safety are co-primary endpoints. Immune monitoring accompanying the trial includes NGS of the TCR repertoire, flow cytometric leukocyte subset analysis, scRNAseq and protocol biopsies (at 6, 12, 24, 36 and 60 months) including transcriptomic analysis. ClinTrials.gov NCT03867617.

Results: Thirteen patients have been enrolled and twelve treated according to the predetermined sample size of six per group. One patient was enrolled but not treated as the Treg cell product was out-of-specification (77% viable cells at 80% cut-off). Treg (1.0-1.5x10^7 cells/kg) and bone marrow cell (0.7-1.9x10^8 nucleated cells/kg) infusions were well tolerated. The study group developed low levels of total leukocyte donor chimerism whereas no chimerism was detectable in the control group. Leukocyte subset analysis and transcriptomics analysis of biopsies (MMDx) are ongoing. TCR repertoire sequencing revealed clonal deletion of donor-specific T cells. The study group shows a favorable clinical course, with GFRs of 33-99 ml/min/1.72m^2 at median follow-up 32 months and no infusion-related safety signals were observed. IS reduction has been completed in three patients currently maintained on belatacept monotherapy and is in progress in all other patients.

Conclusions: Combined Treg therapy and bone marrow transplantation is safe and feasible and induces low-level chimerism which is sufficient to cause clonal deletion of donor specific T cells.

A Hypertension Management App for Salt Restriction in Patients with CKD: The CureApp-CKD Trial

Takayuki Kawaoka, Yusuke Sakaguchi, Yuki Kawano, Tatsufumi Oka, Yohei Doi, Isao Matsui, Jun-Ya Kaimori, Yoshitaka Isaka. *Osaka Daigaku, Suita, Japan*.

Background: Excessive salt intake is harmful to the kidney. In real-world clinical settings of patients with chronic kidney disease (CKD), however, salt restriction is often challenging. Mobile app-based interventions might be useful to reduce salt intake.

Methods: This open-label, single-center, randomized controlled trial involved patients with CKD stages G1-G5 who had a history of hypertension and an estimated 24-hour urinary sodium excretion of ≥100 mmol. Patients randomized to an intervention group used CureApp HT, a hypertension-management app that enables individualized lifestyle modification, in addition to lifestyle counseling by nephrologists for 12 weeks. Patients in the control group received lifestyle counseling only. The primary outcome was a change in the estimated 24-hour urinary sodium excretion from baseline to 12 weeks. Key secondary outcomes were office blood pressure, brachial-ankle pulse wave velocity (baPWV), urinary protein-to-creatinine ratio (UPCR), brain natriuretic peptide (BNP), and body weight. This study was registered at the Japan Registry of Clinical Trials (jRCTs052220164).

Results: A total of 101 patients were randomized, with 51 assigned to the intervention group and 50 to the control group. The mean (standard deviation) estimated 24-hour urinary sodium excretion at baseline was 145 (33) mmol. More patients in the intervention group reported that their salt intake behaviors had "significantly improved" or "somewhat improved" than those in the control group (76% vs. 40%; P<0.001). Despite the subjective improvement, there was no significant between-group difference in changes in the estimated 24-hour urinary sodium excretion (between-group difference, 0.9 mmol; 95% confidence interval [CI], -17.8 to 19.7; P=0.9). Secondary outcomes, including blood pressure levels, baPWV, UPCR, BNP, and body weight, were also not significantly different between groups.

Conclusions: Further advancements in mobile app-based interventions might be needed to effectively suppress salt intake behaviors in patients with CKD.

TH-PO1177

Rilparencel Autologous Cell Therapy in Patients with Diabetes and Advanced CKD: Phase 2 Interim Results

Joseph Stavas,[1] Arnold L. Silva,[2] Theodore F. Saad,[3] Emily L. Butler,[1] Navdeep Tangri,[4] Bruce F. Culleton.[1] *[1]ProKidney, Raleigh, NC; [2]Boise Kidney & Hypertension Institute, Boise, ID; [3]Nephrology Associates, Newark, DE; [4]Department of Internal Medicine, University of Manitoba, Winnipeg, MB, Canada*.

Background: Cell-based therapies in patients with chronic kidney disease (CKD) may repair diseased nephrons and stabilize kidney function. We describe an interim analysis of an open label phase 2 trial (NCT05018416) with *rilparencel*, an autologous cell product made from kidney biopsy tissue.

Methods: The study objectives are to evaluate efficacy and safety measured by change in eGFR slope from baseline to after last injection and procedure- and product-related serious adverse events. Patients with type 1 or 2 diabetes, eGFR 20-50 ml/min/1.73/m^2 and UACR 30-5000 mg/g are randomized into one of two cohorts. Cohort 1 subjects receive two percutaneous *rilparencel* injections: one into the cortex of each kidney 3 to 5 months apart; Cohort 2 subjects receive at least one injection, and a 2nd injection only after a pre-defined biochemical trigger. eGFR slope is presented for only Cohort 1 given its alignment with an ongoing phase 3 trial. Safety data is aggregated across both cohorts.

A post-hoc analysis compares eGFR slope in Cohort 1 with a 10:1 matched synthetic control group. The control group was identified from a subject-level clinical trial database and matched with Cohort 1 based on risk of kidney failure (Klinrisk model).

Results: 49 subjects received the 1st injection (n=24 Cohort 1; n=25 Cohort 2) and 34 subjects received a 2nd injection (n=22 Cohort 1; n=12 Cohort 2); 28 subjects have not completed the study and remain in follow up (n=11 Cohort 1; n=17 Cohort 2). 13 Cohort 1 subjects have greater than 12 months follow up post 2nd injection. Mean age is 63 yrs; 54% are female. At baseline, mean (SD) eGFR is 27.9 (9.5) ml/min/1.73/m^2; median [IQR] UACR is 239 [4, 2392] mg/g. Annualized eGFR slope in Cohort 1 is -1.1 ml/min/1.73/m^2/year (95% CI -3.5, 1.3). Average change in eGFR in the matched control group is -4.0 ml/min/1.73/m^2 over 12-months. Two hematomas and 2 episodes of acute kidney injury occurred after kidney biopsy; 1 hematoma occurred after 83 injections. There were no product-related SAEs.

Conclusions: Interim findings suggest *rilparencel* can stabilize kidney function in patients with diabetes and advanced CKD. Procedure-related AEs are infrequent and typical given the interventions. A global phase 3 study is ongoing to determine efficacy and safety of *rilparencel.*

Radiofrequency Renal Denervation in Patients with Severe CKD, Including Patients on Dialysis: Analysis from the Global SYMPLICITY Registry DEFINE

Markus P. Schlaich,[1] Felix Mahfoud,[2] Krzysztof Narkiewicz,[7] Luis M. Ruilope,[3] Faisal Sharif,[6] Flavio L. Ribichini,[4] Michael Böhm.[5] *[1]Dobrey Hypertension Center, University of Western Australia, Perth, WA, Australia; [2]Medicine, Universitatsspital Basel, Basel, Switzerland; [3]Medicine, Hospital 12 de Octobre, Madrid, Spain; [4]Universita degli Studi di Verona Scuola di Medicina e Chirurgia, Verona, Italy; [5]Universitatsklinikum des Saarlandes, Homburg, Germany; [6]University of Galway, Galway, Ireland; [7]Gdanski Uniwersytet Medyczny, Gdansk, Poland.*

Background: There is a paucity of data regarding the effect of renal denervation in patients with severe chronic kidney disease (CKD).

Methods: This analysis from the Global SYMPLICITY Registry DEFINE assessed blood pressure (BP) and renal function in patients with uncontrolled hypertension treated with radiofrequency (RF) RDN. BP and eGFR changes from baseline through 12 months were compared across three groups according to baseline eGFR (mL/min/1.73m^2): eGFR <45, eGFR 45-59, and eGFR ≥60, adjusted for baseline BP. Furthermore, we assessed these changes among a subset of 36 patients on dialysis.

Results: Baseline office SBP (OSBP) was similar between eGFR subgroups (p=0.28), although ambulatory SBP (ASBP) was higher in those with eGFR<45, p=0.037; **Fig 1A**). Patients in the <45 eGFR subgroup were significantly older, were more likely to have ischemic heart disease, heart failure, or diabetes. At 12 months, each eGFR subgroup had clinically meaningful SBP drops from baseline **(Fig1A)**. At 12 months, eGFR remained stable in the two lower eGFR subgroups (**Fig1B)**. Estimated GFR declined by 5.7±15.8 ml/min/1.73 m^2 in the eGFR ≥60 subgroup. Patients on dialysis (72% on hemodialysis, 33% on peritoneal dialysis) had substantial drops in both OSBP and ASBP after RF RDN **(Fig1C).** Among the dialysis subgroup there were 2 deaths and 2 vascular complications.

Conclusions: Patients with moderate to severe CKD including those requiring dialysis experienced significant OSBP and ASBP reductions from baseline through 12 months after RF RDN. The eGFR of patients with moderate to severe CKD remained stable through 12 months. The data showed that RDN is efficacious and safe for BP reduction in CKD, which needs to be further evaluated.

TH-PO1179

Impact of Adjunctive Active Vitamin D on Kidney Function during Treatment of Secondary Hyperparathyroidism (SHPT) with Extended-Release Calcifediol (ERC) in Nondialysis-Dependent CKD (ND-CKD)

Akhtar Ashfaq,[1] John Choe,[1] Stephen A. Strugnell,[1] Nilay Patel,[1] Stuart M. Sprague,[2] Keith C. Norris,[3] Edgar V. Lerma,[4] Charles W. Bishop.[1] OPKO Health. *[1]Renal Division, OPKO Health Inc, Miami, FL; [2]NorthShore University HealthSystem, Evanston, IL; [3]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [4]Nephrology, University of Illinois Chicago College of Medicine, Chicago, IL.*

Background: Sustained reductions of intact parathyroid hormone (iPTH) with ERC are associated with slower estimated glomerular filtration rate (eGFR) decline without safety concerns in ND-CKD patients with SHPT. Marked iPTH reductions require serum 25-hydroxyvitamin D (25D) of ≥50 ng/mL, and adequate exposure is limited by increased volume of distribution in obesity and the current ERC dose ceiling (60 mcg/day).

