"7+3" cytarabine and anthracycline alongside midostaurin. Before induction therapy, phosphorous ranged from 3-4 mg/dL. By day 3, phosphorus was 1.0 mg/dL, requiring daily oral and intravenous replacement. On day 4, phosphorus was 0.8 mg/dL. Serum creatinine was at a baseline of 0.5 mg/dL, ionized calcium was 1.10mmol/L, serum calcium was 6.8 mg/dL. PTH was 222 pg/mL, Vitamin D level was 37 ng/mL, and uric acid was 1.2 mg/dL. Spot urine electrolytes were obtained. Urine creatinine was 26 mg/dL, urine phosphorus was 52.8 mg/dL, and urine potassium was 20.5 mg/dL. Urine sodium was 114 mg/dL. There was no glucosuria. The fractional excretion of phosphate was 59.7%. Midostaurin was switched to gilternitinib after day 15 and phosphorus and calcium levels improved without further supplementation.

Discussion: We describe the first case of hypophosphatemia attributed to midostaurin use. Like other kinase inhibitors, the exact mechanism of midostaurin related hypophosphatemia is unknown. Theories include PTH mediated hyperparathyroidism, FGF23 interaction, and proximal tubule wasting. Based on our patient's elevated fractional excretion of phosphate, the acuity and refractory nature of her phosphate depletion, she likely had at least contributions from proximal tubular injury. Use of midostaurin should have careful electrolyte monitoring and evaluation, with investigation of etiology if hypophosphatemic. In our patient, discontinuation was followed by resolution of the hypophosphatemia.

SA-PO214

A Rare Case of Severe Hypophosphatemia

Ryan M. Song, Marco A. Bonilla Arevalo. *The University of Chicago Medicine, Chicago, IL.*

Introduction: Tumor-induced osteomalacia (TIO) or oncogenic osteomalacia is a rare paraneoplastic syndrome characterized by excess production of fibroblast growth factor 23 (FGF23), which leads to hyperphosphaturic hypophosphatemia. Clinical manifestations are often nonspecific and the syndrome is underdiagnosed and recognized late. It is important to have a high index of suspicion when evaluating hypophosphatemia, as early intervention of TIO can prevent or reverse osteomalacia and lead to an expedited investigation of a culprit neoplasm.

Case Description: A 67-year-old male with actively-treated mesothelioma was referred to nephrology for hypophosphatemia despite aggressive oral repletion. History and physical revealed nonspecific symptoms of fatigue, myalgias, decreased appetite, and lower extremity swelling, but was negative for malnutrition, causative medications, or other specific etiology. Further labwork revealed a normal parathyroid level, low vitamin-D level, and elevated fractional excretion of urine phosphorous. An FGF23 level was markedly elevated, confirming the presence of a FGF23-mediated hypophosphatemia, consistent with TIO. Vitamin D supplementation and continued oral phosphorous repletion only mildly improved his serum phosphorous. Unfortunately, our patient's cancer was resistant to treatment and he ultimately passed away under hospice care.

Discussion: TIO is rare and underdiagnosed, with a prevalence of less than 1 per 100,000 adults in the general population. Correct diagnosis is often delayed by over 3 years on average after symptom onset, with treatment delayed further. As nephrologists, we routinely measure serum phosphate levels. Once hypophosphatemia is identified, it is paramount to rule out poor diet, medication effects, and other associated conditions (such as refeeding syndrome, hyperparathyroidism or vitamin D deficiency). Renal phosphorus wasting should be confirmed with an inappropriately elevated urinary phosphorous (fractional excretion > 5% or a ratio of tubular maximum reabsorption of phosphate to glomerular filtration rate < 85%). In this setting, an elevated FGF23 level will be diagnostic of FGF23-mediated hypophosphatemia, after which localization of the culprit tumor should be performed with functional imaging studies. Early identification of TIO can lead to early intervention of a causative tumor, and limit the debilitating complications of osteomalacia and malignancy.

SA-PO215

Interleukins and Hyponatremia in Patients with Cancer

Joshua Pantanowitz,[1] Michelle N. Keyser,[2] Pooja D. Amarapurkar.[2] *[1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]UPMC, Pittsburgh, PA.*

Introduction: There is renewed interest in the use of targeted delivery systems and engineered forms of Interleukin-12 (eIL-12) for the treatment of several advanced cancers. We present a unique case of hyponatremia in a patient with eIL-12 therapy for pancreatic cancer that was unresponsive to 3% saline and tolvaptan and treated with tocilizumab.

Case Description: A 77 year old male with invasive poorly differentiated metastatic ampullary adenocarcinoma of the pancreas who failed multiple lines of therapy was seen in the hospital for altered mental status. Initial laboratory data showed a serum sodium of 121 mMol/L. 3% saline was administered after admission to the ICU and he remained hemodynamically stable. The serum sodium remained unchanged for 8 hours after 100 ml bolus and 25 ml/hr of 3% saline for several hours and tolvaptan 7.5 mg. Given the lack of response to 3% saline and tolvaptan, hyponatremia was thought to be related to eIL-12 infusions. After discussion with his oncologist, he received tocilizumab. Within hours of the tocilizumab administration his serum sodium increased to 127 mMol/L in 10 hours. Tocilizumab was repeated the following day with serum sodium stabilizing at 131mMol/L. 3 weeks prior to the current admission he started cycle 1 of eIL-12 and was found to have a hyponatremia with serum sodium of 127 mMol/l (baseline sodium 132-134 mMol/L). This was attributed to cancer-related syndrome of inappropriate anti-diuretic hormone and he was started on sodium chloride tablets 1 gram three times a day as an outpatient, but the hyponatremia persisted. 4 days prior to the current admission he received cycle 2 of eIL-12. Unfortunately, he developed severe cytokine release syndrome with subsequent infusions with disease progression and impending home hospice.

Discussion: With the increased use of immuno-modulatory therapies like eIL-12 and chimeric antigen receptor (CAR) T-cells, it is important to understand their kidney side effects. eIL-12 and CART-cells increase other pro-inflammatory cytokines such as interleukin-6 (IL-6). Evidence supports IL-6 causing a non-osmotic, non-volume-mediated increase in anti-diuretic hormone leading to hyponatremia. Tocilizumab (IL-6 receptor blocker) has been used to treat IL-6 side effects and in our case, hyponatremia. Our case highlights the unique immune mediated pathophysiology of hyponatremia and role of tocilizumab to treat the specific cause.

SA-PO216

New Therapies and New Challenges: Radioligand Therapy-Related Thrombotic Microangiopathy in the Kidneys

Michelle N. Keyser,[1] Joshua Pantanowitz,[2] Pooja D. Amarapurkar.[1] *[1]UPMC, Pittsburgh, PA; [2]University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Introduction: Radioligand therapy (RLT) has been increasingly used to treat metastatic castration-resistant prostate cancer. Intravenous (IV) 177Lu-PSMA and 225Ac-PSMA are two effective and well tolerated agents. Data on kidney-related side effects remain limited from initial clinical trials using these treatments. We present a unique biopsy-proven case of renal thrombotic microangiopathy (TMA) in a patient who received IV 177Lu-PSMA and 225Ac-PSMA resulting in rapid decline in kidney function, dialysis initiation and unresponsiveness to eculizumab.

Case Description: A 75-year-old male with stage 3b prostate adenocarcinoma was treated with radical prostatectomy, pelvic radiation, leuprorelin, bicalutamide, abiraterone. Therapy was changed to enzalutamide and darolutamide for new bone lesions. He traveled to Austria to receive IV RLT with 225Ac-PSMA and 177Lu-PSMA monthly for 8 months. 1 month after RLT his serum creatinine rose from 0.9–1.1 mg/dL to 1.3 mg/dL, and to 2.2 mg/dL at 6 months. Lower extremity edema and hypertension were noted at that time. 360 mg 24-hour urine protein, 516 mg/g UACr, normocytic anemia, elevated LDH, schistocytes on peripheral smear, elevated CH50, normal C3, C4, and SC5b-9 level were noted. A kidney biopsy showed subacute TMA, moderate (25%) interstitial fibrosis and tubular atrophy and 20-25% global glomerulosclerosis with double contour and subendothelial edema in the glomerular capillary walls. Losartan was started for hypertension and proteinuria. Eculizumab was added for possible complement-mediated process, but the kidney function declined rapidly. He started hemodialysis 10 months after his last dose of RLT. Eculizumab was trialed for 6 months without renal recovery.

Discussion: RLT such as 177Lu-PSMA and 225Ac-PSMA deliver targeted radiation to cancer cells. Despite being target specific, they may accumulate in the kidneys over time causing endothelial damage, hypertension, TMA and chronic kidney disease. Data on nephrotoxicity from the initial trials is sparse. Additionally, RLT-related kidney damage with use of dual agents 177Lu-PSMA and 225Ac-PSMA remains to be explored. Our case is a distinctive illustration of kidney side effects of RLT. With the expanding use of RLT, it is vital to educate nephrologists to recognize the kidney effects and develop strategies to prevent rapid decline in kidney function.

SA-PO217

Challenges in the Management of Giant Bilateral Renal Angiomyolipomas in a Young Woman with Tuberous Sclerosis Complex: A Case Report

Mark Gavin C. Dinsay. *Philippine General Hospital, Manila, Philippines.*

Introduction: Tuberous sclerosis complex-associated renal angiomyolipoma (AML) is a fast-growing tumor that develops earlier in life, with a propensity to achieve larger sizes and higher risks for life-threatening hemorrhage. We report a rare case of bilateral giant AMLs wherein a young patient presented with extensive involvement in both kidneys that limited treatment options recommended by current guidelines.

Case Description: A 23-year-old woman with tuberous sclerosis complex (TSC) presented with flank pain, abdominal fullness, hematuria, and hemodynamic instability. CT scan of the abdomen showed that both kidneys had been converted into large aggregates of heterogeneously enhancing and attenuating masses. The right kidney measured 17.4 x 9.7 x 10.3 cm (CC x W x AP) while the left measured 18.4 x 11.4 x 16.2 cm (CC x W x AP). She was transfused 2 units of packed red blood cells and closely monitored. Radiologic intervention with angioembolization was deemed unfeasible due to the diffuse involvement of both kidneys. Bleeding resolved spontaneously albeit with a high risk for recurrence. Prophylactic bilateral nephrectomy was considered but would render the patient in need of renal replacement therapies. After a multidisciplinary conference and discussion with the patient and her family, conservative management and therapy with mTOR inhibitor everolimus were pursued. The patient was apprised of the

need for nephrectomy should refractory life-threatening bleeding occur. On outpatient follow-up after a year, renal function was preserved with an eGFR of 87 mL/min. Although everolimus was discontinued after 1 month due to financial constraints, the patient reported subjective improvement in symptoms and no recurrence of anemia and bleeding.

Discussion: In our patient's case, extensive involvement of both kidneys and massive sizes of the angiomyolipoma presented a dilemma that required balancing the patient's preferences, risk for bleeding, and preservation of renal function. A conservative management approach involves close monitoring, intensive care, and blood transfusions. mTOR inhibition is employed to retard tumor size and growth and reduce the risk for bleeding. The challenge with managing such cases requires a multidisciplinary approach and shared decision-making to arrive at the best patient-centered outcomes.

SA-PO218

An Unusual Case of Steroid Refractory Allergic Interstitial Nephritis Related to Prior Ifosfamide Exposure

Sundus Sardar,[1] Ahmad Matarneh,[1] Victoria Gutgarts,[2] Naman Trivedi,[1] Nasrollah Ghahramani.[1] *[1]Penn State College of Medicine, Hershey, PA; [2]Memorial Sloan Kettering Cancer Center, New York, NY.*

Introduction: Tazemetostat, an EZH2 inhibitor, recently approved for treating solid and hematologic malignancies. EZH2 overexpression and mutations drive tumor growth. While Tazemetostat's side effects have been studied, further investigation is needed to establish their incidence. Reports suggest Tazemetostat can activate the innate immune response with T-cells against an antigen, which could be a medication, infection or an unknown factor. Our case report discusses allergic interstitial nephritis (AIN) presumed to be induced by Tazemetostat in the context of ifosfamide use.

Case Description: A 43-year-old male with metastatic epithelioid sarcoma was initially treated with ifosfamide and doxorubicin, developing Fanconi syndrome from ifosfamide toxicity. Tazemetostat was later initiated as secondary treatment. After 8 months, his renal function deteriorated, with creatinine increasing from 0.8mg/dL to 2.04mg/dL and proteinuria reaching 3.25 g/24h. Tests showed a normal blood count, negative (ANA, ANCA), normal complement levels, but positive PR3-ANCA antibodies. A kidney biopsy confirmed tubulointerstitial nephritis. Despite 6 weeks of oral steroids (60mg daily), renal function did not improve. Mycophenolate (MMF) was introduced for steroid-refractory AIN, but he developed anemia requiring blood transfusion, leading to a dose reduction. Renal function continued to decline, reaching 3.4mg/dL. A second kidney biopsy revealed severe tubulointerstitial nephritis with focal necrosis, suggesting ifosfamide-induced nephropathy. Imaging showed new inguinal lymph node enlargement, under evaluation. MMF is being tapered until biopsy result.

Discussion: Tazemetostat is a novel anticancer agent. Known side effects include nausea, headache, abdominal pain, and increased risks of T-cell lymphoma and myelodysplastic syndrome. No established link between Tazemetostat and AIN exists, necessitating further research. Studies suggest Tazemetostat may trigger an innate T-cell response to an antigen, potentially causing allergic interstitial nephritis. In our patient, we speculate ifosfamide acted as an antigen, triggering an immune response. AIN management involves discontinuing the offending agent and using immunosuppressants like steroids and MMF. Further research is needed to refine Tazemetostat's safety profile and optimize management strategies.

SA-PO219

Leukocyte Chemotactic Factor 2 (ALECT2)-Associated Kidney Amyloidosis in New Mexico: A Report of Two Cases and a Call for Attention to Epidemiologic Surveillance

George Vasquez-Rios,[1] Paul B. Avila,[2] Pablo Garcia.[2] *[1]Glomerular Disease Center, Renal Medicine Associates, Albuquerque, NM; [2]University of New Mexico Health Sciences Center, Albuquerque, NM.*

Introduction: LECT2-associated renal amyloidosis (ALECT2) was first described in the United States, predominantly affecting patients of Hispanic descent. The mechanisms, epidemiological drivers, and long-term prognosis of this disease remain poorly understood. Here, we present two cases from our GN clinic involving patients of Mexican descent residing in New Mexico for over 50 years.

Case Description: Case 1: An 80-year-old male with moderate CKD (sCr: 2 mg/dL), mild albuminuria (450 mg/g), hematuria. He presented with mild hypertension (142/60) and trace edema. **Case 2:** A 69-year-old male with moderate-severe CKD (serum Cr: 2.4 mg/dL), mild albuminuria (700 mg/g), hematuria. Both patients were referred by their PCPs due to slowly progressive kidney function decline over a span of 10-15 years. One of the patients had background of DM2. Comprehensive GN work-up showed mildly elevated ANA and ESR levels, no M-protein, negative SPEP/UPEP, and normal serum free light chain ratio. Bone marrow biopsy and imaging found no cell clonality or evidence of malignancy or clear source of hematuria. Given the concern for potential inflammatory versus MGRS presentations kidney biopsies were obtained. In both cases, kidney biopsies revealed amyloid deposits in glomeruli, blood vessel walls, and tubular interstitium with characteristic green birefringence. Immunohistochemical staining for amyloid A was negative. However, staining with anti-LECT2 antibody by an antigen retrieval technique at pH2 was positive; confirming the diagnosis of ALEC2 renal amyloidosis. Given the absence of cancer, asymptomatic presentation, and slowly progressive nature, we opted for conservative management (ACEi). On follow-up, both patients showed relatively stable CKD.

Discussion: The pathogenesis of ALECT2 remains to be elucidated. It is unclear if genetic or epidemiological factors contribute to its onset predominantly in Hispanics, and whether it can recur in post-kidney transplant patients, considering its major production in the liver. The preferred management includes RAS blockers. These cases highlight the need for increased epidemiologic surveillance and research into the mechanisms and prognosis of ALECT2. Given its prevalence in Hispanic populations, further studies are warranted to understand potential genetic or environmental factors influencing this condition.

SA-PO220

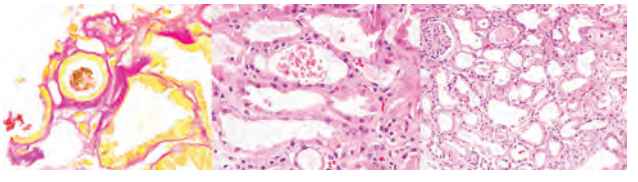
Bile-Cast Nephropathy in a Patient with Perihilar Cholangiocarcinoma

Joseph D. Nguyen,[1] Jill Nehrbas,[1] Monarch Shah,[1] Joel D. Murphy,[2] Uta Erdbruegger,[1] Tushar Chopra.[1] *[1]University of Virginia, Charlottesville, VA; [2]Arkana Laboratories, Little Rock, AR.*

Introduction: Bile cast nephropathy (BCN) is a rare cause of acute renal dysfunction in the setting of liver disease. Kidney injury in BCN is thought to be caused by multiple factors, including bile acid nephrotoxicity, tubule obstruction, and renal hypoperfusion. BCN is diagnosed by kidney biopsy in the appropriate clinical setting. Due to the rarity of the condition, there are few established treatment guidelines. We report a case of BCN diagnosed by kidney biopsy in a 70-year-old male.

Case Description: A 70-year-old male with intrahepatic cholangiocarcinoma with outflow hepatic vein obstruction treated with a single course of dose-reduced cisplatin/gemcitabine and durvalumab was admitted with biliary obstruction and anuria. Physical exam was notable for ascites and labs were notable for acute kidney injury (AKI) with creatinine 5 mg/dl (baseline 0.9 mg/dl), anion gap metabolic acidosis, total bilirubin 27.8 mg/dl, direct bilirubin 17.7 mg/dl, and alkaline phosphatase 1,440 mg/dl. Intermittent hemodialysis was initiated for volume overload. The patient underwent an endoscopic retrograde cholangiopancreatography with biliary sphincterotomy and bilateral biliary stents with transient improvement in serum bilirubin to 22 mg/dl before rising again. Kidney biopsy revealed severe acute tubular injury with bile casts (Fig 1). Due to the unresectable cholangiocarcinoma involving vasculature, cholestatic liver injury worsened. The patient's family elected comfort care due to his guarded prognosis.

Discussion: This case contains three major teaching points: 1) Cholemic nephrosis represents a spectrum of renal injury from proximal tubulopathy to intrarenal bile cast formation in patients with severe liver disease. Bile casts are thought to contribute to kidney injury by both obstruction and bilirubin toxicity. 2) Prevalence of BCN is likely underestimated as a definitive pathological diagnosis by kidney biopsy is often missing due to the increased bleeding risk in coagulopathic liver disease patients. 3) Renal replacement therapy may be necessary to manage severe AKI secondary to BCN. In refractory cases, extracorporeal liver support devices utilizing albumin dialysis may help to reverse AKI.



SA-PO221

Merkel Cell Carcinoma Preceding Renal Primary Amyloidosis: Coincidence or Causality?

Carolina Saldanha Neves Horta Lima, Beatriz Rizkallah Alves, Kelly A. Burdge. *Mass General Brigham Salem Hospital, Salem, MA.*

Introduction: We present a rare association of Merkle Cell carcinoma and nephrotic syndrome.

Case Description: 63-year-old female presented with new proteinuria and lower extremity swelling. She had recently taken 7 days of ibuprofen and amox/clav. She was initially started on furosemide, without improvement. Blood work revealed albumin of 2.3 g/dL and a 24h urine protein 4.35g. Her total cholesterol 449 mg/dL, LDL 319 mg/dL, triglycerides 274 mg/dL. One month prior, she was diagnosed with non-metastatic Merkel cell carcinoma of her right thigh. Further workup revealed normal complements, negative ANCA, negatuve ANA. Kappa and lambda free light chains ratio of 6. SPEP showed hypoalbuminemia. A kidney biopsy dmeonstrated lambda light chain amyloidosis. Bone marrow biopsy identified lambda light chain restricted plasma cell population. Fluorescence in situ hybridization was negative for t(11;14). She was referred to oncology and started on chemotherapy.

Discussion: AL amyloidosis is characterized by the existence of a plasma cell clone in the bone marrow that secretes immunoglobulin light chains. Their deposition leads to variety of presentations, including nephrotic syndrome, restrictive cardiomyopathy, peripheral and autonomic neuropathy. Screening of end-organ involvement is crucial for early treatment due to severity of prognosis. AL amyloidosis is not infrequently related to hematologic malignancies, such as monoclonal gammopathy of undetermined significant and multiple myeloma. Merkel cell carcinoma is a rare and aggressive cutaneous malignancy that affects older adults with light skin, especially in sun-exposed areas. Hematologic malignancies have been reported as a risk factor for Merkel cell carcinoma, most commonly chronic lymphocytic leukemia, more rarely multiple myeloma. Interestingly, patients with a preceding hematologic malignancy have a higher chance of being affected in an area not exposed to sun, such as our patient. This highlights 1) the non-coincidental occurrence of AL amyloidosis and an atypical presentation of Merkle cell carcinoma and 2) the need to further understand common physiopathological pathways. The question whether patients with an atypical Merkle cell carcinoma benefit from screening for hematologic malignancies remains.

SA-PO222

Partial Fanconi Syndrome following Ifosfamide

Piera A. Sosa,[1] Aaron Winer,[1] Sebastian Hinojosa,[1] Adriana Hung.[1,2]
[1]Vanderbilt University Medical Center, Nashville, TN; [2]VA Tennessee Valley Healthcare System, Nashville, TN.

Introduction: Partial or complete Fanconi syndrome is a rare yet known complication of ifosfamide administration. Fanconi syndrome characteristically results in metabolic derangements including metabolic acidosis, hypokalemia, hypophosphatemia, and proteinuria. Although Ifosfamide can lead to Fanconi syndrome, not all patients develop this complication. Therefore, pharmacogenomics, the study of how a person's genetic makeup affects their response to medications and drugs, should be considered when evaluating this disease process

Case Description: A male in his 70's with recently diagnosed dedifferentiated retroperitoneal liposarcoma presented to the ED 6 days after completing a first cycle of ifosfamide-based chemotherapy. His chief complaint was nausea, vomiting, and weakness. Labs on presentation were notable for hypokalemia, hypophosphatemia, and metabolic acidosis. Given his immunocompromised status, a thorough infectious work-up was obtained and he was found to have bacteremia secondary to chemotherapy port infection. Over the next several days, he continued to have profound electrolyte derangements requiring substantial repletion that were initially attributed to refeeding syndrome. However, further investigation into his significant electrolyte wasting revealed a urinalysis with newly developed proteinuria and phosphaturia, without glycosuria, and a transtubular potassium gradient (TTKG) of 8. Based on his clinical presentation and lab findings, along with his recent chemotherapy initiation with ifosfamide, the patient was ultimately diagnosed with partial Fanconi syndrome. Electrolyte repletion requirement slowly improved throughout admission, demonstrating evidence of renal tubular recovery. He was sent home with daily oral electrolyte supplementation with close outpatient monitoring.

Discussion: Close electrolyte monitoring in patients undergoing chemotherapy treatment with ifosfamide is imperative to avoid missing Fanconi syndrome diagnosis and its detrimental complications. Notably, not all patients undergoing treatment with ifosfamide develop nephrotoxicity leading to Fanconi syndrome. Understanding the role of pharmacogenomics, such as variations in genes encoding CYP3A4 and CYP2B6, is an important area of further investigation to minimize adverse effects from ifosfamide.

SA-PO223

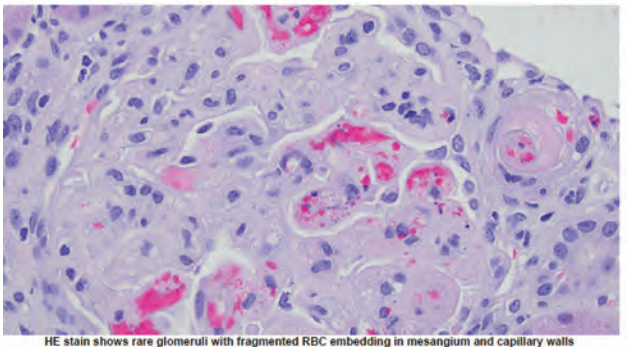
Atypical Presentation of Drug-Induced Thrombotic Microangiopathy: Time Does Not Matter

Nahomie I. Veguilla Rivera, Archi K. Dhamelia, Jan Paul Rosaly Martinez, Naveen Punchayil Narayanankutty. *University of South Florida, Tampa, FL.*

Introduction: Thrombotic Microangiopathy (TMA) is a disorder that causes disseminated occlusive microvascular thrombosis, thrombocytopenia, and end organ damage, commonly in the kidneys and brain. In cancer patients, especially those in multi-drug chemotherapy regimens, TMA is a diagnostic challenge due to overlap with other thrombotic disorders such as TTP, aHUS, and DIC. TMA can occur as a manifestation of the cancer itself and has been reported in mucin-producing adenocarcinomas. Chemotherapy-associated TMA can occur due to immune-mediated reaction or dose-dependent toxicity. TMA secondary to VEGF inhibitors has been described; however, literature reporting TMA due to Tyrosine Kinase Inhibitors (TKI) is limited. We present a case of TMA secondary to lenvatinib and bevacizumab.

Case Description: We report a case of a 31-year-old man with history of metastatic hepatocellular adenocarcinoma who was referred to the hospital with nephrotic-range proteinuria. Prior therapy regimen included bevacizumab and more recently Lenvatinib, last dose 3 weeks prior presentation of AKI. Creatinine increased to 4 mg/dL from a baseline of 1.5 mg/dL. Coagulation panel, ADAMST13 were normal. ALP and LDH were elevated. Other bloodwork revealed new thrombocytopenia and hypoalbunemia. TTP, aHUS and DIC were ruled out. Due to unclear cause, patient underwent renal biopsy that showed Chronic thrombotic microangiopathy with FSGS. After confirmation of results, patient remained on therapy for HCC and was offered hemodialysis.

Discussion: This case highlights the importance of evaluating the etiology of TMA, particularly in patients on chemotherapy independent of the time of administration of therapy. Distinguishing the cause of AKI in this patient is clinically important for appropiate treatment and avoidance of future drug toxicity. It also shows that renal biopsy can aid in the diagnosis. Restarting the offending medication a lower dose may help to avoid recurrent TMA.



HE stain shows rare glomeruli with fragmented RBC embedding in mesangium and capillary walls

SA-PO224

C-terminal Region of the TMEM174 Protein Regulates PTH-Induced NPT2A Endocytosis

Jose Miranda, Shinobu Miyazaki-anzai, Judith Blaine, Makoto Miyazaki. *University of Colorado Anschutz Medical Campus School of Medicine, Aurora, CO.*

Background: Sodium-dependent phosphate cotransporter 2a (NPT2A or SLC34A1) is a solute-carrier (SLC) transporter located in the brush border membrane of kidney proximal tubule that reabsorbs glomerular-filtered phosphate. We recently found that a proximal tubule-specific protein TMEM174 regulates phosphate reabsorption by inducing the degradation of NPT2A (PMID: 35459732). However, the molecular mechanism by which TMEM174 facilitates the degradation of NPT2A is unknown.

Methods: To obtain clues as to how TMEM174 induces the degradation of NPT2A, we examined which region of TMEM174 protein is essential to bind with NPT2A and induce the NPT2A endocytosis by the advanced microscope techniques such as Total Internal Reflection Fluorescence (TIRF) and Förster Resonance Energy Transfer (FRET) microscopy and the immunoprecipitation (IP) assay using DNA constructs containing full length TMEM174, TMEM174 lacking N-terminal 34 amino acids (TMEM174ΔN) and TMEM174 lacking C-terminal 130 amino acids (TMEM174ΔC).

Results: OK-P cells were transiently transfected with plasmids containing TMEM174 with moxCerulean3 (mC3) at its C-terminal and/or NPT2A with eYFP also at its C-terminal in the presence or absence of TMEM174 siRNA. TIRF microscopy analysis showed that treatment with TMEM174 siRNA blocked PTH induced-NPT2A endocytosis and increased the retention of NPT2A in the apical membrane of OK-P cells. In addition, FRET analysis showed that intact TMEM174 and TMEM174ΔN proteins are associated with NPT2A protein because upon PTH treatment NPT2A degradation is no decrease in the FRET ratio. Whereas TMEM174ΔC was significantly disassociated because under PTH treatment the FRET ratio decreased over-time signifying that NPT2A-eYFP was being degraded. IP assay confirmed that intact TMEM174 and TMEM174ΔN but not TMEM174ΔC were pull down with NPT2A.

Conclusions: The C-terminal region of TMEM174 protein is critical for regulating in the NPT2A endocytosis.

SA-PO225

Phosphate Transport through the Type II Sodium Phosphate Cotransporter Npt2a Regulates Metabolism Independent of Phosphate Level

Eleanor D. Lederer,[1,2] Kenneth B. Gagnon,[1] Adam E. Gaweda,[4] Hamid Baniasadi.[3] *[1]The University of Texas Southwestern Medical Center Department of Internal Medicine, Dallas, TX; [2]VA North Texas Health Care System, Dallas, TX; [3]The University of Texas Southwestern Medical Center, Dallas, TX; [4]University of Louisville School of Medicine, Louisville, KY.*

Background: Npt2a expression and function in proximal tubule (PT) are regulated by the Na-H Exchanger Regulatory Factor Isoform 1 (NHERF1). Absence of NHERF1 (NHERF1 KO) is associated with phosphaturia and a metabolic shift toward increased activity of the pentose phosphate pathway and altered glutathione levels. Whether the metabolic shift in NHERF1 KO cortex is due to phosphate (Pi) deficiency or decreased

functional Npt2a expression is unknown. We postulate that the metabolic shift is a result of decreased Npt2a-mediated Pi transport.

Methods: To address our hypothesis, we compared the kidney cortex metabolic profile from WT C57/Bl6 mice with kidney cortex from three models of hypophosphatemia: NHERF1 KO, Npt2a KO, and WT on low Pi diet (0.02%) for 2 weeks. Kidney cortices were subjected to targeted metabolomic assay followed by identification and pathway analysis of significantly different metabolites by Sparse Autoencoder Enabled Neural Network or Metaboanalyst 6.0 (principal component analysis) and pathway analysis.

Results: All hypophosphatemic conditions resulted in altered kidney cortex metabolomics when compared to wild type. WT compared to NHERF1 KO showed significant differences in metabolites related to arginine and proline metabolism, pentose phosphate pathway, and pyrimidine metabolism. WT compared to Npt2a KO showed significant differences in metabolites related to TCA cycle, glucose and pyruvate metabolism, the pentose phosphate pathway, and lysine degradation. WT compared to low Pi diet showed significant differences in their metabolomic profiles, primarily involving amino acid metabolism. Comparison of the metabolomic profiles of NHERF1 KO and Npt2a KO showed significant though not complete overlap (PC 1 42.9%, PC 2 18.7%). In contrast, comparison of NHERF1 KO and low Pi diet kidney cortex showed complete dissociation in metabolic profile.

Conclusions: We conclude that the metabolic shift associated wtih NHERF1 KO deficiency is largely due to loss of Npt2a-mediated Pi transport and not due to Pi deficiency. We also conclude that additional NHERF1-mediated transport processes may contribute to the metabolic shift seen in NHERF1 KO.

Tissue-Specific Deletion of Cyp24a1 Reveals Independent Systemic and Intestinal Vitamin D Regulation in Mice

Michaela A. Fuchs,[1] Alexander Grabner,[1,2] Melody Shi,[1] Susan L. Murray,[1] Emily Burke,[1] Nejla Latic,[3] Venkataramana Thiriveedi,[4] Shintaro Ide,[1] Koki Abe,[1] Hiroki Kitai,[1] Tomokazu Souma,[1] Myles Wolf.[1,5] *[1]Division of Nephrology, Department of Medicine, Duke University School of Medicine, Durham, NC; [2]Department of Medicine, University Hospital Hamburg-Eppendorf, Hamburg, Germany; [3]Veterinarmedizinische Universitat Wien, Wien, Austria; [4]Division of Gastroenterology, Department of Medicine, Duke University School of Medicine, Durham, NC; [5]Duke University Duke Clinical Research Institute, Durham, NC.*

Background: Dysregulation of vitamin D, a central regulator of mineral metabolism, is a severe complication of chronic kidney disease (CKD), leading to hypocalcemia, secondary hyperparathyroidism and increased risk of fractures. The most biologically active form of vitamin D, 1,25-dihydroxyvitamin D (1,25D), is synthesized by the 1α-hydroxylase CYP27B1 in the kidney from its precursor, 25-dihydroxyvitamin D (25D). Catabolism of 1,25D is controlled by the expression of the 24-hydoxylase CYP24A1 in proximal tubules and other important Vitamin D target organs like the intestines or parathyroid glands. Human monogenic diseases and genome-wide association studies support a critical role for CYP24A1 in systemic regulation of mineral homeostasis, but little is known about its tissue-specific effects.

Methods: We used single cell RNA sequencing coupled with novel mouse models of tissue specific CYP24A1 deletion to address these questions. We analyzed the responses of mice with inducible global deletion, kidney-specific, and intestine-specific *Cyp24a1* deletion to standard calcium diet, high calcium diet and 1,25D injection.

Results: Global and kidney-specific *Cyp24a1* deletion caused similar phenotypes of systemic vitamin D intoxication: elevated circulating 1,25D and 25D levels, activation of vitamin D receptor target genes in the kidney and intestine, hypercalcemia, increased levels for fibroblast growth factor 23 and suppressed parathyroid hormone (PTH). In contrast, intestine-specific deletion of *Cyp24a1* led to no changes in systemic levels of 1,25D or 25D, yet vitamin D receptor target genes were activated in the intestine, and PTH was suppressed in response to high calcium diet without detectable changes to serum calcium levels.

Conclusions: These results implicate a central role for renal CYP24A1 in systemic vitamin D regulation, and highlight independent local effects of intestinal CYP24A1, inhibition of which can alter mineral homeostasis without precipitating hypercalcemia. These findings indicate that tissue specific modulation of CYP24A1 activity could present a new theraputical pathway for the treatment of secondary hyperparathyroidism in CKD with a reduced risk of hypercalcemia compared to current treatments with vitamin D and its analogs.

TBX2 Is a CKD-MBD Causal Gene by Regulating Calcium Homeostasis and Inflammation

Shen Li, Katalin Susztak. *University of Pennsylvania, Philadelphia, PA.*

Background: Chronic kidney disease–mineral and bone disorder (CKD-MBD) is a syndrome characterized by biochemical mineral abnormalities, bone fragility, and vascular calcification, leading to increased morbidity and mortality. Genome-wide association studies (GWAS) have identified numerous loci associated with kidney diseases. However, the causal variants, genes, cell types, and disease mechanisms remain largely unknown.

Methods: We integrated GWAS, human kidney expression of quantitative trait analysis using Bayesian colocations, and summary-based Mendelian randomization studies to identify likely causal genes for CKD-MBD. We used single-cell RNA data to pinpoint causal cell types. Additionally, we generated TBX2 knockdown (KD) mice to study mechanism.

Results: We prioritized TBX2 (T-Box Transcription Factor 2) as a CKD-MBD risk gene. Human kidney single-cell epigenetic and immunostaining studies indicated kidney connecting tubular cells and vascular smooth muscle cells (VSMCs) as key disease-causing cell types. TBX2-KD mice exhibited increased urinary calcium excretion at baseline and showed heightened susceptibility to kidney injury in a chronic kidney disease model. These mice also demonstrated elevated tissue calcification, leading to activation of crystal-induced NLRP3 inflammasome pathways and increased inflammation.

Conclusions: In summary, our GWAS identified TBX2 as a risk gene for CKD-MBD. We showed that TBX2 regulates tissue calcification and crystal-induced inflammation, thereby influencing CKD-MBD risk and uncovering a novel mechanism for CKD-MBD development.

Reduced miR122 Increases Fibroblast Growth Factor 23 (FGF-23) in Mice with CKD

Jane J. Thomas, Jadeah J. Spindler, Aline Martin, Valentin David. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Fibroblast growth factor 23 (FGF23) is associated with mortality in chronic kidney disease (CKD). Iron deficiency and inflammation stimulate the production and subsequent proteolytic cleavage of intact FGF23 (iFGF23) to yield C-terminal FGF23 peptides (Cter-FGF23) that play a protective role in iron metabolism. In CKD, FGF23 cleavage is impaired, but the mechanisms of impaired cleavage are unclear. O-glycosylation of iFGF23 cleavage site by GALNT3 prevents iFGF23 cleavage and we identified micro-RNA 122 (miR122) as an inhibitor of GALNT3. We hypothesized that reduction in osseous miR122 expression contributes to increased levels of GALNT3 and iFGF23 in CKD mice.

Methods: We crossed mice harboring a conditional deletion of miR122 in osteoblasts ($miR122^{Osx\text{-}cKO}$) with $Col4a3^{KO}$ mice with CKD to generate WT, $miR122^{Osx\text{-}cKO}$, $Col4a3^{KO}$, and compound (CPD) $Col4a3^{KO}$/$miR122^{Osx\text{-}cKO}$ mice. In all mice, we analyzed serum biochemical, hematological parameters and bone and liver gene expression at 18-weeks of age.

Results: Compared to WT mice, $miR122^{Osx\text{-}cKO}$ mice showed reduced bone miR122 levels, increased bone *Galnt3* expression, and reduced iron levels and transferrin saturation, but normal hemoglobin levels and red blood cells counts. As previously shown, $Col4a3^{KO}$ mice with advanced CKD displayed reduced iron levels and transferrin saturation and were overtly anemic compared to WT mice. They also showed a 2-fold reduction in bone miR122 levels, increased bone *Galnt3* expression (2.2-fold), and a dramatic increase in iFGF23 (7-fold). Further reduction in miR122 in CPD mice led to a 30% increase in bone *Galnt3* expression, a consequent 50% rise in iFGF23 circulating levels, and 20% increase in i/cFGF23 ratio vs. $Col4a3^{KO}$ mice, suggesting a further reduction of FGF23 proteolytic cleavage. As a consequence of reduced iron conserving Cter-FGF23 peptides, CPD mice also showed further reductions in hemoglobin and red blood cell.

Conclusions: Our study demonstrates that reduced expression of osseous miR122 in CKD leads to impaired FGF23 processing, resulting in reduced Cter-FGF23 but increased iFGF23. Therefore, administration of miR122 mimics to mice with CKD could lower iFGF23 and improve CKD-associated adverse outcomes.

Skeletal Muscle Is a Novel Source of Fibroblast Growth Factor 23 (FGF-23) That Regulates Phosphate Homeostasis

Kylie Heitman, Abul Fajol, Madison Thomas, Qing Li, Svetlana Komarova, Christian Faul. *The University of Alabama at Birmingham Department of Cell Developmental and Integrative Biology, Birmingham, AL.*

Background: Fibroblast growth factor 23 (FGF23) is hormone that is secreted from bone in response to elevations in serum phosphate (Pi) levels (hyperphosphatemia) and that targets the kidney to increase Pi excretion. In chronic kidney disease (CKD), the kidney loses its ability to properly respond to FGF23 and to excrete Pi, leading

to elevations in systemic levels of Pi and FGF23 which might contribute to various CKD-associated pathologies. Previous studies suggest that bone might not be the sole source for systemic FGF23 elevations. Here we determine whether mouse models of hyperphosphatemia express FGF23 in skeletal muscle (SM) and whether elevated Pi can induce FGF23 expression in cultured myotubes

Methods: C2C12 and primary mouse and human myotubes were treated with increasing concentrations of Pi for 24 hours, followed by the analysis of FGF23 expression by qPCR and immunocytochemistry as well as ELISA from cell supernatants. We studied four mouse models of hyperphosphatemia: two CKD models, i.e. mice with deletion of collagen 4a3 and mice fed an adenine-rich diet for 14 weeks; and two non-CKD models: klotho deficient mice and mice fed a high-Pi diet for 6 months. Furthermore, we generated mice with SM-specific deletion of FGF23 (SM-FGF23-/-) and administered an adenine-rich or a high-Pi diet. We analyzed FGF23 production in SM tissue by qPCR, immunohistochemistry and ELISA as well as serum levels of FGF23 and Pi. We also injected SM-FGF23-/- with Pi and determined 24 hour urine excretion.

Results: Pi treatments increase the expression and the secretion of FGF23 in MT in a dose-dependent manner. We could detect FGF23 expression in SM of all four mouse models on mRNA and protein level. SM-FGF23-/- on an adenine-rich or a high-Pi diet had significantly reduced FGF23 levels in SM and serum when compared to control mice on the same diet. SM-FGF23-/- mice on a high Pi diet also showed further elevations in serum Pi. Acute Pi load of SM-FGF23-/- mice resulted in reduced urine Pi levels.

Conclusions: Hyperphosphatemia induces FGF23 expression in SM in the absence and presence of CKD. SM-derived FGF23 contributes to the pool of circulating FGF23 and seems to have physiologic activity by increasing renal Pi excretion.

Fibroblast Growth Factor 23 Directly Contributes to CKD Progression in Col4a3 Knockout Mice

Dominik Kentrup, Hao-Hsuan Tsai, Xueyan Wang, Jane J. Thomas, Jadeah J. Spindler, Valentin David, Aline Martin. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Fibroblast growth factor 23 (FGF23) is a phosphate (Pi)-regulating hormone produced mainly by osteocytes. Increased levels of FGF23 are associated with increased mortality in CKD. Whether FGF23 has a direct role on CKD progression is unclear. In this study we tested the hypothesis that increased FGF23 levels accelerate CKD progression independently of phosphate.

Methods: First, we fed adult wild-type (WT) and *Col4a3*^{KO} male mice, an established model of progressive CKD, diets containing either 0.7% Pi (normal Pi, NP) or 2% Pi (high Pi, HP) continuously from 12 weeks of age to show the combined effects of FGF23 and Pi on CKD progression. Next, to separate the effects of FGF23 from hyperphosphatemia we deleted *Fgf23* in the bone (Osx-cre) of WT (*Fgf23*^{cKO}) and *Col4a3*^{KO} (*Col4a3*^{KO}/*Fgf23*^{cKO}) mice fed a NP diet. In all mice, we assessed lifespan, kidney function and markers of mineral metabolism.

Results: Compared to NP-WT mice, dietary Pi supplementation increased circulating FGF23 and PTH levels, resulting in increased urinary Pi excretion and reduced serum Pi levels in HP-WT. NP-*Col4a3*^{KO} mice with advanced CKD showed increased BUN, serum creatinine, FGF23, and PTH levels, late onset hyperphosphatemia, and a reduced lifespan compared to NP-WT mice. Dietary Pi supplementation in *Col4a3*^{KO} mice further increased serum creatinine, FGF23 and PTH levels, and led to earlier onset of hyperphosphatemia. As a result, HP-*Col4a3*^{KO} died on average 2.5 weeks earlier than NP-*Col4a3*^{KO} mice. In contrast, *Fgf23* deletion in WT mice slightly reduced FGF23 and increased serum Pi levels. In *Col4a3*^{KO} mice with CKD, *Fgf23* deletion corrected FGF23 levels by 60%, did not impact PTH levels, and further increased hyperphosphatemia. Despite further increases in Pi levels, BUN and serum creatinine levels were unchanged, and *Col4a3*^{KO}/*Fgf23*^{cKO} mice lived on average 2 weeks longer than *Col4a3*^{KO} mice.

Conclusions: In aggregate, FGF23 excess and hyperphosphatemia accelerated CKD progression whereas FGF23 reduction improved survival despite persistent hyperphosphatemia and hyperparathyroidism. This suggests that increased FGF23 in CKD directly contributes to CKD progression.

Fibroblast Growth Factor 23 Bioactivity Induces General and Cell Type-Specific Kidney Genomic Reprogramming as Detected by Single-Cell Multiomics

Emmanuel Solis,[1] Rafiou Agoro,[1] Kayleigh N. Jennings,[1] Yamil Marambio,[1] Sheng Liu,[1] Mark B. Meyer,[2] Jun Wan,[1] Kenneth E. White.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]University of Wisconsin-Madison, Madison, WI.*

Background: FGF23 functions with its co-receptor Klotho (KL) to regulate phosphate and 1,25D synthesis in the kidney, and this control is dysregulated in diseases such as CKD. The identification of pathways regulated by FGF23 are limited by bulk methodologies, thus significant knowledge gaps remain. Herein, we undertook a novel approach to test FGF23 bioactivity at single-cell resolution, hypothesizing that FGF23 bioactivity would enact cell type-specific transcriptional and genomic changes that could provide insight into the processes driving regulation of phosphate and 1,25D.

Methods: Male and female C57BL/6 mice were injected with recombinant FGF23 over time (0, 1, 4, and 12h) and pooled male/female Multiome (scRNAseq/ scATACseq from the same cell) kidney datasets were generated. Female *Xist* gene and male Y chromosome markers were used to perform 'sex hashing' of cell populations. Data was validated by qPCR.

Results: Dimensionality reduction via UMAP identified 38 distinct clusters in the kidney including unique epithelial, endothelial, and immune cell populations based upon known gene markers. Sex-specific genes, female *Xist* and male *Kdm5d* and *Eif2s3y* showed segregation between female and male mice. *KL* was detected in PT, LOH, CNT, and DCT. In response to FGF23, *Cyp24a1* mRNA and promoter chromatin accessibility increased in PT-S1 whereas *Cyp27b1* had the converse regulation, showing that FGF23 induces rapid chromatin remodeling. Notably, *Hbegf* and *Egr1* mRNAs and accessibility increased across all KL-expressing cell types. Indeed, negative MAPK regulator *Dusp6* showed increased mRNA expression at 4 and 12h in both PT and DCT. Furthermore, within PT-S1, novel FGF23-regulated genes *Slc5a12*, *Fut9*, and *Pah*, all decreased at 4h. Finally, DCT showed decreased accessibility and mRNA of *Pde10a* and increased mRNA expression of *Dcdc2A* at 12h, supporting differential activity of FGF23 depending upon nephron site.

Conclusions: In summary, temporal FGF23 delivery paired with Multiome analyses demonstrated that FGF23 directs both rapid and more chronic renal cell events. Our studies pinpoint transcriptional and chromatin reprogramming that could provide novel pathways for treatment interventions.

Renal Regulation of Fibroblast Growth Factor 23 Expression in Response to Inflammation Is Mediated by a Unique Genomic Mechanism

Seong Min Lee,[1] Mark B. Meyer,[1] J. W. Pike.[2] *[1]University of Wisconsin-Madison Department of Nutritional Sciences, Madison, WI; [2]University of Wisconsin-Madison Department of Biochemistry, Madison, WI.*

Background: Fibroblast growth factor 23 (FGF23) is a peptide hormone produced in bone to control phosphate homeostasis and vitamin D metabolism in the kidney. FGF23 is inappropriately upregulated in many tissues in response to inflammation and disease, potentially causing phosphate wasting and bone disorders. To model inflammation, we have shown that lipopolysaccharides (LPS) increased serum intact FGF23 (iFGF23) production *in vivo* via genomic mechanisms mediated by two distinct enhancers at -16 kb upstream and a large 4 kb proximal enhancer (PE) near the gene TSS in multiple tissues. However, the kidney LPS response is only in PE.

Methods: In this study, we generated 9 mouse strains to dissect the PE enhancer to examine the tissue specific regulation of LPS-induced *Fgf23*. Deletions were introduced by CRISPR/Cas9 editing in C57BL/6J mice and the levels of tissue *Fgf23* mRNA and serum iFGF23 in the mutants were compared with controls after LPS treatment for 6 h. ChIP-seq was performed in kidneys from wildtype mice for inflammatory factors after LPS treatment for 1 h.

Results: The results showed that while the induction in bone marrow, thymus, lung, and intestine was mediated by one region (PE1), a second, independent region (PE2) was responsible for renal *Fgf23* induction. *Fgf23* induction by LPS in bone, liver, and spleen was mediated by both regions (PE1 and PE2). Both PE1 and PE2 were further subdivided to explore mechanisms for *Fgf23* induction in the kidney where inflammation occurs under pathological conditions, such as chronic kidney disease. With these deletions, LPS-treated mice were resistant to *Fgf23* mRNA increases in the kidney, whereas the skeletal response remained. We confirmed complete loss of LPS-mediated *Fgf23* increases in both kidney and bone with a double knockout of the -16 kb region and PE together (DKO). Serum iFGF23 levels were unchanged in the DKO with LPS treatment. Following LPS treatment, ChIP-seq analysis showed increased binding of STAT3, p65, and p50 at these same regions in the kidney.

Conclusions: In conclusion, we have discovered that the regulation of FGF23 production in response to inflammation is orchestrated by a renal-specific enhancer. This leads to a unique mechanism by which tissues produce *Fgf23* and increase iFGF23 that modulates vitamin D metabolism and phosphate handling in disease.

Differential Effects of Iron Overload and Iron Repletion on Bone and Mineral Metabolism in Growing Mice

Eduardo J. Duque, Jadeah J. Spindler, Xueyan Wang, Aline Martin, Valentin David. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Altered iron status is associated with bone and mineral metabolism disorders, including bone loss, increased risk of fracture and altered production and cleavage of the bone-derived phosphaturic hormone fibroblast growth factor 23 (FGF23). In mice and humans, iron deficiency is associated with increased risk of osteoporosis and stimulates FGF23 production and cleavage, leading to excess circulating carboxy-terminal (Cter)-FGF23 fragments, high total FGF23 (cFGF23) but only slightly elevated intact (i) FGF23. However, the effects of iron repletion on bone and mineral metabolism remain to be determined.

Methods: We fed 3-week-old male mice a control (Ctr), an iron deficient (ID) or a high iron diet (HI) for 3 weeks until 6 weeks of age. In addition, we fed 3 week-old male mice an ID diet for one week followed by HI for 2 weeks to study the effects of iron repletion (IR) on the skeleton. In all mice, we analyzed biochemical parameters of mineral metabolism, hematological parameters, and 3D bone microarchitecture.

Results: Compared to Ctr mice, ID mice developed anemia, marked by decreased serum iron and hemoglobin (Hb) content, and showed elevated serum iFGF23 (1.6-fold) and cFGF23 (3-fold) leading to a 7-fold decrease in intact to total (i/c)FGF23 ratio ($p<0.05$). As expected, IR increased serum iron and IR mice were no longer anemic, as shown by corrected Hb levels. IR also decreased iFGF23 (30%) with no impact on cFGF23 compared to Ctr. Interestingly, iron overload also led to anemia in HI mice, despite higher serum iron (2.5-fold) and TSAT (2-fold) levels, and to a 2-fold increase in cFGF23, but reduced iFGF23 and i/cFGF23 by 30 and 70%, respectively ($p<0.05$). ID and IR showed a modest impact on the skeleton. In sharp contrast, and in absence of changes in PTH and phosphate levels, iron overload led to a severe bone loss with a dramatic reduction in BV/TV (-38%), trabecular number (-32%), cortical thickness (-31%) and higher cortical porosity (+36%).

Conclusions: In aggregate, our findings show that dietary iron intake in iron depleted mice corrects anomalies associated with iron deficiency. However, excessive iron consumption leads to extensive skeletal alterations, demonstrating that dietary iron intake affects bone development and FGF23 regulation differently, depending on iron status.

Effects of Intermittent Heparin Administration on Cardiac Tissue in Uremic Rats

Katia R. Neves, Luciene dos Reis, Luzia N. Furukawa, Vanda Jorgetti, Rosa M. Moyses. *Laboratório de Fisiopatologia Renal, Hospital das Clínicas HCFMUSP, Faculdade de Medicina, UNiversidade de São Paulo, São Paulo, Brazil.*

Background: CKD-MBD plays a key role in CKD-associated myocardial hypertrophy (MH). Hyperphosphatemia, hyperparathyroidism and elevated fibroblast growth factor 23 (FGF23) are associated with MH in preclinical and clinical studies. Recently, it was shown that heparin mediates the binding of FGF23 to its receptor FGFR4, promoting MH in a adenine model of CKD in mice. However, this has never been tested in other experimental models or species. In this study, we tested whether intermittent unfractioned heparin (UFHep) or low molecular heparin (LMWHep) administration induces MH in rats submitted to 5/6 nephrectomy (Nx).

Methods: Male Wistar rats (n=50) were submitted to 5/6 Nx, or were sham operated. After a recovery period of one week, we divided the groups as follows, according to the administration: Sham (saline 0.9%), Nx (saline 0.9%), Nx+UFHep (125UI/Kg of UFHep) and Nx+LMWHep (1mg/Kg of LMWHep; enoxaparin). All groups received a standard rodent chow. Infusions were given subcutaneously, 3 times/ week. Tail cuff pressure and weight were measured weekly. After 2 months, serum and 24 hour-urine were collected, and myocardial histology was analyzed

Results: Initial and final body weight did not differ among the groups. Initial tail cuff pressure values were similar among all groups. However, all Nx rats developed hypertension, with no differences among them. Uremia and albuminuria were found in Nx animals (Table). Although no differences were found in serum calcium or phosphate among the groups, Nx rats had higher PTH. Also, Nx and Nx+UFHep rats had slightly higher FGF 23 levels than Sham animals. MH and cardiac fibrosis were found in all Nx groups, with no differences among them. Higher FGFR1 expression was seen in Nx+UFHep and Nx+LMWHep. However, no differences were seen in FGFR4 or TGFBeta expression.

Conclusions: Our data suggests that heparin is not able to worse MH in the absence of severe hyperparathyroidism or highly elevated FGF23. Whether this finding could be translated to clinical practice deserves future investigation.

SA-PO235

Klotho KL1 Domain Directly Prevents Cardiac Fibrosis in a Rat CKD-MBD Model

Arvin Halim, Gayatri Narayanan, Shruthi Srinivasan, Kalisha O'Neill, Neal X. Chen, Sharon M. Moe, Kenneth Lim. *Indiana University School of Medicine, Indianapolis, IN.*

Background: α-Klotho has a bifunctional role as a co-receptor for FGF23 and exerts FGF23-independent cardioprotective effects. However, the fragment of Klotho responsible for direct cardioprotective effects is unknown. Our group's computational modeling suggests that the Klotho KL1 domain (which has a lipid raft binding site and lacks FGF23 binding elements) is the fragment responsible for these effects. This study aimed to assess whether KL1 can exert direct anti-fibrotic effects at the heart in CKD rats.

Methods: Cy/+ male rats (CKD rats) were fed a casein-based diet starting at 22 wks (~50% normal renal function), and then treated daily with intraperitoneal injections of 50 μg/kg KL1 (n=9) or vehicle (n=23) for 5-7 weeks starting at 27 wks. Normal littermates (NL, n=23) were used as controls. At 32-34 weeks (~15% normal renal function), tissues were harvested for molecular and histological analyses. For *in vitro* fibrosis experiments, human cardiac fibroblasts (HCFs) were exposed to 3.8mM phosphate and 2.0mM calcium (P+C) and treated daily for 5 days with 5nM KL1 or vehicle. For immunofluorescence (IF), HCFs were incubated with 500nM AlexaFluor-tagged KL1 and hybridized with anti-asialoGM1 (GA1) antibody to label lipid rafts.

Results: CKD rats had increased left ventricular (LV) and perivascular fibrosis as assessed by Masson's Trichome staining (P<0.0001), TGF-β (P<0.004), and LV mass index (LVMI P<0.0004) compared to NL. This was accompanied by mineral dysregulation (high phosphate, iFGF23 and iPTH (P<0.0006)) and reduced renal function (high BUN and creatinine (P<0.0001)) compared to NL rats. Significantly, KL1-treated rats exhibited reduced fibrosis (P<0.01) and TGF-β (P<0.02) in LV tissue. These effects were independent of changes in LVMI, mineral dysregulation, cardiac inflammatory markers (TNFα, IL-6, and MCP-1), and renal function. In HCFs, KL1 reduced collagen type I (P<0.0001) and α-SMA (P<0.02) cultured under P+C stress. IF demonstrated KL1 localization to the membrane, cytoplasm, and nuclei, but not with GA1-containing lipid rafts.

Conclusions: KL1 directly improved cardiac fibrosis independent of alterations in renal function, mineral metabolism, nor inflammation in CKD rats. Further studies are needed to validate these findings and elucidate the receptor(s) of KL1 responsible for its anti-fibrotic effects.

Characterization of Renal Tubule-Derived Extracellular Vesicles (EVs) and EVs Carrying Klotho

Orson W. Moe,[1,2] Juan D. Salcedo Betancourt,[2] Taylor Davidson,[1,2] Isabelle Carroll,[1,2] Johanne V. Pastor.[1,2] *[1]The Charles and Jane Pak Center for Mineral Metabolism and Clinical Research, Dallas, TX; [2]The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: EVs are cell-derived vesicles that act as organ-to-organ messengers and are studied as potential biomarkers of physiology, disease diagnosis and therapy response. Previous studies found Klotho highly associated with membrane fragments in cell culture supernatants. We aimed to interrogate whether Klotho is carried in EVs in body fluids. Additionally, we try to quantify renal tubule-derived EVs in urine and serum.

Methods: Urine (60 ml) and serum (10 ml) from healthy subjects underwent ultracentrifugation for EV isolation. We compared the concentration of free soluble Klotho (supernatant) with EV-Klotho (EV-enriched pellet) in urine and serum. A mouse model with renal epithelium-derived EVs selectively labeled with GFP (KSP-Cad16-Cre/TIGER CD9) was developed to characterize renal tubule-originated EVs. Isolated urinary EVs underwent fluorescence-activated vesicle sorting based on GFP positivity.

Results: Three methods of EV isolation were compared- size exclusion chromatography, immunoprecipitation and ultracentrifugation- with the latter method being most efficient. EVs from human urine and serum were confirmed by EV-markers (ALIX, Flotillin-1) by immunoblot. A minimal amount of Klotho was found in human urinary EVs compared to free soluble urinary Klotho and no Klotho was detected in human serum EVs. Renal fluorescent histochemistry confirmed tubular apical membrane localization of the GFP-CD9 EV marker. Renal tubule-derived urinary EVs were identified

by direct fluorescent microscopy and flow sorting. After flow sorting, only 23.1% of urinary EVs originated from the renal tubule (CD9+/GFP+ events = 2.8 million vs. GFP- events = 12.2 million). No renal tubule-derived EVs were observed in mice serum.

Conclusions: Only a minimal amount of Klotho is carried in urinary EVs, indicating that Klotho primarily exists in the soluble form in both human serum and urine. Only a subpopulation of urinary EVs in the mouse originated from the renal tubules. Tubular-derived EVs are present in the urine but not in serum, suggesting a selective destination for tubular EV secretion into the urine. One needs to take extreme caution to interpret data from urine EVs and draw conclusions about tubular function. Additional proteomic analysis is ongoing in our lab to assess the content of tubular vs non-tubular urinary-originated EVs.

SA-PO237

Simultaneous Transcriptional Reprogramming in Cortical Bone, Muscle, and Bone Marrow Uncovered by Spatial Transcriptomics in Modeled CKD

Lainey M. Hibbard, Sheng Liu, Yamil Marambio, Kayleigh N. Jennings, Steven S. Welc, Jun Wan, Kenneth E. White. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Musculoskeletal dysfunction in CKD-MBD is common, causing increased morbidity and mortality; however, the contribution of multi-tissue genetic reprogramming is not understood. Further, the interactions between bone and muscle, and among muscle fiber types have only been tested by candidate gene analysis and in individual tissues. Herein, we tested spatially unique transcriptional reprogramming occurring simultaneously across cortical bone, muscle, and marrow.

Methods: Visium spatial transcriptomics (ST) was used on femur-muscle cross sections from male mice with adenine diet-induced CKD (0.2%, 4 wks), or casein control diet.

Results: UMAP analyses paired with hallmark transcript mapping distinguished slow and fast twitch muscle fibers, including three fast-twitch subtypes (IIa, IIx, IIb), as well as cortical bone and bone marrow in the same histology sections. Consistent with disease phenotypes, atrophy-associated genes (Trim63, Fbxo32) were upregulated in CKD muscle, 1.76-1.92 and 1.67-1.94 log_2-fold, respectively. Interestingly, a novel increase in the structural gene Nrap was detected across CKD fast and slow-twitch muscle (1.24-2.29 log_2-fold), whereas fiber subtypes showed specific disturbances, including a slow-twitch muscle increase in Car3 (1.69 log_2-fold) and enrichment of ubiquitin-mediated proteolysis and transcriptional regulation by RUNX1 pathways in fast-twitch muscle. In cortical bone, differing effects of CKD on osteoblast gene expression occurred, with increased mRNAs for Tnc/Mmp13 and decreased expression of Bglap and Col3a1 (96.6% and 95.3%). Further, glycolysis pathways were downregulated in CKD cortical bone. Bone marrow showed expected changes with CKD, including enrichment of inflammation and downregulation of heme biosynthetic pathways. Additionally, we found a novel 89.3% decrease in expression of Hist1h1b, contributing to downregulation of chromatin-related pathways. Along with tissue specific changes, we also identified pathways shared across tissues, most notably increased intrinsic apoptosis signaling with CKD.

Conclusions: Unbiased ST identified novel effects of CKD concurrently within bone, bone marrow, and specific muscle subtypes associated with tissue-unique and -common musculoskeletal pathologies.

SA-PO238

Impact of Phosphate Binders on Bone Protein Expression in Rats Fed Diets with Different Phosphorus Concentrations

Tânia P. Truyts,[1] Juliana C. Ferreira,[1] Katia R. Neves,[1] Wagner Dominguez,[1] Rosilene M. Elias,[1,2] Vanda Jorgetti,[1] Rosa M. Moyses,[1] Luciene dos Reis.[1]
[1]*Laboratório de Fisiopatologia Renal, Hospital das Clínicas HCFMUSP, Faculdade de Medicina, Universidade de São Paulo, Sao Paulo, Brazil;*
[2]*Post-Graduation, Universidade Nove de Julho (UNINOVE), São Paulo, Brazil.*

Background: Managing hyperphosphatemia is important in treating chronic kidney disease (CKD) to prevent bone and cardiovascular complications. Phosphate (P) binders play a key role in this control. This study evaluated the efficacy of calcium carbonate (CaCO3) and sevelamer carbonate (Sev) on the bone expression of proteins involved in the Wnt/β-catenin pathway in nephrectomized (Nx) and parathyroidectomized (PTx) rats fed normal and high P diets.

Methods: Wistar rats underwent 5/6 nephrectomy (Nx), parathyroidectomy (PTx), and were fed diets with different P concentrations (0.6% and 1.2%). The animals were divided according to diet and treatment with the binders. Biochemical analyses were performed on all animals. Bone expression of sclerostin, DKK1, and β-catenin was evaluated using mRNA levels and immunohistochemistry (IH), whereas FGF23 was evaluated only by IH. Statistical analysis using the General Linear Model was applied to study the effects of diet and treatment in these animals.

Results: Table 1 describes the interaction between different P concentrations in the diet and the effects of both treatments on biochemical analysis, IH expression, and mRNA levels. Post-test analysis disclosed that serum P, fractional P excretion and ionized calcium (Cai) were influenced by both the different diets and the two binders, as well as osteocytic expression of sclerostin and FGF23, and mRNA levels of SOST.

Conclusions: Our results showed that treatment with both binders was effective in decreasing serum P and fractional excretion and increasing Cai. Phosphate overload increased FGF23 expression in the bone, and both binders were effective in reducing this expression. The Wnt/β-catenin pathway was blocked by sclerostin, with higher expression in animals with P overload, and both treatments reduced its expression, which was also observed in gene expression. These results demonstrated that P overload can inhibit the Wnt/β-catenin pathway and that both binders effectively reversed phosphate's effects.

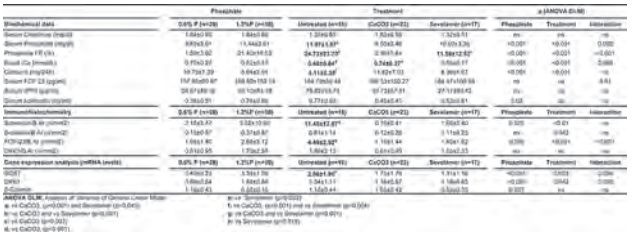

Table 1.

SA-PO239

Impact of Phosphate Binders on Bone Histomorphometry in Rats Submitted to Diets with Different Concentrations of Phosphorus

Tânia P. Truyts,[1] Juliana C. Ferreira,[1] Katia R. Neves,[1] Wagner Dominguez,[1] Rosilene M. Elias,[1,2] Vanda Jorgetti,[1] Rosa M. Moyses,[1] Luciene dos Reis.[1]
[1]*Laboratório de Fisiopatologia Renal, Hospital das Clínicas HCFMUSP, Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil;*
[2]*Post-Graduation, Universidade Nove de Julho (UNINOVE), São Paulo, Brazil.*

Background: Managing hyperphosphatemia is important in treating chronic kidney disease (CKD) to prevent bone and cardiovascular complications. Phosphate (P) binders play a fundamental role in this control. This study evaluated the impact of calcium carbonate (CaCO3) and sevelamer carbonate (Sev) on bone tissue in nephrectomized (Nx) and parathyroidectomized (PTx) rats fed normal and high-phosphorus diets.

Methods: Wistar rats underwent 5/6 nephrectomy (Nx) and parathyroidectomy (PTx) and were fed diets with different P concentrations (0.6% and 1.2%). The animals were divided according to diet and treatment with the binders. Biochemical analyses and bone histomorphometry were performed on all animals. Statistical analysis using ANOVA General Linear Model was applied to study the effects of diet and treatment on bone tissue.

Results: Table 1 describes the interaction between different P concentrations in the diet and the effects of both treatments on biochemical analysis and bone histomorphometry. Post-test analysis showed that P excretion fraction and ionized calcium (Cai) were influenced by both different diets and CaCO3 and sevelamer. Also showed that formation parameters were influenced by P and treatment, significantly high in the rats treated with CaCO3. Resorption parameters were influenced by treatment but not by P, although no interaction was observed.

Conclusions: Our results demonstrated that, although CaCO3 was effective in reducing serum P, it significantly altered bone formation and resorption parameters, possibly due to calcium overload. In contrast, the use of sevelamer did not alter bone parameters. These findings reinforce the importance of considering the side effects related to calcium load when choosing phosphate binders. The study suggests that sevelamer may be a safer alternative to preserve bone health and control hyperphosphatemia in these experimental model.

Uremic Toxin Indoxyl Sulfate Increases Osteocyte Wnt Inhibitor Signaling and Decreases RANKL and Mineralization, Effects Negated by PTH

Neal X. Chen, Kalisha O'Neill, Hannah E. Wilson, Lynda F. Bonewald, Sharon M. Moe. *Indiana University School of Medicine, Indianapolis, IN.*

Background: In CKD, fractures can occur at both high and low PTH levels, indicating non-PTH mediated pathways. We hypothesized that uremic toxin indoxyl sulfate (IS), a potent ligand for the aryl hydrocarbon receptor (AhR), may be a factor in low bone turnover when PTH is not elevated.

Methods: We cultured IDG-SW3 osteocytes that differentiate from osteoblasts to early osteocytes (day 14) and mature osteocytes (day 35). We examined the effect of IS in short term 24 hour exposure, long term (14 or 35 day) exposure, and with and without PTH or CH223191 (an inhibitor of AhR nuclear translocation). We assessed osteocyte gene expression by RT-qPCR, alkaline phosphatase (ALP) activity, and mineralization. AhR canonical signaling was assessed by upregulation of the genes CYP1A1, CYP1B1, and AhRR.

Results: Short term exposure to IS for 24 hours dose dependently increased expression of the Wnt inhibitors SOST, Dkk1, and decreased RANKL in both early and mature osteocytes. IS dose dependently increased canonical AhR activation of CYP genes. Long term incubation of IS in early (IS for 14 days) and mature (IS for 35 days) osteocytes led to similar upregulation of Wnt inhibitors and decreased RANKL expression, ALP, and mineralization. CH223191 reduced AhR canonical CYP gene activation and reversed the IS inhibition of mineralization and alkaline phosphatase activity but did not reverse the IS induced expression SOST, Dkk1, or RANKL in osteocytes. Co-culture with both PTH and IS reversed the IS induced upregulation of SOST, Dkk1, and suppression of RANKL. In both early and mature osteocytes, AhR CYP genes were activated by IS but not PTH, but there was an additive effect of AhR CYP gene expression in the presence of both IS and PTH.

Conclusions: In summary, IS in the absence of PTH, activated canonical and non-canonical AhR signaling to increase osteocyte Wnt inhibitor signaling and decrease RANKL osteoclast activation and mineralization, which would translate to low remodeling. However, in the presence of PTH, these effects were reversed, suggesting IS is likely an important factor in the low turnover bone disease observed in CKD.

Activin A Inhibition Reduces Kidney Fibrosis and Normalizes Bone Abnormalities in AKI

Anders Nordholm,[1,2] Andreas Lodberg,[3,4] Simone Snitgard Rosendal Nielsen,[5] Maria L. Mace,[2] Eva Gravesen,[6] Iain O. Bressendorff,[1] Marya Morevati,[2] Marco Eijken,[7] Christian B. Andersen,[3] Mads Hornum,[2,8] Jesper S. Thomsen,[3] Thomas L. Andersen,[5,9] Ditte Hansen.[1,8] *[1]Department of Nephrology, Copenhagen University Hospital - Herlev and Gentofte, Copenhagen, Denmark; [2]Department of Nephrology, Copenhagen University Hospital - Rigshospitalet, Copenhagen, Denmark; [3]Department of Biomedicine, University of Aarhus, Aarhus, Denmark; [4]Department of Endocrinology and Internal Medicine, Aarhus University Hospital, Aarhus, Denmark; [5]Clinical Cell Biology, Research Unit of Pathology, Department of Pathology, Odense University Hospital, Odense, Denmark; [6]Department of Pathology, Copenhagen University Hospital - Herlev and Gentofte, Copenhagen, Denmark; [7]Department of Clinical Medicine, Aarhus University, Aarhus, Denmark; [8]Department of Clinical Medicine, Faculty of Health Science, University of Copenhagen, Copenhagen, Denmark; [9]Department of Forensic Medicine, Aarhus University, Aarhus, Denmark.*

Background: Activin A inhibition (ActAi) ameliorates progressive kidney fibrosis and bone disease in CKD. In acute kidney injury (AKI) by unilateral ureter obstruction (UUO) activin A is secreted from injured kidneys leading to elevated levels in the circulation. We aimed to determine the effect of ActAi on kidney and bone in AKI.

Methods: Female C57BL/6 mice with UUO for 15 days received either ActAi with an anti-activin receptor type IIA/IIB antibody (s.c., 10mg/kg) twice weekly (UUO Ab, n=10) or vehicle (UUO Veh, n=10), while sham-operated controls received vehicle (Ctrl, n=8). At sacrifice, blood samples, kidneys, femora, and tibiae were collected. Analyses included ELISA, qPCR, histology, μCT, and bone histomorphometry.

Results: UUO Ab had reduced mRNA levels of type I collagen (20±5 vs 35±20, p<0,05) and fibronectin (8±2 vs 17±6, p<0.05) compared to UUO Veh. Histology confirmed diminished fibrosis in UUO Ab. Plasma Urea was similar in both UUO groups. UUO Ab mice had increased volumetric bone mineral density (130±13 vs 106±11 and 103±13mg/cm^3, p<0.001), and trabecular number (4.3±0.1 vs 3.9±0.2 and 3.9±0.2mm^{-1}, p<0.001) compared to similar levels in UUO Veh and Ctrl. In UUO Veh, osteoid surface increased (OS/BS 31±14 to 43±10%, p<0.05) and quiescent surface decreased (QS/BS 13±7 to 7±3%, p<0.05) compared to Ctrl. Both were restored in UUO Ab (p<0.05). Sclerostin mRNA was reduced in UUO Veh compared to Ctrl (0.5±0.3 vs 1.1±0.4, p<0.05) but restored in in UUO Ab (0.9±0.3, p<0.05). FGF23 mRNA levels was unaffected by UUO but decreased in UUO Ab (0.4±0.2 vs 1.2±0.5 and 1.1±0.4, p<0.01). Plasma FGF23 increased in UUO Veh compared to Ctrl (50±13 vs 34±10pg/mL, p<0.05) and was normalized in UUO Ab (33±6pg/mL, p<0.01). Plasma calcium, phosphate, and PTH were similar in all groups.

Conclusions: ActAi ameliorated progressive kidney fibrosis and restored bone-forming osteoid surfaces in AKI mice, indicating a normalization of a potential mineralization defect. ActAi increased bone mineral density and microstructure as well as restored mRNA levels of osteocyte-derived sclerostin. ActAi is a promising therapeutic approach to limit AKI induced renal fibrosis and to normalize bone homeostasis.

Mitochondrial Dysfunction and Mitophagy Blockade Contribute to Renal Osteodystrophy in CKD-Mineral Bone Disorder

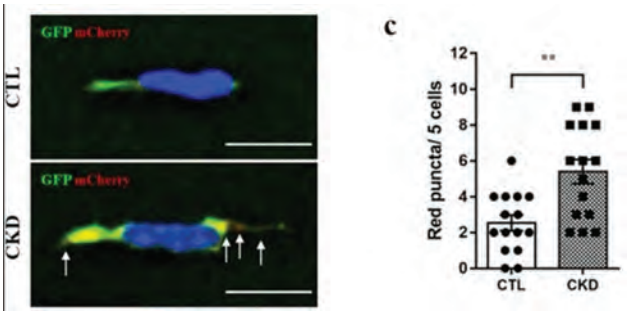
Shun-Neng Hsu,[1,2] Yu-Juei Hsu,[1] Colin Farquharson.[2] *[1]Tri-Service General Hospital Department of Medicine, Taipei, Taiwan; [2]The University of Edinburgh The Roslin Institute, Roslin, United Kingdom.*

Background: Chronic kidney disease–mineral and bone disorder (CKD-MBD) presents with extra-skeletal calcification and renal osteodystrophy (ROD). The origins of ROD likely lie with elevated uremic toxins and/or an altered hormonal profile but the cellular events responsible remain unclear. Here, we report that stalled mitophagy contributes to mitochondrial dysfunction in bones of a CKD-MBD mouse model, and also human CKD-MBD patients.

Methods: C57BL/6J wild-type male mice and *mito*-QC mice were obtained and CKD-MBD was induced using a casein-based diet containing 0.2% adenine for five weeks. 40 wild-type mice were allocated into control and CKD-MBD groups staggered from day 0 to day 35 to assess progressive changes. RNA-seq libraries were prepared and sequenced to provide comprehensive gene expression profiles. Blood serum, μCT of tibiae, and confocal microscopy of stained cryosections assessed CKD-MBD impact.

Results: RNA-seq analysis exposed an altered expression of genes associated with mitophagy and mitochondrial function in tibia of CKD-MBD mice. The accumulation of damaged osteocyte mitochondria and the expression of mitophagy regulators, p62/SQSTM1, ATG7 and LC3 was inconsistent with functional mitophagy, and in *mito*-QC reporter mice with CKD-MBD, there was a 2.3-fold increase in osteocyte mitolysosomes. Altered expression of mitophagy regulators in human CKD-MBD bones was also observed. To determine if uremic toxins were possibly responsible for these observations, indoxyl sulfate treatment of osteoblasts revealed mitochondria with distorted morphology and whose membrane potential and oxidative phosphorylation were decreased, and oxygen-free radical production increased. The altered p62/SQSTM1 and LC3-II expression was consistent with impaired mitophagy machinery and the effects of indoxyl sulfate were reversible by rapamycin.

Conclusions: Mitolysosome accumulation from impaired clearance of damaged mitochondria may contribute to the skeletal complications, characteristic of ROD.



Quantification of mitophagy in osteocytes from CTL and CKD-MBD mito-QC mice.

SA-PO243

Combination Oxylanthanum Carbonate and Tenapanor Lowers Urinary Phosphate Excretion in Rats

Satya Medicherla,[1] Guru Reddy,[1] Pramod Gupta,[1] Glenn M. Chertow,[2] Shalabh Gupta.[1] *[1]Unicycive Therapeutics Inc, Los Altos, CA; [2]Stanford University School of Medicine, Palo Alto, CA.*

Background: End-stage kidney disease(ESKD) affects >7 million people worldwide and ~70% of patients with ESKD have hyperphosphatemia. Tenapanor, sodium/hydrogen exchanger(NHE3) inhibitor, reduces paracellular phosphate(P) absorption by inducing conformational changes in intestinal epithelium. Oxylanthanum carbonate(OLC) is an investigational new drug being developed for treatment of hyperphosphatemia under FDA's 505(b)(2) regulatory pathway. If approved, OLC will share substantially the same product label and prescribing information as reference-listed drug Fosrenol®(lanthanum carbonate), although OLC tablets are smaller in size and swallowed whole with water and not chewed. This study evaluated effects of OLC+tenapanor on urinary P excretion in rats on a high phosphorus diet.

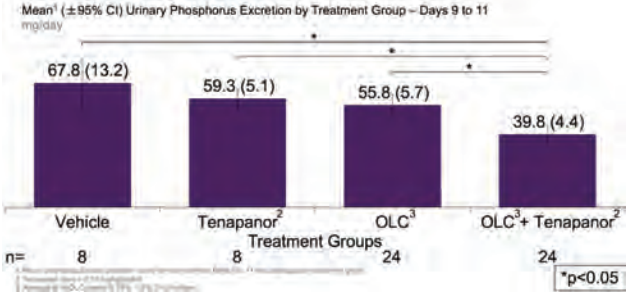
Methods: 64 male Sprague Dawley rats were fed standard chow 1 week prior to study start and then spiked with additional 0.4% inorganic phosphate [1:1 sodium:potassium salt, 1.1%(wt/wt) total phosphate content] for rest of the study. On study Day -1, animals were randomized into 8 groups(n=8 in each): 1) vehicle, 2) tenapanor 0.15mg/kg, 3) vehicle+OLC 0.75%, 4) vehicle+OLC 1.5%, 5) vehicle+OLC 3%, 6) OLC 0.75%+tenapanor 0.15mg/kg, 7) OLC 1.5%+tenapanor 0.15mg/kg, and 8) OLC 3%+tenapanor 0.15mg/kg. Vehicle and tenapanor were dosed PO twice daily whereas OLC was incorporated into the diets. 24-hour urine samples were collected using metabolic cages on day 9, 10, and 11 for urinary P measurements. OLC efficacy data are presented as average of all OLC doses(0.75%, 1.5%, and 3%).

Results: In tenapanor alone and OLC only groups, urinary P excretion was 8.5 and 12.0mg/day lower, respectively, compared to vehicle. In OLC+tenapanor groups, urinary P excretion was 28mg/day lower compared to vehicle.

Conclusions: Combination OLC+tenapanor demonstrates more pronounced P reduction than either agent used alone. The magnitude of P lowering suggests effect of OLC+tenapanor is synergistic rather than additive.

Funding: Commercial Support - Unicycive Therapeutics, Inc.

Figure 1. OLC + Tenapanor Effectively Decreased Urinary Phosphorus Excretion Compared to Tenapanor Only and OLC Only



SA-PO244

Systemic Phosphate Elevations Are Associated with Alveolar Calcification in Mice

Abul Fajol,[1] Seth Bollenbecker,[2] Parveen Kumar,[3] Kylie Heitman,[1] Madison Thomas,[1] Qing Li,[1] Svetlana Komarova,[1] Tanecia Mitchell,[3] Stefanie Krick,[2] Christian Faul.[1] *[1]The University of Alabama at Birmingham Division of Nephrology, Birmingham, AL; [2]Division of Pulmonary, Allergy and Critical Care Medicine, The University of Alabama at Birmingham, Birmingham, AL; [3]Department of Urology, The University of Alabama at Birmingham, Birmingham, AL.*

Background: Increases in serum phosphate levels (hyperphosphatemia) are associated with vascular calcification (VC) and mortality in patients with chronic kidney disease (CKD). Elevated phosphate can target vascular smooth muscle cells and induce inflammatory and osteogenic gene programs and VC. It is unknown whether high phosphate levels can also directly affect the lung.

Methods: We analyzed the lung phenotype of klotho-deficient (*kl/kl*) mice, which is a model for hyperphosphatemia and VC. Tissue calcifications were determined by μCT analysis, Alizarin red and von Kossa stainings, and tissue phosphate content by a colorimetric assay and ICP-MS. Nanoparticles in the bronchoalveolar lavage (BAL) fluid were quantified by NanoSight Technology and visualized by TEM. Cells in the BAL were analyzed by flow cytometry. Human alveolar epithelial cells (A549) and human lung fibroblasts (IMR-90) were cultured in the presence of high phosphate and analyzed by Alizarin red staining. Calcification events in lung tissue and cultured cells were also determined by qPCR analysis of osteogenic and inflammatory markers.

Results: We observed calcifications in the lung of *kl/kl* mice, especially in the alveolar region, as well as increased expression of osteogenic and inflammatory markers and elevated phosphate content. In the BAL of *kl/kl* mice, we detected increased numbers of macrophages and calcium-containing nanoparticles, which had a crystal-like morphology. No such alterations were observed in wildtype mice. A high magnesium diet reduced lung phosphate content and calcification. Exposure of A549 cells and IMR-90 to high phosphate induced osteogenic and inflammatory markers as well as calcium-phosphate deposition, which was abolished in cells co-treated with magnesium.

Conclusions: Our findings suggest that mice with hyperphosphatemia develop lung calcifications, which are accompanied by inflammation and by the appearance of calcium-phosphate crystals. Whether pulmonary calcification also occurs in CKD, needs to be determined. Our in vitro studies suggest that high phosphate can directly target lung cells and induce calcification. Therefore, lowering phosphate or preventing the formation of calcium-phosphate particles systemically or locally might have protective effects on the lung in diseases with hyperphosphatemia.

SA-PO245

Modeling Progression of Uremic Vasculopathy Using Machine Learning

Adam E. Gaweda,[1] Eleanor D. Lederer,[2,3] Michael E. Brier.[1] *[1]University of Louisville, Louisville, KY; [2]The University of Texas Southwestern Medical Center, Dallas, TX; [3]VA North Texas Health Care System, Dallas, TX.*

Background: KDIGO guidelines for Chronic Kidney Disease Mineral Bone Disorder (CKD-MBD) target Phosphate, Parathyroid Hormone, and Calcium as the primary clinical outcomes. To prevent vascular end organ damage due to CKD-MBD, we need better understanding of the mechanism behind uremic vasculopathy. We perform nonlinear analysis of biochemical parameters in the Chronic Renal Insufficiency Cohort (CRIC) and their association with coronary artery calcification (CAC).

Methods: We abstracted 93 biochemical parameters from the CRIC data set and performed 10 data fitting sessions using Multilayer Perceptron Neural Network model, splitting the data into training (70%) and testing (30%) sets. Using sensitivity analysis, we selected the most important parameters from the trained model. We ranked these parameters and analyzed their association with CAC at different CKD stages. Data analysis was performed in IBM SPSS.

Results: The average CAC prediction RMSE was 0.08 (training) and 0.11 (testing). At early CKD stages, CAC appears to be influenced by oxidative stress, mitochondrial dysfunction, and alterations in protein translation and post-translational modification (YKL40, ADMA, succinic acid, NAG+, Tiglylglycine). High CAC scores in early CKD correlate with high FGF23, whereas high Calcitriol appears protective. At late CKD stages, high CAC scores reflect impaired tubular function including xanthosine, BTP, and B2M.

Conclusions: Uremic vasculopathy involves various pathways active at different CKD stages. Biomarker discovery enables identifying these pathways to better understand the disease process, leading to better diagnosis, prevention, and treatment.

Acknowledgment: CRIC data were provided by NIDDK Central Repository, a program of the National Institute of Diabetes and Digestive and Kidney Diseases.

Funding: Veterans Affairs Support

A Nonsteroidal Mineralocorticoid Receptor Antagonist Alleviates Vascular Aging in CKD

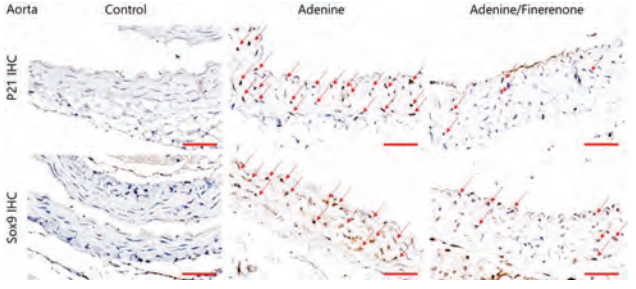
Yoonjoo Jang, Byung Min Ye, Seo Rin Kim, Il Young Kim, Soo Bong Lee, Dong Won Lee. *Pusan National University Yangsan Hospital, Yangsan, Republic of Korea.*

Background: Chronic kidney disease (CKD) is associated with early vascular aging processes, leading to increased morbidity and mortality. Aldosterone may exacerbate these processes, but the impact of mineralocorticoid receptor blocking on vascular complications in CKD remains unknown. This study aims to assess the impact of a novel nonsteroidal mineralocorticoid receptor antagonist, finerenone, on mitigating vascular aging in CKD.

Methods: CKD was induced in mice using an adenine-rich diet. Three groups of C57BL/6 mice were assigned to distinct dietary regimens: standard chow, a diet enriched with 0.25% adenine, and an adenine-enriched diet supplemented with finerenone (10 mg/kg) (n=6, 14, and 14, respectively). After a 6-week diet, renal function was assessed by serum creatinine and urine albumin levels. Vascular aging and calcification were studied on the aorta ex vivo to evaluate the effects of adenine and finerenone. (Figure)

Results: The adenine diet increased serum creatinine levels and urine albumin-to-creatinine ratios, but finerenone treatment improved these measures. Alkaline phosphatase levels in serum and calcium deposits in the aorta increased in mice fed adenine but normalized in the adenine/finerenone group. Whereas, serum aldosterone levels were upregulated in both adenine and adenine/finerenone groups compared to control mice. Aortic expressions of senescence and SASP markers *Cdkn1a, Tnfα,* and *Serpine1* increased in the adenine group but decreased with finerenone treatment. Finerenone also improved the expression of the osteogenic marker *Sox9* in the aorta, correlating with *Cdkn1a* expressions.

Conclusions: CKD triggers osteogenic changes and vascular aging in a murine model, but finerenone mitigates vascular aging, at least partly due to the improvement of Sox9 expression. These findings support the exploration of mineralocorticoid receptor blocking strategies for improving vascular aging in CKD.



SA-PO247

Disorder of Methionine Metabolism Triggers Vascular Calcification via DNMT3A in CKD

Fan He, Xue Xing, Qing Li. *Department of Nephrology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China.*

Background: Vascular calcification is closely related to the occurrence and mortality of cardiovascular disease (CVD) in CKD patients, and the specific mechanism of its pathogenesis is not yet clear. Previous studies have found that elevated levels of methionine metabolites are risk factors for developing cardiovascular disease (CVD), but the mechanism remains unclear. This study aims to explore the role of methionine metabolism in vascular calcification in CKD.

Methods: Liquid chromatography-mass spectrometry was used to detect the levels of S-adenosylmethionine (SAM) and S-adenosylhomocysteine (SAH) in the plasma of CKD patients; 5/6 nephrectomy combined with high phosphorus diet and high phosphorus medium was used to establish in vivo and in vitro CKD vascular calcification models. Methylation-specific polymerase chain reaction (MSP) was used to detect whether the target gene has undergone methylation.

Results: The plasma levels of SAM, SAH, and SAM/SAH ratios in the CKD patient group were significantly increased. Also, CKD patients had significantly increased levels of 5-mC and DNMT3A expression in calcified arteries IHC staining. The proportion of 5-mC modification in the total DNA of blood vessels in CKD mice significantly increased;5Aza alleviated vascular calcification in vivo; Idownregulating the expression of DNMT3A can alleviate VC. Further validation experiments found that under high phosphorus stimulation, the intracellular arginine content of VSMC decreased, and the expression of arginine synthase ASS1 and ASL decreased. Knocking down DNMT3A can reverse the decrease in intracellular arginine content of VSMC caused by high phosphorus stimulation and simultaneously reverse the expression levels of key arginine synthase ASS1 and ASL; MSP detection showed that knocking down DNMT3A can reduce the high methylation levels of ASS1 and ASL under high phosphorus stimulation.

Conclusions: Disordered methionine metabolism in CKD patients with vascular calcification mediates hypermethylation of vascular tissue, accompanied by increased expression of DNMT3A. Inhibiting the expression of DNMT3A can alleviate CKD-related vascular calcification. DNMT3A silences the expression of arginine synthase ASS1 and ASL through DNA hypermethylation, inhibits arginine synthesis, and accelerates the occurrence of vascular calcification.

Inhibitory Dynamics of SBI-425 on Medial Arterial Calcification in Mice with CKD: A Therapeutic Perspective

Takashi Tani, Hitomi Tani, Akiko Mii, Rei Nakazato, Natsumi Kamijo, Akira Shimizu, Yukinao Sakai. *Nihon Ika Daigaku, Bunkyo-ku, Japan.*

Background: Daily oral administration of SBI-425, a TNAP inhibitor, prevents medial arterial calcification (MAC) in CKD mice. This study evaluated the efficacy of continuous TNAP inhibition via mixed feeding in MAC prevention and assessed its therapeutic effect on MAC progression when pre-existing MAC is present.

Methods: The Vehicle group of 10-week-old mice received 0.2% adenine. From 16 weeks, they were subjected to 0.2% adenine and 1.8% phosphorus for 10 weeks. Treatment groups, SBI-10W, SBI-6W, and SBI-4W, were switched to diets containing 0.03% SBI-425 at 16, 20, and 22 weeks, respectively, continuing the adenine and phosphorus load. The Control group was raised under normal conditions for 16 weeks from 10 weeks of age.

Results: Blood urea nitrogen, serum creatinine, serum phosphorus, FGF-23, and intact PTH were significantly elevated in the CKD group compared to the Control group, but there were no significant differences between the CKD groups. Animal CT images showed ectopic calcification in the aorta, heart, and bilateral kidneys in the Vehicle group, and the respective calcification volumes (mm^3) worsened over time after the start of the high-phosphorus diet. Control and SBI-10 groups showed almost no ectopic calcification throughout the experimental period. SBI-6 and SBI-4 groups showed ectopic calcification as in the Vehicle group, although ectopic calcification at all sites tended to be suppressed after the start of pharmacological intervention compared to the Vehicle group. In the aortic and renal histopathology, ectopic calcification with positive Von-kossa staining was observed in the CKD model groups. The area ratios (%) of calcified areas in the tissues of both aorta and kidney were in the order of Vehicle > SBI-4 > SBI-6 > SBI-10 group, indicating that the severity of calcification was inversely proportional to the length of treatment period with SBI-425.

Conclusions: Sustained TNAP inhibition with SBI-425 prevented MAC in CKD mice. TNAP inhibitors showed pharmacological effects proportional to the duration of drug administration, suggesting that they are effective in inhibiting the progression of ectopic calcification even in the presence of pre-existing MAC.

Funding: Government Support - Non-U.S.

Calciprotein Particles (CPPs) Are Cleared Predominantly by Liver, Spleen, and Bone in a Rat Model of CKD

Jeroen H. De Baaij, Lara W. Zeper, Pieter A. Leermakers, Caro Bos, Joost Hoenderop. *Radboud Universitair Medisch Centrum, Nijmegen, Netherlands.*

Background: Calciprotein particles (CPPs) provide an efficient mineral buffering system to prevent the complexation of phosphate and calcium in the circulation. However, in chronic kidney disease (CKD), the phosphate load exceeds the mineral buffering capacity, resulting in the formation of crystalline CPP2 particles. CPP2 have been associated with cardiovascular events and mortality. Moreover, CPP2 have been demonstrated to induce calcification *in vitro.* In this study, we examined the fate of CPP2 in a rat model of CKD.

Methods: Calcification was induced in Sprague Dawley rats by a 5/6-nephrectomy (5/6-Nx) combined with a high phosphate diet. Control rats received a sham surgery and high phosphate diet. Twelve weeks after surgery kidney failure was significantly induced in 5/6-Nx rats as determined by enhanced creatinine and urea plasma levels and abnormal kidney histological architecture. Subsequently, radioactive and fluorescent (FITC)-labeled CPP2 ([^{89}Zr]Zr-CPP2-FITC) were injected *i.v.* to determine clearance *in vivo*.

Results: Using positron emission tomography scans and radioactive biodistribution measurements, it was demonstrated that [^{89}Zr]Zr-CPP2-FITC are mainly present in the liver, spleen, and bones in both 5/6-Nx and sham rats. Immunohistochemistry showed that [^{89}Zr]Zr-CPP2-FITC are predominantly taken up by Kupffer cells and macrophages. However, [^{89}Zr]Zr-CPP2-FITC could also be detected in hepatocytes. In the different parts of the aorta and in the blood, low values of [^{89}Zr]Zr-CPP2-FITC were detectable, independent of the presence of calcification.

Conclusions: CPP2 are cleared rapidly from the circulation by the liver, bones, and spleen in a rat model of CKD. In the liver, Kupffer cells, macrophages, and hepatocytes contribute to CPP2 clearance. Our results suggest that targeting liver CPP clearance may reduce the burden of crystalline CPP in the development of vascular calcification.

Calprotectin Plays an Important Role in the Pathogenesis of Vascular Calcification in CKD

Zhang Jingxuan, Takashige Kuwabara, Ryosuke Date, Daisuke Fujimoto, Tomoko Kanki, Yutaka Kakizoe, Yuichiro Izumi, Masashi Mukoyama.
Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan.

Background: Cardiovascular complications are a major contributor to global mortality rates, with atherosclerosis and vascular calcification (VC) being significant factors. In particular, patients with CKD experience a higher prevalence of VC as their renal function deteriorates, well-known as CKD-MBD, leading to increased mortality rates. Calciprotein particles (CPPs) are colloidal nanoparticles that play a crucial role in the initiation and progression of VC, partly through TLR4 signaling. We recently reported that serum calprotectin (CPT, also known as MRP8/14 or S100A8/A9) levels, which amplify TLR4 signaling, have been found to have a predictive role in mortality among hemodialysis patients with high phosphatemia. The aim of this study is to clarify the pathogenic role of CPT on the cardiovascular calcification involving CPPs in CKD patients.

Methods: Secondary CPP (CPP2) was generated using a phosphate-enriched culture medium (DMEM/10% FBS) incubated at 37°C. Vascular smooth muscle cells (VSMCs) were stimulated by CPP2 concomitant with recombinant CPT or cultured supernatant of macrophages (RAW264.7) treated with LPS. To characterize the significant role of CPT in the calcification of VSMCs, RNA interference experiments using siMRP8 were performed. In in vivo experiment, the CKD-MBD model was developed in myeloid-lineage cell-specific MRP8 KO mice (MyMRP8KO) using adenine combined with a high-phosphate diet.

Results: In VSMCs, the addition of cultured medium from LPS-stimulated RAW264.7, which contains markedly increased CPT, aggravated calcification and Ca^{2+} deposition induced by CPP2. This phenotype was associated with the amplified expressions of pro-osteogenic and -inflammatory genes, which were effectively suppressed by CPT knockdown with siMRP8. In the CKD-MBD model, the aortic calcification was ameliorated in MyMRP8KO compared to WT.

Conclusions: Our study suggested that the inflammation can enhance the calcification through CPT. Inflammation-mediated release of CPT from macrophages exacerbates CPP2-induced VC. The pathogenic role of CPT in CPP2-induced calcification might support our previous cohort study in hemodialysis patients with high phosphatemia. CPT might become a novel therapeutic target to protect against VC in patients with CKD-MBD.

SA-PO251

An Oral Phosphate Challenge in Experimental CKD Reveals the Scope of Deficit in Calciprotein-Based Mineral Buffering Only If Both OsteoSense and T50 Are Used

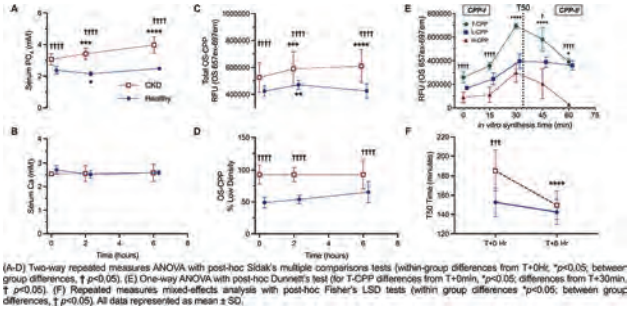
Eric B. Fernandes,[1] Tyler Rowsell,[1] Mandy E. Turner,[1,2] Rachel M. Holden,[1] Michael A. Adams.[1] *[1]Queen's University, Kingston, ON, Canada; [2]Brigham and Women's Hospital, Boston, MA.*

Background: In chronic kidney disease (CKD), disturbed phosphate (PO_4) homeostasis is linked to morbidity and mortality. Fetuin-based calciprotein particles (CPPs) are key to mineral buffering yet their role in health and disease is unclear. This study characterized the phenotype of CPPs in response to acute oral PO_4 challenges in both health and experimental CKD using a multi-modal approach.

Methods: CPPs were profiled in male Sprague-Dawley rats before and after CKD induction (n=10, 0.25% adenine, 6wks). After collecting fasted serum, animals rapidly ate a 1% PO_4 diet (10g, TD.08670) with serum collected at 2 and 6hrs. Serum minerals and OsteoSense detectable CPPs (OS-CPPs) were measured throughout, while type II CPP formation was assessed at 0 and 6hrs via T50 following an *ex vivo* mineral challenge. To contextualize OS-CPP observations, changes in OS-CPP detection versus *in vitro* T50-based CPP synthesis were compared. All differences stated are $p<0.05$.

Results: In CKD, both serum [PO_4] and total OS-CPPs increased by 12% at 2hrs post-challenge and by 30% and 16.6% at 6hrs. In contrast, in healthy rats at 2hrs, serum [PO_4] decreased (-8.7%) and OS-CPPs were elevated (11.5%), though by 6hrs no significant differences remained. Low-density OS-CPPs were much more prevalent than high-density forms in CKD (93±1%) vs healthy (56±8%) across all time points. The overall OS-CPP profile also revealed type II CPPs are poorly detected by OS. The T50 time was decreased in CKD rats (19%) vs healthy (6%) after mineral challenge.

Conclusions: The CPP profile in fasted rats showed near saturation of mineral buffering in experimental CKD as detected by the OS-CPP profile, but not by T50. The acute oral mineral challenge further revealed this near saturation of CPPs via a marked reduction in the T50 time. Given the issues regarding the detection of different forms of CPPs, these findings emphasize the critical need to use multiple protocols to properly evaluate changes in the CPP-based mineral buffering system.



(A-D) Two-way repeated measures ANOVA with post-hoc Sidak's multiple comparisons tests (within-group differences from T+0Hr, *p<0.05; between group differences, † p<0.05). (E) One-way ANOVA with post-hoc Dunnett's test (for T-CPP differences from T+0min, *p<0.05; differences from T+30min, † p<0.05). (F) Repeated measures mixed-effects analysis with post-hoc Fisher's LSD tests (within group differences *p<0.05; between group differences, † p<0.05). All data represented as mean ± SD.

Correction of Paradoxical Mineralization in Murine CKD-MBD by ENPP1 Enzyme Biologics

Hajime Kato,[1] Hana Kim,[1] Tayyaba Ishaq,[1] Dominique Sims,[1] Shivani Srivastava,[1] Paul Stabach,[1] Thomas Carpenter,[2] W. Charles O'Neill,[3] Demetrios Braddock.[1] *[1]Yale University Department of Pathology, New Haven, CT; [2]Yale University Department of Pediatrics, New Haven, CT; [3]Emory University Renal Division, Atlanta, GA.*

Background: Chronic Kidney Disease-Mineral & Bone Disorder (CKD-MBD) is a mineralization disorder characterized by medial arterial calcifications and loss of bone mass, a physiologic process known as 'Paradoxical Mineralization'. Reduced plasma pyrophosphate (PPi) levels in CKD patients suggest a role for the enzyme producing PPi, ENPP1, in the pathogenesis of this condition.

Methods: To induce CKD-MBD, mice were placed on a high phosphate, high calcium, low magnesium diet with alternating adenine (0.15%, 0.2%, or 0.3%) for 33 weeks, after the method of Jia *et al.* (BMC Nephrology 2013, **14**:116). Following the development of renal failure, animals were dosed weekly with either vehicle or soluble (S-) or bone-targeted (BT-) ENPP1-Fc. At 33 weeks, calcifications in the aorta, subcutaneous tissue, and heart were quantitated chemically, by weight, and by micro-CT, respectively. Bone mineralization was assessed using biomechanical testing of femurs and micro-CT analysis of tibial microarchitecture.

Results: The mice on the adenine diet showed progressive renal failure, characterized by elevated BUN and reduced plasma PPi levels. Both S- and BT-ENPP1 reduced aortic and subcutaneous calcification, comparable to the non-CKD control mice (Fig). Biomechanical testing showed improvements in maximum load, post-yield, and total work in both treatment groups compared with the vehicle CKD cohort. Micro-CT analysis showed improvement in trabecular number and spacing in the ENPP1-treated CKD cohort compared with the vehicle CKD controls. Finally, vehicle-treated CKD mice demonstrated an inverse correlation of vascular calcifications with bone mineralization parameters.

Conclusions: Our studies demonstrate that a modified version of the alternating adenine diet reproduces paradoxical mineralization in CKD-MBD which can be treated with an ENPP1 enzyme therapy, supporting the hypothesis that PPi deficiency may be a pathogenic mechanism driving the paradoxical mineralization in CKD-MBD.

Subcutaneous calcifications of CKD-MBD cohorts at 33 weeks

SA-PO253

Magnesium Supplementation Reduces Vascular Calcification by Activating Calcium-Sensing Receptor (CaSR) in Vascular Smooth Muscle Cells

Qi Gao, Onur Cil. *University of California San Francisco, San Francisco, CA.*

Background: Pathological deposition of calcium-phosphate in the arterial wall leads to vascular calcification, which is an important risk factor for cardiovascular mortality in CKD patients. Higher dietary Mg^{2+} intake was shown to reduce vascular calcification and cardiovascular mortality in clinical studies, however the mechanisms of Mg^{2+} effect remain unclear. Extracellular Ca^{2+}-sensing receptor (CaSR) is a protein expressed in many tissues including vascular smooth muscle cells (VSMC). Although Ca^{2+} is considered as

its main physiological agonist, we recently showed that Mg^{2+} (an often neglected CaSR agonist) is a more potent CaSR activator in certain tissues such as gut and lung.

Methods: We studied the roles of CaSR in therapeutic effects of Mg^{2+} in cell and mouse models of vascular calcification.

Results: In both mouse and human primary aortic smooth muscle cells, calcium-phosphate treatment (3 mM Ca^{2+}, 2.5 mM PO_4^{3-} for 7 days) resulted in marked calcification. Increasing Mg^{2+} in culture media concentration-dependently reduced calcification by up to 90% at 1 mM. The protective effects of Mg^{2+} were essentially abolished by CaSR inhibitor NPS-2143. Mg^{2+} concentration had minimal effects on calcification in primary cells derived from VSMC-specific CaSR knockout mice (*SM22-Cre; Casr-flox*), confirming key roles of CaSR in its efficacy. CaSR activation assays showed that Mg^{2+} is 2-5 fold more potent CaSR agonist than Ca^{2+} in human and mouse primary VSMC. In high dose vitamin D-induced vascular calcification model, mice fed with low (0.02%) Mg^{2+} diet had severe aortic calcification which was reduced by 32% and 66% in mice fed with normal (0.2%) and high (0.5%) Mg^{2+} diets, respectively. Aortic CaSR protein expression was found to be reduced by 85% and 60% in mice fed with low and normal Mg^{2+} diets, respectively, compared to controls. Co-staining showed that CaSR expression was primarily reduced in calcified areas. High Mg^{2+} diet resulted in largely preserved aortic CaSR expression in mice.

Conclusions: These results collectively suggest that Mg^{2+} is the key CaSR agonist in VSMC for prevention of vascular calcification. Mg^{2+} deficiency results in reduced CaSR activity and expression, which can be restored by its supplementation. Mg^{2+} supplementation can potentially be used as a simple, safe and effective treatment for preventing vascular calcification in CKD.

Quantitative Image Analysis Reveals the Benefits of Dapagliflozin on Glomerulosclerosis, Podocyte Effacement, and Kidney Fibrosis in the Spontaneously Diabetic Torii (SDT) Fatty Rat Model of Diabetic Nephropathy

Francois Briand,[1] Estelle Grasset,[1] Masami Shinohara,[5] Nicole Endlich,[2] Vedran Drenic,[2] Li Chen,[3] Mathieu M. Petitjean,[3] Blazej Dolicki,[4] Thomas D. Bel,[4] Yasushi Kageyama,[5] Thierry Sulpice.[1] *[1]Physiogenex, Escalquens, France; [2]Nipoka, Greifswald, Germany; [3]Pharmanest, Princeton, NJ; [4]Aiosyn, Nijmegen, Netherlands; [5]CLEA Japan Inc, Tokyo, Japan.*

Background: We aimed to optimize drug efficacy studies in the Spontaneously Diabetic Torii (SDT) fatty rat, a type 2 diabetic model, using quantitative image analysis of kidney. To demonstrate the accuracy of our imaging methods, dapagliflozin (DAPA) was evaluated in SDT fatty rats with unilateral nephrectomy (Unx).

Methods: Unx SDT fatty rats were fed a 0.3% salt diet and treated without or with DAPA for 10 weeks. Sham operated SDT fatty rats and Sprague Dawley (SD) rats were used as controls. Glomerular Filtration Rate (GFR) and urine parameters were measured at baseline, 5 weeks, and 10 weeks. Kidneys were collected at 10 weeks for histology and automated image analysis, including quantitative glomerulosclerosis and tubular impairments (Nephropath AI), Podocyte Exact Morphology Measurement Procedure (PEMP) and quantitative digital pathology of fibrosis (FibroNest platform).

Results: Sham rats showed higher proteinuria, urine albumin/creatinine ratio and KIM-1 levels (all $p<0.05$ vs SD). Those parameters were even higher in Unx rats (all $p<0.01$ vs sham). Hyperfiltration was only observed at baseline in sham rats (80% higher GFR, $p<0.05$ vs SD), while Unx rats showed a significant GFR decline from baseline to 10 weeks. In sham rats, Nephropath AI demonstrated higher number of dilated/atrophic tubuli and sclerotic glomeruli (all $p<0.01$ vs SD). Filtration slit density and filtration slit length measured by PEMP were significantly reduced, indicating podocytes effacement, while FibroNest demonstrated significant increase in phenotypic fibrosis composite scores. All these imaging parameters were significantly aggravated in Unx rats. DAPA significantly reduced hyperglycemia (-67% vs. untreated Unx rats), prevented the GFR decline ($p<0.05$ at 5 and 10 weeks) and reduced urine KIM-1 levels ($p<0.01$). DAPA significantly improved all imaging parameters and kidney inflammation (ED1 immunostaining).

Conclusions: Quantitative image analysis reveals the benefits of DAPA on glomerulosclerosis, podocytes effacement and kidney fibrosis in Unx SDT fatty rat. This experimental setting will help evaluating the efficacy of drugs targeting diabetic nephropathy.

SA-PO255

SGLT2 Inhibitors Attenuate Protein Abundance of Collectin Kidney 1 and Mannose-Binding Lectin in the Kidney and Liver in Mice with Experimental Diabetes

Mia Jensen,[1] Camilla Enggaard,[1] Steffen Thiel,[2] Yaseelan Palarasah,[3] Per Svenningsen,[1] Boye Jensen.[1] *[1]Unit for Cardiovascular and Renal research, Institute of Molecular Medicine, University of Southern Denmark, Odense, Denmark; [2]Department of Biomedicine, Aarhus University, Aarhus, Denmark; [3]Unit for Cancer and Inflammation Research, Institute of Molecular Medicine, University of Southern Denmark, Odense, Denmark.*

Background: Diabetic nephropathy (DN) is a leading cause of end-stage renal disease. Sodium-glucose cotransport-2 (SGLT-2) inhibitors have significantly improved the treatment of DN and its cardiovascular complications. The mechanism behind the broad protection is elusive. We hypothesized that the lectin pathway of the complement system contributes to early kidney injury in DN. Here we investigate if 1) experimental diabetes in mice is associated selectively with increased collectin kidney 1 (CL-K1) abundance and binding, 2) if SGLT-2 inhibitors attenuate CL-K1 and complement activation, and 3) if a functional deletion of CL-K1 protects against diabetic kidney injury.

Methods: Streptozotocin (STZ) and vehicle were intraperitoneally injected in male wild-type (WT) FVB or CL-K1 knockout (KO) mice for 5 consecutive days to induce diabetes. Experiment 1: WT STZ(n=10) and WT vehicle (VEH)-treated(n=10) mice were sacrificed on day 14 and day 35. Experiment 2: WT STZ mice were orally treated with Dapagliflozin(n=10) or vehicle(n=10) for 10 days. Experiment 3: WT STZ(n=4), WT VEH(n=4), CL-K1 KO STZ(n=4), and CL-K1 KO VEH(n=4). Urine, plasma, and organs were collected. mRNA expression and protein abundance of complement products were determined by western blotting, qPCR, and RNAscope.

Results: STZ-treated mice exhibited increased plasma glucose, kidney weight, blood urea nitrogen, urinary excretion of albumin, and KIM-1. CL-K1 protein level increased significantly and progressively in kidney tissue and plasma but not in liver tissue in STZ-treated mice. MBL-C and MASP-1 increased in plasma following STZ. CL-K1 and MBL-C mRNA abundances increased in the kidney. Dapagliflozin lowered fasting plasma glucose (29.7 [5.50] vs. 33.3 [2.10] mmol/L,$p<0.01$) and protein abundance of CL-K1 in liver (0.38 ± 0.13 vs.1.0 ± 0.46 CL-K1/Beta-actin, $p<0.05$) and kidney (0.29 ± 0.34 vs.1.0 ± 0.52 CL-K1/Beta-actin, $p<0.05$), while corresponding mRNA levels were unchanged. CL-K1 KO did not affect kidney injury markers, but a trend toward lower levels of urinary excretion of albumin and KIM-1 was seen in STZ-treated CL-K1 KO mice compared to STZ WT.

Conclusions: CL-K1 increases in kidney and plasma with the progression of kidney injury, and SGLT-2 inhibitors may lower complement activation in diabetic kidneys.

SA-PO256

Blocking Intracellular TXNIP Shuttling Attenuates Reactive Oxygen Species-Associated NLRP3 Inflammasome Activation Induced by Tubulointerstitial Fibrosis in Diabetic Kidney Disease

Li Wang, Bingbing Zhu, Shuang Liu, Yao Xingmei, Yuying Zhou. *Department of Nephrology, Putuo Hospital, Shanghai University of Traditional Chinese Medicine, Shanghai, China.*

Background: Accumulating evidence underscores the pivotal role of tubulointerstitial fibrosis (TIF) in the progression of diabetic kidney disease (DKD). TXNIP is an important regulatory protein that elicits the generation of reactive oxygen species (ROS) that involved in the fibrotic pathogenesis of DKD. However, the potential mechanism of TXNIP in DKD is not yet well understood.

Methods: RNA sequencing and RT-qPCR were used to detect the most significant expression of protein in high glucose-stimulated renal tubular epithelial cells (RTECs). Co-immunoprecipitation, ARE luciferase assay and chromatin immunoprecipitation assay were used to identify the transcriptional relationships between STAT6 and TXNIP. Immunofluorescence and western blot were used to detect the TXNIP shuttling. TXNIP-mediated NLRP3 inflammasome activation were examined via TXNIP siRNA and overexpression in vitro and knockdown in RTECs using AAV-shRNA in vivo. Correspondingly, the efficacy of Astragaloside IV (AS-IV), an active ingredient from traditional formula of Huangqi decoction, was examined in vitro and in vivo.

Results: We found that TXNIP was highly expressed in high glucose-stimulated RTECs and the renal tubules of patients with DKD. Experimental data showed that the TXNIP expression was positively associated with the development of TIF in DKD. p-STAT6 could bind to the promoter of TXNIP and promote its transcription in the nucleus and the interaction of STAT6 and TXNIP could enhance the NLRP3 inflammasome activation. Subsequent the TXNIP shuttling from nucleus to mitochondria increased the NLRP3-mediated TIF both in high glucose-stimulated renal tubular epithelial cells and in db/db mouse. Knockdown of TXNIP both in vitro and in vivo delayed the ROS associated inflammasome activation. Meanwhile, TXNIP was the target for Astragaloside IV to exert inhibitory effect on the STAT6/TXNIP/NLRP3-mediated inflammatory response.

Conclusions: These findings collectively substantiate a critical role of TXNIP shuttling to control inflammasome activation, and presenting AS-IV as a promising therapeutic ingredient for inhibiting TIF in DKD.

CircAkap7 Downregulation Promotes Renal Tubular Epithelial Cell Senescence in Diabetic Kidney Disease

Fenfen Peng, Yao Zeng, Yue Ji, Haibo Long. *Zhujiang Hospital of Southern Medical University, Guangzhou, China.*

Background: Diabetic kidney disease (DKD) exhibits an accelerated tubular epithelial cell senescent phenotype. Our previous studies showed that downregulation of circAkap7 promotes renal fibrosis in DKD.

Methods: Ultrasound mediated gene transfer of circAkap7 plasmids into the kidneys of db/db mice is used. Mouse primary renal tubular epithelial cells (mPTECs) was isolated and cultured in DMEM/F12 medium.

Results: As shown in Figure 1, the SA-β-gal activity and senescence markers P53, P21, and $P16^{INK4A}$ were significantly decreased in the db/db mice with circAkap7 overexpression. Two SASP factors, TGF-β1 and IL-6 were found to be decreased in db/db mice with circAkap7 overexpression. As shown in Figure 2, the mPTECs transfected with circAkap7 siRNA showed an increase in G1-phase cells and a decrease in S-phage cells. Knockdown of circAkap7 increased the level of SA-β-gal staining, P53, P21 and $P16^{INK4A}$ and renal injury marker NGAL, while circAkap7 overexpression decreased the SA-β-Gal activity and abolished the synthesis of P53, P21, and $P16^{INK4A}$ induced by the high-glucose. Medium derived from mPTECs transfected with si-circAkap7 can promotes the synthesis of fibronectin and α-SMA in fibroblast.

Conclusions: Downregulation of circAkap7 promotes renal tubular senescence in DKD.

Funding: Government Support - Non-U.S.

Senolytics (Dasatinib/Quercetin) Inhibit Hedgehog Interacting Protein (Hhip)-Mediated Tubular Senescence in Diabetic Kidney Disease

Shiao-Ying Chang,[1] Min-Chun Liao,[1] Yuchao Pang,[1] Junzheng Peng,[1] Julie R. Ingelfinger,[2] John S. Chan,[1] Shao-Ling Zhang.[1] *[1]Centre de Recherche du Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [2]Harvard Medical School, Boston, MA.*

Background: We recently reported that hedgehog interacting protein (Hhip) promotes tubular senescence-associated secretory phenotype in murine diabetic kidney disease (DKD) (*Diabetiologia, 2023*), the underlying mechanism(s) are not delineated. Here, we asked whether senolytics (dasatinib, D/quercetin, Q) could alleviate Hhip-mediated RPTC senescence in DKD *in vivo* and *in vitro*

Methods: The low-dose streptozotocin (LDSTZ)-induced diabetes in renal proximal tubules (RPTC)-specific *Hhip* transgenic (Tg) mice (*Hhip*-Tg) and their non-Tg littermates at the age of 10-week old were studied. Senolytics (D, 5 mg/kg and Q, 50 mg/kg) in combination were administered by gavage daily for three consecutive days every two weeks from 12 weeks until the mice were 24-weeks old. Vehicle-treated animals served as controls. Primary RPTCs and rat immortalized RPTC cells (IRPTCs) were used for *in vitro* studies.

Results: Diabetic mice displayed typical DKD characteristics (hyperglycemia, increased urinary albumin/creatinine ratio and glomerular filtration rate) and renal dysmorphology (renal hypertrophy, glomerulosclerosis and tubulopathy), and those features were more pronounced in diabetic Hhip-Tg (vs. non-Tg) mice. D/Q senolytics administration ameliorated DKD dysmorphology and renal tubular senescence as measured by heightened β-galactosidase activity in kidneys of diabetic mice. *In vitro*, excessive Hhip induced by overexpressing Hhip in RPTCs triggered the release of extracellular vesicles carrying Hhip, which facilitated RPTC turnover through accelerated cellular senescence, and fibrotic and apoptotic processes. In contrast, D/Q treatment reversed the effects of increased Hhip in RPTCs.

Conclusions: The treatment of senolytic D/Q prevents excessive Hhip-mediated RPTC senescence and DKD-related tubulopathy via the inhibition of Hhip carried by extracellular vehicles in DKD.

Transmembrane Protein 72, Expressed in the Distal Convoluted Tubule, May Play a Potential Role in Diabetic Kidney Disease

Jianteng Xie,[1,2] Min Lu,[1,2] Runli Jia,[1] Danfeng Liu,[1,2] Wenjian Wang.[1] *[1]Guangdong Provincial People's Hospital, Guangzhou, China; [2]South China University of Technology, Guangzhou, China.*

Background: Transmembrane protein 72 (TMEM72) is highly expressed in tubules of the kidney in patients with diabetic nephrology. This study is designed to explore the role and the potential mechanism of TMEM72 in the development of diabetic tubulopathy.

Methods: Serum TMEM72 concentration was tested in health control, patients with diabetes mellitus (DM) and diabetic kidney disease (DKD). The variation trend of TMEM72 was determined by immunohistochemistry on kidney tissues from patients in

different stage of DKD. Immunofluorescence staining was performed with TMEM72, SGLT2, NKCC2 and AQP2 to identify the expression site of TMEM72 in mice renal tubules. To investigate the potential cellular pathway that TMEM72 was involved, an immunofluorescence test was performed with TMEM72, LAMP1, Mito-tracker and Calnexin in cultured distal convoluted tubule (DCT) epithelial cells. Western blot was used to detect the activity of TMEM72 in HK2 cells following HG treatment.

Results: The concentration of serum TMEM72 was lower in DM and DKD groups compared to the health control (P<0.001). The expression of TMEM72 also decreased gradually in human kidney tissue of different stage of DKD following the progression of disease. Co-localization of TMEM72 and NKCC2 in immunofluorescence staining indicated that TMEM72 was mainly expressed in the lysosomes of distal convoluted tubule. In vitro, TMEM72 was markedly down-regulated in mouse tubular cell and HK-2 cells treated with high glucose. Overexpression or knock down of TMEM72 demonstrated a significant increased or decreased mitophagy in high glucose treated HK2. In vivo, tubules specific knock-out of TEME72 exhibited a significantly tubule injury evidenced by marked increase of KIM-1/Cr, NGAL/Cr, Albumin/Cr β-micro globin/Cr in the urine of mouse.

Conclusions: Our current study has revealed that TMEM72 may act as a novel participator in DKD by being involved in the renal tubular injury.

SA-PO260

Transcriptomic Analysis of mRNA Expression in Peripheral White Blood Cells of Genes Encoding Circulating Proteins Associated with the Development of ESKD in Diabetes

Marcus G. Pezzolesi,[1] Katsuhito Ihara,[2,3] Eiichiro Satake,[2,3] Zaipul Md Dom,[2,3] Bozena Krolewski,[2,3] Andrzej S. Krolewski.[2,3] *[1]University of Utah Health, Salt Lake City, UT; [2]Joslin Diabetes Center, Boston, MA; [3]Harvard Medical School, Boston, MA.*

Background: Using global-untargeted proteomics, we recently identified 46 circulating proteins robustly associated the risk of development of end-stage kidney disease (ESKD) in individuals with Type 1 (T1D) or Type 2 diabetes (T2D) during 7-15 years of follow-up. In the present study, we performed transcriptomic analysis on mRNA to examine whether circulating levels of these proteins derive from expression of the risk-associated protein encoding genes in peripheral white blood cells (WBC).

Methods: RNA sequencing was performed on total RNA isolated from peripheral blood from a subset of individuals enrolled in the Joslin Kidney Study (23 T1D and 48 T2D). During 7-15 years of follow-up, 16 of these individuals developed ESKD and 55 remained without ESKD. The resulting sequencing reads were aligned to the GRCh38/hg38 reference genome and annotated using Ensembl (release 102). Differential gene expression analysis was then performed between controls and cases who progressed to ESKD during follow-up or had fast kidney function declining (eGFR slope <-5.0 ml/min/year).

Results: Transcriptome-wide, 4 out of ~22,000 genes (*GRB10*, *IGKV1-9*, *IGKV1-39*, and *NAV3*) were found to be differentially expressed between the two groups after correcting for multiple testing (Bonferroni-adjusted p $<2.26x10^{-6}$). Out of the 46 circulating proteins associated with risk of development of ESKD, 11 genes encoding these proteins were not expressed in WBC, 10 had low expression and 26 had moderate or high expression. Strikingly, and in contrast with our proteomic findings where concentrations of 10 ESKD risk-associated proteins in plasma collected at the same time as these WBC were significantly upregulated in cases relative to controls, expression of these genes was identical in those who progressed and those who did not progressed to ESKD.

Conclusions: These negative transcriptomic findings in WBC contrast with significant statistical differences in concentration of ESKD risk-associated proteins in plasma. These findings suggest that the high concentrations of ESKD risk associated proteins in circulation cannot be accounted for by increased transcription of these genes in WBCs.

SA-PO261

Molecular Mechanisms of Cobalt Chloride in the Treatment of Type 2 Diabetic Nephropathy

Tianyu Deng, Shiyue Yu, Xueqi Chen, Zhenyuan Han, Dechao Yan, Mingda Liu, Xiaoyan Wang. *Nanjing BenQ Medical Center, Nanjing, China*.

Background: Down-regulation of heme-oxygenases (HOs) induced by oxidative stress plays an important role in the pathogenesis of type 2 diabetic nephropathy (T2DN). COPP (cobalt chloride), a HO-1 agonist, has been used in experimental DN. To explore the underlying mechanism, caspase3, Gasdermin-E (GSDME), and other factors related to apoptosis and pyroptosis besides ROS-components were observed in the kidneys of type 2 DN mice with and without COPP treatment.

Methods: Male 7-week-old C57BL/6J mice were fed a 60% high-fat diet for 6 weeks, then injected intraperitoneally with STZ(60mg/kg/day) (DN) or vehicle (HFD) for 3 days. COPP at 3mg/kg was given to the STZ mice (DN+COPP) by weekly intraperitoneal injection (10 doses) while the background group (NFD) was given a 10% normal fat diet and vehicle injections until week 16 of the study (n=5-7/group).

Results: Fasting blood glucose levels in DN group(26.2±1.0, mmol/L) were higher than those in NFD(8.0±0.8) and HFD (8.7±0.6) groups but lowered slightly by COPP treatment (22.3±0.9). Serum creatinine (156.6±43.3, mmol/L) was higher than NFD(12.3±0.9) and HFD(21.9±6.1) groups but reversed after COPP treatment (65.8±9.7). Urinary albumin/creatinine exerts similar results in DN group(48.5±3.0, mg/g), NFD(3.0±0.6), HFD(20.7±5.2) groups and DN+COPP group (37.7±5.5). The glomerular basement membrane thickening and podocyte fusion seen in DN group by EM were reversed after COPP treatment. 8-OHdG, an oxidative stress index, increased (163.6±34.5, % of NFD, same as below) in the DN group and decreased after COPP treatment (130.8±22.6). HO-1(302.9±170.3) and PON1(63.0±8.1) was decreased in DN+COPP, after COPP treatment HO-1(701.7±171.1) and PON1(136.4±15.5) were reversed. Similarly, GSDME (139±7.2) and caspase 3(109.7±4.0) increased in DN group, and after COPP treatment GSDME (122.0±4.9) and caspase 3(100.7±2.3) were mitigated. In addition, BAX/Bcl-2, the key factor regulating apoptosis, increased in the DN group (159.0±21.6) and reversed after COPP treatment (94±6.3).

Conclusions: COPP may attenuate renal injury in type 2 diabetic mice by reducing apoptosis and pyroptosis along with its antioxidant effects.

Funding: Government Support - Non-U.S.

Analysis of Single Urinary Extracellular Vesicles from Subregions of the Nephron as a Diagnostic Tool in Early Diabetic Nephropathy

Morgan Greig,[1] Indika V. Mallawaarachchi,[1] Jennie Z. Ma,[1] Clarissa J. Diamantidis,[2] Michael A. Harding,[1] Hayrettin Yavuz,[1] Luca Musante,[3] Michael Solga,[1] Samantha G. Upson,[1] Julia J. Scialla,[1] Uta Erdbruegger.[1] *[1]UVA Health, Charlottesville, VA; [2]Wake Forest University School of Medicine, Winston-Salem, NC; [3]University of Pennsylvania, Philadelphia, PA.*

Background: Urinary extracellular vesicles (uEVs) have been identified as early and sensitive biomarkers in kidney disease, however, their association with diabetic kidney disease (DKD) progression and DKD clinical traits is not yet clear. Characterization of uEVs may allow investigation into the relationship between uEVs of glomerular and tubular origin and distinct pathophysiological and clinical DKD phenotypes.

Methods: We attained uEVs from 24-hour urine collections in 116 adults with diabetes mellitus enrolled in the Simultaneous Risk Factor Control Using Telehealth (STOP-DKD). To determine uEV count, size and cargo, single EV characterization was performed via spectral flow cytometry (SFC) as a high throughput tool and SP-IRIS (Exoview R100) for small sample volumes. We used markers for CD26/DPP4(PT S1)+, CD35/CR1(podocyte)+, CD10/MME/NEP(PT S1,S2,S3)+, and tetraspanin, CD9(EV marker)+ labeled uEVs. Linear regression was used to assess the cross-sectional association of SFC data, kidney function and degree of microalbuminuria (UACR). SP-IRIS analysis compared a cohort of 10 healthy to 10 early DKD patients.

Results: Participants were 63.65±9.20 years of age; 50.4% female. Baseline eGFR was 81±22 ml/min/1.73m^2 and median UACR was 20.26(IQR 8.38 to 92.97mg/g). Higher counts of uEVs detected by SFC carrying DPP4 and MME were significantly associated with higher eGFR after adjustment for sex, race, age, log UACR and total urine creatinine. No markers demonstrated significant association with log UACR, and size was not considered further. SP-IRIS analyzed DPP4 and MME subpopulations captured by the CD63 and CD9 probes for exploration of small sample sizes. DPP4/Total Ratio was significantly higher in healthy patients when captured by CD63(p=0.0176), and results show sample size can be microscaled.

Conclusions: These results suggest that subgroups of tubular derived uEVs detected by SFC are associated with an increase in eGFR in a cohort of early DKD. However, tubular markers are also decreased in DKD when compared to HC. Further exploration is necessary to fully understand if these tubular derived uEVs derive from healthy tubular cells or are expressed more during tubular stress in early DKD.

SA-PO263

Late Clinical-Stage Candidate Rilparencel's Effect on Kidney Function and Biological Pathways in a Type 2 Diabetes and CKD Patient Subset

Prakash Narayan,[1] Brooke Bauer,[1] Guido Filler,[2] Benjamin S. Freedman,[3] Howard Trachtman,[4] Joseph Stavas,[1] Emily L. Butler,[1] Andrew T. Bruce.[1] *[1]ProKidney, Winston-Salem, NC; [2]Western University, London, ON, Canada; [3]University of Washington, Seattle, WA; [4]Renal Strategies LLC, New York, NY.*

Background: Kidney cortical biopsy-derived rilparencel is a 1st-in-class autologous kidney epithelial cell platform being evaluated in late-stage clinical trials for patients with type 2 diabetes (T2D) & chronic kidney disease (CKD). Data from 2 Phase 2 studies suggest that kidney cortical injection of rilparencel may preserve estimated glomerular filtration rate (eGFR). In a proof-of-concept, limited retrospective cohort study we sought to evaluate biological pathways associated with rilparencel's effect on kidney function.

Methods: Banked rilparencel samples from 5 patients with T2D&CKD (NCT02836574) were analyzed with scRNAseq. Kidney cell types were identified with unsupervised clustering & projection on to the KPMP atlas. For each rilparencel cell

type, cell-level & pseudo-bulk differentially expressed genes (DEGs) were identified by Wilcoxon Rank Sum test & DESeq2, respectively, based on each patient's response to rilparencel, i.e. eGFR slope computed across 12 mo post-treatment. Biological pathways were identified with GO.

Results: KPMP-anchored molecularly profiled kidney cell types in rilparencel include glomerular parietal epithelial cells (PECs), adaptive proximal tubules (PT), ascending thin limb (ATL) & adaptive thick ascending limb-2 (TAL-2), distal convoluted tubule, connecting tubule & intermediate collecting ducts (DCT/CNT/IMCD). For each cell type, DEGs correlating with renal function were identified. Increased epithelial cell differentiation (PEC), negative regulation of inflammatory response genes (PT), increased expression of cell migration genes within Loop of Henle limbs & decreased cell adhesion (DCT/CNT/IMCD) appear to exhibit improved eGFR slopes.

Conclusions: In a limited retrospective cohort of T2D&CKD patients reparative & restorative pathways can be detected with rilparencel's effect on kidney function. Our approach might serve as a roadmap for unveiling the mechanism of action of cell-based therapies.

Funding: Commercial Support - ProKidney

rilparencel cell type	DEGs correlating with eGFR slope (0-12 mo)	biological pathway
PEC	TMEM220 (R~1, p<0.05)	increased epithelial cell differentiation
adaptive PTs	NETO2 (R~1, p<0.05)	reduced inflammation
ATL / adaptive TAL-2	SYTL2, TEX41, TINAG, ERBB4, CDHR1 (R~1, p<0.05)	increased cell migration
ATL / adaptive TAL-2	CNN3 (R~1, p<0.05)	increased cell migration
DCT/CNT/IMCD	ST14, CDH1, CPXM2, LINC02274, COL11A1, SAA2 (R~1, p<0.05)	decreased cell adhesion

Top. KPMP-defined cell types within rilparencel. Bottom. DEGs within each cell type correlating with kidney function & reparative & restorative pathways detected with rilparencel's effect on kidney function.

SA-PO264

C-reactive Protein Exacerbates Diabetic Kidney Disease through Smad3-ACSM3-Mediated Ferroptosis

Yifan Wang,[1] Yongke You,[2] Jianbo Guo,[1] Baoyi Shao,[1] Jianan Wang,[3] Haidi Li,[3] Hui Y. Lan,[4] Hai-Yong Chen.[1,5] *[1]School of Chinese Medicine, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, China; [2]Department of Nephrology, Shenzhen University General Hospital, Shenzhen University, Shenzhen, China; [3]Anhui Medical University, Hefei, China; [4]Li Ka Shing Institute of Health Sciences, The Chinese University of Hong Kong, Hong Kong, China; [5]Department of Chinese Medicine, The University of Hong Kong-Shenzhen Hospital, Shenzhen, China.*

Background: Accumulated evidence indicated that C-reactive protein (CRP) enhances diabetic kidney disease (DKD) via Smad3 signaling pathway. Acyl-CoA synthetase medium-chain family member 3 (ACSM3) locates on the membrane of mitochondria to catalyze fatty acids. Ferroptosis is one type of cell deaths, featured with iron-dependent phospholipid peroxidation. This study determined whether CRP promotes DKD via Smad3-ACSM3 mediated ferroptosis and explore potential therapeutics.

Methods: CRP transgenic (Tg)×db/db, CRPtg×db/m, Smad3 knockout (KO)×db/db and Smad3 KO×db/m mice were used in the study. Differentially expressed genes in CRPtg×db/db mice were analyzed by RNA sequencing. To evaluate the protective role of ACSM3, AAVs with ACSM3 overexpression were administered into db/db mice. In vitro, HK-2 cells were treated with CRP with/without blocking of CRP receptor by CD32b antibody or treated with Smad3 inhibitor SIS3 were employed. Ferroptosis indexes were measured by IF, WB and qPCR. High through output molecular docking and cellular thermal shift assay (CETSA) were conducted to identify candidate compounds targeting ACSM3.

Results: Overexpression of CRP in diabetic mice significantly enhanced ferroptosis in kidneys. The RNAseq result indicated that ACSM3 level was significantly downregulated in CRPtg×db/db mice, compared to CRPtg×db/m mice. Interestingly, deletion of Smad3 alleviated ferroptosis and reversed ACSM3 deficiency in diabetic kidneys. Overexpression of ACSM3 in diabetic mice led to ferroptosis alleviation in kidneys. Consistently, the ferroptosis induced by CRP in vitro were reversed by SIS3, or the blockade of CRP receptor, or the overexpression of ACSM3. Furthermore, through the high through output molecular docking prediction and CETSA, we found that Rhapontin was one of potential compounds to suppress ferroptosis by targeting ACSM3.

Conclusions: Targeting on ACSM3 and SMAD3 have therapeutic potential for CRP induced ferroptosis in DKD.

Upregulated C1qa Signaling Antagonizes Glomerular Health in Aged Kidneys

Hyun Ji Lim, Tae Hoon Lee, Yoosun Joo, Young yoon Moon, Su Woong Jung, Yang Gyun Kim, Sangho Lee, Ju young Moon. *Kyung Hee University Hospital at Gangdong, Gangdong-gu, Seoul, Republic of Korea.*

Background: Renal aging is closely associated with the prevalence of end-stage renal disease requiring renal replacement therapy and a higher incidence with lower recovery rates of acute kidney injury. The progressive structural changes and decline in glomerular number during renal aging contribute to a decrease in estimated glomerular filtration rate, an increase in albuminuria, and the development of age-related kidney diseases. Despite its clinical significance, the underlying mechanisms driving glomerular aging remain inadequately understood.

Methods: To investigate the specific changes occurring in glomeruli over time, we performed RNA-sequencing on glomeruli isolated from young (2 months old), intermediate (12 months old), and old (24 months old) mice. This approach allowed us to focus on the glomerular enrichment and identify age-related alterations. Our findings revealed significant alterations in genes associated with immune system processes, innate immune responses, inflammatory responses, and chemotaxis between 12- and 24-months old glomeruli.

Results: Among the upregulated complement pathways, the classical complement pathway stood out as the most prominent during glomerular aging. Specifically, the genes encoding complement 1 (C1) elements, including C1r, C1s, C1qa, C1qb, and C1qc, showed increased expression. These upregulated complement gene signatures were particularly observed in aged podocytes. Immunostaining of C1qa in human kidneys also demonstrated an age-dependent increase. To further investigate the role of C1qa in podocytes, we transduced C1qa lentivirus into podocytes and observed that the upregulated C1qa signaling significantly increased reactive oxygen species production and aggravated albumin permeability.

Conclusions: In summary, our transcriptome analysis has advanced our understanding of the molecular mechanisms involved in glomerular aging. Furthermore, it provides evidence for the crucial role of increased C1qa signaling in glomerular aging. These findings shed light on potential therapeutic targets and strategies to mitigate age-related kidney diseases.

LXR/mTOR Signaling Axis Modulation: A Novel Approach for Regulating Autophagy in Diabetic Kidney Disease

Sahar Alkhansa, Sarah Almoussawi, Rachel Njeim, Sarah Hamade, Ghaith S. El Danaf, Nabih Habib, Fuad N. Ziyadeh, Assaad Antoine Eid. *American University of Beirut, Beirut, Lebanon.*

Background: Podocyte damage is crucial in diabetic kidney disease (DKD) pathogenesis. As podocytes have limited division capacity, autophagy is essential for their repair and homeostasis. Autophagy is described to be deregulated in diabetes. Yet, the underlying mechanism is still unclear. The mTOR complexes and oxidative stress have emerged as potential key players in mediating diabetes-induced autophagy imbalance. The role of the Liver-X-Receptor (LXR) in DKD has been mildly highlighted, but its role in autophagy and its crosstalk with key mechanistic pathways in DKD remains unclear. In this study, we investigate the role of the LXR/mTOR axis in autophagy and its possible link to podocyte injury in type 1(T1DM) and type 2 diabetes mellitus (T2DM).

Methods: An immortalized human podocyte cell line was used for our in vitro studies. Human podocytes were transfected with siRNA against LXR-α/β, Raptor, Rictor, or LC3B. For the in vivo model, T1DM and T2DM were experimentally induced in mice. Mice were treated with LXR activator T0 or DMHCA, mTORC1 inhibitor Rapamycin,

or the mTORC2 inhibitor JR-AB2-011. In parallel experiments, control mice were treated with autophagy inhibitor Hydroxychloroquine (HCQ). We assessed functional, histological, biochemical, and molecular parameters of the kidneys.

Results: Our results show that LXR activation attenuates podocyte and renal injury by inhibiting Nox4-dependent reactive oxygen species production and restoring autophagy. Mechanistically, this effect is mediated through the downregulation of both mTORC1 and mTORC2 activity. Interestingly, inactivation of either mTORC1 or mTORC2 pathways, both in vitro and in vivo, recapitulates the protective effects observed upon LXR activation, without altering the LXR pathway itself. Furthermore, our findings underscore the clinical relevance of autophagy signaling in DKD, as treatment with HCQ in control mice mimics the renal alterations seen in diabetes. Importantly, our study identifies mTORC2, in addition to mTORC1, as a key regulator of autophagy in the context of DKD.

Conclusions: This study highlights the interplay between LXR inactivation and mTORC1 activation, leading to autophagy dysregulation in DKD. Additionally, the activation of mTORC2 emerges as a critical factor in this process.

Mapping Progression of Diabetic Kidney Disease (DKD) in Renin Adeno-Associated Virus (AAV) UNx db/db Mice Utilizing Time-Series RNA Sequencing

Adam B. Marstrand-Jørgensen,[1,2] Martin R. Madsen,[1] Ole Joergen Kaasboell,[3] Mette V. Østergaard,[4] Louise Dalbøge,[1] Michael Christensen.[1] *[1]Gubra A/S, Hørsholm, Denmark; [2]Kobenhavns Universitet, Kobenhavn, Denmark; [3]Tribune Therapeutics AS, Oslo, Norway; [4]Novo Nordisk A/S, Bagsvaerd, Denmark*.

Background: The adeno-associated virus-mediated renin overexpression (ReninAAV) uninephrectomized (UNx) db/db mouse model of diabetic kidney disease (DKD) recapitulates hallmarks of DKD complicated by hypertension. Gaps persist in our understanding regarding temporal patterns of glomerular gene expression and pathophysiology during hypertensive DKD. The present longitudinal study characterized glomerular transcriptome changes during disease progression in ReninAAV UNx db/db mice.

Methods: Female *db/db* (BKS.Cg-Dock7m +/+ Leprdb/J) received a single i.v. dose of renin-encoding AAV. Untreated db/m mice (BKS.Cg-Dock7m +/+ Leprdb/J) served as healthy controls. One week after AAV injection, ReninAAV mice underwent UNx and subsequently randomized and stratified into 4 groups according to fed blood glucose levels and body weight measured 3 weeks post-UNx. ReninAAV UNx mice were terminated at 4, 8, 12 and 16 weeks (w4-w12) after UNx. Healthy db/m mice were terminated at 12 weeks. Endpoints included urine and plasma biochemistry, kidney histology (Col1a1 and glomerulosclerosis scoring) and RNA sequencing of glomeruli isolated by laser-capture microdissection.

Results: ReninAAV UNx db/db mice showed onset of progressive glomerulosclerosis from w8 and albuminuria from w4. More than 3,000 differentially expressed genes (DEGs) were detected in glomeruli at each timepoint, including fibrosis, inflammation and glomerular injury markers. A subset of DEGs were also clinical drug targets. Shifting gene regulation was noted across all categories, including late downregulation of *Ednrb* and *Glp1r* and late upregulation of *Col1a1* and *Col3a1*. Additionally, temporal changes were seen in interacting targets, e.g. a shift from early temporary upregulation of *Adam17* to late upregulation of *Adam10*.

Conclusions: The ReninAAV UNx db/db mouse model of hypertensive DKD demonstrates progressive glomerulosclerosis and albuminuria paralleled by dynamic shifts in glomerular gene expression signatures. Notably, the identification of temporal patterns of gene expression provides novel insights into DKD pathophysiology and progression. This underscores the ReninAAV UNx db/db mouse as an applicable model of human DKD in preclinical target and drug discovery.

Adenine Is a Marker and Potential Driver of Heart Failure in Cardiovascular-Kidney-Metabolic Syndrome

Ian M. Tamayo,[1] Hak Joo Lee,[1] Esmeralda Trevino,[1] Soumya Maity,[1] Richard Montellano,[1] Su-chi Lim,[2] Jan D. Lanzer,[3] Ravi Iyengar,[5] Petter Bjornstad,[4] Katherine R. Tuttle,[6] Vasan S. Ramachandran,[7] Ahmed Abdel-Latif,[9] Julio Saez-Rodriguez,[3] Jean C. Bopassa,[8] Kumar Sharma.[1] *[1]Center for Precision Medicine, University of Texas Health San Antonio, San Antonio, TX; [2]Clinical Research Unit, Khoo Teck Puat Hospital, Khoo Teck Puat, Singapore; [3]Heidelberg University, Faculty of Medicine, and Heidelberg University Hospital, Institute for Computational Biomedicine, Heidelberg, Germany; [4]Division of Nephrology, Department of Medicine and Section of Endocrinology, Department of Pediatrics, University of Colorado Anschutz Medical Campus, Aurora, CO; [5]Department of Pharmacological Sciences and Institute for Systems Biomedicine, Icahn School of Medicine at Mount Sinai, New York, NY; [6]Division of Nephrology, Department of Medicine, University of Washington, Seattle, WA; [7]Division of Cardiology, University of Texas Health San Antonio, San Antonio, TX; [8]Department of Cellular and Integrative Physiology, University of Texas Health San Antonio, San Antonio, TX; [9]Department of Medicine, University of Michigan, Ann Arbor, MI*.

Background: Cardiovascular-kidney-metabolic syndrome (CKM) is a risk factor for heart failure following the onset of diabetic kidney disease (DKD). Prior work identified a role for endogenous adenine in progressive DKD and urinary adenine to be predictive for progression. However, the underlying metabolic pathways of CKM are unknown.

Methods: Mass spectrometry imaging (MSI) and bulk tissue LC-MS were performed on human hearts from healthy and diabetic donors with left ventricular hypertrophy (LVH) (n = 5-6 per group). Sc-RNA-seq results from patient hearts with heart failure were analyzed for cell-specific changes in methylthioadenosine phosphorylase (MTAP) which produces adenine. Urinary adenine was measured in 661 participants with DKD as part of the Singapore Study of Macro-Angiopathy and Reactivity in Type 2 Diabetes (SMART2D), which tracked incident heart failure over a 10-year period. In addition, heart tissues from both a db/db diabetic mouse model (n=6 per group) and a high fat with L-NAME-treatment mouse model of heart failure (n=4-6 per group) were studied.

Results: In human hearts, MSI revealed an increase in adenine in coronary blood vessels from diabetics with LVH and was correlated with total heart weight. Sc-RNA-seq showed cardiac endothelial cells increase MTAP expression during heart failure. Results from the SMART2D studies show urinary adenine improves prediction of heart failure among DKD patients (unadjusted HR 1.54, 95% CI 1.15-2.05, adjusted 1.56, 95% CI 1.13-2.16). In the HFD+L-NAME mice heart tissues, vascular adenine and MTAP gene expression were increased. In db/db mice, urinary adenine correlated with heart adenine expression. Also, inhibition of MTAP in mice reduced urinary and vascular heart adenine, reduced heart size, and improved echocardiogram function.

Conclusions: Patients with CKM syndrome face a risk for both heart and kidney disease. MSI of human and mouse heart tissue revealed adenine to be localized to coronary blood vessels and intervention studies demonstrate a key role for adenine to mediate diabetic heart dysfunction. Taken together, adenine presents as a potentially actionable target in treatment of CKM syndrome.

Plasma and Urine Degradome Integration Reveals Sexual Dimorphic Prognostic Biomarkers for ESKD in Type 1 Diabetes (T1D)

Michael Merchant,[1] Gavin E. Arteel,[3] Daniel W. Wilkey,[1] Lauren T. Adams,[1] Rachel G. Miller,[2] Panayiotis Benos,[4] Tina Costacou.[2] *[1]University of Louisville School of Medicine, Louisville, KY; [2]University of Pittsburgh School of Public Health, Pittsburgh, PA; [3]University of Pittsburgh School of Medicine, Pittsburgh, PA; [4]University of Florida Health, Gainesville, FL*.

Background: DKD is a highly prevalent, severe microvascular T1D complication associated with altered expression/turnover of matrisomal proteins. Proteomics has identified several candidate surrogate biomarkers for DKD progression, but most studies did not consider urine/plasma proteome integration or sexual dimorphic responses. We hypothesized integration of plasma/urine low molecular weight proteome (degradome) could reveal sex-dependent differences associated with T1D ESKD incidence.

Methods: Paired urine & plasma samples for eight age/sex matched ESKD incident cases and non-ESKD controlswere randomly selected from the Pittsburgh Epidemiology of Diabetes Complications (EDC) T1D study biorepository. Samples were shipped to the University of Louisville and processed for degradome analysis using high resolution mass spectrometry in a data dependent analysis (DDA) fashion. De novo spectral assignments used PeaksX software. Uni-/multi-variate analysis compared feature abundances ($p<0.05$ for significance). MatrisomeDb and TopFinder assigned matrisome composition

and imputed likely protease activity. Comparisons were made using XIC areas for (1) individual peptides, (2) summed related, overlapping peptide sequences (degradome domains) and (3) peptides compiled for parent proteins. Exploratory confirmation studies of parent protein abundance were conducted by ELISA.

Results: More than 22,000 peptides, corresponding to 955 parent proteins were observed. 1,792 plasma and 1,041 peptides were observed in more than 50% of the samples with many unique to plasma (11) or urine (69). 191 matrisomal proteins were identified including known T1D DKD markers (COL1A1, BGN, AGT, TNFSF12, and EGF). Significantly enriched imputed proteases included MMP12, MMP7, MMP3, and MMP14. Fragments of fifteen proteins including PGRMC1, ORM1, A1BG, AGT, and APOA2 distinguished all cases from controls. Sexual dimorphic effects were observed for SerpinD1, MGP, AGT and EGF. EGF ELISA confirmed urine EGF degradome findings.

Conclusions: T1D DKD is associated with plasma and urinary degradomic changes observable ~12 yrs before ESKD onset. These differences may provide mechanistic insights into DKD progression and lead to novel surrogate diagnostic and target engagement biomarkers for ESKD intervention.

SA-PO270

Candidate Gene Product for Diabetic Nephropathy Protein 4.1O Locates to Ribosomes and Silences C-Myc Transactivation

Lorenz Sellin, Anica D. Biermann, Theresia Vienken, Lars C. Rump, Dennis Sohn, Eva Koenigshausen. *Heinrich-Heine-Universitat Dusseldorf, Dusseldorf, Germany*.

Background: Protein synthesis and its control are an important contributor to the pathogenesis of diabetic nephropathy. Previously FRMD3 coding for Protein 4.1O was identified as a potential target gene causing diabetic nephropathy in type 1 diabetes in a GWAS of the north American population. We were interested in the cellular functions of the Protein 4.1O.

Methods: Protein 4.1O isoforms and mutants were expressed HEK 293T cells and cos7 cells. Subcelluar fractionation was performed to track the appearance of Protein 4.1O and its mutants using a ultracentrifuge with 186.000xg. The samples of the different cellular compartments were subjected to SDS-PAGE and western blot analysis. Cos7 cells expressing Protein 4.1O were stained for Protein 4.1O and cellular organell markers by appropriate antibodies. Secondary antibodies with immunofluorecent dyes were used for visulization with an immunofluorecent microscope. Luciferase reporter assays were used to assess the c-myc transactivation in the presence of increasing doses of Protein 4.1O.

Results: Protein 4.1O its isoforms and mutants were detected in the ribosomal compartment by western blot which was generated by cellular farctionation. The rps3 was used as a positive control for adequate ribosomal preparation. By immunofluorecence Protein 4.1O was detected in the cytosol, ER and in submebranous regions. Protein 4.1O mutants were enriched in the nucleus sparing the nuceoli. Luciferase reporter assays show a dose dependent reduction for c-myc transactivation by Protein 4.1O.

Conclusions: Protein 4.1O can be deteced in the ribosomal fraction by subcellular fractionation with cosedimentation with established ribosomal markers. Immunofluorecent imaging confirms Protein 4.1O apperance in the ER. Increasing doses of Protein 4.1O silence c-myc transactivation in a dose dependet fashion. These finding shed new light on the potential cellular signficance of Protein 4.1O in the pathomechanism of diabetic nephropathy.

SA-PO271

Identifying Key Genes and Mechanisms in Active Vitamin D Treatment for Diabetic Kidney Disease

Gao Ping. *Zhongnan Hospital of Wuhan University, Wuhan, China*.

Background: Diabetic kidney disease (DKD) presents a healthcare challenge with limited treatments. Active vitamin D may address DKD-related fibrosis, but its mechanisms are unclear

Methods: Utilized scRNA-Seq data from DKD mice treated with calcitriol and bulk RNA data from GEO. Employed Mendelian randomization and enrichment analyses to explore gene-immune cell interactions. Validated key gene expression with scRNA-Seq and GSE30529. Assessed renal function association with NephroseqV5 and confirmed protein expression with the Human Protein Atlas

Results: Active vitamin D reduced proliferative cells. Enrichment analyses highlighted FoxO signaling's role. SUMO3 and CD74 emerged as potential markers correlated with immune infiltration. Significant correlations found between SUMO3, CD74, creatinine levels, and eGFR. Confirmed higher SUMO3 and CD74 protein expression in DKD

Conclusions: Increased SUMO3 and CD74 expression in DKD is associated with active vitamin D treatment, affecting fibrosis via the FoxO pathway. They could serve as DKD protection markers

Effects and Dynamics of D-alanine under Diabetic Conditions

Tomonori Kimura,[1] Shinsuke Sakai,[1] Masashi Mita,[2] Masayuki Mizui,[1] Yoshitaka Isaka.[1] *[1]Osaka Daigaku, Suita, Japan; [2]Kagami Inc., Ibaraki, Japan.*

Background: D-Alanine, a rare enantiomer of alanine, protects from viral infections and mediates renal gluconeogenesis through the transcriptional network of circadian clock. These features of D-alanine are associated with the diabetic conditions; the aberrant circadian rhythm is a feature of diabetes, and diabetes is a worsening factor for Covid-19. This study investigated the effects and dynamics of D-alanine in the diabetic conditions.

Methods: The blood and urinary levels of D-alanine in diabetic model mice and in patients with diabetic kidney disease were measured using two-dimensional high performance liquid chromatography system. Gluconeogenetic activity of D-alanine was analysed using glucose production assay in *ex vivo*-cultured kidney cells. Glucose tolerance test was performed in mice treated with D-alanine.

Results: The circadian rhythm of D-alanine, which is clearly present in mice, was lost in mice model of diabetes. The urinary excretion profile of D-alanine was abnormal in patients with diabetic kidney disease. Like normal kidney, D-alanine induced gluconeogenesis in kidney from diabetic model mice. While treatment of D-alanine induced the transient increase of blood glucose level, repetitive treatment of D-alanine did not worsen the glucose tolerance.

Conclusions: D-Alanine also acts on the kidney from diabetic mice, whereas treatment of d-alanine does not worsen the diabetic conditions. D-Alanine may provide a therapeutic option for diabetes through the correction of circadian rhythm and treatment of viral infections.

SA-PO273

Expression and Distribution of Different Protein Kinase A Isoforms in Healthy and Diseased Kidneys

Sally S. Prueschenk,[1] Susan Taylor,[2] Jens Schlossmann.[1] *[1]Universitat Regensburg Fakultat fur Chemie und Pharmazie, Regensburg, Germany; [2]University of California San Diego School of Medicine, La Jolla, CA.*

Background: Diabetic nephropathy (DN) is a major universal problem caused by hyperglycaemia and might require dialysis or renal replacement. Still, the signalling events causing diabetic kidney disease and the effective treatment options are poorly understood. Alterations in the signalling of cyclic nucleotides and its regulated kinases might be involved in the development of this disease. Protein kinase A (PKA) signalling pathways are known to modulate extracellular matrix metabolism in diabetic kidneys. Multiple isoforms of PKA regulatory and catalytic subunits exist, leading to functional specificities of this kinase. However, localization of the specific PKA subunits, as well as other signalling proteins involved in this pathway, still need to be explored comprehensively. PKA, which is activated through cAMP, was described to exert antifibrotic effects and might therefore be important in prevention of fibrosis or DN. The aim of our project is to get an overview about distribution pattern of different PKA subunits in various cell types of the kidney. Furthermore, amount of PKA expression in healthy and diabetic kidneys is compared.

Methods: Type 1 diabetes was induced with streptozotocin in wild-type (WT) and endothelial NOS knockout (eNOS-KO) mice for 12 weeks. Kidneys were analysed by immunohistochemistry and stained with specific antibodies for different PKA subunits and markers for specialized renal cell types. Amount of catalytic subunit expression was quantified and compared between healthy and diabetic kidneys.

Results: The catalytic subunits PKA-Cα and PKA-Cβ reveal a different expression pattern in different segments of the kidney and interestingly the intracellular localization varies. Furthermore, PKA-Cα seems to be the predominant isoform in a lot of cell types. We also observe an altered amount of catalytic subunit expression in diabetic kidneys compared to healthy kidneys.

Conclusions: Our data show that catalytic subunits of PKA reveal a different distribution pattern in specialized cell types of the kidney as well as a different intracellular localization. Furthermore, the amount of catalytic subunit expression varies between healthy and diabetic kidneys. Therefore, PKA might play an important role in pathophysiology of DN and targeting the PKA signalling pathway could be a potential treatment approach.

SA-PO274

5-Lipoxygenase Inhibition Ameliorates Diabetic Kidney Disease by Attenuating Renal Tubular Epithelial Cell Ferroptosis

Min Heui Ha, Hyun-Ju An, Min ji Sung, Hyeyun Jeong, Jihyun Baek, So-young Lee, Yu ho Lee. *CHA University Bundang Medical Center, Seongnam, Gyeonggi-do, Republic of Korea.*

Background: The enzyme 5-lipoxygenase plays a pivotal role in the conversion of arachidonic acid into 5-hydroperoxyeicosatetraenoic acid (5-HPETE), which is a key source of lipid peroxides and leukotrienes. This study aims to elucidate the pathophysiological implications of 5-lipoxygenase in diabetic kidney disease (DKD), focusing on its impacts on lipid peroxidation and tubular cell ferroptosis.

Methods: HKC-8 cells, a human-derived renal proximal tubular cell line, was used to perform in vitro experiments. Diabetes induction in male C57BL/6J mice was achieved through streptozotocin injection. Zileuton was used to inhibit 5-lipoxygenase activity.

Results: Hyperglycemic stimuli upregulated the expression of 5-lipoxygenase both in HKC-8 cells. The overexpression of 5-lipoxygenase aggravated hyperglycemia-induced increases in the expression of profibrotic cytokines and reactive oxygen species (ROS) production, while its suppression mitigated these detrimental effects. High glucose also led to downregulations of glutathione peroxidase 4 (GPX4) and upregulations of Acyl-CoA synthetase long chain family member 4 (ACSL4), ferritin heavy chain 1 (FTH-1), and malondialdehyde (MDA), indicating the activation of pro-ferroptotic pathways. The overexpression of 5-lipoxygenase exaggerated hyperglycemia-induced ferroptotic cell death, which is attenuated by the inhibition of 5-lipoxygenase or ferrostatin-1 treatment. Additionally, streptozotocin-induced diabetic mice exhibited worse kidney function and interstitial fibrosis in association with decreased GPX4 and increased ACSL4 and FTH-1 levels compared to normoglycemic mice. Zileuton administration significantly ameliorated these hyperglycemia-induced kidney dysfunction and ferroptosis activation.

Conclusions: These findings demonstrate the central role of 5-lipoxygenase in intracellular lipid peroxidation and subsequent tubular cell ferroptosis under sustained hyperglycemic conditions. Inhibition of 5-lipoxygenase not only mitigates ferroptotic tubular cell death but also alleviates hyperglycemia-induced renal dysfunction. This suggests that 5-lipoxygenase could serve as a potential therapeutic target for the treatment of DKD.

SA-PO275

DNA Methyltransferase Inhibitor Alleviates Kidney Inflammation and Injury by Reversing DNA Hypermethylation-Associated Klotho Suppression in Diabetic db/db Mice

Qianling Liu, Xiaoyan Li, Jinjin Fan, Wei Chen. Dept of Nephrology, The First Affiliated Hospital, Sun Yat-sen University. *Sun Yat-Sen University, Guangzhou, China*.

Background: Klotho is a well-known anti-aging gene with anti-inflammatory effects. The renal expression of klotho is reduced both in patients with diabetic kidney disease (DKD) and diabetic mice. However, its mechanism is unclear. Studies have indicated elevated DNA methylation levels in the klotho promoter region of the kidney in DKD patients. Since DNA methylation can suppress gene expression, we speculate whether demethylation treatment can alleviate renal inflammation and improve DKD by upregulating renal klotho expression?

Methods: Male diabetic db/db (C57BLKS/J-LepR^{db}/LepR^{db}) mice and age-matched wild-type (BKS) mice were utilized in the study. At 8 weeks of age, db/db mice were given intraperitoneal injection of the DNA methyltransferase inhibitor 5-azacytidine (1 mg/kg body weight or 2 mg/kg body weight) or saline as control every other day. After 12 weeks of treatment, the blood, urine and kidney samples were collected for measurements.

Results: The renal expression of klotho in db/db mice is significantly reduced, along with an increase in DNA methylation levels in the promoter region. 5-azacytidine reduced the renal klotho DNA methylation level and increased klotho expression in db/db mice. This indicates that DNA methylation is involved in the downregulation of klotho in the kidney of DKD. In db/db mice, the renal expression levels of NF-κB and its downstream inflammation-related genes are elevated in db/db mice.5-azacytidine alleviated the renal expression of these inflammatory mediators. It also alleviated the activation of kidney inflammasome and macrophage infiltration. KEGG enrichment analysis of the RNA sequencing results showed that the differentially expressed genes were mainly enriched in NF-κB and TNF signaling pathways. In addition, 5-azacytidine concentration-dependently reduced serum levels of glucose and improved systemic insulin sensitivity. The urinary albumin excretion and serum creatinine in db/db mice were markedly decreased. This was accompanied by alleviation of glomerular hypertrophy, mesangial matrix expansion, glomerular basement membrane thickness and the extent of foot process effacement.

Conclusions: DNA methyltransferase inhibitor could alleviate renal inflammation and improve DKD by reversing DNA hypermethylation-associated klotho suppression in diabetic db/db mice.

SA-PO276

Dapagliflozin Significantly Suppresses Glomerular Hypertrophy in Rats with Type 2 Diabetes

Yuri Ishizaki, Masao Kikuchi, Koichi Kaikita, Shouichi Fujimoto. *Miyazaki Daigaku, Miyazaki, Japan.*

Background: Dapagliflozin, a sodium-glucose cotransporter 2 (SGLT2) inhibitor developed for the treatment of type 2 diabetes mellitus (DM), is a clinically very effective drug that inhibits the progression of chronic kidney disease with or without type 2 DM. However, the underlying mechanisms are unknown. We performed a histological evaluation to explore the renoprotective effects of SGLT2 inhibitors.

Methods: Twenty-four male SDT fatty rats, a model of type 2 diabetes, were divided into four groups: sham + placebo group (n=6), sham + dapagliflozin (dapa, 1.5 mg/kg/day) group (n=6), uni-nephrectomy (UNx) + placebo group (n=6), and UNx + dapa group (n=6). UNx or sham surgery was performed at week 6, rats were euthanized at week 12, and kidneys were harvested for histopathological evaluation. The number and size of podocyte nuclei were determined using Wilms tumor 1 (WT1) immunofluorescence staining, and glomerular tufts were estimated using the podocyte cytoplasmic marker glomerular epithelial protein 1 (GLEEP1) immunoperoxidase. Thirty glomeruli per rat were selected and evaluated using an image analyzer.

Results: Dapagliflozin significantly reduced glomerular hypertrophy in both the sham surgery and UNx groups (P<0.0001 and P=0.0099, respectively). However, the suppression was smaller in the UNx group. There were no significant differences in the number or density of podocytes.

Conclusions: Dapagliflozin significantly suppressed glomerular hypertrophy in a diabetic rat model. It was suggested that the renoprotective effect of dapagliflozin may be mediated through inhibition of glomerular hypertrophy.

SA-PO277

Inhibition of D-amino Acid Metabolism May Improve Glucose Metabolism via Reduction of Insulin Resistance

Eriko Hayashi, Keisuke Sako, Kiyoaki Ito, Shinji Kitajima, Ichiro Mizushima, Norihiko Sakai, Miho Shimizu, Yasunori Iwata. *Kanazawa Daigaku, Kanazawa, Japan.*

Background: D-amino acids are optical isomers of L-amino acids, and D-amino acid oxidase (DAO) is an enzyme that degrades certain D-amino acids. Risperidone, one of the major drug for schizophrenia, is also known to inhibit DAO. Previously, we reported a lower incidence of eGFR decline in the risperidone group in patients with schizophrenia, suggesting a renoprotective effect of risperidone via DAO inhibition. However, the significance of DAO activity inhibition in the pathogenesis of other diseases is unknown. We recently found that treatment with risperidone in type 1 diabetic mice model reduced fasting and postprandial blood glucose levels. Therefore, we further investigated the effect of risperidone on insulin resistance.

Methods: We administered risperidone to 7-week-old male C57BL/6J(B6) mice, non-diabetic mice, and DAO activity-deficient (DAO-KO) mice. We measured body weight, blood glucose levels, insulin levels, amount of food intake, urinary glucose levels, and urine volume. *In vitro*, we used C2C12 cells, a cell line derived from mouse rhabdomyosarcoma muscle. C2C12 cells were stimulated with risperidone at concentrations of 1 nM, 10 nM, and 50 nM. Glucose uptake experiments were performed to evaluate the glucose uptake capacity of the cells.

Results: Among B6 mice, administration of risperidone showed no significant change in body weight, blood glucose levels, insulin levels, amount of food intake, urinary glucose levels, or urine volume. However, in the glucose tolerance test, the risperidone-treated group showed decreased blood glucose at 0, 30, 60, 120, and 180 minutes. In addition, insulin levels also decreased at 0 minutes($p<0.05$). In DAO-KO mice, blood glucose levels decreased at 120 and 180 minutes. Insulin levels also showed a decreasing trend. These results indicated the potential role of risperidone via DAO inhibition in improving insulin sensitivity. In the insulin tolerance test, blood glucose levels were decreased in B6 mice treated with risperidone at 45 and 60 minutes ($p<0.05$), while no significant difference was observed in DAO-KO mice. *In vitro*, glucose uptake was enhanced in the risperidone groups at 1 nM and 10 nM concentrations ($p<0.05$).

Conclusions: Risperidone, an inhibitor of DAO metabolism, may improve insulin resistance.

Effects of Global SGLT2 Knockout on Heart Failure with Preserved Ejection Fraction

Margaret E. Fain,[1] Sol Misener,[1] Yalu Zhou,[1] Thomas Rousselle,[2] Valeria R. Mas,[2] Susan E. Quaggin.[1] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]University of Maryland School of Medicine, Baltimore, MD.*

Background: Until recently, there were no effective regimens for heart failure with preserved ejection fraction (HFpEF); however, clinical data from the EMPEROR-Preserved trial has shown that sodium glucose cotransporter 2 inhibitors (SGLT2is) reduce hospitalization and mortality in HFpEF patients. However, the mechanism(s) responsible for cardioprotection following inhibition of a kidney-restricted SGLT2 cotransporter is incompletely known. However, off- versus on- target drug effects remain unclear, and a clear explanation would allow for more directed drug therapy development.

Methods: To investigate the effect of SGLT2i on-target drug action, we used the SweetPee (SP) *Slc5a2* loss-of-function model on a high fat diet (HFD) L-NAME model of HFpEF to model the effects of on-target Sglt2 inhibition in new onset HFpEF. 8-10-week-old SP or wild type (WT) mice were maintained on either 60% HFD+L-NAME (0.5 g/L) or normal diet (ND) for 8 weeks. The animals were monitored every two weeks with echocardiography, blood pressure measurements, and weight surveillance, and were also tested for cardiovascular function using an exercise tolerance test before sacrifice and harvesting. The lung wet-to-dry weight ratio was also recorded in these animals as evidence of pulmonary edema.

Results: Echocardiography data showed no significant difference in ejection fraction, as is expected in HFpEF condition; however, the WT HFD+L-NAME group showed a trend towards an increase in E/e' relative to the SP HFD+L-NAME group, indicating an increase in left ventricular filling pressure which is a hallmark of heart failure. Furthermore, WT HFD-LNAME trended towards a higher systolic and diastolic blood pressure and lung wet-to-dry weight ratio and a decrease in running distance as measured via treadmill. These changes show that the SP genotype was protective against incipient HFpEF as induced by an HFD-L-NAME model.

Conclusions: These results show promise that cardioprotection observed in patients stems from on-target drug inhibition of the SGLT2 cotransporter. Future directions will identify potential molecular pathways underlying protection, as well as distinguish on-target from off-target effects.

CDA1(TSPYL2) Deficiency Attenuates Kidney Fibrosis and Inflammation in db/db Diabetic Mice

Jiali Tang, Minling Huang, Tieqiao Wu, Mark E. Cooper, Zhonglin Chai. Diabetes Dept. *Monash University Faculty of Medicine Nursing and Health Sciences, Melbourne, VIC, Australia*.

Background: Diabetic kidney disease (DKD) is the most common cause of end-stage renal disease worldwide, which increases morbidity and mortality in diabetes. Targeting Cell Division Autoantigen 1 (CDA1, also known as Tspyl2) has been demonstrated to retard diabetes-associated renal injury in type1 diabetes mouse models. However, whether such beneficial effects would extend to type 2 diabetes (T2D) is unknown.

Methods: This study investigated the effect of global genetic deletion of CDA1 on the development of DKD in a T2D mouse model. We generated a db/db CDA1 knockout (KO) mouse strain, assessed their kidney function and performed morphometric analysis at 16 weeks of age. To explore potential molecular mechanisms underlying the effects of CDA1 deficiency in the diabetic kidney, transcriptomic and proteomic analyses were performed on the renal cortex of these mice (n=6-10 mice/group).

Results: Deletion of CDA1 significantly reduced diabetes-induced albuminuria by ~40%, and normalized mesangial expansion and collagen deposition, without affecting glucose, body weight, or lipid levels. The expression levels of renal profibrotic and proinflammatory genes were increased in the db/db diabetic mice, such as collagens I, III and IV, fibronectin, alpha-smooth muscle actin, vascular cell adhesion molecule 1, monocyte chemoattractant protein 1, tumour necrosis factor-alpha and interleukin 6. These diabetes-induced changes were attenuated in db/db CDA1 KO diabetic mice to levels similar to those seen in non-diabetic db/h control mice. As observed in the previous studies using STZ-diabetes models, CDA1 deficiency reduced the gene expression levels of TGF-β ligands and its receptors in the diabetic kidney. These results demonstrate the anti-fibrotic and anti-inflammatory effects of CDA1 deletion. Transcriptomic and proteomic analyses confirmed these effects and revealed underlying potentially injurious pathways, such as the TGF-β and NFκB pathways, as well as complement/coagulation cascades, cellular senescence and other relevant pathways.

Conclusions: These results demonstrate the efficacy of targeting CDA1 in reducing renal injury as seen by targeting relevant proinflammatory and profibrotic pathways in the T2D model of db/db mice, thereby confirming that CDA1 is a promising therapeutic target for DKD in T2D.

Oral Butyrate Reduces Progression of Kidney Damage in a Diabetic Kidney Disease Mouse Model

Maria Novella Nicese, Angela Koudijs, Reshma Lalai, Cristina Avramut, Sander Kooijman, Roel Bijkerk, Bernard van den Berg, Joris I. Rotmans. *Universiteit Leiden, Leiden, Netherlands*.

Background: Patients with diabetic kidney disease (DKD) display an altered gut microbiome composition when compared to healthy subjects, with a lower prevalence of short chain fatty acids (SCFAs)-producing bacteria. Such reduction might exacerbate DKD, since SCFAs, including butyrate, are associated with health benefits. For this reason, we hypothesized that oral butyrate supplementation reduces DKD progression in mice.

Methods: For this study, L-NAME dissolved in drinking water was administered to diabetic BKS *db/db* male mice (80/mg/kg/day) for 4 weeks to accelerate DKD progression. Together with L-NAME, mice also received either standard diet or food with 5% sodium butyrate (n=10 per group), starting at the same time. In this period, blood pressure, glomerular filtration rate (GFR), besides total body water, glycemia and albuminuria were monitored during follow up period. After 4 weeks, animals were sacrificed whereupon blood samples and organs were collected.

Results: In animals fed with regular diet, L-NAME caused a reduction in GFR of 17% at 3 weeks, when compared to baseline. In contrast, mice treated with butyrate did not show any decline in GFR. Furthermore, mice on standard diet showed a significant increase in albuminuria when compared to baseline (p=0.03), which was not the case for the mice that received butyrate (p=0.5). Such difference in kidney function might explain the difference in total body water, which was higher in mice fed with regular diet (p=0.03). Interestingly, glycemia and blood pressure were comparable between groups, suggesting that other mechanisms underlie the effect of butyrate on kidney function. Analysis of kidney biopsies revealed smaller glomeruli (p=0.03) and less mesangial expansion (p=0.0082) in mice treated with butyrate, as well as less fibrosis in the medulla (p=0,04), when compared to mice fed with standard diet. This is also supported by a reduction in Collagen I mRNA expression extracted from whole kidney homogenate (p=0.08).

Conclusions: Our results show that oral sodium butyrate supplementation diminishes DKD progression by protecting against mesangial expansion and fibrosis. Future microbiome sequencing from feces and caecum content, together with metabolomic analysis on plasma samples, will help to further understand the effect of butyrate on DKD.

SA-PO281

Effects of Nucleobindin-2 on Tubular Cells and Mitochondria and Their Mechanisms

Yoshihisa Nakatani. *Kinki Daigaku Igakubu Daigakuin Igaku Kenkyuka, Osakasayama, Japan*.

Background: We have reported that serum NUCB2 (Nucleobindin-2) is a potential biomarker of tubular tissue damage and prognostic factor in DKD. However, the mechanism by which NUCB2 improves renal tubular damage remains unclear. In this study, we investigated the effects of Nucleobindin-2 on tubular cells and mitochondria and the mechanisms underlying these effects.

Methods: We analyzed the effects and mechanisms of NUCB2 on oxidative stress, apoptosis, and mitochondria under high glucose (HG) conditions using proximal tubular cells (HK2, RPTEC).

Results: In oxidative stress cultured HG, NUCB2 reduced ROS production by 20% (Ample Red method), SOD2 expression was unchanged, HO-1 expression was decreased, and oxidative stress scavenging gene expression was not enhanced. Nrf2 expression was decreased both in the nucleus and cytoplasm, P22phox expression was decreased, poldip2 expression was increased, and p47phox expression was increased. This suggests that the expression balance of NOX2/NOX4 is altered, which may reduce oxidative stress production at the basal level for cellular maintenance. Cleaved caspase 3 expression was reduced by 40%, while Bax was decreased and Bcl2 was increased in a NUCB2 concentration-dependent manner, pERK was increased at HG concentration with NUCB2, suggesting that mitochondria were affected via the cRaf-ERK pathway. Analysis of mitochondrial dynamics revealed changes in mitochondrial fusion and fission-related proteins at the protein level and by electron microscopy. Furthermore, NUCB2 enhanced the LC3 1/2 ratio, suggesting that autophagy may also be involved. When we examined metabolism, piruvate kinase, GAPDH, and lactate were unchanged regardless of blood glucose, but PEPCK expression was increased, suggesting an enhancement of the glycogenic system. This may be due to the increased activity of the pentose pathway, which may have suppressed oxidative stress by producing NADPH. In addition, the expression of lipolysis (beta oxidation) and synthesis was enhanced by NUCB2 administration, regardless of blood glucose level. These results may indicate a correlation between lipid profiles and serum NUCB2 concentrations in humans.

Conclusions: NUCB2 may reduce oxidative stress production, suppress apoptosis, and ameliorate mitochondrial damage at high glucose concentrations. NUCB2 may also have an effect on the metabolic system and lipid synthesis.

SA-PO282

TW-37, a Senolytic Agent and Inhibitor of KIM-1-Mediated Endocytosis, Reduces KIM-1 Expression, NF-κB-IL-1β Axis, and p16-Mediated Cellular Senescence

Yutaro Mori, Makiko Mori, Yuki Nakao, Yuta Sekiguchi, Shintaro Mandai, Fumiaki Ando, Koichiro Susa, Takayasu Mori, Eisei Sohara, Shinichi Uchida. *Department of Nephrology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University, Tokyo, Japan*.

Background: Chronic KIM-1 expression is known to be detrimental. Previously, we identified TW-37 as an inhibitor for KIM-1 mediated endocytosis. We discovered KIM-1-mediated endocytosis of palmitic acid-bound albumin leads NLRP3 inflammasome activation, DNA damage response, cell cycle arrest, cellular senescence and inflammatory fibrotic cytokine production. TW-37 is also known as a senolytic which induce cell death on senescent cells. In this study, we tested relatively long-term effects of TW-37 on primary human renal proximal tubular epithelial cells (hRPTECs).

Methods: We established primary hRPTECs from a patient's resected kidney due to a malignancy with a written informed consent. Uninvolved parts of kidneys were cultured on serum-free media containing epidermal growth factor. We seeded 6 x 10^5cells on day 0 and changed the medium to 10% fetal bovine serum-DMEM (high glucose) containing TW-37 or control DMSO on day 2. We cultured the cells for 8 days (day 2-10) with changing media containing TW-37 or DMSO. KIM-1, NF-κB, IL-1β, p16, caspase-3 and PD-L1 were evaluated by western blotting.

Results: Treatment of TW-37 reduced KIM-1 expression. It also reduced NF-κB and IL-1β, probably indicating NF-κB-NLRP3 inflammasome-IL-1β axis was upregulated. In the control p16 was expressed. Treatment of TW-37 reduced expression of p16 but did not increase expression of caspase-3, suggesting that TW-37 may have non-apoptotic anti-senescence effects. Finally, TW-37 reduced PD-L1 expression.

Conclusions: TW-37 as known for a senolytic and an endocytosis inhibitor for KIM-1 mediated endocytosis may induce intracellular anti-inflammatory and anti-senescence process by downregulating KIM-1, which can be renoprotective effects.

Myokine SIRPα Leads to Defective Heart-Kidney Fatty Acid Oxidation in Type 1 Diabetes

Helena Zhang, Jiao Wu, Sandhya S. Thomas. *Baylor College of Medicine, Houston, TX*.

Background: Dysregulated insulin signaling has been associated with maladaptive alterations in metabolism, cardiac dysfunction and adverse remodeling contributing to cardio-renal diseases. We have previous identified myokine signal regulatory protein alpha (SIRPα), an endogenous mediator of insulin resistance, is upregulated in response to hyperglycemia or uremia, modulating heart-kidney crosstalk. The impact of cardiac-specific SIRPα knockout (KO) regulation on heart-kidney metabolism in the absence of insulin is largely unknown.

Methods: A single dose of 150 mg/kg of STZ was administered to (Myh6Cre)-control and cardiac-specific (cs) SIRPα KO mice. At five weeks post-treatment, M-mode transthoracic echocardiography was performed by an experienced sonographer who was blinded to the study groups. Real-time PCR analysis was used to quantify relative mRNA transcript levels of fetal genes in the heart, fatty acid oxidation genes, fibrotic genes, and inflammatory cytokines. Statistical significance was calculated using 2-tailed unpaired Student's *t* test.

Results: Cardiac-specific SIRPα KO mice exposed to STZ exhibited improved cardiac output (ml/min), fractional shortening (%), and ejection fraction (%) compared to Myh6Cre-control mice with similar heart rates. STZ-treated csSIRPα KO mice displayed downregulation of fetal genes including ANP, BNP, and MHC-alpha as well as suppressed cardiac fibrosis when compared to control mice. These cardiac changes were importantly associated with a downregulation of transcripts encoding genes involved in fatty acid oxidation genes in both the heart and kidneys. Finally, kidney tissue from STZ-treated csSIRPα KO mice exhibited substantially decreased inflammatory markers and fibronectin when compared to control mice.

Conclusions: These results emphasize the role of myokine SIRPα in reprogramming of the fetal genes and cardiac dysfunction while contributing to kidney inflammation and fibrosis. Since chronic kidney disease is a significant independent risk factor for cardiovascular mortality, further examination is imperative in understanding the impact of dysregulated muscle metabolism, specifically myokine triggers on heart-kidney FAO responses independent of insulin in a model of type 1 diabetes.

SA-PO284

Physical Exercise Reduces the Morbidity of Diabetic Rats Exposed to Polymyxin B Nephrotoxicity

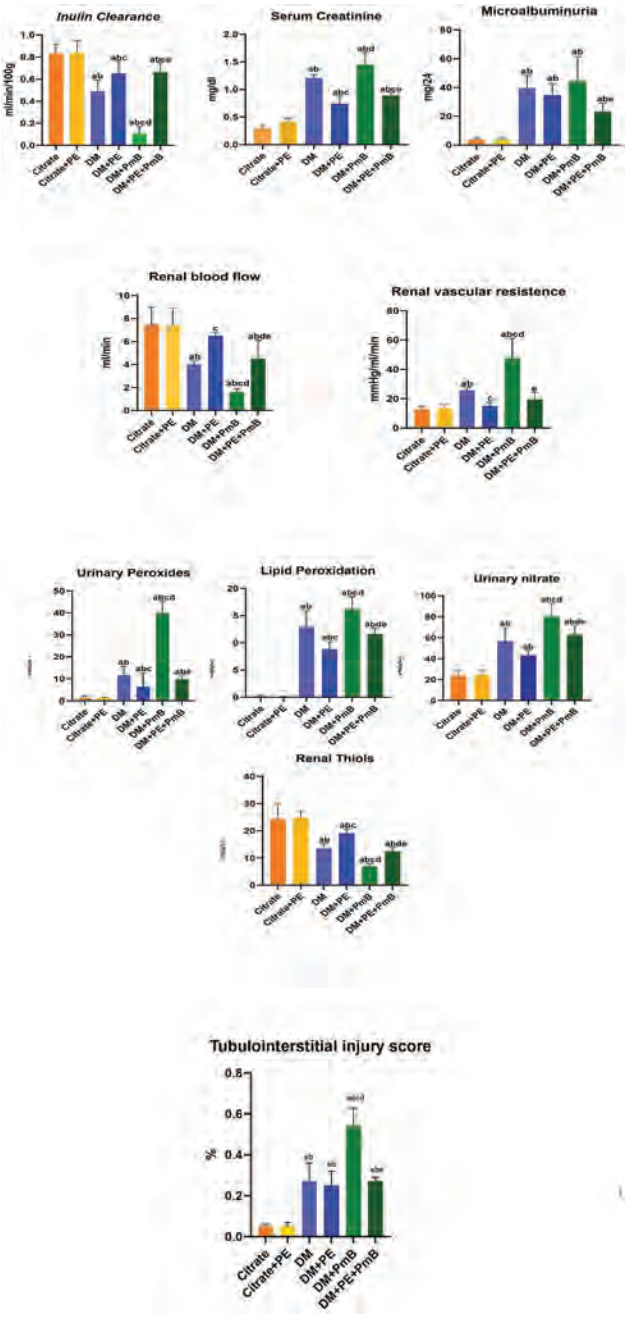
Eloiza O. Silva,[1,2] Carla D. Victoria,[1] Juliana V. Silva,[1] Maikol L. Gonçalves,[1] Jessica P. García,[1] Guilherme H. Ferreira Vieira,[1] Mykelly G. Alves,[1] Camila Lima,[1] Alessandra Oliveira Maia,[1] Luciana Soares C. Santos,[1,2] Maria De Fatima Vattimo.[1] Group of Studies on Acute Kidney Injury. *[1]Universidade de Sao Paulo, Sao Paulo, Brazil; [2]Faculdade de Ciencias Medicas da Santa Casa de Sao Paulo, Sao Paulo, Brazil*.

Background: Diabetic kidney disease (DKD) is a significant global health concern and the leading cause of terminal chronic kidney disease (CKD). Polymyxin B (PmB), a nephrotoxic drug, precipitates acute kidney injury (AKI) on DKD patients, elevating risk of disease progression. Physical exercise (PE) is a non-pharmacological intervention that alleviates DKD complications. The objective of this study is to evaluate the impact of PE on renal function in rats with DKD that received PmB.

Methods: Adult Wistar rats were randomized in: Citrate (CT): rats receiving streptozotocin vehicle (citrate; i.v., caudal, single dose); Citrate+PE: citrate rats subjected to daily swimming training (1 hour, 4 weeks); Diabetes Mellitus (DM): rats receiving streptozotocin (STZ, 60 mg/kg; i.v.; single dose, up to the 28th day); DM+PE: DM rats subjected to swimming training; DM+PmB: DM rats receiving PmB (4 mg/kg/day, i.p., once a day, 5 days); DM+PE+PmB: DM rats receiving PmB and subjected to PE. Renal function, renal hemodynamics, oxidative profile and renal histology were evaluated.

Results: The DM+PmB group reduced Clin, RBF and renal thiol levels, while CrS, microalbuminuria, RVR, the excretion of oxidative metabolites and tubulointerstitial injury score significantly increased. PE attenuated the deterioration of renal function in the DM groups.

Conclusions: Findings revealed that DKD rats with PE did not manifest acute DKD when exposed to PmB. These results offer an innovative insight into the interplay between PE and nephrotoxicity in DKD and the renal disease morbidity and pave the way for promising interventions in management of the DKD.



SA-PO285

Combination of Renin AAV and L-NAME Accelerates the Progression of Kidney Disease in Diabetic Mice

Leah L. Porras, Brent Poling, Asim Dey. *Eli Lilly and Company, Indianapolis, IN*.

Background: Diabetic kidney disease (DKD) is a major cause of end stage kidney disease with increasing prevalence worldwide. Rodent models that recapitulate human disease are currently lacking, and many existing models show low proteinuria or take a longer time to develop the disease phenotype. Here we describe a rodent model with accelerated disease progression by combining hypertension and reduced nitric oxide bioavailability on the background of hyperglycemia.

Methods: Nine-week-old male *db/db* obese mice (BKS.Cg-+Leprdb/+Leprdb/OlaHsd-00642) from Jackson Laboratories were injected with Renin AAV (1×10^9 GC) or Lac-Z AAV and provided access to normal chow and water *ad libitum*. These two groups of mice were further divided into two subgroups each based on uACR and half of each subgroup was switched to drinking water containing L-Name (20 mg/L). The 4 subgroups (Lac-Z AAV + water, Lac-Z AAV + L-Name, Renin AAV + water, and Renin AAV + L-Name) were then followed for 5 weeks. Changes in proteinuria were evaluated every

two or three weeks for study duration. In addition, blood pressure was measured via tail cuff and 4 h fasted blood glucose levels measured with a glucometer. At study termination, animals were euthanized, and blood and organs were harvested for further analysis.

Results: Mice treated with a combination of Renin AAV and L-Name showed a significant increase in proteinuria compared to Lac-Z AAV + water group, at two weeks and renal dysfunction continued to progress up to five weeks. Blood pressure was not significantly increased during the study. All mice in the study showed hyperglycemia, with blood glucose levels above 600 mg/dL. Gene expression data from the kidney showed increases in markers of kidney injury and fibrosis in the Renin AAV + L-Name treated group compared to Lac-Z AAV + water group. Urinary biomarker data also showed an increased in kidney injury biomarker in the combination group compared to the Lac-Z groups.

Conclusions: Our results show that combination of Renin AAV and L-Name markedly accelerates the onset of DKD in male *db*/*db* mice, with signs of kidney dysfunction seen at 2 weeks. This model has the potential to be utilized for rapid evaluation of novel therapeutic interventions for DKD.

SA-PO286

Chronic Intermittent Hypoxia Aggravates Progression of Diabetic Nephropathy via Inducing Endoplasmic Reticulum Stress and Mitochondrial Dysfunction

Junjie Jia,[1,2] Haoran Feng,[1] Niansong Wang,[1] Ying Fan.[1] *[1]Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China; [2]Huashan Hospital Fudan University, Shanghai, China*.

Background: Obstructive sleep apnea-hypopnea syndrome (OSAHS) is a common complication of diabetic nephropathy (DN), which has been found to exacerbate the progression of DN. Chronic intermittent hypoxia (CIH) is one of the most important pathophysiological mechanisms of OSAHS, but its exact impact on DN remains unknown.

Methods: Renal biopsy specimens and the clinical data of 18 biopsy-proven DN patients were collected to observe the correlation of the severity of OSAHS in these patients with their renal function indexes and renal pathological damage. An animal model of DN combined with OSAHS was established by subjecting type 2 diabetic db/db mice to in vivo CIH stimulation for 12 weeks. RNA-sequencing was performed on the kidney cortex tissue from mice to identify the factors CIH mediating the progression of DN. In vitro, HK-2 cells were induced by high glucose (HG) combined with CIH stimulation to confirm the effect of CIH on diabetic tubular injury.

Results: In the current study, we found that the severity of OSAHS was significantly correlated with renal function decline and tubular pathological damage in biopsy-proven DN patients. In vivo, the kidney damage, especially renal tubular injury of the 12-week-CIH-stimulating db/db mice was more severe as compared to normoxic controlled db/db mice and wild-type littermates. RNA-sequencing revealed that increased severity of tubular injury caused by CIH might be associated with activated endoplasmic reticulum stress (ERS), mitochondrial dysfunction, and the exacerbation of apoptosis as well. The *in vitro* experiments confirmed the results, demonstrating that HK-2 cells treated with HG combined CIH exhibited worsened cell apoptosis, ERS, and mitochondrial dysfunction.

Conclusions: This is the first basic research study to investigate the impact of OSAHS on the progression of DN. Our findings show that OSAHS is an important risk factor for the deterioration of renal function and aggravated tubular damage in the course of DN, in which the mechanism is related to the exacerbation of ERS and mitochondrial dysfunction caused by CIH.

SA-PO287

Phase 3 Clinical Candidate Rilparencel Demonstrates Distinct Secretomic Signatures at Key Points in Manufacturing, Suggesting a Reduced Inflammatory and Fibrotic Profile

Ashley Greenawalt, Mark A. Rohlfing, Brooke Bauer, Andrew T. Bruce, Dominic M. Justewicz. *ProKidney LLC, Morrisville, NC.*

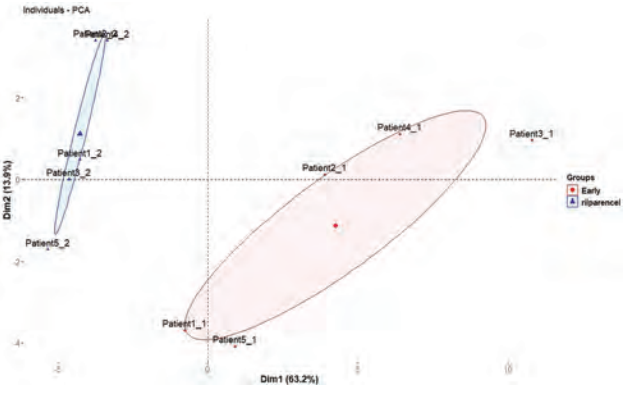
Background: Kidney cortical biopsy-derived rilparencel is a first-in-class autologous kidney epithelial cell platform in Phase 3 clinical trials for patients with type 2 diabetes (T2D) and chronic kidney disease (CKD). Data from two Phase 2 studies suggests that kidney cortical injection of rilparencel may preserve organ function as measured by estimated glomerular filtration rate (eGFR). T2D and CKD are associated with inflammation and tissue fibrosis. In a small pilot proof-of-concept study, we sought to characterize how the rilparencel secretome may facilitate kidney repair and restoration.

Methods: In a subset (NCT02836574) of 5 patients with T2D and CKD, conditioned-medium (CM, 24 hr) was collected from 2 stages, early and final product/rilparencel, during the manufacturing process. The CM was queried for 51 secreted inflammatory and fibrotic markers (Luminex xMAP, Intelliflex) whose expression levels were used to generate principal component analysis (PCA) plots.

Results: Secretomes exhibited distinct clustering with a secretory profile of reduced levels of inflammatory and fibrotic markers in rilparencel CM vs. early-stage CM.

Conclusions: This small pilot study suggests that our manufacturing process results in a product, rilparencel, that secretes reduced inflammatory and fibrotic markers, which may in part underlie its reparative and restorative activity. Secretomic profiling may also inform a potency assurance strategy for rilparencel.

Funding: Commercial Support - ProKidney LLC



PCA plot, based on inflammatory and fibrotic secretory markers, demonstrates distinct clusters between early-stage CM (red) and final-stage/rilparencel CM (blue).

SA-PO288

The Ketone Body β-Hydroxybutyrate Mitigates Diabetic Kidney Disease through Metabolic Reprogramming

Saroj Chakraborty, Manikanta S. Arnipalli, Judy J. Baek, Pradeep Kayampilly, Subramaniam Pennathur. Pennathur Lab. *University of Michigan, Ann Arbor, MI*.

Background: Diabetic kidney disease (DKD) is the most common cause of end-statge renal disease and need for renal replacement therapies. Metabolic dysregulation plays a pivotal role in the pathogenesis of DKD. Recent research has highlighted the link between ketone body, beta-hydroxybutyrate (BHB), and kidney function in humans; and the reno-protective effect in animal models via reduction of inflammation and fibrosis and a potential pathway through which SGLT2 inhibitors are effective. However, how BHB exerts its renoprotective effects is unknown and the focus of this work.

Methods: We collected the plasma, urine, and kidney from 24 weeks old diabetic db/db mice and control db/+ mice. BHB was measured by LC-MS based targeted metabolomics. In order to determine whether further increase in BHB would impact DKD, db/db mice were fed with 20% 1,3-Butanediol (v/v in drinking water; 1,3-BD), which is a precursor of BHB and DKD metrics including albuminuria were measured. We quantified post-translational beta-hydroxybutyrylation (BHBylation) of proteins in db/db vs. db/+ mice. In HK-2 cell, mitochondrial function and BHB's effect on TCA cycle metabolism were tested by LC/MS based metabolic flux analysis.

Results: We found that BHB level is significantly higher in plasma (db/+ 26.2±5.8 uM vs db/db 456.95±143.21 uM), urine (db/+ 0.234±0.04 M BHB per M creatinine vs db/db 119.87±33.43 M BHB per M creatinine), and kidney cortex (db/+ 4.48±0.97 pmole BHB per mg protein vs db/db 53.33±17.87 pmole BHB per mg protein) in diabetic mice. 1,3-BD feeding further reduced urinary albumin level (albumin/creatinine: db/db 6.58±2.12 vs db/db+1,3-BD 1.89±0.205) in diabetic mice. We found that diabetic mice have significantly higher BHBylated lysine levels compared to non-diabetic controls. BHB increased the flux of TCA cycle metabolites, implying improved mitochondrial function in HK-2 cells.

Conclusions: To summarize, BHB and BHBylated protein levels were higher in diabetic conditions, and supplementation with the BHB precursor, 1,3-Butanediol, led to lower urinary albumin excretion consistent with improved DKD. Increased in BHBylation associated with this protection suggests key role of this posttranslational modification in mediating improved mitochondrial function (enhanced TCA flux), metabolic rewiring in DKD and associated renoprotection.

SA-PO289

Dissection of Key Molecular Events in Podocyte Response to Hyperinsulinemia and Its Implications in Prediabetic Microalbuminuria

Mengxuan Chen, Yan Ge, Lance D. Dworkin, Rujun Gong. *The University of Toledo Medical Center, Toledo, OH*.

Background: Epidemiological evidence suggests that insulin resistance, manifested as compensatory hyperinsulinemia, is an independent risk factor for chronic kidney disease. However, whether hyperinsulinemia *per se* is a cause for kidney injury is unknown.

Methods: Pre-diabetic *db/db* mice were examined for renal histology, glycemia, insulinemia and albuminuria. Insulin signaling profile was estimated in glomerular podocytes in *db/m* and *db/db* mice. Immortalized podocytes were exposed to high ambient insulin, following ectopic expression of a kinase-dead mutant of GSK3β (KD), a constitutively active GSK3β mutant (S9A), or treatment with a GSK3β inhibitor tideglusib. Cell injury and insulin signaling were examined.

Results: Hyperinsulinemia preceded hyperglycemia in pre-diabetic *db/db* mice, and was associated with microalbuminuria and early signs of podocyte impairment. In glomeruli isolated from young *db/db* mice, an exhausted insulin signaling was noted, marked by insulin receptor (INSR) depletion and hypoactivity of insulin signaling mediators like IRS1 and Akt. This was associated with loss of repression of the constitutively active GSK3β, as indicated by diminished inhibitory p-GSK3β^{S9}. GSK3β hyperactivity was also confirmed in glomerular podocytes in pre-diabetic *db/db* mice, correlating with the degree of hyperinsulinemia or microalbuminuria. Furthermore, GSK3β co-localized and physically interacted with IRS1 in podocytes, suggesting IRS1 acts as a putative substrate for GSK3β. In cultured podocytes, prolonged exposure to high ambient insulin depleted the expression of INSR, leading to GSK3β hyperactivity and inhibitory p-IRS1^{S332}. S9A reinforced inhibitory p-IRS1^{S332} and thereby desensitized insulin signaling, as evidenced by further reduction in Akt phosphorylation. This was associated with exacerbated podocyte injury. Conversely, KD mitigated the inhibitory p-IRS1^{S332} and thereby restored insulin signaling sensitivity, resulting in attenuated podocyte injury. This protective effect was mimicked by tideglusib.

Conclusions: Hyperinsulinemia elicits podocyte injury and microalbuminuria *via* a series of key molecular events, involving depletion of INSR, desensitization of insulin signaling, and GSK3β hyperactivity, which promotes inhibitory p-IRS1^{S332} and thereby forms a vicious cycle of insulin signaling resistance and podocyte injury.

SA-PO290

Modulation of IRS1 Activity by GSK3β Dictates Insulin Signaling Sensitivity in Podocytes: Implications for Diabetic Kidney Disease

Mengxuan Chen, Yan Ge, Lance D. Dworkin, Rujun Gong. *The University of Toledo Medical Center, Toledo, OH.*

Background: Insulin signaling in kidney cells, in particular podocytes, plays a critical role in kidney homeostasis independent of glycemic levels. As a critical transducer of insulin signaling, GSK3β also acts as a convergent point for myriad pathways implicated in kidney injury. However, its role in DKD remains elusive.

Methods: Mouse podocytes were exposed to insulin or a type 2 diabetic milieu, following GSK3β silencing, ectopic expression of a constitutively active GSK3β mutant (S9A), or treatment with tideglusib, an inhibitor of GSK3β. Podocyte injury and insulin signaling were assessed and validated in kidneys from *db/db* or control mice.

Results: Upon insulin stimulation, insulin signaling mediators like Akt and GSK3β, were phosphorylated, associated with increased glucose uptake and expression of GLUT1 and 4. GSK3β silencing sensitized insulin signaling, marked by potentiated induction of p-Akt and p-ERK1/2 and enhanced glucose uptake and GLUT expression. Conversely, S9A de-sensitized insulin signaling and mitigated GLUT induction and glucose uptake. Among the many insulin signaling transducers, IRS1 co-precipitated and interacted with GSK3β. Moreover, *in silico* analysis indicated that IRS1^{S332}, which is known to negatively regulate IRS1 activity and target IRS1 for proteasomal degradation, resides in the consensus motifs for phosphorylation by GSK3β. Indeed, insulin-induced p-IRS1^{S332} was suppressed by GSK3β silencing but was enhanced by S9A. Furthermore, in podocytes exposed to a type 2 diabetic milieu, inhibitory p-GSK3β^{S9} was suppressed, denoting GSK3β hyperactivity. This was associated with enhanced p-IRS1^{S332}. Tideglusib treatment counteracted this effect, re-sensitized insulin signaling, and averted diabetic podocyte injury. In *db/db* mice, glomerular expression of p-IRS1^{S332} was augmented in glomerular podocytes. Based on immunoblotting of isolated glomeruli, the expression ratio of p-GSK3β^{S9}/GSK3β in glomeruli was repressed in *db/db* mice as compared with control mice, denoting GSK3β hyperactivity, and this was negatively correlated with the level of p-IRS1^{S332}.

Conclusions: Diabetes-associated GSK3β hyperactivity promotes IRS1 phosphorylation, contributing to desensitization of insulin signaling in podocytes. Therapeutic targeting of GSK3β could re-sensitize insulin signaling in podocytes *via* regulation of IRS1.

Deletion of Angiotensinogen in Renal Tubule Attenuates Diabetic Kidney Disease Progression in Diabetic Mice

Wenxia Yang,[1] Ke Su,[1] Jing Zhou,[1] Min-Chun Liao,[1] Junzheng Peng,[1] Daniel N. Leal,[4] Michifumi Yamashita,[4] Kana Miyata,[5] Janos G. Filep,[3] Julie R. Ingelfinger,[2] Shao-Ling Zhang,[1] John S. Chan.[1] *[1]Centre de Recherche du Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [2]Massachusetts General Hospital, Boston, MA; [3]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [4]Cedars-Sinai Medical Center, Los Angeles, CA; [5]Saint Louis University, St Louis, MO.*

Background: We previously reported that mice overexpressing angiotensinogen (AGT) in renal proximal tubular cells (RPTCs) developed hypertension and kidney injury Kidney Int. 2006). AGT is highly expressed in renal tubules (RTs) in mice and patients with diabetic kidney disease (DKD). We investigated whether genetic deletion of *Agt* only in renal tubules (RT) could attenuate DKD progression in type 1 diabetic Akita mice.

Methods: Male Akita mice with RT-specific *Agt* knockout (Akita RT-*Agt* KO) at 20 weeks of age were studied +/- selective A1 adenosine receptor inhibitor (A1aRi), which counteracts the effect of RT-*Agt* KO. Male Akita controls were also studied. We examined immunohistochemistry in kidney sections, electron microscopy to assess glomerulus basement membrane (GBM) thickness and podocyte foot process effacement, intra-vital confocal microscopy to determine the diameter of glomerular afferent and efferent arterioles, and Western blot and real-time qPCR of protein and gene expression in isolated renal proximal tubules (RPTs). HK2 (human immortalized RPTC cell line) cells were also studied.

Results: Akita RT-*Agt* KO mice had slightly lower systolic blood pressure and fasting blood glucose levels than Akita mice. Akita RT-*Agt* KO mice displayed significantly attenuated oxidative stress, decreased glomerular hyperfiltration, and decreased glomerulomegaly, tubular injury score, podocyte loss, GBM thickness and podocyte foot process effacement. These findings were associated with decreased urinary albumin/creatinine ratio (UACR), urinary AGT and Ang II levels and SGLT2 expression in RPTs. Intra-vital microscopy revealed decreased afferent arteriole (AA) diameter and increased efferent arteriole (EA) diameter in Akita RT-*Agt* KO mice cf. Akita mice. Treatment of Akita RT-*Agt* KO mice with A1aRi increased glomerular filtration rate. In cultured HK2 cells, Ang II stimulated SGLT2 expression, which was attenuated by losartan, NADPH oxidase inhibitors and antioxidants.

Conclusions: RT-specific *Agt* deletion mitigated DKD progression in Akita mice by reducing glomerular hyperfiltration and UACR, decreasing AA and increasing EA diameter, and decreasing podocyte loss, GBM thickness, podocyte foot process effacement and SGLT2 expression in RTs.

Deletion of Angiotensinogen in Renal Tubules Attenuates Tubular Senescence in Diabetic Kidney Disease

Wenxia Yang,[1] Ke Su,[1] Min-Chun Liao,[1] Junzheng Peng,[1] Kana Miyata,[2] Janos G. Filep,[3] Julie R. Ingelfinger,[4] Shao-Ling Zhang,[1] John S. Chan.[1] *[1]Centre de Recherche du Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [2]Saint Louis University, St Louis, MO; [3]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [4]Massachusetts General Hospital, Boston, MA.*

Background: We reported previously that renal tubule (RT)-specific angiotensinogen (*Agt*) deletion attenuates kidney injury in type 1 diabetic Akita mice by reducing glomerular hyperfiltration, tubular injury score, urinary albumin-creatinine ratio and SGLT2 expression in renal proximal tubules (RPTs) (ASN'23, SA-PO423). Angiotensin II (Ang II) elicits reactive oxygen species (ROS), triggering oxidative DNA damage, cellular senescence and senescence-associated secretory phenotype (SASP). This study aimed to investigate whether RT-*Agt* deletion attenuates kidney injury by mitigating tubular senescence in Akita mice.

Methods: Diabetic Akita mice with RT-specific deletion of *Agt* (Akita RT-*Agt KO*) were generated by crossbreeding Pax8-Cre mice with *Agt*-floxed Akita mice. Male non-diabetic control, RT-*Agt* KO, Akita, and Akita RT-*Agt* KO mice were studied at 20 weeks of age. In vitro, Madin-Darby Canine Kidney (MDCK, a distal tubule (DT) cell line) cells and HK-2 (human immortalized proximal tubule cell line) cells were used.

Results: Akita mice exhibited increased urinary AGT and Ang II, as well as senescence-associated β-galactosidase positive renal tubules vs. control and RT-*Agt* KO mice and these were normalized in Akita RT-*Agt* KO mice. Notably, immunofluorescent staining of Ang II was increased and colocalized with the DT marker (lycopersicon esculentum lectin (LEL)) in Akita mice, along with elevated markers of oxidative DNA damage (8-Hydroxy-2'-deoxyguanosine (8-OHdG)) and senescence marker (p16) staining. These changes were normalized in Akita RT-*Agt* KO mice. Moreover, SASP components including CCL2, CXCL1, and TNF-α mRNA were upregulated in Akita mouse kidneys and attenuated in Akita RT-*Agt* KO mice. In vitro, Ang II-induced senescence in MDCK, which was attenuated by losartan (an AT1R blocker) or NAC

(N-acetyl L-cysteine, an ROS inhibitor). Finally, addition of senescent MDCK-derived conditioned medium to HK-2 culture facilitated the epithelial-to-mesenchymal transition, which was reversed by losartan or NAC treatment.

Conclusions: RT-derived Agt/Ang II triggers cellular senescence in renal tubules via ROS-mediated DNA damage and the p16 pathway, leading to SASP and increased tubular injury in Akita mice. These results highlight the importance of inhibiting intrarenal RAS to prevent DKD progression.

SA-PO293

Improving the Histological Classification of Diabetic Nephropathy Based on Transformative Research in Diabetic Nephropathy (TRIDENT)

Samer Mohandes,[1] Amy K. Mottl,[2] Julia J. Scialla,[3] Salem Almaani,[4] Tamara Isakova,[5] Shweta Bansal,[6] Christos Argyropoulos,[7] Gaia M. Coppock,[1] J. Charles Jennette,[2] Katalin Susztak,[1] Matthew Palmer.[1] *[1]University of Pennsylvania, Philadelphia, PA; [2]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [3]University of Virginia, Charlottesville, VA; [4]The Ohio State University Wexner Medical Center, Columbus, OH; [5]Northwestern University Feinberg School of Medicine, Chicago, IL; [6]The University of Texas at San Antonio, San Antonio, TX; [7]University of New Mexico Health Sciences Center, Albuquerque, NM.*

Background: Diabetic Nephropathy is the most common cause of kidney disease in the world. The diagnostic and prognostic utility of the current Renal Pathology Society Classification (RPS) system is not established. We aim to evaluate RPS system and compare it with our proposed Transformative Research in Diabetic Nephropathy (TRIDENT) histopathologic classification.

Methods: TRIDENT is a multicenter prospective observational study of subjects with diabetes mellitus undergoing a kidney biopsy. Unsupervised k-means clustering of 29 light microscopy features divided the cohort into 5 clusters. The association of this TRIDENT classification with kidney outcomes, defined as 40% change in eGFR or ESRD over 4 years of follow-up, was assessed by Cox proportional hazard models with Harrell's C-statistic for predictive accuracy. Decision curve analysis was used to compare the potential clinical utility of the TRIDENT and RPS classifications across risk thresholds.

Results: The RPS class showed some association with kidney outcomes, but not between classes 3&4 (65% of the cohort). The TRIDENT classification (table 1) grouped the cohort into risk groups with better predictive accuracy of renal risk at 1 year (AUC 0.75 vs 0.66) and 2 years (AUC 0.8 vs 0.74) compared to RPS. Class 5, which includes epithelial features, had the most rapid progression. Addition of the TRIDENT classification to the 2 year kidney failure risk equation resulted in improved discrimination (C statistic 0.759-0.766, ROC AUC at 2 years 0.803-0.837). A higher net benefit in the TRIDENT classification compared to RPS was seen using a decision curve analysis.

Conclusions: We developed a new TRIDENT classification system that improves on currently used methods to capture the severity of DN and predicts kidney outcomes. This classification identifies a subgroup with significant epithelial changes and a more severe kidney outcome.

Funding: Commercial Support - TRIDENT consortium

TRIDENT Classification System

TRIDENT Class	Description
1	GBM thickness without mesangial expansion
2	Mesangial matrix expansion without KW nodules
3	Mesangial matrix expansion and KW nodules without mesangiolysis
4	Mesangiolysis without epithelial hyperplasia
5	Mesangiolysis with epithelial hyperplasia

SA-PO294

Clinical Characteristics of Nodular Lesions in Patients with Diabetic Kidney Disease

Hisashi Kamido, Shigekazu Kurihara, Masayuki Yamanouchi, Tatsuya Suwabe, Yoshifumi Ubara, Naoki Sawa. *Toranomon Byoin Bunin, Kawasaki, Japan.*

Background: Nodular lesions are recognized as typical renal pathology findings in patients with diabetic kidney disease (DKD), although many cases without nodular lesions have also been documented. In diabetic animal models, maintaining a hyperglycemic state alone rarely results in nodular lesions, suggesting the involvement of other contributing factors. However, the pathogenesis remains unclear. This study investigates nodular lesions' clinical features in patients with DKD.

Methods: We conducted a retrospective study of 163 patients diagnosed with DKD via renal biopsy at our institution from 2008 to 2023. The patients were divided into two groups: those with nodular lesions and those without. We examined clinical and laboratory examinations, as well as renal pathology findings.

Results: Comparing the groups with and without nodular lesions, there were no significant differences in renal function (eGFR 34.2 ml/min/1.73m^2 vs. 36.4 ml/min/1.73m^2, p=0.92) or HbA1c (6.9% vs. 6.9%, p=0.43) at the time of biopsy. However, the group with nodular lesions was younger (56 years vs. 70 years, p<0.01) and had a shorter duration of type 2 diabetes (13 years vs. 18 years, p<0.02). Despite these factors, this group exhibited higher systolic blood pressure (152mmHg vs. 137mmHg, p<0.01), higher rates of hematuria (23% vs. 10%, p<0.03), and higher levels of proteinuria (6.2 g/gCr vs. 2.8 g/gCr, p<0.01). Additionally, the group with nodular lesions had higher rates of retinopathy (79% vs. 52%, p<0.01) and dialysis initiation (60% vs. 36%, p<0.01), as well as a shorter duration from biopsy to dialysis (4 years vs. 10 years, p<0.01). Light microscopy findings revealed that the group with nodular lesions had greater intimal thickening in interlobular arteries (p<0.01) and a higher incidence of exudative lesions (80% vs. 61%, p<0.02) and mesangiolysis (62% vs. 21%, p<0.01).

Conclusions: If hyperglycemia were the primary factor in the formation of nodular lesions, an increase in nodular lesions would be expected in older patients with a longer history of diabetes. However, our study found that the group with nodular lesions was younger with a shorter duration of diabetes. This group also exhibited higher blood pressure, more exudative lesions, and mesangiolysis, suggesting that endothelial cell injury plays a crucial role in the formation of nodular lesions.

Challenge of Kidney Biopsy in Diabetic Patients: A Northwest Italy Large Cohort

Roberta Fenoglio, Dario Roccatello. *CMID-nephrology and Dialysis Unit, San Giovanni Bosco Hospital and University of Turin, Torino, Italy.*

Background: Diabetic kidney disease is one of the most severe long-term complications of diabetes. The aim of the study was to retrospectively analyze monocentric case history of kidney biopsies performed in diabetic patients over a period of 10 years. Patient's data were collected both at the time of histological examination and during follow-up

Methods: Data of renal biopsies (RB) performed in patients with diabetes mellitus from 1st January 2014 to 31th July 2023, were collected. Patient identification was performed by reviewing clinical histories and histopathological charts. Data on the indication for RB were collected from the medical report of the hospitalisation when the procedure was performed or from the visit when the indication was given.

Results: 297 patients were included in the study, regardless of diagnostic suspicion and histological findings. Histological examination revealed diabetic nephropathy (DN) in 112 cases (group 1), DN associated with another kidney disease in 56 cases (group 2) and nondiabetic renal diseases alone in the remaining 129 cases (62%) (group 3). In group 2 the kidney disease most frequently associated with DN was focal and segmental glomerulosclerosis, FSGS followed by IgA nephropathy, IgAN. The histological examination led to specific therapeutic indications in 22 pts. In group 3 the most frequently observed kidney disease was FSGS followed by ANCA-vasculitis, membranous nephropathy and IgAN. In this population, histological examination led to a specific therapeutic indication in 67 pts. During a mean follow up of 41.6±31.8 months, 53 pts reached ESKD (16.5 months). In our population the presence of DN associated with another biopsy-proven nephropathy was especially prevalent. Having double nephropathy conferred a relative risk-RR for dialysis of 1.8089 (95% CI 1.0094 to 3.2415, p=0.0464).

Conclusions: To our knowledge this is the largest cohorts of diabetic patients receiving renal biopsy even reported in a Western country. Our data proved kidney biopsy not to be an academic exercise in diabetic pts. Clinical and laboratory features do not predict histologic findings. Renal biopsy allowed the identification of unsuspecting nondiabetic kidney injuries and double nephropathies, which could be susceptible to different outcomes, and paved the pathway for treatment of potentially manageable histological changes.

SA-PO296

Utility of Kidney Biopsy in Patients with Diabetic Nephropathy: A Retrospective Study of 13,995 Cases

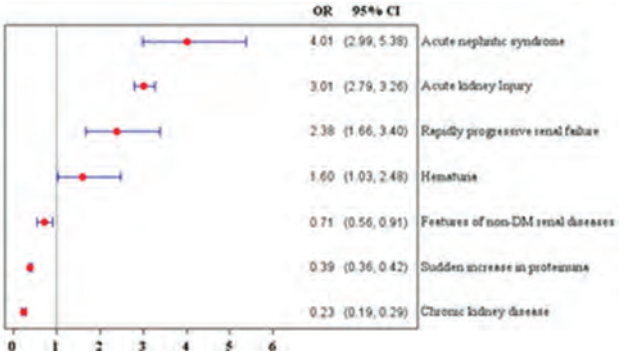
Tiffany Caza,[1] Vivek Charu,[2] Dao-Fu Dai,[4] Vicki G. Davis,[3] Patrick D. Walker.[1] *[1]Arkana Laboratories, Little Rock, AR; [2]Stanford University School of Medicine, Stanford, CA; [3]Statistical Consultant, Afton, VA; [4]Johns Hopkins Medicine, Baltimore, MD.*

Background: The number of renal biopsies performed in patients with diabetes has increased rapidly in the last twenty years. The value of the biopsy has been questioned because of the reported variability of finding a non-diabetic kidney disease (NDKD). We sought to determine the percentage of patients with a NDKD or diabetic nephropathy (DN) alone and to determine clinical indications, demographic factors, and histologic parameters that increase the odds of finding a NDKD on kidney biopsy.

Methods: A retrospective analysis of clinical and pathologic parameters from patients with DN received from 2001 through 2022 at Arkana Laboratories was performed. Inclusion criteria included a diagnosis of DN, available clinical information, and an adequate biopsy with ≥10 glomeruli.

Results: A total of 13,995 patients with DN were identified. A second diagnosis of a NDKD was identified in 27.1%. Of the 55 different NDKD diagnoses, acute tubular injury and infection-associated glomerulonephritis accounted for almost 50%. Acute kidney injury and acute nephritic syndrome had greater odds of a second diagnosis (Figure 1). The youngest (≤30 years) and oldest (≥60 years) patients had a higher prevalence of a second diagnosis. Higher chronicity indices on biopsy were associated with a lower prevalence of a second diagnosis.

Conclusions: Patient age and clinical indication for biopsy influences the odds of finding a NDKD on biopsy. Given the wide array of NDKDs found (55 diagnoses in total), the renal biopsy remains a critical tool in the care of diabetic patients.



Odds of a second diagnosis by clinical indication. Odds ratios (OR) and 95% confidence intervals (95% CI) for a second diagnosis are presented by clinical indication for N=13,995 renal biopsies with a diagnosis of diabetic nephropathy. ORs >1 (<1) imply a higher (lower) probability of a second diagnosis for patients presenting with that clinical indication versus patients with a different indication.

SA-PO297

Characterization of Diabetic Kidney Disease in 235 Patients: Clinical and Pathological Insights with or without Nondiabetic Kidney Disease

Qin Zhu. *Hangzhou Hospital of Traditional Chinese Medicine, Hangzhou, China.*

Background: Diabetic kidney involvement primarily manifests as diabetic kidney disease (DKD). However, some diabetic patients may solely present with diabetes mellitus or non-diabetic kidney disease (NDKD), or DKD combined with NDRD. This study statistically analyzed patients with DKD alone and DKD+NDKD, investigating their pathological and clinical characteristics, and identifying the independent factors associated with DKD+NDKD to aid clinical differentiation.

Methods: A retrospective analysis of 235 patients admitted to the Department of Nephrology at Hangzhou Hospital of Traditional Chinese Medicine was conducted between 2014-7 and 2022-12. These patients underwent renal biopsy and received a pathology-based diagnosis of DKD. They were categorized into the DKD alone group (93 cases) and the DKD+NDKD group (142 cases). DKD pathology grading criteria published in the American Journal of Kidney Diseases were used as a reference for grading.

Results: In the DKD alone group, gender distribution was even, with ages mainly between 50-59 years, and a disease duration of less than 5 years, primarily presenting nodular diabetic glomerulosclerosis. In contrast, the DKD+NDKD group had a higher male incidence, a wider age range, longer disease duration, and prevalent diffuse diabetic glomerulosclerosis. Acute and chronic tubulointerstitial lesions and IgA nephropathy were the predominant types of combined NDKD, accounting for 40.14% and 35.21%, respectively. Clinical correlation analysis revealed associations between glomerular grading, tubulointerstitial lesions, renal arteriolar vitelliform lesions, renal vascular atherosclerosis, and clinical parameters such as 24-hour urine protein, hemoglobin, and urinary specific gravity. Multifactorial logistic regression analysis identified independent factors affecting DKD+NDKD, including body mass index, serum creatinine (Scr), microscopic erythrocyte grade, urinary immunoglobulin G (IgG)/creatinine ratio, and serum immunoglobulin A (IgA).

Conclusions: Our research underscores distinctions in age, gender distribution, disease duration, and renal pathology between DKD alone and DKD+NDKD groups. Additionally, significant discriminative factors including BMI, Scr, microscopic erythrocyte grade, UIgG/urine creatinine ratio, and serum IgA levels help differentiate DKD from NDKD, thereby enabling personalized treatment approaches.

SA-PO298

Establishment and Validation of a Risk Prediction Model for Kidney Prognosis of People with Type 2 Diabetic Kidney Disease Diagnosed by Kidney Biopsy

Wenjian Wang,[1] Xiaojie Chen.[1,2] *[1]Department of Nephrology, Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, Southern Medical University, Guangzhou, China; [2]Department of Nephrology, the First Affiliated Hospital of Shenzhen University, Shenzhen Second People's Hospital, Shenzhen, China.*

Background: Diabetic kidney disease (DKD) is the most common cause of end-stage renal disease (ESRD) and is associated with increased morbidity and mortality in patients with diabetes. Identification of risk factors associates with renal progression(50%eGFR decline and/or progressed to ESRD) of DKD is expected to result in early detection and intervention and improve prognosis.

Methods: Between January 2010 and December 2023, a total of 186 Chinese patients with T2DM and DKD confirmed by renal biopsy were enrolled and followed up for at least 90 days. Three machine learning algorithms (Logistic Regression, LASSO and stepwise AIC) were used to identify the critical clinical and pathological features and to build a risk prediction model for renal prognosis.

Results: There were 107 renal outcome events (57.53%) during the 2.27 year median follow up. The stepwise AIC algorithm showed the best performance at predicting progression to ESRD, showing the highest AUC (0.88). The stepwise AIC algorithm identified eight major factors: HDL-C, gender, hemoglobin (Hb), 24-hour urine urinary total protein, 24-hour urine urea nitrogen, baseline estimated glomerular filtration rate, age and renal hyalinosis of renal arterioles.

Conclusions: Our model can efficiently predict the incident renal prognosis in DKD patients. Compared with the previous models, the importance of 24-hour urine urea nitrogen, Hb, and renal hyalinosis of renal arterioles were highlighted in the current model.

Funding: Government Support - Non-U.S.

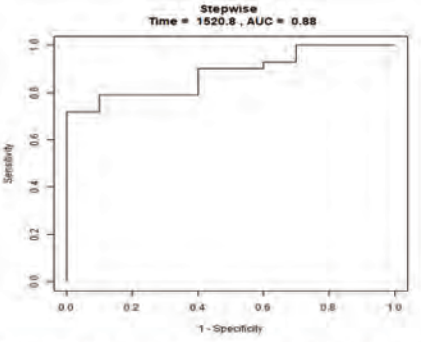


Figure 1. ROC for stepwise AIC algorithm predicts the results of renal prognosis in validate data set.

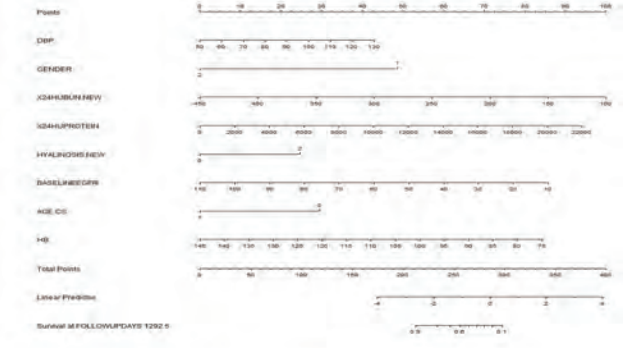

Figure 2. Prognostic nomogram to predict individual renal survival probability in T2DM patients with DKD diagnosed by biopsy. The nomogram allows the user to obtain renal survival corresponding to a patient's combination of variables. Points are assigned for each variable by drawing a straight line upward from the corresponding value to the "Points" line. Then, sum the points received for each variable, and locate the number on the "Total Points" axis.

Exploring the Subtle, Novel, and Early Kidney Pathological Changes in Diabetic Nephropathy Using Clustering with Deep Learning

Tomohisa Yabe, Ai Fujii, Keiichiro Okada, Norifumi Hayashi, Keiji Fujimoto, Hitoshi Yokoyama, Kengo Furuichi. *Kanazawa Ika Daigaku, Kahoku-gun, Japan*.

Background: As diabetes mellitus (DM) is a leading cause of CKD, early diagnosis of diabetic kidney disease is essential to decrease the number of chronic kidney disease (CKD). However, the pathological changes occurred in early stages of diabetic nephropathy have not been fully elucidated yet.

Methods: Nephrectomized kidneys (partial/total) in Kanazawa Medical University from 1998 to 2019 were used in this study. We performed invariant information clustering (IIC)-based clustering on glomerular images obtained from nephrectomized kidneys of patients with and without diabetes. Visualizing techniques (gradient-weighted class activation mapping (Grad-CAM) and generative adversarial networks (GAN)) were also used to identify the novel and early pathological changes on light microscopy in diabetic nephropathy.

Results: Overall, 13,251 glomerular images (7,799 images from diabetes cases and 5,542 images from non-diabetes cases) obtained from 45 patients were clustered into 10 clusters by IIC. Diabetic clusters that mainly contained glomerular images from diabetes cases (Clusters 0, 1, and 2) and non-diabetic clusters that mainly contained glomerular images from non-diabetes cases (Clusters 8 and 9) were distinguished in the t-distributed stochastic neighbor embedding (t-SNE) analysis. Grad-CAM demonstrated that the outer portions of glomerular capillaries in diabetic clusters had characteristic lesions. Cycle-GAN showed that compared to Bowman's space, smaller glomerular tufts was a characteristic lesion of diabetic clusters.

Conclusions: The findings in this study would be the novel and early pathological changes on light microscopy in diabetic nephropathy and could be key to its early diagnosis to reduce the number of patients with CKD.

Funding: Government Support - Non-U.S.

Morphometric Analysis of Different Nephron Segments in Patients with Diabetic Nephropathy and Overt Proteinuria

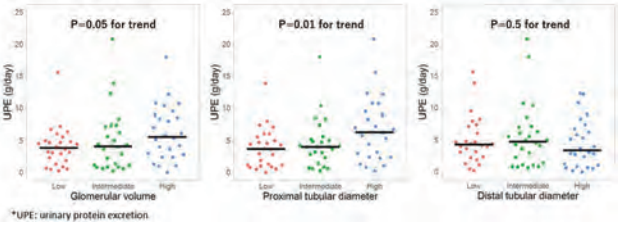
Akane Miura, Masahiro Okabe, Takaya Sasaki, Yusuke Okabayashi, Kotaro Haruhara, Nobuo Tsuboi, Takashi Yokoo. Dept of Nephrology and Hypertension, The Jikei University School of Medicine. *Tokyo Jikeikai Ika Daigaku, Minato-ku, Japan*.

Background: Patients with diabetic nephropathy (DN) are characterized by kidney enlargement, and heavy proteinuria is associated with poor kidney function outcomes. The relationship between hypertrophic changes in single nephrons and the development of proteinuria has not been studied in DN patients.

Methods: Glomerular volume (V_{glom}), proximal tubular diameter (D_{prox}) and distal tubular diameter (D_{dist}) were measured using biopsy specimens from DN patients with overt proteinuria. Nephron-related parameters were estimated using combination of computed tomography imaging and biopsy stereology. These include number of total non-globally sclerotic glomeruli (N_{NSG}), number of globally sclerotic glomeruli (N_{GSG}) and single-nephron GFR (SNGFR), which was estimated by deviding eGFR by N_{NSG} of both kidneys. The proteinuria level at biopsy were compared among tertile groups based on V_{glom}, D_{prox}, and D_{dist}.

Results: A total 78 patients were included in this study (median 56 [quartile 46-67] years, 82% male, eGFR 40.0 [27.4-53.5] ml/min/1.73m^2, urinary protein 4.3 [2.0-6.9] g/day). Of the V_{glom}, D_{prox}, and D_{dist} tertiles, only D_{prox} showed a significant trend to correlate with urinary protein levels (**Figure**). Among the D_{prox} tertile, there were no differences in age, sex, hypertension, eGFR, and HbA1c among the groups, while body mass index showed an increasing trend with D_{prox}. N_{NSG}, N_{GSG}, and SNGFR were not statistically different among the D_{prox} tertile. D_{prox} showed an increasing trend with glomerular lesions characteristic of DN, but V_{glom}, and D_{dist} did not show such a trend.

Conclusions: The present study is the first to morphologically demonstrate the involvement of proximal tubular hypertrophy in the pathophysiology of proteinuria in DN. Morphological findings of different nephron segments, as shown in this study, may provide clinically useful insights when combined with response to treatment and kidney function outcomes.



Comparison of proteinuria levels according to morphological measurement of different nephron segments

SA-PO301

Enlarged Kidney Parenchymal Volume Predicts Poor Kidney Outcomes in Advanced Stage Diabetic Nephropathy

Akane Miura, Masahiro Okabe, Takaya Sasaki, Yusuke Okabayashi, Kotaro Haruhara, Nobuo Tsuboi, Takashi Yokoo. Dept of Nephrology and Hypertension, The Jikei University School of Medicine. *Tokyo Jikeikai Ika Daigaku, Minato-ku, Japan*.

Background: Early diabetic nephropathy (DN) is characterized by enlarged kidneys, but its clinical significance in advanced stages is not well understood. This study aimed to determine whether total kidney parenchymal volume (V_{TKP}) is associated with renal outcomes in advanced stage DN patients with overt proteinuria.

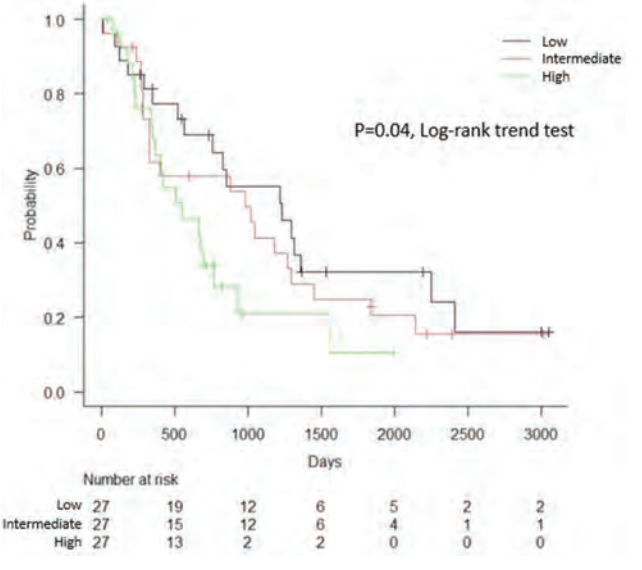
Methods: V_{TKP} was estimated in biopsy-proven DN patients using unenhanced computed tomography imaging. Clinicopathological findings, kidney morphometric parameters and renal outcomes were compared among tertile groups based on V_{TKP}. The end point was defined as a 50% reduction in eGFR or ESKD.

Results: A total 81 patients were included in this study (84% male, median 55 years, eGFR 38 [24-52] ml/min/1.73m^2, urinary protein 4.4 [2.2-7.0] g/day and median 1.8-year follow-up). Median values of V_{TKP} were 111 [98-121], 156 [149-164], and 214 [191-243] cm^3/kidney in the low, intermediate, and high V_{TKP} groups. There were no differences in sex, hypertension, HbA1c and BMI among groups. Age showed a decreasing trend, while eGFR and proteinuria showed an increasing trend with V_{TKP}. In the log-rank trend test, greater V_{TKP} was significantly associated with poor renal outcomes (**Figure**). Interestingly, the associations between V_{TKP} and renal outcomes were independent of age, eGFR and proteinuria levels at presentation (**Table**).

Conclusions: In patients with advanced stage DN, greater V_{TKP} at presentation is associated with poor renal outcomes, independent of kidney function and proteinuria levels.

Cox proportional hazard model

Variable	Hazard ratio	95% confidence interval	P value
Age, per year	1.01	0.99-1.04	0.2
Urinary protein, per g/day	1.10	1.04-1.16	<0.001
eGFR, per mL/min/1.73m2	0.97	0.95-0.98	0.001
VTKP, per 10cm3	1.09	1.01-1.18	0.001



eGFR ≥50% decline or ESKD

Noninvasive Prediction Tool of Nondiabetic Kidney Diseases in Patients with Type 2 Diabetes

Narayan Prasad, Vamsidhar Veeranki, Jeyakumar Meyyappan, Brijesh Yadav.
Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.

Background: Despite being the gold standard in detecting non-diabetic kidney diseases(NDKD) in Type-2 Diabetes Mellitus, renal biopsy has an inherent risk of life-threatening complications. The current study is aimed to develop and validate a non-invasive scoring tool to predict NDKD using clinical and laboratory variables.

Methods: We developed a model to detect NDKD using multivariable binary logistic regression analysis with the backward Wald elimination method. A nomogram was developed from the multivariate logistic regression model and the probability of NDKD was assessed for each predictor variable using the strength of association. We included all patients of T2DM who had an indication kidney biopsy for NDKD during the study period. The model performance was analyzed using AUC-ROC curve on both the derivational (internal validation) and external cohorts from other centers (multicentric external validation).

Results: Out of 538 patients, 376 were included in the derivational, and 162 in the validation cohort. The model consists of the following variables, T2DM duration< 5 years(p=0.003), absence of coronary artery disease(p=0.05), absence of diabetic retinopathy(p=0.001), oliguria(p=0.02), acute rise in s.creatinine(p< 0.001) and low serum C3 level(p=0.001) significantly predicted NDKD on renal biopsy. Using a nomogram, statistical predictive models are converted into a single numerical estimate of probability of NDKD in the form of a graph(Figure.1,2). The model performance performed robustly with an AUC-ROC of 0.869(95% CI:0.805-0.933) in the validation cohort and 0.883(95%CI:0.830–0.937) on multicentric external validation.

Conclusions: The clinical and laboratory parameter-based non-invasive prediction model robustly predicted the NDKD among T2DM patients with renal dysfunction, and the prediction model has a high sensitivity of 86% and an equally good specificity of 80%.

Correlation Analysis between Extracapillary Hypercellularity, Segmental Sclerosis, and Clinical Features of Diabetic Nephropathy

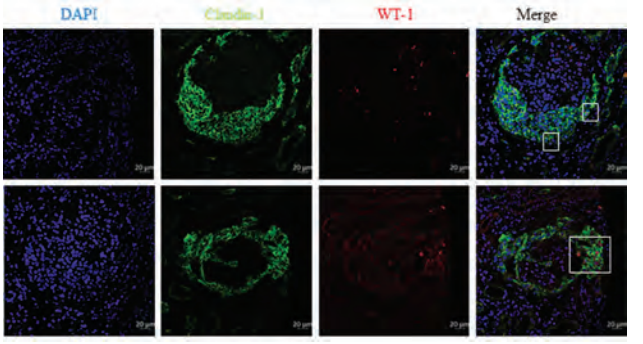
Huan Jiang, Jiaoqing Li, Haosen Xu, Peimin Liu, Ting Zhang, Xiaoyan Bai.
Guangdong Provincial People's Hospital, Guangzhou, China.

Background: Extracapillary hypercellularity(EXHC) and segmental sclerosis(SS) were poor prognostic features of diabetic nephropathy(DN). We stated the difference of EXHC and SS, and analyzed the correlation between EXHC or SS and clinical features. We also evaluated the pathological significance of EXHC and SS and studied the cellular origin of the EXHC structure.

Methods: Clinical and pathological information was collected from 115 biopsy-proven DN patients from 2021 to 2023. Welch t test, Chi-square test or Mann-Whitney U test was used to compare the difference. Correlation analysis was conducted using Spearman correlation analysis. The cellular component of EXHC was shown by immunofluorescence.

Results: The number of patients with EXHC and SS structure was 44 and 79, respcetively. There was significant difference in height between patients with EXHC and those without. There was significant difference in urea nitrogen, uric acid, 24-h proteinuria, urinary protein/creatinine ratio, urinary albumin/creatinine ratio, diabetic retinopathy in patients with SS compared with those without. A positive correlation was found between the number of EXHC and patients' height. Correlation analysis revealed that SS correlated with serum creatinine, e-GFR, urea nitrogen, 24-h proteinuria, urinary protein/creatinine ratio, urinary albumin/creatinine ratio, and diabetic retinopathy. Most of the EXHC structure consisted of Claudin-1 positive glomerular parietal epithelial cells and a little was WT1 positive podocytes.

Conclusions: We found in DN patients with SS, the level of serum creatinine, proteinuria, diabetic retinopathy and low e-GFR was higher than patients without SS. Although EXHC associated with height, the finding that podocytes were observed in the EXHC structure suggested that they may play a role in the formation of the unique structure.



Immunofluorescence staining for Claudin-1(green), WT1(red) in DN patients with EXHC.

Diagnostic Accuracy of MicroRNAs in Diabetic Nephropathy: A Meta-Analysis

Gantsetseg Garmaa,[1] Tamás Kói.[2] *[1]Semmelweis Egyetem, Budapest, Hungary; [2]Budapesti Muszaki es Gazdasagtudomanyi Egyetem, Budapest, Hungary.*

Background: MiRNAs play a significant role in the pathophysiology of diabetic nephropathy (DN), as demonstrated by numerous preclinical and cohort studies. They are potential diagnostic biomarkers but also promising therapeutic agents. However, to accelerate their clinical application, it is crucial to systematically review and summarize their diagnostic performance in various biological samples during DN.

