Background: Home dialysis offers numerous patient-centered and economic benefits for patients with ESRD. Despite advancements in federal policy initiatives, only 13.4% of patients with ESRD dialyze at home in the US. Home dialysis is an optimal treatment modality for ESRD patients with disabilities who have increased challenges in activities of daily living. As COVID-19 exacerbated access challenges across healthcare settings, we hypothesized that disabled ESRD patients may utilize home dialysis to a lesser degree post-pandemic compared to prior to the pandemic.

Methods: We used 100% Medicare Fee-For-Service (FFS) claims data to identify patients with ESRD who initiated in-center renal replacement therapy (hemodialysis) between July 1, 2017 and September 30, 2017 (Pre-Pandemic Cohort) or between July 1, 2021 and September 30, 2021 (Post-Pandemic Cohort) and maintained in-center hemodialysis for at least three months from their initial visit. Among these patients, we identified those who transitioned to home peritoneal dialysis within 18 months following the 3-month period of in-center hemodialysis. We stratified beneficiaries by their original reason for Medicare entitlement.

Results: After COVID-19, the relative proportion of disabled Medicare FFS beneficiaries who initiated home hemodialysis decreased from 34.5% in the Pre-Pandemic Cohort to 25.9% in the Post-Pandemic Cohort ($p<0.001$). There were no statistically significant differences between the cohorts in age, dual status, race, sex, or beneficiary state.

Conclusions: Findings suggest that COVID-19 exposed a multi-layered disparity, exacerbating access barriers in the healthcare delivery system for patients with both ESRD and disabilities. Future research and policy should focus on increased support for dialysis patients with disabilities, ensuring equitable access to treatment modalities.

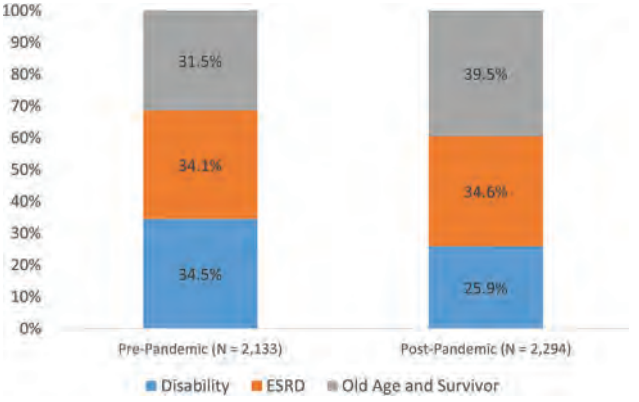

Figure 1: Distribution of Original Reason for Medicare Entitlement among Medicare FFS ESRD Patients Initiating Home Dialysis Service

Short- and Long-Term Outcomes in Critically Ill Patients with COVID-19 and AKI

Juliana A. Andrade,[1,2] Gisele Meinerz,[1,2] Eduardo L. Rech,[2] Raphael H. Palma,[1,2] Marco Antônio V. Dall Agnese,[1] Elizete Keitel.[1,2] *[1]Universidade Federal de Ciencias da Saude de Porto Alegre, Porto Alegre, Brazil; [2]Santa Casa de Misericordia de Porto Alegre, Porto Alegre, Brazil.*

Background: Acute kidney injury (AKI) in the setting of COVID-19 infection is associated with worse outcomes. The aim of this study was to follow-up a sample of critically ill patients with COVID-19 and AKI analyzing AKI stages, kidney replacement therapy (KRT), and outcomes at 90 days and at 365 days after hospitalization.

Methods: Observational, prospective cohort study of hospitalized adults (> 18 years old) with severe COVID-19 admitted to the Intensive Care Units (ICUs) in a tertiary hospital in south of Brazil. Patients with nephrological assessment for AKI were included from May 1st, 2020, and April 30th, 2021. Outcomes within 3 months after the COVID-19 included death and kidney function recovery. Survived patients had the glomerular filtration estimated (eGFR) at baseline, discharge and at 12 months. Kaplan-Meier method was used to survivals and ANOVA to compare means. Risk factors for death was analyzed by Cox regression.

Results: 360 patients were enrolled in the study, among them 60.6% were male, the mean age was 63.9 ± 12.5 years, 38.1% had diabetes, 68.6% had hypertension, 44.2% were obese, and 17.1% had ischemic cardiopathy. Median BMI was 29.0 (IQR 25.0-33.2). 98% required mechanical ventilation. AKI stage 1, 2 and 3 was detected in 3.6%, 5.6% and 90.8% of patients, respectively. KRT was indicated in 89.0% of patients. At 90 days follow-up, 317 (88.1%) of patients died before discharge, 7 (1.9%) remained on KRT, and 36 (10.0%) had kidney function recovered. Age (each 10 years increased risk 18%), requirement of KRT, and mechanical ventilation were associated with death within 90 days. Forty-three (43) patients (11.9% of the whole sample) survived beyond 90 days. Of those, 8 (18.6 %) patients died between 90 and 365 days and 5 (11.6 %) remained on KRT at 365 days. Thirty (30) patients (69.7%) were alive and free of KRT. The eGFR was not different between baseline (85.5 ± 23.6ml/min) and at discharge (81.7 ± 29.5ml/min). However, the mean eGFR at 365 days (65.9 ± 24.8ml/min) was lower ($p=0.003$).

Conclusions: Severe COVID-19 infected patients that developed AKI in ICU environment presented high mortality at 90 days (88,1%). Among survived patients 87% were free of dialysis. However, survivors at one year had a lower renal function compared to baseline.

TH-PO1144

AKI in Intensive Care Unit (ICU) Patients in the Omicron Surge: Insights from a Multinational Study

Pedro H. Gois,[1,2] Danyang Dai,[1] Sally Shrapnel,[1] Marina Wainstein,[1] Moji Ghadimi,[1] Nicholas S. Spyrison,[1] Rolando Claure-Del Granado,[3] Jason D. Pole.[1] ISARIC Characterization Group. *[1]The University of Queensland, Brisbane, QLD, Australia; [2]John Hunter Hospital, New Lambton Heights, NSW, Australia; [3]Universidad Mayor de San Simon, Cochabamba, Bolivia, Plurinational State of.*

Background: Acute kidney injury (AKI) is a common and serious complication of COVID-19. Few studies have investigated the prevalence of AKI in patients admitted to Intensive Care Units (ICU) during the Omicron surge. We aim to examine the relationship between AKI and the Omicron variant in critically ill patients using the International Severe Acute Respiratory and Emerging Infection Consortium (ISARIC) COVID-19 global dataset.

Methods: This is a prospective observational study of COVID-19 patients admitted to ICU across 6 countries between June 2021 and October 2022. AKI was defined as per KDIGO serum creatinine (sCr) criteria within 7 days of hospitalization, using the first available sCr as baseline. Patients were categorized into “Pre-Omicron” (before Dec 1, 2021) and “Omicron” (after Jan 1, 2022). Multivariable logistic regression was used to analyze the association between Omicron and AKI.

Results: The analysis included 3,908 patients (3,203 pre-Omicron, 705 Omicron). AKI distribution by countries/variants is shown in Figure 1A. AKI prevalence and dialysis were not different between Omicron and prior variants (24.7% vs 22.9%, p=0.32; and 45% vs. 52%, p=0.15, respectively). Most patients had stage 3 AKI (Figure 1B). Patients in the Omicron wave were older and had more comorbidities. After adjusting for confounders, Omicron patients were ~40% less likely to develop AKI compared to prior variants. Survival curves for AKI patients showed no significant differences between Omicron and prior variants (Figure 2).

Conclusions: Patients hospitalized during the Omicron wave were less likely to develop AKI compared to previous eras, highlighting the importance of continued research to elucidate the evolving characteristics of the disease.

TH-PO1145

Persistent Increase in the Blood Urea Nitrogen/Creatinine Index (PI-BUN/Cr) Phenotypes the Clinical Course of Patients with Severe COVID-19

Gustavo A. Casas-Aparicio,[1] Rolando Claure-Del Granado.[2] *[1]Instituto Nacional de Enfermedades Respiratorias, Mexico, Mexico; [2]Hospital Obrero No 2, Division de Nefrologia, Cochabamba, Bolivia, Plurinational State of.*

Background: PI-BUN/Cr in patients with COVID-19 is an important clinical marker that extends beyond simple prerenal injury, reflecting more complex underlying pathophysiological processes. Understanding and interpreting PI-BUN/Cr in this context is crucial due to its potential implications for mortality.

Methods: We analyzed a retrospective and longitudinal cohort of patients admitted to a single center in Mexico City. Between March 5, 2020, and August 25, 2021, patients with confirmed positive diagnosis for SARS-CoV-2, age >18 years, and a ratio of partial oxygen pressure to inspired oxygen fraction <300 mmHg on admission were included. Data was obtained from electronic medical records. PI-BUN/Cr was defined as an increase in the BUN/Cr ratio >30 in more than 60% of the measurements recorded during hospitalization. AKI was defined based on the K-DIGO guidelines. The primary objective was to analyze the risk factors for mortality.

Results: The cohort included 3,007 patients, with a median age of 54.6 ±14.5 years. Thirty-five percent of patients died; 44.6% developed PI-BUN/Cr ratio and 71.4% AKI. Mortality was associated with older age >60 years [Hazard ratio (HR)]=1.45, 95%CI:1.28-1.65; p<0.001); male (HR=1.25, 95% CI: 1.09-1.44; p=0.002); and AKI (HR=3.29, 95% CI: 2.42-4.46; p<0.001). PI-BUN/Cr was not associated with mortality (HR=0.95, 95% CI:0.83-1.07; p=0.417). According to the PI-BUN/Cr and AKI status, mortality was higher in the groups with PI-BUN/CR & Non-AKI (HR=2.82, 95% CI: 1.61-4.93; p<0.001); Non-PI-BUN/CR & AKI (HR=5.47, 95% CI: 3.54-8.44; p<0.001); and PI-BUN/CR & AKI (HR=4.26, 95% CI: 2.75-6.62, p<0.001). Survival analysis is shown in Figure 1.

Conclusions: While PI-BUN/Cr alone may not directly associate with mortality, its capacity to phenotype patients according to their AKI status holds significant promise in offering valuable insights into patient prognosis and outcomes.

TH-PO1146

Humoral Response to SARS-CoV-2 Vaccination in Lupus Nephritis

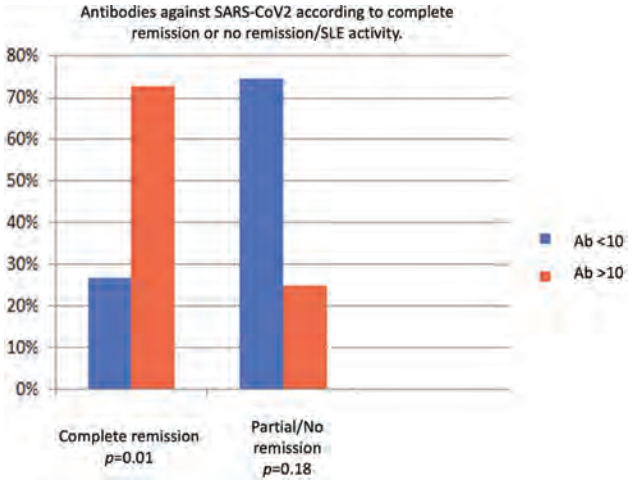
Ana S. Fernandez, Agustin Noboa, Jose Boggia, Gabriela Ottati. *Hospital de Clinicas Doctor Manuel Quintela, Montevideo, Uruguay.*

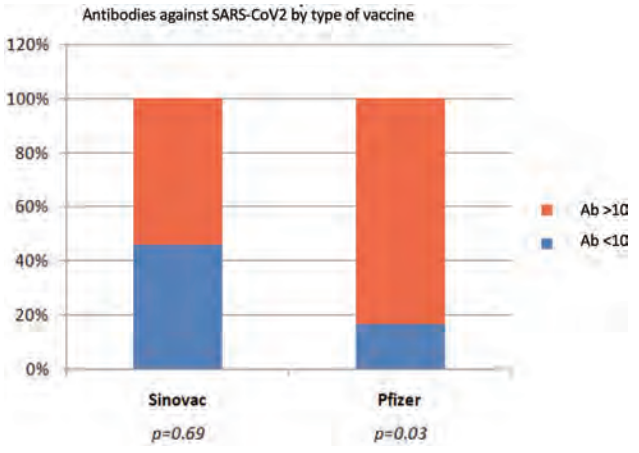
Background: Vaccine development has been the best control measure for the SARS-CoV-2 pandemic. However, patients with lupus nephritis (LN) have not been included in studies assessing vaccine efficacy. The objective is to analyze LN patients’ ability to generate antibodies against SARS-CoV-2 after vaccination while under immunosuppressive treatment.

Methods: A prospective study was conducted on patients with LN. One month after receiving the second SARS-CoV-2 vaccine, a blood sample was taken to test for the presence of antibodies using an ELISA test sensitized with the Receptor Binding Domain (RBD) fragment of the SARS-CoV-2 Spike protein. Adverse effects and changes in the SLEDAI score were documented following the vaccine administration.

Results: We recruited 19 patients, with a median age of 35.5 years and 89% female. The overall seroconversion rate was 63% (p=0.11). Patients in complete remission (CR) exhibited a significantly higher antibody response. The antibody production rate was higher for Pfizer® at 83% (p=0.03) compared to Sinovac at 54% (p=0.69). Patients who initially received Cyclophosphamide treatment showed a significant reduction in antibody production after vaccination (p=0.009).

Conclusions: Patients vaccinated with Pfizer or in complete remission showed higher anti-SARS-CoV-2 seroconversion rates.





TH-PO1147

Humoral and Cellular Immunity following Bivalent mRNA Boosters in Patients on Hemodialysis

Tsai-chieh Ling, Jia-Ling Wu, Chien Yao Sun, Wei-Ren Lin, Chieh-Hsin Huang, Yu T. Chang. *National Cheng Kung University Hospital, Tainan, Taiwan.*

Background: Dialysis patients are at high risk of SARS-CoV-2 related morbidity and mortality. Although bivalent vaccines targeting Omicron subvariants were recommended, data on the immunogenicity in the hemodialysis (HD) population remain limited.

Methods: In this prospective observational study, we enrolled patients on maintenance HD scheduled to receive bivalent mRNA vaccines. Immune responses were assessed before, and one and three months after vaccination (baseline, M1 and M3), and also at M1 and M3 after breakthrough infection. Age-matched healthy adults served as controls. Humoral immunity outcomes included anti-SARS-CoV-2-S antibody, surrogate viral neutralization tests (sVNT) against the ancestral virus, Omicron BA.1, BA.2 and BA.4/5, and pseudovirus neutralization tests against Omicron BF.7, B.2.75, BQ.1.1 and XBB.1.5. Cellular immunity was evaluated with interferon-γ release assay (IGRA) targeting spike proteins from various variants.

Results: A total of 106 HD patients (median age 66) received Spikevax Original/Omicron BA.1 (89.6%) or BA.4-5 (10.4%) from October 2022 to February 2023. Of these, 25.5% had prior infection, and 93.4% had received four doses of vaccines including two AZD1222 and two mRNA vaccines. Anti-SARS-CoV-2-S antibody levels increased by 4.2-fold and subsequently halved at M3. sVNT showed increased neutralization against Omicron subvariants peaked at M1 and positive rates remained high(75.3~96%) at M3. Pseudovirus neutralizing capacity against Omicron BF.7, B.2.75, BQ.1.1 and XBB.1.5 increased by 2-to-9.9 times. However, only 58.1% of patients showed a positive IGRA response at M1, with no correlation to humoral outcomes. No significant differences in humoral and cellular immunity were demonstrated between HD patients and health controls. In those with 5 immunizations, Anti-SARS-CoV-2-S antibody and sVNT against BA.4/5 at M3 were higher following hybrid immunity than pure vaccinations. In multivariate linear mixed effect model, previous SARS-CoV2 infection attenuated neutralization against the ancestral virus.

Conclusions: Bivalent mRNA vaccines boosted antibody titers and broaden neutralization against new Omicron subvariants in HD patients. However, cellular immunity was suboptimal despite multiple immunizations including bivalent vaccines and infection, highlighting a potential area for further investigation.

TH-PO1148

Mild COVID-19 Infection Does Not Affect CKD Indices

Avital Angel-Korman,[1,2] Adi Leiba,[1,2] Tal Brosh-Nissimov,[1,2] Ori Mayer.[3] *[1]Assuta Ashdod University Hospital, Ashdod, Israel; [2]Ben-Gurion University of the Negev, Beer-Sheva, Israel; [3]Tel Aviv University Faculty of Medicine, Tel Aviv, Israel.*

Background: COVID-19 in hospitalized patients has been implicated in the deterioration of several indices associated with chronic kidney disease (CKD), including new onset hypertension, and worsening of proteinuria and kidney function. Nevertheless, the influence of COVID-19 on these parameters in patients with CKD has not been fully elucidated. We aimed to study the effect of COVID-19 on blood pressure (BP), proteinuria, and eGFR in a community-based cohort of patients with CKD

Methods: A retrospective cohort study using data obtained from Maccabi Healthcare Services (MHS) during COVID-19 pandemic. MHS, is a nationwide payer-provider healthcare system, with an extended database including laboratory information, vital signs documentation and a well validated CKD registry. Included in the study were all adults (over 18 years of age) with CKD stages I-V insured in MHS, who had a first documented mild-moderate laboratory-confirmed COVID-19, not requiring hospitalization. All reported BP clinic measurements within one year prior to and following COVID-19, were averaged, and so were urine albumin and serum creatinine (sCr) measurements

Results: 43,875 patients were registered as having CKD in MHS and had a documented 1st COVID-19 infection between 2020-2022. Mean age was 69.3 (±12.9) years and 21,775 (49.6%) were males. Following COVID-19, systolic BP was 1 mmHg lower and diastolic BP was 0.6 lower compared with pre-COVID-19 values (P-value 0.03 and 0.004, respectively). 8918 patients had at least 2 documented urine albumin to creatinine ratio (UACR) measurements. The mean UACR was 64mg (±233) before and 93mg (±322) after COVID-19, accounting for an absolute difference of 29mg (±294), p<0.001. Patients with baseline albuminuria >300mg had a mean decrease in albumin level of 263mg (±676) following COVID-19. In 37,923 patients who were tested for sCr, eGFR was 73.2ml/min (±19.8) and 72.2ml/min (±20) before and after COVID-19, respectively - an absolute difference of 1ml/min (±8.9), p<0.001. Adjustment for changes in medications including ACE INH, ARBs, diuretics MRAs and SGLT2 inhibitors did not significantly affect the results

Conclusions: Although some differences in CKD indices were statistically significant given the large cohort size, none were clinically significant. Mild-moderate COVID-19 did not affect indices of CKD and is therefore unlikely to be associated with CKD progression

TH-PO1149

Vaccination Strategies in Patients Receiving Dialysis: Should We Watch the Clock?

Nivetha Subramanian,[1] Xue Yu,[1] Meri Varkila,[1] Geoffrey A. Block,[2] Julie Parsonnet,[1] Glenn M. Chertow,[1] Shuchi Anand,[1] Maria E. Montez-Rath.[1] *[1]Stanford Medicine, Stanford, CA; [2]US Renal Care Inc, Decatur, GA.*

Background: Previous studies reported that early morning vaccination was associated with a more robust antibody response than late afternoon or evening vaccination. Circadian changes in the immune system may yield better immunogenicity in the morning than later in the day. We examined peak and longitudinal SARS-CoV-2 antibody response by vaccine timing in a nationwide cohort of patients on hemodialysis.

Methods: Patients were documented in the electronic medical record to have received at least 1 dose of mRNA vaccine at the dialysis facility during their assigned shift and had available data on antibody indices after 1st dose (n=1229). Using a semiquantiative Siemens RBD IgG assay and quantile regression, we estimated unadjusted and adjusted median RBD IgG indices over time by dialysis shift.

Results: The mean age of patients receiving vaccine in the early morning (~530 am) shift was younger than those in the mid-day (~10 am) or late afternoon (~2 pm) shifts: 60(SD 13), versus 66(13) and 62(15) years, respectively. Patients in the early morning shift were more likely to receive the BNT162b.2 vaccine than those who dialyzed in mid-day or late afternoon shifts (57% versus 52% and 42%, respectively). A larger proportion of patients who dialyzed in early morning (19%) had detectable RBD IgG indices prior to vaccine compared with patients in mid-day (12%) and late afternoon (14%) shifts. In unadjusted analyses, the early morning cohort had higher RBD IgG indices 30-60 days post-vaccine. Adjusting for age, diabetes, years on dialysis, type of vaccine, and baseline IgG eliminated difference by shift (Fig1).

Conclusions: In this nationwide cohort of patients receiving dialysis and mRNA vaccines, we found that early morning vaccination did not yield a better immunogenicity as measured by antibody response. Prior analyses reporting an association of vaccine timing with immune response may not have accounted for prior SARS-CoV-2 infection or other relevant differences in patient characteristics.

Funding: Other NIH Support - NIH U01AI169477

Figure 1: Median RBD Ig by dialysis shift when vaccine was administered

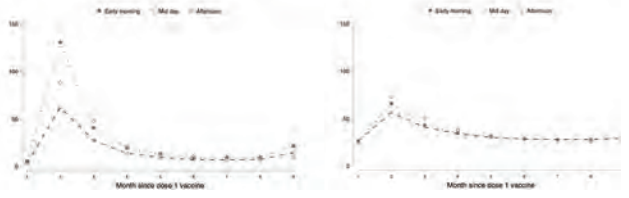
1b. Adjusted for age, diabetes, vaccine type, dialysis vintage, and baseline RBD Ig levels



TH-PO1150

Wunderlich Syndrome in a Patient with ESKD Diagnosed with COVID-19: A Case Report

Maricar Mae A. Marquez, Annabelle S. Lim, Abigayle Therese R. Guiritan. *St. Luke's Medical Center, Quezon City, Quezon City, Philippines.*

Introduction: Wunderlich syndrome is a rare clinical syndrome characterized by an acute onset of spontaneous renal hemorrhage into the subcapsular, perirenal, and/or pararenal spaces, without a history of antecedent trauma. Patients may present with a multitude of symptoms ranging from abdominal pain to serious manifestations such as hypovolemic shock. In this case report, we presented an end stage renal disease patient diagnosed with Covid 19 who developed Wunderlich syndrome.

Case Description: This is a case of 68-year-old female, with known chronic kidney disease stage 5 on hemodialysis, presented with abdominal pain and hypotension. On the day of admission, patient was scheduled for over-the-wire IJ catheter exchange. Post-procedure, patient developed hypotension and abdominal pain localized to the right upper and lower quadrant. Despite fluid resuscitation, she remained hypotensive. Significant physical examination revealed bibasal crackles. On work up, there was anemia (Hgb: 8.5g/dL, dropping to 6.6g/dL in 6 hours), and bilateral lower lung densities on chest X-ray. COVID RT PCR was positive. Other work up such as 12Lead ECG, 2D echo, Procalcitonin, Urinalysis, Liver Function Test were unremarkable. CT scan thoraco-abdominal aortogram was done which revealed right renal subcapsular acute hemorrhage. Since the patient was hemodynamically unstable, patient underwent renal angiogram with renal artery embolization. She was eventually weaned off inotropic support, anemia was corrected via blood transfusion and adequate antibiotic coverage was given for the pneumonia. Hemodialysis was continued. Following stabilization and completion of isolation, she was discharged. Follow-up imaging showed resolution of the renal subcapsular hemorrhage.

Discussion: Wunderlich syndrome is a life threatening condition with high morbidity and can be fatal if not treated promptly and aggressively. End stage renal disease is a rare cause for Wunderlich syndrome. Patients with ESRD are predisposed to bleeding diathesis. Another rare but possible cause is the presence of COVID-19 infection in the patient. Studies have suggested that COVID-19 can cause a spontaneous hemorrhage and can increase incidence of bleeding. Both of these in combination can cause endothelial dysfunction which could lead to increased bleeding events.

TH-PO1151

Unplanned Initiation of Maintenance Hemodialysis: Patient Background and Survival in Pre- and Post-COVID-19 Emerging

Mineaki Kitamura,[1,2] Tomoya Nishino.[1] [1]*Nagasaki Daigaku Byoin, Nagasaki, Japan;* [2]*Nagasaki Minato Medical Center Shimin Byoin, Nagasaki, Japan.*

Background: The initiation of hemodialysis, especially when unplanned, often leads to a decline in functional status and an increased risk of cardiovascular diseases, malnutrition, and infections. Several factors associated with unplanned dialysis have been reported; however, patient background differences between pre-and post-COVID-19 emerging have not been elucidated. We aimed to identify factors contributing to unplanned hemodialysis and evaluate patient prognosis in collaboration with maintenance hemodialysis centers.

Methods: We analyzed patients initiating hemodialysis at our facility between 2016 and 2023, stratified by pre-April 2020 and post-April 2020 periods based on the declaration of a state of emergency from the Japanese Government. Unplanned hemodialysis was defined as initiation during emergency admission, regardless of arteriovenous fistula presence. Data on patient demographics, comorbidities, and clinical course were collected. Multivariable logistic and Cox regression models assessed factors associated with unplanned hemodialysis initiation and patient mortality, respectively.

Results: We included 290 patients (age:71±12 years old, 64% male) and divided them into the groups pre-(n=149) and post-April 2020 (n=141). Unplanned hemodialysis was initiated in 77 (55%), and 69 (46%) patients in both periods. The prevalence of any infections was higher in patients initiating unplanned dialysis (P<0.001). Multivariable logistic regression analysis indicated that unplanned dialysis initiation throughout the entire period was significantly associated with infections (OR: 15.79, 95% CI: 5.45-45.75, P<0.001). This trend was almost similar in pre- and post-April 2020. Notably, the prevalence of pneumonia in the post-April 2020 group was lower (n=13, 8%) than that in the pre-April 2020 group (n=25, 17%) (P=0.02). During the follow-up period (median 766 days), 89 patients died, and infections were the most prevalent cause of death (34%). Unplanned hemodialysis was an independent risk factor of death (HR:1.96, 95%CI:1.20-3.18, P=0.007)

Conclusions: As patients with renal failure are susceptible to infections, special attention should be paid even after the post-COVID-19 pandemic. Increased awareness of hygiene practices can improve prognosis in patients with renal failure.

TH-PO1152

Incident Obstructive Sleep Apnea in Patients with Primary Aldosteronism following COVID-19 Infection

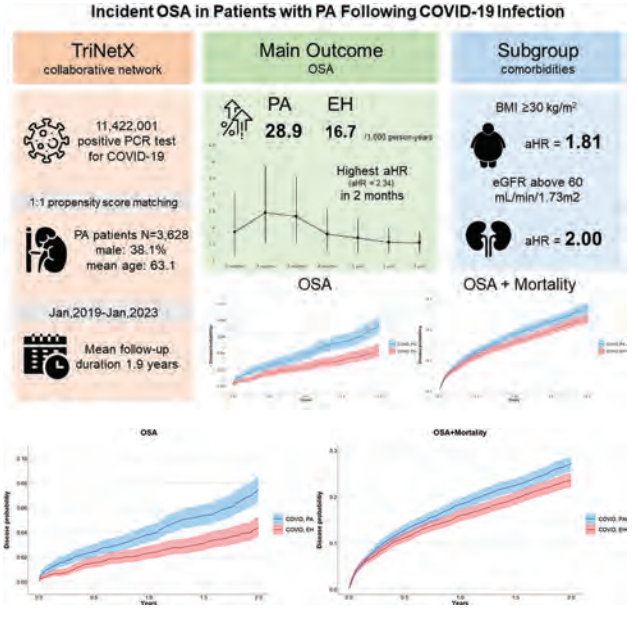
Wen-Kai Chu, Vincent Wu. *National Taiwan University Hospital, Taipei, Taiwan.*

Background: In the context of the COVID-19 pandemic, there is growing concern about the virus's effects on individuals with existing endocrine disorders such as primary aldosteronism (PA). This study explores the potential relationship between PA and the risk of developing obstructive sleep apnea (OSA) after a COVID-19 infection.

Methods: In this retrospective cohort study, we utilized data from the TriNetX database, covering the period from January 2019 to January 2023. We identified essential hypertension (EH) patients as the control group, employing 1:1 propensity score matching. The endpoints included incident OSA and all-cause mortality.

Results: Among 11,422,001 patients with PCR positive COVID-19, we identified 3,628 PA patients (mean 63.1 years old, male 38.1 %). After a medium follow up of 1.9 years, the rate of OSA was 28.9 per 1,000 person-years in PA patients compared to EH with 16.7. We showed a significant increase in incident OSA (adjusted hazard ratio [aHR] 1.58, p < 0.001) and mortality (aHR 1.12, p = 0.04) in PA patients than EH post-COVID-19. The horizon plot revealed that patients with pre-existing PA had the highest risk of OSA at 2 months (aHR = 2.34) post COVID-19. In subgroup analysis, PA patients with a high body mass index (≥30 kg/m^2) (aHR 1.81, p=0.001) or preserved kidney function (aHR 2.00, p<0.001) had increased OSA incidences post-COVID-19.

Conclusions: Our study underscores a notable rise in incident OSA among PA patients post-COVID-19, highlighting the imperative for diligent OSA screening, particularly among individuals with obesity or preserved kidney function.



TH-PO1153

COVID-19 Pandemic and Peritonitis in Patients with ESKD on Peritoneal Dialysis

Hye Soon Shin, Sun Moon Kim, Hyunjeong Cho, Ji Hye Kim, Mi Ran Park, Hye-Young Kim. *Chungbuk National University Hospital, Cheongju, Chungcheongbuk-do, Republic of Korea.*

Background: Coronavirus disease 2019 (COVID-19) pandemic has changed patients' behaviors and social relationships. However, the influence of COVID-19 pandemic on the peritonitis in patients on peritoneal dialysis (PD) remains to be elucidated. Thus, we investigated the impact of COVID-19 pandemic on the incidence and clinical outcome of peritonitis in end-stage kidney disease (ESKD) patients on PD.

Methods: A single-center retrospective study was conducted. Medical records of all the ESKD patients on maintenance PD were reviewed from Jan 2017 to Dec 2022: clinical characteristics, prescription of PD, pathogens, hospitalization, and clinical outcome of peritonitis. We compared the incidence and clinical outcome of peritonitis three years before (2017-2019) and after COVID-19 pandemic (2020-2022).

Results: A total of 572 medical records were analyzed. The incidence of PD-related peritonitis decreased after COVID-19 outbreak. The incidence of peritonitis was 0.187/patient-year in 2017-2019 and 0.120/patient-year in 2020-2022. The microbiologic features were not different. The most common pathogen of peritonitis were gram-positive bacteria. The proportion of peritonitis-related hospitalization and catheter removal associated with treatment failure did not differ between before and after COVID-19 pandemic.

Conclusions: This study suggests that during the COVID-19 pandemic the incidence of PD-related peritonitis was decreased whereas pathogens and hospitalization did not change.

TH-PO1154

Effect of RAAS Inhibitors in People with COVID-19: An Independent Participant Data Meta-Analysis

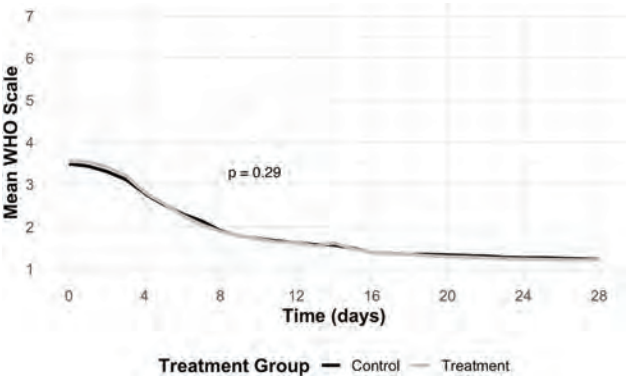
Tae won Yi,[1,2] Kylie-Ann Mallitt,[3] Arlen Wilcox,[2] Michael A. Puskarich,[4] Daniel Freilich,[5] Matthew Geriak,[6] Cecilia M. Shikuma,[7] Meg Jardine.[2] *[1]The University of British Columbia, Vancouver, BC, Canada; [2]NHMRC Clinical Trials Centre, Camperdown, NSW, Australia; [3]University of Sydney, Camperdown, NSW, Australia; [4]University of Minnesota Twin Cities, Minneapolis, MN; [5]Bassett Medical Center, Cooperstown, NY; [6]Sharp Healthcare, San Diego, CA; [7]University of Hawai'i at Manoa, Honolulu, HI.*

Background: SARS-CoV-2 infection is mediated by angiotensin-converting enzyme 2 receptors. Trials in different settings were initiated to test whether renin-angiotensin-aldosterone system inhibitors (RAASi) improved clinical outcomes in people with COVID-19.

Methods: We performed an individual participant data (IPD) meta-analysis of randomized controlled trials (RCTs) evaluating the effects of RAASi in people with COVID-19. The primary outcome of WHO Clinical Progression scale over 28 days was evaluated using a linear mixed model. All-cause mortality was evaluated with Cox proportional hazards.

Results: Six trials evaluating losartan, telmisartan, and candesartan were included, with sample sizes ranging from 12 to 787. Trials were conducted in the USA, Australia, and India; four were completed as planned, and 5 were placebo controlled. The 1,130 participants had a median age of 50 years and 38% were female. The majority of the cohort was Asian (73%) and Caucasian (16%). The median BMI was 25 kg/m^2, 29% had hypertension, 21% had diabetes, and 17% had a smoking history. The baseline mean WHO score was 3.6 in the RAASi arm and 3.5 in the control arm. Most participants resolved with a mean WHO score of 1.2 in the RAASi arm and 1.2 in the control arm at day 28, with no significant difference in WHO scale progression (Figure 1, p=0.29). RAASi did not affect overall mortality (26 deaths, event rate 0.04 and 18 deaths, event rate 0.03 in the RAASi and control arms respectively: HR 1.42 [0.77-2.64], p=0.261).

Conclusions: This IPD meta-analysis presents the largest randomized report of the effects of commencing RAASi for acute COVID-19. There is no evidence supporting a benefit for RAASi in COVID-19 patients.



TH-PO1155

Impact of COVID-19 Vaccination on Racial Disparity in COVID-19 Mortality from a National US Dialysis Provider

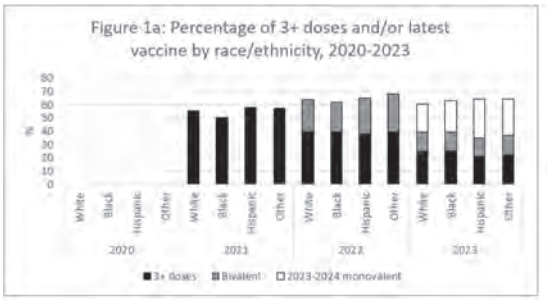
Monica Shieu,[1] Austin Gibson,[1] Nien Chen Li,[1] Harold Manley,[1] Antonia Harford,[1] Caroline M. Hsu,[2] Daniel E. Weiner,[2] Dana Miskulin,[2] Doug Johnson,[1] Eduardo K. Lacson.[1,2] *[1]Dialysis Clinic Inc, Nashville, TN; [2]Tufts Medical Center, Boston, MA.*

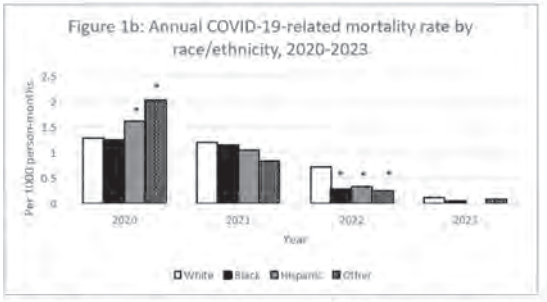
Background: The pandemic has negatively affected vulnerable dialysis patients especially minorities. We examined the impact of providing universal access to COVID-19 vaccines in dialysis clinics on COVID-19 mortality by racial/ethnicity (RE) group from a national provider.

Methods: Adult maintenance dialysis patients at Dialysis Clinic, Inc. from 2020-2023 were included. The percentage of 3+ doses and/or latest updated vaccine at the end of each year was examined. The outcome of interest was death with COVID as the primary cause within 90 days of diagnosis. Distribution of vaccine status among RE groups was analyzed with ANOVA. Change in mortality rate over the years and by RE groups were both assessed by linear regression.

Results: The cohort included 41,257 patients of White (42%), Black (37%), Hispanic (7%), and Other (14%) race. In 2020, White had the lowest mortality rates (1.3 per 1000 person-months) while Other (2.0) and Hispanic (1.6) had the highest rates (p<.001). All RE groups had similar percentages of 3+ doses and/or latest vaccine: 50-58% in 2021 to 60-64% in 2023 (p>0.08) (Fig 1a). Since COVID vaccines became available in 2021, mortality rates among all RE groups have decreased significantly (b=-0.45, p<.001) (Fig 1b). In 2022, mortality rate declined the least among Whites but was similar again in 2023.

Conclusions: With universal access to vaccines provided in the dialysis clinics, more than 50% of dialysis patients were vaccinated with 3+ doses and/or the latest vaccine. Mortality rate among all RE dropped significantly after the availability of COVID vaccines in 2021. Availability of vaccination in the dialysis clinics may have improved racial disparity in COVID-19. Maintaining equal access to vaccines may enable better outcomes and reduce disparities in this high-risk population, even beyond the COVID-19 pandemic.





White is the reference group within each year. *p<0.05. Since COVID vaccines became available in 2021, mortality rates among all RE groups have decreased significantly (b=-0.45, p <.001).

TH-PO1156

Four-Year Impact of the COVID-19 Pandemic on Mortality and Hospitalization Trends among Patients on Maintenance Dialysis from a National US Dialysis Provider

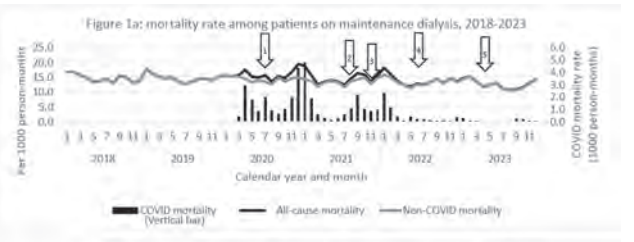
Monica Shieu,[1] Nien Chen Li,[1] Harold Manley,[1] Antonia Harford,[1] Caroline M. Hsu,[2] Daniel E. Weiner,[2] Dana Miskulin,[2] Doug Johnson,[1] Eduardo K. Lacson.[1,2] *[1]Dialysis Clinic Inc, Nashville, TN; [2]Tufts Medical Center, Boston, MA.*

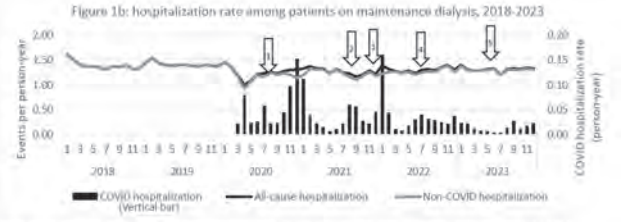
Background: Longitudinal trends in mortality and hospitalization rates during the COVID-19 pandemic period (2020-2023) vs. prior two years (2018-2019) among patients receiving maintenance dialysis from a national provider were described.

Methods: Adult maintenance dialysis patients at Dialysis Clinic, Inc. between 1/1/2018 to 12/31/2023 were included. Hospitalization stays over two midnights and death events were obtained from electronic medical record. COVID-19 hospitalization and death were defined as within 30 days and 90 days of a COVID-19 diagnosis, respectively.

Results: The study included 41,257 patients. All-cause mortality among prevalent patients receiving dialysis decreased by 15.4%, from 16.9 to 14.3 (per 1000 person-months) between 2018-2023, with a spike in 03/2020 when the pandemic started. Mortality peaked that winter (19.4 per 1000 person-months) until the availability of COVID-19 vaccines in early 2021 (Fig 1a). All-cause hospitalization rates decreased between 2018-2023. There was a sudden drop in hospitalization rates when the pandemic began (1.61 from 01/2018 to 1.18 03/2020 and 1.01 from 04/2020 per person-year); these rates never recovered to the overall rates observed prior to the pandemic (Fig 1b).

Conclusions: The pandemic has impacted mortality and hospitalization rates among patients on maintenance dialysis, with a drastic increase in all-cause mortality vs. a sudden drop in all-cause hospitalization when the pandemic started. All-cause mortality and hospitalization rates, 2018-2021, are lower than the rates in 2023 USRDS. The profound impact of vaccination in reducing severe outcomes from COVID-19 is evident. Strategies to maintain updated vaccination status to prevent COVID-19-related hospitalization and death in this high-risk population are warranted.





Numbered arrows indicate pandemic timepoints: 1 (pandemic started, national lockdown), 2 (COVID vaccines became available), 3 (Delta variant dominance period started), 4 (Omicron variant dominance period started), 5 (updated bivalent vaccine recommendation).

Tixagevimab-Cilgavimab for Breakthrough COVID-19 Prevention in Dialysis Patients: A Prospective Study

Suchai Sritippayawan,[1] Sarinya Boongird,[2] Thatsaphan Srithongkul,[1] Sethanant Sethakarun,[3] Jackrapong Bruminhent,[4] Sasisopin Kiertiburanakul,[4] Arkom Nongnuch,[2] Chagriya Kitiyakara.[2] *[1]Department of Medicine, Faculty of Medicine, Siriraj Hospital, Mahidol University, Bangkok, Thailand; [2]Division of Nephrology, Department of Medicine, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; [3]Bhumirajanagarindra Kidney Institute, Bangkok, Thailand; [4]Division of Infectious diseases, Department of Medicine, Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand.*

Background: Tixagevimab-cilgavimab (T/C), a monoclonal antibody for pre-exposure prophylaxis (PrEP), holds promise among immunocompromised individuals for preventing COVID-19. However, data on T/C effectiveness in the dialysis population is limited.

Methods: This multi-center, prospective study evaluated the impact of T/C as PrEP for breakthrough COVID-19 in vaccinated dialysis patients during the Omicron BA.2.75 and XBB variant surge. Patients were assigned to either the T/C group, receiving a single 150 mg/150 mg intramuscular dose, or an age-matched control group not receiving T/C. All participants were followed for a period of 6 months. The primary outcome was breakthrough COVID-19 rate. Secondary outcomes included COVID-19 related hospitalization, ICU admission, and mortality. Safety of T/C was assessed in the intervention group.

Results: A total of 200 participants (100 in the T/C and 100 in the control group) were enrolled. The mean age of participants was 66 years old, with over 80% on hemodialysis. At 6 months, the cumulative incidence of breakthrough infection did not differ significantly between groups (17% T/C vs. 15% control; p = 0.66). However, among those who developed breakthrough infections, the median (IQR) time to diagnosis tended to be longer in the T/C group compared to controls [4.9 (2.81–4.98) months vs. 1.96 (1.65–2.91) months; p = 0.08]. T/C administration significantly reduced COVID-19 related hospitalization rates (5.9% vs. 40.0%; p = 0.02) among participants with breakthrough infections. No significant differences were observed in ICU admission, intubation, or death rates from COVID-19. All reported T/C-related adverse events were mild and resolved within 7 days.

Conclusions: Breakthrough COVID-19 can occur in vaccinated dialysis patients receiving T/C during the Omicron surge; however, these patients are likely to experience fewer hospitalizations. Further research on other investigational monoclonal antibody or alternative prevention strategies is needed for this population.

RescuE pLAsma eXchange in Severe COVID-19 (RELAX Trial): A Multicenter Randomized Controlled Trial

Christian Nusshag,[1] Christian Morath,[1] Florian Kälble,[1] Claudius Speer,[1] Jan Meis,[2] Vedat Schwenger,[3] Thorsten Brenner,[4] Martin G. Zeier,[1] David Czock,[5] Markus A. Weigand,[6] Uta Merle.[7] *[1]Heidelberg University Hospital, Department of Nephrology, Heidelberg, Germany; [2]University of Heidelberg, Institute of Medical Biometry, Heidelberg, Germany; [3]Klinikum Stuttgart Katharinenhospital, Department of Nephrology, Hypertension and Autoimmune Disorders, Heidelberg, Germany; [4]University Hospital Essen, Department of Anesthesiology and Intensive Care Medicine, Heidelberg, Germany; [5]Heidelberg University Hospital, Department of Clinical Pharmacology and Pharmacoepidemiology, Heidelberg, Germany; [6]Heidelberg University Hospital, Department of Anesthesiology, Heidelberg, Germany; [7]Heidelberg University Hospital, Department of Gastroenterology, Heidelberg, Germany*.

Background: Evidence suggests a multi-level inflammatory syndrome in critically ill COVID-19 patients, resembling inflammatory, coagulopathic and autoimmune diseases. Plasma exchange (PE) is controversially discussed as a potential therapy. Here we report the first results of a multicenter, randomized controlled trial evaluating PE versus standard of care (SOC) in severe COVID-19.

Methods: Critically ill COVID-19 patients were enrolled in the RELAX trial (SOC n=33, SOC+PE n=34). Inclusion criteria were SARS-CoV-2-induced ARDS requiring mechanical ventilation, fever ≥ 38.5°C, D-dimer ≥ 2mg/dL, and dexamethasone therapy for at least two days. Patients received either SOC or SOC plus at least three PE treatments. The primary endpoint was 30-day mortality. Secondary endpoints included 60-, 90-, and 365-day mortality and procedure-related complications.

Results: The PE group underwent a median of 4 PE procedures (Interquartile range [IQR] 3-6), exchanging a plasma volume of 3.9L per treatment (IQR 3.7-3.9L). Hemodynamics and vasopressor support improved after PE treatments. Kaplan-Meier analysis showed no significant survival benefit at 30 days, but a significantly improved 90- and 365-day survival in the PE group (Figure 1). No severe complications occurred. Complications included allergic reactions (1.7%), hypertensive episodes (17.9%), hypocalcemia (75.7%), cardiac arrhythmia (0.6%), and catheter dysfunctions (1.7%). Allergic reactions were limited to skin rash, hypocalcemia was mild (1.1 mmol/L [IQR 1.0-1.1 mmol/L]), and arrhythmia occurred in one patient with prior episodes of atrial fibrillation.

Conclusions: Plasma exchange significnatly improved long-term survival in critically ill COVID-19 patients. Exploring potential mechanisms of PE on inflammation and coagulopathic drivers may have large clinical implications for other viral diseases and sepsis

Rebound and Protracted COVID-19 in Patients Receiving Rituximab for Autoimmune and Glomerular Diseases

Orhan Efe, Gabriel Sauvage, James L. Chung, Anushya Jeyabalan, Ayman Al Jurdi, Harish Shanthanu Seethapathy, Katherine M. Cosgrove, Karen A. Laliberte, John Niles. Vasculitis and Glomerulonephritis Center at Massachusetts General Hospital. *Massachusetts General Hospital, Boston, MA.*

Background: B cell depletion with rituximab abrogates antibody responses against SARS-CoV-2 and is associated with severe COVID-19. The risk and best treatment of rebound COVID-19 with recent strains of SARS-CoV-2 in patients using rituximab is unknown.

Methods: We conducted a retrospective study of patients who developed COVID-19 between 5/25/23-3/1/24 while receiving rituximab at Vasculitis and Glomerulonephritis Center at Massachusetts General Hospital. Patient characteristics, treatments, and outcomes of COVID-19 were evaluated.

Results: A total of 48 patients were included. The median age was 62 (IQR 47–72). 63% (30/48) had ANCA-associated vasculitis. Patients received a median of 5 (IQR 3–6) vaccinations and had 1 (IQR 0–1) prior infection. The median time from the last rituximab dose to COVID-19 was 4.2 (IQR 1.5–11.1) months, and 88% (42/48) had B cell depletion. 19% (9/48) had moderate, severe, or critical disease per NIH symptom scale and required hospitalization. 85% (41/48) received treatment, including nirmatrelvir/ritonavir (56%), remdesivir (21%), and IVIG (4%) (**Table 1**). One patient died. 38% (18/48) developed rebound or protracted (>30 days) COVID-19, of whom all had full B cell depletion, 56% (10/18) developed at least moderate COVID-19, and 67% (12/18) received treatment (**Table 1**). 50% (9/18) were treated with IVIG adjunctive to antivirals, which raised serum anti-SARS-CoV-2 antibodies (**Fig.1**) and improved all except one who died.

Conclusions: COVID-19 in B cell-depleted patients is associated with high rates of rebounding disease and hospitalization despite available treatments and vaccines. IVIG is effective as an adjunct strategy.

Population-Level Trends in Kidney Function before and during the COVID-19 Pandemic: A Province-Wide Retrospective Study from Alberta, Canada

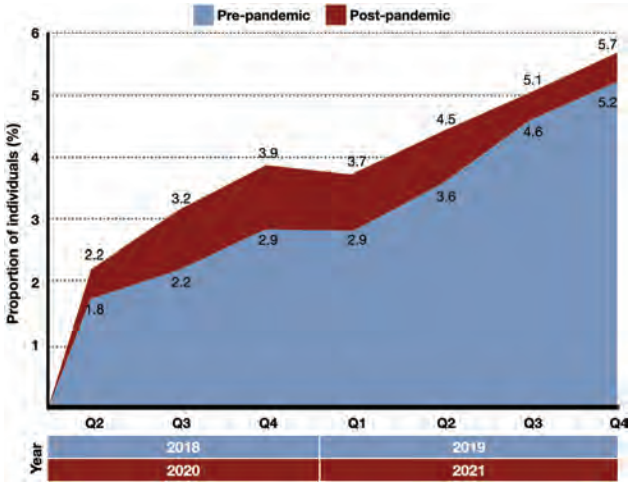
Somkanya Tungsanga, Aminu K. Bello, Gavin Oudit, Ikechi G. Okpechi. *University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada.*

Background: COVID19 infection is linked to the development of kidney-related adverse consequences via direct and indirect kidney injury. We explored changes in kidney function pre and during COVID-19 pandemic at population-level in Alberta, Canada.

Methods: This retrospective study using a province-wide administrative health data from Alberta, Canada, between 2018 and 2021. We included all adults residing in Alberta who had ≥1 annual visit to general practitioner and underwent outpatient serum creatinine tests. Data from each quarter of 2018-2019 was considered as pre-pandemic, while data from each quarter of 2020-2021 was considered during pandemic. Primary outcome was the proportion of individuals with eGFR decline, defined by sustained drop of ≥25% from baseline ≥3 months apart. Secondary outcome was the proportion of individuals with reduced eGFR who progressed to advanced stages of kidney dysfunction (eGFR <30 ml/min/m^2).

Results: A total of 214,496 and 214,103 individuals were included in the study, pre-pandemic and during pandemic, respectively. The mean age was 58.3±17 years and 43% were male. At baseline, 16.5% and 17.3% of individuals had a reduced eGFR of <60 ml/min/m^2 pre and during pandemic. The proportion of individuals with eGFR decline was higher during compared to pre pandemic era, particularly in the third and fourth quarter of 2020 (Q3: 3.2% vs 2.2%, Q4: 3.9% vs 2.9%) (Figure 1). Of those with reduced baseline eGFR, the proportion of individuals who progressed to advanced stages of kidney dysfunction was higher during the pandemic era.

Conclusions: This population-based, province-wide retrospective cohort showed a significant trend in the trajectory of kidney function decline with COVID-19 at the population level. These findings highlight the impact of the COVID-19 pandemic on kidney function, and a need for close monitoring of kidney function (particularly for the high-risk group) at the population level.



Proportion of individuals with eGFR decline in each quarter pre and during pandemic

TH-PO1161

Long-Term Kidney Function of COVID-19 Survivors: A Prospective Cohort Study

Heitor S. Ribeiro, Marcella M. Frediani, Geraldo F. Busatto, Carlos R. Carvalho, Lia J. Marçal, Guilherme P. Santa Catharina, Luis Yu, Emmanuel A. Burdmann. HCFMUSP COVID-19 Study Group. *Universidade de Sao Paulo Faculdade de Medicina, Sao Paulo, Brazil*.

Background: Long COVID encompasses symptoms that persist >2 months. Its effects on kidney function remain poorly understood. We aimed to investigate the long-term kidney function of COVID-19 survivors.

Methods: A prospective cohort of moderate and severe COVID-19 surviving patients was analyzed. Eligible patients were contacted at 6–9 months after hospital discharge. Kidney function at hospital admission, discharge, and follow-up was assessed by estimated glomerular filtration rate (eGFR; CKD-EPI serum creatinine race-free equation). Urinary albumin was evaluated at follow-up. Major Adverse Kidney Events (MAKE) at follow-up was defined as eGFR <60 ml/min/1.73 m^2, eGFR decline ≥40% from discharge, or albuminuria (>30 mg/L). MAKE-associated factors were investigated by binary logistic regression.

Results: We assessed 655 patients (55±14 years, 45% ≥60 years, 46% female, 50% black). At hospital admission, eGFR was 82.2 ml/min/1.73 m^2 (IQR:49.3–103.5). During hospital stay (median 15 days), peak SCr was 1.52 (IQR:1.02–3.26), 67% were admitted to intensive care units, 46% required intubation, 79% had acute kidney injury (35% at admission; 43% during hospitalization), and 14% needed dialysis. At hospital discharge, eGFR was 92.3 (IQR:64.3–107.4). After 7.8±1.6 months of follow-up, 14% of the patients showed eGFR decline >40% (median -5.4%; IQR:-26.7 – 30.2), and 16% of the patients showed eGFR <60 ml/min/1.73 m^2. MAKE was found in 39% of the patients. The factors independently associated with MAKE were older age (odds ratio [OR]=1.54, 95%CI:1.11–2.14) and peak SCr (OR=1.20, 95%CI:1.10–1.32).

Conclusions: Long-term kidney dysfunction was found in a large proportion of COVID-19 survivors, suggesting that kidney long COVID might be a significant health problem. Older age and peak SCr during hospitalization were independent risk factors associated with MAKE.

TH-PO1162

Impact of Gross Hematuria after COVID-19 mRNA Vaccination on Renal Outcome in Patients with IgAN

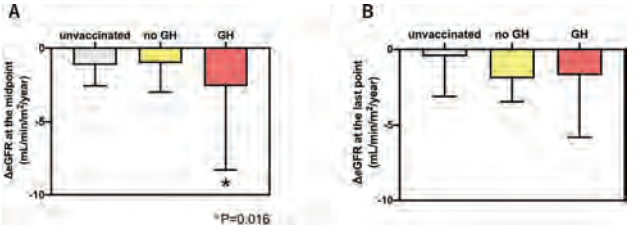
Shinya Yokote,[1,2] Nobuo Tsuboi,[1] Akihiro Shimizu,[1] Masahiro Okabe,[1] Kotaro Haruhara,[1] Saeko Hatanaka,[1] Takaya Sasaki,[1] Hiroyuki Ueda,[1] Takashi Yokoo.[1] *[1]Tokyo Jikeikai Ika Daigaku, Minato-ku, Japan; [2]Kawaguchi Shiritsu Iryo Center, Kawaguchi, Japan*.

Background: The long-term renal prognosis of patients with immunoglobulin A nephropathy (IgAN) presenting with gross hematuria (GH) after COVID-19 mRNA vaccination is unknown. In this study, we aimed to determine whether the post-vaccination GH was associated with long-term renal prognosis of patients already diagnosed with IgAN.

Methods: Japanese patients with biopsy-proven IgAN who visited four Jikei university-affiliated hospitals between 1 February 2021 and 20 September 2021 were recruited. The change in estimated glomerular filtration rate (eGFR) was calculated from the change in eGFR between the baseline and the observation point, divided by the number of days in the outpatient visit period and converted to 365 days. We investigated the relationship between post-vaccination GH and the change in eGFR (ΔeGFR). The factors associated with ΔeGFR were also assessed.

Results: A total of 442 Japanese patients with IgAN (median age, 51 years; 56% female; eGFR, 57.4 mL/min/1.73 m^2) were included. Patients were divided into three groups: unvaccinated group (n=25), post-vaccination GH group (n=25) and post-vaccination no GH group (n=392). ΔeGFR (ml/min/1.73m^2/year) at the midpoint, measured at a median of 597 days from the baseline, was lowest in the GH group at -2.61, compared with -1.16 in the unvaccinated group and -1.03 in the no GH group (Figure 1A, P=0.02). In a multivariable analysis, the presence of post-vaccination GH was associated with ΔeGFR at the midpoint observation (OR 3.01, P=0.04). However, at the last observation, measured at a median of 756 days from the base line, there was no difference in ΔeGFR between groups (-0.45 in the unvaccinated group, -1.93 in the no GH group and -1.72 in the GH group, Figure 1B) and no association between the presence of post-vaccination GH and ΔeGFR at the last observation.

Conclusions: This study suggests that the rate of decline in renal function over about 2 years was similar in IgAN patients with and without post-vaccination GH.



TH-PO1163

Metabolomics Profile of Hemodialysis Patients during the COVID-19 Putative Incubation Period

Gabriela Ferreira Dias,[1] Chenxi Fan,[2] Maggie Han,[1] Xin Wang,[1] Xiaoling Wang,[1] Hanjie Zhang,[1] Nadja Grobe,[1] Wensheng Guo,[3] Peter Kotanko,[1,4] Yuedong Wang.[2] Renal Research Institute's Laboratory Research. *[1]Renal Research Institute, New York, NY; [2]University of California Santa Barbara, Santa Barbara, CA; [3]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Hemodialysis (HD) patients are at high risk of developing serious complications from COVID-19. To the best of our knowledge, metabolic alterations occurring before COVID-19 diagnosis in the HD population have not been studied. Using untargeted metabolomics, we aimed to (a) identify early alterations in the metabolome of HD patients within the putative incubation period (PIP, defined for the purpose of this research as two weeks before COVID-19 diagnosis) and (b) evaluate their longitudinal metabolic profiles.

Methods: We analyzed routinely collected serum samples from HD patients from 60 days before and 60 days after a positive SARS-CoV-2 RT-PCR. Metabolites were extracted using cold methanol and subjected to reverse phase liquid chromatography/mass spectrometry (LC/MS). Metabolite identification was achieved with library matching (mass, retention time and MS/MS fragmentation spectra). A linear mixed-effects model was fitted to evaluate the change in metabolic feature levels from baseline phase (days -60 to -15) to the PIP (days -14 to 0). False Discovery Rate (FDR) adjusted p-value cutoff was 0.05.

Results: We analyzed 201 serum samples from a cohort of 30 HD patients (59.2 ± 13.3 years, 57% male). Untargeted analysis of these samples revealed 422 metabolic features, 15 of which showed alterations between baseline and the PIP (**Fig.1a**). Notably, α-guanidinoglutaric acid and sialic acid levels increased between baseline and PIP. (**Fig.1b**).

Conclusions: The metabolomics profile of HD patients is altered in the PIP of COVID-19. These molecular fingerprints - as well as α-guanidinoglutaric acid and sialic acid as potential biomarkers - could contribute to the development of predictive models for early COVID-19 detection in HD patients.

Funding: NIDDK Support

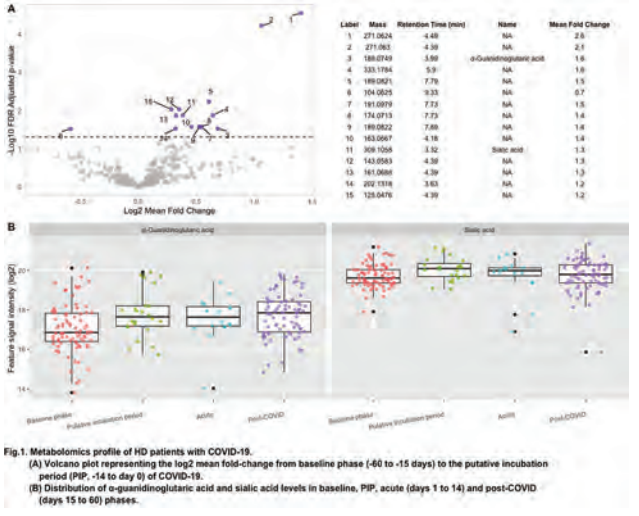


Fig.1. Metabolomics profile of HD patients with COVID-19.

Oral Biguanide Use Is Associated with Lower Incidence of AKI and Mortality in COVID-19 Patients: A Nationwide Study Using the Diagnosis Procedure Combination System in Japan

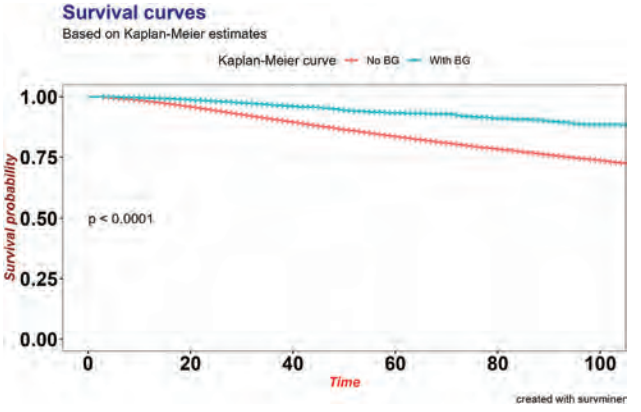
Mari Sugimoto, Hiroaki Kikuchi, Akihiro Hirakawa, Risako Mikami, Koji Mizutani, Eisei Sohara, Shinichi Uchida. Translational Systems Biology Center. *Tokyo Ika Shika Daigaku Daigakin Ishigaku Sogo Kenkyuka, Bunkyo-ku, Japan.*

Background: Recent studies have reported renoprotective effects of biguanides (BG), but their effectiveness in COVID-19 patients remains unclear.

Methods: From the 2021 and 2022 DPC inpatient databases, which cover the era following the development of COVID-19 vaccines, we extracted data on 106,161 COVID-19 patients aged 20 to under 70 years who also had diabetes treated with oral antidiabetic agents including biguanides, dipeptidyl peptidase-4 inhibitors (DPP-4), sodium-glucose cotransporter type 2 inhibitors (SGLT2), sulfonylureas (SU), alpha-glucosidase inhibitors (aGI), glucagon-like peptide-1 (GLP-1) analogs, thiazolidinediones (TZD). Using propensity score matching, based on variables such as age, sex, BMI, and chronic kidney disease stage, we compared two groups: those taking BG medications (n = 7997) and those not taking BG medications (non-BG group, n = 7997). The primary outcome was in-hospital mortality, and the secondary outcome was the incidence of acute kidney injury (AKI) during hospitalization. Logistic regression analysis and Cox proportional hazards models were used for analysis.

Results: The incidence of in-hospital mortality was significantly lower in the BG group (0.7%) compared to the non-BG group (1.2%) (p = 0.002). Similarly, the incidence of AKI during hospitalization was significantly lower in the BG group (0.7%) compared to the non-BG group (1.1%) (p = 0.025). Kaplan-Meier analysis showed a significantly better survival rate in the BG group (hazard ratio 0.675, 95% confidence interval 0.484-0.941, p < 0.0001).

Conclusions: In COVID-19 patients, oral biguanide use may be associated with a reduced risk of AKI and in-hospital mortality.



Kaplan–Meier estimates of all-cause mortality for COVID 19 patients with DM stratified by biguanide medication usage

The Duke Paired Undergraduate Mentoring Program in Uronephrology: PUMPing Up the Research Workforce

Jennifer D. Varner,[1] Loryn W. Dass,[1] Matthew A. Sparks,[2] Anna E. Williams,[1] Rasheed A. Gbadegesin.[1] *[1]Duke Children's Hospital and Health Center, Durham, NC; [2]Duke Health, Durham, NC.*

Background: There is a looming nephrology clinical and research and urology research workforce crisis. Attrition is high in the STEM career pipeline, especially among students from underrepresented minority backgrounds and women. Feelings of self-efficacy are important determinants for motivating a student for a career in science, and scientic identify formation is important for persistence in the field. We developed a pipeline program designed to instill feelings of self-efficacy and demonstrate the potential for students to become scientists in STEM fields through triangular mentorship. We describe short term outcomes from Duke PUMP in uronephrology.

Methods: PUMP is an R25 funded by the NIDDK that uses a triangular mentorship model with a named junior mentor providing day-to-day oversight coupled to a senior investigator providing overall mentorship. After the summer in person research, participants have professional development and networking sessions throughout the year and are invited to return for a second summer for project continuation. We used anonymously collected pre and post surveys to assess feelings of self-efficacy, identification as a scientist, and mentor support among the first set of participants. We conducted structured interviews to add additional insight to survey responses.

Results: We recruited students through partnership with STEM undergraduate and minority-serving institutions throughout the Southeastern U.S. Eleven students applied and four were invited to participate. All four participants are female, three are from underrepresented groups, and two are from HBCUs. The most common reasons for choosing to participate were "to gain practical experience for a future career" and "it sounded interesting." The largest positive change was seen in "I have a strong sense of belonging to the community of scientists." The largest decline in confidence was seen in "I am able to work through obstacles or challenges." The areas of largest reported benefit gain were in learning laboratory techniques and understanding how scientist work on real problems.

Conclusions: Short-term data from the inaugural cohort of Duke PUMP participants exhibited an increase in participant feelings of belonging to the scientific community which is predictive of persistence in scientific research.

ESCAPE! A Nephrology Themed Escape Room Curriculum for Internal Medicine Residents

Lauren Haggerty,[1] Tyler Woodell,[2] Nayan Arora.[1] *[1]University of Washington, Seattle, WA; [2]University of California San Diego, La Jolla, CA.*

Background: New generations of learners are increasingly utilizing non-traditional resources for educational purposes. In a survey of US Nephrology fellows, gamification demonstrated the greatest growth of any resource type. Escape rooms are team-based games in which players solve clues to "escape" a room within a time limit. We created a nephrology escape room curriculum (NERC) at the University of Washington, designed to engage internal medicine residents in nephrology topics and encourage interest in nephrology as a career.

Methods: We designed a NERC to accommodate approximately 50 internal medicine residents, divided into groups of 6-8, who completed each escape room simultaneously. We created two escape room sessions to teach acid-base disturbances and hyponatremia, topics identified in an internal survey as particularly challenging for incoming residents. Each session consisted of 30 minutes of content related lecture, followed by 1 hour of game play and debrief. We analyzed post-game survey results using descriptive statistics and thematic analysis of open-ended response questions.

Results: A summary of post-game survey responses is displayed in Table 1. Sample responses from the open-ended questions are shown in Figure 1. Thematic analysis revealed that residents learned and enjoyed the innovative design and team building. Constructive feedback included a request for more lecture time prior to the game.

Conclusions: Gamification, such as medical escape rooms, are gaining popularity and acceptance as effective teaching tools. Grounded in adult learning theory, our escape room curriculum can be utilized to disseminate Nephrology themed content in an active and enjoyable atmosphere, while promoting Nephrology as a subspecialty. Future iterations will include additional topics and employ more rigorous evaluation methods to determine effective content retention.

Did this increase your interest in Nephrology as a career?	10 (40)	15 (60)

"MORE ESCAPE ROOMS"

"Great experience! This was a fun way to work through acid base disorders and definitely enhanced my understanding."

"The questions were appropriately difficult and the clues were so well hidden!!"

"Great interactive experience. I would want to do it again."

"Helpful exercise. Working through the various hyponatremia labs was particularly helpful learning."

"Definitely a good use of in person time."

"This was the best academic half day ever!!!"

"Super engaging and I felt appropriately challenged with the difficulty level."

FR-PO003

A Qualitative Study of Trainee Experiences with Home Dialysis Education in US Nephrology Fellowship Programs

Wen Qing Wendy Ye,[1] Anjali B. Saxena,[2,3] Kerry Leigh,[4] Yuvaram N. Reddy.[5,6] *[1]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; [2]Stanford University School of Medicine, Stanford, CA; [3]Santa Clara Valley Medical Center, San Jose, CA; [4]American Society of Nephrology, Washington, DC; [5]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [6]Corporal Michael J Crescenz VA Medical Center, Philadelphia, PA.*

Background: Home dialysis has clinical benefits over in-center hemodialysis (HD) yet its use remains low. One barrier is a lack of comfort in clinical management among graduating nephrology fellows. Prior surveys suggest that fellows desire more training in home dialysis, yet little is known about the best approach to systematically enhance training. To identify opportunities to enhance in-person trainee experiences, we sought to better understand current home dialysis training experiences in US nephrology fellowship programs.

Methods: Using a qualitative approach, we conducted one-on-one semi structured interviews with nephrology trainees who attended Home Dialysis University (HDU) and the American Society of Nephrology Home Dialysis Virtual Education Program (ASN-HDU). Using a constant comparison approach, we developed and refined a codebook to identify themes describing participant's interest and exposure to home dialysis during training, and their comfort with managing patients on home dialysis.

Results: 10 semi-structured interviews were completed between Dec 2023 – Mar 2024. 5 of 10 participants attended the ASN-HDU program. Participants were from a variety of training programs and locations. We identified 3 main themes: (1) Home dialysis education during training is serendipitous rather than systematically built into existing curriculum. Opportunities to increase exposure to home dialysis exist, but trainees must be internally motivated to seek out these opportunities due to their serendipitous nature. (2) There is limited exposure to outpatient management of PD, resulting in a spectrum of comfort levels, which causes concern as trainees envision transitioning to independent practice. (3) Home HD exposure is sparse leading to an overwhelming lack of comfort.

Conclusions: Home dialysis training during nephrology fellowship remains serendipitous, suggesting the need for systematic efforts. There is limited exposure to outpatient PD and home HD resulting in a lack of comfort. Although the American Board of Internal Medicine requires 8 PD clinics to graduate, trainee experiences suggest that fellowship programs may not be able to meet this requirement. The results of our study should inform curriculum changes, while fellowship programs identify new opportunities to enhance trainee comfort in home dialysis.

Funding: Other U.S. Government Support

FR-PO004

Kidney Point-of-Care Ultrasonography (POCUS): Development and Evaluation of a Training Program for Nephrology Fellows

Tony Fang,[1] Sara S. Jdiaa,[2] Mohammad Azfar Qureshi,[3] Alireza Zahirieh,[3] Ann Young,[2] Darren A. Yuen.[2] *[1]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]Sunnybrook Health Sciences Centre, Toronto, ON, Canada.*

Background: Insonation is now considered the 5th pillar in physical examination. Despite its exciting potential, the uptake of POCUS in nephrology training curricula is slow. Our study aims to evaluate a locally developed program to train nephrology fellows to accurately perform a kidney POCUS scan to answer two important questions in the workup of kidney dysfunction in hospitalized patients: 1) is there urinary tract obstruction? and 2) are there small kidneys?

Methods: The program consisted of two workshops that included a didactic session and hands-on training session. Trainees identified the presence or absence of urinary tract obstruction in each native kidney or kidney allograft. They also performed a measurement of kidney length. POCUS findings were compared with the abdominal ultrasound exams performed in the medical imaging department. All nephrology fellows participating in the workshop completed pre- and post-workshop surveys to document self-reported comfort level with the use of renal POCUS. Patients were asked to complete a patient satisfaction questionnaire.

Results: A total of 56 native kidneys were assessed. Assessment of hydronephrosis compared to radiology-read kidney imaging reports revealed a specificity of 0.96. Assessment of small right and left kidney size showed a specificity of 0.81 and 0.75, respectively. A total of 32 transplant kidneys were assessed. Assessment of hydronephrosis and kidney allograft size revealed a specificity of 0.96 and 0.97, respectively. Post-workshop, 10 out of 11 trainees had an overall comfort level of 5 or greater out of 7 using POCUS for kidney assessment, in ruling out urinary tract obstruction and measuring kidney size. A total of 51 patients were surveyed. Most patients (71%) strongly agreed that their interaction with their doctors was improved with POCUS.

Conclusions: Our study shows that training programs can provide trainees with the confidence to acquire and apply skills in POCUS and the downstream benefits from patient satisfaction.

FR-PO005

Shared Decision-Making and Enhancement of Patient Autonomy in the Selection of Kidney Replacement Therapy: A Retrospective Study at a Single Center, Seoul National University Bundang Hospital

Julee You,[1] Eun-Jeong Kwon,[1] Ho Jun Chin,[1,2] Sejoong Kim,[1,2] Seokwoo Park.[1,2] *[1]Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [2]Seoul National University College of Medicine, Jongno-gu, Seoul, Republic of Korea.*

Background: In patients with CKD approaching end-stage kidney disease(ESKD), effective shared decision-making(SDM) plays a crucial role in selecting the most suitable renal replacement therapy(RRT). We examined the impact of the SDM program on the preference for kidney transplantation or peritoneal dialysis(KT/PD) over hemodialysis(HD), and its potential to reduce unplanned dialysis.

Methods: The SDM program commenced at Seoul National University Bundang Hospital, South Korea, in March 2021, as part of the SDM-ART trial. Adult patients predicted to reach ESKD within a year, were enrolled in the SDM. Participants received extensive education using materials and videos, followed by in-depth discussions with physicians based on self-assessment items at months 0 and 2, in contrast to standard brief consultations. Data were collected in a single center from CKD patients with an eGFR of less than 15 ml/min/1.73m^2 over 3 months, during March 2018 to March 2023, excluding those with contraindication for PD. Logistic regressions were used to compare the likelihood of selecting KT/PD over HD and the occurrence of unplanned dialysis before and after the SDM program. Physicians were categorized based on their involvement in the SDM, and the interaction between SDM implementation and physicians' participation was analyzed.

Results: Among 556 patients starting RRT, 34.0% chose KT/PD, while 41.7% underwent unplanned HD with central venous catheters before long-term RRT. Before SDM, there was no significant difference in the preference for KT/PD vs HD between physicians who participated in SDM and those who did not. However, post-SDM, patients under SDM-participating physicians significantly favored KT/PD (OR, 4.24; 95% CI, 1.29-14.50), unlike those under non-participating physicians(Table 1). SDM could not significantly reduce unplanned dialysis in this cohort.

Conclusions: Our SDM program demonstrated a significant shift in the preference for RRT modality towards KT/PD, highlighting the critical importance of overcoming informational barriers.

Table 1. Impact of SDM on choosing KT/PD over HD, by physician participation, before and after SDM implementation.

		Model 1*		Model 2†		Model 3‡	
SDM	Participation	Odds ratios (95% CI)	*P*-value	Odds ratios (95% CI)	*P*-value	Odds ratios (95% CI)	*P*-value
Before	No	1 (ref)		1 (ref)		1 (ref)	
	Yes	1.05 (0.69-1.57)	0.830	1.08 (0.66-1.77)	0.755	1.34 (0.73-2.46)	0.337
After	No	0.53 (0.26-1.02)	0.070	0.41 (0.10-1.65)	0.203	0.32 (0.07-1.40)	0.127
	Yes	4.09 (1.71-10.19)	0.002§	5.41 (1.87-16.39)	0.002§	4.24 (1.29-14.50)	0.019§

FR-PO006

Innovating Nephrology Point-of-Care Ultrasonography Education: Artificial Intelligence-Assisted Curriculum Integration with Human Expert Feedback Loops

M. Salman Sheikh, Kianoush Kashani, Charat Thongprayoon, James R. Gregoire, Iasmina Craici, Wisit Cheungpasitporn, Fawad Qureshi. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Point-of-care ultrasound (POCUS) education is crucial for nephrology fellowship programs to enhance timely diagnostic accuracy, procedural guidance, and patient management. Integrating a comprehensive POCUS curriculum is essential for advancing educational quality and preparing fellows for effective clinical practice in a timely manner. This quality improvement project involved experts using AI tools to develop a Nephrology POCUS curriculum.

Methods: An AI-assisted curriculum development process was conducted at the Mayo Clinic Minnesota Nephrology Fellowship Program in April 2024. The process involved multiple stages of feedback and refinement using several AI models, including GPT-4.0, Claude 3.0 Opus, Gemini Advanced, and Meta AI with Llama 3. GPT-4.0 generated initial curriculum drafts, while other AI agents provided iterative feedback for improvement. Finally, blinded Nephrology POCUS experts provided insights and expertise to refine the AI-generated curriculum further.

Results: The refinement process included 12 ChatGPT-4.0 revisions and a 29 communications across four AI tools, encompassing initial feedback, subsequent revisions, and final approvals from the AI tools. It yielded in a curriculum with broadened core topics, educational methods, assessment mechanisms, and integration into rotations. POCUS experts provided positive and constructive feedback, expressing satisfaction with the overall curriculum while offering suggestions for improvement. These suggestions included placing more emphasis on using POCUS for assessing fistulas and grafts, making volume assessment open-ended, structuring training to progress fellows from novice to expert, and utilizing Qpath software for mentored scans. Experts also questioned the inclusion of specific procedures and suggested pursuing certification through ASDIN.

Conclusions: The AI-assisted project effectively developed a comprehensive Nephrology POCUS curriculum at the Mayo Clinic Minnesota, significantly enhancing the educational offerings of the fellowship program. Integrating expert feedback, the curriculum emphasizes core POCUS applications, educational diversity, and robust assessment techniques. This innovative approach melds expert insights with AI capabilities, promising substantial improvements in POCUS education.

FR-PO007

A Multicenter Survey on Artificial Intelligence in Nephrology Education: Insights from Mayo Clinic Fellows

M. Salman Sheikh,[1] Charat Thongprayoon,[1] Iasmina Craici,[1] Fawad Qureshi,[1] Michael A. Mao,[2] Musab S. Hommos,[3] Mary B. Prendergast,[2] Sumi Sukumaran Nair,[3] Kianoush Kashani,[1] Wisit Cheungpasitporn.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Mayo Clinic in Florida, Jacksonville, FL; [3]Mayo Clinic Arizona, Scottsdale, AZ.*

Background: Artificial Intelligence (AI) has the potential to support clinical practice, medical education, and research. This study aimed to describe current perceptions and utilization of AI among nephrology fellows in three programs, and perform needs assessment for an educational intervention focused on AI learning.

Methods: An online survey was sent to 23 learners including fellows in general nephrology, kidney transplant, and onco-nephrology at the Mayo Clinic's three sites: Minnesota, Arizona, and Florida. The survey evaluated the current state of AI perceptions, utilization, and integration in practice. It also identified attitudes toward AI training, and perceived barriers to AI adoption in nephrology fellowship education.

Results: Of the 23 trainees, 21 completed the survey (response rate of 91%). The survey revealed that 76% of respondents have never or rarely used AI in their clinical or research activities, and none had formal AI education. However, respondents expressed a strong acknowledgment of AI's significance within nephrology, with 76% of respondents rating AI's current relevance as moderately to highly relevant to the field and 76% of fellows expressed moderate to high interest in receiving targeted AI. The majority of trainees identified interactive workshops as the preferred method of delivering AI training. The majority of fellows identified limited knowledge as the primary barrier to AI adoption. Optimism about AI's potential in nephrology was pronounced, especially for predictive modeling (86%) and diagnostic imaging (81%). However, confidence in AI for clinical decision-making remained cautious, with 33% neutral and 48% uncertain.

Conclusions: The findings underscore a significant interest among nephrology fellows in AI education, along with a critical need for formal education and training. The enthusiasm for AI's potential contrasts with a cautious perspective towards its current use in clinical decision-making, highlighting the necessity for educational initiatives that bridge the knowledge gap and foster confidence in AI technologies in Nephrology fellowship.

FR-PO008

How Education Affects Treatment Decision-Making: Novel Mechanistic Insights into Patients' Knowledge-Seeking and Psychological Changes

Rebecca Campbell-Montalvo,[1] Darin Ftouni,[1,2] Popy Shell,[1] Shobha Subhash,[1] Kailyn Pearce,[1] Ashutosh M. Shukla.[1,2] *[1]VA North Florida South Georgia Veterans Health System, Gainesville, FL; [2]University of Florida, Gainesville, FL.*

Background: KRT-directed comprehensive pre-kidney failure education (CoPE) is a basic necessity to increase informed home dialysis use. Existing cognitive behavior theories and patient-level data suggest that CoPE may enhance knowledge, behavioral capacity, and self-efficacy to improve self-management and health outcomes. However, mechanistic effects of CoPE on these intermediate and patient outcomes have not been articulated.

Methods: To inform on these mechanistic effects, we draw on data from 42 of 511 Veterans participants of TEACH-VET, a randomized trial aimed to assess the effects of CoPE on a variety of outcomes including informed dialysis decision-making. These qualitative interviews were designed under Theoretical Domains Framework (TDF) – a metatheory involving a range of factors impacting health behavior and focused on participants' perspectives on educational content of CoPE and treatment decisions about home dialysis (HoD). Interviews were thematically analyzed, grounded in the TDF as well as Cultural Model Theory. Key social-psychological mechanisms involved in decision making were elucidated through qualitative modeling.

Results: We found novel mechanistic insights into how people understand and think about illness and treatment in ways that motivate their decisions. Specifically, we found that CoPE impacted HoD selection by prompting participants to seek additional knowledge and spurring a range of psychological changes (Figure 1). These changes include new feelings of optimism about treatment, belief in one's treatment capabilities, increased confidence in decision making, and feelings of security with care provided by the VA. Knowledge seeking and psychological changes ushered participants to plan for the future and make treatment decisions, supporting better management of CKD and kidney health outcomes.

Conclusions: This complex modeling identifies new aspects of how education impacts patient decision making which enhances our understanding and informs the design of patient education programs and informs future research.

FR-PO009

Development of Entrustable Professional Activities in Adult Nephrology Fellowship Training

Maria-Eleni Roumelioti, Namita Singh, J. Pedro Teixeira, Christos Argyropoulos, Hayley Israel, Raja Ravender, Zan Shareef. *University of New Mexico Health Sciences Center, Albuquerque, NM.*

Background: Entrustable Professional Activities (EPAs) are units of observable work that a competent healthcare professional does in everyday practice. EPAs explicitly build on the principles of competency-based training and assessment and serve as means to translate competencies into clinical practice. To our knowledge there are no established EPAs for US nephrology training programs. We aim to develop a list of EPAs that represent the scope of nephrology practice.

Methods: An initial list of EPAs was developed and refined by the research group using a modified Delphi method. The panel (study participants) included 9 nephrologists (8 faculty, 1 fellow). Responses were given on a 5-point Likert scale and agreement was reached if (A) and (B) were met: (A) mean ≥4 with a SD<1; (B) >75% of respondents rated the item ≥4. After agreement EPAs that scored poorly were excluded from the next Delphi round. The panel provided additional comments and feedback on which EPAs to prioritize and how to proceed with implementation.

Results: Our research group (4 attendings, 1 researcher, 2 fellows) met 3 times and developed an initial list of 25 EPAs covering 10 fields in everyday nephrology practice. After 3 Delphi rounds and revisions, 22 remaining items were established as final EPAs. These EPAs will be linked to target competencies and will serve as a list of training goals to be reached by renal fellows during the implementation and evaluation phase of the study. All panel members had prior experience with clinical work and renal fellowship training (**Table**). Most members believed that renal fellows should have increased exposure to chronic kidney disease and dialysis clinics, should use lay medical terminology, and should treat patients holistically.

Conclusions: Graduating renal fellows must be prepared to meet specific standards, including cultural competence, safety, leadership, and professional development. The EPAs represent the scope of nephrology practice and will facilitate future educational research and curriculum development.

Participants' Characteristics (n=9)

Age (mean ±SD)	47.2 (±8.7)
Females (%)	44.4
Attendings (%)	88.9
Years of clinical experience (academic and/or private) (mean ±SD)	13.7 (±9.97)
Fellows (%)	11.1

FR-PO010

Nephrology Program Director and Fellow Home Hemodialysis (HHD) Curriculum Survey

Nupur Gupta,[1] Andrew J. Howard,[2] Christina M. Yuan.[2] [1]*Indiana University School of Medicine, Indianapolis, IN;* [2]*Walter Reed National Military Medical Center, Bethesda, MD.*

Background: Home hemodialysis (HHD) patients are a minority of those receiving chronic dialysis, and unevenly distributed geographically. Nephrology fellows may not encounter many (if any) HHD patients. The Accreditation Council for Graduate Medical Education (ACGME) requires fellows receive enough HHD training to achieve competence. We performed a survey of US Nephrology program directors and their fellows regarding their HHD curriculum.

Methods: Anonymous on-line survey (12/4/2023-2/4/2024) of 150 US nephrology program directors, who were asked to forward a survey link to their fellows, and indicate the number of fellows to whom they forwarded the link.

Results: 55 program directors responded (37%), 80% completed the survey. 37 forwarded the survey to their fellows (25% of US programs). Respondent program directors and fellows were from programs of similar size and geographic distribution to those nationally. 93% (42/45) of programs had an HHD curriculum or were developing one. 86% (37/43) reported that fellows attend a longitudinal HHD clinic either routinely or during a block rotation. The predominant barrier to incorporating HHD into the curriculum was lack of HHD patients in the area (50%). 237 fellows were forwarded the survey link; 53 (22%) responded and 50/53 completed the survey (94%). 80% (40/50) reported receiving HHD training and of those 24/50 (48%) had followed HHD outpatients. Those who saw HHD outpatients (n=24) were more likely than those who did not (n=26) to be confident in managing specific HHD tasks, and perceived a significantly greater degree of preparation to care for HHD patients after graduation (p=0.0003. Fisher exact test).

Conclusions: The majority of nephrology programs have or are developing an HHD curriculum, but the greatest barrier was lack of HHD patients available to the program. Fellows who had experience following HHD outpatients were significantly more likely to be feel prepared and confident in their ability to care for HHD patients. Disclaimer: The views expressed are those of the authors and do not necessarily reflect the official policy of the Department of Defense or the U.S. government.

FR-PO011

A Survey of Pregnancy and Parenthood among Physician Trainees: How Do Nephrology Fellowships Compare?

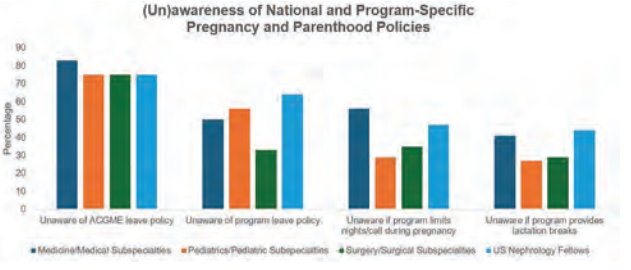
Angelina M. Dixon, Allison H. Martin, Braidie L. Campbell, Anna Ostrow, Jessica B. Kendrick. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: National policies outlining parental leave for physician trainees are inconsistent. We recently demonstrated that most US nephrology fellows are unaware of national and program-specific parental leave policies and pregnancy and lactation accommodations. Here, we examine awareness of current policies in physician trainees across all fields at the University of Colorado (CU) to determine how their perspectives compare to those of US nephrology trainees.

Methods: An anonymous, on-line survey of CU physician trainees (residents and fellows) was undertaken from February to May 2024.

Results: 223 physician trainees submitted the survey (23% male, 76% female, 0.5% nonbinary). The majority of fellow respondents were unaware of individual program specific (47%) or ACGME (78%) mandated parental leave policies. 41% of trainee respondents were unsure if their program limited night shifts or shifts greater than 24 hours for pregnant trainees and 33% reported they were unsure if their program provided lactation accommodations. Almost 70% of trainees agreed or strongly agreed that they would avoid a pregnancy during residency/fellowship due to concern that they would have to extend their training. Still, 59 trainees had children during training. When asked about the duration of parental leave taken during training, trainees most frequently responded (30%) that they received 6-8 weeks of family leave. 80% of trainees who had children prior to or during training reported their career plans did not change as a result of pregnancy or parenthood. These results were similar to what was seen in US nephrology fellows (Figure).

Conclusions: Most physician trainees report that they would avoid pregnancy during training and are unaware of parental leave policies and pregnancy/lactation accommodations that would support pregnancy and parenthood. This lack of awareness is consistent across all training programs, including nephrology programs.



(Un) awareness of national and program-specific policies for pregnancy/parental leave among physician trainees at CU and nephrology fellows across the US

FR-PO012

Improved Management of Nephrological Emergencies through Immersive Technology

Philipp G. Russ, Muriel L. Morgenschweis, Jonas Einloft, Hendrik L. Meyer, Simon Bedenbender, Ivica Grgic. *Philipps-Universitat Marburg Fachbereich Medizin, Marburg, Germany.*

Background: Medical emergencies require rapid initial assessment and immediate action. Many medical students and young physicians often feel overwhelmed in such situations and report inadequate preparation for real-world emergencies. Immersive technologies, such as Virtual Reality (VR), offer new opportunities for realistic simulation training with significant potential in practice-based medical education, including emergency management. To investigate its effectiveness in the field of nephrology, we selected rapidly progressive glomerulonephritis (RPGN) as a well-known prototypical nephrological emergency, which requires swift action to avert life-threatening complications.

Methods: Using an innovative approach, we conducted a single-center study employing a self-designed, 3D virtual, interactive RPGN case represented by an avatar patient on the VR simulation platform STEP-VR, which we recently developed and validated in partnership with ThreeDee. We compared the competencies of third-year medical students before and after VR training with those of a control group. Additionally, we evaluated the impact of synchronous tutorial support during the training on learning outcomes.

Results: A total of 275 medical students participated in the study, with an average age of 25.4 years; 64% of the participants identified as female (n=176). The VR training group showed significantly improved outcomes in the diagnosis of RPGN, based on clinical presentation, laboratory diagnostics, urine dipstick, and urine sediment analysis (p<0.0001 for all comparisons). The VR group also significantly outperformed the control

group in managing RPGN-associated complications, such as severe hyperkalemia and metabolic acidosis ($p < 0.0001$). Additional guidance by a human tutor led to further improvements in diagnosis and treatment performance.

Conclusions: Our findings highlight the potential of immersive technology as an effective medium for enhancing clinical nephrological knowledge and skills. Specifically, the use of realistic and practice-oriented VR simulation training in medical education and training could lead to improved competence in handling nephrological emergencies and, consequently, enhance the quality of patient care. Taken together, VR may be an effective, cost-efficient, and scalable alternative to traditional simulation methods.

FR-PO013

Is Artificial Intelligence (AI) the Missing Member of the Fellowship Interview Panel?

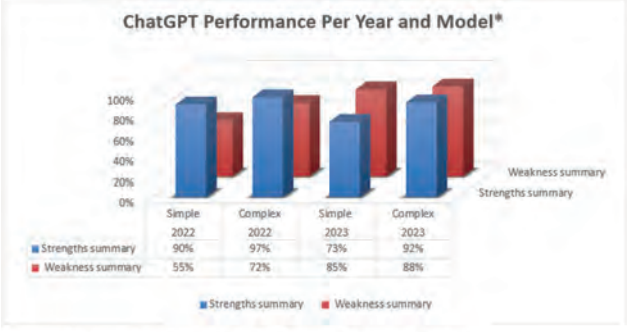
Musab S. Hommos, Bhavna Bhasin-Chhabra, Mira T. Keddis. Mayo Clinic Arizona Nephrology Fellowship. *Mayo Clinic Arizona, Scottsdale, AZ.*

Background: Creating an objective summary of the interviewers' feedback to rank fellowship applicants is a challenging task that can be adversely affected by implicit bias. In this study, we examined the performance of ChatGPT (CGPT) in summarizing interviewers' evaluations of the applicants and compared the CGPT-generated ranking to our rank list.

Methods: For each applicant, 4 faculty independently generated evaluation narratives, each about 100 words. PD use these narratives to create a list of strengths & weaknesses for the ranking meetings. In this study, we provided de-identified narratives to CGPT4.0. We compared the performance of two prompts: a simple prompt that requested CGPT to summarize the strengths and weaknesses and rank applicants without program-specific details and a complex prompt that described our program's mission, aims, and desired applicant attributes. We used data from the 2022 & 2023 seasons. Spearman rank correlation coefficient was used to compare CGPT rank list to the final rank list by the program. The study was deemed exempt by IRB.

Results: There were 29 applicants from 2022 and 26 from 2023. Narratives from 2022 were about 50% shorter. The performance of the complex CGPT prompt was superior to the simple prompt in detecting strengths and weaknesses and in the final ranking. **The complex prompt-generated rank list had a correlation coefficient with our rank list of 0.95 ($p<0.001$) for 2022 and 0.99 ($p<0.001$) for 2023. The simple prompt correlation was 0.85 ($p<0.001$) and 0.83 ($p<0.001$).** See Figure 1

Conclusions: A longer evaluation narrative and more complex prompt that included the program-specific information resulted in an excellent performance by CGPT in summarizing the applicants' strengths & weaknesses, which resulted in a final rank that correlated very closely with the program's rank list. AI limitations included missing subtle applicant attributes that a program may consider necessary but not defined in the prompt. Future research is needed to study the effect of AI-assisted ranking on implicit bias during ranking.



*compared to manual summary of evaluation forms by the program director

FR-PO014

Enhancing Trainee Orientation with Artificial Intelligence (AI)-Powered Gamification

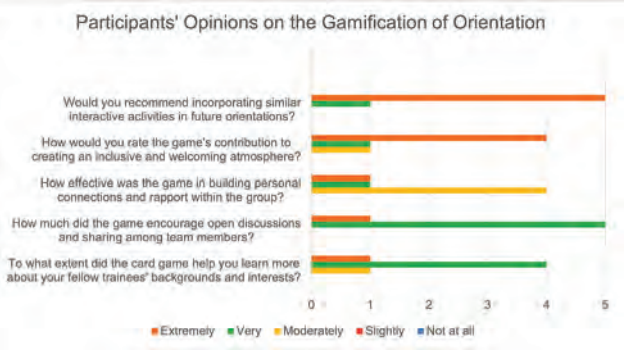
Paavana Varanasi, Musab S. Hommos. *Mayo Clinic Arizona, Scottsdale, AZ.*

Background: Every summer, training programs welcome new trainees and complete their onboarding process, which serves multiple purposes: equipping trainees with valuable information like program expectations, delivering mandated knowledge, and fostering camaraderie. However, orientation can often be overwhelming, with information overload and numerous online modules. This educational study explores the use of conversational AI in building cohesive teams and streamlining the orientation process.

Methods: The authors developed a customized game using ChatGPT. Two sets of cards were created: one with questions regarding the fellowship program, the institution, training expectations, medical knowledge concepts, and historical facts from the field of nephrology and one with "getting to know you" questions. The ChatGPT prompt was designed to generate both sets of cards after being provided with program information available in the training handbook. The game was first trialed with incoming general and transplant nephrology fellows and the respective program leadership. Game content and rules were refined to include more desired information and ensure trainees answered questions from both card decks.

Results: An anonymous online survey was administered to the participants with a 67% response rate. The survey revealed that 100% of respondents thought the game fostered a stronger sense of belonging and teamwork among the participants. The game was also highly effective, based on high ratings, in facilitating learning about trainees' backgrounds and interests, encouraging open discussions among team members, building rapport within the group, creating an inclusive and welcoming atmosphere, and was strongly recommended for future orientations.

Conclusions: This case demonstrates the potential of conversational AI to enhance medical education by creating interactive orientation tools. Developing this game took approximately 30 minutes over three sessions and was well-received by both trainees and program leadership. AI can improve various aspects of training program orientations and further integration is encouraged.



FR-PO015

Interdisciplinary Point-of-Care Ultrasonography (POCUS) Program Led by Nephrology

Eduardo Pino Domenech, Maria V. DeVita, Andrew A. Moses. *Lenox Hill Hospital, New York, NY.*

Background: POCUS has been touted as the fifth pillar of the physical exam: inspection, palpation, percussion, auscultation and insonation. The use of POCUS in nephrology has been growing throughout the country, and now Nephrology has a unique position to increase the use of POCUS in both nephrology and medicine. We describe the POCUS program at our institution unifying various programs under one umbrella.

Methods: One lead nephrologist has developed a curriculum and POCUS has been taught as part of the nephrology training curriculum since 2021. Bi-weekly hour-long sessions with a combination of didactics, hands on sessions, and image reviews to ensure both technical proficiency and diagnostic capability has been created. This is in concordance with ASDIN guidelines for certification. Our target is that Nephrology fellows will become certified 12-18 months into their fellowship and subsequently become superusers and help teach the rising first years and internal medicine residents.

Results: In order to teach the residents, a bimodal approach was used with the critical care faculty teaching weeklong boot camps for interested and available residents. Alternatively, interested residents who were unable to attend the weeklong program, were given similar didactics and hands on teaching spaced out over the year by nephrology POCUS faculty. This increased the total number of residents who had POCUS exposure and improved usage of POCUS. At present, we have 32 house-staff involved. We have also started a parallel program with several hospitalists, with the same intention of establishing 1-3 super users. Presently we are using 8 Phillips Lumify devices, expanded from only a single POCUS device outside of the ICU in 2020. As we have more users, utilizing the resource effectively becomes even more important.

Conclusions: We feel that Nephrology led POCUS initiatives are important because it puts the probe in the hands of users who need to optimize the tools used to master volume status and are most familiar with the physiology of many hospitalized patients. By leading POCUS initiatives throughout the hospital nephrologists can be leaders in guiding internists into the future. With nephrology championing the education of house-staff our objective to expand the program so that all of our nephrology fellows with be superusers, and expand the training to other departments.

FR-PO016

Kahoot Is a Hoot: Gamification of Ambulatory CKD Lectures for Internal Medicine Residents

Kevin Labagnara,[1] Gary Tan,[1] Farhana Begum,[1] Aarika Mehrishi,[2] Kenar D. Jhaveri.[1] *[1]Northwell Health, New Hyde Park, NY; [2]Jericho High School, Jericho, NY.*

Background: The time constraints of medical residency make it challenging to keep learners engaged while covering essential topics. Emerging literature suggests gamification may be an effective supplement, and in some cases an alternative, to the traditional lecture. We aimed to study how game-based lectures affect resident content mastery by utilizing the online trivia-based platform Kahoot.

Methods: A single-center, prospective study was conducted on categorical internal medical residents during their ambulatory CKD lecture series. Residents received either a traditional in-person lecture or a similar version gamified with the Kahoot platform, followed by pre- and post-lecture surveys including board-style questions on CKD management. Those who completed both pre- and post-lecture surveys were included in the final sample. Statistical analysis utilized the Mann Whitney U and Chi-Square tests, along with logistic regression to control for the training year.

Results: 62 residents completed both surveys, of which 36 (58%) received the gamified lecture. 40% (n=25) were in their first year of training, while 2nd and 3rd years comprised 34% (n=21) and 26% (n=16) of respondents respectively. 58% (n=36) scored higher on the post-survey, while the majority reported higher confidence (n=39, 63%) and comfort (n=46, 74%) in managing CKD. When analyzing changes in pre- and post-lecture survey metrics, no significant differences were noted between traditional and gamified groups in total score and percent (p=0.45), confidence (p=0.18), or comfort (p=0.54) (Table 1). Furthermore, no differences were noted when controlling for the PGY training year (OR=0.84, 95% CI: 0.28-2.49, p=0.74).

Conclusions: Our study shows that when used as a supplement, Kahoot may be an effective method to engage learners while maintaining lecture content and quality. Further studies are needed to assess its effectiveness in a virtual setting.

Figure 1: Baseline characteristics between traditional and gamified cohorts (A) with associated bar graph comparing mean pre- and post-survey total score (B). Chi-square used for categorical variable analysis and Mann-Whitney U for Score, Percent, and Likert-Scale response analysis. P value of <0.05 used to indicate statistical significance

Development, Implementation, and Assessment of an Innovative Kidney Pathology Curriculum

Douglas R. Farrell, Layla Fattah, Samira S. Farouk. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: 33% of nephrology fellows indicated an interest in additional pathology education on a 2016 education needs assessment performed by ASN. Fellows at our institution expressed this interest despite scoring higher than the national median on the 2023 In-Training Exam pathology section. WhatsApp®, a free messaging application for mobile devices, has been shown to be an effective educational tool. We designed and implemented a WhatsApp®-based pathology curriculum and hypothesized that it would be well-received and increase confidence in pathology skills.

Methods: A pre-survey of 18 questions was administered to nephrology fellows prior to initiation of the WhatsApp® curriculum. It included questions addressing the quality of their perception of pathology education, interest in supplemental education, confidence in the subject, and brief knowledge assessment.17 nephrology fellows at Mount Sinai Hospital were invited to join a WhatsApp® group. The chat was designed to be used only for pathology education. Once the curriculum began, the peer educator presented a pathology image weekly, followed by a multiple-choice question (MCQ). Participants submitted answers to the MCQ via an anonymous online submission form. On Friday of each week, a comprehensive slide was shared with pathology educational content which included the answer to the MCQ. A post-survey was sent to all nephrology fellows after the 24-week curriculum.

Results: 5/17 responded to the pre-survey (29%), of which all were senior fellows. All expressed an interest in additional pathology education. On average, 13/14 fellows read the content, and 5/14 submitted MCQ questions weekly. 36% responded to the post-survey. All respondents strongly agreed that content was relevant. All respondents strongly agreed/agreed that WhatsApp® was an effective learning platform and reported higher confidence in pathology skills. The mean rating of the program was 8.2/10. All respondents answered that they would recommend the curriculum to other fellows.

Conclusions: Nephrology fellows want more pathology education and are not confident in their pathology skills. A supplemental pathology course is feasible utilizing WhatsApp®. Nephrology fellows rated WhatsApp® as an effective medium for kidney pathology education, report high satisfaction with its curriculum, and report higher confidence in pathology because of the curriculum.

FR-PO018

Curricular Innovation to Improve Performance on Internal Medicine In-Training Exam Nephrology Items

Gauri Bhutani,[1] Samantha J. Strennen,[2] Sarah L. Floden,[1] Andrew Coyle,[1] Suzanne M. Norby.[1] *[1]University of Wisconsin System, Madison, WI; [2]University of Minnesota Twin Cities, Minneapolis, MN.*

Background: Performance on the Internal Medicine In-Training Exam (IM-ITE) is one method by which both resident knowledge and residency program effectiveness is measured. In 2020, our program's aggregate score for all post-graduate years (PGYs) on Nephrology (Neph) specific items was <50th percentile (%ile). Since Nephrology is not a required rotation in our program, a curricular innovation (CI) was developed to be available to all residents to help improve residents' Nephrology specific knowledge.

Methods: Case scenarios based on Nephrology topics with lower % correct score with 3- tier questions for knowledge and difficulty level were disseminated bimonthly to IM residents via e-mail and Twitter (*X*) as free open access meducation (FOAMed). The questions were also open to any interested online viewers. Answers were submitted via a Qualtrics survey tool with options for anonymity and feedback. A robust in-person didactic curriculum was present in all years, though the delivery of this curriculum changed with a transition to an X+Y model in academic year (AY) '22-23 which did lead to a decrease in the number of unique Nephrology sessions from 16 in AY '21-22 to 7 in '22-23. Additionally, PGY1s did not take the IM-ITE after 2021 as part of IM residency program changes.

Results: Over AYs '20-21 to '22-23, a total of 17 CI sessions were disseminated with average resident engagement of 25 (19-31) per question and a class size of 25-32 PGY per year. Most participants (94%) felt they learnt new information. Percent of Nephrology IM-ITE questions answered correctly (% correct) and %ile over time are reported in Table.

Conclusions: Aggregate performance for all PGYs improved on the 2021 examination. 2022 and 2023 data by PGY level shows inconsistent trends, with higher percentiles in 2022 as compared to 2020, and higher percent correct in 2023. These changes occurred in the background of other curricular and ITE utilization changes in the IM residency program and thus, direct correlations between CI implementation and IM-ITE performance cannot be made presently and a longer observation period is needed.

	2020 (% correct [%ile])	2021	2022	2023
PGY1	58% (37th)	64% (51st)	NA	NA
PGY2	68% (53rd)	76% (88th)	57% (64th)	74% (60th)
PGY3	72% (67th)	74% (55th)	64% (80th)	74% (41st)
All PGYs	65% (48th)	71% (67th)	60% (89th)	74% (73rd)

FR-PO019

Empowering Future Nephrologists: Crafting a Leadership Curriculum for Nephrology Trainees

Fahad Aziz, Ali I. Gardezi, Tripti Singh. *University of Wisconsin System, Madison, WI.*

Background: Leadership skills are increasingly recognized as crucial for medical professionals to navigate the complexities of healthcare and improve patient outcomes. Traditional medical training often lacks formal leadership development, leaving a gap in preparing trainees for real-world leadership challenges.

Methods: We developed a leadership curriculum for our nephrology trainees and junior faculty. The proposed curriculum aims to fill this gap by equipping medical trainees with essential leadership competencies, such as communication, teamwork, conflict resolution, and giving and receiving feedback. Participants completed surveys before and after the curriculum to evaluate their comprehension of leadership topics.

Results: The curriculum had 16 participants with a mean age of 33 ± 4 years. Of the participants, 67% were male, 80% were white, and 75% were US medical graduates. Before the curriculum, 44% of participants considered themselves leaders at the workplace; post-curriculum, this number increased to 76% (p=0.06). Initially, 72% of participants understood the difference between leadership and a position, which improved to 100% after the curriculum (p=0.02). Before the curriculum, 42% felt well-equipped to handle workplace conflicts; this improved to 90% after (p=0.004). Comfort in giving feedback increased from 60% before the curriculum to 92% after (p=0.04).

Conclusions: Medical trainees and junior faculty often lack the necessary knowledge and skills in leadership. However, these skills can be taught, as evidenced by the significant

improvement in understanding and confidence among participants. We suggest that such a curriculum be integrated into nephrology training to develop better leaders in the field.

FR-PO020

Impact of Continuing Medical Education/Continuing Education (CME/CE) Course on Primary Care Provider's Understanding of Kidney Diseases and Genetic Testing

Jemetra Collins,[1] Michael Spigler,[1] Lucia Kim,[2] Melanie Paris.[1]
[1]American Kidney Fund, Rockville, MD; [2]Pri-Med LLC, Boston, MA.

Introduction: Genetic conditions as an underlying cause of certain types of kidney disease (KD) have garnered increased attention in nephrology. Although genetic testing has led to more accurate diagnoses and targeted treatment plans for KD patients, identification of potential genetic-based KDs by primary care providers (PCPs) for referral to nephrologists poses barriers to timely and appropriate intervention. Because PCPs often manage earlier stages of CKD independently, limitations in detecting possible genetic KD and understanding of genetic testing may result in missed opportunities to slow progression toward kidney failure. As a remedy, a one-credit, PCP-targeted continuing medical education (CME/CE) webinar was created to educate PCPs on nephrology referral.

Case Description: CME/CE was delivered by a nephrologist and a PCP initially as a live webinar, then posted as an enduring activity, December, 2022-2023. One of four learning objectives was introducing genetic testing options (GTO) and benefits. Faculty discussed screening and diagnosis of CKD, how to recognize which patients may have genetic causes of kidney disease requiring a nephrologist and the role of genetic testing in diagnosis. Pre/post-activity polling measured learner (n=4,540) knowledge competence, confidence along 5 levels, ranging from misinformed to mastery with two questions. Data were analyzed in aggregate.

Discussion: Analysis showed low baseline, with performance moderately better in the live setting than the enduring. Learner mastery increased from <5% pre to >30% post, with a decrease in learners guessing from ~60% to ~1/5. Analysis suggests effectiveness in educating PCPs via a CME/CE course on genetic testing and targeted treatments. PCP education should highlight genetic testing and other CKD diagnostic procedures, especially for patients with KD family history and those with traits consistent with APOL1 gene mutation. PCP-targeted KD CME/CEs can enhance understanding of CKD, referral criteria, and the benefits of timely specialist involvement.

FR-PO021

American Kidney Fund's Kidney Health Coach Online Course Improved Confidence, Knowledge, and Practice Intentions among Health Care Professionals

Rhea Suarez, Sana Siddique, Ryan Woolley, Melanie Paris, Michael Spigler.
American Kidney Fund, Rockville, MD.

Background: People at-risk for or living with chronic kidney disease (CKD) have unique care needs that health care professionals (HCPs) must be prepared to meet. However, there is limited HCP training and education on CKD prevention and management, especially among allied health care. To address this need, the American Kidney Fund (AKF) created Kidney Health Coach (KHC) a community health education program that trains HCPs and lay audiences to educate their patients and the community about preventing and managing CKD. KHC includes a 2-hour online training course discussing disparities and burden of CKD, diagnosis and treatment options, prevention strategies, and best practices to tailor health information for specific audiences.

Methods: AKF analyzed online course self-reported pre- and post-evaluation data to assess differences in HCP coaches' (n=2,160) confidence (4-5 on 6-point Likert scale), knowledge, and intention to make practice changes in their role or clinical setting. Data were stratified by provider type to assess for differences.

Results: Most HCP coaches are nurses (26%), dialysis technicians (DT) (15%), and social workers (SW) (14%). Pre- and post-evaluation comparisons revealed HCP confidence in knowledge about CKD increased 57% to 95% and confidence in ability to educate others about CKD increased 54% to 91%. Nurses had the highest average increase in confidence (61%) compared to DTs (45%) and SWs (51%). Post only evaluation data revealed 89% of HCPs are confident KHC improved their ability to better function as a member of the health care team and 64% indicated they would make changes in their practice or role. Compared to DTs (61%) and SWs (57%), nurses (68%) were most likely to make changes in their practice or role.

Conclusions: Findings support the need for CKD education and training of HCPs across practice settings. KHC is an effective tool that provides HCPs with up-to-date clinical content and best practices in plain language and health literacy. KHC enhanced HCP confidence and knowledge in CKD prevention and management, which leads to HCPs who are better equipped to meet the needs of their patients. Further outreach is needed to build capacity among HCPs to be responsive to the needs of people at-risk for or living with CKD.

Developing a Participant-Focused Educational Podcast to Enhance Engagement in the Cure Glomerulopathy (CureGN) Study Cohort

Myda Khalid,[1] Tina Creguer,[2] Laura H. Mariani,[2] Shannon Mulroy,[3] Keisha L. Gibson,[4] Sherry L. Wilson,[1] Zubin J. Modi,[2] Caroline J. Poulton.[4]
[1]Riley Hospital for Children at Indiana University Health, Indianapolis, IN; [2]University of Michigan, Ann Arbor, MI; [3]Kidney Solutions, Kerrville, TX; [4]The University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC.

Background: CureGN is an NIH-funded longitudinal cohort study that has enrolled over 2,000 research participants. Engagement is fundamental to encourage retention and to provide value and education to participants. Previous initiatives including newsletters and online "fireside chats" had low participation rates.

Methods: An audio podcast was trialed and evaluated to enhance participant education and engagement. Kidney Chats by CureGN, developed by CureGN's Recruitment and Retention workgroup, launched October 2023. The educational series on glomerular disease topics is accessed on multiple platforms (Spotify, Apple, Amazon, web search); themed episodes are clearly titled by topic. A study participant interviews an expert on a topic suggested by participants. Initial topics included nutrition and prednisone. Newsletters introduce a topic and point readers to the podcast for more in-depth information via a QR code. Social media promotes the podcast.

Results: Three episodes have launched ranging from 16 to 31 minutes long, with new episodes planned at a two-to-three-month cadence. 86 downloads/listens have been logged, surpassing performance of fireside chats in a much shorter amount of time. The podcast reaches participants across all age ranges, with particular strength in ages 28 to 34 and over 60. Listenership by gender is 52% female, 41% male, and the remaining non-binary or not specified. Listeners hail largely from the US, with 77% located in the US. Another 12% tuned in from Germany, 7% from Canada, and 4% from other locations.

Conclusions: For CureGN, an integrated communications strategy that incorporates a highly accessible medium as its centerpiece effectively disseminates relevant research to participants, as well as topics addressing lifestyle topics and helping participants find community by hearing others' lived experiences with kidney disease.

FR-PO023

Clinical Impact of Kidney Educational Program on Elderly Nocturnal Hypertensive Patients with CKD

Akira Ishii,[1] Ryo Sato,[1] Kosuke Mochizuki,[1] Kansei Otsuka,[1] Kyoka Fujita,[1] Satoshi Kurahashi,[1] Jun Takeoka,[1] Hisako Hirashima,[1] Naohiro Toda,[1] Toshiyuki Komiya,[2] Eri Muso.[1] *[1]Kansai Denryoku Igaku Kenkyujo, Osaka, Japan; [2]Otsu Red Cross Hospital, Shiga, Japan.*

Background: It has been reported that hypertension progresses with age and the rhythm of blood pressure variability is disrupted in the elderly due to autonomic dysfunction and arterial stiffness, which can easily induce nocturnal hypertension. Furthermore, elderly patients with nocturnal hypertension are recognized as being at higher risk of cardiovascular events and chronic kidney disease (CKD) exacerbation. We aimed to elucidate the clinical impact of renal educational program on elderly nocturnal hypertensive CKD patients.

Methods: We reviewed 60 Japanese CKD patients who participated in our one-week CKD educational program from April 2019 to March 2023. All patients took low-salt diet (6 g/day) and were carried out 24-hour urine testing twice and 24-hour ambulatory blood pressure monitoring (ABPM) during the program.

Results: The mean age on admission was 71.6 ± 8.5 years, body mass index (BMI) was 25.6 ± 3.6, and eGFR was 19.2 ± 10.3. Diabetic kidney disease was the most common diagnosis (38% [22 of 58]), followed by nephrosclerosis (19% [11 of 58]), IgA nephropathy (3.4% [2 of 58]) and so on. Of the patients, 25 (43.1%) were non-dipper type and 12 (20.7%) were riser type (these two types (63.8%) were combined into the non-dipper group). During one-week program, the mean body weight decreased from 68.4 to 66.9 kg (2.2% reduction), systolic blood pressure during daytime decreased from

136.9 to 129.9 mmHg (5.1% reduction), urinary protein decreased from 4.10 to 3.93 g/day (4.1% reduction) and the 24-hour urinary sodium excretion decreased from 121.7 mEq/day to 106.1 mEq/day (12.8% reduction). The non-dipper group had a higher BMI but had similar daytime systolic blood pressure and diabetes mellitus complication rates compared with the dipper group. Furthermore, while the non-dipper group showed a decrease in the slope of the pressure-natriuresis curve, there was no obvious difference in the rate of eGFR decrease after one year of hospitalization between two groups.

Conclusions: While the non-dipper group showed increased salt sensitivity compared to the dipper group, there was no obvious difference in the degree of renal function decline after one year of intervention, which was considered by multifaceted intervention effect of CKD education, such as salt reduction instruction.

Abstract Withdrawn

FR-PO025

Sex-Related Differences in Incidence and Prevalence and Outcomes of AKI

Ruqiyya Bano, Sian E. Piret, Henry Yip, Andreas P. Kalogeropoulos, Sandeep K. Mallipattu. *Stony Brook University, Stony Brook, NY.*

Background: Acute kidney injury (AKI) is a common condition affecting hospitalized patients. While male sex has been correlated as a risk factor for AKI, our aim was to evaluate if age-related sex disparities exist in AKI development and post-AKI outcomes.

Methods: Using the Stony Brook University (SBU) and US Collaborative TriNetX Networks, inpatient encounters for both male and female sex between January 2014 and December 2023 were queried for individuals 0-89 years of age. Outcomes of AKI were assessed using ICD-10 billing codes. Short- and long-term outcomes were defined as having AKI within 90 days and 1 year of inpatient encounter, respectively. Mortality was assessed for within 1 year of reaching the short-term or long-term outcome. Propensity score matching was utilized to match SBU cohorts based on race, ethnicity, and comorbidities (HTN, DM, CVD, Obesity). Hormone replacement therapy (HRT) was defined as use of estrogens, progestins, gonadotropins, or ICD-10 code for HRT. Absolute risk difference (RD), risk ratio (RR), and hazard ratio (HR) comparing risk of AKI/mortality were measured.

Results: The overall risk of developing AKI was greater in males vs females in both SBU (short term RD: 2.063%, $p < 0.0001$; long term RD: 2.332% $p < 0.0001$) and US (short term RD: 1.538% $p < 0.0001$; long term RD: 1.749% $p < 0.0001$) cohorts. In age-related analyses, the RR of AKI was highest in the 30-39 decade of age in the SBU cohort for both short-term (RR: 3.316) and long-term (RR: 2.778) outcomes, while US cohort showed highest risk ratio at 20-29 in short term (RR: 2.518) and 30-39 in long-term (RR: 2.498). AKI risk increased per decade of year in both males and females. In the SBU cohort, females exhibited higher risk of death within 1 year of AKI diagnosis, regardless of short-term (HR: 0.890, $p = 0.006$) or long-term (HR: 0.886, $p = 0.001$) AKI outcome. Females not on HRT also showed lower risk of developing AKI as compared to females on HRT both short-term (HR= 0.613, $p <0.0001$) and long-term (HR = 0.571, $p <0.0001$).

Conclusions: Incidence and prevalence of AKI diagnosis is higher in males as compared to females across all age groups, with a peak in risk ratio noted at 30-39. However, females with AKI had higher risk of death as compared to males with AKI. The use of HRT did not mitigate the risk of AKI in females.

FR-PO026

Age-Dependent Sex Differences in the Incidence of AKI among Patients with CKD: The OCKR Study

Yuki Kawano, Tatsufumi Oka, Yusuke Sakaguchi, Takayuki Kawaoka, Yuta Asahina, Isao Matsui, Masayuki Mizui, Jun-Ya Kaimori, Yoshitaka Isaka. *Department of Nephrology, Osaka University Graduate School of Medicine, Suita, Japan.*

Background: While basic studies revealed a protective effect of female hormones against acute kidney injury (AKI), the Kidney Disease Improving Global Outcomes (KDIGO) guideline states that females have a higher risk of AKI. A meta-analysis of observational studies reported an inconsistent sex difference in AKI with a considerable degree of heterogeneity. Sex differences in AKI have not been studied in the chronic kidney disease (CKD) population. We investigated whether sex affects the incidence of AKI and its impact on the risk of kidney failure among patients with CKD.

Methods: The Osaka Consortium for Kidney Disease Research (OCKR) is a retrospective, multicenter cohort study that includes patients who attended the outpatient departments of nephrology at five hospitals in Osaka, Japan, from January 2005 to December 2021. In the present study, 15,220 patients with an estimated glomerular filtration rate (eGFR) of 15-60 mL/min/1.73 m^2 were included. AKI was defined as a ≥1.5 times increase in a serum creatinine level from its median value over the past year, according to the National Health Service England AKI algorithm. The association of sex with AKI and sex-specific relations of time-dependent AKI with kidney failure with replacement therapy (KFRT) were examined using time-dependent Cox proportional hazards models.

Results: The mean (standard deviation) age and eGFR at baseline were 69 (14) years and 37 (13) mL/min/1.73 m^2, respectively, and 62% were male. Over a median follow-up of 2.9 years, 1,974 (13.0%) patients developed AKI and 1,316 (8.6%) experienced KFRT. Males had a significantly higher hazard of AKI (hazard ratio [HR] 1.20; 95% confidence interval [CI], 1.07-1.33) after adjustment for potential confounders. This association was stronger in patients aged <50 (HR 1.51; 95% CI, 1.05-2.17) than in those aged 50 or older (HR 1.16; 1.03-1.30) (P for interaction=0.04). Males also had an 85%-higher hazard of KFRT (95% CI, 1.58-2.18) than females. In contrast, the hazard of KFRT associated with time-dependent AKI was similar between sexes (P for interaction =0.87). Similar trends were observed when analyzed according to AKI stages.

Conclusions: Females had a lower incidence of AKI, especially in the younger population, but a similar hazard of KFRT after AKI, compared to males.

FR-PO027

Sex Disparities in the Risk of Urgent Dialysis following Acute Aortic Dissections in Japan: A Real-World, Nationwide Study

Yuta Nakano,[1,2] Shintaro Mandai,[2] Daiei Takahashi,[3] Ken Ikenouchi,[2] Yutaro Mori,[2] Fumiaki Ando,[2] Koichiro Susa,[2] Takayasu Mori,[2] Soichiro Iimori,[2] Shotaro Naito,[2] Eisei Sohara,[2] Kiyohide Fushimi,[2] Shinichi Uchida.[2] *[1]Ome Medical Center, Ome, Japan; [2]Tokyo Ika Shika Daigaku, Bunkyo-ku, Japan; [3]Musashino Sekijuji Byoin, Musashino, Japan.*

Background: The global outcome of acute aortic dissection (AD) remains poor, with a high risk of acute kidney injury (AKI) and the need for urgent dialysis. This study aimed to clarify the association between sex and the requirement for urgent dialysis within 30 days after admission among patients with AD.

Methods: This study included 83,297 cases who were hospitalized due to AD in Japan from 2010 to 2020 using an administrative claims database. The association between the risk of urgent dialysis within 30 days after admission and sex was investigated using cumulative incidence functions and the Fine and Gray model.

Results: There were 5,640 events of urgent dialysis. Patients were classified into two groups based on the Stanford classification: type A AD (TAAD) and type B AD (TBAD). In TAAD, the cumulative incidence of urgent dialysis at 30 days was 8.6% [95% confidence interval (CI): 8.1–9.0] in women and 15.2% (95% CI: 14.7–15.8) in men ($p < 0.001$) (Figure 1). In TBAD, the cumulative incidence was 1.6% (95% CI: 1.4–1.8) in women and 3.5% (95% CI: 3.3–3.7) in men ($p < 0.001$) (Figure 1). In adjusted models, lower subdistribution hazard ratios (SHRs) in women were observed in both groups: TAAD (SHR: 0.62, 95% CI: 0.58–0.67); TBAD (SHR: 0.59, 95% CI: 0.52–0.68).

Conclusions: Our study revealed that women had a lower risk of requiring urgent dialysis than men in TAAD and TBAD. Further research is needed to clarify the underlying role of sex in AKI in patients with AD.

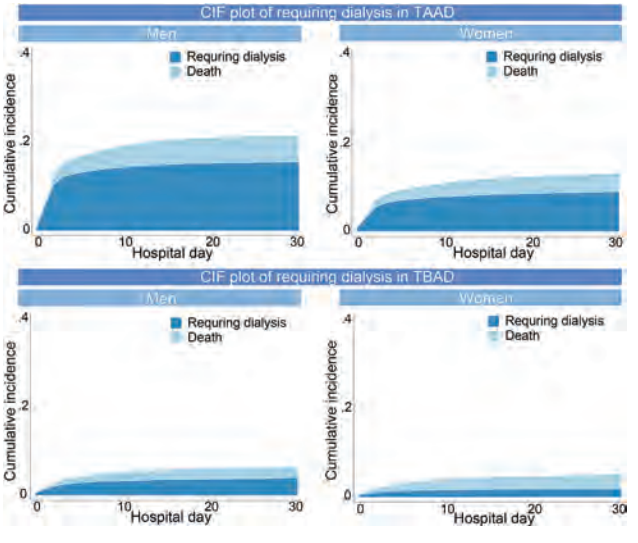

Figure1

FR-PO028

More Hospitalized Pregnant Women in the United States Are Dying with AKI

Chyng-Wen Fwu,[1] Susan R. Mendley,[2] Christine Maric-Bilkan,[2] Shannon S. Givens-Bradley,[2] Paul L. Kimmel,[2] Raquel C. Greer,[2] Kevin L. Chan,[2] Kenneth J. Wilkins,[2] Ivonne H. Schulman.[2] *[1]Social and Scientific Systems, Inc., a DLH Holdings Corp (DLH) company, Silver Spring, MD; [2]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.*

Background: Recent national trends for death occurring in hospitalized pregnant women who have acute kidney injury (AKI) have not been reported. Increased delivery-related hospitalizations with AKI were reported between 2006-2015 but did not include all pregnancy-related hospitalizations.

Methods: The 2019-2021 Healthcare Cost and Utilization Project National Inpatient Sample (HCUP-NIS) was analyzed to 1) describe the in-hospital rate of AKI, as primary or secondary diagnosis, and death; 2) evaluate associations of all-cause death with AKI after adjustment of pre-defined predictors; and 3) estimate the number needed to harm (NNH), a death due to AKI, in women ages 12-49 years with pregnancy-related hospitalizations, including delivery or non-delivery, and excluding hospitalizations with end-stage renal disease diagnosis. ICD-10-CM codes and/or the Clinical Classifications Software Refined diagnostic categories were used. Mortality trend and association between in-hospital AKI diagnosis and death were examined using multivariate logistic regression.

Results: Table shows the number of pregnancy hospitalizations recorded in the HCUP-NIS during 2019-2021, the increased rate of in-hospital AKI and death, and the increased number and rate of deaths among hospitalizations with AKI. AKI was one of the major comorbid conditions in pregnant women who died (40%). Deaths with AKI as a percentage of total deaths increased from 35% to 41%. Overall mortality difference between hospitalizations with and without AKI was 2.52%. The NNH with AKI was 40. Adjusted for age, race/ethnicity, CVD, cancer, infection, hemorrhage, and pregnancy-related complications, the odds of death increased annually by 40% per year (Adjusted Odds Ratio (AOR), 1.40; 95% confidence interval (CI), 1.23 to 1.60). AKI was significantly associated with death (AOR 26.33, 95% CI 20.61 to 33.65).

Conclusions: From 2019-2021, increased numbers of hospitalized pregnant women died with AKI. Additionally, deaths with AKI are increasing faster than total deaths.

Funding: NIDDK Support

Table. Number of AKI and number of deaths in hospital stay per 100,000 hospitalizations, HCUP-NIS 2019-2021

Year (Number of hospitalizations)	2019 (N=780,844)	2020 (N=748,706)	2021 (N=759,532)	Percent increase From 2019 to 2021
Hospitalizations with AKI diagnosis				
Number of hospitalizations with AKI diagnosis	1,763	2,012	2,319	32%
Number of hospitalizations with AKI diagnosis, per 100,000 hospitalizations	226	269	305	
Died in hospital stay				
Number of deaths in hospital stay	83	123	184	122%
Number of deaths in hospital stay, per 100,000 hospitalizations	11	16	24	
Died in hospital stay among hospitalizations with AKI				
Number of deaths in hospital stay	29	50	75	159%
Number of deaths in hospital stay, per 100,000 hospitalizations	1645	2485	3234	
Died in hospital stay among hospitalizations without AKI				
Number of deaths in hospital stay	54	73	109	102%
Number of deaths in hospital stay, per 100,000 hospitalizations	7	10	14

Clinical Features and Outcomes of Pregnancy-Related AKI: A Single Tertiary Center Study

Tarek A. Ghonimi, Islam A. Elsayed, Ayman R. Abd El-Hameed. *Zagazig University Faculty of Human Medicine, Zagazig, Egypt.*

Background: Pregnancy-related acute kidney injury (Pr-AKI) is a major cause of maternal and fetal morbidity and mortality in developing countries. The aim of our study was to study the clinical characteristics and outcomes of patients with Pr-AKI at our center.

Methods: This prospective study at Zagazig University Hospital, Egypt, from October 1, 2023, to March 1, 2024, included patients with post-partum AKI. These women were compared to a matched cohort of healthy pregnant women without pre-existing AKI. Multivariate analysis is used to identify risk factors.

Results: Out of 900 pregnant patients who delivered during the study period, 52 patients developed post-partum AKI with incident of 5.7%. The majority were multiparous(59.6%), and most delivered by cesarean section (67.3%). The most common cause of AKI is preeclampsia (51.9%), followed by ante-partum hemorrhage (40.4%) and HEELP syndrome (36.5%). Stage 3 AKI (KDIGO classification) was the most prevalent occurring in 23% of cases. Maternal death occurred in 13.5% of cases, while fetal death was 17.3%. Follow- up showed that 42.3% had complete recovery, 30.7% CKD and 13.4% remained dialysis-dependent. Risk factors for AKI included high WBC, low Hb, low platelets, and high bilirubin levels, with p-values of 0.004, <0.0001, and 0.031, respectively. Additionally, nulliparous women had significantly lower odds of developing AKI (0.248, p = 0.017). However, the significance of these risk factors disappeared in multivariate analysis.

Conclusions: Post-partum AKI is a relatively common pregnancy complication with significant maternal and fetal mortality risks. Preeclampsia and ante-partum hemorrhage are major risk factors. Larger, long-term follow-up studies are recommended to confirm these findings.

Incidence, Risk Factors, and Outcomes Associated with Pregnancy-Related AKI in Northwest Nigeria

Aishatu M. Nalado. *Aminu Kano Teaching Hospital, Kano, Nigeria.*

Background: Although largely preventable, pregnancy-related acute kidney (PRAKI) continues to be a significant contributor to maternal and perinatal mortality in low- and middle-income countries. Data are scarce on the incidence and impact of PRAKI in Nigeria. Thus, this study aimed to evaluate the incidence, risk factors, and maternal-fetal outcomes of patients with

Methods: This is a prospective multicenter study conducted among 841 women at the Obstetrics and Gynecology units of two large referral hospitals in urban Kano, Nigeria, between 1st October 2022 and 30th March 2023. We employed multivariate logistic regression analysis to determine independent predictors of PRAKI in this resource-constrained setting.

Results: The mean age ± standard deviation (SD) of respondents was 27.8 ± 6.7 years. The prevalence of PRAKI was 11.4%, with the majority (55.2%) being in KDIGO stage 1. The most common risk factors for PRAKI were pre-eclampsia (24%), postpartum hemorrhage (16.7%), sepsis (15.6%), and eclampsia (14.6%). The overall maternal and perinatal mortality rates were 7.4 % and 21.9 %, respectively. PRAKI was independently associated with the use of traditional medications (adjusted odds ratio, aOR =1.94; 95% CI: 1.18, 3.18), history of pregnancy-induced hypertension (aOR = 2.61; 95% CI: 1.49-4.59), an established diagnosis of hypertension (aOR = 2.53; 95% CI: 1.42, 4.50), and advanced maternal age (aOR=0.50; 95% CI: 0.27-0.92, ≥35 years vs. 18-24 years).

Conclusions: PRAKI is common in women presenting for care in our setting and is associated with significant maternal and perinatal mortality. The important risk factors for development of PRAKI in our study population include hypertensive disorders of pregnancy, established diagnosis of hypertension, postpartum hemorrhage, and sepsis.

Atypical Abruptio Placentae with AKI: Interventional Dilemma

Muhammad Yasir Baloch, Ignacio A. Portales Castillo, Benjamin D. Humphreys. *Washington University in St Louis, St Louis, MO.*

Introduction: Alterations in the complement cascade can affect many organs and lead to renal, hematological, or obstetric complications. Here, we present a case of pregnancy complicated by abruptio placentae and severe acute kidney injury (AKI) requiring dialysis, where we identified a genetic predisposition to complement dysregulation.

Case Description: A 37-year-old female G5P3 at 36 weeks pregnancy, presented to the ER with abdominal pain. Fetal bradycardia was detected, prompting an urgent C-section. During surgery, placental abruption was diagnosed, she became hypotensive, requiring 2 liters of blood products. Post-surgery, she was anuric despite intravenous fluids and resolution of hypotension. Laboratory results were notable for AKI (Cr 2.2), transaminitis, anemia (Hb 7.6), thrombocytopenia (Plt 80), low haptoglobin, fibrinogen of 422md/dl and very elevated lactate dehydrogenase (LDH) at 3080U/L. The peripheral blood smear showed few schistocytes. Complement levels and ADAMTS13 were unremarkable. Hemodialysis was initiated on day 2. The clinical diagnosis was thrombotic microangiopathy (TMA) secondary to either HELLP syndrome vs atypical hemolytic uremic syndrome (aHUS). Eculizumab was considered but not given as her hematologic parameters rapidly improved. Two weeks later, she remained dialysis dependent. Three

weeks after admission results of genetic testing for complement pathway related genes, revealed homozygous bi-allelic loss of Complement Factor H (CFHR3 – CFHR1) genes, which has been recently categorized as pathogenic. Eculizumab was then started. Her renal function improved, and she successfully transitioned off dialysis.

Discussion: Despite carrying pathogenic variants associated with complement dysregulation, many patients remain asymptomatic for most of their lives. Several conditions, including pregnancy, can precipitate episodes of TMAs, which can be mistaken for preeclampsia. Advances in complement genetics have transformed our understanding of TMAs, but interpreting complement genetics is complex and often requires expertise from geneticists and complement biology specialists. This case illustrates the need to remain vigilant about atypical obstetric complications, as adequate treatment of aHUS can prevent irreversible renal injury.

FR-PO032

Improving AKI Diagnosis: Estimating Baseline Serum Creatinine Using Kidney Volume Regression Equation

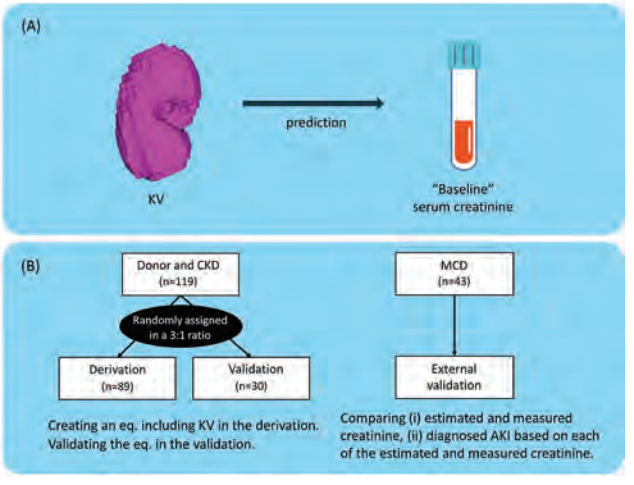
Takaya Sasaki, Takeshi Tosaki, Hideaki Kuno, Hirokazu Marumoto, Yusuke Okabayashi, Kotaro Haruhara, Go Kanzaki, Kentaro Koike, Akimitsu Kobayashi, Izumi Yamamoto, Nobuo Tsuboi, Takashi Yokoo.
Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan.

Background: Diagnosing acute kidney injury (AKI) relies on baseline serum creatinine (Cr) levels, which are often unavailable. As shown in **Figure A**, our study aimed to create a regression equation linking kidney volume to function in kidney donors and chronic kidney disease patients, and also sought to estimate baseline Cr in minimal change disease (MCD) patients, which is a common AKI-predisposing condition.

Methods: Kidney donors and patients with chronic kidney disease (CKD) were selected for our study (n = 119, 40% donors, mean age 60 years, 50% male), and randomly divided into derivation and validation groups (**Figure B**). An equation based on kidney volume (KV) was developed in the derivation group and validated in the validation group. We also estimated baseline Cr in MCD patients (n = 43, mean age 45 years, 61% male) using the KV-based equation and compared with their 6-month post-MCD onset Cr values.

Results: The created equation for the estimated glomerular filtration rate (eGFR) was as follows: eGFR (mL/min/1.73m^2) = 0.38 x KV (cm^3) + (-0.40) x age (years) + (-2.9) x male sex + (-13) x hypertension + (-14) x diabetes + (-0.21) x height (cm) + 82 (intercept). In the validation group, the eGFR and estimated Cr values correlated well with the measured values (r = 0.46, p = 0.01 and r = 0.51, p = 0.004, respectively). In the MCD group, the baseline Cr values were significantly correlated with the estimated baseline Cr values (r = 0.52, p <0.001), effectively diagnosing AKI (kappa = 0.76, p <0.001).

Conclusions: The regression equation including KV established in the present study holds promise for estimating baseline Cr values and diagnosing AKI in patients with MCD. Further validation in diverse populations with AKI is necessary.



FR-PO033

A Population-Based Imputation Approach for Missing Baseline Serum Creatinine Values

David R. Chang,[1] Hsiu-Yin Chiang,[2] Yi-Ching Chang,[2] Tomonori Takeuchi,[3,4] Che-Chen Lin,[2] Jin Chen,[3] Javier A. Neyra,[3] Chin-Chi Kuo.[2,1] *[1]China Medical University Hospital Department of Internal Medicine, Taichung, Taiwan; [2]Big Data Center, China Medical University Hospital, Taichung, Taiwan; [3]The University of Alabama at Birmingham, Birmingham, AL; [4]Tokyo Ika Shika Daigaku, Bunkyo-ku, Japan.*

Background: Diagnosing acute kidney injury (AKI) requires a baseline serum creatinine (S-Cre), which is often missing in the real world. We aimed to develop and validate a new method for estimating baseline S-Cre and compare it to existing methods

Methods: From all S-Cre measurements collected from adult outpatients at CMUH in 19 years, we excluded those were 1) <0.3 or >30 mg/dL, 2) from patients with end-stage kidney disease or nephrectomy, 3) within 72 hours following dialysis or cardiopulmonary resuscitation, or 4) within 24 hours after massive transfusion, resulting in 3403528 measurements for baseline S-Cre reference. We developed the "median" imputation methods that utilized the median S-Cre within subgroups stratified by age, gender, and chronic kidney disease (median A), or in combination with body mass index (median B). A sepsis cohort meeting Sepsis-3 was used to assess the performance of 4 imputation methods (median A, median B, eGFR 75, and multiple imputation [MI]) in discriminating AKI according to KDIGO criteria. Bland-Altman plot was used to visualize bias between measured and imputed S-Cre.

Results: In the sepsis cohort, median A and B method had a smaller mean of difference, compared to eGFR 75 and MI method. Median A method demonstrated the highest agreement for AKI (84%; Kappa 0.68), compared with eGFR 75 (82%; 0.63) and MI method (81%; 0.62). eGFR 75 had superior sensitivity (85% vs 82%), while MI showed higher specificity compared to median A method (92% vs 86%).

Conclusions: The median methods showed satisfactory agreement in AKI detection comparable to eGFR 75 and MI approaches, offering a simple and intuitive approach for real-world application for baseline S-Cre estimation. External validation in the US population is underway.

Imputation Methods	Pearson's r (p-value)	Mean of Difference (imputed - true)	Kappa	AKI Classification				
				Sensitivity	Specificity	PPV	NPV	Agreement
Median by age (1 year), gender, CKD	0.61 (p < 0.001)	-0.02 (-0.96, 0.91)	0.68	81.7%	85.9%	83.4%	84.4%	83.9%
Median by age (1 year), gender, CKD, BMI	0.61 (p < 0.001)	-0.01 (-0.92, 0.89)	0.60	68.0%	90.1%	86.3%	76.7%	80.2%
eGFR 75 (converted by MDRD formula)	0.05 (p < 0.001)	-0.17 (-1.36, 1.02)	0.63	85.0%	78.5%	77.4%	85.8%	81.5%
Multiple imputation	0.52 (p < 0.001)	0.34 (-1.13, 1.80)	0.62	69.4%	91.6%	87.7%	77.5%	81.3%

ePidEmiology, Risk FactORs, and outcoMes of AKI (PERFORM-AKI)

Amanda Y Wang,[1,2] Johnathan Ngo,[3,4] Praveen S. Perera,[1] Kathryn Higgins,[1] Natashja Eyles,[1] Zoltan Endre,[5,6] Shaundeep Sen,[7,8] Muh Geot Wong,[7,8] Lucinda A. Wynter,[8,9] John P. Killen,[2,10] Séverine Bompoint,[1] Rinaldo Bellomo,[11] Martin P. Gallagher.[6] *[1]The George Institute for Global Health, Sydney, NSW, Australia; [2]Macquarie University Faculty of Medicine Health and Human Sciences, Sydney, NSW, Australia; [3]Department of Renal Medicine, Liverpool Hospital, Liverpool, NSW, Australia; [4]Western Sydney University School of Medicine, Sydney, NSW, Australia; [5]Department of Nephrology, Prince of Wales Hospital, Randwick, NSW, Australia; [6]School of Clinical Medicine, Faculty of Medicine and Health, UNSW, Sydney, NSW, Australia; [7]Department of Renal Medicine, Concord Repatriation General Hospital, Concord, NSW, Australia; [8]Faculty of Medicine and Health, University of Sydney, Camperdown, NSW, Australia; [9]Department of Medicine, Canterbury Hospital, Campsie, NSW, Australia; [10]Department of Renal Medicine, Northern Beaches Hospital, Frenchs Forest, NSW, Australia; [11]Austin Hospital, Heidelberg, VIC, Australia.*

Background: Acute kidney injury (AKI) is common in hospitalised patients and associated with significant morbidity and mortality. Many AKI studies focus upon Intensive Care Unit (ICU) patients, while literature on non-ICU patients with AKI is often limited by retrospectively defined cohorts with varying definitions. The PERFORM-AKI study aims to assess epidemiological and clinical characteristics of hospitalised non-ICU patients with AKI.

Methods: PERFORM-AKI is a multicentre prospective cohort study across 5 centres in Australia. The KDIGO criteria for AKI were used for diagnosing and staging. Baseline data at initial renal consult and follow up data at day 14 or at discharge (whichever occurred first) were collected. Partial renal recovery was defined as the serum creatinine level at the time of follow up has returned to within 50% of baseline levels.

Results: The study included 639 hospitalised patients with AKI diagnosed outside ICU from February 2021 to October 2023. The mean age was 75 years (SD 14.6 years) with a male predominance (57%). The top three pre-existing comorbidities were hypertension (77.3%), cardiovascular disease (58.1%) and diabetes (43.7%). The most common causes of AKI were hypovolaemia (57.0%), sepsis (43.0%) and drug-induced nephrotoxicity (26.6%). Treatments used for AKI were intravenous fluids (57.6%), cessation of nephrotoxic agents (47.3%), and administration of antibiotics (37.2%). There was no significant difference in diagnosis and management of AKI between the initial and follow up renal consultation. AKI was graded as stage 1 in 51.1%, stage 2 in 25.1% and stage 3 in 23.8 % of patients. Mortality across the cohort was 5.6%, few patients (1.7%) required renal replacement therapy, and 75 patients (11.8%) met the definition for partial renal recovery.

Conclusions: Epidemiology and outcomes of AKI in non-ICU patients are distinct to their ICU requiring counterparts. Hypovolaemia is the most common cause of AKI in this cohort, and most patients had incomplete renal recovery by day 14. Since persistent AKI is associated with higher mortality, this study suggests early nephrology follow-up should be encouraged or even mandated in these patients.

FR-PO035

Predicting Early AKI in Two Large Multicenter Pediatric Critical Care Datasets

Adam Dziorny,[1] Stephen C. Drury,[2] Alex Clark,[2] Martin S. Zand,[2] L. Nelson N. Sanchez-Pinto.[3] *[1]Golisano Children's Hospital, Rochester, NY; [2]University of Rochester Medical Center, Rochester, NY; [3]Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Machine learning (ML) can predict adverse events such as acute kidney injury (AKI) in critically ill children, allowing for proactive care strategies. Most models for pediatric AKI prediction are developed on single-center data which limits generalizability. In this study we externally validate an existing single-center-derived AKI prediction model, recalibrate, and add features on two of the largest multicenter pediatric critical care datasets available.

Methods: Retrospective cohort study within two datasets: (1) a 5-center dataset linking Virtual Pediatric Systems with the PEDSnet (VPS-PN) using probabilistic methods, and (2) the 8-center PICU Data Collaborative (PDC) dataset. We predict AKI within 72 hours of admission, defined by KDIGO serum creatinine criteria. We applied standard ML techniques, including data splitting, imputation, feature selection, and model training, to develop and cross-train a new model. We evaluated prediction score effectiveness with multiple standard measures (area under ROC, AUROC; area under precision-recall curve, AUPRC; and PPV [precision] at two sensitivity thresholds).

Results: Our two datasets included a combined 190,054 ICU encounters, of which 4,797 (2.5%) had AKI within 72 hours of ICU admission. We first applied the existing single-center model and found lower AUROC (0.59 and 0.60) and lower PPV at the 90th percent cut point (0.08 and 0.07) compared to the published single-center results. We developed and tested a new multicenter logistic regression model with 12 features on dataset (1) and recalibrated this model to dataset (2) [**Table 1**]. We evaluated multiple models, feature selection routines, and imputation methods. Optimal performance was targeted to AUPRC and PPV based on goal implementation without excessive false alarms.

Conclusions: We externally validated and subsequently developed a new optimal AKI prediction model within two of the largest pediatric critical care datasets. We specifically identified features that are relevant and available at the time of prediction. Ongoing work is applying this model using FHIR resources within a silent implementation to monitor performance.

Funding: NIDDK Support

Performance characteristics of the two developed models

Performance of an Artificial Intelligence-Generated Risk Score for AKI Prediction

Rolando Claure-Del Granado,[1,2] Juan C. Moya-Mamani,[2] Rakesh Malhotra,[3] Subhasis Dasgupta.[4] *[1]Division of Nephrology, Hospital Obrero No 2 - Caja Nacional de Salud, Cochabamba, Bolivia, Plurinational State of; [2]Universidad Mayor de San Simon, Cochabamba, Bolivia, Plurinational State of; [3]University of California San Diego School of Medicine, La Jolla, CA; [4]University of California San Diego, La Jolla, CA.*

Background: Acute kidney injury (AKI) is a frequent complication in hospitalized patients and is associated with worse short—and long-term outcomes. Recent advancements in Generative AI have facilitated the development of a model that enhances risk management and decision-making processes across different acute kidney disease (AKD) cohorts. Through collaboration with OpenAI and prompt engineering, we have created a promising algorithm for assessing the risk of a group of AKD patients.

Methods: We included 303 consecutive hospitalized patients who were at moderate to high risk of AKI using the AKI Risk Assessment algorithm (**Figure 1**). The LLM model score was calculated at admission. Renal function was followed up daily for seven days. AKI was defined and classified by KDIGO sCr criteria. We analyzed the predictive value of this score for the subsequent development of AKI, the need for kidney replacement therapy (KRT), and mortality.

Results: The incidence of AKI was 28% (n=84) most of cases (84.5%) were mild (KDIGO stage 1), with 53.5% of cases secondary to the use of nephrotoxins. The risk score performance was assessed with the area under the curve receiver operating characteristics (AUC ROC). The AUC ROC for AKI was 0.705 (95% CI 0.638 – 0.771; p = 0.001). The performance of the risk prediction score for AKI generated by ChatGPT showed a sensitivity of 85.71%, specificity of 36.07%, with a positive predictive value of 96.2%, a negative predictive value of 11.73%, and an odds ratio of 3.39 (95% CI of 1.7317 to 6.6197; p = 0.0004).

Conclusions: This parsimonious model, encompassing readily available clinical features, displayed acceptable efficacy in predicting AKI. Furthermore, the parsimonious model's integration into clinical practice could support patient risk stratification and inform treatment decisions.

Higher Spot Urinary Sodium Concentration Is Associated with Better Decongestion and Lower Risk of AKI in Acute Heart Failure

Rolando Claure-Del Granado,[1,2] Noelia B. Miranda-Velásquez,[2,3] Sergio Villarroel-Espinoza,[3] Edward J. Garcia-Peñaloza,[3] Israel D. Rivas Salazar.[1,2] *[1]Division of Nephrology, Hospital Obrero No 2 - Caja Nacional de Salud, Cochabamba, Bolivia, Plurinational State of; [2]Universidad Mayor de San Simon, Cochabamba, Bolivia, Plurinational State of; [3]Division of Cardiology, Hospital Obrero No 2 - Caja Nacional de Salud, Cochabamba, Bolivia, Plurinational State of.*

Background: Spot urinary sodium concentration (UNa) is recommended in guidelines for assessing diuretic response and adjusting dosage in acute heart failure (AHF) based solely on expert opinion. This study aims to investigate spot UNa levels in patients admitted with decompensated AHF and evaluate its relationship with acute kidney injury (AKI), its efficacy in guiding decongestion, and its impact on short-term outcomes.

Methods: Fifty consecutive AHF patients were included in the study, all of whom received standard care, including the AKI/STOP protocol for patients with AKI. Spot urinary sodium (UNa) levels were measured six hours after the initiation of diuretic therapy, with diuretic insufficiency defined as a UNa <70 mmol/L. Kidney function was monitored daily for up to 7 days. AKI was defined and classified according to the KDIGO serum creatinine criteria.

Results: The mean age of the patients was 70.84 ± 11.19 years, with 62% being women, and the average left ventricular ejection fraction (LVEF) was 43 ± 14%. Patients who received a lower total furosemide dose within 24 hours (37.86 ± 11.34 mg vs. 43.64 ± 7.90 mg; p=0.014) had a UNa ≤ 70 mmol/L. Twenty-four patients (48%) developed AKI within 48 hours of admission. The risk of AKI was lower in patients with a UNa ≥ 50 mmol/L, with an odds ratio (OR) of 0.02 (95% CI 0.0005-0.130; p < 0.0001). Patients with complete or incomplete recovery from AKI had higher UNa values compared to patients with non-recovery (73.2 ± 29.5 vs. 76.6 ± 22.3 vs. 52.6 ± 26.4; p=0.377). There were no significant differences in terms of signs and/or symptoms of clinical congestion or weight loss (9.7 ± 3.3 kg vs. 10.3 ± 2.4 kg; p=0.445). Patients with a UNa > 70 mmol/L had a lower 30-day mortality rate (2% vs. 10%; p=0.0203) and readmission rate (10% vs. 26%; p=0.0142). Additionally, the length of stay was shorter in patients with a UNa > 70 mmol/L (median LOS 6.2 ± 1.6 days vs. 8.5 ± 2.9 days; p=0.002).

Conclusions: Our findings suggest that UNa is a valuable tool for assessing diuretic response and guiding dosage titration in patients AHF. A UNa threshold of ≥70 mmol/L was associated with improved clinical outcomes. Conversely, a lower UNa was indicative of diuretic insufficiency and higher risk of AKI.

FR-PO038

Global Risk of AKI and Tubulointerstitial Nephritis following Anticancer Drug Administration, 1967-2023: Long-Term Pharmacovigilance Analysis

Soo-Young Yoon,[1] Dae Kyu Kim,[1] Su Woong Jung,[2] Jin Sug Kim,[1] Ju young Moon,[2] Hyeon Seok Hwang,[1] Kyunghwan Jeong.[1] *[1]Kyung Hee University Hospital, Dongdaemun-gu, Seoul, Republic of Korea; [2]Kyung Hee University Hospital at Gangdong, Gangdong-gu, Seoul, Republic of Korea.*

Background: Various anticancer drugs are being used worldwide with the advancement of anticancer drugs. Anticancer agents may be nephrotoxic and the aim of this study was to analyze the global risk of renal adverse reactions based on different types of anticancer drugs.

Methods: Between December 1967 to July 2023, we analysed the association between different types of anticancer drugs and the risk of acute kidney injury (AKI) or tubulointerstitial nephritis (TIN) using the World Health Organization pharmacovigilance database. The effect size was assessed using the reporting odds ratio (ROR) through disproportionate Bayesian reporting method. The 306 anticancer drugs were classified into four groups: cytotoxic therapy, hormone therapy, immunotherapy, and targeted therapy.

Results: We identified 32,722 cases of AKI and 2,056 cases of TIN that were reported as renal adverse reactions related to anticancer drugs. Cytotoxic therapies consistently accounted for 13,925 cases, while AKI cases related to targeted therapies and immunotherapies increased to 14,236 and 3,816 cases, respectively, over three decades. The use of immunotherapy between 2015 and 2020 led to a significant increase in TIN, surpassing other categories of anticancer drugs. The highest disproportionality signal for AKI was associated with immunotherapies (ROR, 8.92; confidence interval [CI], 8.63–9.21, followed by cytotoxic therapies (ROR, 7.14; 95% CI, 7.01–7.26), targeted therapies (ROR, 5.83; 95% CI, 5.73–5.93), and hormone therapies (ROR, 2.59; 95% CI, 2.41–2.79). The analysis showed a significantly higher disproportionality signal for immunotherapies (ROR, 21.74; 95% CI, 20.39–23.18) in the case of TIN, followed by cytotoxic therapies (ROR, 2.60; 95% CI, 2.40–2.82), and targeted therapies (ROR, 1.54; 95% CI, 1.40–1.69).

Conclusions: AKI and TIN were observed significantly after administering anticancer drugs. It is crucial to note that renal adverse reactions were more prominent with immunotherapy, which is increasingly used, compared to other types of anticancer drugs.

FR-PO039

Using Machine Learning to Predict AKI in Trauma Patients: A Single Trauma Center Study with Temporal Validation

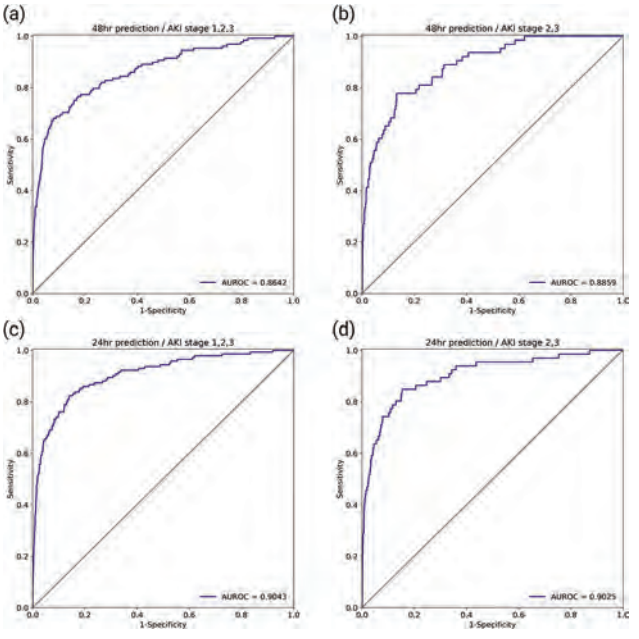
Sunggyul Lim, Yongjin Yi. *Dankook University Hospital, Cheonan, Chungcheongnam-do, Republic of Korea.*

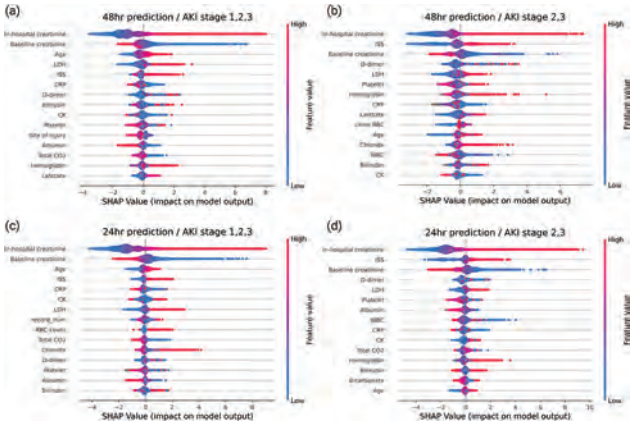
Background: Acute kidney injury (AKI) is a common and serious complication among trauma patients, associated with increased mortality and longer hospital stays. Early identification of AKI in this population is difficult due to its complex causes and the unique characteristics of trauma patients.

Methods: We conducted a retrospective study using electronic health records (EHRs) from a trauma center to develop and validate with extreme gradient boosting (XGBoost) predictive model for predicting AKI. The model was trained on data from Jan 2015 to Jul 2021 and validated on data from Aug 2021 to Jul 2023, internally. Model performance was assessed using the AUROC, and feature importance was evaluated using SHapley Additive exPlanations values.

Results: A total of 11,687 patients (9,063 in the development set and 2,624 in the validation set) were included. The incidence of AKI was 6.6% in the development and 5.4% in the validation group. The models showed AUROCs of 0.864 and 0.886 for predicting AKI stages 1-3 and stages 2-3 at 48 hours, and AUROCs of 0.904 and 0.903 for predicting AKI stages 1-3 and stages 2-3 at 24 hours. Important features influencing model predictions included in-hospital creatinine, age, and laboratory markers such as lactate dehydrogenase.

Conclusions: The machine learning models effectively predict AKI in trauma patients up to 48 hours in advance using readily available EHR data. The performance of this approach highlights the potential for machine learning to enhance predictive capabilities in trauma care.





FR-PO040

Epidemiologic Investigation of Contrast-Induced AKI Based on an In-Hospital Electronic Monitoring System

Xingyue Zheng, Youjun Xu, Fangfang Zhou, Qun Luo. *Ningbo No 2 Hospital, Ningbo, China.*

Background: With the gradual promotion of cardiovascular disease interventions, contrast-induced acute kidney injury (CI-AKI) has become the third most common cause of medically induced kidney injury. Patients with CI-AKI have a poor prognosis, which increases the incidence of end-stage renal disease and the risk of death, and the 2-year survival rate for patients with CI-AKI requiring dialysis is only 18.8%. AKI alerts and corresponding interventions based on electronic surveillance system data have been shown in selected studies to improve AKI patient regression, reduce AKI-related mortality, and decrease hospital length of stay.

Methods: 11,874 adult inpatients who underwent angiography with contrast agents at Ningbo No. 2 Hospital from June 1, 2019 to April 30, 2024 were included, and patients with CI-AKI were screened by an in-hospital electronic monitoring system according to the Kidney Disease Improvement Global Prognosis Organization (KDIGO) criteria.

Results: Of the 11,874 hospitalized patients, 63.36% were male, with an age distribution of 2.08% between 18 and 40 years old, 39.49% between 41 and 65 years old, and 58.43% 66 years old and over. The electronic monitoring system detection rate was 10.49% (1245/11874), of which only 7.47% (93/1245) patients with CI-AKI were invited to nephrologists for consultation, and only 5.30% (66/1245) patients with CI-AKI were discharged with a diagnosis that included an AKI-related diagnosis (acute renal insufficiency/acute renal failure/acute renal damage/acute kidney injury). Of the CI-AKI patients, 46.67% (581/1245) were medical patients, 22.41% (279/1245) were surgical patients, and 30.12% (375/1245) were in intensive care medicine.

Conclusions: The majority of physicians have insufficient knowledge of CI-AKI, serious underdiagnosis, and low consultation rate in nephrology. The establishment of an in-hospital electronic monitoring system is extremely important for improving the prevention and diagnosis of AKI and improving the prognosis of patients.

FR-PO041

Relationship of Surgical Type and Fluid Balance with Noncardiac, Perioperative AKI in Neonates

Morgan E. Beebe,[1] Brett Klamer,[3,1] Rain Miller,[2,1] Jonathan L. Slaughter,[1,3] Tahagod Mohamed.[1,3] *[1]Nationwide Children's Hospital, Columbus, OH; [2]The University of Toledo College of Medicine and Life Sciences, Toledo, OH; [3]The Ohio State University College of Medicine, Columbus, OH.*

Background: Few studies examine the relationship between noncardiac surgeries and neonatal acute kidney injury (AKI), with fewer focusing on the effects of fluid balance. Our study aims to evaluate the odds of noncardiac, peri-operative AKI development in neonates based on surgery class and fluid balance at our institution.

Methods: This is a retrospective review of neonates admitted to the neonatal intensive care unit at a single center from Nov 14-Jan 22. Neonates who required a major, minor, or procedural noncardiac surgery in the first 28 days of life were included for analysis. Neonates requiring cardiac surgery, ECMO, lethal chromosomal abnormality, or with significant underlying renal disease were excluded from analysis. Data were evaluated for the development of AKI in the 72 hours following intervention according to revised neonatal Kidney Disease: Improving Global Outcomes (nm:KDIGO) criteria for serum creatinine and urine output. We also reviewed the relationship between peri-operative fluid balance and AKI. Descriptive statistics were used to summarize patient characteristics. Statistical significance was set at an alpha level of 0.05.

Results: 764 neonates were included for final analysis. Following intervention, 715(94%) of neonates did not develop AKI, while 49(6%) did. A more positive fluid balance in the peri-operative period was associated with AKI development on POD 1,2, and 3 (p=0.003,0.002,0.023, respectively). In multivariate logistic regression, the odds of perioperative AKI were significantly higher in neonates undergoing minor surgeries compared procedures. Statistical significance was achieved between the odds of developing AKI in neonates undergoing minor surgery vs procedures [OR 0.52(0.15-1.36);OR 0.19(0.01-0.94), respectively], with a higher odds ratio of AKI after a minor surgery.

Conclusions: In this single-center retrospective analysis, we seek to evaluate associations between AKI and other variables within 72 hours of surgery. Significant factors associated with AKI include a more positive fluid balance, with a higher odds of AKI development in neonates undergoing minor surgery compared to a procedure. AKI surveillance should be undertaken in neonates undergoing noncardiac surgeries, with special attention to fluid balance peri-operatively to further reduce risk of AKI development.

FR-PO042

Rates of AKI with ACE Inhibitor and Angiotensin-Receptor Blocker Use

Michael I. Tabet, Mary V. Sarrazin, Diana I. Jalal, Jason Misurac, Benjamin R. Griffin. *University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: Nephrotoxic medications are a substantial contributor to in-hospital acute kidney injury (AKI). Studies suggest that angiotensin converting enzyme inhibitors and angiotensin receptor blockers (ACEi/ARB) are often stopped in the setting of AKI and not resumed on discharge or follow-up, but whether ACEi/ARB should be treated as nephrotoxins is a matter of debate. We hypothesized that among hospitalized patients with high nephrotoxin exposure, receipt of ACEi/ARB would result in similar rates of AKI development as other nephrotoxins.

Methods: Adult patients with ≥1 day of high nephrotoxin exposure from 2014-2022 were included. High nephrotoxin exposure was defined according to Nephrotoxic Injury Negated by Just-in-Time Action (NINJA) criteria as ≥3 nephrotoxins on one day or ≥3 days of intravenous vancomycin or aminoglycoside. The primary outcomes were time to any-stage AKI, AKI stage 1b, and AKI stage 2+3. A Cox proportional hazards model accounted for age, race, sex, BMI, comorbidities, baseline creatinine, vancomycin use, ICU care, and clinical parameters (selected lab values and vital signs) on the day of initial high nephrotoxin exposure.

Results: A total of 13,826 patients had ≥1 day of high nephrotoxin exposure, of which 2,916 (21%) received an ACEi or ARB as part of their nephrotoxin exposure. The ACEi/ARB group was significantly older (64±14 vs 58±15 years) and more likely to have congestive heart failure (16% vs 9%) and diabetes (22% vs 13%), but less likely to be in the ICU (18% vs 25%) and less likely to receive vancomycin (40% vs 67%). All-stage AKI occurred in 31% in both groups (p=0.6); stage 1b AKI occurred in 18% for ACEi/ARB compared to 21% (p<0.001); stage 2+3 AKI occurred in 5.5% vs 7.8% for non-ACEi/ARB (p<0.001). Adjusted hazard ratios for ACEi/ARB exposure were 0.98 (95% CI 0.90-1.09, p=0.6) for any-stage AKI, 0.90 (95% CI 0.81-1.00, p=0.04) for AKI stage 1b, and 0.83 (95% CI 0.69-0.99, p=0.04) for AKI stage 2+3.

Conclusions: Patients receiving two nephrotoxic medications + ACEi/ARB were as likely to develop any-stage AKI as those receiving three nephrotoxic medications (without ACEi/ARB), but had 17% lower hazards for AKI stage 2+3 development.

FR-PO043

Perioperative Kidney Function and AKI in Noncardiac Surgery: A Retrospective Cohort Study in Brasília, Brazil

Petherson M. dos Santos,[1,2] Kirliane D. Rodrigues Lacerda,[3] Rafael F. Rodrigues De Lacerda,[4] Yvve P. Gatto,[4] Gleidson T. Lima,[5] Débora C. Lara,[6] Lucas A. Pinheiro,[7] Priscila de Matos B. Oliveira,[4] Glayson C. Verner,[4] Carolina S. Garcia,[1] Jessica L. Andrade,[1] Lucyana Bertoso de Vasconcelos Freire,[2,6] Cassiane D. da Fonseca,[9] Miguel Angelo Goes.[1,8] Postgraduate Program in Nephrology at the Paulista School of Medicine at the Federal University of São Paulo. *[1]Universidade Federal de Sao Paulo Escola Paulista de Medicina, Sao Paulo, Brazil; [2]Escola Superior de Ciencias da Saude, Brasilia, Brazil; [3]Centro Universitario Unieuro, Brasilia, Brazil; [4]Secretaria de Estado da Saude do Distrito Federal, Brasilia, Brazil; [5]Hospital da Crianca de Brasilia Jose Alencar, Brasília, Brazil; [6]Hospital Universitario de Brasilia, Brasilia, Brazil; [7]Universidade de Brasilia Faculdade de Medicina, Brasilia, Brazil; [8]Sociedade Beneficente Israelita Brasileira Albert Einstein, Sao Paulo, Brazil; [9]Universidade Federal de Sao Paulo Escola Paulista de Enfermagem, Sao Paulo, Brazil.*

Background: Acute Kidney Injury (AKI) remains a significant complication in the perioperative period, associated with increased morbidity and mortality. This study aimed to evaluate the frequency and clinical factors associated with perioperative AKI in patients undergoing noncardiac surgery and to assess the predictive value of the SPARK – Simple Postoperative AKI Risk.

Methods: A retrospective study with 172 noncardiac surgery patients from 2021 to 2022 at a teaching hospital in Brasilia, Brazil. The study population included patients of various ages, genders, and comorbidities who underwent a range of noncardiac surgeries. Demographic and clinical data, such as kidney function (measured by creatinine levels), American Society of Anesthesiologists (ASA) score pre-surgery, and outcomes (including length of hospital stay and need for kidney replacement therapy), were compared between AKI and non-AKI groups. Finally, we performed a multivariate analysis and analyzed SPARK's index discrimination with the ROC curve.

Results: 60 (34.9%) patients developed AKI. Older age and higher ASA scores were significantly associated with AKI (p<0.001), and RDW was identified as a predictor of AKI (IRR 1.28%, 95% CI: 1.04-1.57, p= 0.017). Patients with AKI had more extended surgery. Exposure to nephrotoxic agents and blood transfusion requirements were also higher in the AKI group. The SPARK index showed the AUC of 0.72 (95% CI, 0.65-0.80).

Conclusions: Preoperative RDW levels, in addition to age and ASA score, were independently associated with AKI in noncardiac surgeries. The SPARK score, with its AUC of 0.72, is a valuable tool for preoperative risk assessment. These results underscore the complexity of risk factors associated with AKI in the perioperative setting of noncardiac surgeries. Further research is needed to validate the findings and enhance AKI prevention strategies.

FR-PO044

Evaluation of Scoring Tools to Predict AKI Postpercutaneous Coronary Intervention

Joanna Q. Hudson,[1,2] Tara Parnacott,[1,2] Anna R. Jacobs,[2,1] Carolyn Cummings,[2,1] Margaret C. Hastings,[1,2] Benjamin Duhart.[1,2] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]Methodist Le Bonheur Healthcare, Memphis, TN.*

Background: Radiocontrast-associated acute kidney injury (CA-AKI) is a common cause of in-hospital acute kidney injury (AKI) and other causes of morbidity and mortality. The original Mehran score was developed to predict risk of developing CA-AKI after percutaneous coronary intervention (PCI); however, it requires intraprocedural variables such as contrast volume and cannot proactively identify high-risk patients. The modified Mehran 2 (MM2) score and the CHA_2DS_2-VASc score overcome this limitation, but validation in the clinical setting is limited. This study evaluated the MM2 and CHA_2DS_2-VASc score for prediction of AKI in patients receiving iodinated contrast for PCI.

Methods: A retrospective chart review was conducted of adults (≥ 18 years) admitted to Methodist LeBonheur Hospitals in Memphis, Tennessee between July 2019 and July 2023 who received contrast for PCI. Patients with end-stage kidney disease, AKI prior to receipt of contrast, or with a documented contrast allergy were excluded. MM2 and CHA_2DS_2-VASc scores were evaluated in patients with and without CA-AKI using previously proposed thresholds for high risk (MM2 ≥ 8; CHA_2DS_2-VASc ≥ 4). Predictive ability was analyzed using receiver operating characteristic (ROC) curves for comparison of area under the curve (AUC); p-value < 0.05 considered statistically significant. Other factors associated with AKI not included in the MM2 and CHA_2DS_2-VASc were also evaluated.

Results: One hundred seventy-seven patients were included: 128 without CA-AKI (72.3%), 49 with CA-AKI (27.7%). The MM2 and CHA_2DS_2-VASc scores performed similarly for predicting CA-AKI (ROC AUC 0.68 and 0.67, respectively). The proportion of patients with a high/very high-risk MM2 score was greater in the CA-AKI group (55% vs. 32%; p=0.005). Similarly, more patients in the CA-AKI group had a high-risk CHA_2DS_2-VASc score (51% vs. 31%; p=0.011). The CA-AKI group had a higher rate of hypotension within 48 hours of PCI (41% vs. 12%; p<0.001) and was less likely to have received pre-procedure IV fluids (35% vs. 52%; p=0.035). Patients with CA-AKI had longer hospital length-of-stay (5.3 vs. 3.1 days; p<0.001).

Conclusions: The MM2 and CHA_2DS_2-VASc scores had similar predictive value for CA-AKI after PCI and may provide a practical advantage over the original Mehran score.

FR-PO045

Triglyceride-Glucose Index and Triglyceride-to-High-Density Lipoprotein Cholesterol Ratio as Novel Predictors of AKI: A Large-Scale Prospective Study

Fangfang Zhou, Youjun Xu, Qun Luo. *Ningbo No 2 Hospital, Ningbo, China.*

Background: Our study aimed to comprehensively investigate the associations of the Triglyceride-glucose (TyG) index and triglyceride to high-density lipoprotein cholesterol (TG/HDL-C) ratio with the risk of AKI, based on the data from the UK Biobank.

Methods: A total of 427,659 individuals remained for the final analysis. According to the TyG index levels, patient data were divided into 5 quartiles. The primary outcome of this study was incident AKI, defined based on the International Classification of Diseases edition 10. Participant follow-up started at inclusion in the UK Biobank and was censored on December 31, 2022 or on the date of the first AKI. The analysis involved the utilization of Cox proportional hazard models, log-rank tests, and Kaplan-Meier cumulative incidence graphs. Mediation analyses were carried out to examine the impact of hypertension, diabetes, and dyslipidemia on the relationships between the risk of AKI, the the TyG index, and TG/HDL-C ratio.

Results: Of 427,659 included participants, 22,447 (5.25%) participants developed incident AKI. The median TyG index and TG/HDL-C ratio were 8.68 (IQR 8.31–9.08) and 2.43 (IQR 1.51–3.96), respectively. The risk of AKI elevated progressively with the increased quartiles of both the TyG index and TG/HDL-C ratio, as indicated by Kaplan-Meier curves. Elevated quartiles of the TyG index or TG/HDL-C ratio exhibited strong associations with AKI risk in comparison to lower quartiles, demonstrating respective hazard ratios (95% CI) of 1.16 (1.11-1.22) and 1.05 (1.00-1.10) (p<0.001). After full covariate adjustment, the adjusted smoothed plots displayed U-shaped associations between TyG index and incident AKI, and the relation between TG/HDL-C ratio and the hazard of incident AKI followed a reverse J-shape (p for nonlinearity < 0.001). The results did not change by the sensitivity analysis. In mediation analyses, variables like hypertension, type-2 diabetes, and dyslipidemia emerged as notable intermediaries in the connections between the incident AKI, the TyG index, and the TG/HDL-C ratio (intermediation proportions: 83.5%,74.5%).

Conclusions: Association was detected between the increased TyG index or ratio of TG to HDL-C and increased AKI risks. These associations were mainly influenced by a higher incidence of hypertension, type-2 diabetes, and dyslipidemia.

FR-PO046

Preoperative Fasting Time Is Not Associated with Development of AKI after Cardiac Surgery

Moritz Schanz,[1] Carmen Heidrich,[2] Schmid Nico,[2] Nora Goebel,[1] Tina Oberacker,[1] Severin Schricker,[1] Micha Christ,[2] Joerg Latus.[1] *[1]Robert-Bosch-Krankenhaus GmbH, Stuttgart, Germany; [2]Bosch Health Campus, Stuttgart, Germany.*

Background: Acute kidney injury (AKI) is associated with high morbidity and mortality, therefore prevention is important. The aim of this study was to systematically assess AKI incidence after cardiac surgery depending on the preoperative fasting time.

Methods: This single-center study included n = 8423 patients who had cardiac surgery at Robert Bosch Hospital, Stuttgart (Germany) between 2017 and 2024. All patients scheduled for surgery the next day stop eating and drinking at midnight, irrespective the time of surgery. AKI was classified according to the full definition of Kidney Disease: Improving Global Outcomes (KDIGO), including urinary output.

Results: In our cohort, overall postoperative AKI incidence was 71% during hospital stay. Interestingly, patients with AKI stage 1-3 had significant longer preoperative fasting time compared to patients without AKI (p=0.036; OR 1.15 (IQR 1.05-1.27)). However, after adjusting for important confounding factors e. g. urgency of surgery, age, pre-existing conditions such as CKD, heart failure, obesity, as well as aortic clamping time, duration of surgery, the association was no longer evident (p=0.39; OR 1.07 (0.92-1.25)).

Conclusions: Although preoperative fasting time seems to be a plausible risk factor for AKI development, this study provides evidence that preoperative fasting time is not a risk factor for the development of AKI after cardiac surgery after adjustment for potential confounders.

FR-PO047

Utility of Cystatin C as a Predictor for Postoperative AKI in Noncardiac Surgeries

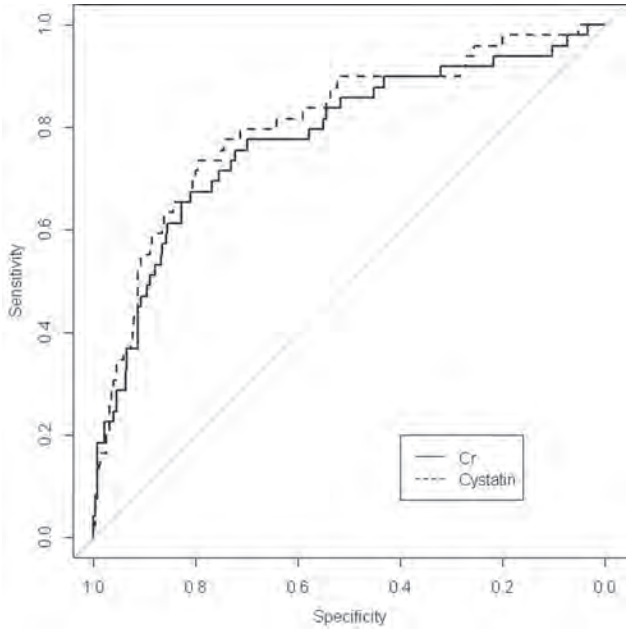
Hae Eun Jeon, Soie Kwon. *Chung Ang University Hospital, Seoul, Republic of Korea.*

Background: Serum creatinine has been widely utilized to estimate glomerular filtration rate (eGFR), although various biomarkers have been developed to address its limitations. Among these biomarkers, the clinical use of Cystatin C is increasingly gaining recognition. However, there is a lack of evaluation regarding the utility of cystatin C in predicting the risk of postoperative acute kidney injury (PO-AKI) in non-cardiac surgeries.

Methods: A retrospective cohort study was conducted on patients who underwent non-cardiac surgeries lasting over 1 hour in five departments. PO-AKI was defined as per KDIGO-AKI criteria occurring within 7 days after surgery. Logistic regression was used to develop a prediction model, and C-statistics and the Delong test were used to compare the performance of each model.

Results: 339 patients were enrolled, with 49 (14.5%) developed PO-AKI. Patients who developed AKI had a higher prevalence of diabetes and prescription of RAS blockers, longer operation duration, and lower eGFR of all types (Table 1). No statistical differences were observed in other laboratory findings between the two groups. The model with eGFR-Cystatin C demonstrated the highest area under the curve (AUC) among the three models (eGFR-Cr: AUC 0.78, 95% CI 0.702-0.857; eGFR-Cystatin C: AUC 0.81, 95% CI 0.735-0.877; eGFR-Cr/Cystatin C: AUC 0.80, 95% CI 0.724-0.871). Only the eGFR-Cystatin C-based model showed significant improvement in prediction compared to the eGFR-Cr-based model in the Delong test (eGFR-Cystatin C vs eGFR-Cr: p-value 0.033; eGFR-Cr/Cystatin C vs eGFR-Cr: p-value 0.055, Figure 1).

Conclusions: Our findings suggest the potential usefulness of cystatin C in predicting the risk of PO-AKI in non-cardiac surgery. Further studies involving larger and external cohorts are essential for validation.



FR-PO048

Validation of Renal Angina Indices in Critically Ill Patients and Assessment of Urinary Biomarker Incorporation for AKI Prediction

Erick Y. Zuñiga Gonzalez,[1] Juan M. Villegas,[1] Noemi Del Toro-Cisneros,[1] Rosario Guadalupe H. Ortega,[2] Pablo E. Galindo,[2] Cristino Cruz Rivera,[1] Olynka Vega.[1] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [2]Instituto de Seguridad y Servicios Sociales de los Trabajadores del Estado, Mexico City, Mexico*.

Background: The renal angina index (RAI) helps to predict acute kidney injury (AKI) in critically ill patients. Moreover, whether incorporation of urinary biomarkers into RAI may enhance severe AKI prediction is not kown.

Methods: This was a prospective cohort of patients admitted in two intensive care units (ICU) at third-level hospitals in Mexico City. Demographic, laboratory data and urinary samples were collected at ICU admission. RAI score was calculated using three methods at Day0: Matsuura, Ortiz-Soriano and Del Toro-Cisneros methods. AKI was defined according to KDIGO guidelines. The study aimed to evaluate RAI's predictive ability for severe AKI (stage 2 or 3) at 24 and 72 hours post-admission.

Results: Of the 134 patients analyzed, nineteen presented a stage 2 or 3 AKI over 72 hr follow-up. After evaluating all indices, RAI Matsuura presented the best performance in receiver-operating characteristics (ROC) analysis (cutoff of 10p) at 24hr (AUC 0.74, 95% IC 0.57-0.90) and 72hr (AUC 0.70, 95% IC 0.56-0.84). Neither urinary neutrophil gelatinase-associated lipocalin (uNGAL) nor urinary heat shock protein-72 (uHsp72) incorporation into RAIs improved ROC curve and discrimination for RAIs. [Table 1]

Conclusions: Our study highlights RAIs as a practical and useful tool for assessment of AKI risk in ICU adult patients. Urinary biomarkers incorporation does not improve accuracy for prediction of severe AKI, promoting RAIs' seamless integration into routine clinical assessments

Performance of different renal angina indices with and w/o addition of uNGAL

	AUC	Sensitivity	Specificity	PPV	NPV
RAI Matsuura [cut-off 10p] 24hr 72hr	0.74 (0.57-0.90) 0.70 (0.56-0.84)	66% 57%	81% 82%	26% 35%	96% 92%
RAI +/ NGAL +* 24hr 72hr	0.66 (0.47-0.84) 0.65 (0.49-0.80)	60% 56%	72% 73%	17% 25%	95% 91%
RAI del Toro [cut-off 10p] 24hr 72hr	0.68 (0.53-0.83) 0.69 (0.56-0.81)	75% 73%	61% 63%	16% 25%	96% 94%
RAI +/ NGAL +* 24hr 72hr	0.70 (0.54-0.86) 0.68 (0.54-0.82)	60% 75%	72% 68%	16% 24%	95% 94%
RAI Ortiz-Soriano [cut-off 10p] 24hr 72hr	0.62 (0.47-0.77) 0.60 (0.55-0.81)	79% 83%	43% 41%	18% 12%	92% 96%
RAI +/ NGAL +* 24hr 72hr	0.66 (0.50-0.80) 0.65 (0.52-0.78)	90% 88%	42% 44%	13% 19%	98% 96%

Predictive performance of RAIs for severe AKI (stage 2/3) at 24 and 72 hr. uNGAL cutoff based on Youden's optimal index: NGAL >152 ng/ml. *Patients included in the analysis n=118.

FR-PO049

Saliva Urea Nitrogen Improves Mortality Prediction in Children with Malnutrition and AKI

Anthony Batte,[1] Quique Bassat,[2] Peter Kotanko,[3] Jochen G. Raimann,[3] Andrea L. Conroy.[4] *[1]Makerere University College of Health Sciences, Kampala, Uganda; [2]Fundacion Privada Instituto de Salud Global Barcelona, Barcelona, Spain; [3]Renal Research Institute, New York, NY; [4]Indiana University School of Medicine, Indianapolis, IN*.

Background: Acute malnutrition is a leading cause of pediatric mortality and a risk for acute kidney injury (AKI). We evaluated the utility of saliva urea nitrogen (SUN) test strips and AKI to predict mortality in children hospitalized with acute malnutrition.

Methods: This study prospectively enrolled 185 children 6 months to 10 years of age hospitalized with acute malnutrition at Mulago National Referral hospital, Uganda from September 2020 to February 2021. Creatinine was measured using the modified Jaffe method that is IDMS-traceable. AKI was defined using a modified Kidney Disease: Improving Global Outcomes AKI definition (mKDIGO) using serial creatinine measures over hospitalization. Of 574 creatinine measures, 193 (33.6%) were below the assay limit of detection and assigned a value of 0.16mg/dL. Children required a maximum creatinine value ≥0.4mg/dL to be classified as having AKI. SUN was measured at bedside using semi-quantitative point of care strips. Enrolled children had weight-for-age or heigh-for-age z-scores <-2 SD. We used the modified Poisson regression and receiver operating curve (ROC) analysis.

Results: A total of 185 children were enrolled (36.2% female) and 25 children died (13.5%). Overall, 43 children (23.2%) met the definition for mKDIGO AKI and a positive SUN test (SUN ≥11mg/dL) was found in 105 children (56.8%). A positive SUN test was associated with a risk ratio (RR) of AKI of 2.88 (95% CI 1.46, 5.66) and severe AKI (AKI stage 2 & 3) RR 4.1 (95% CI 1.7 to 10.2). mKDIGO AKI (RR 3.58 95% CI 1.76 to 7.27) and a positive SUN test (RR 8.76 95% CI 2.12 to 36.22) were associated with mortality. The area under the ROC for AKI and a positive SUN test to predict mortality were 0.67 (95% CI 0.56 to 0.77) and 0.76 (95% CI 0.64 to 0.77), respectively. Incorporating both SUN and AKI significantly improved mortality prediction compared to either marker alone with an area under the ROC of 0.77 (95% CI 0.69 to 0.84).

Conclusions: SUN is a non-invasive tool that is associated with acute kidney injury and mortality in children with acute malnutrition. This point of care tool may provide additional benefit in risk stratification and prognostication of hospitalized children at risk of death when used in combination with creatinine based AKI definitions.

FR-PO050

Kidney and Endothelial Injury Biomarkers among Crossfit Athletes

Renan G. Diniz,[1,2] Júlio C. Nunes Filho,[2] Daniel V. Pinto,[2] Robson S. Matos,[2] Gdayllon C. Meneses,[2] Geraldo B. Silva Junior,[2] Elizabeth D. Daher.[2] *[1]Universidade de Sao Paulo, Sao Paulo, Brazil; [2]Universidade Federal do Ceara, Fortaleza, Brazil*.

Background: Crossfit® (CF) is a high intensive functional trained sport created in 2000. It is not recognized as an official sport by international sports federations. It has attracted many practitioners due to its quick results in muscle mass increase and weight loss. In Brazil, there was a 5900% increase in CF centers between 2012 and 2019, and there are currently more than 15000 centers worldwide. Given this emerging and intense sport, the purpose of this study was to evaluate markers of kidney and endothelial injuries among CF® athletes.

Methods: The study was conducted in two phases: Phase 1 involved proteinuria analysis from urine samples collected before work-out and results comparing recreational athletes (RAs) with competitive athletes (CAs). Phase 2 study compared levels of

endothelial and kidney injury biomarkers, including neutrophil gelatinase-associated lipocalin (NGAL), creatine kinase (CK), albumin, creatinine, and estimated glomerular filtration rate (eGFR) among CAs before and after activity.

Results: In Phase 1, 99 participants were involved. Results showed that 44.4% of CAs had proteinuria levels between 300 and 1000 mg/dL, and 14.8% had levels exceeding -1000 mg/dL. Only 2.8% of RAs had proteinuria levels above 300 mg/dL (p=0.001). In Phase 2, only 10 athletes had completed all the phases. This phase 2 comparing results between and after work out revealed creatinine 1.03 + 0.24 vs. 1.36 + 0.34, mg/dL(p=0.001) and CK 302.40 vs. 2048.80 U/L ; (p 0.005) 24h after the activity, and reduced eGFR (91.55 + 21.15 vs. 66.45 + 20.6, mL/min/1.73m2 p=0.000). ICAM-1, VCAM-1, Syndecan-1, and NGAL did not show statistically significant changes. There was a strong positive correlation between Syndecan-1 and CK (p=0.000, r=0.953).

Conclusions: Despite some limitations (such as not accounting for testosterone use and the small sample size in Phase 2), this is the only study that evaluated proteinuria, endothelial and kidney biomarkers among CF® Athletes. The findings suggest a possible risk of kidney disease in CF® athletes. Further research is warranted with larger sample sizes and more comprehensive risk factors to clarify whether these findings are directly linked to the sport or other confounding factors.

FR-PO051

Construction of a Predictive Model of Risk Factors for Kidney Replacement Therapy after Heart Transplantation

Dinglin Liu, Haofei Hu, Zhiming Ye. *Guangdong Provincial People's Hospital, Guangzhou, China.*

Background: Acute kidney injury (AKI) is one of the common complications after heart transplantation (HT), which seriously affects the quality of life and survival rate of patients after heart transplantation. Severe acute kidney injury requires renal replacement therapy (RRT), and early identification and intervention of risk factors can improve the prognosis, survival and quality of life of heart transplant patients.

Methods: The study enrolled 288 heart failure patients who underwent HT at Guangdong Provincial People's Hospital (Jan 2010-Feb 2023) and Zhongshan City People's Hospital (Jul 2017-Mar 2023). Risk factors were screened using machine learning and one-way analysis, the optimal coefficients were determined using Lasso regression model combined with cross-validation, non-zero coefficient variables were selected to construct a column-line graph prediction model, and prediction equations were established by multifactor logistic regression. The differentiation of the prediction model was assessed by the Area under Curve, the accuracy of the model was tested by the calibration curve, and the clinical applicability was analyzed by the Decision Curve Analysis.

Results: The incidence of severe acute kidney injury requiring RRT after HT was 28.13%. Six risk factors were identified and integrated into a column-line diagram: history of intra-aortic balloon counterpulsation use, preoperative serum albumin, preoperative blood creatinine, intraoperative red blood cell transfusion volume, duration of HT surgery, and intraoperative mechanical circulatory support. The area under the ROC curve for the predictive model was 0.765, and the calibration curve for the column-line diagram model was close to the ideal curve. The clinical decision curve showed that the column-line diagram prediction model performed optimally in the 0.1-0.6 probability interval. Internal validation was performed using Bootstrap method with 500 repetitive samples, yielding a mean AUC of 0.757.

Conclusions: In this study, we analyzed the risk factors for severe acute kidney injury requiring RRT after HT, and established a column-line graph prediction model and its equations. Internal validation proved that the model was stable and effective in predicting the risk of needing RRT after HT, which can help early intervention and improve prognosis.

FR-PO052

Intrarenal Vein Congestion Score but Not Venous Excess Ultrasonography Is Associated with Kidney Perfusion and Etiology of AKI

Arkadiusz Lubas, Adam Rytel, Ewelina Jedrych, Anna Grzywacz, Stanislaw Niemczyk. *Wojskowy Instytut Medyczny - Panstwowy Instytut Badawczy, Warszawa, Poland.*

Background: Proper diagnosis of acute kidney injury (AKI) etiology contributes to adequate treatment and a more favorable renal prognosis. Recently, a 4-point Venous Excess Ultrasound (VExUS) was introduced for AKI prediction. Due to the poor diagnostic performance of Vena Cava Inferior (VCI) maximal diameter in congestion assessment, interlobular renal vein Doppler flow patterns evaluation expressed as IntraRenal Vein Congestion Score (IRVCS) can be more appropriate for AKI etiology diagnosis. The study aimed to investigate the usefulness of IRVCS in predicting AKI etiology.

Methods: Twenty-four patients (10F, 14M; age 64 ±11) hospitalized due to AKI of unknown origin were evaluated in duplex Doppler ultrasound with the assessment of VExUS (grade 0-3): VCI; Hepatic Veins Systolic to Diastolic ratio, Portal Vein Pulsatility Index (PVPI), Real Vein Doppler. Moreover, Peak Systolic (PSV) and End-Diastolic Velocities (EDV) in interlobar renal arteries and IRVCS (stage 0-3) were investigated. Serum blood NT-proBNP and creatinine with eGFR-CKD-EPI calculation were tested. At discharge, the more probable etiology of AKI was identified as hypovolemia, hypervolemia, and inflammation.

Results: Mean creatinine was 3.48 ±1.82 mg/dL (CKD-EPI 22.97 ± 13.15 mL/min/1.73m^2) and NT-proBNP 9169.1 (IQR 5667.2) pg/mL. Abnormal IRVCS was found in 7 (29%) patients (2 – stage 1, 4 – stage 2, and 1 – stage 3), but VExUS revealed congestion in 12 (50%) patients (11 - grade 1, 1 - grade 3); p< 0.001. IRVSC significantly correlated with NT-proBNP (r=0.573; p=0.010), PSV (r= -0.557; p=0.011), EDV (r= -0.442; p=0.045), PVPI (0.485; p=0.026), and VExUS (r= 0.461; p=0.035). However, VExUS correlated only with VCI (r=0.753; p< 0.001) and IRVSC. Hypovolemic AKI etiology was recognized in 8 patients, hypervolemic in 7, and inflammation in 9. Logistic regression revealed that only IRVSC could substantially predict the hypervolemic etiology of AKI (OR 2.763; 95%CI: 1.008-7.570; p= 0.048). VExUS had no corresponding predictive properties (OR 2.070; 95%CI: 0.580-7.388; p= 0.262).

Conclusions: IntraRenal Vein Congestion Score is significantly associated with renal perfusion and can help predict the hypervolemic etiology of AKI. The presented data suggest that IRVCS is more appropriate than VExUS in diagnosing the etiology of AKI.

Development of Urinalysis Screening Criteria for Electronic Health Alerts for Rhabdomyolysis

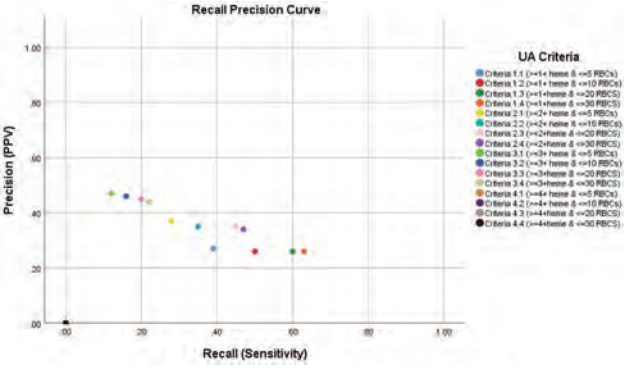
Farah Yasmin,[1,2] Sophia Faulkner,[1,2] Abinet M. Aklilu,[1,2] Yu Yamamoto,[1,2] Dennis G. Moledina,[1,2] Francis P. Wilson.[1,2] Clinical and Translational Research Accelerator (CTRA). *[1]Yale University School of Medicine, New Haven, CT; [2]Clinical and Translational Research Accelerator, Yale University School of Medicine, New Haven, CT.*

Background: Acute kidney injury (AKI) is present in 7-10% of rhabdomyolysis (rhabdo) cases and early intervention can improve outcomes. A discrepancy between heme on dipstick and RBC on microscopy on UA can potentially aid in early rhabdo diagnosis.