Methods: This prospective study examined whether adjunctive active vitamin D could safely improve iPTH control and the related eGFR stabilizing effect of ERC in 78 ND-CKD adults unable to achieve iPTH normalization after 38 weeks of treatment, defined as baseline (BL). Participants had mean age of 66 years, BMI of 35 kg/m^2, 41% were female, 63% White, 36% Black and 19% Hispanic. At ERC initiation, participants had eGFR 15-<60 mL/min/1.73 m^2, plasma iPTH 85-<500 pg/mL, serum 25D 10-<30 ng/mL, corrected serum calcium (Ca) 8.4-<9.8, serum phosphorus (P) 2.0-<5.0, and absence of nephrotic range proteinuria (≤3 mg/mg creatinine). They were randomized to continuing daily ERC (60 mcg) with (n=40) or without (n=38) immediate-release adjunctive daily oral calcitriol (0.25 mcg; n=12), doxercalciferol (0.5 mcg; n=14) or paricalcitol (1.0 mcg; n=14) for 14 weeks. Measurements of eGFR, iPTH, 25D, Ca, P and fibroblast growth factor 23 (FGF23) were obtained at BL and study end.

Results: There were no significant BL inter-group differences. Mean BL 25D was 67 ng/mL and rose 11-13 ng/mL in both groups (p<0.001). Mean BL iPTH was 143 pg/mL and fell by 35% (p<0.001) with adjunctive therapy versus 4% without. Mean Ca and FGF23 increased with adjunctive therapy (p<0.001) by 0.5 mg/dL and 47 pg/mL, respectively, versus 0.0 and 2.0 without. Mean P remained unchanged. Mean BL eGFR was 25.4 mL/min/1.73m^2 and fell by 10% (p<0.05) with adjunctive therapy versus 4% without.

Conclusions: Although adjunctive active vitamin D enabled more iPTH reduction (35%) in CKD patients taking ERC for 52 weeks, it increased serum Ca by 0.5 mg/dL, FGF23 by 136% and hastened eGFR decline by 10%. Higher doses of ERC alone may be more suitable for improving iPTH control and eGFR stabilization in obese patients.

TH-PO1180

Evaluation of an At-Home Creatinine Assay for CKD Management: Pilot Method Comparison Study and Clinical Implications

Vissaagan Gopalakrishnan,[1] Amrutha Anilkumar,[1] Supriya Chavan,[1] Bharath B. Rangaswamy,[1] Richard E. Williams,[1] Anh N. Hoang,[1] James Januzzi.[1,2] *[1]Jana Care, Boston, MA; [2]Division of Cardiology, Massachusetts General Hospital Department of Medicine, Boston, MA.*

Background: Chronic kidney disease (CKD) management relies on regular serum creatinine monitoring, traditionally requiring phlebotomy and central laboratory analysis. There is a large unmet need for reliable at-home tools to measure creatinine, empowering patients, increasing testing compliance, and enabling timely interventions. A smartphone-enabled, low-cost reader system for analyte-specific strips is being developed for patient use in chronic disease management. The initial application is a fingerstick creatinine assay for self-administered at-home use (Fig 1).

Methods: The candidate creatinine assay was evaluated in a pilot study involving study participants across a range of CKD stages. The primary endpoint was a comparison of the fingerstick assay's performance to a central laboratory reference method (Vitros XT 7600 Integrated System, QuidelOrtho). Additional studies included a linearity study across a range of creatinine concentrations, and an interference study involving creatine and ascorbic acid.

Results: Among 50 study participants (mean age 49.7 ± 15.5 years) with a range of CKD severity (mean creatinine 5.74 mg/dL), the assay demonstrated strong agreement with the Vitros XT 7600, achieving correlation coefficients (R) of 0.98 (Fig 2A). Additionally, the linearity study confirmed a direct relationship (R= 0.99) across the tested creatinine concentrations, validating accuracy across the spectrum of CKD severity (Fig 2B). The interference study showed no interference of creatine and ascorbic acid at 6 times physiological concentrations (300μM).

Conclusions: The development of a reliable at-home creatinine assay represents a significant advancement towards the scalable monitoring of CKD progression and early detection of kidney function decline, addressing a critical gap in management practices. By enabling regular monitoring, this assay has the potential to promote equitable health access and improve disease management.

TH-PO1181

Efficacy and Safety of AND017 for Treatment of Anemia in Dialysis-Dependent CKD

Yusha Zhu,[1] Xiaoqiang Ding,[2] Suzanne Wilson,[1] Xiaolu Li,[1] Ping Du,[1] Qi Zhu,[1] Geoffrey A. Block,[3] Pablo E. Pergola.[4] *[1]Kind Pharmaceuticals LLC, Redwood City, CA; [2]Zhongshan Hospital Fudan University, Shanghai, China; [3]US Renal Care Inc, Decatur, GA; [4]Renal Associates PA, San Antonio, TX.*

Background: AND017 is an oral hypoxia-inducible factor prolyl-hydroxylase inhibitor developed for the treatment of renal anemia. It was evaluated in a Phase II clinical trial of patients with end-stage kidney disease (ESKD) in the US and China (NCT05265325).

Methods: This open-label, active-controlled study involved patients with ESKD receiving stable hemodialysis, home hemodialysis, or peritoneal dialysis, on stable erythropoiesis-stimulating agent (ESA) treatment for at least 6 weeks. The trial evaluated two starting dosing regimens of AND017: 10 mg three times per week (TIW) and 16 mg once per week (QW), compared to the active control ESA treatment. Patients were randomized 1:1:1 to one of the treatment groups and were treated for 20 weeks. Dose adjustment was allowed for both AND017 and ESA in the study to maintain hemoglobin (Hb) levels within the target range of 10.0-11.0 g/dL in the US or 10.0-12.0 g/dL in China.

Results: A total of 175 patients were enrolled: 59 in the AND017 10 mg TIW group, 57 in the AND017 16 mg QW group, and 59 in the ESA group. Baseline Hb levels were balanced across treatment groups. The primary efficacy outcome was the mean change in Hb levels from baseline, averaged over Weeks 17-21. AND017 TIW and QW groups demonstrated similar capability in maintaining Hb level with ESA treatment (within the non-inferiority margin). Treatment-emergent adverse events (TEAEs) occurred in 81.4% of patients in the AND017 10 mg TIW group, 75.4% in the AND017 16 mg QW group, and 66.1% in the ESA group. Treatment-related adverse events (TRAEs) were reported in 6.8%, 10.5%, and 3.4% of patients, respectively. A total of 48 patients experienced serious adverse events (SAEs), with 32.2% patients in the AND017 10 mg TIW group, 28.2% in the AND017 16 mg QW group, and 22.0% in the ESA group; none were assessed as related to the study drug or active control.

Conclusions: AND017 was safe and well tolerated in patients with ESKD on stable dialysis. At both TIW and QW dosing frequencies, AND017 effectively maintained Hb levels within the target range after 20 weeks of treatment and demonstrated non-inferiority to ESA treatment.

TH-PO1182

Effect of Hemodialysis with Citrate on Vascular Calcification

W. Charles O'Neill, Jose E. Navarrete. *Renal Division, Emory University, Atlanta, GA.*

Background: Medial arterial calcification (MAC) is a serious problem in hemodialysis (HD) patients that leads to poor outcomes. Citrate, which can inhibit calcium crystallization, is used in some HD solutions but its effect on vascular calcification is unknown. We have shown that MAC can be conveniently measured on standard mammograms (MGs) and correlates with MAC in other locations and with cardiovascular outcomes. Therefore, we used mammography to measure changes in MAC in female HD patients during HD with and without citrate.

Methods: In this cross-over study in 4 outpatient units, patients with pre-existing MAC on MGs were recruited to 1 year periods of HD with and without citrate (Citrasate and Naturalyte, Fresenius) with MGs and measurements of serum Mg and ionized Ca (iCa), and plasma citrate every 6-months (NCT04956120). Lengths of calcified arteries were summed manually and the rate of change determined from the slope of values from the 3 MGs at the start, middle, and end of each arm. Data are means ± SE with analysis by paired t-test, or medians (interquartile range) for MAC with analysis by Wilcoxon test.

Results: 28 of 30 subjects have completed the study, 12 starting on the citrate arm. Durations of the arms did not differ (citrate: 383 ± 8 days; no citrate 407 ± 15). Dialysis adequacy, dialysate Ca, and pre-HD serum total Ca, iCa, and phosphorus did not differ between arms; pre-HD Mg was lower in the citrate arm (2.28 ± 0.05 vs. 2.42 ± 0.07 mg/dl, p=0.003. The change in serum Mg or iCa with HD did not differ significantly between arms. Pre-HD plasma citrate was similar (133 ± 8 vs. 127 ± 6 uM) but was substantially greater after HD with citrate (364 ± 17 vs. 144 ± 9 uM, p<0.001). The change in MAC was greater during citrate HD: 44 (21-121) mm/yr vs. 10 (-5-35), p=0.0002, or 35 (14-104) %/yr vs.12 (-3-23), p=0.002. 22 subjects had a greater change during citrate HD (median: 51 %/yr), while only 6 had a greater change without citrate (median: 14 %/yr). The change in MAC did not correlate with pre-HD serum iCa, P, or Mg.

Conclusions: Citrate HD unexpectedly promoted vascular calcification, which was not explained by changes in mineral metabolism or dialysis adequacy. This result may be related to known effects of citrate to promote or stabilize bone mineralization. Further studies are needed to determine the underlying mechanism and whether this is associated with adverse clinical outcomes.

Double vs. Single Icodextrin Dose in Older Incident Patients on Incremental Continuous Ambulatory Peritoneal Dialysis (CAPD): Results from the DIDo (Double Icodextrin Dose) Study

Eric Goffin,[1] Clémence Béchade,[3] Cécile Courivaud,[5] Karlien Francois,[7] Bert Bammens,[2] Michel Y. Jadoul,[1] Olivier Devuyst,[1] Martin E. Wilkie,[8] Aurélie Bertrand,[4] Thierry Lobbedez.[6] DIDo Study Group. *[1]Nephrology, Cliniques universitaires Saint-Luc, Bruxelles, Belgium; [2]Nephrology, Katholieke Universiteit Leuven, Leuven, Belgium; [3]CHU Clemenceau, Caen, France; [4]Support en Méthodologie et Calcul Statistique, Universite catholique de Louvain, Louvain-la-Neuve, Belgium; [5]Nephrology, Centre Hospitalier Universitaire de Besancon, Besancon, France; [6]Nephrology, CHU Clemenceau, Caen, France; [7]Nephrology, Vrije Universiteit Brussel, Brussel, Belgium; [8]Nephrology, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom.*

Background: Icodextrin, a high MW glucose polymer, provides sustained ultrafiltration (UF) in PD patients through colloid osmosis, leading to improved clinical outcomes. Icodextrin is limited to one bag/day. Improved UF and technical survival have been observed with an off-label use of two bags/day.