Methods: The systematic search involves five databases following the PROSPERO CRD42021282785 protocol. The study includes individuals with DN and those without (healthy or with diabetes mellitus (DM)). MiRNA detection using qRT-PCR is the index test, while clinical diagnoses confirmed by biopsy or laboratory results serve as reference tests. For meta-analyses, the area under the curve (AUC) sensitivity (SEN), and specificity (SPE) of single or panel miRNAs from each study were extracted and analyzed using R software.

Results: Eighty-seven studies met the eligibility criteria, all included in the meta-analysis. The pooled SEN and SPE results in DN compared to healthy controls for single miRNAs were 0.91 (95% CI: 0.86–0.95) and 0.89 (95% CI: 0.77–0.95), respectively. When DN was compared to DM patients, the pooled SEN and SPE were 0.82 (95% CI; 0.76-0.87) and 0.81 (95% CI; 0.74-0.86) for single miRNAs. In the DN with healthy control, only AUC values for a panel of miR-15b, miR-34a, and miR-636 were reported (0.91, 95% CI; 0.86-0.96), and pooled AUC (pAUC) for single miRNAs was 0.85 (95% CI; 0.81-0.89). The pAUC of DN vs. DM was 0.86 (95% CI; 0.82-0.91) for panel miRNAs and 0.79 (95% CI; 0.75-0.82) for single miRNAs. Among the individual studies, a panel of miR-21 and miR-30-b-5p showed a higher AUC in DN patients than in DM patients, 0.93 (95% CI; 0.86–1.0). For DN, blood samples outperformed urine, with a pAUC of 0.87 compared to 0.84.

Conclusions: MiRNAs can differentiate between DN patients, healthy individuals, and patients with DM. Using miRNA panels for diagnosis is more effective than relying on a single miRNA. Additional large cohorts should investigate the diagnostic performance of miRNAs in different stages of DN and biological sample types.

Circulating Proteins Associated with Apoptosis Processes and Fast Progression to ESKD in Diabetic Kidney Disease

Katsuhito Ihara,[1,2] Eiichiro Satake,[1,2] Zaipul Md Dom,[1,2] Bozena Krolewski,[1,2] Andrzej S. Krolewski.[1,2] *[1]Joslin Diabetes Center, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: Many circulating proteins associated with risk of end-stage kidney disease (ESKD) have been identified in diabetic kidney disease (DKD). However, the biological pathways and disease processes they represent are unknown.

Methods: This global-untargeted proteomic study used the Olink platform to measure the concentrations of 455 proteins in plasma specimens obtained at baseline examination of 405 individuals with DKD. We used logistic regression to examine the associations between these proteins and the development of ESKD. This investigation consisted of two nested case-control studies from the Joslin Kidney Study. One study included individuals with T1D, and the other included individuals with T2D who were at risk of developing ESKD during a 7-15 year follow-up period. For pathway enrichment analysis of the differentially expressed proteins, we applied the Database for Annotation, Visualization, and Integrated Discovery (DAVID 6.8). Additionally, to assess whether the models based on apoptosis proteins captured all the predictive information for ESKD, we applied least absolute shrinkage and selection operator (LASSO) logistic regression.

Results: We identified 46 circulating proteins with elevated concentrations that were associated with the development of ESKD (n=149) during a 7-15 year follow-up period (p value $<10^{-5}$ for all 46 proteins). Twenty of these proteins were enriched in the apoptosis/TNF receptors signaling pathways. A small subset of 5 proteins out of the 46 (KIM-1, TNF-R27, IL-1RT1, TNF-R11A, and TNF-R6B in descending order of predictive ability), summarized as the apoptosis score, along with clinical variables, accurately predicted the risk of progression to ESKD.

Conclusions: Elevated levels of numerous circulating proteins, indicating apoptotic processes and TNF receptors signaling pathways, preceded fast progression to ESKD. These proteins may be used to predict and monitor the disease process leading to ESKD in DKD.

Urine Biomarkers for Diabetic Kidney Disease Progression

Sarah J. Schrauben,[1] Joachim H. Ix,[2] Michael Shlipak,[3] Mirela A. Dobre,[4] Orlando M. Gutierrez,[5] Mark J. Sarnak,[8] Ana C. Ricardo,[9] Steven G. Coca,[10] Jason H. Greenberg,[14] Sushrut S. Waikar,[11] Chirag R. Parikh,[12] Debbie L. Cohen,[1] Chi-yuan Hsu,[13] Jonathan J. Taliercio,[15] Jeffrey R. Schelling,[4] Panduranga S. Rao,[16] Paul L. Kimmel,[6] Joseph V. Bonventre.[7] *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]University of California San Diego, La Jolla, CA; [3]San Francisco VA Health Care System, San Francisco, CA; [4]Case Western Reserve University, Cleveland, OH; [5]The University of Alabama at Birmingham Heersink School of Medicine, Birmingham, AL; [6]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [7]Brigham and Women's Hospital Department of Medicine, Boston, MA; [8]Tufts Medical Center, Boston, MA; [9]University of Illinois Chicago, Chicago, IL; [10]Icahn School of Medicine at Mount Sinai, New York, NY; [11]Boston Medical Center, Boston, MA; [12]Johns Hopkins University, Baltimore, MD; [13]University of California San Francisco School of Medicine, San Francisco, CA; [14]Yale University School of Medicine, New Haven, CT; [15]Cleveland Clinic, Cleveland, OH; [16]University of Michigan, Ann Arbor, MI.*

Background: Urine biomarkers of proximal and distal kidney tubular health and inflammation may provide non-invasive ways to identify individuals with diabetes at risk for CKD progression since the extent of tubulointerstitial pathology is related to diabetic kidney disease progression. Prior studies were limited by use of incidence of end-stage kidney disease as an endpoint, focus on fewer biomarkers, and inconsistent findings.

Methods: We performed a case-cohort study among 898 participants in the Chronic Renal Insufficiency Cohort (CRIC). The subcohort (N=599) comprised a group of randomly selected CRIC participants with diabetes and estimated glomerular filtration rate (eGFR) <60 ml/min/1.73m^2 with urine samples assayed for biomarkers. Cases (N=540) were participants with diabetes whose CKD progressed (incident ESKD or ≥40% eGFR decline). Urine biomarkers were assayed 1 yr after enrollment: monocyte chemoattractant protein-1 [MCP-1], kidney injury molecule-1 [KIM-1], a1-microglobulin, epidermal growth factor [EGF], and uromodulin. Weighted Cox regression models related biomarkers, standardized to urine creatinine (transformed as $\log_2$), with CKD progression and were adjusted for covariates, including eGFR and urine albumin-to-creatinine ratio (UACR).

Results: KIM-1/Cr, MCP-1/Cr, and UACR were most strongly correlated (rho = 0.47 - 0.58). In fully adjusted models, KIM-1/Cr was associated with increased CKD progression (HR 1.16 per 2-fold higher, 95% CI 1.05-1.29) and EGF/Cr was associated with decreased risk of CKD progression (HR 0.83 per 2-fold higher, 95% CI: 0.73-0.95) The highest quartiles of KIM-1/Cr and MCP-1/Cr, compared to the lowest quartile, were associated with increased CKD progression (HR 1.69, 95% 1.14-2.51, and HR 1.65, 95% CI 1.11-2.47, respectively). The highest quartile of EGF/Cr, compared to lowest, was protective against CKD progression (HR 0.59, 95% CI: 0.41-0.85).

Conclusions: Urine MCP-1, KIM-1, and EGF may provide non-invasive ways to assess tubule and interstitial disease and health in diabetes and help identify those at higher risk of CKD progression independent of GFR and albuminuria, and aid in the clinical monitoring of individuals with CKD and diabetes.

SA-PO307

Application and Mechanism of Renal Tubular Perilipin 2 in Predicting the Decline in Kidney Function in Patients with Diabetic Kidney Disease

Rui Shen, Qingqing Ke, Xin Yu, Chunsun Dai, Yang Zhou. *The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: To investigate whether the expression of perilipin 2 (PLIN2) in renal tubular cells could predict a decline in renal function in diabetic kidney disease (DKD) patients and to determine the potential mechanisms involved in renal tubular cell injury induced by PLIN2 during the progression of DKD.

Methods: Control individuals and DKD patients were enrolled in this retrospective cohort study. The relationship between expression of PLIN2 in kidney tubules and estimated glomerular filtration rate (eGFR) slope in DKD patients was predicted by Spearman correlation analysis and a generalized linear model. BKS-db/db diabetic mice and streptozotocin-induced diabetic mice were used. Primary renal tubular cells were treated with glucose and transfected with small interfering RNA or plasmid.

Results: The expression of PLIN2 was markedly greater in the tubules of DKD patients than in those of control subjects. After 24 (12, 39) months of follow-up, the eGFR slope of DKD patients was -7.42 (-19.77, -2.09) ml/min/1.73m^2/year. An increase in the baseline percentage of PLIN2-positive tubules was significantly associated with a change in the eGFR slope during the follow-up period (HR = 1.90, 95% CI: 1.00~3.58), indicating that tubular PLIN2 could predict a decrease in renal function in DKD patients. Both the accumulation of lipid droplets and the expression of PLIN2 were markedly greater in the tubules of diabetic mice than in those of control mice. Glucose treatment induced lipid droplet accumulation and PLIN2 expression in renal tubular cells. PLIN2 deficiency significantly alleviated glucose-induced lipid droplet accumulation, whereas PLIN2 overexpression aggravated glucose-induced lipid droplet accumulation. The decrease in mitochondrial oxygen consumption rate (OCR) in renal tubular cells induced by glucose treatment was alleviated after PLIN2 interference. However, overexpression of PLIN2 directly decreased the mitochondrial OCR.

Conclusions: PLIN2 expression in tubules predicts a decline in renal function in patients with DKD. PLIN2 suppresses mitochondrial aerobic respiration and contributes to the accumulation of lipid droplets in renal tubular cells to promote the progression of DKD.

SA-PO308

Effects of Bardoxolone Methyl on Urinary Proximal Tubular Markers: A Subanalysis of the TSUBAKI Study

Michihiro Hosojima,[1] Shoji Kuwahara,[2] Hideyuki Kabasawa,[1] Shunji Kinoshita,[3] Tomohiro Ichikawa,[3] Akihiko Saito.[4] *[1]Department of Clinical Nutrition Science, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [2]Laboratory of Clinical Nutrition, Department of Nutrition, Graduate School of Human Cultures, The University of Shiga Prefecture, Hikone, Japan; [3]Development Division, Kyowa Kirin Co., Ltd, Tokyo, Japan; [4]Department of Applied Molecular Medicine, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: Bardoxolone methyl (BARD) activates nuclear factor erythroid 2-related factor 2, exhibiting antioxidative and anti-inflammatory properties. BARD has been developed as a therapeutic agent for diabetic kidney disease (DKD). Previous clinical trials have demonstrated that BARD increases the estimated glomerular filtration rate (eGFR) and albuminuria. Animal experiments have suggested that the increase in albuminuria induced by BARD is associated with a decrease in the expression of megalin, a proximal tubule endocytic receptor involved in the reabsorption, metabolism, and degradation of glomerular filtrate proteins. However, the specifics of these effects require further elucidation. This study aimed to measure the urinary concentrations of markers associated with megalin in the proximal tubules using urine samples collected from the TSUBAKI study, a phase II clinical trial of BARD administration in DKD patients conducted in Japan, and to examine changes in these markers and their independent effects on eGFR.

Methods: In the TSUBAKI study, urine samples were collected at baseline and at 4, 8, 12, 16, and 4 weeks after administration. The urinary concentrations of A-megalin (megalin ectodomains), C-megalin (full-length megalin), α_1-microglobulin (α_1-MG), and N-acetyl-β-D-glucosaminidase (NAG) were measured. Statistical analyses were performed using mixed-effects models for repeated measures.

Results: Compared with the placebo group, the BARD group showed significantly increased urinary α_1-MG/creatinine (Cr) and A-megalin/Cr at all time points after the start of administration. However, this increase disappeared after the completion of administration. Similar results were found in urinary α_1-MG/Cr/eGFR and A-megalin/Cr/eGFR. In contrast, there were no changes in urinary C-megalin/Cr and NAG/Cr.

Conclusions: BARD administration resulted in changes in urinary proximal tubule markers. The increase in α_1-MG, a ligand of megalin, following BARD administration was consistent with the reduction in megalin expression observed in animal studies. The increase in urinary A-megalin levels suggests that BARD may stimulate the recycling and shedding of megalin, independent of its effect on increasing eGFR.

SA-PO309

Effects of Empagliflozin on Urinary Megalin and Its Ligand α1-Microglobulin in Patients with Diabetic Kidney Disease

Michihiro Hosojima,[1] Hideyuki Kabasawa,[1] Akihiko Saito.[2] *[1]Department of Clinical Nutrition Science, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [2]Department of Applied Molecular Medicine, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: Sodium-glucose cotransporter 2 (SGLT2) inhibitors were initially marketed as oral hypoglycemic agents acting on proximal tubules (PTs) but have also begun to be used worldwide as renoprotective agents. However, the detailed mechanisms underlying these renoprotective effects remain unclear. Megalin is highly expressed in the apical membranes of PTs and serves as an endocytic receptor for various glomerular-filtered proteins, peptides, and drugs. Previous studies have demonstrated that megalin could play a role in the progression of renal injury as a "gateway molecule" for nephrotoxic substances. Furthermore, measuring urinary megalin excretion may help evaluate the severity and pathophysiology of diabetic kidney disease. In particular, A-megalin (megalin ectodomains) may serve as a novel urinary biomarker of the metabolic load in PTs. Therefore, this study aimed to explore whether measuring the excretion of A-megalin helps evaluate the efficacy of SGLT2 inhibitors, including the evaluation of other PT markers such as α_1-microglobulin (α_1-MG), an endocytic ligand of megalin.

Methods: Forty-seven adult patients with type 2 diabetes and mild to moderate renal dysfunction (HbA1c 7.6±1.2%, eGFR 65.8±17.9 mL/min/1.73 m^2, albuminuria 153.6±305.6 mg/g creatinine (Cr)) were enrolled (UMIN000023902). Urinary excretion of megalin, albumin, and PT markers such as α_1-MG was measured at baseline, one month after starting empagliflozin, and then every three months for 36 months, along with evaluation of changes in eGFR.

Results: There were no significant changes in urinary albumin levels at six months compared to baseline. Urinary α_1-MG showed an increasing trend from 9.2±8.7 mg/g Cr at baseline to 12.1±9.2 mg/g Cr at three months and 12.0±9.3 mg/g Cr at six months, and urinary α_1-MG/g Cr/eGFR exhibited a similar trend. Urinary A-megalin, which was 90.0±62.6 pmol/g Cr at baseline, showed a decreasing trend to 64.3±71.2 pmol/g Cr at three months and 56.3±43.1 pmol/g Cr at six months, and urinary A-megalin/g Cr/eGFR exhibited a similar trend.

Conclusions: Administration of empagliflozin led to decreased urinary A-megalin and increased α_1-MG in patients with diabetic kidney disease, even when considering changes in eGFR. Further detailed evaluations are needed to elucidate the relationship between the renal protective effects and megalin function.

SA-PO310

Renal Blood Flow during Adenosine-Stress by Magnetic Resonance Imaging in a Large Cohort of Patients with Type 2 Diabetes

Niclas Sunde,[1,2] Peter Gaede.[3,2] *[1]Kobenhavns Universitet, Kobenhavn, Denmark; [2]Slagelse Sygehus, Slagelse, Denmark; [3]Syddansk Universitet Det Sundhedsvidenskabelige Fakultet, Odense, Denmark.*

Background: Type 2 diabetes (T2D) affects most organs, and clinical evaluation is a task for most specialties in internal medicine, including not only endocrinology, but notably also cardiology and nephrology. Thus, premature morbidity and mortality in T2D is largely related to cardiovascular disease and to increased risk of renal failure. Diabetic nephropathy is a microvascular complication of T2D and a leading cause of end-stage renal disease.

Methods: 297 patients from Næstved/Slagelse/Ringsted Hospitals participated in the largest global study of its kind, with magnetic resonance imaging of the heart. Since T2D not only affects the heart and circulation but also the kidneys, these studies will not only focus on the heart but will utilize scans to determine, using a new technique, whether patients have normal or reduced kidney blood flow

Results: We found that perfusion of the renal cortex and medulla is lower in patients with T2D than in an age-matched control both during rest and adenosine-stress. During rest, blood perfusion of the renal cortex and medulla were 19% and 15% lower in patients with T2D than in normal age-matched control subjects (P=0.06 by unpaired t-test for renal cortex). The cortical/medulla-perfusion ratio was also lower in patients with T2D than in normal subjects. During adenosine-stress, renal cortical perfusion was 20% lower in patients with T2D than in normal subjects (P<0.001 by unpaired t-test). Renal medullary perfusion decreased to 103±46 SI units in normal subjects vs. 98±31 SI units in patients with T2D. Based on our findings, patients with T2D have comparable renal perfusion responses to adenosine but have lowered rest and stress renal cortical as well as medullary perfusions as compared to normal subjects. Further, patients with T2D during adenosine stress have comparably lower cortex/medulla-perfusion ratios than normal subjects, and hence do not seem to exhibit the same intra-renal redistribution of blood flow from the medulla to the cortex as noted in normal subjects.

Conclusions: We found a reduction in renal blood flow during rest and stress, within a cohort of patients with T2D and a board range of kidney function (uAER, eGFR) and diabetes medication compared to an age matched control group.

Complement Pathway Correlates with Rapid Progression of Type 2 Diabetic Kidney Disease in Korean and American Cohorts

Donghwan Yun,[1] Dong Ki Kim,[1] Yon Su Kim,[1] Maryam Afkarian,[2] Seung Seok Han.[1] *[1]Seoul National University College of Medicine, Jongno-gu, Seoul, Republic of Korea; [2]University of California Davis, Davis, CA.*

Background: Rapid progression of certain patients with diabetic kidney disease (DKD) remains a threatening issue despite existing treatments. However, their pathophysiological characteristics have not been well defined. This study addresses this gap by examining both Korean and American type 2 DKD cohorts through untargeted and targeted urinary proteomics, respectively.

Methods: We conducted untargeted proteomics on urine samples collected at the time of kidney biopsy from Korean patients diagnosed with biopsy-confirmed DKD (SNUH-DN cohort) in the context of type 2 diabetes (n=64) and validated the findings using targeted proteomics on those collected at the time of enrollment in the Chronic Renal Insufficiency Cohort study (n=282, CRIC-T2D cohort). Kidney progression as an outcome was defined as either doubling of serum creatinine, ≥50% decrease in eGFR, or the development of ESKD. For untargeted proteomics, analyses for pathways were employed to identify urinary biomarkers associated with kidney progression.

Results: A total of 1,877 proteins were quantified from the patients in SNUH-DN cohort with eGFR of 55 ml/min/1.73m^2 (IQR 44–75) and a random uPCR of 3.1g/g (1.7–7.0). The urinary proteins were clustered into two groups, and kidney progression was primarily observed in one group. This group, exhibiting a tendency for rapid kidney progression, had an elevated complement pathway as a proteomic set. When certain complement proteins were measured as a target in the patients from CRIC-T2D cohort with a baseline estimated glomerular rate of 42ml/min/1.73m^2 (37–49) and 24-hr urine protein of 0.48g (0.10–1.87), those with a high abundance of complements experienced rapid kidney progression compared to those with low abundance.

Conclusions: Urinary proteomic profiling confirms the involvement of the complement pathway in the rapid progression of type 2 DKD. The results will serve as the basis for studies aimed at manipulating relevant complements for the treatment of patients with type 2 DKD.

Potential Defensive Role of TIM-3 on T Lymphocytes in the Inflammatory Involvement of Diabetic Kidney Disease

Guochun Chen, Xiaojun Chen, Runyan Tang. *The Second Xiangya Hospital of Central South University, Changsha, China.*

Background: The aberrant mobilization and activation of various T lymphocyte subpopulations play a pivotal role in the pathogenesis of diabetic kidney disease (DKD), yet the regulatory mechanisms underlying these processes remain poorly understood. The dysregulation of immune checkpoint molecules on T lymphocytes disrupts kidney homeostasis, instigates pathological inflammation, and promotes DKD progression, becoming a new derection for detecting the mechanism of DKD.

Methods: A total of 360 adult patients with DKD were recruited for this study. The expression of immune checkpoint molecules on T lymphocytes was assessed by flow cytometry for peripheral blood and immunofluorescence staining for kidney tissue. Single-cell sequencing (scRNA-seq) data from the kidneys of DKD mouse model were analyzed.

Results: Patients with DKD exhibited a reduction in the proportion of CD3+TIM-3+ T cells in circulation concurrent with the emergence of significant albuminuria and hematuria (p=0.008 and 0.02, respectively). Conversely, the incidence of infection during DKD progression correlated with an elevation of peripheral CD3+TIM-3+ T cells (p=0.01). Both univariate and multivariate logistic regression analysis revealed a significant inverse relationship between the proportion of peripheral CD3+TIM-3+ T cells and severe interstitial mononuclear infiltration (OR: 0.193, 95%CI: 0.040,0.926, p=0.04).

Immunofluorescence assays demonstrated an increase of CD3+, TIM-3+ and CD3+TIM 3+ interstitial mononuclear cells in the kidneys of DKD patients as compared to patients diagnosed of minimal change disease (p=0.03, 0.02 and 0.002, respectively). seq analysis revealed decreased gene expression of TIM3 on T lymphocytes in DKD compared to control. And TIM3's main ligands, Galectin-9 on immune cells showed a decreasing trend in gene expression as kidney damage worsened.

Conclusions: Our study underscores the potential protective role of TIM-3 on T lymphocytes in attenuating the progression of DKD and suggests that monitoring circulating CD3+TIM3+ T cells may serve as a viable strategy for identifying DKD patients at heightened risk of disease progression.

Artificial Intelligence in the Identification of Key Metabolites Associated with Diabetic Kidney Disease

Inha Jung,[1] Sungjin Park,[3] Soon hyo Kwon,[2] Ji A Seo,[1] Hyeong-Kyu Park,[2] Nan Hee Kim.[1] *[1]Korea University Ansan Hospital, Ansan, Gyeonggi-do, Republic of Korea; [2]Soonchunhyang University Hospital, Yongsan-gu, Seoul, Republic of Korea; [3]Korea University Anam Hospital, Seoul, Republic of Korea.*

Background: Despite the increasing prevalence of DKD, reliable biomarkers for its early detection remain scarce. This study aimed to identify urine and serum metabolites that differentiate between DKD stages through bioinformatics analysis.

Methods: We analyzed 92 participants, categorizing them by eGFR and ACR combinations to identify criteria that best distinguish metabolites. Using these criteria, we trained and validated separate AI models. The criterion with the highest accuracy was selected for further investigation of metabolites that varied under this criterion. To understand the relationships and functions of these metabolites, we conducted a metabolic network analysis.

Results: The classification based on ACR achieved the highest prediction accuracy. We identified nine urine and thirteen serum metabolites common among the top 20 from each group. Four metabolites—Adenosine and 5-MTA in urine, and m2,2G and cis-Aconitic acid in serum—demonstrated significant differences across ACR groups (Fig 1). Metabolic network analysis revealed hub proteins and networks linking these metabolites, with significant mRNA expression differences in hub proteins between healthy controls and those with DKD in both urine and serum networks (Fig 2). Notably, IL4I1 mRNA was identified in both urine and serum.

Conclusions: The ACR-based classification demonstrated the highest accuracy. Urinary adenosine and 5-MTA, and serum m2,2G and cis-aconitic acid showed distinct patterns across ACR groups, highlighting their potential as biomarkers. Metabolic network analysis revealed hub proteins, including IL4I1, and networks connecting these differentially expressed metabolites. Further investigation into IL4I1's involvement in DKD is recommended.

Mature MicroRNA (miRNA)-1287-5p and miRNA-197-5p Are Upregulated in Diabetic Kidney Disease

Jonathan M. Wilson,[1] Eiichiro Satake,[2] Behzad Najafian,[3] Kevin L. Duffin,[1] Andrzej S. Krolewski.[2] *[1]Eli Lilly and Company, Indianapolis, IN; [2]Harvard University, Cambridge, MA; [3]University of Washington, Seattle, WA.*

Background: Our previous study examined tissue expression levels of circulating risk miRNAs associated with end-stage kidney disease (ESKD) in diabetes (Satake et al, JASN 2021). The current study aims to extend these finding with larger cohorts and additional analyses of specific ESKD risk miRNAs to understand expression levels and cellular localization in diabetic kidney.

Methods: Localization and levels of mature miRNAs were examined in kidney specimens using a miRNAscope in situ hybridization (ISH) assay. Optimized in silico–designed miRNAscope probes for miR-1287-5p and miR-197-5p were utilized for analyses of kidney tissue expression. Probes were hybridized to formalin-fixed paraffin embedded sections of kidney biopsy tissue obtained from 8 healthy donors (controls), and persons with mild (N=6) or advanced (N=8) biopsy proven diabetic kidney disease (DKD).

Results: miR-1287-5p and miR-197-5p were detected more abundantly in DKD tissues than in controls. miRNA-197-5p was detected at a higher level than miRNA-1287-5p in DKD sections. In DKD, miR-1287-5p and miR-197-5p were detected in tubular epithelia (with more abundance in distal tubules) and glomeruli. Both miRNAs were detected in focal areas of infiltrating inflammatory cells. Both miRNAs were detected in the cytoplasm as well as the nuclei.

Conclusions: Our studies confirm that ESKD risk miRNAs (miRNA-1287-5p and miRNA-197-5p) have higher kidney tissue levels in DKD than normal, especially in tubular epithelial cells. miRNA-1287-5p was validated across multiple donor tissues to be present in DKD vs normal, while novel data show miRNA-197-5p was also present at higher levels in DKD tissue sections. Kidney may be a source of circulating ESKD miRNAs but cellular uptake of circulating miRNA into the kidney may also contribute to higher observed levels. Further studies of tissue expression patterns of ESKD miRNAs will help to advance our understanding of the pathology of DKD and the role of miRNA in disease signaling.

Genetic Risk Factors for Kidney Disease in Type 1 Diabetes

Christine P. Limonte,[1] Xiaoyu Gao,[4] Ionut Bebu,[4] Amy B. Karger,[2] Gayle Lorenzi,[5] Bruce A. Perkins,[3] Ian De Boer,[1] Andrew Paterson.[3] *[1]University of Washington, Seattle, WA; [2]University of Minnesota Twin Cities, Minneapolis, MN; [3]University of Toronto, Toronto, ON, Canada; [4]The George Washington University, Washington, DC; [5]University of California San Diego, La Jolla, CA.*

Background: The genetic risk factors underlying kidney disease in type 1 diabetes (T1D) remain poorly understood. We examined whether previously-established genetic risk scores (GRS) for eGFR and albuminuria from general population cohorts correlate with these measures in adults with T1D beyond established demographic and clinical risk factors in the Diabetes Control and Complications Trial (DCCT)/Epidemiology of Diabetes Interventions and Complications (EDIC) study.

Methods: We applied eGFR and albuminuria GRS derived previously in general population cohorts to 1,304 DCCT/EDIC participants with available genome-wide genotyping. Associations of eGFR GRS with continuous eGFR and of albuminuria GRS with continuous albumin excretion rate (AER) were assessed using linear regression models. Associations of eGFR GRS with incident eGFR <60 ml/min/1.73m^2 and of albuminuria GRS with sustained AER ≥ 30mg/24h and AER ≥ 300 mg/24h were assessed using Cox proportional hazards models. Models were adjusted for age, sex, hemoglobin A1c, diabetes duration, systolic blood pressure, triglycerides, and beta-blocker use.

Results: Overall, participants had a mean age of 60 years and 53% were male. 49% of participants were randomized to intensive versus conventional glucose-lowering therapy in the DCCT. Participants were followed for a median (IQR) 35 (33, 37) years. eGFR GRS was significantly associated with continuous eGFR (2.7±0.3 ml/min/1.73m^2 higher eGFR per 1 SD higher GRS; p<0.0001) and incident eGFR <60 ml/min/1.73m^2 (HR=0.83 [95% CI 0.74, 0.93] per 1 SD higher GRS; p=0.001). Albuminuria GRS was significantly associated with incident AER ≥30mg/24h (HR=1.12 [95% CI 1.03, 1.23] per 1 SD higher GRS; p=0.01), but not incident AER ≥300mg/24h or continuous AER. Associations were similar in analyses stratified by the original DCCT treatment group assignment (intensive versus conventional insulin therapy).

Conclusions: Genetic factors that predict eGFR and albuminuria in the general population are similarly associated with these measures in adults with T1D after adjusting for demographic and diabetes-related clinical risk factors, including glycemic exposure as measured by hemoglobin A1c and by the original DCCT randomization to intensive versus conventional insulin therapy.

Urinary Growth Differentiation Factor 15 May Be a New Biomarker of Kidney Failure Progression in Diabetic Kidney Disease

Shun Watanabe,[1] Takafumi Toyohara,[1] Koichi Kikuchi,[1] Takehiro Suzuki,[1] Jun Wada,[2] Tetsuhiro Tanaka,[1] Takaaki Abe.[1,3] *[1]Tohoku University Graduate School of Medicine, Sendai, Japan; [2]Okayama University Graduate School of Medicine, Sendai, Japan; [3]Tohoku University Graduate School of Biomedical Engineering, Sendai, Japan.*

Background: Sensitive biomarkers can enhance the diagnosis, prognosis, and surveillance of chronic kidney disease (CKD), including diabetic kidney disease (DKD). Plasma growth differentiation factor 15 (GDF15) levels are a novel biomarker for mitochondria-associated diseases. However, plasma GDF15 levels increase with declining renal function, which may limit its utility in CKD. This study explores the potential of urinary GDF15 as a marker for CKD progression.

Methods: Plasma and urinary GDF15, along with 15 uremic toxins, were measured in 103 CKD patients. The relationship between the urinary GDF15-creatinine ratio and uremic toxins, as well as other clinical characteristics, was investigated. Furthermore, the relationship between the urinary GDF15-creatinine ratio and renal failure progression was examined. The urinary biomarker for the continuous and rapid progression of diabetic nephropathy (U-CARE) study was a multicenter, observational clinical study aimed at investigating urinary biomarkers in diabetic nephropathy (UMIN 00011525). Data from 342 patients in U-CARE study were used to evaluate the performance of the urinary GDF15-creatinine ratio as a biomarker for renal failure progression.

Results: Urinary GDF15-creatinine ratios were less related to renal function and uremic toxin levels compared to plasma GDF15 (eGFR and plasma GDF15 r = -0.46, $p < 0.01$, eGFR and urinary GDF15 $r = 0.13$, $p = 0.19$). However, higher urinary GDF15 levels were observed in patients with worsening renal function. In the U-CARE cohort (n = 342), multiple and logistic regression analyses revealed that baseline urinary GDF15-creatinine ratios predicted a decline in estimated glomerular filtration rate (eGFR) over 2 years (multiple regression: $p = 0.03$, logistic regression: $p = 0.05$), suggesting a predictive ability comparable to the existing urinary albumin-creatinine ratio.

Conclusions: Urinary GDF15 may serve as a useful prognostic marker for renal failure progression in patients with DKD, similar to the urine albumin-creatinine ratio. Integrating this marker into clinical practice could facilitate early therapeutic intervention for patients with progressing renal failure.

SA-PO317

Circulating Endotrophin Is an Early Marker of Kidney Disease Development in Persons with Type 2 Diabetes

Solveig S. Groen,[1] Federica Genovese,[1] Alexandra L. Møller,[1] Stefanie Thöni,[2] Felix Keller,[2] Christian Delles,[3] Morten Lindhardt,[4] Tine Hansen,[5,6] Gert J. Mayer,[2] Peter Rossing.[5,6] *[1]Nordic Bioscience, Herlev, Denmark; [2]Department of Internal Medicine IV (Nephrology and Hypertension), Medical University Innsbruck, Innsbruck, Austria; [3]School of Cardiovascular and Metabolic Health, University of Glasgow, Glasgow, United Kingdom; [4]University Hospital Copenhagen, Holbæk, Holbæk, Denmark; [5]Steno Diabetes Center Copenhagen, Herlev, Denmark; [6]Copenhagen University, Department of Clinical Medicine, Copenhagen, Denmark.*

Background: Endotrophin (ETP), a pro-fibrotic fragment generated during collagen type VI formation, has been largely investigated as a biomarker of adverse outcome in persons with diabetic kidney disease. We investigated its potential to predict kidney disease onset in two independent type 2 diabetes (T2D) cohorts.

Methods: Levels of ETP were measured using the nordicPRO-C6™ ELISA (Nordic Bioscience A/S) in baseline plasma from 3226 people with T2D from the Prospective Cohort Study in Patients with Type 2 Diabetes Mellitus for Validation of Biomarkers (PROVALID) and serum from 151 participants with T2D from the PRIORITY trial (NCT02040441). Participants in PRIORITY were normoalbuminuric and with normal or slightly reduced estimated glomerular filtration rate (eGFR) and 976 of the participants in PROVALID had eGFR >90 ml/min/1.73 m^2 at baseline. The investigated outcome was a composite kidney endpoint (sustained 40% decline in eGFR, eGFR <60 ml/min/173 m^2, sustained 30% increase in albuminuria with transition in albuminuria stage, kidney replacement therapy or kidney death) in PROVALID and development of microalbuminuria in at least one morning void sample in PRIORITY. Median follow-up was 4 years in both studies. Cox proportional hazards regression models and Kaplan Meyer survival analysis (for PROVALID participants with eGFR >90 ml/min/1.73 m^2) were applied.

Results: A doubling of ETP was associated with a higher risk of outcome in both PROVALID, after adjustment for age, diabetes duration, HbA1c, history of atherosclerotic cardiovascular disease, systolic blood pressure (SBP), duration of hypertension, BMI, LDL- and HDL-cholesterol, and eGFR (hazard ratio (HR): 1.55, p=0.01; events: 293) and PRIORITY (HR: 1.52, p=0.036, events: 74) after adjustment for sex, age, SBP, eGFR, urinary albumin-creatinine ratio, HbA1c, and CKD273 score. Even in PROVALID participants with eGFR>90 ml/min/1.73 m^2 higher ETP was associated with an increased risk of experiencing the kidney endpoint (p=0.03; n = 69).

Conclusions: Circulating ETP was a risk marker for kidney outcomes in people with T2D without or with early kidney disease. This adds to the evidence that ETP is a relevant biomarker of kidney complications in T2D, even in persons with no or mild kidney disease at baseline.

SA-PO318

Development of a Novel Assay to Quantify Circulating Endotrophin and Validation as a Risk Marker of Complications in Type 2 Diabetes

Federica Genovese,[1] Solveig S. Groen,[1] Alexandra L. Møller,[1] Tine Hansen,[2,3] Peter Rossing.[2,3] BNPCure Study Group. *[1]Nordic Bioscience, Herlev, Denmark; [2]Steno Diabetes Center Copenhagen, Herlev, Denmark; [3]Copenhagen University, Department of Clinical Medicine, Copenhagen, Denmark.*

Background: Endotrophin (ETP), a bioactive fragment of type VI collagen (COL6), has been widely evaluated as a biomarker of risk of outcome in type 2 diabetes (T2D). The most used assay to quantify ETP is a competitive ELISA employing an antibody targeting the C-terminal of the α3 chain of COL6, encompassing part of the ETP sequence (nordicPRO-C6™). We developed a sandwich ELISA targeting specifically the 77 amino acid sequence of ETP (nordicEndotrophin™), which employes a neo-epitope specific antibody targeting the N-terminal end of ETP after cleavage, and the antibody targeting the C-terminal end of COL6A3 (PRO-C6). We evaluated the potential of the two assays as risk markers of T2D adverse outcomes.

Methods: We quantified ETP employing the nordicPRO-C6™ and the nordicEndotrophin™ assays at baseline in serum of 194 individuals with T2D and microalbuminuria from an observational study conducted at Steno Diabetes Center Copenhagen. Endpoints included cardiovascular events (CV mortality, stroke, ischemic CVD, and HF), mortality, and kidney disease progression, defined as decline in estimated glomerular filtration rate (eGFR) of more than 30%. Median follow-up time was 4.9 to 6.3 years. Adjusted Cox-proportional regression analysis was employed to evaluate the association of a 2-fold increase in the biomarkers with the specified endpoints. Adjustment included baseline age, sex, BMI, HbA1c, systolic blood pressure, LDL cholesterol, urinary albumin excretion, eGFR and current smoking.

Results: The nordicEndotrophin™ had accepted linearity, precision, and accuracy in human serum. It showed a similar performance in terms of association to outcome than nordicPRO-C6™, potentially with a higher prognostic power for cardiovascular events than the competitive assay in this cohort (Table). The correlation between the two assay was: Spearman r=0.57, P<0.0001.

Conclusions: The nordicEndotrophin™ assay quantifies specifically the endotrophin molecule in circulation, presenting a similar, or possibly higher, prognostic power for complications of T2D than the competitive ELISA used so far to quantify ETP.

Funding: Commercial Support - Nordic Bioscience

Outcome	PRO-C6 HR (95% CI)	p	Endotrophin HR (95% CI)	p
All-cause mortality (n=25)	2.99 (1.60-5.62)	0.0006	4.97 (2.41-11.70)	0.0002

CKD progression (n=40)	3.22 (1.75-5.92)	0.0002	2.42 (1.22-4.80)	0.01

SA-PO319

Impact of Carbamylation on the Association of Glycated Albumin and Diabetic Kidney Disease (DKD) Progression

Mengyao Tang,[1,2] Anders H. Berg,[3] Sahir Kalim.[1,2] *[1]Massachusetts General Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Cedars-Sinai Medical Center, Los Angeles, CA.*

Background: HbA_{1c} is widely used to estimate glycemia, yet it is less reliable in CKD due to factors such as anemia and competition from another post-translational protein modification, carbamylation, acting on the same amino groups. We previously showed that the association between HbA_{1c} and the risk of CKD progression was modified by anemia and carbamylation. While an alternative hemoglobin-independent glycemic marker, glycated albumin, could overcome the anemia-related limitation of HbA_{1c}, little is known about whether it is impacted by carbamylation in CKD.

Methods: We measured baseline serum glycated albumin and carbamylated albumin levels in 1,550 patients with co-existing CKD and diabetes enrolled in the prospective Chronic Renal Insufficiency Cohort study. A Cox regression model was used to test the association between glycated albumin and CKD progression (ESKD or 50% eGFR decline), with an interaction term of glycated albumin and carbamylated albumin to evaluate whether carbamylation modified this association.

Results: Participant characteristics included mean age 60 (SD 9) years; mean eGFR 38 (15) mL/min/1.73 m^2; median glycated albumin 22 (IQR 18-28) %; and median carbamylated albumin 8 (6-11) mmol/mol. Glycated albumin levels were higher in the higher carbamylated albumin quartiles. During a median 7-year follow-up, 805 (51.9%) individuals developed CKD progression. Overall, higher glycated albumin levels (restricted cubic spline or quartiles) were independently associated with greater risks of CKD progression (**Fig 1**): compared with quartile 1, those in quartile 4 had a 1.35-fold greater risk (95% CI, 1.10 to 1.66). Interaction testing between glycated albumin and carbamylated albumin was not significant (P = 0.43).

Conclusions: In patients with CKD and diabetes, the association between glycated albumin and CKD progression is not modified by carbamylation. This finding suggests that glycated albumin could overcome the carbamylation-related limitation of HbA_{1c} in CKD.

Application of a Validated Prognostic Protein Biomarker Test for Kidney Decline in Type 2 Diabetes to Type 1 Diabetes

Kirsten E. Peters,[1] Wendy A. Davis,[2,3] Scott D. Bringans,[1] James K. Lui,[1] Tasha S. Lumbantobing,[1] Timothy Davis,[2,3] Richard Lipscombe.[1]
[1]Proteomics International, Perth, WA, Australia; [2]The University of Western Australia, Perth, WA, Australia; [3]Australian Centre for Accelerating Diabetes Innovations, Melbourne, VIC, Australia.

Background: Population-based studies have shown that the risk of chronic kidney disease (CKD) appears greater in type 1 diabetes (T1D) versus type 2 diabetes (T2D) across all age strata, and there is evidence of relative underutilization of renoprotective therapies in T1D. These observations argue for validated tests that reliably identify the risk of progressive renal disease at an early stage in T1D and pre-empt preventive management strategies. PromarkerD is a validated blood test developed for predicting renal decline over four years in T2D. This study assessed whether PromarkerD has similar clinical utility as a prognostic test in T1D.

Methods: PromarkerD scores were measured at baseline in 137 participants with T1D from the community-based Fremantle Diabetes Study. Plasma protein concentrations (ApoA4, CD5L, IGFBP3) measured by ELISA were combined with the concomitant age, serum HDL-cholesterol and eGFR to provide PromarkerD scores. Scores were categorised as low-, moderate- or high-risk as determined by pre-specified cut-offs. Renal decline was defined as incident CKD (eGFR <60 mL/min/1.73m^2 in people above this at baseline) or an eGFR decline of ≥30% over four years. Performance was assessed using the area under the receiver operating characteristic curve (AUC).

Results: At baseline, the 137 participants (mean age 45 years, 53% males, median diabetes duration 20 years) with PromarkerD classifying 83% low-risk, 10% moderate-risk and 7% high-risk for renal function decline in the next four years. Of these, 92 (67%) had renal function assessed at the four-year review, with 9 (9.8%) developing outcomes. The biomarkers ApoA4 and CD5L were significantly elevated at baseline in the people with prespecified renal outcomes while IGFBP3 showed no significant difference. The PromarkerD test scores were substantially higher in those with incident renal outcomes; the AUC was 0.93 (95% CI 0.87–0.99), with sensitivity 78%, specificity 98%, PPV 50% and NPV 97%.

Conclusions: The present data suggest that PromarkerD has strong clinical utility in identifying people with T1D at risk of adverse renal outcomes. Further validation studies are underway to confirm this promising performance of the PromarkerD test for predicting CKD in T1D, as has previously been shown for T2D.

SA-PO321

Unraveling the Mechanism of SGLT2 Inhibitors Using Urinary Proteomics in Patients with Diabetic Kidney Disease

Mark A. De la Rambelje,[1] Viji Nair,[2] Niels Jongs,[1] Michael K. Hansen,[3] Adriaan A. Voors,[1] Matthias Kretzler,[2] Wenjun Ju,[2] Hiddo J. Heerspink.[1]
[1]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [2]University of Michigan Department of Internal Medicine, Ann Arbor, MI; [3]Janssen Research and Development LLC, Spring House, PA.

Background: Sodium-glucose cotransporter 2 inhibitors (SGLT2i) confer kidney protection in patients with diabetic kidney disease (DKD). We studied the effect of the SGLT2i canagliflozin (CANA) on the urinary proteome, aiming to identify biological pathways involved in its protective effect.

Methods: We performed a post-hoc analysis in a subgroup of 392 participants with DKD from the phase 3 randomized placebo controlled CREDENCE trial. A total of 5284 proteins were quantified using the SomaScan platform in urine samples collected at baseline and week 52. Change in protein abundance was evaluated in patients receiving CANA after 1 year of treatment. Pathways were identified using ingenuity pathway analysis (IPA). Single-cell RNA expression of genes coding for proteins found to be affected by CANA was assessed in proximal tubule (PT) cells and thick ascending limb (TAL) cells in kidney biopsies from young patients with type 2 diabetes receiving either standard care + SGLT2i or only standard care.

Results: Placebo and CANA groups were well matched based on age (62 years), gender 141 (34.7%) female, albuminuria (median 1016 mg/g), eGFR (mean 60.4 mL/min/1.73m^2). After one year of treatment, 103 proteins were up-regulated (FDR < 0.05), these proteins are enriched in pathways related to gluconeogenesis, carbon metabolism, and hypoxia-inducing factor-1 signaling (Figure). Single cell analysis of young adults with T2D using SGLT2 inhibitors showed that more genes linked to these urinary proteins were upregulated in TAL cells compared to PT cells, suggesting that these urinary proteins more likely originate from TAL cells.

Conclusions: These results suggest that CANA treatment causes an increase in energy-demand in the distal tubule, possibly reflecting compensatory sodium reabsorption following sodium inhibition in the proximal tubule.

SA-PO322

Sex-Specific Methylation Indices Improve Risk Detection for Kidney Disease in the PROFIL Diabetes Study

Sam El-Osta,[1,2] Ishant Khurana,[1] Scott S. Maxwell,[1] Tine Hansen,[2] Tarunveer S. Ahluwalia,[2] Frederik Persson,[2] Peter Rossing.[2] *[1]Baker Heart and Diabetes Institute, Melbourne, VIC, Australia; [2]Steno Diabetes Center Copenhagen, Herlev, Denmark.*

Background: While sex-related differences in type 1 diabetic (T1D) are known to disproportionately affect the development and progression of diabetic kidney disease (DKD), genome wide association studies have failed to discern a genetic influence that stratify disease. This study assessed sex differences in the epigenetic architecture to define novel circulating biomarkers of DKD.

Methods: Despite recent improvements in BeadChip arrays we have used sequencing for broader genomic coverage to define methylation architecture of circulating leukocytes. Constructed on the Kidney Diseases, Improving Global Outcomes (KDIGO) classification of chronic kidney disease we characterised leukocyte methylation profiles by sequencing (methyl-seq) from the Steno Diabetes Centre Copenhagen PROFIL cohort (n=124). The case and control registry comprised of people living without diabetes (n=20) and a low-risk group without DKD (LR, n=36) as well as a moderate risk (MR, n=27), high risk (HR, n=21) and very high risk (VHR, n=20) groups living with DKD. To understand sex-related differences in methylation three-way analyses were performed to distinguish male and female profiles compared to combined sex analyses. Functional methylation analyses assessed pathways and regulatory elements associated with DKD. Differential methylation indices were used to characterise sex-specific biomarkers for DKD risk using eGFR for the prediction of disease progression.

Results: Methylation analyses identified exceptional gene body and promoter methylation in the PROFIL registry emphasizing the importance of sequencing methodologies to improve quantitative epigenetic classification by KDIGO. Methylation was disproportionally associated between sexes for the DKD groups (MR, HR and VHR) when compared to the LR group. Methylation was significantly reduced in females when

compared with increased quantitative methylation observed in males. Combinatorial ROC analysis for DKD risk and eGFR decline identified sex-specific methylation scores predictive of DKD progression.

Conclusions: PROFIL provides a T1D framework into the pathogenesis of kidney disease and define sex-specific methylation indices that improve diagnostic performance above clinical modelling alone.

SA-PO323

Acetazolamide Therapy and Kidney Function in Persons with Type 1 Diabetes: The ATAK-DM1 Trial

Charles Ginsberg,[1] Jesse C. Seegmiller,[2] Volker Vallon,[1] Robert L. Thomas,[1] Joachim H. Ix.[1] *[1]University of California San Diego, La Jolla, CA; [2]University of Minnesota Medical School, Minneapolis, MN.*

Background: Sodium-glucose cotransporter-2 inhibitors (SGLT2i) lower risk of kidney failure through greater sodium delivery to the distal tubule and activation of tubuloglomerular feedback (TGF) thereby lowering glomerular pressure which lowers glomerular filtration rate (GFR). SGLT2i are not widely used in type 1 diabetes mellitus (T1DM) due to diabetic ketoacidosis (DKA) risk. Acetazolamide, a proximal tubule diuretic, delivers sodium to the distal nephron, and may activate TGF without glycemic effects. The kidney response and safety of acetazolamide in T1DM patients are not well known.

Methods: We conducted a dose escalation trial to study the effects of three doses of oral acetazolamide (62.5, 125, and 250mg, all twice daily) in 12 persons with T1DM and eGFR> 45ml/min/1.73m^2. Participants were treated for 2 weeks followed by a 2 week wash out before the next dose level. Blood chemistries were measured before and after each treatment interval. GFR was measured (mGFR) using iohexol. We hypothesized that acetazolamide would safely cause reversible reductions in GFR indicating stimulation of TGF.

Results: The 12 participants had mean age 46±17 years, all participants were White, and 9 were female. The mean mGFR was 89±18ml/min/1.73m^2 at baseline. Acetazolamide caused a 14.7(95%CI 8.5,21.0)%, 13.8(6.5,21.0)%, and 15.4(9.9,21.0)%, reduction in mGFR over 2 weeks on the 62.5, 125, and 250mg doses, respectively (**Figure**). These changes were not attenuated when accounting for body weight changes. GFR returned to baseline after a 2 week washout for each dose. Serum bicarbonate was reduced by 2.3(1.2,3.3), 4.1(3.3,4.8) and 4.4(2.3,6.5)mEq/L with the three escalating doses, respectively. There were no episodes of hypokalemia (serum potassium< 3.5 mEq/L) observed for any dose.

Conclusions: Among persons with T1DM, acetazolamide caused an acute reversible reduction in GFR with moderate concurrent reductions in serum bicarbonate.

SA-PO324

Characteristics of Patients with Type 1 Diabetes (T1D) and CKD Receiving Novel Kidney Protective Therapies (KPT)

M. Luiza A. Caramori,[1] Enrico Repetto,[4] Christopher Perkins,[4] Ambarish Pandey,[3] Peter Rossing.[2] *[1]Cleveland Clinic, Cleveland, OH; [2]Steno Diabetes Center Copenhagen, Herlev, Denmark; [3]The University of Texas Southwestern Medical Center, Dallas, TX; [4]Roche Diagnostics Corp, Indianapolis, IN.*

Background: KPT (SGLT2i, GLP-1RA and nsMRA) for pts with T2D and CKD have not been approved for pts with T1D and CKD. Regardless, a significant proportion of these pts receive these therapies. Herein, we used a case-control design to compare the characteristic of T1D pts with CKD treated or not with KPT and assessed kidney (Kd) outcomes.

Methods: Optum's De-identified Market Clarity database (1/1/2018-6/30/2023) was used to identify pts ≥18 yrs with T1D (Klompas algorithm) and CKD. CKD was defined as any two of CKD ICD-10 codes, eGFR<60 ml/min/1.73m^2, or UACR≥30 mg/g, ≥3 months apart. Pts on dialysis or who had a Kd transplant were excluded. KPT use was defined as any KPT prescription that was refilled ≤180 days from KPT start (index date). An index date was randomly assigned to pts not on KPT (no-KPT). Outcome analysis included T1D CKD pts who had UACR data available ≤540 days prior to and ≥30 days after index date.

Results: Among 408,951 pts with T1D, 128,675 (31.5%) had CKD. 1,970 pts (1.5% of T1D CKD pts) were on KPT, 41% of them on SGLT2i, 70% GLP-1RA, and 3% nsMRA; 14% were on more than one KPT. Pts on KPT were more often females (57 vs 50%), less often White (71 vs 78%), and had higher UACR [157 (114-200) vs 113 (92-135) mg/g] than pts not on KPT, respectively. Proportion of non-Hispanic (75 vs 76%), age (51±13 vs 52±17 yrs) and eGFR (60±28 vs 62±30 mL/min/1.73m^2) were not different. Time to 50% ≥30% UACR reduction (Fig) was 31 (25-47) vs 47 (43-53) months in the KPT (n=381) vs no-KPT (n=3385) cohort, respectively (HR1.24, p≤0.02).

Conclusions: We identified a large number of pts with T1D and CKD treated with off-label KPT. Pts on KPT were more often female and non-White and had more advanced Kd disease as evidenced by higher baseline UACR. The proportion of pts with T1D and CKD achieving clinically meaningful UACR reduction (≥30%) was greater among KPT users and comparable to what was observed among pts with T2D and CKD, supporting the need for trials in T1D.

Glycemic Variability of Hemoglobin A1c-Based Metrics and Mortality in Patients with ESKD Undergoing Dialysis

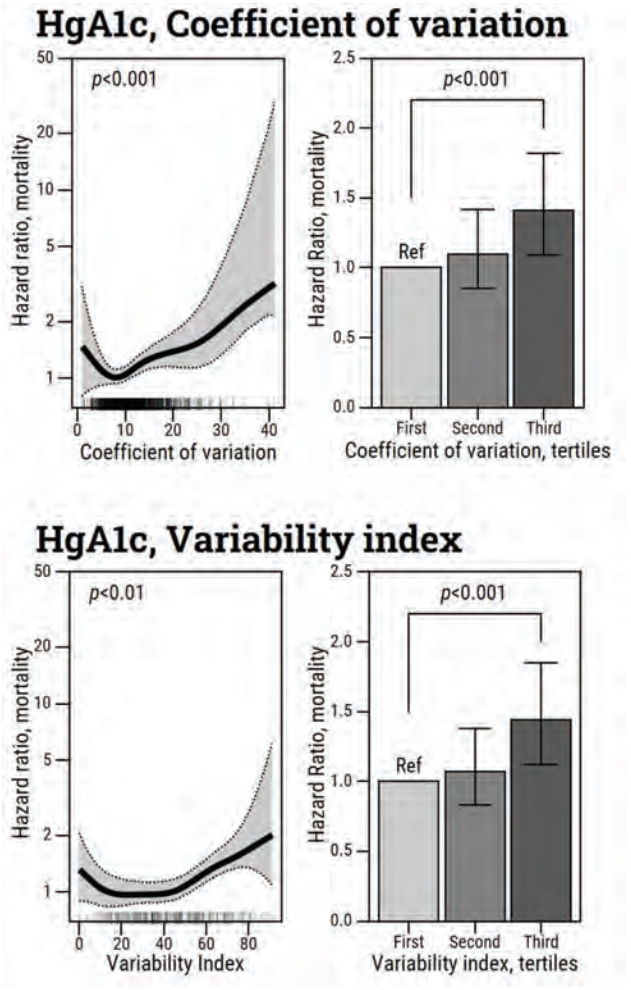
Jose E. Navarrete,[1] Jose Guevara,[2] Lucas Hernandez,[1] Guillermo Umpierrez.[1] *[1]Emory University, Atlanta, GA; [2]Universidad de Especialidades Espiritu Santo, Samborondon, Ecuador.*

Background: HbA1c has long been recommended as the gold standard for assessing glycemic control in patients with diabetes. However, the correlation between glycemic control by HbA1c and outcomes is less than optimal in end-stage kidney disease (ESKD). HbA1c variability has been proposed as a better tool to predict outcomes, including mortality in ESKD. We report the predictive value of HbA1c variability on all-cause mortality in patients undergoing dialysis

Methods: Patients with diabetes new to dialysis, enrolled in an academic dialysis program from 1/2010 to 12/2023. HbA1c was measured quarterly. Patients with at least 90 days on dialysis and 3 consecutive measures of HbA1c were included. The coefficient of variation (CV, standard deviation divided by mean HbA1c) and variability index (VI, change of 0.5% compared to previous value) were used as predictors of mortality. The association between CV, VI and mortality was assessed using Cox models, with CV and VI values as continued variables and tertile of distribution (Figure). Adjustments for age, body mass index (BMI), history of heart failure, and peripheral vascular disease were included in all models

Results: 979 patients were eligible, 91.5% with type 2 diabetes. The median age was 60.5 years (IQR: 50.8-68.7), 52.5% males, 89.2% African-Americans, BMI 27.6 kg/m2, and median follow-up of 3.3 years (IQR: 1.9-5.6). Glycemic variability indices-CV (p<0.001) and VI (p<0.01) were significantly associated with mortality. Their highest tertile- CV (HR 1.42, CI: 1.10-1.83) and VI (HR 1.44, CI: 1.12-1.85) were also associated with higher mortality compared to the lowest tertile

Conclusions: Glycemic variability of HbA1C - coefficient of variation and variability index- were strongly associated with all-cause mortality in ESKD undergoing dialysis



SA-PO326

Impact of Vertical Sleeve Gastrectomy (VSG) on Early Diabetic Nephropathy

Abhijit S. Naik,[1] Fadhl Alakwaa,[1] Jennifer A. Schaub,[1] Phillip J. McCown,[1] Viji Nair,[1] Francesca Annese,[1] Edgar A. Otto,[1] Ye Ji Choi,[2] Justin R. Ryder,[4] Laura Pyle,[2] Kristen Nadeau,[2] Frank C. Brosius,[3] Matthias Kretzler,[1] Petter Bjornstad.[2] *[1]University of Michigan, Ann Arbor, MI; [2]University of Colorado Anschutz Medical Campus, Aurora, CO; [3]Banner - University Medical Center Tucson, Tucson, AZ; [4]Ann & Robert H Lurie Children's Hospital of Chicago, Chicago, IL.*

Background: We explored the impact of VSG on the progression of early diabetic nephropathy (DN) in an adolescent cohort with obesity and type 2 diabetes (T2D).

Methods: 5 of 12 patients from IMPROVE study had renal biopsies before and 1year after VSG. MRI measured change in total kidney volumes (TKV). Kidney tissue was profiled using histology, single-cell RNAseq (scRNAseq), and proteomics. Renal function was measured by assessing glomerular filtration rate (GFR) and albuminuria. Somascan data from TeenLABS study(n=62) was used to evaluate circulating proteomic changes pre- and post. The longitudinal TODAY study provided an association between change in circulating proteome with albuminuria.

Results: All participants had a reduction in weight, BMI, GFR, albuminuria, mean arterial pressure, and insulin resistance. The TKV decreased by 18%. Tissue morphometry showed reductions in glomerular volume, indicating resolving glomerular hypertrophy. scRNA-seq of the proximal tubule (PT) showed enrichment of evolutionarily conserved *PRKAA2 (*AMPK*)* and *FOXO3*-mediated transcription factors post-VSG, consistent with cells experiencing 'starvation stress.' There was a coordinated reduction in transcripts of gluconeogenesis, TCA cycle, ROS mitigation machinery and an increase in Insulin-IGF-1 Signaling (IIS), mitochondrial biogenesis, apoptosis and mitophagy. Circulating proteomic analysis from TeenLABS showed reduced IIS-mediated signaling aligned with the intrarenal transcriptional response after VSG. TODAY participants had decreased albuminuria at 15 years among pathways enriched in TeenLABS participants.

Conclusions: VSG induces a coordinated activation of *AMPK and FOXO3*-mediated transcription factors in youth-onset T2D, resetting molecular programs in the PT with reversal of early DN. These findings are currently undergoing proteomic validation.

Utilization Trends of Tirzepatide, Glucose-Lowering Medications, and Anti-obesity Medications in Patients with CKD with and without Type 2 Diabetes

Panupong Hansrivijit,[1,2] Janinne Ortega-Montiel,[1] Deborah J. Wexler,[3,2] Elisabetta Patorno,[1,2] Julie M. Paik.[1,2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Massachusetts General Hospital, Boston, MA.*

Background: Tirzepatide was approved by the U.S. FDA in May 2022 for glycemic control in adults with type 2 diabetes (T2D). Our study goal was to describe the utilization of tirzepatide, other glucose-lowering medications (GLM), and anti-obesity medications (AOM) in patients with chronic kidney disease (CKD), regardless of T2D status.

Methods: We obtained data from a large U.S. insurance claims database (Optum) from January 1, 2022, to September 30, 2023. We created two cohorts using validated algorithms based on ICD codes: 1) CKD with T2D and 2) CKD without any diabetes. Incident use of any medications was defined as no prior use in 365 days.

Results: We identified 455,047 patients with CKD and T2D treated with any GLM, and 5,978 patients with CKD without any diabetes treated with any AOM. For patients with CKD and T2D, tirzepatide initiation, regardless of dose, comprised 8.4% of all initiated GLM by the end of September 2023 (**Figure 1A**). Of 10,661 tirzepatide initiators, the mean age was 65.9 (9.7) years, 42.2% were male, and 64.2% were of white race. For patients with CKD without diabetes, initiation of tirzepatide was second to subcutaneous semaglutide ≤2 mg, with incidence rising from 0.5% in June 2022 to 36.5% of all initiated AOM in December 2022 (**Figure 1B**). Of 909 tirzepatide initiators, the mean age was 65.4 (10.1) years, 26.2% were male, and 74.4% were of white race.

Conclusions: Tirzepatide use increased over time in patients with CKD. Further studies are needed to assess tirzepatide's effectiveness and safety compared to other GLM and AOM in patients with CKD.

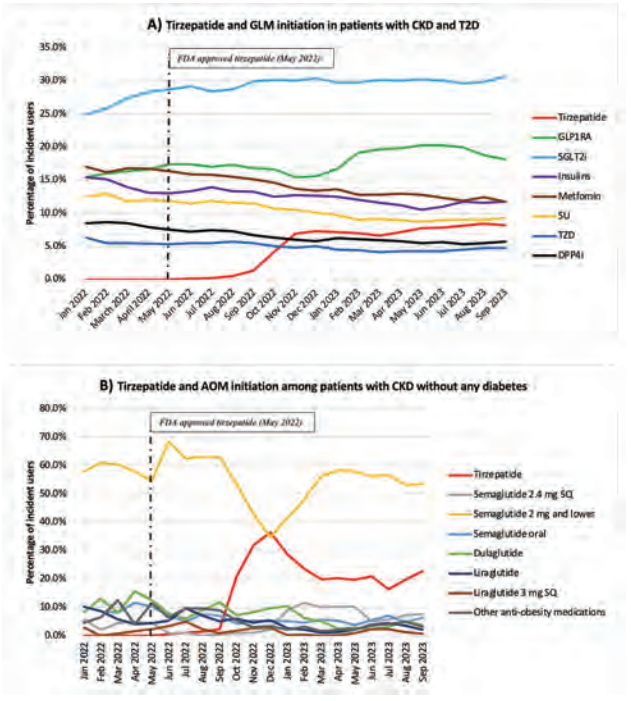

Figure 1. A) Trends of GLMinitiation in patients with CKD and T2D. **B)** Trends of AOM initiation in patients with CKD without any diabetes.

A Novel Potassium Binder Sodium Zirconium Cyclosilicate to Enable RAAS Inhibitor (RAASi) Use in the Treatment of Patients with Diabetic Kidney Disease: The Crystal Study

Weiming Wang,[1] Leyi Gu,[2] Xiujuan Zang,[3] Na Liu,[10] Yangbin Pan,[11] Chunming Jiang,[4] Ying Li,[9] Gengru Jiang,[5] Zhiguo Mao,[6] Jun Xue,[7] Rong Zhou,[8] Hao Xu,[1] Jian Liu.[1] *[1]Shanghai Jiao Tong University Medical School Affiliated Ruijin Hospital, Shanghai, China; [2]Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital Baoshan Branch, Shanghai, China; [3]Songjiang Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China; [4]Nanjing University Medical School Affiliated Nanjing Drum Tower Hospital, Nanjing, China; [5]Shanghai Jiaotong University School of Medicine Xinhua Hospital, Shanghai, China; [6]Shanghai Changzheng Hospital, Shanghai, China; [7]Huashan Hospital Fudan University, Shanghai, China; [8]Shanghai Yangpu District Central Hospital, Shanghai, China; [9]Shanghai Jiading Hospital, Shanghai, China; [10]Tongji University Dongfang Hospital, Shanghai, China; [11]Shanghai Pudong Hospital, Shanghai, China.*

Background: The key treatment strategy for diabetic kidney disease (DKD) involves optimizing the comprehensive management of blood glucose, blood pressure and proteinuria. Renin-angiotensin-aldosterone system inhibitors (RAASis) are preferred due to their effectiveness in lowering blood pressure, reducing urine protein and slowing kidney damage progression. However, RAASi may cause hyperkalemia (HK) in DKD patients, and RAASi reduction or discontinuation due to HK will affect its cardio-renal benefits. Therefore, it is crucial for DKD patients to receive RAASi at target dose while simultaneously managing hyperkalemia.

Methods: This is a multicenter, open-label, randomized clinical study to evaluate the efficacy of sodium zirconium cyclosilicate (SZC) in enabling RAASi usage in DKD patients (stage 3-4 chronic kidney disease). Patients are eligible if they experienced HK (sK>5.0 mmol/L) at least once in the 90 days prior to enrollment. Eligible patients will be randomized 1:1 to enter the SZC + RAASi or RAASi-only group and were followed up for 24 weeks, including a 12-week RAASi titration phase and a 12-week ACEIs/ARBs maintenance therapy phase. The primary endpoint is the proportion of patients with increased dose of RAASi at week 12. The exploratory endpoints include the distribution of patients with ≥50% of labelled maximum dose of RAASi and changes in UACR, serum creatinine and blood pressure at weeks 12 and 24.

Results: The CRYSTAL study has achieved 100% enrollment as of 2023 Dec, enrolling 86 patients with RAASi treatment. Results for the primary endpoint have been collected by March 2024 (week 12) and all follow-up data will be generated by June 2024 Jun (week 24). These results will be presented at the 2024 ASN congress.

Conclusions: This study will provide the first evidence on how SZC optimizes RAASi treatment while controlling hyperkalemia in the Chinese population.

Association of Biopsy-Proven Diabetic Nephropathy with Obstructive Sleep Apnea-Hypopnea Syndrome

Qin Xue, Hui Liu, Niansong Wang. *Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China.*

Background: Both obstructive sleep apnea-hypopnea syndrome (OSAHS) and diabetic kidney disease (DKD) are common disease. As one of the most common microvascular complications of DM, diabetic nephropathy (DN) has become a primary cause of end-stage renal disease (ESRD) worldwide. Previous reports show that patients with severe sleep apnea or sleep-disordered breathing (SDB) were more likely to have diabetes than those without sleep apnea or SDB. However, the correlation of renal pathology of DN with OSAHS is still unclear. The objective of this study is to explore the impact of OSAHS on renal pathology of DN and assess risk factors of OSAHS in patients with DKD.

Methods: We selected 87 patients with DKD who were hospitalized in department of our hospital from September 2020 to February 2023. All participants underwent full-night standard nocturnal polysomnography (PSG) monitoring in the sleep center. The apnea and hypopnea are scored following the definitions of the American Academy of Sleep Medicine guidelines. An apnea hypopnea index (AHI)>5 events/h was consistent with the diagnosis of OSA. 94 CKD Patients without DKD were recruited as control group in this study. Multiple linear regression is used for analysis the risk factors of OSAHS in patients with DKD. 20 biopsy-proven DN patients were divided into two groups based on the level of AHI to analyze the correlation between OSAHS-related parameters and renal pathological features.

Results: The prevalence of OSAHS was 90.8% (79 of 87), with 25.2% (22 of 87) mild, 35.6% (31 of 87) moderate and 29.8% (26 of 87) severe respectively. The Scr (P=0.001), cystatin C (P=0.030), 24h urine protein (P=0.006), AHI (P=0.022), ODI (P=0.011), and CT90 (P=0.046) levels in patients of DKD group were significantly higher than those within non DKD group. Multiple linear regression showed that diabetes course (p=0.048), BMI (p=0.042) were independent risk factors for eGFR. CT90 (p<0.001) was an independent risk factor for UACR. Regarding DKD renal pathology, the overall trend was that the higher the severity of OSAHS, the higher the renal interstitial tubule score and arteriolar hyalinosis score.

Conclusions: OSAHS is high prevalence in patients with DKD. Patients with DKD had more severe renal damage and hypoxemia than those without DKD. Patients of diabetic nephropathy with OSAHS tend to have higher risk of renal pathological impairment.

SA-PO330

Intensive Uric Acid-Lowering Improved Outcomes in Type 2 Diabetes with CKD: A Multicenter, Retrospective, Real-World Cohort Study

Zhang Shaogui X. Xiaoguizi, Danfeng Liu, Runli Jia, Jianteng Xie, Wenjian Wang. *Division of Nephrology, Guangdong Provincial People's Hospital, Guangzhou, China.*

Background: To explorer the effects of intensive uric acid-lowering therapy on the outcomes in type 2 DM with chronic kidney disease (CKD).

Methods: Patients diagnosed of type 2 DM with CKD(DKD) were enrolled in the nephrology department of 8 hospitals from January 2013. The patients were followed up to the end of the follow-up period (October 2023). Primary outcomes encompass a composite endpoint, including doubling of Scr, 40%-decline in eGFR, initiate dialysis, progression to end-stage renal disease or all-cause mortality. The risk factors and the relationship with prognosis were analyzed. To further explore the influence of baseline SUA (B-SUA) and time average SUA (TA-SUA) level fluctuation on the prognosis of DKD patients, logistic and Cox proportional risk regression models were used to analyze. For the HUA group (n=772) and NUA group (n=300),1:1 propensity score matching was used to clarify the optimal range of SUA and explore the benefit of intensive uric acid-lowering therapy to prevent and slow down the kidney damage.

Results: 1651 patients were screened, 1072 patients with a median age of 56.5±10.4 years old, and 700 males (65.3%) were enrolled. The median of follow-up was 60.4±5.6 months. The overall prevalence of hyperuricemia incurrent cohort was 46.1%, which was higher in males than in females. The SUA level increased with age and was negatively correlated with renal function. After adjusting for confounding factors, we found that B-SUA and TA-SUA were independent risk factors for prognosis. In subgroup analysis, TA-SUA 360μmol/L was consistent among subgroups of age, sex, hemoglobin, glycosylated hemoglobin and lipid-lowering, glucose-lowering, blood-pressure lowering, and urico-lowering drug use. The spline curves demonstrated a U-shaped pattern after propensity score matching at B-SUA 360μmol/L and TA-SUA 300μmol/L respectively suggesting a potential threshold effect of SUA on prognostic risk.

Conclusions: In this study, we found that hyperuricemia was an independent risk factor for outcomes. Intensive uric acid-lowering therapy especially maintaining SUA levels around 300~360μmol/L, delays end-point events in DKD.

SA-PO331

Impact of Triglyceride-to-High-Density Lipoprotein Cholesterol Ratio as a Hyperinsulinemia Marker of Kidney Function Decline

Makoto Araki. *Sapporo Tokushukai Hospital, Sapporo, Japan.*

Background: The triglyceride to high-density lipoprotein cholesterol (TG/HDL-C) ratio is known as a surrogate marker for hyperinsulinemia, which underlies obesity, and is also an excellent predictor of progression to type 2 diabetes. This study aims to investigate whether hyperinsulinemia can predict renal function decline in the absence of diabetes and obesity using the proxy marker TG/HDL-C ratio.

Methods: This single-institutional observational study in Japan targeted individuals who had annual health check-ups measuring creatinine, TG, HDL-C, and body mass index (BMI) from 2012 to 2022. Exclusion criteria included individuals under 18, those with an initial estimated glomerular filtration rate (eGFR) below 45, blood test results for less than one year, and initial hemoglobin A1c (HbA1c) levels of 6.5% or higher. Participants were divided into two groups based on their baseline TG/HDL-C ratio and BMI. The TG/HDL-C threshold was set at 2.1, based on the previous report, and the BMI threshold was set at 23, according to Asian overweight criteria. The primary endpoint was the time to an eGFR decline below 45, analyzed using time-to-event analysis.

Results: A total of 3,914 individuals met the criteria (mean age: 50.0 years, 44.5% male, mean BMI: 23.0, mean eGFR: 75.1). During the observation period, 135 individuals (3.5%) developed diabetes, with the incidence rate being 2.51 times higher in the high TG/HDL-C group compared to the low group. Univariate analysis showed that the high TG/HDL-C group had significantly worse renal function (Log-rank p<0.01, hazard ratio 2.2 [1.3-4.0])(Figure). Further analysis of 2,022 non-obese individuals (BMI<23) showed similar results (Log-rank p<0.01).

Conclusions: The TG/HDL-C ratio, a surrogate marker for hyperinsulinemia, was associated with renal function decline in non-diabetic individuals. This association persisted even in non-obese individuals.

Competing Risks of Kidney Failure and Death by Baseline eGFR in Diabetes

Katherine R. Tuttle,[1,2] Lindsey M. Kornowske,[1] Kenn B. Daratha,[1] Cami R. Jones,[1] Christina Reynolds,[1] Alain K. Koyama,[3] Fang Xu,[3] Yoshihisa Miyamoto,[3] Joshua J. Neumiller,[1,5] Radica Z. Alicic,[1,2] Susanne B. Nicholas,[4] Obidiugwu Duru,[4] Keith C. Norris,[4] Meda E. Pavkov.[3] The CURE-CKD Registry. *[1]Providence Health and Services, Spokane, WA; [2]University of Washington School of Medicine, Seattle, WA; [3]Centers for Disease Control and Prevention, Atlanta, GA; [4]University of California Los Angeles, Los Angeles, CA; [5]Washington State University College of Pharmacy and Pharmaceutical Sciences, Spokane, WA.*

Background: The study aim was to assess the competing risks of kidney failure and death in a real-world population with diabetes by baseline estimated glomerular filtration rate (eGFR).

Methods: Providence and University of California Los Angeles health systems provided electronic health record registry data for patients aged ≥12 years with diabetes in 2013-2022. Kidney failure was defined by eGFR <15 mL/min/1.73 m², dialysis, or kidney transplant. Follow-up started at diabetes identification and ended at onset of kidney failure, death, or last encounter. Cumulative incidence functions were assessed by baseline eGFR. Fine-Gray multivariable models for kidney failure were constructed with death as a competing risk.

Results: Among 619,352 people with diabetes, risk of death exceeded kidney failure for eGFR ≥45 mL/min/1.73 m² (**Figure**). At eGFR 30-44 mL/min/1.73 m², these risks were equivalent. At eGFR 15-29 mL/min/1.73 m², 5-year cumulative incidences of kidney failure and death were 62.3% and 15.3%, respectively, with an adjusted hazards ratio for kidney failure of 55.5 (95% CI 51.6-59.6; reference eGFR ≥90 mL/min/1.73 m²). Accounting for competing risk of death, other significant kidney failure predictors were male sex, non-White race, non-commercial health insurance, Providence health system, macroalbuminuria, age 40-59 years, or hospitalization during a 1-year baseline period.

Conclusions: Death was more frequent than kidney failure at eGFR ≥45 mL/min/1.73 m², but the trend reversed at lower eGFR with kidney failure becoming more much common at eGFR <30 mL/min/1.73 m². In the diabetes population, kidney and survival-based risk stratification may help to target management according to risk status.

SA-PO333

Trend Analysis of Kidney Failure and Diabetes Mellitus-Related Mortality, 1999-2020

Mohammad Ammar ur Rahman,[1] Ahmed J. Chaudhary,[2] Laiba Sarfraz,[1] Luqman Munir,[1] Amna Khalid,[1] Saleha Azeem,[1] Mahnoor Fatima.[1] NEURALKEy. *[1]King Edward Medical University, Lahore, Pakistan; [2]Detroit Medical Center, Detroit, MI.*

Background: The interrelation between renal failure and diabetes mellitus lies in insulin resistance. Diabetes mellitus type 2 is a metabolic syndrome resulting in hyperglycemia. High blood glucose causes nonenzymatic glycation of tissue proteins resulting in mesangial expansion. This increases the permeability of blood vessels by weakening the wall. This condition ultimately leads to renal failure as renal blood vessels are damaged. These negatively downgrade the quality of life of the survivors. The mortality due to kidney failure in diabetes mellitus patients is on the decline in the United States. In this study we explored these trends from 1999-2020, using age adjusted mortality rates (AAMR) to pinpoint incongruities between epidemiological groups.

Methods: Our study conducted an in-depth search of the CDC Wonder database, based on the incidence of sequalae of stroke-related Age-Adjusted Mortality Rate (AAMR) per 100,000 individuals. Employing Join point Regression Analysis, we assessed Parallelism and computed Annual Percent Changes (APC) with a 95% Confidence Interval. For a p<0.05, the test of parallelism was considered significant for unparallel.

Results: From 1999 to 2020, a total of 726654 deaths were reported due to the kidney failure due to diabetes mllitus. The overall AAMR showed a decline from 1999 to 2012, with an APC of -0.81. However, following this the AAMR had a rapid decline started to rise from 2012 to 2015, with an APC of -48.20. Following this a rise was seen from 2015 to 2020, with an APC of 13.88. The populations with the highest mortality rates were in males and African Americans. The geographical hotspots for mortality were urban and Black or African American. Tests for parallelism revealed disparate trends across gender (p=0.00022), Black and White races (p=0.06), urban versus rural demographics (p=0.12), and Large Central Metropolitan versus Large fringe Metropolitan (p=0.12).

Conclusions: The mortality due to the kidney failute and diabetes mellitus was on a decline in the US until 2013. However, the recent rise in the mortality is concerning. Furthermore, the disparity among the demographic variables warrant more investigation, and the planning of targeted interventions.

SA-PO334

Trend Analysis of Diabetic Kidney Disease-Related Mortality, 1999-2020

Mohammad Ammar ur Rahman,[1] Ahmed J. Chaudhary,[2] Gul S. Ghouri,[1] Luqman Munir,[1] Amna Khalid,[1] Natalia Azhar,[1] Abdullah Saeed.[1] NEURALKEy. *[1]King Edward Medical University, Lahore, Pakistan; [2]Detroit Medical Center, Detroit, MI.*

Background: A dangerous consequence of diabetes called diabetic kidney disease (DKD) is the progressive loss of kidney function. It results from long-term unchecked blood sugar levels that harm the kidneys' filtering organs. To lessen its influence on general health, early identification and treatment are essential. The mortality due to Diabetic Kidney Disease is on the rise in the United States. In this study we explored these trends from 1999-2020, using age adjusted mortality rates (AAMR) to pinpoint incongruities between epidemiological groups

Methods: Our study conducted an in-depth search of the CDC Wonder database, based on the incidence of sequalae of stroke-related Age-Adjusted Mortality Rate (AAMR) per 100,000 individuals. Employing Join point Regression Analysis, we assessed Parallelism and computed Annual Percent Changes (APC) with a 95% Confidence Interval. For a $p<0.05$, the test of parallelism was considered significant for unparallel.

Results: From 1999-2020, a total of 34195 deaths were reported due to diabetic kidney disease. The overall AAMR showed a rise from 1999-2014, with an APC of 30.62. Following this, the AAMR started to rise again from 2014-2020, with an APC of 11.5. The highest mortality populations were males and African Americans. The geographical hotspots for mortality were rural and west. Tests for parallelism revealed disparate trends across gender ($p=0.012$), African American races ($p=0.033$), urban versus rural demographics ($p=0.007$). However, the parallelism test in west ($p=0.029$) was not significant.

Conclusions: The recent rise in the mortality due to Diabetic Kidney Disease is concerning. Furthermore, the disparity among the demographic variables warrants more investigation, and the planning of targeted interventions.

SA-PO335

Evaluation of Plasma Proteins as Mediators of the Relationship between Kidney Disease and Heart Failure

Benjamin Lidgard,[1] Christine P. Limonte,[1] Jorge R. Kizer,[2] Bruce M. Psaty,[1] Leila R. Zelnick,[1] Nisha Bansal,[1] Jennifer A. Brody.[1] *[1]University of Washington, Seattle, WA; [2]University of California San Francisco School of Medicine, San Francisco, CA.*

Background: Patients with chronic kidney disease (CKD) are at high risk for heart failure (HF). Plasma proteins may indicate pathways associated with both reduced estimated glomerular filtration rate (eGFR) and HF. We tested if circulating proteins may mediate the associations between eGFR and HF.

Methods: We used the SomaLogic 5K platform to measure plasma proteins in 2,993 participants without prevalent HF in the Cardiovascular Health Study. We used linear regression to evaluate associations of each protein with eGFR (by the 2021 combined CKD-Epi equation), and proportional hazards models for associations with HF events. We used a quasi-Bayesian Monte Carlo method with 2,000 draws to test the adjusted mediation effects of proteins (which were associated with both eGFR and HF) on the eGFR-HF association. Bonferroni corrections were used for significance.

Results: The mean (SD) eGFR was 70 (16) mL/min/1.73 m^2; mean age was 74 (5) years. 1074 proteins were significant associated with eGFR. Of these, 44 proteins were significantly associated with incident HF; each was associated with statistically significant mediation effect on the association between eGFR and HF. These included COSA1 (proportion mediated 62%, 95% CI 39-93%) and NT-proBNP (proportion mediated 33%, 95% CI 24-47%).

Conclusions: Multiple plasma proteins were associated with significant mediation effect on association between eGFR and HF. These proteins may indicate pathways by which CKD increases HF risk. However, these statistical mediation analyses assume the directionality of associations. Ongoing work is investigating directionality of associations and joint mediation analyses.

Funding: Other NIH Support - NCATS KL2TR002317

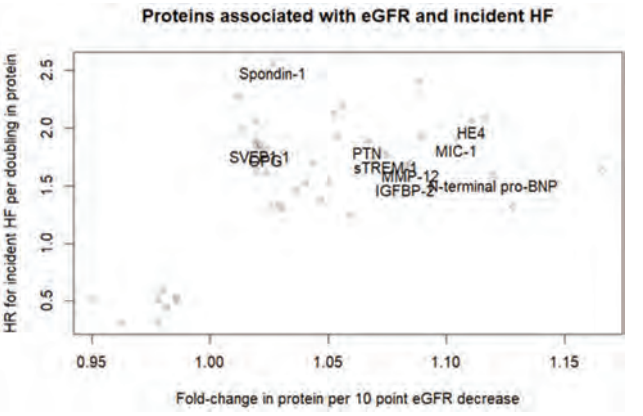

Table: Mediation by individual sphingolipids of the associations between eGFR and cardiovascular outcomes using a quasi-Bayesian Monte Carlo method with 2,000 draws

Protein	Average causal mediation effect (95% CI)	p-value	Proportion mediated (95% CI)	p-value
Cystatin C	-0.79 (-1.16, -0.45)	<2e-16	0.64 (0.37, 0.99)	<2e-16
COSA1	-0.76 (-1.08, -0.48)	<2e-16	0.62 (0.39, 0.93)	<2e-16
PXDN	-0.75 (-1.08, -0.47)	<2e-16	0.62 (0.38, 0.93)	<2e-16
HE4	-0.72 (-0.97, -0.49)	<2e-16	0.59 (0.4, 0.84)	<2e-16
MIC-1	-0.59 (-0.79, -0.41)	<2e-16	0.49 (0.34, 0.69)	<2e-16
b2-Microglobulin	-0.53 (-0.78, -0.3)	<2e-16	0.43 (0.25, 0.67)	<2e-16
ERBB2	-0.44 (-0.63, -0.28)	<2e-16	0.36 (0.23, 0.54)	<2e-16
NT-proBNP	-0.41 (-0.54, -0.31)	<2e-16	0.33 (0.25, 0.46)	<2e-16

Proportional effect is the percentage of the association between eGFR and HF that is mediated by the protein of interest. Adjusted for age, sex, race, smoking, BMI, LDL-C, HDL-C, triglycerides, total cholesterol, SBP, diabetes, prevalent HTN, and prevalent CVD.

SA-PO336

Heart Rate Variability in Dialysis Patients: Changes over the Dialysis Session and Evaluation of a Novel Device

Benjamin Lidgard, Nisha Bansal, Nathaniel Ashford, Leila R. Zelnick, Ian De Boer. *University of Washington, Seattle, WA.*

Background: Decreased Heart Rate Variability (HRV) is a measure of poor cardiovascular health and inability of the autonomic nervous system to respond to stress. Accumulation of uremic toxins in kidney failure, volume shifts, and clearance of uremic toxins by dialysis, may impact HRV. We sought to evaluate how HRV changes over the course of hemodialysis with gold-standard electrocardiogram (ECG) and a novel fingertip HRV sensor.

Methods: Among 22 participants treated with in-center hemodialysis, we evaluated time-domain and frequency-domain HRV metrics with an ECG (Schiller CARDIOVIT AT-10 Plus) and a novel fingertip sensor (EliteHRV CorSense) at five time points during 2 consecutive dialysis sessions. Changes over the session were evaluated by linear mixed models with random effect terms for participant and session. Devices were compared using correlation coefficients, T-tests, and linear regression.

Results: There were no significant changes in HRV metrics over the dialysis session (p-value for trend across ECG 0.11, across CorSense 0.58) (Figure). Time-domain HRV metrics were moderately correlated between the two methods (correlation coefficient for SDNN 0.72 and for RMSSD 0.66), while spectral methods were not (Table). Linear models comparing CorSense and EKG readings suggested strong association for time-domain metrics.

Conclusions: On average, HRV metrics did not significantly change over the course of hemodialysis sessions, suggesting that clearance of uremic toxins may not immediately impact cardiovascular health. A novel fingertip sensor accurately measured time-domain (but not frequency-domain) HRV metrics versus a gold-standard EKG device, which may provide a convenient way to assess autonomic neuropathy in dialysis patients.

Funding: NIDDK Support, Other NIH Support - NCATS KL2TR002317

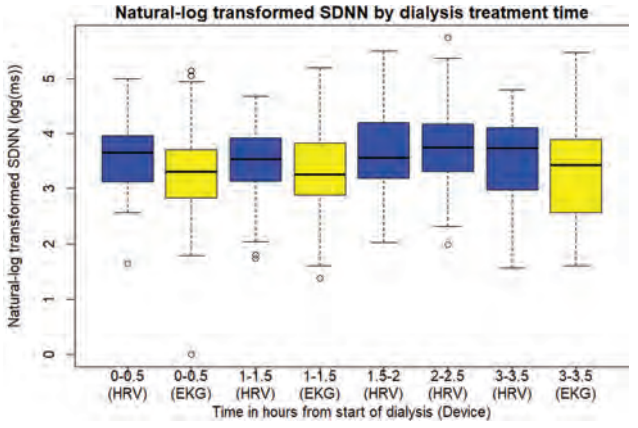

Table: Median (IQR) HRV values by each device with T-test p values and Pearson correlation coefficients

HRV domain	EKG	CorSense HRV	P value for difference	Correlation (Pearson)	Correlation p-value
Time-domain metrics					
SDNN	45.8	42.6	0.57	0.72	<0.0001
RMSSD	55.4	41.6	0.06	0.66	<0.0001
Frequency-domain metrics					
Low frequency (LF)	664.5	791.7	0.50	0.44	<0.0001
High frequency (HF)	1498.6	760.6	0.06	0.57	<0.0001
LF/HF ratio	1.38	7.17	0.32	-0.02	0.85

Abbreviations: Standard deviation of N-N interval, SDNN; root mean square standard difference, RMSSD

Importance of the Cardiorenal Unit for the Management and Monitoring of Highly Complex Patients with Cardiorenal Syndrome

Juan C. León-Román, María Azancot, Marc Patricio-Liébana, Jorge I. Zamora Carrillo, Maria Jose Soler. *Hospital Universitari Vall d'Hebron, Barcelona, Spain.*

Background: Around 70% of patients with heart failure(HF) have kidney disease. The objective of the study is to evaluate the short and long-term clinical performance of patients with CRS who are followed-up by the cardiorenal units(CRU)

Methods: Fifty-four patients admitted in the CRU from April 1 to 30, 2022 at the Vall d'Hebron Hospital were included. Clinical follow-up was performed until October 31, 2023. Anthropometric measurements, signs of tissue and vascular congestion by US, and laboratory parameters were recorded

Results: A total of 47(87%) and 16(30%) patients completed follow-up in the CRU at 6 and 12 months. Baseline characteristics are shown in Table 1. Mean age 70 years(±1.6), 65% men, ischemic heart disease HF(48%), functional classes II and III were most frequent (60% and 35%, respectively). Cardiac ejection fraction (EF) of 40%(±1.6), and HFrEF reduced by 61%. Congestion studies: 15%of patients had pulmonary B lines, 23% vena cava>20mm, and 30% discontinuous renal venous pattern. NT-proBNP and CA-125 were 4623pg/mL[898-28229] and 20.2U/mL[3.9-171], respectively. Mean follow-up 8.6 months(±0.6). Comparing the baseline visit with the control at 6 months, treatment was optimized with sacubitril-valsartan 33% vs 49%(p=0.02) and SGLT2i 48% vs 72%(p=0.008) without significant deterioration in renal function, and a reduction of more than 50% in the number of hospital admissions(p=0.002). 22% required peritoneal dialysis and 20%hemodialysis. Ten(19%) patients died, 5of them due to cardiovascular(CV) events

Conclusions: We showed that the CRU is vital for the management of complex patients since it guarantees greater implementation of drugs that reduce CV mortality and the number of hospital admissions in HF

eGFR Variability in Heart Failure Patients with CardioMEMS Monitoring

Lawrence S. Ullman, Paige N. Beaudry, Gabriel Caldato Barsotti, Jeffrey M. Turner. Yale Nephrology Clinical Research. *Yale University School of Medicine, New Haven, CT.*

Background: Chronic variations in estimated glomerular filtration rate (eGFR) have been associated with an increased risk of stroke, myocardial infarction, and all-cause mortality. Patients with heart failure (HF) are a subpopulation that is commonly associated with variable eGFR. One approach to HF management is the implantation of the CardioMEMS device which allows patients' providers to remotely monitor their pulmonary artery pressure (PAP) to guide care in real-time. We hypothesized that HF patients who received a CardioMEMS implant may exhibit reduced eGFR variability due to the accessibility of acute PAP data to aid in treatment adjustments for volume regulation.

Methods: This retrospective observational study included HF patients identified from the Yale Heart Failure and Transplant CardioMEMS registry. Creatinine measurements were collected from the 12 months prior to the implantation and the 12 months following implantation. The 2021 CKD-EPI equation was used to calculate eGFR, and eGFR variability was quantified by the coefficient of variation (CV). The CV is defined as the standard deviation of the eGFR measurements divided by the mean eGFR. The primary outcome of interest was the difference in the CV in the pre-and post-CardioMEMS implantation periods.

Results: 429 patients received a CardioMEMS implant at Yale between 2017-2023. Of the 429 patients, 424 patients had available creatinine data and were included in the analysis. The mean eGFR of the patient cohort before CardioMEMS implantation was 49.4 mL/min/1.73m² and the mean eGFR post-CardioMEMS implantation was 43.6 mL/min/1.73m² ($p < 0.0001$). The CV of eGFR demonstrated a nonsignificant decrease of 0.0085 (p=0.2509) when comparing before and after CardioMEMS deployment.

Conclusions: In this cohort of heart failure patients who received a CardioMEMS implant, we did not observe an impact of the CardioMEMS intervention on eGFR variability. However, future research utilizing multivariate modeling to account for potentially confounding variables, such as comorbidities and outpatient medications, is warranted to better understand the impact of CardioMEMS-guided care on renal function.

Cardiac Implantable Electronic Device Infections in Patients with Renal Insufficiency: A Meta-Analysis

Deepak Chandramohan,[1] Prathap Simhadri,[2,3] Prabhat Singh,[4] Hari Naga Garapati,[5] Raghunandan Konda,[1] Divya Chandramohan,[6] Nihar K. Jena,[7] Roopa Naik.[8] *[1]The University of Alabama at Birmingham, Birmingham, AL; [2]AdventHealth, Altamonte Springs, FL; [3]Florida State University, Tallahassee, FL; [4]Christus Spohn Health System, Corpus Christi, TX; [5]Baptist Medical Center East, Montgomery, AL; [6]The University of Texas at San Antonio, San Antonio, TX; [7]Trinity Health Oakland Hospital, Pontiac, MI; [8]Geisinger Health, Danville, PA.*

Background: Renal insufficiency is a risk factor for cardiac implantable electronic device (CIED) infection.

Methods: To identify studies, we conducted a comprehensive search of multiple electronic databases. Using the random effects model, we calculated the pooled rates and odds ratios. We utilized the Cochran Q and I2 statistics to detect heterogeneity.

Results: A total of 17 studies comprising 263,819 chronic kidney disease (CKD) and 89,617 end stage renal disease (ESRD) patients were included. The mean age was 68.6 years (95% CI: 66.4-70.8; I2: 99.7). The pooled rate of CIED infection in patients with CKD was 4.3% (95% CI: 2-8.8; I2: 95.7) and ESRD was 5.9% (95% CI: 3.3-10.5; I2: 99.3). The pooled risk of CIED infection in the CKD population was OR 2.5 (95% CI: 1.9-3.3; p <0.001; I2: 21.1), and in ESRD was OR 2.4 (95% CI: 1.01-5.7; p = 0.046; I2: 88.8). ESRD was associated with higher mortality, OR 2.5 (95% CI: 1.4-4.4.8; p = 0.001; I2: 95).

Conclusions: The rates of CIED infections in renal insufficiency are significant. CKD and ESRD are associated with an increased risk of infection. ESRD patients have an increased risk of mortality.

SA-PO340

Open vs. Endovascular Revascularization for Chronic Limb-Threatening Ischemia in CKD

Katherine R. Tuttle,[1,2] Mohammed Hamouda,[3] Matthew T. Menard,[4] Michael B. Strong,[4] Gheorghe Doros,[5] Alik Farber,[5] Mahmoud Malas.[3] On behalf of the BEST-CLI Trial. *[1]University of Washington School of Medicine, Seattle, WA; [2]Providence Inland Northwest Health, Spokane, WA; [3]University of California San Diego, La Jolla, CA; [4]Brigham and Women's Hospital, Boston, MA; [5]Boston University, Boston, MA.*

Background: Chronic kidney disease (CKD) increases risk of chronic limb threatening ischemia (CLTI). We assessed relationships between estimated glomerular filtration rate (eGFR) and clinical outcomes by surgical versus endovascular revascularization.

Methods: The Best Endovascular versus Surgical Therapy in Patients with CLTI (BEST-CLI) trial enrolled patients with CLTI inclusive of those with CKD. Spline modeling was performed across the range of eGFR observed in study participants to assess hazard ratios (HRs) for major adverse limb events (MALE: above ankle amputation, limb reintervention) or death, the primary trial outcome, by randomized assignment. Multiple variable Cox models were used to predict risks of MALE or death.

Results: At baseline, the mean±SD age was 67.4±9.7 years, 28.5% (500/1756) were women, and 27.5% (478/1740) identified as non-White race. CKD was present in 28.4% (499/1754). At eGFR <30 mL/min/1.73m^2, the HR for MALE or death increased with no difference in the primary outcome by randomized surgical versus endovascular revascularization (**Figure**). In adjusted Cox models, the HRs (95% confidence interval) for eGFR <30 versus ≥60 mL/min/1.73m^2 were 2.03 (1.68-2.43, p<0.001) and 3.46 (2.80-4.27, p<0.001) for MALE and death, respectively. In subgroup analyses by the same eGFR strata, antiplatelet agent non-users had increased risk of the primary outcome (HR 2.58, 1.71-3.89, p<0.001) versus no risk increase in users.

Conclusions: In patients with CLTI, risks of MALE and death increased sharply at eGFR <30 mL/min/1.73m^2 with no difference in the primary outcome by surgical or endovascular revascularization. Use of antiplatelet agents may mitigate risks of MALE and death in this high-risk population.

Poststenotic Dilatation (PSD) in Human Renal Artery Stenosis (RAS)

Mina H. Al Saeedi,[1] Tarek Z. Arabi,[1,2] Jakob Nyvad,[1] Shivam Bajpai,[1] Mouaz Oudih,[1] Li Xing,[1] Bo Lu,[1] Lei Zhang,[1] Hui Tang,[1] Xiang yang Zhu,[1] Sanjay Misra,[1] Amir Lerman,[1] Lilach O. Lerman.[1] Nephrology and Hypertension. *[1]Mayo Foundation for Medical Education and Research, Rochester, MN; [2]Alfaisal University College of Medicine, Riyadh, Saudi Arabia.*

Background: A hemodynamically significant RAS may cause renal inflammation and development of PSD. However, beyond local remodeling, the functional significance of PSD, its link to renal function and inflammation, or its reversibility remain unclear. We hypothesized that PSD-RAS is associated with renal dysfunction and inflammatory marker levels in the stenotic renal vein (STK-RV) and would regress after percutaneous transluminal renal angioplasty (PTRA)

Methods: RAS patients with PSD (n=31, Table 1) underwent multidetector CT scanning and STK-RV sampling. In 3D CT images, PSD dilatation diameter ratio (DDR) was defined as the ratio between the maximal PSD diameter and the non-diseased segment proximal to RAS (Fig1). In 7 patients, studies were repeated 3 months after PTRA

Results: Patients had kidney dysfunction and hypertension (Table 1). DDR directly correlated with elevated serum creatinine, STK-RV levels of neutrophil gelatinase-associated lipocalin (NGAL), interleukin-6 (IL-6), and interferon-gamma (INF-γ) (Fig2), and 24h urinary protein levels. After PTRA renal function improved, inflammatory biomarkers declined, and PSD regressed (Fig3)

Conclusions: Development of PSD is reversible but associated with kidney dysfunction and inflammation and may reflect the severity of kidney injury in RAS. Detection of PSD may be beneficial in guiding treatment decisions

Funding: NIDDK Support

Perceptions of Blood Pressure, Self-Monitoring, and Self-Management among Veteran Patients with CKD: A Qualitative Study

Mary K. Good,[1] Daniel D. Ball,[1] Sadaf Akbari,[1,2] Masaaki Yamada,[1,2] Elissa Z. Faro,[1,2] Heather Reisinger,[1,2] Diana I. Jalal.[1,2] *[1]VA Iowa City Healthcare System, Iowa City, IA; [2]University of Iowa Health Care, Iowa City, IA.*

Background: Hypertension, commonly found in Veterans with Chronic Kidney Disease (CKD), is a well-known risk factor for CKD progression, cardiovascular disease, and mortality. As part of a project to improve blood pressure (BP) management in Veterans living with CKD, this qualitative study examines Veterans' perceptions of BP monitoring and management.

Methods: In an ongoing clinical trial, 160 Veterans are randomized to test whether pharmacist-guided self-management of hypertension is more effective than self-monitoring and standard of care. We conducted semi-structured individual interviews covering participants' history and knowledge of hypertension and CKD; self-monitoring routine; perceptions of BP monitoring and management; and experiences with the clinical pharmacist. Transcripts were analyzed using MAXQDA 2024 qualitative software.

Results: The team completed 37 Veteran interviews. Most respondents spoke positively about their role in monitoring BP and interactions with clinical pharmacists. Self-reports of at-home BP monitoring indicated strong adherence to study instructions. Automated reminders promoted consistency in daily BP measurement and recording despite participants' mild irritation. Interest in tracking BP numbers varied by past experience monitoring BP, age, health literacy, and comorbidities like diabetes. Perceptions of BP measurements and trends influenced acceptability of pharmacist-guided self-management of BP. Veteran-specific factors affecting acceptability and adherence included a *Commitment to Serve*: Veterans hoped their participation would improve BP and CKD treatment for other Veterans in the future. Another factor was respect for *Chain of Command*: relationships with providers were seen through the lens of military hierarchy, with compliance interpreted as "following orders."

Conclusions: With proper instructions and technical support, consistent, correct self-monitoring of BP appears to be feasible for Veterans with CKD. Increased education on the importance of BP management and risks of hypertension for CKD patients could help to improve Veteran adherence with home BP monitoring and overall health understanding.

Unattended Compared with Attended Automated Office Blood Pressure Measurements: A Systematic Review and Meta-Analysis

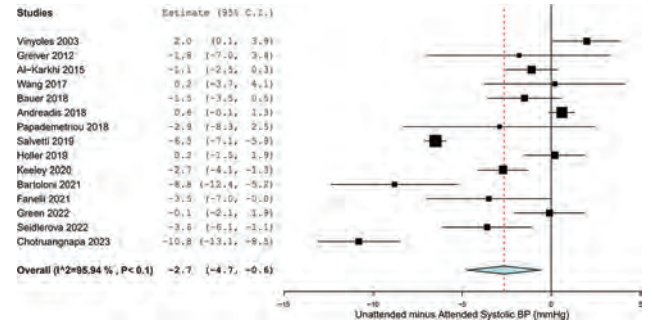
Valérie Deragon,[1] Youssef Baati,[1] Laurence Trudelle,[1] Amel Merabtine,[2,1] Dean S. Picone,[3] Remi Goupil.[2,1] *[1]Universite de Montreal, Montreal, QC, Canada; [2]Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada; [3]University of Sydney, Sydney, NSW, Australia.*

Background: Standardized automated office blood pressure (AOBP) measurement is widely accepted as the preferred method to monitor BP. However, disagreements persist as to the need to perform AOBP in an unattended manner, where the patient is left alone in a quiet room. In 2019, two meta-analyses assessing the differences between unattended and attended BP readings showed opposite results and prompting the publication of several more studies. Our objective was to reevaluate the BP differences between unattended and attended AOBP when both are performed in an identical manner.

Methods: This systematic review with meta-analysis was conducted according to the PRISMA guidelines. Studies were included if both unattended and attended AOBP were measured on the same participants in a randomized or alternating sequence manner during a single visit with the same device and an identical measurement protocol. The primary outcome was the difference between unattended and attended systolic (SBP) and diastolic (DBP) BP, expressed as weighted mean differences (95% confidence interval) using random-effects models.

Results: From 8,088 screened studies, data was extracted from 15 studies which met the inclusion criteria (n=1,747 participants). In the pooled analysis, the attended compared with unattended BP was higher for SBP by 2.7 mmHg (95%CI 0.6 to 4.7) and DBP by 0.9 mmHg (95%CI 0.1 to 1.8). In leave-one out analyses, results were similar except when excluding the study with the most extreme BP difference (Chotruangnapa 2023) where the difference became non-significant.

Conclusions: Standardized attended AOBP measurements result in slightly higher readings than unattended AOBP. Whether such small differences translate into clinically significant changes in management of BP remains uncertain. Therefore, standardized attended AOBP could remain a reasonable option for BP measurement in a real-life clinical setting.



SA-PO344

Measuring the Quality of In-Office Blood Pressure Measurements in Different Specialties

Artem F. Dadamyan, Neil S. Umles, Joel M. Topf. *Ascension St John Hospital, Detroit, MI.*

Background: In-office blood pressure measurements may be done routinely, or standardized. Both ACC/AHA and KDIGO recommend standardized in-office blood pressure measurements. Staffing issues, time constraints, and lack of widespread education of medical professionals may be barriers to proper measurements according to these guidelines. This study evaluated the technique of in-office BP measurements across internal medicine and nephrology specialties.

Methods: We conducted a quality improvement project collecting data by direct observation. The technique was scored by a ten-point checklist derived from ACC/AHA and KDIGO guidelines. Nephrology and Internal Medicine outpatient practices affiliated with Ascension St. John Hospital were observed and graded.

Results: Among nephrology offices, the overall checklist was followed correctly with a mean of 61% and 62% of the time, and an internal medicine clinic 46% of the time. The highest adherences were of patients with uncrossed legs (83%), correct cuff size (90%), and cuff over bare arm (73%). The lowest results were arm raised to level of sternum (13%), and sitting more than five minutes (3.3%). There were significant discrepancies between clinics among these data, with internal medicine clinic accounting for 4/5 of the patients with crossed legs, and having feet on the floor only 13% of the time.

Conclusions: Barriers to standardized blood pressure measurements are increased burden on medical professionals and time needed for proper measurement. This may be due to barriers of staffing, time constraints, and education. The concern for over or under-treatment is of significantly higher concern and therefore urges the need for updating clinic procedures of this standardized method. Home blood pressure monitoring (HBPM) has not been studied in the setting of chronic kidney disease, and although it likely has significant utility, needs to be used in addition to proper in-office measurements to guide appropriate therapy. Given the high recommendation for standardized BP measurement and its use in several clinical trials, the use of this method is of utmost importance to upkeep in general clinical settings in order to follow the recommendations made by clinical findings.

SA-PO345

Effect of Renal Denervation on Plasma Renalase Concentration in Patients with Resistant Hypertension

Marcin Adamczak,[1] Beata Czerwienska,[1] Michal Lelek,[2] Damian Gojowy,[1] Katarzyna Mizia-Stec,[2] Andrzej Wiecek.[1] *[1]Department of Nephrology, Transplantation and Internal Medicine, Medical University of Silesia, Katowice, Poland; [2]1st Department of Cardiology, Medical University of Silesia, Katowice, Poland.*

Background: Renalase is an enzyme produced among others by proximal tubule cells in the kidneys and participates in the degradation of catecholamine. Results of experimental studies shown that renalase secretion is stimulated by increased plasma catecholamine concentration and to some extent also by an increase in blood pressure. Renal denervation (RDN), *i.e.*, percutaneous ablation of the sympathetic nervous system fibers located in the wall of renal arteries by radio frequency waves, is a method of patients with resistant hypertension. This single-center, interventional clinical study aimed to assess the effect of RDN on the plasma renalase concentration in patients with resistant arterial hypertension.

Methods: Twenty-five patients (12 women, 13 men) aged 54.4 ± 8.1 years with resistant hypertension who underwent renal denervation using Simplicity catheters (Medtronic, Inc., Northridge, CA) were enrolled in the study. Plasma renalase concentration was determined by enzyme-linked immunosorbent assay method (Cloud-Clone Corp., Houston, TX, USA) before RDN, 6 and 12 months after RDN. Results were presented as a mean with standard deviation.

Results: Systolic, diastolic blood pressure and heart rate were reduced after RDN (before RDN, 6 and 12 months after RDN, respectively: 190.4 ± 25.0, 161.1 ± 14.7, 155.5 ± 18.3; $p<0.001$; and 111.8 ± 19.3, 88.9 ± 8.5, 91.0 ± 10.4 mmHg; $p<0.001$ and 80.1 ± 16.3, 74.5 ± 11.1, 73.6 ± vs. 11.3 beats/min; $p<0.001$). Plasma renalase concentrations measured before RDN, 6 and 12 months after RDN in the studied group were 25.1 ± 7.5, 22.0 ± 7.1, and 23.1 ± 6.0 [μg/mL], respectively (ANOVA $p<0.001$, Fisher post hoc: before vs. six months $p = 0.01$, before vs. 12 months $p = 0.09$, six months vs. 12 months $p = 0.3$). There were no significant correlations between changes of plasma renalase concentration and decrease of blood pressure and heart rate during the follow-up after RDN.

Conclusions: 1. Renal denervation decreases moderately plasma renalase concentration, however this effect of RDN seems to be not associated with observed decrease of blood pressure. 2. Further studies are required to evaluate whether decrease in plasma renalase concentration is associated with change in plasma catecholamine concentration.

SA-PO346

High Dietary Sodium Increases Urinary Endothelin-1 Excretion in Salt-Resistant Women but Not in Men

Rebecca C. Fetter,[1] Jazmine I. Benjamin,[1] Victoria L. Nasci,[1] Joseph M. Stock,[5] Nathan T. Romberger,[5] Joseph Watso,[2] Matthew C. Babcock,[3] Megan Wenner,[5] Austin Robinson,[4] Eman Y. Gohar.[1] *[1]Vanderbilt Department of Medicine, Nashville, TN; [2]Indiana University Bloomington Department of Kinesiology, Bloomington, IN; [3]Cardiovascular and Applied Physiology Laboratory, Florida State University, Tallahassee, FL; [4]Division of Geriatric Medicine, University of Colorado Denver, Aurora, CO; [5]Department of Kinesiology and Applied Physiology, University of Delaware, Newark, DE.*

Background: Endothelin-1 (ET-1) is a peptide thought to be implicated in gender differences in hypertension (HTN). In the kidney, ET-1 promotes natriuresis, and urinary ET-1 excretion reflects renal ET-1 production. Prior studies in our laboratory demonstrated that female rats exhibited higher urinary ET-1 than males on a normal salt diet. When switched to a high salt diet, only the male rats exhibited increased urinary ET-1. However, potential gender differences in the effect of dietary sodium on the renal ET-1 system in humans are unclear. Thus, we aimed to test the hypothesis that women would have higher overall ET-1 excretion than men and that increasing dietary sodium would augment ET-1 excretion only in men.

Methods: Salt-resistant participants (7 women; 14 men) with a baseline blood pressure (BP) of less than 140/90 mmHg followed recommended sodium (RS; 2300 mg/day) and high sodium (HS; 7000 mg/day) diets for 10 days, administered in random order with a washout of at least 4 weeks between interventions. At the end of each diet, 24-hour ambulatory BP was measured and 24-hour urine collected. ET-1 excretion was quantified

using the QuantiGlo (R&D) ET-1 ELISA. ET-1 excretion on the RS and HS diets in men and women was evaluated using a repeated measures two-way ANOVA with post hoc Sidak's test.

Results: Systolic, mean, and diastolic BP were not different between the RS and HS diets in either gender. Women exhibited higher urinary ET-1 than men, which was most evident on the HS diet (*P*=.0228). Only women experienced a significant increase in ET-1 excretion on the HS diet (196.01±18.40 pg/day) as compared to the RS diet (127.24±19.52 pg/day) (*P*=.0096). There was no significant gender difference or diet difference in urine flow rate (UFR).

Conclusions: Women exhibited higher urinary ET-1 excretion than men. Only women had significantly increased urinary ET-1 during the HS versus the RS diet, which opposes our hypothesis. Understanding gender differences in ET-1-mediated sodium regulation could potentially inform future studies toward developing gender-specific therapeutics for HTN.

Clinical Characteristics and Progression in Patients with Malignant Hypertension and Thrombotic Microangiopathy Kidney Damage

Li Jin, Wanhong Lu, Xiangyun Dang. *The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China*.

Background: Malignant hypertension (MHT) is a group of syndromes characterized by severe hypertension and acute microvascular injury, often accompanied by thrombotic microangiopathy (TMA). This study aimed to establish a high-quality and standardized historical prospective study cohort to preliminarily investigate the possible mechanism of renal injury in MHT with TMA.

Methods: The MHT patients with TMA confirmed by renal biopsy were enrolled from July 2015 to December 2023. General information, clinical data, and renal pathology were collected. Patients were divided into two subgroups: the ESRD group (eGFR<15ml/min/1.73m^2) and the non-ESRD group (eGFR≥ml/min/1.73m^2).

Results: A total of 47 patients were enrolled with an age of 39.4±4.83 years, of which 43 (71.4%) were male. 17 (36.1%) of patients had a family history of hypertension. The highest systolic blood pressure was 204.8±15.0 mmHg and the highest diastolic blood pressure was 140.0±18.7 mmHg. Serum creatinine was 286.0 (158.0, 427.5) μmmol/L and eGFR was 23.6 (14.2, 49.6) ml/min/1.73m^2 at baseline. Renin, angiotensinogen II, and aldosterone were 130.0 (81.9, 301.0) IU/μl, 64.8 (46.6, 85.5) pg/μl and 530.0 (326.0, 1831.3) pg/μl respectively, all higher than normal. ACEI/ARB treatment was given to 30 patients (63.8%). During the follow-up period, 20 (42.6%) patients progressed to ESRD with a median time of 113 (4.5, 332.8) days. 1 patient (2.1%) died of heart failure. The level of baseline hemoglobin (t=5.151, P<0.001), eGFR (z=-4.769, P=0.005), immunoglobulin G (t=2.641, P=0.011), the proportion of ACEI/AERB use (χ^2=8.560, P=0.003) were lower in the ESRD group compared to the non-ESRD group. While the serum creatinine (*Z*=-4.688, P=0.005) and lactate dehydrogenase levels (z=-2.872, P=0.004) were higher in the ESRD group. Multivariate logistic regression analysis showed that lower hemoglobin level (OR=0.937, 95% CI 0.904-0.972, P<0.001) was associated with earlier progression to ESRD in MHT with TMA patients.

Conclusions: The renal prognosis for patients with MHT and TMA renal injury is poor. Patients with MHT and TMA kidney injury had secondary hyperaldosteronism. Baseline plasma hemoglobin level is an independent risk factor for progression to ESRD in patients with MHT and TMA kidney injury.

SA-PO348

Long-Term Efficacy of Renal Denervation in Patients with Resistant Hypertension: A Meta-Analysis of Randomized Controlled Trials

Rajiv Hans S. Menghrajani,[1] Mirtha C. Almanzar,[1] Maria Angela Matabang,[1] John Paul B. Aparece,[2] Edgar V. Lerma.[3] *[1]Lincoln Medical Center, Bronx, NY; [2]Texas Tech University Health Sciences Center El Paso, El Paso, TX; [3]University of Illinois Chicago College of Medicine, Chicago, IL*.

Background: Resistant hypertension, defined as blood pressure (BP) that remains elevated despite the concurrent use of three antihypertensive agents of different classes, represents a significant challenge in clinical practice. The persistent elevation of BP in these patients is associated with an increased risk of cardiovascular events and mortality. Renal denervation (RDN), a minimally invasive procedure targeting the sympathetic nerves within the renal arteries, has emerged as a promising intervention. This study aims to determine the long-term efficacy of RDN in controlling BP in patients with resistant hypertension.

Methods: Electronic databases were searched until March 2024. Three reviewers screened the abstracts, reviewed the full texts, and appraised the quality of the included studies using the PRISMA guidelines. The primary outcomes were decrease in systolic BP at 6 months and 36 months.

Results: Out of 145 articles retrieved, 15 RCTs were included in the meta-analysis (n = 1564). At 6 months, there was a mean difference of -2.24 mmHg [-4.65, 0.17] p = 0.07 in the ambulatory systolic BP, while the office-measured systolic BP showed a mean difference of -1.62 mmHg [-4.51, 1.26] p = 0.27. There is moderate heterogeneity for both the ambulatory and office-measured systolic BP, I2 = 61% and I2 = 42%, respectively. At 36 months, there was a mean difference of -7.40 [-10.39, -4.41] p < 0.00001 in the ambulatory systolic BP, while there was a mean difference of -13.15 [-17.55, -8.76] p <0.00001 in the office measured systolic BP. The heterogeneity for both ambulatory and office-measured at 36 months was 0%.

Conclusions: RDN decreases office and ambulatory-measured systolic BP in resistant hypertension at both 6 and 36 months. However, this effect is only statistically significant in the long term basis (36 months). Studies with longer follow-up can further establish RDN's long term effect.

Can Novel Ambulatory Blood Pressure Monitoring (ABPM) Parameters Change the Way We Treat Hypertension in CKD?

Bahaar S. Athavale, Hardik K. Shah, Dilip Kirpalani. *Bombay Hospital Institute of Medical Sciences, Mumbai, India.*

Background: Blood pressure control rates in CKD continue to remain abysmal, in spite of advanced diagnostics and therapeutics. Novel ABPM entities such as BP variability, morning masked hypertension, "Double Risers" (rise of both nocturnal heart rate and BP) and Early Morning BP Surge (EMBS) by moving average sleep trough method can facilitate efficient management of hypertension in CKD. Our study aims to detect and compare these parameters between CKD and non-CKD patients.

Methods: 100 hypertensive patients - CKD Group (Stage 1 to 4; n=50) and Non-CKD Group (n=50); underwent measurement of Single Office BP (SOBP), Automated averaged Office BP (AOBP) followed by 24 hours ABPM.

Results: In CKD group, 48% had nocturnal non-dipping pattern, 12% had rising pattern of nocturnal BP and 10% were double risers. This was significantly higher than the non-CKD group. The CKD group had significantly higher EMBS (36% vs. 22%; p=0.04) by the newer "moving" average sleep trough method. In this method difference between Average Morning SBP (Average of morning SBPs taken during the first 2 hours after waking up) and Moving Lowest Nighttime SBP (Average of 3 SBP readings centered on the lowest night (nadir) SBP value) is calculated. Masked hypertension was seen in 76% of CKD and 40% of non-CKD patients. However, in CKD group masked hypertension in morning time (between 6 am to 10 am) was significantly higher (70%) than non CKD (12%). BP variability assessment by Standard Deviation method revealed no statistically significant difference between the CKD and the non-CKD groups (15.12±4.05 vs. 15.86±4.20 respectively). However, novel method such as Average Real Variability revealed statistically significant difference between the two groups (12.9±4.18 vs 11.6±3.63; p=0.03). Similarly, while considering Variability Independent of Mean as a parameter, CKD patients had higher BP variability (24.74±16.25) as compared to the non-CKD group (22.2±13.3; p=0.03).

Conclusions: Hypertensive patients with CKD have a greater benefit from utilizing 24 hour ABPM as compared to those without CKD. Novel parameters such as morning masked hypertension, double risers, "moving" average sleep trough and average real variability can be assessed for better therapeutic interventions.

SA-PO350

Efficacy of the Combination of Acetazolamide with Loop Diuretics vs. Double-Dose Loop Diuretics for Decongestion in CKD Patients: A Randomized Controlled Trial

Jiranat Sriswasdi. *Phramongkutklao Hospital, Bangkok, Thailand.*

Background: The combination of acetazolamide and loop diuretics in the setting of hospitalized heart failure has shown promising results in improving diuresis and decongestion. However, the effectiveness of this combination in chronic kidney disease (CKD) with volume overload has yet to be determined.

Methods: CKD patients with fluid overload, confirmed by bioimpedance spectroscopy, were allocated to receive oral acetazolamide 250 mg/day plus furosemide or a doubled dose of furosemide. Volume status, changes of body fluid compartment from body composition monitoring, and urinary sodium were evaluated at baseline, 2, and 4 weeks. The main outcome was the proportion of body weight reduction (> 2 kg and 5%) and mean change of body weight at 2 weeks.

Results: Fifty-two CKD patients with an estimated glomerular filtration rate of 38 mL/min/1.73 m2 were included. Body weight reduction > 2 kg at week 2 (40.7% vs. 12%, risk ratio (RR) 3.39, 95% CI 1.06-10.7) and body weight reduction > 5% at week 2 (25.9% vs 0% RR 2.25, 95%CI 1.62-3.12) significantly occurred in the combination group compared to the doubled-dose group. Additionally, mean difference of body weight reduction between combination group and doubled dose group was -1.37 kg, 95% CI -2.498, -0.242). The combination group showed lower rates of alkalosis and hypokalemia at 4 weeks. No serious adverse events were found in either group.

Conclusions: Adding acetazolamide to loop diuretics ameliorates volume overload in CKD patients without significant or serious side effects.

Effects of Dapagliflozin on Sodium Excretion and Blood Pressure in Patients with Type 2 Diabetes and CKD during Standardized Sodium Intake

Jelle Beernink,[1] Niels Jongs,[1] Vikas Sridhar,[2] Charlotte Mosterd,[5] Rosalie Scholtes,[5] Alyssa Caldwell,[3] Daniel I. Casillas,[3] Lynette M. Driscoll,[3] Peter J. Greasley,[4] Daniël H. van Raalte,[5,6] Petter Bjornstad,[3] David Cherney,[2] Hiddo J. Heerspink.[1] DAPASALT Investigators. *[1]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [2]University Health Network, Toronto, ON, Canada; [3]University of Colorado Anschutz Medical Campus School of Medicine, Aurora, CO; [4]AstraZeneca, Mölndal, Sweden; [5]Amsterdam UMC Locatie AMC, Amsterdam, Netherlands; [6]Amsterdam UMC Locatie VUmc, Amsterdam, Netherlands.*

Background: We previously demonstrated that dapagliflozin reduced blood pressure (BP) without altering natriuresis in patients with type 2 diabetes (T2D) and preserved kidney function. Chronic kidney disease (CKD) is often associated with salt-sensitive hypertension, which is resistant to many anti-hypertensive drugs. In this prospective study, we assessed the effects of dapagliflozin on sodium excretion and BP in patients with T2D and CKD during standardized sodium intake.

Methods: We conducted a prospective open-label study to evaluate the effects of dapagliflozin on 24-hour sodium excretion, 24-hour BP, and extracellular volume (EV) in patients with T2D with CKD (estimated glomerular filtration rate [eGFR] of ≥25 and ≤50 mL/min per 1.73m^2) at the start of treatment (ST) (days 2-4), end of treatment (ET) (days 12-14), and washout (days 15-18) during controlled sodium intake (150 mmol/day).

Results: Thirteen patients (mean age 70 ± 9.6 years, eGFR 41 ± 12.6 mL/min per 1.73m^2, 24-hour systolic BP 130 ± 23.1 mmHg) were included. Mean 24-hour sodium excretion did not change during the study (Table 1). Nominal decreases in 24-hour systolic and diastolic BP were observed, without changes in EV. Mean 24-hour urinary glucose excretion increased at ST and ET and reversed during wash-out.

Conclusions: In patients with T2D and CKD, dapagliflozin reduced BP during standardized sodium intake, without increasing natriuresis. These findings are consistent with those in patients with T2D and preserved kidney function, and suggest that BP lowering with dapagliflozin may be attributed to different mechanisms than natriuresis in patients with and without CKD.

Comparison between Sacubitril-Valsartan and Thiazide Diuretics among Patients with Uncontrolled Hypertension in Japan

Kazuo Kobayashi,[1,2] Mari Sotozawa,[2] Kyoji Chiba,[3] Hiromichi Wakui,[2] Kouichi Tamura.[2] *[1]Committee of Hypertension and Kidney Disease, Kanagawa Physicians Association, Yokohama, Japan; [2]Department of Medical Science and Cardiorenal Medicine, Yokohama City University Graduate School of Medicine, Yokohama, Japan; [3]Department of Nephrology, Yokohama Sakae Kyosai Hospital, Yokohama, Japan.*

Background: The hypertension paradox is an urgent issue in clinical practice. Although ARBs and calcium channel blockers (CCBs) were widely used, less than 10% of patients used thiazide diuretics in Japan. Sacubitril valsartan can be used for not only patients with heart failure but also with hypertension. This study aimed to evaluate the differences of an efficacy and safety between sacubitril valsartan and thiazide diuretics in patients with poorly BP control.

Methods: Patients who showed ≥130/80 mmHg in the office despite a combination treatment of RAS inhibitors and CCBs were included. The comparison between patients treated with the addition of thiazide diuretics (THZ group, n=267) and those transferred from RAS inhibitors to sacubitril valsartan (SacVal group, n=381) was analyzed. A general linear mixed model (GLMM) was used for the analysis of clinical findings at baseline, 4 months, and 12 months. The rate of discontinuation was analyzed using the Cox proportional hazard model.

Results: The baseline backgrounds of the THZ /SacVal group were as follows; female 39/35 (%), mean age, body weight (BW), and eGFR at baseline were 67.8 ± 13.1/72.3±12.6 (years) (p<0.001), 68.1±15.7/66.2±14.2(kg), 61.2±20.9/56.8±20.3 (ml/min/1.73 m^2) (p=0.01), respectively. In the GLMM analysis, significant decrease in office and home BP after treatment was observed in both groups (p<0.001), however, no significant interaction effects between the type of drug and time course were observed for BP. Significant interaction effects were observed for eGFR, uric acid (UA), logarithmic value of ACR (LnACR), BW, and hemoglobin A_{1c} (HbA_{1c}) (all p<0.001). eGFR, UA, and LnACR were significantly decreased (p<0.001), increased (p<0.001), and decreased (p<0.001), respectively, in the THZ group during the time course. Significant decreases were observed in BW and HbA_{1c} in the SacVal group (p<0.001). Treatment discontinuation due to adverse effects was significantly more frequent in 34 cases (13%) in the THZ group, than 12 cases (3%) in the SacVal group with hazard ratio of 6.3 [95% CI, 2.7, 14.9] (p<0.001).

Conclusions: Both treatments decreased BP; however, compared to thiazide, sacubitril valsartan resulted in a superior reduction in BW, HbA_{1c}, and favorable changes in kidney function, with better treatment adherence.

SA-PO353

Effect of Baxdrostat on Albuminuria in Treatment-Resistant Hypertension

Hiddo J. Heerspink,[1] Dustin J. Little,[2] Robin Myte,[2] Nataliia Zaozerska,[2] Robert I. Menzies,[3] Shira Perl,[2] Glenn M. Chertow,[4] Jamie P. Dwyer.[5]
[1]University Medical Center Groningen, Groningen, Netherlands; [2]AstraZeneca Biopharmaceuticals R and D, Warsaw, Poland; [3]AstraZeneca Biopharmaceuticals R and D, Gothenburg, Sweden; [4]Stanford University School of Medicine, Stanford, CA; [5]University of Utah Health, Salt Lake City, UT.

Background: Baxdrostat is an aldosterone synthase inhibitor in development in combination with the sodium glucose cotransporter 2 (SGLT2) inhibitor dapagliflozin for patients with CKD and hypertension (HTN). We performed a *post hoc* analysis evaluating baxdrostat's effect on urine albumin-to-creatinine ratio (UACR) in a phase 2 study in participants with resistant HTN.

Methods: BrigHTN was a randomized, placebo-controlled trial where qualifying participants with resistant hypertension (defined as treatment with at least 3 anti-hypertensive drugs, at least one of which was a diuretic) were randomized 1:1:1:1 to baxdrostat 0.5, 1, or 2 mg or placebo for 12 weeks. We analyzed geometric mean change from baseline to 12 weeks of log-transformed UACR and calculated the percent change within and between randomized groups. We excluded missing values (n=83).

Results: Overall, 275 participants were randomized of whom 39 (14.2%) had baseline eGFR <60 mL/min/1.73m^2 and 60 (21.8%) had UACR >30 mg/g. Baseline median UACR was 12 mg/g with quartile 1 and quartile 3 values of 6 and 36 mg/g, respectively. As reported previously, baxdrostat 1 mg and 2 mg resulted in statistically significant placebo-adjusted reductions in systolic blood pressure. All baxdrostat groups showed placebo-adjusted reductions in UACR (Table 1); changes in the baxdrostat 2 mg group met conventional levels of statistical significance (p=0.011).

Conclusions: In a placebo-controlled trial of baxdrostat for resistant hypertension, baxdrostat 2 mg daily reduced UACR. Relatively few BrigHTN participants had CKD, and any amount of albuminuria was allowed. The phase 3 Arctic trial (NCT06268873) of patients with CKD and hypertension will compare baxdrostat/dapagliflozin to placebo/dapagliflozin both on top of maximally tolerated ACE inhibitors or angiotensin receptor blockers to assess the primary endpoint of change in eGFR over time.

Funding: Commercial Support - AstraZeneca

Table 1: Post-hoc Analysis of Change from Baseline in UACR (mg/g) at 12 Weeks in Study CIN-107-121

Group	Treatment group, Participants (N)	Participants Evaluable (n)	Change, %	Comparison of treatment groups to placebo		
				Change, %	95% CI	p-value
All participants	Placebo (N = 69)	57	-2.8			
	0.5 mg (N = 69)	44	-21.6	-19.3	(-40.0, 8.6)	0.159
	1 mg (N = 70)	47	-19.9	-17.6	(-38.5, 10.4)	0.196
	2 mg (N = 67)	44	-33.7	-31.8	(-49.1, -8.6)	0.011

Change in % is obtained from geometric mean ratios from an ANCOVA model with change in log UACR from baseline as the dependent variable, treatment as a fixed categorical factor and baseline log UACR as a continuous covariate. Missing values are excluded. ANCOVA Analysis of Covariance; CI Confidence interval; n Number of participants included in analysis; N Number of participants per treatment group.

SA-PO354

Is It Nighttime Dipping or Sleep-Time Dipping?

Ali Mirza Onder,[1,2] Songul Onder.[3] *[1]Nemours Children's Hospital Delaware, Wilmington, DE; [2]Thomas Jefferson University Sidney Kimmel Medical College, Philadelphia, PA; [3]University of Maryland School of Medicine, Baltimore, MD.*

Background: Those subjects who work at night-time and sleep at daytime need to replicate the blood pressure dipping (BPD) phenomena during daytime. There is limited information on how well they can replicate night-time dipping.

Methods: 24-hour ambulatory blood pressure monitoring (ABPM) was used for 84 medical professionals during three different work- sleep schedules; work night-time and sleep during daytime, work daytime and sleep at night-time, and for an off-work day, awake at daytime and sleep at night-time. There were four groups within this cohort: *Group A;* subjects who only work at daytime and always sleep at night-time, Group B; subjects who switch from working day to night-time every 3-4 days, Group C; subjects who switch from working day to night-time every 3-4 months, and Group D; those who only work at night-time and always sleep during daytime. Sleep score is defined as the product of the sleep BPD percentage and duration of sleep (hours). The Kruskal Wallis test was used to compare differences among groups, and the Signed rank test was used to evaluate paired differences.

Results: Mean reported sleep durations were similar between the four groups for both periods of work schedule. When Group A was compared to Group D for the median BPD (15.5% vs. 12%) and the sleep score (112 vs. 90), they were statistically indifferent (p=0.31 and p=0.24, respectively). There was no difference for sleep BPD between two different work times for Groups B & C (p=0.47). However, the median sleep score was significantly better when subjects were sleeping at night-time (127.5 vs 103, P=0.02). There was no difference for sleep BPD (p=0.43) and for sleep score (p=0.36), when the four groups were compared for their BPD during an off-work day.

Conclusions: For this cohort, the BPD was associated with sleep-time rather than night-time. Subjects who work at night had similar sleep BPD compared to subjects who work at daytime. The personal history of night-time work did not impact the sleep BPD on an off-work day. A significantly higher sleep score was achieved by the alternating subjects when they slept at night-time, because of longer reported sleep duration.

SA-PO355

Effectiveness, Acceptability, and Feasibility of a School-Based Program for Detecting High Blood Pressure in Children

Jonathan P. Glenning,[1,2] Freya Sheeran,[1,2] Jon Quach,[1,2] Michael Cheung,[1,3] Stephanie Best,[1,2] Catherine Quinlan,[1,3] Jonathan P. Mynard.[1,2] *[1]Murdoch Children's Research Institute, Parkville, VIC, Australia; [2]The University of Melbourne, Melbourne, VIC, Australia; [3]The Royal Children's Hospital Melbourne, Parkville, VIC, Australia.*

Background: Childhood high blood pressure (BP) is associated with cardiovascular morbidity and mortality in mid-adulthood. Community-based BP screening may improve equitable access and awareness, but robust methodology is required. Accordingly, our aim was to assess the effectiveness, acceptability and feasibility of a two-stage school-based BP screening program incorporating targeted 24-hour ambulatory blood pressure monitoring (ABPM).

Methods: 198 children (59% male, 7.6–12.7 years) were recruited from three primary schools in Melbourne, Australia. Following an education session for all eligible children, auscultatory BP was measured five times, alternating between arms and after an initial five minutes of rest. Those with an average BP ≥85th percentile (AAP thresholds) or a risk factor for high BP had this repeated two weeks later, along with ABPM. Families and school staff completed a questionnaire about acceptability post-program.

Results: At the first assessment, 5.6% had elevated BP and 5.0% had a hypertensive BP (14.6% combined if using just the first measure). 29.8% were selected for the second assessment (including 10 with obesity, 15 born premature, four with a history of congenital heart disease, and nine with BP ≥85th percentile, but <90th percentile), of which 52 attended. ABPM indicated that 5.6% of the total cohort had white coat hypertension based on Assessment 1 and 2.5% based on Assessment 2, with a further 1.5% with sustained hypertension, and 1% with masked hypertension. An additional three participants each had either high BPs during school assessment but did not complete, or had inconclusive, ABPMs. Overall, 5.6% were referred for medical follow-up. The majority of participants (67%) who underwent ABPM reported it was tolerable with a 'bothersome' score <8/10 for day and/or night. 96% of families found the program acceptable and 90% welcomed it as part of their child's schooling.

Conclusions: These data indicate that a school-based BP screening program is effective for detecting high BP, acceptable to families and feasible to run in schools. Measuring BP on multiple occasions, with targeted ABPM, is pivotal for minimising false positives and unnecessary referrals.

Incidence and Prevalence of Edema and the Effect of Aprocitentan Treatment Strategy in the PRECISION Study

Markus P. Schlaich,[1] George L. Bakris,[2] Parisa Danaietash,[3] Bruno Flamion,[3] Krzysztof Narkiewicz,[4] Mouna Sassi-Sayadi,[3] Jiguang Wang,[5] Michael A. Weber.[6]
[1]The University of Western Australia Medical School, Perth, WA, Australia; [2]The University of Chicago Medicine, Chicago, IL; [3]Idorsia Pharmaceuticals Ltd, Allschwil, Switzerland; [4]Medical University of Gdansk Department of Hypertension and Diabetology, Gdansk, Poland; [5]Shanghai Jiao Tong University Medical School Affiliated Ruijin Hospital, Shanghai, China; [6]SUNY The State University of New York, New York, NY.

Background: Edema is an expected adverse event with Endothelin Receptor Antagonists (ERAs). PRECISION evaluated the effect of aprocitentan (APRO), a dual ERA in patients with resistant hypertension and increased CV risk (54% diabetes, 22% renal insufficiency, 20% history of heart failure). All patients were on a standardized fixed-dose combination of amlodipine (71% of patients at 10 mg), valsartan and hydrochlorothiazide. Results from PRECISION indicated a lower edema incidence in patients on 12.5 mg vs 25 mg APRO during the first 4 weeks. The objective of this analysis was to evaluate whether 12.5 mg APRO for 4 weeks followed by 25 mg APRO (12.5/25) decreased edema risk compared with 25 mg as initial dosing and throughout the study (25/25).

Methods: The study design included 3 parts: Part 1: double-blind placebo-controlled 12.5 mg or 25 mg APRO, or placebo for 4 weeks; Part 2: prolonged single-blind administration of 25 mg APRO to all patients; Part 3: double-blind placebo-controlled withdrawal phase (25 mg APRO vs placebo). Incidence (new and recurrent onset) and prevalence (new and ongoing events) of AEs indicating edema were evaluated up to 48 weeks by treatment regimen: a) 12.5/25 cohort or b) 25/25 cohort.

Results: The incidence of edema was lower in the 12.5 mg group (9.1%) vs the 25 mg group (15.9%) during the first 4 weeks of treatment (Fig 1). Most new events occurred during the first 8 weeks of treatment. After that, the incidence of edema in both APRO treatment sequences was comparable with the range reported for the placebo group during the first 4 weeks of treatment. The prevalence of edema during the 48-week study was consistently lower in subjects in the 12.5/25 cohort (11% to 17%) vs those in the 25/25 cohort (16% to 21%) throughout the study.

Conclusions: Initiation therapy with 12.5 mg APRO may represent a preferred clinical approach particularly in patients with risk of edema.

Funding: Commercial Support - Idorsia Pharmaceuticals Ltd.

Sodium-Mediated Blood Pressure Increase in CKD and Diabetic Kidney Disease Patients Coincides with Vasodysfunction

Robert E. van Duin,[1,2] Jetta J. Oppelaar,[1,2] Bert-Jan Van den Born,[1,2] Rik H. Olde Engberink,[1,2] Liffert Vogt.[1,2] Dept of Nephrology and Dept of Vascular Medicine. *[1]Amsterdam UMC Locatie AMC, Amsterdam, Netherlands; [2]Amsterdam Cardiovascular Sciences Department of Internal Medicine, Amsterdam, Netherlands.*

Background: Chronic kidney disease (CKD) and diabetic kidney disease (DKD) patients are advised to limit salt intake because of its detrimental effects on blood pressure (BP) and albuminuria. The salt-sensitive BP response in these patients may be attributed to impaired renal ability to excrete sodium (Na+) resulting in fluid overload and/or vasodysfunction. To define which factor relates to BP sensitivity in both CKD and DKD, we studied the Na+-mediated BP response in these patients compared to healthy volunteers (HV).

Methods: In this randomized crossover study, CKD patients (KDIGO stage G2/3A, proteinuria >0.5 g/d), DKD patients (KDIGO stage G2/3A, proteinuria 0.2-0.5 g/d) and HV followed a 7-day low sodium diet (LSD, <50mmol/d) and high sodium diet (HSD, >200mmol/d), respectively. After each diet, assessment of hemodynamics included daytime BP (Mobil-O-Graph) and cardiac output (CO) measurements (NexfinTM), by which SVR was calculated accordingly. Extracellular fluid volume (ECV) change was assessed with multi-frequency body impedance spectroscopy (Fresenius).

Results: We included 20 CKD (mean age 48 yrs, median (IQR) proteinuria 0.7 (0.6-1.6) g/d, mean (SD) eGFR 60.7 (16.3) ml/min/1.73m2) and 8 DKD patients (age 68 yrs, proteinuria 0.3 (0.2-0.4) g/d, eGFR 59.0 (15.9) ml/min/1.73m2), and 16 HV (age 41 yrs). Dietary intervention was successful with mean difference in urine Na+ excretion of 185, 168, and 209 mmol/day in CKD, DKD and HV respectively. After HSD, mean (SD) systolic BP change was 9.3 mmHg (8.9; p<0.001) in CKD and 13.8 mmHg (10.4; p<0.01) in DKD, while systolic BP change (3.1 mmHg (6)) in HV was not significant. After HSD, we observed significant ECV expansion in all groups without differences between groups (CKD 1.6 L, DKD 1.6 L, HV 1.4 L, p=0.27), while no effects on CO were observed. After HSD, the mean (SD) SVR in CKD increased with 125.7 dyn*sec*cm-5 (247.9, p=0.04) and in DKD with 125.5 dyn*sec*cm-5 (142.6, p=0.04), while in HC a non-significant decline of -109.2 dyn*sec*cm-5 was observed (358.2, p=0.24).

Conclusions: Na+-mediated BP rise in both CKD and DKD coincides with an increase in SVR. The absence of differences in ECV and CO between the three groups indicates that salt sensitivity in both CKD and DKD is not completely based on fluid overload but might be due to an inability to induce vasodilation.

A Simplified Lung Ultrasound-Guided Management Protocol of Pulmonary Congestion in Hemodialysis

Saleh Kaysi,[1,2] Abdullah I. Hamad,[3] Maxime Taghavi,[1] Rania A. Ibrahim,[3] Heba M. Ateya,[3] Mincy Mathew,[3] Mohamad M. Alkadi,[3] Hassan A. Al-Malki,[3] Joelle L. Nortier.[1,2] *[1]UVC Brugmann, Brussels, Belgium; [2]Universite Libre de Bruxelles, Bruxelles, Belgium; [3]Hamad Medical Corporation, Doha, Qatar.*

Background: Pulmonary congestion PC is frequent in Hemodialysis HD. We validated the first simplified LUS-guided PC management protocol in HD and evaluated its impact on blood pressure BP.

Methods: Prospective randomized multi-center trial: stable HD patients in 3 countries. Randomized: active A and control C groups. Bedside LUS after mid-week session at: Day 1, 15, 30, 45, 60. LUS according to the 8-zone method. B line score BLS of > 5 represented significant PC. Dry weight DW was adapted according to standard of care in the C group. In the A group, in addition, if BLS was > 5 at day 1 or 15 then DW was reduced by 500 g. Home BP monitoring HBPM weekly.

Results: 100 HD patients up until now. Age (60.5 ± 14.6) years, 60% diabetics. In the A group, mean BLS at day 1 (13.5 ± 9) decreased (8.32 ± 6.8) at day 60. (P<0.001). ***Figure 1,*** with a reduction in DW (P: 0.001) and greater UF (P: 0.047). ***Table 1*** A reduction in diastolic blood pressure was noted (*P: 0.001*) In the control group, BLS did not change.

Conclusions: Our simplified LUS guided management protocol was able to safely reduce the pulmonary congestion in HD patients in addition to better controlling their blood pressure.

Table 2: Evolution of parameters according to groups during the study

	Active group			Control group		
Variable	Baseline	Study end	P value	Baseline	Study end	P value
BLS	13.5 ± 9	8.3 ± 6.8	**<0.001**	15.6 ± 9.4	14.8 ± 13.2	0.805

Cardiovascular Functional Capacity in Patients with CKD: Insights from the FIT-INDY Study

Nolan Groninger,[1] Nikita F. Samanani,[1] Cody A. Altherr,[2] Gayatri Narayanan,[1] Kenneth Lim.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Indiana Center for Musculoskeletal Health, Indianapolis, IN.*

Background: Patients with chronic kidney disease (CKD) exhibit a significantly increased risk of cardiovascular disease beginning in the early stages of kidney impairment. However, whether cardiovascular functional capacity is reduced in early-stage CKD and the pattern of its impairment is largely unknown. The goal of this study was to evaluate the natural history of impairment in cardiovascular functional capacity (by VO_2Peak) as assessed by Cardiopulmonary Exercise Testing (CPET) in patients with early-stage CKD.

Methods: We analyzed data from 139 patients in the ongoing Cardiorespiratory Fitness in Patients with Chronic Kidney Disease in Indiana (FIT-INDY) Study, an ambulatory referral cohort of patients who have undergone CPET as part of their standard of care from 2005 to 2023. Participants were stratified into three groups by estimated Glomerular Filtration Rate (eGFR): eGFR ≥90 (n=79); eGFR 60-89 (n=40); and eGFR <60 (n=20). Associations between eGFR and VO_2Peak were assessed using multiple linear regression modeling.

Results: Patients in the lowest eGFR group <60 (62 [45-71] y) were significantly older compared with the other groups (eGFR 60-89=47 [38-56] y; eGFR ≥90=36 [27-44] y; P<0.001). No significant differences in sex were observed between groups. We report an incremental impairment in VO_2Peak observed with declining kidney function (eGFR ≥90, 21.0 [14.8-26.2] mL/min/kg; eGFR 60-89, 16.2 [12.7-19.5] mL/min/kg; eGFR<60, 12.0 [8.8-13.2] mL/min/kg). Additionally, maximal workload declined serially with declining kidney function (eGFR ≥90, 120.0±49.6 W; eGFR 60-89, 117.0±48.8 W; eGFR<60, 70.9±19.7 W; P=0.002). After adjusting for age and hemoglobin, the relationship between eGFR and VO_2Peak remained significant (P=0.017).

Conclusions: Our study highlights that patients with mild to moderate CKD exhibit impaired cardiovascular functional capacity. These findings emphasize the importance of early cardiovascular assessment and management in individuals with CKD, and the need for further studies examining cardiovascular functional alterations in patients with kidney failure.

N-terminal Pro B-Type Natriuretic Peptide (NT-proBNP) and Cardiovascular Structure and Function in Advanced CKD

Monique O. Campos,[1] William Voors,[1] Thomas Hiemstra,[2] Gayatri Narayanan,[1] Kenneth Lim.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]University of Cambridge School of Clinical Medicine, Cambridge, United Kingdom.*

Background: NT-proBNP is a clinically used diagnostic marker in managing of heart failure. Unfortunately, interpretation of NT-proBNP levels is complicated in patients with CKD as the peptide is renally cleared. Furthermore, few studies, if any have assessed the diagnostic value of NT-proBNP in evaluating impaired cardiovascular functional (CVF) –a major complication in advanced CKD. Herein, we investigated the role of NT-proBNP levels in regulating CV structure and function in patients with advanced CKD.

Methods: We conducted a cross-sectional study of baseline data from 242 participants from the Cardiopulmonary Exercise Testing in Renal Failure and After Kidney Transplantation (CAPER) Cohort: advanced CKD stage 5 and 5D patients on the transplant list (n=159) and hypertension patients (n=83). All patients underwent cardiopulmonary exercise testing (CPET) to assess CVF capacity (VO_2Peak) and echocardiography. Participants were stratified into quartiles per NT-proBNP levels. One-way ANOVA was used for group comparisons and associations assessed using Pearson's Correlation.

Results: NT-proBNP levels across quartiles were: <8.1pg/ml (n=59), 8.2-43pg/ml (n=61), 43.1-262pg/ml (n=61), and >262.1pg/ml (n=61). Age did not significantly differ between the groups (p>0.05). However, patients in the lowest NT-proBNP quartile had higher BMI values (Q1:28.3±3.8 kg/m^2; p<0.0001). Patients with highest quartile had lower GFR (Q4:7.0[5,8] ml/min per 1.73 m^2, median [IQR]). Significantly, patients with higher NT-proBNP had reduced VO_2Peak (Q1:26.4±7.5; Q4:18.4±4.7 mL/min/kg;p<0.0001). Additionally, those in the higher NT-proBNP strata exhibited greater left ventricular mass index (LVMI) (Q1:87.7±18.1; Q4:129.4±40.1 g/m^2), lower heart rate (HR) at peak exercise (Q1:157±18; Q4:123±24 bpm), and ejection fraction (Q1:66 ±5;Q4: 60±10%), p<0.0001 for all. NT-proBNP levels were negatively associated with VO_2Peak (r=-0.18;p=0.006), HR (r=-0.27;p=0.0001), ejection fraction (r=-0.22;p=0.0004), and GFR (r=-0.77;p<0.0001) and a positive correlation with LVMI (r=0.44;p<0.0001).

Conclusions: Higher NT-proBNP levels were associated with impaired CV structure and function in patients with advanced CKD. The study suggests that NT-proBNP is a potential biomarker for assessing CVF impairment in advanced CKD.

Epimeric Vitamin D Is Not Associated with Arterial Stiffness in Patients with Advanced CKD

Monique O. Campos,[1] Eliott Arroyo,[2] Thomas Hiemstra,[3] Gayatri Narayanan,[1] Heather Burney,[1] Kenneth Lim.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Wake Forest University, Winston-Salem, NC; [3]University of Cambridge School of Clinical Medicine, Cambridge, United Kingdom.*

Background: 25-hydroxyvitamin D3 (25-(OH)D3) has the capacity for C-3 epimerization, resulting in the production of 3-epi-25(OH)D3. 3-epi-25(OH)D3 comprises up to ~54% of total 25(OH)D concentrations and therefore could significantly influence end-organ health. We recently demonstrated that 3-epi-25(OH)D3 levels are reduced in patients with advanced CKD and are associated with impaired cardiovascular (CV) functional capacity. However, its role in regulating vascular health in CKD is still largely unstudied. Herein, we investigated the association of serum 3-epi25(OH)D3 with arterial stiffness in patients with advanced CKD.

Methods: We conducted a cross-sectional study of baseline data from 270 participants from the Coventry-Cambridge Vascular Cohort that recruited patients with stage 5 CKD on the transplant list. All patients underwent arterial applanation tonometry to assess arterial stiffness (pulse wave velocity (PWV) and augmentation index at 75 bpm (AI75)). Serum 3-epi-25(OH)D3 was analyzed by liquid chromatography-tandem mass spectrometry. Participants were stratified into 3-epi-25(OH)D3 quartiles, with one-way ANOVA comparing differences and associations assessed using multiple linear regression.

Results: 3-epi-25(OH)D3 levels across quartiles were: < 0.30 ng/mL(n=64); 0.30-0.45 ng/mL(n=71); 0.46-0.73ng/mL(n=68); >0.73ng/mL(n=67). 3-epi-25(OH)D3 quartiles were well matched for age, gender, and BMI (p>0.05). There was a difference in race (<0.001) and dialysis status (p=0.016) among quartiles. The estimated glomerular filtration rate (eGFR) did not significantly differ among 3-epi-25(OH)D3 quartiles (Q1: 8.0 [80,101], Q4: 8.0 [5.3,12.0] ml/min per 1.73 m^2, median [IQR]) p>0.05). There were no differences among quartiles for either PWV (Q1: 7.9 [7.0,9.6], Q4: 7.8 [6.6,9.0] m/s, median [IQR]) p>0.05) and augmentation index (Q1: 20.5 ± 13.7; Q4: 20.4 ± 13.4 %, p>0.05). Multiple linear regression modeling demonstrated that 3-epi-25(OH)D3 was not associated with either PWV and AI75 after adjustment for race and dialysis status (p=0.72).

Conclusions: Our study demonstrates that epimeric vitamin D levels are not associated with modulating arterial stiffness in patients with advanced CKD. Therefore, its relationship with cardiovascular functional capacity in CKD may be mediated by non-vascular targets.

GFR-Adjusted Uric Acid Is Superior in Prediction of All-Cause Mortality Compared with Uric Acid or Uric Acid/Serum Creatinine

Eva Koenigshausen, Lars C. Rump, Lorenz Sellin. *Heinrich-Heine-Universitat Dusseldorf, Dusseldorf, Germany.*

Background: Elevated uric acid (UA) levels and serum UA to serum creatinine ratio (sUA/sCr) are associated with increased cardiovascular risk. We investigated GFR, age and sex-adjusted UA levels (eUA) to further increase precision in cardiovascular risk prediction.

Methods: The eUA formula was validated in the LURIC cohort. Due to GFR restrictions, a subpopulation of 2654 patients was evaluated. Outcome variables (mortality, cardiovascular events, heart failure NYHA > II) were analyzed in a risk group (eUA < UA) compared to the control group (eUA > UA). Uni- and multivariate regression analysis was performed for known risk factors as well as UA, eUA and sUA/sCr.

Results: eUA levels were calculated on the basis of the presented eUA formula. Mortality (OR 1.35; 95 % CI 1.09 -1.67; p = 0.006) and heart failure NYHA > II

(OR 1.91; 95 % CI 1.53 – 2.39; p < 0.001) were significantly increased in patients within the risk group (eUA < UA). Multivariate analysis revealed a better prediction of mortality with eUA (OR 7.41; 95 % CI 3.15 -17.47; p<0.001) compared to sUA/sCr (OR 1.12; 95 % CI 1.05 – 1.19; p < 0.001) or UA (OR 1.09; 95 % CI 1.02 – 1.16; p = 0.006) after adjustment for known cardiovascular risk factors. Cardiac events or heart failure NYHA > II was statistically not associated with eUA levels.

Conclusions: Assessment of the newly calculated eUA identifies patients with a particularly increased cardiovascular risk. eUA is superior in predicting mortality compared to established markers such as UA or sUA/sCr.

Association of Insulin-Like Growth Factor 1 with Cardiovascular Outcomes in Individuals with or without CKD: The UK Biobank Study

Byounghwi Ko, Daseul Huh, Dong Hoon Kang, Ga Young Heo, Cheol Ho Park, Hyung Woo Kim, Jung Tak Park, Tae-Hyun Yoo, Shin-Wook Kang, Seung Hyeok Han. *Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea.*

Background: Insulin-like growth factor-1 (IGF-1) has been implicated in chronic noncommunicable diseases. We aimed to explore the relationship between IGF-1 and adverse outcomes among individuals with or without CKD.

Methods: We included 359,739 participants without CKD (cohort 1) and 19,249 participants with CKD (cohort 2) from the UK Biobank cohort study. CKD was defined as an estimated glomerular filtration rate<60 ml/min/1.73m^2 or random urine-albumin-to-creatinine-ratio>30mg/g. The main predictor was IGF-1 levels, and the primary outcome was all-cause mortality. The secondary outcome included the 3-point major-cardiovascular-event (3P-MACE), defined as a composite of non-fatal myocardial infarct, non-fatal ischemic stroke, or cardiovascular death.

Results: There were 23,100 (6.4%) deaths (the corresponding incidence rate, 4.74) over a median follow-up of 13.6 years. In cohort 1 without CKD, the adjusted hazard ratios (aHRs) (95% CIs) for all-cause mortality were 1.24 (1.19-1.30), 1.00 (0.96-1.05), 0.98 (0.93-1.02), 1.03, (0.98-1.08), and 1.09 (1.08-1.19), for 1st, 2nd, 3rd, 5th, and 6th sextile groups, respectively, compared with 4th sextile as the reference group. The U-shaped association was similar in both cohorts. In cohort 2, the corresponding HRs (95% CIs) were 1.46 (1.29-1.66), 1.17 (1.02-1.34), 1.20 (1.04-1.37), 1.13 (0.98-1.30), and 1.17 (1.02-1.35), respectively. Notably, we observed a consistent U-shaped association with 3P-MACE, only in individuals with CKD. When effect modification was examined, no significant interaction between CKD and IGF-1 levels for the risk of all-cause mortality was observed, while a significant interaction was exhibited for the risk of 3P-MACE only in individuals with IGF-1 levels above the median.

Conclusions: This study revealed a U-shaped association between IGF-1 levels with all-cause mortality and cardiovascular outcomes in CKD patients. In individuals with IGF-1 levels above the median, this association was more pronounced in individuals with CKD, suggesting that IGF-1 may serve a more potent prognostic marker in this patient population.

Comparison of Plasma B-type Natriuretic Peptide (BNP) Levels, N-terminal Pro B-Type Natriuretic Peptide (NT-proBNP) Levels, and the NT-proBNP-to-BNP Ratio in Patients with CKD

Hideki Fujii, Ken Hirabayashi, Keiji Kono, Shunsuke Goto. *Kobe University Graduate School of Medicine, Kobe, Japan.*

Background: Both B-type natriuretic peptide (BNP) and N-terminal pro-B-type natriuretic peptide (NT-proBNP) are utilized for diagnosing and managing patients with heart failure in clinical settings. These parameters are also known to be elevated by other cardiovascular disease (CVD), such as coronary artery disease, arrhythmia, and valvular disease. However, their levels can also be influenced by numerous clinical factors including kidney function, and the details remain unclear in patients with chronic kidney disease (CKD). Then, we assess the clinical factors which can influence BNP levels, NT-proBNP levels, and the BNP/NT-proBNP ratio and their predictive availability for CVD in patients with advanced stage CKD.

Methods: This study included 1,037 patients who visited the division of Nephrology at our hospital between 2014 and 2015. For all study participants, both plasma BNP and NT-proBNP levels were measured simultaneously. Plasma BNP levels, NT-proBNP levels, and the BNP/NT-proBNP ratio were evaluated in each stage of CKD, and also examined a correlation of clinical factors with them. Furthermore, we assessed the correlation of BNP levels, NT-proBNP levels, the BNP/NT-proBNP ratio, and clinical parameters with CVD events in patients with CKD stage 4 and 5.

Results: Patients with CKD stage 1-5D were included in this study. Plasma BNP levels, NT-proBNP levels, and the NT-proBNP/BNP ratio increased and the relationship between BNP and NT-proBNP levels weakened with declining kidney function. In patients with CKD stage 1 to 5, common independent determining factors for BNP and NT-proBNP levels and the NT-proBNP/BNP ratio included Hb levels, phosphate levels, and intact PTH levels. In patients with advanced stage CKD (CKD4 and 5), those with higher levels of BNP, NT-proBNP, or the NT-proBNP/BNP ratio experienced a greater number of CVD events compared to those with lower levels. Additionally, multivariate Cox regression analysis showed that the occurrence of CVD was significantly correlated not with BNP and NT-proBNP levels, but only with the NT-proBNP/BNP ratio (HR [95%CI]: 1.064 [1.029-1.100], p<0.001) in these patients.

Conclusions: Given the complex influence of various factors on plasma BNP and NT-proBNP levels in patients with CKD, careful interpretation of these values is essential.

Elevated Serum Homocysteine Associated with Left Ventricular Remodeling in Patients with IgA Nephropathy

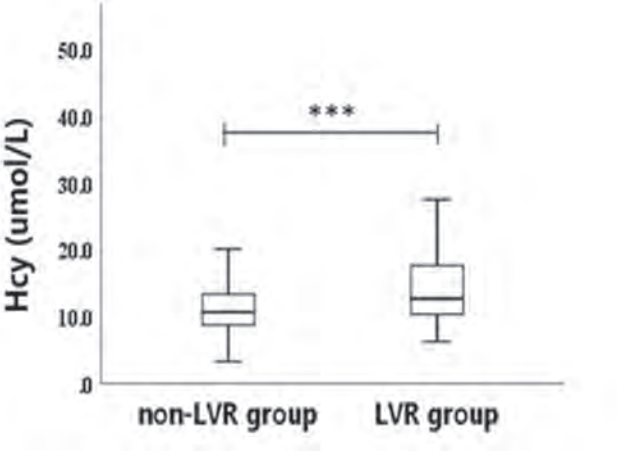
Hao Yu, Zizhen Li, Qianqian Han, Huicong Wu, Rui Zhang, Weicong Zeng, Jiajia Li, Qiongqiong Yang. *Department of Nephrology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China.*

Background: Homocysteine(Hcy) is a non-traditional independent risk factor for cardiovascular disease. Left ventricular remodeling(LVR) is a predictor of poor cardiovascular and renal outcomes in patients with chronic kidney disease(CKD). However, there is little known about LVR in IgA nephropathy(IgAN). We aimed to explore the association between serum Hcy and LVR in IgAN patients.

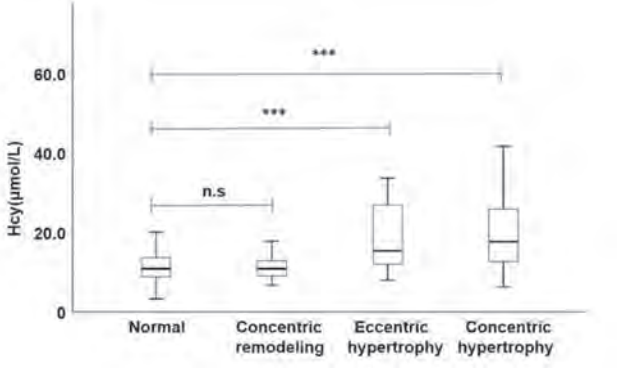
Methods: This retrospective study included 257 patients with IgAN who underwent echocardiography. LVR was defined as left ventricular mass index(LVMI)>115g/m^2 in men and>95g/m^2 in women or relative wall thickness(RWT)>0.42. Spearman correlation and logistic regression analysis were performed to explore the association between Hcy and LVR.

Results: In our study, 28.79% of patients had LVR, and the proportion increased with CKD progression. Patients with LVR were older and had higher serum Hcy[13.95(10.65,19.10) vs 10.90(8.80,13.70)μmol/L, *P*<0.001], body mass index(BMI), blood pressure(BP), serum creatinine(Scr), 24-hour urine protein, triglyceride(TG), and serum phosphorus(P), but lower haemoglobin(Hb) and serum bicarbonate compared to patients without LVR. An adjusted multivariate logistic regression model indicated that elevated serum Hcy was independently associated with increased risk of LVR(OR=1.072, 95%CI=1.001-1.149, *P*=0.047).

Conclusions: Serum Hcy was associated with LVR independent of traditional cardiovascular risk factors as BP, Scr and TG in IgAN patients.



Levels of serum Hcy in LVR group and non-LVR group. ***P<0.001



Levels of serum Hcy in groups according to heart structure. ***P<0.001

Role of Inflammation and High-Sensitivity C-reactive Protein in Atherosclerotic Cardiovascular Disease and CKD: A Survey of Nephrologists

Vlado Perkovic,[1] David Cherney,[2] Edmundo Erazo Tapia,[5] Sofia Gerward,[6] Manisha Sahay,[4] Abhijit V. Shete,[5] Nikolaus Marx.[3] *[1]University of New South Wales, Sydney, NSW, Australia; [2]University of Toronto, Toronto, ON, Canada; [3]University Hospital RWTH Aachen, Aachen, Germany; [4]Aditya Hospital, Abids, Hyderabad, India; [5]Novo Nordisk, Zurich, Switzerland; [6]Novo Nordisk, Copenhagen, Denmark.*

Background: In patients (pts.) with atherosclerotic cardiovascular disease (ASCVD) and chronic kidney disease (CKD), systemic inflammation (SI) contributes to increased cardiovascular (CV) risk. The FLAME-ASCVD-Nephro survey assessed awareness and perception of SI among nephrologists (nephs).

Methods: An online observational study (NCT06322641) of nephs (Feb-April 2024) across 10 countries (Australia, Brazil, Canada, China, France, Germany, India, Italy, Japan, and Saudi Arabia) who treat ≥20 pts. with ASCVD+CKD a month and in practice for ≥3 years, was analyzed using descriptive statistics.

Results: Of 3,778 participants, 294 completed the survey (~30/country). Traditional CV risk factors were most often discussed with pts.; SI to a lesser extent. 78% considered burden of SI higher in pts. with both ASCVD+CKD than CKD alone, and saw SI as an independent risk factor for ASCVD (66%) and linked to the development (63%) and progression of CKD (71%). 76% agreed SI as a contributor to the risk of recurrent CV events; 67% stated residual inflammatory risk persisted despite evidence-based preventive CV therapies. 7/10 reported testing SI to assist with clinical decisions, ie how aggressively to treat ASCVD (64%) and CKD (64%), and 83% used standard CRP. 74% would like to learn more about the role of SI in ASCVD and 35% agreed inclusion of high-sensitivity C-reactive protein (hsCRP) testing in guidelines would support clinical usage.

Conclusions: This survey among nephs show SI was considered a CV risk factor, but not to the level of traditional CV risk factors. There is a need for medical education on the role of SI and guidance on hsCRP testing in pts. with ASCVD+CKD.

Nuclear Magnetic Resonance Lipoprotein Analysis in Nephrotic Syndrome vs. Remission

Michael Hwang,[1,2] Rebecca Brown,[1] Lilian Howard,[1] Meryl Waldman.[1] *[1]National Institute of Diabetes and Digestive and Kidney Diseases Division of Intramural Research, Bethesda, MD; [2]National Institutes of Health, Bethesda, MD.*

Background: Nephrotic syndrome (NS) is associated with lipid abnormalities characterized by elevations in total chol, low density lipoprotein (LDL-C), triglycerides (TG), lipoprotein(a) & apolipoproteins. While dyslipidemia improves with remission (R), unfavorable lipid profiles may persist beyond R & in those with residual proteinuria. These changes have not been well characterized. Comprehensive lipid analysis using nuclear magnetic resonance (NMR) may provide more information about atherogenicity than standard lipid testing during active NS (ANS) compared to R. NMR assesses lipoprotein (LP), particle(P) size, # & concentration, apolipoproteins & inflammation.

Methods: Patients with non-diabetic glomerular disease with paired NMR profiles (Vantera Clinical Analyzer) available during ANS & R (proteinuria >3.5 & <1 g/d, respectively) were included. Statistical comparisons were done for ANS *vs* R, & both ANS & R *vs* healthy controls using paired *t* tests or Wilcoxon tests.

Results: Table 1. 19 patients with membranous nephropathy analyzed (68% male, mean age: 53 y); 68% on lipid lowering drugs. As expected, ANS was associated with an atherogenic lipid profile that improved at R, including ↓ in TG, LDL-C, LDL-P # & apoB. However, TG rich LP remained ↑, notably large & very small TRLP (VS-TRLP). While HDL-C did not change, both HDL -P # & apoA1 ↓ *vs* ANS. GlycA remained ↑ at R despite normal CRP.

Conclusions: This NMR analysis provides a granular snapshot of LP during contrasting disease states. Despite overall improvement in lipids with R consistent with ↓ atherogenicity, the pattern of ↓ apoA1, total & large HDL with persistently ↑ TRLP (particularly highly atherogenic VS-TRLP) may suggest residual atherogenicity. The clinical significance of high GlycA, which reflects systemic inflammation, warrants further investigation in NS as a CVD risk predictor.

Funding: NIDDK Support

Machine-Learning Approaches for Major Adverse Cardiovascular Events (MACE) Prediction in Patients on Hemodialysis

Cheng-Hsu Chen,[1,2] Shun Fang Hou,[1] Min-Shian Wang.[3,4] *[1]Division of Nephrology, Taichung Veterans General Hospital, Taichung City, Taiwan; [2]Doctoral Program in Tissue Engineering and Regenerative Medicine, National Chung-Hsin University, Taichung City, Taiwan; [3]Smart Healthcare Committee, Taichung Veterans General Hospital, Taichung, Taiwan; [4]Dept. of Applied Mathematics, National Chung Hsing University, Taichung, Taiwan.*

Background: Major Adverse Cardiovascular Events (MACE) are common complications of hemodialysis (HD) patients that include myocardial infarction (MI), stroke, cardiac arrhythmia and heart failure (HF). The objective of the current study was to predict MACE among our HD patients.

Methods: HD patients above 18 years old were recruited 29356 HD sessions for the study between 2014 to 2023 from our hospital database of the TSN-KiDiT (kidney, dialysis, and transplantation integrated software), which is integrated operation management system and quality control for Taiwan Society of Nephrology. Different Machine learning algorithms: including RandomForest (RF), XGBoost, logistic regression (LR), and KNN(K Nearest Neighbor) were employed. Clinical attributes, electrolytes, dialysis adequacy and blood flow (BF), cardiothoracic ratio (CT ratio) and biomarkers were explored in predicting MACE. The feature importance was determined using mean decrease accuracy.

Results: Overall, 28788 HD sessions were included in the analyses, there were 3791 events of MACE within 12-month. The XGBoost Model demonstrated a prediction accuracy of 88.92% with the area under the receiver operating characteristic curve (AUROC) 94.42%, which is higher as compared to the RF 84.54% [AUROC 94.95%], the LR model 65.23% [AUROC 65.23%], however, the KNN has the best accuracy 92.45% [AUROC 93.28%] with less sensitivity 59.47%, respectively. The classification accuracy of the models for cardiac arrhythmia was 89.01%, which was higher than prediction accuracy for AMI (83.67%), and heart failure (HF: 82.84%). Age, CT ratio, glucose, transferrin saturation, albumin, ferritin were the major predictors of MACE.

Conclusions: The ML models had shown acceptable performance in predicting MACE in HD patients. Age, CT ratio, glucose and other biomarkers were important predictors of MACE, which is consistent between the individual components of MACE, such as cardiac arrhythmia, MI, and HF. These parameters can be calibrated as prognostic parameters of MACE events in HD patients.

Table 1. Comparison of the performance of different models

		Validation					Testing				
	Classifier	Sens	Spec	Accuracy	AUROC	Precision	Sens	Spec	Accuracy	AUROC	Precision
Follow 12-month	Xgboost	82.75% (1.64%)	89.85% (0.78%)	88.90% (0.75%)	93.94% (0.35%)	55.72% (2.12%)	83.43%	89.70%	88.02%	94.42%	53.58%

	LR	65.86% (2.62%)	65.44% (1.20%)	65.48% (1.04%)	71.29% (1.57%)	14.60% (0.52%)	67.37%	66.47%	66.53%	72.92%	13.83%
	KNN	32.56% (3.23%)	98.42% (0.17%)	93.00% (0.28%)	87.01% (1.20%)	64.82% (3.34%)	38.03%	98.37%	93.90%	90.34%	65.06%
Follow 3-month	Xgboost	53.96% (5.30%)	94.40% (0.56%)	92.64% (0.58%)	88.23% (1.93%)	30.65% (3.12%)	56.34%	93.70%	91.96%	89.33%	30.38%
	RF	79.52% (4.07%)	74.02% (0.58%)	74.26% (0.59%)	85.62% (1.89%)	12.26% (0.61%)	80.97%	74.23%	74.54%	85.44%	13.29%
	LR	64.41% (4.63%)	65.08% (1.00%)	65.05% (0.86%)	70.36% (2.82%)	7.76% (0.46%)	60.82%	66.02%	65.78%	68.63%	8.03%
	KNN	6.90% (1.46%)	99.28% (0.19%)	95.25% (0.22%)	81.84% (2.57%)	31.79% (9.41%)	10.45%	99.34%	95.21%	81.92%	43.75%

- This is an imbalanced dataset, and as the imbalance ratio increases, both sensitivity and AUROC deteriorate.
- The accuracy of predicting follow 12 months with major adverse cardiovascular events is 88.92%.

SA-PO369

Dynamic Prediction of Cardiovascular Events in Incident Patients on Peritoneal Dialysis with Multivariate Joint Models Adjusting for Phosphate, Albumin, and Calcium Trajectories and Competing Risks

Ivan Damgov,[1,2] Meinhard Kieser,[2] Simon J. Davies,[5] Muh Geot Wong,[6] Carol A. Pollock,[3] David W. Johnson,[4] Claus Peter Schmitt.[1] *[1]Center for Pediatric and Adolescent Medicine, University of Heidelberg, Heidelberg, Germany; [2]Institute of Medical Biometry, University of Heidelberg, Heidelberg, Germany; [3]Kolling Institute, Sydney Medical School, University of Sydney, Royal North Shore Hospital, St Leonards, NSW, Australia; [4]Australasian Kidney Trials Network, University of Queensland, Brisbane, QLD, Australia; [5]Faculty of Medicine and Health Sciences, Keele University, Stoke-on-Trent, United Kingdom; [6]Department of Renal Medicine, Royal North Shore Hospital, St Leonards, NSW, Australia.*

Background: Joint models (JM) offer dynamic personalized risk predictions by exploring the link between longitudinal biomarkers and clinical outcomes. We investigated serum phosphate, albumin and calcium trajectories to predict cardiovascular events in peritoneal dialysis (PD) patients for the first time using innovative multivariate JM.

Methods: We evaluated the association of phosphate, albumin and calcium with composite cardiovascular events (CVE) in incident PD patients followed over 8 years in the Initiating Dialysis Early And Late trial. We adjusted time trajectories for non-linearities and considered non-cardiovascular death causes and transfer to hemodialysis as competing events. The complete dataset (N=318 patients) was used for model selection, while dynamic predictive performance was compared using a 4-fold and 10-repeat cross-validation. Individual patient CVE predictions were obtained for forecast horizons until 5 years on PD at cut-offs 1, 1.5 and 2 years utilizing biomarkers trajectory and 4 baseline risk factors.

Results: A median of 10 records per patient and a 28% CVE rate ensured convergence of all 8 JM models investigated. Multivariate JM demonstrated strong positive association of phosphate and strong inverse association of albumin with composite CVE, while calcium adjusted for albumin did not provide additional explanatory nor prognostic value. All JM demonstrated excellent to outstanding predictive performance in both short- and long-term CVE forecasts, regardless of competing risks adjustment. Multivariate JM with phosphate and albumin outperformed univariate JM (5-year forecast area under the curve (AUC) median values at 1, 1.5 and 2 years: 0.85, 0.84 and 0.80). Prediction performance of all multivariate JM surpassed the classical Cox model with baseline parameters only ignoring biomarker trajectories (median AUC = 0.79, 0.78, 0.77).

Conclusions: This first investigation of multivariate JM in PD patients outlines longitudinal phosphate and albumin as independent predictors of composite CVE with excellent potential in dynamic personized forecasts superior to the classical Cox approach.

SA-PO370

A Curious Case of Salt-Sensitive Hypertension

Madhumitha Rajagopal,[1] Joshua L. Rein.[1,2] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]James J Peters VA Medical Center, New York, NY.*

Introduction: Excess NaCl consumption is the top modifiable risk factor for HTN. Despite clear evidence, adherence to dietary NaCl restriction is low. HTN affects half of US adults and among them, half have salt-sensitive (SS)-HTN. We present a case of SS-HTN and its unique management.

Case Description: Patient is a 70 yo Black man with PMHx of resistant HTN (despite clonidine 0.3mcg TID, hydralazine 100mg TID, lisinopril 40mg TID, and labetalol 800mg BID). Over the years, he developed severe constipation from Ca^{2+} channel blockers, gynecomastia from spironolactone, and HCTZ induced hyponatremia. He weighed 95kg, had no edema, and BP was labile, 124-200/68-104 mmHg. Labs were notable for K^+ 3.5-4.0 mEq/L, TCO_2 23-28 mEq/L, creatinine (SCr) 1.3-1.6 mg/dL, and PAC/PRA < 1.0-2.3 ng/dL / 0.3-1.4 ng/mL/hr. Renal US was unremarkable and CT showed bilateral adrenal thickening. A positive correlation was observed between BP and NaCl intake based on 24h dietary recall (24H). Given suppressed RAAS (volume expanded state), low dose torsemide (10mg QD) and amiloride (5mg QD) were started, lisinopril was continued, and hydralazine, labetalol, and clonidine doses were halved. Two weeks later, he was hypotensive (90/60) with pre-renal AKI (SCr 2.8) that improved with IV fluids. Diuretics, lisinopril, and hydralazine were stopped, and clonidine dosing was decreased. However, BP rebounded over a few weeks to 158-190/88-108. Torsemide+amiloride were resumed and BP improved within 1 week to 106-144/68-85, allowing for a lower labetalol dose. Over the next 6 months, BP was controlled (106-144/68-85) and hypervolemia improved (PAC/PRA 6.5/0.8) with torsemide 10 QD, amiloride 5 QD, labetalol 200 BID, and clonidine 0.1 BID. Natera Renasight genetic testing revealed a heterozygous VUS in *NR3C1*, encoding the glucocorticoid (GC) receptor. Pathogenic homozygous mutations cause GC resistance, with elevated ACTH and cortisol levels leading to SS-HTN from mineralocorticoid receptor activation.

Discussion: After years of ineffective anti-HTN therapy missing the mechanism of SS-HTN, serial PAC/PRA measurements with 24H, prompted an unconventional diuretic combination to achieve HTN control and reduce pill burden. This case highlights: 1) the utility of serial PAC/PRA with 24H to diagnose SS-HTN; 2) the efficacy of non-thiazide distal diuretics to treat SS-HTN; and 3) an evolving role for genetic testing to further our understanding of SS-HTN.

SA-PO371

Liddle Syndrome and Recurrent Spontaneous Coronary Artery Dissection

Ritu Seethapathy,[1] Andrew Klufas,[2] Adina S. Voiculescu.[3] *[1]Landmark Medical Center, Woonsocket, RI; [2]Roger Williams Medical Center, Providence, RI; [3]Brigham and Women's Hospital, Boston, MA.*

Introduction: Liddle Syndrome is an autosomal dominant form of resistant hypertension (HTN) characterized by suppression of plasma renin activity and aldosterone secretion with early onset HTN and hypokalemia.

Case Description: A 45-year-old woman with treatment resistant HTN since her twenties, presented to the ED for chest pain. She was hypertensive, with elevated troponins and ST-segment elevation on EKG. In the Cath Lab she was found to have mid-LAD occlusion secondary to dissection with subsequent balloon angioplasty, and was discharged on Carvedilol, Losartan, HCTZ, and DAPT. Two years later she developed similar chest pain with recatheterization showing spontaneous dissection of first obtuse marginal artery. She was placed on regimen of five maximally tolerated medications (Losartan/HCTZ, Carvedilol, Diltiazem, Clonidine, and Isosorbide Mononitrate). Further workup showed low plasma renin activity and aldosterone, normal catecholamine levels, and chronic hypokalemia. Surveillance imaging showed a cavernous carotid artery aneurysm and renal artery beading suggestive of fibromuscular dysplasia (FMD), thought to demonstrate a shared pathophysiologic process. However, Renal Artery Doppler showed normal flow velocity bilaterally. Liddle Syndrome was suspected given unusual labs and lack of renal artery stenosis, and amiloride was recommended pending genetic test results.

Discussion: Liddle Syndrome is caused by mutations in genes encoding epithelial sodium channels (ENaC). Increased ENaC activity results in increased sodium reabsorption, causing HTN through intravascular volume expansion, and hypokalemia through high distal tubule potassium secretion. HTN also causes decreased renin and aldosterone production through JGA feedback. Treatment involves potassium sparing diuretics (triamterene and amiloride), which block ENaC channels. Mutant ENaC channels prevent action of mineralocorticoid receptor antagonists (spironolactone). Genetic studies are required for confirmation as phenotypic variability often leads to misdiagnosis; however, it cannot definitively rule out disease as not all associated mutations are known. Spontaneous coronary artery dissection (SCAD) has been associated with underlying connective tissue disease or arteriopathy, most commonly FMD. To our knowledge this is the first case reported of recurrent SCAD in the setting of possible Liddle Syndrome without evidence of FMD.

SA-PO372

Lisinopril-Induced Rhinorrhea: A Case Report

Alice Amudzi, Giro R. Samale, Xavier F. Parada. *Berkshire Medical Center, Pittsfield, MA.*

Introduction: A 47-year-old woman presents to our clinic with a chief complaint of rhinorrhea; she had a medical history of chronic hypertension managed with antihypertensive drugs, including Lisinopril. While dry cough is a well-known side effect of ACE inhibitors, this case highlights a common chief complaint yet less recognized side effect of ACE inhibitors. It further emphasizes that overall, angiotensin receptor blockers may be a better drug of choice in hypertension due to their favorable side effect profile.

Case Description: We present the case of a 47-year-old woman with chronic hypertension who presented to our clinic with a runny nose for more than a year. The patient denied cough, fever, facial pain, sneezing, polyps, pruritus, headaches, conjunctivitis, or sore throat. She had a sister with chronic hypertension who experienced rhinorrhea after starting Lisinopril and a father who similarly experienced facial flushing. After several office visits, Lisinopril was discontinued, and their symptoms resolved. Her physical exam was unremarkable. Given her strong family history and Losartan's low side effect profile, we substituted Lisinopril. Two weeks later, her rhinorrhea improved and resolved entirely by week four.

Discussion: Lisinopril belongs to a class of medications called ACE inhibitors. It works by inhibiting the conversion of angiotensin I to angiotensin II to regulate blood pressure. Lisinopril may result in the accumulation of bradykinin and substance P, which increases vascular permeability and fluid leakage from blood vessels into the surrounding tissues. This later mechanism mediates symptoms like postnasal drainage, rhinitis, and rhinorrhea. URTI is among the three top diagnoses in outpatient settings in the USA, and having a broad differential is crucial in treating patients to avoid unnecessary diagnostic testing. Most clinicians are aware of ACE-I-induced cough but less frequently recognize rhinorrhea as a side effect. Not everyone using an ACE-I will experience rhinorrhea, and some studies suggest a genetic predisposition. With the increasing prevalence of hypertension notwithstanding the benefits of ACE-I use, we favor the use of ARBs over ACE-Is when indicated in the management of hypertension and renal disease, more so in patients who are intolerant to ACE inhibitors, especially since ARBs are reasonably comparable in effectiveness and tolerability.

SA-PO373

Unmasking Secondary Hypertension: Renal Artery Stenosis Concealing Primary Hyperaldosteronism

Paul Wurtz, Alexandra Stewart. *Brooke Army Medical Center, Fort Sam Houston, TX*.

Introduction: In young adults with new onset hypertension, complete secondary workup is warranted. We present a patient ultimately found to have an aldosterone-secreting adenoma after a complex diagnostic journey.

Case Description: A 21-year-old woman with no medical history was found to have elevated blood pressures (BP) in both the home and office setting. Lab values were significant for hypokalemia and metabolic alkalosis with elevated plasma aldosterone concentration (PAC) of 16.1, plasma renin activity (PRA) of 0.442, and aldosterone to renin ratio (ARR) of 36.4. Subsequent values were non-diagnostic (Table 1) with normal 24-hour urine aldosterone and CT abdomen negative for adrenal adenoma. Additionally, renovascular workup revealed focal right renal artery stenosis of 40% concerning for fibromuscular dysplasia. One year later, due to increasing BP, angiogram revealed ~73% stenosis therefore angioplasty was performed. This did not improve her HTN, thus she sought opinion from an outside renovascular specialist re-visiting the possibility of primary hyperaldosteronism. Reassessment of primary hyperaldosteronism revealed elevated PAC and ARR levels with Adrenal MRI revealing a 1.7cm left adrenal adenoma. Adrenal venous sampling (AVS) confirmed the presence of a hyperfunctioning adenoma. Surgical removal of the adrenal gland resulted in successful weaning of all BP medications.

Discussion: We present a case with multiple confounders representing diagnostic dilemmas encountered with complex testing. Although the gold standard for diagnosing RAS is invasive angiography, the non-invasive tests such as doppler ultrasound and magnetic resonance angiography have reasonably high sensitivity and specificity. However, these tests are operator dependent which may impact reliability. Additionally, interpreting the plasma aldosterone and renin is nuanced with many factors affecting results including time of day, medications, and positioning of the patient. A multidisciplinary approach ultimately led to the diagnosis after an arduous evaluation.

Table 1

Date	Aldosterone	Renin	Aldosterone/Renin Ratio
04/28/2020	16.1	0.442	36.4
05/18/2020	4.2	1.621	2.6
06/10/2020	10.7	0.402	26.6
04/15/2022	8.3	0.468	17.7
06/12/2023	23.1	1.783	13
07/10/2023	2.4	3.118	0.8

SA-PO374

A New Cause of Glycyrrhizic Acid-Induced Apparent Mineralocorticoid Excess (AME) Syndrome with Hyperadrenergic Symptoms

John A. Szendrey, Gregory L. Braden, Daniel L. Landry, Anthony E. Poindexter, Jeffrey Mulhern. Kidney Care and Transplant Services of New England. *Baystate Medical Center, Springfield, MA*.

Introduction: AME is caused by genetic or drug-induced inhibition of renal 11Beta-hydroxysteroid dehydrogenase-2(11βDSH-2) inactivating conversion of cortisol to cortisone, leading to major cortisol activation of the renal mineralocorticoid receptor (MR). Acquired AME can occur due to the ingestion of glycyrrhizic acid(GA), found in licorice root and chewing tobacco. However, the brain contains 11βDSH-1 which can affect the level of brain catecholamines We present a new cause for AME from Advanced Liver Support supplements who also presented with never before reported hyperadrenergic symptoms associated with AME which we believe are due to the additional brain effects of 11BDSH-1 inhibition.

Case Description: A 65-year-old female developed accelerated hypertension, hypokalemia, metabolic alkalosis and adrenergic symptoms 4 months after daily ingestion of 4 tablets/day of Advanced Liver Support, Advanced BioNutritionals (Nacros, Georgia). Each pill contained 250 mg of GA. She had a BP 220/120 mmHg with episodes of palpitations, sweating & tremors. Her Na was 141 mmol/L, K 3.1 mmol/L, Cl 101 mmol/Land HCO3 30 mmol/L. Fasting free catecholamines were normal, plasma renin activity was reduced at 0.437 ng/mL/hr & serum aldosterone level was less than 1 ng/dL. Cessation of the liver supplement resulted in complete resolution of her hypertension, adrenergic symptoms & abnormal lab values within a few days, and her two blood pressure medications were discontinued. She has been followed for a year without reoccurrence of hypertension.

Discussion: GA is increasingly found in unregulated nutritional supplements and has the potential to induce a reversable syndrome of AME. Numerous other health supplements containing GA are available, which clinicians must consider in cases of AME. Acquired AME differs from genetic AME due to GA inhibition of both 11βDSH-1 and 2 enzymes. 11βDSH-2 inhibition increases local renal and CNS cortisol levels, while 11βDSH-1 inhibition increases pituitary hypothalamic tract mediated catecholamine release which can be responsible for additional hyperadrenergic effects of drug- induced AME.

SA-PO375

Pediatric Hypertension: A Case Series

Nikhila Aimalla, Divya Sai Vunnam, Rebecca Blonsky. *Marshfield Clinic Health System, Marshfield, WI*.

Introduction: Pediatric hypertension (HTN) is an increasingly common health concern. Essential HTN now surpasses secondary causes in prevalence amongst children. Early diagnosis and management are crucial. Pediatric HTN is diagnosed with three elevated systolic or diastolic blood pressure (BP) readings (≥ 95th percentile) adjusted for age, height, and sex.

Case Description: Case A: A 17-year-old female presented following an elevation of her blood pressure. On further history, she reported hot flashes, diaphoresis, palpitations, and lightheadedness in association with significantly elevated pressures. Pheochromocytoma was suspected, and serum catecholamines and CT confirmed the diagnosis. She underwent robotic resection, and pathology confirmed a paraganglioma with surgical correction of hypertension. **Case B:** A 9-year-old morbidly obese female was noted to have intermittently elevated BP for two years. She was evaluated for concerns about secondary HTN. Serologic evaluation and imaging were unremarkable. She was diagnosed with essential HTN and managed with medication and lifestyle modifications. **Case C:** A 16-year-old male presented for visual changes and was found to have optic nerve swelling with retinal hemorrhage due to a hypertensive emergency. The workup revealed an elevated serum creatinine, and a kidney biopsy was performed. The patient was found to have IgA nephropathy with extensive necrotizing and fibrous crescents with interstitial fibrosis. Hemodialysis was initiated, and he is awaiting a kidney transplant.

Discussion: The evaluation of pediatric HTN starts with a comprehensive history. Documenting dietary habits, physical activity, family history, and screening for obstructive sleep apnea is crucial. Annual BP measurements for children ≥3 years with more frequent checks for those at higher risk should be performed. Secondary causes such as endocrinologic, vascular, and renal disorders should be excluded. In addition to serologic evaluation, ambulatory BP monitoring can aid in determining the presence of true HTN. Pediatric patients, especially those presenting before puberty or with any laboratory abnormality, should trigger an evaluation for secondary causes of HTN.

SA-PO376

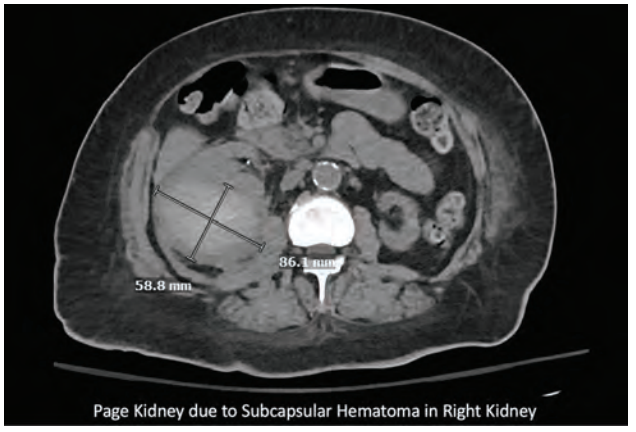
A Rare Case of Atraumatic Page Kidney in a Patient with ESRD

Jiya Mulayamkuzhiyil, Jonathan London, Shemrine Mark, Inaas Shirazi, Neeru Kumar. *Long Island Community Hospital, Patchogue, NY*.

Introduction: Page kidney is a rare cause of secondary hypertension occurring due to renal parenchymal compression from subcapsular hematoma which induces renal microvascular ischemia and activation of the renin-angiotensin-aldosterone system. The major causes include trauma, iatrogenic, tumor, and vasculitis. Rarely, Page kidney can be caused due to anticoagulation use. We describe a rare case of atraumatic Page kidney in ESRD due to anticoagulation use leading to malignant hypertension.

Case Description: A 60-year-old female with past medical history of ESRD, type 2 diabetes mellitus, hypertension, and CVA presented with fever, shortness of breath, and chest pain for 1 week. Patient denied abdominal pain and recent trauma. She was bedbound since having a CVA one month ago and was on heparin for DVT prophylaxis. On exam, patient was noted with elevated blood pressure 210/110 mm Hg. CT chest showed left lower lobe pneumonia with incidental finding of hematoma right kidney. Ultrasound of the kidney showed a large right renal subcapsular collection 12.5 x 6.9 x 8.0 cm with compression of the renal parenchyma suggestive of Page kidney with minimal vascular flow on color Doppler. CT abdomen showed similar findings with bilateral atrophic kidney. Labs were significant for WBC 19.8, Creatinine 5.7. Hemoglobin was 10.6 and was stable during hospital course. Blood pressure was controlled by starting antihypertensive medications, namely Amlodipine and Labetalol. Anticoagulation was held due to hematoma. Given stable hemodynamics, patient was conservatively managed with blood pressure control and renal function monitoring and was discharged with outpatient follow up for repeat renal ultrasound to ensure hematoma resolution.

Discussion: Our case is unique as it is one of the first cases of Page kidney occurring in the setting of anticoagulation use in ESRD. Page kidney should be considered a possibility for malignant hypertension in the setting of anticoagulation use in ESRD.



SA-PO377

A Case of Page Kidney Secondary to Spontaneous Bilateral Retroperitoneal Hemorrhage

Dao Le, Joshua M. Chan, Hugo Paz y Mar. *University of California Irvine, Irvine, CA.*

Introduction: Page kidney is an uncommon etiology for secondary hypertension and renal insufficiency in which outward mass effect causes stimulation of the renin-angiotensin-aldosterone system (1). Although the exact prevalence is difficult to estimate given its rarity, Page kidney is typically traumatic or iatrogenic with subcapsular hematoma formation (2). We report a case of Page kidney in an elderly male with spontaneous bilateral retroperitoneal hemorrhage and bilateral renal artery stenosis.

Case Description: An 83-year-old male with hypertension and chronic kidney disease presented for cough. His hospitalization was complicated by asymptomatic, severe hypertension with a systolic blood pressure ranging from 180 to 230 mm Hg. On hospital day 5, he developed abdominal distension and acute anemia from 9 to 7g/dl. There was no history of trauma or therapeutic anticoagulation. An abdominal computed tomography angiography revealed displacement of the left kidney by retroperitoneal hematoma and stenosis of bilateral renal arteries. On hospital day 7, he underwent a left iliolumbar and L4 lumbar artery embolization. Nevertheless, his renal dysfunction progressed. Continuous renal replacement therapy was initiated on hospital day 10, with successive transition to intermittent hemodialysis. He exhibited spontaneous renal function recovery without further dialysis requirements. However, he was transitioned to comfort care on hospital day 16 given an unrelated acute coronary syndrome with poor cardiac catheterization candidacy.

Discussion: This case is unique because it illustrates the interplay between two rare entities. Page kidney is commonly due to trauma or abdominal instrumentation. In our case, this phenomenon was secondary to spontaneous retroperitoneal hemorrhage (SRH), a rare condition on its own. The recognition of a reversible cause of secondary hypertension by external compression of the renal parenchyma prompted rapid treatment without unnecessary testing. Failure to identify extrinsic renal compression may result in irreversible kidney failure. Furthermore, the resultant hypertension may mask hemodynamic compromise, providing a false sense of stability in SRH, a potentially fatal condition. It is important to consider extrinsic renal compression as an etiology of hypertension and acute kidney injury in patients with spontaneous retroperitoneal bleeding.

SA-PO378

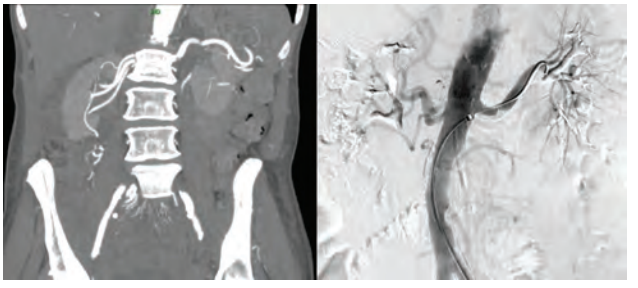
An Abundance of Anything Is Harmful: Accessory Renal Arteries as a Rare Cause of Flash Pulmonary Edema

Liliia Harris, Zaid M. Zahid, Jesus Diaz Acevedo, Nimrat K. Bains. *Hamilton Medical Center, Dalton, GA.*

Introduction: Flash pulmonary edema (FPE) typically develops from bilateral renal artery stenosis (RAS) or unilateral RAS with a solitary functional kidney. In rare instances, unilateral RAS with both functional kidneys can also trigger FPE. We describe a novel case of FPE stemming from unilateral RAS and multiple accessory RAs (ARA)

Case Description: A 68yo woman presented to ER with 3rd episode of FPE and HTN emergency Initial evaluation, including laboratory tests and RA ultrasound, showed no abnormalities. However, a CTA of the abdomen revealed a single heavily calcified L main RA with severe atherosclerosis extending into the lumen of the aorta and the proximal L main RA. Three RAs supply R kidney with questionable stenosis of superior, smaller R RA. Atherosclerotic plaque is present at the origin of the inferior R RA, but no definitive significant stenosis is detected Unilateral RAS and multiple ARAs were suspected as the cause of HTN and FPE. An aortogram with stenting was performed by vascular surgery. It confirmed > 75% stenosis in the L RA, prompting stent deployment. However, no significant stenosis was observed in R ARAs. BP control was achieved with a single agent

Discussion: FPE is a life-threatening syndrome. It is usually accompanied by cardiac systolic or diastolic dysfunctions. Recurrent FPE due to bilateral RAS was described by Pickering et al. Although its exact mechanism is not completely understood, it is believed to result from hypervolemia due to decreased sodium excretion Could the presence of ARA mimic the pathophysiology of RAS? It has been theorized that ARA may lead to HTN due to reduced blood flow to kidneys, caused by its longer and narrower caliber, leading to high resistance, hypoperfusion, stenosis. The Poiseuille equation, rearranged to $R=8\mu L/\Delta P\pi R4$ (where R=resistance, μ=viscosity, L=vessel's length, P=pressure, R=vessel's radius), suggests that radius and length of ARAs may play a role. In summary, ARAs are a common anatomical variation. Their specific characteristics may contribute to resistant HTN and FPE via renin-dependent hyperaldosteronism



SA-PO379

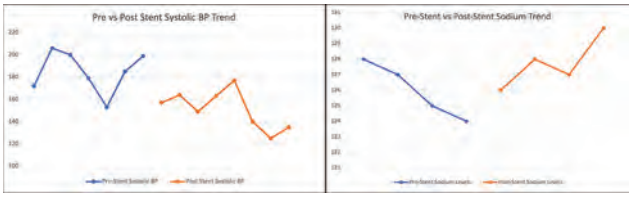
When Hyponatremia Meets Hypertension: The Impact of Renal Artery Stenosis

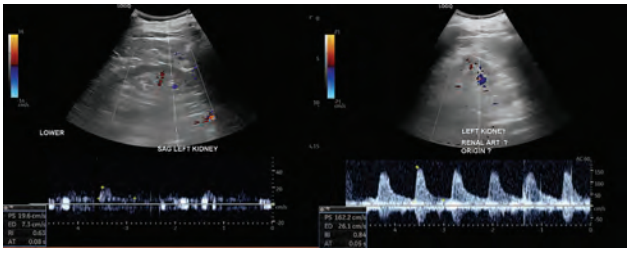
Muhammed Y. Jumani,[1] Yusra S. Jumani,[2] Murad Kheetan.[1] *[1]Marshall University, Huntington, WV; [2]Dow University of Health Sciences, Karachi, Pakistan.*

Introduction: Hyponatremic hypertensive syndrome (HHS) is characterized by severe hypertension and hyponatremia caused by unilateral renal artery stenosis (RAS). The ischemic kidney activates the renin-angiotensin system, causing hypertension. This leads to pressure diuresis in the non-ischemic kidney, with aldosterone and ADH secretion causing hyponatremia, hypokalemia, and polydipsia. Seemingly rare and under-diagnosed, this case report highlights HHS with underlying RAS in an elderly male with multiple comorbidities.

Case Description: 92-year-old male with HFpEF, aortic stenosis, CAD, and hypertension presented with confusion, lethargy, hyponatremia (Na 125), and hypertension (BP 200/100). Normal TSH and cortisol levels ruled out hypothyroidism or adrenal insufficiency. Ultrasound showed high-grade left kidney stenosis. CTA confirmed 85-90% stenosis in the left renal artery. Fluid restriction initially exacerbated hypertension. Left renal artery stenting was performed, improving sodium levels and blood pressure, with significant improvement in renal artery blood flow. Lisinopril and salt tabs were added upon discharge.

Discussion: Hyponatremic hypertensive syndrome (HHS), particularly in the presence of RAS, requires comprehensive clinical evaluation and diagnostic imaging. Unilateral renal artery stenosis leads to high renin release from the ischemic kidney, causing hypertension and pressure diuresis in the non-ischemic kidney. This results in polyuria, polydipsia, and urinary sodium loss, leading to hyponatremia. Early diagnosis is crucial to prevent complications and preserve renal function. Renal artery stenting improves perfusion and sodium levels, while ACE inhibitors reduce intraglomerular pressure and renal injury progression. In summary, managing HHS in the context of RAS requires understanding the pathophysiology, careful diagnostic workup, and a combination of interventional and pharmacologic treatments to improve outcomes.





Pre stent vs post stent in left renal artery

SA-PO380

Hypertensive Crisis Secondary to Afferent Baroreceptor Failure following Head and Neck Radiation

Christopher R. Showers, Nathaniel Reisinger, Jordana B. Cohen. *Penn Medicine, Philadelphia, PA.*

Introduction: Afferent baroreceptor failure is an uncommon cause of hypertension (HTN) that may result from carotid sinus injury. Characterized by labile HTN, postural blood pressure (BP) variation, orthostatic hypotension, and hypertensive crises, afferent baroreceptor failure is typically irreversible and often severely debilitating.

Case Description: A 67-year-old woman with labile HTN, hypothyroidism, and oral squamous cell carcinoma treated with hemiglossectomy and high dose radiation to the head and neck in 2009 presented to our hospital with headaches, BP of 230/120, and stage 1 acute kidney injury. She reported paroxysms of headache, visual blurriness, nausea, and lightheadedness since at least 2015. Inpatient BP values ranged from 90/60 to 190/100, including orthostatic hypotension, supine HTN, and wide variations with use of short acting intravenous medications. Daily home medications included amlodipine 10 mg, hydrochlorothiazide (HCTZ) 25 mg, valsartan 320 mg, and pramipexole for restless leg syndrome, which was stopped. Renin activity was 0.8 ng/mL/h and aldosterone concentration was 6.1 ng/dL. CT angiography showed right renal artery stenosis estimated at 70%. Echocardiography demonstrated mild concentric hypertrophy. Amlodipine was continued, HCTZ was stopped, valsartan was reintroduced at a lower dose, and a clonidine patch was started. Serum creatinine returned to her baseline. Lower extremity compression stockings and an abdominal binder were applied and postural maneuver training was performed with physical therapy. BP logs demonstrated markedly fewer BP fluctuations and attenuation of BP extremes; the patient reported a reduction in paroxysmal symptoms ascribed to BP extremes.

Discussion: Afferent baroreceptor failure from injury to carotid sinus neural structures may result in failure of counterregulatory signals during conditions that provoke extremes of blood pressure. Labile blood pressure, including paroxysms of HTN and symptomatic hypotension, can result in iterative end organ injury and disabling symptoms. Wider BP ranges are tolerated and avoidance of BP extremes is prioritized. Long-acting, central acting sympathetic blocking agents are often beneficial along with postural maneuver training, compressions stockings, and abdominal binders.

SA-PO381

A Case of Reninoma in a 42-Year-Old Patient with Recurrent Strokes

Michael Chau,[1] Solomon Dawson.[1,2] *[1]Cooper University Health Care, Camden, NJ; [2]Rowan University Cooper Medical School, Camden, NJ.*

Introduction: Secondary hypertension can be due to vasculopathy, endocrinopathy, or medications. Although uncommon, secondary hypertension can be due to a reninoma leading to secondary hyperaldosteronism. We discuss a case of a patient with a reninoma and describe his clinical presentation and medical course for this rare disorder.

Case Description: A 42-year-old male with a history of hemorrhagic strokes in 2016 and 2018 with and hypertension (HTN) diagnosed 8 years prior to admission presented to the hospital for acute onset aphasia and was found to have an acute ischemic left sided stroke. Vital signs were remarkable for a blood pressure of 204/130. Hospital labs showed a serum creatinine of 0.86 mg/dL, sodium of 140, potassium of 3.7, AM renin level of 11 ng/mL/h, AM aldosterone level of 2 ng/dL, and total serum metanephrine level of 279 pg/mL. A renal artery ultrasound did not show renal artery stenosis. A CT abdomen and pelvis without contrast revealed a 2.8 cm proteinaceous cyst in the right kidney. He was discharged on Hydralazine 75 mg twice a day, Quinapril 20 mg twice a day, and Labetalol 300 mg nightly. Repeat testing 3 months later in clinic showed an AM renin level of 46 ng/mL/h, AM aldosterone level of 71.2 ng/dL, serum creatinine of 0.87 mg/dL, sodium of 139, and potassium of 3.4. Urine metanephrine/catecholamine levels were within normal limits. His blood pressure remained uncontrolled averaging 150s systolic over 90s diastolic during his office visits and his regimen was uptitrated to Lisinopril 40 mg daily, Spironolactone 75 mg daily, Hydralazine 75 mg thrice daily, and Carvedilol 12.5 mg twice a day. He could not tolerate diuretics due to frequent urination or calcium channel blockers due to persistent headaches. An MRI of his kidneys was ordered to further assess the proteinaceous cyst and he was found to have a Bosniak 4 3.6 cm right renal lesion. He underwent a partial nephrectomy to address the mass with urology. Pathology showed a vascular-rich renal mesenchymal tumor that was compatible with a juxtaglomerular cell tumor. His blood pressure regimen improved to Lisinopril 5 mg daily 2 months after his surgery.

Discussion: Less than 100 cases of reninoma have been reported over the last 40 years. The mean age at diagnosis was 27 years with a mean duration of HTN of 47 months. Our case highlights the importance of keeping reninoma on the differential of causes of secondary HTN.

SA-PO382

Bilateral Nephrectomy as a Salvage Therapy for Resistant Hypertension in ESKD

Wajeeha Shahid,[1] Awiza Ali,[2] Waris Rafique,[2] Talha Shahid,[3] Mehdi Mushtaq.[2] *[1]The Wright Center for Graduate Medical Education, Scranton, PA; [2]Patel Hospital, Karachi, Pakistan; [3]Liaquat College of Medicine and Dentistry, Karachi, Pakistan.*

Introduction: Chronic hemodialysis patients face challenge with resistant hypertension and exhibit resistant to volume control and antihypertensive medications. Although bilateral nephrectomy has shown promising outcomes, it appears to be an underutilized option.

Case Description: 30 years male, past medical history of hypertension, hyperlipidemia, ESRD on intermittent hemodialysis admitted to the hospital with hypertensive emergency, systolic BP > 200, complicated with non-ST-elevation myocardial infarction, diastolic heart failure, pleural effusion. The patient's antihypertensive regimen included clonidine, hydralazine, methyldopa, lisinopril, doxazosin, nifedipine, and spironolactone. Minoxil was unavailable in country and was not used. The patient's BP was controlled with the addition of intravenous glyceryltrinitrate. The secondary causes of resistant hypertension in this patient were investigated, serum renin and aldosterone level came normal, plasma free metanephrine level was also unremarkable, renal angiogram was negative for large vessel stenosis only tortuous and anomalous origin of renal arteries was noted. The patient remained dependent on a glyceryltrinitrate drip despite >7 oral antihypertensives and daily four-hours hemodialysis sessions and intensive ultrafiltration. Choices for the treatment of this patient's refractory hypertension were considered, including renal denervation and bilateral nephrectomy. Interdisciplinary meetings resulted to proceed with bilateral nephrectomy. The option of renal denervation was postponed due to its invasive nature and unproven effectiveness. The patient underwent a bilateral nephrectomy without any significant complications. Following the procedure, the patient was closely monitored in the intensive care unit for a week. Subsequently, the patient's blood pressure gradually normalized over a three-month period. Post-surgery, Lisinopril was stopped, labetalol was discontinued after one month, and the doses of other antihypertensive medications were gradually reduced.

Discussion: The prevalence of bilateral nephrectomy as a treatment option ranges from 0 to 7% in various countries.[1] Bilateral nephrectomy leads to reduction in the levels of renin, angiotensin and aldosterone, which subsequently lowers the BP in resistant hypertension.[2] [1]doi: 10.1016/j.ijscr.2022.107566 [2]doi: 10.7759/cureus.9031

SA-PO383

More Than an Accessory: Renal Artery Stenosis in a Second Renal Artery Driving Uncontrolled Hypertension

Sunny R. Parmar, Ali Mehdi. *Cleveland Clinic, Cleveland, OH.*

Introduction: Renovascular hypertension may result from renal artery stenosis (RAS), because significant compromise in renal blood flow results in excessive renin release and drives renin-angiotensin system (RAAS) activation from the affected kidney. This may not be expected from a stenosed accessory artery, which would supply only a limited portion of the kidney. However, an uncommon anatomic variant with two ipsilateral renal arteries originating from the aorta does exist. We hereby present a case of uncontrolled renovascular hypertension emanating from RAS of one of two such renal arteries, initially confused for an accessory artery.

Case Description: A 51 year-old male presented to nephrology clinic with recently uncontrolled hypertension. Previously controlled on lisinopril and hydrochlorothiazide, blood pressure was now uncontrolled on five blood pressure agents of different classes. Secondary workup was pursued showing a direct renin concentration of 1,704 pg/mL (plasma renin activity of 324 ng/mL/h). A renal Doppler study described an "accessory" renal artery having 60-99% stenosis whereas the "main" left and right renal arteries showed 0-59% stenosis. Given renin elevation and worsening hypertension, a contrast enhanced CT scan was done showing two left renal arteries of similar caliber originating from the aorta with one having severe proximal stenosis. Angioplasty with stenting was done following which serial renal Dopplers confirmed resolution of stenosis up to two years later. On the most recent follow up, his blood pressure remained controlled on lisinopril-HCTZ 20-12.5mg daily alone.

Discussion: This case describes an unusual scenario where one of two ipsilateral renal arteries of similar size had severe stenosis, leading to renovascular hypertension.

The initial Doppler study might have been misleading pointing to a potentially insignificant, albeit stenotic, accessory renal artery. The severely high renin activity levels was the main clue that prompted further evaluation of this ultrasound finding ultimately leading to stenting which proved impactful on his hypertension management. In investigating renovascular hypertension, one should utilize renin levels and consider unusual anatomy when a stenosed accessory renal artery is described.

SA-PO384

Hereditary Paraganglioma Pheochromocytoma Syndrome (HPPS) Presenting as Resistant Hypertension in Patients with ESKD: A Rare Presentation

Arfa Amjad, Tahir A. Jatoi, Subodh J. Saggi, Sandeep R. Sasidharan, Fnu Pariya.
SUNY Downstate Health Sciences University, New York City, NY.

Introduction: End-stage renal disease (ESRD) is a growing public health concern, with uncontrolled hypertension (HTN) being a frequent complication. While pheochromocytoma, a catecholamine-secreting tumor, can cause HTN, its diagnosis in ESRD patients can be challenging. We present a rare mutation as the cause of pheochromocytoma in an ESRD patient.

Case Description: A 39-year-old AA woman with a history of ESRD, uncontrolled HTN with vitreous hemorrhage, MI, and CVA with family history of early MI & CVA presented with severe headaches and palpitations for many days and had 6 similar admissions for the last year. Her BP was uncontrolled with post HD BP noted to be >160/110 & with four antihypertensive. Normal physical exam with vitals stable except for BP of 210/125, confirmed with repeat. EKG was unchanged with T Inversion in a few leads. A secondary HTN workup showed low Dexamethasone <30 mg/ml, Urinary Dopamine <30 mcg, elevated Aldosterone 42.6 ng/dl, Renin 34.9 ng/ml/hr, normetanephrine 534 nmol/L. 24-hour urine showed Epinephrine 67 mcg, Norepinephrine 436 mcg, 24-hour normetanephrine 1041 mcg. CT abdomen scan showed a 1.4 cm left adrenal mass. Genetic testing revealed paraganglioma with SDHAF2 mutation. The 123I-MIBG scan was negative. She is to have a DOTATE 68 gallium PET scan for localization and paraganglioma surgery. She continues to be on HD with multiple antihypertensives.

Discussion: Hereditary Paraganglioma Pheochromocytoma Syndrome (HPPS) is characterized by elevated urinary metanephrines, catecholamine levels, and an SDHAF2 mutation. Pheochromocytoma diagnosis in ESRD patients presents challenges due to altered catecholamine metabolism and limited urine sampling. Our case highlights unique diagnostic features, including lower norepinephrine levels and a negative MIBG scan, along with a rare SDHAF2 mutation association. This syndrome is associated with the Succinate Dehydrogenase gene & manifests in four distinct syndromes. Our case corresponds to PGL type 2 with an SDHAF2 mutation. Families with SDHAF2 mutations are exceptionally rare and affected individuals typically present exclusively with head and neck paragangliomas. There is no case of this gene mutation reported in ESRD patients. Surgical removal remains the mainstay of treatment, often preceded by alpha-adrenergic blockade.

SA-PO385

An Unusual Case of High-Renin Hypertension

Adi Leiba,[1,2] Avital Angel-Korman.[1,2] *[1]Assuta Ashdod Hospital, Ashdod, Israel; [2]Ben-Gurion University of the Negev Faculty of Health Sciences, Beer-Sheva, Israel.*

Introduction: We present an unusual case in which negative sodium balance was the etiology of high renin hypertension

Case Description: A 75-year-old woman consulted us due to high blood pressure. **PMH:** LBP, history of excessive NSAIDS use, s/p partial colectomy **Meds :** amlodipine, zolpidem, bisacodyl, pregabalin, acetaminophen tramadol, brotizolam, atorvastatin, ezetimibe, esomeprazole **BP**- 150/84mmHg **Labs** - 24 hour urine collection – 240 mg protein (0 albumin), intermittent leukocytuia **Renal US –** echogenic diminished parenchyma On addition of low dose ARB (25mg losartan) her creatinine rose from 1.28 to 1.87 mg/dL, blood pressure dropped to 101/64 mmHg, and renin was found to be elevated to >500 microunits/ml. Aldosterone was also extremely elevated to 64.7ng/dl Renal artery doppler showed no evidence of renal artery stenosis. She reported keeping to a low salt diet as well self-prescribing 10 tabs of bisacodyl every evening (!) We suspected sodium malabsorption, and, indeed, her 24 hour urinary sodium was below detection limit. The patient was advised to liberalize sodium intake, to take salt tablets, and reluctantly agreed to cut down her laxative use into 3-4 tabs/day. Within a month her plasma creatinine improved, renin and aldosterone levels trended down, and sodium reappeared in her urine (Table 1). Despite sodium "loading" Her blood pressure was stable (132/74mmHg)

Discussion: Hypovolemia due to negative sodium balance can still cause hypertension due to the effect of the resultant high renin, angiotensin II and aldosterone. This case emphasizes the importance of the colon in sodium reabsorption and the complex interplay of the colon, the kidneys, and the adrenal gland. Secondary hyperaldosteronism would usually cause avid sodium reabsorption through colonic eNac, but, in our case, sodium malabsorption was dominant due to short colon and laxative abuse. Our intervention affected this colonic-renal-adrenal axis, relieving the patient from chronic hypovolemia, negative sodium balance, worsening kidney function and uncontrolled hypertension

changes related to liberalization of salt intake, addition of salt tabs and partial bisacodyl withdrawal

	April 2nd 2023	May 8th 2023
Creatinine	1.76 mg/dl	1.39mg/dl
24 hour urinary sodium	below detection limit	235 millimole
24 hour urinary potassium	16 millimole	26.4 millimole
Direct Renin	183.8 micro IU/ml	45.3 micro IU/ml
Plasma Aldosterone	64.7 ng/dl	19.5 ng/dl

SA-PO386

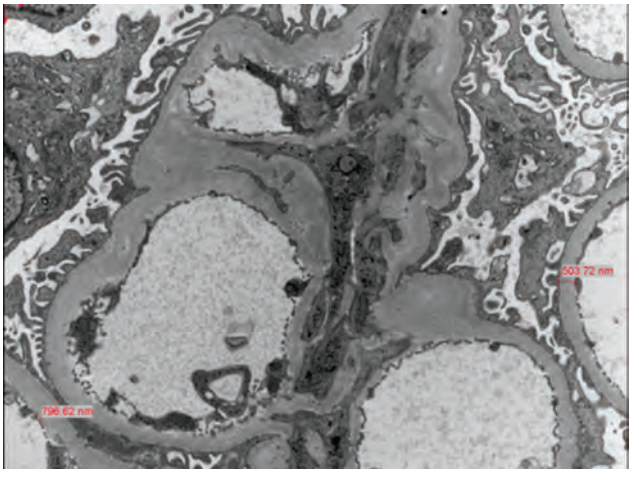
Cystinuria Screening Reveals Uncontrolled Hypertension and Subnephrotic-Range Proteinuria in a 20-Year-Old Patient: A Case Report

Muhammed Mumin,[1] Syed Mohammed Faizaan Zabiullah,[2,3] Viqarunnisa Faaiza Zahid,[4] Rebecca V. Levy,[1] Erika Drury,[1] Mohammad A. Yousuf,[1] Jerome L. Jean-Gilles.[1] *[1]University of Rochester, Rochester, NY; [2]Unity Hospital, Rochester, NY; [3]New York Medical College School of Medicine, New York, NY; [4]University of Minnesota Twin Cities, Minneapolis, MN.*

Introduction: Cystinuria is an autosomal recessive disorder caused by defects in the SLC3A1 gene that mediates sodium-independent transport of cysteine and dibasic amino acids in proximal tubule and small intestine. Cystinuria commonly presents as renal stones.

Case Description: A 20 y.o male with history of ADHD on amphetamine-dextroamphetamine presented for cystinuria screening. Family history was notable for a sister with cystinuria. He had no complaints. On examination, he is a young muscular man with BMI of 23.7 kg/m2. His office BP is 134/63 mm Hg. Physical examination is otherwise unremarkable. Urinalysis showed +1 protein. 24 hour urine showed proteinuria of 1842 mg/day, microalbuminuria of 1124.4 mg/day and cystinuria (1096 mg/day). The eGFR (CKiD U25) was 103 ml/min/1.73m2. Serology and immunological workup was normal. Renal biopsy revealed diffuse segmental mesangiolysis and IgM mesangial deposits of unclear significance. EM showed glomerular BM thickening (286-796 nm) with segmental lamina rara interna expansion and mesangiolysis. The overall findings were suggestive of chronic endothelial injury. Ambulatory BP monitoring showed markedly elevated BP readings(mean systolic 152 mm Hg). Preliminary diagnosis was masked hypertension with hypertensive kidney disease, lisinopril was started and stimulant was discontinued. Endocrine evaluation for secondary hypertension was negative. Echo revealed LV hypertrophy. Genetic testing showed biallelic pathogenic mutations in SLC3A1 consistent with known cystinuria.

Discussion: This case highlights a rare combination of cystinuria and hypertensive kidney disease. It is unclear in this patient whether the cystinuria and hypertension are linked. It also emphasizes the importance of screening of close family members for Cystinuria, which in this patient has led to early discovery of his hypertension and prevented severe end-organ damage.



SA-PO387

Implausible Hemolysis with the New Chinese Standard for Testing Dialyzer Hemocompatibility

Detlef H. Krieter,[1] Marieke Rueth,[2] Horst-Dieter Lemke,[2] Christoph Wanner.[1]
[1]University Hospital Würzburg, Nephrology, Würzburg, Germany; [2]eXcorLab GmbH, Obernburg, Germany.

Background: A new standard for testing dialyzer hemocompatibility (YY/T 1920-2023) has been introduced in China. With current international standards (e.g., EN ISO 10993-4 and ASTM F756) and the previous Chinese Standard (GB/T 14233.2 (2005)), certified dialyzers passed the hemolysis criteria easily (hemolysis <2%). In contrast, YY/T 1920-2023 led to aberrant results with several filters. Purpose of the present study was to analyze possible causes for these unexpected findings.

Methods: According to YY/T 1920-2023. (n=3), 0.5 g samples were cut from dialyzer membrane bundles and incubated for 30 min in saline at 37°C. Rabbit blood was added, slewed, incubated for 100 min at 37° C and then stirred with a pipette tip. Liquid was aspirated, centrifuged and the supernatant photometrically assessed at 545 nm. Hemolysis was calculated based on a positive control and two negative controls (A, saline; B, samples incubated only for 1 min). Baxter Revaclear 300 (PES; steam-sterilized), Bain DORA® B-16HF (PS; g-radiated), and Jafron JM 16H (PUREMA™ H; g-radiated, PET spacer yarn) were investigated. Native PUREMA™ (PES) was also tested: with and without PET; non-sterile and g-radiated; no cutting, stirring and suction.

Results: Hemolysis rates of the Revaclear, DORA®, and JM membranes were 5.1±1.1%, 1.1±0.1%, and 7.6±1.0%, resp. For PUREMA™, hemolysis for non-sterile/no PET bundles was 1.5±0.3%, γ-radiated/no PET 2.4±0.4%, non-sterile/with PET 4.3±0.7%, γ-radiated/with PET 6.3±0.1%, non-sterile/with PET/no-cutting 3.7±0.8%, non-sterile/with PET/no stirring and suction 0.9±0.4%. In the negative control B, which investigated the membrane samples with short incubation of 1 min, also hemolysis between 0.9±0.0 and 3.0±0.0% was observed.

Conclusions: Compared to current international standards, in vitro hemolysis determined with YY/T 1920-2023 can be significantly higher. Applying YY/T 1920-2023 is characterized by mechanical stress in form of compression from stirring and negative pressure from suction on blood cells which is particularly susceptible to operator influence. The outside surfaces of the dialysis membranes, which never come into contact with patient blood, also influence hemolysis as sterilization, the presence of a spacer yarn, and cut fragments have adverse effects. Consequently, the validity of the new Chinese Standard YY/T 1920-2023 must be questioned.

Elevated Lipoprotein(a) Levels Are Associated with Endothelial Dysfunction Measured by Vascular Reactivity Index in Patients on Chronic Hemodialysis

Yu-Hsien Lai,[1,2] Yu Chi Chang,[1] Bang-Gee Hsu.[1,2] *[1]Division of Nephrology, Buddhist Tzu Chi General Hospital, Hualien, Taiwan; [2]School of Medicine, Tzu Chi University, Hualien, Taiwan.*

Background: Lipoprotein(a)(Lp(a)) accelerates the formation of atherosclerotic plaque by its proatherogenic, prothrombotic, and proinflammatory actions and has a positive correlation with cardiovascular disease. We aimed to evaluate the association between serum Lp(a) levels and endothelial function in patients with maintenance hemodialysis (MHD).

Methods: We enrolled 123 MHD patients, and their blood samples and medical records were obtained. We measured endothelial function as vascular reactivity index (VRI) by a non-invasive digital thermal monitor, and serum Lp(a) concentration was measured by a commercial enzyme-linked immunosorbent assay.

Results: Eighteen (14.6%) MHD patients were classified as having poor vascular reactivity, 51 (41.5%) MHD patients as having intermediate vascular reactivity ($1.0 \le VRI < 2.0$), and 54 (43.9%) MHD patients were classified as having high vascular reactivity ($VRI \ge 2.0$). The serum alkaline phosphatase (ALP, $p = 0.002$) and Lp(a) ($p < 0.001$) levels significantly increased as VRI decreased. The logarithmic transformation of serum ALP (log-ALP, $r = –0.252$, $p = 0.005$) and log-Lp(a) ($r = –0.578$, $p < 0.001$) was negatively associated with the VRI values by univariate linear regression analysis. Multivariate stepwise linear regression analysis showed a significantly negative association of log-ALP (standardized $\beta = –0.212$, adjusted R^2 change = 0.040; $p = 0.001$) and log-Lp(a) (standardized $\beta = –0.562$, adjusted R^2 change = 0.328; $p < 0.001$) with VRI values in MHD patients. Serum Lp(a) was independently associated with vascular reactivity dysfunction (odds ratio (OR) = 1.006; 95% confidence interval (CI) = 1.002–1.009; $p = 0.001$) and poor vascular reactivity index (OR = 1.009, 95% CI = 1.004–1.014, $p < 0.001$) in MHD patients by logistic regression analysis.

Conclusions: In this study on MHD patients, along with serum ALP levels, the most significant clinical implication was that serum Lp(a) levels were negatively correlated to the VRI and can be used as a potential novel biomarker of endothelial dysfunction.

SA-PO389

Prognostic Value of Secretoneurin in Patients Treated with Chronic Hemodialysis

Caroline H. Liboriussen,[1,2] Louis Nygaard,[1,2] Magnus N. Lyngbakken,[3,4] Jens D. Jensen,[1] Rie I. Glerup,[1] Torbjorn Omland,[3,4] Helge Rosjo,[3,4] My Svensson.[1,2] *[1]Aalborg Universitetshospital, Aalborg, Denmark; [2]Aalborg Universitet, Aalborg, Denmark; [3]Akershus Universitetssykehus HF, Lorenskog, Norway; [4]Universitetet i Oslo, Oslo, Norway.*

Background: Secretoneurin (SN) is a novel biomarker with an upper reference limit (97.5th percentile) of 60 pmol/L in healthy subjects. High SN concentrations are associated with increased risk of mortality in patients with cardiovascular (CV) disease. This study investigated the association between SN and the risk of CV events and all-cause mortality in patients receiving hemodialysis (HD).

Methods: Prospective multicenter cohort study with 5 years of follow-up. Serum SN (pmol/L) was measured at baseline. Primary outcome was CV events; secondary outcomes were all-cause mortality and each component of CV events. The population was divided into tertiles according to SN concentrations (pmol/L): tertile 1 <110.7, tertile 2 from 110.7-143, and tertile 3 >143. The association between SN tertiles and outcomes was analyzed with adjusted Cox regression analysis.

Results: The study included 336 patients on HD. Median SN concentration was 126 (IQR 100-153) pmol/L. During follow-up 60% died and 42% had a CV event. After adjusting for relevant confounders neither SN tertile 2 nor SN tertile 3 were associated with the risk of CV events ($HR_{tertile2}$ 1.27 (95% CI 0.84-1.93) and $HR_{tertile3}$ 1.20 (95% CI 0.76-1.90)) or all-cause mortality ($HR_{tertile2}$ 0.84 (95% CI 0.60-1.18) and $HR_{tertile3}$ 0.90 (95% CI 0.62-1.31)), when compared to tertile 1 (**Fig. 1**).

Conclusions: Patients receiving HD have high SN concentrations; however, SN was not associated with CV events or all-cause mortality. High concentrations of SN, possibly explained by both impaired renal clearance and a high prevalence of cardiomyopathy, may limit its prognostic relevance in patients receiving HD.

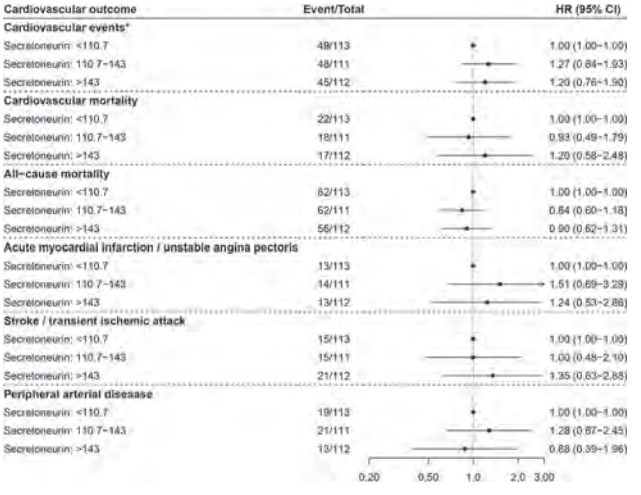

Fig 1. Association between secretoneurin tertiles and outcomes. *Cardiovascular (CV) events include acute myocardial infarction, unstable angina pectoris, stroke, transient ischemic attack, peripheral arterial disease, and CV mortality.

SA-PO390

Lectin Pathway Initiators Ficolin-1 and Collectin-11 Are Associated with Mortality in Patients on Hemodialysis

Philip De Laval,[1] Rie I. Glerup,[2] My Svensson,[2] Niclas Eriksson,[3] Laura Pérez Alós,[4] Peter Garred,[4,5] Bo Nilsson,[6] Kristina N. Ekdahl,[6,7] Bengt C. Fellstrom,[1] Inga Soveri.[1] *[1]Department of Medical Sciences, Uppsala University, Uppsala, Sweden; [2]Department of Nephrology, Aalborg University Hospital, Aalborg, Denmark; [3]Uppsala Clinical Research Center, Uppsala, Sweden; [4]Department of Clinical Immunology, Copenhagen University Hospital, Copenhagen, Denmark; [5]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; [6]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden; [7]Department of Chemistry and Biomedical Sciences, Linnaeus University, Kalmar, Sweden.*

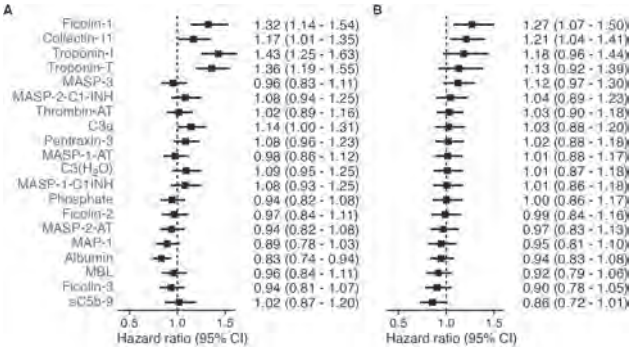
Background: Cardiovascular disease (CVD) is the leading cause of death in hemodialysis (HD) patients. The complement system may contribute to inflammation, which is considered a non-traditional risk factor for CVD, through activation of the lectin pathway during HD. Intradialytic complement activation has been linked to cardiovascular (CV) events but studies on the lectin pathway with regards to outcome in HD are few. We aimed to assess if baseline levels of lectin pathway factors are associated with clinical outcome in HD patients.

Methods: We conducted a cohort study with five years of follow-up. All patients > 18 years of age in five HD facilities in Jutland, Denmark without acute kidney injury were asked to participate. Plasma levels of complement factors C3a, sC5b-9, C3(H_2O), MBL, ficolin-1,-2,-3, pentraxin 3, collectin-11, MASP-1- and MASP-2-Antithrombin/C1-inhibitor complexes, MASP-3 and MAP-1 were analyzed using ELISAs. The endpoints were all-cause mortality, infection-related mortality, CV-mortality and CV-events. Hazard ratios (HR) were modeled using cox regression on one standard deviation increase in $\log_2$ complement levels. Known risk factors for mortality in HD were added in a second model. These were age, $\log_2$ dialysis vintage, diabetes mellitus, previous CVD and $\log_2$ albumin, CRP, troponin I, and troponin T.

Results: In total, 331 patients were included. During follow-up, 198 (60%) died. Ficolin-1 and collectin-11 levels were associated with all-cause mortality in both the crude (Fig. 1A) and adjusted (Fig. 1B) model. Collectin-11 was significantly associated with CV-mortality in the adjusted (HR 1.35 [95% CI 1.02-1.77]) but not in the crude model (HR 1.26 [95% CI 0.98-1.63]).

Conclusions: Lectin pathway initiators ficolin-1 and collectin-11 are associated with death in HD patients, independently of known risk factors. This suggests an adverse role for the lectin complement pathway in HD patients.

Funding: Private Foundation Support, Government Support - Non-U.S.



SA-PO391

A Comprehensive Skin Gas Analysis of Substances Related to Uremia

Toyohiro Hashiba,[1] Yosuke Hirakawa,[1] Hiroyasu Yamahara,[2] Yasuo Yano,[2] Yuka Yamada,[2] Hitoshi Tabata,[2] Masaomi Nangaku.[1] *[1]Division of Nephrology and Endocrinology, Graduate School of Medicine, The University of Tokyo, Bunkyo-ku, Japan; [2]Department of Bioengineering, Graduate School of Engineering, The University of Tokyo, Bunkyo-ku, Japan.*

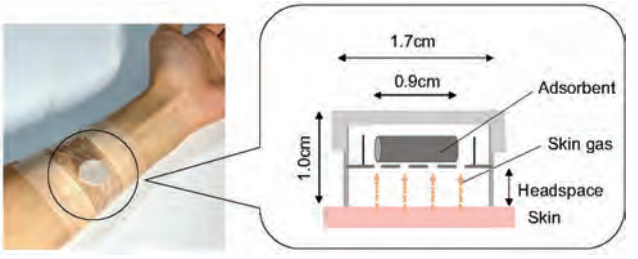
Background: Recent progress in gas-sensing technology has enabled highly sensitive analysis of skin gases associated with body odor, which are collected more continuously and unconsciously than blood or urine. Patients with end-stage kidney disease (ESKD) have a characteristic uremic odor, which fades after initiating kidney replacement therapy. We investigated the possibility of quantitatively evaluating the substances that cause uremia.

Methods: Skin gases were collected by placing a passive flux sampler on the forearm for 20 min (Figure), heating rapidly, and measuring peak intensity by gas chromatography-mass spectrometry. We investigated the changes in gases obtained from the hemodialysis (HD) group before and after the first HD session of patients undergoing incident dialysis. We compared skin gases between the ESKD (HD, non-HD), chronic kidney disease (CKD) stage G2, and the healthy group.

Results: Of the 176 volatile molecules collected from the HD group (N=5), we focused on 27 substances detected in all patients. Five volatile molecules included in 6-methyl-5-hepten-2-one derived from squalene specific to human sebum were detected in all participants: the ESKD (N=11), CKD stage G2 (N=6), and healthy (N=7) groups. In addition, benzaldehyde excreted in the urine as hippuric acid of uremic substances in the blood showed significantly higher intensities in the ESKD group than in other groups (p=0.012).

Conclusions: Although there were individual differences, a comprehensive skin gas analysis was helpful for inter-individual comparisons of uremia-related substances.

Funding: Government Support - Non-U.S.



The figure shows a passive flux sampler attached to the participant's left forearm to collect the skin gases and a cross-sectional view.

Plasma Oxalate and Microbiome Assessment in Patients on Hemodialysis

Nadim Zaidan,[1] Karim Jaber,[2] Boyan Zhou,[2] David M. Charytan,[2] Laura M. Dember,[3] Lama Nazzal.[2] *[1]Staten Island University Hospital, Staten Island, NY; [2]NYU Langone Health, New York, NY; [3]University of Pennsylvania, Philadelphia, PA.*

Background: Uremic toxins accumulation in patients with end-stage kidney disease (ESKD) undergoing maintenance hemodialysis (HD) is associated with increased cardiovascular (CV) mortality. Plasma oxalate (POx) stands as a potentially significant contributor to CV complications in ESKD. Oxalate-degrading bacteria (ODB) are pivotal in oxalate metabolism, yet their prevalence and functional activity remain unexplored in ESKD patients. This pilot study explored the ODB community of ESKD patients.

Methods: Plasma (P) and fecal samples from 12 ESKD patients were obtained from the 8-week pretreatment phase of "The Microbiome and p-Inulin in Hemodialysis: A Feasibility Study" and used for our study. POx was calculated at both weeks 0 and 8 using a metabolomics platform (HPLC-MS) and colorimetric enzymatic assay. Fecal DNA from Week 1 and Week 8 were extracted using the Qiagen 96-well extraction kit and metagenomics sequencing was performed at NYU's Genome Technology Center. The raw sequencing data was processed and analyzed using the Kraken2 as well as our bioinformatics pipeline specific to ODB.

Results: The within-person percentage change of POx between weeks 0 and 8 was 10.67% + 62.93 % and -0.67% ±9.2% using the enzymatic assay and metabolomics platform, respectively. No significant variation between weeks 0 and 8 in both alpha and beta diversities indices highlighted microbiome stability across time for ESKD patients receiving hemodialysis. Several species were positively or negatively correlated with POx measured by the enzymatic and metabolomic assay (Table 1).

Conclusions: In conclusion, our study highlights the stability of the microbiome over time in patients with ESKD undergoing hemodialysis. Several ODB bacterial taxa are associated with POx levels in ESKD patients.

Analysis of Characteristics of Patients on Maintenance Hemodialysis and Subjective Cognitive Decline Based on Intestinal Flora

Hua Liu. *The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China.*

Background: To study the relationship between intestinal flora and subjective cognitive decline (SCD) in patients with maintenance hemodialysis (MHD).

Methods: From July 2022 to July 2023,84 patients with MHD in the department of severe renal disease and blood purification, first affiliated hospital of the Xi'an Jiaotong University were enrolled, the subjects were divided into SCD Group (SCD group, N = 40, MMSE score≥24 and SCD-Q9 score≥5) and normal cognition group (NC Group, N = 44, MMSE score≥24), to investigate whether SCD is related to flora disturbance, the difference of flora at family and genus level was judged and the difference of KEGG function was predicted based on 16srDNA.

Results: SCD-Q9 score in SCD Group was significantly higher than that in NC Group ($P < 0.05$). There were 11 different bacterial families in the SCD Group, and Erysipelatoclostridiaceae and Enterobacteriaceae had higher relative abundance in the SCD group. Among the 9 major differential bacteria, the highest relative abundance in SCD group was in Escherichia-Shigella, Ruminococcus gnavus and erysipelato-clostridium, and the positive correlation between Escherichia-Shigella and SCD-Q9 was the strongest

($P < 0.01$), and the negative correlation between Escherichia-Shigella and MMSE was the strongest ($P < 0.01$). Ruminococcaceae had the strongest negative correlation with SCD-Q9($P < 0.01$) and Faecalibacterium had the strongest positive correlation with MMSE ($P < 0.01$). Rikenellaceae, Marinifilaceae, Alistipes, Ruminococcus gnavus and Odoribacter were more effective in identifying SCD. Compared with NC group, SCD increased bacterial invasion, Shigella and p-nitrotoluene degradation in epithelial cells, down-regulated the biosynthesis, Nonribosomal peptide structure, and biosynthetic function of neomycin, kanamycins and gentamicin Prodigiosin, it is suggested that the dysbacteriosis of SCD may lead to the increase of pathogenic metabolic pathway and the decrease of healthy metabolic function.

Conclusions: The results of this study suggest that the cognitive function of MHD patients has been altered during SCD, which is characterized by a decrease in the abundance of beneficial anti-inflammatory bacteria and an increase in the abundance of certain harmful pro-inflammatory bacteria, which indicates that intestinal flora disturbance is related to SCD and may predict SCD and become a target of intervention.

SA-PO394

Hepatic Function Is Impaired in Inflamed Haemodialysis Patients

Oscar Swift,[1,2] Bobby VM Dasari,[3,4] Malcolm A. Finkelman,[5] Yonglong Zhang,[5] Sivakumar Sridharan,[1,2] Enric Vilar,[1,2] Ken Farrington.[1,2] *[1]East and North Hertfordshire NHS Trust, Stevenage, United Kingdom; [2]University of Hertfordshire, Hatfield, United Kingdom; [3]University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; [4]University of Birmingham, Birmingham, United Kingdom; [5]Associates Of Cape Cod Inc, East Falmouth, MA.*

Background: Impaired hepatic function may drive inflammation in ESKD via reduced gut-derived toxin removal. (1-3)-β-D glucan (BDG), found in cell walls of bacteria and fungi, is often raised in ESKD and may reflect systemic translocation of gut material. This study evaluated hepatic function in inflamed and non-inflamed individuals on haemodialysis (HD). BDG was used as a surrogate marker of gut permeability.