Methods: We did a retrospective electronic chart review of adult inpatients hospitalized between Jan 2020-Dec 2022 who met KDIGO-creatinine criteria for AKI, had UA within the same hospitalization pre-AKI, no rhabdo suspicion (i.e., no creatine kinase (CK) test pre-AKI), and no lab evidence of hemolysis.16 screening criteria were formulated to identify individuals at elevated likelihood of rhabdo using combinations of heme ≥1+, ≥ 2+, ≥ 3+, ≥ 4+ and RBC ≤5, ≤10, ≤20, ≤30 thresholds whose accuracy was assessed using post-AKI CK>500 U/L as the definition of rhabdo diagnosis.

Results: A total of 12,284 patients were included of which 20.5% had serum CK levels checked. Of those, 17.4% (440) met the diagnostic criteria for rhabdo. Rhabdo patients had significantly higher incidence of mortality, dialysis, and AKI progression. The median (IQR) time between UA and AKI was 1.97 (4.55-0.84) days. UA criteria of ≥1 heme + ≤30 RBCs (met by 35.1% of patients) had the highest sensitivity for rhabdo (63.4%). Within this criterion, a quarter (1079/4308) had their CK checked, of whom a quarter (279/1079) had CK levels consistent with rhabdo. The UA criteria of ≥ 3+ heme + ≤5 RBCs (met by 2.0% (246) patients) had a specificity of 97.2% and sensitivity of 11.2%. This criterion included the highest proportion of patients with CK measurement (111/246, 45.1%), and nearly half of those tested (52/111) had levels consistent with rhabdo (Fig. 1).

Conclusions: CK testing was overall uncommon under all definitions, suggesting missed rhabdo cases. As UA is obtained frequently in AKI workup (and other conditions) automated electronic screening of UA parameters with clinical decision support to order CK may be a viable mechanism to increase the diagnosis of rhabdo.



FR-PO054

Chloride Variation as an Independent Risk Factor for AKI Development and In-Hospital Mortality in Patients with Rhabdomyolysis

Lucas Araujo, Tania d. Spada, Bruna F. Silva, Heitor S. Ribeiro, Lucia Andrade, Emmanuel A. Burdmann, Jose M. Vieira Jr.. *Hospital das Clinicas da Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil.*

Background: Rhabdomyolysis (RB) is considered as an important cause for acute kidney injury (AKI) and mortality. Studies have suggested that acidosis is a risk factor for AKI. We alternatively hypothesized that serum chloride variation (SCV) might be associated with AKI and mortality in RB patients.

Methods: We studied a retrospective cohort of RB (>5x reference values of CPK) patients admitted in a tertiary hospital during a year. Demographic, clinical and laboratorial data were assessed and a regression analysis (RA) was performed in order to identify the independent variables associated with AKI and 28d mortality, including SCV.

Results: We included 291 patients admitted with RB due to diverse causes, from which 67% developed AKI. AKI patients were older, had more comorbidities and were sicker during admission (shock 35 vs 13%; $p < 0.0001$, mechanical ventilation, MV 49 vs 29%; p= 0.0015; sepsis 11 vs 3%; p=0.03). Peak CPK levels were higher in the AKI group (4218 IQR 2316-8968 vs 3221 IQR 1940-6206 U/L; p=0.04). Serum bicarbonate (SBic) and chloride did not differ between AKI and non-AKI at admission (21.0 IQR 18-24 vs 21.5 IQR 20-24 mEq/L, p=0.3; and 107 IQR 102-111 vs 107 IQR 113-111 mEq/L, p=0.5, respectively). During hospitalization, SCV was higher in the AKI group (2 IQR 0-10 vs 0 IQR 0-10 mEq/L, p=0.0003), and SBic was lower (18 IQR 14-21 vs 21 IQR 19-24 mEq/L, p< 0.0001). After RA, SCV remained as an independent variable associated with AKI (OR 1.09 CI 1.01-1.16, p=0.020), along with baseline hypertension (p=0.024) and SBic (p<0.001). AKI patients had higher mortality (39 vs 3.5%, p<0.0001) and RA showed that SCV was associated with mortality in the entire cohort (OR 1.082 CI 1.006-1.163, p=0.035), along with increased age, use of MV, AKI, use of renal replacement therapy, trauma and higher serum lactate.

Conclusions: Higher serum chloride variation was an independent risk factor for AKI and death in hospitalized patients with RB.

FR-PO055

AKI in Patients with Babesiosis: Incidence, Risk Factors, Clinical Features, and Outcomes

Audrey E. Monson,[1] Julio Baigorri,[1] Ahmad Jaser,[1] Sarah A. Kaunfer,[1] Shobana Krishnamurthy,[1] Guillermo Socorro Matos,[1] Peter J. Krause,[2] David E. Leaf.[1] *[1]Mass General Brigham Inc, Boston, MA; [2]Yale New Haven Health System, New Haven, CT.*

Background: Babesiosis is an emerging tickborne illness caused by the intraerythrocytic parasite, *Babesia microti*, which is endemic in the northeastern U.S. Complications have been observed in >20% of hospitalized patients, though AKI remains poorly described, with most data derived from case reports and small case series.

Methods: We reviewed the records of 1317 patients at Mass General Brigham with an ICD code or positive test result for *Babesia* between 2015-2023, of whom 272 (20.7%) were hospitalized. Among those hospitalized, we collected detailed data by manual chart review on demographics, comorbidities, medications, labs, and outcomes. We sought to characterize the incidence, severity, clinical features, risk factors, and outcomes of AKI, defined as a ≥50% increase in serum creatinine above baseline or receipt of kidney replacement therapy (KRT). We used multivariable logistic regression to identify independent risk factors for AKI.

Results: A total of 93 patients (34.2%) developed AKI, including 52 (55.9%), 23 (24.7%), and 18 (19.4%) with stages 1, 2, and 3 (**Fig. 1A**), 7 of whom (7.5%) received KRT. The most common etiologies of AKI were ATN, pre-renal azotemia, and hemolysis (**Fig. 1B**). Independent risk factors for AKI included older age, smoking, higher LDH, higher parasitemia load, and hematuria (**Fig. 1C**). Eight of 50 patients (16%) with data available had persistent kidney dysfunction at day 90.

Conclusions: In the largest study to date, we found that more than one third of hospitalized patients with babesiosis developed AKI, nearly half of which was stage 2 or 3. We identified five independent risk factors for AKI, including markers of hemolysis and severity of parasitemia.

FR-PO056

University of California Irvine Supported Vascular Endothelial Growth Factor Inhibitor (Intravitreal) Systemic and Renal Toxicity Registry: 24-Month Update

Matthew D. Nguyen,[1,2] Ryan E. Fekrat,[3] Vu Q. Nguyen,[3] Samir D. Patel,[2] Tai Truong,[2] Rebecca S. Ahdoot,[2] Ira Kurtz,[4] Ramy M. Hanna.[2] *[1]University of California Irvine School of Medicine, Irvine, CA; [2]University of California Irvine Nephrology Hypertension & Kidney Transplantation, Orange, CA; [3]University of California, Irvine - Department of Medicine, Irvine, CA; [4]University of California Los Angeles - Division of Nephrology, Los Angeles, CA.*

Background: Intravitreal Vascular Endothelial Growth Factor inhibitors (IVEGFi) are used in treatment of diabetic retinopathy. As we have previously reported there increasing number of cases documenting IVEGFi with renal injury and increased concentrations in the serum. To assess this claim, UCI Dept. of Nephrology has developed a novel reporting system through an electronic registry for cases of suspected VEGFi injury.

Methods: A website with data protection sets was organized to educate, promote awareness, and record cases of suspected intravitreal VEGFi toxicity. The website focused on displaying the biology of VEGF signaling, the process of absorption into the bloodstream, and the reporting of studies showing risks on case, cohort, and epidemiologic levels. A HIPAA compliant patient intake form was designed to collect renal, cardiovascular, cerebrovascular, renal biopsy and function data along with drug type, indication, and frequency of administration.

Results: In our updated cohort we added 17 total cases from the literature showing signs of renal injury from the patient population receiving VEGFi. In current literature, 46 cases of VEGFi related renal injury have been documented. To them we add our 17 cases for a total of 63 cases.

Conclusions: The current database for VEGFi related nephrotoxicity constitutes the largest case series presented for this condition. This study suggests future studies to evaluate what subgroups experience AKI, proteinuria and HTN exacerbations. Additionally, we may expand on our database to include timeline markers for symptomatic-correlative VEGFi usage and, in time, predictive measures in larger scale to correlate comorbidity/drug use with drug effect and mechanism of action.

Patient Number	Age	Gender	Comorbidities	Reason for the Intravitreal macular degeneration, diabetes, and central retinal vein obstruction	IVEGF/i Drug frequency	Drug	Drug Effects (Renal+systemic)
1	30	Male	Chronic Kidney Disease Diabetes Hypertension	DME	Daily	Bevacizumab	sCr 1.4-->2-->3 since starting avastin 2022-->2024 upcr 6g max 1.3 g-->4 g 2022-->2024 htn worsening +DR DM/DN
2	36	Male	Chronic Kidney Disease Diabetes Hypertension	DME	Monthly	Bevacizumab	sCr 1.3-->1.5-->2.5 over last 2 years proteinuria 1g-->2. 7-->3.5 g over last 2 years

10	43	Female	Chronic Kidney Disease Hypertension	VEGFi for DME	Monthly	Bevacizumab	2000mg/g of proteinuria (albuminuria) initially in 2017 when started intravitreal vegf --> increase to 10 g/day of proteinuria.
11	67	Female	Chronic Kidney Disease Diabetes Heart Attack Hypertension	DME	Monthly	Bevacizumab	patient with worsening renal function (accelerated DM and DN)
12	63	Male	Chronic Kidney Disease Diabetes Heart Attack Hypertension Stroke	Diabetic macular edema	Monthly	Bevacizumab	microalbumin/creatinine ratio of 70
13	75	Male	Hypertension	AMD	Bi-monthly or less often	Aflibercept	no proteinuria or hematuria
14	74	Male	Chronic Kidney Disease Hypertension	Macular degeneration	Monthly	Aflibercept	no proteinuria noted, but accelerated hypertension, with swings. HTN diagnosis normal to start around time of starting intravitreal VEGFi.
15	53	Male	Chronic Kidney Disease Diabetes Hypertension	DR	Bi-monthly or less often	Bevacizumab	nephrotic range proteinuria
16	58	Male	Chronic Kidney Disease	Diabetes	Bi-monthly or less often	Bevacizumab	Yes, ACi went from 1.3 -> 5 gram in span of 5 months. UPCr 4.7 grams.
17	47	Female	Hypertension	Proliferative diabetic retinopathy	Monthly	Other	worsening hypertension and worsening proteinuria.

FR-PO057

AKI after Vancomycin Treatment: Need for Kidney Biopsy

Anjali A. Satoskar,[1] Laura Biederman,[1] Mineaki Kitamura.[2] [1]*The Ohio State University, Columbus, OH;* [2]*Nagasaki Daigaku Daigakuin Ishiyakugaku Sogo Kenkyuka, Nagasaki, Japan.*

Background: Vancomycin is the antibiotic of choice for methicillin-resistant Staphylococcus aureus infections, often given empirically, even before culture results become available. However it is known for its nephrotoxic effect. Acute tubular necrosis (ATN) and mild acute interstitial nephritis (AIN) are the morphologic correlates in the kidney. But a substantial number of kidney biopsies performed for AKI following Vancomycin treatment instead show infection-related glomerulonephritis (IRGN). It is difficult to predict one versus the other. Analysis was performed to see if significant differences in demographic features exist that might help.

Methods: We searched our Pathology files for kidney biopsies with the term "vancomycin" in the clinical history. We retrieved a total of 354 biopsies between 2004 and 2017. Three broad diagnostic categories emerged: Group I- ATN with or without AIN (n=200); Group II - infection-related glomerulonephritis (IRGN) (n=94); and Group III (n=60) - other glomerular or vascular disease (n=60). Statistical comparison was performed for patient age, sex and ethnicity between these groups.

Results: Groups II and III comprised 44% of this cohort. In Group II, 23/94 showed resolving IRGN with mild IgA deposits and 67/94 also showed active proliferative glomerular lesions. Group III contained cases of ANCA-associated GN, cryoglobulinemic GN, proliferative GN with monoclonal IgG deposits (PGNMID), a few lupus nephritis, fibrillary GN and thrombotic microangiopathy (TMA). No significant differences in age or sex were identified between the three groups. Average age was 55.7, 57.7 and 56.8 years respectively. African American ethnicity was more represented in Group III (Pearson Chi-square test p = 0.0005).

Conclusions: AKI in patients receiving Vancomycin may not always be due to drug-induced ATN/AIN alone. Other concomitant pathologies may be present. IRGN can develop despite ongoing antibiotic treatment, in some but not all patients with infection, but is difficult to predict. Although, IRGN is reported to show predilection for older age, male sex and Caucasian background, these demograpic features did not help predict IRGN vesus Vancomycin-induced ATN in this cohort. Urinalysis may offer clues in non-oliguric patients. But kidney biopsy assumes importance. Further studies with urinalysis findings, Vancomycin trough levels, nature of infection are needed.

FR-PO058

Comparison of Clinical Characteristics of AKI between Glufosinate and Glyphosate Poisoning

Ju hwan Oh, A young Cho, Haeun Lee, In O Sun. *Presbyterian Medical Center, Jeonju, Jeollabuk-do, Republic of Korea.*

Background: There are few studies comparing the clinical characteristics of acute kidney injury (AKI) between glufoinate and glyphosate poisoning. In this study, we investigated the clinical characteristics of AKI in patients with glufosinate and glyphosate poisoning, and compared the clinical features of AKI between two groups.

Methods: This study performed between 2008 and 2021 included 76 patients with glufosinate poisoning and 184 patients with glyphosate poisoning. This study included 76 patients with glufosinate poisoning and 184 patients with glyphosate poisoning in the period from 2008 to 2021. Based on Risk, Injury, Failure, Loss of kidney function, and End-stage kidney disease classification, we investigated the incidence, clinical characteristics, and severity of AKI between two groups [(glufosinate-induced AKI (Glu-AKI, n=54) and glyphosate-induced AKI (Gly-AKI, n=82)].

Results: The incidence of AKI in patients with glufosinate poisoining is higher than that of glyphosate poisoning (57.5% vs 44.5%, P<0.05). However, there is no difference of AKI severity between two groups (Glu-AKI; Risk 56.2%, Injury 36.9%, Failure 6.9% vs Gly-AKI; Risk 56.2%, Injury 14.6%, Failure 29.2%, P=NS). Comparing two groups, there is also no difference in age (62.6±14.2 years vs. 63.3±16.2 years, *P*=NS) and renal function on admission (63.9±25.2 mL/min/1.73 m^2 vs. 62.2±22.9 mL/min/1.73 m^2, *P*=NS). The length of hospitalization was longer (17.2±17.2 days vs. 10.7±12.1 days, *P*<0.05) in Glu-AKI group than that of Gly-AKI group. The mortality rate was higher in the Gly-AKI group than Glu-AKI (11.1% vs. 18.3%, *P*=NS). Multivariate logistic regression analysis showed that serum bicarbonate concentration on admission was a significant predictors of AKI in patients with AKI after glyphosate and glufosinate intoxication

Conclusions: Although there is a higher incidence of AKI in glufosinate poisoning, there is no difference in clinical characteristics between the two types of intoxication.

FR-PO059

AKI Associated with Intestinal Ostomies

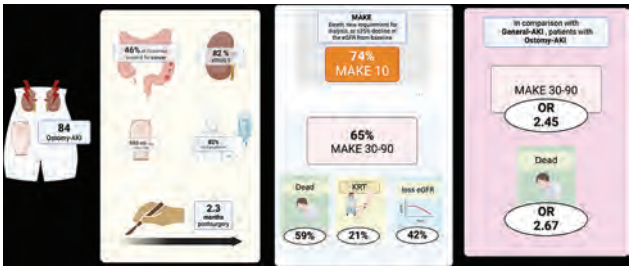
Jonathan Chavez,[1,2] Karla Hernandez Morales,[1] Guillermo Garcia-Garcia,[1] Ramon Medina,[1,2] Jahir R. Camacho,[1] Edgar J. Carmona,[1] Alexa N. Oseguera Gonzalez,[1] César Murguía Soto,[1] Alejandro Martínez Gallardo González.[2] [1]*Universidad de Guadalajara, Guadalajara, Mexico;* [2]*Hospital Civil de Guadalajara, Guadalajara, Mexico.*

Background: People with ostomies can have high output and be complicated by acute kidney injury (AKI). The clinical description of these patients and their association with the composite of major adverse kidney events (MAKE) has not been explored in depth.

Methods: In a retrospective cohort conducted at the Hospital Civil of Guadalajara Fray Antonio Alcalde. We included patients with AKI associated with ostomies (Ostomy-AKI) and compared them with AKI of other etiologies (General-AKI), with the objectives of describing and differentiating their clinical presentation and their association with early MAKE (MAKE10) and after 30 -90 days (MAKE 30-90), in addition to its individual components as death, new requirement for dialysis, or ≥25% decline in the eGFR from baseline. Analyzed the risk by logistic regression model and a multivariate Cox proportional hazard.

Results: During the period from February 2020 to October 2023, 84 patients in Ostomy-AKI were included and compared with 348 in General-AKI. The total cohort is composed mostly of men (59.3%), with an mean age of 55 years (41-67). In AKI-Ostomy patients were largely males (78.7 vs 56.2%), the output through the ostomy was 980 ml /day (760-1700), 82.9% required fluid adjustment; the cause of the ostomy was cancer in 46% and they had an average of 2.3 months with it. The etiology of AKI frequently due to hypovolemia (48.9 vs 24.5%) and they had more frequently AKI KDIGO stage 3 (82.9 vs 63.9%). Both groups had the same frequency of MAKE10 (94%), as were its individual components. The MAKE30-90 occurred more frequently in Ostomy-AKI (65.9 vs 49.3%), increasing more than two-fold the risk (OR 2.459, CI 1.134-5.332, p = 0.023), and it was very similar to its individual component of death (59.5 vs 37%) (OR 2.678, CI 1.260-5.689, p = 0.010).

Conclusions: In comparison with General-AKI, patients with Ostomy-AKI present with more hypovolemia and higher mortality during the 30-90 day follow-up, and a 2.5-fold increase risk of MAKE, especially that of mortality.



FR-PO060

AKI with Proximal Tubular Epithelium Vacuolization following SGLT2 Inhibitor Overdose

Makoto Araki, Yayoi Ogawa, Mitsuru Yanai. *Sapporo Tokushukai Hospital, Sapporo, Japan.*

Introduction: Sodium-glucose cotransporter-2 inhibitors (SGLT2i), commonly used to treat diabetes, heart failure, and chronic kidney disease, have been occasionally linked to acute kidney injury (AKI). Although osmotic renal injury is suspected to be one of the causes due to the drug's pharmacological effects, there are few histological studies on this issue.

Case Description: A 76-year-old woman with a history of two prior suicide attempts through drug overdose was admitted to our hospital after ingesting a large dose of her husband's medications an hour before arrival. The medications included 160 mg of esomeprazole, 1740 mg of azosemide, 725 mg of eplerenone, and 290 mg of dapagliflozin. She had diabetes, an HbA1c level of 8.1%, and bipolar disorder, but her family carefully managed her medications to prevent overdose. Following admission, diuretic-induced polyuria exceeded 150 mL/h. Ten hours later, a drop in blood pressure and signs of dehydration prompted an increase in fluid infusion. On the second day, her urine output increased to 5 liters per day, but then decreased sharply. By the fourth day, she became anuric. Subsequently, she remained anuric with her creatinine level rising to 4.12 mg/dl, leading to a diagnosis of stage 3 AKI and the initiation of dialysis. A renal biopsy conducted the following day revealed significant vacuolization and swelling in the proximal tubular cells, confirming osmotic tubular damage likely caused by SGLT2i, given the absence of hyperosmotic agents or severe potassium imbalance. Fortunately, her urine output gradually improved from the sixth day, allowing for the cessation of dialysis. Her renal function normalized by the twelfth day, and she was subsequently transferred for psychiatric care on the eighteenth day.

Discussion: Osmotic tubular injury, characterized by diffuse vacuolization and swelling of proximal tubular cells and traditionally associated with hyperosmotic agents, is now also sporadically reported with the use of SGLT2i. Risk factors include chronic kidney disease, advanced age, dehydration, and diuretic use. In this case, a combination of uncontrolled hyperglycemia, diuretic-induced dehydration, and high-dose SGLT2i likely caused the tubular injury. The prognosis for SGLT2i-induced damage remains uncertain, though it was favorable here.

FR-PO061

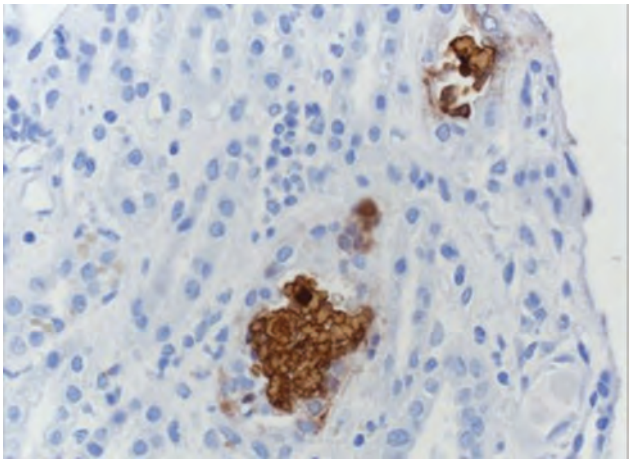
A Rare Case of Herpes Simplex Virus (HSV)-Associated Rhabdomyolysis

Cameron T. Lawson. *East Carolina University, Greenville, NC.*

Introduction: Viral myopathy is an important cause of massive rhabdomyolysis leading to acute renal failure. Many cases involving influenza A and B, Epstein Barr virus, and adenovirus have been reported. To my knowledge, this is only the second case of rhabdomyolysis secondary to herpes virus in a previously healthy patient that has been reported in the English literature.

Case Description: A 23-year-old female without significant past medical history presented to the ER for muscle aches, fevers, and hematuria. No recent trauma, increased exercise, or drug use was reported. The exam was notable only for genital ulceration. Labs were notable for BUN of 52 mg/dL, creatinine of 6.09 mg/dL, AST of 2,126 U/L, and ALT of 424 U/L. Creatine kinase elevated to 426,700 U/L. Ethanol < 10 mg/dL. Viral testing for HIV, Parvovirus B19, RSV, Influenza A, Influenza B, and COVID were all negative. Anti-JO-1 antibodies and complete myositis-specific autoantibody were both negative. Urine analysis showed no active sediment but urine protein: creatine ratio was 3.7 g/day. A kidney biopsy showed 1) diffuse acute tubular injury with extensive myoglobin casts and 2) mild acute interstitial nephritis. HSV-2 serum PCR was positive and valacyclovir was started. She remained anuric and hemodialysis was initiated. A muscle biopsy was performed to rule out autoimmune myositis. Creatinine was 5.6 mg/dL on discharge. Repeat creatinine at two weeks post-discharge was 1.9 mg/dL. The patient remained off dialysis and the muscle biopsy was read as necrotizing myopathy. No morphologic evidence of glycolysis, lipidosis, or mitochondrial myopathy was seen.

Discussion: Herpes virus is a rare cause of rhabdomyolysis leading to acute renal failure. As with other viral myopathies, muscle weakness accompanies this condition and can range from myalgias to myolysis. Rhabdomyolysis can be life-threatening and early recognition and treatment can prevent renal dysfunction. Evaluation for HSV should be included in the workup for viral myopathy.



Myoglobin cast

FR-PO062

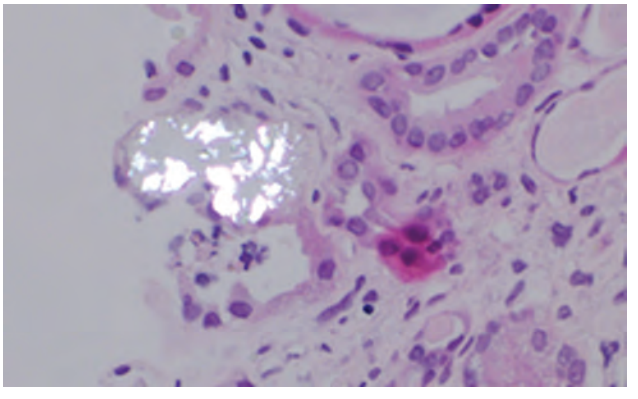
Hyperoxaluria: The Diet before the Riot

Aman Pal, Emmanuel A. Aydin-Ghormoz, Andrea R. Lightle, Geovani Faddoul. *Albany Medical Center, Albany, NY.*

Introduction: Oxalate nephropathy is a rare condition involving the accumulation of oxalate crystals within the nephrons. Primary hyperoxaluria involves enzymatic defects in the metabolism of glyoxylate, while secondary hyperoxaluria includes dietary and malabsorption related etiologies. Our case highlights the early diagnosis of oxalate nephropathy secondary to excessive intake of nuts and vitamin C.

Case Description: A Caucasian male in his 80s presented to the hospital with an AKI on CKD stage 4 in the setting of a new antibiotic prescription. Creatinine had increased to 4.2mg/dL from a baseline of 2.2mg/dL, with no etiology identified on urinalysis or renal ultrasound. Renal biopsy revealed an acute tubular injury with intraluminal calcium oxalate crystals deposits, confirming a diagnosis of oxalate nephropathy (Fig. 1). A detailed history revealed excessive dietary intake of oxalate-rich foods, including nuts, and daily ingestion of 2g of vitamin C. The patient was counselled on adjusting his diet and stopping vitamin C supplementation which led his creatinine to return close to baseline 2-months post-discharge.

Discussion: Dietary oxalate varies in individuals ranging from 44-351mg/day with there being a non-linear association between dietary and urinary oxalate content. The addition of 1000mg of vitamin C has also been shown to increase urinary oxalate up to 13mg/day. Consuming excessive amounts of oxalate can result in urinary levels above the threshold of 44mg/day for association with calcium oxalate stones. Our case emphasizes the possibility of excessive consumption of almonds, walnuts, peanuts, pine nuts and vitamin C as etiologies. The patient consumed approximately 30g of these nuts several times a day, which approximates 242mg of oxalate per serving. Additionally, our patient consumed 2000mg of Vitamin C daily. These factors played an integral part in the development of his AKI, highlighting the importance of collecting a thorough dietary history and keeping a low threshold to performing a kidney biopsy to prevent progression into ESKD.



FR-PO063

Epidemiological and Clinical Characteristics of Atypical Hemolytic Uremic Syndrome in China

Hua Zheng, Limeng Chen. *Peking Union Medical College Hospital Department of Nephrology, Beijing, China.*

Background: Atypical hemolytic uremic syndrome (aHUS) is a rare thrombotic microangiopathic disease that can lead to acute renal failure and hemolysis. Nevertheless, there is lack of nationwide data in China. This study intended to review and summarize the epidemiological characteristics and outcome of aHUS in China.

Methods: In this observational cohort study, we collected data from the Hospital Quality Monitoring System of China, a direct reporting system of medical data that covers abstract medical records from 5800 public hospitals in 31 provinces and municipalities from 2018 to 2022. All patients diagnosed with aHUS based on ICD-10 coding were enrolled. Patients missing unique identifier number or basic demographic information were excluded.

Results: 372 unique aHUS patients were identified, 45.6% of whom were male. Age distribution showed double peaks: children and women at thirties (Figure 1). Prevalence rates varied greatly among provinces, with the top 5 provinces being Inner Mongolia, Chongqing, Xinjiang, Guangxi, and Xizang, four of which were minority autonomous regions. The incidence of aHUS increased from 0.038 (2018) to 2.996 per million hospital admission (2022). 81% of the patients were first diagnosed in tertiary hospitals, with an average length of stay of 17.6 days. The top five admitting departments were nephrology, intensive care unit, pediatrics, hematology and general internal medicine. 37.5% of patients received dialysis, 20.3% received plasma exchange, 5.1% of patients underwent renal biopsy. The proportion of plasma exchange increased from 14.3% (2018) to 25.8% (2022), while intensive care unit support increased from 9.5% (2019) to 29.6% (2022). The combined proportion of discharges against medical advices and in-hospital deaths dropped from 33.3% (2019) to 16.9% (2022).

Conclusions: AHUS manifested with age and gender preference. With intensive support and treatment being increasing common, the proportion of adverse outcomes decreased through years in China.

Funding: Government Support - Non-U.S.

Thrombotic Microangiopathy Due to Liposomal Daunorubicin/ Cytarabine

Luke Webster, Dinna Cruz. *University of California San Diego, La Jolla, CA.*

Introduction: Thrombotic Microangiopathy (TMA) is a syndrome defined by microangiopathic hemolytic anemia, thrombocytopenia and end organ damage. With the rise of new chemotherapy regimens, drug induced TMA (DITMA) represents an important and growing cause of TMA. While DITMA has been occasionally reported with conventional daunorubicin/cytarabine we present the first case report of liposomal daunorubicin/cytarabine (lipo-dau/cyt) as a cause of TMA and Acute Kidney Injury (AKI).

Case Description: A 70F was admitted for management of Acute Myeloid Leukemia with lipo-dau/cyt. Patient with PMHx of well controlled HTN and Stage 2 carcinoma of left breast s/p bilateral mastectomy and adjuvant chemotherapy. One month after initiating lipo-dau/cyt, creatinine (Cr) rose from 0.94 to 1.68 with peak Cr 2.2. Patient reported worsening lower extremity edema and denied any skin rashes, lesions, or hematuria. Vitals showed worsening HTN with BP 165/107 despite previously being well controlled on outpatient antihypertensives, along with 14lb weight gain. Exam showed new 3mm pitting edema bilaterally to the knees. Labs showed Plt 8, Hgb 6.4, LDH 800, AST 52, ALT 37, UA with new 3+ proteinuria and 1+ urobilinogen. A 24h urine showed 4.9gm proteinuria. Complement activity Sc5-9: 633 ng/ml (h), haptoglobin was <10, ADAM-TS13 normal (74), and other serologic workup negative (SSA/SSB, ANA, ANCA, Anti-Sm, PLA2R, Shiga Toxin, SPEP). A peripheral smear showed numerous schistocytes. A kidney biopsy was performed which showed TMA with acute tubular injury. Lipo-dau/cyt was discontinued. Two months post withdrawal of medication Cr improved to 1.3 and LDH, platelets and haptoglobin normalized.

Discussion: This case illustrates the potential for liposomal daunorubicin/cytarabine to cause drug induced TMA. While older non-liposomal formulations have been associated with TMA in the past, this would be first report of its occurrence with the liposomal formulation. Early recognition of liposomal dauno/cyta-associated TMA is important for treatment modification and to help preserve kidney function.

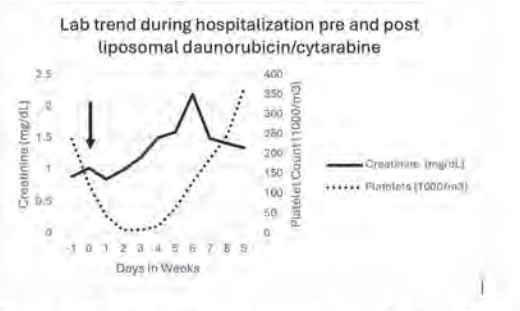

Figure 1: Creatinine trend pre and post exposure to liposomal daunorubicin/cytarabine with time zero representing initiation of therapy (indicated by arrow).

FR-PO065

Rifampin-Induced Hemolytic Anemia and Pigment Nephropathy Requiring Dialysis in an Adolescent

Lana Bridi,[1] Nadine M. Benador,[1,2] Natalie Ellington,[2] Caitlin E. Carter.[1,2]
[1]University of California San Diego, La Jolla, CA; [2]Rady Children's Hospital San Diego, San Diego, CA.

Introduction: Rifampin (RIF) is a commonly used anti-microbial and rarely causes acute kidney injury (AKI). We report a pediatric patient with dialysis dependent AKI due to hemoglobin cast nephropathy from hemolysis while taking RIF for latent tuberculosis (TB).

Case Description: 14 yo with latent TB on RIF with intermittent medication adherence presented with acute onset abdominal pain and intractable emesis. Labs revealed serum creatinine (Cr) 4.2 mg/dL, BUN 62 mg/dL, hemoglobin12.3 g/dL, platelet 77 × 10^9/L, LDH 3107 U/L, haptoglobin 10 mg/dL. Schistocytes were not observed. There was also a pattern of hepatocellular injury with elevated AST, ALT, bilirubin, aPTT and INR. Urine revealed microscopic hematuria, proteinuria (UPCR 4.2 g/gm), and muddy brown casts. Kidneys were both large and echogenic on ultrasound. He developed oliguria and required intermittent hemodialysis (iHD) for 10 days. Kidney biopsy revealed acute tubular injury secondary to hemoglobin casts and moderate interstitial inflammation. Two weeks after last iHD treatment, Cr remains elevated 1.09 mg/dL, eGFR 63 mL/min/1.73m^2.

Discussion: RIF associated AKI is caused by several pathologic patterns: interstitial nephritis and tubular necrosis are most common. Rifampin induced immune hemolytic anemia and thrombocytopenia with kidney injury has been described in adults. Kidney biopsy in this child showed an overlapping pattern of heme pigment nephropathy and interstitial nephritis leading to severe AKI. Sporadic rifampin administration has been associated with this phenomenon in adults. Discontinuation of RIF often results in resolution of hemolysis and AKI although can recurr if re-exposed to RIF. RIF induced AKI secondary to hemoglobin-cast nephropathy has not been reported in children. Adolescents, in whom medication adherence is often inconsistent, may be at higher risk and should be monitored for renal dysfunction.

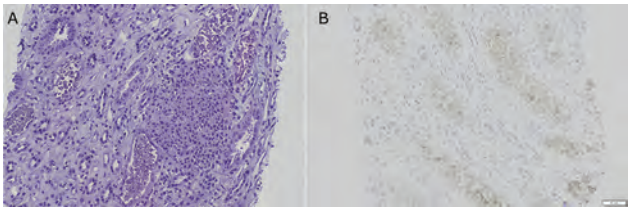

Figure 1. (A) Hemoglobin (Hgb) casts were granular, globular or rope-like in appearance. Focal tubular rupture is seen with adjacent non-necrotizing granulomatous response. (Hematoxylin and eosin). (B) Immunohistochemistry for Hgb showed positive staining within casts.

FR-PO066

A Late and Delayed Case of Rhabdomyolysis with Trabectedin Use

Adnan Barazi, Patricia Khalil, Amr Habbach. *Allegheny Health Network Graduate Medical Education, Pittsburgh, PA.*

Introduction: Trabectedin, a marine-derived alkylating agent, is used in treating Liposarcoma by disrupting the cell cycle and inducing cancer cell death. It, however, has been associated with rhabdomyolysis. What sets this case apart is the delayed onset of Trabectedin-induced rhabdomyolysis, manifesting approximately 3 weeks after the patient's last dose.

Case Description: 38-year-old female with a history of liposarcoma of the left femur with disease progression despite surgery and chemotherapy, has been undergoing palliative chemotherapy with trabectedin. She presents with fever and generalized weakness and laboratory evaluation showed a Creatinine Kinase (CK) level of 2751 U/L. She developed an acute kidney injury with a creatinine of 5.09 mg/dL. CK levels peaked on day 20 from the last dose at 10915 U/L. Trabectedin induced rhabdomyolysis was diagnosed and patient was started on hemodialysis. On outpatient follow-up, her renal function improved leading to discontinuation of hemodialysis with complete resolution of rhabdomyolysis.

Discussion: Trabectedin is an effective drug in treating advanced sarcoma. One of the rare side effects associated with its use is rhabdomyolysis. Its etiology is not completely clear. The most reported cases of rhabdomyolysis associated with Trabectedin occurred on average 2 weeks following the administration of Trabectedin. Most of the cases reported toxicity in the first few cycles of Trabectedin. In our case, rhabdomyolysis occurred 3 weeks after the 5th cycle. Therefore, one should remain vigilant about late and delayed cases of rhabdomyolysis with Trabectedin use. To note, the CK level was elevated after the third cycle at 1,124 U/L. The current recommendation is to check CK after each cycle and to adjust therapy with no discontinuation of therapy unless rhabdomyolysis occurs. This case highlights the need to explore if more stringent CK criteria and monitoring need to be placed to prevent rhabdomyolysis cases.

FR-PO067

Acute Interstitial Nephritis in the Setting of Ipilimumab and Nivolumab Therapy

Rupinder Kaur,[1] Somesh Singh,[2] Nabeel Siddiqui,[1] Bhoomi Shah,[1] Olawale M. Osunsanya.[1] *[1]Southeast Health, Dothan, AL; [2]Alabama College of Osteopathic Medicine, Dothan, AL.*

Introduction: Certainly, immune checkpoint inhibitors (ICIs) like Ipilimumab and Nivolumab, have become an important strategy in cancer therapy; however, the incidence of renal complications arising from the widespread use of ICIs may be underestimated. A less-known adverse reaction from checkpoint inhibitors is acute interstitial nephritis (AIN), and there are only a few case reports demonstrating AIN related to checkpoint inhibitors.

Case Description: A 74- year-old-male with a recent diagnosis of squamous cell lung carcinoma, on combination therapy with nivolumab (1 mg/kg) and ipilimumab (3 mg/kg) for almost 2 months, presented to us with nausea, vomiting, and associated generalized weakness. On presentation vitals were unremarkable. Creatinine 5.2 mg/dl(baseline 0.8- 0.9 mg/dL), Urine microscopy revealed >100 white blood cells, 1+ protein and 1+ bacteria, urine protein creatinine ratio 926 mg/g, and urine culture resulted negative. Renal ultrasound was unremarkable for any acute findings. He was started on IV fluids. On the next day, his creatinine worsened to 5.5mg/dl, and urine output was noted to be decreased. A urine Hansel stain was performed which showed increased eosinophils. Eventually, he started on oral prednisone 60mg PO daily for possible drug-related AIN. A renal biopsy revealed acute tubulointerstitial nephritis. Immunotherapy was discontinued. His creatinine subsequently improved, and he was discharged on 4-week taper of oral prednisone.

Discussion: The significant ICI-induced renal adverse event known as AIN is brought to light in this case, emphasizing the need for careful monitoring of renal function in patients undergoing immunotherapy with these drugs. AIN can occur days to several months after initiation of an offending agent. Although AIN is typically associated with medications such as non-steroidal inflammatory agents, proton pump inhibitors, or antibiotics, checkpoint inhibitors related to AIN have been reported. A brief course of corticosteroid therapy is a viable therapeutic strategy to attain full or partial remission. The true incidence of renal complications from ICIs is underestimated. Early recognition of this rare nephrotoxic reaction by healthcare providers may be important for the subsequent clinical course and recovery from AKI.

FR-PO068

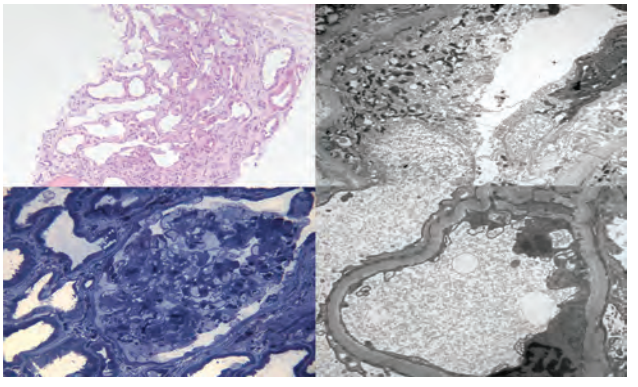
Dengue-Associated Tubulopathy with Resultant AKI and Dialysis Dependence

James Allen, Madhia B. Ahmad, Joshua Kaplan, Smita Mahendrakar. *Rutgers University Newark, Newark, NJ.*

Introduction: Dengue disease remains a prevalent mosquito transmitted viral infection worldwide. The incidence of dengue has increased 30-fold in the past 50 years. Acute kidney injury (AKI) is a serious complication of dengue with high morbidity and mortality. The available data regarding AKI in dengue is sparse and mostly originates from case series and case reports. We present a case of acute tubular injury secondary to dengue.

Case Description: A 59-year-old male presented with AKI on CKD with proteinuria, shortness of breath and lower extremity swelling. He was diagnosed with dengue fever and thrombocytopenia 1 month prior to admission in Brazil, where nephrotic range proteinuria was also found. Labs were significant for a creatinine of 10.1mg/dL and albumin of 1.9gm/dL. Protein to creatinine ratio was 12g/day. Proteinuria work up included C3, C4, Hepatitis B, C panel, HIV screen, anti-PLA2R, P-ANCA, C-ANCA, kappa/lambda ratio, free kappa light chains, and free lambda light chains was non-diagnostic. With worsening renal function and development of volume overload, hemodialysis was initiated, and renal biopsy was obtained. Biopsy demonstrated acute tubular injury denoted by markedly dilated tubules lined by flattened epithelium. Ultrastructural findings support acute tubular injury with loss of brush border. Methylene blue stained section revealed increase in mesangial matrix and protein resorption vacuoles in podocytes with acute tubular injury noted in surrounding tubules. With no signs of renal recovery, patient was discharged on scheduled dialysis and follow up with renal function monitoring.

Discussion: This case illustrates the potential long-term complications with dialysis dependence resulting from tubular injury caused by dengue infection. Dengue is an emerging source of global disease burden with limited data regarding cases complicated by AKI. Earlier recognition and management may lead to a significant reduction in dengue related renal complications in endemic areas.



FR-PO069

Rare Presentation of Renal Infarction Due to Protein S Deficiency

Thin Thin Soe,[1,2] Arfa Amjad,[1,2] Isha Puri,[1,2] Muhammad Azhar,[1,2] Mary C. Mallappallil.[1,2] *[1]New York City Health and Hospitals Corporation, New York, NY; [2]SUNY Downstate Health Sciences University, New York City, NY.*

Introduction: Protein S deficiency is a rare hematologic disorder which can be hereditary or acquired. Protein S deficiency is associated with increased risk of venous thromboembolism. However, there is no clear evidence of PS deficiency and arterial thromboembolic.

Case Description: We present the case of a 55-year-old female patient with no significant medical history who presented with 3 days of left sided flank pain, nausea and vomiting. She had mild leukocytosis, normal hemoglobin, unremarkable metabolic profile and with RBCs in urine microscopy, but no pyuria or bacteria. CAT scan of abdomen and pelvis with intravenous contrast revealed large well demarcated hypodensity in the upper pole of the left kidney, read as renal infarct (see image). CT angiogram of abdomen and pelvis was done to confirm thromboembolism, which revealed the occlusion of peripheral distal segmental branch of the distal left renal artery supplying upper pole of the kidney. She has 2 children, no history of spontaneous fetal losses. There is no family history of blood clotting disorders. She is a smoker 1 pack of cigarette for more than 30 years (>30 pack years). Hypercoagulable work up revealed very Low protein S levels – 26%, normal protein C, antithrombin III assay, Factor V Leiden mutation, Lupus anticoagulants, Cardiolipin, Beta 2 Glycoprotein 1 ab, no PNH clone, or JAK 2 mutation. We ruled out cardiac embolic source by echocardiogram and electrocardiogram did not show any Atrial fibrillation, flutter or other arrhythmias. She was treated with oral Apixaban for 6 months, and counseled about smoking cessation.

Discussion: In literature reviews, smoking nicotine can increase risk of thrombotic events such as stroke and myocardial infarction. There are studies that prove free protein S is significantly lower in smokers, and it contributes to thrombotic complications.

FR-PO070

Incidence and Clinical Outcomes of Sepsis-Associated AKI: A Multicenter Contemporary Cohort Study

Tomonori Takeuchi,[1,2] Alexander H. Flannery,[3] Lucas J. Liu,[4] Augusto Cama-Olivares,[5] Jin Chen,[6] Sarah C. Huen,[7] Ashita J. Tolwani,[1] Javier A. Neyra.[1] *[1]The University of Alabama at Birmingham, Birmingham, AL; [2]Tokyo Ika Shika Daigaku, Bunkyo-ku, Japan; [3]University of Kentucky, Lexington, KY; [4]Fred Hutchinson Cancer Center, Seattle, WA; [5]Brookwood Baptist Health, Birmingham, AL; [6]The University of Alabama at Birmingham, Birmingham, AL; [7]The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: The Acute Dialysis Quality Initiative defines sepsis-associated acute kidney injury (SA-AKI) as meeting both Sepsis-3 and KDIGO criteria within 7 days of sepsis diagnosis. We aim to evaluate the epidemiology of SA-AKI based on this contemporary definition.

Methods: This multicenter retrospective cohort study used EHR data from two academic hospitals, focusing on ICU admissions for individuals aged ≥18 from 2/2010 to 6/2022. Patients with ESKD or kidney transplant were excluded. Using culture and antibiotic timestamps, we identified infection occurrence and classified sepsis if the SOFA score reached 2 or more during the same period. AKI was identified using KDIGO serum creatinine (SCr) and urine output criteria. We compared patients with SA-AKI to those who developed AKI without sepsis (AKI only) and those who developed sepsis without AKI (sepsis only). Clinical outcomes included in-hospital mortality and major adverse kidney events at discharge (MAKE), evaluated by multivariable Cox regression and logistic regression models, respectively.

Results: Among 187,888 identified ICU patients, 63,621 developed sepsis, and 70,692 developed AKI. Of these, 29,615 met the SA-AKI criteria. The median age of ICU patients was 59 [IQR: 47, 70] years, with 43.3% being women. The prevalence of diabetes, cardiovascular disease, and chronic kidney disease was 21.6, 30.4, and 13.7%, respectively. In-hospital mortality was 11.2 for sepsis only, 11.8 for AKI only, and 25.0% for SA-AKI, and the HRs were 1.18 (95% CI: 1.12-1.25) for AKI only and 1.59 (1.51-1.66) for SA-AKI, with sepsis only as the reference group (Figure). The incidence of MAKE was 12.9 for sepsis only, 18.6 for AKI only, and 37.7% for SA-AKI, and the ORs were 1.58 (1.50-1.66) for AKI only and 3.35 (3.19-3.51) for SA-AKI, with sepsis only as the reference group.

Conclusions: In critically ill adults, SA-AKI is a frequent condition that is associated with increased mortality and a higher incidence of MAKE compared to sepsis only and AKI only.

FR-PO071

Acute Kidney Disease Staging Based on Estimated Glomerular Filtration Rate Predicts Outcomes Better than Staging Based on Serum Creatinine in Patients with Dialysis-Requiring AKI

Szu-Yu Pan,[1] Naichi Teng,[2] Likwang Chen,[2] Vincent Wu.[1] *[1]National Taiwan University Hospital, Taipei, Taiwan; [2]National Health Research Institutes, Zhunan, Taiwan.*

Background: The comparative performance of two staging systems for acute kidney disease (AKD), designated AKD_{eGFR} and AKD_{sCr}, remains uncertain. Our objective is to assess the predictive ability of these staging systems concerning outcomes.

Methods: This population-based retrospective observational cohort study identified 71,289 hospitalized patients with acute kidney injury requiring dialysis between July 1, 2015, and June 30, 2022, in the Taiwan National Health Insurance Research Database. AKD stages were defined according to the ADQI 16 Workgroup (AKD_{sCr}) and 2021 KDIGO Consensus (AKD_{eGFR}). Cox proportional hazard models were constructed to examine associations between AKD stages and outcomes including mortality and sustained renal recovery.

Results: The AKD_{eGFR} staging system predicted both outcomes better than the AKD_{sCr} staging system (**Figure 1**). Hazard ratios and 95% confidence intervals for mortality across increasing AKD_{eGFR} stages were 1.27 (1.18 - 1.36), 1.70 (1.59 - 1.82), 2.49 (2.35 - 2.64), 2.96 (2.78 - 3.15), and 5.22 (5.02 - 5.43). Conversely, within the AKD_{sCr} staging system, hazard ratios and 95% confidence intervals for mortality across ascending stages were 1.00 (0.93 - 1.07), 1.00 (0.91 - 1.10), 0.93 (0.81 - 1.07), and 3.37 (3.27 - 3.46). Subgroup and sensitivity analyses yielded consistent results.

Conclusions: The AKD_{eGFR} staging system performs better than the AKD_{sCr} staging system in patients with acute kidney injury requiring dialysis regarding all-cause mortality and kidney recovery.

Funding: Government Support - Non-U.S.

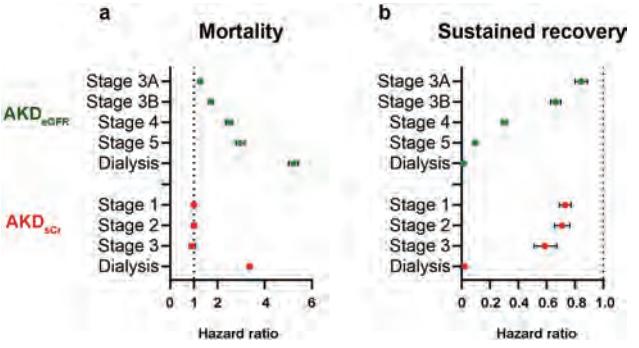

Figure 1. The adjusted hazard ratios (HRs) for mortality (Figure 1a) and sustained renal recovery (Figure 1b) across AKD stages in the AKD_{eGFR} (up) and AKD_{sCr} (down) staging systems were shown. AKD stage 0 served as the reference. Dots and error bars represented the point estimates and the 95% confidence intervals of the HRs.

FR-PO072

Machine Learning-Derived Personalized Fluid Intake Strategy in Sepsis-Associated AKI

Wonsuk Oh, Kullaya Takkavatakarn, Roopa D. Kohli-Seth, Girish N. Nadkarni, Ankit Sakhuja. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Sepsis associated acute kidney injury (SA-AKI) is common and associated with poor outcomes. While intravenous fluids are mainstay of therapy for these patients, recent literature suggests that restrictive fluid administration may be beneficial in certain patients with SA-AKI. This study aims to identify SA-AKI patients who would benefit from restrictive fluid administration.

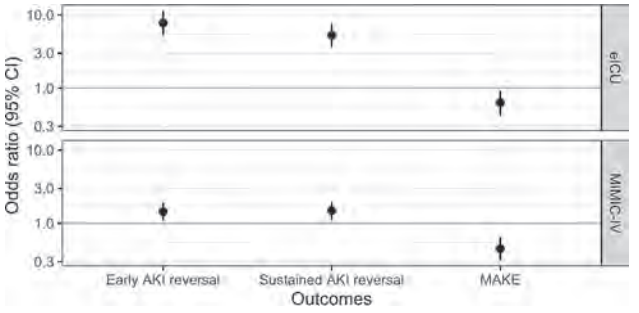
Methods: This retrospective study used eICU database for development and MIMIC-IV for external validation. We identified 2,086 SA-AKI patients in eICU and 6,532 patients in MIMIC-IV using KDIGO criteria for AKI. We defined restrictive fluid as administration of <500mL of fluid in 24 hours after SA-AKI. Primary outcome was early AKI reversal within 48 hours of AKI onset. Secondary outcomes included sustained AKI reversal for at least additional 48 hours after early AKI reversal and Major Adverse Kidney Events (MAKE) by discharge (defined as death, need for new dialysis, or discharge creatinine>=200% of baseline). We used causal tree and policy tree algorithms to estimate individual treatment effects and identify patients benefiting most from fluid restriction, and multivariable logistic regression to assess its impact on outcomes.

Results: 38% patients in the eICU and 43% patients in MIMIC-IV were recommended restrictive fluids. Among those recommended, only 26% patients in eICU and 8% patients in MIMIC-IV received restrictive fluids. Among patients that were recommended restrictive fluids, those that received had higher rates of early AKI reversal (eICU: 73% vs 27%, p<.01; MIMIC-IV: 53% vs 44%, p<.01) and sustained AKI reversal (eICU: 52%

vs 18%, p<.01; MIMIC-IV: 36% vs 29%, p<.01), and lower rates of MAKE at discharge (eICU: 26% vs 38%, p<.01 ; MIMIC-IV: 20% vs 32%, p<.01) in both eICU and MIMIC-IV (validation set). These effects were similar after adjustment of confounders (Fig 1).

Conclusions: In this study using a novel, machine learning approach we have developed and validated a strategy to identify SA-AKI patients who would benefit from a restrictive fluid administration.

Funding: NIDDK Support



FR-PO073

Multisystemic Support Therapies for AKI in Latin America: Current Status and Preliminary Report

Lilia M. Rizo Topete,[1] Dario Xavier Jimenez Acosta,[2] Rolando Claure-Del Granado,[3] Olynka Vega,[4] Alejandra Molano-Triviño,[5] Daniela Ponce,[6] David A. Ballesteros Castro.[7] SLANH AKI and Blood Purification Committee. *[1]Hospital Universitario "Jose Eleuterio Gonzalez", Universidad Autonoma de Nuevo Leon, Monterrey, Mexico; [2]Hospital Enrique Garces, Quito, Ecuador; [3]Universidad Mayor de San Simon, Cochabamba, Bolivia, Plurinational State of; [4]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [5]Fundacion Cardioinfantil Instituto de Cardiologia, Bogota, Colombia; [6]Universidade de Sao Paulo Instituto de Ciencias Biomedicas, Sao Paulo, Brazil; [7]Universidad del Cauca, Popayan, Colombia.*

Background: Kidney replacement therapy (KRT), including extracorporeal organ support (ECOS), is vital for treating acute kidney injury (AKI). Understanding available resources is crucial. Therefore, the Acute Kidney Injury Committee of the Latin American Society of Nephrology and Hypertension (SLANH) surveyed to gather information on human resources and equipment for KRT/ECOS treatment of AKI in Latin America.

Methods: A 30-question survey form was created to assess KRT/ECOS characteristics, including human resources, equipment, and types of procedures. Conducted online using Google Forms®, the survey was available for four months.

Results: 325 responses were collected, 89% from nephrologists. Among the nephrologists, 38% were women, and the main age group was 35-45 years. Participants were from 18 countries, with the highest responses from Mexico (29%), Ecuador (15%), and Colombia (13%). The survey highlighted the need for more training in CRRT (50%), ECMO (53%), ECCO2R (47.6%), TPE (46%), and HA (53%). Notably, 80% of participants' hospitals lacked ECMO. The most available therapies were IHD, CRRT, and PD, with the most common machines being IHD, PD, and CRRT. Only 42% could perform TPE, and 28% could provide other liver support therapies, with hemoadsorption available to only 23%. Nephrologists were responsible for prescribing therapies in 80% of cases, with joint decisions in 15%. The most frequent indication was fluid overload (30%), followed by uremic syndrome (26%) and oliguria (24%). Heparin was the most used anticoagulant for CRRT in Latin America (72%).

Conclusions: The lack of statistics in our region is a reality, but the shortage of technologies, equipment, and opportunities for patients and trainees is overwhelming. The new era of renal replacement therapies, like CRRT as a platform for other ECOS therapies, is in the hands of young nephrologists who need support and training.

FR-PO074

Hemodialysis Factors Associated with Kidney Function Recovery in Patients with AKI Receiving Outpatient Dialysis

Seda Babroudi,[1] Hocine Tighiouart,[2,1] Daniel E. Weiner,[1] Javier A. Neyra,[3] Ronald Sanders,[4] Harold Manley,[4] Eduardo K. Lacson,[4,1] David A. Drew.[1] *[1]Tufts Medical Center, Boston, MA; [2]Tufts Medical Center Institute for Clinical Research and Health Policy Studies, Boston, MA; [3]UAB Hospital, Birmingham, AL; [4]Dialysis Clinic Inc, Nashville, TN.*

Background: Patients with acute kidney injury receiving outpatient dialysis (AKI-D) represent 10% or more of annual new hemodialysis starts in the United States, of whom approximately one-third recover kidney function. We examined the relationship of novel hemodialysis prescription factors with kidney function recovery in patients with AKI-D.

Methods: Using a multi-center retrospective cohort design, we evaluated the association of hemodialysis treatment frequency, treatment duration, ultrafiltration rate, net ultrafiltration, intradialytic hypotension, and dialysate temperature and electrolyte concentrations at baseline with kidney function recovery to dialysis independence among patients with AKI-D who initiated dialysis between 2017 and 2021 at a medium-sized dialysis provider. We used Cox proportional hazard models adjusting for demographic and clinical factors.

Results: 2,544 adults with AKI-D treated across 238 dialysis facilities were analyzed. The mean (SD) age was 65 (14.2) years, 58% were men, and 19% were Black. A total of 857 (34%) patients recovered kidney function, with a median (IQR) time-to-kidney function recovery of 29 (17,54) days. Fewer than three hemodialysis treatments per week significantly positively associated with kidney function recovery as compared to three or more treatments per week in the first thirty days. Longer treatment duration, higher net ultrafiltration, and higher ultrafiltration rate significantly negatively associated with kidney function recovery after multivariable adjustment (Table 1). Intradialytic hypotension and hemodialysate characteristics did not associate with kidney function recovery.

Conclusions: Among patients with AKI-D, longer treatment duration, higher net ultrafiltration, and higher ultrafiltration rate significantly negatively associated with kidney function recovery. Fewer than three hemodialysis treatments per week, however, significantly positively associated with kidney function recovery. These results support further study of ultrafiltration rate thresholds and dialysis deprescribing to promote kidney recovery.

Cumulative Detrimental Effect of Hypotension during Intermittent Hemodialysis on Kidney Recovery in Critically Ill Patients with AKI Requiring Dialysis

Joonhee Yoon, Kipyo Kim. *Inha University, Incheon, Republic of Korea.*

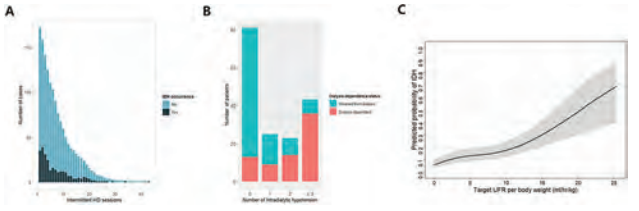
Background: Acute kidney injury requiring dialysis (AKI-D) severely affects the mortality and kidney outcomes of critically ill patients. Intermittent hemodialysis (IHD) is commonly implemented throughout the entire period of kidney replacement therapy

(KRT) in AKI-D patients, irrespective of initial modality of KRT. There remain concerns about hemodynamic instability during IHD, but the impact of intradialytic hypotension (IDH) during IHD on kidney recovery remains undetermined.

Methods: We retrospectively enrolled individuals who were diagnosed with AKI and received IHD at intensive care units of Inha University from January 2018 to February 2024. IDH was defined as having a nadir systolic blood pressure < 90 mmHg, newly starting vasopressors or increasing the dose during IHD sessions, or early termination of dialysis due to hemodynamic instability. We ascertained IDH occurrences and dialysis dependence at discharge in survivors from AKI-D.

Results: Of a total of 1,473 patients received kidney replacement therapy due to AKI, 765 patients died, and 276 patients did not undergo IHD. Therefore, 172 patients receiving IHD were included in the main analysis. Median number of IHD sessions were 7.0 (IQR 3-11.5), and the proportion of IDH per patient was approximately 14%. Of these, 67 patients (45.9%) were dialysis-dependent at discharge. Multivariable logistic regression analyses revealed the number of IHD (as a continuous variable) was a significant predictor for dialysis dependence (OR, 1.71; 95% CI, 1.17-2.64). When the number of IHD was categorized (0, 1-2, and ≥3), the risk of dialysis dependence was substantially higher for individuals with the number of IDH ≥3 compared to those without IDH (OR, 10.41; 95% CI, 2.22-58.93). In the per-session analysis, target UFR was the independent risk factor for IDH occurrence.

Conclusions: Our study revealed that IHD-related hypotension during hospitalization has the cumulative adverse impact on kidney recovery in AKI-D survivors. To improve kidney outcomes following AKI-D, the prevention for hemodynamic instability during IHD might be crucial.



FR-PO076

Predicting Which Newborns Will Benefit from Early Peritoneal Dialysis following Cardiac Surgery: A Quest for Precision Medicine with Comparative Outcomes

Ali Mirza Onder. *Nemours Children's Hospital Delaware, Wilmington, DE.*

Background: This retrospective single center study was conducted to investigate the accuracy of a clinical strategy in predicting newborns who will benefit from early peritoneal dialysis (PD) following cardiac surgery (post-op). Comparative outcomes are reported.

Methods: There were forty-nine newborns. PD catheters were placed for all in the operating room (OR) following cardiopulmonary bypass (CPB). Those with longer CPB times, post-op oligo-anuria and worsening fluid overload were selected for early PD start (PD +). All PD + were started within the first post-op 24 hours. The primary outcomes were 5% fluid overload at post-op 48 hours and severe AKI at post-op day 5.

Results: Twenty-nine subjects were started on early PD (PD +) and twenty used the PD catheter as abdominal drain (PD -). Baseline demographic data were indifferent. Both groups were oliguric during post-op first 8 hours (p= 0.906). The Early PD (+) group produced significantly less urine output during post-op day 1 (0.98 vs 3.02 ml/kg/hour; p= 0.001). At post-op 48 hours, early PD (+) group had similar prevalence of 5% fluid overload as early PD (-) group, (p= 0.427). Severe AKI incidence at post-op day 5 was low and similar between the groups (17.3% vs 5.0%; p=0.204).

Conclusions: Persisting oliguria during post-op 24 hours may successfully identify those who will benefit from early PD. The first post-op 8 hours was indiscriminative for this decision. Placing the PD catheter in the OR may be an advantage. Early PD start may ameliorate the disadvantage for the designated group.

FR-PO077

Patterns of Readmission and Death after Admission with AKI: A Data-Linkage Study

Zena Barakat, Timothy J. Pianta. *Northern Centre for Health Education & Research, Epping, VIC, Australia.*

Background: Despite episode-level data, and health-service level studies, patient-level incidence of AKI across Australia or its major jurisdictions has not been characterized to date. Important outcomes including discharge to residential aged care, hospital readmission, and mortality remain undefined. Data linkage allows clarification of patient-level outcomes across a jurisdiction to permit system-level policy and planning and potentially refine resource allocation.

Methods: Data linkage analysis of jurisdiction-wide administrative data in Victoria, Australia. The study linked the Victorian Admitted Episodes Dataset (VAED), Victorian Death Index (VDI), Victorian Integrated Non-admitted Health (VINAH), and Victorian Cancer Registry (VCR) in July 2016 to June 2017. Index admissions with AKI were defined with follow up to 36 months.

Results: 2,817,000 admissions were complicated by AKI in 198,966 (7.1%) episodes of care in Victorian hospitals. 38,033 individual adult patients accounted for the 96,549 AKI episodes identified in adults admitted overnight to acute care. AKI incidence was greatest amongst elderly (age ≥75 years; 57.6%), overseas-born, and comorbid patients, but paradoxically less amongst socioeconomically disadvantaged patients. Inpatient mortality complicated 1,984 (5.2%) of the index admissions. Most AKI survivors were readmitted [23,757 (65.9%)] at least once (median 3, range 0 – 33), and a majority [20,244 (85.2%)] experienced recurrent AKI within 12 months. At 12-months, overall mortality was 27.2%, and 22.9% amongst survivors of the index episode with 28.0% of these deaths within 30 days. At 3 years, overall mortality was 46.2%. Cancer was the leading cause of death followed by cardiovascular disease, sepsis, dementia, and kidney failure.

Conclusions: Despite likely underreporting of AKI in Victoria, AKI was a commonly reported and relapsing condition of predominantly elderly patients. An index episode of AKI was associated with recurrent admission and recurrent AKI in most patients. Discharge to a residential aged care facility was common. AKI was associated with high mortality, most commonly attributable to cancer rather than cardiovascular disease. Education, interventional studies, and policy can better reflect the epidemiology of AKI. Further analysis should clarify previously unexplored interactions between AKI, cancer, residential aged care, avoidable readmission, and mortality.

FR-PO078

Value of Post-AKI Protein-to-Creatinine Ratio (PCR) in Discriminating Risk of Kidney Disease Progression: Insights from the CRIC Study

Yuenting D. Kwong,[1] Kathleen D. Liu,[1] Alan S. Go,[6] Ian E. McCoy,[1] Anthony N. Muiru,[1] Matthew R. Weir,[2] Mark L. Unruh,[3] Hernan Rincon-Choles,[4] L. Lee Hamm,[5] Jing Chen,[5] Jesse Y. Hsu,[7] Xiaoming Zhang,[7] Chi-yuan Hsu.[1] *[1]UCSF Medical Center, San Francisco, CA; [2]University of Maryland Medical System, Baltimore, MD; [3]University of New Mexico Health System, Albuquerque, NM; [4]Cleveland Clinic, Cleveland, OH; [5]Tulane University, New Orleans, LA; [6]Kaiser Permanente, Oakland, CA; [7]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

Background: Proteinuria after AKI quantified by albumin-to-creatinine ratio (ACR) measured 3 months after AKI is a strong discriminator for rapid loss of kidney function (c-statistic 0.82 in Hsu JAMA 2020). Measuring proteinuria by protein-to-creatinine ratio (PCR) after AKI is less expensive and expanding the timing for collection beyond 3 months may increase flexibility in processes of care. Limited knowledge exists on the implications of using post AKI PCR collected within 1 year in discriminating risks of kidney disease progression in patients with pre-existing CKD.

Methods: We followed participants who had AKI between 7/1/2013-12/1/2021 in the Chronic Renal Insufficiency Cohort (CRIC) cohort from the time of first post AKI PCR within 1 year of AKI discharge to the primary outcome of kidney disease progression defined by halving of eGFR or progression to ESKD. Cox proportional hazards modeling was applied to evaluate the association of log-transformed post AKI proteinuria with kidney disease progression. Analysis was repeated after adjusting for demographic variables, diabetes status, BMI, eGFR, AKI stage, systolic blood pressure, and use of ACEi and ARBs.

Results: 554 CRIC participants had PCR measured a median of 147 [IQR 79-233] days after AKI discharge. Their mean age was 67 years, 43% were female and 51% were non-Hispanic Black. Mean initial post AKI eGFR was 43 mL/min/1.73m^2 and PCR was 0.3 g/g. 82% had AKI stage 1, 15% had AKI stage 2, and 3% had AKI stage 3. Over the mean follow-up of 2.6 years, 124 had kidney disease progression. Higher post AKI PCR was associated with increased risk of kidney disease progression (hazard ratio 2.01 for each doubling of proteinuria 95% CI 1.63-2.49). Post AKI PCR was a strong discriminator of kidney disease progression (c-statistic 0.80 in the unadjusted model, 0.86 in the adjusted model with clinical risk factors). AKI severity was not associated with kidney disease progression.

Conclusions: Proteinuria evaluation by PCR obtained any time up to 1 year after AKI was independently associated with subsequent kidney disease progression in patients with CKD and may be a low cost, flexible alternative to ACR at 3 months for detecting those at risk of kidney disease progression after AKI.

Quantifying Change in Proteinuria after AKI among Patients with CKD from the CRIC Study

Yuenting D. Kwong,[1] Kathleen D. Liu,[1] Alan S. Go,[2] Anthony N. Muiru,[1] Ian E. McCoy,[1] Matthew R. Weir,[3] Mark L. Unruh,[4] Hernan Rincon-Choles,[5] L. Lee Hamm,[6] Jing Chen,[6] Jesse Y. Hsu,[7] Xiaoming Zhang,[7] Chi-yuan Hsu.[1]
[1]UCSF Medical Center, San Francisco, CA; [2]Kaiser Permanente, Oakland, CA; [3]University of Maryland Medical System, Baltimore, MD; [4]University of New Mexico Health System, Albuquerque, NM; [5]Cleveland Clinic, Cleveland, OH; [6]Tulane University School of Medicine, New Orleans, LA; [7]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.

Background: Few studies have rigorously investigated if increased proteinuria is an important pathway by which AKI contributes to development or progression of CKD. Numerous published studies lacked appropriate non-AKI controls; Parr et al (KI 2018) relied on semiquantitative dipstick measurements obtained as part of clinical care and Hsu (JASN 2019) included only participants hospitalized shortly before enrollment. Neither study focused exclusively on patients with CKD, who are particularly vulnerable to AKI. To fill this knowledge gap, we analyzed data from the multicenter, prospective Chronic Renal Insufficiency Cohort (CRIC) study.

Methods: We analyzed CRIC study data from 7/1/2013-12/1/2021. Hospitalized AKI was defined as ≥1.5 peak to nadir inpatient serum creatinine (SCr). Mixed effects regression was applied to examine the association between AKI and natural log-transformed urine protein creatinine ratio (uPCR) ascertained at yearly CRIC research study visits. We adjusted for sex, race, clinical center as well as time-updated age, eGFR, SBP, diabetes, number of anti-hypertensive medicines, and use of ACEi or ARB.

Results: The final cohort included 3,197 participants with mean age of 65 years, 44% were female, and 42% self-identified as non-Hispanic Black. The median baseline eGFR was 52 mL/min/1.73m2 and uPCR was 0.14g/g. During a median follow-up time of 6 years, 560 patients experienced AKI and 2637 did not. Most AKI episodes were stage 1 (65%) rather than stage 2 (28%) and stage 3 (7%). We quantified a 4% increase in uPCR (relative change ratio of 1.04, [95% CI 1.02-1.06, p<0.01) after an AKI episode in the multivariable adjusted model. More severe AKI was associated with a greater change in uPCR, with stage 3 AKI being associated with a 10% increase in uPCR (relative change ratio of 1.10, [95% CI 1.02-1.19], p=0.01).

Conclusions: Episodes of AKI may result in residual structural damage to the kidneys as reflected by worsening proteinuria. However, most of the proteinuria observed among AKI survivors was already present prior to AKI.

Defining Key Elements of Communication after AKI: A Modified Delphi Process by the AKINow Workgroup

Yuenting D. Kwong,[1] Samuel A. Silver,[2] Javier A. Neyra,[3] Ian E. McCoy,[1] Jia Hwei Ng,[4] Emaad M. Abdel-Rahman,[5] Leslie S. Gewin,[6] Erin F. Barreto,[7] Bonnie L. Freshly,[8] Anitha Vijayan.[9] *[1]UCSF Medical Center, San Francisco, CA; [2]Queen's University, Kingston, ON, Canada; [3]The University of Alabama at Birmingham, Birmingham, AL; [4]Northwell Health, New Hyde Park, NY; [5]University of Virginia, Charlottesville, VA; [6]Washington University in St Louis, St Louis, MO; [7]Mayo Clinic Minnesota, Rochester, MN; [8]American Society of Nephrology, Washington, DC; [9]Intermountain Medical Center, Murray, UT.*

Background: Lack of consensus exists on the key elements of communication about an AKI event between inpatient and outpatient care teams and the information that should be provided to patients and their care partners. We aim to develop and refine standardized communication tools that promote AKI awareness and management based on consensus stakeholder feedback.

Methods: We conducted the first of three semi-structured sessions using the modified Delphi process. We recruited stakeholders through purposive and snowball sampling and surveyed them on a 5-point Likert scale (1-strongly disagree to 5-strongly agree) the population that should receive AKI education and the key elements of post-AKI communication. We then conducted virtual discussions to gather additional insights.

Results: The first session had 36 stakeholders from 7 countries, including 22 physicians (18 nephrologists), 4 nurses, 3 pharmacists, 2 physician assistants, 1 physical therapist, 3 patients with history of AKI, and 1 caregiver. The stakeholders strongly agreed (median rating 5) that AKI education should be provided to patients with AKI stage 2-3, AKI requiring dialysis (AKI-D), AKI with only partial recovery by discharge, and AKI in the setting of CKD stage 3-5. On communication between inpatient and outpatient care teams, the most strongly agreed upon elements were medications to be resumed (94%), baseline creatinine (88%) and discharge creatinine (85%). For patients on dialysis, last dialysis date (94%) and dialysis initiation date (91%) were important. On communication between care teams and AKI survivors, the most strongly agreed upon elements were medication changes (91%) and nephrotoxins to avoid (91%). For patients on dialysis, dialysis appointment (94%), AKI-D education (88%), and catheter care (85%) were important. Qualitative evaluation showed the need to further define who provides post-AKI education and care, preferred communication methods and timing, and actionable guidance on managing post AKI sequelae, especially medications and diet.

Conclusions: In the first of three sessions, stakeholders showed consensus on many key elements of AKI communication for care teams and patients. Subsequent sessions will refine standardized communication tools for clinical use.

Multistate Modeling Patient Transitions from AKI to CKD or Death Using Electronic Health Records (EHR)

Jordan G. Nestor, Yilu Fang, Chunhua Weng. *Columbia University, New York, NY.*

Background: Patients with AKI are at high risk for CKD and death. The epidemiology of these transitions is poorly understood. This study aims to characterize patient health trajectories from the initial AKI episode to CKD or all-cause mortality using EHR data from NewYork-Presbyterian/Columbia University.

Methods: This retrospective study included 20,699 patients. Clinical states were identified by clustering patient vectors derived from temporal medical codes and serum creatinine (SCr) time series using natural language processing models. Transition probabilities between clinical states and to outcomes (CKD or death) were estimated using multi-state modeling.

Results: In the AKI cohort, 17% developed CKD and 19% died. We identified 15 clinical states with varying disease burdens. Each state had unique transition probabilities over 5 years (Figure). Risk factors for each outcome were identified within different AKI subpopulations based on clinical state trajectories (Table).

Conclusions: This study enhances our understanding of patient trajectories from an initial AKI episode to CKD diagnosis or death by tracking the progression of medical conditions, interventions, treatments, and SCr levels over time.

Funding: Other NIH Support - The project was supported by grants from the NIH (grants R01LM012895, R01HG013031, and UL1TR001873). Funding was also provided by the ASN KidneyCure-Harold Amos Medical Faculty Development Program (ASN-AMFDP) Grant (JGN)., Private Foundation Support

Predicting Persistent AKI Using Machine Learning: A Multicenter External Validation Study

Kianoush Kashani,[1] Simone Zappalà,[2] Francesca Alfieri,[2] Andrea Ancona.[2]
[1]*Mayo Clinic Minnesota, Rochester, MN;* [2]*U-Care Medical srl, Torino, Italy.*

Background: Acute Kidney Injury (AKI) correlates with higher morbidity and mortality, and its longer duration leads to acute and chronic kidney disease progression. Prompt interventions with externally validated prediction models for those at increased risk of AKI could change its course. We aim to validate the Persistent Electronic Alert (PersEA), a machine learning model, using routinely collected medical data in intensive care units, in predicting Persistent AKI.

Methods: Acute Kidney Injury (AKI) was defined and staged using Kidney Disease Improving Global Outcomes guidelines. Persistent AKI was defined as AKI stage 3 lasting for ≥72 hours or leading to death or necessitating renal replacement therapy. This retrospective study included Adult (≥18 years old) admissions at the Mayo Clinic exhibiting at least AKI stage 2. Model performance was assessed using a specific metric that penalizes late alarms, measuring the area under the receiver operating characteristic (auROC) and the area under the Precision-Recall (auPR) curves. The generalizability of the alerting system was measured through sensitivity, specificity, precision, and lead time under different cutoff criteria. The dataset was stratified into subpopulations according to the reason for admission, comorbidities, and demographics to measure possible biases.

Results: Among the ICU admissions at the Mayo Clinic, a cohort comprising 5,589 cases met the selection criteria and were subsequently included in the conclusive analyses. While the internal validation cohort demonstrated an 11% incidence of persistent AKI, the Mayo Clinic cohort exhibited a lower incidence of 5%. The PersEA model achieved an auROC of 0.98 (95% CI, 0.97-0.98) and an auPR of 0.67 (95% CI, 0.60-0.73). By selecting the threshold that reached 0.80 sensitivity in the internal cohort, PersEA achieved 0.88 sensitivity, 0.94 specificity, and 0.47 precision on Mayo Clinic data.

Conclusions: PersEA model exceptionally performed on an external cohort, showing that the model is scalable on high-quality data with little to no tuning once a noisy training set is chosen.

FR-PO083

Six-Year Prospective Study of Kidney Outcomes after Withdrawal of Concurrent RAAS Blockade in Patients Presenting with New, Progressive, Otherwise Inexplicable AKI

Macaulay A. Onuigbo. *The University of Vermont Medical Center, Burlington, VT.*

Background: We described the new syndrome of late onset renal failure from angiotensin blockade (LORFFAB) in 2005 – this was new progressive AKI defined by >25% increase in baseline creatinine in patients on concurrent stable RAAS blockade in the absence of known traditional precipitating risk factors. We present a 6-year prospective follow-up in our previously reported Vermont cohort following withdrawal of RAAS blockade in the face of new progressive otherwise inexplicable AKI.

Methods: We conducted an ongoing interim prospective cohort analysis of patients enrolled between February 2018 and May 2021 in an outpatient Academic Nephrology Clinic in Vermont. Kidney function was monitored after elective withdrawal of long-term RAAS blockade in CKD patients presenting with new-onset otherwise inexplicable progressive AKI, defined by a >25% increase in baseline serum creatinine.

Results: In 2022, there were 51 surviving patients from the original Vermont cohort of 71 patients - baseline serum creatinine (SC) was 1.30 ± 0.42 (0.66-2.70) mg/dL, peak enrollment SC was 2.17 ± 1.06 (1.1-8.3) mg/dL, and SC after four years was 1.58 ± 0.54 (0.84-3.3) mg/dL. By May 2024, there were 9 deaths, 5 ESRD, and 8 were restarted on RAAS blockade. 30 patients were available for this analysis - M:F=12:18, age 74.4 ± 9.1 (64-99), latest SC 1.59 ± 0.6 mg/dL (0.71 – 3.63); latest eGFR 45.2 ± 20.4 (16-101). Of the 9 patients that died, cause of death was mostly cardiac, and the majority died despite improved or stable renal function. SC trajectory of one of these patients following withdrawal of Olmesartan in January 2020 is demonstrative (Figure).

Conclusions: There remains controversy as to the impacts of continuing versus discontinuing RAAS blockade in advanced CKD. Our report is peculiar since RAAS blockade was electively withdrawn in patients presenting with de novo progressive and otherwise inexplicable AKI. We believe that this specific group of patients unequivocally benefit from withdrawal of RAAS blockade (Figure).

↑- Olmesartan 40 mg daily since February 2024 was discontinued in January 2020 due to AKI

FR-PO084

Primary Care Perspectives (PCPs) on Monitoring and Follow-Up after Hospitalization with AKI

Saniya Kaushal,[1] Matthew T. James,[4] Samuel A. Silver,[2] Adeera Levin,[3,5] Peter C. Birks.[3] *[1]University College Cork School of Medicine, Cork, Ireland; [2]Queen's University, Kingston, ON, Canada; [3]The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada; [4]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [5]BC Provincial Renal Agency, Vancouver, BC, Canada.*

Background: AKI is associated with an increased risk of chronic kidney disease (CKD), cardiovascular disease, and mortality. KDIGO guidelines recommend at minimum rechecking creatinine and urine albumin to creatinine ratio (ACR) within 3 months of AKI. Furthermore, nephrology referral after AKI remains low despite an association with improved patient outcomes. The objective of this study was to analyze perspectives of PCPs on monitoring and follow-up of AKI following hospitalization.

Methods: We surveyed Canadian PCPs using clinical vignettes about choices of laboratory monitoring and nephrology referral, following patient hospitalizations with AKI. The vignettes described various demographic and clinical factors, as well as different severities of AKI and degrees of AKI recovery.

Results: 53 PCPs participated, completing at least one question. 90% of PCPs would 'definitely' or "probably" suggest a follow-up creatinine within 3 months of patient hospitalization with AKI, irrespective of patient variables. Participants were more likely to 'definitely' or 'probably' suggest follow up creatinine in patients with less recovery of kidney function (98%), for those receiving dialysis (98%), and for those with comorbidities (100%). 80% or more of PCPs would 'definitely' or "probably" suggest a follow-up measurement of urine ACR within 3 months of AKI and were more likely to recommend proteinuria monitoring in those with pre-existing CKD (90%). Less than 50% of PCPs would 'definitely' refer to a nephrologist following a patient's AKI, unless they required acute dialysis during hospitalization (54%). Factors associated with increased referrals to nephrology included severe AKI (e.g. stage 3 AKI), less renal recovery, and comorbidities. Less than 25% of PCPs would 'definitely' or 'probably' seek specialist input prior to restarting a patient's ramipril, metformin, and empagliflozin post-AKI if the creatinine improved to 100 μmol/L.

Conclusions: Most PCPs suggest monitoring their patient's creatinine within 3 months of hospitalization with AKI. PCPs often would not refer to nephrology for follow up or medication advice after cases of moderate or severe AKI. Education and quality improvement initiatives warrant further testing to help PCPs optimally monitor and manage patients after a hospitalization with AKI.

FR-PO085

AKI Outcomes among Hospitalized Patients with Acute Myeloid Leukemia and Sepsis

Udit Nangia,[1] Prathap Simhadri,[3,4] Tomonori Takeuchi,[2] Hari Naga Garapati,[6] Sreekant Avula,[7] Nihar K. Jena,[8,9] Devansh H. Patel,[2] Prabhat Singh,[5] Deepak Chandramohan.[2] *[1]UH Parma Medical Center, Parma, OH; [2]The University of Alabama at Birmingham, Birmingham, AL; [3]AdventHealth East Florida, Daytona Beach, FL; [4]Florida State University, Tallahassee, FL; [5]Christus Spohn Health System, Corpus Christi, TX; [6]Baptist Medical Center South, Montgomery, AL; [7]University of Minnesota Twin Cities, Minneapolis, MN; [8]Trinity Health Oakland Hospital, Pontiac, MI; [9]Wayne State University, Detroit, MI.*

Background: Sepsis in patients with Acute Myeloid leukemia (AML) is a common cause of Acute kidney injury (AKI). Data on the outcomes of these patients is lacking.

Methods: We queried the 2016-2020 National Inpatient Sample (NIS) database to collect data on hospitalized adults with sepsis and AML. A multivariable logistic regression was performed while adjusting for potential confounders to generate adjusted odds ratios for the outcomes of interest. The outcomes assessed were inpatient mortality, length of stay (LOS), total hospital charges, fluid and electrolyte disorders, septic shock, vasopressor support, and the requirement for mechanical ventilation.

Results: Out of 288,435 hospital admissions of patients with sepsis and AML, 61,955 (21.4%) had AKI. Patients with AKI were older (mean age 66.1 vs. 60.4 years), more likely to be males (63.1% vs. 52.8%), more blacks were affected (12% vs. 9.2%) and overall had more comorbidities. Tumor lysis syndrome was present in 11.1%. Compared to patients without AKI, patients with AKI had higher LOS days (15.4±18 vs. 10.8±13.1, p<0.001 and hospital charges (229425.2 $ vs. 134930.3 $, p<0.001). Multivariable analysis showed that the patients with AKI had higher odds of mortality (OR: 3.8, 95% CI: 3.6-4.1, p<0.001). They also had a higher risk for electrolyte disorders (OR: 2.2, 95% CI: 2.1-2.4, p<0.001), septic shock (OR: 6.3, 95% CI: 5.7-6.9, p<0.001), vasopressor requirement (OR: 5, 95% CI: 4.3-5.8, p<0.001) and mechanical ventilation (OR: 5.2, 95% CI: 4.7-5.7, p<0.001).

Conclusions: AKI in patients with sepsis and AML was associated with higher mortality than sepsis alone. Further large studies are required to identify factors that could improve outcomes.

Outcomes of AKI among Hospitalized Patients with Infective Endocarditis

Deepak Chandramohan,[1] Prathap Simhadri,[9,2] Nihar K. Jena,[3,4] Sreekant Avula,[5] Prabhat Singh,[6] Renish Contractor,[2] Michael R. Filoramo,[2] Devansh H. Patel,[1] Boney J. Lapsiwala,[8] Divya Chandramohan.[7] *[1]The University of Alabama at Birmingham, Birmingham, AL; [2]Florida State University, Tallahassee, FL; [3]Trinity Health Oakland Hospital, Pontiac, MI; [4]Wayne State University School of Medicine, Detroit, MI; [5]University of Minnesota Twin Cities, Minneapolis, MN; [6]Christus Spohn Hospital Corpus Christi Memorial, Corpus Christi, TX; [7]The University of Texas at San Antonio, San Antonio, TX; [8]Government Medical College Surat, Surat, India; [9]AdventHealth Daytona Beach, Daytona Beach, FL.*

Background: Patients with infective endocarditis (IE) are more susceptible to acute kidney injury (AKI). We aimed to assess the characteristics and outcomes of patients with AKI and IE.

Methods: The 2016-2020 National Inpatient Sample (NIS) database was utilized to include adult admissions with AKI and IE. A multivariable logistic regression was performed while adjusting for potential confounders to generate adjusted odds ratios for the outcomes of interest. The primary outcome was inpatient mortality. Secondary outcomes included length of stay (LOS), total hospital charges, septic shock, cardiogenic shock, vasopressor support, and requirement of mechanical ventilation.

Results: Of 63,725 admissions with IE, 16,295 (25.5%) had AKI. When compared with patients without AKI, patients with AKI were more likely to be male (63% vs. 57.6%, p<0.001), had higher Elixhauser Comorbidity Index >5 (73% vs. 44%, p<0.001), diabetes with complications (18.1% vs. 9.9%, p<0.001), congestive heart

failure (50.5% vs. 28.1%, p<0.001), cardiac arrhythmias (45.5% vs. 31.6%, p<0.001) and chronic kidney disease (36.2% vs. 13.6%, p<0.001). They also had higher LOS of 17±16.1 days and mean hospital charges of 239046.8 ± 303977.3 $. Multivariable analysis showed higher odds of mortality (OR: 2.22, 95% CI: 1.81-2.73, p<0.001), septic shock (OR: 3.78, 95% CI: 2.97-4.82, p<0.001), cardiogenic shock (OR: 3.37, 95% CI: 2.65-4.28, p<0.001), vasopressor requirement (OR: 1.99, 95% CI: 1.52-2.60, p<0.001) and mechanical ventilation (OR: 2.75, 95% CI: 2.33-3.24, p<0.001).

Conclusions: Our analysis demonstrated that patients with AKI and infective endocarditis had adverse hospital outcomes, increased mortality, LOS, and hospital costs.

FR-PO087

Prognosis of Community-Acquired Kidney Injury in the Emergency Department

Telma H. Ragnarsdóttir,[1,2] Margret Kristjansdottir,[1] Gisli Gislason,[1,2] Runolfur Palsson,[1,2] Olafur S. Indridason.[1] *[1]Landspitali, Reykjavik, Iceland; [2]Heilbrigdisvisindasvid - Haskoli Island, Reykjavik, Iceland.*

Background: Acute kidney injury (AKI) is a common and serious complication of acute illness, significantly affecting outcomes. While the course and prognosis of hospital-acquired AKI has been thoroughly studied, the outcome of community-acquired AKI has not been well characterized. The aim of this study was to prospectively examine the outcome of patients with community-acquired AKI.

Methods: This was a prospective comparative cohort study in which serum creatinine (SCr) of all individuals presenting to the emergency department (ED) of Landspitali University Hospital were examined for the presence of AKI. All patients who met the SCr component of the KDIGO criteria for AKI were invited to participate. Randomly selected control cases (1:2) were paired according to age, sex, and date of ED admission. Participants answered questions about their medical history and use of medications. Past medical history was also obtained from medical records. Hospital admissions, re-admissions and survival rates were explored over a one-year follow-up period. Groups were compared using the $\chi 2$ test for categorical variables and t-test for continuous variables.

Results: During the study period, AKI was identified in 574 persons, 488 of whom participated in the study (512 cases). The mean (±SD) age of AKI cases and controls was 67.1±16.6 years and 67.2 ±16.2 years, respectively; 48% of cases and controls were female. AKI cases were significantly more likely than controls to be admitted to the hospital following the ED visit (77.1% vs 59.9%, p<0.001), and had longer hospital stays (8.0 ± 10.9 days vs 4.9 ± 15.4 days, p<0.001). Compared with the control group, in-hospital mortality was higher among AKI cases (6.3% vs. 2.4%, p<0.001), as was 90-day mortality (11.1% vs 4.9%, p<0.001) and one-year mortality (17.4% vs 11.2%, p<0.001). No significant difference in readmission rates within one month (14.9% vs 12.4%) or one year (40.8% vs 38.6%)- was observed.

Conclusions: Patients presenting to the ED with community-acquired AKI are significantly more likely to require hospitalization and experienced longer hospital stays, and higher mortality rates than those without AKI. However, the readmission rate is similar to controls.

Adverse Long-Term Outcomes following AKI in Hospitalized Children: A Meta-Analysis

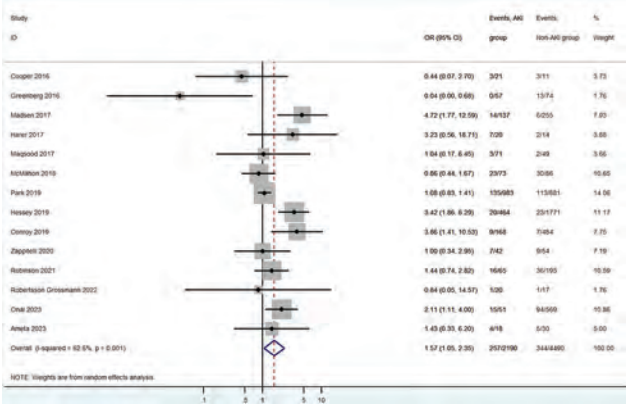
Jitendra Meena,[1] Shanzey Ali,[2] Dua Kamran,[5] Dima Sabeeh,[6] Heather M. Ajoy,[4] Jason H. Greenberg,[3] Cal Robinson,[7] Joginder Kumar Yadav,[8] Rahul Chanchlani.[2] *[1]All India Institute of Medical Sciences, New Delhi, India; [2]McMaster Children's Hospital, Hamilton, ON, Canada; [3]Yale University School of Medicine, New Haven, CT; [4]Toronto Metropolitan University Faculty of Science, Toronto, ON, Canada; [5]University of Waterloo Faculty of Science, Waterloo, ON, Canada; [6]McMaster University Faculty of Science, Hamilton, ON, Canada; [7]The Hospital for Sick Children, Toronto, ON, Canada; [8]Post Graduate Institute of Medical Education and Research, Chandigarh, India.*

Background: Acute kidney injury (AKI) is common during pediatric hospitalizations and is associated with adverse short-term outcomes. However, long-term outcomes among survivors of pediatric AKI remain uncertain. We performed a systematic review to determine the risk of long-term outcomes following an episode of AKI.

Methods: We conducted a systematic literature search in EMBASE, PubMed, and Web of Science for studies reporting adverse events at least three months following AKI defined using standardized definitions in participants aged <18 year. We excluded studies if they reported outcomes in children with obstructive lesions, renal vascular disorder (i.e HUS), or solid organ transplantations. Random effect meta-analyses were performed to calculate pooled estimates.

Results: Of 12817 records identified through our initial search, 38 studies (14892 participants) were included in the final analysis. Pooled cumulative incidence of participants with CKD, mortality, proteinuria, and hypertension was 16% (95% CI: 12 to 19), 6% (3 to 8), 19% (11 to 26) and 13% (10 to 17) respectively, following an episode of AKI. Only 24 studies with follow up period ranging from 6 months to 15 years included a comparator group of patients without AKI. The odds of developing CKD was higher among children with AKI as compared to those without AKI (OR: 1.57, 95% CI: 1.05 to 2.35; Figure 1). Mortality was also higher after AKI (OR: 1.84, 95% CI: 1.28 to 2.63). There was no significant association between AKI and proteinuria (OR: 1.13, 0.63 to 2.03) or hypertension (OR: 1.27, 0.75 to 2.15) at follow up.

Conclusions: Children with AKI are at a higher risk of developing long-term CKD and mortality. These findings support enhanced surveillance of kidney function after an episode of AKI, with the aim of improving long-term kidney and patient survival.



Pooled odds ratio of chronic kidney disease

FR-PO089

Outcomes of AKI Hospitalization among Patients with Protein-Calorie Malnutrition: A Nationwide Analysis

Iskandar Berbari, M Kenan Rahima, Fayaz A. Khan. *TriHealth Inc, Cincinnati, OH.*

Background: AKI can lead to malnutrition due to reduced appetite, dietary restrictions and increased protein breakdown. Pre-existing malnutrition can also exacerbate AKI by impairing the body's ability to recover from kidney injury. Our objective is to examine outcomes among patients presenting with both AKI and protein-calorie malnutrition (PCM).

Methods: We accessed the National Inpatient Sample from 2017-2020 to identify adult patients with PCM hospitalized due to AKI. The primary outcome was inpatient mortality. The secondary outcomes included cardiac arrest, gastrointestinal bleeding (GIB), intubation, length of stay (LOS), and total hospital charges. We utilized multivariable logistic regression analysis to estimate clinical outcomes, considering a significance threshold of $P < 0.05$.

Results: We identified 19,300,000 hospitalizations with AKI, among which 1,687,445 (8.7%) presented with PCM. Patients with AKI and PCM exhibited higher rates of PVD and anemia, but lower occurrences of obesity, AFIB, DM, PVD, HF, dyslipidemia, CKD and HTN. Clinical outcomes revealed stark differences between PCM and Non-PCM cohorts: in-hospital mortality rates were 13% vs 7.3 % (OR 1.67, CI 1.6-1.7); cardiac arrest rates were not significantly different, GIB rates were 12.2% vs 5.8% (OR 2.1, CI 2.09-2.16), need for intensive care was 13.3% vs 7.8% (OR 1.55, CI 1.52-1.58); LOS was 12.2 days vs 6.9 days (IRR 1.71, CI 1.69-1.172); and hospital charges were $36,910 vs $20,164 (IRR 1.76, CI 1.72-1.78). All data demonstrated a p-value < 0.001 and were adjusted for various factors including age, sex, race, obesity, atrial fibrillation, diabetes mellitus, hypertension, peripheral vascular disease, acute kidney injury, chronic kidney disease, alcohol use, stroke, and inflation during 2017-2020.

Conclusions: Despite having lower rates of comorbidities, the PCM group showed significantly worse clinical outcomes, including substantially higher mortality rates, adverse events (GIB), prolonged hospital stays, and increased resource utilization. Clinicians should consider PCM as a negative predictor when managing patients with AKI. Improved patient safety and outcome can be achieved by optimizing inpatient nutrition.

Impact of Kidney Replacement Therapy during Extracorporeal Membrane Oxygenation Support in Terms of Mortality: A Systematic Review and Meta-Analysis

Pramod K. Guru. *Mayo Clinic, Jacksonville, FL.*

Background: Renal replacement therapy (RRT) is frequently administered to patients receiving extracorporeal membrane oxygenation (ECMO). RRT helps to manage the fluid and electrolyte imbalances in ECMO-supported patients with or without evidence of advanced kidney failure. The use of RRT on ECMO has been linked to higher fatality rates in both adult and pediatric patients. There are many controversies concerning the timing, type, and temporal relationship of combined RRT and ECMO in patient outcomes. We aimed to analyze the impact on mortalities from the available studies in the use of a combination of these two extracorporeal systems.

Methods: We searched PubMed, EMBASE, and google scholar databases until February 2024 for case–control, cross-sectional, or cohort studies investigating the mortality of RRT on ECMO. We followed PRISMA guidelines to conduct the study. We filtered the study based on title and abstract followed by the full text. Data extraction was done in MS Excel and statistical analysis was done using RevMan v5.4. Relative risk (RR) and 95% confidence intervals (95% CIs) were pooled in the meta-analysis.

Results: We evaluated a total of 22 studies which included a total number of 6,117 patients who were on ECMO support. All the studies were of high quality, ranging from 7 to 9. The presence of RRT was associated with a significant increase in mortality (22 studies, Relative Risk (RR): 1.83, 95% CI: 1.61–2.07, $p < 0.001$ **Figure 1**, I2= 64%) when compared to patients on ECMO support alone.

Conclusions: Combination of simulatenous extracorpreal therapies by RRT & ECMO is associated with significantly high patient mortalites. Future studies ought to concentrate on reducing renal dysfunction in individuals on ECMO support, and determining the ideal time for initiation as well as form RRT in these patient population.

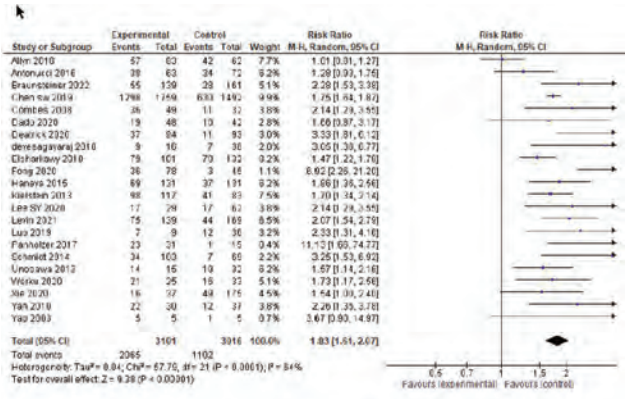

Figure 1: Forest plot showing increased risk of mortality in patients receiving combined therapies (ECMO: extracorporeal membrane oxygenation, RRT: renal replacement therapy).

Forest plot showing increased risk of mortality in patients receiving combined therapies (ECMO and RRT).

FR-PO091

Timing of Acute eGFR Declines in Acute Heart Failure and Their Association with Cardiovascular and Kidney Outcomes

Wendy I. McCallum,[1] Hocine Tighiouart,[1,3] Marcelle Tuttle,[1,3] Anuradha Lala-Trindade,[4] Maria Rosa Costanzo,[5] Isabel V. Bautista,[2] Tatsufumi Oka,[1] Jeffrey M. Testani,[2] Marvin Konstam,[1] Mark J. Sarnak.[1] *[1]Tufts Medical Center, Boston, MA; [2]Yale University School of Medicine, New Haven, CT; [3]Tufts Clinical and Translational Science Institute, Boston, MA; [4]Icahn School of Medicine at Mount Sinai, New York, NY; [5]Midwest Cardiovascular Institute, Naperville, IL.*

Background: The association of declines in estimated glomerular filtration rate (eGFR) with cardiovascular and kidney outcomes in patients with acute heart failure (AHF) have been inconsistent, perhaps due to differences in assessment of timing of the decline.

Methods: Using data from the Efficacy of Vasopressin Antagonism in Heart Failure Outcome Study With Tolvaptan (EVEREST) trial, we used multivariable Cox regression models to evaluate the association between declines in eGFR at 48-hours after randomization, at hospital discharge and at 14-days after randomization with all-cause mortality, a composite of cardiovascular (CV) mortality and heart failure (HF) hospitalization, as well as with longer term kidney outcomes including eGFR decline by >40% and incident chronic kidney disease (CKD) Stage ≥4.

Results: Among 3931 patients over a median follow-up of 9.9 months, eGFR decline at 48-hours was not associated with mortality (aHR=0.96 [95% CI 0.85, 1.10] per 30% eGFR decline) or with the composite outcome of CV mortality or HF hospitalization (HR=0.95 [0.86, 1.06]), with similar results for eGFR decline at discharge. In contrast, eGFR decline at 14-days was associated with higher risk of mortality (aHR=1.32 [1.20, 1.46] per 30% eGFR decline) and the composite outcome (HR=1.19 [1.10, 1.29]). eGFR declines at the 48-hour, discharge and 14-day time points were associated with significantly higher risk of eGFR decline by >40% and incident CKD Stage ≥4 (Figure).

Conclusions: Among patients admitted for AHF, incorporating timing of acute declines in eGFR is pivotal for interpreting prognostic importance from the cardiovascular standpoint. In contrast, declines in eGFR at all time points are associated with worse longer term kidney function.

Funding: NIDDK Support

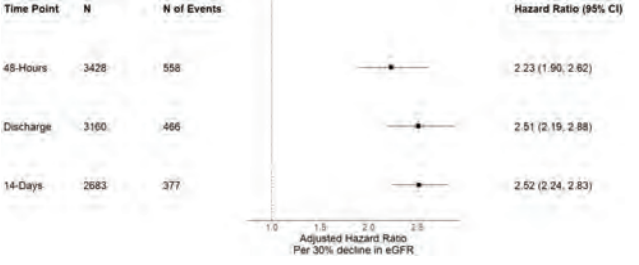

Figure. Adjusted hazard ratios for incident CKD Stage ≥4 based on three different time points of acute decline in eGFR: 48-hours after randomization, at the time of discharge, and 14-days following randomization. Hazard ratios displayed per 30% decline in eGFR.

FR-PO092

Evaluation of the Glomerular Filtration Rate in AKI by Kinetic Estimated Glomerular Filtration Rate in a Tertiary Referral Hospital in Mexico

Carolina Gonzalez-Fuentes, Pamela M. Prado Lozano, Martin B. Yama Estrella, Francisco J. Hernandez Copca, Nicte Alaide R. García, Fani G. Ruiz Rivera, Juana C. De La Torre, Victor M. Ulloa Galvan, Mario Alamilla-Sanchez, Martin O. Carbajal. *Centro Medico Nacional 20 de Noviembre ISSSTE, Mexico City, Mexico*.

Background: Estimating glomerular filtration rate (GFR) in acute kidney injury (AKI) is problematic as plasma creatinine changes rapidly. There is no widely accepted method for estimating renal function in AKI. Kinetic estimated GFR formula and creatinine clearance is an estimate of immediate biomarker clearance derived from two discrete measurements that may better represent the acute function. However, neither the kinetic GFR formula nor the four-hour creatinine clearance have been evaluated in the Mexican population.

Methods: Prospective, analytical study, in patients with acute kidney injury outside of critical care unit. Urinary creatinine clearance was performed along with the calculation of GFR using the kinetic estimated GFR formula and the 2021 CKD-EPI formula with creatinine-cystatin C.

Results: Data were analyzed for 68 patients with a mean age of 67.21 years, 61% were male, and 47% of patients had chronic kidney disease. The mean baseline creatinine was 1.4 mg/dl and the mean GFR was 65.85 mg/dl. The main aetiological factor for AKI was sepsis (33%), followed by cardiorenal syndrome. A Pearson correlation of 0.80 (p= 3.19e-16 CI 95 0.70-0.87) was found between the kinetic estimated GFR formula and four-hour creatinine clearance; concordance was analyzed by the Bland-Altman method with a mean difference of -0.14 with upper LoA of 21.10 (CI 95 16.4-25.7) and lower LoA -21.40 (CI 95 -26.0 -16.7). However, the concordance for the formula kinetic estimated GFR and 2021 CKD-EPI cystatin formula was 0.33.

Conclusions: In Mexican patients with AKI, there is no standardization for GFR calculation. However, with creatinine determinations, GFR can be estimated using the kinetic estimated GFR formula, although it can also be evaluated by 4-hour creatinine clearance, which showed statistical concordance. Evaluation of GFR in AKI with cystatin did not correlate well with either the kinetic estimated GFR formula or the 4-hour creatinine clearance.

FR-PO093

Impact of Baseline Kidney Function in Determining the Efficacy of Terlipressin in Patients with Hepatorenal Syndrome

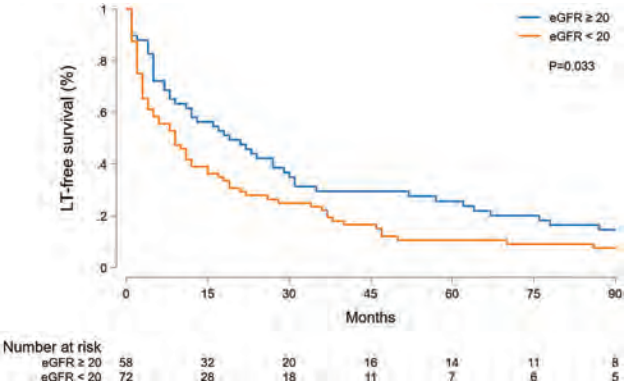
Seung Yun Chae,[1] Young soo Kim,[2] Yaeni Kim.[1] [1]*The Catholic University of Korea Seoul St Mary's Hospital, Seoul, Seo-cho gu, Republic of Korea;* [2]*The Catholic University of Korea Uijeongbu St Mary's Hospital, Uijeongbu, Gyeonggi-do, Republic of Korea*.

Background: We examined the influence of estimated glomerular filtration rate (eGFR) on survival outcomes in patients with hepatorenal syndrome undergoing treatment with terlipressin and albumin. This therapeutic strategy, acknowledged for its ability to improve survival rates and extend the waiting period for liver transplantation, is constrained by korean reimbursement policies. These policies necessitate a diagnosis of HRS-acute kidney injury (AKI) based on serum creatinine levels, thereby restricting the treatment to patients with markedly advanced conditions.

Methods: We performed a retrospective analysis of 130 patients diagnosed with hepatorenal syndrome who were treated with terlipressin and albumin. Our investigation focused on identifying factors linked to liver transplantation-free survival.

Results: In our study, which included patients with an average age of 56 and predominantly male (92%), liver failure was mainly caused by alcohol (71.5%), followed by hepatitis B (14.6%), non-alcoholic fatty liver disease (8.5%), hepatitis C (3.1%), and autoimmune hepatitis (2.3%). The median liver transplantation-free survival was 12 days. Patients with a MELD score greater than 30 had worse survival rates compared to those with a score less than 30. Additionally, individuals with an eGFR above 20 ml/min/1.73 m^2 showed better survival rates than those with an eGFR below 20. Logistic regression analysis identified eGFR below 20 and MELD scores above 30 as significant risk factors for reduced survival in both univariate and multivariate analyses.

Conclusions: Our study found that an increase in eGFR above 20 ml/min/1.73 m^2, along with a lower MELD score, correlated with better liver transplantation-free survival. This suggests that using eGFR rather than creatinine (Cr) as a criterion for terlipressin treatment may result in greater improvements in eGFR and thereby enhance survival outcomes.



LT-Free Survival Curves of Groups Divided by the eGFR cutoff of 20 ml/min/1.73 m^2

FR-PO094

In Vitro Assessment of Proenkephalin a 119-159 (PenKid) Removal in Hemofiltration, Hemodialysis, and Hemoadsorption

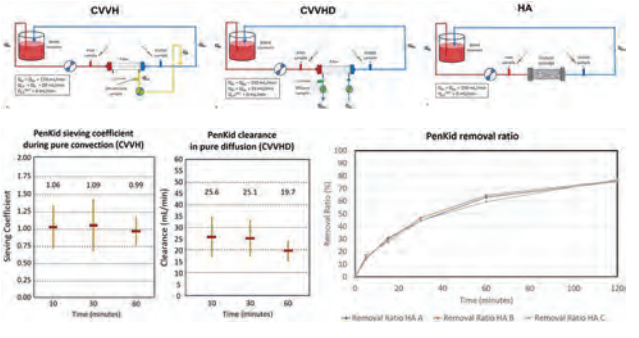
Anna Lorenzin,[1,2] Natascha Perin,[1,2] Massimo de Cal,[1,2] Alessandra Brendolan,[2] Paolo Lentini,[3] Monica Zanella,[1] Claudio Ronco.[2] [1]*Department of Nephrology, Dialysis and Transplantation, St. Bortolo Hospital, Vicenza, Italy;* [2]*International Renal Research Institute of Vicenza (IRRIV), Vicenza, Italy;* [3]*Department of Nephrology and Dialysis, St. Bassiano Hospital, Bassano del Grappa (Vicenza), Italy*.

Background: PenKid is a stable surrogate marker for enkephalins (endogenous opioids regulating kidney function). PenKid plasma concentration correlates to glomerular filtration rate and increases in acute kidney injury (AKI), therefore it can be used for prediction and diagnosis of AKI, need of renal replacement therapy (RRT), and prediction of the successful weaning. Whether the penKid concentration is affected by RRT, is a controversial point. To address the issue, we simulated *in vitro* different conditions of RRT: continuous veno-venous hemofiltration (CVVH) to determine the sieving coefficient, continuous veno-venous hemodialysis (CVVHD) to determine diffusive clearance, and hemoadsorption (HA) to define the penKid removal ratio.

Methods: Blood was spiked with lyophilized synthetic penKid to achieve target concentrations: 150 and 500 pmol/L in both CVVH and CVVHD, and 700 pmol/L in HA. For each experiment, a blood batch of 1L was utilized, at 37° and stirred. Circuits and flow rate set-up is shown in Figure 1. AV1000 dialyzer (Fresenius) was utilized for CVVH and CVVHD and samples were taken after 10, 30, 60 minutes from the initiation of circulation. A minimodule of HA380 cartridge (Jafron) was used for HA and samples were taken after 5, 15, 30, 60 and 120 minutes. All the experiments were conducted in triplicate.

Results: Initial penKid concentrations in blood corresponded to the desired targets in all the experiments. Significant removal of PenKid was observed (Figure 2): in CVVH sieving coefficients remained stable over time (1.04±0.27) in CVVHD clearance values decreased over time (23.08±0.89) in HA removal ratio displayed high values (76.1±1% after 120 minutes) Remarkable consistency in measured values was observed confirming a consistent interaction between the sorbent and penKid.

Conclusions: Significant removal of penKid was obtained by the extracorporeal modalities tested. Further investigation is needed to assess if these findings are confirmed during *in vivo* treatments.



FR-PO095

Urine Output at Continuous Kidney Replacement Therapy Discontinuation Predicts 1-Year Mortality and Kidney Outcome in Critically Ill Patients with AKI

Sungmi Kim,[1] Ji Won Min,[2] Eun jeong Ko,[2] Eun Sil Koh,[3] Hyung Duk Kim,[1] Byung ha Chung,[4] Yu Ah Hong.[5] *[1]The Catholic University of Korea Eunpyeong St Mary's Hospital, Eunpyeong-gu, Seoul, Republic of Korea; [2]The Catholic University of Korea Bucheon St Mary's Hospital, Bucheon, Gyeonggi-do, Republic of Korea; [3]The Catholic University of Korea Yeouido Saint Mary's Hospital, Yeongdeungpo-gu, Seoul, Republic of Korea; [4]The Catholic University of Korea Seoul St Mary's Hospital, Seocho-gu, Seoul, Republic of Korea; [5]The Catholic University of Korea Daejeon St Mary's Hospital, Daejeon, Republic of Korea.*

Background: Continuous renal replacement therapy (CRRT) is crucial for managing critically ill patients with acute kidney injury (AKI). However, the prognostic indicators for long-term prognosis after CRRT, especially present in the early stage of AKI, remain unclear. This study aimed to identify predictors of long-term clinical outcomes in patients with severe AKI, focusing on urine output (UO) at CRRT discontinuation.

Methods: This retrospective study included 851 AKI patients undergoing CRRT at three tertiary hospitals. Patients were categorized into four groups based on 24-hour UO at CRRT discontinuation. We analyzed one-year all-cause mortality and the development of end-stage kidney disease (ESKD).

Results: During one year after CRRT discontinuation, 333 (39.1%) of 851 patients died, and 150 (30.1%) of 499 patients progressed to ESKD. In multivariable analysis, UO was inversely associated with the risks of all-cause mortality (UO <100 ml/day: hazard ratio [HR] 3.08, 95% confidence interval [CI] 2.23–4.26, $P < 0.01$; UO 100–499.9 ml/day: HR 2.25, 95% CI 1.58–3.19, $P < 0.01$; UO 500–1499.9 ml/day: HR 1.71, 95% CI 1.18–2.47, $P < 0.01$), and the development of ESKD (UO <100 ml/day: odd ratio [OR] 16.17, 95% CI 7.67–34.09, $P < 0.01$; UO 100–499.9 ml/day: OR 7.50, 95% CI 3.48–16.18, $P < 0.01$; UO 500–1499.9 ml/day: OR 3.40, 95% CI 1.54–7.48, $P < 0.01$) when using UO ≥1500 ml/day as the reference category. There were linear relationships between UO and the risks of ESKD (P for nonlinearity = 0.07) and mortality (P for nonlinearity = 0.22) throughout a wide range of UO. Though diuretics use was not associated with ESKD risk and did not affect the association between UO and ESKD risk, UO remained significantly predictive of the risk of ESKD irrespective of diuretics use.

Conclusions: This study underscores the importance of monitoring UO in predicting long-term risks of ESKD and mortality in critically ill AKI patients undergoing CRRT.

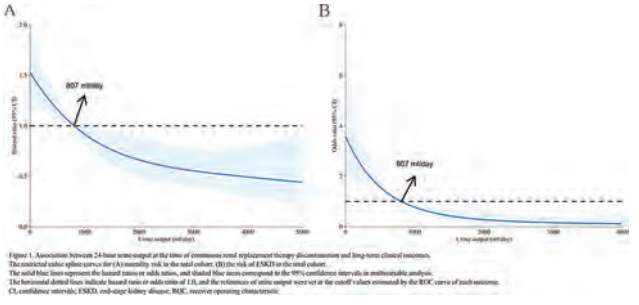


Figure 1. Association between 24-hour urine output at the time of continuous renal replacement therapy discontinuation and long-term clinical outcomes.
The restricted cubic spline curves for (A) mortality risk in the total cohort, (B) the risk of ESKD in the total cohort.
The solid blue lines represent the hazard ratios or odds ratios, and shaded blue areas correspond to the 95% confidence intervals in multivariable analysis.
The horizontal dotted lines indicate hazard ratio or odds ratio of 1.0, and the references of urine output were set at the cutoff values estimated by the ROC curve of each outcome.

FR-PO096

Lower Fractional Excretion of Urinary Sodium among Patients with Muddy Brown Granular Casts Does Not Portend Lesser AKI Severity

Pooja A. Punukollu,[1] Vipin Varghese,[2] Joshua Baguley,[1] Conor Kiely,[1] Jaclyn R. Gerschultz,[1] Stephanie K. Lewis,[1] Rami N. Muhtaseb,[1] Dustin R. Chalmers,[4] Juan Carlos Q. Velez.[1,3] Ochsner Group. *[1]UQ-Ochsner Clinical School, New Orleans, LA; [2]University of Michigan Division of Nephrology, Ann Arbor, MI; [3]Ochsner Health, New Orleans, LA; [4]Louisiana State University, Baton Rouge, LA.*

Background: We previously reported poor concordance between fractional excretion of urinary sodium (FENa) and presence of muddy brown granular casts (MBGCs) by microscopic examination of the urinary sediment (uSEDI) in that patients with acute tubular injury (ATI) can present with abundant MBGC and yet have a low FENa (<1%) [suggesting prerenal acute kidney injury (AKI)]. It has been hypothesized that cases with MBGC and low FENa may reflect early ATI whereas those with high FENa (>1%) reflect advanced ATI. To probe for this, we examined AKI outcomes stratified by uSEDI and FENa.

Methods: We conducted a prospective observational study of patients with AKI seen in inpatient nephrology consultation over 6-yrs in whom uSEDI was performed and a FENa was simultaneously obtained. Outcomes examined included: need for dialysis (AKI-RRT) and acute kidney disease (AKD) (increase in serum creatinine (sCr) >1.5 times baseline sCr) at discharge.

Results: FENa and uSEDI were completed in 489 patients, 44% women, median age 59. Median sCr was 3.4 mg/dL. Main etiologies of AKI were ischemic ATI (41%) and toxic ATI (12%). Greater than 10% low power fields with MBGCs (MBGC+) were found in 180 patients (37%). MBGC+ with FENa <1% were found in 78 (43%) whereas MBGC+ with FENa ≥1% were found in 102 (57%). Thus, uSEDI/FENa concordance for ATI was 59% (kappa 0.17, slight agreement). When concordance assessment was restricted to oliguric patients (urine volume <500 mL/day), it modestly improved to 68% (kappa 0.29, fair). AKI-RRT occurred in 41% of the MBGC+/FENa≥1% group and in 46% of the MBGC+/FENa<1% group (p=0.50). AKD occurred in 38% of the MBGC+/FENa≥1% group and in 29% of the MBGC+/FENa<1% group (p=0.20). Peak sCr was slightly greater in the MBGC+/ FENa≥1% group [5.1 (IQR 4.0-7.8) vs 4.6 (IQR 3.4-6.5) mg/dL], p=0.04 (statistically significant, not clinically significant).

Conclusions: Our findings do not support the hypothesis that in cases with MBGC+, a low FENa may reflect earlier stage of ATI or a less severe insult. In addition, our findings confirm poor concordance between uSEDI and FENa in ATI but do support prior contention that FENa performs slightly better during oliguria.

FR-PO097

Flow-Cytometric Quantification of Urine Kidney Epithelial Cells Specifically Reflects Tubular Damage and Extent of Injury in Acute Kidney Diseases

Leonie F. Wagner,[1,2] Jacob Kujat,[1] Valerie S. Langhans,[1] Luka Prskalo,[2,1] Nina Goerlich,[1,2] Emil Grothgar,[2] Diana Metzke,[2] Sabine Baumgart,[2] Matthias Ochs,[1] Sara Timm,[1] Adrian Schreiber,[1] Philipp Enghard,[1,2] Jan Klocke.[1,2] *[1]Charite Universitatsmedizin Berlin, Berlin, Germany; [2]Deutsches Rheuma-Forschungszentrum Berlin, Berlin, Germany.*

Background: Despite tubular injury being one of the main mechanisms driving acute kidney injury (AKI), clinicians still have a limited diagnostic repertoire to precisely monitor damage to tubular epithelial cells (TEC). In our previous work we used single cell sequencing to identify TEC subsets as main component of the urine signature in AKI. The aim of this study was to establish TEC as a clinical marker for tubular damage.

Methods: In total, 195 patients were analyzed. To compare mRNA with protein expression, we collected urine samples of 7 patients with AKI and glomerular disease. By aligning single-cell transcriptomes and TEC-surface proteins using CITE-Seq (Cellular Indexing of Transcriptomes and Epitopes by Sequencing), we developed a protocol for flow cytometric quantification of CD10/CD13+ proximal and CD227/CD326+ distal TEC in urine. The marker combinations were confirmed in healthy kidney biopsies. We validated our approach across 3 cohorts with 188 patients, including patients with AKI (n=63), ANCA-associated vasculitis with active disease and stable remission (AAV, n=110) and healthy and in-patient controls (n=15).

Results: Our findings demonstrate that CD10/CD13 and CD227/CD326 adequately identify proximal and distal urinary TEC respectively. Both proximal and distal urinary TEC counts correlate with the severity of AKI based on KDIGO stage (each $p < 0.001$) and can successfully discriminate AKI from healthy controls (AUROC = 0.938/0.919) as well as glomerular disease (AUROC = 0.818/0.821). Patients with AAV also present with elevated amounts of urinary TEC compared to healthy controls ($p < 0.05$), albeit to a lesser extent.

Conclusions: We propose urinary CD10/CD13+ and CD227/CD326+ TEC counts as a specific, non-invasive marker for tubular injury in AKI. Our protocol provides the basis for a deeper phenotypic analysis of urinary TEC.

FR-PO098

Urinary Protein-to-Creatinine Ratios during Hospitalization Are Not Invalidated by AKI

Ian E. McCoy, Aris Oates, Chi-yuan Hsu. *University of California San Francisco, San Francisco, CA.*

Background: Experts have warned that urine protein to creatinine ratio (UPCR) measurement is invalid during acute kidney injury (AKI) because creatinine levels in the blood and urine are rapidly changing. The theoretical concern is that the UPCR will be falsely elevated when the serum creatinine is rising since the urine creatinine in the denominator of the UPCR will be lower during this period. While some anecdotal experiences seem to corroborate this theoretical concern, the issue has not been systematically investigated using real-world clinical data.

Methods: We examined adults hospitalized with stage 2 or 3 AKI (defined as peak:nadir serum creatinine during hospitalization ≥2) at the University of California, San Francisco 1/1/2014 to 12/31/2021. Between a pair of UPCRs measured in the same patient, we used linear regression to look for associations between the difference in UPCR values and the difference in serum creatinine slopes at the time of UPCR collection. We also calculated test characteristics of inpatient UPCR cutoffs to predict outpatient UPCR cutoffs.

Results: At least one UPCR was measured during hospitalization in 19% of the AKI patients in our cohort. Among 329 patients with multiple UPCRs measured during AKI hospitalization (median difference in serum creatinine slopes 0.37 mg/dL per day), the UPCR value with the steepest upward serum creatinine at the time of measurement was similar to the UPCR value with the steepest downward serum creatinine (median difference in UPCRs 0.06 g/g, 95% CI -0.26 to 0.50 g/g). There was no association between the difference in serum creatinine slopes when the UPCRs were collected and the difference in UPCR values (UPCR 0.05 g/g higher per mg/dL/day serum creatinine slope, 95% CI -0.36 to 0.47, p=0.80). This remained true in a subset analysis of those with serum creatinine slope differences > 1 mg/dL per day. An inpatient UPCR ≤ 3.0 g/g ruled out outpatient nephrotic-range proteinuria (> 3.0 g/g) more than 90% of the time (inpatient UPCR ≤ 0.15 g/g ruled out outpatient proteinuria >0.15 g/g > 79% of the time).

Conclusions: UPCRs were commonly measured during an episode of AKI and were not systematically affected by the serum creatinine slope at the time of UPCR collection. UPCRs measured during an episode of AKI remain informative despite non-steady state serum creatinine at the time of collection and should not be wholly disregarded.

FR-PO099

Nonalbumin Proteinuria (NAP): An Accessible, Affordable, and Easy-to-Use Biomarker for Predicting AKI in Patients with Acute Heart Failure (NAP-AHF Study)

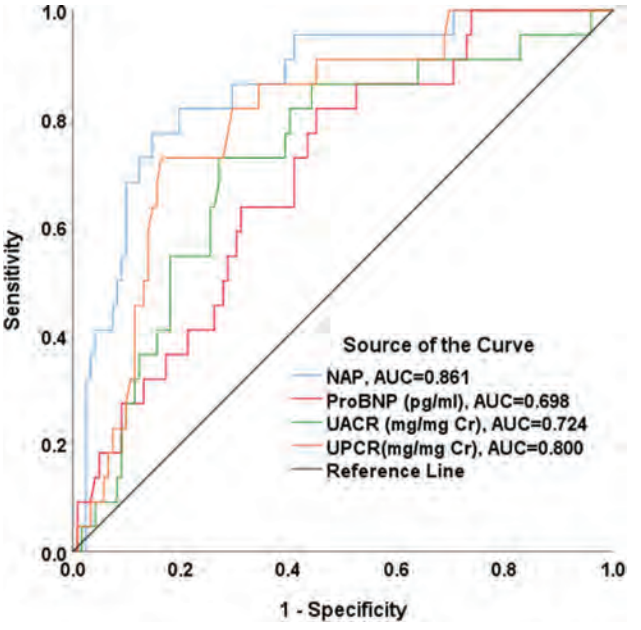
Solos Jaturapisanukul,[1] Khageephan Jaiprasart,[1] Kavee Limbutara,[1] Peerapat Thanapongsatorn,[2] Punnawit Laungchuaychok,[1] Tanun Ngamvichchukorn,[1] Wanjak Pongsitisak.[1] *[1]Navamindradhiraj University, Bangkok, Thailand; [2]Thammasat University Hospital, Khlong Nueng, Thailand.*

Background: Early identification of AKI in patients with acute heart failure (AHF) is challenging in low- to middle-income countries, due to the high costs and limited access to many biomarkers. This study evaluates the effectiveness of non-albumin proteinuria (NAP), as measured by the difference between the Urine Protein-to-Creatinine Ratio (PCR) and the Urine Albumin-to-Creatinine Ratio (ACR), in predicting AKI among AHF patients.

Methods: This prospective study was conducted in a single center in Thailand, from August 2023 to April 2024. We assessed patients admitted with AHF to determine whether NAP at the time of AHF diagnosis could predict the development of AKI within 7 days. Serum creatinine were monitored at baseline, day 2, day 7, and day 28. Exclusion criteria included a PCR ≥ 3 g/gCr, presence of pyuria or hematuria, CKD stage 5, or AKI stage 2-3 or need of KRT.

Results: 144 AHF patients studied, 15.28% developed AKI. The levels of NAP at admission were significantly higher in patients who developed AKI (0.51 vs 0.23, $p < 0.001$). A NAP value ≥ 0.3 g/gCr was significantly associated with the development of AKI by day 2 (30.2% vs 4.3%, $p = 0.022$), by day 7 (34% vs 4.4%, $p < 0.001$), and with acute kidney disease (AKD) by day 28 (15.1% vs 3.3%, $p < 0.01$). Multivariate analysis identified a NAP value ≥ 0.3 g/gCr as a significant predictor of AKI in AHF patients, with a sensitivity of 81.8% and a specificity of 73.0%. Furthermore, the AUROC for NAP was 0.861, demonstrating better predictive ability than PCR, ACR, or pro-BNP for AKI in AHF patients.

Conclusions: An increase in NAP, indicative of tubular protein damage, correlates with the development of AKI in AHF patients. Thus, NAP presents as a promising tool for predicting AKI in this patient population.



AUROC to evaluate the parameters' predictive capability for AKI in acute heart failure patients

FR-PO100

Urinary Proteomics Profiles Classify AKI Subphenotypes

Ian B. Stanaway,[1] Leila R. Zelnick,[1] Frances L. Mabrey,[1] Neha A. Sathe,[1] Zoie A. Bailey,[1] Jordan J. Lo,[1] Jonathan Himmelfarb,[1] Carmen Mikacenic,[2] Laura Evans,[1] Mark M. Wurfel,[1] Eric D. Morrell,[1] Pavan K. Bhatraju.[1] *[1]University of Washington School of Medicine, Seattle, WA; [2]Benaroya Research Institute at Virginia Mason, Seattle, WA.*

Background: Acute kidney injury (AKI) is a common form of organ failure in the intensive care unit. AKI has two distinct sub-phenotypes (SP1 and SP2) that differ in clinical outcomes and response to treatment, with SP2 having worse outcomes. Identification of AKI sub-phenotypes using urine biomarkers could overcome invasive blood sampling and highlight kidney specific pathology.

Methods: We prospectively enrolled 173 ICU patients admitted with a suspected respiratory infection. Of these, 86 patients had AKI and 66 were classified as SP1 and 20 as SP2 using plasma markers of endothelial dysfunction (ANGPT1, ANGPT2) and inflammation (TNFR1). We modeled risk of renal replacement therapy (RRT) adjusting for sex, age, BMI, diabetes, CKD, and COVID-19. Somalogic aptamers assessed 5,212 urine protein abundances collected on admission. We developed urinary proteomic models to predict AKI sub-phenotypes by randomly splitting the data into training (75%) and test sets (25%) and sampling 1000 bootstrap data splits. LASSO 10-fold cross validation was applied to top proteins associated with AKI sub-phenotype (FDR<0.2) in training sets with sex and age as covariates. Iterations over 1000 random data splits obtained a mean area under the curve (mAUC) in test sets. We predicted patients with SP2 among all patients, and predicted SP2 versus SP1 among patients with AKI. We combined training and test sets for final models of selected proteins. For comparison, we also tested a clinical model, which included age, sex, and plasma creatinine.

Results: SP2 patients were more likely to develop incident RRT (OR=12.5 (95% CI 1.9-82.4)). Among all patients, a 32 urinary protein model predicted SP2: mAUC=0.86 (95% CI 0.69-0.99). Among the subset of patients with AKI, a 26 urinary protein model predicted SP2 from SP1: mAUC=0.79 (95% CI 0.58-0.98). The clinical model predicted SP2 from all patients: mAUC=0.77 (95% CI 0.53-0.94) and SP2 from SP1: mAUC=0.68 (95% CI 0.46-0.89).

Conclusions: These results suggest that urinary proteomics can detect AKI SP2 with clinically useful accuracy. Urine tests for AKI sub-phenotypes may be developed for use in hospitals for bedside diagnostics and in low resource settings such as low-middle income countries, military field hospitals, rural and remote regions.

Urinary Waxy Casts Are Associated with Glomerular Etiology of AKI and Greater Risk for AKI Severity and Post-AKI Chronicity

Stephanie K. Lewis,[1] Vipin Varghese,[2] Pooja A. Punukollu,[1] Joshua Baguley,[1] Conor Kiely,[1] Jaclyn R. Gerschultz,[1] Rami N. Muhtaseb,[1] Dustin R. Chalmers,[3] Juan Carlos Q. Velez.[4] Ochsner Group. *[1]UQ-Ochsner Clinical School, New Orleans, LA; [2]University of Michigan Division of Nephrology, Ann Arbor, MI; [3]Louisiana State University, Baton Rouge, LA; [4]Ochsner Health, New Orleans, LA.*

Background: Identification of muddy brown granular casts (MBGC) by microscopic examination of the urinary sediment (uSEDI) has been reported to predict increased acute tubular injury (ATI) severity. Waxy casts have been traditionally linked to chronic kidney disease (CKD). Recent preliminary observations unveiled diagnostic and prognostic value of WxC in acute kidney injury (AKI). We aimed to explore the relationship of AKI phenotype and outcome with identification of WxC, isolated or in combination with MBGC, in an expanded prospectively-generated AKI cohort.

Methods: We conducted a prospective observational study in patients seen for inpatient nephrology consultation with AKI who had uSEDI performed, over a 6-yr period. Presence of >10% of low power fields with MBGC or WxCs was recorded. Outcomes included need for dialysis (AKI-RRT) and acute kidney disease (AKD) [serum creatinine (sCr) >1.5 times baseline sCr] at discharge and at 6 months.

Results: 801 patients [median age 60, 42% women] were included. Median sCr was 3.4 (IQR 2.3-4.7) mg/dL. The most common etiology of AKI was ischemic ATI (45%). MBGCs and WxCs were found in 45% and 36%, respectively. In those with WxC, 57% had *de novo* AKI (no preexisting CKD). Glomerular etiology of AKI accounted for only 4% of cases with MBGC but 13% of those with WxC (p=0.0003). MBGC were associated with increased risk for AKI-RRT [OR: 1.8 (1.4-2.6, p=0.0001)] but not for AKD [OR: 1.3 (0.8-2.0, p=0.28)]. WxCs were associated with increased risk for AKI-RRT [OR: 1.9 (CI 1.4-2.7, p=0.0001)] and AKD [OR: 2.5 (CI 1.4-4.4, p=0.002)]. Presence of both MBGC and WxC was associated with even greater risk for AKI-RRT [OR: 2.6 (1.7-3.9, p=0.0001)] and AKI-RRT at 6 months [OR: 4.8 (1.9-11.9, p=0.0008)].

Conclusions: WxC can be identified in AKI without pre-exisiting CKD and are more commonly found in glomerular disease compared to MBGC. Prognostically, WxC are associated with increased AKD risk, and co-identification of MBGC and WxC are strongly associated with greater risk for AKI-RRT during hospitalization and at 6 months. Further validation of these clinically relevant observations is warranted

FR-PO102

Adjudication Methodology to Assess Novel Urine Biomarkers Panel Detection of Nephrotoxicant Exposure in Presence or Absence of KDIGO-Defined AKI to Support Biomarker Qualification

Nicholas M. King,[1] Steven G. Coca,[2] Steven C. Hoffmann,[5] Patrick T. Murray,[3] Jai Radhakrishnan,[4] Katrina J. Peron,[1] Gary S. Friedman.[1] PSTC and FNIH BC Kidney Safety Project. *[1]Critical Path Institute, Tucson, AZ; [2]Yale University School of Medicine, New Haven, CT; [3]University College Dublin, Dublin, Ireland; [4]Columbia University Irving Medical Center, New York, NY; [5]Foundation for the National Institutes of Health, North Bethesda, MD.*

Background: Critical Path Institute (C-Path) convened 6 expert nephrologist adjudicators (ENAs) to interpret blinded standard & novel clinical and biomarker (SBM & NBM, respectively) data from 2 prospective studies (N=195 patients) to assess NBM sensitivity for detecting drug-induced kidney injury (DIKI) in KDIGO AKI positive & negative participants. Provided SBM and/or NBM baseline (BL) and post-baseline (PBL) patient-level data packets, each ENA determined presence/absence of KDIGO AKI and presence/absence of PBL increase in NBMs-Clusterin, Cystatin C, KIM-1, Osteopontin, NAG, NGAL. In parallel, presence/absence of AKI and DIKI were programmatically quantified using a NBM geometric mean composite measure (GMCM).

Methods: ENAs assessed patient-level electronic case report forms (eCRFs) (N=195). C-Path programmatically generated CDISC SDTM formatted tables to compare programmatic and "human-in-the-loop" adjudication decisions using SBM only [serum creatinine, serum cystatin C, eGFR, Urine Albumin & Protein-Creatinine Ratio (UACR, UPCR)]; NBM only; or combined SBM+NBM (see two 3-member adjudication panels 3-step process).

Results: ENAs unanimity or consensus was achieved in 100% of cases (N=195). Correlation between "human-in-the-loop" NBM adjudication & programmatic NBM GMCM quantitation are primary endpoints within the FDA Qualification Plan submitted to FDA.

Conclusions: NBM panel full qualification is contingent upon demonstration that NBM PBL change is more sensitive than KDIGO AKI criteria for adjudicating nephrotoxicant exposure. If qualified, academic, clinical, pharma NBM PBL and GMCM utilization will drive global clinical nephrology consensus of NBM panel implementation. Periodic re-interrogation of cumulative SBM+NBM data & NBM GMCM under pre-specified statistical analysis plans (SAP) may be a post-qualification commitment to FDA. C-Path's Biomarker Data Repository (BmDR) housing adjudicated participants' deidentified data (n=195 patients) & patient-level SBM+NBM data from Pharma trials + SAFE-T Consortium trials (~700 participants) may address post-qualification requirements.

Impact of Biomarkers in the Eligibility Criteria of AKI Randomized Controlled Trials: A Systematic Review with Meta-Analysis

Fella Chennou,[1] Michael Strader,[2] William Beaubien-Souligny,[1,3] Jean Maxime Cote.[1,3] *[1]Universite de Montreal, Montreal, QC, Canada; [2]University College Dublin, Dublin, Ireland; [3]Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada.*

Background: There is a growing interest around novel approaches for assessing acute kidney injury (AKI). Some clinical trials have used kidney biomarkers as part of their eligibility criteria to better select participants. This might cause a selection bias, as the expected event rate used to measure the sample size is based on prior studies without such criteria.

Methods: We searched for studies published after 2010 in MEDLINE, EMBASE, GOOGLE Scholar, EBM Reviews, MedRxiv and PROSPERO. We included RCTs with biomarkers as eligibility criteria that assess kidney outcomes, defined as the incidence or composite of acute kidney injury, major adverse renal or cardiac events, initiation of dialysis or death. The main aim of this review was to quantify the discrepancy between the anticipated (used in sample size estimation) and the observed event rates for control and intervention groups.

Results: A total of 14 RCTs involving 3817 patients were included. Biomarkers of interest were NGAL (4 studies), TIMP-2*IGFBP7 (3 studies), proteinuria (3 studies), albumin, NT-pro-BNP, homocysteine and uric acid. The mean risk difference between the anticipated and observed event rates was 0.098 (SD±0.115, p=0.58) for control groups and 0.116 (SD±0.106, p<0.01) for intervention groups. For RCTs with tubular damage biomarkers (NGAL, TIMP-2*IGFBP7 and proteinuria), the mean risk differences were 0.118 (SD±0.130, p=0.46) and 0.154 (SD±0.103, p=0.008) for the control and intervention groups respectively.

Conclusions: The use of biomarkers as an enrichment method for selecting participants in AKI RCTs is associated with a difference between expected and observed incidence rates. Investigators must consider the implications of integrating such criteria on the event rate of RCTs.

FR-PO104

Uridine Diphosphate (UDP) Sugars Predict AKI in Cardiac Surgery Patients

Christine Legare,[1] Patrick Caron,[1] Chantal Guillemette,[1,4] Siamak Mohammadi,[2,3] Sylvie Breton.[1,3] *[1]Centre Hospitalier Universitaire de Quebec-Universite Laval, Quebec, QC, Canada; [2]Institut Universitaire de Cardiologie et de Pneumologie de Quebec - Universite Laval, Quebec, QC, Canada; [3]Universite Laval Faculte de Medecine, Quebec, QC, Canada; [4]Universite Laval Faculte de Pharmacie, Quebec, QC, Canada.*

Background: UDP-sugars including UDP-glucose (UDP-Glc), UDP-galactose (UDP-Gal), UDP-N-acetylgalactosamine (UDP-GalNAc), UDP-N-acetylglucosamine (UDP-GlcNAc), and UDP-glucuronic acid (UDP-GlcA) activate the pro-inflammatory P2Y14 receptor. Previously, we showed elevated urine UDP-Glc in intensive care unit patients with AKI compared to those without AKI. In addition, renal ischemia reperfusion injury in mice led to an increase in UDP-Glc urine concentration, followed by activation of P2Y14 in intercalated cells (ICs), initiating an inflammatory cascade that worsened AKI. Ischemic-AKI is prevalent among cardiac surgery patients. Here we investigated whether UDP-sugars serve as early markers of AKI in these patients.

Methods: Urine and plasma samples were collected from 53 cardiac surgery patients: prior to initiation of cardio-pulmonary bypass (CPB), at the end of CPB, and 4h, 12h, 24h, 48h, and 72h post-CPB. The concentration of UDP-sugars was quantified using mass spectrometry. The ROC-AUC was used to evaluate the association between urinary and plasma UDP-sugars and AKI. Correlation analysis was performed with urinary kidney injury molecule -1 (KIM-1), measured by electroluminescence.

Results: Compared to patients without AKI, urinary concentration of UDP-Glc (P=0.002), UDP-Gal (P=0.001) and UDP-GalNAc/GlcNAc (P= 0.0001) increased 12h post-CPB, followed by a return to reference levels in patients diagnosed with AKI 24h after surgery. Urinary UDP-GlcA and plasma UDP-sugars did not vary with AKI. Optimal threshold values of UDP-Glc, UDP-Gal, UDP-GalNAc/GlcNAc, and their sum, predicted AKI with AUC values of 0.71, 0.72, 0.75 and 0.76, respectively. Urinary levels of UDP-Glc and UDP-Gal correlated with KIM-1 at 12h post-CPB (R > 0.43).

Conclusions: Our findings indicate that UDP-Glc, UDP-Gal and UDP-GalNAc/GlcNAc measured in urine are predictors of AKI. Given the correlation observed between KIM-1 - a marker indicative of proximal tubule (PT) injury - and UDP-Glc and UDP-Gal, we suggest that these UDP-sugars are actively released by damaged PT during CPB. Following their release, they are eliminated in the urine, where they trigger the activation of the P2Y14 receptor in ICs. This study, thus, identifies P2Y14 as a key driver in AKI.

Exploring the Plasma and Urine Extracellular Vesicles in Sepsis-Induced AKI

Chih-chin Kao, Tanyu Chang, Isabel I-Lin Tsai. *Taipei Medical University, Taipei, Taiwan.*

Background: Half of critical-ill patients with sepsis develop acute kidney injury (AKI), while these patients are associated with poor outcomes. Early recognition of AKI in sepsis is important for optimal treatment and avoiding further kidney injury. The serum creatinine is a late biomarker due to its delayed elevation post-kidney damage. Therefore, we aimed to investigate the plasma and urine extracellular vesicles (EVs) to identify potential biomarkers for early detection of sepsis-induced AKI (S-AKI) by proteomics analysis.

Methods: In this study, 30 sepsis patients were examined, including 19 with S-AKI and 11 with sepsis only. EVs from plasma and urine were isolated using size exclusion chromatography (SEC) and confirmed by using western blot, nano-particle tracking analysis (NTA), and transmission electron microscopy (TEM). EVs were precipitated with acetone and digested with urea, dithiothreitol (DTT), iodoacetamide (IAA), and trypsin before liquid chromatography-mass spectrometry (LC-MS) analysis. Metabolomics analysis was conducted on the soluble portion post-acetone precipitation. MaxQuant processed MS data for identification and label-free quantification. Volcano plot analysis via MetaboAnalyst 6.0 identified differentially expressed proteins (DEPs). Gene enrichment was performed using FunRich software (v3.1.3), and pathway analysis was executed using the Kyoto Encyclopedia of Genes and Genomes (KEGG).

Results: We discovered 38 DEPs in the urine EV dataset and 28 DEPs in the plasma EV dataset. For the gene enrichment study, the DEPs from both datasets mainly come from extracellular, exosome, and extracellular regions. Meanwhile, the molecular function and biological processes of the DEPs in both datasets showed a great relationship with complement activity. Further, the pathway analysis showed these were enriched in complement and coagulation cascades, and Staphylococcus aureus infection. For metabolomics analysis in urineEV dataset, differentially expressed metabolites are enriched in tyrosine metabolism. As for the plasmaEV dataset, differentially expressed metabolites are enriched in nicotinate and nicotinamide metabolism.

Conclusions: These findings underscore the potential of EVs as biomarkers and therapeutic targets in S-AKI, offering new insights into the pathophysiology and potential treatment strategies for this critical condition.

FR-PO106

Clinical Utility and Performance of Urinary L-FABP as a Potentially Suitable Biomarker for Early Detection of Contrast-Induced AKI among Adult Filipino In-Patients Undergoing Coronary Angiography

Anne Laurene Tayo, Donnah Franceska De Leon. *Manila Doctors Hospital, Manila, Philippines.*

Background: Contrast-induced AKI (CI-AKI) is now considered the third most common cause of AKI in hospitalized patients and is recognized as a frequent complication of percutaneous cardiovascular procedures. One significant barrier to improving clinical outcomes in patients with AKI is the delayed administration of potentially beneficial therapies. This delay is compounded by the unreliability of serum creatinine as a marker of GFR in acutely ill patients. Urinary levels of L-FABP have been shown to increase earlier than serum creatinine in patients who develop AKI and is particularly linked with tubular dysfunction. This biomarker could be valuable for assessing a patient's risk, and for the early diagnosis of CI-AKI.

Methods: This analytic prospective cohort study was conducted to determine diagnostic utility of urinary L-FABP in the early detection of CI-AKI among adult Filipino in-patients who underwent coronary angiography from December 2023 to April 2024. Baseline and 4-6 hour post-procedure urinary L-FABP levels were measured using point-of-care kits and compared between patients who developed CI-AKI (diagnosed using KDIGO criteria) and those who did not develop the disease.

Results: The final analysis included 86 patients, 3 of whom were diagnosed with CI-AKI during the study period. ROC analysis showed that baseline urinary L-FABP exhibited 100% sensitivity and 73.49% specificity at a cut-off value of 2.71 ng/ml, while the 4-6 hour urinary L-FABP had 100% sensitivity and 98.8% specificity at a cut-off value of 10.99 ng/ml. The AUC for the baseline urinary L-FABP was 0.89 representing a good test, and 1.0 for the 4-6 hour urinary L-FABP indicating an excellent test in CI-AKI diagnosis.

Conclusions: This study demonstrates that urinary L-FABP could serve as a clinically useful predictive biomarker to detect CI-AKI onset even before contrast media exposure. This biomarker, which has high sensitivity and good negative predictive value in the detection rate of AKI, may enable and improve timely initiation of preventive strategies and potentially beneficial therapies for CI-AKI.

FR-PO107

Renal Tubular Injury Biomarkers (BMs) in the Identification of Subclinical AKI and Drug-Induced Kidney Injury: IMI/SAFE-T/TransBioLine

Michael Strader,[1] Xavier Benain,[3] Nunzio Camerlingo,[2] Gary S. Friedman,[2] Stefan Sultana,[4] Patrick T. Murray.[1] *[1]University College Dublin, Dublin, Ireland; [2]Pfizer Inc, New York, NY; [3]Sanofi SA, Paris, France; [4]AstraZeneca PLC, Cambridge, United Kingdom.*

Background: Drug-induced kidney injury (DIKI), a subphenotype of AKI, is a side effect of cisplatin chemotherapy. Current AKI functional BMs are limited and therefore at the 23rd ADQI consensus conference proposed using novel BMs to enhance AKI criteria.

Methods: In this prospective study, 105 cisplatin-treated patients (Treated), 20 non-cisplatin-treated cancer controls (Non-Treated), and 34 Healthy controls were enrolled. Blood and urine samples from the Treated group were collected at specified timepoints. Standard BMs and novel BMs (eight urinary, one serum) were assessed. Three blinded nephrologists determined the presence or absence of DIKI in cisplatin-treated patients. BM accuracy was defined by sensitivity, specificity, AUROC, and changes (absolute and percentage) from baseline were compared between groups, with median time to peaks calculated.

Results: All biomarkers showed significant changes from baseline in the Treated group versus Non-Treated group. Most urinary BMs effectively detected cisplatin exposure (AUROC > 0.8). Novel BMs peaked earlier, with α-GST peaking first (Day 1), followed by serum CYSC and KIM-1 (Day 2). Treated group were adjudicated into DIKI (N = 24) and No-DIKI (N = 71) groups. Significant differences were observed in all BMs between both DIKI and No-DIKI groups compared to controls. No significant differences were found in urinary BMs, except for neutrophil gelatinase-associated lipocalin and cystatin-C, between DIKI and No-DIKI groups.

Conclusions: Novel BMs detected DIKI more sensitively and timely than standard BMs. A panel of BMs is likely superior for comprehensive nephrotoxicity assessment, which aligns with FDA's 2018 qualification letter supporting novel BMs with standard BMs in phase 1 drug development.

Clinical Impact of Wnt5a Expression on the Persistence of AKI in Patients with Urosepsis

Yoonho Kim, Dong-jin Oh, Hye Min Choi, Young Eun Kwon, Song in Baeg.
Myongji Hospital, Goyang, Gyeonggi-do, Republic of Korea.

Background: This study aimed to investigate the association between Wnt5a values and organ alterations in urosepsis patients.

Methods: Serum creatinine (Cr) and Wnt5a levels were measured in 28 healthy volunteers and on day 1, 5, and discharge day in 87 urosepsis patients. The patients were classified into an improving AKI group and a worsening AKI one by comparing the stages of AKI on day 1 and 5. The impacts of Wnt5a values on major adverse kidney events (MAKE), stage 3 AKI, new renal replacement therapy (RRT), and death. Logistic regression analysis was performed to determine the probability of clinical outcomes. Reversal patterns after AKI were also evaluated.

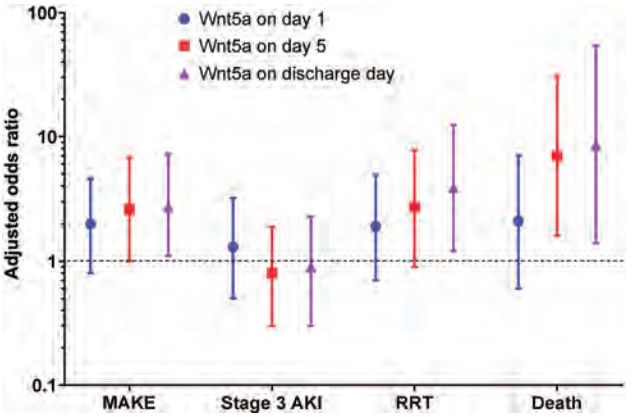
Results: Wnt5a levels were significantly elevated in urosepsis patients compared to healthy volunteers (P=0.009). There were 28 (32.2%) in the worsening AKI and their levels of Wnt5a were consistently higher than those in the improving AKI (Table 1). The association between Wnt5a values and worsening AKI persisted after the adjustment for age, sex, baseline serum Cr, and disease severity (P=0.044, 0.005, and 0.001, at respect time point). Elevated Wnt5a level was related to the raising risk of MAKE (P=0.119 on day 1, 0.060 on day 5, and 0.039 on discharge day), increased RRT needs or 30-day death (P=0.109, 0.003, and 0.004, respectively). (Fig 1). This study identified the patterns that high Wnt5a values on discharge day was associated with unrecovered AKI, irrespective of the confounders. The trajectory of Wnt5a over time differed according to the pattern and discharge renal function (P=0.004 and 0.003).

Conclusions: Wnt5a measurment may serve as a valuable biomarker for identifying at-risk individuals with urosepsis.

Baseline Wnt5a values

Wnt5a, ng/mL	Improving AKI (N=58)	Persistent or worsening AKI (N=29)	P value
On day 1	2.0 (1.8, 2.3)	2.3 (2.0, 2.6)	0.012
On day 5	1.9 (1.7, 2.3)	2.3 (1.9, 2.7)	0.009
On discharge day	2.0 (1.7, 2.3)	2.5 (2.1, 2.7)	0.001

Data are expressed as median (interquartile range).



The adjusted likelyhood of Wnt5a for each component in urosepsis patients.

Dynamic Changes of SERPINA3 in the Serum of Patients after Cardiac Surgery and Mouse Kidneys Post Ischemia-Reperfusion Injury

Wenli Sai,[1] Yun Jiang,[1] Yanan Wang,[1] Fei Chen,[1] Lili Huang,[1] Fenfen Xiong,[1] Jun Zhu,[1] Yuanyuan Wu,[2] Jiahai Shi,[1] Bin Yang.[3] *[1]Affiliated Hospital of Nantong University, Nantong, China; [2]Nantong University, Nantong, China; [3]University of Leicester College of Life Sciences, Leicester, United Kingdom.*

Background: Serine proteinase inhibitor class A member 3 (SERPINA3) plays crucial roles in regulating serine proteases and various biological processes, but its involvement in acute kidney injury (AKI) remains unclear. Herein, the dynamic change of SERPINA3 in the serum of AKI patients and kidneys of AKI mice were evaluated.

Methods: The serum level of SERPINA3 was analyzed by enzyme-linked immunosorbent assay (ELISA) in patients underwent cardiopulmonary bypass at pre- and post-cardiac surgery at 0, 6, 12 hours (h) and 1,2,3 and 7day(s). In addition, amouse bilateral renal ischemia-reperfusion (IR) model was established by 30-min ischemia and followed by reperfusion for 6 h to 7 days. The expression of SERPINA3 and its localization in kidneys were also evaluated.

Results: Compared with pre-operation, SERPINA3in serum was upregulated from 6 and 12 h, and reached a statistical significance at Day 1,2,3 and 7 after operation in patients without AKI and with AKI stage II/II, and significantly increased at Day1,2 and 3 in patients with AKI stage I. Most interestingly, the level of serum SERPINA3 was peaked at Day 1 or Day 2, and decreased afterwards in both patients without AKI and AKI stage I, but remained high at Day 3 and Day 7 in patients with AKI stage II/III, which may indicate a potential of chronic progression. In addition, the expression of SERPINA3 was significantly raised in kidneys at 24 and 72 h, but gradually decreased afterwards. The immunostaining of SERPINA3 was mainly in interstitial areas and the cytoplasm and nucleus of tubular cells in IR kidneys. The staining in interstitial areas was increased at 6 h post IR, while that intubular areas was remained over 6-24 h. The level of SERPINA3 protein in IR kidneys was positively correlated with the score of tubulointerstitial damage, but was not related with serum creatinine.

Conclusions: SERPINA3 may be a potential early biomarker for IR-AKI, as well as an indicator for its chronic transition. The role of SERPINA3 in AKI and underlying mechanisms need to be further investigated.

SLPI and Serpin E1 Differentiate between and Can Be Used as AKI Biomarkers in Patients with and without Obesity

Naomi A. Brown,[1] Marcin Wozniak,[1] Haiyan Pan,[2] Barbara Horley,[3,4] Lathishia Joel David,[1] Hardeep Aujla,[1] Gavin J. Murphy,[1] Bin Yang.[3,5] *[1]Department of Cardiovascular Sciences and NIHR Cardiovascular Biomedical Research Unit, University of Leicester, Leicester, United Kingdom; [2]Affiliated Hospital of Nantong University Department of Cardiology, Nantong, China; [3]Department of Cardiovascular Sciences, College of Life Sciences, University of Leicester, Leicester, United Kingdom; [4]University Hospitals of Leicester NHS Trust, Leicester, United Kingdom; [5]Nantong-Leicester Joint Institute of Kidney Science, Department of Nephrology, Affiliated Hospital of Nantong University, Nantong, China.*

Background: Acute kidney injury (AKI) is among the most common complications after cardiac surgery, with an 18% prevalence and is associated with an increased risk of death. Cardiopulmonary bypass surgery generates danger-associated molecular patterns that trigger a release of proinflammatory molecules that can lead to AKI. Obesity is also associated with chronic low-grade inflammation and an increased risk for AKI. We investigated the utility of inflammatory molecules in the diagnosis of AKI in obese and non-obese cardiac surgery patients.

Methods: A panel of 13 circulating plasma molecules, including CXCL1, CXCL10, CXCL13, CCL22, IL-5,6,8,10,16, SLPI, TIM1, Properdin, Serpins E1 and A3, was measured using MAGPIX. The samples were collected from 95 MaRACAS patients (NCT02315183) before and 6-72 hours (h) after surgery. Obesity was defined as BMI>=32, based on our previous study.

Results: There was no significant difference in the incidence of AKI between obese (46%) and non-obese patients (58%). The levels of the selected molecules were compared between AKI and non-AKI groups in patients with and without obesity. In obese patients with AKI, the levels of serpin E1 were lower before surgery (22.16 vs 40.94ng/mL, q=0.03) and higher 6h post-surgery (49.26 vs 21.65ng/mL, q=0.02), while properdin was lower 72h post-surgery (11.12 vs 14.35ng/mL, q=0.01). In the non-obese group, CXCL10 was higher in the AKI group 6-48h post-surgery, peaking at 6h (218.5pg/mL vs 131.38pg/mL, q=0.02); CXCL13 was higher at 6h (435.78 vs 291.0pg/mL, q=0.04) and 24h (215.18 vs 157.49pg/mL, q=0.04); IL-16 was higher at 6h (256.01 vs 174.44, q=0.04) and 24h (344.94 vs 174.02, q=0.02); and SLPI was higher 6-72h post-surgery, peaking at 6h (50.44 vs 33.53 at 6h, q<0.01). ROC AUC analyses showed that Serpin E1 had a diagnostic value for AKI in obese patients pre (75.6%, 58.3%-92.8%) and 6h post-surgery (80%, 64.6%-95.4%); while SLPI had a diagnostic value in non-obese patients 6h after surgery (75.0%, 62.2%-87.8%).

Conclusions: AKI leads to different expression levels of proinflammatory molecules in obese and non-obese patients undergoing cardiac surgery. SLPI and Serpin E1 have diagnostic potential as biomarkers, but should be validated in larger cohorts.

FR-PO111

Urinary Follistatin-Like 3 Is Increased in Patients with AKI and Reflects Severity of Tubular Injury

Mari Okada, Izumi Nagayama, Shunsuke Takahashi, Kaori Takayanagi, Hajime Hasegawa, Akito Maeshima. *Saitama Medical Center, Saitama Medical University, Kawagoe, Japan.*

Background: Follistatin is an essential physiological regulator of activin and other members of the TGFβ superfamily. In animal models of acute kidney injury (AKI), blockade of activin A by exogenous follistatin has been shown to attenuate renal injury and improve renal function. This suggests that endogenous activin A negatively modulates tubular repair following AKI. Follistatin serves as a local regulator of activin A in numerous tissues. In addition, urinary follistatin, which is undetectable in normal rats, was significantly increased in ischemic rats. Conversely, follistatin-like 3 (FSTL3) exhibits substantial structural and functional similarity to follistatin, albeit with some notable differences, including its prominent nuclear localization. Nonetheless, the precise role of FSTL3 remains unclear.

Methods: To address this issue, we investigated the localization of FSTL3 in normal human kidneys and measured urinary FSTL3 in patients with AKI to evaluate its potential as a marker for AKI. A total of 127 patients with AKI and 19 healthy adults participated in this study. Serum and urinary FSTL3 levels were quantified using ELISA. We analyzed the correlations between urinary FSTL3 and other clinical parameters.

Results: FSTL3 was localized in renal tubules of normal kidney. FSTL3-producing cells were positive for Na-Cl co-transporter and uromodulin but were negative for aquaporin 1, megalin and aquaporin 2. Urinary FSTL3, undetectable in healthy adults, was significantly increased in patients with AKI (0.00 ± 0.00 vs. 18.09 ± 17.66 ng/mL, p <0.0001). This increase was most pronounced in cases of sepsis (37.65 ± 17.56 ng/mL). In stages of the KDIGO classification, urinary FSTL3 was positively correlated with the severity of AKI (stage I, 7.34 ± 8.75 ng/mL, p<0.05; stage II 9.02 ± 7.60 ng/mL, p<0.01; stage III 25.62 ± 18.66 ng/mL, p<0.0001). There was a significant correlation of urinary FSTL3 with urinary protein, urinary NAG, urinary alpha1-microglobulin, urinary beta2-microglobulin, urinary NGAL, KIM-1 and serum FSTL3. Meanwhile, FSTL3 did not correlate with L-FABP and urinary serum creatinine.

Conclusions: FSTL3 is localized in the distal tubules of normal kidneys. Urinary FSTL3 increases in AKI patients and serve as a valuable marker for monitoring the severity of acute tubular damage in AKI.

FR-PO112

Fibroblast Growth Factor 23 and Klotho in Cardiac Surgery-Associated AKI

Cheng chia Lee, Ming-Jen Chan, Chih-Hsiang Chang. *Chang Gung Memorial Hospital Linkou, Taoyuan, Taiwan.*

Background: Acute kidney injury (AKI) frequently occurs as a complication following cardiac surgery, leading to increased mortality and prolonged hospital stays. Elevated serum FGF23 levels have been suggested to be associated with a greater degree of systemic inflammation in critical ill patients. This study aims to evaluate the roles of serum FGF23 and klotho levels post-cardiac surgery, and to determine their impact on the occurrence of severe AKI in these patients.

Methods: We included adult patients who underwent on-pump cardiac surgery in a tertiary care university hospital. All prospective clinical and laboratory data were evaluated as predictors of AKI. Serum FGF23 and klotho level were measured within 6 hours after cardiac surgery. The discriminative power for predicting severe AKI (stage 2 or 3) was assessed using the area under the receiver operator characteristic curve (AUROC).

Results: We investigated 214 adult patients with a mean age of 59.9 year. Severe AKI was diagnosed in 32 patients (15.0%). Patients with severe AKI had longer bypass time. Higher FGF23 level and lower klotho level were independent risk factors for severe AKI, even after adjustment for clinical risk factors. The clinical prediction model for severe AKI had an AUROC of 0.71. Adding FGF23 to the clinical model increased the AUROC for predicting severe AKI to 0.76, while combining FGF23 and klotho increased it further to 0.79. The optimal cutoff values for FGF23 and klotho is 2264 pg/ml and 100 pg/ml, respectively. We also performed ROC analysis of the single serum FGF23/klotho ratio, which revealed an AUROC value of 0.71, with a sensitivity of 62.5% and a specificity of 80.2% for predicting severe AKI at a threshold value of 29.5.

Conclusions: The combination of elevated FGF23 level and reduced klotho level could serve as a potential biomarker for the predicting severe AKI.

Table. Baseline characteristics and postoperative biomarkers among the study patients (n = 214)

Characteristics	Non-AKI (n = 122)	Mild AKI (n = 60)	Severe AKI (n = 32)	p for trend
Age (years)	60.3 ± 12.0	58.2 ± 12.4	61.7 ± 12.5	0.568
Men [n (%)]	76 (62.3%)	44 (73.3%)	23 (71.9%)	0.160
Diabetes mellitus [n (%)]	34 (27.9%)	13 (21.7%)	11 (34.4%)	0.772
Body mass index	25.3 ± 4.5	25.3 ± 3.9	26.3 ± 5.0	0.279
Ejection fraction (%)	61.0 ± 14.3	59.8 ± 14.7	58.4 ± 15.4	0.414
Preoperative Cr (mg/dl)	0.78 ± 0.20	0.82 ± 0.21	0.80 ± 0.24	0.710

Concordance of Prebiopsy and Postbiopsy Diagnosis in Patients with Suspected Acute Interstitial Nephritis or Acute Tubular Injury

Steven Menez,[1] David Hu,[1] Heather Thiessen Philbrook,[1] Celia P. Corona Villalobos,[1] Yumeng Wen,[1] Dennis G. Moledina,[3] Steven G. Coca,[2] Chirag R. Parikh.[1] *[1]The Johns Hopkins University School of Medicine, Baltimore, MD; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Yale University School of Medicine, New Haven, CT.*

Background: Percutaneous kidney biopsy remains the gold standard for evaluation of acute kidney injury (AKI), given that clinicians' pre-biopsy clinical impression of AKI, based on history, exam, and non-invasive testing may often be inaccurate. In this study, we evaluated the concordance of pre-biopsy clinical diagnosis with post-biopsy final diagnosis among patients with AKI.

Methods: We leveraged data collected through the Novel Approaches in the Investigation of Kidney Disease (NAIKiD) Study between 2020 and 2023, in which adult patients admitted to the Johns Hopkins Hospital and scheduled for clinical kidney biopsies consented to provide biosamples (blood, urine, and kidney tissue) and data collection. Up to 3 pre-biopsy clinical diagnoses were recorded for each patient, along with up to 3 final diagnoses, adjudicated by a study nephrologist post-biopsy. We investigated the

concordance of pre and post-biopsy diagnoses among patients with suspected acute interstitial nephritis (AIN) or acute tubular injury (ATI).

Results: Among 164 total patients, 29 patients had supsected AIN and 47 had supsected ATI pre-biopsy. Among the patients with suspected AIN, only 7 (24%) had AIN confirmed on biopsy. Of the 22 other biopsies, alternative diagnoses noted on histology included focal segmental glomerulosclerosis (FSGS), ATI, and various glomerular diseases. Out of 47 patients with suspected ATI, ATI was confirmed on biopsy in 27 (57%) patients. In the 20 biopsies without ATI, alternative diagnoses also included glomerular diseases, diabetic nephropathy, and FSGS predominantly.

Conclusions: Patients with suspected ATI or AIN who undergo percutaneous kidney biopsy are often found to have alternative, significant findings present on histology. Among inpatients without relative or absolute contraindications, kidney biopsy remains an essential part of clinical evaluation.

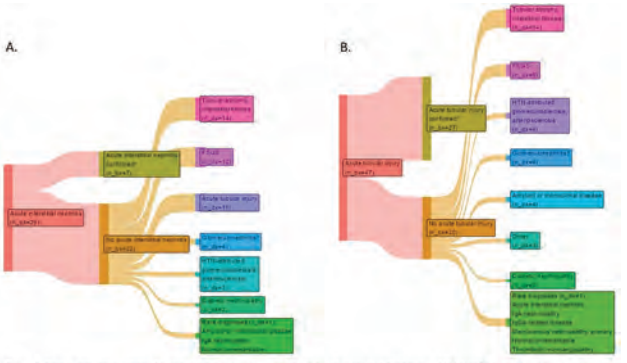

Figure 1. Sankey plots demonstrating final adjudicated diagnoses among patients with suspected diagnoses of AIN (A) and ATI (B) prior to kidney biopsy.
n_bx refers to the number of biopsies in this category, while n_dx refers to the number of diagnoses in this category
*Among the 7 confirmed cases of AIN and 27 confirmed cases of ATI, up to 2 additional diagnoses may be present (not displayed)

FR-PO114

Point-of-Care Ultrasonography for the Diagnosis of Hydronephrosis: A Systematic Review and Meta-Analysis

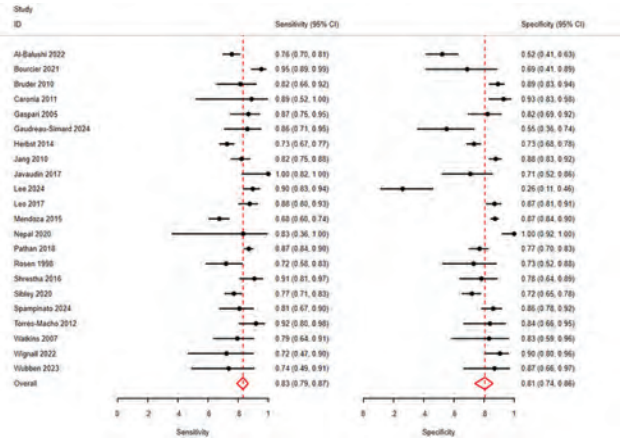
Dominic Wang,[1] Michael K. Wang.[2] *[1]The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada; [2]McMaster University, Hamilton, ON, Canada.*

Background: Hydronephrosis is a common sign of urinary tract obstruction detected on imaging. The diagnostic test accuracy of point-of-care ultrasound (POCUS) for hydronephrosis is uncertain.

Methods: We searched MEDLINE, EMBASE, and CENTRAL for observational studies and randomized controlled trials without language restrictions from inception until April 2024. We included studies reporting the diagnostic accuracy of POCUS for hydronephrosis compared to formal radiographic imaging as the reference standard (i.e., ultrasound, computed tomography, and/or intravenous pyelogram performed by a radiology technician or radiologist). We pooled sensitivity and specificity using random-effects models and reported their corresponding 95% confidence intervals (CIs).

Results: We included 22 observational studies (n=4893). The pooled population included patients presenting with flank pain (13 studies), acute kidney injury (AKI) (2 studies), either flank pain or AKI (2 studies), or were unspecified (5 studies). Twenty studies were conducted in the emergency department, 1 study was conducted in hospital wards, and the remaining study was conducted in both an intensive care unit and hospital wards. POCUS had a pooled sensitivity of 0.83 (95% CI 0.79-0.87) and specificity of 0.80 (95% CI 0.74-0.86) for the diagnosis of hydronephrosis when compared to formal imaging. In a subgroup analysis of 3 studies (n=1078), the diagnosis of any severity of hydronephrosis on formal imaging based on moderate to severe hydronephrosis on POCUS demonstrated a pooled sensitivity of 0.32 (95% CI 0.28-0.37) and specificity of 0.96 (95% CI 0.93-0.98).

Conclusions: POCUS has moderate sensitivity and specificity for hydronephrosis and may be used to rule out urinary tract obstruction in patients with a low pre-test probability. Moderate to severe hydronephrosis on POCUS is highly specific for hydronephrosis detected on formal imaging.



Sensitivity and specificity forest plot

Back to Bedside: Kidney Point-of-Care Ultrasonography (POCUS) by Resident Physicians for Identification of Hydronephrosis in Patients with AKI

Sundus Sardar,[1,5] Rohit Sharma,[2] Abdullah Mohammad Arshad,[3] Mohammed Alamin,[3] Bashar Tanous,[4] Jaweria Akram,[3] Fateen Ata,[3] Rawand Jebril,[3] Abdulrahman Al-Mashdali,[3] Zohaib Yousaf,[6] Muhammad Zahid.[3] *[1]Penn State Health Milton S Hershey Medical Center, Hershey, PA; [2]Department of Internal Medicine, Geisinger Health System, Wilkes-Barre, PA; [3]Hamad Medical Corporation, Doha, Qatar; [4]Department of Internal Medicine, UCSF Fresno, San Francisco, CA; [5]Pennsylvania State University College of Medicine, Hershey, Pennsylvania, Hershey, PA; [6]Tower Health, West Reading, PA.*

Background: POCUS has emerged as a valuable adjunct to bedside clinical examinations. In context of acute kidney injury (AKI), bedside POCUS may facilitate early identification of hydronephrosis indicative of obstructive uropathy as the underlying etiology, thereby enabling timely diagnosis, expediting therapeutic management and decreasing fragmentation of care. Incorporating renal POCUS training in the internal medicine residency program allows residents to develop new skills for day-to-day clinical practice and enhance bedside assessment of patients with AKI.

Methods: We conducted a prospective observational study at Hamad General Hospital, Qatar. Patients were selected from a convenience sample in the Acute Medical Assessment Unit (AMAU) and medical wards for AKI evaluation. Internal Medicine residents underwent mandatory training, including a 30-minute didactic session by a certified physician and performing ten supervised bilateral renal POCUS scans to ensure proper technique. Residents performed bedside renal POCUS to assess hydronephrosis, with findings compared to blinded departmental scans using a common grading system.

Results: Fifty patients with provisional AKI diagnoses based on clinical presentation and renal parameters were included, all pending official renal ultrasound scans. Bedside POCUS identified hydronephrosis in nine patients (one bilateral, eight unilateral). Of these, five were confirmed by departmental ultrasound, and one additional patient with hydronephrosis was missed by POCUS but identified on the formal scan.

Conclusions: This project demonstrated that using POCUS for diagnosing and managing AKI to identify hydronephrosis had a sensitivity of 83.3%, specificity of 93%, positive predictive value of 55.6%, and negative predictive value of 98%. The strength of our study is utilization of senior clinical physicians for POCUS training to guide junior residents in enhancing their skills and bedside assessment of patients with AKI. POCUS-enhanced bedside exams allow residents to identify hydronephrosis in a sensitive and time-efficient manner, facilitating timely diagnosis of obstructive uropathy and appropriate patient management.

FR-PO116

Provider-Performed Point-of-Care Ultrasonography Evaluation of the Kidneys after Kidney Biopsy

Kanza Haq, Nityasree Srialluri, Steven Menez, John Sperati. *Johns Hopkins University, Baltimore, MD.*

Background: Real-time ultrasonographic guidance is standard practice for performing kidney biopsies and is also used to identify post-biopsy bleeding complications. In this study, we aimed to evaluate the accuracy of provider-performed Point-of-Care Ultrasound (POCUS) in identifying post-biopsy bleeding complications.

Methods: Adult patients undergoing outpatient ultrasound (U/S)-guided native kidney biopsy at the Johns Hopkins Hospital between August 2022 – June 2023 were included in the study. Immediate post-biopsy and 4-hour post-biopsy U/S imaging were performed by U/S technicians. POCUS assessments by the nephrology provider were conducted

upon patient arrival to the recovery bay and 4 hours post-biopsy. The nephrology provider was blinded to the findings of the U/S technician. Presence of hematoma, hematoma size, presence of vascular jet, and presence of intra-renal arteriovenous fistula were documented. The prevalence of each complication and sensitivity and specificity of POCUS were calculated.

Results: A total of 82 patients were enrolled. Average age of participants was 55.2 years (SD: 16.5), BMI 28.8 (SD: 6.1), 54.9% were male, 37.8% were Black, and a nephrology attending performed most biopsies (86.6%). Formal radiology U/S detected hematoma and AV fistula in 20.7% (17) and 3.7% (3) immediately post-biopsy and in 40.2 % (33) and 13.4% (11) at 4-hours. By POCUS, hematoma was detected in 19.5% (16) and AV fistula in 2.4% (2) of patients immediately post-biopsy and in 32.9% (27) and 4.9% (4) of patients at 4 hours. When compared with the formal radiology performed U/S, the sensitivity of POCUS for hematoma detection immediately post-biopsy and at 4 hours was 82.4% (95%CI 56.5-96.2) and 75.8% (95%CI 57.7-88.9), respectively. The specificity was 96.2% (95%CI 89.2-99.6) immediately post-biopsy and 95.9% (95%CI 86.0-99.5) at 4 hours. Inter-rater agreement between POCUS and formal radiology U/S for hematoma detection was 93.9 % (κ 0.81) immediately post-biopsy and 87.8 % (κ 0.74) at 4 hours.

Conclusions: Provider-performed POCUS was able to detect post-biopsy bleeding complications with high sensitivity and specificity. This valuable, easily accessible tool should be considered for immediate assessment post-biopsy to expedite decision-making at the bedside. Additional studies are needed to evaluate the utility of POCUS to determine appropriateness for discharge after kidney biopsy.

FR-PO117

Computed Tomography-Measured Subcutaneous Adipose Tissue as a Protective Factor in Patients with Sepsis-Associated AKI Undergoing Continuous Kidney Replacement Therapy

Haeun Lee, Dong Min Kang, Ju hwan Oh, A young Cho, In O Sun.
Presbyterian Medical Center, Jeonju, Jeollabuk-do, Republic of Korea.

Background: The obesity paradox, a phenomenon in which obese patients exhibit improved survival compared to normal weight patients, has been observed in sepsis. However, body mass index does not adequately reflect adipose tissue mass and distribution. We investigated the association between abdominal adiposity and mortality among patients with sepsis-associated acute kidney injury (SA-AKI) undergoing continuous renal replacement therapy (CRRT).

Methods: Between 2011 and 2022, 1,390 adult patients with SA-AKI required CRRT at Presbyterian Medical Center. After excluding those on chronic dialysis, those who died within 24 hours of CRRT initiation, and those with missing data, 330 patients were included in the study. Subcutaneous adipose tissue (SAT) and visceral adipose tissue (VAT) areas were quantified at the L4-L5 level from abdominal CT scans (**Figure 1**). Patients were divided into tertiles based on VAT or SAT values. The second tertile served as the reference, with the first and third tertiles as low and high groups, respectively. The primary outcome was 28-day mortality.

Results: In the high SAT group, 28-day survival was superior compared to the reference group, with no such difference in the low SAT group (**Figure 2A**). In contrast, no significant difference in 28-day survival was observed between the groups based on VAT (**Figure 2B**). Adjusted Cox model analysis indicated high SAT reduced 28-day mortality risk (hazard ratio: 0.675, confidence interval: 0.460 – 0.990).

Conclusions: SAT, but not VAT, may provide a protective effect in patients with SA-AKI requiring CRRT.

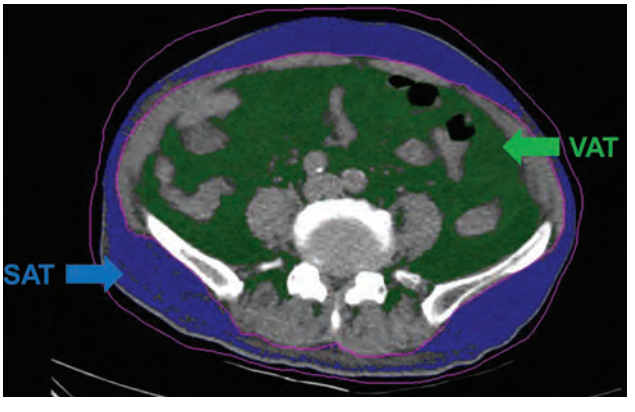

Figure 1. Adipose tissue area quantification

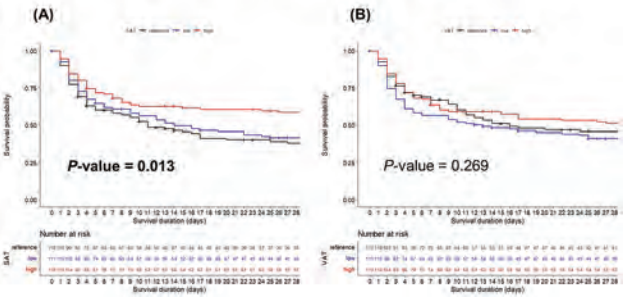
Figure 2. Kaplan-Meier curves according to the SAT and VAT



FR-PO118

Total Kidney Volume and Recovery of Kidney Function in AKI Patients with Kidney Replacement Therapy

Nozomi Kadota, Takuya Fujimaru, Chiharu Aizawa, Kasumi Konishi, Yugo Ito, Masahiko Nagahama, Fumika Taki, Masaaki Nakayama, Michiko Suzuki.
St.Luke's International Hospital, Tokyo, Japan.

Background: Among patients with acute kidney injury (AKI), 10% require renal replacement therapy (RRT), and 15% progress to end-stage renal disease (ESRD) with higher in-hospital mortality. While preexisting chronic kidney disease (CKD) is a risk factor for progression from AKI to ESRD, assessing preexisting CKD at AKI onset is challenging. Total kidney volume (TKV) is known to decrease in CKD. The aim of this study is to investigate whether TKV can predict kidney function recovery in AKI patients.

Methods: We retrospectively investigated AKI patients who required more than three times of RRT from April 2003 to November 2023. Exclusions criterion were the patients with post-kidney transplantation, with polycystic kidney disease, without CT imaging six months before admission, with unmeasurable TKV on CT, or with vascular access for maintenance hemodialysis. The primary outcome was RRT discontinuation within 90 days and no need for RRT for two weeks after discontinuation. TKV was measured using SYNAPSE VINCENT(R) from CT images. Clinical characteristics and laboratory data at RRT initiation were extracted.

Results: Among 446 patients (71.7% male, mean age 68.3 years, mean hospital stay 90.0 days), 179 (40.1%) discontinued RRT within 90 days. In-hospital mortality was significantly lower in the discontinuation group (64.0% vs 17.9%, p<0.001). In multivariate Cox regression analysis with age, sex, TKV, suppressor use, diabetes mellitus (DM), cancer, AKI after surgery, AKI due to acute tubular necrosis, serum albumin and hemoglobin as independent variables, TKV [ml], DM and hemoglobin [g/dl] were significantly associated with dialysis discontinuation (hazard ratio 1.00, 0.70 and 1.11, respectively; 95% confidence interval 1.001 to 1.004, 0.51 to 0.97 and 1.04 to 1.18, respectively).

Conclusions: TKV may predict renal function recovery, offering broader management strategies.

Factors	Hazard Ratio	95% CI for Hazard Ratio	Significance (p value)
Age [yo]	1.00	0.99 to 1.02	0.44
Female	0.76	0.52 to 1.11	0.16
TKV [ml]	1.00	1.00 to 1.00	<0.001
DM	0.70	0.51 to 0.97	0.029
Cancer	0.77	0.53 to 1.11	0.16
Surgery	1.09	0.78 to 1.52	0.62
Suppressor use	0.83	0.61 to 1.13	0.25
AKI due to ATN	1.27	0.80 to 2.02	0.32
Operation	1.09	0.78 to 1.52	0.62
Alb [g/dl]	1.08	0.86 to 1.36	0.49
Hb [g/dl]	1.11	1.04 to 1.18	<0.001

FR-PO119

Serial Multiparametric Kidney Magnetic Resonance Imaging in a Prospective Cohort of Patients with AKI

Rebecca A. Noble,[1,2] Eleanor F. Cox,[2] Maarten W. Taal,[1,2] Nicholas M. Selby,[1,2] Susan Francis.[2] *[1]University Hospitals of Derby and Burton NHS Foundation Trust, Derby, United Kingdom; [2]University of Nottingham, Nottingham, United Kingdom.*

Background: Recovery from acute kidney injury (AKI) is traditionally measured using serum creatinine but this often over-estimates the degree of renal recovery. Magnetic resonance imaging (MRI) is an imaging modality with promise to improve the understanding and characterisation of renal pathophysiology. In a single renal multiparametric MRI (mpMRI) scan, measures can assess renal morphology, tissue microstructure, oxygenation, perfusion and blood flow. This study aimed to assess the degree of change between 30- and 90-days post AKI, as the first 90 days after AKI appear to be the important in terms of determining outcomes.

Methods: Prospective observational study of 10 participants with AKI of all stages recruited at the time of AKI and followed up with monthly blood and urine samples. MRI scans collected on a Philips 3T Ingenia at Visit 1 (V1, 30-60 day) and Visit 2 (V2, day 90). The MRI protocol included: T2-weighted scans for total kidney volume (TKV), T1 and T2 mapping, DWI, ASL, phase contrast MRI, TRUST-MRI and BOLD $T2^*$.

Results: Participants (5M:5F, median age 64y (IQR 54–68)) had predominantly severe AKI (n=5 stage 3, n=4 stage 2, n=1 stage 1, with median baseline eGFR 82ml/min/1.73m^2 (60-89)) and were heterogeneous in terms of AKI aetiology and subsequent recovery. At V1, 7/10 participants had elevated cortex T1 compared to the healthy range (mean group T1 at V1: 1606±89ms), 3 of these 7 participants returned to the healthy range by V2 (group T1 at V2: 1551±83ms). 3 participants had reduced T2 at V1 compared to the healthy range (group average 99.7±8ms at V1, and group average 100±5ms at V2). Those participants who did not recover renal function at V2 typically had higher T1 and lower T2 at V1, with a trend towards the healthy range at V2.

Conclusions: We observed different patterns of MRI parameter change after AKI which appear to relate to the degree of kidney damage: high T1 suggesting more inflammation and/or oedema and a low T2 suggesting a greater degree of hypoxia. Further analysis will explore how these MRI changes are related to other markers of kidney damage.

FR-PO120

Early Clinical Indicators of ESKD Transition or Kidney Recovery in Patients with AKI on Dialysis

Scott Sibbel,[1] Claire Ryan,[1] Carey Colson,[1] Cicely N. Gibson,[2] Irina Goykhman,[2] Francesca Tentori,[1] Steven M. Brunelli.[1] *[1]Davita Clinical Research, Minneapolis, MN; [2]DaVita Inc, Denver, CO.*

Background: Previous studies reporting factors impacting renal recovery in acute kidney injury (AKI) patients were limited to the inpatient setting. With the 2017 changes to Medicare Reimbursement, patients with AKI that dialyze in the outpatient setting (AKI-D) are increasing in number. We sought to investigate which early indicators in AKI-D patients, those preceding or captured during the hospitalization, predict the likelihood of transition to ESKD or recovery.

Methods: For this analysis, we used the Optum® de-identified Integrated Claims-Clinical Dataset that links administrative claims and clinical data from providers across the continuum of care.[1] Patients included in the study (n=760) were >18 years old, had a claim from 2017-2023 for in-hospital dialysis and an AKI diagnosis and began outpatient dialysis within 3 days of discharge; patients with a previous dialysis treatment or ESKD diagnosis were excluded. We employed a case control study among those that recovered vs. those yet to have recovered.

Results: Those that recovered were younger (63 vs. 68 years old), were more likely to have AKI attributed to acute tubular necrosis (ATN) and/or sepsis during hospitalization; and less likely to have prior diagnoses of CKD 4/5 or cardiovascular disease (PVD, CAD, CVD, and CHF). A heuristic developed from the integrated data set segregates patients into two groups: high likelihood of recovery (64%) vs. a low/medium likelihood of recovery (30% and 45%, respectively).

Conclusions: When considered together, these attributes of patient's medical history and diagnoses can be used to reasonably predict the AKI patients that will recover in the outpatient setting. However, better data collection strategies, testing, and validation are necessary to ensure validity. [1] Optum's de-identified Integrated Claims-Clinical dataset (2007-2021)

	Percent of patients	Likelihood of Recovery
Absence of ATN Or Prior history of CKD 4/5	55%	Low (30%)
+ATN; No prior history CKD 4/5 With History of PVD	16%	Medium (45%)
+ATN; No prior history CKD 4/5 And History of PVD	29%	High (64%)

FR-PO121

Derivation and Validation of Clinical Subphenotypes of AKI with Prognostic Implications in Critically Ill Children

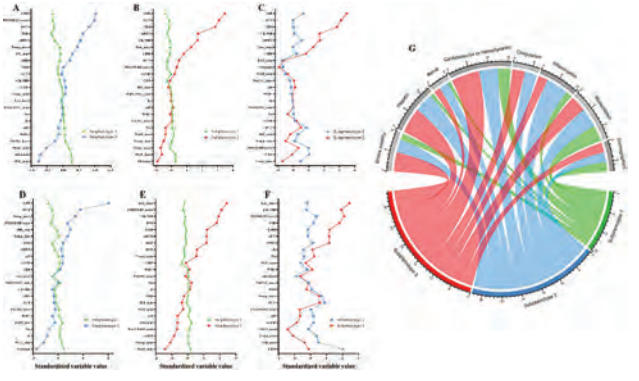
Yanhong Li, Junlong Hu. *Soochow University, Suzhou, China.*

Background: AKI is a heterogeneous syndrome. Identification of distinct clinical subphenotypes (SPs) may allow more precise therapy and improve care. We aim to derive and validate AKI SPs and determine whether the SPs were relevant with respect to outcomes in critically ill children.

Methods: This is a secondary analysis of our prospective multicenter cohort study, including AKI children met KDIGO criteria or predicted by our prediction model. Medical characteristics easily obtained within the first 24h after PICU admission were employed to select features using the SHapley Additive exPlanation. Latent profile analysis (LPA) was used to identify distinct SPs in derivation cohort and validated in external cohort.

Results: Three SPs were derived among 332 children and validated in 242 using LPA applied to 23 features. Children in SP1 (74.9%) exhibited the least severe illness and organ injury and responded well to milrinone; those in SP2 (19.5%) suffered severe inflammatory response and homeostatic imbalance; those in SP3 (5.6%) suffered more severe hepatic and cardiovascular dysfunction and the highest risk of mortality.

Conclusions: Three SPs were identified in critically ill children with AKI that correlated with outcomes. Further research is needed to determine the utility of the SPs in clinical care and trial design.



Comparison of variables contributing to SPs. Chord diagrams showing abnormal variables by SPs

A Global Data Approach to Prediction of 30-Day Readmission among Patients with Heart Failure and AKI

Meredith C. McAdams,[1,2] Yaser Elnakieb,[1] Samir M. Parikh.[1] *[1]The University of Texas Southwestern Medical Center, Dallas, TX; [2]Veterans Affairs North Texas Health Care System, Dallas, TX.*

Background: Heart failure (HF) is the leading hospitalization diagnosis in the US. Acute kidney injury (AKI) affects between 10-43% of individuals admitted with HF. Published outcomes models for HF complicated by AKI have poor predictive performance due to small patient numbers, single center data, and variable definitions of AKI.

Methods: The global healthcare database *TriNetX Research* was used to identify patients hospitalized with HF and AKI. Electronic health record (EHR) data including diagnoses, procedures, demographics, vital signs, medications, and laboratory values were obtained. Variables were encoded and pre-processed and the data was split into training and testing cohorts. Various machine learning models were used to build preliminary risk prediction models for 30-day readmission with 5-fold cross-validation. Initial models included only information available during the index hospitalization, no historical data was used. Model performance was evaluated on the hold-out test sets, assessing accuracy, sensitivity, specificity, area under the ROC curve (AUC), and balanced accuracy to comprehensively measure each model's predictive power.

Results: Of 250 million unique patients in *TriNetx*, 271,388 patients hospitalized with HF and AKI were identified. Of these individuals, 78,806 (29%) were readmitted within 30 days. A preliminary logistic regression model for 30-day readmission had an area under the curve (AUC) of 0.63. An initial random forest model had an AUC of 0.65. Adding different feature selection techniques to the models did not improve the AUC. Variables with high importance in both the logistic and random forest models included elements of the complete blood count, blood gas, metabolic profile, urinalysis, and electrocardiogram.

Conclusions: We have identified a large cohort of patients hospitalized with HF who have concurrent AKI. Importantly, this group has a high rate of 30-day readmission. Both models performed poorly for the prediction of 30-day readmission despite converging on variables that routinely inform clinical care in this morbid population. A unique opportunity therefore exists to develop a well-powered and robust risk prediction model by adding machine learning techniques, including deep learning and transformers, and including historical and dynamic EHR data elements.

FR-PO123

Acute Kidney Cortical Necrosis following Cardiac Catheterization: A Diagnostic Challenge

Johanna Marie S. Orejo, Aala Jabero. *Boston Medical Center, Boston, MA.*

Introduction: Atheroembolic renal disease is a rare but serious cause of renal failure among patients who underwent cardiac catheterization. It can lead to ischemic renal cortical necrosis due to microvascular injury. Renal biopsy is the gold standard for the definitive diagnosis, however, this is not possible for patients who are at high risk of bleeding. We present a case of a patient who developed severe acute kidney injury (AKI) following cardiac catheterization. He was diagnosed with renal cortical necrosis using a nuclear dimercaptosuccinic acid (DMSA) renal scan.

Case Description: A 61-year-old male with a past medical history of hypertension and coronary artery disease was sent to the emergency department after a routine Cardiology follow-up for evaluation and management of AKI. His laboratory test showed elevated BUN of 57 mg/dL and serum creatinine of 15.14 mg/dL from a baseline of 1 mg/dL. 3 weeks prior, the patient underwent left heart catheterization and drug-eluting stent (DES) placement for NSTEMI. His hospital course was uncomplicated and he was discharged with a stable renal function. On presentation, the patient reported decreased urine output, otherwise the history and physical examination were unremarkable. His work-ups including a renal ultrasound were unrevealing. A renal biopsy was planned, however, the patient was at high risk for bleeding due to his dual antiplatelet therapy for a recent coronary DES placement. Upon discussion with the Nuclear Medicine department, a DMSA renal scan was obtained to assess the kidney function and to help in the diagnosis of possible cortical infarction. The patient's results showed heterogeneity of uptake compatible with suspected cortical necrosis. The patient had a good renal recovery after undergoing a few treatments with hemodialysis.

Discussion: The diagnosis of atheroembolic renal disease following cardiac catheterization is challenging as the patients may present with non-specific symptoms and unrevealing AKI workups. Renal biopsy is the gold standard to confirm the diagnosis, however, this is a diagnostic challenge as there is a high risk of bleeding for patients who are receiving dual anti-platelet therapy following DES. DMSA, a renal nuclide scan, can provide both functional and anatomic information. This case highlights that radionuclide studies may be utilized in such cases when kidney biopsy is not possible.

FR-PO124

Markers for Cell Death and Purine Metabolites in Patients with and without Delayed Graft Function after Kidney Transplantation

Max Warncke,[1] Armelle Lafont,[1] Laurent Klein,[1] Monica R. Nakamura,[2] Helio T. Silva,[2] Karl Welzenbach.[1] *[1]Novartis AG, Basel, Switzerland; [2]Hospital do Rim, Goionia, Brazil.*

Background: Delayed graft function (DGF) is defined as the dysfunction of the kidney after transplantation (TX) and manifestation of acute tubular necrosis (ATN). Tubular necrosis is one hallmark of DGF, but there is still an incomplete understanding about the trajectories of biomarkers of tissue injury post transplantation. Markers to identify patients at risk for DGF would support the development of novel therapeutic treatments to ameliorate or reduce DGF in the globally growing number of transplanted patients.

Methods: Plasma and urine samples of 41 patients receiving grafts of living donors (10), or grafts from deceased donors with standard criteria (16) or expanded criteria donors (15) were prospectively collected over 28 days after TX. Markers of tissue injury (plasma LDH, Cystatin C (CycC), AST, ALT, CK), NGAL and urinary purine metabolites (ATP, adenosine) were assessed. The association of markers early post TX with DGF diagnosis was evaluated.

Results: Among the 31 patients who received a deceased donor graft, 19 developed DGF, while the remaining 11 did not experience DGF. The incidence of DGF in patients receiving a cadaveric graft was 61%. The 10 patients with grafts from living donors did not develop DGF. Markers of tissue damage were modulated in plasma of patients following TX. Patients receiving living donor organs showed significantly lower TX-induced modulation of biomarkers suggesting a milder insult on grafts and recipients. Urinary adenosine was significantly lower in the 28 days after transplantation in patients with DGF correlating well with increased plasma CysC and NGAL levels. All markers normalized 3-4 weeks after TX. The relative elevation of LDH and AST at 4h after surgery preceded the development of DGF in ~40% of patients who received a graft of a deceased donor.