Methods: DIDo is a prospective, international, 1:1 randomized controlled trial. It investigates superiority and safety of using two vs one icodextrin bag/day to extend the duration of incremental (3 bags/day) CAPD in older (> 60 yrs) incident patients. After a 2-months *run-in period*, patients were randomized to two icodextrin + one glucose (group A) or one icodextrin + two glucose - the reference treatment - (group B) daily. Hypothesis was that group A would remain longer on 3 exchanges/day. Primary outcome was a composite of excessive predefined hypertonic dialysates use, transfer to another dialysis modality or death at M9. Secondary outcomes included mortality, daily UF, technique survival, and rates of peritonitis and hospitalizations at M18. SAEs and side-effects potentially related to icodextrin (low serum sodium, hypotension, skin rash and sterile peritonitis) were assessed.

Results: 41 patients were randomized to group A and 42 to group B. Baseline characteristics (demographics, comorbidities, lab and CAPD parameters, and medications), were well balanced between groups. Median FU was 31 months. At M9, the proportion of patients who discontinued 3 exchanges/day was similar between group A and B [16 (39%) *vs*. 21 (50%)]. There were no differences between both arms in any primary outcome component, nor significant interaction with clinical characteristics. The results were similar at M18 [(24 (59%) *vs*. 24 (57%)]. Patients in group A had significantly higher (>400 mL) daily net UF at all time points. Rates of peritonitis, hospitalizations, residual urine output and all AEs were similar between groups.

Conclusions: In older patients on incremental CAPD, a double icodextrin dose initiated at PD onset did not reduce the cumulative incidence of the composite primary outcome compared to a single icodextrin dose. Significantly enhanced UF was observed in patients receiving the double icodextrin dose while no safety issues were observed.

Community Health Worker Intervention for Latinos Receiving Hemodialysis: A Randomized Controlled Trial

Lilia Cervantes,[1] Neil R. Powe,[2] Daniel Cukor,[3] Brenda Beaty,[1] Lauren Mcbeth,[1] Romana Hasnain,[4] Michel Chonchol.[1] *[1]Medicine, University of Colorado Anschutz Medical Campus School of Medicine, Aurora, CO; [2]University of California San Francisco Department of Medicine, San Francisco, CA; [3]NYU Langone Health, New York, NY; [4]Denver Health Main Campus, Denver, CO.*

Background: Latino groups face a disproportionate burden of ESKD, social and structural issues, and subsequent kidney health disparities. While community health worker (CHW) interventions serve to reduce health disparities, effectiveness for Latinos with ESKD remains unknown.

Methods: In a randomized controlled trial, we tested a multi-level CHW intervention among Latino adults with ESKD receiving hemodialysis. Participants were randomized to receive resources for social needs, culturally responsive dietary education, and support from a CHW, or to usual care (i.e., standard treatment). A longitudinal segmented linear model with generalized estimating equations evaluated the effect of the intervention on the primary outcome of interdialytic weight gain (IDWG%) and the secondary outcome of a Patient Activation Measure (PAM).

Results: 139 individuals at 5 urban Denver dialysis facilities from 10/7/2020 to 4/29/2022 were recruited and 68 randomized to the CHW arm and 71 to the control arm **(Table 1)**. Baseline characteristics and demographic factors were similar between the groups. The post-intervention slopes differed between the intervention and control, corresponding to a decrease of 0.04% in IDWG per 30 days for intervention participants and an increase of 0.03% per 30 days for usual care (p=0.01) (**Figure 1)**. The median change in PAM for the intervention group was 1.8 points (IQR -2.2, 5.5) compared to -2.2 (IQR -7.4, 2.5) for the usual care group; Wilcoxon text p=0.005.

Conclusions: Among Latino individuals with ESKD receiving standard in-center hemodialysis, a multicomponent CHW intervention reduced IDWG and improved patient activation as compared to usual care.

Background: High-flux hemodialysis (HD) and high-dose hemodiafiltration (HDF) are established treatments for patients with kidney failure. HDF has been associated with improved survival rates compared to HD. This study evaluated the cost-effectiveness of HDF compared to HD.

Methods: Cost–utility analyses were performed from a societal perspective alongside the multinational randomized controlled CONVINCE trial, with a two-year and a lifetime time-horizon using a Markov model. Costs of dialysis sessions were based on published data. Other healthcare resource use, productivity losses and quality of life were collected in the eCRF or by country-adapted, self-reported questionnaires. Scenario and probabilistic sensitivity analyses were performed.

Results: HDF was associated with higher utility values compared to HD (0.80 vs 0.78 per year alive), and higher costs (€775 difference per year alive), mainly due to increased dialysis costs (€4/session). Combining these findings with observed mortality in

the model resulted in a quality-adjusted life year (QALY) gain of 1.00, with incremental costs per QALY (ICER) ranging from €36,590 to €51,386. The ICER was €15,768 when excluding all costs in additional life years. Sensitivity analyses showed the probability of cost-effectiveness was >75% at willingness-to-pay threshold of €60,000/QALY, and <30% at €20,000/QALY.

Conclusions: Compared to HD, HDF resulted in an additional year in perfect health at increased costs. The probability of cost-effectiveness is mainly driven by dialysis costs in life years gained. At a €60,000/QALY threshold, probability of HDF being cost-effective exceeded 75%. As costs may differ between countries and centers, we recommend translating our results to local settings.

Ferric Citrate for the Prevention of Renal Failure in Adults with Advanced CKD: The FRONTIER Trial

Geoffrey A. Block,[1] Steven K. Burke,[2] Martha Block,[1] Stephanie Brillhart,[1] Amanda Leppink,[1] Gerard J. Smits,[6] Mohammad R. Mizani,[5] Pablo E. Pergola,[3] F. David Newby,[4] Varshasb Broumand,[5] Bryce S. Foote,[2] Mary O. Dittrich.[1]
[1]US Renal Care, Plano, TX; [2]Akebia Therapeutics Inc, Cambridge, MA; [3]Renal Associates PA, San Antonio, TX; [4]Nephrology and Hypertension Specialists, PC, Dalton, GA; [5]South Texas Renal Care Group, San Antonio, TX; [6]CSC, Inc., Santa Barbara, CA.

Background: In a prior study of patients (pts) with advanced CKD, Ferric Citrate (FC) significantly reduced time to a composite endpoint of death, dialysis or kidney transplant. Important study design limitations constrain the interpretation of these findings.

Methods: In this 9-month, randomized, double-blind, placebo-controlled clinical trial, pts with eGFR ≤20 ml/min/1.73m^2 were randomized 1:1 to receive fixed dose (2 tablets/meal) FC or matching placebo. The primary endpoint was time to a composite endpoint of initiation of maintenance dialysis or all-cause mortality. Secondary endpoints were time to first hospitalization and individual components of the primary endpoint. Analysis used ITT with ANCOVA adjusting for age, baseline eGFR, and history of diabetes, ASCVD and CHF.

Results: 289 pts were randomized to FC (n=144) or placebo (n=145). The treatment arms were well balanced with no statistical differences in pt characteristics. We observed a statistically non-significant 27% reduction in risk of the primary composite endpoint, (Fig. 1, p=0.12). Individual components of the primary endpoint are shown in Fig. 1. 24% of pts randomized to FC experienced ≥1 serious adverse events vs 32% of pts given placebo. FC was associated with a statistically non-significant reduction in mean hospitalizations (p=0.46), mean hospital days (p=0.41) and time to first hospitalization (p=0.22) (Fig. 2). Similarly, there was a statistically non-significant reduction in time to first ESA use (p=0.79) and time to first IV iron use (p=0.07).

Conclusions: In pts with advanced CKD, fixed dose FC resulted in clinically meaningful, though statistically non-significant, reductions in time to the composite endpoint of death or dialysis, hospitalization, ESA use and IV iron use. The sample size of the trial likely reduced the ability to demonstrate statistically significant results. These findings strongly suggest that re-purposing FC for prevention of kidney failure in pts with advanced CKD may meaningfully improve outcomes.

Effects of Oxylanthanum Carbonate in Patients Receiving Maintenance Hemodialysis with Hyperphosphatemia

Geoffrey A. Block,[1] Glenn M. Chertow,[2] Guru Reddy,[3] Sanjay S. Mourya,[3] Martha Block,[1] Steve Hasal,[3] Shalabh Gupta,[3] Pablo E. Pergola.[4] *[1]US Renal Care Inc, San Antonio, TX; [2]Stanford University School of Medicine, Stanford, CA; [3]Unicycive Therapeutics, Inc., Los Altos, CA; [4]Renal Associates PA, San Antonio, TX.*

Background: In patients with chronic kidney disease (CKD) on dialysis, hyperphosphatemia is managed by reducing dietary intake of phosphate (P) and phosphate lowering therapies. Oxylanthanum carbonate (OLC) is a phosphate binder in development with high potency and low pill burden. This study assessed the general tolerability of OLC in hyperphosphatemic CKD patients on hemodialysis.

Methods: We conducted a Phase 2, open-label, single-arm, multicenter, multidose study in adult patients with hyperphosphatemia receiving maintenance hemodialysis. The primary objective was to evaluate the tolerability of OLC at clinically effective doses (goal serum P ≤5.5 mg/dL). The study included Washout, Titration, and Maintenance Periods. Eligible patients had serum P ≥4.0 mg/dL and ≤7.5 mg/dL for at least 8 weeks prior to screening while on stable hemodialysis and P-lowering regimens. Patients started titration when their serum P was >5.5 mg/dL and entered maintenance once their serum P was ≤5.5 mg/dL, or after 6 weeks, whichever was sooner. The starting dose of OLC during titration was 1500 mg/day (500 mg TID). We assessed tolerability based on the incidence of discontinuations due to adverse drug reactions (ADRs).