Methods: 25 inflamed adults with ESKD (baseline hs-CRP >5mg/L) and 25 non-inflamed adults with ESKD (hs-CRP ≤5mg/L) were recruited from four UK outpatient HD units. Dynamic hepatic function was assessed by indocyanine green (ICG) clearance. ICG levels were measured transcutaneously to calculate plasma disappearance rate (ICG-PDR) and retention at 15 minutes (ICG-R15min). Fibroscan imaging assessed hepatic steatosis and fibrosis.

Results: ICG-PDR and ICG-R15min were, respectively, reduced and elevated, in inflamed individuals. Hepatic steatosis and fibrosis, and pre-HD BDG were similar between groups (Table 1). Post-HD BDG was higher in the inflamed group (Table 1), and in those with hepatic impairment (Figure 1).

Conclusions: Hepatic function is impaired in inflamed individuals receiving HD. Impaired hepatic function associates with elevated BDG post-HD, suggesting that impaired hepatic removal of gut-derived toxins may propagate chronic inflammation in ESKD.

Funding: Other NIH Support - National Institute for Health and Care Research (NIHR) Research Capability Funding, East and North Hertfordshire Hospitals Charity, Commercial Support - Associates of Cape Cod provided assays for BDG measurement gratis

Protein-Bound Uremic Toxin-Lowering Effects of Sevelamer in Patients on Chronic Hemodialysis with Hyperphosphatemia: A Multicenter Randomized Controlled Trial: A Preliminary Report

Napas Srifa,[1] Jeerath Phannajit,[1] Sookruetai Lekhyananda,[2] Kamonrat Chongthanakorn,[3] Sipanan Thamratnopkoon,[3] Wannasit Wathanavasin,[3] Yingyos Avihingsanon,[1] Somchai Eiam-Ong,[1] Paweena Susantitaphong.[1] *[1]King Chulalongkorn Memorial Hospital Department of Internal Medicine, Bangkok, Thailand; [2]Priest Hospital, Bangkok, Thailand; [3]Charoenkrung Pracharuk Hospital, Bangkok, Thailand.*

Background: P-cresol (pCS) is an important protein-bound uremic toxin (PBUT) linked with cardiovascular mortalites in chronic hemodialysis patients. Dialysis modalities have a limitation in removing PBUTs. Recent approaches focus on decreasing toxin generation, increasing gut absorbent, and preserving residual kidney function (RKF). Sevelamer, used as a phosphate binder, has limited data on pleiotropic effects on PBUTs in these patients. This study investigated the pCS-lowering effect of sevelamer in a open-label multicenter randomized controlled trial (TCTR20230530004).

Methods: Chronic hemodialysis patients with persistent hyperphosphatemia were randomly assigned to receive either sevelamer or calcium carbonate for 24-week using protocol-based dosage titration to achieve the target phosphate of 3.5-5.5 mg/dL. Blood samples were collected before and at 8, 16, 24 weeks. Mean differences between two groups including sub-group analysis stratified by RKF, phosphate binders dose, HD frequency, mean phosphate level and protein intake were analyzed using linear mixed model.

Results: Of the 73 initial participant, 3 patients dropped out leaving 35 in both treatment groups for the per-protocol analysis. Fifty-five percent were anuric (RKF < 100 ml/day). Significant phosphate lowering was observed in both groups. The mean changes in pCS were not different between groups. Interestingly, a trend towards reducing serum pCS levels was observed in sevelamer group among anuric patients and those using high dose phosphate binders (as figure). However, the changed were not significantly different when compared with calcium carbonate.

Conclusions: Sevelamer may reduce pCS in chronic hemodialysis with minimal RKF, suggesting potential pleiotropic effects. However, long-term follow-up is still required.

Dynamics of Amyloid-β and Total Tau in Cerebrospinal Fluid and Plasma of Patients on Hemodialysis

Hassan Gorji,[1] Lin-Chun Wang,[1] Ohnmar Thwin,[1] Joshua E. Chao,[1] Ludovic Debure,[3] Nadja Grobe,[1] Xin Wang,[1] Hanjie Zhang,[1] Stephan Thijssen,[1] Thomas Wisniewski,[3] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai Department of Medicine, New York, NY; [3]NYU Langone Health, Department of Neurology Center for Cognitive Neurology Alzheimer's Disease Research Center - Biomarker Core, New York, NY.*

Background: While hemodialysis (HD) can reduce Amyloid beta protein (Aβ) in the blood, its impact on cerebrospinal fluid (CSF) Aβ levels has not been studied. This research is the first to investigate the dynamics of Aβ and total tau levels in both CSF and plasma of HD patients.

Methods: Three chronic HD patients with ventriculo-peritoneal shunts participated in this study. The patients underwent thrice weekly high-flux HD. During HD, plasma samples were collected at six different timepoints, shown in figures A1, B1, C1. Two patients had repeated VPS taps to collect CSF samples. One subject was withdrawn over safety concern. Aβ1-40, Aβ1-42, total tau in the CSF and plasma samples were quantified using the Neuro 3-Plex assays (Quanterix, MA, USA).

Results: Our findings indicate a decrease in plasma levels of Aβ1-40 and Aβ1-42 by 40% and 35% respectively, while total tau levels increased by 16% (Figures A1, B1, C1). The mean levels of these proteins in plasma and CSF during the intervals between HD sessions (interdialytic period) are shown in Figures A2, B2, C2. Notably, during the interdialytic intervals, there was an inverse relationship in protein levels: while plasma levels of Aβ1-40, Aβ1-42, and total tau increased, their respective CSF levels decreased (Table1, Figures A2, B2, C2).

Conclusions: This study is the first to demonstrate CSF dynamics of Aβ1-40, and 42, and total tau in HD patients. We observed that after HD, in the interdialytic period, the CSF levels of Aβ1-40 and 42, and total tau declined. Interestingly, while CSF levels of Aβs and total tau decreased during the interdialytic periods, their respective plasma levels tended to increase. The biological significance of these findings warrants further studies.

Figures: (A1, B1, C1) Mean plasma levels of Amyloid-βs and tau protein during dialysis sessions (Mean ± 95%CI, RM-ANOVA (A2, B2, C2)) Mean plasma and CSF levels of Amyloid βs and tau protein during the intervals between dialysis sessions (Mean ± 95%CI), p<0.05 was considered significant.

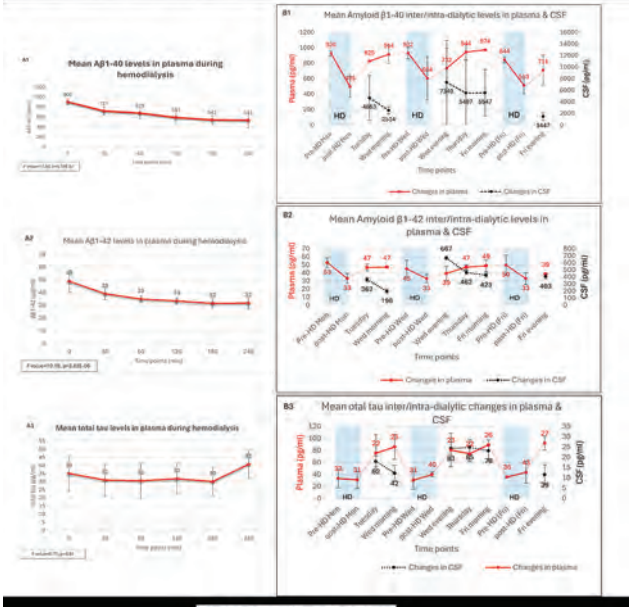

Table 1: Mean percent change of protein levels in plasma and CSF between dialysis sessions.

Dialysate	Plasma	CSF
Amyloid β1-40	0.22	-0.45
Amyloid β1-42	0.12	-0.41
Total tau	0.13	-0.18

Does Hemodialysis Weaken GDF-15 Impairing Pulmonary Hypertension in Chronic Kidney Failure?

Yifang Tang, Zhu Zhou. *First Affiliated Hospital of Kunming Medical University, Kunming, China.*

Background: Pulmonary hypertension (PH) is a common complication of chronic renal failure (CRF) and contributes to mortality. However, the occurrence of mechanism or risk factors in CRF complicated with PH remains unclear.

Methods: One hundred and twenty subjects were prospectively recruited and divided into CRF group (n=79) and control group (n=41). The CRF group were subsequently divided into the pre-hemodialysis group (n=41) and the hemodialysis group (n=38). The GDF-15 levels of all subjects were tested by ELISA. The levels of GDF-15 in groups were compared each other. The association between GDF-15 and other clinical parameters was analyzed as well as the association between pulmonary artery pressure (PAP) and other factors with the stepwise regression analysis.

Results: GDF-15 levels in CRF group were significantly higher than that in control group. There was no difference between pre-hemodialysis and hemodialysis groups. Positive correlations between GDF-15 and PAP, urea, creatinine, or uric acid (UA) were found with or without adjusting for age, sex, and body mass index (BMI). Additionally, GDF-15 was positively associated with PAP or creatinine. Moreover, PAP was positively associated with hypertension other than GDF-15, while negatively with total bilirubin (TBIL) or glucose (GLU).

Conclusions: GDF-15 is significantly elevated and positively associated with PAP in CRF patients. GDF-15 may be a therapeutic target for PH in CRF. Hemodialysis can't weaken GDF-15 impairing PH because there is no difference in plasma levels of GDF-15 between pre-hemodialysis and hemodialysis patients with CRF. Moreover, PAP is negatively associated with TBIL or GLU in CRF.

Comparison of Platelet Aggregation Test before and after Hemodialysis in Patients with Kidney Failure

Sirihatai Konwai,[1] Suwikran Wongpraphairot,[1] Pirun Saelue,[2] Atthaphong Phongphithakchai,[1] Suntornwit Praditaukrit.[1] *[1]Nephrology Unit, Division of Internal Medicine, Faculty of Medicine, Prince of Songkla University, Songkhla, Thailand; [2]Hematology Unit, Division of Internal Medicine, Faculty of Medicine, Prince of Songkla University, Songkhla, Thailand.*

Background: One of the important signs of uremic toxin accumulation in renal failure patient is uremic bleeding. Renal replacement therapy is the way to stop uremic bleeding. However, opinions on how hemodialyis affects platelet function in uremia patients are divided.

Methods: This prospective cohort study included patients initiating hemodialysis with a blood urea nitrogen level more than 60 mg/dL. Blood samples were collected before and after the first, second, third, and day thirty of hemodialysis for the platelet aggregation test. The The primary outcome was the platelet aggregation test results before and after hemodialysis. Secondary outcomes included 30-day mortality and events of bleeding.

Results: Of the 15 cases that were included, 53.3% were female. There were 10 patients with chronic renal failure. The median values for hemoglobin, platelet counts, and fibrinogen were 9.00 mg/dL, 240000/microliter, and 758.4 mg/dl. Comparing the thirty-day pre-dialysis with the first pre-dialysis session, there was a higher percentage of platelet aggregation in adenosine diphosphate (ADP) (difference in aggregation level was 9.76, 95% CI 1.93-17.60). The first pre-dialysis session and the thirty-day pre-dialysis session show a significant difference in the slope after stimulation with ADP and epinephrine (difference 28.03, 95%CI 13.67-42.39 and 38.96, 95% CI 14.64-63.29). There was no death or bleeding for thirty days.

Conclusions: ADP and epinephrine-related platelet aggregation can be improved by initiating hemodialysis at least two sessions in advance. Hemodialysis can therefore be utilized to prevent uremic bleeding.

Funding: Private Foundation Support, Government Support - Non-U.S.

Study of the Relationship between QTc Time Trends and Microglobulin during Hemodialysis

Yasuyuki Mimura, Akihiro Kuma, Masayoshi Nanami, Takahiro Kuragano. *Department of Cardiovascular and Renal Medicine, Hyogo Medical University, Nishinomiya, Japan.*

Background: Several studies have revealed a relationship between an abnormal QTc interval of electrocardiogram, mortality, and sudden death in patients undergoing hemodialysis (HD). However, only some studies have investigated the changes in the QTc interval during HD sessions and the determining factors. Therefore, our aim was to investigate the relationship between various parameters and QTc interval during HD.

Methods: This cross-sectional study enrolled 53 patients undergoing maintenance HD. The QTc was measured hourly from HD initiation. Blood samples were collected at the beginning of each HD session. Blood Ca, Mg, K, and HCO3-levels were evaluated at the beginning, 2 h after, and at the end of the HD session. The relationship between changes in the QTc interval and various parameters was analyzed using Spearman's correlation and multiple regression analyses.

Results: The patients were aged 37–91 years (Mean, 66.9) years, and the dialysis duration was 1–402 months (median, 2 months). Of the patients, 39.6% were diagnosed with a prolonged QTc interval (≥460 ms) at HD initiation (median, 455 ms). The QTc interval was shortened by 11 ms at 2 h and then increased by 3 ms at the end. Peak changes in the QTc interval occurred 2 h after HD initiation. Thus, we estimated the factors that affected the change in QTc 2 h after dialysis initiation (ΔQTc2h). HD treatment duration ($r = 0.312$, $P = 0.025$) and serum levels of β2MG ($r = 0.324$, $P = 0.019$) were positively correlated with ΔQTc2h. The 2 h change in corrected Ca (ΔcCa2h) ($r = -0.31$, $P = 0.03$), intact PTH ($r = -0.30$, $P = 0.035$), and α2MG ($r = -0.46$, $P = 0.001$) were negatively correlated with ΔQTc2h. The association between β2MG and ΔQTc2h was evaluated separately in the high and low β2MG groups. β2MG significantly suppressed the decline in QTc interval in the high β2MG group ($P = 0.03$). According to the multiple regression analysis, β2MG ($\beta = 0.389$, $P = 0.0027$) and α2MG ($\beta = -0.326$, $P = 0.020$) were significant predictors of ΔQTc2h.

Conclusions: The change in QTc time 2 h after dialysis initiation correlated significantly with β2MG and α2MG. The QTc time was expected to change proportionately to serum Ca; however, the QTc time was shortest after 2 h of dialysis. Removal of β2MG and α2MG by dialysis depends on HD treatment time, which may affect prolonged QTc interval in QTc 2 h after dialysis initiation.

SA-PO400

Small-Vessel Disease in Patients with ESKD Evidenced by Elevated Peak Width of Skeletonized Mean Diffusivity

Changmin Heo, Yang Wook Kim, Bongsoo Park, Sihyung Park, Yoo jin Lee, Eul Jo Jeong, Jiyae Yi. *Inje University Haeundae Paik Hospital, Busan, Republic of Korea.*

Background: The peak width of skeletonized mean diffusivity (PSMD) is a novel marker for small vessel disease. The aim of this study was to investigate the small vessel disease in patients with end-stage renal disease (ESRD) using PSMD.

Methods: We prospectively enrolled patients with ESRD, and also included age and sex-matched healthy controls. Diffusion tensor imaging (DTI) was performed using the three tesla MRI scanner in patients with ESRD and healthy controls. We obtained the PSMD based on the DTI by several steps including preprocessing, skeletonization, application of a custom mask, and histogram analysis. We compared the PSMD between the groups, and also performed correlation analysis between PSMD and clinical factors.

Results: We enrolled the 38 patients with ESRD and 38 healthy controls. There was significant difference of the PSMD between the patients with ESRD and healthy controls. The PSMD was higher in the patients with ESRD than that in the healthy control group (2.945 vs. 2.552×10^{-4} mm^2/s, $p<0.001$, Fig 1). In addition, the PSMD was positively correlated with age ($r=0.370$, $p=0.022$). However, PSMD did not differ depending on the types of dialysis or presence of diabetes mellitus.

Conclusions: We demonstrate that patients with ESRD exhibit higher PSMD compared to healthy controls, indicating greater small vessel disease. The findings provide crucial information for clinical management and treatment strategies, highlighting the importance of addressing small vessel disease in patients with ESRD.

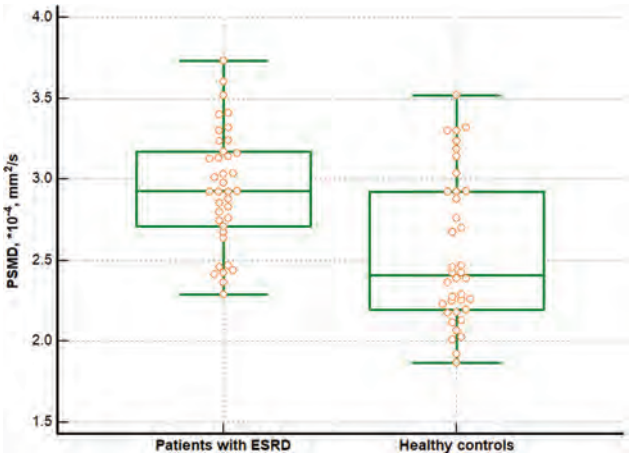

Figure 1. Difference in the PSMD between patients with ESRD and healthy controls

SA-PO401

Association of Diabetes with Heart Rate Variability in Hemodialysis

Brona Moloney,[1,2] Glenn M. Chertow,[3] Finnian R. McCausland.[1,2]
[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Stanford University School of Medicine, Stanford, CA.

Background: Autonomic dysfunction is common among patients with diabetes mellitus (DM) receiving hemodialysis (HD) and may contribute to a higher risk of intra-dialytic hypotension. We explored the association of DM with heart rate variability (HRV; a surrogate of dysautonomia) and explored if HRV modified the relation between DM and intra-HD systolic blood pressure (SBP).

Methods: In a post hoc analysis of the Frequent Hemodialysis Network Daily Trial, we used: 1) random effects linear regression to estimate the association of DM (vs. none) with log-transformed low-frequency power [LF], high-frequency power [HF], LF/HF, and standard deviation of the R-R interval [SDNN] measured on a per-visit basis (baseline and 12-months); 2) linear regression to explore associations with changes in HRV parameters over 12 months. We performed mediation analyses to explore if the association of DM with intra-HD SBP was related to HRV. Models adjusted for age, sex, designated race, height, access, HD vintage, heart failure, pre-HD SBP, heart rate, ultrafiltration rate, hemoglobin, albumin, calcium blockers, diuretics, LV mass, and randomized treatment.

Results: Of patients with available data and without atrial fibrillation (n=198), 82 (41%) had DM. Median values for HRV parameters at baseline and 12 months are shown in Table 1. In adjusted random effects models, DM (vs. none) was not significantly associated with differences in LF 9% (95%CI -18, 46), HF 9% (95%CI -10, 32), or LF/HF -1% (95%CI -16,17), but was significantly associated with SDNN -18% (95% CI -26, -8). DM was not associated with a change from baseline to 12 months in any HRV parameter. In mediation analyses, HRV was estimated to mediate -8% (95%CI -52, 15) of the association between DM and nadir SBP.

Conclusions: DM (vs. none) was associated with 18% lower SDNN, a surrogate of overall heart rate variability, among participants of FHN on a per-session level. SDNN does not appear to mediate the association of DM with intra-dialytic nadir SBP.

Funding: NIDDK Support

Association of Changes in Vector Length with Changes in Right Ventricular Magnetic Resonance Imaging Indices among Patients on Maintenance Hemodialysis

Enass Sayed,[1,2] Glenn M. Chertow,[3] Finnian R. McCausland.[2,1] *[1]Harvard Medical School, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Stanford University School of Medicine, Stanford, CA.*

Background: Shorter vector length (a bioimpedance proxy of hypervolemia) is known to be associated with higher left ventricular volume indices among patients receiving maintenance hemodialysis (HD). However, the association of hypervolemia with right ventricular (RV) parameters is less clear.

Methods: Using data from the Frequent Hemodialysis Network Daily Trial (n=160), we used linear regression to assess the association of changes in vector length from baseline to month 12 with changes in magnetic resonance imaging (MRI) measures of RV parameters (RV end-diastolic volume (RVEDV), RV end-systolic volume (RVESV), RV stroke volume (RVSV), and RV ejection fraction (RVEF). We adjusted for baseline vector length, baseline outcome measurements, randomized treatment, age, sex, designated race, Quételet (body mass) index, access type, vintage (<2, 2-5, >5 years), pre-HD systolic BP, hypertension, heart failure, diabetes, residual urea clearance (0, ≤1, >1 to 3, >3 ml/min), hemoglobin, phosphate, ultrafiltration rate, angiotensin-converting enzyme inhibitor (ACEi) or angiotensin receptor blocker (ARB) use, log-transformed erythropoietin dose, and eKt/V.

Results: The mean age was 50 ±13 years; 35% were female. In the fully adjusted models, a decline in vector length (per 50 Ω/m; i.e., a proxy for an increase in volume) was associated with an increase of 14.4 (95%CI 5.8, 23.0), 9.7 (95%CI 4.2, 15.2), and 4.7 (95%CI -0.6, 10.1) mL in RVEDV, RVESV, and RVSV, respectively; the relation between change in vector length an RVEF was curvilinear. Continuous associations are presented in restricted cubic splines (Figure 1).

Conclusions: Change in vector length over 12 months, a bioimpedance-derived proxy of volume status, was inversely associated with RVEDV and RVESV measured by cardiac MRI in patients randomized to conventional or frequent hemodialysis.

Proteomics-Based Machine-Learning Approach for Predicting Cardiac Dysfunction in Patients on Hemodialysis

Ping-Hsun Wu,[1,2] Yi-Ting Lin,[1,2] Yi-Wen Chiu,[1,2] Mei-Chuan Kuo,[1,2] Shang-Jyh Hwang.[1,2] *[1]Kaohsiung Medical University Chung Ho Memorial Hospital, Kaohsiung, Taiwan; [2]Kaohsiung Medical University College of Medicine, Kaohsiung, Taiwan.*

Background: Evaluating cardiac function is crucial for hemodialysis patients due to its association with cardiovascular mortality. Evaluating cardiac function in hemodialysis patients is crucial, and blood-based biomarker testing represents a potentially convenient and insightful approach for assessing cardiac function in this population. This study aims to explore using cardiovascular proteomics and machine learning (ML) to predict cardiac dysfunction in hemodialysis patients.

Methods: The study enrolled 347 hemodialysis patients who underwent cardiac ultrasonography to assess cardiac dysfunction, which was defined as an ejection fraction < 50% (primary analysis) or < 45% (sensitivity analysis). The proteomic analysis measured 184 proteins using proximity extension assays. ML techniques (classification and regression tree [CART], Least Absolute Shrinkage and Selection Operator [LASSO], random forest, Ranger, eXtreme Gradient Boosting [XgBoost]) were applied to develop predictive models using the proteomic and clinical data. Model performance was evaluated by area under the curve (AUC). The Significance of the Hierarchical Averaging of Shapley Values (SHAP) values identified key predictive features.

Results: The proteomic biomarkers outperformed routine clinical/laboratory variables in predicting cardiac dysfunction across ML models. LASSO and XgBoost models with feature selection highlighted N terminal pro B type natriuretic peptide (NT-ProBNP) as the top predictor, followed by Chitotriosidase 1 (CHIT1), Angiotensin-Converting Enzyme 2 (ACE2), and Matrix Metalloproteinase-2 (MMP-2). SHAP analysis confirmed these findings.

Conclusions: Cardiovascular proteomics combined with ML enables superior prediction of cardiac dysfunction compared to clinical variables alone in hemodialysis patients. The NT-proBNP and CHIT1 emerged as important protein biomarkers, potentially facilitating early interventions for preventing cardiovascular complications.

SA-PO404

Chronotropic Incompetence Rather than Stroke Volume Is the Main Driver of Impaired Cardiac Output Response in Patients on Hemodialysis

Aaron K. Wills, Monique O. Campos, Gayatri Narayanan, Heather Burney, Andrew R. Coggan, Sharon M. Moe, Kenneth Lim. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Impaired cardiovascular functional capacity (CFC) is a major complication in hemodialysis (HD) patients and contributes to diminished survival rates and compromised quality of life. Reduced CFC (as assessed by VO_2Peak) is known to arise from both reduced cardiac output (CO) response and impaired oxygen extraction at the level

of the contracting skeletal muscle (Fick Principle). However, at the CO level, it is unclear which determinant, heart rate (HR), or stroke volume (SV) primarily drives impaired response at peak exercise (PE) in patients on dialysis. Herein, we sought to determine the major cardiac determinants of impaired CO response during PE in HD patients.

Methods: We recruited seven HD patients and five healthy controls (CON). All participants underwent comprehensive breath-by-breath cardiopulmonary exercise testing (CPET) with simultaneous 12-lead EKG, pulse oximetry and CO monitoring via impedance cardiography. A t-test and a repeated measures two-way ANOVA were performed for analysis between groups, and a multiple linear regression to test for associations.

Results: Both groups were well-matched by age (HD:47±15,CON:51±8yr) and BMI (HD:28.2±5.0, CON:26.7±2.9kg/m^2). VO_2Peak was impaired in HD patients compared to CON (HD:12.9±4.5; CON:27.1±6.3mL/min^{-1}kg^{-1}, p<0.001). Both HD and CON patients demonstrated progressive increase in HR, SV, and CO during warm-up to the PE compared to resting measures (p<0.05). However, HD patients exhibited significant chronotropic incompetence at PE (HRR:+36±20%) compared to CON (HRR: +82±5.2%, p<0.05). The delta changes observed at rest to PE were significantly lower in the HD group compared to the CON group for HR (+34.±18;CON: +86±22 bpm;p=0.001), SV (+20±6;CON:+38±14mL;p=0.008), and CO (+4.7±1.5;CON:+14.8±4.6L.min-1; p=0.0002). Multiple linear regression modeling showed that delta changes in HR, but not in SV were associated with CO at peak exercise (β(standard error)= 0.08(0.02), p=0.008) in HD patients.

Conclusions: HD patients exhibited a smaller increase in HR and SV at peak exercise. However, our findings suggest that chronotropic incompetence is the major cardiac determinant of impaired CO response at PE in patients on dialysis.

Real-Time Forecasting of Intradialytic Hypotension Using Deep Learning and Multimodal Data Integration

Yunfei Luo,[1] Siwei Zhao,[2] Subhasis Dasgupta,[1] Tauhidur Rahman,[1] Rakesh Malhotra.[1] *[1]University of California San Diego, La Jolla, CA; [2]Sanderling Renal Services, Nashville, TN.*

Background: Intradialytic hypotension (IDH) is a common and serious complication during hemodialysis and is linked to high morbidity and mortality. Early prediction of IDH can facilitate timely interventions and potentially reduce IDH rates.

Methods: We developed a transformer-based deep learning model to predict IDH events 30-60 minutes before their occurrence. IDH was defined using multiple criteria: Nadir 90, Nadir 100, Fall 20, Fall 30, Fall 20 plus Nadir 90, Fall 30 plus Nadir 90, KDOQI (SBP reduction ≥20 mmHg and associated symptoms), and HEMO (any drop in SBP resulting in an intervention). We utilized real-time physiological data from dialysis sessions and electronic health records (EHR), including demographics, past dialysis records, labs, and comorbidities. The model employed multimodal fusion methods and was trained using a multitask learning approach to account for different IDH definitions. We performed a 5-fold cross-validation by splitting the patients into five disjoint groups. Model performance was assessed using the area under the receiver operating characteristic curve AUROC.

Results: Our study included data from 1,452 patients, encompassing 21,129 dialysis sessions. The mean age was 65 years. The model achieved AUROC scores ranging from 0.85 to 0.94 across different IDH definitions as shown in Fig 1. The model performance was similar with or without integration of EHR module.

Conclusions: We successfully developed a rmodel using available clinical data to predict IDH during dialysis sessions. Future research should focus on validating our model within independent datasets. Implementing this predictive system could facilitate timely therapeutic interventions, and mitiogate the severe consequences of IDH.

Figure 1: Discriminative ability of the model expressed as AUC across different IDH definitions.

IDH Definitions	ROC AUC	Specificity	Sensitivity	Balance Accuracy
Fall 20	0.85±0.003	0.74±0.005	0.79±0.037	0.76±0.006
Fall 30	0.87±0.004	0.81±0.003	0.76±0.032	0.79±0.003
Nadir 90	0.94±0.006	0.92±0.006	0.80±0.017	0.86±0.011
Nadir 100	0.93±0.006	0.87±0.010	0.85±0.006	0.86±0.007
Nadir 90 Fall 20	0.91±0.004	0.97±0.004	0.50±0.022	0.74±0.010
Nadir 90 Fall 30	0.91±0.002	0.98±0.004	0.49±0.031	0.64±0.026
HEMO	0.81±0.002	0.71±0.025	0.76±0.023	0.73±0.002
KDOQI	0.81±0.004	0.93±0.016	0.34±0.067	0.64±0.026

SA-PO406

Noninvasive Blood Pressure Monitoring in Patients on Chronic Hemodialysis

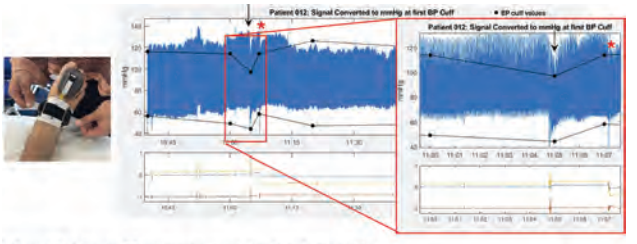
Frank Lee,[1] Tai Truong,[2] Whitney Li,[1] Abigail Cabush,[3] Akhil Chaudhari,[3] Parth Kumar,[2] Ekamol Tantisattamo,[2] Wei Ling Lau.[2] *[1]University of California Irvine School of Medicine, Irvine, CA; [2]Division of Nephrology, Department of Medicine, University of California-Irvine, Irvine, CA; [3]Vena Vitals, Irvine, CA.*

Background: Intradialytic hypotension (IDH) during hemodialysis is associated with adverse outcomes including cerebral ischemia and increased cardiovascular and all-cause mortality. Standard blood pressure (BP) monitoring is done every 30 min via an inflatable cuff, and data is lacking to guide optimal frequency of intradialytic BP measurements. Variability in cuff size, the patient's sitting position, and location of cuff placement (arm vs leg) may affect BP readings. Here, we present pilot data from a study evaluating a noninvasive continuous BP sensor during outpatient hemodialysis treatments.

Methods: The non-invasive BP sensor patch (AcuPulse) was provided by Vena Vitals, Inc. (Irvine, CA). The sensor detects pressure changes via conformal electrodes within a flexible silicone patch. Nineteen adults at the Fresenius Kidney Care Dialysis Center of Orange were enrolled for data collection. The BP sensor was secured over the radial or dorsalis pedis artery sites, to capture a continuous waveform during hemodialysis. Standard arm cuff BP readings were collected every 30 minutes for the duration of the hemodialysis treatment, with additional BP rechecks done per discretion of the dialysis staff. BP waveforms were analyzed and graphed on MATLAB.

Results: From the 19 subjects, 10 had usable datasets for analysis. Average age was 56 years and 7 of the 10 subjects were male. Excluded datasets were due to missing BP cuff readings (n=3), weak waveform due to improper device setup (n=1), signal artifact due to BP sensor placed on the same arm as BP cuff (n=1), and excessive motion artifact (n=4). Preliminary data shows that the BP sensor waveform tracks BP cuff measurements closely (example shown in Figure). The sensor detected IDH prior to the standard BP cuff in 3 subjects.

Conclusions: Our results demonstrate that a non-invasive sensor has potential utility for continuous BP monitoring during dialysis treatments, for timely detection of IDH. Technological refinements are ongoing to optimize sensor fidelity and to adjust for motion artifact.



Left panel: Non-invasive BP sensor secured over dorsalis pedis pulse on foot.
Right panel: Example of hypotensive episode (arrow) captured on the BP sensor waveform that correlated with BP cuff measurements. A "low diastolic" alarm on the dialysis machine prompted additional BP cuff checks by the dialysis staff. The tracing also shows an example of motion artifact (isolated spike after the hypotensive episode, red asterisk).

SA-PO407

Guideline-Concordant vs. Routinely Measured Predialysis Blood Pressure (BP), and Home BP in Prevalent Hemodialysis (HD) Patients

Judy A. Ukrainetz,[1,2] Branko Braam.[1,2] *[1]University of Alberta, Edmonton, AB, Canada; [2]Alberta Health Services, Edmonton, AB, Canada.*

Background: Pre-HD blood pressure is a pivotal vital sign in clinical decision-making. Yet, obtaining accurate measurements remains challenging. Pre-HD BP has been reported to poorly correlate with home BP. In this study, we investigated whether guideline-concordant measured pre-HD BP taken by the research team is better correlated to home BP than routine BP measurements taken by HD nurses.

Methods: Three automated and three manual BP measurements were obtained pre-HD by the research team strictly following Hypertension Canada guidelines. BP was also measured by the HD nurses as per program routines using the HD machine. Patients measured BP at home at 4 occasions. We observed and recorded whether nurses followed the 10 quality guidelines. Data are mean±sd.

Results: The 37 patients were 61±15 years of age, 49/51% female/male. HD vintage was 1 year and 7 months (2 months-8 years). Automated BP was 136/71±31/17 mmHg and manual BP was 135/69±31/17 mmHg (NS) as assessed by the research team. Routine nurse measured BPs averaged 140/63±29/19 mmHg. Pulse pressures were 60±18 by the research team, 77±26 by the nurses and 60±19 mmHg by patients at home (P<0.01, home vs. nurses). There was a significant correlation between SBP, DBP, and PP between measurements taken by the research team and nurses, but not between those and home BPs. A strong discrepancy was observed between research and nurse measurements, as assessed by the level of agreement for DBP, SBP, and PP (Bland Altman). None of the 36 observed BP measurements by 22 nurses were fully concordant with the guidelines. The time of resting before the measurement was highly variable (0-15 minutes). None

of the patients were asked whether food, drinks, or caffeine were consumed, or if people had smoked within 30 minutes prior to the measurement. No more than 1 pre-HD BP measurement was conducted in any of the cases. Nurses did not refrain from talking to patients during BP readings in 92% of the cases, which is known to potentially elevate readings by 25-40% within the first 30 sec of talking.

Conclusions: This study failed to show that not following guidelines for BP measurements could explain the previously reported discrepancy between home and pre-HD BPs, despite that guideline-concordant BP assessment in the HD unit was poor. Measuring BP accurately is essential in directing care for our HD patients.

SA-PO408

Nadir Systolic Blood Pressure during Hemodialysis Highly Correlates with Hospital Admission

Heidi A. Bleyer, Anthony J. Bleyer, Carl D. Langefeld. *Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: Establishing blood pressure (BP) targets during hemodialysis (HD) may improve the ability to achieve dry weight and avoid hospitalization. While Kt/V targets have been mandated and maximum fluid removal recommended, BP targets for HD have not been established. The purpose of this study was to identify whether the lowest systolic BP values attained during HD (LSBP) were associated with hospitalization. Hypothesis: LSBP < 100 or >160 mm Hg is associated with an increased risk of hospitalization

Methods: We performed a retrospective cohort study of 1668 HD patients cared for by nephrologists at Wake Forest School of Medicine from 1/1/2018 to 12/31/2023 and admitted to Atrium Health Wake Forest Baptist Medical Center for deteriorations in health. We performed a mixed model logistic regression where individual was the random effect, with the outcome variable being HD sessions occurring 0-3 days prior to a hospital admission vs. HD sessions unrelated to hospital admission and dependent variables including age, race, gender, LSBP, dialysis dose.

Results: There were 497,561 HD treatments during this time period and 1984 hospital admissions in 1668 HD patients (58% male, 54% White, 45% Black). During the study period there were 1984 admissions for patients who had undergone HD 0-3 days prior to admission. The figure shows the odds ratio for LBSP for HD treatments 0-3 days pre-admission vs. HD treatments not associated with admission, with a LSBP 120 to <130 mm HG as the reference range. LSBP readings from 100-150 mm Hg were associated with the lowest risk of hospitalization.

Conclusions: A nadir HD systolic BP <100 or >150 mm Hg is associated with an increased risk of hospital admissions. Targeting nadir systolic BP during HD may help to prevent morbidity and possibly mortality.

Assessing the Role of Cooling on Hemodynamics of Patients on Dialysis in Inpatient Settings

Hui Xue,[1] In-Lu Amy Liu,[2] Aiyu Chen,[2] Edward Lin,[3] Beth Creekmur,[2] Antoine C. Abcar,[4] Josephine J. Chiu,[3] Paula S. Cho,[3] Patrick Fong,[3] John J. Sim,[4] Annie Suh,[3] Behzad Ali.[3] *[1]Kaiser Permanente Southern California, San Diego, CA; [2]Kaiser Permanente Southern California Department of Research & Evaluation, Pasadena, CA; [3]Southern California Permanente Medical Group, Pasadena, CA; [4]Kaiser Permanente Southern California, Los Angeles, CA.*

Background: The effect of cooling dialysate to reduce intradialytic hypotension (IDH) in the inpatient setting is unknown.

Methods: Retrospective Cohort: Session Level: 2019 inpatient (IP) HD sessions (n=17357) were evaluated at Kaiser Permanente Southern California (KPSC). Using multivariable repeated measure models; covariates included age, gender, race, IP utilization, IP duration, HD sessions, HD temp, blood pressure (Bp), fluid removed, BMI, and Elixhauser index (EI). Patient Level: 3243 patients received IP HD. Multivariable analysis (Fine and Gray, Cox proportional hazards, Robust Poisson, multiple regression) examined 30-day and 12-month outcomes: re-admissions (re-IP), total IP/day, 30-day-alive-at-home, hospice referral and death. Covariates included age, sex, race, index IP characteristics, prior utilization and comorbidity. **Prospective cross-over design cohort:** Session: Examined Cooled dialysate <36.5°C (CD) on IDH in 6 KPSC hospitals over 6-months in 2022. Each hospital served as its own control and was assigned to either 37.0°C or 35.5°C for the first 3 months, then switched in the 2nd 3 months. 6698 IP HD sessions were evaluated using a nested multivariable repeated measure model. Covariates included assigned temp (AT) and retrospective variables listed above. Patient: 1159 patients were followed for 12-months using models, covariates and outcomes similar to retrospective patient analyses with the addition of AT.

Results: Retrospective Cohort: Session: IDH risk factors were CD, older age, prior IP, lower ultrafiltration, under-weight, service area and higher EI. Higher Bp significantly reduce risk. Patient: IDH significantly increased risk of death, total IP/day and increased re-IP in 30-day. **Prospective cross-over design cohort:** Session: Lower AT (35.5 °C) and higher Bp could significantly reduce IDH risk. Patient: Lower AT tended to reduce outcomes for patients with less comorbidities (EI < 11) in 30-day. Due to small sample size, no risk reductions were significant. **Comparison:** Session: Prospective cross-over design reduced the effect of unmeasured confounders and shows AT (35.5 °C) could significantly reduce IDH risk (0.83 (0.71-0.97)).

Conclusions: CD reduced the risks of IP IDH, healthier patients had the greatest short-term benefits. Larger sample size needed for future work.

SA-PO410

Blood Pressure-Lowering Effects of Ultraviolet Light in Patients on Hemodialysis: Identification of Specific Wavelengths

Caroline Yovanovich,[1,2] Richard B. Weller,[3] Peter Kotanko,[4] Yuedong Wang.[2] *[1]Medtronic, Northridge, CA; [2]University of California Santa Barbara, Santa Barbara, CA; [3]The University of Edinburgh Division of Health Sciences, Edinburgh, United Kingdom; [4]Renal Research Institute, New York, NY.*

Background: Evidence from hemodialysis (HD) patients suggests an inverse correlation between solar ultraviolet (UV) radiation and systolic blood pressure (SBP) (Weller, *J Am Heart Assoc;* 2020). The exact nature of this relationship across the UV spectrum remains unknown.

Methods: Using longitudinal pre-dialysis SBP measurements and UV and temperature data from public sources, we explored whether distinct UV wavelengths (280 to 400 nm) are associated with SBP reduction. We used longitudinal SBP measurements from 2,214 HD patients and obtained daily ground-level UV spectral irradiance and temperature. Treating UV radiation over wavelengths as functional data, we fit functional linear mixed effects models with longitudinal SBP as the response variable and daily UV radiation functions as the independent variable, adjusting for hypertension, age, access type, BMI, IDWG, ESA dose, hemoglobin, serum albumin, Na^+, K^+, ambient temperature, and trend over time.

Results: Wavelengths <325 nm were associated with a decline of SBP, when adjusted for clinical variables. While still significant, adjusting for ambient temperature muted the effect size (Fig. 1).

Conclusions: These findings corroborate and expand previous findings of an association between solar UV light and SBP reduction. Narrow band 311 nm phototherapy lamps to treat psoriasis were developed based on the maximal divergence between therapeutic and erythemal/carcinogenic effects at this wavelength. We hypothesize that such lamps could similarly offer SBP lowering effects.

Funding: Commercial Support - Renal Research Institute

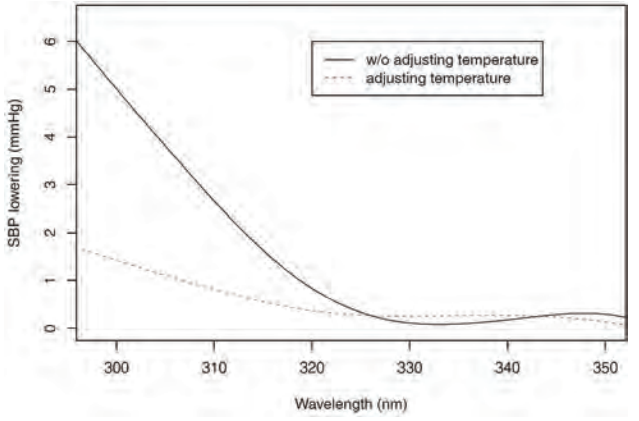

Fig. 1: Wavelength vs. SBP lowering effects. The solid black line indicates the effect with adjustment for clinical variables, the red dashed line with additional adjustment for ambient temperature.

Pharmacologic and Nonpharmacologic Management of Intradialytic Hypotension in ESKD: A Systematic Review and Meta-Analysis

Rajiv Hans S. Menghrajani,[1] Mirtha C. Almanzar,[1] Maria Angela Matabang,[1] Kevin Elissandro Gumabon,[2] Ankur Shah,[3] Edgar V. Lerma.[4] *[1]Lincoln Medical Center, Bronx, NY; [2]Philippine General Hospital, Manila, Philippines; [3]Brown University Warren Alpert Medical School, Providence, RI; [4]University of Illinois Chicago College of Medicine, Chicago, IL.*

Background: Although life-saving, hemodialysis has many complications, intradialytic hypotension (IDH) being one of most frequently recognized occurring in ~10-12% of treatments. In this study, we aim to establish the efficacy of available strategies in managing IDH in end-stage kidney disease (ESKD) patients on hemodialysis (HD) or hemodiafiltration (HDF).

Methods: Electronic databases were searched up to March 2024. Three reviewers independently screened the abstracts, reviewed full-text papers, and critically appraised the quality of included studies using PRISMA guidelines. The primary outcome is the frequency of IDH per hemodialysis session among identified pharmacologic and non-pharmacologic interventions.

Results: Out of 412 articles retrieved, 17 randomized trials were included in a systematic review, 6 of which evaluated pharmacologic while 11 evaluated non-pharmacologic interventions. Of the 17 studies, 8 were included in the meta-analysis (n=745 patients, N=80, 093 dialysis sessions). Pharmacologic interventions (fludrocortisone, mannitol, levocarnitine) showed a significant decrease in IDH frequency [RR 0.40, p < 0.00001 95% CI: 0.17 - 0.92]. However, non-pharmacologic interventions (bicarbonate in HD solution, citrate in HD solution ultrafiltration (UF) profiling, body composition monitoring, UF biofeedback) did not significantly decrease IDH frequency [RR 0.93, p= 0.34 95% CI: 0.81 - 1.08]. Both groups had significant heterogeneity, with I2 = 90% and I2 = 89%, respectively.

Conclusions: Pharmacologic interventions lessened the frequency of IDH among ESKD patients on HD or HDF. However, larger randomized trials with more patients and HD sessions are needed to firmly establish its effect.

Controlling Sodium Balance in Maintenance Hemodialysis (MHD) Treatment: Study Protocol of a Randomized Controlled Registration Trial

Hui Hua Pang,[1] Leyi Gu,[1] Li Zuo,[2] Jiaxiang Ding,[3] Lihua Wang,[4] Hongtao Zhang,[5] Liang Wang,[6] Andreas Maierhofer,[7] Jennifer Braun,[7] Manuela Stauss-Grabo,[7] Weiwei Qi,[8] Qing Lin,[8] Yuanying Guo,[8] Kakiu Ho.[9] *[1]Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital Baoshan Branch, Shanghai, China; [2]Peking University People's Hospital, Beijing, China; [3]Peking University International Hospital, Beijing, China; [4]Second Hospital of Shanxi Medical University, Taiyuan, China; [5]Henan Provincial People's Hospital, Zhengzhou, China; [6]Wuxi People's Hospital, Wuxi, China; [7]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [8]Fresenius Medical Care Shanghai Co Ltd, Shanghai, China; [9]Fresenius Medical Care Asia Pacific Ltd, Hong Kong, Hong Kong.*

Background: Restoring and controlling fluid volume homeostasis remains a challenge in patients with end-stage kidney disease. Na plays an important role in this process. However, most MHD patients are treated with a fixed dialysate Na concentration, potentially resulting in intradialytic plasma Na shifts. Recently it has been demonstrated these shifts can be minimized by application of a Na control algorithm. The 6008 dialysis machine (Fresenius Medical Care) enables monitoring and control of intradialytic Na fluxes between dialysate and plasma.

Methods: We report the protocol of a multicenter, open-labelled, randomized, superiority registration trial with parallel groups and balanced randomization with a 1:1 ratio. The trial plans to enroll 136 -MHD adult patients with pre-dialysis plasma Na from last 3 routine tests between 130 to 150 mmol/L. After informed consent, patients will be randomized into two groups and stratified with centers and the pre-dialysis plasma Na concentration. The control group will receive dialysate Na concentration set according to current center practice by 5008 series machines (Fresenius Medical Care). The investigational group will receive zero diffusive Na balance setting on 6008 machines. All subjects receive 2-times high-flux HD and 1-time post-hemodiafiltration in a week. Other dialysis treatment parameters will be set per prescription. The primary outcome of this study will be the correlation between the intradialytic average dialysate Na concentration and the average pre-dialysis plasma Na concentration The main outcome will be reflected by the comparison of the value of the correlation coefficient R in both groups.

Results: The expectation is that applying zero diffusive Na control on 6008 machine results in a better correlation between the average dialysate Na concentration and the average pre-dialysis plasma Na concentration than with current center practice.

Conclusions: This will provide evidence that the Na control function individualizes dialysate Na prescription and minimizes the impact of diffusive Na transfer on plasma Na concentration during hemodialysis. This study is ongoing and will be completed in 2027.

Comparison of Individualized Sodium Management vs. Standard Treatment in Hemodialysis: The SODIAH Study

Jennifer Braun,[1] Ngoc Pham,[1] Krister Cromm,[1] Andreas Maierhofer,[2] Manuela Stauss-Grabo.[1] *[1]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [2]Fresenius Medical Care Deutschland GmbH Werk Schweinfurt, Schweinfurt, Germany.*

Background: Conventional fluid and sodium (Na) management in dialysis patients includes adjusting dry weight based on clinical judgement and ancillary tools. An innovative approach to optimize Na management during dialysis has been developed with an automated Na control that has been evaluated in proof-of-concept studies (Kuhlmann et al.,2018; Sagova et al., 2019). However, the long-term clinical benefits were not addressed. Recently, Maduell et al. (2023) showed that automated Na control was potentially advantageous in reducing intradialytic weight gain (IDWG), improving blood pressure (BP) control, and decreasing intradialytic serum Na changes.

Methods: SODIAH (NCT06341452) is a prospective, parallel, randomized controlled trial with an intervention period of 12 weeks, to be conducted with the 6008 CareSystem (Fresenius Medical Care) in DE, CZ, ES, BE. The study will include 130 anuric HD-patients with a diffusive Na-load during standard dialysis and at least one of the following: IDWG>4% of dry weight, systolic BP (SBP)>180 mmHg, intradialytic morbid events (IMEs), and pre-dialysis fluid overload≥2.5L. To assess variables from patients' perspective, questionnaires covering fatigue, SBP issues, quality of life, thirst and xerostomia were included. These were translated into the local languages and culturally adapted after cognitive debriefing to ensure accuracy and cultural relevance in the target population.

Results: Our study is designed to assess the impact of Na zero-diffusive dialysis on performance indicators, particularly IDWG, intradialytic hemodynamic stability, IMEs, fluid status, and impact on symptom-related well-being of patients. Study results are planned to be reported in 2025.

Conclusions: SODIAH aims to broaden the knowledge of Na zero-diffusive dialysis and its clinical benefits. Culturally adapted questionnaires will be available in new languages supporting analysis of symptom-related well-being.

Hemodynamic Impact of High- vs. Low-Sodium Dialysate Concentrations in Patients with ESKD on Hemodialysis: A Crossover Clinical Trial

Diana Laura Muñoz,[1] Diana N. Sanchez,[2,1] Adriana Banda Lopez,[1] Salvador Mendoza Cabrera,[2] Caren D. Castro,[1,2] Jorge Andrade-Sierra,[1,2] Enrique Rojas-Campos,[2] Moises Cruz Landino,[2] Ricardo Parra Guerra.[2] Servicio de Nefrología y Trasplante, Hospital de Especialidades Centro Médico Nacional de Occidente, México. *[1]Universidad de Guadalajara Centro Universitario de Ciencias de la Salud, Guadalajara, Mexico; [2]Instituto Mexicano del Seguro Social Delegacion Jalisco, Guadalajara, Mexico.*

Background: The prescription of sodium dialysate concentration in the hemodialysis (HD) setting remains controversial. The aim of this study is to evaluate the hemodynamic impact of high versus low sodium dialysate concentrations in prevalent HD patients

Methods: A crossover clinical trial was conducted in chronic HD patients at one tertiary care center. Patients were randomized 1:1 into two arms: (1) dialysate sodium 135 mEq/L, and (2) dialysate sodium 145 mEq/L for 4 weeks, and a washout period with dialysate sodium at 138 mEq/L for 2 weeks. Figure 1 summarizes methods. Interdialytic weight gain (IDWG), blood pressure (BP), plasma sodium concentration, and C-reactive protein (CRP) concentrations were measured before and after each phase. Self-administered questionnaires were used to assess dialysis disequilibrium symptoms in each HD session.

Results: 27 patients were enrolled: 55% women, mean age: 37.5 ± 12.5 years, and mean time on HD: 7.6 ± 6.5 years. Main vascular access was arteriovenous fistula in 23 patients (79%), antihypertensive drugs were used by 15 patients (59%). The average BP at the beginning and end of each phase showed no statistically significant difference. The dialysate sodium prescription of 145 mEq/L showed an increase in CRP values (p = 0.004) and IDWG (p = 0.02), and showed a significant increase in thirst and edema.

Conclusions: Low sodium dialysate does not confer greater hemodynamic instability. This approach could reduce inter and intradialytic disequilibrium symptoms, as well as systemic inflammation.

Plasma Refill Rate and Intradialytic Hypotension during Hemodialysis in Hospitalized Patients

Christina H. Brotman, Charlie Hull, Laura M. Dember. *University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

Background: Fluid removal during hemodialysis (HD) is often complicated by acute illness and comorbid conditions that render patients susceptible to hemodynamic instability even with modest fluid removal goals. We previously developed a straightforward method to quantify the rate of plasma refilling during HD, plasma refill rate (PRR), and found that PRR was associated with intradialytic hypotension (IDH) among patients receiving outpatient HD. We sought to investigate whether PRR is associated with IDH in hospitalized patients.

Methods: We performed a prospective study of hospitalized patients receiving HD for either acute kidney injury (AKI) or end-stage kidney disease (ESKD) at a single center. Hematocrit monitoring (using CritLine-IV®) and ultrafiltration data were used to calculate PRR during HD, defined as the interval ratio of plasma refill volume to ultrafiltration volume, as previously established. Vital signs data, patient symptoms, and provider interventions were collected prospectively throughout HD. Cox proportional hazard regression was used to examine the relationship between PRR in the first 10 minutes of each HD session and time to IDH.

Results: In interim analysis, we analyzed data from 99 patients with 1 to 3 HD sessions per patient. HD was performed for ESKD in 70% and AKI in 30% or participants. Mean pre-dialysis systolic blood pressure was 136.9±22.9 mmHg, serum albumin was 2.8±0.6 g/dL, and ultrafiltration rate was 8.1±3.5 ml/kg/h. We found that PRR in the first 10 minutes of HD was associated with IDH even after adjusting for age, sex, and pre-dialysis blood pressure. Specifically, low (PRR <0.5) compared to adequate PRR ≥0.5 was associated with an increased risk of IDH in patients with acute kidney injury (HR 2.93; 95% CI:1.62, 5.29) and midodrine-dependence (HR 2.38, 95% CI:1.25, 4.52).

Conclusions: Low PRR early during the HD session was associated with an increased hazard of IDH, particularly in patients with AKI and midodrine-dependence. These results highlight the potential role of PRR for monitoring HD in patients with acute illness who may be susceptible to fluid shifts. Further studies are needed to understand the dynamics of PRR throughout the HD session and determine whether PRR is modifiable.

Impaired Cerebrovascular Reactivity Is a Risk Factor for Cerebral Ischemia during Hemodialysis

Dawn F. Wolfgram,[1,2] Claire C. Seigworth,[1] Isabelle L. Grassl,[1] Yan Gao.[1] *[1]Medical College of Wisconsin, Milwaukee, WI; [2]VA Milwaukee Healthcare System, Milwaukee, WI.*

Background: Patients with end-stage kidney disease treated with hemodialysis (HD) have significant atrophy and ischemic type lesions noted on brain imaging. Circulatory stress during HD can lead to drops in systemic blood pressure. During change in blood pressure, cerebrovascular reactivity (CVR) is needed to maintain stable cerebral perfusion. Due to the high prevalence of vascular disease in HD patients, impaired CVR may be common and place patients at higher risk for cerebral hypoperfusion and ischemia during HD.

Methods: We used transcranial Doppler (TCD) to monitor change in cerebral blood flow velocity during induced hypercapnia to measure CVR in HD patients. We monitored intradialytic cerebral perfusion using continuous cerebral oxygen saturation measurements during HD sessions, calculating both maximum drop and overall decline in cerebral oxygen saturation during the HD session. We used linear regression to measure the association between CVR and decline in cerebral perfusion during HD, adjusting for covariates.

Results: We completed the CVR measure in 42 HD patients. The mean (SD) age of the cohort was 58.5 (11.0) years, 59.5% had diabetes, and 87.7% had hypertension. The mean CVR for the cohort was 2.7 (1.6) %/mmHg, with 42.9% having a CVR < 2.0%/mmHg, consistent with impaired CVR. The maximum drop in cerebral oxygen saturation was a decrease of 5.9% (2.8) and overall decline was 2.2% (2.5). A lower CVR was associated with greater drop and overall decline in cerebral oxygen saturation during HD ($p = 0.01$ for both). This relationship was strengthened when accounting for changes in blood pressure during HD.

Conclusions: Lower CVR is associated with decline in cerebral perfusion during HD. This measurement may be able to help identify patients who are at highest risk for cerebral ischemic injury during HD and help understand the pathophysiology of intradialytic cerebral hypoperfusion.

Change of Central Venous Oxygen Saturation during Hemodialysis: A Real-Time Window into Intradialytic Hemodynamics

Andrea Nandorine Ban,[1] Vincent Filardi,[1] Lin-Chun Wang,[1] Xiaoling Ye,[1] Peter Kotanko,[1,2] Hanjie Zhang.[1] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Low central venous oxygen saturation ($ScvO_2$) is associated with morbidity and mortality in hemodialysis (HD) patients. However, the exact dynamic of $ScvO_2$ during HD remains unknown.

Methods: In patients with central venous catheter (CVC) as vascular access, we used the Crit-Line monitor (CLM; Fresenius Medical Care, Waltham, MA) to record $ScvO_2$ every 10 seconds. Data were uploaded to the cloud in real-time. We extracted CLM data between 1/14/2021, and 7/30/2023. Per Fick's principle, $ScvO_2$ is determined by the upper body blood flow (UBBF), arterial oxygen saturation (SaO_2) and oxygen content (1.34×Hgb), and the upper body oxygen utilization ($utilO_2$) as follows: $ScvO_2 = SaO_2 - (100 \times utilO_2) / (1.34 \times Hgb \times UBBF)$. For the derivation of this equation see Rosales et al. (Blood Purif, 2018). $ScvO_2$ at HD start is calculated as the mean $ScvO_2$ between minutes 5 and 20. $ScvO_2$ at the HD end is calculated as the mean $ScvO_2$ in the last 5-20 minutes. We dropped the treatments with less than 5 minutes measurements either at the beginning or at the end of the session.

Results: After data cleaning, our analytic cohort comprised over 1 million HD sessions in more than 31,000 patients with CVC. Average $ScvO_2$ at the beginning of the HD session was 64.7±8.3% and at the end 62.1±9.5%, indicating a mean intradialytic $ScvO_2$ decline of 2.65% (95% CI: 2.63 to 2.66) (Fig. 1).

Conclusions: Our results show a drop of $ScvO_2$ during HD. We hypothesize that an intradialytic decline of cardiac output, and consequently also of UBBF, is the predominant factor leading to the drop in $ScvO_2$. The goal of future research is to correlate $ScvO_2$ changes with clinical outcomes. Monitoring $ScvO_2$ during HD could provide real-time insights into intradialytic hemodynamics and may eventually result in improved HD procedures.

Effect of Hemodialysis on Hemoglobin Oxygen Affinity

Shilpa Sharma,[1] Isidro B. Salusky,[1] Tomas Ganz,[1] Joachim H. Ix.[2] *[1]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [2]University of California San Diego, La Jolla, CA.*

Background: Hemoglobin (Hg) changes its affinity for oxygen (O_2) binding depending on ambient O_2 tension, acid/base status, 2,3 diphosphoglycerate (2,3 DPG) and other factors. 2,3 DPG is a key regulator of O_2 affinity within red blood cells and its levels are affected by blood phosphate. P50 is a marker of O_2 availability in tissues- A P50 reduction indicates increased Hg:O_2 affinity, decreased O_2 release and worsening tissue hypoxia. We measured P50 changes during hemodialysis (HD) and explored their predictors.

Methods: Venous blood gas, and other laboratory parameters were measured pre and post HD in 18 stable maintenance HD patients. We analyzed patients with tunneled dialysis catheters to avoid arterio-venous mixing. Associations of P50 with laboratory parameters and demographics were examined using linear regression models.

Results: Mean age was 72, 89% were male, and median dialysis vintage was 2.5 (IQR 0.9, 3.5) years. P50 levels decreased from a mean (±SD) of 27.1±0.9 mmHg to 26.2±0.7 mmHg during HD (**Figure**; $P<0.001$). Among 12 predictors evaluated, only higher baseline serum phosphate, and greater reductions in phosphate during HD were the predictors of P50 change (**Table**).

Conclusions: The HD procedure induces consistent reductions in P50, increasing Hg:O_2 affinity. The magnitude of mean P50 change was large – similar to that observed among Mt. Everest climbers (1). This observation provides a new potential mechanism leading to tissue hypoxia during HD. P50 changes were strongly associated with phosphate changes. Future studies should determine if intra-dialytic phosphate repletion may ameliorate tissue hypoxia and its adverse cardiac consequences in HD patients. In Patients on Hemodialysis, Relative Blood Volume Ranges Related to Improved Survival Are Associated with Increased Volume Reductions in Vascular and Interstitial Spaces

Felix J. Meigel,[1] Kevin Ho,[2] Peter Kotanko,[3,4] Doris H. Fuertinger.[1] *[1]Fresenius Medical Care AG, Bad Homburg, Germany; [2]Fresenius Medical Care Holdings Inc, Waltham, MA; [3]Renal Research Institute, New York, NY; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Observational research has identified in-target relative blood volume ranges (iRBV) that are associated with improved hemodialysis (HD) patient survival [1]. Employing an in-silico approach, we investigated differences in fluid removal between virtual patients (avatars) achieving RBV either within or above these iRBV ranges.

Methods: We generated 10,694 avatars based on real-world data from HD patients in an anonymized dialysis database (Apollo Dial DB). Data comprised weight, sex, treatment duration, and ultrafiltration volume. Pre-HD blood volume (Nadler formula) and fluctuating plasma refill rate (PRR) profiles were created to be statistically in line with published data [1,2]. Assuming constant ultrafiltration rates (UFR), we computed RBV profiles for each avatar. We compared the 'in-target' avatar group (RBV values within iRBV) with the 'above-target' group (RBV values above iRBV ranges).

Results: In-target and above-target groups differed by post-HD weight (79.3 ± 22.3 vs 86.0 ± 23.6 kg) and sex (58% vs 67% male). The in-target group had higher UFRs compared to the above-target group [median (IQR): 10.1 (8.2, 11.6) vs 7.1 (5.4, 9.0) ml/kg/h]. In the in-target group, volume reduction rates were increased in both vascular [2.5 (2.2, 2.9) vs. 1.2 (0.8, 1.5) ml/kg/h] and interstitial (PRR) spaces [7.5 (5.7, 9.0) vs. 5.9 (4.3, 7.8) ml/kg/h].

Conclusions: Volume reduction was greater in vascular and interstitial spaces in the in-target group compared to the above-target group. The increased blood volume reduction does not appear to translate to higher intradialytic hypotension rates in the in-target group [1]. **References:** [1] P. Relationship between Fluid Overload and Anemia in the US Hemodialysis Population

Lin-Chun Wang,[1] Lemuel Rivera Fuentes,[1] Ariella E. Mermelstein,[1] Hanjie Zhang,[1] Ulrich Moissl,[3] Jochen G. Raimann,[1] Stephan Thijssen,[1] Frank van der Sande,[4] Jeroen Kooman,[4] Peter Kotanko.[1,2] [1]*Renal Research Institute, New York, NY;* [2]*Icahn School of Medicine at Mount Sinai, New York, NY;* [3]*Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany;* [4]*Maastricht Universitair Medisch Centrum+, Maastricht, Netherlands.*

Background: Current guidelines do not consider fluid overload (FO) when treating anemia in patients on hemodialysis (HD). Fluid status can be quantified using bioimpedance spectroscopy (BIS). We aimed to explore the association between FO and hemoglobin (Hgb) levels.

Methods: Pre-HD FO was assessed once per patient by BIS (Body Composition Monitor, Fresenius Medical Care, Germany). For each treatment within ±30 days from the BIS measurement, we calculated the pre-HD FO by assuming that differences in pre-HD body weight were equivalent to variations in FO. We built linear mixed effects models with Hgb as the dependent and FO as the independent variable. Inflammation was considered and adjusted with neutrophil-to-lymphocyte ratio (NLR). Patients were further divided into 3 groups according to fluid status (fluid depleted: <-1.1 l; normal hydrated: -1.1–1.1 l; fluid overloaded: >1.1 l).

Results: We studied 169 patients (61 years; 60% male), 78% were treated with erythropoietin stimulating agents (ESA). Hgb was inversely associated with increasing FO in the overall population [slope estimate -0.16 (95% CI: -0.20 to -0.12) g/dl per 1L of FO, P < 0.0001] (**Fig. 1a**). While significant in cohorts both with and without ESA, this effect was more pronounced in patients who did not receive ESA [slope estimate -0.20 (-0.30 to -0.095) g/dl per 1l of FO] (**Fig. 1b and 1c**). Adjustments for NLR did not alter the results. The comparison between the 3 sub-groups is shown in **Fig. 2**.

Conclusions: Hgb is inversely associated with FO in HD patients. While ESA administration mitigates the hemodilution effect, FO remains the main contributor to low Hgb. The present study showed that fluid status should be considered in the anemia management of patients on HD.

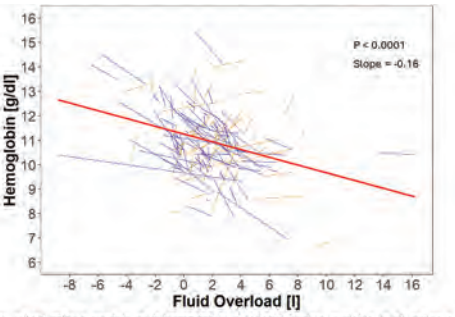

Figure 1a. Linear mixed effects models with hemoglobin as the dependent variable in all patients

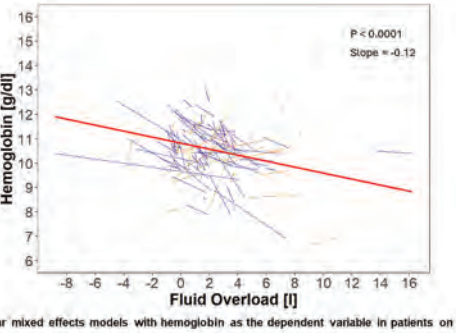

Figure 1b. Linear mixed effects models with hemoglobin as the dependent variable in patients on ESA

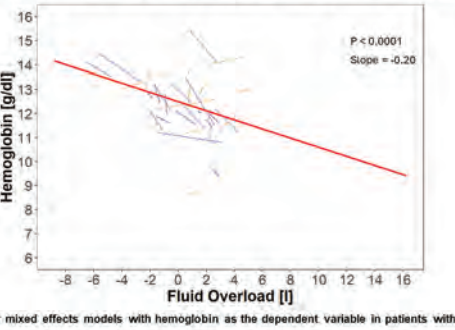

Figure 1c. Linear mixed effects models with hemoglobin as the dependent variable in patients without ESA

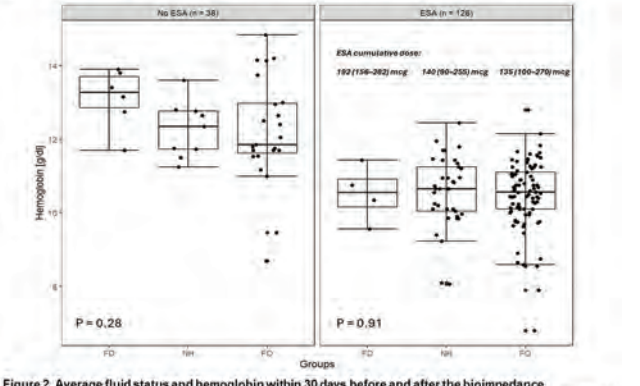

Figure 2. Average fluid status and hemoglobin within 30 days before and after the bioimpedance spectroscopy measurement. ESA, Erythropoiesis-Stimulating Agents; FD, fluid depletion; NH, normal hydration; FO, fluid overload. Majority of patients on methoxy polyethylene glycol-epoetin beta are shown on the ESA plot; cumulative doses are expressed in median (Q1-Q3). ANOVA was used to assess differences between groups.

Impact of Anemia on Echocardiographic Parameters in Asymptomatic Patients with CKD on Hemodialysis

Paola Gomez-Aviles,[1,2] Pavel Martinez-Dominguez,[5] José R. Gómez,[6] Marianela Rodney,[4] Mario Jimenez Hernandez.[3,1] *[1]Universidad de las Americas Puebla, Cholula, Mexico; [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [3]Hospital Universitario de la Benemerita Universidad Autonoma de Puebla, Puebla, Mexico; [4]Instituto Cardiorenal de Puebla, Puebla, Mexico; [5]Instituto Nacional de Cardiologia Ignacio Chavez, Ciudad de Mexico, Mexico; [6]Hospital Angeles de Xalapa, Xalapa, Mexico.*

Background: Anemia and cardiac abnormalities play a crucial role in the complications associated with chronic kidney disease (CKD). However, there is insufficient information regarding the impact of anemia on cardiovascular outcomes

Methods: A cross-sectional multicenter study of hemodialysis patients with CKD was conducted. Data was collected from electronic medical records, cardiac function was assessed with echocardiography. Spearman rank correlation analysis and linear regression models adjusted for potential confounding variables were performed to assess anemia and cardiovascular remodeling. A p-value < 0.05 was considered statistically significant.

Results: Among the 124 individuals included (median age: 48 years), groups were divided by hemoglobin (Hb) level in non/mild anemia (Hb >10 mg/dL) and moderate/severe anemia (Hb <9.9 mg/dL) (Table). The moderate/severe anemia group had increased left ventricular (LV) posterior wall thickness (11mm vs. 10mm), increased left atrial (LA) volume (39 mL/m2 vs. 35 mL/m2), and decreased left ventricular ejection fraction (LVEF) (55% vs. 60%). Negative correlations (Figure) were found between Hb levels and LV posterior wall thickness (r= -0.22, p=0.013) and LA volume (r= -0.18, p=0.038). Linear regression models indicated a positive association between Hb and LVEF, and negative associations between Hb and LA volume, LV posterior wall thickness, and septum thickness.

Conclusions: Anemia degree was associated with multiple echocardiographic parameters, revealing complex interactions. This study highlights the importance of further prospective research to improve early identification and stratification of anemia in CKD patients to reduce subsequent cardiac complications.

Characteristic	Overall, N = 124[1]	Non/mild, N = 74[1]	Moderate/Severe, N = 50[1]	p-value[2]
Age	48 (34, 63)	53 (35, 66)	44 (32, 56)	**0.028**

SA-PO422

Association of Erythropoiesis-Stimulating Agent Dose and Cardiac Magnetic Resonance Imaging Parameters in Patients Undergoing Hemodialysis

Armida Lefranc Torres,[1,2] Glenn M. Chertow,[3] Finnian R. McCausland.[1,2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Stanford University School of Medicine, Stanford, CA.*

Background: Erythropoiesis-stimulating agents (ESAs) are commonly prescribed to patients on hemodialysis (HD) to treat anemia; however, ESA use to target higher vs. lower hemoglobin has been linked with adverse cardiovascular (CV) outcomes. Using data from the Frequent Hemodialysis Network (FHN) Daily Trial, we explored the association of ESA dose with MRI metrics of cardiac structure and function.

Methods: Among patients with available baseline and 12-month MRIs (n=184), random effects linear regression models were fit to explore the association of mean weekly ESA dose (≤5000, >5000-≤20000, >20000 EPO equivalent units) with cardiac MRI parameters on a per-visit basis, including left ventricular (LV) and right ventricular (RV) end-diastolic volume (EDV), end-systolic volume (ESV), stroke volume (SV), ejection fraction (EF), LV mass (LVM), and LV mass index (LVMI). Models were adjusted for age, sex, designated race, BMI, randomized treatment, access, pre-HD systolic BP, heart failure, diabetes, hypertension, residual urea clearance (0, ≤1, >1 to 3, >3 ml/min), ultrafiltration rate, ACE inhibitor or ARB use, hemoglobin, phosphate, dialysis vintage (<2, 2-5, >5 years), and eKt/V_{urea}.

Results: In adjusted models, compared with an ESA dose of ≤5000 U per week, the highest category was significantly associated with 12.7 (95%CI 2.2, 23.1) g higher LVM, 6.6 (95%CI 1.1, 12.0) g/m2 higher LVMI, 8.4 (95%CI 0.0, 16.8) mL higher LVSV, and 13.7 (95%CI 0.8, 26.6) mL higher LVEDV. No significant differences were observed with LVESV, LVEF, or any of the RV parameters (Table 1).

Conclusions: After adjusting for an array of potential confounders, higher mean weekly ESA dose was associated with significantly higher LVM, LVMI, LVEDV, and LVSV in patients receiving conventional and frequent HD. Future studies are needed to identify the mechanism(s) responsible for these associations and whether these findings, if directly related to ESAs, can be ameliorated or reversed.

Changes in Fluid Overload during the First 6 Months of Dialysis among More than 13,000 Patients

Melanie Wolf,[1] Linda Ficociello,[2] Meijiao Zhou,[2] Len A. Usvyat,[2] Stefano Stuard,[1] Jeffrey L. Hymes,[2] Franklin W. Maddux.[2] *[1]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [2]Fresenius Medical Care, Waltham, MA.*

Background: Fluid overload (FO) is a recognized risk factor for mortality in dialysis patients; however, less has been reported on factors related to changes in FO. Whole-body bioimpedance spectroscopy (BIS) has been validated for hydration assessment. We used Body Composition Monitor (BCM) data, a whole-body BIS, to evaluate changes in the degree of FO during the first 6 months of hemodialysis (HD) or hemodiafiltration (HDF) and characteristics associated with those changes.

Methods: Data was extracted from the global anonymized dialysis database, Apollo Dial DB. All patients with 2 BCM measurements separated by ~6 months, with the first being ≤90 days after HD/HDF start, were included. FO was dichotomized at ≥2.5L overhydration (OH) or at ≥15%/≥13% (for men and women, respectively) OH adjusted for extracellular water (OH/ECW). The patients were grouped into four groups (FO-FO, FO-No overload (NO), NO-FO, and NO-NO) by change in OH in liters (OH-L) and OH relative to ECW (OH-%) between these two measurements.

Results: A total of 13,221 adult HD/HDF patients were included who started dialysis treatment in 2018 or 2019. Baseline characteristics by change in fluid status (OH-L and OH-%) are shown in table 1. There was consistency between both methods of FO definition. Among patients starting with FO (n=8,147/8,354), 40%/37% were not FO at 6 months, for OH-L and OH-%, respectively. The two groups with FO at 6 months, were on average, older and diabetes was more prevalent.

Conclusions: In this first descriptive analysis, we observed improvement in many patients' fluid status within the first 6 months after initiating HD/HDF. Further research is needed to evaluate whether improvement in FO is associated with better patient outcomes.

SA-PO424

Rapid Fluid Assessment in Patients on Hemodialysis Using Portable Single-Sided Magnetic Resonance Sensor

Won-Seok Heo,[1] Sydney Sherman,[1,2] Alexa S. Zammit,[1,3] Houda Bouchouari,[4,5] Haley Higginbotham,[1,6] Oliver Nicholls,[1] Sahir Kalim,[4,5] Sagar U. Nigwekar,[4,5] Michael J. Cima.[1,3] *[1]Massachusetts Institute of Technology Koch Institute for Integrative Cancer Research, Cambridge, MA; [2]Harvard-MIT Division of Health Sciences and Technology, Cambridge, MA; [3]Massachusetts Institute of Technology Department of Materials Science and Engineering, Cambridge, MA; [4]Massachusetts General Hospital Nephrology Division, Boston, MA; [5]Harvard Medical School, Boston, MA; [6]Massachusetts Institute of Technology Department of Mechanical Engineering, Cambridge, MA.*

Background: Fluid overload poses health risks caused by hypertension among hemodialysis (HD) patients. Current fluid assessment methods, such as urine or blood screening and bioimpedance, are not sensitive to early-stage changes in volume. This study presents a noninvasive, rapid, and cost-effective method for assessing fluid status using a portable single-sided nuclear magnetic resonance (NMR) sensor, enabling multicomponent T2 relaxometry analysis of intra- and extra-cellular fluid in skeletal muscle tissues.

Methods: The NMR sensor (22×18×11 cm) consists of 0.5 in cube N52 Nd magnets, creating a homogeneous 0.2 T magnetic field 8 mm above the surface at 8.4 MHz. A CPMG pulse train is transmitted via a single surface transceiver coil, seated on a 0.5 mm AlN layer for heat dissipation. The clinical study measured T2 from end-stage renal disease (ESRD) patients' calves undergoing HD, excluding those with obvious signs of edema, compared to healthy controls (HC). T2 relaxation was modeled as tri-exponential decay using a nonlinear least squares optimization method to obtain relative amplitude 2 (RA2).

Results: We observed a decrease in RA2 from pre- to post-HD in every individual case. Population average RA2 values were approximately 41.5% and 31.5% for pre- and post-HD at MGH (p = 0.021), 43% and 38% for pre- and post-HD at Fresenius Kidney Care (FKC), and 30% for HC at MIT, showing lower RA2 compared to both pre-HD measurements at MGH (p = 0.014) and FKC (p = 0.022) (Fig. 1). Additional consented HD outpatients and HC volunteers will be measured in the coming months to support our findings.

Conclusions: This work demonstrates quantitative point-of-care volume status evaluation using an NMR sensor in vivo, providing noninvasive, real-time monitoring of fluid loss during dialysis by performing multicomponent T2 relaxometry localized to skeletal muscle, reducing system complexity and cost compared to MRI. These findings suggest that bedside NMR can effectively identify fluid overload or dehydration in ESRD patients and other hypervolemic conditions.

A Novel Approach to Monitoring Fluid Status of Patients on Maintenance Hemodialysis Using Remote Dielectric-Sensing Technology

Qiuling Fan. *Department of Nephrology, Shanghai General Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China.*

Background: Remote Dielectric Sensing (ReDS) is a non-invasive radar wave lung water monitoring instrument, the ReDS technology allows quantification of lung fluid content. Due to its high efficiency and convenience, this instrument can help in the management of patients with heart failure. However, the role of the ReDS technology in predicting MHD patient's fluid status is unclear.

Methods: Patients undergoing MHD at the hemodialysis center of Shanghai General Hospital from March 2023 to April 2023 were examined using the ReDS technology before and after dialysis, and related clinical data were collected. Our objective is to evaluate the correlation between ReDS and BNP, and to analyze the significance of ReDS detection data through case studies using limited data;

Results: According to the inclusion and exclusion criteria, there were 31 patients with ReDS data before and after translucency, including 18 males (58%) and 13 females (42%), aged 19-83 years, with an average age of (59.8±15.6) years. There were 84 patients with ReDS data after translucency, including 48 males (57%) and 36 females (43%), aged 19-83 years, with an average age of (62.7±14.2) years. All selected patients have pre-treatment BNP data. The results showed a positive correlation between pre dialysis ReDS and BNP, and there was no direct relationship between the difference in pre-dialysis and post-dialysis ReDS and net ultrafiltration volume. We analyzed different cases and inferred that patients with pre dialysis ReDS greater than 36% may have excessive weight gain during the dialysis interval. For patients with ReDS greater than 36% after penetration, titration is required to reduce dry weight; If the ReDS after penetration is less than 24%, the ultrafiltration amount needs to be adjusted, and the dry body weight needs to be increased by titration; MHD patients with ReDS less than 24% before penetration should be analyzed based on their nutritional status and specific circumstances.

Conclusions: Our center's research preliminarily confirms that ReDS data has a certain guiding role in capacity load management for MHD patients. Further exploration is needed, such as the specific significance of the difference in ReDS before and after penetration.

SA-PO426

Utility of Point-of-Care Ultrasonography (POCUS) in Guiding Clinical Decision-Making

Kevin Zhang, Raphael J. Rosen. Stamford Health Nephrology. *Stamford Hospital, Stamford, CT.*

Introduction: Point-of-care ultrasound (POCUS) refers to ultrasound utilized by healthcare providers at the bedside for immediate clinical decisions, in contrast to consultative ultrasonography. POCUS is becoming more utlized in routine clinical practice across various medical specialties. In nephrology, POCUS has myriad applications, including rapid assessment of genitourinary tract, assessing volume and dialysis access, and differentiating causes of hypotension. POCUS also has utility across the spectrum of patient care, ranging from outpatient to inpatient to the dialysis unit. We present a case in which POCUS was used in the dialysis unit to personalize care and avioid harm.

Case Description: A 62-year-old woman with ESRD from HTN/DM on hemodialysis, CAD, and PVD developed progressive dyspnea. Echocardiogram demonstrated preserved LVEF but decreased RV function and elevated estimated PASP. Her cardiologist diagnosed presumed volume overload and recommended to decrease her target weight. The patient's dry weight was decreased but this resulted in worsening intradialytic hypotension and cramping. Nephrologist-performed POCUS in the dialysis unit demonstrated an IVC diameter < 2.1 cm with over 50% collapse with inspiration, suggesting low right atrial pressure. While RV dysfunction can cause plethoric IVC even without hypervolemia, on the contrary, small and collapsible IVC in this setting was felt to be reliable evidence of hypovolemia. The patient's estimated dry weight was increased, and intradialytic hypotension improved. A right heart catheterization demonstrated a right atrial pressure of 3 mmHg, a pulmonary artery pressure of 75/26 and a PCWP of 7mmHg, indicating normal LV filling pressures. She had no evidence of autoimmune etiologies, primary pulmonary etiology, or pulmonary embolism. Her diagnosis is presumed WHO type V pHTN from dialysis and is scheduled for follow up at a pHTN referral center.

Discussion: The integration of POCUS into nephrology practice provides additional tool for rapid and personalized patient assessment. In this case, nephrologist-performed POCUS in the dialysis unit mitigated harm by correcting an inappopriate dry weight reduction. Furthermore, an understanding of the strengths and limitations of cardiac ultrasonography avoided excess reliance on other providers' assessments, in this case a presumptive dry weight reduction based on an echocardiographic finding of pulmonary hypertension.

SA-PO427

Using Point-of-Care Ultrasonography (POCUS) in Volume Assessment in Patients on Hemodialysis

Leanna V. Ritchie, Michael A. Mao. *Mayo Foundation for Medical Education and Research, Jacksonville, FL.*

Background: The POCUS (point-of-care ultrasound) has been well studied in its superior ability to assess high volume status in the heart and lungs, however is not a standard of practice for volume assessment in dialysis patients. Hypervolemia in the end stage kidney disease (ESKD) population is associated with increased mortality and hospitalizations. We hypothesized that POCUS would identify hypervolemia with increased accuracy and safety to reduce hypervolemia complications compared to traditional physical exam.

Methods: This observational cohort study included 62 participants: 15 patients underwent POCUS and 45 patients had volume management by traditional physical exam. Hypervolemia criteria by POCUS included: IVC with < 50% diametric collapsibility, or the detection of at least 3 confluent B lines in >2/6 lung zones with at least one zone positive bilaterally. If exam met criteria for hypervolemia, then estimated dry weight (EDW) was adjusted to a delta of negative 0.5 kg for subsequent dialysis sessions. A traditional clinical physical exam was performed in all patients to assess for hypervolemia. Patients followed for total 6 months including 3 months post intervention for hospitaliztions, heart failure, medication changes, hypotension and death.

Results: In the POCUS group: 100% (15/15) met criteria for hypervolemia on initial POCUS exam and had their EDW adjusted after initial POCUS. However, 7/15 (46.67%) participants demonstrated persistent hypervolemia via second POCUS and

underwent a second EDW adjustment. Physical exam identified hypervolemia in 5/15 (33.33%) participants. The average length of POCUS exam decreased from 7.2 minutes to 6.1 minutes on first and second POCUS assessments, respectively. There were no hospitalizations related to hypervolemia in any of the POCUS participants compared to >15% of hospitalization related to complications of hypervolemia in control group.

Conclusions: The POCUS exam is efficient, timely and easy to learn. The use of POCUS is a safe adjunct to clinical volume assessment in the ESKD popoulation to reduce hypervolemia, hospitalization and improve quality of life.

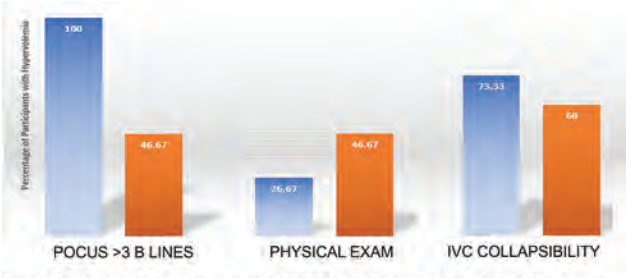

Figure 1. Comparing hypervolemia measurement by POCUS, physical exam and IVC collapsibility. Blue indicates POCUS Week 1. Orange indicates POCUS Week 3..

SA-PO428

Comparison between Lung Ultrasonography and Clinical Assessment for Volume Control in Patients on Chronic Hemodialysis

Sawinee Kongpetch. *Khon Kaen University, Nai Mueang, Thailand.*

Background: The management of volume overload to achieve dry weight improves hypertension and survival in hemodialysis patients. Several techniques are used for volume assessment, however, interventional studies with fluid-guided management are scarce. We aimed to compare between lung ultrasonography (LUS) and clinical assessment to guide volume reduction for blood pressure (BP) control.

Methods: The randomized control trial was conducted in chronic hemodialysis patients between December 2018 and March 2023. The study group was performed LUS every week for total 8 weeks to assess volume status and reduction of dry weight 0.05 and 0.1 kg/10-kg body weight if LUS score 16-30 and > 30, respectively. The control group was reduced dry weight as clinically indicated. Group-blindly investigators measured bioelectrical impedance analysis (BIA) in all participants at the start and finish times of study to assess the optimal dry weights and these results were concealed. At weeks 4 and 8, both groups were compared BP levels, dry weight achievement, cardiothoracic ratio evaluated by chest x-ray, number of antihypertensive drugs, N-terminal-pro-Brain Natriuretic Peptide (NT-proBNP) levels and intradialytic complications.

Results: A total of 83 patients with a mean age of 62.6±13 years and 72.5% male were randomized into the LUS group (n=41) and the clinical group (n=42). Baseline levels of the LUS vs. clinical groups were (a) systolic BP 146±17 vs. 143±11 mmHg, (b) cardiothoracic ratio 0.57±0.06 vs. 0.53±0.06, (c) median NT-proBNP 3,758 vs. 3,607 pg/mL. At weeks 4 and 8, systolic BP adjusted with baseline levels were significantly lower in the LUS groups (weeks 4; 134±13 vs.142±16, p <0.01 and weeks 8; 137±18 vs. 143±15, p=0.01). At the end of study, the LUS group also had (a) higher proportion of participants requiring less antihypertensive drugs (60% vs. 10%, p=0.002), (b) greater percentage of median cardiothoracic ratio reduction (-1.78% vs. 0.98%, p=0.03) and (c) closer levels of optimal dry weight obtained by BIA, than the clinical group. Incidences of intradialytic complications were similar in both groups.

Conclusions: LUS was helpful in volume assessment and fluid-guided management to achieve dry weight and control blood pressure. Further larger clinical trials should be conducted to prove benefit in survival of HD patients.

Comparing Ejection Fraction (EF) Using E-point Septal Separation from Point-of-Care Ultrasonography (POCUS) vs. Standard Two-Dimensional Echocardiography (ECHO) Using the Simpson Method in Patients with Stage 5 CKD on Hemodialysis at Victoriano Luna Medical Center: A Prospective Observational Study

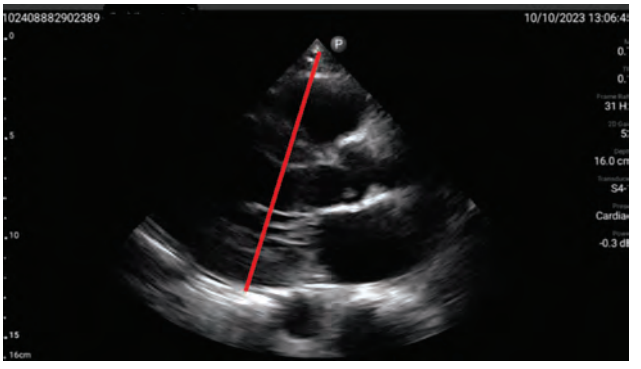
Yvonne P. Bulong. *Armed Forces of the Philippines, Quezon City, Philippines.*

Background: Patients with Chronic Kidney Disease Stage V undergoing Hemodialysis are at risk of developing cardiovascular complications including Coronary Artery Disease and Heart Failure which can be objectively evaluated through 2Dechocardiography. This study obtained the ejection fraction from POCUS through EPSS and compared to the standard 2Dechocardiography ultrasound using Simpson Method as an alternative screening test for Cardiovascular Complications.

Methods: Observational study design with prospective data collection was utilized in the study. Patient undergone both 2DECHO Ultrasound and Point of Care Ultrasound. EF was measured through Simpsons Method and E-point Septal Separation (EPSS). The difference in the mean ejection fraction between EPSS Method and Simpsons method was compared using Paired T-Test and Fischer's Exact Test and P values <0.05. Weighted kappa was used to determine the category of the EF on both methods.

Results: A total of 27 Chronic Kidney Disease Stage V patient were included. The mean EF for EPSS method is 55.4 with standard deviation of 15.4 while Simpson's Method was 59.2 with standard deviation of 16.5. Comparing the EF from the two methods, results showed that they are significantly different (t-value: -3.1995, p-value:0.0036). However, In the EF Category, both the Simpsons and EPSS has the same classification which is important in the deciding treatment of patients. Using both methods, 21 patients has preserved EF, 2 has mildly reduced EF and 4 has reduced EF. The weighted kappa is 1.000 which indicates perfect agreement between the two methods.

Conclusions: Point of Care Ultrasound using EPSS can be used as a screening method in determining the ejection fraction of patient with high risk of developing Cardiovascular Complication such as Chronic Kidney Disease Patients.



Measurement of Ejection Fraction using EPSS Method

Rationale and Design of the NIH THYROID-HD Trial: A Randomized Controlled Trial of Thyroid Hormone Supplementation in Patients on Hemodialysis

Yoko Narasaki,[1] Andrea C. Daza Aguilar,[1] Alejandra Novoa Vargas,[1] Amy S. You,[1] Kamyar Kalantar-Zadeh,[2] Danh V. Nguyen,[3] Connie Rhee.[1] *[1]University of California Los Angeles, Los Angeles, CA; [2]Harbor-UCLA Medical Center, Torrance, CA; [3]University of California Irvine, Irvine, CA.*

Background: Hypothyroidism is a highly prevalent yet under-recognized endocrine complication in CKD patients, affecting ~25% of those receiving dialysis. Prior evidence shows that higher TSH levels, even within the normal laboratory range, are strongly associated with impaired HRQOL and CV disease in this population. While levothyroxine is one of the most frequently prescribed medications in dialysis patients, its efficacy and safety in this population have not been well-studied.

Methods: The multi-center NIH THYROID-HD Trial is a randomized double-blind placebo-controlled trial enrolling dialysis patients with high-normal or subclinical hypothyroid range TSH levels to determine the effects of 24 weeks of levothyroxine vs. placebo on HRQOL assessed by the Short Form 36 and coronary artery calcification (co-primary endpoints). The main secondary endpoints include assessment of HRQOL measured by the ThyPRO survey, physical performance, endothelial function, vascular calcification inhibitors, and total body fat. A subcohort of patients are also undergoing exploratory endpoints of muscle strength, systolic function, and resting energy expenditure (Figure 1).

Results: The THYROID-HD Trial's enrollment target is 336 patients, based on an anticipated 10% attrition rate. Among 242 patients recruited and randomized thus far, baseline characteristics show that the mean ± SD age is 54±13 years old; 42% are female; 9%, 6%, 3%, 80%, and 3% are of Asian, Black, NHOPI, White, or Other race; 75% are of Hispanic ethnicity; and 71% vs. 29% have TSH levels in the high-normal vs. subclinical hypothyroid range.

Conclusions: The THYROID-HD Trial will determine the effects of thyroid hormone replacement on patient-reported outcomes, CV endpoints, and metabolic health in dialysis patients with high-normal or subclinical hypothyroid range TSH levels, and inform the management of this prevalent endocrine complication in ESKD patients.

SA-PO431

Altered Lactate Metabolism at Peak Exercise in Patients on Dialysis

Nolan Groninger,[1] Eliott Arroyo,[2] Heather Burney,[1] Gayatri Narayanan,[1] Sharon L. Karp,[1] Kenneth Lim.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Wake Forest University, Winston-Salem, NC.*

Background: Patients with end-stage kidney disease (ESKD) on hemodialysis commonly exhibit exercise intolerance, as reflected by decrements in oxygen uptake at peak exercise (VO_2Peak). Cardiopulmonary exercise testing (CPET) is the gold-standard for obtaining VO_2Peak and requires participants to exercise past their anaerobic threshold, leading to increased blood lactate concentrations. The purpose of this study was to compare lactate response to maximal exercise in patients with ESKD versus healthy controls.

Methods: We analyzed data from the ongoing "Comparison of the Self-Paced versus Ramp Incremental Exercise Protocols on Patients with Kidney Failure (SPARK)" trial. Participants completed CPET and capillary blood samples were taken at rest, warm-up, and every 2 minutes of exercise and analyzed for blood lactate levels. Wilcoxon tests were conducted to compare blood lactate values between patients with ESKD and healthy controls. Adjusted analysis was conducted using multiple linear regression modeling.

Results: A cohort of 10 patients with ESKD (n=4 men, mean [SD] age=49 [11] years, dialysis vintage=27 [IQR: 14-45] months) and 21 healthy controls (n=10 men, age=55 [9] years) were included in this analysis. Hemoglobin was significantly lower in ESKD patients (11.5 [1.7] g/dl) compared to healthy controls (14.3 [1.0] g/dl; P<0.001). There were no differences in age (P=0.10) or sex (P=0.99) between groups. Resting lactate levels were significantly greater in ESKD patients (1.3 [0.4] mmol/L) than in healthy controls (0.9 [0.3] mmol/L; P=0.029). Significantly, lactate levels at peak exercise were lower in ESKD patients (3.4 [2.7-4.3] mmol/L) compared with healthy controls (7.8 [7.0-9.2] mmol/L; P<0.001), even after adjusting for hemoglobin (P<0.001).

Conclusions: ESKD is complicated by lactatemia in the resting state and may in part, be a direct consequence of impaired renal clearance. The lower levels of lactate at peak exercise in patients with ESKD are reflective of impaired exercise intolerance in the anaerobic phase and indicate a reduced capacity to sustain exercise above the lactate threshold.

SA-PO432

Optimal Protocol for Cardiopulmonary Exercise Testing (CPET) in Patients on Dialysis

Nolan Groninger,[1] Eliott Arroyo,[2] Heather Burney,[1] Gayatri Narayanan,[1] Sharon L. Karp,[1] Kenneth Lim.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Wake Forest University, Winston-Salem, NC.*

Background: Patients with end-stage kidney disease (ESKD) on hemodialysis commonly present with impaired physical function which is linked to adverse outcomes including frailty, fractures, reduced quality of life, and mortality. Peak oxygen uptake (VO_2Peak) is usually obtained by standard ramp incremental testing, but this protocol may underestimate VO_2Peak. To determine the most accurate method for obtaining VO_2Peak in patients on dialysis, we sought to compare the ramp protocol with two novel CPET protocols, the self-paced (SP), and RISE (ramp incremental step exercise) that are considered alternative options to the traditional incremental ramp test.

Methods: We analyzed data from the ongoing "Comparison of the Self-Paced versus Ramp Incremental Exercise Protocols on Patients with Kidney Failure (SPARK)" study, a randomized cross-over study comparing patients on dialysis versus healthy controls. Participants completed three CPET protocols on three separate visits: 1) standard ramp 2) SP (five 2-min stages with self-selected workload) and 3) RISE. Testing was completed for patients with ESKD on a non-dialysis day. A repeated measures ANOVA test was performed to compare VO_2Peak values between each protocol.

Results: A cohort of 11 ESKD patients (n=5 men, mean [SD] age=49 [10] years, dialysis vintage=30 [IQR: 10-48] months) and 21 healthy controls (n=10 men, age=55 [9] years) participated in the study. No significant differences in sex or age were observed (P>0.05) but there was significant difference in race (P=0.003) and ethnicity (P=0.002). There was no significant difference in VO_2Peak between protocols in ESKD patients (ramp=13.5 [1.2] mL/min/kg; SP=13.2 [0.9] mL/min/kg; RISE=13.2 [0.8] mL/min/kg; P=0.77). However, there were significant differences in healthy controls (ramp=30.3 [1.4] mL/kg/min; SP=28.7 [1.4] mL/min/kg; RISE=30.9 [1.2] mL/min/kg; P=0.017). Time-varying covariates remained the same across all visits.

Conclusions: We found that the RISE protocol resulted in higher VO_2Peak averages in healthy controls, but there were no differences in VO_2Peak values between the three protocols in ESKD patients. Therefore, the ramp protocol is the most established CPET methodology and should be selected for objectively determining cardiovascular functional capacity in patients with ESKD.

SA-PO433

Associations between Physical Function Questionnaires and VO2Peak in Patients on Hemodialysis

Nolan Groninger, Drake Dillman, Gayatri Narayanan, Kenneth Lim. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Cardiopulmonary exercise testing (CPET) is well-recognized as the gold standard tool for quantifying cardiovascular functional capacity (as assessed by oxygen uptake at peak exercise, VO_2Peak). VO_2Peak is a strong predictor of survival in patients with chronic kidney disease (CKD). It is currently unknown whether physical function questionnaires can reliably predict VO_2Peak in patients with advanced CKD. Herein, we sought to assess the predictive value of the International Physical Activity Questionnaire (IPAQ) and Patient Reported Outcomes Measurement Information System (PROMIS) evaluations for VO_2Peak in patients on hemodialysis.

Methods: We analyzed data from the "Effects of long interdialytic intervals on Cardiovascular Functional Capacity (ECON)" study, a randomized crossover trial of patients on hemodialysis. All participants underwent CPET and completed questionnaires on a non-dialysis day. A total of 31 patients completed ECON, however 2 patients were excluded in this analysis due to incomplete questionnaire data. Multiple linear regression analysis was used to assess the association between IPAQ and PROMIS results with VO_2Peak.

Results: 29 patients were dichotomized based on the median VO_2Peak value of 11.3 mL/min/kg into a High group (n=15, 11 [73%] men, age=53 [11]; VO_2Peak=14.9 [12.2-16.5] mL/min/kg) and a Low group (n=14, 4 [50%] men, age=54 [12]]; VO_2Peak=10.2 [9.3-10.8] mL/min/kg). The High group had a lower BMI (26.7 [23.5-27.5] kg/m2) compared to the Low group (33.2 [27.8-38.9] kg/m2; P=0.021). No group differences were observed in age, sex, race/ethnicity, dialysis vintage, hypertension, or diabetes (all P's>0.05). The High group had a higher median number of days walked per week (P=0.037) on the IPAQ and a higher average score on the PROMIS Mobility questionnaire (P=0.006). The PROMIS Function questionnaire and all other IPAQ results were not statistically different between groups (P>0.05). The number of days walked per week (P=0.15) and PROMIS Mobility questionnaire (P=0.06) were not significantly associated with VO_2Peak after adjusting for age and sex.

Conclusions: Our results indicate that physical function questionnaires are not effective for predicting VO_2Peak in dialysis patients. CPET is therefore recommended to objectively determine cardiovascular functional capacity and exercise intolerance.

SA-PO434

Evolution of Nutritional Status in Patients on Hemodialysis after 1 Year of Intervention by a Team of Kidney Dietitian-Nutritionists: Is It Possible to Correct Malnutrition from More Severe Stages?

Shaira Martinez Vaquera, Ascension Lupiañez-Barbero, Christian I. Alfaro Sanchez, Sonia C. Molina, Antoni B. Gil, Maria Paz Sorribes López, Teresa Martinez Sanchez. Diaverum Spain Team. *Diaverum Renal Services, Catalonia, Spain.*

Background: Given the complexity of protein energy wasting (PED) in hemodialysis (HD), prevention and treatment options are complex. There is no single treatment approach. Objective: To retrospectively evaluate the evolution of the nutritional status of HD patients.

Methods: Descriptive, retrospective and multicenter study of 130 HD patients. We performed individualized nutritional intervention by Dietitians-Nutritionists (DN) integrated in a multidisciplinary team. We collected demographic, clinical, nutritional and nutritional screening variables, MIS1 and DPE2, at baseline and one-year follow-up. Parametric and non-parametric statistics for related groups.

Results: Median age 75.77 years [65.43-83.83], time on HD 33.91 months [23.06-57.26], Charlson index 7 [5-9], BMI 24kg/m2 [21-27], LVEF 54.6%, DM 45.4%, diabetic nephropathy 22.3%, history of previous RF 30.8%, men 64.6%, non-EU origin 15.4%. In the annual follow-up, 82.3% of the patients remain active. A total of 5.4% were transplanted, 9.2% died and 3.1% were discharged. All patients receive dietary education (DE). Patients with moderate-severe malnutrition without improvement only with DE were added: 33.7% Oral nutritional supplementation (ONS) through hospital coordination, 16.8% intradialytic phosphosoda, 9.3% appetite stimulants, 7.5% food support by social services in coordination with the social work unit. An improvement in

MIS screening scores was observed (baseline 7 [5-10] vs follow-up 5 [5-7]), especially those who received ONS (baseline 10 [7-13] vs follow-up 7 [6-9]). Even more evident in patients who received ONS during the entire period evaluated (baseline 12 [9-13] vs follow-up 7 [5-9]). A progression of malnutrition was observed and, likewise, a decrease in severe malnutrition ($p \leq 0.05$).

Conclusions: Individualized dietary advice in combination with different nutritional strategies from a multidisciplinary approach contributes to improve MIS scores and reverse malnutrition in more severe stages.

SA-PO435

Evaluation of Intradialytic Parenteral Nutrition Indication: Mirage or Reality?

Shaira Martinez Vaquera, Ascension Lupiañez-Barbero, Christian I. Alfaro Sanchez, Sonia C. Molina, Jose Luis Pizarro Leon, Teresa Martinez Sanchez, Maria Paz Sorribes López. Diaverum Spain Team. *Diaverum Espana, Madrid, Spain.*

Background: The estimated prevalence of protein energy wasting (PEW) in haemodialysis (HD) is between 28-54%, and may be even higher[1]. Different nutritional strategies are available: dietary advice by a Dietitian-Nutritionist (DN), oral nutrition (ONS) or Intradialytic parenteral nutrition (IDPN), among others[2]. The economic cost or the lack of DN in dialysis units are barriers that limit its use. Objective: To determine the prevalence of HD patients who are potential candidates for IDPN.

Methods: Descriptive, retrospective and multicentre study of 3544 patients who responded to the KDQOL-SFTMV[1,3] surveys during 2022. We analysed the generic part (SF-36), the Summative Physical (ISF) and Mental Index (ISM)[3]. We collected demographic and clinical data, used the DPE scale[4] and the expert consensus[5] as screening for PIND. We assessed normality and performed non-parametric statistics.

Results: 62.4% male, 73 years, BMI 25.8kg/m2, albumin 3.93g/dl, creatinine 6.5mg/dl, CRPn 0.98 g/kg/d, FSI 49.14 [39.58-55.69], MSI 34.88 [27.75-42.55]. 45.4% had DM, 60.9% were on dialysis with AVF and 35 months on HD [15-67]. According to DPE screening components: 33% albumin <3.8g/dl; 4.1% creatinine <3.8mg/dl; 26.3% BMI <23kg/m2; 20.8% nCRP <0.8g/kg/d. 59.2% had some degree of malnutrition. 21.3% could be candidates for NPID due to moderate-severe malnutrition. According to expert consensus: 27.4% albumin <3.8g/dl plus creatinine <8mg/dl; 3% BMI <18.5kg/m2; 14.4% CRPn <0.75g/kg/d; 0.6% weight loss> 10% in the last 6 months. Only 0.23% met at least 3 of these criteria and would be candidates for NPID. We observed association between nutritional status and quality of life (QoL) (table 1).

Conclusions: We found huge discrepancy in the prevalence of patients who were candidates for NPID according to the criteria used. The decision to provide NPID not only impacts on the clinical prognosis and QoL of the patient, but also entails relevant costs that could be avoided.

Extra Domain A-Spliced Fibronectin Variant Contributes to Peritoneal Inflammation and Fibrosis in a Murine Model of Peritoneal Fibrosis

Sami Ullah, Susan Yung, Rafter Y. Wu, Tak Mao D. Chan. *Department of Medicine, School of Clinical Medicine, the University of Hong Kong, Hong Kong SAR, Hong Kong.*

Background: Peritoneal dialysis (PD) is an important mode of renal replacement therapy but preservation of the structural and functional integrity of the peritoneal membrane is a major challenge limiting the feasibility of long-term treatment. Onset of tissue fibrosis is characterized by the presence of fibronectin (FN) isoforms including extra domain A-spliced FN variant (EDA-FN). We investigated the role of EDA-FN in a murine model of PD.

Methods: Male wild-type (WT) and EDA-FN knockout (KO) mice were randomized to receive saline (Control Group) or glucose-based PD fluid containing 40 mM methylglyoxal (PDF Group) by intra-peritoneal injection twice daily for 4, 8 and 12 weeks, after which time the parietal peritoneum was harvested to investigate peritoneal membrane histology and expression of mediators of inflammation and fibrosis using a combination of qPCR, Western blot analysis and cytochemical staining. Human peritoneal mesothelial cells were isolated from omentum to investigate the mechanism of EDA-FN induction.

Results: PDF-treated WT mice developed submesothelial thickening after 12 weeks compared to saline-treated mice, accompanied by a marked influx of immune cells and mesothelial cell denudation. EDA-FN gene expression was increased in the peritoneal membrane of PDF-treated mice (1.00 ± 0.13 vs 15.46 ± 9.83 arbitrary units, saline vs PDF, $p = 0.0095$), accompanied by increased gene and/or protein expression of TGF-β1, IL-1β, IL-6, native FN, collagen I and III, α-smooth muscle actin and Adgre1 (F4/80). PDF-induced peritoneal membrane pathology and thickening were markedly reduced in EDA-FN KO mice compared to WT mice, with reduced immune cell infiltration and mediators of inflammation and fibrosis. In cultured mesothelial cells, PDF induced native FN and EDA-FN expression through the synergistic effect of TGF-β1 and IL-1β.

Conclusions: Our data suggest that increased peritoneal EDA-FN expression in PDF-treated mice contributes to peritoneal inflammation and fibrosis in PD.

Peritoneal Fibrosis Activated by Glucose-Based Peritoneal Dialysis Solutions Can Be Reverted by XyloCore

Valentina Masola,[1] Luciano D'Apolito,[3,2] Angelo D'Alessandro,[4] Luigi Vecchi,[5] Mario Bonomini,[6] Giovambattista Capasso,[3,2] Francesco Trepiccione,[3,2] Maurizio Onisto,[1] Tommaso Prosdocimi,[7] Jose C. Divino-Filho,[8] Arduino Arduini.[7]

Background: One of the major drawbacks of peritoneal dialysis (PD) is the decline in ultrafiltration capacity. Prolonged exposure to traditional high glucose-based PD fluids can induce severe pathological conditions such as peritoneal fibrosis, angiogenesis and epithelial-mesenchymal transition (EMT), ultimately leading to membrane failure. The introduction of new glucose-sparing PD solutions may provide a means to restore peritoneal filtration capacity.

Methods: Mesothelial cells were initially exposed to conventional PD solution for two days, followed by treatment with XyloCore (a novel glucose-sparing PD solution maintaining iso-osmolality by replacing glucose with L-carnitine and xylitol) for the subsequent three days, along with appropriate controls. Similarly, rats were subjected to peritoneal dialysis for 15 days with daily intraperitoneal injections of conventional glucose-based PD fluids, followed by XyloCore or appropriate controls for another 15 days. Multi-photon microscopy (MPM) was utilized to assess blood flow, grade of fibrosis, and vessel spreading. Gene and protein expression of TGF-b, VEGF, EMT, and inflammatory markers were investigated in both in vitro and in vivo samples.

Results: Both in vitro and in vivo findings demonstrated that XyloCore treatment mitigated the upregulation of TGF-b, VEGF, EMT, and inflammatory markers induced by conventional PD fluids. Moreover, XyloCore treatment in rats led to decreased collagen deposition in the sub-mesothelium and reduced compactness of collagen fibers. Additionally, the number of vessels and their branching were contracted.

Conclusions: XyloCore appears to have the ability to reverse the fibrotic process initiated by conventional PD fluids. This potential could facilitate functional recovery and potentially extend the functional life of the peritoneal membrane, even in individuals undergoing peritoneal dialysis with conventional solutions for prolonged periods of time.

Nicotinamide Nucleotide Transhydrogenase Is Critically Involved in High Glucose-Mediated Peritoneal Damage

Margarete C. Ohse,[1] Song Rong,[1] Michael S. Balzer,[2,1] Sibylle Von Vietinghoff,[3,1] Hermann Haller,[1,4] Yulia Kiyan,[1] Nelli Shushakova.[1,5] Dept of Nephrology and Hypertension, Hannover Medical School. *[1]Department of Nephrology and Hypertension, Hannover Medical School, Hannover, Germany; [2]Medical Department, Division of Nephrology and Internal Intensive Care Medicine, Charité Universitätsmedizin Berlin, Berlin, Germany; [3]Nephrology Section, Medical Clinic 1, University Hospital Bonn, Bonn, Germany; [4]Mount Desert Island Biological Laboratory, Salsbury Cove, ME; [5]Phenos GmbH, Hannover, Germany.*

Background: High glucose (HG)-induced mitochondrial dysfunction contributes to peritoneal membrane damage during peritoneal dialysis (PD). Nicotinamide Nucleotide Transhydrogenase (NNT) is critically involved in maintaining the mitochondrial redox balance and energy metabolism. The enzyme catalyzes the transfer of redox potential between the mitochondrial NAD(H) and NADP(H) pools by utilizing the inner mitochondrial membrane potential.

Methods: The role of NNT in peritoneal membrane damage was investigated *in vivo* using a mouse model of PD applied in C57BL/6N wild-type and NNT-deficient C57BL/6J mice. *In vitro*, NNT silencing was performed in mouse peritoneal mesothelial cell line (MPMC), mouse primary peritoneal macrophages and NIH3T3 fibroblasts.

Results: Exposure of the peritoneum to PD fluid in C57BL/6N mice resulted in the loss of the mesothelial cell monolayer, peritoneal membrane fibrosis, neoangiogenesis, an inflammatory response, and macrophage infiltration, which was paralleled by reduced ultrafiltration capacity. In contrast, C57BL/6J NNT-deficient mice demonstrated much less structural and no functional damage of the peritoneal membrane. *In vitro*, a reverse NNT reaction in fibroblasts has been shown to contribute to HG-induced mitochondrial ROS accumulation. NNT silencing prevented mitochondrial ROS accumulation, decreased pro-inflammatory mediator release from MPMC and fibroblasts, prevented pro-inflammatory M1 macrophage polarization, and strongly decreased fibroblast proliferation under HG conditions.

Conclusions: Acting in reverse mode NNT contributes significantly to HG-induced PM damage. Inhibition of NNT activity could have therapeutic implications.

Proteomic Analysis of Extracellular Vesicles in Peritoneal Dialysis Effluent from Patients with Ultrafiltration Failure

Chi Wei Shih, Chih-Chien Sung. *Tri-Service General Hospital, Taipei, Taiwan.*

Background: Ultrafiltration failure (UFF) is a critical problem in patients with peritoneal dialysis (PD). Although Aquaporin-1 level in the PD effluent (PDE) has been reported as a non-invasive biomarker to predict PD efficiency and UFF, comprehensive analysis in UFF patients remains lacking.

Methods: PDE was collected from 70 patients, divided into two groups based on peritoneal membrane transport type: High (high and high average, n=35) and Low (low and low average, n=35). PDE extracellular vesicles (PDE-EV) were isolated by ultracentrifugation and analyzed using LC–MS/MS, followed by bioinformatic analyses.

Results: PDE-EV was confirmed by nanoparticle tracking analysis and immunoblotting of CD9 and Mesothelin. Of the 390 identified proteins, 44 were differentially expressed ($p<0.05$, $|\log2(\text{High/Low})|>0.5$), with 25 upregulated and 19 downregulated (Figure 1A and 1B). AQP1 and SLC2A1 transporters were significantly downregulated in the High group. Gene ontology analysis of upregulated proteins highlighted immune response and complement activation, indicating an inflammatory response.

Conclusions: This study demonstrated the PDE-EVs could be a non-invasive approach way to evaluate the peritoneal membranous function and understand the pathogenesis of UFF.

Metabolomic Analysis of Peritoneal Dialysis Effluent across Different Peritoneal Transport Types

Xiaoling Wang,[1] Hasib Absar,[1] Nadja Grobe,[1] Mark Kakembo,[1] Xin Wang,[1] Gabriela Ferreira Dias,[1] Lela Tisdale,[1] Fansan Zhu,[1] Laura Rosales M.,[1] Lin-Chun Wang,[1] Maggie Han,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: The efficiency of peritoneal dialysis (PD) depends on the peritoneal transport rate, which varies among patients. High transporter characteristics are associated with PD technique failure and increased mortality. Understanding the biochemical changes in different transport types over time is crucial for optimizing PD.

Methods: Sixteen PD patients participated in this study. All patients completed a 2-hour PD session using 2-liter 2.5% dextrose dialysis fluid. Additionally, six patients underwent a separate 4-hour PD session with the same solution on another day. PD effluent (PDE) was collected at the end of each PD session, with serum collected midway. Patients' transport types were determined using dialysate-to-serum creatinine ratio and D/D0 of glucose at 2 hours and were classified as high/high-average (H/HA) and low/low-average (L/LA). Untargeted metabolomics of PDE was conducted using semi-quantitative liquid chromatography mass spectrometry.

Results: A total of 1,987 features (predicted formula and retention time) met quantification criteria. We first selected features with intensities differing between the 2-hour and 4-hour PD sessions within the same patient (paired t-test threshold of $p<0.05$) for 6 patients. Subsequently, the remaining 474 significantly different features were compared between the H/HA and L/LA groups (unpaired t-test; **Figure 1A**). We observed significant differences ($p<0.05$) in 102 features between the two transport types. Among these, 15 metabolites were identified (**Figure 1B**).

Conclusions: Our analysis revealed 150 metabolites in PDE. Notably, 15 metabolites showed potential as biomarkers indicating transport status and/or membrane function under the same prescription regimen. Further validation and exploration of these findings are warranted to understand their clinical applications.

A Multicohort Biomarker Study in Patients with Advanced CKD on Peritoneal Dialysis or Hemodialysis and in Healthy Volunteers Investigating Inflammatory Markers

Guido Junge,[1] Fabienne Aregger,[2] Dominik E. Uehlinger,[2] Martin K. Kuhlmann,[5] Eric Seibert,[3] Fernanda Do Valle Duraes,[1,4] Romy Höppli,[1] Anette C. Orjuela Leon,[1] Claire Malinverni,[1] Karine Jeanneau,[1] Grazyna Wieczorek,[1] Abdelkader Seroutou,[1] Bernd Hohenstein.[3] *[1]Novartis Pharma AG, Basel, Switzerland; [2]Department of Nephrology and Hypertension, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland; [3]Nephrology Center, Villingen-Schwenningen, Germany; [4]Nouscom AG, Basel, Switzerland; [5]Department of Nephrology, Vivantes Clinic in Friedrichshain, Berlin, Germany.*

Background: CKD and ESKD lead to a significant increase in inflammatory cytokines contributing to long-term complications such as anemia, malnutrition, atherosclerosis, and CV disease. This trial explores the potential role of the NLRP3 inflammasome and complement system for the underlying chronic inflammation in CKD patients w/wo KRT.

Methods: BASICHR0052 is a multi-center, prospective biomarker study conducted in pre-KRT CKD4/5, and ESKD patients on KRT (PD or HD at RRT start, month(M) 2-6, or >M12) to assess inflammatory markers in plasma and PD dialysate. Healthy volunteers' (HVs) samples from 12 subjects were collected as part of another study.

Results: 46 subjects (17 CKD4/5, 16 HD, 13PD) were enrolled. We observed a stepwise increase of apoptosis-associated speck-like protein containing CARD (ASC), a marker of NLRP3 activation, IL-18, IL-18BPa and CXCL9 plasma concentrations from HV to CKD and ESKD patients. Key inflammatory cytokines such as IL-1RA, IL-18 and IL-6 were higher in all CKD groups compared to HV. ASC and CXCL9 were removed during HD. IL-6 was higher in the PD dialysate compared to plasma levels, suggesting a modality related, inflammatory peritoneal component. Alternative complement pathway activation was evidenced by significant increase of iC3b and Bb in CKD and HD compared with HV. Dialysis raised levels of both fragments. Significant increase of FD in CKD and HD pre-dialysis were also observed. No significant difference was observed in TCC, FB and C3.

Conclusions: Overall, subjects with advanced CKD stages and especially those under KRT presented evidence of chronic activation of the NLRP3 inflammasome and the complement system. HD resulted in reduction of ASC and CXCL9 and an increase of iC3b and Bb. IL 6 concentrations were comparable between HD and PD patients but were higher in dialysate of PD patients compared to plasma. Further studies are required to validate those findings as potential new therapeutic targets for patients with advanced CKD w/wo RRT.

Association between Serum Leptin Levels and Vascular Reactivity Index in Patients on Long-Term Peritoneal Dialysis

Yu Chi Chang,[1] Yu-Hsien Lai,[1,2] Bang-Gee Hsu.[1,2] *[1]Division of Nephrology, Buddhist Tzu Chi General Hospital, Hualien, Taiwan; [2]School of Medicine, Tzu Chi University, Hualien, Taiwan.*

Background: Leptin directly affects vascular function, including atherosclerotic effects, endothelial dysfunction resulting from the long-term effect of leptin on nitritic oxidase synthesis, and disturbed bioavailability. This study investigated the correlation between serum leptin levels and endothelial dysfunction in patients undergoing peritoneal dialysis (PD).

Methods: This cross-sectional, single-center study included 74 patients with long-term PD for end-stage kidney failure. A digital thermal monitoring device calculated the vascular reactivity index (VRI) to measure endothelial function, and an enzyme immunoassay was used to determine serum leptin levels. In this study, VRI < 1.0 denoted poor vascular reactivity, 1.0 ≤ VRI < 2.0 intermediate vascular reactivity, and VRI ≥ 2.0 good vascular reactivity.

Results: Out of the long-term PD patients, thirty-four (45.9%) displayed poor vascular reactivity (VRI < 1.0), while 29 (39.2%) exhibited intermediate vascular reactivity (1.0 ≤ VRI < 2.0), leaving the remaining 11 patients demonstrating good vascular reactivity. Higher waist circumference ($P < 0.001$), elevated serum C-reactive protein (CRP, $P = 0.003$), and leptin levels ($P < 0.001$) were found to be associated with poor vascular reactivity. Waist circumference ($r = –0.336$, $P = 0.003$), log-transformed serum levels of CRP (log-CRP, $r = –0.552$, $P < 0.001$), and serum leptin levels ($r = –0.497$, $P < 0.001$) exhibited a negative correlation with VRI values in long-term PD patients. Following the multivariate linear regression test, serum log-CRP level (β = –0.431, adjusted R^2 change = 0.295, $P < 0.001$) and leptin level (β = –0.346, adjusted R^2 change = 0.098, $P = 0.001$) emerged as significantly and independently associated with VRI values among PD patients. Using the Spearman correlation analysis, the log-PD vintage ($r = –0.234$, $P = 0.048$) was negatively correlated, while waist circumference ($r = 0.412$, $P < 0.001$) and log-CRP level ($r = 0.351$, $P = 0.002$) was positively correlated with serum leptin level.

Conclusions: In patients with long-term PD, a negative association was observed between serum log-CRP and leptin levels and endothelial dysfunction determined by VRI values.

SA-PO443

Impact of Peritoneal Dialysis on Peritoneal Macrophage Immunometabolism and Its Relation to Systemic Inflammation and Cardiac Function

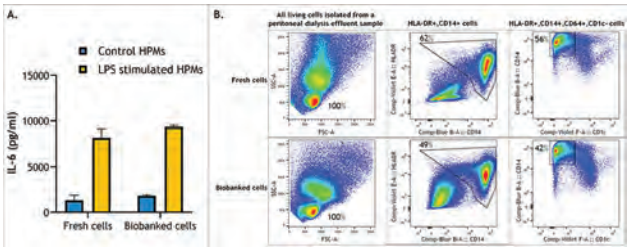
Micky Karsten,[1,2] Nico Hahn,[3,2] Puck Vree,[1,3] Marc G. Vervloet,[4] Jan Van den Bossche,[3,2] Lily Jakulj.[1,5] *[1]Amsterdam UMC Locatie AMC, Amsterdam, Netherlands; [2]Amsterdam Cardiovascular Sciences, Amsterdam, Netherlands; [3]Amsterdam UMC Locatie VUmc, Amsterdam, Netherlands; [4]Radboud Universiteit, Nijmegen, Netherlands; [5]Dianet Dialysis Center Amsterdam, Amsterdam, Netherlands.*

Background: Heart failure with a preserved ejection fraction (HFpEF), is in part driven by invading macrophages and is common in peritoneal dialysis (PD) patients. The glucose rich PD-effluent (PDE) triggers peritoneal inflammation, alike to what is seen in HFpEF. However, the role of macrophages in PD-induced peritoneal injury is unknown. We hypothesize that human peritoneal macrophages (HPMs) of PD-treated patients exhibit an inflammation-driven immunometabolic profile that may ultimately aggravate damage in remote tissues such as the myocardium.

Methods: In adult PD-patients, we collected PDE-derived HPMs and peripheral blood mononuclear cells (PBMC) and performed echocardiography to measure left ventricular global longitudinal strain (LVGLS). We evaluated the impact of biobanking by comparing fluorescence-activated cell sorting (FACS) and (LPS-stimulated) IL-6 production between fresh and thawed HPMs. We will obtain complex immunometabolic HPM and PBMC profiles by lactate, resazurin and SCENITH analysis. Phenotype will be analyzed with FACS and functionality is assessed by in vitro exposure to M1 and M2 inducers. We will relate HPM characteristics to systemic PBMC profiles and other markers of systemic inflammation and LVGLS.

Results: We successfully isolated HPMs from 16 PD-patients (mean age 61,9 (±19,3) years, median PD-vintage 9,5 [4-44,3] months and median LVGLS -17% [-18;-13]). Phenotype and functionality was evaluated both in fresh and thawed HPMs. FACS showed stable high percentages of CD14+HLA-DR+CD64+ macrophages and IL-6 production was maintained after biobanking both with and without lipopolysaccharides (LPS) stimulation.

Conclusions: We successfully isolated and biobanked HPMs from the easily accessible PDE, with maintained functionality. With the proposed protocol we will obtain in depth immunometabolic HPM profiles and relate these to cardiac function and systemic inflammation.



Panel A: No difference in IL-6 production of fresh and biobanked HPMs with or without LPS; Panel B: FACS showed no difference between fresh and biobanked HPM populations

SA-PO444

Estimating Transport in Peritoneal Dialysis Using Sodium Kinetics

Jakob Helman, Carl M. Öberg. *Lunds Universitet Institutionen for Kliniska Vetenskaper Lund, Lund, Sweden.*

Background: Reliable tests to assess membrane function in peritoneal dialysis are critically needed to individualize prescription, monitor membrane integrity, and improve outcomes of patients treated with peritoneal dialysis. Dialysate sodium kinetics could theoretically be used to estimate both osmotic water transport and solute diffusion across the peritoneal membrane. Here we tested the hypothesis that solute and water transport can be predicted solely from sodium kinetics.

Methods: We derived a modified version of the three-pore model based on the Nernst-Planck equation, which accounts for the Gibbs-Donnan and plasma water effects. Computer simulations were compared with data from an experimental rat-model of peritoneal dialysis (n = 25), divided into six groups by dialysate glucose strength (1.5%, 2.3% and 4.25%) and fill volume (20 ml and 30 ml). The diffusion capacity of sodium and the area to diffusion length ratio were set as parameters and fitted to data consisting of sodium measurements during dialysis, using a non-linear least squares algorithm.

Results: After running the regression, the model fit sodium data well (figure 1). Intraperitoneal fluid volume over time closely matched experimental data for all glucose strengths (figure 2). Predictions of the concentrations of ^{51}Cr-EDTA over time in dialysate closely matched experimental data for most groups, but there was a slight deviation from datapoints in lower glucose strengths (figure 2).

Conclusions: In conclusion, we demonstrate that sodium kinetics can predict changes in intraperitoneal volume and transport of small solutes, such as ^{51}Cr-EDTA. This is in line with earlier results where sodium kinetics have been shown to closely correspond to changes in peritoneal fluid volume. The model should be further validated for other solutes, which might require adjustments of the model.

Ultrafiltration Patterns during Automated Peritoneal Dialysis

Osama El Shamy,[1] Ankur Shah,[2] Nicole Wyatt,[3] Sagar Patel,[4] Naief N. Abudaff,[5] Thomas A. Golper,[3] Andrew Guide,[3] Robert Greevy,[3] Juan Pablo Arroyo Ornelas.[3]
[1]The George Washington University, Washington, DC; [2]Brown University Warren Alpert Medical School, Providence, RI; [3]Vanderbilt University Medical Center, Nashville, TN; [4]Renal Associates LLC, Columbus, GA; [5]Arizona Kidney Disease and Hypertension Center, Phoenix, AZ.

Background: With the growing use of automated peritoneal dialysis (APD), it is important to improve our knowledge of the clinical patterns and physiology of APD treatment sessions. The ultrafiltration achieved during each cycle of an APD treatment is assumed to be relatively linear if the delivered prescription is the same. We set out to determine if that is case.

Methods: Single-center, cross-sectional study of APD patients > 18 years old, who had been on APD for ≥3 months were included. CAPD patients or those with peritonitis within 3 months were excluded. Individual treatment data from 7 consecutive APD treatment sessions with consistent dialysate composition were collected.

Results: 39 subjects were enrolled. A total of 273 APD treatment days were analyzed. The probability of yielding a positive UF was 48.9% for cycle 1, gradually rising to 90.5% by cycle 6. Adjusting for average dextrose concentration, dwell time, tidal PD status, fill volume, solute transfer rate, and number of cycles, we observed that cycles 2 through 6 achieved progressively higher UF volumes than cycle 1 ($p < 0.001$). To adjust for a potential "last cycle effect", assessment of a middle cycle compared to the first and last cycles demonstrated statistically significantly cycle UF volumes (-230 ml and 277 ml, respectively, $p < 0.001$), in-line with our other findings.

Conclusions: This is the first study investigating variations in UF volumes achieved between APD cycles. Adjusting for all potentially confounding factors, as the APD treatment progressed, the UF achieved per cycle increased. While the exact explanation of these findings is unclear, peritoneal surface area recruitment, mesenteric elasticity, and cumulative glucose concentration in the interstitium are possible factors.

Table 1. Predicting cycle ultrafiltration using the Generalized Estimating Equations (GEE) longitudinal model analysis, adjusting for average dextrose concentration, dwell time, tidal PD status, fill volume, transfer status, and cycle number*

Variable	Estimate (Std Error)	p-value
Average Dextrose Concentration		
1.5%	32.39 (64.01)	0.613
2.5%	77.20 (27.19)	0.005
3.38%	124.51 (24.41)	< 0.001
Dwell Time	-0.09 (0.86)	0.917

5	420.50 (76.31)	< 0.001
6	417.47 (93.55)	< 0.001

SA-PO446

Examining Ultrafiltration Variance across Two Peritoneal Dialysis Prescriptions of the Automated Wearable Artificial Kidney (AWAK) in a Porcine Model

Arsh Jain,[1] Siti N. Huda,[2] Sridhar Chirumarry,[2] Jason T. Lim,[2] Sheena Gow,[2] Mandar Gori,[2] Suresha B. Venkataraya,[2] Sanjay Singh.[2] *[1]London Health Sciences Centre, London, ON, Canada; [2]AWAK Technologies Pte Ltd, Singapore, Singapore.*

Background: AWAK PD uses sorbent-based tidal therapy that regenerates spent dialysate into clean dialysate fluid that returns to the peritoneum. Our aim was to study the ultrafiltration (UF) generation per gram of glucose exposed and absorbed (UF efficiency – UFE) under 2 AWAK PD prescriptions.

Methods: This study was conducted in a 5/6 nephrectomised porcine (*Sus Scrofa, male*). The animal (Low transporter; $D/P_{creatinine}$ at 4 hour = 0.40) was maintained on automated PD therapy (5 exchanges of 2L fills of 1.5% Dianeal® over 10 hours) in between the test periods. During the test period, daily 9-hour AWAK PD therapy was conducted; it consists of a 7-hour tidal sorbent phase and a 2-hour non-sorbent dwell phase (initial fill 2L, 1.5% Dianeal®). Glucose was dosed using AWAK's glucose management system Setting 3; 4 settings are available, ranging from 0.3 – 6.8mL of Glucose 70%, every 7.5 minutes in the first 7 hours of tidal dialysis and during the 2-hour non-sorbent dwell, glucose was dosed every 7.5 minutes (Test A) or 15 minutes (Test B). The animal also had daily last fills (1L, 2.5% Dianeal®) throughout the study period. Post-AWAK PD therapy dialysate data were collected for glucose analysis and UF calculation.

Results: The difference in UF between the 2 tests was statistically insignificant (p-value = 0.81). The UF ranges and UFE rates are shown in Table 1. Higher UFE (exposed and absorbed) were observed for Test B and would be a preferred treatment prescription as it was able to achieve similar UF with lowered glucose exposure. This experiment was performed on a porcine model with a low transport status and the results may vary for a high transport status peritoneal membrane.

Conclusions: With a reduced requirement of glucose, the device size can be improved. Further long-term studies in both animals and humans are needed to ascertain the efficacy of the glucose management system and prescription implications of AWAK PD therapies.

Funding: Commercial Support - AWAK Technologies Pte Ltd

Table 1: Summary of UF results from 2 glucose prescriptions

Glucose dosing in non-sorbent phase	Test A - every 7.5 minutes [n = 14 days]	Test B - every 15 minutes [n = 14 days]
Average UF volume (mL); min-max	852 (413 – 1046)	867 (448 - 1064)
UFE – exposed (mL/g)	9.4	10.3
UFE – absorbed (mL/g)	18.0	19.2

SA-PO447

Peritoneal Equilibration Test: Comparison of Different Cutoff Values

Noemi Del Toro-Cisneros,[1] Rosario Guadalupe H. Ortega,[2] Erick Y. Zuñiga Gonzalez,[1] Alejandro Quinonez-Flores,[1] Omar Fueyo,[1] Rodolfo Rincon-Pedrero.[1] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [2]Department of Nephrology, ISSEMyM Ecatepec, State of Mexico, Mexico.*

Background: The aim of this study was to compare the type of peritoneal transport using the Peritoneal Equilibration Test (PET) performed at 2 and 4 hours with the cut-off values described by Twardowski (1) and Cueto-Manzano (2) and to propose neu cut-off values for the test at 2 and 4 hours.

Methods: This was a retrospective study, we included patients on peritoneal dialysis with PET in two tertiary care centers in Mexico between 2016-2023. The type of peritoneal transport obtained from Creatinine D/P was compared at 2 hours vs. 4 hours, depending on the result it was classified as high (H), high average (HA), low average (LA) and low (L). In addition, new cut-off values are proposed using the method initially described by Twardowski (1) based on the mean and +/- standard deviation.

Results: Two hundred and two PET studies were included. Eighty-three patients (41%) were men, median age was 43 years (interquartile range 27-58 years). The main causes of chronic kidney disease (CKD) were diabetes 39% (79 patiens) and unknown cause 35% (71 patients). The median time in dialysis was 18 months. The indications for performing PET were initiation of dialysis 48% (97), failure of ultrafiltration 8% (16), after peritonitis 7% (15), and the rest for therapy adequacy. **Table 1** presents the type of peritoneal transport according to the cut-off values described in the literature as well as the values proposed from this study. As can be seen, the cut-off values at 2 hours described bye Cueto-Manzano and Twardowski compared to 4 hours incorrectly classify 13 and 6% respectively as high transporters, while in the low transportes they classified 13 and 8% less patients in the category.

Conclusions: In this study we found that the cut-off values established for the PET study at 2 hours overestimate patients with high transport and underestimate those with low transport. The new proposed value appropriately classifies patients with high and low solute transport.

Solute Transport	Creatinine D/P 2h, Cueto-Manzano	Creatinine D/P 4h, Cueto-Manzano	Creatinine D/P 2h, Twardowski	Creatinine D/P 4h, Twardowski	Creatinine D/P 2h, new cut-off	Creatinine D/P 4h, new cut-off
High	55 (27)	29 (14)	40 (20)	29 (14)	30 (15)	29 (14)
Cut-off	0.58-0.75	0.81-0.94	0.63-0.87	0.82-1.03	0.65-0.96	0.80-1.07
High Average	54 (27)	56 (28)	78 (39)	83 (41)	61 (30)	83 (41)
Cut-off	0.49-0.57	0.69-0.80	0.49-0.62	0.66-0.81	0.52-0.64	0.66-0.80
Low Average	68 (34)	67 (33)	70 (35)	59 (29)	83 (41)	59 (29)
Cut-off	0.39-0.48	0.57-0.68	0.34-0.47	0.50-0.64	0.38-0.50	0.50-0.64
Low	25 (12)	50 (25)	14 (7)	31 (15)	28 (14)	28 (14)
Cut-off	0.20-0.38	0.41-0.56	0.23-0.33	0.34-0.49	0.23-0.37	0.18-0.49

Table 1. Comparison of solute transport with the original cut-off values proposed by Twardowski at 2 and 4 hours and assessed in the Mexican population by Cueto-Manzano, as well as the new proposed cut-off values.

SA-PO448

Effect of Icodextrin on Volume and Metabolism: A Multicenter Clinical Study

Yao Li, Zhu Zhou. *First Affiliated Hospital of Kunming Medical University, Kunming, China.*

Background: Icodextrin is a novel peritoneal dialysis fluid that enhances fluid clearance. It works through the formation of colloidal osmotic pressure, so it maintains effective ultrafiltration for a longer period of time, and the incidence of ultrafiltration (UF) failure is much lower than that of glucose peritoneal dialysis solution. The aim of this study was to compare the changes in volume and metabolism of patients before and after icodextrin treatment, expecting more evidence to support the effectiveness of icodextrin.

Methods: After screening for inclusion and exclusion criteria, we included 20 cases of continuous ambulatory peritoneal dialysis (CAPD) patients from seven hospitals of Yunnan Province. These patients were given a 3-month long-stay nocturnal treatment with icodextrin. We compared nocturnal net UF, peritoneal creatinine clearance(Ccr), and body weight, BNP. And related metabolic parameters, including fasting blood glucose(FBG), cholesterol(TC), and triglycerides(TG), before and after icodextrin treatment.

Results: After 3 months of treatment with icodextrin, patients showed significant increase in nocturnal long-stay abdominal net UF and peritoneal Ccr. The mean nocturnal long-stay net abdominal UF was (57.78±257.63) ml at baseline and (681.85±168.23) ml after treatment (difference -624.07, 95% CI -742.69 –-505.45, t=-11.10, P<0.001). The patient's peritoneal Ccr was (2.10±0.40) ml/min at baseline and (3.10±0.48) ml/min after treatment (difference -1.00, 95% CI -1.31–0.68, t=-6.72, P<0.001). Pre-treatment weight (64.98±10.79) kg Post-treatment weight (63.09±10.28) kg, (difference 1.89, 95% CI 0.58–3.21, t=3.05, P=0.007). After treatment, the patients' BNP decreased, but the difference was not statistically significant (P>0.05); FBG, TG and TC increased afterward, but the mean values were still in the normal range, and the difference was not statistically significant (P>0.05).

Conclusions: In this study, icodextrin was found to increase UF and peritoneal Ccr as well as improve volume control in patients. It can remove more water and reduce patients' body weight. But no significant effect of icodextrin in improving glycolipid metabolism and lowering BNP has been detected for the time being, and the effect of icodextrin on cardiac function needs to be further explored, and its long-term effects and potential application in specific patient groups need to be further investigated.

SA-PO449

Identification of Body Fluid Distribution in Patients on Hemodialysis and Peritoneal Dialysis Using Whole-Body and Segmental Bioimpedance Analysis

Fansan Zhu,[1] Samer R. Abbas,[1] Laura Rosales M.,[1] Peter Kotanko.[1,2] [1]*Renal Research Institute, New York, NY;* [2]*Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: The understanding of fluid transport in dialysis patients is based on a two-compartment model between the whole body's extracellular volume (ECV) and the intravascular compartment. We developed a segmental method to measure ECV in the arm, trunk, and leg. This study aims to evaluate change in ECV in the segments of hemodialysis (HD, Fig.1) and peritoneal dialysis (PD, Fig. 2) patients during dialysis.

Methods: Twenty HD (9 females, age 68.7±24.4 year) and 19 PD patients (10 females, age 54.6±11.6 year) were studied. Whole body and segmental bioimpedance spectroscopy (Hydra 4200) were performed pre and post-treatment (Fig. 3). Changes in the whole body ECV (ΔECV_W) and in the arm (ΔECV_A), trunk (ΔECV_T), and leg (ΔECV_L) were estimated (post – pre ECV). Ultrafiltration volumes (UFV) were recorded. The difference between UFV and ΔECV_W was calculated (DIFF=UFV – ΔECV_W). The ratios of changes in segmental ECVs to UFV ($2*\Delta ECV_A$/UFV; ΔECV_T/UFV; and $2*\Delta ECV_L$/UFV) were defined as *effective removed volume* (ERV, %).

Results: UFV in HD patients was larger compared to PD patients (2.65±0.83 L vs. 0.36±0.22 L, p<0.0001), but treatment time did not differ (3.82±0.67 h vs. 4.00 h, p=0.27). DIFF in HD was larger than in PD patients (Fig. 4). In HD patients, the mean of leg ERV (-44±45 %) was larger than in the trunk ERV (-29±20 %; p=0.23), as well as larger than in the arms (-4±28 %; p<0.01) (Fig. 5). In contrast, in PD patients, trunk ERV (-57±21%) was larger compared to ERV of leg (-33±26%, p=0.1) and arms (-9±55 %, p=0.07) (Fig. 6).

Conclusions: In HD patients, more than 40% of UFV was removed from the legs, while in PD patients more than 50% of UFV was removed from the trunk. These different fluid distributions may cause errors in the estimation of fluid removed by the whole body bioimpedance method. Fluid distribution models may further make a better understanding of fluid dynamics in patients treated with different dialysis modalities, and therefore, improve precision care.

Initial Feasibility Pilot Study of Interdialytic Peritoneal Ultrafiltration to Manage Volume Status in Patients on Hemodialysis (iPUF-HD)

Patrik Deleaval,[1,2] Jarrin D. Penny,[1] Amy Freeman,[1] Christopher W. McIntyre.[1,3] [1]*London Health Sciences Centre London Kidney Clinical Research Unit, London, ON, Canada;* [2]*NephroCare Tassin-Charcot, Saint Foy-les-Lyon, France;* [3]*Western University, London, ON, Canada.*

Background: Increased dietary sodium (Na) and reduced Na excretion drive interdialytic weight gain (IDWG). High ultrafiltration (UF) rates are associated with mortality in hemodialysis (HD) patients. Achieving complete removal of IDWG is often challenging with conventional HD. Combination therapy with peritoneal dialysis (PD) allows additional UF but significantly increases treatment burden. We report first use of short dwell PD, delivered passively, immediately after HD for 2/3 sessions per week. To maximize Na removal and address congestion we instilled low volume 0% sodium fluid with short dwell time.

Methods: We studied 5 anephric HD patients with history of difficult to manage IDWG [(> 4% of dry weight) within conventional HD regimen. After catheter implantation/healing, patients underwent two short dwell (2 hours) peritoneal treatment sessions per week (immediately after HD), using 10% dextrose. Low volume (500ml) was used to limit glucose exposure (no more than conventional 2.5% dextrose/sodium containing PD fluid). Patients were treated for 3 weeks with additional one-washout. IDWG, hemodynamics, effluent composition, tolerability, serum sodium/osmolality and intradialytic serial echocardiography (HD-induced myocardial stunning) were assessed.

Results: Low volume Na-free peritoneal solution effectively removed 4.83±1.37g of Na and 251±190ml UF per session. Na-free 10% dextrose PD solution was well tolerated without treatment interruption (pain score 0 -1/5). During intervention period, IDWG progressively decreased (from 1820 to 950ml), markedly greater than achieved peritoneal UF. Serum potassium, hs-troponin, calcium, and hemoglobin concentrations remained stable. Serum Na modestly decreased from 136.64±4.46 to 132.11±2.96mmol/L (p < 0.0001), with no adversity attributable to hyponatremia. Systolic blood pressure and continuous intradialytic hemodynamics remained unchanged throughout. Of those with viable echo images (for strain analysis), HD-induced myocardial stunning was reduced in 2/3 patients.

Conclusions: This pilot study suggests that additional Na removal can be achieved with use Na-free peritoneal fluid delivered post-dialytic. Such a regimen appears to be capable of improving the congestive state (and its consequences) in patients otherwise unable to be adequately managed with conventional HD.

SA-PO451

Impact of Peritoneal Dialysis Modality on Quality of Life in Hypervolemic Patients

Suchai Sritippayawan,[1,2] Usa Chaikledkaew,[3] Piyatida Chuengsaman,[5] Montarat Thavorncharoensap,[3] Nipa Aiyasanon,[4] Sasima Tongsai.[4] APDICO Project Group. *[1]Division of Nephrology, Faculty of Medicine, Siriraj Hospital, Mahidol University, Bangkok, Thailand; [2]Nephrology Society of Thailand, Bangkok, Thailand; [3]Mahidol University Faculty of Pharmacy, Bangkok, Thailand; [4]Mahidol University Faculty of Medicine Siriraj Hospital, Bangkok, Thailand; [5]Banphaeo General Hospital, Samut Sakhon, Thailand.*

Background: Hypervolemia significantly affects outcomes and quality of life (QOL) in peritoneal dialysis (PD) patients. Limited data compare the QOL across the PD modalities. Our study aims to study the QOL in hypervolemic patients treated with Continuous Ambulatory Peritoneal Dialysis (CAPD), CAPD with 1 cycle of icodextrin (ICO) and nighttime Automated Peritoneal Dialysis (APD).

Methods: 180 CAPD patients with systolic blood pressure (BP) >140 mmHg, diastolic BP >90 mmHg, edema from volume excess or a history of heart failure within the past year from 16 hospitals were randomized into 3 groups of 60 each: CAPD, ICO and APD. Hypertonic solutions, antihypertensive drugs and daily dialysate volume were adjusted based on patients' BP, symptoms and total weekly Kt/Vurea. QOL was assessed using the EQ-5D-5L and KDQOL-36 questionnaires at week 0, 24, 48, 104 and 156. The relationship between the treatment groups and the QOL scores was analyzed using Generalized Estimating Equations in linear regression. The model coefficients determined the intensity and direction of these correlations.

Results: At enrollment, the groups showed no significant differences in age, urine volume, PD duration, Charlson Comorbidity Index (CCI) score, blood pressure, serum albumin, previous peritonitis rate, total weekly Kt/Vurea, or QOL scores. By week 156, 20, 21, and 11 patients remained in the study, while 30, 19, and 32 had died in the CAPD, ICO, and APD groups, respectively. Two patients each withdrew from the CAPD and ICO groups. Patients on ICO and APD showed significantly better utility and VAS scores on EQ-5D-5L compared to those on CAPD ($p<0.05$). KDQOL-36 also revealed higher scores in all domains for the ICO group compared to the CAPD group (significant or trending). The APD group achieved higher KDQOL-36 scores in the Effects and Burden of Kidney Disease and SF-12 Physical Component Summary domains compared to the CAPD group. There were no differences between APD and ICO groups in any domain.

Conclusions: In hypervolemic patients, treatment with ICO offered better QOL than CAPD alone, but was similar to APD. APD offered advantages in specific aspects of QOL compared to CAPD. The ICO group also had a higher survival rate than the CAPD and APD groups. This suggests ICO may improve QOL for PD patients.

SA-PO452

Impact of Hydrolysis on the Change of Icodextrin Amount during Peritoneal Dialysis

Joanna Stachowska-Pietka,[1] Jacek Waniewski,[1] Bengt Lindholm.[2] *[1]Instytut Biocybernetyki i Inzynierii Biomedycznej im Macieja Nalecza Polskiej Akademii Nauk, Warszawa, Poland; [2]Karolinska Institutet, Stockholm, Sweden.*

Background: During peritoneal dialysis (PD), icodextrin (Ico), a mixture of glucose polymers, disappears from peritoneal cavity (PC) due to various processes: absorption (A), diffusion (D), convection (C), and hydrolysis (H) of Ico in PC leading to shortening of glucose polymers. The impact of H on amount of Ico molecules (Ico_M, mmol) and their fractions during PD was not investigated so far. We analysed changes of Ico_M in PC using three pore model (TPM) applied to clinical data.

Methods: Extended TPM, which includes hydrolysis of Ico, was applied to clinical data from 8 Ico-naïve PD patients during 16 h dwell with Ico-based solution and frequent sampling of dialysate and blood. Based on the measured polymers distribution, Ico was described by 7 fractions of different molecular weights, Tab.1. The change of Ico_M was calculated for the 16 h dwell time.

Results: The decrease of Ico_M (ΔIco_M in mmol) in dialysate was around 40% of Ico initial amount after 16-hour dwell and was mostly due to A (91% of ΔIco_M) as the decrease due to D&C (74% of ΔIco_M) was almost counterbalanced by enhanced Ico_M caused by H (65% of ΔIco_M). For the fractions, the decrease in Ico_M was the highest for F2-F4 (88, 25 and 13% of ΔIco_M, respectively); however we observed the increase of F1 (31% of ΔIco_M), Tab.1. The impact of A, D, C and H on the decrease of F1-F7 amount is presented in Tab.1. For F1, overall amount increased (solely due to H); this increase was higher than the F1 decrease related to D, C and A, Tab.1.

Conclusions: Decrease of Ico amount from PC was mostly due to A and mainly related to the decrease of F2 amount, and to some extent also of F3-F4, whereas F1 was increased at the dwell end. The increase of F1 amount was solely due to H that greatly exceeded the F1 removal caused by A, D&C. For fractions F2 and F5, H and A have similar impact on the decrease of fraction amount, whereas for F3 and F4 the observed decrease was mostly due to A. On the contrary, H was the main contributor to the observed decrease of the fractions F6-F7 amount, while the contribution of A was smaller.

Tab 1. Share (in %) of total decrease of Ico fraction amount in the overall Ico amount decrease, and the share (in %) of Ico fraction amount decrease by various processes: peritoneal absorption (**A**), Ico transport by diffusion and convection (**D&C**) and Ico hydrolysis (**H**), in the overall decrease of Ico fractions F1-F7 amount and MW - molecular weight.
Negative sign denotes increase of the amount of molecules and MW - molecular weight

Fractions		Share of Ico frac. amount decrease in total Ico amount decrease	Share of Ico frac. amount decrease by process in Ico frac. amount decrease		
Symbol	MW range	Total, %	A, %	D&C, %	H, %
F1	up to 1.08 kDa	-30.79	84	184	-368
F2	1.08 - 4.44 kDa	87.77	37	19	44
F3	4.44 - 9.89 kDa	24.90	74	1	25
F4	9.89 - 21.4 kDa	12.51	98	1	1
F5	21.4 - 43.5 kDa	5.11	44	0	56
F6	43.5 - 66.7 kDa	0.47	20	0	80
F7	over 66.7 kDa	0.03	10	0	90

SA-PO453

Mechanism of Macrophage Extracellular Traps Involved in the Formation of Encapsulating Peritoneal Sclerosis

Juan Sun, Hui Peng. *The Third Affiliated Hospital of Sun Yet-sun University Department of Nephrology, Guangzhou, China.*

Background: Encapsulating peritoneal sclerosis (EPS) is one of the most severe complications of peritoneal dialysis and poses a serious threat to the lives of peritoneal dialysis patients. However, the mechanism of the development of EPS is still unclear, and there is a lack of effective treatment.

Methods: We collected cells from the peritoneal dialysis effluent of EPS patients for single-cell transcriptome sequencing and used scanning electron microscopy and immunofluorescence to co-localize and identify macrophage extracellular traps(METs), while using fluorescent tracer cells to observe the "netting effect" of METs in vitro. We also used the EPS mouse model and PAD4 knockout mice for in vivo experiments. We stimulated fibroblasts with purified METs in vitro to explore the downstream molecular mechanism.

Results: The ratio of myofibroblasts in the peritoneal cavity of EPS patients was significantly increased compared with that of other patients by using scRNA-seq analysis. In addition, the macrophage-fibroblast interaction was significantly increased and the proportion of pro-inflammatory macrophages (S100A8+ Macro) was significantly higher in EPS patients. Immunofluorescence also showed that fibroblasts and macrophages were the most predominant cellular components in the adhesion region of the abdominal. Intrestingly, the METs formation pathway was significantly enriched in this celltype. The level of METs was positively correlated with the severity of EPS. Both PAD4 knockdown and injection of DNase-I effectively reduced METs and adhesion in EPS mice. In vitro study showed that METs induced fibroblast activation via p38/MAPK pathway.

Conclusions: Our study found that Macrophages in the peritoneal cavity produce METs under severe stimulation, and the reticular structure of METs can act as a scaffold to form "adhesion bridges" between cells in the peritoneal cavity and induce fibroblast activation through the p38/MAPK signaling pathway, which promotes peritoneal thickening and adhesion formation. Both knockdown of PAD4 and inhibition of METs by DNaseI were effective in improving EPS.

SA-PO454

Clinical Outcomes of Encapsulating Peritoneal Sclerosis Treated with Tamoxifen in Patients with ESKD: A Retrospective, Single-Center Analysis

Soy Kang, Binna Park, Dongeun Yang, Won Suk An. *Dong-A University, Busan, Republic of Korea.*

Background: Encapsulating peritoneal sclerosis (EPS) is a serious complication of peritoneal dialysis(PD). Patients with EPS showed 25-55% mortality rate, but the optimal treatment for EPS is not clear. EPS treated with tamoxifen is associated with lower mortality, but other studies showed no difference in outcome. This study aimed to evaluate the clinical outcomes of EPS treated with tamoxifen in end-stage kidney disease patients.

Methods: We conducted a 20-year (from January 2004 to December 2023) retrospective observational study. We included 34 EPS patients (mean age: 59.0 ± 11.7 years, male: 55.9%) who were diagnosed with abdominal computed tomography and treated with tamoxifen in Dong-A university hospital. We also analyzed data according to 10-year period (period 1: 2004-2013, n=24, period 2: 2014-2023, n=10).

Results: The mean duration of PD before diagnosis of EPS was 79.0 ± 45.0 months (range 27-192). Four patients had treated with hemodialysis prior to diagnosis of EPS. The length of hospital stay was 40.1 ± 28.4 days at time of diagnosis and survival time was 32.0 ± 32.2 months. Prescribed dose of tamoxifen was 22.3 ± 7.4 mg and prescribed days were 106.6 ± 172.1 (range 5-880). Four patients were also treated with low dose prednisone and five patients were treated with tamoxifen over 5 months. The length of hospital stay was shorter at period 2 compared to period 1 (26.0 ± 18.2 vs. 46.0 ± 30.1).

Four patient required surgical treatment and one patient died after surgery. The peritoneal culture at diagnosis of EPS showed fungus (32.4%), no growth (29.4%) and gram-negative bacteria (26.5%). The overall mortality rate was 14.7%. No adverse reaction related to tamoxifen was found.

Conclusions: Tamoxifen may be safe and essential for EPS treatment in patients with history of PD treatment. Further studies are necessary to evaluate the effectiveness of long term treatment with tamoxifen.

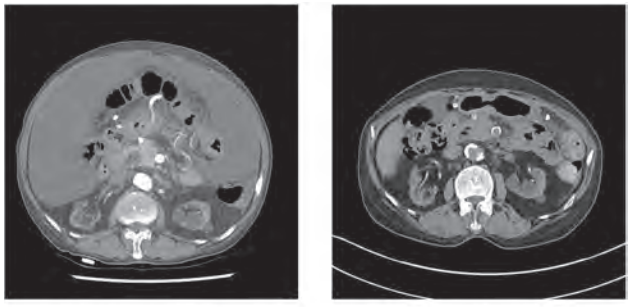

Figure 1. CT images of a EPS patient treated with Tamoxifen

SA-PO455

Association of Hypokalemia Duration and First Episode Peritonitis in Patients on Peritoneal Dialysis: A Single-Center, Retrospective Analysis

Geraldine P. Cercado. *National Kidney and Transplant Institute, Quezon City, Philippines*.

Background: Hypokalemia is a common condition in end-stage renal disease (ESRD) patients undergoing peritoneal dialysis (PD). Peritonitis is one of the most common complications associated with peritoneal dialysis. PD-associated peritonitis (PDAP) carries high morbidity for PD patients, which can cause catheter loss and transition to hemodialysis. First episode of peritonitis affects survival of peritoneal membrane as well as survival of PD patients. Several previous studies were done to determine association the association of hypokalemia and peritonitis. However, previous studies have differing results on the association of hypokalemia and PDAP.

Methods: A single center retrospective study design was conducted in the National Kidney and Transplant Institute, Philippines, reviewing patients initiated with peritoneal dialysis and had first-episode peritonitis from January 2018 to December 2022. A total of 336 patients were included. Hypokalemia duration was calculated as the total number of months that a patient's serum potassium level was continuously below 3.5 mmol/L.

Results: Most patients (246, 73.4%) with first-episode peritonitis had hypokalemic episodes. Shorter duration of hypokalemia had significant association with the peritonitis (p=0.004). Specifically, 50.4% (169) had hypokalemia for a duration of 1-3 months, while 12.2% (41) for 4-6 months and 10.7% (36) for >6 months. It is noteworthy that among hypokalemic patients with peritonitis in the first year, 41% (49 of 117) had early-onset peritonitis and most of these patients (39, 73%) had hypokalemia in the first 3 months of peritoneal dialysis. *Pseudomonas aeruginosa* in Gram-negative, and *Streptococcus spp* in Gram-positive bacteria were the main organisms in this study. Hypokalemic patients had significantly higher incidence of *Staphylococcus aureus* than patients without hypokalemia.

Conclusions: Most patients with PD-associated peritonitis were hypokalemic and most had hypokalemia duration of only 1-3 months. This signifies that PDAP can occur even with the shortest duration of hypokalemia.

SA-PO456

Au@PDA Nanotag-Based Lateral Flow Immunoassay Platform for Highly Sensitive Screening of Pathogenic Bacteria and Fast Evaluation of Antibacterial Agents

Fangfang Zhou, Qun Luo. *Ningbo No 2 Hospital, Ningbo, China*.

Background: Peritoneal dialysis associated peritonitis (PDAP) is one of the most common complications of PD. Timely and accurate diagnosis of PDAP is the key to improving the dialysis quality and survival rate of PD patients.

Methods: We developed lateral flow immunoassays (LFIAs), which had the merits of low cost, quick screening, and on-site detection are competitive technologies for bacteria detection, but their detection limits depend on the optical performance of the adopted nanotags. Herein, we presented a LFIA platform for bacteria detection using polydopamine (PDA) functionalized Au nanoparticles (denoted as Au@PDA) as the nanotag. The introduction of PDA could provide enhanced light absorption of Au, as well as numerous functional groups for conjugation. Small recognition molecules i.e. vancomycin (Van) and p-mercaptophenylboronic acid (PMBA) were covalently anchored to Au@PDA, and selected as the specific probes towards Gram-positive (G+) and Gram-negative (G-) bacteria, respectively. Taken Staphylococcus aureus (S. aureus) and Escherichia coli (E. coli) as the representative targets of G+ and G- bacteria, two LFA strips were successfully constructed based on the immuno-sandwich principle.

Results: The LFIA platform could quantitatively detect S. aureus and E. coli both down to 102 cfu/mL, a very competitive detection limit in comparison with other colorimetric or luminescent probes-based LFIAs. Furthermore, the proposed two strips were applied for the quantitative, accurate, and rapid screening of S. aureus and E. coli in food and human urine samples with good analytical results obtained. In addition, they were integrated as a screening platform for quick evaluation of diverse antibacterial agents within 3 hours, which is remarkably shortened compared with that of the traditional bacterial culture (over 3 days) and the common plate coating method (over 24 hours).

Conclusions: Au@PDA nanotag-based lateral flow immunoassay platform is highly sensitive screening of pathogenic bacteria and fast evaluation of antibacterial agents for peritoneal dialysis associated peritonitis.

Changes of Incidence and Microbiological Spectrum of Hospitalized Patients with Peritoneal Dialysis-Associated Peritonitis over Time: Results from the TRI-PoD Consortium

Moritz Schanz,[1] Tina Oberacker,[1] Severin Schricker,[1] Gabriele C. Eden,[3] Benedikt Kolbrink,[2] Jan T. Kielstein,[3] Roland Schmitt,[2] Kevin Schulte,[2] Joerg Latus.[1] *[1]Robert-Bosch-Krankenhaus GmbH, Stuttgart, Germany; [2]UKSH Campus Kiel Klinik für Innere Medizin IV mit den Schwerpunkten Nieren- und Hochdruckkrankheiten, Kiel, Germany; [3]Braunschweig Municipal Hospital, Braunschweig, Germany*.

Background: PD-associated peritonitis is the most common infectious complication of PD. The incidence and microbiological spectrum in hospitalized patients with PD-associated peritonitis in Germany is not known, which holds especially true for the time of the SARS-CoV-2 pandemic. The TRI-PoD project, a consortium of three major German nephrology centers (Braunschweig Municipal Hospital, Kiel University Hospital and Robert Bosch Hospital Stuttgart) investigated this topic as part of our mission to overcome barriers to PD initiation and improving PD care.

Methods: The incidence, baseline data and microbiological spectrum of hospitalized patients with PD-associated peritonitis in the period 2017-2023 from the three nephrological centres in Braunschweig, Kiel and Stuttgart were prospectively recorded and retrospectively evaluated.

Results: A total of n=368 patients were included in the analysis. Median (IQR) age was 62 years (50-75). 42.4% of the patients were of female sex. Median body mass index (BMI) was 28.0 kg/m^2 (24.4-32.0). Median initial cell count from the peritoneal dialysate was 6,306/µL (1,980-14,123). Median hospital stay was 9 days (5-18). In 19.8% of the cases catheter removal was necessary. Microbiological results showed sterile peritonitis in 22.0% of the cases. In total, 48.1% were gram positive and 24.2% gram-negative pathogens. A mixed spectrum with gram-positive and negative pathogens was found in 7.1% of cases.

Conclusions: Incidence of PD-associated peritonitis requiring hospitalization has declined over the 5 years, possibly due to increased outpatient management. Beyond that, our data showed a trend towards a lower rate of hospitalized patients with PD associated peritonitis and an increased percentage of gram-positive results in PD dialysate during the SARS-CoV-2 pandemic. A high rate of sterile cultures was found, presumably due to outpatient pretreatment. In addition, a high rate of gram-negative bacteria found. The latter one was related to a high catheter explantation rate. This relative increase in risk might be attributed to the fact that only more severe cases of PD associated peritonitis had been hospitalized.

SA-PO458

Predictive Value of Gram Stain in Peritoneal Dialysis-Associated Peritonitis: Preliminary Results of a Single-Center Pilot Study

Bhavya Chatragadda,[1] Christina A. Raker,[3] Susie L. Hu,[2] Ankur Shah.[2] *[1]University of Rhode Island, Kingston, RI; [2]Brown University Warren Alpert Medical School, Providence, RI; [3]Lifespan Health System, Providence, RI*.

Background: Peritoneal dialysis-associated peritonitis (PDAP) is a common and serious complication in patients undergoing peritoneal dialysis (PD). Early diagnosis and appropriate treatment are crucial for optimal patient outcomes. Gram stain is a rapid

diagnostic tool that may help guide initial treatment decisions. This pilot study aims to evaluate the ability of gram stain to predict culture results in PDAP.

Methods: This single-center, retrospective observational study included all adult patients with PDAP at our institution over a 5-year period (*** to (***). Electronic medical records were reviewed to collect data on peritoneal fluid gram stain and culture results at the time of peritonitis. Gram stain results were categorized as gram-positive, gram-negative, or no organisms seen. Culture results were considered the gold standard for diagnosis. Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of gram stain were calculated.

Results: A total of 56 patients with PDAP (n = 87 episodes) were included. The mean age was 54 years, and 62.5% were male. Median time on peritoneal dialysis was 1.2 years. Gram stain results showed 29.9% gram-positive, 16.1% gram-negative, 6.8% yeast/polymicrobial, and 47.1% no organisms seen. Culture results were positive in 69.3% of cases, with the most common organisms being coagulase-negative staphylococci (28.8%), Staphylococcus aureus (10.2%), and Klebsiella pneumoniae (10.2%). The overall sensitivity and specificity of gram stain for predicting culture results were 72.9% and 92.3%, respectively. The sensitivity for gram-positive was 79.3%, and for gram-negative, 63.2%. The PPV was 88.5% for gram-positive and 92.3% for gram-negative. The NPV was 89.8% for gram-positive and 90.3% for gram-negative organisms.

Conclusions: While we demonstrate a high sensitivity, specificity, PPV, and NPV of gram stain in predicting culture results it is important to exercise caution when interpreting gram stain results, as inappropriately narrowing antibiotic coverage based solely on gram stain findings can result in undertreatment. Our study provides preliminary information to support larger, multicentric trials to evaluate the potential of gram stain to decrease antibiotic exposure.

SA-PO459

Incidence and Outcomes of Nontuberculous Mycobacterium Infections in Patients Undergoing Peritoneal Dialysis

Rachael Lazar,[1] Meredith L. Zywno,[1] Eric D. Weinhandl,[2,4] Mihran V. Naljayan.[1,3]
[1]DaVita Inc, Denver, CO; [2]Davita Clinical Research, Minneapolis, MN; [3]LSU School of Medicine, New Orleans, LA; [4]University of Minnesota Twin Cities, Minneapolis, MN.

Background: Nontuberculous mycobacterium (NTM) infections in peritoneal dialysis (PD) can lead to morbidity, including hospitalization and catheter removal. Our aim was to describe demographics and outcomes associated with NTM infections among a population of PD patients.

Methods: The study population comprised PD patients with at least one positive exit site or PD fluid culture collected between 1/1/19 and 12/31/23. Data included lab results, demographics, and hospital admission and dialysis treatment dates obtained from electronic medical records at a large dialysis provider (average 26,000 PD patients treated annually). Infection events were defined by positive cultures. Cultures resulting in any NTM organism were categorized as NTM infection events, and cultures resulting in non-NTM organism(s) were categorized as "other." Outcomes were hospital admission and discontinuation of PD within 30 days of culture collection date.

Results: Over the 5-year period, NTM (N=305) showed greater tropism for exit site (vs PD fluid) than other organisms (79% vs 44% infections at exit site). Regarding demographics among patients with NTM infection, median age at infection was 60 years; 62% were male and 46%, 24%, and 18% were non-Hispanic White, Hispanic, and non-Hispanic Black, respectively. At the time cultures were collected, median time on PD was 5 months (IQR: 2-13). The majority of cases occurred in the Southeast (49%) or Southwest (21%) regions of the US. Thirty-day risks for hospital admission and discontinuation of PD were greater following NTM infection events (35%, 28%, respectively) than following non-NTM infections (21%, 7%, respectively): adjusted odds ratio (aOR) 3.1, 95% CI: 2.8-3.3 for hospital admission and aOR 8.3, 95% CI: 8.0-8.6 for PD discontinuation. Exit site infection-specific risks for outcomes were also greater for NTM infections (aOR 2.0, 95% CI: 1.7-2.3 for hospital admission and aOR 7.9, 95% CI: 7.5-8.2 for PD discontinuation).

Conclusions: NTM infections among PD patients most commonly occurred among patients treating in the southern US and as exit site infections rather than PD fluid infections. Even after controlling for culture source and demographic factors, NTM infection events were associated with more frequent negative outcomes, including hospitalization and discontinuation of PD, compared with other infections.

SA-PO460

Development of Risk-Prediction Tool for Peritoneal Dialysis-Associated Peritonitis and External Validation in the PDTAP Cohort

Yumeng Qiao, Jie Dong. *Peking University First Hospital, Beijing, China.*

Background: Although peritoneal dialysis related peritonitis is a common complication among peritoneal dialysis (PD) patients, there is no validated and recognized tool to predict disease prognosis. This limits patient-specific risk stratification and treatment decisions.

Methods: A single-center peritonitis cohort was used for model derivation and Peritoneal Dialysis Telemedicine-assisted Platform (PDTAP) cohort was used for external validation. Logistic regression models were used to analyze the risk of treatment failure within 1 month of peritonitis, i.e. a composite of peritonitis-related mortality and transferring to hemodialysis. The discrimination and calibration were evaluated using C statistics, Hosmer-Lemeshow (HL) test, Akaike information criterion (AIC), Bayesian information criterion (BIC) and calibration curves. Predictors were weighted to calculate a risk score.

Results: Totally, 528 and 1190 first-episode peritonitis were included in the derivation cohort and validation cohort, respectively. A total point of 5 in basic model was developed including baseline albumin <35g/L and PD duration >25months, and a total point of 29 in extended model was developed including age >60 years old, PD duration >25months, the white cell count >300/mm3 in dialysis effluent on the day 3, and causative organism. Compared with basic model, the extended model performs better with higher C statistic [0.744 (95%CI 0.684-0.804) vs. 0.635 (95%CI 0.574-0.696), P = 0.012], HL statistic [6.73 (8df; P = 0.566) vs. 3.27 (2df; P = 0.195) and lower AIC (389.10 vs. 509.74) and BIC (421.99 vs. 522.50). Both models in the validation cohort performed similar or better discrimination and calibration, as shown in C statistics [0.620 (95% CI 0.579-0.661) in basic model; 0.871 (95%CI 0.837, 0.905) in extended model] and HL statistic [0.31 (2df; P = 0.858) in basic model; 7.86 (8df; P = 0.447) in extended model].

Conclusions: In this study, the basic and extended models for predicting treatment failure of peritonitis were established based on commonly used clinical data, which were applicable to different clinical scenarios and facilitated clinical doctors to identify high-risk individuals and adjust treatment decisions.

SA-PO461

High Effluent Lactic Acid Levels Predict the Adverse Outcomes of Peritoneal Dialysis-Associated Peritonitis: A New Role for an Old Marker

Xiao Yu,[1,2] Ying Ma.[2] *[1]The Second Affiliated Hospital of Shaanxi University of Traditional Chinese Medicine, Xianyang, China; [2]The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China.*

Background: Peritonitis remains the major complication of peritoneal dialysis(PD). Acute inflammation promotes glycolysis and increases the production of lactic acid by increasing the NADH-NAD^+ ratio. The role of monitoring effluent lactic acid levels during treatment of peritoneal dialysis-associated peritonitis(PDAP) deserves attention.

Methods: We retrospectively collected effluent and serum lactic acid levels, and other laboratory and clinical characteristics, as well as treatment outcomes of PDAP occurred between November 2022 and October 2023. Adverse outcomes of PDAP were defined as no cure, including recurrent, relapse, catheter removal, transfer to hemodialysis and death. According to treatment outcomes, PDAP episodes were divided into cure group and no cure group. Characteristics at the beginning of PDAP were compared between the 2 groups. Factors associated with clinical outcome were analyzed using logistic regression modeling.

Results: Totally, 80 PDAP episodes were recorded in 67 PD patients. Their baseline average age was 52.4±13.8 years old, among which 64.2% were men. As for the clinical outcomes of the PDAP, 60 episodes were cured, while 20 episodes experienced adverse outcomes (no cure), among which relapse was the leading one (n=12, 15.0%), followed by catheter removal. No difference was observed in age, gender, Charlson's Comorbidity Index, blood pressure, BMI, PD duration, peritoneal membrane transport type or Kt/V microbiologic cause between cure group and no cure group. Effluent lactic acid levels was significantly higher in no cure group[7.95(6.43,12.1) Vs 6.45(3.13,8.9), p=0.006], accompanied by a higher Day-5 effluent WCC. Multiple Logistic regression analysis showed higher effluent lactic acid levels was the independent risk factors for peritonitis adverse outcomes(odds ratio(OR)=0.822, p=0.012). ROC analyses of effluent lactic acid levels yielded a moderate discriminative capacity for adverse outcomes (area under curve(AUC)=0.71, p=0.006). The threshold values with the highest Youden's index were 5.25 mg/L (sensitivity=100%, specificity=45%). Calibration for the ROC curve of effluent lactic acid concentration in diagnosing adverse outcome of PDAP was 0.291(Hosmer-Lemeshow goodness-of-fit test:x^2=13.667, p=0.091).

Conclusions: Higher effluent lactic acid levels could predict adverse outcome of PDAP independently.

SA-PO462

Peritonitis Trends and Patient Outcomes in Peritoneal Dialysis from a Portuguese Center: Decades of Data Unlocked

Joana P. Dias,[1] Vitória V. Paes de Faria,[1] Maria B. Bessa,[1] Rute Carmo,[1] Daniela Lopes,[1] Clara Almeida,[1] Ana Marta Gomes.[1,2] *[1]Unidade Local de Saude de Vila Nova de Gaia/Espinho, Vila Nova de Gaia, Portugal; [2]Universidade do Porto Unidade Multidisciplinar de Investigacao Biomedica, Porto, Portugal.*

Background: Peritonitis is a common and severe complication of peritoneal dialysis (PD). This study aims to ascertain how the rate of peritonitis is evolving in our center, examine the factors that influence these cases and their outcomes, including the causative infectious agent, hospitalization and technique transference.

Methods: Between January 1, 1999, and December 31, 2023, 152 patients who started PD at our institution were included in the study. All PD-related peritonitis episodes were collected. Complicated peritonitis included recurrent, relapsing, repeating or refractory cases, guided by ISPD 2022 recommendations.

Results: The rate of peritonitis showed a steady decline over the study period, dropping from 0.7 episodes/patient in 1999 to 0.27 by the study's end. The majority of infections (76.3%) were managed on an outpatient basis and 72.4% progressed to healing. The most common causative agents were Gram-positive (GP) (57.9%), including coagulase-negative staphylococci (22.6%). GP infections were significantly linked to recent antibiotic exposure (p=0.017). Moreover, fungal peritonitis was found to be more common among male patients (p=0.032) and those with diabetes (p=0.046). Cases involving Gram-negative (GN) and fungal microorganisms exhibited worse outcomes, as depicted in Table 1.

Conclusions: Over the years, our center observed a notable decline in PD-related peritonitis, with most cases being effectively treated on an outpatient basis due to improved aseptic techniques, enhanced patient education, advancements in PD equipment, better antibiotic protocols, and regular monitoring and follow-up care. GP organisms remained the major cause of PD-related peritonitis, while GN and fungal peritonitis were associated with worse outcomes and a higher rate of PD failure, which is aligned with current literature. Understanding the trajectory of our center's experience provides invaluable insights for the development and continuous growth of our practices, enhancing patient outcomes and elevating the standards of care in PD.

Outcome	Gram Positive (n=208)	Gram Negative (n=44)	Fungal (n=9)	Polymicrobial (n=16)
Complicated peritonitis	80 (38.5%), p = 0.711	24 (54.5%), p = 0.051	8 (88.9%), p = 0.003	11 (68.8%), p = 0.014
Catheter removal	49 (32.5%), p = 0.010	18 (40.9%), p = 0.009	9 (100%), p < 0.001	8 (50%), p = 0.036
Hospitalization	45 (29.8%), p = 0.024	18 (40.9%), p = 0.004	6 (66.7%), p = 0.007	5 (31.3%), p = 0.546
Technique transference	28 (18.5%), p = 0.007	11 (25%), p = 0.011	5 (55.6%), p = 0.002	3 (18.8%) p=0.446

SA-PO463

Technique Survival after Relapsing Peritonitis: Experience from a Center in Mexico

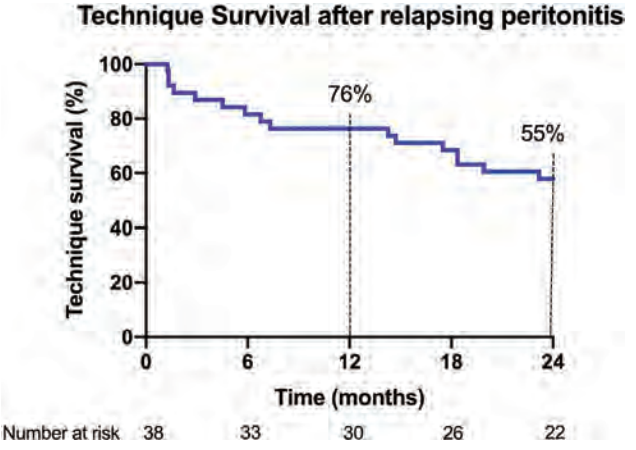
Miguel Angel Franco Barrera, Luis A. Camacho-Murillo, Hugo Sergio Breien Alcaraz. *Hospital Regional Valentin Gomez Farias ISSSTE, Zapopan, Mexico.*

Background: Relapsing peritonitis significantly impacts the outcomes of peritoneal dialysis patients. Catheter removal and temporary migration to hemodialysis are part of the routine management in some cases. In these instances, the response or failure of antibiotic treatment guides therapeutic decisions and patient outcomes. An alternative approach involves simultaneous or short-term catheter removal and repositioning in episodes where infection control is evident.

Methods: A retrospective cohort analysis was conducted from January 1, 2013, to December 31, 2023, at a peritoneal dialysis center in Guadalajara, Jalisco, Mexico. The entire population enrolled in the peritoneal dialysis program was included in the study. The aim of this research is to describe the outcomes (technique survival, 30-day mortality) observed in patients with relapsing peritonitis that remained in peritoneal dialysis.

Results: Total population of the program included 854 patients. Among 281 patients, 585 episodes of peritonitis were recorded, and 51 episodes were classified as relapsing and included in the analysis. Of them 13 (25%) were transferred to hemodialysis, and 38 (75%) remained in peritoneal dialysis. Among patients who remained on peritoneal dialysis, the median technique survival was 32 months. Seventy-six percent maintained the technique at 12 months, and 65% at 24 months. Among the population that remained on dialysis, 2 (4%) patients died within 30 days following the recurrence event.

Conclusions: In patients with relapsing peritonitis, continuation of peritoneal modality is achievable with an acceptable technique survival.



SA-PO464

Trends, Outcomes, and Economic Implications of Peritoneal Dialysis-Associated Peritonitis: A National Cohort Study

Shagun Vashisth,[1] Christina A. Raker,[2,1] Susie L. Hu,[1,2] Ankur Shah.[1,2] *[1]Brown University Warren Alpert Medical School, Providence, RI; [2]Rhode Island Hospital, Providence, RI.*

Background: Peritoneal dialysis-associated peritonitis (PDAP) is a serious complication of peritoneal dialysis, associated with significant morbidity, modality transition, and mortality. We provide an update on the national burden of this significant complication in the US, highlighting trends in demographics, treatment practices, and in-hospital outcomes of PDAP from 2016 to 2020.

Methods: Utilizing a national all-payer dataset of hospitalizations in the US, we conducted a retrospective cohort study of adult hospitalizations with a primary diagnosis of PDAP from 2016 to 2020. We analyzed demographic, clinical, and hospital-level data, evaluating in-hospital mortality, PD catheter removal, length of stay, and healthcare spending. Multivariable logistic regression adjusted for demographic and clinical covariates was employed to identify risk factors associated with adverse outcomes.

Results: This study included 17,335 PDAP hospitalizations from 2016 to 2020. In-hospital mortality was observed in 3.29% of cases and 23.2% of episodes resulted in removal of the PD catheter. Healthcare expenditures associated with PDAP totaled over $75,000 per admission. Additionally, geographic variations in treatment patterns were present, with treatment at western and teaching hospitals associated with increased rates of catheter removal relative to northeastern and non-teaching centers and a mean cost of nearly $55,000 more in Western states compared to Midwest states. Risk factors associated with adverse outcomes are represented in Table 1.

Conclusions: PDAP is a major cause of mortality among PD patients, and there is a vital need for future studies to examine the impact of hospital location and teaching status on PDAP outcomes, which can inform treatment practices and resource allocation.

Table 1. Adjusted Odds Ratios for Catheter Removal and Mortality by Risk Factors

Risk Factor	Adjusted Odds Ratio (95% CI) for Catheter Removal	Adjusted Odds Ratio (95% CI) for Mortality	Adjusted Odds Ratio (95% CI) for Catheter Removal or Mortality
Age (per year)	1.00 (1.00 - 1.01)	1.03 (1.02 - 1.05)	1.01 (1.00 - 1.01)

Peritonitis and Stool Burden on Plain Abdominal Radiographs in Patients on Peritoneal Dialysis

Kentaro Nakai, Yuho Ota, Mako Ochiai, Sonoda Shinichiro, Keitaro Uehara, Masanori Tokumoto. *Fukuoka Sekijuji Byoin, Fukuoka, Japan.*

Background: Peritonitis is a significant and troublesome complication of peritoneal dialysis. It is imperative to overcome peritonitis to preserve peritoneal function and prolong peritoneal dialysis. Bacterial translocation from the intestinal tract is the most probable candidate for a bacterial portal of entry in peritonitis associated with peritoneal dialysis, and it has been postulated that constipation may be related to this mechanism. The definition of constipation is based on stool characteristics and subjective evaluation, which is often difficult to assess objectively. Attempts have been made to assess the degree of stool burden with plain abdominal radiographs, which can be obtained routinely.

Methods: This was a retrospective study comprising 45 patients who were on peritoneal dialysis at the end of 2020. Patients were divided into two groups according to the median score of stool retention on plain abdominal radiographs. The three-year clinical outcomes of transition to hemodialysis and peritonitis were calculated for each group using the Kaplan-Meier method, and adjusted hazard ratios were calculated using the Cox regression model.

Results: There were no significant differences between the two groups in age, gender, diabetes status, dialysis vintage, history of peritonitis, and biochemical parameters. A total of 13 patients (29%) developed peritonitis related to peritoneal dialysis. Of these, 22 patients (49%) were converted to hemodialysis, 1 patient (2%) died, and 1 patient (2%) underwent renal transplantation. The Kaplan–Meier analysis demonstrated that patients in the high-score group exhibited a significantly shorter time to first peritonitis than those in the control group, even after adjusting for confounding factors. However, no significant association was found between radiographic scores and transition to hemodialysis.

Conclusions: The stool burden score was evaluated by plain abdominal radiographs and demonstrated a significant independent correlation with the time to first peritonitis, though no such correlation was observed with death or transition to hemodialysis. The results of this study may be utilized to assess the efficacy of potential interventions aimed at reducing peritonitis.

Gut Microbiota in Patients on Peritoneal Dialysis

Shutov Evgeny, Stepan B. Alexeevich, Irina Fedoseeva. *Botkin Hospital, Moscow, Russian Federation.*

Background: In recent years, the research of the structure and role of the gut microbiota in patients with CKD has been of increasing interest due to the cumulation of data on the involvement of intestinal microflora in the onset of typical complications. The investigation of the gut microbiota in patients on peritoneal dialysis is especially relevant given the high frequency of dialysis peritonitis caused by intestinal flora, up to 40%.

Methods: In our study we included 39 patients, age 55±16.4 years (22 f/17 m), who received peritoneal dialysis at our nephrology center. The intestinal microbiota was analyzed using 16s rRNA sequencing. Correlation analysis was carried out using the Pearson and Spearman coefficient.

Results: Fig.1 shows microorganisms at the phylum, class, order, family and genus level in patients receiving PD. The visual shows that, on average, the prevailing phylum in the samples was Bacillota, and the second largest phylum was Bacterioidota. Bacterioidia of the Bacterioidota phylum and Clostridia and Bacilli of the Bacillota phylum were significant at the class level. The phylum Actinomycetota included the classes Coriobacteriia and Actinobacteria. At the order level, the 10 most represented taxonomic groups included Lachnospirales, Oscillospirales, Lactobacillales, Erysipelotrichales, Christensellales, Peptostreptococcales, Bacteroidales, Bifidobacteriales, Coriobacteriales and Enterobactertales. A high positive correlation (R =0.7, p<0.005) was found for ferritin and bacteria of the genera Citrobacter, Ligilactobacillus, Lactococcus, Porphyromonas, Klebsiella, Leuconostoc, Lachnoclostridium and Fusobacterium. The analysis of alpha diversity showed an inverse correlation (R -0.5,p<0.001) between the Simpson, inverted Simpson and Shannon indices and the number of peritonitis transferred, The decrease in alpha diversity was significantly inversely correlated with ferritin levels (p < 0.01).

Conclusions: A decrease in the alpha diversity of microorganisms correlates with high ferritin levels and the frequency of dialysis peritonitis. There were no significant correlations with age and the studied biochemical parameters.

Defining the Optimal Frequency of Dialysis Adequacy Test for Patients on Peritoneal Dialysis

Jack K. Ng, Winston W. Fung, Cheuk-Chun Szeto. *The Chinese University of Hong Kong, Hong Kong, Hong Kong.*

Background: Peritoneal Dialysis (PD) is a cost-effective treatment for end-stage kidney disease, with the adequacy of small solute clearance being a key factor in determining the PD regimen. Although regular monitoring of small solute clearance is recommended, recent guidelines emphasize a person-centered approach. We hypothesize that peritoneal Kt/V(urea) remains stable in most patients and does not require frequent monitoring.

Methods: We reviewed 11427 PD adequacy tests in 1874 PD patients. The serial change in Kt/V-PD was compared. The effect of daily exchange volume, peritonitis episodes, PD solution osmolality, duration of dialysis, and other baseline parameters were explored.

Results: The median duration between two dialysis adequacy tests was 7.0 months (IQR 5.6 to 11.0 months). The average change in Kt/V-PD between two tests was 0.024 ± 0.319. The change in Kt/V-PD was significantly higher after an increase in exchange volume than those with a static PD exchange volume (0.176 ± 0.453 vs 0.012 ± 0.302, p<0.0001). When dialysis adequacy test pairs that had a static PD exchange volume were analyzed, the change in Kt/V-PD did not differ between tests that were interposed with peritonitis episodes and those without (0.006 ± 0.317 vs 0.013 ± 0.300, p = 0.4). The change in Kt/V-PD was similar when the adequacy test was repeated after an increase in PD solution osmolality as compared to those with a static PD regimen (-0.011 ± 0.367 vs 0.014 ± 0.296, p = 0.1). There was no correlation between the change in Kt/V-PD and the duration between two adequacy tests (r = 0.002, p = 0.8).

Conclusions: Our result shows that Kt/V-PD remains stable in most patients within 12 months and does not require frequent monitoring.

SA-PO468

Decline of Kidney Function before and after Start of Peritoneal Dialysis (PD)

Markus Björksten,[2,1] Abdul Rashid T. Qureshi,[2] Peter Stenvinkel,[2,1] Olof Heimburger.[2,1] *[1]Karolinska Universitetssjukhuset, Huddinge, Sweden; [2]Karolinska Institutet Institutionen for Klinisk Vetenskap Intervention och Teknik, Huddinge, Sweden.*

Background: Residual kidney function (RKF) is a key component for PD adequacy and is associated with improved volume status, and clinical outcome. The RKF decline rate has been reported to diminish after PD initiation. The aim was to compare kidney function decline, and diuresis decline, before and after start of PD, and to compare eGFR and GFR from urine collections (uGFR) predialysis.

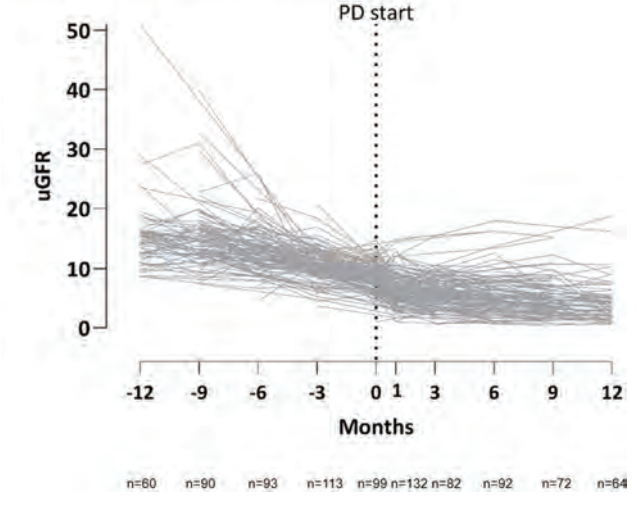
Methods: We studied 138 patients (42% females, mean age 55±13 years) starting PD during 2000-2019 in a prospective study. Inclusion criteria were ≥ 1 urine collection before, and ≥ 1 after PD initiation, PD initiation < 6 months after study inclusion and > 6 months of PD. Data was collected from 12 months before to 12 months after PD start. uGFR was calculated as average of creatinine and urea clearance from 24-hour urine collections corrected for BSA. eGFR was calculated using CKD-epi 2021.

Results: The mean uGFR was 15.5±6.2 and eGFR 12.1±5.8 at 12 months before PD start, and PD was started at mean uGFR 8.5±2.3 and eGFR 5.8±1.9 ml/min/1.73m². The GFR decline rate before PD start was similar using eGFR or uGFR. However, uGFR was higher than eGFR. The uGFR decline rate was slower after PD start. Notably, there was a marked attenuation at 1 month of PD. However, urine volume decline rate increased after PD start, likely because of peritoneal ultrafiltration.

Conclusions: The results could suggest that an earlier initiation of PD may be beneficial for preservation of RKF.

Funding: Private Foundation Support

Decline of uGFR before and after PD start



Decline of kidney function and diuresis before and after PD start[1]

	Before PD initiation	After PD initiation
GFR	-0.59	-0.34
eGFR	-0.52	NA
Diuresis	-26	-106

[1]Values are described as average decline rate per month. uGFR and eGFR are presented as mL/min/1.73m². Diuresis is presented as ml/day.

A Single-Centre Experience with Assisted Home Hemodialysis in Long-Term Care Facilities: A Cost-Feasibility Study

Gihad Nesrallah,[1,2] Jessica Wang,[1] Monica Silva,[1] Justin M. Ashley,[1] Shabnam Hamidi,[1] Danica Lam,[1] David C. Mendelssohn.[1,2] *[1]Humber River Health, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada.*

Background: For hemodialysis (HD) recipients residing in long-term care (LTC), the COVID-19 pandemic created several barriers to care. To address these challenges, we established a pilot program of fully-assisted HD provided on-site to LTC residents (LTC-HD) by registered nurses (RNs), registered practical nurses (RPNs) and personal support workers (PSWs).

Methods: We performed a cost-feasibility analysis from the provider perspective using a bottom-up micro-costing approach based on real costs incurred between March 2020-March 2023. We examined a range of staffing models (in-sourced vs. out-sourced/agency and 1:1 vs higher patient:staff ratios) for providing daily (6/week, 2hrs) and conventional (3/week, 4hrs) HD. Direct costs included labor, medical supplies, and dialysis consumables using standard (Fresenius 4008K) and portable (NxStage) equipment. Indirect costs included equipment maintenance, injectables, travel, and staff replacement costs. We excluded capital, patient-borne, non-dialysis costs, and physician fees. Costs are reported in CAD/year using FY2022/23 prices.

Results: During follow-up, 44 patients received LTH-HD at 15 facilities. Bundled rates were $50,076 and $83,467 for conventional and daily HD, respectively. Conventional HD with PSWs (1:1) yielded a net loss of $2,947 vs. net surplus of $3,076 with out- vs. in-sourcing, respectively. Staffing with in- and out-sourced RNs and RPNs yielded net losses with 1:1 staffing but generated surpluses of $17,426 and $20,546 when insourced RPNs and RNs treated provided 2:1 and 3:1 clustered HD. Daily HD with NxStage cost $13,681/yr more vs. standard equipment resulting in net losses in all scenarios. Daily HD yielded a surplus when staffed by in-sourced staff with further savings under clustered models.

Conclusions: Fully-assisted LTC-HD is financially feasible under current bundled rates in Ontario, with greater savings in clustered settings with in-sourced staff.

Table 1. Cost-feasibility of LTC-HD under varying operating models for daily and conventional hemodialysis. Operating models are ranked by net cost; red font denotes net deficit.

Staff Type	Care Setting/Location	In vs. Out-Sourced	Patient:Staff Ratio	HD Equipment	Bundle Amount	Direct Labour Costs	Consumable Costs	Total Expenses	Surplus/Deficit per Annualized Patient

SA-PO470

A Single-Centre Experience with Assisted Home Hemodialysis in Long-Term Care Facilities

Justin M. Ashley,[1,2] Shayne K. Joseph,[3] Shabnam Hamidi,[1] Gihad Nesrallah,[1,2] Danica Lam,[1] David C. Mendelssohn.[1,2] *[1]Humber River Health, Toronto, ON, Canada; [2]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; [3]McMaster University, Hamilton, ON, Canada.*

Background: To address challenges imposed by the COVID-19 pandemic, our renal program expanded assisted home hemodialysis (HD) services to provide on-site HD to patients residing in long-term care (LTC) facilities. The purpose of this study was to describe the patient and treatment characteristics and outcomes in a cohort of patients undergoing home HD in LTC facilities.

Methods: We conducted a retrospective review of all consecutive patients across 15 LTC facilities within our catchment area in Toronto who converted from in-centre HD to LTC-HD between March 2020 and March 31, 2023. We included all adult patients who received assisted conventional (3 HD/week, 3-4 hr) and short-daily (5-7 HD/week, 2-3 hr) HD provided by a registered nurse, registered practical nurse, or personal support worker during the study period. We extracted all data from our hospital electronic record system, including baseline demographics, comorbidities, dialysis prescriptions, deaths, hospitalizations, COVID-19 related and unrelated infections.

Results: The mean age among 44 eligible patients was 75.6 years with 30 (70%) male patients and 13 (30%) female patients. Thirty-one (67%) patients had type two diabetes. There were 20 patients (45%) on conventional HD and 24 patients (54%) on daily HD at the time of enrolment. Eighty-five percent had limited mobility or were bedbound and

33% had dementia. During follow-up, there were 23 deaths with a one-year mortality rate of 45%. There were 69 hospitalization events, including 13 intensive care unit (ICU) admissions, with an average length of stay of 11 days. The number of access related complications was 18. There were 10 COVID-19 infections.

Conclusions: Assisted hemodialysis in LTC facilities is a patient-centered means by which to provide dialysis to a frail and vulnerable patient population. As expected, clinical outcomes were relatively poor. Additional analyses with control data as well as costing and ethical evaluations are ongoing and will be reported separately.

SA-PO471

Connected Home Hemodialysis Machine Use and Transition to In-Center Hemodialysis

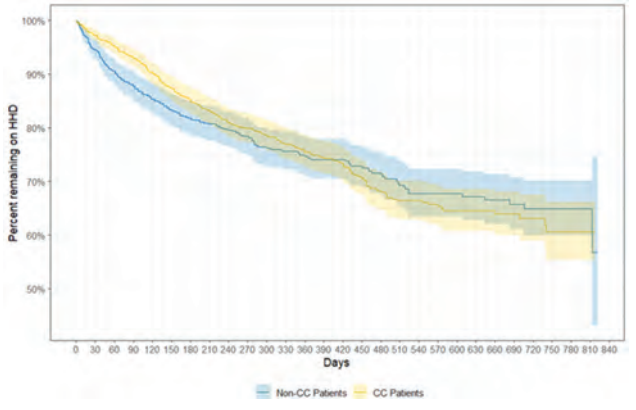
Miranda Hurtado,[1] Meredith L. Zywno,[1] Eric D. Weinhandl,[2] Mihran V. Naljayan.[1,3] *[1]DaVita Inc, Denver, CO; [2]Davita Clinical Research, Minneapolis, MN; [3]LSU School of Medicine, New Orleans, LA.*

Background: Although home hemodialysis (HHD) has been growing rapidly, ongoing expansion is constrained by relatively high rates of transition to in-center hemodialysis (ICHD) during the first year of therapy. We aimed to assess whether the use of an internet-connected home hemodialysis machine (CC), which employs a tablet and relays treatment data to dialysis providers, was associated with a decreased rate of transitioning to ICHD.

Methods: The study population included all HHD patients who began treatment in a large dialysis provider organization between July 2021 and December 2022 and initiated use of a CC [NxStage System One with Nx2me Connected Health, Fresenius Medical Care] within 30 days of first documented treatment. Patient data were obtained from electronic medical records and initiation of CC was ascertained from electronic treatment records. Patients were followed from 30 days after HHD initiation until the earliest of transition to ICHD, death, kidney transplant, or end of study follow-up. Kaplan-Meier estimation and Cox regression were used to compare technique survival in CC and non-CC patients at 90 days and 360 days; death and transplantation were classified as censoring events.

Results: The study cohort included 1,563 patients, among whom 930 (60%) used a CC. Mean age among patients was 55.8 years, and 39% of patients were female. In the HHD patient population, CC and non-CC patients had no significant difference in risk of transitioning to ICHD (HR: 1.00, 95% CI: 0.82, 1.21). However, when follow-up was limited to the first 180 days, CC patients experienced a 22% lower rate of transition to ICHD, compared to non-CC patients (HR: 0.78, 95% CI: 0.61, 1.00).

Conclusions: The use of a CC was not associated with a differential risk of transition to ICHD from HHD in our study population, although there was evidence of potential benefit during the first 6 months. More study is needed to determine whether this technology could positively impact home modality retention.



SA-PO472

Association of Connected Cycler Use with Rate of Transition from Peritoneal Dialysis to In-Center Hemodialysis

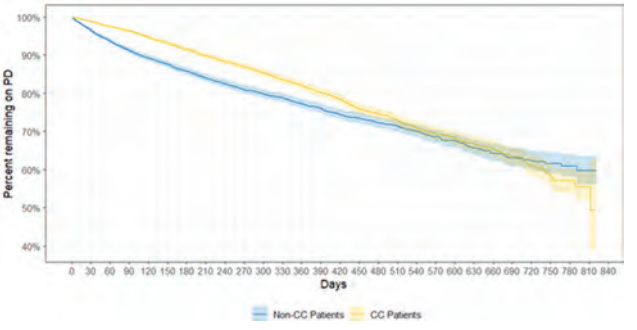
Miranda Hurtado,[1] Meredith L. Zywno,[1] Eric D. Weinhandl,[2] Mihran V. Naljayan.[1,3] *[1]DaVita Inc, Denver, CO; [2]Davita Clinical Research, Minneapolis, MN; [3]LSU School of Medicine, New Orleans, LA.*

Background: Attrition from home dialysis is an ongoing challenge, sometimes attributable to the difficulty of assessing prescription adherence in real time. With increasing use of remote monitoring platforms, we aimed to assess whether the use of an internet-connected automatic peritoneal dialysis cycler (CC), which transmits treatment data to the dialysis provider on a daily basis, was associated with lower rate of transition to in-center hemodialysis (ICHD).

Methods: The study population included all peritoneal dialysis (PD) patients who began treatment in a large dialysis provider organization between July 2021 and December 2022 and initiated use of a CC [Homechoice Claria or Amia, Baxter International] within 30 days of first documented treatment. Patient data were obtained from electronic medical records and initiation of CC was ascertained from electronic treatment records. Matched pairs of CC PD patients and non-CC PD patients were constructed, based on clinical and demographic factors, to address measurable confounding. Patients were followed from 30 days after PD initiation until the earliest of transition to ICHD, death, kidney transplant, or end of study follow-up. Kaplan-Meier estimation and Cox regression were used to compare technique survival in CC and non-CC patients; death and transplantation were classified as censoring events.

Results: The study cohort included 5,308 pairs of CC and non-CC PD patients. Mean age was 60.5 years, and 41% of patients were female. Among CC patients, 5% experienced transition to ICHD after 90 days, compared to 10% of non-CC patients. After 360 days, 18% of CC patients experienced transition to ICHD, compared to 25% of non-CC patients. CC patients had a 16% lower rate of transition to ICHD, compared to non-CC patients (HR: 0.84, 95% CI: 0.78, 0.91).

Conclusions: The use of a CC for peritoneal dialysis was associated with a significantly lower risk of transition to ICHD. Broader use of this technology may facilitate improvement in retention of patients undergoing PD.



SA-PO473

Teledialysis: The First Northeast Italy Experience of Telehealth in Peritoneal Dialysis

Paolo Lentini, Claudia Benedetti, Antonino Previti, Giorgio Laudadio. *Nephroloy, "S.Bassiano Hospital", Bassano del Grappa, Italy.*

Background: Telehealth may facilitate patient care in peritoneal dialysis(PD). We report our experience with Teledialysis(TD), a combination of PD technique and new technology devices that we used together to overcome clinical, social and psychological barriers toPD.

Methods: Pilot study-25 consecutive Automated Peritoneal Dialysis(APD)pts. TD was perform by the combination of 2 systems A- A Web platform *Sharesource*(Baxter®) that supports remote patient management and provide to the clinician the ability to act on that assessment by updating the cycler. B-*Totem eVISUS* System(TesiSquare®);a plug-play system consisting of two units:1) a transportable remote station**(Totem)**equipped with high performance camera, touchscreen monitor, speaker microphone, internet routers for fixed and mobile phone, wireless access point and remote control to answer calls remotely and 2) a **Control Station** used form our healthcare personnel to connect to one or more pts at the same time [Fig 1]. We check all PD sessions by Sharesource and we perform clinical evaluation status with eVISUS System for medications/monitoring of catheter, PD effluent color and to give instructions for PD training/session management.

Results: On 24 months-25 consecutive pts(14M/11F) with an average age of 73 yrs [Fig 2]. We perform 103 TDsessions with an average duration of 26' mins/each visit. We don't detect any exitSite Infection, Tunnel infection or Peritonits; none of our pts require hospital admission.

Conclusions: Our results shown that TD is safe, reliable and is easy to use for our pts;we assert that technology can help nephrologist to improve PD program and aid patients to overcome barriers to select PD. Teledialysis promote a real integration between Hospital and our territory by a new care pathway.

Caregiver Support on Tablo Home Hemodialysis

Cynthia J. D'Alessandri-Silva,[1] Christopher Gunter,[1] Michael A. Aragon,[1] David E. Henner.[2] *[1]Outset Medical, San Jose, CA; [2]Bershire Medical, Pittsfield, MA.*

Background: The treatment of End-Stage Renal Disease (ESRD) at home can significantly impact daily activities and health-related quality of life (QOL) for patients. With home hemodialysis (HHD), care partners often share in the physical, mental, and social burden of self-care at home. Understanding and quantifying that burden provides opportunity to create technology and develop resources to better support patients and families performing home hemodialysis.

Methods: The HOME Registry Study (NCT04526301) is an ongoing multi-center, prospective, single-arm study investigating clinical and QOL outcomes on patients receiving HHD with the Tablo® Hemodialysis System (Tablo). In this interim analysis, the Care Partner-Net Promotor Score (NPS), Care Partner-Post Training Questionnaire, and Zarit Burden Interview (ZBI) were analyzed to quantify the impact of Tablo training on the care partner's perception of readiness and QOL once home assisting with treatment.

Results: Ninety-nine participants were enrolled into the HOME Registry Study, mean age 57, 73% male, 78% non-Hispanic/Latino, with 70% married or in a domestic relationship, and 50 care partners reporting at baseline. Of care partner responses after completing training, 96% agree or strongly agree with "being satisfied with Tablo training received", 98% agree or strongly agree they are "confident in supporting my partner's dialysis treatment with Tablo System", and 100% of care partners agree or strongly agree with being "satisfied with what is being asked of them as a care partner". At month 12, 100% of responses reported: Sometimes, Rarely, or Never "feeling stressed between caring for their relative and meeting my own responsibilities" and to "feeling that I've lost control of my life since my relatives' sickness". In addition, 89% reported: Sometimes, Rarely, or Never "feeling I don't have enough time for myself due to my relative's HHD". Mean care partner NPS at month 12, reported on a 10 point scale from 1 "not at all likely" to 10 "extremely likely", was 8.94 at month-6 and 8.90 at month-12.

Conclusions: Care partners surveyed in the HOME Registry study report confidence in their training and their ability to care for their loved one with little impact on their own QOL. In addition, based on their experience, care partners of patients on Tablo at home were very likely to recommend Tablo HHD to others.

SA-PO475

Improvement of Depressive Symptoms and Quality-of-Life in Patients on Home Hemodialysis

Cynthia J. D'Alessandri-Silva,[1] Christopher Gunter,[1] Michael A. Aragon,[1] David E. Henner.[2] *[1]Outset Medical, San Jose, CA; [2]Berkshire Health Systems, Pittsfield, MA.*

Background: Patients with end-stage renal disease (ESRD) commonly report depressive symptoms (e.g., feeling hopeless, suicidal thoughts), significantly impacting quality-of-life (QOL) and feelings of self-worth (e.g., feeling like a failure, letting your family down). These symptoms can impact a patient's overall sense of well-being as well as treatment recovery time. The HOME Registry Study (NCT04526301) is a multi-center, prospective, study on patients receiving home hemodialysis (HHD) with the Tablo® Hemodialysis System.

Methods: In this interim analysis of HOME we report results from the Patient Health Questionnaire-9 (PHQ-9), Time-to-Recovery (TTR), and Participant Net Promotor Score (NPS) to quantify the impact of Tablo HHD on participants' mental health and perceived QOL.

Results: 99 subjects were enrolled into the HOME Registry, with mean age of 57, 73% male, 78% non-Hispanic/Latino, and 70% married or in a domestic relationship. PHQ-9 responses from baseline to month-12 are as follows- Q1: no incidence of "feeling down, depressed, or hopeless"- baseline 68%, 12 month 74%; (90% reported this feeling ≤2 times over a 2-week period at 12 months); Q2: no incidence of "feeling bad about yourself-or that you are a failure"- baseline 65%, 12 months 77% (84% reported this feeling ≤2 times over a 2-week period at 12 months). Q3: no incidence of "thoughts that you would be better off dead or hurting yourself"-baseline 89%, 12 months 94%; (7% reporting this feeling ≤2 times over a 2-week period). Over 80% of participants at month-12 reported their HHD making no/some impact on their ability to work, take care of their home and getting along with others. TTR of <60min trended positively over 12 months of HHD, increasing 5.5%. Mean NPS score for likelihood of recommending HHD with Tablo to other ESKD patients on a point scale from 1 "not likely" to 10 "extremely likely" was 9.2 at month-6 and 9.3 at month-12 visit.

Conclusions: HOME Registry patients on Tablo report improvement in depressive symptoms and low time to recovery out to 12 months. At both 6 and 12 months at home performing self-care, patients are extremely likely to recommend home hemodialysis via Tablo to other patients.

SA-PO476

Provider Perspectives on Patient Burnout in Peritoneal Dialysis

Spencer A. King,[1] Karine E. Manera,[2] Jenny I. Shen.[1] *[1]Harbor-UCLA Medical Center, Torrance, CA; [2]The University of Sydney, Sydney, NSW, Australia.*

Background: Peritoneal dialysis (PD) can provide more independence and flexibility for patients compared with in-center hemodialysis (ICHD). However, this self-adminstered home-based modality can also cause burnout, which we define as mental, emotional, or physical exhaustion leading to negative attitudes towards PD. These attitudes can lead to poor outcomes, including depression, increased risk of peritonitis, and transfer to ICHD. We aimed to describe the perspectives on PD burnout by nephrologists with patients on PD.

Methods: We conducted semi-structured interviews of 29 nephrologists with experience with treating patients on PD in Australia, Canada, Columbia, Hong Kong, Japan, New Zealand, Singapore, US, UK, Uruguay, and Thailand from Apr 2017 to Nov 2019. Transcripts were analyzed thematically.

Results: Two major themes were identified that was similar to previous themes noted from a parallel study on patients'/carers' perspectives on burnout. 1) Suffering an unrelenting responsibility: providers viewed their patients and carers being overwhelmed by the daily regimen and bearing alone the burden and uncertainty of what to expect from PD. 2) Adapting and building resilience: providers witnessed patients drawing hope and support from family and finding meaning in other activities. A third theme was coping with the aid of therapy: providers oberved patients and caregivers benefitting from meeting with a psychologist, psychiatrist, social worker and support groups, but also noted that such resources are not always readily accessible.

Conclusions: Nephrologists with patients on PD are aware of burnout among their patients on PD and of means of coping. Further work is needed to identify effective ways for providers, patients, and families to openly communicate about burnout and to more broadly implement interventions to prevent it.

Illustrative Quotes

Theme	Quote
Suffering an unrelenting responsibility	"I think the long PD treatment can cause the patient to feel burnout. And the high frequency of the bag exchange by themselves, many times of the bag exchange cause patients feeling burnout." "If they find that they don't have enough time in their day to do their daily activities as well...they really burnout and they are really down in the dumps."
Adapting and building resilience	"And we see a lot of cases have caregiver burnout...But normally in Asian countries, I think we have a big family. So they can rotate to the other son, or daughter." "But I think having a family, children around for elderly is helpful."
Coping with the aid of therapy	"I think it would be good to have early psychological support or counseling if they, if we find that they're really struggling, because we can only do so much to help them, but we need to be able to refer them early on to a professional that can help, if they're feeling like they're starting to burn out or they're not coping with their diagnosis and their medical conditions, and the burden of debt. Because sometimes it hits them really hard, starting treatment." "And then we don't have a lot of resource. So we have one psychiatrists, but she just retired. And like every centers, we don't have that much help."

SA-PO477

Patient and Care Partner Perspectives on Challenges of Home Dialysis and Interventions to Prevent Dropout

Christina E. Tse,[1] Ayesha Anwaar,[3] Wael F. Hussein,[3] Karine E. Manera,[2] Nicole J. Scholes-Robertson,[2] Jenny I. Shen.[1] *[1]Harbor-UCLA Medical Center, Torrance, CA; [2]The University of Sydney, Sydney, NSW, Australia; [3]Satellite Healthcare, San Jose, CA.*

Background: High rates of transition from home dialysis to in-center hemodialysis (ICHD) place a strain on patients and healthcare systems. We explored patients' and care partners' difficulties with home dialysis and their recommendations to prevent transitioning to ICHD.

Methods: Participants were patients and their care partners who had transitioned from home dialysis to ICHD or were at high-risk for transitioning. Focus groups were conducted via ZOOM Aug 2021-Jan 2022 and analyzed thematically. Participants ranked their top 3 preferred interventions to reduce transitions using nominal group technique.

Results: There were 29 participants: 16 had transitioned (11 patients, 5 care partners) and 13 were on home dialysis (7 patients, 6 partners). They were aged 30-75, 48% female, 45% white, and were on home dialysis <1 to 5 years. 78% had care partners; 45% were employed. Challenges of home dialysis included management of comorbidities, machine issues, prep and dialysis time, storage needs, isolation, dependency on dialysis, and fear of making an error. The top ranked interventions to prevent transitions were in-home assistance, family involvement in modality education, and peer support programs.

Conclusions: Participants identified challenges with home dialysis and expressed the need for further support and education from providers and peers for both patients and their families.

Interventions to prevent transition to ICHD, as ranked by participants

Intervention	Total Ranking Score
In-home assistance	35.5
Family involvement in modality education	23
Peer support program	20
Early & continuous education about life on home dialysis	15.5
Respite care	13.5
Prolonged training or re-training	13
Dialysis prescription change (cycler, fewer hours)	13

Participant reported challenges and interventions

SA-PO478

Capacity Coaching: A Pilot Randomized Trial of a Self-Management Intervention for Patients on Dialysis

Maria B. Mateo, Ricardo J. Loor Torres, Vicky L. Hines, Victor Montori, Maria Lourdes Gonzalez Suarez, Kasey Boehmer. *Mayo Foundation for Medical Education and Research, Rochester, MN.*

Background: End Stage Kidney Disease (ESKD) patients are trusted to handle numerous healthcare tasks associated with managing their disease, often overwhelming their capacity. This can lead to poor health outcomes and increased healthcare use. Capacity Coaching (CC) aims to bolster patients' ability to manage their treatment load. This pilot study evaluates the feasibility of CC in ESKD care and its potential effects on clinical and patient-reported outcomes (PROs).

Methods: This randomized mixed-methods pilot trial involved English-speaking adult ESKD patients receiving in-center or home dialysis care at a large academic medical center. Intervention consisted of 6 CC sessions with a board-certified wellness coach embedded in their clinical care plan. Clinical outcomes included hospitalizations, Emergency Department (ED), primary care (PC) visits, shortened or missed dialysis sessions, interdialytic weight, and serum albumin levels. PROs analyzed included treatment burden, self-efficacy, fatigue, emotional distress, and illness intrusiveness. Mixed models were used, adjusting for fixed effects of arm, time (baseline, 3 and 6 months), their interaction, and the random effect of the patient. Secondary analysis results were adjusted based on adherence to the intervention (≥ 3 CC sessions) using the FREQ procedure.

Results: Of the 93 patients approached, 33 consented and were randomized (16 to CC, 17 to usual care [UC]). Of the 16 patients randomized to CC, 11 were adherent to the intervention. CC was feasible within the team, with patients attending an average of 3.6 (SD 2.13) sessions overall, and 4.8 (SD 1.17) when adjusted for adherence. CC patients had fewer ED visits compared to the control group in the overall analysis (p=0.03), with increased significance when adjusted for adherence (p=0.008). While CC showed reduced shortened and skipped dialysis sessions, this was not statistically significant. Moreover, fatigue was significantly decreased (p=0.047) in the CC arm compared to the UC arm when adjusted for adherence.

Conclusions: Capacity Coaching appears effective in reducing ED visits and fatigue for ESKD patients who adhere to the intervention, suggesting its potential for larger trials. The pilot highlights the need for improved patient-reported outcome data collection.

SA-PO479

Psychosocial Barriers to and Enablers of Peritoneal Dialysis Utilization: A Literature Review

Janice J. Tng, Melissa Chew. *Woodlands Health, Singapore, Singapore.*

Background: With an ageing population comes the concomitant increase in Chronic Disease prevalence. In Singapore, most patients with End-Stage Renal Disease (ESRD) are on Haemodialysis (HD). Peritoneal Dialysis (PD) take-up rate is rather low at 21% of the total number of dialysis patients compared to other countries. Our Ministry of Health aims to boost PD uptake to 30% by 2025. With rising ESRD prevalence and insufficient HD centres to meet demand, it is crucial for patients to opt for PD. This review aims to identify the psychosocial barriers and enabling factors to PD, service gaps and areas for improvement.

Methods: Medline (OVIDsp) and the Cumulative Index to Nursing & Allied Health Literature databases were used to find studies published in English from year 2000 to present, using relevant key words. Reference lists of selected studies were also perused for relevant literature.

Results: 18 studies were selected from databases and 11 met the inclusion criteria. Of these, 6 relevant studies were chosen from the reference lists. A total of 17 studies were reviewed - 3 analytical studies, 1 cross-sectional survey, 2 literature reviews, 4 observational studies, 1 prospective study and 6 qualitative studies. Lack of social support or PD caregiver are common reasons for choosing HD, especially those who are unable to perform PD on their own. Fear is a salient theme - fear of the failure to perform PD adequately to prevent infection and medical complications, and the fear of social isolation. PD is usually done at home while HD allows for social interactions at the HD centres. Patient's health beliefs and insight into their health are enablers to increase PD uptake. Performing PD allows a sense of perceived control as it is done independently in the comforts of their home. Regular reviews by the hospital's renal team and external PD nurse can motivate patients to cope better and helps the healthcare team to build relationships with patients.

Conclusions: Dialysis is physically demanding and emotionally intensive. There are many factors that influence patients' decision-making when it comes to choosing a dialysis modality and psychosocial factors play a major role. Reducing barriers and increasing enablers can help boost PD uptake. Majority of the existing literature focuses on barriers to PD and this is a good chance for further research to better understand the psychosocial enablers to PD.

SA-PO480

Caregiver's Word Choices, Definitions, Roles, and Functions in Peritoneal Dialysis Caregiving: A Systematic Scoping Review

Piyawat Kantagowit,[1] Krit Pongpirul,[2] Talerngsak Kanjanabuch.[3]
[1]Chulalongkorn University Faculty of Medicine, Bangkok, Thailand; [2]King Chulalongkorn Memorial Hospital Department of Preventive and Social Medicine, Bangkok, Thailand; [3]King Chulalongkorn Memorial Hospital Division of Nephrology, Bangkok, Thailand.

Background: Caregivers are vital in peritoneal dialysis (PD) care, with the understanding and classification of PD self-care tasks crucial in defining caregiver roles. Due to inconsistencies in the existing literature, we conducted a systematic exploration of the variations surrounding the term 'caregiver' in PD studies.

Methods: We conducted a thorough systematic search using PubMed, Embase, and CENTRAL databases for English-language studies relevant to caregiver support for PD patients up to June 2, 2023. Our analysis focused on word choices, definitions, caregiver identities, and their associated functions.

Results: Out of 4,130 potential studies, 468 articles were screened, of which 177 met the criteria. These studies involved 102,180 patients across 38 countries. 'Caregiver(s)' was used in 88.7% of studies, 'carer(s)' in 15.3%, and other terms in 11.3%. Multiple terms were found in 15.3% of studies. However, only 8.5% provided explicit definitions. Caregiving roles were referenced in 53.7% of studies, primarily identifying parents (38.4%), spouse (33.9%), other family members (33.9%), descendants (31.1%), non-relative non-healthcare workers (21.5%), friends (15.8%), and healthcare workers (14.1%). Functions were delineated in 38.4% of studies, with PD-specific tasks in 33.3%, instrumental activities of daily living (IADLs) in 9.0%, and basic activities of daily living (ADLs) in 7.3%.

Conclusions: Our findings reveal a wide variability in definition and scope of PD caregivers across studies. To facilitate accurate assessment of PD caregiver impact and inform policy development, we advocate for consistent definitions and detailed functional descriptions within the field.

Summary of Key Findings and Proposed Components Defining a Peritoneal Dialysis Caregiver

Component	Key Findings
Word Choice	'Caregiver' was the most used term (89%) 27 studies (15%) used more than one term for 'caregiver'.
Definitions	Only 15 out of 177 studies provided a definition.
Persons Performing Caregiving	Approximately 46% of studies did not specify.
Functions	Only 38% of studies mentioned caregiver functions. Most studies identified caregivers based on PD-specific tasks (87%).
Additional Findings	Certain studies grouped patients and caregivers together.
Suggestions	Use consistent terminology with clear, detailed definitions. Address caregivers separately from patients.

Abbreviations: PD, Peritoneal dialysis.

SA-PO481

Effects of Shared Decision-Making on the Prognosis of Patients with Peritoneal Dialysis

Hark Rim,[1,2] Byeonghwa Bak,[1,2] Ye na Kim,[1,2] Ho Sik Shin,[1,2] Yeonsoon Jung.[1,2] *[1]Kosin University Gospel Hospital, Busan, Republic of Korea; [2]Transplantation Research Institute, Kosin University College of Medicine, Busan, Republic of Korea.*

Background: Patients with chronic kidney disease (CKD) require shared decision-making (SDM) processes when choosing a dialysis method. Peritoneal dialysis (PD) guarantees patient autonomy; thus, SDM is even more important. Based on these findings, we aim to highlight the benefits of PD and increase the rate in which patients choose PD. In order to increase the rate of PD implementation, patients must actively participate in dialysis decisions, and SDM process is necessary between doctors and patients. So, we investigated the effect of SDM on the prognosis of patients with CKD. We focused on the effects of SDM on patient death, survival rates, hemodialysis conversion, emergency room visits, hospitalization days, and outpatient visits. The results of this study suggest that SDM has a positive impact on increasing the number of patients who choose PD and reduce unneccessary medical cost

Methods: Among patients with chronic kidney failure from eight hospitals in Korea who started dialysis, 256 who participated in a pilot project for home management of PD were included in the present study. A mixed-methods study was conducted using questionnaires and semi-structured interviews. Our study focused on the effects of SDM on patient death, survival rate, hemodialysis conversion, emergency room visits, hospitalization days, and outpatient visits.

Results: A significant difference was observed in the number of days of hospitalization per admission ($p = 0.0044$) between the SDM and non-SDM groups. However, no significant differences were observed in survival rate, rate of conversion to hemodialysis (HD), survival rate after conversion to HD, emergency room visit rate, number of hospitalizations per patient, outpatient visit rate, medical cost, hospitalization cost, outpatient cost, and phosphate-binding agent prescription rate.

Conclusions: The number of hospitalization days per admission decreased throughout the SDM process. Continued communication between patients and medical staff on how to manage PD in the long term after making the decision to undergo dialysis will be beneficial in promoting the home management of PD patients.

Table 1
Basic characteristics of patients with educational counseling for dialysis type confirmation.

		Shared decision making (IBS11)
Number		408
Age (yr)		58.9 ± 13.3

SA-PO482

Addressing Cognitive Impairment in Peritoneal Dialysis: A Systematic Review of Prevalence, Risk Factors, and Outcomes

Noppawit Aiumtrakul,[1] Charat Thongprayoon,[2] Pitchaporn Yingchoncharoen,[5] Chalothorn Wannaphut,[1] Supawadee Suppadungsuk,[2,3] Pajaree Krisanapan,[2,4] Wisit Cheungpasitporn.[2] *[1]Department of Medicine, John A. Burns School of Medicine, University of Hawaii, Honolulu, HI; [2]Division of Nephrology and Hypertension, Department of Medicine, Mayo Clinic, Rochester, MN; [3]Chakri Naruebodindra Medical Institute, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Samut Prakan, Thailand; [4]Department of Internal Medicine, Faculty of Medicine, Thammasat University, Pathum Thani, Thailand; [5]Department of Medicine, Texas Tech University Health Sciences Center, Lubbock, TX.*

Background: Cognitive impairment (CI) is a critical complication in peritoneal dialysis (PD), associated with increased hospitalization and mortality rates. Despite its significant impact, the prevalence and consequences of CI in PD patients are not well understood. This study aimed to determine the prevalence, risk factors, and outcomes of CI in PD.

Methods: We performed systematic reviews in OVID Medline, Embase, and Cochrane databases until January 2024 to identify cross-sectional and cohort studies on CI (identified by cognitive exams) in PD patients. Data on sample size, mean age, sex, prevalence of CI, risk factors, and outcomes were extracted. Pooled meta-analysis of prevalence was performed using a random-effects model. Risk factors for CI were ranked based on odds ratios (ORs) and other available metrics. Longitudinal studies were analyzed for objective data on CI-related outcomes. The protocol was registered in the International Prospective Register of Systematic Reviews (CRD42024526057).

Results: A total of 19 studies were identified, involving 2,882 PD patients. The weighted mean age was 55.02±9.42 years, and 52.38% of participants were male. The pooled prevalence of CI in PD patients was 47.7% (95% CI: 35.8-59.9%). Continuous Ambulatory PD (CAPD) (OR=7.7), depressive symptoms (OR=7.67), being female (OR=3.3), diabetes mellitus (DM) (OR=1.67), older age (OR=1.1), and fewer years of education (OR=0.78) were identified as significant risk factors for CI. Multiple linear regression showed that Automated PD (R^2 =0.64) and Serum Na (R^2=0.56) were significantly associated with a decline in MoCA score. Cohort studies found that CI was significantly associated with higher rate of hospitalizations (HR=1.96) and peritonitis (HR=1.51), compared to those without CI. However, there was no difference in mortality in PD with CI, compared to non-CI groups (HR=0.58-1.18).

Conclusions: CI is common and appears to be underrecognized in PD patients. CAPD, depression, female, age, and DM are major risk factors for CI. CI in PD is associated with an increased rate of hospitalization and peritonitis. Further research is needed to establish standardized cognitive exams and guidelines for the timely management of risk factors of CI in PD patients.

SA-PO483

Patient Perspectives on Incremental Peritoneal Dialysis: A National Survey

Jeffrey Perl,[1,2] Arti Dhoot,[3,2] Michael Spigler,[5] Bruce M. Robinson.[4]
[1]St Michael's Hospital, Toronto, ON, Canada; [2]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; [3]Sunnybrook Health Sciences Centre, Toronto, ON, Canada; [4]University of Michigan, Ann Arbor, MI; [5]American Kidney Fund, Rockville, MD.

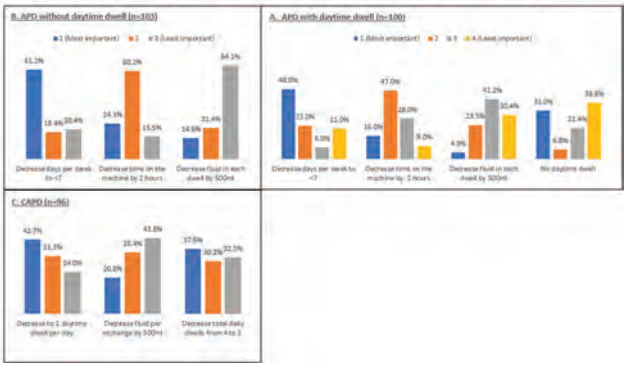
Background: Incremental peritoneal dialysis (PD) may improve quality of life, reduce therapy burden and ease transition to PD. Incremental approaches for automated PD (APD) include: less than 7 days a week, carrying no daytime dwell, reduced dwell volumes or less time on the cycler. For CAPD, decreasing the exchange frequency or reducing dwell volumes are also strategies. We sought to understand patient preferences for various strategies via the dissemination of a national survey to individuals on PD.

Methods: A pilot tested, anonymous, voluntary survey was administered in Aug-Sep 2023. The American Kidney Fund (AKF) distributed the survey via an online link to those receiving charitable assistance from AKF, social media platform, and AKF's monthly newsletter. The survey was for those over 18 years, on PD now or in the past year, and the goal was "to learn about ways that PD can help patients have a good quality of life". Descriptive results were analyzed.

Results: Of the 564 respondents, 9.6% were aged 18- 39 years, 75.9% between 40-69 years and 23.8% over 70 years with 59.1% females, 62.5% Caucasian, and 15.5% identifying as black. PD was initiated ≤1 year in 35.1% of patients. Within 6 months of PD-start, 70.6% of patients reported performing PD treatment 7 days a week. Patients ranked various initial preferred PD prescriptions between 1-4, with 1 as most important as shown in figure 1. Less days of PD treatment per week consistently emerged with the highest priority rankings (ranging from 48- 61.2%) among those receiving APD versus reducing to a single daily dwell for CAPD (42.7%).

Conclusions: Patients value less days of PD treatment per week or a single daily exchange over other approaches to incremental PD. Days off from PD as a strategy is currently underutilized in most patients at time of PD initiation. Further research should evaluate the safety and feasibility of providing these prescription variations in select incident individuals.

Figure 1: Ranked patient responses to the following APD/CAPD prescription changes in order of importance to their quality of life.



SA-PO484

Assessing Global and Regional Interest in Home Dialysis Modalities, 2004-2024

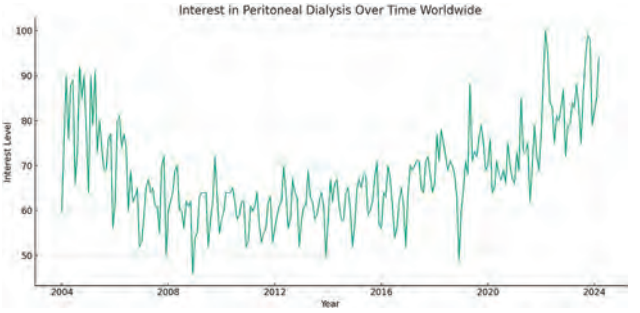
Paul W. Davis,[1] Charat Thongprayoon,[1] Jing Miao,[1] Supawadee Suppadungsuk,[1,2] Iasmina Craici,[1] Wisit Cheungpasitporn.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Chakri Naruebodindra Medical Institute, Samut Prakan, Thailand.*

Background: Home dialysis, including peritoneal dialysis and home hemodialysis, represents crucial renal replacement therapy options for patients with end-stage kidney disease. With the internet becoming a primary source for healthcare information, this study aimed to analyze global and regional interests in home dialysis using Google Trends™ data from January 2004 to March 2024.

Methods: A comprehensive analysis was conducted using Google Trends™ with the search terms "Peritoneal Dialysis" and "Home Hemodialysis." The study extracted worldwide trends and detailed regional interests within the United States. Interest levels were quantitatively assessed based on Google Trends™ indices, providing insights into temporal patterns and geographical distributions of public interest.

Results: The study found fluctuating global interest in PD, with a peak in March 2022 and the lowest interest in December 2008. The most recent data from March 2024 showed a significant interest level of 94, indicating a recent upward trend. Notably, Mexico exhibited the highest relative interest in PD. Within the United States, Tennessee demonstrated the highest interest. For Home Hemodialysis, peak interest was recorded in July 2004, with the most recent data from March 2024 showing a modest increase in interest. The United States led in relative interest for Home Hemodialysis, followed by Australia, Canada, and the United Arab Emirates. Mississippi was the state with the highest interest within the United States.

Conclusions: This study offers crucial insights into the global and regional landscape of interest in home dialysis modalities, highlighting the significance of leveraging online platforms to increase public awareness, education, and engagement in peritoneal dialysis and home hemodialysis. By understanding the temporal and geographical patterns of interest, healthcare providers, policymakers, and patient advocacy groups can develop targeted strategies to promote the benefits of home dialysis, address knowledge gaps, and improve access to these life-sustaining treatments.



SA-PO485

What Are the Keys to Promoting Home Dialysis in a Country Where In-Center Hemodialysis Is Highly Developed?

Ikuto Masakane. *Yabuki Byoin, Yamagata, Japan.*

Background: In the past decade, the promotion of home dialysis has been recognized as a pressing global issue for several view points; to reduce the medical costs for chronic dialysis, to improve the accessibility to dialysis therapy, and to avoid "dialysis-related pandemic" which was recognized during the COVID-19 pandemic. Another aspect of promoting home dialysis is to create a home care environment for chronic kidney disease patients in the highly aging society. However, Japan's rate of home dialysis, peritoneal dialysis (PD) and home hemodialysis (HHD) remain the lowest of the countries listed in the USRDS annual reports. The aim of this study is to clarify the keys to promoting home dialysis in Japan where in-center HD has highly developed.

Methods: The data about home dialysis was extracted from the Japanese Society for Dialysis Therapy Renal Data Registry. The data of reimbursement was referred to those of our facilities. The data was evaluated in relation to the social and reimbursement events.

Results: As of the end of 2022, the total number of chronic dialysis patients was 347,474, and 10,531 (3.0%) patients were treated by PD including 2,138 patients, and 827 (0.2%) patients. The number of PD patients had increased until 1997, but plateaued until 2020. It seemed to be the result from the shock of the life-threatening complication of PD, encapsulating peritoneal sclerosis. After the installation of an additional payment for providing proper options of renal replacement therapy, the number of PD patients are gradually increased. The number of HHD patients had been around between 100 and 150 until 1997, but it suddenly dropped because of the penalty to the doctor and the facility for false billing suspicion. Since government reimbursement for HHD was installed in 1998, the HHD patients have gradually increasing, and it was accelerated by the two positive revisions of reimbursement for HHD. There are several regulations to limit the promotion of both PD and HHD.

Conclusions: The government policy, proper reimbursement and deregulation of certain regulations are important key to promote home dialysis in countries where in-center HD was highly developed.

SA-PO486

Enhancing Peritoneal Dialysis Access: Overcoming Catheter Insertion Barriers for Patients Who Are Older or Have Obesity

Michael Corr,[1] Stephen O'Neill.[2] *[1]Queen's University Belfast, Belfast, United Kingdom; [2]Belfast City Hospital, Belfast, United Kingdom.*

Background: With rising numbers of patients with end-stage kidney disease, peritoneal dialysis PD is a cost-effective alternative to haemodialysis (HD), aligning with international goals for home-based dialysis. Our study aimed to demonstrate how access to PD was successful expanded in our region, particularly for older frail patients and those with obesity, populations typically underrepresented in PD due to perceived risk of complications from catheter insertion.

Methods: Changes included appointing a PD surgical lead and having a dedicated interventional radiologist for fluoroscopically guided PD catheter insertion. Data were prospectively collected on all patients who had a PD catheter inserted in 2020-2022. Patient demographics, insertion techniques, and outcomes up to 1-year post insertion were summarised. Additionally, a comparison was made between outcomes of PD catheter insertion in patients with and without obesity.

Results: The annual number of PD catheter insertions doubled following service change. Patients receiving percutaneous insertions and able to avoid anaesthesia were older (median age 76 vs. 56, $p < 0.0001$) and had less previous abdominal surgery (25% vs. 54%, $p=0.05$. Outcomes showed a primary patency rate of 85%, primary assisted patency of 94%, and secondary patency of 97%. For patients with obesity, primary and primary-assisted patency rates were similar to those without obesity. However, individuals with obesity exhibited lower secondary patency rates. Patients with obesity showed a trend towards higher transfer rates to haemodialysis within the first-year post-insertion.

Conclusions: We have effectively doubled the annual incident PD population in our region, including older, frailer patients and those with obesity. This study highlights the

benefits of a flexible, multi-faceted approach to PD catheter insertion, improving access and offering an effective alternative to HD for a wider range of patients. The inclusion of laparoscopic and fluoroscopically guided techniques allowed a tailored approach, ensuring appropriate patient selection and timely catheter insertion. Our results suggest that such reconfigurations can significantly enhance PD accessibility, benefiting both patients and healthcare systems.

SA-PO487

Development and Validation of a Formative Objective Structured Clinical Examination (OSCE) Assessing Home Hemodialysis (HHD) Clinical Skills

Jason A. Jones,[1] Trevor W. Tobin,[6] Maria Bermudez,[2] Gregory L. Braden,[3] Nupur Gupta,[4] Evan I. Fisher,[1] Daniel L. Landry,[3] Robert Nee,[1] Bret N. Pasiuk,[5] Christina M. Yuan.[1] Nephrology Education Research and Development Consortium. *[1]Walter Reed National Military Medical Center, Bethesda, MD; [2]Geisinger Medical Center, Danville, PA; [3]Baystate Medical Center, Springfield, MA; [4]Indiana University School of Medicine, Indianapolis, IN; [5]SSM Health Care of Wisconsin, Fond du Lac, WI; [6]Eisenhower Army Medical Center, Fort Gordon, GA.*

Background: The Accreditation Council for Graduate Medical Education(ACGME) requires that graduating nephrology fellows demonstrate competence in HHD. Because low patient numbers may lead to gaps in training, there is an opportunity to enhance clinical experience using simulation. We designed a case-based formative OSCE assessing clinical care of an uncomplicated patient initiating HHD.

Methods: The blueprint, test and rubric were developed by a nephrology fellow, an academic nephrologist, and 4 nephrologists practicing HHD (2 academic, 2 community-based). It was further refined by a 9-member test committee: 5 in HHD practice; 5 in academic nephrology; 1 in regulatory administration; 1 nephrology fellow (who had been a HHD partner). The final test consisted of 27 items (31 points), 4 (10 points) of which were evidence based. Median time in practice: 12 years. Pass threshold was set at 20/31 points (with one possible negative point). 3/27 items were assessed as "hard", the others were of "medium" to "easy" difficulty. Median relevance for all items was "important" or "essential", with a test content validity index of 0.84.

Results: 11 validators, all board-certified, 4 with outpatient HHD practices, took the test. Median years of practice: 10 (range 3-35) All passed: percentage correct 77-97%, mean score 28 ± 2 points. Inter-grader agreement was high; Kappa: 0.83 (95% CI 0.667-0.992). 24 fellows at 4 programs have thus far taken the test, 15 have been graded. 100% (15/15) passed (percentage correct 65-89%); mean score 24 ± 1 points. 73% (8/11) validators vs. 80% (12/15) fellows correctly indicated 4 benefits/2 risks associated with HHD, 64% (7/11) vs. 27% (4/15) correctly defined minimum recommended standard weekly Kt/V, 91% (10/11) vs. 87% (13/15) correctly defined flow fraction, and 100% (11/11) vs. 80% (12/15) described risks associated with buttonhole cannulation.

Conclusions: The HHD OSCE may be used as a formative assessment of fellow knowledge and confidence in prescribing HHD. Disclaimer: The views expressed are those of the authors and do not necessarily reflect the official policy of the Department of Defense or the U.S. government.

SA-PO488

Home Hemodialysis (HHD) Practice and Curriculum Recommendations among Graduates of a Training Program without a HHD Clinic Experience

Andrew J. Howard,[1] Nupur Gupta,[2] Christina M. Yuan.[1] *[1]Walter Reed National Military Medical Center, Bethesda, MD; [2]Indiana University School of Medicine, Indianapolis, IN.*

Background: The 2019 Advancing American Kidney Health initiative set a goal for ≥ 80% of new ESRD patients to receive home dialysis or kidney transplant by 2025. Home hemodialysis (HHD) rates have remained low (about 15K patients in the U.S.) and not evenly distributed between states. One barrier to increasing HHD prevalence may be a lack of familiarity among nephrologists, and lack of sufficient training during nephrology fellowship.

Methods: We performed an anonymous survey of 92/94 graduates of the Walter Reed program (1984-2023) regarding their HHD practice and training. The program's home dialysis program is limited to peritoneal dialysis patients, and HHD training is limited to didactics and training with machines used for low-flow home dialysis. The survey was conducted from 12/4/2023-2/4/2024.

Results: 52/92 (57%) responded with 50/52 (96%) completing the survey. All were in clinical practice. 75% (38/51) had been in practice ≦20 years. 43% (22/51) had (or had at one time) an HHD practice, and 54% (12/22) had been HHD directors/co-directors. Of those who practiced HHD, 73% (16/22) had started within the last 10 years. The majority of HHD practitioners were in the southern (50%) or western (23%) U.S., and 32% had rural practices. 54% (12/22) followed 6-10 patients. "On the job" training (68%) was the predominant way they reported learning HHD skills. Barriers most commonly cited by HHD practitioners were lack of patient interest (41%), lack of patient partners (27%), and lack of nursing staff to train patients (27%). Respondents indicated that the minimum effective curriculum to achieve HHD competence should include block/longitudinal HHD clinic (84%), familiarization with HHD machines (82%), didactic lectures (80%), and training in effective counselling for HHD (80%).