Conclusions: This study provides a comprehensive trajectory of established and more recent markers of kidney function, potentially graft quality and the relationship to DGF after kidney transplantation in kidney TX patients. The early induction of tissue damage markers shows the importance to start therapies to protect from DGF as early as possible. The observed decrease of urinary adenosine in patients with DGF point to an important function of the purinergic pathway in this patient population.

FR-PO125

Decrease in Platelet Count in Patients with AKI and Its Association with Major Adverse Kidney Events

Jonathan Chavez,[1,2] Guillermo Garcia-Garcia,[1] Ramon Medina,[1,2] Zarahi Andrade,[1] Juárez Correa de León,[1] Eduardo M. Hernández,[1] Jorge L. Padilla Armas,[1] Rebeca L. Ornelas Ruvalcaba,[1] Jose S. Cabrera Aguilar,[1] Alejandro Martínez Gallardo González,[1] Maria de la Luz Alcantar Vallin,[1] Guillermo Navarro Blackaller.[1] *[1]Universidad de Guadalajara, Guadalajara, Mexico; [2]Hospital Civil de Guadalajara, Guadalajara, Mexico.*

Background: A reduction in platelet count in critically ill patients is a marker of severity of the clinical condition. However, whether this association holds true in acute kidney injury (AKI) is unknown. We analyzed the association between platelet reduction in patients with AKI and major adverse kidney events (MAKE).

Methods: In this retrospective cohort, we included AKI patients at the Hospital Civil of Guadalajara, in Jalisco, Mexico. Patients were divided according to whether their platelet count fell >21% during the first 10 days. Our objectives were to analyze the associations between a platelet reduction >21% and MAKE at 10 days (MAKE10) or at 30-90 days (MAKE30-90) and death.

Results: From 2017 to 2023, 400 AKI patients were included, 134 of whom had a >21% reduction in platelet count. The mean age was 54 years, 60% were male, and 44% had sepsis. The mean baseline platelet count was 194 x 103 cells/mL, and 65% of the KDIGO3 patients met these criteria. Those who underwent hemodialysis (HD) had lower platelet counts. After multiple adjustments, a platelet reduction >21% was associated with MAKE10 (OR 4.2, CI 2.1-8.5) but not with MAKE30-90. The mortality risk increased 3-fold (OR 2.9, CI 1.1-7.7, p= 0.02) with a greater decrease in the platelets (<90 x 103 cells/mL). As the platelets decreased, the incidence of MAKE was more likely to increase. These associations lost significance when accounting for starting HD.

Conclusions: In our retrospective cohort of patients with AKI, a >21% reduction in platelet count was associated with MAKE. Our results are useful for generating hypotheses and motivating us to continue studying this association with a more robust design.

FR-PO126

Procalcitonin (PCT) Levels in Septic and Nonseptic Participants with AKI before and during Continuous Kidney Replacement Therapy (CKRT)

North Foulon, Kayo Okamura, Zhibin He, Matt R. Kennis, James F. Colbert, Sarah Faubel. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: PCT is a 14.5 kDa protein and biomarker of bacterial infection. PCT is increased in ESKD and plasma levels decline after hemodialysis, suggesting clearance by the kidney and KRT. Herein, we measured plasma PCT in septic and non-septic patients with AKI and tested the hypothesis that PCT would be increased in AKI without sepsis and cleared by CKRT.

Methods: Plasma and effluent PCT were determined in septic and non-septic subjects with AKI that were selected from a prospective observational cohort of 126 patients who received CKRT at a single center. Plasma was collected prior to CKRT initiation, and plasma and effluent were collected on days 1, 2, and 3 of CKRT. Inclusion criteria for sepsis subjects were: 1) AKI without CKD, and 2) clinical diagnosis of sepsis and 2/2 positive blood cultures. Inclusion criteria for non-septic subjects were: 1) AKI without CKD, and 2) no clinical diagnosis of sepsis and no positive blood cultures. The sepsis cohort contained 9 patients, and the non-septic cohort contained 27 patients. 9 healthy control (HC) subjects with neither kidney disease nor sepsis were also studied.

Results: Plasma PCT was significantly increased in non-septic subjects with AKI vs. healthy controls. Plasma PCT was significantly increased in septic AKI subjects compared to non-septic (Figure 1). No significant difference existed in serum PCT of septic or non-septic AKI patients after 3 days of CKRT compared to pre-CKRT samples (Figure 2A and 2B). The average sieving coefficient for procalcitonin was 0.27 (Figure 3A). The average procalcitonin clearance was 7.05 L on day 1, 12.84 L on day 2, and 10.94 on day 3 of CKRT (Figure 3B).

Conclusions: Plasma PCT is significantly increased in non-septic patients with AKI suggesting that acute kidney function decline affects plasma PCT levels. Although some level of PCT clearance by CKRT was observed, changes in serum PCT were unpredictable during CKRT in both septic and non-septic patients. Our data suggest PCT results should be interpreted cautiously in patients with AKI prior to and during CKRT.

FR-PO127

Magnesium Levels and Mortality in Critically Ill Patients with AKI

Supawadee Suppadungsuk,[1,2] Charat Thongprayoon,[1] Waryaam Singh,[1] Wisit Cheungpasitporn,[1] Kianoush Kashani.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Chakri Naruebodin Medical Institute, Bang Phli, Thailand.*

Background: Magnesium derangement affects endothelial function and inflammation. It also associated with a declines in renal function and increases the risk of death in chronic kidney disease (CKD) and hemodialysis patients. This study aims to assess the significance of serum magnesium derangements in short—and long-term outcomes among critically ill patients with acute kidney injury.

Methods: This cohort study was conducted among patients with AKI admitted to the intensive care units at Mayo Clinic from January 2007 to December 2017. Serum magnesium levels at AKI onset were categorized into five groups of <1.7, 1.7-1.9, 1.9-2.1, 2.1-2.3, and ≧2.3 mg/dL, with 1.9-2.1 mg/dL as the reference group for outcome comparison. Multivariable logistic regression was used to evaluate the association between serum magnesium levels and mortality.

Results: Among 20,198 critically ill patients with AKI, the mean age was 66±16 years, and 57% were male. The mean serum magnesium at AKI onset was 1.9±0.4 mg/dl. The overall incidence of in-hospital and 1-year mortality were 11.6% and 31%, respectively. In multivariable analysis, hypermagnesemia (>2.3 mg/dl) was associated with increased risk of in-hospital and 1-year mortality with the odds ratio of 1.4 (95% CI 1.22-1.65) and 1.48 (95% CI 1.33-1.65), respectively.

Conclusions: Hypermagnesemia (Mg ≧2.3 mg/dL) was associated with increased in-hospital and 1-year mortality in critically ill AKI patients. Serum magnesium monitoring and proper magnesium level correction in critically ill patients with AKI should be considered. Further studies that evaluated the magnesium treatment effect are recommended.

FR-PO128

Comparative Efficacy of Frailty and Barthel Index in Predicting AKI in Critically Ill Geriatric Patients

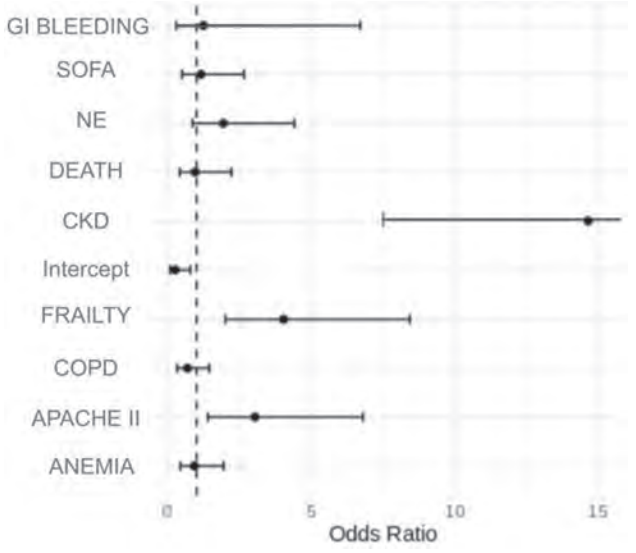
José A. Novoa Burquez. *Hospital Civil de Guadalajara Unidad Hospitalaria Fray Antonio Alcalde, Guadalajara, Mexico.*

Background: The Barthel Index describes functional independence and the FRAIL questionnare predicts fragility in theelderly, this comorbidity is a risk factor to develop acute kidney injury (AKI). Thisstudy, aimed to explore the association between Barthel Index, Fraility and AKI in a geriatric ICU population.

Methods: In a retrospective cohort in the Hospital Civil of Guadalajara, elderly ICU patientswere recluted. Frailty was measured CFS and FRAIL questionnare, functional independence by Barthel Index and AKI by KDIGOguideline. We test the predictive capability of Barthel Index and Fraility to develop AKI by logistic regression analysis and predictive accuracy.

Results: In a total of 207 geriatric ICU patients with mean age of 78 years, 48% being classified as frail and 60% developed AKI. AKI presented in 59.5% in the frailgroup, and in 30.9% of non-frail. The mean Barthel Index was 67, it has nocorrelation with the risk of AKI (p = 0.9). Frailty has a positive correlation with thedevelopment of AKI (adjusted odds ratio = 4.04, p < 0.001). ROC curve analysis 0.6432, further indicated that frailty predicts better the occurrence of AKI than the Barthel Index.

Conclusions: Frailty is a good predictor of AKI in ICU elderly patients, and is better than the Barthel Index.



FR-PO129

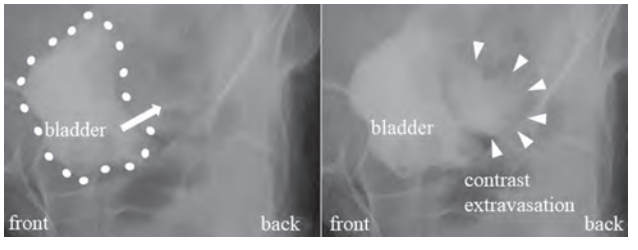
An Overlooked Cause of Pseudo-Kidney Failure Due to Spontaneous Bladder Rupture 8 Years after Radiation Therapy

Makoto Ando, Akiko Kudo, Hiroki Uchida, Takeshi Nakata, Akihiro Fukuda, Hirotaka Shibata. *Department of Endocrinology, Metabolism, Rheumatology and Nephrology, Faculty of Medicine, Oita University, Yufu, Japan.*

Introduction: Pseudo-renal failure is characterized by acute renal failure-like abnormalities despite normal renal function. The most common cause is bladder rupture. Pseudo-renal failure occurs secondary to reverse peritoneal dialysis. The initial diagnosis rate of bladder rupture is low; it is often misdiagnosed as peritonitis or acute renal failure. We report a case of pseudo-renal failure due to spontaneous bladder rupture and discuss its diagnostic challenges.

Case Description: A 55-year-old woman underwent total hysterectomy and chemoradiotherapy for cervical cancer 8 years previously. She visited her family hospital because of abdominal pain and diarrhea, and ascitic effusion and elevated serum creatinine (S-Cr) were found. Fluid therapy was given for dehydration due to diarrhea, and antibiotic therapy was given for peritonitis due to enteritis. However, she was admitted to our hospital because of her high S-Cr level (9.7 mg/dL) and increased ascites. She had oliguria and uremic symptoms, and we performed diagnostics while initiating hemodialysis. We suspected urinary ascites because the serum cystatin C level (1.2 mg/dL) was inconsistent with the S-Cr level, and both the urea nitrogen (125.8 mg/dL) and creatinine (27.5 mg/dL) levels in the ascites were extremely high. Cystography showed leakage of contrast medium into the abdominal cavity (Figure), indicating pseudo-renal failure due to spontaneous bladder rupture. The S-Cr level normalized 2 days after urethral catheter insertion, and the ascites disappeared.

Discussion: The incidence of spontaneous bladder rupture is approximately 0.002%, and pelvic radiation and alcohol intoxication are the most common causes. The initial misdiagnosis rate is 64% because of the nonspecific symptoms, and delayed diagnosis is common. Cystography is useful for definitive diagnosis. In this case, the increased ratios of S-Cr to cystatin C and ascites creatinine to S-Cr assisted the diagnosis, as reported in previous studies. The differential diagnosis of pseudo-renal failure is important when acute renal failure with ascites effusion occurs after pelvic radiation.



FR-PO130

Inflammation and Infection: An AKI Diagnostic Dilemma

Hailey V. Hildebrand,[1,2] Emily G. Jeon,[1] Lisa M. Miller.[1] *[1]University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; [2]Chronic Disease Innovation Centre, Seven Oaks General Hospital, Winnipeg, MB, Canada.*

Introduction: Glomerular full-house immune complex deposition is a characteristic finding of lupus nephritis; however, in rare cases it can occur with other glomerulopathies. We present a case of non-lupus glomerulonephritis leading to full-house immunostaining on renal biopsy.

Case Description: A 50-year-old gentleman presents with a one-month history of rash and a 20-kilogram weight loss over the past year. He denied infectious symptoms, arthralgias, or other constitutional symptoms. His examination was remarkable for palpable purpura on his legs. Initial investigations revealed an elevated creatinine 114 mmol/L, proteinuria (72mg/mmol) and hematuria. Further work-up showed low serum complements, but normal antinuclear antibodies and anti-double stranded DNA. CT imaging of the abdomen showed splenic infarcts and normal kidneys. He was started on empiric prednisone due to suspicion for an autoimmune process, but on further assessment, he was found to have poor dentition concerning for infectious endocarditis. Prednisone was stopped, and blood cultures returned positive for streptococcus mutans. He was hospitalized and started on ceftriaxone. A transesophageal echocardiogram showed vegetations on the mitral and aortic valves. A kidney biopsy was performed which showed moderate endocapillary hypercellularity with no significant tubular atrophy or interstitial fibrosis. Immunofluorescence was positive for IgG, IgA, IgM, C3, and C1q consistent with full-house immunostaining, suggesting a diagnosis of diffuse proliferative lupus nephritis. However, based on the lack of clinical manifestations and the negative lupus serology, it was suspected that this was a rare biopsy finding associated with infection-related glomerulonephritis (IRGN). He underwent CABG with atrial and mitral valve repair. Following completion of antibiotics his creatinine had normalized consistent with a resolved IRGN.

Discussion: Glomerular full-house immunostaining typically occurs in lupus nephritis; however, it can occur in other diseases including IgA nephropathy, membranoproliferative glomerulonephritis, and IRGN. It is speculated that this deposition may occur in more severe forms of IRGN due to superantigen formation. This case emphasizes the importance of clinical presentation when interpreting renal biopsy findings as rarely patients with full-house immunostaining may have a diagnosis other than lupus nephritis.

FR-PO131

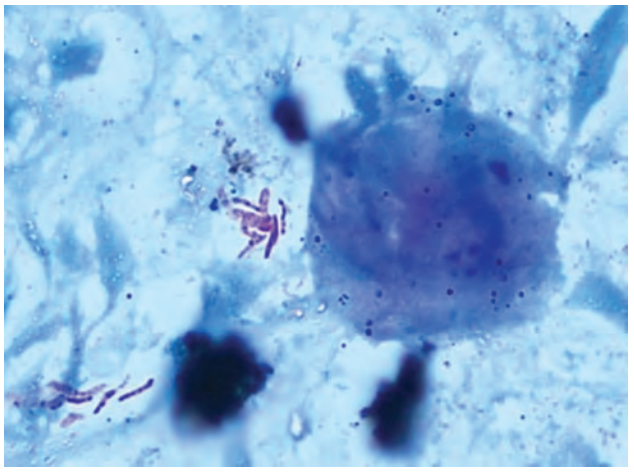
Importance of Kidney Biopsy in Interstitial Nephritis Caused by Mycobacterium Tuberculosis: A Case with Negative Noninvasive Test Results

Itzel A. Martinez,[1] Ana S. Vargas,[1] Victor M. Muñoz,[1] Maria J. Sanchez Perez,[1] Cristopher C. Sanchez Rodriguez,[1] John Hernandez Flores.[1,2] *[1]Operadora de Hospitales Angeles SA de CV, Ciudad de Mexico, Mexico; [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico.*

Introduction: Mycobacterium tuberculosis (MTB) is an intracellular pathogen with a wide range of clinical manifestations, including interstitial nephritis (IN). Diagnosing IN due to MTB can be challenging, as non-invasive tests like QuantiFERON and GeneXpert may yield negative in some cases. Renal biopsy (Rb) remains the gold standard.

Case Description: A 61-year-old man with a urothelial cancer treated with lymphadenectomy and bladder resection with robotic neo-bladder creation in March 2023. He finished at july 2023 gemcitabine and cisplatin with a GFR of 80, free tumor activity. Four months after, he presented weakness and weight loss. His creatinine up over two months along with leukocyturia, hematuria, glycosuria, and proteinuria. He presented at hospital with hemodialysis emergency and severe anemia (normal transferrin receptor/ elevated ferritin levels). US reported a small right kidney and an enlarged left one, indicating a high risk for Rb. Infectious and autoimmune tests were performed (Figure 1). He recieved 3x methylprednisolone boluses and rapid tapering. The Rb showed granulomas, severe tubular damage, and ZN positive bacilli, 50% fibrosis and tubular atrophy. The patient started third-line anti-MTB: rifampicin, isoniazid, clarithromycin, levofloxacin, linezolid, and amoxiclav for two months induction. The last GFR is 30 and continue improving since he discontinued hemodialysis in the first month.

Discussion: Rb remains the gold standard for diagnosing MTB-induced IN, even in patients with negative non-invasive test results. Early diagnosis and treatment are essential for improving the prognosis of patients with this disease.



Etiology	Tests				
Infectious (All Negative)	CMV, HSV, HBV, HCV, HIV.	Galactomannan urine antigen.	Brucella.	Chlamydia, Neisseria, Ureaplasma, Mycoplasma, Trichomonas.	QuantiFERON Gene-Xpert Bacilloscopy.
Autoinmmune (All Negative)	C3, C4, ANAs.	Subclasses IgG4.	Anti SSA / Ro, Anti SSB / La.	MPO/ PR3.	Angiotensin converting enzyme.
Inflamatory	Ferritin >2000mg/dl.	ESR >150mm/h.	CRP > 100 mg/dl.	IL-2 alfa receptor >1584 U/mL	

FR-PO132

Brewing Trouble: Tea Consumption and AKI in a Patient on Immune Checkpoint Inhibitor Therapy

Renata Vallecillo, Carl S. Dernell, Paul Hanna. *Medical College of Wisconsin, Milwaukee, WI.*

Introduction: Acute interstitial nephritis (AIN) is a well-recognized immune related adverse effect (irAE) of immune checkpoint inhibitors (ICIs). AIN can also be secondary to other drugs such as proton pump inhibitors (PPIs), and less commonly, hyperoxaluria – which may result from malabsorption or excessive dietary intake of oxalate-rich foods. Thus, AIN poses a diagnostic challenge in patients with multiple risk factors, often necessitating a kidney biopsy to identify the underlying cause.

Case Description: A 70-year-old female with chronic kidney disease, gastric bypass, and lung adenocarcinoma on immunotherapy was evaluated for acute kidney injury (AKI). The patient had recently started ICI and PPI therapies and had an increase in serum creatinine from a baseline of 1.7 mg/dL to 2.9 mg/dL seven days post-initiation of ICI therapy. Urinalysis was negative for hematuria and proteinuria. ICI-induced nephritis was considered unlikely due to the timing of AKI onset and absence of other irAEs. The patient reported substantial tea consumption preceding the AKI. A kidney biopsy revealed AIN with scattered tubulointerstitial calcium oxalate crystal deposition (**Fig 1**). Discontinuation of her tea and initiation of a prolonged steroid taper led to a return of renal function to baseline.

Discussion: This case highlights the diagnostic challenge of AKI in the context of multiple potential AIN culprits, including ICI therapy in CKD, PPI use, and dietary consumption of tea in gastric bypass patients. AKI in patients on ICI therapy warrants a broad differential diagnosis, including a full assessment of irAEs, past medical and surgical history and dietary habits. This case highlights the value of kidney biopsy in distinguishing between potential etiologies and guiding appropriate management without interrupting lifesaving cancer treatment.

FR-PO133

Idiopathic Hypocomplementemia and Interstitial Nephritis: A Case Report

Rucci Marcus C. Foo, Shimontini Mitra, George J. Kavalam, Jeffrey H. William. *Beth Israel Deaconess Medical Center, Boston, MA.*

Introduction: Interstitial nephritis is a significant cause of renal failure in patients with autoimmune disease. Typically, this condition is associated with IgG4-related disease or systemic lupus erythematosus, often presenting with low complement levels. Here, we present a case of idiopathic hypocomplementemia with interstitial nephritis without evidence of IgG4-related disease.

Case Description: A 64-year-old woman with a history of right-sided pulmonary embolism, a large exudative pleural effusion in October 2023, moderate pulmonary hypertension, hypertension, and sarcoidosis presented in November 2023 with elevated creatinine levels of 2.8 mg/dL. On exam, she exhibited severe edema. During her hospitalization, her creatinine subsequently rose to 5.4 mg/dL. She was given pulse-dose steroids for three days, without improvement in the acute kidney injury. Her C3 was 30 mg/dL; her C4 was 3 mg/dL. ANA and dsDNA were positive. The renal biopsy showed immune complex-mediated glomerulonephritis with mesangial deposits immunoreactive for C3 and C1q, with weak reactivity for polyclonal IgG and IgA. Immunofluorescence revealed extensive, diffuse immune complexes within the tubular basement membranes, interstitium, and vasculature. There were no cellular crescents, fibrinoid necrosis, or endocapillary hypercellularity observed. Additionally, no plasma cells were identified, making IgG4-related disease less likely. Importantly, there was severe acute interstitial nephritis with associated acute tubular injury, likely a response to the numerous tubulointerstitial deposits. Frequent finely granular electron-dense deposits were present in the mesangium. The patient eventually succumbed to acute kidney injury, complicated by septic shock in the setting of immunosuppression and extent of illness. Autopsy reaffirmed the diagnosis of an autoimmune process most consistent with idiopathic hypocomplementemia and interstitial nephritis.

Discussion: Idiopathic hypocomplementemia and interstitial nephritis is a rare entity that can cause renal failure and death if not identified promptly. Over the past few decades, many cases initially considered idiopathic have been recategorized under IgG4-related disease. This case illustrates the continued utility of renal biopsy in diagnosing undifferentiated renal failure and identifying the underlying disease process.

FR-PO134

Scleroderma Renal Crisis as First Manifestation of Systemic Sclerosis

Buadi K. Tandoh, Milagros Yunes. *Montefiore Medical Center, Bronx, NY.*

Introduction: Scleroderma renal crisis (SRC) is a rare life-threatening complication of scleroderma typically characterized by abrupt onset of severe hypertension and progressive kidney failure. Most cases occur in patients with diffuse scleroderma compared to individuals with limited cutaneous disease. SRC mostly occurs in the first four years of diagnosis of scleroderma but may rarely, be the herald sign of underlying scleroderma. Here, we describe a patient with no prior diagnosis of scleroderma presenting with SRC.

Case Description: 51-year-old female with normal renal function, right ventricular dysfunction, severe pulmonary hypertension on home oxygen, who presented to the emergency room with one-week of shortness of breath and orthopnea. She also had a two-year history of intermittent painful ulcers on fingertips. At home, she was on furosemide 20mg daily and recently prescribed a 14-day course of prednisone 40mg daily. On presentation, blood pressure was 171/119, lung with rales, extremities with sclerodactyly and tender ischemic ulcers on fingertips. Laboratory data with serum creatinine (Scr) of

2.7 mg/dl (from baseline of 0.6 mg/dl). Urinalysis with moderate blood, 100 red blood cells, microalbumin-creatinine ratio of 478mcg/mg and total urine protein-creatinine ratio of 1.7g. Given clinical features of sclerodactyly, hypertension, and renal failure, SRC was considered. Oral captopril was started. Serologies with positive Anti-Nuclear-Antibody titer >1:1280 in a speckled pattern, positive ribonucleic (RNA) polymerase III antibody, negative topoisomerase I antibody and 61% ADAMTS13 activity. Scr continued to rise, and a renal biopsy was done. Light microscopy showed subacute thrombotic microangiopathy with predominant involvement of the blood vessels, diffuse ischemic glomerular changes and moderate tubulointerstitial scarring consistent with SRC. A skin punch biopsy showed fibrosing dermopathy consistent with scleroderma. She required hemodialysis due to worsening renal function. The patient's hospital course was complicated by seizure, superior sagittal sinus thrombosis and then cardiac arrest for which she was pronounced dead.

Discussion: SRC has a high mortality rate and prompt aggressive care is warranted. Although being a rare presentation, SRC should be considered in clinical situations where patients present with suspected skin features despite no established diagnosis of scleroderma.

FR-PO135

Two Cases of Atypical Sarcoidosis Presenting with AKI: Clinical Significance of Sequential Fluorodeoxyglucose (FDG) Positron Emission Tomography (PET)/CT Images

Yui Mohri,[1] Shinya Yamamoto,[1] Yoko Shimizu,[1] Sho Koyasu,[2] Motoko Yanagita.[1]
[1]Department of Nephrology, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [2]Department of Diagnostic Imaging and Nuclear Medicine, Kyoto University, Kyoto, Japan.

Introduction: Refractory hypercalcemia can be caused by sarcoidosis, which can induce severe and irreversible renal impairment without appropriate therapy. Therefore, clinicians must correctly diagnose sarcoidosis using serological, radiological, and pathological evaluation.

Case Description: **Case1**: A 76-year-old female was admitted to our hospital with general fatigue. Laboratory tests revealed renal dysfunction (sCre: 2.77 mg/dL), hypercalcemia (12.9 mg/dL). The levels of activated vitamin D was elevated. No respiratory, skin or eye lesions were observed. Renal biopsy revealed no granulomatous lesions. PET/CT showed accumulation in the muscles of the whole body with Tiger-man sign. Muscle biopsy showed granuloma with multinucleated giant cells. The patient was finally diagnosed with muscular sarcoidosis. After starting oral prednisolone 0.7 mg/kg/day, hypercalcemia and renal dysfunction improved. Three months later, PET/CT showed that the accumulation had disappeared. **Case 2**: A 74-year-old male was referred to our hospital with swallowing pain and diagnosed with esophageal cancer. PET/CT showed accumulation in the hilar and mediastinal lymph nodes and bilateral thigh muscles. The patient started chemotherapy. Two months later, repeated PET/CT showed reduced accumulation in the lymph nodes, but new accumulations in the lower leg. Blood tests revealed renal dysfunction (sCre: 3.5 mg/dL) and hypercalcemia (14.3 mg/dL). Muscle biopsy revealed a non-caseating epithelioid cell granuloma. The patient was finally diagnosed with sarcoidosis. Renal biopsy showed lymphocytic infiltration of interstitial and necrotizing vasculitis. Anti-neutrophil cytoplasmic antibodies were negative. After starting oral prednisolone 0.8 mg/kg/day, hypercalcemia and renal dysfunction improved.

Discussion: PET/CT is useful for diagnosis of sarcoidosis, especially in patients without typical organ lesions and in cancer patients with hypercalcemia and lymphadenopathy. While sequential PET/CT in Case 1 clearly showed a good response to treatment, that in Case 2 suggested that emerging muscle lesions contributed to vitamin D activation. In addition, renal biopsy of Case 2 revealed vasculitis, which is a rare complication in patients with sarcoidosis. As previously reported, cancer may trigger sarcoidosis and vasculitis via immune or macrophage abnormalities.

FR-PO136

Granulomatosis with Polyangiitis (GPA) Presenting with Granulomatous Nephritis but No Glomerulonephritis

Mohamed Abdali,[3,1] Praveena Koneru,[1,2] Mili J. Shah,[1,2] Madhumita J. Mohanty.[1,2] *[1]John D Dingell VA Medical Center, Detroit, MI; [2]Wayne State University, Detroit, MI; [3]Detroit Medical Center, Detroit, MI.*

Introduction: We report a patient with worsening renal function and positive ANCA antibody with atypical clinical and histological findings

Case Description: A 83-year-old male with a history of hypertension and working diagnosis of sarcoidosis with recurrent uveitis, skin lesions with biopsy consistent with possible sarcoidosis, and pulmonary nodules, was being treated with mycophenolate mofetil (He was previously on methotrexate). He had an increase in plasma creatinine from 2.2 mg/dl in December 2023 to 4.5 mg/dl in March 2024. His blood pressure was normal, and his examination was unremarkable. He had no proteinuria, hematuria, or urinary casts. Renal ultrasound showed normal sized kidneys with no hydronephrosis. Plasma calcium and complement C3 and C4 were normal. ANA, dsDNA, rheumatoid factor, hepatitis C antibody, hepatitis B surface antigen and QuantiFERON TB Gold Plus were negative. Angiotensin converting enzyme was not high. ANCA immunofluorescence titer was negative but serine protease 3, IgG was elevated at 47 AU/ml (normal: 0-14). He had a kidney biopsy in March 2024 which showed granulomatous nephritis with non-caseating granulomas in the interstitium with possible small artery /arteriole disrupted by granulomatous inflammation. Granulomas were somewhat loose and not clearly defined. There was no definitive glomerulonephritis, glomerular necrosis or crescents. There were occasional neutrophil casts. There was patchy interstitial infiltrate in 40% of cortex with mononuclear and plasma cells in some regions and neutrophil and eosinophils in some regions. There was no evidence of histoplasmosis or AFB in the biopsy. The differential included GPA and sarcoidosis. Loose organization of granulomas, neutrophil casts, interstitial infiltrate with neutrophils and eosinophils and possible destructive arteriolitis all favored GPA over sarcoidosis. The patient was treated with prednisone and rituximab with improvement of plasma creatinine to 2.1 mg/dl.

Discussion: ANCA vasculitis may lead to worsening renal function without glomerular involvement. Renal involvement of ANCA vasculitis should be considered in patients with positive ANCA even in the absence of hematuria, proteinuria or urinary casts and early renal biopsy should be considered in these patients so that treatment may be started before the onset of irreversible renal injury

FR-PO137

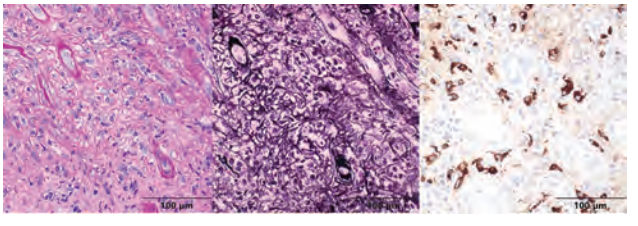
Breakthrough IgG4 Disease-Related Tubulointerstitial Nephritis Treated with Rituximab as Maintenance Therapy

Jill Nehrbas, Joseph D. Nguyen, Monarch Shah, William F. Glass, Tushar Chopra. *University of Virginia, Charlottesville, VA.*

Introduction: IgG4-related disease (IgG4-RD) is a systemic immune-mediated condition that can affect almost any organ system. In the kidneys, the most common manifestation is IgG4-related tubulointerstitial nephritis (IgG4-TIN), characterized by fibrosis and IgG4-positive plasma cell infiltrates in the interstitium. IgG4-RD is typically treated with immunosuppressives, including steroids and rituximab (RTX), which have demonstrated efficacy in achieving disease remission. We present a case of a patient with recurrent IgG4-RD manifesting as IgG4-TIN despite successful treatment of autoimmune pancreatitis and cholangitis.

Case Description: A 69-year-old male with a history of IgG4-RD treated with two courses of prednisone and four infusions of RTX for flares presented with non-oliguric acute kidney injury (AKI) (serum creatinine (sCr) of 2.1 mg/dL (baseline 1.1 mg/dL)). AKI was associated with hypertension, proteinuria (urine protein/creatinine ratio of 0.41 g/g), and hypocomplementemia consistent with IgG4-TIN. Kidney biopsy was also consistent and demonstrated diffuse "bird's eye" fibrosis in the cortex and medulla, extensive tubular destruction, and numerous IgG4-positive plasma cells (Fig 1). IgG4-TIN was treated with pulsed steroids and maintenance remission therapy of RTX 1 gm every 14 days for two doses every six months. At one year, sCr improved to 1.1 mg/dL and urine protein/creatinine ratio improved to 0.08g/g (normal ≤ 0.15g/g), and he remained relapse free.

Discussion: This case has three main teaching points: 1) It is important to maintain a high index of suspicion for IgG4-TIN when AKI is superimposed on IgG4-RD and ensure close follow-up for refractory cases. 2) IgG4-TIN can develop despite appropriate steroid therapy and remission in other involved organs with RTX. 3) Maintenance therapy with RTX retreatment was associated with longer relapse-free survival at 12 months of follow up in this case. Our patient had no severe infections or hypogammaglobulinemia ≤5 g/l with RTX, confirming RTX's safety and efficacy in maintenance remission therapy for recurrent IgG4-TIN.



FR-PO138

Lupus, the Great Mimicker: Unmasked by Urine Microscopy

Zach Kisley, Veronica Zamora-Olivencia. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Introduction: Systemic Lupus Erythematosus (SLE) can present in a variety of ways, making it difficult to diagnose. By analyzing the urine microscopy of a critically ill patient, a complex case of SLE was identified and effectively treated.

Case Description: A 75 year old female with a history of chronic L staghorn calculus, recurrent pyelonephritis, and L kidney atrophy presented with dizziness and difficulty ambulating and was found to have multifocal strokes. She developed acute hypoxic respiratory failure with bilateral infiltrates, thought to be multifocal pneumonia. ICU team noted bloody endotracheal secretions. Nephrology was consulted for acute

kidney injury (AKI). Serum creatinine: 1.5-2.0mg/dL (baseline 0.9-1.0 mg/dL). Urinalysis showed persistent hematuria, long attributed to staghorn calculus, with new proteinuria. Urine microscopy revealed RBC casts, acanthocytes, and oval fat bodies seen in figure 1. Serologies revealed ANA >1:1280, elevated dsDNA, anti-smith, RNP, SSA Ro antibodies, low C3/C4, but otherwise negative. Urine protein creatinine ratio: 2.42mg/mg. Given the urine sediment, nephrology recommended bronchoalveolar lavage, revealing diffuse alveolar hemorrhage. Biopsy was deferred given her acute illness and solitary kidney, but data was strong enough to presume class III/V or IV/V lupus nephritis as well as pulmonary and CNS lupus vasculitis. She promptly received a steroid pulse and cyclophosphamide. She was ultimately extubated, had complete resolution of her AKI, had less active urine sediment, and is making a neurologic recovery.

Discussion: The novelty of our case includes the simultaneous presentation of three severe manifestations of SLE, but more importantly highlights the pivotal role of urine microscopy in the evaluation of AKI with an "active" UA. Although not a replacement for biopsy, urine microscopy allowed for prompt treatment, multi-disciplinary agreement, and identification of the unifying diagnosis, lupus vasculitis.

FR-PO139

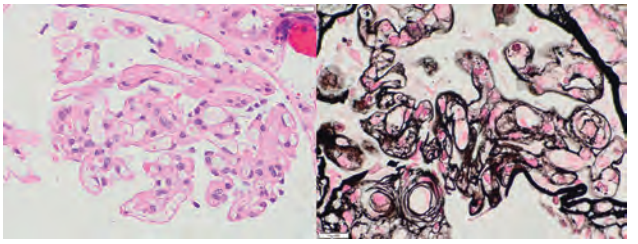
Navigating Atypical Hemolytic Uremic Syndrome (aHUS) in Pregnancy

Mayssaa Hoteit,[1] Hala M. KFoury,[2] Ali K. Abu-Alfa.[2,3] *[1]Bridgeport Hospital Internal Medicine, Bridgeport, CT; [2]American University of Beirut, Beirut, Lebanon; [3]Yale New Haven Hospital, New Haven, CT.*

Introduction: AKI during pregnancy can stem from various causes. Notably, conditions like preeclampsia, HELLP syndrome, TTP, and aHUS present diagnostic challenges due to overlapping symptoms. Understanding these diverse etiologies is crucial for accurate diagnosis and appropriate management strategies. We describe a case of AKI during pregnancy, diagnosed as aHUS.

Case Description: A 21-year-old female with a history of CKD presented during pregnancy with worsening Cr. At age 5, her kidney biopsy showed MPGN with C3 deposition on IF. Her Cr remained stable over the years, around 1.2-1.5 mg/dl, but increased during her pregnancy to 1.6-1.7 with worsening proteinuria. At 36 weeks GA, she was admitted for elevated BP. Laboratory investigations showed Hb of 10.7 g/dl, Plt of 221,000/mcL, Cr of 2.1 mg/dl, LDH of 425 IU/L, and haptoglobin of 0.25 g/L. She was started on magnesium, and labor was induced. Six weeks postpartum, she presented with tonic-clonic seizures, diffuse body edema, elevated Cr, and hemolytic anemia. Further investigations, including CT chest-abdomen-pelvis and CT brain, revealed fluid overload and no acute changes in the brain. An echocardiogram showed a hyperdynamic LV. Initially diagnosed with postpartum eclampsia, she received magnesium but developed severe hypermagnesemia, requiring urgent dialysis. Subsequently, her Cr continued to rise with associated anemia and thrombocytopenia.

Discussion: A suspicion for TMA was raised, leading to further investigations: ADAMTS13 activity returned as 67%, and kidney biopsy showed swelling of the endothelial cells, extensive double contour formation, and one glomerulus showed a thrombus, with non-specific fibrinogen staining on IF. Despite treatment with 10 plasma exchange sessions, her Cr continued to rise, necessitating the initiation of chronic dialysis. The possibility of aHUS was raised, but unfortunately, eculizumab was unavailable. It was eventually secured four months later, but its intermittent administration failed to improve her condition, and she remained dialysis-dependent. As part of her pre-transplantation workup, genetic testing for aHUS revealed a class 3 variant in the C3 gene and another variant of unknown significance in the CFHR5 gene.



Kidney biopsy

FR-PO140

A Case of Thrombotic Thrombocytopenic Purpura Initially Suspected as Shiga Toxin-Producing Escherichia coli Hemolytic Uremic Syndrome Due to the Preceding Symptoms of Hemolytic Anemia with Vomiting, Hematochezia, and AKI

Sonoka Niida, Masaaki Terao, Tomonari Ogawa, Hajime Hasegawa, Akito Maeshima. *Saitama Medical Center, Saitama Medical University, Kawagoe, Japan.*

Introduction: Thrombotic Thrombocytopenic Purpura (TTP) should be suspected in patients presenting with microangiopathic hemolytic anemia and severe thrombocytopenia. Additional findings indicative of TTP include significantly elevated lactate dehydrogenase, elevated indirect bilirubin and negative Coombs testing. Creatinine levels may be normal or slightly elevated, with levels exceeding 2 mg/dL being uncommon. Here, we report a case of TTP with features resembling hemolytic uremic syndrome (HUS), including vomiting, hematochezia, and acute kidney injury.

Case Description: A 59-year-old man developed vomiting, hematochezia, and gross hematuria after eating sashimi. After receiving intravenous therapy at a local clinic without improvement, the patient was transferred to our hospital. At admission, the patient's temperature was 37.2°C. Urinalysis showed proteinuria 2+, and hematuria 3+. The blood test revealed hemoglobin 7.3 g/dL, reticulocytes 4.1%, schistocytes 3‰, platelet count 5,000/μL, serum creatinine 2.41 mg/dL, C-reactive protein 0.89 mg/dL, lactate dehydrogenase 1,160 U/L, indirect bilirubin 2.6 mg/dL, and haptoglobin 2 mg/dL. Based on the clinical symptoms and laboratory findings, HUS caused by Shiga toxin-producing Escherichia coli (STEC) was suspected. The patient received continuous fluid therapy but developed oliguria, leading to initiation of hemodialysis on the second day. On the third day, seizures and confusion occurred. We diagnosed TTP and initiated steroid pulse therapy and plasma exchange. On the fifth day, ADAMTS13 activity was confirmed to have dropped to 1%, along with the detection of an ADAMTS13 inhibitor. The stool culture was negative. Thrombocytopenia, consciousness disorders, and renal dysfunction gradually improved. Dialysis ended successfully on the 7th day. Subsequently, rituximab was given, and the patient was discharged on the 38th day with no recurrence.

Discussion: The classic pentad of TTP symptoms comprises thrombocytopenia, microangiopathic hemolytic anemia, neurological issues, kidney dysfunction, and fever. However, these symptoms and lab findings may not occur simultaneously. It is crucial to maintain a high level of suspicion for TTP during management, even when atypical symptoms or laboratory values are present.

FR-PO141

Acute Kidney Failure and Nephromegaly as Initial Presentation of Recurrent Hematologic Malignancy

Alison Nguyen, Sahil Patel, Renu Regunathan-Shenk. *Inova Fairfax Hospital, Falls Church, VA.*

Introduction: Acute Lymphoblastic Leukemia (ALL) is most commonly diagnosed and monitored for recurrence based on laboratory findings such as leukopenia, anemia, and thrombocytopenia. It rarely presents as acute kidney injury (AKI) due to infiltration of leukemia cells into kidney tissue. Only a few cases have been reported in the literature thus far.

Case Description: We present a case of a 27 year old male with a history of Philadelphia negative B Cell ALL who achieved remission after chemotherapy and matched unrelated peripheral stem cell transplant in 2022 who then presents to the hospital with fatigue one year after remission. His fatigue was initially attributed to recently diagnosed atrial flutter that persisted despite outpatient medical management. Labs on admission revealed white blood cell count 4 X 10 3/uL, hemoglobin 9 g/dL, platelet count 200 x103/uL, creatinine 6.9 mg/dL, blood urea nitrogen 98 mg/dL, bicarbonate 9 mEq/L, and with an anion gap of 15. Renal ultrasound showed enlarged bilateral kidneys measuring at 18 cm for the right kidney and 19.5 cm for the left kidney with diffuse abnormal renal cortical parenchymal texture. Due to concern for infiltrative disease, he underwent a kidney biopsy. His biopsy revealed renal cortical tissue diffusely infiltrated by a densely cellular neoplasm composed by atypical lymphoid cells. Patient was started on chemotherapy and eventually underwent Chimeric Antigen Receptor T- cell therapy to treat his ALL

recurrence. With treatment, his kidney function improved and has remained stable at a new baseline of Creatinine of 2 mg/dL. Our case highlights AKI and nephromegaly as a sign of recurrent ALL.

Discussion: Renal dysfunction is an uncommon presentation of recurrent ALL especially in absence of leukopenia, anemia, and thrombocytopenia. Nephromegaly can be caused by several diseases such as diabetes mellitus, HIV associated nephropathy, interstitial nephritis, and infiltrative diseases such as hematologic malignancies and amyloid. Renal biopsy was crucial in diagnosing the cause of our patient's AKI as well as his recurrent malignancy as he did not have hematologic signs of recurrence. This case report highlights the importance of renal biopsy in patients who present with nephromegaly, especially in patients with known cancer history.

FR-PO142

Delayed Diagnosis of Multiple Myeloma and Amyloidosis Due to Anchoring and Availability Biases Attached to Cardiorenal Syndrome

Alexandra E. Conway,[1] Clay A. Block,[2] Charles W. Hopley.[2] *[1]Dartmouth College Geisel School of Medicine, Hanover, NH; [2]Dartmouth Hitchcock Medical Center, Lebanon, NH.*

Introduction: Anchoring bias (excess reliance on initial information) and availability bias (shortcuts based on prior/recent experience) are among the most common types of cognitive biases resulting in diagnostic errors. We present a case of a 75-year-old man with CKD and episodic AKI in the context of heart failure with preserved ejection fraction (HFpEF). The patient's history and the prevalence of cardiorenal syndrome (CRS) resulted in adoption of this diagnosis without additional investigation until work up for frank hypercalcemia revealed plasma cell dyscrasia.

Case Description: A 75-year-old man with a history of afib, HFpEF, tricuspid and mitral regurgitation, pulmonary hypertension, hypertension, macrocytic anemia, monoclonal gammopathy of undetermined significance (MGUS), and two prior episodes of dyspnea and AKI attributed to CRS, presented with altered mental status, bradycardia, complete heart block, hyperkalemia (7 mmol/L), hyponatremia, AKI (creatinine 4.82 mg/dL vs 2.1 baseline), and hypercalcemia requiring renal replacement therapy and insertion of a permanent pacemaker. Echocardiography demonstrated preserved ejection fraction without specific amyloidosis features. Due to hypercalcemia, the patient's previously known paraprotein was reevaluated and found to have increased (0.8 to 1.6 g/dL). The kappa-to-lambda free light chain ratio was increased to 10.8 (normal 0.4 to 2.6). Bone marrow biopsy demonstrated a plasma cell infiltrate diagnostic of IgG-kappa multiple myeloma as well as kappa light chain (AL) amyloidosis.

Discussion: The patient's CKD and episodic AKI were previously attributed to CRS due to the availability of and anchoring on this common diagnosis. Multiple myeloma/amyloidosis were not considered until hypercalcemia occurred despite clues such as macrocytic anemia, proteinuria, and prior MGUS diagnosis. Clinicians also relied on the absence of amyloidosis echocardiographic stigmata (e.g. relative apical sparing of longitudinal strain), although these features are insensitive and amyloidosis is underdiagnosed in patients with HFpEF. The absence of such findings should not dissuade clinicians from further investigation, and index of suspicion should remain high when signs are not explained by HFpEF. This case highlights the power of availability and anchoring biases to delay diagnosis.

FR-PO143

Sex-Dependent Dynamic Transcriptional Responses in AKI in Mice

Jiakang Wang, Tej Bahadur, Robert Bronstein, Sian E. Piret, Nehaben A. Gujarati, Yiqing Guo, Sandeep K. Mallipattu. *Stony Brook University Renaissance School of Medicine, Stony Brook, NY.*

Background: Previous studies demonstrated the role of sex differences in protection from acute kidney injury (AKI). However, the mechanism(s) that increase the susceptibility to AKI in males vs females remains unclear. We aim to investigate the sex-specific transcriptomic differences with single nucleus multiome sequencing data to identify mediators that increases the susceptibility to AKI in males vs females post-aristolochic acid I (AAI) injury in mice.

Methods: Male and female mice were injected with one dose of DMSO or AAI (2mg/kg) and perfused after 72 hours. Using 10X Genomics, single nuclear multiome (scRNA and scATAC) sequencing on the kidney samples was performed. CellRanger-ARC aligned the sequencing data and proceeded through the ArchR pipeline for data mining. Alevin-fry generated splice counts on the original data and scVelo performed RNA velocity analysis. Kidneys were stained for FOSL1 and JUNB by immunofluorescence.

Results: Compare to females, 4 unique PT clusters formed in males after AAI. Two of these were similar to uninjured PT clusters, but the other two showed increased expression of injury markers, including AP-1 transcription factors(TF) (Fosl1, Junb; injury cluster), NF-kB signaling pathway (Rela, Relb, Nfkb1, Nfkb2; intermediate cluster). Immunostaining validated expression of these unique proteins in injured PT clusters in male mice vs female mice post-AAI. The injury cluster demonstrated high expression of Junb, as well as motif enrichment and footprinting bias. Consistent with its role as an early response gene, RNA velocity showed that Junb was already fully spliced, suggesting earlier upregulation. By contrast Fosl1, had lower expression, but a higher RNA velocity, suggesting ongoing upregulation. Fosl1 motifs were already open, suggesting that chromatin in these cells was already primed for Fosl1 binding. In the intermediate cluster, NFKB pathway genes showed less well defined dynamics, but enrichment for open motifs and footprinting analysis suggested active transcription. Analysis of downstream target genes showed high expression and dynamics of Plau, Tnfaip3, and Vcam1. Expression, motifs, and footprinting analyses for these TFs in female PT clusters after AAI were all negative.

Conclusions: AKI induced dynamic AP-1 and NFKB transcriptional activity in two distinct injured PT clusters in male, but not female mice.

FR-PO144

Resistance to Aristolochic Acid-Induced AKI in Female Mice

Asha Rath, Samaneh DiMartino, Sian E. Piret. *Stony Brook University, Stony Brook, NY.*

Background: Females are less susceptible to acute kidney injury (AKI) compared to males, in both humans and mice. The resistance of female mice to developing AKI poses a significant barrier to pre-clinical therapeutic studies, and many studies only use male mice. Our aim was to establish a protocol to induce AKI in female mice using the proximal tubule (PT)-specific nephrotoxin, aristolochic acid I (AAI).

Methods: Male and female C57Bl/6 mice aged 12 weeks were injected intraperitoneally with 2 doses of 3mg/kg AAI, and female mice were also given 2 doses of 4mg/kg – 6.5mg/kg AAI. All doses were given 72 hours apart, followed by euthanasia 24 hours after the last injection. Body and kidney weights were recorded and serum collected for creatinine and urea nitrogen measurements. Kidneys were analyzed using hematoxylin and eosin (H&E) and periodic acid Schiff staining, and immunofluorescence for cytokeratin-20 (KRT-20; injured PT) and Lotus lectin (LL; uninjured PT). Liver morphology was assessed using H&E.

Results: Female mice given the standard male AKI dose of 3mg/kg AAI did not show any histological injury, whereas male mice had extensive PT death. Female mice given 4-6.5mg/kg AAI lost weight, but there was no difference between different doses, and kidney weights did not change. Serum creatinine and urea nitrogen concentrations were not elevated in response to any of the AAI doses. Histologically, kidneys showed minimal injury at 4mg/kg and 5mg/kg, and only small areas of PT cell death and mild loss of brush border at 6mg/kg and 6.5mg/kg AAI. LL and KRT-20 staining showed a linear trend towards reduced LL across increasing AAI doses (one-way ANOVA test for trend), and minimal, non-significant increases in KRT-20. AAI is activated in the liver and H&E showed significant liver vacuolization in mice treated with 6mg/kg AAI, despite only mild kidney injury.

Conclusions: Female mice had mild kidney injury and no loss of kidney function at AAI doses double that needed to cause AKI in male mice. Furthermore, high doses caused liver injury, thus limiting their utility. Studies using high doses of AAI should be interpreted with caution due to the likelihood of liver injury. Further studies are needed to identify a protocol to induce robust AKI in female mice without liver injury, to facilitate future pre-clinical therapeutic studies.

FR-PO145

Endothelin-1 Derived from Failed-Repair Proximal Tubular Cells Exacerbates Fibrosis after Kidney Injury

Yasuto Sunahara, Yuhei Kirita, Tomohiro Nakata, Tetsuro Kusaba, Keiichi Tamagaki. *Department of Nephrology, Graduate School of Medical Science, Kyoto Prefectural University of Medicine, Kyoto, Japan.*

Background: Endothelin signaling contributes to the progression of chronic kidney disease across multiple etiology including acute kidney injury (AKI). Previously, single-cell transcriptomic analysis of mouse AKI kidney revealed that a distinct failed repair proximal tubular cell (FR-PTC) state drives fibrosis after injury and endothelin-1 (Edn1) signaling between FR-PTCs and fibroblasts were significantly upregulated (PNAS. 2020). However, the mechanistic link between FR-PTC derived Edn1 and renal fibrosis remains unclear.

Methods: Tamoxifen-inducible proximal tubule-specific Edn1 knockout mice (*Edn1*$^{flox/flox}$::*Slc34a1*$^{CreERT2/+}$) underwent unilateral ischemia-reperfusion injury(IRI) surgery or administration of aristolochic acid (AA), following vehicle or tamoxifen treatment. Mice were sacrificed at 4 weeks after IRI or 2 weeks after AA-induced injury for phenotypic assessment. Immortalized tubular epithelial cells (NRK52E) and fibroblasts (NRK49F) were used in vitro. Furthermore, RNA sequencing (RNA-seq) was performed on Edn1-treated fibroblasts.

Results: Proximal tubule-specific Edn1 deletion decreased the expression levels of profibrotic and proinflammatory genes (e.g. *Tgfb1, Acta2, Ccl2 and Cd68*) after injury. Moreover, immunofluorescence staining showed decrease of αSMA positive myofibroblasts around FR-PTCs. In vitro, RNA-seq revealed that profibrotic and proinflammatory pathways, also NFkB and ERK signaling were upregulated in Edn1-treated

NRK49F. Western blotting revealed that Edn1 activated the phosphorylation of ERK in NRK49F. Edn1 expedited the proliferation and migration of NRK49F, which was attenuated by an ERK inhibitor. Conditioned medium (CM) from AA-treated NRK52E in which Edn1 was upregulated expedited the proliferation and migration of NRK49F. The enhanced fibroblast proliferation and migration was nullified by CM from AA-treated NRK52E with CRISPR-mediated Edn1 knockout.

Conclusions: In this study, we clarified the important role of the proximal tubule-derived Edn1 on pERK-mediated fibroblast proliferation and migration in renal fibrosis. Our results also suggested that Edn1 induced NFkB-mediated profibrotic and proinflammatory signals on fibroblasts which may exacerbate renal fibrosis. Inhibition of Edn1 may be a therapeutic target for preventing renal fibrosis.

FR-PO146

Using Imaging Mass Cytometry to Define Cell Identities in AKI and CKD in Humans

Tifanny Budiman,[1] Ashish Shelar,[2] Megan L. Baker,[1,3] Marlene Weiss,[1,4] Lloyd G. Cantley,[1] Vijayakumar R. Kakade.[1] Kidney Precision Medicine Project (KPMP). *[1]Yale University School of Medicine, New Haven, CT; [2]Yale University, New Haven, CT; [3]Yale University Graduate School of Arts and Sciences, New Haven, CT; [4]Charite Universitatsmedizin Berlin, Berlin, Germany*.

Background: Acute kidney injury (AKI) is a complex clinical syndrome that arises in patients in response to many etiologies, with up to 50% of critically ill patients developing AKI. An episode of AKI is associated with an increased risk of developing chronic kidney disease (CKD), leading to risks of both short- and long-term mortality. Though we have made significant progress in our understanding of many kidney diseases, less attention has been focused on the pathogenesis and treatment of human AKI. Imaging mass cytometry (IMC), allows staining of up to 40 proteins on a formalin fixed paraffin embedded (FFPE) section and provides semiquantitative expression data of each protein with a one square micron resolution. In this study, we applied IMC to define cell types, their activation states, and cell-cell interactions with spatial context in human reference, AKI, and CKD samples from KPMP participants.

Methods: IMC with a validated panel of 34 antibodies was performed on healthy reference tissue (HRT n=6), AKI (n=8), CKD (n=9) and QC tissues. Cell segmentation was performed using the deep learning Mesmer segmentation algorithm and the data was analyzed by imcRtools.

Results: 391,738 cells were identified across 23 KPMP biopsies, with 42 distinct cell clusters generated using Rphenograph clustering. Analysis of tubule cell type marker expression in proximal tubule and thick ascending limb clusters showed that megalin expression per proximal tubule cell is significantly reduced in both AKI (1.641 ± 1.078, $p<0.0001$) and CKD (2.633 ± 2.283, $p<0.0001$) as compared to HRT (6.793 ± 8.442, a.u.), and is significantly lower in AKI as compared to CKD ($p<0.0001$). Similarly, the expression of uromodulin in thick ascending limb cells is significantly decreased in both AKI (2.503 ± 1.552, $p<0.0001$) and CKD (6.300 ± 5.171, $p<0.0001$) as compared to HRT (12.48 ± 11.56, a.u.), and significantly lower in AKI compared to CKD ($p<0.0001$).

Conclusions: We applied quantitative high-dimensional imaging analysis to human reference, AKI and CKD biopsies. This analysis shows a significant reduction in the expression of the tubular cell proteins megalin and UMOD in injured kidneys as compared to healthy reference tissue, with greatest reduction detected in samples from patients with AKI.

FR-PO147

Single-Nucleus RNA Sequencing Identifies Transcriptional Differences in Sepsis- and Ischemia-Induced AKI in Mice

Francis N. Forbi, Nelli Shushakova, Hermann Haller, Kai M. Schmidt-Ott, Heiko J. Schenk, Robert Greite, Christian Hinze. Research Group Hinze. *Medizinische Hochschule Hannover, Hannover, Germany*.

Background: Acute kidney injury (AKI) is frequently observed in hospitalized patients and associated with increased mortality. Two of the most common causes of AKI are sepsis and conditions with kidney ischemia. However, whether and how these two AKI causes differ at the molecular level is incompletely understood. Here, we aimed to identify gene sets that are specific for sepsis or kidney ischemia associated AKI using well-defined mouse models.

Methods: Septic AKI was induced by cecal ligation and puncture (CLP) in adult male C57BL/6 mice (n=6) with sham operated mice as controls (n=3). Kidneys were harvested at 4 and 20 hours after CLP (n=3 each and subjected to single nucleus RNA sequencing (snRNA-seq). Unbiased clustering and marker gene expression analysis enabled the identification of major renal cell types. To account for molecular differences with ischemia-reperfusion injury (IRI)-induced AKI, we integrated our data with two published IRI datasets. To derive sepsis- and IRI-specific gene sets, we systematically searched for genes that are exclusively up- or downregulated in sepsis when compared to IRI in each major cell type and vice versa.

Results: Our analysis resulted in lists of sepsis- and IRI-specific gene sets for each cell type. Sepsis-specific genes (specifically up- or downregulated in CLP kidneys but not in IRI) showed cell type-specific gene expression patterns with little overlap between the cell types. Sepsis-specific genes were mostly present in collecting duct principal cells, endothelial and interstitial cells at 20 hours post-CLP. These genes were enriched in pathways associated with cytoskeletal remodeling (collecting duct principal cells), endothelial activation (endothelial cells) and extracellular matrix production (interstitial cells). In contrast, genes specifically upregulated in IRI were mostly restricted to the proximal tubules. These genes were strongly enriched in pathways associated with cell cycling and DNA damage repair.

Conclusions: Our analyses provide a comprehensive set of cell type-specific marker genes specific for sepsis- and IRI-induced AKI. We highlight strong transcriptional differences between sepsis- and IRI-induced AKI, which involve different cell types.

FR-PO148

Spatial Transcriptomics Define Injury-Specific Microenvironments in the Adult Mouse Kidney and Novel Cellular Interactions in Regeneration and Disease

Louisa M. Gerhardt,[1,2] Michal Polonsky,[3] Jina Yun,[3] Kari A. Koppitch,[1] Long Cai,[3] Andrew P. McMahon.[1] *[1]Keck School of Medicine of the University of Southern California, Los Angeles, CA; [2]University Medical Center Mannheim, Mannheim, Germany; [3]California Institute of Technology, Pasadena, CA.*

Background: Acute kidney injury (AKI) disrupts the highly complex architecture of the kidney resulting in reduced kidney function and triggering intrinsic repair processes. These repair processes can lead to functional recovery of the kidney, but AKI can also invoke inflammation and fibrosis resulting in chronic kidney disease (CKD). Development of targeted treatment strategies to halt disease progression after AKI is still hampered by an incomplete understanding of the underlying pathophysiologic processes. Deciphering molecular and cellular interactions driving injury-invoked inflammation and fibrosis is challenging due to the intricate renal architecture.

Methods: We leveraged sequential Fluorescence In Situ Hybridization (seqFISH) to quantify the expression of 1300 genes within the spatial context at single cell resolution in the mouse kidney during the AKI to CKD transition at day 28 after ischemia-reperfusion injury (n=3). Kidneys from non-surgery mice (n=3) were used as controls.

Results: Clustering 220,753 high-quality cells based on gene expression identified all major cell types in the kidney and revealed changes in the kidneys' cellular composition at 4 weeks post AKI: While immune cells, fibroblasts and injured proximal tubule cells were abundant in the injured kidney, cortical vasculature and proximal tubule segment 3 cells were reduced. Clustering the cells based on the neighborhood cell type composition revealed injury-specific and spatially-dependent gene expression patterns in distinct cellular microenvironments within the kidney. This analysis also predicted novel cell interactions, such as a molecular interplay between persistently injured proximal tubule cells and neighboring fibroblasts via *Clcf1-Crfl1*. Immune cell types play a critical role in organ repair and the spatial analysis revealed cellular microenvironments resembling early tertiary lymphoid structures.

Conclusions: Collectively, this study provides a high-resolution characterization of injury-invoked changes in the kidney, highlighting injury-specific cellular microenvironments and cell-cell interactions relevant to inflammation and fibrosis development after AKI.

FR-PO149

Optogenetic Stimulation of Kidney Sympathetic Nerves as a New Protective Approach to AKI

Ryusuke Umene,[1,2] Chia-Hsien Wu,[1] Norito Washimine,[2] Sayumi Matsuo,[2] Tomoya Nishino,[2] Tsuyoshi Inoue.[1] *[1]Department of Physiology of Visceral Function and Body Fluid, Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan; [2]Department of Nephrology, Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan.*

Background: Acute kidney injury (AKI) is a life-threatening condition with a poor prognosis. Once AKI develops, there is a high risk of developing chronic kidney disease (CKD), a condition that carries a high risk of cardiovascular disease and death. Even though the number of patients with AKI is increasing every year, there is currently no curative treatment for kidney disease, highlighting the need for innovative therapies. Recent research suggests that renal sympathetic nerve modulation may offer protective effects. Traditional methods lack specificity, so this study employs optogenetics, a minimally invasive technique for precise neural activation, to investigate the renal protective mechanisms of sympathetic nerve stimulation.

Methods: Using optogenetics, we specifically stimulated renal sympathetic nerves in transgenic mice expressing channelrhodopsin-2 in sympathetic neurons (DbHCre-ChR2). Blue light was directed at the kidneys to stimulate these nerves. We optimized stimulation

parameters (duration, frequency, intensity) by monitoring blood pressure, heart rate, and renal norepinephrine levels. To assess protective effects, we induced AKI with bilateral renal ischemia-reperfusion injury (IRI) and LPS-induced sepsis models. Single-cell RNA sequencing (scRNA-seq) on renal tissues identified cells receiving sympathetic signals and their interactions.

Results: Optogenetic stimulation of renal sympathetic nerves significantly reduced renal injury in acute kidney injury models. Protection was observed against bilateral renal IRI following nerve stimulation. scRNA-seq revealed that tubular epithelial cells responded to sympathetic stimulation, with upregulated expression of protective factors, indicating direct renal protection via the sympathetic nervous system, independent of systemic immune modulation.

Conclusions: This study introduces a novel optogenetics-based method for specific stimulation of renal sympathetic nerves, demonstrating its potential to reduce renal injury. The identification of specific cellular responses and protective mechanisms advances our understanding of the renal protective role of sympathetic nerves. These findings pave the way for developing new therapeutic devices and drugs targeting renal sympathetic modulation, offering promising prospects for kidney disease treatment.

FR-PO150

Mechanistic Representation of Clusterin, a Damage Biomarker for Early Detection of Drug-Induced AKI

Nader Hamzavi, Jeffrey Woodhead. *Simulations Plus Inc, Lancaster, CA.*

Background: Biomarkers have the potential to address several challenges in acute kidney injury (AKI). Novel biomarkers such as clusterin have emerged as promising candidates to address limitations of conventional biomarkers in early detection of acute kidney injury (AKI). To fully leverage the clinical potential of these biomarkers, a mechanistic understanding of the biochemical processes that lead to biomarker release is essential.

Methods: We developed a mechanistic model of clusterin release within the framework of RENAsym, a QST model of drug-induced AKI that incorporates key cellular injury mechanisms and renal hemodynamics. After tubular injury, clusterin starts to upregulate on dedifferentiated tubular epithelial cells and appear in the urine. The clusterin model in RENAsym was used to predict urinary clusterin following cisplatin administration to rats in connection with proximal tubular cell necrosis and regeneration.

Results: The clusterin submodel parameters were calibrated using urinary clusterin data following cisplatin administration into rats: 3 mg/kg and 6 mg/kg single dose, and 1 mg/kg daily dose for two weeks. Clusterin release was modeled to be linked with cellular necrosis to capture timing of observed peak. Simulated urinary clusterin peaked on day 5 matching the peak of necrotic flux and remained elevated for a few more days, in accordance with preclinical data. Representing clusterin during regeneration to replicate the observed delayed clusterin resolution was required to accurately represent clusterin dynamics.

Conclusions: A mechanistic submodel of clusterin was developed in RENAsym that captures the kinetics of urinary clusterin in rats dosed with cisplatin. This modeling effort informed us that signals from necrotic tubular cells predicted the peak timing of urinary clusterin, and clusterin release during regeneration was required to capture clusterin delayed resolution observed in cisplatin-treated rats. This effort demonstrates the ability of QST modeling to provide mechanistic insight into the behavior of novel kidney injury biomarkers.

FR-PO151

SALL1 Is Essential for Histone H3K27 Methyltransferase EZH2 to Regulate Apoptotic Responses in Kidney Ischemia-Reperfusion Injury

Shuqin Mei. *Department of Nephrology, Shanghai Changzheng Hospital, Shanghai, China.*

Background: The role of histone methylation modifications in renal disease, particularly in ischemia/reperfusion-induced acute kidney injury (AKI), remains unclear. This study aims to investigate the potential involvement of the histone methyltransferase zeste homolog 2 (EZH2) in ischemia/reperfusion-induced AKI and its impact on apoptosis.

Methods: We first examined the expression of EZH2 in the kidney of ischemia/reperfusion-induced AKI mice and hypoxia-stimulated tubular epithelial cells. We next constructed the EZH2 knockout mice to further confirm the effects of EZH2 on apoptosis response in AKI. Subsequently, we constructed the EZH2 knocked-down cells again and performed Chromatin Immunoprecipitation sequencing to screen out the target genes regulated by EZH2 and the enrichment pathway. Then we confirmed the EZH2 target gene and its regulatory pathway in vivo and in vitro experiments.

Results: The study found that EZH2 was upregulated in ischemia/reperfusion-induced AKI and that silencing EZH2 could reduce renal tubular injury by decreasing apoptosis response of tubular epithelial cells. Chromatin immunoprecipitation sequencing and polymerase chain reaction identified SALL1 as a target of EZH2. EZH2 was found to be enriched on the promoter of SALL1. Silencing EZH2 resulted in a significant increase in the transcriptional level of SALL1 and activation of the Wnt/β-catenin signaling pathway. The study further reversed the effects of EZH2 silencing by silencing SALL1 or administering the Wnt/β-catenin inhibitor icg001. It was also found that SALL1 positively regulated the expression of Wnt/β-catenin pathway-related genes. Finally, the study showed that the EZH2 inhibitor GSK-126 significantly alleviated ischemia/reperfusion-induced AKI.

Conclusions: Our results indicate that silencing EZH2 can protect renal function by relieving transcriptional inhibition of SALL1, activating the Wnt/β-catenin pathway, and attenuating tubular epithelial apoptosis response. These results highlight the potential therapeutic value of targeting EZH2 in ischemia/reperfusion-induced AKI.

FR-PO152

Inhibition of Histone Lysine Demethylases 5 Attenuates AKI but Does Not Impact Acute Kidney Disease or CKD

Sungjin Chung, Eun Sil Koh. *The Catholic University of Korea College of Medicine, Seoul, Republic of Korea.*

Background: Histone lysine demethylases 5 (KDM5) are part of the Jumonji C domain-containing family of histone demethylases, which catalyze the removal of di- and tri-methyl groups from the fourth lysine of histone 3 (H3K4me2/3). The KDM5 family is implicated in various physiological and pathological processes, including cell differentiation, motility, senescence, and epithelial-mesenchymal transition (EMT), through both demethylase-dependent and independent mechanisms in homeostasis and disease. This study investigated the role of KDM5 in renal fibrosis development and progression in acute kidney injury (AKI), chronic kidney disease (CKD), and the transition from AKI to CKD (acute kidney disease, AKD).

Methods: The therapeutic effects of KDM5 inhibition were evaluated in three mouse models: AKI induced by unilateral nephrectomy plus contralateral ischemia-reperfusion (IR) injury, AKD induced by unilateral IR injury followed by removal of the contralateral uninjured kidney 8 days post-IR injury, and CKD induced by unilateral ureteral obstruction (UUO).

Results: The KDM5 inhibitor C70 prevented increases in blood urea nitrogen and reduced areas stained by trichrome, Sirius red, F4/80, and α-smooth muscle actin in kidneys 7 days post-IR injury. Significant reductions in renal mRNA levels of pro-inflammatory cytokines/chemokines, EMT, and pro-fibrotic markers (IL-1β, IL-6, TNF-α, CCL2, CCL3, GM-CSF, MMP9, fibronectin, vimentin, TGF-β1, COL4A1) were observed, along with decreased mRNA levels of KDM5a-c. Additionally, renal protein levels of antioxidants such as catalase, SOD1, and SOD2 were increased in KDM5 inhibitor-treated mice. However, no significant differences in renal fibrosis and inflammation parameters were found between treated and untreated mice in both the AKD and CKD models.

Conclusions: Inhibition of KDM5 can prevent renal inflammation and fibrosis following acute severe IR injury, suggesting that KDM5 activation may be an early step in the development of renal fibrosis after AKI.

Funding: Government Support - Non-U.S.

FR-PO153

N6 Methyladenosine-Modified CircNfix Attenuates Sepsis-Induced AKI by Facilitating the Ubiquitination of YTHDF2 and Increasing DAPK2 mRNA Stability

Peng Wang. *Affiliated Hospital of Guangdong Medical University, Zhanjiang, China.*

Background: Increasing evidence shows that circRNAs play an important role in sepsis-induced acute kidney injury (SAKI). However, the mechanisms of circRNAs in SAKI have not been reported except the way of miRNA sponges. Notably, the function of N^6-methyladenosine (m^6A)-modified circRNA in SAKI remains undiscovered. Therefore, global profiles of circRNAs in kidneys with SAKI are needed, which will contribute to uncovering novel mechanisms underlying circRNAs in pathophysiology of SAKI.

Methods: SAKI-associated circRNAs were screened via circRNA microarray and examined using in situ hybridization (ISH) in mouse renal tissue. The role of circNfix in YTHDF2-induced pro-inflammatory or pro-apoptotic response of tubular epithelial cells (TECs) was assessed by luciferase reporter assay and Annexin V/ PI staining assay in vitro. Adeno-associated virus was used to deliver circNfix to the kidneys of SAKI mice to study the function of circNfix in vivo. The mechanism underlying circNfix-mediated activation of NF-κB signaling was examined by Mass spectrometry, RNA pull-down, MeRIP-qPCR and ISH. To evaluate the biomarker potential of circNfix to predict SAKI, expression level of circNfix in the urine and plasma of 52 sepsis patient was examined using qPCR.

Results: circNfix expression was downregulated in TECs following SAKI, leading to apoptosis and inflammatory injury in TECs in vitro and in vivo. Mechanistically, circNfix was found to provide a scaffold for the interaction between YTHDF2 and HECTD1, which was augmented by circNfix m^6A modification, facilitating YTHDF2 ubiquitination and degradation. By decreasing the expression of YTHDF2, circNfix promoted the

stabilization of DAPK2 mRNA, a negative regulator of NF-κB signaling, to protect LPS-induced TECs injury. Restoring circNfix in an experimentally-induced mouse SAKI model suppressed the activation of NF-κB signaling, thereby improving renal function and ameliorating tubular injury. Spearman's test demonstrated a remarkable negative correlation between urinary circNfix and serum creatinine in sepsis patients.

Conclusions: Collectively, m^{6}A modified-circNfix suppresses NF-κB-driven renal inflammation via a YTHDF2-dependent mechanism during SAKI, and restoring circNfix might represent a therapeutic strategy for SAKI.

Dietary Fiber-Derived Microbial Metabolites Prevent Acute and Chronic Kidney Ischemia-Reperfusion Injury (IRI) through G Protein-Coupled Receptor GPR43

Alexander Gilbert,[1,2] Anita Chitsaz,[1] Guozhen Zhu,[1] Julian J. Singer,[1,2] Steven J. Chadban,[1,2] Huiling Wu.[1,2] *[1]The University of Sydney Charles Perkins Centre, Sydney, NSW, Australia; [2]Royal Prince Alfred Hospital, Camperdown, NSW, Australia*.

Background: Short-chain fatty acids (SCFAs) derived from gut microbial fermentation of fiber exert anti-inflammatory effects and have been found to attenuate the development of inflammatory diseases. We investigated the impact of dietary fiber on kidney IRI in a murine model.

Methods: C57BL/6 mice were fed a high fiber diet (HFD) and controls received normal chow (NC). Kidney ischemia was induced for 22 min followed by reperfusion. Samples were collected 24 hours and 28 days after reperfusion. Kidney histology and gene expression was examined. Stool was assessed by 16S rRNA sequencing (gut microbiome) and ^{1}H NMR spectroscopy (SCFAs).

Results: HFD mice were protected against acute and chronic kidney IRI, with lower serum creatinine, less tubular damage, and tubulo-interstitial infiltrate accumulation compared with NC controls ($p<0.05$). HFD mice had less proteinuria and interstitial fibrosis at 28 days. HFD significantly reduced pro-inflammatory cytokines, chemokines and fibrosis-related gene expression within IRI-kidney compared with NC controls ($p<0.05$-0.01). Kidney IRI-associated dysbiosis and significant expansion of pathobionts was evident in NC-IRI mice compared to NC sham-operated controls ($p<0.05$-0.001), however this was attenuated in HFD-IRI mice ($p<0.05$-0.001). HFD-IRI mice also exhibited significant expansion of SCFA-producing bacteria compared to NC controls. Pearson correlation analyses showed that at a family level, Enterobacteriaceae and Clostridia_vadinBB60_ group were most strongly associated with kidney injury. In contrast, SCFA producers were associated with better kidney histology and function. Consistent with changes in the gut microbiome, HFD mice had significantly higher serum acetate and fecal SCFA concentrations. HFD provided significantly less protection in GPR43-/- mice compared to wild type HFD-IRI-mice, though HFD remained protective in GPR109A$^{-/-}$ mice.

Conclusions: Dietary fiber protects against acute and chronic kidney IRI through modulation of the gut microbiota, enrichment of SCFA-producing bacteria, and increased SCFA production, ameliorating IRI-associated dysbiosis. This protection is partially mediated through GPR43.

Intravenous UNI-494 Slows the Progression or Halts/Reverses AKI When Administered after Ischemia-Reperfusion in Rats

Satya Medicherla, Guru Reddy, Shalabh Gupta. *Unicycive Therapeutics Inc, Los Altos, CA*.

Background: There are no effective treatments approved for acute kidney injury (AKI). Inflammation and reactive oxygen species driven mitochondrial permeability transition pore (mPTP) opening causes mitochondrial dysfunction/swelling and cell death. This is implicated in acute diseases originating from ischemia-reperfusion (I/R) injury or delayed graft function (DGF). Unresolved inflammation exacerbates sustained mPTP opening, evident in chronic kidney diseases. UNI-494, a selective mitochondrial ATP-sensitive potassium channel activator, reverses mitochondrial dysfunction by closing the mPTP. We evaluated in vivo efficacy of intravenous (IV) UNI-494 administered therapeutically after unilateral I/R in AKI rat model.

Methods: Rats were anesthetized, right kidney removed, I/R induced by clamping renal vessels in left kidney (30 minutes). After 1 or 4 hours of reperfusion with established renal injury confirmed by elevated serum creatinine (sCr), 10 mg/kg of UNI-494 was administered IV. After 24 hours reperfusion in metabolic cages, blood samples were collected for sCr and blood urea nitrogen (sBUN) levels, and urinary samples collected for albumin-creatinine ratio (uACR) and neutrophil gelatinase-associated lipocalin (uNGAL). At necropsy, clamped left kidney was collected and processed for histology for tubular injury scores.

Results: I/R induced significant increases of sCr, sBUN, uACR, uNGAL, and proximal convoluted tubular injury scores in vehicle treated I/R group vs No I/R sham group. A single IV dose of 10 mg/kg of UNI-494 improved kidney functional markers sCr, sBUN, uACR, uNGAL, and proximal tubular injury scores (Figure 1).

Conclusions: Single IV doses of 10 mg/kg of UNI-494 administered after I/R significantly reduced serum and urinary AKI markers and improved proximal tubular injury scores. These data indicate therapeutic administration of UNI-494 slows down, or even halts/reverses, AKI progression. UNI-494 is a potential candidate for prevention of DGF and other AKI clinical conditions.

DNase-1 Exerts Protective Effects after Severe Kidney Ischemia-Reperfusion Injury

Elena Tutunea-Fatan, Shabitha Arumugarajah, Lakshman Gunaratnam. *Western University, London, ON, Canada*.

Background: Kidney Injury Molecule-1 (KIM-1) is a transmembrane receptor expressed by proximal tubular epithelial cells during injury. KIM-1 recognizes phosphatidylserine, an "eat me" signal that marks apoptotic cells for phagocytic clearance. Notwithstanding that, severe acute injury (AKI) leads to persistent KIM-1 expression and drives fibrosis. Herein, we design a study to evaluate whether DNase1 contribute to the pathogenesis of KIM-1- mediated renal fibrosis.

Methods: To assess the functional role of KIM-1 expression, KIM-1+/+, KIM-1-/-, and Tim1fl/fl SLC34a1 C57BL/6 mice were subjected to both moderate (25 minutes) and severe (45 minutes) unilateral ischemia reperfusion injury (UIRI). Kidneys were isolated after 3, 7, 28, and 42 days of reperfusion to assess histology and markers of injury and fibrosis. To examine gene expression profile, RNA sequencing of kidneys from KIM-1+/+ and KIM-1-/- mice after 45 min UIRI was performed. DNase1 expression and activity was assessed by using in situ and in vitro analyses of kidneys and sera. To test the therapeutic potential of DNase1 after severe UIRI, mice received repeated doses of DNase1 (2 mg/kg) or vehicle-solution (NaCl 0.9%).

Results: Our data indicate that by clamping the renal pedicle for 45 min and following the mice for 42 days, the injured KIM-1+/+ kidneys were markedly reduced in size and fibrotic compared with control kidneys. By contrast, the injured KIM-1-/- kidney recovered completely. The fibrotic phenotype was not observed with the moderate injury model. Also, a strong upregulation of mRNA encoding a panel of cytokines and growth factors was observed at both 7 and 42 days after injury in KIM-1+/+ kidney compared with KIM-1-/-. This highlights the possibility that KIM-1 might directly regulate epithelial cytokine and fibrotic marker expression. In addition, DNase1 was among the top downregulated genes in the KIM-1+/+ kidney exposed to severe injury. Renal DNase1 expression was completely abrogated in KIM-1+/+ kidney compared to KIM-1-/- kidney at all time points analysed. Early decline of DNase1 activity directly correlated with lower injury score and fibrosis. DNase-1 treatment significantly reduced the pro-inflammatory response and histopathological changes observed in KIM-1+/+ kidney after severe AKI.

Conclusions: DNase1 therapy is protective following severe AKI and attenuates murine kidney fibrosis.

DNA-Binding Protein-A Promotes Kidney Ischemia-Reperfusion Injury and Participates in Mitochondrial Function

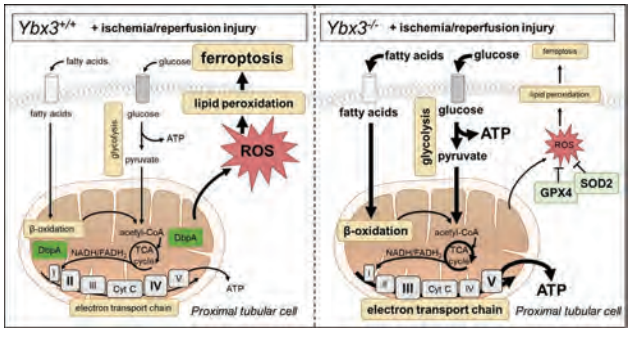
Charlotte Reichardt,[1,2] Sabine Brandt,[1] Anna Krause,[1] Jonathan A. Lindquist,[1] Robert Geffers,[4] Tobias Franz,[1] Sascha Kahlfuß,[1] Akash Mathew,[3] Rajiv Rana,[3] Peter R. Mertens.[1] *[1]Otto-von-Guericke-Universitat Magdeburg, Magdeburg, Germany; [2]Universitatsklinikum Jena, Jena, Germany; [3]Universitat Leipzig, Leipzig, Germany; [4]Helmholtz-Zentrum fur Infektionsforschung GmbH, Braunschweig, Germany*.

Background: DNA binding protein A (DbpA), encoded by the *Ybx3* gene, is a member of the cold shock protein family and is involved in cell cycling, transcription, translation, and tight junction communication. While DbpA is known to be upregulated in chronic nephritis, its functions in acute injury models, such as renal ischemia/reperfusion injury (IRI), remain unclear.

Methods: Mice with *Ybx3*$^{+/+}$, *Ybx3*$^{+/-}$, or *Ybx3*$^{-/-}$ genotypes were characterized over a period of 24 months and following experimental renal IRI. Metabolic processes such as mitochondrial function, number and integrity were analyzed by mito/glycolysis stress tests, MitoTracker staining, Western blotting and electron microscopy. Additionally, RNA sequencing, immunohistochemistry, Western blotting, and flow cytometry were performed to measure tubular cell damage, tissue scarring, and immune cell infiltration.

Results: DbpA is dispensable for kidney development and tissue homeostasis under healthy conditions. Notably, the endogenous DbpA protein is localized within the mitochondria of primary tubular epithelial cells (TECs). However, genetic deletion of *Ybx3* leads to notable changes in TECs, including increased mitochondrial membrane potential, enhanced lipid uptake and metabolism, elevated oxygen consumption rates (OCR), and glycolytic activities. In mice lacking *Ybx3*, protection against IRI is observed, characterized by reduced immune cell infiltration, diminished endoplasmic reticulum (ER) stress, less tubular cell damage, and decreased fibrosis. A putative protective mechanism is identified via upregulated antioxidant activities and reduced ferroptosis, when *Ybx3* is deleted.

Conclusions: Here, experimental evidence shows that DbpA acts as a mitochondrial protein and has significant negative effects on cell metabolism. Moreover, the genetic deletion of *Ybx3* reveals a protective effect against IRI.



FR-PO158

Global but Not Tubule Cell-Specific Knockout of STING Attenuates Kidney Injury in Mice with Unilateral Ureteral Obstruction

Emily S. Yeung, Madiha Zahra Syeda, Duc Tin Tran, Suzanne L. Advani, Youan Liu, Sri nagarjun Batchu, Andrew Advani. *Keenan Research Centre for Biomedical Science, St. Michael's Hospital, Toronto, ON, Canada.*

Background: Recent studies have identified a key role for the inflammatory mediator STING in kidney injury. Because it is activated by the cellular response to displaced DNA, it has been proposed that STING mediates kidney injury when mitochondrial DNA leaks into the cytosol of damaged tubule epithelial cells. However, STING is not specific to tubule cells, also having an important regulatory function in other cell-types, amongst them immune cells. Here, we compared the effects of deletion of STING from tubule cells with the effects of global STING deletion in mice with kidney injury caused by unilateral ureteral obstruction (UUO).

Methods: Experiments were performed in wildtype mice, Sting$^{fl/fl}$ mice, Pax8Cre^{+}Sting$^{fl/fl}$ mice (tubule cell-specific STING knockout mice; STING^{TubKO}) and global STING knockout mice (STING^{KO}) 14 days after sham surgery or UUO.

Results: mRNA and protein levels of STING were both increased >5-fold in mice after UUO. In situ hybridization and immunostaining confirmed presence of STING in damaged tubule cells, occasional glomerular cells and notably in infiltrating interstitial cells in UUO kidneys. Knockout of STING was confirmed in STING^{KO} mice by immunoblotting; and in STING^{TubKO} mice by immunohistochemistry 24h after ischemia reperfusion injury. Kidney injury was then determined by measuring mRNA levels of *Havcr1*, the gene encoding KIM-1, in control (Sting$^{fl/fl}$) mice, STING^{TubKO} mice and STING^{KO} mice 14 days after UUO or sham surgery. *Havcr1* mRNA levels were increased >120-fold in Sting$^{fl/fl}$ mice after UUO and they were unaffected by tubule-cell specific STING knockout. In contrast, *Havcr1* mRNA levels after UUO, while increased >60-fold in global STING knockout mice, and were significantly lower than in Sting$^{fl/fl}$ and STING^{TubKO} mice after UUO (P<0.01).

Conclusions: Kidney injury in UUO mice, as assessed by *Havcr1* mRNA levels, is attenuated by global STING deficiency rather than tubule cell-specific STING deficiency. These findings indicate that the actions of STING in kidney disease extend beyond mediating the response to mitochondrial damage in tubule cells. The effects of STING may be primarily due to its actions in other cell-types, especially in infiltrating immune cells.

Wnt5a Promotes AKI to CKD Transition via p-JNK/Snai1 Signaling

Sijie Gu, Haoran Feng, Xiaomei Li, Ying Fan, Niansong Wang. *Shanghai 6th Peoples Hospital Affiliated to Shanghai Jiao Tong University, Shanghai, China.*

Background: The transition from acute kidney injury(AKI) to chronic kidney disease(CKD) is the major obstacle in the clinical treatment of AKI. In our previous study, we found Wnt5a-induced noncanonical signaling is a contributing mechanism for renal tubular inflammation in diabetic nephropathy. However, its role of Wnt5a in AKI to CKD transition still remains unknown.

Methods: Renal biopsy sample of 10 AKI patients and their clinical data were collected to analyze the correlation of Wnt5a with renal function and pathological characteristics. Wnt5a knockdown mice (Wnt5a$^{+/-}$) was generated, and two animal models of AKI by inducing renal ischemia-reperfusion (IRI) or unilateral ureteral obstruction (UUO) were established with the observation of 2 weeks post-surgery. *In vitro*, HK-2 cells were treated with transforming growth factor-β (TGF-β) or oxygen-glucose deprivation (OGD). RNA-sequencing was introduced to detect the downstream mechanism of Wnt5a signaling.

Results: The expression of Wnt5a in the kidney section of AKI patients was significantly increased mainly in the renal proximal tubules, and was associated with the decline in kidney function and interstitial fibrosis. In mice with IRI or UUO, Wnt5a elevation promoted the phosphorylation of JNK (p-JNK), increased the expression of Snai1, a transcription factor well known for inducing renal fibrogenesis. In a global Wnt5a knockdown (Wnt5a$^{+/-}$) mouse model subjected to IRI or UUO, reduction of Wnt5a alleviated renal tubule injury and interstitial fibrosis, attenuated the progression from AKI to CKD. *in vitro*, inhibition of Wnt5a in OGD induced HK-2 cells suppressed expression of p-JNK and Snai1, suggesting a strong association between Wnt5a/p-JNK and Snai1. Conversely, overexpression of Wnt5a in HK-2 cells increased the expression of p-JNK and Snai1, thus aggravated renal fibrosis. We further found a direct binding between p-JNK and Snai1 by Co-IP and mutation of JNK phosphorylation site (T183A) reduced the expression of Snai1, indicating a p-JNK/Snai1 pathway downstream of Wnt5a.

Conclusions: Our data revealed that Wnt5a is a key molecule mediating the progression from AKI to CKD, which shed light on the new Wnt5a/p-JNK/Snai1 pathway in AKI to CKD transition.

FR-PO160

Time-Restricted Feeding Protects against Kidney Ischemia-Reperfusion Injury in Mice

Yoonjoo Jang, Byung Min Ye, Seo Rin Kim, Il Young Kim, Dong Won Lee, Soo Bong Lee. *Pusan National University Yangsan Hospital, Yangsan, Republic of Korea.*

Background: Ischemia–reperfusion injury (IRI) in the kidneys stands as a significant contributor to acute kidney injury (AKI). Time-restricted feeding (TRF), known for its metabolic health benefits and alleviation of various chronic diseases without calorie restriction, was investigated for its potential protective effects against IRI-induced AKI.

Methods: C57BL/6 male mice underwent unilateral IRI, and their kidneys were harvested after 2 days. Mice assigned to the TRF group had unrestricted access to standard chow daily but were restricted to an 8-hour feeding window during the dark cycle for two weeks prior to IRI induction. The mice were categorized into four groups: Control, TRF, IRI, and TRF + IRI.

Results: In the TRF + IRI mice, there was a significant reduction observed in the tubular damage score compared to the IRI group. Additionally, the TRF + IRI mice displayed decreased levels of phosphorylated NF-κB and F4/80-positive macrophages relative to the IRI mice. Moreover, markers denoting oxidative stress for protein, lipid and DNA were notably diminished in the TRF + IRI mice in comparison to the IRI mice. Furthermore, TUNEL-positive tubular cells and cleaved caspase-3 expression were observed at lower levels in the TRF + IRI group than in the IRI group.

Conclusions: TRF, without the imposition of calorie restriction, effectively mitigated renal damage by attenuating inflammatory reactions, oxidative stress, and tubular apoptosis in an experimental model of renal IRI. This underscores TRF's potential as an innovative dietary strategy for averting IRI-induced AKI.

FR-PO161

Noncontrast Resting State Magnetic Resonance Imaging Measures Tubuloglomerular Feedback Function and Detects Functional Changes after AKI

Edwin Baldelomar,[1] Jennifer R. Charlton,[2] Kevin M. Bennett.[1] *[1]Washington University in St Louis School of Medicine, St Louis, MO; [2]University of Virginia School of Medicine, Charlottesville, VA.*

Background: The tubuloglomerular feedback (TGF) is a critical autoregulatory mechanism that plays a significant role in modulating single nephron filtration and hyperfiltration in response to acute kidney injury (AKI). There are no clinical tools to measure TGF. Noncontrast resting state magnetic resonance imaging (rsMRI) has

recently been used to detect hemodynamic fluctuations in the kidney, potentially linked with autogregulation. Here, we investigated if fluctuations (0.02-0.05 Hz) measured by rsMRI reflect TGF. We further tested if rsMRI detects changes in fluctuations, reflecting function, after AKI that are not detected by standard metrics.

Methods: *TGF study* – rsMRI was performed during saline infusion (20µl/min, 30min, baseline) and furosemide infusions (20µg/mL, ~45min) on male Sprague Dawley (SD) rats (N=4). *AKI study* – For AKI injury, female SD rats were stratified to folic acid (FA, 200 mg/kg) or sodium bicarbonate(N = 9). rsMRI was performed prior to AKI and again at 10, and 36 day after FA. Transcutaneous GFR, sCr, and BUN were measured days 3 and 59. rsMRI spectra were computed as published. Significance (t-test) at $p<0.05$.

Results: *TGF study, Figure 1A-B* - Furosemide attenuated the rsMRI spectral peaks at 0.015-0.05Hz in cortex. Power in this band was ~60% lower after furosemide, and 70% fewer voxels had a peak in that band. *AKI Study, Fig1C-D* - AKI was confirmed on day 3 after AKI. On day 36, the distribution of power between 0.015-0.055Hz in cortex, and distribution of power between 0.055-0.1 Hz in outer medulla were lower in the FA group. There was no difference in GFR, or BUN and creatinine 3 and 59 days after AKI.

Conclusions: TGF can be measured using noncontrasted rsMRI. Changes in TGF after AKI remain present despite normalization of renal function. This suggests rsMRI could be a translatable tool to understand the role of TGF in disease progression after AKI or in response to therapies.

Trap1 Lactylation Promotes Tubular Regeneration after AKI through Modulation of PIF1 Transcription

Jinhua Li,[1] Hongjie Zhuang,[2] Jiayi Yang,[2] Shuhan Zeng,[2] Xiaoyan Bai,[1] Zhiming Ye,[1] Xueqing Yu.[1] *[1]Guangdong Provincial People's Hospital and Guangdong Academy of Medical Sciences, Guangzhou, China; [2]The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China.*

Background: Recent studies have identified that the modification of histone protein lysine (K) residues by lactylation (La) promotes a wound healing gene transcription profile in macrophages, suggesting that lysine lactylation (KLa) may have a broader role in regulating the tissue repair response. Aim of the study is to identify which KLa has potential to enhance regeneration after acute kidney injury (AKI) and investigate the mechanism by which the identified KLa drives the repair process.

Methods: AKI model was established by a peritoneal injection of folic acid (FA). Mass spectrometry was performed to identify the KLa as a potential regeneration driver after AKI from 5-day FA nephropathy. The biological function of the identified KLa was corroborated with wild type and mutant mice in which lysine was replaced with T to mimic persistent KLa or replaced with R to mimic blockade of lactylation of lysine. Renal function was assessed by histology and biochemical parameters.

Results: Four KLa sites were identified through mass spectrometryand bioinformatic analysis. They were individually overexpressed in the mouse renal tubular epithelial cells (MTEC) via a retroviral vector. The cell proliferation assay clearly demonstrated that Trap1 K126T significantly enhanced MTEC proliferation with the proliferative capability K126T > WT > K126R under both normoxia and hypoxia conditions. Confocal microscopy demonstrated that the number of Pax8+/Ki67+/K126La+ cells were significantly higher than that of Pax8+/Ki67-/K126La+ in human chronic kidney disease (CKD) and FA nephropathy. There were no differences in serum creatinine levels at day 2 after FA administration; but at days 5 and 7 the serum creatinine levels declined faster in Trap1 K126T mice and reduced fibrosis on day 28 compared with WT and Trap1 K126R mice. RNA seq and IP/WB identified that Trap1 K126T upregulates transcription of PIF1 through interaction with Nat14, while PIF1, a DNA-dependent ATPase and 5′-3′ DNA helicase can efficiently unwind G-quadruplex (G4) DNA structures and forked RNA-DNA hybrids and resolve G4 structures, preventing replication pausing and double-strand breaks (DSBs) at G4 motifs.

Conclusions: Trap1 K126La promotes tubular regeneration after AKI through modulation of PIF1 expression. Trap1 K126La may be a therapeutic target in AKI-CKD transition.

Funding: Government Support - Non-U.S.

FR-PO163

Gut Microbiome and Olfactory Receptor 78 in Experimental AKI

Shishir K. Patel, Qisen Guo, Radhika Kapoor, Mahta F. Gooya, Mackenzie Kui, Lois J. Arend, Sanjeev Noel, Jennifer L. Pluznick, Hamid Rabb. *Johns Hopkins Medicine, Baltimore, MD.*

Background: Olfactory receptor 78 (Olfr78) is a short-chain fatty acid (SCFA) receptor activated by gut microbiome-derived acetate and propionate. Olfr78 is expressed in the afferent arteriole, vascular smooth muscle cells, and immune cells. SCFAs are hypothesized to mediate gut microbiome effects in AKI and CKD. We studied the role of Olfr78 in ischemic and cisplatin induced AKI in mice.

Methods: Male and female, wild-type **(**WT) and Olfr78 knockout (KO) C57BL6 mice were subjected to bilateral ischemic or cisplatin AKI. Mice were also studied long-term after severe unilateral ischemic AKI (UIRI). Endpoints included survival, kidney function (SCr, GFR by FITC-sinistrin clearance), histology and kidney immune cell phenotyping (FACS).

Results: In moderate bilateral ischemic AKI, Olfr78 KO mice had worse survival at 72 hrs than WT mice ($P<0.01$). However, no changes were found in kidney function or structure. Cisplatin induced AKI was comparable in KO and WT mice. Female mice were more susceptible to cisplatin, while males more susceptible to ischemic AKI. In the UIRI model, KO had lower GFR than WT at baseline (1369.9±106.4 vs 1170.7±196.5, $P\leq0.05$), 24h after UIRI (959.4±8 vs 837.0±7, $P< 0.05$) and after 21d (1166.1±54.5vs 807.6±11, $P< 0.0001$). After severe UIRI KO mice showed a decrease in double negative (DN) (9.6±1.6 vs 4.0±1.6%, $P<0.001$) and increase in double-positive cells (DP) T cells (0.2±0.1 vs 0.5±0.3%, $P<0.001$). In the CD4 subset, activation marker CD69 (32.6±4.0 vs 74.8±7.6%, $P< 0.0001$), effector cells ($CD44^{+}CD62L^{-}$) (93.1±1.2 vs 94.6 ±0.93%, $P<0.05$), and immune checkpoint molecule TIGIT (12.8±4.5 vs 21.9±3.9%, $P<0.01$) increased in KO vs. WT. In CD8 cells, there was an increase in CD69 (40.8±8.8 vs 55.8±8.6%, $P<0.01$), TIGIT (7.9±2.4 vs 17.4±11.3 %, $P<0.01$) and CTLA4 (0.1±0.14 vs 0.7 ±0.5%, $P<0.01$); There was a decrease in B cells (25.5±2.4 vs 15.7±2.2, $P<0.001$) and an increase in NKT cells (1.0±0.3 vs 2.4±0.70, $P<0.001$) and dendritic cells (2.0±2.2 vs 5.4±6.3, $P<0.001$) in Olfr78 KO vs. WT.

Conclusions: Absence of Olfr78 reduced short-term survival after moderate AKI, but with minimal effects on renal function/structure. However, GFR and kidney immunophenotypes were modified by Olfr78 after severe UIRI. Olfr78 has subtle effects during AKI but is likely not a major mechanism by which gut microbiome influences outcomes in AKI.

FR-PO164

Long-Term Maladaptive Repair of the Kidney Medulla after Reversal of Ureteric Obstruction

Thitinee Vanichapol,[1] Alan J. Davidson,[1] Mark P. de Caestecker.[2] *[1]The University of Auckland, Auckland, New Zealand; [2]Vanderbilt University Medical Center, Nashville, TN.*

Background: There is a long-term decrease in urinary concentrating capacity (UCC) after urinary tract obstruction. UCC is dependent on the correct cellular organization and function of the inner medulla (IM), but little is known about the regenerative potential of the IM, nor the long-term structural and functional effects after reversal of urinary tract obstruction.

Methods: Ureteric clamps were placed in mice for 5 to 8 days to induce reversible unilateral ureteric obstruction (R-UUO), with contralateral nephrectomies to assess renal function. GFR and urine osmolality were measured, and kidneys harvested at Day 28 and 84. Renal histology (PAS), immunostaining, and genetic lineage analysis performed using Six2 and HoxB7 Cre; tdTomato Cre reporter mice. scRNA-Seq was performed using FLEX on isolated renal medullas.

Results: Survivable R-UUO clamp times varied between mouse strains, but all showed a marked decrease in UCC 84 days after R-UUO. Renal histology showed IM damage with papillary necrosis, followed by active tubular repair. Most tubular structures were repopulated by day 28, and the IM appeared indistinguishable from controls by day 84. Unsupervised clustering of scRNA-Seq data identified multiple clusters of loop of Henle (LOH), collecting duct (CD), and endothelial cell (EC) subtypes, likely reflecting their spatial location in the IM. There was a reduction in subsets of these cells and appearance of "injured" clusters at day 28 post R-UUO, with a loss of vasa recta ECs and persistence of injured CD and LOH cells at day 84. Inflammation and fibrosis genes were also increased in "non-injured" CD and LOH populations, suggestive of a persistent

inflammatory state. Immunostaining confirmed a reduction in IM capillary density (CD31) and LOH (AQP1). However, CD markers recovered and expanded in the distal IM by day 84. Since dedifferentiation may affect cell identification, we confirmed these findings independently by genetic lineage labelling studies using Six2-Cre and HoxB7-Cre mice, respectively.

Conclusions: These data indicate that despite robust repair, there is a persistent defect in UCC associated with incomplete repair of vasa recta and LOH cell types in the IM, and persistence of "injured" LOH-derived cells. The CD recovers and expands but also retains populations of injured and inflammatory cells, suggestive of a persistent maladaptive repair state.

FR-PO165

Investigation of the Vulnerability of the Remaining Kidney Postunilateral Nephrectomy under Crystalline Nephropathy Conditions

Neydiana B. Lopes, Maria Oliveira-Souza. *Universidade de Sao Paulo Instituto de Ciencias Biomedicas, Sao Paulo, Brazil.*

Background: The loss of a kidney is a common outcome of single kidney transplantation, renal trauma, and renal cancer. Despite many studies showing stable function after unilateral nephrectomy (UNx), it can lead to overload of the remaining kidney. This overload may become a relevant factor in the development of Acute Kidney Injury and increase the vulnerability of the remaining kidney to Chronic Kidney Disease (CKD). Therefore, the present study aims to investigate the function of the remaining kidney after UNx, its response to crystalline nephropathy, and the potential factors and mechanisms involved in its vulnerability state.

Methods: Eight-week-old male C57BL/6J mice (n=23) were divided into four groups: sham, subjected to UNx, sodium oxalate (intraperitoneal injection of 9 mg/100 g of NaOx to induce crystalline nephropathy), and UNx treated with sodium oxalate (UNx/NaOx). Six days after the sham or UNx surgery and twenty-four hours before the euthanasia, mice were treated according to their group and placed in metabolic cages for metabolic parameters and kidney function track. At the end of twenty-four hours, the animals underwent isoflurane anesthesia (0.8 L/min/rate 5%), blood and urine collection, removal of the left kidney and euthanasia by exsanguination.

Results: One week after the surgery, the UNx animals showed a significant increase in urinary flow (p< 0,04), kidney weight/body weight ratio (p<0,003) and in plasma creatinine(p<0,004) when compared to sham animals. They also showed a significant increase in mRNA expression for *Mki-67* (p<0,02), a biomarker to measure tubular regeneration and renal repair. Still in this group, we observed an increase in mRNA expression for *Col1a1*(p<0,05) and *Col4a1*(p<0,05) and in the protein expression of a specific macrophage marker, F4/80(p<0,004). Faced with NaOx insult, UNx/NaOx animals showed more pronounced renal hypertrophy (p<0,02), greater accumulation of creatinine in plasma (p<0,003) and greater expression of mRNA for tubular injury factors such as *Havcr1* (Kim-1) (p<0,006) and *LCN2* (NGAL) (p<0,0006) and protein expression of Kim-1(p<0,003), when compared to NaOx animals.

Conclusions: Our findings indicate that the remaining kidney has vulnerability, which affected its response to the insult, and can potentially hindering improvement and contributing to the development of CKD.

FR-PO166

CD146 Deletion Protects against Kidney and Heart Damage after AKI

Louis Boutin,[1,3] Stefanny M. Figueroa,[1] Safia Hadjadj,[1] Mouhamed Amar,[1] Elena Roger,[1] Nadia Elganfoud,[3] Marcel Blot-Chabaud,[2] François Depret,[3] Jane Lise Samuel,[3] Feriel Azibani,[3] Christos E. Chadjichristos.[1] *[1]UMR_S 1155, Common and Rare Kidney Diseases, Tenon Hospital, Paris, France; [2]Aix-Marseille Univ, INSERM INRA, C2VN, Marseille, France; [3]UMR-942, MASCOT, Cardiovascular Markers in Stress Condition, University Paris Cité, Paris, France.*

Background: AKI is linked to a higher risk of mortality and has been shown to increase heart failure, in months or years following the injury. CD146, an adhesion molecule mainly expressed in vascular endothelial cells, is elevated in patients with both renal and heart diseases. Recent findings show that CD146 increased expression within renal damaged endothelium exacerbates kidney inflammation and promotes tissue fibrosis in experimental nephropathy. Furthermore, mechanisms underlying AKI-induced cardiovascular damage remain poorly understood, including the role of CD146 in this process. Thus, this study assessed the role of CD146 in the progression of renal-cardio damage after renal ischemia-reperfusion (rIR).

Methods: Wild type (WT) and CD146 knock-out (KO) (2-3m) male mice, underwent a unilateral rIR of the left kidney after nephrectomy, with 25min of ischemia followed by 24h, 48h, and 28d of reperfusion. Sham group was submitted to a procedure without nephrectomy and rIR. Renal function was assessed by measuring creatininemia. Histological damage was evaluated by PAS or Sirius Red. Echocardiography was used to analyze heart function, and proinflammatory cytokines were studied by qPCR.

Results: CD146 was highly increased within renal endothelium at 24h (P<0.05) and 48h (P<0.01) in WT mice after rIR, and in the heart at 28d (P<0.05). As expected, after rIR renal function was temporarily altered as shown by plasma creatinine, increased at 24h (24.3±4.7 *vs.* 10.1±0.6μM in Sham), and 48h (20.0±3.1 *vs.* 6.3±0.4μM in Sham) and decreased over time. Interestingly, this increase was not observed in KO mice. In accordance, PAS showed preserved renal damage at 48h in KO mice compared to WT (P<0.05). In addition, increased expression of mRNA for proinflammatory cytokines, such as CCL2 and IL-1β, after 24 and 48h of rIR within damaged kidneys, and CCL2 in the heart at 28d, was blunted in KO (P<0.05). Furthermore, collagen deposition at 28d post-rIR in both kidney and heart was prevented in KO compared to WT mice (0.6 and 0.5 times, respectively). Finally, the absence of CD146 prevented the reduction in fractional shortening caused by rIR at 28d (46% in WT *vs.* 65% in KO mice).

Conclusions: Our results suggest that CD146 deletion protects against AKI and further heart damage after rIR in mice.

Pathophysiology of Cardiorenal Syndrome in an Experimental Model Due to Isolated Right Ventricle Failure: Beyond Systemic Congestion

Firoozeh Farahmand. *Saint Louis University, St Louis, MO.*

Background: Cardiorenal syndrome (CRS) and right heart failure (RHF) have complex and interrelated pathophysiology that involve mechanisms beyond isolated dysfunction of the heart and kidneys. This study investigates changes in antioxidants and oxidative stress in the right ventricle(RV) and the kidney as well as systemic congestion in CRS. This will shed light on pathophysiology based new therapeutic targets and preventive measures in CRS in addition to symptomatic relief with diuretics.

Methods: CRS due to isolated RVF was produced in rats by a single injection of ALK. Animals were observed daily for any clinical signs of dyspnea, cyanosis, subcutaneous edema and ascites. At 1 week post injection serial echocardiography was performed to monitor cardiac function. RV systolic pressure (RVSP), RV hypertrophy (RVH), and RV function, RV and kidney levels of superoxide dismutase (SOD), catalase, glutathione peroxidase (GSHPx) and lipid peroxidation (LPX) were measured. After sacrificing animals, hearts and kidneys were removed for histopathology. Lung and liver wet to dry weight ratio were measured to investigate pulmonary edema and liver congestion.

Results: At 1 week post ALK injection renal histopathology was consistent with CRS. There was no clinical sign of fluid overload. Antioxidant enzymes activities including SOD and GSHPx were decreased in the kidney and the RV. There was LPX in the kidney and the RV. RV pressure overload and RV hypertrophy with no RV dysfunction were observed. There was no lung or liver congestion.

Conclusions: New & noteworthy: This experimental model of CRS due to isolated RV dysfunction provides novel data that oxidative stress is the key contributor to pathophysiology of RV-Kidney deleterious cross talk and systemic congestion develops in later stage. Thus, antioxidants may have a crucial role in management of CRS.

Computational Workflow for Spatiotemporal Transcriptomics Analysis of Cold vs. Warm Ischemic Kidney Injury

Srujan Singh, Sanjeev Noel, Shishir K. Patel, Zhaoli Sun, Hamid Rabb, Jean Fan. *Johns Hopkins University, Baltimore, MD.*

Background: Increasing cold ischemia (CI) time leads to AKI, limits lifespan of transplanted organs and increases organ discard. However, there is limited comparison of the molecular pathogenesis between CI and warm ischemia (WI) injury. We performed full-transcriptome characterization in a CI murine model using the 10X Visium spatial transcriptomics (ST) platform for comparison with previously published WI data.

Methods: We induced CI in murine kidneys in UW solution at 4°C (0, 12, 24 and 48 hours), then generated ST datasets (n=1 per timepoint), containing 12530 spatial spots with 19465 shared gene species profiled per kidney tissue section. We developed a computational workflow which facilitates batch correction (via Harmony) to identify shared cell types across all datasets. We segmented kidney tissues into three different compartments, namely the cortex, medulla, and corticomedullary junction based on cell types and their anatomical location. We identified differentially expressed genes (DEGs) across time points unique to each compartment using DESeq2, clustered DEGs into different temporal trends, and further characterized enriched pathways per compartment per trend using ClusterProfiler. We implemented a similar workflow on WI injury kidneys.

Results: We integrated 0, 12, 24 and 48 hours CI kidney ST datasets and identified shared cell types across all timepoints that demarcated similar anatomical locations. We identified shared temporal trends affecting distinct genes and pathways within different kidney compartments. In particular, autophagy-related pathways were uniquely

upregulated in the cortex of CI kidney at an early timepoint (12 hours) whereas upregulation of immune-related pathways emerged in the medulla at a later timepoint (48 hours). Comparisons between CI and WI further elucidated molecular differences within corresponding kidney compartments. For example, the *Fosb* gene was upregulated early in the cortex of the CI kidneys while it was confined to the medulla of WI kidneys.

Conclusions: CI and WI induce pleiotropic transcriptional effects in a spatially and temporally distinct manner. Developing strategy for spatiotemporal molecular characterization can enhance our understanding of CI to improve outcomes and reduce organ discard.

Role of CDKL1-SOX11 Signaling Axis in AKI

Josie A. Silvaroli, Ji Young Kim. *The Ohio State University, Columbus, OH.*

Background: The biology of CDKL (Cyclin-Dependent Kinase-Like) kinase family remains enigmatic. Contrary to their nomenclature, CDKLs do not rely on cyclins for activation and are not involved in cell cycle regulation. Instead, they share structural similarities with MAPKs (Mitogen-Activated Protein Kinases) and GSK3 (glycogen synthase kinase 3), though their specific functions and associated signaling pathways are still unknown. Previous studies have shown that the activation of CDKL5 kinase contributes to the development of acute kidney injury (AKI) by suppressing the protective SOX9-dependent transcriptional program in tubular epithelial cells. The role of other CDKL family members in kidney biology and disease remains unknown.

Methods: Mouse models of renal ischemia reperfusion, and rhabdomyolysis were used to assess the effect or germline CDKL1 and tubular specific SOX11 conditional knockout mice in the severity of AKI.

Results: In the current study, we measured the functional activity of all the five CDKL kinases and discovered that, in addition to CDKL5, CDKL1 is also activated in tubular epithelial cells during AKI. To explore the role of CDKL1, we generated a germline knockout mouse which exhibited no abnormalities under normal conditions. Notably, when these mice were challenged with bilateral ischemia reperfusion and rhabdomyolysis, they were found to be protected from AKI. Further mechanistic investigations revealed that CDKL1 phosphorylates and destabilizes SOX11, contributing to tubular dysfunction. In summary, these studies have unveiled a previously unknown CDKL1-SOX11 axis that drives tubular dysfunction during AKI.

Conclusions: This study underscores the importance of CDKL1 kinase in kidney injury and supports the development of targeted small-molecule inhibitors as potential therapeutics.

Bilirubin Nanoparticles Protect against Kidney Ischemia-Reperfusion Injury through Antioxidant Activity

Honglin Piao, Jaeseok Yang. *Yonsei University, Seoul, Republic of Korea.*

Background: Renal ischemia-reperfusion injury (IRI) is a common complication but there was no definite treatment, except supportive care. Basic mechanisms of renal IRI is acute inflammation, where oxidative stress plays an important role. Despite potent reactive oxygen species (ROS)-scavenging effects, free bilirubin has an important limitation of water-insolubility, interfering with clinical application. Recently, Brixelle, a PEGylated bilirubin nanoparticle has been developed to improve water solubility.

Methods: This study aimed to assess renoprotective effects of bilirubin nanoparticles against renal IRI. We injected bilirubin nanoparticles intravenously 1 h before and 1.5 h after mouse renal IRI and assessed their renoprotective effects on renal IRI on day 1, 3, and 28, compared to free bilirubin.

Results: Bilirubin nanoparticles suppressed *in vitro* ROS generation and secretion of TNF-α and IL-1β from activated neutrophil-like cells and macrophages, whereas free bilirubin did not show any suppressive effect. Moreover, Bilirubin nanoparticles increased *in vitro* cellular viability of renal tubular epithelial cells against ROS. Intravenous administration of bilirubin nanoparticles led to an increased uptake in the kidney with minimal migration to brain after renal IRI. Peri-IRI administration of bilirubin nanoparticles improved renal function and attenuated renal tissue injury as well as renal tubular apoptosis on day 1 after IRI to greater extent than free bilirubin. Renal infiltration of neutrophils and expression of TNF-α and MCP-1 were also suppressed by bilirubin nanoparticles. Furthermore, bilirubin nanoparticles increased renal tubular regeneration (Ki67) on day 3 and suppressed renal fibrosis as well as renal expression of αSMA, fibronectin, and type IV collagen on day 28 after IRI to greater extent than free bilirubin. Bilirubin nanoparticles suppressed expression of nicotinamide adenine dinucleotide phosphate oxidase (NOX) and iNOS, increased expression of nuclear factor erythroid-2-related factor 2 (Nrf2) and HO-1, and attenuated ROS generation after IRI to greater extent than free bilirubin.

Conclusions: Bilirubin nanoparticles effectively attenuates ROS generation and acute renal injury, facilitates subacute renal recovery, and suppressed chronic fibrosis after renal IRI, having a potential as a new therapy for renal IRI.

Inhibition of RNA-Binding Protein Hu Antigen R (HuR) Prevents AKI-to-CKD Transition in Aristolochic Acid-Induced Nephropathy

Zhou Wang, Lili Zhuang, Yufeng Huang. *University of Utah Health, Salt Lake City, UT.*

Background: Acute kidney injury (AKI) is a significant risk factor for developing chronic kidney disease (CKD). The RNA-binding protein HuR is known to critically influence the progression of CKD, primarily by upregulating inflammation and facilitating fibrosis. We hypothesized that HuR might also play a pivotal role in the transition from AKI-to-CKD and inhibition of HuR could potentially mitigate persistent kidney damage.

Methods: We utilized a model of aristolochic acid nephropathy, induced by the administration of aristolochic acid (AA), which is characterized by tubular atrophy and interstitial fibrosis, mirroring the AKI-to-CKD transition observed in humans. After optimizing the AA dosage, male mice aged at 10 weeks received AA injections of 1.5mg/kg BW daily for 4 consecutive days. Concurrently, these mice were treated either without or with HuR inhibitor KH3 (adminstered at 40mg/kg-BW daily) for 14 days. Normal mice recevied saline injections.

Results: Repeated AA injections significantly increased HuR expression in the kidneys, particularly in tubular cells, which was effectively suppressed by KH3 treatment. AA-induced kidney injury was evidenced by elevated plasma levels of blood urea nitrogen and creatinine, along with decreased glomerular filtration rate and increased urinary albuminuria. Histological analyses revealed markedly tubular atrophy, apoptosis, capillary rarefaction, inflammatory cell infiltration and fibrosis. These findings were determined using periodic acid-Schiff and Masson's trichrome staining, alongside immunofluorescent staining for markers including Tunel+, CD31+, alpha-smooth muscle actin, fibronectin, collagen III, and F4/80+. Treatment with KH3 mitigated these pathological changes in AA-injured mice. Additionally, the increased renal expression of NF-kBp65 and phosphorylated Akt- molecules implicated in AA-induced tubular cell DNA damage, apoptosis, and necrosis- along with gamma-H2AX, cleaved caspase-3, and PARP expression, were inhibited by KH3 treatment.

Conclusions: Our findings demonstrate that elevated HuR levels in renal tubular cells, stimulated by AA, critically contribute to the progression from AKI-to-CKD. This effect is likely mediated through the HuR-cellular DNA signaling pathway. These results highlight the therapeutic potential of HuR inhibitors in treating AKI-to-CKD transition.

Atypical Protein Kinase C Zeta Is Indispensable for Calcium Oxalate Crystal Clearance in a Dietary-Induced Mouse Model of Kidney Injury

Melina Messing,[1] Nickolas J. Holznecht,[1] Sebastian Strubl,[2,1] Jacob A. Torres,[1] Brina A. Aceves,[1] Margaret Schimmel,[1] Rachel Wong,[1] Thomas Weimbs.[1] *[1]University of California Santa Barbara, Santa Barbara, CA; [2]Universitat zu Koln, Koln, Germany.*

Background: Previously, we showed that renal calcium oxalate (CaOx) crystal deposition triggers reversible tubular dilation to expel crystals from normal kidneys and accelerates disease progression in polycystic kidney disease (PKD) rodent models. Given our previous report that atypical protein kinase C zeta (PKCζ) expression is downregulated in patients with autosomal dominant polycystic kidney disease (ADPKD) and that restoration of PKCζ improves the condition, we investigated the role of PKCζ in the kidneys during and after CaOx deposition.

Methods: To explore reversible tubular dilation and signaling activity in PKCζ-knockout (KO) kidneys following CaOx deposition, we administered a 0.67% sodium oxalate (NaOx) diet to P56 male wild-type and PKCζ-KO mice for up to 14 days, followed by a recovery period of up to 28 days after cessation of NaOx treatment.

Results: Both groups demonstrated substantial renal crystal deposition; however, wild-type mice remained healthy throughout the dietary intervention. In contrast, PKCζ-KO mice showed increased susceptibility to injury, leading to mortality around day 10. Further investigation revealed significantly higher crystal accumulation in PKCζ-KO mice compared to wild-type. Notably, reintroduction of a normal diet after 3 days on NaOx allowed for crystal clearance in wild-type mice, but not in PKCζ-KO mice, where crystals persisted. Additionally, PKCζ-KO mice displayed enduring renal damage characterized by significant collagen deposition and inflammation, even after a 28-day washout period.

Conclusions: These findings underscore the critical role of PKCζ in managing CaOx crystal deposition and suggest its potential as a therapeutic target for preventing chronic kidney disease progression following crystal-induced injury.

Exploring the Role of ELMO1 in AKI

Blandine Baffert. *University of Virginia School of Medicine, Charlottesville, VA.*

Background: Acute kidney injury (AKI) is a sudden episode of kidney failure linked to a wide range of health conditions. High mortality in AKI highlights the need to identify new therapeutic approaches. Recent studies revealed the association of ELMO1 gene polymorphisms with diabetic nephropathy and lowering *Elmo1* expression was protective against severe disease. ELMO1 is a cytoplasmic protein that promotes cytoskeletal reorganization during apoptotic cell clearance and cell migration. We have previously shown that loss of ELMO1 in neutrophils reduces neutrophil recruitment in inflammatory arthritis, without affecting bacterial recruitment or killing. Since immune cell recruitment and renal cell death directly affect AKI outcomes, we examined the role of ELMO1 in mouse models of AKI.

Methods: We subjected wild type and *Elmo1*$^{-/-}$ mice to two different models of AKI: 1. Renal ischemia-reperfusion (IRI), a model of traumatic or post-operative kidney injury and 2. Cisplatin-induced nephrotoxicity.

Results: In the bilateral renal IRI model, Elmo1$^{-/-}$ mice reduced expression of the kidney injury marker NGAL and local and global levels of inflammatory cytokines IL-6 and TNFα, as well as a significant decrease in remodeling gene expression. ELMO1-deficient mice also showed a reduction in neutrophils (Ly6G^{+}) and apoptotic cells in renal tissue. Surprisingly, *Elmo1*$^{-/-}$ mice subjected to cisplatin-induced AKI displayed accelerated loss of kidney function and trends toward increased kidney injury marker NGAL and histological damage. We also noted elevated levels of apoptotic cells (cleaved caspase-3 stained) in the kidneys of cisplatin-injected *Elmo1*$^{-/-}$ mice, indicating potential for ELMO1 function in clearance of dying cells during cisplatin nephrotoxicity.

Conclusions: Collectively, our data suggest distinct roles of ELMO1 in acute kidney injury induced by different damage trigger. Our ongoing studies are focused on cells involved in the phagocytosis of apoptotic cells (efferocytosis), having shown that the efferocytosis capacity of macrophages and renal tubular epithelial cells (RTEC) is not altered by loss of ELMO1. Our hypothesis is that ELMO1 could represent an attractive therapeutic target in ischemic injury, while potentially detrimental in the context of chemotherapy.

Role for Actin Organization vs. Tight Junction Membrane Protein Cross-Linking in Regulation of Renal Paracellular Permeability to Macromolecules

Kurt Amsler. *NYIT College of Osteopathic Medicine, Old Westbury, NY.*

Background: The Leak Pathway mediates macromolecule paracellular permeability across the tight junctions of epithelia. Changes in Leak Pathway permeability have been associated with many renal and other epithelial diseases states. The basic cellular processes and regulation of the Leak Pathway are poorly understood. The cytoplasmic ZO-1 protein provides a scaffold for crosslinking tight junction membrane proteins and for linking these proteins to the actin cytoskeleton. It also shuttles TOCA-1 protein, which facilitates formation of branching actin networks, to the tight junction. In MDCK II cells, knockdown of ZO-1 (ZO-1 KD) and knockout of TOCA-1 (TOCA-1 KO) increase Leak Pathway permeability.

Methods: The flux rates of a size panel of fluorescein-dextran molecules (FD) were determined across monolayers of wild type MDCK II cells, ZO-1 KD cells, and TOCA-1 KO cells.

Results: We hypothesized that depletion of these two proteins would similarly affect the Leak Pathway properties, opening number and opening size. Both TOCA-1 KO and wild type MDCK II cells exhibited similar proportional decreases in flux rate with increasing FD molecular size. ZO-1 KD cells exhibited a diminishing difference from wild type cells with increasing FD size. Plotting apparent permeability (P_{app}) versus solute Stokes radius on semilog plots demonstrated that the rate of decrease in P_{app} as a function of FD size was similar for wild type MDCK II and TOCA-1 KO cell monolayers. In contrast, ZO-1 KD cells exhibited a more rapid decline in P_{app} as solute size increased such that a large FD molecular size exhibited a similar P_{app} in wild type and ZO-1 KD MDCK II cells.

Conclusions: Based on theoretical considerations, opening number should not affect P_{app} as a function of solute size. Opening size, however, should affect P_{app} as a function of solute size. Our results support the conclusion that depletion of TOCA-1 increases opening number without significantly affecting opening size. In contrast, ZO-1 depletion increases opening number and decreases opening size. These results suggest that crosslinking of tight junction membrane proteins, a property of ZO-1 but not TOCA-1, may be important for determining the size of the Leak Pathway openings, whereas, interaction of the tight junction with actin structures may affect preferentially opening number.

FR-PO176

Role of Versican in Cisplatin-Induced AKI to CKD Transition

Dan Wang,[1] Juan P. Arango Velasquez,[2] Diana Zepeda-Orozco,[3] Sethu M. Madhavan,[1] Samir V. Parikh,[1] Navjot Pabla,[2] Nicholas J. Ferrell.[1] *[1]The Ohio State University Wexner Medical Center, Columbus, OH; [2]The Ohio State University, Columbus, OH; [3]Nationwide Children's Hospital, Columbus, OH.*

Background: Versican is an extracellular matrix (ECM) proteoglycan with five isoforms (V0-V4) that impacts immunity and inflammation. Studies have shown that versican is upregulated following injury in lung, heart and liver, and versican deficiency protects from acute lung injury. However, the role of versican in regulating renal response in AKI and AKI-CKD transition has not been studied. We hypothesize that versican plays a role in response to AKI and primes ECM for fibrosis in the setting of AKI-CKD transition.

Methods: Mass spectrometry data on human CKD biopsy samples were used to analyze the correlation between versican expression and interstitial fibrosis. We use two cisplatin-induced mouse models: AKI with single high-dose cisplatin (25mg/kg), and AKI-CKD where acute injury transitions to chronic injury and fibrosis with 2 low-doses (10 mg/kg) of cisplatin. C57BL/6J male mice (8-10 weeks) were euthanized 3 days, 2wks, or 1 month post-injection. Kidney tissues were collected and processed for histological analysis, immunofluorescence staining, and immunoblot and qPCR analysis of isoform specific versican expression. Marker of kidney injury (KIM-1 and NGAL) and fibrosis (tenacin C, periostin, aSMA, ACTA2, and col1a1) were evaluated by qPCR.

Results: Versican expression is upregulated in chronic injury and correlates strongly with the degree of interstitial fibrosis in human CKD. Gene expression for all kidney expressed isoforms of versican (V0, V1, V3, Vtotal) and protein expression are upregulated at 72 hours after AKI. In the setting of AKI-CKD transition, versican gene expression increases initially, peaks at 2wks, and then decreases but remains upregulated at 1 month after treatment. This indicates the kidney injury persists and transitions to chronic kidney damage. Gene expressions of fibrosis markers are upregulated in AKI-CKD model. This study shows that versican is rapidly upregulated following acute injury and persists during transition to CKD.

Conclusions: We show upregulation of versican mRNA and protein expression during AKI and AKI-CKD transition. Versican may play a role in ECM remodeling and progressive fibrosis during AKI-CKD transition. Future studies aim to determine the role of versican in promoting fibrogenesis during AKI-CKD transition.

Excess Dietary Sodium Partially Corrects Salt and Water Homeostasis Caused by Loss of the Endoplasmic Reticulum Molecular Chaperone, GRP170, in the Mouse Nephron

Aidan W. Porter,[1,2] Hannah E. Vorndran,[3] Allison L. Marciszyn,[3] Stephanie Mutchler,[3] Arohan R. Subramanya,[1] Thomas R. Kleyman,[3,1] Jeffrey L. Brodsky,[3] Teresa M. Buck.[3] *[1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]Children's Hospital of Pittsburgh of UPMC Department of Pediatrics, Pittsburgh, PA; [3]University of Pittsburgh, Pittsburgh, PA.*

Background: Correct folding and trafficking of ion channels and transporters by renal tubular epithelial cells is essential to maintain fluid and electrolyte homeostasis. These processes rely on proteins termed molecular chaperones to sustain protein biogenesis and coordinate the repair and recycling of misfolded proteins. We previously found that conditional loss of one such HSP70-like chaperone, GRP170, which resides in the endoplasmic reticulum (ER) of murine tubular epithelial cells leads to hypovolemia, electrolyte imbalance, and an AKI-like phenotype evidenced by tubular injury and elevated kidney injury markers. GRP170 deletion also compromises protein homeostasis and activates an ER quality control mechanism known as the Unfolded Protein Response (UPR). Based on these data, we hypothesized that UPR induction underlies hyponatremia, volume depletion, and AKI in rodents, but that these features might be rectified by intervention to maintain intravascular volume and, hence, renal perfusion.

Methods: Male and female inducible, nephron-specific GRP170 knockout (KO) mice were fed a control or an 8% sodium chloride diet. Serum and urine chemistries and concentration were measured. AKI markers and UPR induction was monitored by qPCR, western blot, and imaging. Renal histology and ER morphology were also assessed.

Results: Sodium supplementation improved electrolyte balance, intravascular volume, and AKI markers but failed to prevent weight loss or restore tubule integrity and function in GRP170 KO mice. UPR induction and ER morphology were also unaffected by excess sodium. Compared to males, female mice had milder kidney dysfunction, which was better ameliorated by sodium. However, GRP170 deletion produced a unique, sodium-independent UPR profile in both sexes.

Conclusions: An aberrant UPR contributes to kidney dysfunction in an inducible nephron-specific GR170 knockout mouse model. Moreover, GRP170 expression in the murine tubule is indispensable for protein homeostasis, cell integrity, and electrolyte balance. The distinct sex-specific phenotypes also indicate that the UPR may contribute to the relative susceptibility of each sex to kidney injury, highlighting the need to account for sex in AKI studies.

FR-PO178

Changes of Kidney and Urinary Klotho Reflect the Involvement of Distal Convoluted Tubules in Lipopolysaccharide (LPS)-Induced AKI in Rats

Weiwan Wang,[1] Mingzhuo Zhang,[1,2] Anni Xie,[1,2] Mingda Liu,[1] Yutao Jia,[1,2] Haonan Duan,[1,2] Xiaoyan Wang.[1,2] *[1]The Core Laboratory, Nanjing BenQ Medical Center, Nanjing, China; [2]The Affiliated BenQ Hospital of Nanjing Medical University, Nanjing, China.*

Background: Sepsis is one of the common causes for acute kidney injuries (AKI).

Methods: To seek a noninvasive but early biomarker, we determined klotho, an anti-aging protein secreted by renal distal convoluted tubules, in kidneys and urines from sepsis-like AKI rats at 6, 12, 24-h respectively after a single intraperitoneal injection of LPS at 5 mg/kg.

Results: The LPS-rats exhibited similar appearances, body weights and urine volumes as the controls. Serum creatinine concentration was not altered at 6, and 12-h but elevated at 24h (51.0±5.0 vs 31.0±1.6, mmol/L??? n=5/group, p<0.05). Compared with baseline (28.8±1.7, ng/ml), serum klotho declined in the rats at 12 (18.5±3.4) and 24h (19.6±3) but not 6h while serum kidney-injury-molecular-1,cystatin C were not changed at all time points. Klotho was detected in rat renal distal convoluted tubules and colocalized with positive staining of NCC at apical membranes. Renal klotho was lowered at 6 (66.8±6.4, % of controls, same as below), 12 (38±1.6) and 24-h (40.5±6.2) in LPS rats than controls. Klotho mRNA expressions were decreased at 6 (27.9±4.6), 12 (36.2±10.7) and 24-h (22.2±3.8). Furthermore, klotho in urinary exosomes was much enriched relative to original urines. Urinary exosomal klotho excretions, corrected by corresponding creatinine concentrations, were elevated at 6 (245.2±56.2), 12-h (246±53), not 24h in LPS rats relative to vehicle controls. NCC in kidneys was unchanged but increased in urinary exosomes at 6 (394.01±137.57) and 12-h (658.83±220.56).

Conclusions: Thus, LPS impaired renal functions including synthesis and production of klotho from distal convoluted tubules while the decrease of klotho in kidney is followed by its decrease in serum. However, the rises of urinary exosomal klotho and NCC may reflect their leakages from kidney into urines during the AKI process and could be considered as early biomarkers for the septic AKI.

FR-PO179

Severity of Kidney Dysfunction in Obstructing Tubulopathy Is Associated with the Number of Renal Tubular Obstructing Foci by Light Microscopy

Ping L. Zhang, Hassan D. Kanaan, Wei Li. *Corewell Health, Royal Oak, MI.*

Background: Etiologies of renal failure due to renal tubular injury may result from either ischemic/toxic injury of proximal tubules (ATN), variants of interstitial nephritis or obstructing tubulopathy by the luminal blocking of either monoclonal casts, uric acid or calcified deposits. We hypothesized that the serum creatinine (SCr) levels and the number of tubular obstructing deposits such as calcium oxalate deposits in proximal tubules, and uric acid or monoclonal cast depoists in distal tubules were correlated so that the pathologic identification of obstructing foci can be predictable for the extent of renal dysfunction.

Methods: Eight controls with mild to moderate acute tubular injury and 11 cases with calcium oxalate nephropathy (calcium group) were selected for the study. Other type of tubular obstructing diseases by uric acid and monoclonal casts were also evaluated. The patient's SCr values were obtained from electronic medical records and the number of polarizable calcium oxalate crystal deposits in the lumina of proximal tubules seen on Hematoxylin & Eosin stained slides at 400x high power field were recorded for each biopsy. Umpired student T-test was used to compare the two groups. Linear regression analysis was used to correlate SCr and the number of calcium oxalate deposits.

Results: Mean ages were not significantly different between two groups (49 ± 8 years in controls and 64 ± 6 years in calcium group). SCr was significantly higher in the calcium group (5.97 ± 0.68 mg/dl*) than in the control group (2.59 ± 0.37 mg/dl). No calcium oxalate deposits were seen in any of the controls, but the number of calcium oxalate deposits ranged from 3 to 7 in the calcium group. In our study, there was a significant linear correlation between SCr and the number of calcium oxalte deposits /high power field, when all cases were taken together (r value = 0.783, p value = 0.0002*). Additional pilot data also showed the similar correlation between the SCr levels and either uric acid deposits or monoclonal cast foci.

Conclusions: Our data indicate that the severity of renal dysfunction in obstructing tubulopathy, calcium oxalate variant, was significantly linked to deposit foci seen microscopically. Identifying the foci of obstructing tubulopathy may be a simple but reliable microscopic method to correlate with patients' SCr levels.

Evaluation of Urinary NKCC2 and NCC in Rats with AKI Induced by Candesartan Plus Low-Salt Diet in Rats

Anni Xie,[1,2] Leijuan Xiao,[1] Mingzhuo Zhang,[1,2] Haonan Duan,[1,2] Zhiyun Ren,[2] Ping Wang,[2] Yutao Jia,[1,2] Mingda Liu,[2] Jizhuang Lou,[1] Xiaoyan Wang.[1,2] *[1]The Department of Nephrology, The Affiliated BenQ Hospital of Nanjing Medical University, the Fourth Clinical Medical College, Nanjing, China; [2]The Core Laboratory for Clinical Research, The Affiliated BenQ Hospital of Nanjing Medical University, the Fourth Clinical Medical College, Nanjing, China.*

Background: Dietary-salt-restriction and angiotensin-II-receptor-1-blockade are often suggested to the patients with renal and cardiovascular diseases.

Methods: We studied the dietary effects of low-salt(LS, 0.01%NaCl), normal-salt(NS,0.8%NaCl) and high-salt(NS, 2%NaCl) on renal functions and urinary exosomal renal sodium-potassium-chloride-cotransporter-2(NKCC2) and sodium-chloride-cotransporter(NCC) in rats treated with candesartan(1mg/kg/day,IP), a common angiotensin-II-receptor-1-blocker, to determine if the combination of the two strategies were beneficial and how to detect renal dysfunction early. All rats were treated with candesartan. Model I: LS, NS and HS were fed rats respectively for 7 days. Model II: NS was pretreated for 4 days before switching to LS for 3 days in experimental group. Model III: similar as model II, but the diet was switched back to HS for extra 3 days.

Results: Serum creatinine (SCr) increased on day 7(55.83±6.46) of model I and on day 3 of model II(56.56±8.28). Urinary exosomal NKCC2(905.76±127.59, % of day0) and NCC(637.51±87.35) increased on day 7 in Model I. In model II, urinary exosomal NKCC2(908.12±227.46, % of day 0) started to increase on day 1, which was 2 days earlier than increased SCr, and kept high for 3 days. NCC(160.6±23.85) was increased only at day 1. In model III, switching diet back to HS reversed the increases of SCr(39.40±2.56 vs 34.80±1.28,umol/L, day3 vs day+3, p<0.05) and urinary exosomal NKCC2(43.54±17.75,% of day3) and NCC(3.60±0.87,% of day3). NKCC2 was located in the renal apical membranes of rat outer medullary tubules while NCC was in the apical side of certain cortical tubules next to glomeruli, in agreement with their respective distribution in kidney. Their protein expressions were not affected in whole kidney homogenates except an increase of NKCC2 in model I.

Conclusions: Thus, low salt diet induces acute kidney injury in candesartan-treated rats which can be reversed by a moderate salt load. Urinary exosomal NKCC2 and NCC may be considered as early biomarkers for detection of AKI accordingly.

Primary Cultures from Injured and Healthy Mouse Kidneys: A Comparative Transcriptomic Analysis

Karen I. López-Cayuqueo,[1] Arnold Tsamo Tetou,[1,2] Dorothee Günzel,[2] Kai M. Schmidt-Ott.[1] *[1]Medizinische Hochschule Hannover, Hannover, Germany; [2]Charite Universitatsmedizin Berlin, Berlin, Germany.*

Background: Primary cell cultures from mouse kidneys are widely used to investigate kidney physiology and pathophysiology. It is known culture systems are far from being an ideal model but there is still a need for *in vitro* systems to validate different hypotheses. Here, we prepared primary cell cultures of renal cortex from both healthy and injured kidneys, and we compare their transcriptomics landscape intending to determine whether cultured kidney cells from an injured kidney are representative of *in vivo* injury states.

Methods: Unilateral Ischemia-Reperfusion Injury was performed in C57BL/6N mice. After 21 days of reperfusion primary cell cultures were prepared from the renal cortex of both contralateral and injured kidneys. The cells were kept in culture for 6 days before being analyzed using bulk RNAseq and single-cell sequencing. Additionally, cell cultures were compared to uncultured kidney cells from contralateral and injured kidneys (from the same mouse).

Results: Cell cultures only partially resemble *in vivo* conditions. During culturing, the differences between cells from injured kidneys and those from healthy kidneys become less pronounced. Surprisingly, cultured renal cells from healthy kidneys adopt an injured kidney phenotype, detonated by the upregulation of kidney injury markers such as Havcr1 and Vcam1. Despite the similarities between healthy and injured cultured cells, it is possible to identify key differences at the single-cell level, such as the identification of additional clusters represented by monocyte and macrophage markers.

Conclusions: We demonstrated that primary cell cultures from healthy mouse renal cortex could be a suitable model to investigate injury-associated pathways since the culturing step induces in the cells a kidney injury-associated phenotype. However, culturing cells from an injured kidney potentially offers additional information, such as the presence of immune cells.

Proximal Tubule-Specific Knockout of G3bp1 Enhances Kidney Injury after Cisplatin Administration and Kidney Ischemia-Reperfusion

Shixuan Wang,[1] Zheng Dong.[1,2] *[1]Augusta University Medical College of Georgia, Augusta, GA; [2]Charlie Norwood Department of Veterans Affairs Medical Center, Augusta, GA.*

Background: Stress granule, mainly containing RNA-binding proteins (RBPs) and RNAs, is one type of cytoplasmic membraneless structure formed upon stress in eukaryotic cells. G3bp1 is a core protein in stress granule. The role of G3bp1 and associated stress granules in renal pathophysiology is largely unknown.

Methods: To study the function of stress granule and G3bp1 in the kidney, we established a kidney proximal tubule-specific G3bp1 knockout (PT-G3bp1-KO) mouse model by crossing G3bp1-floxed mice with PEPCK-Cre mice. PT-G3bp1-KO mice and their wild-type (WT) littermates were subjected to cisplatin nephrotoxicity or renal ischemia/reperfusion to induce acute kidney injury.

Results: Compared with WT mice, PT-G3bp1-KO mice had more severe kidney injury after cisplatin or ischemia/reperfusion treatment in histological analysis. Consistently, KO mice showed significantly higher levels of serum creatinine after AKI challenge. By TUNEL staining, more apoptotic cells were found in KO mice than in the wild-type. Immunoblotting also detected higher level of caspase-3 cleavage or activation in KO mice kidneys than in wild-type tissues. Additionally, more Ki-67-positive cells were found in KO mice kidney tissues than in the wild-type.

Conclusions: Our data indicate that G3bp1 and associated stress granules play a protective role in proximal tubule cells during acute kidney injury, suggesting a new strategy for the prevention and treatment of this devastating renal diseases.

Trauma of Origin: The Impact of Maternal AKI on Progeny

Rose Odom,[1] Danielle E. Soranno,[1,2] Andrew L. Schwaderer,[1,2] Michelle C. Starr,[1,2] David P. Basile.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Riley Hospital for Children at Indiana University Health, Indianapolis, IN.*

Background: Acute Kidney Injury (AKI) results in both short- and long-term systemic sequelae. The impact of AKI on future generations, however, has not been studied. Here, we investigate the impact AKI has on female mice and their progeny.

Methods: Wild-type, C57 female mice underwent bilateral ischemia-reperfusion AKI. Control groups included sham operated mice (no pedicle clamping) and unmanipulated controls. To confirm AKI had been obtained, serum BUN values were measured 24hrs post procedure. Two weeks after recovery, all mice underwent testing via transcutaneous Glomerular Filtration Rate (tGFR) to assess kidney function. They were then bred and allowed to deliver naturally. Serial measurements of progeny weight and length occurred at birth and then weekly through 42 days of age.

Results: Litter Size: For dams with AKI, we found a correlation between higher 24hr BUN to subsequent litter size produced. Dams with BUN's of 90-115 produced 7 pups in a litter whereas dams with BUN's between 140-175 produced 6 or 3 pups respectively. [SAL1] Weight: At birth, male pups from AKI dams had lower weights than males born to control dams (p=0.02); whereas female pups had no significant changes across all groups. By day 7, all animals' weights had "caught up" to their counterparts in other groups. By day 35, males from AKI dams had weights that surpassed those in control and sham groups (p=0.04). Length: At birth, males from AKI dams were significantly shorter than males from control dams (p=0.005) while females from AKI-dams were significantly shorter than those from sham dams (p=0.01). Like the weight data, all animals "caught up" to their counterparts by day 7 of life, lasting through day 35. At day 42, however, both males and females born to AKI-dams surpassed animals in other groups in length (p=0.0002 in males and p=0.04 in females).

Conclusions: Litter size was significantly reduced post-AKI compared to sham and control animals, and the anthropometrics of the progeny were also significantly impacted at the time of birth. Growth was more impacted in males than females. Throughout the study, progeny from post-AKI dams did obtain "catch up" growth with sham and control progeny. Testing of neurocognitive status and nephron endowment is currently underway to elucidate any other sequelae in the progeny.

FR-PO184

Low Birthweight Impacts the Ability to Recover from Childhood AKI in Mice

Sage Timberline,[1] Kimberly Deronde,[1] Wyatt Johnson,[1] Kevin M. Bennett,[2] Jennifer R. Charlton.[1] *[1]University of Virginia, Charlottesville, VA; [2]Washington University in St Louis, St Louis, MO.*

Background: Low birthweight is a risk factor for the development of chronic kidney disease (CKD). Birth weight and nephron number are highly correlated. In rodents, maternal protein restriction during gestation results in low birthweight offspring with fewer nephrons. Acute kidney injury (AKI) independently increases the risk of CKD. However, the impact of low birthweight on the ability to recover from AKI is unknown.

Methods: Pregnant CD-1 dams were fed a normal protein (NP, 18%) or low protein (LP, 8%) diet from conception through weaning. NP and LP offspring were stratified to receive vancomycin (400 mg/kg intraperitoneal on days 7 and 8, n=6-12/group) or no injection, creating four groups – NP^{V}, LP^{V}, NP^{0}, LP^{0}. At 6 weeks, glomerular filtration rate (GFR) was measured transcutaneously. Kidneys were prepared for histologic evaluation of atubular glomeruli percentage (ATG) using Amira (Thermo Fisher Scientific software). Data were analyzed using Prism 9 (GraphPad software) with significance set at $p<0.05$. Groups were stratified by sex *a priori*.

Results: LP^{0} males had lower GFRs and more ATG compared to NP^{0} males (Table). After AKI, all LP^{V} animals had lower GFRs and more ATG compared to same-sex NP^{V} animals. When compared to LP^{0}, LP^{V} animals had more ATG. LP^{V} animals had lower GFRs than NP^{V} animals. LP^{V} males had lower GFRs compared to LP^{0} males, while LP^{V} and LP^{0} females were similar.

Conclusions: Changes in kidney structure and function after AKI were more severe in LP animals. LP animals exposed to vancomycin AKI had more ATGs, suggesting that AKI is an additional risk factor for development of non-functional glomeruli in low birthweight animals. LP animals exposed to vancomycin AKI also had lower GFRs compared to NP^{V} animals, but only LP^{V} males had lower GFRs than LP^{0} counterparts. This suggests that the degree of impact on kidney function from AKI on low birthweight animals may be sex-specific.

Functional Role of a Novel Renal Protective Protein TMEM52B in Kidney Fibrosis

Rui Xue, Qijun Wan. *Shenzhen Second People's Hospital, Shenzhen, China.*

Background: Renal fibrosis, especially tubulointerstitial fibrosis, is the primary pathological hallmark of renal injury and signifies the progression of end-stage renal disease. Through exome sequencing of various human organs and tissues, our study has identified significant enrichment of transmembrane protein 52B (TMEM52B) expression in the kidney, highlighting its close correlation with renal function. Consequently, our upcoming studies aim to elucidate more deeply the exact role and underlying mechanisms of TMEM52B in renal tubular injury, specifically in tubulointerstitial fibrosis.

Methods: We employed *CRISPR-Cas9* technology to construct TMEM52B gene system knockout C57BL/6 mice. Subsequently, we performed unilateral ureteral obstruction (UUO) surgery to induce renal injury and tubulointerstitial fibrosis. Following the surgery, we then conducted a series of analyses and proteomics testing to investigate the changes after TMEM52B knockout. Finally, we conducted additional *in vitro* experiments to further validate the molecular mechanism of TMEM52B in renal fibrosis.

Results: TMEM52B expression was decreased significantly in UUO mice and nearly absent in the kidneys of TMEM52B knockout mice. Tubular injury and fibrosis markers in UUO mice were aggravated by TMEM52B knockout which was preserved with more tubular injury and fibrosis compared to control mice. Proteomic analysis showed Myeloid-Derived Growth Factor (MYDGF) expression was significantly decreased in the kidney tissue of UUO model mice, and further markedly decreased in TMEM52B system knockout UUO model mice. *In vitro*, TMEM52B expression significantly decreased under TGF-β1 stimulation, and altering TMEM52B levels correspondingly changed MYDGF expression.

Conclusions: Knock-out of TMEM52B could exacerbate tubular injury and alleviate tubulointerstitial fibrosis in UUO mouse model. This process is a cascade coordinated by the regulation of MYDGF. Our findings suggest a critical role of TMEM52B in the pathogenesis of tubular injury and further provide a potential novel therapeutic target for renal fibrosis.

Induction of Podocyte-Specific SMPDL3b Mitigates Radiation-Induced Kidney Damage

Anis Ahmad,[1] Shamroop Kumar Mallela,[2] Saba Ansari,[1] Mohammed Alnukhali,[1] Sandra M. Merscher,[2] Youssef Zeidan,[3] Alessia Fornoni,[2] Brian Marples.[4]
[1]Department of Radiation Oncology, University of Miami, Miller School of Medicine, Miami, FL; [2]Peggy and Harold Katz Family Drug Discovery Center and Division of Nephrology, Department of Medicine, University of Miami, Miami, FL; [3]Dept of Radiation Oncology, Lynn Cancer Institute, Baptist Health South Florida, Boca Raton, FL; [4]Department of Radiation Oncology, University of Rochester, Rochester, NY.

Background: The kidneys' high sensitivity to radiation limits the dose used in radiotherapy (RT) for abdominal and paraspinal tumors, leading to radiation nephropathy (RN). This study investigates the role of the lipid-modifying enzyme sphingomyelin phosphodiesterase acid-like 3b (SMPDL3b) in renal podocyte response to radiation or cisplatin-induced injury.

Methods: 10-14-week-old WT received 4 Gy bilateral kidney irradiation with or without cisplatin (3 mg/kg). 20 weeks post-RT, urine, and serum samples were analyzed for ACR, BUN, and creatinine levels, and glomerular basement membrane (GBM) ultrastructure was assessed via TEM. Another group of mice with podocyte-specific doxycycline-inducible SMPDL3b expression (SMPDL3b transgenic mice (SMP Tg)) kidney received 14 Gy. 20 weeks post-RT, kidney sections were stained with H&E, Periodic Acid-Schiff, and Picro Sirius Red. Kidney cortex samples were analyzed for ceramide-1-phosphate (C1P) levels using mass spectrometry.

Results: 20 weeks post-4Gy or cisplatin treatment: i) RT or cisplatin significantly reduced podocyte number and SMPDL3b expression ($p < 0.001$), with no further change observed with combined treatment; ii) RT or cisplatin significantly increased GBM thickness and foot process width ($p < 0.05$), which further increased with combined treatment ($p = 0.0005$ and 0.002); iii) RT or cisplatin significantly increased serum BUN levels ($p < 0.05$), with no further increase observed with combined treatment; iv) RT or cisplatin significantly increased serum creatinine levels ($p < 0.05$), which further increased with combined treatment ($p < 0.002$); v) RT did not significantly increase urine ACR, while cisplatin did ($p = 0.03$), but there was no significant difference with combined treatment; vi) RT did not increase C1P levels, but combined treatment did. 20 weeks post-14 Gy irradiation: i) RT significantly decreased podocyte number in WT mice ($p = 0.006$), but not in SMP Tg mice; ii) RT significantly increased the mesangial expansion score in WT mice, but not in SMP Tg mice; iii) RT did not significantly affect serum BUN, creatinine, urine ACR, and C1P levels in SMP Tg mice.

Conclusions: Induction of SMPDL3b reduces radiation-induced podocyte injury and restores C1P levels, suggesting that SMPDL3b is a potential therapeutic target for mitigating RN.

Adenosine Triphosphate Coincubation with Alkaline Phosphatase Reduces H2O2-Induced Endothelial Barrier Disruption

Thei S. Steenvoorden,[1] Fabienne Podieh,[2] Juan Miguel Tellez Garcia,[1] Frederike J. Bemelman,[1] Peter Hordijk,[2] Liffert Vogt.[1] *[1]Amsterdam UMC Locatie AMC, Amsterdam, Netherlands; [2]Amsterdam UMC Locatie VUmc, Amsterdam, Netherlands.*

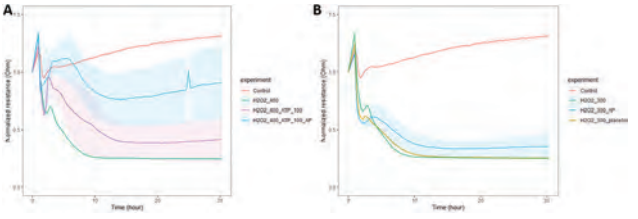
Background: Endothelial damage mediated by oxygen radicals is a key part of ischemia-reperfusion-induced acute kidney injury (IRI-AKI). Nucleotides e.g., adenosine triphosphate (ATP), are released from cells in response to IRI and can cause endothelial barrier disruption. ATP's base, adenosine (ADO), however, might improve barrier function. Alkaline phosphatase (ALP) can dephosphorylate ATP to form ADO. ALP treatment has been shown to protect mice against IRI-AKI. It is unknow if ALP can protect endothelium against IRI.

Methods: We exposed quiescent monolayers of human umbilical vein endothelial cells (HUVECs) to H_2O_2 (300μM and 400μM) and measured the trans-endothelial electrical resistance with Electric Cell-Substrate Impedance Sensing (ECIS). Confocal imaging was used to assess VE-cadherin. HUVECs were co-incubated with either ALP (10IU/ml bovine intestinal ALP), placebo, 100μM ATP, or 100μM ATP with ALP.

Results: Exposure of HUVECs to H_2O_2 led to strong reduction of elctrical resistance, indicating loss of barrier function. Co-treatment with 100 μM of ATP alleviated some of the induced damage. This effect was enhanced by the addition of ALP (Figure A). In the low H_2O_2 concentration, ALP addition resulted in partial rescue of endothelial barrier function (Figure B), however, there were large inter-experimental differences. Partial recovery of endothelial barrier function could be confirmed by immunofluorescent staining of VE-cadherin.

Conclusions: Co-incubation of ATP with ALP reduces H_2O_2 -induced barrier disruption. ALP may protect HUVECs against high levels of oxygen radicals, however, it is unlikely that HUVECs release enough substrate to guarantee stable protection during reperfusion. To determine if ADO generated from ATP dephosphorylation is responsible for the observed barrier protection, endothelial barrier function measurements will be repeated with ADO receptor inhibition.

Funding: Commercial Support - Health Holland B.V. and Alloksys Life Sciences B.V.



Normalized resistance over endothelial monolayer. Red: untreated. Green: H2O2 only. Blue: AP treated with H2O2 with (A) or without (B) ATP. Gold: placebo and H2O2.

FR-PO188

Long Noncoding RNA GSTM3P1/gstm2-ps1 Mediates Sepsis-Associated AKI

Jing Huang,[1,2] Zheng Dong,[1,3] Qingqing Wei.[1] *[1]Augusta University Department of Cellular Biology and Anatomy, Augusta, GA; [2]Department of nephrology, Renmin Hospital of Wuhan University, Wuhan, China; [3]Charlie Norwood Department of Veterans Affairs Medical Center, Augusta, GA.*

Background: Long non-coding RNAs (lncRNAs) are important regulators in various kidney injuries. Our previous study has identified a pro-injurious lncRNA, GSTM3P1 (human orthologue)/gstm2-ps1 (mouse orthologue) in ischemic acute kidney injury (AKI). However, its role in other AKI conditions is unclear.

Methods: More recently, we examined the role of GSTM3P1/gstm2-ps1 in cultured renal proximal tubular cells and in mice with/without proximal tubular specific gstm2-ps1 knockout.

Results: We found that this lncRNA exacerbated sepsis-induced AKI. Overexpression of GSTM3P1 significantly increased the renal proximal tubular cell death induced by LPS treatment, evidenced by the lower cell viability by MTT assay. GSTM3P1 is a lncRNA derived from pseudogene of glutathione S-transferase Mu 3 (GSTM3), which is a protein belonging to GST family and responsible for oxidative stress detoxification by GSH conjugation. We found that GSTM3P1 regulated its parent gene GSTM3 expression, by reducing GSTM3 protein and mRNA level. A lower GSH:GSSG ratio was detected in GSTM3P1 overexpressed cells. Furthermore, the proximal tubular specific gstm2-ps1 knockout mice were protected from LPS induced AKI, showing better renal function and less tubular apoptosis in kidney.

Conclusions: In conclusion, lncRNA GSTM3P1/gstm2-ps1 contributes to renal proximal tubular cell death in sepsis AKI, potentially through the regulation of GSTM3 and enhancement of oxidative stress relief and detoxification.

FR-PO189

Nano-carrier Based Approach to Target the Inflamed Kidney Endothelium

Boaz Y. Bishop,[1,2] Swagat H. Sharma,[1] Simseok A. Yuk,[1] Sultan Almunif,[1] Susan E. Quaggin,[1] Ratnakar Tiwari,[1] Evan Scott,[1] Pinelopi P. Kapitsinou.[1]
[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Rambam Health Care Campus, Haifa, Israel.

Background: Previous studies have demonstrated that endothelial cell (EC) derived mechanisms are sufficient to suppress EC activation of leukocyte adhesion molecules and subsequent inflammation promoting repair from acute kidney injury (AKI). Nevertheless, there are significant challenges for the translation of these findings into the clinical domain, in part because drugs and drug carriers have no natural endothelial affinity. Therefore, precise EC drug delivery is a potential strategy to advance the development of novel therapeutics in AKI. Here, we developed nanocarriers for enhanced drug delivery to inflamed kidney endothelium.

Methods: PEG-b-PPS micelles (MC) were decorated with two different high affinity peptides selected for targeting of inflamed kidney endothelium. The first peptide (CYNTTTHRC) was reported to bind specifically to inflamed endothelial cells (IEC) and is homologue to Scube 1 & 2, previously associated with ischemia reperfusion injury (IRI). The second peptide, (CLPVASC), was reported to bind specifically to kidneys. Average MC diameter (25nm) with PDI<0.1 were assessed by DLS. MC morphology, characterized by MALDI-TOF MS, cryoTEM and by SAX, remained consistent when dual peptides were added. For in vivo studies, we used a unilateral IRI rodent model induced by 30 minutes clamping of renal pedicle.

Results: Using imaging with In vivo imaging system (IVIS) analysis showed a significantly increased uptake of the targeted MC to the ischemic kidney compared to contralateral (non-inflamed) kidney (by 3.4-fold, $p<0.0001$). The uptake was also significantly increased compared to non-targeted MC while at the same time, there was significantly reduced off-target uptake by other major organs such as liver, heart and lungs ($n=8$, $p<0.0001$).

Conclusions: Our work has shown that peptide-based targeting can enhance the delivery of MCs to the post-ischemic kidney. This represents a significant technological advance enabling improved targeted delivery of novel kidney therapeutics.

FR-PO190

Characterization of a Novel Macrocyclic Molecular Glue That Selectively Inhibits the Nucleoside Transporter ENT1 and Demonstrates Tissue Protection in Ischemic-Reperfusion AKI In Vivo

Matthew W. Olson. *Rapafusyn Pharmaceuticals, Baltimore, MD.*

Background: Acute kidney injury (AKI) from renal ischemia and reperfusion (IR) is a major clinical issue, particularly during the perioperative period, and lacks effective therapy. AKI is characterized by a sudden decline in renal function over hours to days from injuries within renal tissue architecture. We report the in-vitro and in-vivo profile of a novel macrocyclic molecular glue (RAP-0001) that exhibits potent and selective inhibition of equilibrative nucleoside transporter 1 (ENT1). These results and our mechanism of action provide a novel therapeutic strategy to mitigate renal damage following ischemic-reperfusion events that occur in cardiovasclar surgeries (CABG and TAVR). Preclinical molecular genetics (1-4), preclinical and human pharmacological evidence via a novel mechanism of action (5-12), and human clinical genetics (13-14) suggest that inhibition of ENT1 would be an effective approach.

Methods: Functional cell-based assays, Biophysical binding assays, X-ray crystallography, In vivo PK and efficacy studies.

Results: RAP-001 forms a ternary complex with FKPB12::RAP-0001::ENT1 on the intracellular side of the cell membrane. RAP-0001 is a potent and selective inhibitor of ENT1 forming molecular glue via the formation of a FKPB12::RAP-0001::ENT1 complex. Our X-ray structure of RAP-0001 bound to FKBP-12 shows the contacts RAP-0001 with FKBP12 where the solvent exposed region can contact ENT1. The efficacy of RAP-0001 was demonstrated in a rat ischemic-reperfusion acute kidney injury model where the compound conferred tissue protection as measured by biomarkers and histological data.

Conclusions: The data presented support the pusuit of IND enabling studies.

Antifibrotic Effects of Caffeic Acid in a Kidney Ischemia-Reperfusion Injured Mouse Model

Giovambattista Capasso,[1,2] Anna Iervolino,[2,1] Mario Zevola,[2,1] Antonio Miele,[2,1] Antonella Iannaccone,[2,1] Benedetta Sasso,[3,1] Francesco Trepiccione,[2,1] Alessandra Perna.[2] *[1]Biogem, Biology and Molecular Genetics Institute, Ariano Irpino, Italy; [2]University of Campania "L. Vanvitelli", Naples, Italy; [3]University of Naples Federico II, Naples, Italy.*

Background: Acute kidney disease due to renal ischemia/reperfusion (I/R) is a major clinical problem without effective therapies. The injured tubular epithelial cells may undergo epithelial–mesenchymal transition (EMT). The formation of scar tissue in the interstitial space during renal remodeling is caused by the excessive accumulation of extracellular matrix components and induced fibrosis. One of the primary causes of end-stage renal illness is renal tubulointerstitial fibrosis. In this work, we examined the effects of a natural phenolic antifibrotic drug, caffeic acid, on a mouse model of renal fibrosis.

Methods: I/R was induced by clamping bilaterally the renal artery and vein for 30 minutes. A single daily oral gavage of caffeic acid (40 mg/kg) was administered following the procedure. Renal fibrosis and kidney function were assessed 14 days later.

Results: The I/R treated with caffeic acid showed a recovery of renal function as compared to the other I/R groups analyzed. This was proven by a significant rise in urinary creatinine and urea excretion, along with a significant decrease in urine volume, serum creatinine, and proteinuria. Histological analysis, using Masson's trichrome and Picrosirius red staining, revealed that renal interstitial fibrosis and collagen deposition were elevated in I/R and significantly decreased in response to caffeic acid treatment, indicating the inhibitory role of caffeic acid on EMT. Then we investigated the effect of caffeic acid on myofibroblast activation markers, such a-SMA. After I/R, immunofluorescence showed a significant increase in a-SMA expression, which drastically decreased with the administration of caffeic acid. Moreover, using DHE, a fluorescent probe for the detection of Ros, specific for superoxide and hydrogen peroxide, we observed a reduction in Ros generation due to the caffeic acid treatment in the I/R group.

Conclusions: In conclusion, our study demonstrates that caffeic acid attenuates renal injury in an I/R animal model, preventing myofibroblast activation, ECM deposition, Ros generation, and renal interstitial fibrosis deposition.

Evaluating Proteomics in a Rat Model of AKI

Denise L. Schwabauer,[1] Jeannie M. Camarillo,[2] Toni L. Richards,[1] Daniel C. Liebler,[2] Kenneth H. Minor.[1] *[1]Inotiv, Inc., Westminster, CO; [2]Inotiv, Inc., Nashville, TN.*

Background: Acute kidney injury (AKI) secondary to acute renal ischemia is associated with high mortality and morbidity, few effective treatments, and risk of chronic kidney disease. AKI therapeutics can be advanced with well characterized disease models, which inform early therapeutic development. Here we describe the proteomic landscape of a rat model of AKI and describe characteristic injury pathways and potential therapeutic targets.

Methods: Rats were subjected to sham or warm, bilateral renal ischemia (40′) using proprietary vascular clamps. Rats were housed in metabolic cages for 24 or 48 hours post-reperfusion. In 24 hour intervals, blood and urine samples were collected and evaluated for progression of kidney injury biomarkers. At each endpoint, renal tissue was harvested and subjected to global proteomic analysis using tandem mass tags (TMT) and high resolution mass spectrometry (MS) to define quantitative changes in the kidney proteome following renal ischemia/reperfusion (I/R). Gene set enrichment analysis (GSEA) was utilized to identify cellular pathways significantly altered between sham and I/R timepoints.

Results: Proteomic analysis identified 3,084 proteins that were altered across the I/R time course. GSEA identified several protein networks and pathways that displayed time-dependent alteration with development of AKI. Pathways significantly upregulated with injury include complement and coagulation cascades, cell adhesion and metabolic pathways, and kidney inflammation/injury-associated pathways. Proteomic alterations were correlated with data from orthogonal approaches including gene expression profiling and immunohistochemistry.

Conclusions: Proteomic profiling captures both well-characterized and novel molecular alterations underlying renal injury. Global proteomics enables quantitative assessment of changes in the kidney proteome in the progression of AKI. GSEA with rich proteome data enables rapid identification of cellular pathways significantly altered following renal I/R and represents all the features of the injury phenotype. Variations of the protocol may enable nuanced dissection of injury. Moreover, targeted MS provides robust biomarker assays for any protein, without antibodies. Distinct biomarker expression profiles of varying durations of renal I/R can identify potential therapeutic targets and possible new AKI diagnostic markers.

Role of HTRA1 in an Ischemia-Reperfusion (I/R)-Induced AKI-Mice Model

Naruemon Wikan,[1] Laurence H. Beck,[3] Laith Al-Rabadi,[1] Chio Oka.[2]
[1]The University of Utah School of Medicine, Salt Lake City, UT; [2]Nara Sentan Kagaku Gijutsu Daigakuin Daigaku Sentan Kagaku Gijutsu Kenkyuka Bioscience Ryoiki, Ikoma, Japan; [3]Boston University, Boston, MA.

Background: Ischemia-Reperfusion (I/R), commonly observed in surgical settings, heightens risks of acute kidney injury (AKI), mainly attributed to sudden decreases in blood flow, which cause deoxygenation and increases in reactive oxygen radicals. An important member of the heat-shock-induced serine protease group, HTRA1 plays a role in extracellular matrix's homeostasis, by cleaving numerous substrates.

Methods: As HTRA1's role in kidney functions has yet to be elucidated, the research group opted to investigate its function in the AKI I/R setting. HTRA1-knockout (KO) and wild type (WT) mice (C57BL/6) underwent unilateral renal pedicle clamping, thereby replicating AKI I/R injury with a flank incision with 30 m occlusion time until nephrectomy and after 24 h and 72 h reperfusion.

Results: Renal tubular injury was observed in WT and KO mice, after 24 hours. However, it was prolonged and persistent in the HTRA1 KO mice, and still evident after 72 hours. This was supported by the presence of the kidney injury molecule-1 (KIM-1), an AKI marker. Regarding AKI I/R-KO there were significantly increased inflammatory cascade and oxidative stress, along with decreased levels of anti-oxidant and autophagy activation.

Conclusions: HTRA1 could play an efficacious role in kidney recovery, given the impact of AKI I/R's role in causing renal tubular injury.

FR-PO194

Angiotensin-Converting Enzyme 2 in AKI Was Attenuated by Uremia Toxin Indoxyl Sulfate and Restored by Renin-Angiotensin-Aldosterone System Inhibitors

Guang-huar Young,[1,3] Vincent Wu.[2] The Consortium for Acute Kidney Injury and Renal Diseases (CAKs). *[1]Department of Biomedical Sciences, Chang Gung University, Taoyuan, Taiwan; [2]National Taiwan University Hospital, Taipei, Taiwan; [3]Kidney Research Center and Department of Nephrology, Chang Gung Memorial Hospital, Taoyuan, Taiwan.*

Background: The accumulation of uremic toxins in patients after acute kidney injury (AKI) is harmful to long-term adverse outcome, but their effects on the severity of AKI by affecting intra-renal renin-angiotensin-aldosterone-system (RAAS) remain uncertain. Indoxyl sulfate (IS) as a representative uremic toxin, causes well-known detrimental effects during kidney injury.

Methods: Human renal proximal renal cells (HK2) were provoked with cobalt chloride to induce hypoxia injury and then supplied with indoxyl sulfate (IS) for the designated time peroids. Cell proliferation was mwasured by MTT assay and cellular ROS was evakuated by DCFDA methods. Male w/t (C57BL6) and homozygous angiotensin-converting enzyme 2 (ACE2)-knockout mice were used for animal model of AKI with uremia. Mice were randomly assigned to six groups: (1) Negative control group; (2) AKI group, unilaterial renal ischemia/reperfusion (I/R) injury to induce AKI; (3) AKI/IS group, AKI mice received IS injection; AKI/IS mice administrated with (4) direct renin inhibitor (DRI), (5) angiotensin II receptor blocker (ARB), and (6) alpha-1-adrenergic blocker, respectively.

Results: Cell study examined the expressions of ACE2 and related downstream metabolites under hypoxia/IS-induced injury. HK2 exposed to cobalt chloride/IS raised cellular oxidative stress and reduced ACE2 levels. These effects were mitigated by DRI or ARB treatment. Similarly, IS activated the ACE/angiotensin II axis of RAAS in mice after renal I/R injury and caused the reduction of ACE2 in mice kidneys. RAASi administration restored the renal ACE2 expression and Angiotensin1–7 (Ang1-7) levels and reduced neutrophil gelatinase-associated lipocalin expression and reactive oxygen species production in IS-enhanced AKI mice. Yet, these effects were absent in ACE2-knockout mice, even after RAASi therapy. Renal microcirculation analysis also showed that RAASi therapy improved the renal hypoperfusion, especially in AKI/IS mice. In hypertensive CKD patients, both DRI and ARB attenuated oxidative stress and increased serum Ang1-7 levels. ARBs, but not DRI, further restored patients' serum ACE2 levels.

Conclusions: Our study revealed that IS enhanced the suppression of the ACE2/Ang1-7 axis in intrarenal RAAS after I/R injury, whereas RAASi restored ACE2 expression and decreased oxidative stress.

Expression and Functional Effect of ACE2 in Heme Protein-Mediated AKI (HP-AKI) in Rodents

Anthony J. Croatt, Raman D. Singh, Allan W. Ackerman, Karl A. Nath.
Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN.

Background: Our prior study demonstrated that ACE2 expression is markedly reduced following acute renal ischemia (IRI-AKI) [Kidney360 2(7):p 1095-1106, 2021]. As ACE2 has previously been shown to be protective in IRI, we now investigate whether a similar expression profile exists in HP-AKI, and the functional significance of ACE2 in this model.

Methods: The glycerol model of HP-AKI was induced in Sprague Dawley rats and C57BL/6J mice by intramuscular injection (6 and 5 mL/kg, respectively). $ACE2^{+/+}$ and $ACE2^{-/-}$ mice were also subjected to HP-AKI (6 mL/kg). Assessments of ACE2 mRNA and protein expression were performed, as well as measurements of renal ACE2 activity. Assessments of renal functional markers (serum creatinine and BUN) were also undertaken.

Results: In the rat, ACE2 mRNA and protein were both reduced significantly at 1 day after induction of HP-AKI. At 2 days after HP-AKI, ACE2 protein expression and activity were both markedly reduced (by approximately 50% and 36%, respectively). In the mouse, ACE2 mRNA expression was reduced at 1 day post HP-AKI induction (8.4±1.0 vs 4.2±0.4, P=0.0013), but was not significantly altered at 8 hours after HP-AKI induction. Serum creatinine following HP-AKI was significantly lower in $ACE2^{-/-}$ mice, compared with $ACE2^{+/+}$ mice (2.2±0.1 vs 2.7±0.1 mg/dL, P=0.0096). BUN levels, however, were not significantly different between $ACE2^{+/+}$ and $ACE2^{-/-}$ mice subjected to HP-AKI at this time point.

Conclusions: As in our previous IRI-AKI studies, the present rat and mouse studies show that ACE2 mRNA, protein, and activity levels are all significantly reduced after HP-AKI induction (as early as 1 day and through at least 2 days). In contrast to prior studies showing that ACE2 deficiency exacerbates the IRI-AKI model, our studies failed to show a similar exacerbation in $ACE2^{-/-}$ mice subjected to HP-AKI. Indeed, as assessed by 1 of 2 functional markers (serum creatinine), we observe a mild protective effect of ACE2 deficiency. These findings point to significant differences between IRI-AKI and HP-AKI as regards the functional roles of ACE2. Further study is required to delineate the basis for the reduced expression of ACE2 in HP-AKI and the functional significance of ACE2 in this model.

Deficiency of Leucine-Rich α2-Glycoprotein 1 Suppresses Kidney Fibrosis Caused by Ischemia-Reperfusion Injury

Naohito Okami, Hiromichi Wakui, Kengo Azushima, Shinya Taguchi, Tomohiko Kanaoka, Kouichi Tamura. *Yokohama Shiritsu Daigaku, Yokohama, Japan.*

Background: Acute kidney injury (AKI) is recognized for its potential to progress into chronic kidney disease (CKD), a transition known as AKI to CKD. Developing strategies to manage this progression is crucial. Ischemia-reperfusion injury (IRI) serves as a model for AKI and is known to lead to renal fibrosis over time, primarily through the TGF-β pathway. Leucine-rich alpha-2-glycoprotein 1 (LRG1) is endogenously expressed in renal tubular epithelial cells and regulates renal fibrosis by modulating the TGF-β/Smad3 signaling pathway (Kidney Int, 2022). Additionally, LRG1 silencing attenuates AKI following IRI by regulating autophagy and apoptosis via the TGFβ1-Smad1/5 signaling pathway (Arch Biochem Biophys, 2024). However, the role of LRG1 during the remodeling phase of IRI remains unclear. This study investigates the functional role of LRG1 in the AKI to CKD transition using the IRI model in systemic LRG1 knockout (KO) mice.

Methods: *Experiment 1*: Unilateral IRI was performed on wild-type (WT) 6- to 8-week-old male C57BL/6 mice. Ischemia was induced by a retroperitoneal approach to the left kidney using an atraumatic vascular clip for 30 minutes. Mice were sacrificed at 2, 7, 14, and 28 days after surgery to evaluate renal histological findings and LRG1 expression. *Experiment 2*: Male LRG1 KO mice and their littermate control (LC) mice, aged 6-8 weeks, underwent unilateral IRI. They were sacrificed on days 2, 7, and 28 post-surgery for renal histological comparison.

Results: *Experiment 1*:LRG1 mRNA expression in the kidney was significantly higher on the operated side than on the sham side throughout the period, peaking on day 7 and then gradually decreasing. *Experiment 2*: LRG1 KO mice exhibited significantly

reduced renal fibrosis area compared to LC mice on day 28. Furthermore, renal mRNA expression levels of collagen type 1 and type 3, as well as TGFβ, were lower in LRG1 KO mice than in LC mice on day 28 postoperatively, concomitant with the suppression of TGF-β signaling pathway.

Conclusions: Renal LRG1 expression was persistently upregulated until the remodeling phase after IRI. LRG1 knockout mice showed suppression of chronic fibrosis post-IRI and a reduction in TGF-β signaling. Therefore, LRG1 is implicated in the pathogenesis of the AKI to CKD transition and represents a potential therapeutic target.

Histologic and Immunologic Phenotypes of Immune Checkpoint Inhibitor-Mediated Nephrotoxicity in a Novel Humanized Immune System Mouse Model

Sarah C. Asby,[1] Lauren E. Thompson,[1] Michael J. Goedken,[2] Jordi Lanis,[1] Zander C. Kostka-Newman,[1] Roberta Pelanda,[1] Julie Lang,[1] Lauren Aleksunes,[2] Melanie S. Joy.[1] *[1]University of Colorado Anschutz Medical Campus, Aurora, CO; [2]Rutgers The State University of New Jersey, Piscataway, NJ.*

Background: Kidney immune-related adverse events (irAEs) following cancer treatment with immune checkpoint inhibitors (ICIs) have been observed in 5-25% of patients, with approximately 20% developing new onset chronic kidney disease within 5 years. Humanized immune systems (HIS) mouse models, as opposed to conventional syngeneic pre-clinical mouse models, represent a promising avenue for detecting and evaluating irAEs. The purpose of this study was to characterize the histologic and immunologic phenotypes of ICI-mediated kidney toxicity in humanized immune system (HIS) mice.

Methods: At 17-21 weeks of age, non-humanized (BRGS) and humanized (HIS-BRGS) mice were implanted s.c. with MDA-MB-231 cancer cells and treated with vehicle (PBS) or a combination of ipilimumab and nivolumab (ipi/nivo 10 mg/kg each 1x/wk) i.p. for 4 weeks. H&E-stained sections of kidneys were analyzed for histomorphological evidence of injury with incidence and severity scores (0=none, 1=mild, 2=moderate, and 3=severe), rank ordered and assessed by two-way ANOVA. Tissue sections from formalin-fixed kidneys were co-stained for molecular markers of human immune cell populations and single cell spatial proteomics performed using ChipCytometry (Canopy Biosciences). Flow cytometry was performed on collected tissues and assessed using Welch and Brown-Forsythe ANOVA. $P<0.05$ was considered statistically significant.

Results: Ipi/nivo treatment significantly reduced tumor weight compared to vehicle in HIS-BRGS mice ($p<0.01$). Histological evaluation from ipi/nivo treated HIS-BRGS mice showed increased incidence and severity of renal pathologies including vasculitis/periarteritis ($p<0.001$) and interstitial nephritis ($p<0.05$) compared to vehicle-treated HIS-BRGS mice and non-humanized BRGS mice ($p<0.001$). Ipi/nivo-treated HIS-BRGS mice showed reductions in the % CD8+ T cells and CD4+ T reg cells ($p<0.05$, $p<0.06$) and increase in % TNFα+ CD4+ T cells in the kidneys ($p<0.05$). Single cell proteomics showed a majority of CD4+ T helper vs. CD8+ cytotoxic T cells of total CD45+ cells in the region of kidney injury.

Conclusions: This study demonstrated the utility of a novel HIS mouse model as a translational tool to study the histological and immunological phenotype of ICI-mediated kidney injury.

Impact of Immune Checkpoint Inhibitors on AKI Incidence and Mortality in Patients with Bladder Cancer: A Single-Center Experience

Shina Lee, Seung-Jung Kim. *Ewha Womens University Mokdong Hospital, Seoul, Republic of Korea.*

Background: Immune checkpoint inhibitors (ICPi) have increasingly become a therapeutic option for bladder cancer. Among bladder cancer patients, ICPi-associated acute kidney injury (AKI) has emerged as a significant toxicity. This study aims to describe the incidence, risk factors, renal outcomes, and mortality of AKI in patients receiving ICPi.

Methods: Patients who received ICPi between January 2021 and December 2021 at a single institution were retrospectively identified using the electronic medical database. AKI was defined as an increase in serum creatinine of ≥1.5 times the baseline value, based on the Kidney Disease: Improving Global Outcomes criteria. Cox proportional hazard regression analysis was used to assess risk factors for AKI and to evaluate the relationship between AKI and mortality.

Results: Among 108 patients with bladder cancer receiving checkpoint inhibitors, the overall incidence of AKI was 55.6%. Half of all AKI cases were associated with checkpoint inhibitors. Checkpoint inhibitor-associated AKI was mostly low-grade and occurred a median of 2 months after initiating the checkpoint inhibitors. AKI stage, the period from ICPi initiation to AKI occurrence, and the use of H2 blockers differed significantly between the non-ICPi AKI group and the ICPi-AKI group. However, the presence of all-cause AKI or checkpoint inhibitor-associated AKI did not lead to increased mortality.

Conclusions: This study shows that AKI frequently occurs in bladder cancer patients receiving ICPi. However, the presence of all-cause AKI and AKI related to ICPi toxicity did not increase mortality in these patients.

Cox proportional hazard regression analysis of relationship between AKI group and mortality.

	Crude	Adjusted
	HR (95%CI)	HR (95%CI)
No AKI	Reference	Reference
AKI development	55.2(0.25 - 4217)	0.91 (0.80-1.04)
ICPi related AKI	2.52 (0.67 - 9.39)	0.27 (0.05 - 1.42)
Non ICPi related AKI	2.94 (0.79 - 11.0)	3.06 (0.70 - 18.5)

Infliximab for Immune Checkpoint Inhibitor-Associated Acute Interstitial Nephritis: A Biomarker-Guided Approach

Elena-Bianca Barbir, Priscilla Koirala, Luis E. Gutierrez, Sandra Herrmann. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Immune checkpoint inhibitor associated acute interstitial nephritis (ICI-AIN) occurs in 3-5% of patients receiving ICI therapy, and is typically steroid responsive. A minority of cases are steroid dependent. We review the outcomes of patients with steroid-dependent ICI-AIN treated with Infliximab at our center, as well as the relationship between several non-invasive biomarkers and response to therapy.

Methods: We describe 3 cases of biopsy-proven ICI-AIN for which Infliximab was used as a steroid sparing agent. We followed several biomarkers including: urine CXCL9, urine TNF-α, urine RBP -- all normalized to creatinine, serum IL2r and CRP at varying time points in the disease course. Serum TNF-α was measured to monitor Infliximab response.

Results: Clinical characteristics are described in Table 1. Figure 1 depicts biomarker trends over time as a function of therapy. All 3 patients had relapse of their ICI-AIN with prednisone taper ≤ 20 mg. Post 1 infliximab infusion, patient 2 was tapered off steroids. Patient 1 and 3 remained on Prednisone 10 mg post 2 doses of Infliximab for other indications. Serum TNF-α was suppressed with Infliximab in all cases. All patients had elevated urine TNF-α/Cr, CXCL9/Cr, RBP/Cr, and serum IL2r at initial diagnosis which decreased with therapy. When measured around the time of ICI-AIN relapse, urine RBP/Cr, CRP, urine TNF-α/Cr, and urine CXCL9/Cr all rose.

Conclusions: In all cases, Infliximab facilitated steroid taper and biomarker trends helped determine the number of Infliximab doses before significant rises in creatinine occurred. Controlled studies are needed to clinically validate these biomarkers for ICI AIN diagnosis and relapse.

Table 1

	Patient 1	Patient 2	Patient 3
Age (y) and Sex	63, Male	90, Female	74, Male
Cancer Type and ICI Therapy	Renal Cell Carcinoma, on Ipilimumab and Nivolumab	Breast Cancer, on Pembrolizumab	Non-Small Cell Lung Cancer, on Pembrolizumab
Preceding Immune Related Adverse Events	Pneumonitis, Hypophysitis	Myocarditis	Myocarditis
ICI Re-Challenge	Yes, on Prednisone 10 mg daily	No, cancer remains in remission	Yes, on Prednisone 10 mg daily

Hidden Kidney Impact of Immunotherapy in Patients with Metastatic Kidney and Bladder Cancer: "Nothing Is What It Seems"

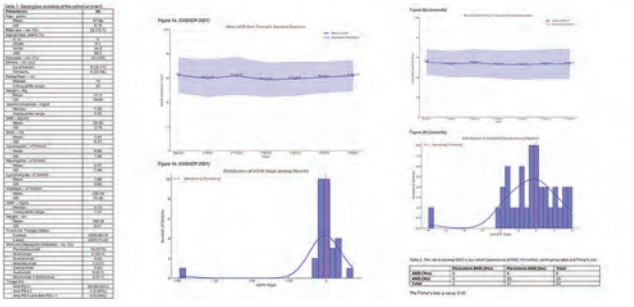
Francesco Trevisani,[1] Andrea Angioi,[2] Matteo Floris,[2] Mariadelina Simeoni,[3] Barbara Galassi,[4] Fiorella Ruatta,[4] Ornella Garrone,[4] Michele Ghidini.[4]
[1]IRCCS Ospedale San Raffaele, Milano, Italy; [2]Azienda Ospedaliera Brotzu, Cagliari, Italy; [3]Universita degli Studi della Campania Luigi Vanvitelli, Caserta, Italy; [4]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy.

Background: Immunotherapy has emerged as a pivotal treatment for metastatic renal and bladder cancer. Hovewer, its impact on renal function in term of Acute Kidney Disease (AKD), remains a critical concern. In addiction, the role of nephrologist in this asset of patients remains ancillary and only related to AKI events. Therefore, our aim was to elucidate the incidence and persistence of the insidious and dangerous AKD condition in a cohort of 33 consecutive urological metastatic pts subjected to immunotherapy.

Methods: We conducted a retrospective analysis of 33 patients receiving first-line immunotherapy for metastatic renal and bladder cancer. Patient demographics, clinical characteristics, and treatment details were extracted. Labs were done monthly and kidney function was assessed with eGFR (CKD-EPI 2021; Janowitz formula). AKD was defined as an increase in serum creatinine by ≥0.3 mg/dL or an increase to ≥1.5 times the baseline, persisting for ≥7 days post-exposure and < 3 months in line with K-DIGO 2023 guidelines.

Results: Descriptive analysis is shown in table 1. The incidence of AKD in 6 months of treatment was 24.24%, observed in 8 patients; among these, 6.06% (2 patients) exhibited persistence of AKD over three consecutive months, which was significant at Fisher's test (p=0.05). The slope of eGFR from baseline to six months showed that most patients had minimal changes in kidney function, with a mean slope of 0.634 mL/min/1.73m^2 per month (Figures 1a, 2a,1b,2b). Notably, some patients experienced significant declines, with slopes as steep as -40 mL/min/1.73m^2 per month.

Conclusions: This innovative study highlights for the first time a significant and unexpected incidence (24%) of AKD in patients treated with immunotherapy for metastatic renal and bladder cancer. Because AKD can often evolve in CKD, an onco-nephrological counseling able to reduce the incidence of AKD is mandatory



FR-PO201

Measured GFR Using Renal Scan Improves Preoperative Clinical Decision in Patients with Kidney Cancer Who Are Surgical Candidates

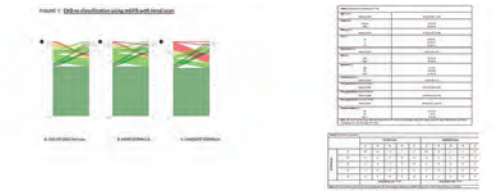
Francesco Trevisani, Giuseppe Rosiello, Pietro Scilipoti, Giacomo Musso, Chiara Re, Francesco Cei, Federico Belladelli, Francesco De Cobelli, Arturo Chiti, Fabrizia Gelardi, Francesco Montorsi, Andrea Salonia, Roberto Bertini, Umberto Capitanio. *IRCCS Ospedale San Raffaele, Milano, Italy.*

Background: Measured GFR (mGFR) using Renal scan before renal surgery represents a precise tool able to better define the "real" renal status of oncological patients candidate to partial or radical nephrectomy. Moreover, Renal scan can also show the split renal contribution of kidneys. Nevertheless, its use in the preoperative workflow is controversial. Thus, we aimed at evaluating the role of renal scan in patients undergoing renal surgery comparing the mGFR with the most used eGFR formulas.

Methods: We prospectively performed renal scan in 94 patients undergoing kidney surgery for cT1-2 renal mass between 2019 and 2022. Renal scan GFR measurement was compared with the most used eGFR formulas (MDRD, CKD-EPI 2021, JANOWITZ). CKD stages were defined according to the KDIGO 2023 classification. Sankey diagram was used to depict concordance between the different GFR estimates.

Results: Descriptive analysis is shown in table 1. The agreement between eGFR formulas and measured GFR using renal scan is represented in table 2. Using the mGFR via renal scan, the baseline pre-operative reclassification of patients was greater than 35% with each type of eGFR formulas. (Figure 1).

Conclusions: If renal scan is routinely used before kidney surgery, patient reclassification is observed in a non-negligible proportion of patients. Moreover, renal scan can identify patients with different split renal function, which does represent a key information for surgical planning and nephrological counseling.



FR-PO202

National Audit of Immune Checkpoint Inhibitor Use in Kidney Transplants

Blathnaid O'Connell,[1] Cliona Cowhig,[2] Jennifer B. Hanko,[3] Michael Clarkson,[2] Peter J. Conlon.[1] *[1]Beaumont Hospital, Dublin, Ireland; [2]Cork University Hospital, Cork, Ireland; [3]HCS Belfast Health and Social Care Trust, Belfast, United Kingdom.*

Background: Cancer is one of the leading causes of death in kidney transplant patients. The incidence of skin cancers among solid organ transplant recipients (SOTR) is markedly higher than general population. Immune checkpoint inhibitors (ICPIs) have revolutionized cancer treatment and have become standard of care for many cancers, including cutaneous malignancies. However, SOTR have been excluded from trials due to risk of allograft rejection, and because immunosuppression may compromise the anti-tumour effect of ICPIs. To date, this is the first case series looking at outcomes of this patient cohort in Ireland.

Methods: This was a multicentre retrospective study assessing kidney transplant recipients treated with ICPIs in Ireland. Cases were identified by members of the Irish Nephrology Society. Data collection included demographics, history of the transplantation, tumour type, ICPI use, changes to immunosuppression and outcomes.

Results: Five patients were included (4 male, 1 female), aged 54–72 years. Three patients received DBD transplants + 2 received living related transplants. 80% had metastatic melanoma, 20% had metastatic squamous cell carcinoma. Four patients were maintained on calcineurin inhibitors (CNI), mycophenolate mofetil (MMF) & prednisolone prior to diagnosis. One was on a CNI & prednisolone alone. Three patients commenced pembrolizumab, one commenced nivolumab and one commenced ipilimumab/nivolumab. None had systemic cancer treatments. MMF was stopped in all relevant cases, and prednisolone dose increased in one case. The majority weaned/stopped their CNI at ICPI initiation, but one switched from tacrolimus to sirolimus. One patient had a transplant biopsy, showing borderline T-Cell mediated rejection. Three patients (two on pembrolizumab, one on nivolumab) had reduction in metastatic burden and showed no evidence of disease progression at 25, 44 and 32 months, respectively and are currently maintained on treatment. All 3 returned to haemodialysis within 42-79 days of ICPI initiation. Two patients died at 53 days & 67 days post ICPI initiation.

Conclusions: The efficacy of ICPIs in kidney transplant patients appears promising, warranting prospective clinical trials. There are currently no guidelines on the use of ICPIs in SOTR, but ultimately, when the question becomes of life versus graft, discussion between the patient & physician is crucial.

FR-PO203

Delayed Immune Checkpoint Inhibitor-Induced Acute Tubulointerstitial Nephritis (ICI-ATIN) Relapse with Proton-Pump Inhibitor Re-exposure Despite ICI Discontinuation: A Case Report

Julia G. Andres,[1] Joycelyn Jie Xin Lee,[2] Hui Zhuan Tan.[1] *[1]Singapore General Hospital, Singapore, Singapore; [2]National Cancer Center Singapore, Singapore, Singapore.*

Introduction: While immune-related adverse events (irAEs) usually occur during active use of immune checkpoint inhibitors (ICI), their sporadic development after ICI discontinuation has been rarely described. We report a case of delayed ICI-acute tubulo-interstitial nephritis (ICI-ATIN) relapse occurring in context of proton pump inhibitor (PPI) re-exposure despite ICI cessation.

Case Description: An 84-year-old Chinese female with colorectal cancer was referred for KDIGO Stage 2, non-oliguric acute kidney injury (AKI) [baseline sCr 84μmol/L, peak sCr 162μmol/L] 4 months after initiation of pembrolizumab. Urinalysis showed hematuria (28 RBC/μL), pyuria (85 WBC/μL) and minimal proteinuria (uPCR 0.35g/g). Only ANA was borderline detected (titre 1:160), while the remaining autoimmune markers were negative. PPI use, but not NSAIDs or antibiotics, was noted. As ICI-ATIN was highly suspected, she received a 10-week tapering course of empiric prednisolone (0.7mg/kg starting dose) with clinical improvement (recovery sCr 112μmol/L). She remained off immunotherapy over the next 5 months, but was inadvertently restarted on PPI for dyspepsia. AKI was observed 4 weeks later (peak sCr of 190μmol/L). ATIN was confirmed on kidney biopsy. Prednisolone at 1mg/kg was recommenced, with improvement of sCr to 124μmol/L after 7 weeks. Vonaprazan was started for dyspepsia. PPI was permanently stopped and recorded as an adverse drug reaction.

Discussion: Our case highlights important observations concerning the use of PPI in ICI-treated patients. The temporal correlation of PPI re-exposure and ATIN relapse supports the postulation that PPI potentiates the development of ICI-ATIN. While PPI avoidance is recommended in ICI rechallenge, it is unknown if and when PPI can be safely resumed after ICI is permanently withdrawn. Long-lasting effects of ICIs surpassing their pharmacokinetic half-lives have been described, with resultant implications for their related immune-related toxicities. We advise continued caution with PPI use in all patients with a history of ICI-ATIN, even when ICI is stopped. Awareness of this association amongst healthcare providers (HCPs) is necessary as PPI use is common. Systematic documentation of irAEs with disease-specific codes, as well as implementation of EHR alerts to identify and inform HCPs of potential irAE triggers are additionally required.

FR-PO204

Sequential Development of Immune Checkpoint Inhibitor-Induced Acute Tubulointerstitial Nephritis (ICI-ATIN) following Stevens-Johnson Syndrome (SJS)-Like Reaction in Patient on Pembrolizumab and Meropenem: A Common Drug Trigger?

Julia G. Andres,[1] Joycelyn Jie Xin Lee,[2] Hui Zhuan Tan.[1] *[1]Singapore General Hospital, Singapore, Singapore; [2]National Cancer Center Singapore, Singapore, Singapore.*

Introduction: Multisystem immune-related adverse events can occur with immunotherapy but their predictors and implications remain unknown. We report a case of immune checkpoint-related acute tubulo-interstitial nephritis (ICI-ATIN) occurring successively after progressive immunotherapy-related mucocutaneous eruption (PIRME), an ICI-related Steven Johnson syndrome (SJS)-like reaction, in the context of meropenem exposure.

Case Description: A 71-year-old Chinese Male receiving pembrolizumab therapy for Stage IV bronchial squamous cell carcinoma, was referred for evaluation of KDIGO Stage 3, non-oliguric AKI [baseline sCr 76 μmol/L, peak sCr 353 μmol/L], occurring one week after the development of biopsy-proven PIRME. Notably, patient received meropenem in the last two weeks for treatment of lung abscess. There was no exposure to PPIs or NSAIDs. First and last dose of ICI were given 9 weeks and 3 weeks prior to AKI, respectively. Evaluation showed mild pyuria (urinary WBC 10/μL) and sub-nephrotic range proteinuria (uPCR 0.90 g/g). Serum C-reactive protein was elevated at 90.5 mg/L. Autoimmune markers and virologies were negative. Prednisolone at 60mg OD (1mg/kg) was started empirically. Kidney biopsy performed subsequently confirmed ATIN. Rebound of AKI observed after 4 weeks, and mycophenolic acid 360mg BD was added. Partial renal remission was observed after 3 months (sCr 107μmol/L).