Results: A total of 86 patients were treated with OLC during the study. At screening, serum P was ≤5.5 mg/dL in 51 (59%) patients on a stable P-binder regimen. A total of 78 patients entered maintenance, and 71 (91%) patients had serum P <5.5 mg/dL on a median dose of 1500 mg/day. The most common ADRs were gastrointestinal and included diarrhea (9%) and vomiting (6%); all other ADRs were reported in <5% of patients. Two patients discontinued due to ADRs during titration and 1 patient during maintenance.

Conclusions: In this open-label study, use of OLC enabled adequate control of serum P in >90% of patients who entered maintenance. OLC was safe and generally well-tolerated with ADRs commonly seen in this patient population and with other P binders.

Which Patients Benefit the Most from Hemodiafiltration Compared with Hemodialysis? Prediction of Individualized Treatment Effects

Peter J. Blankestijn,[1] Robin W. Vernooij,[1,2] Michiel L. Bots.[2] The CONVINCE Study Group. *[1]Department of Nephrology and Hypertension, Universitair Medisch Centrum Utrecht, Utrecht, Netherlands; [2]Julius Center for Health Sciences and Primary Care, Universitair Medisch Centrum Utrecht, Utrecht, Netherlands.*

Background: High-dose haemodiafiltration (HDF) reduces all-cause death. No differences in treatment effects are found for specific patient populations when defined on a single characteristic in subgroup analyses. Yet, it is unclear to what extent individual patients, characterized by a combination of clinical characteristics, may benefit from HDF. This study aimed to develop and internally validate a treatment effect prediction model to determine which individual patients would benefit most from well dosed HDF, compared with haemodialysis (HD), in terms of survival.

Methods: Individual participant data from five randomized controlled trials (CONTRAST, ESHOL, Turkish HDF study, French HDF study, CONVINCE) comparing HDF with HD on all-cause mortality were used to derive a Royston-Parmar model for exploring the prediction of absolute treatment effect of HDF based on pre-specified patient and disease characteristics, notably age, sex, body mass index, diabetes mellitus, history of cardiovascular disease, creatinine levels, and c-reactive protein levels. Internal validation of the model was performed using internal-external cross validation.

Results: Among 4153 participants, with a median follow-up of 30 months (Q1-Q3: 24-36), death from any cause occurred in 558 patients (27.2%). The median predicted survival benefit of HDF compared with HD was 6.9 (Q1–Q3: 5.6–9.0) months, with a range of 2 to 42 months. Patients who were predicted to benefit most from HDF were younger, less likely to have diabetes or a cardiovascular history and had higher serum creatinine levels. Internal-external cross validation showed adequate discrimination and calibration.

Conclusions: All-cause mortality is reduced by HDF compared with HD in ESKD patients. Yet, the absolute survival benefit seems to considerably differ between individual patients. Our results suggest that the effects of HDF on absolute survival can be predicted using a combination of readily available patient and disease characteristics. This prediction model approach exemplifies the potential of prediction algorithms in supporting clinical decision-making for the choice of treatment options.

Background: Limited data exists on the effects of intradialytic exercise and ketoanalogue(KA) supplementation on muscle mass, function and fatigue in Hemodialysis (HD) patients

Methods: In a randomized controlled trial, 80 HD patients were assigned to one of four groups: (1) KA supplementation only, (2) intradialytic exercise only, (3) both interventions combined, and (4) a control group with standard care. Over 3 months, KA was given as one tablet per 10 KG of patient weight daily, and exercises included knee extensions, hip abductions with ankle weights. Outcomes measured were muscle mass by bioimpedance, quadriceps rectus femoris and vastus intermedius thickness by ultrasonography (US), functional assessments (sit-to-stand test, hand grip strength), and fatigue (Modified Fatigue Impact Scale (MFIS)).

Results: There were no statistically significant differences in baseline parameters between groups. The KA supplementation only- group showed a statistically significant improvement in MFIS, with median values changing from 26(IQR 37) pre-trial to 16.5(15) post-trial (p=0.01), and in the sit-to-stand test showed significant improvements in the number of unaided trials, with median values increasing from 8.5(7) to 10(7) (p=0.02). Hand grip strength also improved from 22.2(14.7) to 25.6(3.6)(p=0.008). The combined interventions group showed significant MFIS improvement, with median values from 29(32) pre-trial to 24(20) post-trial (p=0.03), and hand grip strength improved from 13.1(10) to 21(14.2)(p=0.006). No significant differences in improvement of fatigue scores or hand grip strength were found between the KA supplementation and combined interventions groups. The intradialytic exercise only- group had a significant increase in hand grip strength from 16.1(13.5) to 21.8(7.8)(p=0.006). The control group showed no significant changes. There were no significant differences among groups in anthropometric measures, quadriceps muscle US measurements, or Skeletal Muscle Index assessed by bioimpedance.

Conclusions: KA supplementation could enhance physical performance in HD patients, as evidenced by improvements in fatigue and functional strength. However, the effects on muscle mass were not significant.

TH-PO1191

Long-Term Experience of Treating CKD-Associated Pruritus (CKD-aP) with Difelikefalin at a Large Dialysis Organization in the United States

Rachel A. Lasky,[1] Despina Ruessmann,[2] Linda Ficociello,[1] Maria Gil Mir,[3] Hans-Juergen Arens,[3] Michael S. Anger.[1] *[1]Global Medical Office, Fresenius Medical Care, Waltham, MA; [2]Medical Affairs, CSL Vifor Pharma Group, Glattbrugg, Switzerland; [3]Frenova, Fresenius Medical Care, Bad Homburg, Germany.*

Background: Difelikefalin (DFK), a selective κ-opioid receptor agonist, is the first medication approved for treatment of moderate-to-severe CKD-aP among patients (pts) on chronic hemodialysis. The ability of DFK to lower itch has been shown in clinical and real-world studies. However, long-term, real-world experience of DFK treatment has not been described. The current analysis aims to describe the routine clinical use of DFK in pts for up to 6 months.

Methods: The analysis included in-center hemodialysis pts aged 18-89 years having 1) DFK initiated between 12/1/2022 and 12/31/2023, 2) completed at least one Worst Itch Numeric Rating Scale (WI-NRS) assessment during the 90 days before DFK treatment start and one during DFK treatment, and 3) received ≥ 30 doses of DFK during the first 12 weeks. Pts were then categorized into groups based on their treatment experience after 12 weeks, including those who 1) continued DFK without a gap, 2) paused treatment for 14-44 days then restarted DFK (short gap), 3) paused treatment for > 44 days then restarted DFK (long gap), and 4) discontinued DFK. Each WI-NRS available was determined to be during treatment with DFK (within 14 days of last DFK treatment) or after DFK treatment.

Results: Of 619 pts included in the analysis (56% male, 44% female), 70 had baseline moderate itch and 549 had baseline severe itch. On average, pts were 66.2 years old with a dialysis vintage of 4.1 years. The mean itch score for all groups before DFK treatment ranged between 8.3 and 8.5. A mean itch reduction of at least 3 points on the WI-NRS assessment while being treated with DFK was observed for each group (Table 1). The mean itch score increased for all groups during a gap in DFK treatment or after discontinuation.

Conclusions: Despite differences in treatment patterns after initial 12 weeks of DFK treatment, all pt groups experienced a reduction in itch while receiving DFK. Mean itch scores also increased in all groups after pausing or discontinuing DFK treatment.

DIalysis Symptom COntrol-Pruritus Outcome Trial (DISCO-POT): A Multicenter, Randomized, Double-Blinded, Placebo-Controlled Crossover Trial

David T. Collister,[1,2] Kathy Cherepak,[3] Navdeep Tangri,[1,3] Michael Walsh.[4,5] DISCO-POT Investigators. *[1]Medicine, University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada; [2]Medicine, University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; [3]Chronic Disease Innovation Center, Winnipeg, MB, Canada; [4]Medicine, McMaster University Faculty of Health Sciences, Hamilton, ON, Canada; [5]Population Health Research Institute, Hamilton, ON, Canada.*

Background: Uremic pruritus affects 50% of patients with kidney failure and negatively impacts quality of life. Itch often persists despite effective pharmacologic treatments. Cannabinoids may reduce pruritus. We evaluated nabilone, a synthetic cannabinoid, to treat uremic pruritus.

Methods: Eligible participants were adults age≥25 years receiving in-center or home hemodialysis at least 2x weekly or peritoneal dialysis daily for at least 90 days and at least moderate itch defined by a mean worst visual analogue scale (VAS) >40mm during a 1-week screening period. Participants were randomly allocated to oral nabilone 0.5mg daily x 1 week then nabilone 0.5mg twice a day x 3 weeks or an identical placebo regimen. Then, after a 2-week washout, participants received an identical regimen of nabilone or placebo, whichever they did not receive in the first treatment period. The primary outcome was the difference in worst VAS over the last 24 hours over each 4 week crossover period.

Results: Of 14 participants randomized, the mean (SD) age was 60.5 (12.7) years, 4 (28.6%) were female sex, 8 (57.1%) had diabetes, and all were on hemodialysis for a mean (SD) of 3.29 (0.73) sessions per week for a mean (SD) 4.04 (0.50) hours/treatment. The mean (SD) worst VAS was 69mm (25). Baseline co-interventions included topical emollients in 12 (85.7%) and alpha 2 delta ligands in 7 (50%). Self-reported and pill count adherence was >90%. Nabilone did not reduce the worst VAS to a greater extent than placebo (Figure 1). The worst VAS was 4.79 (95% CI -3.95 to 13.5, p=0.28) higher with nabilone compared to placebo, indicating worse itch. Nabilone also had no effect on other measures of itch, sleep, quality of life or adverse events.

Conclusions: This small trial detected no effect of nabilone on uremic pruritus compared to placebo. (ClinicalTrials.gov NCT05180968)

Real-World Effectiveness of Patiromer among Hemodialysis (HD) Patients: 1-Year Follow-Up on a Retrospective Cohort

Meijiao Zhou,[1] Despina Ruessmann,[2] Linda Ficociello,[1] Maria Gil Mir,[3] Hans-Juergen Arens,[3] Michael S. Anger.[1] *[1]Global Medical Office, Fresenius Medical Care, Waltham, MA; [2]Medical Affairs, CSL Vifor Pharma Group, Glattbrugg, Switzerland; [3]Frenova, Fresenius Medical Care, Bad Homburg, Germany*.