Conclusions: Among graduates of a training program without an HHD clinical experience, 43% reported subsequently practicing HHD. The majority learned their skills "on the job". Overall, graduates felt that a block/longitudinal HHD clinic was the most effective way for fellows to learn HHD skills during training. Disclaimer: The views expressed in this abstract are those of the authors and do not necessarily reflect the official policy of the Department of Defense or the U.S. government.

SA-PO489

Assessment of Body Composition by Whole-Body Bioimpedance and Body Cardio Scale in Patients on Peritoneal Dialysis

Jun Yi,[1] Fansan Zhu,[1] Laura Rosales M.,[1] Lela Tisdale,[1] Maricar Villarama,[2] Valeria Gusmao Bittencourt,[1] Barbara M. Murphy,[1] Amir Golnabi,[1] Peter Kotanko.[1,3] *[1]Renal Research Institute, New York, NY; [2]Mount Sinai Health System, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Quantitative assessment of body composition is important for optimizing individualized treatment regimens in peritoneal dialysis (PD) patients. This study aims to compare body composition using the body cardio scale (BCS) and whole-body bioimpedance based on a body composition model (BCM).

Methods: Nine PD patients (6 males, age 50.1±12.8 years) were stuided. BCS (Withings) was used (Fig.1) with the patient standing on the scale. Total body water (TBW_{BCS}), fat (Fat_{BCS}), and muscle mass (MM_{BCS}) were provided. Whole body bioimpedance spectroscopy (Hydra 4200) was used to estimate extracellular (ECV) and intracellular (ICV) volume. Four electrodes were donned on the hand and foot (Fig 2). Overhydration (OH), fat (Fat_{BCM}), muscle mass (MM_{BCM}) andTBW_{BCM} (ECV+ICV) were calculated (Chamney, Am J Clin Nutr 85:80-9, 2007). Linear regression analysis and Bland-Altman plots were applied to evaluate the correlation and agreement between BCS and BCM.

Results: A strong correlation was observed between TBW_{BCS} and TBW_{BCM} (R^2=0.94, p<0.0001), with a minor bias (0.67±2.47 kg) (Fig.3a and 3b). Fat_{BCS} and Fat_{BCM} were also highly correlated (R^2=0.97, p<0.0001), albeit with a substantial negative bias (-12.06±7.92 kg) which inversely correlated with fat mass (Fig.3c and 3d). MM_{BCS} correlated reasonably well with MM_{BCM} (R^2=0.82, p<0.001), but MM_{BCS} overestimated muscle mass (bias, 12.75±4.68 kg) (Fig.3e and 3f). Furthermore, BCM indicated the degree of overhydration (OH =1.47±2.0 kg).

Conclusions: While BCS offers easy-of-use and no specific electrodes, the big biases limit its applicability in dialysis patients. The bias may be attributed to a calculation of fat-free mass (FFM) by a general formular (FFM=TBW/0.73) which may not be appropriate for dialysis patients. We refrain from recommending it as a precise assessment of body composition in dialysis patients.

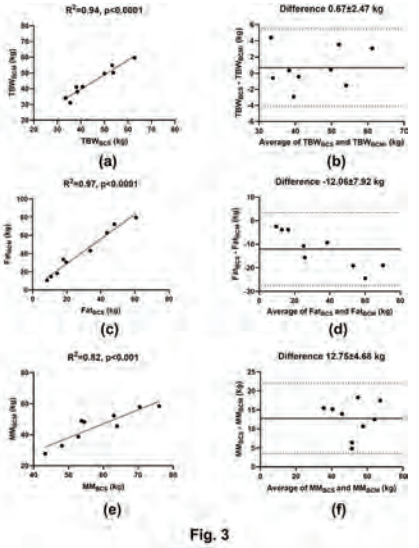

Fig. 3

SA-PO490

Reversible Encephalopathy after Exposure to Glyphosate-Based Herbicide (GBH) in a Patient with ESKD

Joseph H. Brezin. *Drexel University College of Medicine, Philadelphia, PA.*

Introduction: GBH are known to be neurotoxic and often lethal following ingestion. Environmental exposure leads to respiratory and transdermal absorption and prompt renal elimination. However, GBH may be toxic in patients with CKD.

Case Description: A 60 year old man with ESKD attributed to diabeties presented to the ER with progressive symptoms of speech apraxia, jerking movements of his upper extremities, and an unsteady gait over the past five days. Fully compliant with CCPD for the past 11 months; recent weekly Kt/V was 1.95. No history of fever, trauma, foreign travel, or substance abuse. Medications: vitamins, calcium acetate, omeprazole, and antihypertensives. He prepared 2 gallons of RoundUp in his garage and sprayed his property for 30-60 minutes wearing a surgical mask 36 hours befor symptoms arose. Exam: 78 kg man with normal vital signs. Oriented to person and place; responded slowly to simple questions without dysarthria or aphasia; positive myoclonic jerkes of extremities, asterixis, and unsteady gait. Rest of neurological and general exam was unremarkable. BUN 43 mg/dL, creatinine 12.8 mg/dL, normal electrolytes; Hemoglobin 13.3 gm/dL, WBC 16,500 /uL, normal differential. Glucose 124 mg/dL, ammonia <9 umol/L TSH 0.78 mIU/mL. CT, MRI/MRA of brain without acute findings. CSF clear with 3 WBC's, 112 RBC's, protein concentration 74 mg/dL (15-45), and glucose 78. PCR panel negative for CNS pathogens. Urine drug screen negative. He was empirically given loading doses of IV acyclovir and piperacillin-tazobactam after the LP and then underwent 4 hours of high efficiency hemodialysis for presumed glyphosate neurotoxicity. He was sedated during the LP and line placement but awakened within 30 minutes and manifested myoclonic jerks and slow speech. These symptoms abated throughout the treatment and he was able to speak in complete sentences and drink a cup of water without difficulty by the end of dialysis. A full neurologic recovery was noted the following morning and he walked without assistance. He received another hemodialysis treatment and was discharged to resume nocturnal PD. An assay for serum levels of glyphosate was not available.

Discussion: Glyphosate is a glycine based substance with MW 169 daltons. It binds to the NMDA receptor leading to calcium influx and excititoxicity. Heavy routine household exposure in a PD patient led to an encephalopathy consistent with this pathway.

SA-PO491

Revisiting the Urinary Anion Gap: A Sound Concept during Hyperchloremic Metabolic Acidosis

Bilal Khan Mohammed, Ahmed Ismail, Mohammed Z. Rehman, Robert M. Rosa, Daniel Batlle. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: The urine anion gap (UAG) has been used since the late 80s with the primary idea of estimating if urine ammonium (NH_4^+) increases appropriately, as in patients with hyperchloremic metabolic acidosis MA of gastrointestinal etiology, or not as in patients with with distal renal tubular acidosis or chronic kidney disease in whom its excretion is markedly diminished. The use of the UAG as a marker of urinary NH4+ has been criticized because there is a very poor correlation between urine NH_4^+ and UAG in large databases. Here we go over the concept of the UAG measured as the difference in unmeasured anions (UA) and unmeasured cations (UA) to illustrate how in MA a robust rise in NH4+ results in a corresponding fall in the UAG.

Methods: We used published data from Leman et al (JCI, 1966, many years before the UAG was introduced) where all the anions and cations were measured before and after MA induced by NH_4Cl. This way, the UAG could be calculated using measured anions and compared to the the calculated by the formula UAG = $(Na^+ + K^+) - Cl^-$. The following are the reported mean values (mEq/day): **NH_4^+: Before NH4Cl = 28, NH_4Cl = 171 Ca^{++}:** Before NH4Cl = 4, NH4Cl = 7 **Mg^{++}:** Before NH4Cl = 11, NH_4Cl =12 **SO_4^{--}:** Before NH4Cl = 34, NH4Cl = 38 **OA:** Before NH4Cl = 29, NH4Cl = 27 **PO_4^{---}:** Before NH4Cl = 20, NH_4Cl=23

Results: Based on the principle of electroneutrality, the sum of all anions and all cations should be equal; $(Cl^- + HCO_3^-) + (UA) = (Na^+ + K^+) + (UC)$ After rearranging, **= UA – UC = $(SO_4$+P+OA) – (Ca+Mg+ NH_4) = Measured UAG** Before NH4Cl = (34 + 20 + 29) – (4 + 11 + 28) = 40 NH_4Cl = (38 + 23 + 27) – (7 + 12 + 171) = -105 **Calculated UAG = $(Na^+ + K^+) - Cl^-$** Before NH4Cl = (127 + 49) – 135 = 41 NH_4Cl = (136 + 67) – 316 = -113

Conclusions: Ammonium chloride induced MA in normal people results in a marked decrease in the UAG, both measured and calculated, that matches perfectly the induced increase in urine NH4+ excretion. Such perfect correlation, is not seen or expected in the clinical setting where other changes in urine anions and cations take place but the UAG still roughly reflects if there is or not an increase in ammonium excretion in response to hyperchloremic MA supporting its use as an initial diagnostic tool.

SA-PO492

The Citrate and Oxalate Association Is Likely Driven by Diet

Megan Prochaska, Elaine M. Worcester. *University of Chicago Division of the Biological Sciences, Chicago, IL.*

Background: Higher urine oxalate excretion has been associated with higher urine citrate excretion. The mechanism for this association may be due to simultaneous dietary intake oxalate and citrate in food or transporter linkage of SLC26A6 and NaDC1 in the kidney.

Methods: Nineteen participants were admitted to the clinical research center and given sodium oxalate. Timed pre-sodium oxalate (3) and post-sodium oxalate (6) urine samples were collected every hour. Fourteen participants also consumed a low oxalate, low citrate breakfast at the time of the sodium oxalate and 5 participants remained fasting for the duration of the protocol. Means of baseline values and ratios of oxalate (mmol)/creatinine (mg) and citrate (mmol)/creatinine (mg) were calculated. Mean and standard error were graphed per period and mixed methods longitudinal models were generated to compare change over time versus pre-oxalate value (mean 3 values, Period 1).

Results: Ten of the 19 participants were female with mean age 54 years. For the 14 who had breakfast, urine oxalate/creatinine was higher than baseline in periods 3, 5, and 6 and urine citrate/creatinine was higher than baseline in periods 4 and 5 (Figure 1A and 1B). For the 5 who had no breakfast, urine oxalate was higher than baseline in periods 3, 5, 6, and 7 and urine citrate did not increase above baseline in any period (Figure 2A and 2B).

Conclusions: After consumption of sodium oxalate participants had a rise in urine oxalate excretion, as expected. However, only participants who had food at the time of sodium oxalate administration also had a rise in urine citrate. The association between oxalate and citrate excretion is likely driven by dietary intake though additional participants need to complete the protocol.

Association of Dietary Acid Load and Its Dietary Sources with Aciduria in Community-Dwelling Japanese Adults

Keiko Kabasawa,[1] Michihiro Hosojima,[1] Hideyuki Kabasawa,[1] Ribeka Takachi,[2] Kazutoshi Nakamura,[1] Junta Tanaka,[1] Ichiei Narita,[1,3] Yumi Ito.[1] *[1]Niigata University, Niigata, Japan; [2]Nara Women's University, Nara, Japan; [3]Niigata Institute for Health and Sports Medicine, Niigata, Japan.*

Background: The composition of certain diets, such as contemporary Western diets, leads to chronic subclinical metabolic acidosis, which can lead to urine acidification. Methods for estimating dietary acid load have been established in Western countries, but such estimates have not been fully evaluated in Asian populations, which have different dietary habits. Here, we evaluated associations of dietary acid load and the corresponding nutrient compositions with aciduria.

Methods: This study was based on data from a Japanese community-based cohort comprising 6,274 adults aged ≥40 years, 51.0% women). We cross-sectionally assessed dietary acid load and aciduria (spot urine pH <6.0). Dietary acid load was estimated by net endogenous acid production (NEAP) score and its components, calculated from energy-adjusted nutrients based on a validated food frequency questionnaire. Associations with aciduria were analyzed by using multivariable logistic regression analysis with adjustment for potential confounders.

Results: Median NEAP and eGFR were 38.8 mEq/day and 74.0 mL/min/1.73m^2, respectively. Higher NEAP was significantly associated with aciduria (P for trend <0.001, Figure). When intake of dietary protein and protein sources were analyzed separately from potassium, higher potassium intake showed a significant inverse association with aciduria, while relatively high animal protein intake, but not total protein, was positively associated with aciduria (both P for trend <0.05, Figure).

Conclusions: Our findings suggest that estimated diet-dependent net acid load was associated with aciduria, and low potassium intake and relatively high animal protein out of total protein intake may be contributors to aciduria in Japanese community-dwelling adults.

Funding: Government Support - Non-U.S.

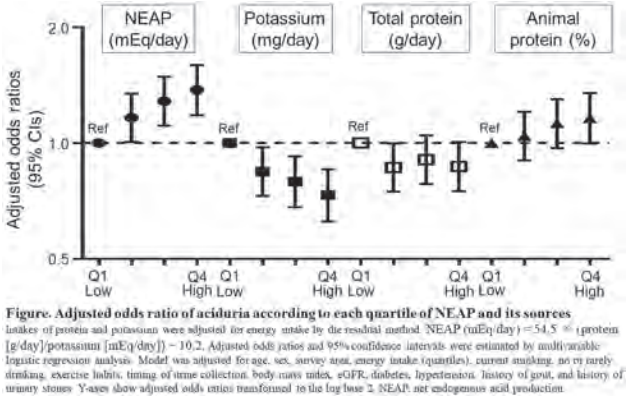

Figure. Adjusted odds ratio of aciduria according to each quartile of NEAP and its sources
Intakes of protein and potassium were adjusted for energy intake by the residual method. NEAP (mEq/day) = 54.5 × (protein [g/day]/potassium [mEq/day]) − 10.2. Adjusted odds ratios and 95% confidence intervals were estimated by multivariable logistic regression analysis. Model was adjusted for age, sex, survey year, energy intake (quartiles), current smoking, no or rarely drinking, exercise habits, timing of urine collection, body mass index, eGFR, diabetes, hypertension, history of gout, and history of urinary stones. Y-axes show adjusted odds ratios transformed to the log base 2. NEAP, net endogenous acid production.

Adjusted odds ratio of aciduria according to each quartile of NEAP and its sources

Effect of Sodium Bicarbonate Therapy on Calciprotein Particles in Patients with CKD Stages 3 and 4 and Mild Metabolic Acidosis

Wei Chen,[1,2] Mirela A. Dobre,[3] Seiji Koike,[4] Jodi A. Lapidus,[4] Garry A. Graham,[1] Matthew K. Abramowitz,[1,2] Thomas H. Hostetter,[5] Alfred K. Cheung,[6] Kalani L. Raphael,[6] Michal L. Melamed.[7,1] *[1]Albert Einstein College of Medicine, Bronx, NY; [2]Montefiore Medical Center, New York, NY; [3]University Hospitals, Cleveland, OH; [4]Oregon Health & Science University, Portland, OR; [5]The University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; [6]University of Utah Health, Salt Lake City, UT; [7]NYU Langone Health, New York, NY.*

Background: Animal studies suggest that sodium bicarbonate, used to treat metabolic acidosis of CKD, may worsen vascular calcification. Calciprotein particles (CPPs) are nanoparticles of calcium phosphate crystals and calcification inhibitors. Faster transformation (i.e., low T_{50}) from primary to secondary CPP (CPP2) and larger CPP2 indicate a reduced mineral buffering capacity in blood and are associated with mortality. In people with CKD, we tested the hypothesis that sodium bicarbonate therapy reduces T_{50} and increases CPP2 size.

Methods: We performed secondary analyses of a double-blind, placebo-controlled trial, in which 149 participants with CKD stage 3 or 4 with serum bicarbonate levels 22-26 mEq/L were randomized to receive either sodium bicarbonate 0.4 mEq/kg/day or placebo. In the stored serum samples at baseline, month 2 and 6, we measured the time for half maximal CPP transformation (T_{50}) using nephelometry and CPP2 size using dynamic light scattering. Linear mixed effect models were used to test the effects of sodium bicarbonate on the changes in T_{50} and CPP2.

Results: 54% were women and 58% were Black. At baseline, mean (±SD) age was 62±10 years; serum bicarbonate was 24.0±2.2 mEq/L; eGFR was 36±11mL/min/1.73m^2; T_{50} was 131±36 min; and CPP2 was 193±49 nm. At Month 2, serum bicarbonate in the intervention group increased to 26.4 mEq/L and T_{50} increased by 10 min. These changes were significantly higher than placebo ($p<0.001$ and $p=0.03$, respectively). At Month 6, mean serum bicarbonate was 25.5 mEq/L and there was no change in T_{50} compared to placebo. There was no significant change in CPP2 at either Month 2 or 6.

Conclusions: In contrary to our hypothesis, oral sodium bicarbonate therapy in people with CKD increased T_{50} after 2 months, suggesting improved mineralization capacity; however, this effect was not sustained at 6-month follow-up. Further studies are required to confirm these findings and to investigate whether this increase in T_{50} improves vascular calcification and survival.

SA-PO495

Oral Sodium Bicarbonate in Patients on Maintenance Hemodialysis: A Systematic Review and Meta-Analysis

Adrian L. Santos, Jayson M. Villavicencio, Maxine Camela S. Sta. Maria. *Philippine General Hospital, Manila, Philippines.*

Background: Metabolic acidosis, one of the complications of chronic kidney disease (CKD), can lead to malnutrition and increased protein catabolism. Oral sodium bicarbonate supplements have been used to address this consequence among non-dialytic CKD patients. However, the evidence of their continued use among patients already on regular maintenance hemodialysis is still the subject of many studies. This study aims to determine the effect of oral sodium bicarbonate supplements on the nutritional status and interdialytic potassium gain of CKD patients on maintenance hemodialysis.

Methods: Searches for eligible studies were done on PubMed, ProQuest, the Cochrane Library, and ClinicalTrial.gov until December 2023. Studies included were randomized controlled trials of CKD patients on maintenance hemodialysis given oral sodium bicarbonate supplements. The primary outcome is change in nutritional status which was assessed by different parameters, while the secondary outcome of interest is interdialytic potassium gain. Three reviewers independently screened the studies and assessed the quality using the Cochrane RoB tool. Random-effects meta-analysis was done using Review Manager 5.4.

Results: Two studies, both moderate quality RCTs, were included in this review, involving a total of 93 patients. The parameters employed for the assessment of nutritional status included normalized protein catabolic rate (nPCR), interdialytic weight gain, and handgrip. Pooled analysis showed that sodium bicarbonate was as effective or better in terms of in nPCR, mean difference 0.09 g/kg/day (95% CI -0.05 to 0.23, I2=37%; associated with an increase in interdialytic weight gain compared to control, mean difference of 0.43 kg (95% CI 0.01 to 0.84, I2=39%), and as effective compared to control (no sodium bicarbonate) in terms of improving handgrip, mean difference of 3.57 kg (95% CI -10.72 to 17.85, I2=80%). The sodium bicarbonate group also showed lower levels of pre-dialysis potassium, mean difference of 0.33 mmol/L (95% CI -0.58 to -0.11, I2 = 0%).

Conclusions: There is low certainty of evidence to suggest that oral sodium bicarbonate supplementation among patients on hemodialysis may result in a slight improvement in the nutrition and interdialytic potassium gain of these patients.

SA-PO496

Among Patients Meeting the KDIGO CKD Practice Point Criterion for Treatment of Metabolic Acidosis, Higher Serum Bicarbonate Concentrations Are Associated with Slower CKD Progression

Bhupinder Singh,[1] Navdeep Tangri,[2] Glenn M. Chertow,[3] Pablo E. Pergola,[4] Stewart A. Turner,[1] Jessica B. Kendrick,[6] Donald E. Wesson.[5] *[1]Renibus Therapeutics, Southlake, TX; [2]University of Manitoba, Winnipeg, MB, Canada; [3]Stanford University, Palo Alto, CA; [4]Renal Associates PA, San Antonio, TX; [5]University of Texas, Austin, TX; [6]University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Lower serum bicarbonate concentrations in patients with CKD and metabolic acidosis are associated with worse clinical outcomes including faster CKD progression. Less clear is to what extent raising bicarbonate delays CKD progression. The 2024 KDIGO CKD guideline recommends, as a practice point, the use of pharmacological treatment in patients with serum bicarbonate < 18 mEq/L. We explored the relation between achieved serum bicarbonate and CKD progression using data from the VALOR-CKD study, which evaluated the safety and efficacy of veverimer, a non-absorbed polymer that removes hydrochloric acid from the gastrointestinal tract. In this study, 1,480 patients with CKD (eGFR 20-40 mL/min/1.73 m^2) and metabolic acidosis (serum bicarbonate 12-20 mEq/L) were randomized, after a single-blind active treatment period, to veverimer or placebo and followed for a median of 24.5 months. The difference in achieved serum bicarbonate concentrations between treatment groups was only 1.3 mEq/L and the trial failed to show a slowing of CKD progression.

Methods: In a post-hoc analysis restricted to patients with baseline serum bicarbonate ≤18 mEq/L, we evaluated the relation between the average serum bicarbonate concentration achieved over the course of the randomized treatment period (<20, ≥22 mEq/L, ie ≥ 4 mEq/L serum bicarbonate increase), and CKD progression using a Cox proportional hazards model. CKD progression was defined as the time to the first kidney composite endpoint (KCE) of a confirmed reduction in eGFR ≥40%, ESKD (requiring dialysis or transplantation), or death.

Results: The patients who achieved average serum bicarbonate concentrations ≥22 mEq/L, irrespective of treatment received, experienced a significantly reduced risk of KCE, HR=0.52 (CI 0.36 to 0.75), p <0.0005, relative to those with serum bicarbonate concentrations <20 mEq/L.

Conclusions: This post-hoc analysis from the VALOR-CKD trial provides supportive evidence that in a CKD population with serum bicarbonate concentrations meeting the KDIGO practice point criterion for treatment of metabolic acidosis (< 18 mEq/L), higher achieved serum bicarbonate concentrations are associated with slower CKD progression.

SA-PO497

Variability in the Delta Anion Gap/Delta Bicarbonate (ΔAG/ΔHCO3) Ratio in Lactic Acidosis

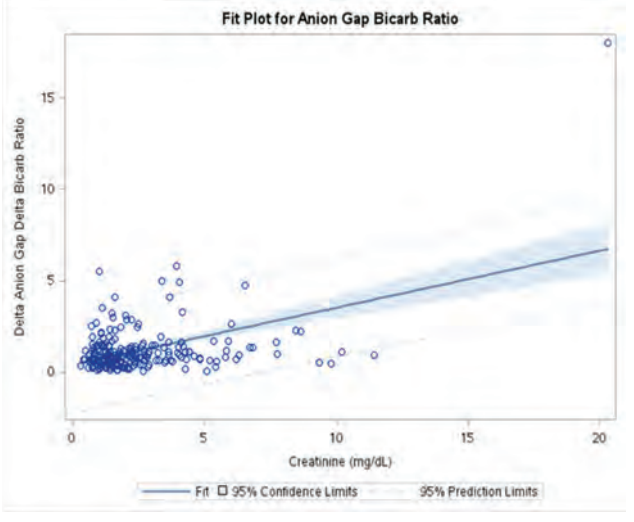
Garrett Yu,[1,2] In-Lu Amy Liu,[3] Richard M. Treger.[1,4] *[1]Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA; [2]Cedars-Sinai Medical Center, Los Angeles, CA; [3]Kaiser Permanente Department of Research and Evaluation, Pasadena, CA; [4]Kaiser Permanente Bernard J Tyson School of Medicine, Pasadena, CA.*

Background: The delta anion gap (AG) to delta bicarbonate (HCO_3) ratio ($\Delta AG/\Delta HCO_3$) is useful for detecting complex acid-base disorders in the setting of elevated anion gap metabolic acidosis. Consistent with published studies, our data demonstrated that $\Delta AG/\Delta HCO_3$ in lactic acidosis has significant variability, ranging from 0.07-5.79. This variability is not well explained. This study aims to better understand what factors explain the variability in $\Delta AG/\Delta HCO_3$.

Methods: This is a retrospective cohort study of adult ICU patients with sepsis and lactic acidosis. $\Delta AG/\Delta HCO_3$ was calculated using albumin-corrected AG and each patient's baseline AG and HCO_3. Pearson correlation was used to determine the association between creatinine, BUN, BUN/Cr, chloride, and potassium and $\Delta AG/\Delta HCO_3$.

Results: 484 patients were included. Creatinine (Figure; $R^2 = 0.225$; $p < 0.0001$), BUN ($R^2 = 0.0233$; $p < 0.026$), and serum chloride ($R^2 = 0.045$; $p = 0.002$) were significantly correlated with $\Delta AG/\Delta HCO_3$. No association was found between $\Delta AG/\Delta HCO_3$ and serum potassium or BUN/Cr

Conclusions: Creatinine and BUN were significantly correlated with $\Delta AG/\Delta HCO_3$, likely due to accumulation of organic and inorganic anions that occurs with renal dysfunction. Serum chloride was significantly associated with $\Delta AG/\Delta HCO_3$, but only explained 4.5% of variance in $\Delta AG/\Delta HCO_3$, suggesting that concurrent normal AG metabolic acidosis (NAGMA), as with large volume saline infusion, diarrhea, or early renal failure did not play a clinically significant role in the variability in $\Delta AG/\Delta HCO_3$. Lack of statistically significant association between $\Delta AG/\Delta HCO_3$ and serum potassium, as well as BUN/Cr, supports the absence of diarrhea (as a cause of NAGMA) or concurrent metabolic alkalosis, respectively. Additional work needs to be done to identify other important factors that can further explain the variability in $\Delta AG/\Delta HCO_3$, which limits the utility of $\Delta AG/\Delta HCO_3$ in diagnosing mixed acid-base disorders.



SA-PO498

Sodium Bicarbonate Supplementation May Be Harmful in Septic Patients with Severe Lactic Acidosis: A Retrospective Analysis

Dongeun Yang, Binna Park, Soy Kang, Won Suk An. *Dong-A University, Busan, Republic of Korea.*

Background: Lactic acidosis is a common cause of metabolic acidosis in severely ill patients. Administrating sodium bicarbonate may be considered in lactic acidosis with pH <7.0, however the effect of sodium bicarbonate on mortality remains controversial. We aimed to evaluate the effect of sodium bicarbonate on mortality in patients with severe septic lactic acidosis.

Methods: Single-center analysis was conducted from May 2011 to April 2021 at Dong-A University Hospital, Korea. We screened 1987 patients with initial pH<7.2, lactate<19.8mg/dL(2.2mmol/L), and positive blood culture. 695 patients with pCO2>45mmHg or without follow-up lactate were excluded. We classified 1292 patients into two groups depending on sodium bicarbonate supplementation.

Results: Sodium bicarbonate group was 746 and control group was 545. Mean age was 66.8±13.3 years and male was 60.4%. Sodium bicarbonate group had significantly higher 7-day(25.2% to 15.0%) and 28-day(48.5% to 32.1%) mortality rate. More patients were treated with CKRT(continuous kidney replacement therapy), ventilator, and catecholamine in the sodium bicarbonate group. The difference of 7-day and 28-day mortality rate between two groups was prominent in patients below pH<7.0, whereas patients with pH 7.1-7.2 showed no difference of mortality rate. Similar results were shown in the Kaplan-Meier curve(Figure 1). Sodium bicarbonate was associated with 7-day(HR=1.800, p<0.001) and 28-day(HR=1.601, p<0.001) mortality in the Cox regression model. Sodium bicarbonate was only associated with 7-day(HR=2.245, p=0.034) and 28-day(HR=2.285, p=0.004) mortality in patients below pH<7.0.

Conclusions: Administrating sodium bicarbonate may be harmful in septic patients with severe lactic acidosis. Sodium bicarbonate should be carefully administered in septic lactic acidosis even with pH<7.0.

Tris(hydroxymethyl)aminomethane Reverses Tumor-Induced Lactic Acidosis

John A. Szendrey, Daniel L. Landry, Gregory L. Braden, Jeffrey Mulhern. Kidney Care and Transplant Services of New England. *Baystate Medical Center, Springfield, MA.*

Introduction: Tumor-induced(TI) lactic acidosis (LA) occurs in lymphomas due to impaired liver L metabolism & the Warburg effect of anaerobic glyolysis in the tumor. We describe a patient with large B cell lymphoma with severe respiratory distress & Kussmaul breathing from TI LA. The use of tris-hydroxymethyl aminomethane (THAM) which provides HCO3 without the generation of CO2, rapidly cleared his lactic acidosis.

Case Description: A 73 yr old man had severe dyspnea after 1 month of an enlarging groin mass He had a RR of 30/min with Kussmaul respirations. Lungs were clear & heart exam normal. A V/Q scan showed no pulmonary embolus. Table 1 shows a severe anion gap LA on admission. His glucose, BUN & creatinine, CPK, aspirin, acetaminophen & beta-hydroxybutyrate levels were normal. He was transfered to the ICU due to severe respirtory fatigue. THAM at a dose of 575 ml via a 0.3 mmo/L solution was given. Four hours later his LA dropped from 14.7 to 8.7 & his HCO3 rose to 20 mEq/L with markedly improved breathing & no intubation. The next day this same THAM dose was repeated with a greater fall in LA. A biopsy showed diffuse large cell B-lymphoma. & methylprednisolone was started. By the fourth day his LA was gone.

Discussion: Sodium bicarbonate IV in TI LA worsens LA. We chose to use THAM in our patient as it rapidly alkalinizes tissue & the liver within three minutes. This patient's LA quickly reversed with THAM doses calculated to increase the serum bicarbonate by 5 mmol/L per dose, prreventing intubation. We conclude that THAM can reverse TI LA without liver mets by the following mechanisms: a) alkalosis Increases lactate uptake & metabolism by hepatocytes, b) alkalosis increases liver conversion of lactate to pyruvate by stimulation of lactate dehydogenase (LHD) A and inhibition of LDH B, & c) reversal of the Warburg effect by increasing pyruvate dehydogenase(PDH) by inhibition of (PDH) kinase its breakdown enzyme with enhanced shuttling of pyruvate into the alkalosis-stimulated Krebs cycle. THAM is a new therapy for TI LA.

	Day 1	Day 2	Day 3	Day 4

Lactate Gap: A Diagnostic Clue for Diagnosing and Managing Ethylene Glycol Poisoning

Prathap Simhadri,[1] Deepak Chandramohan,[2] Renish Contractor,[1] Prabhat Singh,[3] Pradeep Vaitla,[4] Michelle Neuman,[5] Ujjwala Murari.[5] *[1]Florida State University, Tallahassee, FL; [2]The University of Alabama at Birmingham, Birmingham, AL; [3]Christus Spohn Health System, Corpus Christi, TX; [4]The University of Mississippi Medical Center, Jackson, MS; [5]West Virginia University, Morgantown, WV.*

Introduction: Ethylene glycol(EG) is a type of toxic alcohol, and its ingestion is associated with the development of an osmolar gap and elevated anion gap metabolic acidosis. Early identification and aggressive management of this condition are critical in improving outcomes. We used lactate gap as a diagnostic tool in two patients with ethylene glycol poisoning.

Case Description: A 59-year-old male with a history of Hepatitis C and hypertension was brought for altered mental status(AMS) and had a GCS of 3. Labs showed serum osmolality of 319 mOsm/Kg with an osmolar gap of 69; Chemistry showed an anion gap(AG) of 28 mmol/l and bicarb of 8 mmol/L, ABG showed pH of 7.02, with blood gas lactate of > 17 mmol/L. Serum lactate was 1.5 mmol/L. EG poisoning was suspected, given the significant lactate cap. He was started on fomepizole and aggressive intermittent hemodialysis. EG level later came back as 1205 mg/dl and was undetectable by 48 hours with aggressive treatment. A 60-year-old male was admitted for AMS, acute respiratory failure, and shock. He also had an osmolar gap of 135; chemistry showed an AG of 35, bicarb of <5 mmol/L; ABG showed pH of < 7.00, and lactate of > 18 mmol/L and serum lactate of 2.5 mmol/L. EG poisoning was suspected, given the significant lactate cap; the patient was started on fomepizole and aggressive CRRT. EG level later came back as 344 mg/dl, and the CRRT was discontinued once the EG level was < 20 mg/dl.

Discussion: Ethylene glycol metabolizes into glycolic acid and oxalic acid; these metabolites are responsible for elevated anion gap metabolic acidosis. It is also associated with minimal lactic acid production. Lactic acid can be measured using lactate oxidase and lactate dehydrogenase methods. The lactate oxidase method measures the hydrogen peroxide generated from the metabolism of lactic acid to pyruvate via lactic oxidase. Glycolic acid is structurally similar to lactate, and it can also generate hydrogen peroxide, which causes a false elevation of lactic acid. Conversely, the measurement of lactic acid by the dehydrogenase method is not interfered with by glycolic acid. The closure of the lactate gap can hint at the successful removal of ethylene glycol metabolites through dialysis. Conclusion: The lactate gap can be a diagnostic tool to diagnose and manage ethylene glycol poisoning.

SA-PO501

Fireball Whiskey-Induced Severe Lactic Acidosis

Priya Kumari Maheshwari,[1,2] Michel J. Sabra,[1,2] William W. Goldsmith,[1,2] Maro Issac,[3] Anil Harrison,[1,2] Peter Fahim.[1,2] *[1]HCA Florida West Hospital, Pensacola, FL; [2]University of Central Florida, Orlando, FL; [3]German University in Cairo, New Cairo, Egypt.*

Introduction: Propylene glycol (PG) is metabolized by alcohol dehydrogenase in the liver into lactate, which further converts to pyruvate. Excessive consumption of Fireball whiskey, containing PG, can lead to lactic acidosis.

Case Description: A 36-year-old patient with a history of alcoholism presented to the ED due to increased work of breathing and SOB. Upon arrival, the patient was afebrile with a heart rate of 128 bpm, BP of 112/52 mmHg, RR of 28 breaths per minute, and SpO2 of 98% on room air. He was encephalopathic, and the rest of his physical examination was unremarkable. Initial laboratory investigations were significant for severe anion gap metabolic acidosis with a bicarbonate level of 13 mmol/L and an anion gap of 31, elevated lactic acid of 19.3 mmol/L, hyponatremia, hypomagnesemia, hypophosphatemia, elevated transaminases, elevated total bilirubin, and neutrophilic leukocytosis. A chest CT scan with IV contrast was unremarkable. Additionally, an EKG revealed sinus tachycardia. ABG revealed a pH of 7.4, pCO2 of 16, and bicarbonate of 8.8. The ethanol level was negative. The patient received fluid resuscitation with 30 ml/kg and empiric antibiotics and was admitted to the medical floor. Subsequently, the patient was transferred to ICU due to respiratory distress and concerns regarding potential intubation needs. In the ICU, serum osmolality was measured at 281 mosm/kg with no osmolar gap, and a urine drug screen returned negative. Further inquiry revealed heavy Fireball whiskey consumption over recent days with concern for PG intoxication. Treatment included fluid resuscitation and aggressive electrolyte replacement, resulting in the clearance of lactic acid. However, the patient's hospital course was complicated by acute respiratory failure secondary to aspiration pneumonia, necessitating intubation, critical illness myopathy leading to extubation failure and requiring tracheostomy, and acute kidney injury which resolved. Fortunately, the patient was successfully decannulated before discharge.

Discussion: This case illustrates a low threshold to consider PG intoxication in alcoholic patients presenting with severe lactic acidosis. Our patient didn't have a high osmolar gap as the PG had already been metabolized to lactic acid. Hence, fomepizole was not administered, and given that he cleared lactic acid with fluid resuscitation, hemodialysis was not performed.

SA-PO502

Case of 2,4-Dinitrophenol Intoxication: A Lethal Weight-Loss Alternative Returns

Javier A. Ortega, Pooja Maknoor, Stephen B. Tanner. *Baylor Scott and White Central Texas, Temple, TX.*

Introduction: Initially used as a weight loss suplemment, 2,4 Dinitrophenol (DNP) was banned due to its toxicity. However, its use resurfaced among bodybuilding and dieting groups as a weight loss alternative pushed by online blogs and marketplaces seemingly circumventing heavy regulation.

Case Description: A 43-year-old man with history of depression and previous suicide attempts was transferred to our institution following ingestion of a weight loss supplement. He was brought by police officers who responded to a welfare check by his ex-wife. They stated the patient earlier expressed desire to commit suicide with ingestion of 10 instead of his usual daily 3 drops of DNP. He was started on cooling measures due to hyperpyrexia (41C), dantrolene was administered, then airlifted to our institution. Laboratories showed acute kidney injury, worsening lactic acidosis, and elevated creatinine kinase, with refractory hyperkalemia. Clinical deterioration ensued, with worsening diaphoresis, tachycardia, tachypnea, yellowing of distal extremities, and hypotension requiring escalating vasopressor support, mechanical ventilation and dialysis. Complications included rhabdomyolisis with bilateral lower extremity compartment syndrome requiring bedside fasciotomies and lastly, DIC. Unable to sustain adequate perfusion despite four vasopressors, the patient expired 30 hours after ingestion.

Discussion: Identified in both accidental and intentional intoxications, once ingested DNP is a potent decoupler of oxidative phosphorylation at the mitochondria, shifting to anaerobic respiration. Pyrexia and rhabdomyolysis are common complications along with characteristic discoloration of skin culminating in multiorgan failure. No known antidote is available at this time, and mortality remains high with scarce data to guide treatment. Therefore, it is crucial to raise awareness as preventing ingestion is likely the best available strategy to save lives.

Figure 1

SA-PO503

The Warburg Effect: A Case of Severe Lactic Acidosis and Hypoglycemia

Juan J. Adams Chahin, Janice M. Cuevas Rivera, Ileana E. Ocasio Melendez, Carlos G. Rivera-Bermudez. *Universidad de Puerto Rico Recinto de Ciencias Medicas, San Juan, Puerto Rico.*

Introduction: The Warburg effect, observed in cancer cells, is a type of cellular adaptation where lactate fermentation is favored for biosynthetic needs regardless of oxygen levels leading to type B lactic acidosis. Additionally, due to heightened glucose demand by malignant cells, hypoglycemia may be present. The Warburg effect is predominantly observed in aggressive lymphoproliferative disorders and is linked to a poor prognosis due to significant tumor burden.

Case Description: We present a 36-year-old male with history of diffuse B-cell lymphoma, complicated by pulmonary embolism and deep vein thrombosis on anticoagulation. The patient was brought to ED with complaints of respiratory distress and altered mental status. On exam, the patient appeared disoriented and tachypneic (respiratory rate of 34) with a peripheral oxygen saturation of 95% on room air. Physical exam revealed a prominent mass in the right thigh. Laboratory showed hypoglycemia (45), elevated creatinine and azotemia consistent with non-oliguric acute kidney injury type 1, alongside severe metabolic acidosis (pH: 6.8, pCO2: 14, HCO3: 3.1) with high anion gap (31.9) (delta ratio: 1.2), attributed to lactatemia (151 mg/dL). Aggressive intravenous hydration and bicarbonate drip failed to improve acidosis, necessitating intermittent hemodialysis (IHD). Despite four days of daily IHD, severe lactic acidosis persisted (pH: 7.2, HCO3: 7, and lactic acid: 130 mg/dL), requiring intubation. Induction chemotherapy was initiated, leading to marked improvement in acidosis (HCO3: 16, pH: 7.3) by day two for which dialysis was discontinued.

Discussion: The Warburg effect presents as a rare, complex, and challenging clinical situation in patients with hematologic malignancies, necessitating early identification and intervention to improve prognosis. Tachypnea without low oxygen levels is a characteristic manifestation. Treatment primarily focuses on prompt initiation of chemotherapy alongside supportive measures, yet efficacy of bicarbonate or hemodialysis is uncertain, often offering partial or no correction. Further research into kidney replacement therapy's potential benefits is warranted.

SA-PO504

Severe Lactic Acidosis in Hemophagocytic Lymphohistiocytosis

Andrea Broka, Juan P. Moreno-Ortiz, Nandakishor Kapa. *UC Davis Health, Sacramento, CA.*

Introduction: Hemophagocytic lymphohistiocytosis (HLH) is a catastrophic disease with multiple triggers, and often results in poor outcomes. We present a case of severe, persistent lactic acidosis in a rare presentation of HLH secondary to parvovirus B19 infection that improved after steroids and IL-1 inhibitor treatment.

Case Description: A 79-year-old man with diabetes mellitus and cirrhosis presented after a fall, 5 days of progressive malaise, fever, nausea, vomiting, melena, and hematemesis and was to be found febrile to 101° F and hypertensive. Workup showed serum creatinine 1.28 mg/dL, lactic acid (LA) 15.9 mmol/L, pancytopenia, and VBG pH of 7.2 with severe metabolic acidosis (HCO3 9 mEq/L). IV fluids and antibiotics were started, and GI ulcer was treated on EGD. His clinical condition deteriorated with persistent lactic acidosis, shock, decreased urine output, worsening transaminitis, elevated LDH, low haptoglobin, and with concern for potential metformin toxicity, hemodialysis was initiated. Lactic acid decreased from 20 to 13 mmol/L but increased to 20 mmol/L after stopping dialysis. A viral blood panel was positive for Parvovirus B 19 IgG. With ongoing fevers, pancytopenia, elevated ferritin at 8378 ng/mL and hypertriglyceridemia, he met 7 of 9 HLH-2004 criteria (H-score 284). Soluble IL-2Ra/CD25 was elevated at 4778.9 pg/mL. Bone marrow biopsy showed hypercellularity 70% with hemophagocytic lymph histiocytosis. Treatment with dexamethasone and anakinra improved the pancytopenia, liver enzymes, and lactic acidosis. Due to refractory septic shock, he was ultimately transitioned to comfort care.

Discussion: HLH is a rare, aggressive syndrome with dysregulated cytokine release, histiocyte activation, and multiorgan failure. Studies have reported an increased activity of lactate dehydrogenase A and inhibition of pyruvate dehydrogenase due to inflammatory cytokines increasing the production of lactate. The Warburg effect, where cells may preferentially use the lactic fermentation pathway even in the presence of oxygen and without significant mitochondrial dysfunction may also play a role. Lactic acidosis in patients with HLH is underrecognized, but if identified may prompt earlier treatment and improved outcomes.

SA-PO505

Linezolid-Induced Lactic Acidosis

Ritu Seethapathy,[1] Andrew Klufas,[2] Michael J. Monsour.[1] *[1]Landmark Medical Center, Woonsocket, RI; [2]Roger Williams Medical Center, Providence, RI.*

Introduction: Linezolid inhibits bacterial protein synthesis by preventing formation of 70S initiation complex needed for bacterial reproduction. This site of action is unique to linezolid, distinguishing it from other protein synthesis inhibitors.

Case Description: A 93-year-old woman presented to the hospital after nursing home labs showed elevated creatinine, nitrite positive urinalysis, and normal lactic acid. Urine culture grew VRE susceptible to linezolid and she was discharged on a course of linezolid. Two weeks post-discharge, the patient was readmitted with dyspnea, with labs showing AKI and significant lactic acidosis (LA). CT C/A/P revealed bilateral opacities consistent with pneumonia. She was started on a bicarbonate drip per Nephrology recommendations. Her FeUrea was consistent with prerenal AKI and urine output was ~400 cc/dy. Unfortunately, the patient then became hypotensive requiring pressor support, thought to be secondary to her significant LA causing her hemodynamic instability, rather than the inverse. Linezolid toxicity was the leading diagnosis and she was switched to meropenem and started on IV thiamine. Although the patient's pH normalized, her LA worsened. Hemodialysis was declined per the family's wishes and patient was made CMO after extensive goals of care discussion.

Discussion: Linezolid Induced Lactic Acidosis (LILA) is due to an interaction between the drug and mitochondrial ribosomes; inhibition of mitochondrial protein synthesis causes impaired oxidative phosphorylation, thus limiting aerobic energy production. LILA is a diagnosis of exclusion after ruling out common causes of LA and has been found to cause hemodynamic instability in patients. Previous studies have shown that mortality from LILA does not have a strong correlation with age, gender or duration of treatment, however, mortality is as high as 50% in patients with shock. LILA can often be associated with hypoglycemia however our patient was normoglycemic throughout hospitalization. Management of LILA consists of withdrawal of the drug and supportive care. Previous case reports suggest that critically ill patients further benefit from concurrent renal replacement therapy, like treatment of metformin induced lactic acidosis. LILA is a poorly understood side effect of patients treated with even a short course of linezolid. Given high rate of mortality, further investigation is warranted to study etiology of LILA to prevent its occurrence.

SA-PO506

Severe Lactic Acidosis in a Patient with Type 2 Diabetes Mellitus on Metformin

Dean Mellas, Xueguang (Gary) Chen. *Southern Illinois University School of Medicine, Springfield, IL.*

Introduction: Metformin-associated lactic acidosis (MALA) is a complication of altered lactate and hydrogen metabolism leading to life-threatening lactic acidosis in the setting of Metformin use or overdose. The major risk factors for developing MALA include poor renal function, impaired hepatic metabolism, and diseases that can cause increased production of lactate.

Case Description: A 67-year-old female with type 2 diabetes mellitus on Metformin and chronic kidney disease (baseline creatinine: 1.4) presented to a local ER with nausea, vomiting, diarrhea, and abdominal pain for three days. She was found to have severe lactate metabolic acidosis (pH: 6.84, bicarbonate: 8, lactate: 11.6) without hemodynamic instability. The patient underwent emergent hemodialysis for severe acidosis and hyperkalemia (K: 8.2) in the setting of acute kidney injury (serum creatinine: 7.47, BUN: 56). She was transferred to our hospital with persistent metabolic acidosis (pH: 6.97, bicarbonate: 7, lactate: 17) despite 4 hours of hemodialysis at the local hospital. On arrival to the ICU, the patient remained hemodynamically stable. CRRT was initiated urgently and lasted about 48 hours. Her lactic acidosis resolved, and the patient was discharged 8 days later with serum Cr 2.19. At 2-week follow up at renal clinic, her kidney function improved with creatinine back to baseline (1.4).

Discussion: Metformin is widely used to treat type 2 diabetes mellitus, and is generally considered a safe drug. However, patients with preexisting chronic kidney disease are at increased risk of developing a potentially fatal lactic acidosis. This case demonstrated the importance of early recognition and treatment of MALA as evidenced in this patient with known history of Metformin use and severe lactic acidosis. Hemodialysis continues to be the definitive treatment of MALA and should be initiated in any patient with severe acidosis.

SA-PO507

Dapagliflozin-Associated Ketoacidosis in the Absence of Diabetes

Loai Dweik,[1] Wesam Aleyadeh,[1] Pratik Rath,[1] Dania Salih Bacha,[2] Natthavat Tanphaichitr.[1] *[1]Cleveland Clinic Akron General, Akron, OH; [2]Cleveland Clinic, Cleveland, OH.*

Introduction: Dapagliflozin is a sodium-glucose transport protein 2 (*SGLT-2*) inhibitor developed for diabetes management and has emerged as a therapeutic option for heart failure. Use of these agents in the perioperative period remains an area of concern, with growing reports of adverse events and perioperative complications. We describe a case that highlights the importance of management and monitoring of SGLT-2 inhibitors in non-diabetic patients during the perioperative period.

Case Description: A 71-year-old female with a history of hypertension, restless leg syndrome, and depression presented with left hemiparesis. Physical examination revealed normotension, left lower facial droop, left hemiparesis with left upper extremity strength 4/5, left lower extremity 3/5 and ataxia. Complete blood count and creatinine were within normal range. She was subsequently diagnosed with a right middle cerebral artery (MCA) infarct. She underwent cerebral angiogram with right MCA thrombectomy. Post-procedurally, she was found to have an elevated anion gap (19 mmol/L), low bicarbonate (14 mmol/L), and high beta hydroxybutyrate (>2.00 mmol/L). A venous blood gas showed acidemia with primary metabolic acidosis and respiratory compensation. Her hospital course was complicated by new onset atrial fibrillation and systolic dysfunction with findings of a low ejection fraction (35%) on echocardiogram and initiation of dapagliflozin for heart failure with reduced ejection fraction. Nephrology was consulted for progressively worsening serum bicarbonate. Workup showed normal renal function, absence of diabetes (HbA1c: 5.2%), unremarkable ethylene glycol, methanol, and salicylate levels.

Discussion: The patient's serum bicarbonate levels continued to downtrend with persistent acute high anion gap metabolic acidosis (HAGMA). The patient had no history of Type 1 diabetes making euglycemic diabetic ketoacidosis (DKA) unlikely. Suspicion fell on dapagliflozin, which had been prescribed shortly after admission and post-thrombectomy. It was subsequently discontinued with HAGMA resolution. Despite lacking a history of diabetes, the patient's prolonged fasting, surgical stress, and dapagliflozin use may have contributed to the observed metabolic disturbance. Clinicians must exercise caution when continuing SGLT-2 inhibitors during the perioperative period, even in non-diabetic heart failure patients.

SA-PO508

Metformin Toxicity and Euglycemic DKA: A Tale of Two Acidosis

Aditya Yelamanchi,[1,2] Sharmilee Vuyyuru,[1] Andrea Chau,[1] Amanda Nguyen,[1] Brian Y. Young.[1] *[1]University of California Davis, Davis, CA; [2]NorthShore University HealthSystem, Evanston, IL.*

Introduction: Metformin associated lactic acidosis (MALA) and euglycemic diabetic ketoacidosis (euDKA) from SGLT2 inhibitor use are well known life-threatening metabolic disorders where immediate recognition and treatment is imperative to decrease mortality in patients. However, MALA and euDKA have rarely been cited in literature to occur simultaneously, as seen in our case.

Case Description: A 60 year old male with chronic kidney disease stage 3B, diabetes mellitus with retinopathy and peripheral neuropathy was admitted from a nursing facility with altered mental status, abdominal pain, decreased oral intake, and emesis. History was limited on admission. He was found to have a severe anion gap metabolic acidosis and anuric acute kidney injury. Admission creatinine was 10.06mg/dL (baseline ~ 2), serum bicarbonate level was 10mmol/l, anion gap was 44mmol/L, blood glucose was 154mg/dL, and pH on venous blood gas was 7.17. Nephrology was consulted, which prompted a more extensive workup revealing urinalysis with trace ketones and many granular casts, serum beta-hydroxybutyrate level at 6.84mmol/L, and lactic acid level at 6.4mmol/L. This combination of findings was concerning for dual euglycemic DKA and metformin toxicity. Given the high mortality of untreated metformin toxicity, empiric emergent hemodialysis was initiated. Post 2 dialysis treatments, there was significant renal recovery, with creatinine stabilizing at 2.2mg/dL and normalization of lactic acid. It was later found that the patient was taking both metformin 500mg bid and empagliflozin 10mg daily before admission. Metformin level sent prior to dialysis returned 2 weeks later at 23mcg/mL (therapeutic range 1-2; toxic level 5).

Discussion: MALA is a rare and lethal diagnosis with mortality rates ranging from 25-50%, without a significant correlation between degree of acidosis. While concurrent euDKA and MALA is rare, this scenario should be considered given increasing use of both agents. When clinical suspicion is high for this dual acidosis, waiting on serum metformin levels should not delay dialysis given the high mortality. Treatment of euDKA should also be initiated simultaneously.

SA-PO509

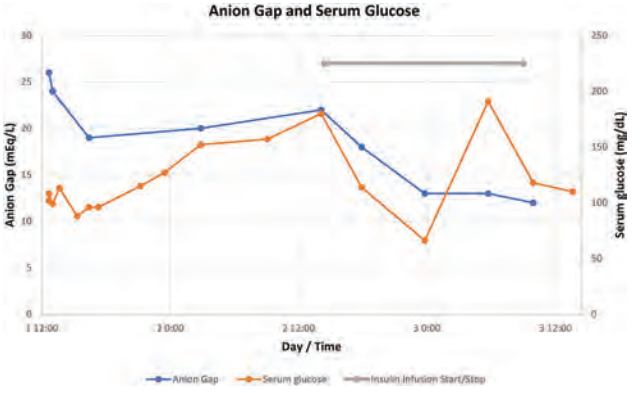
A Case of Cocaine-Induced Euglycemic Diabetic Ketoacidosis

Amir Moghaddam, Zan Shareef, Song Liu, J. Pedro Teixeira. *University of New Mexico Health Sciences Center, Albuquerque, NM.*

Introduction: Severe anion gap metabolic acidosis (AGMA) may be life-threatening and often requires specific therapy, but prompt diagnosis may be challenging. We present a case of euglycemic diabetic ketoacidosis (euDKA) likely triggered by cocaine use.

Case Description: A 69-year-old man with diabetes, hypertension, and polysubstance use presents after being found unresponsive by his son. He is intubated for airway protection and is found to have acute kidney injury and severe acidosis with creatinine 3.5 mg/dL, BUN 75 mg/dL, pH 7.13, pCO2 35 mmHg, bicarbonate 10 mEq/L, anion gap 26 mEq/L, lactate 2.0 mmol/L, negative toxic alcohol panel, and serum glucose 66-191 mg/dL. Urinalysis reveals ketonuria and serum beta-hydroxybutyrate is 3.2 mmol/L. Urine drug screen is positive for cocaine. Despite treatment with IV dextrose and IV bicarbonate for >24 h, anion gap remains >20 (Figure). Nephrology is consulted and recommends IV insulin with dextrose which results in normalization of his anion gap within 24 h, at which point his mental status improves sufficiently for extubation.

Discussion: The severity of the AGMA, lack of response to dextrose alone, need for insulin, and glucose consistently <200 mg/dL all strongly suggest euDKA in this case rather than starvation ketosis or classic DKA. Though increasingly identified in patients taking sodium-glucose cotransporter-2 inhibitors, euDKA may be triggered by stressful events such as pregnancy, surgery, or pancreatitis. A classic trigger of DKA, cocaine stimulates counterregulatory hormones like epinephrine and cortisol which normally raise blood glucose, inhibits insulin secretion, and stimulates breakdown of free fatty acids into ketones. One study found 14% of DKA cases to be related to cocaine. However, cocaine may less commonly trigger euDKA via suppression of feeding centers that results in oral intake poor enough to prevent hyperglycemia. Given the specific therapy required, nephrologists and intensivists alike must recognize cocaine-induced euDKA as a potential cause of unexplained severe AGMA.



SA-PO510

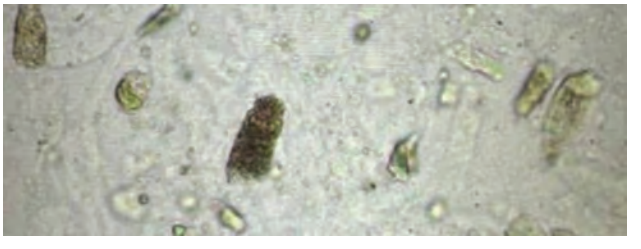
Unveiling the Deceptive Diagnosis: Exploring False-Positive Ethylene Glycol Poisoning

Aakriti Jain, Hafsa Jawaid, Pulkit Gandhi, Roopali G. Gandhi. *Rochester General Hospital, Rochester, NY.*

Introduction: Ethylene glycol (EG) poisoning can lead to significant mortality if left untreated. When unable to elicit exposure history, determining blood EG levels becomes critical for diagnosis and guides antidote administration. While gas chromatography is gold standard for diagnosis, its utility is limited due to restricted availability. Surrogate diagnostic tests are often used and should be interpreted with caution.

Case Description: A 66-year-old female with history of alcohol use disorder and COPD presented with dyspnea and confusion. History of EG ingestion could not be obtained. She was hypotensive, tachycardic, in respiratory distress and had decreased breath sounds bilaterally. Laboratory work showed pancytopenia, respiratory and metabolic acidosis (pH 6.87), anion gap of 31 mmol/L, osmolol gap of 9 mOsm/kg, and lactic acidosis (17.4 mmol/L). A right lower lobe lung opacity on CT raised suspicion for respiratory source of septic shock. She was emergently intubated, treated with IV fluids, antibiotics, vasopressors, and initially got fomepizole for severe EG toxicity after spectrophotometric assay revealed elevated EG levels of 49 mg/dL. Since no calcium oxalate crystals were present on urine sediment (Image) and the osmolal gap was normal, the blood sample taken upon admission, which indicated elevated EG levels, was subjected to gas chromatography coupled with mass spectrometry. It resulted negative for EG. Due to worsening acidosis and anuria, CRRT was initiated with no improvement and she passed away. Respiratory culture resulted positive for staphylococcus, making pneumonia and sepsis a likely diagnosis.

Discussion: EG levels can be falsely elevated by spectrophotometry in presence of severe lactic acidosis. It uses enzymatic method to detect nicotinamide adenine dinucleotide levels produced by oxidation of both EG and lactic acid. This leads to misdiagnosis and use of inappropriate and costly therapies. Thus, laboratory tests should be interpreted with caution. When suspicion for EG toxicity is high in patients with lactic acidosis, gas chromatography coupled with mass spectrometry should be used.



Urine without calcium oxalate crystals.

SA-PO511

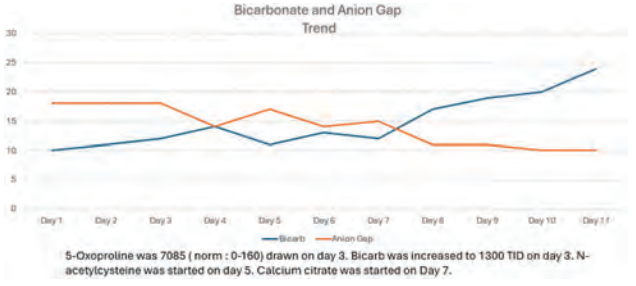
Treatment of 5-oxyproline Anion Gap Acidosis with N-acetylcysteine

Ryan Fields, Harold A. Franch. *Emory University, Atlanta, GA.*

Introduction: Over 60 million Americans use acetaminophen (APAP) weekly. Mitochondrial APAP metabolism requires the consumption of glutathione which is produced by the glutathione cycle (GC) consuming the amino acid, cystine. 5-oxoproline anion gap (AG) metabolic acidosis occurs when high dose APAP therapy combined with inadequate protein intake leads to depletion of cystine. Low cystine levels block the GC causing accumulation of 5 oxyproline. N-Acetylcysteine, used to threat APAP overdose, restores the GC and should reduce 5-oxoproline production.

Case Description: 81 y.o. woman with past Roux-n-Y gastric bypass, leukemia s/p bone marrow transplant, cervical vertebral collapse s/p surgeries was admitted for cervical and abdominal pain and anorexia and found to have UTI and severe constipation. Her pain does not respond to narcotics: she took APAP 650 BID and 2 tablets of Fioricet (APAP 600 mg) q 8 hours at home. She received IV APAP 1000 mg BID and 2 Fioricet BID in hospital. Her baseline normal gap metabolic acidosis is treated with Ca citrate, but on admission patient had mixed non-gap and AG metabolic acidosis with normal ketones, lactate, eGFR. Urine electrolytes showed sodium 35 mEq/L but chloride was undetectable, suggesting anion drag. On Day 2 riifaxamin was started for presumed bacterial overgrowth AG acidosis. She refused to stop APAP, but reduced to ~ 2200 mg daily and N acetyl cysteine 35 mg/kg BID stared day 5. AG normalized day 8. Samples obtained day 2 showed serum d-lactate normal and urine organic a 5-oxoproline was 44-fold top of normal range with no other organic acid elevated more than 6-fold (lactate 4-fold).

Discussion: Clinical recognition of 5-oxoproline metabolic acidosis is important given delays in urinary organic acid results. Treatment is discontinuing APAP and feeding protein. This first report of N-acetylcysteine treatment may provide an option if APAP cannt be discontinued when adequate protein intake is not possible.



5-Oxoproline was 7085 (norm : 0-160) drawn on day 3. Bicarb was increased to 1300 TID on day 3. N-acetylcysteine was started on day 5. Calcium citrate was started on Day 7.

SA-PO512

GOLD MARK "S": A Unique Cause of High-Anion Gap Metabolic Acidosis

Hassan H. Allahrakha, Akash Hazari, Roberto L. Collazo-Maldonado. *Methodist Dallas Medical Center, Dallas, TX.*

Introduction: Calcific uremic arteriolopathy (CUA) is a serious disorder characterized by vascular calcifications that can affect patients with advanced chronic kidney disease. Currently, there is no approved therapy for CUA, but sodium thiosulfate (STS) has been used off-label for CUA. Mehta et. Al proposed a new anion gap mnemonic for the 21st century: GOLD MARK. TS is also a cause of high anion gap metabolic acidosis (HAGMA). We present two cases of STS-induced HAGMA.

Case Description: The first patient was a 58-year-old male with end-stage renal disease (ESRD) who presented with left toe gangrene. He was diagnosed with chronic CUA. He received STS (50 g) and underwent dialysis. Eleven days following admission, he developed HAGMA (anion gap: 27 mEq/L, CO_2: 17 mEq/L). The second patient was a 32-year-old female with ESRD secondary to diffuse proliferative lupus nephritis who was admitted for central retinal artery occlusion. She was diagnosed with a painful ulcer on the right thigh secondary to CUA. She received STS and developed HAGMA during her hospitalization (anion gap: 22 mEq/L). In both cases, HAGMA resolved following discontinuation of STS.

Discussion: The mechanism of how STS causes HAGMA is unknown. It is presumed to be due to oxidation of thiosulfate to sulfate by the liver or intestinal bacteria, which is enhanced in patients with ESRD due to reduced clearance of the medication. A new HAGMA mnemonic has been proposed: GOLD MARK (**G**lycols [ethylene and propylene], **O**xoproline, **L**-lactate, **D**-lactate, **M**ethanol, **A**spirin, **R**enal failure, and **K**etoacidosis). We propose that STS be considered in the differential diagnosis of HAGMA, and that "S" for STS be added to the end of the mnemonic GOLD MARK.

SA-PO513

Severe Metabolic Acidosis in a Patient with Spinal Muscular Atrophy

Joyita Bharati, Kevin Tong, Afolarin A. Amodu. *Boston Medical Center, Boston, MA.*

Introduction: Ketogenesis starts early after starvation in healthy individuals. However, ketoacidosis develops after ~2 weeks of starvation. We report a case of severe ketoacidosis after a short period of fasting in a patient with spinal muscular atrophy (SMA).

Case Description: A 59-year-old wheelchair-bound male with SMA and a recent history of percutaneous cholecystostomy presented to the hospital with purulent drainage. His food intake mainly comprised ground vegetables and protein. The patient was nil per oral overnight on day 2 for cholecystostomy tube exchange and reported abdominal pain and vomiting on day 3 of admission. Home medications included baclofen and sertraline. Physical examination was noted for muscle atrophy without any distress. Blood pressure was 124/66 mm Hg, pulse rate was 85/min, respiratory rate was 22/min, and oxygen saturation was 98% on room air. Laboratory evaluation: serum bicarbonate 11 mmol/L, anion gap 22, pH 7.17 with partial pressure of carbon dioxide of 30 on day 3 of admission. Severe high anion gap metabolic acidosis (without adequate respiratory compensation) was confirmed with repeat tests. Sodium bicarbonate infusion was started due to severe acidosis while being further evaluated. Serum creatinine was 0.49 m/dl, and electrolytes were within range. Serum lactate was 0.8 mmol/L (0.5 to 2 mmol/L), osmolar gap was 4 (<10), serum ethanol, methanol, ethylene glycol, salicylate, and acetaminophen, respectively, were negative. The urine dipstick showed 2+ ketones, serum acetone was 20 mg/dL (0-5 m/dL), and serum beta-hydroxybutyrate was 8.52 mmol/L (0.28 mmol/L). His blood sugar was 93 mg/dl on day 1 and 63 mg/dl on day 3 of admission. Low-normal blood sugar and ketoacidosis in the setting of ~18 hours of fasting prompted a diagnosis of starvation ketoacidosis. Serum bicarbonate remained ~12 mmol/L on bicarbonate infusion. Dextrose infusion normalized bicarbonate (25 mmol/L) within four hours.

Discussion: Starvation ketoacidosis is described within 12-24 hours of starvation in patients with SMA in isolated case reports. Poor ketone body consumption by low muscle mass is postulated to cause severe ketoacidosis in SMA patients upon a short period of starvation. Timely treatment and prevention with dextrose, including during fasting for procedures, are crucial to prevent this complication in SMA patients.

SA-PO514

Therapeutic Plasma Exchange Complicated by Hyperchloremic Metabolic Acidosis in a Patient with Myasthenia Gravis and CKD

Michael Gilleo, Hassan Mahmoud. *Maine Medical Center, Portland, ME.*

Introduction: Therapeutic plasma exchange (TPE) is commonly associated with metabolic derangements such as hypocalcemia and hypomagnesemia. Hyperchloremic metabolic acidosis is a rare complication previously reported in patients undergoing multiple days of consecutive TPE. We present a case of hyperchloremic acidosis in a patient with baseline renal dysfunction undergoing TPE every other day.

Case Description: An 88 year old with CKD 3B was admitted for acute myasthenia gravis with respiratory failure, a category I indication for plasma exchange. They underwent TPE treatment on two consecutive days, followed by another three treatments each separated by 48 hours. Plasma was replaced at 105% fluid balance with 50 g/L albumin in saline solution (3-4L per treatment). Citrate anticoagulation was used for the apheresis circuit. The patient developed hyperchloremic acidosis following initial TPE treatment (Figure 1). The anion gap was normal. The acidosis persisted throughout the duration of TPE therapy and corrected two days after therapy completion.

Discussion: This case highlights the rare complication of hyperchloremic acidosis during TPE. The acidosis was likely caused by replacement of plasma with large volumes of chloride-containing fluids, with underlying renal dysfunction impairing excretion of excess chloride. Chloride concentrations of 109-145 mmol/L have been reported in albumin solutions, but this measurement was not made for the albumin used in this patient. Citrate toxicity was not a factor, as hepatic function and total-to-ionized calcium ratio were normal. Hyperchloremic acidosis may result in reduced renal perfusion, increased ventilatory needs, and symptoms such as nausea, vomiting, or myalgias. Providers must be aware of this risk associated with TPE, even when treatment frequency is reduced to every 48 hours. Early recognition may allow for treatment of the acidosis, or changes to replacement fluids used during plasma exchange.

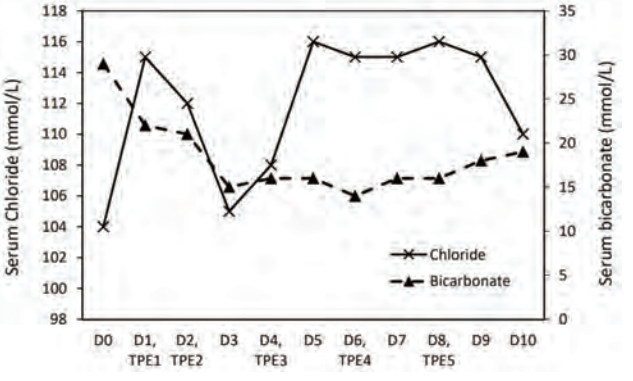


Figure 1: Serum chloride and bicarbonate throughout TPE treatment

SA-PO515

Distal Renal Tubular Acidosis as Initial Presentation of Sjogren Syndrome in Pregnancy

Chintan V. Shah, Issa R. Haddad. *Division of Nephrology, Hypertension, and Renal Transplantation, University of Florida College of Medicine, Gainesville, FL.*

Introduction: Sjogren's syndrome (SS) is a chronic autoimmune disorder characterized by lymphocytic infiltration of exocrine glands, leading to dryness of mucosal surfaces. While renal involvement in SS is not uncommon, its initial presentation as distal renal tubular acidosis (dRTA) in pregnancy is rare. dRTA is a renal tubulopathy characterized by impaired acid secretion in the distal nephron, resulting in metabolic acidosis.

Case Description: A 44-year-old female physician with a history of Hashimoto's thyroiditis was referred to the nephrology clinic for elevated creatinine levels at 19 weeks of gestation without any specific symptoms. Laboratory investigations revealed serum potassium of 3.7 mmol/L, serum CO2 of 12 mmol/L with a normal anion gap of 13, and serum creatinine level of 1.4 mg/dL. Urinalysis showed persistent alkaline urine pH >7. dRTA was suspected and confirmed with 24-hour urine demonstrating undetectably low citrate with ammonium of 14 mmol/24hr. Further rheumatology evaluation revealed positive antinuclear antibodies (ANA), elevated SSA and SSB antibodies, and a positive Schirmer test (right eye 4mm, left eye 4mm) after 5 minutes, suggesting Sjogren's syndrome (SS). Renal US did not show evidence of nephrocalcinosis or hydronephrosis. Treatment with oral potassium citrate 30 mEq twice a day was initiated with normalization of serum CO2 to 23 mmol/L. Kidney biopsy revealed acute on chronic tubulointerstitial nephritis. Consequently, the patient was initiated on prednisone 60 mg/d, followed by a taper. Despite initial clinical improvement, symptoms recurred with prednisone less than 20 mg/d. Azathioprine 50 mg/d was added, and the dose increased gradually while simultaneously tapering off steroids. Significant improvements have been noted in the patient's symptoms and fetal growth, demonstrating a positive shift from the 3rd to the 13th percentile with immunosuppression.

Discussion: Extra-glandular renal manifestations are not uncommon presentations of Sjögren's syndrome. SS is associated with various renal manifestations, including tubulointerstitial nephritis and renal tubular acidosis. This case highlights the challenges in managing Sjogren's syndrome during pregnancy and emphasizes the importance of tailored treatment strategies to alleviate the patient's symptoms and mitigate fetal complications.

SA-PO516

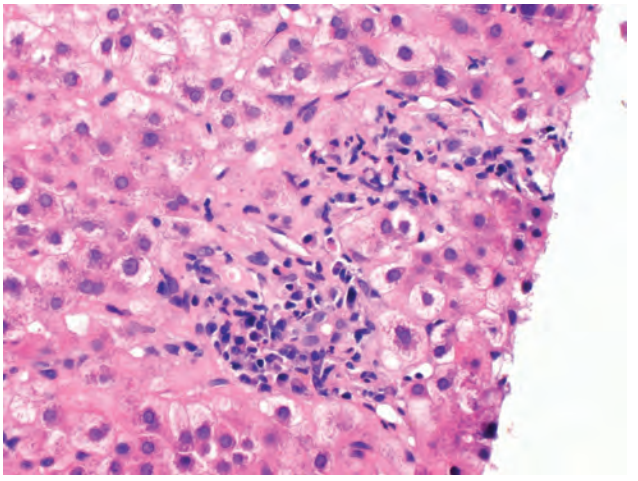
Worsening of Distal Renal Tubular Acidosis (dRTA) as a Sign of Recurrent Autoimmune Hepatitis after Liver Transplant

Samir A. Elshouny,[1] Ayat S. Al saeed,[2] Ahmed F. Elfar.[1] *[1]King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia; [2]Royal Commission for Jubail and Yanbu, Jubail, Saudi Arabia.*

Introduction: dRTA is characterized by hyperchloremic non-anion gap metabolic acidosis, marked hypokalemia and alkaline urine. Patients with dRTA almost always have hypocitraturia which increase the risk of calcium phosphate stones and nephrocalcinosis. dRTA develops because of autoimmune diseases including Sjögren's syndrome, autoimmune hepatitis and other causes.

Case Description: A 32 years old female with a history of autoimmune hepatitis complicated with cirrhosis underwent living related liver transplant. Her family history was negative for any autoimmune diseases. Few years prior to liver transplant, she was diagnosed with dRTA secondary to autoimmune hepatitis. Her disease was complicated by kidney stones which required surgical removal. Post-transplant, she has remained stable clinically and biochemically. 6 months after the transplant surgery, she presented to our hospital with fatigability, low energy, continuous vomiting, and poor appetite. Blood pH 7.14. Serum creatinine 129 umol/L (close to baseline), K 2.9 mmol/l, HCO3 10 mmol/L. T.Bilirubin 216 umol/L, D.Bilirubin 187 umol/L, ALT 176 U/L, AST 156 U/L alk. phosphatase 323 U/L. Urine pH 7, urine K 8.55 mmol/L, urine creatinine 1.1 mmol/l. Urine K/C Ratio 7.77 mmol/mmol indicating renal potassium wasting. MRCP showed focal biliary anastomotic stricture with minimal intrahepatic biliary dilatation. She underwent ERCP mediated dilatation and stenting. A biopsy of the liver was consistent with recurrent autoimmune hepatitis. The patient was discharged on steroid tapering dose and K citrate.

Discussion: We present a new correlation between worsening dRTA and recurrence of autoimmune hepatitis in a post liver transplant patient. Our case highlights that worsening dRTA could be a sign of recurrence of the primary disease in the transplant graft. To our knowledge, this finding has never been reported in the literature.



SA-PO517

A Case of Fanconi Syndrome with Biopsy-Proven Acute Proximal Tubular Injury Induced by a Dietary Supplement, Benikoji

Masato Habuka, Michihiro Hosojima, Hideyuki Kabasawa, Asa Ogawa, Yumi Ito, Suguru Yamamoto, Akihiko Saito. *Niigata Daigaku Igakubu Igakuka Daigakuin Ishigaku Sogo Kenkyuka, Niigata, Japan.*

Introduction: Fanconi syndrome is a common consequence of drug-induced nephrotoxicity characterized by diffuse injury of the proximal tubules that results in the malabsorption of various electrolytes and substances. However, cases of dietary supplement-induced Fanconi syndrome are rare and there is no report on renal histology in these patients. Herein, we present a case of dietary supplement-induced Fanconi syndrome confirmed by renal biopsy.

Case Description: A 49-year-old woman who had been taking a lipid-lowering dietary supplement, Benikoji, was referred to our hospital due to anorexia and nausea over the past 13 days. Blood examinations revealed renal dysfunction, hypokalemia, hypophosphatemia, hypouricemia, and metabolic acidosis. Urinalysis showed proteinuria, glycosuria, hematuria, aminoaciduria, increased excretion of potassium, phosphorus, and uric acid levels, which were not explained by plasma concentration, along with high levels of urinary β_2-microglobulin and N-acetyl-beta-D-glucosaminidase. A drug-induced lymphocyte stimulation test of her serum showed positive for the dietary supplement. A percutaneous kidney biopsy was performed on the second day after admission. Light microscopy analysis showed significant tubular changes, with 50% of the tubular epithelial cells showing simplification, vacuolization, and shedding, indicating acute tubular necrosis. Immunohistochemical staining with an anti-megalin antibody, a proximal tubule marker, was positive for the damaged tubules. Acute proximal tubular injury due to the intake of the dietary supplement was found based on her medical history, laboratory examination, and pathological findings, which led to diagnosis of Fanconi syndrome. Her general condition and clinical laboratory data markedly improved after discontinuation of the dietary supplement and correction of dehydration and electrolyte imbalance. She was discharged 14 days after admission.

Discussion: Clinicians should consider dietary supplement-induced Fanconi syndrome as a differential diagnosis if patients are taking dietary supplements. Kidney biopsy is useful for diagnosing and determining the pathogenesis of dietary supplement-induced Fanconi syndrome. However, further reports are warranted to investigate the exact mechanism of dietary supplement-induced Fanconi syndrome.

SA-PO518

Sheep in Wolf's Clothing: Pseudohypobicarbonatemia in a Patient with Multiple Myeloma

Ziad Alahmadi, Zain Haq, Joshua D. King, Ami M. Patel. *University of Maryland Medical Center, Baltimore, MD.*

Introduction: There are multiple methods to measure serum bicarbonate level which is crucial for diagnosis and management of acid-base disturbances. The most common method is directly measuring the total serum carbon dioxide (CO2) concentration in basic metabolic panel (BMP) via a method based on phosphoenolpyruvate carboxylase (PEPC); another method is by indirect calculation of the bicarbonate concentration via the Henderson-Hasselbalch equation using the measured pH and partial pressure of CO2 (pCO2) in plasma. Multiple confounders can cause discrepancies in the measured bicarbonate in each method, such as increased concentration of serum proteins that can affect the PEPC assay leading to spuriously low bicarbonate values.

Case Description: A 47 year old male patient with multiple myeloma, chronic kidney disease (CKD) and hypertension who presented with hypoxia due to pneumonia

and volume overload in the setting of hypertension and acute kidney injury on top of CKD. Patient improved after antibiotics, intravenous (IV) diuresis, and blood pressure control. He was noted to have significantly low total CO2 level in BMP on admission to 10 mmol/L with anion gap (AG) of 23 mmol/L. Patient was thought to have high anion gap metabolic acidosis and was treated with an IV bicarbonate infusion. Patient had a normal lactate, normal blood sugar, and no apparent contributing factor that would explain this acid-base disturbance. A simultaneous venous blood gas (VBG) showed a pH of 7.35, pCO2 of 42 mmHg and bicarbonate of 22 mmol/L. IgA level and lambda light chain were both significantly elevated at 3804 mg/dL and 1788.97 mg/L respectively. The discrepancy of bicarbonate level between VBG and BMP was explained by increased paraproteins, which have resulted in artifactual errors in PEPC-based laboratory analysis of serum HCO3. The patient's AG and accuracy of serum bicarbonate level measurement improved as their IgA and lambda light chain levels subsequently decreased.

Discussion: Interpretation of serum CO2 is usually accurate; rarely, there are factors that can cause false readings. Arterial or venous blood gas bicarbonate value can guide you to detect pseudohypobicarbonatemia in the appropriate clinical setting.

Discrepancy in HCO3 levels based on paraprotein levels

	HCO3 BMP	Anion Gap BMP	pH VBG	CO2 VBG	HCO3 VBG	Lambda light chain	IgA level
Day 1 of MM treatment	10 mmol/L	23	7.35	42 mmHg	22 mmol/	1788.97 mg/L	3804 mg/dL
Day 7 of MM treatment	19 mmol/L	13	7.41	37 mmHg	23 mmol/L	812.98 mg/L	2276 mg/dL

SA-PO519

A Case of Metabolic Alkalosis, Hyponatremia, and Hypokalemia Secondary to Dietary Chloride Deficiency Syndrome in a J Tube-Dependent Patient

Amitha N. Kapyur,[1,2] John C. Ong,[1,2] Sapna Shah.[2,1] *[1]Los Angeles General Medical Center, Los Angeles, CA; [2]Keck Hospital of USC, Los Angeles, CA.*

Introduction: Chloride deficiency is a well-established contributor of metabolic alkalosis. Hypochloremia results predominantly from renal and extra-renal losses, and rarely from decreased intake. Here, we report a case of metabolic alkalosis, hyponatremia, and hypokalemia from insufficient chloride content in enteral formula in a J-tube dependent patient.

Case Description: A 36 year-old-male with past medical history of caustic injury secondary to alkali ingestion with laryngeal, esophageal, and pyloric strictures who is J-tube dependent for nutrition presents for routine J tube exchange, and is admitted for electrolyte abnormalities. He is otherwise in normal health without any gastrointestinal symptoms or abnormal gastrostomy output. Laboratory tests were notable for pH7.64, PaCO2 53 mm Hg, bicarbonate >50 mEq/L, Na 130 mEq/L, K 2.6 mEq/L, Cl 65 mEq/L, BUN 119 mEq/L and Cr 2.67 mEq/L. XR demonstrated appropriate positioning of his GJ tube. His outpatient enteral nutrition prescription was 5 cartons of TwoCal formula daily. The nutritional chloride content of this prescription is 1.1g/day which is significantly below the daily recommended intake

Discussion: Metabolic alkalosis is one of the most common acid-base disturbances encountered in the hospital setting and is associated with an increased mortality. In a population where nutrition is entirely dependent on an artificial formulation, insufficient electrolyte additions can lead to severe complications. TThere are hundreds of formulations available for enteral feeding, with each varying in their composition. Per USDA, the recommended amount of intake of chloride in an adult is thought to be about 2.3 - 3.1g, though no standardized number has been established. Electrolytes such as sodium and potassium often receive a lot of focus due to their role in metabolic homeostasis while chloride is often overlooked. We suggest that clinicians should include chloride content in their decision making when choosing enteral artificial nutrition in order to avoid an under-recognized potential complication of metabolic alkalosis, hyponatremia, and hypokalemia due to chloride deficiency syndrome.

SA-PO520

Detergent Pica Causing Alkalemia, Life-Threatening Hypokalemia, and Profound Hypochloremia

Munsef Barakat, Anand Achanti, Waleed A. El Sheikh Mohammed. *Medical University of South Carolina, Charleston, SC.*

Introduction: Metabolic alkalosis is characterized by elevated serum bicarbonate and result from either a net loss of acid via the renal or GI tracts or via accumulation of exogenous base. History may reveal unusual cause like detergent PICA. Renal handling of excess bicarbonate is limited by the low GFR, hypovolemia, hypokalemia and hypochloremia.

Case Description: 32 years old lady presented with progressive lower limb weakness, nausea and one episode of vomiting without hematemesis. On further history she reported drinking detergent (Gain & Oxiclean). **Examination:** BP125/70mmHg, HR 77bpm (no orthostatic changes), and normal oxygen saturation 96%. Neurological exam showed mild weakness in proximal lower limbs muscle with normal reflexes. **Labs:** BMP: K 1.3mmo/l, Cl 65mmol/l, HCO_3- 49mmol/l, CPK 3042U/L. Normal TSH, genetic testing was negative for Bartter, Gitelman and Liddle syndrome. PH 7.71, PCO_2 51mmHg, HCO_3- 62mmol/l, ionized calcium 0.93mmol/l. **Urine study:** Cl 87mmol/l, K 8.6mmol/l, Na 24 mmol/l and Cr 90mmol/l **ECG:** prolonged QTc interval and low T- wave amplitude with U-wave. Based on presentation, the likely diagnosis was metabolic alkalosis secondary to pica disorder with consumption of bicarbonate found in detergents which is exacerbated further by the hypokalemia and hypochloremia which limited the kidney ability to mitigate such high alkali load. Furthermore, her severe hypokalemia caused mild rhabdomyolysis as evident by the elevated creatine kinase level. She was admitted to the ICU for telemetry monitoring, started IV chloride rich IV fluids, aggressive parenteral potassium replacement via central venous catheter, she required total of 560mEq of potassium chloride and another 360mEq of oral potassium chloride. 72 hours post admission alkalemia resolved with resolution of the hypokalemia and correction of hypochloremia.

Discussion: Approach to metabolic alkalosis should takes into consideration its different phases of development, the generation, maintenance, and recovery phase. Both hypochloremia and hypokalemia have an inhibitory effect on the pendrin exchanger in the B-intercalated cells as hypochloremia impair the bicarbonate secretion and hypokalemia will downregulate the pendrin expression. In conclusion the correction of metabolic alkalosis require correction of concomitant hypokalemia, hypochloremia and volume resuscitation when clinically appropriate.

SA-PO521

Rapid Correction of Chronic Respiratory Alkalosis Leading to Profound Hyperphosphatemia in a Patient in the Cardiac Intensive Care Unit (ICU)

Kirollos Eskander,[1] Akshita Sahi,[1] Talha Siddique,[1] Jarrod B. Post.[2] *[1]UConn Health, Farmington, CT; [2]Hartford HealthCare, Hartford, CT.*

Introduction: In critically ill patients, changes in extracellular buffer (i.e. bicarbonate) concentrations are expected and usually trigger further work-up into the underlying acid-base disorder. However, hyperphosphatemia in a patient with acute renal failure is often thought to be in the setting of reduced creatinine clearance. But what about 'bone buffering'?

Case Description: Our patient is a 59-year-old female with mixed ischemic and nonischemic cardiomyopathy status post orthotopic heart transplant with a post-transplant course complicated by biopsy-negative rejection with subsequent cardiogenic shock. She developed acute kidney injury and respiratory failure in the setting of hypervolemia. She was initiated on pulse dose steroid and continuous veno-venous hemodialysis with improvement in her oxygenation. The patient had been tachypneic for several months with mild respiratory alkalosis. In light of hypocapnia and normal oxygen saturation, we hypothesize this to be due to alveolar capillary J-receptor stimulation in the setting of chronic pulmonary edema secondary to decompensated heart failure. [1] However, blood gas indicated worsening alkalemia and change in mentation. Labs showed pH 7.60, pCO2 23, bicarbonate 23, and an anion gap of 12. She underwent serum electrolyte mass removal with normal saline replacement to induce therapeutic dilutional acidosis. However, the patient developed concomitant steroid-induced diabetic ketoacidosis the following day with repeat labs showing pH 7.40, pCO2 19, bicarbonate 12, and an anion gap of 28. Within 24 hours, her phosphorus increased from 2.5 to 11.8 with a slight increase in serum calcium from 7.2 to 8.3. Her hyperphosphatemia improved with insulin therapy and with a subsequent increase in pH to 7.56.

Discussion: Our patient's pH, while within the acceptable range at 7.40, reflected a rapid increase in serum H^+ concentration with a drop from 7.60 overnight. Our patient's respiratory compensation was already maximized due to her persistent tachypnea, and she was unable to renally excrete acid due to her AKI. Therefore, we believe this case highlights bone resorption and intracellular buffers such as phosphate in strict control of serum hydrogen ion concentrations. This is congruent with the concomitant increase in serum calcium.

SA-PO522

Acute Hypophosphatemia Due to Rapid Correction of Respiratory Acidosis

Sruthi Sundaram, Payaswini Vasanth, Mohammad Kazem Fallahzadeh Abarghouei. *Emory University Woodruff Health Sciences Center, Atlanta, GA.*

Introduction: Acute respiratory alkalosis is a known cause of acute hypophosphatemia. Here we describe a case of acute hypophosphatemia due to rapid correction of respiratory acidosis in a patient with acute kidney injury (AKI) superimposed on chronic kidney disease (CKD).

Case Description: A 59-year-old male with end stage renal disease due to focal segmental glomerulosclerosis status post renal transplant 17 years prior, chronic kidney disease stage 3b of the allograft, scoliosis with restrictive airway disease, obstructive sleep apnea, and chronic hypercapnic respiratory failure, presented with encephalopathy and acute on chronic respiratory acidosis requiring intubation and mechanical ventilation. He was also noted to have an AKI. As expected in a patient with AKI on CKD, he had hyperphosphatemia on presentation, but did not require renal replacement therapy. However, after intubation and mechanical ventilation, which resulted in an acute decline in his pCO2 level from 88 mmHg to 31 mmHg and an acute rise in pH to 7.53, his phosphorus level acutely dropped to 1.0 mg/dL. His serum phosphorous levels rose to 3.0 mg/dL after being given 20 mmol of intravenous sodium phosphate, which was still within low-normal range despite remaining in an AKI state suggesting these values were true.

Discussion: Hypophosphatemia in acute respiratory alkalosis can occur from a rapid decline in pCO2 and an increase in intracellular pH which induces phosphofructokinase activity and glycolysis, leading to intracellular phosphorus consumption as phosphorylated glucose precursors are produced. As a result, extracellular phosphorus shifts intracellularly acutely dropping serum phosphorus levels. The correction of our patient's hypercapnic respiratory failure with intubation and mechanical ventilation induced a rapid decline in pCO2, which subsequently resulted in a similar decline in serum phosphorus levels likely through a similar mechanism. This case illustrates the importance of monitoring serum phosphorous levels in patients being treated for hypercapnic respiratory failure to avoid complications from acute hypophosphatemia.

SA-PO523

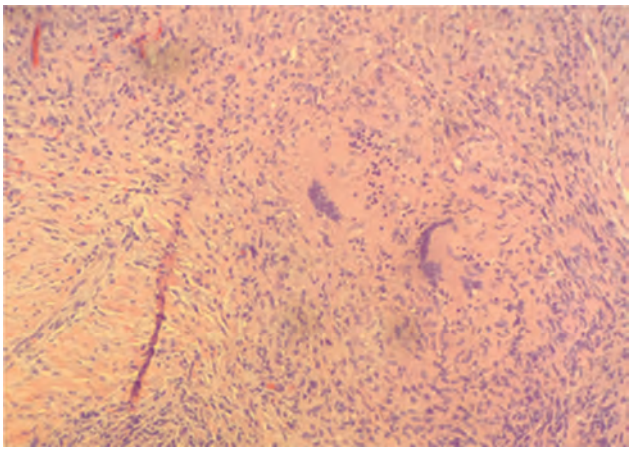
A Case of Hypercalcemia Due to Peritoneal Sarcoidosis Presenting as Appendicitis and Recurrent Sterile Intra-abdominal Abscess with Skin Fistula

Thin Thin Soe,[1,2] Ao Wang,[1,2] Isha Puri,[1,2] Muhammad Azhar,[1,2] Mary C. Mallappallil.[1,2] *[1]New York City Health and Hospitals Corporation, New York, NY; [2]SUNY Downstate Health Sciences University, New York City, NY.*

Introduction: Sarcoidosis is a systemic inflammatory disease which affects multiple organs. The lungs and lymphatic systems are most commonly affected. We present a case of peritoneal involvement.

Case Description: A 47 year old man who had no prior history presented to ED with sudden onset abdominal pain, was diagnosed with acute appendicitis, and underwent laparoscopic appendectomy. The hospital course was complicated by intermittent fevers without leukocytosis, sterile intraabdominal pus like fluid collection and provoked pulmonary embolism. He was discharged with indwelling intraabdominal Jackson-Pratt drain and oral metronidazole. One month later, he presented with abdominal pain, swelling at the surgical site and 20 lbs weight loss. His serum calcium was 16.3, repeated CT abdomen and pelvis revealed mass-like consolidation along the right anterior greater omentum, multiple intra-abdominal rim-enhancing fluid collection (see image). Hypercalcemia workup showed: PTH 8.4, PTHrP <2.0, 25OH VitD 7.03 and 1,25OH VitD 101, ACE level 176. Due to high suspicion of granulomatous disease all infectious causes and malignancy were ruled out with peritoneal fluid cytology. Omental biopsy was done which showed Fibro adipose tissue with non-necrotizing granulomas, Acute and Chronic inflammation with Giant cell reaction (see image). He was diagnosed with sarcoidosis and started on Prednisone after which he clinically improved and hypercalcemia resolved

Discussion: As sarcoidosis is a diagnosis of exclusion, sometimes diagnosing sarcoidosis can be challenging because of its indolent nature, and similar presentation to inflammatory, chronic infectious diseases or malignancy. Peritoneal involvement of sarcoidosis is a rare manifestation.



SA-PO524

Utility of N-terminal Parathyroid Hormone-Related Protein in Evaluating Hypercalcemia in Patients with CKD

Vincent Anthony S. Tang, Anthony Russell Villanueva. *Division of Adult Nephrology, Department of Medicine, University of the Philippines - Philippine General Hospital, Manila, Philippines.*

Introduction: Humoral hypercalcemia of malignancy (HHM) is commonly seen among patients with cancer, and its incidental finding in asymptomatic individuals may be the first indication of an occult malignancy. Parathyroid hormone-related protein (PTH-RP) has been implicated as the circulating factor mediating HHM. However, the diagnostic evaluation of HHM in the setting of CKD can be challenging due to associated alterations in parathyroid (PTH) physiology as well as impaired clearance of PTH-RP metabolites among these patients.

Case Description: A 48-year old female, with CKD 5 from Diabetic Kidney Disease on hemodialysis since 2018, consulted for incidental finding of hypercalcemia. 8 months prior, she was diagnosed with secondary hyperparathyroidism given her hyperphosphatemia, hypocalcemia, and elevated PTH levels. Interim, she was prescribed dietary modifications and non-calcium-based phosphate binders. However, on her most recent laboratory tests, she was noted to have mild hypercalcemia, normophosphatemia, normal vitamin D3 levels, and low-normal PTH levels. She was asymptomatic and denied intake of calcium or vitamin D supplements. Rest of the ancillary history was non-contributory. Her vital signs were normal, and systemic physical exam was unremarkable. Since a PTH-independent cause was considered, N-terminal PTH-RP assay was requested, which came out elevated thus confirming the suspicion of HHM. Screening mammogram revealed an irregularly-shaped, high-density right breast mass. Core needle biopsy and immunohistochemistry staining showed invasive ductal carcinoma (pT2N1M0; grade I; positive for estrogen and progesterone receptors; negative human epidermal receptor-2 status). She was then scheduled for lumpectomy, and adjuvant hormonal therapy. Post-operatively, her calcium levels gradually normalized.

Discussion: Historical trends of calcium, phosphate, and vitamin D levels can aid clinicians to identify concomitant PTH-independent hypercalcemia among patients with CKD. When an occult malignancy is suspected, clinicians should specifically request for N-terminal PTH-RP assays to accurately confirm the diagnosis of HHM. Although more commonly available, C-terminal PTH-RP levels can be falsely elevated in patients with CKD without cancer due to reduced glomerular filtration in this population.

SA-PO525

A Modern and Hip Cause of Profound Hypercalcemia

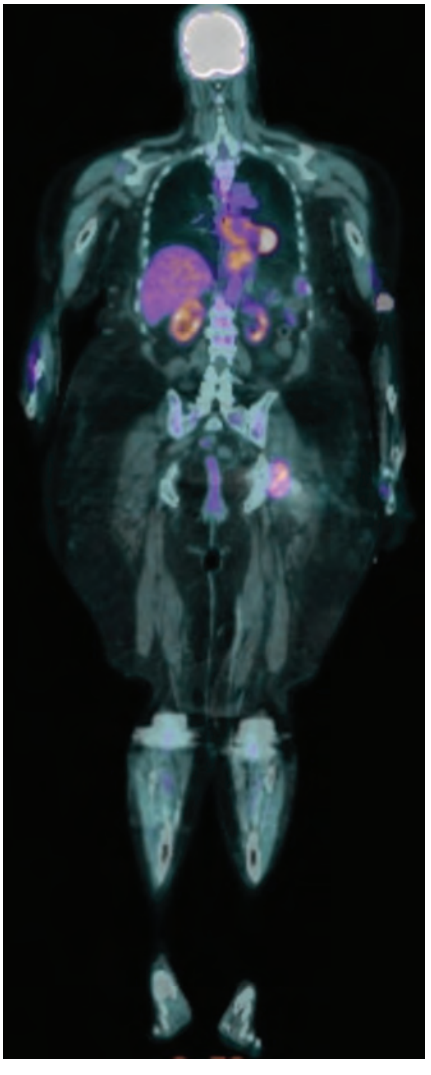
Saud A. Alsaleh, Trevor C. Stevens, William H. Fissell. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Autoimmune/Inflammatory Syndrome Induced by Adjuvants (ASIA) is triggered by adjuvants causing abnormal immune responses. Though usually linked to vaccines and medical products, its link to arthroplasty and cement leak is unexplored. We describe a hypercalcemia case due to ASIA after left hip arthroplasty.

Case Description: A 69-year-old woman with chronic kidney disease had a left hip replacement complicated by dislocation. During revision, there was cement leak into her intramedullary canal. Post-operatively, she developed intermittent episodes of hypercalcemia, which progressed to hypercalcemia (14.7 mg/dL) four years later. Work-up in (see table) was suggestive of granulomatous disease. A PET scan showed intense uptake around the hip arthroplasty and iliac adenopathy, soft tissue biopsy was unrevealing. Therapy with steroids improved her condition along with Vit D 1,25 level, tapering led to return of hypercalcemia and chorioretinitis. Symptoms and response to steroids suggested ASIA with a sarcoid-like reaction.

Discussion: The cement leak from arthroplasty exposes individuals to components, potentially acting as adjuvants and triggering ASIA-like symptoms. ASIA is linked to manifestations such as granulomas, hypercalcemia, uveitis, and CKD. The temporal relationship in this case between cement leak and the onset of autoimmune symptoms suggests ASIA as a potential complication of arthroplasty. More research is needed to establish diagnostic criteria and treatment for ASIA.

Test	Result	Test	Result
PTH	14 pmol/L	Free light chain	Normal ratio
25 Vitamin D	23 pg/mL	Serum Histoplasmosis	Negative
1, 25 OH Vitamin D	150 pg/mL	Serum Blastomycosis	Negative
PTHrp	8 pmol/L	Immunoglobulins	Normal levels
ACE	95 U/L	IGRA	Negative
SPEP/UPEP	No monoclonal disease	HIV	Negative



SA-PO526

Recurrent Hypercalcemia in a Patient with Hodgkin Lymphoma with Concurrent Elevated Parathyroid Hormone-Related Peptide (PTHrP) and Vitamin D

Zachary Appelbaum, Christina H. Brotman. *University of Pennsylvania, Philadelphia, PA.*

Introduction: Hypercalcemia occurs in approximately 30 percent of patients with malignancy. Malignancy-associated hypercalcemia has been attributed to several distinct mechanisms: osteolytic metastases, humoral production of parathyroid hormone-related peptide (PTHrP), excess 1-alpha hydroxylase associated production of 1,25 dihydroxyvitamin D (1,25(OH)2D), and rarely ectopic parathyroid hormone (PTH) secretion. We report a case of hypercalcemia associated with elevated levels of both 1,25(OH)2D and PTHrP in a patient with newly diagnosed Hodgkin lymphoma.

Case Description: A 68 year old man with a history of hypertension initially presented for inguinal hernia repair and was found to have a mediastinal mass on cross sectional imaging. A biopsy revealed Hodgkin's lymphoma. He was scheduled to start chemotherapy as an outpatient, but was found to have severe hypercalcemia with a serum calcium level of 14.7 mg/dL and impaired kidney function with serum creatinine of 2.85 mg/dL. He was hospitalized and received intravenous normal saline, calcitonin 8 units/kg twice daily for 48 hours, and intravenous pamidronate. A workup revealed a suppressed PTH level of 1.4 pmol/L, elevated PTHrP of 3.6 pmol/L, and elevated 1,25(OH)2 D of 220.8 pg/mL. His calcium improved to 9.6 mg/dL and the creatinine improved to 2.0 mg/dL prior to discharge. The following week, his calcium was elevated to 11.4 mg/dL, and he was prescribed prednisone 100 mg for five days. The calcium continued to rise to 13.9 mg/dL and he was again hospitalized and received intravenous fluids, calcitonin, and bisphosphonate therapy.

Discussion: Hypercalcemia of malignancy can be due to a single or a combination of disparate mechanisms. Solid organ tumors are typically associated with PTHrP production while hematologic malignancies are typically associated with increased activity of 1-alpha hydroxylase. We report a case of a patient with Hodgkin lymphoma associated hypercalcemia with elevated levels of both PTHrP and 1,25(OH)2D. His hypercalcemia was not responsive to oral corticosteroids despite the elevated 1,25(OH)2D, suggesting that the hypercalcemia was at least partially attributable to the PTHrP. There have been a few cases of co-secretion of PTHrP and 1,25(OH)2D in Non-Hodgkin's lymphoma; this appears to be the first reported case in a patient with Hodgkin lymphoma.

SA-PO527

Abnormally Normal? A Patient with Hypercalcemia of Malignancy Presenting with Normal PTH

Amelito Manuel L. Andaya,[1] Amelito Miguel L. Andaya.[2] Piedmont Athens Regional GME. *[1]Piedmont Athens Regional Internal Medicine Residency Program, Athens, GA; [2]University of Santo Tomas Faculty of Medicine and Surgery, Manila, Philippines.*

Introduction: In malignancy-related hypercalcemia, serum PTH are usually suppressed with noted elevation in PTHrP. We present a case of hypercalcemia of malignancy due to suspected lung cancer with normal PTH levels.

Case Description: A 73 year old man with multiple substance use including tobacco and alcohol, hypothyroidism, and hypertension presented with a several-day history of confusion and eventually unresponsiveness. He was hypotensive on presentation that responded to normal saline bolus. On exam, he was somnolent, tachycardic, had severely dry oral mucosa, impaired skin turgor, and generalized abdominal tenderness. Pertinent workup showed hypercalcemia at >18, hypernatremia at 154, elevated creatinine at 2.18 and BUN at 66. Ionized calcium was high at 1.81. On further investigation, PTH was normal at 24.30 but PTHrP was elevated at 85. Chest CT scan with contrast demonstrated multiple pulmonary nodules, right hilar and mediastinal adenopathy, lymphangitic carcinomatosis, and bilateral small pleural effusions. Aggressive IV hydration with IV lactated ringers at 150 mL/hr was done. IV zoledronic acid and calcitonin were started. Serum calcium then improved and stabilized to 10.7 however patient's altered sensorium persisted, eventually becoming more agitated. He was then assessed to have metastatic lung cancer and was transitioned to hospice after extensive discussion with the patient and his family.

Discussion: Excessive secretion of PTHrP is said to be the most common cause of hypercalcemia of malignancy. This patient presented with normal PTH levels of 24.30 which would have otherwise led the diagnostic trail to other non-malignant causes of hypercalcemia. Although there is no standard, any PTH greater than 20 pg/mL is considered unsuppressed. In addition, another interesting development was the persistence of the patient's mentation despite eventual successful lowering of the serum calcium. This was hypothesized to be likely secondary to other factors including possible CNS metastasis, hypothyroidism, or undiagnosed dementia. Hence, with the findings of this case, clinicians should not always expect suppression of PTH and at the same time, must be careful in interpreting parameters of improvement in hypercalcemia especially in patients with multiple risk factors.

SA-PO528

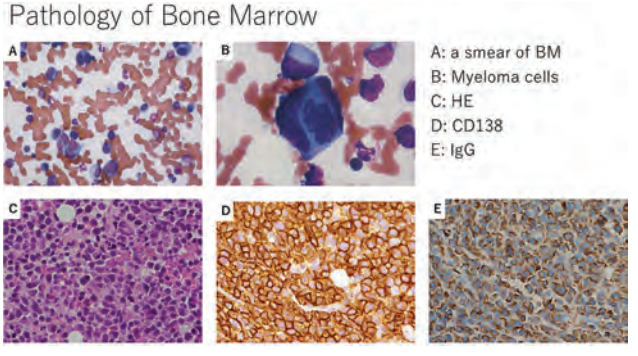
A Rare Case of Nonsecretory Multiple Myeloma: Pitfall of Hypercalcemia

Hitomi Miyata. *Kyoto Katsura Byoin, Kyoto, Japan.*

Introduction: Hypercalcemia is a common disorder normally caused by primary hyperparathyroidism or malignancy. Basically some disease signals seem to come out on the process of differential diagnosis. However, non-secretory multiple myeloma (NSMM) is a rare case and might not show any signs and lead us hard to diagnose it.

Case Description: An 80-year-old man was urgently admitted to our hospital with lower back pain, appetite loss and progressed his limitation of movement and weakness. He had type 2 diabetes and hypertension in his past history. The laboratory data just showed acute kidney injury(serum creatinin 1.63mg/dl) with hypercacemia(serum calcium 1.32mg/dl, calcium ion 1.61mmol/L), moderate higher CRP(5.59mg/dl), hyperuricemia (13.2mg/dl) and metabolic alkalosis. Computed tomography was not detected any abnormality. Both of Urinary BJP and M protein was negative. On Day 21, we rechecked abdominal CT and it showed newly osteolytic lesion on the left ischium. Bone marrow aspiration revealed eventually malignant myeloma and non-producer and non-secretory myeloma cells with both negative findings of M protein and deviation of free light chains.

Discussion: We experienced a rare case of NSMM with acute kidney injury and hypercalcemia. We struggled about differential diagnosis of hypercalcemia without M peak in serum and urinary Bence Jones protein (BJP). Only osteolytic lesions in the lumbar, appeared in three weeks after admission, led us to diagnosis of multiple myeloma. We should seek the examination of bone marrow aspiration and smear of peripheral blood if we get nothing of causes in regard to hypercalcemia.



SA-PO529

Denosumab-Associated Severe Symptomatic Hypocalcemia in a Patient with Multiple Myeloma and AKI

Nerihan Hadji, Hitesh H. Shah. *Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY.*

Introduction: Denosumab, a human monoclonal antibody has several FDA-approved indications including treatment of hypercalcemia of malignancy. Hypocalcemia is a known side effect of this medication however severe symptomatic hypocalcemia has been rarely described in patients with hypercalcemia of malignancy. We present a case of severe symptomatic hypocalcemia following a single dose of Denosumab in a patient with AKI and hypercalcemia from multiple myeloma.

Case Description: 78-year-old male with recent history of multiple myeloma, AKI and hypercalcemia presented to our hospital for abdominal discomfort, back pain, tremors and confusion. Admission labs were significant for severely low serum calcium (SCa) level of 4.8 mg/dL and an elevated serum creatinine (SCr) level of 4.06 mg/dL. Two weeks prior to current presentation, our patient was hospitalized for back pain, AKI and hypercalcemia. During that hospital stay, patient was found to have multiple myeloma on bone marrow biopsy. Scr on that admission was elevated at 2.56 mg/dL and SCa was elevated at 12.0 mg/dL. Patient initially received two doses of calcitonin however as serum calcium remained elevated a dose of Denosumab was administered. SCa normalized to 8.9 mg/dL on discharge. During this hospital stay, patient received multiple doses of intravenous calcium with daily oral calcium and calcitriol therapy for several days for management of persistent hypocalcemia. SCa finally improved to 8.4 mg/dL on discharge. Pt. was discharged on oral calcium and calcitriol therapy with close outpatient monitoring of SCa.

Discussion: Our patient with AKI and hypercalcemia in setting of multiple myeloma developed severe symptomatic hypocalcemia following a single dose of Denosumab treatment. Our patient required prolonged hospitalization for management of severe and persistent hypocalcemia. Based on our experience, we recommend caution with Denosumab use in patients with AKI and hypercalcemia of malignancy. We also recommend very close outpatient monitoring of SCa following Denosumab treatment in this patient population.

SA-PO530

Stepwise Teamwork Approach Saves Patients Extensive Work-Up

Anas R. Alshwayat, Nithin Karakala, Ahmed Abdallah. *University of Arkansas for Medical Sciences, Little Rock, AR.*

Introduction: Hypercalcemia is a relatively common clinical entity that can arise from a variety of etiologies, including primary hyperparathyroidism, malignancies or medications. In most of these cases, the underlying cause can be determined through a thorough clinical evaluation, including a detailed patient history, physical examination and targeted laboratory testing. We present a case with significant hypercalcemia, highlighting the diagnostic approach taken to identify the underlying cause through systematic analysis of the patient's symptoms, laboratory results and imaging studies

Case Description: 77-year-old male with past medical history of hypertension, prostate cancer status post-excision and CKD stage IIIB, was transferred from an outside hospital for evaluation of suspected multiple myeloma. Physical exam was stable but initial laboratory work up showed a serum calcium level of 15.3 mg/dL. He was started on IV fluids with a slight improvement in serum calcium level to 12 mg/dl however it rebounded to 13 g/dl the next day prompting a consultation for Nephrology for management of acute kidney injury and hypercalcemia. A bone marrow biopsy ruled out for multiple myeloma, leading to consideration of other differentials. Parathyroid hormone (PTH) was appropriately low, and 25-Hydroxyvitamin D level was normal, but 1,25-Dihydroxyvitamin D was elevated at 108 pg/mL. This raised the suspicion of hypervitaminosis D due to granulomatous disease (sarcoidosis vs. infection). Detailed history revealed that the patient lived on a farm with various animals, including birds raising suspicion for an inhalational insult. CT scan of the lung that showed a left lung nodule. This was followed by a bronchoscopy that revealed high beta-D-glucan levels and fungal culture showed growth of Pneumocystis Carinii pneumonia. The patient was subsequently treated for PCP. After two months, his hypercalcemia was completely resolved.

Discussion: Pneumocystis pneumonia is recognized for triggering a granulomatous response that stimulates the overproduction of 1,25-dihydroxyvitamin D, resulting in hypercalcemia and a range of complications, including AKI. Hypercalcemia associated with PCP proves resistant to standard treatments and should trigger a thorough patient history inquiry. In many cases, a comprehensive history and examination offer vital diagnostic insights even for non-immunocompromised patients.

SA-PO531

Hypercalcemia-Associated AKI and Nephrogenic Diabetes Insipidus in the Hospital Setting: A Cohort Study

Fnu Suman, Juan Carlos Q. Velez. Ochsner Group. *Ochsner Health, New Orleans, LA.*

Background: Hypercalcemia (hyperCa) can cause acute kidney injury (AKI) through a variety of mechanisms that include renal vasoconstriction, a loop diuretic-like effect, nephrogenic diabetes insipidus, and nephrocalcinosis. Although these clinical associations are well-recognized, their incidence and interrelationship are sparsely reported. We examined the rate of AKI and hypernatremia (hyperNa) during episodes of hyperCa in hospitalized patients.

Methods: A retrospective review of medical records was conducted searching for inpatient adults with hyperCa at Ochsner Medical Center over a 1-year period. Hypercalcemia was defined as serum calcium (sCa) > 11.0 mg/dL. Etiology of hyperCa was determined based on history and available laboratory and imaging data. We examined the rate of AKI (by KDIGO) registered during the hyperCa event, as well as the rate of hyperNa. Patients with end-stage kidney disease or kidney transplant were excluded.

Results: A total of 102 patients with in-hospital hypercalcemia were included. Median age was 72, 35% women, 48% White, 29% Black. Etiology of hyperCa was malignancy in 58 (57%) (multiple myeloma, metastatic bone disease, PTH-related peptide production, or 1,25-vitamin D), exogenous calcium or vitamin D supplements in 29 (28%), thiazide in 3 (3%), sarcoidosis in 3 (3%), and immobilization in 9 (9%). Median peak sCa was 12.1 (11.2-17.8) mg/dL. Corrected sCa was available in 65%, with a median of 12.8 (11.7-15.4) mg/dL. High ionized Ca was verified in 36%. AKI was present in 14 (14%). Hypernatremia was present in 8 (8%). The most severe case of hyperNa had a serum Na 168 mEq/L and a urine osmolality of 110 mOsm/kg, suggesting nephrogenic diabetes insipidus. The second most severe case of hyperNa had a serum Na 150 mEq/L and a urine osmolality of 603 mOsm/kg, suggesting absence of ongoing water losses. Urine osmolality was not measured in the remaining 6 hyperNa cases. Concomitant AKI and hyperNa only occurred in 2 (2%).

Conclusions: AKI occurred in 1 in 7 cases of hyperCa, whereas hyperNa occurred in 1 in 12 cases. Urine osmolality is seldom obtained in cases of hyperNa. Because hyperNa was only present in 2/14 (14%) of AKI cases, the primary mechanism of AKI in hyperCa may not relate to nephrogenic diabetes insipidus. Further investigation is warranted.

SA-PO532

Antineoplastic Agents Associated with Hypomagnesemia and Effect Modifiers for the Associations

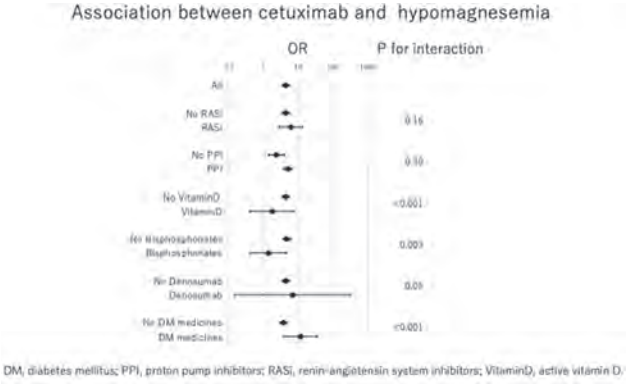
Kodai Suzuki, Miho Murashima, Yuki Miyaguchi, Takahisa Kasugai, Tatsuya Tomonari, Minamo Ono, Masashi Mizuno, Takayuki Hamano. *Nagoya Shiritsu Daigaku Daigakuin Igaku Kenkyuka Igakubu, Nagoya, Japan.*

Background: Hypomagnesemia (hypoMg) is common and associated with worse outcomes among patients with malignancy. In this study, we aimed toidentify anti-neoplastic agents associated with it and modifiable factors for the associations.

Methods: In this retrospective cohort study, we enrolled patients receiving antineoplastic agents at Nagoya City University Hospital from 2018 to 2020. We employed mixed-effects logistic regression models to identify factors associated with hypoMg (Mg<1.8mg/dL) and effect modifiers for the associations. As a sensitivity analysis, missing data for dipstick proteinuria were multiply imputed and the data were analyzed by Poisson regression with frequency of laboratory measurements as an exposure variable.

Results: A total of 2644 patients were included. The mean age was 63.8 (16.5) years and the mean eGFR was 71.9 (21.1) mL/min/1.73m2. Serum magnesium (Mg) was measured at least once in 1692 (64.0%) patients, of these, 718 (42.4%) developed hypoMg (15.5 events/100 patient-measurements). Cetuximab was most strongly associated with hypoMg (OR 4.36 [3.44-5.54]), followed by platinum drugs (2.20 [1.87-2.59]). Loop diuretics were negatively associated with hypoMg (0.76 [0.61-0.96]), while eGFR was not. Cetuximab was associated with hypoMg among non-users of vitamin D recptor activator (VDRA) (4.36 [3.44-5.54]) and non-users of bisphosphonates (4.70[3.65-6.04]) but not among users of these agents (p for interaction <0.001 and 0.003, respectively). In the sensitivity analyses, the effect modification by VDRA was consistent, while the effect modifications by bisphosphonates were not observed. Proteinuria was not associated with hypoMg and no effect modifications were seen by eGFR or proteinuria.

Conclusions: HypoMg was common among those with malignancy, while only about two-thirds of patients had Mg measurements. Cetuximab was the agent most strongly associated with hypoMg, and cetuximab-induced hypoMg might be prevented by using vitamin D or bisphosphonates.



DM, diabetes mellitus; PPI, proton pump inhibitors; RASi, renin-angiotensin system inhibitors; VitaminD, active vitamin D.

SA-PO533

Evaluating the Prognostic Significance of Magnesium Levels in Emergency Department Admissions: The Largest Retrospective Cohort Study

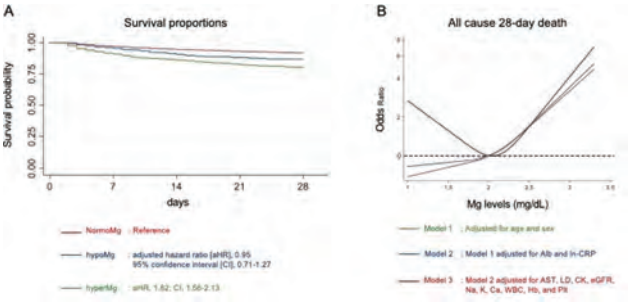
Keita Hattori, Nobuhiro Nishibori, Masaki Okazaki, Nobuhide Endo, Kazuhiro Furuhashi, Shoichi Maruyama. *Nagoya Daigaku, Nagoya, Japan.*

Background: Previous research has reported hypermagnesemia (hyperMg) in the emergency department (ED) as an independent mortality factor, however there are no studies which evaluated consecutive cases because magnesium (Mg) is routinely measured. On the other hand, hypomagnesaemia (hypoMg) in the ED is controversial. Our study aims to address these limitations and provide a comprehensive analysis of the relationship between Mg levels and mortality.

Methods: We conducted a retrospective cohort study of patients admitted in the ED of the Anjo Kosei Hospital, Japan. Consecutive patients more than 18 years old from January 2017 to December 2019 were included. Patients were divided into three groups according to Mg categories (Mg ≦ 1.5, 1.5 < Mg ≦ 2.4, and Mg < 2.5 mg/dL). We investigated association Mg levels and 28-day death using multivariable Cox proportional hazard model. Restricted Cubic Spline (RCS) analysis was also performed for evaluation of non-linear relationship.

Results: There were 43,100 ED visits and 43,808 cases of Mg data are available. Among included 11,532 patients (mean age, 75 years; 58% male; mean Mg, 2.1 mg/dL; mean length of hospital stay, 11days), 404 (3.6%), 9,826 (85.2%), and 1,302 (11.2%) patients were classified as hypoMg, normoMg, and hyperMg, respectively. Survival curves are shown in Figure A. RCS analysis in Figure B showed no significant increase in the hazard ratio for hypomagnesemia, but a significantly higher hazard ratio for hypermagnesemia in multivariate-adjusted models after adjustment for CRP and Alb.

Conclusions: In patients admitted from the ED, HyperMg was associated with 28-day mortality, while hypoMg was not associated.



SA-PO534

Correlation between Ionized and Total Magnesium in Children on Continuous Kidney Replacement Therapy

Shruthi Mohan,[1] Denise C. Hasson,[2] James Rose,[1] Stuart Goldstein,[1,3] Stefanie W. Benoit.[1,3] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]NYU Langone Health Hassenfeld Children's Hospital, New York, NY; [3]University of Cincinnati College of Medicine, Cincinnati, OH.*

Background: Abnormal magnesium (Mg) levels are associated with poor outcomes in critically ill children. Regional citrate anticoagulation (RCA) during continuous renal replacement therapy (CRRT) may deplete Mg by chelating ionized Mg (iMg) and lead to negative Mg balance. iMg data in children on CRRT are sparse, and existing concordance data between iMg and total Mg (tMg) levels are conflicting. We assessed iMg/tMg correlation in critically ill children during CRRT with RCA.

Methods: Blood samples collected prospectively to measure iMg immediately before, 1-2, and 18-24 hours after the first CRRT start. We compared iMg to tMg levels obtained for clinical purposes. Normal iMg and tMg were based on reference ranges of 0.44-0.65 and 0.66-1.07 mmol/L, respectively.

Results: 17 patients provided 48 iMg and 37 tMg samples. Low iMg was seen in 12% (2/17) at CRRT start, 35% (6/17) at 1-2 and 70% (12/17) at 18-24 hours. iMg decreased over time (β = - 0.005, $p < 0.001$). iMg and tMg levels showed moderate correlation ($r = 0.71$, $p < 0.0001$). The citrate dose, CRRT effluent dose, CRRT fluid type, or Mg dose in parenteral nutrition did not differ between patients with normal *vs.* low iMg at 24 hours after CRRT initiation.

Conclusions: iMg and tMg showed moderate correlation in critically ill children receiving CRRT with RCA. Increased prevalence of low iMg within 24 hours of CRRT initiation highlights the need for vigilant Mg monitoring and further exploration of Mg trends after 24 hours.

Funding: Commercial Support - Nova Biomedical provided critical care blood gas analyzer and supplies for research

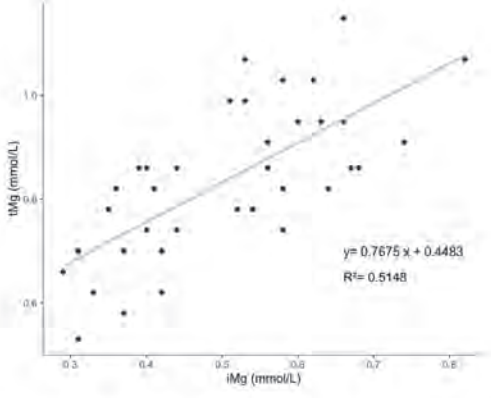


Figure 1: Correlation between iMg and tMg in CRRT. Grey line indicates the simple linear regression line. Pearson's Correlation coefficient for iMg and tMg showed moderate association ($r = 0.717$, $p < 0.0001$)

Table 1: Comparison of normal vs. low iMg groups 24 hours after CRRT initiation. Median, IQR for numeric variables, and N (%) for categorical variables are shown. Mann Whitney U test or Fisher Exact test showed no significant differences between the groups.

Variables	Normal iMg (n = 5/17) Median (IQR)	Low iMg (N = 12/17) Median (IQR)	P value
Age (years)	14 (2 -14)	3 (0.9 – 14.3)	0.49

Genome-Wide Association Study of Candidate Genes Associated with Hypomagnesemia in the MyCode Population

Adwait S. Chafale,[1] Ian Dinsmore,[2] Tooraj Mirshahi,[2] Alexander R. Chang.[2] *[1]Geisinger Commonwealth School of Medicine, Scranton, PA; [2]Geisinger Health, Danville, PA.*

Background: Magnesium is the second most common intracellular cation with many critical roles in enzymatic reactions the body. Consequently, hypomagnesemia has been linked to dysfunction of multiple diseases. Our aim in this study was to identify potential genetic causes of hypomagnesemia.

Methods: We conducted a genome-wide association study (GWAS) using data from 68620 participants with outpatient serum magnesium levels in the Geisinger MyCode DiscovEHR study, a health system-based cohort in central and northeast Pennsylvania. Cases of hypomagnesemia were defined as magnesium levels <1.75 mg/dL (n=7704; 11.2%).

Results: Using a genome-wide significance cutoff ($p < 5x10^{-8}$), we identified numerous significant loci (Figure). The top loci associated with hypomagnesemia identified included rs11255473 located near the *TAF3* gene (p =7.02E-14), rs2070803 located near *MUC1/TRIM46* (p = 2.25E-13), rs7133329 located near MIR4491 (p=1.41E-10), rs78116544 located near *HERC2P3* (p=1.07E-10), rs11079428 located near *BCAS3* (p=1.26E-9), rs11079428 located near TBX2-AS1 (p=1.26E-9), rs1210864775 located near 5_8S-rRNA (p=3.78E-09), and rs2844882 on chromosome 14 (p=2.81E-09).

Conclusions: Our hypomagnesemia GWAS confirms an association between *TAF3* and hypomagnesemia, and identifies several other novel loci associated with magnesium.

SA-PO536

Critical Hypermagnesemia Induced by Excessive Milk of Magnesia in Acute Kidney Failure

Pooja V. Nangrani, Shikha Jaiswal. *UC Health Medical Center, Cincinnati, OH.*

Introduction: Hypermagnesemia is rare, usually caused by excessive magnesium intake, impaired renal excretion, or both, with most cases being mild and asymptomatic. Here, we present a case of severe Hypermagnesemia in the setting of Peptic Ulcer disease and Acute Renal Failure.

Case Description: 68-year-old Male with a history of Heart Failure with Reduced Ejection Fraction, EF 45%, Mobitz II, status-post pacemaker, and prior percutaneous cholecystostomy, normal baseline renal function, presented with nausea, vomiting, and epigastric pain. Initial CT showed pneumonia but no intraabdominal abnormalities. Labs were unremarkable, with a magnesium of 1.5 mg/dL. Suspecting Peptic ulcer disease, he was given 3 doses of 400 mg magnesium oxide and 2 doses of 2400 mg Milk of Magnesia. Thereafter, He left Against Medical Advice (AMA), only to return 12 hours later with worsening abdominal pain, hypotension, and tachycardia. Repeat CT showed large pneumoperitoneum. EKG was notable for paced rhythm and prolonged QTc. He was emergently taken for exploratory laparotomy for suspected duodenal perforation, even before labs could be obtained. Post-op labs showed critically elevated magnesium at 11.6 mg/dL, and serum creatinine at 2.5, with oliguria. He was started on normal saline, with Lasix and calcium gluconate as a temporizing measure. He then underwent urgent intermittent hemodialysis (HD), followed by continuous Renal replacement therapy for 24 hours. Magnesium gradually improved to 4.7, and to 2.5 over the next 24 hours. He admitted to drinking ¾ bottles of Milk of Magnesia after leaving AMA. After discontinuing HD, magnesium levels remained in the normal range, and urine output and creatinine gradually improved.

Discussion: Significant exogenous magnesium intake can exceed the kidneys' excretory capacity, especially in cases of renal impairment. Gastrointestinal inflammation can lead to increased absorption. Magnesium levels greater than 10mg/dl can lead to neuromuscular paralysis and even cardiac arrest and require emergent hemodialysis. Calcium gluconate antagonizes hypermagnesemia's neuromuscular and cardiac effects and should be given promptly. This case highlights the need for concise patient history, judicious medication administration, emergent therapies for electrolyte abnormalities, and patient education to prevent risks associated with self-medication and AMA discharges.

SA-PO537

Making Haste in Magnesium Waste: A Case for Genetic Testing

Andrea Chau, Michael T. Sim, Brian Y. Young. *UC Davis Health, Sacramento, CA.*

Introduction: Hypomagnesemia is estimated to affect between 2-15% of the general population. While the most common etiologies of hypomagnesemia are acquired, genetic causes need to be considered and can be associated with additional complications. Our case describes a patient found to have an HNF1B gene mutation.

Case Description: A 22-year-old female with multiple sclerosis and borderline primary hyperparathyroidism was found to have hypomagnesemia during work up for chronic headaches and fatigue. Despite discontinuation of a PPI, the patient had persistent hypomagnesemia requiring intermittent IV repletion. Laboratory testing showed isolated hypomagnesemia as low as 1.0mg/dL, with normal serum potassium and other electrolytes, high-normal calcium, and creatinine of 0.7mg/dl. Renal ultrasound was unremarkable. Her initial FeMg at 2% was borderline and non-diagnostic for renal wasting. A 24-hour urine magnesium was done, with results suggestive of renal wasting at 155mg in the presence of hypomagnesemia (normal < 30mg/24 hours). Of note, the patient was still receiving IV magnesium repletion, which may confound 24-hour urinary testing. Ultimately, genetic testing was pursued given diagnostic uncertainty, and it revealed a heterozygous mutation in HNF1B.

Discussion: Unlike most patients with HNF1B mutations who have renal cystic disease or hypoplasia, our patient's kidneys were anatomically normal. Her only clinical manifestation was hypomagnesemia, which occurs in up to 50% of patients. Of its many roles, HNF1B regulates the transcription of a subunit of Na/K-ATPase in the kidney and is involved in distal convoluted tubule magnesium reabsorption. The HNF1B mutation may also explain this patient's hyperparathyroidism, as mutations can cause loss of PTH transcription repression. Absent clear indicators for the etiology of hypomagnesemia, genetic testing was imperative. Providers may now screen for associated complications of HNF1B mutations, such as early-onset diabetes, chromophobe renal cell carcinoma, CKD, and abnormal liver function. HNF1B is only one of many genetic causes of hypomagnesemia and has variable phenotypic manifestations. Genetic testing should be considered in the evaluation of hypomagnesemia because diagnosis can allow for early identification and prevention of comorbidities, as well as referrals to genetic counseling.

SA-PO538

Overlooked Cause of Hypomagnesemia

Nidhi Gupta, Golnaz Vahdani. *Banner - University Medical Center Tucson, Tucson, AZ.*

Introduction: Hypomagnesemia can occur due to GI losses or renal wasting. Genetic causes of hypomagnesemia usually include Bartter/ Gitelman syndrome or isolated hypomagnesemia. We present a case of hypomagnesemia that was initially misdiagnosed as Gitelman syndrome, however later diagnosed as HNF1beta mutation.

Case Description: A 25-year-old female with history of Gitelman syndrome presented to our hospital for evaluation of jaundice. Jaundice that began at age 17, with prior liver biopsies revealing idiopathic ductopenia. Nephrology was involved in the treatment of electrolyte abnormalities. At age 18, the patient was noted to have hypokalemia and hypomagnesemia with fractional excretion of magnesium at 32%. Renin was elevated and the patient was diagnosed with Gitelman syndrome. On admission, she was noted to have hypocalcemia which did not fit the diagnosis of Gitelman syndrome. Genetic testing was recommended in addition to replacing her electrolytes. Patient underwent a liver biopsy and genetic testing, and was eventually discharged on spironolactone, potassium chloride, oral magnesium and calcium carbonate supplementation along with outpatient appointment for iv magnesium infusions. She was readmitted for decompensated cirrhosis and acute kidney injury requiring renal replacement therapy and underwent liver transplantation. Kidney imaging revealed bilateral simple cysts measuring upto 2.1 cm. Genetic reports showed 17p-12 deletion syndrome which explained her liver and kidney disease. Patient to date continues to receive iv magnesium infusions weekly. She was recently started on dapagliflozin.

Discussion: 17p-12 deletion encompasses 23 known genes, one of which includes hepatocyte nuclear factor 1 beta mutation. This mutation is associated with renal magnesium wasting due to dysfunction of distal convoluted tubule with 100% occurrence by at 13.8-18 years. These patients may be misdiagnosed as Gitelman syndrome, hence early recognition of this mutation in patients presenting with liver and kidney disease should be considered to avoid extensive diagnostic evaluation and economic burden to the health system.

"Tubular Intoxication": Phosphatidylethanol Testing to Diagnose Alcohol-Induced Hypomagnesemia

Sophia M. Cima,[1] Aj Lowe,[1] Jay L. Hawkins,[2] Prasanth Ravipati.[2]
[1]University of Nebraska Medical Center College of Medicine, Omaha, NE; [2]University of Nebraska Medical Center, Omaha, NE.

Introduction: Hypomagnesemia occurs with chronic alcohol (EtOH) use through multiple pathways including intestinal malabsorption, decreased dietary intake, and importantly, renal magnesium wasting. Previous data has shown that discrepancy between patient reported EtOH consumption and true EtOH intake is common. A new test, called Phosphatidylethanol (PEth), is an invaluable tool in identifying EtOH consumption patterns and alcohol-related disorders. PEth accumulates with repeat ethanol exposure, and thus, PEth reliably indicates a person's EtOH consumption over the prior 28 days. We present a case series of 3 patients with uncertain etiology of hypomagnesemia, in which PEth testing confirmed a diagnosis of chronic EtOH consumption resulting in renal magnesium wasting.

Case Description: A 68-year-old man and 58-year-old woman were referred to nephrology clinic for hypomagnesemia refractory to supplementation. They had chronic magnesium levels of 1.2-1.4 mg/dL and 1.1-1.5 mg/dL, respectively. A 33-year-old man was admitted to the hospital due to muscle spasms and weakness and was found to have magnesium level of 0.9 mg/dL. Fractional excretion of magnesium on a random urine sample was greater than 8% in all patients. All patients had normal renal function, were without additional risk factors for renal magnesium wasting, and reported consuming less than 6 drinks per week. PEth levels (ng/mL) were 1,401, 206, 337 – indicating severe EtOH consumption (level > 200) and consistent with EtOH intake beyond the patients' report.

Discussion: In the setting of hypomagnesemia associated with renal magnesium wasting, the differential is broad, including EtOH consumption. EtOH consumption as reported by patients can be difficult to quantify and can be misleading. With the novel use of PEth testing, these three patients were ultimately diagnosed with EtOH use disorder as the cause of their hypomagnesemia and referred to addiction services. In the evaluation of hypomagnesemia, PEth testing can help clinicians identify EtOH use disorder and help optimize management strategy, potentially reducing the need for additional work up (genetic testing, medication adjustments, additional consultations).

SA-PO540

Severe Hypomagnesemia Due to Renal Magnesium Wasting in Patient with HNF1B Mutation and Pseudogout

Michael Che, Peter Magner, Caitlin Hesketh, Pierre-Antoine Brown. *University of Ottawa, Faculty of Medicine, Division of Nephrology, Ottawa, ON, Canada.*

Introduction: Hepatocyte nuclear factor 1β (HNF1B) is a transcription factor that is essential for proper development of the kidney and pancreas. Here, we report a case of severe hypomagnesemia and cystic kidney disease due to *HNF1B* mutation in a patient with pseudogout.

Case Description: A 41-year-old female with hypothyroidism and frequently flaring pseudogout with severe chondrocalcinosis in multiple joints was referred to nephrology for assessment of hypomagnesemia refractory to oral magnesium (Mg) supplementation. There was no history of gastrointestinal losses, offending medications, or family history of hypomagnesemia. Plasma Mg was 0.35 mmol/L and she had metabolic alkalosis with total CO2 of 32 mmol/L but normal plasma calcium, potassium, sodium, phosphate, creatinine, and parathyroid hormone. Plasma Mg was very low for at least one year prior to nephrology assessment. Urine fractional excretion of Mg (FEMg) was 3.9%, consistent with renal Mg wasting. Genetic testing for hereditary causes of renal Mg wasting revealed a heterozygous pathogenic *HNF1B* gene variant, identified as 1.26 Mb deletion, seq[GRCh37] del(17)(q12), chr17:g.34842466_36104935del. An abdominal CT scan revealed a congenital agenesis variant of the dorsal pancreas and multiple left renal cysts, both in keeping with her *HNF1B* mutation. She was treated with amiloride, titrated to 15 mg BID, to reduce renal Mg wasting, in addition to oral Mg glycinate supplementation, but her Mg continued to remain low. Consequently, she was also started on IV Mg sulfate 5 mg weekly. Plasma Mg improved slightly to 0.5 mmol/L but FEMg remained high at 5.5%. Dapagliflozin 10 mg daily was further added and FEMg improved to 2.6%. Her plasma Mg fluctuates depending on timing relative to weekly IV Mg infusion but has been as normal as 0.9 mmol/L. She continues on oral Mg supplementation, weekly IV Mg infusions, and amiloride and dapagliflozin.

Discussion: Severe hypomagnesemia is known to cause increased chondrocalcinosis likely contributing to the patient's poorly controlled pseudogout. Numerous renal manifestations are associated with *HNF1B* mutations including cystic kidney disease and renal Mg wasting as demonstrated in this case. Hypomagnesemia when associated with *HNF1B* variants may be severe, refractory to oral Mg supplementation, and consequently may benefit from IV Mg infusions and diuretic therapy.

SA-PO541

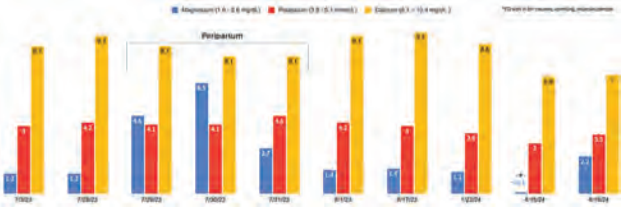
Severe Hypomagnesemia in Pregnancy

Ankita Ashoka, Monica L. Reynolds. *The University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Introduction: Hypomagnesemia in pregnancy has been associated with a higher risk for perinatal complications. We report a case of severe hypomagnesemia of unknown etiology in a woman presenting for prenatal care. Genetic testing revealed mutations in the transient receptor potential cation channel membrane 6 (TRPM6) gene leading to intestinal and renal magnesium(Mg) wasting with secondary hypocalcemia.

Case Description: A 37-year-old woman with a history of infantile seizures was referred to nephrology clinic for prenatal evaluation of hypomagnesemia. She reported pediatric work-up revealing hypomagnesemia and one episode of breakthrough seizure in adolescence after stopping chronic Mg supplements. Family history was noted to be unremarkable. Laboratory values were notable for Creatinine 0.65mg/dL, fractional excretion(Fe) of Mg 2.5%, Fe calcium(Ca) 1.9%. Trends for Mg, Ca, and potassium are noted in the image. Kidney-centered genetic testing identified two mutations in TRPM6: one known to cause intestinal losses (c.1081C>T; p. Gln361*) and a variant of uncertain significance (c.1732-3C>G; p.?). At 36 weeks 3 days, the patient developed preeclampsia with severe features and was treated with intravenous (IV) Mg, maintaining levels > 4 mg/dL at time of delivery, and was discharged on oral Mg supplements. At 8 months postpartum, she presented to the hospital with seizures and was noted to have a Mg level of <0.1 mg/dL requiring IV Mg supplementation.

Discussion: For most women in the United States, prenatal care is their sole contact with the health care system, offering a rare opportunity to diagnose and optimize chronic disease. Through nephrology referral and genetic testing, our patient was able to secure a diagnosis and understand implications for inheritance in her offspring. Though it is uncertain if the mutations found in our case are biallelic, her clinical history and lab findings suggest these mutations together are pathogenic in an autosomal recessive manner. We advocate for early genetic testing in patients presenting with severe hypomagnesemia to improve diagnosis and management. Aggressive management of hypomagnesemia during the prenatal period is also warranted, given its association with pre-eclampsia and preterm birth.



SA-PO542

A Case Study of Treatment-Resistant Hypomagnesemia in a Young Adult with HNF1B Mutation

Ryan M. Trimble. *Atrium Health Wake Forest Baptist Medical Center, Winston-Salem, NC.*

Introduction: It is well-established that genetic mutations can cause familial hypomagnesemia syndromes. One of the most common inherited causes of renal malformation is mutation in the transcription factor hepatocyte nuclear factor 1B (HNF1B) which can result in renal tubular dysfunction, leading to magnesium wasting (1). HNF1B plays a role in the regulation of FXYD2 gene transcription, involved in the tubular handling of magnesium through encoding the γ a-subunit of the Na+-K+-ATPase. HNF1B is important in nephrogenesis and maintaining tubular function (2). In addition to these renal manifestations, HNF1B mutations have been linked to other clinical issues including exocrine pancreatic insufficiency, renal cysts, liver dysfunction, gout, and genital tract malformations (3). This high clinical variability can hamper clinical diagnosis.

Case Description: We report a 35 year old female patient with a history of migraines, chronic hypokalemia, and hypomagnesemia presenting with refractory hypomagnesemia despite supplementation. She had several episodes of syncope and consistently low magnesium level ranging between 0.8-1.1 mmol/l for the past 7 months while on 8 tablets of magnesium supplementation (64 mg). Her potassium levels were normal with daily supplementation of 40 mEq. A 24-hour urinary magnesium test revealed hypermagnesuria and hypocalcuria. Genetic study revealed a whole gene deletion of HNF1B.

Discussion: The patient's persistent hypomagnesemia raised concern for a genetic disorder affecting magnesium regulation. The presence of high magnesium and low calcium levels on a 24-hour urinary test further suggests this. Genetic analysis revealed a complete deletion of the HNF1B gene aligning with a diagnosis of HNF1B-related autosomal dominant tubulointerstitial kidney disease, a condition characterized by kidney cysts, diabetes, and issues with electrolyte regulation, including low magnesium and potassium levels. This case emphasizes the importance of considering genetic mutations in patients with stubborn hypomagnesemia and underscores the need for healthcare providers to refer such patients to a nephrologist or genetic counselor for thorough assessment. In summary, mutations in HNF1B are a common genetic cause of kidney malformations and tubular dysfunction. Identifying and addressing these related conditions are essential for providing optimal care to individuals with HNF1B syndrome.

SA-PO543

SGLT2 Inhibitors: Unlocking the Solution for Refractory Hypomagnesemia in Suspected Gitelman Syndrome

Irtiza Hasan, Bhaktidevi Makadia, Vishal Jaikaransingh, Charles W. Heilig. *University of Florida College of Medicine - Jacksonville, Jacksonville, FL.*

Introduction: Hypomagnesemia is a rare and poorly understood magnesium (Mg+) disorder, often resistant to conventional therapies. Emerging studies suggest sodium-glucose cotransporter 2 inhibitors (SGLT2i) may help. We present a case of complex refractory hypomagnesemia with suspected Gitelman Syndrome successfully treated with SGLT2 inhibitors.

Case Description: A 70-year-old woman with PMH of CKD stage 2, DM T2, HTN presented with chronic severe hypomagnesemia & frequent muscle cramps. She was on Pantoprazole & HCTZ for >7 years, discontinued 1 year before presentation. Workup as follows: Na+ 140 mmol/L, K+ 3.4 mmol/L, CO2 27 mmol/L, BUN 8 mg/dL, Creatinine 0.8 mg/dL, Glucose 205 mg/dL, Ca+ 9.9 mg/dL, & Mg+ ranging between 1.0 to 1.3 mg/dl. 24-hour urine lytes: Mg+ 59.4 mg, Ca+ 68 mg/dL, K+ 50 mmol, Na+ 90 mmol. Creatinine 0.8 g. Fractional excretion (FE) of Ca+ 0.01% & Mg+ 6.9%. Suspected a case of Gitelman Syndrome (genetic test pending) and initially started on oral Mg+ as well as Mg+ IV infusion (4g/4 weeks), which was later increased to 4g weekly for 4 weeks with maintenance at 4g-biweekly. Due to the refractory nature, she started on an SGLT2i (Empagliflozin 10 mg daily), resulting in dramatic improvement & stable Mg+ levels (>2.0 mg/dl) without any further infusion. Interestingly, three of her four children also developed low magnesium after age of 50, requiring supplements, currently under investigation.

Discussion: To the best of our knowledge, this is the first reported case of Gitelman treated with SGLT2i. Studies suggest SGLT2i can improve magnesium homeostasis, especially in diabetic patients. Possible mechanisms include glycemic control with magnesium redistribution and enhanced intestinal absorption/renal resorption via TRPM6-medicated transport. Further research is needed to define the role of SGLT2i in treating hypomagnesemia & its inclusion in treatment guidelines for refractory cases.

Developing a Highly Sensitive Meso Scale Discovery (MSD) SLIT Immunoassay for Chronic Kidney and Eye Disease

Easton J. Liaw,[1,2] Sudhir Kumar,[1,3] Xueping Fan,[1,3] Courtney Huynh,[1,3] Insa M. Schmidt,[1,3] Sara I. Shoushtari,[1] Zahra Sheikh,[1,3] Manju L. Subramanian,[1,3] Sushrut S. Waikar,[1,3] Weining Lu.[1,3] *[1]Boston University Chobanian & Avedisian School of Medicine, Boston, MA; [2]Boston University Sargent College of Health & Rehabilitation Sciences, Boston, MA; [3]Boston Medical Center, Boston, MA.*

Background: Both kidney failure and blindness are common complications of poorly controlled diabetes mellitus, which afflicts over 150 million people around the world. The kidney and eye share several structural similarities and developmental pathways that may account for their shared susceptibility as end-organ complications of diabetes. SLIT is a ligand for ROBO receptors. SLIT/ROBO pathway plays essential roles in kidney and eye development. Published ELISA results showed upregulation of SLIT protein expression in both chronic kidney and eye diseases. Recently, a novel SLIT inhibitor has advanced to a phase II clinical trial for proteinuric kidney disease. However, the low sensitivity and dynamic range of the ELISA assay have made the SLIT immunoassay results unreproducible.

Methods: We developed a highly sensitive Meso Scale Discovery (MSD) immunoassay using an electrochemiluminescence detection technique with a greater dynamic range that may replace previously developed ELISAs for SLIT detection. In a process similar to a sandwich ELISA assay, we detected and quantified standard SLIT recombinant protein and unknown SLIT concentration in human and mouse samples using the MESO QuickPlex SQ120 instrument.

Results: Our data showed a greater dynamic range and more precise and accurate readings on a lower concentration of SLIT using the MSD assay (LLoD=5 pg/ml, ULoD=20,000 pg/ml) compared to regular ELISA (LLoD=1,000 pg/ml, ULoD=50,000 pg/ml). We also found the optimal concentrations of the capture and detection antibodies that best suit the SLIT measurements. Besides the newly developed SLIT MSD assay able to detect low protein levels, we also discovered 7-fold higher SLIT levels in vitreous humor compared to blood samples in humans and an 80% serum SLIT level reduction in mice treated with a SLIT inhibitor.

Conclusions: We have developed a highly sensitive MSD assay across 4 orders of magnitude for SLIT in humans and mice. This assay may be used in clinical trials as a target engagement biomarker for SLIT inhibitors and in preclinical animal models of diabetic kidney and eye diseases.

SA-PO545

Developing a Model of Urosepsis Using a Kidney and Lung-on-a-Chip System

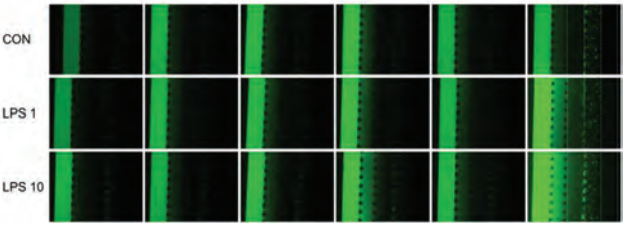
Eun Mi You, Eun-Jeong Kwon, Sejoong Kim. *Seoul National University Bundang Hospital, Seongnam, Republic of Korea.*

Background: The emergence of organ-on-a-chip models has revolutionized preclinical investigations, yet a crucial gap persists in the absence of an in vitro model for lung injury resulting from urosepsis. To address this, we engineered a novel 3D microfluidic chip capable of mimicking urosepsis within the kidney, lung, and vascular microenvironments.

Methods: Our kidney and lung-on-a-chip platforms were designed with five channels, facilitating co-culture of HK-2 (human kidney proximal tubule epithelial) cells, HUVEC (human umbilical vein endothelial) cells, lung fibroblasts, and BEAS-2B (immortalized bronchial epithelial cell) cells. Confocal imaging was employed to assess tubular formation induced by shear stress. Urosepsis was simulated by administering LPS (lipopolysaccharide) to HK-2 cells over a 3-day period. Subsequent to LPS treatment, cell injury was evaluated, including cell-to-cell distance measurement via CK8 staining, cadherin expression analysis in HUVEC cells to gauge cell adhesion, and assessment of cell permeability and protein expression using FITC and dot blot analysis. The observation of Beas2B cell death due to LPS was inconclusive in our findings.

Results: Application of shear stress during cell culture led to increased cell proliferation and the formation of well-defined tubular structures. Following induction of urosepsis via LPS exposure to HK-2 cells, we observed a dose-dependent increase in FITC permeability, compromised cell integrity. This was concomitant with an elevation in cell-to-cell distance among HK-2 cells and a reduction in cadherin expression in HUVEC cells, suggesting rapid dissemination of LPS to lung cells. Urosepsis-induced lung injury was associated with heightened expression of IL-6 and NGAL. But, The observation of Beas2B cell death due to LPS was inconclusive in our findings

Conclusions: Utilizing a kidney and lung-on-a-chip system, we developed a model for urosepsis, enabling the sequential observation of tubular damage, vascular impairment, and the effects of urosepsis on bronchial cells. This approach enhances our comprehension of urosepsis-related lung injury, thereby providing a promising platform for future therapeutic investigations.



SA-PO546

Exploring Monocyte Trafficking: Unveiling MicroRNA (miRNA) Contributions with Organ-on-Chip Vessel Models

Miguel Hueso,[1,2] Adrián Mallén Bareas,[2] Estanis Navarro,[3] Jordi Bover.[4,3] *[1]Hospital Universitari de Bellvitge Servei de Nefrologia, L'Hospitalet de Llobregat, Spain; [2]Institut d'Investigacio Biomedica de Bellvitge, Barcelona, Spain; [3]Fundacio Institut d'Investigacio en Ciencies de la Salut Germans Trias i Pujol, Badalona, Spain; [4]Hospital Universitari Germans Trias i Pujol, Badalona, Spain.*

Background: Monocytes play pivotal roles in numerous inflammatory disorders, including vascular and renal diseases. Environmental signals at site of inflammation mediate rapid monocyte migration and dictate differentiation programs. However, the molecular mechanisms of the migration of monocytes remain poorly understood. Since, proinflammatory activation of monocyte-derived macrophages were associated with a concomitant increase in miR-125b we will study if miR-125b contribute to the regulation of the traffic of monocytes using in vivo and in vitro models.

Methods: In the ApoE$^{-/-}$ mice model fed with a high fat diet for 14 weeks, we inhibited miR-125b using an antagomir over a 4-week period. We explored the mechanism using a Vessel-on-Chip adhesion assay, constructed with Human Aortic Endothelial Cells (HAoEC) stimulated with TNFα, along with Transwell studies.

Results: We observed a significant reduction in infiltration of F4/80 macrophages and attenuation of NF-κB^{+} activation in vascular lesions. We observed an impairment in the trafficking of miR-125b transfected THP-1 monocytes, accompanied by the downregulation of the CD11b/CD18 integrin and the CCR7 receptor. Furthermore, we demonstrated a direct regulation of the CCR7 receptor by miR-125b using a reporter plasmid construct (p_CCR7.WT) containing the 3'UTR region of CCR7 gene fused with a luciferase coding sequence. In addition, miR-125b transfected monocytes inhibited CCR7 cell migration induced by the CCL21 ligand but did not affect migration induced by others ligands such as MCP1. Finally, we confirmed the downregulation of CCR7 in coronary plaques in both ApoE$^{-/-}$ mice and patients with coronary artery disease.

Conclusions: Organs-on-chip, engineered to mimic the complexity of organs and replicate specific microenvironments are valuable models for studying biological mechanisms. In our study, we demonstrated that miR-125b contributes to monocyte trafficking by downregulating the CD11b/CD18 integrin and the CCR7 receptor. Thus, miR-125b could be a potential therapeutic target in renal or vascular inflammatory disorders.

Kim-1 Targeted Black Phosphorus Nanoplatforms: Antioxidation and Efferocytosis Recovery for AKI Treatment

Zhiwen Wang, Chun Zhang. *Huazhong University of Science and Technology Tongji Medical College Union Hospital, Wuhan, China.*

Background: Acute kidney injury (AKI) is a global public health issue with high morbidity and mortality rates. Past research on AKI treatment has predominantly focused on antioxidation and anti-inflammation, with little attention given to the clearance of apoptotic cells post-AKI. The clearance of apoptotic cells, or efferocytosis, is crucial for resolving inflammation. However, the inflammation triggered by oxidative stress in the damaged tissue region of AKI often impedes efferocytosis, hindering the clearance of apoptotic cells and exacerbating inflammation, thereby causing tissue damage.

Methods: In this study, we designed a kidney dual-targeted nanotherapy platform utilizing the Kim-1 protein-targeting peptide LTH combined with the therapeutic agent 4-octyl itaconate (4OI), based on novel two-dimensional black phosphorus nanosheets, to treat AKI induced by various etiologies.

Results: The nanoplatform rapidly anchors to damaged renal tubular epithelial cells, clearing intracellular ROS overload, thereby reducing tubular dilation and inhibiting cast formation. Following intervention, the expression of NGAL in the kidneys of AKI mice significantly decreases, indicating substantial alleviation of tissue damage. Moreover, the improvement in efferocytosis facilitates the clearance of apoptotic cells, effectively mitigating renal tissue injury following rhabdomyolysis and renal ischemia-reperfusion injury.

Conclusions: The novel kidney dual-targeted nanoplatform achieves rapid targeting and anchoring to damaged renal tubular epithelial cells post-AKI. Through antioxidative stress and enhancement of efferocytosis, it enables specific treatment of AKI in the affected regions. We believe this platform presents a new solution for AKI treatment induced by various causes and holds promise as an innovative drug delivery system for the treatment of other diseases.

Engineered Renal-Targeting Nanozyme Achieves Sequential Treatment of AKI through Reactive Oxygen Species Clearance and Immune Modulation

Zhiwen Wang, Chun Zhang. *Huazhong University of Science and Technology Tongji Medical College Union Hospital, Wuhan, China.*

Background: Effective countermeasures for acute kidney injury (AKI) remain unsatisfactory. During AKI progression, the appropriate and timely transition of macrophages from pro-inflammatory to anti-inflammatory states is crucial for promoting the resolution of acute inflammation and tissue repair. Timely clearing excess reactive oxygen species (ROS) and promoting M2 polarization of macrophages determines the extent of AKI progression.

Methods: In this study, we designed an engineered renal-targeting nanozyme constructed from a novel two-dimensional nanomaterial, MXene nanosheets, through surface conjugation of the anticomplement component 5a aptamer (ac5a-Apt) and magnesium ions (Mg^{2+}).

Results: The results revealed that after AKI, the engineered nanozyme can not only target the kidneys but also navigate towards inflammatory areas under the guidance of the ac5a-Apt, clear excessive ROS, inhibit the C5a-C5aR complement system activation and promote M2 polarization of macrophages. Importantly, after MXene reacts with ROS and degrades, the surface-loaded Mg^{2+} is released, which can further suppress the MAPK/ NF-κB signaling pathway to achieve sequential therapy.

Conclusions: The engineered renal-targeting nanozyme provides a novel strategy based on ROS clearance and immune modulation for AKI sequential treatment. And as a novel engineered nanozyme, its remarkable biocompatibility and excellent therapeutic effectiveness establish the foundation for its substantial potential in clinical translation.

Integrative Systems Analyses Reveal Calcineurin Inhibitor-Mediated Control of Human Podocyte Biophysics and Physiology

Jacob M. Wright,[1] Anthony Mendoza,[1] Jonathan C. Haydak,[1] Jenny Wong,[1] Linda M. Rehaume,[2] Kirk N. Campbell,[1] Evren U. Azeloglu,[1] Maria Paola Santini.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Aurinia Pharmaceuticals Inc, Victoria, BC, Canada.*

Background: Calcineurin inhibitors (CNIs), such as cyclosporine A (CsA), tacrolimus (TAC), and voclosporin (VCS), have been used to regulate the immune response in a number of conditions, including kidney transplantation, lupus nephritis and other autoimmune disorders. Whereas the immunosuppressive functions of CNIs are regulated by the calcium-calmodulin pathway, the mechanisms by which they control glomerular cell biology remain elusive. We previously showed that CsA treatment in LPS-induced proteinuria was associated with cytoskeletal stabilization of podocytes leading to preserved glomerular integrity.

Methods: We combine network, enrichment and pathway analyses of transcriptomics, isobaric-tagged quantitative phospho- and total proteomics, atomic force microscope elastography and high content image analytics with classical cell biological assays to understand the role of CNIs in podocyte biology and biomechanics.

Results: We discovered that podocyte physiology is significantly modulated by all CNIs, and that this regulation converged on the cytoskeletal architecture. Divergent phosphoproteomic signatures highlighted the differential impact of each drug in microtubule organization, post-translational modifications, and histone methylation. Downstream gene transcription showed a significant upregulation of focal adhesion molecules, GEF/GAPs and cytoskeletal-adhesion organizers. Our phoshoproteomic observations recapitulated several previously known targets, such as synaptopodin, and detected a number of novel cytoskeletal posttranslational modifications. Interestingly, we observed that at maximal clinically relevant concentrations lower than CsA and TAC, VCS affected these signaling pathways for enhancing cytoskeletal stability, which is confirmed via focal adhesion morphometrics, spreading area and cellular elasticity.

Conclusions: Based on these findings, our study contributes significantly to the understanding of the role of CNIs in podocyte function, independently from other cell biological impacts, and it represents an integrative cellular and molecular atlas to guide the discovery of novel drug-induced modulators of glomerulopathies and evaluate the effect of new CNIs on podocyte biophysical and biomechanical features.

Kidney-Targeting Mesoscale Nanoparticles for Delivery of Gene Therapy in CKD

Edgar A. Jaimes,[1] Anastasiia Vasylaki,[2] Arantxa Roach,[2] Pratyusha Ghosh,[2] Melis Baltaci,[1] Ryan Williams.[2] *[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]The City College of New York, New York, NY.*

Background: Despite the rapidly increasing number of gene therapies being introduced into clinical practice, no such treatment is available for kidney diseases. One of the major obstacles in gene therapy implementation is the difficulty in delivering biological molecules to the disease site due to their easily degradable nature, immunogenicity, and inability to permeate through cell membranes. Here, we developed a polymer nanoparticle gene delivery system for chronic kidney disease.

Methods: We optimized the formulation of kidney-targeted polymeric mesoscale nanoparticles (MNPs) to maximize the encapsulation of siRNA and mRNA gene therapies for kidney diseases. Specifically, we formulated MNPs from poly-lactic-co-glycolic polyethylene glycol di-block (PLGA-PEG) polymer. This process was optimized for loading of a luciferase reporter mRNA, which was evaluated for renal delivery and protein expression in hairless mice. Separately, it was optimized for loading of cytokine-specific siRNA (IL-6, IL-1B, and TNFa), which were evaluated for therapeutic efficacy in a mouse model of unilateral uretral obstruction (UUO) and a rat model of Dahl Salt-Sensitive (DSS) salt-induced hypertension. We evaluated blood and urine markers of renal function in both models, as well as performed histology.

Results: We optimized mesoscale nanoparticles for maximal siRNA and mRNA therapy loading while maintaining a 300 – 400 nm polymeric MNP diameter. In healthy immunocompetent hairless mice, we found that MNPs specifically localize to the kidneys and deliver functional luciferase reporter mRNA via in vivo bioluminescence imaging. In both mouse and rat chronic kidney disease models (UUO and DSS, respectively), we administered inflammatory cytokine-silencing siRNA-loaded MNPs. These studies demonstrated substantial therapeutic efficacy and reduction of inflammation from kidney-targeted siRNA delivery as measured by renal fibrosis and injury markers. MNPs localize to the kidneys with up to 26-fold specificity compared to other organs with little to no off-target delivery or toxicity.

Conclusions: We anticipate further pre-clinical development of both mRNA and siRNA-targeted delivery to the kidneys for chronic kidney diseases will result in a highly specific novel therapy with minimal off-target effects for CKD and other renal diseases.

Growth, Maturation, and Light Sheet Microscopy of Autologous Induced Pluripotent Stem Cell-Derived Kidney Organoids in Tunable Gelatin Methacrylate (GelMA) Hydrogels

Ivan Krupa,[1] Shane Clerkin,[1] Jessie Davis,[1] Sara Knezevic,[1] Robert Lees,[2] Dermot F. Brougham,[1] John Crean.[1] *[1]University College Dublin, Dublin, Ireland; [2]Science and Technology Facilities Council, Swindon, United Kingdom.*

Background: Recent advances in the generation of hiPSC derived kidney organoids have successfully established their use as a novel disease-modelling platform. Here we describe the utility of gelatin methacryloyl (GelMA) hydrogels as support matrices for kidney organoids in which manipulation of biophysical parameters like stiffness and shear flow acts as a mechanism for control of cell composition and structure.

Methods: Kidney organoids were generated from hiPSCs using established methods (Treacy et al., *Bioactive Matertials*, 2023). Light sheet fluorescence microscopy (LSFM) imaging was conducted on a Leica SP8 Digital Light sheet microscope. Hydrogel rheology was conducted using the Anton Parr Physica MCR301 rheometer. For experiments investigating the effects of shear flow via the use of an orbital shaker system, a modified version of a protocol published by Przepiorski et al., (2021) was utilised in conjunction with GelMA hydrogel encapsulation of kidney organoids.

Results: Rheological measurements show that chemically crosslinked GelMA hydrogels retain their mechanical storage moduli over a prolonged period of time in culture. Therefore, this biomaterial provides a means of studying the effects of a constant storage modulus of the surrounding matrix on the growth of organoids. We have recently evaluated the utility of LSFM as a technique for rapid 3D imaging of organoid samples and a means for characterising the effects of the biophysical microenvironment on kidney organoid generation. In this pilot study, we imaged the development of $MAFB^{+ve}$ cells, representing developing podocytes, within kidney organoids grown in GelMA, with live low-phototoxicity light sheet imaging. We also observed $CD31^{+ve}$ endothelial cells in GelMA supported kidney organoids with fixed and cleared light sheet imaging. The extent of the vascularisation observed was comparable to that previously described (Ryan et al., *Developmental biology,* 2021).

Conclusions: Overall, our study suggests that modification of biophysical properties such as matrix stiffness and shear flow can be used as an instructive cue to modify kidney organoid maturation. With this work we hope to inform the development of increasingly physiologically authentic kidney organoids for the advancement of 3D models of disease and drug responses.

Electrospun Polyacrylamide Nanofiber Mats for Renal Cell Tissue Culture

Harold D. Love,[1] Shuvo Roy,[3] William H. Fissell.[1,2] The Kidney Project. *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Veterans Health Administration, Washington, DC; [3]University of California San Francisco, San Francisco, CA.*

Background: We have previously used soft polyacrylamide (PA) based hydrogels for renal cell tissue culture. PA gels functionalized with amino groups promote robust attachment and differentiation of primary proximal tubule cells under fluid shear stress. We have now developed a method of electrospinning (ES) PA nanofibers with 50-200 nm diameters. When functionalized with ECM protein, renal cells attach on the ES nanofiber mats and express increased levels (up to 10X) of several transporters, exceeding those cultured on non-permeable PA gels.

Methods: Linear PA was prepared by polymerizing a 3.75% solution of acrylamide monomer without bis-acrylamide at room temperature. The linear PA was precipitated with isopropanol and redissolved at ~10% concentration in water. Glutaraldehyde and HCl were added to crosslink the linear PA into stable fibers. Crosslinking required incubation at 60ºC overnight after spinning. ES was performed at 0.1-0.2 ml/hour at 15KV. Atomic force microscopy was used to measure the elastic modulus of the resulting mats. The crosslinked mats were mounted in transwell supports, functionalized using Sulfo-SANPAH and Geltrex and sterilized with 70% ethanol. PA gels incorporating N-(3-Aminopropyl) methacrylamide (APMA) were used as non-permeable controls. Primary proximal tubule cells (Lonza) were then seeded on mats and gels. Cultures were placed on oscillating platforms at 72 RPM for 2-4 weeks.

Results: ES mats consisted of randomly oriented fibers 50-200 nm diameter with an elastic modulus of ~0.9 kPa. Cells attached rapidly to fibers and APMA gels and maintained attachment up to 4 weeks. Cells formed confluent patches on the mats but did not form complete monolayers as seen on APMA gels. The expression (qPCR) of several renal markers (LRP2, NHE3, OAT1-3, NKCC2 and SGLT2) were 3-10 fold higher in cells on ES mats than on APMA gels.

Conclusions: Primary human renal cells were found to attach to PA nanofiber mats functionalized with ECM. Cells formed confluent patches and remained attached for at least 4 weeks, under fluid shear stress (~2 dyn/cm^2). RNA levels for several renal genes in cells on mats were increased 3-10 fold compared to levels seen on non-permeable APMA gels. We conclude that our linear PA spun nanofiber mats can significantly increase expression levels of several important genes in cultured renal cells in standard media over those seen on non-permeable PA gels.

Organized Tubular Scaffolds to Build Vascularized Kidney Proximal Tubules

Anne Metje van Genderen,[1] Sebastian Beusink,[1] Thibault Sampon,[1] Marta Garcia Valverde,[1] Tina Vermonden,[1] Jitske Jansen,[2] Silvia M. Mihaila,[1] Rosalinde Masereeuw.[1] *[1]Universiteit Utrecht Utrechts Instituut voor Farmaceutische Wetenschappen, Utrecht, Netherlands; [2]Division of Nephrology and Clinical Immunology, Institute of Experimental Medicine and Systems Biology, Medical Faculty RWTH Aachen University, Aachen, Germany.*

Background: Kidney tubular engineering requires structures of small sizes (≲1mm) to mimic curvature of native kidney proximal tubule (PT), which is key for cellular functionality and maturation. Here, we created highly porous rhombus tubules using melt-electrowriting (MEW) to build a vascularized PT.

Methods: A MEW device was used to print small polycaprolactone tubular scaffolds (inner ø: 1 mm) with defined rhombus microarchitectures (winding angles of 30°, 50° and 70°). Human conditionally immortalized PT epithelial cells (ciPTEC) and glomerular endothelial cells (ciGEnC) were seeded alone or consecutively in the scaffolds and evaluated via immunofluorescent stainings for monolayer formation and tightness (zonula occludens-1, cluster of differentiation 31 (CD31)), cell directionality (F-actin), polarization (a-tubulin, Na^+K^+-ATPase) and extracellular matrix (ECM) production (collagen IV). Furthermore, gene expression of endothelial (CD31 and Von Willebrand Factor) and PT (organic cation transporter-2, P-glycoprotein (P-gp), multidrug resistance protein) markers was measured via RT-qPCR, and P-gp transport was studied in the tubular scaffolds.

Results: Tubular scaffolds (length: 2 cm, inner ø: 1 mm) with different rhombus microarchitectures were manufactured by controlling key instrument parameters. Both ciPTEC and ciGEnC formed tight monolayers within the tubular scaffolds and generated collagen IV-enriched ECM. The 30° winding angles induced preferential cell alignment along the scaffold fiber direction for ciPTEC and ciGEnC, and facilitated formation of polarized monolayers. Consecutive seeding of first ciPTEC and, after monolayer formation, ciGEnC enabled growth of endothelial cells on the ECM deposited by ciPTEC, thereby forming a vascularized PT, maintaining high gene expression of PT markers, and showing increased functionality of P-gp in co-culture.

Conclusions: MEW tubes with highly controlled microarchitectures advance ciPTEC and ciGEnC organization and ECM deposition. Our results show the first prototype of a vascularized scaffold, where the basement membrane formed by ciPTEC supports ciGEnC adhesion and growth. This innovative approach not only shows the potential of MEW in tissue engineering but also sets a new benchmark for the creation of functional, bioengineered kidney models.

Tubuloid Production from Primary Cultured Renal Tubular Epithelial Cells Derived from Resected Unfunctional Kidneys of Patients on Dialysis

Makiko Mori, Yutaro Mori, Yuki Nakao, Yuta Sekiguchi, Shintaro Mandai, Hiroaki Kikuchi, Fumiaki Ando, Koichiro Susa, Takayasu Mori, Eisei Sohara, Shinichi Uchida. *Department of Nephrology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University, Tokyo, Japan.*

Background: Renal tubular organoids (tubuloids) developed by our technology have the potential to serve as an alternative, more human-like model of human pathology. Tubuloids are made from patient kidney-derived primary cells, not stem cells, and mimic kidney tubules. We have previously produced tubuloids from normal and mild chronic kidney disease (CKD) kidneys. Here, cells from unfunctional kidneys of dialysis patients will be 3D engineered.

Methods: 5 patients receiving hemodialysis and 5 patients with normal kidney function were joined to this study with written informed consents. Using kidneys obtained from patients by surgery for malignancy, only primary cultures of renal tubular epithelial cells were selectively grown. Growth factors and Matrigel were then added. After several days of culture, tubuloids are obtained. In primary cultured cells in 2-dimensional condition and tubuloids, Western blotting and immunostaining are used to determine renal tubular and CKD properties.

Results: Primary cultured renal epithelial cells of normal kidneys show a large number of fine, swollen epithelial cells. On the other hand, those of unfunctional kidneys from dialysis patients are elongated, and some cells are giant in size. At the beginning of 3-dimentional culture, the speed of growth of normal tubuloids is faster than that of renal cells from unfunctional kidneys. Eventually, however, the size difference between normal renal tubuloids and tubuloids from dialysis patients is not very discernible. Western blotting of the completed tubuloids showed that p16, a marker of cellular senescence, was predominantly expressed in the dialysis tubuloids. KIM-1, which appears in damaged kidneys, was confirmed in two of the dialysis tubuloids strongly.

Conclusions: We have established primary renal epithelial cells from patient kidneys derived from healthy kidneys and from unfunctional kidneys of hemodialysis patients, and now we have successfully produced tubuloids derived even from unfunctional kidneys. The results also revealed that tubuloids derived from unfunctional kidneys have the properties of cellular senescence. These tubuloids are expected to be used as a simple model for a new type of human pathology, more similar to humans than mice.

Optimized Culture Media Extends Human Kidney Organoid Longevity to 6 Months

Sophie M. Blackburn, Arjun Sen, Benjamin S. Freedman. *University of Washington - Division of Nephrology, Department of Medicine, Kidney Research Institute, and Institute for Stem Cell and Regenerative Medicine, Seattle, WA.*

Background: Although kidney organoids, derived from human pluripotent stem cells (hPSC), mature *in vitro* in approximately 3 weeks, there is an interest in using this model to study the effects of microgravity on the kidney during long-term space flight. The most widely used kidney organoid protocols consider their structures mature between day 16 and day 28 of differentiation, generally completing experimental assays at that time or shortly thereafter.

Methods: Standard kidney organoid differentiation was performed until cultures reached the renal vesicle stage. We then supplemented our standard differentiation media with organoid tubular enhancing media (OTEM) which contains components proposed to promote epithelial cell growth and limit de-differentiation. Organoid counts were obtained using full-well brightfield images and nephron segments were visualized using immunostaining. Viability was assessed with a colorimetric assay. Transcriptomic analysis was performed via single-cell RNA sequencing of kidney organoid cultures at days 25 and 180 of differentiation.

Results: OTEM drastically improved the longevity of kidney organoids, whereas no kidney organoids survived past day 100 when treated with standard media. After six months of culture, structural and transcriptomic analyses showed viable podocytes, proximal tubules, and distal tubules present in OTEM treated kidney organoids. We also identified an early glomerular epithelial cell cluster that grew relative to other cell types over the course of the experiment. At day 26 of differentiation, cultures treated with OTEM had four-fold more kidney organoids than those grown in standard media. Furthermore, the OTEM-treated cultures had less stromal overgrowth and contained twice as many viable cells compared to controls.

Conclusions: Our findings indicate that OTEM is improving the stability of kidney organoids and supporting the proliferation of cell types that indicate increasing maturity of the structures. This is a simple yet powerful change to our differentiation protocol that sets the stage for future studies of organoid aging on earth and in space.

Recapitulation of Cellular Senescence, Inflammation, and Fibrosis in Human Kidney-Derived Tubuloids by Repeated Cisplatin Treatment

Yuki Nakao, Yutaro Mori, Makiko Mori, Shintaro Mandai, Tamami Fujiki, Hiroaki Kikuchi, Fumiaki Ando, Koichiro Susa, Takayasu Mori, Eisei Sohara, Shinichi Uchida. *Department of Nephrology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University, Tokyo, Japan.*

Background: In the pursuit of more accurate pathophysiological models for assessing renal drug response, the development of kidney organoids derived from human pluripotent stem cells represents a significant step forward. However, recapitulating aging/senescence associated pathophysiology within these models remains challenging. Here, we present an innovative approach to generate more homogeneous epithelial-like structures known as “tubuloid” using primary human renal proximal tubular epithelial cells (hRPTECs) cultured from human resected kidneys as a refined alternative and try to evaluate their ability to show aging/senescence associated pathophysiology.

Methods: Primary hRPTECs were established from the non-tumor kidney tissue removed from patients with malignancies with written informed consents. Cells were cultured on ultra-low attachment plates in media containing basement membrane gel and multiple growth factors. To assess the disease-modeling potential of tubuloids, we evaluated the efficacy of tubuloids using cisplatin treatment at three different concentrations: 0.2, 2.0, and 20.0 μg/mL.

Results: Upon exposure to cisplatin, γH2AX expression increased in a dose-dependent manner, indicating DNA damage. Cisplatin treatment also resulted in the expression of Kidney Injury Molecule-1 (KIM-1) and Cleaved Caspase-3, which are indicators of kidney injury and apoptotic signaling, respectively. Repeated cisplatin administration resulted in upregulation of the cellular senescence marker p16, alongside increased secretion of inflammatory cytokines IL-1β and IL-6, indicating the induction of a senescence-associated secretory phenotype (SASP). Furthermore, supernatant collected from repeated cisplatin treated tubuloids induced myofibroblast activation, indicating the onset of renal fibrosis.

Conclusions: We successfully established a tubuloid-based model that goes beyond the immediate effects of cisplatin nephrotoxicity to simulate the transition from AKI to CKD, or even model CKD itself, using hRPTECs. Tubuloids can recapitulate cellular senescence, SASP, and fibrosis, making them a promising pathophysiological model for chronic kidney disease (CKD) providing insights into the disease’s fibrotic mechanisms.

Surgical Refinement of Silicon Nanopore Membrane Devices for Implantable Kidney Replacement Therapy: 7-Year Experience across 90 Prototypes

Jarrett Moyer,[1] Charles Blaha,[1,3] Mark W. Wilson,[1] Shant M. Vartanian,[1] Lynda Frassetto,[1] William H. Fissell,[2,3] Shuvo Roy.[1,3] *[1]University of California San Francisco, San Francisco, CA; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Silicon Kidney, LLC, San Francisco, CA.*

Background: Silicon nanopore membranes (SNM) are highly permeable and selective filters providing a pathway to next-generation implantable renal replacement therapies (RRT). SNM enable needle-free hemodialyzers, low-resistance hemofilters, and immuno-protective renal tubular cell bioreactors. Implantation of these first-of-their-kind prototypes requires strategies to overcome the recipient anatomy, immune response, and blood-materials interactions. Here we describe iterative refinement of surgical technique over seven years and 90 implants of SNM RRT prototypes.

Methods: Surgical refinement was iterative with experimental results from of each of the 90 implants informing subsequent ones. Initial prototypes housed 2 cm^2 of SNM surface area, progressing to 832 cm^2 over the seven-year period. Implants occurred in the dorsolateral neck or retroperitoneum of swine with vascular anastomoses to the cervical or iliac vessels, respectively. The retroperitoneum accommodated devices with more SNM area (mean 204 cm^2 compared to 20 cm^2 in the neck). Prototypes were implanted for 3-32 days with subjects receiving anti-platelet agents. Patency was assessed using angiography and direct visualization upon retrieval.

Results: Patency across all prototypes was 67% (60/90) for up to 32 days. An advanced hemofilter housing 166 cm^2 of SNM surface area exhibited 100% patency

(n=9). Of 30 thrombosed prototypes, 17 were due to mechanical obstruction from graft kinks. The largest SNM RRT prototypes were more likely to kink (5 of 8, compared to 10 kinks in 82 small-scale prototypes, p=0.005). Following observation of kinks in 75% of initial implants, a series of protective silicone graft sleeves was applied leading to a reduction to 16% kink rate (p=0.020).

Conclusions: Iterative adaptation of surgical approach and SNM RRT prototypes across 90 implants achieved patency for up to 32 days, while enabling a 416-fold increase in blood-contacting silicon surface with no systemic anticoagulation. Mechanical obstruction to blood flow proved to be the most common cause of device failure and was more likely to occur in the largest prototype. Protection of the vascular graft interface with a silicone sleeve reduced the rate of graft kinks.

Transport and Barrier Function in Cultured Primary Tubule Cells Are Preserved after Brief Cold Storage

Rachel C. Evans,[1] Shuvo Roy,[2] H. David Humes,[3] William H. Fissell.[1]
The Kidney Project. *[1]Vanderbilt University Medical Center, Nashville, TN; [2]University of California San Francisco, San Francisco, CA; [3]University of Michigan Michigan Medicine, Ann Arbor, MI.*

Background: Implantable bioartificial kidneys will need to be distributed to clinical sites distant from the point of manufacture. Renal allografts are typically shipped cool surrounded by ice-water baths with or without perfusion, while suspended cells are typically shipped frozen in dry ice. Freezing a device to -78ºC is likely impractical as it subjects a device to destructive mechanical stresses from thermal expansion, and there may be incomplete survival of cells upon thawing, jeopardizing function. We simulated cold transport by examining survival and function of primary renal proximal tubule cells in monolayer culture after storage at 5ºC.

Methods: Primary human renal proximal tubule cells were grown on permeable supports in serum-supplemented 50:50 DMEM:F12 with an inhibitor of TGF-βR1 on a rotary shaker table at 37ºC and 5%CO_2/air for 28 days. Baseline apicobasal barrier was assessed by leak of TRITC-labeled dextrans from apical to basolateral compartments, and function was assessed by diuretic-inhibitable apicobasal volume transport assessed by weighing apical and basolateral supernatants. Cells were removed from the incubator and culture trays wrapped in sterile parafilm. Cell culture trays were placed in a conventional household 5ºC refrigerator for 24, 48, 72, and 96 hours (n=3 wells each condition) without any media exchanges. After the specified chill time, cell culture trays were removed from the refrigerator and chilled media exchanged for fresh warmed media. Cell culture plates were returned to culture at 37ºC and 5%CO_2/air. At 1, 12, and 40 days after chill exposure, cell barrier and transport function were again measured.

Results: Cells chilled for 24,48, and 72 hours maintained barrier integrity and transport function out to 40 days post chill. Cells chilled for 96 hours had an initial 28-fold increase in leak that persisted at lower levels to 40 days post exposure.

Conclusions: Renal tubule cells in bioartificial kidneys need to present a barrier to reabsorption of toxins and need to transport salt and water to concentrate filtered toxins. Primary renal tubule cells grown on permeable supports retained function and barrier even after 72 hours at 5C. Transport of bioartificial kidneys from manufacturing facilities to clinical sites may be possible with non-hazardous simple ice-water refrigeration.

Machine Perfusion of Mice Kidneys to Deliver a Protective Bioengineered Soluble ACE2 Protein

Cosimo Cianfarini, Fatmah N. Yamani, Jan Wysocki, Dinesh Jaishankar, Zheng J. Zhang, Daniel Batlle. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Machine perfusion of donor kidneys has emerged as a promising approach to improve transplant outcomes by decreasing storage-related injury and reducing the occurrence of delayed graft function (DGF). Activation of the renin-angiotensin-system (RAS) has been shown to play a role in the pathophysiology of DGF and countering this overactivity may improve transplant outcomes. Here we investigated the delivery of a short soluble ACE2 protein, bioengineered in our lab and termed ACE2-618-ABD, to mice kidneys using hypothermic machine perfusion as a strategy to reduce RAS activity.

Methods: Kidneys from c57bl6 ACE2 Knock-Out (ACE2-KO) and c57bl6 wildtype (WT) mice were harvested and the renal artery cannulated. We adapted a perfusion system previously used for rats to be used with mice kidneys. The mice kidneys were perfused with phosphate buffered saline (PBS) either alone or with added ACE2 618-ABD for four hours at four degrees celsius through the cannulated renal artery in a closed-circuit perfusion system using a peristaltic pump. ACE2 enzymatic activity was then measured using a fluorogenic assay and ACE2 protein levels determined by Western Blot.

Results: While ACE2 enzymatic activity and protein were undetectable in non-perfused ACE2-KO kidneys, enzymatic activity and protein by Western Blot were found in ACE2-618-ABD perfused ACE2-KO kidneys. In WT kidneys perfused with ACE2-618-ABD, Western Blot showed two distinct bands for ACE2 protein at ~100kD and ~85kD. The ~100kD band reflects the native ACE2, the ~85kD represents the perfused short soluble ACE2-618-ABD which was not found in the PBS- and non-perfused WT kidneys. In kidney lysates, the cytosolic compartment of ACE2-618-ABD perfused kidneys had increased ACE2 enzymatic activity and protein demonstrating intracellular uptake.

Conclusions: Delivery of a bioengineered, short soluble ACE2 protein to mice kidneys can be accomplished via machine perfusion of the renal artery which results in passage of the glomerular filtration barrier and tubular uptake. Ex-vivo perfusion of kidneys with ACE2-618-ABD results in cytosolic uptake as demonstrated by increased protein and enzymatic activity. This approach may result in improved quality of kidneys prior to transplantation.

A Bypass Flow Model to Study Endothelial Cell Mechanotransduction across Diverse Flow Environments

Zhuotao Xiao,[1,2] Rudmer J. Postma,[1] Anton J. Van Zonneveld,[1] Bernard van den Berg,[1] Wendy M. Sol,[1] Nicholas White,[1,4] Asad M. Mirza,[3] Jun Wen,[5] Roel Bijkerk,[1] Joris I. Rotmans.[1] *[1]Leids Universitair Medisch Centrum, Leiden, Netherlands; [2]First Affiliated Hospital of Soochow University, Suzhou, China; [3]Florida International University, Miami, FL; [4]Technische Universiteit Delft, Delft, Netherlands; [5]Southwest University of Science and Technology, Mianyang, China.*

Background: Disturbed flow is one of the pathological initiators of endothelial dysfunction in intimal hyperplasia (IH) which is commonly seen in vascular bypass grafts, and arteriovenous fistulas. Various *in vitro* disease models have been designed to simulate the hemodynamic conditions found in the vasculature. Nonetheless, prior investigations have encountered challenges in establishing a robust disturbed flow model. In the present study, we aim to address this gap by introducing an *in vitro* bypass flow model capable of inducing disturbed flow and other hemodynamics patterns through a pulsatile flow in the same model, Fig. A.

Methods: We employed computational fluid dynamics (CFD) to simulate hemodynamics and compared the morphology and functions of human umbilical venous endothelial cells (HUVECs) under disturbed flow conditions to those in physiological flow or stagnant conditions.

Results: CFD analysis revealed the generation of disturbed flow within the model, pinpointing the specific location in the channel where the effects of disturbed flow were observed, Fig. B. High-content screening, a single-cell morphological profile assessment, demonstrated that HUVECs in the disturbed flow area exhibited random orientation, and morphological features were significantly distinct compared to cells in the physiological flow or stagnant condition after a two days of flow exposure, Fig. C D. HUVECs exposed to disturbed flow underwent extensive remodeling of the adherens junctions and expressed higher levels of endothelial cell activation markers compared to other hemodynamic conditions.

Conclusions: In conclusion, our *in vitro* bypass flow model provides a robust platform for investigating the associations between disturbed flow pattern and vascular diseases.

Green Tea Polyphenol Sandwich-Assisted Construction of Endothelial Biomimetic Coatings with Hyaluronic Acid Platform and Nitric Oxide Release for Hemodialysis Access Stents to Prevent Thrombosis and Restenosis

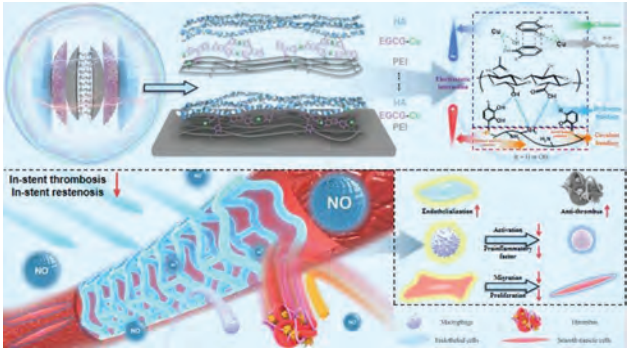
Chong Chen, Liang Ma, Ping Fu. *West China Hospital of Sichuan University, Chengdu, China.*

Background: Vascular stent is one of the main means of treating dialysis access stenosis. However, in-stent thrombosis (IST) and in-stent restenosis (ISR) always limit effectiveness of stents in clinical applications. Vascular endothelial cells play an important role in regulating the physiological structure and function of vessels, so endowing vascular stents with the bionic function of endothelial cells is an effective solution to address complications such as IST and ISR.

Methods: In this paper, an endothelial bionic coating for stents constructed by layer-by-layer self-assembly method was developed. We used positively charged polyethyleneimine (PEI) and negatively charged hyaluronic acid (HA) as polyelectrolytes, assisted construction by a chelate sandwich of epigallocatechin gallate (EGCG) with copper (Cu). The biocompatibility of the coatings was verified by systematic materialogical characterization, in vitro and ex in vivo hemocompatibility experiments, in vitro cell culture experiments, and in vivo experiments of subcutaneous implantation and stent implantation.

Results: The results showed that this strategy was able to improve the loading, stability and homogeneity of the coating through various interations, such as electrostatic adsorption, hydrogen bonding, π-π stacking, and chemical cross-linking of phenalkamines. The coating was able to synergistically improve the antithrombotic ability of vascular scaffolds with HA and nitric oxide, and promote the rapidly endothelialization of the stents, inhibit intimal hyperplasia and regulate the inflammatory response.

Conclusions: This polyelectrolyte endothelial biomimetic coating constructed by metal polyphenol sandwich can effectively reduce complication such as IST and ISR of stents and improve the clinical outcomes of vascular stenting for dialysis access stenosis.



The scheme of coating for hemodialysis access stents to prevent IST and ISR.

Prolonged Bactericidal Activity in Extracorporeal Hemoadsorption with Vancomycin-Functionalized HA380 Sorbent Cartridge

Gerd Klinkmann,[1,2] Anna Lorenzin,[1,3] Massimo de Cal,[1,3] Anna Italia Toscano,[1] Gonzalo Ramirez Guerrero,[1,4] Thiago A. Reis,[1,5] Monica Zanella,[1,3] Claudio Ronco.[1,3] *[1]Fondazione IRRIV, Vicenza, Italy; [2]Department of Anaesthesiology, Intensive Care Medicine and Pain Therapy, University Medical Center Rostock, Rostock, Germany; [3]Ospedale San Bortolo di Vicenza, Vicenza, Italy; [4]Hospital Carlos Van Buren, Valparaiso, Chile; [5]Fenix Nephrology, São Paulo, Brazil.*

Background: Blood purification therapies hold promise in addressing complications linked to bacteremia, a key predictor of mortality in sepsis. However, antibiotic treatment, the current standard therapy, poses risks of organ toxicity. To alleviate this burden and expand the scope of sorbent technology, we propose using surface-modified adsorption cartridges to reduce circulating bacteria. The current study investigates the in vitro efficacy of a sorbent device (mini-module with HA380 beads, Jafron Medical, China) functionalized with vancomycin, evaluating its impact on circulating *Staphylococcus aureus* and compare it to standard of care antibiotic treatment in a simulated circulation model.

Methods: In an *in vitro* model, 1400 mL of heparinized blood containing bacterial load were split in 2 reservoirs. In Setting 1, 700 ml of blood circulated through a cartridge functionalized with vancomycin. In Setting 2, 500 mg of vancomycin were added to blood reservoir 2 and, circulated through a non-functionalized cartridge. Closed-loop hemoadsorption circuits were set up using 2 HA380 mini-modules. Circulations were maintained at 250 mL/min for 1 hour, blood reservoirs were heated to 37°C, and stirred. Samples were drawn at predefined time points, to determine time to positivity (TTP) for bacterial replication, vancomycin levels and cytokine profiles. Reservoir 2 underwent Setting 2 twice consecutively.

Results: Dynamics of TTP exhibited a similar trajectory in both settings after 60 minutes of hemoadsorption. Following an additional hour of incubation, TTP remained unchanged in Setting 1, whereas a significant decline occurred in Setting 2. Notably, the concentration of vancomycin in Reservoir 2 decreased significantly after the first cycle of hemoadsorption. Following a second dose (500 mg) of vancomycin into Reservoir 2, TTP increased significantly again. These dynamic changes were observed again after the second cycle of hemoadsorption with the non-functionalized cartridge.

Conclusions: Using antibiotic-functionalized cartridges for bacteremia may mitigate drug toxicity concerns. Delayed bacterial growth post-vancomycin cartridge passage hints at benefits. Early adjunctive use with standard therapy may aid infection resolution, pending confirmatory clinical trials.

Myoglobin Adsorption Kinetics: An In Vitro Model

Matteo Marcello,[1] Anna Lorenzin,[1] Massimo de Cal,[1] Gonzalo Ramirez Guerrero,[2] Claudio Ronco.[1] *[1]Ospedale San Bortolo di Vicenza, Vicenza, Italy; [2]Hospital Carlos Van Buren, Valparaiso, Chile.*

Background: Rhabdomyolysis is a condition in which a severe injury to the muscles leads to the release of muscle cells' content, including myoglobin, into the blood with consequent acute renal injury. Myoglobin is a middle molecular weight uremic toxin presents a two-compartment model of distribution in the body. A possible therapeutic option is the use of high cut-off membranes but with the risk of significant loss of albumin and other proteins. The use of adsorption cartridges can overcome these limitations. Our study aimed to assess the adsorption capacity of neutral microporous styrene-divinylbenzene copolymer sorbent towards myoglobin.

Methods: Using a downscaled module of HA380 cartridge, we set up an *ex-vivo* circulation experiment in which 1 liter of saline solution with high concentration of myoglobin was pumped through the cartridge. We collected samples (3 mL) at different time points to measure myoglobin concentration. We calculated the removal ratio (RR) and mass adsorbed at given time points.

Results: Initial myoglobin concentration was 326,338 μg/L. Final myoglobin concentration after 4 hours of experiment was 2,042 μg/L. Removal Ratio at the end of the experiment was 99.4 % with a mass adsorption of 324.30 mg of myoglobin.

Conclusions: To our knowledge, this is the first experiment that assessed the adsorption capacity of polistyrene-divinylbenzene sorbent towards myoglobin and demonstrated high affinity to bind this molecule. Our results confirmed adsorption treatment as an effective option in rhabdomyolysis, avoiding complications associated to current dialytic treatment.

Time (min)	Concentration in the reservoir (μg/L)	Mass in the reservoir (mg)	Mass adsorbed (mg)	RR (%)
0	326,338	326.34	0.00	0.0
10	196,761	194.99	129.58	39.7
30	130,211	128.65	196.13	60.1
60	76,338	75.19	250.00	76.6
120	40,070	39.35	286.27	87.7
180	12,958	12.69	313.38	96.0
240	2,042	1.98	324.30	99.4

Metyos K-Patch: A Novel Biowearable for Real-Time Potassium Level Monitoring

Olga Chashchina, Alexandre Boulanger, Maroua Hamami, Louis X. Cacheur, Paul Durand Estebe, Frederic Abboud, Emilie Jemmi. *Metyos, Paris, France.*

Background: Abnormal serum potassium (K+) levels or dyskalemia are dangerous due to the risk of cardiac rhythm disturbances. The reference method of K+ monitoring based on venous blood sampling is invasive, painful and takes up to several days to provide a result. The ability to dynamically and non-invasively monitor changes in K+ levels could reduce the morbidity and mortality due to dyskalemia in both acute and chronic situations.

Methods: Metyos K-Patch is a remote patient monitoring solution integrating a biowearable for monitoring K+ in real time thanks to a microneedle array inserted in the patient's dermis. The sensor sticks to the skin with medical adhesive and is worn for 8 consecutive days. Despite the efficiency of transdermal penetration, microneedles do not exceed 1mm in length and cause no pain upon device's placement. They are modified with ion selective membrane for specific reaction with K+. The electrochemical sensor generates an electrical response proportional to the concentration of K+ that can be measured as a potential difference. The registered signal is then transmitted via Bluetooth to the patient's smartphone.

Results: The potentiometric cell based on the microneedles was sufficiently sensitive for detecting real-time changes in K+ concentrations. It exhibits linear behavior with Nernstian slope 59mV for the complete range of physiological K+ concentrations (2-10mM) when tested in complex matrix. Its analytical performance remains stable during 8 days. No needle deformation or degradation has been registered upon the insertion of the device both in pig skin and volunteers' skin. General ease of use has been tested by 10 volunteers of age 34-72 y.o.

Conclusions: The wearable Metyos K-Patch has shown promising results for continuous K+ tracking. These results pave the way towards remote K+ monitoring in patients with dyskalemia.

Evaluation of Clinical Performance of an In Vitro Diagnostic Medical Device for Detecting Microalbuminuria Using a Smartphone Application

Jiwon Ryu,[1] Yun Jung Oh,[2] Dong-Hoon Lee,[3] Eung-Kyu Park.[3] *[1]Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [2]H Plus Yangji Hospital, Seoul, Republic of Korea; [3]QSTAG Incorporation, Seoul, Republic of Korea.*

Background: Microalbuminuria indicates kidney damage and can serve as a marker for treatment and prognosis in patients with kidney disease or diabetes mellitus. Urine albumin tests are typically conducted in hospitals, which is impractical for daily patient monitoring. We assessed the feasibility of using a commercially available in-vitro diagnostic medical device to measure urine microalbumin in daily life.

Methods: In our study, we enrolled 303 patients from three tertiary care hospitals who tested positive for urine protein using dipstick tests. We utilized a self-checking semi-quantitative urine test strip with QR code technology to evaluate urinary microalbumin and creatinine levels. Integrating QR code technology and correction color pads significantly enhanced QR code recognition and color reaction extraction accuracy. The device utilizes pH indicators and benzoic acid for precise microalbumin and creatinine measurement. A mobile application scans the QR code to provide semi-quantitative values of microalbumin and creatinine. These results were compared to those obtained from a hospital's benchtop machine, with a predefined class agreement for semi-quantitative data set at 95%.

Results: Variations in application environments, laboratory conditions, and hospital settings impacted QR code recognition and the detection of urine microalbumin and creatinine, necessitating adjustments to the colorimetric extraction formula. Comparing results between patients and experts, the agreement rates for urine microalbumin were 92.9%, 92.5%, 97.4%, and 97.3% for normal range, 1 positive, 2 positive, and 3 positive, respectively. After accounting for urine creatinine, the agreement rates for the urine microalbumin/creatinine ratio were 97.1%, 100%, and 98.0% for "Good", "Moderate", and "High", respectively. Expert data on urine microalbumin correlated well with semi-quantitative results from the benchtop machine, with agreement rates of 66.7%, 94.1%, 100.0%, and 87.0% for normal range, 1 positive, 2 positive, and 3 positive in the dipstick test, respectively.

Conclusions: Using this in-vitro diagnostic medical and software enable semi-quantitative urine microalbumin assessment outside hospitals, supporting disease management and patient prognosis in real-life settings.

SA-PO566

Artificial Diuresis: Development of a Mathematical Model to Assess Ultrafiltration

Anna Lorenzin,[1,2] Alessandra Brendolan,[2] Claudio Ronco,[2] Monica Zanella.[1] *[1]Department of Nephrology, Dialysis and Transplantation, San Bortolo Hospital, Vicenza, Italy; [2]International Renal Research Institute of Vicenza (IRRIV), Vicenza, Italy.*

Background: Fluid overload (FO) is associated with adverse outcome both in heart failure and critically ill patients admitted to intensive care. Extracorporeal ultrafiltration (UF) represents a solution to avoid acute kidney injury due to FO; an UF miniaturized device AD1 has been developed. Reduced priming volume, low pressures and flows at which it operates make AD1safer and smaller than the conventional machines. AD1 has been already tested in vitro and in animal studies, no adverse events have been reported. The aim of this study was to develop an UF mathematical formulation capable to mimic the UF behaviour of AD1. Data collected from the animal study were used to validate the model.

Methods: AD1 is equipped with a peristaltic pump for blood flow (Q_b) and a polysulfone mini-filter. Transmembrane pressure (TMP) is modulated by Q_b setting and the height at which is hanging the bag for UF. This generate a negative pressure in the filter UF compartment: higher is the gap between AD1 and the bag, greater the negative pressure, increasing TMP and ultrafiltration rate (Q_{UF}). In animal study, 6h UF sessions were scheduled in 3 pigs with a Q_b=30mL/min and the bag placed 20cm below AD1. Clinical parameters and UF data were collected. The UF mathematical formulation is based on hydrostatics and hydrodynamics laws. Parameters considered are Q_b, height of the bag, haematocrit, catheter features. Experimental data were compared with the formulation.

Results: In the animal sessions the Q_{UF} was in a range of 3-5ml/min. Average data of target Q_{UF}, observed Q_{UF} during the animal study and the model estimation are reported. In all treatments the Q_{UF} was obtained in the absence of major clinical or technical problems with a maximum deviation from the target Q_{UF} lower than 10%. Formulation reported a maximum error compared to the experimental data less than 10%.

Conclusions: The model reported data comparable with the results observed in the animal study. The selected parameters and the implementation adequately estimate the Q_{UF} in the animal model. Data derived from clinical trials will be necessary to further assess and improve the model.

Animal ID	Htc	Target Q_{UF} (mL/min)	Observed Q_{UF} (mL/min)	Estimated Q_{UF} (mL/min)
I31	26.8%	4.16	4.40	4.00
I29	31.3%	4.16	4.17	4.09
I50	25.9%	4.16	4.28	3.97

SA-PO567

In Vitro Per- and Polyfluoroalkyl Substances (PFAS) Adsorption Assessment through Mesoporous Styrene-Divinylbenzene Sorbent Cartridge

Anna Lorenzin,[1,2] Natascha Perin,[1,2] Massimo de Cal,[1,2] Alessandra Brendolan,[2] Monica Zanella,[1] Claudio Ronco.[2] *[1]Department of Nephrology, Dialysis and Transplantation, St. Bortolo Hospital, Vicenza, Italy; [2]International Renal Research Institute of Vicenza (IRRIV), Vicenza, Italy.*

Background: Per- and polyfluoroalkyl substances (PFAS) are chemical substances used in a wide range of fields as construction materials, biocides, flame retardants etc. Due to their high stability in the environment and resistance to biodegradation, all PFAS are persistent, and many are highly mobile in global waters. High blood levels of PFAS have been associated with adverse health effects including increased risk of kidney or testicular cancer. Classic extracorporeal therapies have demonstrated limited efficiency and new approaches based on adsorption should be explored. The aim of this study was to assess the potential adsorption capacity of HA380 cartridge towards PFAS from patients with high blood levels.

Methods: We developed an *in-vitro* model of hemoadsorption using GALILEO testing platform. We recirculated a highly polluted batch of water (4 liters) through a HA380 cartridge (Jafron medical, Zuhai, China) for 120 minutes at a flow rate of 150mL/min (Figure a). We collected samples after 5,30,60, and 120 minutes from the initiation of circulation and analyzed 39 different PFAS compounds. Removal Ratio (RR) was calculated to assess PFAS adsorption.

Results: PFAS compounds with concentrations significantly above normal showed a RR close to 90% already within the first 60 minutes of circulation leading to almost complete elimination of all pollutants at the end of the circulation (Figure b). RR is remarkably high already at the outset of the adsorption process demonstrating a high capacity of removal of HA380 cartridge. This is likely dependent on the interaction of the different solutes with the molecular structure of the sorbent.

Conclusions: The *in-vitro* model of hemoadsorption suggests the possible application *in-vivo* of this technique to reduce/normalize the concentrations of PFAS in patients exposed to water or environmental pollution. Hemoadsorption may therefore be considered as a new possible approach in patients with high blood levels of PFAS.

Kidney Prognosis in Patients with TSC2/PKD1 Contiguous Gene Deletion Syndrome

Mateus Guerreiro,[1] Eduardo Valle,[1] Jose O. Reusing,[2] Elieser H. Watanabe,[1] Luiz F. Onuchic.[1] Disciplinas de Nefrologia e Medicina Molecular. *[1]Universidade de Sao Paulo Faculdade de Medicina, São Paulo, Brazil; [2]Serviço de Transplante Renal, Hospital das Clinicas da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil.*

Background: Patients with TSC2/PKD1 contiguous gene deletion syndrome (CGS) have classically been associated with a much more severe kidney phenotype than observed in isolated autosomal dominant polycystic kidney disease (ADPKD), displaying childhood onset and progression to end-stage kidney disease (ESKD) within the three first decades of life. Recent reports, however, revealed a more variable clinical course.

Methods: A survey of all reports of CGS was conducted using the terms "TSC2" and "PKD1" or "tuberous sclerosis" and "polycystic" on Pubmed. Thirty studies including patients with genetically confirmed CGS were selected, comprising 74 such cases. The addition of 11 cases from two novel pedigrees totalized 85 evaluated patients, who were analyzed at the demographic, clinical, and genetic levels.

Results: The median kidney survival of CGS patients was 35 (28-43) years. The age of ESKD onset did not differ between patients with germline deletion and cases in whom germline deletion could not be confirmed and mosaicism could not be excluded (Unknown group) (28 [20-37] vs 33 [31-43] years, respectively; p=0.09). Mosaic patients did not reach ESKD during the follow-up. Deletion extension did not affect kidney survival. The relative prevalences of TSC manifestations did not differ between CGS and TSC patients, except for higher frequencies of lymphangioleiomyomatosis and retinal hamartomas in CGS.

Conclusions: CGS patients have a slower progression to ESKD than previously believed, though usually faster than severe ADPKD cases (Figure 1). Thereby, CGS should be considered in ADPKD or significantly cystic TSC patients with severe CKD progression, particularly before the 5th decade. Our data suggest that the frequencies of most TSC clinical features do not significantly differ between CGS and TSC individuals.

Funding: Government Support - Non-U.S.

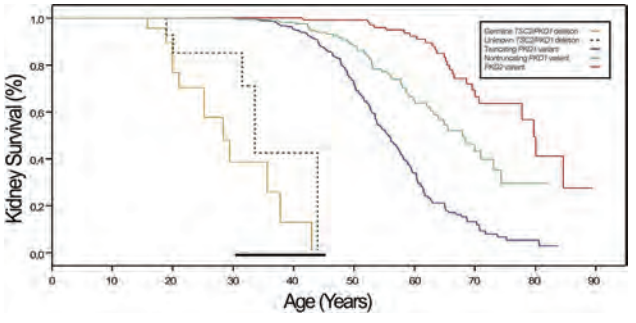

Figure 1. Cumulative kidney survival according to the variant type/classification (adapted from Cornec-Le Gall et al, J AmSoc Nephrol, 24:1006-1013, 2013). The ESKD onset age overlap between the most severe ADPKD cases and the milder CGS cases is depicted by the black bar.

Genetic Characteristics of Autosomal Dominant Polycystic Kidney Disease in a Greek Population

Dimitra Gkalitsiou,[1] Eirini Evangelou,[1] Danai Palaiologou,[2] Maria Konsta,[3] Leandros Lazaros,[2] Niki Markou,[1] Tsielestina Poulli,[1] Aggeliki Poula,[1] Emmanouel Kanavakis,[2] George I. Tsirpanlis.[1] *[1]Department of Nephrology, General Hospital of Athens "G. Gennimatas", Athens, Greece; [2]Genesis Genoma Lab, Genetics Diagnosis, Clinical Genetics & Research, Athens, Greece; [3]Department of Rheumatology, Sismanoglion General Hospital, Athens, Greece.*

Background: Autosomal Dominant Polycystic Kidney Disease is the predominant monogenic renal genetic disorder. Confirmatory genetic testing defines the disease, provides prognostic information and may support therapeutic management. This study aims to investigate the genetic characteristics of a cohort of ADPKD patients from a single Greek center.

Methods: Ninety-three patients (46 females, 47 males, mean age: 34±15 years) were enrolled from 59 distinct families attending our outpatient ADPKD clinic. Genetic analysis included Targeted next-generation sequencing of over 600 genes, Sanger sequencing, and Multiplex ligation-dependent probe amplification. MRI was performed in 74 patients, revealing more than 10 renal cysts in all but one patient. Children with positive family history (FH) displayed at least one cyst, while two without FH had multiple renal cysts.

Results: Genetic diagnosis was established in 88 of 93 patients (94.5%). Seventy patients (75%), had single nucleotide variants (SNVs) and large deletions (4 patients) in the PKD1 gene, whereas SNVs and large deletions (5 patients) in the PKD2 gene were identified in 15 (16%) cases. Other gene mutations were found in 3 patients (3.5%). Two cases, involving a father and son, revealed a SEC61B variant; the father displayed more than 10 renal and liver cysts in the MRI, while the son had only liver cysts. Another patient with nephrolithiasis and over 10 renal cysts, had a SLC3A1 variant. Five patients (5.5%) had negative genetic analyses. Truncating mutations in PKD1 were observed in 43 cases, (61%), while the rest (39%) had non-truncating mutations. Variants were classified as Pathogenic (45.5%), Likely Pathogenic (36%), and Variants of Uncertain Significance (VUS 13.5%), according to the guidelines of the American College of Medical Genetics. Reclassification to Likely Pathogenic could be proposed for 6 VUS cases with noted family segregation. Finally, 52% and 82% of the detected variants have not been previously reported in ClinVar and gnomAD databases, respectively.

Conclusions: In this ethnically homogenous population, truncating mutations in PKD1 gene were the predominant genetic cause of ADPKD, followed by PKD1 non-truncating mutations, PKD2 gene variants and other rare or undefined genetic etiologies.

SA-PO570

Integrating Genotype and Phenotype Data Is Required for Kidney Survival Prediction in Autosomal Dominant Polycystic Kidney Disease

Dimitra Gkalitsiou,[1] Eirini Evangelou,[1] Maria Konsta,[3] Kiriaki Vasiliou,[1] Aggeliki Poula,[1] Niki Markou,[1] Tsielestina Poulli,[1] Leandros Lazaros,[2] Paraskevi Liaveri,[1] George I. Tsirpanlis.[1] *[1]General Hospital of Athens Georgios Gennimatas, Nephrology Department, Athens, Greece; [2]Genesis Genoma Lab Genetics Diagnosis, Clinical Genetics & Research, Athens, Greece; [3]Department of Rheumatology, Sismanoglion General Hospital, Athens, Greece.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is the cause for 5-10% of End Stage Kidney Disease (ESKD) worldwide. Accurate renal prognosis is essential for effective disease management. Investigation of the prognostic value of combining genetic and phenotypic characteristics in a cohort of ADPKD patients is attempted.

Methods: In 66 ADPKD patients (mean age 33 ± 12 years, 32 males), the genetic diagnosis (using targeted Next Generation, tNGS, or Sanger Sequencing or Multiplex ligation-dependent probe amplification, MLPA) and the Mayo Clinic Imaging Category (MCIC) (through Renal Magnetic Resonance Imaging, MRI, for Total Kidney Volume measurement) were assessed. The prediction of ESKD was performed using the Mayo Clinic formula (Irazabal MV et al JASN, 2015). The calculation incorporated variables such as sex, age, e-GFR, and the MCIC. The PROPKD score was derived by considering both phenotypic factors (sex, hypertension and urologic events before the age of 35 years) and genetic data (PKD1-truncating, PKD1- non truncating and PKD2).

Results: Adjusted for age, the e-GFR was on average, 26 and 27 ml/min higher in PKD2 patients compared to ADPKD-PKD1-truncating and ADPKD-PKD1-non-truncating patients, respectively (p = 0.001). The median prediction of ESKD for ADPKD-PKD1-truncating, ADPKD-PKD1-non-truncating and PKD2 patients was 22 (11-31) years, 22 (11-34) years and 31 (21-59) years, respectively (NS). In patients categorized as high risk according to PROPKD (score 7-9) the predicted time to ESKD was 16 (9-30) years, for those at intermediate risk (score 4-6), 25 (13-34) years and for those at low risk (score 0-3), 28 (16-55) years (NS). Finally, the PROPKD score showed an inverse correlation to the years of ESKD prediction, as determined by the Mayo Clinic formula; a higher PROPKD score was associated with a shorter prediction period for ESKD (Spearman r = -0.3, p = 0.04).

Conclusions: Prognosis of renal survival in ADPKD patients requires not only a specific genetic diagnosis but also consideration of the phenotypic data, as incorporated in the PROPKD score, enhancing the accuracy of renal survival prediction.

SA-PO571

Exploring the Personal Narratives of Patients with Autosomal Dominant Polycystic Kidney Disease: The NaMe-PKD Study

Anuva Mittal, Jessica Porras, Samar Chackerreza, Kayvon Solaimanpour, Nuria M. Pastor-Soler. *USC/UKRO Kidney Research Center, Keck School of Medicine of University of Southern California, Los Angeles, CA.*

Background: For patients with chronic diseases, including autosomal dominant polycystic kidney disease (ADPKD), previous studies have shown that patients' disease progression, outcomes, and goals can be impacted by their illness perceptions. Specifically, in the case of genetic diseases, patients' perceptions may be shaped even before their own diagnoses by observing their family members' experiences with the disease. Few studies contrast patients' perceptions of their genetic disease before and after their diagnoses and how this information may inform their management goals. Our study asks patients with ADPKD, specifically those who observed family members with the disease prior to their diagnosis, to reflect on the way their understanding of ADPKD pre-diagnosis may have influenced their experience post-diagnosis.

Methods: This study was approved by the Social Behavioral Institutional Review Board. An IRB-approved questionnaire was administered in person with verbal responses from participants. Using a grounded theory approach, a thematic analysis of these transcribed interviews was performed.

Results: While recruitment is ongoing, five participants have met inclusion criteria and have been interviewed. Men and women from ages 36 to 53 years old are represented. Thematic analysis led to the creation of three categories of themes: 1) Illness perception pre-diagnosis, 2) Illness perception initially post-diagnosis, and 3) Acceptance of the diagnosis. Illness perception pre-diagnosis entailed secrecy, surprise, and misinformation; post-diagnosis entailed a sense of isolation, denial, and guilt; and acceptance entailed inevitability and resilience.

Conclusions: Patients expressed ideas of protective secrecy and sometimes misinformation surrounding the discussion of ADPKD before their diagnosis, with some mentioning the complete lack of discussion of the disease in their families and others equating ADPKD with dialysis. Furthermore, as patients came to terms with their diagnosis and related to their family members' experiences, they described shifts in their attitude from denial and helplessness to later incorporating disease management into their lifestyle. Ultimately, we hope to use our findings to help clinicians more effectively approach conversations related to the trauma around the initial diagnosis of ADPKD.

SA-PO572

Patient Experience with Genetic Testing in ADPKD

Diana Etwaru, Ying Gao, Meyeon Park. *University of California San Francisco, San Francisco, CA.*

Background: Genetic testing for diagnosis in autosomal dominant polycystic kidney disease (ADPKD) has become more common since the development of panel tests including PKD1 and PKD2 and related cystic genes. We sought to explore attitudes about genetic testing among individuals with ADPKD.

Methods: We generated a web-based Qualtrics survey comprising 23 questions and incorporating a validated survey about public attitudes toward genetic testing (Henneman PMID 16792518). The survey was pilot-tested by volunteers from our clinical center. The survey was distributed to 16,773 individuals with PKD above the age of 18 through the PKD Foundation e-mail listserv.

Results: 226 individuals responded. 70% were female and 88% were White / Caucasian. 127 out of 201 individuals answered "No, never discussed" to the question, "has the possibility of getting a genetic test to detect a PKD variant (mutation or abnormality) been discussed with you by a doctor or healthcare provider?" Out of 113 individuals who did undergo genetic testing, 54 were unable to remember their results. 39 out of 94 individuals reported that the results "did not change anything" about their feelings about their kidney disease, while 10 felt more "optimistic / positive," 14 felt more "pessimistic / negative," and 31 were "not sure." The range of feelings expressed are shown in Figure 1.

Conclusions: Many individuals with ADPKD have not participated in discussions about genetic testing with healthcare providers. Among individuals who have undergone testing, the majority do not recall their results. Most individuals with testing felt that the tests did not change their feelings, while many were unsure. A wide range of feelings associated with testing were reported. Given the growing role of genetic knowledge in ADPKD, further work is needed to ensure patients are educated about genetic testing and its potential implications for management, and to include patients of all backgrounds in studies investigating this evolving area. This is an investigator sponsored study which was funded by Otsuka Pharmaceutical Development and Commercialization, Inc.

Effect of Genotype on Kidney Outcomes among Patients with Inherited Cystic Kidney Disease

Hayne C. Park,[1] Dha Woon Im,[2] Yong Chul Kim,[3] Yaerim Kim,[4] Yun Kyu Oh.[5] *[1]Hallym University Kangnam Sacred Heart Hospital, Seoul, Republic of Korea; [2]Eulji University Uijeongbu Eulji Medical Center, Uijeongbu, Gyeonggi-do, Republic of Korea; [3]Seoul National University Hospital, Seoul, Republic of Korea; [4]Keimyung University Dongsan Medical Center, Daegu, Republic of Korea; [5]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Seoul, Republic of Korea.*

Background: Inherited cystic kidney disease is a constellation of heterogenous genetic diseases that commonly share renal cystic phenotype. We have analyzed renal outcome (annual change of estimated glomerular filtration rate (eGFR) and total kidney volume (TKV)) among Korean genetic cohort of inherited cystic kidney disease.

Methods: Primary genetic analysis was conducted using a targeted gene panel including 89 ciliopathy-associated genes. A total of 705 patients were included in the cross-sectional analysis. A total of 375 patients with longitudinal data without history of Tolvaptan treatment were included in the renal outcome analysis. Genotypes were classified into PKD1, PKD2, minor genotypes, or double variants (DV).

Results: PKD1 group showed younger age at diagnosis of cystic kidney disease and hypertension, and higher proportion of rapid progressor. Interestingly, the patients with minor genotypes showed better renal function but smaller kidneys than PKD1 group. The DV group demonstrated similar profiles with PKD1 group. PKD1 genotype showed faster eGFR decline (-2.69± 9.2 mL/min/1.73m^2/yr) compared to PKD2 (-0.15 ± 8.1 mL/min/1.73m^2/yr) and minor genotypes (0.68 ± 9.5 mL/min/1.73m^2/yr, p=0.03). The DV group demonstrated faster eGFR decline rate than PKD1 genotype (-3.53 ± 7.4 mL/min/1.73m^2/yr). PKD1 group (59.2 ± 93.0 mL per year) and PKD2 group (47.5 ± 79.5 mL per year) demonstrated TKV growth during study period while minor genotypes showed shrinkage of kidneys (-8.6 ± 55.8 mL per year, p=0.052).

Conclusions: PKD1 genotype demonstrated poorer renal outcome compared to other genotypes. Minor genotypes showed favorable renal outcome with shrinkage of kidneys.

Funding: Government Support - Non-U.S.

Renal outcome according to genotypes

	PKD1-PT	PKD1-NT	PKD1-IFindel	PKD2	Minor genotypes	P-value
Annual change of eGFR (n=375)	-2.78 ± 9.7	-2.36 ± 8.57	-3.89 ± 5.9	-0.15 ± 8.09	0.68 ± 9.53	0.043
Annual change of TKV (n=102)	63.0 ± 107.1	60.3 ± 55.8	-1.4 ± 49.0	47.5 ± 79.5	-8.6 ± 55.8	0.026

Minor genotypes: COL4A5, HNF1β, TSC1, COL4A3, GANAB, UMOD, DYNC2H1, TSC2, AHI1, AVP, COL4A1, CPLANE1, HSPA6, NEK8, PAX2, PRKCSH, SEC31B, TRPV1, WFS1

Exome Sequencing "Firsthand" for Polycystic Kidney Diseases: Impact beyond PKD1/PKD2 Identification on ADPKD Clinical Management

Laurent Mesnard,[1,2] Ilias Bensouna,[1,2] Marine Serveaux Dancer,[3] Thomas Robert,[4] Alice Doreille.[5] *[1]Sorbonne Universite, Paris, France; [2]Inserm UMR S1155, Paris, France; [3]Eurofins Biomnis Lyon, Lyon, France; [4]Assistance Publique Hopitaux de Marseille, Marseille, France; [5]Montreal General Hospital, Montreal, QC, Canada.*

Background: Genetic testing is currently considered non-mandatory for managing typical autosomal dominant polycystic kidney disease (ADPKD) patients. However, an increasing number of genes are associated with ADPKD. For atypical forms of ADPKD, the diagnostic yield may be lower with targeted genetic analysis. Genome-wide analysis can highlight incidental findings that could impact clinical management. Recent studies suggest that exome sequencing (ES) could be as efficient as standard methods, even for PKD1/PKD2 analysis.

Methods: Among 3523 index cases undergoing ES genetic testing at Sorbonne University, Paris, France, 721 patients were categorized as having cystic diseases (149 with typical ADPKD and 572 with atypical ADPKD). We compared the diagnostic yield in both typical and atypical ADPKD. Then, we analyzed the rate of incidental findings impacting ADPKD clinical management (pathogenic variants not anticipated that explain part of the phenotype, or for which the patient is not/pre-symptomatic, or variants of interest in genetic counseling) among patients with a pathogenic variant in PKD1/PKD2 genes and compared this to the entire cystic nephropathy cohort.

Results: Of the 721 patients with cystic nephropathy, 239 had a positive genetic test with a pathogenic or likely pathogenic variant (33%). The diagnosis rate was 59.1% for typical ADPKD patients compared to 26.4% in the atypical cystic nephropathy population. In the typical ADPKD group, PKD1 and PKD2 represented only 60.3% of pathogenic variants found by ES. Double hits represented 13.1% of patients with a positive genetic test, reaching 20.6% in the PKD1/PKD2 population.

Conclusions: Our results showed a great diversity in genes responsible for adult's cystic nephropathies, even in the typical ADPKD population. We observed a significant rate of incidental findings impacting clinical ADPKD management. Our work suggests that ES should be considered a first-tier test for any ADPKD patients to optimize their clinical management.

Percentage of patients carrying a second variant in a second gene among patients with a positive genetic diagnosis.

SA-PO575

ADPKD Progression by Variant Type and Molecular Domain: An Evaluation of Time-Series Disease Trajectories among HALT Participants

Robert L. Sucholeiki,[1] Elena Jochum,[1] Arlene B. Chapman,[2] Peili Chen,[2] Oliver Wessely.[3] University of Chicago Medicine Section of Nephrology. *[1]University of Chicago Division of the Biological Sciences, Chicago, IL; [2]University of Chicago Pritzker School of Medicine, Chicago, IL; [3]Cleveland Clinic, Cleveland, OH.*

Background: As the leading monogenic cause of kidney failure, autosomal dominant polycystic kidney disease (ADPKD) affects over 12 million people worldwide. Understanding predictors of ADPKD severity is important for prognosis, long-term management, and treatment. Disease severity has been shown to depend on the gene affected by the pathogenic variant (*PKD1* vs *PKD2*) and its truncating effect. However, the association between ADPKD disease phenotype and the location of genetic variants in functional polycystin protein domains is not understood.

Methods: We studied time-series height-adjusted total kidney volume (htTKV), eGFR, and Mayo Imaging Class (MIC) distribution among 334 early-stage patients with ADPKD in the HALT A dataset (a randomized clinical trial dataset of early-onset ADPKD individuals) to examine the impact of variant location in the *PKD1* gene on disease progression over time. HALT A provided Sanger sequencing information for the pathogenic variant of each patient. We referenced the UniProt and cBioPortal genetic databases for protein domain information. We assigned non-truncating genetic variants (n=110) by location to key structural or functional domains in polycystin-1 or polycystin-2. We used RStudio to plot time-series htTKV and eGFR progressions and ran linear regressions for each participant. We compared patients' longitudinal disease trajectories for truncating vs non-truncating variant status and the protein domain location of non-truncating *PKD1* variants.

Results: *PKD1* non-truncating pathogenic variants in the REJ (90.5 ml/m/year; 95% CI [66.5–112.5]) and PLAT (80.3 ml/m/year; 95% CI [58.0–102.6]) domains demonstrated rapid htTKV growth, while variants in the C-type lectin (26.8 ml/m/year; 95% CI [10.8–42.8]) and PKD repeat (19.6 ml/m/year; 95% CI [1.3–37.8]) domains demonstrated significantly slower growth ($p<0.0001$). Variants in these fast- and slow-progressing regions also showed clinically and statistically significant differences in MIC distribution ($p<0.0001$) and eGFR rate of change (-4.26 vs -2.67 ml/min/year; $p<0.0001$).

Conclusions: Our findings shed light on protein domain location as a clinically substantive marker of ADPKD disease progression that can be valuable for disease prognosis in early-stage patients with non-truncating variants in *PKD1*.

SA-PO576

Comparative PKD1 and PKD2 Missense Variant Profiling Aids Molecular Diagnoses and Reveals Common Pathomechanisms and Variant Subtypes across the ADPKD Spectrum

Cynthia J. Sieben,[1] Vladimir G. Gainullin,[1,2] Christina M. Heyer,[1] Doaa E. Elbarougy,[1] Sarah R. Senum,[1] Zhifei Wang,[3] Xiaobo Sun,[1] Hana Yang,[1] Ines Sturmlechner,[1] Yong Yu,[3] Peter C. Harris.[1] *[1]Mayo Clinic Research Rochester, Rochester, MN; [2]Exact Sciences Corporation, Madison, WI; [3]St. John's University, Queens, NY.*

Background: ADPKD is characterized by the formation and growth of fluid-filled renal cysts, often leading to kidney failure (KF). Typically, monoallelic *PKD1* or *PKD2* (encoding PC1 and PC2) variants cause ADPKD, however, complex inheritance and a broad phenotypic spectrum exist. The advent of genomewide variant screening emphasizes the importance of ADPKD molecular diagnostic methods to reliably determine the pathogenicity of variants of uncertain significance (VUS).

Methods: Here, we evaluated the pathogenicity/penetrance of 48 *PKD1* and 44 *PKD2* missense variants using *in silico* (ACMG guidelines [clinical] and Variant Strength Group [VSG; research] categorization) and *in vitro* (PC1 maturation/trafficking to the cell surface [sPC1; requires PC1/2 complex formation] using a cell-based flow cytometry assay, and PC1/2 channel activity employing *Xenopus* oocytes) methods. The *in vitro* results were correlated with *in silico* predictions and patient phenotypes (htTKV, eGFR, and KF), including employing the population-based, Mayo Clinic Biobank (MCBB).

Results: The majority of proposed monoallelic *PKD1* and *PKD2* variants assayed close to fully penetrant (~68%, <20% sPC1), whereas biallelic and digenic *PKD1* and *PKD2* variants ranged from strong hypomorphs (25% biallelic *PKD1*; 20-40% sPC1) to mild or benign (75% biallelic *PKD1*, 100% biallelic/digenic *PKD2*; 50-110% sPC1). Most were associated with aberrant folding (~85% *PKD1*, 68% *PKD2*). Analysis of Ca^{2+} channel activity for mild/benign sPC1 variants (12 *PKD1* and 14 *PKD2*, monoallelic and complex), occasionally suggested channel defects (~8% *PKD1*, 14% *PKD2*). Variant sPC1 levels showed correlations with clinical endpoints (htTKV, eGFR, and KF). Analyses of two hypomorphic variants (*PKD1* p.Arg3277Cys and p.Ile3167Phe) in the MCBB, revealed correlations between sPC1 levels (~27 and 64%) and disease penetrance (~20 and 5% with ICD cystic codes).

Conclusions: Together, these studies reveal: 1) the value of combining *in silico*, functional, and population data for *PKD1* and *PKD2* variant evaluation, 2) aberrant PC1 trafficking as a common *PKD1/2*-mediated pathomechanism and disease determinant, and 3) enhanced PC1/2 folding as a potential therapy in ADPKD.

A Microhomology-Mediated End-Joining (MMEJ)-Based F0 Assay in Zebrafish for Rapid Screening of Genetic Modifiers of Kidney Cysts

Ping Zhu, Xiaolei Xu, Xueying Lin. *Mayo Foundation for Medical Education and Research, Rochester, MN.*

Background: Autosomal-dominant polycystic kidney disease (ADPKD) is one of the most prevalent and potentially lethal genetic diseases. ADPKD patients exhibit highly variable phenotypes, of which genetic modifiers are thought to play an important role. However, the identity of the genetic modifiers remains largely unknown because of the lack of an efficient method. Prompted by the success of applying microhomology-mediated end joining (MMEJ)-based genome editing technology for the identification of genetic modifiers of cardiomyopathy in the F0 generation, we decided to explore the F0-based genetic assay for discovering genetic modifiers of ADPKD.

Methods: We generated zebrafish mutants of *IFT140*, a newly identified ADPKD gene. All *ift140* mutants exhibited distinctive pronephric cysts and were otherwise normal till approximately 2 weeks of age. Injection of a MMEJ-inducing sgRNA against *ift140* consistently resulted in pronephric cysts in >90% of the injected embryos, and the cysts can be easily scored under a light microscope at 4-6 dpf. To test the feasibility of developoing a modifier screen platform, we co-injected MMEJ-inducing sgRNAs targeting *ift140* and a gene of interest into one-cell staged wild type embryos and assessed kidney cysts at 5 dpf.

Results: In a pilot screen, we tested 18 genes that are implicated in the signaling pathways known to be dysregulated in ADPKD. Inactivation of genes that were previously suggested beneficial, such as *mtor*, was found to reduce the number of $ift140^{MJ}$ embryos with pronephric cysts. By contrast, inactivation of genes that were previously suggested detrimental did not suppress pronephric cyst formation. Besides genes with known modifying effects, novel protective modifiers such as *ulk1a* have been suggested from our pilot screen. Using *mtor* and *ulk1a* stable mutants, we confirmed the protective modifying effects of mTor and Ulk1a inhibition in *ift140*-based as well as *pkd1*-based kidney cyst development.

Conclusions: Thus, $ift140^{MJ}$ embryo can be used as a surrogate to rapidly discover candidate protective modifiers of kidney cysts, which can be validated by generating stable mutants and extended to *pkd1*-based cystogenesis.

Funding: NIDDK Support

SA-PO578

Assessment of Key Indicators of Pathogenicity in PKD1/2 Variants

Dinah Clark, Robert T. Burns, Michelle Bloom, Elizabeth Garrity, Sumit Punj, Stephen Andrews. *Natera Inc, Austin, TX.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is primarily caused by pathogenic (P) and likely pathogenic (LP) variants in *PKD1* and *PKD2*, with ~5% of affected individuals remaining genetically unresolved. Due to the high rate of novel variants seen in *PKD1/2*, many will be variants of uncertain significance (VUS) with insufficient evidence to be classified as either LP or likely benign (LB), and may comprise a significant proportion of the unresolved cases. According to ACMG, evidence including phenotypic and prevalence data in affected and/or unaffected populations can be used to support VUS reclassification. Here we utilized unaffected population prevalence and renal phenotypes to assess VUS in *PKD1/2*.

Methods: A retrospective analysis of *PKD1/2* variants identified via a 385 renal gene panel (the Renasight™ test) was performed. The gnomAD database (v2.1.1) was queried for variant population prevalence. Claims information were abstracted from the Komodo Health database to assess phenotypes based on the absence or presence of kidney cystic ICD codes (Q61.0-.9 and/or N28.1).

Results: Across 61057 cases with test results, 4002 cases had a P/LP variant (1565 unique variants) and 5409 had a VUS in *PKD1/2* (2900 unique variants) with no P/LP in a cystic gene. 97.3% of P/LP *PKD1/2* variants were absent from gnomAD and none were present in >3 alleles (excluding 2 hypomorphic variants). Likewise, 70% (n=2025) of VUS were present in ≤ 3 alleles in gnomAD, of which 1310 (64.7%) were absent. 22.8% (n=661) of all VUS were both absent and had ≥1 patient with a cystic ICD code. Patients with the remaining absent VUS (n=649) had incomplete clinical profiles, preventing further evaluation by the testing lab.

Conclusions: Absence of a variant from gnomAD and cystic disease ICD-10 codes are examples of evidence supporting pathogenicity, yet they are not sufficient to enable reclassification without additional evidence. Here we demonstrate that less than a quarter of VUS identified in *PKD1/2* satisfy these pieces of evidence, edging these variants closer to LP. For an additional 22%, phenotypic information was lacking but could support reclassification. These findings highlight the important role physicians have in providing phenotypic information to the testing lab for patients with rare VUS.

Population Frequency of Undiagnosed Pathogenic Variants in PKD Type 1 and Type 2

Santosh Varughese, Judith A. Savige. *The University of Melbourne Faculty of Medicine Dentistry and Health Sciences, Melbourne, VIC, Australia.*

Background: The estimated population frequency of AD polycystic kidney disease in recent epidemiologic studies has varied from one in 1000 to one in 2000 but when based on a genetic analysis is closer to one in 1000 (PMID:30135240). This study has reexamined the commonest genes affected, *PKD1* and *PKD2*, for pathogenic variants including assessing missense changes with highly stringent criteria, with Alamut and REVEL, in order to more accurately determine the ADPKD population frequency.

Methods: *PKD1* and *PKD2* variants were downloaded from gnomAD v2.1 and annotated in ANNOVAR. Structural and null variants were considered pathogenic and missense variants assessed for pathogenicity based on rarity, positivity in three computational tools and whether they affected a residue conserved in vertebrates. The occurrence of these variants in people of different ancestries was also examined. Our approach for assessing missense variants was compared with positivity in Alamut (scores ≥5 or ≥6), and REVEL (≥0.932), and the accuracy of these approaches evaluated using 20 benign and 20 pathogenic variants reported in LOVD.

Results: One in 1500 of the population have a null *PKD1* variant and one in 2500 have a null variant in *PKD2*. Thus the population frequency of null variants is greater than one in 1000 (8/7500) and 60% of variants affect *PKD1*. Null variants are most frequently found in people of African/African American, East Asian and South Asian ancestries. Our strategy for assessment of missense changes in *PKD1* had a sensitivity of 65% and a specificity of 95%, and missense changes in *PKD2* had a sensitivity of 40% and specificity of 100%. However the population frequencies of missense variants were more variable with different approaches.

Conclusions: These results suggest that *PKD1* and *PKD2* pathogenic null and missense variants occur more often in the population than the previously-estimated one in 1000. Missense changes in *PKD1* and *PKD2* remain difficult to evaluate accurately for pathogenicity.

Population frequencies of predicted pathogenic structural, null and missense variants and strategy evaluation

	PKD1	Sensitivity	Specificity	PKD2	Sensitivity	Specificity
Structural and null variants						
Total null and structural variants	70 or one in 1500			44 or one in 2500		
Comparison of evaluation of missense variants						
Our assessment	569 or one in 178	65%	95%	81 or one in 1357	40%	100%
Alamut > or equal to 5	One in 183	55%	100%	One in 1221	55%	90%
Alamut > or equal to 6	One in 1400	20%	75%	One in 2389	20%	100%
REVEL > 0.932	One in 52,534	0%	100%	One in 18,318	25%	100%

SA-PO580

ADPKD-Spectrum Phenotype in Carriers of IFT172 Pathogenic Variants

Doaa E. Elbarougy,[1] Rohail Jameel,[1] Hana Yang,[1] Rachel S. Schauer,[1] Sean Rogers,[1] Shannon K. McDonnell,[1] Jacob A. Frank,[1] Jun Ma,[1] Nikola Zagorec,[3] Marie-Pierre Audrezet,[3] John A. Sayer,[2] Emilie Cornec-Le Gall,[3] Nicholas B. Larson,[1] Peter C. Harris.[1] *[1]Mayo Clinic Research Rochester, Rochester, MN; [2]Newcastle University, Newcastle upon Tyne, United Kingdom; [3]INSERM, Paris, France.*

Background: ADPKD is mainly due to *PKD1* and *PKD2* mutations. However, ~10% are genetically unresolved or due to other loci, including *IFT140*. Here, we link another ciliary structural protein gene, *IFT172* to the ADPKD like-phenotype.

Methods: We screened ADPKD-like patients on a 356 gene panel (Mayo PKD Center) or a custom gene panel (CHU Brest). In addition, we screened the Mayo Clinic Biobank (MCBB), UK Biobank (UKBB) and Genomics England 100kG Project cohorts, for *IFT172* loss of function (LoF) variants. MCBB carriers of *IFT140* LoF variants were also identified for comparison.

Results: In the cystic population, we identified 6 monoallelic *IFT172* probands with LoF variants and clinical and imaging data. The mean age ±SD was 54.2±20.8, and the mean eGFR 62.8±32.3. The kidney cyst count ranged from 5 to >50. Two probands (33%) had a family history of kidney cysts. In the 52,786 MCBB individuals, we identified 66 (0.13%) with *IFT172* LoF variants and 83 (0.16%) with *IFT140* LoF variants. Of the 38 *IFT172* patients with imaging, nine (24%) had kidney and liver cysts, 18 (47%) only kidney cysts, and four (10.5%) ICD codes for kidney cysts, including three with ADPKD codes. Of the 48 *IFT140* individuals with imaging, nine (18.8%) had kidney and liver cysts, 32 (67%) only kidney cysts, and nine (18.8%) ICD codes for kidney cysts, including two with ADPKD codes. The mean eGFR ±SD were similar, 72.9±22 in the *IFT172* group and 70.2±20 in the *IFT140* group. Figure 1 shows the number of kidney (A) or liver (B) cysts per patient in both groups; 14.3% and 2.3% of the *IFT172* and 23% and 10% of the *IFT140* had ≥10 kidney or liver cysts, respectively. In the UKBB, *IFT172* LoF variants were associated with cystic kidney disease ICD code Q61 (burden test p-value: 0.0114). In the 100kG project, 37 *IFT172* LoF alleles were identified in a rare disease cohort of probands (n=34,082); 2 probands (5.4%) had a cystic kidney phenotype.

Conclusions: *IFT140* and *IFT172* LoF heterozygous variants show incomplete penetrance. The *IFT172* kidney phenotype in affected patients is mild PKD with large cysts and few liver cysts, similar to monoallelic *IFT140*.

Funding: NIDDK Support

SA-PO581

Characterizing Kidney and Liver Cysts in Monoallelic PKHD1 Individuals Identified in a Population-Based Study

Doaa E. Elbarougy,[1] Tabinda Jawaid,[1] Hana Yang,[1] Shannon K. McDonnell,[1] Jacob A. Frank,[1] Jun Ma,[1] Adriana Gregory,[1] Vicente E. Torres,[1] Fouad T. Chebib,[2] Christian Hanna,[1] Timothy L. Kline,[1] Nicholas B. Larson,[1] Peter C. Harris.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Mayo Clinic in Florida, Jacksonville, FL.*

Background: Biallelic-*PKHD1* pathogenic variants are associated with ARPKD, while monoallelic-*PKHD1* mutations have recurrently been related to mild liver or kidney cysts. Here, we employed the population-based Mayo Clinic Biobank (MCBB) cohort with whole exome sequencing data to clinically characterize monoallelic-*PKHD1* individuals.

Methods: A cohort of 52,786 MCBB individuals was screened for known pathogenic variants in *PKHD1* and clinical records were screened using Mayo Data Explorer. Kidney and liver cysts were counted via automated segmentation or manually, respectively.

Monoallelic-*PKHD1* individuals identified from ARPKD families and through genetic screening of cystic subjects in the Mayo PKD Center (MPC) were also characterized and compared to the MCBB *PKHD1* carriers.

Results: A total of 975 *PKHD1* carriers were identified in MCBB (1.85%); 267 (27.4%) had protein truncating and 708 (72.6%) non-truncating pathogenic variants. Based on radiology reports of the 581 with abdominal imaging, 142 (24.4%) had both kidney and liver cysts, 149 (25.6%) only kidney cysts, and 57 (9.8%) only liver cysts; 30.6% with appropriate imaging had nephrolithiasis. ICD9/10 codes for kidney or liver cysts were positive in 37 (6.5%) patients, including three with ADPKD codes. Figure 1 shows the number of kidney (A) or liver (B) cysts per patient out of 259 MCBB individuals with analyzed imaging; 17% and 15.8% had ≥10 kidney or liver cysts, respectively. Corresponding frequencies were 12.5% and 25% in 16 ARPKD family members and 70.6% and 51.5% in 33 MPC sporadic individuals. With age adjustment, the mean eGFR ±SE was higher in the MCBB group (74.9±0.7), than in the ARPKD families (62.5±5.8; p=0.04) and the MPC sporadic individuals (57.2±5; p<0.001). A total of 25 *PKHD1* MCBB cases had CKD5, but in each case other comorbidities were identified.