Discussion: Our case supports the hypothesis that multisystem irAEs may represent a combination of irAEs that share common pathobiology such as HLA genotypes, autoantibody formation or external triggers such as co-medications (PPIs, NSAIDs and antibiotics). Co-medications have been increasingly implicated in the development of ICI-ATIN, which is postulated to be a result of drug-mediated, kidney-specific immune responses occurring unchecked in the setting of lowered immune tolerance during ICI use. A similar phenomenon has been proposed in the development of PIRME. It is probable that meropenem triggered both cutaneous and renal irAEs in our patient. Patients with PIRME should receive close monitoring of renal function during and after the event. ICI-ATIN occurring together with PIRME may warrant extended or additional immunosuppression, although more research is required to confirm our findings.

FR-PO205

IgG4-Tubulointerstitial Nephritis Due to Pembrolizumab

Alice H. Won,[2,1] Steven Salvatore,[1] Insara Jaffer Sathick.[2] *[1]Weill Cornell Medicine, New York, NY; [2]Memorial Sloan Kettering Cancer Center, New York, NY.*

Introduction: Immune checkpoint inhibitors (ICIs) such as pembrolizumab have revolutionized cancer treatment by promoting T cell-mediated antitumor response. There have been increasing reports of ICI-related renal toxicity such as acute tubulointerstitial nephritis (ATIN). Here we describe a case of IgG4 tubulointerstitial nephritis (IgG4-TIN) associated with pembrolizumab in a patient with metastatic serous endometrial carcinoma.

Case Description: The patient is a 71-year-old woman with history of hypertension, diabetes mellitus, and serous endometrial carcinoma who had undergone surgical removal, radiation, and chemotherapy (carpoplatin-taxol) with metastatic recurrence to the peritoneum. She was started on pembrolizumab 200 mg every 3 weeks and received 23 doses when she was hospitalized for recurrent acute kidney injury in the setting of urinary tract infection complicated by hydronephrosis. Laboratory findings showed elevated serum creatinine (sCr) of 4.1 mg/dL (from 1.0 mg/dL) with microscopic hematuria, pyuria, and proteinuria (urine protein-creatinine ratio 1.2 g/g). Kidney biopsy was performed due to persistent AKI despite successful stent placement, revealing diffuse tubulointerstitial inflammation with lymphoplasmacytic cell infiltration stained positive for IgG4. Immunoglobulin levels showed elevated IgG (2,347 g/L) and IgG4 (207 g/L) levels. She was started on prednisone 60 mg daily with subsequent improvement in sCr to 2.1 mg/dL, transitioned to a slow taper. At 18-month follow-up, sCr was 1.1mg/dL without any new symptoms. After discontinuing pembrolizumab she was treated with trastuzumab with continued tumor response.

Discussion: Here, we report a novel toxicity of ICIs in the form of IgG4-TIN, which is characterized by rich IgG4-positive plasma cell infiltration as well as serologic abnormalities including elevated serum IgG, IgG4, and IgE. We hypothesize that immune dysregulation induced by ICIs can manifest as IgG4-TIN in rare cases, as observed in our patient. Prompt discontinuation of ICI and initiation of steroid therapy are effective in the management of this complication.

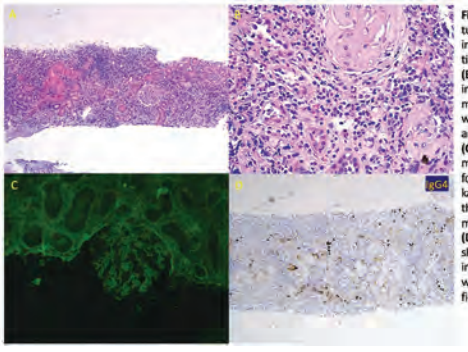


Figure 1: (A) Diffuse active tubulo-interstitial inflammation involving >90% of the cortical tissue (PAS). **(B)** Interstitial inflammatory infiltrates are composed of mainly plasma cells admixed with lymphocytes, eosinophils, and some macrophages (PAS). **(C)** Immunofluorescence microscopy reveals no staining for IgG, IgA, complements, kappa or lambda light chains – there are no immune-complex mediated lesions. **(D)** Immuno-peroxidase stain shows positive staining for IgG in all infiltrating plasma cells, with >8-10 cells per high-power field positive for IgG4.

FR-PO206

Rituximab in Treatment of Glomerulonephritis Induced after Immune Checkpoint Inhibitors

Yazen Alasadi,[1] Naszrin Arani,[1,2] Amanda Tchakarov,[3] Ala Abudayyeh.[1] *[1]The University of Texas MD Anderson Cancer Center, Houston, TX; [2]Baylor College of Medicine, Houston, TX; [3]The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX.*

Introduction: Immune checkpoint inhibitors have been shown to induce and exacerbate autoimmune side effects especially in those patients with underlying autoimmune disease. Although glomerular disease is a rare entity (less than 1%), it adds further complexity to the cancer patients care. In this report we describe 4 cases of glomerulonephritis successfully treated with rituximab and resumed ICI with continued renal response.

Case Description: A 64-year-old with diagnosis of mesothelioma and treated with nivolumab, after two cycles he developed nephrotic range proteinuria with biopsy confirmation of membranous nephropathy with positive antibody to PLA2R. The patient was initiated on rituximab 1 g IV on Day 1 and 15 and achieved complete renal response while continuing therapy on nivolumab for 3 years and PET/CT imaging ccancer remission and serum Anti-PLA2R negative. Another patient is a 71 y.o with diagnosis of squamous cell cancer of the anal canal who did not respond to cisplatin and 5 FU and was started on nivolumab. After fourth cycle she developed 15g proteinuria. Biopsy confirmed minimal change disease and treated with a short dose of steroids and rituximab. She achieved complete remission of her proteinuria and tumor response with continued ICI treatment. The third case is a 65 y.o male with primary membranous nephropathy 20 years ago with reactivation after Stage IV Melanoma diagnosis and exacerbated ICI treatment. Rituximab achieved excellent response and resolution of proteinuria after one cycle which was maintained on ICI for over 2 years with no exacerbation of his membranous nephropathy and complete tumor response. Our final case is a 65 y.o. male with diagnosis of anaplastic thyroid carcinoma, treated with dabrafenib, trametinib, and pembrolizumab. 2 weeks after pembrolizumab patient developed AKI creatinine increase 3.5mg/dl, nephrotic range proteinuria. Kidney biopsy attained confirmed minimal change disease. He was treated with rituximab and proteinuria improved from 20grams to 0.5 grams. Patient was restarted on pembrolizumab and after 2 doses creatinine is less than 0.9mg/dl and proteinuria less than 1gram.

Discussion: In this report we have presented four unique cases of membranous nephropathy and minimal change disease in a cancer patient after ICI exposure successfully treated and re-challenged on ICI with continued renal and tumor response.

FR-PO207

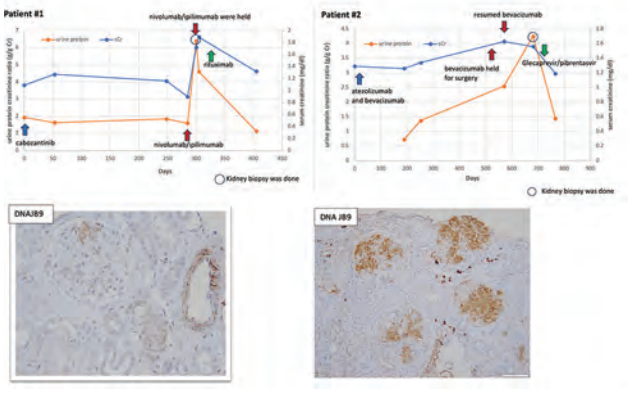
Fibrillary Glomerulonephritis in a Patient on Dual Immune Checkpoint Inhibitor and Tyrosine Kinase Inhibitor Therapy

Api Chewcharat, Raad B. Chowdhury, Romela Petrosyan, Sujal I. Shah, Shruti Gupta. *Brigham and Women's Hospital, Boston, MA.*

Introduction: Fibrillary glomerulonephritis (FGN) is a glomerular disease characterized by nonbranching, randomly arranged 20 nm fibrils which usually stain positive for DNAJB9. The pathogenesis of FGN remains unclear, but recent studies reported an association with autoimmune diseases and hepatitis C infection. Here, we report 2 cases of FGN occurring after dual treatment with an immune checkpoint inhibitor (ICI) and a tyrosine kinase inhibitor (TKI).

Case Description: Patient #1 is a 69-year-old man with a history of metastatic thyroid cancer treated with cabozantinib for nine months. This was stopped due to diarrhea, and he was switched to nivolumab/ipilimumab. After the first cycle, the patient developed AKI, with serum creatinine (sCr) 1.9 mg/dL from a baseline of 1.1 mg/dL and UPCR 2g/g Cr. A kidney biopsy was performed and showed FGN along with chronic TMA. Further ICI was held, and rituximab was started. sCr decreased to 1.2 mg/dL, with UPCR 0.18 g/g Cr after two doses of rituximab. **Patient #2** is a 77-year-old man with a history of untreated hepatitis C viral (HCV) infection and hepatocellular carcinoma treated with atezolizumab and bevacizumab. After two years of treatment, the patient developed AKI, with sCr 1.6 mg/dL from a baseline of 1.3 mg/dL and UPCR 4.2g/g Cr. A kidney biopsy was performed and revealed FGN. Bevacizumab was held due to significant proteinuria and Glecaprevir/pibrentasvir was started for HCV. Follow-up sCr fluctuated between 1.2-1.4 mg/dL, with 24h urine protein 1.4 g.

Discussion: These cases highlight 2 patients treated with dual immunotherapy and targeted therapy who presented with FGN. In the second case, the patient had HCV, which could be implicated; however, glomerular diseases have been described with both ICIs and TKIs. This potential association with FGN warrants further study, particularly given FGN's poor prognosis and the implications it has for holding potentially life-saving cancer treatments.



FR-PO208

The Intersection between Chimeric Antigen Receptor T Cell (CAR-T) Therapy and the Kidneys: A Multicenter Study of Outcomes

Ahmad Matarneh, Sundus Sardar, Rafael Portela, Muhammad Abdulbasit, Navin Verma, Naman Trivedi, Nasrollah Ghahramani. *Penn State College of Medicine, Hershey, PA.*

Background: Chimeric Antigen Receptor T-cell (CAR-T) therapy has revolutionized the treatment of refractory hematologic malignancies. Despite its remarkable efficacy, CAR-T therapy is associated with serious adverse effects, including electrolyte abnormalities and acute kidney injury (AKI).

Methods: This study aims to determine the incidence of electrolyte abnormalities and AKI in patients receiving CAR-T therapy. Additionally, we assessed survival outcomes following these events and compared risk differences in patients with and without AKI. We conducted a retrospective multi-center cohort study using the TriNetX database. We identified 3,537 patients who received CAR-T therapy and subsequently developed electrolyte abnormalities or AKI. Survival following these events was also evaluated

Results: The incidences of abnormalities and respective survival properties were as follows: - Hyponatremia:16.5%, survival probability: 78.9%. - Hypernatremia: 3.8%, survival probability: 94.9%. - Hypocalcemia: 7%, survival probability: 90.4% - Hypercalcemia: 6.6%, survival probability: 91.2%. - Hypophosphatemia: 14.7%, survival probability: 80.7%. - Hyperphosphatemia: 1.5%, survival probability: 80.5%. - AKI: 22.4%, survival probability: 70.4%. Compared with the non-AKI cohort, the AKI group had a higher incidence of: - Hyponatremia (24% vs. 14%), associated with lower survival (67.7% vs. 83.1%); - Hypernatremia (8.7% vs. 1.3%), associated with lower survival (88.2% vs. 98.2%); - Hypocalcemia (11.7% vs. 5.8%), associated with lower survival (84.2% vs. 93.2%); - Hypercalcemia (11.6% vs. 3.6%), associated with lower survival (84.5% vs. 95.2%). - Hypophosphatemia (25% vs. 12.2%), associated with lower survival (66% vs. 85.1%); - Hyperphosphatemia (25.5% vs. 12.2%), with similar survival Mortality was higher in patients with AKI following CAR-T therapy, with a risk of 39.5% compared to 18.2% in patients without AKI (RR 0.461, 95% CI 0.415-0.512).

Conclusions: CAR-T therapy is associated with multiple electrolyte derangements and a significant incidence of AKI. These imbalances correlate with increased mortality risk. Patients who develop AKI are at higher risk of electrolyte abnormalities and have lower survival probabilities. Overall, careful monitoring and management of electrolyte disturbances in patients undergoing CAR-T therapy are crucial.

FR-PO209

Clinical Characteristics of AKI Associated with Chimeric Antigen Receptor T Cell (CAR-T) Therapy in Kyoto University Hospital

Tatsuaki Kosaka, Shinya Yamamoto, Yasuyuki Arai, Hideki Yokoi, Motoko Yanagita. *Kyoto Daigaku Igakubu Fuzoku Byoin, Kyoto, Japan.*

Background: CAR-T therapy was approved in 2017 for the treatment of several refractory hematologic tumors and is expected to be expanded to other hematologic and solid tumors in the future. Side effects include cytokine release syndrome (CRS) and, in severe cases, multiple organ failure. However, evidence of AKI associated with CAR-T cell therapy is limited.

Methods: We investigated the incidence of CRS and AKI, cause of AKI, background factors of patients, and renal prognosis in 131 patients treated with CAR-T therapy between December 2019 and December 2023 at our hospital. A two-sample *t*-test was performed for continuous variables, and the chi-square test for categorical variables. In addition, the renal pathology of two autopsies after AKI due to CRS was examined to reveal the pathogenesis of AKI due to CRS.

Results: CRS occurred in 121 cases (92.4%), and AKI occurred in 7 cases (5.3%, Stage 1: 1 case, Stage 2: 1 case, Stage 3: 5 cases). The causes of AKI were CRS (6 cases) and tumor lysis syndrome (1 case). The number of previous chemotherapy regimens, poor response to primary disease, CRS severity, poor response after CAR-T therapy, and higher basal lactate dehydrogenase (LDH), C-reactive protein (CRP), and ferritin levels were significantly associated with AKI development. Four patients recovered to baseline renal function after AKI, one patient remained with renal impairment, and two patients died. Renal pathology of autopsy cases showed glomerular and peritubular capillary congestion, interstitial edema, and acute tubular necrosis without glomerular nephritis.

Conclusions: In our study, higher tumor volume was considered a risk factor for AKI. Evaluation of tumor volume in the primary disease, such as measurement of serum markers or tumor size on a CT scan, may be useful in predicting the development of AKI after CAR-T therapy. Approximately 70% of AKI cases were stage 3, but about half of the patients recovered to baseline renal function, suggesting that renal prognosis is relatively good when the patient survives. The main pathological features of AKI associated with CRS are interstitial edema, and acute tubular necrosis, indicating that hemodynamic changes could induce AKI associated with CAR-T therapy.

FR-PO210

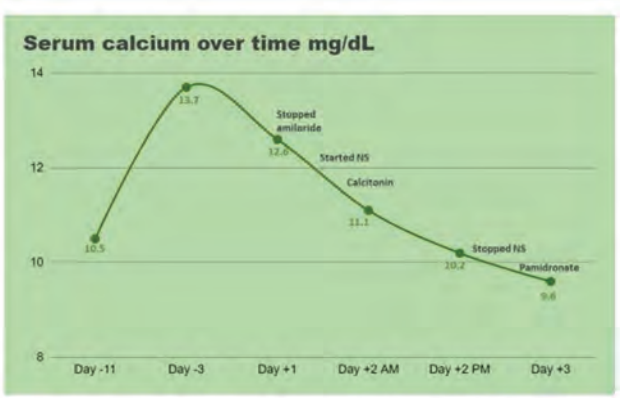
Hypercalcemia in a Patient with Cancer on an Immune Checkpoint Inhibitor, a Tyrosine Kinase Inhibitor, and Amiloride: Which Is the Culprit?

Carolina Saldanha Neves Horta Lima,[1] Meghan E. Sise,[3] Shruti Gupta.[2] *[1]Mass General Brigham Salem Hospital, Salem, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Massachusetts General Hospital, Boston, MA.*

Introduction: Hypercalcemia in oncologic patients can be malignancy-related, but can occur after immune checkpoint inhibitors (ICIs) and amiloride use.

Case Description: A 64-year-old patient with a history of stage IV renal cancer presents with fatigue, weakness and constipation. She was found to have AKI (creatine of 1.77 mg/dL from a prior of 0.9 mg/dL) and hypercalcemia of 13.7 mg/dL. She had been recently started on pembrolizumab, an ICI, and Lenvatinib (a tyrosine kinase inhibitor [TKI]). Within 24 hours of starting Lenvatinib, she had developed hypertension, requiring escalating doses of lisinopril, amlodipine, and metoprolol; amiloride was added for yet uncontrolled blood pressure. She denied use of excessive vitamin D supplements or antacids. Workup showed a 25 (OH) vitamin D of 71 ng/mL, a PTH of 8 pg/mL, a PTHrp of 0.7 pmol/L and a vitamin D 1,25 OH of 67 pg/mL. There was no disease progression or metastasis, pointing to a hypercalcemia not mediated by calcitriol and not cancer-related. Upon admission, amiloride was discontinued and patient received normal saline, calcitonin and pamidronate (Figure). There was normalization of calcium and creatinine.

Discussion: This case highlights, first, how TKI-related hypertension can present so quickly and severly. Thus, the need for further understanding of optimal anti-hypertensive therapies for these patients. And second, how the start of amiloride unmasked a hypercalcemia under ICI use. Amiloride acts by blocking sodium reabsorption through epithelial sodium channels. Amiloride-associated hypercalcemia is an entity mostly theoretical. It is thought to occur due to membrane hyperpolarization in the setting of sodium reabsorption, thereby promoting calcium entry. It is also possible that concurrent treatment with ICIs exacerbated the hypercalcemia, as ICIs have been reported to cause hypercalcemia by endocrinopathies, sarcoid-like granuloma, humoral hypercalcemia due to parathyroid-related hormone and hyperprogressive disease following ICI initiation.



FR-PO211

Chimeric Antigen Receptor T Cell Therapy-Induced Hypophosphatemia (HypoPhos) Due to Renal Phosphate Wasting

Marco Ramos, Brock Gilsdorf, Isaac Teitelbaum. *University of Colorado Anschutz Medical Campus School of Medicine, Aurora, CO.*

Introduction: Chimeric antigen receptor T cell (CAR-T) therapy for refractory malignancies has been a major advance in the field of oncology. Several electrolyte abnormalities related to CAR-T therapy have been reported including hyponatremia, hypokalemia, and hypoPhos. The role of phosphaturia in the pathogenesis of CAR-T related hypoPhos has not been well defined.

Case Description: A 36-year-old male with relapsed B-acute lymphoblastic leukemia underwent CAR-T therapy. The patient developed grade 1 cytokine release syndrome (CRS) which was treated with single dose tocilizumab. He developed severe hypoPhos (<1.0 mg/dl) one week later. His fractional excretion of phosphate (FePO4) was initially 36.64% (nl < 20%) and peaked at 116.46%. Fibroblast growth factor 23 (FGF23) was measured daily with initial value <14 pg/ml and peak 31 pg/ml at day 4 day. Markers for CRS are depicted below with serologies in table 1. Oral sodium or potassium phosphate replacement started at day 2, twice or thrice daily (at the discretion of the treating team). While the patient did develop hyponatremia, he did not develop glucosuria, AKI or metabolic acidosis.

Discussion: The mechanism of CAR-T induced hypoPhos has not been well defined. It has been speculated that it might be related to increased metabolic consumption of extracellular phosphorus by CAR-T cells, but the potential role of increased renal wasting has not been examined. While animal models of AKI or CKD have shown a relationship between IL-6 induction of FGF23 and subsequent hypoPhos, this has not been shown in CAR-T cell models. We demonstrated that increased renal excretion does play a significant role. Though FGF23 levels increased, they remained within the normal range. Nevertheless, the FEPO4 greater than 100% indicates addition of phosphate to the urine beyond the amount filtered, i.e. tubular secretion, which might be mediated by FGF23. The absence of glucosuria and acidosis suggests that this was not due to diffuse proximal tubular dysfunction. Further study is necessary to define the mechanism(s) underlying renal phosphate wasting with CAR-T therapy.

Table 1

	Day 1	Day 2	Day 3	Day 4
Sodium (mmol/L)	127.6	122.6	129.6	132.3
Phosphorus (mg/dl)	2.6	0.9	1.6	2.2
Serum IL-6 (pg/ml)	12.1	49.6	9.5	10.4
Serum iFGF23 (pg/ml)	13	13	17	31
FePO4 (%)	36	38	116	40.33
CRP (mg/L)	74.5	183	159	65.5

Remote Organ Cancer Adversely Alters Kidney Physiology and Induces Kidney Injury and Inflammation

Dana Hammouri, Andrew Orwick, Dianet Sanchez Vega, Levi J. Beverly, Leah J. Siskind. *University of Louisville School of Medicine, Louisville, KY.*

Background: Approximately 30% of cancer patients experience kidney complications, which hinder optimal cancer management, imposing a burden on patients' quality of life and the healthcare system. The etiology of kidney complications in cancer patients is often attributed to nephrotoxic oncological therapies. However, the direct impact of cancer on kidney health is underestimated, as most nephrotoxic oncological therapies have been studied in animal models that do not have cancer. Our previous study demonstrated that lung cancer adversely alters kidney physiology and function, and chemotherapy-induced nephrotoxicity is exacerbated, indicating cancer-kidney crosstalk. This study examines whether this phenomenon is specific to the employed cancer model.

Methods: Mice of various strains were injected with different cell lines representing human and mouse lung cancer, breast cancer, and melanoma. Mice were euthanized upon reaching IACUC protocol endpoints. Kidney tissues were analyzed for toxicity and compared to controls.

Results: The impact of cancer on the kidney varied by cancer type. Breast cancer and specific subtypes of lung cancer, including KRAS- and EGFR-mutant cancer, pathologically altered kidney physiology and function in a stage-dependent manner. This was independent of mouse strain, sex, cancer cell delivery route, and cell line origin. Moreover, tumor DNA was not detected in the kidney tissue. Lewis lung carcinoma and melanoma did not cause nephrotoxicity, regardless of the tumor stage.

Conclusions: Our results confirm cancer-kidney crosstalk in specific cancer types and highlight gaps in understanding renal complication risk in cancer patients. In the era of precision medicine, further research is essential to identify at-risk oncology populations, enabling early detection and management of renal complications.

FR-PO213

Fibroblast Growth Factor Receptor Inhibitor-Induced Hyperphosphatemia: A Case Series from a Tertiary Care Center and Literature Review

Rose Mary Attieh, Kenar D. Jhaveri, Pratap Kumar Upadrista. *Northwell Health, New Hyde Park, NY.*

Background: Fibroblast Growth Factor Receptor Inhibitors (FGFRi) are promising cancer drugs, effective against FGFR2-rearranged cholangiocarcinoma and advanced urothelial carcinoma. Despite their efficacy, they are frequently associated with side effects, notably hyperphosphatemia (hyperP), a significant on-target off-tumor adverse event (AE).

Methods: We conducted a search of the electronic health records system at Northwell Health, a large tertiary healthcare system in New York, to identify patients who received treatment with any FGFRi between January 2020 and December 2023. We collected data on the duration of cancer therapy, the incidence and grade of hyperP, time-to-onset of hyperP, and changes in therapy due to hyperP. Additionally, we scrutinized data from landmark clinical trials and the FDA Adverse Event Reporting System (FAERS) database regarding hyperP as an AE associated with FGFRi.

Results: In our series, 13 patients were treated with erdafitinib, 2 patients received futibatinib, and 1 patient received pemigatinib. 15 out of the 16 patients (94%) developed hyperP with a median time-to-onset of 12 days with futibatinib, 29 days with erdafitinib, and 90 days with pemigatinib. Most hyperP AEs were grade 2 in patients exposed to erdafitinib. Treatment with phosphate binders was required in all patients on futibatinib and pemigatinib, as well as in 58% of patients on erdafitinib. 4 (33%) of patients treated with erdafitinib required FGFRi dose reduction and 1 (8%) required therapy interruption due to hyperP. **Table 1** summarizes the main findings from our cohort, contrasting them with those from large FGFRi randomized clinical trials. Review of the FAERS database showed that hyperP occurred with all FGFRi and constituted 5-15% of all AEs reported with these drugs.

Conclusions: Nephrologists should be aware of hyperP as a possible complication of FGFRi therapy. Collaboration with oncologists is essential to maximize treatment benefits and mitigate AEs without therapy interruption.

FGFRi: fibroblast growth factor inhibitor, hyperP: hyperphosphatemia, AKI: acute kidney injury. Hyperphosphatemia was graded as follows: grade 1 = serum phosphate ≥4.5 mg/dL and <5.5mg/dL, grade 2 = serum phosphate ≥5.5mg/dL and <7.0mg/dL, grade 3 = serum phosphate ≥7.0mg/dL and <10.0mg/dL, and grade 4 = serum phosphate ≥10mg/dL.

FR-PO214

Accuracy of Glomerular Filtration Rate Estimates among Patients with Cancer

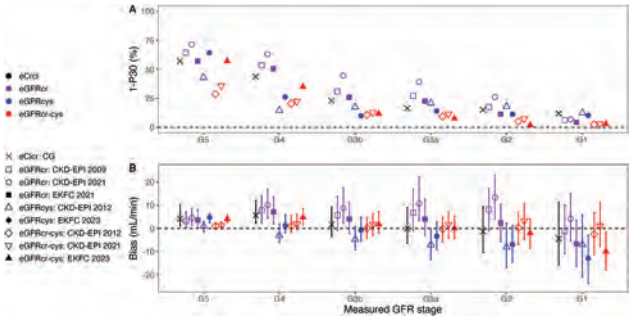
Jennifer S. Lees,[1,3] Edouard Fu,[2] Anne-Laure Faucon,[3] Benjamin M. Elyan,[1] Lesley A. Inker,[4] Andrew S. Levey,[4] Patrick B. Mark,[1] Juan J. Carrero.[3]
[1]University of Glasgow, Glasgow, United Kingdom; [2]Leids Universitair Medisch Centrum, Leiden, Netherlands; [3]Karolinska Institutet, Stockholm, Sweden; [4]Tufts University School of Medicine, Boston, MA.

Background: Little is known about the accuracy of glomerular filtration rate (GFR) assessment among people with cancer. Most cancer guidelines and trials recommend estimated creatinine clearance (eClcr) using the Cockcroft-Gault (CG) equation. Accuracy is key to determine cancer prognosis, treatment eligibility and correct dosing of treatments with narrow therapeutic index.

Methods: We performed a cross-sectional study including 1,781 adults with incident cancer referred for 1,989 determinations of measured GFR (mGFR) using single-point plasma clearance of iohexol in Stockholm, Sweden, with concurrent measurements of creatinine and cystatin C. We assessed the performance of eClcr, estimated GFR based on creatinine (eGFRcr: CKD-EPI 2009/2021, EKFC 2021), cystatin C (eGFRcys: CKD-EPI 2012, EKFC 2023) and the combination (eGFRcr-cys: CKD-EPI 2012/2021, EKFC 2023) equations against mGFR. Values were non-indexed to body surface area and reported in mL/min. Accuracy was reported as % of patients with estimated values that differed by more than 30% of mGFR (1-P30). Bias was estimated as median (interquartile range; IQR) difference between mGFR and eCrcl or eGFR.

Results: Mean age was 64 (SD 14) years, 36% were female with mean mGFR 76 (SD 31) mL/min. The most common cancers were bladder (41%), lung (15%) and colorectal (13%); 13% had metastatic disease. 1-P30 was best for eGFRcr-cys (6-8%). eClcr (1-P30: 17%) had similar accuracy to eGFRcr (1-P30: 13-26%) and eGFRcys (1-P30: 12-17%). Accuracy varied by mGFR (Figure A). Median bias was lowest for eGFRcr-cys CKD-EPI 2012 (-0.5, IQR -6.2 to 6.4 mL/min) and highest for eGFRcr CKD-EPI 2021 (9.8, IQR 0.9 to 19.7 mL/min). Across mGFR categories, eGFRcr-cys equations were the least biased (Figure B).

Conclusions: Non-indexed eGFRcr-cys with CKD-EPI and EKFC equations provide the most accurate estimates of mGFR in patients with cancer, with potential to improve dosing and classification across treatment thresholds compared to eClcr and eGFRcr.



FR-PO215

Performance of a Score for Stratifying the Risk of CKD in Patients with Renal Cell Carcinoma Undergoing Nephrectomy

Liliana M. Kassar,[1,2] Veronica T. Costa e Silva,[1] Benedito J. Pereira,[2,3] Luciana G. Lutf,[1] Francisco Z. Mattedi,[1] Karoline W. Silva,[2] Mauricio D. Cordeiro,[1] Dirce M. Zanetta,[4] Emmanuel A. Burdmann.[4]
[1]Universidade de Sao Paulo Instituto do Cancer do Estado de Sao Paulo, Sao Paulo, Brazil; [2]Hospital das Clinicas da Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil; [3]A C Camargo Cancer Center Centro Internacional de Pesquisa, Sao Paulo, Brazil; [4]Universidade de Sao Paulo, Sao Paulo, Brazil.

Background: Nephrectomy to treat patients with kidney cancer increases the risk of chronic kidney disease (CKD) in the middle and long term. Although new clinical tools have been developed to identify patients at higher risk and promote appropriate follow-up, these instruments have not been externally validated. We aim to assess the performance of the Australian risk stratification score for CKD (ARSC) after nephrectomy in patients with renal cell carcinoma (RCC).

Methods: We screened all adult patients with histology-confirmed RCC submitted to partial or total nephrectomy between 2010 and 2021 at the São Paulo State Cancer Institute – University of São Paulo (Brazil). Patients with a pre-operative (baseline) estimated glomerular filtration rate (eGFR) > 60ml/min/1.73m^2 and with at least one eGFR between 12 and 15 months after surgery were included. The ARSC score was calculated based on baseline characteristics (age, eGFR, diabetes mellitus [DM]) and type of nephrectomy. The primary outcome was eGFR ≤ 45 m/min/1.73m^2 (stage 3b CKD) one year after nephrectomy. eGFR was calculated using the race-free CKD-EPI equation based on the serum creatinine level.

Results: We enrolled 349 patients. The mean age was 58±10 y, 61% were male; 60% and 27% had hypertension and DM, respectively. Median baseline eGFR was 91 (63-123) mL/min/1.73m^2; nephrectomy was radical in 49% of patients. The ARSC score presented satisfactory discrimination; the area under the receiver operation characteristic curve was 0.70 (0.57 – 0.80, p=0.01). However, the score overestimated the outcome in patients at moderate and high risk (≥ 7 points) (Table).

Conclusions: The ARSC score presented satisfactory discrimination but overestimated the outcome of stage 3b CKD in this Brazilian cohort of patients with RCC.

Risk level (ARSC Score)	Predicted risk of stage 3b CKD	Observed outcome (stage 3b CKD)
Negligible (0-3)	<2%	3.7%
Low (4-6)	3-14%	7.2%
Moderate (7-8)	21-26%	14%
High (9-10)	46-69%	21%

ARSC: Australian risk stratification score for CKD; CKD: chronic kidney disease

FR-PO216

Impact of Conventional Antitumoral Therapy on Estimated Glomerular Filtration Rate in Patients with Cancer Using Serum Creatinine and Cystatin C: A Prospective Cohort Study

Renato A. Caires,[1] Lesley A. Inker,[2] Andrew S. Levey,[2] Emmanuel A. Burdmann,[3] Veronica T. Costa e Silva.[1]
[1]Universidade de Sao Paulo, Sao Paulo, Brazil; [2]Tufts Medical Center, Boston, MA; [3]Universidade de Sao Paulo Laboratorios de Investigacao Medica, Sao Paulo, Brazil.

Background: The effects of chemotherapy on the estimated glomerular filtration rate (eGFR) are largely based on retrospective data, relying on serum creatinine (SCr). We aim to sequentially assess the impact of antitumoral conventional therapy on eGFR equations based on SCr and cystatin C (SCysC).

Methods: This is a prospective cohort of adult patients with solid tumors exposed to conventional antitumoral treatment at the São Paulo State Cancer Institute. eGFR was calculated through race-free CKD-EPI equations based on SCr (eGFRcr), on SCysC (eGFRcys), and the combined version (eGFRcrcys) in three moments: before the initiation of treatment (T0), during treatment (TM) and after the end of antitumoral therapy (TF). SCr and SCysC were measured through certified reference materials at the University of Minnesota.

Results: 485 adult patients with solid tumors were recruited between Oct 2017 and Jan 2019. Patients were 53±15y, 62.3% female. The most frequently prescribed drugs were platinum compounds (cisplatin, carboplatin, oxaliplatin) (53.7%), paclitaxel (39.8%), and doxorubicin (27.4%). Patients received a median of 4(3-6) cycles during 105(63-148) days of chemotherapy. Median follow-up was 28(21-32) months. TM was collected 98 (84-119) days after T0, and TF was collected 124(44-204) days after the end of treatment. A significant decline in eGFR over time was observed in elderly patients, those with eGFRcrcys<60mL/min/1.73m2, reduced performance status, and exposed to cisplatin (Table).

Conclusions: Groups at higher risk of eGFR decline should be closely monitored and might be suitable candidates for prophylactic measures to minimize the impact of cancer treatment on GFR.

eGFR: estimated glomerular filtration rate expressed in mL/min/1.73m^2; cr: creatinine; cys: cystatin C; crcys: creatinine and cystatin C; T0: sample collected before the start of antitumoral therapy; TM: sample collected in middle of treatment; TF: sample collected after the end of antitumoral treatment; ECOG: Eastern Cooperative Oncology Group performance score. Values expressed as mean ± standard deviation. Paired t-test: *p<0.05 between TM and T0; †p<0.05 between TF and T0; ¥p<0.05 between TF and TM.

FR-PO217

CT-Defined Sarcopenia and Performance of GFR-Estimating Equations in Patients with Cancer

Veronica T. Costa e Silva,[1] Meghan E. Sise,[3] Lesley A. Inker,[2] Fernando L. Strufaldi,[1] Lea Mantz,[3] Tianqi Ouyang,[3] Renato A. Caires,[1] Marcelo T. Sapienza,[1] Emmanuel A. Burdmann.[1] *[1]University of São Paulo, São Paulo, Brazil; [2]Tufts Medical Center, Boston, MA; [3]Massachusetts General Hospital, Boston, MA.*

Background: Estimated glomerular filtration rate (eGFR) equations based on serum creatinine (Scr)(eGFRcr) combined or not with serum cystatin C (Scys) present worse accuracy in patients with low body mass index (BMI). This analysis aims to evaluate the impact of sarcopenia, defined by computed tomography (CT), on the performance of the CKD-EPI equations without race based on Scr and Scys in patients with cancer.

Methods: We included adult patients undergoing treatment for solid tumors between May 2017 and October 2017 and an abdominal CT scan within 90 days of measured GFR (mGFR) using the plasma clearance of ^{51}Cr-EDTA. Body composition on an axial image at the third lumbar vertebral body level was performed using a previously validated machine-learning pipeline. Skeletal muscle index was defined as cross-sectional skeletal muscle area [cm^2] divided by the square of the patient's height [m^2]. Sarcopenia was defined using independently established cutoffs of skeletal muscle index (< 39 cm^2/m^2 for women, < 55 cm^2/m^2 for men).

Results: Of 465 included patients (50% women, mean age 58 [14] y), 34% had sarcopenia. Mean (SD) mGFR was 78.0 (22.5) ml/min/1.73 m^2. The table shows the performance of eGFR equations by sarcopenia and BMI categories. Even in patients with high BMI, those with sarcopenia had large eGFRcr overestimation (median bias: -14.7 [-18.1, -11.6] ml/min/1.73 m^2), and poor accuracy (1-P30: 41.7 [29.2, 52.8] %).

Conclusions: This is the first study to demonstrate large bias and poor accuracy for eGFRcr and eGFRcrcys in patients with CT-defined sarcopenia, demanding other instruments such as Scys or mGFR to assess GFR more accurately in this population. Overweight and obese patients might benefit from body composition analysis to unveil underlying sarcopenia.

		Bias (median) (ml/min/1.73 m^2)

eGFRcr	89.3 (21.7)	26.5 (22.2, 30.1)	42.0 (34.4, 49.6)	18.5 (14.3, 23.1)	35.7 (27.4, 42.7)	21.8 (17.2, 26.3)	41.7 (29.2, 52.8)	15.7 (10.6, 19.9)
eGFRcys	73.6 (25.5)	15.3 (11.8, 18.5)	20.4 (14.0, 26.8)	12.7 (8.8, 16.2)	15.9 (9.6, 21.7)	14.9 (10.7, 18.8)	20.8 (11.1, 29.2)	13.1 (8.9, 17.3)
eGFRcrcys	82.5 (23.8)	11.0 (8.0, 13.8)	14.0 (8.3, 19.1)	9.4 (6.2, 12.3)	15.3 (9.6, 20.4)	8.8 (5.5, 11.7)	12.5 (4.2, 19.4)	7.6 (3.8, 10.6)

Data are presented with 95% confidence intervals. Bias was calculated as the median value of (mGFR-eGFR). 1-P$_{30}$ is the percentage of estimates that differed by more than 30% from the measured GFR. Non-overlapping confidence intervals indicate statistical significance. eGFR: estimated glomerular filtration rate using the race-free CKD-EPI (Chronic Kidney Disease Epidemiology Collaboration) equation, eGFRcr: eGFR based on the serum level of creatinine (SCr); eGFRcys: based on the serum level of cystatin C (SCys); eGFRcrcys: eGFR based on SCr combined with Scys. SCr and SCys were measured through certified reference materials. Sarcopenia: SMI < 39 39 cm^2/m^2 for men and < 55 cm^2/m^2 for women; SMI: skeletal muscle index, calculated by dividing the skeletal muscle cross-sectional area by the patient's height squared. BMI: body mass index.

Cystatin C as a Superior Biomarker for Melphalan Dosing in Patients with Multiple Myeloma Undergoing Autologous Stem-Cell Transplant: A Single-Center Retrospective Analysis

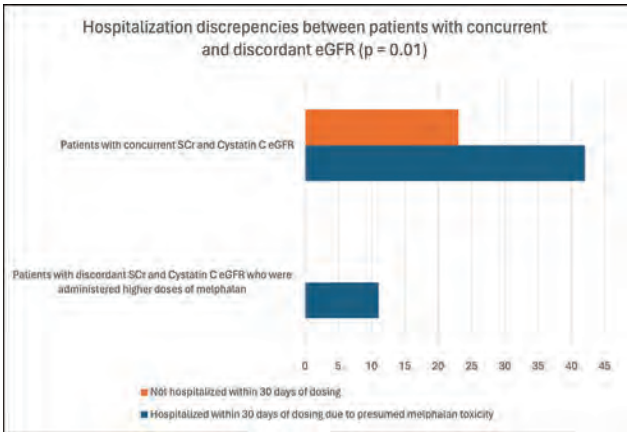
Benjamin R. Teruel, Elaine Park, Blaithin A. McMahon. *Medical University of South Carolina, Charleston, SC.*

Background: Accurate dosing of melphalan is critical for patients with multiple myeloma undergoing autologous stem cell transplant (ASCT). Traditionally, serum creatinine (SCr) is used to estimate glomerular filtration rate (GFR) for melphalan dosing calculations. This study seeks to evaluate the effectiveness of Cystatin C in predicting appropriate melphalan induction doses compared to SCr in patients with multiple myeloma undergoing ASCT.

Methods: A retrospective cohort study was conducted on 76 patients diagnosed with multiple myeloma who received melphalan conditioning before ASCT. Melphalan dosing in all patients was based on pre-transplant eGFR calculated from SCr. This dosing is 200 mg for eGFR >50 mL/min/1.73m^2, 140 mg for eGFR <50. Patient GFR was estimated using Cystatin C levels immediately prior to transplantation. The primary outcome was the incidence of melphalan overdosing, defined as those cases that exceeded the therapeutic dose, due to GFR estimation discrepancies between the two biomarkers and the presence of a hospitalization related to melphalan toxicity within 30 days of Melphalan therapy.

Results: Of the 76 patients, 11 (14.5%) were identified as having received a higher dose of melphalan than anticipated when GFR was estimated using SCr compared to Cystatin C. These patients exhibited higher incidences of treatment-related toxicity due to diarrhea, mucositis, and/or fever and resulted in hospitalization in 100% of patients with melphalan overdose. Of note, 23 patients (35%) of patients with appropriate melphalan dosing as per SCr eGFR and Cystatin C eGFR did not experience toxicity (p = 0.01).

Conclusions: While melphalan is associated with a high baseline toxicity, use of Cystatin C in place of SCr to estimate GFR could significantly decrease the incidence of melphalan toxicity. Further prospective studies are warranted.



FR-PO219

Impact of CKD Stages Based on Measured vs. Estimated Glomerular Filtration Rate on the Overall Survival of Patients with Cancer

Rayra G. Ribeiro,[1] Abhijat Kitchlu,[2] Lesley A. Inker,[3] Veronica T. Costa e Silva,[1] Renato A. Caires,[1] Elerson Costalonga,[1] Marcelo T. Sapienza,[1] Emmanuel A. Burdmann.[1] *[1]Universidade de Sao Paulo, Sao Paulo, Brazil; [2]University of Toronto, Toronto, ON, Canada; [3]Tufts University, Medford, MA.*

Background: Data assessing the impact of chronic kidney disease (CKD) stages on the overall survival (OS) of cancer patients are largely retrospective and rely on the serum level of creatinine (SCr) to estimate the glomerular filtration rate (eGFR). We aimed to evaluate the impact of different CKD stages on the OS of patients with cancer admitted for treatment using measured GFR (mGFR) and eGFR.

Methods: This is a prospective cohort of adult patients with solid tumors (diagnosed in the last 90 days) initiating treatment at the Sao Paulo State Cancer Institute. mGFR was determined by plasma clearance of ^{51}Cr-EDTA. eGFR was calculated using the 2021 CKD-EPI equations, based on SCr (eGFrcr), Scys (eGFRcys), and the combined version (eGFRcrcys). CKD stages were classified according to the KDIGO guidelines using mGFR, eGFRcr, eGFRcys, and eGFRcrcys.

Results: A group of 1,011 patients recruited from April 2015 to September 2017 were included for analysis and censored in March 2023. Patients were 50.6 ±13 y, 50.7% female. The most common cancer sites were breast (22.4%), gastrointestinal (21.9%), and male genital (21.2%); 15.5% had metastasis. ECOG 0, 1, and 2&3 comprised 64%, 32%, and 6% of patients, respectively. Time of follow-up was 5.7 (2.5-6.5) y; overall mortality was 27.4%. In the adjusted Cox regression model, stage 3b CKD based on mGFR and eGFRcys and stages 3a and 3b based on eGFRcys were associated with worse OS. CKD stages based on eGFRcr were not associated with OS (Table).

Conclusions: This is the first study assessing the impact of CKD stages on the OS of patients with solid tumors incorporating mGFR and SCys. Our results endorse the utility of eGFRcys and mGFR as valuable instruments in the kidney care of cancer patients.

Table

Variables	P value	Hazard Ratio (95% Confidence interval)
CKD stage based on mGFR		
Stage 2 or greater *	0.042**	1.51 (1.09 – 2.11)
Stage 3a	0.014	1.24 (0.77 – 2.00)
Stage 3b	0.38	
CKD stage based on eGFRcr		
Stage 2 or greater*	0.67**	1.13 (0.69 – 1,84)
Stage 3a	0.62	1.34 (0.65 – 2.77)
Stage 3b	0.43	
CKD stage based on eGFRcys		
Stage 2 or greater *	< 0.001**	
Stage 3a	<0.001	1.63 (1.22 – 2.18)
Stage 3b	0.008	1.63 (1.13 – 2.34)
CKD stage based on eGFRcr-cys		
Stage 2 or greater *	0.10**	
Stage 3a	0.03	1.50 (1.03 – 2.17)
Stage 3b	0.53	1.18 (0.71 – 1.95)

Models were adjusted for age, sex, cancer site, metastasis, ECOG, and C-reactive protein. *Reference group. **p value for the overall group. CKD: chronic kidney disease; GFR: glomerular filtration rate; eGFR: estimated GFR using the race-free CKD-EPI (Chronic Kidney Disease Epidemiology Collaboration) equation; eGFRcr: eGFR based on the serum level of creatinine (SCr); eGFRcys: based on the serum level of cystatin C (SCys); eGFRcr-cys: eGFR based on SCr combined with SCys. SCr and SCys were measured through certified reference materials. CKD Stage 2 or greater: GFR>60ml/min/1.73m²; CKD stage 3a: GFR 59-45ml/min/1.73m²; CKD stage 3b: GFR <45ml/min/1.73m².

FR-PO220

Temporal and Apparent Decrease of Creatinine-Derived eGFR in the Patients with Cancer Treated with Poly ADP-Ribose Polymerase Inhibitors

Shiho Morimoto,[1,3] Yasuhiro Onishi,[1] Saori Ariki,[2] Hiroshi Morinaga,[1] Katsuyuki Tanabe,[1] Haruhito A. Uchida,[1] Yoshito Zamami,[2] Hisashi Masuyama,[5] Motoo Araki,[4] Jun Wada.[1] *[1]Department of Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan; [2]Department of Pharmacy, Okayama University Hospital, Okayama, Japan; [3]Department of internal medicine, Tsuyama Chuo Hospital, Tsuyama, Japan; [4]Department of Urology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan; [5]Department of Obsterics and Gynecology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.*

Background: Poly ADP-ribose polymerase (PARP) inhibitors, novel molecular targeted drugs used mainly for Breast cancer gene (BRCA) mutation-positive tumors, have been reported to cause an increase in serum creatinine (Cr). It has been reported that PARP inhibitors, which are molecularly targeted drugs, have an off-target effect on tubular transporters (MCT2, MATE1) and suppress Cr secretion into the urine, leading to an increase in serum Cr independent of glomerular filtration rate. With this study, we aimed to assess the relationship between renal function and PARP inhibitors.

Methods: We retrospectively recruited the patients attending Okayama University Hospital who received PARP inhibitors for the first time from April 2018 to December 2022. We compared the levels of BUN, serum Cr, and Cr-derived eGFR at baseline, on treatment, and off treatment using one-way repeated measures ANOVA and post-hoc analyses.

Results: Of 85 patients, with an average age of 60.7±12.5 years and 96.5% female, the mean eGFR was calculated as 72.9±13.1 ml/min/1.73m². eGFR significantly decreased to 62.6±12.3 one month after starting PARP inhibitor (P<0.001), but improved to 71.6±16.6 one month after discontinuation (P<0.001) and there was no significant increase in BUN (Figure 1A, B). Until 96 weeks, creatinine-derived-eGFR remained unchanged from one month after initiation of PARP inhibitor (Figure1C). Multiple regression analysis showed a negative correlation between post-treatment eGFR decline and starting eGFR (P<0.001).

Conclusions: The present study showed that the increase in serum Cr after the PARP inhibitor was temporary and did not increase BUN, suggesting the apparent change in eGFR.

Aberrant SIX2 Expression in Neonatal Kidney Stem Progenitor Cells Is Sufficient to Drive Malignant Transformation

Hildo C. Lantermans,[1] Willem Kraan,[1] Lambertus P. Van den Heuvel,[2] Fanny O. Arcolino,[1] Elena Levtchenko.[1] Paediatric Nephrology. *[1]Amsterdam UMC Locatie AMC, Amsterdam, Netherlands; [2]Radboud Universitair Medisch Centrum, Nijmegen, Netherlands.*

Background: Wilms tumor (WT) is the most common paediatric renal tumor with an annual incidence of 4 to 10 per million children. WT is thought to arise in renal progenitor cells as it resembles nephrogenic cells both morphologically and transcriptionally. Although the underlying genetic causes of WT are diverse, *in vitro* models to study WT are largely restricted to a few WT cell lines which do not fully represent the diversity observed in patients. In order to expand the *in vitro* models of WT and improve the knowledge on its molecular pathogenesis we investigated whether we could induce malignant transformation of healthy non-immortalized neonatal kidney stem progenitor cells.

Methods: We have previously isolated and characterized kidney stem progenitor cells from the urine of preterm neonates (nKSPC). We transduced nKSPC with retroviral particles encoding for *SIX2*, a transcription factor that is crucial during nephrogenesis and aberrantly upregulated in most WT cases. We monitored changes in cell growth and viability by flow cytometric analysis and investigated molecular reprogramming on both the RNA and protein level.

Results: Intriguingly, overexpression of solely SIX2 in a minor fraction of nKSPC (~5 %) provided the overexpressing cells with a growth advantage that was sufficient to outcompete most non-transduced cells within two weeks. Moreover, the growth of SIX2 overexpressing nKSPC is no longer contact-inhibited and their cellular morphology resembles that of primary WT cells. Whereas the parental nKSPC maintain self-renewing for more than 20 passages, SIX2 overexpressing nKSPCs grow rapidly up to more than 30 passages. On both protein and RNA level we show that SIX2 overexpression results in downregulation of Wnt signaling with concurrent strong upregulation of the oncogene Myc and the cell cycle regulator cyclin D1, which have both been implied in WT pathogenesis.

Conclusions: We show that nKSPCs can serve as a valuable tool to establish *in vitro* WT models and to study WT pathogenesis. As proof of principle we show that overexpression of a single gene involved in WT pathogenesis, *SIX2*, is sufficient to drive malignant transformation and immortalization of nKSPCs.

Influence of the Extracellular Matrix on the Tumor Microenvironment and Cancer Progression

Astgik Petrosyan,[1,2] David S. Koos,[2] Matthew E. Thornton,[1] Paola Aguiari,[2] Valentina Villani,[2] G. Esteban Fernandez,[2] Brendan Grubbs,[1] Roger E. De Filippo,[2] Laura Perin.[1,2] *[1]University of Southern California, Los Angeles, CA; [2]Children's Hospital Los Angeles, Los Angeles, CA.*

Background: This study explores how the extracellular matrix (ECM) in the tumor microenvironment influences cell behavior in Wilms Tumor (WT), a pediatric kidney cancer. We compare the effects of 2D cultures and cancerous versus normal kidney ECM on cellular activities using decellularization techniques, two-photon excited fluorescence (TPEF) microscopy, and transcriptomics.

Methods: We optimized the decellularization technique for normal kidney and WT samples and characterized the decellularized matrices (dECM) with second-harmonic generation (SHG) microscopy (up to 700um in depth) and immunohistochemistry. Protein expression in WT dECM was compared to normal kidney dECM using Oncology Arrays. Bulk transcriptomics was performed on WT and normal human kidney (hFK) nephron progenitors cultured in 2D and on normal kidney and WT dECM scaffolds for 21 days.

Results: Imaging of tumor ECM revealed structural differences, with denser, elongated fibers in the outer layers and mesh-like structures deeper inside. Tumor ECM showed higher expression of oncoproteins (e.g., CEA, PSA-ACT), receptors (e.g., IGF 1R, IGF-II), and markers of cell adhesion and migration (e.g., PDGFR alpha). Cells cultured on tumor dECM exhibited upregulation of genes related to immune response, cancer progression, and metastasis, whereas 2D cultures primarily showed genes involved in basic cellular processes. Cellular behavior and transcriptomic profiles were significantly altered when cultured on tumor versus normal ECM, with tumor ECM promoting proliferation pathways and inhibiting differentiation pathways. Normal cells seeded on tumor ECM activated cancer development pathways and inhibited apoptotic pathways.

Conclusions: This study underscores the critical role of the ECM in influencing cancer cell behavior. These findings are crucial for developing physiologically relevant in vitro tumor models and identifying new therapeutic targets that focus on the ECM in cancer treatment.

P-cresyl Sulfate and Indoxyl Sulfate: Uremic Toxins Implicated in the Progression of Colorectal Cancer in Individuals with CKD

Mariadelina Simeoni,[1,2] Rossella Di Paola,[1] Francesco Trevisani,[3] Marianna Abate,[1] Alessandra Perna,[1] Silvia Zappavigna,[1] Alessia M. Cossu,[1] Marco Bocchetti,[1] Federica Melisi,[4] Clara Iannarone,[4] Lucia S. Pasquale,[1] Marianna Scrima,[4] Michele Caraglia.[1,4] *[1]Universita degli Studi della Campania Luigi Vanvitelli, Caserta, Italy; [2]IRCCS Ospedale San Raffaele, Milano, Italy; [3]San Raffaele Scientific Institute, Milan, Italy; [4]Biogem Scarl, Ariano Irpino, Italy.*

Background: Patients with chronic kidney disease (CKD) have a higher incidence of colorectal cancer (CRC) and a significantly poorer prognosis compared to the general population. The reasons for this are not yet understood. One common issue in CKD patients is gut dysbiosis, which is marked by an excess of aerobic bacteria in the gut microbiota. Their metabolic activity results mainly in two metabolites: P-cresyl sulfate (P-cs) and Indoxyl sulfate (IS). Many studies indicate that these metabolites are instrumental in triggering various cancer-causing processes, such as chronic intestinal inflammation and oxidative stress. Given the cancer-promoting effects of P-cs and IS in CKD patients, it appears plausible that these toxins could play a significant role in the advancement of CRC in these individuals.

Methods: To assess the impact of IS and P-cs on three CRC cell lines (Hct116, LoVo, and HT-29), we conducted a range of in vitro experiments. We examined various concentrations of IS and P-cs and used a WST 8 to measure their influence on cancer cell proliferation. We subsequently applied the Wound Healing Assay and invasion assay to evaluate the migratory and invasive abilities of CRC cells after exposure to the toxins. To identify the pathways altered by the toxins, we performed qPCR and ROS assay experiments to assess the inflammatory pathway and the production of ROS.

Results: We noted an enhancement in cell growth following the treatment with toxins. Moreover, the concentrations of IS and P-cs triggered a significant escalation in cell migration and invasion. An examination of the expression of genes linked to the inflammatory process (INOS and IL-6) revealed an increased regulation of the latter across all cell lines. Lastly, a rise in oxidative stress was also detected in the cells treated with toxins when compared to the control group.

Conclusions: From our findings, it seems that IS and P-cs significantly contribute in vitro to the advancement of CRC. Future investigations in translational studies are needed to explore whether these conclusions can be extended to CKD patients with CRC, also exploring potential new target therapies and diagnostic tools

SGLT2 Inhibitor Use and Kidney Outcomes in Persons Receiving Cisplatin

Abiodun B. Idowu,[1] Kevin Bryan Lo,[4] Roy O. Mathew,[5,6] Pranav S. Garimella,[2] Janani Rangaswami.[3,7] *[1]Jefferson Einstein Philadelphia Hospital, Philadelphia, PA; [2]University of California San Diego Division of Nephrology-Hypertension, La Jolla, CA; [3]Division of Nephrology, Veterans Affairs Medical Center, Washington, DC; [4]Brigham and Women's Hospital Division of Cardiovascular Medicine, Boston, MA; [5]Loma Linda University, Loma Linda, CA; [6]Loma Linda VA Healthcare System, Loma Linda, CA; [7]The George Washington University, Washington, DC.*

Background: SGLT2i are protective against progressive kidney function loss, yet their role in preventing drug toxicity is unknown. We sought to determine safety of concurrent SGLT2i use with cisplatin, a chemotherapy with significant nephrotoxicity

Methods: A Retrospective analysis of patients ages 18–65 years treated with cisplatin from 1st January 2000 to 31st May 2023 in TriNetX database. Patients were divided into 2 groups based on SGLT2i use (first-time exposure to SGLT2i within 3 months before or up to 3 months after first cisplatin administration). Cohorts were balanced via nearest-neighbor 1:1 propensity-score matching (PSM). Survival analysis was done via Kaplan-Meier curves with log-rank tests over a 1-year follow-up

Results: After PSM, we identified 150 patients per cohort (Fig 1). At 1 year, there was a significant decline of eGFR by 17.1±4.16 mL/min/1.73m^2 in the SGLT2i group and 16.3±3.61 mL/min/1.73m^2 in the non-SGLT2i group. There were fewer MAKE event rates, as well as its components (AKI, RRT, and mortality) in the SGLT2i group vs non SGLT2i, but the differences were not statistically significant (HR 0.88, 95%CI: 0.58-1.34, p=0.553) (Fig 2)

Conclusions: SGLT2i use during cisplatin therapy was not associated with increased AKI or MAKE risk. Prospective studies are needed to assess the nephroprotective potential of SGLT2i while on cisplatin therapy

Figure 2: Characteristics of cisplatin-treated cancer patients before and after propensity matching

Incidence of Cancer in People with CKD: A Systematic Review

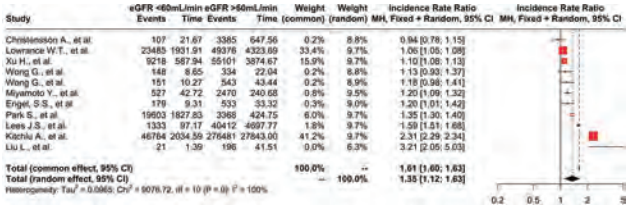
Benjamin M. Elyan,[1,2] Beatrix Tan,[3] Emilie Lambourg,[4] Robert J. Jones,[5,1] David A. Mcallister,[6] Ninian N. Lang,[1,2] Patrick B. Mark,[1,2] Jennifer S. Lees,[1,2] Samira Bell.[3,4] *[1]University of Glasgow College of Medical Veterinary and Life Sciences, Glasgow, United Kingdom; [2]Queen Elizabeth University Hospital, Glasgow, United Kingdom; [3]Ninewells Hospital and Medical School, Dundee, United Kingdom; [4]University of Dundee Division of Population Health and Genomics, Dundee, United Kingdom; [5]Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom; [6]University of Glasgow School of Health and Wellbeing, Glasgow, United Kingdom.*

Background: Cancer incidence in people with chronic kidney disease (CKD) who do not require kidney replacement therapy remains inadequately characterised. This systematic review aimed to estimate cancer risk in people with CKD.

Methods: A systematic search of three online bibliographic databases until January 17, 2023, identified studies reporting cancer incidence in CKD cohorts (PROSPERO CRD42022359690). Meta-analyses using inverse variance method compared incidence rates in individuals with low eGFR (<60mL/min/1.73m2) with available cohorts with normal eGFR (≥60mL/min/1.73m2 or both 60-89 and ≥90mL/min/1.73m^2) for all cancers and site-specific cancers. Multiple meta-regression analyses explored associations of eGFR and age.

Results: In 27 studies (5,519,778 people with CKD), from 10 countries spanning 2009-2022, incidence rates of cancer were associated with worse CKD severity. Incidence rate ratio (IRR) comparing people with an eGFR <60mL/min/1.73m2 to ≥60mL/min/1.73m2 was 1.35 [95% CI:1.12-1.63, p=0.002, I^2=99.9%]. People with eGFR <60mL/min/1.73m2 were at elevated rate of cancer compared with eGFR ≥90mL/min/1.73m^2 (IRR 1.48 [95% CI:1.04-2.10, p=0.03, I^2=100%]) and those with eGFR 60-89mL/min/1.73m^2 (IRR 1.21 [95% CI:1.11-1.33, p<0.01, I^2=92%]). Age was associated with increased cancer incidence (β=0.31, p=0.02) on multiple meta-regression analysis. There was no association between site-specific cancer incidence in CKD patients, but these had wide confidence intervals.

Conclusions: Individuals with CKD have an elevated incidence of cancer, with increasing age contributing to this association. These findings emphasise the importance of investigating whether CKD independently elevates cancer risk, building evidence for tailored cancer screening into CKD patient care.



Forest plot showing the pooled incidence rate ratios for people with eGFR <60mL/min/1.73m2 vs ≥60mL/min/1.73m2

Liquid Silicone Injections: An Infrequent Cause of CKD and Kidney Stones

Ivette Gomez, Anu Sharma, Olesya Ilkun. *University of Florida, Gainesville, FL.*

Introduction: The use of body-modifying cosmetic injections have increased over the last decades. Here we present an infrequent case of severe kidney-related complications due to hypercalcemia arising years after silicone injections.

Case Description: A 44-year-old man with stage 4 chronic kidney disease, hypertension and human immunodeficiency virus on antiretroviral therapy, was found to have acute kidney injury (AKI). The patient's creatinine rose to 3.72 mg/dL from baseline of 2.5 mg/dL. Serum calcium was elevated at 13.5 mg/dL and ionized calcium at 1.79 mmol/L. Parathyroid hormone was at 20 pg/mL, relatively suppressed for CKD4. CT of abdomen and pelvis showed bilateral kidney stones, some larger than 2 cm, and extensive subcutaneous calcifications in the bilateral flanks, proximal thighs and buttocks (Figure 1). The patient disclosed that he had multiple silicone injections in those areas in 2001. His AKI and hypercalcemia improved with intravenous fluid, denosumab, and calcitonin. 25-hydroxyvitamin D, QuantiFERON gold, serum free light chain ratio, and SPEP were unremarkable. 1,25-dihydroxyvitamin D was at the upper limit of normal at 69.2 pg/mL and PTH-r peptide was mildly elevated at 5.8 pmol/L. PET-CT whole body was negative for occult malignancy. Unfortunately, the patient did not follow-up for confirmatory tissue biopsy or to receive outpatient denosumab.

Discussion: We present a rare case of advanced CKD and extensive nephrolithiasis in the setting of hypercalcemia due to likely silicone injection-induced granulomatosis. Cosmetic silicone injections are not approved by the U.S. Food and Drug Administration for any anatomic site, and have been associated with 0.2 to 1% risk of granuloma formation, typically associated with 1,25 vitamin D mediated hypercalcemia. Although tissue biopsy was not obtained, the work-up for other causes of hypercalcemia was negative. There is no effective treatment to date. If silicone cannot be removed, the treatment focuses on reduction of hypercalcemia and removal of kidney stones.

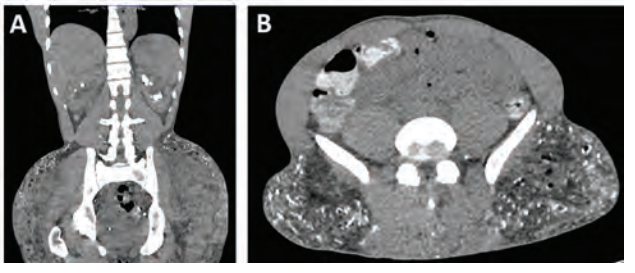

Figure 1. CT scan abdomen and pelvis (A) showing kidney stones and axial view (B) showing extensive bilateral calcifications of the buttocks

Renal Tubular Calcium Oxalate Crystals Induce Mitochondrial Damage and cGAS-STING Activation

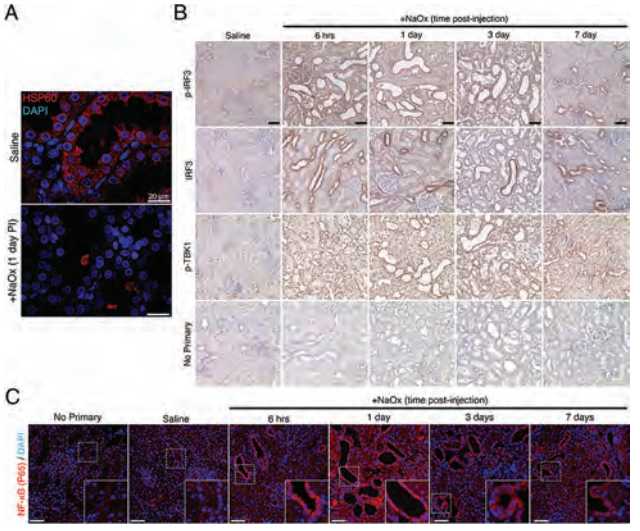
Elizabeth H. Sharpe, Shaina M. Sharma, Jacob A. Torres, Thomas Weimbs. *University of California Santa Barbara, Santa Barbara, CA.*

Background: The kidney is subject to the formation of microscopic calcium oxalate (CaOx) crystals which can cause damage. Previous *in vitro* studies indicate that CaOx-induced damage involves mitochondrial dysfunction, but the specific pathways have yet to be elucidated. The cGAS-STING pathway is a key regulator of the inflammatory response and fibrosis in acute kidney injury (AKI), and activation by cytosolic dsDNA leads to the production of pro-inflammatory cytokines. Activated STING recruits kinases TBK1 and IKK, resulting in activation of transcription factors IRF3 and NF-κB. Activation is triggered by both foreign and self-DNA, including mitochondrial DNA released after mitochondrial damage. Here, we found that mitochondrial damage and activation of the cGAS-STING pathways occurs following acute CaOx crystal deposition in wild type (WT) rats.

Methods: WT S.D. rats received 1 mg/kg sodium oxalate (NaOx) by intraperitoneal injection to induce acute CaOx crystal formation. Immunohistochemical and immunofluorescence staining was used to visualize protein localization in kidney sections at various time points post-injection.

Results: NaOx administration led to decreased mitochondrial HSP60 in renal epithelial cells (**Figure 1A**), indicative of mitochondrial damage. NaOx also promoted activation of downstream STING targets, including an increase in p-TBK1 and p-IRF3 (**Figure 1B**), as well as nuclear translocation of NF-κB (**Figure 1C**).

Conclusions: CaOx crystals promote mitochondrial damage and subsequent activation of the cGAS-STING pathway. Persistent CaOx crystal deposition as a form of subclinical AKI throughout life may drive renal functional decline.



Staining of kidneys from WT S.D. rats at indicated timepoints post-injection with NaOx or saline control (**A**) IF staining of HSP60 (**B**) IHC staining of p-IRF3, IRF3, and p-TBK1 (**C**) IF staining of of NF-κB

Genotyping Patients with Medullary Sponge Kidney (MSK)

Ahmed E. Ali,[1] Andrea G. Cogal,[1] Barbara M. Seide,[1] David J. Sas,[1] Peter C. Harris,[1] John C. Lieske,[1] David S. Goldfarb.[2] Rare Kidney Stone Consortium. *[1]Mayo Clinic Minnesota, Rochester, MN; [2]New York University, New York, NY.*

Background: The underlying genetics of MSK risk are uncertain, with evidence of increased prevalence of radiologic abnormalities in first-degree relatives of affected patients, *GDNF* was suggested as causative in a few cases. MSK has a characteristic appearance on excretory urogram, but this imaging is now rarely used; ultrasounds and CT scans are often read as "suggestive of MSK" when nephrocalcinosis is observed. We genetically screened a cohort of patients with a clinical diagnosis of MSK to determine if any had a possible monogenic cause.

Methods: We solicited research participants from a Facebook page (~3000 members): "Medullary Sponge Kidney Awareness, Support, and Research". Participants self-identify as having MSK; we did not require radiologic confirmation. 98 patients replied via email and were sent consent forms and kits for returning saliva to Mayo Clinic. The study was approved by Mayo Clinic IRB. The cohort was screened by targeted next generation sequencing with a panel consisting of 160 known and candidate monogenic urinary stone disease (MUSD) genes. Clinical information from participants was collected.

Results: 96 individuals from 87 families were screened. The participants were 94% women, average age 49 y. We identified 9 pedigrees with single pathogenic/likely pathogenic (P/LP) variants in genes associated with monoallelic disease: *ATP6V0A4, CASR, PKHD1(2), SLC2A9, SLC34A1(2), SLC34A3(2)*. An additional 5 pedigrees were heterozygous for P/LP variants in 4 genes associated with biallelic MUSD and 24 pedigrees were heterozygous for variants of unknown significance (VUS) in 16 MUSD genes. Only 1 individual carried the *GDNF* promoter variant, that we classified as a VUS given its normal population frequency.

Conclusions: We did not identify one known or candidate MUSD gene to explain a significant proportion of the screened MSK cases (including *GDNF*), but 10.3% had a P/LP variant in a monoallelic MUSD gene, many associated with nephrocalcinosis, that may explain or partially explain the MSK phenotype. The finding of P/LP variants in recessive MUSD genes and many other MUSD gene VUS suggest that MSK individuals may be enriched for risk factor variants. MSK is a complex disease with multiple genetic and environmental inputs. This study supports genetic screening of patients with a clinical MSK diagnosis to identify monogenic causes of nephrocalcinosis.

Long-Term Efficacy and Safety of Lumasiran in Patients with Primary Hyperoxaluria Type 1: Final Analysis of the ILLUMINATE-A Trial

Jeffrey Saland,[1] John C. Lieske,[2] Richard G. Willey,[3] Yaacov Frishberg,[4] Martin Coenen,[5] Julien Hogan,[6] Cristin Kaspar,[3] Sally Hulton.[7] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Mayo Clinic, Rochester, MN; [3]Alnylam Pharmaceuticals, Cambridge, MA; [4]Division of Pediatric Nephrology, Shaare Zedek Medical Center, Jerusalem, Israel; [5]Institute of Clinical Chemistry and Clinical Pharmacology, Bonn, Germany; [6]Pediatric Nephrology Department, Hopital Robert-Debré, APHP, Paris, France; [7]Department of Nephrology, Birmingham Women's and Children's Hospital, Bermingham, United Kingdom.*

Background: Primary hyperoxaluria type 1 (PH1) is characterized by hepatic oxalate overproduction, kidney stones, and progressive kidney disease. Lumasiran is approved to treat PH1 in pediatric and adult patients (pts). Here we report final, 60-month (M) data from ILLUMINATE-A (NCT03681184).

Methods: ILLUMINATE-A is a study in pts age ≥6 y with PH1 and eGFR ≥30 mL/min/1.73m^2. A 6M double-blind, placebo-controlled primary analysis period was followed by an extension period of up to 54M in which all pts received lumasiran.

Results: Of 39 pts enrolled, 25/26 (lumasiran/lumasiran group) and 13/13 (placebo/lumasiran group) completed the study. Mean 24-h urinary oxalate (UOx) reductions at end of study (EOS) relative to baseline (BL) were 54% (lumasiran/lumasiran; 60M post–lumasiran initiation) and 56% (placebo/lumasiran; 54M post–lumasiran initiation). For each time point in the extension period, ≥50% of pts in each group achieved 24-h UOx excretion ≤1.5 × upper limit of normal (0.514 mmol/24h/1.73m^2): 50%–88% (lumasiran/lumasiran) and 54%–92% (placebo/lumasiran). Mean reductions in plasma oxalate from BL to EOS were 37% and 50% in the lumasiran/lumasiran and placebo/lumasiran groups, respectively. During the first 6M of lumasiran treatment, plasma glycolate increased (mean change from BL, 119% [lumasiran/lumasiran] and 154% [placebo/lumasiran]), then plateaued and remained stable. From BL through EOS, eGFR remained stable (mean [SEM] change from BL, −2.892 [2.747] and −12.860 [3.894] mL/min/1.73m^2 in the lumasiran/lumasiran and placebo/lumasiran groups, respectively). Kidney stone event (KSE) rates were low (0.47/person-year [PY] and 0.54/PY in the lumasiran/lumasiran and placebo/lumasiran groups, respectively, overall during lumasiran treatment; 0.09/PY and 0/PY, respectively, during the final 6M of the study). Medullary nephrocalcinosis (NC) grade improved at EOS in 16/20 pts with NC. The most common lumasiran-related adverse events were mild injection-site reactions (36% of pts).

Conclusions: Long-term lumasiran treatment (54–60M) in pts with PH1 led to sustained UOx reduction, with an acceptable safety profile and encouraging clinical outcomes data (low rates of eGFR decline, minimal KSEs, and improved medullary NC).

Characteristics of Patients with Enteric Hyperoxaluria

Trisha D. Laxamana, Frank Modersitzki, Miri Cazes, Bronya L. Sandorffy, David S. Goldfarb, Lama Nazzal. *New York University, New York, NY.*

Background: Enteric hyperoxaluria (EH) is a condition characterized by oxalate (Ox) overabsorption in the digestive tract leading to increased renal excretion. It predisposes patients to recurrent kidney stones, nephrocalcinosis, & progressive kidney impairment w/ severe cases requiring renal replacement therapy. Management remains a challenge due to heterogeneity of underlying etiologies, lack of standard laboratory cut-offs for the development of its consequences, & individual treatment responses.

Methods: We conducted a retrospective cohort study of 40 patients enrolled in the EH Registry at NYU Langone Health w/ an aim to contribute to the understanding of EH. Through comprehensive chart review, the study explores demographic characteristics including age, gender (male (M) vs. female (F)), EH etiology, eGFR & interventions including calcium (Ca) supplement & potassium (K) citrate. A cross-section analysis of 24-hour urinary collections was conducted (Table 1).

Results: The cohort comprised 40 patients w/ EH (50% M, 50% F) w/ a mean age of 59 (58 M, 61 F). Etiologies were Crohn's disease (40%), Roux-en-Y gastric bypass (12.5%), pancreatic insufficiency (25%), and short bowel syndrome (22.5%). Patients had eGFR >60 ml/min (70%), 45-59 (10%), 30-44 (10%), 15-29 (5%), <15 (2.5%), & unknown (2.5%). For intervention, 32.5% were on K citrate, 57.5% w/ history of K citrate use, and 22.5% were on Ca supplements. Urine collections showed significant risk for recurrent CaOx stones w/ high Ox & CaOx supersaturation (SS).

Conclusions: This cohort includes patients w/ mild to moderate CKD. Crohn's disease was the most common etiology. Significant gender differences were observed in urinary profiles in EH patients, w/ M showing higher Ox & SS CaOx despite higher volumes & citrate. Supplementation w/ citrate & Ca are used by a significant portion of this cohort but did not alleviate significant risk of stone recurrence or progressive CKD.

Table 1. 24-hour Urinary Profile

	M (n=20) (mean/SD)	F (n=20) (mean/SD)
Volume (L/d)*	2.46(0.96)	1.75(0.92)
SS CaOx (L/d)	13.67(76.70)	12.51(42.95)
Ox (mg/d)	74.96(64.62)	59.26(36.64)
Ca (mg/d)*	137.08(118.28)	80.90(58.06)
Citrate (mg/d)*	426.74(274.99)	288.84(284.23)
pH	6.38(5.55)	6.21(0.78)

Enteric Hyperoxaluria: A 13-Year Retrospective Analysis of Urine Metabolic Risk Factors and Kidney Stone Events across Different Etiologies

Ryan Tatton,[1] Stephen R. O'Neill,[1] Deondre Jordan,[2] Lisa E. Vaughan,[2] John C. Lieske,[2] Mira T. Keddis.[1] *[1]Mayo Clinic, Phoenix, AZ; [2]Mayo Foundation for Medical Education and Research, Rochester, MN.*

Background: Enteric Hyperoxaluria (EH) increases the risk for calcium oxalate nephrolithiasis. This retrospective observational study compared baseline patient characteristics and subsequent nephrolithiasis rates by enteric etiology among EH patients.

Methods: Patients with a measured urine oxalate>40 mg/24hr between Jan1,2010, and Oct31,2023 with an enteric pathology consistent with EH and eGFR >30ml/min at the time of EH diagnosis were included. A stone event was defined as surgical management of kidney stones, stone composition analysis, or emergency department visit with a nephrolithiasis diagnosis. Patient characteristics and nephrolithiasis parameters were evaluated.

Results: Of 715 patients meeting inclusion criteria, the most common EH etiology was malabsorptive bariatric surgery(63%). Characteristics varied significantly by EH cause: non-bariatric surgically associated malabsorption(SAM) patients exhibited the greatest hyperoxaluria, profound hypocitraturia, and lowest eGFR, while Celiac patients had greater hypercalciuria and highest calcium oxalate supersaturation (**Table 1**). Over an average follow-up of 5.3(±3.9) years, the overall median (IQR) stone event rate was 0.6(0,1.54) per year. Exocrine pancreatic insufficiency, SAM, and Celiac groups had the highest stone burden (1.06,0.94, and 0.86 events per year, respectively).

Conclusions: This large EH cohort with comprehensive urine metabolic data reveals significant heterogeneity by enteric etiology. Malabsorptive bariatric surgery was the most common EH cause but had the lowest nephrolithiasis event rate. Other etiologies were less common but had more severe disease with higher stone events and different urine risk profiles, leading to higher overall SS. This study highlights the significant stone burden EH patients face (approximately 1 stone per year) and the need for a robust EH patient registry to define natural history, appropriate endpoints, and targets for tailored treatment across the heterogenous EH population.

Enteric Hyperoxaluria Mouse Model: Malabsorption and Gut Permeability

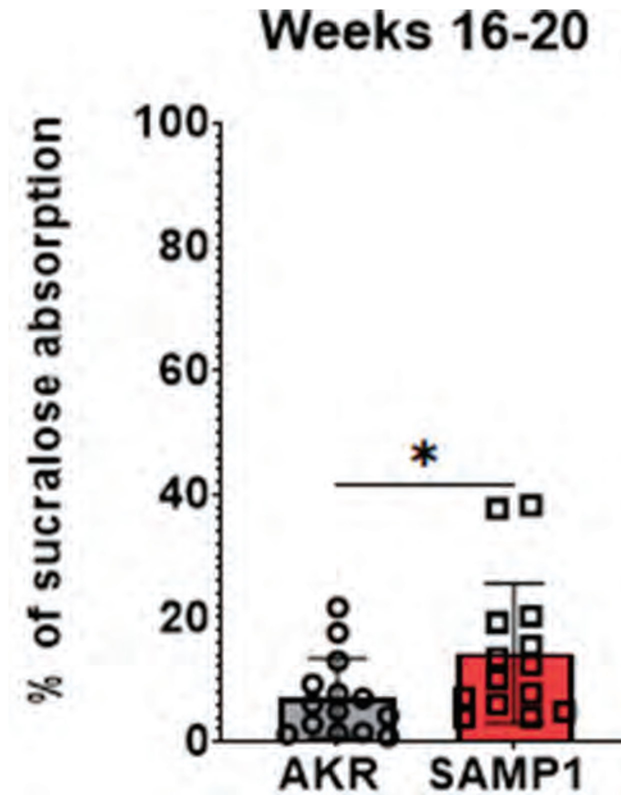
Karim Jaber,[1] Nadim Zaidan,[2] Kyle Merritts,[1] Xiaozhong Xiong,[1] Lama Nazzal.[1] *[1]NYU Langone Health, New York, NY; [2]Staten Island University Hospital, Staten Island, NY.*

Background: Enteric hyperoxaluria (EH) arises from enhanced oxalate (Ox) absorption in the gastrointestinal (GI) tract, often seen in patients with inflammatory bowel diseases. Several mechanisms could contribute to this, including elevated Ox bioavailability, decreased fat absorption, and altered GI permeability. The SAMP1/YitFc (SAMP1) mouse model exhibits spontaneous ileal inflammation resembling Crohn's disease. We hypothesize that SAMP1 mice exhibit increased gut permeability and develop an EH phenotype.

Methods: To assess intestinal permeability, we performed gavage of 10 AKR and 10 SAMP1 mice (1:1 F:M) with sucralose and C-13 Ox at weeks 16, 20, and 26 of life. We collected 24-hour urine post-gavage and measured sucralose via Hydrophilic Interaction Liquid Chromatography (HILIC). To evaluate the impact of ileitis and dietary fat, SAMP1 and AKR mice (n=10/group) were initially fed normal chow before transitioning to a low-fat diet, then a very high-fat diet. Ox was then introduced with incremental decrease in dietary fat. Urine (U) and plasma (P) samples were collected for Ox and creatinine measurements, and fecal samples were collected for Ox and lipidomics analysis to investigate fat malabsorption.

Results: SAMP1 mice had higher % of sucralose absorption, suggesting increased intestinal permeability in IBD mice. Increased dietary fat did not induce increase in UOx. However, dietary oxalate addition to fat led to an increase in UOx, POx and fecal oxalate. Fecal lipidomics indicated increased lipids, particularly fatty acids, in SAMP1 mice confirming fat malabsorption.

Conclusions: SAMP1 mice develop an EH phenotype characterized by increased fat malabsorption, leading to elevated dietary Ox bioavailability. These mice had increased gut permeability, likely promoting passive oxalate absorption across the intestinal membrane.



FR-PO233

Understanding Gastrointestinal Oxalate Metabolism in Kidney Stone Disease: A Stable Isotope Study

Lisa Deesker,[1] Sander F. Garrelfs,[1] Dewi van Harskamp,[2] Tim de Meij,[1] Michiel J. Oosterveld,[1] Jaap Groothoff.[1] *[1]Emma Kinderziekenhuis Amsterdam UMC, Amsterdam, Netherlands; [2]Stable Isotope Research Laboratory, Amsterdam University Medical Centers, Amsterdam, Netherlands.*

Background: Intestinal oxalate metabolism plays a significant role in calcium oxalate (CaOx) kidney stone disease. However, the gastrointestinal oxalate metabolism remains insufficiently understood, leading to dietary restrictions for patients based on limited evidence. With this study, we aim to obtain more insight into the gastrointestinal absorption and breakdown of oxalate. Measurement of oxalate absorption will be combined with assessment of the gut microbiome, which has been found to correlate with CaOx stone disease and could be one of the key influences on the gastrointestinal bio-availability of oxalate.

Methods: In this cross-sectional case-control study, we aim to study the influence of dietary oxalate on urinary oxalate levels by quantifying the intestinal oxalate absorption in patients with primary or secondary hyperoxaluria and non-hyperoxaluric CaOx stone formers vs. healthy controls, using an oral stable isotope method described by Von Unruh et al. (1998). After ingesting an oral dose of ^{13}C-oxalate, ^{13}C-oxalate enrichments will be measured in plasma and urine samples using GC-MS/MS. In breath samples, $^{13}CO_2$ will be analyzed as an indirect measure of intraluminal oxalate degradation. Intestinal oxalate absorption will be calculated and correlated with microbiome diversity and abundance of oxalate-degrading bacteria measured in fecal samples by 16S rRNA sequencing (F1).

Results: The study is currently ongoing. Preliminary data (in healthy controls, n=4) show that plasma oxalate enrichments peaked between 1-3 hours after tracer ingestion and that 75-89% of ^{13}C-oxalate is excreted via the urine within 6 hours. Similarly, $^{13}CO_2$ enrichments in breath samples (n=2) peaked between 1-3 hours, indicating intestinal oxalate degradation. ^{13}C-oxalate absorption/degradation rates and microbiome correlations will be presented at the congress based on the final results (n≈45).

Conclusions: This study will be the first to combine oxalate absorption, degradation, and intestinal microbiome analysis. This provides unique insights into gastrointestinal oxalate metabolism, the role of the microbiome, and potential new therapeutic targets for different subgroups of CaOx stone formers.

Discovery of Small Molecule Drugs with Therapeutic Potential for Hyperoxalemia, Hyperoxaluria, and Related Kidney Stones

Hatim A. Hassan,[1] Marina Subramaniam,[1] Sara F. Dunne.[2] *[1]Mayo Foundation for Medical Education and Research, Rochester, MN; [2]Northwestern University, Evanston, IL.*

Background: Kidney stones (KS) are very common, excruciating, and account for >1.3M ER visits. ~80% of KS are composed of calcium oxalate and very small increases in urine oxalate significantly enhance the stone risk. Oxalate also potentially contributes to CKD and its progression, emphasizing the urgent need for plasma and urinary oxalate lowering therapies, which can be achieved by enhancing enteric oxalate secretion. We previously identified *Oxalobacter*-derived peptides stimulating oxalate transport by human intestinal Caco2-BBE (C2) cells via the oxalate transporters SLC26A6 [A6] & SLC26A2 [A2] and PKA activation. A main limitation of therapeutic peptides is their short half-life due to degradation by proteolytic enzymes. Many attempts to optimize our peptides decreased their functions by 45-100%. Small molecule (SM) therapeutics are superior to peptide-based drugs given their overall favorable drug profile.

Methods: To develop a cell-based high throughput screening (HTS) assay to identify SM activators for A6 and/or A2, Fischer rat thyroid (FRT) cells were engineered to stably co-express human A6 or A2 and a Cl-sensitive yellow fluorescent protein (YFP).

Results: A suitable HTS assay was successfully developed, in which extracellular addition of oxalate (Ox)-containing buffer drives A6/A2-mediated Cl/Ox exchange, leading to increased (dequenched) YFP fluorescence measured by a high content imager. The assay conditions were validated using the anion exchange inhibitors niflumic acid and DIDS, which inhibited the oxalate exchange. Addition of Ox did not change YFP fluorescence in control FRT cells (has YFP but no A6/A2). FDA-approved library was screened, and 24 drugs (22 in human clinical use; including 4 tyrosine kinase inhibitors and 7 drugs interacting with GPCRs) were identified as likely true positive hits, many of which serve as antagonists for pathways that we previously showed to inhibit A6-mediated intestinal oxalate transport. Interestingly, 22 drugs significantly stimulated (~17-107%) apical oxalate transport in C2 cells, with one drug had no effect and another significantly inhibited (~20.5%) oxalate transport.

Conclusions: Several SM drugs were discovered, which greatly stimulated oxalate transport by C2 cells and have significant potential to serve as novel therapeutics for hyperoxalemia, hyperoxaluria, and related KS.

High-Oxalate Diets Increase Urinary Oxalate Excretion and Nanocrystalluria in Healthy Adults and Calcium Oxalate Kidney Stone Formers

Tanecia Mitchell, Parveen Kumar, Shali Zhang, Mary A. Doamekpor, Vivek Verma, Vinoy Thomas, Dean G. Assimos. Mitchell Laboratory. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: Kidney stones (KS) affect approximately 10% of the United States population. The majority of KS are comprised of calcium oxalate (CaOx). Urinary oxalate is derived from dietary sources as well as endogenously synthesized. It may exist in soluble or crystalline forms in urine. We recently developed a novel method to detect and quantify nanocrystals in urine. We previously reported that a single dietary oxalate load augments urinary oxalate output and nanocrystalluria in healthy adults within 5 hours. The aim of this study was to determine whether increasing dietary oxalate augments urinary oxalate excretion and nanocrystalluria in CaOx KS formers (CaOx KSF) and healthy adults.

Methods: Sixteen healthy adults without a history of KS and 6 CaOx KSF adults were randomly assigned to consume one of two controlled diets: (50 mg oxalate and 800 mg of calcium/day) or (250 mg oxalate and 800 mg of calcium/day) for 4 days. After a 10-day washout period, they consumed the other diet for 4 days. Urine was collected on the last day of both dietary regimens. Urinary oxalate excretion and the number of nanocrystals were characterized using ion-chromatography-mass spectrometry and nanoparticle tracking analysis, respectively. Microscopy and spectroscopy were used to evaluate morphology and chemical crystal composition.

Results: Both cohorts had increased urinary oxalate excretion while consuming the higher oxalate containing diets compared to the lower oxalate containing diets (Healthy adults – low 6.23 ± 0.80 vs high 13.46 ± 1.46 mg oxalate/g Cr, p<0.007; CaOx KSF – low 7.81 ± 0.59 vs high 13.67 ± 2.03 mg oxalate/g Cr, p<0.069). In addition, nanocrystalluria was significantly elevated (Healthy adults – low 1.39E+08 ± 2.65E+07 vs high 3.00E+08 ± 4.02E+07 particles/mL, p=0.008; CaOx KSF – low 1.91E+08 ± 3.98E+07 vs high 3.90E+08 ± 7.00E+07, p=0.049). Microscopy revealed that the nanocrystals had CaOx morphology, and spectroscopy confirmed that they were composed of CaOx.

Conclusions: These findings suggest that intake of meals containing moderate/large amounts of oxalate augments urinary oxalate excretion and promotes nanocrystalluria, which is more profound in CaOx KSF. Such responses may play a role in KS formation and could be a potential marker for KS risk.

Comparison of Thiazide vs. Alkali Citrate for Kidney Stone Recurrence among Individuals with Hypocitraturia and High Urine pH

Ryan Hsi,[1] Mary K. Oerline,[4] Joseph J. Crivelli,[2] Sara L. Best,[5] John R. Asplin,[5] Vahakn Shahinian,[4] John M. Hollingsworth.[3] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]University of Alabama, Birmingham, AL; [3]NorthShore University HealthSystem, Evanston, IL; [4]University of Michigan, Ann Arbor, MI; [5]Laboratory Corporation of America Holdings, Burlington, NC.*

Background: The comparative effectiveness of thiazide versus alkali citrate for the prevention of kidney stone recurrence is unknown among individuals with low urinary citrate and high urine pH. We sought to compare symptomatic stone recurrence among individuals with low urinary citrate and high urine pH prescribed thiazides versus alkali citrate.

Methods: Among Medicare beneficiaries with a 24-hour urine collection obtained between 2010 and 2019, we identified individuals with hypocitraturia (≤300 mg/day for males and ≤350 mg/day for females) and high urine pH (>6.3) who had not received thiazides or alkali citrate in the 6 months prior to the collection. Then, we identified a subset who subsequently received a prescription fill for a thiazide or alkali citrate, but not both, within 6 months after the urine collection. We used the Kaplan-Meier method and multivariable Cox modeling, adjusting for demographic and baseline 24-hour urine parameters to compare the incidence of a symptomatic stone event (i.e., an emergency department visit, hospitalization, or surgery for kidney stones) by 3 years after initiating medical therapy.

Results: Among 1270 individuals (mean age 62.8 years and 68% female), we identified 107 and 1163 people receiving thiazides and alkali citrate, respectively. Comparing those prescribed thiazides versus alkali citrate, we found baseline differences in mean 24-hour urinary citrate (195 mg vs 171 mg, p=0.01) and calcium (209 mg vs 151 mg, p<0.001), but not urine pH (6.7 for both groups). The unadjusted cumulative incidence of a symptomatic stone event was 23.8% for the thiazide group and 33.6% for the alkali citrate group at 3 years (p<0.05). Compared to alkali citrate, thiazide use was associated with a significantly lower hazard of a symptomatic stone event (HR=0.645, 95% CI 0.429-0.970, p=0.04). A sensitivity analysis matching thiazide to alkali citrate users 1:1 by baseline calcium and citrate (n=200) showed similar results (HR=0.445, 95% CI 0.257-0.770, p<0.01).

Conclusions: Compared to alkali citrate, thiazides were associated with a reduction in symptomatic stone events among individuals with hypocitraturia and high urine pH. These data suggest that a prospective trial is warranted to compare their effectiveness.

Recurrent Kidney Stones and Normocalcemic Hyperparathyroidism: A Report of Two Cases

Matthew C. Breeggemann, Stephen L. Gluck. *University of California San Francisco, San Francisco, CA.*

Introduction: Normocalcemic hyperparathyroidism is a risk factor for the development of kidney stones and can be challenging to identify. We report two patients with recurrent nephrolithiasis who were diagnosed with normocalcemic primary hyperparathyroidism.

Case Description: Patient 1: A 73 year old man with recurrent calcium oxalate nephrolithiasis presents to a nephrology based kidney stone prevention clinic. He has spontaneously passed one kidney stone and required one stone removal procedure. His most recent kidney ultrasound is negative for renal calculi. His 24 hour urine chemistry results are notable for a urine calcium level of 369 mg (< 250 mg/d). He is found to have a PTH of 79 ng/L (18-90 ng/L) and a serum calcium of 10.1 mg/dL (8.6-10.2 mg/dL). A parathyroid ultrasound and nuclear medicine scan are consistent with a parathyroid adenoma for which he undergoes a parathyroidectomy procedure. Subsequent lab testing demonstrates resolution of hypercalciuria (67 mg/d) and reduction in both the PTH (30 ng/L) and serum calcium levels (9.3 ng/dL). Patient 2: A 65 year old man with recurrent calcium nephrolithiasis presents to a nephrology based kidney stone prevention clinic. He has spontaneously passed one kidney stone and required four stone removal procedures. His most recent kidney ultrasound is notable for multiple bilateral non-obstructing calculi. His 24 hour urine chemistry results are notable for a urine calcium level of 562 mg. He is found to have a PTH of 125 ng/L and a serum calcium of 9.7 mg/dL. A parathyroid ultrasound and nuclear medicine scan are consistent with a parathyroid adenoma for which he undergoes a parathyroidectomy procedure. Subsequent lab testing demonstrates resolution of hypercalciuria and reduction in both the PTH and serum calcium levels.

Discussion: Primary hyperparathyroidism is commonly diagnosed following biochemical work up for patients found to have hypercalcemia and is a risk factor for the development of hypercalciuria and calcium based kidney stones. More rarely, patients with primary hyperparathyroidism will be diagnosed after presenting with normal serum calcium and variable PTH levels. Establishing a diagnosis of normocalcemic hyperparathyroidism is more challenging and warrants consideration in patients with unexplained hypercalciuria along with PTH levels elevated out of portion to serum calcium levels.

Cholecystectomy Association with Kidney Stone Occurrence

Nadim Zaidan,[1,2] Hachem Araji,[1,2] Toni Habib,[1,2] Khalil El Gharib,[1,2] George C. Bonifant,[1,2] Elie El-Charabaty,[1,2] Suzanne E. El Sayegh.[1,2]
[1]Staten Island University Hospital, Staten Island, NY; [2]Northwell Health, New Hyde Park, NY.

Background: Patients with steatorrhea are at increased risk of calculi formation. For instance, malabsorptive bariatric surgery leads to steatorrhea and calcium chelation, which contributes to higher oxalate bioavailability and enteric hyperoxaluria. A disruption of the biliary acid cycle has been described after cholecystectomy which could lead to altered lipid digestion and subsequently increased oxalate reabsorption. We hypothesize that this potential post-surgical bile acid malabsorption could be associated with the occurrence of nephrolithiasis.

Methods: We used the National Inpatient Database (NIS), between 2016 and 2020, to identify patients with diagnoses of urinary tract calculus (CCSR: GEN005) and cholecystectomy (CCSR: HEP006) through the appropriate ICD-10 codes. Only adult patients (>18 years) with identifiable body mass indices (BMI) levels were included in the study. Binary logistic regression was performed to assess whether cholecystectomy was independently associated with nephrolithiasis, while adjusting for basic demographic covariates and known risk factors for kidney stone formations. All statistical analyses were performed using the SAS software.

Results: A total of 5 646 289 patients were included in the final cohort, 1.56% of which had undergone cholecystectomy. 56 234 patients had a diagnosis of kidney or urinary tract calculus, with a mean age of 60.39 years and a female predominance (53.60%). Cholecystectomy was found to be independently associated with the occurrence of calculi (Chi-Square = 51.96; p-value < 0.0001). After adjusting for demographic covariates (age, sex, race, geographic location, payer type, income level) and medical comorbidities (diabetes mellitus, gout, alcohol use, tobacco use, BMI), we found an odds ratio of 1.223 [1.151 – 1.299] of urinary tract calculi in patients that underwent this surgery compared with patients that still had their gallbladder, which indicates an 18.23% percentage increase in risk.

Conclusions: The association between cholecystectomy and urinary tract calculus and the percentage increase in risk in patients that underwent the surgery highlights the underappreciated impact of bile acid physiology on lipid digestion and its potential link with kidney stone disease. Further analysis involving prospective cohorts will be necessary to confirm and better elucidate this association.

FR-PO239

Net Gastrointestinal Alkali Absorption and Risk of Bone Disease

Calyani Ganesan,[1] Gary C. Curhan,[2] Pietro Manuel Ferraro,[3] Julie M. Paik.[2]
[1]Stanford University School of Medicine, Stanford, CA; [2]Brigham and Women's Hospital, Boston, MA; [3]Universita degli Studi di Verona, Verona, Italy.

Background: Studies suggest that the modern Western diet provides a net acid load to the body and may negatively impact bone health. The role of dietary alkali in neutralizing this acid load and mitigating acid-related injury to bone remains unknown. The objective of this study was to investigate the association between gastrointestinal alkali absorption and bone disease.

Methods: We analyzed the association between net gastrointestinal alkali absorption (NGIA) and incident bone disease using three large cohorts - the Health Professionals Follow-up Study, Nurses' Health Study I and Nurses' Health Study II. We estimated NGIA according to the Oh equation using 24-hour urine measurements. The primary composite outcome of bone disease included osteopenia, osteoporosis and fracture (hip, vertebral and wrist). We performed Cox proportional hazards regression to identify the incident risk of bone disease by level of NGIA. We adjusted for factors that impact bone health such as age, sex, body mass index, and smoking status.

Results: We included data from 4,592 participants (1,023 men and 3,569 women). A total of 1,226 bone disease cases were confirmed. The incidence rate of bone disease was 1,922 per 100,000 person-years. The mean (SD) NGIA for quintile 1 was 4 (9.4), for quintile 2 was 19.6 (5.1), for quintile 3 was 29.8 (5.2), for quintile 4 was 41 (6.6) and for quintile 5 was 64.1 (15.9). When compared with the lowest quintile of NGIA, the adjusted HRs of bone disease were 1.12 (95% CI 0.90, 1.35) for quintile 2 of NGIA, 1.07 (0.88, 1.29) for quintile 3, 1.10 (0.91, 1.33) for quintile 4 and 1.27 (1.06, 1.53) for quintile 5 (p-trend=0.20). Results did not materially differ by sex. Factors associated with an increased risk of bone disease included body mass index < 21 kg/m^2 (HR 1.7; 95% CI 1.38, 20.8) and current smoking status (HR 1.50; 95% CI 1.17, 1.93).

Conclusions: When compared with the lowest levels of NGIA, there was no significant association between moderate levels of NGIA and the risk of bone disease; however there was a significant association between the highest levels of NGIA and the risk of bone disease. The heterogeneity in the strength of the association between moderate to high levels of NGIA and bone disease suggests that dietary alkali likely has a modest effect on bone health when compared to other risk factors such as low body mass index and smoking status.

FR-PO240

Association of Serum Vitamin D Levels with Cardiovascular and All-Cause Mortality among Kidney Stone Formers: The National Health and Nutrition Examination Survey, 1988-1994 and 2007-2018

Eduardo Cadore Guzzo, Christina A. Raker, Jie Tang. *Brown University, Providence, RI.*

Background: The associations between serum 25-hydroxy-vitamin D (25D) levels and mortality outcomes in individuals with kidney stone disease (KSD) remain unclear.

Methods: We assessed the relationship between 25D levels and mortality among a sample of US adults (age ≥20 years), using the National Health and Nutrition Examination Survey (NHANES) 1988-1994 and 2011-2018, and its Linked Mortality File (through 2019). KSD was defined as a self-report of any previous episode of kidney stone. Cox proportional hazard regression analyses were used to estimate the risks of all-cause and cardiovascular disease (CVD) mortality.

Results: We included 42,207 participants in the analysis; among them, 3,378 had KSD. Stone formers (SF) tended to be male, white, and older, had a higher BMI, and were more likely to have hypertension, diabetes, and CVD. However, the estimated GFR was similar between SF and non-SF. Among SF, the mean serum 25D was 69.1 ng/ml, there were 749 all-cause deaths and 209 CVD deaths with a median follow-up of 7.8 years, whereas among non-SF, the mean serum 25D was 66.6 ng/ml, and there were 7,761 all-cause deaths and 2,231 CVD deaths with a median follow up of 10.3 years. In both unadjusted and adjusted analyses, unlike non-SF where higher serum 25D was associated with a lower risk for death and CVD death, higher serum 25D was associated with a lower risk for CVD death but not all-cause death in SF [Table].

Conclusions: Among SF, higher serum 25D was associated with a reduced risk for CVD death but not all-cause death. Future prospective studies are needed to clarify the effect of 25D on survival among SF.

Funding: Private Foundation Support

Association of Rotating Night-Shift Work with Kidney Stone Risk in the Nurses' Health Studies

Joseph J. Crivelli,[1] Kyle Wood,[1] Eva S. Schernhammer,[2,3] Gary C. Curhan.[2] *[1]The University of Alabama at Birmingham Heersink School of Medicine, Birmingham, AL; [2]Brigham and Women's Hospital, Boston, MA; [3]Harvard T H Chan School of Public Health, Boston, MA.*

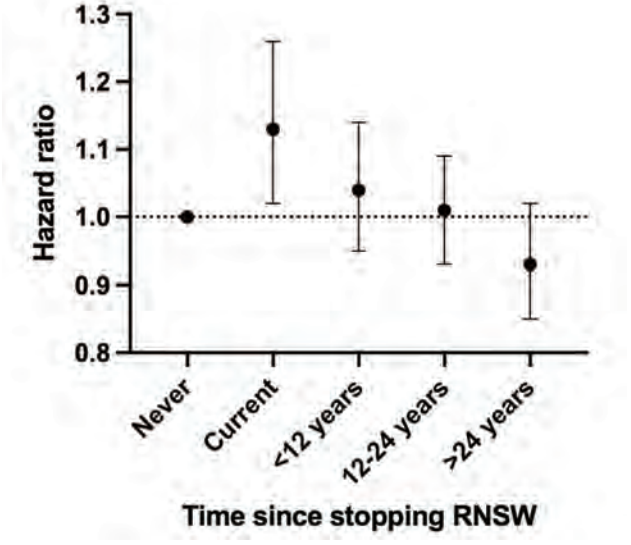
Background: Night shift work is associated with adverse health outcomes including cancer and cardiovascular disease. The extent to which sleep behavior influences kidney stone risk is unknown. We examined the association of rotating night shift work (RNSW), a state of chronically disrupted circadian biology, with incident kidney stone risk in the Nurses' Health Studies (NHS).

Methods: Female participants of NHS I and II with no history of kidney stone disease at baseline (1988-1989) were included in this analysis. Lifetime duration (in years) of RNSW (≥3 night shifts per month plus day and evening shifts) was determined at baseline in NHS I and II and updated every 2-4 years in NHS II. We used multivariable adjusted Cox models to estimate the risk of incident kidney stone disease as a function of RNSW.

Results: A total of 63,493 participants of NHS I and 91,497 participants of NHS II met study criteria. During 24 years of follow-up in NHS I and 32 years of follow-up in NHS II, there were 1,874 and 4,550 incident kidney stones. There was no statistically significant association between duration of RNSW and incident kidney stones in NHS I and II. However, in NHS II, compared to women who have not worked RNS, those with current RNSW had statistically significantly higher kidney stone risk (hazard ratio, 1.13 [95% confidence interval, 1.02-1.26]), with risk decreasing as time since stopping RNSW increased (Figure).

Conclusions: Among female registered nurses, current RNSW was associated with increased kidney stone risk, with waning risk after cessation; however, a consistent dose-response relationship between duration of RNSW and kidney stone risk was not observed.

Funding: NIDDK Support, Other NIH Support - NHS I and II infrastructure grants: UM1CA186107 and U01CA176726., Government Support - Non-U.S.



Hazard ratios of incident kidney stone disease among participants of NHS II stratified by time since stopping rotating night shift work (RNSW). No history of RNSW is the reference group.

FR-PO242

Changes in Diet among Adult Kidney Stone Formers in the United States: The National Health and Nutrition Examination Survey, 1988-2018

Jie Tang, Christina A. Raker. *Brown University Warren Alpert Medical School, Providence, RI.*

Background: Kidney stone disease (KSD) is highly influenced by dietary factors. Here we aim to examine the changes in dietary pattern of adult stone formers (SF) in the United States from 1988 to 2018.

Methods: We examined the dietary data of prevalent SF among a nationally representative sample of US adults (age ≥20 years) using the National Health and Nutrition Examination Survey (NHANES) III and 2007-2018. Weighted multiple linear regression analyses were used to examine the trend.

Results: The study was divided into four time periods, 1988-1994, 2007-2010, 2011-2014 and 2015-2018. Number of SF (males/females) were 450/311, 591/420, 459/427, 573/451 respectively. The KSD prevalence rate increased from 5.5% in 1988-1994 to 10.8% in 2015-2018, with a male-to-female ratio slightly decreased from 1.38 to 1.32. Changes in dietary pattern were shown in the table.

Conclusions: There was a significant increase in polyunsaturated fat, calcium, and fluid intake over time. But dietary potassium intake was reduced. Overall, there were no changes in dietary calories, protein, carbohydrate, fiber, saturated fat, and sodium. The rising KSD prevalence in US is unlikely driven by dietary changes alone.

Funding: Private Foundation Support

Table. Changes in dietary pattern among SF in US adults: NHANES 1988 - 2018

	Population	1988-1994	2007-2010	2011-2014	2015-2018	P value

Changes in dietary pattern among SF in US adults: NHANES 1988 - 2018

FR-PO243

Trend Analysis of Kidney Stone-Related Mortality, 1999-2020

Luqman Munir,[1] Ahmed J. Chaudhary,[2] Mohammad Ammar ur Rahman,[1] Amna Khalid,[1] Azka Ijaz.[1] *[1]King Edward Medical University, Lahore, Pakistan; [2]Detroit Medical Center, Detroit, MI.*

Background: Kidney stones (KS) are hard deposits that can form inside the kidney or the urethra, obliterating the flow of urine and causing sharp pain. It might consist of calcium oxalate, uric acid and struvite. The stones may pass in urine painlessly, if hydrated enough or may require procedure like lithotripsy for treatment. This study explores the trend of deaths in the US from 1999 to 2020 in relation to kidney stones using age adjusted mortality rate (AAMR) to identify disparities among specific epidemiological groups (age, gender, race, urban/rural).

Methods: Our research involved analysis of death certificates between 1999 to 2000 obtained from the Centers for Disease Control and Prevention Wide Ranging Online Data for Epidemiologic Research (CDC Wonder) database related to AAMR per 100,000 people. And annual percentage change (APC) with 95% confidence interval were determined. Joinpoint regression Program was used to conduct test for parallelism and to determine variations among key demographic groups. (age, gender, race, urban/rural).

Results: A total of 18,539 deaths were recorded in relation to kidney stones from 1999 to 2020 in the US. The AAMR trend is increasing as it was 2.269 in 1999 and 3.554 in 2020. The recorded APC from 1999 to 2014 was 0.4719 and from 2014 to 2020 was 6.1495. There were higher mortality rates in Whites, males, those aged >85 years,

and those residing in rural and western areas. Tests for parallelism revealed disparate trends across Male and Female (p=0.002222), Black and White races (p=0.004222), South and West (p=0.004889), Northeast and South (p=0.002444), Midwest and northeast (p=0.043111) and urban vs. rural demographics(p=0.012000).

Conclusions: An upward trajectory has been seen in kidney stones related deaths from 1999 to 2020. This accentuates the need for further research in kidney health to minimize such rates in upcoming years.

FR-PO244

Combined Occurrence of Cardiovascular and Bone Events in Individuals with Kidney Stone Disease

Pietro Manuel Ferraro,[1] Eric N. Taylor,[2] Gary C. Curhan.[3] *[1]Universita degli Studi di Verona, Verona, Italy; [2]Maine Medical Partners, Portland, ME; [3]Brigham and Women's Hospital, Boston, MA.*

Background: Kidney stone disease (KSD) has been linked to increased risk of adverse cardiovascular (CV) and bone events. This has led to the hypothesis that a shared pathogenic pathway may underlie these events. However, it is unclear whether adverse CV and bone events commonly occur in the same individual. We examined the patterns of occurrence of CV and bone events in individuals with a history of KSD and analyzed their characteristics.

Methods: We analyzed data from three large prospective cohorts, the Health Professionals Follow-up Study (HPFS, men) and the Nurses' Health Study (NHS, women) I and II. Individuals with a self-reported diagnosis of KSD during follow-up and no previous CV or bone events at the time of KSD diagnosis were included in the study and followed until the combination of a CV event (fatal or non-fatal myocardial infarction, need for coronary revascularization) and a bone event (fracture, osteoporosis); individuals who developed cancer or were lost to follow-up were censored. Characteristics of stone formers who experienced only one event (CV or bone), both events, or none were compared with the appropriate statistical tests.

Results: Our study included data from 15,041 individuals with KSD. In HPFS, 28.7% of the participants experienced at least one event: 17.4% a CV event, 8.4% a bone event and 2.8% both events. In NHS I, 46.9% of the participants experienced at least one event: 7.4% a CV event, 33.2% a bone event and 6.3% both events. In NHS II, 27.8% of the participants experienced at least one event: 2.2% a CV event, 24.5% a bone event and 1.1% both events. Baseline characteristics according to the type of event experienced are reported in Table 1: across cohorts, age, BMI, use of thiazides, use of calcium and vitamin D supplements, prevalence of hypertension and diabetes tended to differ between groups.

Conclusions: Cardiovascular and bone events are common in KSD; however, their simultaneous occurrence in the same individual is uncommon, suggesting that risk factors might not be shared between cardiovascular and bone events.

Correlation of Global Climate Change and Kidney Stone Awareness: A Temporal Trends Analysis, 2004-2023

Noppawit Aiumtrakul,[1] Methavee Poochanasri,[2] Chutawat Kookanok,[2] Charat Thongprayoon,[3] Supawadee Suppadungsuk,[3,4] Pajaree Krisanapan,[3,5] Wisit Cheungpasitporn.[3] *[1]Department of Medicine, John A. Burns School of Medicine, University of Hawaii, Honolulu, HI; [2]Department of Medicine, Phramongkutklao College of Medicine, Bangkok, Thailand; [3]Division of Nephrology and Hypertension, Department of Medicine, Mayo Clinic, Rochester, MN; [4]Chakri Naruebodindra Medical Institute, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Samut Prakan, Thailand; [5]Department of Internal Medicine, Faculty of Medicine, Thammasat University, Pathum Thani, Thailand.*

Background: Kidney stones become more prevalent and create impacts on global health. Stone formation is a multifactorial process influenced by dietary, genetic, lifestyle and geographical factors. This study aims to investigate relationships between kidney stone awareness on Google search trends and global temperature over the past 20 years.

Methods: The study utilized Google Trends to quantify awareness of kidney stones, measured by relative search volume (RSV). Pearson's correlation and linear regression model were employed to evaluate the association between the RSV of kidney stones and average global land temperature each month from 2004 to 2023.

Results: The scatter plot showed a clear positive correlation between land temperature and the RSV of kidney stones, indicating increased searches as temperature rises. Despite some data dispersion, the linear regression line's imperfect fit highlighted the relationship's complexity. The modest R-squared value at 0.227 suggested temperature explains only a small portion of search volume variance, hinting at additional influencing factors. The predicting equation for kidney stone search volume by land temperature is Y=39.87+ 20.65*X. In regression analysis, for every unit increase in land temperature, RSV increases by 20.65 ($p < 0.01$). For every standard deviation increase in land temperature, RSV increases by 0.477 ($p < 0.01$).

Conclusions: The correlation between kidney stone RSV and global temperature underscores climate change impact on public health information-seeking behavior. While temperature is influential, other factors also found affect search volume, highlighting the necessity for comprehensive research. Further exploration of these factors is vital for effective public health interventions and management strategies.

Facility-Level Variation in Nephrology Care among Veterans after Urinary Stone Events

Kaleb Thomas,[1] Calyani Ganesan,[1] Sai Liu,[1] Maria E. Montez-Rath,[1] Simon John Christoph Soerensen,[1] John Leppert,[1,2] Alan C. Pao.[1,2] *[1]Stanford Medicine, Stanford, CA; [2]VA Palo Alto Health Care System, Palo Alto, CA.*

Background: Nephrologists are uniquely qualified to manage recurrent urinary stone disease. The objective of this study was to determine the frequency of nephrology visits after a urinary stone event, a key window of opportunity to assess stone risk.

Methods: We used nationwide data from the United States Veterans Health Administration to identify patients who had an incident stone event between 2016 and 2018. We defined a stone event as having an (index) inpatient or outpatient stone diagnosis code followed by an additional stone diagnosis or procedure code within 6 months of the index diagnosis. We examined the proportion of patients who visited a nephrology clinic within 6 months of a stone event.

Results: We identified 45,133 Veterans who had an incident urinary stone event. Within six months of the stone event, only 5.6% of patients visited nephrology if they did not have a prior nephrology visit; whereas 70% of patients visited nephrology if they had a prior nephrology before the stone event. Veterans who had a lower eGFR were more likely to see a nephrologist after a stone event (for patients who visited nephrology previously OR 2.28, 95% 2.01-2.58; for patients who had not visited nephrology previously OR 5.19, 95% 4.69-5.74). The median odds ratio for a nephrology follow-up visit was 1.51 for patients who had a past nephrology visit, whereas the median odds ratio was higher for patients who did not have a past nephrology visit (1.74). Figure 1 shows the proportion of patients who saw a nephrologist after their stone event across 104 sites.

Conclusions: Nephrologists are infrequently and variably involved in the care of patients with urinary stone disease, suggesting potential for quality improvement.

Funding: Veterans Affairs Support

Acute Kidney Disease (AKD) following Ureteroscopy and Laser Lithotripsy: The Latest Frontier for Nephrologists

Francesco Trevisani,[1] Luigi Candela,[1] Eugenio Ventimiglia,[1] Alessia d'Arma,[1] Christian Corsini,[1] Daniele Robesti,[1] Olivier Traxer,[2] Francesco Montorsi,[1] Andrea Salonia,[1] Luca Villa.[1] *[1]IRCCS Ospedale San Raffaele, Milano, Italy; [2]Tenon hospital, Parigi, France.*

Background: Ureteroscopy (URS) with laser lithotripsy is the gold-standard for treating ureteral and kidney stones up to 2 cm, but complications can occur in up to 25% of cases. AKI post-URS is underestimated due to exclusive urological management. AKD, a transient kidney function alteration lasting less than 90 days, is under-researched despite its high CKD risk. This study aims to evaluate the occurrence and evolution of AKD in stone patients treated with URS.

Methods: A consecutive cohort of 284 patients treated with URS for urinary stones in a tertiary institution was considered. According to KDIGO 2023, AKD was defined as postoperative acute kidney injury (AKI) occurrence, estimated glomerular filtration rate (eGFR) decrease ^{3}35%, or serum creatinine (SCr) increase ^{3}50%. AKI was defined as SCr increase ^{3}0.3 mg/dL or ^{3}50%. AKD evolution was evaluated 60 days post-URS. Univariable (UVA) and multivariable (MVA) logistic regression analyses tested the association of patients' characteristics and perioperative data with the occurrence of AKD.

Results: Descriptive statistic is shown in table 1. Overall, postoperative AKD occurred in 32 (11.3%) patients. Recovery from AKD was found in 26 (82%) patients and persistent AKD occurred in 6 (18%) patients. At UVA, age at surgery (p=0.05), baseline SCr (p=0.02), baseline CKD category (p=0.006), Charlson comorbidity index (p=0.01), operative time (p=0.04) and postoperative complications (<0.001) were associated with AKD (table 2). At MVA, CKD category (OR 2.99, 95% CI= 1.4-6.3; p=0.004), operative time (OR 1.01, 95% CI=1.001-1.018; p=0.023) and postoperative complications (OR 3.5, 95% CI=1.46-8.49; p=0.005) were independent predictors of AKD. (table 3)

Conclusions: AKD is a frequent insidious complication in patients treated with URS. Therefore, a tailored nephrological assessment should be mandatory.

FR-PO248

Risk Factors for Postevaluation Symptomatic Kidney Stones in Donor Candidates: A 17-Year Follow-Up Study

Mira T. Keddis,[1] Jaxon Quillen,[1] Nan Zhang,[1] Andrew D. Rule.[2] *[1]Mayo Clinic, Scottsdale, AZ; [2]Mayo Foundation for Medical Education and Research, Rochester, MN.*

Background: We aimed to identify characteristics of kidney donor candidates who develop symptomatic kidney stone events after donor evaluation and assess whether donor status influences the risk of developing a symptomatic stone event.

Methods: A survey was conducted in 2022-2023 among 412 adults with a self-reported history or CT imaging evidence of nephrolithiasis at the time of their kidney donor evaluation at Mayo Clinic between 2000 and 2011. The survey inquired about post-evaluation symptomatic kidney stone events (renal colic pain or gross hematuria), complications, and management. Analyses were performed to assess stone characteristics and risk factors between donor candidates who experienced a symptomatic stone event versus those who did not.

Results: Of the 147 respondents (36% response rate), 94 donated, and 53 did not, with 25 non-donors attributed to kidney stone disease. After a median follow-up of 17 years, 26 respondents (18%) experienced a symptomatic stone event, with 13% being donors and 26% non-donors. Characteristics of donor candidates who experienced a symptomatic stone event post-evaluation are shown in Table 1. Non-donation was a risk factor for a symptomatic stone event in the unadjusted model (OR=2.44, p=0.041). Multivariate analysis indicated younger age (OR=1.05, p=0.031) and the presence of ≥2 kidney stones on imaging (OR=3.09, p=0.02) were associated with symptomatic stone events, while donor status was not (OR=1.49, p=0.41).

Conclusions: Kidney donor candidates who experience symptomatic kidney stones after evaluation tend to be younger, have a higher stone burden on imaging, require more surgical and medical management for stone disease, and were less likely to donate. Our findings suggest that our current donor evaluation process is generally effective in excluding younger stone formers with signficant stone burden on imaging and that these are the key factors to consider in stone formers undergoing donor evaluation.

Table 1. Comparison of demographics, stone characteristics, risk factors, and management among stone formers with versus without a symptomatic kidney stone event post evaluation.

Characteristics	Summary, mean (SD), number (%), or median (Q1-Q3)

Mineral Bone Disorders after Preemptive Kidney Transplantation

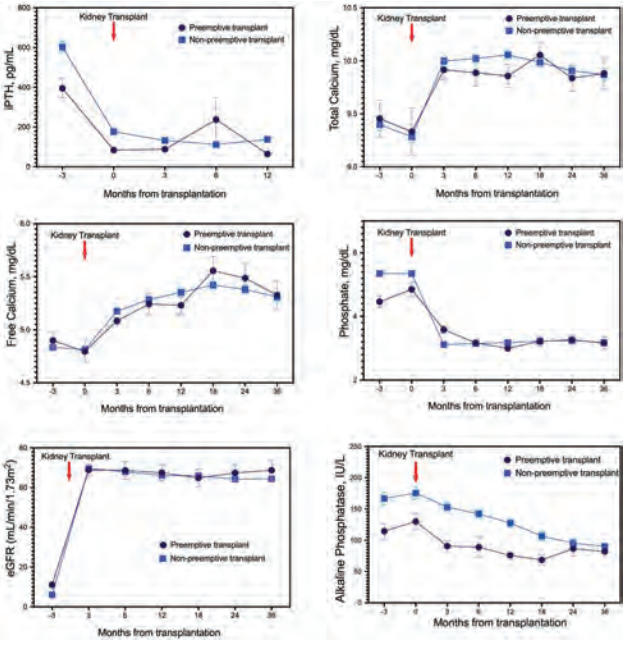
Denisse N. Tinajero Sánchez, Carlos A. Castro Almanza, Nathan Berman, Vianca A. Canaviri, Gabriel Cojuc, Lluvia A. Marino-Vazquez, Luis E. Morales-Buenrostro, Juan Carlos Ramirez-Sandoval. *Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico.*

Background: Mineral bone disorders are common after kidney transplantation. Preemptive kidney transplantation (PKT) may reduce these risks. We aimed to assess the long-term effects of PKT on mineral metabolism outcomes

Methods: Retrospective cohort study with a median follow-up time of 4 years (range 1-9). We compared kidney transplant recipients (KTRs) who underwent PKT (n=26) with KTRs who received hemodialysis before transplantation (n=359). The outcomes included iPTH, free calcium, phosphate, and eGFR trajectories, as well as the presence of post-transplant persistent hyperparathyroidism (iPTH > upper reference level), persistent hypercalcemia (free Ca >5.2 mg/dL) and graft dysfunction (<30 mL/min/1.73m2). Asymptomatic mild hypercalcemia was monitored unless complications developed

Results: Pre-transplant iPTH levels were similar between the PKT and non-PKT groups (median 479 [238-828] Vs 392 [145-603]; p=0.064). There were no differences in the trajectory of biochemical parameters between groups after transplantation. Similarly, when comparing PKT and non-PKT KTRs, we observed no differences in persistent hyperparathyroidism (39% Vs. 45%, P=0.54), persistent hypercalcemia (73% Vs. 62%, p=0.17), and graft dysfunction (4% Vs. 6%, p=0.58). In both groups, PTH levels below 300 were a protective factor against the development of post-transplant hyperparathyroidism or hypercalcemia

Conclusions: PKT in KTRs without controlled hyperparathyroidism did not decrease the risk of hyperparathyroidism or persistent hypercalcemia after transplantation. Medical treatment of mineral bone disorders, with a target iPTH below 300, likely decreases the risk of adverse outcomes in KTRs, including individuals undergoing PKT



FR-PO250

Bone Phenotype and Fracture Risk in Patients with Type 2 Diabetes at the Time of Kidney Transplantation

Sabina C. Hauge,[1] Hanne S. Joergensen,[5,4] Kathleen Claes,[2,3] Patrick D'Haese,[6] Anja Verhulst,[6] Etienne Cavalier,[7] Ditte Hansen,[1,8] Pieter Evenepoel.[2,3]
[1]Copenhagen University Hospital - Herlev and Gentofte, Herlev, Denmark; [2]Katholieke Universiteit Leuven, Leuven, Belgium; [3]University Hospital Leuven, Leuven, Belgium; [4]Aarhus University, Aarhus, Denmark; [5]Aalborg University Hospital, Aalborg, Denmark; [6]University of Antwerp, Antwerpen, Belgium; [7]University of Liege, Liege, Belgium; [8]University of Copenhagen, Copenhagen, Denmark.

Background: Type 2 diabetes mellitus (T2DM) associates with an increased fracture risk in patients with and without chronic kidney disease (CKD), but underlying mechanisms remain poorly understood. This study investigates the mineral and bone phenotype as well as the fracture risk in patients with T2DM and CKD grade 5-5D (CKDG5-5D).

Methods: Parameters of mineral metabolism (fibroblast growth factor 23 (FGF23), sclerostin) and bone turnover (bone alkaline phosphatase (BALP), pro-collagen type I N-terminal propeptide (intact PINP), tartrate-resistant acid phosphatase 5b (TRAP5b)), bone mineral density (BMD, n=555), and trabecular bone score (TBS, n=198) were assessed in 647 patients (T2DM, n=102) at time of kidney transplantation. Bone histomorphometry was available for 188 patients. Patients with type 1 diabetes were excluded. Fragility fractures were retrieved from medical records.

Results: T2DM associated with higher Z-scores at the lumbar spine (-0.066 vs. -0.760, p<0.001) and femoral neck (-0.679 vs. -0.961, p=0.041), but lower TBS (1.223 vs. 1.294, p=0.010). Intact PINP (68.4 vs. 82.0 ng/mL, p=0.033) and FGF23 (1516 vs. 2449 pg/mL, p=0.027) were lower, while sclerostin (2.1 vs. 1.8 ng/mL, p=0.042) was higher in T2DM vs non-T2DM. Bone histomorphometry revealed no differences in bone microarchitecture, turnover or mineralization. During a median follow-up of 10 years 17% with T2DM and 13% non-T2DM sustained a fragility fracture (p=0.343). In cox regression analysis T2DM did not associate with increased fracture risk of fragility fracture (HR: 1.25; CI 0.71-2.18, p=0.437) after adjusting for age, sex, and BMI.

Conclusions: T2DM associated with a distinct bone phenotype characterized by suppressed bone turnover, higher BMD at trabecular sites, and higher circulating sclerostin levels, but T2DM did not associate with an increased fracture risk.

Dual-Energy CT Bone Findings in Kidney Transplant Recipients with Uncontrolled Gout

Bradley A. Marder,[1] Nicola Dalbeth,[2] Abdul A. Abdellatif,[3,4] John K. Botson,[6] Ada Kumar,[1] Lissa Padnick-Silver,[1] Zana Vranic,[1] Fabio Becce.[5] *[1]Amgen, Inc., Thousand Oaks, CA; [2]Department of Medicine, University of Auckland, Auckland, New Zealand; [3]Baylor College of Medicine, Nephrology, Houston, TX; [4]CLS Health, Houston, TX; [5]Department of Diagnostic and Interventional Radiology, Lausanne University Hospital, University of Lausanne, Lausanne, Switzerland; [6]Orthopedic Physicians Alaska, Anchorage, AK.*

Background: CKD pts are at risk for metabolic bone disease including osteopenia and deposition disease. Monosodium urate crystal (MSU) deposits in gout also cause bone erosions/joint damage. The PROTECT study examined pegloticase safety/efficacy in immunosuppressed kidney transplant recipients (KTRs) with uncontrolled gout; a subset underwent dual-energy CT (DECT). Here we report baseline bone-related findings.

Methods: Pts (eGFR≥15,>1yr post-transplant) with baseline DECT were included. Standard protocols were used to acquire images (bilateral hands/wrists, feet/ankles, and/or knees); default post-processing for MSU detection. A central reader interpreted images (typical DECT artifacts removed) and calculated erosion scores (additive% of pre-specified bones [OMERACT RAMRIS scoring[1]]).

Results: 18regions of 8pts included (all male, 52.3±11.2yrs, time since transplant:18.7±6.9yrs, eGFR:45.6±12.4; SU:10.4±2.1mg/dL, 5.3±4.6 flares/6mo). DECT showed multiple bone abnormalities in all pts, including erosions and osteopenia/osteomalacia (trabecular bone loss, cortical thinning, and/or bone resorption). Erosions were common in feet/ankles and hands/wrists (both 7/8[88%]) and most severe in feet/ankles (≥10% eroded: 3/8[38%], ≥40% eroded: 2/8[25%]) and were adjacent to MSU deposits, non-MSU mineralized matrix, and/or not adjacent to any deposits (**Figure**).

Conclusions: These images provide new insight on bone/soft tissue abnormalities in KTRs with uncontrolled gout. Though not an intended PROTECT outcome, DECT showed overall poor bone health. Given additional erosive bone/joint damage MSU deposits can cause, findings suggest effective gout management as an opportunity to improve an aspect of bone health in KTRs with gout. **Reference** 1. Dalbeth N et al. *Rheumatology* 2011;50:410-6

Funding: Commercial Support - Horizon Therapeutics (now Amgen, Inc.)

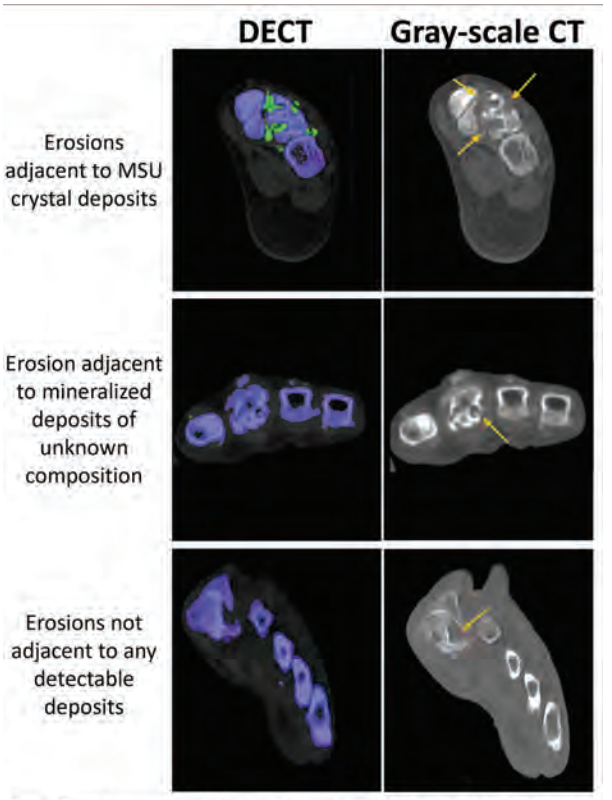

Figure. Renal transplant recipients with uncontrolled gout had notable evidence of bone abnormalities including osteopenia/osteomalacia and bone erosions (arrows). **Top:** Long axis CT image of the foot demonstrated multiple erosions at the bases of the 3rd and 4th metatarsals. DECT imaging revealed MSU crystal deposits (green) adjacent to erosions. **Middle:** Axial CT image of the hand demonstrated mineralized matrix of unknown etiology (white) surrounding the head of the third, fourth, and fifth metacarpal bones with a bone erosion of the 2nd metacarpal head. No definitive MSU color-coded deposits were present on DECT. **Bottom:** Long axis CT image of the foot demonstrated erosions of the 1st metatarsal head. There was no adjacent MSU deposition on DECT or mineralized matrix adjacent to the lateral erosion; possible mineralized matrix/calcium crystal deposits adjacent to the medial erosion with no adjacent MSU deposition on DECT.

FR-PO252

Comparison of Parathyroidectomy vs. Cinacalcet in Treatment of Hyperparathyroidism after Kidney Transplant: A Meta-Analysis

Raphael H. Palma,[1,2] Eduardo L. Rech,[2] Juliana A. Andrade,[1,2] Gisele Meinerz,[1,2] Elizete Keitel.[1,2] *[1]Universidade Federal de Ciencias da Saude de Porto Alegre, Porto Alegre, Brazil; [2]Santa Casa de Misericordia de Porto Alegre, Porto Alegre, Brazil.*

Background: Hyperparathyroidism after kidney transplant (PT-HPT) is a common condition and up to 50% of patients have persistent elevated parathyroid hormone (PTH) levels after 1 year after transplant. The persistent PT-HPT has been associated with higher risk of bone fractures, increased mortality, and decreased allograft survival; therefore, the management of this pathology has varied between transplant centers. Due to the controversies of evidence, we performed a meta-analysis comparing cinacalcet with surgical treatment in PT-HPT.

Methods: We systematically searched PubMed, Scopus, and Cochrane Central Register using terms: ("Kidney Transplantation"[Mesh]OR"Kidney transplantation" OR "Kidney transplant") AND ("Cinacalcet"[Mesh] OR Cinacalcet OR Calcimimetic OR Calcimimetics) AND ("Parathyroidectomy"[Mesh] OR Parathyroidectomy OR surgery). This review was registered in PROSPERO. RevMan Web was used for statistical analysis. Pooled treatment effects for binary endpoints were compared using risk ratio (RR) with 95% confidence interval (CI) and continuous outcome were compared through mean difference. Heterogeneity was examined with Cochran Q test and I 2 statistics. A random effect model was used for outcomes. Risk of bias and quality assessment of individual studies were analyzed with the Cochrane Collaboration's tool.

Results: From 682 screened studies eleven were included, nine retrospective studies and 2 randomized trials. Mean follow-up ranged from 90 days to 2.500 days. Normal calcium serum levels were more frequent in the surgery group (94.1%) than cinacalcet group (71%) and the difference was statistically significant between groups (OR 1.33;

95% CI 1.20-1.48; p < 0.00001, I^2=0%). The incidence of normalized PTH levels was significantly higher in the surgery group (52.5% vs 22.3%, OR 3.18; 95% CI 1.15 - 8.81, p = 0.03, I^2 = 90%). Graft failure was significant lower in parathyroidectomy group (2.1% vs 2.6%, OR 0.45; 95% CI 0.26-0.77, p= 0.004, I^2= 0%). There was no significant difference in mortality between surgery (1%) and cinacalcet group (0.9%), OR 0.61, 95% CI 0.26 - 1.43, p= 0.26, I^2= 0%).

Conclusions: Parathyroidectomy is more effective in controlling calcium and PTH levels in patients with PT-HPT and reduces risk of graft failure but without impact in mortality.

Impact of DNA Methylation Variation on Risk of Kidney Failure in Type 1 Diabetes Is Mediated through Increased Levels of Circulating Proteins

Eiichiro Satake,[1,2] Zhuo Chen,[3] Sok Cin Tye,[1,2] Zaipul Md Dom,[1,2] Marcus G. Pezzolesi,[4] Rama Natarajan,[3] Andrzej S. Krolewski.[1,2] *[1]Joslin Diabetes Center, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]City of Hope Beckman Research Institute, Duarte, CA; [4]University of Utah Health, Salt Lake City, UT.*

Background: In our recent study (*Chen Z, et al. ASN Kidney Week 2023*), we identified 17 whole blood DNA methylation (DNAmet) sites associated with risk of progression to kidney failure (KF) in type 1 diabetes (T1D) patients. Our prior study (*Md Dom Z I, et al. ASN Kidney Week 2022*) found multiple circulating proteins associated with progression to KF in diabetes. The current study aims to explore the possibility that the effect of DNAmet variation at KF-associated sites on risk of KF is mediated through elevated levels of KF-associated proteins.

Methods: We evaluated data from 264 T1D patients with diabetic kidney disease from the Joslin Kidney Study. The analysis focused on 17 KF-associated DNAmet sites in whole blood DNA and 21 circulating proteins associated with KF progression. Using the SAS MEDIATE Macro, we conducted mediation analyses within a Cox model framework, with the DNAmet as exposures, circulating proteins as mediators, and progression to KF as the outcome.

Results: Out of the 17 DNAmet sites investigated, variations at 5 were significantly associated with variation of at least one of the 21 KF-associated proteins. Among them, three DNAmet sites demonstrated an effect on risk of KF mediated through a single protein, while the remaining two DNAmet sites mediated effects on risk of KF through multiple proteins, cumulatively accounting for over 30% of the total effect on KF progression when combining the proteins as multiple mediators (Figure).

Conclusions: Our findings provide evidence for the first time that the impact of DNAmet variations at certain KF-associated DNAmet sites on risk of kidney failure is partially mediated by variation of plasma levels of multiple KF-associated circulating proteins. These findings may not only propose a novel predictive model for KF risk in patients with diabetes but may also help elucidate the molecular pathways involved in the KF progression in diabetes.

Sources and Carriers of Circulating MicroRNAs Associated with ESKD in Diabetes

Eiichiro Satake,[1,2] Bozena Krolewski,[1,2] Zaipul Md Dom,[1,2] Maryalice Hartley,[3] Jill Willency,[3] Monika A. Niewczas,[1,2] Jonathan M. Wilson,[3] Kevin L. Duffin,[3] Andrzej S. Krolewski.[1,2] *[1]Joslin Diabetes Center, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Eli Lilly and Company, Indianapolis, IN.*

Background: Our previous study identified 17 (8 risk and 9 protective) circulating miRNAs associated with end-stage kidney disease (ESKD) in diabetes (*Satake et al, JASN 2021*). The current study investigated tissues/sources and carriers of these miRNAs.

Methods: We measured 2,083 human mature miRNAs in plasma and urine obtained from patients enrolled in the Joslin Kidney Study using the HTG EdgeSeq platform, which requires a small sample volume (15 µl) and does not require RNA extraction. Seventeen miRNAs associated with ESKD from these studies were quantified in blood exosomes, urine, lysates, and supernatants of HUVECs (human umbilical vein endothelial cells), RPTECs (renal proximal tubular epithelial cells), and fibroblasts to identify potential sources of miRNA expression and secretion. Plasma from patients was fractionated by FPLC and by size exclusion spin filters to help identify miRNA carriers in blood.

Results: Out of 17 ESKD miRNAs, none were derived from platelets. Risk miRNAs were predominantly found in plasma rather than cell components, while protective miRNAs were more abundant in cellular components. Several risk miRNAs were more abundant in urine than in plasma; most protective ones were abundant in plasma and almost absent in urine. In vitro experiments showed that risk miRNAs were more abundant in supernatants than in cell lysates in HUVECs and RPTECs, but not in fibroblasts. Regarding carriers, most ESKD miRNAs had significantly higher levels in plasma than in exosomes. Size exclusion chromatography identified that ESKD miRNAs were more abundant in the plasma free fraction that included smaller proteins than in lipoprotein particle fractions.

Conclusions: Our findings suggest that endothelial and proximal tubular cells could be a significant source of circulating ESKD miRNAs, and most of these miRNAs were bound to non-exosomal carriers that included proteins smaller than HDL cholesterol. It is important to understand the regulation of circulating ESKD miRNAs secretion, trafficking, and function to advance our understanding of the mechanisms of the progression of diabetic kidney disease to ESKD, so new therapeutic strategies can be developed.

Spatially Resolved Transcriptomic Profiling of Diabetic Kidney Disease with Stepwise Analysis by Clinical Severity

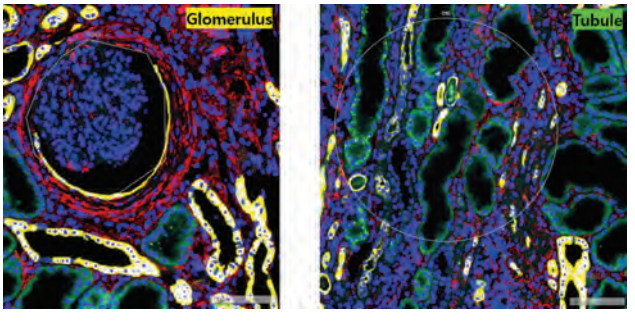
Jae-ik Oh,[2,1] Hyunah Ku,[1] Sehoon Park,[2] Dong Ki Kim.[1] *[1]Seoul National University College of Medicine, Jongno-gu, Seoul, Republic of Korea; [2]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.*

Background: Diabetic kidney disease (DKD) is the leading cause of chronic kidney disease worldwide. Using spatial transcriptomics, we investigated glomerular and tubulointerstitial gene expression profiles in DKD to uncover novel insights for potential biomarkers.

Methods: Spatial transcriptomic profiling using GeoMx was performed on FFPE kidney biopsy specimens from 26 DKD patients and 10 control samples collected from donor kidney biopsy. We configured 73 glomerular and 77 tubulointerstitial ROIs from DKD samples. We compared the gene expression levels of DKD samples with the controls using DESeq2, and performed linear regression analysis for DKD samples categorized as follows, proceeding in the order: 1) random UPCr < 3g/g & eGFR≥60, 2) UPCr≥3 & eGFR≥60, 3) UPCr≥3 & eGFR<60. Gene ontology (GO) annotation was performed using EnrichR and ToppGene, and DEG interactions were mapped with STRING.

Results: The STAT family, VCAM1, TGFB family, and VEGF family, all well known to be associated with DKD, appeared as significant DEGs and showed a significant trend in linear regression analysis (p-value < 0.05). In the tubulointerstitium, 1519 genes showed a negative correlation with worsening proteinuria and eGFR, including metallothionein gene family members (MT1F, MT1H, MT1X) known to mediate SFN renal protection fromd diabetes. G protein-coupled receptor activity and voltage-gated channel activity were among the top enriched GO terms. In the glomeruli, 153 genes showed a positive correlation with worsening proteinuria and eGFR, including SREBF1 and PARL, which are associated with mitophagy regulation. This suggests that a PARL inhibitor may help prevent DKD progression by promoting efficient removal of damaged mitochondria from hyperglycemic conditions. Ribosomal subunits and collagen-containing extracellular matrix were among the top enriched GO terms.

Conclusions: Our study identifies potential therapeutic targets for DKD, supported by consistent trends observed in linear regression analysis. Especially, our findings suggest the potential clinical significance of targeting PARL in DKD.



FR-PO256

Cell States and Niches in Diabetic Kidneys Identified by Spatial Mapping of Targeted Gene Panel at Single-Cell Resolution

Su Woong Jung, Ju young Moon, Sangho Lee, Tae Hoon Lee, Yang Gyun Kim, Hyun Ji Lim, Young yoon Moon, Yoosun Joo. *Kyung Hee University, Seoul, Republic of Korea*.

Background: Technical advance in single-cell genomics ushers into deeper understanding of kidney disease. As kidney is an elaborately organized structure, single-cell research at spatial context in this organ is highly required but few of researches have been tried. Here, we investigated spatial organization of various types of cells in diabetic kidney disease using Xenium In Situ.

Methods: Using Xenium In Situ, we generated single-cell spatial datasets for 475 targeted genes from 4 formalin-fixed, paraffin-embedded human kidney tissues obtained by renal biopsy, which were pathologically diagnosed as advanced stage of diabetic kidney disease.

Results: We created an atlas composed of 168,904 cells and identified major cell types in the kidneys by supervised annotation of marker gene expressions, such as WT1 for podocyte, AQP1 for proximal tubular cells and descending limb of Loop of Henle, CXCL12 for fibroblast, and PTPRC for immune cells. Most of proliferating cells belonged to B cells and macrophages were classified into LYVE^{high}, CCL2^{high}, LGMN^{high}, and others. We defined 12 spatial cellular niches, some of which corresponded to nephron and collecting duct comparment and injury-associated specific cell-enriched comparments such as myofibroblast, B cells, T cells, and plasma cells. These pathologic niches were in close promixity each other, of which forms tertiary lymphoid tissues in which plasma cell niches were surrounded outwardly by B cell and fibroblast niches.

Conclusions: Targeted spatial datesets defines normal and pathologic cellular niches in diabetic kidneys, the latter of which are thought to be the hub for disease propagation.

Liquid Chromatography Tandem Mass Spectrometry Analysis of Lipidomic Differences between Renal Cortex and Medulla in db/db Mice

Hyun Ji Lim,[1] Tae Hoon Lee,[2] Young yoon Moon,[2] Yoosun Joo,[2] Su Woong Jung,[2] Yang Gyun Kim,[2] Sangho Lee,[2] Ju young Moon.[2] *[1]Kyung Hee University, Seoul, Republic of Korea; [2]Kyung Hee University Hospital at Gangdong, Gangdong-gu, Seoul, Republic of Korea*.

Background: Lipids play crucial roles in various biological processes and are involved in the development and progression of many diseases, including diabetes. The lipid compositions in the renal cortex and medulla are different, each performing distinct functions in maintaining body homeostasis. Increased accumulation of lipid droplets and alterations in lipid metabolism have been reported, suggesting potential implications for understanding pathological mechanisms associated with diabetes.

Methods: To further explore lipidomic variations across kidney compartments, we employed tandem mass spectrometry and MALDI-Imaging mass spectrometry. We utilized db/db mice, a widely used model for examining diabetic nephropathy, and lipid extractions were performed on the cortex and medulla for LC-MS/MS while for IMS assessment, we prepared FFPE kidney tissue slides using the whole kidney.

Results: As a result, we identified a total of 390 lipids in medulla and 396 lipids in the cortex. The lipid profile differed between the renal cortex and medulla. In the medulla, ceramide-1-phosphate showed significant changes, while in the cortex, ceramide and phosphatidic acid were notably altered. When comparing the MALDI imaging results with the LC-MS/MS results, PC 34:4 and PC 34:3 increased in the medulla, while PC 32:0 increased in the cortex. Furthermore, the levels of PA 36:0 decreased in the cortex, while TG 46:0 and PE 40:3 decreased in the medulla. Pathway enrichment analysis using relational database of metabolomics pathways (RaMP) revealed distinct biological pathway alterations between renal cortex and medulla. Notably, signaling pathways such as insulin signaling exhibited showed significant changes in the medulla, whereas inflammation and immune-related pathways were altered in the cortex.

Conclusions: Our comprehensive examination of lipid composition revealed distinct differences in lipid metabolism between the kidney cortex and medulla. This study could help in identifying pathogenic alterations in the kidney, shedding light on the mechanisms underlying lipid dysmetabolism and diabetic kidney disease.

Calciprotein Particles Appear to Be Uniquely Present in Diabetic Kidneys

John P. Shapiro,[1] Angela R. Blissett,[1] Leon J. Schurgers,[2] Anjali A. Satoskar,[1] Brad H. Rovin.[1] *[1]The Ohio State University, Columbus, OH; [2]Universiteit Maastricht, Maastricht, Netherlands.*

Background: Diabetes mellitus is commonly associated with diabetic kidney disease (DKD) that can progress to chronic kidney disease and end stage kidney disease. Mass spectrometry (MS) proteome analysis was performed on kidney biopsies obtained from the Kidney Precision Medicine Project (KPMP). Potential biomarkers and molecular mediators of DKD were explored.

Methods: KPMP obtained frozen kidney biopsy sections with DKD (n=11) and AKI (n=4) and normal controls from OSU biorepository (n=4) were analyzed using laser capture microdissection in combination with mass spectrometry. Spectral count global normalization was performed and the proteome of DKD was compared to AKI and controls. Immunofluorescence (IF) microscopy was performed on a cohort of OSU DKD and normal biopsies to confirm mass spectrometry findings.

Results: Analysis of MS data identified secreted phosphoprotein 24 (SPP24), Matrix gla protein (MGP), fetuin-A (AHSG) and serum amyloid P-component (APCS) as uniquely overexpressed in the glomeruli of DKD patients. All 4 proteins demonstrated IF co-localization within the mesangium and interstitial vasculature showing punctate and diffuse staining. These 4 proteins are known to bind to calciprotein particles (CPPs) which are protein decorated cores of calcium/phosphate. Using a monoclonal antibody specific to uncarboxylated MGP (ucMGP), a version of MGP associated with vascular calcification, we demonstrated similar IF staining pattern as the other proteins. Examination of electron micrographs from patients with kidney disease indicates the characteristic presence of electron dense particles only in the expanded mesangium of DKD patients. We believe the IF staining observed in the mesangium and interstitial vasculature and the electron dense particles observed ultrastructurally in DKD glomeruli are correlated and consist of SPP24, ucMGP, APCS and ASHG decorated CPPs.

Conclusions: SPP24, ucMGP, APCS and AHSG decorated CPPS are present in the mesangium and vasculature of DKD patients. Further studies are required to examine the effects of the CPPs and associated proteins in the glomeruli and vasculature of diabetic patients but they could be responsible for induction of endothelial and vascular smooth muscle inflammation and calcification.

FR-PO259

Understanding the Protective Role of Podocyte-Specific ApoJ in Diabetic Kidney Disease

Nehaben A. Gujarati, Malaika Zaidi, Emily Htam, Sandeep K. Mallipattu. *Stony Brook University Renaissance School of Medicine, Stony Brook, NY.*

Background: Mechanisms that confer resistance to progression of diabetic kidney disease (DKD) are unclear. While podocyte loss occurs early in DKD, proximal tubule (PT) injury ultimately determines DKD progression. ApoJ/Clusterin, a secreted molecular chaperone, is increased in human and mouse models of diabetic kidney disease (DKD). However, the role of ApoJ in mediating the progression of DKD remains understudied. Here, we investigate the mechanism by which podocyte-specific ApoJ preconditions the proximal tubule to attenuate the progression of DKD.

Methods: Human podocytes with ApoJ overexpression were generated using lentiviral method and the podocyte secretome was collected. Uninephrectomy + streptozotocin was used as a diabetic mouse model with the respective control mice. Pharmacological inhibition of CaMK1d, using STO-609, was conducted in primary PT cells and diabetic mice. Oxygen consumption rate (OCR) was measured using a seahorse analyzer. PAS, H&E, picrosirus red, immunofluorescence staining, qPCR and western blot were performed.

Results: Primary PT cells treated with the secretome from podocytes overexpressing ApoJ demonstrated an increase in OCR and pDrp1 levels with a decrease in mitochondrial fragmentation under high glucose (HG) conditions compared to control conditions. Inhibition of Lrp2/megalin using cilastatin mitigated this increase in OCR, suggesting that podocyte-specific ApoJ binds to Lrp2. ApoJ also colocalizes with Lrp2 by immunostaining in the apical surface of the proximal tubule in diabetic mice. IP for calmodulin demonstrated that ApoJ interacts with CaMK1d. *Camk1d-/-* as well as treatment with STO-609 reduced pDrp1 levels, OCR, and CaMK1d kinase activity with an increase in mitochondrial fragmentation and cell injury in primary PT cells. Similarly, STO-609-treated diabetic mice exacerbated PT injury as compared to VEH-treated diabetic mice.

Conclusions: These data suggest that under diabetic conditions, the podocyte-specific ApoJ preconditions the PT against injury by undergoing PT uptake via Lrp2, leading to CaMK1d-mediated restoration of mitochondrial function to prevent DKD progression.

FR-PO260

STING-Dependent Podocyte Injury Is Associated with Impaired Mitophagy in Diabetic Kidney Disease (DKD)

Veronika Semenova. *University of Miami Miller School of Medicine, Miami, FL.*

Background: Inflammation plays a significant role in the pathogenesis of diabetic kidney disease (DKD), the most prevalent cause of end stage kidney disease in the USA. We have demonstrated increased glomerular and podocyte expression of the stimulator of interferon genes (STING) pathway in DKD, suggesting that modulated innate immune responses may contribute to glomerular injury. Release of mitochondrial DNA (mtDNA) into the cytoplasm leads to STING activation but the exact mechanism is unknown. Cytosolic mtDNA leakage in DKD is associated with loss of mitochondrial transcription factor A (TFAM) and altered PTEN-induced putative kinase 1 (PINK1)-mediated mitophagy. We hypothesize that TFAM deficiency causes mtDNA escape and STING-mediated podocyte injury via defective PINK1-mediated mitophagy.

Methods: In vitro, human podocytes with knockdown of STING (shSTING), TFAM (shTFAM) and scrambled control (shCTRL) were used to evaluate mitophagy and cytosolic mtDNA. STING and PINK1 expression in shTFAM was assessed by Western blot. In vivo, 16-week-old control (db/+) and diabetic (db/db) mice were used to evaluate TFAM and PINK1 expression by Western blot, mitochondrial morphology by TEM and renal cortical cytosolic mtDNA content by qRT-PCR. Control and STING knockout (STING KO) mice were treated with mtDNA (5mg/kg, 24h) and mice with podocyte specific Tfam deletion (pTFAMfl/fl) were injected with streptozotocin (STZ, 40 mg/kg) to induce diabetes followed by urinary albumin-to-creatinine ratio (ACR), histological and serum analyses. Two-tailed t-test or One-Way ANOVA followed by Tukey's post-test were used to detect statistical changes.

Results: Increased levels of renal cytosolic mtDNA in db/db mice were associated with decreased glomerular TFAM expression and increased PINK1 expression. shTFAM podocytes had increased PINK1 expression and less efficient mitophagosome formation. STING deficiency protected from mtDNA-induced injury in vitro and in vivo. While pTFAMfl/fl mice had no baseline renal injury, STZ treatment resulted in worse renal injury in pTFAMfl/fl mice compared to wildtype.

Conclusions: Our data suggest that podocyte STING activation is driven by TFAM deficiency-mediated mitophagy in association with increased PINK1. Targeting the TFAM/PINK1/STING pathway may lead to new treatment options for DKD.

FR-PO261

Aberrant N-glycation of Complement Factor H Contributes to Alternative Pathway Activation and Disease Progression in Diabetic Kidney Disease

Ying Zhang, Guolan Xing. *The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China.*

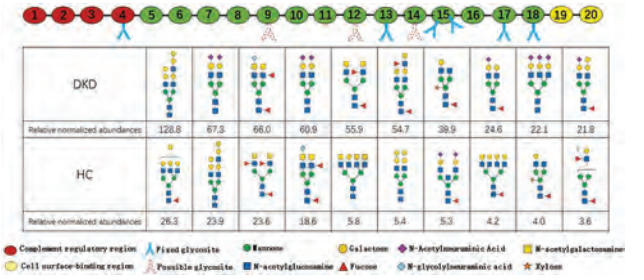
Background: An increasing body of evidence points to an essential role for the activation of complement alternative pathway (AP) in the pathogenesis of diabetic kidney disease (DKD). However, the precise mechanisms of AP activation in DKD are still poorly defined. Complement factor H (CFH), the key regulator of the AP, exerts its decay acceleration activity and cofactor activity to tightly control AP activation. Of note, CFH is a glycoprotein containing 9 N-glycosites, where N-glycation probably affects its 3D structure and function.

Methods: Site-specific N-glycation profile of CFH, including glycosite occupancies, glycan compositions, structural types, and branching patterns, were analyzed using high-performance liquid chromatography with tandem mass spectrometry (HPLC-MS/MS). MS data were processed using Byonic software for glycopeptide identification. Subsequently, the AP activity and decay acceleration activity of CFH were measured by ELISA, and the cofactor activity of CFH was evaluated by SDS-PAGE.

Results: Among the 9 N-glycosites, 3 sites (Asn529, Asn718, and Asn822) were unoccupied in controls but occupied in DKD patients. The remaining 6 sites showed consistent N-glycation, with 4 of them exhibiting a higher occupancy rate in DKD. A total of 147 N-glycan compositions were identified in CFH of DKD patients, far exceeding the 25 N-glycans found in controls. CFH from DKD patients revealed increased relative normalized abundances of N-glycans compared to controls. Sialylation was a common branching pattern of CFH, with higher levels observed in DKD. Both the decay acceleration activity and cofactor activity of CFH were reduced, while levels of AP activity were elevated in DKD patients. The amounts of N-glycans in CFH was positively correlated to proteinuria and negatively correlated to eGFR.

Conclusions: Advanced N-glycation of CFH reduced its regulatory capacities, leading to complement AP activation. Aberrantly N-glycated CFH was demonstrated in DKD patients and associated with the activity and severity of renal injury.

Funding: Government Support - Non-U.S.



N-glycation profile of CFH from DKD patients and healthy controls

Leucine Predicts Progression of Diabetic Kidney Disease and Mediates Metabolic Remodeling in Kidney Tubular Cells of Diabetic Models

Caifeng Shi, Songyan Qin, Aiqin He, Xiaomei Wu, Yemeng Wan, Yu Xiao, Dandan Liu, Lei Jiang, Chunsun Dai, Yang Zhou. *The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: Diabetic kidney disease (DKD) is the leading cause of chronic kidney disease and end-stage renal failure; however, the dominant mechanisms remain obscure and few biomarkers are available. We recently performed a targeted metabolomics study to identify leucine as a novel metabolite biomarker of DKD. Here, we evaluated whether leucine could play a role in progression of kidney disease in patients with diabetes.

Methods: Urine from participants with diabetes from two independent cohorts determined whether urinary leucine-to-creatinine ratio (ULeuCR) could be a mechanistic biomarker for progression of DKD as demonstrated by composite kidney outcomes, including rapid decline in kidney function, end-stage renal failure, and death from a renal cause. Whether defective leucine degradation causes DKD was assessed by metabolic flux assay and metabolomics analysis in kidney tubular epithelial cells and diabetic mice models.

Results: Composite kidney outcomes were associated with the higher ULeuCR quantile in both discovery cohort (HR 4.55, 95% CI 1.40-14.78) and validation cohort (HR 2.93, 95% CI 1.44-5.97). Kidney function decline was associated with the higher ULeuCR quantile in both female (HR 3.78, 95% CI 1.31-10.95) and male (HR 3.35, 95% CI 1.64-6.82) patients with diabetes. Metabolites and enzymes measurement suggested defective leucine degradation in kidney tubular epithelial cells during the progression of DKD. Genetic or pharmacological improvement of leucine degradation by repressing branched-chain ketoacid dehydrogenase kinase (BCKDK) relieved glucose-induced metabolic remodeling in tubular cells and mitigated DKD in diabetic mice models. Hypoxia inducible factor 1α promoted BCKDK expression. In vitro experiment indicated that leucine stimulated metabolic remodeling in tubular cells via mTOR signaling pathway. Restriction of dietary leucine content was found to dramatically reduce albuminuria, kidney hypertrophy and lipid accumulation in diabetic mice models.

Conclusions: We reveal defective leucine degradation in kidney tubules from diabetic subjects and propose leucine as a causative factor in DKD, which warrants further exploration as therapeutic targets.

Funding: Government Support - Non-U.S.

FR-PO263

Mitochondria-Associated Endoplasmic Reticulum Membranes Activating Mitochondrial Apoptosis through Rtn4b/P53/Ei24 Pathway in Podocytes under High-Glucose Condition

Shanzhi Yang, Xiaoyan Bai, Peimin Liu. *Guangdong Provincial People's Hospital, Guangzhou, China.*

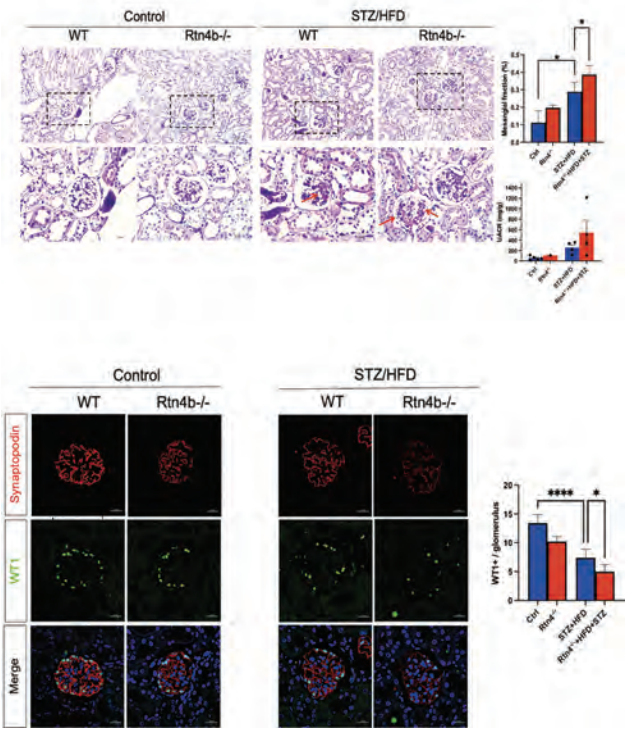
Background: Diabetic nephropathy (DKD) is a global health problem with complex pathogenesis and limited treatment options. The mitochondria-associated endoplasmic reticulum membrane (MAM) is essential for maintaining the normal function of both organelles. In our previous studies, we found the expression level of reticulon 4B (Rtn4b) in renal biopsy tissues of patients with DKD was significantly decreased.

Methods: Here, we explore the underlying role and mechanism in deletion of RTN4B induces podocyte injury.

Results: Results showed as the DKD progresses, the expression level of Rtn4b was gradually decreased in renal biopsy tissues (Fig 1). Altered expression was also observed in type 2 diabetes mice. As with the extension of time of high-glucose exposure, the expression level of Rtn4b in podocytes was gradually decreased. Inhibition of the expression of Rtn4b significantly down-regulated podocyte marker protein synaptopodin, nephrin and podocin.(Fig 2) In *vivo*, global knockout (KO) of Rtn4b deterioated renal function and pathology as presented by aggravated albuminuria, expanded glomerular mesangium and worsened podocyte injury in diabetic mice model (Fig 3). Mechanistically, p53 signaling pathway was among the top 10 enriched items, and mitoptosis related

marker Ei24 ranked the highest score in the differential analysis in HG-cultured podocytes transfected with Rtn4b siRNA (Fig. 4). silencing Rtn4b promoted P53 activation via Ei24 mediated mitochondrial apoptotic pathway (Fig. 5).

Conclusions: Altogether, these results suggest that Rtn4b protects podocytes from diabetic injuries by preventing ER-Mitochondrial crosstalk from mitoptosis and targeting Rtn4b may be a potential therapeutic approach in DN.



FR-PO264

Single-Cell Spatial Metabolomics Reveal That Methylthioadenosine Phosphorylase (MTAP)-Derived Adenine Production Regulates Tubular Mitochondrial Bioenergetics in Type 1 Diabetes (T1D)

Soumya Maity,[1] Ian M. Tamayo,[1] Guanshi Zhang,[1] Alaa Kroma,[1] Hak Joo Lee,[1] Laura Pyle,[2] Ye Ji Choi,[2] Petter Bjornstad,[2] Kumar Sharma.[1]
[1]The University of Texas Health Science Center at San Antonio, San Antonio, TX; [2]University of Colorado Anschutz Medical Campus School of Medicine, Aurora, CO.

Background: Type 1 diabetic patients (T1D) have an estimated 50% risk of developing diabetic kidney disease (DKD) over time. Mitochondrial dysfunction is associated with DKD progression. Our prior study identified endogenous adenine accumulation as a causative factor for DKD and methylthioadenosine phosphorylase (MTAP) as a major adenine-producing enzyme in Type 2 diabetes. In this study, we employed matrix-assisted laser desorption ionization mass spectrometry imaging (MALDI-MSI) to determine the cell-type-specific MTAP-derived adenine effect on mitochondrial bioenergetics.

Methods: Kidney biopsies from young T1D patients (n=17; 24.4±2.6 year) and healthy controls (HC) (n=7; 23.7±4.05 year) were subjected to MSI to estimate the adenine abundance *in situ*. Human proximal tubular (HK2) cells and rat podocytes were co-cultured in normal glucose (5.5mM) containing media on the ITO-coated slide. The cell monolayer was fixed with 4% formalin followed by MSI with 10 µm spatial resolution to evaluate cell-type specific adenine production. The pre-MALDI autofluorescence (AF) image was overlaid with the MALDI ion image to determine the metabolomic signature of a single cell. Western blot and mitochondrial oxygen consumption rate (OCR) were performed in MTAP knockdown mouse proximal tubular (MCT) cells to investigate the role of MTAP in adenine-induced renal pathology and mitochondrial bioenergetics.

Results: MSI data revealed that adenine is significantly accumulated in T1D kidneys compared to HC. Single-cell spatial metabolomics revealed substantially higher adenine production in HK2 cells compared to podocytes. Moreover, 24h 25 mM glucose (HG) treatment showed adenine overproduction in HK2 cells compared to normal glucose. MTAP protein level was significantly increased with HG, suggesting MTAP-derived adenine overproduction in diabetic conditions. Knockdown of MTAP with siRNA enhanced OCR and inhibited HG-induced fibronectin expression in MCT cells, indicating intracellular adenine abundance regulates mitochondrial bioenergetics and DKD pathology in proximal tubules.

Conclusions: Our findings demonstrate that MTAP-derived adenine overproduction may be associated with tubular mitochondrial dysfunction in diabetes, and high kidney adenine may be an early driver of kidney disease in T1D.

Prevention of Diabetic Nephropathy with Mesenchymal Stromal Cells in Cardiac Surgery Patients and in Nonobese Diabetic (NOD) Mice and Diabetic Dogs with "Neo-Islets," Three-Dimensional Organoids of Mesenchymal Stem Cells (MSCs), and Pancreatic Islet Cells

Christof Westenfelder,[1,2] Anna Gooch.[2] *[1]University of Utah Health, Salt Lake City, UT; [2]SymbioCellTech, LLC, Salt Lake City, UT.*

Background: The most common cause of dialysis requiring ESKD is DNP. Prevention of this serious complication is urgently needed. We addressed this need by utilizing the potent capacity of MSCs to prevent AKI and 2° CKD and to provide immune isolation in Neo-Islet (NI) treated autoimmune T1DM. In a Clinical Trial (NCT00733876) in cardiac surgery patients, at high risk for post-op AKI, we compared the renoprotective efficacy of allogeneic MSCs in diabetic to that in non-diabetic subjects. In 2 preclinical studies we investigated whether the therapy of auto-immune T1DM in NOD mice and dogs (INAD012-776) with allogeneic NIs would prevent DNP.

Methods: Clinical Trial: 16 adult patients, 7 diabetic, undergoing on-pump cardiac surgery (CABG ± valve) and being at high risk for post-op AKI were infused via the suprarenal aorta with allogeneic MSCs. Vital signs, renal function and glycemic control were monitored for 10 yrs and compared to those of well-matched historical controls (n=105). Therapy (i.p.) of diabetic NOD mice and dogs with allogeneic NIs: the response of diabetic NOD mice (n=7) vs. controls (n=7) was monitored x 12 wks and in diabetic dogs (n=9) x 3 yrs. Immune responses and mouse renal pathologies were examined.

Results: Clinical Trial: none of the MSC treated diabetic and non-diabetic patients developed post-op AKI or progressed over 10 years to DNP/ESKD. No mortality and no allo-immune response. In contrast, a significant percentage of historical controls developed post-op AKI, progressed to ESKD and suffered mortalitiy. Response of diabetic NOD mice and dogs to NIs: All NOD mice became euglycemic, none developed DNP, while diabetic controls did. Daily insulin needs of TIDM dogs were durably (3 yrs) reduced by 50% ($p< 0.01$), body weights were stable, blood glucose and HbA1C levels and albuminuria were normalized, renal and liver functions, lipid profiles and CBCs remained normal, and no immune responses to NIs or AEs/SAEs were observed.

Conclusions: These studies demonstrate that these biotherapies prevented the development of DNP and ESKD, and this without the need for anti-rejection drugs. The FDA approved the conduct of our IND-enabling study needed for the planned Phase I/II Clinical Trial in which the therapeutic efficacy of human NIs will be tested in T1DM subjects.

LncRNA evf-2 Exacerbates Podocyte Injury in Diabetic Nephropathy by Inducing Cell-Cycle Reentry and Inflammation through Distinct Mechanisms Triggered by Heterogeneous Nuclear Ribonucleoprotein U (hnRNPU)

Jia Guo, Chaojie Zhang, Zhangsuo Liu. *The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China.*

Background: Albuminuria is a hallmark of diabetic nephropathy (DN), heralding the onset of progressive renal dysfunction. Podocyte injury stands as a primary contributor to proteinuria in DN. Our previous study revealed a significant upregulation of lncRNA EVF-2 in podocytes of DN patients, correlating with cell cycle re-entry and inflammation. Notably, the potential contribution of evf-2 to the pathogenesis and progression of kidney diseases, particularly DN, remains largely unexplored.

Methods: We used specific knockout or knockdown of lncRNA evf-2 in diabetic mice or cultured podocytes to confirm the effects of evf-2 in DN. RNA sequencing of evf-2-overexpressing podocytes was used to find out the molecular pathways. Chromatin Isolation by RNA purification-mass spectrometry (ChIRP-MS) was performed to find out the binding proteins of evf-2.

Results: Specific knockout or knockdown of lncRNA evf-2 in diabetic mice or cultured podocytes alleviated podocyte injury driven by cell cycle re-entry and inflammation. RNA sequencing of evf-2-overexpressing podocytes unveiled a predominant enrichment of upregulated mRNAs in cell cycle and inflammation pathways, with alternative splicing events occurring in cell cycle-related mRNAs Ccnb1 and Tacc3 but not in upregulated inflammatory factors. Chromatin isolation by RNA purification- mass spectrometry (ChIRP-MS) analysis highlighted the involvement of ribonucleoprotein complex and mRNA processing-related proteins, with hnRNPU emerging as the primary binding partner of evf-2 in spliceosomes. Partial restoration of the upregulation of the cell cycle and inflammation-related mRNA expression induced by evf-2 overexpression occurred upon hnRNPU-specific knockdown, accompanied by changes in splice variants of Ccnb1 and Tacc3 mRNAs (Ccnb1-202/201 and Tacc3-207/206).

Conclusions: Our study elucidates the interaction between lncRNA evf-2 and hnRNPU, culminating in the upregulation of cell cycle-related genes and inflammatory factors through diverse pathways, potentially involving transcriptional activation, RNA stability modulation, alternative splicing or translational regulation. These findings introduce a novel molecular target and signaling pathway for the treatment of DN.

Cell Type- and Diabetic Kidney Disease-Specific Expression of Long Noncoding RNAs in Human Kidneys

Juliette A. de Klerk,[1,2] Roderick Slieker,[2] Haojia Wu,[3] Yoshiharu Muto,[3] Floris Herrewijnen,[2] Leen M. 't Hart,[2] Rudmer J. Postma,[1] Loïs van der Pluijm,[1] Janneke H. Peerlings,[2] Hans J. Baelde,[4] Tessa Gerrits,[4] Anton J. Van Zonneveld,[1] Benjamin D. Humphreys,[3] Roel Bijkerk.[1]
[1]Department of Internal Medicine, Division of Nephrology, Leiden University Medical Center, Leiden, Netherlands; [2]Department of Cell and Chemical Biology, Leiden University Medical Center, Leiden, Netherlands; [3]Department of Medicine, Division of Nephrology, Washington University School of Medicine, Saint Louis, MO; [4]Department of Pathology, Leiden University Medical Center, Leiden, Netherlands.

Background: Long non-coding RNAs (lncRNAs) play diverse roles within cells, often show cell type-specific expression and impact kidney function. Despite the emergence of single-cell RNA sequencing studies to understand cell specificity, past studies focus solely on the protein coding genome. We hypothesize that lncRNAs, due to their cell type-specific nature, have crucial functions within specific renal cells. Our study aims to characterize and explore the roles of lncRNAs in different cell types in human kidneys and their relationship with diabetic kidney disease (DKD).

Methods: To focus specifically on the non-coding region of the genome We reprocessed single-cell RNA sequencing data from kidney samples that were obtained from six control patients, and seven patients with diabetic kidney disease. We characterized lncRNAs in individual cells and identified cell type-specific lncRNAs as well as lncRNAs which were differentially expressed in DKD. RNAscope was used to validate identified lncRNA expression in the kidney.

Results: Among the 10,342 lncRNAs present in the single-cell RNA-seq dataset (constituting 37.5% of the total transcripts in the scRNA-seq), 349 exhibit cell type-specific expression across 15 different cell types in the human kidney, with 104 showing significant associations with DKD. We set up gene regulatory networks to explore functional roles of differentially expressed lncRNAs in the different cell types. We identified *TARID*, a podocyte-specific lncRNA, to be upregulated in DKD, and to strongly correlate with genes involved in podocyte morphology abnormalities (such as abnormal podocyte foot processes), nephrotic syndrome, and albuminuria, while podocyte-specific expression of *TARID* was validated using RNAscope.

Conclusions: Our study provides a valuable resource for lncRNA expression across cell types in the human kidney and as illustrated by the identification of the podocyte specific lncRNA *TARID*, highlights the potential importance of cell type-specific lncRNAs in diabetic kidney disease.

FR-PO268

Targeting Dynein Activator, Dctn1, Ameliorates Podocytopathy in Streptozotocin (STZ)-Induced Diabetic Mice

Jillian Williquett, Chantal Allamargot, Emily J. Steinbach, Hua Sun.
University of Iowa Health Care, Iowa City, IA.

Background: Diabetic nephropathy (DN) is a severe complication of diabetes that contributes to 30-50% of patients developing end stage kidney disease. In our recent work, we showed an upregulation of dynein genes in diabetes. We have since demonstrated that diabetes suppresses AMP-activated protein kinase (AMPK), which activates specificity protein 1 (SP1)-mediated transcription of these dynein genes. Increased dynactin 1 (Dctn1), a dynein subunit that activates the motor protein, promotes trafficking of nephrin to lysosomes for degradation. The upregulation of Dctn1 correlates with a poor renal outcome in human DN, but its exact role in DN pathogenesis has not been defined. We hypothesize that inactivation of dynein via prevention of Dctn1 upregulation can rescue the disruptions to nephrin trafficking that lead to DN.

Methods: We generated a conditional transgenic mouse line with tamoxifen-inducible podocyte-specific knockdown of Dctn1 in C57BL/6 mice by crossing tamoxifen-inducible NPHS2-icre mice with Dctn1$^{loxp/}$ mice. Diabetes was induced by intraperitoneal (IP) injection of Streptozotocin (STZ) in Cre positive wt/wt and wt/loxp mice. Two weeks later, both the diabetic and nondiabetic mice received IP injections of tamoxifen. Co-staining of Cre recombinase and WT1 was performed to confirm a successful flox of Dctn1 in podocytes. The proteinuria of the mice, histology and ultrastructure of the mouse kidney were compared among diabetic and nondiabetic mice with or without podocyte-specific knockdown of Dctn1.

Results: Mice with STZ-induced diabetes showed features of DN, including proteinuria, glomerulosclerosis, and podocytopathy characterized by reduced nephrin protein with upregulated Dctn1. While Dctn1$^{icre, +/-}$ mice did not undergo spontaneous podocytopathy, they showed rescued disruptions to nephrin and podocytes in diabetic mice, as well as the subsequent development of proteinuria and glomerulosclerosis. The knockdown and normalized expression of Dctn1 in diabetic mouse podocytes prevented the loss of nephrin protein and preserved the foot processes and slit diaphragm structure of podocytes.

Conclusions: Inactivation of dynein via prevention of Dctn1 upregulation protects STZ-mice from developing DN. By elucidating the protective effect of targeting dynein in diabetes-induced mistrafficking of nephrin, we provided a new therapeutic strategy for DN.

VAPB Regulates Fatty Acid Oxidation via Maintaining the Integrity of Mitochondria-Associated Endoplasmic Reticulum Membranes in Diabetic Kidney Disease (DKD)

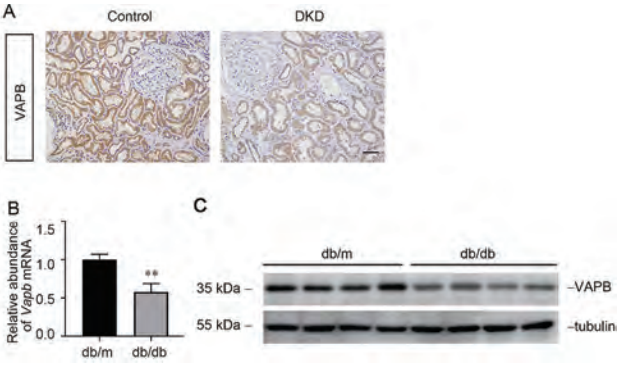
Ting Cai, Xiaobin Liu, Liang Wang. *The Affiliated Wuxi People's Hospital of Nanjing Medical University, Wuxi, China.*

Background: Defective fatty acid oxidation (FAO) in renal tubular epithelial cells plays an important role in the progression of diabetic kidney disease (DKD). Contact between lipid droplets and mitochondria facilitates mitochondrial FAO. We performed transcriptome-wide association studies (TWAS) and identified vesicle-associated membrane protein-associated protein B (VAPB),an ER-anchored protein that mediates tethering between ER and mitochondria, as a potential causative gene for DKD. In this project, we aim to investigate whether VAPB affects FAO in DKD and to elucidate the underlying mechanism.

Methods: VAPB adenovirus or negative control was delivered to the kidneys of male db/db mice and littermate db/m mice at 12 weeks of age by intra-parenchymal injection, and kidneys were harvested 4 weeks after injection. Primary renal tubular cells were transfected with VAPB adenovirus or negative control and then exposed to the high glucose (30mM) treatment for the indicated time.

Results: VAPB expression was found to be decreased in renal tubules of patients with DKD and db/db mice. Inducing overexpression of VAPB attenuated tubular injury and lipid droplet accumulation, and restored expression level of FAO-related enzymes (PPAR-α,ACADL) both in vivo and in vitro. Mechanistically, analysis of VAPB binding partners and membrane contact sites revealed that mitoguardin2 (MIGA2), a mitochondria outer membrane protein and lipid droplet binding protein, may interact with VAPB to maintain the integrity of mitochondria-associated endoplasmic reticulum membranes (MAMs). We found that high glucose reduces the binding of VAPB to MIGA2, disrupts the integrity of MAMs, and increases the distance between lipid droplets and mitochondria in vitro.

Conclusions: We proposed that VAPB may regulate fatty acid oxidation in renal tubules in DKD by maintaining the integrity of MAMs through interaction with MIGA2, which promotes contact between lipid droplets and mitochondria.



FR-PO270

Novel Variant of ARHGEF18 Increases Susceptibility to Adriamycin-Induced Podocyte Injury

Nanditha Anandakrishnan, Jonathan C. Haydak, Anika Hudson, Maria Paola Santini, John C. He, Girish N. Nadkarni, Evren U. Azeloglu. *Icahn School of Medicine at Mount Sinai Department of Medicine, New York, NY.*

Background: Diabetic kidney disease (DKD) is a leading cause of end-stage kidney disease (ESKD) however, therapies have been limited due to disease heterogeneity. Using deep learning we recently identified a novel nonsynonymous disease-causing variant within the Rho GTPase regulatory gene *ARHGEF18* associated with higher risk of ESKD. Overexpression of ARHGEF18 in human podocytes led to impairments in focal adhesion

architecture, cytoskeletal dynamics, cellular motility, and RhoA/Rac1 activation. Here, we further validate the pathophysiology observed *in vitro* using a transgenic mouse model.

Methods: Publicly available KPMP snRNA-seq data was analyzed using Seurat. We created a transgenic mouse line using CRISPR-Cas9 knock-in system to introduce a global G>A point mutation on the mouse *Arhgef18* gene (A1268T), replicating the human rs117824875 variant. We performed retroorbital Adriamycin (ADR) injections in male mice aged 11-13 weeks at 15 mg/kg and urine was collected at baseline and after 1 week to measure the urinary albumin-creatinine ratio (UACR).

Results: We previously showed that rs117824875 led to a pathological accumulation of ARHGEF18 in immortalized podocytes due to increased protein stability, suggesting that increased levels of ARHGEF18 are detrimental to podocytes. Podocyte snRNA-seq data from the KPMP database showed an increased expression of ARHGEF18 in DKD as well as CKD patients (**Figure 1A**). In our transgenic mouse model, we observed a significant increase in UACR in the A1268T mice compared to the WT at one-week after ADR injections (**Figure 1B**). PAS staining and transmission electron microscopy showed increased glomerular area and podocyte foot process effacement, respectively in the A1268T mutant mice compared to the WT (**Figure 1C-D**).

Conclusions: Our data shows that A1268T transgenic mouse model showed increased susceptibility to ADR induced kidney injury. Targeted degradation strategies could be developed as a therapeutic option for management of DKD and CKD.

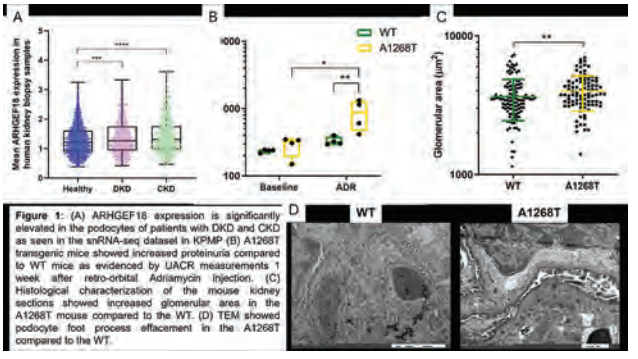


Figure 1: (A) ARHGEF18 expression is significantly elevated in the podocytes of patients with DKD and CKD as seen in the snRNA-seq dataset in KPMP (B) A1268T transgenic mice showed increased proteinuria compared to WT mice as evidenced by UACR measurements 1 week after retro-orbital Adriamycin injection. (C) Histological characterization of the mouse kidney sections showed increased glomerular area in the A1268T mouse compared to the WT. (D) TEM showed podocyte foot process effacement in the A1268T compared to the WT.

FR-PO271

Dehydrolithocholic Acid Mitigates Diabetic Kidney Disease by Activating TGR5 and FXR

Hua Zhou. *The Third affiliated Hospital of Soochow University, Changzhou, China.*

Background: Diabetic kidney disease (DKD) is a significant contributor to chronic kidney disease, with metabolic factors playing a crucial role in its development. Our study aimed to investigate the impact of bile acid (BA) metabolism on DKD progression and to explore the mechanisms through which BA metabolism influences DKD.

Methods: Plasma BA levels in healthy control (HC), type 2 diabetes mellitus (T2DM), and DKD groups were measured using ultrahigh-performance liquid chromatography tandem-mass spectrometry (UPLC-MS/MS). Following the identification of potential biomarkers in the clinical study, further in vivo validation was performed. Dehydrolithocholic acid (DHLCA) intervention was administered to DKD mice, and samples of blood, urine, feces, and kidney tissues were collected at 20 weeks of age. Kidney injury was assessed using HE, PAS, and Masson staining. The expression of Takeda G protein-coupled receptor 5 (TGR5) and farnesoid X receptor (FXR) in kidney tissues was analyzed using immunohistochemistry, immunofluorescence, real-time quantitative polymerase chain reaction (RT-qPCR), and western blot (WB). Gut microbiota (GM) metagenomic analysis and targeted BA metabolomics were conducted on fecal samples to assess changes in GM composition and BA levels following DHLCA intervention.

Results: Variations in BA levels were noted among HC, T2DM, and DKD groups. The DHLCA levels in the DKD with macroalbuminuria group were significantly lower compared to the T2DM group, and univariate correlation analysis revealed that DHLCA had the strongest correlation with the urine albumin-to-creatinine ratio (UACR) ($r = –0.329$, $P = 0.001$). In the DKD+DHLCA group, UACR, fasting blood glucose (FBG), liver function, and total BA (TBA) levels were significantly reduced compared to the DKD group alone. Kidney tissue pathology showed that DHLCA intervention mitigated renal tubular injury in DKD. Compared to the DKD group, the expression of TGR5 and FXR in kidney tissues was restored following DHLCA intervention. Metagenomic analysis revealed a significant alteration in GM composition in mice post-DHLCA intervention, marked by an increased presence of *Firmicutes*, particularly *Lachnospiraceae bacterium*.

Conclusions: BA metabolism is altered with the progression of DKD. DHLCA may enhance DKD renal tubular recovery by activating TGR5 and FXR. DHLCA could serve as a potential biomarker for DKD diagnosis and treatment.

Loss of Diabetic Nephropathy Phenotype and Higher Esm-1 Map to Germline Mutation in Splicing Factor Sfswap in Inbred Mice

Keshav Narang,[1] Haochen Guan,[1,2] Xiao Ran Luo,[1,3] Randeep S. Nandal,[1] Demetri Maxim,[1,4] Xiaoyi Zheng,[1,5] Vivek Bhalla.[1] *[1]Stanford University School of Medicine, Stanford, CA; [2]Anhui Provincial Hospital, Hefei, China; [3]Duke-NUS Medical School, Singapore, Singapore; [4]Nephrogen Inc., New York, NY; [5]BriaCell Therapeutics, Philadelphia, PA.*

Background: Only a subset of diabetic DBA/2 DN-susceptible mice develop albuminuria and glomerular leukocyte infiltration. Plasma levels of endothelial cell-specific molecule-1, Esm-1, an anti-inflammatory, secreted proteoglycan inversely correlate with albuminuria in mice and humans. Moreover, over-expression of Esm-1 in diabetic DN-susceptible mice prevents albuminuria and podocyte injury independent of blood glucose. Given an inverse correlation of Esm-1 and features of DN that we observed across generations of inbred mice, we explored the genetic regulation of plasma Esm-1 and susceptibility to DN.

Methods: Genomic DNA was extracted from frozen kidney tissue of N=4 mice / generation from before and after a loss of the DN phenotype and rise in plasma Esm-1. Next-generation sequencing (NGS) of 2x150 bp PCR-free paired-end libraries was performed on a NovaSeq 6000 S4 sequencer to a coverage depth of 30x. NGS data were analyzed using the Genome Analysis Toolkit pipeline for variant calling. Restriction fragment length Polymorphism with StuI and Sanger sequencing at a candidate variant locus were used to validate NGS data in N=21 non-diabetic mice across five generations.

Results: We identified a missense variant (nt 1407 CàA, Asn469Lys (N469K) in the Splicing Factor, Arginine/Serine-Rich 8 (Srsf8, Sfswap) gene. Analysis of this variant indicated a significant association of high plasma Esm-1 with presence of the homozygous variant compared to wild-type mice (4.54±0.45 vs. 1.25 ±0.26 ng/mL, $p<0.0001$). We found low (< 3 ng/mL) plasma Esm-1 in 10 out of 11 wild-type but only 2 out of 10 heterozygous or homozygous mutant mice. Heterozygote variant mice had an intermediate phenotype, indicating a gene dosage effect. Asn-469 is located in a binding domain indispensable for binding of Sfswap to similar splicing factors and is evolutionarily conserved. Further experiments to edit this variant in mouse endothelial cells and to quantify secreted Esm-1 are forthcoming.

Conclusions: Our findings reveal that the Sfswap mutant genotype is highly correlated with plasma Esm-1 levels in DN-susceptible mice. In addition to elucidating genetic drift within the DBA/2 mouse colony, these results may provide novel insights into the genetic regulation of Esm-1 and opposing roles of Sfswap and Esm-1 in protection from DN.

Set7 Methyltransferase and Phenotypic Switch in Diabetic Glomerular Endothelial Cells

Sam El-Osta.[1,2] *[1]Baker Heart and Diabetes Institute, Melbourne, VIC, Australia; [2]Monash University Faculty of Medicine Nursing and Health Sciences, Melbourne, VIC, Australia.*

Background: Hyperglycemia influences the development of glomerular endothelial cell damage, and nowhere is this more evident than in the progression of diabetic kidney disease (DKD). While the Set7 lysine methyltransferase is a known hyperglycemic sensor, its role in endothelial cell function in the context of DKD remains poorly understood.

Methods: Single-cell transcriptomics was used to investigate Set7 regulation in a mouse model of DKD, followed by validation of findings using pharmacological and short hairpin RNA inhibition inhibition of Set7.

Results: Set7 knockout (Set7KO) improved glomerular structure and albuminuria in a mouse model of diabetes. Analysis of single-cell RNA-sequencing data showed dynamic transcriptional changes in diabetic renal cells. Set7KO controls phenotype switching of glomerular endothelial cell populations by transcriptional regulation of the insulin growth factor binding protein 5 (IGFBP5). Chromatin immunoprecipitation assays confirmed that the expression of the *IGFBP5* gene was associated with mono- and dimethylation of histone H3 lysine 4 (H3K4me1/2). This generalizability was investigated in human kidney and circulating hyperglycemic cells exposed to TGFβ1. We showed that the highly selective Set7 inhibitor (R)-PFI-2 hydrochloride attenuated indices associated with renal cell damage and mesenchymal transition, specifically (*1*) reactive oxygen species production, (*2*) *IGFBP5* gene regulation, and (*3*) expression of mesenchymal markers. Furthermore, renal benefit observed in Set7KO diabetic mice closely corresponded in human glomerular endothelial cells with (R)-PFI-2 hydrochloride inhibition or Set7 short hairpin RNA silencing.

Conclusions: Set7 regulates the phenotypic endothelial–mesenchymal transition switch and suggests that targeting the lysine methyltransferase could protect glomerular cell injury in DKD.

FR-PO274

Branched-Chain Amino Acids Drive Mesangial Expansion in Diabetic Kidney Disease

Junichiro Hagita,[1,2] Tomohito Doke,[1] Toshiki Tsuboi,[4,1] Shoma Tsubota,[3] Sawako Kato,[1] Yasuhiko Ito,[2] Takuji Ishimoto,[2] Shoichi Maruyama.[1]
[1]Nagoya Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Nagoya, Japan; [2]Aichi Ika Daigaku Daigakuin Igaku Kenkyuka Igakubu, Nagakute, Japan; [3]Nagoya Daigaku Igakubu Seikagaku, Nagoya, Japan; [4]Shiritsu Yokkaichi Byoin, Yokkaichi, Japan.

Background: The elevation of serum branched-chain amino acids (BCAAs) in diabetic patients has been observed for more than half a century, and it is reported to be associated with obesity and insulin resistance. We previously reported the unbiased metabolomics study identified significantly elevated levels of BCAAs in the kidneys and serum of db/db mice compared to db/m mice. Furthermore, these increases were reduced with SGLT2 inhibitor, Tofogliflozin. However, the contribution of BCAA to the development or progression of DKD has not been elucidated. This study is aimed to identify the effect of modulating BCAA catabolism on DKD.

Methods: The db/db and db/m mice were given 3,6-dichlorobenzo(b) thiophene-2-carboxylic acid (BT-2) (40mg/kg/day), a small molecule allosteric inhibitor of branched-chain α-keto acid dehydrogenase kinase (BDK) for 12 weeks. As an experimental model for BCAA overload, db/db and db/m mice were given a BCAA enrichment mixture (BCAAem) dissolved water for 8 weeks. The blood glucose levels, body weight, and food intake were regularly examined. Urinary albumin, serum leucine levels, and urinary thiobarbituric acid reactive substances (TBARS) were measured. PAS, PAM, and collagen IV staining were performed on FFPE sections.

Results: Body weight, blood glucose levels, albuminuria, and urinary TBARS levels were not significantly reduced in db/db mice treated with BT2 compared to db/db mice. However, serum leucine level, mesangial expansion, and collagen IV accumulation in the glomeruli were reduced in db/db mice treated with BT2. In contrast, the level of albuminuria and serum leucine were significantly increased in db/db mice treated with BCAAem with no change of urinary TBARS levels. Moreover, mesangial expansion in the glomeruli deteriorated in db/db mice treated with BCAAem.

Conclusions: Mesangial expansion induced by diabetes improved with the accompanying decrease in serum leucine concentration due to BT2 treatment. BCAA enrichment diet in diabetes deteriorates albuminuria and mesangial expansion. These findings suggest that circulating BCAA levels modify DKD progression. Intervention in BCAA metabolism may potentially prevent the progression of DKD.

SGLT2-Independent Effects of Canagliflozin on NHE3 and Mitochondrial Complex I Activity Inhibit Proximal Tubule Fluid Transport and Albumin Uptake

Wafaa N. Albalawy,[1,2] Elynna B. Youm,[1,2] Katherine E. Shipman,[1] Kimberly R. Long,[1] Youssef Rbaibi,[1] Michael J. Jurczak,[1] Ossama B. Kashlan,[1] Ora A. Weisz.[1] *[1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]University of Pittsburgh School of Public Health, Pittsburgh, PA.*

Background: Beyond glycemic control, SGLT2 inhibitors have protective effects on cardiorenal function. Renoprotection has been suggested to involve inhibition of NHE3 leading to reduced ATP-dependent tubular workload and mitochondrial oxygen consumption. NHE3 activity is also important for regulation of endosomal pH, but the effects of SGLT2i on endocytosis are unknown

Methods: We used a highly differentiated cell culture model of proximal tubule (PT) cells to determine the direct effects of SGLT2i on Na+-dependent fluid transport and endocytic uptake in this nephron segment. BCECF-AM were used to measure intracellular pH. The effect of gliflozins on albumin uptake and on fluid transport was quantified in opossum kidney (OK) PT cells; cana vs the NHE3 inhibitor S3226 effect on early endosome pH in OK cells was measured using fluorescence ratio imaging. Effects of gliflozins on AMPK pathway were determined by immunoblotting. 10 week-old male C57BL/6 mice were given cana or empa by oral gavage daily following vehicle gavage. Urine was collected via metabolic cages at baseline and after 24h and 48h. Creatinine and albumin were measured by ELISA

Results: Canagliflozin but not empagliflozin reduced fluid transport across cell monolayers and dramatically inhibited endocytic uptake of albumin. These effects were independent of glucose and occurred at clinically relevant concentrations of drug. Cana acutely inhibited surface NHE3 activity, consistent with a direct effect, but did not affect endosomal pH or NHE3 phosphorylation. In addition, canagliflozin rapidly and selectively inhibited mitochondrial complex I activity. Inhibition of mitochondrial complex I by metformin recapitulated the effects of cana on endocytosis and fluid transport, whereas modulation of downstream effectors AMPK and mTOR did not. Mice given a single dose of cana excreted twice as much urine over 24 h compared with empa-treated mice despite similar water intake

Conclusions: We conclude that cana selectively suppresses Na^+-dependent fluid transport and albumin uptake in PT cells via direct inhibition of NHE3 and of mitochondrial function upstream of the AMPK/mTOR axis. These additional targets of cana contribute significantly to reduced PT Na^+-dependent fluid transport in vivo

SGLT2 Inhibition Alters Methionine Metabolism in Diabetic Kidney Disease

Hiroshi Maekawa, Yalu Zhou, Yuki Aoi, Margaret E. Fain, Navdeep S. Chandel, Susan E. Quaggin. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: SGLT2 inhibition protects the kidney although underlying mechanisms are incompletely known. We hypothesized that cell-specific metabolic pathways activated by SGLT2 inhibition in diabetic kidney disease (DKD) underlie benefits.