Background: Patiromer (PAT) is a sodium-free, non-absorbed, calcium-based potassium (K^+) binding polymer indicated for treating hyperkalemia. This study aimed to describe PAT utilization and evaluate the changes in serum K^+ (sK) before and after PAT prescription in hemodialysis (HD) patients (pts) over a one-year follow-up period.

Methods: Adult Fresenius Kidney Care HD pts first prescribed PAT monotherapy between 1/2016- 12/2022 were included in the analysis. Eligible pts were on thrice-weekly HD for at least 90 days at the start of PAT and had available sK lab values in the 91 days prior to PAT initiation (baseline; bl; -3M to -1M) and during one year of PAT treatment (follow up; fup; Q1 to Q4; M1 to M12). Changes in lab measurements and prescribed dialysate were compared between bl and fup.

Results: At bl, pts (n=10854) had mean age of 60 years, HD vintage 58 months, 42% were female, 67% had diabetes, 20% had congestive heart failure, and 92% were not on K^+ binders. As shown in the figure, sK increased from 5.41 to 5.76 mEq/L before PAT initiation and decreased to 5.34- 5.21 mEq/L after PAT initiation. % of pts with sK<5.5 mEq/L nearly doubled from bl to Q4. Most pts initiated PAT at 8.4 g (91%) once daily (56%). Over fup, the average PAT dosage was one 8.4 g packet per day. Serum calcium was 8.93 mg/dL at bl and 8.96 mg/dL at Q4; serum sodium was 136.8 and 137.0 mEq/L at bl and Q4, respectively. % pts with calcium-phosphate product <4.4 $mmol^2/L^2$ increased from 58.7% at bl to 63% at Q4. Dialysate calcium and sodium remained stable during the study period. % of pts prescribed one or more treatments with 1 mEq/L K^+ bath decreased from 17.1% at bl to 11.0% at Q4.

Conclusions: Maintenance HD pts prescribed PAT experienced reductions in sK that were maintained over a year-long fup. % pts achieving sK<5.5 mEq/L nearly doubled from 35.5% at bl to 70.1% at Q4.

SPARKLE: A Multicenter, Open-Label Study to Evaluate the Safety and Diagnostic Efficacy of ACE-MBCA in Patients with Known or Suspected Focal Liver Lesions and Severe Renal Impairment

Anna Laura Croci Chiocchini,[1] Andreas L. Norlin,[2] Nadilka Hettiarachchige,[2] David I. Ortiz Melo.[3] *[1]Nephrology, IRCCS Azienda Ospedaliero-Universitaria di Bologna Policlinico di Sant'Orsola, Bologna, Italy; [2]Ascelia Pharma AB, Malmo, Sweden; [3]Duke University, Durham, NC.*

Background: ACE-MBCA (Ascelia Pharma Manganese Based Contrast Agent, proposed trade name Orviglance) is an oral manganese-based liver-specific MRI contrast agent. Over 35 million Americans have renal disease, those severely affected at higher risk of safety concerns associated with Gadolinium Based Contrast Agents (GBCAs). This phase 3 study evaluates the safety and efficacy of ACE-MBCA in patients with focal liver lesions and severe renal impairment, a group for which the FDA has issued a black-box warning for all GBCAs due to the kidneys' reduced ability to remove the GBCAs from the bloodstream. The study uniquely includes patients with severe kidney disease, often excluded due to high safety risks, addressing a critical gap in imaging research and providing insights into the safety and efficacy of ACE-MBCA for liver MR contrast agent alternatives.

Methods: In this global phase III study, patients (N=85) with known or suspected focal liver lesions and severe renal impairment received a liver MRI before and 4±1 h after the administration of ACE-MBCA (800 mg). The primary analysis, improvement in visualization of focal lesions, was evaluated by 3 independent readers by qualitative scoring of the change in two co-primary variables, lesion contrast (LC) and border delineation (BD) (scores from 1= poor to 4= excellent). Safety follow-ups, at 24 (± 4) h, 48 (± 4) h, and 5 (± 2) days post-dose.

Results: In 85 patients, the primary analysis showed highly significant ($p<0.001$) improvement of the mean LC and BD scores in combined MRI (CMRI: combined contrast-enhanced + unenhanced MRI) compared to unenhanced MRI: Across the 3 readers, the mean (SD) LC increased by between 0.65 (0.622) and 0.95 (0.824) score points and mean (SD) BD was increased by between 0.81 (0.678) and 1.02 (0.909) score points. No patients were withdrawn from the study. The most reported post-dose AEs were mild to moderate nausea (16.1%), diarrhea (13.8%), vomiting (9.2%), and blood urea increased (3.4%). No drug-related serious AE or deaths were reported.

Conclusions: ACE-MBCA 800 mg significantly improves diagnostic efficacy over unenhanced MR, offering a promising future diagnostic tool for kidney-impaired patients who currently lack safer options for contrast-enhanced liver MRI.

Azithromycin for the Prevention of Hemolytic Uremic Syndrome in Shiga Toxin-Positive Diarrhea: A Proof of Concept

Gianluigi Ardissino,[1] Letizia Dato,[2] Maria Cristina Mancuso,[1] Thomas Ria,[1] Laura Daprai,[3] Alessandra Gazzola,[4] Alessandra Bazzucchi,[3] Michela Piccoli,[3] Ilaria Possenti,[5] Alice Monzani,[2] Laura Martelli,[6] Angela Amoroso,[6] Giovanni Raimondo Pieri,[5] Antonio Vergori,[7] Sonia Monticone,[2] Marta Cerutti,[2] Cristina Partenope,[2] Anna Elisabetta Bussolini,[8] Alessandra C. Ferrari,[9] Elisa La Barba,[10] Giulia M. Smylie,[11] Simone V. Benatti,[12] Mario V. Luini.[13] ItalKid-HUS Network. *[1]Center for HUS Prevention, Control and Management, Pediatric Nephrology, Dialysis and Transplantation Unit, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milan, Italy; [2]Division of Pediatrics, Department of Health Sciences, Università del Piemonte Orientale, Novara, Italy; [3]Laboratory of Microbiology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [4]Experimental Zooprophylactic Institute of Lombardy and Emilia-Romagna, Lodi, Italy; [5]Pediatric Unit, Pediatric Hospital C. Arrigo, Alessandria, Italy; [6]Pediatric Unit, ASST Papa Giovanni XXIII, Bergamo, Italy; [7]Pediatric Unit, Ospedale F. Del Ponte, Varese, Italy; [8]Pediatric Unit, ASST Settelaghi, Tradate, Italy; [9]Pediatric Unit, ASST Cremona, Cremona, Italy; [10]Pediatric Unit, ASST Lariana, Cantù, Italy; [11]Pediatric Unit, Ospedale di Busto Arsizio, ASST Valle Olona, Busto Arsizio, Italy; [12]Clinic of Infectious Diseases, Dept of Health Sciences, University of Milan, ASST Santi Paolo e Carlo, Milan, Italy; [13]Institute of Agricultural Biology and Biotechnology – IBBA-CNR, National Research Council, Lodi, Italy.*

Background: During the last decade, it has become increasingly common to diagnose Shiga Toxin *Escherichia Coli*-related (STEC) infection before Hemolytic Uremic Syndrome (HUS) has developed, providing a potential window of treatment opportunity that, besides generous rehydration, goes underexploited. Antibiotic treatment is historically contraindicated in Shiga Toxin-positive diarrhea on the assumption that it may trigger STEC-HUS. However, this concept is based on weak evidence mostly concerning bactericidal agents and may not apply to bacteriostatic antibiotics. Several *in vitro* and *in vivo* studies both on animal models and on humans indicate that azithromycin may be safe and effective in preventing HUS or mitigating disease severity.

Methods: All STEC infections were treated with azithromycin 10 mg/kg/die orally until diarrhea remission (maximum of 5 days).

Results: Twenty-seven patients (median age 4.4 years) with STEC-positive diarrhea were treated with azithromycin. The treatment was started after a median time of 4 days since the onset of symptoms (2 days since the onset of bloody diarrhea) and it was continued for a median time of 5 days. Of the treated patients, 19% were positive for Stx1, 44% for Stx2, 37% for both Stx1 and Stx2. One out of 27 patients developed HUS after the first dose of azithromycin. No treatment-related side effect was observed.

Conclusions: Azithromycin seems safe and may represent a useful therapeutic option in patients with STEC-positive diarrhea to prevent HUS. A controlled study is necessary but, in the meantime, STEC-infected patients should be treated based on the currently available evidence.

TH-PO1197

GFR Changes Following Urinary Tract Infection (UTI) in Children with Vesicoureteral Reflux (VUR)

David S. Hains, Michelle C. Starr, Andrew L. Schwaderer. *Pediatrics, Indiana University School of Medicine, Indianapolis, IN.*

Background: The Randomized Intervention for Children with Vesicoureteral Reflux (RIVUR) trial examined whether continuous antibiotic prophylaxis (CAP) prevented recurrent UTIs in children with VUR. Kidney scarring by dimercaptosuccinic acid (DMSA) scan was a secondary outcome. CAP did not prevent kidney scarring at 2-year study conclusion. Intra-patient changes in kidney function were not assessed. We determined eGFR changes in RIVUR participants with vs without UTI.

Methods: We calculated eGFR via Schwartz formula in RIVUR participants aged ≥6 months with entry and exit serum creatinine measurements available. Exposure: study and lifetime UTIs. Outcome: ΔeGFR, calculated as 2-year exit eGFR minus entry eGFR. We also performed multivariable linear regression.

Results: Children with >1 study UTI had a mean ΔeGFR 12.3 lower than those with ≤1 UTI (*P*=.03). Children with >1 symptomatic UTI receiving placebo had a mean ΔeGFR 19.9 lower than those with ≤1 UTI (*P*=.01). Children with >1 febrile UTI receiving placebo had a lower net ΔeGFR by 27.1.vs. those with ≤1 UTI (*P*=.02). In multivariable analysis, the association between >1 study febrile UTI and ΔeGFR remained after adjustments in the overall cohort and placebo group. No difference was seen between among those treated with CAP. While no differences existed in any groups with a single study UTI, this does not account for individuals that had multiple UTIs at entry. Thus, we examined lifetime UTIs and found those that had >1 lifetime UTI had lower net ΔeGFR (Table). Finally, ΔeGFR was not associated with new DMSA scar formation during the study.