Conclusions: Carriers of *PKHD1* pathogenic variants are common and kidney and/or liver cysts are often seen, but polycystic kidneys and/or livers are quite rare (<20% of individuals), as is eGFR decline.

Funding: NIDDK Support

Determining the Pathogenic Mechanism Underlying Childhood ADPKD Caused by a Monoallelic Pathogenic Variant in NEK8

Chuan Chen, Peter C. Harris, Kun Ling. *Mayo Clinic Minnesota, Rochester, MN.*

Background: While autosomal dominant polycystic kidney disease (ADPKD) typically manifests in adults, a fraction present early and rapidly progress to kidney failure during infancy and childhood. We recently identified a monoallelic variant in *NEK8* (c.133C>T (p.Arg45Trp)), resulting in an enzymatic deficient serine/threonine kinase that resides in primary cilia. Unlike biallelic pathogenic *NEK8* variants causing systemic ciliopathies, the p.Arg45Trp variant causes early-onset ADPKD with few extrarenal defects. Thus, NEK8^{R45W} seems specific for renal cystogenesis and is a unique tool to dissect the pathogenic mechanism of PKD in children.

Methods: Mouse renal epithelial cell lines null for NEK8 were generated using CRISPR/Cas9 and wild type (WT) or R45W human NEK8 constructs were reexpressed: Ciliary biogenesis, structure, and signaling were analyzed. Phospho-site and proximity-dependent proteomics were conducted using the cell lines to identify proteins that are differentially phosphorylated, deposited into cilia, or associated with NEK8 variants. We constructed a mouse model to study the physiological role of NEK8^{R45W}.

Results: Although Nek8-null cilia are shortened, NEK8^{R45W} cilia retained comparable length and overall structural integrity to the WT cilia, but the PKD1/PKD2 proteins, PC1 and PC2, were significantly reduced in NEK8^{R45W} cilia. Although the ciliary level of GPR161 remained unchanged, SAG induced less accumulation of Smoothened and Gli3 in NEK8^{R45W} cilia than WT, indicating a weaker activation of the Hedgehog (Hh) signaling. Phospho-site proteomics results supported the defective kinase activity of NEK8^{R45W} and revealed mis-regulated pathways in cells expressing NEK8^{R45W}. Importantly, *Nek8*$^{+/R45W}$ mice showed aggressive renal cystogenesis within 3 weeks after birth, recapitulating the early-onset ADPKD phenotype in patients.

Conclusions: We further study the characteristics of the monoallelic *NEK8* p.Arg45Trp and determined that the kinase activity of NEK8 in cilia is necessary for the ciliary trafficking of the PC complex, activation of Hh signaling, and epithelial morphogenesis. These signaling pathways may collectively contribute to the establishment and maintenance of renal tubule structures. Understanding the crosstalk between these pathways via studying the role of NEK8^{R45W} may reveal potential drug targets for the treatment of ADPKD in children.

SA-PO583

Functional Analysis of a De Novo Monoallelic NEK8 Variant Supports Pathogenicity for a Polycystic Kidney Disease Phenotype

Whitney Thompson, Chuan Chen, Hana Yang, Tracy A. Baker, Carl H. Cramer, Peter C. Harris, Kun Ling, Christian Hanna. *Mayo Clinic Minnesota, Rochester, MN.*

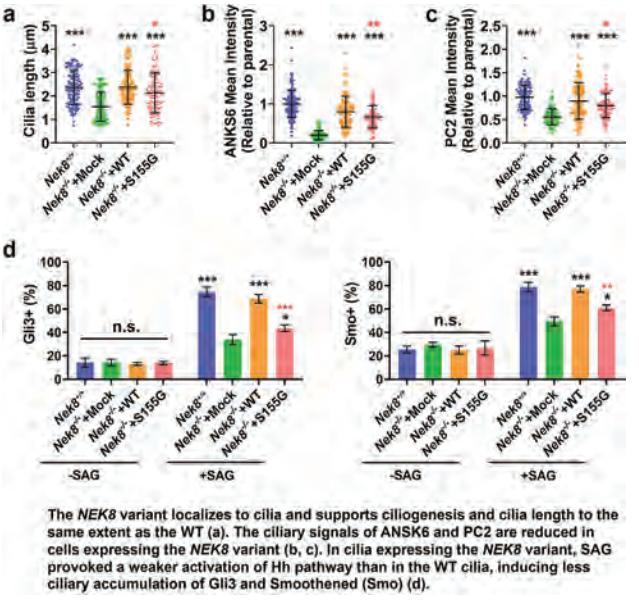
Background: While *PKD1* and *PKD2* pathogenic variants are most common in ADPKD, additional genes linked to primary cilia are increasingly recognized in ADPKD. One such gene, *NEK8*, encodes a ciliary serine/threonine kinase involved in renal and cardiovascular development. Biallelic pathogenic variants in *NEK8* cause renal-hepatic-pancreatic dysplasia-2; however, certain monoallelic *NEK8* variants have been recently linked to ADPKD, causing phenotypes ranging from childhood-onset kidney failure to typical ADPKD. Decreased polycystin-2 (PC2) in cilia have been reported in Nek8 null cells. Herein, we report studies on a novel monoallelic *NEK8* variant (c.463A>G, p.Ser155Gly) in a pediatric patient.

Methods: Genetics and the clinical phenotype were characterized and the *NEK8* variant was stably expressed in Nek8 null cells. The ciliary biogenesis, protein composition, and Hedgehog (Hh) signaling were compared between the empty vector (Mock), the Myc-tagged *NEK8* wild type (WT), and *NEK8* (p.Ser155Gly).

Results: A 12-year-old male was diagnosed incidentally with bilateral medullary kidney cysts. PKD panel screening found a de novo *NEK8* variant of uncertain significance (VUS), c.463A>G (p.Ser155Gly), as the most likely pathogenic change. This *NEK8* variant localizes to cilia and supports ciliogenesis and cilia length to the same extent as the WT (Fig 1a). Yet, the ciliary signals of ANSK6 and PC2 are reduced in cells expressing the *NEK8* variant (Fig 1b, c). In *NEK8* variant cilia, SAG weakly activated the Hh pathway compared to WT cilia, inducing less ciliary accumulation of Gli3 and Smoothened (Smo) (Fig 1d).

Conclusions: Functional analysis supports the pathogenicity of our patient's *NEK8* VUS. Monoallelic *NEK8* should be considered in childhood ADPKD cases.

Funding: Other U.S. Government Support



The *NEK8* variant localizes to cilia and supports ciliogenesis and cilia length to the same extent as the WT (a). The ciliary signals of ANSK6 and PC2 are reduced in cells expressing the *NEK8* variant (b, c). In cilia expressing the *NEK8* variant, SAG provoked a weaker activation of Hh pathway than in the WT cilia, inducing less ciliary accumulation of Gli3 and Smoothened (Smo) (d).

Cystic Development in Ift140 Knockout Mice Depends on Knockout Timing

Hana Yang, Zoey Mann, Kristian M. Kennedy, Cynthia J. Sieben, Gurparneet K. Sohi, Peter C. Harris. *Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common genetic disease, causing kidney failure, and is primarily caused by mutations in *PKD1* (~81%) or *PKD2* (~13%), however, >8 minor genes, including *IFT140*, have been identified. The ADPKD-*IFT140* phenotype is distinct, featuring a lower number of large cysts. IFT140, an intraflagellar transport protein, is critical for the generation and function of primary cilia, but the monoallelic cystic disease pathomechanisms are unclear.

Methods: We employed an inducible conditional mouse model (*Ift140*$^{flox/flox}$;*Pax8*-rtTA;(tetO)7-Cre) to achieve kidney tubule-specific *Ift140* knockout (KO) at different stages. Doxycycline treatment (*Ift140* KO) via food was introduced to pregnant or nursing dams at embryonic day (E) 14.5 and 16.5, or postnatal day (P) 1, and 7. To monitor PKD severity/progression, MRI and total kidney volume (TKV) were assessed at 1, 3, and 6 months (m) in living animals, and histological and kidney function analyses performed post-sacrifice.

Results: TKV was significantly increased at 1m in E14.5 and E16.5-induced mice (Fig. 1), but P1 and P7-induced mice were unaffected. The degree of cystic severity at 1m differed greatly between the E14.5 and E16.5 groups, showing a steep decline from E14.5 to E16.5. Furthermore, P1 and P7-induced mice did not develop cysts up to 6m. However, E14.5-induced mice had severe disease, with lethality by 1m, whereas E16.5 mice, with milder disease, survived beyond 3m in some cases.

Conclusions: The timing of *Ift140* removal greatly influenced the rate of cyst development in mice between E14.5 and E16.5, while no cysts formed at or after P1. This dramatically contrasts with the later kidney development switch point between severe and mild PKD for *Pkd1* (~P13). This raises questions about when embryonic reduction of IFT140 in ADPKD-*IFT140* may be critical for cyst development and how this contrasts with ADPKD-*PKD1*. To further elucidate IFT140 pathomechanisms, we will analyze ciliary protein trafficking and structure at different time points.

Heterozygous Mutations in Three Novel Candidate Genes, IFT122, WDR19, and WDR35, Cause Autosomal Dominant Polycystic Kidney Disease

Dan Colombo,[1] Denisse Romero Cruz,[1] George W. Wan,[1] Adriana C. Barreiro-Rosario,[1] Ahona Dam,[1] Alexandra Diamond,[1] Giada Bianchi,[2] Christopher S. Oglivy,[1] Samer S. Nasser,[1] Elizabeth A. Phipps,[3] Walter P. Mutter,[4] Emily Robinson,[2] Katherine S. Ravi,[2] Peter G. Czarnecki.[1]
[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Mount Auburn Hospital, Cambridge, MA; [4]Newton-Wellesley Hospital, Newton, MA.

Background: Autosomal-dominant polycystic kidney disease (ADPKD) is one of the most common monogenic diseases in mankind. Despite the identification of two major and various minor causative genes, many cases remain genetically unresolved ("ADPKD-NMD", "no mutation detected"). We sought to identify novel disease-causing genes by analyzing the genotypes of patients with ADPKD-NMD, and we found numerous variants in IFT122, WDR19 and WDR35. Given the similarity of disease phenotypes and the common biochemical function of the ADPKD gene, IFT140, with the 3 novel candidate genes, we hypothesize that our newly discovered variants are causative in PKD.

Methods: Chart review to identify patients with ADPKD-NMD Family pedigree genotype-phenotype correlation CRISPR/Cas9 gene knockout Lentiviral transduction Immunofluorescent confocal microscopy Co-immunoprecipitation/Western blot

Results: Chart analysis revealed 3 families with heterozygous alleles in IFT122 and WDR19, segregating with a clinical PKD phenotype across two generations. We further identified 3 additional IFT122 and 2 WDR35 alleles in singletons, coinciding with clinical PKD. In summary, we found a truncation in WDR19, 2 truncations in WDR35, a truncation and a large in-frame deletion in IFT122, and three missense variants in IFT122. After CRISPR/Cas9-knockout of the endogenous IFT122, WDR19 and WDR35, and lentiviral add-back transduction, none of the truncation or in-frame deletion alleles rescued the ciliogenesis defect in mIMCD-3 cells. Although the missense variants in IFT122 allowed for cilia formation, ciliary length was significantly reduced compared to the wildtype. We further show by co-immunoprecipitation and Western blot that the truncation mutations disrupt IFT-A subcomplex formation between IFT140, IFT122, WDR19 and WDR35. IFT122 missense variants exhibit a significantly reduced affinity to their native binding partner, WDR35.

Conclusions: We present the discovery of 3 novel ADPKD genes, IFT122, WDR19 and WDR35. Along with the recently identified ADPKD gene, IFT140, the novel genes represent components of the IFT-A complex that is essential for ciliary handling of PKD1 and PKD2.

SA-PO586

Characterization of IFT140 Phenotype in Patients with ADPKD Using Advanced Imaging Biomarkers

Ahmad Ghanem,[1] Fadi George Munairdjy Debeh,[1] Abdul Hamid Borghol,[1] Stefan N. Paul,[1] Bassel Alkhatib,[1] Nay Nader,[1] Adriana Gregory,[2] Hana Yang,[2] Christian Hanna,[2] Neera K. Dahl,[2] Timothy L. Kline,[2] Peter C. Harris,[2] Fouad T. Chebib.[1] *[1]Mayo Clinic in Florida, Jacksonville, FL; [2]Mayo Clinic Minnesota, Rochester, MN.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is commonly caused by pathogenic variants in *PKD1* and *PKD2* genes. This study aims to characterize the phenotype of ADPKD-*IFT140*, the third most common pathogenic variant associated with milder ADPKD, and compare it with the phenotypes of nontruncating-*PKD1* (*PKD1NT*) and *PKD2* pathogenic variants.

Methods: In this retrospective cohort study, ADPKD patients with pathogenic variants in *IFT140*, *PKD2*, or *PKD1NT*, and imaging prior to any event that may affect total kidney volume (TKV) were identified and matched by sex, age, and closest htTKV. Advanced imaging biomarkers were assessed using an automated cyst segmentation deep learning model as shown in **Figure**.

Results: Of the included ADPKD patients (27 each in *IFT140*, *PKD1NT*, *PKD2*), 48% were male with a mean (±SD) age at imaging of 57.7 (±13.3) years. Imaging biomarkers analyses across the 3 groups is shown in **Table**. Although no significant difference was observed in total cyst volume (TCV) between the 3 groups, ADPKD-*IFT140* patients were characterized by a smaller total number of cysts (median TCN: 42 in *IFT140* vs. 277 in *PKD2* vs 217 in *PKD1NT*, p<0.01) and larger average cyst volumes (median: 12.1 mL in *IFT140* vs. 2.2 in *PKD2* and 1.0 mL in *PKD1NT*, p<0.01). Furthermore, the cyst-parenchymal surface area was significantly smaller in the ADPKD-*IFT140* group (median: 182.3 cm^2 in *IFT140* vs. 1222.4 cm^2 in *PKD2* and 678.3 cm^2 in *PKD1NT*, p<0.01).

Conclusions: ADPKD-*IFT140* patients develop enlarged kidneys with fewer but significantly larger cysts compared to ADPKD-*PKD2* and ADPKD-*PKD1NT.*

Table

	IFT140	*PKD2*	*PKD1NT1*	p-value
Height-adjusted total kidney volume (htTKV) (mL/m), median (Q1-Q3)	424.8 (263.7 - 858.7)	915.8 (345.2 - 1402.1)	448.0 (312.5 - 1141.1)	0.13

SA-PO587

Characterization of GANAB Phenotype in Patients with ADPKD Using Advanced Imaging Biomarkers

Fadi George Munairdjy Debeh,[1] Vineetha Rangarajan,[1] Ahmad Ghanem,[1] Abdul Hamid Borghol,[1] Stefan N. Paul,[1] Bassel Alkhatib,[1] Nay Nader,[1] Adriana Gregory,[2] Hana Yang,[2] Christian Hanna,[2] Neera K. Dahl,[2] Timothy L. Kline,[2] Peter C. Harris,[2] Fouad T. Chebib.[1] Chebib's Clinical Team. *[1]Mayo Clinic in Florida, Jacksonville, FL; [2]Mayo Clinic Minnesota, Rochester, MN.*

Background: Autosomal dominant polycystic kidney disease (ADPKD), primarily caused by pathogenic variants in the *PKD1* and *PKD2* genes, is the most prevalent inherited kidney disorder leading to kidney failure. Rarely, other genes like *GANAB* can cause ADPKD with a lower risk of kidney failure. This study aims to characterize the renal and hepatic manifestations of ADPKD-*GANAB* and compare them with nontruncating-*PKD1 (PKD1NT)* and *PKD2* pathogenic variants.

Methods: In this retrospective cohort study, ADPKD patients with pathogenic variants in *GANAB*, *PKD2*, or *PKD1NT*, and imaging prior to any event that may affect total kidney volume (TKV) were identified and matched by sex, age, and closest htTKV. Advanced imaging biomarkers were assessed using an automated cyst segmentation deep learning model.

Results: Of the included ADPKD patients (14 each in *GANAB*, *PKD1NT*, *PKD2*), 78% were female with a mean (±SD) age at imaging of 56 ±11.5 years. Imaging biomarkers analyses across the 3 groups is shown in **Table**. Median total liver volume and percentage of patients with >100 liver cysts were similar between the 3 groups. However, ADPKD-*GANAB* patients had a significantly lower htTKV (median: 214.5 in *GANAB* vs. 324 in *PKD2* vs. 288.3 in *PKD1NT*, p=0.03), total cyst volume (TCV) (median: 4.1 in *GANAB* vs. 119 in *PKD2* vs. 69.2 in *PKD1NT*, p=0.02), and total cyst number (TCN) (median: 12.5 in *GANAB*, vs. 145 in *PKD2* vs 98 in *PKD1NT*, p<0.01).

Conclusions: Compared to ADPKD-*PKDNT1* and ADPKD-*PKD2*, ADPKD-*GANAB* patients have similar hepatic manifestations, but milder renal manifestations characterized by significantly smaller kidneys with a fewer number of cysts. These findings suggest that *GANAB* pathogenic variants lead to a liver-dominant phenotype with milder renal cystic burden.

Table

	GANAB	*PKD2*	*PKDNT1*	p-value
Height adjusted kidney volume (htTKV) (mL/m), median (Q1 – Q3)	214.5 (156.8 – 264.1)	324 (252.2 – 756.1)	288.3 (226.2 – 452.4)	0.03

The Co-chaperone DNAJB11 in Polycystic Kidney Disease: Molecular Mechanisms and Cellular Origin of Cyst Formation

Bjoern Neubauer, Tilman Busch, Lars Schmitt, Lukas Westermann, Alexis Hofherr, Michael Kottgen. *Department of Medicine IV - Nephrology and Primary Care, Faculty of Medicine and Medical Center, University of Freiburg, Freiburg, Germany*.

Background: Autosomal dominant polycystic kidney disease (ADPKD) arises due to mutations in the genes *PKD1* and *PKD2*, which encode the membrane proteins polycystin-1 (PC1) and polycystin-2 (PC2). PC1 and PC2 form a receptor-ion channel complex participating in the regulation of the renal tubular diameter. Loss of polycystin function results in cyst formation from epithelial cells of all nephron segments. Mutations in genes, which encode endoplasmic reticulum (ER)-resident proteins have been previously demonstrated to cause atypical forms of ADPKD. Here, we investigate the function of DNAJB11, an ER co-chaperone, in the development of ADPKD.

Methods: Murine models with constitutive and inducible *Dnajb11* inactivation as well as *Dnajb11*-deficient renal epithelial cells were generated to investigate the genetic mechanism underlying autosomal dominant inheritance, the specific cell types driving cyst formation, and molecular mechanisms that lead to DNAJB11-dependent polycystic kidney disease.

Results: Through the use of mouse models with constitutive and conditional *Dnajb11* inactivation, we show that homozygous loss of *Dnajb11* results in polycystic kidney disease, while heterozygous animals are healthy. This suggests that cyst formation is recessive at the cellular level. The formation of cysts begins *in utero* and the timing of *Dnajb11* inactivation significantly influences the severity of the phenotype. In contrast to classical ADPKD, cysts in *Dnajb11*-related kidney disease originate almost exclusively from proximal tubular cells. In addition, we identify impaired processing of Polycystin-1 as a molecular mechanism contributing to cystogenesis, but also find additional proteins that are dysregulated in *Dnajb11* deficient cells.

Conclusions: We show that biallelic loss of *Dnajb11* causes cystic kidney disease and fibrosis in mice, closely resembling human disease characteristics. These findings contribute to a better understanding of the pathogenic mechanisms of DNAJB11-related kidney disease. The observation that cysts already form in embryonic kidneys and emanate exclusively from proximal tubules has important implications since the knowledge of disease-specific time points and cell types is critical for the future development of therapeutic approaches.

New Mutation Associated with Polycystic Kidney Disease Type I: A Case Report

Vanya Rai,[1] Manisha Singh,[2] Joseph H. Holthoff.[2] *[1]Mayo Clinic Research Rochester, Rochester, MN; [2]University of Arkansas for Medical Sciences, Little Rock, AR*.

Introduction: Autosomal dominant polycystic kidney disease (ADPKD) is one of the most prevalent heritable disorders, characterized by the progressive development of kidney cysts leading to renal failure. The disease is primarily caused by mutations in the PKD1 and PKD2 genes, which account for approximately 85% and 15% of cases, respectively. The PKD1 gene, encoding polycystin-1, plays a crucial role in maintaining renal tubular structure and function. This case report describes a previously unreported mutation in the PKD1 gene, identified in a family involving an aunt and her niece, both diagnosed with ADPKD.

Case Description: The index case, a 56-year-old female with chronic kidney disease stage 3b secondary to ADPKD and hypertension, exhibited a strong family history of polycystic kidney disease (PKD). Initial genetic evaluations did not identify any recognized pathogenic mutations, leading to a more detailed genetic investigation, which revealed a novel in-frame deletion in the PKD1 gene, a mutation previously not known to be pathogenic. This mutation was also found in her niece, who presented with severe manifestations of the diease from an early age. The familial consistency of these presentations prompted the investigation into this genetic mutation's potential significance in disease phenotype and progression.

Discussion: The identification of a heterozygous six-nucleotide deletion, c.2084_2089del, resulting in the in-frame deletion of two amino acids, p.Pro695_Ala696del, in the PKD1 gene has significant implications for the clinical outcomes in both patients. The discovery of this novel PKD1 mutation highlights the necessity of considering novel genetic variants in patients with typical clinical presentations but without identifiable mutations in the common loci associated with ADPKD. It also emphasizes the need for continuous updates to genetic data and the benefits of comprehensive genetic screening in families with a history of the disease.

SA-PO590

Liddle Syndrome in a Family Presenting with Early-Onset Hypertension, Sudden Death, and Bilateral Kidney Cysts

Janewit Wongboonsin,[1,2] Nadine N. Channaoui,[5] Anna Verwillow,[1,3] Carolyn Ho,[1] Ana C. Onuchic-Whitford.[1,4] *[1]Brigham and Women's Hospital, Boston, MA; [2]Mahidol University Faculty of Medicine Siriraj Hospital, Bangkok, Thailand; [3]Massachusetts General Hospital, Boston, MA; [4]Boston Children's Hospital, Boston, MA; [5]Mass General Brigham Inc, Boston, MA*.

Introduction: Liddle syndrome is an autosomal dominant form of monogenic hypertension (HTN). Caused by gain-of-function variants in genes encoding subunits of ENaC, classical presentation includes early-onset HTN, hypokalemia and metabolic alkalosis. Here, we describe a family with early-onset HTN referred for history of sudden death and bilateral kidney cysts, found to have Liddle syndrome.

Case Description: A 40-year-old (yo) female with early-onset HTN presented for evaluation of kidney cysts. Diagnosed with HTN at 18 yo, imaging revealed small bilateral kidney cysts, attributed to polycystic kidney disease (PKD). She was treated with lisinopril, HCTZ and metoprolol, with normal serum potassium (mid-high 3s) and renal function. A prior cystic kidney genetic panel was negative. At our clinic, a broad kidney genetic panel was sent to further explore her cystic disease/HTN, revealing a heterozygous pathogenic variant in *SCNN1B* c.1853C>T (p.Pro618Leu) consistent with Liddle syndrome (LS). No variants were found in PKD-related genes. 24-hour urine study showed undetectable aldosterone and high potassium. A younger sister with early HTN had sudden death at 37yo, during a high-altitude trip after episodes of vomiting. Autopsy revealed cardiomegaly and hypertrophic cardiac remodeling due to HTN, with multiple small bilateral kidney cysts. Cardiomyopathy gene panel (not inclusive of *SCNN1B*) was negative, with insufficient DNA for further testing. Their 70 yo father had early HTN, stroke, hypokalemia, bilateral kidney cysts, and found to have the same *SCNN1B* variant. The patient and father were transitioned to amiloride with excellent control of HTN.

Discussion: LS is a tubulopathy typically characterized by hypokalemic HTN and metabolic alkalosis. Lack of this full triad may result in delayed diagnosis and HTN-associated end-organ damage. Although kidney cysts are not regarded as part of LS, here all affected family members had small bilateral cysts, independent of hypokalemia. Additionally, association of LS with sudden cardiac death was suspected due to hypertensive cardiomyopathy, potassium loss, and likely arrhythmia. Increased genetic testing in nephrology may contribute to phenotypic expansion of Mendelian diseases, enable earlier molecular diagnoses, and support inclusion of relevant genes in phenotype-driven panels.

SA-PO591

An Unusual Case of Cystic Kidney Disease in a Patient with CACNA1H Mutation and Hyperaldosteronism

Jerin Karingattil, Yinelka G. Silverio De Castro, Minesh Khatri.
NYU Langone Health, Mineola, NY.

Introduction: Studies have reported an elevated prevalence of renal cysts in patients with primary aldosteronism. A proposed mechanism is that chronic hypokalemia results in renal tubular cell injury and cyst expansion. We report a case of a patient with chronic kidney disease (CKD) who was found to have numerous bilateral renal cysts and a variant of uncertain significant (VUS) mutation in CACNA1H, associated with Familial Hyperaldosteronism Type IV. Our case highlights the role of hyperaldosteronism on the development of renal cysts. Especially unique here is the absence of hypokalemia, suggesting an alternative mechanism by which aldosterone influences renal cyst formation and growth.

Case Description: A 68-year-old female was evaluated in our clinic for hypertension and CKD. She has no family history of cystic kidney disease. Imaging revealed bilateral renal cysts mostly at the corticomedullary junction, suspicious for medullary cystic kidney disease (MCKD). She also had two stable pancreatic cysts concerning for autosomal dominant polycystic kidney disease (ADPKD) or Von Hippel-Lindau (VHL). Genetic testing was negative for mutations in MCKD1-2, PKD 1-2, VHL genes, but it detected a VUS mutation in CACNA1H. Lab data revealed an aldosterone level of 57.9 ng/dL, plasma renin activity of 0.6 ng/mL/hr, and aldosterone/renin ratio 96.5, suggesting primary aldosteronism. There was no hypokalemia or metabolic alkalosis. She was started on spironolactone to mitigate effects of hyperaldosteronism.

Discussion: While initial presentation of numerous renal cysts and CKD suggested ADPKD, MCKD or acquired cystic kidney disease, genetic testing eventually discovered a CACNA1H VUS mutation. This has been associated with Familial Hyperaldosteronism type IV and is the likely cause of the medullary renal cysts in this patient. While prior studies have postulated that chronic hypokalemia leads to cyst formation and growth, our patient's hyperaldosteronism was without hypokalemia. One should consider alternative mechanisms, such as aldosterone inducing signaling cascades that enhance cell multiplication and modify ion transport activities in renal cells. Along with broadening the differential for cystic kidney disease to include CACNA1H mutation, further research is needed to determine mechanistic pathways by which aldosterone influences cyst growth.

SA-PO592

Unmasking the Mimickers: HNF1B Variants in Pediatric Kidney Diseases

Jordy Salcedo-Giraldo, Krista R. Wink, Andrew Freiman, Louise C. Pyle, Ashima Gulati. *Children's National Hospital, Washington, DC.*

Introduction: Hepatocyte nuclear factor 1 beta (*HNF1B*) variants are associated with a spectrum of phenotypic manifestations including renal, pancreatic, and metabolic disorders. These variants can pose diagnostic dilemmas due to their diverse clinical presentations, often mimicking other congenital kidney conditions.

Case Description: A retrospective case series of 12 pediatric patients (age 4 months to 10 years) referred to our Renal Genetics Clinic with varied kidney phenotypic findings ultimately attributed to heterozygous disease-causing *HNF1B* variants. Each case exhibited unique clinical features, including cystic and non-cystic renal abnormalities, early-onset diabetes, and abnormal liver tests. Table 1 lists the clinical, laboratory, and kidney imaging findings at clinical presentation. Genetic investigation revealed two types of *HNF1B* defects: (i) whole gene deletion (67%); and (ii) truncating or missense variant predicted to be pathogenic (33%), which were *de novo* in all cases but one.

Discussion: Our findings highlight the importance of considering *HNF1B* variants in the differential diagnosis of pediatric patients presenting with structural kidney abnormalities with or without cystic kidney disease or specific multisystemic features. Despite disparate presentations, the genetic evaluation revealed a unifying etiology in all cases. Enhanced awareness of the protean nature of *HNF1B*-related disorders is valuable for accurate prognostication and optimization of multidisciplinary management strategies.

Table 1

Pt	Variant	Cystic	Non-Cystic	Abn LFT	DM	↓ Mg	↑ U	GD	FH

SA-PO593

COL4A1 Mutation: Hereditary Angiopathy with Nephropathy, Aneurysms, and Muscle Cramps (HANAC) Syndrome, an ADPKD Mimicker

Harshil Fichadiya,[1] Vraj Patel,[2] Andrew J. Bentall.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Canton Medical Education Foundation, Canton, OH.*

Introduction: Type 4 collagen(T4C) has 6 alpha subunits(A1-6) and is responsible for synthesis of most basement membranes. Alport syndrome involving defect in synthesis of A5 and rarely A3/A4 subnits is the most common known genetic syndrome resulting from faulty T4C synthesis. While A3,4,5 collagen network replaces A1,1,2 network during embryogenesis in the GBM, A1,1,2 network is the most common network in Bowmans space, tubular BM, rest of the body, including blood vessels HANAC syndrome (Heridetary Angiopathy, Nephropathy, Aneurysm and Muscle Cramps) has been described with AD inheritance in families with defective A1 subunit synthesis. Kidney disease is characterized by mild hematuria and renal cyst. Emmanuelle etal characterized phenotypes from 3 families having HANAC syndrome and reported glycine mutation in exon 24 and exon 25

Case Description: 74 year old female referred for evaluation of preemptive kidney transplant. She first presented with microhematuria and was first diagnosed with CKD at age 30. CKD progressed gradually over multiple years to stage 4 CKD in 2023. She has persistent microhematuria and proteinururia has gradually progressed to 1.5g/24hrs, reported strong family history of PKD in aunts, uncles and cousins. Multiple USG over the years revealed small kidneys with 2-3 partially regressing cyst bilaterally, largest cyst 3cm. Genetic analysis using next generation sequencing revealed mutation in COL4A1 gene. She described experiency occasional muscle cramps. MRA revealed 3 mm right and left ICA aneursyms She is listed for DDKT

Discussion: Since most ADPKD cases are diagnosed based on imaging criteria and positive family history when available, COL4A1 mutation can be easily confused for ADPKD when genetic testing is not performed. It is important to make this distinction as specific therapies available for ADPKD may not be as effective in patients with COL4A1 mutation. HANAC syndrome is a rare genetic syndrome characterized by cystic kidney disease aneurysm involving mutiple organ systems & retinal vessel (vs mainly CNS in ADPKD), cardiac, and muscular abnormalities causing cramping and occasionally hypotonia with developmental delay. Additionally digenic genotype with both COL4A1-PKD mutation have been identified with earlier progress to ESRD,50 years age. Our case presented with small kidneys, hematuria, 2-3 renal cyst and mild CNS aneurysms with ocassional cramping and slow progression

SA-PO594

Oral-Facial-Digital Syndrome Type 1: An Underestimated Differential Diagnosis of PKD in Women

Constantin A. Wolff,[1] Marie-Pierre Audrezet,[2] Emilie Cornec-Le Gall,[2] Jan Halbritter.[1] AG Halbritter, AG Cornec-Le Gall. *[1]Klinik m. S. Nephrologie und internistische Intensivmedizin, Charité - Universitätsmedizin, Berlin, Germany; [2]Service de Néphrologie, Centre Hospitalier Régional Universitaire de Brest and INSERM UMR1078, Brest, France.*

Background: OFD1 (oral-facial-digital syndrome type 1) is an X-linked inherited multi-systemic disorder with variable presentation. Although first identified in 2001, little is known about the true prevalence, natural course, and outcomes of *OFD1*-related kidney disease. With this case series, we aim to highlight *OFD1*-related kidney disease as an underestimated phenocopy of autosomal-dominant polycystic kidney disease (ADPKD) in women.

Methods: We performed a retrospective study of patients with a genetically confirmed *OFD1* diagnosis who presented to multiple centers in European renal clinics between 2006 and 2024. We collected demographic, clinical, laboratory, imaging, and histopathological data for statistical analysis.

Results: We identified 19 females from 15 families with *OFD1*-related kidney disease (mean age: 54y ± 4y). The median age at diagnosis was 38y ± 4y. Erroneously 11 patients were classified as typical ADPKD, and partially treated with tolvaptan (n=6). Genetically, all patients harbored monoallelic truncating variants N-terminal of the SDCCAG8-interaction domain (Fig.1). Phenotypically, all patients presented with majorly non-enlarged PKD. Estimated glomerular filtration rate varied widely and showed no overall trend even within families and age groups. Eight patients developed kidney failure (KF) at a mean age of 47.5 years. In addition to PKD, typical extra-renal features (e.g. frenulum, syndactyly, epilepsy, cleft lip and palate, intellectual disability) were observed in 11 patients (58%) to variable degrees.

Conclusions: Our study highlights the importance of considering OFD1 in the differential diagnosis of normal-sized PKD with or without further extra-renal abnormalities, particularly in young females. Early detection and timely initiation of general kidney protection measures may improve treatment outcomes and delay progression to KF. Further studies are required to evaluate specific treatment options for *OFD1*-related PKD, as the benefit of otherwise licensed tolvaptan has not been demonstrated.

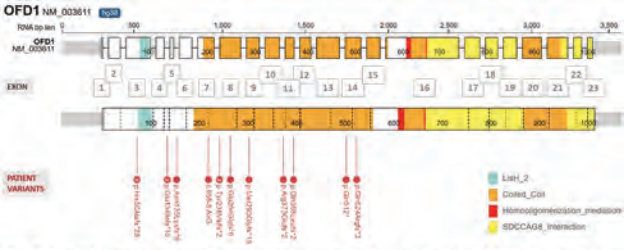

Fig. 1: A modified protein structure with protein length, patient variants and structure of OFD1 is shown in this figure. All patient variants are located in the Coiled-Coil domain, likely resulting in protein truncation of the SDCCAG8 domain. Image made with proteinpaint.stjude.org

Fig.1: A modified protein structure of OFD1 with patient variants.

SA-PO595

Cystic Phenotypes Associated with Monoallelic COL4A3/A4/A5 Pathogenic Variants Identified in a Population-Based Cohort

Gurparneet K. Sohi, Doaa E. Elbarougy, Hana Yang, Rachel S. Schauer, Shannon K. McDonnell, Jacob A. Frank, Jun Ma, Neera K. Dahl, Marie C. Hogan, Vicente E. Torres, Peter C. Harris. *Mayo Foundation for Medical Education and Research, Rochester, MN*.

Background: In Alport syndrome, mono/biallelic *COL4A3*/*COL4A4* or hemizygous *COL4A5* pathogenic variants cause glomerular disease, leading to hematuria, proteinuria and kidney failure. A milder, monoallelic (including *COL4A5*), glomerular phenotype can be evident, while kidney cyst development has also been described. We screened the Mayo Clinic Biobank (MCBB) patients (pts) cohort with available electronic medical records (EMR) and whole exome sequencing (WES) for *COL4A3/4/5* monoallelic individuals.

Methods: We screened 52,786 MCBB individuals for likely pathogenic (LP) variants and renal/hepatic cyst-related ICD codes in the *COL4A3/4/5* genes. Those with LP variants were evaluated using EMR and imaging to determine cystic phenotype penetrance.

Results: We identified 459 individuals with single LP variants: 232: *COL4A3*, 201: *COL4A4*; 26, *COL4A5*. Phenotypes included hematuria (microscopic/gross) (COL4A3: 62%, COL4A4: 65.6%, COL4A5: 61.5%), proteinuria (>150 mg/day) (COL4A3: 36%, COL4A4: 233%, COL4A5: 42.3%) and hypertension (COL4A3: 52%, COL4A4: 57.7%, COL4A5: 65.3%). Using 15 renal/hepatic cyst related ICD codes in pts with imaging (n=281) we identified 27 (9.6%) pts with cysts, 8.6%: *COL4A3*, 11%: *COL4A4*, and 6.2%: *COL4A5*; 0.7% coded for ADPKD. By image analysis, kidney cysts were present 56% of *COL4A3*, 45.2% of *COL4A4* and 30.7% of *COL4A5* (see Fig1); median eGFR was 74, 75 and 78 ml/min/1.73 m^2. Additionally, 2.5% *COL4A4* and 7.7% *COL4A5* monoallelic individuals had FSGS.

Conclusions: Monoallelic LP variants in *COL4A3/A4/A5* often have glomerular phenotypes and cyst development seen in 30-50% of cases, although multiple cysts are rarer. Therefore, genetic screening panels for PKD pts should encompass *COL4A3/A4/A5*.

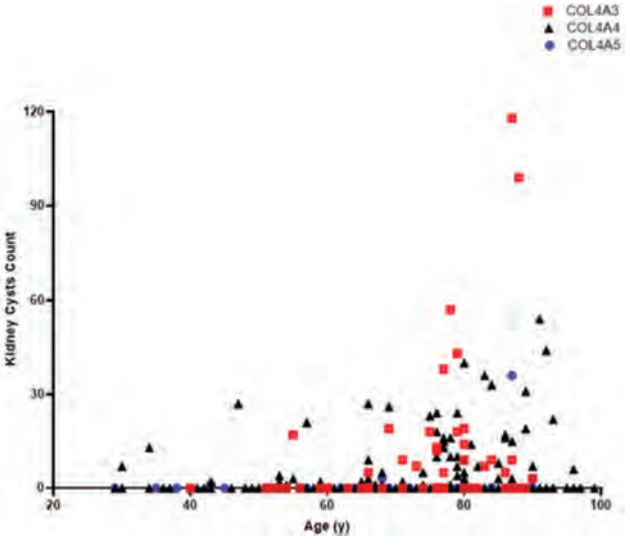

Fig1: Kidney Cysts by age in COL4A3/A4/A5 mutation individuals

SA-PO596

Genetics behind the Phenotypic Spectrum of Polycystic Kidney Disease

Raquel Martínez Pulleiro,[1,2] Ana Barcia de la Iglesia,[1] Catarina A. Toscano,[2] Noa C. Carrera Cachaza,[1] Miguel A. Garcia-Gonzalez.[1] [1]*Instituto de Investigacion Sanitaria de Santiago de Compostela, Santiago de Compostela, Spain;* [2]*Universidade de Santiago de Compostela, Santiago de Compostela, Spain*.

Background: Polycystic kidney disease (PKD) is an inherited disorder with a broad range of clinical presentations. The most common form is autosomal dominant PKD (ADPKD), caused by mutations in *PKD1* or *PKD2* genes. ADPKD typically manifests in adulthood, leading to bilateral kidney cysts, kidney enlargement, and end-stage chronic kidney disease (ESKD). Autosomal recessive PKD (ARPKD), caused by *PKHD1* gene mutations, is more severe and usually appears in childhood or adolescence. Atypical presentations exist, characterized by variations in family history, renal imaging patterns, and phenotypic variability. Here, we want to analyse the genetics behind the cases in our cohort of atypical PKD.

Methods: A retrospective cohort study was performed. Inclusion criteria were 1) having a request for genetic analysis specifying the condition of atypical polycystic disease or mentioning the presence of multiple cysts among its clinical manifestations, 2) having a pathogenic variant in one of the less common cystic genes after genetic analysis, regardless of clinical suspicion.

Results: In our preliminary cohort of 142 patients, 60.68% have received a genetic diagnosis. In 36.75% of cases, no mutation was detected (NMD), and 2.56% remain inconclusive pending further testing. Preliminary data suggest that 14.53% of atypical polycystic disease cases result from *PKHD1* gene mutations. *COL4A3* and *COL4A4* mutations account for 15.38% of cases, presenting with bilateral renal cysts and microhematuria. The next gene that explains more atypical cases is *HNF1B*, which shows great phenotypic heterogeneity. Other mutated genes in our cohort include *ALG8*, *GANAB*, *IFT140*, *DNAJB11*, *PKD1*, *SEC63*, and *TSC1*.

Conclusions: Our preliminary atypical PKD cohort has a mutation detection rate of 60,68% The gene responsible for 14% of cases is *PKHD1* in heterozygosity *COL4A3* and *COL4A4* are responsible for approx. 14% of cases. In general, the inheritance pattern is dominant When analyzing genetic results in an atypical PKD case, it's crucial to consider multiple polycystic disease-associated genes. Additionally, we shouldn't overlook different modes of inheritance and the variable impact of genetic variants.

Prevalence and Severity of Polycystic Liver Disease (PLD) in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Taher Dehkharghanian,[1] Mauricio A. Miranda Cam,[1] Sol M. Carriazo Julio,[1] Xuewen Song,[1,2] Yasmina Sarie,[2,1] Saima Khowaja,[1] Timothy L. Kline,[3] York Pei.[1,2] [1]*University Health Network, Toronto, ON, Canada;* [2]*University of Toronto, Toronto, ON, Canada;* [3]*Mayo Clinic Minnesota, Rochester, MN*.

Background: Liver cysts are common in patients with ADPKD, but the prevalence of clinically significant PLD has not been well defined. Here we report the prevalence, severity and clinical characteristics of PLD from the Toronto Genetic Epidemiology Study of PKD (TGESP), a large prospective cohort study of patients with ADPKD from the Greater Toronto Area.

Methods: All study patients underwent a research protocol with detailed clinical, laboratory (including genetic testing) and abdominal MRI between 2013-2023. An automate liver segmentation model was applied on coronal T2 MRI to calculate TLV and HtTLV. We analyzed baseline clinical characteristics and liver volume measurements of 617 study patients who were found to have a PKD1 protein-truncating (PT), PKD1 (inframe insertion/deletion), PKD1 non-truncating (NT), or PKD2 mutation. Patients were divided into quartiles based on their HtTLV and clinical characteristics, shown in Table 1.

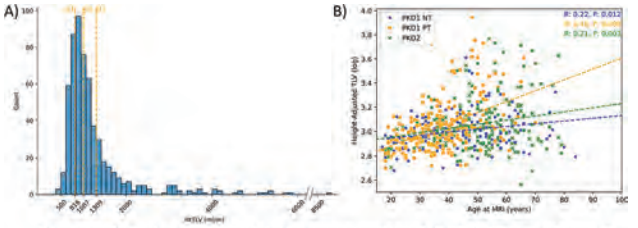
Results: The mean ± sd of TLV and HtTLV of the study cohort were 2163 ± 1466 ml and 1251 ± 856 ml/m; 57% were female. In total, 25% of patients had high HtTLV ranging between 1309 to 8810 ml/m (Figure 1A). The average HtTLV was larger in patients with PKD1 PT mutations in all age groups. However, the difference was only significant between PKD1 NT and PKD1 PT of age 50-59 years (p value: 0.02). Statistically significant positive correlations between HtTLV and TLV were seen among the three mutation classes (Figure 1B).

Conclusions: Up to 25% of patients with ADPKD have moderate to severe PLD (i.e. 2.5 to 10x normal LV). TLV and volume growth rate appeared to be higher in PKD1 PT patients. Multivariate analysis including age, sex, body mass index will be performed to delineate the effects of mutation class on PLD severity.

Funding: Government Support - Non-U.S.

	Q1 (< 817 ml/m)	Q2 (818-1007 ml/m)	Q3 (1008-1308 ml/m)	Q4 (1309 ml/m <)	Overall
Age	39 (± 16)	42 (± 13)	43 (± 12)	50 (± 12)	44 (± 14)
Sex	63% F	51% F	43% F	67% F	57% F
Weight (kg)	67 (± 13)	74 (± 13)	83 (± 16)	81 (± 22)	76 (± 18)
BMI	24 (± 4)	25 (± 4)	28 (± 5)	28 (± 6)	26 (± 5)
PKD1 NT (134)	30%	27%	22%	21%	
PKD1 PT (274)	28%	25%	24%	24%	
PKD2 (209)	29%	25%	23%	23%	

Clinical characteristics of the patients divided into 4 groups based on their HtTLV quartiles.



A) Distribution of HtTLV of our cohort. Orange dashed lines represent quartile cut-offs. B) HtTLV in logarithmic scale versus age shows a positive correlation for all 3 mutation classes, with *PKD1* PT having a higher growth rate.

SA-PO598

Patients with Polycystic Kidney Diseases with Normal Kidney Function Report Poor Sleep Quality

Erin C. Hanlon, Stephanie N. Sintetas, Elizabeth Salvo, Qiyi Ding, Arlene B. Chapman. *University of Chicago Division of the Biological Sciences, Chicago, IL.*

Background: In general, kidney disease has been reported to be associated with poor sleep quality, sleep disturbances, and sleep disorders including obstructive sleep apnea (OSA). While these abnormalities have been reported in CKD population, little is known about sleep characteristics in patients with autosomal dominant polycystic kidney disease (ADPKD), the most common monogenic kidney disorder worldwide. It is possible that aspects unique to ADPKD (increased kidney and liver volumes) may contribute to altered respiratory mechanics that can contribute to sleep abnormalities. These increases in organ volume occur in the setting of normal kidney function. Thus, in this pilot, we examined self-reported sleep characteristics in ADPKD patients with normal kidney function (eGFR > 90 mL/min) compared to a group of BMI, age, and sex matched healthy controls.

Methods: ADPKD and matched controls were asked to fill out gold-standard questionnaires that assess aspects of sleep quality (Pittsburgh Sleep Quality Index - PSQI) and risk for the sleep disorder OSA (Stop-Bang). Chronotype was also assessed with the Owl/Lark Questionnaire in all individuals.

Results: Seven individuals with PKD (4 women, 3 men) with a mean age of 34 years (± 9.5) and body mass index (BMI) of 30.9 kg/m^2 (± 9) were compared to seven matched controls (4 women, 3 men) with a mean age of 32 years (± 8) and a BMI of 34 kg/m^2 (± 10). Both groups reported to be morning types with similar scores on the Owl/Lark Questionnaire (PKD: 55.3 ± 11.3 vs Control: 57.5 ± 13.9) and were both at low to intermediate risk for OSA according to the STOP-Bang questionnaire (ADPKD: 1.9 ± 1.1 vs Control: 1.5 ± 0.8). Six ADPKD individuals completed the PSQI, and interestingly, when compared to their six matched controls, ADPKD subjects had significantly higher PSQI ratings than controls (ADPKD: 5.3 ± 1.8 vs Control: 3.7 ± 0.8, p = 0.019) indicating that they had poorer sleep quality.

Conclusions: These data suggest that ADPKD individuals may experience poor sleep quality when compared to healthy matched controls, that is not a product of diminished kidney function. The contributions to reduction in sleep quality in ADPKD may be multifactorial including increased abdominal girth due to liver and kidney cyst burden, chronic pain and/or the psychological impact of having a hereditary kidney disorder.

SA-PO599

Monoallelic PKHD1 Loss-of-Function Variants Could Be a Cause of Adult Polycystic Kidney Disease

Takuya Fujimaru,[1,2] Takayasu Mori,[1] Akinari Sekine,[3] Motoko Chiga,[4] Shintaro Mandai,[1] Hiroaki Kikuchi,[1] Yutaro Mori,[1] Yu Hara,[1] Tamami Fujiki,[1] Fumiaki Ando,[1] Koichiro Susa,[1] Soichiro Iimori,[1] Shotaro Naito,[1] Tatsuya Suwabe,[3] Yoshifumi Ubara,[3] Shinichi Uchida,[1] Eisei Sohara.[1] *[1]Tokyo Ika Shika Daigaku Daigakin Ishigaku Sogo Kenkyuka, Bunkyo-ku, Japan; [2]Sei Roka Kokusai Byoin, Chuo-ku, Japan; [3]Toranomon Byoin, Minato-ku, Japan; [4]Tokyo Ika Shika Daigaku Byoin, Bunkyo-ku, Japan.*

Background: *PKHD1* is known as a causative gene of autosomal recessive polycystic kidney disease (ARPKD). Recently, it has been suggested that heterozygous *PKHD1* variants may cause autosomal dominant polycystic kidney disease (ADPKD). However, there are few reports that have investigated the clinical characteristics and genetic background of such patients. We investigated the presence of *PKHD1* pathogenic variants in patients with adult polycystic kidney disease.

Methods: We performed a comprehensive genetic analysis in 236 adult polycystic kidney families using either the cystic kidney disease-associated gene panel or the chronic kidney disease-associated gene panel.

Results: In our cohort, 166 patients (70.3%) did not have polycystic kidneys in their parents. Through this analysis, 92 patients (39%) had pathogenic variants in *PKD1* or *PKD2* genes. Additionally, 17 patients (7.2%) had pathogenic variants in other genes (*IFT140*, n = 7; *HNF1B*, n = 3; homozygous *PKHD1*, n = 2; *COL4A3*, n = 1; *MUC1*, n = 1; *NPHP4*, n = 1; *OFD1*, n = 1; *PRKCSH*, n = 1). In 6 of 127 patients (4.7%) who did not have any apparent pathogenic variant in known causative genes, heterozygous loss-of-function (LOF) variants of *PKHD1* were detected (nonsense, n = 4; frameshift, n = 1; splicing, n = 1). In the patients with heterozygous LOF variants in *PKHD1*, age at the time of genetic analysis ranged from 35 to 64 years, and total kidney volumes ranged from 135 to 1193 ml. Two patients had end-stage renal disease, and the remaining four had eGFR ranging from 11 to 61 ml/min/1.73m^2. Furthermore, two of the six patients had heterozygous truncated variants of other autosomal recessive cystic kidney disease related genes.

Conclusions: It has been suggested that heterozygous LOF variants of *PKHD1* may acquire pathological phenotypes due to the coexistence of modifiers such as modifier genes.

Sex Differences and Aging Influence the Association between Kidney Prognosis and Intracranial Aneurysms in Patients with ADPKD: Attribute-Based Medicine (ABM) Insights

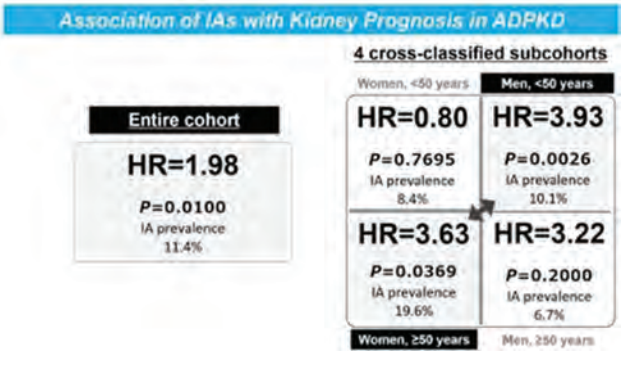
Yusuke Ushio, Hiroshi Kataoka, Toshio Mochizuki, Shun Manabe, Momoko Seki, Shiho Makabe, Ken Tsuchiya, Kosaku Nitta, Junichi Hoshino. *Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan.*

Background: There is a recognized tendency for intracranial aneurysms (IAs) to occur more frequently in elderly women. We aimed to elucidate the association of IAs on kidney disease progression in ADPKD patients, taking into account age and sex as pivotal factors.

Methods: Our study included 494 patients with ADPKD. Renal outcome, defined as a 50% reduction in estimated glomerular filtration rate or initiation of renal replacement therapy, was evaluated using Cox regression analysis and Kaplan-Meier analysis.

Results: Multivariable Cox analyses indicated that IAs were significantly associated with kidney disease progression across the entire cohort (hazard ratio [HR]=1.93). Sub-group analyses showed significant associations between IAs and kidney disease progression in men with <50 years (HR=3.93) and in women ≥50 years (HR=3.63). Kaplan–Meier analysis demonstrated that kidney survival rates were significantly lower in patients with IAs compared to those without, across all cohorts. The 5-year renal survival rate of ADPKD patients with IAs was 51.2% for the entire cohort, 73.5% for women <50 years, 46.2% for men <50 years, 39.9% for women ≥50 years, and 37.5% for men ≥50 years, indicating a extremely poor renal prognosis.

Conclusions: IAs were associated with a poor renal prognosis in patients with ADPKD, especially in men <50 years and women ≥50 years. Susceptibility to IAs in ADPKD patients varies by age and sex. Younger patients are primarily affected by genetic mutations, while older patients, particularly elderly women, may be influenced by a combination of genetic mutations and lifestyle factors, potentially impacting their kidney prognosis.



SA-PO601

Sex- and Age-Related Variations in Intracranial Aneurysms among Patients with ADPKD: Significance of Middle Cerebral Artery Aneurysms in Elderly Women

Yusuke Ushio, Hiroshi Kataoka, Toshio Mochizuki, Shun Manabe, Momoko Seki, Ken Tsuchiya, Kosaku Nitta, Junichi Hoshino. *Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan.*

Background: The effects of sex differences on intracranial aneurysms (IAs) in patients with autosomal dominant polycystic kidney disease (ADPKD) are not fully elucidated.

Methods: We enrolled 519 patients with ADPKD. Logistic regression analyses using sex, age ≥50 years, hypertension, family history of IA or subarachnoid hemorrhage (IA/SAH), and chronic kidney disease (CKD) stages 4–5 or height-adjusted total kidney volume (htTKV) were conducted to identify factors related to IAs.

Results: Sex disparities in intracranial aneurysms (IAs) were evident among ADPKD patients. Women showed a higher prevalence of anterior circulation IAs compared to men (62.7% vs. 44.8%; P=0.0403), with women also experiencing SAH at an older age than men (46 years vs. 37.5 years; P=0.0490). In the entire cohort, female sex was significantly linked with IA (OR=1.78). Stratified by sex, CKD stages 4–5 (OR=4.21), family history of IA/SAH (OR=3.11), and hypertension (OR=2.22) were significantly associated with IA in females, while in males, only family history of IA/SAH (OR=2.35) and CKD stages 4–5 (OR=2.21) were risk factors for IA. Interestingly, when classified by sex and age (≥50 years), gender disparities in IAs were pronounced among patients aged ≥50 years. Anterior circulation IAs (OR=4.58: 71.4% in women vs. 35.3% in men; P=0.0173), particularly middle cerebral artery IAs (OR=10.88: 40.5% in women vs. 5.9% in men; P=0.0113), were more prevalent in women aged ≥50 years compared to men. Moreover, women aged ≥50 years had a significantly higher prevalence of hypertension (OR=4.11), CKD4–5 (OR=10.60), IAs (OR=3.06), and middle cerebral artery IAs (OR=5.93) compared to those <50 years. Additionally, women over 50 years exhibited an increased incidence of middle cerebral artery aneurysms, with multivariate logistic analysis associating these aneurysms with female gender and hypertension.

Conclusions: IAs in patients with ADPKD were affected by attributes (age and sex). Sex and age-specific medical treatment might be desirable, especially, women should pay attention to the incidence of middle aortic aneurysm and its risk factors, which increase with age.

SA-PO602

Progressive Intrarenal Microvascular Damage Presents Early On and Is Preceded by Vascular Molecular Changes in ADPKD

Santu K. Singha,[1] Ahmed Abdelfattah,[1] Christian Hanna,[1] Marie C. Hogan,[1] Alejandro R. Chade,[2] Alfonso Eirin,[1] Maria V. Irazabal.[1] *[1]Mayo Clinic, Rochester, MN; [2]University of Missouri, Columbia, MO.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) progression has been mainly attributed to the continuous development and expansion of kidney cysts, but the role of the intrarenal microvasculature and the mechanisms leading to vascular damage are still unclear. We hypothesized that intrarenal microvascular structural abnormalities are present from early stages and preceded by vascular molecular changes.

Methods: ADPKD (*Pkd1*$^{RC/RC}$) and WT mice (n=16 each, 8M/8F) were studied at 1, 6, and 12 months (mo). Disease severity and progression were evaluated by kidney weight/body weight (KW/BW), body-length adjusted total kidney volume by MRI (blTKV), cystic area (CA), fibrotic area (FA), and BUN, and intrarenal microvasculature architecture by 3D (micro-CT), capillary density (H&E), and perivascular fibrosis (Trichrome). In randomly selected *Pkd1*$^{RC/RC}$ and WT kidneys (n=5, each per time point, 30 animals), mRNA-sequencing (seq) was performed to identify vasculature-related differentially expressed genes (DEGs). Transcription Factors (TFs) of the DEGs were predicted and ranked, and their gene expression examined.

Results: KW/BW, blTKV, and CA were higher in *Pkd1*$^{RC/RC}$ from 1mo, but FA and BUN were similar until 12mo. Spatial density of cortical and medullary microvessels was preserved at 1mo but progressively decreased at 6 and 12mo **(Figure)**, associated with vessel tortuosity (vascular immaturity), capillary loss, and perivascular fibrosis. A total of 110, 48, and 201 vasculature-related genes were DE at 1, 6, and 12mo, respectively. Interactions among the Top 50 TFs involved in regulating DE vasculature-related genes in *Pkd1*$^{RC/RC}$ increased from 1 to 12mo, and the expression of 18 Top TFs followed the same pattern as their targeted genes.

Conclusions: In ADPKD, intrarenal microvasculature abnormalities are present early on and may constitute a synergistic therapeutic target. Early vascular molecular signatures may serve as biomarkers for disease progression.

SA-PO603

Intracranial Aneurysms Are Detected in 11.2% of Polycystic Patients Undergoing Kidney Transplant Assessment, Particularly in Tall and Hypertensive Patients

Tana Berisha, Laurence Seidel, Vinciane Dideberg, Laurent E. Weekers, Francois Jouret. ULiege Transplant Group. *Universite de Liege, Liege, Belgium.*

Background: The risk of developing an intracranial aneurysm (ICA) is quadrupled in autosomal dominant polycystic kidney disease (ADPKD) compared with the general population, with a prevalence of ~13%. Some risk factors have been suggested in the ADPKD population, such as family history of ICA, *PKD1* genotype, smoking, hypertension and female gender. A systematic screening for ICA during the pre-transplant work-up enabled us to study (i) the prevalence and (ii) the risk factors for ICA in ADPKD patients with end-stage renal disease (ESRD).

Methods: The presence of an ICA was systematically sought in all ADPKD patients undergoing a pre-transplant work-up between 01/2002 and 12/2023 in our center. The clinical, genetic and radiological parameters, as well as comorbidities, were statistically compared between the 2 groups of patients with *versus* without ICA, with an uncertainty level of 5%.

Results: Our cohort included 169 patients, 81 of whom were women (47.9%). The median age at first dialysis and at transplantation was 52.4 [46.7; 62.7] and 54.8 [49.1; 64.1] years respectively. There were 27 pre-emptive transplants, and 30 patients still on the waiting list. Median body mass index was 25.9 [23.1; 29.2] kg/m^2. Hypertension and/or diabetes were diagnosed in 167 (98.8%) and 57 (33.7%) patients, respectively. The median age at diagnosis of hypertension was 41.4 [31.3; 50.4] years. Left ventricular hypertrophy was detected in 75 patients (46%). Smoking was found in 98 (58%) patients. A family history of ICA was reported in 35 patients (23%). Molecular confirmation of PRAD was carried out in 57 patients, 43 of whom had a *PKD1* variant, 8 *PKD2* and 6 others. In this cohort of 169 transplant candidates with ADPKD, the prevalence of ICA reached 11.2%. These 19 patients with ICA were significantly taller than ICA-negative patients: 176 ± 9 *vs* 170 ± 9 cm, p=0.015. Blood pressure levels were significantly higher in ICA-positive patients (systolic: 152 ± 15 *vs* 136 ± 18 mmHg, p=0.0002; diastolic: 86 ± 11 *vs* 81 ± 12 mmHg, p=0.11).

Conclusions: ICA is a frequent complication of ADPKD, which is associated with higher height and systolic hypertension. The other above-mentioned risk factors were not statistically confirmed in our retrospective monocentric cohort including ESRD patients.

SA-PO604

Genetic Mutation Type and Cerebral Aneurysm Screening in Patients with ADPKD

Noella Ahn,[1] Evgenia Preka,[3] Joshua K. Mulligan,[2] Daniel P. Gale.[2,1] *[1]Royal Free London NHS Foundation Trust, London, United Kingdom; [2]University College London, London, United Kingdom; [3]Paris Centre de Recherche Cardiovasculaire, Paris, France.*

Background: Subarachnoid haemorrhage (SAH) is a devastating complication of Autosomal Dominant Polycystic Kidney Disease (ADPKD) due to increased rate of intracranial aneurysm (IA) formation in this population compared to the general population. The cause of IA formation is thought to be due to *PKD1* and *PKD2* gene mutation however, genetic risk factors or a geneotype-phenotype relationships are unclear unlike the correlation seen in renal manifestations of ADPKD. We report outcomes of our targeted screening of patients with personal or positive family history of IA or SAH with a five-yearly scans at a single large tertiary centre, alongside their genetic variants, to identify genetic risk factors or the presence of genotype-phenotype relationships in IA formation.

Methods: A retrospective review of 701 ADPKD patients in Royal Free Hospital between January 2012 to October 2022. Their medical records were reviewed for the development of IA, SAH, adherence to screening policy and their genetic tests.

Results: Of the 701 patients, 127 (18.1%) underwent screening as per the local guideline. 12 (1.7%) were eligible for screening but had not been screened. Within those screened, 21 (16.5%) had IA with zero SAH in this group. Of those unscreened, 8 (1.4%) had IA and 17 (3.0%) had SAH. Of the 701, 499 (71.2%) had genetic tests with clinically diagnostic variants in *PKD1* in 260 (52.1%) with 169 truncating mutations, *PKD2* in 102 (20.4%) with 78 truncating mutations, other genes in 78 (15.6%) and no reportable findings in 59 (11.8%). In 46 patients with IA or SAH, 33 (71.7%) had genetic tests of whom 21 (63.6%) had *PKD1* which 13 were truncating, 6 (18.2%) had *PKD2* which 4 were truncating, 6 (18.2%) had no genetic variants reported. These figures did not differ significantly from the overall patient cohort. 11 (8.6%) of the 127 screened patients received intervention for their aneurysms.

Conclusions: Cerebral aneurysm screening is a key part of ADPKD management. Amongst the screened group, no SAH were observed, although this did not differ significantly from the event rate of the unscreened group. The lack of evidence of increased risk of IA or SAH in those with truncating *PKD1* mutations suggest that the mechanism mediating this manifestation of ADPKD differs from the somatic loss of the normal allele that is thought to be important in kidney cyst formation and hence renal failure in ADPKD.

SA-PO605

Ryanodine Receptor 3 (RYR3) as a Candidate Modifier of Aneurysm Formation in ADPKD

Kasturi Roy,[1] Ashima Gulati,[3] Jianlei Gu,[1] Melissa M. Shaw,[1] Zhaoxia Sun,[1] Whitney Besse,[1] Terry J. Watnick,[2] Stefan Somlo.[1] *[1]Yale University School of Medicine, New Haven, CT; [2]University of Maryland, College Park, MD; [3]Children's National Hospital, Washington, DC.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the primary inherited cause of kidney failure, caused by mutations in *PKD1* or *PKD2*. Among its extrarenal manifestations, intracranial aneurysms (ICA) pose a significant mortality risk, with a prevalence approximately five times higher than the general population, and further elevated when a family member has ADPKD and ICA. We hypothesize that the development of ICA in ADPKD involves one or more genetic modifiers in addition to the germline PKD mutation.

Methods: To investigate this hypothesis, we established a cohort comprising individuals with ADPKD and ICA, alongside controls. Whole exome sequencing (WES) was performed to identify germline PKD mutations and to assess for enrichment of genes or pathways with rare genetic variants in those with ADPKD and ICA vs. control cases. To investigate candidate targets, a zebrafish model with *pkd2* mutation (*pkd2*^{hi4166Tg}) was employed. Candidate modifiers were inactivated using CRISPR/Cas9 system and scored for intracranial hemorrhage (IH) without knowledge of genotype.

Results: We identified *RYR3* as having increased occurrence of rare predicted deleterious missense variants in ICA-ADPKD cases compared to ADPKD controls without known ICA (p=2.75e-8; OR=11.6). Given this enrichment of *RYR3* variants within the cohort, we proceeded with a secondary validation screen in zebrafish models. *ryr3* was inactivated by CRISPR/Cas9 in heterozygous *pkd2*^{hi4166Tg} fish and both acute and germline transmission of *ryr3* knockout (*ryr3*$^{-/-}$) were examined. Acute *ryr3*$^{-/-}$ resulted in a 2-fold increase in brain bleeds while germline *ryr3*$^{-/-}$resulted ~4-fold increase in brain bleeds in heterozygous *pkd2*^{hi4166Tg} fish compared to respective *ryr3*$^{+/+}$ controls observed at 56 hpf. Imaris analysis showed a 0.6-fold reduction in vascular branching in *ryr3*$^{-/-}$; *pkd2*$^{hi4166Tg/+}$ fish compared to *ryr3*$^{+/+}$; *pkd2*$^{hi4166Tg/+}$ fish.

Conclusions: *RYR3* is a potential modifier of vascular integrity in the context of ADPKD mutations. Further replication and validation studies are warranted.

SA-PO606

Genetic and Clinical Characterization of Patients with ADPKD and Intracranial Aneurysms: The PKD-VASC Cohort

Puja Patel,[1] Whitney Besse,[2] Ashima Gulati,[11] Melissa M. Shaw,[2] Jon D. Blumenfeld,[3] York Pei,[7] Berenice Y. Gitomer,[4] Ronald D. Perrone,[5] Yasar Caliskan,[6] Hayne C. Park,[12] Alan S. Yu,[8] Neera K. Dahl,[9] Frederic F. Rahbari-Oskoui,[10] Stefan Somlo,[2] Terry J. Watnick.[1] *[1]University of Maryland Baltimore, Baltimore, MD; [2]Yale University School of Medicine, New Haven, CT; [3]Rogosin Institute, New York, NY; [4]University of Colorado Anschutz Medical Campus, Aurora, CO; [5]Tufts Medical Center, Boston, MA; [6]Saint Louis University School of Medicine, St Louis, MO; [7]University Health Network, Toronto, ON, Canada; [8]The University of Kansas Medical Center, Kansas City, KS; [9]Mayo Clinic Minnesota, Rochester, MN; [10]Emory University School of Medicine, Atlanta, GA; [11]Children's National Research & Innovation Campus, Washington, DC; [12]Hallym University Kangnam Sacred Heart Hospital, Yeongdeungpo-gu, Seoul, Republic of Korea.*

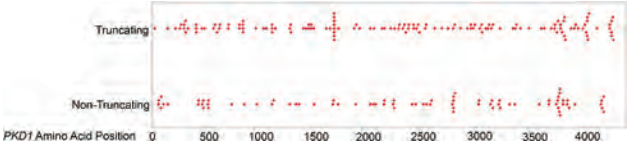
Background: ADPKD is associated with a ~4-5-fold increase in the prevalence of intracranial aneurysm (ICA) compared with the general population. This risk is intensified ~4-fold in ADPKD families with a history of ICA suggesting an inherited predisposition.

Methods: To investigate the genetic underpinnings of ICA in ADPKD, we assembled an international cohort of individuals with ADPKD and ICA: the PKD-Vasc cohort. We collected clinical data and DNA for whole exome sequencing (WES) from 289 self-referred participants or colleague-referred de-identified cases with both ADPKD and ICA.

Results: The PKD-Vasc cohort is ~70% female and 46% had either a ruptured ICA or required neurosurgical intervention. The remaining 54% had an unruptured ICA of at least 2mm and 22.5% had more than one ICA. Most participants (85%) had a family history of ADPKD and 38% had a family history of ADPKD with ICA. Of note 19% had a history of ICA in a family member without a diagnosis of ADPKD. Most participants (89%) were hypertensive, most had never smoked cigarettes, and a minority (18%) had ESKD at the time of their ICA diagnosis. As has been reported, most unruptured ICA were small (<5mm) and located in the middle cerebral, internal carotid, and anterior communicating arteries. WES identified a *PKD1* mutation in 220/289 (76%), a *PKD2* mutation in 38/289 (13%) and there was no causative mutation detected in 11%. A small number of cases had disease caused by minor ADPKD genes. These cases were excluded from primary analysis. Among participants with truncating *PKD1* variants, 55% had a ruptured ICA or an ICA requiring intervention. We looked at the distribution of truncating and non-truncating *PKD1* mutations and we found that variants were scattered along the gene with no obvious genotype/phenotype correlation.

Conclusions: Genetic modifiers in the setting of *PKD1/PKD2* may influence the risk of ICA. The PKD-Vasc cohort will be a valuable tool for investigating this question.

Funding: Other U.S. Government Support



Distribution of PKD1 mutations plotted against their amino acid location within the PKD1 protein.

Unraveling Rarity: Atypical Presentation of Polycystic Kidney Disease

Jessica E. Lowe,[1] Angelina Edwards.[1,2] *[1]Houston Methodist Hospital, Houston, TX; [2]Division of Kidney Disease, Hypertension and Transplantation. Houston Methodist Hospital, Houston, TX.*

Introduction: Autosomal dominant polycystic kidney disease (ADPKD) is a genetic disorder commonly associated with mutations in *PDK1* and *PDK2* and presents with enlarged kidneys seen on imaging due to cyst formation, typically classified by the Mayo Clinic Imaging Classification. However, genetic testing increasingly identifies other pathogenic variants leading to a spectrum of ADPKD. We present a case of an individual with poorly controlled hypertension and bilateral renal cysts whose imaging was not concordant with ADPKD but ultimately was positive based on genetic testing.

Case Description: A 73-year-old Caucasian woman with history of resistant hypertension presented for evaluation of elevated serum creatinine. One year prior, a CT scan performed for evaluation of abdominal pain showed incidental bilateral renal cysts. She was referred to Urology for further evaluation and underwent drainage of an 8 cm right renal cyst, without significant improvement in blood pressure control or abdominal pain. She then presented to nephrology clinic for referral for elevated creatinine and concern for chronic kidney disease. Laboratory testing revealed creatinine 1.51 mg/dL, blood urea nitrogen 31 mg/dL, and no proteinuria. Given the atypical cysts, genetic testing was pursued. Results confirmed pathogenic variant in the *IFT140* gene, a rare cause of atypical ADPKD.

Discussion: Biallelic mutations in *IFT140* are known to cause Mainzer-Saldino syndrome, a severe ciliopathy that causes skeletal and kidney abnormalities including cysts. However, monoallelic *IFT140* loss of function variants have been emerging as a cause of atypical ADPKD beyond *PKD1*/*PKD2*, associated with large renal cysts, mild renal insufficiency, few liver cysts, and unknown extra-renal manifestations. This case highlights the critical role of genetic testing, particularly when imaging is equivocal, and may help with in widening the group of atypcial ADPKD-spectrum disorders.

SA-PO608

Cerebral Aneurysm in an Adult with Autosomal Recessive Polycystic Kidney Disease (ARPKD)

Songul Onder, Terry J. Watnick. *University of Maryland School of Medicine, Baltimore, MD.*

Introduction: Intracranial aneurysms (ICA) are seen in 8-12 % of patients with autosomal dominant polycystic kidney disease (ADPKD). There are only a few case reports of ICA in autosomal recessive polycystic kidney disease (ARPKD) published to date.

Case Description: We present a 24-year-old woman with a genetic diagnosis of ARPKD. Abdominal MRI showed normal liver. The left kidney volume was 254.3 cc and the right kidney volume was 242.8 cc. She presented with chronic kidney disease stage 4 with eGFR of 22 ml/min. There was no family history of ADPKD or ICA. Her mother was with history of post traumatic subarachnoid hemorrhage (SAH). Due to intermittent headaches and family history of SAH, MRA of head was performed as part of kidney transplant evaluation. MRA revealed a 6 mmx5 mm unruptured ICA. aneurysm. She underwent to microsurgical clip reconstruction of unruptured anterior circulation aneurysm. Due to the negative family history of ADPKD and relatively small kidney size in the setting of advanced CKD, a whole exome panel genetic testing done. There were two heterozygous missense variants in the *PKHD1* gene.

Discussion: There are only a few cases with ARPKD and ICA reported within the last decade. To our knowledge, this is the 8th reported case of ICA with ARPKD. Previously reported cases presented with aneurysm rupture or were diagnosed during the investigation of neurologic symptoms. In addition, there have been two cases of extracranial aneurysm reported in ARPKD. Although most experts agree that ADPKD patients with a family history of ICA should undergo MRA screening, there are no recommendations for individuals with ARPKD. Taken together these cases suggest that there may be a link between ARPKD and vascular aneurysms that may warrant additional investigation. Screening patients for ICA in ARPKD should be considered in appropriate settings.

Unveiling Kidney Disease Progression in Autosomal Recessive Polycystic Kidney Disease with Hypertension: Insights from the SS-PCK Rat Model

Aya Yoshimura,[1] Takahiro Shirozu,[1] Masanori Kugita,[1] Kanako Kumamoto,[1] Akiko Takizawa,[2] Melinda R. Dwinell,[2] Masumi Hirabayashi,[3] Kazuo Takahashi,[4] Harold M. Aukema,[5] Tamio Yamaguchi,[6] Shizuko Nagao.[1]
[1]Fujita Health University, Toyoake, Japan; [2]Medical College of Wisconsin, Milwaukee, WI; [3]National Institute for Physiological Sciences, Okazaki, Japan; [4]Fujita Health University School of Medicine, Toyoake, Japan; [5]University of Manitoba, Winnipeg, MB, Canada; [6]Suzuka University of Medical Science, Suzuka, Japan.

Background: The SS-PCK rat model offers a novel approach to investigate autosomal recessive polycystic kidney disease (ARPKD) complicated by salt-sensitive hypertension. This model integrates the mutated human orthologous *Pkhd1* allele from PCK rats into a Dahl salt-sensitive (SS) background, providing a unique platform to explore the influence of salt sensitivity on cyst formation and renal pathology. Intriguingly, male SS-PCK rats demonstrated significantly elevated blood pressure and renal pathology even under normal salt conditions, presenting distinct medullary cyst formation and reduced renal cyst size compared to PCK rats. Histological examination revealed small cysts in both cortical and medullary regions of SS-PCK kidneys, with renal function parameters declining progressively with age. We examined cellular mechanisms and the effects of an ACE inhibitor.

Methods: PCK and SD rats were obtained from The Jackson Laboratories Japan, Inc, and SS and SS-PCK rats were from Medical College of Wisconsin. Males were given standard chow with a normal salt level. Furthermore, Enalapril was administrated in SS-PCK rats from 5 to 16 weeks of age. Kidney samples were prepared for analytical studies.

Results: Expression analyses indicated decreased levels of Cytochrome P450 4 (*Cyp4*) family genes, including *Cyp4a3* and *Cyp4a8*, in SS-PCK rats compared to PCK rats, while epithelial sodium channel (*ENaC*) expressions, specifically β-*ENaC* and γ-*ENaC*, were significantly elevated. Additionally, Aquaporin-2 (*AQP2*) expression was notably higher in SS-PCK rats. Enalapril treatment in SS-PCK rats improved renal function, evidenced by significantly lower serum urea nitrogen and creatinine levels, along with increased *Cyp4a1* expression. Furthermore, Enalapril treatment reduced β-ENaC and γ-ENaC expressions, without affecting AQP2 expression.

Conclusions: These findings elucidate the complex mechanisms underlying ARPKD progression, emphasizing the involvement of the Cyp4 signaling pathway and Angiotensin II-induced ENaC expression. Enalapril treatment effectively mitigated hypertension and renal complications, highlighting the therapeutic potential of ACE inhibitors in managing ARPKD and hypertension-associated renal disease.

Disruption of the Human Cystin-1 Myristoyl-Electrostatic Switch Causes Autosomal Recessive Polycystic Kidney Disease (ARPKD)

Chaozhe Yang,[1] Naoe Harafuji,[1] Jacob Watts,[1] Claire Moran,[5] Jenna Clements,[5] Kailyn M. Price,[5] Natalie Burrill,[2] Juliana S. Gebb,[2] Shelly Soni,[2] Edward R. Oliver,[2] Jill Savla,[2] Avni Santani,[3] Erum A. Hartung,[2] Rudolfo Karl,[4] Dagmar Wachten,[4] Zsuzsanna M. Bebok,[7] Landon S. Wilson,[6] Ljubica Caldovic,[1,5] Lisa M. Guay-Woodford.[1,2] *[1]Children's National Hospital, Washington, DC; [2]The Children's Hospital of Philadelphia, Philadelphia, PA; [3]Veritas Genetics, Danvers, MA; [4]Universitatsklinikum Bonn, Bonn, Germany; [5]The George Washington University School of Medicine and Health Sciences, Washington, DC; [6]The University of Alabama at Birmingham Department of Pharmacology and Toxicology, Birmingham, AL; [7]The University of Alabama at Birmingham Department of Cell Developmental and Integrative Biology, Birmingham, AL.*

Background: Autosomal recessive polycystic kidney disease (ARPKD; MIM#263200) is primarily caused by pathogenic variants in *PKHD1*. The *Cys1*$^{cpk/cpk}$ (*cpk)* mouse expresses a renal lesion that closely phenocopies ARPKD. *Cys1* encoded cystin is a myristoylated protein that traffics to the primary cilium and the nucleus, where it regulates gene expression.

Methods: Clinical characterization of siblings with ARPKD and Cystin-1$_{G2S}$ variant. Bioinformatics analysis of mammalian cystin sequences. Immunofluorescence (IF) staining and optogenetic stimulation assay to determine subcellular localization of wild-type and mutant cystin. Tandem affinity purification (TAP) and mass spectroscopy (MS) to identify cystin-binding partners. Evaluation of cystin serine-17 (S17) phosphorylation.

Results: The homozygous Cystin-1$_{G2S}$ variant identified in the siblings is predicted to disrupt the G2 myristoylation site within the cystin MGxxxSx N-terminal motif. Alignment of 97 mammalian cystin sequences showed high conservation of a putative myristoyl-electrostatic switch that can regulate reversible protein binding to membranes. The conserved region includes the N-myristoylation site and an adjacent arginine-rich stretch flanked by S17 residues. Using IF staining and site-directed mutagenesis, we confirmed that S17 phosphorylation modulates cystin membrane association and intracellular trafficking. In turn, optogenetic activation of ciliary cAMP signaling reduced the cystin ciliary localization in a PKA-dependent manner. TAP-MS identified the protein phosphatase PPM1A as a cystin-interacting partner. Inhibition of PPM1A with sanguinarine impeded cystin S17 de-phosphorylation confirming functional interaction.

Conclusions: Our study demonstrates that cystin intracellular trafficking and nuclear function are regulated by a myristoyl-electrostatic switch mechanism, and further supports *CYS1* as a disease-causing gene for human ARPKD, providing the first mechanistic insight for disease pathogenesis.

Role of the Proto-oncogene c-KIT in Tuberous Sclerosis Complex Renal Cystogenesis

Sharon L. Barone,[1,2] Kamyar A. Zahedi,[1,2] Nathan Zaidman,[3] Marybeth Brooks,[1,2] Manoocher Soleimani.[1,2] Soleimani Lab. *[1]University of New Mexico Health Sciences Center, Albuquerque, NM; [2]Veterans Health Administration, Albuquerque, NM; [3]University of New Mexico School of Medicine, Albuquerque, NM.*

Background: Tuberous sclerosis complex (TSC) is caused by mutations in *TSC1* or *TSC2* genes. In the kidney, TSC presents with cysts and angiomyolipomata that can lead to renal failure. The cyst epithelium in TSC mouse models and in TSC patients is comprised of A-intercalated (AIC) cells. Deletion of Foxi1 abrogates the kidney cysts in TSC.

Methods: To identify the molecules critical to kidney cystogenesis in TSC, RNAseq analyses were performed in *Tsc1*KO (which display many cysts) and *Tsc1/Foxi1*dKO (that display no cysts) vs. WT mice. The mRNA and protein expression of differentially expressed transcripts (DET) was confirmed, their localization was ascertained and the effect of their ablation on cystogenesis was determined.

Results: RNAseq identified c-*Kit* as a vigorously up-regulated DET in the kidneys of *Tsc1*KO mice, with a profound downregulation in *Tsc1/Foxi1*dKO mice. Confirmatory analyses proved robust expression of c-*Kit* in the kidneys of *Tsc1*KO mice, and immunofluorescence microscopy showed its localization to the basolateral membrane of cyst epithelia. Ablation of c-*Kit* gene in *Tsc1*KO mice by generating *Tsc1/c-Kit* dKO mice completely abrogated kidney cysts and inhibited mTORC1 activity. Expression of c-*Kit* in M1 CCD cells increased their proliferation, along with the activation of ERK1/2 and RSK1 signaling. The potentiation of ERK1/2 and RSK1 signaling were also demonstrated in kidneys of *Tsc1*KO mice and inhibited in *Tsc1/c-KIT* dKO mice.

Conclusions: Activation of c-KIT, a proto-oncogene and a resident molecule in AIC cells in *Tsc1*KO mice point to a novel pathway that disrupts the regulation of mTORC1 function and leads to unregulated cell growth and cystogenesis in TSC. The effect of *c-Kit* ablation in *Tsc1*KO mice strongly suggest that the modulation of KIT signaling may be a novel treatment for TSC renal cysts.

SA-PO612

Role and Mechanism of mTOR Signaling Activation in Nephronophthisis Type I

Liangzhong Sun, Baojuan Zou, Qianying Wang. *Southern Medical University Nanfang Hospital, Guangzhou, China.*

Background: Nephronophthisis (NPH), a group of autosomal recessive ciliopathies, is a lead- ing genetic cause of renal failure in children and adolescents. Over 20 NPH genes have been identified, among which *NPHP1* is the most frequent. It is generally believed that dysfunctional ciliary signa- ling leads to uncontrolled cellular growth and proliferation by activating the mTOR signaling, which leads to organ cystogenesis such as polycystic kidney disease (PKD). However, NPH is prominently featured by extensive tubular atrophy and interstitial fibrosis, whereas its cystic load are relatively mild. Hence, it's of great interest whe- ther abnormal ciliary signaling in NPH activates mTOR signaling along with cell proliferation similar to PKD.

Methods: In this study, wild-type and *NPHP1*-knockout (*NPHP1*$^{-/-}$) MDCK cells, an well as mice, are used to explore the role of mTOR signaling in NPH and figure out whether mTOR inhibition can rescue renal lesions in NPH type I.

Results: *NPHP1* deletion activates mTOR signaling in MDCK cells and mouse kidneys, featured by a significant increase of p-S6/S6 and p-4EBP1/4EBP1. Expression of Deptor, a natural mTOR inhibitor, declines singularly with *NPHP1* deletion in vitro and in vivo. Proliferation decreased in *NPHP1*$^{-/-}$ cells and mRNA analysis showed an alteration in p21, with a 1-fold higher expression compared with wild-type. Knockdown of Deptor, which activates mTOR signaling, promotes proliferation in wild-type but not in *NPHP1*$^{-/-}$ MDCK cells. p21 expression was induced in *NPHP1*$^{-/-}$ but suppressed in wild-type MDCK cells by Deptor-siRNA. *NPHP1*$^{-/-}$ MDCK cells shows increased resistance to rapamycin, which further reduces Deptor expression. Rapamycin alleviates renal fibrotic, cystic, and inflammatory lesions of *NPHP1*$^{-/-}$ mice and improves their renal function. However, it brings about adverse effects, including loss of weight gain and aggravated cell senescence in kidney.

Conclusions: mTOR signaling is excessively activated in renal tubular cells of NPH type I, due to a decreased expression of Deptor. Despite mTOR activation, *NPHP1* deficiency restrains proliferation in renal tubular cells. Rapamycin significantly alleviates renal fibrotic, cystic and inflammatory lesions and improves renal function of *NPHP1*$^{-/-}$ mice. However, adverse effects include loss of weight gain and aggravated cell senescence of kidney in rapamycin treatment.

NBL1 Correlates with Kidney Disease in a Mouse Model for Alport Syndrome, but Is Not Causal

Courtney Willey,[1,2] Rei Bufi,[1] Abigail Brackett,[1] Susan M. Sheehan,[1] Ron Korstanje.[1,2] *[1]The Jackson Laboratory, Bar Harbor, ME; [2]The University of Maine, Orono, ME.*

Background: Alport syndrome (AS) is a rare genetic condition that often results in progressive loss of kidney function and end-stage kidney disease. Although the causal genes for AS are well characterized, individuals with AS still display a wide range of variation in kidney function and age of onset, suggesting the presence of modifiers. Recently, several studies identified levels of neuroblastoma suppressor of tumorigenicity 1 (NBL1) in the blood to be strongly and independently associated with more severe progression of diabetic nephropathy and IgA nephropathy. We decided to investigate the role of NBL1 in a genetically diverse population of Diversity Outbred (DO) mice with X-linked Alport Syndrome (DO-XLAS) and found a significant correlation between NBL1 and kidney function. However, it is still unclear whether NBL1 is causal or consequential to kidney disease.

Methods: To test causality, we created an NBL1 knockout (KO) mouse model and confirmed that heterozygous (HET) animals have significantly lower NBL1 levels in their blood compared to wildtype (WT). We then induced AS by breeding a mutated Col4a5 allele into our NBL1 KO mice and investigated differences in kidney function and damage.

Results: We did not find a difference in GFR or albuminuria between HET and WT animals, suggesting that NBL1 does not have a causal role in disease progression. We are performing a genetic analysis on 600 DO-XLAS mice to identify the drivers of increased plasma NBL1 levels and better understand the underlying mechanism and relationship with kidney disease.

Conclusions: NBL1 does not appear to have a causal role in disease progression and increased NBL1 levels are more likely to be a consequence of kidney disease. The exact role of NBL1 in kidney disease remains to be elucidated.

Systematic Metabolomics Study in the Serum and Urine of a Mouse Model of Alport Syndrome

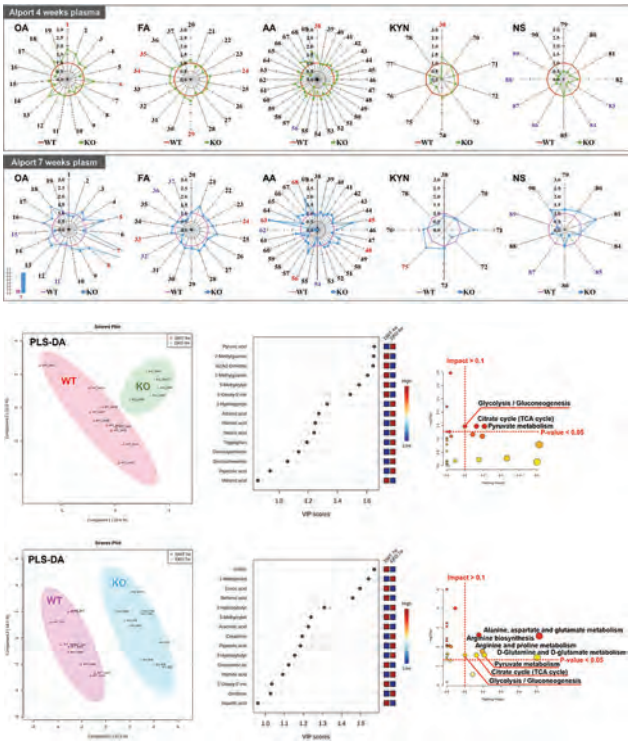
Hong Sang Choi,[1,2] Sang Heon Suh,[1,2] Chang Seong Kim,[1,2] Eun Hui Bae,[1,2] Seong Kwon Ma,[1,2] Soo Wan Kim.[1,2] *[1]Chonnam National University Medical School, Gwangju, Gwangju, Republic of Korea; [2]Chonnam National University Hospital, Gwangju, Gwangju, Republic of Korea.*

Background: Alport syndrome (AS) is a hereditary nephropathy characterized by progressive kidney disease and hearing loss, which is caused by mutations in the genes encoding the alpha 3, 4, or 5 chain comprising the type IV collagen that forms glomerular basement membrane. There is a limited understanding of the metabolites related to progressive kidney disease in AS.

Methods: Metabolomics study was performed for monitoring of biomarker and altered metabolism related with disease progression in serum and urine from male *Col4a3* knockout mice and age-matched wild-type mice at 4 and 7 weeks. Profiling analysis for metabolites, including organic acids, amino acids, fatty acids, kynurenine pathway metabolites, and nucleosides in the serum and urine was performed using gas chromatography-tandem mass spectrometry and liquid chromatography-tandem mass spectrometry combined with star symbol patterns and partial least squares discriminant analysis (PLS-DA).

Results: A total of 29 and 44 metabolites from the serum and urine of *Col4a3*$^{-/-}$ mice were distinguished from those of wild-type mice, respectively, based on P-value (< 0.05) and variable importance in projection scores (> 1.0) of PLS-DA. In the serum of 4 weeks AS mice, metabolites of the glycolysis, gluconeogenesis, pyruvate metabolism and TCA cycle were increased, whereas those involved in alanine, aspartate and glutamate metabolism, arginine and proline metabolism, arginine biosynthesis and D-glutamine and D-glutamate metabolism were altered in serum of 7 weeks AS mice.

Conclusions: Altered metabolic pathway and metabolites are associated with progressive kidney disease in AS.



SA-PO615

Dysregulated Glomerular Proteins in 1-Day-Old Col4a3 Knockout Mice

Vanessa S. De Gregorio,[1] Akanchaya Rana,[2] Emine B. Caparali,[1] Samantha Ricardo,[1,3] Ana Konvalinka,[1,4] Moumita Barua.[1,4] *[1]Toronto General Hospital Research Institute, Toronto, ON, Canada; [2]Princess Margaret Hospital Cancer Centre, Toronto, ON, Canada; [3]Institute of Medical Science, University of Toronto, Toronto, ON, Canada; [4]Division of Nephrology, University Health Network, Toronto, ON, Canada.*

Background: Alport syndrome (AS) is a hereditary disorder caused by pathogenic variants in *COL4A3*, *COL4A4* and/or *COL4A5*, encoding the α3α4α5 chains of type IV collagen typically expressed in the mature glomerular basement membrane (GBM) of the kidney. In AS due to truncating variants, podocytes do not form the α3α4α5(IV) basement membrane and instead, there is persistence of the flexible α1α1α2(IV) trimer normally present during development. To understand the earliest mechanisms of disease in AS, we elected to study glomerular changes in *Col4a3* $^{-/-}$ (knockout; KO) mice at postnatal-day 1 (P1), when trimer switching is occurring.

Methods: P1 *Col4a3* KO and wildtype mouse glomeruli were isolated using Dynabeads. Protein extracts from glomerular samples were subjected to mass spectrometry. Pathway analysis was performed using Gene Ontology and protein interactors were identified using STRING.

Results: More than 1,000 proteins from glomerular extracts were significantly dysregulated in P1 female KO compared to wildtype. In assessing protein-protein interactions between significantly dysregulated proteins, those with the greatest number of interactors included ACTB, GAPDH, ATP5B, EEF2, and SDHA. Over 70 pathways were identified as significantly different in female P1 KO compared to wildtype. Notably, these pathways were related to K63-linked deubiquitinase activity, alternative mRNA splicing, via the spliceosome, establishment or maintenance of transmembrane electrochemical gradient, actin filament binding, and NF-κB binding. In P1 male KO compared to wildtype, 17 proteins from glomerular extracts were identified as significantly dysregulated but no significantly different pathways were identified.

Conclusions: Pathways related to alternative splicing, cell maintenance, actin binding, and inflammation are dysregulated in the glomerulus at the earliest stage of disease in *Col4a3* KO mice. These dysregulated pathways will be further explored to understand biological mechanisms in disease and to inform therapeutic development in the future.

Development and Assessment of Col4a5 Missense Mouse Model of Alport Syndrome

Aimi Owaki, Yuya Sannomiya, Jun Horizono, Mary Ann Suico, Tsuyoshi Shuto, Hirofumi Kai. Dept of Molecular Medicine. *Kumamoto University, Kumamoto, Japan.*

Background: Mutation in type IV collagen α3, α4 or α5 results in the abnormal formation and secretion of α345(IV) trimer causing Alport syndrome (AS), a progressive hereditary nephritis. Missense mutations in α5(IV) are the most frequently reported. Current symptomatic therapies are unable to prevent the progression to end-stage renal failure. Therefore, the development of novel drugs is needed but is hampered by the lack of a mouse model of missense mutant AS that enables the evaluation of drug efficacy.

Methods: We previously developed a nanoluciferase-based trimer evaluation system (Cell Chem Biol 2018) and focused on the human α5(IV) G1244D mutation, whose secretion is significantly decreased and is reported to be clinically severe. We generated mutant mice using the kick-in method that can generate knock-in mice.

Results: The results showed that while the α5(IV) G1244D mutation causes severe renal disease in humans it does not cause renal disease in mice, indicating a phenotypic divergence. To elucidate the cause of this species difference, we constructed an evaluation system for mouse type IV collagen trimer. We assessed clinically reported 34 missense mutations in α5(IV) and evaluated the trimer function. The results showed that the trimer secretion by the G1244D mutation in mouse α5(IV) was normal, unlike that in human. Furthermore, when the trimer secretion ability of 34 mutants was compared between human and mouse, only 15 mutations showed similar secretion. These results indicate that the trimer behavior of human and mouse mutants does not necessarily coincide. Furthermore, we are currently generating mouse models of missense mutations that cause a significant decrease in mouse trimer secretion. Phenotypic analysis will be performed to provide much-needed information for a new AS missense mouse model.

Conclusions: Human and mouse α345(IV) trimer behavior diverges, necessitating a thorough assessment of each mouse mutant to produce a missense mouse model that recapitulates the clinical phenotypes of human AS missense mutant pathologies.

Nephrotic Syndrome-Associated Variants Dysregulate TRIM8 Functions in Biomolecular Condensates, Cell Adhesion, and Glomerular Injury

Vineeta Sharma,[1] Hari R. Singh,[2] Sunwoo Hong,[1] Alexander Rubin,[1] David A. Ball,[1] Victoria C. Gauntner,[1] David J. Salant,[3] Friedhelm Hildebrandt,[1] Amar J. Majmundar.[1] *[1]Boston Children's Hospital, Boston, MA; [2]Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany; [3]Boston University Chobanian & Avedisian School of Medicine, Boston, MA.*

Background: C-terminal truncating TRIM8 variants (tripartite motif containing 8) cause human nephrotic syndrome (NS) and mislocalization of TRIM8 from nuclear bodies. However, the effects of these variants at the physicochemical, molecular, cellular and whole organism levels are poorly understood.

Methods: Tagged TRIM8 constructs were expressed in U2OS cells or immortalized human podocytes. Time lapse fluorescence microscopy, immunofluorescence staining, confocal microscopy, coimmunoprecipitation and immunoblotting were performed. CRISPR/Cas9-mediated gene editing in immortalized human podocytes and in mice was performed to generate disease mimicking C-terminal truncating variants.

Results: Tagged TRIM8 nuclear bodies exhibited rapid fluorescence recovery after photobleaching (T-half=10s) and fusion consistent with liquid-like condensates in U2OS cells. Supporting this classification, as bulk tagged TRIM8 concentration increased to 4 μM, its concentration within nuclear bodies increased up to 20 μM while remaining low outside (<2 μM). In silico algorithms (ESpritz, IUPred, PrDOS, PONDR) detected intrinsically disordered region (IDR) features in the TRIM8 C-terminus. In correlation, truncation of the IDR impaired TRIM8 condensate formation in vitro. In immortalized podocytes, NS-associated C-terminal IDR truncating variants impaired tagged TRIM8 polyubiquitination and 26S-dependent degradation, suggesting potential gain-of-function. Endogenous proteasome components (PSMD4, PSMD12) co-localized with tagged wildtype TRIM8—but not NS mutants—in condensates, implicating these condensates in proteasome-dependent TRIM8 regulation. TAK1 is a published TRIM8 substrate that regulates cell adhesion and murine podocyte homeostasis. TAK1 co-localized with wildtype TRIM8 in condensates and coimmuoprecipitated, which NS variants reduced. Rather, TRIM8 NS mutant protein caused reduced TAK1 protein levels. At the cellular level, CRISPR-mediated TRIM8 variants led to reduced immortalized podocyte adhesion. As compared to wildtype controls, Trim8 mutant mice developed increased albuminuria after nephrotoxic serum injury.

Conclusions: TRIM8 forms proteasome-associated biomolecular condensates that may impact its regulation of TAK1, cell adhesion, and podocyte injury.

SA-PO618

Pathogenic Variants in NFATC1 and NFATC3 Can Cause Nephrotic Syndrome

Sue Zhang,[1] Hariel G. Peters,[1] Megan Chryst-Stangl,[1,2] Guanghong Wu,[1,2] Rasheed A. Gbadegesin,[1,2] Brandon M. Lane.[1,2] *[1]Duke University, Durham, NC; [2]Duke Molecular Physiology Institute, Durham, NC.*

Background: Nephrotic syndrome (NS) is a kidney condition that is characterized by disruption of the glomerular filtration barrier leading to proteinuria and progressive kidney damage. While dysregulation of the calcineurin (*CN*) signaling pathway has been implicated in the pathogenesis of NS, the role of pathogenic variants in calcineurin signaling pathway (CNP) genes in the etiology of genetic NS remains unclear. To address this, we performed whole exome sequencing on >500 children with nephrotic syndrome and performed targeted analysis of 67 CNP genes.

Methods: We carried out whole exome sequencing in >500 children with NS and use previously published filtering algorithm to identify pathogenic variants in CNP genes in these children. To determine the pathogenicity of the variants on podocyte homeostasis, we used lentiviral shRNA and plasmid transduction to modulate *NFATC1* and *NFATC3* gene expression in immortalized podocyte cell lines and examined changes in cell migration using automated live-cell imaging.

Results: We identified two variants in NFAT genes (*NFATC1* c.insC2463; p.G821fs and *NFATC3* c.G1519A; p.A507T) in two families with steroid resistant nephrotic syndrome (SRNS). The two variants segregate with disease in the family. Knockdown of NFATC1 and NFATC3 in immortalized human podocyte cell lines reduces podocyte motility and disruption of cytoskeleton regulation.

Conclusions: Our data suggests that *NFATC1* and *NFATC3* are new candidate genes for nephrotic syndrome.

SA-PO619

Transgenic Human Nephrin in Drosophila Nephrocytes Facilitates Variant Analysis

Julia M. Wolff,[1] Konrad Lang,[1] Julian Milosavljevic,[1] Mengmeng Chen,[1] Martin Helmstädter,[1] Sami Bahar,[3] Maximilian H. Ulbrich,[2] Tobias F. Hermle.[1] *[1]University Medical Center Freiburg Department of Medicine, Divison of Nephrology, Freiburg, Germany; [2]University of Freiburg, Faculty of Medicine, Department of Anatomy and Cell Biology, Department of Neuroanatomy, Freiburg, Germany; [3]An-Najah National University, Faculty of Medicine and Health Sciences, Department of Medicine, Nablus, Palestine, State of.*

Background: Nephrin, the key structural protein of the slit diaphragm, is encoded by *NPHS1*. Pathogenic variants in this gene are the primary cause of congenital nephrotic syndrome. About 400 variants have been described but functional characterization is curtailed by the lack of slit diaphragm formation within *in vitro* models. A molecularly conserved and accessible slit diaphragm can be found in the *Drosophila* nephrocyte model.

Methods: Human nephrin was transgenically expressed in *Drosophila* nephrocytes in combination with silencing of the nephrin ortholog *sns*. Nephrocytes were phenotypically characterized by immunofluorescence, tracer studies, and transmission electron microscopy including immunogold labeling. Automated image annotation was employed to quantify distinct staining patterns. A novel nephrin variant was identified in a patient with congenital nephrotic syndrome using whole exome sequencing. Transgenes reflecting this novel and another variant of *NPHS1*, previously identified as deleterious, were generated for functional analysis in *Drosophila*.

Results: Transgenic human nephrin assembled into a complex linear architecture in nephrocytes after silencing of *Sns*. This suggests lateral clustering of nephrin into a macromolecular configuration within the podocyte-like cells. Transgenic nephrin colocalized with the endogenous slit diaphragm protein Pyd, ortholog of ZO-1, suggesting a hybrid multi-protein complex. Upon transgenic co-expression of murine Neph1, nephrin similarly recruited its binding partner. However, the linear nephrin exhibited an atypical, tubular ultrastructure and did not adequately direct actin remodeling, underscoring the need for further indispensable co-factors. The linear nephrin assembly was disrupted in transgenes reflecting canonical patient variant S366R as well as novel variant V1241G, which affects the nephrin C-terminus. Automated annotation of Pyd staining patterns provided a quantitative read-out for investigation of these patient-derived variants.

Conclusions: Transgenesis of *NPHS1* in nephrocytes is a viable approach for investigation of basic steps of slit diaphragm formation and functional characterization of patient variants in *NPHS1*.

Funding: Government Support - Non-U.S.

SA-PO620

Mutation in NUP155 Causes Activation of Autophagy in Podocytes through Retraining the YAP in the Cytoplasm to Induce Podocyte Loss and Subsequent Nephrotic Syndrome

Anqun Chen, Zhuoyuan Jiang. *The Second Xiangya Hospital of Central South University, Changsha, China.*

Background: Hereditary nephrotic syndrome (HNS) is a clinical syndrome characterized by increased permeability of the glomerular filtration barrier. Recently, mutations in a class of genes encoding nucleoporins (NUPs) have been found to cause NS.

Methods: First, whole-exome sequencing, and Sanger sequencing were performed in Chinese familial patients with NS. A Drosophila model with Nup154 (the NUP155 ortholog) knockdown (KD) was established. NUP155-Knockdown stably transfected cell lines of human immortalized podocytes were constructed and the rescued experiments were performed by overexpressing the mutants and wild NUP155 in NUP155-KD cells. Co-IP mass spectrometry was used to explore the downstream mechanism of *NUP155* mutation causing NS.

Results: We identified mutations in the *NUP155* gene, coding an inner ring sub-unit of the nuclear pore complex, in Chinese familial patients with NS, manifested as FSGS.

The missense variant (c.397G>T) results in p.Asp133Tyr. The other mutation in the splice region (c.4037+2T>C) led to four kinds of alternative splicing transcripts, all encoding premature proteins. The intensity of NUP155 in the patients' kidneys was diffusely decreased compared with the control. Meanwhile, podocyte-specific expression of WT1 and NPHS2 was significantly reduced, showing podocyte loss. In adult Nup154-KD drosophila, the number of nephrocytes is decreased. NUP155-KD podocytes exhibit reduced proliferation and migration abilities and heightened susceptibility to injury. Recovering two mutant proteins cannot rescue these phenotypes. The variants in NUP155 affected the interaction with NUP133 and NUP93, causing disrupted nuclear pore complex (NPC) assembly. Additionally, autophagy activation, an increase in YAP phosphorylation, and a reduction of nuclear YAP localization in NUP155-KD podocytes and proband kidney, suggesting NUP155 is essential for YAP nuclear import and aberrant nuclear localization of YAP leads to increased autophagy.

Conclusions: We show that the mutations in *NUP155* could cause NS, which led to abnormal NPC, retraining nucleocytoplasmic shuttling of YAP, and activation of autophagy, eventually leading to dysplasia and impaired function of glomerular podocytes.

SA-PO621

In Vivo Mechanisms of LAMB2 Variants in Isolated Nephropathy: Insights from Knock-In Mouse Models

Mika Okutsu,[1,2] Taeko Hashimoto,[5] Yamato Kikkawa,[3] Akira Shimizu,[4] Yutaka Harita.[1] *[1]Tokyo Daigaku, Bunkyo-ku, Japan; [2]Tokyo Ika Shika Daigaku, Bunkyo-ku, Japan; [3]Tokyo Yakka Daigaku, Hachioji, Japan; [4]Nihon Ika Daigaku, Bunkyo-ku, Japan; [5]Yamagata Daigaku, Yamagata, Japan.*

Background: Loss of function mutations of *LAMB2* encoding laminin β2 (β2) cause Pierson syndrome. Typical *LAMB2* mutations found in Pierson syndrome are truncating mutations or mutations that inhibit extracellular secretion of β2. In recent years, a series of missense variants within specific domains of β2 (e.g. p.G699R) have been identified in cases of isolated nephropathy without extrarenal symptoms. The allele frequency of these mutations varies greatly regionally, with p.G699R being more frequent in East Asians (0.0085). We previously demonstrated that these variants have biochemical features distinct from loss-of function mutations causing Pierson syndrome. The variants found in isolated nephropathy preserved extracellular secretion of β2, but enhanced interactions between β2 and components in the glomerular basement membrane (GBM) (Kikkawa et al. JCI Insight 2021). To date, the in vivo effects of these variants are unknown.

Methods: We generated knock-in (KI) mice with the mutation corresponding to the *LAMB2* p.G699R. We investigated the phenotype of KI mice, including the effects of adriamycin (ADR)-induced nephropathy.

Results: In the homozygous KI mice, β2 secretion in the GBM was maintained, which supports the results of the in vitro analysis. Long-term observation showed increased proteinuria in some homozygous KI mice. After ADR administration, KI mice had significantly more proteinuria than wild type mice. KI mice showed significantly increased mesangial area enlargement, focal thickening of the GBM and FSGS lesions in the renal tissue after ADR administration, and markedly enlarged subendothelial lumen and abnormal endothelial fenestrae by the electron microscopy. RNA-seq analysis suggests that KI mice have more intense changes in tissue inflammation than wild-type mice.

Conclusions: *LAMB2* p.G699R exerts changes in the plasticity of glomerular injury by altering the adhesive capacity of the GBM, and could act as a risk factor for the development of renal disease.

SA-PO622

Deletion of Gapvd1 Sensitizes Murine Podocytes to Adriamycin-Induced Injury

Lea Gerstner, Dominik Spitz, Julian Milosavljevic, Lina L. Kampf, Marc Brettel, Camille Lempicki, Martin Helmstädter, Wibke Bechtel-Walz, Gerd Walz, Tobias F. Hermle. *Renal Division, Department of Medicine, Faculty of Medicine and Medical Center - University of Freiburg, Freiburg, Germany.*

Background: DNA variants in *GAPVD1*, an activator of endosomal protein Rab5, are a monogenic cause of nephrotic syndrome. The encoded protein interacts with nephrin and previous studies in podocyte-like nephrocytes in *Drosophila* suggested a crucial function for slit diaphragm integrity. However, the role of this gene remained unexplored in mammalian animal models.

Methods: To generate a conditional knockout, we established a *Gapvd1* allele with loxP sites flanking exon 4. Gapvd1$^{fl/fl}$ mice were crossed with *Nphs2*-Cre for podocyte-specific deletion and *Six2*-Cre for deletion in nephron progenitor cells. To apply toxicity stress, sixteen week old *Nphs2*-Cre; Gapvd1$^{fl/fl}$ mice and control animals (Gapvd1$^{fl/fl}$) were treated with intravenous Adriamycin. For phenotypic characterization, we determined serum creatinine and urinary albumin-to-creatinine ratios (ACR) and further applied histochemistry, immunofluorescence and electron microscopy.

Results: In situ hybridization indicated a successful conditional knockout of Gapvd1. However, unstressed animals using *Nphs2*-Cre or *Six2*-Cre for deletion of *Gapvd1* revealed no overt phenotype including changes in glomerular architecture, renal function and urinary ACR. In contrast, Adriamycin-injected *Nphs2*-Cre, *Gapvd1*$^{fl/fl}$ mice presented with elevated proteinuria compared to the control group. Periodic acid-Schiff staining of kidney sections indicated focal segmental glomerulosclerosis in stressed knockout animals, which further exhibited significantly less WT1-positive podocytes per glomerulus in immunofluorescence. Analysis of glomeruli with scanning electron microscopy revealed shortened and partially fused foot processes and transmission electron microscopy confirmed foot process effacement.

Conclusions: *Gapvd1* seems dispensable for podocyte homeostasis in unstressed mice, likely due to compensation by another Rab5-regulating protein. However, loss of Gapvd1 sensitized animals to Adriamycin-induced podocyte injury resulting in podocyte loss and proteinuria.

Funding: Government Support - Non-U.S.

SA-PO623

Characterization of Steroid-Resistant Nephrotic Syndrome-Associated Motor Domain Mutations in MYO1E

Kazi Sayeeda, Mira Krendel. *SUNY Upstate Medical University, Syracuse, NY.*

Background: Myosin1e (Myo1e) is a cytoskeletal protein highly expressed in podocytes and localized to cell-cell junctions/slit diaphragm complexes, which are required for these cells' structural and functional integrity. As podocytes are the final gatekeepers of the filtration barrier, they rely on the actin cytoskeletal organization to maintain their intricate architecture and respond to mechanical stresses from fluid flow and capillary distension. Myo1e binds to actin and may modulate actin cytoskeletal assembly and dynamics. Mutations in the gene encoding Myo1e have been found in patients with steroid-resistant nephrotic syndrome (SRNS) and focal segmental glomerulosclerosis (FSGS). In this project, we have analyzed recently identified *MYO1E* mutations associated with SRNS/FSGS (Warejko et al. Clin J Am Soc Nephrol 2018, Krendel et al. Pediatr Nephrol 2023) that have not been functionally characterized.

Methods: EGFP-tagged Myo1e constructs (mutant or wild-type (WT)) were introduced into the Myo1e-KO podocyte-derived cells via adenovirus-mediated transduction to test the effects of these mutations on Myo1e localization and podocyte junctional properties.

Results: Similarly to Myo1e localization in the WT podocytes, WT Myo1e was enriched at cell-cell contact points and colocalized with actin. Unlike WT Myo1e, the mutants showed primarily cytoplasmic subcellular localization. One of the mutants, G562R, was partially localized at the cellular junction, but its enrichment at the cell-cell junctions was significantly lower than that of the WT. Although none of the mutants colocalized with actin at the podocyte-podocyte intersection, their expression as the sole source of Myo1e did not affect the actin enrichment at those sites.

Conclusions: WT Myo1e frequently localizes at the cell-cell contacts and may play a role in regulating junctional integrity. Mis-localization of the Myo1e mutants that we have studied indicates that these disease-associated mutations disrupt the ability of Myo1e to perform its functions at the sites of cell-cell contact.

Potentiated JAK-STAT Signaling Differentiates Stem Cell-Derived Podocytes of Patients with APOL1-Associated FSGS from Those of Healthy Carriers with a High-Risk APOL1 Genotype

Somenath Datta, Karen Soldano, Daniel P. Silas, Guojie Li, Sarah Nystrom, Melanie E. Garrett, Allison Ashley-Koch, Opeyemi A. Olabisi. *Duke University, Durham, NC.*

Background: An estimated 20% of the 6 million Black Americans who carry *APOL1* high-risk genotype (HRG) will develop APOL1-kidney disease (AKD) in their lifetime, while the remaining 80% will remain free of AKD. There is an urgent, unmet need for predictive biomarkers that could distinguish the 20% at risk of AKD prior to the onset of the disease. Podocytopathy, including FSGS, is a key manifestation of AKD. We hypothesized that genetically-encoded differences in podocyte in response to AKD triggers, such as interferons, could explain the incomplete penetrance of AKD among carriers of HRG.

Methods: To identify potential differences in interferon-gamma (IFN-γ)-induced podocyte gene expression that might lead to risk or protection from AKD, we generated iPSC-podocytes from 21 adults with HRG and biopsy-proven FSGS (high-risk (HR) cases) and 12 adults with HRG and normal eGFR and no proteinuria (HR controls). The iPSC-podocytes were treated with or without IFN-γ followed by whole genome transcriptomic analysis and compared with published transcriptome of laser-captured glomeruli of FSGS cases from the NEPTUNE cohort.

Results: We discovered that IFN-γ induced higher expression of several genes including *CXCL9, CXCL10 CXCL11,* and *APOL1* in iPSC-podocytes of HR cases versus HR controls. The expression of these genes is regulated by JAK-STAT signaling. At baseline, there were no differences in JAK-STAT signaling between HR cases and HR controls. Our comparative analysis of iPSC-podocyte transcriptome with published glomeruli transcriptome from the NEPTUNE cohort confirmed that elevated JAK-STAT signaling is a common feature of HR cases in iPSC-podocytes and glomeruli.

Conclusions: Our results identified potentiated JAK-STAT-mediated gene expression including chemokines in human iPSC-podocytes, which could serve as a predictive biomarker of APOL1-kidney disease. This promising finding suggests that measurement of IFN-γ-induced chemokine expression in iPSC-podocytes of HRG carriers could serve as a tool for predicting the likelihood of future incidence of AKD. Validation in a larger sample size would facilitate clinical translation of this finding.

Differential Pathway Activation by APOL1 G1 and G2 Variants in Induced Pluripotent Stem Cell (iPSC)-Derived Endothelial Cells: Insights from Proteomic Analysis

Miguel Carracedo, Meztli Matadamas-Guzman, Bojana Lazovic, Ramesh Tati, Orsolya Bilkei-Gorzo, Grzegorz Sienski, Pernille B. Laerkegaard Hansen, Mark Lal. *AstraZeneca, Mölndal, Sweden.*

Background: Apolipoprotein-L1 (APOL1) risk variants (RV), named G1 and G2, are associated with increased risk of chronic kidney disease (CKD) in people of African ancestry. Recent evidence has highlighted the role of APOL1 RVs as drivers of endothelial cell (EC) activation. However, the specific molecular mechanisms driving APOL1-mediated EC activation in humans and the differences between G1 and G2 variants remain unknown.

Methods: We employed CRISPR Xential, a novel CRISPR/Cas9-based method to select and enrich for cells with two edited copies of a gene of interest, to engineer induced pluripotent stem cells (iPSCs) with inducible APOL1 expression. iPSCs were differentiated into ECs and treated with doxycycline for 24 or 48 hours to induce expression of APOL1 variants G0 (control), G1, and G2. We assessed EC viability and conducted global proteomics and bioinformatics analyses.

Results: APOL1 induction reduced EC viability in a time-dependent manner, most significantly with G2 followed by G1 and G0. Proteomics analysis revealed more protein changes (119) after 24h in the G2 expressing ECs when compared with G1 (75) and G0 (6). After 48h, G2 and G1 showed similar amount of differentially regulated proteins, 154 and 175, respectively, whereas G0 expressing ECs presented 44. Among these proteins, IL8 and GLUT1 were upregulated in all conditions. Pathway enrichment analysis revealed inflammatory response and TNFa pathways to be common between G1 and G2 expressing ECs. Interestingly, after 48h, G1 expression led to changes in pathways related with EMT transition and hypoxia, whereas G2 enhanced pathways related with cell cycle and DNA replication.

Conclusions: Our findings corroborate APOL1's role in EC activation and unveil distinct pathways influenced by G1 and G2 variants, underscoring their differential contribution to endothelial dysfunction.

APOL1 Induction Increases Cytosolic Calcium in 293 Cells but Not HeLa or Isogenic Induced Pluripotent Stem Cell (iPSC)-Derived Podocytes

Korey Bartolomeo, John F. O'Toole, Yaping Gu, Leslie A. Bruggeman, Uyen Tran, Oliver Wessely, John R. Sedor. *Cleveland Clinic, Cleveland, OH.*

Background: Coding variants in APOL1 are associated with a spectrum of kidney diseases, but the biology underlying this genetic association remains uncertain. The channel function of APOL1 imparts its trypanolytic activity and *in vitro* models demonstrate APOL1 can insert into lipid bilayers conferring a non-selective cation transport without variant-dependent differences. Recently overexpression of APOL1 kidney disease variants in cell culture models of 293 cells were shown to increase intracellular calcium. However, these model systems rely on APOL1 overexpression that may lead to aberrant APOL1 trafficking and cytotoxic phenotypes that may not reflect the pathogenesis of human APOL1 kidney disease. Our data suggests that APOL1-mediated cytosolic calcium elevations are cell line dependent.

Methods: We utilized isogenic induced pluripotent stem cell (iPSC) with APOL1-G0 and gene edited to G1 or G2, and differentiated to podocytes using a differentiation protocol developed in our lab. We also used tetracycline regulated G0, G1 or G2 in HeLa or 293 cells. We performed surface biotinylation with streptavidin pulldowns, SYTOX microplate viability assays and fura-2 microplate calcium assays after 6h (293), 24h (HeLa and iPSC) and 72h (iPSC) of tetracycline or IFN-γ induced APOL1 expression.

Results: In 293 cells APOL1 localizes to the plasma membrane after 6h of induced expression and is associated with an increase in intracellular calcium in a variant independent manner ($p < 0.05$ Kruskal-Wallis). In HeLa cells after 24 hours of APOL1 induction APOL1 does not localize to the plasma membrane and there is no APOL1 mediated cell death ($p > 0.05$ Kruskal-Wallis). Similarly, iPSC-derived podocytes do not have APOL1 localization at the plasma membrane even after 72h of IFN-γ induction and there is no variant-dependent differences in cell viability or intracellular calcium at 24h, 48h or 72h ($p > 0.05$ Kruskal-Wallis).

Conclusions: Our data indicates that overexpression of APOL1 in 293 cells results in plasma membrane insertion and variant independent intracellular calcium elevations and cell death. On the other hand, tetracycline induced APOL1 induction in HeLa cells and IFN-γ APOL1 induction in isogenic iPSC derived podocytes do not have APOL1 plasma membrane localization, intracellular calcium differences or cytotoxicity.

The Novel MYH9 Variant, c.1270C>G, p.Arg424Gly, Causes Epstein-Fechtner Syndrome by the Modification of Nonmuscular Myosin IIA Contraction

Lena Pollinger,[1] Johannes N. Greve,[5] Sara Kaliman,[6] Shada Abuhattum,[6] Martin Kräter,[6] Antje Wiesener,[4] Francesca Pasutto,[4] Melanie Grosch,[1] Jan René Haak,[1] Cathiana Kolb,[1] Christoph Daniel,[3] Kerstin U. Amann,[3] Mario Schiffer,[1,2] Dietmar J. Manstein,[5] Michael S. Wiesener,[1,2] Tilman Jobst-Schwan.[1,2] *[1]Department of Nephrology and Hypertension, University Hospital Erlangen, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany; [2]Research Center On Rare Kidney Diseases (RECORD), University Hospital Erlangen, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany; [3]Department of Nephropathology, Institute of Pathology, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany; [4]Institute of Human Genetics, University Hospital Erlangen, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany; [5]Institute for Biophysical Chemistry, Fritz-Hartmann-Centre for Medical Research, Hannover Medical School, Hannover, Germany; [6]Max-Planck-Institut fur die Physik des Lichts, Erlangen, Germany.*

Background: The *MYH9* gene encodes the heavy chain of non-muscular myosin IIA (NMMIIA). Mutations in *MYH9* cause autosomal-dominant monogenic disorders that include macrothrombocytopenia, proteinuric kidney disease and elevated liver enzymes.

Methods: Whole exome sequencing was performed in a patient with end-stage renal disease. Segregation analysis in all affected family members was done by Sanger sequencing. Patient tissue biopsies were analyzed. Primary skin fibroblasts were used in migration assays. Immortalized human podocytes were transfected and stained for NMMIIA. Blood smears were inspected by light microscopy and stained for NMMIIA. Blood cell deformability was analyzed by microfluidic technique. Functional analysis of recombinant protein was performed using *in vitro* motility assays.

Results: We identified the putative deleterious *MYH9* variant *c.1270C>G*, p.Arg424Gly (ACMG class 4, CADD score 22, evolutionary highly conserved), heterozygous in 5 affected family members. The variant affects the O-helix in the upper 50k subdomain of the motor domain, which contributes to the conformational coupling between the actin binding site, the nucleotide binding site and the lever arm region. All 5 patients presented with proteinuria, elevated liver enzymes and intermittent thrombocytopenia. No Döhle-like bodies and NMMIIA-positive conglomerates were found in granulocytes. However, granulocytes had modified deformability compared to healthy controls. Patient skin fibroblasts showed elongated morphology and reduced surface area. *MYH9 c.1270C>G* transfected immortalized human podocytes displayed NMMIIA -positive conglomerates. Further functional assays revealed a 22% increase in motility at molecular level compared to wild-type protein.

Conclusions: We identified a novel variant in the *MYH9* gene in a family with hepato-renal disease as the major phenotype of the intrafamilial syndrome. Functional data confirmed the predicted pathogenicity of this variant by identifying altered mechanical properties and highlighted the multicellular function of the protein, even though typical intracellular findings in granulocytes could not be detected.

Biallelic Variant in ENPP6 Alters Choline Metabolism in Humans and Conveys Loss of Enzymatic Function In Vitro

Nils D. Mertens,[1,2] Kuniyuki Kano,[4] Gijs A. Franken,[1,2] Sherif M. El Desoky,[3] Jameela A. Kari,[3] Shirlee Shril,[1,2] Friedhelm Hildebrandt.[1,2] *[1]Boston Children's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]King Abdulaziz University Hospital, Jeddah, Saudi Arabia; [4]Tokyo Daigaku Daigakuin Yakugakukei Kenkyuka Yakugakubu, Bunkyo-ku, Japan.*

Background: Congenital Anomalies of the Kidneys and Urinary Tract (CAKUT) are the leading cause of chronic kidney disease before 25 years of age. In previous studies, we have proposed *ENPP6*, encoding a membrane-bound choline-specific phosphodiesterase, as a potential novel candidate gene for monogenic CAKUT.

Methods: Segregation analysis of a potentially pathogenic *ENPP6* variant (c.727A>G; p.M243V) was performed via exome sequencing in a family with CAKUT and correlated with choline metabolites in urine samples measured via mass spectrometry. A fluorescent probe cell assay was established to quantify the enzymatic activity of full-length human wildtype and mutant ENPP6.

Results: In parents and four brothers, we detected a potentially pathogenic homozygous *ENPP6* variant (c.727A>G; p.M243V) in a boy with posterior urethral valves and neurogenic bladder. Both parents and two brothers are unaffected heterozygous

carriers. One brother is biallelic wildtype. We collected urine samples from the whole family and detected the phosphocholine metabolite beta-GPC exclusively in the urine of the affected boy. These findings are consistent with urine analysis on published *Enpp6* knockout mice. Next, we demonstrated that wildtype full-length human *ENPP6* transiently overexpressed in HEK293 cells catalyzes the release of strongly fluorescent 2-Me-4OMe TG from a non-fluorescent synthetic probe (TG-mPC) consisting of the ENPP6 substrate phosphocholine linked to the fluorophore Tokyo green in a time and concentration-depended manner. Mutated ENPP6^{M243V} had reduced release of fluorescent 2-Me-4OMe TG compared to wildtype ENPP6.

Conclusions: This study provides functional evidence that biallelic variants in *ENPP6* can cause human CAKUT.

A Novel CLC-Kb Pore Mutation Disrupts Glycosylation and Associates with Distal Tubular Remodeling

Robin H. Lo,[1] Yogita Sharma,[1] Victor N. Tomilin,[2] Holly A. Deremo,[1] Wuxing Dong,[1] Vivek Charu,[1] Neeraja Kambham,[1] Kerim Mutig,[3,4] Oleh Pochynyuk,[2] Vivek Bhalla.[1] *[1]Stanford University School of Medicine, Stanford, CA; [2]The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX; [3]Charite Universitatsmedizin Berlin, Berlin, Germany; [4]Pervyj Moskovskij Gosudarstvennyj Medicinskij Universitet Imeni I M Secenova, Moskva, Russian Federation.*

Background: Bartter's and Gitelman's syndromes are inherited, monogenic autosomal recessive tubulopathies resulting in defects of renal electrolyte handling with a propensity for chronic kidney disease. One type of Bartter's syndrome involves inactivating mutations in *CLCNKB*, a gene encoding the chloride channel CLC-Kb expressed on the basolateral membranes of the thick ascending limb and the distal tubule. Here, we identified a family with a mixed Bartter's/Gitelman's phenotype and early-onset kidney failure and employing a candidate gene approach, discovered a novel mutation (ntG499T, G167C) in exon 6 of *CLCNKB* in the index patient.

Methods: The mutation was identified via Sanger and whole exome sequencing. Wild type and mutant *CLCNKB* plasmid constructs were generated and transfected *in vitro* for electrophysiological analysis via patch-clamp experiments. Wild type and mutant CLC-Kb N-link glycosylation patterns were analyzed by Endo H or PNGase F digestion and localization by cell surface biotinylation or subcellular fractionation. Nephrectomy samples from the index patient and healthy controls were used for histology, morphometry, and qualitative immunofluorescence.

Results: Compared to wild type CLC-Kb, the G167C mutant conducted less current. The G167C mutation also caused impaired N-linked CLC-Kb glycosylation. By targeted mutagenesis of potential CLC-Kb glycosylation sites, we demonstrated that complex N-linked glycosylation at Asn-364 glycosylation is required for proper channel function but not for its surface expression. Moreover, using other known CLC-Kb mutations, we deduced that lack of glycine rather than gain of cysteine is responsible for the findings. Morphologic evaluation of kidney biopsies revealed basolateral localization of mutant G167C CLC-Kb in cortical distal tubular epithelia. However, we detected attenuated expression of distal sodium transport proteins, changes in abundance of distal tubule segments, and hypokalemia-associated intracellular condensates from the index patient compared to control nephrectomy specimens.

Conclusions: We demonstrate a novel regulatory mechanism of CLC-Kb activity by glycosylation and demonstrate nephron remodeling caused by mutant CLC-Kb, with implications for renal electrolyte handling, blood pressure control, and kidney disease.

Characterization of a Novel Mutation Associated with Renal Tubular Acidosis

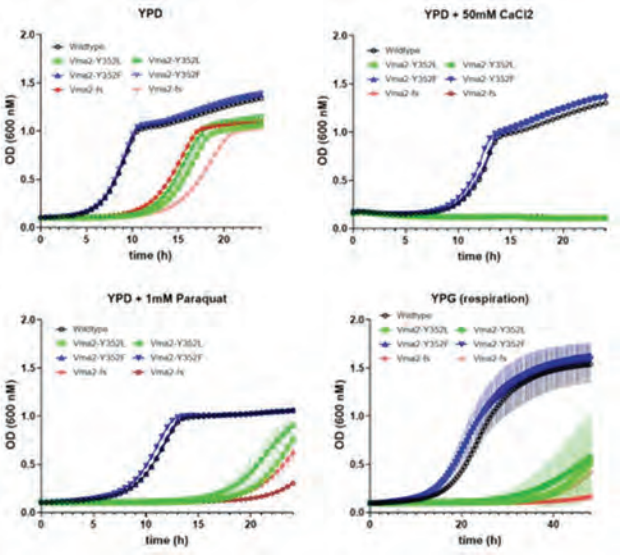
Christopher M. Bernert,[1] Bryce Mendelsohn,[2] Anne S. Salyer,[2] Anna K. Breen,[1] Brian Wasko.[1] *[1]Western University of Health Sciences College of Osteopathic Medicine of the Pacific-Northwest, Lebanon, OR; [2]Kaiser Permanente, Oakland, CA.*

Background: Primary Distal Renal Tubular Acidosis (dRTA) is a condition involving an impaired ability of the distal renal tubules to remove protons from blood. *ATP6V1B1* encodes a kidney specific protein subunit of the V-ATPase proton pump involved in acid secretion into urine. A patient with classic dRTA has been identified with a de novo single nucleotide polymorphism (SNP) in *ATP6V1B1*, resulting in a Phe365Leu mutation of uncharacterized pathogenicity. Evolutionary conservation between *Homo sapiens ATP6V1B1* and *Saccharomyces cerevisiae* (yeast) *VMA2* allows for the use of yeast to elucidate the impact of the novel *ATP6V1B1* mutation on V-ATPase function.

Methods: CRISPR/Cas9 was used to generate yeast strains expressing *VMA2* Tyr352Leu, which serves as an analogous mutation to *ATP6V1B1* Phe365Leu. Additional yeast strains were generated containing Tyr352Phe as well as a frameshift mutation for use as controls. V-ATPase function was assessed by assaying *S. cerevisiae* growth under conditions previously shown to inhibit growth of V-ATPase mutants. The growth assays included control YPD media, YPD with 50 mM $CaCl_2$, YPD with 1 mM paraquat (forming reactive oxygen species), and glycerol containing YPG media (to induce respiration).

Results: *S. cerevisiae* haploid strains containing a *VMA2* Tyr352Leu mutation were found to exhibit growth phenotypes consistent with a complete loss of V-ATPase activity, including an inability to grow when exposed to 50 mM $CaCl_2$, an inability to grow under respiratory conditions, and sensitivity to reactive oxygen species. Yeast containing the humanized *VMA2* Tyr352Phe mutation were not found to display these phenotypes.

Conclusions: Our results provide supportive evidence that a Phe365Leu mutation within *ATP6V1B1* results in a loss of function and thus is highly probable to contribute to dRTA.



Growth of haploid yeast *VMA2* mutants under various assay conditions.

SA-PO631

Identification of Pathogenetic Pathways in Autosomal Dominant Tubulointerstitial Kidney Disease Due to Mutations in REN

Celine Schaeffer,[1,2] Maurizio De Fusco,[1] Elena Pasqualetto,[1] Caterina Scolari,[1,3] Santo Diprima,[1] Claudia Izzi,[4,5] Francesco Scolari,[4,5] Luca Rampoldi.[1,2] Molecular Genetics of Renal Disorders Unit. *[1]IRCCS Ospedale San Raffaele, Milano, Italy; [2]Universita Vita Salute San Raffaele, Milano, Italy; [3]Universita degli Studi di Torino, Torino, Italy; [4]Universita degli Studi di Brescia, Brescia, Italy; [5]Azienda Socio Sanitaria Territoriale degli Spedali Civili di Brescia, Brescia, Italy.*

Background: Autosomal Dominant Tubulointerstitial Kidney Disease (ADTKD) is a rare genetic disorder leading to progressive chronic kidney disease. ADTKD is caused by mutations in different genes including *REN* encoding for renin. Renin is a secreted protein composed of 3 domains: the leader peptide allowing its insertion in the endoplasmic reticulum (ER), a pro-segment regulating its protease activity, and the mature part. Mutations in mature renin lead to ER retention of mutant protein and to a late onset disease, while mutations in the leader peptide, associated with defective ER translocation, and mutations in the pro-segment, accumulating in the ER-to-Golgi compartment, lead to early onset disease.

Methods: We used transiently and stably transfected cells to further investigate the effect of mutations on renin trafficking and performed RNA sequencing on cells expressing renin isoforms under an inducible Tet-ON promoter.

Results: We demonstrate an unprecedented effect of mutations in the leader peptide and pro-segment leading to full or partial mistargeting of mutated protein to mitochondria. The pre-pro sequence of renin, carrying mutation in either the leader peptide or the pro-segment, is necessary and sufficient to drive mitochondrial rerouting. In turn, this leads to mitochondrial import defect and mitochondria fragmentation. Transcriptome profiling of cells expressing mutant renin isoforms in the leader peptide (L16R, L16del), pro-segment (E48K) and mature part (L381P) clearly shows that mutants mislocalised to mitochondria induce similar cellular responses that are only partly overlapping with the ones observed for the ER retained mutant. Specific responses are consistent with the observed trafficking defect (i.e ER stress and Unfolded Protein Response for the ER retained mutant and signs of mitochondrial dysfunction in mutants misrouted to mitochondria). However, all mutants converge to the induction of similar stress molecules as CHOP.

Conclusions: Despite the different cellular phenotype (mitochondrial vs ER localisation) and the severity of the associated clinical features, all ADTKD renin mutations converge to similar kidney damage. We are currently investigating how this endpoint is reached starting from stress signals emerging from the ER and mitochondria.

SA-PO632

Mesencephalic Astrocyte-Derived Neurotrophic Factor (MANF) Is Indispensable for Maintaining Mitochondrial Homeostasis in Uromodulin-Associated CKD

Yili Fang,[1] Chuang Li,[1] Chenjian Gu,[1] Anuradhika Puri,[1] Meredith Jackrel,[1] Maria Lindahl,[2] Ying M. Chen.[1] *[1]Washington University in St Louis, St Louis, MO; [2]Helsingin yliopisto, Helsinki, Finland.*

Background: Autosomal dominant tubulointerstitial kidney disease due to uromodulin mutations (ADTKD-*UMOD*), a leading hereditary kidney disease, has no targeted therapies. UMOD is expressed in the thick ascending limb (TAL) tubules, and mutant UMOD causes endoplasmic reticulum (ER) stress. Mesencephalic astrocyte-derived neurotrophic factor (MANF) is a novel ER resident molecular chaperone and ER stress-inducible secreted protein. The biological role of endogenous MANF in the regulation of mitochondrial function has not been studied.

Methods: CRISPR was utilized to generate the first *Umod* deletion mutation mouse model carrying *Umod* p.Y178-R186del, analogous to human H177-R185del, the most prevalent human mutation. To assess the function of MANF in ADTKD, tamoxifen-inducible TAL-specific MANF knockout mice were generated. Meantime, stable HEK cell line harboring WT or H177-R185del UMOD was established, and shRNA was employed to knockdown MANF *in vitro*. Bood urea nitrogen was monitored along the disease course. Immunoblotting, q-PCR and immunofluorescence staining were employed. Mitochondria function was assessed by electron transport chain protein expression, OROBOROS Oxygraphy system and Seahorse assay.

Results: MANF is induced in the TALs carrying the *Umod* deletion mutation. Genetic ablation of MANF in the mutant TALs suppresses phosphorylation of AMP-activated protein kinase (AMPK) and downstream expression of peroxisome proliferator-activated receptor gamma coactivator 1α (PGC1α) and forkhead box O3 (FOXO3) in isolated primary TAL cells, resulting in impaired mitochondrial biogenesis/oxidative phosphorylation and mitophagy, respectively. The *in vitro*results are in line with the *in vivo* findings. Consequently, MANF deficiency in TALs activates mitochondrial DNA leak-induced STING (stimulator of interferon genes) signaling and hyperinflammation, leading to accelerated renal fibrosis and kidney dysfunction in ADTKD.

Conclusions: For the first time, we discover that MANF is required to maintain mitochondrial homeostasis and acts as a critical molecular linker between ER and mitochondria homeostasis in ADTKD. The key role of MANF in mediating ER-mitochondria crosstalk may also have important implications in other protein misfolding diseases, such as Alzheimer.

SA-PO633

Unraveling the Role of Mitochondrial Dysfunction in the Pathogenesis of Clc-k2-Deficient Bartter Syndrome Mice

Amir Zaidi, Emily Morrison, Yiwen Chen, Chih-Jen Cheng. Cheng Lab. *University of Iowa, Carver College of Medicine, Iowa city, IA.*

Background: Mutations in human ClC-Kb (Clc-k2 in mice) lead to Bartter syndrome (BS) type 3, a congenital renal tubulopathy. Our previous research showed the constitutive deletion of Clc-k2 in mouse kidneys hindered the postnatal development of thick ascending limbs (TALs) through mechanisms not yet fully understood. Our recent extracellular flux analysis revealed that low transport activity in renal tubules resulted in low mitochondrial mass and respiratory capacity. This alarming discovery prompted us to delve deeper into the mitochondrial functions in Clc-k2-deficient TALs and explore the potential of peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC1-α), the master activator of mitochondrial biogenesis, in rescuing Bartter syndrome.

Methods: We analyzed the mitochondrial biogenesis and bioenergetics in isolated TALs using mitochondrial DNA copy numbers, seahorse-based mitochondrial assays, and electron microscopy. We also conducted a comparative transcriptome analysis using isolated Clc-k2 KO vs. wild-type TALs. Uromodulin-positive TAL/DCT cells were pulled down and used for cell cycle and proliferation assays. Pseudohypoaldosteronism type 2 (PHA2) WNK4$^{D561A/+}$ mutant knockin mice and PGC1-α transgenic mice were crossed with Clc-k2 KO mice to rescue the transport activity/mitochondrial function, respectively. Mouse phenotypes then analyzed and compared.

Results: Clc-k2-deficient TALs had reduced mitochondrial-to-nuclear DNA ratio and mitochondrial respiratory capacities, indicating downregulated mitochondrial biogenesis and bioenergetics. Transcriptome analysis confirmed suppression of mitochondrial genes in Clc-k2-deficient TALs. These cells were prone to G1-S cell cycle transition and proliferation delay. PHA2 WNK4$^{D561A/+}$ mutant improved the mitochondrial mass/function, cell cycle, and proliferation of Clc-k2-deficient TAL cells and rescued the activity of NKCC2 and NCC cotransporter of Clc-k2-deficient mice. Overexpression of PGC1-α in Clc-k2 KO mice improved mitochondrial function of TAL, NKCC2/NCC activities, and BS phenotype.

Conclusions: Our results support that low transport activity suppresses mitochondrial biogenesis/bioenergetics in renal tubules, thereby aggravating renal salt wasting, cell cycle delay, and TAL hypoplasia in Clc-k2-deficient BS mice. Mitochondrial-targeting therapy could be promising to BS.

Novel Models to Study Fanconi Syndrome and CKD Due to Heterozygous GATMP341L Mutations

Daniel F. Arroyo Ariza,[1] Rhea Singal,[1] Andrew S. Allegretti,[2] Benjamin D. Humphreys,[1] Harald Jüppner,[2] Ignacio A. Portales Castillo.[1] *[1]Washington University in St Louis, St Louis, MO; [2]Massachusetts General Hospital, Boston, MA.*

Background: Autosomal dominant Fanconi syndrome due to *GATM* mutations (GATM-FS) presents during childhood with evidence of proximal tubular (PT) dysfunction and progresses to end stage kidney disease in adults. Kidney biopsies of patients with GATM-FS show PT injury and Arginine:glycine amidinotransferase (AGAT), the enzyme encoded by *GATM*, accumulates in PT mitochondria. Besides renal dysfunction, we found lower levels of guanidinoacetate (GAA) and creatine in patients with *GATM* P341L mutations. To further study the pathophysiology of this disease, we tested the enzymatic function of AGAT P341L using patient-derived cells, generated human kidney organoids and a novel Gatm^{P341L} mouse.

Methods: GAA synthesis by the AGAT mutant was measured in patient-derived immortalized lymphocytes using stable isotopes of arginine and glycine, and the effect of creatine on *GATM* expression was assessed in wild-type kidney organoids. We generated mice carrying the Gatm^{P341L} mutant, using CRISPR/Cas9 methodologies.

Results: In comparison to wild-type cells, GAA synthesis by patient-derived GATM$^{P341L+/-}$ LCL cells was reduced by ~50%, consistent with our findings of low GAA and creatine in plasma and urine of affected patients. Creatine supplementation (5 g daily) restored plasma creatine levels in a patient with GATM-FS, and in vitro creatine (10 mM) down-regulated AGAT expression in kidney organoids. At 4 weeks of age, Gatm$^{P341L/+}$ mice showed higher phosphate excretion than wild-type littermates (median Pi/Cre: 0.97 vs 0.42, $p<0.05$). At 8 weeks, blood urea nitrogen also tended to be higher in plasma of Gatm$^{P341L/+}$ vs wild-type mice, 66.5 vs 21.8 mg/dl in males.

Conclusions: Our results support the hypothesis of deficient creatine metabolism in GATM-FS and the possible use of low levels of GAA as biomarker of this disease. We now developed several promising experimental models, kidney organoids, LCLs, and Gatm$^{P341L/+}$ mice for evaluating the role of abnormal creatine metabolism in renal disease and the potential therapeutic effect of creatine supplementation in GATM-FS.

SA-PO635

Establishment of a Quantitative Evaluation System for Interferon Pathways in Patients with Lupus Nephritis

Jiahui Zhang, Yangyang Zhang, Ying Jin, Changming Zhang, Zhihong Liu. *National Clinical Research Center of Kidney Diseases, Jingling Hospital, Nanjing University School of Medicine, Nanjing, China.*

Background: The interferon (IFN) pathway is one of the important pathogenic factors of lupus nephritis (LN), however, there is currently a lack of unified and clear quantitative assessment scoring system for its expression level, making difficulties in its applications in clinical practice.

Methods: RNAseq of 271 LN patients (before IFN-inhibition: n=261; after IFN-inhibition: n=10) and 94 healthy controls were conducted. ROC analysis were used to analyze the best performing scoring model. Data distribution analysis were made by R-mclust.

Results: Pivotal IFN genes in LN were highly expressed in patients, and decreased after JAK inhibitor therapy (**Fig 1A)**. The analyses based on different datasets of LN patients resulted in two sets of genes, named 11-gene and 14-gene **(Fig 1B)**. The z-score algorithm was used to calculate IFN scores based on each gene sets. The set of 11-gene had the best performance as LN biomarkers, followed by 14-gene set. And the previous reported gene sets generated from wider spectrum of autoimmune diseases had relatively lower AUC values **(Fig 1C)**. Besides, the 11-gene score (IFN11) had bimodality of expression with different data distribution ranges and trends in different cells **(Fig 1D)**, indicating the necessity to establish different thresholds for whole blood and PBMCs, two common materials for clinical tests, and the bimodality can provide basis for threshold delineation.

Conclusions: It is very feasible to develop a specialized IFN scoring system for LN patients, and IFN11 has good clinical application prospects in assessing disease status, guiding treatment, and predicting the risk of recurrence in clinical practise.

Funding: Government Support - Non-U.S.

The preliminary screening of characteristic genes in the IFN pathway through differential expression analysis. **B.** IFN gene sets previously reported (28IRS and score A) and obtained from this study (11-gene and 14-gene). **C.** ROC analysis of several IFN gene sets. **D.** The bimodality of 11-gene IFN score.

SA-PO636

Chromatin Conformation and Histone Modification Profiling across Human Kidney Anatomic Regions

Dian Li,[1] Haikuo Li,[1] Pierre Isnard,[1] Benjamin D. Humphreys.[1,2] *[1]Division of Nephrology, Department of Medicine, Washington University in St. Louis, St. Louis, MO; [2]Department of Developmental Biology, Washington University in St. Louis, St. Louis, MO.*

Background: Delineating human kidney anatomical structures using high-throughput transcriptomic methodologies has provided a deeper understanding of region-specific function and pathophysiology. Less is known concerning epigenetic mechanisms, such as 3D chromatin architecture and histone modification and how this changes in different kidney cell types and regions.

Methods: We leveraged our recently developed high-yield nuclei extraction method to simultaneously profile chromatin conformation capture with Hi-C and H3K4me3/H3K27 histone modification with Cleavage Under Targets and Release Using Nuclease (CUT&RUN) sequencing samples of human kidney cortex, medulla, and papilla dissected from a healthy donor. We also performed inter-study comparisons of 3 previously published CUT&RUN datasets.

Results: We generated 6 Hi-C and 18 CUT&RUN libraries, at an average depth of 578 million and 19 million reads. We built Hi-C chromatin contact maps for each kidney region at a resolution of 5,000 bp and inter-region difference maps. We observed that long-cis interactions (>20 kb apart), accounted for >50% of the contact events. Interestingly, we identified region-specific contact enrichments along with their marker genes (RUNX1, Fig. 1A). Regarding CUT&RUN, we detected that over 75% of H3K4me3 (enhancer) peaks were localized to the promoter regions, and 34% to 51% of H3K27me3 (repressor) peaks over distal intergenic regions. Similarly, we identified variations in peak abundances across different kidney regions, with the medulla accounting for the fewest peaks for both histone modifications (Fig. 1B).

Conclusions: We describe a comprehensive epigenetic landscape across human kidney anatomical regions. Importantly, we identified region-specific epigenetic modifications which further emphasizes at a molecular level the importance of segment-specific differentiation of the human kidney.

Targeted Delivery of Small Interfering RNA (siRNA) to Proximal Tubule Cells in the Kidneys

Shiying Ding,[1] Kimberly R. Long,[2] Jeremy Cunniff,[1] Johnny Lucas,[1] Haojing Rong,[1] Adam Belanger,[1] Hongmei Zhang,[1] Jonathan F. Lawrence,[1] Youssef Rbaibi,[2] Ora A. Weisz,[2,3] Alfica Sehgal.[1] *[1]Judo Bio, Cambridge, MA; [2]University of Pittsburgh Department of Medicine, Pittsburgh, PA; [3]University of Pittsburgh Department of Cell Biology, Pittsburgh, PA.*

Background: Small interfering RNA (siRNA) is a clinically validated therapeutic modality, which silences gene expression via RNA interference (RNAi). Although siRNAs are secreted through the kidney, siRNA mediated knock-down in the kidney is still limited, largely due to challenges with optimal delivery. Proximal tubule epithelial cells (PTECs) within the nephron are attractive targets for utilizing RNAi, where the primary mode of entry is likely endocytic uptake. Here we describe a targeted approach to deliver conjugated siRNAs exploiting the PTECs' internalizing receptors. Understanding the mechanisms of siRNA uptake in kidney PTECs is pivotal for developing efficient and safe delivery platforms targeting renal diseases.

Methods: In the present study, we investigated siRNA uptake in vitro and in vivo using conjugated siRNAs. A well-differentiated, opossum kidney (OK) PTECs cell line was used as a model system to mimic proximal tubule biology both morphologically and functionally, for studying siRNA uptake. Fluorescently tagged siRNAs were employed to observe uptake and intracellular trafficking. Additionally, siRNAs conjugated with target ligands were administered in mice to assess exposure in vivo, measured by mass spectrometry and microscopy. We further measured siRNA mediated knock-down across multiple genes in mouse kidneys.

Results: The siRNAs were taken up by OK cells in both time and concentration dependent manners, predominantly from the apical surface. We further studied the mechanism of conjugated siRNA uptake using specific inhibitors and cell specific knockouts of various PTEC endocytic receptors. Conjugation with selected ligands of megalin significantly enhanced siRNA uptake both in OK cells and in mouse kidneys. In addition, these conjugations led to significant gene knock-down across multiple targets.

Conclusions: The work suggests that PTECs employ megalin to facilitate siRNA uptake via endocytosis and can be used for gene silencing. Elucidating the mechanism(s) for siRNA uptake in the proximal tubule aids in the development of RNA-based therapeutics. Future work will focus on ligand conjugation optimization and chemical modification to improve kidney specific silencing activity.

Towards a Translatable Model for Studying Therapeutic Efficacy in Alport Syndrome

Yanling Zhang, Linda Nghiem, Hai Wang, Kerri Thai, Chiara Oliveira, Richard E. Gilbert. *Unity Health Toronto, Toronto, ON, Canada.*

Background: Reducing GFR loss is the primary outcome for studying therapeutic effectiveness in Alport syndrome (AS). Unlike humans, standard dose ACE inhibition (ramipril 10 mg/kg) almost completely normalizes the kidney in the Col4a3 KO (AS) mouse. We sought to establish a model with more similarity to its human counterpart by (1) comparing the reliability of GFR methods, and (2) using GFR as the primary outcome to establish a model for testing agents on top of ACE inhibition.

Methods: *Study 1* GFR was measured (mGFR) in wild type and Col4a3 KO mice comparing the gold standard of fluorescein-labeled sinistrin (inulin analogue) with plasma creatinine, BUN and cystatin C. In *Study 2*, having established cystatin C as a preferred method, we assessed the ACE inhibitor dose-response relationship, aiming for an approximate 50% improvement in GFR, akin to human disease. Urinary ACR, glomerulosclerosis and interstitial fibrosis were also assessed.

Results: *Study 1.* At 8 weeks of age, the between group difference between WT and Col4a3 KO was 11-fold for sinistrin-GFR, 4.9 fold for plasma creatinine, 2.6 fold for BUN and 6.9 fold for cystatin C. All comparisons $p < 0.001$. *Study 2 (Table 1).* In comparison with untreated Col4a3 KO mice, ramipril induced dose-dependent reductions in cystatin C. ACR, glomerulosclerosis and interstitial fibrosis while near-normalized by ramipril 10 mg/kg were unaffected by lower doses.

Conclusions: Changes in cystatin C most closely resemble sinistrin-based mGFR. ACE inhibition with ramipril provided dose-dependent improvements in cystatin C with an approximate 50% reduction at 1 mg/kg, akin to findings of standard of care in humans. Accordingly, 1 mg/kg may be an appropriate dose to use in studies testing the efficacy of new additive agents. The dynamic range for UACR, GSI and IF may be too narrow to allow for such testing.

Oral L-lysine Treatment Ameliorates Proximal Tubular Damage in Mice with Alport Syndrome

Suresh K Ramakrishnan,[1] Jiayi Li,[1] Verena Rickert-Zacharias,[1] Jeffrey H. Miner,[2] Matias Simons.[1] *[1]UniversitatsKlinikum Heidelberg, Heidelberg, Germany; [2]Washington University in St Louis School of Medicine, St Louis, MO.*

Background: Chronic kidney disease (CKD) is characterized by a long-term decline of kidney function. Proteinuria induced by glomerular damage is one of the hallmarks of CKD. Apart from the glomerular damage, the increased tubular load of proteins and protein-bound lipids can damage proximal tubular cells (PTC), causing tubulointerstitial fibrosis. Treatment with the basic amino acid L-lysine, which is shown to be safe in humans, has been shown to inhibit protein uptake in PTC. Therefore, we hypothesized that blocking PTC protein uptake via L-lysine might protect against tubulointerstitial damage in glomerular diseases, such as Alport syndrome.

Methods: *Col4a3* Wildtype (WT) and knockout (Alport mice) in 129/Sv background were treated with and without L-lysine chloride (50mg/ml) in drinking water from 5 weeks of age for 3 weeks. Blood gas analysis and transdermal glomerular filtration rate (GFR) was measured. Kidney samples were analyzed for histology and injury markers. Induced renal epithelial cells (iRECs) grown on filters were used. Albumin-Alexa 647 uptake studies were performed upon treatment with different concentrations of L-Lysine chloride. Lipotoxic effects were studied upon treatment with albumin-bound palmitic acid.

Results: We observed a significant increase in albuminuria on day 1 of the L-Lysine treatment in both WT and Alport mice. Interestingly, there was a progressive decrease of albuminuria in L-Lysine-treated Alport male mice starting from week 1 to the end of the study. Gene expression of kidney injury and fibrosis markers were significantly ameliorated in the Alport male mice treated with L-lysine. No change in GFR was found between the groups. Albumin uptake was reduced in iRECs treated with L-lysine. We confirmed that iRECs express megalin and cubilin on the apical surface when plated on Transwell filters. L-lysine treatment significantly decreased the lipotoxicity exhibited upon addition of palmitic acid.

Conclusions: Our preliminary data suggests that oral L-Lysine treatment has beneficial effects in Alport mice. We are currently performing proteomics and metabolomics on renal cortical samples on these mice to identify the mechanisms underlying the protective effects. In the future, L-Lysine could be proposed as an efficient and safe therapeutic strategy to prevent proximal tubular damage in glomerular diseases.

SA-PO640

Kidney Protection by a Novel Keap1-Nrf2 Protein-Protein Interaction Inhibitor for a Mouse Model of Alport Syndrome

Jun Horizono,[1] Shota Kaseda,[1,4] Yuya Sannomiya,[1] Mary Ann Suico,[1] Hirohiko Fukiya,[2] Hidetoshi Sunamoto,[2] Hiroshi Watanabe,[3] Takehiro Nakano,[3] Kai Tokumaru,[3] John B. Davenport,[4] Tsuyoshi Shuto,[1] Rachel Lennon,[4] Kazuhiro Onuma,[2] Hirofumi Kai.[1] *[1]Department of Molecular Medicine, Graduate School of Pharmaceutical Science, Kumamoto University, Kumamoto, Japan; [2]Pharmaceuticals Research Laboratory, UBE Corporation, Yamaguchi, Japan; [3]Department of Biopharmaceutics, Graduate School of Pharmaceutical Sciences, Kumamoto University, Kumamoto City, Japan; [4]Wellcome Centre for Cell-Matrix Research, University of Manchester, Manchester, United Kingdom.*

Background: Keap1-Nrf2 pathway plays an important role in the defense mechanism against oxidative stress in the kidney. We have shown that UBE-1099, a Keap1-Nrf2 protein-protein interaction (PPI) inhibitor, exerts renoprotective effects in Alport syndrome (AS) mice (*Kidney 360*, 2022). Furthermore, we found a more promising Keap1-Nrf2 PPI inhibitor UD-051 having a high Nrf2 activation potency at lower concentrations. In the present study, we aim to elucidate the effects of UD-051 on AS pathophysiology.

Methods: We studied the effects of UD-051 using AS (Col4a5-G5X) and Nrf2 KO-AS mice. In addition, we evaluated the survival of AS mice treated with UD-051 in combination with losartan, an angiotensin II receptor blocker (ARB).

Results: UD-051 improved the glomerular and tubular damage, renal inflammation, and fibrosis in AS mice. UD-051 transiently increased proteinuria in AS mice. The renoprotective effect of UD-051 and the transient increase in proteinuria were abolished in Nrf2 KO-AS mice. Interestingly, UD-051 suppressed the albumin accumulation in the proximal tubules of AS mice, and decreased the expression of albumin reabsorption transporter megalin. These results suggest that UD-051 inhibits excessive albumin reabsorption in the tubules of AS mice and exerts a tubular protective effect. Moreover, UD-051 decreased oxidized albumin ratio (OAR), the clinical biomarker for the progression of kidney disease in the plasma of AS mice. Importantly, OAR highly inverse correlated with the expression level of *Nqo1* which is the Nrf2 target gene in vehicle- and UD-051-treated AS mice kidney tissue, suggesting that OAR is a highly sensitive biomarker that reflects Nrf2 activity in kidney tissue. Notably, survival studies showed that UD-051 (3 mg/kg, *p.o.*) increased the median survival of AS mice by 22 %, losartan alone by 8.4%, and the combination of UD-051 (3 mg/kg, *p.o.*) and losartan extended the median survival by 65% more than the vehicle-treated AS mice.

Conclusions: The present study demonstrated a renoprotective effect of UD-051. The results also suggest that the combination treatment with UD-051 and ARBs may be useful for AS and other chronic kidney diseases.

SA-PO641

Protective Effect of Ambrisentan on Proteinuria in Patients with Alport Syndrome

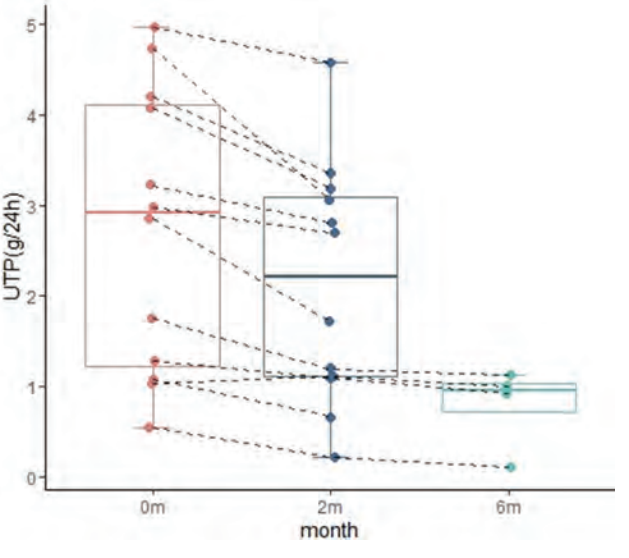
Zhuoran Song, Yang Li, Hong Zhang, Xu-jie Zhou. *Peking University First Hospital Department of Nephrology Renal Division, Beijing, China.*

Background: In recent years, endothelin receptor antagonists (ERAs) have stepped into the spotlight of chronic kidney disease treatment, showing a significant reduction in proteinuria and preservation of kidney function, such as SONAR study in diabetic nephropathy, DUPLEX trial in focal segmental glomerulosclerosis (FSGS) and PROTECT trial in IgA nephropathy. However, whether they are effective in Alport syndrome (AS) is unclear.

Methods: This was a real-world study. AS patients that had been treated with RAASi or RAASi combined with sodium-dependent glucose transporters 2 inhibitors (SGLT2i) / mineralocorticoid receptor (MRA) in stable doses for at least 3 months but still with proteiuria (>0.5g/d)and eGFR>25 ml/min/1.73m^2 were included. All of them received ambrisentan 5 mg daily. Efficacy was assessed by the changes in proteinuria. The safety outcomes included renal function change and tolerance.

Results: In total, 12 patients with AS were included. The mean baseline 24-hour urinary protein (UTP) (±SD) was 2.73 ± 1.56g/d and decreased to 2.14 ± 1.32g/d after two-month treatment (P=0.001). The mean eGFR was stable in the two months (mean 57.08 vs. 58.98 ml/min/1.73m^2 at baseline). 2 patients discontinued due to edema and 2 due to headache in the second month. Other patients never reported any side effects. Among the patients, four have been followed over 6 months with additional 4 months follow-up data. We observed a continued decrease trend in urinary protein, additional 20.85±10.67% from the second month in the UTP reduction, and 36.61±16.06% reduction from the baseline. The eGFR remained stable.

Conclusions: The pilot study suggests that introducing of ERA on top of RAASi with or without SGLT2i/MRA provides an additional antiproteinuric effect in AS.



SA-PO642

Adeno-Associated Virus (AAV)-Mediated Gene Therapy in Nphs1 Knockout Mice: A Strategy for Treating Congenital Nephrotic Syndrome

Ken Saida,[1] Seyoung Yu,[1] Alina Braun,[1] Gijs A. Franken,[1] Kraisoon Lomjansook,[1] Katharina Lemberg,[1] Caroline M. Kolvenbach,[1] Bshara Mansour,[1] Kirollos Yousef,[1] Korbinian M. Riedhammer,[1] Nils D. Mertens,[1] Izzeldin Elmubarak,[1] Ronen Schneider,[1] Shirlee Shril,[1] Florian Buerger,[1,2] Friedhelm Hildebrandt.[1] *[1]Boston Children's Hospital, Boston, MA; [2]University Children's Hospital, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background: Finnish-type congenital nephrotic syndrome (CNS) causes nephrin dysfunction and disrupts glomerular filtration barrier. Podocyte-specific *Nphs1* knockout mouse models recapitulate the human CNS phenotype and have a median survival of 18 days (Buerger F. *Am J Physiol Renal Physiol* 2024). Establishing AAV-based gene therapy in neonatal mice is crucial for treating CNS. Although AAV serotypes exhibit broad organ tropism, efficient kidney targeting, particularly in podocytes, remains challenging. In addition, the efficiency of AAV-mediated gene expression in neonatal mouse kidneys remains unclear.

Methods: Retro-orbital (RO) and intrarenal injections of AAV capsids (AAV9, AAV-PHP.S, AAV-DJ, and AAV-KP1) carrying the CAG promoter and tdTomato were administered to P1 mice (*Nphs1*$^{tm1.1Pgarg}$/J *Nphs2*-Cre^{+} vs. control). The injected AAV dose was >1E+14 vg/kg. For RO injections, 10 µL of AAV was injected into each eye using a 31-gauge insulin syringe under cryo-anesthesia. For intrarenal injections, 10 µL AAV was percutaneously delivered into the left kidney over a minute using a syringe pump. The mice were dissected three weeks post-injection, and transduction efficiency was assessed by immunofluorescence (IF) and flow cytometry (FC).

Results: RO injection in P1 mice resulted in transduction of the proximal tubules and glomeruli. In glomeruli, distinct podocyte transduction was confirmed by super-resolution microscopy. FC analysis of AAV9 and AAV-PHP.S injected mice shows transduced podocytes accounting for >13%, as indicated by the presence of podocalyxin-positive cells expressing tdTomato. Intrarenal injection of AAV-KP1 into the left kidney of P1 mouse resulted in significant tdTomato expression in both tubular and glomerular cells, whereas the uninjected right kidney showed only glomerular transduction. We achieved a podocyte transduction rate of >50% in most of the mature glomeruli via intrarenal injection.

Conclusions: This study demonstrated the feasibility of podocyte transduction, providing a proof-of-principle for AAV gene therapy in a CNS mouse model. Further optimization is required to enhance the efficiency of AAV delivery to podocytes.

SA-PO643

Treatment of Autosomal Dominant Tubulointerstitial Kidney Disease Uromodulin (ADTKD-UMOD) with Antisense Oligonucleotides

Kathy Y. Morgan, Nino Jungels, Christopher Greer, Stephanie Garcia, Emily G. Thompson, Tushare Jinadasa, Xuyu Tan, Kailash Adhikari, Vincent Guerlavais, Ryan Oliver. *Sarepta Therapeutics Inc, Cambridge, MA.*

Background: Autosomal Dominant Tubulointerstitial Kidney Disease-Uromodulin (ADTKD-UMOD) is a genetic disease caused by destabilizing mutations in uromodulin (UMOD). Misfolded UMOD protein aggregates and accumulates inside the loop of Henle and the distal convoluted tubule, leading to progressive and irreversible chronic kidney disease. We hypothesized that peptide-conjugated phosphorodiamidate morpholino oligomers (PPMOs) could knock down *UMOD* expression and potentially reduce the disease-causing UMOD aggregation inside the cells.

Methods: A library of PPMOs was designed to bind to the complementary sequences of the mouse *Umod* gene and induce nonsense-mediated decay. These PPMOs were screened in mIMCD-3 cells, which express endogenous *Umod* to identify the most active compounds. The most efficacious PPMO compound was tested in both wildtype and UMOD C93F mice, a well characterized disease model of ATDKD, to determine the ability of the PPMO to reduce UMOD expression at the transcript and protein levels.

Results: A single dose of PPMO resulted in a 70% knockdown of UMOD protein in WT mice. The reduction in UMOD protein was sustained for at least 28 days. Two subsequent weekly doses of PPMO increased the amount of UMOD knockdown further, demonstrating an additive effect of PPMO dosing over a two week period. Furthermore, Umod MOD protein expression was reduced in the UMOD C93F animals after a single dose of PPMO.

Conclusions: PPMO technology can be used to reduce UMOD transcript and protein levels *in vitro and* in vivo. These findings demonstrate that PPMOs have the potential to preserve renal function in patients with ADTKD.

SA-PO644

Ccr2 Targeting Does Not Ameliorate Disease Phenotype in a Model of UMOD-Related Autosomal Dominant Tubulointerstitial Kidney Disease

Mariapia Giuditta Cratere,[1,2] Francesca Nicola,[1,2] Matteo Trudu,[1,2] Celine Schaeffer,[1,2] Luca Rampoldi.[1,2] Molecular Genetics of Renal Disorders Unit. *[1]Universita Vita Salute San Raffaele, Milano, Italy; [2]IRCCS Ospedale San Raffaele, Milano, Italy.*

Background: Mutations in *UMOD*, encoding uromodulin, cause *UMOD*-related Autosomal Dominant Tubulointerstitial Kidney Disease (ADTKD-*UMOD*). The common gain-of-function effect of *UMOD* mutations is endoplasmic reticulum (ER) retention and aggregation of mutant uromodulin. In a transgenic mouse model of the disease (Tg^{UmodC147W}) we detected significant upregulation of pro-inflammatory chemokines already at one day *post-natal*, well before any sign of kidney damage, suggesting a key role of early inflammation in disease pathogenesis. All upregulated chemokines are ligands of the C-C Motif Chemokine Receptor Ccr2, mainly expressed by circulating monocytes and important for their migration to inflamed sites. Here, we investigated the effect of targeting Ccr2-axis on ADTKD-*UMOD* kidney disease.

Methods: We adopted a genetic approach by generating Tg^{UmodC147W}/*Ccr2*$^{-/-}$ mice that were characterized at 1 week (presymptomatic) and 24 weeks (late disease) of age and compared with both Tg^{UmodC147W}/*Ccr2*$^{+/+}$ and WT/*Ccr2*$^{+/+}$ mice (non-transgenic littermates).

Results: *Ccr2* ablation did not affect *Umod* expression levels nor mutant uromodulin ER retention in kidneys of Tg^{UmodC147W} mice. Following extensive phenotype analysis, we did not observe decreased inflammation, fibrosis and expression of tubular damage markers at any studied timepoint in kidneys of Tg^{UmodC147W}/*Ccr2*$^{-/-}$ mice compared to age-matched Tg^{UmodC147W}/*Ccr2*$^{+/+}$, demonstrating that deletion of *Ccr2* receptor is not sufficient to improve phenotype of Tg^{UmodC147W} mice. To assess possible compensatory inflammatory pathways acting in response to loss of Ccr2 signalling, we studied Ccr1, Ccr3 and Ccr5 axes. Tg^{UmodC147W}/*Ccr2*$^{-/-}$ mice showed increased expression of *Ccr5* (24-weeks of age) and *Ccr1* (1 and 24 weeks of age). These data suggest that *Ccr2* ablation in Tg^{UmodC147W} mice induces compensatory activation of inflammatory pathways contributing to disease onset (*Ccr1*) and sustainment (*Ccr5*) in Tg^{UmodC147W}/*Ccr2*$^{-/-}$ mice.

Conclusions: Our results demonstrate that Ccr2 targeting is not sufficient to block inflammation and prevent kidney disease progression in ADKTD-*UMOD*. These data provide evidence for the context-dependent redundance of Ccr receptors in triggering the inflammatory process.

Funding: Private Foundation Support, Government Support - Non-U.S.

Developing New Therapies for Autosomal Dominant Tubulointerstitial Kidney Disease Caused by Uromodulin Mutations by Screening a Small Molecule Library

Matthias T. Wolf, Rory A. Sebastian, Krish D. Patel, Sung Wan An, Huiyuan Wu. *University of Michigan Michigan Medicine, Ann Arbor, MI.*

Background: Autosomal Dominant Tubulointerstitial Kidney Disease (ADTKD) caused by Uromodulin (*UMOD*) mutations, is the third most common inherited kidney disease. *UMOD* mutations result in a misfolded UMOD protein which is less secreted and accumulates intracellularly resulting in apoptosis and kidney failure. We want to identify new therapies for patients with ADTKD caused by *UMOD* mutations applying a high-throughput screening (HTS) assay.

Methods: We developed stable cell lines expressing C150S or wild-type (WT) UMOD tagged to luciferase. We used the luciferase activity in the cell culture supernatant as the readout how well a compound improved C150S UMOD secretion. 8,000 compounds from the UT Southwestern HTS core library were screened. Best candidates were counter-screened for cell viability, effect on apoptosis, restoring TRPV5 current density (applying patch-clamp recording), and UMOD secretion using an ELISA assay.

Results: The initial screen resulted in 124 candidates which increased C150S UMOD secretion to at least 20% of WT UMOD. We picked the best 99 candidates and confirmed them in triplicates at three different concentrations. Next, we chose the best 24 candidates which increased UMOD secretion to 40% of WT UMOD. To exclude any cytotoxic compounds, we removed 14 of the 24 candidates which reduced cell viability by more than 40%. Out of the 10 remaining candidates three small compounds increased UMOD secretion to 80-100% of WT UMOD. All three small molecules reduced apoptosis by more than 20%. Dose-response curves were performed for all three compounds. Compounds restored TRPV5 current density with C150S UMOD comparable to WT UMOD, and UMOD ELISA assays confirmed UMOD secretion. Western blot studies after treatment with these candidates showed a reduction of caspase 3 and an increase of the endogenous chaperone Hsp70.

Conclusions: Our proof-of-concept study shows that screening of a small molecule library allows to identify potential new therapies for kidney diseases. Thorough counter-screening is required to remove false positive candidates. Further experiments including analysis of the targeted molecular pathway, structure-activity relationships, pharmacokinetics and -dynamics, and *in vivo* experiments in mutant UMOD mice will be required.

Funding: NIDDK Support

SA-PO646

Characterization and Regulation of the Disease-Causing Mucin 1 Frameshift Protein in Patient-Derived Cells Affected by Autosomal Dominant Tubulointerstitial Kidney Disease (ADTKD)-MUC1

Hannah Schwarz,[1] Karl X. Knaup,[1] Florian J. Wopperer,[1] Mario Schiffer,[1] Maike J. Buettner,[2] Kerstin U. Amann,[2] Michael S. Wiesener.[1]
[1]Universitatsklinikum Erlangen Medizinische Klinik 4 Nephrologie und Hypertensiologie, Erlangen, Germany; [2]Friedrich-Alexander-Universitat Erlangen-Nurnberg, Erlangen, Germany.

Background: Autosomal Dominant Tubulointerstitial Kidney Diseases (ADTKD) are rare monogenic diseases of the kidney, which are mainly caused by germline mutations of *UMOD* and *MUC1*, leading to end-stage renal disease (ESRD) usually in mid adulthood. ADTKD-*MUC1* is caused by a characteristic frameshift mutation, leading to the *de novo* protein MUC1-fs. MUC1-fs is believed to play a distinct role in terms of a "toxic proteinopathy", mainly accumulating in TMED9-containing vesicles (Dvela-Levitt et al., Cell 2019). The substance BRD4780 is reported to re-route MUC1-fs towards lysosomal degradation, with interventional trials being in preparation. Therefore, we aimed to gain more insights into MUC1-fs temporal and spacial regulative characteristics with respect to (pharmacological) intervention with TMED9.

Methods: To analyze MUC1-fs protein in more detail, we generated iTCs (immortalized Tubular Cells) from huPTC (human urinary Primary Tubular Cells) of several patients with ADTKD-*MUC1*. Clonal selection of cells was performed to retrieve immortalized clones with MUC1-fs expression. From these cells functional studies including immunoblotting, immunofluorescence and electron microscopy (EM) were performed to analyze the temporal and special expression of MUC1-fs and TMED9 in more detail.

Results: Immunofluorescence studies confirmed that MUC1-fs accumulates in the cytoplasm, possibly the secretory pathway. Co-localization was only partially observed with TMED9 (which localizes to COP vesicles), being involved in protein trafficking within the early secretory pathway. TMED9 negative components of this pathway also showed MUC1-fs staining, such as the Golgi apparatus and Early Endosomes. Immunogold EM of iTCs reveals MUC1-fs expression within the ER and vesicular structures, compatible with the secretory pathway. BRD4780 led to profound reduction of MUC1-fs. However, this effect was not specific. Protein half-life and reconstitution of MUC1-fs after blockade comprise a few hours.

Conclusions: Our data confirm and extend previously published information on intracellular MUC1-fs localization and regulation. The small molecule BRD4780 is effective, but not specific.

Proximal Tubule-Targeted Adeno-Associated Virus (AAV) Gene Therapy for Cystinuria

Jennifer L. Peek,[1,2] Alan Rosales,[3] Julie Qi,[4] Anna Menshikh,[4] Richard C. Welch,[4] Fabian Bock,[4] Lauren E. Woodard,[4,5] Aravind Asokan,[3,6] Matthew H. Wilson.[4,5] *[1]Vanderbilt University Medical Scientist Training Program (MSTP), Nashville, TN; [2]Vanderbilt University Department of Cell and Developmental Biology, Nashville, TN; [3]Duke University Department of Biomedical Engineering, Durham, NC; [4]Vanderbilt University Division of Nephrology and Hypertension, Nashville, TN; [5]VA Tennessee Valley Healthcare System, Nashville, TN; [6]Duke University Department of Surgery, Durham, NC*.

Background: Gene therapy for kidney disease remains a challenge primarily due to lack of gene delivery. Cystinuria, the most common inherited kidney stone disorder, results from deficiency of cystine transport and reabsorption in the proximal tubule. Cystinuria patients suffer from cystine stones, obstruction, and CKD development; effective treatments are lacking for this lifelong disease. We have previously shown significant reductions in urinary cystine levels in murine models of type A (*Slc3a1*$^{-/-}$) cystinuria through plasmid delivery of *Slc3a1*, which encodes rBAT. However, gene transfer was estimated to be <5% of proximal tubular epithelial cells (PTECs) and therefore did not affect stone formation.

Methods: Recent innovations in viral vectors have improved kidney transduction. With novel adeno-associated viruses (AAV) including AAV.cc47, we have shown efficient kidney delivery *in vivo*, *in vitro*, and in human kidney organoids. We have used AAV.cc47 to deliver fluorescent reporters and therapeutic transgenes in both healthy and cystinuric mice. Immunofluorescence analysis and statistics were performed in QuPath and GraphPad Prism, respectively.

Results: We observed that AAV.cc47 consistently targeted the kidney, with >80% of PTECs transduced in all mice injected with at least 1x10^{11} viral genomes (p=0.0011). Further quantification revealed a dose-dependent increase in the % transduced PTECs and strength of transduction. We next identified AAV.cc47 specifically targets S1 and S2 PTECs in the kidney, as >90% of all transduced cells were SGLT2+ (p=0.0009). Finally, we have shown rBAT expression post-delivery of AAV.cc47-*Slc3a1* to cystinuric mice and investigation of phenotypic changes is ongoing.

Conclusions: We have shown *Slc3a1* gene delivery for type A cystinuria gene therapy *in vivo* utilizing a proximal tubule-targeted vector, AAV.cc47. Phenotypic correction of a kidney disease remains a challenge, but our current efforts to optimize the delivery and stable expression of desired transgenes provide hope for overcoming the barriers to kidney gene therapy.

2,8-Dihydroxyadenine Impacts Kidney Cell Health and Barrier Integrity in an In Vitro Model of Adenine Phosphoribosyltransferase (APRT) Deficiency

Hildur R. Helgudottir,[1] Runolfur Palsson,[1,2] Vidar O. Edvardsson,[1,3] Thorarinn Gudjonsson.[1,4] *[1]Faculty of Medicine, School of Health Sciences, University of Iceland, Reykjavik, Iceland; [2]Division of Nephrology, Landspitali University Hospital, Reykjavik, Iceland; [3]Children's Medical Center, Landspitali University Hospital, Reykjavik, Iceland; [4]Division of Laboratory Hematology, Landspitali University Hospital, Reykjavik, Iceland*.

Background: Adenine phosphoribosyltransferase (APRT) deficiency is a rare genetic disorder that results in excessive generation and excretion of 2,8-dihydroxyadenine (DHA), leading to kidney stones and crystal nephropathy. This condition causes inflammation and fibrosis of the kidneys. Although the effects of other types of crystal nephropathies and kidney stone diseases have been studied in cell culture models, the mechanism of DHA-mediated kidney injury is not well understood. This study aimed to establish a comprehensive cell culture model to investigate DHA crystal-induced kidney injury and identify therapeutic targets for clinical intervention.

Methods: Three kidney cell lines, MDCK, HK-2, and HEK293, were tested in both monolayer and 3D cultures, including liquid-liquid interface (LLI) and "on-top" of Matrigel methods. Cells were exposed to DHA at concentrations similar to those found in the urine of APRT-deficient patients. Cell viability and migration assays, RT-PCR, western blotting, phase-contrast microscopy, and immunostaining were used as read-out assays. Immunohistochemistry (IHC) was used to analyze kidney tissue samples from APRT deficiency patients and healthy controls obtained from Landspitali University Hospital Biobank.

Results: DHA exposure decreased kidney cell viability and migration across all cell lines. Rising DHA concentrations increased CD44 expression, suggesting enhanced crystal-binding potential of the kidney cells. In a 3D environment "on-top" of Matrigel, MDCK cells maintained polarized structures despite DHA accumulation and did not show an increase in the EMT phenotype compared with TGFβ-treated cells. MDCK cells formed a polarized cell layer grown on Transwell polyester membranes and demonstrated trans-epithelial electrical resistance (TEER) in LLI, which decreased when the cells were treated with DHA. Analysis of patient kidney tissue samples revealed increased collagen I and III expression, well-known markers of fibrosis, in APRT deficiency patients.

Conclusions: Our findings demonstrate the deleterious effects of DHA on kidney cell health, barrier function, and its potential role in promoting fibrosis in APRT deficiency. Future studies in 3D cultures will focus on further exploring the phenotypic changes in kidney cells after exposure to DHA both at the cellular and molecular level.

SA-PO649

Clinical Utility of a Novel Ultraperformance Liquid Chromatography-Tandem Mass Spectrometry (UPLC-MS/MS) Plasma 2,8-Dihydroxyadenine Assay in Patients with Adenine Phosphoribosyltransferase (APRT) Deficiency

Unnur A. Thorsteinsdottir,[1,3] Hrafnhildur L. Runolfsdottir,[2] Finnur F. Eiriksson,[1,3] Vidar O. Edvardsson,[2,1] Margret Thorsteinsdottir,[1,3] Runolfur Palsson.[2,1] *[1]Heilbrigdisvisindasvid - Haskoli Island, Reykjavik, Iceland; [2]Landspitali, Reykjavik, Iceland; [3]ArcticMass, Reykjavik, Iceland.*

Background: Treatment with a xanthine oxidoreductase inhibitor (XORi), allopurinol or febuxostat, reduces urinary 2,8-dihydroxyadenine (DHA) excretion and slows CKD progression in adenine phosphoribosyltransferase deficiency (APRTd). We have developed and validated an ultra-performance liquid chromatography-tandem mass spectrometry (UPLC-MS/MS) plasma assay for the simultaneous quantification of DHA, adenine, allopurinol, oxypurinol and febuxostat in human plasma. The aims of the current study were to assess the clinical applicability of the assay.

Methods: DHA, allopurinol, oxypurinol and febuxostat were quantified in 82 bio-banked plasma samples using the novel assay. Clinical patient data were obtained from our APRT Deficiency Patient Registry. Plasma DHA concentration was correlated with age, sex, XORi treatment status and estimated glomerular filtration rate (eGFR).

Results: The average plasma concentration was 323 ng/mL for DHA and 292 ng/mL for adenine in untreated (n=28) APRTd patients. When treated with allopurinol 400 mg/day (n= 29) or febuxostat 80 mg/day (n=25), the average concentration of DHA was 61 ng/mL and below the limit of quantification, respectively, and of adenine 818 and 1264 ng/mL, respectively. DHA was not detected in plasma samples from controls (n=9). The average plasma concentration of allopurinol, oxypurinol and febuxostat in patients receiving XORi therapy was 1695 ng/mL, 11612 ng/mL and 313 ng/mL, respectively. There was a moderate negative correlation between the plasma DHA concentration and eGFR in untreated patients. No significant correlation was found between age and sex and the DHA plasma concentration.

Conclusions: The UPLC-MS/MS plasma assay for quantification of DHA, adenine, allopurinol, oxypurinol and febuxostat in human plasma can be used for therapeutic monitoring in APRTd. Measurement of plasma DHA will also be a useful test for the diagnosis of APRTd.

Effect of Allopurinol and Febuxostat on Plasma and Urine 2,8-Dihydroxyadenine: A Clinical Trial

Hrafnhildur L. Runolfsdottir,[1] Unnur A. Thorsteinsdottir,[2,3] Inger M. Agustsdottir,[1] Margret Thorsteinsdottir,[2,3] Runolfur Palsson,[1,2] Vidar O. Edvardsson.[1,2] *[1]Landspitali, Reykjavik, Iceland; [2]Haskoli Islands, Reykjavik, Iceland; [3]ArcticMass, Reykjavik, Iceland.*

Background: In patients with adenine phosphoribosyltransferase (APRT) deficiency, treatment with allopurinol or febuxostat reduces urinary 2,8-dihydroxyadenine (DHA) excretion, preventing stone formation and progression of chronic kidney disease. The aim of this study was to determine the effects of allopurinol 400 and 800 mg/day and febuxostat 40 and 80 mg/day on plasma and urinary DHA levels in patients with APRT deficiency.

Methods: Patients with estimated glomerular filtration rate (eGFR) >30 ml/min/1.73 m^2 listed in the APRT Deficiency Registry of the Rare Kidney Stone Consortium were enrolled in a 168-day clinical trial. Following a 4-week washout period, patients were randomized to a single daily dose of allopurinol 400 mg or febuxostat 40 mg for 28 days, after which the dose was elevated to 800 mg of allopurinol and 80 mg of febuxostat. A second washout period was then followed by cross-over to the alternative study drug. Plasma and urine levels of DHA were measured using an ultra-performance liquid chromatography-tandem mass spectrometry assay, and the urinary excretion expressed as DHA/creatinine ratio.

Results: Seven patients completed the study. Their median (range) age was 57.7 (37.3-65.1) years; 3 were female. The median urinary DHA/creatinine ratio was 7.5 (4.3-14.0) ng/mmol off treatment, 2.1 (1.0-4.9) and 0.79 (0.2-2.2) on 400 and 800 mg of allopurinol, respectively, and 0.6 (0.3-1.0) and 0.6 (0.2-5.4) on 40 and 80 mg of febuxostat, respectively. The median plasma DHA concentration was 289 (216-432) ng/mL during both washout periods and 50 (32-95) ng/mL on 400 mg of allopurinol in 4 patients, while the other 3 patients had concentrations below the level of quantification (BLQ). On allopurinol 800 mg/day, the plasma DHA concentration was BLQ in all but 2 patients, and BLQ in all but 1patient on both doses of febuxostat.

Conclusions: Urinary DHA excretion and plasma concentration was lower in patients on allopurinol 800 mg/day compared to 400 mg/day. There was no apparent difference in DHA plasma concentration or urinary DHA excretion between the two prescribed febuxostat doses. Febuxostat was more efficacious than allopurinol in the prescribed doses.

SA-PO651

Burden of Illness of Primary Hyperoxaluria with CKD

David S. Goldfarb,[1] Jing Voon Chen,[3,4] Olivia Li,[2] Jeffrey R. Skaar,[2] Sandra Salem,[4] Frank Modersitzki.[1] *[1]NYU Langone Health, New York, NY; [2]Trinity Partners LLC, Waltham, MA; [3]Genesis Research LLC, Hoboken, NJ; [4]Novo Nordisk Inc, Plainsboro, NJ.*

Background: Primary hyperoxaluria (PH) is a rare genetic disorder characterized by the overproduction of oxalate, which combines with calcium to form calcium oxalate crystals, leading to kidney stones, CKD, and kidney failure. The burden of illness for people with PH and CKD (PH-CKD) relative to people with CKD alone (non-PH-CKD) is unclear. This study aims to understand epidemiology, patient characteristics, treatment, healthcare resource utilization, and cost of care of people with PH who have normal or impaired kidney function.

Methods: This retrospective, non-interventional, observational study uses real-world US administrative data from the 2017-2021 Merative MarketScan® Commercial Claims and Encounters databases and the 2017-2021 CMS Medicare Fee-For-Service Limited Data Set. The study includes people with PH (at least 1 medical claim with PH diagnosis in 2020-2021 and no secondary hyperoxaluria or Crohn's disease), PH-CKD (PH criteria and at least 1 medical claim with CKD diagnosis in 2017-2021), and non-PH-CKD (no PH or secondary PH diagnosis in 2017-2021 and CKD criteria).

Results: There were ~4,500 people with diagnosed PH in US in 2021; 37% presented with early (stage 1-3; 65%) or advanced (stage 4-5 or end-stage kidney disease [ESKD]; 33%) CKD. People within the PH-CKD group were ~5 years older than the overall PH population. Pharmacotherapy, particularly potassium citrate (33%), was more common in people with PH and early-stage CKD, while people with PH and advanced CKD were more likely to undergo procedural interventions, including dialysis (48%) and kidney transplant (16%). People with PH and advanced CKD had ~13x and ~5x higher median all-cause semi-annual healthcare costs compared to people with only PH or PH-CKD (stage 1-3), respectively. The PH-CKD cohort had higher burden compared to the matched non-PH-CKD group, including higher rates of kidney stones and urinary tract infections ($p<0.05$). The PH-CKD cohort had higher use of potassium citrate (stage 1-3; $p<0.05$) and dialysis (stage 4-5/ESKD; $p<0.05$) compared with the non-PH-CKD. PH-CKD (stage 1-3) had higher utilization and cost differences (~2x) compared to a matched non-PH-CKD cohort.

Conclusions: People with PH-CKD show a higher clinical and economic burden of illness compared to non-PH-CKD people. Among people with PH, the health burden increases with CKD stage.

Evaluation of the Impact of SGLT2 Inhibitor Treatment in a Mouse Model of Dent Disease

Elise de Combiens, Nadia Frachon, Stéphane Lourdel. *Centre de Recherche des Cordeliers, Paris, France.*

Background: Dent's disease is a rare disorder affecting the proximal tubule. It is characterized by urinary loss of low-molecular-weight proteins (LMWPs), and other electrolytes such as calcium. It generally progresses to chronic kidney disease (CKD), and is due to a mutation in the CLCN5 gene encoding the ClC-5 protein which plays a crucial role LMWPs endocytosis. To study the mechanisms involved in the progression of this disease to CKD, we created a Knock In (KI) mouse model carrying a CLCN5 mutation. The transgenic mice develop the main clinical features observed in patients, presents fibrosis and inflammation with age, as well as an alteration of their glomerular filtration rate. In an attempt to slow-down the progression of the disease to CKD, we treated our mice with empagliflozin, a SGLT2 inhibitor which have been described to display nephroprotective effects in many diabetic and non-diabetic CKD patients.

Methods: empagliflozin was administered in the diet of mice for 8 months at a dose of 30mg/kg of mice per day. At 10 months, mouse kidneys were collected to evaluate fibrosis and inflammation and quantify the tubular damage marker NGAL.

Results: Surprisingly, the treatment did not slow-down the progression of Dent's disease, as the mice showed significant inflammation and fibrosis at 10 months, as well as high levels of NGAL compared with WT mice.

Conclusions: Contrary to other murine models of CKD, empagliflozin does not appear to slow-down the progression of Dent's disease. Some clinical studies suggest that SGLT2 inhibitors act synergistically with inhibitors of the renin angiotensin system, another treatment commonly administered in patient with CKD. It would therefore be interesting to evaluate the effect of these 2 treatments on our mouse model.

Nedosiran in Pediatric Patients with PH1 (PHYOX8)

David J. Sas,[1] Sevcan A. Bakkaloglu,[2] Vladimir Belostotsky,[3] Wesley N. Hayes,[4] Jing Zhou,[5] Verity Rawson,[5] María Gema Ariceta Iraola.[6] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Gazi Universitesi, Ankara, Turkey; [3]McMaster University, Hamilton, ON, Canada; [4]Great Ormond Street Hospital for Children NHS Foundation Trust, London, United Kingdom; [5]Novo Nordisk A/S, Bagsvaerd, Denmark; [6]Hospital Infantil i l'Hospital de la Dona de Vall d'Hebron, Barcelona, Spain.*

Background: Primary hyperoxaluria type 1 (PH1) is a rare genetic disorder leading to excessive hepatic production of oxalate, which can cause deposition of calcium oxalate crystals in the form of recurring kidney stones and nephrocalcinosis.PH1 often presents in childhood and, if left untreated, may result in progressive damage to kidneys and other organs. Nedosiran is a synthetic RNA interference (RNAi) agent designed to selectively reduce hepatic LDH (encoded by the *LDHA* gene) to decrease oxalate burden. Nedosiran is administered as a monthly subcutaneous injection and is FDA-approved for patients with PH1 (≥9 years of age; eGFR ≥30mL/min/1.73 m^2).

Methods: PHYOX8 (NCT05001269) is a phase 2 clinical trial evaluating the efficacy and safety of nedosiran in lowering urinary oxalate (Uox) excretion in pediatric participants (birth to 11 years) with PH1 and eGFR ≥30mL/min/1.73m^2. Reported here are the results of 15 pediatric patients (2 to 10 years of age) with PH1 who received nedosiran once monthly for 6 months in PHYOX8 (Feb 2022 to Aug 2023).

Results: A substantial reduction in spot Uox:creatinine (cr) ratio was observed in patients treated with nedosiran (**Figure 1**): the least squares (LS) mean of percent change in spot Uox:cr ratio from baseline to month 6 was -64.1% (95% CI: -83.8, -44.4). At the month 6 visit, 6 (40%) participants had normal (i.e. ≤ULN) spot Uox:cr ratios, whereas 11 (73%) had Uox:cr ratios ≤1.5 x ULN. Further, there was a mean reduction of 10% in the surface area of kidney stones from baseline to month 6. The mean eGFR remained stable. Nedosiran was well tolerated; 3 participants experienced treatment-related AEs that did not result in discontinuation of treatment or from the study. There were no treatment-related serious AEs. One participant (6.7%) experienced an injection-site reaction. No muscle pain or weakness was observed.

Conclusions: Nedosiran appeared to be safe and well-tolerated in children aged ≥2 years with PH1. Nedosiran treatment led to a substantial reduction of spot Uox:cr in this population.

Funding: Commercial Support - Dicerna Pharmaceuticals, a Novo Nordisk Company

Lucerastat Effect on Kidney Function in Patients with Fabry Disease: Results from the Phase 3 Clinical Program

Eric L. Wallace,[1] Dominique P. Germain,[5] Derralynn Hughes,[6,7] Peter Nordbeck,[4] Martine Clozel,[2] Aline Frey,[2] Christoph Wanner.[3] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]Idorsia Pharmaceuticals Ltd, Allschwil, Switzerland; [3]Fabry Center for Interdisciplinary Therapy, Würzburg, Germany; [4]University Hospital of Würzburg, Würzburg, Germany; [5]University of Versailles, Versailles, France; [6]University College London, London, United Kingdom; [7]Royal Free London NHS Foundation Trust, London, United Kingdom.*

Background: Substrate reduction therapy with lucerastat, an oral glucosylceramide synthase (GCS) inhibitor, aims to reduce Gb3 synthesis and prevent further Gb3 accumulation in patients with Fabry disease. Here, we describe a surprising effect of lucerastat on kidney function from the ongoing global Phase 3 clinical trial, MODIFY, and its open label-extension (OLE).

Methods: MODIFY (NCT03425539)(Wanner et al. 2022) randomized adult patients with Fabry disease 2:1 to lucerastat 1000 mg b.i.d. orally (dose adjusted based on eGFR) or placebo for 6 months. Participants who completed MODIFY were eligible to enter the OLE (NCT03737214) for up to 72 months. Prespecified efficacy endpoints included the change from baseline to Month-6 in eGFR in MODIFY and the annualized eGFR slope in the OLE.

Results: Of 118 participants randomized, 117 received study treatment (80 lucerastat, 37 placebo), 107 (91%) enrolled in the OLE, and 78 (67%) were ongoing at the Month-18 OLE interim analysis. Participants' demographic and baseline characteristics were similar across treatment groups. Kidney function remained stable in lucerastat-treated participants in MODIFY, and in the 39 participants with baseline renal impairment (eGFR <90 mL/min/1.73m^2), eGFR increased at Month-6 with lucerastat (mean [SE] 3.8 [2.2] mL/min/1.73m^2) and decreased with placebo (-1.6 [4.0] mL/min/1.73m^2). This unexpected renal effect was confirmed at Month-18, where lucerastat markedly slowed eGFR decline in the 93 participants with pre-randomization eGFR data, including in subgroups with severe disease course (baseline eGFR <90 mL/min/1.73m^2, classic males) and independent of gene variant amenability to migalastat. Lucerastat was well tolerated.

Conclusions: GCS inhibition with lucerastat might be a novel approach to stabilize or slow the progression of kidney dysfunction, a major therapeutic goal in patients with Fabry disease.

SA-PO655

A Phase 4 Study to Evaluate the Safety and Tolerability of Higher Infusion Rates of Agalsidase Beta to Shorten Infusion Duration in Fabry Disease: Interim Analysis

Maryam Banikazemi,[1] Ozlem Goker-Alpan,[2] Khan J. Nedd,[3] Manish Maski,[4] Chase Lee.[4] *[1]Department of Human Genetics, New York Medical College, New York, NY; [2]Lysosomal Disorders Research and Treatment Unit, Fairfax, VA; [3]Infusion Associates, Grand Rapids, MI; [4]Sanofi, Cambridge, MA.*

Background: Recombinant human α-galactosidase A (agalsidase beta), an enzyme replacement therapy (ERT) for treatment of Fabry disease (FD), is dosed biweekly at 1 mg/kg body weight, and infusion rates can be increased based on tolerability. The FDA label specifies ≥ 90 min infusions for all patients and maximum infusion rate of 15 mg/hr in patients ≤ 30 kg. The present study is evaluating the safety and tolerability of agalsidase beta at approved dose at an increased infusion rate with reduced total infusion volume.

Methods: This ongoing Phase 4 (NCT06019728), open label, single arm study will enroll 18 participants (≥2 to ≤65 years) with confirmed diagnosis of FD into five cohorts. The primary endpoints are percentage reduction of infusion duration from prestudy mean of the most recent three infusions and from an initial 120 minutes, along with shortest infusion duration each participant can tolerate. Here we present data from Cohort 1 and part of Cohort 2, with three heterozygous females and one male with variants in the *GLA* gene. All 4 patients were previously treated with agalsidase beta without any infusion associated reaction (≥ 30 kg).

Results: Three female patients aged 22, 19, and 49 years (mean body weight, 70.7 kg) and one male patient (age: 61 years, body weight: 100 kg) were enrolled. The duration of previous agalsidase beta treatment was 132, 60, 58, 43 months, and the prestudy mean duration of the three most recent infusions was 133, 136, 120, 90 minutes, respectively. The initial duration for first infusion in all three female patients was 120 minutes and was 60 minutes for the male patient. In subsequent infusions (four for the female patients and 2 for the male patient), the infusion time was gradually reduced to 20 minutes without any patient experiencing any infusion associated reaction (IAR). The plasma lyso-GL3 remained low and stable, and antidrug antibodies to agalsidase beta remained negative, in all four patients throughout the study.

Conclusions: Agalsidase beta infusion was given safely at a final time of 20-minute infusion duration in ERT-experienced female and male patients without any IAR. Further findings from this study will help in establishing a protocol to reduce duration of agalsidase beta infusion and minimize the treatment burden.

SA-PO656

Early Intervention with Angiotensin Blockade to Reverse Proteinuria in Glycogen Storage Disease Type Ia (GSD Ia)

Feng-Jung Yang,[1,2] Yin-Hsiu Chien.[1,3] *[1]National Taiwan University Hospital, Taipei, Taiwan; [2]National Taiwan University Hospital Yun Lin Branch, Douliou, Taiwan; [3]National Taiwan University, Taipei, Taiwan.*

Introduction: Glycogen storage disease type Ia (GSD Ia) is caused by a deficiency in glucose-6-phosphatase (G6Pase) activity. This enzyme deficiency affects not only the liver but also the kidneys. In adolescents with GSD Ia, "silent" glomerular hyperfiltration commonly develops, progressing to microalbuminuria and, eventually, overt proteinuria. The progression to decreased glomerular filtration rate (GFR) is attributed to focal segmental glomerulosclerosis and interstitial fibrosis. Angiotensin blockade has long been employed to reduce proteinuria and slow GFR decline in renal diseases characterized by hyperfiltration injury, such as diabetes mellitus. Emerging evidence suggests that similar therapeutic benefits are observed in GSD Ia patients, with angiotensin blockade improving glomerular hyperfiltration and temporarily restoring normal GFR rates.

Case Description: Between January 2002 and July 2024, we retrospectively reviewed the clinical profiles and renal outcomes of patients diagnosed with GSD Ia at National Taiwan University Hospital. Thirteen patients were included in our study, four

of whom had a history of proteinuria. Among these, two patients experienced complete resolution of proteinuria following treatment with angiotensin receptor blockers (ARBs). One patient, treated with ARBs showed a reduction in proteinuria but subsequently developed acute renal failure, which resolved after discontinuing Diovan. Only one patient experienced a rapid decline in renal function, ultimately requiring dialysis and receiving a renal transplant one year later.

Discussion: Angiotensin blockade appears to decelerate the progression of GFR loss in patients with GSD Ia once it commences. Although systematic studies on angiotensin blockade in GSD Ia are lacking, early intervention upon the onset of persistent microalbuminuria holds potential as a strategy to mitigate the factors leading to accelerated glomerular obsolescence, microalbuminuria, proteinuria, and renal insufficiency. Given the generally favorable tolerance of these agents and the likelihood of their eventual use in the lifelong management of GSD Ia, early initiation of angiotensin blockade presents minimal risk and may alter the natural progression of GSD-associated nephropathy. Therefore, early administration of ARBs should be considered to optimize renal outcomes in GSD Ia patients.

SA-PO657

Hospitalization in Children: Experience of the Italian Registry of Pediatric Dialysis

Edoardo La Porta,[1] Rachele Spagnol,[2] Ester Conversano,[3] Enrico Vidal.[2] *[1]Istituto Giannina Gaslini, Genova, Italy; [2]Universita degli Studi di Padova Scuola di Medicina e Chirurgia, Padova, Italy; [3]Ospedale Pediatrico Bambino Gesu, Roma, Italy*.

Background: Children in dialysis experience complications leading to hospitalizations. This nationwide retrospective observational study, performed within the Italian Registry of Pediatric Chronic Dialysis (IRPCD), aims to describe complications in children on chronic dialysis and to compare hospitalization rates between dialysis modalities

Methods: Pediatric patients receiving HD or PD were recorded from 2000 to 2019 by the IRPCD. Hospitalization was defined as an admission involving at least one overnight stay, excluding hospitalizations for dialysis initiation and kidney transplantation. Reasons for hospitalization were categorized into infections related to dialysis, non-infectious complications related to dialysis, other infections, other non-infectious conditions, diagnostic tests, procedures or surgery, and other complications

Results: 847 incident dialysis patients (493 PD, 354 HD) were enrolled. The median age at dialysis initiation was 5 (1.0-10.7) years for PD and 13 (9.6-15.3) years for HD, females in both groups (59.6% and 54.8%). The primary cause of ESKD was CAKUT in both groups (41.6% in PD, 32% in HD); a significant difference was noted for glomerulonephritis, with a higher prevalence in the HD group (25.4 vs. 16.1%). Of the 847 patients, 418 (49.3%) required hospitalization, predominantly in the PD group (314 [75%] vs. 104 [24%] in HD). Median hospitalization duration was 6 days in HD (IQR 4.5-11) and PD (4-9) patients. Infections related to dialysis were the main cause of hospitalization (35%), followed by other non-infectious medical conditions (18%) and other ESKD-related complications (14%). The hazard of hospitalization over time was significantly lower for HD compared to PD patients (aHR 0.54[0.42;0.70]) and it decreased with increasing patient age (aHR 0.97[0.95;0.98]) and calendar year since dialysis initiation (aHR 0.97[0.96;0.98]). The hazard of hospitalization was not related to the primary renal disease but increased significantly with the number of complications. Children on PD for over 1 year had a higher aHR (1, ref) for changing treatment compared to HD patients (0.29[0.10;0.81])

Conclusions: The risk of hospitalization is linked to younger age at dialysis initiation and decreases in more recent calendar years. Children on PD face a higher risk of hospitalization resulting in a higher chance of switching dialysis modality.

SA-PO658

Assessment of Medication Adherence among Children with Glomerular Diseases

Jill Krissberg,[1] Maria Larkina,[2] Margaret Helmuth,[2] Abigail R. Smith,[3] Chia-Shi Wang,[4] Tetyana L. Vasylyeva,[7] Richard A. Lafayette,[5] Katherine R. Tuttle.[6] Cure Glomerulonephropathy. *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]University of Michigan, Ann Arbor, MI; [3]Northwestern University, Evanston, IL; [4]Emory University, Atlanta, GA; [5]Stanford University School of Medicine, Stanford, CA; [6]University of Washington School of Medicine, Seattle, WA; [7]Texas Tech University Health Sciences Center, Lubbock, TX*.

Background: Children with glomerular disease (GD) are subjected to complicated medication regimens where a high frequency of nonadherence has been described. While adult studies in kidney disease have identified differences in adherence for patients of racial or ethnic minorities, little is known in children with GD, and what may be driving any observed differences. This study aims to assess patient, treatment, and disease characteristics associated with medication nonadherence practices.

Methods: CureGN is a prospective cohort study of patients with GD diagnosed by biopsy within 5 years prior to enrollment. Adherence is assessed at enrollment and longitudinally by child (≥8 years) or parent (<8 years) completed questionnaires (adapted Medication Adherence Scale or Morisky MGL Medication Adherence Scale). We used multivariable mixed effects logistic regression models to explore associations between race and ethnicity and odds of nonadherence, sequentially adjusting for socioeconomic status, disease characteristics, and medications.

Results: In 692 children with GD (63% Non-Hispanic White, 21% Black, 6% Asian, 10% Hispanic White; 42% female; median [IQR] age of 11 [6, 14] years; 46% privately insured [US] at enrollment) 534 (77%) reported medication nonadherence at least once (median follow-up of 14 [4, 36] months with 4 [2, 6] completed surveys). Odds of nonadherence was higher for Black children (OR 1.58, 95% CI 1.06-2.38) and Hispanic White children (OR 1.64, 95% CI 1.00-2.68) vs Non-Hispanic White children, and for children with obesity (OR 1.99, 95% CI 1.43-2.79). Older age, international public insurance, hypertension, and presence of edema were associated with lower odds of non-adherence.

Conclusions: Medication non-adherence is common in children with GD and associated with Black race, Hispanic ethnicity and obesity, while lower odds of nonadherence were observed with older age, insurance type, and markers. These characteristics may help inform strategies to support medication adherence.

SA-PO659

Incidence and Severity of Extra-Kidney Manifestations and Outcomes in Pediatric Hemolytic Uremic Syndrome: A Retrospective Cohort Study

Keval Yerigeri, Rupesh Raina. *Department of Nephrology, Akron Nephrology Associates/Cleveland Clinic Akron General Medical Center, Akron, OH*.

Background: Hemolytic uremic syndrome (HUS) is a relatively uncommon disease amongst children with an annual incidence rate of 5.08 per 100,000. Through data analysis gathered using an electronic health record (EHR), we aimed to assess incidences of extra-renal manifestations involved with HUS, explore clinical outcomes, and conduct an epidemiological analysis on the renal profiles of these patients.

Methods: An observational, retrospective analysis was conducted using the data analytics program TriNetX. We assessed the cumulative incidence and 1-year mortality risk of extra-renal manifestations of hemolytic uremic syndrome (HUS) in pediatric patients at 3-, 6- and 12-months following diagnosis: hypertension, noninfective colitis, acute upper respiratory tract infections, disorders of GI tract, GERD, pulmonary edema and ARDS, epilepsy, heart disease, stroke, muscular disorders, and abnormal serum enzyme levels. We also analyzed clinical outcomes (incidence of ICU admissions, mechanical ventilation, hospitalizations, emergency department (ED) visits), mortality, and treatment over a 1-year follow-up period and the progression of overall kidney disease.

Results: Hypertensive diseases were the most prevalent cumulative incidence outcome, with a cumulative incidence of 25.7% and a survival probability of 70.4% at 1-year post-diagnosis. At 1-year post HUS diagnosis, 44/2,142 (2.1%) patients were deceased, 460/2,142 (21.5%) patients had an ED visit, 760/2,142 (35.5%) patients were hospitalized, 137/2,142 (6.4%) patients were admitted to the ICU, and 171/2,142 (8.0%) patients were mechanically ventilated/intubated. At 1-year post diagnosis in pediatric HUS patients 154/2,142 (7.2%) patients received treatment with Eculizumab, 86/2,142 (4.0%) patients received a transfusion of non-autologous platelets, and 248/2,142 (11.6%) patients ended up receiving hemodialysis. At 1-year post HUS diagnosis, 726/2,142 (34.0%) patients developed AKI and 85/2,142 (4.0%) patients developed ESRD. 323/2,142 (15.1%) patients developed CKD.

Conclusions: We present short term outcomes of pediatric HUS from a large database, including novel findings of the rates of hospitalization and ED visits, outcome of hypertension and extrarenal manifestations, as well as mortality and kidney disease progression over 1-year follow-up.

SA-PO660

Kidney ANCA-Associated Vasculitides (AAV) Manifestations and Outcomes in a Diverse Pediatric Cohort: A Single-Center Experience

Alvaro H. Orjuela, Emily Frierson, Sharanya Joginpalli. *Baylor College of Medicine, Houston, TX.*

Background: Renal involvement and long-term outcomes in childhood ANCA-associated vasculitides (AAV) has been understudied in various racial and ethnic minority groups.

Methods: This is a retrospective analysis of pediatric patients with renal AAV diagnosed between 2011 and 2023, followed at Texas Children's Hospital. We report the clinical features, histopathology, renal outcomes, and prognostic factors in a diverse pediatric patient cohort.

Results: A total 37 cases of pediatric renal AAV were identified. 17 (46%) patients presented with rapidly progressive glomerulonephritis (RPGN). At diagnosis, 3 (8%) patients had normal kidney function, 25 (68%) had an AKI, and 8 (22%) patients had an AKI that required acute renal replacement therapy (RRT). 24 (65%) patients received induction immunosuppression with cyclophosphamide and rituximab. 10 patients had therapeutic plasma exchange for RPGN. 8 of these patients were dialysis-dependent from diagnosis. As creatinine increases, the odds of dialysis dependency increases (OR=2.23, 95%CI [1.41, 3.5], p=0.001). Presentation with AKI not requiring RRT is associated with less dialysis dependency (OR=0.04, 95%CI [0.01, 0.29], p=0.001), while presentation with an AKI requiring RRT is associated with dialysis dependency (OR=60.67, 95% CI [5.26, 699.82], p=0.001). Kidney biopsies were scored using the renal ANCA renal risk score (ARRS) by Brix et al. The AUC for Brix score predicting dialysis dependency is 0.944 (95% CI=0.876-1.00) with a sensitivity of 88.89% and specificity of 88.46% for a score of >=9.

Conclusions: In a racially and ethnically diverse pediatric cohort, approximately a third of patients developed ESKD. As Brix score increases, the odds of dialysis-dependency increases.

Clinicopathological Differences between Young Children and Adolescents in Childhood IgA Nephropathy

Yuko Shima,[1] Hironobu Mukaiyama,[1] Yu Tanaka,[1] Wataru Shimabukuro,[2] Hiroshi Kaito,[3] Ryojiro Tanaka,[3] Kandai Nozu,[4] Kazumoto Iijima,[4] Daisuke Tokuhara,[1] Norishige Yoshikawa,[5] Koichi Nakanishi.[2] *[1]Wakayama Kenritsu Ika Daigaku, Wakayama, Japan; [2]Ryukyu Daigaku Igakubu Daigakuin Igaku Kenkyuka, Nakagami-gun, Japan; [3]Hyogo Kenritsu Kodomo Byoin, Kobe, Japan; [4]Kobe Daigaku, Kobe, Japan; [5]Shakai Iryo Hojin Aijinkai Takatsuki Byoin, Takatsuki, Japan.*

Background: Proteinuria remission is the most significant predictive factor for kidney outcome in childhood IgA nephropathy (c-IgAN). In our previous study, younger children were more likely to achieve proteinuria remission and less likely to proteinuria recurrence. Among c-IgAN, there might be differences in clinicopathological findings depending on age regardless of the timing of kidney biopsy. So, the purpose of this study is to clarify the clinicopathological features between younger children whose onset age〈 10 years old and adolescents whose onset age ≧ 10 years old in this study.

Methods: From July 1976 to December 2022, among 567 children with biopsy-proven IgAN at Kobe University and Wakayama Medical University, those with age at onset were available in 557. We investigated clinicopathological differences in 213 (38.2%) younger c-IgAN and the other 344 (61.8%) adolescent c-IgAN. A 1:1 propensity score matching was performed to account for between-group differences (duration from onset to kidney biopsy and kidney biopsy before or after 1990), and 204 matched pairs were obtained.

Results: Adolescent c-IgAN were more detected by school screening program (80.4 vs. 71.1%, p=0.04). Proteinuria was more in younger c-IgAN (0.8 vs. 0.5 g/gCr, p=0.02). The prevalence of tubular atrophy/interstitial fibrosis present was higher in adolescent c-IgAN (44.3 vs.54.9%, p=0.04). The Kaplan-Meier analysis of proteinuria remission showed that younger c-IgAN achieved significantly higher proteinuria remission than ad adolescent c-IgAN (75.4 vs 54.9% at 10 years; 95%CI: 67.4-82.1 vs. 44.8-64.5, p=0.0004).

Conclusions: In adolescent c-IgAN, tubular atrophy/interstitial fibrosis are more likely to be formed regardless of the timing of kidney biopsy, making it difficult to achieve proteinuria remission.

SA-PO662

Single-Cell Transcriptome Sequencing Identifies New Molecular Markers for Pathogenicity of IgA Deposition in the Mesangial Region

Wan JunLi,[1,2] Qilin Chen,[1,2] Li Qiu.[1,2] *[1]Children's Hospital of Chongqing Medical University National Clinical Research Center for Child Health and Disorders, Chongqing, China; [2]Children's Hospital of Chongqing Medical University Ministry of Education Key Laboratory of Child Development and Disorders, Chongqing, China.*

Background: In a variety of glomerular diseases represented by IgA nephropathy, significant IgA deposition can be seen in the glomerular mesangial area. However, the biomarkers of the pathogenic changes of mesangial cells caused by it are still unclear.

Methods: Children with nephrotic syndrome who had minimal change disease (MCD) with IgA deposition in the mesangial area who were referred to our center in the past 10 years were enrolled as IgA+MCD group. MCD without IgA deposition were enrolled as MCD group. IgAN nephropathy with nephrotic syndrome were defined as NS-IgAN group. The general data, laboratory examination, treatment and follow-up informations of patients were collected and analyzed. Single-cell transcriptome sequencing (scRNA-seq) was performed on renal biopsy tissues. Finally, the findings of scRNA-seq were verified by immunohistochemical staining of renal tissue.

Results: The albumin of all the enrolled patients was less than 30g/L, there was no significant difference between the group IgA^+MCD and the group MCD, but they both were lower than that of group NS-IgAN ($P<0.05$). There was no significant difference in the efficacy of glucocorticoid therapy between group IgA^+MCD and group MCD. The analysis of proportion of cell subtypes and the similarity of transcription levels by scRNA-seq of renal biopsy tissue suggested that the transcription level of children with IgA+MCD was similar to that of children with MCD. Comparative analysis of different expression genes in mesangial cells suggested that the expression level of FN1 in children with NS-IgAN was significantly higher than that in children with IgA+MCD. Whether mesangial cells or podocytes, IgAN group was related to molecular characteristics such as extracellular matrix and fibrosis, while other groups were not obvious. Immunohistochemical staining of FN in renal tissue showed that the expression of FN in kidneys of children with NS-IgAN was significantly higher than that of group IgA+MCD and group MCD.

Conclusions: The chilid with IgA^+MCD was similar to MCD in clinical features and molecular status of renal tissue. The deposition of IgA in the mesangial region did not cause the increase of extracellular matrix represented by the increase of FN expression and the enhancement of pro-fibrotic function, which meant that the deposition of IgA did not have a pathogenic effect

SA-PO663

Impact of Proteinuric Glomerular Disease on Educational Outcomes in the Cure Glomerulonephropathy (CureGN) Study

Mahie M. Abdullah,[1,2] Matthew Schuchman,[1,2] Laura J. Castellanos,[1,2] Pamela Singer,[1,2] Abby M. Basalely,[1,2] Carol L. Shen,[1,2] Rachel Frank,[1,2] Suzanne Vento,[1,2] Christine B. Sethna.[1,2] On behalf of CureGN. *[1]Northwell Health, New Hyde Park, NY; [2]Cohen Children's Medical Center, Queens, NY.*

Background: Children with chronic health disorders frequently experience difficulties within the educational system, which can result in poorer educational outcomes (EO). However, EO in proteinuric glomerular diseases remain understudied. The objective was to assess how glomerular disease diagnosis (GDD) and kidney function affect school enrollment, special education and educational attainment.

Methods: Longitudinal analysis included all visits from children aged 5-18 years enrolled in CureGN. Main exposures were GDD (minimal change disease [MCD], focal segmental glomerulosclerosis [FSGS], membranous nephropathy [MN], IgA nephropathy [IgA]) and glomerular filtration rate (eGFR, CKID U25). EOs were absenteeism (>15 days of missed school/year), school enrollment (part-time/home schooled/not enrolled), special education and grade repetition. Generalized estimating equations (GEE) examined the association of GDD and eGFR individually with EOs in models adjusted for age, sex, maternal education and duration of diagnosis.

Results: Of 901 children (12.65±3.56 years, 58.8% male, 28.23 months follow-up), the prevalence of absenteeism was 11.1%, part-time enrollment was 1.4%, not enrolled was 2.8%, special education was 12.5%, and grade repetition was 1.9%. In adjusted models, the diagnosis of IgA was associated with lower odds of absenteeism compared to MCD. eGFR was not associated with any EO. (Table)

Conclusions: In CureGN, GDD was associated with absenteeism, highlighting the importance of developing individualized approaches to decrease the risk of adverse EOs and promote academic success. Further research is needed to understand the underlying mechanisms of GDD that promote such disparities in this vulnerable population.

Funding: NIDDK Support

Predictors of Lack of Remission in Pediatric Patients with IgA Vasculitis with Nephritis: A Retrospective Review

Virginia Hoch,[1,2] Sandra G. Yang,[3] Carlos E. Araya,[4] Ali Mirza Onder.[2]
[1]Christiana Care Health Services Inc, Wilmington, DE; [2]Nemours Children's Hospital Delaware, Wilmington, DE; [3]Thomas Jefferson University Sidney Kimmel Medical College, Philadelphia, PA; [4]Nemours Children's Clinic, Orlando, FL.

Background: Despite favorable outcomes in the majority of cases, 3-5% of children with IgA vasculitis with nephritis (IgAVN) fail to respond to treatment and progress to advanced chronic kidney disease or end stage renal disease (ESRD). It is therefore crucial to predict early markers of progressive disease so that treatment regimens can be quickly escalated. This retrospective study was conducted to investigate predictors of lack of remission in pediatric IgAVN patients.

Methods: We identified pediatric patients from two hospital campuses at our academic institute diagnosed with biopsy-proven IgAVN from 2013 to 2023. We retrospectively collected demographic, clinical, laboratory and histopathologic variables at diagnosis and during 2 years of follow-up. The primary outcome was lack of remission at 6 months follow-up. Secondary outcomes were progression to ESRD and lack of remission at last data point. To assess for association with lack of remission, we performed logistic regressions as well as Mann-Whitney U tests and Pearson's chi-squared or Fisher's exact tests for numerical and categorical variables, respectively.

Results: Thirty-one patients were identified for analysis in our study (23 male and 8 female) with mean age of 10 years at diagnosis. Remission was achieved in 26/31 (84%) of cases, with 15/31 (48%) achieving remission by 6 months. Lack of remission at 6 months was associated with presence of gross hematuria (p=0.024) and nephritic-nephrotic syndrome (p=0.022) during the study period. Three patients (9.6%) progressed to ESRD during the study period; no variables were significantly associated with this outcome. Full remission was associated with lower serum albumin (p=0.03) and higher eGFR (p=0.023) at 9 months.

Conclusions: In the studied cohort, presence of gross hematuria and nephritic-nephrotic syndrome was associated with lack of remission at 6 months. We found no early predictors for progression to ESRD. Our ESRD prevalence is higher than that in previous reports, which may be due to our sample size. We also found a lower rate of full remission and a slower rate of achieving full remission in our cohort. Further research including larger patient populations is needed to better identify predictors of lack of remission and progression to ESRD for pediatric IgAVN patients.

SA-PO665

Association of Serum Free Cortisol and Kidney Function in Children and Adolescents with Type 1 Diabetes Mellitus

Lance A. Sloan,[1] Katia P. Sloan,[1] Eduardo F. Chagas,[2] Sandra M. Barbalho,[2] Jesselina F. Haber.[2] *[1]Texas Institute for Kidney and Endocrine Disorders, Lufkin, TX; [2]Universidade de Marilia Faculdade de Medicina e Enfermagem, Marilia, Brazil.*

Background: The treatment of Type 1 Diabetes mellitus (DM1) has always been a challenge for health care professionals due to the difficulties of achieving good glycemic control. Poor glycemic control can result in hyperfiltration and the development of diabetic kidney disease. Cortisol plays an essential role in the body's metabolism and chronic elevation or dysregulation of cortisol levels can have adverse effects on renal function and glycemic control. Our objective was to investigate the association between serum free cortisol and renal function in children and adolescents with DM1

Methods: A cross-sectional observational study was conducted with 61 individuals of both sexes (6-19 years) diagnosed with DM1 for at least 12 months and with C-peptide values < 0.3ng/ml. Renal function was measured as glomerular filtration rate (eGFR) using CKiD equation. Serum albumin (g/dL), creatinine (mg/dL), urea (mg/dL), and free cortisol (µg/dL) were collected in the morning in a fasting state. An early morning urine sample was collected for urine albumin to creatinine ratio (uACR). A multiple linear regression was used to explore the effect of cortisol (independent variable) on the dependent variables (eGFR, Creatinine, urea, albumin, uACR) controlling the effect of the independent covariates (sex, age, BMI-z, HbA1C and length of diagnosis).

Results: Increases in Cortisol, length of diabetes, HbA1c and being female was associated with an increase in eGFR and possibly hyperfiltration. Age was associated with a reduction in the eGFR. A significant effect of serum cortisol and gender explained 13.6% (R^2) of the creatinine variation and 19.0% (R^2) of the urea variation. Increases in cortisol in males was associated with an increase in creatinine and increases in cortisol in females was associated with a decrease in urea. An increase in cortisol was positively associated with uACR and inversely related to serum albumin.

Conclusions: There is a direct relationship between cortisol, eGFR, and uACR in children and adolescents with DM1. Cortisol may be having an impact on renal function which in the long term could potentially play a role in the progression of kidney disease in this population.

SA-PO666

Urinary DKK3 as a Novel Biomarker for Kidney Function Decline in Children with Alport Syndrome

Jan Boeckhaus, Oliver Gross. *Universitatsmedizin Gottingen, Gottingen, Germany.*

Background: CKD progression in children with Alport syndrome (AS), a common genetic kidney disease, is hard to predict. DKK3 predicts declining kidney function in adults and advanced CKD children, but its usefulness in early AS detection is unknown.

Methods: Urine samples from 50 children enrolled in the EARLY PRO-TECT Alport trial were analyzed to address this hypothesis.

Results: DKK3 levels were higher than those of the general population reported in the literature. DKK3 levels were also higher elevated in patients with later AS stages. Furthermore, children, who were not treated with RASi, had higher DKK3 levels compared to treated children. Children with above-average DKK3 levels were more likely to experience increased albuminuria compared to children with below-average DKK3 levels after 2 years of follow-up.

Conclusions: This study demonstrated that urinary DKK3, a biomarker for CKD progression, is significantly increased in children at very early stages of AS. Children with above-average DKK3 had higher risk of disease progression.

Age (years)	9.0±4.2

Pediatric Proliferative Glomerulonephritis with Unique IgG4

Gabriela Rocha, Jessamyn S. Carter. *University of Michigan Michigan Medicine, Ann Arbor, MI.*

Introduction: Proliferative Glomerulonephritis with monoclonal IgG deposits (PGNMID) is a recently established diagnosis defined by monoclonal immunoglobulin deposition in the glomerulus. PGNMID is rare and typically found in the adult population. Here, we present a unique case of pediatric PGNMID secondary to IgG4 deposition.

Case Description: A 10-year-old female with history of metastatic neuroblastoma status post extensive chemotherapy and abdominal radiation in remission on long-term difluoromethylornithine developed hematuria, proteinuria (protein:creatinine ratio 14), glycosuria, and hypertension. She was determined to have stage 3a chronic kidney disease and was started on amlodipine. While awaiting renal biopsy she developed hypoalbuminemia, edema, and acute kidney injury requiring admission for augmented diuresis. Biopsy showed proliferative glomerulonephritis with IgG4 and kappa immunoglobulin deposits with moderate glomerular scarring and 15% interstitial fibrosis and tubular atrophy. Bone marrow biopsy was negative for clonal disorder. Serum protein electrophoresis was nondiagnostic due to oligoclonal bands from recent IVIG infusion. Urine Bence-Jones screen showed lambda light chain M-protein, an unexpected finding as the biopsy showed kappa. For her PGNMID versus IgG4-related disease, the patient was recently started on steroids and rituximab.

Discussion: PGNMID is a recently described diagnosis, more commonly seen in adults, which can be a source of progressive kidney disease in children. PGNMID is most often caused by IgG3 and can be a monoclonal gammopathy of renal significance. In this case, PGNMID would not explain glycosuria which, along with IgG4 restriction and the light chain mismatch, leads to diagnostic uncertainty. Her disease may instead represent an overlap with IgG4 disease. Our goal in sharing this case is to raise awareness for both PGNMID and IgG4 disease in pediatric patients and emphasize the potential overlap in pathophysiology.

Assessment of Kidney Size in African American Children with Sickle Cell Disease: A Matched-Pair Analysis

Asma B. Shaoba, Yaoping Zhang, Angelika C. Gruessner, Okwudili Nnaji, Anil K. Mongia, Oluwatoyin F. Bamgbola. *SUNY Downstate Health Sciences University, New York City, NY.*

Background: Sickle cell disease (SCD) is caused by a beta-globin gene mutation that produces sickling of red blood cells. Increase in cardiac output from sickle cell anemia produces hyperfiltration that results in a progressive increase in renal size. We aim to examine the impact of SCD morbidity on kidney size using renal ultrasound.

Methods: The study included 31 African Americans with SCD aged 3 to 20 years and 57 matched controls who were seen in outpatient clinic from 01/ 2018 to 12/2022. Cases were matched with controls at 1:2 ratio. We examined the impact of the severity of hemoglobinopathy on kidney size by stratification of subjects based on HBSS and HBSC subtypes, and SCD morbidity score.

Results: Four subjects had HBSC and 27 had HBSS genotypes. The right and the left kidney volume of SCD cases were significantly larger than of controls [$p < 0.0001$] (Table 1). There was a significant difference in eGFR between subjects and controls, and among individuals with HBSS and HBSC genotypes (Table 1 and Fig. 1). A unit increase in SCD morbidity score was associated with 5.7 and 5.1 cm3 volume increase for right and left kidneys respectively.

Conclusions: Severity of sickle cell anemia positively correlates with a greater eGFR and (therefore) volume of hyperfiltration, which in turn, are the primary determinants of nephromegaly.

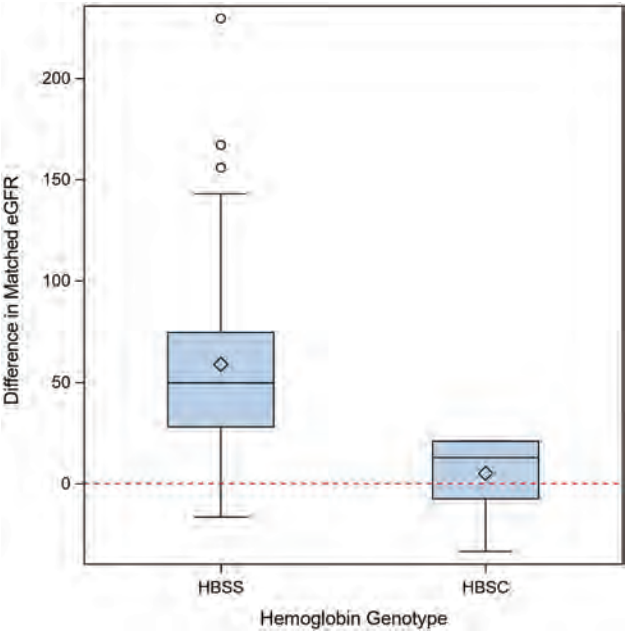

Fig 1: Box plot of eGFRs for the difference between matched subjects by hemoglobin genotypes.

Table 1: Comparison of the kidney volume, hemoglobin concentration and estimated GFR between Sickle cell disease subjects and controls.

Parameters	Number of SCD subject-control matches	Difference in the median values between SCD cases and Controls	p-values
Right kidney volume (cm^3)	57	36 (-166 – 27)	< 0.0001
Left kidney volume (cm^3)	57	28 (-133 – 48)	< 0.0001
Hemoglobin (gm/dL)	49	-3.8 (-8.4 – 2)	< 0.0001
Estimated GFR (ml/min/1.73 m^2)	52	43 (-34 – 230)	< 0.0001

Kidney Pathological Findings in MYH9-Related Disease

Ryo Nakatani,[1] Kenichiro Miura,[1] Yoko Shirai,[1] Yasufumi Ohtsuka,[4] Yoko Ohwada,[5] Takao Konomoto,[7] Tamaki Morohashi,[9] Koji Tsugawa,[6] Sekiko Taneda,[1] Kazuho Honda,[2] Shinji Kunishima,[8] Kenji Ishikura,[3] Motoshi Hattori.[1]
[1]Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan; [2]Showa Daigaku Daigakuin Igaku Kenkyuka Igakubu, Shinagawa-ku, Japan; [3]Kitasato Daigaku Igakubu, Sagamihara, Japan; [4]Saga Daigaku Igakubu Daigakuin Igakukei Kenkyuka, Saga, Japan; [5]Dokkyo Ika Daigaku, Shimotsuga-gun, Japan; [6]Hirosaki Daigaku Igakubu Daigakuin Igaku Kenkyuka, Hirosaki, Japan; [7]Miyazaki Daigaku Igakubu Daigakuin Ikagaku Kangogaku Kenkyuka, Miyazaki-gun, Japan; [8]Gifu Iryo Kagaku Daigaku, Seki, Japan; [9]Nihon Daigaku Igakubu Daigakuin Igaku Kenkyuka, Itabashi-ku, Japan.

Background: *MYH9*-related disease (*MYH9*-RD) is characterized by congenital macrothrombocytopenia, progressive kidney failure, and sensorineural hearing loss. There are limited data of kidney pathological findings of *MYH9*-RD because of the low platelet count. Although focal segmental glomerulosclerosis (FSGS) and glomerular basement membrane (GBM) abnormalities similar to Alport syndrome have been anecdotally described, no comprehensive studies have been performed.

Methods: We conducted a cross-sectional nationwide survey in Japan. Questionnaires were initially sent to 145 institutions. We asked the eligible patients if a kidney biopsy had been performed. Eight kidney biopsy samples from seven patients were finally included in the study. All pathological samples were examined by pediatric nephrologists and pathologists at our institution. This study was supported by "Research on Rare and Intractable Diseases, Health and Labor Sciences Research Grants" from the Ministry of Health, Labour and Welfare (Grant No. 20FC1028), Japan.

Results: All seven patients had pathogenic variants in the *MYH9* gene: R702C in three patients, R702H in two patients, D1424H in one patient, and Q1068_L1074dup in one patient. The median ages at onset of proteinuria and kidney biopsy were 7 years and 11 years, respectively. Mesangial matrix expansion was observed in all samples, and two samples also showed FSGS. Immunofluorescence study showed significant depositions of immunoglobulin and complement in two samples: IgG and C1q in one patient and IgA and C3 in one patient. Electron microscopy showed segmental foot process effacement, endothelial cell swelling, and electron-dense deposits (EDD) in eight, six, and five samples, respectively. GBM abnormalities such as thinning, thickening, and splitting of the lamina densa were observed in three samples.

Conclusions: Mesangial matrix expansion and focal foot process effacement were commonly observed in *MYH9*-RD patients. In addition, a variety of pathological findings including immunoglobulin and complement depositions with EDD and GBM abnormalities were also observed. These results may have important implications for the disease mechanism and treatment of *MYH9*-RD.

Utility of Adult-Derived Biomarkers for Assessment of Kidney Function in Pediatric ANCA-Associated Vasculitis

Kelly Brown,[1,2] Simranpreet K. Mann,[3,2] Kirandeep Toor,[3,2] Else S. Bosman,[4] Audrea Chen,[5] Cherry Mammen,[4,1] David A. Cabral,[4,1] Kimberly Morishita.[4,1]
On behalf of the Pediatric Vasculitis (PedVas) Investigator Network.
[1]The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada; [2]BC Children's Hospital Research Institute, Vancouver, BC, Canada; [3]The University of British Columbia, Vancouver, BC, Canada; [4]BC Children's Hospital, Vancouver, BC, Canada; [5]The Hospital for Sick Children, Toronto, ON, Canada.

Background: In adults with anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV), measures of ANCA positivity and antigen specificity, estimated glomerular filtration rate (eGFR), and urine proteins are informative of kidney function and aid treatment decisions. Despite aggressive therapy, two-thirds of pediatric AAV patients have persistently reduced renal function. The objective of this study is to evaluate the utility of adult-derived kidney markers in pediatric AAV.

Methods: Eligible participants < 18 yrs of age in the ARChiVe/PedVas initiative had a diagnosis of small vessel vasculitis including AAV, ANCA positive pauci-immune glomerulonephritis, and unclassified primary vasculitis. Kidney disease activity was defined by the renal component of the pediatric vasculitis activity score. Kidney function was categorized by eGFR into KDIGO stages. Predictive analysis of ANCA and baseline eGFR for 1- to 2-year outcomes were conducted using adjusted regression models and/or a proportional odds logistic regression model. Concentrations (ELISA) of MCP-1, sCD25, and sCD163 in time-of-diagnosis urine was measured for correlations with baseline and 1-year kidney state using R statistical language.

Results: At diagnosis, patients with MPO-ANCA had similar levels of overall disease activity to those with PR3-ANCA but had 2.4 times higher odds of kidney involvement ($P = 0.008$) and 6.0 times higher likelihood of worse kidney dysfunction ($P < 0.001$). Time-of- diagnosis eGFR was informative to future kidney function with the odds of worse kidney function at 1-year being 18.2 times higher for children with moderately-severely reduced function at onset. Urine proteins performed poorly as indicators of kidney disease activity at onset and follow up.

Conclusions: The results of this study show mixed utility of adult derived biomarkers for use in the pediatric population, with severe kidney disease at onset and function over the first 1-year being best informed, respectively, by MPO-ANCA seropositivity and baseline eGFR. The study illustrates the need for pediatric AAV-focused studies for novel kidney biomarker discovery.

Rapidly Progressive Kidney Failure in a Patient with Longstanding Juvenile Dermatomyositis

Sarah Rogal,[1] Donghyang Kwon,[2] Sun-Young Ahn.[1] *[1]Children's National Hospital, Washington, DC; [2]MedStar Georgetown University Hospital, Washington, DC.*

Introduction: Juvenile dermatomyositis (JDM) is an inflammatory myopathy characterized by proximal muscle weakness, heliotrope rash and Gottron papules. Collapsing focal segmental glomerulosclerosis (cFSGS) and glomerulocystic disease have not been previously reported with JDM.

Case Description: A 21 year-old male with JDM (diagnosed 9 years ago), osteoporosis, calcinosis, and restrictive lung disease presented with a 3-week history of left knee and foot pain concerning for cellulitis. He recently discontinued mycophenolic acid and tofacitinib for a low white blood cell count but continued hydroxychloroquine, prednisone, and monthly intravenous immunoglobulin. Initial labs were concerning for serum creatinine of 2.9 mg/dl, increased from baseline of 0.92 mg/dl, serum albumin 1.7 g/dl, and urine protein to creatinine ratio 4.8. An ultrasound showed increased renal echogenicity. C3 was 84(nl>90 mg/dl), C4 and creatinine kinase normal, ANA 1:80, while anti-dsDNA, HIV, hepatitis B and C were negative. His cellulitis was treated with IV clindamycin and cefepime. A kidney biopsy showed cFSGS, glomerulocystic changes, and tubules with microcystic dilatation(Fig 1). Widely scattered immune complex deposits were seen on electron microscopy and IV methylprednisolone was given for 3 days. However, his kidney function continued to worsen leading to the initiation of hemodialysis.

Discussion: Renal involvement in JDM is rare with acute kidney injury secondary to myoglobinuria and nephrotic syndrome reported. Collapsing FSGS has been reported in patients with parvovirus B19 and HIV, both of which were absent in our patient. It has also been observed in patients who received high doses of pamidronate; however, our patient's cumulative dose(given for osteoporosis) was much lower than the reported cases(300 mg vs. 1170-3960 mg). This is the first report to our knowledge of cFSGS and glomerulocystic features in a patient with JDM. Further investigation is needed to elucidate whether there is a genetic or immunologic predisposition for patients with JDM to develop cFSGS and glomerulocysts.

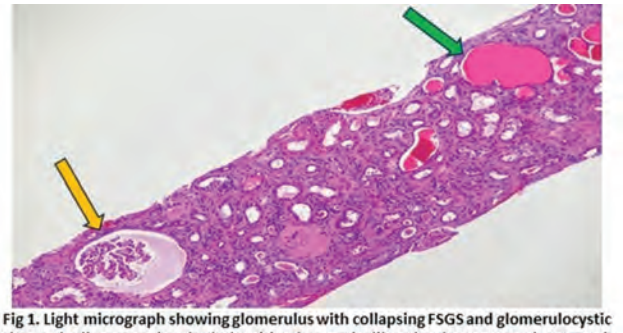

Fig 1. Light micrograph showing glomerulus with collapsing FSGS and glomerulocystic change (yellow arrow) and tubule with microcystic dilatation (green arrow); H&E stain.