Methods: Kidneys harvested from 10-week-old male Sglt2 mutant (MT) and wildtype (WT) mice, fed with normal or high fat diet (HFD, 60% calories from fat) for eight or eighteen weeks, were analyzed. Single cell RNA sequence (scRNA seq) was performed on libraries prepared from whole kidneys. Metabolomic analysis of renal cortex was conducted by Metabolon, Inc. Methionine Adenosyltransferase 2A inhibitor (MAT2Ai, 10 mg/kg BW), an inhibitor of the methionine cycle, was injected into intraperitoneal cavity of WT/MT mice with prior exposure to HFD for eight weeks. Bulk RNA seq and Cleavage under targets and release using nuclease were performed on libraries prepared from renal cortex.

Results: HFD-induced obesity was similar in both MT and WT while compensatory hyperphagia was observed in MT. Glucose intolerance occurred in mice fed HFD (WT>MT). Molecular and functional markers of kidney injury including serum creatinine, KIM-1, number of apoptotic cells and albuminuria were higher in WT-HFD. Analysis of scRNA seq showed emergence of a new class of proximal tubular cells (PTC-H), predominantly found in WT-HFD. PTC-H showed increased expression of genes related to epithelial–mesenchymal transition, apoptosis and inflammation. Analysis of metabolomics uncovered differences in WT-HFD vs MT-HFD; metabolites of methionine cycle including SAM were preferentially increased in MT-HFD. MAT2Ai abrogated renal protection with downregulation of NFκB-target genes in MT. Trimethylation of lysine 27 on histone H3 (H3K27me3), a marker of inactive regions of the genome, within genes related to inflammatory signaling were increased in MT-HFD. Especially, H3K27me3 at the promoters of NFκB-target genes, *Fos*, *Jun*, and *Junb* was enhanced in MT-HFD. H3K27me3 was mostly unchanged at the regions with broad peaks, where this mark is already present in WT. A deposition of the H3K27me3 at the SAM-regulated genes in MT-HFD was decreased by MAT2Ai.

Conclusions: SGLT2 inhibition prevents the emergence of a new class of PTC with inflammatory phenotype via region-specific enhancement of repressive histone methylation through methionine metabolic modulation in DKD.

TOMM7 Alleviates Diabetic Kidney Disease by Regulating PINK1/Parkin-Mediated Mitophagy via Intracellular Redistribution of PLA2G6

Yihui Wang.[1,2] *[1]Peking University, Beijing, China; [2]Peking University First Hospital, Beijing, China.*

Background: Accumulating evidence showed that renal tubular injury is crucial for the development of diabetic kidney disease (DKD), and mitophagy is a pivotal event to maintain mitochondrial homeostasis especially in renal tubular cells, which are rich in mitochondria. However, the underlying mechanisms of mitophagy regulation remain largely unknown. This study aims to investigate the role of translocase of outer mitochondrial membrane subunit 7 (TOMM7), a critical regulator of mitophagy, in the pathogenesis of DKD.

Methods: TOMM7 expression was determined in the kidney sections of DKD patients. Subcellular fractions of mice kidney were isolated, and mitochondrial proteomics was used to explore the underlying mechanism, which was further validated in HK-2 cells.

Results: Here, we found that the expression of TOMM7 was significantly downregulated in renal specimens of DKD patients and *db/db* mice as well as high glucose/palmitic acid (HG/PA) treated HK-2 cells accompanied by impaired PINK1/Parkin-mediated mitophagy. TOMM7 overexpression in *db/db* mice significantly alleviated renal injury and restored PINK1/Parkin-mediated mitophagy. Mechanistically, TOMM7 regulated PINK1/Parkin recruitment through modulating intracellular redistribution of PLA2G6 between nucleus and mitochondria in renal tubular cells. Moreover, we identified zinc finger and BTB domain containing 12 (ZBTB12) as a transcription repressor of *TOMM7* and developed renal tubular cells targeted small interfering RNA (siRNA) to achieve specific upregulation of TOMM7 in the kidney. In addition, treatment with *Zbtb12* siRNA could relieve tubular injury and improve mitophagy by increasing TOMM7 expression in *db/db* mice.

Conclusions: In conclusion, this study highlighted that TOMM7 improved PINK1/Parkin-mediated mitophagy through intracellular redistribution of PLA2G6 in renal tubular cells in DKD models, and *Zbtb12* siRNA could be a potential treatment strategy targeting renal tubular cells for DKD.

Long-Term Proteomic Changes from Human Urinary Extracellular Vesicles in Diabetic Patients after Administrating SGLT2 Inhibitors

Chih-Chien Sung, Min-Hsiu Chen, Yi-chun Tsai, Shih-Hua P. Lin. *Division of Nephrology, Department of Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan.*

Background: Sodium-glucose cotransporter-2 (SGLT2) inhibitors exert their effect by selectively blocking the SGLT2 transporters in the renal proximal tubules and provide nephroprotective effects. However, the long-term effects of SGLT2 inhibitors on human renal proteins and transporters remain unclear.

Methods: We collected urine from eighteen patients with type 2 diabetes treated with SGLT2 inhibitors before SGLT2 inhibitors and at 3, 6, 9 months after SGLT2 inhibitors. Urinary extracellular vesicles (uEVs) were isolated by ultracentrifuge. We carried out large-scale LC-MS/MS-based quantitative proteomics from purified uEVslabeled by tandem mass tags (TMT).

Results: Characterization of uEVs was confirmed by nanoparticle tracking analysis, transmission electron microscopy, and immunoblotting. Totally, 1108 quantifiable proteins were identified from uEVs. Functional enrichment analysis from upregulated proteins involved in “inhibition of epithelial cell proliferation” and “cell adhesion remodeling”. Downregulated proteins mainly affected cell membrane such as PODXL, ATP1B1, and AQP1. In addition, we identified the co-expressed differentially expressed proteins (DEPs) including upregulated proteins (GPR110, CHMPA4, APPL2, TPPP3) and downregulated proteins (IGHG1, PODXL, SLC4A4, COBLL1) at different time points. After clustering of DEPs from uEVs based on nephron segments, SGLT2 inhibitors recovered the changed renal tubular proteins identified in diabetic patients compared to healthy controls. Among renal solute carrier groups (SLCs), SGLT2 inhibitors mainly affected the SLCs in proximal tubules (SLC5A1, SLC5A2, and SLC4A4) but not the distal tubules (SLC12A1 and SLC12A3). Moreover, proteomic analysis of uEVs in db/db mice administered with SGLT2 inhibitors also showed the changed proteins in terms of “Focal adhesion” and “Slit diaphragm”.

Conclusions: SGLT2 inhibitors affected renal proteins involving changes of membrane proteins and cellular differentiation in diabetic patients. The effects of SGLT2 inhibitors on solute carrier group (SLCs) mainly focused on proximal tubules. This uEVs proteomic study could help us know how long-term effects of SGLT2 inhibitors on human kidney.

Circulating YRNAs and Their Fragments Associate with Diabetic Kidney Disease and Endothelial Cell Function

Qiao Zhao, Rudmer J. Postma, Jacques Duijs, Juliette A. de Klerk, Joris I. Rotmans, Anton J. Van Zonneveld, Roel Bijkerk. *Leids Universitair Medisch Centrum, Leiden, Netherlands.*

Background: Diabetic kidney disease (DKD) occur commonly in patients with diabetes. Early detection of DKD may guide therapeutic strategies, so it is important to discover new biomarkers and therapeutic targets. Non-coding RNAs have been recognized as potential biomarkers or therapeutic targets in many diseases. yRNAs (RNYs), a class of non-coding RNAs, are highly conserved and can be processed into small fragments. Interestingly, yRNAs and their fragments are highly abundant in circulation. Here, we aim to investigate whether yRNAs and their fragments may serve as biomarkers for DKD and investigate their potential causal role.

Methods: RNA was extracted from serum of patients with diabetes (DM, n=12), DKD (n=18) and healthy controls (HC, n=12), as well as from extracellular vesicles (EVs) isolated from these sera. qRT-PCR was used to measure expression levels of yRNAs and their fragments. Also yRNA subtypes ratios were determined, as it was previously shown that unique quantitative ratios of yRNA subtypes may reflect injury status. Human umbilical vein endothelial cells (HUVEC) and Human Dermal Microvascular Endothelial Cells (HDMEC) were used for *in vitro* studies. siRNA-mediated knockdown was performed to inhibit RNY1 expression. Barrier formation and function of endothelial cells were measured via the Electric Cell-substrate Impedance Sensing (ECIS) method.

Results: The ratios of full length RNY4/RNY3 and RNY4/RNY1 increased in serum of patients with DKD, while the ratio of circulating RNY3/RNY1 and RNY4/RNY1 fragments decreased in DKD as compared to HC. We observed that circulating yRNAs are mostly present in EVs. Interestingly, for each type of yRNA, the ratio of fragment to full length yRNA expression increased in the serum of patients with DM but decreased in the DKD group suggesting a general effect on fragmentation. In addition, in vitro studies demonstrate that, upon stimulation with TGF-β and TNF-α, yRNA expression decreased in endothelial cells. Furthermore, RNY1 inhibition impeded the barrier function of endothelial cells that could be mainly attributed to the loss of cell-cell contacts and membrane capacitance.

Conclusions: Our findings suggest that yRNAs are potential biomarkers for DKD, while yRNAs may also be directly involved in vascular injury through regulating EC barrier function.

Impact of the Nonsteroidal Mineralocorticoid Receptor Blocker Esaxerenone on Glomerular Hemodynamics in Diabetic Kidney Disease

Rie Tatsugawa, Kengo Kidokoro, Seiji Kishi, Hajime Nagasu, Tamaki Sasaki, Naoki Kashihara. *Kawasaki Ika Daigaku, Kurashiki, Japan.*

Background: The FIDELIO-DKD trial showed finerenone, a non-steroidal selective mineralocorticoid receptor blocker (MRB), reduced kidney failure and disease progression in diabetic kidney disease (DKD). Esaxerenone, another non-steroidal MRB, decreased albuminuria in hypertensive patients with type 2 diabetes in the ESAX-DN study. However, the mechanisms behind these effects remain unclear. A decrease in eGFR is observed from the early phase of MRB treatment, and eGFR increases again upon discontinuation. This suggests that MR activity functionally regulates GFR and is likely involved in the pathogenesis of glomerular hyperfiltration in DKD. We hypothesize that MR activation induces glomerular hyperfiltration in DKD by diminishing tubuloglomerular feedback (TGF) through a NO-mediated mechanism in macula densa (MD). We examined the suppressive effects of MRB on glomerular hyperfiltration and elucidated its underlying mechanisms.

Methods: Male Sprague-Dawley (SD) ratswere administered aldosterone (1.0 μg/h via osmotic pumps) and esaxerenone orally (3 mg/kg/day). After three days, single nephron GFR (SNGFR), afferent/efferent arteriolar diameters, and glomerular volume were measured using a multiphoton microscope. The effects of esaxerenone on glomerular hemodynamics were also assessed in male db/db mice (type 2 diabetes) and control db/+m mice, both fed a high-salt diet (3% NaCl) and treated with esaxerenone (3 mg/kg/day). SNGFR and arteriolar diameters were measured in vivo. An adenosine A1 receptor (A1aR) antagonist (1 mg/kg) was used to explore TGF mechanisms.

Results: Aldosterone increased afferent arteriolar diameter and SNGFR in SD rats, indicating glomerular hyperfiltration. Esaxerenone mitigated these changes, confirming the role of MR activation in GFR regulation. Db/db mice exhibited higher urinary albumin levels and SNGFR compared to control. Esaxerenone reduced albumin levels and glomerular hyperfiltration. Combining esaxerenone with the A1aR antagonist diminished the inhibitory effect of esaxerenone on glomerular hyperfiltration.

Conclusions: In DKD, MR activation is implicated in glomerular hyperfiltration, likely through a mechanism mediated by TGF. The impact of MR activation in maculodensin on TGF is currently under investigation.

Liraglutide-Mediated Renoprotection in Type 1 Diabetes: Modulating M1/M2 Macrophage Balance via NOX/TRP Cross-Talk

Natalie Youssef, Mohamad Noureldein, Sarah Almoussawi, Tala R. Kaddoura, Fuad N. Ziyadeh, Assaad Antoine Eid. Eid’s Lab. *American University of Beirut, Beirut, Lebanon.*

Background: Diabetic Kidney Disease (DKD) poses a substantial health burden for patients with diabetes. While studies have demonstrated the renoprotective effects of the GLP-1RA liraglutide in type 2 diabetes (T2D), its impact in type 1 diabetes (T1D) remains less explored. Although some studies suggest renoprotection in T1D, the underlying mechanism remains elusive across both T1D and T2D. Recent evidence highlights the

role of macrophages in the initiation and progression of DKD, where macrophages tend to polarize to an M1 pro-inflammatory instead of an M2 anti-inflammatory phenotype. Besides, extensive data showed that ROS overproduction and calcium signaling dysregulation play a crucial role in DKD progression. Therefore, this study investigates the reno-protective mechanism of liraglutide in T1D and elucidates its effect on restoring macrophage polarization balance by modulating NOX-TRP crosstalk.

Methods: C57/BL6J mice were divided into 3 groups: control group, STZ-induced insulin deficient model mimicking T1D, and a T1D group treated with 0.3mg/kg s.c. injections of liraglutide twice daily. After 13 weeks of treatment, the kidneys were isolated for analysis.

Results: Despite hyperglycemia, liraglutide treatment significantly reduced kidney hypertrophy and improved renal function. Histopathological data confirmed reduced glomerular hypertrophy, glomerulosclerotic index, and collagen deposition. Additionally, fibronectin, Col4, WT1, nephrin, and podocin levels normalized. While liraglutide didn't decrease macrophage infiltration, it did reduce inflammatory cytokine expression and specific M1 macrophage markers. Conversely, anti-inflammatory cytokines increased, along with markers of M2 macrophages. Liraglutide also attenuated ROS overproduction by reducing NADPH oxidase activity. However, further analysis revealed differential modulation of the different NOX isoforms. This finding underscores the pivotal role played by NOX in kidney function and macrophage responses. Besides, liraglutide restored normal TRPM2 and TRPC6 expression and increased TRPM7 expression.

Conclusions: This is the first study to show a reno-protective effect of liraglutide in T1DM manifested by a shift in macrophage polarization from M1 inflammatory to M2 anti-inflammatory phenotype by modulating NOX-TRP crosstalk.

FR-PO282

Protective Role of ST2 Signaling in Diabetic Nephropathy

Vikram Sabapathy, Sai K. Gajula, Saanvi Acharya, Bushra Mehkri, Rahul Sharma. *University of Virginia School of Medicine, Charlottesville, VA.*

Background: Diabetic nephropathy (DN) contributes to morbidity in Diabetes patients (DM), for whom glycemic control remains the primary treatment. The IL-1 superfamily member IL1RL1 (ST2), is activated by its ligand IL-33 was identified in type 2 immune response Recent data suggests loss of IL-33 or its receptor ST2 resulted in increased susceptibility to Type-2 diabetes, increased adiposity, and worsened metabolic profile. Studies from our lab have shown that a novel hybrid cytokine IL233, bearing activity of IL-2 and IL-33, enhances T-regulatory cells (Tregs) and attenuated the loss of kidney function in diabetic Ob/Ob mice, as shown by proteinuria, urinary albumin creatinine ratio (ACR). Histopathology of kidney showed lower inflammation with attenuation of glomerular hypertrophy and mesangial expansion in IL233 treated mice. However, there is lack of knowledge for the role of ST2 signaling in DN.

Methods: We investigated the difference between wild type (WT) and ST2KO mice for susceptibility to DM and DN. We also generated mice with ST2 deletion in Tregs cells (*Il1rl1*$^{fl/fl}$*Foxp3*$^{YFP\text{-}Cre}$) to understand the role of ST2 expressing Tregs in DN. Mice were subjected to multiple low dose streptozotocin (STZ). The structure and function of pancreas and kidney were probed using flow cytometry, histology, immunohistochemistry, ELISA, quantitative PCR as well as enzymatic and biochemical analysis.

Results: Histological analysis of the pancreatic tissue through hematoxylin and eosin staining indicated ST2KO mice had a lower number of islets with smaller islet diameters. Single cell RNA sequencing unraveled unique cell states in knockout islets compared to the WT counterparts. Both immunostaining and transcriptomic analysis indicated lower insulin levels in ST2KO islets compared to WT islets. *In vivo* studies using low dose STZ suggested ST2 deficient mice were more susceptible to diabetes compared to WT mice. In addition, Urinary ACR assay indicated both the global as well as Treg specific loss of ST2 worsened the susceptibility and severity of DN. Flow cytometry data showed increased inflammatory milieu in the pancreas and the kidneys of mice lacking ST2 expression globally or in Tregs.

Conclusions: Results from our studies demonstrate a prominent role of ST2 in islet function, maintain immune homeostasis and protection from DN in a Treg-dependent manner.

GDF-15 Is a Novel Therapeutic Target for Diabetes-Induced Kidney and Cardiac Injuries in Preclinical Models of Type 2 Diabetes (T2D)

Amani W. Slika, Dalal M. Jomaa, Rita Yehya, Sahar Alkhansa, Sarah Almoussawi, Assaad Antoine Eid. *American University of Beirut, Beirut, Lebanon.*

Background: Diabetic kidney disease (DKD) and diabetic cardiomyopathy (DCM) are severe complications of diabetes, with poorly understood underlying mechanisms. GDF-15, a cytokine belonging to the transforming growth factor-β family, has been recently proposed as a novel biomarker for diabetic complications. Several clinical studies have shown that elevated GDF-15 expression is associated with the development of DKD and DCM. However, the pre-clinical role of GDF-15 as a risk predictor requires further investigation. We have previously shown NETosis, a specialized form of neutrophil-specific cell death, to be involved in the pathogenesis of diabetes. In this study, we examine the role of GDF-15 and its effect on NETs formaion in the development of renal and cardiac injuries associated with type 2 diabetes (T2D).

Methods: Male C57BL/6J mice were used. T2D was induced using a high-fat diet/STZ protocol (DiaComp). Two sets of experiments were conducted. In the first series, mice were categorized into: control mice, GDF-15 antibody (AV-380)-treated control mice (at 7.5mg/kg or 20mg/kg), T2D-induced mice, and AV-380-treated T2D mice (at 7.5mg/kg or 20mg/kg). Short-term treatment was administered for 8 weeks. The second series of experiments included control mice, T2D mice, and AV-380-treated T2D mice (at 7.5mg/kg or 20mg/kg) with long-term treatment administered for 15 weeks. Functional, histopathological, and molecular studies were performed.

Results: Our data show that inhibiting GDF-15 restores renal and cardiac homeostasis in T2D mice. Both short and long term treatments reduced proteinuria, glomerulosclerosis, collagen deposition in the kidneys and heart, as well as improved cardiac ejection fraction in AV-380 treated diabetic mice. The expression levels of prominent inflammatory markers were decreased. Furthermore, increased expression of the cardiac hypertrophic proteins and the reduced expression of cardioprotective markers associated with diabetes were restored following AV-380 treatment. Additionally, GDF-15 inhibition reduced the expression of NETosis markers.

Conclusions: The findings of this study suggest that GDF-15 is a therapeutic target in diabetes-induced cardiac and kidney injuries.

Renal Cell Type-Associated Therapeutic Effects of Semaglutide in a Mouse Model of Hypertension-Accelerated Diabetic Kidney Disease

Adam B. Marstrand-Jørgensen,[1,2] Louise Dalbøge,[1] Henrik H. Hansen,[1] Ida Rune,[1] Michael Christensen.[1] [1]*Gubra A/S, Hørsholm, Denmark;* [2]*Kobenhavns Universitet, Kobenhavn, Denmark.*

Background: Obesity, hyperglycemia and hypertension are critical risk factors for development of diabetic kidney disease (DKD). While emerging evidence suggests that glucagon-like peptide-1 receptor (GLP-1R) agonists improve cardiovascular and renal outcomes in type 2 diabetes patients, their mode of action is presently unclear. Using paired bulk and single-nucleus RNA sequencing (RNAseq), we profiled renal transcriptome signatures of the long-acting GLP-1R agonist semaglutide alone and in combination with antihypertensive standard-of-care (ACE inhibitor, lisinopril) in a model of hypertension-accelerated, advanced DKD facilitated by adeno-associated virus-mediated renin overexpression (ReninAAV) in uninephrectomized (UNx) female *db/db* mice.

Methods: Seven weeks after ReninAAV administration and six weeks post-UNx, *db/db* UNx-ReninAAV mice were administered (q.d.) vehicle, semaglutide (30 nmol/kg, s.c.) or semaglutide (30 nmol/kg, s.c.) + lisinopril (30 mg/kg, p.o.) for 11 weeks. Endpoints included blood pressure, urine biochemistry, kidney histopathology as well as paired bulk and single-nucleus RNA seq. Cell type deconvolution was performed by referencing expression of treatment-affected genes across all major kidney cell types using single nuclei RNAseq.

Results: Semaglutide robustly reduced hyperglycemia, hypertension, albuminuria and glomerulosclerosis severity. Co-administration of lisinopril further ameliorated hypertension and glomerulosclerosis. Renal gene expression changes after semaglutide mono- and combination treatment were primarily associated with the immune system and extracellular matrix organization. Semaglutide promoted discrete renal gene expression changes in *db/db* UNx-ReninAAV mice with notable suppression of macrophage-associated genes. Combined semaglutide and lisinopril administration resulted in more widespread transcriptome changes in several renal cell types, including macrophages, mesangial cells, podocytes and proximal tubule cells.

Conclusions: Semaglutide improves disease hallmarks in the db/db UNx-ReninAAV mouse model of advanced DKD and suppresses gene expression markers of ECM remodeling and immune system activation. Outcomes were further improved by combined antihypertensive standard-of-care.

Single-Cell Sequencing Detects Enrichment of ESKD Biomarkers in Injured Proximal Tubule

Parker C. Wilson,[1] Katsuhito Ihara,[2,3] Eiichiro Satake,[2,3] Benjamin D. Humphreys,[4] Andrzej S. Krolewski.[2,3] [1]*University of Pennsylvania Department of Pathology and Laboratory Medicine, Philadelphia, PA;* [2]*Joslin Diabetes Center, Boston, MA;* [3]*Harvard Medical School, Boston, MA;* [4]*Division of Nephrology, Department of Medicine, Washington University in St. Louis, St Louis, MO.*

Background: Diabetic kidney disease (DKD) leads to rapid decline in some patients, but there are no biomarkers to identify these individuals. Proteomics profiles hundreds to thousands of candidate biomarkers, but little is known about how DKD affects these

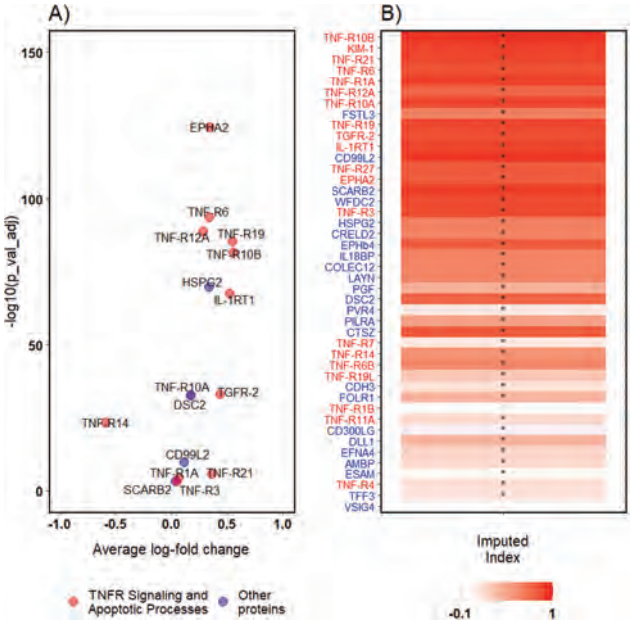
proteins or the cell types they originate from. Here, we identify circulating proteins that predict progression to ESKD using high-throughput proteomics (see Ihara K et al. Kidney Week 2024). We integrate these data with a single-cell atlas from patients with DKD to determine which cell types express these proteins.

Methods: We measured plasma concentration of 455 proteins among 405 individuals with diabetes using the OLINK platform. Elevated concentration of 46 proteins at baseline associated with progression to ESKD after 7-15 years. Single nucleus RNA sequencing (snRNA-seq) from patients with DKD (Wilson et al. 2022) was evaluated for cell-specific expression of biomarkers using Seurat. We focused on injured proximal tubule cells that variably express *HAVCR1* and *VCAM1* because the abundance of this cell type has been associated with kidney function decline.

Results: snRNA-seq showed that 14 of 46 circulating proteins predictive of ESKD were overexpressed in injured proximal tubule cells, including 11 genes encoding apoptosis and TNF-related receptor proteins (Figure A). Cell-specific expression of these biomarkers was correlated with aggregate expression of 205 apoptosis pathway genes. Imputation was performed to mitigate the sparsity of snRNA-seq, which increased the correlation between circulating biomarker expression and apoptosis pathway genes (Figure B).

Conclusions: We hypothesize that injured proximal tubule cells are a significant source of circulating biomarkers that predict progression to ESKD in individuals with diabetes.

Funding: NIDDK Support



FR-PO286

Single-Cell Profiling of Peripheral Blood Mononuclear Cell Identifies Immune Populations Associated with Progression of Diabetic Kidney Disease

Jia Fu,[1] Zeguo Sun,[1] Huei Hsun Wen,[1] Dongyuan Chang,[1,2] Gohar Mosoyan,[1] Kyung Lee,[1] Steven G. Coca,[1] Girish N. Nadkarni,[1] John C. He.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Peking University First Hospital, Beijing, China.*

Background: Emerging evidence has highlighted the pivotal role of inflammation in the development and progression of DKD. Notably, TNF receptors have demonstrated notable associations with eGFR decline in both early and advanced DKD. However, to date, there has not been a comprehensive characterization of circulating immune cell phenotypes in DKD and their relationship with disease progression at the single-cell level.

Methods: In this study, we performed single-cell RNA sequencing of PBMCs from 12 patients, stratified based on high and low serum TNFR levels. Our aim was to discern immune cell subpopulations and their transcriptomic signatures associated with the DKD progression.

Results: By assessing the eGFR slope, serum levels of TNFR-1 and TNFR-2, we have discerned 12 patients demonstrating varying degrees of underlying DKD. Our scRNAseq analysis profiled 109,955 PBMCs, revealing TNFR1 and TNFR2 genes predominantly expressed on CD14 and CD16 monocytes. Circulating TNFR-1 levels correlated positively with monocyte population and negatively with T cells and dendritic cells, while TNFR-2 levels correlated negatively with dendritic cells and CD8 T cell proportion. Increased CD14 and CD16 monocytes and decreased plasmacytoid dendritic cells (pDCs) and CD4 T cells were observed to correlate with DKD progression. Profound alterations in circulatory immune cell signatures were noted, with more upregulated differential expressed genes (DEGs) in slowly progressed DKD and subsequent downregulated in advanced stages. These DEGs primarily involved in cytokine expression, immune-related pathways, apoptotic signaling, and response to IFN, suggesting potential immunomodulatory roles of elevated circulating TNFR in DKD activation. Additionally, important co-expressed genes with TNFR1 and TNFR2 implicated processes such as osteoclast differentiation, cytokine interaction, endocytosis, and MAPK pathways.

Conclusions: Our study utilized single-cell RNA sequencing of PBMCs to comprehensively profile immune cell dynamics in patients stratified by serum TNFR levels, revealing their intricate interplay in the progression of DKD. These findings provide valuable insights into potential immunomodulatory targets for therapeutic intervention in DKD.

FR-PO287

Acute Inflammation Enhances SGLT2-Positive Myeloid Population in Bone Marrow

Ariana G. Alcantar,[1] Alexis P. Jimenez Uribe,[1] Yanxia Cao,[1] Ryan Spear,[1] Steve Mangos,[1] Jochen Reiser,[2] Eunsil Hahm.[1] Hahm Lab. *[1]Rush University Medical Center, Chicago, IL; [2]The University of Texas Medical Branch at Galveston Development Office, Galveston, TX.*

Background: Sodium-glucose cotransporter 2 inhibitors (SGLT2i) have exhibited benefits beyond controlling blood sugar levels, including improving cardiac function. Since SGLT2 expression predominantly occurs in kidney proximal tubule cells, understanding SGLT2 expression and its pathophysiological functions outside the kidney remains limited. This study aims to investigate the expression of SGLT2 in immune cells and its implications.

Methods: Leukocytes were isolated from peripheral blood and bone marrow (BM) of *BALB/c* and *C57BL/6* mice under normal conditions and after lipopolysaccharide (LPS)-induced systemic inflammation. CD34+ human hematopoietic cells (HSCs) from healthy donors and the human myelocyte cell line (HL-60) were cultured to study for in vitro myelopoiesis. Staining for SGLT2 and cell markers was performed using multicolor flow cytometry.

Results: Under normal conditions, approximately 1.5% of mouse BM contains an SGLT2+ population that expresses myeloid markers (Ly6C and Ly6G) but not lymphoid markers (CD3 and CD19). Interestingly, this SGLT2+ population increases after LPS challenge in bone marrow, not in peripheral blood. Further characterization shows that these cells display an immature phenotype (Sca-1+), arise from the myeloid lineage (CD11b+), and are monocytic in nature (CD14+). Consistent with our *in vivo* results, in vitro myelopoiesis assays demonstrated that inflammatory signals (TNFa or LPS) increase the SGLT2+ myeloid cells during cell differentiation.

Conclusions: This study reveals that SGLT2 expression is not limited to the kidney. In both mouse and human immune systems, we identified a myeloid population of SGLT2+ cells in the bone marrow that increases under inflammatory conditions. While further investigation is necessary to understand the role of SGLT2 in BM myeloid cells during inflammation, our results imply a novel role for SGLT2 in immune cells. This points to potential clinical implications of SGLT2 inhibitors on immune regulation.

FR-PO288

A Novel Function of FOXO4 and mTORC2 for Regulation of Kidney Gluconeogenesis

John E. Demko, Bidisha Saha, Enzo Takagi, Robert Weber, David Pearce. *University of California San Francisco, San Francisco, CA.*

Background: The proximal tubule of the kidney and the liver are the only organs capable of gluconeogenesis (GNG). Insulin signaling through mTORC2 and Akt2 regulates GNG in the liver, and our recent work confirmed that mTORC2 coordinates regulation of GNG and glucose transport in the kidney. FOXO1 is a well-established transcription factor for GNG in the liver. However, the major gluconeogenic transcription factor in the kidney has not been identified. We initially assumed it was FOXO1, but western blot anomalies suggested a FOXO family member with different molecular weight.

Methods: Rictor deletion causes selective disruption of the mTORC2 complex. Male and female mice with inducible tubule-specific Rictor knockout (TRKO) were made with the Pax8-rtTA TetOCre Rictorflox/flox system. Mice were fasted then refed to induce insulin signaling prior to sacrifice and tissue collection. Whole kidney phosphoprotein abundance was normalized to respective total protein abundance by western blotting.

Results: Our prior work has shown that TRKO mice have situational hyperglycemia due to increased GNG and overexpression of gluconeogenic enzymes. In the current study, we found no difference in phosphorylation of FOXO1 between TRKO and WT mice after refeeding (6.77±0.81 vs 8.25±0.82AU; not significant [ns] by t-test; n=10 per group) or fasting (5.29±1.39 vs 7.19±2.00AU; ns; n=6 per group). However, there was a dramatic reduction in phosphorylation of FOXO4 in TRKO compared to WT mice after

both refeeding (0.068± 0.017 vs 12.44±2.35AU; p<0.001) and fasting (0.40± 0.12 vs 15.31±31AU; p<0.01). Phosphorylation of Akt2 at S473, the target of mTORC2, was reduced in TRKO compared to WT mice after refeeding (4.91± 0.25 vs 6.40± 0.53AU; p<0.05) and fasting (2.98±0.28 vs 10.86±1.47AU; p<0.001). Reduced phosphorylation of FOXO4 and Akt2 followed the same pattern.

Conclusions: These data suggest that FOXO4, rather than FOXO1, is the mTORC2-dependent transcription factor that regulates GNG in the kidney. Akt2 is activated by mTORC2, and Akt2 is likely to directly phosphorylate FOXO4 and FOXO1 given their sequence homology. We propose that FOXO4 plays plays a unique role in the kidney compared to the liver because GNG and glucose transport occur in the same cells of the proximal tubule. Additional experiments are required to confirm and further explore the role of FOXO4 in renal glucose homeostasis.

FR-PO289

IL-32 Is a Lipid Droplet-Associated Mediator of Tubular Injury in Diabetic Kidney Disease

Hyunjae Chung,[1] Sarthak Sinha,[1] Mona L. Chappellaz,[2] Arthur Lau,[2] Waleed Rahmani,[1] Sisay G. Belay,[2] Asha K. Swamy,[2] Kevin R. Chapman,[1] Graciela Andonegui,[2] Hallgrimur Benediktsson,[1] Peter K. Stys,[1] Daniel A. Muruve,[1] Justin Chun.[1] *[1]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [2]University of Calgary, Calgary, AB, Canada.*

Background: Diabetic kidney disease (DKD) is the leading cause of kidney failure worldwide. The mechanisms contributing to DKD progression remains poorly characterized. In biopsies of human DKD, lipid droplets (LD) accumulate primarily in tubules with advanced stages of DKD. The contribution of lipid dysregulation is not well understood for DKD. Here we use human kidney biopsies and DKD patient-derived kidney organoids to investigate how LDs contribute to the pathogenesis of DKD.

Methods: Human kidney biopsies of the DKD as classified by the Renal Pathology Society classification of DKD were stained using Nile Red and analyzed to LD distribution and numbers. To model DKD, induced pluripotent stem cells (iPSC) were reprogrammed from healthy controls and DKD patients and differentiated to kidney organoids. Kidney organoids were treated with diabetic conditions in the absence of the SGLT2 inhibitor canagliflozin and analyzed by single cell RNA sequencing, in vitro assays, digital spatial imaging (CosMx), molecular spatial imaging (GeoMx) and live kidney organoid imaging.

Results: High glucose uptake promoted prominent LD formation in proximal tubular cells (PTC) of human kidney organoids derived from the iPSC of DKD patients. Single cell RNA sequencing of kidney organoids identified *IL32*, a gene encoding a pro-inflammatory cytokine induced by high glucose and downregulated by the SGLT2 inhibitor canagliflozin. Analysis of human DKD biopsies by Nanostring's digital spatial transcriptomics and molecular spatial imaging confirmed enrichment of *IL32* mRNA in injured proximal tubules. In human DKD organoids, IL-32 localized to tubular LD and its upregulation led to mitochondrial reactive oxygen species generation, mitochondrial fragmentation and tubular basement membrane thickening, attenuated by *IL32* knockdown. Overexpression of the beta and gamma isoforms of IL-32 in primary human proximal tubular epithelial cells induced mitochondrial fragmentation, ROS, and caspase-3 and GSDME-mediated cell death.

Conclusions: These findings identify IL-32 as a potential mediator linking metabolic dysfunction to chronic inflammation in DKD. IL-32 is a potentially targetable LD-associated cytokine that can be used to delay the progression of DKD.

Restoration of Branched-Chain Amino Acid Catabolism Improves Kidney Function in Preclinical CKD Models

Rachel Roth Flach, Eliza Bollinger, George E. Williams, Mary Piper, Kimberly L. Steen, Kelly T. Neale, Xian Chen, Mackenzie E. Marshall, Srinath Jagarlapudi, Ying Zhang, Elaine Kuang, Daniel Callahan, John Stansfield, Natalie A. Daurio, Justin Crane, Dinesh K. Hirenallur-Shanthappa, John D. Groarke, Bei B. Zhang. *Pfizer Inc, New York, NY.*

Background: Patients with metabolic syndrome and heart failure (HF) often have accompanying kidney dysfunction, which was recently defined as cardiovascular-kidney-metabolic (CKM) syndrome. Prior metabolomics profiling of metabolic syndrome patients identified a plasma branched chain amino acid (BCAA) signature, and BCAAs are elevated in HF patient myocardium. The rate limiting step of BCAA catabolism is decarboxylation by branched chain ketoacid dehydrogenase enzyme (BCKDH), which is negatively regulated by BCKDH kinase (BCKDK or BDK), and BDK inhibitors improve metabolism and heart failure preclinically. BDK inhibitors such as BT2 have been used preclinically and have demonstrated improvements in cardiometabolic outcomes, but the role of BDK inhibition in renal dysfunction has not been evaluated.

Methods: The BDK inhibitor BT2 was used in the ZSF1 (cross between Zucker diabetic ZDF rat and spontaneously hypertensive SHHF rat) rat model and SDT (spontaneously diabetic torii) rat model with uninephrectomy to test the impact of BDK inhibition on CKM parameters including urine output, albuminuria, GFR, and histology.

Results: BCAA catabolic impairment is associated with and may be causal to CKM, as treatment with the BDK inhibitor BT2 improved urine protein content, glomerular filtration rate, kidney hypertrophy, and kidney pathology in CKM models. Coadministration of BT2 and empagliflozin restored renal function and gene expression signatures towards that of healthy rats.

Conclusions: These data suggest that BDK inhibition could represent a therapeutic avenue for CKM.

Associations between Renin-Angiotensin System and Abnormal Renal Energy Metabolism in a Mouse Model of Diabetic Kidney Disease

Kengo Azushima,[1] Shinya Taguchi,[1] Ryutaro Morita,[1] Kenta Nomura,[1] Kentaro Kawasoe,[1,2] Hiromichi Wakui,[1] Kouichi Tamura.[1] *[1]Yokohama City University Graduate School of Medicine, Yokohama, Japan; [2]Tokyo Women's Medical University, Tokyo, Japan.*

Background: Renin-angiotensin system (RAS) has been a hallmark of the pathogenesis of diabetic kidney disease (DKD), but its underlying mechanisms remain unclear. Recently, abnormal renal energy metabolism has been reported as a novel pathogenesis of DKD. To investigate the association between the RAS and renal energy metabolism, we generated a mouse model of DKD characterized by systemic RAS activation.

Methods: We generated a mouse model of DKD with underlying activation of the RAS by systemic deficiency of angiotensin II (Ang II) type 1 receptor (AT1R)-associated protein (ATRAP), an endogenous suppressor of AT1R signaling, in combination with Ang II stimulation on streptozotocin (STZ)-induced type I diabetes. DKD and non-diabetic control (Ctrl) mice were euthanized to evaluate renal injuries after measurements of urinary albumin excretion (UAE). Renal energy metabolism was estimated by real-time quantitative PCR and western blotting analyses.

Results: A combination of ATRAP deletion with Ang II stimulation in STZ-infused C57BL/6 mice resulted in advanced DKD which had features of human DKD, including overt albuminuria (UAE, Ctrl vs DKD: 10.6±2.0 vs 852.0±195.6 μg/day, p<0.001), glomerular hypertrophy, podocyte loss, mesangial expansion, renal interstitial fibrosis, and functional insufficiency, concomitant with increased angiotensinogen and AT1R expression in the kidneys. Compared to the Ctrl mice, mRNA expression of PGC-1α, a key regulator of mitochondrial metabolism, was significantly increased in DKD mice. In addition, western blotting analysis showed that protein levels of phosphorylated AMPK in DKD mice were significantly decreased, indicating a substantial abnormality of renal energy metabolism in the mouse model of DKD.

Conclusions: Systemic RAS activation induced by the combination of ATRAP deletion with Ang II stimulation accelerated the development of DKD in STZ-induced type I diabetes. In their kidneys, local RAS activity was upregulated along with a perturbation of mitochondrial energy metabolism. Taken together, our findings suggest substantial associations between the RAS and abnormal renal energy metabolism, which might be involved in the underlying mechanisms contributing to the development of DKD.

Tubular Injury-Derived Exosome Interve Podocyte Cytoskeleton Rearrangement in Diabetic Mice

Rui Zhang,[1,2] Rui Yan.[1] *[1]Department of Nephrology, Affiliated Hospital of Guizhou Medical University, Guiyang, China; [2]Department of Pathophysiology, Guizhou Medical University, Guiyang, China.*

Background: Renal tubular epithelial cells are the major source of exosomes in the kidney, carrying biological payload of proteins and nucleic acids to facilitate cellular communication. Here, we aimed to investigate the effect of renal tubule-derived exosomes on podocyte skeletal rearrangement in diabetic mice.

Methods: The mice renal tubular epithelial cells (mRETC), from which exosomes were purified and intravenously injected into wt mice, were cultured under normal glucose as control and high glucose combined with palmitic acid (HG+PA). MicroRNA (miRNAs) sequencing was performed to conduct whole-genome analysis of exosome miRNA by Illumina Hiseq2500. *db/m* mice and *db/db* mice were intravenously injected adeno-associated virus (AAV) vecor knockdown of miR-20a-5p and miRNA mimics overexpression (OE) of miR-20a-5p respectively. The expressions of nephrin, CD2AP, myosin X were detected by real-time PCR or westernblot. F-actin were detected by confocal microscopy. *In vitro* studies were performed in human podocyte cell tranfected with miRNA mimics overexpression of miR-20a-5p, podocyte cell were cultured with normal glucose, high glucose combined with palmitic acid.

Results: In WT mice with HG+PA exosome, renal histology showed podocyte foot process effacement by transmission electron microscope, nephrin, CD2AP, myosin X

were significantly decreased compared with control mice. MiR-20a-5p was identified as one of the most regulated miRNAs in the exosomes from injure human kidney-2 (HK-2). The *db/m* mice treated with miR-20a-5p-OE exist more severely podocyte foot process effacement. In *db/db* mice treated with miR-20a-5p-AAV shRNA, renal histology showed foot process effacement decreased, expression level of nephrin, CD2AP, myosin X were significantly increased compared with *db/db* mice. *In vitro* the dual-luciferase reporter assay verified the binding of miR-20a-5p to *MYH10* promoters, mutant *MYH10* gene had downregulated nephrin, CD2AP expression and exhibited F-actin as polymerized state.

Conclusions: In diabetic mice, the expression of miR-20a-5p in exosomes from renal tubular epithelial cells is elevated. This miR-20a-5p mediates cytoskeletal rearrangement in podocytes by inhibiting myosin X, leading to foot process effacement. Consequently, targeting exosomes could represent a novel therapeutic approach for treating

FR-PO293

Loss of Globotriaosylceramide Protects against Diabetic Kidney Disease

Suresh K Ramakrishnan,[1] Shruti Naik,[1] Indira Dibra,[1] Verena Rickert-Zacharias,[1] Roger Sandhoff,[3] Hermann-Josef Groene,[2] Matias Simons.[1] *[1]UniversitatsKlinikum Heidelberg, Heidelberg, Germany; [2]Philipps-Universitat Marburg, Marburg, Germany; [3]Deutsches Krebsforschungszentrum, Heidelberg, Germany*.

Background: Globotriaosylceramide (Gb3) is a glycosphingolipid that is formed by the addition of a galactose molecule to lactosylceramide by Gb3 synthase (Gb3S). In acute kidney injury models, Gb3 knockout has shown a protective effect on proximal tubular cells (PTCs). This can be attributed to loss of Gb3 contributing to reduced uptake of potentially damaging excess filtrates, such as albumin, lipids and toxins by PTCs. Here, we aimed to study the therapeutic potential of Gb3 inhibition in a mouse model for diabetic kidney disease (DKD).

Methods: 8 week-old Gb3S wildtype (WT) and knockout (KO) mice were injected with streptozotocin (STZ-50mg/ml) consecutively for 5 days. A high fat diet enriched with saturated fatty acids (SFA) was given from 11 weeks until 24 weeks of age. These STZ-SFA mice were described by us to exhibit DKD features (Perez-Marti et al, 2022). Transdermal GFR, urinary parameters, kidney injury and fibrosis markers (qPCR) were measured at the end point of the experiments. Histopathological analysis of kidney sections was performed. Oil red O-staining was used to check for lipid droplets. Western blotting was performed to quantify kidney and lipid markers protein expression.*Drosophila* nephrocytes were used to study lipid droplets upon knockdown of α4GT1, fly ortholog of Gb3S, using UAS-GAL4 system. Bodipy (493/503) staining was used to visualize lipid droplets (Confocal microscopy).

Results: Compared to STZ-SFA WT mice the STZ-SFA KO mice have normal GFR. Also, they display significantly decreased expression of kidney injury and fibrosis markers as well as lower albuminuria and glucosuria. Interestingly, we observed depletion of lipid droplet accumulation in the S2 and S3 proximal tubular segments of STZ-SFA KO mice compared to STZ-SFA WT mice. Protein expression of Perilipin-2 which coats lipid droplets was downregulated in the STZ-SFA KO kidney samples compared to STZ-SFA WT samples. Furthermore, α4GT1 knockdown nephrocytes lacked lipid droplets, suggesting a cell-autonomous effect of Gb3S deficiency on lipid droplets.

Conclusions: Our data suggest that loss of Gb3 is beneficial in alleviating kidney damage in the STZ-SFA mouse model. We speculate that decreased lipid uptake and lower lipid droplet accumulation in the proximal tubules may be one of the possible reasons for the beneficial effects.

FR-PO294

Esm-1 Prevents Glycocalyx Depletion in Glomerular Endothelial Cells in Diabetic Nephropathy

Haochen Guan,[1,2] Alexandre Gaudet,[1,3] Xiaoyi Zheng,[1,4] Vivek Bhalla.[1] *[1]Stanford University School of Medicine, Stanford, CA; [2]University of Science and Technology of China, Hefei, China; [3]Universite de Lille, Lille, France; [4]BriaCell Therapeutics, Philadelphia, PA.*

Background: Glomerular endothelial cell (GEnC) injury is one of the early characteristic signs of diabetic nephropathy (DN). Thus, markers or mediators of GEnC injury may be important to predict or prevent kidney disease, respectively. The GEnC glycocalyx forms the first part of the glomerular filtration barrier and its damage is a key initiator of albuminuria. Endothelial cell-specific molecule-1, Esm-1, is an anti-inflammatory, secreted proteoglycan. Plasma Esm-1 deficiency inversely correlates with markers of DN in humans and mice, and over-expression of Esm-1 in diabetic mice attenuates albuminuria and podocyte injury. However, it is still unclear whether and how Esm-1 modulates GEnC function in DN.

Methods: DN-susceptible DBA/2 mice were subjected to intraperitoneal injections of streptozotocin and fed a high-fat diet, and randomly assigned to receive hydrodynamic injection to overexpress Esm-1. Glycocalyx abundance was quantitated by WGA lectin staining. *In vitro*, human, conditionally immortalized GEnCs were maintained in the presence of glucose, insulin, TNF-α, and IL-6 to mimic a diabetic milieu. We also utilized glomerular RNAseq to characterize effects of Esm-1 expression on GEnC-expressed genes from DN-susceptible mice.

Results: Glycocalyx abundance was reduced following exposure to diabetic conditions both *in vivo* and *in vitro*. Systemic Esm-1 overexpression limited the reduction in WGA lectin glycocalyx staining in DN-susceptible mice (mean fluorescence intensity of Control *vs*. DM *vs*. DM+Esm-1, 101.9±3.643 *vs.* 61.47±2.786 *vs.*101.1±3.814; p<0.0001). Additional studies of GEnC phenotypes *in vitro* are ongoing. In 234 of 300 endothelial-enriched genes, we observe inverse correlations between glomerular Esm-1 mRNA expression and albuminuria (κ=0.53; p=2.29*10-29). For 206 of these 234 correlation genes, systemic over-expression of Esm-1 reverses the expression profile (κ=0.25; p=3.4*10-6), with 'vascular development' and 'blood vessel morphogenesis' being the dominant ontologies among reversible genes.

Conclusions: Our findings indicate that Esm-1 exerts a protective effect against DM-induced GEnC glycocalyx depletion. These data provide a more detailed explanation for potential mechanisms of protection from diabetes-induced albuminuria through significant changes in gene expression across GEnC.

FR-PO295

Mechanism of Disease Progression by Renin Overexpression in the db/db-UNx Model: A Proteomic Analysis

Srinath Jagarlapudi, Rose A. Keenan, Sabra D. Al-Harthy, Simone Romoli, Charles Halsey, Jeffrey A. Culver, Jeffrey Morin, Dinesh K. Hirenallur-Shanthappa, Denis Feliers. *Pfizer, Cambridge, MA, Cambridge, MA*.

Background: The db/db-UNx-renin model has gained in popularity, showing both increased albuminuria and reduced glomerular filtration rate (GFR). Our aim was to characterize the renal injury of db/db-UNx-renin mice using proteomics and to understand the role of renin overexpression in disease progression.

Methods: Four weeks-old db/db mice were subjected to uninephrectomy, two weeks later received an intravenous injection of an AAV containing either an empty vector or the human renin gene and the experiment was terminated at 16 weeks of age. Albuminuria was measured every two weeks, renal oxygen content and renal volume and transcutaneous GFR were determined at the end of the experiment. The remaining kidney was harvested, and proteomics analysis performed on the cortical fraction.

Results: Compared to db/m mice, GFR and renal oxygenation were increased in db/db-UNx mice, indicating a state of hyperfiltration. Renin overexpression caused a significant reduction in GFR in these mice. In db/db-UNx mice, albuminuria progressed throughout the experiment, while in db/db-UNx-renin mice, albuminuria peaked 2 weeks after AAV-renin injection and remained high. Renal hypertrophy was evident in db/db-UNx mice while cardiac hypertrophy was only observed in db/db-UNx-renin mice. Proteomics analysis of renal cortex showed that pathways associated with protein synthesis, energy metabolism, transport activity, mitochondria and respiration, adipogenesis and glycolysis and gluconeogenesis and amino acid metabolism were activated in db/db-UNx mice, suggesting a metabolic adaptation to the hyperfiltration seen in these mice. Renin overexpression, on the other hand, activated pathways associated with renal injury, extracellular matrix remodeling, inflammation, complement activation, macrophage activation, secretion of pro-angiogenic and pro-proliferative factors, and clot formation.

Conclusions: This study sheds light on the mechanism of kidney injury during diabetes and distinguishes two phases of the disease. In the hyperfiltrating phase, the renal tubules adapt by increasing their transport activity and energy production, while activation of complement, inflammation and coagulation pathways seem to play a role in the disease progression phase caused by renin overexpression.

FR-PO296

Single-Nucleus RNA Sequencing Reveals Sex-Specific Renoprotective Mechanisms in Diabetic Kidney Disease

Shuya Liu,[1,2] Tianran Zhang,[1,5] Shun Lu,[1,2] Martin Strauch,[4] Michaël Goedertier,[3] Ivan Costa,[3] Peter Boor,[4] Stefan Bonn,[5] Tobias B. Huber.[1,2] *[1]III. Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Hamburg Center for Kidney Health (HCKH), University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [3]Institute for Computational Genomics, RWTH Aachen University Clinic, Aachen, Germany; [4]Institute of Pathology, RWTH Aachen University Clinic, Aachen, Germany; [5]Institute of Medical Systems Biology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*.

Background: Diabetic kidney disease (DKD) is a major complication of diabetes and the leading cause of end-stage renal disease worldwide. Sodium-glucose co-transporter 2 inhibitors (SGLT2i) and angiotensin receptor blockers (ARB) have shown promise in preventing DKD progression, but their molecular mechanisms remain to be elucidated.

Methods: We treated DKD mice (BTBR *ob/ob*) with SGLT2i, ARB or their combination for 12 weeks. Healthy BTBR wild-type and vehicle-treated BTBR *ob/ob* mice served as controls. Notably, only female DKD mice showed significantly reduced albuminuria across all treatments. To explore the mechanisms, single-nucleus RNA sequencing (snRNA-seq) was performed on kidneys from female mice in each group (n=2/group).

Results: A total of 98,684 single nuclei were identified, which were characterized into 22 clusters and classified into 12 meta-cell types. Differential gene expression analysis was performed to define treatment responsive and non-responsive genes in each meta-cell type. Proximal tubule epithelial cells showed the most significant treatment response, whereas glomerular cell types showed limited responses. CellChat was used to identify renoprotective intercellular communication networks. Pattern recognition showed that proximal tubule epithelial and glomerular cells emerged as key signaling sources, suggesting their crucial role. The limited glomerular response suggests that current therapies may not fully address the disease in these cells. To identify potential therapeutic targets, Drug2Cell was used to predict glomerular cell-specific drug targets for each treatment, highlighting critical signaling pathways and offering insights for future drug development.

Conclusions: This study presents a comprehensive snRNA-seq analysis of female DKD mice treated with SGLT2i and ARB, revealing differential treatment responses by cell type. Intercellular communication networks highlight the importance of glomerular targeting and the discovery of novel drug targets for improved glomerular protection. Future work will integrate the framework for large-scale histomorphometry (FLASH) to correlate morphological lesions with the snRNA-seq data, aiming to provide a more comprehensive picture of DKD treatment at both transcriptomic and morphological levels.

Association of the Polymorphisms of the Angiotensin-Converting Enzyme and FRMD3 Genes in the Development of Diabetic Kidney Disease

Juan D. Diaz Garcia,[1] Enrique F. Morales Lopez,[2] Irving G. Ramirez.[1]
[1]Hospital Clinic de Barcelona, Barcelona, Spain; [2]Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico.

Background: Individual genetic biomarkers, called single nucleotide polymorphisms (SNPs), have been proposed that could represent potential non-invasive markers for the early diagnosis of diabetic kidney disease (DKD), in addition to their association with a characteristic phenotype. Aim: To determine the association of polymorphisms of the Angiotensin Converting Enzyme and FRMD3 genes with the risk of developing ERD in patients with type 2 diabetes.

Methods: Case-control study, comparative, observational, ambispective and cross-sectional, in which men and women, over 18 years of age with T2D with and without ERD and healthy patients, who underwent DNA extraction, participated. genomic and subsequent genotyping, and detection of SNPs by mass spectrometry.

Results: A total of 400 patients participated, 199 men and 201 women, within which they were divided into three groups: 100 patients with type 2 diabetes and ERD confirmed by renal biopsy, 100 patients with type 2 diabetes without ERD and 200 healthy controls. A total of 3 polymorphisms of the ACE and FRMD3 genes were studied. Among the polymorphisms analyzed in the logistic regression, rs179975 CA (OR, 6.2; 95% CI: 1.15-7.48, p=0.03), rs1888747 GA (OR, 6.6; 95% CI: 4.60-8.45, p=0.002) and rs10868025 resulted. CG (OR, 4.1; 95% CI: 2.40-5.60, p=0.002) Table 1.

Conclusions: Our study demonstrated the association of well-established genetic variants of the ACE and FRMD3 gene polymorphisms with the presence of ERD, showing that these SNPs, specifically rs179975 CA, rs1888747 GA and rs10868025 GC, may represent important genetic markers in the development of ERD and could be a predisposing factor due to the high frequency and strength of association that were observed in our studied population, this being the first study in Latin America.

FR-PO298

Scalable Micro-Kidneys for Unbiased Phenotypic Drug Discovery and Target Identification in Diabetic Nephropathy and Inherited Kidney Diseases

Fred Etoc. *RUMI Scientific, New York, NY.*

Background: A key bottleneck in the discovery of therapeutics in nephrology is the lack of physiological models that are compatible with drug discovery at a high-throughput scale for target identification. Currently, available in vitro models consist of impressive reconstitution of kidney tissues that are impractical for screening: 3D mini-kidneys, or micro-physiological systems that are all too large, too variable or too complex to be employed at scale within drug screens. At the other end, 2D cell models are very scalable but lack structural organization. RUMI has uniquely developed a platform that bridge this gap by allowing scalable screening and target ID in fully scalable and standardized complex micro-kidneys. We are leveraging this tool for in-house drug discovery, building a pipeline centered around high unmet needs areas such as DKD and inherited kidney diseases.

Methods: The key component of our platform is a micropatterning technology that allows for the arrayed generation of nearly identical self-organizing human micro-kidney tissues, which are derived from human embryonic stem cells. One multi-well plate can easily generate more than 5'000 replicates, and >100 plates can be generated at once. These large data sets of micro-kidneys images, in disease and control conditions, then enable the use of AI/deep learning to quantify subtle yet robust disease features within micro-kidney structures, as well as the potential for drugs to reverse the disease state to normal, paving the way towards discovery of new therapeutic candidates. Moreover, it has the potential to be coupled with CRISPR-KO genetic "suppressor screens", which are the gold standard for target identification which today and cannot be performed with alternative technologies.

Results: We will present our micro-kidney's characterization, and demonstrate how this system can be leveraged to model multifactorial aspects of the diabetic injury related to DKD. We will show that a key hallmark of kidney injury, KIM1, can be alleviated by knocking out of SLC5A2, demonstrating the validity of our platform in reproducing established clinical results. Moreover, we will discuss our preliminary results for phenotypic discovery of inherited kidney diseases such as Alport Syndrome and Polycystic Kidney Disease.

FR-PO299

Study on the Pathogenic Role of CDA1 in Diabetic Kidney Disease (DKD) in Diabetic Akita Mice

Minling Huang, Jiali Tang, Tieqiao Wu, Mark E. Cooper, Zhonglin Chai.
Monash University Faculty of Medicine Nursing and Health Sciences, Melbourne, VIC, Australia.

Background: CDA1 has been demonstrated to enhance TGF-β signaling and plays a pathogenic role in experimental diabetic kidney disease (DKD) in STZ-diabetic ApoE knockout mice. The role of CDA1 in other animal models with diabetes induced by different mechanisms is unknown and the mechanisms underlying CDA1's actions have not been fully elucidated. In this study, the pathophysiologic role of CDA1 was investigated in the Akita mouse model of DKD, an insulin-deficient animal model, with RNA-seq analysis performed to explore potential molecular mechanisms.

Methods: Metabolic and relevant renal parameters, such as glomerulosclerosis injury (GSI) index, urine albumin-to-creatinine ratio (ACR), renal mRNA and protein levels of profibrotic and proinflammatory genes, were examined in non-diabetic WT and diabetic Akita mice at the age of 16 weeks in the presence (CDA1 WT) or absence (CDA1 KO) of a functional CDA1 gene. RNA sequencing (RNA-seq) was performed using total RNA isolated from the kidney tissues of these mice (n=6/group).

Results: Akita mice exhibited increased kidney injury, evidenced by elevated GSI (1.4-fold) and ACR (4-fold), as well as increased expression of both profibrotic and proinflammatory markers (2-fold). Importantly, deletion of CDA1 markedly attenuates these changes in Akita mice, leading to a notable 26.7% decrease in ACR and normalization of GSI, fibronectin gene expression, as well as protein expression levels of Collagen III and α-SMA to levels similar to non-diabetic controls. RNA-seq analysis revealed that CDA1 deletion modulates multiple signaling pathways closely associated with fibrosis, inflammation and cell cycle regulation, including the cytokine-cytokine receptor interaction pathway, complement and coagulation cascades, AGE-RAGE, TNF, chemokine, and relaxin signaling pathways. Notably, the expression levels of the p21 (Cdkn1a), a gene crucial in regulating cellular senescence, and senescence-associated secretory phenotype (SASP) expression, including TNF-α and MCP-1, were elevated in Akita mice, these parameters attenuated in Akita mice with CDA1 deletion.

Conclusions: Targeting CDA1 effectively attenuated diabetes associated renal injury, as a result of reduction in the cellular senescence leading to attenuation of the profibrotic and proinflammatory pathways.

FR-PO300

Identification and Validation of Pivotal Genes Driving Diabetic Kidney Disease Progression through Weighted Gene Co-Expression Network Analysis

Siyang Ye, Manhuai Zhang, Meng Zhang, Dingding Wang, Jinjin Fan, Bin Li, Yi Zhou, Wei Chen. *The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.*

Background: Currently, the core factors governing the progression of diabetic kidney disease (DKD) remain elusive. Our study aims to explore the progression-related genes of DKD through comprehensive bioinformatics analysis and *in vivo* validation, thus providing novel therapeutic targets for retarding DKD progression.

Methods: Differentially expressed genes (DEGs) within kidney from early and advanced DKD samples were detected using GSE142025 dataset. Besides, the weighted gene co-expression network analysis (WGCNA) and protein-protein interaction (PPI) network were conducted, followed by key module analysis and recognition of pivotal genes driving DKD progression. Furthermore, enrichment analysis was used to determine the biological features of pivotal genes associated with DKD progression, and correlation analysis was utilized to explore the potential link between pivotal genes and altered immune status within DKD tissues. Finally, certain pivotal genes were validated by Western blot and immunohistochemistry (IHC) in diabetic mice kidney.

Results: A total of 44 DEGs were identified between early and advanced DKD specimens. Using WGCNA, the turquoise module was deemed as the DKD progression-related module. A total of 18 genes related to DKD progression were obtained by intersection analysis between the upregulated DEGs and the turquoise module. Enrichment analysis indicated that the above 18 genes were primarily involved in necroptosis and other immune inflammatory responses. Moreover, four genes (*STAT1, MYC, NLRP3,* and *TNFAIP3*) were recognized as pivotal genes implicated in DKD progression by PPI analysis. Correlation analysis showed that the above pivotal genes were mainly positively correlated with the infiltration of T cells. More importantly, Western blot and IHC analysis revealed that the protein levels of these pivotal genes were significantly increased in the kidneys of advanced DKD mice compared to those in the early DKD group.

Conclusions: Our findings suggest that necroptosis, as well as immune and inflammatory responses, are crucial biological events driving DKD progression. Of note, *STAT1, MYC, NLRP3,* and *TNFAIP3* were identified as pivotal genes promoting the progression of DKD. Consequently, targeting necroptosis and the above pivotal genes might represent a promising therapeutic strategy for delaying DKD progression.

FR-PO301

WWP2-Induced Pericytes to Myofibroblast Transition Contributes to the Progression of Fibrosis in CKD in Diabetes

Paola Pontrelli,[1] Francesca Conserva,[1] Antonella Cicirelli,[1] Maria Venneri,[1] Rossana Franzin,[1] Alessandra Stasi,[1] Giorgia Sclavo,[1] Elena Squiccimarro,[1] Anna Gallone,[1] Francesco Pesce,[2] Marco Fiorentino,[1] Loreto Gesualdo.[1] *[1]University of Bari Aldo Moro, Bari, BA, Italy; [2]Universita Cattolica del Sacro Cuore Facolta di Medicina e Chirurgia, Roma, Italy.*

Background: CKD in diabetes presents different histological phenotypes commonly classified as diabetic Nephropathy (DN), non-diabetic renal disease (NDRD) and mixed forms (DN+NDRD) and only true DN is characterized by activation of the lysine63 (K63-Ub) ubiquitination pathway involved in the progression of renal fibrosis. WWP2 is an E3 ligase enzyme that modulates myofibroblast activation in cardiac fibrosis and metabolic reprogramming in CKD. The aim of the study was to evaluate the role of WWP2 in renal fibrosis in diabetes and its involvement in K63-Ub.

Methods: The expression of WWP2, K-63Ub, a-sma, PDGFBR, vimentin, NG2 was evaluated by immunohistochemistry, immunofluorescence, qPCR, western blotting and/or flow cytometry in: i) renal biopsies of patients with DN (n=11), nephroangiosclerosis or other renal damage in diabetic patients (NDRD) (n=8) and mixed forms DN+NDRD (n=3); ii) DBA/2J mice treated with streptozotocin in the presence or absence of a specific K63Ub inhibitor (NSC697923); iii) HK2 tubular cells, EAHY926 endothelial cells and pericytes.

Results: WWP2 was expressed at tubular, glomerular and vascular levels in both DN and DN+NDRD compared to NDRD ($p<0.05$ and $p<0.01$ respectively). Increased expression of WWP2 in DN was associated with the accumulation of K63Ub proteins in the tubular and vascular compartment, particularly in pericytes. In diabetic DBA/2J mice, K63Ub inhibition with NSC697923 significantly reduced WWP2 expression in the kidney ($p < 0.05$). Also in vitro, in HK2 cells, NSC697923 significantly reduced hyperglycemia-induced WWP2 and a-sma expression ($p < 0.01$). In pericytes, hyperglycemia induced the expression of WWP2 (RR>3), a-sma (RR>4), PDGFBR (RR>4), vimentin (RR>2) and reduced NG2 (RR>2) suggesting the transition from pericytes to myofibroblasts, and this effect was blocked by NSC697923 ($p<0.05$).

Conclusions: These findings suggest that WWP2 is involved in the K63-Ub pathway and promotes fibrosis progression in DN patients through pericytes to myofibroblasts transition. WWP2 could therefore represent a novel target in preventing the progression of renal damage in patients with DN.

FR-PO302

Nuclear Factor Erythroid 2-Related Factor 2 (Nrf2) Activates Hedgehog Interacting Protein (Hhip)-Mediated Renal Tubular Cell Senescence in Diabetic Akita Mice

Min-Chun Liao,[1] Xin-Ping Zhao,[1] Shuiling Zhao,[1] Ke Su,[1] Shiao-Ying Chang,[1] Yuchao Pang,[1] Kana Miyata,[2] Junzheng Peng,[1] Julie R. Ingelfinger,[3] John S. Chan,[1] Shao-Ling Zhang.[1] *[1]Centre de Recherche du Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [2]Saint Louis University, St Louis, MO; [3]Harvard Medical School, Boston, MA.*

Background: We recently reported that hedgehog interacting protein (Hhip) activates sodium-glucose cotransporter 2 (Sglt2) expression and promotes tubular senescence in murine diabetic kidney disease (DKD) (*Diabetologia 2023*). However, the underlying mechanism(s) are poorly understood. Nuclear factor erythroid 2–related factor 2 (Nrf2) plays a key role in Sglt2 inhibition-reduced tubular cell senescence in DKD (PMID: 34318973); here, we aimed to elucidate the underlying mechanism of Hhip and Nrf2 interaction on tubular senescence in DKD *in vivo* and *in vitro*.

Methods: Male Akita, Akita/Nrf2$^{-/-}$ and Akita/Nrf2$^{-/-}$ mice with renal proximal tubular cell (RPTC)-specific Nrf2 transgene (Akita/Nrf2$^{-/-}$/Nrf2^{RPTC}-Tg), and their respective control mice (non-Akita or Nrf2$^{-/-}$) were studied. Primary RPTCs and human immortalized HK-2 cells were the *in vitro* model used.

Results: Compared to respective controls at the age of 20 weeks, Akita mice displayed typical DKD characteristics (increased urinary albumin/creatinine ratio and glomerular filtration rate) and renal dysmorphology (renal hypertrophy, glomerulosclerosis and tubulopathy); those changes were attenuated in Akita/Nrf2$^{-/-}$ mice. As compared with Akita, Akita/Nrf2$^{-/-}$ mice had less renal tubular Hhip gene expression and decreased tubular senescence as assessed by β-galactosidase activity and p16-, p21-, and p53- immunostaining. However, these protective features were markedly lost in Akita/Nrf2$^{-/-}$/Nrf2^{RPTC}-Tg kidneys. *In vitro*, Nrf2 activators (oltipraz or CDDO-Me) significantly stimulated Hhip gene expression (promotor activity, Hhip mRNA and protein expression), while also promoted cellular senescence. Those effects were more pronounced under high glucose milieu. In contrast, HK-2 cells with Nrf2 knockout largely prevented the above phenotypes.

Conclusions: Nrf2 activates Hhip gene expression in RPTCs. In diabetes, activation of both Nrf2 and Hhip works in concert to accelerate tubular senescence in DKD.

Funding: Government Support - Non-U.S.

FR-PO303

Clearance of P16-Positive Senescent Cells Delays Diabetic Kidney Disease (DKD) by Normalizing Glycolysis and Mitochondrial Metabolic Disorder

Xiao Lu,[1] Jiao Wu,[1] Ewud Agborbesong,[1] Xiaogang Li.[1,2] *[1]Mayo Clinic Department of Internal Medicine, Rochester, MN; [2]Mayo Clinic Minnesota, Rochester, MN.*

Background: Diabetic kidney disease (DKD) is one of the complications of diabetes, which is characterized by kidney damage and abnormal renal energy metabolism. Studies have shown that senescence is associated with the course of DKD. Recently, attention has focused on the effect of purging p16-positive senescent cells in transgenic mice on the increase of mean lifespan. However, whether and how p16 positive senescent cells promote the progression of DKD remain unknown.

Methods: To evaluate the role and mechanisms of p16 positive senescent cells in DKD progression, we established type 1 diabetes model (DM) through injection of streptozotocin in INK-ATTAC transgenic mice, which allowed a removal of p16Ink4a-positive cells upon administration of a drug, AP20187. We treated human renal tubular epithelial cells (HK2) cultured with different concentration of glucose. We also isolated the primary tubular epithelial cells from vehicle and AP treated DM INK-ATTAC mouse kidneys.

Results: We found that the expression of p16 was increased in renal tubular cells in the kidneys of DM mice and DKD patients as well as in HK2 cells cultured in high glucose media, which promoted senescence and elevated senescence-associated secretory phenotypes (SASPs), including TNF-α, IL-6 and IL-1β, in those kidneys and cells as examined with SA-β-gal staining and qRT-PCR analysis. Importantly, we found that clearance of p16-positive cells 1) delayed the progression of DKD as seen by the decrease of serum creatinine and urine microalbumin in DM INK-ATTAC mouse treated with AP20187, 2) alleviated kidney injury in diabetic mice through Rb-CDK4 pathway and the decrease of SASPs, and 3) restored ATP content, decreased the expression of the key glycolytic enzymes, and improved the metabolic reprogramming in DM INK-ATTAC mouse kidneys. In addition, clearance of p16-positive cells normalized the expression of the genes involved in mitochondrial metabolism through AMPK and mTOR pathway, suggesting that p16 positive senescent cells also played an important role in renal mitochondrial metabolic disorder in DKD.

Conclusions: Our study indicates that p16 positive senescent cells plays an important role in the progression of DKD, and their clearance delays the progression of DKD through normalizing glycolysis and mitochondrial metabolic disorder, which is a novel therapeutic target for DKD.

FR-PO304

Cytochrome P450 Is a Metabolic Regulator of Diabetic Kidney Disease (DKD) Progression

Batoul Dia,[1] Sarah Almoussawi,[1] Sarah Hamade,[1] Sam El-Osta,[2] Assaad Antoine Eid.[1] *[1]American University of Beirut, Beirut, Lebanon; [2]Baker Heart and Diabetes Institute, Melbourne, VIC, Australia.*

Background: Cytochrome P450 (CYP) epoxygenases metabolize arachidonic acid (AA) into 20-HETE (20-Hydroxyeicosatetraenoic acid) and EETs (Epoxyeicosatrienoic acids). Our group has demonstrated the involvement of CYPs and their metabolites in the pathogenesis of diabetic kidney disease (DKD) by activating reactive oxygen species (ROS) production. Polymorphisms of CYP genes can alter the expression of these enzymes, influencing DKD prognosis. We hypothesize that alterations in 20-HETE and EET levels contribute to ROS elevation via an SGLT2/mTOR-dependent mechanism in diabetes. Additionally, we have assessed the genetic contribution in the AA-metabolizing CYPs associated with the progression of DKD

Methods: We enrolled healthy volunteers (n=15) and patients with type 2 diabetes (T2DM) with (n=30) or without (n=70) DKD. We measured 20-HETE and EET levels in

urine and plasma samples by Enzyme Linked Immunosorbent Assay. We also assessed CYP expression in kidney biopsies. SNPs for the CYP4A11, CYP4F8, and CYP2B6 genes were detected using TaqMan PCR assays on DNA extracted from blood samples. To study the preclinical significance, molecular and histological analyses were performed using a T2DM mouse model treated with the pharmacological inhibitors of 20-HETE (HET0016), sEH (AUDA), SGLT2 (Dapagliflozin), and mTOR (Rapamycin, JR-AB2-011 and PP242). In vitro validation studies were performed using human podocyte and proximal tubular epithelial cells

Results: Patients with DKD had elevated 20-HETE levels compared to T2DM patients without DKD, who had higher levels than healthy volunteers. This increase was associated with higher expression of CYP4A11 and CYP4F8 in kidney biopsies. EET levels were lower in DKD patients compared to T2DM patients without DKD, correlating with decreased CYP2B6 expression in kidney biopsies. We identified novel SNPs for CYP2B6 and CYP4A11 in patient groups, suggesting an increased risk with the mutant alleles for diabetes and DKD. Regulation of 20-HETE and EET levels were associated with renal injury mediated by the SGLT2/mTOR/NOX4 axis. This was confirmed in the T2DM mouse mode and validated in the human renal cells

Conclusions: This study provides a framework into novel CYP450 pathways involved in diabetes-induced renal injury. We also describe the potential prognostic and diagnostic biomarkers related to CYP associated pathways in the progression DKD

FR-PO305

Role of Gut Microbiota in the Development of Diabetic Kidney Disease

Sarah Almoussawi,[1,2] Leonard Lawandos,[1] Sarah Hamade,[1] Taghreed Shouman,[1] Sahar Alkhansa,[1] Batoul Dia,[1] Mohamad Noureldein,[1] Assaad Antoine Eid.[1]
[1]American University of Beirut, Beirut, Lebanon; [2]Universite de Limoges, Limoges, France.

Background: The role of microbiota in Diabetes Mellitus (DM) and its complications has garnered significant attention recently. Our research highlighted that DM is associated with intestinal dysbiosis, characterized by decreased *Bacteroidetes* to *Firmicutes ratio*, the two main bacterial species constituting more than 90% of intestinal microorganisms. Interestingly, fecal microbial transplantation (FMT), i.e. the administration of fecal matter from a healthy donor into a recipient's gastrointestinal tract, is emerging as a promising treatment approach for several diseases. Remarkably, reports established the capability of FMT to restore a healthy gut microbiome and alleviate symptoms of these diseases. Herein, we hypothesize that modifying gut microbiota by FMT might affect the pathogenesis and progression of diabetic kidney diseases (DKD) and serve as an effective treatment approach

Methods: FVB/NJ and non-obese type 2 diabetic MKR transgenic mice were used. Mice were divided into three groups: sham, group treated with FMT from healthy mice donors, and group treated with FMT from MKR diabetic donors. Treatment was administered by oral gavage twice weekly for 8 weeks after depleting their gut microbiota using an antibiotic cocktail. Urine and kidneys were collected for functional, histological, and molecular analyses

Results: Our study show a decline in kidney function, as evidenced by increased albuminuria (UAE) and urine albumin-creatinine ratio (UACR) in the FVB group treated with MKR FMT. Histological changes were also observed, along with elevated reactive oxygen species (ROS) production and inflammation, underscoring the presence of dysbiosis in renal deterioration. These findings closely mirrored the results observed in the MKR group, where elevated albuminuria levels and UACR were accompanied by increased sclerosis and collagen deposition, and paralleled by increased NOX induced ROS production and inflammation. Intriguingly, these adverse effects were reversed in the MKR group treated with FVB FMT. This reversal was associated with reduced ROS production, decreased expression of NADPH oxidase (NOX), and dampened inflammation. Notably, the expression of inflammatory cytokines was significantly lower in this group

Conclusions: This study presents novel findings on the impact of microbiota in diabetes-induced renal injury

FR-PO306

PPP2R2B Variant Reduces Protein Phosphatase 2A (PP2A) Complexity and Worsens Diabetic Kidney Disease (DKD) Progression

Zhengying Fang, Zeguo Sun, Kyung Lee, Ruijie Liu, John C. He.
Icahn School of Medicine at Mount Sinai, New York, NY.

Background: We have previously shown that protein phosphatase 2A (PP2A), a major Ser/Thr phosphatase in the kidney, is involved in regulation of podocyte function in diabetic kidney disease. Podocyte-specific knockout of PP2A catalytic unit leads to more severe podocyte injury and progression of DKD. Here, we report the identification of variants in the *PPP2R2B* gene, encoding the podocyte-specific regulatory subunit of PP2A, in DKD patients with ESKD.

Methods: We carried out clinical studies and genetic analyses, including genome-wide linkage analysis and whole-exome sequencing to identify candidate variants. Transgenic mice models were generated to validate the phenotype of the candidate variant. Functional studies on the disease-associated variant were performed in transgenic mice glomeruli and cultured cells.

Results: Several variants of *PPP2R2B* gene were found to be associated with renal outcome in DKD patients. To help elucidate the underlying mechanism, we generated a knock-in mice model with one of the clinical worst outcome-related *PPP2R2B* missense variants (p.T222M). We induced diabetes in these knock-in mice and their littermate controls. We found that mice carried *Ppp2r2b* p.T222M developed worse DKD phenotype such as proteinuria, glomerular hypertrophy, and mesangial expansion, as compared to littermate controls. Crucially, *Ppp2r2b* p.T222M results in impaired glomerular PP2A activity as measured by PP2A activity assay and phosphorylation of its substrate NF-kB. However, the protein expression level of glomerular Ppp2r2b was not affected by the variant. In addition, using in vitro studies, we showed that *PPP2R2B* p.T222M variant reduced PP2A complexity, thus altering cellular PP2A activity and downstream phosphorylation of NF-kB.

Conclusions: Our findings confirmed that mice carrying *Ppp2r2b* p.T222M variant developed more severe renal phenotype. We also demonstrated that *PPP2R2B* p.T222M variant led to impaired glomerular PP2A activity by reducing the complexity of the PP2A holoenzyme, without affecting the protein expression levels. Our study help us better understand the role of PP2A complex in the pathogenesis of human DKD and might provide new insights into therapeutic targets for DKD.

FR-PO307

Inhibition of p53 Ameliorates Adenine-Induced Kidney Injury in Mice

Hak Joo Lee,[1,2] Guanshi Zhang,[1,2] Richard Montellano,[1,2] Ian M. Tamayo,[1] Esmeralda Trevino,[1] Jean C. Bopassa,[1] David G. Md,[1] Kumar Sharma.[1,2]
Center for Precision Medicine. *[1]University of Texas Health San Antonio, San Antonio, TX; [2]Audie L. Murphy Memorial Veterans' Hospital, STVHCS, San Antonio, TX.*

Background: Diabetes is associated with premature senescence and an increase in apoptosis in the kidney of patients with diabetes in association with upregulation of p53. In addition, inhibition of production of the endogenous nephrotoxic metabolite adenine ameliorated diabetes-induced kidney injury in mice with type 2 diabetes and adenine has been found to stimulate the senescence associated secretory phenotype (SASP) including p21 mRNA expression in the kidney of WT mice. We therefore hypothesized that deletion of p53 ameliorates adenine-induced kidney injury by inhibiting p21-apoptosis pathway in mice.

Methods: We randomized 8-10 weeks age of p53KO and WT male mice. Mice received 0.2 % adenine-containing diet or normal chow for 4 weeks (n=5-12 per group).

Results: Adenine decreased body weight, blood glucose level, and kidney, liver, and heart weight to tibia length ratio in WT and p53KO mice. p53KO significantly reduced adenine-induced albuminuria, kidney fibronectin accumulation and plasma blood urea nitrogen increment in mice. However p53KO did not affect adenine-increased kidney injury molecules-1 level in the kidney. Adenine increased mRNA expression of SASP in the kidney of both WT and p53KO mice. p53KO significantly decreased adenine induced IL-6 and partially reduced other SASP components (p16, TGFβ1, and IL-1β). p53KO inhibited adenine-induced p21 mRNA expression and degradation of Bcl2.

Conclusions: Our data suggest that the adenine-p53-apoptosis pathway contributes to kidney injury in mice. Adenine-p53 axis could be used for a therapeutic target of diabetes kidney disease and other kidney diseases characterized by adenine excess production.

FR-PO308

Spatial Metabolomics via Matrix-Assisted Laser Desorption Ionization Mass Spectrometry Imaging (MALDI-MSI) Identifies Bioenergetic and Tricarboxylic Acid (TCA) Cycle Metabolites as Pharmacodynamic Biomarkers of Losartan for Diabetic Kidney Disease

Leila Hejazi,[1] Shoba Sharma,[1] Aaron Ruiz,[1] Ian M. Tamayo,[2] Soumya Maity,[2] Guanshi Zhang,[2] Fabio C. Tucci,[3] Kumar Sharma.[2] *[1]SygnaMap, San Antonio, TX; [2]The University of Texas Health Science Center at San Antonio, San Antonio, TX; [3]Epigen Biosciences Inc, San Diego, CA.*

Background: Spatial metabolomics is a powerful platform for drug development for identifying pharmacodynamic biomarkers and mechanism of action (MoA) of therapeutics. Herein, we used an advanced MALDI-MSI platform to identify metabolites regulated by a specific treatment losartan (an angiotensin II receptor blocker used for clinical diabetic kidney disease).

Methods: Fresh frozen kidney tissues were obtained from vehicle-treated and losartan-treated Zucker diabetic fatty (ZDF)-rats (5/group). After sectioning and DAN matrix application, MALDI-MSI was performed using a ThermoFisher Orbitrap QE-Exactive-HFX coupled with a Spectroglyph MALDI/ESI source. All imaging data was uploaded to METASPACE for metabolite annotations using HMDB. Autofluorescence- and histochemical-images were used to identify kidney margins and to correlate different kidney tissue features to the MSI data using MSI-DeepPath and obtain pixel-level annotated metabolites.

Results: Using METASPACE, an average of 300 endogenous metabolites were annotated in each kidney tissue section. To compare levels of metabolites across tissue sections and animal groups, intensity data extracted from METASPACE were co-registered to corresponding tissue sections, normalized and quantified using the MSI-DeepPath platform. Statistically significant results ($p < 0.02$) showed that the most highly up-regulated metabolites in response to losartan treatment were uridine 5'-diphosphate (UDP), orotidylic acid (OMP), and adenosine diphosphate (ADP). The most significantly down-regulated metabolites ($p < 0.005$) were malic acid and fumaric acid, key intermediates in the TCA cycle pathway.

Conclusions: Losartan can reduce levels of fumarate, a potential fibrogenic metabolite in the diabetic kidney, confirming a prior report that losartan can lower urine fumarate. Additionally, losartan increased levels of nucleotides such as UDP, ADP, and OMP, which may significantly impact energy levels and overall metabolic state of a cell. MSI-DeepPath identified losartan's novel effects on fumarate and bioenergetic metabolites, thereby demonstrating the power of quantitative spatial metabolomics for pharmacodynamic biomarkers/MoA.

FR-PO309

Investigating the Therapeutic Potential of Mannose in Diabetic Nephropathy: Targeting Epithelial-Mesenchymal Transition

Sharui Ma,[1] Liumei Song,[2] Xiangchun Liu.[3] *[1]Shaanxi Provincial People's Hospital, Xi'an, China; [2]Xi'an Jiaotong University, Xi'an, China; [3]The Second Hospital of Shandong University, Jinan, China.*

Background: Diabetic nephropathy progression often involves epithelial-mesenchymal transition (EMT) of proximal tubular epithelial cells, driven in part by the activation of transforming growth factor-beta (TGF-β) signaling in response to high glucose levels. Mannose, a hexose sugar, has shown promise in mitigating type 2 diabetes progression by suppressing TGF-β activity and enhancing regulatory T (Treg) cell function.

Methods: Human renal proximal tubular epithelial cells (HRPTECs) were cultured and subjected to control conditions, high glucose exposure, or high glucose combined with mannose treatment. Cell migration was assessed using wound scratch assays, and the expression of EMT-related proteins (E-cadherin, N-cadherin, and Vimentin) was analyzed via Western blotting. Further experiments investigated the regulatory effect of mannose on TGF-β through Western blotting, quantitative real-time polymerase chain reaction (qRT-PCR), and co-immunoprecipitation assays. Rescue experiments involved the overexpression of TGF-β followed by assessment of EMT reversal.

Results: High glucose exposure significantly promoted EMT in HRPTECs, whereas mannose treatment effectively reversed this progression. Mannose also attenuated the upregulation of EMT-related proteins induced by high glucose. Mechanistically, mannose was found to reduce TGF-β protein levels through increased ubiquitination and subsequent degradation, without affecting mRNA levels. Notably, overexpression of TGF-β counteracted the mesenchymal-epithelial transition (MET) induced by mannose, confirming the inhibitory effect of mannose on EMT via TGF-β regulation.

Conclusions: Our findings demonstrate that mannose inhibits high-glucose-induced EMT in HRPTECs by promoting the degradation of TGF-β. This suggests the therapeutic potential of mannose, a simple sugar, in the treatment of diabetic nephropathy.

FR-PO310

Photobiomodulation in Kidney Function in Rats with Diabetic Kidney Disease

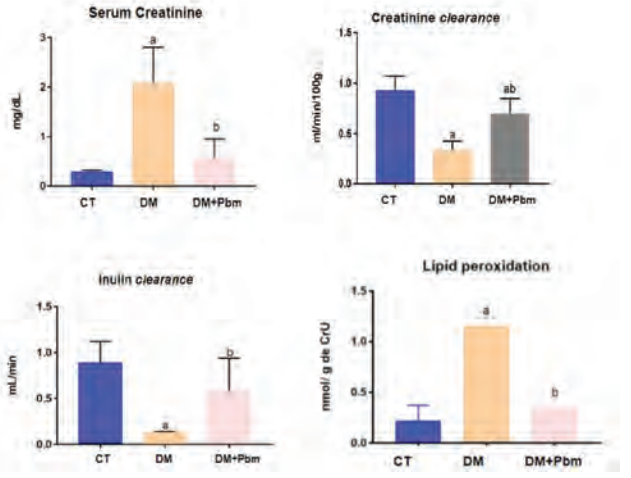
Jessica P. García,[1] Eloiza O. Silva,[1,2] Guilherme H. Ferreira Vieira,[1] Carla D. Victoria,[1] Maikol L. Gonçalves,[1] Alessandra Oliveira Maia,[1] Juliana V. Silva,[1] Mykelly G. Alves,[1] Camila Lima,[1] Luciana Soares C. Santos,[1,2] Mirian Watanabe,[3] Maria De Fatima Vattimo.[1] Group of Studies on Acute Kidney Injury. *[1]Universidade de Sao Paulo, Sao Paulo, Brazil; [2]Faculty of Medical Sciences of Santa Casa de Sao Paulo, Sao Paulo, Brazil; [3]United Metropolitan Colleges University Center, Sao Paulo, Brazil.*

Background: Diabetic kidney disease (DKD) is a serious microangiopathic complication of diabetes mellitus (DM). Photobiomodulation therapy (Pbm) is a non-pharmacological therapy based on the red spectral range. Studies with a CKD model in rats showed positive results in CKD after the application of Pbm, such as reduced blood pressure, increased glomerular filtration rate and decreased tubulointerstitial fibrosis. The aim of this study is to evaluate the impact of Pbm on the function of rats with DRD.

Methods: Wistar rats weighing 280-300 g randomized as follows: Citrate (CT): animals that received streptozotocin vehicle (citrate; iv, caudal, single dose); Diabetes Mellitus (DM): animals that received streptozotocin (STZ, 60mg/kg; iv; single dose); Diabetes Mellitus + Low-intensity laser (DM+Pbm): DM animals, in the third, were irradiated with a low-intensity infrared laser (wavelength 808nm, power 100mW, energy 3 Joule, a point on the right flank on the left, 3 times a week, 6 weeks). Renal function (serum creatinine-CrS; creatinine clearance; inulin clearance-Clin) and oxidative profile (urinary peroxides, lipid peroxidation) were evaluated.

Results: The DM group reduced renal function when evaluating serum creatinine, creatinine clearance and inulin, while the DM+Pbm group increased these parameters, attenuating the deterioration of renal function and improving the oxidative profile. The group subjected to photobiomodulation showed a reduction in oxidative stress compared to the DM group.

Conclusions: The results confirmed that photobiomodulation attenuates the reduction in renal function induced by diabetic kidney disease.



FR-PO311

Long-Term Impact of PM2.5 Exposure on Diabetic Kidney Disease Patients Considering Time-Dependent Medication Adjustment

Soie Kwon,[1] Jung Pyo Lee.[2] *[1]Chung Ang University Hospital, Seoul, Republic of Korea; [2]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea.*

Background: Ambient air pollutants adversely affect renal function and increase type-2 diabetes incidence. However, the impact of air pollution on diabetic kidney disease (DKD) patients remains underexplored, with limited consideration of medication-related effects. We assessed the influence of air pollutants on DKD patients while meticulously adjusting for medication usage.

Methods: We retrospectively enrolled DKD patients. Primary and secondary outcomes included end-stage kidney disease (ESKD) and a composite (ESKD, mortality). Nationwide forecasted ultrahigh-resolution air-pollutant data ($PM_{2.5}$, PM_{10}, NO_2, CO) were obtained from AiMS-CREATE. Monthly updated ambient air pollutants and medication prescription information were considered time-varying variables in multivariable time-dependent Cox analyses.

Results: Patients (n=9,482) were followed for a median of 9 (ESKD) and 11 (composite outcome) years; 20.6% progressed to ESKD, and 46.7% experienced composite outcomes. The DKD-stage patient distribution was 12.5% (stage 1-2), 35.8% (stage 3), and 51.6% (stage 4-5). Initial RAS blocker use increased from 37.4% to 58.5% during Year 1 then gradually declined. During follow-up, all four air pollutant concentrations significantly decreased, with CO exhibiting the most pronounced decline. $PM_{2.5}$ was significantly associated with greater ESKD progression (aHR=1.19, 95% CI=1.020–1.396) and composite outcome (aHR=1.17, 95% CI=1.055–1.299) risk. Unexpectedly, PM_{10} increases were associated with decreased ESKD progression and composite outcome risk, potentially influenced more by social factors (e.g., air pollution alerts).

Conclusions: In this study, there was evidence of $PM_{2.5}$ exposure-related adverse effects on ESKD progression in DKD even after comprehensive medication usage adjustment.

Association between end-stage kidney disease progression or composite outcome and air pollutant exposure.

Air pollutant (unit)	ESKD			Composite outcome		
	HR	95% CI	p value	HR	95% CI	p value
NO2 (10ppb)	1.09	0.967–1.224	0.162	1.00	0.926–1.088	0.924
CO (10ppb)	1.00	0.989–1.015	0.813	1.00	0.991–1.009	0.973
PM10 (10ug/m3)	0.91	0.853–0.963	0.002	0.92	0.886–0.965	<0.001
PM2.5 (10ug/m3)	1.19	1.020–1.396	0.027	1.17	1.055–1.299	0.003

Air pollutants were considered time-dependent covariates. All analyses were adjusted for time-fixed covariates and time-dependent confounders (antidiabetic drug usage and renin-angiotensin blocker usage).

FR-PO312

Modeling Cardiorenal Protection with SGLT2 Inhibition in Type 1 Diabetes: An Analysis of DEPICT-1 and -2

Massimo Nardone,[1] Luxcia Kugathasan,[1] Vikas Sridhar,[1] Pritha Dutta,[3] David Campbell,[2] Anita T. Layton,[3] Bruce A. Perkins,[4] Sean Barbour,[5] Tony K. Lam,[6] Adeera Levin,[5] Leif Erik Lovblom,[1] Istvan Mucsi,[1] Remi Rabasa-Lhoret,[7] Valeria E. Rac,[6] Peter A. Senior,[8] Ronald J. Sigal,[2] Aleksandra Stanimirovic,[6] Alessandro Doria,[9] David Cherney.[1] *[1]Toronto General Research Institute, Toronto, ON, Canada; [2]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [3]University of Waterloo, Waterloo, ON, Canada; [4]Sinai Health, Toronto, ON, Canada; [5]The University of British Columbia, Vancouver, BC, Canada; [6]University of Toronto, Toronto, ON, Canada; [7]Universite de Montreal, Montreal, QC, Canada; [8]University of Alberta, Edmonton, AB, Canada; [9]Harvard Medical School, Boston, MA.*

Background: Sodium-glucose co-transporter-2 (SGLT2) inhibitors improve glycemic control and lower insulin requirements in type 1 (T1D) and type 2 diabetes (T2D). While SGLT2 inhibitors lower cardiovascular disease (CVD) and end-stage kidney disease (ESKD) risk in T2D, dedicated cardiorenal outcome trials have not been performed in T1D. Using validated risk prediction models, the current analysis evaluated the effect of SGLT2 inhibition on estimated CVD and ESKD risk in a T1D cohort.

Methods: Demographics, medical history, biomarkers, and blood pressure were extracted from 1,473 participants with T1D enrolled in the DEPICT-1 and -2 trials. Data at baseline, week -24, -52, and -56 (4 weeks off-treatment) were used to estimate 10-year CVD and 5-year ESKD risk using the Steno T1 Risk Engine (SRE) and the Scottish Diabetes Research Network (SDRN) risk prediction models. Risk reduction was determined based on the percent change in risk from baseline between participants receiving dapagliflozin (pooled 5 and 10mg) vs. placebo, and evaluated statistically using a two-factor repeated measures ANOVA.

Results: The relative 10-year estimated CVD risk was significantly lower following 52 weeks of dapagliflozin treatment (SRE: -5.8% [-8.4, -3.3%] & SDRN: -11.9% [-16.1, -7.8%]; ; P<0.01). The 5-year ESKD risk was also significantly lower following 52 weeks of dapagliflozin treatment (SRE: -8.4% [-12.4, -4.4%]; P<0.01). The greatest improvement in ESKD risk was observed at week 56 (-12.8% [-16.6, -9.0%]; P<0.01), in conjunction with an expected rise in eGFR post drug cessation.

Conclusions: Dapagliflozin improves estimated CVD and ESKD risk in T1D participants, emphasizing the need for cardiorenal outcome trials in people living with T1D. By avoiding the acute, reversible GFR “dip” with SGLT2 inhibition, estimation of ESKD risk using models that incorporate GFR may be best performed when drug is discontinued.

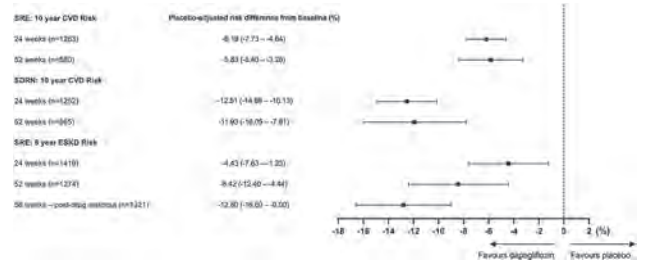


Figure 1.

FR-PO313

Simulated Effect of Dapagliflozin on Reducing Incidence of Albuminuria and CKD Using the Urinary Proteomics Classifier CKD273 in Normoalbuminuric Type 2 Diabetes

Viktor Rotbain Curovic,[1] Frederik Persson,[1] Tine Hansen,[1] Peter Rossing.[1,2] The PRIORITY Study Group. *[1]Steno Diabetes Center Copenhagen, Herlev, Denmark; [2]Kobenhavns Universitet Det Sundhedsvidenskabelige Fakultet, Kobenhavn, Denmark.*

Background: Higher urinary proteomic classifier CKD273 levels are associated with higher albuminuria and chronic kidney disease (CKD) grade 3 risk, in type 2 diabetes (T2D). Treatment with dapagliflozin have shown to significantly lower CKD273 levels. We have investigated if the magnitude of CKD273 reduction, seen after treatment with dapagliflozin, is associated with a lower risk of developing albuminuria and CKD grade 3 in normoalbuminuric T2D.

Methods: Post-hoc simulation of the observational PRIORITY (NCT02040441) study originally designed to assess CKD273 as a predictor of albuminuria. People with T2D and normal albuminuria and eGFR were included. CKD273 levels at baseline were releveled according to the CKD273 reduction seen after dapagliflozin treatment in the DapKid (NCT03509454) study (-0.221 arb. units). Endpoints were development of persistent urinary albumin creatinine ratio >30 mg/g and development of CKD grade 3 (eGFR <60 ml/min/1.73m^2). Cox proportional hazard models were fitted per -0.221 difference in baseline CKD273 level. Models were adjusted for sex, baseline age, diabetes duration, HbA_{1c}, systolic blood pressure, and eGFR.

Results: In total, 1589 were included, 995 (63%) were men, and followed for a median (IQR) of 2.4 (2.0, 3.0) years. Baseline mean (SD) age was 61.9 (8.3) years, diabetes duration was 11.8 (7.8) years, HbA_{1c} was 7.4 (1.1) %, and eGFR was 87 (16) ml/min/1.73m^2. Crude Cox analyses showed a 24% lower risk of albuminuria per 0.221 lower CKD273 levels at baseline (HR (95% CI): 0.76 (0.70, 0.83), p<0.001) and remained significant after adjustment (0.87 (0.80, 0.95), p=0.002). Similar results were seen with development of CKD grade 3, with 27% lower risk in crude models (0.73 (0.70, 0.84), p<0.001), confirmed in adjusted (0.84 (0.76, 0.92), p<0.001).

Conclusions: Across 2.4 years, in a population with T2D and no albuminuria, a 0.221 lower level of CKD273 was associated with a 24% lower risk of developing albuminuria and 27% lower risk of developing CKD grade 3. Associations remained significant after adjustment for relevant risk factors. Our results suggest that a reduction in CKD273 on par with that seen after treatment with dapagliflozin may lower renal events already in normoalbuminuric type 2 diabetes.

FR-PO314

Development and Validation of a Model to Predict a Positive CKD Screening among Patients with Type 2 Diabetes

Gregorio T. Obrador,[1] Ana Freyria,[1] Alma Sotelo,[3] Alejandro Chevaile,[2] Rafael Valdez-Ortiz,[4] Nikita Karuzin,[1] Eduardo Brenner Muslera,[1] Nadia Olvera.[5] *[1]Universidad Panamericana School of Medicine, Ciudad de México, Mexico; [2]Universidad Autonoma de San Luis Potosi, San Luis Potosi, Mexico; [3]Universidad Panamericana School of Nursing, Ciudad de México, Mexico; [4]Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico; [5]Universidad Panamericana, Ciudad de Mexico, Mexico.*

Background: Cost barriers limit chronic kidney disease (CKD) screening in low- and middle-income countries. This study aims to provide a formula for identifying patients with type 2 diabetes mellitus (T2DM) who will be screened positive for CKD to optimize available resources.

Methods: The development cohort consisted of adult patients with T2DM who participated in a CKD screening program in three Mexican states. Demographic and clinical data were collected. Standardized serum creatinine was measured, and the glomerular filtration rate was estimated with the 2021 CKD-EPI equation. The albumin/creatinine ratio was assessed using Siemens’ *Clinitek Status*. Univariate and multivariate logistic regression models were developed, and odds ratios with 95% confidence intervals, receiver operator characteristic curves (ROC), and area under the curve (AUC) were calculated. The validation cohort consisted of adult patients with T2DM who were screened for CKD in three clinics of Mexico City’s Secretariat of Health. Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) are reported in each cohort.

Results: Overall, 602 patients with T2DM underwent screening in the development cohort. The mean age was 57 years, and 73% were female. The multivariate model included the following variables (ORs): age (1.02), female gender (0.82), fasting glucose (1.0008), years with T2DM (1.01), and family income (0.99). AUC from the ROC was 71.8% (Fig. 1). After setting the threshold to 0.2 to reduce false negatives, the sensitivity was 80.7%, specificity 46.3%, PPV 15.2%, and NPV 95.2%. The validation cohort consisted of 449 patients with T2DM. The mean age was 60 years, and 66% were female. With the same threshold of 0.2, sensitivity reached 80.0%, specificity 38.5%, PPV 4%, and NPV 98.3%.

Conclusions: The formula’s accuracy, high NPV, and easy availability of the included variables make it a valuable tool, mainly when CKD screening resources for patients with T2DM are limited.

FR-PO315

Longitudinal Risk Assessment by kidneyintelX.dkdTM to Guide Adaptive Clinical Trials

Steven G. Coca,[1] Sharon Stapleton,[2] Girish N. Nadkarni,[1] Fergus Fleming,[2] Hiddo J. Heerspink.[3] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Renalytix plc, London, United Kingdom; [3]Rijksuniversiteit Groningen, Groningen, Netherlands.*

Background: Albuminuria has been used as a biomarker to guide adaptive clinical trials in Diabetic Kidney Disease. Intra-individual coefficient of variation of albuminuria within an individual is high and 2024 KDIGO CKD guidelines state that increases in UACR less than a doubling, or reductions in albuminuria smaller than 50% are consistent with random fluctuations. The FDA De-novo marketing authozied kidneyintelX.dkd test incorporates biomarkers and clinical variables and categorizes patients at low, moderate, or high risk for progression of Diabetic Kidney Disease. Time-updated changes in future risk per kidneyintelX.dkd may help delineate response to DKD therapy, particularly in those with UACR changes in the ambiguous zone (i.e., -49% to +99%).

Methods: We measured tumor necrosis factor receptor 1 (TNFR-1), tumor necrosis factor receptor 2 (sTNFR-2), and kidney injury molecule (KIM-1) on banked plasma from CANVAS trial participants with baseline DKD (eGFR <60 ml/min/1.73 m^2 or UACR ≥30 mg/mg). We determined the kidneyintelX.dkd risk level at baseline and year 1 and assessed how changes in kidneyintelX.dkd were associated with subsequent DKD progression (composite outcome of ≥40% sustained decline in eGFR, or kidney failure) in those with ambiguous changes in UACR in the same period.

Results: 933 participants with prevalent DKD had baseline and year 1 plasma samples, a median eGFR of 66 ml/min and median UACR of 55 mg/g. Post year 1, 78 (8.4%) participants experienced the outcome over the following median of 4.9 years. Of these, 31% experienced a 50% reduction and 13% experienced more than a doubling of uACR at year 1. In the ambiguous population (56%), 40% initially scored kidneyintelX. dkd moderate or high risk. Of these, at year 1, 27% moved to low risk with event rate was 3.3% (ref), 58% stayed at or moved to moderate risk with event rate 3.3-fold higher at 11%. In those that remained or moved to high risk (14%), the event rate was over 14-fold higher at 45%.

Conclusions: Re-assessment of risk via kidneyintelX.dkd at 1 year in those with ambiguous change in albuminuria robustly stratified patients for future progression of DKD. Adaptive clinical trials can consider kidneyintelX.dkd risk levels over time as a criterion to tailor interventions, particularly for those with moderate or high risk of progression after randomization.

Health Care Costs and Utilisation for Diabetes Mellitus among Hospitalised Patients in Ireland: The National Kidney Disease Surveillance System

Leonard Browne,[1] Meera Tandan,[1] Austin G. Stack.[1,2] National Kidney Disease Surveillance System and Quality Assurance Programme.
[1]University of Limerick, Limerick, Ireland; [2]University Hospital Limerick, Dooradoyle, Ireland.

Background: A better understanding of the frequency, length of stay, and costs of inpatient hospitalisation for diabetes mellitus (DM) is crucial for effective national healthcare planning and resource allocation. We explored the rates of diabetes-related hospitalisations and associated healthcare costs in Ireland.

Methods: We utilised data from the National Hospital In-Patient Enquiry (HIPE) database in 2022, which captured all hospitalisations to public hospitals in Ireland. We included all ICD-10 hospital admissions with a principal or additional diagnosis of diabetes (E10, E11, E13, E14, O24). Age-standardised rates (ASR), length of stay, and costs were computed and compared across demographic characteristics, Charlson comorbidity score (0, 1-2, and ≥3), and 8 health regions. Rates were standardised to the European Standard Population from 2012, and rate ratios (RR) were determined and compared.

Results: In 2022, 8.6% of all hospitalisations in Ireland (146,362/1,711,564) recorded diabetes as a principal or additional diagnosis, costing €601 million. Diabetes as principal diagnosis accounted for 10,511 hospitalisations with the following breakdown: type 2 diabetes (58.5%), type 1 diabetes (28.4%) gestational diabetes (12.7%), and other or unspecified diabetes (0.2%). Average LOS was 4.9 days and increased significantly rising Charlson Comorbidity score (range 3.9 to 9.2 days). Hospital admissions, LOS, and costs increased significantly with increasing comorbidity burden. The most frequent complications were kidney, eye, and circulatory complications. Age standardised rates were higher in men than women (4,071 vs 2,844 per 100, 000 population) and men experienced significantly higher rates than women for kidney (x 1.9 times), eye (x1.8 times), circulatory (x3.6 times), and neurological complications (x1.9 times). Hospitalisation rates varied significantly by region: lowest in the Southwest RR 0.8 (0.8-0.8) and highest in the Midland region RR 1.8 (1.7-1.8) (P<0.01) compared to the national average (RR 1.00).

Conclusions: Diabetes mellitus contributes substantially to healthcare utilisation and costs in Ireland driven by complications related to kidney disease, eye disease and circulatory disease. Demographic and regional disparities exist and highlight the need for strategic healthcare planning and early preventive care.

FR-PO317

Effect of Sotagliflozin on eGFR Slope by Baseline Kidney Function and Glycemic Control

Vikas Sridhar,[1] Deepak L. Bhatt,[4] Ayodele Odutayo,[1] Michael Szarek,[5] Michael J. Davies,[2] Phillip Banks,[2] Bertram Pitt,[3] Philippe Gabriel Steg,[6] David Cherney.[1] *[1]University of Toronto, Toronto, ON, Canada; [2]Lexicon Pharmaceuticals Inc, The Woodlands, TX; [3]University of Michigan, Ann Arbor, MI; [4]Icahn School of Medicine at Mount Sinai, New York, NY; [5]SUNY Downstate Health Sciences University, New York City, NY; [6]Universite Paris Cite, Paris, France.*

Background: In a secondary analysis of the SCORED trial using the complete laboratory dataset, sotagliflozin (SOTA), a dual SGLT1 & 2 inhibitor, reduced the risk of kidney and cardiorenal composite endpoints in patients with type 2 diabetes (T2D) and diabetic kidney disease (DKD). This *post hoc* analysis of SCORED evaluated the effect of SOTA versus placebo on eGFR slope and the impact of baseline kidney function and glycemia.

Methods: We derived the acute eGFR slope (from baseline to week 4), chronic slope (week 4 to month 12) and total slope using a spline mixed effects repeated measures model on the entire cohort and in the following baseline subgroups – eGFR <30, 30 to <45, ≥45 ml/min/1.73m^2; A1, A2 and A3 albuminuria; glycated hemoglobin A1C <8%, ≥8 to <9%, ≥9%.

Results: Within the entire cohort of 10,574 participants, a placebo-adjusted acute decline in eGFR of -2.59 ml/min/1.73m^2/year (95% CI -2.88, -2.30; p<0.0001) was observed. The chronic slope, measured after this acute decline, was 1.99 ml/min/1.73m^2/ year in favor of SOTA (95% CI 1.63, 2.34; p<0.0001). The total placebo-adjusted slope was -0.08 ml/min/1.73m^2/year (95% CI -0.43, 0.27; p=0.67). The magnitude of the acute decline attenuated across progressively lower eGFR subgroups (P-interaction =0.017). Effects on chronic slope were consistent across baseline eGFR and A1C subgroups (P-interaction=0.48 and 0.22). Compared to placebo, SOTA had a greater benefit on chronic slope with increasing baseline albuminuria (P-interaction=0.023)

Conclusions: In participants with DKD, treatment with SOTA conferred kidney protection across a spectrum of baseline kidney function and glycemic control. The magnitude of kidney protection was larger with increasing albuminuria.

FR-PO318

Effects of Canagliflozin on Albuminuria and eGFR Decline Using an Individual Preintervention eGFR Slope

Satoshi Miyamoto,[1] Hiddo J. Heerspink,[2] Dick de Zeeuw,[2] Kota Sakamoto,[1] Michihiro Yoshida,[1] Hiromi Kuramoto,[1] Kenichi Shikata.[1] *[1]Okayama University Hospital, Okayama, Japan; [2]University Medical Center Groningen, Groningen, Netherlands.*

Background: Demonstrating drug efficacy in slowing kidney disease progression requires large clinical trials when targeting participants with early stage of chronic kidney disease (CKD). To assess the effect of canagliflozin on kidney function in patients with type 2 diabetes (T2D) and microalbuminuria, we used a novel trial design using the individual's change in the rate of estimated glomerular filtration rate (eGFR) decline before (preintervention slope) and during treatment (chronic slope).

Methods: We conducted a randomized, parallel-group, open-labeled trial (CANPIONE study) at 21 sites in Japan. We randomly assigned (1:1) participants with T2D, urinary albumin-to-creatinine ratio (UACR) of 50 to <300 mg/g, and an eGFR of ≥45 mL/min/1.73m^2 to receive 52 weeks of canagliflozin or guideline-recommended treatment except for SGLT2 inhibitors (control). The first and second primary outcomes were the geometric mean percentage change from baseline in UACR and the change in eGFR slope (chronic−preintervention), respectively. The study is registered with the Japan Registry of Clinical Trials (jRCTs061180047).

Results: Of 98 randomized participants, 96 received at least one study treatment. The least-squares mean change from baseline in log-transformed geometric mean UACR was greater in the canagliflozin group than the control group (between-group difference, −30.8% (95%CI −42.6 to −16.8); p=0.0002). The change in eGFR slope (chronic−preintervention) was 1.4 (95%CI −0.6 to 3.3) and −3.1 (95% CI −5.1 to −1.0) mL/min/1.73m^2 per year in the canagliflozin and control groups, respectively, resulting in a between-group difference (canagliflozin−control) of 4.4 mL/min/1.73m^2 per year (95%CI 1.6 to 7.3, p=0.0022). The effect of canagliflozin in slowing the rate of eGFR decline was more pronounced in participants with steeper preintervention slope than that in slow progressors (5.6 vs. 3.1 mL/min/1.73m^2 per year).

Conclusions: Canagliflozin reduced albuminuria and the patient-specific eGFR trajectory in patients with T2D and microalbuminuria. The results from the CANPIONE study suggest that the within-individual change in eGFR slope may be a novel approach to identify participants with faster preintervention eGFR decline and to determine the kidney protective potential of new therapies in early stage of CKD.

FR-PO319

SGLT2 Inhibitors Are Associated with Lower Risk of CKD Progression in Type 2 Diabetes (T2D) than Glucagon-Like Peptide 1 Receptor Agonists (GLP-1 RAs): An Emulated Clinical Trial

Sydney E. Hartsell,[1,2] Amara Sarwal,[1,2] Ravinder Singh,[1,2] Mckenna R. Nevers,[1,2] Jincheng Shen,[1,2] Guo Wei,[1,2] Robert E. Boucher,[1] Tom Greene,[1] Stavros Drakos,[1,2] Srinivasan Beddhu.[1,2] *[1]The University of Utah School of Medicine, Salt Lake City, UT; [2]VA Salt Lake City Health Care System, Salt Lake City, UT.*

Background: There is a paucity of data on head-to-head comparisons between GLP1-RA and SGLT2i on the risk of CKD progression in T2D.

Methods: We used an active comparator, new user design to compare insulin glargine (IG), GLP1-RA and SGLT2i among veterans with T2D and CKD (eGFR <60) on metformin who initiated one of these drugs between 01/01/18 and 12/31/21 (N=26,624). Generalized propensity score based inverse probability weighting (IPW) was used to minimize confounding in comparisons across the three drug classes. Outcomes were CKD progression (50% eGFR drop or eGFR <15 sustained over 2 consecutive labs), all-cause mortality (ACM) and renal/ACM composite, followed through 3/31/23. We will add ESRD data with follow-up until 12/21 via USRDS linkage when available July 2024. IPW Cox regression models related study drug class to kidney and mortality outcomes, additionally adjusted for demographics, comorbidities, diabetes severity, and baseline labs and medications.

Results: Prior to weighting, 9,829, 3,799 and 12,996 veterans initiated IG, GLP1-RA and SGLT2i respectively with baseline eGFRs of 48.7(9.0), 48.8(8.0) and 51.1(6.7) ml/min/1.73m^2, mostly in Stage 3A (73.3%, 72,6% and 83.3% respectively). Few had albuminuria >300mg/g (7.7%, 7.7% and 8.2% at baseline) but most did not have urine albumin lab data available within 365 days prior to study drug initiation date (41-46% missing across all groups). Pairwise comparisons of unweighted and weighted event rates and hazard ratios are shown in the table. Compared to those on GLP1-RA, veterans with T2D and CKD on SGLT2i had a 39% lower hazard of 50% decrease in eGFR or progression to CKD Stage V (HR 0.61, 95%CI 0.49-0.75) and a 22% lower hazard of renal/ACM (HR 0.88, 95%CI 0.79-0.98). IG was associated with a higher risk of CKD progression compared to SGLT2i or GLP1-RA.

Conclusions: These data from a large national cohort of veterans with T2D and CKD suggest that SGLT2i may have a renoprotective advantage over GLP1-RA.

Risk-Based Implementation of SGLT2 Inhibitors: Insights from the CANVAS Program and CREDENCE Trial

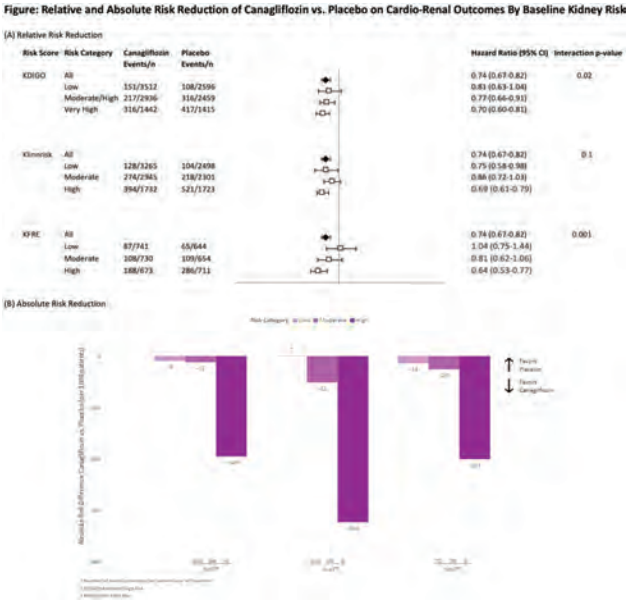
Emily K. Yeung,[1] Thomas W. Ferguson,[2,3] Navdeep Tangri,[2,3] Muthiah Vaduganathan,[4] Clare G. Arnott,[5,6] Min Jun,[5] Sradha S. Kotwal,[5,7] Meg Jardine,[8,9] Vlado Perkovic,[5,10] Hiddo J. Heerspink,[5,11] Brendon L. Neuen.[5,12] *[1]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; [2]University of Manitoba Faculty of Health Sciences, Winnipeg, MB, Canada; [3]Seven Oaks General Hospital, Winnipeg, MB, Canada; [4]Washington DC VA Medical Center, Washington, DC; [5]The George Institute for Global Health, Sydney, NSW, Australia; [6]Royal Prince Alfred Hospital, Camperdown, NSW, Australia; [7]Prince of Wales Hospital and Community Health Services, Randwick, NSW, Australia; [8]NHMRC Clinical Trials Centre, Camperdown, NSW, Australia; [9]Concord Repatriation General Hospital, Concord, NSW, Australia; [10]University of New South Wales, Sydney, NSW, Australia; [11]Rijksuniversiteit Groningen, Groningen, Netherlands; [12]Royal North Shore Hospital, St Leonards, NSW, Australia.*

Background: The Kidney Disease Improving Global Outcomes (KDIGO) 2024 guideline for the evaluation and management of chronic kidney disease (CKD) recommends using a validated risk score to estimate absolute risk of kidney failure (1A recommendation). Given that those at highest risk of CKD progression are also at highest risk for cardiovascular outcomes, we sought to determine if a risk-based approach would identify those who benefit most from a cardio-kidney perspective with SGLT2 inhibition.

Methods: In this post-hoc individual participant data analysis of the CANVAS program and CREDENCE trial, we categorized participants according to risk of CKD progression using the KDIGO classification of CKD, Klinrisk algorithm, and the Kidney Failure Risk Equation (restricted to participants with eGFR <60 mL/min1/1.73m2). Effects of canagliflozin on a cardio-kidney composite outcome of 40% decline in eGFR, kidney failure or death due to cardiovascular or kidney disease were analyzed using Cox and Poisson regression models.

Results: Across higher kidney risk categories, participants were more likely to have lower eGFR, higher urine albumin:creatinine ratio, higher systolic blood pressure, and longer duration of diabetes (all p<0.0001). Overall, canagliflozin reduced the relative risk of the cardio-kidney composite outcome by 26% (HR 0.74, 95% CI 0.67-0.82). The relative benefits of canagliflozin were at least as large across higher kidney risk categories (Figure; Panel A). Absolute risk reductions were largest in participants at highest baseline risk (Figure; Panel B).

Conclusions: The use of validated kidney risk scores can accurately identify those who benefit most from SGLT2 inhibition with canagliflozin.



FR-PO321

Assessing Heterogeneity of Treatment Effects from Canagliflozin (CANA) on Kidney Outcomes Using the Joslin Kidney Panel: Insights from the CREDENCE Trial

Sok Cin Tye,[1,2] Zaipul Md Dom,[1,2] Eiichiro Satake,[1,2] Michael K. Hansen,[3] Matthew D. Breyer,[3] Andrzej S. Krolewski.[1,2] *[1]Joslin Diabetes Center, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Janssen Research & Development, LLC, Springhouse, PA.*

Background: SGLT2 inhibitors reduce kidney outcomes among patients with type 2 diabetes (T2D) and chronic kidney disease (CKD). The Joslin Kidney Panel of 21 proteins (JKP) predicts end-stage kidney disease (ESKD) in patients with diabetes.[1] This study aims to develop a JKP-based risk model and assess heterogeneity of treatment effects (HTE) in patients with T2D and CKD.

Methods: Post-hoc analysis of the CREDENCE trial, including 1374 participants with CKD stage 3. Baseline JKP protein levels measured via Olink® platform. The kidney outcome studied was first occurrence of estimated glomerular filtration rate (eGFR) decline by 50% or ESKD. A Cox proportional hazard model was used to first derive a clinical markers model with four predictors from the Kidney Failure Risk Equation. Next, JKP was integrated and final model selected using a stepwise Akaike's Information Criterion. Participants classified into risk quartiles (Q1-Q4), with event rates, relative risks, and cumulative incidence (CI) differences estimated.

Results: During 2.6 years follow-up, 155 (placebo) and 82 (CANA) kidney events recorded. The final model, comprising age, sex, eGFR, urinary-albumin-creatinine-ratio, and six JKP proteins, yielded a C index of 0.82 (95% CI 0.77 to 0.87). Estimated median baseline risk was 20.9% (IQR 8.6%-47.0), demonstrating considerable variation among individual patients. Notably, ~50% of patients (N=688) in this study with a lower predicted risk (Q1,Q2) did not benefit from CANA. However, those in the higher risk quartiles showed a substantial relative treatment benefit with hazard ratios (HR) of 0.35 (95% CI 0.19 to 0.66) and HR 0.42 (95% CI 0.30 to 0.59) in Q3 and Q4 respectively. They also had greatest absolute benefit of CANA, shown by a notable CI rate difference. **(Table 1)**

Conclusions: Integrating the JKP into the risk stratification model improves the prediction of kidney outcomes among patients with T2D and CKD. HTE was observed among CANA-treated patients, with those at higher baseline risk benefiting the most

Funding: NIDDK Support, Other NIH Support - Hearst foundation

Table 1: Kidney outcome risk and treatment effects of canagliflozin vs. placebo in CREDENCE subpopulation (N=1374), categorized by risk quartiles.

Predicted risk quartiles	Placebo (N=679) Cumulative risk, % (Events, N)	Canagliflozin (N=695) Cumulative risk, % (Events, N)	Risk difference % (95% CI)	Hazard ratios (95% CI)

Dosing, Treatment Pattern, and Safety of Finerenone Use in Routine Care: An Interim Analysis of the Prospective, Real-World, and Observational FINE-REAL Study

Christoph Wanner,[1] David C. Wheeler,[2] Kevin M. Pantalone,[3] Lixin Guo,[11] Nihar Desai,[4] Ricardo Correa-Rotter,[5] Sankar D. Navaneethan,[6] Susanne B. Nicholas,[7] Samuel T. Fatoba,[8] Andrea Horvat-Broecker,[9] Martin Merz.[10] *[1]Hospital Würzburg, Würzburg, Germany; [2]University College London, London, United Kingdom; [3]Cleveland Clinic, Cleveland, OH; [4]Yale University School of Medicine, New Haven, CT; [5]Instituto Nacional de Ciencias Médicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [6]Baylor College of Medicine, Houston, TX; [7]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [8]Bayer US LLC, Whippany, NJ; [9]Bayer AG, Wuppertal, Germany; [10]Bayer AG, Berlin, Germany; [11]Beijing Hospital, National Center of Gerontology, Institute of Geriatric Medicine, Chinese Academy of Medical Sciences, Beijing, China.*

Background: FINE-REAL (NCT05348733) is evaluating the use of finerenone in patients (pts) with chronic kidney disease (CKD) and type 2 diabetes mellitus (T2D) in routine clinical practice. This interim analysis describes the dosing, treatment pattern, and safety of finerenone.

Methods: Global, prospective, single-arm, non-interventional study of pts aged ≥18 years with CKD and T2D treated with finerenone.

Results: Of the 1826 pts in this analysis, 1179 (65%) were male and 1682 (92%) were aged ≥50 years. Median follow-up time (IQR) was 269 (150–363) days. At baseline, UACR was available for 1081 (59%) pts, with a median (IQR) UACR of 300 (89–809) mg/g. Mean (SD) eGFR was 54 (24) mL/min/1.73 m^2 (n=1331). At baseline, ACEi/ARBs, SGLT2i, or GLP-1 RA were used by 1298 (71%), 946 (52%), and 522 (29%) pts, respectively. At initiation, 1475 (81%) pts received 10 mg finerenone and 349 (19%) pts received 20 mg finerenone. At 12 months, 372 (25%) pts starting with 10 mg were up-titrated at least once, while 27 (8%) pts starting with 20 mg were down-titrated at least once. At 12 months, 70% of pts with no UACR available (n=253) received 10 mg finerenone; 29% received 20 mg. Of those with UACR available at 12 months, pts with UACR <30 mg/g (n=22) were less likely to receive 20 mg vs 10 mg finerenone (18% vs 82%) than those with UACR 30–300 mg/g (n=83; 37% vs 62%) or >300 mg/g (n=121; 41% vs 59%). Hyperkalemia events were observed in 140 (8%) pts. Treatment-emergent adverse events (AEs) and serious AEs were observed in 574 (31%) and 153 (8%) pts, respectively.

Conclusions: By UACR, the FINE-REAL study population has milder renal impairment than in other pivotal analyses such as FIDELIO DKD. Comedication of finerenone with ACEi/ARBs, SGLT2i, or GLP-1 RA is more optimized in the FINE-REAL study population than is typically observed in real-world practice. Pts with higher UACR received higher finerenone doses, and pts with no UACR available at baseline received lower doses. Safety was consistent with the known safety profile of the drug.

Utilization of the Nonsteroidal Mineralocorticoid Receptor Antagonist (MRA) Finerenone with or without Previous Steroidal MRA

Zihe Zheng,[1] Samuel T. Fatoba,[1] Matthew Novin,[1] German Guerrero,[1] Yunxun Wang,[1] Youssef M. Farag,[1] Connor W. Mckee,[2] Wei Huang,[2] Hongping Tian,[2] Rakesh Singh,[1] Yuxian Du,[1] Jon W. Mares,[1] Marco Lavagnino,[1] Drew Rockett,[1] Karthik Sankaralingam.[1] *[1]Bayer US LLC, Whippany, NJ; [2]Cobbs Creek Healthcare LLC, Newtown Square, PA.*

Background: Finerenone is an FDA-approved non-steroidal MRA indicated for reducing cardiovascular risk and slowing CKD progression in patients with CKD and T2D. Treatment inertia with nsMRA may stem from prior use of traditional steroidal MRAs (sMRA) that are known to be associated with increased hyperkalemia. To begin addressing this practice uncertainty, we described the key characteristics of finerenone users in real-world, with and without known prior sMRA use. We expect nsMRA use among eligible prior sMRA users.

Methods: We conducted retrospective study of finerenone users from July 2021 to December 2023 using the IQVIA Longitudinal Access and Adjudication Data. Adult patients with ≥ 12 months of continuous activity prior to their first filled finerenone claim date (index) were included. Patients with claims for both finerenone and sMRA on the same day were excluded. We described baseline demographics, comorbidities, and comedications of finerenone users by prior sMRA use status.

Results: The largest claim-based finerenone user cohort of 107,143 patients were included, among them 8,025 (7.5%) and 3,315 (3.15%) were prescribed sMRA within the past year and over a year, respectively, prior to initiating finerenone. The mean age was 67 with female percentage at 45-47% across subgroups. Those with prior sMRA prescription exhibited a 23-27% higher prevalence of HF and a 26-30% higher loop diuretic use. Comedication percentage for SGLT2i (47-51%) and GLP1RA (35-37%) remained consistent, regardless of prior sMRA use.

Conclusions: Our study shows that almost 11% of current finerenone users had prior or recent prescription of traditional sMRA. These patients exhibited different comorbidities and comedication profiles from those without prior sMRA prescription at the time of finerenone initiation. Future research should investigate the CV, kidney, and safety outcomes of finerenone users who recently used sMRA to inform clinical practice.

FR-PO324

Utilization of Guideline-Directed Medical Therapies in Finerenone Users

Zihe Zheng,[1] Samuel T. Fatoba,[1] Matthew Novin,[1] German Guerrero,[1] Yunxun Wang,[1] Youssef M. Farag,[1] Connor W. Mckee,[2] Hongping Tian,[2] Rakesh Singh,[1] Yuxian Du,[1] Jon W. Mares,[1] Drew Rockett,[1] Karthik Sankaralingam,[1] Wei Huang,[2] Marco Lavagnino.[1] *[1]Bayer US, LLC, Whippany, NJ; [2]Cobbs Creek Healthcare LLC, Newtown Square, PA.*

Background: Non-steroidal MRA finerenone reduces CV risk and slows CKD progression in patients with CKD and T2D. Clinical guidelines recommend finerenone for patients with UACR > 30mg/g despite maximum tolerated RAS inhibitor (ACEi/ARB). However, it is reported that 30-50% of patients with CKD and T2D do not receive ACEi/ARBs, and about 30% of those discontinue within 6 months, contributing to the inertia for new disease-modifying therapies. To address this inertia, we assess the key characteristics of finerenone users in real-world setting with and without concomitant ACEi/ARB.

Methods: We conducted a retrospective study of finerenone users from July 2021 to December 2023 using the IQVIA Longitudinal Access and Adjudication Data. Adult patients with ≥ 12 months of continuous activity prior to their first filled finerenone claim date (index) were included. Patient demographics, comorbidities, and comedications stratified by ACEi/ARB status were described.

Results: The largest finerenone user cohort of 107,323 patients were included, among them 49,864 (46.5%) initiated finerenone in the absence of concomitant ACEi/ARB therapy. Patient age, gender, and key comorbidities were largely comparable, except for that finerenone users without ACEi/ARB had slightly higher prevalence of HF (22%) compared to those with ACEi/ARB (16%). Comedications use were 3-10% less common in the finerenone user without ACEi/ARB group, including SGLT2is and GLP1RAs. Interestingly, 5,077 (4.7%) finerenone users initiated SGLT2i after starting finerenone.

Conclusions: Our study shows that 46.5% patients initiated finerenone without concomitant ACEi/ARB. Finerenone use in the absence of ACEi/ARBs is common in routine clinical practice, suggesting that despite guideline recommendations, therapies are used in a variety of sequences and combinations to accommodate patient profiles. Future study should examine CV, kidney, and safety outcomes of finerenone users with and without ACEi/ARB.

Funding: Commercial Support - Bayer US LLC

Table. Demographics, comorbidities and comedication of finerenone initiators by ACEi/ARB status

	With ACEi/ARB (n= 57,459)	Without ACEi/ARB (n= 49,864)

Reduction in Urinary Albumin-to-Creatinine Ratio (UACR) in People with CKD and Type 2 Diabetes Initiating Finerenone: A Comedication Subgroup Analysis from the FOUNTAIN Platform

Csaba P. Kovesdy,[1] J. Bradley Layton,[4] Bishnu B. Thapa,[2] Gary C. Curhan,[2] Luis M. Rangel,[2] Alfredo E. Farjat,[3] Fangfang Liu,[3] Catherine B. Johannes,[5] David Vizcaya,[3] Nikolaus G. Oberprieler.[3] *[1]Division of Nephrology, University of Tennessee, Memphis, TN; [2]OM1, Inc., Boston, MA; [3]Bayer AG, Berlin, Germany; [4]RTI Health Solutions Research Triangle Park, Research Triangle Park, NC; [5]RTI Health Solutions Waltham, Waltham, MA.*

Background: Evidence from clinical trials demonstrates that finerenone reduces UACR and the risk of adverse cardiovascular and renal outcomes among people with CKD and T2D. Here we aim to describe the change in UACR across subgroups of users of other medications in people initiating finerenone in clinical practice in the United States.

Methods: This cohort study included people with prior diagnoses of CKD and T2D initiating finerenone between July 2021 and August 2023. Data were obtained from US electronic health records and insurance claims (OM1 Real-World Data Cloud™). Median UACR was determined at baseline, 4 and 12 months, and we described relative changes from baseline to 4 and 12 months, respectively, with 95% confidence intervals.

Results: Amongst 15,948 new users of finerenone, co-exposure to comedications was frequent: RASi, (49.4%), SGLT2i, (38.0%), GLP-1 RA, (25.6%). UACR measurements were available for 2,137 (13.4%) people at baseline, with a median UACR (Q1, Q3) of 211 mg/g (56, 750). From baseline the median UACR of the overall population decreased by 39.3% (50.8%-27.8%) and 41.2% (55.1%-27.3%) at 4 and 12 months, respectively. The observed reduction of median UACR from baseline to 4 and 12 months for comedication subgroups are depicted in the figure.

Conclusions: This analysis from the FOUNTAIN platform suggests that median UACR level decreases approximately 40% within 4 months after initiating finerenone in routine clinical practice and that this effect is sustained over 12 months. This reduction appears to be consistent irrespective of co-exposure to RASi, SGLT2i, or GLP-1 RA.

FR-PO326

Reduction in Urinary Albumin-to-Creatinine Ratio (UACR) in People with CKD and Type 2 Diabetes Initiating Finerenone: A CKD Stage Subgroup Analysis from the FOUNTAIN Platform

Csaba P. Kovesdy,[1] J. Bradley Layton,[4] Bishnu B. Thapa,[2] Luis M. Rangel,[2] Gary C. Curhan,[2] Alfredo E. Farjat,[3] Fangfang Liu,[3] Catherine B. Johannes,[5] David Vizcaya,[3] Nikolaus G. Oberprieler.[3] *[1]Division of Nephrology, University of Tennessee, Memphis, TN; [2]OM1, Inc., Boston, MA; [3]Bayer AG, Berlin, Germany; [4]RTI Health Solutions Research Triangle Park, Research Triangle Park, NC; [5]RTI Health Solutions Waltham, Waltham, MA.*

Background: Evidence from clinical trials shows that finerenone reduces UACR and the risk of adverse cardiovascular and renal outcomes among people with CKD and T2D. We aim to describe the change in UACR across subgroups of CKD and albuminuria stages in people initiating finerenone in clinical practice in the US.

Methods: This cohort study included people with prior diagnoses of CKD and T2D initiating finerenone between July 2021 and August of 2023. Data were obtained from US electronic health records and insurance claims (OM1 Real-World Data Cloud™). Median UACR was determined at baseline, 4 and 12 months, and we described relative changes from baseline to 4 and 12 months, respectively, with 95% CIs.

Results: Amongst 15,948 new users of finerenone, 3,604 (22.6%) had both a routine UACR and eGFR measurement in the 365 days before initiating finerenone. The proportion of people in the respective CKD stages and albuminuria categories is shown in Figure 1. For the UACR change analysis, routine UACR measurements were available for 2,137 (13.4%) people at baseline, with a median UACR (Q1, Q3) of 211 mg/g (56, 750). From baseline, UACR of the overall population decreased by 39.3% (50.8%-27.8%) and 41.2% (55.1%-27.3%) at 4 and 12 months, respectively. The observed reduction of UACR from baseline to 4 and 12 months by eGFR and albuminuria are depicted in the figure 2.

Conclusions: These results suggest that in clinical practice finerenone is used irrespective of CKD stage and albuminuria category. UACR decreases within 4 months after initiating finerenone and this effect is sustained over 12 months. UACR reduction appears to be consistent, albeit with some variation across CKD stages.

Funding: Commercial Support - Bayer AG

Figure 1: Proportion of people initiating finerenone across respective CKD stages and albuminuria categories

		A1 <30	A2 30-<300	A3 ≥300	Total
G1	≥ 90	90 (0.78%)	188 (5.22%)	166 (4.61%)	382 (10.60%)

Analysis of the Kidney-Brain Axis via the Fractional Amplitude of Low-Frequency Fluctuation in Patients with Diabetic Nephropathy

Jinlei Lv.[1,2] *[1]Renal Division, The First Affiliated Hospital of NanChang University, NanChang, China; [2]Institute of Molecular Immunology for Kidney Disease of NanChang University, NanChang, China.*

Background: Central neuropathies caused by diabetic nephropathy (DN) may share similar characteristics. The fractional amplitude of low-frequency fluctuation (fALFF) technique was applied to detect resting brain function alterations in patients with diabetic nephropathy, and their relationships with Brain clinical manifestations and the kidneys and are discussed. This study aimed to analyze the changes in brain function of patients with DN based on the kidney–brain axis.

Methods: We recruited patients with DN and healthy controls (n=23 per group). All participants underwent brain resting-state functional magnetic resonance imaging examination, and the fractional amplitude of low-frequency fluctuation (fALFF) values were calculated. The sensitivity, specificity, and Youden index were used to assess the authenticity of the diagnosis by constructing receiver operating characteristic curves. We analyzed the correlation between mean fALFF values and DN data using Pearson's correlation.

Results: Compared with control subjects, patients with DN had lower fALFF values in the right cingulum anterior segment (RCA) and left cingulum middle segment(LCM), and increased fALFF values in the right cingulum middle segment(RCM). Furthermore, the mean fALFF values in the RCA correlated with the estimated glomerular filtration rate in DN patients.

Conclusions: There were significant changes in brain function in DN patients compared to the control group. Changes in the central nervous system in patients with DN were mainly due to the dual negative effects of kidney function and diabetes mellitus. We found significant differences in fALFF values in the default mode network and visual cortex-related areas, which may be highly valuable for understanding the kidney–brain axis mechanisms of DN, as well as the associations between diabetic microvascular complications. .

Medication Adherence to SGLT2 Inhibitors vs. Glucagon-Like Peptide-1 (GLP-1) Receptor Agonists: A Meta-Analysis

Whitney Sussman, Erin R. Weeda, Conner E. Johnson. *University of South Carolina School of Medicine Greenville Campus, Greenville, SC.*

Background: Glycemic control with antihyperglycemics in individuals with diabetes has long been associated with reductions in the incidence of chronic kidney disease (CKD). Recent evidence has also demonstrated that sodium-glucose cotransporter-2 inhibitors (SGLT2Is) slow the progression of CKD. However, optimal medication adherence with antihyperglycemics is needed to achieve outcomes. We sought to perform a meta-analysis to compare medication adherence to SGLT2Is versus glucagon-like peptide-1 receptor agonists (GLP-1RAs).

Methods: A systematic search of Medline and Embase was conducted through October 2023. To meet inclusion criteria, articles had to be published in the full text form and directly compare medication adherence to SGLT2Is versus GLP-1RAs. Only studies evaluating real-world data and utilizing proportion of days covered (PDC) to measure adherence were included. Non-adherence, defined as the proportion of patients with a PDC<80%, was the primary outcome for this study. A subgroup analysis evaluating results among studies conducted in the US was performed.

Results: We identified 8 studies evaluating 205,103 patients for inclusion. Most studies derived data from the US (n= 5 studies). The proportion of patients with non-adherence (i.e., a PDC<80%) ranged from 27%-62% among those taking SGLT2Is and 26%-80% among those taking GLP1-RAs across included studies. Upon meta-analysis, SGLT2I use was associated with a numerically lower risk of non-adherence compared to GLP-1RA use but no statistical difference was observed (relative risk [RR] = 0.86; 95% confidence interval [CI] 0.72-1.02). In the analysis including only US studies, SGLT2I use was associated with a 23% lower risk of non-adherence compared to GLP-1RA use (RR = 0.77; 95% CI 0.72-0.82).

Conclusions: In this meta-analysis of 8 studies that included ~200,000 patients, SGLT2I use was associated with numerically higher medication adherence vs. GLP-1RA use; however, this difference was not statistically significant in the overall analysis. SGLT2I use was associated with significantly higher adherence when the analysis was limited to US studies. Adherence may differ across antihyperglycemic regimens and thus impact outcomes achieved with these regimens.

FR-PO329

Transitioning Adults with CKD and Type 2 Diabetes from a Dipeptidyl-Peptidase 4 Inhibitor to a SGLT2 Inhibitor: A Population Health Initiative

Stephanie M. Toth-Manikowski,[1,2] Abigail Forte,[1] Richmond Kwawu,[1] Morgan E. Urdaneta,[1] Howard Shaps.[1] *[1]Healthmap Solutions, Tampa, FL; [2]Alivio Medical Center, Chicago, IL.*

Background: Sodium-glucose cotransporter-2 inhibitors (SGLT2Is) are first-line therapy in adults with chronic kidney disease (CKD) and type 2 diabetes (T2DM). Compared to dipeptidyl peptidase-4 inhibitors (DPP-4Is), SGLT2Is superiorly slow CKD progression and may be cost neutral, depending on the payor or pharmacy benefit manager. This initiative evaluated the effect of using a population-level approach and provider outreach to improve SGLT2I prescribing patterns among diabetic adults with CKD already taking a DDP-4I.

Methods: Healthmap Solutions, a kidney population health company, used payor claims to identify adults with a "SGLT2I opportunity," defined as having Stage 3 or 4 CKD, T2DM, and a prescription fill for a DPP-4I but not a SGLT2I. Healthmap communicated this information to primary providers of these individuals. Outreach was deemed successful if individuals with a SGLT2I opportunity were reviewed with the provider or staff via 1) an in-person visit or 2) email/fax communication, per provider request. During a 3-month follow-up period, pharmacy claims were reviewed to identify the proportion of individuals with a new SGLT2I prescription fill. A proportional t-test was used to determine significant change.

Results: Of an initial pool of 53,255 adults, we identified 364 eligible for the initiative (**Figure**). Successful outreach occurred with providers of 273 (75%) individuals of which 12 (4%) started a SGLTI in the follow-up period. Mean time to initiation was 10 days after outreach. Among individuals whose providers were not successfully reached (n=91; 25%), SGLT2I was initiated in 1 (1%) individual (z-score 1.47; p=0.07). Member characteristics by outreach were similar (**Table**).

Conclusions: A population-level approach can be used to identify individuals with T2DM and CKD who may benefit from SGLT2I initiation. More studies are needed to understand how best to engage providers in optimizing pharmaceutical management of CKD in this population.

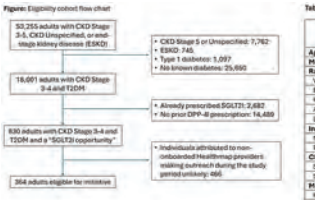

Figure: Eligibility cohort flow chart

Table: Characteristics of individuals with a SGLT2i opportunity, by provider outreach

	Successful Provider Outreach (n=273)	Unsuccessful Provider Outreach (n=91)
Age, years	76	80
Male sex, n (%)	124 (45)	35 (38)

Diabetes Mellitus Duration and Glycemic Control as Predictors of Diabetic Kidney Disease Progression: Evidence from 2019-2021 Korean National Health and Nutrition Examination Survey

Chang Seong Kim,[1,2] Sang Heon Suh,[1,2] Hong Sang Choi,[1,2] Eun Hui Bae,[1,2] Seong Kwon Ma,[1,2] Soo Wan Kim.[1,2] *[1]Chonnam National University Medical School, Gwangju, Republic of Korea; [2]Chonnam National University Hospital, Gwangju, Republic of Korea.*

Background: The natural progression of diabetic kidney disease (DKD) is characterized by persistent proteinuria followed by a declining glomerular filtration rate (GFR). However, limited epidemiological data exist regarding the duration of diabetes mellitus (DM) and the severity of hyperglycemia with the progression of chronic kidney disease. We investigated the relationship between DM duration and glycemic control and DKD in South Korea by using data from the 2019-2021 Korea National Health and Nutrition Examination Surveys (KNHANES).

Methods: Among the 18,511 participants aged ≥20 years who completed the KNHANES, we analyzed 2,303 patients with DM in this study. DKD was defined as an estimated GFR (eGFR) below 60 ml/min per 1.73 m^2 or urinary albumin-to-creatinine ratio (UACR) of ≥30 mg/g. DM duration and severity were classified into six categories: new onset, <5, 5-10, 10-15, 15-20, and ≥20 years; and hemoglobin A1C (HbA1c) <6.5, 6.5-7, 7-8, 8-9, 9-10 and ≥10 %.

Results: The estimated prevalence of DKD among patients with DM aged ≥20 years was 26.7%. As DM duration and severity increased, UACR also increased gradually in a dose-dependently. The risk of DKD was significantly increased after 10 to 15 years of DM duration or with an HbA1c of 8 to 9% or higher compared to patients with newly diagnosed DM or those with HgA1c <6.5%. Albuminuria (UACR ≥30 mg/g) developed with a shorter duration of DM and at lower HbA1c levels than eGFR decline (<60 ml/min per 1.73 m^2). In multivariable logistic regression models, compared with newly diagnosed patients and those with HgA1c <6.5%, the adjusted odds ratios for DKD were 3.77 (95% CI, 2.60–5.45) and 4.91 (95% CI, 2.80–8.63) in patients with DM duration ≥20 years and HbA1c ≥10%, respectively.

Conclusions: The overall prevalence of DKD among Korean adults is estimated to be three in ten patients with diabetes. Albuminuria was observed in early stages or in less severe hyperglycemic states. We should focus on surveilling kidney function in patients with a long duration of diabetes mellitus or uncontrolled hyperglycemia to prevent the progression of DKD.

FR-PO331

Exploring Patient and Physician Perspectives on the Use of SGLT2 Inhibitors for Adjunct-to-Insulin Treatment in Patients Living with Type 1 Diabetes

Vikas Sridhar,[1,2] Pamela L. Leblanc,[7] Chloe Parezanovic,[7] David Campbell,[7] Bruce A. Perkins,[8,2] Peter A. Senior,[5] Ronald J. Sigal,[7,9] Anita T. Layton,[3] Sean Barbour,[4] Adeera Levin,[4] Tony K. Lam,[1,2] Istvan Mucsi,[1,2] Remi Rabasa-Lhoret,[6] Leif Erik Lovblom,[1] Aleksandra Stanimirovic,[1,2] Valeria E. Rac,[10] David Cherney.[1,2] *[1]University Health Network, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]University of Waterloo, Waterloo, ON, Canada; [4]The University of British Columbia, Vancouver, BC, Canada; [5]University of Alberta, Edmonton, AB, Canada; [6]Universite de Montreal, Montreal, QC, Canada; [7]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [8]Sinai Health, Toronto, ON, Canada; [9]University of Calgary Department of Cardiac Sciences, Calgary, AB, Canada; [10]University of Toronto Dalla Lana School of Public Health, Toronto, ON, Canada.*

Background: Sodium-glucose co-transporter inhibitors (SGLTi) have proven cardiorenal benefits in type 2 diabetes and are promising as adjunct-to-insulin therapy in patients with type 1 diabetes (T1D). However, their regulatory approvals and clinical use in T1D have been limited owing to the augmented risk of diabetic ketoacidosis (DKA). Patient and physician input is critical in understanding how and when the risk-benefit ratio with these therapies is perceived to be favorable for users. This study aimed to explore how risks and benefits of SGLTi are considered by patients with T1D and physicians who treat the condition, particularly in the context of diabetic kidney disease (DKD).

Methods: We used a qualitative descriptive study design, in which we conducted semi-structured interviews with T1D patients (with and without DKD) and physicians who treat this population. Participants were sampled from multiple Canadian sites via online recruitment. Transcripts were analysed inductively using conventional qualitative content analysis to identify themes.

Results: We interviewed 22 patients with long-standing T1D including those with DKD, whose duration of living with diabetes ranged from 8-62 years. We also interviewed 7 physicians, including endocrinologists and nephrologists with a range of 4-20+ years in practice. Our analysis revealed four major themes: i) Strong motivation towards innovative treatments that can improve glycemia and yield cardiorenal benefits; ii) The need for a personalized approach when considering SGLTi initiation – as it was considered to be "not for everyone"; iii) Mitigating risk of DKA through proactive patient and prescriber-oriented strategies; and iv) Concern over absence of empirical evidence and regulatory approvals for this indication.

Conclusions: While there is great interest and motivation toward the use of SGLTi among patients with T1D (both with and without DKD), and the physicians who treat them, there is also clear understanding by all, of the need for personalization of therapy and support for robust evidence to inform care.

FR-PO332

The SGLT2 Inhibitor Visual Tour: Bringing Visuals to Increase Prescribing for CKD Plus Type 2 Diabetes Mellitus (T2DM)

Sruthi Sundaram, Siddartha Bhandary, Sana Waheed, Sarah A. Johnson.
Emory University Woodruff Health Sciences Center, Atlanta, GA.

Background: Chronic kidney disease (CKD) is growing in prevalence in the US, and the importance of controlling proteinuria in patients with CKD due to diabetes cannot be overstated. Multiple studies have shown that sodium glucose cotransporter 2 inhibitors (SGLT2i) reduce proteinuria and slow progression of proteinuric CKD. Here, we present a visual aid system that helped increase physician prescribing of SGLT2i to those with clinical indications.

Methods: This quality improvement initiative was conducted in an urban CKD specialty clinic in Atlanta, Georgia. Baseline data over the span of 6 weeks was collected to determine the utilization of SGLT2i in patients who met criteria, which included all patients with type 2 diabetes mellitus (T2DM) who had GFR ≥ 20 mL/min/1.73m^2 - ≤ 75 mL/min/1.73m^2 and urine microalbumin: creatinine ratio ≥ 200 mg/g. Then, a visual aid reminder for physicians that included a large informational poster listing the above criteria was posted in the main physician workroom, and an educational session on indications for prescribing SGLT2i was conducted for providers. Two weeks of post-intervention data was collected to assess utilization of SGLT2i.

Results: There were 360 patient encounters conducted by 16 physicians that were reviewed in the pre-intervention phase. Out of these, 111 patients met the criteria for prescribing SGLT2i, of which 63% were prescribed or already taking an SGLT2i. Common reasons for deferring SGLT2i were the history of UTI or yeast infections. In the post-intervention phase, 83 encounters were reviewed, of which 41 patients met indications for SGLT2i and 73% of those were prescribed an SGLT2i.

Conclusions: Despite numerous studies showing the efficacy of SGLT2i in reducing proteinuria, more than one third of the patients in our CKD clinic were not on one despite meeting the indications. This highlights the importance of both provider education and an augmenting visual aid system to positively impact prescribing practices for SGLT2i among eligible CKD patients. These interventions demonstrated preliminary efficacy in our clinic. Continual reinforcement and patient-directed educational resources may also further the efficacy of these measures. Additional interventions might be necessary to achieve enhancements in adhering to guidelines for prescribing and optimizing care for this vulnerable patient group.

FR-PO333

Use of SGLT2 Inhibitors and Glucagon-Like Peptide 1 (GLP-1) Receptor Agonists in Australian Primary Care Patients with Type 2 Diabetes Mellitus (T2DM) Stratified by CKD Status

Hannah Wallace,[1,2] James Wick,[3] Daniel B. Ketema,[1] Brendon L. Neuen,[1] Meg Jardine,[5] Jialing Lin,[4] Craig L. Nelson,[2] Sallie Pearson,[4] David Peiris,[1] Mark Woodward,[1] Paul E. Ronksley,[3] Martin P. Gallagher,[1,4] Sradha S. Kotwal,[1] Min Jun.[1,4] CKD-CARE. *[1]The George Institute for Global Health, Sydney, NSW, Australia; [2]The University of Melbourne, Melbourne, VIC, Australia; [3]University of Calgary, Calgary, AB, Canada; [4]University of New South Wales, Sydney, NSW, Australia; [5]NHMRC Clinical Trials Centre, Camperdown, NSW, Australia.*

Background: SGLT2i and GLP1-RA reduce the risk of kidney failure and cardiovascular events in patients with T2DM and CKD. We aim to understand their use in Australian primary care patients with T2DM by CKD status.

Methods: We identified adults (≥18 years) with T2DM who attended 1 of 392 general practices participating in a national quality improvement program (MedicineInsight) and had ≥1 eGFR measure between 2011-2019. CKD was defined according to KHA-CARI/KDIGO guidelines. Outcomes assessed were ≥1 prescription for SGLT2i (if eGFR ≥20ml/min/1.73m^2) or GLP1-RA (if eGFR ≥15ml/min/1.73m^2) during 2020-2021, by CKD status. Two secondary analyses were conducted; SGLT2i use in patients with CKD with UACR ≥22.6mg/mmol, and GLP1-RA use in those meeting CKD outcome trial enrolment criteria (NCT03819153; see figure for eGFR/UACR definitions).

Results: 114,499 adults with T2DM were included (113,563 and 113,940 with eGFR ≥20 and ≥15mL/min/1.73m^2, respectively), with a median age of 68, of whom 45% were female, and 32% had CKD. SGLT2i were prescribed 13% in patients without CKD, 14% with CKD and 17% with CKD and UACR ≥22.6mg/mmol (p values vs. no CKD: <0.05). GLP1-RA were prescribed in 8% of patients without CKD, 10% with CKD and 11% meeting CKD outcome trial inclusion criteria (p values vs. no CKD: <0.05).

Conclusions: In this large, contemporary primary care cohort of patients with T2DM, SGLT2i and GLP1-RA prescription rates were higher in CKD than those without, but relatively low across both groups. Implementation strategies to improve medication uptake, with a focus on those who are likely to derive greatest benefit are needed.

Proteinuria Burden and Clinical Outcomes in Patients with Diabetes: A Nationwide Cohort Study

Junseok Jeon, Kyungho Lee, Jung eun Lee, Wooseong Huh, Hye Ryoun Jang.
Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.

Background: Proteinuria is a well-known risk factor for ESKD, cardiovascular disease (CVD), and all-cause mortality in patients with diabetes mellitus (DM). However, clinical implications of fluctuating proteinuria are poorly understood. We aimed to investigate the association between proteinuria burden outcomes using the Korean National Health Insurance Service data.

Methods: This retrospective cohort study included all patients with DM who participated in national health screening between 2015 and 2016 and three health screenings before. Proteinuria burden was defined as the cumulative number of positive dipstick urine protein at each health screening. Outcomes are end-stage kidney disease (ESKD), cardiovascular disease (CVD), and all-cause mortality. Hazard ratio (HR) with 95% confidence interval (CI) were analyzed using Cox proportional hazards regression analysis.

Results: Among total 1,262,194 patients, 1,089,833 (86.3%), 118,835 (9.4%), 31,468 (2.5%), 14,827 (1.2%), and 7,231 (0.6%) had proteinuria burden 0, 1, 2, 3, and 4, respectively. There were dose-dependent association between the proteinuria burden and risk of ESKD, CVD, and all-cause mortality (Compared to proteinuria burden 0, adjusted HR [95% CI] for proteinuria burden 1, 2, 3, and 4, respectively: for ESKD, 3.723 [3.421–3.051], 9.565 [8.810–10.384], 15.079 [13.879–16.383], and 20.009 [13.238–21.845]; for CVD, 1.257 [1.214–1.301], 1.578 [1.491–1.671], 1.969 [1.832–2.117], and 2.221 [2.023–2.437]; for all-cause mortality: 1.364 [1.320–1.410], 1.653 [1.565–1.745], 2.069 [1.932–2.216], and 2.206 [2.016–2.414]). Early positive proteinuria was worse outcomes than late positive proteinuria within same proteinuria burden.

Conclusions: Our study demonstrated that proteinuria burden was dose-dependently associated with ESKD, CVD, and all-cause mortality in patients with DM. Patients with DM who have even a single positive dipstick test require active management.

FR-PO335

Influence of Sex and Other Risk Factors, Including Kidney Function, on Myocardial Microvascular Function in Individuals with Type 2 Diabetes Free of Overt Cardiovascular Disease: The DiaHeart Study

Anne-Cathrine Skriver-Møller,[1] Philip Hasbak,[3] Ida Kirstine B. Rasmussen,[1] Martin B. Blond,[1] Victor Wasehuus,[1] Mats H. Lassen,[2] Morten Lindhardt,[4] Allan Kofoed-Enevoldsen,[6] Urd Lynge Kielgast,[5] Emilie Zobel,[1] Lene Holmvang,[3] Peter Rossing,[1] Tor Biering-Sørensen,[1] Rasmus S. Ripa,[3] Andreas Kjaer,[3] Tine Hansen.[1] *[1]Steno Diabetes Center Copenhagen, Herlev, Denmark; [2]Gentofte Hospital, Hellerup, Denmark; [3]Rigshospitalet, Kobenhavn, Denmark; [4]Zealand University Hospital Holbaek, Holbaek, Denmark; [5]Sjaellands Universitetshospital Koge, Koge, Denmark; [6]Nykobing F Sygehus, Nykobing, Denmark.*

Background: Type 2 diabetes (T2D) is a stronger risk factor for cardiovascular disease (CVD) in women than in men and increased with progressive CKD. This might in part be due to women being more susceptible to developing myocardial microvascular dysfunction when compared with men with a similar risk profile. The myocardial flow reserve (MFR) represents the function of the epicardial arteries and the microvasculature and can be measured with a cardiac (Rb^{82})-PET/CT. We investigated the presence of sex dependent differential effects of CV risk factors, including kidney function, on MFR in people with T2D, free of overt CVD.

Methods: Cross-sectional analysis of a prospective study including 901 T2D individuals. All underwent a cardiac ^{82}Rb-PET/CT for estimation of MFR. Associations between MFR and other risk factors were assessed using linear regression. Differential effects of risk factors by sex were assessed by including an interaction term between one risk factor and sex at a time.

Results: Mean (SD) age was 65 (9) years and 266 (30%) were women. Mean eGFR was 82.1 (21.8) ml/min/1.73^2 and median (IQR) UACR 7.7 (4.9-19.9) mg/g. MFR was lower in women than in men (2.44 (0.61) vs. 2.59 (0.77), p=0.003). MFR was lower with increasing degree of albuminuria; 2.61 (0.73) for normal, 2.35 (0.67) for moderately and 2.11 (0.72) for severely increased albuminuria, p<0.001. In a model including age, sex, diabetes duration, BMI, smoking, systolic blood pressure, logUACR, eGFR, HbA1c, and LDL-cholesterol MFR was negatively associated with female sex β -0.19 (95%CI -0.29 to -0.09, p<0.001), age -0.19 (-0.25 to -0.13, p<0.001), and logUACR -0.09 (-0.13 to -0.05, p<0.001). There were no statistically significant interactions with sex for any of the risk factors.

Conclusions: In individuals with T2D free of overt CVD, MFR was lower in women than in men and lower with higher level of albuminuria. Despite lower MFR in women, we found no indications of sex dependent differential effects of any risk factors including UACR and eGFR on MFR.

FR-PO336

Referral to Nephrologists Mitigates the Progression of Kidney Dysfunction in Patients with Type 2 Diabetes: A Causal Inference Study

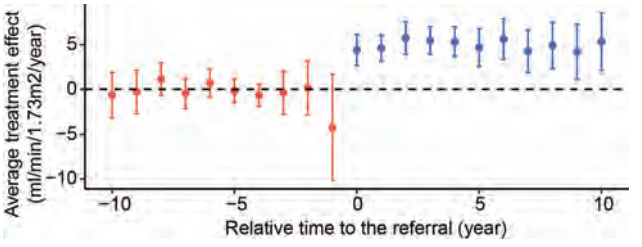
Donghwan Yun, Dong Ki Kim, Yon Su Kim, Seung Seok Han. *Seoul National University College of Medicine, Jongno-gu, Seoul, Republic of Korea.*

Background: Chronic kidney disease is a major complication of type 2 diabetes, necessitating effective management to mitigate kidney progression. This study evaluates the effect of referrals from endocrinologists to nephrologists on kidney function in diabetic patients through causal inference analysis.

Methods: This study included patients with type 2 diabetes who initially visited the diabetes clinic between July 2004 and November 2023. Patients were either referred to a nephrology clinic or continued under the care of endocrinologists. The slope of eGFR per year was calculated based on the annual median difference in yearly eGFRs, and cases were censored when the values dropped below 10ml/min/1.73m^2. We applied a difference-in-differences model to this time-series dataset with an inverse propensity weighting estimator to evaluate the effect of referral to nephrologists.

Results: Among 30,160 patients who visited the diabetes clinic, 3,885 patients (13%) were referred to nephrologists (referral group), while others continued under the care of endocrinologists alone (no referral group). The referral group, compared to the no referral group, had low baseline eGFR (73 [IQR, 59–87] vs 88 [76–98] ml/min/1.73m^2) and high uACR (38 [12–199] vs 14 [8–39] mg/g). The averaged treatment effect of referral to nephrologists displayed an improvement in the eGFR slope, with an increase of 5.8 (95% CI, 4.8–6.8) ml/min/1.73m^2/year. The referral group exhibited higher usage of antihypertensive agents and hypoglycemic agents other than metformin (e.g., DPP-4i and SGLT2i) than the no referral group. Kidney biopsies were more frequently performed in the referral group than in the no referral group (3.8% vs 0.05%), and 50% of patients who received biopsies were diagnosed with other diseases, with or without diabetic nephropathy.

Conclusions: Referral to nephrologists reduces the progression of kidney dysfunction in patients with type 2 diabetes, supporting the need for appropriate referral to nephrologists in type 2 diabetic patients.



The event study plot of the nephrology referral on average treatment effect.

FR-PO337

Improving Conformity to Diabetic Kidney Disease Clinical Guidelines

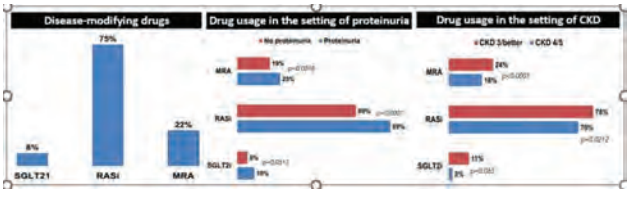
Nicole Piero,[1] Prakash S. Gudsoorkar,[1] Karthikeyan Meganathan,[1] Paul Lewis,[1] Charuhas V. Thakar.[2] *[1]University of Cincinnati, Cincinnati, OH; [2]Queen's University Belfast, Belfast, United Kingdom.*

Background: In the US, 31.5 million adults have chronic kidney disease (CKD), primarily due to type 2 diabetes (DM). KDIGO updated the clinical practice guidelines (CPG) for DM and CKD management, using research on sodium glucose cotransport 2 inhibitor (SGLT2i), glucagon like peptide1 receptor agonist (GLP1RA), and mineralocorticoid receptor antagonist (MRA), with angiotensin converting enzyme inhibitors and angiotensin receptor blocker (RASi).

Methods: We present a two-phase project. Phase 1, an observational cohort on adults with type 2 DM and CKD stages 1-5, excluding those with a prior solid organ transplant or dialysis, at a tertiary academic center renal clinic in 2019. It assessed CKD stage, proteinuria, and conformity to RASi, SGLT2i, and MRA treatments. Chi-square was used to compare groups. Phase 2 analyzed data from Aug to Oct 2022 of renal fellow clinics, using the same criteria as Phase 1. An educational session was conducted on the CPG with an algorithm for optimal prescribing CPG recommended medications. Effectiveness was assessed using pre and post questionnaires assessing knowledge of CPG and Likert scale ratings (1-5) to evaluate prescribing intent.

Results: Phase 1 (fig) identified 1330 adults with CKD and DM seen in a nephrology clinic: 75% were on RASi [89% with proteinuria, 69% without (p<0.0001)], 8% on SGLT2i [10% with proteinuria, 6% without (p=0.018)], and 22% on MRA [25% with proteinuria, 19% without (p=0.0515)]. Medication usage was lower in CKD 4/5 compared to stages 1-3 [SGLT2i 2% vs 11% (p<0.0001); RASi 70% vs 78% (p=0.0212); MRA 18% vs 24% (p=0.065)]. In Phase 2 baseline and prescription characteristics in fellow clinics was similar to phase 1. Phase 2 found that post-education answers on knowledge questions improved from 2 to 3/5. Likert scale (rating 1-5) for self-rated knowledge increased from 3.4 to 4.4. Intent to prescribe ratings rose for SGLT2i from 3.6 to 4.4, GLP1RA from 2.4 to 3.9. Confidence in the impact on guideline adherence improved from 3.6 to 4.2.

Conclusions: Our study demonstrated an implementation gap and an intervention to address it. Continued monitoring and larger scale implementation can improve conformity and patient outcomes.



FR-PO338

Primary Cause of Kidney Failure in 40 Countries in Apollo Dial DB

Yue Jiao,[1] Melanie Wolf,[2] Kaitlyn R. Croft,[2] Paola Carioni,[3] Mitesh Soni,[1] Anke Winter,[2] Luca Neri,[3] Sheetal Chaudhuri,[1] Kanti Singh,[1] Milind Nikam,[4] Stefano Stuard,[2] Adrian M. Guinsburg,[5] Dinesh K. Chatoth,[1] Jeffrey L. Hymes,[1] Kirill Koulechov,[2] Len A. Usvyat,[1] John W. Larkin,[1] Franklin W. Maddux.[6] *[1]Fresenius Medical Care, Waltham, MA; [2]Fresenius Medical Care, Bad Homburg, Germany; [3]Fresenius Medical Care, Crema, Italy; [4]Fresenius Medical Care, Singapore, Singapore; [5]Fresenius Medical Care, Buenos Aires, Argentina; [6]Fresenius Medical Care AG, Bad Homburg, Germany*.

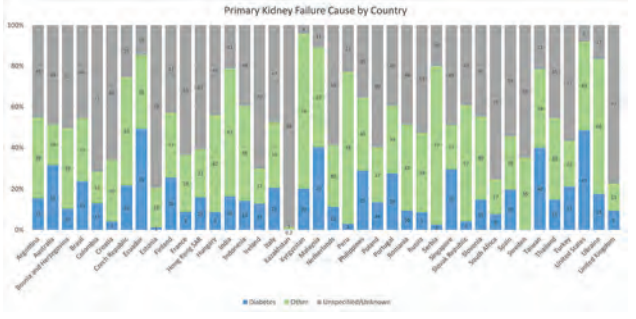
Background: Diabetes is a main cause of kidney failure, but the variability in rates of disease etiology is unknown. We used a global dialysis database, Apollo Dial DB, to assess the primary cause of kidney failure in 40 countries.

Methods: Apollo Dial DB is an anonymized database constructed from real-world data at a kidney care network (Fresenius Medical Care, Bad Homburg, DE). Longitudinal data is captured on an observation-level (each treatment, lab, value). First version has >360 variables (demographics, dialysis, labs, medications, surveys, & outcomes) from 01Jan2018-31Mar2021. Data anonymization was performed in alignment with recommendations from a re-identification risk determination (Privacy Analytics, Ontario, CA). We analyzed the primary cause of kidney failure defined as due to diabetes, other causes, or unspecified/unknown causes.

Results: In 543,169 adults (age ≥18 years) treated by dialysis, 455,769 (80.6%) had a known primary kidney failure cause. Globally, kidney failure due to diabetes was 39.8%, other causes were 40.8%, and unspecified/unknown cause was 19.4%). Cause of primary kidney failure varied dramatically by country ranging for: diabetes from <1% to 49%, other causes from 1% to 77%, and unspecified/unknown cause from 4% to 98% (**Figure 1**).

Conclusions: Leading primary cause of kidney failure is diabetes in four countries, other causes in 13 countries, and unspecified/unknown in 23 countries. Diabetic nephropathy is meaningful in select countries, but considering a global landscape, needs to be determined. The importance of other causes of kidney disease, such as hypertensive and glomerular disorders (including those in diabetes), need to be considered at a local level. The cause of kidney failure appears undetermined in many parts of the world. Findings bring to light the potential role of underdiagnosis, as well as diseases of unknown origin.

Funding: Commercial Support - Fresenius Medical Care



FR-PO339

Regional Differences in Kidney Replacement Therapy in Diabetic Kidney Disease: Apollo Dial DB

Yue Jiao,[1] Melanie Wolf,[2] Kaitlyn R. Croft,[2] Paola Carioni,[3] Mitesh Soni,[1] Anke Winter,[2] Luca Neri,[3] Sheetal Chaudhuri,[1] Kanti Singh,[1] Milind Nikam,[5] Stefano Stuard,[2] Adrian M. Guinsburg,[4] Dinesh K. Chatoth,[1] Jeffrey L. Hymes,[1] Kirill Koulechov,[2] Len A. Usvyat,[1] John W. Larkin,[1] Franklin W. Maddux.[6] *[1]Fresenius Medical Care, Waltham, MA; [2]Fresenius Medical Care, Bad Homburg, Germany; [3]Fresenius Medical Care, Crema, Italy; [4]Fresenius Medical Care, Buenos Aires, Argentina; [5]Fresenius Medical Care, Singapore, Singapore; [6]Fresenius Medical Care AG, Bad Homburg, Germany*.

Background: It is unknown if kidney replacement therapy (KRT) types vary in diabetic kidney disease (DKD). We assessed KRT patterns by primary kidney failure etiology in a global database (Apollo Dial DB) representing care in six continents.

Methods: Apollo Dial DB contains longitudinal observation-level data (each treatment, lab, value) from 40 countries in a kidney care network (Fresenius Medical Care, Bad Homburg, DE). Data anonymization was performed in alignment with recommendations from a re-identification risk determination (Privacy Analytics, Ontario, CA). Dataset has >360 variables (demographics, dialysis, diagnoses, labs, medications, surveys, & outcomes) from 01Jan2018-31Mar2021. Analysis assessed KRT rates after dialysis initiation stratified by region. Modality was defined as use of hemodialysis (HD) only, peritoneal dialysis (PD) ever, or transplant.

Results: Among 543,169 adults (age ≥18 years) in 40 countries, 455,769 had a known kidney failure etiology (diabetes=39.8%, other=40.8%, unspecified=19.4%). Overall, 84.8% used HD only, 11.0% used PD, and 4.1% received a transplant for KRT after dialysis initiation. KRT used in DKD showed 40.7% used HD only, 39.1% used PD, and 21.9% received a transplant. PD and transplant rates differed across regions, with lower PD and transplant rates in DKD (**Figure 1**). Regional differences in unspecified etiology were also present.

Conclusions: KRT patterns in DKD may differ from other etiologies. Worldwide, transplant occurred half as often in DKD; greater regional variations existed. Regionally, PD was less frequently used in DKD, specifically in Northern and Latin America, South Africa, and Eastern Europe. Kidney failure etiology is largely unspecified in select regions. Opportunities may exist in expanding KRT options in DKD.

FR-PO340

Supporting Self-Management of Kidney Health in Diabetic Patients via a Novel Digital Health Intervention: Protocol for a Prospective Interventional Study

Jingyi Wu,[1] Hong'an Pan,[1] Qing Li,[1] Jinwei Wang,[2] Pengfei Li,[1,4] Luxia Zhang.[3,2] *[1]Advanced Institute of Information Technology, Peking University, Hangzhou, China; [2]Renal Division, Department of Medicine, Peking University First Hospital; Peking University Institute of Nephrology, Beijing, China; [3]National Institute of Health Data Science, Peking University, Beijing, China; [4]Institute of Medical Technology, Peking University, Beijing, China*.

Background: Diabetes has become the leading cause of chronic kidney disease in China. Preventing and managing diabetic kidney disease (DKD) is crucial for diabetics, but it often goes undetected due to a lack of early symptoms and low awareness. Urine albumin-to-creatinine ratio (UACR) is an effective early indicator of kidney damage, and we have developed a digital intervention, the UACR home-testing kit (UTK), for self-monitoring of kidney health based on computer-vision algorithms. UTK has been validated to be highly accurate and sensitive in albuminuria screening, and can be a promising new strategy for cost-effective management of kidney health. We proposed a prospective interventional study to evaluate the efficacy of the UTK-based digital intervention in diabetics.

Methods: This study has been conducted since August, 2023 and will recruit over 2,000 diabetics from Yinzhou district, Ningbo city in China for the intervention group. The sample size is calculated based on the assumed odds ratio of 1.3 for the treatment rate of DKD for a matched case-control design. The intervention group will receive a routine UACR home-monitoring using UTK for one year at a recommended frequency by KDIGO, and will complete baseline and final questionnaires and estimated glomerular filtration rate (eGFR) examinations. The control group will be extracted from all 90,940 adult diabetics recorded in Yinzhou Regional Health Information System with repeated eGFR measurements during the study period. The primary outcome is the treatment rate of DKD, and the secondary outcome is DKD progression measured as the incidence rate of a 10% eGFR decline after one-year follow up.

Results: The study is ongoing and has enrolled 4,554 eligible diabetic patients (mean age 68.5±9.2 years, 42.4% males) for the intervention group, with a median follow-up duration of 5.8 (4.0-7.1) months. The baseline eGFR was 86.2±23.1 mL/min per 1.73m^2, and among 445 participants with eGFR < 60 mL/min per 1.73m^2, only 17 (3.8%) of them have received treatment of DKD.

Conclusions: This study will provide quantitative evidence for promising benefits of this user-friendly and cost-effective digital intervention for diabetics self-managing kidney health, which could potentially alleviate the heavy burden on healthcare systems for kidney disease in China.

Intraindividual Difference between Creatinine- and Cystatin C-Based GFR and Association with Cardiovascular Events

Maria Tydén,[1] Gorav Batra,[1,2] Bengt C. Fellstrom,[1] Claes O. Held,[1,2] Johan Lindbäck,[2] Inga Soveri,[1] Ralph A. Stewart,[3] Maria K. Svensson,[1,2] Harvey D. White,[3] Lars Wallentin.[1,2] *[1]Uppsala Universitet Institutionen for Medicinska Vetenskape, Uppsala, Sweden; [2]Uppsala Clinical Research Center, Uppsala, Sweden; [3]Green Lane Cardiovascular Service, Auckland City Hospital and Auckland University, Auckland, New Zealand.*

Background: Association between $eGFR_{ratio}$ ($eGFR_{cys}$/$eGFR_{cr}$) and outcomes, was studied in patients with chronic coronary syndrome.

Methods: A post-hoc analysis of 14,513 patients from the STABILITY trial investigated the association between baseline $eGFR_{ratio}$ and major adverse cardiac events (MACE) and death using Cox-regression. Analyses were adjusted for $eGFR_{cr}$, $eGFR_{cys}$, or both. Discriminative ability was assessed using the C-index, and the incremental value was measured using the fraction of new information (FNI). 2021 CKD-EPI eGFR equations were applied.

Results: The mean age was 65 years, 82% were male. Mean $eGFR_{cys}$ was 77 (61-94) and $eGFR_{cr}$ 79 (65-91) mL/min/1.73 m^2. During median follow-up of 3.7 years, there were 1449 MACE and 1063 deaths. Table 1 presents a comparison of $eGFR_{ratio}$ of 0.7 with 1.0. After adjustment for $eGFR_{cys}$, the $eGFR_{ratio}$ contributed marginally when assessed by FNI. Figure 1 illustrates the adjusted one-year-risk for MACE and death as a function of $eGFR_{ratio}$ for different eGFR levels, indicating a weaker association with the ratio when adjusted for $eGFR_{cys}$.

Conclusions: In patients with chronic coronary syndrome, lower $eGFR_{ratio}$ is associated with higher risk of adverse outcomes. After adjustment for $eGFR_{cys}$ the added value of $eGFR_{ratio}$ is limited.

The Difference between Cystatin C- and Creatinine-Based Estimated Glomerular Filtration Rate and Risk of Peripheral Artery Disease

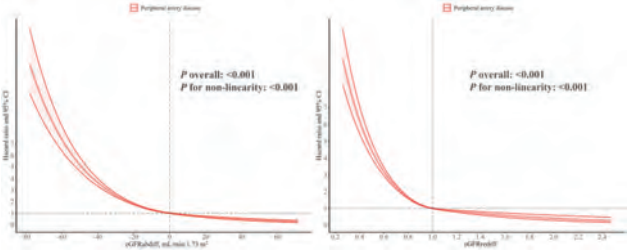
Daijun He,[1] Chenglong Li,[2] Bixia Gao,[1] Chao Yang,[1] Jinwei Wang,[1] Ming-Hui Zhao,[1] Luxia Zhang.[1,2] *[1]Peking University First Hospital Department of Nephrology, Beijing, China; [2]Peking University Health Science Center, Beijing, China.*

Background: The difference between cystatin C-based and creatinine-based estimated glomerular filtration rate (eGFRdiff) has been suggested to reflect factors that are associated with cardiovascular and microvascular risk, independent of kidney function. However, the association between eGFRdiff and risk of peripheral artery disease (PAD) has not been extensively evaluated.

Methods: This prospective cohort study included 466,245 participants with concurrent measured serum creatinine and cystatin C and free of PAD at baseline (2006 to 2010) from the UK Biobank. eGFRdiff was calculated using both absolute difference (eGFRabdiff) and the ratio (eGFRrediff) between cystatin C- and creatinine-based eGFR. Incidence of PAD was ascertained using electronic health records. Cox proportional hazards regression models were used to evaluate the associations of eGFRdiff with PAD. The relative importance of eGFRdiff in predicting PAD was evaluated. We also calculated the area under the curve (AUC), net reclassification improvement (NRI), and integrated discrimination improvement (IDI) to examine the additive value of eGFRdiff in predicting PAD.

Results: During a median follow-up of 13.8 years, PAD developed in 7,210 participants. Each standard deviation increment of eGFRabdiff was associated with a 33% lower risk of PAD. For each 10% increment in eGFRrediff, the hazard ratio (95% confidence interval) was 0.78 (0.77, 0.80) for PAD. eGFRrediff and eGFRabdiff ranked 6th and 11th in the relative importance of PAD prediction, surpassing eGFRcr and some traditional risk factors. Adding eGFRabdiff or eGFRrediff into the established model could improve the performance of PAD prediction (ΔAUC 0.013, NRI 0.325, IDI 0.003 for adding eGFRabdiff; ΔAUC 0.012, NRI 0.287, IDI 0.003 for adding eGFRrediff).

Conclusions: eGFRdiff was associated with risk of incident PAD and had additional value in predicting PAD. These findings may have implications for the management of patients at risk of incident PAD.



Restricted cubic spline models assessing exposure-response associations between eGFRdiff with PAD.

Advanced CKD and Vascular Disease: Characterization of Cardiovascular Phenotype

Agustin Noboa, Matías Pécora, Cecilia Baccino, Oscar A. Noboa, Jose Boggia. *Universidad de la Republica Uruguay, Montevideo, Uruguay.*

Background: Cardiovascular disease is the leading cause of morbidity and mortality in patients with advanced chronic kidney disease (ACKD). In individuals with chronic kidney disease (CKD), the number of cardiovascular events and mortality increases as glomerular filtration decreases. Non-invasive techniques such as carotid intima-media thickness determination, could allow early detection of vascular damage. Objectives: Determine and compare phenotypes of vascular damage in patients with ACKD and undergoing renal replacement therapy (RRT) with dialysis techniques.

Methods: Cross-sectional study of individuals with ACKD and those undergoing RRT. Patients were recruited from the ACKD outpatient clinic, as well as those undergoing hemodialysis and peritoneal dialysis. Carotid intima-media thickness (IMT) and the presence of atherosclerotic plaques were evaluated.

Results: 37 individuals were evaluated with ultrasound, and 56.7% had carotid atherosclerotic plaques. Age greater or equal to 65 years and being a former smoker were associated ($p < 0.005$) with the presence of atherosclerotic plaques. When compared with population studies of healthy individuals, our cohort had increased IMT in 45.9% or 37.8% of cases, according to Spanish and Argentinean studies, respectively. 75% showed some alteration, either increased IMT or atherosclerotic plaques. No significant differences were found between individuals with ACKD without RRT and those with ACKD on RRT.

Conclusions: Most of patients with ACKD, regardless of the initiation of RRT, present objectively measurable vascular damage. Age equal to or greater than 65 and being a former smoker were associated with the presence of carotid atherosclerotic plaques. In a high percentage of patients, significant vascular damage precedes the initiation of RRT, which should reinforce the prevention of vascular damage in earlier stages of CKD.

Risk Factors for Total Stroke in Patients with CKD: The Chronic Renal Insufficiency Cohort Study

Jing Chen,[1] Myra A. Kleinpeter,[1] Alex R. Zhang,[2] Cong Zhao,[1] Siyi Geng,[1] Flor Alvarado,[1] Arnold B. Alper,[1] Rhea Bhargava,[1] Ivo Lukitsch,[3] Allison N. Marshall,[1] L. Lee Hamm,[1] Jiang He.[1] *[1]Tulane University, New Orleans, LA; [2]Boston University, Boston, MA; [3]Ochsner Health, New Orleans, LA.*

Background: The incidence of stroke is much higher in CKD patients than in the general population. In addition, CKD is associated with a worse outcome after stroke. We studied the risk factors for stroke in a cohort of CKD patients.

Methods: 3,547 participants in the Chronic Renal Insufficiency Cohort (CRIC) Study were included in this analysis after excluding 392 participants with stroke at the baseline visit. Stroke events were reported by participants and adjudicated by 2 vascular neurologists. Cox proportional hazards models with backward selection were used to investigate the association of risk factors with incident stroke. All risk factors, including traditional cardiovascular risk factors, eGFR, urine albumin, inflammatory biomarkers, mineral bone disorder biomarkers, fibrotic biomarkers, and NT-proBNP, were included in the model.

Results: The average baseline age was 57.3 years and 54.7% were women. Over a mean follow-up time of 10.7 years, 167 incident stroke events occurred. The age-adjusted incidence of total stroke was 4.4 per 1,000 person-years: 4.9 per 1,000 person-years in men, and 3.9 per 1,000 person-years in women. The significant multivariable-adjusted hazard ratios (HR) and 95% CI for stroke associated with various risk factors are presented in the **Table**.

Conclusions: This study indicates that age, black race, smoking, albuminuria, and mineral bone disorder are independently associated with an increased risk of stroke. Future studies are warranted to assess the benefits of specific interventions to reduce the risk of stroke in individuals with CKD.

FR-PO345

Glomerular Filtration Rate by Differing Measures and Prediction Utility of Peripheral Artery Disease

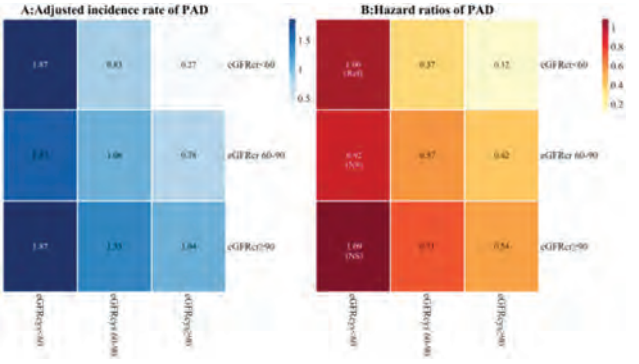
Chenglong Li,[1] Daijun He,[2] Bixia Gao,[2] Chao Yang,[2] Jinwei Wang,[2] Ming-Hui Zhao,[2] Luxia Zhang.[2,1] *[1]Peking University Health Science Center, Beijing, China; [2]Peking University First Hospital Department of Nephrology, Beijing, China.*

Background: The utility of creatinine-based estimate glomerular filtration rate (eGFRcr) for predicting peripheral artery disease (PAD) has been evaluated. However, some guides recommended incorporating cystatin C, either alone or in combination with creatinine, into eGFR formulae, which perform better than eGFRcr in estimating GFR and in predicting the risk of cardiovascular disease and mortality. Therefore, we aimed to determine whether incorporating cystatin C into eGFR formulae would improve risk stratification and prediction for PAD.

Methods: We included 466,245 participants free of PAD at baseline (2006 to 2010) from the UK Biobank. The 2012 Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) cystatin C equation and 2021 race-free CKD-EPI equations were used to calculate eGFRcys, eGFRcr, and eGFRcr-cys, respectively. Incidence of PAD was ascertained using electronic health records. Cox proportional hazards regression models were used to evaluate the associations of eGFRs with PAD. The relative importance of differentiating eGFRs in predicting PAD was evaluated. We also calculated net reclassification improvement and integrated discrimination improvement to examine the additive value of eGFRs in predicting PAD.

Results: During a median follow-up of 13.8 years, a total of 7,210 PAD cases were recorded. eGFRcys was most evidently associated with PAD and the most important predictor for PAD. Regardless of the eGFRcr, the adjusted incidence rate (aIR) and the hazard ratios (HRs) of PAD were low when eGFRcys≥60 mL/min/1.73 m^2. Conversely, with eGFRcys<60 mL/min/1.73 m^2, the aIR and the HRs of PAD have no difference between eGFRcr groups. eGFRcys presented the most significantly additive value in predicting PAD, while no significant utility was identified for eGFRcr.

Conclusions: eGFRcys appears to be more sensitive and specific for PAD risk. These findings underscore the importance of incorporating cystatin C into eGFR formulae to improve risk stratification and prediction for PAD.



FR-PO346

Serum C-reactive Protein and Risk of Major Kidney Outcomes in Adults with Atherosclerotic Cardiovascular Disease Managed in Routine Care

Katherine R. Tuttle,[6] Faizan Mazhar,[1] Edouard Fu,[1,2] Anne-Laure Faucon,[1,3] Paul Hjemdahl,[1] Jimmi Mathisen,[4] Iram Faqir Muhammad,[4] Oscar Plunde,[4] Vlado Perkovic,[5] Juan J. Carrero.[1,7] *[1]Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden; [2]Department of Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands; [3]Department of Clinical Epidemiology, Paris-Saclay University, Paris, France; [4]Novo Nordisk A/S, Søborg, Denmark; [5]University of New South Wales, Sydney, NSW, Australia; [6]School of Medicine, University of Washington and Providence Inland Northwest Health, Spokane, WA; [7]Danderyd Hospital, Danderyd, Sweden.*

Background: Inflammasome pathway activation is involved in atherosclerotic cardiovascular disease (ASCVD) and chronic kidney disease (CKD), but it is unclear if systemic inflammation, measured by serum C-reactive protein (CRP), predicts major kidney outcomes in patients with ASCVD.

Methods: This was an observational study of adults with ASCVD undergoing routine CRP testing in Stockholm, Sweden. Baseline CRP was defined as the mean of serum CRP test levels over a 3-month window, excluding tests associated with illness or medications. Baseline CRP was analyzed via cause-specific Cox regression for subsequent risk of acute kidney injury (AKI; diagnosis code or KDIGO criteria) or CKD progression (>30% eGFR decline or kidney failure).

Results: A total of 83,928 adults with ASCVD were included (54% men, mean age 71 years, 59% with CRP ≥2 mg/L). A progressive increase in CRP levels was observed across lower eGFR categories. Over median follow-up of 6.4 years (IQR 3.1–9.8), 8371 CKD progression events, 10,757 AKI events, and 24,954 deaths were recorded. Compared with CRP <1 mg/L, higher CRP levels were associated with increased risks of CKD progression and AKI (Figure). Associations were consistent across subgroups defined by age, albuminuria, selected comorbidities, and use of lipid-lowering therapy. Results were robust when excluding extreme CRP values or early events, and did not appear to be explained by differences in eGFR testing rates.

Conclusions: In a population of adults with ASCVD, systemic inflammation was associated with higher risk of major kidney outcomes.

Funding: Commercial Support - This study was funded by Novo Nordisk A/S.

Figure. Cumulative incidence, incidence rates, absolute risks, and hazard ratios for CKD progression (A) and AKI (B), by baseline CRP category

A) CKD progression

	IR/1000 PY (95% CI)	5-year AR, % (95% CI)	HR (95% CI)[a]
Per SD higher CRP	16.5 (16.2–16.9)	–	1.07 (1.05–1.09)
By CRP category			
<1 mg/L	11.7 (11.1–12.3)	5.2 (4.9–5.6)	Reference
1–3 mg/L	15.7 (15.1–16.3)	7.6 (7.2–7.9)	1.16 (1.09–1.23)
>3–10 mg/L	19.1 (18.4–19.8)	9.8 (9.4–10.0)	1.24 (1.17–1.32)
>10–≤20 mg/L	23.6 (22.3–25.0)	14.0 (13.0–14.0)	1.35 (1.25–1.46)

B) AKI

	IR/1000 PY (95% CI)	5-year AR, % (95% CI)	HR (95% CI)[a]
Per SD higher CRP	21.7 (21.3–22.1)	–	1.07 (1.06–1.09)
By CRP category			
<1 mg/L	14.0 (13.4–14.7)	6.8 (6.5–7.2)	Reference
1–3 mg/L	20.3 (19.6–21.0)	10.0 (9.7–11.0)	1.18 (1.12–1.25)
>3–10 mg/L	26.3 (25.5–27.1)	14.0 (13.0–14.0)	1.34 (1.27–1.42)
>10–≤20 mg/L	31.8 (30.3–33.4)	18.0 (17.0–19.0)	1.37 (1.28–1.47)

[a]Adjusted for age, sex, time since ASCVD, eGFR, albuminuria, comorbidities (angina, atrial fibrillation, cancer, COPD, diabetes, heart failure, hypertension, MI, peripheral vascular disease, rheumatoid diseases, and stroke/TIA), procedures (coronary artery bypass grafting and percutaneous coronary intervention), and ongoing medications (ACEi/ARBs, MRAs, β-blockers, SGLT-2is, diuretics, calcium channel blockers, digoxin, lipid-lowering treatments, antiplatelets, NSAIDs).
ACEi, angiotensin-converting enzyme inhibitor; AKI, acute kidney injury; AR, absolute risk; ARB, angiotensin receptor blocker; ASCVD, atherosclerotic cardiovascular disease; CI, confidence interval; CKD, chronic kidney disease; COPD, chronic obstructive pulmonary disease; CRP, C-reactive protein; eGFR, estimated glomerular filtration rate; HR, hazard ratio; IR, incidence rate; MI, myocardial infarction; MRA, mineralocorticoid receptor antagonist; NSAID, nonsteroidal anti-inflammatory drug; PY, person years; SD, standard deviation; SGLT-2i, sodium-glucose cotransporter-2 inhibitor; TIA, transient ischemic attack.

10-Year Cardiovascular Risk Score for Coronary Artery Calcification Progression Depending on Prevalent Coronary Artery Calcification in East Asian Patients with CKD: Findings from KNOW-CKD

Byounghwi Ko, Jong Hyun Jhee, Dong Hoon Kang, Daseul Huh, Ga Young Heo, Cheol Ho Park, Hyung Woo Kim, Jung Tak Park, Seung Hyeok Han, Shin-Wook Kang, Tae-Hyun Yoo. *Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea.*

Background: Chronic kidney disease (CKD) is a well-known risk factor for atherosclerotic cardiovascular disease (ASCVD). However, no established prediction model exists for the progression of coronary artery calcification (CAC) in CKD patients. We investigated the association between CAC progression and 10-year ASCVD risk prediction models in CKD patients, particularly in relation to baseline CAC.

Methods: From a nationwide, prospective cohort of Korean patients with CKD, 1,177 were available for CAC progression data analysis. Of these, 809 patients, who were without prevalent ASCVD and eligible for the Pooled Cohort Equation, were included in the study. The main predictor was the 10-year cardiovascular risk score from the Pooled Cohort Equation. Prevalent CAC was defined using computed tomography, with an Agatston score greater than zero. CAC progression was defined as an increase in Agatston score of more than 15% per year at the 4-year follow-up in patients with baseline CAC, while any increase in CAC was defined as progression for those without baseline CAC. For both groups, coronary stenting during the 4-year follow-up period was considered as CAC progression.

Results: Prevalent CAC was observed in 394 (48.7%) patients. CAC progression was observed in 104 (25.1%) patients without baseline CAC, and 259 (65.7%) in those with baseline CAC. Compared with 1st quartile, the odds ratios (95% confidence intervals) for CAC progression of 2nd, 3rd, and 4th quartiles were 2.25 (1.48-3.44), 3.29 (2.16-5.01), and 4.27 (2.80-6.52) in unadjusted model, respectively. However, this graded association was disappeared in those with baseline CAC. A consistent association was observed in complete case analysis and different cutoffs for CAC progression (>30%/yr).

Conclusions: A higher score on the 10-year risk prediction model is associated with CAC progression in CKD patients without baseline CAC, whereas this association is less pronounced in those with prevalent CAC.

FR-PO348

Trends in the Burden of Ischemic Heart Disease among Patients with CKD in Alberta

Matthew Cooper,[1] Feng Ye,[3] Anukul Ghimire,[2] Gavin Oudit,[3] Aminu K. Bello.[3] *[1]University of Toronto, Toronto, ON, Canada; [2]University of Calgary, Calgary, AB, Canada; [3]University of Alberta, Edmonton, AB, Canada.*

Background: Ischemic heart disease (IHD) is a leading cause of mortality in patients with chronic kidney disease (CKD). The last decades have witnessed significant improvements in both IHD and CKD care. Information on the burden of IHD in the Canadian CKD population is limited.

Methods: Using the Alberta Kidney Disease Network database, we created a cohort with CKD (aged 18 years and above) who received a diagnosis of IHD between 2003 and 2019. CKD was defined based on standard methods. Case definitions for IHD, STEMI, and NSTEMI were determined using ICD-10 codes and obtained from hospital discharge records, physician billing claims, and ambulatory care classification system (ACCS) files. The date of diagnosis of IHD was the date of inpatient hospital separation or the physician visit, whichever came first. Univariate least squares regression analysis and the negative binomial model were used to evaluate the trend in the adjusted prevalence and incident rates for the conditions of interest. The rates were standardized by age group and sex based on the 2011 Canadian population. STATA v18 was used in the analysis and $p < 0.05$ as the threshold for statistical significance.

Results: The age and sex standardized prevalence of IHD increased across all stages of kidney function. Compared to patients with an eGFR ≥ 60 ml/min, the rate of change in the prevalence of IHD was higher in patients with an eGFR 45-59 ml/min, with an annual rate of change of 0.86 (95% CI: 0.66 - 1.05; test for interaction $p < 0.001$). The incidence of STEMI decreased across all eGFRs from 2003 to 2019 except for patients with an eGFR 45-59 ml/min/1.73m2 (incidence risk ratio (IRR) of 0.93 (CI 95% 0.87, 1.00). The incidence of NSTEMI decreased across all eGFRs from 2003 to 2019 except for patients with an eGFR <15 ml/min/1.73m2 (IRR: 0.96; CI 95%: 0.91, 1.02).