Conclusions: Multiple UTIs may have a detrimental effect on kidney function. CAP may preserve eGFR. Our findings indicate that recurrent febrile UTIs are associated with a decrease in eGFR of up to 27 mL/min/1.73². DMSA scans do not reflect clinically relevant changes in kidney function.

Table. Change in Kidney Function in Children Aged 6 Months or Older[a]

	Unadjusted Mean (Standard Deviation) ΔeGFR[2 b]			Adjusted Difference in ΔeGFR (95% CI), mL/min/1.73[2c]
	Overall	>1 UTI	≤1 UTI	
Overall	9.5 (24.1)			
Prophylaxis (N=89)	6.8 (21.4)			
Placebo (N=99)	11.9 (26.2)			
UTI During Study (N=188)		-1.9 (20.5)	10.4 (24.2)	-8.6 (-21.8 to 4.6)
Prophylaxis (N=89; 4 with >1 UTI)		8.3 (28.4)	6.7 (21.3)	-8.0 (-30.6 to 14.5)
Placebo (N=99; 10 with > 1 UTI)		-5.9 (16.5)	14.0 (26.4)	-11.3 (-30.4 to 7.8)
Febrile UTI During Study (N=188)		-4.0 (23.5)	10.2 (24.0)	-16.7 (-32.1 to -1.3)
Prophylaxis (N=89; 4 with > 1UTI)		8.3 (28.4)	6.7 (21.3)	-8.0 (-30.6 to 14.5)
Placebo (N=99; 5 with > 1 UTI)		-13.9 (15.0)	13.3 (26.0)	-22.3 (-43.5 to -1.0)
Lifetime UTI (N=188)[d]		3.7 (3.2)	11.8 (2.1)	-2.7 (-6.8 to 1.5)

Placebo (N=99; 32 with > 1 UTI)		4.3 (4.6)	15.6 (3.1)	-5.1 (-10.1 to -0.1)
Number of Lifetime UTIs[d]	Unadjusted Median (IQR) ΔeGFR[2 e]			
	Overall	Prophylaxis (N=89)	Placebo (N=99)	
1	10.1 (-5.4, 25.4)	6.6 (-8.7, 24.4)	16.2 (-1.3, 32.5)	
2	4.0 (-8.6, 21.3)	3.4 (-14.7, 10.7)	9.3 (-8.6, 29.3)	
3	6.1 (-15.2, 26.3)	18.0 (-4.0, 37.5)	0.59 (-15.8, 25.8)	
4	1.1 (-6.5, 6.5)	1.1 (-0.07, 2.2)	-1.2 (-13.0, 10.7)	
5	-7.3 (-19.3, 5.2)	NA	-7.3 (-19.3, 5.2)	
Adjusted Difference in ΔeGFR (95% CI) for each additional lifetime UTI	-2.6 (-11.4, 6.3)	2.3 (-10.0, 14.6)	-5.5 (-17.7, 6.7)	

Abbreviations: ΔeGFR, change in estimated glomerular filtration rate; UTI, urinary tract infection

[a] All ΔeGFR values represent the eGFR in ml/min/1.73 m² at 2-year exit minus the eGFR at enrollment

[b] Given normality, statistical comparisons are reported with mean with standard deviation and comparisons were performed using 2-tailed t test

[c] Adjusted difference in ΔeGFR between groups after adjustment for eGFR at enrollment, bowel and bladder dysfunction at baseline (absent or present, not toilet trained), and age in months (6-11, 12-23, 24-36 and ≥36) using ordinary least squares.

[d] Includes index UTI and UTI prior to index if applicable

[e] Given non-normality, statistical comparisons were reported as medians with IQR and comparisons between were performed using ANOVA.

TH-PO1198

Effect of Pravastatin on Kidney Disease Outcomes in Adult Patients with Early-Stage Autosomal Dominant Polycystic Kidney Disease

Berenice Y. Gitomer,[1] Wei Wang,[1] Anna Ostrow,[1] Kristen L. Nowak,[1] Diana George,[1] Erin R. Coleman,[1] Nayana Patel,[2] Anna Jovanovich,[1] Jelena Klawitter,[1] Zhiying You,[1] Michel Chonchol.[1] *[1]Medicine, University of Colorado Anschutz Medical Campus School of Medicine, Aurora, CO; [2]Radiology, University of New Mexico Health Sciences Center, Albuquerque, NM.*

Background: We previously showed that pravastatin slowed the rate of increase in height adjusted total kidney volume (HtTKV) over 3-years in children and young adults with autosomal dominant polycystic kidney disease (ADPKD). To assess whether pravastatin has similar kidney benefits in adults we performed a randomized, placebo-controlled, clinical trial in patients with ADPKD and preserved kidney function.

Methods: 150 patients, aged 25-60 years with an estimated glomerular filtration rate (eGFR) ≥ 60 ml/min/1.73m² were randomized to receive either 40 mg/day pravastatin or a placebo over 2-years. Total kidney volume was assessed by magnetic resonance imaging and renal blood flow by magnetic resonance angiography. Kidney function was measured by iothalamate (mGFR) and estimated using a cystatin-based equation. Patients with baseline and 2-year data were included in the analyses. The primary outcome was the annual % change in HtTKV. Secondary outcomes were the annual rate of decline in mGFR and the change in renal blood flow.

Results: The mean age of patients was 40±10 years and 65% were female. Eleven subjects withdrew and 1 subject was excluded from the analyses. Among the 138 patients who completed the study, there were no significant differences in changes in HtTKV, measures of kidney function or renal blood flow between placebo and pravastatin treated patients (Table 1).

Conclusions: Pravastatin did not affect the rate of cyst growth. The minimal effects on renal blood flow observed in the study are consistent with the known effect of statins on the vasculature.

Funding: Other U.S. Government Support

Table 1 Effect of Pravastatin on kidney volume and function

Parameter	Overall, N	Placebo	Pravastatin	p-value[1]

Outcomes of the DUPLEX Trial in Patients with Genetic Focal Segmental Glomerulosclerosis (gFSGS)

Jennifer Lai Yee,[1] Wu Gong,[2] Jula K. Inrig,[2] Michelle N. Rheault,[3] Radko Komers,[2] Howard Trachtman.[1] *[1]Department of Pediatrics, Division of Nephrology, University of Michigan, Ann Arbor, MI; [2]Travere Therapeutics, Inc., San Diego, CA; [3]Department of Pediatrics, University of Minnesota Medical School, Minneapolis, MN.*

Background: gFSGS, caused by mutations in podocyte genes, is generally refractory to most available treatments. The DUPLEX trial evaluated the efficacy and safety of sparsentan (SPAR) vs irbesartan (IRB) in patients with FSGS. Overall, the trial showed a greater reduction of proteinuria with SPAR treatment; however, it is uncertain if SPAR's efficacy varies by underlying pathogenesis. Therefore, this post hoc analysis aims to assess the efficacy of SPAR in the subset of DUPLEX patients with gFSGS.

Methods: A total of 355 study patients were genotyped by the FSGS panel of Prevention Genetics. Patients with pathogenic or likely pathogenic variants in podocyte genes were classified to have gFSGS with Mendelian inheritance. The outcome analysis examined changes in proteinuria (percentage reduction; achieving complete remission [CR; urine protein-to-creatinine ratio <0.3 g/g at any time]) and proportion of patients reaching end-stage kidney disease (ESKD; estimated glomerular filtration rate [eGFR] <15 mL/min/1.73 m^2, dialysis, or transplant) with SPAR vs IRB.

Results: Overall, 8.7% (n=31) were identified to have gFSGS. At baseline, patients with gFSGS were younger and had higher eGFR vs the overall DUPLEX population, and most had nephrotic-range proteinuria. SPAR showed a more rapid and more pronounced reduction in proteinuria vs IRB, and this effect was sustained (**Table**). The same pattern was observed in the subset of patients with *NPHS2* mutations. CR was achieved only in SPAR-treated patients with gFSGS (n=1 [8%] vs n=0), whereas reaching ESKD was more frequent with IRB (n=3 [17%] vs n=1 [8%]).

Conclusions: There was more pronounced early antiproteinuric response to SPAR vs IRB in patients with gFSGS that was sustained over the treatment period. The findings support a recommendation for SPAR administration to reduce proteinuria and achieve long-term kidney health benefits in this high-risk group of patients with gFSGS.

Funding: Commercial Support - Travere Therapeutics, Inc.

Outcomes

All gFSGS		SPAR (n=13)	IRB (n=18)
Reduction in proteinuria, %*	Week 12	−53 (−67 to −33)	−25 (−44 to 2)
	Week 36	−63 (−74 to −48)	−35 (−52 to −12)
	Week 108	−49 (−66 to −23)	−27 (−49 to 3)
Complete remission, n (%)	At any time	1 (8)	0 (0)
ESKD, n (%)	At any time	1 (8)	3 (17)

ESKD, end-stage kidney disease; gFSGS, genetic focal segmental glomerulosclerosis; IRB, irbesartan; LS, least square; SPAR, sparsentan.
*Geometric LS Mean Percent Change from Baseline (95% CI).

RGLS8429 Increases Urinary PC1 and PC2 and May Reduce Height-Adjusted Total Kidney Volume (htTKV) in Patients with ADPKD

Alan S. Yu,[1] Rekha Garg,[2] Keith A. Bellovich,[3] Arnold L. Silva,[5] Claire S. Padgett,[2] Edmund C. Lee,[2] Tania M. Valencia,[2] Timothy L. Kline,[4] Adriana Gregory,[4] Kevin Carroll,[6] Vishal Patel.[7] *[1]The University of Kansas Medical Center, Kansas City, KS; [2]Regulus Therapeutics Inc, San Diego, CA; [3]St. Clair Nephrology Research, Detroit, MI; [4]Mayo Clinic Minnesota, Rochester, MN; [5]Boise Kidney and Hypertension Institute, Boise, ID; [6]KJC Statistics Limited, Cheadle, United Kingdom; [7]The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: ADPKD is caused by mutations in either PKD1 or PKD2, leading to reduced expression or function of PKD-encoded proteins PC1 and PC2. This results in widespread dysregulated gene expression, hyperproliferation of renal tubular epithelia, formation of multiple cysts, progressive enlargement of the kidneys, and declining renal function. The microRNA miR-17 inhibits PKD1 and PKD2 and is implicated in the dysregulated gene expression observed in ADPKD. RGLS8429 is an anti-miR-17 oligonucleotide that derepresses miR-17 mRNA targets, including PKD1 and PKD2, leading to increased PC1 and PC2 and amelioration of PKD in multiple mouse models.