SA-PO672

ACTION3 Phase 3 Clinical Trial Assessing the Efficacy and Safety of DMX-200 (Repagermanium): Mid-trial Safety Assessment and Pharmacometric Model-Informed Pediatric Dose Selection

David E. Fuller,[1] Erno van Schaick,[2] Alisha J. Smith,[1] Robert Shepherd,[1] Carl White.[1] *[1]Dimerix Bioscience Pty Ltd, Melbourne, VIC, Australia; [2]Calvagone, Amsterdam, Netherlands.*

Background: DMX-200 (repagermanium) is a C-C chemokine receptor type 2 (CCR2) inhibitor which when administered with an angiotensin II receptor blocker (ARB) inhibits CCR2/AT1R complex function. This modulates the aberrant response to inflammation, blocking attraction of inflammatory cells into the kidneys and reducing

both proteinuria and podocyte loss. Following encouraging Phase 2 data, Dimerix have commenced a Phase 3 randomized double-blind placebo-controlled study (ACTION3) investigating the efficacy and safety of DMX-200 (120 mg BID) compared with placebo in patients with FSGS on a stable ARB dose. In March 2024 the study passed an interim futility assessment, and following safety review, PK assessment and pharmacometric modelling, will now include adolescent patients aged 12-17 years.

Methods: An interim safety analysis covered the first n=91 patients randomised in ACTION3. PK data from n=46 DMX-200 evaluable patients was assessed in a population PK model (popPK) built on previous data from Phase 1 and 2.

Results: Median duration of exposure to DMX-200 or placebo was 9.1 months (range 0.5-17.3) with median total exposure of 65.76 g (range 3.6-124.56 g). 277 individual adverse events (AEs) were reported by 72/91 (79%) patients. 80% of AEs were rated as "mild" and reflected the underlying disease (FSGS) and associated comorbidities. DMX-200 has a half-life ($t_{1/2}$) of 3.6 hrs and is not metabolised. PK data were variable with a wide exposure range due to the short $t_{1/2}$ of DMX-200 but were comparable with prior data and supported the use of the popPK model to predict adolescent exposure. Simulations of exposure in renally impaired adolescent patients (AP) showed that AP will generally have similar drug exposures to adults. APs with a combination of very low body weight and poor renal function may experience higher exposure that is likely covered by the observed exposures in adults.

Conclusions: No safety signal that would preclude paediatric dosing was identified. Based on this comprehensive review of safety, PK data and PopPK modelling of predicted exposure, a dose of 120mg BID will be used for adolescents (12-17 years) who are now being recruited into the ACTION3 study.

Pediatric Peritoneal Dialysis after Cardiopulmonary Bypass: Long-Term Outcomes

Sarah Couser, Stuart Goldstein, David L. Morales, David S. Cooper, Michael A. Carlisle. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Acute kidney injury (AKI) with fluid overload is a common complication for children undergoing congenital heart surgery and is associated with increased mortality and extended length of hospital stays (LOS). We and others have demonstrated early initiation of peritoneal dialysis (PD) in the post-operative period is associated with decreased fluid accumulation, ICU LOS and mortality. Since 2010, our institution developed a systems-wide practice to electively place PD catheters at the time of cardiopulmonary bypass (CPB) surgery in a child deemed to be at high risk for AKI. Although outcomes for these patients are often excellent, there has been no investigation into the outcomes of patients who continue to require PD beyond AKI. We aimed to further understand the outcomes our population in order for providers to better counsel families on goals on care.

Methods: This is a retrospective cohort study of patients aged birth to 18 years deemed at risk for AKI who received placement of a PD catheter in the OR after CPB between 2018 and 2023.

Results: 342 patients received a PD catheter over the study period. 112 (33%) had continuous PD for a median time of 2 days (IQR 1-5 days, range 1-157 days). 9/112 (8%) of these patients required PD for >14 days. Of these 9 patients, 5/9 survived until CICU discharge and 4/9 survived until hospital discharge. 2/4 patients who survived until hospital discharge never recovered kidney function. 1/8 patients survived until a year after PD initiation, with an additional patient surviving, but currently only 11 months old. 5/9 patients became tracheostomy and ventilator dependent, 2/9 remained intubated until time of death, and 2/9 were discharged home with low flow nasal cannula oxygen supplementation.

Conclusions: The requirement of PD for >14 days was associated with more than 50% in-hospital mortality, poor respiratory outcomes, and 1-year survival less than 25%. Despite the excellent clinical outcomes we have observed for patients receiving PD in the post-operative AKI period, patients who require PD for prolonged courses appear to have poor clinical outcomes and may need different care counseling.

SA-PO674

Association of Sleep-Disordered Breathing with Isolated Diastolic Hypertension in Youth Referred for Hypertension Disorders

Ashna Pudupakkam,[1] Sahar Siddiqui,[1] Fallon Campbell,[1] Andrew M. South,[2] Elizabeth A. Onugha.[1] *[1]Baylor College of Medicine, Houston, TX; [2]Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: Sleep-disordered breathing is associated with an increased risk of hypertension. Studies have shown that adults with sleep-disordered breathing have a higher prevalence of isolated diastolic hypertension. While youth with sleep-disordered breathing have higher daytime diastolic blood pressures, the association of sleep-disordered breathing with isolated diastolic hypertension in youth is unclear. We aimed to determine the association of sleep-disordered breathing with isolated diastolic hypertension in youth referred for hypertension disorders.

Methods: Cross-sectional analysis of baseline data from the Study of the Epidemiology of Pediatric Hypertension (SUPERHERO), a multisite Registry that retrospectively collects electronic health record data validated by manual record review. We included patients with ICD-10 codes for hypertension disorders at the index visit at subspecialty hypertension clinics who were aged <19 years. We excluded patients with ICD-10 code-identified pregnancy, kidney failure on dialysis, or kidney transplantation. Our exposures were an ICD-10 code visit diagnosis for sleep-disordered breathing at the index visit. Our outcomes included blood pressure severity at the index visit. We used unadjusted generalized linear models.

Results: In our cohort, 5% of participants (560 of 10,968) had an ICD-10 code for sleep disordered breathing. Participants with an ICD-10 code for sleep-disordered breathing had higher odds of having blood pressure at the isolated diastolic hypertension level at baseline.

Conclusions: In our large cohort of youth referred for hypertension disorders, we found that sleep disordered breathing was associated with isolated diastolic hypertension at baseline. This study may have been impacted by lack of longitudinal blood pressure data and variation in pharmacologic management of hypertension. In future studies, we plan to investigate the association of sleep-disordered breathing with target organ injury to determine the long-term impact of isolated diastolic hypertension in youth.

Table 2: Association of sleep-disordered breathing with isolated diastolic hypertension at the index visit in youth referred for hypertension disorders

Outcome	Unadjusted OR (95% CL) n=6,790	Adjusted[a] OR (95% CL) n=6,744
Isolated diastolic hypertension (reference isolated systolic hypertension)	1.4 (1.02 to 1.92)	1.55 (1.13 to 2.13)
Isolated diastolic hypertension (reference combined hypertension)	1.99 (1.43 to 2.78)	1.99 (1.42 to 2.8)
Isolated systolic hypertension (reference combined hypertension)	1.42 (1.11 to 1.83)	1.28 (0.996 to 1.66)

Generalized estimating equations with generalized logit link function and multinomial distribution. Red font indicates statistically significant results. [a]Multivariable models included directed acyclic graph-informed adjustment set containing obesity.

Risk Factors for Incident Hypertension in Children with Mild-Moderate CKD (CKiD Study)

Smitha R. Vidi,[1] Mark Mitsnefes,[2] Joseph T. Flynn,[3] Bradley A. Warady,[4] Susan L. Furth,[5] Wanpen Vongpatanasin.[1] *[1]The University of Texas Southwestern Medical Center, Dallas, TX; [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [3]Seattle Children's Hospital, Seattle, WA; [4]Children's Mercy Kansas City, Kansas City, MO; [5]The Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Hypertension (HTN) affects > 50% of children with chronic kidney disease (CKD). Increased aortic stiffness contributes to the development of hypertension and left ventricular hypertrophy in adults. Electrolyte disturbances including hyperphosphatemia and hypercalcemia are known to be associated with vascular stiffness in adults as CKD progresses. However, the role of hypercalcemia and hyperphosphatemia in the development of arterial stiffness and incident HTN in the early stages of pediatric CKD is unknown.

Methods: We studied children aged 5-18 years with CKD (U25 eGFR 30-90 ml/min/1.73m2) who were normotensive without anti-HTN medications at baseline using data from the CKiD cohort. Aortic stiffness index (ASI) was measured by echocardiography; serum electrolytes and 24-hour ambulatory BP were measured at baseline and during at least one follow-up visit. HTN was defined as either wake/sleep mean SBP/DBP ≥ gender/height-specific 95th percentile for <13 yrs of age and ≥ 130/80 mmHg for wake BP or ≥ 110/65 mmHg for sleep BP or mean ambulatory 24 hr BP ≥ 125/75 mmHg for ≥ 13 yrs of age.

Results: Out of 132 participants included in our study, 50 were not on anti-HTN medications. 26 participants had a follow up 24-hour ABPM study conducted 2 years after study entry. Mean age (76% males) was 11.6±3.7 yrs; mean eGFR 50±15 ml/min/1.73m2. 96% of participants on anti-HTN therapy and 92% without antihypertensives had abnormally high ASI compared to healthy controls. Higher baseline ASI and serum calcium were not associated with incident HTN at 2 years. Similarly, low serum potassium and phosphorous levels were not associated with incident HTN (Table) in unadjusted and adjusted analyses for age and eGFR.

Conclusions: Higher aortic stiffness index and serum calcium, potassium, and phosphorous were not associated with development of HTN after 2 yrs in children with CKD. Additional studies in larger cohorts or with longer follow-up times are needed.

Funding: NIDDK Support, Other NIH Support - The CKiD Study is funded by the National Institute of Diabetes and Digestive and Kidney Diseases, with additional funding from the National Institute of Child Health and Human Development, and the National Heart, Lung, and Blood Institute (U01-DK-66143, U01-DK-66174, U24-DK-137522, U24-DK-66116).

Association of aortic stiffness and serum electrolytes with development of HTN

Exposure	Unadjusted Odds Ratio, 95% CI	Adjusted Odds Ratio, 95% CI
Aortic Stiffness	1.17 CI (0.62 -2.19)	1.26 CI (0.66-2.4)
Serum potassium	0.25 CI (0.03-1.89)	0.24 CI (0.03-2.2)
Serum phosphorous	0.74 CI (0.17-3.1)	0.63 CI (0.12-3.4)
Serum calcium	2.9 CI (0.33-25.1)	2.29 CI (0.24-22.23)

COVID-19-Associated Worry and Emotional Distress in Children with CKD

Joann M. Carlson,[1] Erin M. Jones,[6] Matthew Matheson,[7] Sharon L. Manne,[5] Cynthia Wong,[9] Camille Wilson,[8] Amy Kogon,[2] Judith Jerry-Fluker,[7] Marc Lande,[11] Lyndsay Harshman,[10] Susan L. Furth,[2] Bradley A. Warady,[3] Stephen R. Hooper,[4] Rebecca J. Johnson.[3] *[1]Rutgers University New Brunswick, New Brunswick, NJ; [2]The Children's Hospital of Philadelphia, Philadelphia, PA; [3]Children's Mercy Kansas City, Kansas City, MO; [4]The University of North Carolina at Chapel Hill Libraries, Chapel Hill, NC; [5]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ; [6]Emory University School of Medicine, Atlanta, GA; [7]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [8]Nationwide Children's Hospital, Columbus, OH; [9]Stanford University, Stanford, CA; [10]University of Iowa Health Care, Iowa City, IA; [11]University of Rochester, Rochester, NY.*

Background: The COVID-19 (C19) pandemic impacted youth mental/behavioral health, with 26% reporting significant emotional distress. Little is known about the emotional impact of C19 for youth with chronic kidney disease (CKD). We examined rates of C19 associated worry and emotional distress in youth with CKD and associations with socioeconomic and disease-related variables.

Methods: Caregivers completed the C19 questionnaire adapted from the Women's Interagency HIV Study and Multicenter AIDS Cohort Study. Covariate data was collected at or prior to C19 questionnaire. Analyses examined rates of C19 emotional distress and worry and included logistic regression to identify associations with covariates.

Results: Sample included 320 participants from the Chronic Kidney Disease in Children Study: 63% male, 18% African American, 10% Hispanic, median age 16 years, median estimated GFR 52 ml/min/1.73m2 among pre-ESKD participants and median urine P:C 0.27. 27% were post-kidney replacement, 29% had household income <$36,000 and 29% had maternal education of high school or less. 19% and 17% endorsed C19 emotional distress and worry, respectively (see Figure 1). Having eGFR <30 pre-KRT was associated with endorsement of emotional distress (OR 3.34; p= 0.046). Low household income was associated with endorsement of C19 worry (OR 5.43; p=0.01).

Conclusions: Youth with CKD endorsed C19 associated emotional distress and worry at rates lower than what has been observed nationally. Being pre-KRT with eGFR <30 was associated with increased C19 emotional distress, and low household income was significantly associated with C19 worry. This study did not assess social-emotional health broadly among youth with CKD but suggests those with poorer kidney function and lower income were more likely to endorse distress and worry related to C19.

SA-PO677

Energetic Profiles of Children with CKD Compared with Profiles of Healthy Controls

Amy Kogon, Jonathan Mitchell, Susan L. Furth, Sandra Amaral, Babette Zemel. *University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

Background: Children with CKD who are obese develop earlier cardiovascular disease (CVD), a leading cause of mortality. Understanding how the components of energy balance, which include resting energy expenditure (REE), physical activity (PA) and energy intake, affect obesity in pediatric CKD is critical to prevent it and reduce CVD risk.

Methods: Participants were 8-21 years old with CKD stages 3-5 not on dialysis or healthy controls (HC) of similar age, sex and BMI category. REE was measured by open circuit indirect calorimetry, PA by child PROMIS PA measure, energy intake by 24-hour dietary recall, and body composition by DXA. Linear regression models were used to determine if the components of energy balance differed between CKD and HC participants, adjusting for age and sex and for lean body mass (LBM), the primary determinant of REE, when evaluating group differences in REE.

Results: Twenty-two participants with CKD and 14 HC completed baseline studies. REE was measured in 16/22 CKD and 10/14 HC participants. Self-reported PA levels and energy intake were similar between groups. After adjusting for age and sex, for a given LBM, REE was 116 kcal/day lower in CKD participants (p=0.026).

Conclusions: Total energy intake and PA levels were similar between CKD and HC participants, but REE was significantly lower in the group with CKD, even after consideration for LBM. This suggests that energy imbalance in CKD may be related to lower-than-expected energy utilization by LBM.

Body Mass Index Trajectories among Adolescents and Young Adults with CKD

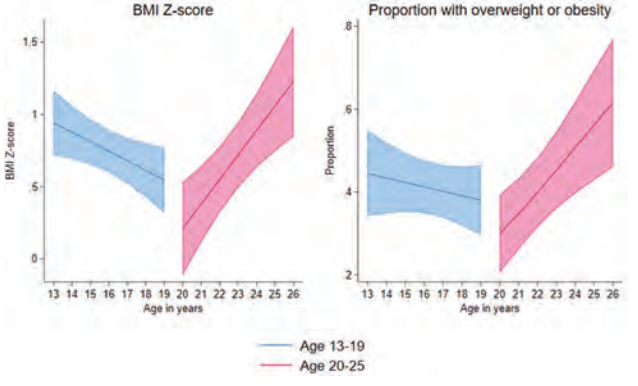
Pierina P. Parraga,[1] Caleb W. Easterly,[2] Guido Filler,[4] Donna B. Gilleskie,[3] Maria E. Ferris.[1] *[1]The University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; [2]The University of North Carolina at Chapel Hill Gillings School of Global Public Health, Chapel Hill, NC; [3]The University of North Carolina at Chapel Hill College of Arts and Sciences, Chapel Hill, NC; [4]London Health Sciences Centre, London, ON, Canada.*

Background: Nearly 1 in 5 US children and adolescents have obesity, a risk factor for cardiovascular disease. We examine longitudinal body mass index (BMI) patterns among adolescents and young adults (AYA) with chronic kidney disease (CKD) during the age of transition to adulthood.

Methods: We conducted an historical cohort study of AYA with CKD stages 1-5 aged 13-25 at a southeastern health system in the USA. Electronic medical record (EMR) appointment and laboratory data from Jan 2005-May 2015 were extracted, and CKD patients with ≥4 height and weight measurements were included (*N*=7,978 observations from 255 patients). Age- and sex-specific BMI Z-scores and percentiles were calculated using the 2000 CDC growth chart (normal weight: BMI >5th and <85th percentile; overweight: BMI ≥85th and <95th percentile; obese: BMI >95th percentile). We modeled BMI Z-score as a linear function of age allowing for different intercepts and slopes for adolescents (aged 13-19) and young adults (aged 20-25), adjusting for sex, race/ethnicity, birth year, and CKD etiology (glomerular, non-glomerular, other primary diagnosis). Logistic regression estimated the proportion of patients with overweight or obesity by age.

Results: At baseline, patients' mean age was 14.9 years, 53% were male; 35% had glomerular conditions, 32% non-glomerular conditions, and 33% had other primary diagnoses. BMI Z-scores decreased with age among adolescents (-0.066 standard deviations [SD] per year of age; P = 0.022) and increased with age for young adults (0.170 SD per year of age; P < 0.001). The proportion of adolescents with overweight or obesity did not change with age (P = 0.643), but the proportion of young adults with overweight or obesity increased by 0.037 with each year of age (P < 0.001), reaching 0.62 by age 25.

Conclusions: Trends in BMI increase as adolescents with CKD move into young adulthood.



Adjusted for age, race/ethnicity, birth year, and CKD etiology. 95% confidence intervals are shaded.

SA-PO679

Global Health Burden of Pediatric CKD of Varying Etiologies: A Longitudinal and Comparative Analysis

Raghav Shah,[1] Manan Raina,[2] Bryce Pember,[1] Thomas J. Cahill,[1] Sidharth K. Sethi.[3] *[1]Northeast Ohio Medical University, Rootstown, OH; [2]Hawken High School, Cleveland, OH; [3]Medanta The Medicity Medanta Institute of Kidney and Urology, Gurugram, India.*

Background: Chronic Kidney Disease (CKD) affects >10% of the adult global population. Data on the incidence of CKD in the pediatric population is scarce and the epidemiology is not clear. This study estimates: the distribution of pediatric-CKD (pCKD) by geography, sociodemographic indices (SDI), age, and gender; 2-decade pCKD-trends between 1990 to 2019; and compares its different etiologies (diabetes type 1 (T1DM), diabetes type 2 (T2DM), hypertension (HTN), and glomerulonephritis (GN)).

Methods: Using the Global Burden of Disease 2019 database, the incidence, prevalence, death rates, and DALY rates per 100,000 children and adolescents with CKD identified 4 major etiologies: T1DM, T2DM, GN, and HTN. Average annual percentage change (AAPC) over 20 years at global and regional levels was measured and stratified by age, gender, and socio-demographic index (SDI). The SPSS package was utilized.

Results: Globally, the overall pCKD incidence rates increased over 20 years in all 4 etiologies: GN (AAPC 0.478), T1DM (AAPC 0.490), T2DM (AAPC 1.022) HTN (AAPC 1.026). Overall prevalence rates increased for T2DM (AAPC 0.249), T1DM (AAPC 0.504), GN (AAPC 0.649), and HTN (AAPC 0.828). The increase in overall incidence/prevalence was higher in boys than girls and in older versus younger ages. Regarding SDI, AAPC was greater with lower SDI. Concerning geography, the incidence of AAPC was two-fold higher in Asia, America, and Africa than in Europe. Globally, death rates decreased for CKD due to T1DM (AAPC -1.377), GN (AAPC -0.976), T2DM (AAPC -0.862), and HTN (AAPC -0.474). Similarly, the overall DALY rates decreased for T1DM (AAPC -0.849), GN (AAPC -0.755) and T2DM (AAPC -0.745) and increased for HTN (AAPC 0.139). Overall death/DALYs decreased more sharply in females than males, and in younger children than older. Similarly, lower SDIs showed higher death/DALY AAPC. For geography, the decrease in death/daily AAPC was observed to be higher among those in Europe as compared with America, Asia, or Africa.

Conclusions: In conclusion, there has been an overall significant increase in the global incidence and prevalence of pediatric CKD over 20 years as indicated by varied distribution patterns of etiology, SDI, DALY rates, and geography underscoring the need for targeted public health interventions, especially in vulnerable populations.

SA-PO680

Pediatric and Adult Kidneys Have Largely Similar Gene Expression in CKD and Non-CKD

Marvin Sinsakul,[1] Maria Ryaboshapkina,[2] Dianne Acoba,[2] Stefanie Breitenstein,[3] Mario Berger,[3] Anna Reznichenko.[2] *[1]AstraZeneca, Gaithersburg, MD; [2]AstraZeneca, Gothenburg, Sweden; [3]Bayer AG, Pharmaceuticals, Wuppertal, Germany.*

Background: Understanding the molecular similarities between kidney diseases in children and adults is important for pediatric drug development. Here, we assessed age-related changes in kidney gene expression.

Methods: We surveyed public pediatric transcriptomics data and analyzed 5 cohorts (non-diseased GSE11024, GSE70503, GSE147451, mostly glomerular CKD GSE104954 and GSE68127). Differential expression analysis was adjusted for batch as appropriate and APOL1 risk group in GSE68127. Genes with false discovery rate < 5% were considered significant. CKD molecular category (Reznichenko et al. 2024 PMID38286178) was predicted for children in GSE68127.

Results: In total, the 5 cohorts included 53 children from 0 to 17 and 388 adults from 18 to 90 years. Pediatric and adult kidney samples did not clearly segregate on principal component analysis (PCA), neither in CKD nor in non-CKD cohorts (**Fig 1A**). We detected no to minimal differential expression changes, which constituted < 0.5% of measured genes in every cohort (**Fig 1B**). All adult CKD molecular categories were detected among children, with relative proportions and technical mapping quality similar to the adult CKD (**Fig 1C**).

Conclusions: Age *per se* had minimal effect on kidney gene expression. Instead, the gene expression profile in CKD was driven by molecular pathophysiology of CKD.

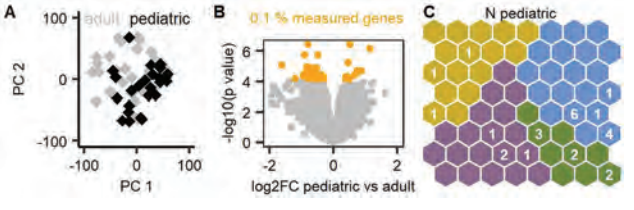


Fig. 1. Representative results in tubulointerstitium. 26 children (6-17 years) and 29 adults (18-74 years) with nephrotic syndrome GSE68127. **A.** PCA. **B.** Differential expression (significant genes in orange). **C.** Children mapped on to the adult CKD molecular categorization map.

SA-PO681

Resolution of Pica with Kidney Transplant

Nicole Vegh,[1,2] Diego H. Aviles.[1,2] *[1]LSU Health New Orleans, New Orleans, LA; [2]Children's Hospital New Orleans, New Orleans, LA.*

Introduction: Pica, compulsive consumption of non-nutritive substances, has been documented in end stage renal disease (ESRD) requiring dialysis with a prevalence of 38-42% in adults and 46% in pediatric patients. Pica is often thought to be secondary to iron deficiency (ID), which is common in ESRD, however, it is debated if the ID drives the compulsion or the compulsion results in ID through impaired absorption of iron. Majority of patients who experience pica endorsed ice pica; hard pica is the ingestion of other substances aside from ice that can result in significant health consequences including death. A prior study in pediatric dialysis patients showed that the presence of anemia and dialysis duration >5 years was associated with increased odds ratio of pica and showed no statistical difference between hemodialysis (HD) vs peritoneal dialysis (PD) modalities or Kt/V between those with pica and those without. They also suggested an underlying cultural or stressful state of ESRD as risk factors for pica (Katsoufis et al, 2012).

Case Description: We present an African American male with ESRD secondary to focal segmental glomerulonephritis (FSGS) on PD for approximately 5.5 years with pica

ingestion, most frequently laundry detergent and carpet cleaner. He developed profound and persistent metabolic alkalosis which led to the discovery of pica. Despite maintaining adequate hemoglobin, iron stores and treatment for depression, his pica persisted. He developed pica near the onset of his kidney disease and 5 years before the initiation of dialysis. Pica resolved immediately following kidney transplantation.

Discussion: This case highlights the need for further evaluation of underlying causes of pica in patients not only in ESRD but also those with chronic kidney disease. Though previous studies have not demonstrated an association between decreased Kt/V and increased risk of pica, this case makes an argument for further investigation. The onset of his symptoms at the time of decreasing GFR, and resolution of symptoms with transplant and normalization of eGFR suggests significant renal insufficiency as a risk factor for pica. Kt/V is not a one-size fits all. Does the onset of pica symptoms suggest a need for improved clearance and a more personalized dialysis prescription?

SA-PO682

Derivation and Validation of a Novel Automated Algorithm for Staging Infant Blood Pressures

Chloe N. Williams,[1] Tasha A. Jawa,[2] Vedran Cockovski,[1] Sophia Nunes,[1] Adree Khondker,[3] Chia Wei Teoh,[1] Seetha Radhakrishnan,[1] Michael Zappitelli.[1] *[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]Queen's University, Kingston, ON, Canada; [3]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada.*

Background: Infant blood pressure (BP) is assessed by visual evaluation of sex and age specific BP curves (i.e., "manual staging"). Manual staging is time consuming and error prone, but is the standard method to assess infant BP. We developed and evaluated accuracy of a novel computerized algorithm to stage BP category in infants.

Methods: We retrospectively acquired BP data in electronic health records (EHRs) from infants hospitalized at a quaternary healthcare center between June 2018-August 2019. Infants <1 year old with paired systolic/diastolic BP were included. First or last admission BP was randomly selected for evaluation. An algorithm to estimate published BP curves was created by digitizing age and sex-based infant BP cutoff curves into a series of points, then deriving each curve's equation of best fit via regression. All BP's were staged manually by two raters (normal, elevated or hypertensive [stage 1 or 2]). The algorithm was evaluated for agreement (using Cohen's kappa and % agreement) with manual staging.

Results: Of 2407 BP measurements, 1304 patients were staged as normal, 298 elevated BP, and 805 hypertensive by manual staging (inter-rater agreement for manual staging was kappa 0.82 [0.58-1.00]). By the algorithm, 1368 had normal BP, 323 elevated BP and 716 hypertensive. Agreement between manual and algorithm classification was 89.4% (kappa 0.83 [0.82-0.85]). Discrepancy between manual vs. algorithm BP staging was noted for 255 BPs. Five BPs (2% of errors) were incorrectly staged by the algorithm and correctly staged by manual staging; 63 BP's (24.7% of errors) were incorrectly staged by manual staging and correctly staged by the algorithm. The remaining discrepancies (73.3% of errors) were BPs on/near the curve at the border of normal vs. abnormal BP. The algorithm has been made into a ShinyApp (developed by A. Khondker), available at https://sickkidsnephrology.shinyapps.io/InfantHypertension/ (Figure 1).

Conclusions: The new infant BP staging algorithm has strong agreement with manual staging and may be used to stage BP in infants in the clinical setting and within EHRs.

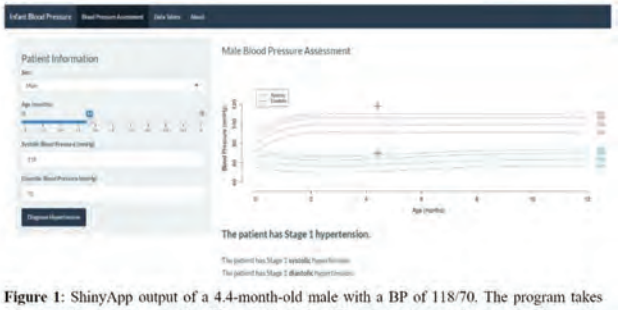

Figure 1: ShinyApp output of a 4.4-month-old male with a BP of 118/70. The program takes sex, age (in months), systolic BP, and diastolic BP input values and automatically stages hypertension using the computerized algorithm.

Late Relapse of Atypical Hemolytic Uremic Syndrome 36 Months after Discontinuation of Complement Blockade Therapy

Ganesh Prasanna, Abhijeet Pal. *The University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Introduction: Complement-mediated atypical hemolytic uremic syndrome (aHUS) manifests as microangiopathic hemolytic anemia, renal failure, and thrombosis, stemming from dysregulated complement system activation. The outcomes include end-stage kidney disease and death. The advent of complement blockade therapy has improved the prognosis, but with prohibitive costs and the inconvenience of infusions. So, discontinuation is often considered, though there is a 30% risk of relapse, which typically happens within weeks of stopping the treatment. In our case, the relapse occurred years later, raising new questions about this contentious subject.

Case Description: In 2020, a five-year-old boy presented with fever, non-bloody diarrhea, and a rash shortly after an influenza infection. He was hypertensive and febrile, along with jaundice and petechiae. Lab results indicated anemia (Hb 10 g/dL) with schistocytes, thrombocytopenia (platelets 17,000/mm3), and acute kidney injury (BUN 44 mg/dL; creatinine 3 mg/dL). Normal ADAMTS-13 activity (99%), and negative stool culture and ELISA for shigella led to the diagnosis of atypical HUS. Along with supportive therapy and plasmapheresis, eculizumab, a complement 5 blocker, was started, inducing remission. Genetic analysis showed a heterozygous mutation of the C3 gene at the binding site for factor H, predisposing to complement dysregulation. Remission was maintained with eculizumab, which was changed to ravulizumab given its longer half-life. During a year of therapy, he was asymptomatic with normal hematological and renal parameters. Ravulizumab was stopped in March 2021. Thirty-six months later, a relapse occurred in March 2024, with another influenza infection. Thus, eculizumab was restarted.

Discussion: Prior studies have indicated a median relapse time of 13 weeks after discontinuation of complement blockade. However, our case underscores the potential for delayed relapse, and advocates for extended periods of surveillance. Our decision to discontinue Ravulizumab was guided our patient's negative C3 deposition assay and his mother's asymptomatic status, though she had the same mutation. Secondly, influenza might have been a "second hit", triggering the relapse. Clinicians must recognize that aHUS can recur despite pre-discontinuation risk assessment. Further research is needed to inform the optimal treatment duration.

Combined Liver-Kidney Transplant in Children

Amber J. Kazi,[1] Juhi Kumar,[2] Jodi M. Smith,[1] Nicole A. Hayde,[3] Lyndsay Harshman,[4] Chloe E. Douglas,[1] Sarah J. Kizilbash,[5] Sharon M. Bartosh,[6] Rachel M. Engen.[6] *[1]Seattle Children's Hospital, Seattle, WA; [2]UPMC Children's Hospital of Pittsburgh, Pittsburgh, PA; [3]Montefiore Medical Center, New York, NY; [4]University of Iowa Health Care, Iowa City, IA; [5]University of Minnesota Twin Cities, Minneapolis, MN; [6]University of Wisconsin-Madison, Madison, WI.*

Background: Data describing outcomes of pediatric combined liver-kidney transplant (CLKT) are limited.

Methods: Retrospective cohort study of pediatric CLKT, liver-alone transplants (LT), and kidney-alone transplants (KT) in US from 1/1/2001 to 12/31/2019 using SRTR data. Primary outcomes include demographic and clinical characteristics, graft, and patient survival.

Results: There were 284 CLKT recipients with a median age of 10 yrs; 22.5% had polycystic kidney disease and 18.7% had primary hyperoxaluria (Table 1). CLKT recipients were more likely to have a history of prior transplant, be listed at multiple centers, and be on dialysis prior to CLKT. CLKT were more likely to receive a whole liver and be listed with exception points compared to LT. CLKT were more likely to have en bloc kidney transplants, KDPI 35-85% donor kidneys, and DGF compared to KT. CLKT graft survival was superior to LT but inferior to KT long term (Fig 1). CLKT patient survival was inferior to KT but similar to LT.

Conclusions: CLKT recipients have different transplant characteristics and outcomes compared to LT or KT alone recipients. Further research is needed to understand the factors driving these differences.

Role of Angiopoietins in Pediatric Heart Transplant Recipients with and without Kidney Dysfunction

Melvin Chan,[1] Stephanie J. Nakano,[1] Shelley Miyamoto,[1] Scott R. Auerbach,[1] Gabriel M. Cara-Fuentes.[2] *[1]University of Colorado Anschutz Medical Campus School of Medicine, Aurora, CO; [2]Nationwide Children's Hospital, Columbus, OH.*

Background: Angiopoietins have been implicated in worse cardiac outcomes but haven't been studied in pediatric heart transplant recipients (HT) with or without chronic kidney disease (CKD).

Methods: We included 17 healthy subjects and 82 HT recipients. In the latter group, patients were matched with and without CKD based on gender, age at the time of collection +/- 4 years, time from transplant +/- 3 years. Estimated glomerular filtration rate (eGFR) was based on serum creatinine using the CKiD U25 calculator. By commercial ELISA kits, we measured Angiopoietin-1 (Ang-1), Ang-2, and Tie-2 levels a single serum sample per subject. Clinical outcomes included HT rejection, diagnosis of coronary allograft vasculopathy (CAV) at the time of sample collection and decline in eGFR.

Results: A total of 41 CKD patients were matched to 41 patients without CKD. About 90% of those with CKD were stage 2. There were no differences in the distribution of age at time of collection, gender, race, ethnicity, primary cardiac diagnosis, time from transplant at collection time, and presence of CAV or any rejections. For healthy controls, biomarker levels were similar to those with HT but no CAV and/or CKD. Ang-2 levels and Ang-2/Ang-1 levels were higher in those with CAV and/or CKD as compared to those with HT but no CAV and/or CKD (Figure 1). Higher Ang-2 levels were also seen in those with any rejections. None of these markers were associated with worsening eGFR after a median of 3 year follow-up from time of collection.

Conclusions: Angiopoetins appear to play a role in predicting CAV with and without CKD and rejections. More studies involving severe CKD patients need to be conducted to see if Ang-2 and Ang-2/Ang-1 levels are higher in those with CAV and rejections based on renal function.

Prevalence and Consequences of Glomerular Hyperfiltration (HF) in Pediatric Solid-Organ Transplant (SOT) Recipients

Melvin Chan, Amy Feldman, Scott R. Auerbach. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: The prevalence and sequalae of glomerular HF are unknown in pediatric SOT. We aimied to describe HF in a pediatric SOT cohort.

Methods: We reviewed all actively followed SOT at a large quatenary pediatric referral center from 2002-2023. Patients were excluded if they had muscular dystrophy or were under the age of 2. The primary outcome was estimated renal function (creatinine based CKiD U25) yearly during the first 5 years post-transplant and the most recent visit. HF was defined as 2 standard deviations above the mean eGFR for age at anytime. Chronic kidney disease (CKD) was defined as an estimated glomerular filtration rate (eGFR) of less than 90mL/min/1.73m2. Secondary outcomes included any rejections and hypertension (HTN). We used a contigency table to determine odds ratio.

Results: A total of 402 patients were eligible. Of the 129 kidney transplant recipients, only one had HF. The clinical characteristics of the remaining patients are shown in Table 1, with 44 (16%) demonstrating HF at some point during the first 5-years post-transplant. Table 2 depicts the clinical associations based on renal function in liver and heart transplant recipients. Patients in both the HF and CKD groups had a 2.22 higher odds of having HTN compared to those with normal function (p=0.024 and 0.008, respectively). The non-renal transplant CKD group also had a 1.8 higher odds of having any episodes rejection (p=0.02).

Conclusions: While HF is uncommon in pediatric kidney transplant recipients, it is prevalent in pediatric liver and heart transplant recipients. HF and CKD are both independently associated with an increased risk for HTN in these non-renal transplant patients. Close follow-up for progression and sequalae of CKD is thus warranted in this high risk SOTr population.

Table 1: Clinical Characteristics

Mean (STD)/Count (%)	Non-Hyperfiltration (n=229)	Hyperfiltration (n=44)
Age at Transplant (Years)	5.9 (6.4)	4.2 (5.5)
Sex

Utility of Donor-Derived Cell-Free DNA in Pediatric Kidney Transplantation: Initial Results from the NAPRTCS Registry Centers

Vikas R. Dharnidharka,[1] Sara A. Boynton.[2] NAPRTCS Investigators.
[1]Washington University in St Louis, St Louis, MO; [2]Johns Hopkins University, Baltimore, MD.

Background: Peripheral blood donor-derived cellfree DNA (dd-cfDNA) percentage is a novel biomarker for acute rejection (AR) in adults, but studies in a large cohort of children are lacking. The North American Pediatric Renal Trials and Collaborative Studies (NAPRTCS), a voluntary multi-center consortium that has been collecting data on children with kidney transplants (pKT) since 1987, expanded the registry with a CareDx grant in 2022 to collect dd-cfDNA data.

Methods: In addition to pKT data routinely collected by NAPRTCS, dd-cfDNA percentage results obtained as part of standard care were collected. Centers provided the assay type used (Allosure; Prospera or other) and whether the test was associated with a biopsy or an episode of AR.

Results: To date, we have 1386 dd-cfDNA results, from 305 unique recipients (median 3 results per patient, IQR 2, 6), from test dates 10/8/18 to 2/2/24, representing pKT dates 10/8/08 to 4/2/24, from 14 different centers, median 16 patients and 58 results per center. Recipient demographics mirrored the overall population. The dd-cfDNA test used was Allosure in 1294 (93.3%; median result 0.34%, range 0.04-16.0) and Prospera in 92 (6.7%; median 0.83, range 0.04-18.44). On the forms, test results were associated with a biopsy for 706 Allosure (median dd-cfDNA 1.1%; range 0.07-16, Fig 1 panel A) and 64 Prospera results (median 2.9%; range 0.1-9.46, panel B) and to AR in 122 Allosure (median 1.4%, range 0.07 -13, panel C) and 11 Prospera results (median 4.2%, range 0.1-9.46, panel D).

Conclusions: In this large pediatric cohort study, higher dd-cfDNA levels associated with pKT biopsy or an AR event. Further analyses will calculate AR test efficacy via ROC curves, separated by surveillance or for-cause detailed biopsy results.

Use of the Seraph 100 Microbind Affinity Blood Filter in a Pediatric Patient with Persistent BK Nephropathy

Meredith Harris, Mahima Keswani, Theresa A. Mottes, Priya S. Verghese.
Ann and Robert Lurie Children's Hospital of Chicago, Chicago, IL.

Introduction: BK nephropathy (BKN), a cause of kidney failure in solid organ transplant recipients, has no approved treatment strategy. Most providers trial immunoreduction which risks rejection of the transplanted organ. The Seraph® 100 Microbind® Affinity Blood Filter (Seraph® 100) (ExThera Medical Corporation) mimics the action of the natural glycocalyx to bind pathogens via heparin sulfate proteoglycans in patients on Continuous Renal Replacement Therapy (CRRT). It has been used to treat COVID-19, Adenovirus, Epstein-Barr Virus, and Cytomegalovirus with variable efficacy. Based on aforementioned viral load reduction with the Seraph® 100, we hypothesize this filter will reduce BK viral load in our patient.

Case Description: A 14 yo female with dilated cardiomyopathy presented 8 years following cardiac transplant with new onset BK viremia (BKV). Her BK PCR titers peaked at 9,600,000 IU/ml. She was treated with Leflunomide, IVIG and immunoreduction. Despite reduction in BK titers, her glomerular filtration rate progressively declined. Persistent BKV was considered a contraindication to kidney transplant for which she would have otherwise qualified. With her impending need for dialysis, CRRT was initiated using the Seraph® 100 for 48 hours with a filter change at 24 hours. No adverse effects were noted. The patient was discharged to continue outpatient hemodialysis. **Figure 1** shows trends of BK levels from time of initiation of Seraph® 100. Two months post Seraph® 100, BK level was undetectable without any new interventions. She underwent kidney transplant and is 3 months post-transplant without recurrent BKV. Surveillance biopsy at 3 months demonstrates no evidence of BKN.

Discussion: We demonstrate the clearance of BKV in a heart transplant patient with BKN related end stage kidney disease, 2 months post utilizing the Seraph® 100 filter, allowing for successful kidney transplant. Ongoing studies are needed to confirm and evaluate continued success of the Seraph® 100 in patients with BKV.

Figure 1: BK viral load in relation to initiation of Seraph® 100 use. Time 0 is the time of initiation of the Seraph® 100 filter.

Immune Monitoring by Torque Teno Virus Load in Addition to Virus-Specific T Cells after Pediatric Kidney Transplantation

Lars Pape. *Universitatsklinikum Essen, Essen, Germany.*

Background: Pharmacokinetic monitoring alone is insufficient to estimate the intensity of immunosuppression after kidney transplantation (Tx). The IVIST RCT demonstrated that additional steering of immunosuppressive therapy by virus-specific T cells (Tvis) is safe and reduces exposure to immunosuppressants. Another promising biomarker is the torque teno virus (TTV) load that was associated with risk for rejections and infections in some observational trials. We have now evaluated a possible benefit of additional analysis of TTV load to improve immune monitoring in the IVIST cohort.

Methods: In the IVIST trial, 31 pediatric kidney recipients were randomized to the intervention group with additional steering by Tvis levels. The immunosuppressive regimen consisted of cyclosporine A (CsA), everolimus (Eve) and glucocorticoids. In 27/31 patients of the intervention group (11.7±3.3 years) a retrospective analysis of TTV-DNA was performed by PCR in frozen plasma samples obtained from 20 visits (1-24 months after Tx). TTV and Tvis changes from baseline levels have been evaluated by paired t-test, the correlations to CsA and Eve trough levels by Pearson correlation coefficients.

Results: Median TTV-DNA of all plasma samples (n=474) was 2.5E4 cop/ml (2.3E1 to 2.8E9). High TTV loads were found under the intensified immunosuppression during the initial post-transplant period (2 mo post Tx: mean log number 11.6) and a significant TTV-decrease after reduction of immunosuppression (6 mo post Tx: 9.8, p=0.009; 22 mo post Tx: 9.3, p=0.005). In contrast, ADV-Tvis levels increased over time: from 1.47 cells/µl (2 mo post Tx) to 1.98 (6 mo post Tx, p=0.056) and 2.36 (22 mo post Tx, p=0.008). (Figure 1). TTV-load showed weak correlations to trough levels of CsA and Eve (24 mo post Tx: TTV vs. CsA r=0.33; vs. Eve r=0.37).

Conclusions: The first combined analysis of TTV load and ADV-Tvis showed an opposite course over the first two years after Tx. Both biomarkers were related to the intensity of immunosuppression but with high interindividual variations and weak correlations to trough levels of immunosuppressants. Therefore, a combined post-Tx monitoring may have an additional value to identify over- and underimmunosuppression. Further randomized controlled trials are needed to confirm the benefit of a combined use of TTV and Tvis to optimize dosing of immunosuppressants.

SA-PO690

Outcomes Using Alemtuzumab Induction in Pediatric Kidney Transplant Recipients

Yifeng Zhang, Juhi Kumar. *UPMC Children's Hospital of Pittsburgh, Pittsburgh, PA.*

Background: No standard guidelines for induction immunosuppression exist in pediatric kidney transplant and the choice is usually institution specific. Alemtuzumab (Campath) is a humanized monoclonal antibody that binds to the CD-52 membrane glycoprotein and causes profound depletion of T and B lymphocytes. Recent review of the NAPRTCS Registry showed that only 17.5% of patients received Alemtuzumab, compared to 48.5% thymoglobulin and 30.1% Basiliximab. It is the least used agent with minimal data on its longitudinal effects. Alemtuzumab has been associated with the development of de novo donor specific antibodies (DSAs) which has been shown to increase risk for allograft loss. Our center uses one dose of Alemtuzumab as induction with tacrolimus and mycophenolate mofetil maintenance immunosuppression. Aim of the study is to review our institution's transplant outcomes with Alemtuzumab induction.

Methods: We did a retrospective chart review of 170 kidney transplant patients, aged 2 to 26 years old, transplanted between January 2010 to December 2023 who received Alemtuzumab as induction therapy. We examined incidence of viremia (CMV, BKV, EBV), BK viruria, DSAs, acute rejections, and patient and allograft survival rates.

Results: Median age at transplant was 12 years, (IQR 6-23). 60% of the patients were male. 50% received a deceased donor transplant. Incidence of viremia 6 months and 1 year post transplant for CMV was 3.6% and 2%, EBV 23% and 28%, BKV was 16% and 14%, and BK viruria was 31.9% and 31.2%, respectively. Incidence of Class II DSAs was 2% at 6 months, 3.4% at 1 year, 6.9% at 3 years, and 7.7% at 5 years post-transplant. Incidence of rejection at 6 months and 1 year post-transplant was 5.8% and 8.3%, respectively. Graft survival was 99.4% at 1 year, 94.7% at 3 years, and 93.5% at 5 years post-transplant. Patient survival was 96.4% and graft survival was 91.1% over the study period duration.

Conclusions: Alemtuzumab is a reasonable option for induction immunosuppression given its ease of administration with outcomes that are comparable to those reported for other induction agents in the literature.

SA-PO691

Metabolic Screening to Assess Cardiovascular Risk in Pediatric Kidney Transplant Recipients

Yifeng Zhang, Juhi Kumar. *UPMC Children's Hospital of Pittsburgh, Pittsburgh, PA.*

Background: Post-transplant immunosuppression, such as steroids and calcineurin inhibitors, have been implicated in the development of new onset diabetes after transplantation (NODAT) and dyslipidemia increasing the risk of cardiovascular events affecting allograft and patient survival. The estimated incidence of NODAT in the pediatric transplant population is around 3-20%. Yet the incidence of metabolic syndrome, defined as a constellation of cardiovascular risk factors such as obesity, dyslipidemia, insulin resistance, and hypertension, has been difficult to establish among pediatric kidney transplant recipients. A contributing factor is a lack of guidelines to effectively screen these patients. We implemented a quality improvement (QI) project to streamline how our patients are screened. Our aim is to identify at-risk patients earlier with the goal of decreasing the morbidity and mortality related to the metabolic syndrome.

Methods: Non-fasting lipid panel, random plasma glucose and hemoglobin A1c (HgbA1c) were obtained annually. 162 pediatric kidney transplant patients aged 2 years to 20 years old were screened. Patients were referred to endocrinology if BMI was > 90% percentile, HgbA1c > 6 %, and abnormal fasting lipid profile was present. Primary outcome of interest is the percentage of patients who received metabolic syndrome screening labs pre and post implementation. Secondary outcome is the incidence of metabolic syndrome.

Results: Prior to QI initiation, only 18 patients (0.1%) had metabolic syndrome screening labs. After initiation, 91 patients (56%) received screening labs. HgbA1c level > 6% was found in 4 patients and they were referred to endocrinology and 7 patients had HgbA1c in the pre-diabetic range (5.6-6%). 4 patients had abnormal non-fasting lipid panels that will require reassessment on a fasting sample. The prevalence of patients with a component of metabolic syndrome was 18%.

Conclusions: Early identification and regular screening for metabolic syndrome in pediatric kidney transplant recipients is critical for the overall health and survival of the patient and their allograft. Without a standardized process to screen these patients, there is a risk of missing a group of patients with early signs of disease. The results of this QI intervention show that standardized screening is feasible and leads to early recognition of abnormal metabolic profile.

SA-PO692

Sex Disparities in Access to Second Kidney Transplantation among Adolescents

Alexandra Bicki, Sang M. Nguyen, Gabriela Accetta Rojas, Charles E. Mcculloch, Elaine Ku. *University of California San Francisco, San Francisco, CA.*

Background: Prior work has demonstrated disparities in access to kidney transplantation by sex, with women being less likely to receive a first transplant compared to men. We aimed to determine whether this disparity persists in relation to access to second kidney transplantation.

Methods: We performed a retrospective cohort study of people ≥13 years with first graft failure from 2006-2019 according to the United States Renal Data System. Using Cox proportional hazards models, the primary predictor was sex and the primary outcome was receipt of a second transplant overall, living, or deceased donor transplantation. We tested for interaction between age at first graft failure and sex.

Results: Of the 36,215 individuals included, median age at first graft failure was 48 years (IQR 37-58 years; 59% male). Median vintage of the first graft was 8 years (IQR 4-13 years), with no difference by sex (p=0.44). Over the observation period, 6,935 individuals (19%) died prior to second transplant receipt, and 18,610 individuals (51%) received a second transplant. There was an interaction between age and sex (p_{int}<0.05) such that girls 13-<18 years at first graft failure had reduced access to second transplant as compared to same-aged boys (HR 0.65, 95% CI 0.55-0.76). This relationship was not observed among older age groups. Findings were more prominent for deceased (vs living) donor transplantation in the adolescent age group.

Conclusions: Adolescent girls had substantially reduced access to second transplant compared to adolescent boys, a disparity that was not observed in other age groups. Given the high priority of children on the national waitlist, further studies are needed to understanding the sources of this disparity.

Funding: NIDDK Support

Hazard of second kidney transplant by sex, stratified by age at first graft failure

Hazard and 95% CI for women vs. men (reference)	Any transplantation	Living donor transplantation	Deceased donor transplantation
Overall	1.02 (0.99-1.05)	1.06 (1.01-1.11)	1.00 (0.97-1.03)
13-<18 years	0.65 (0.55-0.76)	0.89 (0.64-1.24)	0.59 (0.49-0.72)
18-<40 years	1.05 (1.00-1.11)	1.05 (0.96-1.13)	1.06 (1.00-1.13)
40-<65 years	1.04 (1.00-1.08)	1.09 (1.02-1.16)	1.01 (0.97-1.06)
≥65 years	0.92 (0.83-1.00)	0.94 (0.78-1.13)	0.91 (0.81-1.02)

Models adjusted for age and body mass index at first graft failure, sex, race/ethnicity, neighborhood income, calendar period (before vs. after 2014 Kidney Allocation System changes were made), insurance type, ABO blood group, and comorbidities.

SA-PO693

Need to Know, Want to Know: Characterization of Pediatric Kidney Transplant Education Materials

Taylor R. House,[1] Makayla Thomas,[1] Aaron G. Wightman,[2] Ari Pollack,[2] Susan P. Wong.[3] *[1]University of Wisconsin-Madison, Madison, WI; [2]Seattle Children's Hospital, Seattle, WA; [3]University of Washington, Seattle, WA.*

Background: Educational materials are meant to empower patients and families with information about kidney transplant, making their content and accessibility vital to supporting family-centered care and optimizing outcomes.

Methods: We conducted a mixed inductive and deductive content analysis of educational materials used by pediatric kidney transplant centers associated with a national research consortium to assess readability and relevance to four established priorities shared by patients, parents, and clinicians: kidney function, infection, life participation, and survival. We assessed readability using validated measures and summarized data descriptively.

Results: We obtained educational materials from 23 centers (32% response rate), averaging 81±69 pages in total length. Six centers (26%) used materials targeted to pediatric patients. All centers' materials addressed kidney function and infection, 22 (96%) also addressed life participation, and 18 (78%) addressed survival. Materials tended to feature more pages addressing infection (12±8 pages) and kidney function (10±6 pages) than life participation (7±7 pages) and survival (3±4 pages). Among aspects of life participation, psychological well-being was most frequently addressed (Figure). Over one-third (38%) of all life participation references were negatively framed – discouraging or cautioning aspects of life post-transplant. Mean grade level readability of materials was 8.9±1.7 with Simple Measure of Gobbledygook and 9.5±1.8 with Flesch-Kincaid Grade Level.

Conclusions: Pediatric kidney transplant centers use educational materials that are infrequently targeted to children, exceed recommended readings levels, and unevenly address stakeholder priorities. There is an opportunity to better address child and caregiver prioritized outcomes, particularly life participation, to promote greater goal concordance and shared expectations among patients, families, and clinicians.

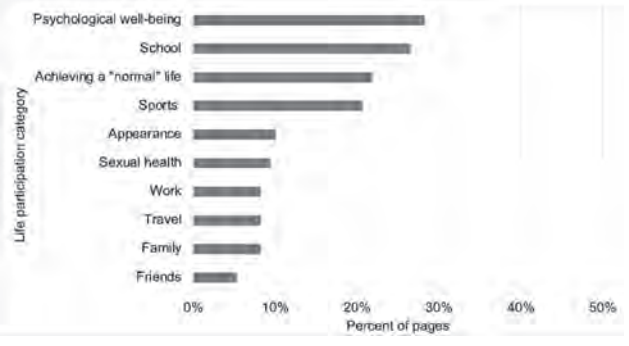

Figure: Of pages referencing life participation, percent discussing varying categories of life participation.

SA-PO694

Pediatric-to-Adult Kidney Transplant Transition Clinic in a Single Center: 3-Year Experience

Namita Singh, Craig S. Wong, Amy Staples. *University of New Mexico School of Medicine, Albuquerque, NM.*

Background: The transition of adolescents from child-centered to adult-oriented health care systems is a complex phenomenon. It is unique for each individual, affected by demographic, personal, ecological factors, as well as degree and specific features of one's disease. Failure of proper transition in kidney transplant (KT) recipients can lead to medical non-adherence, and subsequent loss of graft and return to dialysis.

Methods: We present the framework and findings of the KT Transition clinic at an academic center serving predominantly American Indian and Hispanic population. The clinic consists of a multi-disciplinary team including a lead nephrologist, nurse, pharmacist, social worker, dietician, and psychologist. Regular transition care meetings are conducted between pediatric and adult transplant teams to discuss each eligible patient at length, to understand the medical and social history, as well as to identify any potential barriers for successful transition which can be addressed in a timely and efficient manner. Pre-transition stage occurs at ages 14- 18 years, under the care of pediatric team, where the individual and caregivers are assessed for readiness to transition. Active transition stage starts at 18-21 years age and management is collaborative between the pediatric and adult teams. Complete transition to adult care happens with consensus among the patient, caregivers, and providers. These KT recipients are followed in the transition clinic for up to 26 years age with routine labs and office visits at least every 3 months.

Results: Since the re-establishment of the transition process and protocols in January 2021 and until December 2023, we have managed about 30 patients in the clinic with majority identifying as Hispanics (76%). Compliance with clinic visits has increased and remained consistently above 85%. Three out of 4 allograft failures were noted due to biopsy-proven chronic rejection, with none in the past year.

Conclusions: We report improved patient compliance and graft outcomes in young adult KT recipients in a single center, achieved through a standardized transition protocol and efficient crosstalk between pediatric and adult provider teams.

Time period	Number of rejections	Number of allograft failure
Jan- June 2021	2	0
July- Dec 2021	1	1
Jan- June 2022	1	2
July- Dec 2022	0	1
Jan- June 2023	0	0
July- Dec 2023	0	0

SA-PO695

Impact of a Health Care Transition (HCT) Clinic on Health Outcomes in Patients with Kidney Diseases: A Single-Center Experience

Demah Alobaidi, Sai Kaumudi Saridey, Cortney T. Zimmerman, Sahar Siddiqui. *Baylor College of Medicine, Houston, TX.*

Background: HCT from pediatric to adult focused care in patients with renal disease can be a challenging process. Inadequate HCT can cause interruption in continuity of care, which can lead to poor health outcomes like disease progression. A HCT clinic can be effective tool in building trust, communication and better health outcomes in adolescents and young adults (AYA). This abstract highlights the impact of a HCT on patients who utilized this at a Children's hospital in collaboration with an affiliate hospital in southwest USA.

Methods: We included patients who utilized the HCT clinic from 2021-2023 comprising of two visits (pediatric and adult clinics) to achieve thorough hand-off. We collected data on health related outcomes by manual review of EHRs. Our outcomes were: 1. Retention in adult renal care as measured by regular follow up with adult provider 2. Adequate communication between patient and provider measured via MyChart utilization 3. Significant events by noting adverse events such as hospitalization, renal transplant rejection & unplanned pregnancies.

Results: 29 patients utilized the HCT clinic (8 M, 21 F). 16(55%) with renal transplants, 7(24%) with Lupus Nephritis and 6(20%) with CKD. Retention in adult renal care was good 96%(28 out of 29) followed up regularly with their renal provider and only one patient was lost to follow up. All patients (100%) utilized MyChart to communicate with their adult renal providers. There were adverse events: 2(6%) patients who experienced complications of renal transplant requiring hospitalization and disease management. Patients were sent to transplant team in the same hospital for closer monitoring. 3 female patients got pregnant.

Conclusions: We found that AYA can benefit with HCT clinic. Overall retention in adult renal care was favorable and majority of the patients maintained good communication with their pediatric and adult renal providers. Outcomes for patients utilizing the HCT clinic appear positive with only 2 patients developing transplant rejection. In the future, we plan to look in to women's health especially after HCT with pregnancy and disease progression.

Health Outcomes from HCT clinic

1) Retention in adult health care	28/29 patients followed up with adult renal provider 1 patient with ESRD – transitioned to local dialysis unit 1 patient with insurance issues transitioned to in-network renal 1 patient was lost to follow up
2) Communication between patient and provider	29/29 patients active on my chart
3) Significant events	Two patients with transplant complication transitioned to transplant team in same adult hospital Three patients had pregnancies

SA-PO696

Barriers to Caring for Adolescents and Young Adults with Kidney Diseases

Angelina M. Dixon,[1] Anna Ostrow,[1] Andrew Vissing,[2] Eliza Blanchette,[1] Jessica B. Kendrick.[1] *[1]University of Colorado Anschutz Medical Campus, Aurora, CO; [2]Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Adolescents and young adults (AYA) with CKD experience morbidity and mortality outcomes at unacceptably high rates, and a lack of knowledge and communication among nephrology providers is a contributing factor to adverse outcomes. Here, we evaluate adult nephrology providers' self-perceived education gaps, comfort, and reported barriers in transitioning patients from pediatric to adult care.

Methods: An anonymous, on-line survey of US nephrologists was undertaken from January 30 to May 7, 2024. The survey included questions regarding awareness and implementation of healthcare transitions (HCT) guidelines and knowledge of childhood-onset kidney disease, pediatric nephrology treatment guidelines, and AYA care.

Results: 152 adult nephrologists and 22 pediatric nephrologists submitted the survey. 71% of adult respondents were unfamiliar with the American Academy of Pediatrics (AP) Six Core Elements (vs.18% of pediatric nephrologists, p<0.001) and 63% were unfamiliar with the ISN/IPNA consensus statement on transitioning patients from pediatric to adult nephrology care (vs. 27% of pediatric nephrologists, p<0.001). In addition, adult nephrologists report they are not familiar or slightly familiar with youth health/adolescent medicine (68%), childhood/congenital causes of kidney disease (27%), and medications approved for patient <18 with kidney disease (51%). 48% of respondents had not received training in HCT. Of those who had received HCT training, 73% received training after completion of their formal training. 65% of respondents felt that further training in HCT would be useful and felt it should be included in residency training (37%), fellowship training (96%), and after completion of formal training (37%).

Conclusions: Most adult nephrologists are unaware of HCT guidelines and unfamiliar with caring for AYA with CKD. The creation of a HCT curricula that addresses these topics is imperative.

SA-PO697

Barriers to Communication with Providers among Pediatric Kidney Transplant Patients and Their Caregivers

Kaushalendra Amatya,[1,2] Kristen Sgambat,[1,2] Mesgana Dagnachew,[3] Asha Moudgil.[1,2] *[1]Children's National Hospital, Washington, DC; [2]The George Washington University School of Medicine and Health Sciences, Washington, DC; [3]Georgetown University, Washington, DC.*

Background: Effective communication between pediatric transplant patient/families and the treatment team is essential to adjustment and adherence to medical regimen. Barriers to communication such as language, health literacy, trust and comfort in providers, and cultural beliefs can impact outcomes and thus should be identified and addressed. This project aimed to obtain baseline data on the major barriers to healthcare communication in transplant patients and families.

Methods: Participants were patients (n=30) and caregivers (n=29, total n=59) presenting to the post-kidney transplant clinic in a pediatric hospital. A survey of healthcare communication consisting of demographics and factors related to healthcare communication was developed and administered to patients or caregivers using an electronic tablet.

Results: The self-reported racial distribution was 21 Latinx (35.6%), 19 Black (32.2%), 10 White (16.9%), 4 Asian (6.7%), 3 Middle Eastern (5.08%), and 2 Other. 28 patients (47.4%) identified English and 15 (25.4%) identified Spanish as their primary language; others reported were Arabic, Korean, and Urdu. Participants noted being most comfortable talking to the treatment team about medications and least comfortable talking about emotional health and financial concerns. 2 participants noted feeling uncomfortable or somewhat uncomfortable reaching out to providers between visits and 1 noted feeling their healthcare providers are not invested in the patient's health. 94.9% participants noted they think the healthcare providers' advice is very important (others neutral) and 81.3% noted completely trusting their providers (others neutral or somewhat trust).

Conclusions: Patients presenting to our pediatric kidney transplant clinic are racially diverse and a significant portion do not use English as their primary language. While most patients and families are comfortable discussing medications with providers and trust provider's advice, some may not feel comfortable reaching out to providers as needed and may not want to discuss certain topics that have direct and indirect implications on healthcare outcomes. It is imperative that these barriers be identified and adequately addressed. Future research should further explore barriers to communication and identify remedial methods to improve transplant outcomes.

SA-PO698

It Takes Two to Tango: Pediatric and Adult Kidney Transplant Providers' Perspectives and Practices for Transition of Care

Omar Alomar,[1] Beverly Kosmach-Park,[2] Tarek Alhamad,[1] Song C. Ong.[3] On behalf of the AST KPCOP-PCOP Transition of Care Workgroup. *[1]Washington University in St Louis, St Louis, MO; [2]UPMC Children's Hospital of Pittsburgh, Pittsburgh, PA; [3]The University of Alabama at Birmingham, Birmingham, AL.*

Background: Kidney transplant (KT) recipients aged 17-24 face the highest graft failure risk, coinciding with their transfer to adult care. Healthcare transition (HCT) can help preparing young adults (YA) for adult care, yet practices of American Society of Transplantation (AST) members serving this vulnerable population have not been studied.

Methods: An on-line survey developed by the AST Kidney-Pancreas and Pediatric Communities of Practice was distributed between July 2023 and March 2024.

Results: There were 131 responses: 60 Pediatric Providers (PP) and 71 Adult Providers (AP), mostly US attending physicians (PP 78%, AP 83%). Out of 69 KT centers where UNOS ID was disclosed, 80% had one respondent. Most PP and AP (91%, 84%) agreed that transition is a joint responsibility and valued having a transition program (PP 97%, AP 94%). More PP had transition programs (70% vs 48%), and both groups were familiar with their centers' transition programs (PP 82%, AP 73%). A formal transition policy was often lacking, with AP more likely to lack one (79% vs. 57%, p=0.008). PP were more likely to have a transition coordinator (67% vs 48%). Multidisciplinary transition clinics were rare (PP 27%, AP 23%). Both groups felt Transition Readiness Assessment was key to timing transfer (PP 87%, AP 73%). 62% of PP had no age limit in their centers and would delay transfer if needed. Both cited mental health status, inadequate self-management and self-advocacy skills as significant barriers. Systemic barriers included the YA relationship with PP, fragmentation of adult care, lack of community resources, and staffing/training issues. Only 19% of AP felt YA were well-prepared for transfer, few continued transition training post-transfer (15%). Outcome measures were tracked by 34% of PP and 42% of AP. Feedback from YA/caregivers was rarely obtained by PP (24%/18%) or AP (37%/24%).

Conclusions: This is the first AST survey on AP and PP perspectives regarding HCT. PP and AP endorse transition as a collaborative process and share similar concerns on barriers to successful HCT. With increased awareness of HCT's importance for improving outcomes, efforts should focus on program development starting with the pediatric team and continued into young adulthood post-transfer, both systemically and locally.

SA-PO699

The State of Pediatric Nephrology in the United States: Survey of Division Directors

Priya S. Verghese,[1] Joseph T. Flynn.[2] ASPN Division Director Interest Group. *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Seattle Children's Hospital, Seattle, WA.*

Background: Targeted interventions to address the conflict in demand with a workforce shortfall in pediatric nephrology services require a better understanding of current state.

Methods: The American Society of Pediatric Nephrology interest group of 92 Pediatric Nephrology Division leaders, developed a survey to describe the scope of practice and faculty activity for pediatric nephrology, with operational details of their programs.

Results: Survey completion was 83% and 56% respondents were from small programs (≤4 faculty). The number of nephrologists were 1-21 (median 4); with 1-12 purely clinical faculty(cFTE>0.7) per group. Small groups had significantly greater fraction of primarily clinical (>0.7 cFTE) faculty. Large programs had more outreach, ancillary staffing, independent transplant programs, diverse renal replacement options, and on-site outpatient dialysis. Small programs have a disproportionately large outpatient volume per cFTE until recruitment / transition to the large program model. Heterogenous operations for transplant/dialysis/fellowship programs did not mitigate the administrative burden, which were often minimally supported.

Conclusions: These results highlight the diversity of academic pediatric nephrology divisions and identify areas where increased administrative support is needed to maintain division operations.

Small Molecule Inhibition of APOL1 Channel Activity Protects Podocytes from Mitochondrial Dysfunction, Cell Death, and Barrier Disruption Induced by APOL1 Risk Variants

Sylvain Galvani, Kelly E. Sullivan, Heather Weber, Michael Parsons, James J. Mann, Prachi Matsye, Timothy J. Senter, Leslie Dakin, Evanthia Nanou, Brinley Furey, Brandon Zimmerman. *Vertex Pharmaceuticals Incorporated, Boston, MA.*

Background: The presence of two copies of *apoliprotein L1 (APOL1)* genetic variants, *APOL1 G1* or *G2*, along with a 'second hit' (IFNg, HIV, cytokines, etc.), can cause damage to specialized kidney cells called podocytes. We sought to examine the impact of *APOL1* variants in podocytes and the potential impact inhibition of APOL1-mediated ion flux could have on these effects.

Methods: To enable this effort, we developed tetracycline inducible, human immortalized podocyte lines expressing *APOL1 G0* (reference allele), *APOL1 G1* or *APOL1 G2* and examined cell survival following APOL1 induction using a cell death assay. We also studied the potential for APOL1 variants to disrupt cell adhesion, cell-cell junctions and mitochondrial function and the ability of APOL1 ion channel inhibition to modulate these effects.

Results: APOL1 G1 and G2 induction led to a loss in podocyte viability that was rescued by treatment with Compound 3, a close analog of our clinical candidate inaxaplin. We also demonstrate that prophylactic inhibition of APOL1 prevents cell detachment and mitochondrial dysfunction and preserves podocyte barrier formation. Further, therapeutic administration of compound enabled restoration of these three outcomes, highlighting the potential to rescue damaged podocytes.

Conclusions: These data highlight the critical importance of APOL1-mediated ion flux in APOL1 driven cell injury and suggest that damaged podocytes can be recovered to restore their critical filtration barrier.

SA-PO701

Small Molecule APOL1 Channel Inhibitor Reduces Proteinuria, Rescues Podocyte Injury, and Reverses eGFR Decline in an APOL1-Mediated Kidney Disease Mouse Model

Angelo Blasio, Gizelle Mccarthy, Shyamesh Kumar, Kathy Stavropoulos, Timothy J. Senter, Leslie Dakin, Jennifer Proctor, Brinley Furey, Brandon Zimmerman. *Vertex Pharmaceuticals Incorporated, Boston, MA.*

Background: APOL1-mediated kidney disease (AMKD) is a progressive, proteinuric nephropathy caused by gain-of-function variants (G1 or G2) in APOL1. There are currently no treatments addressing the underlying cause of AMKD. We reported results from a proof-of-concept clinical study with inaxaplin (IXP, VX-147), a small molecule inhibitor of APOL1, which has potential to become the first genetically-targeted therapy for kidney disease. Our previous preclinical data demonstrated that therapeutic intervention with a small molecule APOL1 channel inhibitor with similar structure and potency to IXP (Compound 3) reduced proteinuria and podocyte injury in a chronic AMKD mouse model.

Methods: To develop a chronic AMKD mouse model with glomerulopathy, we used transgenic *APOL1* mice homozygous for the *APOL1 G2* variant ($G2_{SC}$). A plasmid encoding interferon γ (IFNγ) was hydrodynamically injected (HDI) into $G2_{SC}$ mice to continuously secrete IFNγ from the liver. Mice were treated for 7 days with Compound 3 or vehicle at two therapeutic timepoints after HDI. Proteinuria and eGFR were assessed throughout the study. Morphological assessment of podocyte health was evaluated using 3D-structural illumination microscopy.

Results: HDI of IFNγ plasmid into $G2_{SC}$ mice led to a dramatic and sustained increase in proteinuria and progressive glomerulopathy. Therapeutic intervention with Compound 3 at both intervention timepoints dramatically reduced proteinuria. Morphological assessment of podocytes showed that loss of filtration slit density was present prior to treatment initiation and was reversed with Compound 3, highlighting the recovery of effaced podocytes. Furthermore, therapeutic intervention with Compound 3 preserved the eGFR when administered early, and reversed eGFR decline back to near baseline level at a later timepoint of intervention.

Conclusions: Here we demonstrate that APOL1 channel inhibition by Compound 3, a close analog of the clinical candidate inaxaplin, reduces proteinuria and glomerulopathy and reverses eGFR decline after APOL1-mediated glomerular damage is well established.

A Kidney-Specific Fasting-Mimicking Diet Induces Podocyte Reprogramming and Restores Kidney Function in Glomerulopathy

Valentina Villani,[1] Xiaogang Hou,[1] Paolo Cravedi,[3] Sean P. Monji,[1] Roberta Buono,[4] Stefano Da Sacco,[1] Silvia Lai,[5] Alessandro Laviano,[5] Diana G. Eng,[6] Stuart J. Shankland,[6] Kevin V. Lemley,[1] Roger E. De Filippo,[1] Valter Longo,[2] Laura Perin.[1] *[1]Children's Hospital Los Angeles, Los Angeles, CA; [2]University of Southern California, Los Angeles, CA; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]University of California Irvine, Irvine, CA; [5]Universita degli Studi di Roma La Sapienza, Rome, Italy; [6]University of Washington Division of Nephrology, Seattle, WA.*

Background: Dietary changes are recommended for chronic kidney disease (CKD) patients. Yet no dietary intervention has shown glomerular regeneration. Cycles of a fasting-mimicking diet (FMD) were previously shown to promote regeneration and reduce damage in the pancreas, blood, gut, and nervous systems but its effect in glomerulopathies are yet unknown.

Methods: We applied cycles of a low-salt FMD (LS-FMD) to puromycin aminonucleoside-induced nephrotic (PAN) rats and monitored renal function and performed histological analysis. We performed qPCR arrays on whole glomeruli and whole kidney snRNA seq during one cycle of LS-FMD and refeeding. Alport syndrome (AS)-FUCCI (Fluorescence Ubiquitin Cell Cycle Indicator) mice were fed with FMD and used to track the cell cycle specifically in podocytes. To determine whether parietal epithelial cells (PECs) contribute to the replacement of podocytes, inducible dual transgenic PEC-Podo mice that lineage trace PECs (red) and podocytes (green) simultaneously were fed LS-FMD following adriamycin-induced nephropathy. To translate these findings, we also performed a pilot clinical trial on CKD patients receiving three 5-day cycles of the human version of the FMD and monitored renal and other physiological parameters up to 1 year post treatment.

Results: Cycles of a LS-FMD lowered proteinuria, and restored nephron structure and function in PAN rats. LS-FMD induced the expression of nephrogenic markers, mimicking kidney developmental processes in multiple kidney structures. Specifically in the glomerulus, LS-FMD prevented podocyte loss by preventing entrance to G1/S phase, in addition to activating PEC-podocyte-lineage reprogramming, as evidenced by lineage tracing studies. In the pilot randomized cross-over study in CKD patients, FMD cycles promoted renoprotection including long-term reduction of proteinuria and improved endothelial function.

Conclusions: We have developed a dietary intervention with the potential to limit and even reverse kidney damage by preserving the number and function of podocytes, and reducing inflammation and glomerulosclerosis.

Canagliflozin Reduces Podocyte Hypertrophic Stress and Progression of Nephropathy by Suppressing the mTOR/p70S6K/cyclin D1 Signaling Pathway in a Model of Obesity-Related Nephropathy

Miho Suzuki, Akihiro Fukuda, Ryo Kurimoto, Akiko Kudo, Takeshi Nakata, Hirotaka Shibata. *Department of Endocrinology, Metabolism, Rheumatology and Nephrology, Faculty of Medicine, Oita University, Yufu, Japan.*

Background: We recently suggested that SGLT2 inhibitors (SGLT2i) suppressed podocyte hypertrophy in models of obesity-related nephropathy (ASN2023). In this study, we examined the underlying mechanisms of the podocyte-protective effects of SGLT2i.

Methods: Zucker fatty rats with non-diabetic obesity were divided into three groups (non-treated: n=6, SGLT2i: n=6, calorie restriction (CR): n=6). Starting at 12 weeks, both the non-treated and SGLT2i groups were fed same quantities of diet. From 24 weeks, the SGLT2i group received canagliflozin (10 mg/kg/day) for 8 weeks, while the CR group was on a diet restricted to match the urinary glucose excretion of the SGLT2i group. Kidney tissue and urine samples were collected at 32 weeks to assess podocyte injury through measurements of urinary protein, urinary sediment podocin (U-sed pod) mRNA using qRT-PCR, glomerular volume (GV), podocyte volume (PV), and podocyte density (PD). To investigate the underlying mechanism, RNA sequencing of the renal cortex was performed for a Zucker Lean (ZL) group as a control, and for the non-treated and SGLT2i groups. Additionally, the IGF-1/mTOR pathway was examined through phosphorylated S6 (pS6) immunostaining and IGF-1 expression using ELISA in the kidney cortex of all four groups.

Results: In the SGLT2i group, body weight, urinary protein, GV, PV, and U-sed pod mRNA significantly decreased, while PD increased, compared to the non-treated group. These effects were more pronounced than those observed in the CR group. RNA sequencing revealed a significant increase in cyclin D1 expression in the non-treated group, which plays an important role in cell cycle and hypertrophy, but a decrease in the SGLT2i group. Western blot analysis confirmed these trends in cyclin D1 expression. Additionally, the expression of the IGF-1/mTOR pathway components (IGF-1 and phosphorylated S6), which are upstream of cyclin D1, was upregulated in the non-treated group but downregulated in the SGLT2i group. The CR group had intermediate levels between the non-treated and SGLT2i groups.

Conclusions: In obesity-related nephropathy, SGLT2i may protect podocytes and reduce hypertrophic stress by suppressing the mTOR/p70S6K/cyclin D1 signaling pathway, independently of reductions to body weight.

MAP4K1 Downregulation by Glucagon-Like Peptide 1 (GLP-1) Receptor Agonists Alleviates Podocyte Injury and Inflammation via the cGAS-STING Pathway in Glomerular Diseases

Aili Cao, Qiye Liu, Ying Chen, Li He, Jiayin You, Niansong Wang. *Department of Nephrology, Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China.*

Background: GLP1R agonists, widely known for their role in glycemic control, have also been observed to confer renal protective effects independent of their blood glucose-lowering properties. Despite these benefits, the underlying mechanisms by which GLP1R agonists exert renoprotective effects remain inadequately understood.

Methods: Our study aimed to elucidate these mechanisms, focusing on the effects of the GLP1R agonist liraglutide on podocyte function and gene expression. We employed RNA-seq sequencing to analyze gene transcription in podocytes treated with liraglutide. Additionally, we investigated the role of the gene MAP4K1 by generating podocyte-specific MAP4K1 knockout mice and inducing nephropathy with adriamycin (ADR) and lipopolysaccharide (LPS) models.

Results: RNA-seq sequencing revealed that liraglutide significantly modulates gene transcription in podocytes, notably causing substantial downregulation of MAP4K1 expression. Data from the Nephroseq database indicated that MAP4K1 is upregulated in focal segmental glomerulosclerosis (FSGS) patients, suggesting its significant role in kidney pathology. In the ADR nephropathy model, liraglutide administration resulted in a marked decrease in MAP4K1 expression in podocytes, correlating with improved kidney functions. Podocyte-specific MAP4K1 knockout mice exhibited significant amelioration of podocyte injury upon ADR-induced nephropathy, associated with suppression of the cyclic GMP-AMP synthase-stimulator of interferon genes (cGAS-STING) pathway. Additionally, in the LPS model, MAP4K1 knockout mice showed reduced levels of inflammatory cytokines and notable improvements in podocyte integrity and kidney functions.

Conclusions: These findings underscore the pivotal role of MAP4K1 in mediating podocyte injury and the inflammatory response in kidney disease. Targeting the MAP4K1-cGAS-STING axis could be a viable strategy for developing new treatments for chronic kidney disease (CKD), highlighting the therapeutic potential of GLP1R agonists in renal protection.

Reversal of Established CKD by Weekly Subcutaneous Recombinant Human Mutated Angiopoietin-Like 4

Jose L. Sanchez Gloria,[1] Ariadna J. Ortega Lozano,[1] Ranjan Das,[1] Joubert B. Kharlyngdoh,[1] Maria Del Nogal Avila,[1] Hector Donoro Blazquez,[1] Eduardo Molina-Jijon,[1] Camille E. Mace,[1] Carmen Avila-Casado,[2] Lionel C. Clement,[1] Sumant S. Chugh.[1] Glomerular Disease Therapeutics Laboratory. *[1]Rush University Medical Center, Chicago, IL; [2]Toronto General Hospital, Toronto, ON, Canada.*

Background: We investigated the therapeutic potential of recombinant mutated human Angiopoietin-like 4 (ANGPTL4), previously shown to reduce proteinuria in diabetic and FSGS (Buffalo Mna) rats (*Clement LC Nat. Med. 2014*), in established chronic kidney disease (CKD). ANGPTL4 binds integrins β_1 and β_5 (podocyte $\alpha_3\beta_1$, glomerular endothelial $\alpha_v\beta_5$, interstitial capillary endothelial $\alpha_1\beta_1$), and has potent anti-apoptotic activity.

Methods: Included with results.

Results: As a proof of concept, transgenic expression of wild type rat *Angptl4* from adipose tissue in Buffalo Mna rats (372-B. Mna) prevented doubling of serum creatinine (measured by LC-MS) between age 6 to 8 months ($P<0.001$), eliminated tubulo-interstitial fibrosis, and improved glomerular morphology compared to B. Mna rats (n = 4 to 6 rats / group). Interstitial infiltrate in 372-B. Mna rats contained mostly macrophages. Recombinant human mutated ANGPTL4 protein 8520 (Nat. Med. 2014) was purified and ultra-purified from HEK 293 stable cell lines grown in FiberCell systems. In a declining dose study (starting with 500 μg weekly subcutaneous 8520 or control rat albumin, n = 5 ZSF1 diabetic rats / group), serum creatinine was lower in the 8520 group compared to control between week 5 (dose 500 μg; $P<0.001$) and week 9 (dose 125 μg; $P<0.05$), but not at subsequent lower doses. Within the 8520 group, serum creatinine was lower on week 9 than Day 0 ($P<0.05$). Upon euthanasia (week 28), interstitial capillary endothelium apoptosis (TUNEL stain) was lower in 8520 compared to control ($P<0.001$). Using the lowest effective 8520 dose (125 μg / week) with or without ACE inhibitor (enalapril 5 mg/Kg/day), inulin clearance GFR at 16 weeks was higher in 8520 ($P<0.05$) and 8520 + enalapril ($P<0.01$) groups, tubulo-interstitial fibrosis lower ($P<0.01$ both groups) and interstitial capillary endothelial apoptosis lower ($P<0.001$ both groups) compared to control treated

ZSF1 rats (age on Day 0, 19 weeks; n = 4-5 rats / group). Enalapril alone did not improve GFR. Studies with higher doses of 8520 are in progress.

Conclusions: 8520 reverses established CKD to improve GFR via a multi-compartment anti-apoptosis effect that keeps capillaries open for repair.

Trametinib Ameliorated Adriamy-Induced Podocyte Injury In Vivo and In Vitro by Inhibiting METTL3-Mediated RCAN1 m6A RNA Methylation

Hua Zhou, Feifei Miao, Yonghe Zhang, Junjun Luan. *Shengjing Hospital of China Medical University, Shenyang, China.*

Background: Trametinib can protects mice from adriamycin(ADR)-induced focal segmental glomerulosclerosis (FSGS). Recently, METTL3, a m^{6}A writer, is reported to involve in pathogenesis of kidney diseases. We aimed to investigate whether Trametinib can attenuate podocyte injury through regulating METTL3 and its modified downstream gene in ADR-induced FSGS mice and injured podocytes.

Methods: TREW database was used to find regulator calcineurin 1(RCAN1) as METTL3 modulated mRNA. First we examined WT-1, METTL3, and RCAN1 in biopsied kidney tissue from FSGS patients. Second, FSGS was induced by ADR injection in BALB/c mice in both normal and pretreated with trametinib. Urinary albumin to creatinine ratio (UACR) and serum albumin (sALB) were measured. Kidney damages were evaluated by PAS, Masson and EM. Third, overexpression and knockdown of METTL3 were performed in human podocytes *in vitro*. Podocyte specific gene WT-1 and synaptopodin (SYNPO); Profibrotic COL-1, α-SMA, and fibronectin (FN); and RCAN1 were assessed at mRNA by qPCR and protein levels by western blotting and immunostaining both *in vivo* and *in vitro*. The level of total m6A was measured by the m6A colorimetric qPCR and m^{6}A methylated mRNA of RCAN1 wwa examined by SELECT qPCR.

Results: WT-1 was downregulated, METTL3 was increased, and RCAN1 was decreased in biopsied kidney sections compared with normal control kidney sections. Trametinib alleviated ADR-induced proteinuria, hypoalbuminuria, hyperlipidemia, and renal dysfunction; podocyte foot process effacement, and sclerotic glomeruli. It also reverted the downregulation of WT-1 and SYNPO as well as reduced production of profibrotic COL-1,α-SMA, and FN protein in FSGS mice. Importantly, Trametinib inhibited the increment of METTL3 and decrease of RCAN1. In vitro study, overexpression of METTL3 in normal podocyte or knockdown of METTL3 by siRNA or Trametinib in ADR-treated podocyte, the changes of podocyte markers and profibrotic proteins displayed similar to those in vivo. The change directions of total level of m^{6}A RNA methylation and relative level of METTL3 methylated mRNA of RCAN1 in podocytes were same as the expressiom changes in vivo.

Conclusions: Trametinib attenuated podocyte injury in FSGS mice and ADR-treated podocyte by regulating METTL3/RCAN1 axis. Trametinib might serve as a potential agent to protect podocyte injury

Autophagic Inhibitor ROC-325 Ameliorates Glomerulosclerosis and Podocyte Injury via Inhibiting Autophagic Flux in Experimental FSGS Mice

Xinling Liang, Li Zhang, Jiaying Li, Yan Yang, Lu-an Li. *Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China.*

Background: Podocyte-specific Yes-associated protein (YAP) deletion mice(YAP-KO mice), is considered a new animal model to study the underlying mechanism of FSGS. We sought to determine the therapeutic benefit of ROC-325, a novel small-molecule lysosomal autophagy inhibitor in FSGS model.

Methods: Mass spectrometry were used to profile the downstream pathways in YAP-KO mice. Foot process morphology and autophagy level were detected by transmission electron microscopy. Immunofluorescence measured autophagy level and autophagic flux.

Results: Mass spectrometry showed the processes linked to lysosome dysregulation have been significantly enrich in the YAP-KO mice. The results showed albuminuria, mesangial matrix expansion, and focal segmental glomerulosclerosis in YAP-KO mice were significantly attenuated by ROC-325. Corrugated capsule formation was greatly altered by ROC-325. Furthermore, ROC-325 treatment inhibited the autophagy activaty induced by YAP-KO by inhibiting autophagosome-lysosome fusion, and accumulation of LC3 and p62. Meanwhile, preapplication of ROC-325 in podocyte markedly suppressed autophagic flux.

Conclusions: These results showed that the role of autophagic activity in FSGS and ROC-325 could be a promising agent for the treatment of FSGS.

Pharmacologic Inhibition of Urokinase-Type Plasminogen Activator Receptor (uPAR)-Formyl Peptide Receptor (FPR) Signaling Prevents Podocyte Damage in Primary Podocytopathies

Manuel A. Podestà,[1] Deborah Mattinzoli,[1] Masami Ikehata,[1] Min Li,[1] Silvia Armelloni,[1] Francesca Zanoni,[1] Carlo Alfieri,[1,3] Piergiorgio Messa,[1] Alberto Diana,[3] Luca Del Giacco,[3] Vincenzo Pavone,[2] Giuseppe Castellano.[1,3]
[1]*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy;* [2]*Universita degli Studi di Napoli Federico II, Napoli, Italy;* [3]*Universita degli Studi di Milano, Milano, Italy.*

Background: Primary podocytopathies are a group of disorders characterized by nephrotic syndrome and frequent progression to kidney failure in patients not responding to treatment, with high rates of recurrence after transplantation. Glomerular upregulation of the urokinase-type plasminogen activator receptor (uPAR) has been linked to podocyte dysfunction in these disorders. We tested the hypothesis that inhibition of uPAR signaling via the formyl peptide receptor (FPR) would ameliorate podocyte damage in primary podocytopathies.

Methods: Renal biopsies and serum from patients with recurrent primary podocytopathies were collected. Podocyte and podocyte-endothelium co-cultures to model the glomerular filtration barrier were carried out according to previously published protocols. RT-PCR and immunostaining were performed with standard methodology. Zebrafish larvae exposed to adriamycin were used as a podocytopathy in vivo model. The peptide UPARANT was used in all experiments to inhibit the uPAR-FPR crosstalk.

Results: uPAR upregulation in kidney biopsies of patients with primary podocytopathies was accompanied by increased expression of FPR2 and integrin-αvβ3 (Fig1A). The same molecules were upregulated in podocytes exposed to sera from patients with recurrent disease (Fig1B), and pharmacologic inhibition of the uPAR-FPR interaction led to normalization of this effect. uPAR-FPR crosstalk inhibition prevented podocyte damage induced by recurrent sera (Fig1C), resulting in significant functional rescue in an *in-vitro* model of the glomerular filtration barrier (Fig 1D). Consistently, targeting of uPAR-FPR crosstalk in a zebrafish larval model of podocytopathy led to functional (Fig1E, high-MW dextran clearance) and ultrastructural (Fig1F) rescue of the disease phenotype.

Conclusions: Pharmacologic targeting of the uPAR-FPR axis confers protection against podocyte damage and may preserve renal function in primary podocytopathies.

SA-PO709

Voclosporin Ameliorates Proteinuria and Directly Protects Podocytes in a Model of Noninflammatory Glomerular Disease

Yu Kamigaki,[1] Julie Dougherty,[1] Amanda P. Waller,[1] Linda M. Rehaume,[2] Laura Biederman,[3,5] Bryce A. Kerlin,[1,4] William E. Smoyer.[1,4] *[1]The Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]Aurinia Pharmaceuticals Inc, Victoria, BC, Canada; [3]The Ohio State University Wexner Medical Center, Columbus, OH; [4]The Ohio State University College of Medicine, Columbus, OH; [5]Nationwide Children's Hospital Department of Pathology, Columbus, OH.*

Background: Idiopathic nephrotic syndrome (INS) is one of the most frequent glomerular diseases in children. There is a critical need for the development of more effective and less toxic treatments. Voclosporin (VCS) is a second generation calcineurin inhibitor (CNI) approved in the USA, EU, Great Britain, and Switzerland on a background of immunosuppressive therapy for the treatment of adults with active lupus nephritis. VCS does not require therapeutic drug monitoring due to an improved pharmacokinetic profile. We investigated whether VCS could reduce proteinuria in a non-inflammatory animal model of NS.

Methods: Rats received 50 mg/kg puromycin aminonucleoside (PAN) or saline via tail vein injection and were gavaged twice daily with vehicle (VEH, vitamin E-TPGS, MCT oil, Tween 40, and 95% ethanol 4:2:2:1, by weight), VCS (4 mg/kg/dose), or cyclosporine (CsA, 10mg/kg/dose) as clinically relevant doses. Rats were euthanized on day 11, and proteinuria, lipid profile, glomerular cell injury, hypercoagulability, and histopathology were assessed. To validate the direct protective effect of VCS on podocytes, cultured human podocytes were also treated with PAN (5 μg/ml) + vehicle (DMSO), VCS (0.1 μg/ml), or CsA (0.1 μg/ml) for 72 hours and podocyte viability and actin stress fiber changes were analyzed.

Results: VCS improved proteinuria, hypercoagulopathy, lipid profile, and TUNEL positivity of glomerular podocytes. PAN + VCS rats exhibited a significantly decreased mean total tubular injury score (1.07 ± 0.23) compared with PAN + VEH (2.00 ± 0.37, $P < 0.05$), while PAN + CsA mean total injury score (1.75 ± 0.34, $P = 0.66$) was only slightly better than PAN + VEH. Cultured podocyte viability of the PAN + VCS group was significantly improved (100% ± 2.6%, $P < 0.01$) compared with PAN + DMSO (91% ± 2.5%), while PAN + CsA (94% ± 4.4%, $P = 0.28$) was mildly better than PAN +DMSO. Also, PAN + VCS cells had more intact actin-fiber cells and fewer actin-fiber-disrupted cells than PAN + DMSO and PAN + CsA.

Conclusions: Compared to CsA, a clinically relevant dose of VCS more effectively ameliorated PAN-induced proteinuria, hypercoagulopathy, NS-associated dyslipidemia, and tubular injury in rats, as well as cell viability and actin cytoskeleton of cultured podocytes.

Similarities and Differences in Gene Expression between Glucocorticoids and Pioglitazone in a Rodent Model of Nephrotic Syndrome

Yu Kamigaki,[1] Julie Dougherty,[1] Sagar Bhayana,[1] Amanda P. Waller,[1] Bryce A. Kerlin,[1,2] William E. Smoyer.[1,2] *[1]The Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]The Ohio State University College of Medicine, Columbus, OH.*

Background: Idiopathic nephrotic syndrome (INS) is one of the most frequent glomerular diseases in children with first line treatment of glucocorticoids (GCs), an immunosuppressant with myriad side effects. Thus, there is a critical need to develop more effective and less toxic options. Pioglitazone (Pio), a non-immunosuppressant, is FDA-approved for type 2 diabetes mellitus. Pio has been associated with proteinuria reduction in adults and children with NS, so it has potential as a non-immunosuppressive alternative or supplement to GC treatment. Therefore, we wanted to compare changes in gene expression and pathways between the two drugs.

Methods: Male Wistar rats received 50 mg/kg puromycin aminonucleoside (PAN) or saline injection and treated daily with vehicle, methylprednisolone (MP, 15 mg/kg), or Pio (10 mg/kg). Rats were euthanized on day 11 and glomerular RNA was sequenced. Differentially expressed genes were analyzed for pathway activation, upstream regulators, and causal networks.

Results: MP and Pio significantly improved proteinuria compared to PAN-only treated animals. We filtered glomerular data for genes significantly up- or down-regulated in PAN-treated animals compared to controls, then compared expression of PAN + MP and PAN + Pio. Our recent article addressed PAN-induced up-regulated genes ameliorated by both drugs. This study analyzed the PAN-induced down-regulated genes commonly improved by both drugs. Common upstream regulators included calcitriol, EGLN family, KRAS, MYOD1, and SORL1. We also analyzed expression changes unique to either drug. MP had 46 unique upstream regulators, including immune regulators and transcription regulators such as HDAC1/2, TBX3, and ATF3. The list of uniquely altered genes for Pio was too short for pathway analysis but included CD36, IL34, RHOQ, and SHPRH, among others.

Conclusions: These studies illustrated the common and unique changes in glomerular gene expression in a rodent NS model treated with immunosuppressive (MP) and non-immunosuppressive (Pio) drug.

miR-193a and Nanoparticle Technology: A Novel Therapeutic Approach for Alport Syndrome

Laura Perin,[1,2] Paola Aguiari,[1] Astgik Petrosyan,[1,2] Yi Huang,[2] Qi Zhang,[1] Xiaogang Hou,[1] Roger E. De Filippo,[1,2] Kevin V. Lemley,[1,2] Eun ji Chung,[2] Stefano Da Sacco.[1,2] *[1]Children's Hospital Los Angeles, Los Angeles, CA; [2]University of Southern California, Los Angeles, CA.*

Background: Significant molecular changes in podocyte cell cycle regulation are responsible for the progression of renal damage. miR-193a has been reported to regulate podocyte phenotype and to ensure maintenance of their differentiated G0 state. We observed elevated levels of miR-193a in human podocytes from Alport Syndrome (AS) biopsies and in AS mice. Here, we study the role of miR-193a in Alport podocytes and if miR-193a inhibition by podocyte-targeting nanoparticles could restore podocyte quiescent state.

Methods: To study the effects of miR-193a, we used miR-193a mimic and antagomir on podocytes from AS FUCCI mice (cell cycle indicator mouse model) and in the glomerulus-on-a-chip system (GOAC), generated with AS patient-derived podocytes. Podocyte-targeted nanoparticles (micelles) were developed and tested for specificity in vitro and in the GOAC and for assessing the efficiency of a miR-193a inhibition therapy. In situ hybridization, Digital Spatial Profiling (DSP, Nanostring), and protein arrays were used to investigate changes in miR-193a targets in murine podocytes and human AS biopsies.

Results: We observed specific upregulation of miR-193a in podocytes vs other glomerular cells, and upregulation of miR-193a targets osteopontin, VEGFA, and ItgαV, and downregulation of WT1 in AS glomeruli. Our data shows that miR-193a regulates

the cell cycle: WT podocytes re-enter the cell cycle when exposed to miR-193a (G1/S), while miR-193a inhibition rescues the AS podocyte G0 and modulates P18, cyclin A1 and cyclin C, important cell cycle regulators. We successfully generated miR-193a inhibitor-mediated micelles enhancing targeting to podocytes and preliminarily proved effective in safeguarding the glomerular filtration barrier. In human AS glomeruli, DSP revealed changes in gene expression in miR-193a targets and cell cycle regulators.

Conclusions: Our data indicate that the elevation of miR-193a plays a key role in regulating podocyte biology by controlling the podocyte cell cycle. Inhibiting miR-193a using micelle technology may re-establish glomerular function by modulating important molecular pathways responsible for podocyte survival to prevent further injury representing a therapeutic target for AS.

SA-PO712

Dapagliflozin in Addition to Ramipril Ameliorates Kidney Disease Progression in Mice with Alport Syndrome

Kana Miyata,[1] Denise Smith,[1] Michifumi Yamashita,[2] Shimok Kim,[1] Faith A. Yeargin,[1] Melisa Beganovic,[1] Daniel N. Leal,[2] John C. Edwards,[1] Shao-Ling Zhang,[3] John S. Chan,[3] Jeffrey H. Miner.[4] *[1]Saint Louis University School of Medicine, St Louis, MO; [2]Cedars-Sinai Medical Center, Los Angeles, CA; [3]Centre de Recherche du Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [4]Washington University in St Louis, St Louis, MO.*

Background: Renin-angiotensin-aldosterone system inhibitors (RAASi) have been the most extensively studied treatment for Alport syndrome, demonstrating established benefits for renal function and survival in both animals and humans. We presented that Ramipril (an angiotensin-converting enzyme inhibitor) had more renoprotective effects in mice with Alport syndrome than sodium glucose cotransporter 2 inhibitors, Dapagliflozin (ASN Kidney Week 2023). The objective of this study is to investigate whether combination treatment with Dapagliflozin and Ramipril exerts a better kidney-protective effect than treatment with Ramipril alone in Col4α3 knockout (KO) mice (an Alport syndrome model).

Methods: We studied both sexes of Col4α3 KO and wild-type (WT) mice (129S1/SvImJ background). Dapagliflozin (1.5 mg/kg/day), Ramipril (10 mg/kg/day), or a combination of both were orally administered via drinking water for 6 weeks, starting at 4 weeks of age (N=8-10/group). The control mice received vehicle for the same duration. Glomerular filtration rate (GFR) was measured by inulin-FITC clearance in conscious mice, and kidneys were processed for histology (PAS, Masson's Trichrome staining and electron microscope). Another set of mice were monitored for their survival.

Results: At 10 weeks of age, Col4α3 KO mice developed a significant weight loss, decreased GFR/body weight, elevated BUN and urine albumin/creatinine ratio. These findings were attenuated by Ramipril, and further improved by the combination treatment. Histologically, Col4α3 KO kidneys showed the severe degree of global and segmental glomerulosclerosis, tubulointerstitial fibrosis, and thickened glomerular basement membrane, which were more significantly improved by the combination treatment than by Ramipril alone. Furthermore, the combination treatment prolonged the life of Col4α3 KO mice; median survival was 157 days in combination treatment while 127 days in Ramipril alone ($p<0.01$).

Conclusions: The combination of Dapagliflozin and Ramipril had more favorable outcomes on preservation of renal function and histology than Ramipril alone in Col4α3 KO Alport mice. Studies are currently ongoing to investigate the underlying mechanisms of action.

SA-PO713

Reducing Proteinuria by Antagonizing αVβ3 Integrin with a Novel Inducible Co-stimulator Ligand-Based Peptide

Alexis P. Jimenez Uribe,[1] Yan Xu,[1] Yanxia Cao,[1] Ryan Spear,[1] Kwi Hye Koh,[2] Adrian P. Mansini,[1] Ariana G. Alcantar,[1] Felix Kliewe,[3] Nicole Endlich,[3] Jochen Reiser,[4] Steve Mangos,[1] Eunsil Hahm.[1] *[1]Rush University, Chicago, IL; [2]Morphic Therapeutic Inc, Waltham, MA; [3]Universitatsmedizin Greifswald, Greifswald, Germany; [4]The University of Texas Medical Branch at Galveston, Galveston, TX.*

Background: Activation of $\alpha_V\beta_3$ integrin has been linked to early stages of glomerular diseases, leading to podocyte injury and proteinuria. To date, no $\alpha_V\beta_3$ antagonists have been successful in clinical trials. Our group has recently discovered a novel protective role for the inducible co-stimulator ligand (ICOSL) in the kidney, functioning as an antagonist of $\alpha_V\beta_3$integrin independently of its canonical immune function and mitigating glomerular damage through its RGD-motif. Here, we developed a 19-mer peptide based on the human ICOSL structure (hICOSL-19) and evaluated its therapeutic potential *in vitro* and *in vivo*

Methods: Data were obtained from the Nephroseq database. The interactions between ICOSL or its derived peptide and integrins were analyzed using surface plasmon resonance (SPR) and proximity ligation assay (PLA). The antagonistic effects of peptides were evaluated through podocyte adhesion, cancer cell proliferation and invasion assays, and western blotting. PEGylation was applied to extend the peptide half-life. The in vivo efficacy of ICOSL-based peptides was tested in mice injected with lipopolysaccharide (LPS) or nephrotoxic serum (NTS).

Results: Analysis of the Nephroseq database confirmed the reduction of ICOSL expression in the glomeruli across several kidney diseases. SPR analysis revealed the preferential binding of ICOSL to $\alpha_V\beta_3$ integrin over other RGD-binding integrins. PLA tests confirmed this ICOSL-$\alpha_V\beta_3$ interaction at both cellular and tissue levels. Similar to the full-length hICOSL protein, hICOSL-19 demonstrated a high affinity for $\alpha_V\beta_3$ integrin. In vitro assays demonstrated that hICOSL-19 effectively blocks $\alpha_V\beta_3$ integrin-mediated downstream signaling. Additionally, unlike cRGDfV, hICOSL-19 maintained its antagonistic effects even at low concentrations. Treatment with hICOSL-19 peptide reduced proteinuria in a mouse model of LPS-induced kidney damage. PEGylation of this hICOSL-19 extended its plasma half-life and maintained its antagonistic effect against $\alpha_V\beta_3$ integrin in vitro and in vivo.

Conclusions: The hICOSL-19 peptide is a promising therapeutic option for treating glomerular disease associated with $\alpha_V\beta_3$activation. Its applications might also extend to conditions involving $\alpha_V\beta_3$ integrin activation, including cancer and fibrotic disease.

SA-PO714

Stabilization of Integrin a3b1 with Novel Activating Antibodies Protects against FSGS

Santiago Balza Pineda,[1] Darlah M. Lopez-Rodriguez,[1] Mohamed Youssef,[2] Sheri Brackman,[2] Antonio Barbosa,[1] Vineet Gupta.[2] *[1]149 Bio, LLC, Miami, FL; [2]The University of Texas Medical Branch at Galveston, Galveston, TX.*

Background: Healthy podocytes maintain the normal function of the glomerulus. The cell surface integrin a3b1 helps podocytes adhere to the extracellular basement membranes. Inflammatory injury, mutations in a3b1 or associated protein CD151, or defects in the integrin-linked cytoskeleton result in reduced cell adhesion, podocyte detachment and urinary loss. This weakening of the filtration barrier contributes to progressive glomerular diseases, including focal segmental glomerulosclerosis (FSGS). Enhancing podocyte retention through increased integrin-mediated cell adhesion presents a promising therapeutic strategy in FSGS.

Methods: Podocytes were used in High-Content Screening (HCS) assays to measure cell damage induced by puromycin aminonucleoside (PAN) and measure the protective effects of integrin agonists. To identify a3b1-activating antibodies (Abs), we employed a naive human phage display library. For discovery and in vitro characterization assays, we used recombinant integrin constructs, K562 cells stably expressing a3b1, differentiated podocytes, and human SK-OV3 cells. Albuminuria was assessed in a lipopolysaccharide (LPS)-induced mouse model of FSGS.

Results: Results from the HCS assay revealed observable changes in F-actin fiber formation, focal adhesion formation, and active integrin levels in podocytes following PAN injury. Notably, known b1 integrin agonists (Ab 9EG7 and Pyrintegrin) and novel a3 Abs demonstrated protective effects against PAN-induced injury in podocytes. The agonist Abs also increased cell adhesion and decreased cell migration *in vitro*. Ab mapping experiments show selective and allosteric binding of the new Abs to the a3 head-domain, away from the ligand binding pocket. In an animal model of FSGS, treatment with the new a3 Ab resulted in a significant reduction in albuminuria compared to control groups, highlighting the therapeutic potential of a3b1 activation in mitigating glomerular dysfunction.

Conclusions: Activation of integrin a3b1 in podocytes enhances adhesion to matrix proteins and confers protection against cellular damage. Ongoing *in vivo* efficacy studies will provide additional insights into the therapeutic potential of this approach, offering a promising strategy against various glomerular diseases.

SA-PO715

Activation of Podocyte-Specific MC5R Signaling by Melanocortin Therapy Protects against THSD7A-Associated Membranous Nephropathy

Jing Liu, Yan Ge, Lance D. Dworkin, Rujun Gong. *The University of Toledo Medical Center, Toledo, OH.*

Background: Melanocortins, exemplified by adrenocorticotropic hormone (ACTH), have demonstrated a unique beneficial effect in membranous nephropathy (MN). The underlying mechanism remains elusive. This study tested the role of melanocortin 5 receptor (MC5R), one of the 5 MCRs of the melanocortin system and reported to be expressed in podocytes.

Methods: Wild-type (WT) and MC5R knockout (KO) mice were injected with a rabbit anti-THSD7A antibody to develop MN. Beforehand, some KO mice received hydrodynamic transfer of a plasmid encoding MC5R driven by *Nphs2* promoter. Subsequently, melanocortins were given, including repository corticotropin injection (RCI; Purified Cortrophin® Gel, ANI Pharmaceuticals, Inc.), the nonsteroidogenic

pan-MCR agonist NDP-MSH, and the selective MC5R agonist PG901. Glomerular disease was evaluated. *In vitro*, primary podocytes from WT or KO mice were exposed to the anti-THSD7A antibody in the presence or absence of melanocortins and cellular injury was assessed.

Results: After anti-THSD7A antibody insult, WT mice developed massive proteinuria and a pathology resembling human MN. Despite granular subepithelial deposition of the rabbit IgG in glomeruli to a comparable extent, KO mice sustained more severe glomerular injury than WT mice, as evidenced by heavier proteinuria, worsened podocytopathy, and increased expression of the podocyte injury marker. Melanocortin treatment with RCI, NDP-MSH or PG901 ameliorated proteinuria and glomerular damage in WT mice, coinciding with an improvement in podocyte injury. The beneficial efficacy of melanocortins was drastically blunted in KO mice. Mechanistically, MC5R is expressed in glomeruli in WT mice, and co-localized with podocyte markers like podocalyxin. Melanocortin treatment directly protected WT podocytes against the anti-THSD7A antibody-elicited cytopathic changes, including actin cytoskeleton disruption, cellular hypermotility, oxidative stress, and apoptosis. This protective effect was abolished in cultured KO podocytes. In contrast, glomerular podocyte-specific reconstitution of MC5R in KO mice attenuated the experimental MN, and restored the beneficial efficacy of melanocortins.

Conclusions: Our findings suggest that podocyte-specific MC5R signaling protects against glomerular injury and proteinuria in MN, and may serve as a novel therapeutic target for treating MN.

SA-PO716

A Novel IKKβ Inhibitor Ameliorates Podocyte and Kidney Injuries

Yiqing Guo,[1] Nehaben A. Gujarati,[1] Andrew K. Chow,[1] Navjot Pabla,[2] Sandeep K. Mallipattu.[1] *[1]Stony Brook University Renaissance School of Medicine, Stony Brook, NY; [2]The Ohio State University, Columbus, OH.*

Background: Previous studies showed that Krüppel-Like Factor 15 (KLF15) plays a protective role in the kidney through maintaining of podocyte differentiation. We developed a high-throughput screening (HTS) to identify KLF15 agonists as a therapy for proteinuric kidney diseases. Based on the structural activity relationship from the HTS, we designed and synthesized a novel compound, BT503 that was found to be protective in both *in vitro* and *in vivo* proteinuric models. Here, we demonstrate that BT503, directly inhibits IKKβ activity, resulting in loss of NFκB signaling.

Methods: IKKβ kinase activity was measured using either wild type IKKβ or gatekeeper mutant (M96V, in the ATP binding pocket) with BT503 as compared to vehicle. *in vitro* and *in vivo* profiling of BT503 was conducted using HPLC/MS/MS to characterize the drug properties. RNA-sequencing, in-silico drug-docking studies, and western blot analysis were also performed.

Results: Initial unbiased RNA-sequencing, in-silico drug-docking studies, and western blot analysis demonstrate that the salutary effects of BT503 in the podocyte are due to inhibition of IκBα phosphorylation, thereby preventing the nuclear translocation of p50/p65 and subsequent downregulation of KLF15. BT503 inhibits IKKβ kinase activity, which was abolished using an IKKβ gatekeeper mutant, suggesting that BT503 directly targets IKKβ. Thermal shift assay showed BT503 directly binds to IKKβ, but not IKKα and TAK1. BT503 also demonstrates low toxicity in cultured human podocytes and in mice. Expression of p50/65 was reduced in BT503-treated as compared to VEH-treated mice in proteinuric mouse models (HIV-1 transgenic mice, NTS-treated mice). Furthermore, knockout of KLF15 in podocytes attenuated the salutary effects of BT503, suggesting that the effects of IKKβ-p50/p65 are in part mediated by KLF15.

Conclusions: These data suggest that the salutary effects of a novel KLF15 agonist (BT503) are mediated through the direct inhibition of IKKβ kinase activity and subsequent canonical NFκB signaling.

Lymphatic Dysfunction and Perirenal Adiposity: Role of Glucocorticoids

Jianyong Zhong, Haichun Yang, Elaine L. Shelton, Valentina Kon. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Glucocorticoids (GCs) are commonly prescribed to treat proteinuric kidney injury, but their use often leads to negative side effects such as visceral adiposity. The impact of GCs on adipocyte growth is well-established, however, their effect on lipid clearance via lymphatic vessels is not understood. This study investigated GCs effects on lymphatic endothelial cell (LEC) permeability which underlies reabsorption of fluids, solutes and lipids from the interstitium and lymphatic vessel contractile functions which regulates transport of lipids.

Methods: Primary cultured mouse LECs were exposed to vehicle, dexamethasone (DXMS), or DXMS+glucocorticoid receptor (GR) antagonist (D06). RNA sequencing was performed and related genes were validated by rtPCR. Additionally, barrier integrity was analyzed by Transepithelial electrical resistance (TEER). Ex vivo pressure myography assessed the contractile function of renal lymphatic collecting vessels of rats treated with DXMS or vehicle x 2 weeks.

Results: GR was detected in both lymphatic vessels and cultured LECs. RNA sequencing revealed DXMS upregulated 771 genes and downregulated 693 genes, with DXMS+D06 reversing expression of 615 genes. GO enrichment and KEGG pathway analysis revealed changes in cell junction-related genes and rtPCR confirmed DXMS upregulation of *TJP1* and *Ocln* junctional genes, reversed by D06. In TEER assays, DXMS increased barrier integrity of LECs. This effect could be reversed with addition of D06. Lymphatic vessels from DXMS-treated rats had reduced amplitude of contraction and ejection fraction. In vivo, DXMS increased perirenal fat by around 56% vs vehicle.

Conclusions: In conclusion, GCs expand perirenal adiposity and blunt lymphatic contractility together with increasing LECs tight junctions and reducing permeability through GR which we propose contribute to development of visceral adiposity.

SA-PO718

Inhibiting STAT3-Mediated Glutathione Metabolism Attenuates Parietal Epithelial Cell Activation in Proliferative Glomerulopathy

Yogesh Gowthaman,[1] Joseph Kim,[1] Yiqing Guo,[1] David J. Salant,[2] Sandeep K. Mallipattu.[1,3] *[1]Stony Brook University, Stony Brook, NY; [2]Boston University, Boston, MA; [3]Northport VA Medical Center, Northport, NY.*

Background: The activation of STAT3 is seen in podocytes and parietal epithelial cells (PECs) in mouse models of proliferative glomerulopathy and human RPGN and subtypes of FSGS. We reported that the loss of STAT3 in PECs reduced PEC activation, and eventual FSGS in nephrotoxic serum (NTS) treated mice. To elucidate the mechanims of STAT3-mediated PEC activation, we performed bulk RNA-sequencing in *Stat3* knockout PECs and identified glutathione (GSH) metabolism as a significantly downregulated pathway. GSH is the major antioxidant in the body which functions to maintain cellular redox homeostasis, however, an overabundance of GSH may fuel pathologic PEC activation.

Methods: CRISPR/Cas9 generated PECs with deletion of *Stat3*. ChIP-qPCR was performed for GSH metabolism genes on *Stat3* KO and control PECs after incubation with total STAT3 and phospho-STAT3 antibodies. GSH metabolism was targeted using an inhibitor of glutamate–cysteine ligase, L-buthionine sulfoximine (BSO). Control PECs were treated with increasing doses of BSO (62.5 - 500 μM), and MTT and mitostress seahorse assays were performed. BSO was given to mice injected with NTS, a mouse model of proliferative glomerulopathy. Osmotic pump released BSO at a dose of 10 mg/kg daily until the mice were collected on day 7, and proteinuria and PEC activation were evaluated.

Results: *Stat3* KO PECs showed a reduction in GSH synthesis and peroxidase activity levels compared to control PECs. STAT3 occupancy in the promoter region of 8 genes involved in GSH metabolism (*Gpx4, Gss, Gstz1, Gsta4, Gstm4, Gstm5,* and *Mgst2*) was significantly reduced in *Stat3* KO PECs as compared to control PECs. Increasing doses of BSO resulted in significantly lower cell viability via MTT assay, and in significantly lower OCR via seahorse assay. Compared to vehicle, BSO treatment reduced albuminuria and crescent formation 7 days post-NTS. Immunostaining and quantification for markers of activated PECs and quiescent PECs, CD44 and AKAP12, respectively, reveals that BSO treatment reduces CD44 expression, but increases AKAP12 expression, suggesting a reduction in pathogenic PEC activation post-NTS treatment.

Conclusions: These data suggest that inhibition of GSH metabolism might be a key target in attenuating PEC activation, proliferation, and crescent formation in proliferative glomerulopathy.

Selective Peroxisome Proliferator-Activated Receptor γ Modulator, GQ-16, Provides Therapeutic Efficacy in a Murine Model of Rapidly Progressive Glomerulonephritis

Antonio S. Novaes, Shipra Agrawal. *Stony Brook University, Stony Brook, NY.*

Background: Rapidly proliferating glomerulonephritis (RPGN) is clinically characterized by rapid decrease in glomerular filtration accompanied with pathologic findings of glomerular epithelial hypercellularity. It often leads to irreversible kidney failure and is a significant health problem globally. Current treatments for RPGN focus on suppressing the immune system, but they are not curative and have serious side effects. Therefore, safer and more effective therapies are needed. We have previously demonstrated therapeutic potential of GQ-16, a selective modulator of peroxisome proliferator-activated receptor γ (PPARγ), in minimal change disease model. We hypothesized that GQ-16 can also provide therapeutic efficacy in a more severe and immunological model of RPGN.

Methods: RPGN was induced by two doses of intraperitoneal administration of rat nephrotoxic serum (NTS) preceded by IgG sensitization, in 7 weeks old male 129/Sv mice. The treatment group received GQ-16 (40 mg/kg) daily by oral gavage, while the control group received vehicle (n=4) for 7 days. Albuminuria and Transdermal Glomerular Filtration Rate (GFR) was measured serially, and kidneys and glomeruli were harvested at the end of the study for analyses.

Results: Robust albuminuria was observed with NTS injury on Day 3 (73.4 ±33.2 mg/mg vs Control 0.22±0.06 mg/mg), which was significantly decreased up to 80% with

GQ-16 treatment (p=0.0025). On Day 7, NTS injured group showed a reduction in GFR, whereas no differences were observed in GFR in the GQ-16 treatment group compared to baseline. Histopathological examination demonstrated segmental sclerosis, hyalinosis, and hypercellularity in Bowman's space in the NTS group (17.7% ± 4.3 glomeruli affected), tubular protein casts (90% ± 2.8) and interstitial inflammation (13% ± 6.0). These pathological findings were not observed in the GQ-16 treatment group. There were no changes in the weight among the groups. Additionally, gene expression of podocyte markers, nephrin, podocin, and WT1 was increased in GQ-16 group treatment compared with the NTS injury group.

Conclusions: Together, our findings suggest that GQ-16 might be an attractive and promising pharmacological intervention for treating RPGN.

Therapeutic Targeting of Antibody-Secreting Cells for the Treatment of Autoimmune Kidney Diseases

Marie Eggers,[1,2] Alessa Z. Schaffrath,[1,2] Thomas Eden,[3] Ming Huang,[1,2] Natalie Tode,[3] Renke Lucas,[1,2] Stephan Menzel,[3] Friedrich Koch-Nolte,[3] Nicola M. Tomas.[1,2] *[1]University Medical Center Hamburg-Eppendorf, Department of Medicine, Hamburg, Germany; [2]University Medical Center Hamburg-Eppendorf, Hamburg Center for Kidney Health (HCKH), Hamburg, Germany; [3]University Medical Center Hamburg-Eppendorf, Institute of Immunology, Hamburg, Germany*.

Background: Antibody-secreting cells (ASCs) are the main source of antibodies and represent an important therapeutic target in antibody-mediated autoimmune diseases. However, molecular targets suitable for the elimination of pathogenic ASCs are sparse. The aim of this study was the identification and evaluation of novel ASC targets for the treatment of antibody-mediated disease.

Methods: We used available cellular indexing of transcriptomes and epitopes by sequencing (CITE-seq) datasets to identify surface molecules with high specificity for ASCs. We then generated nanobody-based heavy chain antibodies (hcAbs) against the identified target and tested their cytotoxic effects in vitro, ex vivo and in vivo. We further used a model of experimental autoimmune membranous nephropathy (EAMN) to evaluate the therapeutic potential of this treatment.

Results: We identified a new potential therapeutic target protein with high membrane expression on both human and murine ASCs. In vitro and ex vivo, hcAbs against this target protein mediated potent cellular lysis of human and murine plasma and myeloma cells. Application of these hcAbs in mice induced a strong depletion of ASCs in bone marrow and spleen. Finally, anti-target protein hcAb treatment strongly reduced the levels of antigen-specific antibodies as well as the degree of podocyte damage and improved clinical outcome in the EAMN disease model.

Conclusions: Our study introduces a promising new target protein for the depletion of ASCs in autoimmune diseases. Considering the global burden of severe autoimmune diseases, further investigation of this potential therapeutic strategy is warranted.

Felzartamab Selectively and Potently Targets CD38+ Antibody-Secreting Cells from Patients with Immune-Mediated Kidney Diseases

Tess A. Delfino,[1] Kristina M. Ilieva,[2] Karin Landgraf,[2] Rainer Boxhammer,[2] Stefan Steidl,[2] Donna Flesher.[1] *[1]Human Immunology Biosciences Inc, South San Francisco, CA; [2]MorphoSys AG, Planegg, Germany*.

Background: CD38+ antibody secreting cells (ASC) such as plasmablasts and plasma cells have been implicated in the pathology of many immune-mediated diseases (IMD). Variability in the efficacy of therapies that target earlier B lineage cells in IMD highlights the need to selectively target the pathogenic cellular drivers of disease. Felzartamab (felza) is a fully human monoclonal antibody that binds to CD38 and has the potential to selectively deplete CD38+ ASC that contribute to IMD through secretion of pathogenic antibodies.

Methods: Flow cytometry based CD38 quantification was evaluated on immune cells from peripheral blood, bone marrow, and *in vitro* differentiated healthy donor and IMD patient ASC. Depletion of ASC after treatment with felza was assessed in an antibody-dependent cell cytotoxicity (ADCC) assay *in vitro* and in NSG-SGM3 mice engrafted with human CD34+ cord blood cells *in vivo*.

Results: CD38 is highly expressed on ASC and other cellular drivers of IMD in peripheral blood, bone marrow, and *in vitro* differentiated ASC from healthy and IMD donors. Felza demonstrated potent ADCC activity on *in vitro* differentiated ASC from healthy donors and IMD patients with Membranous Nephropathy (MN) and IgA Nephropathy (IgAN) (Figure 1), while sparing earlier B lineage cells. Furthermore, felza treatment reduced spleen and bone marrow CD38+ ASC and human immunoglobulin titers in engrafted humanized NSG-SGM3 mice, suggesting depletion activity *in vivo*.

Conclusions: These *in vitro and in vivo* proof of concept studies highlight the capacity of felza to selectively deplete CD38+ ASC, suggesting the potential for clinical utility in antibody-driven IMD. Clinical trials assessing the safety and efficacy of felza in immune-mediated kidney diseases including MN, IgAN, antibody-mediated kidney rejection and lupus nephritis are currently ongoing.

Moss-Produced Human Factor H (CPV-104): Pioneering Rebalancing Therapies for Kidney Complement Disorders

Todor A. Tschongov,[1] Swagata Konwar,[1,2] Paulina Dabrowska-Schlepp,[3] Andreas Busch,[3] Andreas Schaaf,[3] Karsten Häffner.[1] *[1]Universitatsklinikum Freiburg Abteilung Innere Medizin IV Nephrologie und Allgemeinmedizin, Freiburg, Germany; [2]Albert-Ludwigs-Universitat Freiburg Fakultat fur Biologie, Freiburg, Germany; [3]Eleva GmbH, Freiburg, Germany*.

Background: Dysregulation of the complement system can lead to various pathological conditions, particularly in the kidneys. Beside aHUS and C3G, other renal diseases are often associated with unbalanced complement activation. Drugs targeting the complement system often aim to inhibit either specific components or the entire cascade. Utilizing factor H (FH), a natural regulator of the alternative pathway, offers an alternative treatment option by restoring complement balance. Through a moss-based expression system, we developed a recombinant FH variant (CPV-104) with pharmacokinetics and pharmacodynamics comparable to native FH *in vivo*. In this study, we investigated dosing intervals and explored the feasibility of subcutaneous (s.c.) administration of CPV-104 in preclinical models.

Methods: B-cell and CD4 T-cell depletion was performed by injecting FH deficient mice with anti-CD20 antibody SA271G2 and anti-CD4 antibody GK1.5 at certain intervals, respectively. Depletion was confirmed by flow cytometry. Mice were treated intravenously (40 mg/kg) or s.c. (40 mg/kg; 200 mg/kg) with CPV-104 every 3, 4 or 5 days for a total of 3 injections. Blood samples were collected and the amount of FH and C3 quantified using ELISAs. Kidneys were harvested and stained for FH and glomerular C3 deposits. FH antibody formation was tested by incubating mouse sera on FH coated wells and detecting bound mouse IgGs.

Results: B- and CD4 T-cell depletion in mice allowed multiple injections of CPV-104 without causing antibody response. In FH-deficient mice, repeated CPV-104 injections normalized serum C3 levels and degraded kidney C3 deposits. Additionally, the feasibility of s.c. CPV-104 injections was explored. Initial results indicate that multiple s.c. injections lead to prolonged FH availability in mouse sera, resulting in sustained elevation of serum C3 levels and reduced kidney C3 deposits.

Conclusions: By optimizing dosing intervals and exploring s.c. administration, FH availability was significantly improved in conjunction with sustained reduction of glomerular C3 deposits in preclinical models. These findings provide valuable insights into the clinical translation of CPV-104 as a new therapeutic strategy for complement-mediated renal diseases, enabling physiological complement functionality.

Pharmacologic Activation of CD11b Suppresses TLR7-Driven Proinflammatory Myeloid Signaling and Protects against Lupus Nephritis

Xiaobo Li,[1] Viviana Jimenez,[2,1] Billy Nguyen,[2] Nishant Ranjan,[1] David J. Cimbaluk,[3] Jochen Reiser,[1] Vineet Gupta.[1] *[1]The University of Texas Medical Branch at Galveston, Galveston, TX; [2]Rush University, Chicago, IL; [3]Rush University Medical Center, Chicago, IL*.

Background: Lupus Nephritis (LN) is a severe complication of Systemic Lupus Erythematosus (SLE) and occurs in approx. 50% of all patients. Single nucleotide polymorphisms (SNPs) in ITGAM gene, coding for CD11b, shows a high correlation with risk for SLE and LN. We previously showed that ITGAM SNPs that result in less functional protein show heightened inflammatory signaling via toll-like receptors (TLRs), resulting in enhanced systemic immunity. However, how these are linked to increased kidney disease is unclear.

Methods: Human PBMCs from LN patients, primary macrophages, RAW264.7 cells, MRL/lpr genetic and humanized mouse model were utilized in our study. Two orthogonal approaches, genetic and pharmacologic, were utilized to activate CD11b and to measure its effect on TLR7-dependent inflammatory signaling in myeloid cells *in vitro* and in LN *in vivo*.

Results: We found that LN patients carrying *ITGAM* SNPs have significantly elevated serum suPAR levels, suggesting a strong link between the variants and kidney disease. TLR7-stimulation increased suPAR, IFN I, IL-6 and other pro-inflammatory markers in myeloid cells and absence of CD11b exacerbated this response. Conversely, CD11b activation using an oral allosteric agonist called Ontegimod or a gain-of-function point mutation in CD11b (constitutively active) significantly reduced serum suPAR, pro-inflammatory markers, anti-dsDNA antibodies, and ameliorated proteinuria and glomerulonephritis. CD11b activation also reduced splenomegaly and $CD11b^+$ cells infiltration in kidney. Mechanistically, CD11b activation reduced TLR7-dependent NF-kB and IFN-I signaling to suppress suPAR generation, demonstrating therapeutic modality for LN.

Conclusions: CD11b activation reduced TLR7-dependent suPAR levels in LN models. This study provides pre-clinical evidence supporting CD11b activation as a promising therapeutic for treating SLE and LN.

SA-PO724

Targeting M2b Macrophages by Selenium Nanomedicine for the Treatment of Lupus Nephritis

Yiming Zhou,[1] Haoran Lv,[2] Hanzhi Liang,[2] Le Wang,[1] Siweier Luo,[1] Qinghua Liu.[2] *[1]Sun Yan-sen Memorial Hospital, Sun Yan-sen University, Guangzhou, China; [2]The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China.*

Background: Excessive activation of macrophages, particularly M2b macrophages, plays a pivotal role in the progression of lupus nephritis (LN); however, effective treatment strategies remain limited. Selenium possesses immunomodulatory properties; nevertheless, its high toxicity and instability hinder its application. Here, we designed and constructed novel selenium nanoparticles for the treatment of LN by targeting M2b macrophages.

Methods: Primary mouse macrophages were used to observe the toxicity and targeting ability of selenium nanomedicine on macrophages, as well as the immune-regulation of macrophage activation by LPS. RNA-seq and qPCR experiments were used to explore the molecular mechanism of selenium nanoparticles on macrophage activation. Finally, a lupus mouse model was used to investigate the renal protective effect of selenium nanoparticles *in vivo*.

Results: Selenium nanoparticles exhibited excellent stability and biocompatibility. By coating mannose to the selenium nanoparticles, they could selectively target M2b macrophages both in vitro and in vivo, and display increased retention time in kidneys of lupus mice. Selenium nanoparticles significantly inhibited macrophage activation and reduced the expression and releasing of pro-inflammatory cytokines and chemokines. In addition, selenium nanoparticles significantly attunated the ROS production and improved the mitochondrial function in M2b macrophages. Mechanistically, we discovered that selenium nanoparticles regulate M2b macrophages via the JAK1/JAK2-STAT1 pathway through GPX1 expression. In animal, these nanoparticles significantly improved the renal function, preserved the renal structure, and reduced the renal fibrosis by inhibiting M2b macrophage activation in mice with lupus nephritis.

Conclusions: In this study, we developed a novel selenium nanomedicine that selectively targets M2b macrophages and suppresses their activation by attenuating the ROS production and inhibiting the JAK1/JAK2/STAT1 pathway through GPX1 expression, thereby achieving therapeutic efficacy in LN. Our findings provide a new idea for the treatment of LN by targeting specific macrophage population.

SA-PO725

Sinomenine Alleviates Lupus Nephritis in MRL/lpr Mice by Suppressing the Noncanonical NF-kB Pathway

Anqun Chen, Baiyu Feng. *The Second Xiangya Hospital of Central South University, Changsha, China.*

Background: Systemic lupus erythematosus (SLE) is a severe autoimmune disease with significant mortality, often progressing to lupus nephritis (LN), which affects over 50% of patients and can lead to end-stage renal disease. Urgent attention is needed for new drugs in treating LN due to severe complications associated with traditional therapies. Sinomenine, a natural alkaloid with proven anti-inflammatory properties, holds promise for therapeutic efficacy in LN given its success in treating rheumatoid arthritis.

Methods: At 10 weeks, MRL/lpr mice were grouped: vehicle (i.g., PBS, n=6), sinomenine (i.g., 50mg/kg/day, n=6), and dexamethasone (i.p., 1mg/kg/day, n=6). MPJ mice served as controls (i.g., PBS, n=5). At week 18, mice were euthanized. Lymph node and spleen size, renal function, histopathology, autoimmune antibodies, inflammatory cell infiltration, and immune complex deposition were assessed. Spleen cell flow cytometry was conducted, and kidneys underwent single-cell RNA sequencing (scRNA-seq) analysis (n=2/group). Sinomenine's binding affinity to target protein was confirmed via molecular docking, cellular thermal shift assay (CESTA), and drug affinity-responsive target stability (DARTS) assay.

Results: Sinomenine improved renal function in MRL/lpr mice, reducing UACR and Scr while increasing GFR. It also alleviated renal histological injury and suppressed adaptive immunity, evidenced by reduced splenomegaly, serum anti-dsDNA titers, splenic CD8+ T cells, and splenic Th1/Th2 ratio. scRNA-seq data indicated alleviation of tubule cell inflammation and dedifferentiation in sinomenine treatment group. Dexamethasone exhibited a strong inhibitory effect on immune cells in the kidneys, notably promoting the differentiation of mononuclear cells and macrophages towards an immunosuppressive phenotype in the kidneys. Sinomenine decreased Relb regulon activity, inhibiting the non-canonical NF-kB pathway. In vitro, sinomenine suppressed nuclear translocation of RelB-p52 complex, validated by CESTA and DARTS assays confirming its binding to Relb.

Conclusions: Sinomenine protects against LN in MRL/lpr mice by reducing immune cell infiltration and tubular damage through modulating non-canonical NF-kb signaling pathways, suggesting its promise as a therapeutic option for patients with LN.

Funding: Government Support - Non-U.S.

SA-PO726

SGLT2 Inhibition in Nondiabetic CKD: Results in Experimental Lupus Nephritis (LN)

Jordi Vilardell,[1] Conxita Jacobs Cachá,[1] Nerea Martos,[1] Carmen Llorens Cebrià,[1] Aku Enam Motto,[1] Maciej Lech,[2] Irene Martínez Díaz,[1] Hans J. Anders,[2] Maria Jose Soler.[1] Nephrology and Transplantation Research Group. *[1]Vall d'Hebron Institut de Recerca (VHIR), Vall d'Hebron Hospital Universitari, Vall d'Hebron Barcelona Hospital Campus. Nephrology and Transplantation Research Group., Barcelona, Spain; [2]University Hospital, Ludwig-Maximilians-University. Department of Medicine IV, Division of Nephrology, Munich, Germany.*

Background: Sodium glucose cotransporter type 2 inhibitors (SGLT2i) attenuate cardiovascular morbidity and progression of CKD in type 2 diabetes patients. It has been proposed that SGLT2i may also elicit renoprotection in non-diabetic CKD. Our goal is to evaluate if the SGLT2i treatment improves kidney disease progression in a mouse model of LN.

Methods: Female MRLlpr/lpr mice were randomly assigned to (1) vehicle (VH) or (2) empagliflozin (EMP) (10 mg/kg/day) treatment once signs of active systemic lupus erythematosus appeared: proteinuria >100mg/dL or lymphadenopathy in minimum 2 bilateral sites with proteinuria >30mg/dL. 13 mice/group were treated for 4 weeks. Reduction of urinary albumin to creatine ratio (UACR) was the primary endpoint. Glomerular Filtration Rate (GFR), renal histology (LN activity/chronicity index, glomerulosclerosis, interstitial fibrosis) and SLE markers (total serum IgG, anti-dsDNA IgG, IgG deposits, lymph node and spleen weight) were considered secondary endpoints.

Results: After 4 weeks of treatment, no significant differences in glicemia were found between groups. Empagliflozin inhibited SGLT2 in the tubular cells supported by a significant increase of glucosuria (EMP 12.3±5.3 mg/g; VH 1.2±5.3 mg/g, $p<0.001$) and reflected with the increased water intake observed in this group (EMP 7.0±0.95 mg/g; VH 5.0±0.3 mg/g; $p<0.001$). At the end of the experiment, vehicle treated mice showed a significant increase in UACR (post-UACR 3.3±0.7 vs pre-UACR 2.2±0.7mg/g; $p<0.001$) consistent with LN progression that was not reduced by empagliflozin. Empagliflozin did not modify GFR and LN activity/chronicity indexes, glomerulosclerosis or interstitial fibrosis. Regarding SLE markers, empagliflozin was not able to decrease total serum IgG, anti-dsDNA IgG, glomerular IgG deposits or lymph node weight. Only spleen weight decreased significantly in empagliflozin treated mice (EMP 8.5±1.6mg/g; VH 12.1±3.4 mg/g; $p<0.001$).

Conclusions: In our experimental setting, empagliflozin reduced spleen weight suggesting a protective role in SLE in MRLlpr/lpr mice. However, empagliflozin did not modify LN progression probably because the acute LN phase. It is expected that positive effect in terms of reducing proteinuria will be observed in patients with LN and residual proteinuria.

Funding: Government Support - Non-U.S.

SA-PO727

Assessing the Therapeutic Potential of a Myeloperoxidase Inhibitor in a Preclinical Rat Model of MPO-ANCA Autoimmune Vasculitis

Vandana Veenit,[1] Maria Prendecki,[2] Stephen P. McAdoo,[2] Asha Seth,[1] Lorna J. Hale,[1] Birgitta E. Rosengren,[1] Pernille B. Laerkegaard Hansen,[1] Anna Collén,[1] Julie Williams.[1] *[1]AstraZeneca R&D Cambridge, Cambridge, United Kingdom; [2]Imperial College London, London, United Kingdom.*

Background: Antineutrophil cytoplasmic antibody (ANCA)- associated vasculitis (AAV) is a rare systemic autoimmune disease characterised by the inflammation of blood vessels and involves multiple organ systems. ANCA binds to proteins on the neutrophil surface, particularly myeloperoxidase (MPO) which is a major disease driver of AAV.

Methods: We evaluated a tool MPO inhibitor- AZM198 on human AAV relevant readouts using a well characterised preclinical rat model of AAV which involves immunising adult male WKY rats with human MPO followed by an intravenous administration of 1:100 dilution of nephrotoxic serum (NTS) on day 14. We first assessed AZM198 in a prevention setting by dosing AZM198 at 125 mg/kg peroral from day 7 until day 27. We then conducted an intervention study where one group received AZM198 from day 16 until day 35 (early intervention) and another group received AZM198 from day 25 until day 35 (late intervention). Animals were sacrificed one day after the last treatment (AZM-198 or vehicle).

Results: In prevention and early intervention groups, but not in the late intervention group, AZM198 treated rats showed reductions in human AAV pertinent readouts - haematuria, proteinuria, kidney/lung injury and inflammatory cell infiltration compared to vehicles. There was no change in MPO antibody titre or MPO mass in response to AZM198 treatment. However, there was a significant reduction seen for the MPO activity/mass ratio both in plasma and kidney in AZM198 treated animals in prevention and early intervention groups but not in the late intervention group. Interestingly, we also saw a significant correlation between kidney MPO activity and proteinuria in both studies which corroborates the role of MPO activity in driving AAV pathogenesis.

Conclusions: Our preclinical data confirms a key role of MPO activity in AAV aetiology and suggests strongly that inhibition of MPO activity might offer protection in AAV patients.

SA-PO728

Genome Editing to Delete the Proteinase 3 Autoantigen as a Treatment Strategy for ANCA-Associated Vasculitis

Uwe Jerke,[1,2] Claudia Eulenberg-Gustavus,[1,2] Dimitrios L. Wagner,[3,4] Adrian Schreiber,[1,5] Ralph Kettritz.[1,5] *[1]Experimental and Clinical Research Center, a cooperation between the Max Delbrück Center for Molecular Medicine in the Helmholtz Association and Charité Universitätsmedizin Berlin, Berlin, Germany; [2]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Berlin, Germany; [3]BIH Center for Regenerative Therapies (BCRT), Berlin Institute of Health (BIH) at Charité - Universitätsmedizin Berlin, Berlin, Germany; [4]Berlin Center for Advanced Therapies (BeCAT), Charité - Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health (BIH), Berlin, Germany; [5]Department of Nephrology and Medical Intensive Care, Charité - Universitätsmedizin Berlin, Berlin, Germany.*

Background: Proteinase 3 (PR3) is a major autoantigen in ANCA-associated vasculitis (AAV). We performed a proof-of-principle study using ex-vivo genome editing to eliminate the PR3 autoantigen in CD34+ human hematopoietic stem cells (HSC) and assessed functional consequences in a neutrophil differentiation model.

Methods: A ribonucleoprotein (RNP) complex of an endonuclease and a sgRNA was transfected into human CD34+ HSC by electroporation to disrupt PR3 protein expression. Effects on neutrophil differentiation, PR3 protein abundance, and ANCA-dependent and independent neutrophil responses were assessed. Only low-risk off-targets were predicted, which are currently analyzed by amplicon sequencing.

Results: $PR3^{KO}$-HSCs and non-transfected Ctrl-HSCs showed similar neutrophil differentiation at day 10 by flow cytometry using the CD15 differentiation marker (5,515±1,163 MFI in $PR3^{KO}$-HSCs and 5,289±1,393 in Ctrl-HSCs, n=5). Gene editing reduced the PR3 protein efficiently as demonstrated by immunoblotting and the complete absence of PR3-specific proteolytic activity by FRET analysis. In contrast, human neutrophil elastase was not affected. Flow cytometric analysis showed that, while the amount of the PR3-presenting CD177 receptor on the cell surface was unaffected in neutrophil-differentiated $PR3^{KO}$-HSCs, membrane-PR3 was significantly reduced to isotype control levels (p=0.011, n=8). Consequently, extracellular reactive oxygen species (ROS) production in differentiated $PR3^{KO}$-HSCs activated with either monoclonal or human PR3-ANCA was significantly reduced, whereas ROS production with MPO-ANCA stimulation was not affected. PR3-ANCA independent defense functions in neutrophil-differentiated HSCs showed similar responses for $PR3^{KO}$- and Ctrl-HSCs. For neutrophil-differentiated $PR3^{KO}$-HSCs was the phagocytosis index of E.coli bioparticles 91.3%±6.9 of controls, phorbol ester-stimulated intracellular ROS production 95.4%±10.2 of controls, and extracellular superoxide production 98.8%±1.2 of controls.

Conclusions: Our proof-of-principle study showed the feasibility to effectively knock out PR3 in human CD34+ HSCs using genome editing. Our data could provide the basis for developing a drug-free treatment strategy in AAV patients.

SA-PO729

RNK288: A MASP2-Targeting Small Interfering RNA (siRNA) for the Treatment of IgA Nephropathy by Blocking the Activation of Lectin Pathway

Ling Pan,[1] Guofeng Meng,[1] Wei Liu,[2] Cong Huang,[1] Yang Xiaoyan,[1] Guoqing Cai,[1] Xin X. Xu,[1] Ming Yue,[1] Tao He,[1] Lei Wang,[2] Jinyu Huang,[1] Jianwu Fang,[1] Bo Chen,[2] Yibin Shi.[1] *[1]Rona Therapeutics, Shanghai, China; [2]Keymed Biosciences Inc, Chengdu, China.*

Background: IgA nephropathy (IgAN), the most prevalent primary glomerulonephritis, is a major contributor to renal failure, including in young individuals. Accumulating evidence suggests that the overactivation of the lectin pathway critically contributes to the pathogenesis of IgAN. RNK288, a MASP2-targeting siRNA, is developed as a therapeutic agent for IgAN by blocking the activation of the lectin pathway. Here, we demonstrate the efficacy and safety profile of RNK288 in preclinical studies.

Methods: RNK288 was developed by RAZOR™ platform to achieve an optimized PD and safety profile. The knockdown potencies of RNK288 were evaluated using both in vitro and in vivo models, including primary human hepatocytes (PHH), primary cynomolgus monkey hepatocytes (PCH), humanized MASP2 (hMASP2) transgenic mice and non-human primates (NHP). The safety of RNK288 was investigated by in vitro assay, RNA-seq and repeated-dose toxicity studies in rat and NHP. The efficacy of RNK288 was evaluated in rodent disease models, including grouped ddY mice.

Results: RNK288 suppressed MASP2 expression in PCH and PHH with the half-maximal inhibitory concentrations (IC_{50}) of 0.02nM and 0.03nM, respectively. In hMASP2 mice, RNK288 reduced serum MASP2 protein by up to 94% after a single subcutaneous injection of 3 mg/kg. In NHP, a single dose of RNK288 significantly lowered MASP2 protein levels to 3.8% even after 3 months, indicating a robust and long-lasting efficacy. In addition, the activity of lectin pathway, was shown to be reduced to a minimum of 13% of the pre-dose level. In repeated-dose toxicity studies (Q2W, 3 doses), no adverse findings were observed in either rats or monkeys and the No Observed Adverse Effect Levels (NOAEL) were 300 mg/kg (the highest dose) for both species. RNA-seq and in silico analysis also indicated low off-target risk, confirming the good safety profile of RNK288. Moreover, RNK288 demonstrated signs of IgAN improvement in rodent disease models.

Conclusions: RNK288 is a novel siRNA drug candidate for the treatment of IgAN by blocking the activation of lectin pathway. A series of preclinical studies demonstrated the robust and long-lasting efficacy of RNK288 with good safety and tolerability. RNK288 represents a potential therapeutic option for patients with IgAN.

First-in-Class Antigen-Specific Extracellular Protein Degrader, BHV-1400 for IgA Nephropathy, Selectively Targets Galactose-Deficient IgA for Rapid and Efficient Endolysosomal Degradation in the Liver

Seong Lee,[1] Charlotte B. Spliid,[1] Ana Estrella,[1] Kathleen Mcgrath,[1] Hanna Yousuf,[1] Ann Marie Rossi,[1] Brett Rasile,[1] Scott Conroy,[1] David Spiegel,[2] Gene Dubowchik,[1] David Pirman,[1] Bruce D. Car,[1] Lawrence R. Marcin,[1] Anna Bunin,[1] Vlad Coric.[1] *[1]Biohaven Ltd, New Haven, CT; [2]Yale University School of Medicine, New Haven, CT.*

Background: IgA nephropathy (IgAN) is the most prevalent form of glomerulonephritis, affecting 2.5 of 100,000 people worldwide. The production of galactose-deficient IgA1 (Gd-IgA1), and the subsequent formation and deposition of Gd-IgA1-IgG immune complexes in the kidney mesangium drive the onset and progression of IgAN. Targeting pathogenic Gd-IgA1 in IgAN patients offers a promising strategy to decrease immune complex formation, potentially leading to a reduction in kidney inflammation and pathology.

Methods: Biohaven engineered a novel, bifunctional antibody-based, protein degrader, BHV-1400, that specifically targets extracellular Gd-IgA1 for degradation via the ASGPR-mediated endolysosomal pathway in the liver. Here, we present data illustrating the reactivity of BHV-1400 with IgAN patient samples.

Results: In *in vitro* assays, BHV-1400 mediates efficient specific cellular internalization and degradation of monomeric and multimeric deglycosylated IgA (dg-IgA). Pharmacological data indicates that BHV-1400 facilitates a rapid reduction of exogenous dg-IgA both in the bloodstream and tissues, most notably within kidney glomeruli.

Conclusions: Thus, Gd-IgA1 degradation with BHV-1400 offers significant promise as a novel and effective precision, disease-modifying approach for treating IgAN.

mTOR Inhibition: A Novel Regulator of Soluble CD89 Activity via the Mesangial Transferrin Receptor and Its Therapeutic Potential in IgA Nephropathy

Cambier Alexandra,[1] Jennifer Da Silva,[2] Julie Bex,[2] Aurelie Sannier,[2] Amandine Badie,[1] Renato C. Monteiro.[2] *[1]Research Centre Sainte Justine Hospital, Montreal, QC, Canada; [2]Inserm U1149, Paris ile de France, Paris, France.*

Background: IgA nephropathy (IgAN) is the predominant primary glomerulonephritis worlwide. We have recently shown that soluble IgA receptor CD89 induces mesangial cell proliferation via the PI3K/Akt/mTOR axis (Cambier, Kidney Int 2022). Transferrin receptor (TfR), an IgA1 receptor overexpressed in mesangium, is associated with IgAN progression (Tamouza, Kidney Int 2012). sCD89 binds also to TfR (Berthelot, J Exp Med 2012). As mTOR is involved in sCD89-TfR signaling, we explore its inhibitor, the everolimus, in a IgAN model, the $\alpha1^{KI}CD89^{Tg}$ mouse, that express human IgA1 and CD89. Single-cell kidney biopsy techniques were used to delve TfR1 and mTOR expression in mesangial cells from IgAN patients.

Methods: 20 adult $\alpha1^{KI}CD89^{Tg}$ and 6 young rCD89-injected $\alpha1^{KI}$ mice constituted two groups. Treated arms received everolimus (2 mg/kg) for 8 weeks or 4 weeks, respectively, while the control arms underwent a placebo water. Weekly urine collections monitored proteinuria and mice were sacrificed for renal function, immune complex analysis, and histological examination. PI3K/Akt/mTOR activation under sCD89 stimulation was studied with human mesangial cells. Single cell analysis were performed to quantify mTOR and TfR1 expression in 5 patient kidney biopsy and 1 healthy kidney tissue.

Results: Everolimus treatment showed a reduction in mesangial TfR expression, IgA1 and C3 deposits in kidneys of both groups ($p<0.001$, respectively). It also decreased cell proliferation, as indicated by Ki67 staining in glomeruli ($p<0.05$). This treatment led to decreased proteinuria ($p<0.05$). Levels of immune complexes (sCD89-IgA1, IgG-IgA1) were impaired by everolimus treatment. Rec sCD89 induced activation of PI3K/Akt/mTOR pathway in human mesangial cells. Using single cells from kidney biopsies we found overexpression of TfR1 and mTOR in mesangial cells from IgAN patient biopsies but not in healthy kidney.

Conclusions: mTOR inhibitor prevents and treats IgAN in a pre-clinical model. These results open new avenues for future clinical trials in IgAN.

Quantitative Image Analysis Uncovers the Efficacy of the Selective Endothelin A Receptor Antagonist Atrasentan in a Rat Model of IgA Nephropathy

Francois Briand,[1] Estelle Grasset,[1] Nicole Endlich,[2] Vedran Drenic,[2] Blazej Dolicki,[3] Thomas D. Bel,[3] Thierry Sulpice.[1] *[1]Physiogenex, Escalquens, France; [2]Nipoka, Greifswald, Germany; [3]Aiosyn, Nijmegen, Netherlands.*

Background: Our aim was to validate and optimize a rat model of IgA nephropathy for drug efficacy studies using quantitative image analysis of kidney. To demonstrate the accuracy of our imaging methods, we evaluated atrasentan, a selective Endothelin A receptor Antagonist currently evaluated in phase III clinical trials.

Methods: On day 0, Wistar male rats received a single i.v. injection of Thy1.1 antibody to induce IgA glomerulonephritis and were then treated orally BID with vehicle or atrasentan 10mg/kg until day 7. A group of rats were injected i.v. with PBS as control. Urine parameters were measured at day 2 and day 7, while Glomerular Filtration Rate (GFR) was measured at day 7. Kidneys were then collected for histology and automated image analysis, including quantitative mesangial expansion and tubular impairments (Kidney AI suite) and Podocyte Exact Morphology Measurement Procedure (PEMP).

Results: Compared to control, rats injected with Thy1.1 antibody showed significantly higher proteinuria, urine albumin/creatinine ratio (ACR), cystatin-C and KIM-1 levels at both day 2 and day 7, and significantly reduced GFR at day 7. Although it did not improve GFR decline significantly, atrasentan markedly improved all urine parameters above, as compared with vehicle. Compared to control, Thy1.1 antibody injection also led to a significantly higher kidney histopathological scoring (including greater proliferative glomerulonephritis, inflammation scores and tubule alterations), mean glomerular size and % alpha-SMA labelling, and all these parameters were again improved with atrasentan treatment. Filtration slit density and filtration slit length by PEMP were significantly reduced with Thy1.1 injection, indicating podocytes effacement, and both parameters increased in rats treated with atrasentan. Kidney AI suite demonstrated significant increase in glomeruli with mesangial expansion in rats injected with Thy1.1, which was also significantly reduced by atrasentan.

Conclusions: Quantitative image analysis uncovers the efficacy of atrasentan on glomerulonephritis in the Thy1.1 antibody rat model. This experimental setting will help evaluating the efficacy of drugs targeting IgA nephropathy.

Development of GE8820 for Selective and Rapid Removal of Pathogenic Autoantibodies in Primary Membranous Nephritis (PMN) and Other IgG4-Mediated Diseases

Tanmoy C. Ganguly, Jonathan Back, Melinda Hanes, Michela Manni, Stephen Hesler, Hanumantha Rao Madala, Oaklyne Billion, Courtney Oconnell, Kellie Cotter, Tina Schelbert, Manuela Mally, Dominique N. Sirena, Jan L. Hillson, Ganesh V. Kaundinya. *Glycoera Inc, Newton, MA.*

Background: In PMN, anti-PLA2R autoantibodies are used as a diagnostic, levels are associated with disease activity, and most are of the IgG4 isotype. Disease can be transferred to models, and a mechanism of injury was demonstrated with the IgG4 fraction. GE8820 is a bifunctional biologic that selectively binds to human IgG4 and through a glycan mediated engagement of ASGPR on hepatocytes, targets it for liver degradation.

Methods: GE8820 a selective high affinity human IgG4 binder was expressed using the proprietary BiND™ platform. Immuno-depletion experiments were performed in normal and PMN patient sera. In vivo experiments in rodents were performed by exogenously administering human IgG4 followed by GE8820 via iv route.

Results: Human IgG4 was selectively and completely depleted in both normal human sera and PMN sera. Depletion of IgG4 in pMN patient sera resulted in removal of PLA2R autoantibodies to levels below the threshold for serological positivity scores for pMN diagnosis. GE 8820 resulted in rapid (≤ 2hrs) and near complete (≥95%) depletion of IgG4 in a dose dependent manner.

Conclusions: Through selective depletion of the IgG4 subclass, GE8820 removed PLA2R autoantibodies from patient sera. GE8820 is being developed for the treatment of autoimmune diseases driven by pathologic IgG4 autoantibodies such as primary membranous nephropathy, muscle specific kinase driven myasthenia gravis and pemphigus vulgaris.

General, Nervous System, Eye, and Skin Involvement in the Phase 3 Trial of Avacopan for the Treatment of ANCA-Associated Vasculitis

Duvuru Geetha,[1] Rula Hajj-Ali,[2] Raashid A. Luqmani,[3] Christian Pagnoux,[4] Darcy Trimpe,[5] David R. Jayne,[6] Peter A. Merkel.[7] ADVOCATE Study Group. *[1]Johns Hopkins University, Baltimore, MD; [2]Cleveland Clinic, Cleveland, OH; [3]Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom; [4]Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada; [5]Amgen Inc, Thousand Oaks, CA; [6]University of Cambridge, Cambridge, United Kingdom; [7]University of Pennsylvania, Philadelphia, PA.*

Background: The most common types of ANCA-associated vasculitis, granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA), can affect many organs. The phase 3 ADVOCATE trial compared avacopan vs a prednisone taper to treat patients with GPA or MPA. Patients receiving avacopan had improvements in sustained remission and kidney outcomes, with less glucocorticoid (GC) exposure and GC-related toxicity than those receiving a prednisone taper.

Methods: This post hoc analysis of the ADVOCATE trial reports rates of active general, nervous system, mucous membranes/eyes, and skin involvement based on the Birmingham Vasculitis Activity Score (BVAS) at weeks 4, 26, and 52, and changes from baseline to week 52.

Results: In the 330-patient ADVOCATE trial, active involvement of the general, nervous system, mucous membranes/eyes, and skin domains affected 68.2% (n=225), 20.9% (n=69), 20.0% (n=66), and 14.2% (n=47) of patients, respectively; most patients had at least one of these manifestations (**Table**). Similar and substantial improvements in the control of active disease in these domains were achieved in both groups: reductions from baseline to week 52 in the proportion of patients with active manifestations in the avacopan vs prednisone taper group, respectively, were 97.3% vs 96.5% (general), 100% vs 93.5% (nervous system), 100% vs 95.0% (mucous membranes/eyes), and 83.3% vs 100% (skin).

Conclusions: In the ADVOCATE trial, treatment with either avacopan or a prednisone taper was associated with the reversal of nearly all active general, nervous system, mucous membranes/eyes, and skin manifestations of GPA or MPA.

Funding: Commercial Support - Amgen

Table: Proportions of Patients With Active General, Nervous System, Mucous Membranes/Eyes, or Skin Involvement in Prednisone Taper and Avacopan Groups Over Time

	Prednisone taper (N=164)					Avacopan (N=166)

Organ involvement was defined as at least one activity item in the relevant domain of the Birmingham Vasculitis Activity Score Version 3. Seizures (not hypertensive) in the nervous system domain; genital ulcers, adnexal inflammation, and retinal changes in the mucous membranes/eyes domain; and gangrene in the skin domain were not listed, as there was no involvement in either treatment group at any time point.
†"Week 52 % Change from Baseline" indicates the difference in the proportion of patients with activity at week 52 from the proportion with activity at baseline: $((n_{w52}-n_{bl})/n_{bl})*100$.

SA-PO735

Antineutrophil Cytoplasmic Autoantibody Levels in Patients in the Avacopan Phase 3 Trial

Frank B. Cortazar,[1] Duvuru Geetha,[2] Salem Almaani,[3] Christina Song,[4] Tomasz M. Wilmanski,[4] Alana M. Bozeman,[4] Peter A. Merkel,[5] David R. Jayne.[6] ADVOCATE Study Group. *[1]New York Nephrology Vasculitis and Glomerular Center, Saint Peter's Hospital, Albany, NY; [2]Johns Hopkins University, Baltimore, MD; [3]The Ohio State University Wexner Medical Center, Columbus, OH; [4]Amgen Inc, Thousand Oaks, CA; [5]University of Pennsylvania, Philadelphia, PA; [6]University of Cambridge, Cambridge, United Kingdom.*

Background: The utility of measuring serial antineutrophil cytoplasmic autoantibody (ANCA) levels to guide treatment in granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) is controversial. This analysis reports on circulating myeloperoxidase (MPO) and proteinase-3 (PR3) ANCA levels in patients in the avacopan and prednisone taper arms of the phase 3 ADVOCATE trial.

Methods: Serum MPO- and PR3-ANCA levels were measured by a central laboratory using an enzyme-linked immunosorbent assay for the following timepoints: day 1 (pre-treatment), week 13, 26, 39, and 52. Linear mixed effect models were used to evaluate the association of a) avacopan and a prednisone taper; b) background therapy (rituximab [RTX] or cyclophosphamide [CYC]); and c) treatment response (sustained remission at week 52) on MPO- or PR3-ANCA levels.

Results: In patients with MPO-ANCA (n=142) or PR3-ANCA (n=188), baseline mean MPO-ANCA levels were higher than PR3-ANCA levels, but both decreased from baseline over time. At week 13, mean ANCA levels decreased more in patients in the prednisone taper arm vs the avacopan arm (both PR3/MPO p=0.002), but levels converged by week 26 for MPO-ANCA and week 39 for PR3-ANCA (**Figure 1A**). While the decrease in mean PR3-ANCA was greater in patients treated with RTX vs CYC regardless of study treatment (p<0.001), the mean MPO-ANCA trajectories were similar between background therapies (p=0.49) (**Figure 1B**). When stratified by treatment response, the reduction in mean ANCA levels was independent of sustained remission status (**Figure 1C**).

Conclusions: The addition of avacopan to RTX or CYC for treatment of GPA or MPA does not appear to impact ANCA levels. The lack of correlation between ANCA levels and outcome of treatment in the ADVOCATE trial suggests that ANCA levels are an unreliable marker of treatment response.

SA-PO736

Baseline Characteristics of the First Patients in AvacoStar, a Real-World Study of Avacopan in ANCA-Associated Vasculitis

Achim Obergfell,[1] David R. Jayne,[2] Raashid A. Luqmani,[3] Benjamin Terrier,[4] Shaun Flint,[1] Marie E. Boff,[1] Monica Balcells-Oliver,[1] Bernhard Hellmich.[5] *[1]CSL Vifor, Glattbrugg, Switzerland; [2]University of Cambridge, Cambridge, United Kingdom; [3]University of Oxford, Oxford, United Kingdom; [4]Hôpital Cochin (Hôpitaux Universitaires Paris Centre), Paris, France; [5]Medius Kliniken, University of Tübingen, Kirchheim unter Teck, Germany.*

Background: Avacopan, an oral, selective C5a receptor antagonist, was approved by the EMA in January 2022 for the treatment of adults with severe, active granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA), in combination with rituximab or cyclophosphamide. The safety of avacopan is now studied in a real-world cohort followed beyond 1 year.

Methods: AvacoStar (NCT05897684) is a non-interventional, multinational, prospective, post-authorization safety study (≤6 months of data may be collected retrospectively). It will enroll 500 patients in Germany and the UK, in two cohorts of 250: (1) avacopan treated, and (2) receiving a cyclophosphamide- or rituximab-based induction regimen without avacopan. Patients aged ≥18 years with severe, active GPA or MPA in the opinion of the investigator, at the time of commencing avacopan or non-avacopan standard of care induction therapy are eligible. The primary objective is the incidence of defined medical events of special interest (MESI) in the avacopan cohort. MESIs are liver injury, cardiac safety, serious infections, and malignancy. Patients will be followed for up to 7 years. We present the baseline characteristics of the first patients enrolled.

Results: Between Sep 2023 and Mar 2024, 122 patients were enrolled and 118 included in this analysis (n=60 avacopan cohort; n=58 non-avacopan cohort). To date, most patients enrolled are newly diagnosed with renal involvement (Table). Other baseline characteristics are also tabulated.

Conclusions: AvacoStar baseline characteristics are currently similar between groups and consistent with clinical practice, suggesting study outcomes may yield generalizable insights on safety and use patterns of avacopan.

Characteristics and Treatment Patterns before Initiation of Avacopan in the United States

Sushmitha Inguva,[1] Pallavi Rane,[1] Darcy Trimpe,[1] Jasjit Multani,[2] Hsiu-Ching Chang,[2] Duvuru Geetha,[3] Peter A. Merkel,[4] Zachary S. Wallace.[5] *[1]Amgen Inc, Thousand Oaks, CA; [2]IQVIA, Wayne, PA; [3]Johns Hopkins University, Baltimore, MD; [4]University of Pennsylvania, Philadelphia, PA; [5]Massachusetts General Hospital, Boston, MA.*

Background: The FDA approved avacopan to treat adults with severe active granulomatosis with polyangiitis or microscopic polyangiitis in Oct 2021. Real-world data on patients receiving avacopan are sparse.

Methods: In a retrospective cohort study using the United States (US)-based IQVIA open-source pharmacy and medical claims data, patients with ≥1 avacopan claim from Oct 2021 to Sep 2023 were identified, with the first avacopan claim date being the index date. Patients ≥18 years old with ≥12 months of pre-index continuous data were included. Demographics on the index date and clinical characteristics in the 12-month pre-index period are shown.

Results: Overall, 701 patients were identified: mean [SD] age: 55.8 [15.9], 60.6% female, 61.1% commercially insured (**Table 1**). Index avacopan was mostly prescribed by rheumatologists (66.0%) or nephrologists (23.1%). Before starting avacopan, 92.3% received systemic glucocorticoids (GCs) with a median duration of GC use of 102 days (IQR: 45-210) and a cumulative oral prednisone-equivalent dose of 2660 mg (IQR: 900-4905). 56.6% received other immunosuppressive therapy before avacopan. In the pre-index period, 54.5% had kidney involvement, including chronic kidney disease/end-stage kidney disease (ESKD; 40.7%), glomerulonephritis (26.1%), proteinuria (22.3%), hematuria (21.5%), or dialysis (3.4%). Pulmonary (56.5%), constitutional (40.9%), and ear, nose, or throat (34.4%) involvement was also commonly observed.

Conclusions: Among initial users of avacopan in the US, most had kidney (including ESKD and dialysis) and pulmonary involvement, and used GCs in the year before starting avacopan. Future studies will assess outcomes following treatment with avacopan in a real-world setting.

Abdominal		16	2.3%

SD = Standard Deviation, GPA = Granulomatosis with Polyangiitis, MPA = Microscopic Polyangiitis, IQR = Interquartile Range, mg = milligram
[a] "Other" included miscellaneous specialty types. Examples include internal medicine, nurse practitioner, physician assistant, pulmonologist etc.
[b] Categories are not mutually exclusive.
[c] Renal and extrarenal involvement was identified using diagnosis and procedure codes.
[d] "Constitutional" includes myalgia, arthralgia, fever, and weight loss.

SA-PO738

Avacopan for ANCA-Associated Vasculitis in Ireland: A Report on All Patients Who Received Avacopan in the Irish Health Care System

Eithne M. Nic an Riogh,[1] Andy G. Cummiskey,[2] Sinead Stoneman,[3] Michael Clarkson,[3] Sarah M. Moran,[3] Ciara N. Magee,[4] Susan M. McAnallen,[5] Mark A. Little.[1] *[1]Trinity Translational Medicine Institute, Trinity College Dublin, Dublin, Ireland; [2]Mater Misericordiae University Hospital, Dublin, Ireland; [3]Cork University Hospital, Cork, Ireland; [4]Beaumont Hospital, Dublin, Ireland; [5]St James's Hospital, Dublin, Ireland.*

Background: Avacopan is a selective C5a receptor antagonist that inhibits neutrophil chemoattraction and activation. It is indicated for the treatment of severe, active granulomatosis polyangiitis or microscopic polyangiitis in combination with rituximab or cyclophosphamide and is considered a steroid sparing alternative. The aim of this report is to describe the first clinical experience with avacopan in ANCA Associated Vasculitis (AAV) in Ireland.

Methods: To date ten patients have received avacopan for AAV between December 2017 and April 2024 through the Irish early access programme and ADVOCATE trial. For these patients, disease relevant information was extracted from the RITA Ireland Vasculitis (RIV) database and through collaboration with the treating nephrologists. Data collected included commencement date and indication for avacopan initiation, duration of treatment, ANCA subtype, organ involvement, number of flares, immunosuppression medication usage and adverse events experienced.

Results: The average age of patients receiving avacopan in Ireland is 51 years (range 18-69 years). 50% were male and 50% were female. Six patients were MPO positive and four were PR3 positive. The majority of patients had renal involvement (90%). Avacopan was predominately commenced in cases where steroid sparing regimens were sought, e.g. severe osteoporosis, history of steroid induced psychosis, patient preference not to take steroids. Avacopan treatment duration ranged from 1 to 20 months, with an average duration of 4 months. 50% of patients remain on avacopan. On average patients received a total of 2.37 gm of Methylprednisolone prior to avacopan commencement (dose range 0mg to 6.5gm). While most patients tolerated avacopan and had no adverse events, reported side effects in this Irish cohort included headache, limited maculopapular rash as well as neutropenia and persistent liver dysfunction.

Conclusions: This is the first report of real-world experience of all patients who have received avacopan in Ireland. Two minor relapses and no major relpases have been reported in this cohort. Although the number of patients receiving avacopan in Ireland is small, avacopan appears to have a good safety profile in this population.

SA-PO739

Elicitation of Physician Opinions of the Impact of Dynamic Changes in Biomarkers on Perceived Relapse Propensity in ANCA-Associated Vasculitis: Impact of Individual Expert and Patient Characteristics

Eithne M. Nic an Riogh,[1] Maren Hackenberg,[2] Moritz Hess,[2] Cathal D. Walsh,[3] Arthur White,[3] Mark A. Little.[1] *[1]Trinity Translational Medicine Institute, Trinity College Dublin, Dublin, Ireland; [2]Institute of Medical Biometry and Statistics, University of Freiburg, Freiburg, Germany; [3]School of Computer Science and Statistics, Trinity College Dublin, Dublin, Ireland.*

Background: ANCA-associated vasculitis(AAV) has a relapsing and remitting course. Accurate predictive algorithms do not exist. Prior knowledge can help to specify Bayesian prior distributions or generate synthetic observations to augment available data. To elicit prior knowledge on changes in time-varying variables and clinical endpoints, we assessed the beliefs of experts on how biomarker changes affect relapse probability and treatment intention.

Methods: We devised 10 synthetic clinical cases. Experts (immunology n=1, nephrology n=5, rheumatology n=4) with an average of 20.4 years' experience were recruited from Ireland, UK, Spain, Netherlands, Germany and Australia. 10 time-varying biomarkers were selected: creatinine, anti-MPO, anti-PR3, sCD163, lymphocyte count, urine protein, urine blood, IgG level and CD19 count. We assessed the perception of relapse risk and intention to change immunosuppression(IS) over 9-24 months. The questionnaire was refined using a Delphi approach. We assessed biomarker rise and fall, positive to negative, or negative to positive switch. The 290-question survey was conducted using a dimensionless scale with a slider to capture responses with extremes of responses labelled on opposite ends.

Results: Reduction in anti-PR3 and anti-MPO were associated with intention to reduce IS (median 46.5 and 38.5) and reduced relapse risk perception (41.0 and 42.0). A rise in anti-PR3 and anti-MPO were strongly associated with a decision not to reduce IS (81.0 and 82.5) and increased relapse risk perception (72.0 and 68.0). Clinicians intended to reduce IS if lymphocyte count (33.5) or IgG (30.0) levels fell, but this did not influence perception of relapse risk (50.0 - lymphocyte count, 50.0 - IgG). There were higher discrepancies in the responses on stable patient characteristics.

Conclusions: Clinical experts were more confident in reducing IS than relapse probability. This reflects the challenge of accurately identifying long term remission in AAV. Greater variability in responses regarding IS reduction reflects variation in clinical practice. Greater concordance was seen in responses on relapse prediction. This study guides future development of predctive algorithms using Bayesian methodologies.

SA-PO740

Avacopan for Granulomatosis with Polyangiitis (GPA) and Microscopic Polyangiitis (MPA) in a Real-World Setting

Zachary S. Wallace,[1] Sam S. Oh,[2] Darcy Trimpe,[2] Sushmitha Inguva,[2] Naomi J. Patel.[1] *[1]Massachusetts General Hospital Department of Medicine, Boston, MA; [2]Amgen, Thousand Oaks, CA.*

Background: Avacopan is approved for use in adults with severe active GPA/MPA in the US. Data on avacopan in the real-world setting are limited.

Methods: This is an ongoing retrospective cohort study including patients from 12/1/21 to 4/1/24 prescribed avacopan for GPA/MPA at Mass General Brigham. Data are extracted by manual review and as structured data. Data from -12 to +6 months are reported. Complete remission (CR) is defined as Birmingham Vasculitis Activity Score (BVAS v3)=0 at month 6 and no glucocorticoids (GC) after month 5.

Results: At the prescription date in the first 80 patients (Fig. 1), mean age was 59 years, and most were female (70%), newly diagnosed (65%), MPO-ANCA+ (60%), and had MPA (53%). Nephrologists were the most frequent prescribers (56%). Of these 80 patients, 67 initiated avacopan. At initiation, 46% had renal involvement by BVAS (median eGFR 24 ml/min/1.73m^2; urine protein-to-creatinine ratio (UPCR) 1.9g/g). Among the 67 initiators at month 6, median cumulative GC dose was 1,011mg, 82% had BVAS=0, and 66% achieved CR. All 5 patients with ≥1 dialysis session ±30 days of initiation stopped dialysis by month 6; 4 newly initiated dialysis ≥30 days post-avacopan start. Of the 11 with eGFR <20 ml/min/1.73m^2 at initiation, 5 had eGFR ≥ 30 ml/min/1.73m^2 by month 6. By month 6, UPCR was 0.5g/g. Of the 35 GC users who discontinued GC by month 6, the median time from avacopan initiation to GC discontinuation was 50 days. At month 6, 43 remained on avacopan; 8 completed a planned 6-month course and 9 discontinued for AEs.

Conclusions: In this real-world GPA/MPA cohort, avacopan was commonly used in patients with severe renal involvement. Most users discontinued GC by month 5, achieved CR, and had favorable renal outcomes.

eGFR ≥ 30ml/min/1.73m^2 Among Those with eGFR < 20ml/min/1.73m^2 at prescription (n=11) – n (%)	5 (45.5%)
Dialysis-free Among Those on Dialysis at Prescription (n=5) – n (%)	5 (100)
Newly Initiated Dialysis >= 30 days after initiation – n (%)	4 (6.0)
Urine Protein:Creatinine Ratio[†] Among Those with Renal Involvement (n = 31) - g/g, median (IQR)	0.5 (0.27, 1.08)
% Change in Urine Protein:Creatinine Ratio[†]	-74.1%
Absolute Change in Proteinuria[†] – g/g, median (IQR)	-0.79 (-0.06, -1.63)
eGFR Slope[‡] – ml/min over 6 months	+9.9 (+5.4, +16.1)
Remained on avacopan at 6 months – n (%)	43 (64.2)

[†]Spot urine measurement; [a]Defined by presence of renal items on BVAS v3; [a]Relapse was defined as the return (after prior improvement) of vasculitis activity on the bases of ≥1 major BVAS/WG item, ≥3 minor BVAS v3 items, or one or two minor BVAS v3 items for at least two consecutive clinical visits. Relapse is assessed after 1 month and completion of rituximab induction doses.
[‡]Linear mixed models were used to estimate the GFR slope using all available eGFR between initiation and month 6 (median 13 (IQR 6, 20) measurements per person). The analysis was limited to individuals with renal involvement who initiated avacopan.
IQR: Interquartile range; eGFR: estimated glomerular filtration rate; BVAS v3: Birmingham Vasculitis Activity Score Version 3; GC: Glucocorticoid; AAV: ANCA-associated vasculitis; PR3: Proteinase 3; MPO: Myeloperoxidase; ANCA: Anti-neutrophil cytoplasmic antibody

SA-PO741

Use of Avacopan outside the ADVOCATE Inclusion Criteria

Ranjoy Sen, Louise R. Moore, Ajay P. Dhaygude, Lauren Floyd, Adam Morris. *Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom.*

Background: The ADVOCATE (Avacopan Development in Vasculitis to Obtain Corticosteroid elimination and Therapeutic Efficacy) trial was a large randomized controlled trial which has demonstrated the beneficial use of Avacopan in the management of Antineutrophil Cytoplasmic antibody (ANCA)-associated Vasculitis (AAV). However, patients with the most severe disease including those with estimated glomerular filtration rate (eGFR) <15, significant pulmonary haemorrhage and dual positive with anti-GBM antibody were excluded. We report 3- and 6-months outcomes of the use of Avacopan outside the ADVOCATE inclusion criteria in AAV patients with severe and life-threatening disease.

Methods: We reviewed patients with AAV and renal involvement treated with Avacopan outside the ADVOCATE inclusion criteria. The response to treatment was measured on change in eGFR at diagnosis, 3 and 6 months, as well as the resolution of lung haemorrhage.

Results: A total of 37 patients were treated with Avacopan with 15 patients falling outside the ADVOCATE inclusion criteria. The demographics and the serology of the patients is shown in table 1. Two were dialysis dependent at presentation and later regained renal function to become independent of renal replacement therapy (RRT) and two had dual positive antibodies with ANCA and anti-GBM. Two patients had diffuse pulmonary haemorrhage and one was ANCA negative. All patients showed an improvement in their renal functions at 3 and 6 months.

Conclusions: This small case series demonstrate successful use of Avacopan outside ADVOCATE inclusion criteria. Further real-life data is likely to support use of Avacopan for a wider and more severe presentations of AAV.

Age (years)	Sex	Indication outside the ADVOCATE criteria	eGFR at diagnosis (ml/min/1.73m²)	eGFR at 3months (ml/min/1.73m²)	eGFR at 6months (ml/min/1.73 m²)	Overall change in eGFR (ΔeGFR)
74	Female	ANCA & anti-GBM Ab+ve eGFR<15	05	08	10	05
52	Male	eGFR<15	10	52	61	51

SA-PO742

Incidence and Severity of Pediatric-Onset ANCA-Associated Vasculitis (AAV) Glomerulonephritis (GN) during the COVID-19 Pandemic: A Large Tertiary Center Experience

Alvaro H. Orjuela, Sharanya Joginpalli, Emily Frierson, Sameer Thadani. *Baylor College of Medicine, Houston, TX.*

Background: During the SARS-CoV-2 virus global pandemic, there were concerns that changes in access to care would negatively impact both the timely diagnosis and severity of disease at presentation. This study sought to determine the incidence and severity of disease at presentation in patients with AAV seen in our center during the pandemic (03/2020-05/2023) compared to those seen prior to the pandemic (01/2017-2/2020).

Methods: We retrospectively reviewed patients with AAV from 2017 to 2023. Abstracted data included patient demographics, clinical characteristics, durations of symptoms prior to presentation, clinical features on presentation, renal biopsy findings, and renal outcomes. Data were evaluated using standard descriptive statistics

Results: In the study period, 29 patients were identified. ***Figure 1 shows the patient demographic data and clinical characteristics on presentation.*** **The pre-pandemic cohort (N=12)**, 58% had MPA (N=7) and 42% GPA (N=5). Mean onset of symptoms to diagnosis of 1.5 months. At presentation, 68% had reno-pulmonary involvement, 16% ENT/Orbital, 8% isolated pulmonary, and 8% isolated renal disease.**The pandemic cohort (N=15)**, 53% had MPA (N=8) and 47% GPA (N=7). Mean onset of symptoms to diagnosis was 1 month. Organ involvement in presentation: 53% renal-pulmonary, 20% isolated pulmonary involvement, 13% isolated renal disease, and 13% ENT/orbital (P=0.4).

Conclusions: While there was a demonstrable 25% increase in the incidence in patients with AAV during the pandemic with a concurrent increase the frequency of both RPGN and CKD/ESKD (P=0.4), the duration of symptoms prior to presentation was not impacted. These data suggest that there was only a limited impact on access to care during the Pandemic. Factors that impacted disease severity and renal involvement need further investigation

Figure 1	Pre-Pandemic Cohort (Pre-PC) N=12	Pandemic Cohort (PC) N=15
Mean age at presentation	11.8 years (range: 4 to 19 years)	11.7 years (range: 6 to 17 years)
<10 years	41% (N=5)	40% (N=6)
> 10 years	64% (N=7)	60% (N=9)

SA-PO743

French Vasculitis Study Group Score: A Predictor of Outcome or a Tool for Guiding Remission-Induction Therapy?

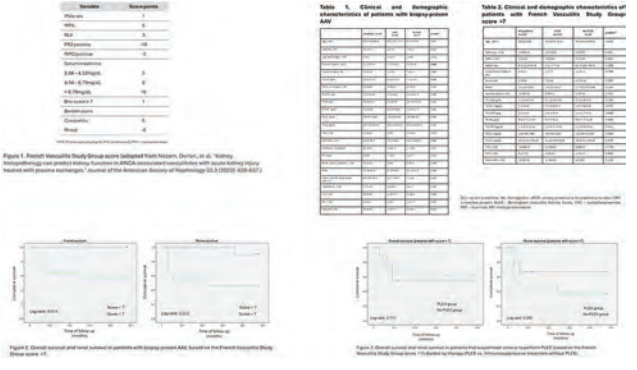
Afonso Santos, Andreia Curto, Fábio D. Henriques, Ana C. Brás, Pedro Campos, Joana E. Santos, Patricia S. Carrilho, Rita Theias Manso, Maria A. Serra, Fernando Domingos. *Hospital Professor Doutor Fernando Fonseca EPE, Amadora, Portugal.*

Background: Patients with antineutrophil cytoplasmic antibodies (ANCA)-associated vasculitis (AAV) develop end-stage kidney disease, despite progress in therapy. To choose patients for whom PLEX would be helpful, the French Vasculitis Study Group (FVSG) suggested a score combining clinical and histopathologic data (Fig. 1). The aim of our study was to evaluate this score's clinical usefulness in patients with AAV.

Methods: This is a retrospective, single-center cohort study. We enrolled adult patients with AAV (kidney biopsy, suggestive clinical features and/or ANCA positivity) between 2011 and 2023. The use of PLEX was uncontrolled. Patients were classified according to the FVSG score and divided in two groups (score >7 the threshold above which PLEX was recommended and <7). Baseline parameters, overall survival, and renal survival were compared. We further compared the subpopulation that received PLEX with those receiving only immunosuppressive drugs, using the same threshold.

Results: The baseline data of the 33 patients are described in table 1. PLEX was performed in 16 patients (48.4%). Serum albumin and creatinine levels were significantly different between the two groups (PLEX vs. no-PLEX, p=0.008). The overall survival and renal survival of patients with score >7 was lower than the patients with score <7 (p=0.015 and p=0.012, respectively, Fig 2.). We found no differences between groups (PLEX vs no-PLEX) for patients with a clinical score >7 (table 2 and Fig. 3).

Conclusions: The FVSG score was successfully used to predict overall and renal survival using the threshold proposed. However, in our retrospective cohort, the patients that would have a survival benefit with PLEX, had similar outcomes to those who did not receive it. In conclusion, in our cohort, this score was predictive of clinical outcome, however it was not helpful at differentiating patients who would benefit from receiving PLEX.



SA-PO744

Urinary Complements as a Predictor of Kidney Outcomes in Patients with ANCA-Associated Vasculitis

Kenta Fujimoto, Masao Kikuchi, Shoko Ochiai, Akiko Baba, Koichi Kaikita, Shouichi Fujimoto. *Miyazaki Daigaku, Miyazaki, Japan.*

Background: Anti-Neutrophil Cytoplasmic Antibody (ANCA) -associated vasculitis (AAV) is a systemic vasculitis characterized by inflammation of small blood vessels that can lead to rapidly progressive glomerulonephritis. Recent research has underscored the significance of C5a in the pathogenesis of this condition. Although there are reports of elevated urinary complement levels during the active phase of AAV, the exact relationship between elevated complement and renal outcome is unclear.

Methods: This study included 36 patients (median age 73 [69, 78] years, 38.9% male, serum Cr 2.26 [1.2, 5.5] mg/dL) with newly diagnosed MPO-ANCA positive AAV with renal involvement who were admitted to our hospital from March 2019 to November 2023. Urine samples were collected at the beginning of treatment and stored in a -30 °C freezer. Urinary complement levels (specifically C5a and C3a) were measured using each ELISA kits (Becton, Dickinson and Company, Franklin Lakes, NJ). Patients were classified into three groups (low, intermediate, and high) based on their respective C5a/Cr and C3a/Cr ratios and their progression to end-stage kidney disease (ESKD) was evaluated. In addition, the relationship between urinary complement levels and renal biopsy findings was also examined (n=32).

Results: Five patients developed ESKD during the 2-year follow-up period, and Kaplan-Meier analysis showed no significant difference among the three groups in C5a/Cr ratio (P=0.053), but there was a significant difference in C3a/Cr ratio among the groups (P=0.025). Histopathological examination showed an associations between C3a/Cr ratio and cellular crescent formation (|ρ|=0.3947, P=0.025) and tubulointerstitial lesions (|ρ|=0.4002, P=0.023), while C5a/Cr ratio was correlated with tubulointerstitial lesions (|ρ|=0.4563, P=0.010).

Conclusions: Urinary complement levels in newly diagnosed AAV patients may be a useful biomarker for assessing the risk of developing ESKD. It also correlates with renal involvement in patients with AAV and may be an alternative to kidney biopsy.

SA-PO745

Risk of ESKD in ANCA-Associated Glomerulonephritis at Presentation and during the Disease Course

Sjoerd Timmermans,[1,2] Daan P. van Doorn,[1,2] Floris T. Voorde,[1,2] Pieter van Paassen.[1,2] Limburg Renal Registry; Expert Center for Immune-mediated Kidney Diseases and Vasculitis. *[1]Maastricht Universitair Medisch Centrum+, Maastricht, Netherlands; [2]Universiteit Maastricht Cardiovascular Research Institute Maastricht, Maastricht, Netherlands.*

Background: Kidney involvement in ANCA vasculitis is common and impacts quality of life and survival. Tools to determine disease activity and predict risk for ESKD may optimize intensity and duration of immunosuppression. The ANCA kidney risk score (AKRiS) predicts ESKD. The AKRiS, however, is based on cross-sectional data. Here, we validated AKRiS in two well-defined cohorts of patients with *de novo* ANCA glomerulonephritis (AGN) and studied the effect of kidney recovery and relapsing AGN on kidney survival.

Methods: We analyzed patients with *de novo* AGN recruited from the Limburg Renal Registry (i.e., historical cohort; *n*=290) and prospective PROMAVAS cohort (*n*=36). Kidney recovery at 12 months and slope of eGFR from 12 months onward were studied, using a two-slope mixed-effects linear spline model.

Results: The historical cohort included 126 (63%), 43 (21.5%), 28 (14%), and 3 (1.5%) patients with low, moderate, high, and very high risk, with follow-up of 10 (IQR, 6-15) years. Creatinine was 2.4 (IQR, 1.4-4.5) mg/dL and 164 (82%) patients were treated using a cyclophosphamide-based regimen. Kidney survival varied from 97.5%, 87.9%, 74.5%, to 33.3% at 36 months, validating AKRiS with good discrimination (C statistic, 0.84). The PROMAVAS cohort (creatinine, 2.4; IQR, 1.8-3.5) mg/dL, including 21 (58.3%) patients treated using a rituximab-based regimen, corroborated these observations (C statistic, 0.92). The eGFR improved +10.4 (95%CI, 7.8 to 12.9) mL/min/1.73m^2 at 12 months, with no differences between patients with an eGFR <30 mL/min/1.73m^2 as compared to those with better kidney function at presentation. eGFR's mean annual slope was -1.0 mL/min/1.73m^2 (95%CI, -1.7 to -0.3) in remitted AGN, contrasting -3.3 mL/min/1.73m^2 (95%CI, -4.4 to -2.2; *P*=0.001) in relapsing AGN. ESKD was associated with eGFR <30 mL/min/1.73m^2 at 12 months.

Conclusions: AKRiS predicts the risk of ESKD in *de novo* AGN. Moreover, CKD stage at 12 months, and relapsing AGN affect eGFR's slope and progression to ESKD. Treatment should therefore focus on maximal kidney recovery using novel drugs, such as, C5aR inhibition, and prevention of relapsing AGN, particularly in patients with eGFR <30 mL/min/1.73m^2 at 12 months, to maintain kidney function. Future trials should focus on the effects of treatment on kidney recovery and eGFR's slope.

SA-PO746

Prediction of Recovery of Kidney Function in Severe ANCA-Associated Glomerulonephritis

Megan Leffek,[1] Kavita Gulati,[3] Jennifer Scott,[4] Gavin Chapman,[12] Benoit Brilland,[5] Cecilia Barnini,[6] Vojtech Kratky,[7] Jens Rathmann,[14] Minhyung Kim,[8] Li Jin Ooi,[2] Zdenka Hruskova,[7] Maria J. Stangou,[15] Ajay P. Dhaygude,[9] Abdulmecit Yildiz,[10] Jean Francois Augusto,[5] Jung eun Lee,[8] Andrea Hinojosa-Azaola,[11] Juan M. Mejia-Vilet,[11] Andreas Kronbichler,[6] Neeraj Dhaun,[12] Marten Segelmark,[14] Mark A. Little,[4] Duvuru Geetha,[13] Stephen P. McAdoo,[3] Silke R. Brix.[1,2] AKRiS Working Group. *[1]The University of Manchester, Manchester, United Kingdom; [2]Manchester University NHS Foundation Trust, Manchester, United Kingdom; [3]Imperial College London, London, United Kingdom; [4]The University of Dublin Trinity College, Dublin, Ireland; [5]Centre Hospitalier Universitaire d'Angers, Angers, France; [6]University Innsbruck, Innsbruck, Austria; [7]Prague City University a s, Praha, Czechia; [8]Samsung Medical Center, Gangnam-gu, Seoul, Republic of Korea; [9]Royal Preston Hospital, Preston, United Kingdom; [10]Bursa Uludag Universitesi, Nilufer, Turkey; [11]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [12]University of Ediburgh, Edinburgh, United Kingdom; [13]John Hopkins University, Baltimore, MD; [14]Lunds Universitet, Lund, Sweden; [15]Aristoteleio Panepistemio Thessalonikes, Thessalonike, Greece.*

Background: Anti-neutrophil cytoplasmic antibody (ANCA) vasculitis often involves the kidneys and kidney failure confers significant morbidity and mortality. An improved prognostication of kidney function recovery will enable tailoring treatment to patients' needs.

Methods: Multicentre, retrospective analysis of newly diagnosed ANCA glomerulonephritis (GN) patients requiring kidney replacement therapy (KRT) at time of diagnosis of 16 registries and vasculitis referral centres. Unadjusted and adjusted multivariable Cox regression for primary outcome of kidney function recovery.

Results: 372 patients required KRT at time of diagnosis and 137 of these recovered kidney function during follow-up (36.8%). The median age was 67 years (interquartile range, IQR, 56 – 74 years) and 57.4% were male. 159 patients were anti-myeloperoxidase positive (42.7%), 174 patients were anti-proteinase 3 positive (46.8%), and 39 patients were ANCA negative (10.5%). Median creatinine and estimated glomerular filtration rate (eGFR) at time of diagnosis were 618mmol/l (IQR 470 – 844mmol/l) and 6.2mls/min (IQR 4.7 – 9mls/min). 243 patients developed ESKD (65.3%) during median follow-up of 3.6 years (IQR 0.6 – 6.2 years). 120 patients died during follow-up (32.3%). Patients recovering kidney function showed a median of 22.8% normal and 33.5% crescentic glomeruli, patients remaining KRT-dependent demonstrated a median of 5.7% normal and 27.3% crescentic glomeruli in their biopsies. The percentage of normal glomeruli, interstitial fibrosis and tubular atrophy (IFTA), creatinine and eGFR associated with kidney function recovery. In a multivariable adjusted analysis, the percentage of normal glomeruli and creatinine correlated with outcome (p<0.001, p<0.001, respectively) while antibody subtype and diagnosis did not.

Conclusions: Kidney function and the percentage of normal glomeruli were predictive of kidney function recovery in patients with newly diagnosed ANCA GN requiring KRT. The percentage of crescentic glomeruli did not differ between patients recovering from kidney failure and patients remaining on KRT.

Temporal Trends in the Utilization of Hydralazine and Diagnoses of ANCA-Associated Glomerulonephritis

Juarez R. Braga,[1] Swathi Muni Reddy,[1] Clarissa A. Cassol,[2] John M. Arthur.[1] *[1]University of Arkansas for Medical Sciences, Little Rock, AR; [2]Arkana Laboratories, Little Rock, AR.*

Background: Hydralazine is used in clinical praactice in the management of hypertension and heart failure. However, hydralazine is associated to the development of ANCA antibodies which can then in turn cause pauci-immune glomerulonephritis (GN). We designed this study to examine temporal trends in the use of hydralazine and in the number of individuals diagnosed with biopsy-proven hydralazine-associated ANCA-GN.

Methods: This study included 2 analyses: (i) a repeated cross-sectional study examining the use of hydralazine among Medicare beneficiaries using Part D Prescription data from 2013 to 2021; (ii) an observational study of ANCA-GN diagnosed with a kidney biopsy at a single renal pathology center, Arkana Laboratories, from 2016 to 2021. From the Medicare part D files, we extracted the number of beneficiaries, the total number of claims, and claims according to provider specialty for hydralazine. Prescription rate was expressed per 100,000 beneficiaries and per 1,000 providers. From the pathology laboratory, we identified cases diagnosed with pauci-immune GN using the ICD code N01.7. Electronic records were then reviewed for a history of positive ANCA antibodies and exposure to hydralazine.

Results: The number of Part D enrollees increased from 35.1 million in 2013 to 46 million in 2021. Meanwhile, the proportion of beneficiaries receiving hydralazine increased from 2% to 2.9%. In absolute numbers, that represented an increase from 718,433 to 1,324,532 beneficiaries in use of hydralazine ($P < .001$). There was an increase in the prescription rate of hydralazine among cardiologists from 1,271 claims per 100,00 beneficiaries in 2013 to 1,639 per 100,000 in 2021 ($P < .001$). The prescription rate, when examined per 1,000 providers, also increased from 41,287 claims in 2013 to 52,795 in 2021 among cardiologists ($P < .001$). This trend was not observed among nephrologists or internists. The number of individuals in use of hydralazine diagnosed with biopsy-proven ANCA-GN increased from 16 cases in 2016 to 36 in 2021 ($P < .001$).

Conclusions: The number of Medicare beneficiaries using hydralazine and the number of biopsy-proven hydralazine-associated ANCA-GN increased significantly over time. Those trends could have broad implications for Medicare spending with dialysis.

Clinical Profile, Histologic Profile, and Outcome of Patients with Rapidly Progressive Glomerulonephritis: Experience from Ethiopia

Hamelmal G. Hailegiorgis.[1,2] *[1]Saint Paul Millennium Medical College, Addis Ababa, Ethiopia; [2]University Teaching Hospital of Kigali, Kigali, Rwanda.*

Background: Rapidly progressive glomerulonephritis (RPGN) is a clinical syndrome defined by the rapid loss of renal function, accompanied by features of the nephritic syndrome with proteinuria, glomerular hematuria, and often oliguria. Although relatively uncommon, early recognition and prompt treatment are crucial to prevent irreversible loss of renal function. Data are scarce regarding RPGN in Africa. This study aims to determine the clinical profile and outcomes of RPGN among patients treated at a tertiary hospital in Addis Ababa, Ethiopia.

Methods: A retrospective study was conducted including all eligible RGPN patients who were managed at St. Paul Millennium Medical College from January 2020 to January 31, 2023. Data from 120 RPGN patients was collected. Patient characteristics are presented using frequencies, mean ± standard deviation (SD), or median with Inter Quartile range (IQR) values. To identify predictors of treatment outcome, a multinomial logistic regression analysis was used and an adjusted odds ratio (AOR), with 95% used for the interpretation of the results

Results: 120 patients diagnosed with rapidly progressive glomerulonephritis (RPGN) were included in the study. The mean age of patients was 40.25 ± 14.6 years. Oliguria and hypertension were the most common presenting symptoms (74.41 and 73.62% respectively).62.5% (n=75) underwent kidney biopsy. Of these 44% showed crescentic RPGN and DPGN in 19 (33.3%) patients. Of the 120 RPGN cases, 28% developed ESRD 13.6% died, and 30.4% achieved CR. Among crescentic RPGN patients, 27.3% developed ESRD,24.2% died, and only 18.2% achieved CR.

Conclusions: In our population, crescentic GN was found to be the most common histopathological diagnosis in patients with clinical RPGN. However, it is important to note that alternative diagnoses without histologic evidence of crescentic GN are also common. Renal histology plays a crucial role in both the diagnosis and prognosis of patients with clinically suspected Rapidly Progressive Glomerulonephritis (RPGN). Routine ancillary serologic tests for this patient group can significantly impact the diagnosis and prognosis of cases.

SA-PO749

Clinical Presentation and Outcomes of SARS-CoV-2 Infection in Patients with Pauci-Immune Glomerulonephritis

Angeliki Sardeli,[1] Evangelia Dounousi,[7] Dimitra Gkalitsiou,[3] Konstantia Kantartzi,[4] Vassilios Liakopoulos,[5] Smaragdi Marinaki,[2,6] Georgios Moustakas,[3] Minas Karagiannis,[1] Petros Nikolopoulos,[1] Stylianos A. Panagoutsos,[4] Sophia Lionaki.[1,2] *[1]Panepistemiako Geniko Nosokomeio Attikon, Athens, Greece; [2]Ethniko kai Kapodistriako Panepistemio Athenon, Athens, Greece; [3]Geniko Nosokomeio Athenon Giorgos Gennematas, Athens, Greece; [4]Demokriteio Panepistemio Thrakes, Komotini, Greece; [5]Aristoteleio Panepistemio Thessalonikes, Thessalonike, Greece; [6]Laiko General Hospital, Athens, Greece; [7]Panepistemio Ioanninon, Ioannina, Greece.*

Background: SARS-CoV-2 infection is characterized by multi-system involvement, affecting not only the respiratory system[1,2]. This study aimed to outline the clinical presentation and outcomes of SARS-CoV-2 infection in patients with pauci-immune GN (PIGN).

Methods: A retrospective analysis was conducted on 29 individuals with PIGN and positive SARS-CoV-2 PCR test, excluding those in end-stage kidney disease (ESKD) prior to infection. Data encompassed immunosuppressive regimens at PIGN diagnosis, treatment outcomes, SARS-CoV-2 infection's clinical course and outcome of PIGN post infection.

Results: The mean age of patients was 61.0(±16.4) years, with 16(55.1%) being female. Upon SARS-CoV-2 infection, 12(41.3%) were on immunosuppressive therapy, of whom 4 (13.7%) were on rituximab maintenance therapy. Almost all patients were symptomatic in terms of the infection and 7(24.1%) required hospitalization. 23(88.4%) experienced complete recovery from Covid-19, 3(3.1%) had prolonged symptoms and 3(11.5%) died due to Covid-19. Among patients in remission, 1(3.8%) experienced a relapse of PIGN following SARS-CoV-2 infection.

Conclusions: In this cohort of patients with PIGN, SARS-CoV-2 infection impacted morbidity and mortality of this vulnerable population.

Demographics, baseline patients' characteristics, symptoms and outcomes of SARS-CoV-2 infection and GN.

Parameter N(%) or mean (SD)	N=29
Age at diagnosis of GN (years)	61.0 (16.4)

SA-PO750

SARS-CoV-2 Vaccination in Patients with Pauci-Immune Glomerulonephritis: A Multicenter Study

Angeliki Sardeli,[1] Evangelia Dounousi,[7] Dimitra Gkalitsiou,[3] Konstantia Kantartzi,[4] Kriki Pelagia,[4] Vassilios Liakopoulos,[5,6] Smaragdi Marinaki,[2,8] Giannakopoulos Panagiotis,[1] Georgios Moustakas,[3] Sophia Lionaki.[1,2] *[1]Panepistemiako Geniko Nosokomeio Attikon, Athens, Greece; [2]Ethniko kai Kapodistriako Panepistemio Athenon, Athens, Greece; [3]Geniko Nosokomeio Athenon Giorgos Gennematas, Athens, Greece; [4]Demokriteio Panepistemio Thrakes, Komotini, Greece; [5]Aristoteleio Panepistemio Thessalonikes, Thessalonike, Greece; [6]Ahepa Hospital, Thessalonikes, Greece; [7]Panepistemio Ioanninon, Ioannina, Greece; [8]Laiko General Hospital, Athens, Greece.*

Background: SARS-CoV-2 vaccination has been shown crucial in stemming the pandemic. This study aimed to describe adverse events associated with SARS-CoV-2 vaccination in patients with a history of pauci-immune glomerulonephritis (PIGN).

Methods: A retrospective analysis was conducted in individuals with PIGN who received the SARS-CoV-2 vaccine, excluding those in ESKD prior to vaccination. Recorded data included histopathological diagnosis, immunosuppressive regimens, clinical outcomes, vaccination type, and related adverse events.

Results: A cohort of 69 individuals diagnosed with PIGN, with an age of 59.6 (±17.5) years, was studied, of whom 36(53.7%) were females. Of these, 34(50.7%) had a medical history of hypertension, and 16(23.9%) type 2 diabetes. Induction therapy was administered in 66(98.5%) cases, with 87.7% of them achieving remission. 50(74.6%) patients received maintenance therapy and 50 (94.3%) were vaccinated against SARS-CoV-2, within 79.5(±70.8) months from the diagnostic biopsy with 3.2(±1.0) doses. At vaccination, 90% of patients were in remission and 44% were on immunosuppression. 26% of patients reported systemic adverse events and 62% local reactions after vaccination. 2(4.3%) patients experienced a relapse of PIGN, within 5.7 (±3.4) months from the first dose.

Conclusions: SARS-CoV-2 vaccination was well-tolerated, with non-significant impact on PIGN relapse probability. Local side effects were common, seen in the majority of patients, while systemic ones occurred in 20.4% of them.

Demographics, baseline characteristics and adverse events of patienst with PIGN following vaccination SARS-CoV-2 vaccination.

Clinical, Serologic, and Histologic Characteristics of Pauci-Immune Renal Vasculitis and Its Response to Treatment in a Mexican Population

Martin B. Yama Estrella, Mario Alamilla-Sanchez, Jose H. Cano Cervantes, Mayra M. Matias Carmona, Citlali Fernandez Vivar, Carolina Gonzalez-Fuentes, Manuel Camacho Luna, Nicte Alaide R. García, Michelle Sánchez, Fani G. Ruiz Rivera, Enrique F. Morales Lopez, Regina C. Hernandez. *Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico.*

Background: Small-vessel vasculitis presents an adverse renal prognosis that can be life-threatening, so it is relevant to know its characteristics and response to treatment

Methods: Retrospective cohort study, conducted between April 2018 and April 2024. The objective was to analyze the characteristics of pauci-immune renal vasculitis and its response to treatment in a third level hospital in Mexico. Patients older than 18 years with a biopsy-proven diagnosis, who had a follow-up of at least 12 months were included

Results: 19 patients were evaluated, with average age 54 years, 13 (68.42%) women. 14 (73.68%) had extra-renal manifestations. In the histological classification 6 (34.58%) were mixed, 5 (26.32%) focal, 4 (21.05%) sclerotic, 3 (15.79%) crescentic and 1 not classified. 9 (47.37%) were associated with MPO, 7 (36.84%) with PR3, and 3 (15.79%) seronegative. 7 (36.84%) had decreased Complement C3 (< 90 mg/dl). At diagnosis, 16 (84.21%) patients had deterioration of the glomerular filtration rate (eGFR < 60 ml/min/1.73m2) and 9 (47.37%) required renal replacement therapy (RRT). As induction treatment all patients received steroids, 6 (31.58%) cyclophosphamide (CYC), 6 (31.58%) rituximab (RTX), 5 (26.32%) CYC + RTX and one mycophenolic acid (Table 1). Until April 2024, patients were followed up for a mean of 31 months, 14 (73.68%) are free of RRT and one (5.26%) died

Conclusions: Deterioration of the GFR was the main renal manifestation. The most common serology was associated with MPO (47.37%). Although not frequently reported, we found C3 hypocomplementemia in 7 (36.84%) patients. The survival of the patients (94.74%) and their renal prognosis (78.95% without RRT) were better than those reported in other populations. The efficacy of the treatments is similar among the regimens we evaluated

Table 1. Follow-up on response to induction therapy

Treatment	Basal	6 months	12 months	18 months	24 months
STR + CYC:

SA-PO752

National Trends and Outcomes of Hospitalizations among Patients with Renal Vasculitides

Chikodili N. Nebuwa,[1] Nnenna A. Ukoha,[2] Victor N. Oboli,[3] Ede Omosumwen,[4] Evaristus Asobara.[5] *[1]Nuvance Health, Vassar Brothers Medical Center, Poughkeepsie, NY; [2]East Tennessee State University, Johnson City, TN; [3]Lincoln Medical Center, Bronx, NY; [4]Richmond Gabriel University, Arnos Vale, Saint Vincent and the Grenadines; [5]Nnamdi Azikiwe University Teaching Hospital, Nnewi, Nigeria.*

Background: Renal vasculitides are a rare and often debilitating diseases characterized by inflammation of blood vessels within the kidneys with risk for severe renal complications. This study aims to characterize recent trends in hospitalization and clinical outcomes for renal vasculitides.

Methods: We used data from NIS between 2017 and 2020 for vasculitides among patients hospitalized for diseases of the kidney and urinary tract (Major Diagnostic Category 11). Diagnoses and comorbidities were identified using CCSR and ICD 10th edition codes. We used pearson chi-square tests to compare baseline characteristics. The primary outcome was in-hospital mortality. Secondary outcomes were length of stay (LOS) and need for dialysis. Cochran-Armitage tests were used for trend analysis with statistical significance set at P<0.05.

Results: We analyzed a total of 9,090 hospitalizations for renal vasculitides. The frequencies were: Granulomatosis with polyangiitis (GPA) (28.5%), anti-glomerular basement membrane disease (anti-GBM) (24.8%), hypocomplementemic urticarial vasculitis syndrome (24.8%), cryoglobulinemic vasculitis (12.5%), Bechet's disease (16.7%), eosinophilic granulomatosis with polyangiitis (8.5%), and polyarteritis nodosa (PAN) (8.9%). The cohort was predominantly female (51.7%), mean age of 55.2 ± 0.4 years. The annual hospitalizations reduced from 2,730 in 2017 to 1,740 in 2020 (P<0.001). A total of 255 mortalities (2.8%) were recorded in the study period, mostly among females (130), White Americans (160). Mortalities reduced from 85 in 2017 to 35 in 2020 (P<0.001). The greatest mortalities were recorded in the GPA (112; 4.3%) and PAN cohorts (34; 4.25%). Mean LOS was 9 days overall. Patients with Bechet's disease spent 5.5 days compared to GPA (11.2 ± 0.5 days). No significant change in LOS was recorded from 2017 to 2020 (8.9 vs 9.4 days; p=0.749). About 795 (8.7%) required dialysis. Most patients dialyzed were men (410) and patients with anti-GBM disease (400) or GPA (274). The mean cost of hospitalization over the study period was $110,895.4 =/-4,003, with increase in cost from $95,891 in 2017 to $125,695 in 2020 (p<0.0001)

Conclusions: The study highlights the hospitalization pattern of renal vasculitides. Hospitalization for renal vasculitides, in-hospital mortality and dialysis requirement decreased significantly over the study period.

SA-PO753

Monoclonal Gammopathy and Its Associations with Kidney Failure in Patients with ANCA-Associated Vasculitis

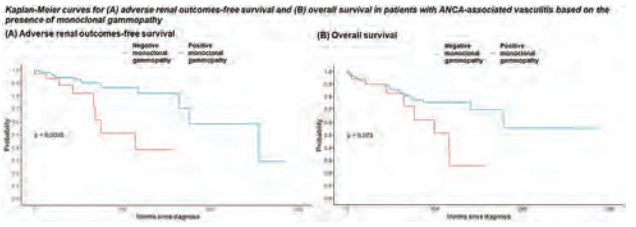
Poemlarp Mekraksakit,[1] Maria Jose Vargas-Brochero,[1] António d. Inácio,[2] Yeshwanter Radhakrishnan,[1] Patrícia A. Domingues,[2] Alessia Buglioni,[1] Ladan Zand.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Centro Hospitalar de Setubal EPE, Setubal, Portugal.*

Background: Up to 30% of patients with ANCA-associated vasculitis (AAV) and kidney involvement progress to end-stage kidney disease (ESKD) despite therapy. The role of monoclonal gammopathy (MG) in disease progression among patients with AAV is not well understood.

Methods: We retrospectively reviewed records of 167 AAV patients with renal involvement tested for MG from January 2000 to December 2023. Patients were divided into monoclonal positive (n=34) and negative (n=133) groups. Multivariate Cox analysis identified predictors of adverse renal outcomes (>40% decline in eGFR or ESKD) and mortality.

Results: The median age of the cohort was 68 years [58.5-74.5], with 85 (50.8%) males. 65.8% tested positive for MPO, and 64.6% received rituximab as induction therapy. Both groups had similar baseline characteristics, but the MG positive group had more moderate/severe Mayo Clinic Chronicity Score (MCCS) (56.7% vs. 33.3%, p=0.01) and less crescentic Berden classification (6.7% vs. 24.8%) on kidney biopsy. Patients in the MG positive group had higher rates of adverse renal outcomes (23.5% vs. 11.3%), ESKD (20.6% vs. 9.8%), death (26.5% vs. 18%), and relapse (35.3% vs. 27.1%) compared to those with no MG. After adjusting for baseline eGFR, hypertension, proteinuria, moderate/severe MCCS, sclerotic Berden class, and induction therapy, MG was associated with adverse renal outcomes (HR 4.64 [95% CI 1.24-17.35]), but not mortality (HR 2.0 [95% CI 0.92-4.3]). Other predictors of adverse renal outcomes were sclerotic Berden classification (HR 12 [2.02-71.9]), proteinuria (HR 1.53 [1.15-2.04] per 1 g/24 hr), and lack of induction therapy (HR 6.3 [1.18-33.5]). Achieving renal remission was associated with lower mortality (HR 0.03 [0.003-0.3]).

Conclusions: AAV patients with renal involvement and MG are at a higher risk of adverse renal outcomes even after adjusting for factors such as eGFR and the degree of chronicity, both of which are known predictors of renal outcomes. The mechanism by which MG worsens outcomes is unclear and requires further research.



SA-PO754

Association of Urinary Adhesion Molecules Derived from Endothelial Cells and Kidney Pathology in ANCA-Associated Glomerulonephritis

Tomoki Tanaka,[1] Ryosuke Umeda,[1] Shun Minatoguchi,[1] Joichi Usui,[2] Kunihiro Yamagata,[2] Midori Hasegawa,[1] Naotake Tsuboi.[1] *[1]Fujita Ika Daigaku, Toyoake, Japan; [2]Tsukuba Daigaku Igaku Iryokei, Tsukuba, Japan.*

Background: Although renal biopsy provides valuable histological information, it is an invasive procedure carrying a risk of bleeding in patients with ANCA-associated glomerulonephritis (ANCA-GN). Therefore, non-invasive urinary biomarkers reflecting renal pathology are highly desirable. ICAM-1 and VCAM-1 belong to the immunoglobulin superfamily serving as cell adhesion molecules and their expression on the cell surface is induced in response to inflammatory stimuli. The aim of the current study is to evaluate the clinical significance of ICAM-1 and VCAM-1 as urinary biomarkers in relation to the pathological findings in ANCA-GN.

Methods: The Japanese nationwide cohort (RemIT-JAV-RPGN cohort, n = 44) and our institutional cohort (FHU cohort, n = 76) for ANCA-GN were subjected to the current study. Urinary concentrations of soluble ICAM-1 and VCAM-1 measured by ELISA were standardized with urinary creatinine (UICR or UVCR), and urine VCAM-1 to ICAM-1 ratio (UVIR) was also obtained. We investigated the association of both biomarkers with renal pathology.

Results: In the RemIT-JAV-RPGN cohort, a correlation between UVIR and the severity of interstitial fibrosis and tubular atrophy (IF/TA) was observed, and similar associations for both UVCR and UVIR were also observed in the FHU cohort. Furthermore, UVIR was found to be a superior indicator for assessing the severity of IF/TA compared with UVCR. In the FHU cohort, when categorizing interstitial damages to interstitial inflammatory cell infiltration (ICI) and interstitial fibrosis (IF), UVIR was consistently increased according to the severity of ICI, but not to IF. Association of urine ICAM-1 or VCAM-1 with cellular crescents was not observed in either cohort. ROC analysis demonstrated that UVIR has superior predictive ability for IF/TA ≥25% in both cohorts. Although the predictive performance of UVIR was comparable to that of urine α1-microglobulin to creatinine ratio (Uα1MGCR) in the FHU cohort, multivariate ROC analysis of UVIR combined with Uα1MGCR improved the prediction ability compared to Uα1MGCR alone.

Conclusions: The urinary ICAM-1 and VCAM-1 are reliable biomarkers that reflect renal pathological activity related to acute interstitial inflammation in ANCA-GN.

Identification of Kidney Transcripts Associated with Prognosis in ANCA-Associated Glomerulonephritis

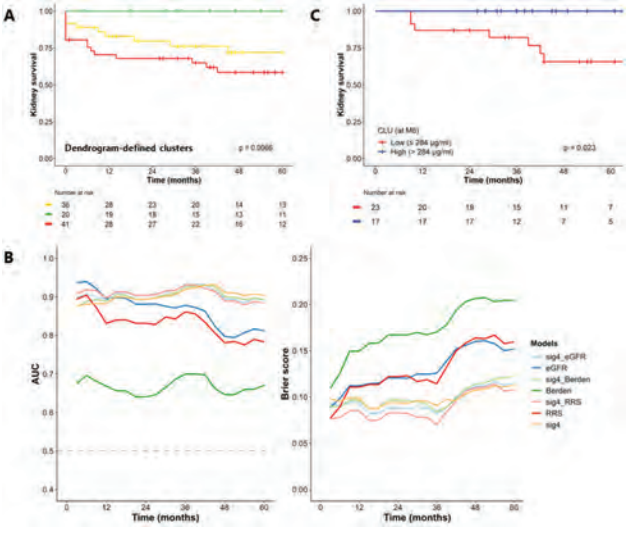
Benoit Brilland,[1] Jérémie Riou,[1] Andrea Boizard-Moracchini,[2] Nathalie Merillon,[1] Maïa Despre,[1] Giorgina B. Piccoli,[3] Assia Ilham Djema,[4] Nicolas Henry,[5] Marie-Christine Copin,[1] David Langlais,[6] Patrick Blanco,[1] Jean Francois Augusto.[1] Maine-Anjou Registry Research Group. *[1]CHU Angers, Angers, France; [2]Centre Hospitalier Universitaire de Bordeaux Groupe hospitalier Pellegrin, Bordeaux, France; [3]Centre Hospitalier du Mans, Le Mans, France; [4]Centre Hospitalier de Cholet, Cholet, France; [5]CH Laval, Laval, France; [6]McGill University, Montreal, QC, Canada.*

Background: Kidney involvement in ANCA-associated vasculitis (AAV-GN) predicts poor patient and kidney survival. To get insights into pathogenic mechanisms or identify biomarkers for refining prognosis, we aimed to investigate the potential prognostic value of kidney transcripts associated with kidney survival.

Methods: Immune gene transcript analysis was performed on RNA extracted from 97 adult AAV-GN kidney biopsies from the French Maine-Anjou Registry using NanoString technology. Transcripts of interest were selected, and their prognostic performance was compared to current histological-based classifications. Following the identification of a possible role for clusterin (CLU), the relationship between serum CLU and prognosis was assessed.

Results: Among the 750 evaluated transcripts, we identified a 4-gene signature (XRCC6, PRKCD, TEK, and CLU) strongly associated with kidney survival (**Figure 1A**). This signature predicted kidney survival better than histological-based classifications (global C-Index 0.87 vs. 0.65 for Berden classification or 0.81 for Renal Risk Score, with better time-dependent AUC and Brier scores) (**Figure 1B**). Among these 4 transcripts, the expression level of the CLU transcript had the highest correlation with glomerular involvement, kidney function at diagnosis, and kidney survival. Serum CLU levels were associated with kidney survival, especially when assessed at 6 months from diagnosis (**Figure 1C**, p = 0.023).

Conclusions: Transcriptomic analysis of kidney biopsies of AAV-GN identified potential transcripts that may improve prediction of kidney survival. This transcriptomic signature may help us gain a deeper understanding of the AAV-GN pathogenesis and provide insights for developing new therapeutic options.



SA-PO756

Immune Profiling-Based Targeting of Pathogenic T Cells with Ustekinumab in ANCA-Associated Glomerulonephritis

Jonas Engesser,[1] Robin Khatri,[1,2] Darius P. Schaub,[1,2] Hans-Joachim Paust,[1] Zeba Sultana,[1] Nariaki Asada,[1] Varshi Sivayoganathan,[1] Victor G. Puelles,[1] Ulrich O. Wenzel,[1] Oliver M. Steinmetz,[1] Elion Hoxha,[1] Hans-willi Mittrücker,[1] Thorsten Wiech,[1] Tobias B. Huber,[1] Stefan Bonn,[1,2] Christian F. Krebs,[1] Ulf Panzer.[1] *[1]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]Universitatsklinikum Hamburg-Eppendorf Zentrum fur Molekulare Neurobiologie Hamburg, Hamburg, Germany.*

Background: Antineutrophil cytoplasmatic antibody (ANCA)-associated vasculitis is a life-threatening autoimmune disease that often results in kidney failure caused by crescentic glomerulonephritis (ANCA-GN). To date, treatment of most patients with ANCA-GN relies on unspecific immunosuppressive drugs that are often only partially effective and harbor serious adverse effects. This underscores the unmet need for the development of pathogenesis-based and safer therapies.

Methods: Here, we performed combined spatial and single cell transcriptome analysis to characterize the inflammatory niches in the kidneys of 34 patients with ANCA-GN. Digital pharmacology was used to predict the most promising drugs for treatment of kidney inflammation. Subsequently, we treated four relapsing ANCA-GN patients in a proof-of-concept study with ustekinumab (90 mg s.c. at weeks 0, 4, 12 and 24) in combination with low dose cyclophosphamide and steroids. Patients were followed up for 26 weeks.

Results: Spatial transcriptome analysis revealed distinct inflammatory niches in both glomerular and tubulointerstitial regions, each associated with T cell activation. By using unsupervised single-cell transcriptomics and epitome mapping of renal T cells, we identified a predominance of proinflammatory, cytokine-producing Th1/Tc1 and Th17/Tc17-like effector T cells. Ensuing digital pharmacology pinpointed ustekinumab, a human monoclonal antibody binding the common p40-subunit shared by IL-12/IL-23, thus blocking Th1 as well as Th17 responses, as the most promising drug to target these pathogenic T cells in a pathogenesis-based treatment approach. The treatment of four ANCA-GN patients with relapsing disease using ustekinumab led to a rapid clinical response in all four patients, including improved kidney function and lower Birmingham Vasculitis Activity Scores. No treatment related adverse effects were observed during the follow up period.

Conclusions: Our findings suggest that immune profiling-based targeting of pathogenic T cells in ANCA-GN patients with ustekinumab is a promising approach and warrants further investigation in clinical trials.

Low Albumin Levels Are Associated with Intrarenal Complement C4d Deposits in Critically Ill Patients with ANCA-Associated Renal Vasculitis

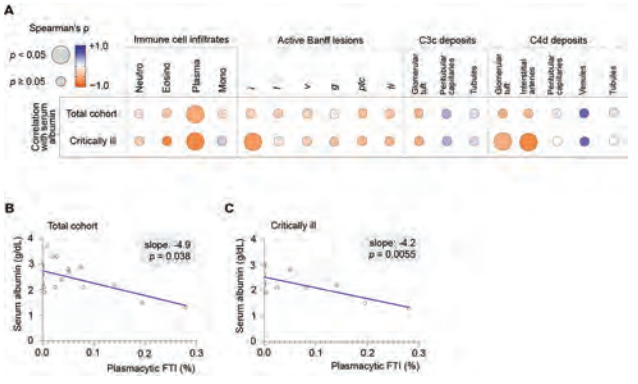
Eva Baier, Bjoern Tampe. *Universitatsmedizin Gottingen Klinik fur Nephrologie und Rheumatologie, Gottingen, Germany.*

Background: Despite serum albumin levels being predictive for clinical outcome in ANCA-associated renal vasculitis (AArV), implications providing a direct link between low serum albumin levels and intrarenal lesions remain elusive. Thus, we here aimed to systematically assess the clinical relevance of low albumin levels and scrutinize clinicopathological correlations to expand our knowledge.

Methods: We retrospectively enrolled biopsy-proven cases of AArV between 2015 till 2020 in a single-center observational study. Survival-curve analyses on short-term clinical recovery were performed. Correlative analyses between serum albumin levels, laboratory parameters, proteinuria levels, and histopathological lesions including tubulointerstitial immune cell infiltrates, lesions analogous to the Banff score and intrarenal complement deposition of C3c and C4d were performed.

Results: Critically ill patients with serum albumin levels below the median of 2.4 g/dL featured an affected short-term clinical recovery (p=0.0082, HR: 3.6, 95% CI: 1.1-11.7). An extrarenal causation of hypoalbuminemia in the critically ill was assumed, since serum albumin levels did not correlate with the urinary marker of tubular damage (β=-0.5, p=0.07). We identified plasmacytic infiltrates to correlate with low albumin levels (β=-0.7, p=0.005) and Banff-scored interstitial inflammation (i) to be inversely correlated with albumin levels (β=-0.7, p=0.02). Intrarenal C4d deposition showed a significant correlation with low serum albumin levels in the glomerular tuft (β=-0.4, p=0.04).

Conclusions: In conclusion, short-term recovery was predicted by low albumin levels in critically ill patients with AArV. We here provide evidence that low levels of serum albumin might directly affect tubulointerstitial inflammation as reflected by plasmacytic immune-cell infiltration, and intrarenal C4d complement deposition in AArV.



SA-PO758

Clinical Phenotype Identifies Individuals with ANCA-Associated Vasculitis Who Do Not Require Kidney Biopsies for Diagnosis of Kidney Involvement

Ayman Al Jurdi, Christopher El Mouhayyar, Gabriel Sauvage, Anushya Jeyabalan, Orhan Efe, Harish Shanthanu Seethapathy, Katherine M. Cosgrove, Karen A. Laliberte, John Niles. *Massachusetts General Hospital, Boston, MA.*

Background: Kidney involvement is common in ANCA-associated vasculitis (AAV). The most common finding on kidney biopsy in AAV is crescentic glomerulonephritis (GN). Guidelines recommend kidney biopsy in individuals with AAV and kidney abnormalities to confirm kidney involvement. Kidney biopsies are associated with a risk of bleeding and may delay treatment for active AAV. Therefore, identification of characteristics associated with a high likelihood of finding crescentic GN on biopsy can avoid the need for kidney biopsy in these individuals and its associated risks and costs.

Methods: We conducted a single-center retrospective cohort study of all individuals with a positive ANCA test and a kidney biopsy between 2000 and 2023 at the Vasculitis and Glomerulonephritis Center at Massachusetts General Hospital. The positive predictive value (PPV) for finding crescentic GN on biopsy based on various clinical findings was evaluated.

Results: 142 individuals met the study's inclusion criteria. The median age was 64 and 55% were female. The median serum creatinine was 2.49 mg/dL, and 89% had microscopic hematuria. 73%, 24%, and 3% were positive for antibodies to myeloperoxidase, proteinase 3, or both, respectively. Crescentic GN was found in 85% of biopsies (Fig. 1A). 100% of individuals with ANCA positivity and rapidly progressive GN (defined as ≥50% eGFR loss in ≤6 months, n = 45) had crescentic GN on biopsy. Over 93% of individuals with ANCA positivity, microscopic hematuria, and ≥1 extra-renal system involvement had crescentic GN on biopsy (Fig. 1B).

Conclusions: The rate of kidney function decline, microscopic hematuria, and extra-renal symptoms identify individuals with AAV who do not require kidney biopsy to establish kidney involvement.

Retrace-Clustering Creatinine Trajectory and Baseline Features for Predicting ESKD

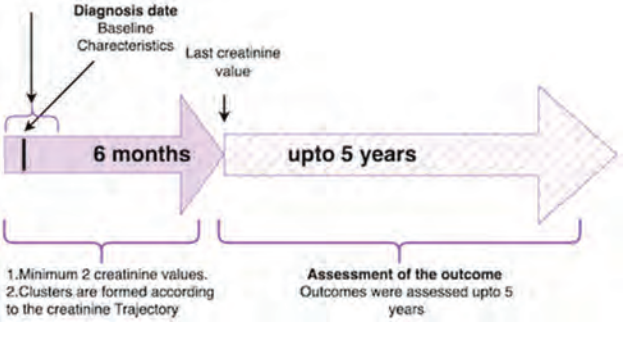
Dearbhail Ni Cathain, Jamsheela Nazeer, James Ng, Jennifer Scott, Eithne M. Nic an Riogh, Angel Mary George, Arthur White, Mark A. Little. *The University of Dublin Trinity College, Dublin, Ireland.*

Background: Patients with ANCA-associated vasculitis (AAV) may experience end-stage kidney disease (ESKD) and mortality. We aim to investigate the connection between the longitudinal trajectory of creatinine and the occurrence of ESKD and mortality.

Methods: We included patients with a minimum of two creatinine measurements, encompassing the baseline period and the following six months (Figure). Creatinine trajectories were formulated using six months of creatinine readings from AAV patients with kidney involvement. We excluded patients who presented with end-stage kidney disease (ESKD). In instances where a patient had multiple creatinine values within a given month, the average of those values was employed. Percentage delta creatinine values, representing the percentage difference between a creatinine value and its baseline, were then calculated. The K-means algorithm for longitudinal data was employed to cluster the creatinine trajectories of AAV patients. The quality of clustering was evaluated using the Calinski-Harabasz Index. We conducted a time-to-event analysis for ESKD and death, assessing the survival rates of the clusters over a five-year follow-up period through Kaplan-Meier Survival analysis.

Results: The study incorporates 273 patients with >1 creatinine values, amounting to a total of 2022 creatinine readings. We identified three renal trajectory groups: A-Stable (140), B-Recovered (N=100), and C- Declining (N=33). The baseline features varied across clusters, specifically in terms of baseline creatinine (284uM, 390uM and 151uM respectively, p<0.001) and ENT involvement (p=0.001). When considering the composite outcome of ESKD and death, Cluster A exhibited a 3-year incidence rate of 23%, Cluster B at 8%, and Cluster C at 28% (p<0.0069).

Conclusions: Trajectory clustering allows for the identification of patients who may require closer monitoring, or targeted interventions based on their cluster assignment and associated risk profile.



SA-PO760

Kinetic eGFR Ratio Predicts Active Lesions and Prognosis in ANCA-Associated Glomerulonephritis

Rina Oba, Go Kanzaki, Takaya Sasaki, Kotaro Haruhara, Masahiro Okabe, Shinya Yokote, Akihiro Shimizu, Kentaro Koike, Keita Hirano, Hideo Okonogi, Nobuo Tsuboi, Takashi Yokoo. *Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan.*

Background: Antineutrophil cytoplasmic antibody-associated glomerulonephritis (ANCA-GN) is a typical vasculitis syndrome presenting with rapidly progressive glomerulonephritis (RPGN). Kinetic estimated Glomerular Filtration Rate (KeGFR) has been proposed to approximate true GFR under non-steady-state conditions. We investigated the clinicopathologic and prognostic significance of KeGFR in patients with ANCA-GN.

Methods: We retrospectively identified 66 patients with ANCA-GN from 3 hospitals in Japan (2004–2020). KeGFR ratio was defined as the ratio of KeGFR difference to baseline eGFR. The primary composite endpoints included end-stage kidney disease and death. We compared clinicopathologic features and long-term outcomes between the high KeGFR ratio group and the low KeGFR ratio group. We also assessed the factors associated with treatment resistance.

Results: Patients with a high KeGFR ratio had a higher incidence of treatment resistance and a higher percentage of cellular crescents and interstitial inflammation (Tables 1 and 2). The cumulative event-free survival rate at 5 years was significantly lower in the high KeGFR group than in the low KeGFR group (Figure 1). In addition, the KeGFR ratio was significantly associated with treatment resistance after adjusting for age, ANCA renal risk score (which included % normal glomeruli, baseline eGFR, and % Interstitial fibrosis/tubular atrophy), and treatment (Table 3).

Conclusions: KeGFR ratio is associated with disease state and acute lesions in ANCA-GN and may be useful in assessing long-term prognosis and treatment resistance.

Long-Term Kidney Outcomes in ANCA-Associated Vasculitis in a Mexican Hispanic Cohort

Adriana Hernández Andrade, María F. Zavala Miranda, Valeria Navarro Sanchez, Alberto Nordmann-Gomes, Andrea Hinojosa-Azaola, Juan M. Mejia-Vilet. *Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico.*

Background: The kidneys are frequently involved in anti-neutrophil cytoplasm antibody-associated vasculitis (AAV). Kidney outcomes are variable among centers and have been scarcely reported in the Latin American region

Methods: Retrospective cohort study including all patients diagnosed with AAV and kidney involvement between 2001 and 2022. All patients were followed for ≥12 months, kidney failure, or death. All outcomes were evaluated by time-to-event analyses.

Results: The cohort included 154 patients with AAV and kidney involvement, 133 (86%) diagnosed by kidney biopsy, with a median follow-up of 74 months (IQR 32-126). The median age was 52 years (IQR 38-61), 104 (67%) female, 82 (53%) diagnosed as granulomatosis with polyangiitis (GPA), 47 (31%) microscopic polyangiitis, and 25 (16%) as renal-limited vasculitis. At presentation, median serum creatinine was 2.4mg/dL (IQR 1.7-4.5), eGFR 23ml/min/1.73m2 (IQR 12-36), and proteinuria 1.8g/g (IQR 1.1-3.2). In the kidney biopsy, the median normal glomeruli were 18% (IQR 0-37), global sclerosis 39% (IQR 6-56%), interstitial fibrosis 30% (IQR 15-50), tubular atrophy 30% (10-60). 52 (34%) patients had renal replacement therapy requirements at presentation, of which x 19 (36%) recovered kidney function. Over long-term follow-up, 54 patients progressed to kidney failure with 5- and 10-year progression rates of 73% and 56%, respectively (Figure 1-A). Twenty-four patients died over follow-up, with patient survival being 88% and 83% by 5 and 10 years (Figure 1-B). The main cause of death was infection (75%)

Conclusions: The kidney outcomes in this Mexican cohort are worse than those described in European and US cohorts. The percentage of patients with initial kidney replacement therapy requirements and advanced sclerosis is higher than in other cohorts, suggesting that late diagnosis is one of the factors associated with dismal prognosis in this cohort.

SA-PO762

Clinical Frailty as a Proxy Measure for Infection Risk in ANCA-Associated Glomerulonephritis

Joshendra Durailingam,[1] Kavita Gulati,[3] Gavin Chapman,[4] Neeraj Dhaun,[4] Stephen P. McAdoo,[3] Silke R. Brix.[1,2] *[1]The University of Manchester, Manchester, United Kingdom; [2]Manchester University NHS Foundation Trust, Manchester, United Kingdom; [3]Imperial College London, London, United Kingdom; [4]University of Edinburgh, Edinburgh, United Kingdom.*

Background: Frailty is a functional term referring to a decline in physiological function that leads to dependency, vulnerability and a high risk for poor health-related outcomes. Anti-neutrophil cytoplasmic antibody (ANCA) vasculitis affects the elderly and often results in a rapid decline in the general health. We aim to better understand the interaction between the rapid evolving ANCA associated inflammation and the impression of frailty to improve prediction modelling for adverse outcomes. Here, we investigated clinical frailty scale (CFS) at time of diagnosis for its association with clinical outcomes.

Methods: We performed a three-centre, retrospective analysis of newly diagnosed ANCA glomerulonephritis (GN) patients in the UK. Wilcoxon-Rank-Sum, Kruskal-Wallis and Fisher-Exact testing were used to analyse the relationships of age, CFS and infections, end stage kidney disease (ESKD) and death.

Results: A total of 275 patients were included, median follow-up 3.8 years (interquartile range, IQR, 2.1 – 5.3 years). The median age at presentation was 66.3 years (IQR, 54.7 – 74.5 years) and 145 were of male gender (52.3%). A total of 86 patients developed ESKD (31.3%), and 77 patients died (28%) during follow-up. Data on infection during the first year was available on 158 patients. Age and CFS did not influence the development of ESKD (p=0.4 and p=0.21). Higher age and CFS were both associated with deaths during follow up (p=0.004 and p=0.002). The frequency and severity of infections did not differ across age (p=0.4 and p=0.2). CFS however associated with infections in frequency and severity (p=0.01 and p<0.001, Figure 1).

Conclusions: An initial frailty assessment at the time of diagnosis might assist in predicting infections in patients with newly diagnosed ANCA GN.

ANCA and Anti-glomerular Basement Membrane (GBM) Dual Antibody Positivity: A Case Series and Proposal for a Clinical Classification

Tara O'Sullivan,[1] Michael Clarkson,[1] Niall P. Conlon,[2] Matthew D. Griffin,[5] Edward P. Mc Monagle,[4] Mark A. Little,[3] Sarah M. Moran.[1] *[1]Cork University Hospital, Cork, Ireland; [2]St James's Hospital, Dublin, Ireland; [3]The University of Dublin Trinity College, Dublin, Ireland; [4]University Hospital Limerick, Dooradoyle, Ireland; [5]Galway University Hospitals, Galway, Ireland.*

Background: Anti-glomerular basement membrane (aGBM) disease and the anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV) are rare vasculitides. ANCA and aGBM dual positivity can occur; up to 40% of patients with a clinical diagnosis of aGBM disease have a positive ANCA (aGBM+AAV) and up to 5% of patients with a clinical diagnosis of AAV have detectable aGBM antibodies (AAV+aGBM). Literature on clinical phenotyping and prognosis is lacking, with no current clinical consensus on definitions. We report a case series of aGBM+AAV and AAV+aGBM from RITA-Ireland, with the following proposed definitions: 1. aGBM+AAV: aGBM disease with linear IgG staining on kidney biopsy and no clinical features of vasculitis outside lung or kidney, with co-existent ANCA positivity in serum 2. AAV+aGBM: clinical AAV with aGBM antibody (pauci immune kidney biopsy findings)

Methods: Dual positive patients with documented renal biopsy were identified from the European reference Network RITA-Ireland Vasculitis (RIV) Registry and Biobank. Clinical and biochemical features, aGBM methodology, renal biopsies, requirement for RRT, progression to ESKD, recovery of renal function, treatment, relapse, and death were retrospectively compared between the two groups.

Results: Thirty patients meeting the inclusion criteria were identified, 7 (23.3%) with AAV+aGBM and 23 (76.7%) with aGBM+AAV. Anti-myeloperoxidase (MPO) antibody was detected in 70%. See figure 1 for results and comparison between groups.

Conclusions: AAV and aGBM disease are rare vasculitides, whose overlap occurs at a higher frequency than determined by chance. There is currently no consensus on nomenclature of aGBM+AAV and AAV+aGBM. This case series highlights differences between these diseases, most notably the higher proportion of relapse in aGBM+AAV, and informs a proposal for a clinical classification to guide future care pathways.

SA-PO764

Efficacy and Safety of Rituximab in Anti-glomerular Basement Membrane (GBM) Disease

Vanja Ivkovic,[1,2] Ingeborg M. Bajema,[3] Annette Bruchfeld,[4,5] Stephen P. McAdoo,[6,7] Marten Segelmark,[8,9] Andreas Kronbichler.[10] *[1]UHC Zagreb, Department of Nephrology, Hypertension, Dialysis and Transplantation, Zagreb, Croatia; [2]University of Rijeka Faculty of Health Studies, Rijeka, Croatia; [3]Department of Pathology and Medical Biology, University of Groningen, University Medical Center, Groningen, Netherlands; [4]Department of Health, Medicine and Caring Sciences, Linköping University, Linköping, Sweden; [5]Department of Renal Medicine, Karolinska University Hospital and CLINTEC Karolinska Institutet, Stockholm, Sweden; [6]Centre for Inflammatory Disease, Department of Immunology and Inflammation, Imperial College London, Hammersmith Campus, London, United Kingdom; [7]Imperial College Renal and Transplant Centre, Imperial College Healthcare NHS Trust, Hammersmith Hospital, London, United Kingdom; [8]Department of Clinical Sciences, Lund University, Lund, Sweden; [9]Department of Endocrinology, Nephrology and Rheumatology, Skåne University Hospital, Lund, Sweden; [10]Department of Internal Medicine IV, Nephrology and Hypertension, Medical University Innsbruck, Innsbruck, Austria.*

Background: Anti-glomerular basement membrane (GBM) disease is a vasculitis caused by pathogenic antibodies targeting the NC1 domain of the α3 chain of type IV collagen and presenting as RPGN and diffuse alveolar haemorrhage (DAH). Decreasing production of these antibodies and their clearance are imperative to achieve patient and kidney survival. The mainstay of therapy is the combination of plasma exchange (PLEX), glucocorticoids and cyclophosphamide. Rituximab, an anti-CD20 monoclonal antibody causing B-cell depletion, has been proposed as a potential treatment for anti-GBM disease, but there is still a paucity of evidence of its efficacy and safety.

Methods: We have performed a systematic review of case reports/series providing individual patient-level data on the efficacy and safety of rituximab in anti-GBM disease. A search strategy of studies indexed in PubMed was performed followed by synthesis and analysis of the collated data.

Results: Twenty-two studies with data on 43 patients (M:F=18:15; median age 34 years, IQR: 20-63) were included who received rituximab in the first (N=18) or second line (N=25). Median serum creatinine was 416 µmol/L (IQR 212-706) with 21 (49%) patients being dialysis-dependent on presentation and 19 (44%) having DAH. Ten patients were positive for ANCA, 8 of them for MPO-ANCA. Almost all patients received pulse and oral glucocorticoids and PLEX (88%, 100% and 95%, respectively) and 62% of them received cyclophosphamide. Patients received a median of 4 (2-4) doses of rituximab with 5 patients (12%) having adverse effects which were all transient. After a median of 14.8 (5.0-33.0) months follow-up, patient survival was 100% and kidney survival 63% (33% in initially dialysis-dependent patients vs. 90% in initially non-dialysis-dependent patients, p<0.001). There were no differences in kidney survival between ANCA-positive and negative patients, those with and without DAH or those who received rituximab in first or second line.

Conclusions: In this, the largest group of anti-GBM disease patients receiving rituximab to date, the treatment had a favourable toxicity and efficacy profile. However, there is a great risk of publication bias and prospective trials are necessary to determine if rituximab should replace cyclophosphamide or be used in conjunction with cyclophosphamide as first line treatment.

SA-PO765

Rituximab in Addition to Plasma Exchange, Cyclophosphamide, and Steroids for the Treatment of Anti-glomerular Basement Membrane (GBM) Disease

Mukunthan Srikantharajah,[1] Jacob Chappell,[2] Maria Prendecki,[1] David Makanjuola,[2] Bhrigu Raj Sood,[2] Stephen P. McAdoo.[1] *[1]Imperial College London, London, United Kingdom; [2]Epsom and Saint Helier University Hospitals NHS Trust, Carshalton, United Kingdom.*

Background: Anti-GBM disease is a rare antibody-mediated vasculitis, usually treated with plasma exchange (PEX), cyclophosphamide (CYC) and steroids. There are limited data regarding the use of B-cell depleting therapies such as rituximab (RTX).

Methods: Two-centre retrospective cohort study of patients presenting from 2003-2023 with anti-GBM disease treated with or without RTX, in addition to standard care, as first-line therapy.