Conclusions: Between 2003 and 2019, the prevalence of IHD increased across all stages of CKD, and there was a concomitant decreasing trend in the incidence of the acute forms of IHD (STEMI and NSTEMI). This may reflect increasing longevity of patients with IHD and CKD in Alberta between 2003 and 2019, due to improvements in their care. Future studies should evaluate the quality of care received by patients with IHD and CKD and relationships to adverse clinical outcomes including hospitalizations, recurrent events and mortality.

FR-PO349

Accuracy of Identification of Cardiovascular Events with International Classification of Diseases (ICD) Diagnosis Codes vs. Physician Adjudication in CKD and ESKD

Anna M. Zemke, Leila R. Zelnick, Ian De Boer, Nisha Bansal. *University of Washington, Seattle, WA.*

Background: Cardiovascular disease (CVD) in chronic kidney disease (CKD) is an important end-point for research studies. Adjudication by a central committee is considered the most rigorous approach of ascertaining CVD outcomes, but it is resource intensive. We aimed to compare the accuracy of unadjudicated ICD codes vs. physician adjudication for hospitalizations for heart failure (HF), stroke, atrial fibrillation (AF), and myocardial infarction (MI) in those with CKD and ESKD.

Methods: Using the Chronic Renal Insufficiency Cohort (CRIC), we evaluated 31,521 hospitalization events. We determined the positive predictive value (PPV), negative predictive value, sensitivity and specificity of primary code position as well as when using all diagnosis codes from the hospitalization. We calculated hazard ratios for the CVD outcomes determined by each type of ascertainment (ICD-10 codes vs. physician adjudicated) for known CVD risk factors.

Results: In those with CKD, comparing primary ICD diagnosis codes with the adjudicated outcomes, we found the PPV to be 82.5% for HF, 80.8% for ischemic stroke, and 87.6% for AF (Table 1). The PPVs were generally similar for participants who were and those who were not on dialysis. MI events by ICD code had much lower PPV rates, 38.4% in non-dialysis dependent CKD, 47.3% in dialysis dependent, and 62.5% in transplant participants. HR of outcomes for those with CVD risk factors diabetes, body mass index, hypertension, age, and eGFR were similar whether ascertained through ICD codes or physician adjudication.

Conclusions: When using ICD codes to determine CVD outcomes in CKD, PPV was near 80% for HF, AF, and ischemic stroke, and was similar amongst those with ESKD. These data may inform the approach to CVD outcome ascertainment in future studies of kidney disease patients.

Table 1. Accuracy of ICD-10 Code Based versus Physician Adjudicated CVD Outcomes in CKD

Event Type	PPV	NPV	Sensitivity	Specificity
CHF				
All Events	80.9%	94.1%	39.7%	99.0%
Non-ESRD events	82.5%	93.9%	42.0%	99.0%
Dialysis events	75.4%	94.2%	33.2%	99.0%
Transplant events	88.9%	98.9%	53.3%	99.8%
CVA				
All Events	83.3%	99.2%	34.6%	99.9%
Non-ESRD events	80.8%	99.0%	33.8%	99.9%
Dialysis events	93.8%	99.5%	39.0%	100.0%
Transplant events	NA	99.7%	0%	100%
MI				
All Events	41.2%	98.6%	45.2%	98.4%
Non-ESRD events	38.4%	98.5%	42.6%	98.2%
Dialysis events	47.3%	98.8%	50.9%	98.6%
Transplant events	62.5%	99.5%	62.5%	99.5%
AF				
All Events	88.8%	92.7%	12.5%	99.9%
Non-ESRD events	87.6%	92.5%	12.2%	99.8%
Dialysis events	90.8%	92.9%	13.0%	99.9%
Transplant events	100%	97.5%	23.8%	100%

FR-PO350

Application of the AHA/ACC/HFSA Heart Failure Staging Guidelines in CKD

Anna M. Zemke,[1] Leila R. Zelnick,[1] Joachim H. Ix,[2] Alan S. Go,[3] Edward D. Siew,[4] Nisha Bansal.[1] *[1]University of Washington, Seattle, WA; [2]University of California San Diego, La Jolla, CA; [3]The Permanente Medical Group Inc, Oakland, CA; [4]Vanderbilt University Medical Center, Nashville, TN.*

Background: The 2013 American Heart Association (AHA)/ American College of Cardiology (ACC)/Heart Failure Society of America (HFSA) Guidelines for the Management of Heart Failure (HF) proposed a staging system to diagnose HF and its severity, ranging from A to D. In 2022, these guidelines were updated to include the use of cardiac biomarkers. The effect of this HF staging system in CKD is not well established.

Methods: 2415 participants from the Chronic Renal Insufficiency Cohort were classified into HF stages using 2013 and 2022 guidelines. Echocardiographic changes and cardiac biomarkers (troponin T ≥10 ng/L in females, ≥15 ng/L in males or pro-brain natriuretic peptide ≥125 pg/mL) were utilized in staging. Incidence rates and 95% CIs for HF hospitalizations and all-cause death during follow-up were calculated.

Results: Only 4.8% of CKD participants were classified as "healthy" using either staging guideline. The inclusion of cardiac biomarkers in the 2022 guideline reclassified 55% (n=469) of 2013 guideline Stage A participants to Stage B. Participants with lower eGFRs were more likely to be reclassified (Table 1). Using 2022 guidelines, the incidence of HF hospitalization in Stage B differed when based on biomarkers (1.7 per 100 person-yrs, 95% CI 1.3-2.1) compared to echocardiographic abnormalities (2.9 per 100 person-yrs, 95% CI 2.6- 3.3) whereas death rates were similar between these groups (Figure 1).

Conclusions: Among large CKD cohort, only 20% of participants met the criteria for "healthy" or "at risk" for HF. There was high reclassification of CKD participants into more advanced HF stages with the addition of cardiac biomarkers. Differing HF hospitalization incidence rates between those classified based on biomarkers alone compared to echocardiographic abnormalities suggest reclassification may not reflect true HF status. CKD-specific thresholds for cardiac biomarkers may be useful to improve accuracy of HF staging in CKD.

Table 1: Reclassification Between 2013 and 2022 American Heart Association/ American College of Cardiology/Heart Failure Society of America HF Staging Guidelines by eGFR Category.

eGFR, mL/min/1.73m²	2013 Stage A	2022 Stage A	2013 Stage B	2022 Stage B			% of Stage A using 2013 Criteria that moved to Stage B using the 2022 Criteria
				All (N= 1505)	B_Biomarkers (n=469)	B_Echocardiogram (N=651)	
≥60	262 (31%)	372 (46%)	215 (31%)	305 (20%)	95 (20%)	215 (21%)	80/262 =34.4%

FR-PO351

CVD Risk Estimates for the US CKD Population with the American Heart Association PREVENT Equation

Carl P. Walther, Lucile Parker Gregg, Sankar D. Navaneethan. *Baylor College of Medicine, Houston, TX.*

Background: Cardiovascular disease (CVD) risk equations can be useful for assessing and mitigating risk in people with CKD. The 2023 AHA PREVENT equations are the first major equations to incorporate the kidney metrics eGFR and UACR. We studied change in 10-year CVD risk prediction estimates in the US CKD population comparing the PREVENT equation to the previous major equation (ASCVD Risk Estim. Plus 2018).

Methods: We calculated US CKD population estimates of 10-year CVD risk using the most recent data (2017-2020) from NHANES, a probability sampled study of the US community population. CVD risk was calculated using the PREVENT equation (with eGFR and UACR) and the prior major equation (ASCVD Risk Estim. Plus) for the relevant CKD population (age 30-79 years without clinical CVD). CKD was identified using eGFR-Cr and UACR and categorized by G stage. Appropriate survey methods were used to obtain cross-sectional population estimates.

Results: We estimated 21.5 (95%CI 18.6-24.4) million individuals with CKD age 30-79 years without known CVD. Mean±SD age was 58±15 years and 58% were female. CKD stage distribution was: G1/2 A2/3 65%, G3a 26%, 5.8% G3b, 1.8% G4, and 1.2% G5. Median (IQR) 10-year risk in the CKD population using PREVENT is 13% (4.6-21%), substantially higher than the estimates using the prior equation: 9.2% (2.8-22%). More severe CKD stages had larger increase in risk with the new equation (Panel A). Using 10-year CVD risk thresholds (low<5%, borderline 5-7.4%, intermediate 7.5-19.9%, high ≥20%), 30% (6.5 million individuals) changed risk threshold group, with 25% moving to a higher risk category and 5.7% to a lower risk category (Panel B).

Conclusions: Nearly 1 in 3 individuals with CKD in the US are estimated to have substantial change in predicted CVD risk with the PREVENT equation incorporating eGFR and UACR, with most moving to a higher risk category. This highlights the public health importance of kidney measurements for risk prognostication and mitigation.

Mild Thiazide-Induced Hyponatremia in Hypertensive Patients Is Associated with Increased Mortality Risk

Steven Achinger,[1,2] Juan Carlos Ayus,[3] Ambuj Kumar,[1] Athanasios Tsalatsanis.[1] *[1]University of South Florida Morsani College of Medicine, Tampa, FL; [2]Watson Clinic LLP, Lakeland, FL; [3]University of California Irvine, Irvine, CA.*

Background: There are over 42 million patients with hypertension taking thiazides in the United States. The goal of this study was to determine if outpatients who start a thiazide diuretic and develop hyponatremia are at increased risk of mortality compared with those who do not develop hyponatremia after starting a thiazide.

Methods: We performed a propensity score matched, retrospective cohort study where all patients aged 40 to 90 years between January 1st, 2010 and December 31st, 2021 with essential hypertension and started on a thiazide diuretic were included. The patients with a a serum sodium ≤ 135 mmol/L after initiation of thiazide formed the hyponatremia group and patients with a serum sodium 136-144 mmol/L after initiation of thiazide formed the control group. Data were obtained from the TriNetX research network comprising de-identified electronic medical records of approximately 93 million patients from 76 healthcare organizations worldwide. The primary outcome was one year mortality. The difference in mortality across compared groups was assessed using the log rank test and summarized as hazard ratio along with 95% confidence intervals (CI).

Results: Overall, 256,523 patients met inclusion criteria and after propensity score matching 22,052 patients remained in the hyponatremia and control groups **(Table 1)**. Patients in the hyponatremia cohort had a significantly higher hazard of mortality than patients in control, HR 1.955 (95% CI:1.716, 2.277, p<0.001) **(Figure 1)**.

Conclusions: Patients who develop hyponatremia (serum sodium ≤ 135 mmol/L) following initiation of a thiazide diuretic have a higher risk of mortality compared with those who do not develop hyponatremia following initiation of a thiazide diuretic.

Consequences of Not Maximizing Renin-Angiotensin System Inhibition Due to Hyperkalemia

Cecelia L. Hickey,[1] John M. Dopp,[1] Jodi Meyer,[3] Laura J. Maursetter.[2,3]
[1]University of Wisconsin-Madison School of Pharmacy, Madison, WI; [2]University of Wisconsin-Madison School of Medicine and Public Health, Madison, WI; [3]William S. Middleton VA Hospital, Madison, WI.

Background: Until March, 2024, potassium binders within the Veterans Health Administration were non-formulary with criteria for use that limited prescribing to persistent moderate-severe hyperkalemia (at least two K values ≥ 5.5 mEq/L). Thus, patients with mild hyperkalemia were at risk of repeated hyperkalemia and dose-reductions or discontinuation of angiotensin converting enzyme inhibitors (ACE-I) and angiotensin receptor blockers (ARB). We sought to determine if patients with persistent mild hyperkalemia experienced subsequent hyperkalemia and if ACE-I/ARB use was affected in adult Veteran's Affairs (VA) patients with difficult-to-control hypertension and chronic kidney disease (CKD).

Methods: Retrospective chart review was performed for patients in a VA renal hypertension clinic who had at least two potassium values ≥ 5.1 but less than 5.5 mEq/L (mild hyperkalemia) documented in the VA electronic health record. Serum creatinine, proteinuria, and ACE-I/ARB use were recorded from the medical record at the time of the second potassium value between 5.1 and 5.49 mEq/L and at the patient's most recent follow-up visit. Longitudinal hyperkalemia events (K ≥ 5.1 mEq/L) were recorded for all patients.

Results: In patients with persistent mild hyperkalemia (n=54), serum creatinine increased from 2.15±0.1 to 3.01±0.28 mg/dL (mean±SEM) and 2 (1-3) (median and interquartile range) hyperkalemia episodes occurred in the time between their second high K value and their most recent follow-up (median 5 years). At time of their second high K value, 89% of patients were taking an ACE-I/ARB. At the most recent follow-up, 48% of patients taking ACE-I/ARB had their ACE-I/ARB dose reduced or discontinued. In addition, urinary protein to creatinine ratio increased by 546±474 mg/g.

Conclusions: Adult VA patients with CKD, hypertension, and mild hyperkalemia are at risk of subsequent hyperkalemia episodes, worsening of kidney function, and worsening proteinuria. Importantly, approximately half of patients with mild hyperkalemia had de-escalation of renoprotective medications. With the removal of VA formulary restrictions for potassium binders, patients with mild hyperkalemia should be candidates for initiation of potassium binder therapy and optimization of ACE-I/ARB therapy to delay progression of kidney disease.

Volume Status by Bioimpedance and Blood Pressure in CKD

Katherine S. Ravi,[1,2] Enass Sayed,[1,2] Brendon L. Neuen,[4] Glenn M. Chertow,[3] Finnian R. McCausland.[1,2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Stanford University School of Medicine, Stanford, CA; [4]The George Institute for Global Health, University of New South Wales, Sydney, NSW, Australia.*

Background: Hypertension is common among patients with chronic kidney disease (CKD) and is a risk factor for cardiovascular events and mortality. Though hypervolemia is thought to be a major contributor to hypertension, the association of objective biomarkers of volume status with blood pressure (BP) among patients with CKD is not well described.

Methods: Using data from the Chronic Renal Insufficiency Cohort (CRIC; n=5,384), we fit unadjusted and adjusted linear regression models and restricted cubic splines to examine the association of vector length (a bioimpedance proxy of volume status) with systolic and diastolic BP (SBP and DBP). We also assessed how the change in vector length over two years was associated with changes in SBP and DBP. Models adjusted for demographics, clinical history, BP medications, and laboratory covariates including log transformed 24-hour urine protein and urine sodium excretion.

Results: Mean age of participants was 59 ±11 years; 44% were female; 43% were Black; and mean SBP and eGFR were 129 ±21 mmHg and 48 ±16 mL/min/1.73m^2, respectively. The adjusted association of vector length with SBP was non-linear (Figure 1). The lowest quartile of vector length (a proxy for relative hypervolemia) was associated with a 3.0 mmHg (95%CI 0.9, 5.1) higher SBP, compared with the third quartile. Similarly, over two years, the lowest quartile of change in vector length (a proxy for more severe hypervolemia) was associated with the largest increase in SBP (3.8 mmHg; 95%CI 1.1, 6.4), compared with the third quartile. No association of vector length with DBP was observed.

Conclusions: Shorter vector length, a bioimpedance proxy of hypervolemia, is independently associated with higher SBP. Whether bioimpedance-guided volume management could improve BP control among patients with CKD requires further exploration.

FR-PO355

Association of an ATTR Cardiomyopathy Risk Score with Cardiac and Kidney Outcomes among Patients with CKD: Insights from CRIC

Catarina Vale,[1,4] Muthiah Vaduganathan,[2,3] Brendon L. Neuen,[5,6] João Sérgio Neves,[1,4] Finnian R. McCausland.[2,3] *[1]Universidade do Porto Faculdade de Medicina, Porto, Portugal; [2]Brigham and Women's Hospital, Boston, MA; [3]Harvard Medical School, Boston, MA; [4]Hospital de Sao Joao, Porto, Portugal; [5]University of New South Wales, Sydney, NSW, Australia; [6]Royal North Shore Hospital, St Leonards, NSW, Australia.*

Background: Transthyretin amyloid cardiomyopathy (ATTR-CM) is thought to be an underdiagnosed cause of heart failure, especially in HF with preserved ejection fraction (HFpEF). A clinical risk-score to predict ATTR-CM has been validated in HFpEF, but its utility among patients with CKD is unclear.

Methods: We applied a 6-variable risk score (age, sex, hypertension, ejection fraction, relative wall thickness, posterior wall thickness; range -1 to +10) to participants of CRIC with available 1-year echocardiographic data (n=2,718) and calculated the prevalence of a high-risk score (≥6 points). Using Cox regression models, landmarked at 1-year, we explored the adjusted association of a high vs. low-risk score with atrial fibrillation (AF), HF, stroke, myocardial infarction (MI), a kidney composite (kidney failure, ≥50% decline in eGFR, eGFR≤15 mL/min/1.73m^2), and all-cause death.

Results: The median score was 4 [2, 5]; 539 (20%) had a high-risk score for ATTR-CM, which was associated with a higher adjusted risk of AF (hazard ratio [HR] 1.87, 95% confidence interval [CI] 1.48, 2.35), HF (HR 1.63, 95%CI 1.27, 2.08), MI (HR 1.82, 95%CI 1.33, 2.49) and all-cause mortality (HR 1.60, 95%CI 1.37, 1.87). There was a trend towards a higher risk of stroke with high (vs low) risk score (HR 1.47, 95%CI 0.94, 2.29) but no association with kidney composite (HR 1.01, 95%CI 0.82, 1.23). Using a restricted cubic spline, a monotonic association of higher risk score with death was evident (Figure 1).

Conclusions: 1 in 5 individuals in CRIC appear to have a high predicted risk for ATTR-CM. A high-risk score was prognostic for adverse cardiac outcomes and death, but not for a kidney composite outcome. Future studies to examine the true prevalence and to determine the optimal screening pathways for ATTR-CM among patients with CKD are warranted.

Cystatin C-based eGFR Predicts Patient-Reported Outcomes in Heart Failure

Blake N. Lackey,[1] Bethany A. Roehm,[1] Justin Grodin,[1] Susan Hedayati.[2] *[1]The University of Texas Southwestern Medical Center, Dallas, TX; [2]Stony Brook University Hospital, Stony Brook, NY.*

Background: Lower eGFR is linked to worse outcomes in people with heart failure (HF) with reduced (HFrEF) and preserved (HFpEF) ejection fractions. Data on patient-reported outcomes (PROs) in HF and eGFR using Cr (GFRcr) are conflicted and scarce using cystatin C (GFRCys).

Methods: We tested the association between baseline eGFR and the Kansas City Cardiomyopathy Questionnaire (KCCQ), Minnesota Living with Heart Failure Questionnaire (MLHFQ), and 6 min walk test (6MWT) at baseline and 6 mo in 769 participants of EXACT-HF (n=253), RELAX (n=216), and FIGHT (n=300) trials. eGFR measures used were GFRcr, GFRcys, a weighted average of both (GFRcr-cys), and GFRcys/GFRcr<0.7, a predictor of mortality in HFrEF and CKD. Linear regression was used, adjusting for age, sex, diabetes, BMI, NYHA class, NT-proBNP, and treatment arm.

Results: Mean (SD) age was 63 (13). 28% were female, 59% had NYHA class 3-4 symptoms, 72% HFrEF, and 20% GFRcys/GFRcr <0.7. Mean GFRcr was 58 (23), GFRcys 54 (25), and GFRcr-cys 57 (24) ml/min/1.73m2. All GFR measures were associated with 6MWT at baseline. Only Cys-derived measures associated with 6MWT at 6 mo in multivariable analyses. GFRcys/GFRcr <0.7 predicted a drop in 6MWT distance by nearly 35 m at 6 mo. All cys-based eGFR associated with KCCQ at 6 mo but not with MLHFQ in multivariable analyses (Table).

Conclusions: GFR estimates using cystatin C but not Cr predicted worse performance on 6MWT and KCCQ in people in HF. No GFR measures predicted MLHFQ score, indicative of MLHFQ's known lower sensitivity to change. These findings offer new insights on the adverse effects of declining kidney function on HF symptoms. More research is needed on the validity of GFRcys as a measure of frailty in HF.

Heart Failure with Preserved Ejection Fraction (HFpEF), Heart Failure with Reduced Ejection Fraction (HFrEF), and the Risk of ESKD in Type 2 Diabetes (T2D)

David Kim,[1] Amara Sarwal,[1,2] Guo Wei,[1,2] Robert E. Boucher,[1,2] Ravinder Singh,[1,2] Sydney E. Hartsell,[1,2] Stavros Drakos,[1,2] Srinivasan Beddhu.[1,2] *[1]University of Utah Health, Salt Lake City, UT; [2]VA Salt Lake City Health Care System, Salt Lake City, UT.*

Background: We examined the hypothesis that kidney blood flow is more compromised in HFrEF compared to HFpEF and, as a result, there is a higher risk of ESKD in HFrEF compared to HFpEF in T2D.

Methods: Using the VA informatics and Computing Infrastructure (VINCI), in a cohort of 2.79 million veterans with a diagnosis of T2D from 1/1/2010 to 12/31/2018, we identified a cohort of 316,762 veterans with first time incident HF hospitalizations. Using a validated algorithm and natural language processing, ejection faction (EF) data was obtained. HF was classified as HFpEF (EF >50), HFrEF (EF <40), HFmrEF (EF 40 to 50) and no EF (no data). Index date was HF hospitalization date. Follow-up was until 12/31/2021. ESKD data was obtained by linkage to US Renal Data System data. In multivariate Cox regression models, we related HF subtypes to the risk of ESKD.

Results: Mean age 72 ± 11 years, 98% male, 17% Black, Mean eGFR 64 ± 29. There were 15,126 ESKD events/1,222,038 years of follow-up. HFrEF had the lowest incidence and HFpEF the highest incidence of ESKD (Figure). These associations were attenuated in multivariate cox regression models (Table).

Conclusions: The risk of developing ESKD is higher in the HFpEF compared to HFrEF but adjusting for baseline covariates attenuated this association. Thus, both HFpEF and HFrEF have similar risk for ESKD.

FR-PO358

Association of Kidney Function and Volume Overload with Incident Pulmonary Hypertension in the Chronic Renal Insufficiency Cohort (CRIC) Study

Marcelle Tuttle,[1,2] Hocine Tighiouart,[1,2] Tatsufumi Oka,[3] Wendy I. McCallum,[1] Nicholas S. Hill,[1] Steven Kawut,[4] Mark J. Sarnak.[1] *[1]Tufts Medical Center, Boston, MA; [2]Tufts Clinical and Translational Science Institute, Boston, MA; [3]Osaka Daigaku, Suita, Japan; [4]University of Pennsylvania, Philadelphia, PA.*

Background: Pulmonary hypertension (PH) is common in patients with chronic kidney disease (CKD), but very few studies have examined risk factors for its development. Tricuspid regurgitation velocity (TRV) measured on echocardiogram (TTE) estimates the pressure difference between the right ventricle and the right atrium and correlates with pulmonary artery systolic pressure.

Methods: We included patients without prevalent PH with 2 or more TRV measurements in the CRIC Study. PH was defined as a TRV >= 2.8 m/s. Incident PH was defined as PH on the final TTE. Estimated glomerular filtration rate (eGFR), 24-hour urine albumin, and brain natriuretic peptide (BNP) were considered as the main independent variables. eGFR was calculated using the CKD-EPI 2021 equation. Multivariable logistic regression adjusting for demographics, comorbid conditions, and medications was used to evaluate the relation of kidney function and BNP to incident PH. In further exploratory models, eGFR models additionally adjusted for BNP and vice versa.

Results: The study sample included 848 subjects. At baseline mean eGFR was 45.3 ml/min/1.73m^2 (SD 14.7), median 24-hour urine albumin was 24.8 mg (IQR 7.3, 142.8), and median BNP was 36.6 pg/ml (IQR 15.8, 64.4). 103 (10.4%) subjects developed PH over a mean (SD) of 3.8 (1.3 years). Lower baseline eGFR was associated with higher odds of developing PH, but the effect was slightly attenuated after adjustment for BNP (Table). BNP was associated with higher odds of incident PH regardless of adjustment. There was no association between albuminuria and incident PH.

Conclusions: Higher baseline BNP and lower eGFR are associated with incident PH in CKD. Volume appears to be a key risk factor for the development of PH in patients with CKD.

Percutaneous Coronary Intervention with a Drug-Eluting Stent Is Associated with Better Survival than Coronary Artery Bypass Grafting in Patients on Peritoneal Dialysis in Taiwan

Szu-Yu Pan,[1] Naichi Teng,[2] Likwang Chen.[2] *[1]National Taiwan University Hospital, Taipei, Taiwan; [2]National Health Research Institutes, Zhunan, Taiwan.*

Background: The optimal revascularization strategy for coronary artery disease in patients under peritoneal dialysis (PD) is unclear. Recently, we reported that percutaneous coronary intervention (PCI) with a drug-eluting stent (DES) is associated with better survival than coronary artery bypass grafting (CABG) in patients under either hemodialysis or PD. We aim to perform a dedicated subgroup analysis to study the comparative effectiveness in patients under PD.

Methods: This retrospective population-based cohort study included PD patients hospitalized for either CABG or PCI with a DES between January 1, 2009, and December 31, 2015, identified in the Taiwan National Health Insurance Research Database. Inverse probability of treatment weighting was used to balance the baseline characteristics. Multivariable logistic regression models and Cox proportional hazard models were used to examine the risks of in-hospital mortality and long-term survival, respectively.

Results: From the 4,165 dialysis patients in our cohort, we selected 333 PD patients receiving either CABG (86 patients) or PCI with a DES (247 patients) for analysis. Compared with patients receiving PCI with a DES, the risk of in-hospital mortality was significantly higher in patients receiving CABG [adjusted odds ratio, 5.70; 95% confidence interval (CI) 1.42-22.83; P = 0.014]. The overall mortality was also significantly higher in patients receiving CABG [adjusted hazard ratio, 1.53; 95% CI 1.13-2.08; P = 0.006]. The long-term mortality hazard associated with CABG remained consistent in several sensitivity analyses (Figure 1).

Conclusions: CABG was associated with both higher in-hospital and long-term mortality than PCI with a DES in our national cohort of Taiwan PD patients.

Funding: Government Support - Non-U.S.

Circulating Mycobiota and Mortality among Patients Undergoing Hemodialysis

Keiichi Sumida,[1] Yamini Mallisetty,[1] Chi-Yang Chiu,[1] Zhongji Han,[1] Cheng Chen,[2] Maki Sumida,[1] Amandeep Bajwa,[1] Jesse C. Seegmiller,[3] Amy B. Karger,[3] Susmita Datta,[4] Michael A. Langston,[2] Csaba P. Kovesdy,[1,5] Joseph F. Pierre.[6] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]University of Tennessee Knoxville, Knoxville, TN; [3]University of Minnesota, Minneapolis, MN; [4]University of Florida, Gainesville, FL; [5]VA Memphis Medical Center, Memphis, TN; [6]University of Wisconsin Madison, Madison, WI.*

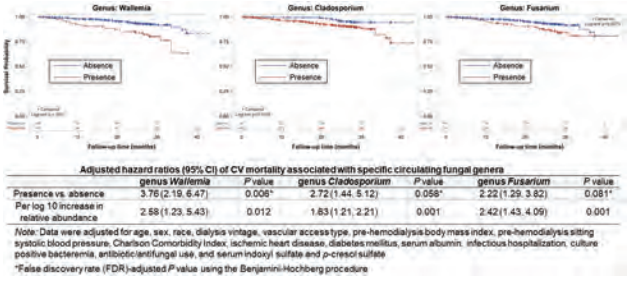
Background: Alterations of the circulating microbiota have recently been implicated in the pathogenesis of cardiometabolic disease. However, the evidence is based primarily on bacterial DNA signatures, and the characteristics and roles of DNA signatures of circulating fungi or 'circulating mycobiota (c-Myco)' remain unknown.

Methods: In a nationwide prospective cohort of 960 patients undergoing hemodialysis (HD), we characterized the signatures of c-Myco (i.e., quantity, α diversity, and composition) in baseline serum samples by means of Internal Transcribed Spacer (ITS) ribosomal DNA (rDNA) sequencing and examined their associations with all-cause and cardiovascular (CV) mortality using the Kaplan-Meier method and multivariable Cox models.

Results: Overall, the mean age was 60 years; 57% of patients had diabetes; and a median HD vintage was 3.1 years. No one used antifungals at baseline. After stringent quality controls, ITS rDNA was detected in 79.8% of patients. Taxonomic analysis demonstrated a total of 397 fungal taxa, including 7 phyla, 149 families, and 241 genera, most of which were rare and observed in <1% of patients at a mean relative abundance (RA) <0.1%. During a median follow-up of 2.2 years, 205 and 75 patients experienced all-cause and CV death, respectively. c-Myco signatures were not associated with all-cause mortality; but higher circulating fungal α diversity (adjusted HR [95% CI], 1.64 [1.14-2.39] per 1 unit increase) and the presence of specific fungal genera (3.76 [2.19, 6.47], 2.72 [1.44, 5.12], and 2.22 [1.29, 3.82] for *Wallemia*, *Cladosporium*, and *Fusarium*, respectively, P_{FDR} <0.1; Figure) were each significantly associated with higher CV mortality. For all three genera, their higher RA was also associated with higher CV mortality (Figure).

Conclusions: c-Myco signatures are independently associated with CV mortality in HD patients. Further studies are needed to determine the reasons for c-Myco detection and the mechanisms underlying the observed association.

Funding: NIDDK Support



Adjusted hazard ratios (95% CI) of CV mortality associated with specific circulating fungal genera

	genus *Wallemia*	*P* value	genus *Cladosporium*	*P* value	genus *Fusarium*	*P* value
Presence vs. absence	3.76 (2.19, 6.47)	0.006*	2.72 (1.44, 5.12)	0.058*	2.22 (1.29, 3.82)	0.081*
Per log 10 increase in relative abundance	2.58 (1.23, 5.43)	0.012	1.83 (1.21, 2.21)	0.001	2.42 (1.43, 4.09)	0.001

Note: Data were adjusted for age, sex, race, dialysis vintage, vascular access type, pre-hemodialysis body mass index, pre-hemodialysis sitting systolic blood pressure, Charlson Comorbidity Index, ischemic heart disease, diabetes mellitus, serum albumin, infectious hospitalization, culture positive bacteremia, antibiotic/antifungal use, and serum indoxyl sulfate and *p*-cresol sulfate

Clinical Characteristics of Undiagnosed Coronary Artery Disease (uCAD) in Individuals Initiating Hemodialysis

Hirohito Sugawara,[1] Kiryu Yoshida,[1] Yoshinori Saito,[1] Masanori Kato,[1] Masahiro Yamamoto,[1] Hidetoshi Ito,[1] Suguru Shimazu,[1] Masahiko Ochiai,[1] Hiroaki Ogata.[1,2] *[1]Showa Daigaku Yokohama-shi Hokubu Byoin, Yokohama, Japan; [2]Showa Daigaku, Shinagawa-ku, Japan.*

Background: Although CAD is prevalent in individuals with CKD, it is difficult to evaluate coronary lesion by coronary angiography (CAG) and coronary computed tomography (CCT) in advanced CKD not on HD because of high risk of contrast nephropathy. We examine the prevalence of uCAD and its clinical characteristics in individuals initiating HD.

Methods: We conducted a cross-sectional study of individuals newly starting HD between January 2002 and December 2023 at our hospital. CAD was screened by CCT immediately after starting HD, and then CAD was confirmed by CCT/CAG. The individuals with history of CAD were excluded. After exclusions, the remaining 272 participants were enrolled in the present study.

Results: A total of 272 participants (mean age, 69 years; female 30%; diabetes, 57%). Coronary lesions were detected in 128 participants (47%). The distribution of stenotic lesions was LAD 73%, LCX 44%, and RCA 49%, respectively. Coronary artery calcification (total Agatston score) was significantly observed in participants with CAD as compared with those without CAD (1290 ± 1652 vs. 390 ± 655; P<0.001). Dyslipidemia, diabetes, and past cerebrovascular disease were more prevalent in participants with CAD. Antiplatelet agents including aspirin and statins were frequently prescribed in participants with CAD. T wave inversion in the ECG were more frequently found in participants with CAD. No significant differences were observed in echocardiographic parameters between participants with and those without CAD. The multiple regression analysis indicated that the history of smoking and the levels of albumin (the odds ratio (OR): 0.53 (95% confidence interval [95% CI], 0.31 to 0.91)) and HDL-C (OR: 0.97 (95% CI, 0.95 to 0.99)) was independently and significantly associated with the formation of CAD.

Conclusions: uCAD were found in approximately half of individuals newly starting HD. Coronary lesions were frequently found in LAD artery. HDL-C and albumin were associated with uCAD.

FR-PO362

Prevalence and Risk Factors of Altered Control of BP during the Night in a Large Hemodialysis Population Evaluated by 48-Hour Ambulatory BP Monitoring

Francesca Mallamaci,[1] Claudia Torino,[2] Pantelis Sarafidis,[3] Robert Ekart,[4] Olga Balafa,[5] Antonio M. Del Giudice,[6] Filippo Aucella,[6] Massimo Morosetti,[7] Rocco Tripepi,[2] Carmela Marino,[2] Giovanni Tripepi,[2] Carmine Zoccali.[8] *[1]GOM Bianchi Melacrino Morelli, Nephrology Unit, Reggio Calabria, Italy; [2]IFC-CNR, Reggio Calabria, Italy; [3]Aristotle University, Thessaloniki, Thessaloniki, Greece; [4]University Clinical Centre Maribor, Maribor, Slovenia; [5]University Hospital of Ioannina, Ioannina, Greece; [6]Nephrology Unit "Casa Sollievo della Sofferenza" San Giovanni Rotondo, San Giovanni Rotondo, Italy; [7]Nephrology Unit, ASL Roma 3, Roma, Italy; [8]Renal Research Institute, New York, NY.*

Background: Altered BP control during the night is recognized as a powerful risk factor for death and CV events in the hemodialysis (HD) population. However, these alterations have been described in relatively small studies and the epidemiology and risk factors for subtypes non-dipping and nocturnal hypertension are still poorly characterized in the current literature. We investigated the problem in the large EURECA-m Registry, the sole adopting 48h ABPM recording in the HD population.

Methods: We included in this analysis 534 HD patients, from 7 centers, led by members of the EURECA-m working group, in 3 European countries. 48h ABPM was measured by using well validated instruments (AAMI/ESH/ISO). As recommended by the ESH guidelines, recordings were made at 15- minute intervals during the day and 30 minutes during the night. Hypertension was defined as 48h blood pressure (BP)>130/80,

nocturnal hypertension as a nighttime BP>120/70 mmHg, non-dipping as a night/day systolic BP fall <10% and reverse dipping as a night/day ratio>1.

Results: Among 534 HD patients, 317 were hypertensive and. 217 normotensive. 274 patients were non-dippers (51%), 32% were reverse dippers, and 381 (71%) had nocturnal hypertension. Of note, forty-one per cent of non-dippers, 37% of reverse dippers and 19% of patients with nocturnal hypertension were normotensives. As expected, the majority of reverse dippers (87%) had frank nocturnal hypertension. In a combined analysis of non-dippers and reverse dippers, as compared to dippers, these patients more frequently exhibited atrial fibrillation and had lower Heart Rate both pre-dialysis (72± 11 vs 77±13 bpm, P=0.004) and post-dialysis (74± 13 vs 78±14 bpm, P=0.03) and lower serum albumin (3.9±0.4 vs 4.0±0.3 g/dL, P=0.02) but did not differ for age and gender.

Conclusions: In a large cohort of HD patients investigated by the state-of-the-art technique, 48hABPM alterations in the nocturnal BP profile were almost universal, and nocturnal hypertension was the more prevalent alteration, followed by non-dipping and reverse dipping. These alterations were independent of age and gender. Long-term, granular follow-up analyses are warranted to identify the prognostic value of these alterations.

FR-PO363

Isolated Diastolic Hypertension in Patients on Hemodialysis

Francesca Mallamaci,[1] Claudia Torino,[2] Pantelis Sarafidis,[3] Robert Ekart,[4] Olga Balafa,[5] Antonio M. Del Giudice,[6] Filippo Aucella,[6] Massimo Morosetti,[8] Rocco Tripepi,[2] Carmela Marino,[2] Giovanni Tripepi,[2] Carmine Zoccali.[7]
[1]CNR-IFC & Nephrology and Renal Transplantation Unit, Reggio Calabria, Italy; [2]IFC-CNR, Reggio Calabria, Italy; [3]Aristotle University, Thessaloniki, Italy, Greece; [4]University Clinical Centre Maribor, Maribor, Slovenia; [5]University Hospital of Ioannina, Ioannina, Greece; [6]Nephrology Unit "Casa Sollievo della Sofferenza" San Giovanni Rotondo, San Giovanni Rotondo, Italy; [7]Renal Research Institute, New York, NY; [8]Nephrology Unit, ASL Roma 3, Roma, Italy.

Background: Isolated diastolic hypertension (IDH) is relatively rare in the general population (prevalence about 6.5%, Front Cardiovasc Med. 2021;8:810105) and of uncertain etiologic implications. The prevalence of this alteration in the hemodialysis (HD) population and the etiologic implications of IDH have not been studied.

Methods: We investigated the prevalence and the risk for all-cause death and cardiovascular events of isolated diastolic hypertension in a population of 534 HD patients enrolled in 7 centres in 3 European countries (the EURECA-m working group). BP was measured by a golden standard method in this population (48h ABPM) using well-validated instruments (AAMI/ESH/ISO). Along with recommendations by the European Society of Hypertension guidelines, recordings were made at 15-minute intervals during the day and 30 minutes at night. According to a consensus document by the EURECAm working group (NDT. 2019;34:1542-1548), isolated diastolic hypertension was defined as 48h diastolic BP > 80 mmHg with a systolic BP <130.

Results: Among 534 HD patients, thirty-one (5.8%) had isolated diastolic HTN, which is very close to the prevalence estimated in the general population (6.5%). During a mean follow-up of 2.6 years, 138 patients died, 188 had at least one CV event, and 249 experienced the combined event. In univariate analyses, diastolic hypertension was associated with death (HR 0.21; 95% CI: 0.05-0.86, P=0.03) and the combined outcome of death and CV events (HR 0.42, 95% CI: 0.20-0.88, P=0.02). However, these associations were no longer significant after adjustment for age and sex (all P≥0.45). Additional sensitivity analyses substantially confirmed these findings. No effect modification by age or gender was observed in these associations.

Conclusions: In a large cohort of HD patients studied by state-of-the-art 48-hour BP monitoring, the prevalence of isolated diastolic hypertension in HD patients (5.8%) is close to that registered in the general population (6.5%). This alteration predicts the risk for clinical outcomes in unadjusted analyses but not after adjustment for age and sex. Isolated diastolic hypertension is as rare as it is in the general population and unlikely to contribute to the high risk of adverse clinical outcomes in the dialysis population.

FR-PO364

Automated Blood Pressure Monitoring Patterns in Peritoneal Dialysis Modalities: Report from a Nephrology Reference Center in Mexico

Rodrigo Quintero Solis, Javier A. Vega Cardona, Edna T. Mendoza Villalobos, Mario A. Ruiz Gonzalez, Felipe De Jesus De La Torre Alvarez, Mireya González Franco, Michelle M. Cedillo, Miriam G. Nava-Vargas, Juan Carlos Anaya, Francisco Robles Garcia, Miguel Angel Franco Barrera, Hugo Sergio Breien Alcaraz, Sidney Torres. *Hospital Regional ISSSTE Valentin Gomez Farias, Zapopan, Mexico.*

Background: Arterial hypertension is a condition that affects most patients with chronic kidney disease and is a modifiable parameter to improve cardiovascular outcomes. Automated Blood Pressure Monitoring is considered the gold standard for surveillance. Various methods of BP measurement have been compared, including office-based measurements and self-monitoring. An analysis by Vaios demonstrated correlation between those compared to ABPM. ABPM classifies BP patterns over 24 hours, specifically during the night when it physiologically decreases, termed as Dipper. If this does not occur, it is considered non-dipper, a condition where BP figures increase, classified as Reverse Dipper, which increases CV risk. There are few studies that relates BP patterns to Renal Replacement Therapy. In a study of 38 patients, failed to demonstrate that the modality of Peritoneal Dialysis modifies BP patterns.

Methods: This is a retrospective, single-center study from 2014 to 2019, involving 150 patients who underwent ABPM for the first time. 64% were male, with a mean age of 49 years. 66% were on APD and 34% on CAPD. 42% were using diuretics, 73% iRAS, 41% calcium channel blockers, 28% a-blockers, and 21% b-blockers.

Results: The study found mean BP of 104 +/- 16 mmHg, daytime mean 105 +/- 16 mmHg, and nighttime mean 102 +/- 19 mmHg. In CAPD, 14% showed Dipper pattern, 36% reverse Dipper; in APD, 21% Dipper, 19% reverse Dipper. Non-parametric distribution confirmed via KS test ($p<0.001$). Significant difference in Dipper distributions by dialysis therapy (Mann-Whitney U test: U=2061.000, Z=-2.005, p=0.045). Significant relationship shown via Pearson's $\chi 2$ ($\chi 2=5.023$, df=3, p=0.170) and linear-by-linear association ($\chi 2=4.260$, df=1, p=0.039). Negative correlation observed through Kendall's Tau-b ($\tau=-0.155$, p=0.045) and Spearman's Rho ($\rho=-0.164$, p=0.045). CAPD had more reverse Dipper compared to APD.

Conclusions: Patients managed with CAPD had a statistically significant higher incidence of reverse Dipper pattern compared to those managed with APD.

FR-PO365

Sex Differences in Re-admissions following Cardiovascular Events in Patients with Kidney Failure

Silvi Shah, Karthikeyan Meganathan. *University of Cincinnati, Cincinnati, OH.*

Background: Hospitalization for cardiovascular disease (CVD) is common in patients with kidney failure. Little is known about sex differences in readmissions following cardiovascular events in patients on dialysis.

Methods: We evaluated 73,210 patients who initiated maintenance dialysis between 7/1/2013 and 6/30/2018 using the United States Renal Data System with linked Medicare claims for all cardiovascular (CV) hospitalizations. Rates of all-cause and CV related readmissions in the ensuing 30 days and 90 days were calculated. Adjusted time-to-event models were used to examine the association of sex with the outcome of 30 day and 90 day all-cause readmissions, CV readmissions, and all-cause death.

Results: Among 140,171 identified CV hospitalizations, the mean age at the time of index CV hospitalization was 70±11 years, and 46.1% of index CV hospitalizations were for women. 34.9% and 57.6% of CV hospitalizations resulted in readmission within 30 and 90 days, respectively; less than one-third of readmissions were CV related (16.1%, 30 days; 29.7%, 90 days). Women had a 6% higher risk of 30 day readmission for any hospitalization (HR, 1.06; 95% CI, 1.11-1.14) and a 14% higher risk of 90-day readmission for any hospitalization (HR, 1.14; 95% CI, 1.11-1.16) after an index CV hospitalization than men. While there was no difference in the risk of 30 readmission for CV hospitalization between men and women, women had a slightly higher risk of 4% for 90 readmission for CV hospitalization (HR, 1.04; 95% CI, 1.01-1.06) after an index CV hospitalization. After an index CV hospitalization, women had a lower risk of 30 day all-cause death (HR, 0.87; 95% CI, 0.84-0.91) and a lower risk of 90 day all-cause death, as compared to men (OR, 0.89; 95% CI, 0.86-0.92).

Conclusions: Among patients undergoing dialysis, women have a higher risk of readmission at 30 days and 90 days for any hospitalization and a higher risk of 90 day readmission for CV hospitalization following an index CV hospitalization than men. Further studies are needed to understand better the factors associated with sex differences in CV outcomes in patients with kidney failure.

FR-PO366

Diastolic Dysfunction Parameters in Patients with Intradialytic Hypertension

Thuylinh M. Nguyen, Andrew Horvit, Peter N. Van Buren. *The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Hypertension and heart failure (HF) are common in hemodialysis (HD) patients, and intradialytic hypertension (IH) further increases mortality risk. We characterized differences in cardiac structure and function in patients with and without IH with a focus on the ratio of mitral inflow velocity (E) to mitral annular early diastolic velocity (e').

Methods: We conducted a retrospective study of Dallas VA HD patients with available transthoracic echocardiograms (TTE). We calculated intradialytic blood pressure slope (IBPS) for each of 3 treatments before and after the TTE using all intradialytic measurements and defined IH as mean IBPS >0. We compared average E/e' in patients with and without IH using Mann Whitney U (raw data) and unpaired t test (log transformed data). We used logistic regression with average E/e' >14 as the primary outcome and IH as the primary predictor

Results: Average E/e' was 17.1 (15-22) in the IH group (n=19) vs. 14.3 (10-18) in the non-IH group (n=37; p=.02). E/A was 1.18 (0.6) in IH vs. 0.95 (0.3) in non-IH (p=.06). IH patients had lower ejection fraction (EF) (p=.04) but higher left ventricular mass index (LVMI) (p=.007). While controlling for age, diabetes, race, and EF, IH predicted E/e' >14 (OR 7.1 [1.6-44]); but this was blunted when controlling for LVMI (OR 3.1 [0.5-31)].

Conclusions: Diastolic dysfunction is common in HD patients and is more severe in IH. LVMI may mediate higher E/e' in IH patients. TTE should be obtained in IH patients to better understand structural and functional abnormalities that may increase CV risk

Funding: NIDDK Support, Veterans Affairs Support

Patient Characteristics

	No IH (N=37)	IH (N=19)	P- Value
Age (years)	65.4 (9.4)	68.1 (9.8)	0.3
Diabetes	29 (78%)	10 (53%)	0.07

Temporal Changes in Cardiac Conduction Disorders in Patients with ESKD on Long-Term Hemodialysis

Taniya Thomas,[1] Thermutis Djanie,[1] Omar Daghstani,[2] Krishnakumar D. Hongalgi,[2] Mikhail Torosoff.[2] *[1]Albany Medical College, Albany, NY; [2]Albany Medical Center, Albany, NY.*

Background: Cardiac amyloidosis is a known complication of end stage kidney disease (ESKD) which manifests with conduction abnormalities, including atrioventricular (AV) blocks, and requires atrial and/or ventricular pacing. The prevalence and temporal changes in conduction disorders in ESKD patients has not been well investigated.

Methods: We conducted a retrospective, IRB approved study of 166 consecutive ESKD patients who underwent arteriovenous (AV) fistula placement between 2006-2023. Electrocardiographic features historically associated with cardiac amyloidosis, including AV blocks and paced rhythms, were examined on pre- and post-AV fistula placement electrocardiograms (ECG).

Results: Mean age was 59.7 +/- 14.7 years old, 41.0% were females, with body mass index (BMI) of 28.1 +/- 6.6, and histories of hypertension in 92.8%, coronary artery disease (CAD) in 48.2%, atrial fibrillation/flutter in 34.4%, diabetes mellitus in 60.8%, chronic obstructive pulmonary disease in 29.5%, coronary artery bypass grafting in 15.7%, and congestive heart failure in 51.2% of patients. The mean duration of hemodialysis (HD) was 57 +/- 50 months. The mean interval between ECG evaluations was 35+/- 28 months. At baseline, 13.9% of patients were noted to have AV blocks or require atrial or ventricular pacing. Advanced age (p=0.03), histories of CAD (p=0.03), and atrial fibrillation/flutter (p=0.02) were strongly associated with conduction abnormalities. Prevalence of AV blocks and the need for pacing significantly increased on the follow-up evaluation, affecting 17.5% of the study cohort (p<0.0001). However, at this point, traditional risk factors for conduction abnormalities were not associated with the need for pacing.

Conclusions: The prevalence of AV blocks and paced rhythms increase overtime in patients with ESKD on long-term HD. These abnormalities are initially more common in ESKD patients with traditional risk factors for cardiac conduction disorders. However, there appears to be no association between traditional risk factors and the prevalence of AV blocks and paced rhythms in ESKD patients on long-term HD post-AV fistula placement. Therefore, routine monitoring for conduction delays is imperative in all ESKD patients on HD.

FR-PO368

Cardiovascular Morbidity Patterns in Patients on Dialysis Globally in Apollo Dial DB

Belen Alejos,[1] Kaitlyn R. Croft,[1] Yue Jiao,[2] Melanie Wolf,[1] Paola Carioni,[3] Mitesh Soni,[2] Anke Winter,[1] Luca Neri,[3] Sheetal Chaudhuri,[2] Kanti Singh,[2] Stefano Stuard,[3] Milind Nikam,[4] Adrian M. Guinsburg,[5] Dinesh K. Chatoth,[2] Jeffrey L. Hymes,[2] Kirill Koulechov,[1] Len A. Usvyat,[2] John W. Larkin,[2] Franklin W. Maddux.[6] *[1]Fresenius Medical Care, Bad Homburg, Germany; [2]Fresenius Medical Care, Waltham, MA; [3]Fresenius Medical Care, Crema, Italy; [4]Fresenius Medical Care, Singapore, Singapore; [5]Fresenius Medical Care, Buenos Aires, Argentina; [6]Fresenius Medical Care AG, Bad Homburg, Germany.*

Background: Cardiovascular diseases (CVDs) affect most people with kidney failure but are undefined globally. We aimed to analyze CVD prevalence among dialysis patients treated in 40 countries across six continents, as represented in the first version of a global dialysis database (Apollo Dial DB).

Methods: Apollo Dial DB includes adult dialysis patient data from a global kidney network during Jan 2018-Mar 2021 (Fresenius Medical Care, Bad Homburg, DE). Data anonymization was performed in alignment with recommendations from a re-identification risk determination (Privacy Analytics, Ontario, CA). This analysis assessed CVD comorbidities based on ICD-10 codes.

Results: Among 543,169 patients included, 79% reported ≥1 CVD condition. The prevalence of CVD conditions showed some differences by age and sex (**Figure 1**). Hypertension was the most common, affecting 73.6% of patients. Atherosclerotic heart disease affected 19.0%, increasing with age (9.9% in 18-44 years to 24.1% in ≥75) and more common in males (20.3%) than females (17.2%). Congestive heart failure affected 17.5%, also increasing with age. Other conditions included peripheral vascular disease (11.5%), cardiomyopathy (7.3%), and cardiac dysrhythmias (7.1%), all more prevalent in older age groups and slightly higher in males.

Conclusions: Hypertension is the most common CVD comorbidity among dialysis patients globally, followed by atherosclerotic heart disease and congestive heart failure. The prevalence of these conditions increases with age and is slightly higher in males. Future analyses are needed to explore differences by world region, which could inform region-specific management strategies.

Diagnosis of CKD in Patients with Hypertension in German Primary Care: The InspeCKD Study

Christoph Wanner,[1] Frederik M. Mader,[2,3] Thomas Frese,[4] Philipp Stahl,[5] Christoph Weber,[6] Ulrich Opfermann,[7] Fabian Burckhardt,[8] Felix Scherg,[8] Frank Radowsky,[9] Elke Schaeffner.[10] *[1]Department for Clinical Studies and Epidemiology, Comprehensive Heart Failure Center, University Clinic Würzburg, Würzburg, Germany; [2]Joint Practice Nittendorf, Nittendorf, Germany; [3]IU International University GmbH, Erfurt, Germany; [4]Institute of General Medicine, Interdisciplinary Center for Health Sciences, Martin Luther University Halle-Wittenberg, Halle, Germany; [5]Joint Family Practice Meinecke and Stahl, Burg, Germany; [6]Practice Rheinlanddamm, Dortmund, Germany; [7]SYMEDICUM MVZ GmbH, Berlin, Germany; [8]BioPharmaceuticals Medical, AstraZeneca, Hamburg, Germany; [9]Family Practice Radowsky, Leipzig, Germany; [10]Institute of Public Health, Charité - University Medicine Berlin, Berlin, Germany.*

Background: Hypertension (HT) is a known risk factor for chronic kidney disease (CKD) and a strong determinant of kidney and cardiovascular (CV) outcomes. Early diagnosis and therapy of CKD with organ protective treatments reduce the risks of kidney failure and CV complications. Therefore, assessment of kidney function by assessing eGFR and UACR in all patients with HT is recommended by the ESH 2023 and KDIGO 2024 guidelines. To date, there is limited data on the frequency of screening, diagnosis,

and guideline-directed medical therapy of CKD in HT patients in general practitioner (GP) practices. The InspeCKD study was designed to fill this gap.

Methods: 1,244 GPs provided fully anonymized individual data sets for analysis. According to the KDIGO screening recommendation, adult patients with HT, diabetes and/or CV diseases with at least one year of observation period were included in the analysis. In this pre-specified sub-analysis, only HT patients were evaluated.

Results: A total of 448,837 patients were included in the study, of whom 75.8% had HT (53.6% female; median age 66 years). Serum creatinine (SCr) to estimate eGFR (CKD EPI) was measured at least once in 43.4% of HT patients during the mean observation period of 1.7 years. Urine dipstick testing for albuminuria was performed at least once in 6.4% of HT patients and UACR was measured at least once in 0.3% of HT patients. 25.8% of HT patients had at least two SCr or UACR measurements at least three months apart to diagnose CKD. Among HT patients with laboratory confirmed CKD according to KDIGO (2x eGFR <60ml/min/1.73m^2 or 2x UACR >30mg/g in ≥3 months), 86.6% were not diagnosed with CKD. Guideline-directed medical therapy for CKD, defined as combination therapy with RASi and SGLT2i, was administered in 8.2% of HT patients diagnosed with CKD.

Conclusions: The analysis demonstrates the inadequacy of laboratory diagnostics in the early detection of CKD in HT patients at risk for CKD, including those with type 2 diabetes. It also reveals substantial gaps in diagnosis and treatment initiation in a country with full healthcare coverage. It is therefore important to raise awareness among GPs for the early detection and treatment of CKD in HT patients.

AKI as a Key Predictor of Cardiovascular Events in Patients with CKD: The CKD-REIN Study

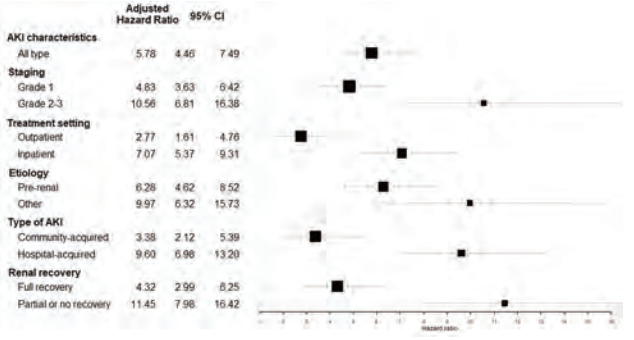
Aghiles Hamroun,[1,2] Estelle Aymes,[1,2] Luc Frimat,[3] Maurice Laville,[4] Celine Lange,[5] Sophie Liabeuf,[6] Ziad Massy,[7] Benedicte Stengel,[8] Natalia Alencar de Pinho,[8] Nans Florens.[9] *[1]Centre Hospitalier Universitaire de Lille, Lille, France; [2]Institut Pasteur de Lille, Lille, France; [3]Centre Hospitalier Regional Universitaire de Nancy, Nancy, France; [4]Universite de Lyon, Lyon, France; [5]Agence de la biomedecine, La Plaine Saint-Denis, France; [6]Centre Hospitalier Universitaire Amiens-Picardie, Amiens, France; [7]AURA Paris, Paris, France; [8]Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; [9]Les Hopitaux Universitaires de Strasbourg, Strasbourg, France.*

Background: Chronic kidney disease (CKD) is a well-established risk factor for cardiovascular events, but less is known about the specific contribution of acute-on-chronic kidney disease events. This study aims to analyze the relationship between incident acute kidney injury (AKI) episodes and subsequent Major Adverse Cardiovascular Events (MACE) in a population of CKD patients.

Methods: From 2013 to 2016, the CKD-REIN prospective cohort enrolled 3033 adults with CKD stages 2-5 from 40 outpatient nephrology clinics in France. During a 5-year follow-up, all AKI episodes were validated by an expert committee according to the KDIGO-AKI definition. Cardiovascular events were classified using clinical trial Cardiovascular and Stroke Endpoint Definitions and cardiovascular deaths adjudicated by expert. The association of incident AKI with subsequent MACE risk was analyzed using a multivariable Cox model, treating AKI as a time-dependent variable and stratifyied by AKI characteristics.

Results: Overall, 530 patients experienced at least one incident AKI episode during follow-up. After adjustment for multiple confounders, we observed a substantial increased hazard of MACE associated with AKI (HR = 5.78 [4.46; 7.49], $p < 0.001$), and this association remained significant for each MACE component. A dose-response relationship was observed, with higher risks in more severe AKI cases and among hospitalized versus non-hospitalized patients (Figure 1). This association was also confirmed across all subgroups, without any interaction with age, sex, CKD stage, nor major comorbidities (diabetes, history of AKI, or cardiovascular events), as well as in the sensitivity analyses.

Conclusions: Our study highlights a strong dose-response relationship between incident AKI and the risk of subsequent MACE in CKD patients. Our findings align with existing pathophysiological evidence, reinforcing the potential causal link between AKI and subsequent cardiovascular remodeling.



FR-PO371

Sex-Specific Relationships between Estimated Potassium Intake and Cardiovascular Outcomes in Patients with CKD: The Fukuoka Kidney Disease Registry Study

Tatsuya Suenaga,[1] Shigeru Tanaka,[1] Hiromasa Kitamura,[2] Kazuhiko Tsuruya,[3] Takanari Kitazono,[1] Toshiaki Nakano.[1] *[1]Department of Medicine and Clinical Science, Graduate School of Medical Science, Kyushu University, Fukuoka, Japan; [2]Department of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan; [3]Department of Nephrology, Nara Medical University, Kashihara, Japan.*

Background: Lower potassium intake is associated with an increased risk of cardiovascular disease (CVD) in the general population, and a sex-specific relationship has also been demonstrated. On the other hand, the relationship between potassium intake and CVD risks and its sex-specificity in patients with chronic kidney disease (CKD) has not been adequately investigated. This study aims to investigate the relationship between potassium intake and CVD risk, in addition to examining its sex-specificity in patients with CKD.

Methods: A total of 4,314 Japanese non-dialysis CKD patients aged 18 years or older in the Fukuoka Kidney disease Registry (FKR) Study were prospectively followed for 5 years. Patients were divided into sex-specific quartiles according to estimated potassium intake assessed by the Tanaka formula from spot urine samples. The primary outcome was occurrence of CVD events, defined as a composite of acute myocardial infarction, stable or unstable angina, ischemic or hemorrhagic stroke, peripheral arterial disease, hospitalization for heart failure, and cardiovascular mortality. We estimated the relationship between estimated potassium intake and CVD events using Cox proportional hazards models adjusted for factors related to potential confounding, risk of CVD, and potassium homeostasis.

Results: A total of 431 patients developed the primary outcome during follow-up periods. Patients in quartile 1 (Q1) of the total population had a significantly higher hazard ratio (HR) for CVD events than those in Q4 in the multivariable-adjusted Cox proportional hazards models (fully multivariable-adjusted HR [95% confidence interval {CI}], 1.48 [1.03–2.14]). In addition, there was a significant interaction between estimated potassium intake and CVD events by sex (p for interaction <0.01), and in women, patients in Q1 had an even significantly higher HR for CVD events than those in Q4 (multivariable-adjusted HR [95% CI]: men, 1.,2 [0.66–1.60]; women, 3.32 [1.62–6.81]).

Conclusions: Lower estimated potassium intake in patients with CKD was associated with an increased risk for CVD, and the relationship was significant only in women and not in men.

FR-PO372

Trends in Cardiovascular Mortality among Patients with CKD

Loai Dweik,[1] Ansaam Daoud,[2] Natthavat Tanphaichitr.[1] *[1]Cleveland Clinic Akron General, Akron, OH; [2]University Hospitals, Cleveland, OH.*

Background: Cardiovascular disease (CVD) is the leading cause of death in patients with chronic kidney disease (CKD). Impaired kidney function accelerates CVD due to factors like hypertension, fluid overload, dyslipidemia, and disturbances in mineral metabolism. Studies investigating trends in cardiovascular mortality among patients with CKD are lacking. We aim to observe the trends in proportionate cardiovascular mortality (PCM) in the last two decades in U.S.

Methods: This retrospective cohort study analyzed data from the Multiple Cause of Death files maintained by the National Center for Health Statistics. The dataset includes death certificates for U.S. residents, specifying the one primary cause of death as determined by the treating physician, up to twenty contributory causes, and demographic details. We explored the trend in PCM, which is the ratio of cardiovascular deaths (primary cause of death coded as I00-I99 in the International Classification of Diseases, version 10 [ICD-10]) to total deaths, in patients diagnosed with CKD (identified by ICD-10 code N18)

from 1999 to 2020. We used Pearson's correlation coefficient for trend analysis and the Chi-square test for comparative assessments.

Results: 1,938,505 deaths occurred in patients with CKD over the study period, with an age adjusted mortality rate of 26.3 per 100,000 people. Overall, 605,384 died of CVD causes (31%). The mean age of CVD mortality was 78 years. PCM decreased from 39% to 24% from 1999 to 2020 (r -0.9326, p<0.0001). PCM was higher in men (32% vs 30%, p<0.0001). Asian or Pacific Islanders exhibited the highest proportionate cardiovascular mortality at 33%, followed by Whites at 32%, African Americans at 28%, and American Indians or Alaska Natives at 24% (p 0.00). The most common cause of cardiovascular deaths was ischemic heart disease at 59%, hypertension 10%, cardiomyopathy 5%, valvular disease 4%, arrhythmia 4% and 20% other causes.

Conclusions: In conclusion, the past two decades have witnessed a significant decline in the proportion of deaths attributed to CVD causes among patients with CKD. Our analysis suggests improved management strategies and potentially highlights the effectiveness of preventative measures in CKD. Further research is needed to elucidate the specific factors contributing to this positive shift in this high-risk population.

FR-PO373

Trend Analysis of Hypertensive Kidney Disease-Related Mortality, 1999-2020

Mohammad Gul Yousaf Khan,[2] Hammad H. Khan,[1] Mohammad Ammar ur Rahman,[1] Luqman Munir,[1] Amna Khalid,[1] Ali Akram Qureshi,[1] Iqra Shahid,[1] Ahsan Zil-E-Ali,[2] Umar Farooq,[2] Fatima H. Abid.[1] NEURALKEy.
[1]King Edward Medical University, Lahore, Pakistan; [2]Penn State College of Medicine, Hershey, PA.

Background: Hypertensive kidney disease is associated with significant mortality because of the associated end-organ damage. This study seeks to evaluate the trend disparities in mortality related to hypertensive kidney disease among various demographic and geographical variables.

Methods: Our research involved a comprehensive analysis of the CDC Wonder database, specifically focusing on hypertensive kidney disease-related age-adjusted mortality rate (AMR) per 1,000,000 people. We conducted a test of Parallelism and calculated Annual Percent Changes (APC) with 95% Confidence Intervals using Joinpoint Regression Analysis. The test of parallelism was deemed significant for unparallel results with a p-value < 0.05.

Results: Overall AMR for hypertensive kidney disease did not significantly change from 1999 to 2020. However, AMR declined from 1999 to 2012 (APC -3.83), followed by a significant increase till 2020 (APC 5.70). All age groups from 25-85+ experienced a significant increase in AMR, with the 85+ having the greatest APC (14.4). There was a significant increase in AMR across all four census regions, with greatest increase in C2: Midwest (APC 11.2). The regions did not differ significantly from one another. Both urban and rural populations saw a significant increase in AMR, with rural population having a significantly greater APC (11.4). The female population experienced a significant decline in AMR, with a significantly negative AAPC of -1.30. The AAPC did not differ significantly between the two genders. The parallelism test was significant for comparison of genders, census regions and urban/rural populations. The Asian or Pacific Islander population experienced a decline in AMR (APC -2.80), with Black population experiencing a significant decrease from 1999-2018 (APC -3.61), followed by a substantial and significant increase till 2020 (APC 24.4).

Conclusions: Hypertensive kidney disease-related mortality has experienced little change in the United States. Certain demographic groups such as the rural population, females, and recently, the Black population experience disparities which require further investigations and directed solutions for these groups.

FR-PO374

Sex Differences in the Association of Cardiovascular Risk Factors with Post-traumatic Stress Disorder (PTSD) among Veterans with CKD

Helena Zhang,[1] David J. Ramsey,[1,4] Sankar D. Navaneethan,[1,2] Joseph Chilcot,[3] Lucile Parker Gregg.[1,4] *[1]Baylor College of Medicine, Houston, TX; [2]Michael E DeBakey VA Medical Center, Houston, TX; [3]King's College London, London, United Kingdom; [4]VA Center for Innovations in Quality Effectiveness and Safety, Houston, TX.*

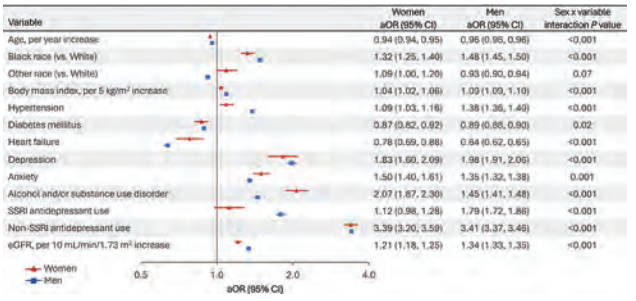
Background: Post-traumatic stress disorder (PTSD) is common among veterans and is associated with chronic kidney disease (CKD) progression and cardiovascular (CV) risk. It is unknown if sex modifies associations of CV risk factors with PTSD in veterans with CKD, who have a unique CV risk profile.

Methods: Using data from the VA Corporate Data Warehouse from 1/1/2009 to 12/31/2020, we conducted a retrospective cohort study of U.S. veterans with incident CKD stages 3-5 (defined as two eGFR values <60 mL/min/1.73 m^2 measured ≥90 days apart with no intervening values ≥60) with and without a diagnosis of PTSD. The index date was the date of the second qualifying eGFR. PTSD was defined by diagnosis codes in ≥2 clinical encounters within 1 year prior to the index date. Multivariable logistic regression assessed associations of demographics, comorbidities, medications, and laboratory values with PTSD, with multiplicative interaction terms to assess if sex modifies these associations.

Results: Of 1,443,878 veterans with CKD, 143,473 (9.9%) had a diagnosis of PTSD. Compared to those without PTSD, those with PTSD were younger (mean [SD] 65 [9] vs 73 [10], standardized mean difference [SMD] .78), more likely to be female (7% vs 3%, SMD .16) and Black (29% vs 16%, SMD .08), and more likely to have CKD stage 3 (97% vs 93%, SMD .15), hypertension (81% vs 70%, SMD .25), atherosclerotic CV disease (23% vs 18%, SMD .13), and depression (43% vs 13%, SMD .70). PTSD was associated with younger age, Black race, hypertension, higher body mass index, depression, anxiety, alcohol or substance use disorder, antidepressant use, and higher eGFR, with significant sex interactions for each. PTSD was more strongly associated with Black race, hypertension, depression, antidepressant use, and eGFR among men, and with anxiety and substance use disorder among women (**Figure**).

Conclusions: PTSD is differentially associated with CV risk factors among men and women veterans with CKD. Studies to improve CV outcomes in patients with PTSD and CKD should stratify by sex.

Funding: Veterans Affairs Support



CV risk factors and PTSD

FR-PO375

Global and Regional Disease Burden of Hypertensive CKD, 1980-2021: An Analysis of GBD Study 2021

Badar U Din Shah,[1] Muhammad Talha Shaukat,[2] Wania Rehman,[2] Aqeeb Ur Rehman,[3] Aleenah Mohsin,[4] Shahzaib Ahmad,[5] John W. O'Bell.[4]
[1]Geisinger Health, Danville, PA; [2]King Edward Medical University, Lahore, Pakistan; [3]The University of Alabama at Birmingham Heersink School of Medicine, Birmingham, AL; [4]Brown University, Providence, RI; [5]Baptist Health South Florida Inc, Coral Gables, FL.

Background: The incidence of hypertensive Chronic Kidney Disease(CKD) has steadily risen over time. The trends of standardized mortality and morbidity of hypertensive CKD are, however, understudied. By analysing trends from 1980-2021, this study provides insight into the longitudinally evolving pattern of hypertensive CKD associated mortality and morbidity.

Methods: Data were extracted from the Global Burden of Diseases (GBD) study, encompassing age-standardized mortality rates (ASMR), Years of Lost Life (YLL), and Disability-Adjusted Life Years (DALYs). The dataset was stratified by continent, with Africa divided into Northern, Southern, Eastern, Western, and Central. Data was further stratified by World Bank income levels and Joinpoint regression determined average annual percentage change (AAPC).

Results: Globally, the Age Standardized Death Rates (ASDR) for hypertensive CKD had an overall incline from 1980-2021. In 1980, ASDR was 4.57 (95% UI:3.8–5.5), which increased to 5.53 (AAPC:0.486; 95% CI:0.415, 0.557) in 2021. Globally, the DALYs were 107.7 (95% UI:91.26-126.9) per 100,000 people in 1990, and climbed to 128.4 (AAPC: 0.566; 95% CI:0.485-0.684) in 2021. From 1990 to 2021, the YLL showed a uniform spike with an AAPC of 0.287 (95% CI:0.19–0.37). In geographical analysis, all continents except Asia had an overall increase in ASDRs, with the highest ASDRs in Africa, and the most prominent spike in America. From 1980-2021, America had AAPC of 1.32 (95% CI:1.15-1.50), Africa had 0.403 (95% CI:0.34-0.46), Europe had 0.54 (95% CI:0.20-0.89) while Asia had -0.19 (95% CI:-0.29- -0.08). Central and Western Africa had the highest ASDRs as compared to other regions of the continent. Upon subanalysis of America, Mississippi and Louisiana had the most prominent incline in ASDRs. According to the World Bank income levels, low and middle income countries(LMICs) also conformed to the global trend and had an increasing death rates trends.

Conclusions: This study reveals a global rise in ASDR for hypertension-related CKD. Moreover, DALYs and age-standardized YLL have also increased, underscoring the need for targeted interventions as well as preventive measures. LMICs also show escalating death rates, emphasizing the need for proactive measures to address this growing health crisis there.

FR-PO376

Incident Hypertension in Young Adults with a Modest eGFR Reduction

Sumaiya Ahmed,[1] Junayd Hussain,[1] Ayub Akbari,[1] Pietro Ravani,[2] Gregory L. Hundemer,[1] Tim Ramsay,[1] Ann Bugeja,[1] Greg A. Knoll,[1] Manish M. Sood.[1] *[1]Ottawa Hospital, Ottawa, ON, Canada; [2]Alberta Health Services, Edmonton, AB, Canada.*

Background: Hypertension (HTN) is a common, modifiable risk factors for cardiovascular (CV) disease with a rising occurrence in young adults (18-39). Advanced chronic kidney disease is well established as a risk factor for HTN, however, uncertainty remains regarding the relationship between modest eGFR declines (between 60 to 100 ml/min) and HTN.

Methods: A retrospective cohort study of 8.7 million individuals (3.6 million aged 18-39 years) using linked provincial healthcare datasets from Ontario, Canada from January 2008 to March 2021. Cox models were conducted to examine the association of categorized eGFR (50-120 mL/min/1.73m^2) and incident HTN, stratified by age (18-39, 40-49, 50-65 years).

Results: Among our cohort (8.7 million individuals, mean age 41.3, mean eGFR 104.2, median follow-up 9.2 years), a step wise increase in blood pressure was observed elevations in blood pressure observed as early as eGFR<90 in young adults (eg. at eGFR 70-80, ages 18-30: 10.5 events per 1000 person-years(p-y), HR 1.31 (1.27-1.40); ages 40-49: 20.4/1000p-y, HR 1.07 (1.05-1.09); ages 50-65: 31.9/1000p-y, HR 1.03 (1.02-1.04) (figure 1). In addition, HTN was detected in patients with mild to negligeable albuminuria with increasing incidence as GFR declined. Among young adults who developed HTN, CV events were higher, and this increased with modest eGFR reductions.

Conclusions: *HTN* in young adults is associated with modest reductions in eGFR (<70-80) and a higher risk of CV consequences warranting early identification, monitoring, and management.

FR-PO377

Influences of Blood Pressure-Lowering Agents on Frailty Progression in Patients with Type 2 Diabetes: A Longitudinal Cohort Study

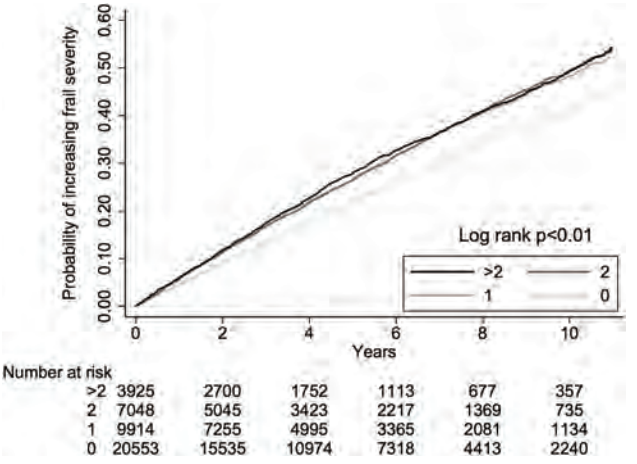
Chia-Ter Chao,[1,2] Jui Wang.[3,1] Cohort of Geriatric Nephrology in NTUH (COGENT Study Group). *[1]National Taiwan University Hospital, Taipei, Taiwan; [2]Min Sheng General Hospital, Taoyuan, Taiwan; [3]National Taiwan University College of Public Health, Taipei, Taiwan.*

Background: Patients with diabetes mellitus (DM) face an elevated risk of developing frailty characterized by increased vulnerability to adverse stimuli. Although the likelihood of frailty development in this population has been explored, few studies investigate the risk factors associated with frailty progression. We examined the influence of different types of blood pressure (BP)-lowering agents on the risk of exacerbating frailty in patients with DM.

Methods: We identified adult patients with type 2 DM from the integrated medical database of National Taiwan University Hospital and its affiliated branches. Clinical variables were recorded and monitored to assess the primary outcome: worsening of frailty. Cox proportional hazards analysis was employed to determine the risk of frailty progression associated with specific classes of BP-lowering agents, adjusting for multiple confounders.

Results: A total of 41,440 patients (mean 64.1 years; 46.3% females) were included, with 27.4% experiencing worsening frailty during 4.09 years of follow-up. The use of at least 1 anti-hypertensive class significant increased the risk of frailty progression (Figure). Cox regression analysis, accounting for potential confounders, revealed that users of diuretics had a significantly higher risk of frailty progression (hazard ratio (HR) 1.12, 95% confidence interval (CI) 1.06-1.18), as did α-blocker users (HR 1.14, 95% CI 1.06-1.23). Conversely, β-blocker users exhibited a significantly reduced risk (HR 0.93, 95% CI 0.88-0.98). Moreover, longer durations and higher dosages of β-blocker use decreased the risk of frailty progression, while diuretics use demonstrated the opposite trend.

Conclusions: Our findings suggest that the choice of BP-lowering agents may significantly impact the risk of frailty progression in patients with DM. Clinicians should carefully consider the potential benefits and risks associated with specific classes of BP-lowering agents when managing hypertensive patients with DM, particularly in relation to frailty-related outcomes.



FR-PO378

Trend Analysis of Hypertensive Heart and Kidney Disease-Related Mortality, 1999-2020

Mohammad Ammar ur Rahman,[1] Ahmed J. Chaudhary,[2] Luqman Munir,[1] Amna Khalid,[1] Muhammad Khan Buhadur Ali,[1] Saleha Azeem.[1] NEURALKEy. *[1]King Edward Medical University, Lahore, Pakistan; [2]Detroit Medical Center, Detroit, MI.*

Background: Hypertensive heart and renal disease is a significant complication of chronic hypertension. Hypertensive heart disease manifests as left ventricular hypertrophy, heart failure, and coronary artery disease, while hypertensive renal disease involves renal parenchymal damage and glomerular injury, leading to progressive kidney dysfunction. In this study, we investigated the increasing mortality rates associated with hypertensive heart and renal disease in the United States from 1999 to 2020. We utilized age-adjusted mortality rates (AAMR) to identify disparities across various epidemiological groups.

Methods: Death certificates from the CDC WONDER (Centers for Disease Control and Prevention Wide-Ranging Online Data for Epidemiological Research) database were examined spanning the years 1999 to 2020. Analyses included determining age-adjusted mortality rates (AAMR) per 100,000 individuals and calculating the annual percent change (APC) with 95% confidence intervals. Trends among demographic groups, including race, gender, age, and urban/rural classification, were assessed using the Joinpoint Regression Program.

Results: 142,363 mortalities due to Spinal Injuries were reported between 1999 and 2020. Overall AAMR showed an upward trend although inconsistently with an AAPC score of 5.225. From 1999 to 2007, the AAMR showed a decline from 1999 to 2001, with an APC of -19.16 then it showed a steady rise from 2001 to 2014, with an APC of 3.71 and finally it showed a rapid rise from 2014 to 2020 with an APC of 18.56. The AAMR itself rose from 16.405 in 1999 to 48.521 in 2020. The populations with the highest mortality rates were in African Americans and males. The geographical hotspots for mortality were urban and Southern region. Tests for parallelism revealed disparate trends across African Americans and Whites (p=0.00022), Northeastern and Southern regions (p=0.00022) and Large fringe metro and Medium Metro (p=0.00022).

Conclusions: The mortality due to the hypertensive heart and renal disease has been rising since 1999 which is very concerning. Furthermore, the disparity among the demographic variables requires more investigation, and the planning of targeted interventions.

FR-PO379

Exploring High Prevalence and Comorbidities of Autonomous Cortisol Secretion in Primary Aldosteronism: A Cohort Study and Systematic Review

Chun-Fu Lai,[1] Chieh Huang,[2] Li-Yang Chang,[2] Vincent Wu.[1] Taiwan Primary Aldosteronism Investigators (TAIPAI) Study Group. *[1]National Taiwan University Hospital, Taipei, Taiwan; [2]National Taiwan University College of Medicine, Taipei, Taiwan.*

Background: Emerging evidence has suggested a significant prevalence of autonomous cortisol secretion (ACS) among patients diagnosed with primary aldosteronism (PA). Recognizing PA with concurrent ACS is challenging and often complicates patient management.

Methods: In the prospectively enrolled Taiwan Primary Aldosteronism Investigators (TAIPAI) cohort, we conducted an evaluation to ascertain the prevalence, characteristics, and comorbidities associated with ACS among 874 patients diagnosed with PA between February 2018 and February 2024. Additionally, we undertook a systematic review and

meta-analysis (CRD42023486755), encompassing publications with comprehensive data up to February 1, 2024, to integrate our findings with global studies for comparative analysis.

Results: Within the TAIPAI cohort (mean age 55.1 ± 11.9 years; female, 52%), a notable proportion (19.8%) of PA patients exhibited ACS. Those with ACS tended to be older (59.4 ± 11.8, *P*< 0.001), have higher aldosterone levels (44.3 ± 31, *P*= 0.003), lower baseline estimated glomerular filtration rates (87.1 ± 29.6, *P*< 0.001), higher glycohemoglobin levels (6.2 ± 1, *P*= 0.019), a greater incidence of adrenal tumors (55.5%, *P*< 0.001) as detected by computed tomography, and larger adrenal tumor sizes(1.86 ± 0.76, *P*< 0.001). The pooled prevalence of ACS among PA patients in the TAIPAI cohort and 11 global studies was 22.8% (95% CI: 20.2, 25.6). [Figure] Significantly, ACS correlated with chronic kidney disease [pooled odds ratio (OR)= 2.09; 95% CI: 1.62, 2.7], diabetes mellitus (pooled OR= 1.63; 95% CI: 1.2, 2.2), and cardiovascular disease (pooled OR=1.63; 95% CI: 1.2, 2.2) among PA patients.

Conclusions: ACS prevalence in PA patients is high, exceeding 20%. There are strong associations between ACS and clinical features of advanced age, impaired kidney function, diabetes, cardiovascular disease, and larger adrenal tumors. These findings underscore the need for vigilant monitoring and prompt detection of ACS in PA patients with these comorbidities.

Forest Plot of ACS Prevalence in PA Patients.

FR-PO380

Prognostic Value of Triglyceride Glucose (TyG) Index in a Population with CKD

Jeong-Yeun Lee, Jin Sug Kim, Hyun Kyu Kim, Dae Kyu Kim, Soo-Young Yoon, Kyunghwan Jeong, Hyeon Seok Hwang. *Kyung Hee University Medical Center, Dongdaemun-gu, Seoul, Republic of Korea.*

Background: The triglyceride glucose (TyG) index has been proposed as a reliable marker of insulin resistance and an independent predictor of cardiovascular (CV) event. However, its prognostic value in chronic kidney disease (CKD) remains unclear. This study aims to assess predictive value of the TyG index for clinical outcomes in CKD population.

Methods: This study was conducted using the Korean National Health Insurance Service database. 91,070 individuals with CKD who underwent a national health examination between 2012 and 2015 were enrolled. The study population was divided into four groups based on the quartile of TyG index levels. The primary outcome was a CV event, including myocardial infarction and stroke, and the secondary outcomes were progression to end-stage kidney disease (ESKD) and all-cause mortality.

Results: During a median follow-up time of 80.4 months, CV event, progression to ESKD, and all-cause mortality occurred in 11,676 (12.8%), 3,776 (4.1%) and 13,481 (14.8%) cases, respectively. The cumulative event rate of cardiovascular events, progression to ESKD, and all-cause mortality was the highest among population with TyG quartile 4 (all P < 0.001). In multivariate Cox-regression analysis, a higher TyG index was associated with an increased risk of CV event. Compared with participants in the lowest quartile of TyG index, hazard ratios (HR) and 95% confidence intervals (CI) for CV event were 1.063 (1.008-1.121), 1.104 (1.047-1.165), 1.290 (1.222-1.363) for those in second, third, and fourth quartile of TyG index. The risk of progression to ESKD was also increased as TyG quartile increased [adjusted HR (95% CI) 1.143 (1.027-1.271), 1.282 (1.143-1.437), and 1.826 (1.635-2.039)] for population with TyG quartile 2, 3, and 4, respectively]. However, there was no significant association with an increase in the risk of all-cause mortality.

Conclusions: The TyG index serves as a valuable predictor of CV event, progression to ESKD and all-cause mortality in CKD population.

FR-PO381

Prevalence of Cardiovascular Kidney Metabolic Syndrome among US Hispanic/Latino Participants in the Hispanic Community Health Study/ Study of Latinos, 2008-2011

Amit K. Chakrabarti,[1] Pooja Kondeti,[1] Robert A. Mesa,[1] Yelena Drexler,[1] Julien Tremblay,[1] Linda C. Gallo,[6] James P. Lash,[2] Sylvia E. Rosas,[3] Nora Franceschini,[7] Daniele Massera,[5] Claudia Martinez,[1] Martha L. Daviglus,[2] Matthew Allison,[4] Tali Elfassy.[1] *[1]University of Miami Miller School of Medicine, Miami, FL; [2]University of Illinois Chicago, Chicago, IL; [3]Joslin Diabetes Center, Boston, MA; [4]University of California San Diego Department of Medicine, La Jolla, CA; [5]NYU Langone Health, New York, NY; [6]San Diego State University, San Diego, CA; [7]The University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Cardiovascular-Kidney-Metabolic (CKM) syndrome is a staging system that describes the clustering of risk factors and clinical progression of disease at the intersection of metabolic disorders, chronic kidney disease (CKD), and cardiovascular disease (CVD). We described the distribution of CKM stage among diverse US Hispanic/Latino adults.

Methods: The Hispanic Community Health Study/Study of Latinos (HCHS/SOL) is a population-based cohort of Hispanics/Latino adults aged 18-74 years from four US communities. During a comprehensive in person examination (2008-2011), information was collected on: body mass index, waist circumference, glucose tolerance, lipids, blood pressure, metabolic syndrome, CKD, 10-year CVD risk (to define sub-clinical CVD), and self-reported CVD. Participants were classified into four stages of CKM based on American Heart Association definitions: Stage 0 (no risk factors), Stage 1 (excess/ dysfunctional adipose tissue), Stage 2 (metabolic risk factors and CKD), Stage 3 (subclinical CVD in CKM syndrome), and Stage 4 (clinical CVD in CKM syndrome). We estimated the age-standardized prevalence of CKM stage by sex and Hispanic/Latino background. All analyses accounted for the HCHS/SOL complex survey design.

Results: Among the 15,832 participants with complete information, mean age was 41.1 years and 52.3% were female. Overall, 10.9% (SE: 0.4) of participants were in CKM stage 0, 27.7% (SE: 0.6) were in stage 1, 53.4% (SE: 0.6) were in stage 2, 2.5% (SE: 0.2) were in stage 3, and 5.5% (SE: 0.3) were in stage 4. CKM stage differed by sex and Hispanic/Latino background group (Figure, chi-square p values <0.05).

Conclusions: Among diverse US Hispanics/Latinos adults, an absence of CKM risk factors was only observed in roughly one in ten adults, while roughly eight in ten adults had evidence of some cardiometabolic dysfunction.

FR-PO382

Mortality Risks of Cardiovascular-Kidney-Metabolic Syndrome Components Based on a Large Asian Cohort of More than a Half Million Participants

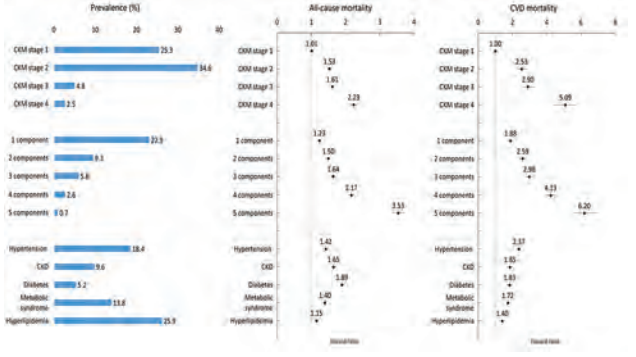
Min Kuang Tsai,[1] Chi Pang Wen,[2] Mei-Yi Wu.[1] *[1]Taipei Medical University Shuang Ho Hospital Ministry of Health and Welfare, New Taipei City, Taiwan; [2]National Health Research Institutes Institute of Population Health Sciences, Zhunan, Taiwan.*

Background: The American Heart Association (AHA) has recently issued guidelines addressing the "Cardiovascular-Kidney-Metabolic (CKM) Syndrome" to mitigate cardiovascular diseases. This interdisciplinary concept of health medicine emphasizes the impact of multiple disease interactions rather than individual disease factors. This study aims to evaluate CKM prevalence and its associated components mortality risks in a substantial Asian cohort.

Methods: The investigation focused on a cohort of 515,602 participants aged 20 years and above enrolled in a health screening program in Taiwan spanning from 1996 to 2017. The study assessed all-cause, cardiovascular disease (CVD) and cause-specific mortality related to CKM stages and its components—hypertension, diabetes, chronic kidney disease, metabolic syndrome, and hyperlipidemia. Multivariate Cox proportional hazards models were employed to calculate hazard ratios (HRs). We use Chiang's life table method to present the years of life lost for each CKM components.

Results: Among this cohort, 67.2% had CKM, with prevalence rates of 25.3%, 34.6%, 4.8%, and 2.5% in Stages 1, 2, 3, and 4, respectively. Among those aged 60 and above, nearly 90% had CKM. CKM was associated with a higher risk of all-cause mortality (HR: 1.37, 95% CI: 1.31-1.43), and CVD mortality (HR: 2.12, 95% CI: 1.89-2.39). Each additional component of CKM was associated with a 23% increase in the risk of death (HR: 1.23, 95% CI: 1.22-1.24) and a 38% increase in the risk of CVD mortality (HR: 1.38, 95% CI: 1.36-1.40) compared to participants without any CKM components. With each additional component, the average life expectancy decreases by 3 years.

Conclusions: The prevalence rates of CKM and its components vary, contributing to distinct risks of mortality. A clustering phenomenon exists among different components, where an increased number of components corresponds to a higher risk of all-cause, CVD mortality and end-stage kidney disease incidence.



FR-PO383

Association between Cardiovascular-Kidney Metabolic (CKM) and Mortality in a Middle- and Older-Aged Asian Population

Charumathi Sabanayagam,[1,3] Pavitra Thyagarajan,[1] Hongwei Ji,[4] Cynthia C. Lim,[2] Tien Yin Wong,[1] Ching-Yu Cheng.[1,3] *[1]Singapore Eye Research Institute, Singapore, Singapore; [2]Singapore General Hospital, Singapore, Singapore; [3]Duke-NUS Medical School, Singapore, Singapore; [4]Tsinghua University, Beijing, China.*

Background: Cardiovascular-kidney metabolic (CKM) Syndrome is recognized by the American Heart Association (AHA) to encompass the interplay among metabolic risk factors, chronic kidney disease (CKD), and cardiovascular disease (CVD). We examined the association between CKM syndrome and all-cause mortality in an Asian population.

Methods: Data for this study was derived from a sample of Chinese, Malay and Indian participants aged 40-80 years (n=6957, men=51.7%) who attended the baseline visit (2004-2011) of the Singapore Epidemiology of Eye Diseases (SEED) study, a population-based cohort study in Singapore. The primary outcome was all-cause mortality obtained by linkage to death registry until 2021. CKM stages (0-4) were defined according to the AHA criteria. As there were few participants in stage 3 (n=31), we combined stages 3 and 4 for analysis. Associations between CKM stages and mortality were assessed using Cox-proportional hazards regression models adjusted for age, sex, and ethnicity, both in the overall population and stratified by sex.

Results: During follow-up (median, 11.8 years), 882 participants died. Most participants were categorized under stage 2 CKM, with prevalence across stages are as follows: 3.2% (stage 0), 7.2% (stage 1), 83.3% (stage 2), and 6.3% (stage 3-4). All-cause mortality was 12.7% (9.3% in women vs. 15.9% in men). CKM stage-specific mortality rates in the overall population were 4.0%, 4.4%, 11.6% and 40.2%. Women had significantly lower mortality than men in all stages ($p<0.05$). In multivariable analysis, compared to stage 0, stage 3-4 CKM showed significant association with all-cause mortality with hazard ratio (HR) (95% confidence interval) of 2.74 (1.39 - 5.38). Sex-specific analysis revealed significant association in stage 3-4 in men only, 2.86 (1.25 - 6.51).

Conclusions: Our findings showed that higher stages of CKM were associated with increased mortality among middle-aged and older Asian adults, particularly in men. Understanding these associations aids in risk stratification and targeted interventions for improved cardiovascular and kidney health outcomes.

FR-PO384

Real-World Analysis of SGLT2 Inhibitors to Prevent Cardiovascular and Kidney Outcomes in Patients with CKD: A Population-Based Cohort Study

Luis Toro, Josefa Valderrama, Diego Polanco. NephroChile Initiative. *Universidad de Chile Facultad de Medicina, Santiago, Chile.*

Background: Randomized clinical trials have shown significant benefits of sodium-glucose cotransporter-2 inhibitors (SGLT2i) in chronic kidney disease (CKD). However, there is little data of real-world effects in this population. The objective of this study was to evaluate the effect in preventing clinical outcomes of SGLT2i in CKD patients, in a real-world population-based cohort.

Methods: Observational cohort study of patients > 18 years with CKD (eGFR 20-45 mL/min/1.7m2 or eGFR 45-90 mL/min/1.7m2 with uACR > 200 mg/g) with RAAS blockage, between January 2021 and April 2024. We included patients with and without type 2 diabetes. We performed propensity score matching at a 1:2 ratio. Clinical outcomes were progression of CKD or death from CV causes, reduction of eGFR, development of ESRD, and death from any cause.

Results: We analyzed 3,036 patients, 1,012 SGLT2i users, and 2,024 non-SGLT2 users. Age: 64.5 ± 11.7 years. Female: 1,254 (41.3%). Diabetes: 1,621 (53.3%). eGFR > 45 mL/min/1.7m2: 1,134 (37.3%). eGFR 30-45 mL/min/1.7m2: 1,621 (53.3%). eGFR < 30 mL/min/1.7m2: 281 (9,2%). No baseline differences were present after propensity score matching. Median follow-up: 2.8 years. Patients with SGLT2i had a lower reduction of eGFR than those without SGLT2i (-2.90 ± 0.32 vs. -4.75 ± 0.21 mL/min/1.7m2 per year; p<0.001. Figure 1). Patients with SGLT2i had a lower rate of progression of CKD or death from CV causes (13.9% vs. 19.2%, p<0.001). Multivariate analysis indicated that SGLT2i use was independently associated with reduced adverse clinical outcomes (hazard ratio: 0.71 [0.56-0.88], p<0.001).

Conclusions: Our results indicate that SGLT2 inhibitors have renal and cardiovascular protective effects in real-world conditions. These results support the implementation of current guidelines in clinical practice to improve clinical outcomes in CKD patients.

FR-PO385

Risk of Target-Organ Damage in Pediatric Patients with CKD and Ambulatory Hypertension: A Systematic Review and Meta-Analysis

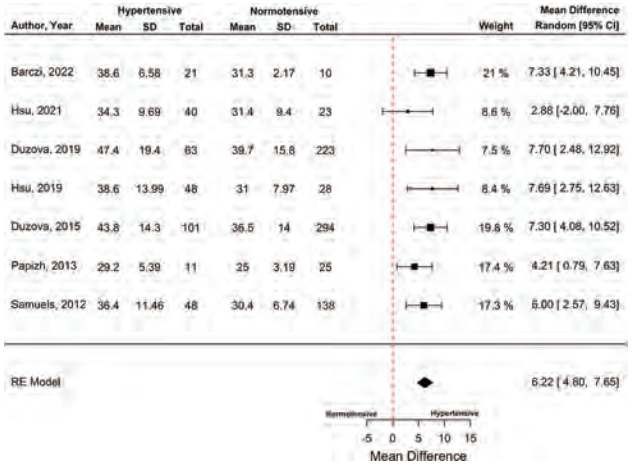
Andrew Yu,[1] Jason Chung,[2] Cal Robinson,[5] Janis M. Dionne,[4] Rulan S. Parekh,[6] Andrew M. South,[7] Mark Mitsnefes,[8] Damien G. Noone,[5] Rahul Chanchlani.[3] *[1]University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada; [2]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; [3]McMaster Children's Hospital, Hamilton, ON, Canada; [4]BC Children's Hospital, Vancouver, BC, Canada; [5]The Hospital for Sick Children, Toronto, ON, Canada; [6]Women's College Hospital, Toronto, ON, Canada; [7]Wake Forest University School of Medicine, Winston-Salem, NC; [8]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

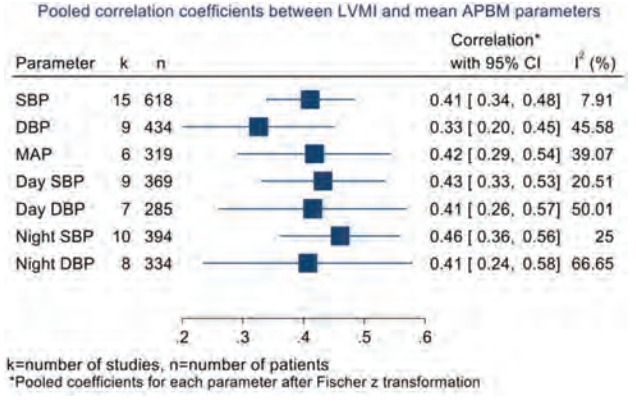
Background: The objective of this systematic review is to determine the association of ambulatory hypertension and various ambulatory blood pressure monitoring (ABPM) parameters with left ventricular mass index (LVMI) in youth with CKD.

Methods: A systematic literature search on nine databases included English publications from 1974-2022. LVMI was indexed to subject height and body surface area ($g/m^{2.7}$). Correlation coefficients were transformed and pooled using a random effects model. All stages of CKD were included for this review. Normative values of ABPM were derived from the German Working Group on Pediatric Hypertension.

Results: Of 1,128 screened studies, 16 studies and 2,254 children and adolescents were included. LVMI was elevated in the CKD hypertensive group compared to the CKD normotensive group (mean difference: 6.22 $g/m^{2.7}$, 95% CI: 4.80-7.65). Youth with hypertension were at 3.34 (95% CI: 2.38-4.68) higher odds of left ventricular hypertrophy compared to normotensive children.

Conclusions: Pediatric CKD patients with ambulatory hypertension especially during nighttime were more likely to have higher LVMI and left ventricular hypertrophy. Adequate blood pressure control among children with CKD may be crucial to avoid the risk of target organ damage and future cardiovascular disease.





FR-PO386

Health Care Resource Utilization and Costs Associated with Childhood Hypertension: A Population-Based Cohort Study

Cal Robinson,[1] Junayd Hussain,[2] Tammy M. Brady,[3] Janis M. Dionne,[4] Sabine Karam,[5] Ashlene M. McKay,[1] Rulan S. Parekh,[6] Rukshana Shroff,[7] Carol Vincent,[8] Rahul Chanchlani.[9] *[1]The Hospital for Sick Children Division of Nephrology, Toronto, ON, Canada; [2]McMaster University Michael G DeGroote School of Medicine, Hamilton, ON, Canada; [3]Johns Hopkins Children's Center, Baltimore, MD; [4]BC Children's Hospital, Vancouver, BC, Canada; [5]University of Minnesota Twin Cities, Minneapolis, MN; [6]Women's College Hospital, Toronto, ON, Canada; [7]University College London, London, United Kingdom; [8]Brenner Children's Hospital and Health Services, Winston-Salem, NC; [9]McMaster Children's Hospital, Hamilton, ON, Canada.*

Background: Pediatric hypertension has risen significantly in recent decades and has been linked to long-term cardiovascular and kidney-related morbidity. However, healthcare resource utilization and costs associated with pediatric hypertension are unclear. This study aims to compare healthcare resource use and costs between children with and without hypertension.

Methods: Population-based retrospective cohort study of children aged 3-18 years diagnosed with hypertension from 1996 to 2021 in Ontario, Canada, using validated case definitions in health administrative databases. Each case was propensity score-matched with five controls without hypertension. Children were followed until death, provincial emigration, or March 31, 2022. Our primary outcome was rates of healthcare system utilization, including hospitalizations, emergency department(ED), and outpatient physician visits, analyzed by negative binomial regression. Secondary outcomes were total healthcare system costs and specialist physician follow-up.

Results: We matched 25,605 children diagnosed with hypertension to 128,025 non-hypertensive controls. Baseline covariates were balanced after propensity score matching. Median age was 15 years[IQR 11-17], 49% were female, and prior comorbidities were uncommon(1% congenital heart disease, 1.7% malignancy, 0.4% diabetes). During median 12.9-year[IQR 6.8-19.9] follow-up, hypertensive children were more likely to be hospitalized(rate ratio [RR] 2.13, 95%CI 2.03-2.22, incidence rate [IR] 105.5 vs 62.8 events per 1000 person-years). Hypertensive children were also more likely to have an ED visit(RR 1.08, 95%CI 1.05-1.11) and outpatient visit(RR 1.33, 95%CI 1.31-1.34). Within 1 year of hypertension diagnosis, 40% of children saw a pediatrician, 24% saw a cardiologist, and 5% saw a nephrologist. Hypertension was associated with substantially higher total healthcare costs throughout follow-up(median $1375 vs. $384 per person-year).

Conclusions: Healthcare utilization and costs were significantly higher among children and adolescents diagnosed with hypertension than matched non-hypertensive children. These results provide a basis for future cost-effectiveness studies of strategies to prevent childhood hypertension occurrence and late complications.

FR-PO387

Racial and Ethnic Disparities in Hypertension Severity and Target Organ Injury at Baseline in Youth Referred for Hypertension Disorders

Elizabeth A. Onugha,[1,2] Ashna Pudupakkam,[1,2] Sahar Siddiqui,[1,2] Andrew M. South,[3] Fallon Campbell,[2,1] Carol Vincent,[3] Giya Harry.[3] *[1]Baylor College of Medicine, Houston, TX; [2]Texas Children's Hospital, Houston, TX; [3]Atrium Health Wake Forest Baptist Medical Center, Winston-Salem, NC.*

Background: Hypertension (HTN) in youth tracks into adulthood and is associated with subclinical cardiovascular disease. Target organ injury (TOI) is identified in up to 30% of children at HTN diagnosis and is associated with HTN severity. Although racial and ethnic disparities in HTN risk are well established, there is limited data on disparities in the association of HTN severity with TOI in children. We set out to describe racial/ethnic differences in the association between HTN severity and TOI at baseline in youth referred for HTN disorders.

Methods: Retrospective cross-sectional analysis of baseline data from the Study of the Epidemiology of Pediatric Hypertension (SUPERHERO), a multisite Registry of youth referred to subspecialty care for HTN disorders using EHR data. Inclusion criteria were an initial subspecialty clinic visit for HTN disorders identified by ICD-10 codes from 1/1/2016–12/31/2023 and age <19 years. Exclusion criteria were youth on dialysis, kidney transplantation, or pregnancy by ICD-10 codes, as well as missing data. The exposure was stage 1 vs. stage 2HTN based on age, sex, and height-based U.S. guidelines. The outcome was TOI by ICD-10 codes. We conceptualized race/ethnicity as a social construct and defined it as an effect modifier; in this analysis. We estimated the associations with unadjusted generalized linear models with an interaction term and stratified models.

Results: Of the 5,562 participants, mean age was 13.3 years (SD 4.1), 38% were male, 58% were White, 22% were African Americans and 19% were Hispanic/Latino. 39% had stage 2 HTN and 5% had evidence of TOI. The overall TOI risk was 1.3 (95% CL 1.0–1.6). Stratification showed this risk was significant in Black/African American (RR 1.7, 95% CL 1.0–2.7) and Hispanic/Latino participants (RR 1.9, 95% CL 1.1–3.2), but there was no evidence of effect modification by race or ethnicity.

Conclusions: We did not find racial disparities in TOI risk based on HTN severity in our large and diverse multisite cohort of youth referred for hypertension disorders. Future studies will evaluate the impact of BP control on racial disparities in TOI risk.

FR-PO388

Multiple Office Blood Pressure Measurement (mOBPM): A Practical Application for Hypertension Diagnosis in Children

Letizia Dato,[1] Maria Cristina Mancuso,[2] Laura Viola,[3] Giacomo Tamburini,[2] Daniele Rossetti,[2] Andrea Gualtieri,[4] Gianluigi Ardissino.[2] *[1]Università del Piemonte Orientale, Division of Pediatrics, Department of Health Sciences, Novara, Italy; [2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Pediatric Nephrology, Dialysis and Transplantation Unit, Milan, Italy; [3]Ospedale di Stato, ISS San Marino, Pediatric Unit, San Marino, San Marino; [4]ISS San Marino, Health Authority, San Marino, San Marino.*

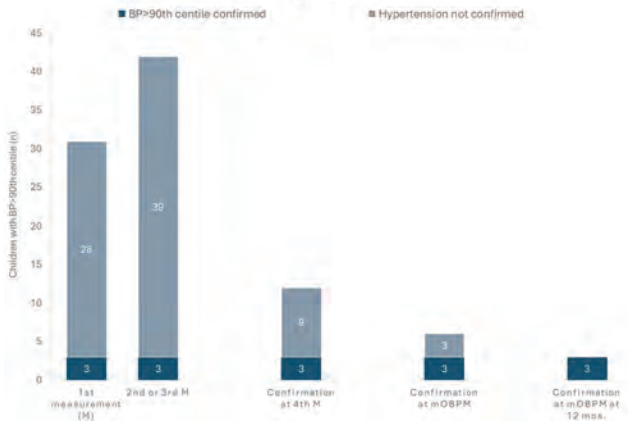
Background: In children office blood pressure (BP) measurement (M) may be unreliable. Multiple office BPM (mOBPM) is the standard practice for hypertension diagnosis in children at our Centre. It consists in taking 10 serial readings at 3-minute intervals by mean of a validated automated oscillometric device, discarding outlier values (<5th and >95th centile), calculating the coefficient of variation (CV) and the mean of the remaining systolic (S) and diastolic (D) BP values through a software. In a previous study, we reported that the first 3 readings are significantly higher than the mOBPM mean, whereas, starting from the 4th one, we found no significant difference. The mOBPM identified a smaller number of subjects with abnormal BP values. This study aimed to test mOBPM as a simple yet effective approach to screen children for hypertension.

Methods: We determined the number of school children with BP>90th centile considering the first 3 readings and the mean of the 2nd and 3rd. Among these, we identified children with pathological BP at 4th M and, subsequently, at mOBPM. Hence, we compared this result with the number of truly hypertensive children confirmed at the mOBPM repeated at 12 months.

Results: One hundred and seventy-five children (93 females, 53%) with a mean age of 8.6±0.3 and a mean BMI of 17.5±2.9 (BMI>20, n=34) were enrolled. Thirteen children were excluded for a CV>15% in SBP or DBP. Figure 1 shows the results. The mean of the 2nd and 3rd M identified 14 children with BP>90th centile, but the 4th showed a further reduction of the number of falsely hypertensive subjects and remains a more practical approach. None of the children with a normal BP value at 4th reading showed a pathological mOBPM result.

Conclusions: Although guidelines recommend 3 readings, our findings suggest that, if the first 3 readings indicate elevated BP values, measuring a 4th value can unmask falsely hypertensive subjects. If the 4th reading is abnormal, we recommend to obtain a complete mOBPM to identify truly hypertensive children.

Figure 1



FR-PO389

Association of Neutrophil-to-Lymphocyte Ratio with Atherosclerotic Cardiovascular Disease and Kidney Outcomes in CKD

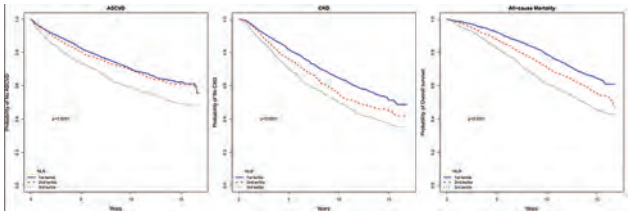
Gauranga Mahalwar,[1] Zhengyi Chen,[2] Edward J. Horwitz,[3] Jonathan J. Taliercio,[1] Mahboob Rahman,[2] Mirela A. Dobre,[2] Andrei Brateanu.[1]
[1]Cleveland Clinic, Cleveland, OH; [2]University Hospitals, Cleveland, OH; [3]MetroHealth Medical Center, Cleveland, OH.

Background: CKD is a highly inflammatory state that results in accelerated atherosclerotic cardiovascular disease (ASCVD). The neutrophil-to-lymphocyte ratio (NLR) is a known inflammatory biomarker related to ASCVD in the general population but is less studied in CKD. We aimed to assess the association between NLR and clinical events in CKD.

Methods: Serum NLR was measured at baseline in 5089 participants with CKD, enrolled in Chronic Renal Insufficiency Cohort (CRIC) study. The primary outcome was a composite incident ASCVD (myocardial infarction, stroke, peripheral arterial disease, and CVD mortality). Secondary outcomes were CKD progression (incident ESKD [either initiation of dialysis or kidney transplantation] or 50% eGFR decline), and all-cause mortality. Cox proportional hazards models were built to investigate the association between NLR tertiles and the time to occurrence of clinical outcomes.

Results: The mean age (SD) was 59.3 (10.8) years and 56% were female. Participants in the highest tertile of NLR were more likely to have diabetes, higher blood pressure, lower eGFR and higher proteinuria levels. Kaplan-Meier curves demonstrated a statistically significant association between higher NLR tertile and clinical outcomes (Figure). In models adjusted for demographics, co-morbidities, medications, eGFR, proteinuria and C-reactive protein, compared to lowest tertile, participants in the highest NLR tertile were more likely to have incident ASCVD (HR 1.27 (1.1, 1.48), p=0.002), CKD progression (HR 1.25 (1.09, 1.44), p=0.002) and all-cause mortality (HR 1.29 (1.12, 1.47), p<0.001).

Conclusions: In a cohort of participants with CKD, elevated NLR levels were associated with a higher risk of ASCVD, progression of CKD and mortality independent of the conventional risk factors. Further research is needed to test whether incorporating NLR into existing risk prediction models would improve their accuracy and facilitate interventions in susceptible CKD patients.



Incidence of the primary ASCVD outcome, kidney events and all-cause mortality by baseline NLR

FR-PO390

Exploring Social Determinants of Hypertension (HTN)

Deepali K. Ernest,[1] Jayna M. Dave,[2] Elizabeth A. Onugha.[2,3] *[1]University of Houston, Houston, TX; [2]Baylor College of Medicine, Houston, TX; [3]Texas Children's Hospital, Houston, TX.*

Background: Many social determinants of health (SDoH) are associated with HTN in adults, but little is known about their contribution to adolescent HTN. We examined the independent and joint effect of common SDoH on HTN among adolescents.

Methods: National Health and Nutrition Examination Survey (2013-2020) data for adolescents 13-18 years were cross-sectionally analyzed. HTN was defined as systolic blood pressure ≥ 130 and/or diastolic blood pressure ≥80mmHg. SDoH included food security, healthcare access, and economic status. SDoH were scored (0=favorable condition, 1=unfavorable condition) and summed to create a joint-impact score (0-9) divided into tertiles. Weighted logistic regression models determined the independent and joint impact of SDoH on HTN risk. Adjusted odds ratios (aOR) and 95% confidence intervals (CI) were reported.

Results: Overall 2,623 adolescents were included (mean age=15.4 years, 50% female, and 58.2% White). 2.9% had HTN, 33% had obesity (BMI>95th percentile), 21% were food insecure, 41% received SNAP benefits, 8% had no health insurance, 12% had no routine place for healthcare, and 47% had family poverty index (FPI) ≤1.85. Receiving SNAP benefits was significantly associated with higher odds of HTN (p<0.05). After adjustment for obesity and race/ethnicity, being non-Hispanic Black, receiving SNAP benefits, not having a routine healthcare site, no insurance, foreign-born, English speaking and FPI≤1.85 had increased odds of hypertension. Every 1 unit increase in SDoH score was associated with 11% higher odds of HTN [aOR=1.11; 95% CI: 0.94, 1.32]. Adolescents with SDoH scores in tertile 2 had significantly higher odds of HTN [aOR=2.53; 95% CI: 1.09,5.88; p=0.03] vs. those in tertile 1.

Conclusions: Our findings suggest that SDoH related to food security & assistance, and healthcare access are associated with higher odds of HTN among adolescents and SDoH can cumulatively contribute to the likelihood of HTN in this population.

Table. Comparison of adjusted and unadjusted effects of individual SDoH on hypertension among adolescents (N=2,623)

Characteristics	Odds Ratios (95% CI) Unadjusted	Adjusted ᵃ
Food Security & Assistance		
Food insecurity (Yes vs. No)	0.94 (0.50,1.77)	0.75 (0.42,1.34)
Emergency food provisions (Yes vs. No)	1.07 (0.52,2.20)	0.93 (0.45,1.88)
SNAP Benefits and food stamps (Yes vs. No)	1.83 (1.04,3.2)*	1.58 (0.90,2.77)
Healthcare Access & Utilization		
Routine Healthcare Site (No vs. Yes)	1.87 (0.68,5.08)	1.94 (0.70,5.37)
Current Health Insurance (No vs. Yes)	1.07 (0.45,2.55)	1.00 (0.40,2.48)
Health Insurance past year (No vs. Yes)	1.91 (0.39,9.32)	1.78 (0.31,10.34)
Culture		
Country of Birth (Foreign vs. U.S)	1.14 (0.47,2.75)	1.60 (0.59,4.34)

Long-Term Exposure to Nitrogen Dioxide on Cardiovascular Event Risks in Patients with CKD Using Machine Learning-Based Ultra High-Resolution Air Pollution Forecasts

Seung hyun Han,[1] Boram Weon,[1] Ara Ko,[2] Jeonghwan Lee,[1] Dong Ki Kim,[2] Yon Su Kim,[2] Chun Soo Lim,[1] Jung Pyo Lee.[1] *[1]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [2]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.*

Background: Preliminary studies have suggested that nitrogen dioxide (NO_2) is linked to increased cardiovascular risks, yet its impact on individuals with chronic kidney disease (CKD) is not well-documented. This study aims to assess the effect of long-term NO_2 exposure on the risk of major adverse cardiovascular events (MACE) in CKD patients.

Methods: A retrospective cohort study was conducted on CKD patients from two major medical centers in seoul, who visited between 2001 and 2016. Participants without prior cardiovascular diseases history were included, with follow-up until February 2023. Machine learning-based forecasts were used to predict NO_2 exposure levels. The association between NO_2 exposure and MACE (acute myocardial infarction, ischemic stroke, cardiovascular death, or revascularization) was analyzed using a time-varying Cox proportional hazards model.

Results: A total of 39,022 CKD patients were included, and 3,446 of them experienced MACE. After adjusting for multivariable covariates, CKD patients showed a significant increased risk of MACE with each 10 ppb increase in NO_2 concentrations (HR, 1.005; 95% CI, 1.002-1.008). Each MACE component analysis, except for cardiovascular death, showed significant results. In subgroup analyses based on kidney function, non-dialysis CKD patients exhibited a significant increased in MACE incidence risk (HR, 1.006; 95% CI, 1.002-1.010), particularly those with an estimated glomerular filtration rate between 15 and 30 mL/min/1.73m^2 (HR, 1.033, 95% CI, 1.020-1.045).

Conclusions: Chronic NO_2 exposure significantly correlates with an elevated risk of cardiovascular events in CKD patients. This underscores the importance of addressing air pollution as a factor in managing cardiovascular risk among CKD patients, especially for those with CKD stage 4.

FR-PO392

Association of Prevalent Kidney Stone Disease with All-Cause and Cardiovascular Disease Mortality among US Adults

Sandipan Shringi,[1,2] Christina A. Raker,[3] Jie Tang.[1,2] *[1]Rhode Island Hospital, Providence, RI; [2]Brown University Warren Alpert Medical School, Providence, RI; [3]Lifespan Biostatistics, Epidemiology, Research Design, and Informatics Core, Providence, RI.*

Background: Kidney stone (KS) disease is associated with multiple cardiovascular disease (CVD) risk factors. We have reported survival among stone formers from US adults from 1988-1994. We now report all-cause and CVD mortality in prevalent KS disease defined as self-report of any previous episode of KS using updated dataset of US adults from 2007-2018.

Methods: We examined the relationship between KS disease and risk of death among a nationally representative sample of US adults (age ≥20 years) using the National Health and Nutrition Examination Survey (NHANES) 2007-2018 and its linked mortality file. Cox proportional hazard regression analyses were used to estimate the risks of all-cause and CVD death.

Results: 27,959 participants were eligible for the final analysis including 2,689 prevalent KS formers. Stone formers tended to be non-Hispanic, white males, had a higher BMI, and more likely to have hypertension, diabetes, and CVD. There was a total of 2,445 all-cause deaths and 601 CVD deaths. Unadjusted analysis showed that stone formers had a higher risk of death from all-causes (HR 1.63, 95% CI: 1.38-1.93, p<0.001) but not CVD (HR 1.28, 95% CI: 0.94-1.75, p=0.12). However, after multivariate adjustment, stone formers no longer had an increased risk of death from all-causes compared to non-stone formers (HR 0.93, 95% CI: 0.80-1.09, p=0.38). Furthermore, risk of death from CVD after multivariate adjustment was lower in stone formers (HR 0.65, 95% CI: 0.47-0.91, p=0.01). [Table] In comparison, in NHANES III (1988-1994), there was a total of 6,069 all-cause deaths and 1,839 CVD deaths. Unadjusted analysis showed that stone formers had a higher all-cause and CVD mortality, however, there was no independent association of KS disease with all-cause or CVD mortality after multivariate adjustment.

Conclusions: Unlike NHANES III, NHANES 2007-2018 shows that prevalent KS disease is independently associated with lower CVD mortality but not all-cause mortality. Further studies are needed to confirm this finding.

Table: Hazard ratios for all-cause and CVD deaths in stone formers

	NHANES 2007-2018				NHANES 1988-1994			
	All-cause		CVD		All-cause		CVD	
Regression Model	HR	95% CI	HR	95% CI	HR	95% CI	HR	95% CI
Unadjusted	1.63	1.38-1.93	1.28	0.94-1.75	1.79	1.57-2.04	1.94	1.51-2.49
Model 1	1.03	0.89-1.19	0.77	0.56-1.04	1.07	0.95-1.20	1.09	0.87-1.35
Model 2	0.94	0.80-1.09	0.66	0.47-0.92	0.95	0.84-1.09	0.92	0.74-1.15

FR-PO393

Kidney Failure Etiology and Modality Worldwide: Apollo Dial DB

Yue Jiao,[1] Melanie Wolf,[2] Kaitlyn R. Croft,[2] Paola Carioni,[3] Mitesh Soni,[1] Anke Winter,[2] Luca Neri,[3] Sheetal Chaudhuri,[1] Kanti Singh,[1] Milind Nikam,[4] Stefano Stuard,[2] Adrian M. Guinsburg,[5] Dinesh K. Chatoth,[1] Jeffrey L. Hymes,[1] Kirill Koulechov,[2] Len A. Usvyat,[1] John W. Larkin,[1] Franklin W. Maddux.[6] *[1]Fresenius Medical Care, Waltham, MA; [2]Fresenius Medical Care, Bad Homburg, Germany; [3]Fresenius Medical Care, Crema, Italy; [4]Fresenius Medical Care, Singapore, Singapore; [5]Fresenius Medical Care, Buenos Aires, Argentina; [6]Fresenius Medical Care AG, Bad Homburg, Germany.*

Background: We used a global database representing kidney care across six continents, Apollo Dial DB, to evaluate modality use by kidney failure etiology.

Methods: Apollo Dial DB captures observation-level data (each treatment, lab, value) from 40 countries in a kidney care network (Fresenius Medical Care, Bad Homburg, DE). Data anonymization was performed in alignment with recommendations from a re-identification risk determination (Privacy Analytics, Ontario, CA). The data has >360 variables (demographics, dialysis, diagnoses, labs, medications, surveys, & outcomes) from 01Jan2018-31Mar2021. Kidney failure etiology considered diabetes, other, or unspecified causes. Modality rates after primary dialysis initiation were assessed by etiology group overall, and by world region. Modality use considered hemodialysis (HD) only, peritoneal dialysis (PD) ever, or transplant.

Results: Of 543,169 adults with kidney failure worldwide, 455,769 (80.6%) had a known etiology (diabetes=39.8%, other causes=40.8%, unspecified=19.4%). Overall, 84.8% used HD, 11.0% used PD, and 4.1% used a transplant after dialysis initiation. Modality use by etiology was consistent worldwide for HD and PD, yet kidney failure due to diabetes was associated with lower transplant rates (**Figure 1**). Regional differences were observed, with lower PD and transplant rates for kidney failure due to diabetes in some regions. Further, large regional differences in unspecified kidney failure etiology were present.

Conclusions: Kidney failure etiology appears to influence modality use. About 40% of people with kidney failure due to diabetes use HD and PD, yet transplant rates are >50% lower. Regional variations exist and kidney failure due to diabetes is also associated with lower PD rates in select regions. Unspecified kidney failure etiology varied by region and further analyses are needed.

FR-PO394

Etiology of Kidney Failure across the World in MONitoring Dialysis Outcomes (MONDO) Dataset

Vladimir Rigodon,[1,2] Yue Jiao,[2] Murilo H. Guedes,[1] Sophanny Tiv,[3] Vincent Peters,[12,7] Melanie Wolf,[4] Kaitlyn R. Croft,[4] Paola Carioni,[5] Anke Winter,[4] Luca Neri,[5] Sheetal Chaudhuri,[2] Milind Nikam,[11] Edwin B. Toffelmire,[6] Constantijn Konings,[7] Stefano Stuard,[5] Rasha H. Hussein,[10] Adrian M. Guinsburg,[9] Roberto Pecoits-Filho,[1] Thyago P. Moraes,[1] Jochen G. Raimann,[8] Xiaoling Ye,[8] John W. Larkin,[2] Peter Kotanko.[8] MONDO Investigators. *[1]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [2]Fresenius Medical Care, Waltham, MA; [3]University of Calgary, Calgary, AB, Canada; [4]Fresenius Medical Care, Bad Homburg, Germany; [5]Fresenius Medical Care, Crema, Italy; [6]Queen's University, Kingston, ON, Canada; [7]Tilburg University, Tilburg, Netherlands; [8]Renal Research Institute, New York, NY; [9]Fresenius Medical Care, Buenos Aires, Argentina; [10]University of Khartoum, Khartoum, Sudan; [11]Fresenius Medical Care, Singapore, Singapore; [12]Catharina Ziekenhuis, Eindhoven, Netherlands.*

Background: **MONDO** initiative is an academic-industry partnership where providers contribute anonymized data to a shared research dataset. We characterized etiology of kidney failure (KF) from the **MONDO 2019** cohort from 41 countries over 20 years.

Methods: Nine institutions contributed longitudinal data to **MONDO 2019** (Jan2000-Dec2019). Data anonymization was performed in alignment with recommendations from a re-identification risk determination (Privacy Analytics, Ontario, CA).

Results: MONDO 2019 represents 289,531 patients, of which 170,910 (59.0%) had a known etiology for KF (**Figure 1**). Worldwide, diabetes (DM) was the leading cause of KF (15.8%), followed by hypertensive diseases (HTD, 14.0%) and glomerular diseases (GD,13.9%). Although DM was the leading cause of KF in North America (NA, 35.1%) and Asia-Pacific (AP, 24.2%), GD was the most common cause of KF in Europe-Middle East-Africa (EMEA, 14.9%) and South America (SA, 16.5%). DM was the second leading cause of KF in EMEA (13.4%) and the third leading cause of KF in SA (12.7%). Other regional differences were observed and included HTD being a more common cause of KF in NA (25.3%) and AP (19.4%) than in SA (14.9%) and EMEA (10.6%).

Conclusions: MONDO 2019 dataset shows that the etiology of KF may vary among world regions and warrants further confirmatory investigations, particularly for glomerular disorders associated with DM. These observations are consistent with findings from registries in US and Europe (Stel VS, et al., NDT 2024).

Distinguishing among Causes of Death in Patients with Kidney Failure on Hemodialysis

Michelle Tran,[1] Chun Xu,[2] Jonathan A. Wilson,[2] Patti Ephraim,[3] Tariq Shafi,[4] Daniel E. Weiner,[5] Julia J. Scialla,[1,6] Benjamin A. Goldstein.[2] *[1]UVA Health, Charlottesville, VA; [2]Duke University, Durham, NC; [3]Northwell Health Feinstein Institutes for Medical Research, Manhasset, NY; [4]Houston Methodist Hospital, Houston, TX; [5]Tufts Medical Center, Boston, MA; [6]University of Virginia Department of Public Health Sciences, Charlottesville, VA.*

Background: Patients treated with maintenance hemodialysis (HD) are at high risk of death from various causes. While predicting all-cause mortality has been shown to be feasible, predicting cause-specific mortality risk could promote personalized treatment. We assessed whether clinical markers can differentiate among distinct causes of death.

Methods: We used electronic health record data from a not-for-profit dialysis provider linked to United States Renal Data System (USRDS) Files for a cohort of adults treated with maintenance in-center HD who died between 2003-2016. We classified USRDS-reported causes of death into five categories: sudden cardiac death (SCD), non-SCD cardiovascular death, infection, other, and unknown. A subcohort was linked to National Death Index (NDI) with similar categories defined. We used gradient boosting trees to discriminate among causes with demographics, vital signs, laboratory measures, health service utilization and comorbidity claims from 30 days prior to death. We created nested case-control populations for each cause of death and used ridge logistic regression to assess clinical factors that associate with distinct causes.

Results: Classification models for USRDS and NDI outcomes had area under the receiver operating curves (AUROCs) between 0.59-0.70 suggesting minimal ability to distinguish among causes of death. In case-control ridge regression models, coefficients were similar across models for distinct causes of death. Correlation of the coefficients across models was very high (Figure) suggesting that most clinical risk factors are shared and do not distinguish among causes.

Conclusions: Using patient-level clinical data from the 30 days prior to death, we were not able to distinguish among causes of death in maintenance HD patients, suggesting that different causes of death in kidney failure either share similar risk factors or that stated causes of death in USRDS or NDI forms are imprecise.

FR-PO396

Sex- and Cause-Specific Mortality among US Adults Receiving Maintenance Dialysis: A National Cohort Study

Jessica L. Harding,[1] Nanzha Abi,[2] Rachel E. Patzer,[3,4] Ana P. Rossi,[5] Stephen O. Pastan.[1] *[1]Emory University School of Medicine, Atlanta, GA; [2]Emory University Rollins School of Public Health, Atlanta, GA; [3]Indiana University School of Medicine, Indianapolis, IN; [4]Regenstrief Institute Inc, Indianapolis, IN; [5]Piedmont Transplant Center, Atlanta, GA.*

Background: We examined sex differences in cause-specific mortality among incident dialysis patients overall and by age and race.

Methods: We identified adults aged ≥18 years initiating dialysis between 2000 and 2020 from the United States Renal Data System (n=2.16 million; 43.3% women). Cause-specific mortality (cardiovascular (CVD), withdrawal, infection, cancer, and all other causes) was defined from the Centers for Medicare and Medicaid Death Notification Form. All individuals were followed from dialysis start date until date of death, 10-years, or end of follow-up (December 31, 2021), whichever occurred first. Multivariable Cox proportional hazards models assessed the association between sex and cause-specific mortality overall and stratified by age and race.

Results: Overall, 67.9% and 70.7% of men and women died with median survival times of 2.69 and 2.72 years, respectively. CVD was the leading cause of death (38.6% women; 40.2% men), followed by withdrawal (11.1% women; 9.6% men) and infections (9.8% women; 8.6% men). Overall, women had a 9% and 4% increased risk for infection, withdrawal, and other-related mortality compared with men, **Figure**. Conversely, women had a 7% and 10% lower likelihood of CVD and cancer-related mortality, respectively, as compared with men. Younger women (vs. men) aged 18-44 years had higher mortality across all specific causes, while older women (vs. men) aged >75 years had lower risks. Black women (vs. men) had higher mortality across all specific causes, but for all other races, sex differences were similar to the overall population.

Conclusions: Adopting a sex-specific approach that additionally incorporates the intersectionality of age and race is crucial to effectively manage complications and mitigate mortality risk among US dialysis patients.

FR-PO397

Association of Risk of Death and Hemoglobin (hgb) Variability in Anemia Management of Patients on Hemodialysis

Ariella E. Mermelstein,[3] Tomislav Kovacevic,[1] Yuedong Wang,[2] Doris H. Fuertinger,[4] Jeffrey L. Hymes,[4] Jochen G. Raimann,[3] Peter Kotanko.[3,5] *[1]Vifor Fresenius Medical Care Renal Pharma Ltd, St Gallen, Switzerland; [2]University of California Santa Barbara, Santa Barbara, CA; [3]Renal Research Institute, New York, NY; [4]Fresenius Medical Care Holdings Inc, Waltham, MA; [5]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: The current target hgb range for US HD patients treated with erythropoietin-stimulating agents (ESAs) for anemia, is between 10 and 11 g/dL. Earlier retrospective studies show lower mortality rates when hgb was within a range of 10.2 to 12.4 g/dL. This wider range was more favorable independent of hgb variability over

time. For the current analysis we studied hgb variability in different strata of cumulatively administered long-acting ESA (Mircera).

Methods: We defined the baseline period as 6 months from the first ESA dose which had to be administered within 90 days of HD initiation. We calculated patient-specific mean baseline hgb. We fit a linear regression model to calculate the variance of the residuals. We stratified the patient cohort as per the cumulative sum of administered baseline ESA doses (50 to 465, 466 to 700, 701 to 1075, and 1076 to 5050 mcg) and built 4 Cox proportional hazard models of mortality risk over the 18-month follow-up period. Models were adjusted for age, sex, race, diabetes, serum albumin, and phosphorus.

Results: We studied 62,181 HD patients (63.4 years, 57.2% male, 38.8% diabetic, mean baseline hgb 10.42 ± 0.72 g/dL). While a wider and higher range of hgb seems to confer a survival advantage, differences in the patterns in the association between risk of death and hgb are seen at different levels of administered ESA, suggesting variability to increase the risk of death with higher cumulatively administered ESA doses.

Conclusions: Current US guidelines indicate hgb target range of 10 to 11 g/dL when treated with ESAs. Our retrospective research identified a wider and higher hgb range to be associated with lower mortality rates independent of variability. Based on the bivariate investigation, increased variability seems to confer a more accentuated risk increase at higher cumulative ESA doses. In-depth investigation in the underlying pathophysiological dynamics of hgb variability is imperative.

FR-PO398

Hemoglobin (hgb) Target Range Associated with All-Cause Repeated Hospitalization in Patients on Hemodialysis Treated with Mircera

Ariella E. Mermelstein,[1] Tomislav Kovacevic,[2] Jeffrey L. Hymes,[5] Yuedong Wang,[3] Jochen G. Raimann,[1] Peter Kotanko.[1,4] *[1]Renal Research Institute, New York, NY; [2]Vifor Fresenius Medical Care Renal Pharma Ltd, St Gallen, Switzerland; [3]University of California Santa Barbara, Santa Barbara, CA; [4]Icahn School of Medicine at Mount Sinai, New York, NY; [5]Fresenius Medical Care Holdings Inc, Waltham, MA.*

Background: A hgb of 10 to 11 g/dL is recommended for anemia HD patients treated with erythropoietin stimulating agents (ESAs) in the US. However, some recent retrospective analyses have shown lower hospitalization and death rates with higher hgb values than target. We previously studied the mortality risk and found the better range of hgb to be between 10.2 and 12.4 g/dL (Raimann, ASN 2023). We repeated our analyses to determine the risk of repeated hospitalizations for all causes.

Methods: Incident HD patients starting Mircera within 90 days of HD initiation were included. In patients with at least 5 hgb measurements during the 6 month baseline period after first dose of ESA, we quantified the mean hgb. We created a proportional hazard model for repeated hospitalizations in the following 18 months. The hazard ratio was plotted as a univariate spline function versus mean baseline hgb. Model was adjusted for age, sex, race, diabetes, serum albumin, and phosphate.

Results: We studied 62,181 HD patients (63.4 years, 57.2% male, 38.8% diabetic). The mean baseline hgb was 10.42 ± 0.72 g/dL). The hgb range associated with a significantly lower hazard ratio for all-cause hospitalization was 10.1 to 12.2 g/dL.

Conclusions: Current US guidelines call for a hgb target range of 10 to 11 g/dL. In our observational research, we identified a wider and higher hgb range to be associated with lower all-cause hospitalization. Limitations of retrospective research apply. Adequately powered and designed experimental studies are needed.

Hemoglobin, Albumin, Lymphocyte, and Platelet (HALP) Score Predicts the Clinical Prognosis of Patients with ESKD on Hemodialysis

Jin Sug Kim,[1] Jeong-Yeun Lee,[1] Hyun Kyu Kim,[1] Dae Kyu Kim,[1] Soo-Young Yoon,[1] Kyunghwan Jeong,[1] Hyeon Seok Hwang,[1] Yang Gyun Kim.[2] K-cohort Study Group. *[1]Kyung Hee University Medical Center, Seoul, Republic of Korea; [2]Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea.*

Background: Recently, the hemoglobin, albumin, lymphocyte, and platelet (HALP) score has emerged as a promising index for indicating nutritional status and systemic inflammation. Previous studies have reported its prognostic value in predicting clinical outcomes in various disease conditions. However, only a few studies have analyzed the HALP score in patients with end-stage kidney disease (ESKD) undergoing hemodialysis (HD).

Methods: This study is based on the K-cohort database, a prospective and multi-dialysis center cohort study. Of the 763 incident HD patients enrolled between 2016 and 2022, 543 with available HALP score calculation were included. Patients were divided into two groups (lower and higher HALP score groups) based on the median HALP score. We investigated the predictive value of the HALP score for the occurrence of cardiovascular events and all-cause mortality.

Results: The median HALP score in the study population was 30.7 (interquartile range 22.5-41.3). During a mean follow-up of 42-month, 89 (16.2%) patients experienced cardiovascular events, and 108 (19.7%) all-cause mortality were observed. Patients with a lower HALP score had a significantly higher incidence of cardiovascular events and all-cause mortality compared to patients with a higher HALP score. Multivariable Cox regression analysis revealed that patients with a higher HALP score had a lower risk of cardiovascular events (hazard ratio [HR] 0.540, 95% confidence interval [CI] 0.329-0.888, p = 0.015) and all-cause mortality (HR 0.558, 95% CI 0.363-0.858, p = 0.008) than patients with a lower HALP score.

Conclusions: We have shown that the HALP score is independently associated with cardiovascular events and all-cause mortality in patients with ESKD undergoing HD. The HALP score, which is easily obtained based on some indicators routinely collected during the treatment, may be a useful predictor of cardiovascular events and all-cause mortality in patients with ESKD undergoing HD.

FR-PO400

Impact of Erythropoietin Administration during Hospitalization on Postdischarge Hemoglobin among Patients on Hemodialysis

Mohammed A. Miqdad, Zainulabdeen S. Al-saedi, Lina Alatta, Sheng F. Kuo, Bruce S. Spinowitz. *New York Presbyterian Queens, Flushing, NY.*

Background: Hemoglobin(Hgb) concentration often decreases post hospital discharge among ESKD resulting from underlying cause of hospitalization, absence of erythropoietin (ESA) administration during hospitalization or inadequate dose of

ESA. There is no standardized guideline for management of anemia in such patients. The management may include conservative monitoring, continuation of ESA, or blood transfusion. To achieve quality care and exact cost efficiency, we planned to give all hospitalized ESKD patients 10,000 units per week subcutanoeous. This dose was intended to maintain a level of ESA to prevent apoptosis and maintain Hgb. An analysis of the outcome follows.

Methods: We undertook a retrospective review of the medical records of hemodialysis patients from a single satellite facility admitted to NYP Queens from January to December, 2023. The following data was extracted: Serum Hgb at time of admission, duration of hospital stay, units of blood transfusion, ESA administration during hospitalization, and post discharge hemoglobin upon return to the dialysis facility. The outcome analyzed was post discharge Hgb stability, defined as maintenance of baseline Hgb or increased Hgb concentration. Fisher exact test was utilized for statistical analysis. The Impact on hemoglobin blood transfusion and length of hospital stay were similarly evaluated. All data was gathered and analyzed in an anonymous fashion

Results: 78 patients met the inclusion criteria and have all the required laboratory parameters for review. 36 of these patients received ESA while 42, for unknown reasons, did not receive any ESA dose. This later group, effectively, served as an internal control. The data is displayed below as 2 x 2 tables with calculated P values.

Conclusions: There was no benefit of ESA administration to patients with ESKD during hospitalization, irrespective of length of stay. We speculate that administration of ESA for short-term hospitalization may not be required, resulting in significant cost savings with no negative clinical impact. Further randomized, blinded, multi-dosing ESA trial for patients with ESKD during acute hospitalization may affirm our finding.

Increased Mortality Risk Is Associated with Abnormal Iron Status in Japanese Patients on Hemodialysis: A Nationwide Cohort Study

Hiroki Nishiwaki,[1] Takahiro Imaizumi,[3] Takeshi Hasegawa,[4,2] Takaaki Kosugi,[5] Yukio Maruyama,[6] Kazuhiko Tsuruya,[5] Yasuhiko Ito,[7] Hirokazu Honda,[4] Takahiro Kuragano.[8] *[1]Showa University Fujigaoka Hospital, Yokohama, Japan; [2]Fukushima Kenritsu Ika Daigaku, Fukushima, Japan; [3]Nagoya University, Nagoya, Japan; [4]Showa University, Yokohama, Japan; [5]Nara Medical University, Kashihara, Japan; [6]Jikei University School of Medicine, Minato, Japan; [7]Aichi Medical University, Nagakute, Japan; [8]Hyogo Medical University, Nishinomiya, Japan.*

Background: There have been numerous studies on the characteristics of iron parameters in patients with end-stage kidney disease undergoing hemodialysis (HD), yet it remains unclear whether the interrelationships among these indicators are associated with increased mortality. We investigated the association between the interrelationships of these parameters and 1-year mortality.

Methods: The data utilized in this study were acquired from the Japanese Renal Data Registry (JRDR) database spanning the years 2019 to 2020. This study included patients who were alive and undergoing HD or hemofiltration three times a week without concurrent peritoneal dialysis therapy at the end of 2019. The exposures of interest were ferritin, transferrin saturation (TSAT), iron (Fe), and total iron binding capacity (TIBC). The outcome measure for this study was one-year all-cause mortality. The association between the combination of ferritin and TSAT, and the combination of TIBC and Fe, with mortality at one year was evaluated using contour plots of multivariate Cox proportional hazards models adjusted for the following variables including demographics, cardiovascular disease, laboratory data including C-reactive protein, and medications.

Results: The contour plot for the combination of ferritin and TSAT (Fig1) showed that the hazard ratio (HR) for mortality did not change significantly regardless of the ferritin value in the low TSAT group, but in the high TSAT group, higher ferritin was associated with death; in the combination of Fe and TIBC (Fig2), the HR for mortality was higher in the low Fe group at higher values of TIBC. This relationship disappeared when Fe was above the reference level.

Conclusions: The combination of ferritin and TSAT has been used in a similar approach in pre-dialysis CKD patients in previous studies (Cho 2019 and Guedes 2021), but the results are very different. The reasons for this difference lie in the disparity in populations and the addition of inflammatory markers as adjustment factors.

FR-PO402

To Be or Not to Be: Elevated Troponin and the Role of Secondary Prevention of Atherosclerotic Cardiovascular Disease in ESKD

Laverne Yip, Ammar A. Vohra, Chee Yao Lim, Kenneth Johan, May Hnin Pwint Soe, Mirtha C. Almanzar, Jorge Gutierrez, Pinal Patel, Juan Martinez Ortega, Rajiv Hans S. Menghrajani, Jiwon Park, Chidinma B. Chijioke, Vidya Menon. *Lincoln Medical Center, Bronx, NY.*

Background: Understanding the association between End-Stage Renal Disease (ESRD) and elevated troponin (cTn) is essential for assessing cardiovascular mortality as well as risk stratification and treatment. Our study aims to analyze mortality rates among ESRD patients with elevated cTn as well as explore the effect of aspirin, beta-blockers and statins on mortality outcomes.

Methods: This single-center observational retrospective study included ESRD patients admitted with elevated cTn from April 2020 to April 2022. Patients with a single cTn measurement on admission, a repeat cTn less than 6 hours from the initial, and admitted for cardiac arrest were excluded from the study. The SONG-HD modified criteria were used to classify the patients into type 1 MI (acute coronary syndrome), type 2 MI (demand ischemia), and chronic cTn elevation groups, and mortality among these was analyzed. Mortality outcomes in patients on aspirin, statin, and beta-blockers were assessed.

Results: 300 patients were included with a mean age of 62±13 years. 60% were male. 48% were Hispanic, 36% Black and 16% were other racial groups. There were no significant differences in mortality rates at admission across Type 1 MI, Type 2 MI, and chronic elevation (p=0.788), and at one year (p=0.699). Aspirin was associated with a significant reduction in mortality at admission (p=0.047) but not at one year (p=0.155). Beta-blockers and statins individually were associated with a significant reduction in mortality both at admission (p=0.001, p=0.005 respectively) and at one year (p=0.049, p=0.024 respectively). When adjusted for age, sex and race, statins were associated with lower mortality odds (OR=0.52, p=0.033) while older age was associated with higher odds (OR=1.024, p= 0.043).

Conclusions: MI subtypes and chronic cTn elevation have comparable mortality. Thus it is vital that diagnostic and therapeutic measures are implemented in all ESRD patients with elevated cTn to improve outcomes. Since ESRD is a low-grade inflammatory state with enhanced risk for atherosclerotic cardiovascular disease, statins, and beta-blockers could benefit ESRD patients. Recent studies have suggested this effect however, more research is needed.

FR-PO403

How Often Do Patients on Haemodialysis Have a Change of Heart? Variability of Troponin I Levels in Patients on Haemodialysis over 1 Year

Ivan Durlen, Petar Babic, Ivana Bedalov Crnkovic. *Dubrava University Hospital, Zagreb, Croatia.*

Background: Patients on chronic haemodialysis (HD) have remarkably higher risk for major adverse cardiovascular events. Haemodynamic and volume changes inbetween dialysis sessions lead to constant cardiac burdain and strain which could increase cardiac troponin levels without signs and symptoms of an acute coronary syndrome (ACS). This makes it more difficult to diagnose acute disorders. Primary goal was to evaluate the basal troponin values of HD patients on their first weekly treatment (the highest volume overload) and observe its oscillations over one year. Our previous trial showed the weekly coefficient of variability (CV) of 20% for troponin in HD patients.

Methods: Data of 55 patients (18 female, 37 male) undergoing chronic HD programme at Dubrava University Hospital were collected after aquiring informed consent. Troponin levels were measured 4 times during the period of one year (every 3 months) while collecting regular monthly tests, using Beckman Coulter High-Sensitivity Troponin I (hs-cTnI) assay - before the first session that week. The upper reference limit (URI) for hs-cTnI is <14.9 ng/L for female patients and <19.8 ng/L for male patients.

Results: The mean hs-cTnI were 30,1 ng/L, 28,0 ng/L, 29,1 ng/L and 33,3 ng/L with mean value of every measurement 29,9 ng/L. The mean values were higher in male patients (33,4 ng/L) than in female patients (22,7 ng/L), but twice more male patients had troponin values in the refference interval, 57% opposed to just 28% in female patients. However, more male patients had troponin values higher than 50 ng/L (6 males, 1 female). Comparing patients on HD and haemodiafiltration (HDF) the average troponine value was two times lower in HD patients (21,9 ng/L) than in HDF patients (43,2 ng/L). The

coefficient of variation was measured for each patient and the mean CV for hs-cTnI values was 31% (3% - 91%) with significant difference between female (26%) and male (34%) patients, and between HD (29%) and HDF (34%) patients.

Conclusions: Our results show that hs-cTnI values were elevated in 53% of patients on chronic HD without signs of ACS. During one year hs-cTnI values had variability of 31%. The variability was lower in female patients (26%) and in patients on HD (29%). Patient's hs-cTnI mean value could be taken as a personal basal value for comparison when diagnosing ACS.

Predictors of New-Onset Atrial Fibrillation in Patients with ESKD: A Multicenter, Retrospective, Observational Cohort Study

Jonathan Mina, Fadi Haddadin, Shaza Almardini, Khalil El Gharib, Suzanne E. El Sayegh. Staten Island Team. *Staten Island University Hospital, Staten Island, NY.*

Background: According to the CDC, A.Fib is the most prevalent heart arrhythmia, cited in 183,321 US deaths in 2019, with 26,535 directly attributed. ESRD is a leading cause of US mortality, impacting 37 million adults. Previous studies link CKD with increased A.fib risk, possibly due to shared risk factors. Our study examines predictive factors for new onset A.fib in ESRD patients at Northwell Health System.

Methods: 6,814 cases of ESRD patients were identified from February 2018 to December 2020. Patients with a prior history of A.Fib were excluded. Patients with missing or extreme BMI data and missing tobacco use data were excluded. Sample size was 5,326. 1,564 diagnosed with ESRD experienced new-onset A.Fib (cases) while 3,762 had no history of A.Fib (controls). Predictors studied were CAD, BMI, Sex, Race, Ethnicity, HTN, Diabetes (DM), and Smoking Status.

Results: Out of the 5,326 ESRD patients, 1,564 (29.4%) were cases, and 3,762 (70.6%) were controls. Increasing age (OR 1.038/yr, p<0.0001), obesity (OR 1.225, p=0.0135), and CAD (OR 1.682, 95%, p<0.0001) were linked to higher odds of A.Fib. African American and other racial patients had decreased odds compared to Whites (OR 0.581 and OR 0.772, respectively). HTN, sex, DM, and smoking did not significantly associate with A.Fib risk.

Conclusions: Age, obesity, and CAD were risk factors for new onset Afib in ESRD, while African American and other racial patients had lower odds compared to Whites. HTN, sex, DM, and smoking showed no significant associations. Further research should delve into underlying mechanisms, explore interventions for A.Fib risk in vulnerable populations, and assess demographic factors' impact on outcomes.

Odds Ratio Estimates

Prevalence and Predictors of Bleeding Events in Patients with ESKD Who Have Autosomal Dominant Polycystic Kidney Disease: A National Database Analysis

Jonathan Mina, Chapman Wei, Fares Saliba, Fadi Haddadin, Ahmad Mustafa, Khalil El Gharib, Suzanne E. El Sayegh. *Staten Island University Hospital, Staten Island, NY.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a genetic disorder characterized by the growth of numerous cysts in the kidneys, often leading to kidney failure and necessitating dialysis. A critical yet underexplored complication in ADPKD patients undergoing dialysis is the incidence and severity of bleeding. This research aims to systematically investigate the prevalence and risk factors of bleeding in ESKD patients with ADPKD.

Methods: ADPKD patients with End Stage Kidney Disease (ESKD) were extracted from the National Inpatient Sample (NIS) database (2016-2018). Demographics, medication history, and comorbidities were extracted from the database using ICD-10 codes. The following bleeding events were analyzed: All Bleeding events, Gastrointestinal (GI) bleeding, Hematuria, Hemorrhagic strokes, Respiratory bleeding, and Other hemorrhages. Patient variables were analyzed using Chi-Square analysis, T-test, and binary logistic regression analysis. P-value < 0.05 was considered significant.

Results: Of the 4255 ADPKD patients with ESKD, there were 185 patients with bleeding events. The most common bleeding event was GI bleed (51.9%), followed by hematuria (36.2%), and hemorrhagic strokes (8.6%). Patients that had bleeding were more likely to be older the 65 years old, have chronic heart failure and have coagulable disorders. After binary logistic regression, the factors that predict bleeding events are chronic heart failure (OR: 1.5 [1.1-2.2]; p=0.02), and obesity (OR:1.6 [1.04-2.32], p=0.03).

Conclusions: In conclusion, 5% of ESKD patients with ADPKD, have a bleeding event. The predictors of bleeding are chronic heart failure and obesity. Larger prospective studies should be performed to corroborate with our findings.

Title: Factors Predicting Bleeding Events in ESKD Patients with ADPKD

FR-PO406

Comparative Outcomes and Risk Analysis of Stroke Incidence in Adult Patients on Dialysis

Sanat Subhash, Haziq H. Rabbani, Rupesh Raina. *Department of Nephrology, Akron Nephrology Associates/Cleveland Clinic Akron General Medical Center, Akron, OH.*

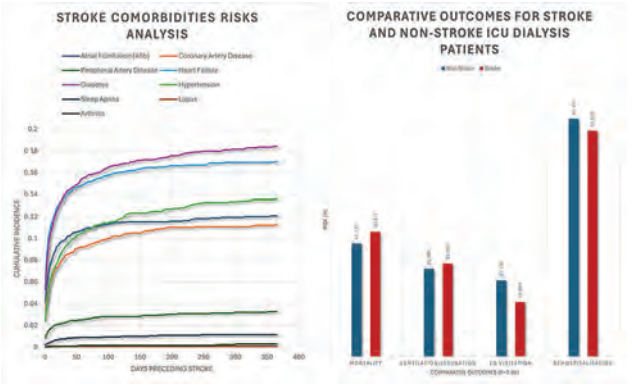
Background: Kidney failure requiring dialysis and its associated costs create substantial burdens on healthcare systems. This study leverages electronic healthcare data to analyze comorbid stroke incidence in ICU dialysis patients over time, characterize stroke epidemiology, and compare outcomes between ICU dialysis stroke patients and non-stroke ICU dialysis patients.

Methods: Using ICD-10 and CPT code queries, adult (18-90 years) ICU patients on dialysis from March 2004 to March 2024 were categorized into three cohorts: (1) non-stroke patients (n=120,414), (2) stroke patients (n=5,750), and (3) ICU dialysis patients (n=128,564). These cohorts were filtered by exclusion factors (kidney transplant status and history of stroke). Cohorts 1 and 2 were propensity-matched for severity of illness (use of vasopressors or ventilation), demographics, diagnoses, medications, and lab values (n=5,698) and used for the comparative outcomes analysis. Cohort 2 pre-matching was also used for the risks analysis, and cohort 3 was used for the incidence and prevalence analysis.

Results: The identified comorbidities for stroke were diabetes (18.42% of patients), heart failure (17.01%), hypertension (13.62%), atrial fibrillation (12.07%), coronary artery disease (11.27%), peripheral artery disease (3.27%), sleep apnea (1.16%), arthritis (0.29%), and lupus (0.08%). ICU dialysis stroke patients had significant increases (p<0.05) in rates of mortality (+4.30%) and ventilation/intubation (+1.98%), while non-stroke

patients had significant increases (p<0.05) in ED visitation (+7.95%) and rehospitalization (+4.42%). ICU readmission rates showed no significant difference (p=0.07). Women and older adults reported higher stroke risk, but there were no significant disparities across racial and ethnic groups.

Conclusions: Stroke has a significant, adverse impact on ICU dialysis patients. Preventative strategies targeting stroke comorbidities are crucial to enhancing patient well-being and mitigating stroke burden.



FR-PO407

Cardiac Arrhythmia and Hypoglycemia in Patients Receiving Hemodialysis with and without Diabetes (the CADDY study): A Danish Multicenter Cohort Study

Dea H. Kofod,[1] Søren Zöga Diederichsen,[1] Tobias Bomholt,[1] Mads Ørbæk Andersen,[1] Ebba Mannheimer,[1] Marianne Rix,[1] Ylian S. Liem,[1] Kristine Lindhard,[2] Henrik P. Hansen,[2] Casper Rydahl,[2] Morten Lindhardt,[3] Kristine D. Schandorff,[4] Julie M. Brøsen,[4] Theis Lange,[6] Kirsten Noergaard,[5] Thomas P. Almdal,[1] Jesper Hastrup H. Svendsen,[1] Bo Feldt-Rasmussen,[1] Mads Hornum.[1]
[1]Rigshospitalet, Kobenhavn, Denmark; [2]Herlev Hospital, Herlev, Denmark; [3]Holbaek Sygehus, Holbaek, Denmark; [4]Nordsjaellands Hospital, Hillerod, Denmark; [5]Steno Diabetes Center Copenhagen, Herlev, Denmark; [6]Kobenhavns Universitet, Kobenhavn, Denmark.

Background: Patients in hemodialysis (HD) are at increased risk of arrhythmias, and dysregulated blood plasma is proposed as a possible risk factor.

Methods: In an 18-month observational cohort study, 70 patients in maintenance HD treatment (35 with diabetes) were monitored with implantable loop recorders and continuous glucose monitoring (CGM). The primary endpoint was the presence of clinically significant arrhythmias (CSA): a combined endpoint of significant bradyarrhythmia, ventricular tachycardia, or ventricular fibrillation. Logistic regressions adjusted for age and sex were used to examine risk factors of CSA.

Results: A total of 1347 CSA were detected in 23 (33%) patients. Table 1 shows CSA and CGM data. Number of hypoglycemic events, time below range, or time above range were not associated with increased odds for CSA (P>0.05), neither in the overall group nor in the diabetes or no-diabetes groups separately.

Conclusions: Patients in HD have a high risk of CSA, but we found no association between CSA and hypoglycemia or time below or above range.

Funding: Commercial Support - Dexcom, Medtronic, Private Foundation Support

Predialysis Causal Blood Glucose Level and Mortality in Diabetic Patients on Hemodialysis: A Nationwide Cohort Study from Japan

Shun Manabe,[1] Momoko Seki,[1] Yusuke Ushio,[1] Yuki Kawaguchi,[1,3] Hiroshi Kataoka,[1] Masanori Abe,[2,3] Norio Hanafusa,[1,3] Junichi Hoshino.[1,3] Committee for Renal Data Registry, Japanese Society for Dialysis Therapy.
[1]Tokyo Women's Medical University, Shinjuku-ku, Japan; [2]Nihon University School of Medicine, Itabashi-ku, Japan; [3]Committee for Renal Data Registry, Japanese Society for Dialysis Therapy, Bunkyo-ku, Japan.

Background: Blood glucose level (BGL) is the simplest indicator for glycemic control in diabetic patients; however, it remains unclear which predialysis causal BGL is associated with the lowest mortality in diabetic hemodialysis (HD) patients. We examined the association between predialysis causal BGL and mortality in a cohort from the Japanese Society for Dialysis Therapy.

Methods: We examined maintenance HD patients with diabetes in December 2018, and followed for 3 years. Patients with insufficient dialysis, those with organ transplantation, those with BGL greater than 401 mg/dL, and those with incomplete records for Hb, Alb, or glycemic control were excluded from the analysis. A total of 104,846 patients (29% female; mean age 68.5±11.5; mean dialysis vintage 5.8±5.0 years) were analyzed. Crude and adjusted hazard ratios (HRs) and 95% confidence intervals (CIs) were calculated for 3-year mortality after adjusting for 20 potential confounders, including age, sex, dialysis vintage, dialysis modality, vascular complications, smoking, type of diabetes, BMI, use of antihypertensive agents, use of hypoglycemic agents, facility type, Kt/V, nPCR, Hb, Alb, CRP, HDL colesterol, Ca, iP, and PTH. Subgroup analyses were performed in patients with serum Alb <3.5 g/dL and those with malnutritional status by the criteria of Global Leadership Initiative on Malnutrition (GLIM).

Results: We found an U-shaped association between 3-year adjusted mortality and predialysis causal BGLs of ≥141-160 mg/dL [HR 1.10 (1.03-1.17)] and ≥161-180 mg/dL [HR 1.14 (1.06-1.21)], respectively, with the lowest mortality at BGLs of 101-120 mg/dL. Similar U-shaped associations were observed in the sensitivity analyses for patients with malnutritional status, though this trend flattened in these patients. In addition, the adjusted HRs were significantly higher at BGLs of 161-180 mg/dL in patients with low serum Alb (<3.5 mg/dL) [HR 1.11 (1.02-1.22)], and in those with GLIM criteria [HR 1.17 (1.03-1.32)].

Conclusions: Predialysis causal BGL was significantly associated with 3-year mortality in diabetic HD patients. In patients with malnutritional status, such as those with serum Alb < 3.5 mg/dL or those with GLIM criteria, a BGL cutoff of 161-180 mg/dL may represent a promising target for glycemic control in these patients.

FR-PO409

Association of Serum Procalcitonin with All-Cause and Cardiovascular Mortality in Patients with ESKD

Kishan Sinojia,[1] Yamini Mallisetty,[1] Zhongji Han,[1] Chi-Yang Chiu,[1] Jesse C. Seegmiller,[2] Amy B. Karger,[2] Csaba P. Kovesdy,[1] Keiichi Sumida.[1,3]
[1]The University of Tennessee Health Science Center, Memphis, TN; [2]University of Minnesota, Minneapolis, MN; [3]VA Memphis Medical Center, Memphis, TN.

Background: Serum procalcitonin (sPCT) is a diagnostic marker of active bacterial infection. Other conditions may also induce sPCT such as proinflammatory cytokines and non-infectious inflammatory conditions. Elevated sPCT has been associated with poor clinical outcomes like cardiovascular disease (CVD) in various patient populations and even in healthy individuals. However, little is known about sPCT associations with all-cause and CV mortality in patients with end-stage kidney disease (ESKD).

Methods: In a nationwide prospective cohort of 941 patients receiving maintenance hemodialysis from 2011-2013, we examined the association of baseline sPCT with all-cause and CV mortality, using the Kaplan-Meier method and Cox proportional hazards models with adjustment for age, sex, dialysis vintage, vascular access type, BMI, systolic blood pressure, Charlson Comorbidity Index, ischemic heart disease, diabetes mellitus, serum albumin, hemoglobin, white blood cell count, infectious hospitalization, culture-positive bacteremia, and antibiotic or antifungal use. Since a sPCT does not have a universal cut-off interval accepted in dialysis patients, sPCT was treated as a median-stratified binary variable (≥ vs. <0.51 ng/mL).

Results: Overall, patients were 60±13 years old; 53% were male; 40% were African American; and 57% were diabetic. The mean dialysis vintage was 4.3±3.8 years. No patient had clinical evidence of infection at baseline. During a median follow-up of 2.2 years, 204 and 74 patients experienced all-cause and CV death, respectively. The all-cause and CV death rates were higher in those with higher sPCT (log-rank P = 0.033 and 0.13, respectively; Figure). The adjusted hazard ratios [95% CI] of all-cause and CV mortality associated with higher sPCT were 1.48 [1.11-1.98] and 1.67 [1.03-2.69], respectively.

Conclusions: Higher sPCT was significantly associated with higher risk of all-cause and CV mortality in patients with ESKD. sPCT may be a useful biomarker for the risk of premature death even in those without overt infection.

Associations between Femoral Neck Bone Mineral Density, Kt/Vurea, and Mortality in Patients on Hemodialysis

Sonoo Mizuiri,[1] Yoshiko Nishizawa,[1] Toshiki Doi,[1,2] Aiko Okubo,[1,2] Kenichi Morii,[1,2] Kazuomi Yamashita,[1] Kenichiro Shigemoto,[1] Tomio Mikami,[1] Takao Masaki.[2] *[1]Iryo Hojin Ichiyokai Harada Byoin, Hiroshima, Japan; [2]Hiroshima Daigaku, Higashihiroshima, Japan.*

Background: Several studies have reported the relationships between bone mineral density (BMD), clinical data, and mortality in patients on hemodialysis (HD). However, the relationship between BMD and dialysis efficiency is unclear, and it is unknown which site has a BMD most strongly associated with mortality.

Methods: The cohort comprised 291 patients on maintenance HD. We evaluated the BMD parameters and influence of the BMD at different sites on mortality. BMD, body composition, and clinical data were obtained at baseline and followed up for 3 years. BMD was measured at femoral neck, distal mid-third radius, and lumbar spine using dual energy X-ray absorptiometry. BMD was expressed as percentage of the young adult mean and used to define osteoporosis (BMD<70%), osteopenia (70%≤BMD<80%), and normal BMD (BMD≥80%). Multiple regression analysis for BMD and Kaplan-Meier survival and Cox-Hazard analyses were performed.

Results: The mean age was 65±12 years, 67% were men, the dialysis duration was 73 (36–141) months, and diabetes prevalence was 42.6%. The femoral neck, radius, and lumbar spine were osteoporosis in 118 (40.6%), 90 (30.9%), and 31 (10.7%) patients, respectively, and were osteopenia in 74 (25.4%), 43 (14.8%), and 26 (8.9%) patients, respectively. Compared with the normal BMD group, patients with osteoporosis or osteopenia at all three sites had a significantly higher age, tartrate-resistant acid phosphatase 5b concentration, and Kt/Vurea, but a significantly lower geriatric nutritional risk index, body mass index, and lean tissue index (P<0.05). Kt/Vurea was a significant predictor of the BMD at the femoral neck (β -0.16), radius (β -0.17), and lumbar spine (β -0.23) after adjusting for age, sex, dialysis duration, and diabetes (P<0.05). The 3-year survival rates were 76%, 89%, and 91%, respectively, in patients with osteoporosis, osteopenia, and normal BMD in the femoral neck (P<0.05); but did not differ according to the BMD of the radius and lumbar spine. The femoral neck BMD was a significant predictor of 3-year all-cause mortality, while the radius and lumbar spine BMDs were not.

Conclusions: In patients on maintenance HD, the femoral neck BMD was a significant predictor of 3-year all-cause mortality. The results also suggested an association between BMD and Kt/Vurea.

Association of Serum Nickel Concentrations with Clinical Characteristics in Patients with ESKD Undergoing Hemodialysis

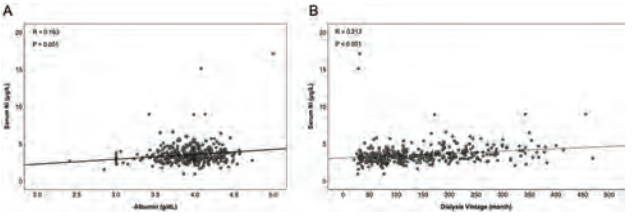
Wen-Yu Ho, Ching-Wei Hsu, Tzung-Hai Yen. Clinical Poison Center, Chang Gung Memorial Hospital. *Department of Nephrology, Chang Gung Memorial Hospital, Taoyuan City, Taiwan.*

Background: Limited studies have investigated serum nickel concentrations in patients with end-stage renal disease (ESRD) undergoing hemodialysis, and the association of serum nickel concentration with dialysis-related profiles is unknown.

Methods: The investigators conducted a prospective cohort study at a tertiary medical center in Taiwan. 409 patients with ESRD undergoing permanent hemodialysis were enrolled. Serum nickel concentrations, hematological and biochemical laboratory data, dialysis-related data, and patient demographics were obtained at baseline. The patients were stratified into 4 quartiles according to serum nickel concentrations. All-cause mortality was recorded after an 18-month follow-up period.

Results: Ninety-eight percent of the patients had elevated serum nickel concentrations compared to the reference value (2 μg/L). There was a significant trend among the four groups, where a greater quartile of serum nickel concentration had higher levels of hemoglobin, albumin, high-density lipoprotein (HDL), and lower levels of white blood cell (WBC), uric acid, triglyceride, and log high-sensitivity C-reactive protein (hs-CRP). Furthermore, a greater quartile of serum nickel had a longer dialysis vintage, higher Kt/V, and higher urea removal rate (URR). Multivariate analysis revealed that albumin level and dialysis vintage were independent factors associated with serum nickel concentration. A positive correlation was observed between albumin level and dialysis vintage with serum nickel concentration (R = 0.163, P = 0.001; R = 0.212, P < 0.001, respectively). There was no statistically significant difference in the all-cause mortality rate across the quartiles.

Conclusions: The majority of ESRD patients undergoing hemodialysis had elevated serum nickel concentrations above the reference level. Longer dialysis vintage and higher albumin level were associated with higher serum nickel concentrations. No association was observed between serum nickel concentration and the all-cause mortality rate.



(A) Correlation between serum nickel and albumin. (B) Correlation between serum nickel and dialysis vintage.

Multiple Air Pollutant Exposure Is Associated with Higher Risk of All-Cause Mortality in Patients on Dialysis: A French Registry-Based Nationwide Study

Aghiles Hamroun,[1,2] Michaël Génin,[1] François Glowacki,[1] Cécile Couchoud,[3] Florent Occelli.[1] *[1]Centre Hospitalier Universitaire de Lille, Lille, France; [2]Institut Pasteur de Lille, Lille, France; [3]Agence de la biomedecine, La Plaine Saint-Denis, France.*

Background: Little is known about the effect of combined exposure to different air pollutants on mortality in dialysis patients. This study aims to investigate the association of multiple exposure to air pollutants with all-cause and cause-specific death in dialysis patients.

Methods: This registry-based nationwide cohort study included 90,373 adult kidney failure patients initiating maintenance dialysis between 2012 and 2020 identified from the French REIN registry. Estimated mean annual municipality-levels of $PM_{2.5}$, PM_{10} and NO_2 between 2009 and 2020 were combined in different composite air pollution scores to estimate each participant's exposure at the residential place one to three years before dialysis initiation. Adjusted cause-specific Cox proportional hazard models were used to estimate hazard ratios per interquartile range (IQR) greater air pollution score. Effect measure modification was assessed for age, sex, dialysis modality, and baseline comorbidities.

Results: Higher levels of the main air pollution score were associated with a greater rate of all-cause deaths (HR, 1.074 [95% CI, 1.053-1.095] per IQR increase), regardless of the exposure lag. This association was also confirmed in cause-specific analyses, most markedly for infectious mortality (HR, 1.559 [95% CI, 1.365-1.781]). Sensitivity analyses with alternative composite air pollution scores showed consistent findings. Subgroup analyses revealed a significantly stronger association among women and less comorbid patients (Figure 1).

Conclusions: Long-term multiple air pollutant exposure is associated with all-cause and cause-specific mortality among patients receiving maintenance dialysis, suggesting that air pollution may be a significant contributor in the increasing trend of CKD-attributable mortality worldwide.

FR-PO413

Prescription Patterns of Proton-Pump Inhibitors and Antiplatelet Therapy as Risk Factors for Gastrointestinal Bleeding in Patients on Hemodialysis

Michael Che,[1] Sumaiya Ahmed,[1] Ryan J. Chan,[2] Ayub Akbari,[1] Deborah Lynn Zimmerman.[1] *[1]University of Ottawa, Faculty of Medicine, Division of Nephrology, Ottawa, ON, Canada; [2]University of Toronto, Department of Medicine, Division of Nephrology, Toronto, ON, Canada.*

Background: There is an increased risk of gastrointestinal bleeding (GI) in patients with end stage kidney disease (ESKD) for reasons including uremic platelet dysfunction, co-morbid illness, and use of antiplatelet agents. Proton pump inhibitors (PPI) reduce GI bleeding and are recommended for high-risk patients such as those prescribed dual antiplatelet therapy (DAPT). Whether inappropriate prescription of DAPT and/or lack of appropriate use of PPIs contribute to gastrointestinal bleeding risk in hemodialysis patients is not currently known. Thus, the objective of our project was to determine whether patients with ESKD are appropriately prescribed DAPT and PPI therapy.

Methods: A chart review was performed at a satellite hemodialysis unit of The Ottawa Hospital in Ontario, Canada in July 2023. Patients' medical history and use of antiplatelets, PPIs, anticoagulants, non-steroidal anti-inflammatories (NSAIDs), and corticosteroids were identified. Patients' indications for PPI and DAPT were elucidated. Subsequently, a note was added to the electronic medical record and communicated to the patients' primary nephrologist stating if a patient was taking DAPT/PPI and whether these medications were indicated. Adjustments to medications could be made thereafter if needed.

Results: Of 88 hemodialysis patients, 44 were on antiplatelet therapy (4 on DAPT), 1 on NSAID, 12 on corticosteroids, 7 on anticoagulants, 2 on histamine H2-receptor antagonists, and 39 on PPIs. Fourteen percent of PPI users had absolute indication for therapy. One patient in whom PPI therapy was indicated was not prescribed one. Three of 4 DAPT users met current indications for therapy; 1 had a prior indication for DAPT and after review with their primary nephrology team, the patient was reduced to single antiplatelet therapy.

Conclusions: Only one patient in our study had an absolute indication for PPI but had not been prescribed one, and one patient prescribed DAPT no longer met criteria for continued use. Overall, prescribing patterns of DAPT and PPI are unlikely to be a major contributor to the increased risk of gastrointestinal bleeding in patients on hemodialysis at our center. Nevertheless, review of medications and medical history may improve outcomes in patients who have been inappropriately prescribed these therapies.

FR-PO414

Prediction of Gastrointestinal Bleeding Hospitalization Risk in Hemodialysis: Machine Learning vs. Logistic Regression

Suman K. Lama,[1] John W. Larkin,[1] Sheetal Chaudhuri,[1] Yue Jiao,[1] Anke Winter,[2] Manuela Stauss-Grabo,[2] Len A. Usvyat,[1] Jeffrey L. Hymes,[1] Franklin W. Maddux,[3] David C. Wheeler,[4] Peter Stenvinkel,[5] Jürgen Floege.[6] On behalf of the INSPIRE Core Group. *[1]Fresenius Medical Care, Waltham, MA; [2]Fresenius Medical Care Germany, Bad Homburg, Germany; [3]Fresenius Medical Care AG, Bad Homburg, Germany; [4]University College London, London, United Kingdom; [5]Karolinska Universitetsjukhuset Huddinge Njurmedicinska kliniken, Stockholm, Sweden; [6]Rheinisch-Westfalische Technische Hochschule Aachen, Aachen, Germany.*

Background: Gastrointestinal bleeding (GIB) is the most common bleeding event in dialysis. INSPIRE group aimed to see if machine learning (ML) models (XGBoost and logistic regression) can identify GIB related hospitalization risk in hemodialysis (HD) patients.

Methods: We used data from adult dialysis patients treated for ≥30 days at a kidney care network (Jan2018-Mar2021). GIB hospitalization was defined based on ICD diagnosis codes recorded as primary, secondary, or tertiary discharge reason. Two distinct models were created using XGBoost and logistic regression on same dataset. Performance was evaluated using area under receiver operating curve (AUROC), accuracy, sensitivity and specificity. Data was randomly divided into 60% training, 20% test and 20% validation datasets. We used unseen patients and data in test data to evaluate the performance of the model.

Results: Incidence rate of 180-day GIB hospitalization was 1.12% in our test data. AUROC was 0.74 for XGBoost and 0.68 for logistic regression. XGBoost achieved a specificity of 0.68 and a sensitivity of 0.65, while logistic regression demonstrated a specificity of 0.57 and a sensitivity of 0.69. Both models identified age, distribution in anemia/iron indices, recent all-cause hospitalization and bone mineral metabolism markers as strong predictor.

Conclusions: ML modeling has potential to detect of GIB hospitalization risk in hemodialysis patients. XGBoost model outperforms logistic regression, yet both performed well. The link between bone mineral metabolism markers and GI bleeding was not anticipated and merits further investigation. Additional validation may be required to ensure model reliability before implementation in a clinical setting.

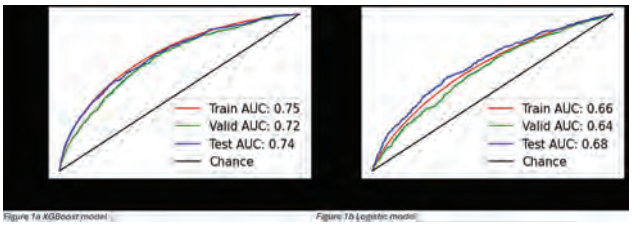

Figure 1 AUROC of GI Bleed model with XGBoost and Logistic Regression model

FR-PO415

Preoperative Kt/Vurea and Postoperative Outcomes in Patients on Maintenance Hemodialysis

Vikram Fielding-Singh,[1] Glenn M. Chertow,[1] Eugene Lin.[2] *[1]Stanford University School of Medicine, Stanford, CA; [2]University of Southern California, Los Angeles, CA.*

Background: Little is known about whether the hemodialysis prescription prior to surgery affects outcomes. This study investigated the association between changes in preoperative hemodialysis dosing and postoperative outcomes.

Methods: We identified adult patients receiving thrice weekly maintenance hemodialysis who underwent surgical procedures from 2011-2020 in the USRDS. The primary exposure was the difference between the Kt/V_{urea} of the last hemodialysis session prior to the procedure and the patient's average Kt/V_{urea} over the previous 6 months (i.e., whether the preoperative session was lower, the same, or higher than usual). All models included the mean and standard deviation of Kt/V_{urea} values for the 6 months preceding the surgical procedure, in addition to demographic and procedural characteristics. To estimate the association between preoperative deviation in Kt/V_{urea} and postoperative outcomes, we fit multivariable Cox proportional hazards models. A 2-sided $p<0.05$ was considered statistically significant.

Results: Of 151,240 procedures, 31,825 (21.0%) of procedures had a preoperative decrease in Kt/V_{urea} of 0.10 or more, 43,790 (29.0%) had a preoperative decrease in Kt/V_{urea} of less than 0.10, 45,058 (29.8%) had a preoperative increase in Kt/V_{urea} of 0 to <0.10, and 30,567 (20.2%) had a preoperative increase in Kt/V_{urea} of 0.10 or more. In adjusted analysis, compared to patients with a preoperative increase in Kt/V of 0 to <0.10, risk of 30-day mortality was 1.50 (95% CI, 1.32, 1.70) times higher with a preoperative Kt/V decrease of more than 0.10 and was 1.16 (95% CI, 1.02,1.31) times higher with a preoperative Kt/V decrease of less than 0.10.

Conclusions: Among Medicare beneficiaries receiving maintenance hemodialysis, preoperative decreases in Kt/V_{urea} were significantly associated with postoperative mortality.

Association Between Change in Preoperative Kt/V From 6-Month Baseline Kt/V and Perioperative Outcomes

FR-PO416

Impact of Lupus on Mortality and Causes of Death in Patients on Dialysis: Okinawa Dialysis Study (OKIDS) Registry

Nanako Oshiro,[1] Kentaro Kohagura,[1] Kenya Kusunose,[2] Kunitoshi Iseki.[3]
[1]Dialysis Unit, University of the Ryukyus Hospital, Nishihara-cho, Japan; [2]Department of Cardiovascular Medicine, Nephrology and Neurology, Graduate School of Medicine, University of the Rykyus, Nishihara-cho, Japan; [3]Nakamura Clinic, Urasoe-city, Japan.

Background: Lupus nephritis is one of the most serious complications of systemic lupus erythematosus (SLE), resulting in end-stage kidney disease (ESKD). Despite the introduction of immunosuppressive drugs in the 1990s, a certain number of patients with SLE still develop ESKD. It is known that after dialysis is initiated, SLE patients experience decreased disease activity and can discontinue steroids and immunosuppressive drugs at reduced doses (burn-out). However, it has been reported that hemodialysis patients with SLE have a lower life expectancy than non-SLE patients, although little is known about the causes of death. Our goal was to assess the relative risk of mortality and its causes associated with SLE among dialysis patients in Japan.

Methods: This retrospective longitudinal cohort study using the Okinawa Dialysis Study (OKIDS) registry included all chronic dialysis patients treated in Okinawa, Japan. Kaplan-Meier survival analyses were performed. The study included dialysis patients treated between 1 June 1971 and 31 December 2000, covering the entire OKIDS registry collection period. Patients were censored at death, renal transplantation, or when moving out of Okinawa. Cox proportional hazard models were used to assess whether SLE as a cause of ESKD was associated with an increased risk of death.

Results: A total of 5,246 patients (2,981 male and 2,265 female) were included in this study. There were 111 patients with ESKD secondary to SLE, 87 of whom were female. The patients with ESKD secondary to SLE had a more than 2-fold increased risk of death compared with other patients with ESKD (hazard ratio [HR]: 2.55, 95% confidence interval [CI]: 1.81-3.47, P< 0.0001), after adjusting for age, era at initiation of dialysis, and gender. When the cause of mortality was analyzed, the risk of cardiovascular death (HR: 1.94, 95% CI: 1.13-3.33, P=0.0158) and death due to infection (HR: 4.12, 95% CI: 2.40-7.37, P< 0.0001) were significantly high in SLE patients.

Conclusions: Our study has revealed the heightened mortality risk among dialysis patients secondary to SLE. While dialysis patients with SLE tend to be relatively young, we need to recognize that they constitute a high-risk group for mortality, emphasizing the importance of careful management of their treatment.

FR-PO417

Decreased Risk of Dialysis-Related Amyloidosis in the 2010s: Results from Japanese Nationwide Surveys in 2010 and 2017

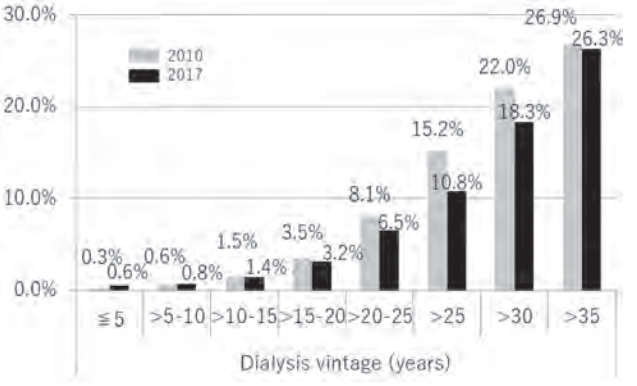
Junichi Hoshino,[1] Yusuke Ushio,[1] Yuki Kawaguchi,[1] Shun Manabe,[1] Hiroshi Kataoka,[1] Suguru Yamamoto,[2] Masanori Abe,[3] Norio Hanafusa.[1] The Committee of Renal Data Registry, the Japanese Society for Dialysis Therapy. *[1]Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan; [2]Niigata Daigaku, Niigata, Japan; [3]Nihon Daigaku, Chiyoda-ku, Japan.*

Background: Incidences and risk factors of dialysis-related amyloidosis may be changed with improvement of dialysis technologies. In this study, we aimed to clarify recent incidences of operation of carpal tunnel syndrome (CTS) by using two large-scale data.

Methods: We used the Japan Renal Data Registries for 2010 and 2017 to compare the crude risk of CTS during the following year, excluding patients with a history of CTS, those who received temporary dialysis or transplantation, and those whose data were incomplete or outliners. The crude risks of new CTS among every 5 years of dialysis vintage up to 35 years or more in the 2010 and 2017 cohorts were analyzed.

Results: A total of 167,793 patients in the 2010 cohort (female, 37%; mean age, 67.4±12.5 years; and mean dialysis vintage, 7.2±6.5 years) and 164,102 patients in the 2017 cohort (female, 35%; mean age, 69.6±12.4 years; and mean dialysis vintage, 7.6±7.0 years) were analyzed. Of the 2010 patients, 1.31% experienced first-time CTS compared with 1.53% of the 2017 cohort. In the 2017 cohort, the crude risks among dialysis vintage 15-20, 20-25, 25-30, 30-35, and over 35 years were 3.2 (95%CI, 2.9-3.5), 6.5 (5.9-7.2), 10.8 (9.7-11.9), 18.3 (16.3-20.5), and 26.3 (23.2-29.6)%, respectively. Those risks were reduced up to 30% from the same dialysis vintage in the 2010 cohort, though the difference was very small in patients with vintage over 35 years.

Conclusions: We previously reported the incidence of first-time onset of CTS was significantly reduced from 1998 to 2010, especially for patients with longer dialysis vintage. The incidence of CTS was also reduced from 2010 to 2017 among the same vintage group, though the degree of reduction was smaller than the previous decade and not observed in patients with dialysis vintage over 35 years.



FR-PO418

Outcomes of Patients with Nonkidney Medical Therapies Dialyzed at Chronic Hemodialysis Centers

Michael A. Kraus, Carol Lee, Amanda Stennett, Lisa E. Koenig, Rheannon Smith, Linda Ficociello, Dinesh K. Chatoth, Jeffrey L. Hymes. *Fresenius Medical Care, Waltham, MA.*

Background: Patients (pts) with non-renal medical therapies (NRMT) such as wearable defibrillators, tracheostomies, continuous cardiac infusions, or left ventricular assist devices (LVAD) may face challenges when seeking dialysis outside of a nursing facility with in-house dialysis or a hospital setting. Fresenius Kidney Care has established policies and a developed process in which requests for dialysis are reviewed by a team of nurses and physicians with collaboration of the dialysis facility. The current analysis aims to determine outcomes of these pts in a chronic hemodialysis unit.

Methods: As part of a quality initiative, we retrospectively assessed time before discharge (due to any reason including renal recovery, transplant, and death) by period (1, 3, 6, and 12 months) for all pts starting treatment 1/22-12/23. At each comparison, only those pts who were eligible for that length of follow-up are included. For the overall analysis, each person is included only once. In the NRMT analysis, a person with multiple NRMT would appear in multiple columns. A group with <5 people (artificial total heart) was not included in the NRMT analysis.

Results: Time on dialysis (no discharge), overall and by NRMT grouping, is shown in table 1. Overall, 87%, 72%, 58%, and 45% of pts were dialyzed at least 1, 3, 6, and 12 months, respectively. There were 0.50 deaths/patient year (py), 0.14 renal recoveries/py, and 0.01 transplants/py. 22% were dialysis dependent AKI and 78% ESKD. Pts with WD were the largest NRMT group, and they had 45% of pts on dialysis at 12 months. In this subgroup, there were 0.48 deaths/patient year (py), 0.13 renal recoveries/py, and 0.01 transplants/py.

Conclusions: Our results show that appropriate pts with destination therapies, NRMT, can be safely cared for at the destination of their choice and do not require life-long institution. Survival, renal recovery and even transplant can be obtained with the assistance of dialysis provided in-center.

Funding: Commercial Support - Fresenius Medical Care

Patients	Overall (one per person)	Non-renal medical therapy			
		wearable defibrillators	continuous cardiac infusion	LVAD	tracheostomy
Patients accepted	942	730	40	64	138
Patients not discharged within 1 months	820 (87%)	637 (87%)	36 (90%)	55 (86%)	107 (77%)
Patients with case start date at least 3 months ago	918	720	39	60	126
Patients not discharged within 3 months	659 (72%)	512 (71%)	27 (69%)	40 (67%)	85 (66%)
Patients with case start date at least 6 months ago	814	641	36	48	109
Patients not discharged within 6 months	476 (58%)	385 (60%)	17 (47%)	18 (38%)	56 (51%)
Patients with case start date at least 12 months	568	463	27	26	61
Patients not discharged within 12 months	256 (45%)	210 (45%)	10 (37%)	8 (31%)	27 (44%)

FR-PO419

A Novel Individualized Patient Performance Scoring System to Predict Hard Outcomes in Patients on Hemodialysis

Carla Santos,[1,2] Carlos Lucas,[1] Eliana Silva,[1] Mathias Haarhaus,[1] Fernando Jose Gordinho R. Macario.[1] *[1]Diaverum AB, Malmo, Sweden; [2]UnIC@RISE, Department of Surgery and Physiology, Faculty of Medicine, University of Porto, Porto, Portugal.*

Background: Patients in hemodialysis (HD) face high mortality and hospitalization. This study introduces an individual patient performance score (IPPS) as a novel tool for predicting outcomes in HD.

Methods: Multicenter, retrospective study in 19 countries. Between January and June 2023, patients were categorized into 2 groups based on: 1) survival status; 2) presence of a hospitalization event. IPPS were recorded from 24 months until of the index date. Prediction models were developed incorporating IPPS values, demographic data and quality of life SF-36 survey results of 2021 and 2022. Model discrimination was evaluated by the area under the curve (AUC) and 95% confidence intervals (CI). IPPS were developed as a combined score of 8 major key areas: Vascular Access (20 points): type of VA, episodes of thrombosis and infection; HD adequacy (20): eKt/V, blood flow and treatment time; Anemia (20): hemoglobin, transferrin saturation, ferritin; Arterial hypertension (10); Mineral Bone disease, MBD (15): iPTH, phosphorus and calcium; Fluid status (5): percentage of fluid gain; Nutrition (5): albumin and phosphorus and Others (5): influenzae vaccination, transplantation status and previous hospitalization. The final score is obtained by the weighted sum of positive and negative factors, ranging from 0 to 100 and with a higher score representing a better medical performance.

Results: 41,125 patients were included, with significant differences in mean IPPS observed between the surviving and deceased groups up to 24 months prior to death and the hospitalized and non-hospitalized groups up to 12 months of the event. This difference was observed in all IPPS areas, with the exception of MBD for death. Multiple logistic regression showed a 4% independent reduction in the odds of death and a 3% independent reduction in the odds of hospitalization with the increase of 1 point in global IPPS ($p<0.01$). Predictive model demonstrated a very good discrimination for mortality (AUC of 0.76 [0.75; 0.78]) and a good discrimination for hospitalization (AUC of 0.70 [0.69; 0.71]).

Conclusions: IPPS showed a strong correlation with patient survival and hospitalization. The incorporation of IPPS into HD patient care evaluation emerges as an effective strategy for improving critical outcomes, such as mortality and hospitalization.

FR-PO420

External Validation of Models to Predict Risk of Major Cardiovascular Events and Death for People with Kidney Failure Having Noncardiac Surgery

Gurpreet S. Pabla,[1] Tyrone Harrison,[2] Navdeep Tangri,[3,4] Reid Whitlock,[4] Thomas W. Ferguson.[4] *[1]University of Manitoba Faculty of Health Sciences, Winnipeg, MB, Canada; [2]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [3]University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; [4]Seven Oaks General Hospital, Winnipeg, MB, Canada.*

Background: Patients with kidney failure undergoing non-cardiac surgery have a significantly higher risk of adverse cardiovascular events and mortality compared to people with normal kidney function. Existing tools for perioperative risk stratification are not valid for patients with kidney failure. Recently, three risk prediction models were developed from a population-based cohort of people with kidney failure in Alberta, Canada. We externally validated the established Alberta models for major cardiovascular events and mortality in patients with kidney failure within 30 days of non-cardiac surgery in Manitoba, Canada.

Methods: Data was sourced from the Manitoba Centre for Health Policy. The cohort included adults (≥ 18 years) with pre-existing kidney failure (estimated glomerular filtration rate < 15 mL/min/1.73m^2 or on maintenance dialysis) undergoing non-cardiac surgery procedures between April 1, 2007, and December 31, 2019. The primary outcome of this study was a composite of acute myocardial infarction, cardiac arrest, ventricular arrhythmia, and all-cause mortality. The models performance was evaluated using C-statistics, Brier scores, and calibration on Manitoba data using two approaches: 1. Model deployment: Used coefficients from the Alberta models to predict outcomes on Manitoba data. 2. Model refitting: Re-estimated model coefficients using logistic regression on Manitoba data while maintaining the same variables as the Alberta models.

Results: We identified 12,082 surgeries and 569 outcomes (5%). All three models performed well with both approaches, with C-statistics ranging from 0.82 for model 1 to 0.87 for model 3 in the first approach. The calibration slopes for models 1, 2, and 3 were 1.3, 1.4, and 1.2, respectively. Once refit, discrimination remained strong with C-statistics ranging from 0.83 (model 1) to 0.86 (model 3). Calibration slopes were 1 across all the models. Brier scores were consistently low at 0.04 for all the models in both approaches.

Conclusions: Our external validation study confirms the original Alberta models' robustness in a geographically distinct Canadian population. Future research should test the impact of these models in clinical care.

Dialysis after Graft Loss: Preliminary Findings of a Large Multinational Database

Oshini Shivakumar,[1] Xiaoling Ye,[2] John W. Larkin,[3] Peter Kotanko,[2] Benjamin E. Hippen,[3] Adrian M. Guinsburg,[4] Jochen G. Raimann,[2] Damien Ashby,[5] Frederick W. Tam,[5] Hutan Ashrafian.[1] *[1]Imperial College London Institute of Global Health Innovation, London, United Kingdom; [2]Renal Research Institute, New York, NY; [3]Fresenius Medical Care Holdings Inc, Waltham, MA; [4]Fresenius Medical Care Argentina SA, Buenos Aires, Argentina; [5]Imperial College Healthcare NHS Trust, London, United Kingdom.*

Background: Dialysis after graft loss(DAGL) make a significant proportion of new dialysis starters; historically reported to have increased mortality compared to transplant-naive(T-N) starters(**Figure1**). This study examines the mortality risk of DAGL compared to T-Ndialysis starters, to ascertain if the former warrant dedicated care.

Methods: A retrospective observational study. All adult patients who started haemodialysis in Fresenius Medical Care from 1stJanuary 2018 to 31stMarch 2021 were identified in the Apollo DialDB dataset. DAGL identified using ICD10 codes 'Kidney transplant failure','Unspecified complication of kidney transplant' and 'Other complication of kidney transplant'. The T-N control group had never received a kidney transplant and had not received immunosuppressants in the first six months of dialysis start.

Results: A total of 360,469 haemodialysis patients from 40countries included in the analysis. 10,010 patients on DAGL, and 350,459 in T-N control group. In univariate analysis, DAGL patients were significantly younger in all age categories and had a higher proportion of male sex. Serum creatinine, ferritin, phosphate and neutrophil-to-lymphocyte ratio were higher in the DAGL group. Haemoglobin was lower in the DAGL group(**Table 1**). In the Cox proportional model adjusted for age, gender, and laboratory markers, patients with DAGL had an equivalent survival probability compared to T-N dialysis starters(HR:0.93,95%CI:0.86,1.02)(**Table 2**).

Conclusions: This preliminary analysis is in line with recent publications of a more equivalent survival in the two groups. Our results are congruous with younger patients receiving kidney transplant early in their renal replacement therapy journey. We posit that DAGL patients may start dialysis at a lower level of renal function, and higher levels of inflammation. We aim to adjust for confounding factors, to present further refined mortality risk comparison by Autumn2024.

Table 1. Summary of patient characteristics in the study group and control group.

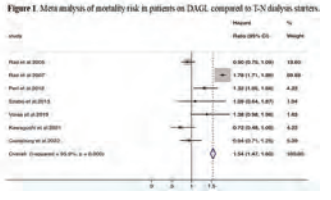
	Transplant naïve (T-N) dialysis starters N = 350,459	*Dialysis after Graft Loss (DAGL)* N = 10,010	*P-value*
Age [years]			
18-44	5,6507 (16%)	3,805 (38%)	<0.0001
45-64	143,221 (41%)	4,488 (45%)	<0.0001
65-74	85,312 (24%)	1,372 (14%)	<0.0001
>=75	65,419 (19%)	345 (3%)	<0.0001
Male [%]	204,615 (58%)	5,984 (60%)	0.0222
Serum Albumin [g/dL]	3.5 (0.5)	3.5 (0.4)	<0.0001
Serum Creatinine [mg/dL]	6.2 (2.6)	7.0 (2.9)	<0.0001
Ferritin [ng/mL]	580 (568)	720 (550)	0.0435
Hgb [g/dL]	10.2 (1.2)	10.0 (1.1)	<0.0001
Serum phosphate [mg/dL]	5.0 (1.3)	5.1 (1.3)	0.0073
NLR	5.5 (23.0)	6.5 (13.4)	<0.0001
MLR	0.5 (1.6)	0.5 (0.4)	<0.0001

Hgb = Haemoglobin, NLR = Neutrophil-to-lymphocyte ratio, MLR = Monocyte-to-lymphocyte ratio.

Table 2. Hazard ratio for all-cause mortality in Cox proportional hazards model.

	HR	*95% CI*	*P-value*
DAGL	0.93	(0.86, 1.02)	0.1287
Age (45-64 vs 18-44)	1.54	(1.46, 1.62)	<0.0001
Age (65-74 vs 18-44)	2.18	(2.07, 2.30)	<0.0001
Age (>= 75 vs 18-44)	2.89	(2.74, 3.05)	<0.0001
Male vs female	1.2	(1.18, 1.23)	<0.0001
Serum Albumin [g/dL]	0.44	(0.43, 0.45)	<0.0001
Serum Creatinine [mg/dL]	1	(1.00, 1.00)	0.0126
Ferritin [ng/mL]	0.74	(0.73, 075)	<0.0001
Hgb [g/dL]	0.92	(0.91, 0.92)	<0.0001
Serum phosphate [mg/dL]	1.05	(1.04, 1.06)	<0.0001
MLR	1.02	(1.01, 1.02)	<0.0001

Figure 1. Meta analysis of mortality risk in patients on DAGL compared to T-N dialysis starters.



FR-PO422

Is the Rate of Resolution of Bacteraemia in Patients Dialysing with Lines Dependent on the Type of Organism Isolated?