Methods: We conducted a randomized, double-blind, placebo-controlled, Phase 2a MAD study in patients with ADPKD evaluating RGLS8429 in 3 weight-based cohorts (1, 2, 3 mg/kg). The key inclusion criteria were Mayo Class 1C, 1D, or 1E, and an eGFR between 30-90 mL/min/1.73 m2. The treatment duration was 12 weeks with RGLS8429 or placebo subcutaneous injection Q2W x 7 doses, with an end of study visit 4 weeks after the last dose. We measured urinary PC1 and PC2 levels before and at multiple points after randomization. An exploratory analysis of the change in htTKV from the baseline compared to the end of study was conducted.

Results: We enrolled 42 subjects (32 RGLS8429, 10 placebo) with balanced baseline characteristics between RGLS8429 group and placebo. RGLS8429 was well tolerated. RGLS8429 treatment raised urinary PC1 and PC2 levels in a dose-dependent manner. The change from baseline to end of study in PC1 and PC2 levels was statistically significant in the 3 mg/kg cohort (n=11) compared to the placebo cohort (n=9). Geometric least squares mean percent change in htTKV over 16 weeks was 2.5, 1.4, -0.6, and -0.6 for placebo, 1, 2, and 3 mg/kg groups, respectively. 70% of subjects receiving 3 mg/kg had a reduction in htTKV.

Conclusions: Results provide clinical proof of dose-responsive RGLS8429 mechanistic activity on PC1 and PC2. Exploratory analysis suggests a reduction of htTKV at 2 and 3 mg/kg doses over a relatively short treatment period. Findings validate miR-17 as a potential therapeutic target for ADPKD. A Phase 2/3 registrational trial is being planned.

Stopping Eculizumab Treatment Safely in Atypical Haemolytic Uraemic Syndrome (SETS aHUS): A Multicentre, Open-Label, Prospective, Single-Arm Trial of the Safety and Impact of Eculizumab Withdrawal

Neil S. Sheerin,[1,2] Sally A. Johnson,[2] Edwin K. Wong,[2] Luke Vale,[4] Michal Malina,[2] Giovany Orozco Leal,[5] Ciara A. Kennedy,[3] Sarah Dunn,[3] David Kavanagh.[1,2] *[1]Translational and Clinical Research Institute, Newcastle University, Newcastle upon Tyne, United Kingdom; [2]National Renal Complement Therapeutics Centre, Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom; [3]Clinical Trials Unit, Newcastle University, Newcastle upon Tyne, United Kingdom; [4]London School of Hygiene & Tropical Medicine, London, United Kingdom; [5]Population and Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom.*

Background: Atypical Haemolytic Uraemic Syndrome (aHUS) is a rare disease which without treatment is associated with high morbidity and mortality. Eculizumab, a monoclonal complement inhibitor, is an effective treatment but the optimal way to use this high-cost medication has not been determined. The SETS aHUS trial aimed to establish the safety of eculizumab withdrawal and the effectiveness of a monitoring protocol to detect disease relapse and safe reintroduction of treatment if disease relapse occurs.

Methods: The SETS aHUS multicentre, open label, prospective, single arm trial enrolled participants from 15 UK hospitals with embedded qualitative and health economic analyses. Patients over two years of age with aHUS who were receiving eculizumab therapy for at least six months were eligible to withdraw from treatment, replacing it with monitoring to assess disease activity with re-introduction of treatment if relapse occurred. The primary outcome measure was harm to a participant as a consequence of eculizumab withdrawal during the 2-year trial period. Participants met a primary outcome if there was a permanent reduction in estimated glomerular filtration rate (GFR), requirement for kidney replacement therapy or significant extra-renal manifestation of disease. The Bayes factor single arm binary model was used to monitor and analyse the trial data, applying pre-trial stopping rules. The trial is registered with the European Union Drug Regulating Authority (EudraCT 2017-003916-37).

Results: One of 28 participants (3.6%) who withdrew from treatment met a primary outcome. Four participants relapsed, all with pathogenic genetic variants in complement proteins. Only participants with an identified cause of complement dysregulation relapsed. It was possible, by monitoring and rapid participant access, to successfully reintroduce eculizumab treatment. Based on the pre-trial analysis plan, withdrawal from treatment is not associated with a greater risk to patients compared to remaining on treatment.

Conclusions: Withdrawal of eculizumab treatment with monitoring of disease activity was not associated with an increased risk of harm compared to continuation of eculizumab.

Rituximab for Adult-Onset Frequently Relapsing or Steroid-Dependent Nephrotic Syndrome: A Multicenter, Double-Blind, Randomized, Placebo-Controlled Trial

Yoshitaka Isaka,[1] Shoichi Maruyama,[2] Mika Sakaguchi,[14] Hiroki Hayashi,[13] Yusuke Kaida,[11] Shin Goto,[10] Tatsuo Tsukamoto,[12] Akito Maeshima,[15] Yoichiro Ikeda,[3] Norihiko Sakai,[4] Naoki Sawa,[5] Kengo Furuichi,[6] Kunihiro Yamagata,[7] Yusuke Sakaguchi,[1] Maki Shinzawa,[1] Takehiko Wada,[5] Yugo Shibagaki,[8] Keiju Hiromura.[9] A-TEAM. *[1]Osaka Daigaku, Suita, Japan; [2]Nagoya Daigaku, Nagoya, Japan; [3]Tokyo Daigaku, Bunkyo-ku, Japan; [4]Kanazawa Daigaku, Kanazawa, Japan; [5]Toranomon Byoin, Minato-ku, Japan; [6]Kanazawa Ika Daigaku, Kahoku-gun, Japan; [7]Tsukuba Daigaku, Tsukuba, Japan; [8]Sei Marianna Ika Daigaku, Kawasaki, Japan; [9]Gunma Daigaku, Maebashi, Japan; [10]Niigata Daigaku, Niigata, Japan; [11]Kurume Daigaku, Kurume, Japan; [12]Igaku Kenkyujo Kitano Byoin, Osaka, Japan; [13]Fujita Ika Daigaku, Toyoake, Japan; [14]Kinki Daigaku, Higashiosaka, Japan; [15]Saitama Ika Daigaku Sogo Iryo Center, Kawagoe, Japan*.

Background: Among adult-onset nephrotic syndromes, side effects of long-term steroid use are problematic in patients with frequently relapsing nephrotic syndrome (FRNS) and patients with steroid-dependent nephrotic syndrome (SDNS). We investigated the efficacy and safety of rituximab on FRNS or SDNS patients.

Methods: We performed a multicenter, double-blind, randomized, placebo-controlled trial at 13 centers in Japan. Adult-onset FRNS or SDNS patients with urinary protein <0.3 g/gCr on at least two urine protein determinations after initiation of steroid therapy for the most recent relapse were enrolled. Patients received rituximab (375 mg/m^2) or placebo twice a week apart, and at 25 weeks. The dose of steroids was reduced and discontinued every 4 weeks in principle. Subjects who relapsed (urinary protein 1 g/g Cr or higher) within 49 weeks from the start date of the investigational drug could receive rituximab treatment once they were in remission after treatment with steroids. The primary endpoint was the relapse-free period. Safety endpoints were frequency and severity of adverse events. Patients who received their assigned intervention were included in analyses. This trial is registered with the University Hospital Medical Information Network clinical trials registry, number UMIN000041475.

Results: 66 patients received the assigned intervention (32 were given rituximab and 34 placebo). The median relapse-free period was significantly longer in the rituximab group (not reached, 95% CI -/-) than in the placebo group(29.8 week, 20.1/-; hazard ratio: 0.16, 0.05-0.46; p=0.0008). The recurrence-free rate at 49 weeks was 86.5% in the rituximab group and 37.2% in the placebo group (p<0.0001). The recurrence-free rate at 49 weeks for patients who entered the treatment phase after relapse was 66.7% (2 of 3 patients) in the rituximab group and 100% (20 of 20 patients) in the placebo group. Four patients (12.5%) in the rituximab group and 2 (5.9%) in the placebo group had at least one serious adverse event.

Conclusions: Rituximab is an effective and safe treatment for the prevention of adult-onset FRNS and SDNS relapse.

AMPLITUDE: A Phase 2/3 Adaptive Trial of Inaxaplin in APOL1-Mediated Kidney Disease

Glenn M. Chertow,[1] George Manos,[2] Ogo I. Egbuna.[2] *[1]Stanford University School of Medicine, Palo Alto, CA; [2]Vertex Pharmaceuticals Incorporated, Boston, MA.*

Background: Two variants in *APOL1* drive progressive, proteinuric nephropathies called APOL1-mediated kidney disease (AMKD). Inaxaplin (IXP), an oral inhibitor of APOL1, reduced proteinuria by 47.6% in persons with 2 *APOL1* variants and FSGS in a Ph2 study. We report interim data from an *APOL1* genotyping study, describe the Ph2/3 IXP trial (AMPLITUDE) design in a broader AMKD population, and provide interim baseline data from the Ph2 portion of AMPLITUDE.

Methods: Our genotyping study is enrolling up to 4000 participants of recent African ancestry with FSGS or nondiabetic kidney disease and UPCR≥0.5g/g. One blood sample is collected to verify *APOL1* genotype by PCR to optimize care and inform eligibility for clinical trials. Our Ph2/3, randomized, double-blind, placebo-controlled, adaptive trial is enrolling persons (Ph2:18-65yrs; Ph3:10-65yrs) with 2 *APOL1* variants, UPCR≥0.7 to <10g/g, and eGFR≥25 to <75mL/min/1.73m^2. In the Ph2 portion, participants received IXP (different doses) or placebo for 12wks to select a dose for evaluation of IXP efficacy/safety in ~400 participants in the Ph3 portion. For the final analysis, the primary endpoint is reduction in rate of decline of kidney function (eGFR slope) by IXP vs placebo; secondary endpoint is time to composite clinical outcome (sustained decline of ≥30% from baseline in eGFR, onset of ESKD, or death). Final analysis will occur when ≥2yrs of eGFR data and ~187 composite clinical outcomes are obtained.