Results: Seventy-eight patients are included; baseline demographics, disease characteristics, treatments and outcomes are summarised in Table 1. All patients were treated with PEX, CYC (oral or IV), and steroids. The addition of RTX treatment was associated with non-significant trends to reduced number of PEX (10 *versus* 14 with no RTX, p=0.30) and lower total CYC dose (3.3g *versus* 3.6g, p=0.78), with reduced time to anti-GBM negativity (2.1 *versus* 3.5 months with no RTX, p=0.67). In the Cox-proportional hazards regression model incorporating age, sex, ANCA status, dialysis need at presentation, lung haemorrhage, CYC and RTX treatment, increasing age was associated with risk of death (HR 1.07 [95% CI 1.01-1.17]) and risk of infection (HR 1.03 [95% CI 1.00-1.06]). Dialysis need at presentation was associated with ESKD-risk (HR 0.05 [95% CI 0.01-0.14]). The addition of rituximab was not significantly associated with risk of death (HR 1.45 [0.38-6.93]), ESKD (HR 0.97 [0.50-1.91]) or infection 0.48 [0.23-1.02].

Conclusions: Addition of RTX to standard treatment for anti-GBM disease was not associated with improved renal or overall survival. However, RTX use permitted lower cumulative doses of CYC and reduction in the number of PEX, without an increased risk of infection. RTX may have a role as a CYC- and PEX-sparing treatment in patients with anti-GBM disease.

Pulmonary-Renal Syndrome from Cocaine-Induced ANCA-Associated Vasculitis: A Case Report

Christopher C. Shrack, Carrie L. Phillips, Simit Doshi. *Indiana University School of Medicine, Indianapolis, IN.*

Introduction: Approximately 71% of cocaine samples obtained in the United States are adulterated with Levamisole, an anthelminthic drug with immunomodulatory properties that is used to increase the weight and potency of cocaine. Case reports have linked Levamisole-contaminated cocaine with an ANCA-associated vasculitis (AAV). We present a case of AAV manifesting as a pulmonary-renal syndrome with undetectable complement levels following cocaine use.

Case Description: A 75-year-old African American man with a past medical history of type 2 diabetes mellitus, hypertension, COPD, heart failure with reduced ejection fraction, paroxysmal atrial fibrillation, chronic Hepatitis C infection, and MGUS presented with chest pain and leg edema without a rash. He reported nasal inhalation of cocaine 3 days prior to admission. Serum creatinine on presentation was 3.22 mg/dL and continued to worsen. Urine microscopy showed muddy brown casts. His hospital course was complicated by new-onset hemoptysis which progressed to diffuse alveolar hemorrhage (DAH) requiring intubation and critical care support. Serum complement levels were undetectable. Hepatitis C titers showed 541,000 copies, however, rheumatoid factor assay and test for cryoglobulinemia remained negative. ANCA titers showed positivity for MPO antibodies. Kidney biopsy specimen showed focal necrotizing and crescentic glomerulonephritis (50% active lesions) in the absence of immune complex deposits compatible with AAV. He received immunosuppression with steroids and cyclophosphamide, underwent 7 rounds of plasmapheresis, and was initiated on renal replacement therapy. He had complete resolution of DAH and was extubated while on pheresis. He remained dialysis dependent at 2 month follow up at the time of discharge to subacute rehabilitation.

Discussion: Cocaine-induced AAV can present with a variety of symptoms and signs due to involvement of multiple organ systems including life-threatening pulmonary-renal syndrome. While role of pheresis is limited in levamisole-induced AAV, resolution of DAH was noted in our patient.

SA-PO767

Rituximab Induction in Rheumatoid-Associated, ANCA-Negative, Pauci-Immune Glomerulonephritis

Chunzi Song,[1] Maurice I. Khayat.[1,2] *[1]The University of Texas Southwestern Medical Center, Dallas, TX; [2]VA North Texas Health Care System, Dallas, TX.*

Introduction: Rheumatoid vasculitis (RV) is a serious complication of rheumatoid arthritis (RA). Adoption of disease modifying antirheumatic drugs (DMARDs) has decreased its incidence. Renal involvement is rare, but pauci-immune glomerulonephritis (GN) with detectable antineutrophil cytoplasmic antibodies (ANCA) has been reported. The optimal therapy for ANCA-negative RV is unknown. Rituximab (RTX) is frequently used to treat articular symptoms, but no cases using RTX for ANCA-negative RV are described.

Case Description: A 68 year-old man with a history of RA presented with anasarca, acute kidney injury and nephrotic syndrome. His RA was diagnosed 15 years prior with erosive arthritis, positive antinuclear antibodies, rheumatoid factor, and anti-cyclic citrullinated peptide antibodies. He was started on methotrexate, but after 5 years he was lost to follow up. On re-presentation after 10 years, labs were notable for a serum creatinine between 2.6-3.0 mg/dL, albumin of <1 mg/dL, and urine protein-to-creatinine ratio between 5.4-14 g/g. Renal biopsy revealed pauci-immune focal crescentic GN, global and segmental glomerulosclerosis without interstitial fibrosis or tubular atrophy (IFTA). Congo red stain was negative. Serologic work up including serum ANCA was negative except as outlined above. No extrarenal manifestations of vasculitis were noted. RTX 1000mg, 2 weeks apart resulted in reduction of proteinuria with unchanged serum creatinine and albumin. Repeat renal biopsy after 3 months revealed resolution of crescentic vasculitis, development of moderate IFTA and focal segmental glomerulosclerosis (FSGS). Complications included hypervolemia requiring temporary renal replacement therapy and persistent nephrotic syndrome. A short course of empiric corticosteroids was stopped due to disease quiescence following biopsy results.

Discussion: ANCA-negative RV with crescentic GN is rare, and the optimal treatment is uncertain. Of the three described cases, all received corticosteroids, two were given cyclophosphamide, and one was treated with plasma exchange. To our knowledge, this is the first reported case utiliizing RTX induction. For our patient, rituximab resulted in remission of active crescentic disease, but not the development of chronic sequelae. While RTX remains an attractive potential treatment option for ANCA-negative RV, further investigation is warranted.

SA-PO768

A Case of Pulmonary-Renal Syndrome (PRS) in ANCA-Negative, Pauci-Immune Necrotizing Glomerulonephritis with High IntelliSep Index

Caroline Stafford, Hollis R. O'Neal, Christopher B. Thomas, Matthew Foy. *LSU Health New Orleans, Baton Rouge, LA.*

Introduction: Pauci-Immune Necrotizing Glomerulonephritis (PING) results from inflammatory vasculitis, often associated with antineutrophilic cytoplasmic antibodies (ANCA). ANCA-negative PING is rare. The role of neutrophils with PING is highly implicated in ANCA-negative cases. We present a case of ANCA-negative PING with PRS. It highlights early recognition and postulates potential methods for utilizing IntelliSep Index (ISI), a rapid (<10 min) assay quantifying immune activation via biophysical properties of leukocytes, to support treating PING.

Case Description: A 67-year-old woman with tobacco use and primary hypertension presented to the hospital with progressive dyspnea and hemoptysis. Labs included creatinine (Cr) 0.71 mg/dL, serum albumin 1.9 g/dL, Hgb 10.3 g/dL and WBC count 14.7 1000/uL; urinalysis positive for protein, large Hgb, 5-10 WBC/hpf and 10-20 RBC/hpf. Chest imaging showed bilateral moderate airspace opacities. ISI Index was 8.8, ISI Band 3. Blood and sputum cultures were negative. Given high suspicion for PRS from small vessel vasculitis, pulse dose steroids were started. Autoimmune workup including ANCA was negative. Renal biopsy revealed necrotizing crescentic glomerulonephritis with granular mesangial staining for C3, IgM, kappa and lambda, but all other stains negative. She was discharged on prednisone, cyclophosphamide (CYC) and

trimethoprim-sulfamethoxazole (TMP-SMX) for Pneumocystis prophylaxis. She had transaminitis 6 weeks later and CYC and TMP-SMX were held. CYC was resumed 2 weeks later and prednisone reduced. She represented to the hospital with a flare 3 weeks later. Workup with proteinuria, hematuria, and Cr elevated to 1.8 mg/dL. Repeat ISI Index was 9.0, ISI Band 3. Prednisone therapy was increased to 60 mg daily. Three months later, after prolonged steroid course and taper, her Cr improved to 1.3 mg/dL, pulmonary symptoms resolved, and she was transitioned to mycophenolate mofetil.

Discussion: Diagnosing PING requires high clinical suspicion to initiate therapy. Standard diagnosis of PING may take several days for biopsy and serology. This case shows a high ISI level on presentation as well as with her flare. Considering clinical context, ISI may be beneficial in stratifying patients to consider early PING induction treatment as well as monitoring treatment response.

SA-PO769

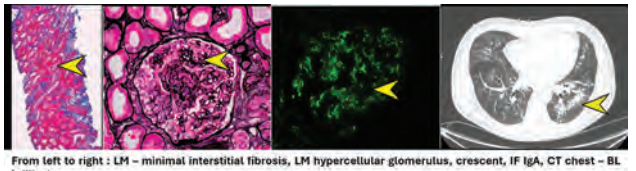
Co-occurrence of Crescentic IgA Nephropathy and Borderline Positive ANCA-Associated Vasculitis: A Perilous Pairing!

Divya Sharma Divyadarshini,[1] Gargi Sharma Priamvada,[2] Kirolos Iskander,[1] Zahid B. Ahmad.[1] *[1]The University of Oklahoma Health Sciences Center, Oklahoma City, OK; [2]East Carolina University, Greenville, NC.*

Introduction: The convergence of IgA nephropathy (IgAN) and Antineutrophil cytoplasmic antibody associated vasculitis (AAV) represents a rare but clinically significant condition. This combination presents with severe clinical manifestations, characterized by biopsy-confirmed IgAN, serological positivity for ANCA, rapid progression of renal failure, and pronounced pulmonary involvement. In this case, we underscore the complexities in management and emphasize the grim prognosis associated with IgAN/ANCA-positive vasculitis.

Case Description: 46-year-old male with alcoholic cirrhosis presented with epistaxis, anemia, and rapidly increasing creatinine levels (from 6.26 mg/dl to 10 mg/dl within 3 days, baseline unknown) necessitating hemodialysis. Urine-protein creatinine ratio of 2.2 g/g, dysmorphic microhematuria, and borderline positive PR3-ANCA at 1.1 U (normal range: 0.0 - 0.9 U) were noted. Renal biopsy showed minimal interstitial fibrosis, endocapillary hypercellularity, 33% cellular crescents, and granular mesangial staining of IgA and C3 on immunofluorescence. CT imaging detected bilateral lung infiltrates. Bronchoalveolar lavage showed nasal ulcers and extensive diffuse alveolar hemorrhage (DAH). Crescentic IgAN with concurrent AAV was diagnosed. Despite aggressive treatment with high-dose steroids, cyclophosphamide, and plasmapheresis, the patient deteriorated due to persistent DAH complicated by infections, resulting in death.

Discussion: This case of IgAN/ANCA+ highlights the importance of thorough serological assessment and early kidney biopsy in individuals with acute pulmonary-renal syndrome. IgAN infrequently presents as rapidly progressive glomerulonephritis and indicates a poorer prognosis necessitating swift intervention. Per literature review, clinicopathological combination of IgAN/ANCA+ is associated with worse clinical outcomes like DAH and acute renal failure, when compared to IgAN/ANCA- or AAV. Management of such mixed glomerulonephritis is inadequately documented. While high-dose steroids, cyclophosphamide/rituximab, and plasmapheresis are potential treatments, their effectiveness is limited by the risk of fatal infections.



From left to right : LM – minimal interstitial fibrosis, LM hypercellular glomerulus, crescent, IF IgA, CT chest – BL infiltrates.

SA-PO770

Case Series of Avacopan in Dual-Positive Anti-glomerular Basement Membrane (GBM) and ANCA Disease

Lauren Floyd,[1] Louise R. Moore,[1] Ranjoy Sen,[1] Ajay P. Dhaygude,[1] Stephen P. McAdoo,[2] Adam Morris.[1] *[1]Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom; [2]Imperial College London, London, United Kingdom.*

Introduction: Anti-glomerular basement membrane(GBM) disease is characterised by rapidly progressive glomerulonephritis(RPGN) & pulmonary haemorrhage & up to 40% can have dual positivity with circulating ANCA antibodies. Treatment include steroids, plasma exchange(PLEX) & cyclophosphamide(CYC). The recent ADVOCATE trial showed Avacopan as a steroid-sparing agent but its effectiveness in other RPGNs including dual positive patients remains uncertain.

Case Description: We present 3 cases of dual positive ANCA & anti-GBM disease treated with Avacopan. The first was a 73yr old lady presenting with severe non-oliguric AKI(eGFR 5ml/min) and dual positivity with MPO-ANCA(Fig1). Renal biopsy showed focal segmental necrotising GN with added tubular injury. She was treated with CYC, rituximab & PLEX. Prior to admission she had a significant GI bleed with erosive gastritis & duodenal ulcers. Consequently, she was managed steroid free, opting for Avacopan as a steroid sparing agent. Case 2 was a 64yr old male presenting with AKI (eGFR 8ml/min) and dual antibody positive with MPO-ANCA. The biopsy showed fibrocellular & cellular crescents and linear IgG. He was treated with PLEX, CYC, rituximab & a rapidly weaning course of steroids alongside Avacopan(Fig.2) The final case was a 22yr old lady presenting with myalgia & cough progressing to pulmonary haemorrhage(Fig 3). She was anti-GBM & PR3-ANCA positive with significant anaemia & proteinuria. She received CYC, PLEX, rituximab & Avacopan alongside a 6week tapering course of steroids. She made a good recovered & is in remission with Avacopan as maintenance treatment

Discussion: We demonstrated the role of Avacopan in anti-GBM disease to facilitate rapid steroid weaning, even in those with severe disease. One patient was managed without steroids, a rare approach in the management of anti-GBM disease & all maintained independent renal function. We suggest Avacopan should be considered in the management of patients with dual positive antibodies

SA-PO771

Evolving ANCA Serotype in a Patient with Dialysis-Dependent ESKD

Peter Dock,[1] James F. Dylewski.[2,1] *[1]University of Colorado Anschutz Medical Campus, Aurora, CO; [2]Denver Health Main Campus, Denver, CO.*

Introduction: ANCA antibody serotype PR3 and MPO has become an increasing focus of care in patients with ANCA associate vasculitis (AAV) since antibody serotype seems to be a more reliable marker for prognosis, response rate, relapse risk, and outcome compared to a clinical diagnosis of GPA or MPA. Furthermore, these serotypes have been reported to have different geographic and genetic factors. Below is a case of a patient who switched serotypes which, to our knowledge, has not been previously described.

Case Description: Ms G is a 49 yo Latina female who initially presented in 2018 with diffuse alveolar hemorrhage and AKI. ANCA testing showed +MPO/+p-ANCA-AAV consistent with a clinical diagnosis of microscopic polyangiitis (MPA). Kidney biopsy was also consistent with ANCA associated pauci-immune GN. Unfortunately, Ms G's disease was difficult to control, and she suffered from multiple disease relapses despite maintenance therapies. While she would clinically improve with re-induction therapies, she remained serologically positive. In December 2019, after multiple disease flares, she became dialysis dependent. After approximately 1 year on dialysis, ANCA and MPO antibodies became negative, and she no longer had features of active AAV. (Table 1) In 2021, 2 years after becoming dialysis dependent, Ms G presented with increasing dyspnea. ANCA serologies were checked and yielded a new positive PR3 antibody (Table 1). Ultimately, her symptoms were attributed to non-ANCA related disease. However, she continued to have a PR3 antibody. In 2024, Ms G presented with upper respiratory symptoms and rash. Biopsy of the rash demonstrated a small vessel vasculitis consistent with AAV. though repeat ANCA testing was negative at that time.

Discussion: To our knowledge, Ms G is the first reported patient to have an evolution in her ANCA vasculitis from an MPO to a PR3 serotype. Additionally, this evolution occurred after the patient had been dialysis dependent for several years, a time when most AAV disease typically becomes inactive. This would suggest the AAV serotype in this patient represents a spectrum of disease rather than a distinct phenotype.

SA-PO772

Rapidly Progressive Glomerulonephritis (RPGN) Due to Myeloperoxidase Anti-neutrophil Cytoplasmic Antibodies (MPO-ANCA)-Associated Vasculitis and Anti-glomerular Basement Membrane (GBM) Disease

Ji-Min Park,[1] Rafael Sancillo,[1] Jesse M. Wickham,[1] Sarwat Gilani.[2]
[1]Brooke Army Medical Center, Fort Sam Houston, TX; [2]The University of Texas Health Science Center at San Antonio, San Antonio, TX.

Introduction: RPGN is a type of nephritic syndrome characterized by rapid decline of kidney function with associated proteinuria, hematuria, and presence of urinary dysmorphic red blood cells/casts. RPGN caused by both MPO-ANCA associated vasculitis and anti-GBM disease (Goodpasture syndrome) is rarely reported and generally results in poorer outcomes. We present such a case in an otherwise healthy 32 year-old woman.

Case Description: A 32 year-old woman with no prior history of kidney disease presented with bilateral lower extremity edema and right flank pain of 1 day duration with associated gross hematuria. Physical exam showed 1+ bilateral lower extremity edema extending up to mid-shins. Initial labs revealed serum creatinine of 5.71 mg/dL (no prior baseline), ESR 62 mm/hr, CRP 68.9 mg/L, and urinalysis with >50 RBCs/HPF and 6-10 WBCs/HPF. Urine protein/creatinine ratio was 5.85 g/g. Additional labs showed elevated myeloperoxidase (MPO) antibody at 2.9 AI and positive IgG glomerular basement membrane antibody (anti-GBM) with negative serine protease 3 (PR3) antibody, cryoglobulins, anti-nuclear antibody, and double stranded DNA antibody. Infectious workup was negative for hepatitis, syphilis, HIV, and tuberculosis. Renal ultrasound showed bilateral echogenic kidneys. Computed tomography of abdomen and pelvis showed mild right renal hydronephrosis. Subsequent kidney biopsy showed crescentic, necrotizing, and sclerosing glomerulonephritis with linear glomerular basement membrane staining for IgG, consistent with anti-GBM nephritis. Interestingly, patient had an isolated renal involvement with no neurologic, cardiac, pulmonary, or gastrointestinal manifestations. She was ultimately diagnosed with RPGN secondary to anti-GBM disease with dual positivity for MPO-ANCA. She was treated aggressively with corticosteroids and cyclophosphamide followed by plasma exchange and rituximab, with reduction of antibody titers and disease regression.

Discussion: RPGN secondary to renal MPO-ANCA associated vasculitis and anti-GBM disease is extremely rare. Currently, there are only three reported cases in the literature. In the absence of signs suggestive of infection, clinicians should initiate prompt investigation of autoimmune causes of RPGN to guide optimal treatment.

SA-PO773

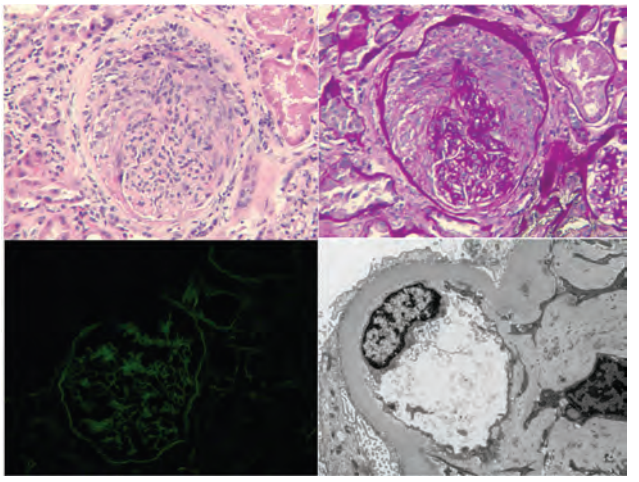
Sweet Syndrome-Associated ANCA-Negative Vasculitis

John Stathopoulos, Bhavana Movva, Casey N. Gashti, David J. Cimbaluk.
Rush University Medical Center, Chicago, IL.

Introduction: Sweet syndrome (SS) is characterized histologically as a neutrophilic dermatosis. It typically presents with fever and an asymmetric, painful, erythematous rash. Lab abnormalities include leukocytosis with predominant neutrophilia, elevated ESR and CRP. It can be drug-induced, infection-related, malignancy associated, or part of a systemic inflammatory disease. SS has been associated with ANCA-associated vasculitis (AAV). The syndrome can predate, occur simultaneously, or follow the onset of AAV. Treatment includes glucocortocoids (GC) in addition to other immunologic agents. We present, to our knowledge, the first case of ANCA-negative crescentic glomerulonephritis associated with sweet syndrome.

Case Description: A 52 y/o male presented with new onset weakness and painful skin rash. His autoimmune and malignancy work up were negative. A diagnosis of SS was established based on skin biopsy. Treatment comprised of GC with a 9-week taper. Four months later, he presented with fever, nausea, and vomiting. His serum creatinine was elevated to 4.48 mg/dL from a baseline of 1.2 mg/dL. Urinalysis showed proteinuria and hematuria. Kidney biopsy revealed pauci-immune necrotizing glomerulonephritis with crescents. Despite negative ANCA serology, treatment mimicked that of AAV, involving GC and rituximab, resulting in renal function and proteinuria improvement.

Discussion: Although association of SS with AAV has been previously reported, we present the first case of such association with ANCA-negative vasculitis. Treatment with GC and rituximab resulted in improvement of acute kidney injury and proteinuria, suggesting that similar immunosuppressive regimen may be efficacious regardless of the ANCA status.



H&E stain (top L) and PAS stain (top R) Active segmental necrotizing lesion with cellular crescents. IMF (Bottom L) pseudo-linear IgG staining. EM (Bottom R) Thickened GBM with no immune deposits

SA-PO774

From Lice to the Heart and Kidneys

Carlos A. Rueda Mantilla, Zach Kisley, Carla L. Ellis, Yusra R. Cheema, Ayotunde Ositelu. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Introduction: Bartonella henselae and quintana, accounting for more than 95% of all Bartonella infections, are the most common cause of culture negative endocarditis in the US. There are many case reports of proteinase-3 (PR3) ANCA vasculitis associated with Bartonella endocarditis. Here we present a case of Bartonella-associated dual-positive myeloperoxidase (MPO) and PR3 renal-limited ANCA vasculitis

Case Description: A 55-year-old male with a history of stage 3 chronic kidney disease, heart failure with preserved ejection fraction (HFpEF), severe mitral regurgitation (MR), Hepatitis B on entecavir, and Hepatitis C presented with shortness of breath, lower extremity edema, and abdominal distention. Initial labs were consistent with a nephritic presentation, acute renal failure with Cr 9.32 mg/dL (baseline 1.7 mg/dL), hematuria, proteinuria, hypocomplementemia, elevated BNP, and hypoalbuminemia. Serologies were notable for strongly positive MPO and PR3 titers. Echocardiogram revealed severe MR with vegetations. Initial blood cultures were negative, but subsequent Bartonella quintana IgG (> 1:1,024) and microbial cell–free DNA were positive. The patient required urgent initiation of hemodialysis and underwent mitral valve replacement. Tissue confirmed Bartonella endocarditis and he was started on doxycycline and rifampin. Renal biopsy showed diffuse crescentic pauci-immune GN and diffuse podocyte foot process effacement. ANCA associated vasculitis (AAV) treatment included pulse dose steroids and induction therapy with RTX ten days following the initiation of definitive antimicrobial therapy and Avacopan two weeks following the completion of rifampin therapy. He demonstrated early signs of renal recovery at dischage

Discussion: We present a case of dual positive MPO/PR3 AAV associated with Bartonella endocarditis leading to diffuse crescentic pauci-immune GN. The severity of findings on renal biopsy prompted an aggressive approach to management despite underlying endocarditis and planned valvular surgery. Treatment with immunosuppression began within days of starting antimicrobial therapy and resulted in early signs of renal recovery nearing discharge. Early initiation of Avacopan therapy (post completion of rifampin to avoid its inducing effects) can be utilized to expedite a prednisone taper in patients with underlying infectious complications or need for adequate wound-healing

SA-PO775

Overlap Syndrome of ANCA-Associated Crescentic Glomerulonephritis, Autoimmune Hepatitis, and Rheumatoid Arthritis

Luis Ng, Duvuru Geetha. *Johns Hopkins Medicine, Baltimore, MD.*

Introduction: The most common renal histopathological in Rheumatoid Arthritis (RA) is Amyloidosis. Conflicting data exist about frequency of other types of glomerulonephritis in RA

Case Description: 46 y.o. female with focal nodular hyperplasia and hemangioma of the liver, hypothyroidism admitted with constitutional symptoms, joint and abdominal pain. Laboratory data revealed abnormal LFTs (AST 336, ALT 498, Alk Phos 227, Albumin 3.0, TBili 5.6, DBili 4.6) and Creatinine 1.8 mg/dL (baseline 1.4). UA: 2+ protein, moderate Hb, 1 WBC, 22 RBC, UPCR 2.2 g/g and UACR 1.3 g/g. Urine microscopy showed granular casts. Serologies were positive for RF 27, Anti CCP >2776.8, ANCA 1:320, MPO>100, Smooth muscle Ab 46.0. C3 and C4 were normala. Sed rate 91 mm/h, C-Reactive protein 3.1 mg/dL. Hepatitis A, B, C, and HIV serology was negative. Simultaneous liver-kidney biopsy obtained. Renal biopsy showed a crescentic glomerulonephritis with fibrous (6/9 glom) and fibrocellular crescents (3/9 glom); reported as inactive associated with chronicity features (45% IFTA) and no activity (endocapillary proliferation, necrosis or thrombi). IF was nonspecific and EM did not show deposits. Liver biopsy showed severe acute hepatitis with extensive necrosis. Given inactive crescents and no activity, the decision was to treat autoimmune hepatitis with Prednisone and start Rituximab for Rheumatoid Arthritis with some collateral benefit on the kidney function. After weeks of treatment, she had improvement in LFTs and symptoms resolved. Kidney function did not significantly change after treatment.

Discussion: This case displays a rare coexistence between three autoimmune entities including MPO ANCA related crescentic glomerulonephritis, Rheumatoid Arthritis and Autoimmune hepatitis. In majority of reported cases, ANCA vasculitis occurs a few years following the diagnosis of RA. Our case is unique for the simultaneous diagnosis of RA, ANCA vasculitis, and autoimmune hepatitis. The lack of improvement of renal despite Rituximab therapy is most likely related to the chronicity findings shown in her kidney biopsy, that was most likely damage from the ANCA related glomerulonephritis. RA can have different histopathologic renal manifestations and it is not limited to Amyloidosis. In the presence of significant proteinuria and hematuria, kidney biopsy needs to be considered in patients with RA.

SA-PO776

Crescentic Glomerulonephritis (GN) with Anti-glomerular Basement Membrane (GBM) Antibodies and ANCA: Double Trouble

Arundhati Sharma, Mugdha Kulkarni, Jacob A. Nysather, Manish Anand, Stephanie M. Bryant. *University of Cincinnati, Cincinnati, OH.*

Introduction: Crescentic GN is characterized by rapid deterioration of kidney function and is caused by antibodies against glomerular basement membrane (anti-GBM), immune complex or pauci-immune etiologies. We present a case of RPGN with anti-GBM Ab and Myeloperoxidase (MPO)-ANCA positivity.

Case Description: 37-year-old male with no prior medical history presented with abdominal pain, hematuria and oliguria. On admission, serum creatinine was 19.72 mg/dL and potassium 7.3 mEq/L. Urine with protein >500 mg/dL and hematuria. Hemodialysis(HD) was started for metabolic abnormalities. Serologies revealed ANA positive, MPO >8units, GBM-Ab >8units, and P-ANCA titer >1:640. Kidney biopsy was obtained after 3 sessions of HD and 10 days after presentation. Biopsy revealed 39/49 glomeruli with circumferential cellular crescents (fig 1) as well as necrotizing arteritis. Immunofluorescence showed GBM linear positivity with IgG 3+ (fig 2), kappa 3+, lambda 3+ and C3 3+. Electron microscopy showed breaks in GBM, and no immune complexes seen. He was transferred to our hospital for further management. Course was complicated by hemoptysis and retroperitoneal hematoma requiring embolization of left renal artery pseudoaneurysm. Steroid induction was promptly started. After stabilization, he received 18 sessions of plasmapheresis and oral Cytoxan 1 mg/kg daily with steroid taper resulting in a drop in anti-GBM Ab to 1.8units. He remains dialysis dependent.

Discussion: Anti-GBM Ab and ANCA associated GNs are rare, but approximately 20%-30% of patients with anti-GBM disease have MPO antibodies. Dual antibody positivity has a worse renal prognosis compared to patients with ANCA related GN. Patient survival is worse in those presenting with acute renal failure requiring dialysis. Our patient's age is much lower than the mean age of presentation for double positive cases. Prompt treatment needs to be started without waiting for biopsy due to fulminant nature of anti-GBM disease followed by longer maintenance therapy due to relapsing nature of ANCA disease.

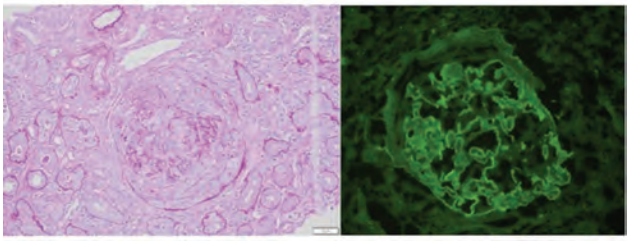

Figure 1(fibro cellular crescent), figure 2(linear pattern of anti GBM antibodies)

SA-PO777

Rapidly Progressive Glomerulonephritis Due to Hypocomplementemic Urticarial Vasculitis Syndrome (HUVS) Masquerading as ANCA-Associated Vasculitis: A Rare Presentation

Sumbal Wajid, Aman Pal, Lilit Grigoryan, Swati Mehta, Krishnakumar D. Hongalgi. *Albany Medical Center, Albany, NY.*

Introduction: Hypocomplementemic urticarial vasculitis syndrome (HUVS) is an immune-complex mediated small-vessel vasculitis with low complement levels. Due to the rarity of HUVS, the existing literature on renal involvement is limited. We present a case of an 87-year-old male who developed rapidly progressive glomerulonephritis (RPGN) due to HUVS.

Case Description: An 87-year-old female was referred to the nephrology clinic with a creatinine surge to 3.5 mg/dL from 0.9 mg/dL a year prior. Urinalysis showed proteinuria and hematuria, with subsequent urine albumin-creatinine ratio of 2g/g and an unremarkable renal ultrasound. Immunological studies indicated normal C3, low C4, elevated p-ANCA and elevated MPO antibody. Concerns for RPGN in the context of ANCA-associated vasculitis (AAV) prompted a renal biopsy, revealing focal crescentic glomerulonephritis with mesangial C3-dominant immune complex deposition. A detailed history revealed episodes of burning facial rash lasing recurring over the past two years alongside arthralgias, weight loss, eye redness and floaters. Physical examination revealed periorbital edema and pitting edema to the ankles. Repeat lab assessment again showed elevated anti-MPO, now with both low C3 and C4 levels. Despite lab findings consistent with microscopic polyangiitis (MPA), the history of urticarial rash, periorbital edema, normal CRP, low complement levels, and C3-predominant immune complex deposition in the mesangium raised suspicion for HUVS. Subsequent testing confirmed low C1Q levels, supporting the diagnosis. Induction therapy was started with cyclophosphamide, rituximab, and steroids, followed with avacopan. She has demonstrated ongoing improvement in creatinine, most recently measuring 2.17 mg/dL.

Discussion: RPGN is characterized by a rapid decline in kidney function and although its etiologies are broad, 40-50% of cases in adults are deemed to be secondary to AAV. However, in our patient, renal biopsy findings contradicted the typical pauci-immune pattern, instead revealing immune complex deposits in the mesangium. This, in addition to the angioedema and low complements, raised suspicion for HUVS, as confirmed using the Schwartz criteria. This case highlights the need for HUVS as consideration of RPGN differentials and emphasizes the necessity for further research on optimal management strategies for this rare condition.

SA-PO778

Rare Biopsy Findings of IgA and C3 on Immunofluorescence in ANCA-Associated Vasculitis

Nazia Habib, Muhammad R. Khan, Sidrah Abid, Geovani Faddoul. *Albany Medical College, Albany, NY.*

Introduction: ANCA associated vasculitis includes GPA, MPA and renal limited vasculitis. It is a severe pauci-immune vasculitis with high mortality which requires prompt management. Some cases have been reported with immune deposits and glomerular C3 deposits. Such cases are now increasingly recognized and associated with worse outcomes. Very rarely there can also be glomerular IgA deposits. Immune

deposits of C3 and IgA are also seen in IRGN and IgA nephropathy which can also be associated with ANCA positivity. This poses a diagnostic challenge which requires ruling out infections as immunosuppressives can be detrimental in such cases.

Case Description: 55-year-old male admitted with recurrent upper respiratory symptoms started 2 months ago. He was initially treated with antibiotics for otomastoiditis. CT chest revealed cavitary lung lesions and was started on appropriate antibiotics for pneumonia. Admission wbc 18 10*3/UL, creatinine (Cr) 1 mg/dl and worsened to 9mg/dl, Positive ANCA 1:80 AI, PR3 30 U/ml, CRP 130mg/L. Anti GBM negative. Kidney biopsy revealed necrotizing and crescentic glomerulonephritis with leukocytoclastic vasculitis, C3/IgA-codominant glomerulonephritis, likely infection-related, mild to moderate interstitial fibrosis and tubular atrophy. Rheumatology and ID were consulted. Any active infection was ruled out before initiating patient on immunosuppressive regimen. He received cyclophosphamide, steroids with taper and transition to Avocapan, PLEX and rituximab. Renal function remained stable but had to be dialyzed once, Clinically, he improved and respiratory symptoms resolved.

Discussion: Our case is unique in which a multispecialty approach was used for management. Although Overlap of ANCA with IRGN possible, this patient received multiple courses of antibiotics during and prior to this admission with no improvement favoring ANCA vasculitis as primary diagnosis. There are no previous cases reported with PR+ ANCA vasculitis with glomerular C3 and IgA deposition. Clinical history, physical examination and characteristic biopsy findings were used together to promptly start management of ANCA associated vasculitis with stabilization of renal function and improvement in respiratory symptoms. A case like this poses a diagnostic challenge for physicians as initiating the appropriate treatment in a timely fashion is extremely important for a patient's recovery.

SA-PO779

Infective Endocarditis-Associated Pauci-Immune Crescentic Glomerulonephritis with Complete Remission after Immunosuppression

Raghunandan Konda, Huma Fatima, Dana V. Rizk, Arun Rajasekaran. *The University of Alabama at Birmingham, Birmingham, AL.*

Introduction: Kidney disease due to infective endocarditis (IE) was first described over 100 years ago. Although initially believed to be primarily embolic, it later became clear that majority of cases represented focal, segmental, or diffuse proliferative glomerulonephritis. Currently, the most common kidney biopsy findings in IE are necrotizing and crescentic GN (~50%), followed by endocapillary proliferative GN (~40%). We describe a rare case of crescentic GN in the setting of renal limited PR3 ANCA Vasculitis (AAV) in a patient with Streptococcus mitis aortic valve (AV) infective endocarditis with complete renal recovery after valve replacement and immunosuppression.

Case Description: 24-year-old male with asthma presented with fevers, chills, and weight loss. Workup revealed bicuspid AV and aortic vegetation. Blood cultures were persistently negative, and he had no prior h/o IV drug use. He received antibiotic therapy, underwent mechanical AV replacement with lifelong anti-coagulation deemed necessary. PCR testing of native AV revealed Streptococcus Mitis. Despite source control and AV replacement, patient developed RPGN. Cr 4.7 mg/dL, Sr albumin 2.3 g/dL, UPCR 2519 mg/g, urinalysis revealed acanthocytes. C3 48 (low), C4 13. PR-3 25. Rest of comprehensive serological workup (incl. Anti-GBM) negative. Kidney biopsy revealed crescentic GN that was pauci-immune with no immune complex or electron dense deposits. Given source control of IE with antibiotics and valvular replacement, induction immunosuppression (IS) with intravenous cyclophosphamide [total - 3g] and glucocorticoids [pulse followed by oral taper] lead to serological remission of AAV [BVAS=0] and complete kidney function recovery with no further RBCs in the urine. He received intravenous rituximab [5 doses of 500 mg so far] for remission maintenance with no flare-ups so far.

Discussion: IE related pauciimmune crescentic GN carries a poor prognosis with a mortality rate of 40-50%. Outcomes have not really improved over time. Treatments have ranged from isolated antibiotic use [~ 60%] and antibiotics with supportive care [35%]. Data on use of IS is lacking and often shows mixed results. Through our case, we postulate the role of IS after early source control has been attained, especially in young patients with no other comorbidities.

SA-PO780

I ANCA Kidding: ANCA-Associated, Pauci-Immune Crescentic Glomerulonephritis with Normal Kidney Function Presenting with Transverse Myelitis

Timothy E. Yen, Maria Clarissa Tio, Ramya Krishna Velagapudi, Neville R. Dossabhoy. *The University of Mississippi Medical Center, Jackson, MS.*

Introduction: Microscopic polyangiitis (MPA) frequently (>80%) manifests with kidney involvement, often presenting with rapidly progressive glomerulonephritis. However, MPA can have a variable presentation with normal kidney function, underscoring the importance of recognizing the extrarenal manifestations of the disease.

Case Description: A 63-year-old Black female was admitted with a 2-week history of falls and progressive lower extremity weakness. Vital signs and electrolytes were normal with creatinine at a baseline of 0.8 mg/dL. Spinal MRI revealed longitudinally extensive transverse myelitis extending from the corticomedullary junction to the thoracic cord. A broad workup for inflammatory, neoplastic, and infectious etiologies was performed and revealed positive ANA (1:320), anti-RNP (1.2U), and anti-myeloperoxidase (1.5U) autoantibodies with P-ANCA positivity raising the concern for MPA with CNS involvement. The patient started plasma exchange (x6) and pulse steroids before being tapered to 1 mg/kg. Despite normal creatinine, nephrology was consulted due to hematuria (RBC >100) and pyuria (WBC >500) on urinalysis and 0.4g/g UPCR. Further, CT chest done for trauma/fall evaluation had revealed asymptomatic lung infiltrates which together with ANCA and renal findings raised concern for a pulmonary-renal syndrome. A transbronchial biopsy was performed first. The initial pathology report from our institution suggested capillaritis, but a second, specialty evaluation reported no vasculitis. The patient subsequently underwent a kidney biopsy which showed pauci-immune crescentic glomerulonephritis (5/20 glomeruli with crescents--3 fibrocellular/2 fibrous crescents; negative immunoglobulins and complements on immunofluorescence) with minimal (~5%) interstitial fibrosis/tubular atrophy. These findings were consistent with MPA and a rituximab-based regimen was started. At four months, the patient's neurologic sequelae have completely resolved while her kidney function has remained at baseline.

Discussion: Although MPA commonly involves the peripheral nervous system, severe central nervous system manifestations such as transverse myelitis are uncommon. In this case, early recognition of the underlying pulmonary-renal syndrome was crucial to ensuring adequate therapy and preserving kidney function.

SA-PO781

Mycobacterium Avium Complex (MAC)-Induced Pauci-Immune Necrotizing Glomerulonephritis

Said Sharawi, Khaled Al-Baqain, Zeid Khitan. *Marshall University, Huntington, WV.*

Introduction: Rapidly progressive glomerulonephritis (RPGN) is a rare syndrome with rapid loss of renal function that has a high rate of renal failure. Histologically, there are numerous glomerular crescents. It is classified according to immune complex deposition. Pauci-immune represents up to 80% of RPGN cases and the incidence in the US is around 7-10 cases per 1 million people per year. ANCAs are negative in approximately 10-30% of patients with pauci-immune necrotizing glomerulonephritis (PING).

Case Description: A 64-year-old male with COPD, OSA, CAD presented with a recent MAC diagnosis awaiting susceptibility. He was doing well until he started having pleuritic chest pain, dyspnea, foamy white sputum, fatigue, nausea, swelling of the lower extremities, and dark urine with reduced urine output. Labs were significant for creatinine of 9.42 from 0.78 a month earlier, BUN 101 from 12, negative ANCA, serology and blood cultures. Active UA. Negative renal ultrasound. PET/CT showed new cavitated lesions within the lungs, diffuse pleural thickening and nodular hypermetabolic activity demonstrated within the left hemithorax, hyperdense material within the right lobe of liver. Echo showed LV thrombus with no vegetations. A kidney biopsy showed severe crescentic GN with ATN and negative IF representing pauci-immune GN. A multidisciplinary team was formed including nephrology, infectious disease and ICU team to discuss this challenging case with recent MAC diagnosis and how to treat in the need of immunosuppression. The patient was started on hemodialysis and the decision was not to start immunosuppression.

Discussion: PING has no deposits or very scant deposits of IgM, IgG or C3 on IF. To our knowledge, our case is the first to link MAC with ANCA negative PING. In a recent unique case series, 9 patient was diagnosed with PING associated with an acute bacterial infection [Staph. A (4), E.coli (1), Klebsiella pneumoniae (1), Strep. parasanguinis (1), and Staph. Epi.(1)]. Bacterial infection-associated PING has no endocapillary proliferation or intense C3 glomerular deposition in contrast to postinfectious glomerulonephritis. Differentiating between infection-associated and other forms of PING is crucial in the management, as the use of immunosuppressive drugs without associated specific treatments may have negative consequences.

SA-PO782

Atypical ANCA-Associated Vasculitis Relapse in ESKD

Veena Aswath, Deanna N. Jones. *Atrium Health Wake Forest Baptist Medical Center, Winston-Salem, NC.*

Introduction: Antineutrophil cytoplasmic autoantibody (ANCA)-associated vasculitides (AAV) are a group of autoimmune diseases affecting small-sized arteries. Despite treatment, many patients have progressive kidney disease. In patients with renal-limited AAV, relapse is rare once dialysis is started. We present a patient with a granulomatous with polyangiitis (GPA) flare four years after diagnosis and one year after starting peritoneal dialysis (PD).

Case Description: A 73 year old male originally presented to the hospital with fatigue, elevated creatinine (3.0 mg/dl), microscopic hematuria (26-40 RBC) and non-nephrotic range proteinuria (800 mg/g). Work-up and kidney biopsy at that time were consistent with AAV. His induction treatment included intravenous (IV) cyclophosphamide for 6 months; and he continued prednisone as maintenance therapy, as he could not tolerate azathioprine. He continued to have mild hematuria and proteinuria, and progressed from chronic kidney disease stage 4 to ESRD three years later. He was started on PD; prednisone was stopped at that time. One year later, he presented with new onset hemoptysis for one week. Serology workup revealed elevated cytoplasmic-ANCA (1:4096), proteinase-3 antibody (4.5 units). Pulmonary hemorrhage was suggested on imaging and confirmed with bronchoscopy--all consistent with active AAV, despite no previous pulmonary involvement.

Discussion: Relapse is recurrence of signs or symptoms of active vasculitis in any organ system after remission is achieved, not due to another cause. Residual proteinuria can reflect active vasculitis or previous, scarred areas in the glomeruli. Risks of continued immunosuppression may outweigh benefits on kidney function. In this case, the patient had only a partial response to his initial treatment, as signified by persistent hematuria, proteinuria, and progression of kidney disease over the next few years. With new symptoms of systemic vasculitis a year later, could he have benefited from continued immunosuppression? However, relapse of renal-limited AAV is rare after progression to ESRD. Uremic toxins are thought to cause a quiescene of the immune system. This "functional" immunosuppression reduces risk of autoimmune disease relapse as compared to those with normal renal function. This case illustrates the need to consider AAV relapse in ESRD patients with recurrent or new systemic symptoms.

SA-PO783

Missed Primary Aldosteronism with HydrANCAzine Consequences

Elias Bassil, Sunny R. Parmar, Georges Nakhoul, Jonathan J. Taliercio, Jagmeet S. Dhingra, Ali Mehdi. *Cleveland Clinic, Cleveland, OH.*

Introduction: Primary aldosteronism (PA) is responsible for up to 25% of treatment resistant hypertension (TRH). However, less than 4% of eligible patients undergo screening. This leads to escalating antihypertensive regimens subjecting patients to otherwise circumventable side effects. We hereby present 3 cases of missed PA sub-optimally managed with hydralazine complicated by drug induced ANCA associated vasculitis (AAV).

Case Description: These are 3 cases of p-ANCA/MPO positive biopsy proven hydralazine induced pauci-immune glomerulonephritis sharing striking similarities (Table 1). All 3 had a diagnosis of TRH on 6 blood pressure medications on average. Notably, none were on mineralocorticoid receptor antagonists. Despite multiple providers spanning many specialties and suggestive biochemical profiles PA testing was not done. In addition to discontinuing hydralazine, significant immunomodulatory therapy was employed to achieve disease remission. PA was diagnosed thereafter, and blood pressure control achieved with only 2-3 medications (including an MRA). Patient #3 also underwent adrenalectomy for unilateral disease.

Discussion: Autonomous hyperaldosteronism has well documented deleterious end-organ effects. Underrecognized PA can lead to unwarranted side effects in attempts to control blood pressure with non-targeted and suboptimal treatments. These cases describe a potentially life-threatening idiosyncratic hydralazine side effect. More importantly they highlight the persistent poor rates of PA screening, underutilization of MRAs, and overreliance on agents relegated to the bottom of our antihypertensive arsenal. Realizing that PA can even have a milder phenotype without overtly obvious biochemical profiles, expanded screening to achieve an accurate diagnosis is instrumental in choosing the right therapy and circumventing significant adverse events such as hydrANCAzine.

SA-PO784

Unveiling the Enigma: ANCA-Negative Granulomatosis with Polyangiitis

Ali Shah, Shila Simkhada, Wajeeha Shahid. *The Wright Center for GME, Scranton, PA.*

Introduction: Granulomatosis with polyangiitis (GPA) is a systemic inflammation of small to medium blood vessels, often linked with anti-neutrophil cytoplasmic antibodies (ANCAs). Diagnosis can be challenging due to diverse symptoms, potentially delaying treatment. Tissue biopsy typically reveals necrotizing granulomatous inflammation, though about 10-20% of cases lack ANCAs complicating identification.

Case Description: A 78-year-old man with COPD, hypertension, high cholesterol, and psoriasis experienced recurrent upper respiratory symptoms, denying hemoptysis or dyspnea. Despite using antihistamines, he had no relief and sought help from his primary care provider. He also had painless hematuria, leading to a scheduled cystoscopy. His recent blood work, ordered by his showed a decrease in hemoglobin from 11.3 to 9.7, an increase in serum creatinine from a baseline of 1.0 to 4.35, and a decrease in glomerular filtration rate (GFR) to 12 prompting an ER visit. Urinalysis revealed proteinuria at 1+, hematuria at 3+, and a high concentration of red blood cells. Renal ultrasound showed non-obstructive right renal calculi without hydronephrosis. Although his potassium levels remained stable, his creatinine continued to worsen (now 7.1), and his urine output decreased, prompting initiation of hemodialysis. Tests for hepatitis and HIV were negative, as were serum tests for various autoimmune markers including ANCA, PR3, anti-MPO, anti-GBM antibodies, and complement levels. Kidney biopsy revealed pauci-immune glomerulonephritis with circumferential fibrous crescents. He was subsequently treated with high-dose intravenous steroids and rituximab in the setting of ANCA-negative Granulomatosis with polyangiitis.

Discussion: The inflammation seen in GPA prompts an immune response, often leading to high ANCA titres. Around 82–94% of GPA patients are ANCA positive, leaving about 10% ANCA negative. These cases without ANCA are often overlooked. Initial symptoms vary, including sinusitis (67%), pulmonary signs like cough, renal failure, skin/mucous membrane ulcers, and abdominal pain with vasculitis. The diagnosis of GPA includes urinalysis showing red blood cell casts, abnormal chest x-ray, oral/nasal ulcers, and granulomatous inflammation on biopsy. Survival without treatment averages 5 months, with a 20% 1-year survival rate. Treatment involves corticosteroids and immunosuppressants.

SA-PO785

When Interstitial Nephritis Hides Vasculitis: A Case of ANCA-Associated Vasculitis

Zachary D. Stello, Deepak Chandramohan, Huma Fatima, Ashita J. Tolwani. *The University of Alabama at Birmingham, Birmingham, AL.*

Introduction: We present a case of anti-myeloperoxidase (MPO) antibody-positive Antineutrophil cytoplasmic autoantibody (ANCA)-associated vasculitis (AAV) presenting as subacute interstitial nephritis on renal biopsy.

Case Description: The patient is a 75-year-old male with a history of pulmonary fibrosis, hypertension, dyslipidemia, and coronary artery disease who presented with worsening renal function following a recent hospitalization where he was diagnosed with new-onset polymyalgia rheumatica. Labs showed a serum creatinine of 1.5mg/dL (known baseline of 1.0), and urinalysis showed trace protein and 1+ hematuria. Acute kidney injury was initially presumed to be secondary to NSAIDs and was stopped. Since the hospital discharge, he also experienced worsening peripheral neuropathy-like symptoms and a new-onset right foot drop. He was seen a week later, and his serum creatinine had continued to rise and was 2.8 mg/dL. His urine protein-creatinine ratio was 688mg/g, and his symptoms remained unchanged. Urine microscopy was negative for dysmorphic RBCs and casts. Serologic studies returned and were notable for perinuclear-ANCA titer of 1:160, rheumatoid factor level of 56U/mL, and anti-MPO antibody level of 33U/mL. Renal biopsy revealed focal subacute tubulointerstitial nephritis with no evidence of crescents, negative immunofluorescence for IgA, IgM, IgG, C3, C1q, and fibrinogen and electron microscopy showed subtotal foot process effacement. He was treated with intravenous methylprednisolone daily and then transitioned to a prednisone taper. Additionally, he was given Rituximab 1000mg with plans for continuation. About 1 month later, his renal function and overall symptom burden improved, and the anti-MPO antibody titers became undetectable.

Discussion: This case represents a rare presentation of AAV with interstitial nephritis and without classical crescentic glomerulonephritis. These patients are usually older and have more nonspecific symptoms.

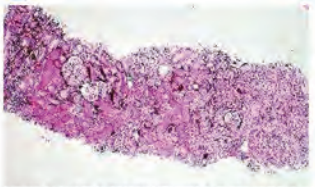

Figure 1: There is patchy interstitial mononuclear inflammatory infiltrate. The glomeruli are unremarkable. Jones Silver x10

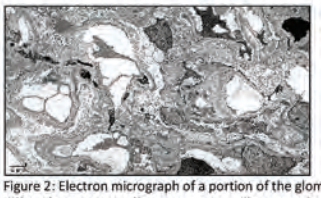

Figure 2: Electron micrograph of a portion of the glomerulus shows features of podocyte injury as diffuse foot process effacement, microvillous transformation and cytoplasmic vacuolization. TEM x2500

SA-PO786

B Cells Unhinged: Concurrent PR3+ ANCA-Associated Vasculitis and Diffuse Large B Cell Lymphoma Treated Effectively

Eliot Sachsenmeier, Yinelka G. Silverio De Castro, James Drakakis, Minesh Khatri. *NYU Langone Hospital - Long Island, Mineola, NY.*

Introduction: We present a case of PR3+ ANCA vasculitis diagnosed simultaneously with diffuse large B-cell lymphoma (DLBCL). Both improved after rituximab and chemotherapy. This appears to be the third case of DLBCL-associated ANCA vasculitis described in the literature. The mechanisms of this association and implications for therapy warrant future investigation.

Case Description: 71-year-old man with hypermetabolic lung and left tonsillar masses on outpatient PET-CT presented for fatigue, anorexia, and weight loss. Laboratory testing showed an elevated creatinine of 5.87 mg/dL. Serologic workup revealed an elevated proteinase-3 level of 183. CT chest confirmed a spiculated right upper lobe nodule measuring 3.1 cm with architectural distortion. He received three dialysis treatments and was started on pulse dose steroids. He underwent renal and lung biopsy, showing diffuse necrotizing and crescentic pauci-immune glomerulonephritis (Fig. 1), and pulmonary parenchyma effaced by sheets of large, atypical B-lymphocytes compatible with DLBCL. Two months later, after daily prednisone, 4 doses of weekly rituximab, and 2 cycles of Pola-CHP, his creatinine was 1.31 mg/dL. Repeat PET-CT showed complete resolution of the hypermetabolic left tonsillar mass and near complete resolution of the right upper lobe mass.

Discussion: While uncommon, malignancy is diagnosed more frequently in patients with ANCA vasculitis, especially granulomatosis with polyangiitis (GPA). The most common cancers diagnosed include bladder cancer, non-melanoma skin cancer, leukemia, and lymphoma. Association with the latter two may relate to overexpression of PR3 in response to granulocyte colony stimulating factor. The overexpression of PR3 may trigger an immune response that harms normal and malignant tissue. Alternatively, PR3-specific B cell clones may proliferate to become lymphoma. Our patient's improvement with combination therapy may support a common cause.

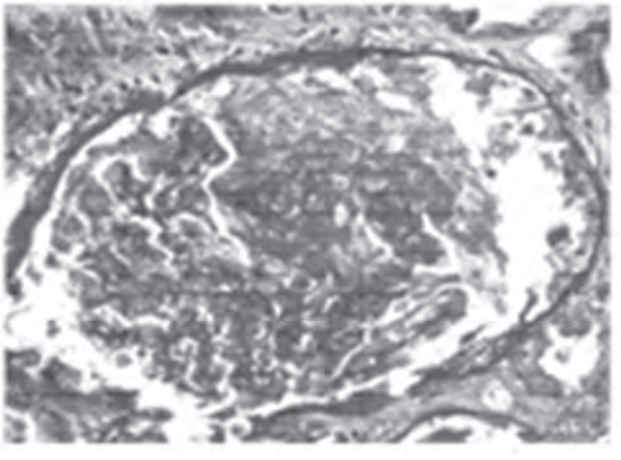

Fig. 1

SA-PO787

Uncommon Presentation of Pauci-Immune Crescentic Glomerulonephritis in a Young Adult with Normal Kidney Function

Nicholas P. James, Ubaid Naeem, Vishwajeeth Pasham, Natalie T. Freidin. *Medical University of South Carolina, Charleston, SC.*

Introduction: Crescentic glomerulonephritis is common in pauci-immune reno-pulmonary disorders, typically presenting with acute kidney injury (AKI) and diffuse alveolar hemorrhage (DAH). We present a case of pauci-immune crescentic glomerulonephritis (PICGN) with migratory polyarthralgia, DAH and remarkably preserved kidney function.

Case Description: 19 year old male presented with seborrheic dermatitis and polyarthralgia with associated recurrent "sinus infections." Workup revealed microscopic hematuria, nephrotic range proteinuria (>5g/24 h), serum creatinine (0.8-1 mg/dl), and positive serology for proteinase-3 (PR3) and c-ANCA. Later developed hemoptysis with bronchoscopy notable for diffuse alveolar hemorrhage. Renal biopsy showed fibro-cellular crescents in 34/45 glomeruli consistent with pauci-immune crescentic GN. Treated with cyclophosphamide and methylprednisone along with plasma exchange with subsequent improvement in symptoms and proteinuria.

Discussion: PICGN is typically associated with rapid eGFR loss correlated with extent of crecent formation. Despite renal biopsy Figure 1 revealing extensive crescents GFR was preserved. Main prognostic factor in PICGN is clinical vigilance and maintaining low threshold for aggressive treatment. Literature review suggests renal biopsy if clinical concern for ANCA vasculitis regardless of presenting renal function. Our case highlights the clininical importance of renal biopsy in long term prognostication and significant pathologic findings despite preservation of GFR. In a cohort of 70 biopsy proven PICGN patients, mean serum creatinine at presentation was 5.5 ± 2.1 mg/dl and mean proteinuria of 2.5 g/24 h. This signifies the importance of clinical diagnosis and management in atypical presentation of cases. The successful management of this case, involving the identification and subsequent initiation of cyclophosphamide, pulse dose steroids, and plasma exchange, highlights the importance of early and aggressive treatment to prevent progression and preserve renal function.

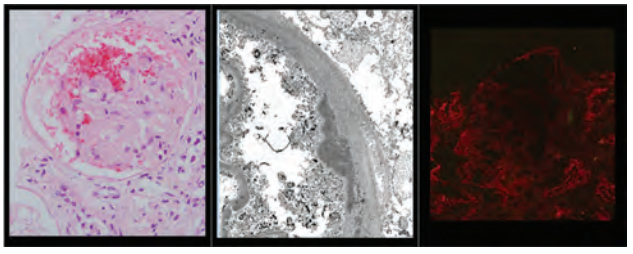
ANCA-Negative Pauci-Immune Crescentic Glomerulonephritis in a 26-Year-Old Postpartum Woman Treated with Oral Steroid and Azathioprine

Joel John C. Mejos, Ruben A. Maguad, Grecia Darunday. *Perpetual Succour Hospital, Cebu City, Philippines.*

Introduction: Pauci-immune crescentic glomerulonephritis (PICGN) is a rapidly progressive condition leading to rapid loss of kidney function within days to weeks and potentially life threatening. PICGN is an idiopathic form of crescentic GN that typically lacks significant immune deposits within glomeruli and often associated with antineutrophil cytoplasmic antibody (ANCA). However, some patients with PICGN are ANCA negative. Treatment for PICGN with or without ANCA includes IV methylprednisolone pulse therapy followed by tapering of oral steroid and cyclophosphamide either IV or orally.

Case Description: A 26 year old Filipina presented with anuria, jaundice and elevated creatinine hours after an emergency cesarian section secondary to arrest of labor. She had BP elevation, edema and blurring of vision. No other signs and symptoms. Her D-dimer, phosphorus and triglycerides were high. Coomb's test are negative, C3/C4 are normal. She underwent hemodialysis (HD) for couple of sessions until her clinical status improved. Renal biopsy showed PICGN with cellular crescents and global glomerulosclerosis. P and C-ANCA were negative. She was given oral steroid and azathioprine (AZA) for 6 months which showed remarkable clinical improvement. Serum creatinine fall to 5mg/dL from 10mg/dL, UPCR to 0.8mg/dL from 3.9 mg/dL. HD was discontinued with stable kidney function and continuously monitored as outpatient.

Discussion: PICGN is the most common cause of RPGN in adults and often associated with the presence ANCA's. Around 10-30% of patients with PICGN lack the ANCA's. The mechanisms of ANCA-negative PICGN are still vague. Neutrophils (PMNs) are the major effector cells in ANCA-positve PICGN. PMNs are also thought to be the major effector cells in ANCA-negative PICGN. The presence of PMNs in pathological lesions exist separately from circulating ANCA's and may include other autoantibodies or T-cell dependent mechanisms. Treatment of patients with ANCA-negative PICGN are usually based on those patients who are ANCA-positive. In our patient, oral steroid and AZA have shown excellent results.



SA-PO789

Pauci-Immune Crescentic Glomerulonephritis Linked to Candida parapsilosis Fungemia

Long Qian,[1] Hugh Carey.[2,1] *[1]Yale New Haven Hospital, New Haven, CT; [2]Metabolism Associates, New Haven, CT.*

Introduction: Infectious endocarditis (IE) typically correlates with infectious glomerulonephritis (GN), presenting as membranoproliferative GN (MPGN) with positive C3 and immunoglobulin staining. However, there are rare instances of pauci-immune GN associated with infectious endocarditis, sometimes with ANCA positivity, but occasionally negative for any ANCA or PR3 or MPO. Here we present a case of Candida parapsilosis endocarditis associated with p-ANCA positive, PR3-negative, MPO-negative pauci-immune GN.

Case Description: A 59-year-old man with a history of intravenous drug use on methadone, compensated cirrhosis due to HCV and alcohol, and HIV, presented with abdominal pain. Creatinine was newly elevated to 4.4 mg/dL (baseline 0.8). Echocardiogram revealed a 1.1 x 0.7cm aortic valve vegetation. Blood cultures grew Candida parapsilosis. Serological testing showed negative PR3 and MPO, positive p-ANCA (1:40), low C3, normal C4, negative cryoglobulin, negative HIV, HBV, and HCV PCR. Kidney biopsy showed crescentic necrotizing GN with negative to trace immunofluorescence for immunoglobulins, C3, and kappa and lambda, and electron microscopy showed no deposits. Immunosuppression was withheld due to fungemia persistent for 4 weeks despite receiving liposomal amphotericin B, flucytosine, and fluconazole. Hemodialysis (HD) was started 3 weeks post-presentation for uremia. After blood cultures cleared, he was started on 60mg/day of prednisone. However, he later developed methicillin-sensitive Staphylococcus aureus bacteremia, thus prednisone was tapered. He received cefazolin with continued antifungals. Aortic valve replacement was performed 2 months post-presentation without complications. He received one session of HD post-surgery but had kidney recovery and HD was stopped. He completed 6 weeks of amphotericin; fluconazole continues for lifelong suppression. He remains off HD.

Discussion: Pauci-immune necrotizing GN is a rare cause of AKI associated with IE. To our knowledge this is the second reported case of MPO, PR3 negative GN associated with Candida parapsilosis IE. The potential mechanism of IE triggering ANCA is unknow and has been hypothesized to be via autoantigen complementarity or molecular mimicry. For treatment, balancing immunosuppression against ongoing infection can be challenging. Favorable prognosis may be achieved with definitive infection control and cautious immunosuppressive therapy.

SA-PO790

Not-So-Pauci-Immune Crescentic Glomerulonephritis: A Management Challenge with Poor Kidney Survival

James B. Hughes, Megha R. Joshi. *Walter Reed National Military Medical Center, Bethesda, MD.*

Introduction: Glomerulonephritis (GN) caused by antineutrophilic cytoplasmic antibody (ANCA)-associated vasculitis (AAV) classically presents on renal biopsy as a pauci-immune GN. However**,** glomerular immune complex deposition is becoming increasingly recognized as a potential pathologic presentation. Studies have reported significant immune complex deposition (26%-41%) in patients diagnosed with AAV. Reported immune deposits on direct immunofluorescence (DIF) have included IgG, IgM, IgA, C3, C4, and C1q in varying combinations. Higher degrees of proteinuria and worse renal outcomes have been associated with reported immune complexes on DIF in AAV patients, particularly with myeloperoxidase (MPO) positivity. Low serum C3 and glomerular IgG deposits are also indicators of poor renal prognosis.

Case Description: We present a patient, previously healthy, who was hospitalized with hypertensive emergency, mixed nephritic and nephrotic syndrome, and acute renal failure requiring initiation of hemodialysis. Labs were notable for MPO positivity with normal C3 and C4. All other serologies were negative. The patient was initiated on empiric induction with intravenous cyclophosphamide and methylprednisolone. Renal biopsy revealed a crescentic GN and DIF positivity for IgG, C3, C1q, kappa, and lambda. Despite induction therapy for over three months duration, the patient remained dialysis dependent with continued positive MPO serologies. Rheumatology evaluation revealed no evidence of extrarenal disease. He was transitioned to mycophenolate mofetil maintenance therapy and is undergoing evaluation for renal transplantation.

Discussion: This case exemplifies the severe nature and therapeutic challenge posed by ANCA-associated RPGN with immune complex deposition and may indicate that current standard therapies may not be adequate for this pathologic variant. Further research is needed to elucidate effective immunosuppressive therapy for these patients.

SA-PO791

First Reported Case of Rapidly Progressive Glomerulonephritis (RPGN) Due to Combined Renal-Limited ANCA-Associated Vasculitis and Anti-glomerular Basement Membrane (GBM) Disease in a Young Man with Koolen-de Vries Syndrome

Vijaya Chelikani, Arun Rajasekaran. *The University of Alabama at Birmingham, Birmingham, AL.*

Introduction: Koolen-de Vries syndrome (KdVS) is characterized by congenital malformations, developmental and intellectual disability, hypotonia, epilepsy, and behavioral features. Other findings include speech and language delay (100%), epilepsy (~33%), congenital heart defects (25%-50%), and renal and urologic anomalies (25%-50%) that include cryptorchidism, hypospadias, hydronephrosis/VUR, and renal duplication. Concomitant glomerular disease has not been reported to date. We describe the first case of combined renal limited ANCA Vasculitis (AAV) and Anti-GBM Disease in a patient with KdVS.

Case Description: A 24-year-old male with KdVS and morbid obesity presented with reduced energy levels and rapid loss of kidney function. He did not have pulmonary manifestations including hemoptysis. His baseline serum creatinine level was unknown. On presentation, Sr Cr 4 mg/dL [was 1.7 mg/dL 1 month prior], Sr albumin 4.3 g/dL, UACR 346 mg/g and UPCR 755 mg/g. Urinalysis revealed acanthocytes. Serological workup revealed ANA (+), 1:320 [homogenous], negative ds-DNA, c-ANCA >1:1280; p-ANCA 1:220; anti-MPO titer of 96, anti-PR-3 titer of 23, anti-GBM titer of 4.7. Remainder of comprehensive serological testing was negative. Kidney USG revealed mild right pelviectasis. Patient refused PLEX and kidney biopsy. Pulse dosing of methylprednisolone and one dose of intravenous cyclophosphamide 1000 mg was given followed by oral cyclophosphamide at 200 mg/day. After 8 months, UPCR 600 mg/g, no acanthocyturia; he has attained serological remission of his MPO, PR-3, and Anti-GBM serologies and has a Sr Cr stable at 2.4 mg/dL.

Discussion: AAV with concomitant anti-GBM disease is a rare, potentially life-threatening disease. Prompt diagnosis with a kidney biopsy is warranted to ascertain extent of cellular activity. Early treatment with PLEX, cyclophosphamide, and glucocorticoids is warranted. Dual AAV (+) Anti-GBM mandates immunosuppression for remission maintenance as well as portend a poor prognosis. We describe the first case of RPGN due to combined renal limited AAV and Anti-GBM Disease in a patient with Koolan-De Vries Syndrome, and the associated challenges with treatments.

SA-PO792

A Case of Bartonella henselae Infection-Related Glomerulonephritis and Endocarditis with Negative Blood Culture Mimicking PR3-ANCA-Associated Vasculitis

Yui Mohri, Shinya Yamamoto, Keisuke Morita, Motoko Yanagita. *Department of Nephrology, Graduate School of Medicine, Kyoto University, Kyoto, Japan.*

Introduction: A case of *Bartonella henselae* infection-related glomerulonephritis and endocarditis with negative blood culture mimicking PR3-ANCA associated vasculitis.

Case Description: A 70-year-old female with a history of aortic stenosis was admitted to our hospital because of fever and fatigue. The laboratory data revealed cytopenia and an elevated creatinine level from 0.50 mg/dL to 0.97 mg/dL with hematuria and urinary protein of 0.5 g/gCr. Immunological tests revealed positive PR3-ANCA (52 U/mL), rheumatoid factor (90.4 IU/mL), and reduced C3 (71.7 mg/dL). Blood culture was negative. Renal biopsy revealed endocapillary proliferation and endothelial cell swelling without crescent formation. Immunofluorescence showed the deposition of IgM and C3c on the capillary wall. The pathological diagnosis was consistent with IRGN. Considering the habit of keeping 30 wild cats, blood polymerase chain reaction (PCR) testing was performed, which was positive for *B. henselae*. Echocardiography and brain MRI revealed newly noted aortic valve regurgitation and subacute cerebral infarction. The diagnoses of *B. henselae* IRGN and IE were confirmed. We initiated rifampicin and doxycycline, which were eventually changed to gentamycin and minocycline due to

adverse events of nausea and vomiting. Cytopenia, renal function, and urinalysis results improved. Subsequently, the patient underwent aortic valve replacement, and the excised valve was positive for *B. henselae* PCR.

Discussion: The differential diagnosis of PR-3 ANCA-positive IRGN and AAV is often challenging, particularly in cases with negative blood or tissue cultures. *B. henselae* cannot be easily isolated from clinical specimens owing to its fastidious nature. In the present case, PCR testing and renal biopsy were essential for confirming *B. henselae* infection and treatment decisions.

Correlations in Histology and Complement Biomarkers in C3 Glomerulopathy

Jillian R. Hall, Monica D. Hall, Lauren O. Fergus, Patrick D. Walker, Yuzhou Zhang, Richard J. Smith, Carla M. Nester. Molecular Otolaryngology and Renal Research Laboratories. *University of Iowa Health Care, Iowa City, IA.*

Background: C3 Glomerulopathy (C3G) is characterized by complement dysregulation and C3 deposition in glomeruli. We reviewed characteristics of baseline kidney biopsies to determine whether features of activity and/or chronicity correlate with clinical parameters and/or complement biomarkers at presentation.

Methods: Data from the University of Iowa's C3G Natural History Study were used. Criteria for entry included baseline native biopsy diagnosis of C3G and complement biomarkers within 1 year of biopsy. Patients with a history of dialysis, transplant, or anti-complement therapy were excluded. Significance was assessed using Pearson correlation coefficients with two-tailed p values (95% confidence) and one-way ANOVA analysis; p-values <0.05 were considered significant.

Results: 57 of 104 subjects (54.8%) presented with an activity score of ≥9; 18 (17.3%) presented with a chronicity score of ≥4 (the a priori determinants of increased risk for progression to renal failure). Higher activity scores were associated with elevated C5Nefs (p = 0.012, R = 0.255) and soluble C5b-9 (p = 0.013, R = 0.259) levels. Higher chronicity scores were associated most strongly with an increase in Ba (p = 8.183e-10, R = 0.677) and a lower GFR (p = 1.665e-9, R = -0.558) and less strongly with increased C3 (p = 0.022, R = 0.265), C5 (p = 0.014, R = 0.331) and Bb (p = 0.037, R = 0.263) levels, and decreased C5Nefs (p = 0.012, R = -0.262 and soluble C5b-9 (p = 0.026, R = -0.232) levels.

Conclusions: The association of higher C5Nefs and soluble C5b-9 levels with increased activity scores is consistent with terminal pathway activity being a driver of inflammation, while the association of increased chronicity scores with a lower GFR and higher Ba reflects declining renal function independent of complement activity. While the increase in C3 and C5 and the decrease in soluble C5b-9 levels reflect decreased complement activity, Bb levels suggest some component of continued alternative pathway activity. In aggregate, these data support a role for complement biomarker testing in C3G.

Clinical and Histological Predictors of Outcomes in C3 Glomerulopathy

Malak A. Ghaddar,[1,2] Hannah J. Lomax-Browne,[5] H. Terence Cook,[5] Erica Daina,[3] Marina Noris,[3] Giuseppe Remuzzi,[3] Manuel Praga,[4] Fernando Caravaca-Fontan,[4,6] Dilshani Induruwage,[2] Matthew C. Pickering,[5] Sean Barbour.[1,2] *[1]The University of British Columbia, Vancouver, BC, Canada; [2]BC Provincial Renal Agency, Vancouver, BC, Canada; [3]Istituto di Ricerche Farmacologiche Mario Negri Centro Aldo e Cele Dacco, Ranica, Italy; [4]Universidad Complutense de Madrid Facultad de Medicina, Madrid, Spain; [5]Imperial College London Department of Immunology and Inflammation, London, United Kingdom; [6]Hospital Universitario 12 de Octubre Servicio de Nefrologia, Madrid, Spain.*

Background: C3 glomerulopathy (C3G) is a rare disease that has significant overlap with idiopathic membranoproliferative glomerulonephritis (MPGN). Risk factors for kidney outcomes remains poorly defined, limited by small cohorts. We aimed to determine risk factors for kidney outcomes and to incorporate them into a prediction model

Methods: Using a cohort of 225 patients with C3G or idiopathic MPGN from three international centers, we evaluated the association between clinical and histologic variables at biopsy and the composite outcome of 30% decline in eGFR or ESKD using Cox proportional hazards models. A prediction model was derived and internally validated through bootstrap resampling

Results: In a multivariable model, lower eGFR, paraprotein presence, and interstitial fibrosis were associated with higher risk of outcome, while native (versus transplant) disease and lower C4 levels were associated with lower risk (Table1). The prediction model including these variables performed well (R^2_D: 53.14%, C-statistic: 0.84 (95% CI 0.82-0.86), integrated calibration index: 0.31), maintaining robustness after internal validation. Adding proteinuria over time showed that a 50% reduction from baseline to <1g/day was associated with a lower risk of outcome (HR 0.35, 95% CI 0.12-0.97)

Conclusions: In the largest C3G/MPGN study to date, baseline eGFR, paraprotein, interstitial fibrosis, low C4 and transplant status were independently associated with kidney outcome. These factors can be used in a prediction model to predict individual patient risk. A 50% reduction in proteinuria to <1g/day was associated with lower kidney risk, suggesting it may be an evidence-based definition of proteinuria remission to use in clinical trials

Covariates for the risk of progression to the composite outcome in a multivariable model

Parameter	Adjusted HR (95% CI)	P value
eGFR (per 1 log base 2-unit decrease)	2.11 (1.66-2.67)	<0.001
Native kidney (versus transplant)	0.35 (0.20-0.60)	<0.001
Paraprotein	4.42 (2.00-9.77)	<0.001
Low C4	0.51 (0.29-0.90)	0.02
Interstitial fibrosis		
1	2.03 (1.03-4.01)	0.04
2	3.01 (1.56-5.83)	0.001
3	4.68 (2.05-10.68)	<0.001

Interstitial fibrosis score: 0 (<10%), 1 (10%-25%), 2 (26%-50%) and 3 (>50%)

Clinical Burden of Native vs. Post-transplant Complement 3 Glomerulopathy (C3G) in the United States: A Retrospective Claims Analysis

Briana C. Ndife,[1] Anirban Bose,[1] Karishma Thakkar,[1] Rahul Khairnar,[1] Xiaolei Li,[2] James B. Young,[2] Hemanth Nair,[2] Mohanram Narayanan.[3] *[1]Novartis Pharmaceuticals Corporation, East Hanover, NJ; [2]Clarivate, PLC, Toronto, ON, Canada; [3]Baylor Scott & White Medical Center Temple, Temple, TX.*

Background: C3G is caused by overactivation of the alternative complement pathway leading to deposition of C3 in the glomeruli. It is a rare disease; its clinical burden has not been well studied. Using medical claims data, this analysis characterized disease progression in a US cohort of patients (pts) with C3G in native kidney (NK) and post-transplant (TK).

Methods: We performed a retrospective cohort analysis of pts ≥12 years of age, diagnosed with C3G (defined by diagnosis codes) within the Clarivate Real-World Data Product database (Jan 2017–Sep 2022). Included pts had database records for ≥12 months (mo) prior to, and ≥6 mo post, the index (date of diagnosis). Pt demographic/clinical characteristics were assessed at index and stratified by transplant status (NK, TK). Time to chronic kidney disease (CKD) progression and/or kidney failure was assessed using Kaplan–Meier analyses.

Results: Of 350 pts with C3G, 244 (69.7%) had NK and 106 (30.3%) had TK; median follow-up was 23.7 mo (interquartile range: 13.9–46.9). Pt characteristics are shown in the **Table**. The median time to first CKD progression was 13.3 mo (95% confidence interval [CI]: 4.5–28.3) for NK and 3.5 mo (95% CI: 1.0–25.5) for TK. A higher proportion of TK pts (90.9%) progressed to kidney failure vs NK (45.8%). Median time to kidney failure was shorter in pts with TK C3G (27.1 mo [95% CI: 12.2–45.0]) vs NK C3G (43.5 mo [95% CI: 32.9–85.7]).

Conclusions: Disease progression to a higher CKD stage and/or kidney failure is faster in pts with TK C3G compared to pts with NK C3G. Given the disease characteristics and progression, these data highlight the need for novel therapies to treat both NK and TK C3G.

Health Care Resource Utilization (HCRU) Burden in C3 Glomerulopathy (C3G) in the United States: A Retrospective Linked Electronic Medical Records (EMR) and Claims Database Analysis

Briana C. Ndife,[1] Rahul Khairnar,[1] Anirban Bose,[1] Karishma Thakkar,[1] Marley K. Boyd,[2] Claudia Leiras,[2] Swastina Shrestha,[2] Laura H. Mariani.[3] *[1]Novartis Pharmaceuticals Corporation, East Hanover, NJ; [2]Genesis Research LLC, Hoboken, NJ; [3]University of Michigan, Ann Arbor, MI.*

Background: C3G is a chronic, rare glomerulonephritis in which pathological deposition of C3 in the glomeruli leads to progressive chronic kidney disease (CKD). This analysis aimed to evaluate C3G-related HCRU in the US.

Methods: We performed a retrospective analysis of patients (pts) diagnosed with C3G (Jan 2017–Sep 2022), with EMRs and linked medical claims in the HealthVerity database. Pts were ≥12 years (y) of age and had records ≥12 months prior to and following first diagnosis (index). Annual, per patient HCRU was assessed by CKD stage (defined as: mild [stage 1–2, reference], moderate [stage 3–4], severe [stage 5]) and proteinuria level (<1, ≥1 g/g) at index. HCRU rate ratios (RRs) for proteinuria groups and CKD stages were estimated using a generalized linear model with log link and negative binomial distribution, with 95% confidence intervals (CIs) and p-values.

Results: At index, the final cohort of 677 pts was majority female (63%), with a mean (standard deviation [SD]) age of 44y (19). Comorbidities included hypertension (55%), type II diabetes (24%), congestive heart failure (11%), atrial fibrillation (4%) and myocardial infarction (3%). Mean estimated glomerular filtration rate (n=152) was 78 (SD 37) mL/min/1.73m^2 and median proteinuria was 1.5 (n=49, interquartile range 0.3–3.3) g/g. Mean number of total visits was 65.7 (SD 74.8). Proteinuria level ≥1 g/g was associated with a 2-fold increase in total visits versus those with levels <1 g/g (RR 2.08, 95% CI 1.18–3.69, p=0.012). Increasing CKD stage associated with increasing total visits (moderate CKD: RR 1.78, 95% CI 1.42–2.23, p<0.0001; severe CKD: RR 2.68, 95% CI 2.04–3.51, p<0.0001) (**Table**).

Conclusions: Pts with higher proteinuria and CKD stage have a higher HCRU burden, highlighting the need for therapies that reduce proteinuria and prevent CKD progression.

Experience with Iptacopan in Patients with Recurrent Complement 3 Glomerulopathy (C3G): Early Access Program Data

Serge Smeets,[1] Soudeh Ansari,[2] Sviatlana Rizk,[1] Induja Krishnan,[3] Nicholas J. Webb,[1] Matthias Meier.[1] *[1]Novartis Pharma AG, Basel, Switzerland; [2]Novartis Institutes for Biomedical Research, Cambridge, MA; [3]Novartis Pharmaceuticals Corporation, East Hanover, NJ.*

Background: C3G is a severe primary glomerulonephritis driven by alternative complement pathway (AP) dysregulation; >50% of patients (pts) progress to kidney failure in <10 years and there is high risk of recurrence after successful kidney transplantation. Iptacopan is an oral proximal complement inhibitor that specifically binds Factor B and inhibits the AP; Phase 2/3 studies have shown efficacy in proteinuria reduction and favorable safety. An early access program (EAP) was initiated in 2018 (NCT05222412) to provide iptacopan for C3G pts (native and recurrent) with progressive renal insufficiency not eligible for any clinical trial who have exhausted all available therapies. We here focus on outcomes in pts with recurrent C3G post transplantation.

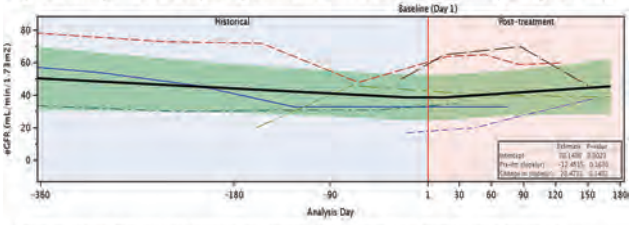
Methods: Unsolicited requests submitted to the EAP were approved if meeting eligibility criteria and applicable local laws/regulations. Recurrent C3G had to be biopsy confirmed. Physicians received a 3-month supply of iptacopan (200 mg twice daily). Resupply requests were submitted generally every 3 months and estimated glomerular filtration rate (eGFR) values collected. Adverse events (AEs) were collected by spontaneous reporting. Cutoff for data collection: 27-Feb-2024.

Results: 12 pts with recurrent C3G received iptacopan: median age 40 y (17-76); 75% male; median iptacopan treatment duration 214 days (15-1017); baseline mean eGFR 44.4 mL/min/1.73m^2 (SD 21.6). Analysis comparing eGFR slope post-transplant prior to and after start of iptacopan treatment suggested potential stabilization of kidney function (**Figure**). 3 pts reported 26 AEs, of which 12 were serious (all judged not related to iptacopan except 1 of bacterial pneumonia).

Conclusions: Following a historic period of eGFR decline post-transplantation without iptacopan treatment, recurrent C3G pts demonstrated potential stabilization of progression with iptacopan treatment. AEs were consistent with the known safety profile of iptacopan; no new safety signals were identified.

Funding: Commercial Support - Novartis Pharma AG

Figure. Change in eGFR trajectory based on historical data (sensitivity analysis*; n=6)



*Includes only patients with both historical and on-treatment data available, more than one resupply of iptacopan, and a period of ≤60 days between eGFR reported at the initial request and treatment initiation. Day 1 denotes start of iptacopan treatment.

SA-PO798

Kidney AA Amyloidosis in a Liver Transplant Recipient

Long Qian, Jeffrey M. Turner. *Yale University, New Haven, CT.*

Introduction: Renal AA amyloidosis is a rare cause of proteinuric AKI occuring in chronic inflammatory states from amyloid A protein deposition in the kidney. AA amyloidosis is rare in immunosuppressed transplant recipients. Such cases can present a diagnostic challenge as potential etiologies include autoimmune disease recurrence, occult infections, and inflammation from graft rejection. We report a case of renal AA amyloidosis in a liver transplant recipient that highlights the spectrum of potential pathologies in such patients.

Case Description: A 34-year-old man with a liver transplant 13 years ago for autoimmune hepatitis/primary sclerosing cholangitis (AIH/PSC) overlap syndrome presented with abdominal pain. Creatinine was newly elevated to 4.5 mg/dL (baseline 1.0) and urine protein creatinine ratio was 5g/g. Kidney biopsy showed deposits positive for Congo red with apple green birefringence, with positive immunohistochemistry for serum amyloid A protein. He had multiple risk factors for AA amyloid including injection drug use, cystic liver lesions on imaging resembling abscesses, and long-standing liver enzyme elevations with prior liver biopsy findings suggestive of recurrent AIH/PSC versus cellular rejection. ANA titer was elevated at 1:1280. Liver-kidney microsomal antibody and smooth muscle antibody were negative. AST, ALT, and ALP fluctuated between normal to elevated. Multiple blood cultures were negative. Direct sampling of the liver lesions was not obtainable due to their small size and difficult anatomical location. The patient received 4 weeks of cefuroxime/metronidazole for potential abscesses, but the liver lesions persisted on repeat imaging. Repeat liver biopsy showed amyloidosis as well as inflammatory changes suggesting AIH/PSC versus rejection. The patient's immunosuppression was modified: sirolimus was replaced with azathioprine, while tacrolimus and low dose prednisone continued. In addition, losartan was started. The patient abstained from further injection drug use. His creatinine improved to 1.57; proteinuria persisted.

Discussion: AA amyloidosis in an immunosuppressed patient with substance use poses diagnostic challenges. In this case, injection drug use seems a likely cause, as renal function improved with self-reported abstinence. However, the liver lesions remain of unclear etiology, and a potential link between AIH/PSC recurrence and AA amyloidosis remains a consideration.

SA-PO799

ADX-097, a Tissue-Targeted Complement Inhibitor for the Treatment of Kidney Diseases: Phase 1 Results in Healthy Participants and Model-Informed Phase 2 Dose Selection

Bernd Jilma,[1] Katherine A. Vernon,[2] Hong Wu,[2] Stefan Wawersik,[2] David Rezendes,[2] Ryan Faucette,[2] Richard Leigh-Pemberton,[2] Justin L. Hay,[3] Christina L. Mayer,[4] Shelia Violette,[2] Jason Campagna.[2] *[1]Medical University of Vienna, Vienna, Austria; [2]Q32 Bio Inc, Waltham, MA; [3]Certara, Radnor, PA; [4]Semivida Research, LLC, Dallas, TX.*

Background: Alternative complement pathway (AP) activation is implicated in the pathogenesis of various autoimmune renal diseases. ADX-097, a C3d mAb – fH_{1-5} fusion protein, was designed to inhibit complement in diseased kidney while avoiding systemic blockade, providing the potential for enhanced activity and safety profile. In preclinical studies, ADX-097 durably inhibited glomerular complement activity and reduced urine protein and sC5b-9 without any impairment of systemic complement. ADX-097 is being evaluated in a Phase 2 renal basket trial in IgA nephropathy, lupus nephritis and complement component 3 glomerulopathy. Here we report results from a Phase 1 study evaluating the safety, pharmacokinetics (PK), and pharmacodynamics (PD) of ADX-097.

Methods: A randomized, double-blind, placebo-controlled study of ADX-097 with single ascending and multiple doses was performed in heathy participants. ADX-097 was administered in single dose cohorts IV at 0.1-30 mg/kg, or SC at 3.75 and 10 mg/kg and in one multiple dose cohort of 450 mg SC QW for 5 doses. Circulating AP activity was measured by Wieslab assay. An exploratory PK/PD model was used to project a dose that maintains circulating drug concentrations in a target range of 0.3 - 3.2 µg/ml, which is associated with maximal tissue pharmacology in preclinical models.

Results: ADX-097 was well tolerated across all dose levels with no clinically significant drug-related safety findings or ADAs observed. ADX-097 demonstrated a robust PK/PD relationship with a systemic AP IC_{50} of 56.3 µg/ml. These data confirmed the in vivo integrity of the fusion protein. PK/PD simulations projected that 450 mg ADX-097 SC QW can attain circulating concentrations in the target range for maximal tissue pharmacology in preclinical models, with a $C_{max,ss}$ ~5-fold below the IC_{50} for systemic AP inhibition.

Conclusions: ADX-097 demonstrated a favorable safety profile and desired PK/PD properties in healthy participants, supporting a Phase 2 dose that is predicted to provide tissue inhibition of complement in glomerular diseases while sparing systemic complement activity.

Pegcetacoplan for Post-transplant Recurrent C3 Glomerulopathy (C3G) or Immune Complex Membranoproliferative Glomerulonephritis (IC-MPGN) in NOBLE: 52-Week Patient Evolution

Anuja Java,[1] Andrew S. Bomback,[2] David Kavanagh,[3] Giuseppe Remuzzi,[4] Gere Sunder-Plassmann,[5] John Kanellis,[6] Erica Daina,[4] Patrick D. Walker,[7] Zhongshen Wang,[8] Zurish Ahmad,[8] Fadi Fakhouri.[9] *[1]Washington University in St Louis School of Medicine, St Louis, MO; [2]Columbia University Irving Medical Center, New York, NY; [3]Newcastle University, Newcastle upon Tyne, United Kingdom; [4]Istituto di Ricerche Farmacologiche Mario Negri, Bergamo, Italy; [5]Medizinische Universitat Wien, Vienna, Austria; [6]Monash Medical Centre, Clayton, VIC, Australia; [7]Arkana Laboratories, Little Rock, AR; [8]Apellis Pharmaceuticals Inc, Waltham, MA; [9]Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland.*

Background: Pegcetacoplan (Peg; targeted C3/C3b inhibitor) may prevent kidney damage in C3G and primary IC-MPGN. NOBLE (NCT04572854) randomized 13 patients with post-transplant recurrent C3G or primary IC-MPGN. At week 12, Peg was well tolerated and showed improvements in histologic, clinical, and biomarker parameters of disease.

Methods: We conducted a post-hoc analysis of 9 NOBLE patients treated with subcutaneous Peg 1080 mg twice weekly plus standard of care for 52 weeks; of these, treatment completers had >80% compliance (n=7).

Results: At week 52, 5/9 (55.6%) patients had reduced C3c staining (p=0.0423 vs baseline). 7/9 (77.8%) had decreased activity score compared to baseline and 2/8 (25%) had absent electron microscopy deposits at week-52 biopsy. Patients with >1 g/g proteinuria at baseline had a median 56.4% decrease in proteinuria (**Table**). 7/9 (77.8%) patients had stable/improved estimated glomerular filtration rate, and 8/9 (88.9%) had both increased serum C3 and decreased sC5b-9. No meningitis cases, graft losses, or deaths were reported. Non-serious rejection episodes were reported for 2/9 (22.2%) patients. 1 patient (11.1%) discontinued for serious adverse event of weight loss.

Conclusions: By inhibiting the breakdown of C3, Peg achieved meaningful histology improvements for 8/9 (88.9%) patients while also improving disease parameters, increasing serum C3, and decreasing plasma sC5b-9. The Phase 3 VALIANT (NCT05067127) trial will further evaluate the safety and efficacy of Peg in patients with native kidney or post-transplant C3G or primary IC-MPGN.

Table. Histological, clinical, and biomarker parameters of disease activity for patients who received 52 weeks of pegcetacoplan

Parameter		Pegcetacoplan Weeks 0–52 (n=9)	Pegcetacoplan Weeks 0-52 Treatment Completers (n=7)
C3c staining intensity on renal biopsy[a]	# of patients with a decrease by ≥2 orders of magnitude compared to baseline, n (%)	5 (55.6) p=0.0423[b]	5 (71.4) p=0.0423[b]
	# of patients with zero staining intensity, n (%)	4 (44.4)	4 (57.1)
Absent EM deposits, n (%)		2 (25.0), n=8[c]	2 (33.3), n=6[c]
Absent podocyte effacement, n (%)		8 (88.9)[d]	6 (85.7)[e]
Histology activity index	# of patients that decreased from baseline, n (%)	7 (77.8)	6 (85.7)
	Score, n/total # pts, n (%)	5 (55.6)	4 (57.1)
	% Change from baseline, median (IQR)	-100 (-100.0, -54.3)	-100 (-100.0, -80.0)
Proteinuria, % change from g/g baseline, median (IQR; n=4)		-56.4 (-84.5, -23.6)	-56.4 (-84.5, -25.8)
Serum C3, % change from baseline, median (IQR)		247.37 (272.98, 314.29)[e]	247.29 (272.98, 314.29)[e]
Plasma sC5b-9, % change from baseline, median (IQR)		-84.2 (-97.8, -48.1)	-84.1 (-97.8, -48.1)
eGFR change from baseline, mL/min/1.73m², median (IQR)		10.0 (-2.0, 26.0)	22.0 (3.0, 27.0)

eGFR, estimated glomerular filtration rate; EM, electron microscopy; IQR, interquartile range; SD, standard deviation.
[a]Study inclusion required ≥2 orders of magnitude in C3c staining.
[b]Analyzed by Cochran-Mantel-Haenszel test.
[c]At baseline, all patients (n=9 for whole group and n=6 for treatment completers; 100%) with available data had EM deposits present.
[d]At baseline, 3/8 (37.5%) patients with available data had absent podocyte effacement.
[e]At baseline, 2/6 (33.3%) patients with available data had absent podocyte effacement.

SA-PO801

Long-Term Safety and Efficacy of Pegcetacoplan in Patients with C3 Glomerulopathy or Primary Immune-Complex Membranoproliferative Glomerulonephritis: The Long-Term VALE Extension Study

Carla M. Nester,[1] María Gema Ariceta Iraola,[2] Anwesha Mukherjee,[3] Li Li,[3] Johan Szamosi,[4] Luis López Lázaro.[4] *[1]University of Iowa, Stead Family Children's Hospital, Iowa City, IA; [2]Universitat Autonoma de Barcelona, Barcelona, Spain; [3]Apellis Pharmaceuticals Inc, Waltham, MA; [4]Swedish Orphan Biovitrum AB, Stockholm, Sweden.*

Background: C3 glomerulopathy (C3G) and primary immune-complex membranoproliferative glomerulonephritis (IC-MPGN) are rare diseases caused by complement overactivation leading to excessive deposition of C3 breakdown products in the kidney, causing inflammation, renal damage, and renal failure. Pegcetacoplan (PEG; C3/C3b inhibitor) blocks overactivation of alternative and classical complement pathway by inhibiting both C3 and C5 convertases (Figure). In the phase 2 trials, PEG demonstrated clinical benefit and was well tolerated. The Phase 3 VALIANT (NCT05067127) trial, in patients with C3G or primary IC-MPGN in native kidney or post-transplant, will further evaluate the safety and efficacy of PEG. Here we describe VALE (NCT05809531), a phase 3 extension study designed to evaluate long-term efficacy and safety of PEG in C3G and primary IC-MPGN.

Methods: Patients ≥12 years old who completed VALIANT through week 52 and achieved clinical benefit will continue to receive twice-weekly doses of PEG for a minimum of approximately 2.5 years. The primary efficacy endpoint is the log-transformed urine protein-to-creatinine ratio vs baseline. Secondary endpoints will evaluate changes in estimated glomerular filtration rate, proteinuria, and patient-reported outcomes, and disease progression defined by a composite clinical outcome. Safety endpoints will assess treatment-emergent adverse events.

Results: Not available.

Conclusions: The VALE extension will assess long-term efficacy and safety of PEG in C3G and primary IC-MPGN.

SA-PO802

Efficacy of Pegcetacoplan in Children with C3 Glomerulopathy

Maria Cristina Mancuso,[1] Antonio Mastrangelo,[1] Letizia Dato,[2] Simona Verdesca,[1] Massimo Cugno,[1] Gianluigi Ardissino.[1] *[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Università del Piemonte Orientale, Novara, Italy.*

Background: C3 glomerulopathy (C3G) is a rare chronic kidney disease caused by a dysregulation of the alternative complement pathway leading to glomerular deposition of complement component 3 (C3) followed by inflammation and tissue damage. Pegcetacoplan is an inhibitor of both C3 and of its active fragment C3b, that can prevent their glomerular deposition. A phase III registration protocol is currently ongoing in patients (adolescents and adults) with C3G, with promising results. Herein we describe our recent experience with Pegcetacoplan in 5 pediatric patients with C3G.

Methods: This retrospective, observational study presents the efficacy and safety of Pegcetacoplan in pediatric patients with biopsy proven C3G over a 12-week treatment period. The drug was administered subcutaneously, twice a week for the first month, then weekly. The primary endpoint was the change in urinary protein-to-urinary creatinine ratio evaluated by the mean of 3 samples collected on different days before each visit at baseline, 8 and 12 weeks. The changes in serum C3, albumine, creatinine and urinary erythrocytes (number/µL) were also evaluated.

Results: Detailed results are shown in Fig.1. Median C3 level increased of more than 600% while proteinuria decreased to 30% of baseline value. Some of the patients with decreased renal function exhibited an improvement of eGFR. No adverse event has been recorded except for some transient discomfort at the injection site.

Conclusions: All our patients showed a rapid over-normalization of the C3 levels, a significant reduction of proteinuria and a significant increase in albuminemia. We think that the present case series, although small and with a short follow up period, may be important to support other physicians to consider this treatment as an opportunity for their C3G patients.

Table 1

Patient	Gender	Age at diagnosis (Yrs)	Age at Peg (Yrs)	C3 (mg/dl)		eGFR (ml/min/1.73m²)		Proteinuria (mg/mg)		sAlbumin (g/dl)		Urinary RBC (n/microL)	
				Wk0	Wk12	Wk0	Wk12	Wk0	Wk12	Wk0	Wk12	Wk0	Wk12
1	M	7.6	12.5	45	364	26	41	7.7	2.8	1.8	3.9	1380	29

SA-PO803

C3 Nephrotic Factor at Diagnosis Is Associated with Better eGFR Preservation in Patients with C3 Glomerulopathy (C3G): Findings from the European Rare Kidney Disease Registry (ERKReg)

Jonas Hofstetter,[1] Marina Vivarelli,[5] Victor Perez-Beltran,[2] Peter J. Conlon,[3] Enrico Vidal,[4] Franz Schaefer.[1] *[1]European Rare Kidney Disease Reference Network, Heidelberg, Germany; [2]Hospital Universitari Vall d'Hebron, Barcelona, Spain; [3]Beaumont Hospital, Dublin, Ireland; [4]Azienda Ospedale Universita Padova, Padova, Italy; [5]Ospedale Pediatrico Bambino Gesu, Roma, Italy.*

Background: C3G and ic-MPGN are complement-mediated rare kidney disorders with variable responsiveness to standard immunosuppressive protocols. Information regarding biomarkers of therapeutic responsiveness is scarce. ERKReg, a longitudinal pan-European registry for rare kidney diseases is currently following >9,000 patients with rare glomerulopathies, including 484 patients with C3G/ic-MPGN. We assessed the database for risk factors associated with a progressive disease course.

Methods: Retrospective diagnostic and prospective follow-up information was extracted from a total of 208 C3G/ic-MPGN patients enrolled in ERKReg between 10/2018 and 05/2024, most commonly (84%) as prevalent patients with a median (IQR) total disease duration of 5.8 (2.9; 9.3) years. Serum C3NeF at time of diagnosis was available for 55 C3G patients (cohort 1) and serum C3 for 146 C3G and 62 ic-MPGN patients (cohort 2). Multivariable, linear mixed-effects models were fitted to longitudinal eGFR adjusted for sex, eGFR and age at first visit (baseline), hypertension and RASi therapy for each cohort to investigate whether C3NeF status and/or serum C3 levels at diagnosis were associated with prospective eGFR change.

Results: Disease onset was observed at childhood age in 77%. Prospective observation time accounted for a median of 21% (0%; 52%) of total disease duration. eGFR at baseline was 103 (66;127) ml/min/1.73m². Systolic hypertension was documented in 21% and RASi therapy in 69% of visits. In cohort 1, eGFR improved with time in C3G patients positive for C3NeF at diagnosis (ß=1.1, p =0.039) whereas C3NeF-negative patients exhibited a negative eGFR slope (ß=-3.9, p <0.01). In cohort 2, low vs. normal C3 levels at time of diagnosis tended to associate with improved eGFR preservation ($ß^{\Delta}$=2.69, p = 0.078). Among the potential confounder variables accounted for in the models, adult age at baseline had a distinct negative association with eGFR over time in both cohorts.

Conclusions: In patients with C3G undergoing standard-of-care management in the past 5 years, the detection of C3NeF at time of diagnosis was associated with better kidney function. We speculate that C3NeF identifies a subset of patients with greater sensitivity to standard immunosuppressive therapies.

SA-PO804

Real-World Effectiveness of Ravulizumab among C5 Inhibitor-Naive Patients with Atypical Hemolytic Uremic Syndrome (aHUS): A Physician Panel-Based Chart Review Study (aHUS IMPACT)

Ramy M. Hanna,[1] Shruti Chaturvedi,[2] Moh-Lim Ong,[3] Dr. Arpita Nag,[3] Rui Song,[4] Lynn Huynh,[4] Jordan Burdeau,[4] Mei Sheng Duh,[4] Yan Wang.[3] *[1]University of California, Irvine, CA; [2]John Hopkins University, Baltimore, MD; [3]Alexion, AstraZeneca Rare Disease, Boston, MA; [4]Analysis Group, Inc., Boston, MA.*

Background: aHUS is a rare disease and form of thrombotic microangiopathy (TMA) caused by complement dysregulation. Ravulizumab (RAV; a C5 inhibitor [C5i]) is approved for aHUS based on registrational clinical studies, but real-world evidence is limited.

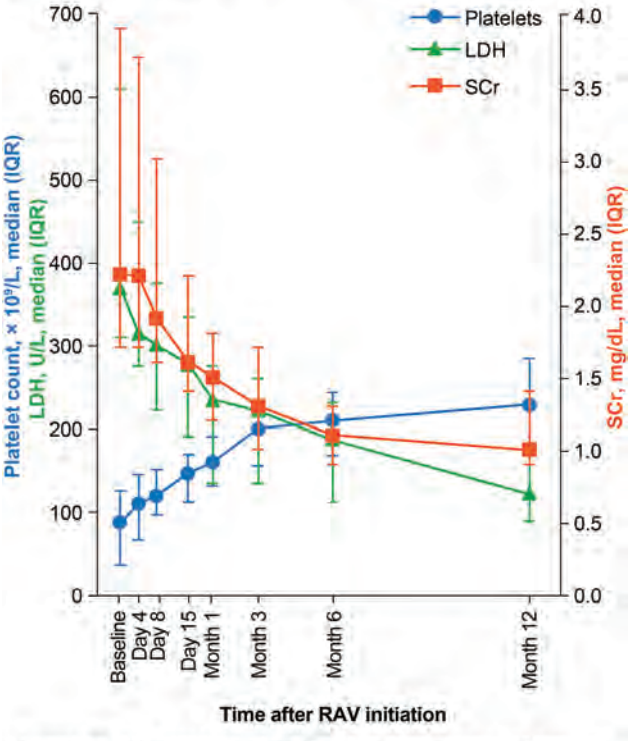
Methods: This was a retrospective, longitudinal, physician panel-based chart review of C5i-naive patients (pts) in the USA treated with RAV. Physicians with medical and laboratory records for ≥1 pt with aHUS randomly selected 1–5 pts with aHUS who had ≥6 months of medical records after RAV initiation, unless the pt died.

Results: Overall, 79 C5i-naive pts with aHUS (enrolled by 31 physicians) initiated RAV. Median (IQR) pt age at RAV initiation was 44 (27–54) years; 3 pts (4%) had a kidney transplant before RAV initiation and 20 (25%) received dialysis 12 months before to ≤2 weeks after RAV initiation. Laboratory parameters over time are shown in the **Figure**. Statistically significant changes from baseline occurred as early as Day 4 (LDH and percent change in serum creatinine [SCr]; both $p<0.001$) and Day 8 (platelet count, $p<0.001$). The proportions of pts with normalization of platelets, LDH and ≥25% improvement in SCr were 19/59 (32%), 17/51 (33%) and 19/58 (33%) at Day 8 and 40/48 (83%), 35/38 (92%) and 42/48 (88%) within 12 months after RAV initiation. Complete TMA response rates were 61% and 70% within 6 and 12 months after RAV initiation, respectively, and the median (IQR) time to complete TMA response was 3 months (1–13).

Conclusions: This study supports the immediate and sustained benefits of initiating with RAV in pts with aHUS as seen by the early response and continued improvement.

Funding: Commercial Support - Alexion, AstraZeneca Rare Disease.

Figure. Platelet count, LDH and SCr from baseline to Month 12 after RAV treatment.



Complete TMA response was defined as normalization of platelet count (≥ 150 × 10⁹/L), normalization of LDH (≤ 246 U/L) and ≥ 25% improvement in SCr.
IQR, interquartile range; LDH, lactate dehydrogenase; RAV, ravulizumab; SCr, serum creatinine; TMA, thrombotic microangiopathy.

Safety and Effectiveness of Switching to Ravulizumab from Eculizumab in Kidney Transplant Recipients with Atypical Hemolytic Uremic Syndrome: A Global Registry Analysis

Anja H. Gaeckler,[1] Imad Al-Dakkak,[2] Nuria Saval,[2] Hans H. Dieperink,[3] Margriet Eygenraam,[7] Larry A. Greenbaum,[4] Nicole Isbel,[5] Johan Vande Walle.[6] *[1]University Hospital Essen, University Duisburg-Essen, Essen, Germany; [2]Alexion, AstraZeneca Rare Disease, Boston, MA; [3]Odense University Hospital, Odense, Denmark; [4]Emory University School of Medicine and Children's Healthcare of Atlanta, Atlanta, GA; [5]The University of Queensland and Princess Alexandra Hospital, Brisbane, QLD, Australia; [6]Ghent University Hospital, Gent, Belgium; [7]aHUS Canada, Brampton, Brampton, ON, Canada.*

Background: Atypical hemolytic uremic syndrome (aHUS) is a disease of complement dysregulation that causes kidney failure and has a propensity to recur after kidney transplant (KTx) with graft loss. Ravulizumab (RAV) and eculizumab (ECU) are

C5 inhibitors approved for the treatment of aHUS. We assessed the real-world safety and effectiveness of switching from ECU to RAV in KTx recipients with aHUS for immediate, complete, and sustained terminal complement inhibition.

Methods: The Global aHUS Registry is a multicenter study (NCT01522183) enrolling patients (pts) with aHUS since 2012. Safety and effectiveness outcomes were assessed in KTx recipients with aHUS who switched from ECU to RAV up to April 22, 2024. Safety analyses included pts with a KTx before RAV initiation; pt characteristic and effectiveness analyses included KTx recipients who received RAV for ≥3 months and had ≤1 month between ECU discontinuation and RAV initiation.

Results: Overall, 29 pts (25 adults) were included in safety analyses; 21 adverse events (AEs) were reported in 15 pts at or after RAV initiation, and none were unexpected. During RAV treatment, no new AEs of thrombotic microangiopathy or kidney impairment, and no meningococcal infections or deaths were reported. Among 21 pts (20 adults) included in the pt characteristic and effectiveness analyses, median (range) age at RAV initiation was 35 (11–72) years, and 67% had a reported pathogenic complement variant or anti-complement factor H antibodies. Median (range) time on treatment was 66 (4–158) months for ECU and 24 (5–43) months for RAV; median (range) time from last KTx to RAV initiation was 56 (4–184) months. Mean (standard deviation) estimated glomerular filtration rate was 50 (25) mL/min/1.73m^2 at last record before or at RAV initiation and 50 (28) mL/min/1.73m^2 at last follow-up after RAV initiation. Among 29 KTx events in these 21 pts, no rejections or graft failures were reported after RAV initiation.

Conclusions: This analysis from the Global aHUS Registry provides real-world evidence of the successful transition from ECU to RAV in KTx recipients with aHUS, with stable kidney function and no unexpected safety concerns.

SA-PO806

Design of an Observational, Longitudinal Data Platform of Patients with C3 Glomerulopathy (C3G) and Idiopathic Immune-Complex Membranoproliferative Glomerulonephritis (IC-MPGN) in the United States

Ali Poyan-Mehr,[1] Rahul Khairnar,[2] Anirban Bose,[2] Jackson Tang,[3] Claire Buchan,[3] Tayler Buchan,[3] Briana C. Ndife.[2] *[1]The Permanente Medical Group Inc, San Francisco, CA; [2]Novartis Pharmaceuticals Corporation, East Hanover, NJ; [3]Asclepius Analytics, New York, NY.*

Background: C3G and IC-MPGN are rare renal diseases characterized by overactivation of the complement system. The absence of a comprehensive United States (US) real-world data (RWD) platform for these diseases limits our understanding of the challenges faced by patients (pts) and their healthcare providers. Here, we describe the development of a national RWD platform to capture, harmonize, and report comprehensive information for pts with C3G and idiopathic IC-MPGN.

Methods: This living data platform will include longitudinal data from prospective and retrospective cohorts of US-based pts of all ages with a diagnosis of C3G or idiopathic IC-MPGN, compiled using coordinated recruitment strategies. Site-based recruitment in collaboration with The GlomCon Foundation (a non-profit consortium of medical centers, clinicians, and pathologists overcoming challenges in glomerular disease through research partnerships) will generate retrospective and prospective cohorts of harmonized patient-level data from various single-center cohorts and patient registries. A patient cohort will also be generated from data collected via retrospective chart review. Variables collected will include demographic and clinical characteristics, comorbidities, biopsy findings, genetic studies, treatment patterns, genetic testing, laboratory values, and key outcomes of interest, including dialysis, transplant, and kidney failure. A data model will harmonize retrospective cohorts for pooled analyses. In a patient-centric recruitment approach, we will complement these center-specific, patient-level data with patient-reported outcomes, including the Functional Assessment of Chronic Illness Therapy–Fatigue *Scale and the EuroQol-5D* Measure of Health-Related Quality of Life.

Results: The site and patient recruitment are ongoing. The first analyses from this data platform are anticipated in 2025.

Conclusions: The development of an RWD platform for pts with C3G and idiopathic IC-MPGN will improve our understanding of the epidemiology, clinical burden, and determinants of clinical outcomes in these rare diseases, across a geographically diverse population in multiple centers and healthcare settings.

SA-PO807

Proteinuria as a Surrogate Predictor of Kidney Failure in Both C3 Glomerulopathy and Primary Immune-Complex Membranoproliferative Glomerulonephritis

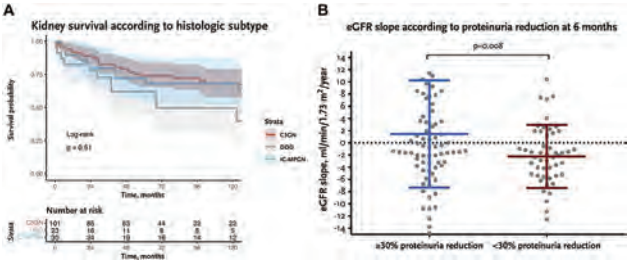
Fernando Caravaca-Fontan,[1] Manuel Praga.[2] GLOSEN Group. *[1]Instituto de Investigacion Hospital 12 de Octubre, Madrid, Spain; [2]Universidad Complutense de Madrid, Madrid, Spain.*

Background: C3 glomerulopathy (C3G) and primary immune complex membranoproliferative glomerulonephritis (IC-MPGN) are rare glomerular diseases sharing similar etiology and pathogenesis. While some studies have shown association between changes in proteinuria and kidney outcomes in C3G, the prognostic significance of proteinuria changes in IC-MPGN remains largely unexplored.

Methods: Multicenter, retrospective cohort study in 37 nephrology departments belonging to GLOSEN group. All patients fulfilling diagnostic criteria of C3G were included, and secondary causes of IC-MPGN were carefully ruled out. A joint modelling of linear mixed-effects models was applied to assess the underlying trajectory of a repeatedly measured proteinuria at 0,1,3,6,12,24,60 or last follow-up, and a Cox model to evaluate the association with the risk of kidney failure.

Results: The study group consisted of 154 patients: 124 with C3G (81%) and 30 IC-MPGN (19%), with a mean age of 33±17 years. Median baseline eGFR was 55 ml/min/1.73m^2 (IQR 24–106) and proteinuria 3 g/day (IQR 1.7–6). No significant clinical or histologic baseline differences were observed across groups. During a median follow-up of 65 months (IQR 30–123), 55 patients (36%) reached kidney failure, without differences between groups. The longitudinal change in proteinuria exhibited a robust association with this outcome, where each 1g/day increase was linked to a 3.4-fold rise in the risk. A ≥30% proteinuria reduction over time was associated with a lower risk of kidney failure (HR 0.97; 95% CI 0.94–0.99; p<0.001), as was a ≥50% proteinuria reduction over time (HR 0.92; 95% CI 0.85–0.95; p<0.001). Results were consistent in both C3G and IC-MPGN. A ≥30% proteinuria at 6 months or a ≥50% proteinuria reduction at 12 months were associated with a slower eGFR decline over time. These results were also confirmed in patients aged >12 years at baseline, eGFR ≥30 ml/min/1.73m^2 and proteinuria ≥1g/day at baseline.

Conclusions: Proteinuria reduction is associated with improved kidney outcomes in both C3G and primary IC-MPGN.



SA-PO808

Analytic Performance of MicroVue Enzyme Immunoassay (EIA) for Measurement of Ba and sC5b-9 for Urine

Cameron Droste, Eric Gorzkowski, Manuel Galvan. *National Jewish Health, Denver, CO.*

Background: Complement mediated kidney diseases, including C3 glomerulopathy (C3G), atypical hemolytic uremic syndrome (aHUS), lupus nephritis (LN), and immunoglobulin A nephropathy (IgAN) are chronic inflammatory conditions characterized by dysregulated complement activation. Traditionally, complement activation is measured in plasma. However, patients with kidney disease often have an abundance of complement activation fragments in their urine – including Ba and soluble C5b-9 (sC5b-9), markers of alternative pathway activation and terminal pathway activation respectively– highlighting the potential value of Ba and sC5b-9 measurement in urine for diagnosis and risk management in patients with C3G, aHUS, LN, IgAN, and other kidney diseases. Herein we evaluated the analytical performance of the Quidel MicroVue Plus EIA Ba and sC5b-9 for urine samples.

Methods: The Quidel MicroVue Ba and sC5b-9 Plus EIA were evaluated using randomly collected healthy urine samples or healthy urine samples spiked with a known concentrations of Ba and sC5b-9, as well as chronic kidney disease (CKD) urine samples.

Results: The analytical performance of the assays met acceptability criteria for accuracy and precision. Assay accuracy was (100 ± 20%) and intra-assay precision as well as inter-assay precision was ≤ 20 % coefficient of variability (CV) for both assays. Ba was detected in healthy urine samples (N=40), but sC5b9 was not. Positive linearity was observed in both assays over a wide range of concentrations. Ba and sC5b-9 measured in urine was stable following three freeze-thaw cycles. Lastly, Ba and sC5b-9 measured in urine was stable when stored at -20°C and -80°C for 4 weeks. Long term stability testing at -80°C is underway.

Conclusions: Quidel MicroVue Ba and sC5b-9 Plus EIA are accurate, and reliable assays for detection of Ba and sC5b-9 in urine samples, making it a viable alternatibe to plasma.

Accuracy and Precision

Retrospective Analysis of Membranoproliferative Glomerulonephritis and C3 Behavior in a Large Brazilian Center

Liliana M. Kassar, Karoline W. Silva, Felipe Carvalho Barros Sousa, Vinícius S. Silveira, José Guilherme R. Gonçalves, Viktoria Woronik, Luis Yu, Cristiane B. Dias, Lectícia Jorge. *Hospital das Clinicas da Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil*.

Background: Membranoproliferative glomerulonephritis (MPGN) is a disease pattern on kidney biopsy that comprises a series of different diagnostic possibilities. Clinical evaluation and laboratory workup are essential steps on the investigation, although renal biopsy is still mandatory on classification between immunocomplex associated MPGN and C3 glomerulopathy. This study aims to describe the profile of MPGN patients in a large center in Brazil.

Methods: Patients with MPGN pattern on kidney biopsy from June 1999 to December 2023 were included. Variables of interest were age, gender, creatinine, estimated glomerular filtration rate (eGFR) by CKD-EPI, proteinuria, intensity of C3 staining on immunofluorescence and serum C3 levels on admission and after 1 year follow-up.

Results: A total of 136 renal biopsies were performed on the studied period, 65% of patients were male, 72% white, 46% had hypertension. Mean age was 46 years old (±16), median creatinine 1.8 mg/dL (0.6-15.8) with median eGFR 40 mL/min (4-135), serum albumin 2,7 g/dL (1-4.5), proteinuria 4.6 g (0.1-20.1), 79% hematuria, serum C3 levels 84 (± 39) on diagnosis and 90 (± 34) after a year follow-up. In our cohort 10% of the patients had schistosomiasis, 13% hepatitis C, 4% hepatitis B, 4% HIV and 9% had a paraprotein on immunofixation tests. There was no correlation between C3 levels and initial creatinine and proteinuria, however lower C3 levels were associated with a stronger C3 staining on kidney biopsy (p 0.016) on Kruskal-Wallis test. Additionally, a serum C3 < 80 was not associated with specific biopsy patterns (p 0.25) and immunosuppressive treatment was not an influencing factor on the rise of serum C3.

Conclusions: Complement activation is a part of the physiopathological pathway on GNMP, therefore lower serum C3 was observed in patients with stronger C3 staining on kidney tissue showing the association with a higher activation on kidney tissue. Although GNMP can be classified between immunocomplex mediated and C3 glomerulopathy, serum complement levels were not able to identify those patterns.

SA-PO810

Long-Term Prognosis after Kidney Transplantation in Patients with Membranoproliferative Glomerulonephritis

Rune Bjoerneklett, Lars S. Bostad, Thomas Knoop, Leif H. Bostad. *Department of Clinical Medicine, University of Bergen, Bergen, Norway*.

Background: Membranoproliferative glomerulonephritis (MPGN) is a distinctive light microscopic damage pattern caused by a wide variety of disease states. About 50% of patients with MPGN progress to end-stage kidney disease (ESKD) and kidney transplantation (KTX) is the preferred treatment. However, recurrence of MPGN in KTX with subsequent graft loss (GL) is a known risk. The prognosis after KTX for patients with MPGN in Norway has not previously been systematically examined. We have therefore analysed the risk of GL in patients with MPGN who have undergone KTX.

Methods: Cases of biopsy-verified MPGN in the period 1991-2012 were identified in Norwegian kidney biopsy registry. The cohort was linked to the Norwegian Kidney Registry, and patients who had received KTX as well as the course after transplantation until May 2024 were identified. GL and death with functioning kidney transplant (DFG) are reported separately. We also analysed risk of GL stratified for C1q +/- in the kidney biopsy, as an indicator of immune complex-MPGN.

Results: We identified 60 patients who had received at least 1 KTX during the course of MPGN. Among these 60, there were 19 cases of GL, 11 of these <5 years after KTX. Furthermore, there were 17 cases of DFG. The average function time for the remaining 24 functioning KTXs was 14.5 years (SD 9). 15 patients were transplanted at least 2 times. Among these, there were 7 cases of GL, 6 of these after <5 years after KTX 2 and 3 cases of DFG. The average function time for the remaining 5 functioning KTX 2 was 6.3 years (SD 5). 4 patients were transplanted 3 times. Among this 1 case of GL, after <5 years. No cases of DFG. The average function time for the remaining 3 KTX 3 was 8.5 years (SD 4). 33 biopsies were C1q positive, this was not associated with risk of GL.

Conclusions: As expected, there were relatively many GL and frequent need for re-transplantations in this cohort of patients with KTX due to MPGN. However, the majority of patients, 52 out of 60, as of May 2024 have functioning KTX or they died with functioning KTX. Følsomhet Intern (gul) Unfortunately, the registry data do not have information about the etiology of MPGN and the causes of GL. This will be further investigated using biopsy material and medical record information.

Long-Term Risk and Risk Factors for ESKD in Membranoproliferative Glomerulonephritis

Rune Bjoerneklett, Lars S. Bostad, Thomas Knoop, Leif H. Bostad. *Department of Clinical Medicine, University of Bergen, Bergen, Norway*.

Background: Membranoproliferative glomerulonephritis (MPGN) is a distinctive light microscopic injury pattern caused by a wide range of different disease conditions. The classification of MPGN has changed over time, it is now common to divide MPGN caused by immune complexes (IC-MPGN) and MPGN caused by dysregulation of the alternative activation pathway in the complement system, complement C3 nephropathy (C3G). The utility of division by IC-MPGN/C3G versus etiological division for diagnosis, treatment, and prognosis, however, is still uncertain. There is a need for more information about the long-term prognosis of MPGN, including risk factors for progression to end-stage kidney disease (ESKD). We have therefore analyzed the risk of ESKD for patients with MPGN registered in the Norwegian Kidney Biopsy registry (NKBR) in the period 1991-2012.

Methods: Cases of biopsy-verified MPGN 1991-2012 including demographic, clinical, laboratory, and histological variables at the time of diagnosis were retrieved from NKBR. Cases of MPGN due to SLE and thrombotic microangiopathy were excluded. The cohort was linked with the Norwegian Kidney Registry for identification of patients with ESKD by May 1, 2014

Results: We identified 158 patients with biopsy-verified MPGN. Male; 85 (54%), age; 47 years (SD 23), systolic BP; 151mmHg (SD 28), diastolic BP; 86 mmHg (SD 16), hypertension; 155 (67%), mean eGFR; 50 ml/min/1.73m2 (SD 35), eGFR<15; 18 (11%), eGFR 15-29; 26 (16%), eGFR 30-59; 49 (31%), s-albumin 28 g/l (SD 7), proteinuria 5.6 g/24h (SD 3.4), nephrotic syndrome; 79 (50%), crescents; 28 (18%), tubulointerstitial fibrosis >50%; 77 (49%) and C1q positive; 111 (70%). During an average observation period of 11 years, 61 (39%) of patients progressed to ESKD. 45 (28%) of the patients died, without ESKD. Cumulative risk for ESKD after 5/10/15/25 y; 25%/37%/43%/48%. A low eGFR was the only significant risk factor of ESKD, 42 vs 55, p=0.03.

Conclusions: A cumulative long-term risk for ESKD in patients with MPGN of around 50% corresponds well with previously published studies. The registry data unfortunately does not allow precise classification by IC-MPGN/C3N. C1q positivity is, however, indicative of IC-MPGN and in this study not a significant prognostic factor.

C3 Glomerulopathy: A Pediatric and Adult Case Series in New Mexico

Paul B. Avila,[1] Namita Singh,[2] Amy Staples,[2] Darren W. Schmidt,[2] Pablo Garcia.[2] *[1]Universidad de San Carlos de Guatemala, Ciudad de Guatemala, Guatemala; [2]University of New Mexico Health Sciences Center, Albuquerque, NM.*

Introduction: C3 glomerulopathy (C3GN) results from alternative complement pathway dysregulation. C3G manifests with proteinuria, decreased kidney function, and low serum C3 levels. Therapeutic options are limited. Improving diagnostic criteria and treatment strategies is essential for better outcomes in C3GN. Here, we report a case series of five cases in our pediatric and young adult population of C3GN with long term follow up in New Mexico.

Case Description: Five patients, aged 8 to 15 years, were diagnosed with C3GN based on kidney biopsy findings or clinical presentation and genetics. All were treated with C5 inhibitor therapy (C5IT), with two receiving additional immunosuppressive therapy (IST) and three undergoing PLEX therapy. Details of each case are summarized in table 1. During C5IT treatment lasting 1 to 9 years, 4 patients showed kidney function improvement. Three patients experienced reduced proteinuria (urine protein-to-creatinine ratio, UPCR), with those initially presenting with lower eGFR and higher C3 levels responding better. Two patients achieved complete remission (UPCR <0.3 g/g), and four showed significant improvement in eGFR post-treatment.

Discussion: In this case series, C3G treated with C5IT showed positive results regarding kidney function. The effect of C5IT on proteinuria reduction was not clear. The role of PLEX in pediatric cases is promising. Two achieved complete remission (UPCR <0.3 g/g). These findings support C5IT as a promising therapy for C3GN. Larger multicenter studies in pediatric and young adult populations are needed. Furthermore, novel therapies are needed to improve outcomes as the degree of proteinuria could correlate with disease activity.

Pt.	Age at Diagnosis (y)	Follow-up (y)	Sex	Cr. at Diagnosis	UPCR at Diagnosis (g/g)	Hx	Genetic Abnormalities	Serum C3 Level (mg/dl)	eGFR at Diagnosis	GS/IFTA	PLEX	IST	C5IT Duration (y)	UPCR on Follow-Up (g/g)	eGFR on Follow-Up
1	8	11.9	F	0.4	5.1	+	Yes	8	107.6	None/<5%	No	P, MMF, T	8	0.06	48
2	13	9.5	F	0.56	4.8	+	Yes	9	122	None/<10% (initial MPGN type 1 C3 3+)	No	P, MMF, T	7.3	0.4	147

Novel Therapy for Recurrent Dense Deposit Disease in an Adolescent Kidney Transplant Recipient

Khaing S. Wei,[1] Carla M. Nester,[2] Nasir Khan.[1] *[1]University of Arkansas System, Little Rock, AR; [2]University of Iowa Health Care, Iowa City, IA.*

Introduction: Dense deposit disease (DDD) is a rare C3 glomerulopathy caused either by genetic or acquired drivers of overactivation of the alternative complement pathway. It most frequently affects children and young adults, and 50% progress to ESKD within 10 yrs of diagnosis. It poses a significant challenge in post-kidney transplant care due to high recurrence rates associated with allograft failure. To date, no specific targeted interventions have consistently improved outcomes for either primary or recurrent C3G. We present a compelling case of early recurrent DDD in a renal transplant adolescent recipient managed with Iptacopan, an oral complement factor B inhibitor.

Case Description: A 19-year-old Caucasian female diagnosed with hypocomplementemic DDD at the age of 6. Disease was associated with high titer nephritic factors and normal genetic studies. She was initially treated with cyclosporine and later switched to tacrolimus (Tac). Persistent proteinuria with UPCR15mg/mg led to a switch to mycophenolate (MMF). Her renal function progressively declined necessitating PD dependence for ESKD at age 14. She underwent DDKT 1.5 months before turning 19. She received ATG and prednisone taper for induction and post-transplant immunosuppressants, including Tac, MMF and prednisone. She suffered primary allograft dysfunction necessitating HD on post-op day 4. An allograft biopsy was performed 1 week postoperatively, which showed recurrent DDD and was negative for acute rejection. The patient was started on Iptacopan 200 mg BID on day 26th post-transplant. Prior to Iptacopan, her C3 was 8, C5 was 8.7, FB was 18.7, soluble C5b-9 was 0.69. 3 days after Iptacopan, C3 increased to 90, C5 to 19.9, FB to 24. C5b-9 decreased to 0.12. After 1 week, C3 increased to 111 and creatinine decreased from 2.6 to 1.8 mg/dl and proteinuria decreased.

Discussion: Iptacopan is an oral, first-in-class and selective inhibitor of factor B, a key component of the alternative pathway. In our patient, after failed conventional treatments, leading to a quick recurrence of disease in the allograft. Iptacopan lead to a significant clinical and biochemical remission of disease. Our case highlights the possibility that this aggressive renal disease is salvable even in the transplant settings by using a targeted treatment approach and further supplements the clinical trial results from native kidney C3G.

SA-PO814

C3 Glomerulonephritis in a Child with Elevated Anti-streptolysin O (ASO) Titer

Jessica M. Rosario-Falero,[1] Ihor V. Yosypiv.[2] *[1]Louisiana State University, Baton Rouge, LA; [2]Tulane University School of Medicine, New Orleans, LA.*

Introduction: C3 glomerulopathy in children is rare with an estimated incidence of 1-4 cases per million population. Most children with C3 glomerulopathy have C3 glomerulonephritis (C3GN). C3GN carries a poor kidney prognosis, with a median time to kidney failure of around 10 years from diagnosis. We report the case of a pediatric patient presenting with features of acute glomerulonephritis (GN) and elevated ASO titer who was promptly diagnosed with C3GN.

Case Description: A previously healthy 14 y.o. male presented to his pediatrician with dark urine color, facial and lower extremity swelling, and headache for 3 days. Family history was non-contributory. Blood pressure was elevated. Laboratory workup showed unremarkable CBC, normal creatinine-based eGFR of 105 ml/min/1.73m2, serum albumin 3.0 mg/dL, normal C4 and reduced C3 (23 mg/dL; ref. range 80-173) complement levels, elevated ASO titer (563 IU/ml; ref. range <350), normal CRP and ESR. Urinalysis had 2+ protein, 3+ blood, 51-99 WBC, >100 RBC and spot protein/creatinine ratio 4.0 mg/mg. Physical exam on admission showed BP at stage 2 hypertension level, mild facial and 2+ pitting edema in lower extremities, and mild ascites. Although presentation was consistent with acute postinfectious GN (APIGN), presence of nephrotic range proteinuria prompted us to perform renal biopsy on admission. Histology showed 4+ staining for C3, +/-peripheral granular staining for C1q, +/- mesangial granular staining for IgM, with no staining for IgG or IgA. EM showed endothelial swelling occluding glomerular capillary lumens, subendothelial electron dense deposits, basement membrane reduplication and extensive foot process fusion. Diagnosis of C3GN was made. Expanded infectious workup was negative. Complement studies showed: normal Factor H auto-antibody, negative *C3*, *CD46*, *CFB*, *CFD*, *CFH*, *CFHR2*, *CFHR5*, *CFI* gene sequence panel and positive C3 Nephritic factor of 13.5 (ref. range 0.0 unit/ml). Therapy with mycophenolate mofetil, oral prednisone and lisinopril was initiated.

Discussion: This case emphasizes the need to consider C3GN in a child presenting with findings consistent with APIGN. As therapies of APIGN and C3GN differ, establishing correct diagnosis promptly is critical. In this case, timely performance of kidney biopsy established correct diagnosis, enabled to initiate in-depth evaluation of alternative complement pathway (ACP) and targeted therapy.

SA-PO815

Complement Chaos: A Perplexing Case of C3G and Seminoma in a Young Man

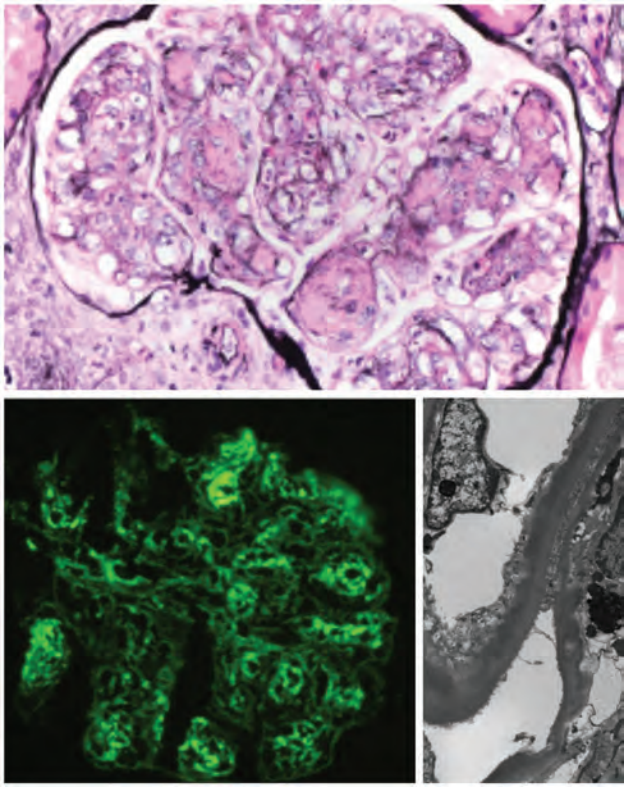
Saud A. Alsaleh, Yihan Wang, Neil S. Sanghani. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: C3G represents a spectrum of glomerular diseases characterized by dysregulation of the alternative complement pathway. Concurrent presentation of solid tumors and C3GN is rare and yet to be reported. Here we present a case of C3G with partial resolution after radical orchiectomy of a seminoma, highlighting the novel interplay between testicular malignancy and complement-mediated injury.

Case Description: A 38-year-old male presented with testicular swelling, severe hypertension, and renal dysfunction. Further evaluation revealed a testicular mass, elevated b-HCG, and histological changes suggestive of C3GN on renal biopsy. Work up for plasma cell dyscrasias and C3 Nephritic factor were unrevealing however, genetic testing revealed a heterozygous mutation in the CFH gene. Following radical orchiectomy for seminoma, renal function showed partial improvement. After initiation of mycophenolic acid and steroids, renal function and proteinuria continued to improve with normalization of C3 levels.

Discussion: In addition to genetic mutations and autoantibodies, this case suggests a potential link between testicular seminoma and C3G. The interplay between testicular seminoma, CFH gene mutation, and complement activation may have contributed to renal dysfunction. Resection of the seminoma, combined with immunomodulatory therapy, likely mitigated immune dysregulation and led to the resolution of renal dysfunction. This highlights the need to consider malignancy as a potential trigger for complement-mediated renal injury in patients with C3G, warranting further investigation into the underlying mechanisms and optimal therapeutic strategies.

Test	Initial evaluation	Post-Orchiectomy	6 months of IS therapy
Cr (mg/dl)	3.6	2.1	1.4
C3 (mg/dl)	N/A	69	143
Urine Protein-Cr ratio (mg/mg)	N/A	7.2	3.6



SA-PO816

C3 Glomerulonephritis and Neuromyelitis Optica in a Patient with Systemic Lupus Erythematosus (SLE)/Sjogren Overlap Syndrome

Vijaya Chelikani, Frida Rosenblum, Arun Rajasekaran. *The University of Alabama at Birmingham, Birmingham, AL.*

Introduction: C3 glomerulopathy (C3G) that includes dense deposit disease (DDD) and C3 glomerulonephritis (C3GN) are rare glomerular disorders triggered by dysregulation of the alternative complement pathway with an estimated incidence of 2-3 cases per million. We describe a rare case of C3GN and neuromyelitis optica in a patient with known SLE/Sjogren overlap syndrome.

Case Description: 51-year-old African-American female with SLE/Sjogren overlap syndrome presented with proteinuric AKI on CKD and newly diagnosed transverse myelitis. Baseline Cr 0.8 mg/dL. Labs on admission: Cr 1.7 mg/dL, Sr albumin 2.8 g/dL, UPCR 5511 mg/g, urinalysis revealed acanthocytes. C3 152, C4 38, ANA 1:320 [speckled], ds-DNA (-), SSA > 150, SSB 106, NMO/AQP4 (+) at 1:10000. Rest of serological workup negative. No e/o infection. Kidney USG unremarkable. Kidney biopsy - LM: 35 glomeruli, no segmental or global sclerosis. Glomeruli normal, no endocapillary hypercellularity noted. IFTA <5%. Mild to moderate arterial and arteriolar sclerosis. IF: Fine granular reactivity for C3 [3+] along capillaries and in mesangium that are chunky. Rest of immunoreactants negative. Pronase IF negative. EM: Few scattered medium to large-sized electron dense deposits present in the mesangium and paramesangial area. Alternative complement pathway functional panel revealed low APFA and Fb levels and elevated C5 levels. C3GN genetic panel revealed a VUS in the THBD and MPLA gene. Patient received repeated doses of rituximab and has attained complete remission of proteinuria and resolution of AKI.

Discussion: C3GN affecting younger patients usually are mediated by genetic abnormalities of the alternative complement pathway. In addition to renal manifestations, a number of other extra-renal manifestations have also been associated with C3G including retinal involvement [drusen] and lipodystrophy, particularly in DDD. To date, concomitant NMO (+) transverse myelitis presenting concomitantly with C3GN has not been described. It remains unclear if the C3G-dominant immune complex-mediated glomerulonephritis was precipitated by the underlying SLE/Sjogren overlap syndrome.

SA-PO817

Possible Link between C3 Glomerulonephropathy and Ulcerative Colitis

Sean P. Mahoney, John Anaya, Aldo E. Torres Ortiz. *Tulane University School of Medicine, New Orleans, LA.*

Introduction: C3 glomerulopathies include both C3 glomerulonephritis (C3GN) and Dense Deposit Disease (DDD). These rare diseases occur from dysregulation of the complement pathway causing C3 deposits in the glomerular basement membrane without immunoglobulins (such as IgG).

Case Description: A 74 year old male with a past medical history of hypertension and ulcerative colitis (UC), with dialysis-dependent AKI on CKD due to colitis flare two months prior, presented with symptomatic COVID pneumonia. The AKI from the recent admission was attributed to a pre-renal state secondary to diarrhea. Further chart review determined that the patient was admitted with creatinine of 1.5, 300mg/dL of proteinuria, and hematuria before dialysis was initiated. During his time with us, the patient failed to show any signs of renal recovery. Workup revealed positive “atypical ANCA,” common in UC. Given suspicion for a glomerulonephritis, a renal biopsy was performed that showed focal proliferative necrotizing glomerulonephritis with no chronicity and C3 deposition with minimal IgG deposits, suggesting C3 Glomerulopathy. Additional tests included persistently low C3 and negative C3 nephritic factor, but genetic testing showed multiple complement pathway abnormalities including a likely pathogenic heterozygous complement Factor B variant.

Discussion: The main differential for our patient was infection-related GN. However, given lack of other immunoglobulins on biopsy and little evidence for infection, the diagnosis was more consistent with C3 glomerulopathy. Risk factors for C3 glomerulopathy have been difficult to identify. Inflammatory bowel disease (IBD) has been linked, and complement factor B gene mutations have previously been tied to familial C3GN. Furthermore, the link between the complement system and IBD has been theorized before. We surmise that C3 glomerulopathy should be considered in patients with renal failure and a history of inflammatory bowel disease, and genetic testing along with biopsy should be employed as part of the workup to help guide diagnosis, treatment, and further research. C3 glomerulopathy is a serious kidney pathology with poor prognosis, especially with late diagnosis. Multiple case studies of patients with IBD and the disease exist, and its association with complement Factor B abnormalities suggest unique associations that may lead to diagnostic or therapeutic breakthroughs.

SA-PO818

Mesoamerican Nephropathy and C3 Glomerulonephritis Leading to Kidney Failure in a Young Male from Guatemala

Devansh H. Patel, Deepak Chandramohan, Frida Rosenblum, Arun Rajasekaran. *The University of Alabama at Birmingham, Birmingham, AL.*

Introduction: Mesoamerican nephropathy (MeN) refers to nonproteinuric CKD that presents in young, agricultural workers predominantly in Central America, in the absence of common etiologies for CKD. C3 glomerulopathy that includes dense deposit disease (DDD) and C3 glomerulonephritis (C3GN) are glomerular disorders triggered by dysregulation of the alternative complement pathway. We present a rare case of a young Central-American male with kidney biopsy features suggestive of C3GN and MeN.

Case Description: A 28-year-old Hispanic male without significant medical history presented with reduced urine output and uremic symptoms. He worked on a sugarcane ranch in Guatemala prior to moving to the US. He did not take any medications. Physical exam was unremarkable. Workup revealed BUN 116 mg/dL, Cr 11 mg/dL, Sr albumin 4 g/dL, and UPCR 5700 mg/g. Urinalysis revealed acanthocytes and RBC casts. C3 level was low at 80 mg/dL; C4 level was normal. Comprehensive GN workup was negative; infection was ruled out. Kidney USG revealed bilateral shrunken kidneys. Kidney biopsy revealed 13/21 globally sclerosed glomeruli. The interstitium contained moderate inflammatory infiltrates, mainly monocytes, and IFTA was 60%. IF revealed granular and smudgy C3 (3+) along the capillaries and mesangium; rest of immunoreactants were negative. Functional C3G panel revealed elevated C5 and C5b-9 levels. Genetic C3G panel was negative. Given evidence of advanced chronicity features, immunosuppression was not offered and dialysis was started.

Discussion: C3GN affecting younger patients usually are mediated by genetic abnormalities of the alternative complement pathway. Our patient had a negative genetic C3G panel highlighting the fact that his C3GN is truly not mediated by a genetic abnormality or that he has a genetic abnormality that our current assays are not detecting (unlikely given the significant advancements made in this area). The co-existing severe tubulointerstitial disease likely points to a concomitant MeN given his place of origin and occupation. It is more likely that the patient had 2 different pathologies affecting the glomeruli (C3GN) and tubulointerstitium (MeN).

SA-PO819

Rapidly Progressive Glomerulonephritis Due to Dense Deposit Disease Overlapping Alport Syndrome

Ruchi J. Sahota. *Mayo Clinic Minnesota, Rochester, MN.*

Introduction: Alport's syndrome is a rare X-linked mutation resulting in structural abnormalities in the glomerular basement membrane. C3 glomerulonephritis (C3GN), specifically dense deposit disease (DDD) is unique due to complement dysregulation of the alternative pathway. There are few cases reported of co-existance of Alport's with DDD. We will be discussing a case of Alport's syndrome complicated by rapidly progressive glomerulonephritis (RPGN) in the setting of DDD.

Case Description: 21 year old male diagnosed with X-linked COL4A5 Alport's variant admitted for hematuria, nephrotic range proteinuria, and elevated creatinine developed RPGN which resulted in the initiation of dialysis. Serology workup was negative for ANA, ANCA, anti-GBM, cryoglobulin, hepatitis, and HIV. Complements, Factor B and Factor H antigen were normal. Biopsy showed crescentic glomerulonephritis in setting of C3GN favoring DDD along with previous glomerular basement changes. Results were compatible with alternative pathway hyperactivation and C3GN was treated with Eculizumab as he had failed immmunosuppression and prednisone trial.

Discussion: Alport's nephropathy has a broad range of progression from advanced age with normal kidney function to rapidly progressive renal failure depending on sex and COL4A genotype. Initial management for both Alport's and C3GN require angiotensin-converting enzyme inhibitor (ACE-I); non-specific therapies include immunosuppressants, steroids, or plasmapheresis. Goal of the immunosuppression is to inhibit cellular immune response to decrease C3a and C5a production; early treatment with immunosuppression can have 100% renal recovery in C3GN. Currently, studies are ongoing for eculizumab and ravulizumab which bind with high affinity to C5 to prevent activation of MAC and C5a. This is one of the unique presentations where DDD occured upon Alport's and patient failed all conservative therapies, leaving renal transplant as the last option.

Thrombotic Microangiopathy Multidisciplinary Team Assessment: Single-Center Case Series

Matthew D. Nguyen,[1] Samir D. Patel,[1] Fawaz Al Ammary,[1] Minh-Ha Tran,[2] Stefan O. Ciurea,[3] Sheetal Desai,[4] Alpesh Amin,[5] Hongyu Zhao,[1] Omid Vadpey,[5] Tai Truong,[1] Antoinette Abdelmalek,[1] Jordan Perkins,[1] Rebecca S. Ahdoot,[1] Fatima T. Malik,[1] Antoney J. Ferrey,[1] Uttam G. Reddy,[1] Ekamol Tantisattamo,[1] Yongen Chang,[1,6] Wei Ling Lau,[1] Yulian Khagi,[6] Lisa Lee,[3] Zahra Pakbaz,[3] Ramy M. Hanna.[1] *[1]University of California Irvine Nephrology Hypertension & Kidney Transplantation, Orange, CA; [2]University of California Irvine - Department of Medicine - Division of Transfusion Medicine, Irvine, CA; [3]University of California Irvine - Department of Medicine - Division of Hematology & Oncology, Irvine, CA; [4]University of California Irvine - Department of Medicine - Division of Rheumatology, Irvine, CA; [5]University of California Irvine - Department of Medicine, Irvine, CA; [6]University of California Irvine - VA LBMC Department of Medicine - Division of Nephrology, Irvine, CA.*

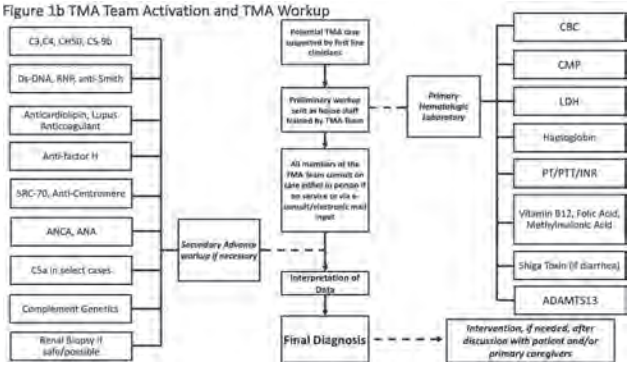
Background: Thrombotic Microangiopathies (TMAs) include an etiological diverse group of phenotypically similar disorders. While individually rare, they are seen as an aggregate with regularity. Prior reports suggested the importance of approaching TMAs in a multidisciplinary fashion. We present the design, structure, evaluation workflow and data in the initial 3-year period of the established University of California Irvine (UCI) TMA team.

Methods: This is a single-center retrospective case series of 51 diverse patients demonstrating demographics, diagnoses, triggers, treatments applied, and outcomes for patients with the diagnosis of TMA

Results: Of the 51 patients, 31 were females with an age range between 18 and 83. Twenty patients were diagnosed with atypical hemolytic uremic syndrome (aHUS). Five patients were diagnosed with Hematopoetic Stem Cell Transplant associated TMA (HSCT-TMA), 2 patients had Thrombotic Thrombocytopenic purpura (TTP). Of the 20 aHUS patients, 13 were treated with anti-complement blockade and 7 were evaluated for potential future use of complement blockade. All patients treated with anti-complement blockade (100%) demonstrated a hematologic response, 75% (9 of 12) of patients requiring renal replacement therapy remain off dialysis after 6-18 months of treatment with anti-complement blockade. HSCT-TMA patients were treated with anti-complement blockade had a less positive response.

Conclusions: This case series highlights the importance of TMA multidisciplinary team to improve diagnosis and optimize outcomes of this rare condition. Future research is needed to assist efficacy and implementation of TMA-multidisciplinary care.

Figure 1b TMA Team Activation and TMA Workup



SA-PO821

IgA Nephropathy with Complement-Associated Thrombotic Microangiopathy: A Case Series

Ryan E. Fekrat,[1] Gayathri Dileep,[1] Matthew D. Nguyen,[1] Omid Vadpey,[2] Jonathan E. Zuckerman,[3] Ramy M. Hanna.[1] *[1]University of California Irvine Nephrology Hypertension & Kidney Transplantation, Orange, CA; [2]University of California Irvine Department of Medicine, Orange, CA; [3]University of California Los Angeles – David Geffen School of Medicine - Department of Pathology and Lab Medicine, Los Angeles, CA.*

Background: Presentation of immunoglobulin A nephropathy (IgAN) with TMA has been commonly documented, however the relationship betwen IgAN and complement activation requires further exploration. Here we present a series of 7 patients with histological findings consistent with IgA nephropathy and TMA with supplementary serological data, suggesting a linkage between complement pathology and IgA nephropathy.

Methods: Coded datasets here are identified by our team using Epic software under consent of participating patients. Patients' biopsy data with histological specimen is complemented by data from patient records. Histological specimen was read by UCLA Health Renal Pathology.

Results: The collected data shown in Table 1 shows 7 patients evaluated at UCI with the average age being 41.6 ± 8.1 years, 5/7 being male and 4/7 being Hispanic. 1/7 of the patients showed evidence of acute systemic TMA while 6 patients had renal limited TMA supported by histological slides. Average initial serum creatinine for all patients was 5.17 ± 4.74 mg/dL, average initial urine protein was 6.75 ± 5.11 g/day, and 5/7 patients had evidence of hematuria in their urine. Serological evaluation of complement levels show 2/7 (28.6%) of patients had low C3 complement levels. 1/7 (14.3%) of patients showed elevated C4 levels.

Conclusions: The patterns of histology show typical IgA nephropathy deposition and TMA. It is suggested that mesangial IgA activates mesangial cells, activating complement through the lectin and alternative pathways. This would not be the first time complement disorder is implicated as the conception of IgA TMA as reflected in some of our patients having lower C3 levels while having normal C4, however this finding may present a precedent for future research and clinical identification.

SA-PO822

Kidney-Limited Thrombotic Microangiopathy (TMA) Is Prevalent along the Spectrum of TMA and Does Not Exclude Complement Defects

Daan P. van Doorn,[1,2] Sjoerd Timmermans,[1,2] Pieter van Paassen.[1,2] Limburg Renal Registry; Expert Center for Immune-mediated Kidney Diseases and Vasculitis. *[1]Maastricht Universitair Medisch Centrum+, Maastricht, Netherlands; [2]Universiteit Maastricht Cardiovascular Research Institute Maastricht, Maastricht, Netherlands.*

Background: The syndromes of TMA are associated with acute kidney injury and risk of ESKD. Patients typically present with systemic hemolysis, that is, thrombocytopenia and microangiopathic hemolytic anemia. Kidney-limited TMA, however, can occur but is often overlooked and undertreated. Here, we studied morphologic features on kidney biopsy and their clinical correlates in patients with TMA.

Methods: Patients with TMA on kidney biopsy were recruited from the Limburg Renal Registry and classified as definite complement-mediated (C-)TMA (i.e., ≥1 pathogenic complement gene variant), probable C-TMA (i.e., massive *ex vivo* C5b9 formation, either with ≥1 complement gene variant of uncertain significance or not), and secondary TMA (i.e., normal *ex vivo* C5b9 formation without complement gene variants). Morphologic features, including activity and chronicity indices, were studied in relation to clinical presentation and outcome.

Results: Patients were classified as definite C-TMA (*N*=14, 18%), probable C-TMA (*N*=21,27%),orsecondaryTMA(*N*=42,55%),including52(66%;*n*/*N*=8/14,10/21,and33/42) patients with kidney-limited TMA. Definite and probable C-TMA presented with higher creatinine (11.0 [IQR, 4.0-13.3] and 5.7 [IQR, 4.0-8.2] vs. 3.2 [IQR, 2.2-5.3] mg/dL; *P*<0.001) and at younger age (33 [IQR, 25-29] and 33 [IQR, 28-44] vs. 40 [IQR, 35-52] years; *P*=0.01) as compared to secondary TMA. Glomerular thrombosis was not associated with systemic hemolysis, but appeared more common in definite and probable C-TMA as compared to secondary TMA (79% and 76% vs. 43%; *P*=0.005). Morphologic features neither defined etiology nor differed between systemic TMA and kidney-limited TMA. Kidney remission, that is, recovery of kidney function and/or ≥25% increase in eGFR, occurred more often in eculizumab treated patients with definite (100% vs. 11%; *P*=0.001) and probable C-TMA (86% vs. 29%; *P*=0.009) but not secondary TMA (60% vs. 67%; *P*=0.7) as compared to untreated patients; chronicity indices did not predict kidney remission.

Conclusions: Kidney-limited TMA is common along the spectrum of TMA, including definite and probable C-TMA. Thus, a kidney biopsy is often needed to detect the TMA but cannot define etiology. Chronicity indices should not be used to withhold complement-specific drugs in patients with definite and probable C-TMA.

Biological Parameters in Biopsy-Proven Renal Thrombotic Microangiopathies

Jean-Michel Halimi,[1,2] Valentin Maisons,[1] Etienne Chardon,[2] Sophie Caillard,[3] Marie Frimat,[4] Laurent Mesnard,[5] Sophie Chauvet,[6] Eric Piver.[1] MATRIX Consortium Cohort Study (NCT05991245). *[1]Centre Hospitalier Regional Universitaire de Tours, Tours, France; [2]INSERM U1327, Tours, France; [3]Universite de Strasbourg, Strasbourg, France; [4]Universite de Lille, Lille, France; [5]Hopital Tenon, Paris, France; [6]Hopital Europeen Georges Pompidou Cancerologie, Paris, France.*

Background: Thrombotic microangiopathies (TMA) are suspected in the presence of anemia, high LDH, low haptoglobin, thrombocytopenia and schistocyte>1%. The kidney is the most frequently affected organ. However, interpreting biological parameters in this context is unclear.

Methods: Biological parameters were studies in 967 patients with biopsy-proven renal TMA from 25 French hospitals during the 2009-2023 period.

Results: Median age was 49 (IQR: 36-64), 53.2% were male. All TMA KDIGO causes were represented. Biomarker sensitivity (ie. proportion of patients with the parameter) ranked as follows: anaemia (81.7%), high LDH (75.4%), low haptoglobin (53.7%), thrombocytopenia (40.3%), schistocytes>1% (34.0%) but varied widely according to fibrinogen, prothrombin time (PT) and serum creatinine. The sensitivity of these biological parameters was preserved (>75%) only in patients with both fibrinogen levels <5 g/L and serum creatinine ≥300 µmol/L, ie 29% of the population. Laboratories used 11 different ways to report schistocytosis: various threshold values and reporting (binary, qualitative, semi-quantitative, quantitative, adjective-based vs numerical) were found. Schistocyte>1% had been used as the sole criterion, suspicion of TMA would have been missed in 66.0% of patients (23.8% to 86.4% according to TMA causes). Unsupervised cluster analysis revealed that biological parameter structuring is strongly linked to specific renal TMA causes. Using fibrinogen, serum creatinine, anemia, LDH and haptoglobin, A simple algorithm identified patients with infrequent (sensitivity <10%) or very frequent (sensitivity: 75-90%) phenotypes.

Conclusions: Schistocyte reporting varies widely and "schistocyte>1%" misses two-thirds of renal TMAs. Biological parameters' results should be interpreted according to fibrinogen, creatinine and PT but careful analysis of these parameters can help differentiate among TMA causes. A simple algorithm provides crucial information regarding the necessity of kidney biopsy, indicating when renal TMA is either unlikely or highly probable.

SA-PO825

A Tale of Two Findings: Thrombotic Microangiopathy and Podocytopathy Due to Graft vs. Host Disease

Jonathan Hall, David A. Mcmillan, Nathaniel Leonardi, Prasanth Ravipati, Ryan Mullane. *University of Nebraska Medical Center, Omaha, NE.*

Introduction: Acute kidney injury (AKI) following hematopoietic stem cell transplantation (HSCT) is common, and typically multifactorial in etiology related to infections, medications, and graft versus host disease (GVHD). Thrombotic microangiopathy (TMA) following HSCT is not uncommon and can be associated with GVHD. When TMA is due to GVHD, it is often refractory to treatment with steroids. Nephrotic syndrome, however, is a rare presentation of kidney disease following HSCT.

Case Description: A 56-year-old female with myelodysplastic syndrome that progressed to acute myeloid leukemia for which she had undergone allogenic HSCT 8 months ago was found to have a serum creatinine of 2.9 mg/dL (prior serum creatinine of 1.0 mg/dL). She reported recent development of leg edema with weight gain. Her serum albumin was 2.5 g/dL, a urine protein to creatinine ratio was 14.7, and urine microscopy revealed microscopic hematuria. A kidney biopsy was performed, and the patient was begun on IV methylprednisolone. Light microscopy revealed mesangiolysis, duplication of basement membranes, and intracapillary red cell fragmentation, consistent with TMA. Electron microscopy showed subendothelial widening with accumulation of flocculent material and podocyte effacement of at least 90% of the sampled capillary surface area. Despite treatment with IV methylprednisolone, the patient had progression of kidney failure and required hemodialysis. Given the biopsy findings of TMA, treatment was started with eculizumab. The patient had subsequent improvement in her kidney function,

and hemodialysis was stopped. Over the next 4 weeks, her serum creatinine decreased from a peak of 5.6 mg/dL to 2.2 mg/dL, and her serum albumin normalized.

Discussion: Co-presentation of TMA with diffuse podocytopathy is a rare cause of kidney dysfunction in patients post-HSCT. TMA due to GVHD is typically refractory to treatment with steroids and is thought to be due to alternative complement pathway dysfunction, necessitating treatment with complement blockade. Combination therapy with eculizumab and corticosteroids in this unusual case of concurrent TMA and podocytopathy led to improvement in the patient's renal function and normalization of the patients' serum albumin.

SA-PO826

Castleman Disease and Kidney Thrombotic Microangiopathy

Wenchy Tan, Melissa Notis, Miriam Chung, John C. He. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: Idiopathic Multicentric Castleman Disease (iMCD) is a rare, life-threatening disorder that causes multiorgan dysfunction, generalized lymphadenopathy and systemic hyperinflammation that rarely affects the kidney. Thrombotic microangiopathy (TMA) is characterized by microvascular thrombosis due to vessel wall abnormalities in arterioles and capillaries. Kidney TMA is a rare manifestation of iMCD. We report a rare case of iMCD with kidney TMA in a young patient.

Case Description: 19 year-old male presented with diarrhea, night sweats, leg swelling and dark urine. Initial workup included creatinine 1.5 mg/dL, albumin 1.9 g/dL, C-reactive protein 310 mg/L, LDH 317 U/L, and platelet 90 K/μL. Urinalysis showed 2+ protein and small blood, urine protein-creatinine ratio 0.3 mg/mg. Kidney biopsy showed glomerular mesangiolysis with fragmented red blood cells and platelets, subendothelial widening and focal areas of glomerular basement membrane duplication consistent with membranoproliferative pattern of TMA. He was started on eculizumab. Further studies revealed normal complements, negative ANA, anti-ds DNA, anti-cardiolipin antibodies, HHV-8, and HIV. CT scan showed multiple retroperitoneal lymph nodes and adrenalitis, concerning for Castleman Disease with supportive excision lymph node biopsy results. His kidney function continued to decline, and hemodialysis was started after three weeks. Siltuximab and high-dose steroids were started after iMCD diagnosis.

Discussion: iMCD has an estimated yearly incidence of 3-4 cases nationwide. Kidney complications are very rare, though kidney TMA and AA amyloidosis have been reported. The pathogenesis of kidney TMA in iMCD is unclear; may involve increased production of interleukin-6 (IL-6) and vascular endothelial growth factor (VEGF) by proliferating plasma cells within lymph nodes. Elevated serum levels of VEGF and IL-6 are reported to decrease VEGF expression within glomerular podocytes, which may have a role in thrombotic glomerular injury. There is no standard treatment for iMCD; IL-6 inhibitors, tocilizumab and siltuximab have demonstrated kidney recovery. In our patient, kidney function rapidly declined requiring dialysis. This highlights the importance of having iMCD as a differential diagnosis for kidney TMA with an atypical presentation and promptly starting treatment.

Penicillin-Induced Thrombotic Microangiopathy

Huanchun N. Lai.[1,2] [1]*McLaren Health Care Corp, Mt Clemens, MI;* [2]*Michigan State University, East Lansing, MI.*

Introduction: Thrombotic microangiopathies (TMA) are characterized by features of thrombocytopenia, microangiopathic hemolytic anemia, acute kidney injury, combined with cardiac and neurologic abnormalities. Drug-induced thrombotic microangiopathy (DITMA) is an acquired condition due to either immune (antibody-mediated) or non-immune (direct toxicity) mediated organ dysfunction secondary to medication exposure. DITMA is an uncommon condition that can be fatal if the diagnosis is missed. It must be considered in the presence of characteristic features, without evidence of systemic causes of TMA. Here, we describe a case of penicillin-induced TMA in a previously healthy individual.

Case Description: A 25-year-old male with no medical history presented with three-day history of hematuria and non-bloody diarrhea. Patient was treated one week prior for a dental infection with penicillin VK for four days. On admission, patient had no other complaints other than persistent hematuria. Initial lab work showed significant thrombocytopenia of 23K/mcL, PBS 2+ schistocytes, haptoglobin <10mg/dL, LDH 2,600U/L, creatinine of 2.1mg/dL, and UA had RBC count of 27. Serologic workup showed normal C3 and C4, ANA, dsDNA, GBM, MPO and PR3 were all negative. DAT, SPEP, and HIV were negative. ADAMTS13 activity was normal. Patient was started on prednisone with improvement of platelets and renal function, without the need for plasma exchange. Patient completed a six week prednisone taper with resolution of symptoms and renal recovery.

Discussion: DITMA is uncommon but poses potential life-threatening complications. It is under-recognized due to diagnostic challenges and lack of standardized testing. Therefore, it is difficult to establish a causal relationship with the implicated agent. Most commonly, DITMA is associated with quinine and chemotherapy agents. There are rare reports of penicillin as cause of DITMA in literature. This case further highlights penicillin as a cause of TMA and illustrates the management and anticipated recovery after the cessation of the offending medication.

Days since initial exposure to Penicillin VK and the progression of DITMA

Labs	Day 9	Day 10	Day 11	Day 12	Day 13	Day 14	Day 15	Day 42
Hgb (g/dL)	15.1	12.9	11.4	10.9	10.9	11.0	11.9	13.6
Platelets (K/mcL)	23	16	21	29	60	123	269	214
BUN (mg/dL)	22	21	20.7	19.8	19.8	16.9	16	14.1
Creatinine (mg/dL)	2.1	2.13	2.0	23	1.6	1.6	1.48	0.9
LDH (U/L)	-	2600	-	2091	1740	1250	1046	207

SA-PO828

Use of Eculizumab in the Management of Drug-Induced Thrombotic Microangiopathy: A Case Report

Afsheen Afzal, Thangamani Muthukumar, Steven Salvatore. *Weill Cornell Medicine, New York, NY.*

Introduction: The use of complement pathway inhibitor, Eculizumab, for managing drug-induced thrombotic microangiopathy (TMA) is controversial. We describe a patient with cancer who developed TMA and acute kidney injury (AKI) associated with the use of bevacizumab/oxaliplatin. Early identification and use of eculizumab resulted in complete recovery of kidney function.

Case Description: 64-year-old female with stage IIb colon cancer on FOLFOX (folinic acid, fluorouracil [5FU], oxaliplatin [Oxa]) & Bevacizumab(Bev) for 6 months, later maintained only on Bev/5FU.2 days after resumption of FOLFOX&Bev infusions, patient was sent to ER by Oncology clinic for reduced urine output, and elevation in serum creatinine (sCr) to 4.96 from 0.65 2 days ago. She was normotensive at presentation, denied diarrhea, reduced fluid intake, NSAIDs or recent IV contrast use. Her hemoglobin was 9.8 (11.3 two days ago) and platelets were 27,000 (90,000 one week ago). Direct and indirect bilirubin were 0.9, AST 97 from 25, LDH 1208 and haptoglobin < 8. Peripheral blood smear revealed 8-10 schistocytes per HPF. Urinalysis revealed hematuria(17 RBCs), proteinuria(>500), glucosuria (50, new). Urine electrolytes were indicative of intrinsic kidney injury. Urine protein/Cr ratio was 2.8g/g and urine microalbumin/Cr ratio was 0.8g/g. ADAMTS-13 levels were normal. The constellation of anemia, thrombocytopenia, elevated LDH, low haptoglobin, schistocytes on peripheral smear and AKI were indicative of microangiopathic hemolytic anemia likely due to Bev/Oxa. Skin biopsy revealed +ve staining for C5b-9 in 8-10 dermal capillaries. Patient was started on Eculizumab 900mg on day 1. There was immediate improvement in hematological markers; however, sCr continued to rise upto 14 over next few days. She underwent a kidney biopsy(10 days after presentation), which revealed severe acute tubular injury with intraluminal material suggestive of hemoglobin casts, diffuse C5b-9 positivity, and focal subacute endothelial injury involving glomeruli with thickening of capillary walls. Patient continued to receive Eculizumab weekly then biweekly with sCr trending down to 1.0 over the course of a month.

Discussion: This case highlights the immediate reversal of microangiopathic hemolytic anemia with the use of Eculizumab. Early use of eculizumab likely reduced the severity of kidney injury and aided in the complete recovery of kidney function.

SA-PO829

Infection-Related Glomerulonephritis with Thrombotic Microangiopathy following Treatment for Streptococcal Bacteremia: A Case Report

Keisuke Onishi, Tadashi Sofue, Tetsuo Minamino. *Kagawa Daigaku, Takamatsu, Japan.*

Introduction: Post-streptococcal acute glomerulonephritis (PSAGN) occurs 1-3 weeks after infections of the upper respiratory tract or skin. Infection-related glomerulonephritis can be accompanied by anemia and thrombocytopenia; however, the detailed mechanism remains unknown. Here, we report a case of PSAGN complicated by thrombotic microangiopathy (TMA) after treatment for streptococcal bacteremia.

Case Description: A 64-year-old woman with no relevant medical history was admitted to our hospital with fever and abdominal pain. Antibiotics were administered because a blood culture revealed group A *Streptococcus*, although the fever and right-sided chest pain persisted. Surgical thoracic drainage was performed after a diagnosis of pyothorax based on CT and pleural fluid analysis. Postoperative fever persisted, and 14 days after admission, serum Cr was 1.2 mg/dL and urinalysis results were normal; however, low C3 and CH50 levels were observed. On day 21 after admission, gross hematuria developed, and urinalysis revealed proteinuria. Based on the patient's medical history and positive ASO findings, she was clinically diagnosed with PSAGN. Progressive thrombocytopenia and hemolytic anemia were also observed, requiring differentiation from TMA. One month after PSAGN onset, serum Cr level had elevated to 1.8 mg/dL. Renal biopsy was performed, and light microscopy revealed membranoproliferative glomerulonephritis with tubulointerstitial nephritis. Immunofluorescence revealed C3 and IgG deposition in the glomerular tuft, and electron microscopy showed dense subepithelial deposits, leading to the diagnosis of PSAGN. Six weeks after the onset of PSAGN, 30 mg prednisolone was administered because her renal function, anemia, and complement levels did not improve. Renal function and hemolytic anemia improved rapidly after treatment initiation, followed by steroid tapering and complete remission of proteinuria after 3 months.

Discussion: There have been few reports of cases of secondary TMA after severe streptococcal infection or of TMA complicated by PSAGN. In this report, we captured the natural history of PSAGN development by observing gross hematuria followed by a drop in complement levels after streptococcal infection. Because TMA occurred simultaneously with PSAGN, a common underlying pathogenesis is hypothesized for both diseases.

SA-PO830

Spectrum of Monoclonal Gammopathy of Renal Significance (MGRS) in a Tertiary Care Hospital in India

Atanu Pal, Rajnarayan Mukherjee, Tathagata Mukherjee, Bibek Maulik. KOLKATA IPGMER Nephrology. *Institute of Postgraduate Medical Education and Research, Kolkata, India*.

Background: MGRS is a heterogeneous group of kidney disorders characterized by direct or indirect kidney injury caused by toxic monoclonal immunoglobulin that does not meet the current hematological malignancy criteria. The concept of MGRS was introduced in 2012 by IKMG. The diagnosis of MGRS is typically made by nephrologist through kidney biopsy. The followings are the Aims of the study: 1.Histopathological spectrum of MGRS patients, 2.Different clinical & pathological variable in MGRS patients, 3.Response to standard of care

Methods: All MGRS patients (IKMG guidelines) attending IPGME & R hospital are included in this study over a period of 1st January'23 - December'23. All data are captured by using preformed proforma & analysed by SPSS software.

Results: 15 patients were included. Median age - 52 years, (2 patients < 40 years). Male : Female 1:1. Diabetes was found in 5/15, one hypothyroid, 3 patients had hypertension, one patient had Urinary bladder Carcinoma. **Presentations**: Nephrotic syndrome - 8, RPRF - 3, AKI - 2, CKD3b -1, CKD4-1. Peripheral blood - Eosinophilia (Absolute count > 500/microlitre) found in 10. **Renal biopsy**: AL amyloidosis - 8, PGNMID - 3, MIDD (LCDD) - 3, C3 glomerulopathy - 1 **Serum Protein Electrophoresis & Immunefixation**: M band was detected in 60% of study population. AL amyloidosis (8) - M band in 5. Immunefixation showed IgG lambda in 6, 2 patients had IgG Kappa. PGNMID (3) - 1 had no M band & Immunefixation failed to detect any monoclonal intact immunoglobulin & or freelight chain. Renal biopsy showed IgG3kappa. Other two patients had no M band, Immunefixation showed IgG Kappa & lambda. LCDD (3) - one patient had no M band, but IgG Kappa was found in one patient, two patients showed IgG lambda. Serum Free light chain ratio was altered in 8, lambda dominance among 5, rest were Kappa.

Conclusions: The MGRS group of kidney diseases often produces diagnostic challenges. So it requires multidisciplinary coordination. Cardiac death is common both pre and post therapy, particularly in AL amyloidosis patients. Therefore early & timely detection are required to improve overall & renal prognosis of patients & also reduces the chance of progression into overt hematological malignancy. Clone based therapy followed by HSCT may be curative.

SA-PO831

A Clinicopathological Study of IgA Variant-Proliferative Glomerulonephritis with Monotypic Ig Deposits (PGNMID)

Margot Poux, Marguerite Vignon, Elise Michelon, Vincent Javaugue, Frank Bridoux, Khalil El Karoui. *Assistance Publique - Hopitaux de Paris, Paris, France*.

Background: Proliferative glomerulonephritis with monotypic immunoglobulin deposits (PGNMID) is a rare form of monoclonal gammopathy of renal significance (MGRS) related to glomerular non-organized monotypic Ig deposits, usually IgG. The IgA variant of PGNMID has been rarely described. We aimed at describing a large cohort of IgA-PGNMID to detail population characteristics, treatment, and renal and hematological outcome.

Methods: We conducted a multicentric retrospective study of all French patients with monotypic IgA glomerular deposits with a PGNMID diagnosis between May 2012 and May 2023. Patients were classified in two groups according to the presence of a detectable monotypic IgA component (blood, urine, or blood marrow). Renal, and hematological, baseline characteristics and long-term follow-up were analyzed.

Results: Forty-three patients were identified. Eighteen (41,8%) patients had a detectable monoclonal IgA clone (IgA-MGRS) and 25 (58,1%) (unproven MGRS) had no identified clone in blood and/or blood marrow. Most patients were men (65%), and the mean age was 52 years. Renal function impairment was frequent at diagnosis (DFG < 60 ml/min in 77,7 % and 68%, in the IgA-MGRS and unproven MGRS groups, respectively) and proteinuria > 1 g/g in 15/18 (83,3%) and 22/25 (88%) cases, in the IgA-MGRS and unproven MGRS groups, respectively. There were no significant differences between groups at baseline, except for hypertension. After treatment with anti-plasmocytic drugs, patients with a detectable clonal IgA and eGFR > 30 ml/min/m2 had a correlation between hematological and renal response after one year follow-up (Fisher p=0,04). 3/7 patients (42,8 %) had disease recurrence after renal transplantation, and all of them had hematological relapse. Four patients developed overt malignancy with MM. At last follow-up, renal survival was significantly lower in IgA-MGRS group than unproven MGRS and primitive polytypic IgA nephropathy groups.

Conclusions: In conclusion, IgA-PGNMID is a distinct entity from IgA nephropathy, with renal outcome correlated with hematological outcome after anti plasmocytic treatment. A pathogenic plasma cell clone is identified in 42% cases and is associated with a worse renal prognosis.

SA-PO832

Monoclonal Gammopathy in ANCA-Negative Pauci-Immune Crescentic Glomerulonephritis: Is There Causality? Case Series

Maria Jose Vargas-Brochero, Poemlarp Mekraksakit, António d. Inácio, Patrícia A. Domingues, Fernando C. Fervenza, Alessia Buglioni, Ladan Zand. *Mayo Clinic Minnesota, Rochester, MN*.

Background: In a subset of patients with diagnosis of ANCA-associated vasculitis, no antibodies(MPO or PR3) can be identified, and these cases are referred to as"ANCA-negative". The antibody or trigger for the disease in this subset of patients has remained elusive. Monoclonal gammopathy(MG) has been shown to directly activate neutrophils. We hypothesized that MG may be the cause for the renal presentation in such patients. We therefore explored the role of MG and its association with disease presentation in cases of ANCA-negative vasculitis.

Methods: We retrospectively analyzed database between Jan2000 through Dec2023 and identified patients with a diagnosis of pauci-immune crescentic glomerulonephritis who had undergone testing for MPO, PR3, and monoclonal gammopathy (MG). Patients positive forMPO, PR3, or anti-GBM and those with a kidney transplant, were excluded. Time-to-event analysis was conducted using the Kaplan-Meier method, death as the event of interest

Results: 14 patients diagnosed with ANCA-negative vasculitis who had undergone monoclonal testing. 8(57%) had evidence of MG, prevalence significantly higher than the anticipated (3%) in the general population over 50 years of age. Mean age of this group was 60.3 (12.2) years, 75% were female, with mean serum creatinine of 4.3(1.92) mg/dL. Most common histological characteristics were Focal Berden Classification(n=5, 62.5%) and Mayo Clinic/Renal Pathology Society Chronicity Score(MCS) of moderate(n=5, 62.5%). Most common heavy chain was IgG(n=4, 50%), and Kappa light chain(n=4, 50%) with serum free light chain ratio of 2.3[1.01-3.41] for involved to uninvolved light chain. Median follow-up time was 3.2 years. At the last follow-up, 3 patients progressed to end-stage kidney disease, and 4 patients died (2 without ESKD). Mean time to death of 3.0(4.1) years. Estimated one-year survival was 85.7%(95% CI 13.2 to 63.3) and two-year survival was 68% (95% CI:18.6 to 40.3).

Conclusions: Our study shows that majority of patients with ANCA-negative vasculitis have evidence of MG and it is possible that the MG is involved in the pathogenesis of the disease and may need to be considered as MGRS lesion in the future. Additional research is needed to better understand the role of MG in causing pauci-immune crescentic GN.

SA-PO833

Collaborative Study: Identifying Risk Factors for ESKD in Leukocyte Chemotactic Factor 2 (ALECT2)-Associated Amyloidosis

Maria Jose Vargas-Brochero,[1] Lisa E. Vaughan,[1] María F. Zavala Miranda,[2] Norma O. Uribe-Uribe,[2] Juan M. Mejia-Vilet,[2] Nelson Leung.[1] [1]*Mayo Clinic Minnesota, Rochester, MN;* [2]*Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico*.

Background: ALECT2 represents the third type of kidney-involved amyloidosis; its clinical prognosis and natural history are uncertain.

Methods: This was a retrospective cohort study of adults diagnosed with kidney biopsy-proven ALECT2 by immunohistochemistry or mass spectrometry between 1/1/2000 and 12/31/2022 at two institutions. Patients with end-stage kidney disease (ESRD) at diagnosis or without follow-up were excluded. ESRD-free survival was estimated using the Kaplan-Meier method. Cox regression was used to evaluate associations between characteristics at diagnosis and risk of incident ESRD

Results: There were 54 patients meeting inclusion criteria for this study (mean (SD) age 63.7 (7.2) years, 28 (51.8%) male and 48 (88.8%) Hispanic. There were a total of 19 (35.2%) ESRD events occurring during a mean (SE) follow-up of 7.1 (0.8) years. Estimated survival was 92% (95%CI: 85%-99%) at one year, 79% (95%CI: 67%-92%) at two years, and 70% (95%CI: 55%-88%) at 5-year follow-up. Patients with a higher percentage of glomerulosclerosis, serum creatinine, proteinuria, interstitial fibrosis/tubular atrophy, and a lower eGFR had a significantly higher risk of incident ESRD (P<0.05 for all; see **Table 1**)

Conclusions: This study reports long-term renal survival for ALECT2 patients and identifies several promising biomarkers associated with worse renal survival

Table 1. Univariable associations between patient characteristics at the time of diagnosis and risk of ESRD

Baseline Patient Characteristic	HR (95% CI)	P
Percent of Glomerulosclerosis (%) (per 10 %)	1.27(1.05-1.53)	0.01
Serum creatinine (per 1 mg/dl)	1.96(1.25-3.08)	0.003
eGFR (per 1 ml/min/1.73m^2)	0.90(0.90-0.98)	0.004
Proteinuria (per 1g/24hr)	1.11(1.03-1.20)	0.006
Interstitial Fibrosis/Tubular Atrophy (per 10%)	1.31(1.04-1.64)	0.018

Longitudinal Clinical Outcomes with Membranous-Like Nephropathy with Monoclonal Light-Chain Deposition: A Case Series

Elaine Park,[1] Blaithin A. McMahon,[1] Guangchen Zou,[2] Mohamed G. Atta,[2] Benjamin R. Teruel.[1] [1]*Medical University of South Carolina, Charleston, SC;* [2]*Johns Hopkins Medicine, Baltimore, MD.*

Background: Membranous-like nephropathy with monoclonal light chain deposition is a rare entity first described in 2014. This pathological entity is very distinct from primary idiopathic membranous nephropathy, with the prominent feature of masked IgG-kappa deposits on immunofluorescence. The purpose of this small case series is to examine the treatment and long-term outcomes for 6 with patients with this disease.

Methods: This six-patient series was identified at Johns Hopkins Medicine and Medical University of South Carolina. We examined demographics, clinical characteristics at presentation, light microscopic findings, glomerular immunofluorescence staining, and long-term renal outcomes. The median duration of follow-up was 12.5 years.

Results: The patients most commonly presented with edema and had a mean 24 hr urine protein of 3.09 g/day. Only one patient had an identifiable MGUS at presentation. All renal biopsies stained positive for IgG kappa light chain. Half of all patients had electron dense deposits at other sites other than at the sub-epithelial membrane (including sub-endothelial and mesangial site). 5 out of the 6 patients were found to have intramembranous deposits. Treatment included no treatment, RAAS blockade, and immunosuppressants. Of the 6 cases, 4 achieved complete remission and 2 progressed to ESRD.

Conclusions: Although this is a small case series, membranous-like nephropathy with IgG kappa light chain deposition can still contribute to ESRD. None of these patients who progressed to ESRD received cyclophosphamide. Additional observational studies are needed to better understand the response to immunosuppressive therapy.

Kidney Prognostic Value of Serum Monoclonal Immunoglobulin in Nonautoimmune Diseases Related to Cryoglobulinemic Glomerulonephritis

Lei Ma, Dandan Liang, Yuanyuan Xia, Feng Xu, Shaoshan Liang, Dacheng Chen, Xinchen Yao, Fan Yang, Xiaodong Zhu, Caihong Zeng. *National Clinical Research Center for Kidney Diseases, Jinling Hospital, Affiliated Hospital of Medical School, Nanjing University, NanJing, China.*

Background: To explore the clinicopathological features and renal outcome in patients with cryoglobulinemic glomerulonephritis (Cryo-GN) without evidence of autoimmunity disorders.

Methods: Sixty-nine patients with Cryo-GN from a single center were recruited in this retrospective study. Their clinical, pathologic, and follow-up data were collected and analyzed. According to whether the serum monoclonal immunoglobulin (MIg) and HBV-DNA/HBV markers or HCV-RNA/anti-HCV antibodies were positive or not, they were classified into four groups: positive serum MIg only (MIg group), positive HBV-DNA/HBV markers or HCV-RNA/anti-HCV antibodies (HBV/HCV) only (HBV/HCV group), positive serum MIg and HBV/HCV (MIg+HBV/HCV group), and all MIg/HBV/HCV negative group.

Results: The male-to-female ratio was 1.38:1 with a mean age of 50.4±14.7 years in the patient cohort. Hypertension was presented in 59.4% of cases, anemia in 73.9%, renal insufficiency in 58.0%, nephrotic proteinuria in 44.9% and microscopic hematuria in 94.2%. The MIg group had significantly lower eGFR levels, higher cryoglobulin levels, and higher rates of abnormal serum-free light chain ratios than the MIg/HBV/HCV negative group. The most common histological pattern of Cryo-GN was membranoproliferative glomerulonephritis (MPGN), and the MIg group had significantly higher scores of the severity of intracapillary cryo-Plugs than the MIg+HBV/HCV group and the MIg/HBV/HCV negative group. Sixty-three patients had a median follow-up of 31.2 months, and 25.4% of them progressed to end-stage renal disease (ESRD). The renal survival was inferior for MIg group than for HBV/HCV group. Multivariate analysis showed that serum MIg and the severity of intracapillary cryo-plugs were independent prognostic factors.

Conclusions: Regardless of the presence of HBV/HCV infection, non-autoimmune diseases related Cryo-GN patients with serum MIg had worse renal function and renal survival. Serum MIg and severity of intracapillary cryo-Plugs were independent risk factors for renal survival in Cryo-GN patients without autoimmune diseases.

SA-PO836

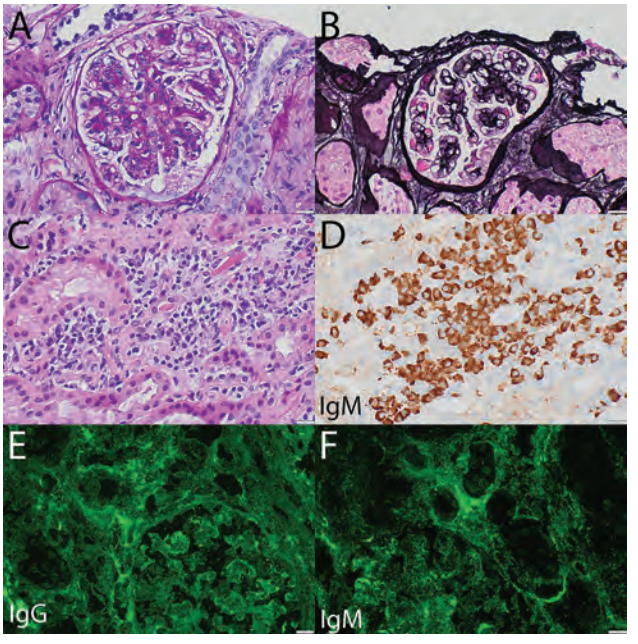
Plasma Exchange to Prevent Cyroglobulinemic Vasculitis Flare in Sjogren Membranoproliferative Glomerulonephritis

Patrick J. Palacios, Akwe Nyabera, Omar A. Ayah, Sarwat Gilani, Mir T. Ali. *The University of Texas Health Science Center at San Antonio, San Antonio, TX.*

Introduction: Cryoglobulinemia related membranoproliferative glomerulonephritis (MPGN) is a described manifestation of renal disease in Sjogren's. Treatment involves steroid therapy and rituximab. Plasma exchange (PLEX) can reduce the incidence of rituximab induced cyroglobulinemic vasculitis (CV) flare. There are differences in literature on when to initiate PLEX prior to rituximab. We describe a case of Sjogren's related MPGN requiring PLEX prior to rituximab in order to prevent CV flare.

Case Description: 73y.o female with PMH of Sjogren's, HTN, HF, noted to have 2.8 g/g of proteinuria and a rise in serum Cr from 1 mg/dL-1.5 mg/dL over a 2-month period. Serology showed positive:anti-SSA (>8), ANA (>1:640), anti-smooth muscle (23.84), cryocrit (79%) and rheumatoid factor (RF) (69.86). Decreased:C3 (89 mg/dL) / C4 (3 mg/dL) and elevated IgM (1139 mg/dL). Hepatitis B/C and HIV were negative. Kidney biopsy showed MPGN and tubulointerstitial nephritis. She was initiated on a prednisone taper, and underwent PLEX prior to rituximab.

Discussion: Risk factors for rituximab induced CV flare are:an elevated cryocrit percentage, extremely low C4 and positive RF. Vascular damage is related to classical pathway activation by both RF-positive IgM cryoglobulin and IgG1 of rituximab. PLEX reduces the incidence of flare. There are differences in the literature on what criteria should be used to determine PLEX prior to rituximab. One recommendation is for IgM levels >4g/dL; our pts levels were lower at 1.1 g/dL. However, other sources recommend PLEX for a cryocrit percentage of >10%, and her cryocrit level was 79%. We suggest that patients with cryoglobulinemic MPGN that meet any of the criteria for possible rituximab induced flare, PLEX therapy should be considered prior to rituximab.



A) MPGN injury
B) Tubulointerstitial inflammation
C) IgM+ plasma cells

Membranoproliferative Glomerulonephritis with Striated Ultrastructural Deposits: A New Pathological Entity? A Case Report and Literature Review

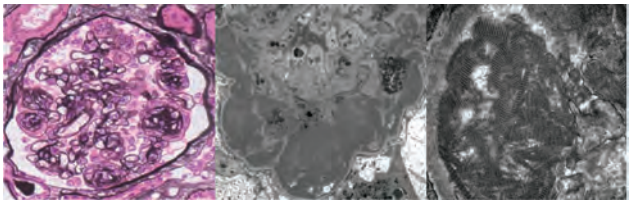
Manna Ishida,[1] Shinya Yamamoto,[1] Yohei Iwashige,[1] Akiko Mii,[2] Akira Shimizu,[2] Motoko Yanagita.[1] [1]*Kyoto Daigaku Igakubu Fuzoku Byoin, Kyoto, Japan;* [2]*Nihon Ika Daigaku, Bunkyo-ku, Japan.*

Introduction: Glomerular diseases with organized deposits can be classified into various etiologies. A diagnostic algorithm based on clinical and pathological findings has been proposed; however, some cases cannot be diagnosed using existing algorithms.

Case Description: A 77-year-old man presented to our hospital with proteinuria, hematuria, and lower leg edema that had developed 1 month prior. Renal biopsy revealed membranoproliferative glomerulonephritis (MPGN). Electron microscopy showed microfilament-like substructures with regularly stacked, straight bands arranged in parallel in the subendothelial space. The examinations and clinical findings were incompatible with known glomerular diseases with organized deposits with organized deposits. During

2 years without immunosuppressive drugs, he developed nephrotic syndrome, and renal impairment. A second renal biopsy revealed that the area occupied by the deposits was prominently extended (Figure). Hemodialysis was initiated 10 months after the second biopsy. We also performed mass spectrometry (MS) and estimated exponentially modified protein abundance index (emPAI) and, significant levels of fibrinogen and fibronectin were detected. Immunostaining for fibrinogen, fibrin, and fibronectin was also positive in the subendothelial space.

Discussion: Our case pathologically showed rare fibril structure mimicking striated fibrin bundles, and clinically showed progressive renal impairment. MS and emPAI analysis suggested the possibility of new disease entity which was associated with endothelial injury induced by fibril structure composed of a fibrin-fibronectin complex. Clinicians should be aware of the findings of glomerulonephritis with striated ultrastructural deposits because these patients do not respond to steroids and have a poor prognosis.



SA-PO838

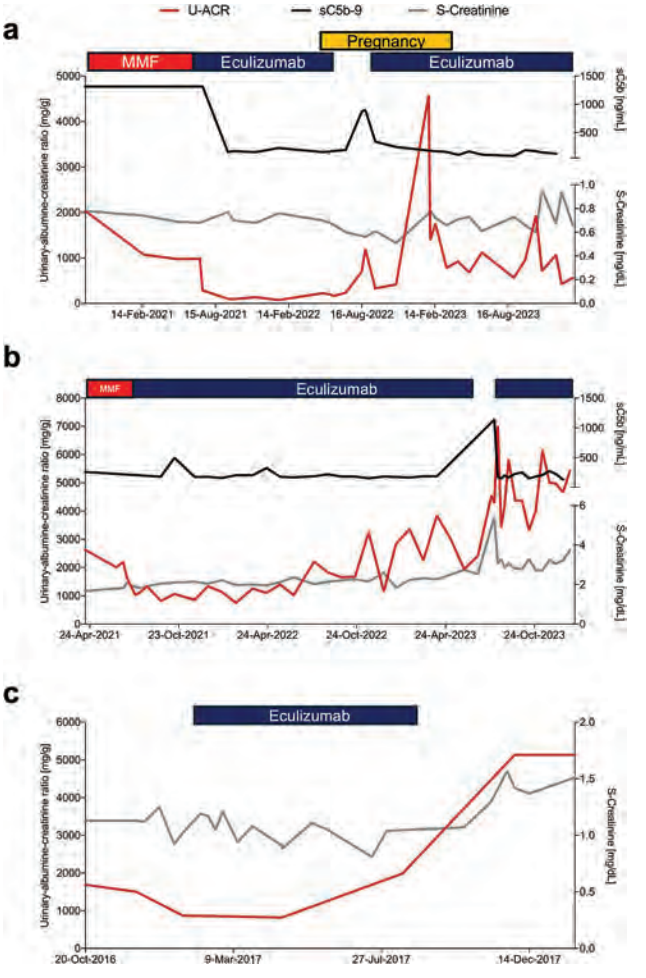
Rebound Albuminuria after Discontinuation of Eculizumab in Three Cases of Idiopathic Membranoproliferative Glomerulonephritis

Max Schuller,[1] Christof Aigner,[3] Marion J. Pollheimer,[2] Alexander R. Rosenkranz,[1] Kathrin Eller.[1] *[1]Medical University of Graz, Division of Nephrology, Graz, Austria; [2]Medical University of Graz, Institute of Pathology, Graz, Austria; [3]Medical University Vienna, Division of Nephrology and Dialysis, Vienna, Austria.*

Introduction: Idiopathic membranoproliferative glomerulonephritis (MPGN) is a rare, clinically challenging entity that frequently affects young individuals and is associated with a poor prognosis. Evidence for an involvement of the complement system in the pathogenesis of MPGN has resulted in the testing of C5 convertase inhibition by eculizumab, but response to treatment has been heterogenous.

Case Description: Here, we describe three patients (two female patients and one male patient) from two different centers with idiopathic MPGN (one IC-MPGN and two C3-GN), who showed a substantial increase in albuminuria and serum-creatinine that was paralleled by a substantial increase in sC5b-9 after stopping eculizumab due to pregnancy in one case and non-response in the other two. Reintroduction of eculizumab resulted in a prompt decrease in sC5b-9 and albuminuria.

Discussion: Our observations highlight the potential risk of increased albuminuria following treatment cessation of eculizumab in MPGN, irrespective of apparent treatment response. It is tempting to speculate that C5 convertase inhibition may suppress disease activity even in apparent non-responders. One may hypothesize that treatment of MPGN might need another form of complement blockade that more effectively inhibits complement activation or inhibits the complement system at an earlier activation step in the complement cascade. Additionally, our report supports eculizumab continuation for MPGN during pregnancy.



SA-PO839

Clinicopathological Profile and Outcomes of Kidney Amyloidosis: A Single-Centre Retrospective Biopsy Registry Cohort Study

Elenjickal E. John,[1,2] Rizwan Alam,[1] Vinoi G. David,[1] Santosh Varughese,[1] Suceena Alexander.[1] *[1]Christian Medical College Vellore, Vellore, India; [2]McGill University, Montreal, QC, Canada.*

Background: Kidney is the most common organ involved in systemic amyloidosis. The two most common types of amyloidosis affecting the kidneys are immunoglobulin (Ig)-derived and AA amyloidosis. Although classified under the same bracket of amyloidosis, each of these subtypes vary in their presentation, histology and outcomes which is not well defined.

Methods: This was an observational retrospective biopsy registry cohort study. done at a single centre in South East Asia. In total, 260 consecutive patients of amyloidosis who underwent kidney biopsy between January 2005 and December 2022 were included in this study.

Results: The mean age of the cohort was 52.5 ± 11.4 years and 67.3% were males. The most common histological type of amyloidosis was Ig amyloidosis (73.1%) followed by AA (14.6%) and undifferentiated amyloidosis (11.5%). Ig amyloidosis included 186 patients of AL amyloidosis and 4 patients of AHL amyloidosis. Extra-kidney involvement was seen in 22.7% patients. Patients with AA amyloidosis were younger, had a lower baseline estimated glomerular filtration rate (eGFR) and none of the patients had cardiovascular involvement. Patients with Ig amyloidosis were older, and almost half of the patients presented with nephrotic syndrome. Histologically, half of the patients had both glomerular and vascular deposits. Vascular and interstitial involvement was less commonly seen in undifferentiated amyloidosis. Majority (82%) of patients with Ig amyloidosis had lambda monoclonal light chain deposits. CyBorD was the most used chemotherapeutic regimen in Ig amyloidosis (38%). Of the 121 patients with follow-up >3months, 21 (17%) patients progressed to kidney failure over a median period of 11 (IQR, 8.5-29.5 months). The predictors of kidney failure were baseline eGFR < 30 ml/min, extensive glomerular amyloid deposits, moderate to severe IFTA and persistent proteinuria at follow-up. On Cox proportional hazard model, the only significant predictor was baseline eGFR < 30 ml/min [HR 4.37 (95% CI 1.01-18.88)]. Patients of Ig amyloidosis who did not attain VGPR were more likely to have persistent proteinuria at follow up (73% vs. 42%).

Conclusions: Clinicopathological presentation and outcomes differ based on the type of amyloidosis. Attainment of VGPR is associated with better kidney outcomes in Ig amyloidosis.

Fibrillary Glomerulonephritis Treated with Rituximab and Cyclophosphamide Combination Therapy: A Retrospective Cohort Study

Gabriel Sauvage,[1] Reza Zonozi,[1,2] Orhan Efe,[1,2] Anushya Jeyabalan,[1,2] Katherine M. Cosgrove,[1] Karen A. Laliberte,[1] John Niles,[1,2] Ayman Al Jurdi.[1,2]
[1]Vasculitis and Glomerulonephritis Center, Massachusetts General Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA.

Background: Fibrillary glomerulonephritis (FGN) is a rare kidney disease with a poor prognosis. Over 50% of patients progress to end-stage kidney disease (ESKD) within two years of diagnosis. Currently, no treatments have been shown to reduce the risk of ESKD in individuals with FGN. In this study, we aimed to describe the outcomes of FGN patients treated with a combination induction regimen of rituximab, low-dose oral cyclophosphamide, and prednisone.

Methods: We conducted a single-center retrospective cohort study including all patients with FGN treated at the Vasculitis and Glomerulonephritis Center at the Massachusetts General Hospital in Boston, MA between 2008 and 2024. The primary outcome was defined as the doubling of serum creatinine or the development of ESKD. Progression of kidney disease at the end of the follow-up period was the secondary outcome subdivided into the following categories: non-progressive (increase in serum creatinine by < 25%), progressive (increase in serum creatinine by > 25%), and ESKD (dialysis initiation or transplantation during the study period).

Results: We identified 14 consecutive patients with biopsy-proven FGN. 13 patients were treated with rituximab, low-dose cyclophosphamide, and prednisone, while one patient was treated with rituximab monotherapy. The median (IQR) follow-up was 3.0 (0.9-5.5) years. Five of 14 reached the primary outcome of doubling of serum creatinine or ESKD at a median of 2.8 years. At the end of follow-up, seven (50%) patients were non-progressors, two (14%) were progressors, and five (36%) had developed ESKD. To evaluate the effectiveness of the combination induction regimen, we compared the outcomes of individuals in our cohort to two historical cohorts (Hogan et al. *Nephrology Dialysis Transplantation* 2014, and Javaugue et al. *Am J Kidney Dis* 2013). Multivariable Cox regression showed that combination induction immunosuppression was associated with an 80% reduction in the incidence of ESKD (HR = 0.20, 95% CI 0.05-0.83, P = 0.03).

Conclusions: Our results suggest that combination therapy with rituximab, low-dose cyclophosphamide, and prednisone, is associated with a slower progression to ESKD in FGN. Clinical trials are needed to confirm these findings.

SA-PO841

A Rare Case of Waldenstrom Macroglobulinemia-Associated AHL Amyloidosis and Nephrotic Syndrome

Alexander M. Smith,[1,2] William Da Silva,[1,2] Swetha Rani Kanduri,[1,2] Ayaa M. Zarm,[1,2] Juan Carlos Q. Velez,[1,2] Chien-Wen Yang.[1,2] Ochsner Group.
[1]Ochsner Medical Center, New Orleans, LA; [2]The University of Queensland, Brisbane, QLD, Australia.

Introduction: AHL amyloidosis (combined heavy and light chain) is a rare subtype of amyloidosis, accounting for 4.2% of the Ig-related amyloidosis. Waldenstrom macroglobulinemia (WM), is linked to 5–7% of the Ig-related amyloidosis. Herein, we present a very rare case of WM-associated AHL amyloidosis who presented with normal serum *kappa/lambda* free light chain (FLC) ratio and positive Congo-red staining for amyloid on renal biopsy and confirmed by mass spectrometry.

Case Description: A 65-year-old woman presented with a 2-month history of bilateral lower legs swelling. Her medical history was pertinent for a remote stage III colon cancer. She had been diagnosed with WM 2 years prior and was managed with rituximab and bendamustine, and switched to acalabrutinib, a BTK inhibitor. On examination, she was hypotensive (86/56 mmHg), had marked bilateral 3+ pitting edema. Laboratory work up revealed a serum creatinine 0.7 mg/dL, albumin 1.8 g/dL, and urine protein-to-creatinine ratio 10 g/g. Serum protein electrophoresis (SPEP) showed a paraprotein peak near gamma. IgM level was high (1590 mg/dL) and *kappa/lambda* FLC ratio was normal (0.83/1.11). Cryoglobulin, anti-PLA2R, RPR, C3/C4 levels were normal. Renal biopsy revealed 25% glomerulosclerosis, 10-20% interstitial fibrosis and tubular atrophy, with immunofluorescence positive for IgM and *lambda* light chain restriction in glomeruli, and positive Congo-red stain. Mass spectrometry confirmed AHL-type amyloidosis. Bone-marrow biopsy showed 5-10% involvement by *lambda* light-chain restricted plasma cells and Congo-red stain positive. Bortezomib-based therapy was contraindicated due to severe neuropathy from prior oxaliplatin exposure, so zanubrutinib, a BTK inhibitor, was started based on efficacy consideration. She remains on this regimen and is being evaluated for bone marrow transplantation.

Discussion: This case exemplifies a very rare presentation of AHL amyloidosis in a patient with previously diagnosed WM. Interestingly, despite significant light chain deposition in renal pathology, serum *lambda* chain levels were normal. Hence, confirmatory tests including Congo-red staining on tissue biopsy and mass spectrometry were required for diagnosis. Renal prognosis is closely related to hematological responses.

SA-PO842

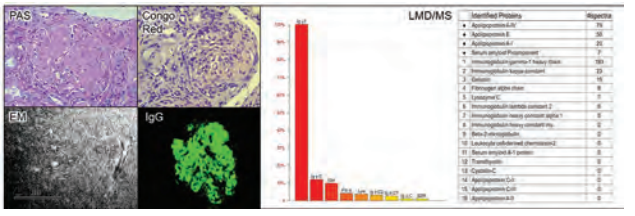
AH Amyloidosis Treated with Rituximab

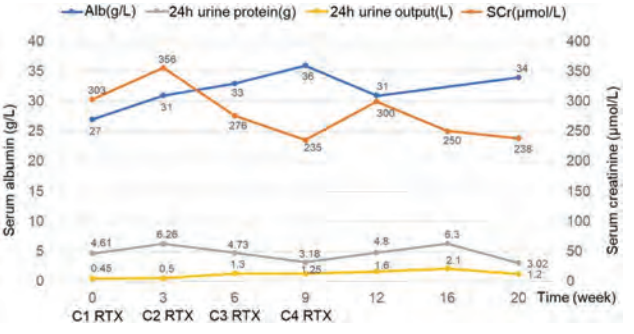
Yan Yang, Shi Jin, Yiqin Shi. *Zhongshan Hospital Fudan University, Shanghai, China.*

Introduction: Heavy chain amyloidosis is a rare type of amyloidosis caused by deposition of monoclonal immunoglobulin heavy chain usually produced by clonal plasma cells. Here we report a case of renal AH amyloidosis caused by clonal B lymphocytes and showed good prognosis after Rituximab treatment.

Case Description: A 67-year-old woman presented with nephrotic syndrome and progressively renal insufficiency was admitted. Laboratory results revealed sCr 303μmol/L, proteinuria 4.6 g/d, serum albumin 27g/L, and pancytopenia. Elevated κ/λ ratio 5.3, IgG κ monoclonal protein were detected. Anti-aCL IgM, aβ2GPI and anti-platelet were strongly positive. Bone marrow biopsy showed 0.2% abnormally mature small B lymphocytes and 0.1% plasma cells expressing κ light chain restriction. Kidney biopsy (figure 1) showed weakly PAS-positive nodules in glomeruli, with bright mesangial and capillary wall staining for IgG by IF and fibrillary deposits under EM. However, Congo red was negative. Laser microdissection/mass spectrometry studies confimed the AH (IgG) amyloidosis by detecting large signature amyloid spectra of IgG1, apo E, and A-IV. Therefore, renal AH amyloidosis was diagnosed. The patient was given rituximab, and kidney function improved with decreased urinary protein (figure 2).

Discussion: LMD/MS analysis is crucial in the diagnosis of rare amyloidosis. The choice of treatment should consider affected organs and the source of malignant cells. The prognosis is relatively good after appropriate therapy.





SA-PO843

A Rare Case of Renal AA Amyloidosis Secondary to Infectious Etiology

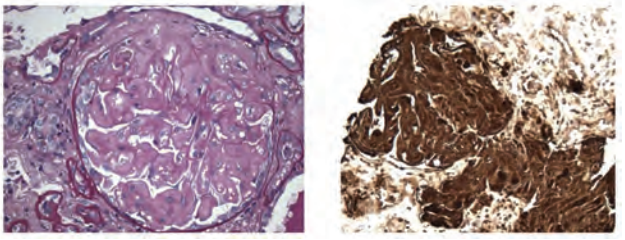
Irvianny Madera, Lorgis I. Jimenez Perez, Bessy Suyin Flores Chang.
SBH Health System, Bronx, NY.

Introduction: AA amyloidosis, characterized by the deposition of serum protein amyloid AA, typically arises in inflammatory settings, such as active infections. While renal involvement is common, cases directly linked to pneumonia leading to end-stage renal disease (ESRD) are exceedingly rare. Here, we present such a case, shedding light on its clinical course and management challenges.

Case Description: 62-year-old male with history of HIV presented to the hospital due to worsening diarrhea and shortness of breath. On admission, he presented with serum creatinine of 9.2 mg/dL (0.6-1.2 mg/dL) (baseline 0.9 mg/dL, two months prior) and a protein/creatinine ratio of 10. He was found to have cavitary lesions in a Computerized Tomography (CT) scan suggesting unresolved necrotizing pneumonia when compared to previous imaging. In the meantime, he required hemodialysis. Due to nephrotic range proteinuria of unknown etiology, a kidney biopsy was performed which showed severe AA amyloidosis with moderate tubular atrophy and interstitial fibrosis. Unfortunately, the patient remains in hemodialysis.

Discussion: We describe a patient with a rapid decline in renal function for whom we hypothesize that the ongoing infection in his immunosuppressive state led to reactive AA amyloidosis. Renal AA amyloidosis is presented rarely in adult-age patients. One case is described similar to our patient where renal AA amyloidosis was caused by pulmonary

Mycobacterial infection associated with diarrhea. However, in our patient, none of the acid-fast bacilli cultures were positive. The standpoint in management is decreasing the inflammatory environment in the patient, however since our patient already had moderate tubular atrophy, prognosis remained poor.



Kidney histology showing AA amyloidosis in H&E stain (left) and immunohistochemistry (right).

SA-PO844

Postkidney Transplant Outcomes among Patients with Prior Diagnosis of Leukocyte Chemotactic Factor 2 (ALECT2)-Associated Amyloidosis: A Case Series

Pablo Garcia,[1] Paul B. Avila,[2] George Vasquez-Rios,[3] Namita Singh,[1] Saeed K. Shaffi,[1] Christos Argyropoulos.[1] *[1]The University of New Mexico, Albuquerque, NM; [2]Universidad de San Carlos de Guatemala Facultad de Ciencias Medicas, Guatemala, Guatemala; [3]Renal Medical Associates, Alburquerque, NM.*

Introduction: ALECT2 amyloidosis, a prevalent form of amyloidosis in the Soutwestern US mainly New Mexico, predominantly affects Hispanic patients and often leads to kidney failure 35%. Notably, long-term outcomes in kidney transplant recipients with ALECT2-associated kidney failure remain understudied. This study fills this gap by analyzing long-term outcomes in this specific patient population.

Case Description: Three patients, aged 45 to 78 years, were diagnosed with ALECT2 based on kidney biopsy findings. All patients underwent kidney transplantation and received immunosuppressive therapy, which included various combinations of envarus, mycophenolate, tacrolimus, and/or prednisone. Details of each case are summarized in the accompanying table. During the follow-up period, ranging from 8 to 60 months, all patients remained stable with preserved estimated glomerular filtration rate (eGFR) and minimal or no urinary protein-to-creatinine ratio (UPCR).

Discussion: The most comprehensive cohorts in ALECT 2 with a follow-up of 30-50 months indicate a higher risk of rapid progression to ESKD in patients with biopsy-proven ALECT2. However, in this post-kidney transplant cohort with long-term follow-up – up to 60 months, there is no evidence of clinically significant renal ALECT2 recurrence. Further research is needed to determine the long-term kidney outcomes among post-transplant recipients with ALECT2.

Age at Txp	Gender	Race/Ethnicity	ESKD	DM	Post Txp eGFR*	Post Txp UPCR**	Follow-up time (months)	Follow-up eGFR	Follow-up UPCR	ISR	Other therapies	ALECT2 post Txp

SA-PO845

A Rare Case of Cryoglobulinemic Membranoproliferative Glomerulonephritis in the Setting of Negative Hepatitis Serologies

Anastasios Papanagnou,[1] Sanjeev Gupta.[2] *[1]NewYork-Presbyterian Hudson Valley Hospital, Cortlandt Manor, NY; [2]Westchester Medical Center, Valhalla, NY.*

Introduction: Membranoproliferative glomerulonephritis (MPGN) accounts for approximately 7-10% of all cases of biopsied glomerulonephritis, characterized (histologically) by mesangial hypercellularity, subendothelial deposition of immune complexes, and duplication of the glomerular basement membrane (tram-track appearance). MPGN is classified as being mediated by immune complexes, complement dysregulation, or neither of the two. MPGN can be caused by chronic infections (especially hepatitis), autoimmune diseases, and paraproteins (including cryoglobulinemia). Cryoglobulinemic MPGN is reported to be highly associated with chronic hepatitis C virus (HCV) infection but there are only a few case reports documenting cryoglobulinemic MPGN in the absence of chronic hepatitis.

Case Description: We present a case of an 81 y/o woman without any underlying hepatitis, with mild to moderate AS, CHF, HTN, LBBB, osteopenia, polymyalgia rheumatica, who presented to the hospital with worsening SOB and LE edema. Labs showed AKI with associated microscopic hematuria and nephrotic range proteinuria (Urine protein/creatinine ratio of 8.18). She was admitted for management of a CHF exacerbation, started on IV Lasix with improvement in her symptoms. Proteinuria work-up revealed ANA (+) 1:1280, C3 83 (mildly depressed), atypical p-ANCA pattern (1:640) and positive cryoglobulins. SPEP/serum immunofixation: no monoclonal proteins, serum FLC ratio 1.48. Blood cultures did not show any growth. HIV and Hepatitis B/C panels were both negative. Renal biopsy showed diffuse endocapillary proliferative and focal crescentic glomerulonephritis with membranoproliferative features with IgM-dominant deposits, mild tubular atrophy, interstitial fibrosis and mild acute tubular injury. The patient was started on a prednisone taper and mycophenolate. She was subsequently discharged with close outpatient renal follow-up. Serial outpatient labs, over the span of 6 months, showed resolution of her AKI and microscopic hematuria, with dramatic improvement of her proteinuria down to trace levels.

Discussion: We discussed a rare case of cryoglobulinemic MPGN with strong IgM staining, without underlying hepatitis, which led to a positive outcome after receiving combination steroid/mycophenolate therapy. Moreover, there is still much to be learned about establishing the standard of care for managing cases, like this one, appropriately.

SA-PO846

A Case of Heavy Chain Deposition Disease

Stela Teferici,[1,2] Aaron S. Stern,[1,2] Nitzy N. Munoz Casablanca.[1,2] *[1]Elmhurst Hospital - Main Campus, Elmhurst, NY; [2]Mount Sinai Health System, New York, NY.*

Introduction: Monoclonal Immune Deposition Disease (MIDD) is a rare manifestation of monoclonal gammopathy of renal significance, with non-organized deposition of monoclonal proteins in the glomerulus. Deposition that only involves the heavy chain portion of a monoclonal immunoglobin is even rarer. We present a case of Heavy Chain Deposition Disease (HCDD).

Case Description: A 61-year-old female was referred to our clinic for edema and nephrotic syndrome. She had facial and pedal edema, hypoalbuminemia and a Urine Protein/Creatinine Ratio of 4. Further work-up revealed antinuclear antibody: 1: 320, Complement 3: 72mg/dL (mildly low), Complement 4: 32mg/dL (normal), Serum protein electrophoresis (SPEP) had a weak gamma paraprotein, Immunofixation electrophoresis (IFE) was positive for immunoglobulin G (IgG) kappa. Serum free light chain kappa (K)/lambda (λ) ratio was 9.1. Renal biopsy showed a pronounced nodular mesangial appearance on light microscopy. Congo-red staining was negative. Immunofluorescence showed deposits composed of IgG along glomerular, tubular, and basement membranes, with negative staining for K and λ light chains, findings consistent with HCDD. The heavy chain subclass was not performed. Electron Microscopy revealed a powdery appearing deposition in the basement membrane.

Discussion: In elderly patients with nephrotic syndrome, diabetes and amyloidosis are common culprits. Our case supported this suspicion with a positive SPEP, IFE, and free light chain assay. However, while the kidney biopsy showed a nodular sclerosis pattern suggestive of amyloidosis, further analysis with staining and immunofluorescence revealed a rarer diagnosis: heavy chain deposition disease (HCDD) associated with a paraproteinemia. On review of the previously reported cases of HCDD, common clinical presentations include nephrotic syndrome, renal insufficiency, hematuria, and, in some cases, hypocomplementemia. Hematologic workup to assess for a plasma cell dyscrasia is ongoing.

SA-PO847

Rituximab for Patients with Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits (PGNMID): A Case Series

Sai Prasad Desikan, Samir V. Parikh. *The Ohio State University Wexner Medical Center, Columbus, OH.*

Introduction: Monoclonal gammopathy of renal significance (MGRS) is defined is a clonal disorder characterized by renal monoclonal immune deposition without adequate criteria for a specific malignancy. PGNMID, a subtype of MGRS, is further defined by granular deposits without organization that are predominantly located in the mesangium and / or subendothelium on electron microscopy. Here we present a case series of 5 patients treated with regimens including rituximab.

Case Description: Patients were aged between 17 and 72. Creatinine on presentation ranged from 0.66 to 3.22 mg/dL. All patients had proteinuria with 4 patients with nephrotic range proteinuria. Three patients had monoclonal IgG3 with kappa predominant deposits. One patient had both kappa and lambda deposits. One patient had lambda restricted deposits. All patients received rituximab and steroids. One patient received cyclophosphamide. Of the 5 patients, three patients responded (> 30% reduction in proteinuria without decrease in GFR >25%) to therapy. These three patients have maintained response to date with progression free survival of 42, 70 and 91 months respectively. None of these patients have required dialysis to date. Two patients did not respond to therapy. One patient later responded to velcade, dexamethasone, and daratumumab. The other patient required dialysis prior to treatment and eventually passed away with a survival of 3.2 months.

Discussion: Here we present a case series of 5 patients that received rituximab-based regimens. Three patients had durable renal remissions with rituximab-based regimens. Two patients did not respond. One of these patients did eventually respond to a plasma

cell directed therapy. This case series suggests that for some patients a rituximab-based regimen is adequate to induce and maintain a renal remission; however, there is a subset of patients that may benefit from plasma cell directed treatment.

SA-PO848

Pregnancy-Associated Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposition

Ram Sinha, Chintan V. Shah, Amer A. Belal. *University of Florida, Gainesville, FL.*

Introduction: Proliferative glomerulonephritis with monoclonal immune deposits (PGNMID) is a rare form of monoclonal gammopathy of renal significance. Although it has been rarely reported at a young age, pregnancy-associated PGNMID represents a unique and rare clinal presentation that requires further understanding. Diagnosis of the condition is challenging as the clinical presentation and lab findings upon presentation are non-specific.

Case Description: A 32-year-old female without any significant past medical history presented at 35 weeks of gestation with elevated blood pressure, a serum creatinine (S. Cr) of 0.58 mg/dL, and proteinuria of 2.8 grams/d. Serum creatinine increased to 1.2 mg/dL. A presumed diagnosis of pre-eclampsia was made, and vaginal delivery was induced at 37 weeks. Six weeks later, the patient was re-admitted with peripheral edema, uncontrolled hypertension, and acute kidney injury with a peak S. Cr of 4.5 mg/dL. Her 24-hour urine protein was 9.4 grams/d, and S. albumin was 1.7 gm/dL. A kidney biopsy showed IgG3-Lambda PGNMID with 80% cellular crescents. A detailed workup to identify pathological clone was negative, including serum protein electrophoresis, serum immunofixation, light chain ratio, peripheral blood flow cytometry, and bone marrow biopsy. Although kidney function improved with high-dose steroids initially with S. Cr of 1.4 mg/dL, the patient remains with persistent and severe nephrotic syndrome after 6 weeks of high-dose steroids (Prednisone 1mg/kg/d) and is being considered for empirical clone-directed therapy, pending insurance approval, at the time of writing this report.

Discussion: The pathogenesis of PGNMID associated with pregnancy requires further understanding. Pregnancy is a state of dramatic immune modulation. The fetus/placenta unit could induce a maternal immune response, as part of the pro-inflammatory state or working as an alloantigen, producing nephrotoxic monoclonal protein resulting in PGNMID. Notably, while two previously reported cases improved after delivery, our patient failed to show clinical improvement with steroids after delivery and requires further treatment with clone-directed therapy. Thus, Pregnancy-associated PGNMID requires further understanding of pathophysiology, treatment options, and clinical prognosis.

SA-PO849

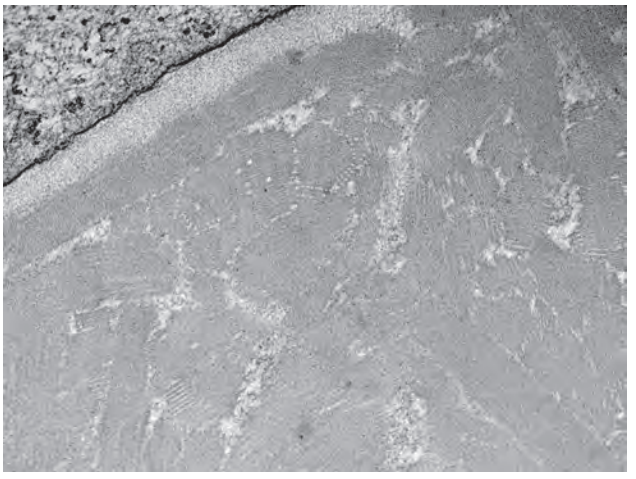
Novel Grid-Like Substructure in a Case of Paracrystalline Monoclonal Gammopathy of Renal Significance (MGRS)

Rajib K. Gupta,[1] Sajid Melvin George,[2] Xin Gu,[3] Lois J. Arend.[4] *[1]UC Davis Medical Center, Sacramento, CA; [2]Richmond Nephrology Associates, Richmond, VA; [3]LSU Health Shreveport, Shreveport, LA; [4]Johns Hopkins University, Baltimore, MD.*

Introduction: Monoclonal deposits with substructure in the kidney are essentially of 3 types – fibrillary, microtubular and crystalline deposits. Grid-like substructure, also known by other descriptors like mesh-like, lattice-like or striated muscle-like, has been described as a rare electron microscopic (EM) appearance of monoclonal deposits occurring in association with monoclonal gammopathy of renal significance (MGRS), most commonly involving the glomeruli. Here we describe a rare case with abundant grid-like monoclonal deposits.

Case Description: Patient is a 62-year-old Caucasian male with pancytopenia, acute kidney injury and a recent diagnosis of MGUS. SPEP showed a monoclonal M-spike 1.1 gm/dL with IgG kappa on serum and urine immunofixation. Bone marrow biopsy showed 5% kappa-restricted plasmacytosis, and a kappa to lambda ratio of 2.7. Serum complements were low. The patient also had motor neuropathy. Urinalysis showed 3+ protein and 3+ blood. Rheumatoid factor, serum cryoglobulin, ANCA and anti-GBM antibodies were negative. ANA was mildly positive. Kidney biopsy revealed glomeruli with a membranoproliferative pattern along with occlusive, large, intracapillary hypereosinophilic pseudothrombi which showed IgG1 and kappa restriction on immunofluorescence. EM revealed massive intraluminal and subendothelial electron-dense deposits having an extremely compact grid-like paracrystalline substructure, vaguely resembling the EM appearance of striated muscle.

Discussion: Grid-like substructure has been described in association with monoclonal renal disease in few reports, most typically type 1 cryoglobulinemic glomerulonephritis (CryoGN) although rare association with proliferative GN with monoclonal immunoglobulin deposits (PGNMID) has also been described. In this patient, the overall histologic findings favored a type 1 seronegative CryoGN. Awareness of such rare substructure and its association with monoclonal glomerular deposits is important for timely diagnosis of MGRS.



SA-PO850

A Case of MGRS-Associated C3 Glomerulonephritis following Acute COVID-19 Infection

Keith L. Saum, Jeffrey B. Hodgin, Jennifer A. Schaub. *University of Michigan, Ann Arbor, MI.*

Introduction: C3 glomerulonephritis (C3GN) is a proliferative GN resulting from mutations or functional inhibition of regulatory proteins in the alternative complement pathway. Rarely, inhibition of complement-regulating proteins may result from monoclonal gammopathy. We present a case of C3GN associated with monoclonal gammopathy of renal significance (MGRS) following acute COVID-19 infection.

Case Description: A 60-year-old female with a history of hypertension developed new edema one month following acute COVID-19 infection which had been managed conservatively as an outpatient. She was subsequently admitted for nephritic syndrome with worsening hypertension, serum creatinine of 1.9 mg/dl, and proteinuria of 2.4g/24hr. Urinalysis was positive for protein and blood with dysmorphic RBCs on urine sediment. Serologic evaluation was notable for a new IgG Lambda M-protein on SPEP with a normal free-light chain ratio and low C3 level. Blood cultures, C4, ANA, cryoglobulins, ANCA, HIV, HBV, HCV, and were normal/negative. Despite adequate blood pressure control with nifedipine and irbesartan, proteinuria and hematuria persisted for >8 weeks. Kidney biopsy showed neutrophilic glomerulitis with a membranoproliferative pattern. Immunofluorescence showed only mesangial and capillary C3 deposits. Pronase digestion of paraffin samples did not reveal masked immunoglobulin deposits. Functional complement testing demonstrated increased C3 convertase activity and negative for autoantibodies to complement regulatory proteins. Subsequent bone marrow biopsy revealed a 5% IgG Lambda plasma cell clone, consistent with MGRS-associated C3GN. She was treated with six cycles of cyclophosphamide, bortezomib, and dexamethasone resulting in improvement in proteinuria and serum creatinine.

Discussion: C3GN is a rare variant of MGRS not associated with infection. Although causality between the preceding COVID-19 infection and the subsequent C3GN cannot be proven, other cases of post-viral MGRS, have been reported. Nephrologists should be aware that not all kidney disease occurring after COVID-19 is due to tubular injury or collapsing glomerulopathy.

SA-PO851

Double Jeopardy: Monoclonal Gammopathy of Renal Significance (MGRS) in the Shadow of Lupus Nephritis

Yara Mouawad, Amanda Tchakarov, Dia R. Waguespack. *The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX.*

Introduction: Monoclonal gammopathy of renal significance remains a clinical challenge given the rarity of the condition and lack of literature regarding treatment and outcomes.

Case Description: This is the case of a 56 year old female with diagnosed APLS, SLE, and cryoglobulinemia. Her disease course was complicated by multiple thrombotic events requiring adjustment of her anticoagulation. She had quiescent disease, and was off treatment except for anticoagulation, when work up showed a rising creatinine, elevated dsDNA titers, and hematuria. A renal biopsy was considered to be high risk given her anticoagulation and thrombocytopenia, therefore she was assumed to have lupus nephritis and was started on Plaquenil, prednisone and later azathioprine. Despite treatment, she had worsening proteinuria up to nephrotic levels. She was switched to mycophenolate, however was unable to tolerate it. At the same time, she complained of a worsening rash on her lower extremities. A renal biopsy was then performed which

revealed "Proliferative Glomerulonephritis with Monoclonal IgG Deposits, specifically IgG kappa restricted deposits". The biopsy did not show evidence of lupus nephritis, APLS or cryoglobulinemic vasculitis. She initially had a normal SPEP and a bone marrow biopsy was normal ruling out any hematological malignancy, MGUS, or MM. Repeat SPEP showed an IgG kappa monoclonal band consistent with deposits seen on renal biopsy. Given the lack of data on treatment of monoclonal gammopathy of renal significance in patients with underlying autoimmune diseases, the decision was made to treat with Rituximab as a clone depleting agent.

Discussion: This case highlights the importance of considering monoclonal gammopathy of renal significance as a cause of glomerulonephritis, particularly in patient with SLE despite its rarity.

SA-PO852

Semaglutide-Associated Minimal Change Disease: A Potential Rare Complication of a Novel Medication

Gary Tan, Kenar D. Jhaveri, Omar Muhammad, Ming Wu, Spencer Weintraub. *Northwell Health, New Hyde Park, NY.*

Introduction: Glucagon-like peptide 1 receptor agonists (GLP1-RAs) are a class of antihyperglycemic medications that have demonstrated benefits for obesity and cardio-renal protection. The increased utilization of these therapies may reveal previously undocumented adverse effects.

Case Description: An 83-year-old male with CKD (baseline Cr 1.7), hypertension, hyperlipidemia, congestive heart failure, hypothyroidism, and obesity (BMI 33) presented to the hospital with 5 days of dyspnea and bilateral leg swelling. He was recently started on Semaglutide in Israel. The patient reports no use of NSAIDs or over-the-counter medications. On exam, he had diminished breath sounds at the lung bases and 2+ bilateral lower extremity pitting edema. Labs showed BUN 34mg/dL, creatinine 2.06mg/dL, and albumin of 2.2g/dL. He had a total serum cholesterol level of 213 mg/dL and triglyceride of 170mg/dL. Urinalysis had 4+ proteinuria. The urinary protein to creatinine ratio (UPCR) was 17.2g/g. Serologic testing of ANCA-ab, ANA, GBM-ab, PLAR2R-ab were all negative. HIV, viral hepatitis, and renal ultrasound studies were unremarkable. A renal biopsy was performed, and light microscopy revealed global glomerulosclerosis. Electron microscopy showed complete visceral epithelial cell foot process effacement, which was consistent with minimal change disease (Figure 1). He was treated with pulse solumedrol for 3 days and transitioned to a 3-month prednisone taper. The patient also received 2 doses of Rituximab during the admission. UPCR improved from 17.2g/g to 9.2g/g. His creatine peaked at 4.1mg/dL and improved to 3.2mg/dL at discharge.

Discussion: Podocytopathies can be associated with certain medications (i.e. NSAIDS, lithium, interferon), but their link with GLP-RAs has not been well described. Therefore, new edema or proteinuria associated with GLP1-RA initiation should prompt investigation for glomerular disease and discontinuation of the medication.

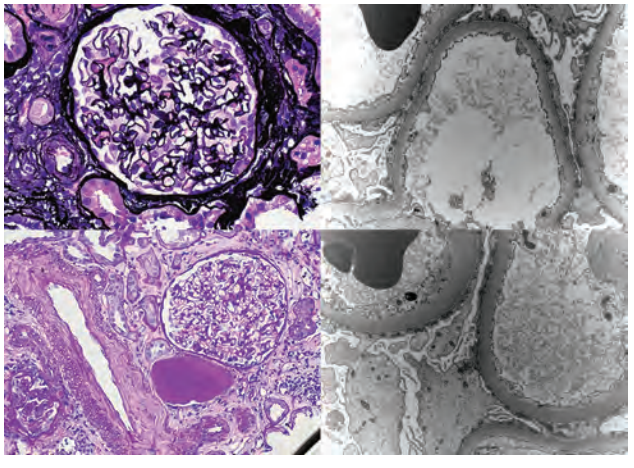


Figure 1

SA-PO853

Mesalamine-Induced Minimal Change Disease

Sahar A. Bhai, Ryan A. Parrish, Jatayah Sheed, Folasade Arinze. *Wellstar Kennestone Regional Medical Center, Marietta, GA.*

Introduction: Minimal change disease frequently manifests as a nephrotic syndrome that is mediated by inflammatory effacement of podocytes, either due to a hypersensitivity reaction or direct toxin effect. The etiology is often idiopathic, but some inciting factors include cancer, infections, and medications. Mesalamine, also known as 5-aminosalicylic acid (5-ASA), is commonly used to treat IBD. Nephrotoxicity is a known but rare adverse effect of 5-ASA with an incidence of 0.17% per year. The most common manifestations include chronic interstitial nephritis, renal calculi, papillary nephritis, idiopathic nephrotic syndrome, and FSGS. However, minimal change disease remains a rare complication and has only been described with the chronic use of mesalamine. We present a case of rapid development of acute nephrotic syndrome after 5-ASA overdose.

Case Description: A 24-year-old man with a history of ulcerative colitis on mesalamine presented with generalized swelling after ingestion of extra doses of his mesalamine. On the day of presentation, he noticed lower extremity and abdominal swelling. His exam was remarkable for 4+ pitting edema of the lower extremities, abdominal distention, and mild periorbital edema. Labs were notable for Na+ 128 mmol/L, creatinine 1.44 mg/dL, albumin 1.4 g/dL, CK 128 IU/L. Urinalysis showed 4+ protein and 2+ blood. His 24-hr urine protein was 16.3g. Testing for HIV, hgb A1C, syphilis, ANA, C3, C4, anti-GBM, and ANCA panel were normal. Renal biopsy showed effacement of podocytes on electron microscopy. He was treated with prednisone during admission with symptom improvement and near-resolution of proteinuria at 3 month follow up with full remission expected.

Discussion: This case report illustrates rapid development of MCD within days of overdose of mesalamine. While previous case reports described patients who developed MCD with chronic mesalamine use, it remains a rare adverse effect. While most adult patients with MCD remain in remission following adequate treatment, approximately 5% will develop a relapsing-remitting disease course that progresses to end-stage renal disease despite treatment. Several organizations have proposed routine intervals to monitor serum creatinine and 24-hour urine protein in patients on 5-ASA. However, recommendations vary and no consensus for monitoring exists. Future guidelines should promote standardization of monitoring.

SA-PO854

Rifampin-Induced Minimal Change Disease

Robert Kosalka, Fitsum T. Hailemariam. *Thomas Jefferson University Sidney Kimmel Medical College, Philadelphia, PA.*

Introduction: Latent *Mycobacterium tuberculosis* affects around 25% of the international and 3.1% of the American population. One of the most common treatments is rifampin. In the past, there have been cases of rifampin-associated interstitial nephritis and nephrotic diseases which have typically resolved with cessation of the offending agent and a short course of steroids. Although rituximab and calcineurin inhibitors (CNI) are effective treatments in frequently relapsing/steroid-dependent patients with primary minimal change disease (MCD), this is the first reported case of their use in rifampin-induced MCD.

Case Description: This is a 33-year-old female with a history of latent tuberculosis who presented to the hospital with edema, nausea, and vomiting. One month before, she was initiated on rifampin 600mg daily with a planned 4-month course. On initial blood work, she had an elevated creatinine of 1.46mg/dL from a baseline of 0.7mg/dL, and an albumin of 2.1g/dL. Urinalysis revealed 3+ protein and 2+ blood. The urine protein-creatinine ratio was 26.2mg/mg. She had negative anti-MPO, anti–PR3, ANA, anti-dsDNA, and anti-GBM antibodies, and normal C3 and C4 levels. Renasight genetic testing revealed no known disease-causing variants. Rifampin was discontinued. Solumedrol 500mg was given and followed with prednisone at 1mg/kg. A kidney biopsy was obtained. Light microscopy was unremarkable, but electron microscopy revealed diffuse podocyte foot process effacement, vacuolization of cell bodies, and villous transformation of the cytoplasm consistent with MCD. Creatinine peaked at 4.18 mg/dL before trending down to baseline. Prednisone was rapidly tapered. Once steroid therapy was completed, the proteinuria returned and prednisone was resumed. Due to refractory proteinuria, she received rituximab 1g twice two weeks apart and tacrolimus (target trough of 3-5mg/dL) and a short steroid taper owing to weight gain and hypertension.

Discussion: When evaluating patients with drug-induced nephrotic syndrome, clinicians should be aware that removing the offending agent is not always enough. This case shows that the principles of treating primary MCD can apply to secondary MCD. This patient with relapsing disease eventually responded to rituximab and CNIs. It is important to monitor proteinuria in these patients to choose the most appropriate treatment.

SA-PO855

Minimal Change Disease Secondary to Adalimumab

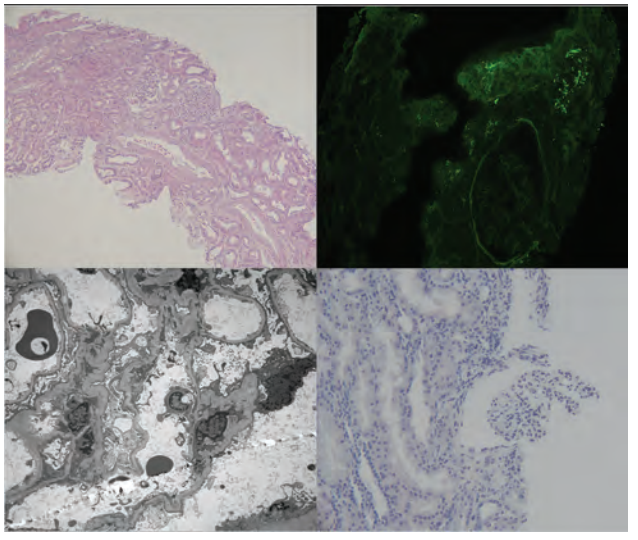
James Allen, Joshua Kaplan, Smita Mahendrakar. *Rutgers University Newark, Newark, NJ.*

Introduction: Adalimumab is a fully human recombinant monoclonal antibody against TNFa. There have been case reports of patients developing proteinuria following treatment with adalimumab for rheumatoid arthritis (RA). Renal pathology demonstrating membranous glomerulopathy, pauci-immune necrotizing and crescentic glomerulonephritis have been reported. We describe a patient who developed minimal change disease as an adverse effect of treatment with the anti-TNFa adalimumab.

Case Description: A 63-year-old female with seropositive RA treated with adalimumab presented to the hospital with generalized swelling. Symptoms started seven days prior to admission after she received her fifth injection of adalimumab. Generalized

swelling was noted the morning after her dose. She met clinical criteria for nephrotic syndrome with nephrotic range proteinuria, hypoalbuminemia, peripheral swelling, and hyperlipidemia. Significant labs included cholesterol and triglycerides of 413mg/dL and 392mg/dL, up from 208mg/dL and 178mg/dL prior to adalimumab injection. Albumin was up from 4.1gm/dL four months prior to 1.6gm/dL on admission. 24-hour urine protein was greater than 3.9g/day. Renal biopsy was obtained which showed minimal glomerular alterations with marked effacement of foot processes ultra-structurally and negative immunofluorescence studies consistent with minimal change disease. Treatment was initiated with 1mg/kg/day of prednisone with following taper after one month. Supportive management including statins and diuretics was prescribed. With the protein to creatinine ratio decreasing to 0.106g/day and albumin improving to 4.2gm/dL on the two month follow up, steroids were discontinued.

Discussion: We present a case of a rare cause of adult-onset minimal changed disease secondary to adalimumab. Patients on anti-TNF therapy should be monitored for signs of nephrotic syndrome including peripheral edema, proteinuria, and hypoalbuminemia.



SA-PO856

Minimal Change Disease and Overlapping IgA Nephropathy Associated with Peripheral Inflammatory Spondyloarthropathy

Hannah Angle, Gilda M. Portalatin, Narender Annapureddy, Anna M. Burgner. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Spondyloarthritis (SpA) describes a group of seronegative rheumatic disorders that cause skeletal inflammation. They are often associated with HLA-B27 and have been linked with kidney disease, specifically IgA nephropathy. However, associations between SpA and other glomerular diseases have not been well elucidated. Here, we present a rare case of minimal change disease (MCD) associated with peripheral SpA.

Case Description: A 50-year-old male with HTN presented with AKI and nephrotic syndrome with Cr 2.9mg/dL and urine protein creatinine ratio (UPCR) 18.6g/g. A few months prior, he developed right knee pain treated with NSAIDs. Kidney biopsy revealed MCD with mild IgA nephropathy. He was treated with prednisone 1 mg/kg daily for 4 weeks until remission was achieved. After a 4-month taper, he developed severe pain and stiffness of multiple distal joints. Labs notable for CRP 86.7 mg/L and UPCR 7.5g/g. Further workup included positive HLA-B27 and synovial fluid analysis consistent with inflammatory arthritis, raising suspicion for peripheral SpA. Prednisone was resumed, and his joint symptoms and proteinuria subsequently resolved. Unfortunately, due to recurring arthritic flares at lower steroid doses, prednisone could not be tapered. Methotrexate was initiated without response. Then, adalimumab was initiated and steroids were tapered off. Over 2 months, CRP and UPCR normalized, arthritis symptoms resolved, and MCD remission was achieved.

Discussion: Kidney involvement is seen in many rheumatic diseases, whether from direct pathologic effect or secondary to treatment. Nephrologists and rheumatologists must work together to manage these patients. SpA with HLA-B27 positivity has previously been linked with kidney disease, specifically ankylosing spondylitis and IgA nephropathy. Our patient with primary MCD associated with peripheral SpA is discordant with existing literature. His joint symptoms were primarily peripheral, unlike ankylosing spondylitis, and there was no clinical evidence to suggest reactive arthritis or arthritis associated with psoriasis or IBD. With adalimumab, his joint symptoms and proteinuria quiesced. This case emphasizes the temporal relationship between MCD and peripheral SpA. Recognizing the interconnection between the diseases played a key role in successfully treating this patient.

SA-PO857

Refractory Primary Podocytopathy: Any Role for Daratumumab?

Victor Martinez Leon, Abdallah Sassine Geara. *University of Pennsylvania, Philadelphia, PA.*

Introduction: Primary Podocytopathy is an autoimmune injury of the podocytes with a characteristic histopathologic lesion of focal and segmental glomerulosclerosis (FSGS) or minimal change disease (MCD). It is associated with abrupt onset of nephrotic syndrome and treated with corticosteroid and anti-B cell therapy.

Case Description: 30-year-old male previously healthy presented with peripheral edema and shortness of breath, his urine protein to creatinine ratio (UPCR) was 5.8 g/g for which he underwent kidney biopsy showing MCD. The patient had a complete remission following a prednisone course however he relapsed at 4 months (during the prednisone tapering) and had a prolonged course of steroid-refractory nephrotic syndrome a repeat kidney biopsy showed FSGS tip lesion. The immunosuppressive therapies and adverse events (AE) were sequentially: 1. Prednisone 80mg for additional 4 months (AE: retinal detachment) 2. Rituximab 1g x2 with successful depletion of CD19+ B cells without decrease in proteinuria (AE: hypogammaglobulinemia) 3. Obinutuzumab 1g x2 followed by 1g at 6 months with worsening proteinuria to 6.4 g/g (AE: fungal pneumonia) 4. Repeat steroid course, tacrolimus (trough: 5-7 µg/l) and Dapagliflozin 10 mg daily (AE: AKI) The patient received Daratumumab 1800mg SC weekly for 8 doses with improvement of the UPCR to to 0.89 g/g, increase albumin to 3.4 g/dL and resolution of the edema that was persistent for more than 2 years.