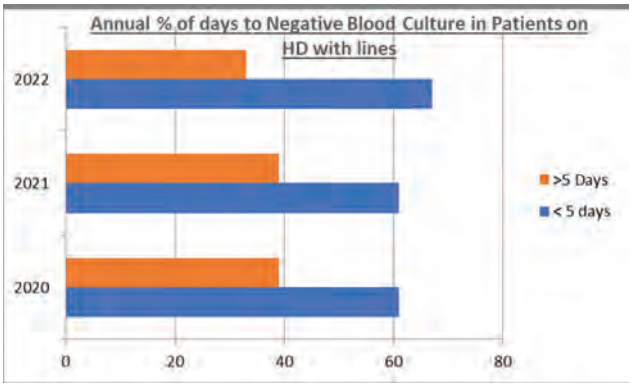
David Makanjuola, Olusegun O. Olalowo, Jahanzaib Chatha, Takudzwa J. Dhlandhlara, Christy R. Ratnakumar. *Epsom and Saint Helier University Hospitals NHS Trust, Carshalton, United Kingdom.*

Background: Infection is a common cause of morbidity and mortality in patients on haemodialysis (HD). The majority of bacteraemias are related to the vascular access, with a greater incidence in patients dialysing through lines. We looked at our dialysis cohort to see whether the rate of resolution of the bacteraemia in patients dialysing with lines was dependent on the type of organism isolated.

Methods: Retrospective review of patients on HD who had bacteraemias between 2020 to 2022. Data collected included blood culture results, time to negativity, and organisms isolated. Patients were split into: group A (GA) – those where cultures became negative within 5 days, and group B (GB), those with negative cultures after > 5 days.

Results: Complete data were available in 111 episodes of bacteraemia in 84 patients. 45 were male. Time to negative blood culture was 1 to 26 days. GA had 69 patients with negative cultures within 5 days, and GB, 41 with negative cultures >5 days. In GA, 48 (69%) were Gram positive organisms, 46 (95.8%), were staphylococci, of which 60% were coagulase negative, and 20 (29%) were Gram negative. In GB, 24 (58.5%) were Gram positive organisms, all were staphylococci, of which 67% were coagulase negative, and 17 (41%) were Gram negative. The percentage of patients in both groups was similar over the 3 years (figure 1).

Conclusions: We did not find a significant difference in the types of organisms causing the bacteraemia and the time to resolution, but there was a suggestion that patients with Gram negative bacteraemias may take a bit longer to resolve.



FR-PO423

Bloodstream Infection Standardized Infection Ratios among ESKD Networks

Leticia A. Lamping,[1,2] Jose E. Navarrete,[1,6] Bria M. Jarrell,[1,3] Tamara L. Hoxworth,[1,2] John Keenan,[1,4] Kira Barbre,[1,4] Lu Meng,[1] Stephanie Clark,[5] Delia Houseal,[5] Shannon Novosad,[1] Jonathan Edwards,[1] Andrea L. Benin,[1] Jeneita Bell.[1] *[1]Centers for Disease Control and Prevention, Atlanta, GA; [2]Chenega Corp, Anchorage, AK; [3]Leidos Inc, Reston, VA; [4]Goldbelt Inc, Juneau, AK; [5]Centers for Medicare and Medicaid Services, Baltimore, MD; [6]Emory University, Atlanta, GA.*

Background: Individuals receiving hemodialysis are at increased risk for bloodstream infections (BSIs), and risk varies by vascular access type and sociodemographic characteristics. The Centers for Medicare and Medicaid Services' End Stage Renal Disease Quality Incentive Program (ESRD QIP) tracks the quality of dialysis care, including bloodstream infections. The ESRD Network Program is the administrative governing body for the ESRD QIP. There are 18 geographically defined ESRD Programs that serve the US and its territories to improve cost-effectiveness, ensure and improve quality of care for dialysis patients, encourage kidney transplantation and home dialysis, and assist patients to return to work. We compared BSI standardized infection ratios (SIRs) across the 18 ESRD network regions between 2018 and 2022.

Methods: This study included data reported to the CDC's National Healthcare Safety Network (NHSN) by outpatient dialysis facilities from 2018-2022. SIRs were calculated as the number of observed infections over the number of predicted infections based on 2014 national aggregate data. A SIR of <1 indicated that fewer BSIs occurred than expected. Pooled SIRs were calculated for each region for each year. The 18 ESRD regions were anonymized using alphabetic codes assigned based on highest to lowest 2018 SIR. The Goodman Kruskal Gamma statistic was used to examine whether the rank order of BSI SIRs among 18 ESRD regions varied significantly between 2018 and 2022.

Results: A total of 6,516 and 6,709 outpatient hemodialysis facilities reported data for 2018 and 2022, respectively. The overall pooled BSI SIR was 0.724 (95% CI 0.715-0.734) in 2018 and 0.367 (95% CI 0.361-0.373) in 2022. Compared to 2018, all ESRD regions had significantly lower SIRs in 2022 ($p<0.05$). The Goodman Kruskal Gamma statistic was 0.3, indicating substantial shifts in regions' SIR rankings between 2018 and 2022. Rankings improved by 6 or more for ESRD networks K, O, and Q in the South, and Network P in the Midwest.

Conclusions: BSI SIRs improved from 2018 to 2022 and the rank order of BSI SIRs by region changed significantly over this time. Further investigation of changes in sociodemographics and facility-level characteristics by ESRD region is warranted.

FR-PO424

Anticoagulation in Dialysis Vascular Access

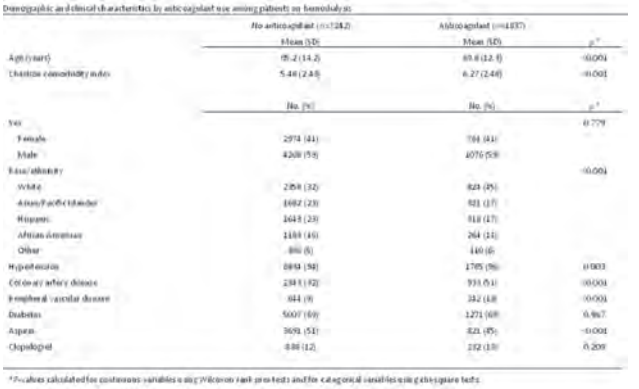
Tariq A. Shaheed, Douglas A. Stram, Aida Shirazi, Sumie Iwasaki, Cynthia Chalk, Sijie Zheng. The KP NCAL CODEX Study Group. *Kaiser Permanente, Oakland, CA.*

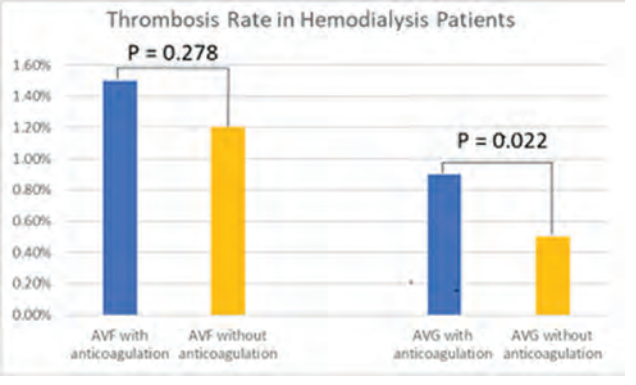
Background: Hemodialysis (HD) patients with dialysis access, arteriovenous fistula (AVF) or arteriovenous graft (AVG), are often placed on anticoagulation to for prevention of future thrombosis. We conducted a retrospective study comparing AVF/AVG thrombosis rates in HD patients with and without anticoagulation within an integrated healthcare network.

Methods: Kaiser Permanente Northern California is an integrated health care system taking care of 4.6 million members. We identified patients on dialysis between Jan 1, 2013, to Dec 31, 2021, who were placed on anticoagulation vs. not. Dialysis initiation date is used as index date. Anticoagulation was started after index date. We compared the AVF and AVG thrombosis rate within one year after the dialysis initiation date.

Results: We identified 9079 patients on hemodialysis in the study period, among them, 7242 did not use anticoagulation and 1837 did. The baseline demographics and comorbidities Indicating an older anticoagulation cohort, has higher Charlson comorbidity Index, HTN, PVD and less use of ASA (table). After one year, the rate of both fistula thrombosis is similar. The graft thrombosis is higher in the anticoagulant patients than non-anticoagulant patients (figure).

Conclusions: In this retrospective study, hemodialysis patients on anticoagulation did not have lower rate of AVF/AVG thrombosis. Baseline patient characteristics might explain this difference. Randomized prospective studies are needed to compare the effect of anti-coagulation in dialysis vascular access patency.





FR-PO425

Efficacy of Patiromer in Management of Long-Weekend Hyperkalemia in Patients on Intermittent Hemodialysis: A Tertiary Centre Experience from Saudi Arabia

Bilal Mohsin, Wael T. Habhab. *King Faisal Specialist Hospital and Research Centre - Jeddah, Jeddah, Saudi Arabia.*

Background: Hyperkalemia is a known complication that is associated with cardiovascular arhythmias and all cause mortality. This complication is frequently encountered in patients with ESKD including those on Intermittent Hemodailysis (IHD) 3 times per week. It is frequently encountered pre dialysis on saturday and sunday in patients on intermittent hemodailysis and is associated with higher incidence of sudden cardiac death specifically after a long weekend without hemodialysis. In our study we tried to identify the incidence of pre dialysis hyperkalemia and efficacy of Patiromer in its management.

Methods: This prospective study was done in Renal dialysis unit of King Faisal Specialist Hospital and Research Centre Jeddah (KFSHRCJ) between 01 January 2024 to 31 March 2024. We screened 161 adult patients on Intermittent hemodailysis by extracting labs pre dialysis after the long weekend i.e. on saturday and sunday. We defined hyperkalemia as serum K more than 5.3 mmol/L. Patiromer was prescribed to patients with serum K more than 5.3 mmol/l over the long weekend and repeat K samples were taken pre dialysis on week 1,2,4,8,12 on saturday and sunday. The changes in serum K levels were recorded as average and percentage and studied according to clinical and demographic characteristics of the patients.

Results: Out of 161 patients, 58 were found to be having pre dialysis hyperkalemia out of who 36 had serum K between 5.3 to 5.9mmol/l; 11 had serum K between 6 to 6.5 mmol/L and 5 had serum K more than 6.5 mmol/L. Patients with age less than 40 years (n=29) had hyperkalemia more than patients above 40 years (n=23). Patiromer was intiated for these patients with a mean reduction of serum K by 0.8-2.6 mmol/l with averge reduction of 1.5 mmol/L and this reduction was persistently observed at a followup at 2,4,8 and 12 weeks. 3 patients dropped out due to lack of compliance, 2 dropped out due to hospitalization and 1 patient refused to continue followup for 12 weeks

Conclusions: Patiormer is an effective tool in the treatment of Predialysis hyeprkalemia and has sustained effect. It can be used with an acceptable tolerance and efficacy specifically during the long weekend in patients on intermittent hemodialysis

FR-PO426

Tenapanor, a Novel Phosphorus Absorption Inhibitor, Softens Stool Properties and Enables Good Phosphorus Management

Kenichi Morii,[1,2] Toshiki Doi,[1,2] Aiko Okubo,[1] Yoshiko Nishizawa,[1] Kazuomi Yamashita,[1] Sonoo Mizuiri,[1] Takao Masaki.[2] *[1]Iryo Hojin Ichiyokai Harada Byoin, Hiroshima, Japan; [2]Hiroshima Daigaku, Hiroshima, Japan.*

Background: Tenapanor is a novel drug that reduces phosphorus absorption from the intestinal tract by inhibiting Na^+/H^+ exchanger isoform 3 (NHE3) in intestinal epithelial cells, thereby decreasing phosphorus permeability in the intercellular space. It is also used as a treatment for constipation-type irritable bowel syndrome (IBS-C) in the United States and Canada. Recently, tenapanor has become available as a hyperphosphatemic treatment for chronic kidney disease patients on dialysis. In this study, we investigated the effects of tenapanor on defecation status and serum phosphorus levels.

Methods: An observational study was conducted on 14 dialysis patients (12 hemodialysis patients, 1 peritoneal dialysis patient, and 1 peritoneal dialysis + hemodialysis hybrid patient) who started tenapanor at our affiliated institutions. A questionnaire was administered to assess the Bristol Stool Form Scale (BSFS: O'Donnell LJ, et al., BMJ 1990) and the number of defecations per week to evaluate the defecation status. Changes in defecation status and serum phosphorus levels after 8 weeks of tenapanor administration were examined.

Results: Four of the 14 patients discontinued medication due to diarrhea, one patient died due to cardiovascular events, and one patient was excluded due to withdrawal of consent. Data from eight individuals were analyzed. A significant difference was found in BSFS between 0 weeks and 8 weeks after starting tenapanor, 3.1 at 0 weeks, and 4.8 at 8 weeks ($P<0.01$). There was no significant difference in the number of defecations per week. Serum phosphorus levels were generally controlled within management goals.

Conclusions: Tenapanor can soften stool properties and control serum phosphorus levels well, although diarrhea has been observed as a side effect.

FR-PO427

Decline in Opioid Prescriptions in US Dialysis and Kidney Transplant Patients, 2011-2020

Paul L. Kimmel,[1] Chyng-Wen Fwu,[2] Thomas D. Nolin,[3] Ivonne H. Schulman,[1] Shannon S. Givens-Bradley,[1] Kenneth J. Wilkins,[1] Susan R. Mendley,[1] Debbie Gipson,[1] Raquel C. Greer,[1] Jenna M. Norton,[1] Kevin L. Chan,[1] Paul Eggers.[1] *[1]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [2]Social and Scientific Systems, Inc., a DLH Holdings Corp (DLH) company, Silver Spring, MD; [3]University of Pittsburgh, Pittsburgh, PA.*

Background: Pain is important for ESKD patients, but opioid medication (OM) prescriptions are associated with morbidity and mortality. The CDC issued OM prescription guidelines in 2016 and 2022, associated with dramatically decreased prescription rates in the U.S. population. It is critical to know if nationwide ESRD OM prescription rates have decreased.

Methods: We analyzed the USRDS database from 2011-2020 to describe trends in the proportion of ESRD dialysis and kidney transplant patients who received one or more, or chronic OM prescriptions, examined factors associated with chronic OM prescriptions, and evaluated associations of all-cause death with short-term or chronic OM prescriptions.

Results: From 2011-2022, the study population ranged between 202,000 and 240,000 patients. Dialysis patients decreased over the study from 80.4 to 76.8%. The percent of ESRD patients who received at least one or more, or who had received chronic OM prescriptions decreased steadily, from 60.4% to 42.1%, and from 22.6% to 13.0% (Table), respectively (both P for trend <0.001). The greatest reductions in prescription rates were for hydrocodone and oxycodone. Similar decreases existed for dialysis and kidney transplant patients. Women, the poor and those in rural settings were more likely to receive chronic OM prescriptions. Prescription rates were highest in White patients and those 45-64 years old. Short-term and chronic OM prescriptions were associated with increased mortality in both dialysis and kidney transplant patients.

Conclusions: ESRD patients' OM prescription rates decreased between 2011 and 2020. Determining the risks and benefits of decreasing OM prescription doses in individual ESRD patients will require clinical judgment and shared decision-making between patients and providers to improve treatment of pain and outcomes.

Funding: NIDDK Support

FR-PO428

Profiles of Home Medication Use in Patients on Dialysis Globally

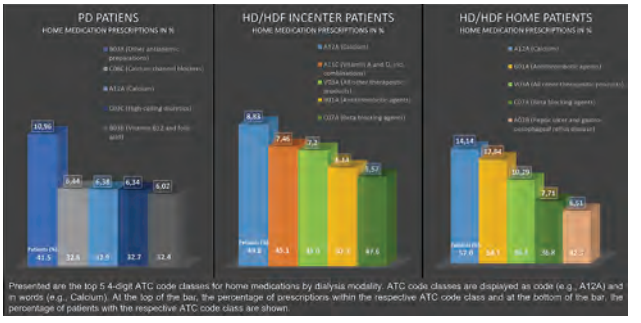
Astrid Feuersenger,[1] Luisa Roth,[1] Melanie Wolf,[1] Otto Arkossy,[1] John W. Larkin,[3] Jan Walter,[2] Hans-Juergen Arens.[1] Global Medical Office. *[1]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [2]Fresenius Medical Care Holdings Inc, Waltham, MA; [3]Fresenius Medical Care Holdings Inc, Waltham, MA.*

Background: Global patterns of medication use in dialysis are undefined. This project aims to provide a real-world view of home medication use in dialysis using a global dialysis dataset from 40 countries called Apollo Dial DB. The most common prescribed medications administered at home by patients were compared by modality.

Methods: Apollo Dial DB includes adult dialysis patient data from a global kidney network during Jan 2018-Mar 2021 (Fresenius Medical Care, Bad Homburg, DE). Data anonymization was performed in alignment with recommendations from a re-identification risk determination (Privacy Analytics, Ontario, CA). Home medications were analyzed based on top (most common) five pharmacological classes defined by first 4-digits of ATC code; classes were stratified by modality.

Results: In Apollo Dial DB 109,888 in-center hemodialysis (HD) patients had 1,459,954 ATC code medication entries (13.3 drugs/patient), 6,466 peritoneal dialysis (PD) patients had 35,873 ATC codes (5.5 drugs/patient), and 1,899 home HD patients 10,228 ATC codes (5.4 drugs/patient). Top pharmacological classes included phosphate binders and antihypertensives for all modalities, yet differences existed by modality (**Figure 1**).

Conclusions: Home medication use appears 2-fold higher for in-center HD versus PD and home HD. Most common medications included calcium phosphate binders, 50% of in-center, 57% of home HD, and 33% of PD patients. Beta-blockers were commonly used for hypertension management in HD (48% in-center, 37% home patients), while calcium channel blockers were most used in PD (33%). Antithrombotics were more prevalent in HD (48% in-center, 54% home patients) and gastroesophageal medications in home HD patients (33%). Antiemetics and diuretics were more prevalent in PD patients (42% and 33%). Insights provide benchmarks for the community. Further research is needed accounting for duration of use and considering real-world application of various drugs (e.g., GLP1 drugs, HIF-PH inhibitors).



Presented are the top 5 4-digit ATC code classes for home medications by dialysis modality. ATC code classes are displayed as code (e.g., A12A) and in words (e.g., Calcium). At the top of the bar, the percentage of prescriptions within the respective ATC code class and at the bottom of the bar, the percentage of patients with the respective ATC code class are shown.

FR-PO429

Hospitalizations Increase Medication Complexity in Patients on Long-Term Hemodialysis

Sharmilee Vuyyuru, Andrew I. Chin. *University of California Davis, Sacramento, CA.*

Background: End stage kidney disease (ESKD) patients are medically complex with significant polypharmacy. Medication regimen complexity index (MRCI) is a validated, non-disease-specific tool that considers medication form, frequency, and special instructions. MRCI has not been well studied in this population. We compared pre and post hospitalization MRCI in hemodialysis (HD) patients.

Methods: This retrospective study included 60 adult patients on HD admitted to a large academic medical center. Data collection included: age; dialysis vintage; hospital length of stay (LOS); admission diagnosis; number of prescriptions and MRCI before hospitalization and at discharge (excluding medications administered at the dialysis clinic). Paired t-test was used to analyze the number of prescriptions and MRCI, comparing pre and post hospitalization. We also examined age, vintage, and LOS for association with MRCI.

Results: Mean age was 63.0 ± 12.7 years, median vintage 5 years (interquartile range 2 to 7), and median LOS 10 days (interquartile range 3 to 19). MRCI was significantly higher post-hospitalization than pre-hospitalization (mean 52.7 versus 48.7; p=0.008). Total medication complexity was driven by both an increase in the number of prescriptions as well as an increase in average prescription complexity (see Table 1). We found no association between pre-hospital MRCI with age, vintage, or LOS.

Conclusions: In ESKD patients on HD, there is a significant increase in MRCI post-hospitalization that is driven by an increase in number of medications as well as average medication complexity. Whether higher MRCI in this population is associated with more adverse outcomes, such as mortality or increased hospital readmissions, remains unanswered.

	Pre-Hosp	Post-Hosp	p-value
MRCI	48.7 ± 19.8	52.7 ± 18.0	0.008
Number of prescriptions	15.8 ± 5.7	16.6 ± 5.3	0.02
Mean MRCI per prescription	3.06 ± 0.44	3.17 ± 0.42	0.03

Table 1: Pre and post hospitalization MRCI and prescription analysis

FR-PO430

Effectiveness of a Multidisciplinary Team Delivered Deprescribing Intervention for Patients with CKD in Qatar: A Preliminary Analysis

Amani Zidan,[1] Abdullah I. Hamad,[2] Hassan A. Al-Malki,[2] Mohamad M. Alkadi,[2] Mohamed A. Elesnawi,[2] Rania A. Ibrahim,[2] Daoud Al-Badriyeh,[1] Muhammad A. Hadi,[1] Ahmed Awaisu.[1] *[1]Qatar University, Doha, Qatar; [2]Hamad Medical Corporation, Doha, Qatar.*

Background: Patients with chronic kidney disease (CKD), especially those receiving hemodialysis (HD), often experience negative consequences related to inappropriate polypharmacy. These can be averted by deprescribing. We aimed to design and assess the impact of a multidisciplinary team-delivered deprescribing intervention for patients receiving hemodialysis in Qatar.

Methods: This study is a randomized, parallel-group, controlled trial (RCT). Adults receiving chronic HD at Qatar's largest ambulatory dialysis center who can communicate in English or Arabic are included. Participants are randomized into the control (usual ambulatory care) or intervention (standardized deprescribing) groups. Intervention patients receive a structured deprescribing intervention using a developed evidence-based guideline. Outcome measures are collected at baseline and six months for all study participants. The primary outcome is the percentage of patients with ≥ 1 potentially inappropriate medication (PIM). The secondary outcomes include pill burden and self-reported adherence (assessed by Adherence to Refills and Medications Scale). A total of 424 patients is needed to reduce the percentage of patients with ≥ 1 PIM by 50%, with an expected attrition rate of 50%.

Results: The study has been ongoing since 19 February 2024. Thirty-seven patients with an average (SD) age of 52.8 (14.6) have been recruited. At baseline, a mean of 1.7 (1.3) PIMs was identified. 83.7% of the patients had at least one PIM prescribed (78.9% control and 88.8% intervention). On average, the participants were taking 132.3 pills per week (131.7 in control and 132.3 in intervention). ARMS mean score was 17.03 (6.12) (control 16.33 (5.16), Intervention 17.76 (7.08)). Twenty-four deprescribing plans have been suggested for 15 patients in the intervention group. Among these, 16 were successfully implemented, 4 were rejected by the physicians, 2 were refused by the patient, and 2 were stopped due to recurrent symptoms.

Conclusions: Our structured deprescribing intervention is promising to improve dialysis patients' health outcomes. With the potential to reduce inappropriate polypharmacy and pill burden, we anticipate a positive impact on patient well-being.

Funding: Government Support - Non-U.S.

FR-PO431

Evaluation of a Novel Pharmacist-Nephrologist Collaborative Care Service for Patients on Hemodialysis in Singapore

Pu En Ow Yong. *Changi General Hospital, Singapore, Singapore.*

Background: The introduction of Collaborative Prescribing by pharmacists has improved the holistic team-based patient care. The standard care (SC) for stable hemodialysis (HD) patients involves a hospital nephrologist's consult in 9-month intervals, with community dialysis team titrating medications every 1-2 monthly. With complex medication regimens and multiple care teams involved, HD patients often face complex and potentially confusing medication regimens. Since medication management is the main activity during nephrologist's consult, we aim to right-site their care with the novel collaborative care (CC) service between nephrologists and pharmacists. In this CC model, stable HD patients are reviewed by a renal pharmacist 6 months after his nephrologist consult. Pharmacist independently conducts a medication review according to patient's clinical status and their HD centre's records. Pharmacists optimise, and prescribe their medications and vaccinations based on the collaborative prescribing framework. This study aims to evaluate safety of the new CC model, with the mean ED visits and all-cause unplanned admissions as the primary outcome.

Methods: A retrospective study of 104 patients in the CC model and 342 patients in SC model in January 2021 – June 2022 was conducted. The patients are matched by the nearest propensity scores, modeled using a multivariate logistic regression adjusted with baseline variables. The number of all-cause unplanned admission and ED visits were compared using a difference-in-difference approach and a negative-binomial mixed effect model.

Results: Mean unplanned admissions was 0.673 and 0.760 for the SC and CC group respectively (p=0.597) with an incidence rate ratio (IRR) of 0.98 (95% CI: 0.58-1.65) for the CC group. The mean ED visits was 0.192 and 0.183 for the SC and CC group respectively (p=0.890) with an IRR for the CC group of 0.73 (95% CI: 0.14-3.81). The differences were not statistically significant. Among patients who require pneumococcal and/or influenza vaccinations, patients in the CC group achieved a higher vaccination rate (pneumococcal: 24.3% vs 3.8%. influenza: 13.5% vs 0.0%).

Conclusions: The study findings support the safety of this novel CC service in ensuring the timely and holistic clinical review of stable HD patients. This new CC service was effectively implemented with no differences in primary safety outcome measures.

FR-PO432

Association between Primary Care Services and All-Cause Mortality among US Patients on In-Center Hemodialysis

Dustin Le,[1] Rohanit Singh,[2] Raquel C. Greer,[1] Morgan Grams,[3] Bernard G. Jaar.[1] *[1]Johns Hopkins Medicine, Baltimore, MD; [2]Yale University School of Medicine, New Haven, CT; [3]New York University Grossman School of Medicine, New York, NY.*

Background: The association between primary care evaluation among individuals requiring maintenance in-center hemodialysis (HD) and all-cause mortality is unclear.

Methods: Using the US Renal Data System (USRDS) and Medicare Parts A, B, and D claims data from 2012 to 2020, we estimated the risk of all-cause mortality, cause-specific mortality, and index hospitalization between those with and without PCP services among incident individuals with pre-existing Medicare coverage who survived the first 90 days on HD. Receipt of PCP services was defined as ≥1 outpatient visits between dialysis initiation and study start (90 days after dialysis initiation) to Family Medicine, Internal Medicine, General Medicine, or Geriatrics. We used inverse probability of treatment weights (IPTW) to achieve exchangeability between those with and without primary care evaluation, and we used Cox-proportional hazards models to estimate the IPTW-hazard ratios (HRs).

Results: We identified 58,011 and 56,653 individuals with and without PCP services in the first 90 days of HD. After IPTW, the average age was 71 years old, 53% were White, and 73% had diabetes. There were 58,982 deaths during a median (interquartile interval) follow-up of 1.78 (0.69 – 3.36) years. The median survival for those with PCP services was 3.2 years vs 3.0 years (a difference of 3.4 months). The IPTW-HR for all-cause mortality was 0.91 (95% CI: 0.89 – 0.92), and there were similar reductions in CV death (0.94 [0.91 – 0.96]), infectious death (0.87 [0.81 – 0.94]), and index hospitalization (0.98 [0.97 – 1.00], p-value = 0.03). There was no difference in first ED visit (1.00 [0.99 – 1.01]). Subgroup analyses such as age, race, Part D subsidy status, and PCP evaluation 3 months prior to dialysis initiation were generally consistent.

Conclusions: Among US Medicare beneficiaries, primary care evaluation within 90 days of in-center HD initiation was associated with lower all-cause mortality and hospitalization.

Sex and Age Differences in Hemodialysis Mortality among US Medicare Beneficiaries

Dustin Le,[1] Grant T. Kirby,[1] Morgan Grams,[2] Nityasree Srialluri.[1]
[1]Johns Hopkins Medicine, Baltimore, MD; [2]New York University Grossman School of Medicine, New York, NY.

Background: Recent literature has challenged the observation that women (vs men) have a modest survival advantage on hemodialysis. We aimed to investigate if age of dialysis initiation contributes to sex differences in mortality outcomes among US Medicare beneficiaries.

Methods: Using the US Renal Data System (USRDS) and Medicare A, B and D claims from 2011-2020 we assessed all-cause and cause-specific mortality (cardiovascular [CVD], infection, and withdrawal), comparing females to males who survived 90 days on in-center hemodialysis. Participants were stratified by age (18 – 50, 51- 60, 61 – 70, and 81 – 90) and analyzed using competing risk models to account for the competing risk of kidney transplantation. We estimated competing risk regression hazard ratios (HRs) in the overall population and then within each age stratum, adjusting for baseline demographics, comorbidities, and medication use.

Results: Among 85,453 women and 93,205 men who initiated and survived 90 days of in-center hemodialysis, women had a survival advantage (HR: 0.96, 95% CI: 0.95 – 0.98) driven by lower CVD mortality (HR: 0.88, 95% CI: 0.86 – 0.91). Women had similar infection-related mortality (HR: 1.04, 95% CI: 0.99 – 1.10) and higher withdrawal-attributed mortality (HR: 1.08, 95% CI: 1.04 – 1.12). Women 18 – 50 did not have a survival advantage for all-cause (HR 1.06, 95% CI: 1.00 – 1.13, p-value: 0.06) or CVD mortality (HR 1.02, 95% CI: 0.93 – 1.13), while women aged 51-60 had higher infection-related mortality (HR: 1.18, 95% CI: 1.01 – 1.39), **Figure 1**. Withdrawal mortality by age strata was consistent with the overall population estimate.

Conclusions: Among US Medicare beneficiaries, the association between sex and mortality varied based on the age at time of dialysis initiation.

Commercial Health Insurance and Quality of Care in US Dialysis Facilities

Kevin F. Erickson,[1] Anshul Bhatnagar,[1] Daniel E. Weiner,[2] Allison C. Reaves.[3]
[1]Baylor College of Medicine, Houston, TX; [2]Tufts University School of Medicine, Boston, MA; [3]Tufts Medical Center, Boston, MA.

Background: Commercial health insurance typically reimburses at a higher rate for dialysis than Medicare. A recent ruling by the US Supreme Court could result in many commercially insured patients who receive dialysis forgoing their commercial health insurance and shifting to Medicare as the primary payer. We examined whether differences in commercial payers as a proportion of a facility's overall payer mix is associated with the quality of care at dialysis facilities.

Methods: We used publicly available data from US Dialysis Facility Reports and the Dialysis Facility Compare websites in 2019 to identify patients receiving dialysis in the United States. In multivariable linear regression models, we examined the association between the percentage of incident dialysis patients with commercial insurance and seven key dialysis facility quality metrics included in dialysis facility STAR ratings.

Results: Among 5,753 US dialysis facilities, on average 12.0% of incident dialysis patients had commercial insurance. Each 10% absolute increase in percentage of dialysis patients in a facility with commercial insurance was associated with an adjusted 6.7% (95% Confidence Interval (CI) 5.5-7.9%) lower standardized mortality ratio, 2.7% (1.9-3.4%) lower standardized hospitalization ratio, and absolute decreases of 4.0% (2.0-6.0%) in the standardized transfusion ratio, 0.2% (0.1-0.2%) in patient months without adequate dialysis, and 0.7% (0.5-1.0%) in months with a long-term catheter. Higher commercial insurance rates were associated with an increase of 0.8% (0.5-1.1%) in the standardized arteriovenous fistula rate and a 0.05 (0.01-0.10) point higher Consumer Assessment of Healthcare Providers and Systems patient experience score.

Conclusions: These findings suggest that shifting coverage from commercial health insurance to Medicare could adversely impact quality of care at dialysis facilities.

Representativeness of Populations Recruited in Randomized Controlled Trials of Hemodiafiltration vs. Hemodialysis: A Systematic Analysis in Comparison with Representative Registry Data

Tom Yuen,[1] Ngoc Pham,[2] Kakiu Ho,[1] Manuela Stauss-Grabo,[2] Giovanni Strippoli,[4,5] Krister Cromm.[2,3] CONVINCE Scientific Committee and CONVINCE Investigators. *[1]Fresenius Medical Care Asia Pacific Ltd, Hong Kong, Hong Kong; [2]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [3]Charite Universitatsmedizin Berlin, Berlin, Germany; [4]Universita degli Studi di Bari Aldo Moro, Bari, Italy; [5]University of Sydney, School of Public Health, Sydney, NSW, Australia.*

Background: The external validity of randomized controlled trials (RCTs) depends on the comparability of involved populations to the ones in "real life", whose data are usually reported in registries. Following the recent publication of the CONVINCE trial, we compared patient baseline characteristics in all existing RCTs of hemodiafiltration (HDF) vs hemodialysis (HD) and with data of key renal registries from Europe, Australasia and America. Our aim was to ascertain existing heterogeneity and whether the coverage in RCTs was representative of prevalent registry populations.

Methods: We performed a systematic search for RCTs of HDF vs HD using Cochrane methodology (1966 to current). We also searched for annual reports of representative registries (2020-2023). For both RCTs and registries we extracted data on patient characteristics (age, sex, diabetes, cardiovascular disease, vascular access). We compared data between RCTs and registries using visual analysis, descriptive statistics and heterogeneity statistics (I^2).

Results: Thirteen RCTs including CONVINCE and 8 registries were identified. There was substantial heterogeneity for all characteristics within RCTs, substantiating that a large and broadly representative array of people are enrolled in existing RCTs of HDF vs HD. These were in line with registry populations for age, proportion of diabetic patients and sex (p=not significant) but not for cardiovascular disease and proportion having a fistula for vascular access (p<0.05).

Conclusions: There was significant heterogeneity in the patient characteristics of existing RCTs of HD vs HDF. Overall, the data are representative of populations reported in registries of different geographies. While individual trials may appear as outliers compared to the prevalent registry population, the totality of evidence covers a broad spectrum of the end stage kidney disease population receiving renal replacement therapy either as HD or HDF. The similarity between characteristics of patients in RCTs and registries supports that existing RCTs adequately represent the real-life population.

Parkinson Disease and ESKD: Understanding Phenotypic Characteristics and Their Impact on Survival

Cydney E. Parmar,[1,2] Grant D. Scheiffele,[2] Nandita Senthil,[1,2] Jonathan Fischer,[1] Aparna Wagle Shukla,[1] Ashutosh M. Shukla.[1,2] *[1]University of Florida, Gainesville, FL; [2]VA North Florida South Georgia Veterans Health System, Gainesville, FL.*

Background: Similar to end-stage kidney disease (ESKD), Parkinson's disease is a major chronic disease affecting older individuals with a negative impact on the quality of life and survival. While there is an emerging literature on the brain-kidney axis, the clinical phenotype of patients with Parkinson's disease initiating dialysis and their overall survival prospects have never been investigated.

Methods: We identified all incident ESKD patients initiating dialysis between 2009 and 2019 from the United States Renal Database System. Of these, we isolated Parkinson's disease patients using ICD 9 and -10 codes. We used a random forest method to generate propensity scores and created a 1:5-matched non-Parkinson's Disease control cohort. We used the Cox proportional hazards model to conduct a survival analysis.

Results: Of the 1,271,443 eligible patients during the study period, 5,462 had Parkinson's disease at incident ESKD. These patients were significantly older (76.1±8.7 vs. 63.6±14.8 years), had higher functional limitations (43.4% vs. 17.4%), and had a burden of comorbidities such as heart failure (38.6% vs. 29.8%), atherosclerotic disease (37.8% vs. 27.5%), depression (37.0% vs. 11.8%), and had a lower incident of home dialysis use (4.5% vs. 9.5%). Median survival was significantly lower in Parkinson's disease cohort (527 days, IQR: 170 - 1153), compared to the propensity-matched non-Parkinson's disease control cohort (562 days, IQR: 166-1227) with an adjusted hazard ratio for death of 1.15 (1.11 - 1.18). Asian race (0.67, 0.62 - 0.72) and females (0.93, 0.90 – 0.93), and use of peritoneal dialysis (0.86, 0.81 – 0.91) were associated with improved survivals, whereas heart failure (1.26, 1.22 – 1.29), obstructive pulmonary disease (1.23, 1.19 – 1.27), and functional disability (1.44, 1.40 – 1.47) were associated with poorer survivals.

Conclusions: Incident ESKD patients with a preexisting diagnosis of Parkinson's disease are older, have higher comorbidity burden and functional limitations, and have worse survival. More pragmatic analyses accounting for quality of life are needed to understand better the benefits and risks of Parkinson's disease patients initiating dialysis.

FR-PO437

Informal Caregiver Burden in Dialysis Care and How It Relates to Patients' Health-Related Quality of Life and Symptoms

Esmee Driehuis,[1,2] Roemer J. Janse,[3] Anneke Roeterdink,[1,2] Wanda Konijn,[4] Thomas S. van Lieshout,[2,7] Theodôr J. Vogels,[5] Namiko A. Goto,[6] Marjolein Broese van Groenou,[8] Friedo W. Dekker,[3] Brigit C. van Jaarsveld,[2] Alferso C. Abrahams.[1] DOMESTICO Study Group. *[1]Universitair Medisch Centrum Utrecht, Utrecht, Netherlands; [2]Amsterdam UMC Locatie VUmc, Amsterdam, Netherlands; [3]Leids Universitair Medisch Centrum, Leiden, Netherlands; [4]Dutch Kidney Patients Association, Bussum, Netherlands; [5]Maxima Medisch Centrum, Veldhoven, Netherlands; [6]Jeroen Bosch Ziekenhuis, 's-Hertogenbosch, Netherlands; [7]Noordwest Ziekenhuisgroep, Alkmaar, Netherlands; [8]Vrije Universiteit Amsterdam, Amsterdam, Netherlands.*

Background: Starting dialysis has a major impact on both patients' and their informal caregivers' lives. Dialysis patients often experience impaired health-related quality of life (HRQoL) and high symptom burden, relying heavily on their informal caregivers. However, providing informal care for someone undergoing dialysis may lead to significant burden and decreased HRQoL for caregivers themselves, potentially also influencing patients' well-being. Despite the crucial role of informal caregivers, there is a lack of research on this topic. Therefore, we aimed to 1) describe informal caregivers' experienced burden and HRQoL and 2) investigate how these are related to dialysis patients' HRQoL and symptoms.

Methods: We conducted a cross-sectional study at dialysis initiation with 202 adult informal caregiver-dialysis patient dyads. Caregiver burden was measured with the Self-Perceived Pressure from Informal Care (SPPIC) questionnaire, HRQoL with the 12-item Short Form Health Survey (SF-12), and symptom number and burden with the Dialysis Symptom Index (DSI). Data were analysed using linear and logistic ordinal regression.

Results: Around 35% of caregivers experienced moderate to high burden. Patients' lower mental HRQoL (adjusted odds ratio [aOR]=0.95, 95% confidence interval [CI] 0.92; 0.99), higher symptom number (aOR=1.07, 95% CI 1.02; 1.12), and higher symptom burden (aOR=1.03, 95% CI 1.01; 1.04) were associated with greater odds of higher caregiver burden. Patients' lower mental HRQoL (β=0.30, 95% CI 0.15; 0.46), higher symptom number (β=-0.55, 95% CI -0.78; -0.31), and higher symptom burden (β=-0.17, 95% CI -0.25; -0.10) were also associated with a lower mental HRQoL in caregivers.

Conclusions: We show that a third of caregivers feel moderate to high burden and that caregiver burden is associated with patients' mental HRQoL and symptoms. These findings highlight the importance of considering and supporting patients and their informal caregivers together in dialysis care, as the kidney disease and its treatment impact many aspects of both their lives.

Identifying Symptom Clusters and Associated Social Determinants of Health in Patients with ESKD and Chronic Pain: A Secondary Analysis of the HOPE Trial

Jennifer L. Steel,[1] Mark Lockwood,[2] Carrie E. Brintz,[3] Kerri L. Cavanaugh,[3] Martin Cheatle,[4] Daniel Cukor,[5] Laura M. Dember,[4] Ardith Z. Doorenbos,[2] Heather B. Howell,[10] Francis J. Keefe,[6] Paul L. Kimmel,[7] Jane Liebschutz,[1] Daniel W. Mcneil,[8] Mark L. Unruh,[9] Jonathan G. Yabes,[1] Jesse Y. Hsu,[4] Manisha Jhamb.[1] HOPE Consortium. *[1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]University of Illinois Chicago, Chicago, IL; [3]Vanderbilt University Medical Center, Nashville, TN; [4]University of Pennsylvania, Philadelphia, PA; [5]New York University Grossman School of Medicine, New York, NY; [6]Duke University, Durham, NC; [7]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [8]University of Florida, Gainesville, FL; [9]University of New Mexico School of Medicine, Albuquerque, NM; [10]Yale University, New Haven, CT.*

Background: Identifying symptom clusters and associated social determinants of health (SDOH) among people with chronic pain and ESKD may facilitate more effective treatment of symptoms

Methods: The HOPE Consortium Trial to Reduce Pain and Opioid Use in Hemodialysis, designed to address chronic pain in adults receiving maintenance HD, enrolled 643 patients with moderate to severe chronic pain. We used latent profile analysis to identify patterns of an *a priori* symptom cluster (pain, fatigue, anxiety, depression and sleep disturbances) with baseline measures of the Brief Pain Inventory, Patient Health Questionnaire-9, Generalized Anxiety Disorder-7, the PROMIS Fatigue and Sleep subscales. We used multinomial logistic regression to assess associations between symptom clusters and SDOH (obtained by self-report and geocoding).

Results: Five symptom cluster phenotypes were characterized based on fit statistics, interpretability, and between-class heterogeneity. There was significant variability in perceived discrimination across the symptom clusters ($p<0.01$). Living in a racially segregated neighborhood was associated with a symptom cluster with high depressive symptoms, relative to "average" symptom cluster (Adjusted OR=1.03, p=0.02). There were no significant associations of symptom clusters with education level, household income, area deprivation index, rural/urban community, walkability index or Gini index of income inequality.

Conclusions: The symptom clusters identified are potentially important to clinicians and researchers for addressing symptom burden. System and individual level SDOH may be important factors to include when developing interventions focused on reducing symptom burden in those with ESKD and chronic pain.

Symptom cluster domains in patients with ESKD and chronic pain

FR-PO439

Emergency-Only Dialysis and the Impact of Transition to Scheduled Dialysis on Survival of Patients with ESKD

Jared G. Imber,[1] Donald A. Molony,[1] Mohammad H. Rahbar,[2] Manouchehr Hessabi,[2] Akram Yazdani,[2] Amirali Tahanan,[2] Rekha K. Trivedi,[3] Jade M. Teakell.[1] *[1]The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX; [2]The University of Texas Health Science Center at Houston, Houston, TX; [3]Harris Health System, Houston, TX.*

Background: Patients with end-stage kidney disease (ESKD) without access to scheduled dialysis present to emergency departments (ED) when their clinical status deteriorates to the extent that they require hemodialysis (HD) emergently to evade death. We hypothesize that the patients who receive emergency-only HD (EOHD) and are subsequently transitioned to scheduled HD or peritoneal dialysis (PD) will have increased overall survival compared to those patients who continued to receive EOHD.

Methods: We interrogated the electronic medical record of the Harris Health System (Houston, TX) to evaluate health outcomes for all adult patients with ESKD requiring dialysis (identified using ICD-10 codes) from 2017 to 2021. We compared overall survival in an EOHD cohort between patients who were transitioned to scheduled dialysis (HD or PD) and those who continued EOHD.

Results: We evaluated the outcomes for 914 adults diagnosed with ESKD without eligibility for or access to a conventional funding source for outpatient dialysis. Of the identified patients, 516 received EOHD, and 398 transitioned to scheduled dialysis (382 HD, 16 PD). Patients receiving EOHD demonstrated an adjusted hazard ratio of 4.553 (95% CI 2.20-9.34) when followed for ≤1 year, 2.222 (95% CI 1.07-4.60) when followed for 1-3 years (total), and 0.2199 (95% CI 0.08-0.61) when followed 3-5 years (total) (Table 1).

Conclusions: The cohort of patients with ESKD who transitioned from EOHD to scheduled dialysis treatments benefited from improved overall survival compared to the patients who continued to receive EOHD, except for those with a follow-up period of 3-5 years. The observed relative improvement in survival outcomes in the EOHD group with greater than 3 years of follow-up is likely due to a survivor effect. These findings provide further evidence that transitioning patients from emergency-only HD to scheduled dialysis as the standard of care will result in better outcomes in this marginalized group of ESKD patients.

Funding: Other NIH Support - CTSA - National Center for Advancing Translational Sciences

Table 1. Mortality and approximated Hazard ratios for patients treated with emergency-only hemodialysis and transitioned to scheduled dialysis for ≤ 1 year, 1-3 years, and 3-5 years of follow-up

Follow-up period	No of patients	Mean Age	Number of deaths	Hazard ratio (95% CI)	
				Unadjusted	Adjusted*
≤ 1 year (Total)	**119**	**53.03**	**50**		
Emergency only	55	55.17	36	5.835 (2.93 -11.62)	4.533 (2.20 - 9.34)
Transitioned to scheduled	64	51.19	14		
1-3 years (Total)	**294**	**51.03**	**35**		
Emergency only	104	53.10	23	3.258 (1.619- 6.557)	2.222 (1.07 - 4.60)
Transitioned to scheduled	190	49.90	12		
3-5 years (Total)	**494**	**50.44**	**26**		
Emergency only	355	50.67	8	0.2109 (0.076- 0.58)	0.2199 (0.08 - 0.61)
Transitioned to scheduled	139	49.86	18		

Note: In this study, the date of death is missing for 7 deceased patients (2 in emergency and 5 in transitioned), so we removed them from the final analysis.
* Adjusted for covariates (age, self-reported sex, and the length of stay in the hospital (days)).

FR-PO440

Comparative Safety and Effectiveness of Heparin vs. Direct Oral Anticoagulants in Patients with Cirrhosis and ESKD

Abhi Lohana,[1] Usman Akbar,[1] Fnu Muhibullah,[1] Nouman Shafique,[3] Syed Adil Mir Shah,[2] Neeharika Muddana.[1] *[1]Camden Clark Medical Center, Parkersburg, WV; [2]Dow Medical College, Karachi, Pakistan; [3]Nishtar Medical College and Hospital, Multan, Pakistan.*

Background: Anticoagulation therapy in patients with cirrhosis and end-stage renal disease (ESRD) presents unique challenges due to the increased risk of both thromboembolic and bleeding events. This study aims to compare the clinical outcomes of patients treated with Heparin versus direct oral anticoagulants (DOACs) in this high-risk patients. Understanding the safety and effectiveness of these treatments in cirrhosis with ESRD is crucial for optimizing patient care and minimizing adverse events.

Methods: We utilized the US collaborative network platform to perform a comparative outcomes analysis on two cohorts: 7333 patients treated with Heparin and 7323 patients treated with DOACs. Propensity score matching was used to balance the cohorts based on demographic and clinical characteristics. Outcomes measured included mortality, stroke, deep vein thrombosis/pulmonary embolism (DVT/PE), acute myocardial infarction (AMI), and major bleeding after 1 year, with risk differences and p-values calculated to assess statistical significance.

Results: The analysis revealed that the Heparin cohort had a significantly higher risk of mortality (risk difference 0.035, p-value 0.000) and major bleeding (risk difference 0.021, p-value 0.005) compared to the DOACs cohort. Conversely, the DOACs cohort exhibited a higher risk of DVT/PE (risk difference -0.025, p-value 0.000). No significant differences were observed between the cohorts for stroke (risk difference -0.001, p-value 0.801) and AMI (risk difference 0.006, p-value 0.204).

Conclusions: This comparative analysis highlights that Heparin is associated with higher risks of mortality and major bleeding, whereas DOACs are associated with a higher risk of DVT/PE. These findings suggest that DOACs may be a safer alternative to Heparin for certain outcomes, although individual patient factors and clinical judgement should guide treatment decisions. Further research is needed to confirm these findings and optimize anticoagulation therapy.

Outcome	Patients with Outcome (Heparin)	Total Patients (Heparin)	Patients with Outcome (DOACs)	Total Patients (DOACs)	Risk Difference	P Value
Mortality	1532	7333	1270	7323	0.035	0.000
Stroke	255	6917	245	6500	-0.001	0.801
DVT/PE	300	7045	420	6223	-0.025	0.000
AMI	534	6531	437	5782	0.006	0.204
Major Bleeding	863	5002	747	4930	0.021	0.0

1-year outcomes of patients being treated with heparin and Direct oral anticoagulants (DOACs) in patients with ESRD and cirrhosis.

FR-PO441

Comparison of Clinical Outcomes between High-Start and Low-Start Dialysate Fill Volume among Patients with CKD on Peritoneal Dialysis at the National Kidney and Transplant Institute: A Randomized Controlled Trial

Rhaffy B. Rapacon. *National Kidney and Transplant Institute, Quezon City, Philippines.*

Background: There is a lack of consensus among nephrologists on the optimal peritoneal dialysis(PD) choice of starting on low fill or high fill volume due to data gaps.

Methods: This randomized controlled trial included 50 CKD patients at National Kidney Transplant Institute from December 2023 to March 2024. Patients were randomly allocated into two groups to receive either high-start or low-start dialysate fill volume. Endpoints of the study are adverse events and changes from baseline of PD parameters at day 14 of the treatment period.

Results: A significant difference in the pre-and post-treatment in terms of improved eGFR in the low-start group (4.3±2.5 vs 6.9±4.0; D =2.63; p<0.001); increased serum albumin in the high-start group (3.2±0.5 vs 3.5±0.4; D =0.30, p=0.025); and decreased BUN in both high-start (106.2±42.8 vs 53.1±21.3; D =53.09; p<0.001) and low-start group (106.1±36.7 vs 50.8±19.6; D =53.09; p<0.001). In terms of adverse events, bleeding was significantly associated with low-start fill volume (p=0.037). However, groups did not vary significantly in terms of pericatheter leak (RR=1.67; p=0.440); abdominal pain (RR=1.27, p=0.659); swelling (RR=1, p=1); catheter migration (p=0.018); obstruction (RR=0.75, p=0.683); peritonitis (p=0.312) and other complications (RR=1.5, p=0.637).

Conclusions: High-start fill volume resulted in significantly improved post-treatment serum albumin and BUN levels. It was well tolerated and associated with significantly lower bleeding rates compared to low-start fill volume.

Complications of high-start and low-start fill volume among peritoneal dialysis patients (Primary Outcome)

Variables		Low-Start Group		High-Start Group		Risk Ratio (95% CI)	p-value
		f	%	f	%

High Variability of Serum Albumin Is Associated with Increased Risk of All-Cause Mortality in Patients on Peritoneal Dialysis

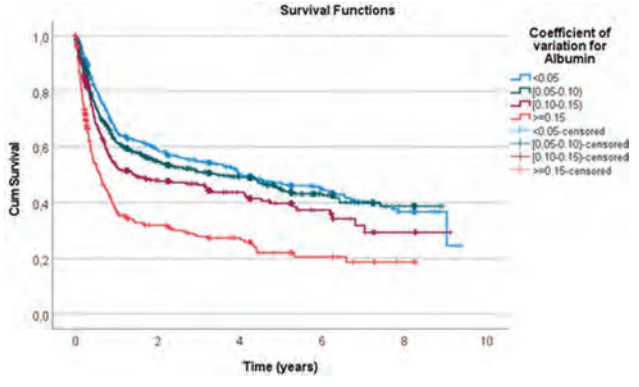
Hanri Afghahi,[1] Salmir Nasic,[1] Björn Peters,[1] Anna Wärme,[1] Helena Rydell,[3] Maria K. Svensson.[2] *[1]Skaraborgs Sjukhus Skovde, Skovde, Sweden; [2]Uppsala Universitet, Uppsala, Sweden; [3]Karolinska Institutet, Stockholm, Sweden.*

Background: Studies that evaluated trends in serum albumin and the association between variability of serum albumin and risk of all-cause mortality with peritoneal dialysis (PD) are limited. **Aim :** The association between variability of serum albumin and the risk of all-cause mortality in patients on maintenance PD.

Methods: 2567 patients with end-stage kidney disease (ESKD) on maintenance PD treatment were followed for mean 3.9±3.5 years by data from the Swedish Renal Register (SRR),. The variability of serum albumin was defined as the coefficient of variation (CV) and the ratio between the standard deviation (SD) and mean value, (SD/mean). The patients were divided in four groups depending on variability of serum albumin. The relationships between serum albumin variability and all-cause mortality were examined by univariable and multivariable Cox regression models and hazard ratios (HR) with 95% confidence intervals (CI) which was adjusted for demographics, laboratory findings, and comorbidities as well as mean value of serum albumin during the study. Lowest serum albumin variability (CV<0.05) was used as reference group for calculation of HR.

Results: During the study period 1144 (45%) deaths occurred. The highest risk of mortality was observed in patients with highest serum albumin variability (CV>0.15) and 59% (237/399) died. Lowest serum albumin variability (CV<0.05) had the best survival and in this group only 42% (303/718) died. In the multivariate analyses, the two groups with the highest serum albumin variability (0.10<CV≤0.15 and CV>0.15) had a significantly increased risk of mortality (HR 1.20, 95% CI 1.002-1.44, p-value=0.048 and HR 1.55, 95% CI 1.27-1.87, p-value<0.001), compared to reference group.

Conclusions: In patients with ESKD and PD high serum albumin variability is associated with increased risk of mortality independent of serum albumin level. Serum albumin variability may be an important risk factor for all-cause mortality in these patients.



FR-PO443

Strict Blood Pressure Control Is Associated with Better Survival in Korean Patients on Hemodialysis, but Not in Patients on Peritoneal Dialysis

Joo Kyung Lee, Min Jee Jo, Gang Jee Ko. *Korea University, Seongbuk-gu, Republic of Korea.*

Background: Adequate blood pressure (BP) control is considered one of main treatment strategies in dialysis patients. However, the goal and ideal range of BP have not been defined exactly among dialysis patients. We aimed to investigate proper management for BP control associated with better survival in dialysis patients.

Methods: Based on the data of health screening results from 2002 to 2018 in the database of the Korean National Health Insurance System (NHIS), we examined the association of BP control with all-cause and cardiovascular mortality among hemodialysis (HD) and peritoneal dialysis (PD) patients using Cox-regression analysis.

Results: A total of 46,649 patients (39,472 HD and 6,177 PD) were enrolled for the analysis. The mean systolic blood pressure (SBP) was 134.4mmHg and 133.8mmHg in HD and PD patients, respectively. A comparable proportion of HD and PD patients was distributed in each SBP category. In this analysis, the reference SBP group was set as 120-140mmHg. In the HD group, the all-cause mortality increased as SBP was managed higher than 140. The mortality risk was also greater when SBP was lower than 120. As well in PD patients, the all-cause mortality risk increased when SBPs were managed below 120mmHg; however, higher systolic BPs in PD patients were not significantly associated with higher mortality. Managing systolic BP above 160mmHg in HD patients showed greater cardiovascular mortality whereas, higher blood pressure was not evidently associated with cardiovascular mortality in PD patients.

Conclusions: Blood pressure should be managed strictly as systolic blood pressure lower than 120mmHg or greater than 140mmHg is associated with higher mortality in Korean hemodialysis patients. Additional research is needed concerning peritoneal dialysis patients, as the impact of the ideal systolic blood pressure target differs from that observed in hemodialysis patients.

Systolic BP (mmHg)	Hemodialysis		Peritoneal Dialysis	
	Adjusted HR (95% CI)	p-value	Adjusted HR (95% CI)	p-value
All-cause mortality				
<120	1.05(0.997-1.111)	0.0647	1.19(1.033-1.364)	0.0158

Impact of Obesity on Peritoneal Dialysis Outcomes: A Nationwide Inpatient Sample Analysis

Supawadee Suppadungsuk,[1,2] Charat Thongprayoon,[1] Wisit Kaewput,[3] Supawit Tangpanithandee,[2] Paul W. Davis,[1] Wisit Cheungpasitporn.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Chakri Naruebodin Medical Institute, Bang Phli, Thailand; [3]Phramongkutklao College of Medicine, Bangkok, Thailand.*

Background: Obesity can pose a significant challenge for performing peritoneal dialysis (PD) in end-stage kidney disease (ESKD) patients. This study aimed to assess the impact of obesity on in-hospital treatments, outcomes, and resource utilization in hospitalized ESKD patients receiving PD.

Methods: This study was conducted using the National Inpatient Sample to identify hospitalized ESKD patients receiving PD from the years 2003 to 2018. The in-hospital treatments, outcomes, and resource utilization were compared between obese and non-obese patients, adjusting for age, sex, race, year of hospitalization, and comorbidities.

Results: A total of 100,523 hospitalized ESKD patients receiving PD were included in the analysis. Of these, 9,890 (9.8%) had an obesity diagnosis. In the adjusted analysis, obese patients had a higher need for procedures for PD catheter adjustment or removal (OR 1.29; 95% CI 1.16-1.43), hemodialysis (OR 1.28; 95% CI 1.19-1.38), and mechanical ventilation (OR 1.29; 95% CI 1.16-1.44), compared to non-obese patients. Obesity was significantly associated with higher risk of PD peritonitis (OR 1.12; 95% CI 1.06-1.19) and fluid overload (OR 1.34; 95% CI 1.23-1.45) but lower in-hospital mortality (OR 0.84; 95% CI 0.73-0.96). No significant differences were observed in the length of hospital stay or hospitalization costs between the two groups.

Conclusions: Among hospitalized ESKD patients receiving PD, obesity was associated with higher PD-related complications but lower mortality. This suggests that while obesity may complicate the management of hospitalized ESKD patients on PD, it does not necessarily translate to increased mortality or healthcare expenses.

	Univariable analysis	p-value	Multivariable analysis	p-value
PD catheter adjustment	1.24 (1.12-1.37)	<0.001	1.29 (1.16-1.43)	<0.001
Hemodialysis	1.17 (1.09-1.25)	<0.001	1.28 (1.19-1.38)	<0.001
Mechanical ventilator	1.23 (1.11-1.36)	<0.001	1.29 (1.16-1.44)	<0.001
PD peritonitis	1.14 (1.08-1.21)	<0.001	1.12 (1.06-1.19)	<0.001

Length of hospital stay (days)	-0.14 (-0.31, 0.02)	0.08	0.11 (-0.06, 0.29)	0.20

FR-PO445

Comparative Outcomes of Peritoneal Dialysis across Different Hospital Settings: An Analysis of Urban Teaching, Urban Nonteaching, and Rural Hospitals

Supawadee Suppadungsuk,[1,2] Charat Thongprayoon,[1] Wisit Kaewput,[3] Paul W. Davis,[1] Supawit Tangpanithandee,[2] Wisit Cheungpasitporn.[1]
[1]Mayo Clinic Minnesota, Rochester, MN; [2]Chakri Naruebodin Medical Institute, Bang Phli, Thailand; [3]Phramongkutklao Hospital, Bangkok, Thailand.

Background: Patients with end-stage kidney disease (ESKD) receiving peritoneal dialysis (PD) are treated in a variety of hospital settings, including urban teaching, urban non-teaching, and rural hospitals. Understanding the differences in clinical characteristics, treatments, outcomes, and resource utilization specific to these hospital types is crucial for optimizing patient care.

Methods: This study utilized the National Inpatient Sample to identify hospitalized ESKD patients receiving PD in the United States from 2003 to 2018, The in-hospital treatments, outcomes, and resource utilization were compared across urban teaching, urban nonteaching, and rural hospitals.

Results: The study included 99,528 hospitalized ESKD patients receiving PD. Notable differences were observed across hospital types. The mean age was 57.2±16.1 years overall, with rural hospitals having older patients (59.5±16.1 years). The study population was 49.8% male. Racial distribution varied significantly, with rural hospitals having a higher proportion of White patients (70.4%). Charlson comorbidity scores were similar across all hospitals, with a median score of 4 (IQR 3-5). Hospitalization year, primary payer, and patient income levels varied significantly. Rural hospitals had shorter hospital stays (4 vs. 5 days) and lower costs ($19,534.5 vs. $31,583.5). Urban nonteaching and rural hospitals had slightly lower odds for PD catheter adjustments and lower odds of mechanical ventilation and palliative care. However, they had higher odds of peritonitis. Adjusted mortality odds were lower in rural hospitals (OR 0.72, 95% CI 0.59-0.87).

Conclusions: Significant differences in clinical characteristics, treatments, outcomes, and resource utilization were observed among hospitalized ESKD patients receiving PD across urban teaching, urban nonteaching, and rural hospitals. These findings emphasize the need for tailored approaches to optimize patient care based on the specific characteristics and needs of each hospital setting.

FR-PO446

Combination of Left Ventricular Ejection Fraction and End-Diastolic Diameter and Outcomes in Patients on Peritoneal Dialysis: A Multicenter Retrospective Study

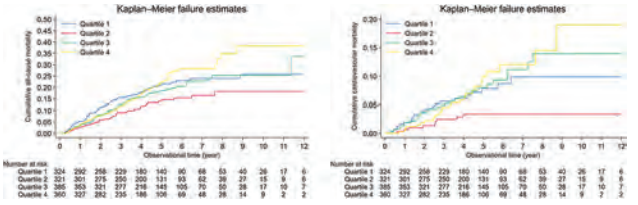
Jiayin You, Xianfeng Wu, Niansong Wang. *Shanghai 6th Peoples Hospital Affiliated to Shanghai Jiao Tong University, Shanghai, China.*

Background: End-stage renal disease (ESRD) is often complicated by left ventricular dysfunction, which is associated with a poor prognosis. This study aims to investigate the association between baseline left ventricular ejection fraction (LVEF) plus left ventricular end-diastolic diameter (LVEDD) with outcomes in peritoneal dialysis (PD) patients.

Methods: In this multicenter retrospective study, 1511 incident Chinese patients on PD between January 1, 2005 and December 31, 2021 were enrolled. Restricted cubic splines (RCS) were used to explore the non-linear associations between LVEF+LVEDD and the risk of mortality. Parametric models for interval-censored survival-time data (stintreg) were used to examine the association between LVEF+LVEDD quartiles and the outcomes.

Results: During 6451.11 person-years of follow-up [median 4.81 (IQR 3.61-6.81) years], 247 (17.8%) patients died, including 88 cardiovascular deaths. RCS showed a U-shaped association between LVEF+LVEDD and the risks of all-cause and CV mortality. According to the quartiles, the optimal range of LVEF+LVEDD associated with the lowest risk of all-cause and CV mortality was 103 to 107, which was set as the reference range. Both higher (≥115) and lower (<103) levels of LVEF+LVEDD were associated with increased risks of all-cause mortality (hazard ratio [HR] 2.20, 95% confidence interval [CI] 1.58-3.07; HR 1.68, 95% CI 1.19-2.36) and cardiovascular mortality (HR 2.51, 95% CI 1.33-4.75; HR 1.86, 95% CI 0.96-3.61).

Conclusions: Low and high levels of baseline LVEF+LVEDD were associated with increased risks of all-cause and cardiovascular mortality in PD patients.



FR-PO447

Efficacy and Survival of Patients with Heart Failure on Peritoneal Dialysis as an Ultrafiltration Option: A 10-Year Experience Based on the Catalan Renal Registry

Sara Nunez-Delgado,[1] María Azancot,[1] Juan C. León-Román,[1] Natalia Ramos,[1] Ana Sanchez Escuredo,[2] Maria Jose Soler.[1] *[1]Nephrology Department. Hospital Universitari Vall d'Hebron, Barcelona, Spain; [2]Nephrology Department. Hospital Sant Joan Despí - Consorci Sanitari Integral, Sant Joan Despí (Barcelona), Spain.*

Background: In heart failure (HF) disease, approximately 20% of patients will develop diuretic resistance over time. Peritoneal dialysis (PD) could be a therapeutic option, although its long-term outcomes were not reported. Our objective was to analyze the long-term outcomes of PD patients with HF indication (PD-HF).

Methods: Retrospective study of the Catalan Renal Registry of PD-HF patients between 2013-2022. Baseline clinical characteristics and follow-up until December/2022 was described.

Results: Of the 1874 patients starting PD, 198 (10.6 %) were PD-HF, median eGFR at start was 22.6 (IQR 14.8-32.8)ml/min1.73m^2 and 73.7% have an eGFR above 15 ml/min1.73m^2. The rest of the baseline characteristics are described in **table 1a**. Previous history of ischemic heart disease, arrhythmia or cardiac surgery was recorded, 39% of patients had ≥2 of these pathologies. HF etiology was described in 52.7%, being ischemic heart disease the most prevalent cause (44.4%). Echocardiographic records were available in 19.6% of patients (**table 1b).** Median survival was 20 months (IQR 16-24) (**figure 1**). In the cox multivariate analysis, age >75 years (HR 1.68 [95%CI 1.09-2.60]), frailty (HR 22.64 [95%CI 6.95-73.77]), and past cardiac surgery (HR 1.61 [95%CI 1.08-2.38]) were associated with poor survival (**table 1c**). 67 patients survived over 24 months. In the logistic regression analysis, age >75 years (OR 4.56 [95%CI 1,60-13,04]) and lower education level (OR 2,41 [95%CI 1,10-5,28]) were associated with higher mortality at 24 months (**table 1d**).

Conclusions: PD-HF is an appropriate option in patients with heart failure in non-advanced stages. Older age, frailty and lower education levels worsens the prognosis of PD-HF patients.

Table 1a. Baseline characteristics (n = 198)		
Sex (male): n (%)		145 (73.2)

Examining the Relationship between Hygiene Practices and Clinical Outcomes in Patients on Peritoneal Dialysis: Insights from the Thailand PDOPPS Initiative

Phatcharida Klinphayom,[1] Jeerath Phannajit,[1] Piyarat Rojsanga,[1] Somchai Eiam-Ong,[1] Kriang Tungsanga,[1] Jeffrey Perl,[3] David W. Johnson,[2] Roberto Pecoits-Filho,[4] Talerngsak Kanjanabuch.[1] *[1]King Chulalongkorn Memorial Hospital Department of Internal Medicine, Bangkok, Thailand; [2]Princess Alexandra Hospital, Woolloongabba, QLD, Australia; [3]St Michael's Hospital, Toronto, ON, Canada; [4]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: Peritonitis is a leading cause of hemodialysis (HD) transfer and mortality. We investigated the association between hygiene behavior and clinical outcomes in patients on PD.

Methods: Personal hygiene was assessed in patients across 22 facilities in Thailand Peritoneal Dialysis Outcomes and Practice Patterns Study (PDOPPS) during 2016-2021. Hygiene behavior was assessed using a short-form hygiene behavioral questionnaire comprising 8 domains (physical hygiene, prevention of contamination, and PD procedure/protocol) with a yes/no answer format. Poor hygiene behavior was defined as a cumulative score of ≥3. Cox proportional hazards model regression and Poisson regression incidence rate ratio (IRR) were employed to estimate associations between hygiene behavior and clinical outcomes, including mortality, HD transfer, and peritonitis.

Results: Of 1566 randomly selected patients on PD from 22 facilities, 669 consented and reported their hygiene behavior. Poor hygiene behavior was prevalent in the PD population (6%), especially in patients with diabetes and caregiver dependence. Poorer self-reported hygiene behavior at baseline was significantly associated with a higher rate of peritonitis and a shorter time to HD transfer but not death. This association persisted after adjusting for age, gender, PD vintage, comorbidities, shared frailty by study sites, and serum albumin.

Conclusions: Personal hygiene behavior was independently associated with higher risk of peritonitis and shorter time to HD transfer, but not death. The findings could potentially pave the way for evaluating hygiene standards using this tool, which could aid in identifying patients at a heightened risk (risk stratification) and determining those who would benefit from preventive measures.

FR-PO449

Higher Peritoneal Dialysis (PD) Facility Census Is Associated with Better PD-Specific Outcomes

Christopher D. Knapp,[1,2] Kirsten L. Johansen,[3,2] Shuling Li.[3] *[1]Hennepin Healthcare System Inc, Minneapolis, MN; [2]University of Minnesota Twin Cities, Minneapolis, MN; [3]Hennepin Healthcare Research Institute Chronic Disease Research Group, Minneapolis, MN.*

Background: Patients who receive PD care at facilities with more PD patients have lower rates of conversion to in-center hemodialysis (ICHD). It is not clear if a higher PD facility census is associated with differences in other outcomes.

Methods: We used the US Renal Data System to identify a cohort of incident PD patients from 2014-2018. Patients were categorized into 3 groups according to the year-end PD census at their initial PD facility: <11, 11-25 and >25 patients. All patients were followed up to one year for mortality and conversion to ICHD. A sub-cohort with Medicare fee-for-service coverage at PD initiation was followed for outcomes of hospitalization for peritonitis or cardiovascular disease (CVD). We used Cox models to estimate the hazards ratios (HR) for mortality, peritonitis, and CVD hospitalization and Fine-Gray competing risk models for conversion to in-center HD. Hazards for each outcome for the PD-census groups were compared.

Results: Of 58,219 PD patients, 15% were managed in a facility with a census of <11 patients, with 32% and 53% in facilities with PD censuses of 11-25 and >25, respectively. Patients in the <11 census group were more likely to be White and to live in non-urban areas. Unadjusted hazards for each outcome were higher for patients managed in lower census facilities (Table). After adjustment, the hazards of conversion to ICHD and peritonitis hospitalization were 6% and 11% higher, respectively (HR 1.06, 95% CI 1.01-1.11 for conversion, HR 1.11, 95% CI 1.01-1.22 for peritonitis) for patients in the 11-25 census group, but they had a 7% lower hazard of mortality compared with the >25 group (HR 0.93, 95% CI 0.87-0.99). Patients in the <11 group had a 20% higher hazard of conversion to ICHD compared with patients in the >25 group (HR 1.20, 95% CI 1.13-1.28).

Conclusions: A high facility PD census was associated with better PD-specific outcomes like peritonitis and conversion to ICHD but not with lower mortality.

Health Services Accessibility and Clinical Outcomes in Peritoneal Dialysis: Findings from the PDTAP Study

Qinghua Wang, Jie Dong. *Peking University First Hospital Department of Nephrology Renal Division, Beijing, China.*

Background: The association between health services accessibility and clinical outcomes has been revealed in patients with chronic kidney disease, but showing inconsistent findings. The study aimed to explore the association of key factors reflecting four dimensions of health services accessibility and clinical outcomes in peritoneal dialysis (PD) patients.

Methods: This is an affiliated study from the Peritoneal Dialysis Telemedicine-assisted Platform (PDTAP) dataset. Healthcare resource accessibility was evaluated by factors for four dimensions, such as hospital type and regional economic level for healthcare resource accessibility, education level and residence for socio-environmental accessibility, medical insurance and annual income for affordability, and travel distance and travel time for spatial accessibility. The primary outcome was all-cause mortality. The secondary outcomes included transfer to hemodialysis and first-episode PD-related peritonitis.

Results: A total of 7416 PD patients were enrolled between June 2016 and April 2019, with the median of 29.0 (14.3, 45.0) months for follow-up. By multivariable Cox regression analyzes, university-affiliated hospitals (HR 0.881, [0.780-0.996], $p < 0.001$), low regional economic level (HR 1.189 [1.035, 1.366], $p = 0.014$), and low annual income (HR 1.210 [1.023, 1.431], $p = 0.026$) were independently associated with all-cause mortality. The low level of regional economy and annual income played a stronger role in predicting all-cause mortality in university-affiliated hospitals as shown in analyzes for interactive effects. After propensity-score matching, university-affiliated hospitals were still associated with all-cause mortality (HR 0.817, [0.701-0.953], $p = 0.010$) and transfer to hemodialysis (HR 1.265 [1.065-1.502], $p = 0.007$) but not associated with first-episode peritonitis.

Conclusions: This study indicated real-world evidences for health services accessibility and clinical outcomes among patients on PD through a nation-level prospective cohort. Health policymakers and physicians in China should explore strategies to promote the equity in health services accessibility for the improvement of clinical outcomes in the PD population.

FR-PO451

Hybrid Dialysis Outcomes in Qatar: 3-Year Experience

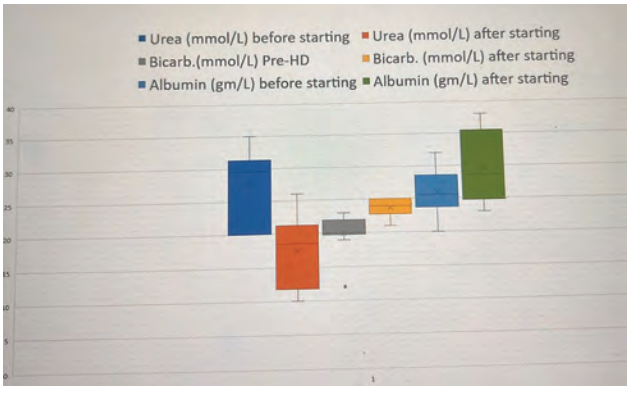
Mohammed E. Hussain, Mohamad M. Alkadi, Hanaa Ahmed, Nahid I. Ali, Merlina Vergel, Linu chacko Chacko, Ahlam B. Ali, Abdullah I. Hamad, Hassan A. Al-Malki. *Hamad Medical Corporation, Doha, Qatar.*

Background: Hybrid Dialysis is a combined dialysis modality using both Hemodialysis and Peritoneal dialysis.

Methods: PD patients with either low solute clearance or inadequate UF despite using the maximum applicable PD regimen were identified. We enrolled twenty-three patients (May 2021-April 2024). All of them were kept on once-weekly HD plus the current PD regimen 6 days per week. We evaluated volume status clinically. Pre-HD urea, potassium, phosphorus, and bicarbonate as indicators of solute clearance, and Albumin level as an indicator of nutritional state. In addition to dialysis catheter-related complications, patient satisfaction and finally checking outcomes.

Results: A significant improvement in volume status was associated with a reduction in mean Systolic Blood Pressure (174 ± 32 Vs 135± 15 mmHg, p < 0.0001). All solute clearance indicators showed significant improvement. Reduction in mean urea by 36.7% *p*-value < 0.001, mean potassium by 23.52% *p*-value <0.0001, and mean phosphorus reduction of 26.5 % *p*-value <0.01. The rise in mean bicarbonate was by 15.6 % *p*-value < 0.001. Improvement of mean serum albumin *p*-value <0.05 was observed. Patient satisfaction index was improved. Five patients (21.7%) shifted to Hemodialysis, Five Patients (21.7%), returned to Peritoneal dialysis, three patients (13%) underwent a kidney transplant, two patient leave the country and eight patients (34.8 %) still doing Hybrid dialysis some of them started more than 25 months, average staying was 16 months.

Conclusions: Hybrid dialysis is a reasonable dialysis model for patients with frequent volume overload, low solute clearance, or both on PD with significant improvement in volume status, Solute clearance, nutritional status, and patient satisfaction. Hybrid dialysis can be used for more than 24 months. Some patients can return to full PD most of them were started due to volume overload. A larger number of patients and is required to generalize the findings of these observations.



FR-PO452

Mortality and Hospitalization and Associated Factors in Assisted Home Hemodialysis Patients in the State of Qatar: A Retrospective Study

Abdullah I. Hamad,[1] Amani Zidan,[2] Mohamed Y. Abdelhai,[1] Mostafa Elshirbeny,[1] Tarek A. Ghonimi,[1] Hamza Ilyes Hassaine,[1] Mossab Filali,[1] Fadwa S. Al-Ali,[1] Mohamad M. Alkadi,[1] Hassan A. Al-Malki.[1]
[1]Hamad Medical Corporation, Doha, Qatar; [2]Qatar University, Doha, Qatar.

Background: Dialysis carries a high burden on patients with end stage kidney disease. It is usually associated with multiple co-morbidities that worsen patients' quality of life and outcome. We established an innovative assisted home hemodialysis (AHHD) program in Qatar in July 2021 for elderly patient who are dependent on ambulance transportation (bed bound or wheelchair). We are presenting data on mortality and hospitalization and associated risk factors in the AHHD program in Qatar.

Methods: We did a retrospective study from July 1st, 2021, to December 31st, 2023. All patients enrolled in our AHHD in Qatar were included. Data were extracted from our national electronic medical record. It included demographics, co-morbidities, laboratory tests, and clinical outcome data. The study was approved by Hamad Medical Corporation IRB.

Results: We included all 120 patients enrolled in AHHD program. Median age was 72.5 and 47.5% were males. The median (IQR) vintage HD was 41 (51) months (among which 13 (10) months of AHHD vintage). 51.7% of the patients used an ambulance with stretcher while 48.3% wheelchair. 87.5% had diabetes, 95% with hypertension, 25% with heart failure, 25% with cerebrovascular accidents, 38.3% with coronary artery disease, and 29.2% with arrhythmias. During the study period, 54.2% were hospitalized at least once. Logistic regression was performed to ascertain the effects of age, gender, AHHD vintage, mobility, and dialysis adequacy on the likelihood of mortality. The regression model was statistically significant, $\chi 2(5) = 28.564$, $p < .0005$. AHHD vintage was the only significant factor and associated with a decreased likelihood of mortality. For each one-month increase in AHHD vintage, the odds of mortality will decrease by 11.4% (CI: 0.801-0.969). For hospitalization, only AHHD vintage was statistically significant risk factor on logitic regression. For each one-month increase in AHHD vintage, the odds of hospitalizations will decrease by 6.9% (CI: 0.877-0.989).

Conclusions: Our study revealed an expected high mortality rate in AHHD program designed for elderly ambulance requiring patients with multiple co-morbidities. Vintage time on AHHD improved survival decreased hospitalization.

FR-PO453

Complexity of In-Hospital Admission Course in Patients on Kidney Replacement Therapy: A Comparative Analysis between Home Hemodialysis and In-Centre Hemodialysis: Experience from Saudi Arabia

Bilal Mohsin, Wael T. Habhab. *King Faisal Specialist Hospital and Research Centre - Jeddah, Jeddah, Saudi Arabia.*

Background: In patients with ESKD, in-center hemodialysis (IHD) and Home Hemodialysis (HHD) are two of the available modalities for Kidney Replacement Therapy (KRT). Patients receiving dialysis, whether in-center or at home, are at a high risk of hospitalization. We wanted to study the in-hospital course in patients undergoing these dialysis modalities.

Methods: This retrospective chart review included 42 adult patients (≥18 years) with ESKD who have completed one year of KRT, either IHD (n=21) or HHD(n=21) at King Faisal Specialist Hospital and Research Centre Jeddah (KFSHRCJ) between 01 August 2022 to 31 July 2023. We studied in-hospital admission encounters in both dialysis modalities in regards to frequency of admission, Inhospital consultations, Estimated length of stay(ELOS), all cause mortality and readmission within 30 days of discharge.

Results: We had a demographically comparable patient population in both groups. There were 59 admission encounters in IHD population as compared to 29 encounters in HHD. For IHD admissions, the number of subspecialities consulted was 2.37 per admission encounter with **total number of consultations (n=140).** In HHD admissions, the number of subspecialities consulted were 2.1 per admission with total **number of consultation (n=61).** The ELOS (Estimated Length of Stay) for IHD patients was 3.7 days per encounter with total hospital days (n=218) in a year follow up as compared to 4.1 days per encounter in HHD patients with total hospital days (n=118). There was **higher readmission rate in IHD** with same or different etiology within 30 days of discharge(n=12) as compared to HHD (n=4). The all cause mortality of patients who completed one year on KRT was 11 in IHD group as compared to 4 in HHD group. The leading cause of mortality was cardiovascular disease in IHD and infections in HHD group.

Conclusions: HHD was associated with lower events of hospitalization, less inhospital consultation burden, less cumulative ELOS, lower all cause mortality and lower rate of readmission as compared to IHD. These findings are limited by small sample size, single centre retrospective followup of one year. We need multicentre study with large sample size over longer duration of time to study the significance of outcomes in our study.

FR-PO454

Peritoneal Dialysis among Patients Initiated on Dialysis at a County Hospital: How to Do Better

Syed Afzal, Neha Siddiqui, Sarwar Khan, Helena Zhang, Hania Kassem. *Baylor College of Medicine, Houston, TX.*

Background: More than 37 million Americans are living with kidney disease. Approximately 800,000 have chronic kidney failure needing dialysis or kidney transplantation. Several studies have demonstrated the cost-effectiveness of peritoneal dialysis (PD) compared to in-center hemodialysis. Despite multiple interventions increasing awareness and incentives for stakeholders, the overall prevalence of patients on PD in the United States remains at less than 12% of total dialysis patients. Our project aimed to increase the rate of PD initiation among patients starting long-term dialysis at Ben Taub, a 402-bed county hospital in Texas, by 50% from baseline.

Methods: An anonymous survey was conducted to assess current understanding of PD among nephrology faculty and trainees at Ben Taub Hospital. The intervention consisted of 1) establishing a screening algorithm to define the eligibility and exclusion criteria for selecting appropriate PD candidates 2) establishing a protocol streamlining the referral process and expediting placement of a PD catheter prior to discharge, and 3) providing an educational session to nephrology faculty and trainees to teach the newly developed algorithm and protocol, bridge knowledge gaps, and address perceived barriers to PD initiation. A chart review study was conducted to collect data on the rates of PD candidacy screening and PD initiation pre- and post-intervention.

Results: In the three months prior to the intervention, a total of 29 ESKD patients were initiated on dialysis. Of those 29 patients, only 8 (27.5%) were screened for PD candidacy and 1 (3.5%) was initiated on PD. At 6 months post-intervention, a total of 78 patients were initiated on dialysis. The percentage of patients initiated on PD increased to 19% (15 of 78 total patients) which reflects nearly a 5-fold increase from baseline. Additionally, the rate of screening improved to 75.6% (59 of 78 total patients).

Conclusions: The results of this study show that simple interventions consisting of providing clinical education on PD to nephrology trainees and faculty and streamlining the referral and initiation process can increase the proportion of ESKD patients screened for PD candidacy and successfully initiated on PD in a county hospital setting.

FR-PO455

Peritoneal Dialysis Is Associated with Lower Mortality and Morbidity Compared with Hemodialysis in Patients Undergoing Cardiovascular Surgery: A Retrospective Cohort Study

Ankur Shah,[1] Osama El Shamy,[2] Jeffrey Perl,[3] Christina A. Raker,[4] Susie L. Hu.[1] *[1]Brown University Warren Alpert Medical School, Providence, RI; [2]The George Washington University, Washington, DC; [3]St. Michael's Hospital, University of Toronto, Toronto, ON, Canada; [4]Rhode Island Hospital, Providence, RI.*

Background: Patients receiving maintenance dialysis face high mortality and complication rates following cardiovascular (CV) surgery. With the growing utilization of peritoneal dialysis (PD), it is important to understand the impact of modality on outcomes following CV surgery.

Methods: This retrospective cohort study used the National Inpatient Sample (2016-2020) to compare outcomes of PD and HD patients undergoing CV surgery. The primary outcome was in-hospital mortality, and secondary outcomes included prolonged ventilation, length of stay, and cost. The primary analysis used multivariable logistic regression to evaluate the association between dialysis modality and in-hospital mortality, adjusting for demographics, comorbid conditions, and hospital factors as potential confounders. Survey-specific analytic procedures incorporated discharge weights, sampling units, and sampling strata to generate nationally representative estimates for all analyses.

Results: A total of 30,155 patients were included in the study, with 28,015 (92.9%) receiving HD) and 2,140 (7.1%) receiving PD. Patients in the PD group experienced better outcomes compared to those in the HD group across all measured variables (table 4). The unadjusted mortality rate was lower in the PD group (4.4% vs 7.8%, OR 0.55, 95% CI 0.35-0.88), and this difference remained significant after adjustment (OR 0.61, 95% CI 0.38-0.97). Similarly, the incidence of prolonged ventilation was lower in the PD group (4.7% vs 9.7%, OR 0.45, 95% CI 0.29-0.71; aOR 0.51, 95% CI 0.32-0.81). The average length of stay was shorter in the PD group (13.6 vs 17.1 days, unadjusted IRR 0.79, 95% CI 0.74-0.85; adjusted IRR 0.85, 95% CI 0.80-0.91). Lastly, total charges were significantly lower in the PD group (mean $307,072 vs $407,556, unadjusted MD -$100,484, 95% CI -$124,773 to -$76,195; adjusted MD -$87,172, 95% CI -$113,523 to -$60,820). Among PD patients, post-operative transition to HD was associated with worse outcomes.

Conclusions: Maintaining PD during the perioperative period may confer benefits over HD, including lower healthcare costs and improved patient outcomes. Careful consideration of dialysis modality in the management of CV surgery patients is needed to optimize clinical outcomes and reduce healthcare costs.

FR-PO456

Associations with Peritoneal Dialysis Treatment Failure in Young Adults: A Mixed-Methods Study

Hannah C. Lyons, Alexander J. Hamilton, Fergus Caskey, Yoav Ben-Shlomo, Lucy E. Selman. *University of Bristol, Bristol, United Kingdom.*

Background: Studies have observed fewer young adults use peritoneal dialysis (PD) compared to haemodialysis (HD). PD is associated with preservation of residual renal function and may provide more flexibility for patients. We sought to understand treatment transitions and patient experiences.

Methods: A sequential explanatory mixed methods study was undertaken. Quantitative analysis utilized data from the Surveying People Experiencing young Adult Kidney failure study, which included individual treatment timelines from 1987 to 2015. Cox proportional hazards analysis examined psychosocial associations with PD failure (defined as a switch to haemodialysis). Semi-structured qualitative telephone interviews were conducted with a purposive sample of young individuals. Transcripts were analysed thematically.

Results: The cohort comprised 470 participants (50% male, 85% Caucasian, mean age of 16 years). Twenty-five percent experienced PD more than once. PD survival rates at 1 and 5 years were 71% and 37% respectively. Risk associations for PD failure included young adulthood (15-19 years hazard ratio (HR) 2.41, 95% confidence intervals (CI) 1.35, 4.28; 20-24 years HR 3.39, CI 1.97, 5.83; 25-30 years HR 3.14, CI 1.65, 6.00; p<0.005, compared to 10-14 years) and primary renal disease (systemic diseases HR 1.97, CI 1.12, 3.46, p=0.02, compared with tubulointerstitial diseases). Leading causes of PD failure were infection (50%), compliance issues (21%), and mechanical problems (18%). Thirteen participants aged 14-29 during PD treatment were interviewed. They had received PD during 2013-2015, but most had received renal transplants by the interview date in 2020 so they explored their experience retrospectively. Major themes included compromised autonomy, life impact and support structures; resilience was reported by PD survivors.

Conclusions: Young adulthood emerges as a high-risk period for returning to haemodialysis both from transplant failure and PD failure. Our study suggests the need for enhanced preparation including detailed information on dialysis modalities including considerations for university life, workplace environments and sexual relationships.

Funding: Government Support - Non-U.S.

FR-PO457

Exploring Peritoneal Dialysis Exits from a Canadian Cohort

Jennifer M. MacRae,[1] Tessa A. Woodside,[1] Bushra Muzammal,[1] Terry J. Smith,[3] Susan A. Jones,[3] Nikhil A. Shah.[2] *[1]University of Calgary, Calgary, AB, Canada; [2]University of Alberta, Edmonton, AB, Canada; [3]Alberta Health Services, Calgary, AB, Canada.*

Background: Growth in a peritoneal dialysis (PD) program is challenging to achieve. In order to increase the number of people receiving PD, the total number of people exiting should be less than the number of new starts. We sought to better understand the PD exits in our program in order to develop interventions to reduce the attrition from PD.

Methods: A 14 month retrospective review of the Alberta Kidney Care (AKC) PD program (comprised of a northern (AKCN, 317 pts) and a southern (AKCS, 298 pts) program with a focus on the reasons why people exited PD from November 1, 2022 until Dec 31, 2023. Differences between programs and between sexes were explored using descriptive statistics and Chi Square where appropriate. The primary outcome was the reason for exit from PD.

Results: During the study period 615 people received PD; 230 patients exited PD during this time frame. There were no differences in demographics between the 2 programs with the overall mean age of 61 ±16.3 years, comorbidities of DM 43% (123), CVD 91% (210) and heart failure 27% (63) and mean time on PD of 2.2 ± 1.9 years. Overall, 37% (230/615) exited PD, 45% (103) transferred to facility-based hemodialysis (HD), 21.3% (49) were transplanted, 19.1% (44) died and 11% (26) withdrew from dialysis. Patients who transferred to HD received PD for a similar amount of time (2.13 ±2.00) as compared to those who were transplanted (2.01± 1.92) or died (2.53 ± 1.88 years). The main reasons for transfer to HD included medical 43% (44), peritonitis 32% (33), and hernia/leaks 24% (24). Despite similar PD peritonitis rates, AKCN had more exit site (8.6% vs 1%) and tunnel (17.1% vs 3%) infections than AKCS. Catheter complications occurred more frequently in AKCS with more leaks (21% vs 8.6%) and catheter associated pain (10% vs 2.9%) in AKCS vs AKCN respectively.

Conclusions: There was a high turnover of people on PD with the majority transferring to HD for reasons of PD related infections and medical etiology. Strategies to reduce PD related infections will be helpful to reduce PD losses in our program. Further research into the differences in catheter complications and PD infections between the two programs is needed.

FR-PO458

Association of Serum Intact Parathyroid Hormone Levels with Sarcopenia in Patients Undergoing Peritoneal Dialysis

Yu Chi Chang,[1] Yu-Hsien Lai,[1,2] Bang-Gee Hsu.[1,2] *[1]Division of Nephrology, Buddhist Tzu Chi General Hospital, Hualien, Taiwan; [2]School of Medicine, Tzu Chi University, Hualien, Taiwan.*

Background: Sarcopenia is highly prevalent in patients undergoing peritoneal dialysis (PD), contributing to adverse clinical outcomes. Animal models suggest that parathyroid hormone (PTH) induces muscle wasting through adipose tissue browning. However, the relationship between PTH dysregulation and sarcopenia in the PD population remains unclear. Thus, we aimed to explore the association between serum intact PTH levels and sarcopenia in PD patients.

Methods: We conducted a cross-sectional analysis using data from the Tzu-Chi PD cohort, comprising 186 PD patients with a mean age of 57.5 ± 14.1 years. Basic information, comorbidities, serum intact PTH levels, and other biochemical data were retrieved. Atherosclerotic cardiovascular disease (ASCVD) includes any history of coronary artery disease, myocardial infarction, peripheral arterial disease, and stroke. All patients were evaluated for appendicular skeletal muscle mass (ASM) using the Body Composition Monitor (BCM), handgrip strength, and 6-meter usual gait speed. Sarcopenia was defined based on the consensus of the Asian Working Group for Sarcopenia 2019. Relative over-hydration (OH) was also assessed using BCM.

Results: The overall prevalence of sarcopenia was 38.2%. Across three groups of PTH levels (< 150 pg/mL, 150-300 pg/mL, and > 300 pg/mL), the prevalence rates were 29.7%, 36.4%, and 46.2%, respectively (p for trend = 0.044). In the unadjusted model, age, ASCVD, subjective global assessment score, body mass index, relative OH, serum phosphorus, and log-transformed intact PTH levels were significantly associated with sarcopenia. After full adjustment for all above factors, age (OR = 1.04, 95% CI = 1.01–1.08), ASCVD (OR = 4.21, 95% CI = 1.37–12.96), BMI (OR = 0.51, 95% CI = 0.41–0.63), relative OH (OR = 1.04, 95% CI = 1.00–1.07), log-transformed intact PTH levels (OR = 3.41, 95% CI = 1.45–8.04) were independently associated with sarcopenia among PD patients.

Conclusions: Among PD patients, elevated serum intact PTH levels are independently associated with sarcopenia. Further longitudinal studies are warranted to confirm their causal relationship.

FR-PO459

Relationship between Exercise and the Occurrence of Abdominal Wall Complications among Patients on Peritoneal Dialysis

Li Xinqiu, Jie Dong. *Peking University First Hospital Department of Nephrology, Beijing, China.*

Background: Concerns about the development of abdominal wall complications are one of reasons for physical inactivity among peritoneal dialysis patients, but there was no direct evidence to confirm the relationship between exercise and abdominal wall complications. In the general population, the relationship between exercise and abdominal wall complications such as hernias remains controversial. This study aims to explore the relationship between exercise and abdominal pressure complications in peritoneal dialysis population.

Methods: A retrospective data analysis of a prospective cohort. Incident and prevalent PD patients between January 2016 and April 2019 were recruited. Abdominal wall complications related to increased intra-abdominal pressure, including hernia, hydrothorax, etc. were recorded during follow-up. Exercise characteristics were collected by outpatient questionnaire, including exercise or not, type of sports, exercise duration and exercise intensity. Competing risk model were used to assess the predictive power of exercise data in the occurrence of abdominal wall complications. The subgroups analysis according to age, gender, diabetes, BMI and eIPP were also performed.

Results: During the median follow-up of 46.0 months among the 475 PD patients, 33 (6.9%) patients developed abdominal wall complications. Totally 377(79.4%) patients had regular exercise. Walking was the major exercise form among 99.5% participants. Only 2 patients combined aerobic and impedance exercise. The median exercise duration per week was 210.0 (140.0, 350.0) minutes. About 52% patients having exercise intensity below fairly light. None of exercise characteristics including exercise or not, exercise duration per week, exercise intensity was found to be associated with abdominal wall complications in univariate or multivariate competing risk analysis. Similarly, no significant prognostic value was found in any subgroup analyses. The number of patients involved in impedance exercise was too small to do further analyse.

Conclusions: This study confirmed for the first time that aerobic exercise in appropriate duration and intensity didn't increase the risk of abdominal wall complications in peritoneal dialysis patients. Further research on resistance exercise and high-intensity exercise need to be further explored in the PD population.

FR-PO460

Summary of Complications in Maintenance Hemodialysis Using Tunneled Cuffed Catheters (TCC) in Our Hospital

Kazue Matsuoka, Kiyoshi Ikeda. *Ikeda Vascular Access Dialysis and Internal Medicine Clinic, Fukuoka, Japan.*

Background: With increasingly older populations, the number of patients using TCC in the long-term is on rising, in contrast to its use as an interim, or bridge, technique in the recent past. We suggest TCC as a vascular access (VA) equivalent to arteriovenous fistula (AVF) and arteriovenous graft (AVG) not only for in-center dialysis (ICHD) but also for patients who are considering home hemodialysis (HHD). In this study, we examined whether TCC can be used as safely as ICHD in HHD, where self-management is more important.

Methods: Patients who underwent maintenance dialysis for at least three months using TCC at our hospital from September 2010 to the end of February 2024 were included in the study. Exit/tunnel infection and bloodstream infection events were extracted retrospectively from the medical records, respectively. The evaluation period was from the date of TCC insertion, and the infection rate was calculated as the number of infections/ total number of dialysis days × 1000. The patency rate was evaluated from the date of insertion to the date of first removal due to complications, excluding bridge use cases.

Results: Among the study participants, 20 were treated with ICHD (TCC inserted age: 61.4 ± 15.2; man:woman ratio: 9:11; insertion period: mean 7.4 years; original disease: diabetes mellitus (DM); non-DM: 11:9) and 11 with HHD (TCC inserted age: 56.5 ± 11.3; man:woman ratio: 8:3; inserted period: mean 4.4 years; original disease: DM; non-DM: 4:7). The exit site/tunnel infection rate in TCC-ICHD was 1.27/1000 dialysis days and the bloodstream infection rate was 1.11/1000 dialysis days. Similarly, for TCC-HHD, the exit site/tunnel infection rate was 0.53/1000 dialysis days and the bloodstream infection rate was 0.91/1000 dialysis days, which were lower than those for TCC-ICHD, although not significantly different. Coagulase-negative *Staphylococci* and *Staphylococcus aureus* accounted for 70-80% of the bacteria detected in the blood cultures for both TCC-ICHD and TCC-HHD. The time to the onset of bloodstream infection was longer for TCC-HHD, averaging 0.5 years for TCC-ICHD and 2.3 years for TCC-HHD, suggesting that a long-term strategy for infection prevention was needed. Catheter patency rates did not differ between TCC-ICHD and TCC-HHD.

Conclusions: TCC represents a safe and effective option as a VA in HHD.

FR-PO461

Effects of Temporary Hemodialysis before Insertion of a Peritoneal Dialysis Catheter

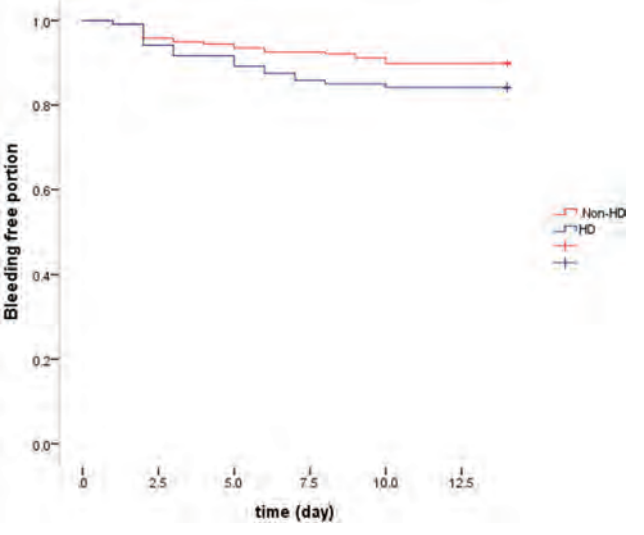
A Young Kim, Seok hui Kang, Ji Hyun Park. *Yeungnam University Medical Center, Daegu, Republic of Korea.*

Background: There is insufficient data on the effects of temporary hemodialysis, such as reducing uremic bleeding side effects when inserting a peritoneal dialysis catheter. We analyzed the effects of pre-emptive hemodialysis before insertion of a peritoneal dialysis catheter.

Methods: We retrospectively analyzed medical records. Patients were divided into two groups: those who underwent temporary hemodialysis before insertion of the peritoneal dialysis catheter and those who did not. Logistic regression and cox regression analysis were used to analyze risk factors affecting bleeding and catheter survival. Statistical significance was set $P < 0.05$.

Results: Of the 336 patients, 120 patients underwent temporary hemodialysis before peritoneal dialysis catheter insertion and 216 patients did not receive hemodialysis. Bleeding complications occurred in 43 (12.8%) of 336 patients. In Logistic regression analysis, there were no risk factors that showed a significant correlation with bleeding in the univariate analysis. In the multivariate analysis, there was a significant correlation between hemodialysis and bleeding (OR=2.2, 95% CI [1.09-4.43], P= 0.001). Hemoglobin and creatinine also showed a significant correlation with bleeding (P=0.027, P=0.017 respectively). The one-year catheter survival rate was 92.3%. Cox regression analysis was performed to analyze risk factors related to catheter survival. In both univariate and multivariate analysis, only infection showed a significant correlation with catheter survival (P= 0,002).

Conclusions: Temporary hemodialysis did not reduce the side effects of bleeding when inserting a peritoneal dialysis catheter. As renal function declines, the risk of uremic bleeding increases. If renal replacement therapy is necessary, it should be performed as soon as possible.



FR-PO462

Association of eGFR at Peritoneal Dialysis (PD) Catheter Insertion with PD-Related Complications

Arti Dhoot,[1,2] Alix Clarke,[3] Robert R. Quinn,[3] Matthew J. Oliver.[1,2] North American PD Catheter Registry. *[1]Sunnybrook Health Sciences Centre, Toronto, ON, Canada; [2]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; [3]University of Calgary Cumming School of Medicine, Calgary, AB, Canada.*

Background: Guidelines now reflect a shift towards an intent to defer dialysis strategy, irrespective of modality. In peritoneal dialysis (PD), this may increase the risk of early complications. The objective of this study was to determine if early PD-related complications were associated with eGFR prior to PD catheter insertion.

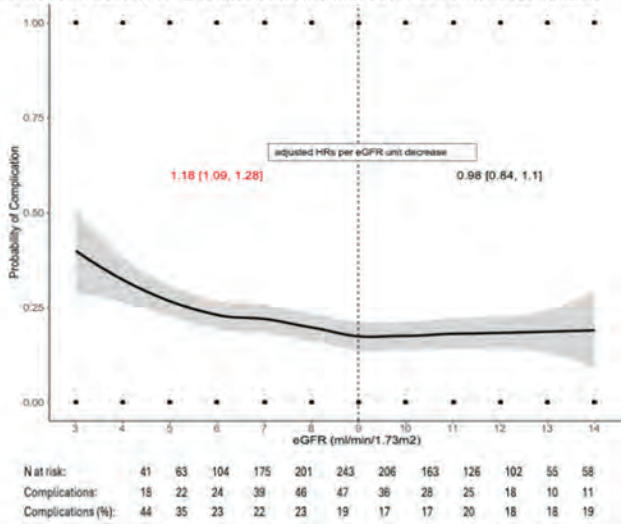
Methods: We conducted a retrospective study using the North American PD catheter registry across 23 sites. Patients undergoing PD catheter insertions were initially grouped by pre-dialysis eGFR ≤ 9 ml/min and ≥10 ml/min. The eGFR was then analyzed as a continuous variable. The primary outcome was the occurrence of PD related complications within 90 days of insertion. Adjusted risk between eGFR and outcomes was calculated using cause-specific Cox models.

Results: Of 1,537 patients with first PD catheter insertions, 1033 (67%) had a pre-dialysis eGFR < 9 versus 504 (33%) with ≥ 10. Patients with eGFR ≤ 9 were more likely to be younger (median age 60 vs.63), female (44 vs 32%) and have fewer comorbidities.

There was no significant difference in PD related complications between the eGFR ≤ 9 and eGFR ≥ 10 groups (aHR 1.12 [0.86, 1.45]). However, in the lower GFR group, which represented two-thirds of the population, there was an increased risk for every 1ml/min eGFR decline below 9ml/min (aHR 1.18 [1.09, 1.28]) (Figure 1). The most common PD-related complications included; flow restriction (7%), leak (3%) and pain (3%).

Conclusions: PD-related complications were similar when comparing an insertion eGFR of ≤9 to ≥10 ml/min. However, when assessing eGFR as a continuum, there was an increased risk of complications by 18% for each 1ml/min drop in GFR below 9ml/min suggesting intent to defer start targets should account for modality.

Figure 1. Probability of PD related outcome with eGFR as a continuous variable



FR-PO463

Novel Use of Intraperitoneal Acyclovir for Herpes Simplex Virus 2-Related Viral Peritonitis: A Case Report

Arti Dhoot,[1,2] Gemini Tanna,[1,2] Bourne L. Auguste.[1,2] *[1]Sunnybrook Health Sciences Centre, Toronto, ON, Canada; [2]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada.*

Introduction: Viral etiologies for peritonitis can be misclassified as culture negative peritonitis due to poor accessibility of viral testing in the effluent fluid. Inaccurate diagnosis and subsequent ineffective treatment can lead to unnecessary catheter removal for presumed refractory peritonitis. We present the only reported case of herpes simplex virus-2 (HSV-2) related PD peritonitis that was successfully treated with intraperitoneal (IP) acyclovir.

Case Description: A 73-year old female on continuous cyclic peritoneal dialysis with a past medical history relevant for HSV-2 genital lesions presented with a cloudy effluent, elevated effluent WBC count with lymphocytic predominance and a recent HSV-2 flare. Initially thought to be culture negative peritonitis but no reduction was seen in cell count on empiric IP cefazolin and ceftazidime. Effluent was sent for viral culture on day 8 and discovered to be positive for HSV-2 via PCR on day 12. Oral acyclovir was used initially but then converted to intraperitoneal route to minimize adverse events. IP acyclovir was reconstituted in a 2.5% Dianeal bag and administered for 14 days based on pharmacokinetic data to achieve serum levels similar to intravenous administration. Patient's cell counts improved and repeat effluent testing was negative for HSV-2 on day 27. Patient had no symptoms of neurotoxicity.

Discussion: Culture negative peritonitis can account for up to 20% of peritonitis cases however the effluent is largely just tested for bacterial and fungal presence. Clinicians should be aware to the possibility of viral peritonitis in patients with refractory culture negative peritonitis, especially if risk factors such as a history of HSV infection are present. Early recognition and timely initiation of antivirals may prevent inadvertent catheter removal for presumed refractory peritonitis and help retain patients on PD. Most importantly, utilizing IP route of administration for acyclovir may lead to lower drug related toxicity whilst achieving therapeutic serum concentrations and allow for ongoing outpatient management of home dialysis patients on PD.

Table 1. Timeline of events - including cell count and differential.

	Day 1	Day 3	Day 4	Day 5	Day 8	Day 11	Day 12	Day 13	Day 15	Day 19	Day 20

Comparison of Peritoneal Dialysis Catheter (PDC) Placement Outcomes via Image-Guided Percutaneous (IGP) Technique vs. Laparoscopic Surgical (ALS) Technique

Ali Poyan-Mehr, Alvina Sundang, Todd Drasin, Neelam M. Bhalla, Sijie Zheng, Leonid Pravoverov. *The Permanente Medical Group Inc, Oakland, CA.*

Background: The IGP technique presents several potential opportunities when placing PDCs. Some cited factors include avoiding general anesthesia, better availability of IR suites, and being less resource-intensive than OR suites. As part of the Kaiser Permanente Northern California (KPNC) quality assurance effort, we have monitored patient and procedure characteristics and compared PDC outcomes by IGP vs. ALS.

Methods: In this retrospective study, we analyzed the outcomes of patients undergoing PDC placement in KPNC from 1/1/18 to 12/31/22. Patients were identified based on procedure codes and ESKD diagnoses. Baseline and outcome variables were extracted electronically.

Results: 3,062 patients underwent PDC placement, and 27% were placed via the IGP technique. As shown in Table 1, patients in the IGP had statistically significantly lower BMI, eGFR, and albumin levels at PDC placement but a significantly higher number of patients with heart failure. A greater proportion of patients in the IGP group had their procedure done while inpatient for other indications. The average length of stay for patients admitted post-procedure was shorter in the IGP group. The 90-day and 180-day catheter intervention rates were lower in the IGP group (not accounting for confounders). There was no statistical difference between the two groups' 30-day readmission and mortality rates.

Conclusions: Expanding utilization of home dialysis is one of the pillars of value-based care in nephrology. This QA study illustrates that IGP can be a safe and effective approach to lowering the barriers to peritoneal dialysis adoption by expanding access to care while maintaining desirable patient outcomes and utilizing fewer healthcare resources.

Partial Replantation Method for Managing Peritoneal Dialysis Catheter Damage and Infections

Seyoung Ryou,[1] Hyung Duk Kim,[2] Yaeni Kim.[1] *[1]The Catholic University of Korea Seoul St Mary's Hospital, Seocho-gu, Seoul, Republic of Korea; [2]The Catholic University of Korea Eunpyeong St Mary's Hospital, Eunpyeong-gu, Seoul, Republic of Korea.*

Background: The revised 2023 guidelines from the International Society for Peritoneal Dialysis (ISPD) emphasize salvage methods for treating refractory exit site infections (ESI) and tunnel infections (TI), preserving the existing catheter by manipulating only the outer cuff above the peritoneum, there by avoiding hemodialysis transfer. Here, we investigated the efficacy of the partial replantation technique.

Methods: In this retrospective study from January 2021 to December 2023 at a single center, we compared 9 patients undergoing salvage methods with 58 patients receiving de novo catheter insertion. Our evaluation included ESI, TI, peritonitis, and catheter dysfunction. The salvage technique involved distal cutting of the infected or mechanically impaired catheter and connecting a new one using a connector comprising a PD adaptor and transfer set [Figure1].

Results: During the study period, nine patients (four males, mean age 56 years) with an average PD duration of 66 months underwent the salvage technique. Post-replantation outcomes included, one ESI case (11.1%), one TI case (11.1%), three peritonitis cases (33.3%), and two catheter removals (22.2%). No procedural complications or catheter

dysfunctions were observed. The control group experienced similar rates of ESI (10.3%), TI (1.7%), peritonitis (19.0%), catheter removal (12.1%), and catheter dysfunction (1.7%). Kaplan-Meier analysis demonstrated no significant differences in outcomes between the two groups (ESI; p=0.31, TI; p=0.094, peritonitis; p=0.84, catheter dysfunction; p=0.69, catheter removal; p=0.39) [Figure2].

Conclusions: This study confirms non-inferiority and effectiveness of the salvage technique compared to de novo for managing ESI, TI and mechanical impairment of the catheter.

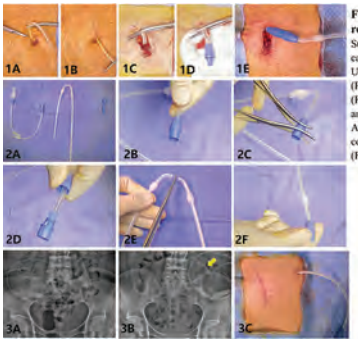

Figure 1. Surgical procedure illustrating the partial replantation technique,
Surgical steps are as follows: Make an incision at the PD catheter exit and cut the proximal part of the catheter (Fig.1B-C). Use Tenckhoff catheter, transfer set, and PD catheter adaptor (Fig.2A). Disassemble the connector with Kelly forceps (Fig.2B-D), cut the new catheter between cuffs (Fig.2E), and connect it at the proximal end (Fig.2F). Attach Luer lock adaptor to old catheter end (Fig.1D), connect to new catheter (Fig.1E), and create a new tunnel (Fig.3C).

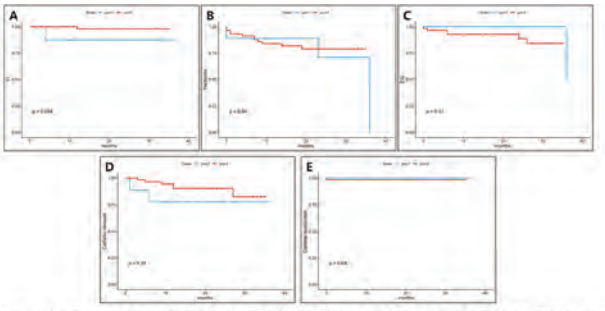

Figure 2. Kaplan-Meier analysis comparing clinical outcomes between partial replantation and de novo catheter insertion of catheters. (A) TI(tunnel infection), p: 0.094, (B) Peritonitis, p: 0.84, (C) ESI(exit-site infection), p: 0.31, (D) Catheter removal, p: 0.39, (E) Catheter dysfunction, p: 0.69, Grp1: catheter replantation, Grp2: de novo catheter insertion

FR-PO466

Tissue Plasminogen Activator (tPA) Use for Peritoneal Dialysis Catheter Dysfunction

Caroline M. Hsu,[1] Harold Manley,[2] Antonia Harford,[2] Austin Gibson,[2] Nien Chen Li,[2] Scot E. Born,[2] Monica Shieu,[2] Daniel E. Weiner,[1] Dana Miskulin,[1] Klemens B. Meyer,[1] Doug Johnson,[2] Eduardo K. Lacson.[2,1] *[1]Tufts Medical Center, Boston, MA; [2]Dialysis Clinic Inc, Nashville, TN.*

Background: Peritoneal dialysis (PD) catheter dysfunction accounts for 10-14% of PD to hemodialysis (HD) transfers. Tissue plasminogen activator (tPA) is sometimes used for PD catheter dysfunction, but reports of its effectiveness vary.

Methods: This retrospective study included all instances of tPA used for poor flow or catheter dysfunction in PD patients from January 1, 2020 to December 31, 2023, excluding tPA use for peritonitis. Data collected from the electronic health record included the number and timing of tPA doses and whether the patient subsequently continued PD therapy, underwent PD catheter revision, or transferred to HD within 30 days of the initial tPA treatment. Manual chart review collected additional detail on reasons for tPA use.

Results: Among 5297 patients receiving PD at DCI during the study period, tPA was administered 114 times for poor flow or catheter dysfunction in 85 patients (catheter vintage median 11 months [IQR 2, 22]). Per manual chart review, 48 instances were for both poor inflow and poor outflow, 52 instances were for poor outflow only, and the indication for tPA could not be determined in 14 instances. Among 64 patients who received a single dose of tPA, 41 continued PD, 22 transferred to HD without further intervention, and one continued PD after catheter revision (Figure). Among 21 patients who received two or more tPA doses, 11 continued PD and 10 transferred to HD, with one transferring to HD after PD catheter revision. Primary reasons for transfer to HD included PD catheter failure (N = 14), intra-abdominal pathology (5), peritonitis (4), ultrafiltration failure (4), inadequate clearance (1), and not documented (4).

Conclusions: Among 85 patients who received 114 tPA treatments, 53 patients (46%) continued PD. More granular data on patient selection, catheter position, and potential causes of catheter failure will inform optimal use of tPA for PD catheter dysfunction.

FR-PO467

Assessment of Glycemic Profiles Using Continuous Glucose Monitoring in Patients with ESKD Treated with Automated Peritoneal Dialysis

Thatsaphan Srithongkul, Methawoot Khemmongkon, Suchai Sritippayawan, Sukit Raksasuk. *Mahidol University Faculty of Medicine Siriraj Hospital, Bangkok, Thailand.*

Background: The patients using automated peritoneal dialysis (APD) faced unphysiological glucose loading during nighttime, which caused difficulty in glycemic control. Data on glucose dynamics in patients using APD was still limited. This study aimed to evaluate 24-hour glycemic profiles in APD patients by continuous glucose monitoring (CGM)

Methods: In this cross-sectional study, 30 APD patients were enrolled, including 10 diabetes (DM) with insulin used, 10 DM without insulin used, and 10 non-DM. All participants underwent seven days of CGM. The primary outcome was the glycemic profiles demonstrated by mean and under the curve (AUC) of interstitial glucose concentrations and the mean amplitude of glycemic excursions (MAGE). Data analysis encompassed the whole 7-day period and compared daytime and nighttime

Results: There were no significant differences in the mean glucose, AUC, and MAGE between the APD and non-APD periods in all groups. The mean difference in glucose during daytime and nighttime was comparable between DM with insulin and non-DM group (p= 0.364). During the APD period, the mean glucose, MAGE, and AUC were significantly higher in DM patients with insulin compared to non-DM patients ($p \leq 0.05$). Dialysate glucose exposure did not influence the disparity in mean glucose concentration and AUC during the APD period in both DM (p=0.508) and non-DM groups (p =1.00). From multivariate analysis, only DM with insulin-used status was associated with mean glucose concentration (coefficient 97.84, p =0.03), while membrane transport status and glucose concentration in dialysate showed no association

Conclusions: ESKD patients using APD demonstrated comparable glycemic profiles during the APD and non-APD period with unphysiological non-glucose dipping during nighttime among all DM statuses

Glycemia Assessed by Continuous Glucose Monitoring among Patients on Dialysis

Laura Mayeda,[1,2] Leila R. Zelnick,[1] Subbulaxmi Trikudanathan,[1] Irl B. Hirsch,[1] Nathaniel Ashford,[1] Yoshio N. Hall,[1] Ian De Boer.[1] *[1]University of Washington, Seattle, WA; [2]Northwest Kidney Centers, Seattle, WA.*

Background: In kidney failure, patients are at risk for hypo- and hyperglycemia due to impaired insulin sensitivity, insulin secretion, and kidney gluconeogenesis. Little is known about glycemia patterns in dialysis patients and HbA1c is biased in kidney failure and does not reflect fluctuations in blood glucose.

Methods: The Blood Sugar Sensing On Maintenance Dialysis (BLOSSOM) study is a prospective community-based cohort of people treated with dialysis, with or without diabetes mellitus (DM), designed to assess the prevalence, causes, and consequences of dysglycemia using continuous glucose monitoring (CGM). Participant wore a Dexcom G6Pro CGM for 10 days. This interim analysis of the first 373 BLOSSOM participants.

Results: Participants had a mean (SD) age of 61 (14) years. We enrolled 231 participants with DM (including 81 HD patients no longer treated with glucose-lowering drugs) and 142 without DM. Mean CGM blood glucose was high and time in range (TIR) was low (below 70% clinical target in diabetes) for participants with DM, regardless of dialysis modality (Table). PD participants without DM also had low TIR (Table). Hyperglycemia increased throughout the day and was the highest in participants with treated DM on PD (Figure). Hypoglycemia was common for HD patients with or without DM (Table).

Conclusions: In this community-based sample of maintenance dialysis patients, uncontrolled hyperglycemia was highly prevalent, especially among participants with DM and PD participants without DM, and hypoglycemia was frequent.

Understanding the Impact of the Kidney Care Choices (KCC) Model on Utilization and Cost of Care

Darin F. Ullman,[1] Brighita M. Negrusa,[2] Richard A. Hirth,[2] Claudia Dahlerus,[2] Sarah E. Lewis,[3] Kelsey R. Bacon,[1] Annalise Maillet,[1] Vahakn Shahinian,[2] Jonathan H. Segal,[2] Jennifer Wiens.[1] *[1]The Lewin Group, Falls Church, VA; [2]University of Michigan, Ann Arbor, MI; [3]Center for Medicare and Medicaid Innovation, Baltimore, MD.*

Background: The Kidney Care Choices (KCC) Model implements provider incentives designed to delay the onset of end-stage renal disease, better prepare patients for dialysis, coordinate care across settings, and increase kidney transplantation. Nephrology practices could join the Kidney Care First (KCF) model option or could combine with transplant providers and other partners such as dialysis facilities to form a Kidney Contracting Entity (KCE) and join the Comprehensive Kidney Care Contracting (CKCC) model option. This study evaluated how this voluntary model affects Medicare payments and utilization, particularly for modalities of dialysis care.

Methods: Using a difference-in-differences (DiD) approach, we estimated the effect of the KCC Model on outcomes relative to a comparison group from before the model (2017–2019) to the Model's first performance year (PY) (2022). For both model options, the comparison group selection process focused on nephrology practices, with separate comparison groups created for CKCC and KCF model options. We evaluated changes in utilization, Total Medicare Parts A & B payments, and service-specific payments. The sample consisted of 293,491 KCC patients (KCF=23,580; CKCC=269,911) and 138,264 comparison patients (KCF comparison=17,997; CKCC comparison=120,267) across the entire study period. KCC Participants (25 KCFs and 53 KCEs) represented 2,856 nephrology professionals and KCE partnerships included 2,217 dialysis facilities and 133 transplant providers.

Results: In KCF, home dialysis (peritoneal dialysis or home hemodialysis) rose by 2.1 percentage points (pp) ($p<0.05$), or 2% in relative terms. In CKCC, peritoneal dialysis increased by 0.74 pp ($p<0.10$), or 8%. CKCC had an increase in home dialysis training (0.15 pp [$p<0.01$], or 32%). Kidney transplant active waitlisting increased by 1.8 pp ($p<0.01$), or 15%, for CKCC. General utilization measures, such as hospitalizations and emergency department use, were unaffected. KCF home dialysis payments increased by $45 per patient per month ($p<0.01$).

Conclusions: Overall, the KCC Model showed some promising effects in its first year, including increased home dialysis use and active transplant waitlisting.

FR-PO470

Impact of a New Payment Model on Optimal ESKD Starts

Claudia Dahlerus,[1] Darin F. Ullman,[2] Richard A. Hirth,[1] Brighita M. Negrusa,[2] Sarah E. Lewis,[3] Jonathan H. Segal,[1] Vahakn Shahinian,[1] Tammie A. Nahra,[1] Joseph Gunden,[1] Jennifer Wiens.[2] Kidney Epidemiology and Cost Center. *[1]University of Michigan, Ann Arbor, MI; [2]The Lewin Group, Falls Church, VA; [3]Center for Medicare and Medicaid Innovation, Baltimore, MD.*

Background: CMS' Kidney Care Choices (KCC) Model aims to delay ESKD^ onset, better prepare patients for chronic dialysis, and increase kidney transplantation. A nephrology practice can participate under the Kidney Care First (KCF) model option, or, nephrology professionals/practices can partner with transplant providers and other optional partners to form a Kidney Contracting Entity under the Comprehensive Kidney Care Contracting (CKCC) model option. One KCC quality metric is the percentage of patients who have an "optimal ESKD start." Credit is given for any of the following outcomes: ESKD patients that start on home dialysis; start in-center hemodialysis with a fistula or graft vs. a catheter; or receive a preemptive kidney transplant. We examined the impact of the KCC Model on optimal ESKD starts.

Methods: We used a propensity score matched comparison group and difference-in-differences (DiD) methods to assess trends pre (2017-2019) and post model implementation (2022), adjusted for patient, practice, and market differences. We used CMS claims and the CMS 2728 Form to identify optimal starts for patients aligned to KCF and CKCC participants relative to practice level matched comparison groups. The sample consisted of eligible FFS Medicare beneficiaries with Stage 4 or 5 CKD or ESKD aligned to the KCF and CKCC model options and matched comparison groups during the study period. There were 22,131 KCC and 15,087 comparison patients across the entire study period. Ninety-one percent of patients were aligned to the CKCC option.

Results: While the proportion of patients who had an Optimal ESKD Start increased over time for both KCC and comparison groups, the KCC Model increased Optimal ESKD Starts 6.9 percentage points ($p<0.05$, 16% of baseline mean) above the baseline trend for beneficiaries aligned to the CKCC option. This impact was driven by increases in home dialysis starts and starting in-center HD with an AV fistula or AV graft. Improvement was not significantly better in the KCF option relative to its comparison group.

Conclusions: Results suggest nephrologists may be able to modify processes of care to improve planned starts for new ESKD patients. ^For the purposes of this abstract, ESKD and ESRD can be used interchangeably. CMS uses ESRD in the KCC Model to be concordant with the ESRD Medicare benefit.

FR-PO471

Quantifying the Waste Associated with Icodextrin in Patients Undergoing Continuous Cycling Peritoneal Dialysis

Anukul Ghimire,[1] David Ward,[1] Elena Qirjazi,[1] Nikhil A. Shah,[2] George Vitale.[1] *[1]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [2]University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada.*

Background: Effective healthcare waste (HCW) management and HCW reduction are important considerations for medical programs. Dialysis is associated with significant hazardous and non hazardous HCW. Icodextrin is commonly used in patients undergoing continuous cycling peritoneal dialysis (CCPD). In Canada, Icodextrin for CCPD is only available as 2.5 L, single-use bags. Patient's often have Icodextrin fill volumes < 2L, with the remainder of the volume being discarded as non-hazardous HCW. We sought to quantify the volume of discarded Icodextrin solution in the CCPD population of the Alberta Kidney Care South (AKC-S) program.

Methods: A cross sectional audit was performed of the AKC-S program including all patients utilizing CCPD in 2022. Data included Icodextrin dwell volume, patient demographics, and estimated costs associated with Icodextrin use in 2021. Descriptive statistics were used to report the data.

Results: Among 205 patients in the AKC-S program on CCPD, the mean age and PD vintage (± standard error of mean) was 62.7 ± 0.9 years and 27.5 ± 2.1 months respectively. The average Icodextrin dwell volume was 1200 mL. 87% of the patients using Icodextrin were using dwell volumes up to 1500 mL. Our patient population tended to be similar in weight compared to those in previous studies evaluating Icodextrin for the long dwell. In 2021, Icodextrin for CCPD cost AKC-S $1.27 million (CAD).

Conclusions: Among patients in the AKC-S program, there is a notable difference in the average fill volume (1200 mL) and available bags of Icodextrin (2.5L) available. This suggests that a large portion of purchased Icodextrin is being discarded as non-hazardous HCW. This practice pattern may also be reflected in other home dialysis programs and further work is needed to (1) understand the large-scale costs and environmental impact associated with Icodextrin waste, (2) develop effective methods to manage HCW in dialysis programs, and (3) implement quality improvement initiatives to reduce HCW associated with peritoneal dialysis.

FR-PO472

Peritoneal Dialysis in Patients with Crohn Disease: Absolute Contraindication or Grey Area with Pink and Purple Polka Dots?

Shannon Ejiofor, Twinkle Patel, Mowaffaq R. Said, Manar Shmais, Kana Miyata. *Saint Louis University School of Medicine, St Louis, MO.*

Introduction: Most end-stage kidney disease (ESKD) patients with inflammatory bowel disease (IBD) undergo hemodialysis (HD) because IBD has traditionally been considered a clinical contraindication to peritoneal dialysis (PD). Literature regarding PD use in IBD patients is scarce. We present two cases where PD was initiated in patients with Crohn's Disease (CD).

Case Description: Case 1: A 46-year-old man with a history of stricturing ileocolonic CD for 20 years developed ESKD from monoclonal gammopathy of renal significance and acute interstitial nephritis possibly related to Vedolizumab. His CD was in clinical remission with Risankizumab at the initiation of PD. He had surgical history of cholecystectomy and bilateral inguinal repair. PD catheter was placed percutaneously with fluoroscopic guidance by Interventional Nephrology. He was started on continuous cycler peritoneal dialysis, which was later transitioned to once-a-day exchange of Icodextrin. He received a kidney transplant 7 month after the initiation of PD. He did not develop any episodes of PD peritonitis during the period. Case 2: A 27-year-old man with a history of CD for 7 years became ESKD from IgA nephropathy. He had non-stricturing non-penetrating ileal CD, previously treated with Azathioprine, Adalimumab, Ustekinumab, and Vedolizumab without persistent response. He was on Risankizumab at the initiation of PD and he was in endoscopic remission based on a normal ileocolonoscopy. He did not have previous abdominal surgeries. A PD catheter was placed under fluoroscopy. However, he immediately experienced outflow failure. A laparoscopic revision of PD catheter was performed with fibrin sheath dissection and partial omentectomy, during which some adhesions from the omentum to the pelvic wall were found. Because he continued to have PD catheter malfunctioning, the catheter was removed, and he was transitioned to HD. He continued HD until he received a kidney transplant 7 months later.

Discussion: We present one successful and one unsuccessful case of PD use in CD. Our cases demonstrate that it may be possible in IBD patients under the proper conditions, with clear remission and a clear plan for prompt transplantation if they are considered candidates. Further research is needed to define the detailed indications and contraindications of PD in patients with IBD.

FR-PO473

Mission P(D)-possible: Enabling Peritoneal Dialysis in Situations Formerly Thought to Be Impossible, Eight Inspiring Cases

Kijanosh Lehmann, Jan T. Kielstein, Amelie Gienapp, Manuela Lindgren, Reinhard K. Wanninger, Gabriele C. Eden. Kielstein Lab. *Stadtisches Klinikum Braunschweig gGmbH, Braunschweig, Germany.*

Introduction: Tom Cruise currently tries for the seventh time to do the impossible in "Dead Reckoning". We try to do the same in PD, an underutilized form of kidney replacement therapy (KRT). In this abstract we present an inspiring collection of 8 individual cases, in which, despite co-diseases currently thought to be contraindications for PD, this treatment modality could successfully implemented.

Case Description: In 2023, 81 PD catheters were implanted at our center, cahnging the view on "contraindications" to PD. PD despite major abdominal surgery including subtotal colectomy and hemicolectomy as well as comtinuation of PD despite colostomy are reported. Further, a patient with ADPKD and liver cysts who undergoes PD with adequate dialysis effectiveness for almost 5 years, despite rejecting unilateral nephrectomy challanged our view about contriaindications for PD. Moreover, Calciphylaxis (CUA) often considered a contraindication for continuing PD, can successfully be managed with intensified PD and administration of sodium thiosulfate. Frequently anuria is viewed as a contraindication to PD, a view we do not share in general. In cases intellectual disability, hemodialysis is often preferred, however, there are cases in which PD can be carried out successfully such as in trisomy 21. Missing arms are a drastic obstacle to carrying out PD. This hurdle could also be solved through technical assistance and interprofessional collaboration, as was the case with our patient with amelia due to thalidomide embryopathy (Figure 1).

Discussion: It will not be before 2025 that Tom Cruise will accomplish a mission impossible again. Meanwhile interprofessional teams worldwide will do the impossible many times by enabling PD in those patients who have chosen this form of KRT, focussing on patient-centered outcomes.

Patient with Contergan induced dysmelia connecting himself to a PD cycler (consent on file).

FR-PO474

Embedded Peritoneal Dialysis Catheter: When Things Go Wrong

Madhab Ray, Niti Madan, Shubha Ananthakrishnan. *University of California Davis, Davis, CA.*

Introduction: Embedment of peritoneal dialysis catheter is sometimes used when a patient with ESRD does not need dialysis immediately, but it may be necessary in the months to come. The procedure of embedment is relatively safe and short, gives time to develop a scar around the catheter and, reduces chance of infection and leak. The catheter becomes readily available for use upon externalization of the tip. Various complications including malfunction and infection are seen when an embedded catheter is externalized. However, some embedded catheters are never externalized and thus the procedure becomes a futile exercise. Infection in an unused embedded catheter is rare. We report a case of infection in an embedded PD catheter which was never externalized or used.

Case Description: A 61yr old female with HIV (CD4 928, viral load undetectable, on ABC/3TC/DTG), positive HBV core antibody, hypertension, hyperlipidemia and CKD G5 A3 (due to NSAIDS, hypertension and side effect of HIV medications with secondary FSGS) got an embedded PD catheter placed. Nine months later the patient presented with abdominal pain. She was found to have cellulitis of the abdominal wall adjacent to embedded catheter and the culture of the purulent fluid from incision and drainage along with her blood culture showed MRSA infection. The patient was treated with appropriate course of antibiotics and her catheter was surgically removed without any further complication. She never required dialysis and got living donor kidney transplant 10 months after removal of the PD catheter.

Discussion: Embedment of a PD catheter in patients with ESRD under consideration of peritoneal dialysis has gained popularity. It helps in increasing the acceptance rate of peritoneal dialysis as the modality of choice. It offers readiness and gives opportunity for scarring of the surgical site providing a seal around the catheter and reducing the possibility of infection and leak. However, different studies question the overall benefit of such a procedure for the risk of nonfunction of the exteriorized catheter, infection, catheter being never used because of a transplant or change of dialysis modality to hemodialysis. These different possibilities need to be considered before planning to embed a catheter. The risk of infection increases with the duration of embedment and more so in the immunocompromised patient. Proper case selection is crucial to minimize such risk.

FR-PO475

Effect of Dupilumab in Treating Refractory Allergic Dermatitis to Peritoneal Dialysis Catheter: A Case Report

Jun Takeoka,[1] Naohiro Toda,[1] Ryo Sato,[1] Kyoka Fujita,[1] Satoshi Kurahashi,[1] Hisako Hirashima,[1] Eri Muso,[1] Toshiyuki Komiya,[2] Akira Ishii.[1] *[1]Kansai Denryoku Byoin, Osaka, Japan; [2]Otsu Sekijuji Byoin Toshoshitsu, Otsu, Japan.*

Introduction: Eosinophilia during induction of peritoneal dialysis (PD) is frequently caused by icodextrin, but allergic reactions to PD catheters has been rarely reported. We report a case of refractory systemic contact dermatitis associated with a PD catheter that was successfully treated with dupilumab, avoiding catheter removal.

Case Description: A 62-year-old man underwent PD catheter implantation by Moncrief-Popovich technique due to progression of diabetic kidney disease five months before admission. One month later, he developed generalized pruritus and his eosinophils were elevated to 2500/μL. Topical steroids and antihistamines were started, but itching did not get better and eosinophil count remained high. One month before admission, he started PD. The itching became unbearably intense, and the patient was hospitalized because of erythema and desquamation on whole body. Eosinophilic peritonitis and reactivation of human herpes virus 6 (HHV6) were not observed. He was started on PSL (10mg daily), but his eosinophil count remained around 2000/μL and his skin rash did not improve. Drug-induced lymphocyte stimulation test (DLST) was negative for several

drug and positive for PD catheter. Systemic contact dermatitis caused by the PD catheter was diagnosed from the DLST result. After the PSL dose was increased to 40 mg daily for refractory systemic contact dermatitis with liver damage, the eosinophil count and skin rash improved. Administration of dupilumab allowed PSL withdrawal and maintained skin status and eosinophil count.

Discussion: As the patient had type 2 diabetes mellitus, long-term oral administration of PSL should be avoided from the viewpoint of glucose tolerance and susceptibility to infection. Dupilumab is an IL4/IL13 receptor monoclonal antibody and is used for refractory atopic dermatitis, but there are no reports of dupilumab use for allergic dermatitis caused by PD catheters. In this case, the use of dupilumab allowed PD continuation without eosinophil elevation or flare-ups of skin rash even after gradual PSL reduction.

FR-PO476

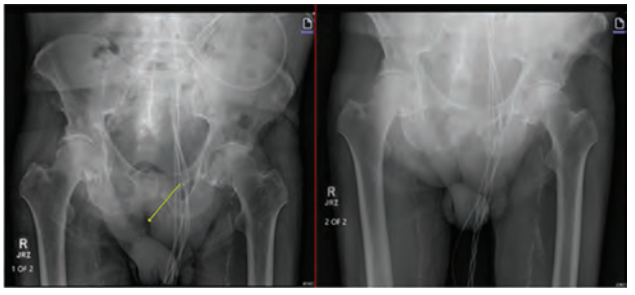
Peritoneal Dialysis Catheter Migration into an Inguinal Hernia

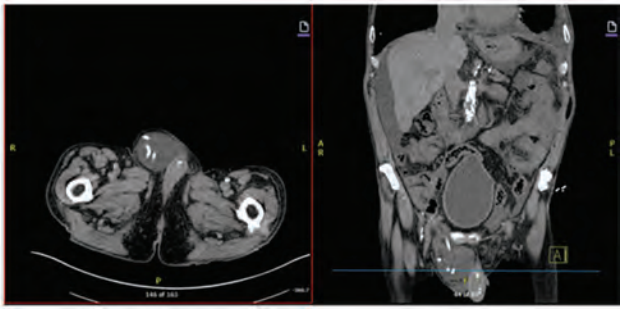
Manuel A. Santos Carrasquillo, Scott D. Cohen, Rute C. Paixao. *Cleveland Clinic Florida, Weston, FL.*

Introduction: Peritoneal Dialysis (PD) is associated with improved patient quality of life compared to hemodialysis. There are important infectious and non-infectious complications of PD that must be recognized to facilitate successful therapy. We present a case of an End Stage Renal Disease (ESRD) patient on Continuous Cyclic Peritoneal Dialysis (CCPD) therapy who presented with catheter malfunction secondary to outflow obstruction.

Case Description: 77-year-old male with a history of ESRD on CCPD and bilateral inguinal hernias presented to the ED with PD catheter drainage problems for 2 days. He underwent a physical exam, a pelvis x-ray (Fig.1) and a CT Abdomen and Pelvis showing a migration of the catheter from the posterior left hemipelvis through his right inguinal hernia into the scrotum (Fig 2). Surgery was consulted and the patient underwent laparoscopy repositioning of the PD catheter and laparoscopic bilateral inguinal hernia repair with mesh (extraperitoneal approach). PD was held after surgery and restarted 48 hrs later with low fill volumes. The patient has continued PD without additional complications to date.

Discussion: It is important to recognize noninfectious complications of PD, including causes of poor catheter drainage. Inguinal hernias are common noninfectious complications in PD (reported in 4–14% of patients). There are several case reports on patients with decreased PD catheter drainage where the catheter was found to have migrated through the inguinal hernia sac. Surgery, ultimately, allowed these patients to continue with PD. Prompt identification and repair of inguinal hernias can facilitate continued PD and prevent catheter drainage issues. Careful physical examination and correction of inguinal hernias are important for PD patients.





FR-PO477

Pleuroperitoneal Diaphragmatic Communication: A Rare Complication in Patients on Peritoneal Dialysis after Cardiac Surgery

Samira M. Samant, Camilo Cortesi. *Kaiser Permanente Santa Clara Medical Center, Santa Clara, CA.*

Introduction: Pleuroperitoneal diaphragmatic communication (PPDC) is an extremely rare but serious complication of peritoneal dialysis (PD). Elevated intra-abdominal pressure creates a fistula between the pleural and peritoneal spaces, allowing peritoneal fluid migration and causing effusions or hydrothorax. While approximately 25% of patients are asymptomatic, presentations include dyspnea or, in extreme cases, lung collapse. To our knowledge, this is the first case of PPDC described in the literature post-cardiac surgery.

Case Description: A 57-year-old female with end-stage renal disease due to focal segmental glomerulosclerosis, recently started on PD and undergoing transplant evaluation, presented with NSTEMI and multivessel coronary artery disease. Post-coronary artery bypass grafting (CABG), she received continuous renal replacement therapy. After her bilateral surgical chest tubes were removed, she resumed PD when off vasopressors three days later. The next day, a routine chest X-ray revealed new bibasilar opacities, and chest CT showed large bilateral pleural effusions. Given her significant negative fluid balance, these large effusions in the absence of hypoxemia were concerning for a pleuroperitoneal leak due to recent chest tubes. Pleural fluid glucose was elevated compared to serum levels. A right chest tube was placed, and she transitioned to hemodialysis with improvement.

Discussion: PPDC, although exceedingly rare, should be considered in PD patients with pleural effusions, particularly if volume negative and postsurgical. PPDC usually arises from increased intra-abdominal pressure due to large-volume PD solution instillation, coughing, straining, or trauma, allowing peritoneal fluid to traverse the diaphragm. In postsurgical patients, recent chest tubes or diaphragmatic instrumentation may be the cause. Elevated pleural fluid glucose indicates peritoneal dialysate presence; MRI or scintigraphy can confirm a fistula. Management includes a PD holiday, pleural cavity tetracycline instillation, surgical patch grafting of the diaphragm, or talc pleurodesis.

CXR with BL chest tubes (left), CXR after chest tube removal with new effusion (middle), CT chest with BL effusions

FR-PO478

The Fastest Way to a Person's Heart: A Case of Peritoneal-Pericardial Leak after Pericardiocentesis in a Patient on Peritoneal Dialysis

Neha Siddiqui, Wolfgang C. Winkelmayer, Hania Kassem. *Baylor College of Medicine, Houston, TX.*

Introduction: While peritoneal dialysis (PD) is a cost effective dialysis modality, it is associated with infectious and non-infectious complications including PD fluid leaks. Leakage of dialysate into the pericardium is an uncommon yet potentially life-threatening complication of PD. To our knowledge, there are very few cases of peritoneal-pericardial leaks reported in the literature.

Case Description: A 55-year-old Hispanic female with a past medical history of CKD stage V secondary to DM and HTN (biopsy proven), presented to the emergency department with shortness of breath and was found to have a pericardial effusion with early tamponade physiology. Patient underwent successful pericardiocentesis via a sub-xyphoid approach with removal of 500cc of serous fluid and was discharged on diuretics. She was readmitted shortly afterwards for shortness of breath, was found to have worsening pleural effusions requiring chest tubes placement, and was initiated on PD urgently during that admission. Patient was admitted again a few days later with similar complaints and was found to have another pericardial effusion. PD was continued during that admission with no improvement in breathing despite multiple changes in the prescription. CXR showed complete opacification of the right lung. Therefore, a CT peritoneography was obtained to rule out pleuroperitoneal communication but showed instead direct communication between the peritoneal dialysate and a large pericardial effusion. Decision was made to discontinue PD and to initiate hemodialysis resulting in improvement in symptoms.

Discussion: Similarly to previous reports, the peritoneal-pericardial communication in this patient likely resulted from pericardiocentesis. The procedure has been reported to cause communications between the pericardium and the pleural and peritoneal space. However, communication with the peritoneum is unlikely to be recognized or be clinically significant except in PD patients due to the possibility of peritoneal fluid leaking into the

pericardium. This represents a rare yet critical complication of PD, posing a significant threat to life. Physicians should be mindful of peritoneopericardial fistulas as a possible complication in PD patients who undergo pericardiocentesis since a timely diagnosis is crucial to promptly discontinue PD and mitigate further risks.

FR-PO479

Peritonitis and Hemoperitoneum in Peritoneal Dialysis: A Rare Traumatic Complication

Michael Liben, Aashvi R. Dalal, Timothy S. Pak, Yuanpu Zheng. *NewYork-Presbyterian Brooklyn Methodist Hospital, Brooklyn, NY.*

Introduction: The most common complications of peritoneal dialysis (PD) catheters include infections and mechanical catheter dysfunction. Perioperative complications of catheter insertion include intraabdominal organ perforation and bleeding, while delayed complications include impaired dialysate flow, pericatheter leakage, and superficial cuff extrusion. Here, we present an interesting case of an acutely ill PD patient with multiple PD complications.

Case Description: A 44 year old man with End Stage Renal Disease (ESRD) on PD presented to the hospital with septic encephalopathy, inability to complete cycler PD for three days, and bloody PD effluent. Preceding the admission, he had a three month history of PD peritonitis treated by his outpatient nephrologist with intraperitoneal (IP) Vancomycin. After hospitalization, he was given broad spectrum intravenous (IV) and IP antibiotics for culture confirmed and recurrent Staphylococcus epidermidis peritonitis. Cycler PD was not reattempted, and the patient was given manual PD with 2.5 liters every six hours including IP cefazolin and heparin as well as hemodialysis (HD). He had continued grossly bloody PD effluent with red blood cell counts of 650,000/uL on admission decreasing only to 320,000/uL after one week, necessitating transfusions of ten units of packed red blood cells over this period.

Discussion: Initial and repeat computed tomography of the abdomen and pelvis demonstrated displaced PD catheter tip terminating in the right abdomen, as well as an expanding intraabdominal fluid collection without active IV contrast extravasation. Surgery performed an exploratory laparoscopy with extensive lysis of adhesions, converted to open laparotomy, and the PD catheter course was tracked entering the lower abdomen directly into the urinary bladder. Cystotomy finally revealed that the source of bleeding was within the bladder itself, and the remaining hematoma was evacuated. The PD catheter was completely removed, and Urology was consulted intraoperatively for bladder repair/closure. The patient later remarked that 3 days prior to admission, he fell onto a truck dolly causing blunt force trauma to his abdomen, followed immediately by PD cycler low flow errors and blood in the PD effluent. He remained anuric throughout the hospitalization and eventually clinically recovered. He was discharged in good condition to continue on HD.

FR-PO480

Peritoneal Dialysis-Associated Peritonitis with Kytococcus schroeteri

Akash Hazari, Alexandra Rosario Aulet, Anupkumar Shetty. *Methodist Dallas Medical Center, Dallas, TX.*

Introduction: Peritonitis is a known complication of PD and common organisms include gram-positive cocci such as *Staphylococcus epidermidis, Staphylococcus aureus and enteric Gram negative bacilli.* We present a case of peritonitis in a PD patient with a rare gram-positive organism, *Kytococcus schroeteri.*

Case Description: 50-year-old male with ESRD due to diabetes mellitus and hypertension on peritoneal dialysis was noted to have signs and symptoms of peritonitis and peritoneal effluent culture grew *Kytococcus schroeteri.* Initial fluid was milky with PD fluid WBC count was 16686 predominantly(80%) neutrophils and it came down to 81 on day 6, <50 on day 11, 65 on day 15 and 99 on day 21 after starting intraperitoneal vancomycin. He received intraperitoneal gentamicin during the first 5 days. Rifampin had to be stopped due to allergic reaction to it. Intraperitoneal tPA was given to break the fibrin in the peritoneum and 2 additional weeks of intraperitoneal vancomycin was given with improvement in the PD WBC count to <10 and effluent culture remained negative. Staining and culture for acid fast bacilli and fungal cultures were negative. Proper hygiene and techniques were reinforced.

Discussion: Kytococcus organisms are rare causes of bacteremia in the immunosuppressed and device related infection. This is the first case of PD related peritonitis caused by *K. schroeteri* based on our literature search even though there is one published case report of PD peritonitis from *Kytococcus sedentarius. K. schroeteri* is resistant to penicillin, cephalosporin, erythromycin and clindamycin and sensitive to vancomycin, rifampin, daptomycin and linezolid. Generally dual therapy is needed and rifampin is an important component associated with successful outcome. Since Kytococcus is a skin organism, root cause analysis should include assessment of dialysis technique to prevent future episodes. ISPD has no specific suggestions on treatment of Kytococcus peritonitis, but 3-4 weeks of treatment with two antibiotics seems reasonable along with fungal prophylaxis.

FR-PO481

Mycobacterium abscessus Peritonitis: An Uncommon Yet Significant Cause of Peritoneal Dialysis-Associated Peritonitis

Devin M. Boe, Chanwoo Nam, Keiko I. Greenberg, Negiin Pourafshar. *MedStar Georgetown University Hospital, Washington, DC.*

Introduction: Peritoneal dialysis (PD) is generally safe and well tolerated, but peritonitis is a common complication. Mycobacterium (M) species associated peritonitis in PD patients is uncommon with complex treatment.

Case Description: We report the case of a 79-year-old female with end-stage renal disease (ESRD) due to diabetic nephropathy on PD, breast cancer in remission, initially presented to our institution with abdominal pain and cloudy effluent. CT scan of her abdomen did not show any abnormalities; Initial analysis of PD fluid was negative, with no organism grown. Empirical PD peritonitis treatment with intra-peritoneal antibiotics did not improve her symptoms. Later, culture of PD fluid showed growth of acid-fast bacilli. She required intravenous antibiotics, PD catheter removal and a switch to hemodialysis. Cultures of the PD fluid later grew M abscessus, and the antibiotic regimen was changed appropriately to therapy with intravenous (IV) micafungin, linezolid, Eravacycline, azithromycin, imipenem, and amikacin, leading to clinical improvement. Auditory function was monitored by audiogram every two weeks due to potential ototoxicity of amikacin. Repeat imaging later revealed that the infection had caused a 2 cm abdominal wall abscess, necessitating a longer course of antimicrobials. She remained stable and was discharged on Eravacycline, Linezolid and Amikacin.

Discussion: Mycobacterium abscessus-associated peritonitis in PD patients is an uncommon occurrence. Clinicians should maintain awareness of this possibility when patients fail to show clinical improvement despite treatment with standard broad-spectrum antibiotics, particularly in cases where PD fluid initially deemed to be culture negative. The complex treatment experienced by our patient underscores the importance of remaining vigilant against opportunistic infections, even among immunocompetent individuals without apparent risk factors. To effectively manage such cases, it is imperative to send PD fluid samples for acid-fast bacillus testing. If Mycobacterium species are detected, further analysis using genome-wide sequencing is recommended to confirm the specific strain of Mycobacterium involved. Prompt removal of the catheter along with peritoneal washout is crucial for achieving clinical improvement and preventing further complications.

FR-PO482

Peritoneal Dialysis-Related Peritonitis from Nontuberculous Mycobacterium abscessus: A Rare Complication

Stephanie D. Ice, Ojaswi S. Tomar. *West Virginia University School of Medicine, Morgantown, WV.*

Introduction: Nontuberculous Mycobacterium (NTM) accounts for 3% of Peritoneal dialysis (PD)-related peritonitis, mostly from M. *Fortuitum.* PD-related peritonitis caused by M. *abscessus* is exceedingly rare. Only 38 cases are reported in the literature since 1998 including just 3 previous cases from the USA. Mean interval between diagnosis and treatment initiation is 4 weeks as culture and antibiotic susceptibility results take weeks. Treatment is challenging and prognosis is poor with 25% mortality rate. Diagnosis requires a high index of suspicion. PD fluid should be stained for acid-fast bacilli. Here we report a case of *M. abscessus* causing PD-related peritonitis in a lung transplant recipient.

Case Description: 69 year-old male with 10-year history of lung transplant presented with 4 days of abdominal pain, cloudy effluent and nausea. Admission labs showed CRP 72 mg/L (<10 mg/L), lactic acid of 3.16 mmol/L (<2 mmol/L), WBC count 9000/microL (4000-11000/microL). PD fluid studies showed 828 cells/mm3 with 94% neutrophils consistent with peritonitis. Broad-spectrum antibiotics were started. PD fluid culture grew gram-positive rods on day 8 and acid-fast bacilli on day 9. MTB complex PCR was negative. On day 13, he developed septic shock. PD fluid culture on day 17 grew M. abscessus. PD catheter was removed, and he was transferred to hemodialysis on day 18. He was discharged at 5 weeks on hemodialysis. He received 1 month of azithromycin, 1 month of linezolid, 6 months of intravenous cefoxitin and oral Omadacycline. He succumbed to lung infections 8 months later.

Discussion: Gram-positive or gram-negative bacteria are most common causes of PD-related peritonitis. NTM-related infections are on the rise, but M. abscessus causing PD-related peritonitis is exceedingly rare. It is often mistaken for Corynebacterium species or diphtheroid on gram stain. Immunocompromised and solid organ transplant recipients are at increased risk, hence a high index of suspicion is required. PD fluid must be examined promptly for acid-fast bacilli using Zeihl-Nelson stain. Eradication is difficult and requires several months of antibiotics, longer in immunocompromised patients. Encapsulating peritoneal sclerosis is a serious complication. ISPD guidelines suggest removing the PD catheter. Prognosis with M. *abscessus* is poorer than with other NTM infections.

FR-PO483

A Case of Rare Polymicrobial Quadruple Zoonotic Peritonitis in a Patient on Continuous Cycling Peritoneal Dialysis (CCPD)

Ao Wang,[1,2] Gilana Gomberg,[2] Shuchita Sharma,[2] Jaime Uribarri.[2]
[1]SUNY Downstate Health Sciences University, New York City, NY; [2]Mount Sinai Health System, New York, NY.

Introduction: Polymicrobial peritonitis is associated with higher hospitalization, catheter removal, permanent HD transfer and death than monomicrobial peritonitis. Zoonotic peritonitis is rare with a reported prevalence of only 0.54% of all peritonitis episodes [1]. We present a case of polymicrobial peritonitis caused by four zoonotic organisms including Neisseria Shayeganii, to our knowledge, this is the first case ever reported of PD-peritonitis associated with Neisseria Shayeganii.

Case Description: A 57-year-old male with ESRD on CCPD for 4 years presented to our PD clinic with mild abdominal pain and cloudy peritoneal effluent. Past medical history was relevant for kidney disease due to MGN status post cyclophosphamide and steroids and prostate cancer status post-prostatectomy. Social history was relevant for owning a cat and a dog. Physical exam was remarkable only for tachycardia and hypotension. Peritoneal effluent analysis showed 774 WBC/uL with 69% neutrophils and culture was sent. He was empirically treated with IP vancomycin and gentamicin for peritonitis. His abdominal pain resolved, peritoneal effluent became clear and showed down trending WBC from 774/uL to 25/uL with 58% neutrophil with no growth on cultures after 3 days. One week later, he again presented with abdominal pain and tenderness with nausea, vomiting and diarrhea and found to be tachycardic and hypotensive. He was admitted to the hospital for sepsis. PD effluent analysis showed 26,460 WBC/uL with 78% neutrophils and gram-negative bacilli and gram-positive rods on gram stain. PD culture from first clinic visit had very slow growth and eventually turned out to be positive for Neisseria shayeganii, Paenibacillus glucanolyticuls/lantus, Cutibacterium(propionibacterium) acnes and Capnocytophaga species. He received IP vancomycin, oral ciprofloxacin, fluconazole and later switched to IV piperacillin-tazobactam for 7 days. His symptoms improved and he was discharged with amoxicillin and clavulanate for 3 weeks. However, he continued to have elevated WBC with predominantly neutrophils in PD effluent. Decision was made to remove PD catheter and transfer to HD.

Discussion: We presented an uncommon case of PD related peritonitis with polymicrobial rare zoonotic organisms. We believe this case can help enhance clinician awareness and understanding of Neisseria Shayeganii and other zoonotic-related peritonitis.

FR-PO484

B Cereus! A Case of Peritonitis

Hamza Arif,[1] Ibraheem Murtaza,[2] Hassaan Iftikhar,[1] Maryam Saleem.[1]
[1]Ohio Valley Nephrology Associates, Owensboro, KY; [2]University of Kentucky, Lexington, KY.

Introduction: Peritonitis is a commonly encountered complication of peritoneal dialysis (PD), often associated with poor dialysis hygiene and constipation. Most common etiologies include Gram-negative rods and Gram-positive cocci, particularly *Staphylococcus aureus*. *Bacillus cereus* has been rarely identified as a causative organism of peritonitis.

Case Description: A 59-year-old gentleman with end stage kidney disease on continuous ambulatory peritoneal dialysis (CAPD) for 3 years presented to the dialysis clinic with abdominal pain and cloudy effluent. He had prior episodes of recurrent peritonitis from coagulase-negative Staphylococci (CONS) requring removal of the PD catheter but was restarted on CAPD 3 months after and did not have any peritonitis episode for 2 years. Initial cell count revealed absolute nucleated cell count of 491 and he was empirically started on intraperitoneal (IP) vancomycin and ceftazidime as well as fluconazole for fungal prophylaxis. Gram stain results 2 days later showed gram positive bacilli. After 4 days, PD cultures revealed *Bacillus* species (not anthracis). Sample was sent for further testing and finally identified *Bacillus cereus* with sensitivity to vancomycin 13 days after initial culture date. The patient initially received a 2-week course of IP vancomycin which was extended to 4 weeks given concern for the formation of spores with *Bacillus cereus*. His symptoms initially resolved, but 2 weeks after finishing the antibitics course, he reported abdominal pain again. PD cultures again revealed *Bacillus cereus* and he was initiated on another 3-week course of IP vancomycin.

Discussion: *Bacillus cereus* are gram-positive, aerobic, spore-forming, rod-shaped bacteria. They are usually described in cases related to food poisoning. Literature review indicates rare reports involving peritonitis from this organism. Prior descriptions of peritonitis with *Bacillus cereus* included relapsing, recurrent peritonitis eventually requiring removal of the PD catheter. The patient's history of recurrent peritonitis due to CONS which required removal of the CAPD catheter two years earlier, along with this new *Bacillus cereus* peritonitis, indicate the importance of maintaining hygiene with each treatment and retraining in patients with peritonitis.

FR-PO485

Raising a Brown Flag: An Unusual Presentation of Aspergillus Peritonitis

Maryn Gardner, Megha Salani. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Fungal peritonitis is a rare complication of peritoneal dialysis (PD), but one with high rates of mortality and technique failure. Candida species represent most causative organisms of fungal peritonitis while infection with Aspergillus is less common but associated with higher mortality. We present a rare case of asymptomatic Aspergillus peritonitis identified due to discoloration in the PD catheter transfer set.

Case Description: A 71-year-old male with a history of liver transplant, diabetes, and end-stage kidney disease due to calcineurin inhibitor toxicity presented for his routine PD clinic visit. An area of brown discoloration was seen in the proximal portion of his catheter transfer set (see Picture 1). He noted the color change over 3 days prior without associated abdominal pain or fever. The transfer set was exchanged and sent to anatomical pathology to evaluate the cause of the brown discoloration. PD fluid was sent for cell count and culture. White cell count was elevated: 432 cell/mcL with 54% neutrophils and 11% eosinophils. Intraperitoneal vancomycin and ceftazidime were started for empiric peritonitis treatment. Last peritonitis episode was 7 months before and he had no recent antibiotic exposure. The pathologist's evaluation of the transfer set revealed septate, acute angle branching hyphal elements consistent with mold. The patient was admitted to the hospital, treated with oral voriconzole, and underwent urgent PD catheter removal with transition to hemodialysis. Peritoneal catheter tip culture was positive for Aspergillus species.

Discussion: Aspergillus peritonitis is a rare complication of PD. Even in the absence of classic peritonitis symptoms, brown discoloration in the PD catheter warrants evaluation for potential fungal infection. Early recognition and intervention, with prompt PD catheter removal, are crucial due to associated high mortality and morbidity.

Picture 1: Bisected transfer set with brown discoloration

FR-PO486

Fungal Peritoneal Dialysis (PD) Peritonitis Managed with Simultaneous PD Catheter Removal and New PD Catheter Insertion

Raeesa Soomar, Vesh Srivatana. *Weill Cornell Medicine, New York, NY.*

Introduction: Guidelines for management of fungal PD peritonitis include PD catheter removal and switch to hemodialysis. Here we present a case where we removed the old PD catheter removal and placed a new PD catheter due to patient's wish to avoid hemodialysis

Case Description: This case is of a 46 year old female with a history of ESRD secondary to IgA nephropathy on peritoneal dialysis (PD) and failed renal transplant, as well as a history of Staph A (penicillin resistant) peritonitis who initially presented to outpatient clinic with cloudly PD effluent and abdominal pain. PD fluid cultures and cell count was obtained after which she was started on empiric IP antimicrobials. Her culture returned positive for yeast, after which she was recommended for hospital admission. In the hospital, she was started on IV micafungin and IP fluconazole, and continued on empiric IP antibiotics. She was recommended by her nephrologist for PD catheter removal and switch to HD, however the patient did not want to do HD even if it resulted in worsening clinical progression or death. Therefore after many discussions, she was planned for and underwent PD catheter removal and placement of new PD catheter. She was continued on IV micafungin and IP fluconazole, while IP antibiotics switched to IV antibiotics. PD fluid cell count and cultures were taken daily. Nucleated cell count peaked at 1650, then decreased to 1 throughout hospital course and with antimicrobials.

Her fungal culture grew aureobasidium pullulans. With input from infectious disease team, her micafungin was changed to IV amphotericin B. She was then started on urgent start PD protocol in the hospital. Subsequent cultures also grew psuedomonas putida and fluorenscens (both sensitive to ceftazidime and levaquin). She was discharged with tunneled PICC line for IV amphotericin for 4 week course. She was continued on IP ceftazidime and oral levofloxacin for 3 weeks after negative fluid cultures.

Discussion: This case is unique in management, as our patient was firmly against starting hemodialysis, even after lengthy discussions involving risk of treatment failure and death. Therefore, to keep the patient's wishes to continue with PD and avoid HD, we had to alter the management plan. In this case, we were able successfully treat fungal peritonitis and do urgent start PD with removal of the old PD catheter and placement new PD catheter.

FR-PO487

Amlodipine-Induced Chylous Ascites in a Patient on Peritoneal Dialysis

Oliver P. Yockey,[1] Katherine W. Kwon,[2] Zachary K. Heeringa.[3] *[1]Corewell Health Southwest Michigan, Saint Joseph, MI; [2]Lake Michigan Nephrology, Saint Joseph, MI; [3]Michigan State University College of Osteopathic Medicine, East Lansing, MI.*

Introduction: Chylous ascites (CA) is the appearance of milky, lipid rich peritoneal fluid, often associated with portal hypertension, lymphatic obstruction, congenital abnormalities, infections, or post-operative complications. Previous studies have proposed that a triglyceride content of >187mg/dL confers a 95% specificity. CA has been associated with use of medications, including dihydropyridine (DHP) calcium channel blockers (CCBs). In this case we discuss the presentation of a peritoneal dialysis (PD) patient with amlodipine induced CA that resolved expeditiously on discontinuation of CCB.

Case Description: A 66-year-old man with history of end stage kidney disease secondary to uncontrolled hypertension presented to the hospital with milky, white PD fluid after request by his dialysis team. He was admitted three weeks prior for bacterial peritonitis and was completing a course of intraperitoneal ceftriaxone and vancomycin. CT abdomen and pelvis imaging at the first admission was negative for masses or abscesses. The etiology of his peritonitis was thought to be related to severe constipation with bacterial translocation, however, cultures remained negative. On this admission he was asymptomatic and vitals were unremarkable. Physical exam revealed a distended abdomen without tenderness; the PD site was without erythema or drainage. PD fluid showed 68 nucleated-cells/μL. Fungal culture, AFB culture and smear were negative. The PD fluid triglyceride level was 322mg/dL, consistent with CA. Antibiotics were continued. Review of the literature revealed case reports of other DHP CCB's causing CA; therefore, amlodipine was suspected and discontinued in hospital. He was discharged the next day. On a follow up two days later, his PD fluid was noted to be entirely clear, without a milky appearance.

Discussion: Previous research has established other DHP CCB's in the formation of CA in PD patients. However, despite widespread use of amlodipine as an anti-hypertensive, it accounts for one documented case of CCB-induced CA. Our case further implicates amlodipine as a rare etiology of CA. Furthermore, cessation of amlodipine led to rapid resolution, similar to other documented CCB-induced CA. This is the first report we have identified where CA developed months following CCB initiation; it is imperative that a careful review of medications be performed in patients with CA of unknown etiology.

FR-PO488

Long-Term Prophylactic Intraperitoneal Antibiotics in Outpatient Peritoneal Dialysis Patients: A Case Series

Derrick Soong,[1] Wasim El Nekidy.[2] *[1]Windsor Regional Hospital, Windsor, ON, Canada; [2]Cleveland Clinic, Abu Dhabi, United Arab Emirates.*

Introduction: Bacterial peritonitis is a potentially fatal complication for peritoneal dialysis patients. Despite following ISPD guidelines, patients in remote areas are at higher risk of developing peritonitis due to decreased direct access to experienced nursing staff. Those patients in remote areas also are less likely to relocate closer to a hemodialysis center if perionteal dialysis cannot be continued. One approach to prevent peritonitis in these patients with frequent peritonitis is to use prophylactic intraperitoneal antibiotics. However, extended use antibiotic prophylaxis to prevent bacterial peritonitis in peritoneal dialysis patients is not well characterized in the literature. The risk of developing multi-drug resistant organisms limits its widespread use.

Case Description: In this case series, we investigated the safety and efficacy of prophylactic intraperitoneal antibiotics in 3 peritoneal patients with a history of relapsing Staphylococcal peritonitis infections unwilling to transition to hemodialysis.

Discussion: Each patient had an exit site infection causing multiple relapsing peritonitis infections whereby each patient refused PD catheter removal during a peritonitis exacerbation, limiting the nephrologist to antibiotic therapy. As a last resort, all three patients received intraperitoneal and an oral antibiotic to double-cover the identifed pathogen. In all three cases, no opportunistic infections were reported in the observation period despite absence of fungal peritonitis prophylaxis. Patients did not report any side-effects after starting prophylactic antibiotics. Dialysis adequacy did not appear to be affected by prophylactic antibiotics in the observation period. Two of the cases passed away due to failure to thrive or to complications after foot amputation. No cloudy effluent or signs of peritonitis was observed near time of death. After this relatively successful case series of prophylactic antibiotics in this small subset of peritoneal dialysis patients, randomized prospective studies should be conducted to assess the feasibility of this novel approach to sustain peritoneal dialysis longevity.

Patient Demographics / Infection Information

Patient	PD Duration	Exit Site Organism / Treatment	Peritonitis History / Treatment	Prophylaxis Regimen

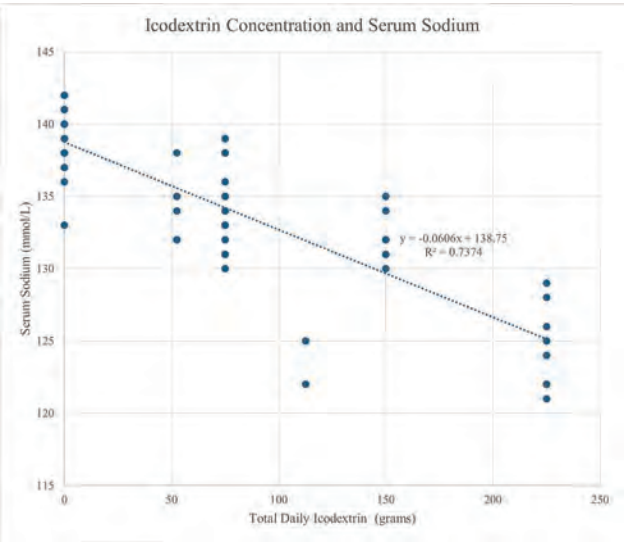
Icodextrin (ICO) Lowers Serum Sodium (Na) in Dose-Dependent Fashion

Sophia Sugar, Marko A. Karakadze, Isaac Teitelbaum. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Introduction: ICO is widely used in peritoneal dialysis (PD). Hyperosmolar hyponatremia (hypoNa) has been reported as an adverse event of ICO but it is unknown whether there is a dose effect relationship between the two. We present a case demonstrating this relationship.

Case Description: A 34.5 Kg woman with ESKD began PD with a single daily dwell of 1L of ICO. Her serum Na (mmol/L) fell from 138.9 ± 2.2 (SD) to 133.6 ± 2.1. She developed a pericardial effusion prompting a change in prescription (Rx) to 4 exchanges of 1.5L, 1.5% dextrose; Na rose to 138. Her effusion improved, and Rx was switched back to 2 cycles of 1.5L of ICO. 11 days later Na was 122. Measured serum osmolality (osm) was 302 with calculated osm 264 and a gap of 38. Whole blood Na matched serum Na. She was intravascularly contracted and given boluses of NS and the same PD Rx was continued. She had a mild increase in Na (≤ 129) but never achieved normonatremia. One month later she was still hypoNa at 121. The Rx was decreased to 1 cycle of 1.5L ICO and Na improved to 125. Her Rx was switched to 3 cycles of 1.5% dextrose with no ICO, and Na improved to 135, during which measured serum osm was 299 and calculated osm of 291 with a gap of 8. She maintained normonatremia (139.2 ± 1.5) for the subsequent 2 years – all while her Rx was dextrose based. Years later a single 2L ICO dwell was started, and she developed hypoNa (131). ICO was stopped, and Na normalized.

Discussion: HypoNa is a risk factor for ESKD patients that leads to increased morbidity and mortality. ICO can cause increases in serum osm and hypoNa, the degree of which, we've shown, is related to the dose of ICO used. The concentration of ICO [ICO] is 75g/L (7.5%). We plotted the Na vs [ICO] and show a strong correlation (R^2 >0.7). For patients considering stopping ICO due to hypoNa it may be reasonable to lower the dose instead.



Serum Na vs. total daily ICO in grams

FR-PO490

Icodextrin Toxicity in a Patient with ESKD Secondary to Multiple Myeloma

Daniel Rospert,[1] Sreedhar A. Mandayam,[2] Justin Bull,[2] Biruh Workeneh.[2]
[1]The University of Texas Health Science Center at Houston, Houston, TX; [2]The University of Texas MD Anderson Cancer Center, Houston, TX.

Introduction: Icodextrin is a peritoneal dialysis solution often used in diabetic patients with difficult to control type 2 diabetes. It is reported to be safer than dextrose containing PD solutions, due to less absorption than dextrose. There are reported adverse effects, the most common being skin rashes and rare cases of other adverse effects. We present a case of icodextrin toxicity in a patient with ESRD secondary to light chain deposition disease from multiple myeloma.

Case Description: 76 year old man with ESRD on peritoneal dialysis was sent for inpatient admission for hyponatremia. ESRD was secondary to light chain deposition disease related to multiple myeloma. Once declared ESRD, he opted for peritoneal dialysis with icodextrin due to difficult to control type 2 diabetes. On initial evaluation he had Na 122, calculated serum Osm 287 in the setting of azotemia and measured Osm 336 with resultant Osm gap of 49. An alcohol panel was negative and immunoglobulin levels were normal. He had elevated liver enzymes with AST 419, ALT 400, and Alk Phos 144 with a negative viral hepatitis evaluation. The constellation of metabolic abnormalities were concerning for icodextrin toxicity. He was transitioned to a mixed bag with 2.5% dextrose dialysate. His hyponatremia resolved over the course of 2 days, with improvement in liver enzymes as well resulting in diagnosis of icodextrin toxicity in the setting of multiple myeloma.

Discussion: Per manufacturer, less than 5% of patients using icodextrin dialysate develop any of hyponatremia, AST, ALT, or alkaline phosphatase. The patient reported had all four. There have been case series of patients who developed a hyperosmolar, hyponatremia as described in the patient presented. There have also been reports of hepatotoxicity related to icodextrin. To our knowledge, there has not been a reported case of icodextrin toxicity resulting in the combination of hyponatremia and transaminitis in a patient with multiple myeloma. It is unclear whether this patient's diagnosis of multiple myeloma made him more susceptible to icodextrin toxicity, however, this case the importance of frequent metabolic evaluation in patients on icodextrin dialysate. More research is needed to determine if patients with multiple myeloma may be more susceptible to icodextrin toxicity.

FR-PO491

Cola-Colored Peritoneal Dialysate in a Patient with Impella Device-Associated Hemolysis

William Qin, Chitra R. Reddy. *Kaiser Permanente Santa Clara Medical Center, Santa Clara, CA.*

Introduction: In PD patients, Cola-colored effluent is a rare and ominous complication, which is usually associated with rhabdomyolysis or hemorrhagic pancreatitis, noted prior cases were fatal. The mechanism by which this occurs is thought to be as a result of breakdown of heme from hemoglobin and myoglobin, subsequent reaction of hemin with albumin to form methemalbumin. This case presents a novel occurrence, as hemolytic anemia from Impella placement resulted in cola-colored dialysate.

Case Description: 48-year-old male with ESRD on PD, CAD s/p multiple PCI and recent DES placement, and HFrEF, who was found to have NSTEMI. He underwent cardiac catheterization with findings of diffuse mvCAD. He developed worsening cardiogenic shock, was transitioned to CRRT – an axillary Impella device was placed on hospital day 12. He was noted to have pink CRRT effluent suggestive of hemolysis, suspected to be due to malposition of the Impella device. The Impella was repositioned with ultrasound guidance. The patient had unconjugated bilirubinemia to 17.0 mg/dL, serum LDH 5866 U/L, and lactic acidosis. PD fluid was drawn to rule out infection, and noted to be dark brown in coloration. The fluid resulted with negative gram stain and culture, however total bilirubin of the fluid was 6.2 mg/dL, LDH was 1626 U/L. Patient had clear peritoneal dialysate until this point.

Discussion: This case of dark PD fluid discoloration was not associated with any of the previously documented risk factors, and is instead associated with hemolysis from impella placement, which is a novel occurrence. The presence of dark discoloration or bilirubin in the dialysate should prompt rule-out of intra-peritoneal sources of heme or bile, and is considered an ominous clinical sign. All documented cases have been fatal, and this patient also expired from complications of refractory shock.

FR-PO492

An Unprecedented Case of Autologous Stem-Cell Transplant in a Patient with Multiple Myeloma with ESKD on Peritoneal Dialysis

Hanna Larson, Danish Waqar, Julia Schneider. *Loyola University Medical Center, Maywood, IL.*

Introduction: Since 2011, when bundled payments changed to equal pay for peritoneal dialysis (PD) and hemodialysis (HD), home PD rates have nearly doubled. Rise in PD utilization has had no significant effect on patient mortality or morbidity. Still little is known about how PD impacts other care aspects, such as stem cell transplant. Autologous stem cell transplants (AutoSCT) in dialysis dependent patients are rare. Given the lack of studies with PD in SCT, patients are often advised to temporarily switch to HD with a central venous catheter (CVC) peri-transplant to avoid peritonitis risks. However, this recommendation is unsubstantiated and may increase serious infection risks like bacteremia. Literature search yields only one other reported case of AutoSCT in a PD patient in Spain. We present a successful AutoSCT in a PD patient without major dialysis-related issues in the US.

Case Description: A 68-year-old man with advancing kidney disease started PD. One month later, he was diagnosed with IgG-Kappa Multiple Myeloma (MM) based on an elevated protein gap and anemia refractory to epoetin. Bone marrow biopsy confirmed Stage III MM. After 5 chemotherapy cycles with a combination of daratumumab, lenalidomide, and dexamethasone, he was admitted for Melphalan AutoSCT. He received standard antibacterial, antifungal, and antiviral prophylaxis with Levaquin, Fluconazole, and Acyclovir. Routine PD exit site care per ISPD guidelines was maintained. Adequate ultrafiltration and clearance were achieved throughout the hospital course. Complications included pancytopenia, hematuria, hemorrhoidal bleeding, mucositis, atrial fibrillation and COVID-19. Despite neutropenia, no PD-related infections occurred. He was discharged on day 13 post-AutoSCT and completed outpatient chemotherapy. MM remains in remission on PD 2 years post-AutoSCT.

Discussion: To our knowledge this is the first successful reported case of AutoSCT in a PD patient without major dialysis-related complications in the US. With routine exit site care and SCT antimicrobials, PD appears safe for those undergoing AutoSCT obliviating the need for CVC insertion. A paradigm shift is needed for PD due to the increasing interest in home dialysis and patient preferences for renal replacement therapy. Further studies are needed to understand the risks and outcomes of patients on HD vs. PD receiving AutoSCT.

FR-PO493

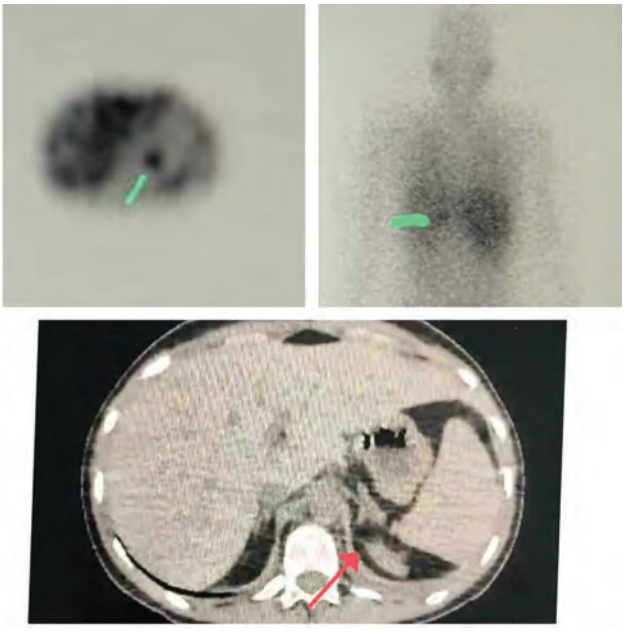
Peritoneal Dialysis Uncovers an Unusual Medical Condition

Emad A. Odeh,[1,2] Jehad Yousef.[1] [1]*Al-Basheer hospital, Amman, Jordan;* [2]*Mutah University, Mutah, Jordan.*

Introduction: PD is used to treat individuals with end-stage kidney disease(ESKD), by introducing dialysate into the peritoneal cavity using the peritoneum as a filter to remove an excess fluids and waste products from the body We present a case of a patient who started on PD, which later uncovered an unusual disease

Case Description: A17-year-old female was diagnosed at the age of 16 with ESKD of unknown etiology, investigations revealed only positive ANA, kidney biopsy not done. At that time she underwent urgent hemodialysis(HD), found to have hypertension which was controlled with amlodipin5mg/day, and discharged on PD After APD initiation she started suffering from reccurent episodes of abdominal pain, headach, and BP-elevation during PD-treatment. These symptoms persist despite several changes in PD settings. Later she presented with cough, hemoptysis, severe HTN and found to have acute pulmonary hemorrhage confirmed by imaging and bronchoscopy. Treated as vasculitis with PLEX and steroid. One month after discharge she again suffered from the same symptoms during PD, followed by a second attack of pulmonary hemorrhage associated with resistant HTN, panic attack and headach that prompted us to exclude secondary HTN. Renal doppler study was normal. Aldosterone renin ratio and serum cortisone were normal. At that time she was anuric so 24hrs urine collection for metanephrine not done. Adrenal MRI without contrast was not informative. MIBIG scan done and confirmed left adrenal pheochromocytoma The patient shifted permanently to HD,BP controlled with doxazocine, lecardipine. Carvidolol was added3weeks later.plan for left adrenalectomy

Discussion: ***Take-home messages:*** several well-known causes of PD failure exist, but occasionally you may encounter an uncommon cause Dialysate instillation during PD can increase intra-abdminal pressure and may lead to catecholamine release from a masked adrenal tumour



FR-PO494

Vasovagal Syncope during Peritoneal Dialysis

Claudia Waters, Neepa Shah, Siddhartha Kattamanchi, Rebecca Blonsky. *Marshfield Clinic Health System, Marshfield, WI.*

Introduction: Vasovagal syncope can be difficult to predict for patients encountering new medical environments. Physicians must identify patients in which vasovagal syncope can interfere with their ability to reliably and safely participate in their care.

Case Description: A 65-year-old man with medical history significant for newly diagnosed ESRD due to IgA nephropathy who was recently started on peritoneal dialysis (PD) presented following a syncopal episode. The patient elected to start with in-center PD prior to dialyzing in his home. With his first ever fill he felt nauseated, but following this he tolerated treatments without symptoms. During his second week of treatment, he experienced a syncopal episode at the completion of his initial fill. His preceding symptoms included lightheadedness, nausea, tunnel vision, and dry heaving. He spontaneously awoke and completed the dwell under supervision of the nursing staff. He remained hemodynamically stable, however, was admitted for further evaluation. Laboratory workup was non-revealing, findings as per table one. Echocardiogram showed mild aortic stenosis which was stable from previous examination. Given the typical vasovagal-like prodrome coupled with an unremarkable cardiac workup, the patient was diagnosed with vasovagal syncope. His beta blocker was discontinued and inpatient PD was tolerated without recurrence of symptoms.

Discussion: Vasovagal syncope is an uncommon complication during early days of PD and usually happens during infusion of the PD fluid. In such scenarios alternate causes of syncope needs to be ruled out. When the cause is thought to be secondary to vasovagal syncope from PD infusion, then the rate of infusion must be lowered and attempted in a hospital setting to see if patient can tolerate this modality. Additionally, vagomimetic agents such as beta blockers should be lowered or stopped. With these interventions our patient was able to successfully remain on PD.

FR-PO495

Broadening Access to Home Hemodialysis with VersiHD GuideMe Software

Kristen R. Lile, Anitha Vijayan. *Intermountain Healthcare, Salt Lake City, UT.*

Introduction: Home hemodialysis (HHD) allows independence for patients with end stage kidney disease (ESKD) & is associated with improved patient satisfaction & clinical outcomes. In addition to bettering quality of life, HHD can improve blood pressure & fluid control. Despite proven benefits, the use of HHD remains limited due to the complexity of HHD training & concern for adverse events. The VersiHD GuideMe software aims to make HHD available to more patients by simplifying HHD.

Case Description: Training for HHD takes 8-12 weeks, leading to significant time commitment for patients & care partners. We followed a patient training for HHD using the VersiHd GuideMe software. This software is available with the NxStage system & provides step-by-step instructions through a simplefied interface to improve ease & speed of learning for patients. Our patient suffered from chronic fluid overload & recurrent hospitalization while undergoing traditional, thrice weekly hemodialysis through an

arteriovenous fistula. Using the VersiHD GuideMe software, the patient & their care partner were able to safely complete HHD training over a span of 3 weeks dating from 2/22/24-3/14/24. As of this writing, the patient has had no adverse events associated with HHD or new hospitalizations. This patient has had improved debilitation & is now undergoing transplant evaluation.

Discussion: Despite improved clinical outcomes with HHD, utilization in practice has remained limited in part due to the technical complexity of treatment. Training for HHD can be a time-consuming process, with training taking 8-12 weeks. Using the VersiHD GuideMe software, our patient was able to complete HHD training in 3 weeks, resulting in an improvement in cardiovascular outcomes that were not achievable with traditional dialysis. The VersiHD GuideMe software provides a user-friendly, succinct method for training patients on HHD therapy, opening the door to more ESKD patients who can benefit from this therapy.

Figure 1: Time in weeks for HHD training, study patient

FR-PO496

A Novel Hybrid Technique for Peritoneal Dialysis Catheter Insertion

Szu-Yuan Li, Ming-Tsun Tsai, Chih-Ching Lin. *Taipei Veterans General Hospital, Taipei, Taiwan.*

Background: Peritoneal Dialysis (PD) is an essential treatment for end-stage kidney disease (ESKD). Existing methods for PD catheter insertion have various limitations. This study introduces a novel hybrid method that combines laparoscopic and Seldinger techniques for PD catheter insertion.

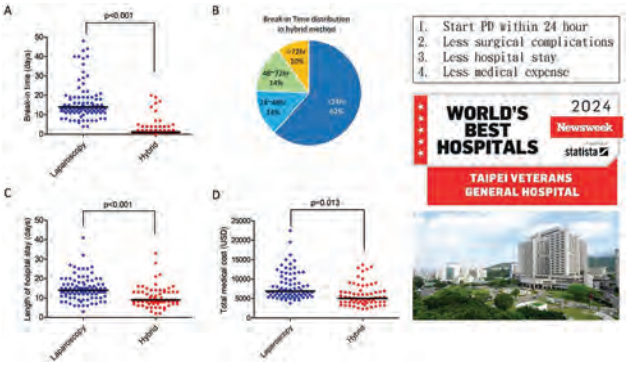
Methods: This retrospective study analyzed 320 patients undergoing their first PD catheter insertion, 23% of whom had a history of abdominal surgery. The cohort had two groups of patients: 170 patients received the traditional laparoscopic method, while 150 underwent the new hybrid method. Surgical outcomes, early and late complication rates, hospital stay duration, and medical expenses were compared between the two groups.

Results: No significant differences were observed in baseline demographics and comorbidities between the groups. The hybrid method had in a significantly shorter break-in period (within 24 hours) and eliminated the need for temporary hemodialysis. Patients in the hybrid group had shorter hospital stays (1 week less) and lower medical expenses (saving $3000 USD) compared to those in the laparoscopic group (all $p<0.05$). The incidence of early complications was lower in the hybrid group, while late complication rates were comparable between the groups.

Conclusions: The hybrid method is a safe and effective alternative for PD catheter insertion, especially for patients with previous abdominal surgeries or at risk of abdominal adhesions. It enables urgent-start PD, reduces hospital stays, and lowers medical costs, supporting its adoption as the new standard of care for ESKD patients requiring PD catheter insertion.

Summary of different PD catheter implantation techniques

	Open surgery	Laparoscope	Seldinger technique	Novel Hybrid method
Operator	Surgeon/Physician	Surgeon	Physician	Surgeon
Anthesis	General anthesis	General Anthesis	Local Anthesis	General Anthesis
Tissue manipulation	More	More	Minimal	Minimal
Direct Visualization	No	Yes	No	Yes
Break-in time	14 days	14 days	1 day	1 day
Suitable for patients with previous abdominal surgery	No	Yes	No	Yes



FR-PO497

Uremic Serum Results in an Activation and Phenotypic Switch of Pig Venous and Arterial Smooth Muscle Cells (SMCs)

Huanjuan Su,[1] Eyla C. Arteaga,[1] Christine Wai,[1] Unimunkh Uriyanghai,[1] Vinay A. Sudarsanam,[1] Samuel Haddad,[1] Edward M. Bahnson,[2] Prabir Roy-Chaudhury,[1] Gang Xi.[1] *[1]The University of North Carolina at Chapel Hill Kidney Center, Chapel Hill, NC; [2]The University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: ESKD patients suffer from both an aggressive vascular access stenosis in the venous segment of AVFs and AVGs and widespread peripheral arterial disease (PAD). Both disease states respond poorly to conventional endovascular and surgical interventions. Despite the magnitude of the clinical problem, the exact pathogenetic role of the uremic state in both these conditions remains unclear.

Methods: Uremic serum was obtained from our previously described pig model of uremia (documented creatinine of >8mg/dL for over 3 weeks). Control serum was obtained from an age matched non-uremic pig. The MTT assay was used to assess cell proliferation and a cell-scratch assay was utilized to assess cell migration. Western blot expression was used to assess markers of cellular proliferation (PCNA and p53), phenotypic switch (myocardin and calponin), extracellular matrix (ECM) production (vitronectin and fibronectin) and calcification (Runx2).

Results: The MTT assay demonstrated that 30% uremic serum was able to stimulate the proliferation of both arterial (1.25±0.14 fold increase) and venous (1.17±0.13 fold increase) SMCs. Uremic serum also consistently enhanced PCNA and p53 expression in both cell types. The production of ECM proteins such as vitronectin and fibronectin was also increased when cells were exposed to uremic serum (ApSMC > VpSMC). SMC migration showed that uremic serum increased the migration of ApSMC (1.21±0.14 fold increase) and VpSMC (1.23±0.12 fold increase). Uremia also induced a phenotypic switch in both cell types (greater in ApSMC), with a suppression of myocardin and calponin expression (indicating a switch to a more activated, dedifferentiated and synthetic phenotype). Uremic serum also significantly stimulated cellular calcification (Runx2) particularly in ApSMC.

Conclusions: Uremia results in phenotypic switch of both venous and arterial SMCs *in vitro* with an increase in proliferation and migration, ECM production and expression of cell calcification markers. These changes were often exaggerated in ApSMCs as compared to VpSMCs. Our findings suggest that uremia per se could play an important role in both the aggressive arteriovenous stenosis and PAD in hemodialysis patients.

FR-PO498

Uremia, Angioplasty Injury, and Vessel Type (Artery vs. Vein) Activate Differential Gene Expression and Pathway Profiles

Unimunkh Uriyanghai, Christine Wai, Huanjuan Su, Eyla C. Arteaga, Vinay A. Sudarsanam, Samuel Haddad, Edward M. Bahnson, Prabir Roy-Chaudhury, Gang Xi. *The University of North Carolina at Chapel Hill Kidney Center, Chapel Hill, NC.*

Background: Patients with CKD and ESKD suffer from aggressive dialysis vascular access stenosis within the venous segment of AVFs and AVGs. They also suffer from a huge burden of vascular disease, which responds poorly to interventions such as angioplasty. Despite the huge morbidity, mortality, and economic costs associated with both dialysis vascular access dysfunction and peripheral vascular disease in CKD and ESKD patients, the pathogenetic pathways responsible for this remain unclear.

Methods: Pigs were made uremic by performing a right sided nephrectomy followed by a selective ligation of the branches of the left renal artery. After 2 weeks of uremic condition, we performed an angioplasty of the femoral artery and vein on one side, with the contralateral side serving as a control. Animals were sacrificed two weeks post angioplasty, and arterial and venous samples from the femoral artery and vein on both

sides were collected for RNA extraction and bulk RNA sequencing. An identical set of experiments was performed on a non-uremic pig.

Results: Differential expression gene analysis revealed that uremia up-regulated 21 genes in the control artery but only 7 genes in the control vein. In contrast, 177 genes were up-regulated in injured vein but only 1 gene was up-regulated in injury artery. In addition, the injury up-regulated 510 genes in normal vein but only 56 genes in normal artery. Additional pathway enrichment studies revealed differentially enriched pathways in different groups. For example, olfactory receptor activity, positive regulation of immune system process and interferon gamma response were the 3 maximally enriched pathways in uremic control artery whereas neuropeptide receptor activity, neuropeptide signaling pathway and molecular transducer activity were the 3 maximally enriched pathways in uremic control vein.

Conclusions: Our results suggest that all three variables, uremia, angioplasty injury, and vessel type contribute to the differential gene expression and pathway analyses. Our data suggests that the optimal therapy to reduce restenosis following angioplasty of the venous segment of an AVF in an ESKD may be very different from that needed to reduce restenosis following arterial angioplasty injury in a CKD/ESKD patient.

FR-PO499

Differential Gene Expression and Signal Pathways Activation Lead to Differences in Cell Proliferation and Migration of Venous and Arterial Pig Smooth Muscle Cells

Eyla C. Arteaga, Huanjuan Su, Christine Wai, Unimunkh Uriyanghai, Vinay A. Sudarsanam, Samuel Haddad, Prabir Roy-Chaudhury, Gang Xi.
The University of North Carolina at Chapel Hill Kidney Center, Chapel Hill, NC.

Background: Arteriovenous fistulae (AVF) are the preferred mode of dialysis vascular access but have a maturation failure rate of over 50% due to a venous segment stenosis, which is characterized by smooth muscle cells (SMCs) proliferation and migration, resulting in neointimal hyperplasia. Despite the clinical significance of venous segment AVF stenosis, the exact gene expression profile and activation pathways responsible for venous SMC proliferation and migration remain unclear.

Methods: Pig arterial SMCs (ApSMCs) and venous SMCs (VpSMC) were cultured in DMEM containing 10% FBS and 1% P/S. Total RNA was isolated for bulk RNA sequencing. Cell lysates were collected for analyzing protein expression levels. MTT assays were used to measure cell proliferation, and cell scratch assays were used to assess cell migration ability.

Results: Bulk RNA sequencing results indicated that 265 genes were expressed highly in VpSMCs, while another 301 genes were highly expressed in ApSMCs. PCA and signal pathway analyses demonstrated clear differences in gene expression and pathway activation between VpSMCs and ApSMCs. For instance, cell migration, cell junction and cell communication pathways were activated in VpSMCs while collagen-containing extracellular matrix and extracellular matrix pathways were activated in ApSMCs. Importantly, different sets of genes were utilized even within the same activated pathways. Western blot results demonstrated that FAK protein levels were increased in VpSMCs while Paxillin and Vinculin levels were similar in both cell types. ECM proteins, such as fibronectin and vitronectin proteins were produced more by VpSMCs. Importantly, VpSMCs proliferated faster than ApSMCs (1.80±0.21 vs 1.56±0.19 fold after 48hr in growth media). However, their response to PDGF in serum free media was similar (1.53±0.16 vs 1.49±0.17 fold after 48hr). Migration assays revealed that VpSMCs had a faster migration as compared to ApSMCs in growth media and serum-free media.

Conclusions: Differential gene expression and pathway activation in VpSMCs and ApSMCs.are likely responsible for their differences in cell proliferation and migration, suggesting a much needed precision medicine approach to AVF maturation failure.

FR-PO500

Impact of CKD on Arteriovenous Fistula Remodeling: Studies in a Murine Model of Autosomal Dominant Polycystic Kidney Disease

Suzanne Laboyrie, Dorien J. Peters, Roel Bijkerk, Juliette A. de Klerk, Margreet R. de Vries, Joris I. Rotmans. *Leids Universitair Medisch Centrum, Leiden, Netherlands.*

Background: The arteriovenous fistula (AVF) is the gold standard for hemodialysis vascular access, although inadequate vascular remodelling and intimal hyperplasia pose a major limitation. We utilised an autosomal dominant polycystic kidney disease (ADPKD) model, the most common hereditary cause of chronic kidney disease (CKD), to study the effect of CKD on AVFs. We hypothesized that CKD accelerates AVF failure.

Methods: Jugular-carotid AVFs were created in adult B6Ola*Pkd1*$^{nl/nl}$ (ADPKD) mice and B6Ola*Pkd1*$^{+/+}$ litter mates. AVFs were harvested seven days post-surgery for bulk mRNA sequencing or three weeks post-surgery for histological analysis. We performed weekly AVF flow measurements using doppler ultrasound and assessed kidney morphology and function by histology and blood urea analysis. Blood pressure was measured using a tail cuff, before and six days after AVF-surgery. Longitudinal flow data was analysed using Mixed-effects model, histological data using the Mann-Whitney U test.

Results: *Pkd1*$^{nl/nl}$ mice developed cystic kidneys and elevated blood urea levels (8.7 ± 2.8 mmol/L versus 24.0 ± 3.8 mmol/L) and higher mean arterial blood pressure (92 versus 113). AVF flow in *Pkd1*$^{nl/nl}$ mice was consistently higher post-AVF creation (1.9-fold difference, p<0.001), with a 50% reduction in intimal hyperplasia and 30% increase in luminal AVF volume. RNA sequencing showed altered regulation of extracellular matrix in the venous ADPKD AVF, with reduced collagen deposition in the venous outflow tract.

Conclusions: *Pkd1*$^{nl/nl}$ mice are a suitable model to study AVF remodeling in a CKD setting, resulting in enhanced luminal volume and higher AVF flow when compared to normotensive mice with healthy renal function.

FR-PO501

Senescence in the Arteriovenous Fistula (AVF): Early Development and the Prosenescent Effects of Heme Treatment In Vivo and In Vitro

Raman D. Singh, Anthony J. Croatt, Allan W. Ackerman, Karl A. Nath.
Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN.