Results: The genotyping study interim analysis included 2866 participants of whom 674(23.5%) have 2 *APOL1* variants; 36 of these participants enrolled in the completed Ph2 portion of AMPLITUDE. A 45mg IXP once daily dose was selected for Ph3 after review of Ph2 efficacy/safety data by an independent data monitoring committee. Among 64 participants dosed, 34(53.1%), 24(37.5%), and 6(9.4%) have *G1/G1, G1/G2,* or *G2/G2* genotypes. The mean (SD) age was 42.7 (11.0) yrs and mean (SD) baseline eGFR was 42.8 (14.0) mL/min/1.73m^2. Ph3 is ongoing in 9 countries.

Conclusions: The high prevalence of 2 *APOL1* variants in participants with recent African ancestry and proteinuric CKD reinforces the importance of *APOL1* genotyping to optimize kidney disease management and enable referral to clinical trials of APOL1-targeted therapies. Our Ph2/3 trial will evaluate the effects of IXP on preserving kidney function and reducing proteinuria in a broad AMKD population.

Zanubrutinib for the Treatment of Primary Membranous Nephropathy (PMN): Results of a Single-Arm Feasibility Study

Richard A. Lafayette,[1] Sean Barbour,[2] Yanyan Chen,[4] Zhen Yao,[4] Shengnan Chen,[4] Guisen Li,[5] Ming-Hui Zhao.[3] *[1]Stanford University Medical Center, Stanford, CA; [2]University of British Columbia, Vancouver, BC, Canada; [3]Renal Division, Peking University First Hospital, Beijing, China; [4]BeiGene Co., Ltd, Shanghai, China; [5]Sichuan Provincial People's Hospital, Chengdu, China*.

Background: Bruton tyrosine kinase (BTK) plays a key role in B cell modulation and is a potential therapeutic target in PMN, an antibody-driven glomerular disease. The efficacy and safety of zanubrutinib, a highly selective inhibitor of BTK, is being evaluated in a 2-part, phase 2/3 open-label study in patients (pts) with PMN. Here, part 1 is presented.

Methods: After a 12-wk run-in with optimal supportive care, pts with anti-phospholipase A2 receptor (PLA2R) antibody (Ab) >50 RU/mL and urinary protein-creatinine ratio (UPCR) >3.5 g/g receive zanubrutinib 160 mg BID for 64 wks, followed by a 40-wk observation period. Primary endpoint: change from baseline in UPCR at wk 24; secondary endpoints: anti-PLA2R Ab titer, serum albumin, overall remission rate, safety.

Results: Of 30 pts, most were men (66.7%) and Asian (93.3%). At baseline, median (range) UPCR was 7.5 g/g (3.6, 14.8), serum anti-PLA2R Ab was 161.0 (51.4, 1219.8) RU/mL, serum albumin was 23.5 (15.4, 42.3) g/L, and eGFR was 85.2 (39.8, 123.0) mL/min/ 1.73m^2. As of July 15, 2024, the median duration of exposure was 26.5 wks, and 20 pts had completed the wk 24 visit (5 pts discontinued early). At 24 wks, median change from baseline in UPCR was -1.5 g/g (-8.8, 5.7); 6 pts (30%) had partial remission (UPCR 0.3–3.5 g/g and ≥50% decrease from baseline, stable eGFR), and the immunological response rate (anti-PLA2R titer reduction to <14 RU/mL) was 60% (**Figure**). Overall, 26 pts (87%) had treatment-emergent adverse events (TEAEs), mostly (≥15% pts) upper respiratory tract infections (27%), rash (20%), and hypokalemia (17%). 4 pts (13%) had severe TEAEs (treatment-related in 1 pt).

Conclusions: Zanubrutinib appears to be generally well tolerated and shows activity in pts with PMN.

Phase II Results of an Investigational RNA Therapeutic to Complement Factor B, IONIS-FB-LRx, for Treatment of IgA Nephropathy

Sean Barbour,[1] Michelle A. Hladunewich,[3] Angela Makris,[7] Sven-Jean Tan,[8] Richard A. Robson,[9] Muh Geot Wong,[4] Jason Choo Chon Jun,[5] Ashley Frazer-Abel,[6] Lixuan Yin,[2] Terry Barrett,[2] Richard Geary,[2] Eugene Schneider,[2] Jon L. Ruckle,[2] Michael Mccaleb,[2] Gary T. Brice.[2] *[1]The University of British Columbia, Vancouver, BC, Canada; [2]Ionis Pharmaceuticals Inc, Carlsbad, CA; [3]Sunnybrook Research Institute, Toronto, ON, Canada; [4]Royal North Shore Hospital, St Leonards, NSW, Australia; [5]Singapore General Hospital, Singapore, Singapore; [6]University of Colorado Anschutz Medical Campus, Aurora, CO; [7]Liverpool Hospital Renal Clinic, Liverpool, NSW, Australia; [8]The Royal Melbourne Hospital, Melbourne, VIC, Australia; [9]NZCR, Auckland, New Zealand.*

Background: Overactivity of the complement Alternative Pathway (AP) has been implicated in pathogenesis of primary IgA nephropathy (IgAN). An antisense oligonucleotide to complement factor B (FB), IONIS-FB-L_{Rx} (ISIS 696844, RO7434656) targets FB mRNA in the liver leading to reduction of AP activation in IgAN patients.

Methods: An exploratory, single-arm, global open-label Ph2 trial (NCT04014335) recruited patients with biopsy-confirmed IgAN with renal C3 deposits, hematuria, and 24-hr protein excretion >1.5g/d, eGFR>40mL/min/1.73m^2 despite maximum tolerated RAAS blockade including 6 patients on stable doses of SGLT2i. Patients received monthly subcutaneous (SC) administration of IONIS-FB-L_{Rx} for 24 weeks followed by voluntary treatment extension. Primary endpoint was change in 24-hr proteinuria at week 29 (or 4 weeks after last dose) compared to baseline (BL).

Results: 23 patients were enrolled (25-62 yr of age, 40% Female, 13 Asian, 9 White, 1 other). One subject discontinued study drug at week 17 to initiate SGLT2i. Median 24-hr proteinuria at BL was 2.0 g/d (IQR 1.64, 4.78 g/d). At week 29, a 43% (95% CI: 23%, 58%) geometric mean reduction of 24-hr proteinuria was observed. Reductions in UPCR and UACR were also observed. There was no change in mean eGFR at week 29 compared to BL (mean±SD; BL 70.4 ±21.6; week 29 73.2±19.9 mL/min/1.73m2). There was sustained reduction of 24-hr proteinuria in all 7 patients who opted for treatment extension, including 4 patients treated for >12 mo. There were selective reductions of plasma complement FB and Factor Bb, serum AP activity, urinary Factor Ba and urinary sC5b-9 without changes in serum CH50. There was one treatment emergent SAE assessed as not related to study drug and transient and reversible ALT elevations (3-5X fold ULN) without a change in serum bilirubin were observed in 3 subjects, all of whom remained on study and completed treatment.

Conclusions: IONIS-FB-L_{Rx} met primary endpoints in patients with biopsy-confirmed IgAN. This Ph2 open-label study provides consistent clinical evidence supporting ongoing Ph3 study of IONIS-FB-L_{Rx} /RO7434656 to reduce the progression of IgAN (NCT05797610).

TH-PO1206

Single-Center, Phase 2, Open-Label Trial Evaluating the Efficacy and Safety of Obinutuzumab in Treatment of Immunosuppression-Resistant Primary FSGS, or Contraindication to High-Dose Corticosteroids

Ladan Zand,[1] Eddie L. Greene,[1] Wisit Cheungpasitporn,[1] Maria Jose Vargas-Brochero,[1] Miriam Machado,[1] Sanjeev Sethi,[2] Pierre M. Ronco,[3] Fernando C. Fervenza.[1] *[1]Division of Nephrology and Hypertension, Mayo Clinic Department of Internal Medicine, Rochester, MN; [2]Laboratory Medicine and Pathology, Mayo Clinic Minnesota, Rochester, MN; [3]Hopital Tenon, Paris, France.*

Background: We investigated the efficacy and safety of obinutuzumab, a type II anti-CD20 antibody, in patients with primary FSGS who were resistant/dependent on immunosuppressive therapy.

Methods: Patients were treated with 2 doses of obinutuzumab (1 gram), 2 weeks apart at baseline and 6 months. Primary outcome was change in proteinuria from baseline to 6 and 12 months. Secondary endpoints were complete (proteinuria <0.3g/d) or partial (50% reduction in proteinuria & proteinuria < 3.5 g/d) remission, & rates of serious adverse events.

Results: Twenty patients were enrolled. Average age 45.3±17.5 years, 55% male. Systolic BP: 132±17.5 mmHg, diastolic BP: 77.1±9.5 mmHg. Patients had failed 2-3 prior therapies. There was significant improvement in proteinuria: baseline [10.7 (7.5 – 13.7)] g/d to 12 months [3.8 (1.5 – 8.6)] g/d (p=0.001), significant improvement in serum albumin, cholesterol, & eGFR (**Table 1**). By 12 months, 8 patients (40%) reached CR/PR, none relapsed. 3 serious adverse events (SAE): 2 in one patient hospitalized for suicidal ideation and pseudo-seizures, 1 SAE was development of follicular lymphoma. SAEs were unrelated to obinutuzumab. Most common AE was infusion-related reaction occuring in 7 patients (none resulted in therapy discontinuation). There were 7 infections, none required hospitalization.

Conclusions: Obinutuzumab significantly reduced proteinuria in patients with primary FSGS who had failed 2-3 prior therapies. Reduction in proteinuria was associated with an improvement in eGFR and serum albumin with an acceptable side effect profile.

Funding: Commercial Support - Genentech