Discussion: Guidelines recommend high-dose steroids as first-line the treatment for primary FSGS and MCD. Tip glomerular lesion has been described to respond to glucocorticoid therapy more than patients with the other FSGS variants. Calcineurin inhibitors and rituximab (anti-CD20 mAb) can be used for the treatment of frequently relapsing MCD or FSGS. Although not yet widely use, the anti-CD38 mAb, Daratumumab, has been used in some cases of post-transplant recurrent FSGS with promising results. Further randomized control trials of patient with multi-drug resistant primary podocytopathy are needed to determine the efficacy of daratumumab.

Clinical course and treatment

SA-PO858

Refractory Nephrotic Syndrome Resulting in Bilateral Achilles Tendon Rupture Due to Relapse by Vaccination after Recovery from COVID-19: A Case Report

Jun Takeoka,[1] Ryo Sato,[1] Kansei Otsuka,[1] Naohiro Toda,[1] Kyoka Fujita,[1] Satoshi Kurahashi,[1] Kosuke Mochizuki,[1] Hisako Hirashima,[1] Toshiyuki Komiya,[2] Eri Muso,[1] Akira Ishii.[1] *[1]Kansai Denryoku Byoin, Osaka, Japan; [2]Otsu Sekijuji Byoin Toshoshitsu, Otsu, Japan.*

Introduction: There are several reports suggesting the involvement of SARS-CoV-2 (COVID-19) infection and COVID-19 messenger RNA (mRNA)-based vaccine respectively in the development and severity of nephrotic syndrome. We report a case of refractory nephrotic syndrome resulting in bilateral Achilles tendon rupture due to relapse by vaccination shortly after recovery from COVID-19.

Case Description: A 60-year-old man was diagnosed with minimal change nephrotic syndrome (MCNS) 37 years ago and was in remission with steroid therapy. Although it recurred a total of five times over the next 36 years, the disease remained relatively stable, Two months before admission, he developed a COVID-19 pneumonia and was cured by treatment. Just two months later, he received the third dose of COVID-19 vaccine and was admitted to our department with generalized edema, rapid weight gain of 12 kg in 2 weeks, proteinuria (3.3 g/gCr) and hypoalbuminemia (2.9 mg/dL). After admission, steroid pulse therapy was started, and renal biopsy revealed MCNS recurrence. The patient was treated with steroid pulse therapy for three times and LDL apheresis, but the response was poor. Eight months after relapse, rituximab therapy was started. Although proteinuria gradually decreased, gait disturbance appeared and bilateral Achilles tendon ruptures were discovered.

Discussion: Although there have been scattered reports suggesting that COVID-19 infection and COVID-19 vaccine respectively have been implicated in the development and severity of nephrotic syndromes, including MCNS, the precise mechanism is not fully understood. In this case, vaccination shortly after COVID-19 recovery may have acted as a booster, causing the immune system to become abnormally activated and trigger a recurrence with severe edema leading to Achilles tendon rupture.

SA-PO859

Minimal Change Disease in a Patient with Sickle Cell Disease

Alexa E. Golbus, Ashley Golbus, Natalie T. Freidin. *Medical University of South Carolina, Charleston, SC.*

Introduction: Renal complications of sickle cell disease (SCD) are common, however, minimal change disease (MCD) as a cause of nephrotic syndrome in SCD patients, to our knowledge, has not been reported. While controversial, there is evidence that focal segmental glomerulosclerosis (FSGS) and MCD may represent different presentations of the same disease process. We present an interesting case of nephrotic syndrome in a patient with SCD, with MCD demonstrated on biopsy and a clinical course detailed over a 9-year period. We propose that our patient's case provides further support that idiopathic MCD and FSGS are presentations of the same disease process.

Case Description: A 17-year-old female with history of SCD presented with one week of fever, left plank pain, and hematuria. BP was 128/74, HR 78, RR 14, and SpO2 98%. No edema was present. sCr was 2.3 mg/dL and she had 24 g/d proteinuria. Hemoglobin variants revealed Hgb S 64%. Renal biopsy showed diffuse foot process effacement, moderate to severe interstitial fibrosis and tubular atrophy, and no glomerular basement membrane changes. Biopsy findings were consistent with MCD. Our patient was initially treated with IV steroids for 3 days, then continued on oral prednisone and ACE-i, with reduction in Cr to 0.5 after 12 months. At extended follow-up 9 years later, Cr has remained stable at 0.8, however mild proteinuria of 1g/g has persisted. Urine protein to creatinine ratio remains elevated at 1600 mg/g and urine microalbumin remains elevated at 698.8 mg/L. At this time, she has CKD stage G2A3, attributed to a combination of previous biopsy proven MCD with interstitial fibrosis and tubular atrophy, hypertension, and sickle cell disease.

Discussion: We propose that while our patient's renal biopsy was consistent with MCD, her persistent steroid resistant nephropathy and significant interstitial fibrosis and tubular atrophy which has likely progressed given her prolonged proteinuria, suggests progression to FSGS. This aligns with ongoing study suggesting that MCD and FSGS are presentations of the same progressive disease. While both MCD and FSGS are histopathological forms of idiopathic nephrotic syndrome, potentially caused by circulating permeability factors, abnormal T cell function, or cytokine alterations impacting glomerular membrane permeability, these pathologies may be related with steroid resistant MCD potentially progressing to FSGS.

SA-PO860

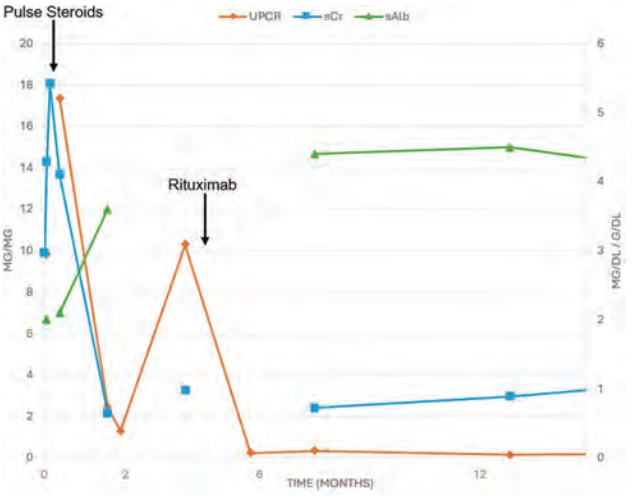
Partial Remission of Minimal Change Disease on Steroids: A Real-Life Case Report

Erica Marnet,[1,2] Kaltrina Sedaliu.[1,2] *[1]Yale New Haven Health System, New Haven, CT; [2]Bridgeport Hospital, Bridgeport, CT.*

Introduction: Minimal change disease (MCD) is a significant cause of primary nephrotic syndrome (NS). Less frequent in adults, around 10-15% of cases, and courses more frequently with hypertension, incomplete remission and steroid dependence. Management is generally extrapolated from pediatric data, highlighting the need to assess different therapies for the adult population.

Case Description: A 49-year-old male, with a history of hyperlipidemia, hypothyroidism presented with nausea, vomiting, oliguria, ascites and gravitational edema up to the abdomen. BP was 155/84 mmHg, serum creatinine (sCr) 2.97, serum albumin (sAlb) 1.8, UA with 4+ protein, 1+ glucose, urine protein/creatinine ratio (UPCR) 9.81. C3/C4, liver function, serologic evaluation and lymphoproliferative disorder work up were negative. Kidney biopsy demonstrated no sclerosis or immune complex deposition, but extensive effacement of foot processes suggestive of MCD. He was started on solumedrol then prednisone with good response. His edema was controlled with diuretics, those not needed on discharge. He did not tolerate steroids due to diabetes and myopathy. This rendered adherence to steroids difficult and his proteinuria worsened (Figure 1). Due to the financial burden of cyclophosphamide (CP) and dosing, he received 2 infusions of rituximab (RTX), followed by complete remission with no relapses, severe infection, or need of additional doses.

Discussion: MCD in adults differs from childhood in various factors as clinical course, relapses, secondary causes and treatment response. Limited data is available on adults. Frequent relapse or steroid dependence in MCD can occur up to 30% of patients. Despite RTX high remission rates in MCD refractory to other immunosuppressants, its role as a first agent after steroids is unknown. RTX is well tolerated in other causes of NS and requires fewer doses when compared to CP. This case shows RTX as a safe and cost-effective option for adult-onset MCD.



SA-PO861

A Minimal Change: Obesity-Related Glomerulopathy (ORG) and Intermittent Nonsteroidal Anti-inflammatory Drug (NSAID) Use as a Precursor to Minimal Change Disease in an Adult Patient

Frederick D. Parks, Jamie Pham, Mahesh Shrestha. *St Francis Emory Healthcare, Columbus, GA.*

Introduction: Minimal change disease (MCD) is predominantly idiopathic and rare in adults, accounting for only 10-15% of proteinuric glomerulopathy cases. The proportion caused by NSAID use is even lower. Typically, obesity-related glomerulopathy (ORG) presents as Focal Segmental Glomerular Sclerosis (FSGS) or Membranous Nephropathy (MN). We present a unique case of adult-onset MCD in an obese female precipitated by intermittent NSAID use.

Case Description: The patient is a 19-year-old Egyptian female studying in the US who abruptly develops edema. She has a BMI of 34.71 kg/m2. Her urinalysis revealed a 3+ proteinuria. The patient admits to taking Advil intermittently one week per month during her menstrual cycle. She has no family history of renal disease or dialysis. The patient exhibited hypercholesterolemia, random urine protein/creatinine ratio of 9.28 g, 24-hour urine collection of over 7.5 g of proteinuria, and hypoalbuminemia of <2.5 g/dL. CT-guided renal biopsy showed global foot process effacement on electron microscopy, with no deposits, sclerosis, crescent formation, or spikes. Serological workup was negative for C3, RPR, RF factor, ANA, MPO/PR3, HIV, and hepatitis. Post-stabilization, she was discharged on anticoagulation, an ACE inhibitor, steroids with GI and bone prophylaxis, lipid-controlling agents, and advised on lifestyle modifications.

Discussion: FSGS is far more commonly seen in ORG, and MCD is less common in adults. However, recent studies identify obesity as an independent risk factor leading to glomerular enlargement and proteinuria. Obesity also triggers biochemical pathways, such as TGF-β and RAAS, exacerbating kidney damage and altering gene expression related to lipid metabolism and inflammation. Studies also reveal ORG increasing in incidence, especially in BMIs ranging from 30.9-62.7 kg/m2. The mechanism of NSAIDs in adult onset MCD is also poorly understood. This case suggests that obesity may lead to MCD in adults, with NSAID use potentially lowering the threshold confounded by underlying immunological effects from obesity. Obesity may also increase the metabolic clearance rate of steroids, necessitating higher doses for full remission. Understanding these dynamics is crucial for managing MCD-type nephrotic syndrome in a growing population of obese patients.

SA-PO862

A Case of Pediatric Steroid-Resistant FSGS Evolving into a Steroid-Sensitive Profile in Young Adulthood

Antonio M. Fontanella,[1] Meghan R. Grewal,[1] Veronica A. Ortigosa Serrano,[3,2] George W. Burke,[1] Alessia Fornoni,[1] David Roth.[1] *[1]University of Miami Miller School of Medicine, Miami, FL; [2]Hospital Beneficente Sao Carlos, Rio Grande do Sul, Brazil; [3]The William J. Harrington Medical Training Programs for Latin America and the Caribbean and Global Observaerships, University of Miami, International Medicine Institute, Miami, FL.*

Introduction: Recurrent focal segmental glomerulosclerosis (rFSGS) is a challenging complication affecting 30-40% of transplanted FSGS patients, which can lead to loss of graft function and end-stage kidney disease. In this case report, I, the first author, will share my recent experience with rFSGS and hope to showcase the use of glomerular biomarkers to monitor disease evolution and guide treatment.

Case Description: I received a kidney transplant at 14 years old due to FSGS and PKD and developed rFSGS within 24 hours. Post-reperfusion renal biopsy showed that I was B7-1 positive, and I have been effectively treated with abatacept at the time and during various episodes of recurrence until the current case. I presented to transplant follow-up with fatigue, edema, and abdominal discomfort. Urine dipstick had shown +2 proteinuria, and labs showed a UPCR of 6.5, with a SCr of 0.9. Over the next 2 months, I received 4 doses of abatacept 1 g IV to no effect, with UPCR increasing to 10.8 and serum albumin falling to 1.8 with worsening symptoms. A cytokine panel found significant elevations in multiple cytokines. (Table 1). Standard treatment with plasmapheresis and rituximab 700 mg IV showed little effect, leading us to pursue allograft biopsy. The glomeruli demonstrated non-collapsing segmental sclerosis (tip variant) and mild mesangial expansion, as well as foot process effacement, consistent with rFSGS. B7-1 staining was negative, marking a shift from my previous status from B7-1 positive. [Figure 1] Plasmapheresis was continued for a total of 10 exchanges, accompanied by bolus steroid dosing followed by oral prednisone taper, and a repeat dose of rituximab 700 mg IV. There was a rapid response with decreasing proteinuria and clinical improvement in symptoms. Follow-up labs obtained 1 week after completion of treatment showed a UPCR of 0.2 with an albumin of 4.1 and SCr of 1.2. [Figure 2]

Discussion: Here, we report the first case of a pediatric patient with steroid resistant B7-1 positive rFSGS who transitioned to a B7-1 negative profile responsive to steroids in adulthood. It is crucial to observe the growing cohort of pediatric rFSGS patients reaching adulthood to determine the effect of age on pathology, outcomes, and treatment response.

SA-PO863

Steroid-Responsive FSGS Secondary to Bisphosphonate Use

Omar Ali, Aman Pal, Geovani Faddoul, Mauricio Monrroy. *Albany Medical Center, Albany, NY.*

Introduction: Focal segmental glomerulosclerosis (FSGS) is a histopathologic renal injury pattern with varying clinical features that poses diagnostic and management challenges. Current KDIGO guidelines recommend immunosuppression to treat primary FSGS, which is associated with nephrotic syndrome and diffuse podocyte effacement (DPE). Secondary FSGS presentations are highly variable, allowing primary and secondary FSGS to have overlapping features. Our case highlights an excellent response to steroids in a patient with secondary FSGS with DPE.

Case Description: A 71-year-old female presenting with an acute on chronic kidney disease stage 3 in the setting of a 2-week history of persistent nausea, vomiting, and diarrhea. Her creatinine was 15.68 mg/dL from a baseline of 1.3mg/dL, with nephrotic-range proteinuria of 4.96g/day and hypoalbuminemia. She started emergent dialysis for acute renal failure and had a renal biopsy showing collapsing FSGS with 100% foot process effacement. Genetic testing revealed a heterozygous mutation for Fanconi anemia. She was on ibandronate for postmenopausal osteoporosis, which was discontinued. She started daily prednisone 60mg and came off dialysis after one month of treatment, with creatinine returning to 1.2mg/dL. A few months later, she continued to have an adequate urine output with appropriate creatinine levels and was tapered to 10mg of prednisone daily. She has remained off dialysis since then and was recently transitioned to oral tacrolimus 0.5mg twice daily due to concerns of steroid-induced myopathy.

Discussion: In our case of FSGS secondary to ibandronate use, the biopsy revealed DPE. Bisphosphonates' exact mechanism of nephrotoxicity remains unclear. However, it was found to directly induce podocytes' loss of differentiation and loss of vital cytoskeletal proteins. This direct insult is similar to the postulated podocyte-toxic factor injury in primary FSGS. The prevalence of bisphosphonate-induced FSGS is well documented. However, its treatment with steroids and immunosuppressants is uncommon. There are reports of successful steroid treatment of secondary FSGS. Our patient demonstrated remarkable recovery after discontinuing ibandronate and starting steroids. She remained off dialysis and returned to her baseline renal function within a few weeks. More studies are needed to validate the role of steroids in secondary FSGS with diffuse podocyte involvement.

SA-PO864

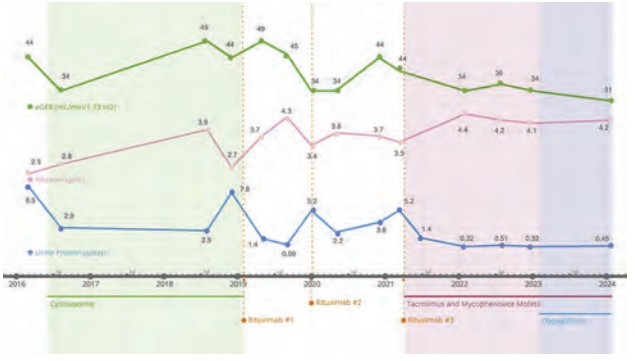
Successful Management of Relapsing Primary FSGS with Tacrolimus and Mycophenolate Multitarget Therapy

Frank Lee,[1] Marrey Ruby L. Quizon,[2] Wei Ling Lau.[2] *[1]University of California Irvine School of Medicine, Irvine, CA; [2]Division of Nephrology, Department of Medicine, University of California-Irvine, Irvine, CA.*

Introduction: Focal segmental glomerulosclerosis (FSGS) is a leading cause of nephrotic syndrome in adults. Multitarget immunosuppressive therapy has shown promise in lupus nephritis, but there is limited evidence in primary FSGS. Here, we describe a case of relapsing FSGS treated using a combination of tacrolimus and mycophenolate with years of stable disease remission.

Case Description: A 75-year-old female presented with recurrent nephrotic syndrome flares over several years. She had 2 native kidney biopsies (done 3 years apart) that showed FSGS (NOS variant with diffuse podocyte foot process effacement, 30% glomeruli with segmental sclerosis, 35% interstitial fibrosis). Other medical history is significant for CKD stage 3b, hypertension, type 2 diabetes mellitus and dyslipidemia. At time of initial diagnosis, the patient had 8.5 g/day of proteinuria and was treated with cyclosporine, on which she achieved partial remission with decrease in proteinuria to 3.5 g/day. The patient declined steroid therapy due to concerns about potential side effects. After 2 years on cyclosporine, she had proteinuria flare 7 g/day and therapy was changed to rituximab (375 mg/m^2 weekly x4 doses). She had good response with decrease in proteinuria <1 g/day, but had annual FSGS flare with nephrotic syndrome requiring repeat rituximab dosing (3 courses over 3 years). In early 2021, the patient was started on multitarget therapy with low-dose tacrolimus and mycophenolate mofetil. SGLT2 inhibitor therapy was added in early 2023. Patient is doing well after 3 years on this combination therapy, with stable proteinuria around 500 mg/day.

Discussion: This case demonstrates the feasibility of using tacrolimus and mycophenolate multitarget therapy to achieve successful long-term management of primary FSGS.



SA-PO865

FSGS in an Adult Transplant Recipient Possibly Linked to a New Antibody against WT1

Khaing S. Wei, Christian Herzog, Sushma Bhusal, John M. Arthur. *University of Arkansas for Medical Sciences, Little Rock, AR.*

Introduction: Focal segmental glomerulosclerosis (FSGS) is a histologic pattern of glomerular injury primarily affecting the glomerular podocytes, characterized by segmental scarring of select glomeruli. Primary FSGS involves circulating factors and can recur after transplant.

Case Description: A 66-year-old female with PMH of hypertension, microscopic hematuria, CKD diagnosed at the age of 30 progressed to ESKD at age 58 requiring HD. She had minimal proteinuria prior to ESKD. Her native biopsy contained only a single glomerulus but revealed thin basement membranes with podocyte effacement. She underwent DDKT at age 61. She had immediate graft function with UPCR of 0.67 mg/mg. Proteinuria resolved (UPCR undetectable) after one year but she again developed proteinuria of 2.1 g at 16 months and 11 g at 18 months. Her eGFR was 19-22 ml/min and serum albumin 3.2g/dl. An allograft biopsy showed FSGS with some collapsing features. Genetic analysis revealed a WT1 gene mutation (Ser466Phe). She underwent regular therapeutic plasma exchange (TPE) with stable Cr levels at 1.8 -2.2 mg/dl and UPCR at 2.0mg/mg. Plasma was collected prior to the first TPE. We performed western blot analysis using her plasma as the source of the primary antibody to determine if she could have an antibody against WT1. Normal human glomerular lysates were separated, transferred to PVDF and incubated with sera of the FSGS patient and two controls. Western blots were probed with secondary Ab against human IgA, IgG/M, IgM and developed with ECL reagent. A strong band at about 50kDa detected in the patient serum probed with anti IgM but not with IgG or IgA, suggested the presence of an antibody against WT1. The band was not present in two control plasma samples.

Discussion: The presence of an antibody that recognizes a glomerular protein at about 50 kDa suggests that this patient could have developed an autoantibody against WT1 after transplantation. Since the patient's kidney expressed a different sequence of WT1, this would be a novel antigen to her immune system. Since WT1 is expressed on podocytes, this antibody could interfere with the glomerular permeability barrier. Disease causing antibodies against nephrin have been described in children with nephrin mutations after kidney transplantation.

SA-PO866

Unveiling the Second Hit: Cytomegalovirus-Induced Collapsing Glomerulopathy in a Patient with Lupus

Vidya K. Bollavaram, Aric Gonter, Maria Bermudez, Kartik Kalra. *Geisinger Medical Center, Danville, PA.*

Introduction: Collapsing glomerulopathy (cGN) is a histological type of focal segmental glomerulosclerosis (FSGS) best described in association with human immunodeficiency virus (HIV). It has been increasingly seen in association with drugs, autoimmune disease, viruses (SARS-CoV2), and in rare cases, with cytomegalovirus (CMV). We present the case of a patient with lupus found to have cGN in the setting of CMV viremia.

Case Description: A 33-year-old African American female with a history of biopsy-proven Class V lupus maintained on hydroxychloroquine and mycophenolate, presented with 1 week of dyspnea and fevers. Lab investigations revealed Serum Creatinine (Cr) of 2.7 mg/dL (baseline 1.1mg/dL), pancytopenia, low C3 (80mg/dL), and C4 (7mg/dL) with negative dsDNA. Urinalysis showed 5-10 RBC. Spot urine Protein/Cr ratio was 10 gm/gm. Her clinical course was complicated by diarrhea and worsening acute kidney injury (AKI) requiring dialysis. The etiology of AKI was initially thought to be a lupus flare, and a kidney biopsy was done. Biopsy showed podocyte hyperplasia, collapse of the underlying glomerular tuft with segmental glomerulosclerosis, 40% interstitial fibrosis, and tubular atrophy. No evidence of an active immune complex-mediated process was noted. Viral studies were positive for CMV (CMV DNA 1,310,085 IU/ml). The patient was started on high-dose steroids and valganciclovir while other immunosuppression was held.

Discussion: cGN represents a variant of FSGS typically presenting with severe nephrosis and AKI. In our case, CMV likely acted as a 'second hit' with a possible underlying high-risk APOL-1 gene mutation, given her ancestry. The mechanism driving development of cGN has been proposed to be mediated by an interferon-chemokine pathway. Second hits such as HIV or SARS-CoV2 activate an inflammatory cascade that interacts with high-risk APOL-1 variants to precipitate cGN. Lupus has been associated with high interferon activity and thus may be another predisposing factor. CMV overall, remains a rare cause for cGN. While flares and class switching are sound differentials for AKI in lupus patients, this case highlights the importance of testing for CMV and considering cGN as a cause for AKI, especially in patients with African American ancestry. It further emphasizes the importance of ruling out opportunistic infections before preemptively adding more immunosuppression.

SA-PO867

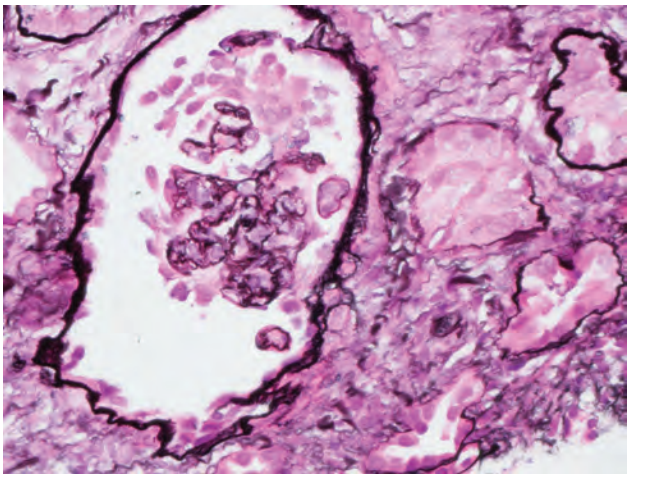
A Rare Cause of Collapsing FSGS: Hemophagocytic Lymphohistiocytosis-Associated with Epstein-Barr Virus

Keyana Khedmati, Josephine Abraham, Sarah Gilligan, Nirupama Ramkumar, Monica P. Revelo Penafiel. *University of Utah Health, Salt Lake City, UT.*

Introduction: Hemophagocytic lymphohistiocytosis (HLH) is a severe, life-threating syndrome of pathologic immune system activation. Viral infection, such as Epstein Bar Virus (EBV) infection, is a known trigger of HLH. Collapsing focal segmental glomerulosclerosis (FSGS), an aggressive variant of FSGS, that may be idiopathic or occur with infectious or inflammatory conditions. Here we present a case of a patient who presented with AKI (acute kidney injury) requiring hemodialysis who was later diagnosed with HLH associated EBV and collapsing FSGS/ATN on renal biopsy.

Case Description: A 42-year-old Somalian male with hypertension and new diagnosis of ESRD presented to the emergency department for hemodialysis (HD). He had presented two weeks prior at an outside hospital with renal failure ultimately thought to be ESRD from hypertension as his serologies were negative and ultrasound did not show obstruction. He had no prior baseline renal function as he did not follow routinely with primary care. During HD, he was found to be tachycardic and febrile, requiring admission. He underwent extensive workup for infectious etiologies and was ultimately diagnosed with HLH associated EBV. Genetic HLH panel was negative. He also underwent renal biopsy during this admission with evidence of FSGS with collapsing features and extensive ATN. He was started on rituximab and dexamethasone with improving results in his EBV titers from 21,000 to 10,000 after dose #4 and was discharged in stable condition. He remained on hemodialysis without evidence of renal recovery. Unfortunately, he presented a month later and was found to be hypotensive, febrile and tachycardic on dialysis. There was evidence of relapse with EBV PCR >110,000 and ferritin >40,000. He was also found to have disseminated cryptococcal infection, encephalopathy, and shock requiring multiple pressors and CRRT and eventually passed during admission.

Discussion: Collapsing FSGS may be idiopathic or occur with infectious or inflammatory conditions. HLH secondary to EBV infectious resulting in collapsing FSGS is rare and the exact mechanism is unknown. This case highlights the important association between HLH associated EBV, and collapsing FSGS in a rapidly progressive course leading to ESRD as well as the need for thorough evaluation of patients with presumed hypertensive kidney disease



SA-PO868

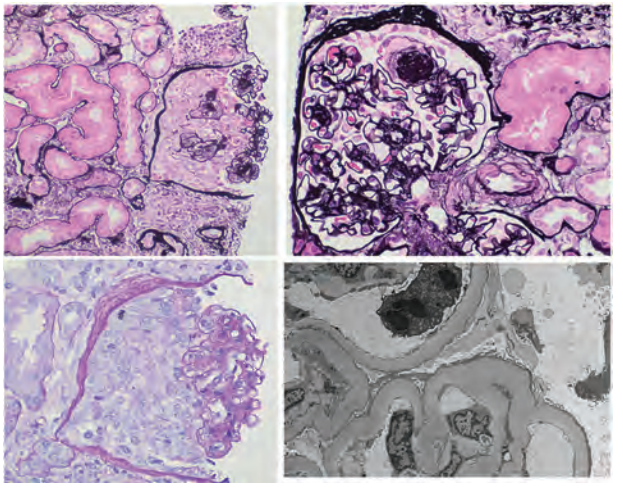
Once in a Blue Moon: Crescentic Diabetic Kidney Disease

Manjot Singh, Bushra Syed, Mohamed Hassanein, Pradeep Vaitla, Ramya Krishna Velagapudi, Mohammad Atari. *The University of Mississippi Medical Center, Jackson, MS.*

Introduction: Diabetic nephropathy is the leading cause kidney disease worldwide. Crescentic diabetic nephropathy is a rare occurrence and herein we present a case of diabetic kidney disease (DKD) with crescents formation in a kidney transplant recipient.

Case Description: A 65-year-old male with type 2 diabetes, hypertension, and atrial fibrillation who received a deceased donor kidney transplant in 2011 presented for routine follow up in clinic. His post-transplant course was unremarkable except for the development of low-grade prostate cancer managed with active surveillance and reduction in immunosuppression. The patient started to have worsening proteinuria up to 4.95 g/d and declining kidney function with creatinine of 1.7 mg/dL. HLA-DSA, PLA2R-Ab, and ANCA all were negative. No monoclonal protein detected by SPEP or UPEP and FLC ratio was normal. Kidney biopsy was pursued which showed characteristic diabetic changes. Interestingly, three glomeruli showed cellular crescents. There was no deposits or linear IgG staining on immunofluorescence. Electron microscopy showed severely thickened glomerular basement membrane without any deposits or fibrils. The patient was started on ARBs and proteinuria started to improve.

Discussion: While DKD is the most common cause of ESKD globally, the formation of crescents within the context of DKD is relatively rare. Crescents formation in the setting of DKD is mainly seen in association with other glomerular pathologies commonly known to present with crescentic glomerulonephritis. The presence of crescents in the setting of DKD is associated with a worse prognosis and points toward a more aggressive diabetic nephropathy. The absence of deposits in our patient with negative serological and monoclonal work up in addition to the absence of linear IgG staining by IF, rules out other pathology responsible for crescents formation.



SA-PO869

Collapsing Focal Segmental Glomerulosclerosis (cFSGS) and Its Association with Influenza A and Positive Cytoplasmic ANCA (C-ANCA) Serology: A Case Report

Amnah T. Kashkari, Ahmed F. Elfar, Rawan Alquaiz. *King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia.*

Introduction: Collapsing FSGS is aggressive variant of glomerular diseases characterized by a rapid decline in renal function and poor prognosis. This report contribute to the existing literature by presenting a case of cFSGS associated with influenza A infection and positive C-ANCA.

Case Description: A 35-year-old male presented with flank pain preceded by upper respiratory tract infection symptoms. Physical examination was unrevealing. Laboratory findings were significant for creatinine of 1013 umol/L, albumin of 28 g/L. Urine studies showed microscopic hematuria, 24 hours urine collection was 300 ml with 2 g of proteins. He tested positive for influenza A. He was admitted and started on pulse steroid. Serology revealed high C-ANCA titer. Renal biopsy showed cFSGS as described in figure 1. He required hemodialysis for refractory hyperkalemia. He was discharged with tapering dose of steroids and hemodialysis twice weekly that was stopped few weeks later. After 6 months, his labs showed stable creatinine with GFR of 27, reduction in proteinuria, and normal serum albumin.

Discussion: The exact etiology of cFSGS is unknown. Several reports highlighted the association with various viral infections. In our case, influenza A virus appeared to have a crucial role in triggering cFSGS. The presentation of rapid decline in renal function, microscopic hematuria and positive C-ANCA may lead to incorrect initial diagnosis of rapidly progressive glomerulonephritis thus signifying the importance of confirming diagnosis with renal biopsy before commencing the patient on aggressive immunosuppressive therapy. Overall, the association between cFSGS, influenza A infection, and positive C ANCA serology suggests a complex interplay between viral triggers, and immune dysregulation.

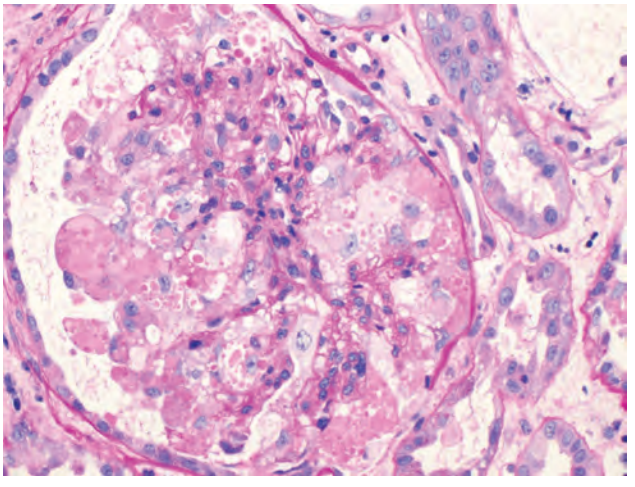


Figure 1: Segmental collapse of glomerular tufts, acute tubular injury and mild interstitial fibrosis and tubular atrophy

SA-PO870

A Diagnostic Dilemma of Lupus Nephritis and ANCA-Associated Vasculitis Overlap Syndrome

Kimberly Remedios,[1] Mateo Montalvo Campana,[1] Erica Marnet,[1] Deepthi Gunasekaran.[2] *[1]Yale New Haven Health - Bridgeport Hospital, Bridgeport, CT; [2]Yale University School of Medicine, New Haven, CT.*

Introduction: Systemic lupus nephritis (SLE) is characterized by the development of antinuclear antibodies (ANAs) and immune complex deposition in the kidney. Antineutrophilic cytoplasmic antibodies (ANCA) associated vasculitis (AAV) predominantly affects small vessels and is typically without immune complex deposition. It is challenging to determine if ANCA positivity in SLE patients is part of lupus nephritis (LN), or whether two different processes occur concurrently

Case Description: An 18-year-old female, without co-morbidities presented with hematuria, dysuria, and headache for one week. She was febrile on presentation. Laboratory tests were significant for acute kidney injury (AKI) and anemia. Treatment started with intravenous fluids and antibiotics. Subsequently, she developed hemoptysis, with a consequent drop in hemoglobin. She became hypoxic, with worsening AKI and required intubation, mechanical ventilation and initiation of hemodialysis. Bronchoscopy showed DAH. She was initiated on steroids and plasma exchange for concern of rapidly progressive glomerulonephritis and pulmonary renal syndrome. Serologies were positive for antinuclear antibodies (1:320), anti-double stranded DNA (51 IU/ml) antibodies, Myeloperoxidase antibodies. Light microscopy showed mesangial hypercellularity with one fibrocellular crescent (Figure 1). IF was positive for IgA, IgM, IgG, C1q negative. She was started on cyclophosphamide and steroid. She was extubated and remained on dialysis

Discussion: It is a challenge to distinguish AAV from LN and the dilemma in treatment options for the two cases. ANCA positivity has been reported to be associated with more severe lupus nephritis in some cases while others have discounted it as a laboratory artefact. Her presentation of DAH is more often associated with ANCA vasculitis along with classic pathology of lupus nephritis in the form of immune complex deposition supports the diagnosis of SLE/ANCA vasculitis overlap syndrome

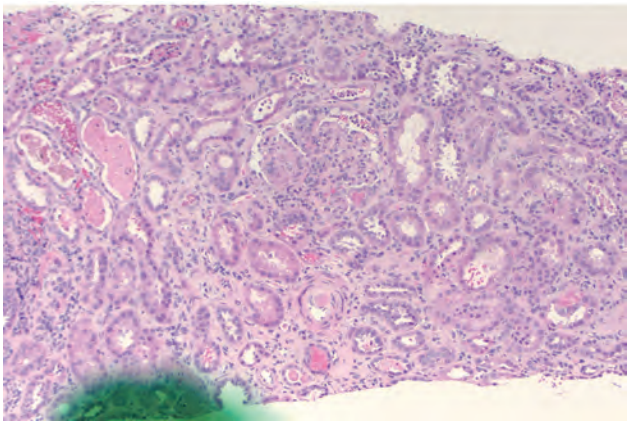

Figure 1: Light microscopy

SA-PO871

Glomerulonephritis (GN) Due to Systemic Lupus Erythematosus in a Seronegative Patient: A Lupus Criteria Dilemma

Sumbal Wajid,[1] Lilit Grigoryan,[1] Aman Pal,[1] Ruben A. Peredo-Wende.[2] *[1]Albany Medical Center, Albany, NY; [2]Albany Stratton VA Medical Center Albany, Albany, NY.*

Introduction: Systemic Lupus Erythematosus (SLE) is a well-recognized autoimmune disease with varying clinical and immunological manifestations. According to the 2019 American College of Rheumatology lupus consensus criteria, a positive ANA at any time is required as an entry criterion. Our case highlights a clinical and pathological diagnosis of SLE with negative ANA and anti-dsDNA.

Case Description: A 54-year-old African-American woman presented with cough, dyspnea, orthopnea, and leg swelling. Initial work up showed hemoglobin 10.2 g/dL, unremarkable EKG, troponin, and BNP. CT chest showed a large pericardial effusion, with TTE confirming tamponade physiology. A pericardial window was performed. All infectious work up including blood and pericardial fliuid cultures remained negative. Further testing was pursued that showed positive direct Coombs test, proteinuria and hematuira on urine analysis, and low C3 and C4 levels. This prompted further work up for renal disease in the context of multisystem disease. Serology came back negative for ANA, anti-dsDNA, ENA panel, and antiphospholipid antibodies, as well as c-ANCA, p-ANCA, anti-MPO and anti-PR3 antibodies. Protein electrophoresis and hepatitis panel were unremarkable. Ultimately, kidney biopsy revealed diffuse mesangial and focal segmental endocapillary proliferative GN with positive immunofluorescence to IgG, IgM, C3 and C1, suggesting immune-complex type GN. Although serologic work up remained negative, a presumptive diagnosis of SLE with lupus nephritis was made, in setting of Coombs positive anemia, serositis, hypocomplementemia and immune-complex type GN. Patient was started on steroids and mycophenolate mofetil. 7 years later, she remains on mycophenolate mofetil with stable creatinine and kidney function.

Discussion: The 2019 EULAR/ACR classification criteria diagnose SLE with a score of 10 or greater. However, these criteria exclude SLE if the ANA is negative. If we were to follow this updated criteria for the diagnosis of SLE, our patient would not be classified as having lupus, even though their score is well over 20, neglecting the negative ANA. Although ANA-negative lupus is quite rare, with only a prevalence of around 2%, it is still crucial to properly diagnose these patients as both early diagnosis and initiation of therapy can greatly benefit our patients.

SA-PO872

Case of Eosinophilic Granulomatosis with Polyangiitis with Kidney Involvement

Ram Sinha, Ivette Gomez, Amer A. Belal. *University of Florida, Gainesville, FL.*

Introduction: Eosinophilic granulomatosis with polyangiitis (EGPA) is a systemic small-vessel vasculitis characterized by asthma, eosinophilia, and ANCA positivity in 40% of patients. Though predominantly a rheumatological process, we present a case with severe renal disease.

Case Description: A 42-year-old male with a history of asthma and tobacco abuse presents complaining of fever, abdominal pain, pleuritic pain, weakness, and weight loss. On admission he was febrile to 101.1F, lab studies were significant for WBC of 13.1, PLT 521, eosinophils 2.11, Cr 2.10 mg/dL from a baseline of 1.0, CRP 285. CT chest abdomen pelvis revealed moderate paraseptal emphysema. Blood and urine cultures, TB, RPR, HIV, and Hepatitis serologies were negative. Urine microscopy revealed acanthocytes and thus renal biopsy was sought. The patient had normal ANA and complement levels however ANCA serologies were positive with p-ANCA pattern at > 1:1250, PR3 Ab 75, and MPO Ab 193. His PLA2R Ab and GBM Ab were negative. The renal biopsy showed severe pauci-immune necrotizing crescentic glomerulonephritis and glomerular cellular crescents involving 66% of the glomeruli with prominent podocyte effacement. Rheumatology was consulted and diagnosed the patient with EGPA. The patient was given methylprednisolone at 1 g daily for 3 days followed by an initial dose of Rituximab 1 g when his Cr was 4.02 mg/dL. His Cr peaked at 4.57 mg/dL the following day before downtrending, and he was discharged on prolonged prednisone taper with follow-up with Rheumatology, Pulmonology, and Nephrology. The patient had IgG 1476, IgM 44, and IgA 197 baseline immunoglobulin levels. His 2nd dose of Rituximab was 3 weeks later and at a reduced dose of 800 mg IV due to issues with insurance authorization. The renal response stalled with a Cr level of 3 mg/dL 6 weeks after his 2nd dose of Rituximab and proteinuria worsened to 13 g/d. Adjunct therapy with Mepolizumab or Cytoxan was discussed with Rheumatology. His follow-up IgG 481, IgM 23, and IgA 108 precluded repeated dosing of Rituximab. Given the patient's refractory EGPA with severe symptoms, the decision was made to proceed with Cytoxan therapy.

Discussion: Renal involvement in EGPA occurs in about 25% of cases compared with other ANCA vasculitis and impacts the patient's prognosis and treatment. Treatment of EGPA with renal involvement is challenging and involves a multidisciplinary approach

SA-PO873

A Rare Case of Concurrent IgA Nephropathy and Anti-glomerular Basement Membrane (GBM) Disease

Phoenix Xu, Rahul Maheshwari, Sebastian Gandarillas Fraga, Stephen C. Ward, Joseph A. Vassalotti, Miriam Chung, Samuel Mon-Wei Yu. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: Anti-glomerular basement membrane (anti-GBM) disease is a rare disorder, characterized by rapidly progressive glomerulonephritis (RPGN) with or without pulmonary involvement. Here, we report a patient presenting with RPGN due to anti-GBM disease, who was found to have mesangial IgA staining on immunofluorescence (IF), suggesting concurrent IgA nephropathy (IgAN).

Case Description: A 38-year-old male with no known past medical history, presented with several days of abdominal pain, nausea, and vomiting. He was found to have acute kidney injury with initial serum creatinine of 7.9 mg/dL requiring hemodialysis. Initial workup included a urinalysis with +4 protein; innumerable RBCs and 5-10 WBCs per HPF; a urine protein-to-creatinine ratio of 3.10 g/g; and an unremarkable kidney ultrasound. Serologic workup was notable for an IgG anti-GBM titer of 2.5 units/mL (reference < 0.9), and anti-nuclear antibody (ANA) titer of 1:320. Other serological studies including MPO, PR3, C3, C4, hepatitis B and C, and PLA2R were normal or negative. Kidney biopsy light microscopy showed 25 glomeruli (20 with cellular and/or fibrous crescents, and 1 with mesangial expansion and hypercellularity). There was moderate interstitial scarring. IF showed linear staining of glomerular basement membrane for IgG (1+) and lambda/kappa (2+) consistent with anti-GBM glomerulonephritis. Additionally, mesangial regions were positive for IgA (1-2+), IgM (1+) and C3 (1+), consistent with IgA nephropathy. Patient received pulse dose glucocorticoids, oral and intravenous cyclophosphamide, and 10 sessions of plasmapheresis. He remained on kidney replacement therapy after induction treatment with an anti-GBM titer of 0.2 units/mL.

Discussion: Concurrent IgAN with anti-GBM disease has been described sporadically in the literature with heterogeneous findings. These findings include linear IgA staining of GBM, concurrent mesangial IgA and linear IgG staining, and linear IgG staining with circulating IgA anti-GBM antibodies. The moderate scarring, mesangial involvement, and variable stages of crescent formation suggest that our patient may have had ongoing undiagnosed IgAN that preceded development of anti-GBM disease. Unlike other similar reported cases, he unfortunately did not have kidney function recovery.

SA-PO874

Diffuse Alveolar Hemorrhage (DAH) Secondary to Influenza B in a Kidney Transplant Recipient with Anti-glomerular Basement Membrane (Anti-GBM) Disease

Muhammed N. Rehmani, Sean Hebert. *The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX.*

Introduction: DAH is a potentially life-threatening syndrome requiring immediate recognition and treatment. In kidney transplant recipients with known Anti-GBM disease in native kidneys, recurrent anti-GBM disease should be suspected if they present with microscopic hematuria, proteinuria, and/or acute kidney injury. However, isolated DAH is rare and poses a diagnostic challenge, particularly if it is secondary to infection.

Case Description: A 48-year-old male with Anti-GBM disease presented to the emergency department with hemoptysis. He had been diagnosed with Anti-GBM disease twelve years earlier, resulting in rapidly progressive glomerulonephritis that was refractory to first and second-line treatments. He became dialysis dependant until his kidney transplant 10 years later. His disease had remained quiescent since transplant and his allograft function was normal on immunosuppression. Upon presentation, his vitals were stable except for a temperature of 100.5 F. Chest radiography revealed infiltrates in the left middle and lower lung lobes. A computed tomography (CT) scan of the chest confirmed these infiltrates and showed surrounding ground glass opacities. Serum electrolytes, creatinine and urinalysis were normal. Bronchoscopy revealed progressively bloody aliquots consistent with DAH. He was treated with daily plasmapheresis for possible recurrent disease for 2 days. This treatment was discontinued when his serum Anti-GBM antibody returned negative, and no evidence of anti-GBM disease was found on lung pathology. Consequently, his DAH was suspected to be secondary to viral pneumonia, specifically Influenza B, and all treatments except antiviral therapy were discontinued.

Discussion: Isolated DAH in a patient with Anti-GBM disease is typically either an initial presentation or an indicator of disease recurrence. However, in this case, the patient presented with alveolar hemorrhage without laboratory findings suggestive of disease recurrence, indicating that the DAH was secondary to viral pneumonia. Infection, although rare, should be considered a possible cause of DAH once more common causes have been excluded. This case highlights the importance of considering infectious etiologies in patients with DAH. Early identification and appropriate management of the underlying cause are crucial for improving patient outcomes.

SA-PO875

Diabetic Nephropathy Complicated by an IgA-Dominant Infectious-Related Glomerulonephritis: A Case Report

Leonardo R. Ramirez Botana. *LSU Health Shreveport, Shreveport, LA.*

Introduction: Acute post-infectious glomerulonephritis (APIGN), in adulthood is common in diabetic, alcoholic, and intravenous drug-abusing patients. APIGN is usually secondary to Staphylococcus aureus infection, occurring after skin infection, deep-seated abscesses and presents a histological pattern identical to acute poststreptococcal glomerulonephritis. This case reported a diabetic nephropathy complicated by an IgA-dominant infectious related glomerulonephritis

Case Description: A 27-year-old female with past medical history of hypertension, diabetes mellitus type 1 and chronic kidney disease was admitted due to acute renal failure, high blood pressure and uncontrolled diabetes mellitus. Physical examination showed bilateral periorbital edema, lower extremities pitting edema, and the presence of left frontal skin abscess. Uncontrolled blood glucose, anemia, hyperkalemia, impaired renal function was documented. Urinalysis revealed moderate urine blood with high total protein. The C4 /C3 complements and anti streptolysin O were within normal rage. Immunological workup was normal including antinuclear antibody and anti-DNA. Head abscess culture was positive for Staphylococcus aureus, and due to a massive proteinuria, renal biopsy was performed. The mesangium biopsy shows PAS-positive nodular mesangial expansion and interstitial fibrosis. Immunofluorescence findings showed capillary loops staining for IgA, C3 and lambda, subepithelial immune type electron dense deposits and global effacement of foot processes consistent with diabetic injury, likely with superimposed port-infectious glomerulonephritis.

Discussion: Few cases have been reported in Puerto Rico, and a major shift has occurred in the epidemiology of this disease. Worldwide numerous cases of APIGN have been identified with intense deposits of IgA as the sole or dominant immunoglobulin on immunofluorescence, similar to our case, characterizing a new entity named IgA-dominant acute post infection glomerulonephritis (GN) The massive proteinuria and the rapid deterioration of renal function in our diabetic patient should suggest that an additional pathologic condition is affecting the kidneys. An IgA-dominant infection related GN was diagnosed, and after treated with antibiotic therapy our patient recovered from the disease and was discharge to home.

SA-PO876

A Case of Nephrotic-Range Proteinuria and False-Positive Anti-phospholipase A2 Receptor (PLA2R) Antibodies

Ying-ying Seow, Ivan Wei Zhen Lee, Swee Ping Teh. *Sengkang General Hospital, Singapore, Singapore.*

Introduction: Autoantibodies to the M-type phospholipase A2 receptor (anti-PLA2R AB) have been demonstrated to be highly specific for the diagnosis of primary membranous nephropathy (MN). We present a case of anti-PLA2R AB positivity with no membranous glomerular pathology.

Case Description: A 45-year-old Malay female was referred for the evaluation of nephrotic-range proteinuria and elevated serum creatinine (sCr). She was admitted for uncontrolled hypertension and acute decompensated heart failure with reduced ejection fraction. She did not have diabetes mellitus. On admission, sCr was 147 umol/L (eGFR 37 ml/min/1.73m^2), serum albumin 42 g/L, urine albumin/creatinine ratio (uACR) 361.1 mg/mmol, protein/creatinine ratio 4 g/g and minimal hematuria (5 cells/uL). 24-hour total urine protein was 0.57 g/d on a suboptimal collection. Serological testing revealed faintly positive antinuclear antibody titer (1:160, homogeneous pattern) and positive anti-PLA2R AB 49.6 RU/ml (IgG ELISA Euroimmun). She was started on goal-directed therapy for heart failure. Serial repeated measurements of anti-PLA2R AB remained elevated over the next 5 months (49.6, 68.46 RU/ml) with persistent proteinuria. A kidney biopsy was obtained, revealing focal segmental glomerular sclerosis, arteriolar hyalinosis and focal arteriolar thrombosis, without features of MN. Immunofluorescence was weakly positive (1-2+) for IgM and C3 along glomerular capillary walls but negative for IgG. Electron microscopy showed mild basement membrane thickening, moderately extensive podocyte foot effacement (30-40% capillary wall surface area), but no subepithelial electron dense deposits were found. The diagnosis of hypertensive nephropathy with thrombotic microangiopathy (TMA) and FSGS was made. Her dose of valsartan was optimized and dapagliflozin was added. Over the next year, her sCr was stable at 151 umol/L (eGFR 36 ml/min/1.73 m^2) and uACR regressed to 39.8 mg/mmol.

Discussion: The specificity of anti-PLA2R AB for MN has been described to be as close to 100%, allowing patients with nephrotic syndrome and positive serology to forego biopsy. Other cases of anti-PLA2R AB positivity without MN have described minor glomerular, FSGS or diabetic nephropathy changes but not TMA. Our case adds to the body of literature of false-positive anti-PLA2R AB and supports pursuing a kidney biopsy especially when nephrotic syndrome is absent.

SA-PO877

Nephrotic-Range Proteinuria in Patient with Syphilis and HIV

Karishma Iyer, Kaitlin Markoja, Lukman Cheraghvandi, Keiko I. Greenberg, Chanigan Nilubol, Donghyang Kwon. *MedStar Georgetown University Hospital, Washington, DC.*

Introduction: Syphilis is a curable sexually transmitted infection caused by Treponema Pallidum. Infection develops in stages (primary, secondary, latent and tertiary), each associated with different signs and symptoms. Kidney manifestations are rare but can be a feature of secondary syphilis. Membranous nephropathy is most commonly observed; syphilis associated kidney disease can also present as nephrotic syndrome, acute kidney injury, membranoproliferative glomerulonephritis, or interstitial nephritis.

Case Description: 34 year old male with newly diagnosed human immunodeficiency virus (HIV), history of gonorrhea, and recent positive syphilis screen (RPR 1:512) presented with bilateral vision loss. He underwent lumbar puncture and was diagnosed with secondary syphilis with ocular/CNS involvement (CSF VDRL 1:16). Treatment with IV penicillin was initiated. His kidney function was normal but a routine urinalysis (UA) was positive for proteinuria. Repeat UA confirmed the presence of albuminuria and was also notable for 8 RBC/hpf. Urine protein creatinine ratio was 4.1 g/g. Serum albumin was normal at 4.0g/dL. His physical examination was notable for improving rashes and no peripheral edema. Further infectious testing was notable for HIV viral load 65,897 copies/mL and CD4 count 171 cells/uL. Hepatitis B surface antigen and hepatitis C antibody were negative. Further workup for nephrotic syndrome was initiated: complement levels were normal, ANA negative, kappa:lambda ratio normal and no monoclonal spike on SPEP or UPEP. Renal biopsy was pursued which showed marked subepithelial deposits along with numerous tubuloreticular structures consistent with membranous glomerulopathy. Immunofluorescence positive for IgG, IgA, IgM, and C3. C1q was negative.

Discussion: Syphilis is re-emerging in the US - in 2022, the highest number of cases of syphilis were reported since 1950 with an increase of 17.3% since 2021. Most cases reported were primary or secondary syphilis. Individuals who present with proteinuria should be screened for syphilis. Although membranous nephropathy has also been reported in HIV, it seemed most likely that this patient's membranous nephropathy was related to syphilis. Proteinuria usually resolves with treatment of syphilis. Our patient was unfortunately lost to follow up so it is unknown if his proteinuria improved following treatment.

SA-PO878

Varicella zoster: A Rare Cause of Membranoproliferative Glomerulonephritis

Anuj Gupta, Muhammed Mumin, Janany J. Sabescumar. *University of Rochester Medical Center, Rochester, NY.*

Introduction: A rare association of Varicella Zoster (VZV) with renal disease was first discovered in 1884 by Henoch[1]. There is scarce literature on the evidence of glomerulonephritis following the incidence of VZV. We are presenting a case of a 72-year-old man who was diagnosed of membranoproliferative glomerulonephritis (MPGN) post shingles.

Case Description: A 72-year-old male with a past medical history of hypertension presented to primary care with profound anasarca and uncontrolled hypertension. Two months ago, he experienced shingles and responded well to antiviral therapy and prednisone. His labs were significant for spot protein/creatinine ratio of 11.35 g/dL and serum creatinine increase from 0.9 mg/dL at baseline to 1.16 mg/dL. Serological work up was revealing for low C3 level 78 mg/dL only. Subsequently after nephrology consultation, he underwent renal biopsy which revealed membranoproliferative glomerulonephritis with 3+ IgM and C3 deposition on immunofluorescence. He was started on weight-based 1 mg/kg of oral prednisone daily followed by steroid taper over a course of three months. Subsequently, his proteinuria reduced to 7.62 g/day whilst on treatment and improvement of anasarca and hypertension.

Discussion: VZV associated with nephritis is uncommon and was proven with only 3 (0.1%) out of 2534 developing clinical nephritis in a 1935 study[2]. Molecular pathologic method (in situ hybridization) verified VZV's growth and reproduction in kidneys causing glomerulonephritis[3]. The mechanism of VZV induced MPGN could be direct or immune mediated[1]. Membranoproliferative glomerulonephritis shows a pattern of injury with distinctive mesangial cellularity and glomerular capillary walls thickening due to subendothelial deposition of complement factors like strong C3 deposition or IgM immune complexes which was noticed in our patient[6-8]. Literature shows that these results are suggestive of immune complex mediated glomerulonephritis[9,10]. Proteinuria occurring in patients post varicella infection should caution clinicians to check for the possible diagnosis of membranoproliferative glomerulonephritis

SA-PO879

When You Close a Door, a Window Opens: A Case of Dupilumab-Induced Autoimmune Glomerulonephritis

Meshaal Alanzi, Avrum Gillespie, Kishore Kumar Mani, Suzanne Boyle, Sheetal Koul. *Temple University, Philadelphia, PA.*

Introduction: Dupilumab, a monoclonal antibody that blocks IL-4 and 13, is indicated for atopic dermatitis management. Eosinophilic granulomatosis with polyangiitis (EGP) has been reported with dupilumab use. We report a case of AKI from lupus-like glomerulonephritis following dupilumab, suggesting that blocking IL-4 and 13 may be linked to autoimmunity.

Case Description: A 61-year-old man with a history of an orthotopic liver transplant for HCV-related cirrhosis five years prior and non-proteinuric CKD (baseline creatinine 2.3 mg/dl) was admitted for generalized fatigue, mild abdominal pain, nausea, and poor appetite. Serum creatinine was 8 mg/dl. Four months before, he started Dupilumab for resistant atopic dermatitis. Further testing revealed normocytic anemia with Hb of 6.5 g/dL and thrombocytopenia 103 K/mm^3. Urinalysis showed hematuria; urine protein to creatinine ratio 4216 mg/gram. Complement C3/C4 normal, ANA, anti-ds DNA, and rheumatoid factor negative. c-ANCA titer was 1:320 (negative for anti-PR-3 and MPO). An ANCA-mediated GN was initially suspected. However, a kidney biopsy revealed a membranoproliferative glomerulonephritis with cellular crescents and a diffuse tubulointerstitial inflammatory infiltrate with "full house" staining on immunofluorescence, consistent with lupus-like nephritis. The patient was managed with steroids (500 mg methylprednisolone for three days, then 1 mg/kg with taper). Ultimately, he needed regular hemodialysis.

Discussion: In this case, Dupilumab was the most likely cause of this "full-house" ANCA-positive nephritis. Dupilumab has also been associated with EGP. The potential mechanism is that blocking IL4 increases autoimmunity. IL-4 is considered an immunoregulatory cytokine with pleiotropic effects on antibody production, inflammation, and T-cell responses. It is suggested that IL-4 has a protective role against autoimmunity as it suppresses T-cell activity and tissue inflammation. In one mouse strain, the pathogenic autoantibody subclasses (IgG21 and IgG3) were suppressed by IL-4. Thus, mice with increased IL-4 had low levels of IgG3 and IgG2a subclasses of anti-DNA antibodies with high IgG1 levels, which is considered protective against lupus-like nephritis development. Consequently, suppressing IL-4 might lead to increased autoantibody subclasses that deposit in the kidney, inducing inflammation.

SA-PO880

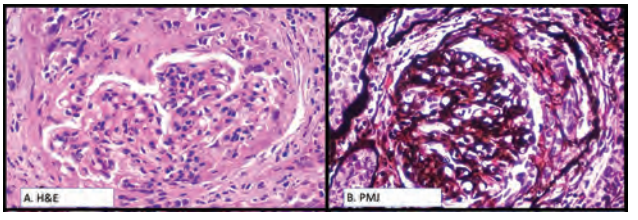
Anti-neutrophil Cytoplasm Antibody-Associated Vasculitis as Paraneoplastic Glomerular Disease

Belén Gallegos, Laura G. Amador Reyes, Gonzalo Ruiz Saucedo, Laura d. Fuentes-Mendez, Angela M. Cordoba Hurtado, L. M. Perez-Navarro, Virgilia Soto, Diana L. Figueroa Gamiño, Ingrid R. Velasquez Lorenzo. *Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico*.

Introduction: Paraneoplastic glomerulonephritis (PGN) is a rare complication of a malignant tumor, with glomerular lesions induced by products of tumor cells. ANCA-associated vasculitis (AAV) occurs in 14-20% of paraneoplastic syndromes associated with renal tumors; 71% are clear-cells carcinoma. In Latin America there are no cohorts that evaluate the association of AAV and renal cell carcinoma.

Case Description: CASE 1: 51 years old male, admitted requiring KRT. We found active urinary sediment and positive anti-MPO. An image of a kidney tumor was found in the echography, later confirmed with CT. Patient had a partial nephrectomy, with pathology result showing clear cell renal cell carcinoma and pauci-immune crescentic glomerulonephritis with focal and segmental sclerosis and grade II interstitial fibrosis. CASE 2: 56 years old male, admitted due to uremic syndrome, and behavior of rapidly progressive glomerulonephritis, starting KRT. We found positivity for anti-MPO, evidence of a kidney tumor in echography and TC. A renal biopsy was performed, reporting active pauci-immune crescentic glomerulonephritis and grade II interstitial fibrosis. He was treated with complete nephrectomy four months later, pathology confirmed clear cell renal carcinoma. CASE 3: 44 years old male, with granulomatosis with polyangiitis since 2020, referred because of proteinuria and chronic kidney disease. Ecography showed a renal tumor, CT was performed suggesting clear cell renal carcinoma.

Discussion: The course of PGN is a rare diagnostic and a therapeutic challenge, so early identification and treatment with close follow-up could help improve the prognosis. It is reasonable to treat AAV with standard immunosuppression, including steroids and/or cyclophosphamide and/or rituximab, given the high associated morbidity and mortality, along with planned cancer treatment.



SA-PO881

Unexplained Chylous Pleural Effusions Diagnosed by Kidney Biopsy

Aju Jose,[1] Amy Ludwig,[1] John T. Ludwig.[2] [1]*Northwestern University McGaw Medical Center, Chicago, IL;* [2]*University of Michigan, Ann Arbor, MI*.

Introduction: Amyloidosis is a group of diseases characterized by extracellular protein deposition of beta-sheet fibrils. Renal amyloidosis is found in about 2% kidney biopsies and is usually secondary to systemic disorders. Here we describe an atypical case of renal AA amyloidosis presenting with chylous pleural effusions and ascites.

Case Description: Patient is a 47 year old paraplegic male with neurogenic bladder, chronic indwelling urinary catheter, chronic sacral wounds, history of osteomyelitis and malnutrition. History of presenting illness included insidious onset of shortness of breath which started 18 months prior to presentation. He was evaluated by his primary care physician who found bilateral pleural effusions and was sent to a thoracic surgeon. He had multiple serial thoracentesis underwent VATS with talc pleurodesis which was unsuccessful. Bilateral pleurX catheters were placed for symptom management. He was referred to our center due to increased drainage from his catheters, anasarca and worsening shortness of breath and consideration of lymphangiogram with interventional radiology. Labs were significant for serum albumin < 1.5 and pleural fluid triglycerides > 135 consistent with chylous efusion and UPCR > 40 g/g. Lymphangiogram showed a patent thoracic duct with no evidence of leak. Renal Biopsy showed changes of amyloidotic nephropathy. Laser dissection and tandem mass spectroscopy confirmed AA amyloid. Pleural fluid cultures revealed VRE and he was treated with daptomycin and ciprofloxacin. Supportive care was provided with nutrition management, wound care and diuresis. Drainage from left pleurX catheter decreased and was eventually removed. He continued to require frequent paracentesis. He was discharged with plans for close follow up but unfortunately passed away 14 days after discharge.

Discussion: Chylous pleural effusions and ascites is a rare presentation of amyloidosis, in this case diagnosed on kidney biopsy. This diagnosis is challenging and requires a high index of suspicion. AA amyloidosis is a rare but serious complication from underlying chronic inflammatory disorders with a sustained acute phase reactant response. Renal dysfunction with proteinuria is the most common manifestation of AA amyloidosis, with high mortality (median survival of 133 months after diagnosis)1. Management typically consists of targeting the underlying inflammatory response.

SA-PO882

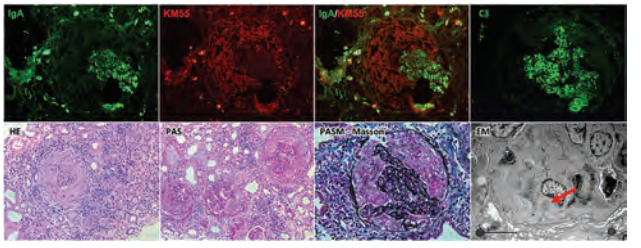
IgA-Dominant Postinfectious Crescentic Glomerulonephritis after a Cervical Smear

Shi Jin. *Zhongshan Hospital Fudan University, Shanghai, China*.

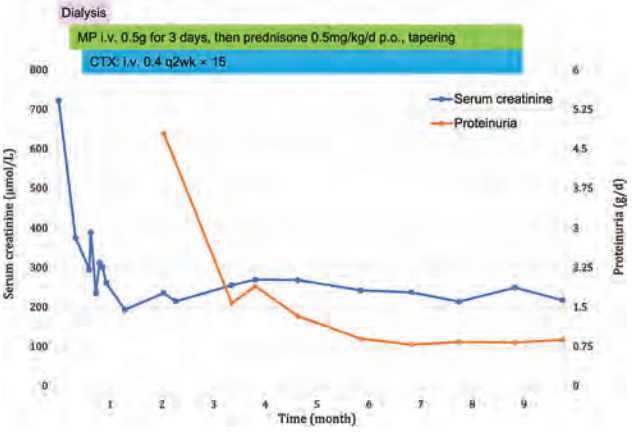
Introduction: IgA-dominant infection-associated glomerulonephritis(IRGN) usually presents diffuse endocapillary and/or mesangial proliferation with a few crescents. Here we report a rare case of IgA-dominant IRGN with diffuse necrotizing cellular crescents, which benefited from corticosteroid and cyclophosphamide treatment.

Case Description: A 29-year-old woman developed rapidly progressive edema and anuria with fever and persistent vaginal discharge of pus after a cervical smear for health checkup. Laboratory analyses revealed serum creatinine of 723μmol/l, serum albumin of 17.4g/l, C-reactive protein of 172mg/l, hypocomplementemia and prominent proteinuria and hematuria. Anti-GBM and ANCA were negative. *Enterococcus faecium* were isolated from culture of vaginal discharge. Kidney biopsy (Figure 1) showed starry sky patten of IgA and C3 deposition along GBM by immunofluorescence. Light microscope showed 90% of glomeruli with necrotizing cellular crescents, endocapillary infiltration and Bowman's capsule rupture. Electronic microscope showed major subepithelial and subendothelial electron-dense deposits with mild mesangial deposits. Therefore, IgA-dominant IRGN was diagnosed. Pulse therapy of methylprednisolone and intravenous cyclophosphamide (CTX) were given after infection controlled. Her urine output began to increase after 3 days and reached dialysis independence after two weeks. She was treated with i.v. CTX 0.4g every 2 weeks with tapering oral methylprednisolone, and maintained stable renal function for ten months(Figure 2).

Discussion: IgA-dominant IRGN can mimic ANCA glomerulonephritis with diffuse necrotizing lesions and crescents. Prompt immunosuppression besides infection control is crucial for kidney function restoration and preservation.



Histopathologic findings of kidney biopsy



Clinical course after presentation

SA-PO883

Don't Forget the Topical Nonsteroidal Anti-inflammatory Drugs (NSAIDs)

Golriz Jafari, Phuong-Chi T. Pham, Hoang Anh Nguyen, Sapna Gopal, Anirudh V. Chandra, Anita Kamarzarian. *UCLA Medical Center Olive View, Sylmar, CA*.

Introduction: Non-steroidal anti-inflammatory drugs (NSAIDs) are known to cause multiple adverse effects to the kidneys including acute kidney injury, interstitial nephritis, hyperkalemia, membranous glomerulonephritis, minimal change disease (MCD) or papillary necrosis. Topical NSAID use is usually considered safe and low risk for these adverse effects; however, it still needs to be considered.

Case Description: A 53-year-old male with poorly controlled diabetes mellitus (DM) type 2 (HgA1C 9.8%) presents with acute onset of bilateral lower extremity, abdominal distention and shortness of beath. Patient was found to have urine albumin/creatinine ratio (UACR) or 6215 mg and nephrotic syndrome. Urine did not show any active

sediment and he had no know personal or family history of kidney disease. Patient had been using regularly topical diclofenac for back and knew pain. Differential diagnosis included DM nephropathy, focal segmental glomerulosclerosis (FSGS) due to obesity, primary FSGS and MCD. All proteinuria serology including hepatitis B and C, HIV, syphilis, immunofixation, phospholipase A2R, ANCA, complement, kappa/lambda, QuantiFERON gold were all within normal limits and patient did not have any evidence of diabetic retinopathy. Given acute onset of nephrotic syndrome and no evidence of retinopathy, patient underwent kidney biopsy which revealed minimal change disease. Patient did not have any history of atopy, or lymphoproliferative disorder. He was instructed to discontinue topical NSAIDs and follow up UACR in 1 month normalized to 7.2 mg.

Discussion: Diabetic kdiney diease is the most common cause of proteinuria and can often cause nephrotic syndrome, however it usually presents insidiously and coincides with diabetic retinopathy. In patients who do not have the typical natural history, kidney biopsy evaluation is imperative to not miss other etiologies. Additionally, although nephrologist often screen for oral NSAIDs during history evaluation, often topical NSAIDs are considered safe. However, if used in excessive amounts this may lead to systemic complications such as MCD in this case.

SA-PO884

Crescentic Glomerulonephritis and Pancytopenia Secondary to Bartonella henselae Bioprosthetic Valve Endocarditis

Juan Salvatierra,[1] Rohini Rao,[2] Rasha Nasri,[1] Liliia Harris,[1] Ahmad Alayyat,[1] Keelan T. Tuel,[1] Rafael O. Duchesne,[1] Lee Connor.[1] *[1]Hamilton Medical Center, Dalton, GA; [2]Riverview Regional Medical Center, Gadsden, AL.*

Introduction: *Bartonella* spp may cause diverse clinical manifestations including endocarditis and cytopenias. The new 2023 Duke-ISCVID criteria include *Bartonella* serology as this infection is often culture-negative. Infection-related glomerulonephritis (IRGN) can be secondary to *Bartonella* endocarditis and usually has an immune-complex deposition pattern.

Case Description: A 53-year-old man with insulin-dependent type 2 diabetes presented to the emergency department with epistaxis, abdominal pain and vomiting for three days. He noted 7-pound weight loss and a leg rash for three weeks. He owns cats. He denied fever or joint swelling. He had undergone bioprosthetic valve replacement for mitral valve prolapse 5 years before. Examination revealed a petechial and purpuric rash on his lower extremities but no heart murmur or lymphadenopathy. Laboratory analyses showed pancytopenia, creatinine 11 mg/dL, 3+ hematuria and proteinuria, and negative ANA and ANCA. Kidney biopsy revealed crescentic glomerulonephritis with codominant IgM and C3 deposits. Hemodialysis was initiated for worsening renal function. Due to negative blood cultures and no vegetation on echocardiogram, he received rituximab and methylprednisolone. Expanded infectious workup returned positive for *B. henselae* titers IgM 1:20 and IgG >1:1024. He was started on doxycycline 100 mg twice daily indefinitely and rifampin 300 mg for 2 weeks and discharged home on a steroid taper.

Discussion: Crescent formation may be indicative of IRGN and should prompt extensive testing if no causative organism is initially identified. We present a rare case of *B. henselae* causing endocarditis, glomerulonephritis, and pancytopenia. Although there are no guidelines for the treatment of *B. henselae* bioprosthetic valve endocarditis, treatment with doxycycline and rifampin followed by permanent suppressive treatment with doxycycline may be reasonable.

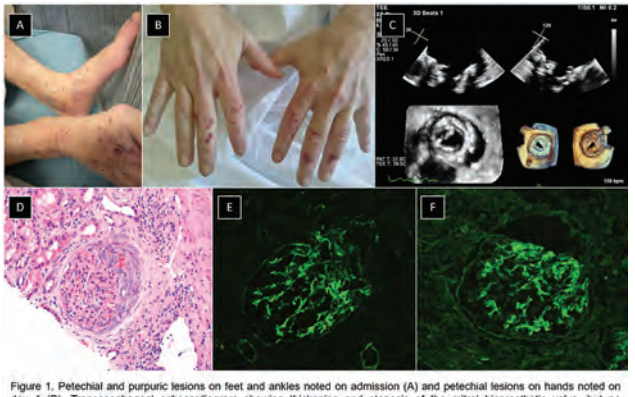


Figure 1. Petechial and purpuric lesions on feet and ankles noted on admission (A) and petechial lesions on hands noted on day 4 (B). Transesophageal echocardiogram showing thickening and stenosis of the mitral bioprosthetic valve, but no vegetation identified (C). Left kidney biopsy showing necrotizing, cellular or fibrocellular crescent formation on H&E stain; representative glomerulus shown (D). Immunofluorescence demonstrating co-dominant C3 (E) and IgM (F) deposition.

SA-PO885

A Unique Case of Primary Renal Sarcoidosis

Bhoomi Shah, Rupinder Kaur, Nabeel Siddiqui, Sreenidhi Kosuri, Benjamin M Easow. *Southeast Health, Dothan, AL.*

Introduction: Renal sarcoidosis is usually associated with other extra-renal sarcoidosis, it usually involves the lungs and renal involvement is only 0.7%. Initial lab work shows elevated serum creatinine, a bland urine sediment or sterile pyuria and high or high-normal calcium. Kidney biopsy is not diagnostic but is useful in making the diagnosis and ususally shows noncaseating granulomas in the interstitium. Treatment of choice is glucocorticoids and is started at 1mg/kg/day with maximum of 80 mg/day followed by a slow taper. Glucocorticoid doses required for renal sarcoidosis are higher than extra-renal sarcoidosis.

Case Description: 44-year-old male patient with past medical history significant for kidney stone, hypertension presents with complaints of high blood pressure and worsening kidney functions, on further investigation it was found that he had a left-sided renal biopsy in Miami about 4 years ago which showed nephrosclerosis with 50% sclerotic glommeruli, focal moderate interstitial fibrosis and mild arteriolosclerosis, chronic inflammatory infiltration with focal tissue calcinosis. At the time of initial diagnosis, his lab work revealed elevatded creatinine, calcium levels with proteinuria. No pulmonary lesions were found. He was started on 50 mg of prednisone daily and gradually taper down to 10 mg every other day and he has been on this dose for about 1.5 year now. He has not had any kidney stones since he started treatment for sarcoidosis and currently he requires supplements for low vitamin D levels.

Discussion: Though primary renal sarcoidosis is uncommon it is important to keep it as a differential in a person with no other extrarenal manifestation of sarcoidosis who presents with elevated creatinine and calcium levels. Patients with renal sarcoidosis are well managed with corticosteroids, though most patients require a higher dose of corticosteroids but some of them can be well managed on lower doses like our patient who was started only on 50 mg of prednisone and was gradually tapered down to 10 mg every other day. He continues to have CKD stage 3B even on this lower doses of corticosteroids and he has been stable there for the last few years. Also another noticeable point is that the patient has low vitamin D stores and requires supplementation currently after being treated for sarcoidosis for a 4 years.

SA-PO886

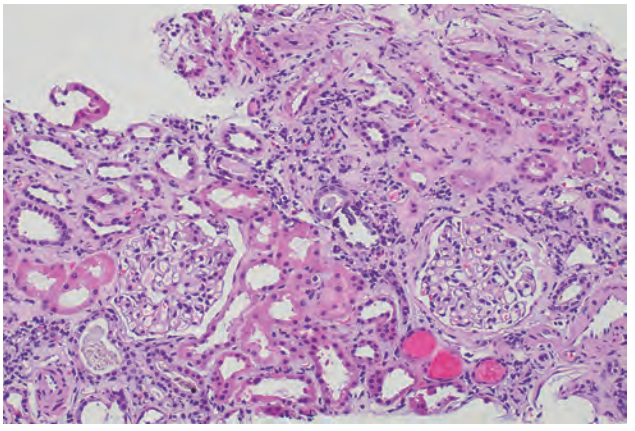
A Genuine Cat's Cradle: An Elusive Case of Bartonella Endocarditis-Associated Glomerulonephritis

Sameer Ahmed,[1] Patricia J. Allen,[2] Virgilius Cornea.[3] *[1]University of Kentucky College of Medicine, Lexington, KY; [2]Veterans Administration Hospital, Lexington, KY; [3]University of Kentucky, Lexington, KY.*

Introduction: We present a 73 yo male patient with Bartonella endocarditis–associated GN. The following describes his initial presentation, the ensuing diagnostic dilemma, and the eventual diagnosis which lead to proper resolution of the infection but unfortunate permanent loss of the patient's kidney function.

Case Description: 1 year after recieving a prosthetic aortic valve, a 73 yo male began developing weight loss, fatigue, and pancytopenia. The patient's pancytopenia and 80lb weight loss led to a malignancy workup that was non-revealing. After 6 months of worsening symptoms the patient was admitted with progressive kidney dysfunction and hematuria. Serological workup revealed low C3 & C4, +ANA, +dsDNA, +PR3, and an RF titer of >256. This led to an initial impression of lupus nephritis. However, a kidney biopsy revealed either infection-related GN or C3 nephritis. The patient's blood cultures were negative for typical organisms, but a TEE showed vegetation in the aortic valve. A search for atypical organisms revealed a Bartonella henselae IgG titer >1.256 and an IgM titer >1.800. As renal function deteriorated the patient was started on HD. The patient was placed on a combination of Rifampin and Doxycycline for 3 months. The patient's overall condition improved except for his kidney function, which progressed to ESKD.

Discussion: B. henselae is one of the most common causes of culture-negative IE. Kidney involvement is seen in up to half of patients with IE, and these patients can exhibit hematuria, infarction of the parenchyma, and glomerulonephritis. Delays in the rapid identification of the causative organism due to a negative blood culture can confuse the differential and delay treatment. B. henselae endocarditis is most associated with an exposure to cats and pre-existing valvular disease. This patient's affection for his feline companions was to a degree that it was noted in a PCP note months prior to admission, revealing the odd ways a patient's history can illuminate etiology.



SA-PO887

A Case of Scabies-Induced Glomerulonephritis

Aditya Ragunathan. *Boston Medical Center, Boston, MA.*

Introduction: Scabies is caused by the parasitic mite *Sarcoptes scabiei var. hominis*. Patients with this disease can present with diffuse skin itching and the excoriations can predispose them to bacterial cellulitis. There have been documented cases of post-streptococcal glomerulonephritis (PSGN), rheumatic fever, and systemic sepsis as a complication. Typically, the treatment of PSGN is supportive, and requires treating the underlying infection. Here, we present a case of scabies causing post-infectious glomerulonephritis (PIGN) requiring dialsyis that recovers with supportive therapy

Case Description: 63 y.o.male with a history of scabies and noted to be homeless who presented with fever, nausea, vomiting and an AKI. Initial exam was noted for bilateral crackles, peripheral edema, diffuse erythematous rash and distended abdomen. Infectious work-up included a chest X-ray without infiltrates, CT abdomen and pelvis with a thickened bladder wall and mild diffuse abdominal pelvic ascites, urinalysis with >100 white blood cells and red blood cells per high powered field. Blood and urine cultures were negative. He was treated for a presumed urinary tract infection with ceftriaxone 1 g daily for 7 days and permethrin baths. Baseline creatinine was 0.7-0.9 mg/dL, but was elevated to 4.2 mg/dL on admission. Serum creatinine increased to 7.37 mg/dL and patient became more volume overloaded. Ultimately, patient was started on dialysis. Serologic work-up of kidney injury was positive for ANA at 1:80, C3 <20 mg/dL, C4 of 12 mg/dL. Protein electrophoresis of serum and urine were negative for monoclonal bands. All other antibody tests performed were negative. A kidney biopsy was perfomed exhibiting the classic appearance of PIGN. Patient underwent dialysis, but was eventually weaned off after two weeks. At follow-up two months later, his serum creatinine had mostly recovered to 1.21 mg/dL

Discussion: Scabies is a common condition across the globe, affecting 300 million people worldwide, and can be associated with concomitant skin infections. PIGN is a complication of this condition and can be treated with supportive care. Patients on dialysis can have their kidney function improve even with severe acute injury, but do not require additional therapy. It is important to note the possibility of multiple infections in patients with scabies infections and keep the possibility of other complications of those infections in minds as a nephrologist.

SA-PO888

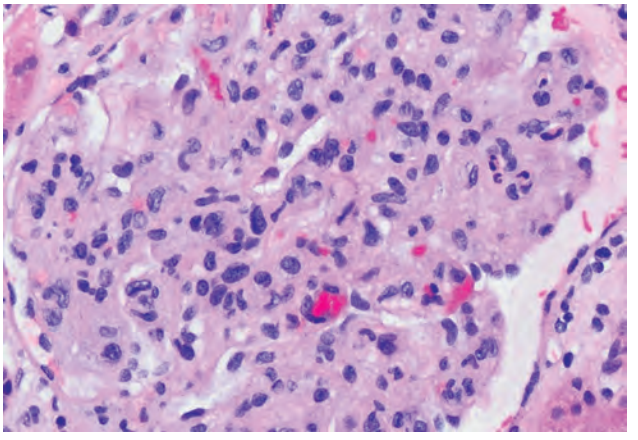
An Unsuspected Case of Idiopathic Multicentric Castleman Disease (iMCD) Presenting with Renal Microangiopathy

Jay V. Dominguez, Ramon A. Lopez. *University of South Florida, Tampa, FL.*

Introduction: iMCD remains an elusive diagnosis because of the non specific clinical manifestations that are common in other systemic diseases. Renal manifestations are rare, but can provide insight in the diagnosis of this elusive disease.

Case Description: A 20-year-old caucasian male presented with fevers, anemia, thrombocytopenia, hepatosplenomegaly, anasarca and unclear etiology of multiorgan failure that required vasopressors, ventilator support and dialysis. He was treated initially empirically for sepsis with antibiotics and then with steroids for autoimmune disease of unknown etiology. After improvement in his respiratory and hemodynamic status he had a renal biopsy with evidence of widespread glomerular endotheliosis with rare RBC fragments and no evidence of immunecomplexes by IF and EM. TTP was ruled out and no other common causes of microangiopathy was found. Bone marrow biopsy had no evidence of malignancy, but excisional axillary lymph node biopsy was consistent with mixed hyaline vascular and plasma cell Castleman disease, HHV8 negative.

Discussion: HHV8 negative iMCD is an uncommon lymphoproliferative disorder characterized by inflammatory systemic manifestations mediated by increased IL-6 and VEGF. Renal manifestations are rare and usually associated with severe disease manifestations as TAFRO syndrome. It can present as a microangiopathy with severe diffuse glomerular capillary endoteliosis and reduction in glomerular filtration rate to require dialysis. Fibrin thrombi or fibrinoid necrosis may not be present as seen in other causes of thrombotic microangiopathy. Some patients have a paradoxical downregulation in renal VEGF expression with similar histologic features as seen with VEGF antagonists. Delayed diagnosis and severity of the disease is associated with worst outcomes. iMCD is difficult to diagnose since the systemic manifestations are non specificic and should be suspected in renal microangiopathies of unclear etiololgy so early therapy can be prescribed.



SA-PO889

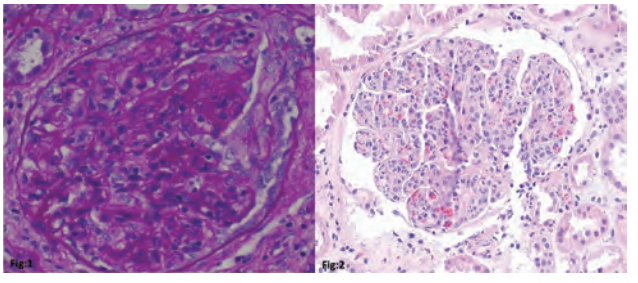
Donor-Derived Proliferative Glomerulonephritis

Kanza Haq,[1] Sami Alasfar,[2] Avi Z. Rosenberg,[1] Fizza F. Naqvi.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]Mayo Clinic Arizona, Phoenix, AZ.*

Introduction: Pre-existing glomerular disease in renal allografts is rarely reported in the literature. A majority of the cases are diagnosed retrospectively following transplant on reperfusion biopsy, or on discovery of the same lesion in both allografts from the donor.

Case Description: Two patients underwent deceased donor kidney transplant from a adult donor who had anoxic brain death in the setting of sepsis due to Streptococcus pneumoniae bacteremia. He was noted to have hematuria and proteinuria on pre-procurement urinalysis. 1st recepient was 50-year-old female with end-stage renal disease (ESRD) from diabetic nephropathy. She received Induction with thymoglobulin and methylprednisolone. Initial maintenance IS included tacrolimus, mycophenolate mofetil, and prednisone. The patient had delayed graft function (DGF). Urinalysis continued to demonstrate hematuria & proteinuria. Renal biopsy on POD 60 showed diffuse proliferative and exudative glomerulonephritis with focal cellular crescents (fig 1). Immunofluorescence was negative and no discrete electron dense immune deposits were seen. Follow-up biopsy 90 days post-transplant showed persistent exudative glomerulonephritis with severe tubulointerstitial scarring. Recipient serological work-up was negative. She remained on dialysis and has no evidence of renal recovery to date. Second recipient was a 52-year-old male with ESRD due to type 2 diabetes mellitus who also developed DGF. Post perfusion biopsy (Fig 2) showed similar diffuse proliferative and exudative glomerulonephritis. A follow-up biopsy 30 days post-transplant showed persistent glomerulonephritis with reduced neutrophilic inflammation and no signs of active immune-mediated rejection. EM was negative for deposits and IF remained negative. 2nd recipient was able to come off dialysis and the creatinine slowly improved to a nadir of 2.5 mg/dL.

Discussion: Preexisting diseases in renal allografts can follow variable courses which often are disease and recipient dependent. This case highlights the importance of pre-engraftment biopsies as current clinical parameters used for donor selection are inadequate to assess pre-existing disease etiology and severity.



SA-PO890

Scleroderma Renal Crisis Requiring Kidney Replacement Therapy

Michael Liben, Aashvi R. Dalal, Varun Madireddy. *NewYork-Presbyterian Brooklyn Methodist Hospital, Brooklyn, NY.*

Introduction: Systemic Sclerosis (SSc) is an autoimmune disease characterized by vascular dysfunction, and fibrosis of the skin and internal organs. Although cutaneous, pulmonary and renal manifestations are most common, every organ system is vulnerable. SSc often presents with acute flares that can be life threatening if not promptly recognized and managed.

Case Description: A 73-year-old woman with SSc presented to the hospital with exertional dyspnea and decreased oral intake. Given prior intolerance to mycophenolate and inability to obtain insurance authorization for Tocilizumab, she was only taking prednisone 20mg. Upon presentation, vital signs were within normal limits except a blood pressure of 180/83. Pertinent labs are shown in Table 1. Further results showed a white blood cell count of 12.3x10^3/uL, hemoglobin of 7.0g/dL, proBNP of 38,000pg/mL, phosphate of 9.0mg/dL, anion gap of 22mmol/L, and lactate of 0.6mmol/L. Urinalysis showed moderate blood, 11/HPF RBCs, 300mg/dL of protein, and a specific gravity of 1.014 without casts. Anti-topoisomerase I antibody titers were elevated. The next day, she developed hyperkalemia and hypervolemia requiring placement of a dialysis catheter and urgent hemodialysis (HD). She was started on captopril which was titrated to maximum tolerated dose.

Discussion: Despite guideline-directed medical therapy, our patient developed a life threatening Scleroderma Renal Crisis (SRC). Ultimately, renal failure necessitated renal replacement therapy and she was discharged with outpatient HD. Three months later, she requires regular HD, and is compliant with ACE inhibitor, prednisone 10mg, and Tocilizumab. SRC affects 2-15% of patients with SSc. It is not managed with high dose steroids, but with ACE inhibitor uptitration. One study showed that after 45.8 months, 54% of patients developed ESRD and 41% died. Another study found that renal recovery could occur after 3 to 18 months of HD and ACE inhibitor use. Although our patient's medication regimen was suboptimal, we highlight the importance of raising clinical suspicion and prompt identification of SRC in the outpatient setting.

	On Arrival	Next Day
Creatinine (mg/dL)	9.85	10.17
Blood Urea Nitrogen (mg/dL)	169	176
Potassium (mmol/L)	5.1	5.7
pH	7.25	7.24
Bicarbonate (mmol/L)	8	9

SA-PO891

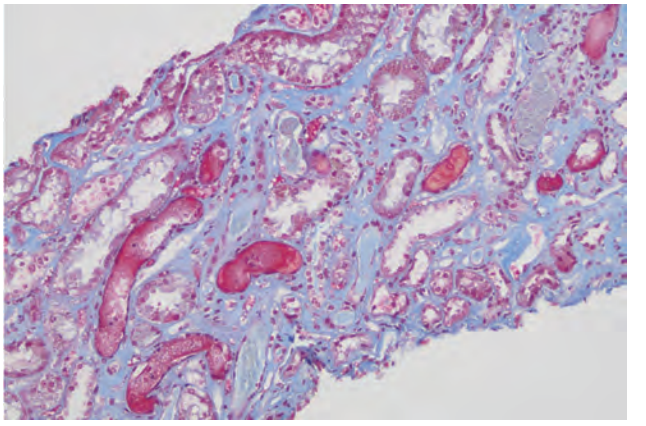
Beyond Blood: A Case Report on Anticoagulation-Related Nephropathy

Divmehar Kaur, Elizabeth A. Phipps. Mount Auburn Hospital. *Mount Auburn Hospital, Cambridge, MA.*

Introduction: Anticoagulation related nephropathy (ARN) is thought to be a frequently undiagnosed complication of anticoagulant therapy. Typically manisfesting as gross hematuria and AKI in individuals on therapeutic anticoagulation doses, its diagnosis remains rare. Its confirmation through renal biopsy is tough, as it may be missed or underreported due to the presence of concurrent pathologies.

Case Description: A 76-year-old male with pertinent history of hypertension, BPH was started on Apixaban for a new diagnosis of atrial fibrillation. Soon after, his creatinine levels nearly doubled from their baseline of 1-1.3 within a year which prompted nephrology involvement. Initial work up showed microscopic hematuria with acanthocytes, raising suspicion for underlying nephropathy. Shortly, this progressed to gross hematuria and was initially attributed to severe BPH causing bilateral hydronephrosis found on renal ultrasound. However, the persistence of hematuria and AKI despite relieving post renal obstruction warranted a kidney biopsy which showed ATN, IgA nephropathy and numerous RBC casts. This raised suspicion for ARN, which was confirmed with improvement in renal function after stopping Apixaban.

Discussion: ARN is known to cause glomerular hemorrhage and occlusion of renal tubules with RBC casts. This is reflected in typical renal biopsy findings showing near complete occlusion of the tubular lumen by numerous RBC casts lacking Uromodulin. Patients with underlying pathologies compromising the glomerular filtration barrier integrity such as IgA nephropathy (identified in our patient) are prone to develop ARN. Ongoing research is looking into thrombin driven activity of PAR-1(expressed in endothelial cells and podocytes) causing local inflammation at the filtration barrier, which along with free iron release (from trapped RBCs) may cause ARN. These insights emphasize the need for further research to better understand ARN and improve patient management and outcomes.



SA-PO892

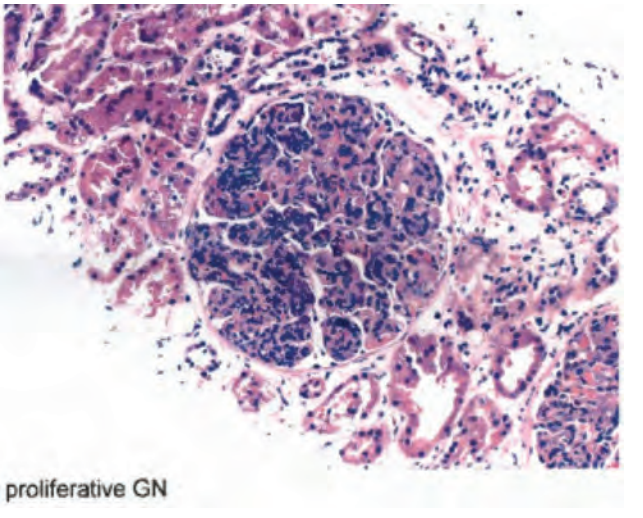
A Case of Type II Cryoglobulinemic Membranoproliferative Glomerulonephritis Associated with Marginal Zone B Cell Lymphoma

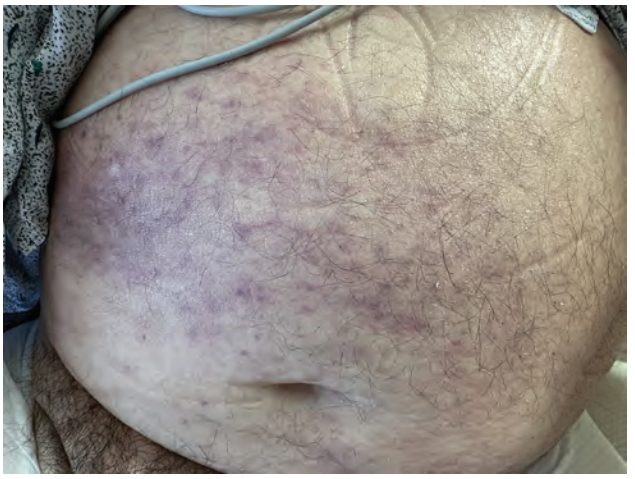
Pooja V. Patel. *Mercy Fitzgerald Hospital, Darby, PA.*

Introduction: Cryoglobulinemia is rare. Renal involvement is seen some cases associated with type II cryoglobulinemia. We present a case of type II Cryoglobulinemic MPGN associated with Marginal Zone B-cell Lymphoma and response to the treatment.

Case Description: A 74-year-old male with history of HTN, DM II, recent LE DVT presented to the hospital with worsening SOB, lower extremity edema, intermittent abdominal pain associated with nausea for 2 days. Upon arrival his BP was 168/79 mmHg. On exam, bibasilar crackles and +1 LE pitting edema. Labs revealed SCr 5.8 mg/dl (baseline 1.5 mg/dl). UA was positive for protein & RBC. Complements C3 and C4 were low. ANA was negative and RF level 1104. Cytology revealed positive cryoglobulin, Hep B core total and sIgG antibody positive with undetectable viral load. Hep C and HIV were negative. Immunofixation showed prominent IgM kappa. Kidney biopsy revealed B-cell lymphoma associated type II cryoglobulinemic glomerulonephritis. Immunofluorescence studies revealed glomerulus immune deposits of IgM and Kappa. Omental mass biopsy showed Marginal zone B-cell lymphoma. He was started on Rituximab and Methylprednisolone. After 3 months of treatment, his renal function improved to 1.5 mg/dl. He developed rash after first few doses of Rituximab.

Discussion: Noninfectious type II cryoglobulinemic GN associated with marginal zone lymphoma is uncommon. Management and prognosis is dependent on disease severity and treatment of underlying cancer.





Rash after Rituximab

SA-PO893

Intermittent Hematuria in a Patient with Crohn Disease: A Case Report

David M. Warner,[1] Prakash S. Gudsoorkar,[2] Jacob A. Nysather.[2]
[1]University of Cincinnati College of Medicine, Cincinnati, OH; [2]UC Health Medical Center, Cincinnati, OH.

Introduction: There are a variety of secondary causes of IgA vasculitis (IgAV) and glomerulonephritis in adults. We report a rare case of IgAV with crescentic glomerulonephritis in a patient with Crohn Disease (CD) treated with infliximab.

Case Description: A 30-year-old male with biopsy-proven CD on infliximab developed intermittent gross hematuria, elevated serum creatinine (SCr), and a palpable purpuric lesion. Genitourinary cancer, hemorrhagic cystitis, and infectious etiologies were ruled out and his infliximab was held. He was referred to nephrology after 6 months of symptom onset. Glomerular serology work-up revealed polyclonal IgA and IgG on immunofixation with a protein gap of 5.1 g/dL; the rest was unremarkable. A kidney biopsy (Figure 1) showed focal fibrocellular crescents with diffuse mesangial expansion and hypercellularity. Immunofluorescence (IF) confirmed IgA glomerulonephritis M1, E1, S0, T1, C1. Pulse steroids with a slow taper and valsartan were started, with improvement in SCr and hematuria (Table 1).

Discussion: Secondary causes of IgA nephropathy (IgAN) include HIV, HBV, HCV, renal cell carcinoma, celiac disease, and lymphoma. Less common secondary causes include inflammatory bowel disease (IBD) and infliximab treatment. CD is thought to cause IgAN through increased IgA glycosylation, which correlates with disease severity, and elevated levels of the apoptosis inhibitor of macrophages (AIM), leading to co-localization of IgA, IgG, and IgM in the glomeruli. Infliximab has been shown to cause secondary IgAN; however, his intermittent hematuria and worsening SCr persisted despite discontinuing infliximab, suggesting CD progression linked to IgAV and nephritis. A recent Japanese study showed patients with IBD have a higher cumulative incidence of IgAN compared to non-IBD (p=0.0028), with CD having a strong association compared to ulcerative colitis.

Pre- and Post-Treatment Labs

Lab Value	Pre-Biopsy	Post-Treatment	Reference Value
Serum Cr	1.84 mg/dL	1.09 mg/dL	0.60-1.30 mg/dL
Serum Cystatin C	2.23 mg/dL	1.77 mg/dL	0.60-1.00 mg/dL
Urine Protein/Cr	3.16	3.05	<0.15
Urine RBC	>100/HPF	25/HPF	0-3/HPF

Recurrent Dialysis-Dependent Rapidly Progressive Glomerulonephritis

Alexandra Stewart,[1] Gabriela Dande.[2] *[1]Brooke Army Medical Center, Fort Sam Houston, TX; [2]The University of Texas Health Science Center at San Antonio, San Antonio, TX.*

Introduction: IgA nephropathy is the most common primary glomerulonephritis. Clinical presentations and kidney outcomes are variable, ranging from asymptomatic microscopic hematuria to nephrotic syndrome with rapidly progressive glomerulonephritis (less than 10 percent).

Case Description: A 69-year-old male with PMHx of microscopic hematuria with negative urologic evaluation and no prior nephrology evaluation, T2DM, HTN, small vessel disease with history of CVA was admitted to the hospital after a fall with rib fractures and a L hemopneumothorax complicated by MRSA empyema s/p thoracotomy. After 3 weeks, he developed nephrotic syndrome with anuric renal failure and volume overload. Physical exam was notable for elevated blood pressures and anasarca. Urine microscopy revealed 40-50 RBC/hpf with at least 30% dysmorphic. Serologic workup was negative for monoclonal protein with normal FLC ratio, vasculitis panel negative for ANCA, negative HIV/ RPR/ Hepatitis B and C, and normal complements. Had 6 g proteinuria on 24 hour urine collection. Prednisone was started at 1 mg/kg/day and renal biopsy was obtained with findings of IgA nephropathy (Oxford score: M1, E1, S0, T0, C1) and diabetic glomerulosclerosis with extensive foot process effacement. Initially had good response to steroids and diuretics, but developed worsening volume overload and was started on hemodialysis. Required a few sessions of HD with renal recovery and was discharged home on prednisone. 1 week after discharge, patient presented again to the hospital for symptomatic hypoglycemia and was found to have worsening renal failure. He was again started on dialysis for uremic symptoms and another renal biopsy was obtained. Biopsy findings were consistent with RPGN with IgA nephropathy (Oxford score: M1, E1, S0, T0, C2) and <10% IF/TA. Despite pulse steroids and 4 cycles of cyclophosphamide, he had no evidence of renal recovery and declared ESKD after 3 months of HD; CYC therapy was discontinued and he was started on a rapid steroid taper.

Discussion: Rapid progression to ESKD in uncommon in patients with IgAN and prognosis is generally poor. Treatment has not been evaluated in randomized trials; and observational trials have used a treatment approach similar to those in idopathic RPGN. We hope to demonstrate the challenges and the need for early intervention/ treatment approach in RPGN in IgAN.

SA-PO895

Unveiling IgA Nephropathy with Crescents: A Prognostic and Therapeutic Dilemma

Fnu Versha, Viral Patel, Kristi Pejo. *Baptist Hospitals of Southeast Texas, Beaumont, TX.*

Introduction: Limited data exists regarding the outcomes, clinical significance, and management strategies for IgA Nephropathy (IgAN) with crescents. The KDIGO 2021 guidelines assert that neither the presence nor the relative number of crescents should predict IgAN progression or dictate the use of immunosuppression. However, some uncontrolled studies suggest otherwise. We present a challenging clinical case that underscores the need for further discussion on this topic.

Case Description: A 62-year-old Caucasian male presented with worsening shortness of breath and bilateral lower extremity edema over two weeks. Initial evaluation revealed a serum creatinine level of 6.4 mg/dL and nephrotic-range proteinuria, indicating severe renal impairment. His baseline eGFR was previously normal. Insufficient follow-up data necessitated a renal biopsy, which identified IgAN with 47% crescents, moderate interstitial fibrosis and tubular atrophy (30%), and a MEST-C score of M1, E1, S0, T1, C2. Refractory hyperkalemia required emergent hemodialysis, continued as outpatient therapy due to lack of renal function recovery. The patient was treated with prednisone, cyclophosphamide, and lisinopril. After six months, although still on hemodialysis, there was partial renal function improvement as evidenced by decreased proteinuria. A follow-up biopsy to assess disease progression is pending.

Discussion: The KDIGO 2021 guidelines recommend that crescents on renal biopsy should not predict disease progression or influence immunosuppression choice in IgAN cases. Contrary evidence suggests the importance of crescents should not be overlooked. Our case indicates potential benefits of steroid-immunosuppression therapy, as demonstrated by partial renal function recovery within a short follow-up period. We propose that evaluating crescents alongside other MEST scores, clinical data, and novel biomarkers can facilitate a personalized therapeutic approach for patients with IgAN.

SA-PO896

IgM Dominant Proliferative Glomerulonephritis (GN), Undetectable Serum C4, and Chronic Lymphocytic Leukemia (CLL) with Persistently Negative Serological Testing for Type 1 Cryoglobulins

Raghunandan Konda, Dana V. Rizk, Arun Rajasekaran. *The University of Alabama at Birmingham, Birmingham, AL.*

Introduction: Cryoglobulins are immunoglobulins (Ig) that precipitate at < 37°C and dissolve on rewarming. Type I cryoglobulinaemia consists of 1 isotype of monoclonal Ig, whereas type II and type III are classified as mixed cryoglobulinaemia [include IgG & IgM]. We describe a likely longstanding type 1 cryoglobulinemia with persistently negative serological testing in a patient with chronically suppressed/undetectable C4 levels, leukocytoclastic vasculitis, IgM kappa paraproteinemia, and IgM dominance in the kidney biopsy with CLL eventually being diagnosed much later.

Case Description: 87-year-old male with diabetes mellitus, chronic leukocytoclastic vasculitis, and persistently low C4 presented with AKI on CKD. Baseline Cr 1.3 mg/dL. Had serum cryoglobulins checked multiple times at different labs that were all negative. Exam sig. for purupuric lesions in LE. Cr 2.3 mg/dL, Sr albumin 3.7 g/dL, UA 1(+) protein, UPCR 340 mg/g, C3 102, C4 <1, RF 72, Sr Kappa (376) and Lambda (138) with FLC 2.7. SPEP/SIFE negative. UPEP/UIFE revealed M-spike with monoclonal IgM kappa LC. Sr cryoglobulin, HCV [Ab & Quant], CCP, and comprehensive GN screen (-). Blood cultures and testing for indolent infections including Bartonella/coxiella (-). ECHO [TTE/TEE] normal. Kidney bx revealed focal proliferative glomerulonephritis. IFTA 50%. IF: Diffuse global granular mesangial staining for IgM [3+], C3 [2+], kappa [2+], and lambda [3+]. Pronase IF negative. EM: No immune deposits. Congo red (-). Patient became sick with worsening abdominal lymphadenopathy that demonstrated IgM kappa CLL [BM Bx neg]. Serum testing for cryoglobulin again (-). Patient subsequently died.

Discussion: Testing for cryoglobulins is complicated by lack of reference range, standards, and stringency in maintaining testing temperature conditions. Despite the overall diagnosis favoring a likely an indolent Type 1 cryoglobulinemic process, our case is rare in that it was never detectable [blood, kidney, skin biopsy] and that the eventual diagnosis of CLL appeared 7 years after initial clinical manifestations. Better modalities to diagnose Type 1 cryoglobulins are therefore warranted.

SA-PO897

A Cascade of Viral Infection to Cardiomyopathy and Lupus Nephritis

William M. Parkinson, Jesse M. Wickham. *Brooke Army Medical Center, Fort Sam Houston, TX.*

Introduction: Systemic Lupus Erythematosus (SLE) affects over 1.5 million Americans, causing significant morbidity and mortality. Lupus onset and flares can be triggered by a range of insults including medications, infections, and environmental factors. Lupus nephritis (LN) is a common manifestation of SLE with symptoms often including edema, hypertension or proteinuria. Lupus myocarditis highlights SLE cardiac involvement with heart failure symptoms. The wide spectrum of organ involvement with Lupus further complicates diagnosis. Appropriately phrased, Hickam's dictum states, "A man can have as many diseases as he damn well pleases". We present a case that highlights Hickam's dictum with a tenuous presentation and multiorgan involvement.

Case Description: A 24-year-old active-duty female with a recent admission for pancreatitis presented to the emergency department with edema, fatigue, and found to be in cardiogenic shock. Previously, she was in excellent health, exercising, and fulfilling military requirements. Labs revealed proteinuria with dysmorphic red blood cells, elevated creatinine, ANA titer 1:320, and positive dsDNA. Kidney biopsy confirmed class III Lupus Nephritis. Cardiogenic shock was initially attributed to Lupus myocarditis. Cardiac MRI revealed an ejection fraction of 20%, dilated cardiomyopathy, severe valvular disease, but no myocarditis. Without myocarditis, Lupus is unlikely causative for cardiomyopathy. Further workup aimed at possible infectious etiologies revealing positive coxsackie antibody titers. The hospital course was further complicated by progressive biventricular failure requiring an intra-aortic balloon pump. Ultimately, the patient was stabilized and transferred for cardiac transplant evaluation. The presentation is thought to be a cascade of coxsackie virus infection driving both cardiomyopathy and new onset lupus with nephritis.

Discussion: The work up for complex patients requires a broad differential without bias. In this case, the initial concern was for Lupus induced myocarditis driving cardiogenic shock. However, further investigation revealed positive antibody titers for coxsackie virus and imaging not consistent with Lupus myocarditis. Broadening the differential to include infectious causes allowed the identification of prior coxsackie infection. This case highlights an interesting cascade from viral infection to cardiomyopathy and nephritis.

SA-PO898

Failure Is a Learning Experience: A Case of Lupus Vasculopathy without Clinical Response to Rituximab

Seshma Ramsawak, Leal C. Herlitz, John R. Sedor, Corey J. Cavanaugh. *Cleveland Clinic, Cleveland, OH.*

Introduction: Lupus vasculopathy (LV) is a rare entity and the pathogenesis is poorly understood. Renal involvement in systemic lupus erythematosus (SLE) is typically an immune complex glomerulonephritis. LV however is a non-inflammatory form of vascular injury. The prognosis is poor and currently there is no standard recommended treatment available. We hereby describe a case of LV that progressed to ESKD despite treatment with high dose corticosteroids, plasmapheresis and rituximab.

Case Description: A 29 year old female with a history of SLE, hypertension and multiple ischemic strokes presented with a 3-week history of malaise and weight loss. The onset of chest pain and shortness of breath prompted medical evaluation with concern for lupus myopericarditis. On presentation serum creatinine was 1.2 mg/dL (baseline 0.7) and UPCR was 4.8 (previously 0.1-0.15). These findings together with hypocomplementemia and elevated dsDNA raised suspicion for lupus nephritis. A kidney biopsy performed revealed findings of lupus nephritis class II. Notably, half of the glomeruli sampled had ischemic changes, likely a result of prominent luminal narrowing of small arteries and arterioles due to immune complexes admixed with hyalin and fibrin. The diagnosis was consistent with LV. The non-ischemic glomeruli on this biopsy were preserved without features of glomerulonephritis. Serological testing for scleroderma and antiphospholipid syndrome were negative. 5 sessions of plasmapheresis were performed followed by rituximab infusions in conjunction with high dose steroids. Despite this, renal function progressively worsened over two months requiring initiation of dialysis without recovery.

Discussion: There is a paucity of data on LV and the existing literature is limited to isolated case reports. Most of these cases have an associated severe lupus nephritis, and use of cyclophosphamide was often reported. Immunosuppressive medications however are "glomerulocentric" and are stratified based largely on the ISN/RPS lupus nephritis classification. There is no standardized treatment of LV alone, and future studies are needed to determine optimal treatment for LV specifically. This report uncovers another rare case of lupus vasculopathy, and highlights the need for a clinically effective treatment.

SA-PO899

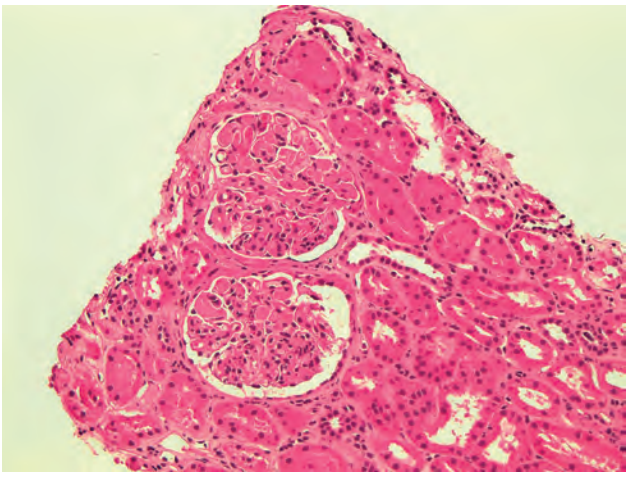
A Rare Case of Lupus Nephritis with Hemophagocytic Lymphohistiocytosis

Sam Beavin, Sameer Ahmed, Fritz E. Lower. *University of Kentucky College of Medicine, Lexington, KY.*

Introduction: In this case, we present a 19 yo female with SLE and lupus nephritis complicated by HLH. The following describes her initial presentation and diagnosis, followed by the treatment of this uncommon complication of SLE.

Case Description: A 19 yo female with a family history of autoimmune disease reported fatigue, joint pain, and a rash on her feet 6 months prior to admission. 3 days prior to admission, she experienced nausea, vomiting, and abdominal distension. On admission, the patient was found to have pancytopenia, severe AKI with proteinuria, and imaging suggestive of cirrhosis with ascites and splenomegaly. Her ANA and anti-DS DNA were positive. Subsequent workup, including a kidney biopsy and bone marrow biopsy, led to a diagnosis of SLE complicated by LN class IV and HLH/MAS. The patient was treated with dexamethasone per the HLH-94 protocol, in addition to HCQ and MMF for SLE and LN. Her inflammatory markers normalized, and AKI resolved. At 6-month follow-up, she had tapered off steroids and continued on HCQ and MMF.

Discussion: Hepatic involvement is rare in SLE and suggests a secondary complication such as aPL-related TMA, autoimmune hepatitis, secondary Still disease, or, as in this patient, HLH. sHLH is a rare disorder that is life-threatening if not promptly treated. It is a diagnostic challenge for clinicians given the overlap in presentation between autoimmune disease and infection. sHLH is an uncommon but severe complication of SLE, where it is called macrophage activation syndrome. It is described in ~8% of new SLE cases, mostly in children. Differentiating features for MAS are high fever, elevated AST, LDH, ferritin, TG, and neutropenia. SLE patients presenting with MAS are more likely to have renal disease. Treatment options for sHLH include disease-specific therapy or chemotherapy. In this patient, disease remission was achieved by combining SLE induction treatment with a higher-than-typical steroid regimen guided by HLH treatment protocols.



SA-PO900

Late-Onset Systemic Lupus Erythematous in a Man with Antiphospholipid Antibody Syndrome and Lupus Nephritis

Yinelka G. Silverio De Castro, Jerin Karingattil, Eliot Sachsenmeier, James Drakakis. *NYU Langone Hospital - Long Island, Mineola, NY.*

Introduction: Late onset systemic lupus erythematosis (SLE) is a subgroup of SLE, with age 50 considered minimum age of onset. As with early onset disease, the incidence here is also higher in females. There is little available data characterizing males with SLE and biopsy proven lupus nephritis. That which is available notes the late onset SLE patients have less renal involvement and historically receive less aggressive treatment. We present a case of a 72 year old male with newly diagnosed SLE with positive antiphospholipid antibodies and proteinuria/hematuria. Renal biopsy ultimately revealed a class III lupus nephritis.

Case Description: 72 year old male with a history of hypertension, presented to ER with pleuritic chest pain. He was found to have left lower extremity DVT. Hypercoagulable testing showed high titer anti cardiolipin & anti beta2 glycoprotein IgG. Additionally, ANA 1:1280 (nuclear, homogeneous), double stranded (ds) DNA antibody 79 IU/mL, C3 89 mg/dL (low), C4 11 mg/dL. Urinanalysis with 3+ protein, large blood and >100 RBCs. Urine protein to creatinine ratio (UPCR) 2112 mg/g. Kidney biopsy revealed focal endocapillary proliferative & crescentic immune complex mediated glomerulonephritis, and endothelial cells containing tubuloreticular inclusions. Rare glomerulus with small active crescent. This was felt to represent focal proliferative lupus nephritis, class III. 3 days of pulse steroids given, transitioning to Prednisone 60 mg daily (tapering). Cellcept added and escalated to 3 g/day. After 3 months of therapy, PCR down to 260 mg/g with negative ANA, ds DNA antibody 4 IU/mL and normal C3. Serum creatinine remained stable at 1.1 - 1.3 mg/dL.

Discussion: This case illustrates the importance of constructing a broad differential diagnosis in older patients presenting with non specific symptoms. Early recognition and diagnosis proved critical to our patient's management. Antiphospholipid antibodies were found on hypercoagulable workup, which in turn prompted consideration of SLE. The active UA was the key to determining the presence of renal involvement, despite the literature noting decreased incidence of nepritis in this population. More information is needed to better characterize this late onset subtype, especially in males. Clincians need maintain a high index of suspicion regardless of age and gender.

SA-PO901

Myeloperoxidase (MPO)-ANCA: From Confounding to Confirming a Case of Lupus Nephritis (LN) in a Silent Patient

Jackson Rajendran,[1,2] Katherine Toma,[1] Sheilabi Seeburun.[1,2] *[1]RWJBarnabas Health, Toms River, NJ; [2]Rutgers The State University of New Jersey, New Brunswick, NJ.*

Introduction: ANCA is positive in up to 23% of LN cases, of which 82% represent MPO-ANCA. Despite this, SLE-ANCA overlap syndrome is very rare (2%). We present a case of an 18-year-old female with supposed Acute Renal Failure (ARF) whose high MPO-ANCA titer confounded her treatment course.

Case Description: An 18-year-old African American female with developmental delay presented with malaise, periorbital edema, oliguria, nausea, and vomiting for one week. No joint pain/swelling, oral ulceration, rash, or alopecia were noted by family. Past medical and surgical histories were otherwise unremarkable. There was no family history of kidney or rheumatologic disease. Upon examination, the patient weighed 51 kg and was hypertensive (205/145 mmHg) and tachycardic (133 beats per minute). She had generalized facial edema without peripheral edema. No cutaneous lesions were found. Labs revealed ARF (Blood Urea Nitrogen 57 mg/dL, creatinine 5.08 mg/dL), anemia (hemoglobin 8.6 g/dL), nephrotic range proteinuria (Protein-creatinine-ratio 4.818) and metabolic acidosis (bicarbonate 18 mEq/L, anion gap 10). She was also found to have a large pericardial effusion with tamponade, which was evacuated. Pathology eventually yielded granulation tissue. Empiric high-dose methylprednisolone and hemodialysis were initiated. Kidney biopsy revealed Class IV and Class V Lupus Nephritis with minimal activity and severe chronicity. Further serology evaluation is summarized in the table. The end-stage nature of the pathology did not warrant aggressive immunosuppression. She was placed on a steroid taper and was given one dose of Rituximab (1 gram) due to the very high MPO-ANCA titer and unclear systemic involvement. Further rheumatologic evaluation confirmed no systemic ANCA-mediated disease. A second dose of Rituximab was therefore not given. The patient remains dialysis-dependent and will eventually undergo renal transplant evaluation.

Discussion: Our patient with limited ability to provide a history presented with severe ARF, pericardial tamponade, and anasarca with nephrotic range proteinuria. Clinical suspicion for LN was confirmed with renal biopsy. High MPO-ANCA titer caused concern for a second autoimmune process but ultimately confirmed the chronicity of her silent chronic renal failure.

Positive serology: MPO-ANCA (521 units), ANA, Smith antibody, Anti-RNP
Negative serology: Anti-dsDNA, Lupus anticoagulant, Anti-cardiolipin, Anti-Beta 2 Glycoprotein, Anti-SSA/ SSB, Anti- PLA2R, C ANCA, Anti-GBM, Antimitochondrial antibodies

SA-PO902

Diffuse Lupus Nephritis Secondary to Ixekizumab Therapy: A Case Report and Literature Review

Nusiba H. Elamin, Essa Abuhelaiqa, Awais Nauman. *Hamad Medical Corporation, Doha, Qatar.*

Introduction: Drug-induced lupus (DIL) is a recognized category of illnesses associated with lupus. There are no standards for diagnosis, DIL differs from the conventional form of SLE in several ways, one of which being the pattern of organ involvement. DIL is often accompanied by constitutional and cutaneous symptoms. Renal system involvement is rare. Management usually is by stopping the offending agent. Up to date several drugs have been identified as being linked in DIL, the introduction of novel medications and the relative decline in the usage of more traditional ones have altered the epidemiology of DIL

Case Description: 69-year-old woman who developed diffuse lupus nephritis after receiving ixekizumab for psoriasis. She exhibited symptoms of lower limb edema and uncontrolled hypertension, and was found to have impaired renal function, positive ANA, anti-double strand DNA antibody, anti-ribonucleoprotein antibodies, significant proteinuria, hypoalbuminemia, and low serum complement levels. Ixekizumab was discontinued, and she was treated with prednisolone and mycophenolic acid, resulting in a favorable clinical and laboratory response as shown in figure 1.

Discussion: There is a growing number of reported cases of lupus erythematosus induced by IL-17 inhibition. Ixekizumab, an IL-17 inhibitor, are approved for the treatment of active psoriatic arthritis and Ankylosing spondylitis. Lupus nephritis after IL-17 inhibition is not well known or documented as a possible adverse effect, it has been reported before only once after secukinumab therapy (another anti-IL17). To our knowledge this is the the first reported case of drug induced lupus nephritis due to Ixekuzumab. The relationship between IL-17 inhibitors and lupus nephritis not yet well established and Further research are needed.

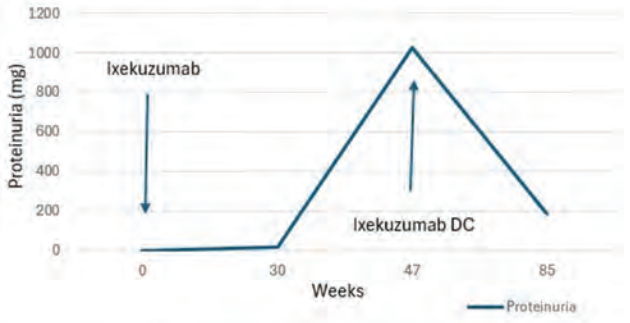

Figure 2. C3 and C4 levels

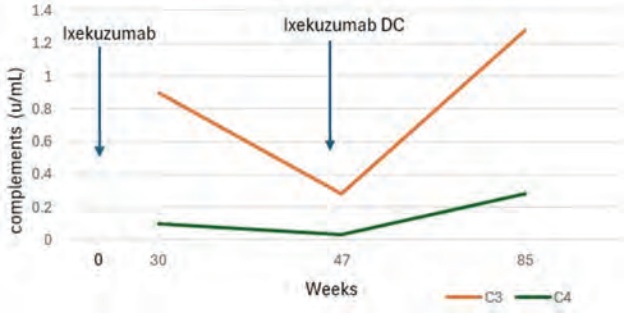

SA-PO903

Postpartum Diagnosis of Lupus Nephritis in a Patient with Preeclampsia Presenting with AKI and Decompensated Heart Failure

Tanya Geranpayeh, Jeannette Crew, Elissa Foster, Gates Colbert.
Baylor Scott & White Health, Dallas, TX.

Introduction: Systemic lupus erythematosus (SLE) is an autoimmune disease that frequently affects women of the childbearing age. Myocarditis complications in SLE are rare and affect less than 10% of patients. Peripartum cardiomyopathy is an idiopathic condition of heart failure. Both diseases can present as acute decompensated heart failure in the postpartum state. We present a unique case of a young woman who presented 6 weeks postpartum with heart failure symptoms and new onset of lupus nephritis.

Case Description: A 19-year-old G1P1 woman presented at 6 weeks postpartum with shortness of breath. She underwent induction for delivery at 37-weeks due to significant hypertension and concerns for pre-eclampsia. Physical examination revealed lung crackles, malar rash, and lower extremity edema. A transthoracic echocardiogram showed an ejection fraction of 36-40%. Laboratory work revealed acute kidney injury with serum creatinine 2.9 (normal baseline) and urine protein to creatinine ratio 3 g/g. Urine microscopy revealed dysmorphic red blood cells with acanthocytes. She was initiated on IV furosemide, metoprolol, spironolactone, hydralazine and isosorbide dinitrate for heart failure treatment. Further workup showed positive ANA (1/160), anti-dsDNA (1/640) and anti-histone (7.5 U) antibodies. C3 (28 mg/dL) and C4 (3 mg/dL) levels were low. Hydralazine was discontinued due to the concern for drug-induced lupus. Kidney biopsy resulted as Class IV lupus nephritis. The patient was initiated on systemic steroids and mycophenolate mofetil, then discharged with plans for outpatient follow up.

Discussion: Differentiating lupus nephritis versus pre-eclampsia in proteinuric pregnant patients without prior history of SLE can be difficult. This patient was recently diagnosed with pre-eclampsia, now presented with acute decompensated heart failure postpartum. The elevated ANA titer, low complement levels and acute kidney injury made SLE a possible differential diagnosis. Definitive diagnosis was solidified by kidney biopsy showing class IV lupus nephritis. This case highlights the challenging diagnosis of SLE myocarditis in patients presenting with peripartum acute heart failure without history of SLE. Clinicians are required to have a high index of suspicion for SLE in these patients to achieve diagnosis and treatment in a timely manner.

Don't Be Fooled by the Full House

Mingyue He. *Temple University Hospital, Philadelphia, PA.*

Introduction: Lupus nephritis (LN) is a common and serious systemic lupus erythematosus (SLE) complication. Some patients exhibit histological features of LN, characterized by the "full house" pattern on immunofluorescence (IF), despite the absence of other criteria for SLE. This rare entity is referred to as non-lupus full-house nephropathy (FHN). Herein, we present a rare case of non-lupus FHN in a kidney transplant recipient.

Case Description: A 37-year-old female with a history of type 1 diabetes and ESRD s/p simultaneous pancreas-kidney transplant in 2004, and recurrent ascites presented with abdominal pain and was found to have cardiac tamponade with pericardial fluid negative for infection and malignancy. Her creatinine levels had increased for months, from 1.9 to 3 mg/dl with 2.2 g proteinuria and bland urine sediment. She had a functioning pancreas. The initial ANA test was 1:160 positive but repeated ANA and dsDNA were negative. Renal graft biopsy revealed membranoproliferative glomerulonephritis (MPGN) with a "full-house" linear pattern on IF and 60% IFTA. Concerned about de novo LN, she was treated with pulse steroid. However, there was no clinical response, and she returned to dialysis. Electron microscopy (EM) results came back later, which did not reveal any immune-type deposits. After a multidisciplinary discussion with pathologists and rheumatologists, the positive IF was interpreted as a nonspecific accumulation of serum protein constituents due to chronic endothelial and membranoproliferative injury associated with transplant glomerulopathy rather than true immune complex (IC) deposition disease.

Discussion: This case presents a diagnostic challenge in distinguishing between de novo LN and non-lupus FHN secondary to transplant glomerulopathy. The combination of pericardial effusion, ascites, an initial ANA of 1:160, and a renal biopsy with full-house features could classify her as having SLE. However, this diagnosis relied heavily on the kidney biopsy interpretation. The development of lupus in a chronically immunosuppressed patient is unusual. Considering the absence of IC and the alternative diagnosis of transplant glomerulopathy, her presentation is not compatible with SLE and can be explained by other factors such as volume overload. This case underscores the importance of EM in diagnosing LN, highlighting that a full-house pattern does not necessarily indicate LN or immune complex deposition disease.

Nonlupus Full-House Nephropathy Presenting with Rapidly Progressive Glomerulonephritis, Hypertensive Emergency, and Heart Failure

Aakash Padodara, Shawn Alonso, Gabriel Contreras, Yelena Drexler.
University of Miami Health System, Miami, FL.

Introduction: Nonlupus full house nephropathy (NLFHN) is a rare and heterogenous clinical entity that is distinct from lupus nephritis. Here, we describe a case of NLFHN presenting with rapidly progressive glomerulonephritis and hypertensive emergency with new onset systolic heart failure.

Case Description: A 43-year-old male with a past medical history only of COVID-19 infection presented with several weeks of headaches, blurry vision, and leg swelling. He was found to have severely elevated blood pressure (224/138 mmHg), severe hypertensive retinopathy, and 3+ pitting lower extremity edema. Laboratories revealed serum creatinine 3.8 mg/dL, serum albumin 2.8 g/dL, hematuria (682 RBC/hpf), and proteinuria (UACR 7723 mg/g). Echocardiogram revealed moderately reduced left ventricular systolic function with ejection fraction 35-40%. Serologies were notable for low total complement and low-normal C3 complement levels, elevated rheumatoid factor, and negative ANA and dsDNA antibodies. Kidney biopsy revealed a light microscopy pattern of membranoproliferative glomerulonephritis with cellular crescents and a full house pattern on direct immunofluorescence with 3+ staining for IgG, 3+ IgM, 2+ IgA, 3+ C3, and 1+ C1q. Workup for secondary causes was negative including testing for HIV, syphilis, hepatitis B/C, anti-neutrophil cytoplasmic antibody, and cryoglobulin.

Discussion: NLFHN is an immune complex glomerulonephritis that can present with different light microscopy patterns accompanied by a typical full-house immunofluorescence pattern, without clinical or laboratory features of lupus. It can be categorized as secondary or idiopathic. Secondary causes include infections, autoimmune diseases, lymphoid neoplasms, or drugs. NLFHN typically has male predominance, higher proteinuria, and less complement consumption than lupus nephritis. Our case highlights that NLFHN can present with clinically challenging conditions including rapidly progressive glomerulonephritis, hypertensive emergency, and heart failure. While a preceding viral illness may have been causative, the patient is being followed for the potential development of an overt autoimmune condition with ANA and dsDNA every 6 months. He is doing well with a partial renal response and recovered left ventricular systolic dysfunction on mycophenolate and tapered prednisone.

SA-PO906

Hepatitis B-Related Cryoglobulinemia: A Case Report of Renal-Pulmonary Syndrome

Mahdi Beydoun, Emily A. Christie. *University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada.*

Introduction: The World Health Organization estimates that approximately 296 million individuals were chronically infected with hepatitis B in 2019, with an annual incidence of 1.5 million new infections. Hepatitis B infection can lead to severe hepatic complications, including cirrhosis, liver failure and hepatocellular carcinoma. Rarely, patients with hepatitis B infection will develop extrahepatic manifestations such as mixed cryoglobulinemia.

Case Description: 47-year-old man with untreated chronic hepatitis B (HBeAg negative) presented with hypoxia, pleuritic chest pain, hemoptysis, and pitting edema. He was noted to have a new normocytic anemia and a stage III AKI with proteinuria and hematuria on urine sediment. A CT pulmonary angiogram showed bilateral pleural effusion, pulmonary nodules and no evidence of embolism. Patient subsequently decompensated requiring intubation due to diffuse alveolar hemorrhage confirmed on bronchoscopy. His kidney biopsy was consistent with cryoglobulinemic glomerulonephritis and serum cryoglobulin testing was positive for mixed cryoglobulinemia. Patient was treated with intravenous pulse corticosteroids and started on entecavir. He responded well to the treatment and was successfully extubated. Following his course of intravenous corticosteroids, he was transitioned to high-dose oral prednisone once daily. His renal function returned to baseline and patient was discharged from hospital with outpatient follow-up.

Discussion: This highlighted a case of HBV-related cryoglobulinemia with renopulmonary syndrome. Cryoglobulinemia is rarely seen in patients with hepatitis B infection and does not commonly lead to diffuse alveolar hemorrhage. Current guidelines recommend treatment for hepatitis B infection if there is evidence of liver injury either through elevated ALT or liver biopsy. The guidelines favor treating chronic hepatitis B infection with evidence of extrahepatic manifestations, however there are no recommendations on how to effectively screen patients. Diffuse alveolar hemorrhage is a life-threatening complication, and physicians should consider a lower threshold to treat patients with chronic hepatitis B infection. Given the rarity of HBV-related cryoglobulinemia with renopulmonary syndrome, there are no definitive guidelines on management; existing literature suggest treating with antiviral and corticosteroids, which was effective in this case.

SA-PO907

Long-Read Single-Cell RNA Sequencing Reveals the Alternative Splicing Landscape across Mouse Kidney Epithelial Cells

Megan L. Noonan, Haojia Wu, Benjamin D. Humphreys.
Washington University in St Louis School of Medicine, St Louis, MO.

Background: There is surprisingly little known regarding alternative splicing (AS) in kidney health and disease, and to date no study has reported cell-specific AS patterns using long-read single-cell RNA-seq (scRNA-seq) in the kidney. Long-read sequencing more accurately identifies full-length gene isoforms to better determine AS that differentiates kidney cell types and can identify cell type-specific transcripts to refine kidney cell identities.

Methods: A 15-week-old C57BL/6J male mouse kidney was dissociated into single cells and barcoded using the 10X Genomics Single Cell 3' GEM kit (v3.1). The library was prepared using Oxford Nanopore Technologies (ONT) PCR-cDNA SQK-PCS111 kit and sequenced on a PromethION flow cell. QC and gene/transcript quantification was performed using ONT's EPI2ME Labs wf-single-cell workflow. Seurat was used for gene- and transcript-level PCA and clustering. DTUrtle was used to determine differential transcript usage (DTU) between cell types.

Results: Gene-level clustering identified known kidney cell types and was used to determine differentially expressed transcripts (DET) and DTU. Long-read scRNA-seq detected differential transcript usage (DTU) in all kidney cell types, with most DTU events observed between epithelial cells such as the proximal tubule (PT), thick ascending limb (TAL), and distal convoluted tubule (DCT). We compared all PT cells to all other cell types in the dataset and found isoform Miox-201 (myo-inositol oxygenase) as the most significant DET and expression was highly specific to PT cells compared to all other cell types, identifying a novel PT cell-specific isoform. DTU analysis between PT-S1 and TAL identified 37 genes and 76 transcripts with significant DTU. DTU genes between these two cell types were in pathways related to Na/K transport, cellular communication, and cell adhesion. The isoform Cldn10-201 (claudin-10) had a 76% increase in usage in PT-S1 versus TAL. This isoform switch results in preferring anions over cations, which corresponds to its function along the nephron.

Conclusions: We show for the first time the single-cell full-length isoform landscape of the murine kidney. Cell type-dependent DTU adds an additional layer of gene regulation, therefore, understanding the mechanisms of AS in the kidney could lead to new targets for future therapeutics to treat kidney diseases.

Adjudication of Kidney Biopsy Histopathology to Establish Consensus Diagnosis of Tubulointerstitial Nephritis

Sagar S. Sadarangani,[1] Melissa M. Shaw,[1] Gilbert W. Moeckel,[1] Deepika Kumar,[1] Michael B. Kuperman,[2] Avi Z. Rosenberg,[3] Randy L. Luciano,[1] Steven Menez,[3] Mark A. Perazella,[1] Francis P. Wilson,[1] Amrita Makhijani,[1] Kyra A. Shelton,[1] Chirag R. Parikh,[3] Dennis G. Moledina.[1] *[1]Yale University School of Medicine, New Haven, CT; [2]Cleveland Clinic, Cleveland, OH; [3]Johns Hopkins University, Baltimore, MD.*

Background: The absence of consensus histological criteria for tubulointerstitial nephritis (TIN) diagnosis leads to high variability and low inter-rater agreement in its reporting. Here, we establish consensus TIN diagnosis through an adjudicated process and test the association of interstitial histological features recorded on a standardized ordinal scale with TIN.

Methods: We selected biopsies from 147 participants enrolled in Yale's kidney biobank including all biopsies with clinically reported TIN (n=106) and a subset of controls (n=41). The adjudication process included two renal pathologists independently reviewing whole slide scans of kidney biopsies, reporting their diagnosis, and rating histological features using a standardized scale. Disagreements were resolved by joint slide review or, if consensus could not be achieved, by a third pathologist. We report inter-rater agreement and test association of reported histologic features with TIN diagnosis.

Results: After independent review, the pathologists reached agreement on 111 cases (agreement, 75%; κ, 0.50; P<0.001), which increased after joint slide review to 144 cases (agreement, 98%; κ, 0.96; P<0.001). Interstitial features associated with consensus TIN diagnosis included severity of infiltrate in preserved areas and tubulitis (**Table**). Among the 106 biopsies that were clinically reported as TIN, consensus diagnosis was TIN in 91 (86%) and 20 were reclassified as non-AIN. Among the 41 without TIN reported clinically, 38 (93%) were adjudicated as non-AIN, where 3 (7%) were reclassified as TIN.

Conclusions: We noted moderate agreement on TIN diagnosis that improved after joint review of slides, which can be used as a gold-standard for research into diagnostic biomarkers and dysregulated pathways in TIN. Our analysis also provides preliminary data on histopathological features associated with TIN that could support future work on establishing consensus criteria for TIN diagnosis.

Association between eGFRcystatin C-to-eGFRcreatinine Ratio and the Nonkidney Factors Muscle Mass, Muscle Strength, and Sarcopenia

Rona Dawar, Agne Laucyte-Cibulskiene, Anders Christensson, Linnea Malmgren, Kristina Åkesson. *Lunds Universitet, Malmö, Sweden.*

Background: Selective glomerular hypofiltration syndromes (SGHS), are linked to cardiovascular disease and mortality, and defined by a low eGFRcysC/eGFRcreat ratio. To correctly define SGHS, non-renal factors potentially affecting creatinine and cystatin C should be accounted for. The aim of our study was to investigate the association between muscle mass, muscle strength, sarcopeni and eGFRcysC/eGFRcreat ratio.

Methods: This study was based on 1044 females from the Osteoporosis Prospective Risk Assessment (OPRA) cohort, all aged 75 at inclusion with additional investigations after 5 (n=683) and 10 (n=355) years. Estimated glomerular filtration rate (eGFR) was based on creatinine and cystatin C using the CKD-EPI equation, and $eGFR_{cysC}/eGFR_{creat}$ ratio was determined. Muscle strength was measured as maximal knee extension and muscle mass measured by dual-energy x-ray absorptiometry (DXA). Sarcopenia was defined according to European Working Group on Sarcopenia in Older People (EWGSOP)2, defined as low muscle strength *plus* low muscle mass. Linear regression models examined the association between the dependent variable, low eGFR ratio, and the independent variables, muscle mass, muscle strength and sarcopenia. Analyses were adjusted for inflammation (CRP), smoking and glucocorticoid treatment. Results are presented as regression coefficients with 95 % confidence intervals (CI), p-value and partial explained variation (R^2).

Results: Sarcopenia was present in 32, 33 and 36 individuals at ages 75, 80 and 85 years respectively. At age 75, sarcopenia was significantly associated with the eGFR ratio (β_{adj}=-0,09, 95% CI = -0,2 to -0,02, p=0,012, R^2=4,9%) (Table). Similar results were observed at age 85, but not at 80. Muscle mass was associated with the eGFR ratio at

age 75 (β_{adj}=0,03, 95% CI = 0,01 to 0,05, p=0,008, R^2= 4,7%) and at age 80, but not at 85. Muscle strength showed a significant association across all ages, with the explained variation decreasing with age (9%, 7,8%, 4,1%).

Conclusions: While the eGFRcysC/eGFRcreat ratio was associated with non-renal factors such as muscle mass, muscle strength and sarcopenia, these parameters explained only a small portion of the variation in the ratio, suggesting limited clinical impact. Further investigations in older populations are warranted to confirm these findings.

SA-PO910

Quantification of Globotriaosylceramide (GL3) in Peritubular Capillary (PTC) Endothelial Cells (ECs) in Kidney Biopsies from Patients with Fabry Disease (FD) Using Machine Learning

David D. Smerkous,[1,2] Michael Mauer,[3] Alex Amedson,[1] Zian Wang,[1] Lexeigh A. Kolakowski,[1] Vanessa Delombaerde,[1] Frank Dastvan.[1]
[1]University of Washington, Seattle, WA; [2]Oregon State University, Corvallis, OR; [3]University of Minnesota Twin Cities, Minneapolis, MN.

Background: Intracellular GL3 accumulation is a hallmark of FD. Clearance of kidney PTC EC has been accepted by FDA as a valid clinical trial endpoint. Current light microscopy PTC EC GL3 inclusion quantitative methods are insensitive for partial clearance, time consuming, and subjective. We aimed to develop an automated electron microscopy (EM) approach for quantification of GL3 inclusions.

Methods: A pre-trained vision transformer (ViT) model was developed using masked auto-encoders (MAE) on ~190K EM images from human kidneys. ~200 EM images of PTC at 5000x from FD patients and controls biopsies were segmented for EC cytoplasm, GL3 inclusions and nuclei using a segmentation utility to serve as the ground truth. Segmentation models were trained on ground truth images using the ViT with minor modification and tested on validation segmentations.

Results: The train and test dices (shown respectively) for PTC EC segmentation were 0.82 ± 0.12 and 0.80 ± 0.07; for GL3 inclusions were 0.83 ± 0.30 and 0.84 ± 0.24; and for EC nuclei were 0.84 ± 0.26 and 0.87 ± 0.13. The intersection over union (IOU; 1=perfect; 0=none) of predicted and ground truth masks for GL3 inclusions, EC and nuclei ranged between 0.8 - 0.87 in test images. Fraction of EC occupied by GL3 [Vv(Inc/EC)] in the Fabry images studied was 0.097 ± 0.117 in manually segmented images and 0.107 ± 0.127 by model prediction. Vv(Inc/EC) in control (non-Fabry) biopsies was 0 by either manual segmentation or model prediction. The absoloue error of segmentation in test images was 0.03 ± 0.07.

Conclusions: Pre-training vision models using self-supervised methods is an effective way to develop performant and robust segmentation models, from large pools of unlabeled data. As exemplified by our GL3 quantification in PTC EC, these models can then be used with limited supervised training data. This approach provides a rapid, automated reproducible approach for GL3 quantification in PTC for clinical trial endpoints, research studies, or clinical purposes.

CKD of Unknown Etiology (CKDu): Histopathology of the Disease in Patients from Nicaragua

Alexei V. Mikhailov,[1] Michael H. Carstens,[1] Sreedhar A. Mandayam,[2] Biruh Workeneh,[2] Nelson B. Garcia Salazar.[3] *[1]Atrium Health Wake Forest Baptist Medical Center, Winston-Salem, NC; [2]The University of Texas MD Anderson Cancer Center, Houston, TX; [3]Mauricio Abdalah Hospital Departamental, Chinandega, Nicaragua.*

Background: Chronic kidney disease of uncertain origin (CKDu) is an endemic disease mainly affecting young male agricultural workers in tropical countries. CKDu displays an inexorable course with rapid deterioration of renal function. Since kidney biopsies are unavailable in endemic countries, our knowledge about the CKDu etiology is limited.

Methods: Patients with CKDu stages 3A-3B were identified by nephrologists in several Nicaraguan agricultural communities. All underwent clinical study, including ultrasonography. 2-3 cores were obtained for each patient via ultrasound-guided percutaneous renal biopsy. Light, electron microscopy, and immunofluorescence studies on pronase-treated paraffin-embedded material were performed.

Results: 21 patients were selected for this study, age 21 to 59 years (mean 41 y.o.), serum creatinine at biopsy 1.9±0.3 mg/dL, eGFR 40±9 mL/min/1.75m^2, resistance index 0.67±0.08, renal volume 131±51 cm^3. The major findings were global glomerulosclerosis affecting 30-88% of glomeruli in 80% of patients and glomerular capillary deflation. Perihilar FSGS was found in 1 biopsy. Tubules displayed fixation artifacts; chronic changes seen in 80% of patients were those of mild to rarely severe focal or diffuse interstitial fibrosis and tubular atrophy associated with mononuclear infiltration. 5 patient biopsies showed mild or moderate arteriosclerosis. Low-intensity segmental IgM deposition was noted in 50% of biopsies on the glomerular capillary walls or in the mesangium. Electron microscopy showed wrinkling of the glomerular capillary walls in 50% of biopsies. One biopsy showed thin glomerular basement membranes (GBMs), and another one- GBM remodeling; podocyte foot process effacement was segmental and rare. Toxic lysosomal inclusions were only rarely observed in the tubular epithelium by light and electron microscopy.

Conclusions: The most common pathological changes in Nicaraguan patients clinically diagnosed with CKDu were those of marked glomerulosclerosis and chronic tubulointerstitial lesions with associated inflammation. The concomitant pathology included arteriosclerosis, perihilar FSGS, and thin basement membrane disease. Our current research explores the treatment of CKDu with intraarterial injection of autologous stromal vascular fraction.

Targeting Alternative Splicing of Fibronectin (Fn) to Reduce Extra Domain A (EDA)+ Fn Production and Inhibit Kidney Fibrosis

Mysore K. Phanish,[1] Felicia Heidebrecht,[1] Pritpal S. Virdee,[1] Frank Rigo,[2] Mark E. Dockrell.[1] Research Team, SW Thames Institute for Renal Research.
[1]SW Thames Institute for Renal Research, Renal Unit, St helier Hospital, Epsom and St Helier University hospitals NHS Trust, St Georges' University of London, London, United Kingdom; [2]Ionis Pharmaceuticals Inc, Carlsbad, CA.

Background: EDA+ isoform of Fn is overexpressed in fibrosis. We investigate the effect of blocking 'splicing in' of EDA exon with antisense oligonucleotides (ASO) on EDA+Fn production and TGFβ1-induced fibrotic events in human primary proximal tubule cells (PTEC) and murine model of aristolochic acid (AA)-induced tubular injury.

Methods: PTEC were treated with TGFβ1 for 48 h, transfected with RNase H-independent ASO designed to block EDA exon inclusion (ASO5, selected after screening targeting 20 ASOs). EDA+Fn RNA and protein expression were analysed along with the expression of pro-fibrotic TGFβ target genes. In vivo, we assessed the expression of EDA+ Fn in murine AA model (IP inj of AA, 3.5mg/kg, D1 & 5; kidney lysate analysed by PCR for target genes on D0, D12, D20 & D100. We assessed the effect of ASO5 (50mg/kg) in mouse models: Short model (D-1 ASO5, neg control, NC or PBS S/C inj followed by a single dose of IP AA, cull D3) and long model (ASO5 or NC-ASO or PBS D-1, D3, x2/wk for 3 wks, weekly until cull D96, IP AA D1 and D5).

Results: ASO5 was effective and selective in reducing EDA+Fn RNA and protein in human PTEC (n=6, p<0.0001). TGFβ1 induced endogenous TGFβ, αSMA, MMP2, MMP9 and Col I mRNA and reduced K-Cadherin expression. These changes were attenuated by ASO5 (n=3-9, p <0.0001). Further increases in αSMA, MMP2, MMP9 (N 3-6, p<0.001) observed 48h after removal of TGFβ was inhibited by ASO5 (P<0.001). In vivo, compared to D0, there was a significant increase in EDA+/EDA- RNA ratio (30-fold, N=6, P<0.0001) on D12 which dropped to 2-fold on D100 (P<0.01). Similar pattern of induction was observed for CTGF, TGFβ1 and LTBP1 mRNA. The effect of ASO5 (50mg/kg) in mouse models: Short model (D-1 ASO5, neg control, NC or PBS S/C inj followed by a single dose of IP AA, cull D3) and long model (ASO5 or NC-ASO or PBS D-1, D3, x2/wk for 3 wks, weekly until cull on D96, IP AA D1 and D5). ASO5 treatment significantly reduced the mRNA levels of EDA+Fn, TGFβ1 (short and long models) and LTBP1 (long model P<0.05). Immunostaining for EDA+ Fn was attenuated in animals treated with ASO5.

Conclusions: EDA+ Fn plays a key role in TGFβ driven pro-fibrotic responses in renal tubule cells and blocking its production with ASO (in vitro and vivo) offers a potential therapy to limit the progression of renal fibrosis.

SA-PO913

m6A RNA Methylation Drives Kidney Fibrosis by Upregulating β-Catenin Signaling

Yinyi Long, Haiyan Fu, Youhua Liu. *Southern Medical University Nanfang Hospital, Guangzhou, China.*

Background: The N^6-methyladenosine (m^6A) methylation plays a crucial role in various biological processes and the pathogenesis of human diseases. However, its role and mechanism in kidney fibrosis remain elusive.

Methods: The level of m^6A methylation and the expression of METTL3 were assessed in mouse models and human kidney biopsies of chronic kidney disease (CKD). Conditional knockout mice with proximal tubule-specific deletion of METTL3 and mice with overexpression of METTL3 were used to corroborate a role of METTL3/β-catenin in kidney fibrosis.

Results: The overall level of m^6A methylated RNA was upregulated and the m^6A methyltransferase METTL3 was induced in kidney tubular epithelial cells in mouse

models and human kidney biopsies of chronic kidney disease (CKD). Proximal tubule-specific knockout of METTL3 in mice protected kidneys against developing fibrotic lesions after injury. Conversely, overexpression of METTL3 aggravated kidney fibrosis in vivo. Through bioinformatics analysis and experimental validation, we identified β-catenin mRNA as a major target of METTL3-mediated m^{6}A modification, which could be recognized by a specific m^{6}A reader, the insulin-like growth factor 2 mRNA binding protein 3 (IGF2BP3). METTL3 stabilized β-catenin mRNA, increased β-catenin protein and induced its downstream profibrotic genes, whereas either knockdown of IGF2BP3 or inhibiting β-catenin signaling abolished its effects.

Conclusions: These results indicate that METTL3 promotes kidney fibrosis by stimulating the m^{6}A modification of β-catenin mRNA, leading to its stabilization and its downstream profibrotic genes expression. Our findings suggest that targeting METTL3/IGF2BP3/β-catenin pathway may be a novel strategy for the treatment of fibrotic CKD.

A Novel Morphometric Approach to Estimate Interstitial Fibrosis from Trichrome-Stained, Whole-Slide Images

Ambarish Athavale,[1] Tushar Patel,[2] Hemant Kulkarni.[3] *[1]University of California San Diego, La Jolla, CA; [2]University of Illinois Chicago, Chicago, IL; [3]M&H Research LLC, San Antonio, TX.*

Background: Interstitial fibrosis (IF) is estimated by visual assessment which leads to significant interobserver variability. Using an image processing approach, we developed a novel algorithm (TRI_IF) to estimate IF from Trichrome whole slide images (WSI).

Methods: TRI_IF (developed in Python) masks out non-cortical area and estimates the proportion of blue stained area in the total cortical area (Figure 1A, 1B). 57 Trichrome WSI from the NEPTUNE study were used. Quality control excluded images with significant over/under staining and those beyond limits of agreement established by Bland-Altman plots. Cortex and glomeruli were manually annotated using QUPath. TRI_IF estimated IF was compared with NEPTUNE pathologists' consensus estimate (NP_IF). Categorization of IF was done using the Banff classification for NP_IF and latent class thresholds (using item response theory) for TRI_IF. Comparisons were made using Pearson's correlation for raw estimates, quadratically weighted Cohen's kappa for clinical classification of IF and association with two clinical endpoints: a) composite of ESRD or 40% reduction of eGFR and b) slope of eGFR decline per year.

Results: Of 57 Trichrome WSI, 16 were excluded after quality control and 41 were included in the analysis. Pearson's correlation between TRI_IF and NP_IF estimates was 0.69 (p<0.0001) and weighted Cohen's kappa for categorized IF was 0.65 (p<0.0001, Figure 1C). Compared with low-to-mild IF (<35% for TRI_IF), Moderate-to-high IF ≥35% for TRI_IF) was associated with a higher risk of the composite outcome (Figure 1D) and faster decline of eGFR (Figure 1D, inset).

Conclusions: A novel algorithm (TRI_IF) for automated estimation of IF on Trichrome WSI showed good agreement with pathologist's estimate of IF. Future studies need to validate this on a larger dataset.

Funding: NIDDK Support

Figure 1. Performance of TRI_IF. (A-B) Example biopsy core and generated IF mask (C) Agreement analysis (D) Association with progression to composite outcome (D, inset) Association with eGFR decline.

Indoxyl Sulfate as Potential Kidney Tubular Function Marker across Kidney Disease Models

Sabbir Ahmed,[1,2] Sebastiaan Knoppert,[2] Rachel V. Harwood,[3] João Faria,[1] Paul J. Besseling,[2] Rolf Sparidans,[1] Silvia M. Mihaila,[1] Patricia Murray,[3] Tri Q. Nguyen,[2] Karin G. Gerritsen,[2] Rosalinde Masereeuw.[1] *[1]Universiteit Utrecht, Utrecht, Netherlands; [2]Universitair Medisch Centrum Utrecht, Utrecht, Netherlands; [3]University of Liverpool, Liverpool, United Kingdom.*

Background: Kidney tubular damage is a strong predictor of end-stage kidney disease (ESKD) progression. Tubular function involves active secretion via transporters, such as organic anion transporters (OATs), to eliminate waste and metabolites, including protein bound uremic toxins (PBUTs). In tubular dysfunction, PBUT accumulation has been associated with many ESKD comorbidities. We hypothesized that PBUTs may be used as sensitive markers for tubular dysfunction.

Methods: We evaluated this in experimental models of chronic (rat nephrectomy and mouse IRI) and acute (mouse and *in vitro* IRI) kidney disease.

Results: In rats, PBUT parameters correlated with urinary tubular injury markers (kidney injury molecule-1 (Kim-1; p<0.001), neutrophil gelatinase-associated lipocalin (NGAL; p= 0.965 to <0.001), Beta-2-microglobuline (B2M; p<0.001) and cystatin C (p<0.001)). Moreover, indoxyl sulfate (IS) correlated better in a subgroup with the lowest tubular injury (p= 0.06 to <0.05) than filtration markers (GFR and plasma creatinine, cystatin C and urea (p= 0.54 to 0.07)). In chronic IRI mice, plasma IS and its clearance correlated with tubular atrophy scores, plasma NGAL and NGAL excretion (p<0.05 to <0.001), whereas filtration markers did not correlate. In acute IRI mice, IS and hippuric acid (HA) clearance correlated with plasma NGAL (p=0.058). Among all PBUTs, IS parameters showed the most consistent correlations with tubular injury markers across the animal models. Furthermore, proximal tubule transporters Oat1/3 expression was downregulated in mouse models and correlated with PBUT parameters. In agreement, OAT1-mediated transport of IS was decreased after inducing IRI *in vitro* using a human kidney proximal tubule cell line.

Conclusions: Our findings suggest that plasma IS and its clearance represent kidney transporters-related tubular function and may serve as sensitive clinical biomarkers for tubular dysfunction in kidney diseases.

Stenosis of Glomerulotubular Necks in a CKD Model

Eric P. Cohen,[1,2] Ann M. Farese,[3] George A. Parker,[4] Thomas J. Macvittie.[3] *[1]New York University Grossman School of Medicine, New York, NY; [2]VA NY Harbor Healthcare System Manhattan Campus, New York, NY; [3]University of Maryland School of Medicine, Baltimore, MD; [4]Charles River Laboratories International Inc, Durham, NC.*

Background: Fibrosis is a marker of injury and a predictor of future loss of renal function. Its intra-renal location may have more significance than its generalized presence. Histological studies of single time points show that fibrotic constriction of the glomerulotubular neck (GTN) may play a mechanistic role to impair nephron function (Cohen, *J Lab Clin Med* 129:567, Sato, *J Pathol* 197:14). We thus evaluated the time-course of the presence of GTN in a non-human primate (NHP) model of chronic kidney disease (CKD) and show that stenotic GTN increase over time in parallel with loss of renal function.

Methods: 38 NHP underwent 10 or 11 Gy partial-body irradiation (PBI) with tibial bone marrow sparing. Eleven NHP were non-irradiated (0 Gy). This model reliably causes progressive fibrotic CKD within months after irradiation (Cohen, *Radiat Res* 188:741). Kidneys were obtained at planned or for-cause euthanasia, whole kidney sections stained with Trichrome, then analyzed in a masked fashion using whole slide scanning. 40 or more glomeruli were identified in each section. Where seen, stenotic GTNs were defined as a narrowing at the beginning of the proximal tubule, while patent GTNs showed no narrowing at that site.

Results: 5%, 3%, and 4% of all glomeruli had visible necks in the 0, 10, and 11 Gy NHP, respectively. 15%, 21%, and 40% of visible necks were stenotic in the 0, 10, and 11 Gy NHP, respectively. The ratio of stenotic to normal necks was 0.2, 0.3, and 0.6 in the 0, 10, and 11 Gy NHP, respectively. The number of patent necks decreased over time after irradiation (figure). The % of visible necks that were stenotic increased progressively over time after irradiation. The serum creatinine increased in parallel to the increase in stenotic necks.

Conclusions: In conclusion, stenosis of the glomerulotubular neck is a definite feature of fibrotic chronic kidney disease. Further study is needed to identify the mechanisms whereby stenotic GTN form, and to identify markers of their presence in life.

Stenosis of the Glomerulotubular Neck Is Associated with Progressive CKD

Eric P. Cohen,[1,2] Aleksandar Denic,[3] Ian W. Gibson,[4] Fnu Aperna,[3] Andrew D. Rule.[3] *[1]New York University Grossman School of Medicine, New York, NY; [2]VA NY Harbor Healthcare System Manhattan Campus, New York, NY; [3]Mayo Clinic Minnesota, Rochester, MN; [4]University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada.*

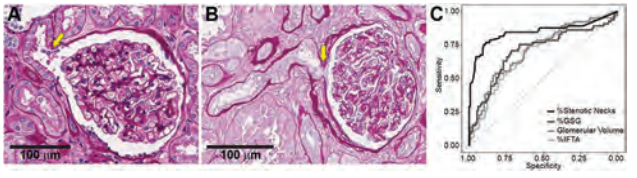
Background: Histopathologic evaluation can clarify the pathophysiology of chronic kidney disease (CKD). We tested whether the occurrence of glomerulotubular neck stenoses associates with progressive CKD.

Methods: We evaluated the non-cancerous parenchyma from radical nephrectomies for tumor between 2000 and 2021 and analyzed the cortex for stenoses of the glomerulotubular neck. Stenosis was defined as a focal narrowing at the neck for which the draining tubule had a greater diameter than at the neck (**Figure 1B**). Progressive CKD was defined as dialysis, kidney transplantation, sustained eGFR <10 ml/min per 1.73m^2 or sustained 40% decline from the post-nephrectomy eGFR during follow-up. Each case of progressive CKD was age-sex-matched to 2 controls without progressive CKD. Logistic regression models assessed the risk of progressive CKD with stenotic necks adjusting for other histological features, kidney function, and CKD risk factors.

Results: There were 65 cases with a mean of 255 glomeruli and 130 controls with a mean of 329 glomeruli. Among both cases and controls, 5% of glomeruli showed visible glomerulotubular necks. The proportion of necks that were stenotic was higher in cases than controls (35% vs. 11%, p<0.0001). Stenotic necks associated with progressive CKD independent of other histologic and clinical characteristics. ROC curves for histological morphometric measures showed that the proportion of stenotic necks was superior to glomerular volume, %GSG, and % IFTA as a classifier for predicting progressive CKD (**Figure 1C**).

Conclusions: Glomerulotubular neck stenosis predicts progressive CKD.

Funding: NIDDK Support, Veterans Affairs Support



Representative images of glomerulotubular necks that are **A**) normal (non-stenotic), and **B**) stenotic. **C**) ROC curves for histological pathology by morphometry as a classifier for subsequent progressive CKD among patients who underwent radical nephrectomy for tumor. The area under the curve (AUC) was 0.847 (95%CI: 0.776 to 0.917) for % stenotic glomerulotubular necks, 0.715 (95%CI: 0.638 to 0.793) for glomerular volume, 0.707 (95%CI: 0.623 to 0.790) for % globally sclerotic glomeruli (%GSG), and 0.695 (95%CI: 0.617 to 0.772) for % interstitial fibrosis and tubular atrophy (%IFTA).

Urinary Extracellular Vesicle Analysis Reveals Early Signs of Kidney Inflammation and Damage in Single-Ventricle Pediatric Patients after Fontan Operation

Cristina Grange, Diego Prudente, Benedetta Bussolati. *Universita degli Studi di Torino, Torino, Italy.*

Background: Extracellular vesicles present in urine (uEVs) are gaining considerable interest as biomarkers, to monitor and predict kidney physio-pathological state. Patients with single ventricle defects and hemodynamic stabilization by Fontan intervention may develop kidney dysfunction as one of the most prevalent extracardiac co-morbidity. Our study aimed to identify markers for monitoring and predicting kidney function in children with single ventricle heart defects who underwent Fontan surgery, as well to get physio-pathological insights on possible mechanisms of tissue damage and progression.

Methods: We isolated uEVs from urine of 60 paediatric patients affected by single ventricle defects, and from 10 healthy subjects. We analysed uEVs for the expression of the reno-protective hormone Klotho, using super- resolution microscopy of single EVs and ELISA. Moreover, we analysed the level of marker of kidney regeneration, such as CD133 and CD24, and of inflammation using a bead-based cytofluorimetric multiplex analysis. Marker expression was correlated with demographical, clinical and surgical data of patients.

Results: uEVs from children with single ventricle defects showed reduced levels of Klotho and CD133, compared with the one of healthy subject. In parallel, the levels of inflammatory markers (CD3, CD56, and HLA-DR) were significantly higher. Interestingly, levels of inflammatory markers correlated with age of patients and distance from surgery.

Conclusions: This study demonstrates that EVs isolated from the urine of single ventricle patients. present distinct expression of biomarkers of fibrosis, regeneration and inflammation in respect to those of healthy subjects, suggesting the presence of early signs of kidney damage.

Development and Validation of an Enzyme-Linked Immunosorbent Assay (ELISA)-Based Method for Quantitative Evaluation of Urinary Extracellular Vesicles as Biomarkers for CKD

Tatsuya Nishimura,[1] Yosuke Hirakawa,[2] Keiichi Takizawa,[1] Yuko Kajiho,[1] Shoichiro Kanda,[1] Yutaka Harita.[1] *[1]Department of Pediatrics, The University of Tokyo Hospital, Bunkyo-ku, Japan; [2]Division of Nephrology and Endocrinology, The University of Tokyo Hospital, Bunkyo-ku, Japan.*

Background: Urinary extracellular vesicles (uEVs) are emerging as promising biomarkers for various diseases. Our previous work highlighted the potential of MUC1 expression levels on uEVs as an indicator for chronic kidney disease (CKD) in children (iScience 2022). We have developed an ELISA-based method for the quantitative assessment of uEVs (STAR Protocols, 2023; ASN 2023). Despite the existence of several techniques for uEVs purification on ELISA plates, their optimization remains incomplete. Furthermore, storage and processing of urine samples suitable for uEVs-ELISA have not been established.

Methods: We generated monoclonal antibodies against MUC1 and evaluated their performance across two uEVs purification methods (Tim4 and CD9 antibodies) on ELISA plates. Selecting the optimal antibody and plate combination, we analyzed urine samples from 160 adult patients (83 males) with varying kidney functions. The median age was 50 years, and the median estimated glomerular filtration rate (eGFR), calculated using serum creatinine, was 57.6 ml/min/1.73m^2.

Results: Among the developed monoclonal antibodies, the most sensitive one, in conjunction with both Tim4 and CD9 antibodies for uEVs purification on ELISA plates, effectively captured variations in MUC1 levels in uEVs. The CD9 plate method more accurately mirrored clinical outcomes. The area under the curve (AUC) values from receiver operating characteristic (ROC) curve analysis for predicting the presence of eGFR <60 or <45, standardized with urine creatinine value, were 0.912 and 0.928, respectively. This predictive accuracy was consistent across gender-specific analyses. This method has been found to provide stable results when storing urine at 4°C for up to a week and over a long period when stored at -80°C.

Conclusions: Given the stability of urine for uEVs-ELISA analysis, this system offers a non-invasive approach, demonstrating significant potential as a clinical biomarker for adult CKD patients as well as children.

Progressive Changes in Urine Extracellular Vesicle Molecular Signatures Predict Phase of AKI

Monica S. Ng,[1,2] Sophie C. Chiang,[1,2] Xiangju Wang,[1,2] Helen G. Healy,[1,2] Andrew J. Kassianos.[1,2] *[1]Kidney Health Service, Royal Brisbane and Women's Hospital, Herston, QLD, Australia; [2]Conjoint Internal Medicine Laboratory, Chemical Pathology, Pathology Queensland, Herston, QLD, Australia.*

Background: Acute kidney injury (AKI) carries risks of severe complications including kidney failure and death. Urine extracellular vesicles (uEVs) released by cells in the urinary tract may have biomarker potential for assessing phase of AKI.

Methods: 50ml urine collected from people with evolving (n=3) and recovering (n=3) stage 3 AKI. Evolving AKI group had rise in serum creatinine and recovering AKI group had improving serum creatinine. uEVs were isolated using sequential centrifugation and size exclusion chromatography. uEVs were confirmed using electron microscopy and uEV related proteins were confirmed with mass spectrometry. uEVs were stained for cell source (podocyte: podocin; mesangial: CD90; endothelial: CD31; tubular: mucin-1; proximal

tubule: CD10, CD13) and inflammatory cytokine receptors (interleukin (IL)-1R1, IL-1R2, IL-6R, IL-2R). Stained uEVs were measured by multiparametric spectral flow cytometry. Counts were normalised to urine creatinine and compared using t-tests with correction for multiple comparisons.

Results: People with recovering AKI had increased uEVs compared to people with evolving AKI (mean: 7.89 x 10^6 uEVs/µmol creatinine vs 1.64 x 10^6 uEVs/µmol creatinine, p=0.048). Compared to people with evolving AKI, people with recovering AKI excreted more uEVs expressing CD90 (mean: 2,605 uEVs/µmol creatinine vs 407 uEVs/µmol creatinine, p=0.039), CD31 (mean: 8,833 uEVs/µmol creatinine vs 2,772 uEVs/µmol creatinine, p=0.012), mucin-1 (mean: 464,330 EVs/µmol creatinine vs 81,535 uEVs/µmol creatinine, p=0.015), IL-1R1 (mean: 8,481 uEVs/µmol creatinine vs 727 uEVs/µmol creatinine, p=0.030) and IL-2R (mean: 58,799 uEVs/µmol creatinine vs 1,671 uEVs/µmol creatinine, p=0.003) [Fig 1].

Conclusions: People with recovering AKI excrete more uEVs from mesangial, endothelial and tubular cells compared to people with evolving AKI. The inflammatory signatures of uEVs have biomarker potential for profiling AKI phase.

Funding: Government Support - Non-U.S.

Measured GFR Implemented in a US Clinical Practice: Comparing 4-Hour and 10-Hour Plasma Iohexol Clearance

Shane A. Bobart, Jacob Nielsen, Xin Yi, Angelina Edwards, Tariq Shafi.
Houston Methodist Hospital, Houston, TX.

Background: It is well recognized that estimated glomerular filtration rate (eGFR) can be highly inaccurate in assessing measured GFR (mGFR) for individual patients. mGFR using non-radiolabeled plasma iohexol clearance is straightforward and easily implementable in clinical practice, but it is not widely available in the US. In 2019, we implemented mGFR by a 4-hour plasma iohexol clearance as part of clinical care at Houston Methodist Hospital. The mGFR is orderable via an Epic order set. Recent studies (White CA; PMID: 32750458) and European Kidney Function Consortium (EKFC; under review) guidelines emphasize the importance of a long plasma clearance interval (10-hours) if the GFR is expected to be low (<30 mL/min/1.73 m^2). We have now updated our mGFR protocols to include both the standard (4-hour) and the long (10-hour) clearances. We present these case studies as an educational tool to enhance the understanding of mGFR and promote dissemination of mGFR protocols.

Methods: We describe 3 patients that had simultaneous measurement of creatinine, cystatin C, and mGFR by 10 hour plasma iohexol clearance. We compared the 4-hour and 10-hour mGFRs with eGFRs. We defined eGFR to be accurate in assessing the mGFR if the eGFR was within ±5 ml/min/1.73 m^2 of the 10-hour mGFR.

Results: See Table 1.

Conclusions: mGFR is the best available test of kidney function and it is not influenced by age, sex, or race. We have successfully implemented standard (4-hour) and long (10-hour) mGFR in routine practice at a busy clinical center in the US. Our cases provide important educational opportunities for nephrologists interested in learning and implementing mGFR in routine clinical care.

Table 1

Characteristic	Patient #1	Patient #2	Patient #3
mGFR indication	CKD in the setting of lung transplant	CKD in the setting of lung transplant	CKD at an old age
Age, years	64	68	83
Race/Ethnicity	W	W	W
CVD	No	Yes	No
Diabetes	Yes	Yes	No
Hypertension	Yes	Yes	Yes
Immunosuppression	Yes	Yes	No
Body surface area, m^2	1.81	1.85	1.84
BMI, kg/m^2	27	30	27
Urine ACR, mg/g	3	63	8
Serum Creatinine, mg/dL	1.92	1.46	1.05
Serum Cystatin C, mg/L	2.83	2.13	1.56
Iohexol GFR (10 hr) mL/min/1.73m^2	**30**	**43**	**41**
Iohexol GFR (4 hr) mL/min/1.73m^2	32	48	43
Overassessment by 4 hr mGFR	7%	11%	4%
CKD-EPI eGFR mL/min/1.73m^2			
Creatinine	**29**	52	52
Creatinine-cystatin C	22	37	**45**
Cystatin C	18	27	**36**
Teaching Points	eGFR creatinine is accurate. Cystatin C is not the "gold standard" for GFR assessment.	None of the eGFRs are accurate.	eGFR using cystatin C equations are accurate but discordant

SA-PO922

Theoretical Analysis of D-serine and D-asparagine as Biomarkers for Glomerular Filtration Rate

Tomonori Kimura,[1,2] Ryo Tanaka,[1] Yoko Higa,[1] Shigeaki Nakazawa,[1] Yoichi Kakuta,[1] Shinsuke Sakai,[1] Masayuki Mizui,[1] Shiro Takahara,[2] Norio Nonomura,[1] Yoshitaka Isaka.[1] *[1]Osaka Daigaku, Suita, Japan; [2]Kansai Medical Clinic for Renal Transplantation, Toyonaka, Japan.*

Background: As biomarkers that potentiate the precise measurement of glomerular filtration rate (GFR), two rare enantiomers of amino acids, D-serine and D-asparagine, are expected in use. This study aimed to analyze why the levels of these D-amino acids reflect GFR.

Methods: We utilized a cross-sectional observational study of 210 living kidney transplant donors and recipient, for whom GFR was measured using clearance of inulin. The levels of D-amino acids in blood and urine were measured using two-dimensional high performance liquid chromatography. The validity as GFR markers was assessed based on four criteria proposed previously: (i) free filtration at the glomeruli, (ii) constant clearance from plasma, (iii) no reabsorption at the tubules, (iv) no secretion at the tubules, (iv) endogenously present preferentially. We added two more criteria: (iv) endogenously present, preferentially, and (v) stable dynamics, regardless of GFR.

Results: D-Serine and D-asparagine are endogenously-present small molecules that are considered to pass through glomerular filtration barrier freely. Scatter plot analysis using clearance of inulin (C-in) as a reference showed that clearances of D-serine (C-dSer) and asparagine (C-dAsn) were well-correlated with C-in. These clearances are close to C-in with small proportional biases; the slope was 1.178 for C-dSer and 0.995 for C-dAsn, while the slope for C-cre was 0.674. Therefore, (i) D-serine and D-asparagine are subject to minor reabsorption and secretion in the tubules, or (ii) the reabsorption and secretion of these D-amino acids is balanced. Blant-Altman plot showed that the dissociations of C-dSer and C-dAsn from C-in were small and unaffected with the reduction of GFR.

Conclusions: D-Serine and D-asparagine are unaffected by tubular reabsorption and secretion after glomerular filtration. Additionally, tubular handling of D-serine and D-asparagine are unaffected by the reduced glomerular filtration. These features are the basis of D-serine and D-asparagine as biomarkers for GFR.

SA-PO923

Detection of Chronic Glomerular Nephritis in Nephrotic Patients Using D-amino Acids

Tomonori Kimura,[1] Shinsuke Sakai,[1] Yukimasa Iwata,[2] Hiroki Okushima,[1] Terumasa Hayashi,[3] Masayuki Mizui,[1] Yoshitaka Isaka.[1] *[1]Osaka Daigaku, Suita, Japan; [2]Sakai Shiritsu Sogo Iryo Center, Sakai, Japan; [3]Osaka Kyuseiki Sogo Iryo Center, Osaka, Japan.*

Background: Patients with chronic glomerular nephritis (CGN) is often complicated with diabetes, and it is often a diagnostic challenge to detect CGN in patients with diabetes. D-amino acids, rare enantiomers of amino acids, are kidney biomarkers that are useful to assess glomerular filtration rate and prognosis of kidney disease. Furthermore, combinational assessment of D-serine, one of D-amino acids, in blood and urine has the diagnostic potential to identify the origin of kidney diseases. We aimed to differentiate diabetic nephropathy from chronic glomerular nephritis in patients with higher level of urinary proteins by broadening the range of D-amino acid measurements.

Methods: Patients with biopsy-proven diabetic nephropathy, minimal change disease, and IgA nephropathy, and participants without kidney disease, were analyzed. The levels of four major D-amino acids in blood and urine were measured using two-dimensional

high-performance liquid chromatography. Multivariate analysis was performed to identify the ideal marker for the diagnosis of CGN from diabetic nephropathy (DN).

Results: A total of 566 patients were analyzed. Multivariate analysis identified that the parameters calculated from the combination of D-amino acids have the diagnostic value to differentiate CGN from DN. ROC curve analysis showed that area under the curve of 0.833 for the differentiation of CGN from DN in patients with the nephrotic range of urinary protein.

Conclusions: Combinational analysis of D-amino acids in blood and urinary excretion is useful in the differentiation of CGN from DN. Profiling of D-amino acids may help the diagnosis of origin of kidney disease in nephrotic patients.

SA-PO924

Development of a Novel Metabolite Filtration Marker Panel to Improve GFR Estimation

Jesse C. Seegmiller,[1] Seiei Shiba,[1] Nora F. Fino,[2] Tom Greene,[2] Benjamin Haaland,[2] Josef Coresh,[3] Ogechi M. Adingwupu,[4] Andrew S. Levey,[4] Lesley A. Inker.[4] CKD-EPI. *[1]University of Minnesota Medical School, Minneapolis, MN; [2]University of Utah Health, Salt Lake City, UT; [3]New York University Department of Medicine, New York, NY; [4]Tufts Medical Center, Boston, MA.*

Background: The GFR is estimated (eGFR) in clinical practice by analyzing endogenous filtration markers creatinine and/or cystatin C. However, current estimates of GFR are not sufficiently accurate across all populations and clinical settings. Using non-targeted metabolomic approaches, we previously identified 32 possible metabolite filtration markers yielding high correlation to measured GFR (mGFR). The goal of these analyses was to identify metabolites providing acceptable analytical properties to develop a targeted measurement procedure for subsequent clinical validation and translation.

Methods: A total of 32 metabolites were pursued based upon mGFR correlation and commercial availability. Analysis was performed in a single measurement procedure using liquid chromatography tandem mass spectrometry employing positive and negative ionization switching to capture this diverse set of metabolites and to allow for maximal quantitative multiplexing. Validation studies included linearity, recovery and imprecision determined from N=21 batches to determine analytical performance.

Results: Of the 32 metabolite filtration markers, 11 passed analytical validation studies (figure). All 11 metabolites displayed a % coefficient of variation (%CV) of < 6.4% over the entire analytical ranges investigated. The lower limit of quantitation (LLOQ) and upper limit of quantitation (ULOQ) were determined empirically and are displayed in figure along with results from the low, medium, and high-quality controls (QC) with imprecision given at each level.

Conclusions: The performance of the novel metabolite filtration marker panel displayed excellent reproducibility < 6.4% CV over the entire endogenous range in QC specimens. Assessing these metabolites may allow for more robust eGFR approaches in patients. Future steps include clinical validation and development of algorithm to estimate the GFR.

Cell Type-Specific Effects of Zinc on Human Kidney Cells in Culture

Zakeya A. Baalawy,[1,2] Zeynep Ulker,[1,4] Christer Hogstrand,[1] Mark E. Dockrell.[2,3] *[1]King's College London, London, United Kingdom; [2]SWT Institute for Renal Research, London, United Kingdom; [3]St George's University of London, London, United Kingdom; [4]Sabanci Universitesi, Istanbul, Turkey.*

Background: Zinc is a nutritionally essential trace element for all living organisms; it is required for development, growth, and tissue repair. However zinc excess is harmful and potentially lethal. High zinc has been shown to cause embryological damage in fish. In adult fish Zinc Chloride ($ZnCl_2$) caused reduction in antioxidant defence systems and neurotoxicity. In man approximately 15% of zinc is cleared through the kidney. Although CCN2/CTGF (Connective Tissue Growth Factor) is considered pathological particularly in fibrotic diseases, expression of CCN2/CTGF is crucial to embryonic development. CCN2/CTGF knockout mice have multiple skeletal dysmorphisms and raised perinatal lethality. In this work we examined the effect of sub-lethal zinc concentrations on human embryonic and adult renal cells with a focus on CCN2/CTGF expression.

Methods: Human Embryonic Kidney cells (HEK 293) and adult human primary proximal tubule epithelial cells (PTEC) were treated with a range of concentrations of $ZnCl_2$. Cell toxicity was measured using CellTox Green Cytotoxicity Assay. Cellular expression of Zinc transport channels (ZIP) was assessed by immunofluorescence microscopy.

Results: $ZnCl_2$ induced a dose and time dependent increase in HEK 293 cell cytotoxicity, which reached statistical significance at 300 µM at 24h. Primary human PTEC appeared more sensitive to $ZnCl_2$ with significant cytotoxicity at 100 µM at 24h. $ZnCl_2$ treatment (20 µM, 24h) significantly reduced CCN2/CTGF expression in HEK 293 cells but had no effect on human primary PTEC CCN2/CTGF expression. Both cell types expressed Zip10 (SLC39A10) zinc channels.

Conclusions: The inhibition of CCN2/CTGF expression in embryonic renal cells may indicate the potential for raised levels of Zinc to induce renal malformation in utero. Zip10 expression has previously been reported in the apical membrane of proximal tubule cells and provides a possible mechanism for zinc entry into the cells however a more comprehensive investigation of Zip protein expression is lacking. An important caveat in the interpretation of our results is that although HEK 293 cells are derived from human embryonic kidney and have an epithelial morphology, the original cells were not fully characterised. Furthermore the cell line is a result of adenovirus transformation.

Analysis of PD-L1 on Kidney Vascular Endothelial Cells

Yoichi Imai, Yoriaki Kaneko, Masato Kinoshita, Junya Suwa, Hiroko Hamatani, Hidekazu Ikeuchi, Keiju Hiromura. *Gunma University Graduate School of Medicine Department of Nephrology and Rheumatology, Maebashi, Japan.*

Background: Programmed death ligand 1 (PD-L1), expressed on various types of cells including vascular endothelia, inhibits T cell activity via PD-1. Anti- PD-L1/ PD-1 antibodies block this interaction and enhance T cell cytotoxicity, which has been utilized as cancer immunotherapy. However, Anti-PD-L1/PD-1 antibodies sometimes induce interstitial nephritis with unclear etiology. This study examines PD-L1 expression on kidney endothelial cells (ECs) and its effects on T cells in mice.

Methods: Female C57BL/6j mice were used. Kidney and lung cells were isolated by collagenase treatment and density gradient centrifugation, then analyzed by flow cytometry (FCM). Glomerular cells were separated using a mesh and collagenase treatment. Specific cell populations were separated using CD45 and CD31 microbeads. Mice received intraperitoneal injections of LPS, anti- PD-L1, or anti-CD3ε antibodies.

Results: FCM analysis in healthy mice showed PD-L1 expression in ECs ($CD31^+CD45.2^-$) of both kidneys and lungs, with higher expression in kidneys. These cells also expressed other EC markers like ICAM-1 and VEGFR2. Immunofluorescence staining (IF) revealed PD-L1 co-staining in CD31+ glomerular ECs, peritubular capillary ECs, and interlobular artery ECs. Glomerular ECs had lower PD-L1 expression compared to peritubular capillary and arterial ECs. Co-culturing renal ECs with splenic cytotoxic T cells ($CD8\alpha^+$) induced IFN-γ secretion, significantly increased by anti-PD-L1 antibody. LPS administration increased PD-L1 expression in ECs of both kidneys and lungs. IF showed enhanced PD-L1 in glomerular and peritubular capillary ECs in kidneys with LPS injection. Anti-CD3ε antibody, inducing high IFN-γ levels, also increased PD-L1 expression in renal ECs, as shown by FCM. Blocking PD-L1 on ECs with anti-PD-L1 antibody before anti-CD3ε treatment led to increased leukocyte infiltration into the renal interstitium and elevated blood urea nitrogen levels.

Conclusions: In healthy mice, PD-L1 is primarily expressed in peritubular capillaries of the kidney, and its expression increases during inflammation. PD-L1 on kidney ECs may inhibit T cell immune activation, suggesting a protective role for the kidneys.

SA-PO927

Microplastics and Bisphenol A Coexposure on Human Kidney Proximal Tubular Cells

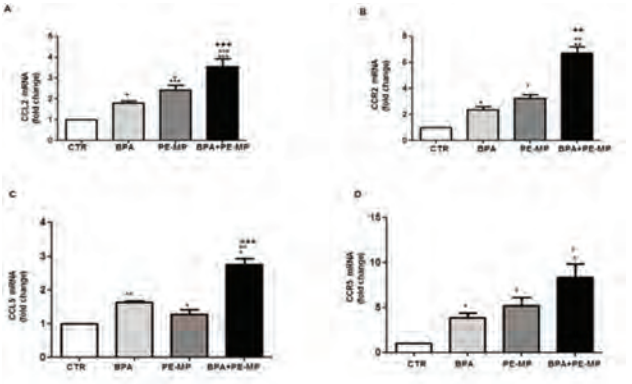
Luca Estienne,[1] Daniela Verzola,[3] Pasquale Esposito,[3] Francesca Viazzi,[3] Andrea Angeletti,[2] Paolo Cravedi,[4] Marco Quaglia,[1] Edoardo La Porta.[2] *[1]Azienda Ospedaliera Nazionale Santi Antonio e Biagio e Cesare Arrigo Alessandria, Alessandria, Italy; [2]Istituto Giannina Gaslini, Genova, Italy; [3]IRCCS Ospedale Policlinico San Martino, Genova, Italy; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Microplastics (MPs) accumulate in human tissues, including kidney. Beyond direct harmful actions, MPs can also adsorb a wide range of toxic substances, such as Bisphenol A (BPA) and so, enhancing their toxicity. MPs have been found in human blood, urine, and several human tissues, including lungs, placenta, blood, heart, and the kidney by Massardo et al. Moreover, it have recently demonstrated that patients with evidence of MPs in carotid artery plaque experience an increased risk of death and cardiovascular event compared with those without MPs.

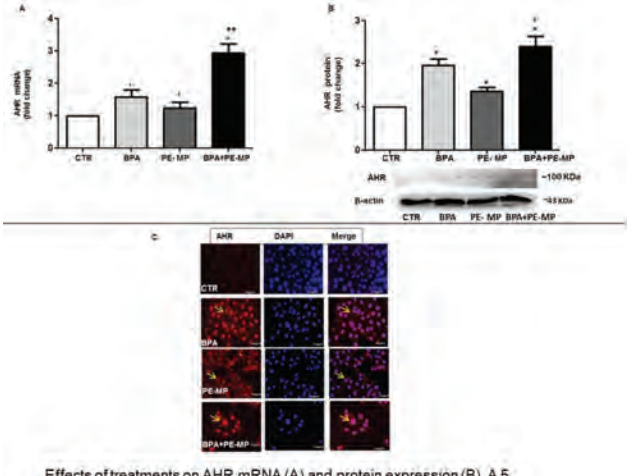
Methods: We exposed a proximal tubular cell line for 5-24 hours to polyethylene (PE)-MPs and BPA alone or combined. MP characterization was performed by by means of Dynamic Light Scattering analyses. We analyzed molecules involved in renal damage through mRNA Analysis, Immunofluorescence and immunocytochemistry and Western Blot Analysis

Results: Compared with the single exposure, the co-treatment was more powerful, reducing cell viability and boosting the pro-oxidant a pro-inflammatory response. Exposition to co-treatment induced a 3.5 and 2.7 fold increase of CCL-2 and -5 (both $p<0.05$ vs CTR). In addition, Heat Shock protein (HSP90), a chaperone involved in multiple cellular functions, was reduced, while Aryl hydrocarbon receptor (AHR) expression, a transcription factor which binds multiple environmental ligands, was increased.

Conclusions: Our study demonstrates that all the treatments influenced the cell behavior, but the co-exposure was more incisive. The combination of PE-MPs and BPA can negatively modify the cellular homeostasis, contributing to the induction of kidney damage.



Effects of treatments on inflammatory molecules. 5 hour exposition increased CCL2 (A), CCL5 (C) and their receptors CCR2 (B) and CCR5 (D), mRNAs were evaluated by rt-PCR. The results represent means ± SEM



Effects of treatments on AHR mRNA (A) and protein expression (B). A 5 hour exposition increased AHR levels. By immunofluorescence (C), AHR was observed in nuclei as pointed out by the yellow arrows. mRNA was evaluated by rt-PCR and protein by western blot. Blots were stripped and reprobed with antibody to β-actin. The results represent means ± SEM

SA-PO928

Kidney Localization of Cardiac Protein in Acute Cardiorenal Syndrome

Daiki Aomura,[1,2] Yoshio Funahashi,[1,2] Adam C. Munhall,[1,2] Tahnee Groat,[1,2] Michael Hutchens.[1,2] *[1]Oregon Health & Science University, Portland, OR; [2]Portland VA Medical Center, Portland, OR.*

Background: In a translational acute cardiorenal syndrome (CRS) model, mouse cardiac arrest and cardiopulmonary resuscitation (CA/CPR), heart-specific cardiac LIM protein (CSRP3) filters into the proximal tubule (PT), and mediates renal fibrosis. In the heart, CSRP3 undergoes stress-induced nuclear translocation and participates in fibrosis signaling. However, how endocrine CSRP3 acts in PT is unknown. Therefore, we characterized CSRP3 appearance in PT after CA/CPR using immunohistochemistry (IHC).

Methods: CA/CPR was performed on wild-type C57/B6J mice. CA was induced with potassium chloride; CPR, started after 8 minutes CA, included chest compressions and epinephrine. Mice were sacrificed on day (d) 1, 3, 7, or 49 after CA/CPR or sham (n=3/group). Kidneys were stained for CSRP3 with IHC. The volume of CSRP3 positivity with respect to kidney (V_{CSRP3}/V_{Kidney}, by Cavalieri method) was quantified using unbiased stereology on whole kidney sections to reduce IHC bias. Kidney compartments were independently segmented on 5 random high-power sections per mouse using machine learning (ilastik) to test localization of CSRP3. Segmentation was manually validated. Plasma CSRP3 was quantified by ELISA. Group differences were assessed with ANOVA and post-hoc tests.

Results: CSRP3 was heterogeneously stained at low level in sham. After CA/CPR (d1-7), CSRP3 was abundant in PT, concentrated at the apical brush border and in intratubular cell punctae. V_{CSRP3}/V_{Kidney} increased after CA/CPR (0.14±0.00 in sham vs 0.16±0.02 on d1 and 0.16±0.00 on d49, p=0.01). PT and nuclear segmentation was adequate (F=0.88). PT-associated CSRP3 increased after CA/CPR ($p<0.001$) and correlated with V_{CSRP3}/V_{Kidney} (r=0.58, p=0.02). Apical-basal distribution of CSRP3 within PT did not vary much with time, however, perinuclear CSRP3 localization within PT was persistently increased after CA/CPR (0.47±0.09 in sham and 0.58±0.10 on d49, $p<0.001$). Plasma of CSRP3 peaked on d1 and declined to baseline by d3 (sham 1.4±0.2, d1 20±4.2 p=0.003 vs sham, d3 3.7±4.0 p=0.9 vs sham, ng/mL).

Conclusions: CSRP3 is present at the renal brush border and in tubular punctae at baseline. PT CSRP3 increases after CA/CPR. Perinuclear distribution of CSRP3 increased immediately after CA/CPR, persisting for weeks. Therefore, CSRP3 is taken up by PT after CA/CPR in a manner suggesting intracellular trafficking.

SA-PO929

Upregulation of Tissue Factor Is Associated with Increased Levels of D-dimer and Decreased Levels of Thrombin Generation in ESKD

Hamzah Hussain,[1,2] Fakiha Siddiqui,[1,3] Debra Hoppensteadt,[1] Elyse Fairand,[1] Emma Abulencia,[1] Jawed Fareed,[1] Vinod K. Bansal.[1] *[1]Loyola University Medical Center, Chicago, IL; [2]Hurley Medical Center, Flint, MI; [3]Universidad Catolica San Antonio de Murcia, Murcia, Spain.*

Background: End-stage renal disease (ESRD) is often associated with vascular complications. Tissue factor (TF) plays a very important role in triggering the thrombogenesis and biomarkers associated with thrombin generation (TG) such as D-Dimer (DD). TF levels in chronic kidney disease are known to be upregulated, however such a study in ESRD patients is not reported. In this study, we sought to measure TF antigen and activity levels and their association with DD and TG potential.

Methods: 72 patients plasma with confirmed ESRD was collected in the Hemodialysis Clinic at Loyola University Medical Center (LUMC). 50 healthy plasma samples from a commercial source and 12 healthy plasma samples from LUMC served as control. Sandwich ELISA methods were used to measure TF antigen and DD levels and a chromogenic substrate method was used for TF activity. TG was quantified by using a fluorogenic method. Applicable statistical methods were performed and $p<0.05$ were considered significant.

Results: ESRD patients showed marked increase in TF and DD levels compared to the control. DD increased from 7.08 to 905.8ng/mL (128-fold, $p<0.05$) and TF concentration increased from 107.5 to 283.6pg/mL (2.6-fold, $p<0.05$). Peak thrombin levels reduced in the patient cohort from 138.4 to 109.9nM (-1.3-fold, $p<0.05$), while lag time increased from 1.7 to 2 minutes (1.2-fold, $p<0.05$). TF activity and ETP showed no significant difference. Table 1 represents the composite results in the patient cohort and controls.

Conclusions: These studies demonstrate that while TF activity is undetectable, TF antigen is quantifiable in ESRD patients. Simultaneously, the peak thrombin level decreased and DD levels increased. These results suggest that coagulation system is activated where thrombin is consumed leading to DD formation. Thus, TF upregulation plays a central role in the pathogenesis of ESRD and its measurement may be helpful in prognostic management.

Table 1

Biomarkers	Controls Median (IQR)	ESRD Median (IQR)	p-value
DD (ng/mL)	7.08 (7.08-44.3)	905.8 (616.5-1831.4)	<0.05
TF Immunologic (pg/mL)	107.5 (60.2-125.1)	283.6 (243.3-352.7)	<0.05
TF Activity (optical density)	0.08 (0.07-0.15)	0.09 (0.07-0.12)	0.66
Peak Thrombin (nM)	138.4 (126.6-155.6)	109.9 (58.1-142.5)	<0.05
Lag Time (min)	1.7 (1.7-2.0)	2.0 (1.6-2.3)	<0.05
Endogenous Thrombin Potential (nM*min)	583.7 (532.8-651.7)	592.0 (388.5-704.2)	0.46

SA-PO930

Novel High-Resolution Three-Dimensional Fluorescent Confocal Imaging Resolves Differences in Urinary Sediment

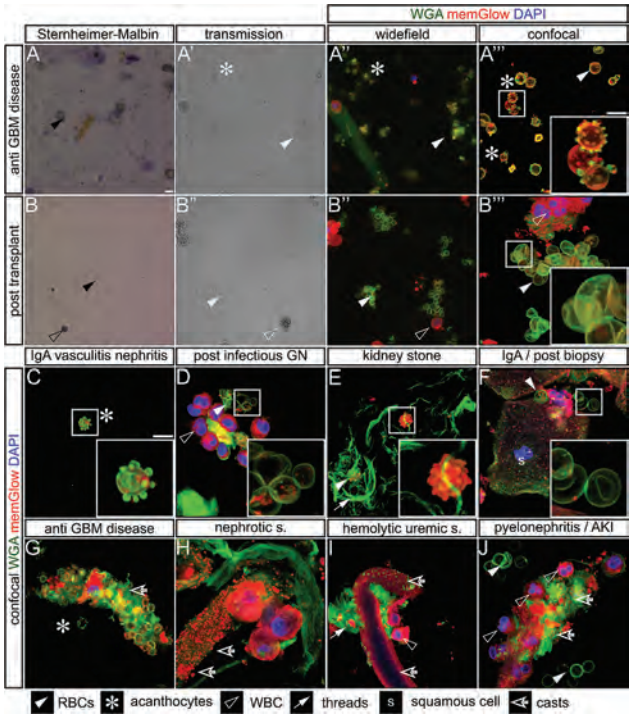
Sarah N. Lipp, Andrew L. Schwaderer. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Although microscopic urinalysis is used as a liquid biopsy to determine kidney disease etiology, it is limited by poor resolution, few stains, and sample instability.

Methods: Fixed urine sediment from pediatric patients with kidney disease was fluorescently stained with lectins, membrane markers, and nuclear stains and imaged using high-resolution confocal microscopy.

Results: Fluorescent stains followed by high-resolution 3D confocal imaging resolved urine sediment structures including of acanthocytes, red blood cells (RBC), white blood cells (WBC), mucus fibers, and casts in higher resolution than standard urine microscopic examination. Widefield fluorescent images (A″-B″) and 3D confocal (A‴-B‴) renderings of urine sediment stained for wheat germ agglutinin (WGA, green), memGlow (red), and DAPI (blue) resolved structure better than transmission (A″-B″) or Sterheimer-Malbin (A-B). Confocal images of urine sediment in disease showed (C) acanthocyte, (D) WBCs, (E) mucous threads, (F and J) eumorphic RBCs, (G) RBC cast, (H) lipid cast, (I) hyaline cast, and (J) WBC cast. GBM=glomerular basement membrane, GN=glomerulonephritis, s.=syndrome, AKI=acute kidney injury. A-B″: 60×, widefield, A″-B‴, C-J: confocal 63×, z=5 µm, inset 3× zoom. Scale bar=10 µm.

Conclusions: The improved resolution of confocal imaging will provide the foundation for quantification and comparison between disease type and response to therapy when affected patients are followed longitudinally. Enhanced analysis of the urine sediment offers a strategy to increase diagnostic insight beyond the standard microscopic evaluation that has been used relatively unchanged for decades.



SA-PO931

Changes in the Composition of Urine Using Urinalysis and Automated Microscopy over 6 Hours at Room Temperature

Pranav C. Parikh,[1] Serena D Souza,[2] Wassim Obeid.[2] *[1]Gilman School, Baltimore, MD; [2]Johns Hopkins University, Baltimore, MD.*

Background: Urinalysis (UA) is a commonly performed test for the diagnosis and prognosis of kidney disease in hospitalized patients. UA involves examining the chemical composition of the urine as well as microscopy to examine the cells and casts. In clinical settings, there is a frequent delay of several hours to perform UA after sample collection. The purpose of this study is to investigate the changes in urine composition over set time intervals in order to confirm the reliability of UA when there are delays in performing the tests.

Methods: We obtained 15 mL of urine from the Foley catheters of five ICU patients. We utilized the state-of-the-art IDEXX Sedivue machine to perform urine microscopy and the Siemens CLINTEK Status+ Urine Analyzer to perform the dipstick tests. We performed both microscopy and dipstick tests at 0, 1, 2, 4, and 6 hours. The samples were left at room temperature between measurements. We altogether tested 30 individual components in the urine. We calculated the %CV for each component by taking 4 repeated measurements at one time period for multiple samples.

Results: After calculating the %CV for each component, we analyzed the trend for each constituent over the 6-hour period. If the percent change over the six-hour interval was significantly more than the %CV, we determined time to have an influence on the results. Significant changes were seen in bacteria (BACc), as the levels increased, RBC and mucus (MUC) where the levels decreased, and crystals (CRY and CRYu) levels were determined inconclusive due to fluctuations in the results (*see figure*). All other components were found to remain unchanged.

Conclusions: The majority of the components were unchanged suggesting that UA results for these could be helpful even if the processing of the sample is delayed in clinical settings. The changes in the levels of bacteria and blood could lead to an incorrect clinical diagnosis. Additionally, changes in some components are highly variable and cannot be compensated for with certainty.

Continuous Antithrombin III Infusion in a Clinically Relevant Sepsis Model

Naoki Hayase, Rohit R. Chari, Yoshitaka Naito, Alef Aragao Carneiro dos Santos, Xuzhen Hu, Peter S. Yuen, Robert A. Star. *National Institutes of Health, Bethesda, MD.*

Background: Despite unacceptably high mortality and economic burden, effective therapeutic strategies for sepsis remain elusive. Discrepancies between drug responses in septic patients and animal models may be caused by differences in drug pharmacokinetics and timing of drug administration. Antithrombin III (AT) is an anticoagulant that might ameliorate sepsis-induced multiple organ dysfunction. Clinical trials using bolus AT infusions are conflicting. AT has a short half-life in mice, so we devised a method to continuously infuse drugs starting 6-12 h after cecal ligation and puncture (CLP) surgery (the time needed for clinical diagnosis of sepsis). We asked, "Is AT effective in our clinically relevant sepsis model?"

Methods: We catheterized mouse jugular veins, then connected catheters to osmotic minipumps containing saline. After 1-week stabilization, we performed CLP surgery and replaced each minipump with one containing AT or saline. We set a 6-12-h time delay between sepsis induction and treatment by incorporating a 4 cm saline-filled catheter in the circuit and validated the delay by using FITC-sinistrin. Infusion continued for 7 days. Survival studies were conducted. In separate experiments, we collected blood, kidney, liver, and lung at 48 h for biochemical, histological, and microbiological analyses. To examine effect of administration route, we also compared continuous AT infusion with a conventional bolus AT injection.

Results: First, continuous AT infusion significantly improved 7-day survival compared to saline-infusion (65% vs. 29%, $p = 0.018$). Additionally, continuous AT infusion markedly increased survival vs. a single injection of AT (65% vs. 19%, $p = 0.003$). Continuous AT attenuated liver injury but not renal and lung injury. Furthermore, vascular leakage and inflammatory cytokine were suppressed only in the liver. Focusing on liver in CLP sepsis, we detected the highest accumulation of bacteria and thrombin production, the target of AT, in the liver at 48 h after CLP.

Conclusions: In summary, continuous AT infusion improved 7-day survival after abdominal sepsis. Continuous AT infusion attenuated vascular leakage, inflammation, and organ injury in the liver in late phase of CLP sepsis. Liver may be a critical site of intervention because bacteria accumulate there and induce thrombin generation.

SA-PO933

Urine Protein to Albumin Gap without Monoclonal Gammopathy

Matthias Bergmann, George J. Kavalam, Rucci Marcus C. Foo, Solab Chitrakar, Nathan H. Raines. *Beth Israel Deaconess Medical Center, Boston, MA.*

Introduction: The urine protein-to-albumin gap (UPAG) describes the difference between total urine protein excretion and urine albumin excretion. The UPAG is usually considered significant when less than 50% of the urine protein consists of albumin. If the UPAG is elevated, this may raise suspicion for monoclonal gammopathies such as multiple myeloma where increased immunoglobulin or light chain excretion in the urine results in proteinuria that is composed of a relatively smaller proportion of albumin. We present the case of a 61-year-old man with elevated UPAG without evidence of monoclonal gammopathies.

Case Description: A 61-year-old man with a past medical history of type 2 diabetes mellitus was admitted with endocarditis in the setting of *Staphylococcus aureus* bacteremia from cellulitis complicated by septic shock and multiple septic emboli involving the brain. He developed acute kidney injury (AKI) and required temporary hemodialysis. His renal function improved and creatinine normalized to 0.8 mg/dL. Urinalysis during the AKI was positive for blood and protein. After resolution of the AKI, hematuria resolved but proteinuria persisted. Urine protein quantification showed a UPCR of 3.2 g/g and a UACR of 533 mg/g, resulting in a UPAG of 2.5 g with albumin only accounting for 16.7% of the proteinuria. The results were confirmed with repeat testing. Urine protein electrophoresis (UPEP) showed multiple protein bands with albumin predominating but no monoclonal immunoglobulins identified. Serum fibrinogen was 565 mg/dL and CRP 122 mg/L. Total serum protein was 6.8 g/dL with hypoalbuminemia of 2.2 g/dL. Serum protein electrophoresis showed polyclonal hypergammaglobulinemia with elevated IgG 2332 mg/dL and IgA 677 mg/dL, decreased IgM 38 mg/dL, and no monoclonal immunoglobulins identified.

Discussion: A 61-year-old man who was admitted with endocarditis was incidentally found to have a UPAG without monoclonal pattern on UPEP. CRP, fibrinogen, and polyclonal IgG and IgA were elevated in the setting of endocarditis. The UPAG is best explained by inflammatory proteins released in the setting of the systemic infection. While a UPAG is commonly considered to be an indicator of monoclonal gammopathies, this case illustrates that inflammatory proteins may reach quantities that can lead to a significant UPAG when excreted in the urine.

Confounded Magnetic Resonance Imaging Contrast Agent Exposures and Gadolinium Retention in Organs

Karol Dokladny,[1,2] Joshua Deaguero,[1,2] Abdul Mehdi S. Ali,[3] Ian Henderson,[2] James H. Degnan,[3] G. P. Escobar,[1,2] Brent Wagner.[1,2] *[1]University of New Mexico Health Sciences Center, Albuquerque, NM; [2]Kidney Institute of New Mexico, Albuquerque, NM; [3]University of New Mexico, Albuquerque, NM.*

Background: In 2006, gadolinium-based contrast agents (GBCAs) were linked to nephrogenic systemic fibrosis, a rare but highly disabling and often fatal condition. GBCAs can also induce kidney injury and fatal encephalopathy. The US Food and Drug Administration ordered a black box warning for all gadolinium-based contrast agents. There are two general classes of GBCAs: linear (e.g., Omniscan) and macrocyclic (Dotarem). Our previous research indicated that prior GBCA exposures influence gadolinium retention in the kidney or liver. The present study aimed to test whether a similar paradigm holds for other vital organs.

Methods: 18 male mice were randomized to five experimental groups: (1) saline-treated controls; gadolinium-based contrast agent-treated (2) Omniscan (OMN), (3) Dotarem (DOT), or in combination (4) OMN (1 week) followed by DOT administration for 3 weeks or (5) DOT (1 week) followed by OMN treatment for 3 weeks. Per our established protocols, saline or contrast agents were administered via intraperitoneal injections 5 days a week for 4 weeks. Lung, heart, adipose tissue, and skeletal muscle tissue were excised and snap-frozen in liquid nitrogen. On average, 15 mg of tissue were digested in nitric acid, and gadolinium concentrations were quantified using PerkinElmer NexION 5000 inductively coupled plasma mass spectrometry (ICP/MS) with a detection limit of 0.01 ppb.

Results: A 4-week treatment of OMN or DOT alone or in combination (OMN-DOT or DOT-OMN) resulted in a significant accumulation of gadolinium in the lung and heart. Gadolinium deposition was equal for Omniscan, OMN-DOT, and DOT-OMN. No differences existed among any group for Zn or P, regardless of the organ.

Conclusions: Gadolinium is retained in the heart and lung for linear, macrocyclic, and confounded agent exposure. Adipose retains macrocyclic agents. Skeletal muscle retains linear agents. Our study is underpowered with respect to the other experimental groups for adipose and skeletal muscle. Future studies are required to determine those tissue-specific differences.

SA-PO935

Interaction of Gadolinium-Based Contrast Agents with Endogenous Compounds: Effect on Stability

Ian Henderson,[1] Karol Dokladny,[2,1] G. P. Escobar,[2,1] Joshua Deaguero,[2,1] Brent Wagner.[2,1] *[1]Kidney Institute of New Mexico, Albuquerque, NM; [2]University of New Mexico Health Sciences Center, Albuquerque, NM.*

Background: Gadolinium-based contrast agents (GBCAs) are widely used in contrast-enhanced magnetic resonance imaging (MRI), improving tissue discrimination by increasing proton relaxation. GBCA complications can be catastrophic, including nephrogenic systemic fibrosis (NSF) and gadolinium encephalopathy. The stability of the metal-ligand bond correlates with gadolinium retention *in vivo*, with stabilities generally expressed in terms of equilibrium constants and kinetic stability. Equilibrium constants do not account for a physiologic milieu and endogenous compounds. We investigated two endogenous compound-mediated mechanisms of GBCA decomposition *in vivo*: associative ligand exchange (direct attack) by oxalic acid (OA) and decomposition through protein-ligand interaction.

Methods: GBCAs reacting with OA were followed spectrophotometrically at 605 nm. We measured precipitation rates. We characterized the products using elemental analysis, thermogravimetric analysis (TGA), and X-ray photoelectron spectroscopy (XPS). Contrast agents were incubated with bovine serum albumin (BSA) for 4 days. We analyzed the nanoparticulate product using transmission electron microscopy and X-ray energy-dispersive spectroscopy.

Results: Linear agents (gadodiamide and gadobenate dimeglumine) reacted with OA, forming gadolinium oxlate. Macrocyclic GBCAs (gadoteridol, gadoteric acid, and gadopiclenol) underwent two-step ligand exchange upon exposure to OA with a wide range of rates, ranging from k ~ 10-2 (gadoteridol) to <<10-6 (gadopiclenol). The presence of BSA (4%) resulted in an increased rate. Incubation of GBCAs with BSA over 4 days formed nanoparticles with a similar morphology to those found in pathologic gadolinium retention.

Conclusions: Oxalic acid, a biologically endogenous compound, can directly attack GBCAs, with linear contrast agents being particularly vulnerable. Protein enhances the rate of gadolinium oxalate formation. Simple protein/ligand interactions destabilize GBCAs. We can detect gadolinium-rich nanoparticles in vitro.

SA-PO936

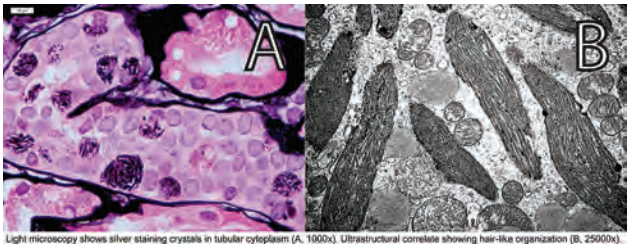
Impaired Kidney Function with Renal Tubular Vacuolization and Paracrystals in Adult Refsum Disease: A Case Report

Chen Yu (Jamie) Lee,[1] Mark Elliott,[3] Anna Lehman,[4] Susanna A. Mcrae,[1,2] Maziar Riazy.[1,2] *[1]Department of Pathology, University of British Columbia, Vancouver, BC, Canada; [2]Department of Pathology, St. Paul's Hospital, Vancouver, BC, Canada; [3]Division of Nephrology, University of British Columbia, Vancouver, BC, Canada; [4]Department of Medical Genetics, University of British Columbia, Vancouver, BC, Canada.*

Introduction: Classic, or adult, Refsum disease (ARD) is a rare peroxisomal disorder characterized by an inability to metabolize the fatty acid phytanic acid (PA). Accumulation of PA leads to polyneuropathy and potentially lethal cardiac arrhythmias. Renal impairment is rarely seen and there is a paucity of information on the histopathology. We present a case of renal impairment due to tubular involvement by ARD.

Case Description: A 55-year-old Fijian female with genetically proven ARD presented with a reduced eGFR without proteinuria or overt tubular dysfunction. Her past medical history includes ARD-related retinitis pigmentosa, DM2, recent MI with PCI, and chronic knee osteoarthritis. Physical examination showed shortened toes consistent with ARD. Serum PA at diagnosis was 180 mcg/mL (ULN 3 mcg/mL). A renal biopsy was performed to assess for diabetic nephropathy versus another cause for her renal impairment. The biopsy showed diffuse vacuolization of renal tubular epithelium, with rare foci of intracytoplasmic crystals (Figure 1A). Ultrastructurally, these crystals were electron dense with unusual parallel linear arrays (or 'paracrystalline formation') (Figure 1B). She continues to be very adherent to her low PA diet and avoidance of fasting, but despite this has experienced a progressive decline in her eGFR. Her PA level remains elevated at 270 mcg/mL.

Discussion: To the best of our knowledge, this is the first description of intracytoplasmic crystals on light microscopy in ARD. The etiology and pathologic effects of these crystals are not yet known, but they may share features with other crystalline nephropathies. This case provides evidence to support renal function monitoring in ARD, which is currently not suggested by the literature. The morphology of the intracytoplasmic crystals are rather distinct but subtle and can be overlooked. Nephropathologists should be vigilant for additional findings in the setting of tubular epithelial abnormalities without a known explanation. Limiting dietary PA is the first-line treatment of choice but may not be sufficient to prevent complications.



Light microscopy shows silver staining crystals in tubular cytoplasm (A, 1000x). Ultrastructural correlate showing hair-like organization (B, 25000x).

SA-PO937

Pregnancy-Related Complications and Snake Bites Are Leading Causes of Renal Cortical Necrosis in India

Anila A. Kurien,[1] Jansi Prema K.S,[1] Malathi Cv,[1] Tiffany Caza.[2] *[1]Renopath Center for Renal and Urological Pathology Pvt Ltd, Chennai, India; [2]Arkana Laboratories, Little Rock, AR.*

Background: Renal cortical necrosis is present in 1-3% cases of severe acute kidney injury and <1% of kidney biopsies. Due to its relative rarity, potential etiologies are incompletely understood and studies are limited to small series. Here, we present the largest kidney biopsy series of renal cortical necrosis from a study of 227 patients who underwent native kidney biopsy in India.

Methods: Patients who underwent native kidney biopsy from 2013-2023 with a diagnosis of cortical necrosis were identified from the renal pathology archives at the Renopath Center for Renal and Urological Pathology in Chennai, India. Demographics, clinical data, and histopathology were reviewed.

Results: A total of 227 patients with renal cortical necrosis were identified. The mean patient age was 32.2 ± 14.2 years. There was female predominance (75.3%). Of the 227 cases, 150 had concurrent thrombotic microangiopathy (TMA, 66.1%), one had membranous glomerulopathy (0.4%), and one biopsy had a concurrent abscess (0.4%). A known etiology for cortical necrosis was identified in 170 cases (74.9%). For those with known etiology, 95 were due to pregnancy-related complications (55.9%), 32 from snake bites (19.8%), 13 from acute pancreatitis (7.6%), 8 from sepsis (4.7%), 5 from NSAID-associated papillary necrosis (2.9%), 5 from ingestion of other substances (2.9%), 4 from other animal and insect bites (2.4%), 3 due to non-pregnancy-related post-op complications (1.8%), 2 due to obstruction (1.2%), 2 due to connective tissue disorders (scleroderma and lupus, 1.2%), and one from venous thrombosis. A similar distribution of diagnoses was seen in patients with and without concurrent TMA, with pregnancy-related complications comprising the majority of cases.

Conclusions: Pregnancy-related complications and snake bites were the leading etiologies of renal cortical necrosis from a large kidney biopsy series in India. The majority of cases demonstrated concurrent thrombotic microangiopathy.

SA-PO938

Epidemiology of Biopsy-Confirmed Kidney Disease: A Single-Practice Study in South Texas

Klarissa A. Saldivar, Umar Khan, Julio P. Zavala Georffino. *University of the Incarnate Word, San Antonio, TX.*

Background: Prevalence of biopsy-proven kidney disease in the United States (US) is fairly limited, especially in Hispanic populations who experience a large burden of kidney disease. This study is aimed to determine the patterns and epidemiological features of kidney disease in a predominantly hispanic population of South Texas.

Methods: Using data from a single nephrology practice in Laredo, TX, we identified patients who underwent kidney biopsies from April 2014 to April 2024. Retrospective analysis was done to obtain demographics, histopathologic diagnosis, and clinical/laboratory data. Results were stratified by age, gender, race/ethnicity, and comorbidities to identify epidemiologic patterns.

Results: Of 260 patients, transplant biopsies and those with insufficient data were excluded, leaving 240 patients for analysis. The median age was 50 years, with 57% female patients. Racial/ethnic demographics included 97% Hispanic patients. Secondary Glomerular Diseases (SGD) were most common with prevalence of 50%, followed by Primary Glomerular Diseases (PGD) (38%) and Tubulointerstitial Diseases (TID) (12%). Diabetic kidney disease (DKD) (*n*=94, 39%) and lupus nephritis (LN) (*n*=17, 7%) were the most common SGD, whereas IgA nephropathy (IgAN) (*n*=17, 7%), AA amyloidosis (*n*=13, 5), membranous nephropathy (MN) (*n*=11, 5%), and focal segmental glomerulosclerosis (FSGS) (*n*=11, 5%) were the most common PGD. The most common TID was acute tubular necrosis (ATN) (*n*=20, 8%). Of patients with FSGS, MCD, and LN ≥ 70% were female. Of patients with amyloidosis, FSGS, Thrombotic microangiopathy (TMA), and LN > 85% were ≤ 50 years of age.

Conclusions: Our study describes the prevalence of biopsy-proven kidney diseases in a Hispanic population. This provides a foundation to better understand patterns for kidney disease in a population underrepresented in literature, and contributes to the current lack of kidney biopsy data in the US.

	Total N(%)	Female N(%)	Median Age (y)	Avg Serum Cr mg/dL
PGD	**90 (38)**	**51 (57)**	**46**	**4.0**
IgAN	17 (7)	10 (59)	48	2.9
AA Amyloidosis	13 (5)	6 (46)	36	3.1

SA-PO939

Comparative Efficacy and Safety of Kidney Biopsies Performed by Nephrologists vs. Interventional Radiologists: A Study in Two Level III Hospitals in Lima, Peru

Hemily Z. Chimoy,[1] Juan O. Lluncor.[2] *[1]Hospital Nacional Alberto Sabogal Sologuren, Callao, Peru; [2]Hospital Nacional Dos de Mayo, Lima, Peru.*

Background: Renal biopsy is an invasive procedure. Formerly, this procedure was exclusive to nephrologists, but currently it is also performed by interventional radiologists. An adequate sample is crucial for the diagnosis, prognosis and treatment of the renal disease. Also, it is important to avoid associated complications.

Methods: All renal biopsies was performed from January to December 2023 in two level III hospitals in Lima, Peru. In the first hospital, renal biopsies were performed exclusively by interventional radiologists without the involvement of nephrologists, while in the second hospital, they were performed by nephrologists (real-time ultrasound guidance or marking point). Quality of the sample was evaluated according to the number of glomeruli reported in the analysis. Pre-biopsy laboratory variables, post-biopsy hemoglobin control, post-renal biopsy events and/or complications were compared as safety variables of the procedure.

Results: A total of 93 renal biopsies were reported during this period (47 renal biopsies performed by interventional radiologists and 46 by nephrologists). The efficacy of the procedure was evaluated by the quality of the sample. The mean number of glomeruli in the first group was 22, and in the second group, it was 18, with no significant difference found between the two groups ($p = 0.343$). No relationship was found between the number of reported glomeruli and any variables such as age, urea, creatinine, pre-procedure hemoglobin, longitudinal diameter, and kidney parenchyma, except for the anteroposterior diameter of the kidney ($p = 0.03$). In terms of safety, a significant difference was found for the presence of post-procedure pain ($p < 0.01$) and renal hematoma ($p = 0.048$) in the group of renal biopsies performed by interventional radiologists. There was also no significant difference in the variation of pre- and post-procedure hemoglobin levels in both groups.

Conclusions: This study demonstrated that the nephrologist-performed biopsies are equally effective and often safer than those performed by radiologists. Considering that the nephrologist is the one who has the initial contact with the patient and provides follow-up for the underlying condition throughout the treatment, it is important not to lose procedural skills for the benefit of our patients.

Low Prevalence of Class 1 Indications for Coronary Revascularization in Patients Undergoing Prekidney Transplant Screening for Coronary Disease

Avantika Israni, Bronya L. Sandorffy, Celina S. Liu, Daniela I. Fraticelli Ortiz, Haley Gross, Joey Nicholson, Miri Cazes, Qandeel H. Soomro, David M. Charytan. *New York University, New York, NY.*

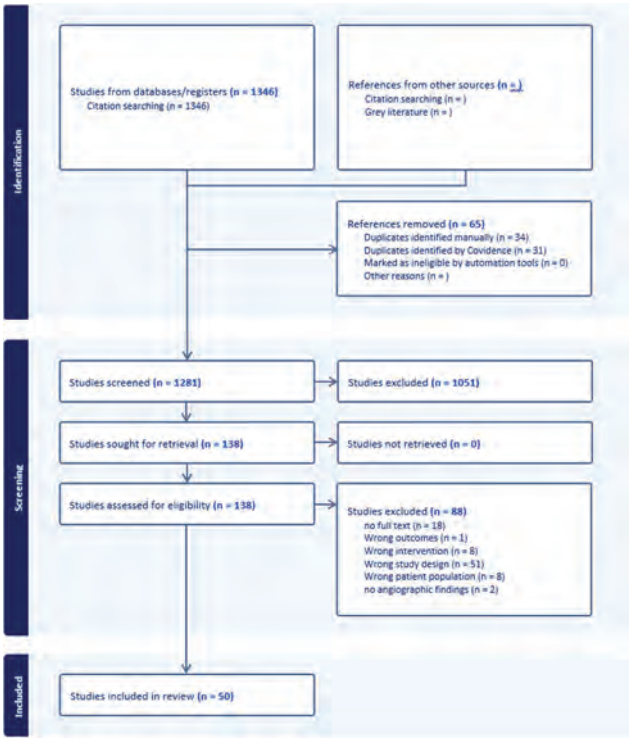
Background: CVD is the most common cause of morbidity and mortality in kidney transplant recipients. Screening for coronary disease is to reduce the risk of perioperative cardiovascular complications, long term cardiovascular morbidity and mortality is frequently required but coronary intervention has not been shown to be beneficial except in complex coronary disease. The likelihood of finding significant coronary artery disease and benefit of routine pre-transplant screening is uncertain.

Methods: We performed a systematic review and meta-analysis to quantify the frequency of detecting significant coronary lesions for which--there are AHA Class 1 indications for revascularization: a) >50% left main stenosis; or b) multi-vessel disease

with EF < 35%. Medline & Embase were searched to identify manuscripts reporting the results of pre-transplant screening published between 1998 and 2024. Screening and data collection was performed by 4 independent authors with disagreements resolved by consensus. Quality assessment was performed using the Joanna Briggs Institute scale. This review was registered with PROSPERO.

Results: We identified 1281 studies, 148 required full text review out of which 50 met eligibility criteria. We extracted data from 50 studies, 17 studies did not report ejection fraction. The mean prevalence of a class 1 indication across these studies was 5.35 %. Analysis of the number of patients with left main disease, triple vessel disease (without an EF < 35%) will be updated.

Conclusions: Identification of class I indications for revascularization during pre-transplant coronary screening is rare and routine screening may not be warranted.



SA-PO941

Accuracy of Myocardial Perfusion Imaging (MPI) in Predicting Post-transplant Cardiovascular Events among Asymptomatic Diabetic Kidney Transplant Candidates

Bilal Mohsin, Yasir Alfi, Shahad Alaydarous, Naief M. Alhowaiti, Nasser O. Odah, Wael T. Habhab. *King Faisal Specialist Hospital and Research Centre - Jeddah, Jeddah, Saudi Arabia*.

Background: Cardiovascular risk assessment is crucial prior to kidney transplantation especially in diabetic patients as nearly 6.6% of recipients have a major adverse cardiovascular event (MACE) within 3 years. This study aims to evaluate the predictive role of MPI among asymptomatic diabetic candidates for post-kidney transplant cardiovascular events.

Methods: This is a retrospective, single center study. We included adult diabetic patients who underwent MPI prior to kidney transplant with a post kidney transplant follow up of 2 years. The primary outcome was a composite of death, ACS, coronary revascularization, hospitalization for heart failure (ADHF), and CVA. These were also studied individually as secondary outcomes. Sensitivity, specificity, PPV and NPV for MPI in detecting obstructive CAD were evaluated in candidates that underwent pre-transplant coronary angiography.

Results: Out of 121 candidates, 76 had normal-MPI and 45 had abnormal-MPI. Primary composite outcome was seen in 9 pateints (11.8%) in the normal-MPI group and in 4 (8.9%) in the abnormal-MPI group. More patients in abnormal-MPI group had ADHF (not statistically significant). Out of the 4 normal-MPI patients that had ACS, 3 required post-transplant revascularization, 2 of them did not undergo pre-transplant coronary angiography. In normal-MPI patients, 55 underwent pre-transplant coronary angiography, 8 of them had obstructive CAD. MPI had a sensitivity, specificity, NPV and PPV of 60%, 59.7%, 85% and 27.9% respectively in identifying obstructive CAD as compared to pre-transplant coronary angiography.

Conclusions: Diabetic candidates with abnormal-MPI had similar incidence of mortality and MACE post-kidney transplant as compare to normal-MPI patients. MPI had a NPV of 85% in ruling out obstructive CAD. The predictive role of MPI pre kidney transplant remains unclear and needs further study.

	Normal-MPI (n=76)		Abnormal MPI (n=45)		p-value*
	(n)	(%)	(n)	(%)

Prognostic Role of Hypertension Remission in Kidney Transplant Recipients with Pretransplant Hypertension

Minji Kim, Kyungho Lee, Junseok Jeon, Jung eun Lee, Wooseong Huh, Hye Ryoun Jang. *Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea*.

Background: Hypertension is commonly associated with advanced chronic kidney disease and end-stage kidney disease. Kidney transplantation (KT) in patients with pre-transplant hypertension has the potential to lead to remission of hypertension. However, the remission rate of hypertension after KT and its prognostic impact on KT outcomes remain unknown.

Methods: KT recipients (2006–2015) who had pre-transplant hypertension were identified and categorized into two groups based on their post-KT hypertension status: "persistent hypertension" and "hypertension remission", using data from the Health Insurance Review & Assessment Service and Korean National Health Insurance System. Cox proportional hazard analyses were performed for death-censored graft failure and all-cause mortality.

Results: A total of 3,109 (27%) among 11,342 KT recipients with pre-transplant hypertension experienced hypertension remission after KT. The patients who experienced hypertension remission had lower prevalences of delayed graft function and major comorbidities including diabetes, ischemic heart disease, and stroke, compared to those with persistent hypertension. Graft failure (incident rate [IR], 6.8 vs 12.0) and mortality rates (IR 5.5 vs 11.1) were both lower in the hypertension remission group (per 1,000 person-years, log-rank P <0.001 for both) than the persistent hypertension group. Hypertension remission was associated with 0.58-fold (95% confidence interval 0.48–0.72) and 0.50-fold (0.40–0.62) lower risks for graft failure and all-cause mortality, respectively, in unadjusted analyses. The adjusted hazard ratio of hypertension remission was 0.59 (0.49–0.73) for graft failure and 0.59 (0.48–0.73) for mortality compared to the persistent hypertension group after adjusting multiple covariates. There were significant interactions with sex for graft failure (stronger protection in females, P for interaction=0.045) and with diabetes status for mortality (weaker protection in recipients with diabetes, P for interaction=0.033).

Conclusions: Kidney transplantation can lead to hypertension remission in a substantial number of patients. Remission of pre-transplant hypertension was associated with better graft survival as well as overall patient survival. We suggest that hypertension remission can be used as an indicator of favorable outcomes in KT recipients.

Cardiorenal Outcomes, All-Cause Mortality, and Arterial Stiffness Parameters in Stable Kidney Transplant Recipients

Zbigniew Heleniak,[1] Alicja Debska-Slizien,[1] Fabian Halleck,[2] Klemens Budde.[2] *[1]Gdanski Uniwersytet Medyczny, Gdansk, Poland; [2]Charite Universitatsmedizin Berlin, Berlin, Germany*.

Background: The objective of the study was to evaluate the predictive value of pulse pressure (PP) and carotid-femoral pulse wave velocity (cfPWV), in relation to cardio-renal outcomes and all-cause mortality in stable renal transplant recipients (RTRs).

Methods: 344 stable RTRs with a median age of 52.7 years, were enrolled. At baseline PP and cfPWV were measured during a routine visit in RTRs without cardiac symptoms and heart failure exacerbation. The follow-up was 54 months.

Results: The mean creatinine level, the value of estimated glomerular filtration rate, and transplantation vintage were 1.47mg/dl, 50.5ml/min/1.73m$^{2.}$ and 73 months, respectively. The median PP and cfPWV were 55mmHg and 7.9m/s respectively. Cut-off values for all-cause mortality, CV events, and renal outcomes were: PP 60, 68, 60mmHg cfPWV 9.90, 8.0, and 10.0 m/s respectively. During the follow-up, the likelihood of patient survival, and cardio-renall outcomes based on PP and cfPWV values (established using the Youden method) were shown in Figures 1 and 2.

Conclusions: Both PP and cfPWV have significant predictive ability for mortality and renal events outcomes in RTRs. Only the cfPWV value was predictive in terms of the incidence of CV events, significantly.

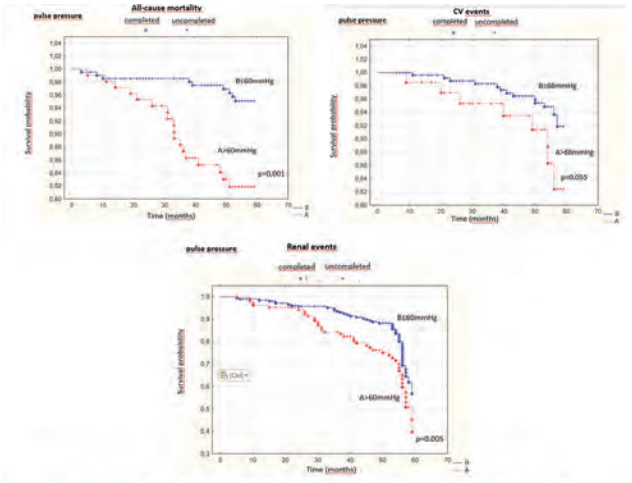

Figure 1 The predictive role of PP in terms of all-cause mortality, cardiovascular (CV) and renal events.

Pulse Pressure: A More Relevant Risk Factor for Graft Outcomes in Deceased Donor Kidney Transplantation than Living Donor Transplantation

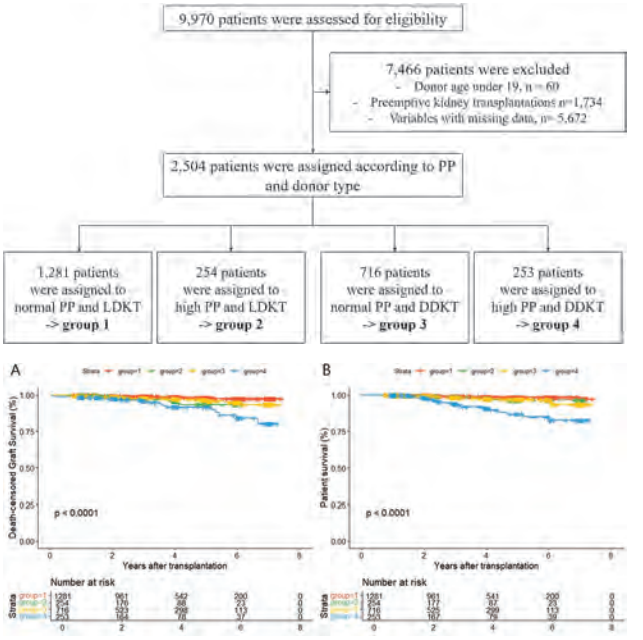
Ji Eun Kim. KOTRY Study Group. *Seoul St. Mary's hospital, Seoul, Republic of Korea.*

Background: Pulse pressure (PP) is a hemodynamic indicator associated with arterial stiffness. However, its role in kidney transplant remains unclear, especially in the context of living donor kidney transplantation (LDKT) versus deceased donor kidney transplantation (DDKT). This study aims to investigate the impact of PP according to donor type in kidney transplant.

Methods: A total of 2,504 kidney transplant patients were analyzed between 2014 and 2022 from the Korea Organ Transplantation Registry database. PP was calculated from systolic and diastolic blood pressure at 1-year post-transplantation. High PP is defined as exceeding 60 mmHg. Patients were stratified into four groups based on PP and donor type: LDKT with normal/high PP, and DDKT with normal/high PP. Primary outcomes were graft loss and mortality over an 8-year period.

Results: Among the kidney transplant recipients, only the group with high PP in DDKT represented markedly higher graft loss (HR 2.260, 95% CI 1.183-4.317, p=0.014) and mortality (HR 2.202, 95% CI 1.098-4.417, p=0.026). Conversely, no significant differences in graft loss or mortality were observed among the other groups. Furthermore, high PP with DDKT group maintained consistently lower estimated glomerular filtration rates throughout the 5-year follow-up period. Additionally, the DDKT group exhibited significantly higher PP compared to the LDKT group at 1-year post-transplantation, with a higher prevalence of high PP in DDKT.

Conclusions: In DDKT, elevated PP is associated with inferior graft survival and increased mortality rates, whereas LDKT recipients show a lesser susceptibility to the effects of PP. When considering higher prevalence and impact of elevated PP in DDKT, it essentially should be considered a crucial risk factor in DDKT.



SA-PO945

Major Cardiovascular Events and Hyperuricemia as an Effect-Modulating Factor in Kidney Transplant Recipients

Inese Folkmane.[1,2] [1]*Faculty of Medicine, University of Latvia, Riga, Latvia;* [2]*Pauls Stradins Clinical University Hospital, Centre of Nephrology, Riga, Latvia.*

Background: Major cardiovascular events (MACE) remain the leading cause of morbidity and mortality in patients with kidney transplants (KT). The risk for MACE is affected by the accumulation of a wide range of traditional and transplant-associated nontraditional cardiovascular (CV) risk factors (RFs). In the last years, studies have shown that many other cardiovascular RFs may be involved, including hyperuricemia (HU).

Methods: We investigated the association between CV risk factors related to KT with MACE, and their effect modification by HU in a cohort of 545 patients transplanted between 2008 to 2019. Univariate and multivariate Cox proportional hazards regression analyses were performed to determine the RFs associated with MACE. To investigate the possibility of effect modification of the uric acid (UA) for the associations of independent factors with MACE, patients were stratified as having a low (< 6 mg/dL), normal (6-7 mg/dL), high (7-8 mg/dL) and very high (> 8 mg/dL) UA level.

Results: MACE occurred in 145 of 545 (26.6 %) KT recipients. Most of the independent variables investigated in this study were univariately related to the MACE. On the multiple logistic regression main model that described 62.1% of changes in MACEs, the most prominent factors associated with MACE were previous CV event (OR = 70.6, 95% CI 24.9 – 200.1), left ventricular hypertrophy (LVH) (OR = 12.6, 95% CI 2.74 – 58.3), HU treatment (OR = 4.29, 95% CI 2.44 – 7.57), anemia (OR = 5.32, 95% CI 2.89 – 9.8). Effect modification by hyperuricemia showed that independent factors associated with MACE were age (OR = 1.03, 95% CI 1.03 – 1.09), previous CV events (OR = 41.70, 95% CI 13.62 – 127.64), LVH (OR = 15.33, 95% CI 2.02 – 116.60), HU treatment (OR = 2.45, 95% CI 1.31 – 4.59) and anemia (OR = 5.36, 95% CI 2.75 – 10.45). Effect modification by very high levels of UA showed that HU treatment was not associated with MACE either for those with or for those without very high levels of UA. The variables that were significantly associated with MACE for those with very high UA were previous CV events (OR = 72.82, 95% CI 9.09 – 583.34) and anemia (OR = 6.46, 95% CI 2.46 – 16.95).

Conclusions: HU was found to be an effect-modifying factor for MACE, especially in association with RFs such as age, previous CV events, LVH, and anemia.

Kidney Transplant Candidates with Reduced Ejection Fraction: Risky Business or Not?

Alice H. Won, Ashwin Kelkar, Maria Karas, Darshana M. Dadhania. New York Presbyterian-Weill Cornell Medicine. *Weill Cornell Medicine, New York, NY.*

Background: Heart failure with reduced ejection fraction (HFrEF) is prevalent among patients with advanced chronic kidney disease. Data remains limited on whether HFrEF at the time of transplant is associated with an increased risk of graft failure and mortality. In this study, we sought to compare the patient and graft survival between the cohorts of patients with or without HFrEF undergoing kidney transplantation (KTx).

Methods: In this retrospective case-control study, we performed a 1:2 matched cohort analysis of 103 KTx patients with pre-transplant EF ≤45% (HF cohort) and 206 patients with EF >45% (control cohort), transplanted between January 2011 - December 2021. Two cohorts were matched based on age, sex, donor type, and transplant year. Simultaneous liver-kidney transplants were excluded.

Results: Baseline characteristics were similar except pre-emptive transplant and thymoglobulin induction were less frequent in the HF cohort. Despite increased delayed graft function (DGF) in the HF cohort, there was no statistically significant difference in the mean creatinine levels at 3-months (1.51 vs. 1.56) and 1-year (1.41 vs. 1.57) post-KTx between the control and HF cohorts (Table 1). At a mean follow-up period of 4.7 years, the two cohorts demonstrated similar overall graft survival and patient survival (Figure 1), with no statistically significant difference in the rates of graft loss due to acute rejection or death due to cardiovascular cause (Table 1).

Conclusions: In our investigation, the graft and patient survival of control and HF cohorts were similar and comparable to the published ten-year KTx outcomes (PMID:26285695). Our data suggests low EF alone should not be a contraindication to KTx and is associated with acceptable long-term survival.

Table 1.

Patient Baseline Characteristics	Control cohort (n=206)	HF cohort (n=103)	p value
Average Age (yr.)	55.5	55.7	0.99
Male sex	157 (76.2%)	76 (73.8%)	0.07
Ethnicity			0.41
White	46%	43%	
Black	23%	28%	
Other / Declined	23%	22%	
Asian	8%	7%	
Repeat transplant	30 (15.6%)	13 (12.6%)	0.64
Pre-emptive transplant	65 (31.6%)	12 (11.7%)	0.0001
Living donor kidney	124 (60.2%)	55 (53.4%)	0.25
Immunosuppression induction			
Thymoglobulin	174 (84.5%)	47 (45.6%)	<0.0001
Simulect	31 (15.0%)	53 (51.5%)	
Left ventricular ejection fraction (LVEF), pre-transplant , mean (SD)	61.7% (6.2)	37.5% (6.8)	<0.0001
Minimum LVEF, Maximum LVEF	47.0%, 80.0%	15.0%, 45.4%	
25% percentile-, Median-, 75% percentile- LVEF	57%, 60%, 66%	35%, 40%, 43%	
Post-transplantation Clinical Outcomes	**Control cohort (n=206)**	**HF cohort (n=103)**	**p value**
Delayed graft function (DGF)	38 (18.4%)	28 (27.2%)	0.03
Hospitalization within 1 year	109 (52.9%)	55 (53.4%)	0.45
Acute rejection within 1 year	15 (7.3%)	14 (13.6%)	0.22
Total graft loss	29 (14.0%)	10 (9.7%)	0.36
Graft loss due to acute rejection	6 (2.9%)	1 (1.0%)	0.43
Total deaths	35 (17.0%)	16 (15.5%)	0.25
Death due to cardiovascular cause	7 (3.4%)	5 (4.9%)	0.54
Mean creatinine at 3-months (mg/dL), mean (SD)	1.51 (0.67); n=197	1.56 (0.68); n=100	0.44
Mean creatinine at 1-year (mg/dL), mean (SD)	1.41 (0.47); n=197	1.57 (0.97); n=95	0.25

SA-PO947

Hurry Up and Wait: Modeling Kidney Transplant Wait Times under Wait-List Expansion Scenarios

Jillian Caldwell, Xingxing S. Cheng, Glenn M. Chertow, Jeremy D. Goldhaber-Fiebert. *Stanford University School of Medicine, Stanford, CA.*

Background: Kidney transplantation offers survival benefits and superior quality of life compared with maintenance dialysis for patients with end-stage kidney disease (ESKD). While over 500,000 Americans currently receive dialysis, deceased donor transplantation is limited to approximately 20,000 patients annually. Expanding access to kidney transplant is a top priority of public policy. Strategies involve adding more patients to the waitlist and increasing organ supply. However, the effect of these interventions on transplant wait times has not been explored.

Methods: We constructed a decision analytic Markov model to simulate a cohort of approximately 660,000 patients with chronic kidney disease (CKD) and estimated glomerular filtration rate (eGFR) <20ml/min and ESKD on dialysis over a ten-year period. We then used Kaplan-Meier survival analysis to estimate median wait time by counting time on the waitlist until transplantation, censoring for waitlist removal and death. We compared current wait times (status quo) to three strategies: 1) waitlist expansion by 10%, 2) waitlist expansion by 50%, and 3) waitlist expansion by 50% combined with a 50% reduction in the kidney nonuse rate.