Background: Our prior studies demonstrated a senescent phenotype in the rat AVF at 1 and 2 weeks after creation, as measured by elevated p16 and p21 mRNA levels, increased senescence-associated-β-galactosidase (SA-β-Gal) activity, and a prominent senescence associated secretory phenotype (SASP). We also showed that chronic treatment with hemin reduced AVF flow, the latter hypothesized to be a pro-senescent effect of this treatment. We now examine whether senescence occurs at an earlier timepoint in the AVF, and if heme treatment induces markers of senescence in the vasculature of rats with AVFs, and in human umbilical vein endothelial cells (HUVECs).

Methods: Subtotal nephrectomy was performed in rats after which an AVF was created by anastomosing the femoral artery and vein. At 3 days after AVF creation, AVF veins were assessed for expression of cell cycle inhibitors (p16 and p21 mRNA), and SASP factor expression. In additional studies, the effects of heme (hemin) treatment were assessed in the aortas of rats with AVFs and in HUVECs using established measurements.

Results: 3 days after AVF creation, p16 and p21 mRNA levels were markedly elevated in AVF veins compared with sham veins and was accompanied by the appearance of a robust SASP (SASP factors such as TNF-a, IL-6, CCL2, IL-1β, CINC-1, and PAI-1 mRNA were all induced). Three-week heme treatment in rats with AVFs induced SASP factor mRNA expression (TNF-a, IL-6, CCL2, IL-1b, SDF-1, TF, CCL5) in the aorta. In HUVECs, 16-hour heme treatment increased p16 protein expression, decreased lamin-B1 protein expression, and significantly increased SA-β-Gal activity and SASP factor mRNA expression - all effects consistent with a senescent phenotype.

Conclusions: We demonstrate that the rat AVF in the presence of CKD exhibits a senescent phenotype as early as 3 days after AVF creation. We also identify heme as a novel inducer of senescence in vitro and in vivo. Intravascular hemorrhage is known to be a driver of atherosclerosis, putatively through the effects of free heme. Neoangiogenesis is also known to occur in both rodent and human AVFs, and this may predispose to intramural hemorrhage. We speculate that, in this manner, heme may contribute to a senescence phenotype in the AVF and, in turn, neointimal hyperplasia and AVF dysfunction.

FR-PO502

Single-Nucleus Transcriptomics Reveal Cell Type-Specific Diversification in Left Ventricle in Mice Undergoing Arteriovenous Fistula Creation with Cardiac-Specific Overexpression of PDE5A

Paul C. Collie, Nguyen T. Nguyen, Tatyana Isayeva Waldrop, Travis Ptacek, Kevin A. Ingle, Lingyun Wang, Timmy C. Lee. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: PDE5A, an enzyme that hydrolyses cyclic guanosine phosphate (cGMP), has been implicated in various cardiovascular conditions. We have observed an increase in protein levels of cardiac PDE5A following arteriovenous fistula (AVF) creation in left ventricle (LV) (Fig.1-A). AVF creation has been associated with increased cardiac output and dilation of LV leading to adverse cardiac remodeling (Fig.1-B). We performed single nuclei RNA-seq to understand the cellular transcriptional profiles and pathway changes after AVF creation and the role of PDE5A in LV remodeling.

Methods: AVF's were created in cardiomyocyte-specific overexpression PDE5A transgenic mice (homozygous, HO) and littermate controls (WT). LVs were collected at day 7. Single nuclei RNA-seq was performed to identify gene signatures in WT (n=5), WT-AVF (n=4), HO (n=5), and HO-AVF (n=4) groups. Integration of Single Nuclei data (10X Chromium) was done using Seurat v.4 package.

Results: We observed 19 different clusters, including 9 subtypes of cardiomyocytes (CM). Two CM clusters were not present in AVF group (Fig.1-C). There was a significant increase in endothelial cell count following AVF creation ($p=3.2e^{-3}$). Notable gene expression changes include a downregulation in genes related to oxidative phosphorylation and ATP production ($p=3.2e^{-18}$), an upregulation in genes linked to cardiomyocyte death and oxidative stress pathways ($p=5.65e^{-310}$), downregulation in genes essential for sarcomere assembly and myofibrillogenesis ($p=1.22e^{-190}$), and downregulation in genes essential for autophagy ($p=1.153e^{-38}$), cytokines and inflammatory response ($p=1.16e^{-99}$).

Conclusions: Our snRNA-seq data indicates that AVF creation and PDE5A expression in cardiomyocytes contribute to cardiac impairment pathways and adverse remodeling.

SGLT2 Inhibitor Ameliorates Smooth-Muscle Cell Proliferation via Endothelial Microparticles Stimulated by Indoxyl Sulfate

Shina Lee, Seung-Jung Kim. *Ewha Womens University Mokdong Hospital, Seoul, Republic of Korea.*

Background: Endothelial microparticles (EMPs) are closely associated with vascular dysfunction. Recent research has revealed a link between SGLT2 inhibition and improved endothelial functions. We investigated the effects of SGLT2 inhibitors (SGLT2i) on EMP generation from indoxyl sulfate-stimulated endothelial cells and their impact on smooth muscle cell (SMC) proliferation.

Methods: We measured CD31+CD42-EMP counts by flow cytometry in supernatants of human umbilical vein endothelial cells (HUVECs) incubated with indoxyl sulfate. We examined the EMP responses to SGLT2i by incubating EMPs from indoxyl sulfate-stimulated HUVECs with or without SGLT2i.

Results: 1. Indoxyl sulfate induced EMP release in HUVECs. 2. SGLT2i inhibited EMP generation induced by indoxyl sulfate. 3. The EMPs induced by indoxyl sulfate stimulated smooth muscle cell proliferation, and this effect was reversed by treatment with SGLT2i.

Conclusions: SGLT2 inhibitor ameliorates smooth muscle cell proliferation via endothelial microparticles stimulated by indoxyl sulfate. SGLT2i could be a treatment option for neointimal hyperplasia in vascular access stenosis.

FR-PO504

Retrograde Flow in Rat Arteriovenous Fistula

Hannah M. Northrup,[1] Timmy C. Lee,[2,3] Yan-Ting E. Shiu.[1,4] *[1]University of Utah, Salt Lake City, UT; [2]University of Alabama at Birmingham, Birmingham, AL; [3]Birmingham VA, Birmingham, AL; [4]Salt Lake City VA, Salt Lake City, UT.*

Background: The arteriovenous fistula (AVF) is the preferred vascular access for patients on maintenance hemodialysis but has high maturation failure rates, due to insufficient increases in lumen diameter and flow of the venous limb. There is a paucity of studies investigating the role of the AVF's distal artery in maturation failure. Retrograde flow in the AVF's distal artery is sometimes seen in patients and is associated with conditions such as steal syndrome. However retrograde flow has been rarely studied in context of AVF remodeling. Both computational fluid dynamics (CFD) and animal models have become a popular research tool to analyze the hemodynamics of the AVF. We have reported that rat femoral AVFs have anastomosis angles and disturbed flow similar to those in human forearm AVFs. Here we present a novel CFD study analyzing retrograde flow in rats with AVF.

Methods: 15 Sprague Dawley rats (12-16 week old males) underwent femoral artery (side) to femoral vein (end) AVF creation. 7 or 21 days after AVF creation rats underwent magnetic resonance imaging (MRI). MRI-based CFD was used to analyze the presence of retrograde flow in the distal artery 5 mm away from the anastomosis, and venous diameter and flow rate 5 mm away from the anastomosis. Spearman correlations were calculated to analyze association.

Results: 14 out of 15 rats exhibited retrograde flow in the distal artery during the cardiac cycle. 2 rats had retrograde flow throughout 5-20% of the cardiac cycle. 7 rats exhibited retrograde flow over 70% of the cardiac cycle and 5 experienced 100% retrograde flow. Correlation between % retrograde flow and venous diameter was -0.140 with a p value of 0.614. Correlation between % retrograde flow and venous flow rate was 0.198 with a p value of 0.477.

Conclusions: Retrograde flow in the distal artery is present and prevalent in rat femoral AVF. Consequently, rat models may be a translational model for studying steal syndrome. There were no statistically significant associations between retrograde flow in the distal artery and AVF venous diameter and flow in rat models. Studies in human and other animal models of AVFs are needed.

Funding: NIDDK Support, Other NIH Support - NHLBI, Veterans Affairs Support

FR-PO505

The Role of SFRP2 in Vascular Remodeling of Arteriovenous Fistula (AVF) Maturation

Chung-te Liu.[1,2] *[1]Division of Nephrology, Department of Internal Medicine, Wan Fang Hospital, Taipei Medical University, Taipei, Taiwan; [2]Department of Internal Medicine, School of Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan.*

Background: The glycoprotein SFRP2 is known to activate Wnt/β-catenin signaling and myofibroblast transition in myocardial fibrosis. Previous studies have indicated that myofibroblast proliferation is present in the vascular thickening of arteriovenous fistula (AVF). Thus, it's hypothesized that SFRP2 may promote AVF maturation.

Methods: In the prospective observational study, native veins (NV) harvested during AVF creation surgeries were examined to determine the correlation between preoperative SFRP2 expression and AVF maturation. In addition, SFRP2 expression was compared between mature and immature AVF. In mouse experiment, SFRP2 will be administered intravenously to find its effect on vascular wall remodeling.

Results: We had obtained 69 specimens of NV during the surgery of AVF creation, which contains 22 mature AVF and 47 nonmature AVF at 2 months. The results showed a trend of higher SFRP2 expression in NV that matured. (Figure 1A-C). Additionally, we collected 7 mature AVF from thrombectomy and 2 nonmature AVF in revision surgery. A trend of higher SFRP2 expression in mature AVF was found. (Figure 1D-F). The above results have not achieved statistical significance. The animal experiment showed that SFRP2 treatment induced vascular wall thickening, increased expression of αSMA and nuclear colocalization of β-catenin similar to that in AVF. (Figure 2).

Conclusions: Our preliminary data showed that SFRP2 may induce vascular wall remodeling associated with AVF maturation in human. Nonetheless, its exact role needs confirmation in further investigation.

Layer-Specific Transcriptomics Changes from Native to Arteriovenous Fistula Vein in Patients on Dialysis

Yong He, Qiongyao Hu, Guoshuai Cai, Scott A. Berceli. *University of Florida, Gainesville, FL.*

Background: The molecular mechanism of hemodialysis arteriovenous fistula (AVF) vein remodeling may be specific to its layers (intima, media, and adventitia) but is poorly understood. To address this gap, we studied layer-specific transcriptomics in veins of two-stage AVF creation.

Methods: Vein samples were collected during the initial creation of brachial artery-basilic vein AVF (1st stage) or the 2nd stage vein transposition surgery 6 weeks later. Veins were sectioned in OCT and tissues from each layer were separately collected by laser microdissection. Following Takara's SMARTer Stranded Total RNA-Seq Pico Input protocol, libraries were constructed and sequenced in NovaSeq. The sequencing reads were processed by fastp, aligned to genome GENCODE 45 by STAR and gene-level counts were estimated by RSEM. Layer-specific differentially expressed genes between 1st and 2nd stage were detected by edgeR and further identified the enriched pathways using Qiagen IPA.

Results: 47 (24 1st stage) veins were collected from 27 patients. 13,522 protein-coding genes that had a raw count of at least 10 in more than 70% of samples were included in analysis. Compared to 1st stage, the 2nd-stage samples showed disproportional upregulation of gene expression with at least 2-fold changes and FDR<0.05 in all layers of intima (511/831), media (260/296), and adventitia (385/535). Among the 3 layers, Intima had the largest number of differentially expressed genes, followed by adventitia and media. Pathway analysis showed that all layers had activated extracellular matrix organization, collagen biosynthesis and modifying enzymes, and assembly of collagen fibrils and other multimeric structures. Cell migration, growth, and proliferation were inferred to be increased while apoptosis was inferred to be decreased in all layers. Angiotensinogen (AGT), TGFB1, TNF, and IL1B were the common key upstream regulators in all three layers. Interestingly, intima shows the least degree of activation of extracellular matrix and p38 MAPK pathway and no increase of cell viability, as compared to the other two layers.

Conclusions: Similarity and difference of transcriptome changes were found in the 3 layers of the vein following AVF creation. This study provides new data of layer-specific mechanism underlying AVF adaptation that can be used to develop layer-specific therapies to improve AVF remodeling.

Single-Cell Determinants of Hemodialysis Fistula Failure

Laisel Martinez,[1] Marwan Tabbara,[1] Filipe F. Stoyell-Conti,[1] Miguel G. Rojas,[1] Simone Pereira-Simon,[1] Roberto I. Vazquez-Padron.[1,2] *[1]University of Miami Miller School of Medicine, Miami, FL; [2]VA Miami Healthcare System, Miami, FL.*

Background: Approximately half of newly created AVFs fail to mature without intervention. Despite this glaring statistic, all efforts to improve maturation have been unsuccessful due to our limited understanding of the venous adaptive response to arterial circulation. Our work presents a comprehensive cellular atlas of veins in ESKD patients before and after anastomosis, with a focus on molecular processes associated with failure.

Methods: We performed single-cell transcriptomic analyses on 70,281 cells obtained from 20 subjects on three different occasions: before anastomosis (n=6), one week after (n=2), and during transposition or revision of second-stage fistulas (n=6 matured, n=6 failed). Unsupervised clustering and gene expression analyses revealed the transcriptomic signature of AVF failure.

Results: The most abundant cells in pre-access veins and AVFs were endothelial cells (EC), fibroblasts, monocyte/macrophages, and NK/T cells. Gene expression profiles uncovered >1,000 differentially expressed genes (DEG) between pre-access veins and early AVFs in most cell clusters. Inflammation, not proliferation, dominated the initial transformation of vascular cells after anastomosis, a phenotype that prevailed in AVFs with unsuccessful maturation. Infiltrated monocytes were the primary source of wall cytokines dominating vascular remodeling. Immunofluorescence further confirmed the higher abundance of macrophages in failed vs. mature AVFs. Sub-clustering analyses discovered two new types of postoperative ECs, expressing hemostasis/shear stress factors or extracellular matrix genes, and a new population of fibroblasts characterized by upregulation of chemokine genes. The number of DEGs between mature and failed AVFs per cluster was less than one-tenth the one observed in the former comparison indicating that most transcriptional changes occur in the first week of remodeling. Upregulation of *COL8A1* in ECs and myofibroblasts was associated with failure, identifying the cell sources for this previously validated failure-associated risk factor.

Conclusions: We uncovered the early and late adaptive response of the human vein after anastomosis at the single-cell resolution. We highlight the essential roles of postoperative EC populations, fibroblasts, and macrophages in orchestrating the reparative response of the vein to secure hemostasis and maturation.

Informing Choices about Arteriovenous Fistula Creation: Insights from a Prospective Cohort Study

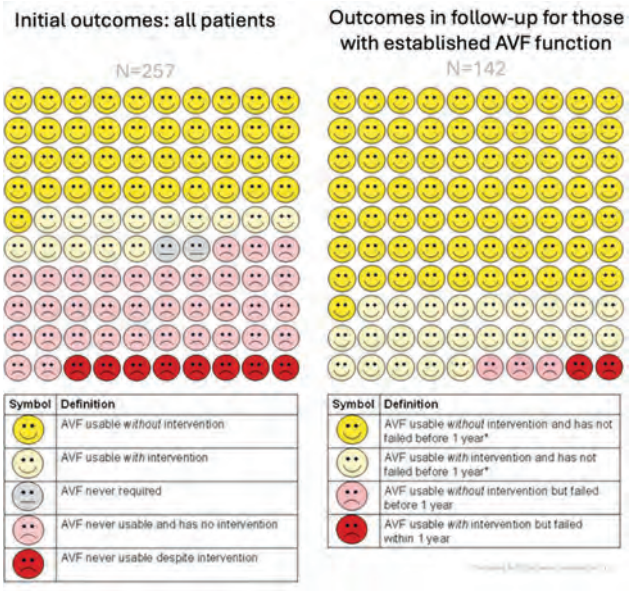
Anukul Ghimire,[1] Anita Lloyd,[3] Susan Szigety,[3] Jose Luis Merino,[2] Robert R. Quinn,[1] Marcello Tonelli.[1] *[1]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [2]Hospital Universitario del Henares, Coslada, Spain; [3]University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada.*

Background: Selection of a dialysis access type should incorporate patients' circumstances and preferences, termed the "Kidney Failure Life Plan". Data on long-term outcomes for arteriovenous fistulas (AVF) can guide decisions surrounding the Plan. We did this study to inform patients' choices about AVF creation, accounting for the risk of primary non-function and the presence of competing risks.

Methods: Prospective observational study of 257 adults with newly created AVF in Alberta, Canada. Participants were followed for 15 years or until the first outcome of death, outmigration, modality switch, or AVF failure/abandonment/ligation/removal. The primary outcome was primary function. Secondary outcomes included loss of primary patency and loss of secondary patency, assessed using Fine-Grey subdistribution hazard models to account for competing risks.

Results: Of 257 participants, 63.0% were male with mean age 62.3y, 54.9% had a radiocephalic AVF, and median follow up was 18.5 months. 50 AVF could not be assessed for primary function, with death being the most common reason. Of the remaining 207 AVF, 105 had primary function, and function was eventually established in 37/102 with primary non-function. In the 142 AVF with established function, loss of primary patency at 1, 3, and 5 years was 36.6%, 65.5% and 66.2% respectively. Similar values for loss of secondary patency were 0.7%, 11.3% and 16.2%. Overall, of 257 participants undergoing AVF creation, only 55% ultimately used that AVF for hemodialysis. These data were used to create the icon array (Figure) which is the basis for a decision aid.

Conclusions: This study highlights patient-important outcomes that may inform patients' Kidney Failure Life Plans and choices about AVF creation. Future studies will validate and refine decision aids with input from patients.



FR-PO509

A Data-Driven, Evidence-Based, Patient-Centered Optimal Initiation Time for Dialysis Treatment

Eva Lee.[1,2] The Kaiser Nephrology Team. *[1]The Data and Analytics Innovation Institute, Atlanta, GA; [2]AccuHealth Technologies, Atlanta, GA.*

Background: When to start dialysis is an important decision for end-stage CKD care. The difficulty in determining a common gold standard lies partly in the high heterogeneity among patients and available treatment conditions, and in random factors in disease progression / treatment process. This work optimizes pre-dialysis care timing.

Methods: A novel interpretable machine learning model ingests EMR / unstructured data to classify treatment effects and disease prognosis wrt each disease staging and timeline. Our ML model can classify disease-action into the same outcome groups under different conditions/features (hence multiple pathways). A ML-knowledge treatment timing model is developed to determine an outcome-driven GFR threshold for creating access of various types that maximizes the goodness of patient's health conditions. Patient preference is incorporated.

Results: 11,913 CKD patients with 213,344 GFR s from 2011-2018 were extracted. Among those with initiated dialysis, 67% initiated HD, 32% PD, and 1% CVC. Current 'sub/optimal' initiation shows diverse variance. AI/ML uncovers critical features that affect outcome; and GFR-windows for dialysis initiation and begin dialysis that render good outcome. Table 1 shows 2 interpretable optimal timing and dialysis start time, w.r.t. patient preferences. Only 2-12% of current practice falls within these optimal initiation time. Simulating the 2 policies for 2 years on 1000 patients shows reduction of 16.4%-35% avoidable deaths and 8%-19% increase in utility reward. A new CPG for Phase I implementation was established.

Conclusions: This work has critical health practice implications. We establish *the optimal initiative timing model for late-stage CKD management*. The novel ML-decision system includes distinct analytic advances as it leverages hidden knowledge within EMR to enable evidence-based patient-centered policy making. The results show that current practice is far from optimal and can be improved considerably. Clinical trial has to be conducted to gauge potential outcome improvemet.

Funding: Other U.S. Government Support

Two optimal timing policies returned from our model (simplified for brevity).

	Policy 1	Policy 1	Policy 2	Policy 2
Type	Optimal Initiation time (pre-dialysis care)	Begin dialysis	Optimal Initiation time (pre-dialysis care)	Begin dialysis
HP	GFR < 20	GFR < 12	GFR < 24	GRF < 15
PD	GFR < 18	GFR < 10	GFR< 21	GFR < 12
Suboptimal	With uremia	GFR < 10	With uremia	GFR < 12
Suboptimal	Without uremia	GFR < 7	Without uremia	GFR < 9

FR-PO510

A Feasibility Study Investigating the Role of Kidney Failure Risk Equation in Optimizing the Timing of Vascular Access Creation

Mohammad Atiquzzaman,[1] Bingyue Zhu,[2] Lee Er,[2] Alexandra Romann,[2] Ognjenka Djurdjev,[2] Adeera Levin.[1] *[1]The University of British Columbia, Vancouver, BC, Canada; [2]BC Provincial Renal Agency, Vancouver, BC, Canada.*

Background: KFRE 2-year risk threshold of >40% along with existing eGFR based referral for vascular access (VA) creation may improve VA resource utilization. We investigated if KFRE score can play a role in optimizing the timing of VA creation.

Methods: We analyzed a cohort of 2,581 patients with CKD who had an eGFR of <20 ml/min/1.73m2 and chose hemodialysis (HD) as their preferred mode of dialysis. We created the cohort using data from PROMIS, a population-level registry database for patients with CKD in BC, Canada. Modality selection date was index date. In step 1, we explored the association between KRFE-2 threshold and timing of HD initiation among patients who reached kidney failure and initiated HD within 24 months from the index date in two ways: First, we categorized the patients based on time to HD initiation into 0-3, 3-6, 6-9, 9-12 and 12-24 months, and investigated the corresponding distribution of KFRE-2 scores at index. Second, we categorized the patients based on index KFRE-2 score into <40%, 40-<50%, 50-<60%, 60-<70%, 70-<80% and >80% and investigated the distribution of time to HD initiation. In step 2, we explored the positive predictive value (PPV) of initiating HD within 6 and 24 months using the aforementioned KFRE-2 thresholds among the entire cohort.

Results: Study cohort included 2581 patients, median age 71 years, and 40% female. Of the 1,562 patients who initiated HD within 2 years, a total of 733 (47%) patients initiated HD within 6 months and the median index KFRE-2 was ≥69% (Table 1A). On the other hand, 207 (13%) patients had an index KFRE-2 of 60 - <70% and the median time to initiate HD was 6.4 months (Table 1B). PPV gradually increased with increasing KFRE-2 threshold for both HD initiation within 6 and 24 months (Fig 1).

Conclusions: KFRE-2 score has the potential to guide the timing of VA creation. Future research using sophisticated methodology is required to identify an optimal KFRE-2 score for fistula/graft creation.

Table 1A: KFRE-2 threshold by time to initiate HD

Time to initiate HD from modality selection date	n (%) (Total N = 1,562)	Median (IQR) KFRE-2 score on index date
0 - <90 days	419 (27%)	73.8 (50.5, 90.6)
90 - <180 days	314 (20%)	68.8 (50.6, 80.8)
180 – <270 days	241 (15%)	61.3 (46.0, 75.2)
270 – <365 days	202 (13%)	54.7 (38.9, 71.7)
365 days – 2 years	386 (25%)	46.8 (31.6, 60.7)

Table 1B: Time to initiate HD by KFRE-2

KFRE-2 score on index date	n (%) Total N = 1,562	Median (IQR) time to initiate HD
<40%	366 (23%)	290.0 (117.0, 475.0)
40% – <50%	196 (13%)	296.5 (161.0, 466.5)
50% – <60%	216 (14%)	260.5 (118.5, 407.0)
60% – <70%	207 (13%)	195.0 (114.0, 339.0)
70% – <80%	223 (14%)	179.0 (94.0, 286.0)
≥ 80%	354 (23%)	82.5 (31.0, 175.0)

Abstract Withdrawn

FR-PO512

Incidence and Determinants of Primary Arteriovenous Access Failure in Dialysis Patients: A Qatar-Based Retrospective Analysis

Tarek A. Ghonimi,[1] Abdullah I. Hamad,[1] Musab Elgaali,[1] Mohamed Y. Ali,[1] Mohamed T. Abdellatif,[2] Anees J. Alomari,[1] Athar I. Ibrahim,[1] Rania A. Ibrahim,[1] Hassan A. Al-Malki.[1] *[1]Hamad Medical Corporation, Doha, Qatar; [2]Misr University for Science and Technology, 6th of October City, Egypt.*

Background: The demand for hemodialysis (HD) among patients with end-stage kidney disease (ESKD) is increasing globally. A well-functioning Arterio-vascular access (AV) is crucial for effective HD therapy. This study aimed to determine the incidence and risk factors associated with primary AV access failure in HD patients.

Methods: This retrospective study included HD patients who underwent AV access creation between 01/01/2021 and 31/12/2023 in Qatar's dialysis centers. Data were obtained from electronic health records, including demographics, medical comorbidities, VA types, time to maturation, and incident of primary AV access failure.

Results: A total of 242 AV accsess creations were included. The incidence of primary AV Access failure was 28%. It was highly significant in patients with Left radio cephalic arterio-veinous fistula (in 32.3%). Significant associations were found between primary AV access failure and older age ($p < 0.001$), diabetes ($p = 0.027$), atherosclerosis ($p = 0.019$) and lower systolic and diastolic blood pressure ($P < 0.016$ and < 0.0001

respectively). However, statin use showed significant reduction in primary AV access failure (p = 0.001). Multivariate analysis identified older age, diabetes, atherosclerosis and lower systolic BP as significant risk factors for AV access failure, while statin use was associated with a reduced risk (odds ratio 0.167, 95% CI 0.080-0.347, p < 0.0001).

Conclusions: Primary VA failure in HD patients is notable, with older age, diabetes, and atherosclerosis as significant risk factors. Interestingly, statin use is linked to lower risk of primary AV access failure, emphasizing the need for early risk factor identification and management to improve AV access outcomes in HD patients.

"Optimal" vs. "Suboptimal" Haemodialysis Start with a Line

Michael Corr,[1] Agnes Masengu,[2] Jennifer B. Hanko.[2] *[1]Queen's University Belfast, Belfast, United Kingdom; [2]Belfast City Hospital, Belfast, United Kingdom.*

Background: Monitoring whether patients commence haemodialysis with a central venous catheter (CVC), or an arteriovenous fistula (AVF) is commonly used to audit the quality of a vascular access service. However, this crude metric of measurement can miss the increasing nuance and complexity of vascular access planning. At times, commencement of haemodialysis with a CVC may be the most appropriate access choice for an individual patient or be due to unpredictable events rather than representing a failure in access service delivery. We aimed to understand whether commencing haemodialysis with a CVC represented an 'optimal' or 'suboptimal' outcome and how this could influence assessment of a vascular access service.

Methods: From a prospective clinical database, patients known to nephrology >90 days before initiating haemodialysis as first ever renal replacement therapy (2011-2020) from a single centre were included. Descriptive statistical analyses were completed using SPSS Statistics.

Results: 158/254 patients started haemodialysis with a CVC, 96 with an arteriovenous fistula. For 91 patients the CVC was deemed 'optimal' care- due to unpredictable deterioration in renal function (n=41) and inadequate veins for AVF creation (n=24). For 67 patients the CVC was 'suboptimal'- no/late referral to access assessment (n=25) and delays in the AVF creation pathway (n=13). Two-year mortality was 53% 'optimal' CVC, 37% 'suboptimal' CVC and 30% AVF start. There was no difference in mean survival between AVF and 'suboptimal' groups (2.53 vs. 2.21 years p= 0.31). There was a survival difference between AVF versus CVC (2.53 vs 1.97 years p=0.002) and 'suboptimal' versus 'optimal' CVC cohorts (2.21 vs 1.40 years p=0.16).

Conclusions: Understanding whether CVC is 'optimal' or 'suboptimal' allows more nuanced analysis of service provision. High mortality in the 'optimal' group suggests a frailer cohort where CVC is potentially best care. Meanwhile, appreciating many 'optimal' CVC patients had unsuitable veins for AVF creation prompted review of our vein preservation strategy. Finally, studying 'suboptimal' CVC starts helps identify practice and system issues preventing 'optimal' care.

FR-PO514

Multidisciplinary Vascular Access Team Impact on the Number of Arteriovenous Fistulae and 12-Month Mortality

Rafael Figueiredo, Miguel L. Relvas de Carvalho, Hugo Diniz, Luis Coentrao. *Centro Hospitalar Universitario de Sao Joao, Porto, Portugal.*

Background: Autologous arteriovenous fistulae (AVF) are the vascular access (VA) of choice for most haemodialysis (HD) patients. The creation of multidisciplinary VA teams (mVAT) improves access-related outcomes, and thus overall survival. This study evaluates our center's mVAT impact on matured AVFs and 12-month mortality.

Methods: A retrospective case-control analysis was performed, comparing our center's incident HD patients from years 2019 and 2022. A mVAT was created in 2021. Patient data was collected from their electronic health record, namely demographic variables, comorbidities, prior nephrology (NA) and vascular access appointments (VAA), access typology at the beginning of HD and the number of unprogrammed initiations. The primary outcome was the number of functioning AVFs in incident and 12-month prevalent HD patients. Secondarily, 12-month mortality was assessed, and its clinical predictors were derived from a combined-year Cox proportional hazard regression model.

Results: 169 and 184 incident HD patients were included from 2022 and 2019, respectively. There were no significant differences between years regarding demographic variables, comorbidities, prior NA/ VAA/ VA construction, and the number of unprogrammed initiations. More incidents started HD with an AVF in 2022 (50.9% vs 37.5%, p= .011), independently of demographic variables and comorbidities. The number of functioning AVFs in 12-month HD prevalents was also greater (85.2% vs 76.6%, p = .041). The 12-month cumulative mortality was 11.2% and 14.7% in 2022 and 2019, respectively (Log Rank X2(1) = 0.881; p= .348), with no significant differences regarding the categorized cause of death between years. In our combined-cohort Cox proportional hazard regression model (X2 (11) = 180.266; p < .001), age (HR 1.05, p= .009) and initiation with a CVC (HR 10.01, p< .001) were predictors of 12-month mortality; and VA construction (HR 0.09, p < .001) and the number of days with a CVC (HR 0.988, p < .001) were negative predictors. No comorbidity obtained statistical significance after adjustment.

Conclusions: Our mVAT impacted both the number of functioning AVFs in incident and 12-month prevalent HD patients. We did not detect a significant mortality difference between years. HD initiation with a CVC appears to be the strongest 12-month mortality predictor.

FR-PO515

Patient and Provider Perspectives Surrounding Arteriovenous Fistulas vs. Grafts: A Qualitative Substudy of the AV Access Trial

Dipal M. Patel,[1] Katherine E. White,[1] Allison Chandler,[3] Ashley E. Strahley,[3] Deidra C. Crews,[1,2] Mariana Murea.[3] *[1]The Johns Hopkins University School of Medicine, Baltimore, MD; [2]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [3]Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: People with kidney failure on hemodialysis (HD) require sustainable vascular access. While the "Fistula First" initiative recommended arteriovenous fistulas (AVF) as the optimal access for all people on HD, AV grafts (AVG) may have similar outcomes in select populations such as older adults who more commonly experience AVF maturation failure. The AV Access trial is a randomized controlled trial studying outcomes of adults > 60 years old with ≥ 1 major comorbidity, on chronic HD with a tunneled catheter, who are then randomized to receive an AVF or AVG. Patient recruitment for this trial has been slower than anticipated. We sought to explore perspectives of relevant stakeholders surrounding the perceived optimal access for HD, and to assess the implications of these perspectives on trials of AV access.

Methods: We planned focus groups with site investigators and individual semi-structured interviews with nephrology providers, vascular access surgery providers, and older adults on HD who were approached for enrollment in the AV Access trial. Thematic analysis was used to analyze data.

Results: Two focus groups (n= 4 nephrology and 4 vascular access surgery site investigators), and 31 semi-structured interviews (n=10 nephrology providers, 9 vascular access surgery providers, and 12 eligible patients) were conducted. We identified three common themes of participant perspectives (**Table**).

Conclusions: Prioritizing AVF placement in all patients on HD is pervasive. Educational initiatives aimed at increasing patient and provider knowledge of potential equipoise between AVF and AVG in select populations, as well as patient-centered practices, may enable patient enrollment in trials studying dialysis vascular access.

Funding: NIDDK Support, Other NIH Support - National Institute on Aging

Themes	Exemplary quotations
Biases stemming from the "Fistula First" initiative are pervasive	"Sometimes in academia, we feel, as specialists, that the information that we have and that we're premising our research on, is common knowledge…We have to explain the controversy and then the premise of our study, and then go on to explain the methodology in our outcome. I think in this situation, it's just unappreciated. Not only how much—how effective 'fistula first' has been, how limited the knowledge is around the existing controversy, but also the impact of the economics that are driving dialysis centers and the nephrologists that manage them to continue to chase the quality performance metrics that underlie reimbursement." (*Vascular surgery site investigator*) "…over the last 20 years, the medical community has really emphasized that the fistula or their own vein is better. The study is now trying to prove that that may not always be the case, but they're going against a big tsunami of 20 years of information that was given to us…" (*Vascular surgery site provider*)
Buy-in from providers surrounding equipoise between AVF and AVG in select populations is key for enrollment	"We sat down, as a group of surgeons, and basically said, "If you want to be a part of this study, you have to be willing to randomize any patient that meets criteria that passes screening. Even if they've got a big cephalic vein, you can't turn them down." We've made a concerted effort to get buy-in amongst the entire surgery group, that they're willing to enroll any patient that meets criteria that passes screening. That seems to have helped us a lot. I think all the group of surgeons now feel like they have buy-in. I think that's—ultimately, I feel like we are the gatekeepers for the trial. I don't think it's the nephrologists. I think it's the surgeons, because we're the ones that sit down and have more conversations about dialysis access with these people than anybody else." (*Vascular surgery site investigator*)
Patient-centered practices and accommodations could facilitate patient participation in research surrounding vascular access	"I don't even know what's gonna happen. I talked to the doctor about it, and I don't know that—I kinda got chased out of the room before I really got explained what was gonna happen anyway. I asked him, "Do you have a—show me a picture of what's gonna happen to my arm or whatever," That kinda got swept under the carpet…." (*Patient approached for trial enrollment*) "I think it's more, to me, the patients are not worried about compensation, but time commitment, right? Up front, if you tell them a clear idea of what is involved, it is probably easier. These are the number of visits. This is what we will do. I think they will have a clear understanding and then can make a decision." (*Nephrology site investigator*)

Assessing Permanent Dialysis Access in Underserved Patients with Advanced Kidney Disease in Austin, Texas

Nidharshan S. Anandasivam, Tessa K. Novick, Raymonda El Khoury, Michelle L. Lubetzky, Paul C. Nader. *The University of Texas at Austin Dell Medical School, Austin, TX*.

Background: Arteriovenous fistulas (AVFs) have several advantages over central venous catheters (CVCs), primarily lower complication rates and more reliable blood flow rates. However, many underserved patients with advanced kidney disease start dialysis with CVCs.

Methods: In this retrospective study, we reviewed the medical records of underserved patients receiving emergency-only hemodialysis (EoHD) at an academic medical center (January 2022-March 2023), and of non-dialysis dependent patients with estimated glomerular filtration rate (eGFR)<20 ml/min/1.73m^2 at two community nephrology clinics (January 2021-December 2023) in Austin, Texas. We assessed the prevalence of each access type. Utilizing questionnaire interviews with health care providers and staff, we discussed barriers to arranging permanent dialysis access and recommendations for intervention.

Results: Among 38 patients receiving EoHD, 29 (76%) had an AVF or arteriovenous graft (AVG) whereas 9 (24%) had a CVC. Average time from first hemodialysis to AVF/AVG creation was 104 days. Among 301 patients receiving care at community nephrology clinics, 71 (24%) had eGFR<20 ml/min/1.73m^2. Of these 71: 19 (27%) had AVF/AVG, 8 (11%) had been referred to Vascular Surgery but did not have AVF/AVG, 15 (21%) had not been referred to Vascular Surgery, and 29 (41%) did not have any recent clinic notes as they may have transitioned their routine nephrology care to a dialysis center. Noted barriers included: primary language other than English, uncertainty of the patient regarding commitment to being treated with dialysis, need for additional patient education about dialysis, and failure to attend scheduled Vascular Surgery appointments. Recommended interventions included: creating culturally sensitive educational materials, and workflow diagrams for providers/staff for referral to Vascular Surgery.

Conclusions: Optimizing permanent vascular access among underserved patients with advanced kidney disease is challenging due to numerous barriers.

FR-PO517

Presurgery Plasma Metabolites Are Associated with Arteriovenous Fistula Maturation Outcomes

Xin Wang,[1] Syed S. Zaidi,[5] Cindy Chan,[4] Yan Yi Cheung,[2] Nadja Grobe,[1] Peter Kotanko,[1,3] Sandip Mitra,[5] Milind Nikam.[2] *[1]Renal Research Institute, New York, NY; [2]Global Medical Office, Fresenius Medical Care, Singapore, Singapore; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Fresenius Medical Care Asia Pacific Ltd, Hong Kong, Hong Kong; [5]Manchester Royal Infirmary, Manchester University NHS Foundation Trust, Manchester, United Kingdom.*

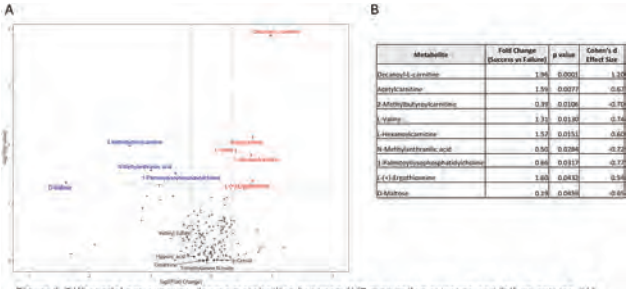
Background: Arteriovenous fistulas (AVFs) are the preferred vascular access for most hemodialysis (HD) patients. Previously, we showed that plasma metabolome clusters prior to AVF surgery associate with AVF maturation outcomes. Here we aim to further annotate pre-surgery plasma metabolites as potential biomarkers of AVF maturation outcomes.

Methods: Successful AVF maturation was defined as either adequate HD or a combination of ultrasound features (vein size > 4 mm with AVF flow ≥ 500 ml/min) and clinical assessment. Pre-surgery plasma samples from the day of AVF creation surgery were analyzed by liquid chromatography-mass spectrometry. Metabolites were identified by matching to in-house and METLIN libraries.

Results: The study cohort included 28 patients with successful AVF maturation and 16 with AVF failure. We annotated 147 metabolites in the pre-surgery plasma samples. In patients with successful AVF maturation, 5 were significantly up-regulated and 4 were down-regulated (**Fig. 1**). The metabolites are linked to the metabolism of lipids, amino acids, or starch. Four of the 9 metabolites are acylcarnitines, which are responsible for transporting fatty acids into the mitochondria for β-oxidation, suggesting a role of energy metabolism in AVF maturation. AVF maturation outcomes did not correlate with age, sex, diabetes, and cardiovascular disease.

Conclusions: Nine pre-surgery plasma metabolites were differentially regulated between patients with successful or failed AVF maturation. If validated by further targeted analysis and corroborated in larger cohorts, these potential biomarkers could inform precision vascular access planning.

Funding: Commercial Support - Renal Research Institute, Fresenius Medical Care, Government Support - Non-U.S.



Metabolite	Fold Change (Success vs Failure)	p value	Cohen's d Effect Size
Decanoylcarnitine	1.94	0.0001	1.30
Acetylcarnitine	1.59	0.0077	0.83
2-Methylbutyroylcarnitine	0.39	0.0106	-0.70

Sacubitril/Valsartan Can Improve Vascular Access Flow in Patients on Hemodialysis with Heart Failure with Reduced Ejection Fraction

Chih-Ching Lin.[1,2] *[1]Taipei Veterans General Hospital, Taipei, Taiwan; [2]National Yang Ming Chiao Tung University, Taipei, Taiwan.*

Background: Sacubitril/valsartan improves heart function in maintenance hemodialysis (HD) patients with heart failure with reduced ejection fraction<40% (HFrEF); however, the effect of sacubitril/valsartan on access flow (Qa) of vascular access in this population is unclear. Therefore, we conducted this study to evaluate this effect.

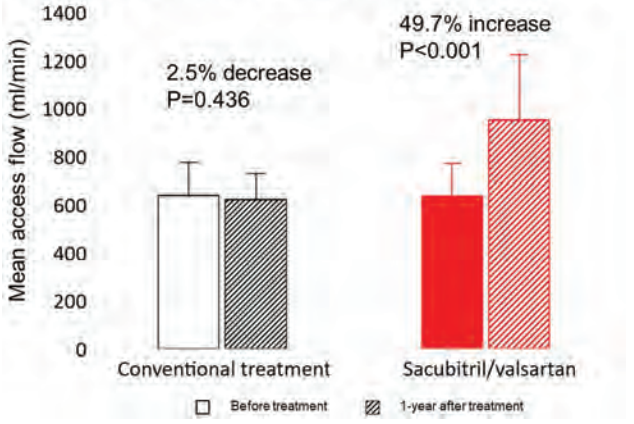
Methods: We retrospectively screened the HD patients in two hospitals. Patients with HFrEF receiving echocardiography and Qa measurement twice at 1 year apart were enrolled and divided into sacubitril/valsartan group and conventional treatment group. We compared the change of Qa(ΔQa) and echocardiographic parameters after 1-year treatment. Correlations between ΔQa and echocardiographic parameters were examined. Multiple linear regression analysis was applied to predict ΔQa.

Results: Thirty-three HD patients with HFrEF were analyzed. Sixteen patients received sacubitril/valsartan treatment; their mean Qa increased significantly from 633.8 to 948.8 mL/min (P<0.001). There was no significant change of Qa for the conventional treatment group (from 637.7 to 621.8 mL/min, P=0.436). The change of left ventricular ejection fraction (ΔLVEF) significantly differed between the two groups. The ΔQa had significant correlation with ΔLVEF(rs = 0.929, p<0.001) and with the change of interventricular septum thickness in diastole (ΔIVSd, rs = -0.736, p=0.001) in sacubitril/

valsartan group. The ΔQa was predicted as -44.034+15.868*ΔLVEF-25.072*ΔIVSd+145.964* (sacubitril/valsartan use or not), with $R^2 = 0.909$ and adjusted $R^2 = 0.899$.

Conclusions: Sacubitril/Valsartan improves Qa ~150 ml/min in HD patients with HFrEF. In addition, ΔQa was ~15ml/min for each % increase of LVEF.

Figure 1. The mean of access flow(Qa) before and after 1-year of conventional treatment or of sacubitril/valsartan.



FR-PO519

Use of Early Ultrasound Scan to Predict Arteriovenous Fistula Maturation

Syed S. Zaidi,[1,2] Cindy Chan,[3] Xin Wang,[6] Yan Yi Cheung,[4] Nadja Grobe,[6] Peter Kotanko,[6,5] Sandip Mitra,[1,7] Milind Nikam.[4] *[1]Manchester University NHS Foundation Trust, Manchester, United Kingdom; [2]The University of Manchester, Manchester, United Kingdom; [3]Fresenius Medical Care Asia Pacific Ltd, Hong Kong, Hong Kong; [4]Clinical Affairs, Global Medical Office, Fresenius Medical Care, Singapore, Singapore; [5]Icahn School of Medicine at Mount Sinai, New York, NY; [6]Renal Research Institute, New York, NY; [7]Manchester Academy of Health Sciences, Manchester University Hospitals, Manchester, United Kingdom.*

Background: The Manchester Vascular Access study (MANVAS) was a prospective observational study which investigated arteriovenous fistula (AVF) maturation. We interrogated the MANVAS data to evaluate whether early doppler ultrasound (DUS) scan could predict AVF maturation.

Methods: Patients undergoing upper limb AVF creation surgery were recruited. In addition to pre-operative vascular mapping, recruited patients had protocolised post-surgery AVF scans, done at weeks 2, 6, 12 after surgery, to assess anatomical and rheological parameters such as blood flow rate and velocities in the index AVF, and the feeding artery. The primary outcome was AVF maturation, which was defined either, as successful haemodialysis using the AVF or a combination of DUS features (vein size > 4 mm with AVF flow ≥ 500 ml/min) and clinical assessment. In this sub-group analysis (where DUS data was available, n=57), we used week 2 post-surgery DUS scan to identify predictors of AVF maturation. We used logistic regression models to explore differences between matured and non-matured groups.

Results: We found that minimal AVF diameter (D-Min), arterial peak systolic velocity (PSV) and end diastolic velocity (EDV), and AVF blood flows (Qa) were significantly higher in matured group compared to non-matured group (Table 1). Of note, the average Qa was almost 2-fold in the group which subsequently had mature AVFs vs the non matured group. After adjusting for age, sex, comorbidities and AVF type, PSV and Qa remained statistically significant.

Conclusions: Vascular flow attributes measured using DUS performed as early as 2 weeks post AVF creation can predict fistula maturation. If validated in a larger cohort, these findings could impact current clinical pathways considering early AVF maturation assessment and intervention.

Funding: Commercial Support - Fresenius Medical Care

Logistic Regression Analysis of Week 2 US Scans (n = 57)

US Parameters	Non matured	Matured	p-Value*
D-Min (cm)	0.31±0.08	0.41±0.12	0.0739

FR-PO520

Comparative Evaluation of UAB and NKF-KDOQI Criteria for Predicting Unassisted Arteriovenous Fistula Maturation Using Postoperative Ultrasound Measurements

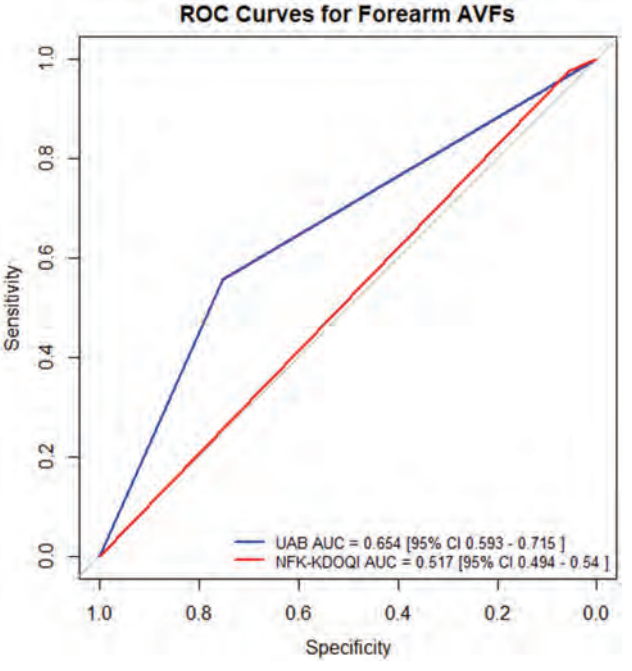
Seung Yun Chae, Yaeni Kim, Hoon suk Park. *The Catholic University of Korea Seoul St Mary's Hospital, Seoul, Seocho-gu, Republic of Korea.*

Background: This study aimed to compare the predictive performance of the University of Alabama at Birmingham (UAB) criteria with the NKF-KDOQI guidelines in forecasting unassisted arteriovenous fistula (AVF) maturation. Additionally, we sought to evaluate how the predictive accuracy of these criteria varies between upper arm AVFs and forearm AVFs.

Methods: We retrospectively analyzed the age, gender, BMI, and comorbidities of chronic kidney disease patients who underwent AVF creation and were monitored from January 2017 to March 2021 at a single medical center. Additionally, we assessed the types of AVFs, the success rate of the first cannulation, and postoperative AVF ultrasound measurements.

Results: Among the 560 patients analyzed, 68.6% experienced unassisted AVF maturation. Specifically, upper arm AVFs had a higher unassisted maturation rate (70.2%) compared to forearm AVFs (66.8%). The NKF-KDOQI guidelines had a higher positive predictive value for overall unassisted AVF maturation (0.85) than the UAB criteria (0.77), while UAB showed a better negative predictive value (0.57). Receiver Operating Characteristic Curve analysis revealed that UAB (AUC = 0.643, 95% CI 0.602–0.684) outperformed NKF-KDOQI (AUC = 0.56, 95% CI 0.532–0.589) in predicting overall AVF maturation. For forearm AVFs, UAB (AUC = 0.654, 95% CI 0.593–0.715) also demonstrated superior predictive ability compared to NKF-KDOQI (AUC = 0.517, 95% CI 0.494–0.540), which was close to random chance.

Conclusions: In conclusion, the UAB criteria proved superior in predicting the overall unassisted maturation of AVFs compared to the NKF-KDOQI guidelines. This was especially evident for forearm AVFs, where the predictive ability of the NKF-KDOQI criteria for unassisted maturation was nearly random.



ROC curve : Forearm AVF

FR-PO521

Efficacy and Safety of Apixaban for Prevention of Recurrent Thrombosis after Thrombectomy of Hemodialysis Vascular Access: A Randomized Controlled Trial

Chih-Cheng Wu. *National Taiwan University Hospital, Hsin-Chu Branch, Hsinchu City, Taiwan.*

Background: Dialysis vascular access thrombosis poses a substantial challenge for individuals undergoing hemodialysis. The efficacy and safety of apixaban, a direct oral Xa inhibitor, in preventing recurrent access thrombosis have yet to be explored.

Methods: This was a multi-center randomized control studyregistered at ClinicalTrials. Gov (NCT04489849). The study enrolled hemodialysis patients who underwent successful endovascular thrombectomy within 48 hours. Participants

were assigned to standard care or standard care plus apixaban, 2.5mg twice daily for three months. The trial design involved open-label administration, with independent adjudication of endpoints. The primary efficacy endpoint was recurrent access thrombosis within 3 months after thrombectomy.

Results: A total of 186 patients were enrolled; 93 patients randomized to the apixaban group and 93 to the control group, with well-balanced baseline characteristics. The apixaban group demonstrated a lower rate of access thrombosis at 3 months than the control group (24.0% vs. 40.8%; hazard ratio, 0.52 [HR]; 95% confidence interval [CI], 0.31-0.88, p=0.01), along with a better primary patency failure rate at 3 months (32.2% vs. 49.5%, HR, 0.57, 95% CI 0.36-0.91, P=0.02). Safety outcomes showed comparable death rates and major bleeding incidents but higher incidence of minor bleeding in the apixaban group (22.6% vs. 7.5%, p=0.01). The effect of apixaban did not show interaction in subgroups of different access types, antiplatelet usage, or history of thrombosis.

Conclusions: Apixaban effectively reduces the risk of recurrent thrombosis in hemodialysis vascular access. Despite a minor increase in bleeding adverse effects, the net clinical benefit supports the use of apixaban in this context.

Funding: Government Support - Non-U.S.

Efficacy outcomes

Outcomes	Hazard Ratio	95% CI(LB)	95% CI(UB)	P value
Access thrombosis at 3 mo	0.52	0.31	0.88	0.01
Primary patency failure at 3 mo	0.57	0.36	0.91	0.02
Secondary patency failure at 3 mo	2.55	0.49	13.1	0.26
Access thrombosis at 6 mo	0.63	0.41	0.98	0.04
Primary patency failure at 6 mo	0.65	0.44	0.96	0.03
Secondary patency failure at 6 mo	1.70	0.41	7.12	0.47

Far Infrared Radiation Does Not Improve Time to Cannulation in Newly Placed Arteriovenous Fistulas in Patients on Hemodialysis

Kristine Lindhard,[1] Henrik P. Hansen,[1] Kirstine M. Gliese,[5] Emilie K. Hansen,[1] Kristine Hommel,[2] Boye Jensen,[3] Ylian S. Liem,[4] Brian L. Pedersen,[4] Mahshid Pourarsalan,[6] Marianne Rix,[4] James Heaf,[5] Ditte Hansen.[1]
[1]Herlev Hospital, Herlev, Denmark; [2]Holbaek Sygehus, Holbaek, Denmark; [3]Syddansk Universitet, Odense, Denmark; [4]Rigshospitalet, Kobenhavn, Denmark; [5]Sjaellands Universitetshospital Roskilde, Roskilde, Denmark; [6]Nordsjaellands Hospital, Hillerod, Denmark.

Background: There is a need to improve arteriovenous fistula (AVF) maturation and decrease the number of central venous catheter days in patients on hemodialysis (HD). Far infrared radiation (FIR) is a treatment modality, which may improve AVF maturation and patency. The present trial examined FIR's effect on AVF maturation

Methods: A randomized, controlled, open-label clinical trial was performed. Patients were randomized to receive FIR treatment (FIR) or no FIR (control). After AVF placement, the FIR group received FIR on their AVF for 40 minutes at every HD treatment for one year. The primary outcome was the difference in time to cannulation, defined as the number of days from AVF placement to the first HD treatment with two functioning dialysis needles in the AVF. The difference was explored in a Kaplan-Meier analysis censored for thrombosed AVFs, death, loss to follow-up, and change of renal replacement therapy. Hazard ratios (HR) were determined by Cox regression analyses and adjusted for age, sex, diabetes, cardiovascular disease, albumin, type of AVF, size of AVF in mm at placement, and peroperativ flow.

Results: In total, 91 patients were randomized to FIR (n=46) or control (n=45). There were no differences in baseline characteristics between groups. No significant difference in time to cannulation with median days of 68 days [52;109.5] in the FIR group and 68 days [56.5;85] in the control group (p=0.8) was seen. The HR for chance of cannulation was 0.71; (95% confidence interval (CI), 0.43-1.18, p=0.19) in the FIR group compared to the control group. HR after adjustment for clinical variables was 0.68 (95% CI 0.40-1.15, p=0.12) in the FIR group compared to the control group. The number of thrombosed AVFs before cannulation was 9 in the FIR group and 4 in the control group (p=0.23)

Conclusions: FIR does not improve time to cannulation in newly placed AVFs in patients on hemodialysis. However, the influence of FIR on clinical maturation, the long-term risk of thrombosis, and the number of interventions in the AVFs are yet to be explored.

FR-PO523

Arteriovenous Fistula Failure Prediction Using Single Treatment Information

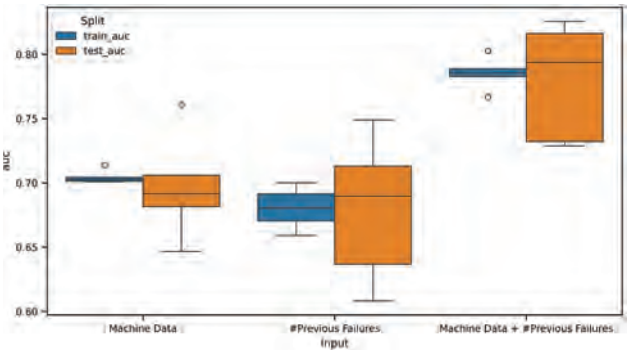
Alessandro Bregoli,[1] Francesco Bellocchio,[2] Andreas Maierhofer,[3] Jeffrey L. Hymes,[4] Len A. Usvyat,[4] Luca Neri,[2] Fabio Stella.[1] *[1]Universita degli Studi di Milano-Bicocca, Milano, Italy; [2]Fresenius Medical Care Italia SpA, Palazzo Pignano, Italy; [3]Fresenius Medical Care AG, Bad Homburg, Germany; [4]Fresenius Medical Care Holdings Inc, Waltham, MA.*

Background: Predicting the natural course of AVF complications with technical surveillance has been an elusive task. We developed a machine learning algorithm assessing the risk of failure of AVF using information collected by the dialysis machine in a single treatment.

Methods: We included all patients undergoing hemodialysis with AVF from the clinics belonging to Nephrocare France between 2021 and 2022. We extracted data from the European Clinical Database (EuCliD), and we combine it with the data sampled every minute from the sensors of the dialysis machine. We developed a model combining a continuous time naive Bayes and a logistic regression to access the risk of failure of a fistula within a month using as input variables the number of previous failures and the machine data of a single dialysis session such as: venous pressure, arterial pressure, blood flow and clearance.

Results: We included 171,969 hemodialysis sessions performed with an AVF over 1,845 French patients in the period from June 1, 2021, to May 31, 2022. During this period, 164 AVF failures were observed among 90 distinct patients. We evaluated the performances of the classifiers calculating the Area Under the Curve (AUC) over a 5-fold cross validation. Figure 1 shows that the classifier combining machine data and number of previous failures achieves the best performance. This result's statistical significance was accessed with a Wilcoxon signed-rank test ($p<0.1$).

Conclusions: Considering the performances obtained, the simplicity of the model and the prevalent use of machine data, this might suggest that it would be possible to install such a model directly on dialysis machines to have a timely assessment of the risk of failure at each treatment without performing any specific time-consuming test.



Performance obtained in cross validation by the 3 classifiers

Software-Based Surveillance Supplementing Clinical Monitoring for Hemodialysis Vascular Access

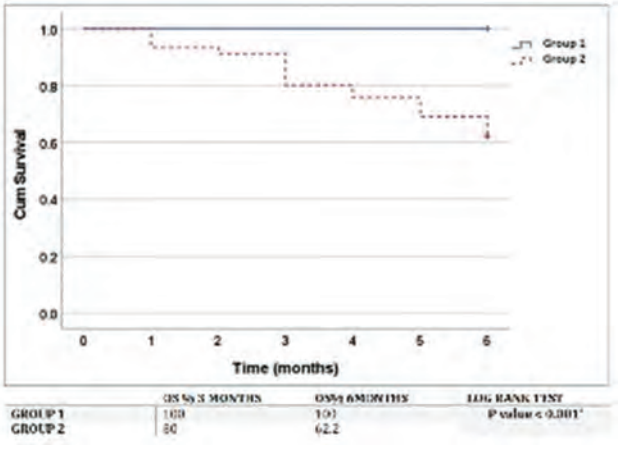
Dimitrios J. Poulikakos,[1,2] Rosemary L. Donne,[1,2] David M. Lewis,[1] Maharajan Raman,[1] Zulfikar A. Pondor,[1] Paul S. Hinchliffe,[1] Jan Cowperthwaite,[1] Jazzle Lim,[1] Paula J. Gleave,[1] Jonathan Allsopp,[1] Marinela L. Resiga,[1] Alshymaa R. Eltahan.[3,1] *[1]Northern Care Alliance NHS Foundation Trust Salford Care Organisation, Salford, United Kingdom; [2]Manchester Metropolitan University, Manchester, United Kingdom; [3]Helwan University, Helwan, Egypt.*

Background: Efficient arteriovenous access (VA) surveillance is vital for early identification of dysfunctional access, allowing timely intervention to prevent thrombosis. This study compares the efficacy of adding remote software surveillance to standard clinical care across our units.

Methods: We conducted a 12-month prospective study on maintenance hemodialysis (HD) patients, using Vasc-Alert software for clinical decision-making in 2 satellite HD units (Group 1), while providing standard care in 3 other HD units (Group 2). Patients with high Vasc-Alert access risk scores (≥7) received clinical assessments and were referred for fistulogram based on Kidney Disease Outcome Quality Initiative (KDOQI) criteria. We collected data on referrals for fistulograms, preemptive stenosis corrections, avoidable thrombosis (defined as thrombosis occurring while waiting for elective stenosis correction), and VA-related costs. We also measured the post-intervention primary patency rate.

Results: In Group 1, there were 23 (28.1%) preemptive stenosis corrections and 6 (7.3%) thrombosis episodes, while Group 2 had 40 (19.5%) corrections and 21 (10.2%) episodes (p = 0.155 and 0.587, respectively). Avoidable thrombosis occurred in 83% of Group 1 compared to 19% in Group 2 (p = 0.004). The median time from fistulogram request to thrombosed VA was 26 days. Group 1 showed better post-intervention primary patency rates (p < 0.001). The average VA-related cost per patient was £1600 for Group 1 and £1868 for Group 2.

Conclusions: Supplementing clinical surveillance with Vasc-Alert technology was associated with improved early detection of high-risk VA and higher primary patency rates, Improving elective interventional radiology (IR) capacity for timely intervention is crucial to materialize the benefits of enhanced surveillance.



FR-PO525

Investigation of the Effect of Variations in the Puncture Site of the Arteriovenous Fistula on Access Blood Flow Measurement by Ultrasound Dilution Method

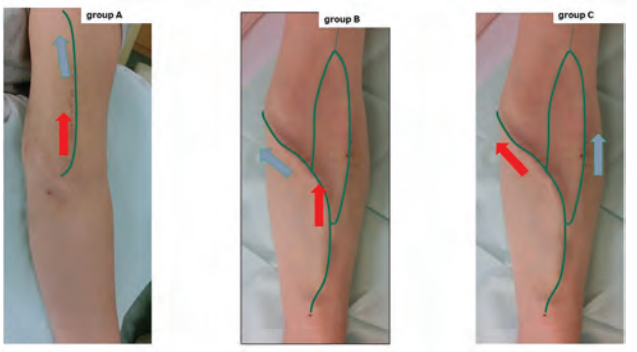
Toshihide Naganuma, Kentaro Shin, Tomoaki Iwai, Yoshiaki Takemoto, Junji Uchida. *Osaka Metropolitan University Graduate School of Medicine, Osaka, Japan.*

Background: In assessing vascular access (VA) function, access blood flow (Qa) using the UDM method is more common. However, because of the wide variety of vascular branches in arteriovenous fistula (AVF), Qa measurement may be difficult depending on the puncture position, considering the measurement principle of the ultrasound dilution method (UDM). In this study, we investigated the effect of puncture variation on Qa measurement in AVF. The results were also compared with Qa by ultrasonic Doppler method (Qa (DU)).

Methods: The 337 dialysis patients with AVF were divided into 3 groups (Figure1) (Group A:117 patients without a vascular branch between A and V at the puncture site, Group B:112 patients with a vascular branch, and Group C:98 patients with a separate vessel). Qa was measured during dialysis using HD03 dialysis monitor. Qa (DU) was also measured in the brachial artery by the ultrasonic Doppler method. This study protocol was conducted in accordance with the Principle of the Declaration of Helsinki, and was approved by the Ethics Committee of Osaka Metropolitan University (approval No.2021-243).

Results: As a result, Qa measurement errors in group A were 28/117 (23.9%), in group B 39/122 (32.0%), and in group C 96/98 (98.0%). Qa (DU) was measurable in all groups in this case. Moreover, group A showed a significant positive correlation between Qa and Qa (DU) (R=0.712, P<0.0001), group B showed a significant positive correlation between Qa and Qa (DU) (R=0.565, P<0.0001), and group C showed no correlation between Qa and Qa (DU) due to many measurement errors of Qa.

Conclusions: Based on these results, we believe that the choice of puncture position is important for Qa measurement by UDM, and that if recirculation is not observed or if a vascular bifurcation is present, the puncture position is not suitable for Qa measurement. On the other hand, Qa(DU) could be measured in all cases, which may be a better method of measuring access flow in AVF.



FR-PO526

Probability of Heart Failure with Preserved Ejection Fraction and Outcomes after Arteriovenous Fistula Creation

Karina S. Kanamori,[1] Darah Dilmaghani,[2] Barry A. Borlaug,[1] Vesna D. Garovic,[2] Karl A. Nath,[2] Yogesh N. Reddy.[1] *[1]Mayo Clinic, Department of Cardiovascular Medicine, Rochester, MN, Rochester, MN; [2]Mayo Clinic Department of Internal Medicine, Rochester, MN.*

Background: End stage renal disease (ESRD) patients develop symptomatic fluid retention related to renal failure with difficulty to differentiate from heart failure (HF). Therefore, clinical implications of co-existing myocardial dysfunction related to HF with preserved ejection fraction (HFpEF) on outcomes in ESRD following arteriovenous fistula creation (AVF) remain unknown.

Methods: Patients undergoing AVF from 2000 to 2015 who had echocardiography (echo) before AVF were retrospectively reviewed. HF with reduced ejection fraction (HFrEF) was defined by baseline EF<50%. Among those with EF≥50%, baseline probability of HFpEF was determined using a validated HFpEF score algorithm. Patients at risk for HFpEF were stratified as low(<25%), intermediate(25-75%) and high(>75%) probability. Baseline cardiac structure and function by echo and outcomes of mortality, HF hospitalization, and AVF maturation rate were compared across HFpEF probability groups.

Results: There were 366 patients(213 men) who underwent AVF and had echo before the procedure. Most patients(79%) had EF≥50% at the time of AVF, while 21% had HFrEF. Of those with EF≥50%, 131(45%) had high, 120(41%) had intermediate and 39(13%) had low probability for HFpEF. Higher HFpEF probability grouping was associated with higher echo estimated filling pressures as assessed by E/e'(13.4±5.1, 16.6±7.3, 19.0±8.7, p=0.0008), larger LA volume index(33.3±12.2. 37.3±11.7, 43.0±15.3, p=0.0006), higher right atrial pressure(5.9±2.3, 7.3±3.9, 8.8±4.2, p=0.0003), higher pulmonary artery systolic pressure(33.8±10.7, 40.1±13.7, 45.3±13.8, p=0.0003) and increased LV mass(200±79, 225±76, 246±86, p=0.01). AVF maturation rates were not different across HFpEF probability groups(31,33,35% p=0.56). Increasing HFpEF probability was associated with worse survival(HR per decile of HFpEF probability 1.11 [95%CI 1.06-1.17], p<0.0001) and increased risk of death or HF hospitalization(HR per decile of HFpEF probability 1.12 [95%CI 1.07-1.18], p<0.0001).

Conclusions: Increasing probability of HFpEF in patients with ESRD undergoing AVF is associated with worse cardiac remodeling and increased risk of death and HF hospitalization on maintenance hemodialysis. Whether treatment targeting the myocardial HFpEF component in patients with ESRD is beneficial requires further study.

A Change of Heart: Effect of High-Flow Arteriovenous Fistulas on Cardiovascular Outcomes, a Systematic Review and Synthesis without Meta-Analysis (SWiM)

Nasir A. Shah,[1,2] Morgan E. Hind,[3] Zoltan Endre,[2,1] Blake Cochran,[4] Tracie Barber,[5] Jonathan H. Erlich.[1,2] *[1]University of New South Wales School of Clinical Medicine, Sydney, NSW, Australia; [2]Prince of Wales Hospital and Community Health Services, Randwick, NSW, Australia; [3]The University of Notre Dame Australia School of Medicine, Fremantle, WA, Australia; [4]University of New South Wales School of Biomedical Sciences, Sydney, NSW, Australia; [5]University of New South Wales School of Mechanical and Manufacturing Engineering, Sydney, NSW, Australia.*

Background: Heart failure is a common cardiovascular condition in patients on haemodialysis. Case reports and a selection of studies have found associations between arteriovenous fistula (AVF) flow and heart failure, but the exact relationship remains unclear. The aim of this study was to describe the relationship between AVF flow and cardiac outcomes.

Methods: A comprehensive search of the PubMed, EMBASE, and Cochrane databases was used to identify observational studies and randomized controlled trials reporting clinical, echocardiographic, or biomarker effects of AVF flow on cardiac outcomes. Study heterogeneity made meta-analysis not feasible. Synthesis without meta-analysis (SWiM) was performed using vote counting of direction of effect as the primary outcome.

Results: The initial search strategy retrieved 3622 studies. After screening, 100 studies were analysed including a total of 8414 patients. A positive direction of effect was observed with cardiac output (29/34 studies), BNP (13/18 studies), ANP (2/3 studies), left ventricular hypertrophy and left ventricular mass (10/15 studies), left ventricular mass index (11/19 studies), left atrial volume index (10/12 studies) and incident heart failure or heart failure symptoms (21/25 studies). A neutral direction of effect was observed with ejection fraction (29/41 studies), E/A ratio (13/13 studies), E/E' ratio (8/11 studies), tricuspid annular plane systolic excursion (6/9 studies), and measures of pulmonary hypertension (13/26 studies). A negative direction of effect was observed for all-cause mortality (3/7 studies).

Conclusions: This systematic review and synthesis without meta-analysis showed a positive direction of effect between AVF flow and several cardiovascular outcomes, but an inverse relationship between AVF flow and mortality. The methodological heterogeneity of studies highlights the need for well-designed prospective research with standardised definitions of high flow AVFs and measures for reporting of cardiovascular outcomes.

FR-PO528

Arteriovenous Fistula-Associated Ascites

Michael D. Kolman, Lincoln J. Kavinsky, William L. Whittier, Roger A. Rodby. *Rush University Medical Center, Chicago, IL.*

Introduction: Dialysis-associated ascites (DAA) is a diagnosis of exclusion in End-Stage Kidney Disease (ESKD). The prognosis is grim and typically obviates kidney transplantation. We present a case of refractory ascites in a hemodialysis (HD) patient initially diagnosed as DAA, later determined to be cardiac ascites from arteriovenous fistula (AVF) related high-output heart failure (HOHF). The ascites resolved and the HOHF improved with AVF ligation and the patient was subsequently able to receive a kidney transplant.

Case Description: A 43 year-old woman with ESKD on HD via a mildly aneurysmal AVF developed ascites with a serum albumin ascitic gradient (SAAG) < 1.1 g/dL. After comprehensive workup for ascites, she was diagnosed with DAA. Later she was found to have an ejection fraction (EF) of 25% and due to this plus her ascites, she was deemed to not be a kidney transplant candidate. Doppler studies of the AVF showed elevated peak systolic velocities and subsequent right heart catheterization (RHC) revealed a high cardiac index (CI) that normalized upon AVF occlusion (see Table). After AVF ligation and tunneled dialysis catheter placement for HD, her EF improved to 45% and ascites resolved in 3 months. She became eligible for and received a kidney transplant 9 months later.

Discussion: DAA is a diagnosis of exclusion and has a mortality rate of 45% within 15 months of diagnosis. While a kidney transplant is the definitive treatment, our patient was unsuitable due to her reduced EF and ascites. Flow studies of her AVF were elevated and subsequent RHC revealed an abnormally high CI that normalized with AVF occlusion. An AVF alters peripheral circulation hemodynamics, reducing resistance and increasing cardiac output. Excessive blood influx can raise central venous pressure and left ventricular end-diastolic pressure, resulting in HOHF and cardiogenic ascites. With AVF ligation, her EF improved to 45%, ascites resolved, and she recieved a kidney transplant. This case emphasizes the need to consider AVF related HOHF as a reversible cause of ascites in the patient with ESKD, especially if the AVF is aneurysmal.

Cardiac output (CO) and Index (CI) before and after AVF occlusion with a BP cuff

Condition	CO	CI (nl 2.6-4.2)
Baseline	6.7L/min	4.5L/min
Cuff Inflated	4.1L/min	2.7L/min
Cuff Deflated	6.7L/min	4.4L/min

FR-PO529

Chylothorax and Chylopericardium in a Patient on Dialysis

Chelsea Gertze, C. E. Cervantes, Mohamad A. Hanouneh. *The Johns Hopkins University School of Medicine, Baltimore, MD.*

Introduction: Chylous effusions, a rare complication in hemodialysis patients, was observed in a patient with central venous stenosis (CVS) following arteriovenous fistula (AVF) creation.

Case Description: A 24-year-old man with acute kidney injury on CKD stage IV underwent hemodialysis via right intrajugular venous catheter. After creating a left arm AVF, he developed dyspnea and left arm swelling. CT chest showed bilateral pleural and pericardial effusions with milky fluid extracted from a right chest tube and pericardial drain with triglycerides levels of 1,008 mg/dL and 1,349 mg/dL respectively, indicating Chylothorax and Chylopericardium (Fig 1). Dynamic MR lymphangiography and 3-D MR angiography revealed bifid thoracic duct with dilation and lymphatic leakage around the diaphragmatic hiatus and right lower thorax (Fig 2A). Stenosis was noted in the right brachiocephalic vein and superior vena cava (SVC) with occlusion in the left brachiocephalic and left subclavian veins (Fig 2B). He recovered to CKD stage IV after 6 months of dialysis. He underwent AVF ligation, dialysis catheter removal, and venoplasty of SVC, left subclavian, brachiocephalic veins, followed by kissing stents through SVC and brachiocephalic veins (Fig 2C). Despite these interventions, stenosis reccurred. Consequently, ligation of the right thoracic duct and embolization of the left one resolved the effusions.

Discussion: CVS involves narrowing of central veins, commonly seen in dialysis patients. AVF creation can exacerbate symptoms by raising venous pressure. Rarely, CVS leads to Chylous effusions due to increased pressure in the thoracic duct causing leakage. In our patient, chylous effusions resulted from aggravated CVS, worsened by the dialysis catheter and elevated venous pressure after AVF creation.

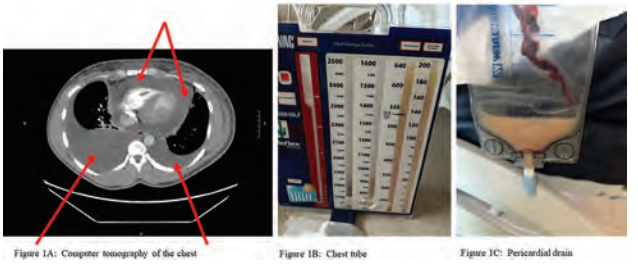

Figure 1A: Computer tomography of the chest Figure 1B: Chest tube Figure 1C: Pericardial drain

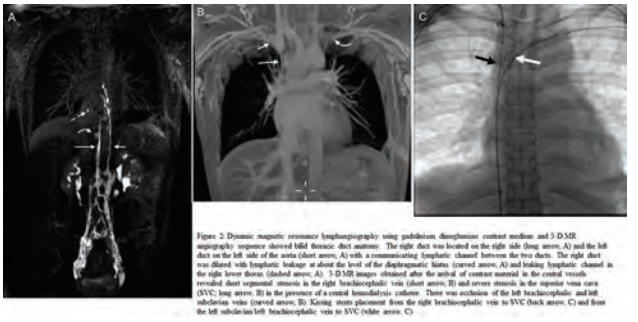

Figure 2: Dynamic magnetic resonance lymphangiography using gadolinium dimeglumine contrast medium and 3-D MR angiography sequence showed bifid thoracic duct anatomy. The right duct was located on the right side (long arrow; A) and the left duct on the left side of the aorta (short arrow; A) with a communicating lymphatic channel between the two ducts. The right duct was dilated with lymphatic leakage at about the level of the diaphragmatic hiatus (curved arrow; A) and leaking lymphatic channel in the right lower thorax (dashed arrow; A). 3-D MR images obtained after the arrival of contrast material in the central vessels revealed short segmental stenosis in the right brachiocephalic vein (short arrow; B) and severe stenosis in the superior vena cava (SVC; long arrow; B) in the presence of a central hemodialysis catheter. There was occlusion of the left brachiocephalic and left subclavian veins (curved arrow; B). Kissing stents placement from the right brachiocephalic vein to SVC (back arrow; C) and from the left subclavian/left brachiocephalic vein to SVC (white arrow; C)

FR-PO530

Closure of an Endovascular Arteriovenous Fistula Initially Created for Dialysis Access by Placement of Radial Artery Covered Stent

Hector Quintero Alvarez,[1] Carlos Claudio-Rodriguez,[2] Julio A. Peguero,[2] Cesar F. Hernandez-Arroyo.[1,2] *[1]Universidad Central Del Caribe, Bayamon, Puerto Rico; [2]Azura Vascular Care, Juana Diaz, PR.*

Introduction: Endovascular arteriovenous fistula (eAVF) creation offers a minimally invasive technique for creating arteriovenous fistulas for hemodialysis. The Ellipsys® System has demonstrated safety and effectiveness in creating eAVFs. However, questions remain regarding the optimal approach for reversing eAVFs when necessary. We present the first documented closure of a radial artery to perforator vein eAVF using a proximal radial artery covered stent.

Case Description: 50-year-old man with end-stage renal disease on hemodialysis sought closure of his eAVF due to chronic left upper arm swelling attributed to total occlusion of left innominate vein. Ultrasound confirmed patency and flow of the radial and ulnar arteries. The radial artery was cannulated, patient heparinization, and a catheter and guidewire were advanced into the brachial artery for direct arteriogram to identify the anatomy and arterial anastomosis. A Gore Viabhan endoprosthesis was deployed under fluoroscopic guidance, angioplasty done to anchor stent, and finally a direct brachial artery arteriogram confirmed occlusion of eAVF anastomosis.

Discussion: As proceduralists gain more experience, they become increasingly adept at maintaining this new type of access. Our aim is to provide insights into the potential closure of eAVFs and remain optimistic about the improved quality of care and reduced overall health complications this innovative technology offers.

FR-PO531

The KIDNEY-CAP: A Novel Device in the Management of Bleeding in Intermittent Hemodialysis Patients

Adam Forster,[1,2] Faisal Rehman,[1,2] Benjamin K. Thomson.[3] KIDNEY-CAP.
[1]Western University Schulich School of Medicine & Dentistry, London, ON, Canada; [2]London Health Sciences Centre, London, ON, Canada; [3]Johns Hopkins University, Baltimore, MD.

Background: Out of hospital arteriovenous graft (AVG) and arteriovenous fistula (AVF) bleeding occurs in 1-3/1000 hemodialysis patients per year. It is associated with hospitalization, hemorrhagic shock, and death. Presently there are no approved out of hospital devices available to aid patients if they develop an out of hospital bleed. The KIDNEY-CAP is a 3D printed cap that has been developed for patient use in this scenario. This study assessed attitudes towards vascular access, transplantation, and home dialysis in nephrology health care workers (NHCs) such as nephrologists, nephrology nurse practitioners, and body access coordinators, as well as ESKD patients on hemodialysis (ESKD-D) and how the KIDNEY-CAP influences these impressions.

Methods: Survey 1 studied KIDNEY-CAP introduction into the CKD/ESKD patient experience, and how it would impact NHC recommendations for kidney care. Parameters such as recommendation for transplantation, vascular access modality, and home dialysis opportunities were explored. In survey 2, in-center ESKD-D patients were evaluated for how the KIDNEY-CAP might modify decisions regarding their end stage kidney disease care. When survey respondents already had an AVG/AVF, their level of concern regarding AVG/AVF bleeding was quantified, while evaluating for common bleeding risk factors.

Results: In survey 1, 41% of respondents indicated that they were more likely to recommend home dialysis and vascular access with AVG/AVF if a KIDNEY-CAP was available. Providers were more likely to recommend these options in patients not yet on dialysis. In survey 2, 66% of patients indicated at least slight concern about bleeding from their access site. 66% also felt they would benefit from having a device to help control bleeding outside the dialysis unit. 27.8% indicated that they would be more likely to select AVG/AVF as their vascular access of choice if they had a KIDNEY-CAP. There was no difference in feelings toward home dialysis or transplantation.

Conclusions: We demonstrate that the KIDNEY-CAP is a device of interest for providers in determining vascular access for patients approaching dialysis. There may also be benefit to patient comfort with vascular access should the KIDNEY-CAP be available. Further exploration in the predialysis patient population is warranted, as is prospective study on the KIDNEY-CAP's adoption.

FR-PO532

Comparative Analysis of Anti-phospholipid-Antibody Positivity and Confirmation as Potential Risk Factors for Arteriovenous Fistula Thrombosis in Patients on Hemodialysis

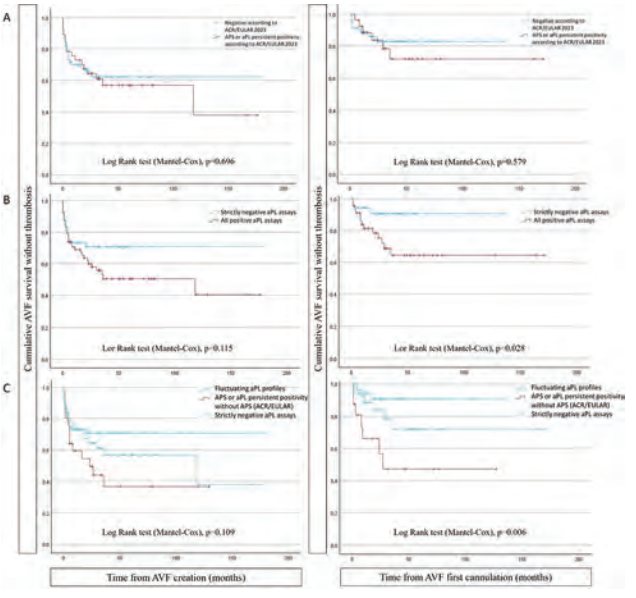
Maxime Taghavi,[1,2] Lucas Jacobs,[1,2] Frederic Collart,[1,2] Joelle L. Nortier.[1,2]
[1]UVC Brugmann - Site Victor Horta, Brussels, Belgium; [2]Universite Libre de Bruxelles, Bruxelles, Belgium.

Background: The classification criteria (CC) for antiphospholipid syndrome require antiphospholipid antibody (aPL) persistent positivy (aPL PP)(i.e. confirmation assay at 12 weeks). aPL PP frequent in hemodialysis (HD) (prevalence up to 56%) and seems to be associated with native arteriovenous fistula (AVF) thrombosis, but studies have a heterogeneous aPL positivity definition. This study aims compare real-life situation of aPL positivity in terms of AVF thrombosis.

Methods: We retrospectively identified 127 HD patients with native AVF. We performed Kaplan-Meier analyses and compared AVF thrombosis prevalence during the follow-up. We evaluated different subgroups of patients representative of real-world practice: Analysis 1 according to CC; Analysis 2 comparing all patients with at least one positive aPL assay to strictly negative patients and analysis 3 comparing 'aPL PP according to CC' and 'patients with one aPL positive assay' and 'strictly negative patients'.

Results: aPL PP represented 30% of the cohort, only 8% of the patients were aPL+ once (without confirmation) and 16% were aPL+ with a negative control. The prevalence of AVF thrombosis was significantly higher in analysis 2 and tended to signification in analysis 3. Kaplan-Meier analysis showed significant shorter access survival without thrombosis from AVF first cannulation in analyses 2 and 3 (Mean time to first event (months ± SD) was 115.8 ± 12.7 *vs* 124.0 ± 6.6 in analysis 2 and 124.0 ± 6.6 *vs* 128.6 ± 15.1 in analysis 3 (Figure 1)).

Conclusions: The present in-depth comparative analysis of different aPL profiles encountered in real life situations, shows an significant associated with AVF thrombosis. Detection of aPL positivity could be a useful tool for the clinicians in assessing AVF thrombosis risk.



FR-PO533

Drug-Eluting Stents in Treating Arteriovenous Graft Thrombosis: A Pilot Study

Ivana Boktor,[1] Ahmed E. Ali,[2] Alian Albalas,[3] Ammar Almehmi.[3] *[1]George Walton Comprehensive High School, Marietta, GA; [2]Mayo Foundation for Medical Education and Research, Rochester, MN; [3]The University of Alabama at Birmingham, Birmingham, AL.*

Background: Thrombosis of the arteriovenous graft (AVG) related to venous anastomosis stenosis is associated with poor access survival in dialysis population. The use of standard and drug-coated balloons and covered stents is associated with poor primary access patency. On the hand, drug-eluting stents (DES) have been used successfully in coronary and peripheral interventions with low reintervention rates.

Hence, this study sought to explore the effect of DES in treating AVG thrombosis and subsequent overall access patency.

Methods: This is a retrospective study that included a total of 9 patients receiving dialysis via AVGs who presented with thrombosis and underwent DES deployment during the thrombectomy procedure. Patient demographics and post-intervention follow-up data were extracted from the vascular database. Primary endpoints included graft primary patency, procedural success, and complication rates.

Results: The cohort included 4 men and 5 women with a median age of 55 years (ranging from 22 to 81 years). Common comorbidities included hypertension 100% (9/9), diabetes mellitus 67% (6/9), and hyperlipidemia 44% (4/9). The main indication for DES deployment was recurrent thrombosis of an existing AVG. After the procedure, all the patients were prescribed dual antiplatelet therapy for one month. All stents were deployed successfully and no immediate complications were encountered. The target lesion for DES placement was the venous-graft anastomosis. The median follow-up period was 421 days (IQR: 78). Results showed a significant improvement in graft patency rates, with a target lesion primary patency rate of 55.5%. During the follow-up, 5 patients required no interventions, the other 4 patients continued to suffer from access thrombosis requiring a new dialysis access placement.

Conclusions: The findings of this case series underscore the potential role of DES in managing AVG thrombosis related to venous anastomosis stenosis. Moreover, while this study is hypothesis-generating in nature, it invites further investigation to understand the complex pathophysiology of dialysis access lesions.

65-year-old female presented with clotted arteriovenous graft (AVG) due to venous anastomosis (VA) lesion treated with Percutaneous transluminal angioplasty (PTA) and Eluvia stent with no intervention needed in the follow-up period.

FR-PO534

A Novel Use of JETi Thrombectomy Device Mediates Embolic Complication during Graft Thrombectomy

Luis G. Osorio, Kevin T. Onofrey, Loay Kabbani, Lalathaksha Murthy Kumbar. *Henry Ford Hospital, Detroit, MI.*

Introduction: We present a case detailing the use of a novel thrombectomy device to treat acute upper limb ischemia as a complication of percutaneous arteriovenous graft (AVG) thrombectomy. The JETi Hydrodynamic thrombectomy System (Abbot Vascular, Abbot Park, IL) is a mechanical thrombectomy device indicated for peripheral vasculature which has demonstrated efficacy in acute venous thromboembolism[1] and acute arterial limb ischemia (ALI)[2].

Case Description: A 59-year-old female presented with a clotted AVG of 6-day duration. Mechanical rheolytic thromboaspiration using the Angiojet Thrombectomy system (Boston Scientific, Marlborough, MA) was performed followed by angioplasty of venous stenosis. Stenosis at arterial anastomosis was also identified and angioplastied. Completion angiogram showed patent AVG with no residual stenosis. Completion arteriogram also revealed an embolus in the distal brachial artery with no flow distal to the occlusion. Angioplasty and Angiojet thrombectomy interventions proved unsuccessful. Subsequently, the JETi thrombectomy system was employed, leading to the successful retrieval of the clot and restoration of blood flow into the forearm.

Discussion: While arterial embolism during percutaneous thrombectomy of dialysis access is a recognized complication, it is uncommon.[3] The JETi thrombectomy system integrates clot fragmentation and catheter aspiration.[1] Traditionally used for deep venous thrombosis and ALI, this case exemplifies a unique utilization of the of the JETi system in managing a complication from AVG thrombectomy where more traditional methods failed. The JETi thrombectomy system presents a promising alternative for addressing embolic complications resulting from percutaneous AVG thrombectomies and warrants consideration as a primary treatment modality. However, further studies investigating AVG thrombectomies are imperative to ascertain its suitability as a standard of care.

FR-PO535

Trends in Epidemiologic Characteristics and Clinical Patterns of Vascular Access of Incident Hemodialysis Patients: Nationwide Cohort Study (2006-2019) in Korea

Kyoung Sook Park. *National Health Insurance Service Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea.*

Background: The number of patients with end-stage kidney disease (ESKD) undergoing hemodialysis (HD) was rapidly growing in Korea. Although there was a Korean Renal Dialysis System (KORDS) registry for analyzing HD practice patterns in Korea, the registration rate (63.8% in 2022) wasn't sufficient to represent real-world aspects. Thus, we analyzed HD patients' clinical practice patterns in Korea using National Health Insurance System (NHIS) data.

Methods: Subjects were extracted from NHIS data, comprising patients with code V001 for financial support in rare incurable patients (i.e., ESKD) and code O70102 for HD from 2006 to 2019. We examined epidemiological characteristics and practice patterns of vascular access in initiated HD patients. We defined the central venous catheter (CVC) user to the presence of O7012, CVC-related code for the charge of the Health Insurance Service Procedure 6 months before encoding the HD-related code, and the arteriovenous (AV) access user to the presence of AVF-related codes (O2083, O2056, O2081, O2082, O2083, and O2059) 6 months before encoding the HD-related code.

Results: Patients initiating HD surged from 4,927 in 2006 to 14,049 in 2019. The proportion of those aged 70-79 and above 80 rose from 10% and 1% in 2006 to 25% and 18% in 2019, respectively. CVC usage increased from 43% in 2006 to 54% in 2019, while AV access rose from 15% to 28%. Especially in the 60-79 age group, AV access users increased significantly (from 5% in 2006 to 15% in 2019). The mean duration after AV access creation before usage increased (from 2.3 months in 2006 to 3.6 months in 2019).

Conclusions: The trends in epidemiologic characteristics showed similarities compared to the KORDS registry. However, clinical patterns of vascular access in HD initiation differed. Our report might help represent real-world aspects in ESKD patients who have started HD.

FR-PO536

Bedside Ultrasound (US)-Guided Nonfluoroscopic Insertion of Right-Sided Tunneled Dialysis Catheter: Largest Experience from a Single Center

Sejal Khandelwal,[1] Audrey Tassillo,[2] Mukesh Khandelwal.[2] *[1]Western University Schulich School of Medicine & Dentistry, London, ON, Canada; [2]Niagara Health System, St. Catharines, ON, Canada.*

Background: Tunneled dialysis cuffed catheters (TDCs) are often used for initial access in crash start and other hemodialysis (HD) patients due to lack of arteriovenous fistulae. While the NKF-KDIGO guidelines recommends fluoroscopic-guided TDC insertion by interventional radiology (IR) as the standard of care, there is a growing body of evidence supporting the safety, efficacy, and promptness of bedside ultrasound (US)-guided nonfluoroscopic TDC insertion. This study aims to evaluate the feasibility and safety of bedside US-guided TDC insertion by a nephrologist.

Methods: A comprehensive retrospective chart review of patients who underwent bedside TDC insertion at Niagara Health from 2011-2024 was conducted. Patients were identified from office electronic medical records (EMR) using the provincial billing code for TDC insertion. Inclusion criteria comprised a patent right internal jugular (RIJ) vein, INR<1.5, absence of anticoagulation at the time of insertion, and the ability to assume a supine or at least 30° upright position. Exclusion criteria encompassed patients with right-sided pacemakers or AICDs, severe coagulopathy, active sepsis, an occluded RIJ vein, or known superior vena cava stenosis.

Results: A total of 901 catheters were inserted in 867 patients by one nephrologist. Four patients were unsuccessful due to guidewire negotiation issues and necessitated IR intervention. Catheter tip position was confirmed by nephrologist and chest x-ray. Catheter tip was in the right ventricle in two cases, and one patient had azygos vein placement. In one patient with a right-sided pacemaker, left-sided TDC was attempted, but catheter tip ended in right IJV and required repositioning by IR. Complications include occasional premature ventricular contractions, one hyperkalemia-induced cardiac arrest with successful resuscitation, catheter kinking in 2 cases, and minor bleeding in 12 cases. Additionally, two cases with very high BMI (> 700 lbs) that were deemed unsuitable by IR underwent successful bedside insertion. Furthermore, another case with a right-sided pacemaker had successful insertion of a right TDC, after cardiology approval.

Conclusions: US-guided bedside TDC insertion by nephrologists is highly successful and safe, offering a viable alternative to fluoroscopic-guided insertion.

FR-PO537

Implantation of Hemodialysis Catheter in the Iliac Vein vs. Placement in Femoral Vein with Ultrasound Guidance

José J. Gutiérrez Hernandez, Brenda Aguilar, Hugo B. Espinoza, Francisco J. Padilla Gomez, Carolina Covarrubias Castellon, David A. Juárez, Rosa M. Resendez Gonzalez, Christian Ali R. Esquinca, Brenda G. Rosales Torres, Cristian J. Ramos Mares, Javier Soto-Vargas, Paulina De Niz Hernández, Renato Parra Michel, Juan O. Romero Tafoya, Jose A. Barbarin Sosa, Diana M. Reyes Martinez. *Instituto Mexicano del Seguro Social, Guadalajara, Mexico.*

Background: We compare the results of implantation of hemodialysis catheter in the iliac vein versus placement in femoral vein both guided with ultrasound, analyzing complications, technique and survival

Methods: All patients required chronic hemodialysis and to who were determined not to place a catheter in the internal jugular vein, femoral with history of multiple vascular access, AV fistula or grafts where it was essential to obtain an alternative vascular access. When the procedure for the insertion for the iliac vascular access was realized was

always with US guidance. The results were compared with patients who underwent the implantation of a tunneled vascular access in the femoral region

Results: The insertion of catheters were realized by the nephrologists experts in vascular access from the HGR 46 of the IMSS in Guadalajara, Jalisco, Mexico, between 2021-2024. A total of 12 iliac catheters were implanted all with US guidance. The iliac catheter group had the same amount of punctures as the femoral catheter group, arterial punctures were rare in both techniques. No differences were observed in complications related to the procedures.

Conclusions: Implantation of iliac catheters in patients with impossibility for conventional site insertion is a safe procedure and feasible in patients with vascular exhaustion. The rate of complications and survival was not inferior to the femoral catheter group. It is necessary to know the inguinal region anatomy as well as the correct selection of patients.

	Femoral catheter (n=15)	Iliac catheter (n=12)

Long-Term Outcomes after Percutaneous Transluminal Angioplasty for Hemodialysis Catheter Placement

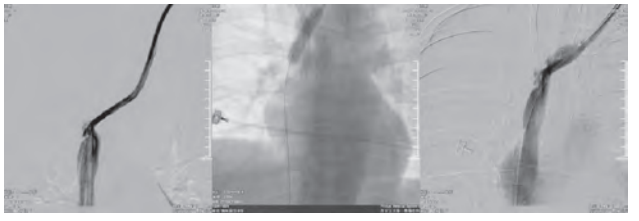
Kehui Shi. *Department of Critical Care Nephrology and Blood Purification, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China*.

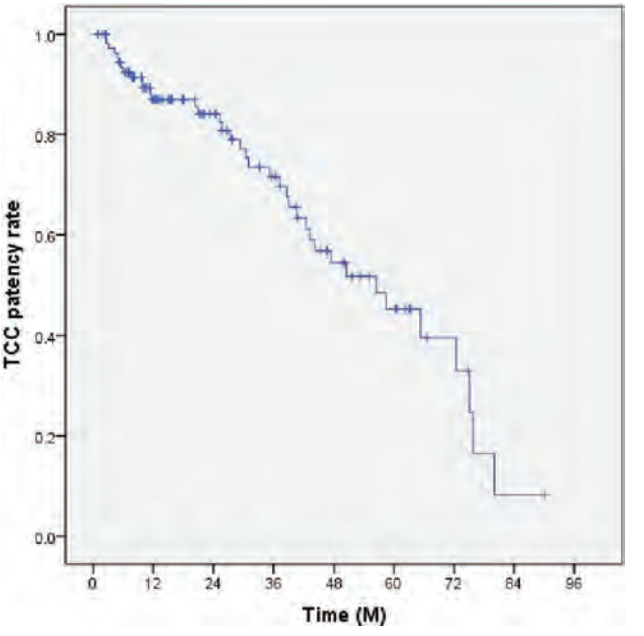
Background: Percutaneous transluminal angioplasty (PTA) is the treatment of central vein stenosis or occlusion, it has been applied during hemodialysis catheter placement. However, data came from case reports or small series, and the long-term outcome has rarely been reported. This retrospective study aims to observe the application of PTA for hemodialysis catheter placement and the Long-term outcomes after surgery.

Methods: Retrospective analysis of patients who underwent digital subtraction angiography (DSA) guided tunneled cuffed catheter (TCC) placement surgery from March 1, 2015 to August 31, 2023. When there was central vein stenosis (CVS) or occlusion, or fibrin sheath, PTA was performed to dilate the central vein or disrupt the fibrin sheath (Figure 1). Then, a new catheter was inserted. The Kaplan-Meier method was used to investigate the survival rates of the catheters.

Results: A total of 149 TCCs were placed in 125 patients, of which 106 cases were underwent PTA. There were 98 cases (66%) of fibrin sheath formation, 76 cases (51%) of CVS, 20 cases (13%) of central vein occlusion, and 6 cases (4%) of central vein thrombosis. The technical success was 98.7% (147 of 149), and the clinical success with resumption of at least one session of normal dialysis occurred in 145 cases (97.3%). The median follow-up was 21.9 months (range, 1–90 months). The survival rates of the catheters at 12, 24, 36, and 60 months were 87%, 84%, 72%, and 46%, respectively. (Figure 2)

Conclusions: PTA is safe and effective for hemodialysis catheter placement when there was CVS or central vein occlusion or fibrin sheath formation.





FR-PO539

Persistence of Left Superior Vena Cava Anomalies: From Shrewd Suspicion to Accurate Diagnosis

Pedro G. Pascoal, Juliana Hickmann de Moura, Luiggy J. Vaca Demera, Vanderlei C. Bertuol, Ariana Custodio Vieira, Arthur G. Manfro, Gusthavo Mandelli, Gustavo G. Thomé. *Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil*.

Introduction: Persistent left superior vena cava (PLSVC) is an important anatomical variation that challenges hemodialysis (HD) vascular access placement and may lead to adverse outcomes. We present three cases of PLSVC, including one leading to an inaccurate thoracotomy.

Case Description: Case 1: A 17-year-old kidney recipient with graft failure returning to HD had a non-tunneled catheter (NTC) inserted in his left internal jugular vein (LIJV). Computed tomography (CT) revealed unusual left mediastinum anatomy, suggesting a perforation of the catheter through the left atrium, which led to urgent thoracotomy. The procedure revealed a PLSVC with a lateral course to the aorta, without atrial perforation. The anomalous vein encircled the left atrium and drained into the inferior cavoatrial junction, where the catheter tip resided. Case 2: A 46-year-old woman admitted for HD underwent a catheter insertion through the right internal jugular vein. Fluoroscopy revealed guidewire path through the brachiocephalic vein to the LSVC. It was then opted to cannulate the LIJV, with the catheter going through the LSVC to the right atrium. CT confirmed an isolated persistent left superior vena cava (IPLSVC). Case 3: A 60-year-old woman with a corrected atrial septal defect was admitted to the intensive care unit due to sepsis-associated kidney injury requiring dialysis. After a NTC was inserted via the LIJV, CT demonstrated a PLSVC with the catheter tip in the right atrium. The catheter functioned properly.

Discussion: PLSVC occurs in 0.3-0.5% of healthy individuals and 1.3-11% of those with congenital heart diseases (CHD). Embryologically, it arises due to persistence of the left common cardinal vein. IPLSVC is rarer, manifesting in 0.09%-0.13% of patients with CHD. Often asymptomatic, PLSVC can lead to complications during HD vascular access placement or misinterpretation of exams. These cases highlight the importance of awareness of this anatomical variation.

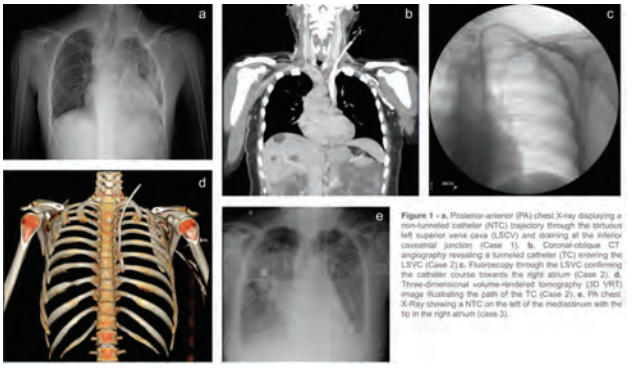


Figure 1 - a. Posterior-anterior (PA) chest X-ray displaying a non-tunneled catheter (NTC) trajectory through the tortuous left superior vena cava (LSCV) and draining at the inferior cavoatrial junction (Case 1). **b.** Coronal-oblique CT angiography revealing a tunneled catheter (TC) entering the LSVC (Case 2).**c.** Fluoroscopy through the LSVC confirming the catheter course towards the right atrium (Case 2). **d.** Three-dimensional volume-rendered tomography (3D VRT) image illustrating the path of the TC (Case 2). **e.** PA chest X-Ray showing a NTC on the left of the mediastinum with the tip in the right atrium (case 3).

FR-PO540

Rare Complication of Hemodialysis Catheter Insertion: Tissue Dilator Embolism

Jasper Sim,[1] Sajan Das,[2] Sonali Gupta.[1,2] *[1]Albert Einstein College of Medicine, Bronx, NY; [2]Montefiore Medical Center, New York, NY.*

Introduction: Central line catheterization is one of the most common invasive procedures performed. Of the potential complications, mechanical complications are often overlooked given the assumption of device integrity. While catheter fragmentation has been previously reported in literature, there has only been one reported case of a tissue dilator fracture and embolism during femoral catheterization. In this case report, we describe a tissue dilator fracture and embolism during left internal jugular vein catheterization.

Case Description: A 55-year-old male with non-ischemic cardiomyopathy and prior LVAD placement was admitted with biventricular heart failure and underwent RVAD. Hospital course was complicated by persistent cardiogenic shock, hypoxic respiratory failure, volume overload and acute respiratory distress syndrome. It was decided to begin slow continuous ultrafiltration to manage his volume status. During an attempt to obtain vascular access, the tissue dilator tip fractured and migrated to the right pulmonary artery. Interventional radiology attempted retrieval of the foreign body but was unable to retrieve it after multiple snare attempts. Procedure was complicated by hemorrhage requiring embolization of the right pulmonary artery branch. Over the next few days, the patient remained hemodynamically unstable, and the family eventually decided to withdraw care.

Discussion: Our case highlights how a simple, routine procedure can be associated with grave complications. There are occasional reports of vascular catheter tips or guidewire fragmentation, but dilator tip fragmentation is rare. It is important to note the expiration date and integrity of instruments and devices, such as the guidewire, catheter, and dilator, before use. It is also crucial to ensure all devices used for a vascular procedure contain a radiopaque marker for rapid identification in the case of fragmentation. As retained foreign bodies increase the risk for sepsis, hemorrhage, embolism, cardiac arrythmia and mortality, retrieval should be done promptly after discovery. In this case, the foreign body failed to be recovered despite minimally invasive methods.

FR-PO541

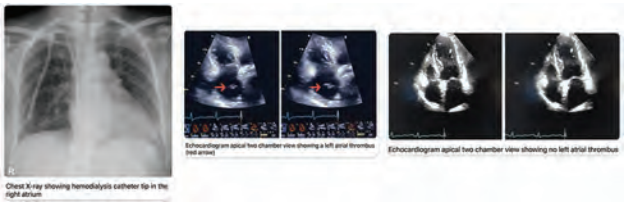
Catheter Tip Thrombus: A Rare but Serious Complication

Mendell Ray T. Sinda, Grecia Darunday, Ruben A. Maguad, Eratosthenes S. Polito. *Perpetual Succour Hospital, Cebu City, Philippines.*

Introduction: The hemodialysis catheter serves as a crucial instrument in renal replacement therapy. While it can be life-saving, its insertion is not without risks. Despite being rarely reported, catheter tip thrombosis lacks a standardized approach due to its infrequency.

Case Description: We present a case involving a 62-year-old woman with diabetes and hypertension, along with a history of ischemic stroke and one year of dialysis. Initially, she had a temporary hemodialysis catheter placed in the right internal jugular vein due to a non-maturing arteriovenous fistula (AVF) on her left arm. However, she experienced intermittent palpitations and chest discomfort exacerbated by certain movements, eating, and dialysis sessions. Cardiac arrhythmias (supraventricular tachycardia and rapid atrial fibrillation) were documented, necessitating pharmacological cardioversion. A chest X-ray revealed the catheter tip was erroneously positioned in the right atrium, likely contributing to the arrhythmias. Though repositioning was planned, echocardiography revealed a 1.1 cm x 0.4 cm thrombus attached to the catheter tip in the right atrium, increasing the risk of embolization during manipulation. Hence, a conservative approach was adopted, initiating intravenous anticoagulation and dual antiplatelet therapy (clopidogrel and aspirin). Symptoms gradually improved over six days of treatment, with a subsequent echo scan showing thrombus resolution. Anticoagulation was ceased, and the patient was discharged on antiplatelet therapy, now undergoing dialysis without symptoms.

Discussion: Catheter tip thrombosis in hemodialysis patients represents a rare yet grave complication associated with considerable morbidity. Its diagnosis requires a high index of suspicion since it can mimic an acute coronary syndrome, particularly in patients predisposed to cardiac events. In hemodynamically stable individuals, considering anticoagulation and antiplatelet therapy as treatment options may prove beneficial.



FR-PO542

Tunneled Catheter-Associated Quadruple Valve Endocarditis

Heather Rowe, Zeyad J. Rifai, Nirali B. Ramani. *Southern Illinois University School of Medicine, Springfield, IL.*

Introduction: The Advancing American Kidney Health (AAKH) initiative was launched in 2019 to establish a new framework for kidney care in the United States (US). Unfortunately, the complexities of addressing health equity were left out of the initiative.

Case Description: A 45-year-old African American man experiencing homelessness with untreated schizophrenia, nicotine dependence, and uncontrolled hypertension complicated by End-Stage Renal Disease (ESRD) via tunneled catheter presented to the hospital with fever, rigors, malaise, dyspnea, chest pain, and pain over his tunneled catheter site since catheter exchange 3 weeks ago. His last dialysis session was two days prior. The patient has a history of missed dialysis sessions likely due to his untreated schizophrenia and lack of transportation. Blood cultures showed Methicillin Sensitive Staphylococcus Aureus with echocardiogram revealing vegetations on the pulmonic valve, new mitral and tricuspid valve flail chords, and new severe aortic insufficiency compared to echocardiogram from 2 weeks prior. The patient underwent catheter exchange after a line holiday and negative repeat blood cultures, and was prescribed an intradialytic regimen of cefazolin.

Discussion: This unfortunate case of quadruple valve endocarditis is a sobering reminder of the moral obligation of healthcare professionals to care for all individuals, particularly the most vulnerable. Patients with schizophrenia have an increased prevalence of diabetes, hypertension, and cardiovascular disease which are all risk factors for kidney disease. Nephrologists must work closely with psychiatrists, dialysis nurses, and other healthcare providers to create a comprehensive care plan that addresses both the psychiatric and medical needs of the patient. Comanagement with a psychiatrist may implement and support behavioral strategies to improve adherence to dialysis to avoid catastrophic outcomes. Raising awareness in the Nephrology community is a step toward compassionate, inclusive care for our most vulnerable patients.

FR-PO543

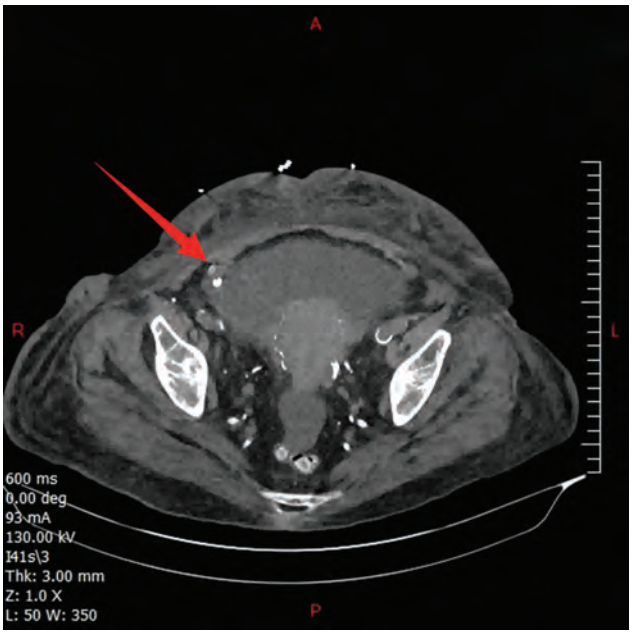
Beyond Appearances: A Case Report of Mistaken Identity in Dialysis Access

Ephrem D. Demie,[1] Shahin C. Owji,[2] Mohammad Shafiq,[2] Srikanth K. Raayasa.[2] HCA Nephrology Team. *[1]HCA Healthcare Inc, Nashville, TN; [2]HCA Healthcare Graduate Medical Education, Brentwood, TN.*

Introduction: In this case report, we present a remarkable case involving a patient with a transhepatic hemodialysis (HD) catheter. The transhepatic hemodialysis catheter involves placing a catheter through the right or middle hepatic veins when other options have been exhausted. The catheter became dislodged into the peritoneal cavity and was subsequently mistaken for a peritoneal dialysis catheter.

Case Description: A 34-year-old female with a history of lupus, hypertension, and end-stage renal disease on hemodialysis presented to the ER with concerns about a malfunctioning hemodialysis catheter for a week. During her ER visit, an initial x-ray revealed a percutaneous catheter in the right abdomen. A CT scan of the abdomen and pelvis showed a dislodged transhepatic hemodialysis catheter, misinterpreted as a peritoneal dialysis catheter, leading to a delay in treating the potential causes of the patient's symptoms. Both the ER physician and the hospitalist failed to promptly diagnose the issue, resulting in the patient not receiving timely appropriate surgical intervention and renal replacement treatment.

Discussion: Catheters utilized for hemodialysis access, such as transhepatic access, exhibit varying radiographic appearances, yet share common features of large bore catheters with a double lumen. A properly positioned transhepatic hemodialysis catheter traverses subcutaneously through the liver parenchyma, hepatic vein, and inferior vena cava before terminating within the right atrium. However, transhepatic catheters are susceptible to migration, often evidenced by imaging depicting the catheter tip retrogressing into the hepatic vein or descending into the peritoneal cavity. This can lead to delays in diagnosis and management, as was evident in this case.



CT scan showing the Transhepatic HD catheter

FR-PO544

Use of Central Venous Catheter (CVC) as Vascular Access at Hemodialysis Entry in Brazil: Impact on 2-Year Mortality

Guilherme Schittine Bezerra Lomba,[1] Angelica P. Da Silva,[1] Fabiana B. Nerbass,[3] Helbert N. Lima,[4] Ricardo Sesso,[2] Jocemir R. Lugon.[1] *[1]Universidade Federal Fluminense Hospital Universitario Antonio Pedro, Niteroi, Brazil; [2]Universidade Federal de Sao Paulo Escola Paulista de Medicina, Sao Paulo, Brazil; [3]Pró-Rim Foundation, Joinville, Brazil; [4]Universidade da Regiao de Joinville, Joinville, Brazil.*

Background: The recommended access for starting HD is arteriovenous fistula (AVF), but CVC is frequently used. Its use has been associated with higher mortality worldwide, but Brazilian data on this is scarce. Using data from the Brazilian Dialysis Registry, we aimed to evaluate the time trend of CVC use at the start of HD and assess its impact on all-cause mortality over 2 years.

Methods: This was a national registry-based retrospective cohort study with data of ≥18-year incident HD patients from Jan-2011 to Dec-2023. The variable of primary interest was the initial vascular access: CVC or AVF/graft. The main outcome was all-cause 2-year mortality. For analyses, we used the Kaplan-Meier method and Cox proportional hazards regression.

Results: We studied 10,466 patients. The mean age was 58±16 years; 60% were male, and 33% had diabetes. CVC use at HD entry increased in the last 10 years (Fig. 1). Two-year survival curves are in Fig. 2. In a univariate Cox regression model, the HR of CVC use was 2.56 (95%CI 2.10-3.14); after adjustment for age, sex, BMI, diabetes, hypertension, Hep B and C, HIV, albumin, and Hb, it was 1.92 (95%CI 1.30-2.83). Other independent variables associated with mortality were: age (HR 1.04; 95%CI 1.03-1.05), BMI (HR 0.97; 95%CI 0.95-0.99), albumin (g/L) (HR 0.91; 95%CI 0.89-0.93), and Hb (g/L) (HR 0.96; 95%CI 0.95-0.97).

Conclusions: CVC use was associated with a 2-fold increase in the risk of 2-year mortality. The upward trend in CVC use in Brazil is worrying and calls for changes in medical care aimed at the early implementation of permanent vascular access for HD start.

FR-PO545

Access-Related Infections in Icelandic Patients on Hemodialysis

Lára B. Birgisdóttir,[1] Olafur S. Indridason,[2] Runolfur Palsson,[2,1] Asta D. Jonasdottir.[2,1] *[1]Haskoli Islands, Reykjavik, Iceland; [2]Landspitali, Reykjavik, Iceland.*

Background: Hemodialysis (HD) requires a well-functioning access to the vascular system, preferably an arteriovenous (AV) fistula or graft. Many patients initiate maintenance HD using a central venous catheter (CVC) which is prone to complications, including bacteremia. The aim of the study was to examine the frequency of CVC use for HD access in Iceland, and the incidence of catheter-related complications.

Methods: This was a retrospective study that included all patients aged >18 years who started HD for end-stage kidney disease in Iceland in 2017-2022. Demographic and clinical information, including the type of vascular access and access related complications was obtained from electronic medical records. Access-related bacteremia was defined as positive blood culture from a peripheral vein or the dialysis circuit and absence of other cause of the infection. The incidence of infections was calculated per patient-year for each access type.

Results: Among 164 patients who initiated HD during the study period, 79 (42.8%) started with a tunneled CVC as vascular access, 35 (21.3%) a non-tunneled CVC, 47 (28.7%) an AV fistula and 3 (1.8%) with an AV graft. A tunneled or non-tunneled CVC was used by 127 (77.4%) patients at some point. The use of tunneled CVCs increased during the study period, with 23 catheters placed in 18 individuals in 2017, while 38 were placed in 32 individuals in 2022. The use of non-tunneled CVCs decreased markedly, as13 such catheters were placed in 12 individuals in 2017, but only a single non-tunneled CVC in 2022. Cumulative patient-years with each access type was 98.2 for tunneled CVCs, 2.9 for non-tunneled CVCs, 198 for AV fistulas and 20.1 for AV grafts. The incidence of access-related bacteremia was 0.28 per patient-year (0.77 per 1000 CVC days) for tunneled CVCs, 1.37 per patient-year (3.8 per 1000 CVC days) for non-tunneled CVCs, 0.025 per patient-year for AV fistula, no bacteremia was observed in patients with AV grafts. The most common infectious agent was Staphylococcus aureus, causing 14 (37.8%) bacteremia episodes, followed by coagulase-negative staphylococci causing 10 (27%) episodes.

Conclusions: The use of CVCs is high in Iceland compared to other countries in Europe. However, the decreasing proportion of non-tunneled catheters is exemplary and likely explains the low incidence of bacteremia in patients with CVCs.

FR-PO546

Vascular Access-Related Hospitalizations in Hemodialysis

Leonella Luzardo,[1,2] Maria A. Zinoveev,[1] María Laura Ceretta,[1] Alejandro Ferreiro,[1,2] Maria C. Gonzalez-Bedat.[1] *[1]Uruguayan Dialysis Registry, Montevideo, Uruguay; [2]Nephrology Center, Hospital de Clínicas, Montevideo, Uruguay.*

Background: Arteriovenous fistulas (AVF) are recommended for patients on HD due to their benefits over catheters(CAT), that are associated with higher morbidity. The aim of this research is to analyze vascular access–related hospitalizations.

Methods: We analyzed the HD cohort of patients on HD during 2022 in Uruguay. Data was extracted from the Uruguayan Dialysis Registry. Vascular access were divided into catheters (CAT) or arteriovenous grafts or fistulas(AV). Vascular access–related hospitalizations were classified into infectious or non-infectious and 4 categories were established: CAT-inf, CAT-non inf, AV-inf, AV-non inf. Those complications that did not require hospital admission were not included. We calculated the rate of admissions/1,000 HD sessions.

Results: A total of 3,472 patients (60.1% M; 66.2% diabetes) were included, 62.9 years (SD ± 16.2). 390,920 chronic HD sessions were performed, on 64.4% of them the vascular access was an AV graft or fistula. We analyzed 716 vascular access – related admissions (589 patients) and 69.7% of them were nonrelated to infection. The rate of admissions related to AVFs was 2,18/1000 HD session (95% CI: 2,00–2,36) and the rate of admissions related to CAT was 1,21/1000 HD session (95% CI:1,04–1,41). Hospitalizations due to an AV-non inf complication were the most frequent with a rate of 1,82/1000 HD session (table1). Patients who required admission had similar age (63.0vs62.7 years; *p*=ns) but had more diabetes (70.5% vs 60.4%; *p*=0.02).

Conclusions: Unexpectedly, mechanical complications of AVFs were responsible for most admissions. This is probably multifactorial and is related to the comorbidities of the population and a decrease in infectious complications of catheters due to their improvement. An analysis of the trend over the last years would be of interest for a better understanding of the complications associated with vascular access.

Table 1. Vascular access-related morbidity rate.

AV-INF	0.36
AV-non INF	1.82
CAT-INF	0.91
CAT-non INF	0.30

Admissions /1,000 HD sessions. AV-inf: arteriovenous graft or fistula infections; AV-non inf: arteriovenous graft or fistula non infection; CAT-inf: catheter related infections; CAT-non inf: catheter related non infection.

FR-PO547

Hospital Admissions for Bloodstream Infections Acquired during Outpatient Hemodialysis through a Central Venous Catheter (HD-CVC): Patient Population and Selected Outcomes

Jared L. Crandon,[1] Sharada Weir,[2] Mary P. Michaud,[1] Peter Sullivan,[1] Liz Hurlburt.[1] *[1]CorMedix Inc., Berkley Heights, NJ; [2]Health economist in private practice, Austin, TX.*

Background: HD-CVC patients are at an increased risk for catheter related bloodstream infections. The purpose of this study was to characterize the demographics, clinical baseline characteristics, and selected outcomes for HD-CVC patients who were hospitalized for treatment of bloodstream infections (BSIs).

Methods: All admissions of adult HD-CVC patients in the Premier Healthcare Database with discharge dates during 2020-2022 were retrospectively evaluated. The first hospital admission in which each patient presented with a BSI was included in the final analysis. BSIs were identified by ICD-10 codes and blood culture collection dates. A BSI was deemed present-on-admission (BSI-POA) if the blood culture date was <3 calendar days after admission. Descriptive analyses included baseline demographics, clinical characteristics, and outcomes. Hospital costs were estimated based on patient level data reported from each hospital.

Results: Admissions were identified for 91,448 unique patients; 25% (N=22,902) presented with a BSI. Patients were 58.2% white, 27.1% black, and 56.6% male. Most (59.3%) were aged ≥60 years and more than three-quarters resided in census tracts above the median ranking on CDC's Social Vulnerability Index, with 47.0% in the most vulnerable quartile of neighborhoods nationwide. Patients had many comorbidities at baseline with 87.8% having ≥3 Charlson comorbid conditions and 42.6% with ≥6. Median length-of-stay was 16 days, with 53.8% of admissions including time in the ICU (median: 8d). 26.8% of patients were readmitted within 90 days, 46.3% were BSI-related. All-cause, in-hospital mortality was 10.3%, with a further 4.7% expiring within 90d of discharge. The median total admission cost was $157K. Of which, a median cost of $65K was allocated to ICU care.

Conclusions: We described the characteristics of HD-CVC patients who presented to hospitals with BSIs. These data highlight the complexity and social vulnerability of these patients and the extensive healthcare utilization resultant from these infections. Moreover, care of these patients was associated with considerable healthcare costs and 1-in-10 patients died whilst inpatient. Future studies should characterize risk factors and evaluate potential prevention strategies for this high-risk population.

FR-PO548

Efficacy of Using Chlorhexidine Impregnated Foam Dressing (BIOPATCH) among Patients on Haemodialysis with Tunneled Haemodialysis Catheters

Nasreen Samad, Dharshi Hewa Wellalage, Jerilyn Lalu, Santhi Selvakumar. *Barts Health NHS Trust, London, United Kingdom.*

Background: Tunneled haemodialysis catheter related blood stream infections (CRBSI) lead to increased morbidity and mortality, including hospital admissions and antibiotic resistance with increased health care costs. Therefore, proper tunneled haemodialysis line exit site care and dressings are a vital step in preventing the above mentioned consequences. With this background an audit was performed to confirm the efficacy of (BIOPATCH) in reducing the exit site infections in haemodialysis patients in single dialysis unit.

Methods: All patients with Tunneled haemodialysis catheters in Queens Hospital Haemodialysis unit, Romford, UK were included in the audit. Patients were verbally consented for dressing change and exit sites swabs. Audit and re-audit cycles spanned over a total period of 15 months. All exit site routine swab positivity data was collected over this period. From January 1, 2023 to May 30, 2023 sterile transparent dressing without BIOPATCH was used. From May 31, 2023 to October 30, 2023 all the patients were offered chlorhexidine impregnated foam dressing (BIOPATCH) as a standard practice. The first audit cycle was completed and haemodialysis staff was informed about the findings of the audit with emphasis on adherence to strict aseptic protocols and completion of IPC chart (Infection Prevention and Control Chart) for each haemodialysis session. Thereafter a re-audit was carried out from November 1, 2023 to March 30, 2024.

Results: Total number of patients were 52. 13 patients had positive exit site swabs from January to May 2023 where only the transparent dressing was used without BIOPATCH. From May to October 2023 when BIOPATCH was initially used, 20 exit site positive swabs were found. During reaudit from November 1, 2023 to March 30, 2024, BIOPATCH use with increased compliance with aseptic protocols resulted in reduction of positive swabs to 9.

Conclusions: BIOPATCH dressing with adherence to aseptic practice led to the lowest number of patients (9) with tunneled line exit site positive swabs. However, using BIOPATCH without meticulous adherence to infection control protocol did not improve exit site swab positivity rate. The use of chlorhexidine impregnated foam dressing (BIOPATCH) along with the strict aseptic protocols is superior in reducing the exit site swab positivity rates.

FR-PO549

Maintaining Zero Central Line-Associated Bloodstream Infections in Dialysis Catheters

Marlyn A. Batan, Bernadette Garcia, John Varilla, Maria Monique M. Granados. LHH Dialysis. *Lenox Hill Hospital, New York, NY.*

Background: The Dialysis team at Lenox Hill Hospital gives high priority to preventing central line-associated bloodstream infections (CLABSI) related to hemodialysis (HD) central line catheters. In 2014, two incidences of HD CLABSIs were reported. The Dialysis team, Quality Management Department, and Infection Control held root cause analysis meetings for these cases. As a result, there was a re-evaluation of dressing kits and in-services for nursing teams were conducted on dressing changes and catheter monitoring. This resulted in a decrease of HD CLABSIs to 1 in 2015 & 2016, 0 in 2017 and 1 in 2018. The team was determined to reach 0 HD CLABSIs. In 2019, 2 new processes were added to achieve 0. Since then, there have been 0 HD CLABSIs

Methods: 2 monitoring processes were created and added to the dialysis workflow. First, a daily central venous catheter (CVC) monitoring tool was created to assess and document the state a HD catheter is in. Monitoring is done daily and performed for all HD patients in the hospital regardless of the frequency of dialysis sessions. The tool includes fields for demographics, CVC type, location, date of insertion, if the dressing is intact, if the patient is allergic to chlorhexidine, and the plan of care for the site. Next, an access tracking tool to trace any access issues, the licensed provider who inserted the line or is taking care of the patient, the plan of care for the access, and communication with any long-term care facility, was created.

Results: After adding the two monitoring workflows there have been 0 HD CLABSIs to date, despite having an increased amount of dialysis treatments done through a CVC. In 2019, 1367 out of 2892 total dialysis sessions were of patients with a HD CVC (47.27%). In 2023, 1405 out of 2415 had a HD CVC (58.18%). This suggests that despite the increase in volume of treatments with dialysis catheters, the monitoring workflows may have contributed to the prevention of HD CLABSIs.

Conclusions: These processes may have contributed to maintaining 0 HD CLABSIs. Additional opportunities found including a deeper dive into catheter maintenance and line caregiver knowledge for home dialysis or long-term care bound patients. Recent findings show that patients discharged with home dialysis were frequently readmitted with infected dialysis catheters. These findings call for additional data analysis.

FR-PO550

Hemodialysis Catheter and Infections from a National US Cohort, 2018-2023

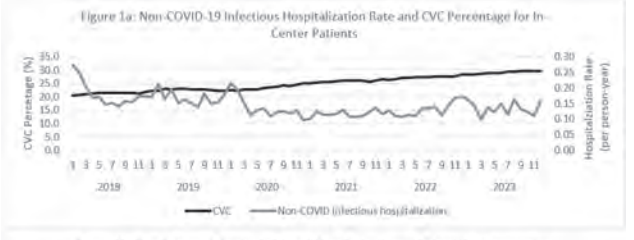
Monica Shieu,[1] Nien Chen Li,[1] Harold Manley,[1] Antonia Harford,[1] Caroline M. Hsu,[2] Daniel E. Weiner,[2] Dana Miskulin,[2] Doug Johnson,[1] Eduardo K. Lacson.[1,2] *[1]Dialysis Clinic Inc, Nashville, TN; [2]Tufts Medical Center, Boston, MA.*

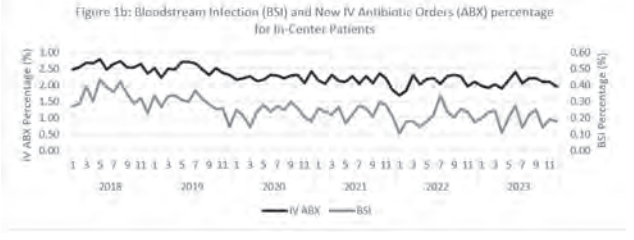
Background: Multiple factors have impacted arteriovenous hemodialysis (HD) vascular access creation and central venous catheter (CVC) usage throughout the pandemic. We describe longitudinal trends in CVC use, bloodstream infections (BSI), new IV antibiotics orders (ABX), and non-COVID-19 infection-related hospitalizations (INFH) from a national US dialysis provider.

Methods: Among adult maintenance HD patients treated at Dialysis Clinic, Inc. from 2018-2023, monthly percentages of patients with CVC, BSI, and ABX were calculated. INFH was defined by length of stay of at least 2 nights. For patients with a CVC, the mean time to first fistula/graft surgery was ascertained.

Results: Among 36,849 maintenance HD patients, there was a 44.4% increase in CVC use during the study period. There was a 40.7% decrease in INFH (Fig. 1a), 33.3% decrease in BSI, and 21.4% decrease in ABX (Fig. 1b). Among incident HD patients, CVC was the sole access present at initiation in 59% of patients in 2018, 62% in 2019, 67% in 2020, 69% in 2021, 72% in 2022, and 70% in 2023. Among initial access surgeries within the first year of a CVC, mean time to fistula/graft surgery was 97 days in 2018, 106 days in 2019, 107 days in 2020, 117 days in 2021, 121 days in 2022, and 124 days in 2023.

Conclusions: From 2018-2023, CVC use increased with more patients initiating HD with CVC alone and waiting longer for fistula/graft surgeries. Despite this, percentages of infections and ABX declined, suggesting maintenance of care process integrity within dialysis facilities, particularly infection precautions and prevention procedures during the pandemic. To minimize morbidity from CVC-related infections, the nephrology community should maintain these infection control practices and additionally work with regulators, payers, surgeons, and hospitals to reduce CVC use to pre-pandemic levels.





FR-PO551

mTORC1-Mediated Megalin Phosphorylation Acts as a Switch between Endocytosis and Cell Proliferation

Eileen Dahlke, Madlen Kunke, Hannah Knöfler, Yuanhao Shen, Yaman Anan, Franziska Theilig. *CAU Kiel Institute of Anatomy, Kiel, Germany*.

Background: The importance of proper renal proximal tubular (PT) function is displayed by its loss of function in Fanconi syndrome which can be induced by mTORC1 inhibition. Protein endocytosis is one of the main PT function and involves the scavanger receptor megalin (LRP2) to internalize a variety of proteins from the ultrafiltrate. mTORC1 induces PT endocytosis and we discovered a specific mTORC1 phosphorylation site on megalin S4577 which function we aimed to identify.

Methods: Transient transfection of megalin mini-construct 2 (MMR2) with mutations in S4577 (MMR S->A mimics permanent non-phosphorylated state, MMR2 S->D mimics permanent phosphorylated state) in MDCK2 or EBNA/HEK cells, followed by functional endocytosis assays, immunocytological stainings and super resolution STED microscopy, western blotting, surface expression analysis, and co-immunoprecipitations were performed.

Results: Megalin phosphorylation by mTORC1 in S4577 was confirmed. MMR2 S4577 phosphorylation showed no impact on MMR2 surface expression level, but demonstrated a reduced endocytosis rate for albumin. The subcellular distribution of mutants showed minor alterations in co-localization with clathrin vesicles and early endosomes and no difference in co-localization with Rab35-positive vesicles. Surprisingly, S4577 phosphorylation leads to stronger binding affinity of MMR2 to the endocytosis adaptor protein ARH. In culture conditions, MMR2 was occassionally observed to be colocalized with alpha-tubulin in mitotic spindles and S4577 phosphorylation reduced cell proliferation rate.

Conclusions: mTORC1 mediated phosphorylation of megalin C-terminus at S4577 lowers endocytosis rate to allow increased cell proliferation and may therefore be encountered as cellular switch between endocytotic function and cell proliferation.

FR-PO552

Gout Risk Variant ABCG2 Q141K Alters Renal Amino Acid Metabolism and Alpha-Ketoglutarate

Owen M. Woodward,[1,2] Yong Li,[2] Victoria L. Halperin Kuhns,[1] Ava M. Zapf,[1] Anna Kottgen.[2] *[1]University of Maryland School of Medicine, Baltimore, MD; [2]Albert-Ludwigs-Universitat Freiburg Medizinische Fakultat, Freiburg, Germany*.

Background: ABCG2 is an epithelial and proximal tubule efflux transporter. A common missense variant, Q141K, increases hyperuricemia and gout risk. GWAS studies identified associations of *ABCG2* SNPs and HbA1c levels, BMI, LDL, creatinine, and C-reactive protein, suggesting a metabolic role for ABCG2. The relationship between ABCG2, renal function, urate and metabolic disease remains unclear.

Methods: We conducted a metabolomic study on paired plasma and urine samples of 1033 carriers and 3879 non-carriers of *Q141K ABCG2* participating in the GCKD study. To dissect causal mechanisms for observed differences, *i.e. ABCG2* dysfunction versus hyperuricemia, similar paired metabolomics as well as whole-kidney RNA-seq data were generated from two hyperuricemia mouse models: the orthologous *Q140K Abcg2*, and an inducible uricase knockout, *Uox-iKO*.

Results: Enriched pathways based on altered metabolites identified in both human and mouse *ABCG2* variants were highly correlated (plasma r=0.83; $p=2.4x10^{-54}$, urine r=0.7; $p=8.47x10^{-32}$), supporting the use of the *Q140K Abcg2* model to study mechanisms in humans. In urine, the strongest enrichment of metabolites comparing *Q141K* carriers and non-carriers was observed for urate and related pathways, including organic nitrogen compounds. The most significant non-urate containing pathways were carboxylic acids (*FDR-p*=$3.02x10^{-9}$) and organic acid derivates (*FDR-p*=$2.87x10^{-6}$). To discern a role for ABCG2 in renal function, we focused on metabolites in these pathways that were only altered in urine of human *Q141K ABCG2* carriers, and found lower polyamine, urea cycle metabolites and alpha-ketoglutarate (AKG; all $p<0.05$). The *Q140K Abcg2* mice also displayed lower urinary polyamine metabolites and AKG. Kidney RNA-seq found significantly altered key genes of the polyamine and urea cycle in *Q140K Abcg2* mice: *Agr2* and *Cpt1* and AKG transporter *SLC13A3*. In contrast, *Uox iKO* mice showed higher urinary polyamide, urea cycle metabolites and AKG along with altered expression of the AKG receptor *Oxgr1* and the HCO3-/Cl- exchanger *Slc26a4* (pendrin). Physiological data suggested increased urinary AKG altered plasma HCO3- in the *Uox iKO* mice, consistent with OXGR1 activation of pendrin.

Conclusions: Combination of orthologous human and mouse metabolomic data suggests a role for ABCG2 in regulating proximal tubule amino acid metabolism and AKG.

FR-PO553

KCNJ16-Depleted Kidney Organoids Recapitulate Tubulopathy and Lipid Recovery with Statin Treatment

Anne Metje van Genderen,[1] Elena Sendino Garví,[1] Gijs J. van Slobbe,[1] Jeroen H. De Baaij,[2] Joost Hoenderop,[2] Manoe J. Janssen,[1] Rosalinde Masereeuw.[1] *[1]Universiteit Utrecht Utrechts Instituut voor Farmaceutische Wetenschappen, Utrecht, Netherlands; [2]Radboud Universitair Medisch Centrum, Nijmegen, Netherlands*.

Background: The *KCNJ16* gene has recently been associated with a kidney tubulopathy phenotype, including disturbed acid-base homeostasis, hypokalemia and altered renal salt transport as main disease features. *KCNJ16* encodes for Kir5.1, which together with Kir4.1 constitutes a potassium channel located in the basolateral membrane of the tubular kidney cells. Despite previous *in vitro* and rodent models provided with mechanistical links between Kir5.1 and the recently described disease phenotype, the pathophysiological mechanisms of the disease are still poorly understood. In this project, we aimed to generate a characterize a novel advanced kidney organoid model that better recapitulates the disease phenotype to further investigate the pathophysiological mechanisms underlying the disease.

Methods: For this we used CRISPR-Cas9 to generate heterozygous and a compound heterozygous *KCNJ16* mutant cell lines from healthy human induced pluripotent stem cells (iPSC). Both the healthy (*KCNJ16*^{WT}) and mutated (*KCNJ16*$^{+/-}$ and *KCNJ16*$^{-/-}$ iPSC lines were differentiated into kidney organoids using a 25-day differentiation protocol and maturation in an air-liquid interface environment.

Results: After successful depletion of Kir5.1, *KCNJ16*-depleted kidney organoids showed transcriptomic impairment of key electrolyte and water-balance transporters such as AQP1, NBC1, SNAT-3 and PEPCK. We also observed cysts formation ($p<0.01$) and staining with the bodipy probe and collagen-I revealed lipid droplet accumulation ($p<0.001$) and fibrosis ($p<0.01$). Following these results, we performed a large scale and a glutamine tracer flux metabolomics analysis and found that KCNJ16-/- depleted organoids display TCA cycle and lipid metabolism impairments when compared to *KCNJ16*^{WT} ($p<0.01$-0.0001), particularly at glutamine and citrate levels. By testing different drug compounds on the kidney organoids, we discovered that treatment with statins reversed the lipid droplet accumulation ($p<0.01$-0.0001) and collagen I deposition ($p<0.01$) in *KCNJ16*$^{-/-}$ kidney organoids.

Conclusions: In conclusion, mature kidney organoids represent a relevant *in vitro* model for investigating Kir5.1 function, providing novel molecular targets for this genetic tubulopathy and identifying statins as a potential therapeutic strategy.

FR-PO554

Additive Diuretic Action of SGLT2 Inhibitor and Loop Diuretic Combination Avoids Body Fluid Loss by Promoting Vasopressin-Independent Compensatory Fluid Intake

Takahiro Masuda,[1] Masahide Yoshida,[1] Tatsushi Onaka,[1] Volker Vallon,[2] Daisuke Nagata.[1] *[1]Jichi Medical University, Shimotsuke, Japan; [2]University of California San Diego, La Jolla, CA.*

Background: We have shown that SGLT2 inhibitors maintain euvolemic fluid status by stimulating antidiuretic hormone (vasopressin: AVP) secretion and fluid intake in response to diuresis, whereas loop diuretics reduce AVP secretion and cause net body fluid loss (Physiol Rep 2020, AJP Renal 2022). In addition, we recently reported that the combination of SGLT2 inhibitor and loop diuretic maintains body fluid balance in chronic kidney disease patients (Front Med 2023), but the mechanism remains unclear.

Methods: Non-diabetic Sprague-Dawley rats were divided into 4 groups: 1) Vehicle (Veh), 2) SGLT2 inhibitor ipragliflozin 5 mg/kg (Ipra), 3) loop diuretic furosemide 50 mg/kg (Furo), and 4) ipragliflozin and furosemide combination (Ipra+Furo) with free access to fluid and normal rodent chow. Drugs were suspended in 0.5% methylcellulose and given by gavage, and rats were kept in metabolic cages for 2 days. * $p<0.05$ vs. Veh; $^{\#}$ vs. Ipra; $^{+}$ vs. Furo.

Results: Urine volume on day 2 increased equally in Ipra and Furo and was highest in Ipra+Furo (Veh 8±9, Ipra 120±21*, Furo 102±26*, Ipra+Furo 287±112* %). The change in fluid intake was highest in Ipra+Furo, with a smaller increase in Furo (-4±5, 21±5, 11±8, 50±6^{+} %). Urinary AVP (0.24±0.04, 0.38±0.06, 0.10±0.03$^{\#}$, 0.06±0.01$^{\#}$ ng/day/100g bw) and solute-free water reabsorption (13.3±1.5, 23.5±1.6, 11.1±1.4$^{\#}$, 16.6±1.2$^{\#}$ mL/day/100g bw) were elevated by Ipra but decreased by Furo and Ipra+Furo combination vs. Ipra. The changes in fluid balance (fluid intake-urine volume) (1±8, -8±5, -32±9*, 6±6^{+} %) and plasma volume calculated by the Strauss formula (16±6, 18±4, -8±4$^{\#}$, 14±5^{+} %) were negative in Furo but positive in Ipra+Furo. The changes in serum Na^{+} (-1.3±0.5, 0.1±0.5, -1.1±0.5, -2.0±0.7$^{\#}$ %) and Cl^{-} (0.8±0.7, 1.5±0.6, -3.3±1.2*$^{\#}$, -3.1±0.9*$^{\#}$ %) concentrations were significantly lower in Ipra+Furo vs. Ipra. Serum osmolality was similar among the 4 groups.

Conclusions: Combination of SGLT2 inhibitor and loop diuretic avoided body fluid loss by promoting compensatory fluid intake despite suppressed AVP tone and absence of serum Na^{+} and osmolality increase. These results may indicate a novel non-osmoregulatory thirst mechanism induced by the combination of SGLT2 inhibitors and loop diuretics.

FR-PO555

Modeling Kidney Proximal Tubular Crystallopathy In Vitro

Rosalinde Masereeuw, Mara Vonk, Chaja Klein, Manoe J. Janssen, Devon Barnes. *Universiteit Utrecht, Utrecht, Netherlands.*

Background: Kidney crystallopathy can be characterized by the presence of crystals within renal tubules, leading to obstruction, cytotoxic effects, and inflammatory responses. Here, a novel proximal tubule cell model was developed to investigate the mechanisms underlying toxicant-induced crystal formation and renal inflammation.

Methods: Conditionally immortalized proximal tubule epithelial cells (ciPTECs) were used to investigate the role of uric acid, a known crystal-forming metabolite, and the influence of pH on crystal formation. A series of *in vitro* assays were used to assess cytotoxicity, oxidative stress, mitochondrial function, inflammation as well as the expression of NLRP3 inflammasome related markers on the protein level.

Results: Exposing ciPTECs to uric acid decreased cell viability, which was more pronounced under reduced pH conditions with a significant reduction starting at 200 μg/ml at pH 5.5 *vs* 800 μg/ml at pH 7.4. Various shapes of uric acid crystals were formed (Figure 1). Reactive oxygen species production was increased at 200 μg/ml at all pH levels tested (*viz.* 5.5, 6.0 and 7.4). Furthermore, uric acid induced the expression of the inflammasome-related markers caspase-1, ASC, TNFα at the mRNA level, and IL-1β at the protein level. In line with cell viability, these effects were most pronounced with higher uric acid concentrations and at lower pH levels.

Conclusions: A novel model was established simulating kidney crystallopathy and its impact on inflammasome components, caspase activity, cytokine production, and the NF-κβ pathway. This model will be used to study crystallopathy in more detail to provide an adverse outcome pathway for crystal-forming nephrotoxicants. *This project received funding from the European Union's Horizon 2020 research and innovation programme (GA No 963845, ONTOX).*

Funding: Government Support - Non-U.S.

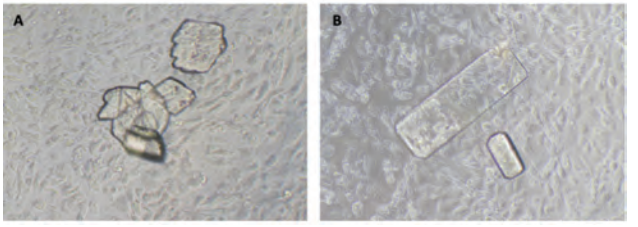

Figure 1. Uric acid crystals formed after 72h incubation with A) 800 μg/ml at pH 5.5 and B) 600 μg/ml at pH 5. 10x magnification.

FR-PO556

Differentiated Cell Types in the Kidney's Thick Ascending Limb: Functional Insights on TAL α and TAL β

Jessica P. Bahena-López,[1] Jonathan W. Nelson,[2] Xiao-Tong Su,[1] Hasan Demirci,[3] Joshua N. Curry,[1] Markus Bleich,[4] Sebastian Bachmann,[3] David H. Ellison.[1] *[1]Oregon Health & Science University, Portland, OR; [2]University of Southern California, Los Angeles, CA; [3]Charite Universitatsmedizin Berlin, Berlin, Germany; [4]Christian-Albrechts-Universitat zu Kiel Islamwissenschaft, Kiel, Germany.*

Background: The Thick Ascending Limb (TAL) plays a key role in reabsorbing NaCl and Ca^{++} and Mg^{++}, driven ultimately by NKCC2. Spanning from the outer medulla to the cortex, the TAL has traditionally been viewed as a single functional cell type, but recent transcriptomic findings indicate the existence of two TAL cell clusters, with high Claudin 10 and Claudin 16 expression (PMID 28028216). Beyond mosaic expression of claudins, however, the specifc functions of these two cell types are unknown. Here, to better understand the heterogeneity within the TAL population, we enriched for TAL nuclei and performed single-nucleus transcriptomics.

Methods: Kidneys from male NKCC2-Cre-INTACT (Isolation of Nuclei TAgged in specific Cell Types, which fluorescently labels nuclei) mice were harvested for single-nucleus RNA-seq to create an enriched TAL dataset. Data were compared with re-analyzed datasets from mouse (PMID 31689386), rat (PMID 37023747), and human (PMID 37468583). IHC of kidney from the same species was performed.

Results: Enriched TAL sn-RNA sequencing identified two cell clusters: TAL α and TAL β. Differential Gene Expression analysis showed distinct gene profiles. TAL α cells express *Cldn10* and factors regulating sodium transport, including *Wnk4*, *Stk39*, and *Avpr2*, and display arachidonic acid signaling genes like *Ptger3*. TAL β express *Cldn16* and genes related to calcium homeostasis, such a *Casr*, *Pth1r* and *Vdr*, as well as higher levels of *Kcnj10* and *Wnk1*. TAL clustering also shows segregation following a gradient-like pattern across kidney zones, revealing TAL subtypes or states unique to each zone. This transcriptional heterogeneity was similar among mouse, rat, and human. Immunofluorescence confirmed two cell types. In the cortex and OSOM, Kir4.1 was coexpressed with CaSR and Claudin-16 (TAL β), while apical ROMK was observed in TAL α cells, expressing Claudin-10. In the ISOM, Kir4.1 and ROMK maintained their exclusive patterns, with Claudin-10 present in both cell types.

Conclusions: Combined morphological and transcriptomic analyses identified two distinct TAL cell types, each linked to specific transport pathways, presenting a novel model of interconnected ion transport in the TAL.

FR-PO557

Heterogeneity in the Renal Thick Ascending Limb Cell Composition: Insights from Ultrastructure, Immunohistochemistry, and Single-Cell Transcriptomics

Hasan Demirci,[1] Jessica P. Bahena-López,[2] Jonathan W. Nelson,[3] Xiao-Tong Su,[2] David H. Ellison,[2] Sebastian Bachmann.[1] *[1]Charité-Universitätsmedizin Berlin, Department of Anatomy, Berlin, Germany; [2]Oregon Health & Science University, School of Medicine, Division of Hypertension and Nephrology, Portland, OR; [3]University of Southern California, Department of Medicine, Los Angeles, CA.*

Background: The thick ascending limb (TAL) provides the driving force for the renal concentrating mechanism through its capacity to dilute the urine via the "single effect" of reabsorbing NaCl. It also transports divalent cations like $Ca2^+$ and $Mg2^+$. A single, terminally differentiated cell type with zone-related specificities has so far been defined to line TAL, but recent transcriptomic findings report distinct TAL cell clusters with mosaic expression pattern, illustrated by differential expression of ion transporters and junctional components. Here we couple structure and immunohistochemistry with single-cell (sc) RNA sequencing technology to define unique cell features across kidney zones and local mosaicism.

Methods: Rat, mouse, and human kidney samples were used to examine the morphology of medullary (mTAL) and cortical (cTAL) TAL epithelia. Immunohistochemistry was used to assess the expression of ROMK, NKCC2, pNKCC2, Kir4.1, CaSR, Cldn10 and Cldn16 in TAL. Additionally, scRNA-seq datasets (PMID: 31689386) from mouse kidney were leveraged to define transcriptomic signatures of TAL.

Results: NKCC2 was expressed throughout TAL and macula densa. Mosaic expression of ROMK in TAL showed 46 ± 7% ROMK-negative cells in mTAL, decreasing with cTAL. ROMK-negative cells inversely displayed p-NKCC2 signal chiefly in mTAL, suggesting mosaic NaCl transport activity. Cldn10 and ROMK were colocalized in mTAL and cTAL. CaSR and Kir4.1 were mutually exclusive to ROMK, and a subset of CaSR/Kir4.1 cells expressed Cldn 16 in outer stripe and cTAL cells; here, Cldn 16 dominated over Cldn 10 in mosaic junctional belt conformation. Macula densa expressed exclusively Cldn 10. ScRNA-seq analysis defined Cldn 10 and Cldn 16 as distinct cell clusters, with Cldn 10 coexpressing Stk39, Ptger3, and Cryab, and Cldn16 cells coexpressing Kir4.1, CaSR, Wnk1, and Pth1r.

Conclusions: TAL cells exhibit marked heterogeneity in transporter and tight junction protein expression, correlated with distinct cell clusters from scRNA seq. Modeling TAL function with two distinct cell types, one providing transepithelial voltage generation, the other paracellular divalent cation transport suggests separate functions within TAL cells serving renal concentrating ability and ion transport homeostasis.

FR-PO558

Lack of Role of NHE4 in Renal Ammonia Metabolism

Hyun-Wook Lee,[1] Autumn N. Harris,[1] Kelly A. Hyndman,[2] I. D. Weiner.[1,3] *[1]University of Florida, Gainesville, FL; [2]The University of Alabama at Birmingham, Birmingham, AL; [3]Gainesville VAMC, Gainesville, FL.*

Background: Renal ammonia absorption by the thick ascending limb of Henle's loop (TAL) is a critical step in renal ammonia handling and excretion. The Na^+/H^+ exchanger, isoform 4 (NHE4) has been proposed to have a critical role in TAL ammonia reabsorption by acting as a basolateral Na^+/NH_4^+ exchanger mediating basolateral NH_4^+ exit. This study's purpose was to determine whether NHE4 gene deletion alters renal ammonia metabolism.

Methods: We backcrossed homozygous NHE4 KO mice (Jax Labs, MMRRC stock #34266) with 129S6/SvEv mice (Taconic Biosciences, 129VE), which matches the ES cell used to generate NHE4 KO mice, to obtain heterozygous NHE4 KO mice. We then bred heterozygous dams and sires. All studies compared homozygous deletion ~4-month-old mice with wild-type (WT) littermates. Both male and female mice were studied.

Results: Under basal conditions, serum Na^+, K^+, and HCO_3^- did not differ between WT and KO mice. KO mice had a urine pH that was significantly more acidic than WT mice and also exhibited significantly increased urinary ammonia, titratable acid, and net acid excretion. Immunoblot analysis showed that NHE4 KO increased the expression of phosphoenolpyruvate carboxykinase (PEPCK), a critical ammonia-generating enzyme. It decreased the expression of glutamine synthetase (GS), a critical ammonia-recycling enzyme in cortical proximal tubule segments. After acid-loading for seven days, neither urine pH and ammonia excretion changes nor serum Na^+, K^+, and HCO_3^- differed significantly between WT and NHE4 KO mice. Thus, NHE4 deletion-induced increases in ammonia excretion involve increased PEPCK expression and decreased GS expression, and its deletion does not alter the response to acid-loading. Because of this lack of effect of NHE4 KO to inhibit ammonia metabolism, we examined its expression using KO mice as a negative control. Both immunoblot analysis and immunohistochemistry showed no detectable NHE4 expression. snRNA-seq analysis of WT mouse kidney showed no significant NHE4 expression in TAL1 or TAL2 cells or cortical TAL.

Conclusions: We conclude that: 1) NHE4 is neither expressed in the TAL nor does it contribute to renal ammonia metabolism; and (2) extrarenal roles of NHE4 may induce mild metabolic acidosis upon its deletion that leads to a compensatory stimulation of ammonia metabolism.

FR-PO559

A Novel State-of-the-Art Intravital Microscopy Technique to Track Magnesium in Living Kidneys

Pieter A. Leermakers,[1] Georgina Gyarmati,[2] Janos Peti-Peterdi,[2] Veronika Shchepetkina,[3] Daniela Buccella,[3] Joost Hoenderop,[1] Jeroen H. De Baaij.[1] Dept of Medical BioSciences. *[1]Radboud Universitair Medisch Centrum, Nijmegen, Netherlands; [2]University of Southern California, Los Angeles, CA; [3]New York University, New York, NY.*

Background: Magnesium is an essential mineral for human physiology. Therefore, the serum magnesium concentration is tightly controlled by the kidney. It is currently not possible to measure real-time renal magnesium reabsorption in living organisms. To study the regulation of magnesium reabsorption in the kidney, we aim to perform multi-photon microscopy using a novel ratio-metric magnesium-reporter (MagZet1).

Methods: Mice were anesthetized, received a cannula, and were surgically prepared for kidney imaging. Subsequently, the superficial kidney cortex was continuously imaged with multiphoton microscopy for ratio-metric emission of magnesium-bound and magnesium-free MagZet1, and Albumin-AF594 as a contrast agent. During imaging, injections of Albumin-AF594 and MagZet1 were followed by bolus injections of $MgSO_4$, CaGluconate, or saline.

Results: *in vitro*, MagZet1 ratio-metric emission can be used to discriminate <0.2mM changes in $[Mg^{2+}]$ in plasma filtrate. *In vivo*, i.v. injection of MagZet1 results in free renal filtration, and MagZet1 can be detected in plasma and tubular segments in the kidney of live animals. The maximal imaging depth of MagZet1 is less than 100 μm, so only superficial proximal and distal tubules can be imaged with this technique. Injection of $MgSO_4$ results in an increased MagZet1 fluorescence emission ratio in all visible tubular segments, while injection of saline or CaGluconate did not change the MagZet1 fluorescence emission ratio.

Conclusions: MagZet1 is a magnesium dye that is discriminative of small changes in $[Mg^{2+}]$ in physiological conditions. MagZet1 can be detected in live animals *in vivo* using multi-photon microscopy for at least two hours after injection. In future experiments, we aim to screen the effects of genetic models and candidate drugs on renal magnesium reabsorption.

Genomic Organization and Regulation of Gene Expression in the Distal Convoluted Tubule

Jeroen H. De Baaij, Eveline Kahlman, Lotte Tholen, Sara B. van Katwijk, Femke Latta, Joost Hoenderop. *Radboud Universitair Medisch Centrum, Nijmegen, Netherlands.*

Background: The distal convoluted tubule regulates blood pressure, K^+ balance and Mg^{2+} homeostasis. The complex regulation of DCT-specific ion channels, metabolic activity and hormonal signaling pathways depends on DNA accessibility, polymerase binding and transcription factor activity. Here, we aimed to determine DCT-specific transcriptional regulation by integration of RNA-seq, ATAC-seq, chromosome confirmation capture and histone-modification ChIP-seq datasets.

Methods: We generated a comprehensive atlas of transcriptional regulation in a mouse DCT cell line by generating and integrating chromatin accessibility (ATAC-seq), gene expression (RNA-seq) and histone mark ChIP-seq datasets (H3K4me3, H3K27ac). Moreover, we generated a chromosome conformation capture (Hi-C) map to unravel 3D genomic interactions.

Results: ATAC sequencing demonstrated 14,231 open chromatin regions in the mouse DCT cells. Fifty percent of these regions contained promoter elements and twenty percent active enhancer regions, characterized by H3K4me3 and H3K27ac respectively. GO-term analysis of these regulatory regions demonstrated enrichment of epithelial pathways, such as cilia development, cell junctions and cytoskeleton organization. Hi-C uncovered the basis of 3D genome characteristics in the DCT. As example of how our map of DCT genome organization can be used, we studied the importance of long-range chromatin interactions in transcriptional regulation mediated by transcription factor HNF1β. Our analysis revealed that promoter bound HNF1β primarily controls the expression of genes with general cell functions, such as mRNA processing and protein transport. In contrast, HNF1β binding to enhancer regions at large distance of the promoter was associated with expression of HNF1β-specific processes, such as kidney and urogenital development.

Conclusions: In conclusion, we describe the first comprehensive map of genome organization in a DCT cell line and demonstrate that the 3D architecture of the genome controls specificity of HNF1β-mediated gene transcription.

FR-PO561

Lipopolysaccharide-Responsive Beige-Like Anchor Protein Is Essential for Sodium and Water Homeostasis

Yu Hara, Fumiaki Ando, Hideki Yanagawa, Kanako Nagaoka, Tamami Fujiki, Hiroaki Kikuchi, Shintaro Mandai, Yutaro Mori, Takayasu Mori, Koichiro Susa, Eisei Sohara, Shinichi Uchida. *Tokyo Ika Shika Daigaku, Bunkyo-ku, Japan.*

Background: Lipopolysaccharide-responsive beige-like anchor protein (LRBA) is essential for aquaporin-2 (AQP2) phosphorylation, and its absence results in the polyuric phenotype in mice. Most of the biallelic pathogenic mutations in the *LRBA* gene cause instability of the protein, resulting in LRBA deficiency. LRBA deficiency is a rare disease characterized by immune dysregulation and chronic diarrhea; however, the polyuric phenotype of LRBA deficiency has not been reported.

Methods: We established an international observational registry including 38 patients with LRBA deficiency. The physiological role of LRBA in sodium homeostasis was examined using *Lrba*$^{-/-}$ mice.

Results: The urine specific gravity of LRBA deficiency patients (median, 1.008, n=17) was similar to *Lrba* $^{-/-}$ mice, and urine was dilute in spite of diarrhea-induced dehydration. Low urinary concentrating ability usually induces hypernatremia due to free-water diuresis. However, the serum sodium level of LRBA deficiency patients was low (median, 135 mEq/L, n=38). Therefore, we next investigated renal sodium homeostasis using *Lrba* knockout mice. Low-sodium diet (LSD) decreased serum sodium and chloride concentration in *Lrba* $^{-/-}$ mice (WT vs. *Lrba* $^{-/-}$: Na 146.5 vs. 143.6 mEq/L, Cl 110.1 vs. 105.9 mEq/L). Thiazide diuretics which are inhibitors of sodium-chloride cotransporter (NCC) did not increase FENa in *Lrba* $^{-/-}$ mice fed with LSD. Due to the impairment of NCC activity, blood pressure was low in *Lrba* $^{-/-}$ mice and unresponsive to thiazide treatment. WNK-SPAK-NCC signaling is a main trigger to promote sodium reabsorption from urine via NCC. LRBA was colocalized with SPAK at intercellular vesicles in the distal convoluted tubules. In *Lrba* $^{-/-}$ mice, the protein expression level of SPAK was decreased and that of WNK was compensatorily increased. LRBA directly bound to SPAK and inhibited its lysosomal degradation.

Conclusions: We demonstrated that LRBA is essential for the activation of both NCC and AQP2, thereby ensuring sodium and water homeostasis in renal tubules. LRBA deficiency causes a loss of sodium and water into the urine, as well as diarrhea, which may be a strong risk factor for prerenal kidney failure due to dehydration. Careful attention to the sodium and water balance in patients with LRBA deficiency is required to prevent severe dehydration.

Funding: Government Support - Non-U.S.

Heterotypic Site-Specific Interactions between WNK4, TSC22D2, and NRBP1 Promote Kinase Activity and Co-localization in WNK Bodies

German R. Magaña,[1,2] Hector Carbajal-Contreras,[1,2] Norma H. Vázquez,[1] Gerardo Gamba,[1,2] Maria Castañeda-Bueno.[1] Unidad de Fisiología Molecular. [1]*Universidad Nacional Autonoma de Mexico, Ciudad de Mexico, Mexico;* [2]*Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico.*

Background: The WNK4 kinase regulates the activity of the thiazide-sensitive Na:Cl cotransporter, NCC, through the activation of the kinases SPAK/OSR1. Disregulation of this pathway is associated with altered sodium and potassium homeostasis. Recently, we found that WNK kinases associate in vivo with the pseudokinase NRBP1 and with proteins of the TSC22D family. These proteins co-localize with the kinase WNK4, KS-WNK1, and SPAK in biomolecular condensates called "WNK-bodies" that are observed in distal convoluted tubule (DCT) cells. The SPAK-WNK interaction is well characterized and involves RFXV motifs present in WNK kinases and a Conserved C-Terminal (CCT) domain present in SPAK. So how is WNK4 interacting with NRBP1 and TSC22Ds? Long TSC22D proteins have a conserved RFXV motif, NRBP1 has a conserved CCT domain, and WNK kinases have two CCT domains in addition to the RFXV motifs. In this work, our objective was to study the effect of these proteins in the WNK4-SPAK pathway and to investigate their interaction mechanisms.

Methods: HEK293 cells were transiently transfected with NRBP1, TSC22D1.1,TSC22D2, WNK4 and SPAK. Western blots of cell lysates and immunoprecipitated proteins and immunofluorescent stainings were performed.

Results: We observed that mutations in the CCT domain of WNK4 dramatically decreased WNK4's activity, TSC22D2 binding, and colocalization of WNK4 with TSC22Ds in condensates. Interestingly, SPAK co-expression allowed for TSC22D2 recruitment into condensates formed with the WNK4-CCT mutant. The loss of both, the CCT domains and the RFXV motif in WNK4 produced an inactive WNK4 that was not activated by NRBP1/TSC22D2, and that was not able to co-localize in TSC22D condensates in the presence of SPAK.

Conclusions: In conclusion, our data show that TSC22D1.1, TSC22D2, and NRBP1 are novel components of WNK-bodies in vivo in the DCT. NRBP1 and long TSC22D isoforms positively modulate WNK activity. Heterotypic interactions established by the CCT domains and the RFXV motif of WNK kinases permit co-localization of WNKs with TSC22D proteins and NRBP1 in condensates and promote activation of the kinase. Redundancy in interactions between these proteins can preserve the activity of the pathway when one interacting motif or domain is affected.

Funding: Government Support - Non-U.S.

FR-PO563

CRISPR/Cas9 Screening Identifies Key Transcription Factors Regulating Aqp2 Gene Transcription

Lihe Chen, Adrian R. Murillo-de-Ozores, Euijung Park, Shuo-Ming Ou, Mark A. Knepper. *National Institutes of Health, Bethesda, MD.*

Background: Aqp2, responsible for water reabsorption in kidney collecting duct cells, plays a crucial role in water balance. Prior translational studies demonstrated that dysregulation of *Aqp2* transcription plays a central role in a variety of water balance disorders, yet the underlying regulation of *Aqp2* transcription remains unclear.

Methods: We engineered an mpkCCD cell line to express GFP under the control of the *Aqp2* promoter and also stably express Cas9 and designed a lentiviral sgRNA library targeting over 1500 transcription factors (TFs) in the mouse genome. We then conducted CRISPR/Cas9 screens to identify TFs involved in regulation of *Aqp2* transcription.

Results: We demonstrated that the GFP provided a quantitative readout of Aqp2 and was sensitive to the stimulation of dDAVP and consequently could be used for the TF screen based on flow sorting. Two independent screens using the sgRNA TF library were carried out and the cells were sorted based on the GFP expression levels. The enrichment of sgRNA sequences was analyzed by *MAGeCK*. We hypothesize that sgRNAs targeting positive regulators of *Aqp2* would be enriched in GFP^{negative}/GFP^{low} relative to GFP^{high}, while those sgRNAs targeting negative regulators would show enrichment in GFP^{high} relative to GFP^{negative}/GFP^{low}. The screens identify several known positive regulators for *Aqp2* including *Gata3*, *Nfat5*, *Hnf1b*, *Grhl2*, *Nr3c1*, and *Pax8*. In addition, the analyses identify some novel positive regulators, among these are transcription factors that form DNA-binding heterodimers, transcription factors that are associated with histone modifications and chromatin remodelers, and several zinc finger TFs. For each of these candidates, cell lines with loss-of-function mutations were generated. Among the cell lines lacking the positive regulators, *Gata3*KO, *Nfat5*KO, *Hnf1b*KO, and *Nr3c1*KO cell lines showed no increase in the abundance of Aqp2 protein with dDAVP in contrast to control cell lines that showed large increases. Subsequent RNA-seq confirmed modulation of *Aqp2* transcripts upon knockout of the candidate transcription factors. Further ATAC-seq analyses identified critical DNA elements involved in *Aqp2* transcription.

Conclusions: CRISPR/Cas9 identifies both positive and negative regulators for *Aqp2* transcription, significantly expanding our understanding of *Aqp2* gene regulation.

FR-PO564

Kidney Tubuloid Model to Study Aquaporin 2-Mediated Water Transport in the Collecting Duct

Joost Hoenderop,[1] Emre Dilmen,[1] Charlotte Olde Hanhof,[1] Femke Latta,[1] Marianne C. Verhaar,[2] Idil Orhon,[1] Jeroen H. De Baaij,[1] Jitske Jansen.[3] [1]*Radboud Universitair Medisch Centrum, Nijmegen, Netherlands;* [2]*University Medical Center Utrecht, Utrecht, Netherlands;* [3]*Universitatsklinikum Aachen, Aachen, Germany.*

Background: The last segment of the kidney tubules is the collecting duct (CD), where finetuning of sodium and water reabsorption occurs. A dysfunction of this process can lead to nephrogenic diabetes insipidus (NDI) that causes the inability to concentrate urine which can lead to severe dehydration. NDI is caused by dysfunction of the water channel aquaporin 2 (AQP2) or the vasopressin 2 receptor (V2R) in the CD. Despite promising results of pre-clinical experiments, clinical trials often fail due to ineffectiveness or side-effects. Tubuloids are kidney organoid models that are derived from adult stem cells with the promise to study kidney (patho) physiology with increased translational value compared to conventional in vitro research models. By utilizing these tubuloid models, our lab previously demonstrated functional CD-specific sodium regulation. In this study, we show that tubuloids are capable of physiological CD-specific water transport regulation by AQP2 and V2R.

Methods: Tubuloids derived from human kidney tissue were grown were exposed to differentiation medium and differential expression was studies by single cell RNA-seq. The differentially expressed genes were studied by gene ontology analysis. The CD marker and water transporter AQP2 expression and localization was characterized by western blot and immunocytochemistry. Functional water transport assay was performed by measuring swelling over time.

Results: Tubuloids can be differentiated towards the distal tubules, including CD as shown by single cell sequencing. Further experiments revealed that the endogenously expressed AQP2 can be regulated by forskolin and desmopressin shown by significantly increased expression of AQP2 protein. In addition, the translocation towards the apical membrane of AQP2 where it increases water permeability was observed. Finally, we performed 3D swelling assays which confirmed that CD tubuloids are indeed capable of increased water transport and thereby respond to stimuli by swelling.

Conclusions: Human kidney tubuloids endogenously express relevant markers for CD-specific water transport, and AQP2 signaling regulated by physiological stimuli which is measurable in 3D functional assays. These results further confirm that kidney tubuloid models hold great promise to study kidney (patho) physiology, including NDI.

FR-PO565

Single-Cell CRISPR Screening Is a Powerful Tool for Gene Regulatory Network Studies in Kidney Collecting Ducts

Shuang Cao,[1,2] Karen I. López-Cayuqueo,[1] Kai M. Schmidt-Ott.[1,2]
[1]Medizinische Hochschule Hannover, Hannover, Germany; [2]Charite Universitatsmedizin Berlin, Berlin, Germany.

Background: The renal collecting duct plays a crucial role in maintaining the body's fluid and electrolyte balance, which is essential for overall physiological homeostasis. However, the molecular mechanisms governing the functions of the medullary collecting duct remain insufficiently understood. Recent advancements in single-cell genomics and CRISPR-based genetic tools have opened new avenues for dissecting the complex regulatory networks. By identifying and characterizing the molecular regulators of the renal collecting ducts, we can gain deeper insights into their physiological mechanisms and potentially uncover novel understandings of collecting duct disorders.

Methods: 1. SCENIC analysis: We used established snRNA-seq data from mouse kidneys and applied SCENIC methods to construct cell type-specific regulatory networks, and identified regulons based on gene co-expression and binding motifs. 2. Identification of transcription factors: From the constructed networks, we identified 24 specific transcription factors associated with collecting duct principal cells that exhibited significant gene regulatory network activities. 3. CRISPR-based single cell screen: To investigate the biological functions of these 24 TFs, we performed a CRISPR-based single cell screen experiment in an in vitro mIMCD3 cell model, perturbing TF expression and assessing the resulting transcriptomic phenotypes to understand their impact on gene expression profiles.

Results: The single-cell CRISPR screen effectively reproduced the transcriptional regulatory influence of the established transcription factor Grhl2 on downstream target genes, including Cldn4. The perturbation of the transcriptome profile of this transcription factor, which served as a central quality control parameter for the entire screen experiment, demonstrated the reliability of the study conducted. Among 24 candidates, we identified the transcription factor Ilf2 as a novel potential functional regulator of medullary collecting duct cell homeostasis.

Conclusions: Our study highlights the potential of CRISPR single cell screening as a powerful tool for uncovering the functions of novel genes in kidney cells. This approach improves our understanding of the molecular mechanisms involved in collecting duct cell physiology and provides a promising framework for future kidney disease research in nephrology.

FR-PO566

Artificial Intelligence (AI)-Based Prospective Repurposing Studies for the Identification of New Promising Vasopressin V2 Receptor Ligands

Ines Angelini,[1] Daniela Trisciuzzi,[2] Mariangela Centrone,[1] Annarita Di Mise,[1] Marianna Ranieri,[1] Giovanna Valenti,[1] Cosimo D. Altomare,[2] Susanna Cotecchia,[1] Orazio Nicolotti,[2] Grazia Tamma.[1] *[1]Department of Biosciences, Biotechnologies and Environment, University of Bari "Aldo Moro", Bari, Italy; [2]Department of Pharmacy - Pharmaceutical Science, University of Bari Aldo Moro, Bari, Italy.*

Background: The vasopressin V2 receptor (V2R) controls renal water balance. As a G protein-coupled receptor (GPCR), the V2R transduces the vasopressin signals activating the cAMP/PKA pathway. Besides water reabsorption, the activation of V2R is involved in abnormal cell proliferation, cancer, and cyst enlargement in polycystic kidney disease. In this perspective, we performed an inverse screening of a large collection of known drugs to identify novel V2R ligands that might modulate different receptor-mediated effects.

Methods: The inverse screening campaign was run by using PLATO, our homemade target fishing platform. Structure-based studies were also carried out. Renal collecting duct MCD4 cells, stably expressing human V2R and aquaporin-2 (AQP2), were used as an experimental model to test the effects of drugs. Fluorescence Resonance Energy Transfer (FRET), and calcein fluorescence quenching (CFQ) were applied to evaluate changes in intracellular cAMP and DDAVP-induced water flux.

Results: Our prospective repurposing studies identified five promising drugs as potential V2R ligands (perphenazine, cloxacillin, clopidogrel, cabergoline, and F2544). FRET studies were conducted to test whether these compounds affect the DDAVP-induced cAMP responses. Interestingly, only one of them (F2544) at 1nM concentration significantly reduced the DDAVP-dependent cAMP production. Functional CFQ studies revealed that this modulator reduced the DDAVP-induced water reabsorption, with effects comparable to tolvaptan, a well-known V2R antagonist. In this respect, an *in-depth* computational investigation showed a nice overlap of the molecular interaction fields generated from the binding sites of V2R and F2544. Finally, molecular docking simulations returned a promising posing and scoring of F2544 in the V2R binding site.

Conclusions: The present findings identify for the first time new V2R ligands by applying an AI-based approach. Moreover, by combining *in-depth* computational investigations and functional studies F2544 was prioritized for being repurposed for treating diseases associated with abnormal V2R signaling.

FR-PO567

CRISPR/Cas9 Screening for Protein Kinases That Regulate Aquaporin-2 Gene Transcription in Collecting Ducts

Euijung Park, Lihe Chen, Mark A. Knepper. *National Heart Lung and Blood Institute, Bethesda, MD.*

Background: Water transport in the collecting duct is controlled in part through regulation of transcription of the gene that codes for aquaporin-2 (AQP2). Animal models of water balance disorders have revealed defective control of AQP2 transcription in both polyuric and water retention disorders. Here, we have used CRISPR screening of the entire kinome in a mouse cortical collecting duct cell line (mpkCCD) to identify protein kinases that regulate AQP2 gene transcription.

Methods: A CRISPR knockout pooled library was utilized, targeting 713 protein kinases with 4 guides (gRNAs) for each gene. These gRNAs were simultaneously transduced into GFP-reporting mpkCCD cells, allowing GFP as a reporter for AQP2 transcription. In the presence of vasopressin analog dDAVP, the gRNA-transduced cells were sorted into four groups (GFP-negative, low, mid, and high) based on GFP intensity. RNA sequencing was then performed to identify the targeted kinases.

Results: Among 713 targets, 29 protein kinases showed significant bias in GFP abundance including 16 positive regulators of AQP2 gene transcription and 13 negative regulators. One positive regulator was PKA catalytic α (Prkaca) that had been previously identified as a positive regulator. Conversely, PKA regulatory subunit (Prkar1a), is known to inhibit PKA catalytic subunit, was identified as a negative regulator. These findings provide positive controls for the methodology. Novel positive regulators include AKT1, PIM3 and the polarity kinase MARK2. Negative regulators include both subunits of the TGF-β receptor (previously implicated in the vasopressin escape phenomenon) and several components of the stress-activated MAP kinase pathway (Map3k1, Map2k4, and Map2k7).

Conclusions: Whole kinome CRISPR screening identified 29 protein kinases as putative regulators of AQP2 gene transcription. Pending one-by-one systematic validation of roles for each kinase as determinants of AQP2 protein abundance, the data will provide a basis for understanding mechanisms involved in defective transcription of the AQP2 gene in water balance disorders and a valuable information resource guiding future studies of regulation in collecting duct principal cells.

FR-PO568

GPR39 Activation Alters Cytoskeleton Integrity and AQP2 Trafficking in Collecting Duct Cells

Mackenzie Kui,[1] Helle A. Praetorius,[2] Jennifer L. Pluznick.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]Aarhus Universitet, Aarhus, Denmark.*

Background: Despite being highly expressed in the kidney, the G-protein coupled receptor, GPR39, has no known role in renal physiology.

Methods: A Gpr39 RNAScope probe was used to localize renal Gpr39. Activation by a GPR39-specific agonist, cpd1324, was used in murine principal kidney cortical collecting duct cells (mpkCCDs); we also utilized GPR39 knockout (KO) cells (made via CRISPR). mpkCCD respond to vasopressin (dDAVP) by expressing and trafficking AQP2 to the apical membrane. Endpoint assays included immunofluorescence (IF), transepithelial resistance (TER), Western Blots (WB) and cAMP assays.

Results: RNAScope for Gpr39 and IF for aquaporin 2 (AQP2) revealed colocalization of Gpr39 transcripts in AQP2-positive cells of the inner medullary and cortical collecting ducts. To study the effect of GPR39 activation, mpkCCD cells were treated with 1μM GPR39 agonist cpd1324 with 10μM cofactor $ZnCl_2$ or $ZnCl_2$ alone. After 4 hours, cpd1324 impaired TER (WT/veh=12.5±0.7, WT/cpd = 0.92±0.35, KO/veh = 7.9±0.2, KO/cpd = 8.9±0.3, n=3 per condition ($k\Omega x cm^2$), disrupted tight junctions (zona occludens-1 (ZO-1), Fig 1A), altered apical membrane morphology (apical marker wheat germ agglutinin (WGA), Fig 1B), targeted F-actin to the basolateral compartment (phalloidin, Fig 1C), and induced AQP2 internalization (Fig 2). After 24 hours of treatment, AQP2 was degraded (by WB), but the cytoskeleton morphology and TER recovered. These effects were not seen in GPR39 KO cells. In cAMP assays, 15-minute dDAVP treatment induced cAMP accumulation from 206.5±0.3 pmol/mL to 213.11±1.3 pmol/mL; however, 4h and 24h pretreatment with cpd1324 only reduced dDAVP-mediated cAMP pools to 211.3±0.6 and 210.0±1.5 pmol/mL, respectively. These data suggest that the effect on AQP2 and the cytoskeleton are only minimally affected by reductions in V2-receptor signaling.

Conclusions: These data suggest that the effect on AQP2 and the cytoskeleton are only minimally affected by reductions in V2-receptor signaling.

The TRIM28-PARP1-CTNNB1 Complex Is Associated with the Transcriptional Elongation Machinery for Aqp2 Gene Transcription

Hyo-Ju Jang,[1] Euijung Park,[2,4] Hyun Jun Jung,[3] Tae-Hwan Kwon.[1]
[1]Kyungpook National University School of Medicine, Daegu, Republic of Korea; [2]National Heart Lung and Blood Institute, Bethesda, MD; [3]The Johns Hopkins University School of Medicine, Baltimore, MD; [4]National Institutes of Health, Bethesda, MD.

Background: Vasopressin enhances water reabsorption in collecting duct cells by increasing the abundance of Aquaporin-2 (AQP2) through transcriptional and post-translational mechanisms. We recently discovered that a complex comprising CTNNB1 and PARP1 acts as a transcriptional regulator of Aqp2 gene transcription in response to vasopressin. In this study, we introduce a Bromodomain protein, Tripartite motif-containing 28 (TRIM28; also known as KAP1), into the transcriptional machinery that controls RNA polymerase II (RNA Pol II) transcription elongation in the AQP2 regulation.

Methods: For in vitro experiments, we used the mouse collecting duct cell line mpkCCDc14, grown on semipermeable filters and treated with dDAVP for 24 h to induce AQP2 expression. We applied siRNA-mediated knockdown of Ctnnb1 or Trim28 using a reverse transfection strategy. RNA sequencing (RNA-Seq) was then conducted on mpkCCD cells with Ctnnb1 knockdown. We employed immunolabeling and immunoblotting to verify TRIM28 protein expression in kidney tissues and immunoprecipitated proteins.

Results: RNA-Seq demonstrated that dDAVP significantly induces Aqp2 expression, which is reduced after Ctnnb1 knockdown. Bioinformatic analysis identified transcriptional regulators related to the promoters of genes differentially expressed after dDAVP treatment or Ctnnb1 knockdown, and highlighted the role of these regulators in RNA Pol II modulation. Bioinformatics and immunoprecipitation assays identified several Bromodomain proteins, including TRIM28, as interacting partners of CTNNB1 and PARP1 associated with RNA Pol II elongation. Immunohistochemistry demonstrated the nuclear presence of TRIM28 in mouse kidney collecting duct cells. Importantly, siRNA-mediated knockdown of Trim28 in mpkCCDc14 cells significantly reduced the dDAVP-induced Aqp2 gene expression, observable at both mRNA and protein levels after 6 and 24 h of treatment. An immunoprecipitation assay further confirmed a direct interaction between TRIM28 and RNA Pol II.

Conclusions: This study reveals TRIM28 as a crucial element of the transcriptional machinery that regulates RNA Pol II activity in the transcription of the Aqp2 gene. These findings provide insights into the transcriptional regulation of Aqp2, highlighting the role of the TRIM28-containing regulatory complex in controlling RNA Pol II function.

Development of Direct AQP2 Water Channel Inhibitors

Chisato Takahashi,[1] Shinya Harada,[1] Shotarou Michizoe,[1] Makoto Abe,[1] Yumi Noda,[2] Sei Sasaki,[2] Tatemitsu Rai.[1] *[1]Dokkyo Ika Daigaku, Shimotsuga-gun, Japan; [2]Tokyo Ika Shika Daigaku, Bunkyo-ku, Japan.*

Background: The regulation of urinary output is essential for the maintenance of body fluid homeostasis. Loss-of-function mutations of aquaporin-2 (AQP2) water channel cause renal diabetes insipidus and severe dehydration. In contrast, gain of function of AQP2 is implicated in the pathogenesis of congestive heart failure, liver cirrhosis, and SIADH. Inhibitors of AQP2 are expected to be potent pure water diuretics with few side effects, but their development has not been successful so far.

Methods: The objective of this study is to establish a drug screening system for the development of direct inhibitors of AQP2. 1. mpkCCDcl4 cells, which are immortalized cultured cells derived from renal collecting duct epithelial cells of SV40 large T cell antigen transgenic mouse, were utilized. The expression of AQP2 in mpkCCDcl4 cells and its cellular localization upon vasopressin stimulation were confirmed by Western blotting and fluorescent immunostaining. 2. mpkCCDcl4 cells were seeded on semipermeable filters (96-well polycarbonate Transwell plate, 0.4-μm pore size) to form an epithelial cell layer. Sucrose was added to the basolateral side to apply high osmotic pressure (Δ 850 mOsm). Water permeability was evaluated by the decrease in volume of the apical compartment. 3. Small molecule compounds in the compound library were applied to the apical compartment of this system to screen for the water permeability inhibitory effect of each compound. DMSO was applied as a negative control.

Results: 1. mpkCCDcl4 cells expressed AQP2, which showed polarized trafficking to the apical plasma membrane in response to vasopressin stimulation. 2. In mpkCCDcl4 cells cultured in a 96-well Transwell plate, the volume of fluid transported from the apical to the basolateral side were 27.2±1.6% of the initial volume (mean±SD, n=8) in the presence of osmotic gradient. Osmotic water flux across the grown cells was inhibited by 0.3 mM $HgCl_2$. 3. Among the 156 compounds applied for initial screening, 13 compounds exerted inhibitory effect on osmotic water flux by under -2SD of the negative control.

Conclusions: An effective screening system was established to evaluate the water permeability of AQP2 using cultured cells. Initial screening of small-molecule compounds revealed several compounds with possible water permeability inhibitory effects.

FR-PO571

Can Acetylation of Lysine 282 of Aquaporin 3 Improve Urinary Concentration in Mice with Lithium-Induced Nephrogenic Diabetes Insipidus?

Nha V. Huynh, Cassidy Rehage, Phi-Hung Nguyen, Kelly A. Hyndman.
The University of Alabama at Birmingham Division of Nephrology, Birmingham, AL.

Background: The principal cell basolateral water channel AQP3 is decreased in lithium-induced nephrogenic diabetes insipidus (NDI) and AQP3-null mice have an NDI phenotype with polyuria. We previously identified a novel AQP3 post-translational modification, acetylation of lysine 282 (K282), which we found to affect protein membrane localization. We hypothesized that lysine acetylation of AQP3 may improve the polyuria in NDI.

Methods: Mice with homozygous mutations of AQP3 K282R (deacetylated mimetic, R) or K282Q (acetylated mimetic, Q) were compared to wild type K282 (WT) mice. Male and female 11–16-week-old mice were fed a lithium-containing diet or control diet (40 mmol LiCl or NaCl/kg dry food) for 14 days (n = 5-6/group). 24 h food and water intake, urine flow, and plasma osmolality at day 14 were measured.

Results: On the control diet, food intake (WT 6.8±0.3, Q 6.3± 0.7, R 6.2±0.8 g/day, p=0.9), water intake (WT 3.6±0.3, Q 3.4±0.3, R 4.0±0.2, p=0.9), and urine flow (WT 1.4±0.4, Q 1.3±0.3, R 1.3±0.3 ml/day, p = 0.9) were similar among the male mice. The control diet females also had similar food intake (WT 6.4±0.4, Q 6.2±0.3, R 6.2±0.7 g/day, p = 0.38), water intake (WT 3.2±0.3, Q 3.4±0.2, R 3.9±0.4, p=0.9), and urine flow (WT 0.2±0.1, Q 0.5±0.1, R 0.5 ±0.2 ml/day, p=0.9). As expected, the lithium-diet fed mice developed polyuria/polydipsia. In male mice, food intake was lower in the WT (5.5±0.3 g/day) than Q and R (7.4±0.6 and 7.0±0.4 g/day, p = 0.02); however, R mutant mice had greater urine flow (12.8 ± 1.2 ml/day) than WT (4.8±0.5 ml/day) and Q mice (7.9±1.8 ml/day, p=0.0004). The females ate similar amounts of lithium diet (WT 6.4±0.3, Q 6.4±0.5, R 5.4±0.5 g/day, p=0.99) but urine flow was enhanced in Q (9.8±1.4 ml/day) and R (8.5±1.3 ml/day) mice compared to WT (4.8±0.5 ml/day, p=0.02). Water intake was significantly increased in all lithium-fed mice regardless of genotype (p<0.001). There were no significant effects of treatment or genotype on plasma osmolality among the groups.

Conclusions: Contrary to our hypothesis, AQP3 acetylation- and deacetylation-mimetics had worsened polyuria in lithium-induced NDI, suggesting that K282 is an important regulatory site for AQP3 function perhaps independent of acetylation status.

Funding: NIDDK Support

FR-PO572

Downregulation of the Vasopressin-AQP2 Pathway Explains Secondary Nephrogenic Diabetes Insipidus Associated with Cystinosis: In Vivo and In Vitro Evidence

Angela Ferrulli,[1,2] Rik Gijsbers,[2] Annarita Di Mise,[1] Arend Bokenkamp,[4] Sara Cairoli,[5] Grazia Tamma,[1] Lambertus P. Van den Heuvel,[2,3] Elena Levtchenko,[4] Giovanna Valenti.[1] *[1]Universita degli Studi di Bari Aldo Moro, Bari, Italy; [2]Katholieke Universiteit Leuven, Leuven, Belgium; [3]Radboud Universiteit, Nijmegen, Netherlands; [4]Amsterdam UMC Locatie AMC, Amsterdam, Netherlands; [5]Ospedale Pediatrico Bambino Gesu, Roma, Italy.*

Background: Cystinosis, an autosomal recessive lysosomal storage disease, is caused by mutations in the *CTNS* gene, encoding cystinosin, leading to the accumulation of cystine. Kidneys are the first and most affected organs, with severe tubular dysfunction and glomerular damage. Secondary Nephrogenic Diabetes Insipidus (NDI) has been reported in cystinosis. The lack of a collecting duct *in vitro* model for cystinosis has however limited the research on the mechanisms involved in the impairment of urine concentrating ability. In this study, we established the first mouse collecting duct *in vitro*

model knocked out for *CTNS* using the CRISPR/Cas9 technology. In parallel, the renal response to vasopressin was tested in four cystinosis patients.

Methods: By employing virus-like particles carrying CRISPR/Cas9 technology, *CTNS* was efficiently knocked out in MCD4 cells, a mouse renal collecting duct cell line stably expressing the human AQP2 and the vasopressin receptor 2 (V2R). Sanger sequencing, qPCR and mass spectrometry were performed to validate the editing efficiency and assess cystine accumulation. Urinary AQP2 excretion in cystinosis patients was evaluated by ELISA.

Results: The CTNS KO cell line showed a strong reduction of AQP2 expression. In CTNS KO cells, exposure to desmopressin did not increase osmotic water permeability, likely due to reduced AQP2 expression. Interestingly, inhibition of the autophagic pathway by chloroquine treatment resulted in a significant increase in AQP2 expression, indicating that the observed AQP2 reduction in CTNS KO cells is mediated by enhanced autophagic degradation. In cystinosis patients, AQP2 excretion, a biomarker for collecting duct responsiveness to vasopressin, did not significantly increase after desmopressin administration and urine osmolarity remained below 800 mOsm/L.

Conclusions: In conclusion, we established the first collecting duct *in vitro* model for the study of secondary NDI associated with cystinosis, demonstrating that vasopressin resistance associated with cystinosis depends on reduced expression of AQP2 due to autophagy-mediated degradation. These data together with the *in vivo* study indicate that secondary NDI in cystinosis is due to a defect in the vasopressin-AQP2 axis.

Elexacaftor/Tezacaftor/Ivacaftor (ETI) Treatment Corrects the Salt-Losing Phenotype in People with Cystic Fibrosis

Jens G. Leipziger,[1] Samuel L. Svendsen,[1] Amalie Q. Rousing,[1] Sascha Bandulik,[2] Richard Warth,[2] Mads V. Sorensen,[1] Majbritt Jeppesen,[3] Peder Berg.[1] *[1]Aarhus Universitet, Aarhus, Denmark; [2]Universitat Regensburg, Regensburg, Germany; [3]Aarhus Universitetshospital, Aarhus, Denmark.*

Background: PwCF have an increased risk for fluid and electrolyte imbalances caused by fluid and salt loss. Congruently, guidelines advocate increased salt intake. In this study, we investigate the effect of ETI treatment on blood pressure and fluid- and electrolyte homeostasis in pwCF.

Methods: We quantified the effect of 6 months ETI treatment in pwCF (n=45) on blood pressure; electrolyte- and acid-base balance; aldosterone levels; and the diuretic response to an oral $NaHCO_3$ loading test. Furthermore, to explore sweat-independent pathophysiological mechanisms contributing to the phenotype of pwCF, we NaCl-depleted CF, pendrin KO, and WT mice for 7 days. Hereafter, the renal adaptation and systemic electrolyte and acid-base homeostasis were assessed.

Results: In pwCF, ETI treatment increased: blood pressure, venous Na^+, and the diuretic response to oral $NaHCO_3$-loading. Congruently, treatment markedly decreased heart rate, aldosterone levels, venous tCO_2 and the proportion of pwCF with low Na^+ levels. In CF mice, NaCl depletion caused lower Na^+, K^+, and Cl^- levels while HCO_3^- and aldosterone levels were increased. Interestingly, CF mice failed to increase renal pendrin protein abundance. During NaCl depletion, pendrin KO mice developed severe hyponatremia, hypochloremia, hypokalemia, metabolic alkalosis, and weight loss.

Conclusions: In pwCF, ETI treatment improves NaCl and fluid conservation. CF mice have an impaired ability to retain salt and fluid when NaCl-depleted, which is explained by insufficient renal pendrin regulation. Hence, part of the treatment effect in pwCF is likely attributed to correction of renal CFTR. Salt repletion appears less necessary in ETI-treated pwCF.

FR-PO574

Influence of Murine Background Strain on Renal Water Balance and Urine Concentration

Sarah Christine Whelan, Stephanie Mutchler, Thomas R. Kleyman, Shujie Shi. *University of Pittsburgh, Pittsburgh, PA.*

Background: Kidneys are essential in maintaining body fluid and electrolyte balance. Several mouse strains, specifically C57 and 129, are widely used for studying renal physiology and diseases. Previous observations suggest background strains influence urinary behaviors and diuretic responses in mice; however, a systematic analysis has not yet been performed and the underlying mechanisms for these differences remain unclear.

Methods: The present study aims to examine differences in salt and water handling between the C57 and 129 mouse strains. Adult male mice were housed in metabolic cages for 24-hour urine collection. Weight, water, and food intake were measured daily. At the end of the study, mice were sacrificed for blood and tissue collections.

Results: We show that while C57 mice demonstrate greater 24-hour water consumption and 24-hour urinary output, plasma osmolality and blood chemistry between strains remain comparable. Both strains demonstrate greatest urination during dark periods. Despite having a greater body weight, kidneys were significantly smaller in C57 male mice compared to 129s. Western blot reveals C57 mice have remarkably reduced expression of both the Na-K-Cl cotransporter (NKCC2) and renal outer medullary potassium channel (ROMK), suggesting reduced Na^+ reabsorption in the thick ascending limb of C57 mice. Notably, the expression of the sodium-chloride transporter (NCC) remains consistent between the two strains. Additionally, C57 mice show significantly less expression of several aquaporins (AQPs), specifically AQP1, AQP2, and AQP3; indicating impaired water reabsorption along the nephron. Taken together, our data suggests differences in sodium and water handling, as a consequence of NKCC2 and AQPs expression, contribute to the discrepancies in water balance and urine concentrating abilities seen between C57 and 129 mice. Finally, both uromodulin expression and PKA-phosphorylated substrate abundance were appreciably lower in the C57 strain and as such, may contribute to the decreased expression of AQP2 and NKCC2 by means of the vasopressin-cAMP-PKA pathway.

Conclusions: Our data emphasizes the idea that murine background strains are highly variable and should be considered in designing renal physiology studies.

Tamoxifen Prevents the Lithium-Induced Increased Cilium Length and Necroptosis Reduction

Mariangela Centrone,[1] Ines Angelini,[1] Mariagrazia D'Agostino,[1] Annarita Di Mise,[1] Barbara Barile,[1] Grazia Paola Nicchia,[1] Stine Julie Tingskov,[2] Rikke Norregaard,[2] Giovanna Valenti,[1] Grazia Tamma.[1] *[1]Department of Biosciences Biotechnologies and Environment, University of Bari Aldo Moro, Bari, Italy; [2]Department of Clinical Medicine, Aarhus University, Aarhus, Denmark.*

Background: Lithium is often used to treat some mental illnesses including bipolar disease. However, numerous adverse effects have been reported including acquired nephrogenic diabetes insipidus, a disorder characterized by a defective renal concentrating ability that causes a significant water loss. Tamoxifen, an estrogen receptor modulator, mitigates the onset of lithium-induced NDI by regulating the expression and function of AQP2 and AQP3.

Methods: Renal collecting duct MCD4 cells were used as an experimental model. *Ex vivo* and *in vivo* experiments were performed as well. Western Blotting analysis was applied to evaluate the expression and function of proteins involved in controlling cell deaths.

Results: *Ex vivo* and *in vivo* experiments revealed that treatment with Tamoxifen prevented the lithium-induced reduction in necroptosis. Specifically, Western Blotting data showed that lithium administration significantly decreased the expression levels of RIPK3 and MLKL which are key players in controlling necroptosis. Conversely, these effects were prevented by Tamoxifen treatment. *In vitro* experiments confirmed those findings. Also, a decrease in the expression of BID and an increase of beclin, selective markers of apoptosis and autophagy respectively, were found as well. Moreover, lithium exposure increased cell proliferation, the transepithelial electrical resistance (TEER), and the length of the primary cilium as assessed by the super-resolution stimulated emission depletion (STED) microscopy. The lithium responses were prevented by Tamoxifen treatment.

Conclusions: Together, these data revealed for the first time that exposure of renal collecting ducts to lithium resulted in a significant reduction in the expression level of selective markers of necroptosis. In addition, lithium promotes inappropriate cell proliferation possibly associated with increased transepithelial electrical resistance and elongation of the primary cilium. All these effects are prevented by Tamoxifen.

Claudin-3: Physiological Role in Renal Cortical Collecting Duct

Thibaut Charlemagne, Alexandra Chassot, Eric Feraille, Ali Sassi. Eric Feraille's Group. *Department of Cellular Physiology and Metabolism, Faculty of Medicine, Geneva, Switzerland.*

Background: In the kidney, ion and fluid transport across epithelia can occur *via* the transcellular or paracellular pathways. Tight junctions play a key role in mediating paracellular ion reabsorption in the kidney. The renal collecting duct (CD) is the place of fine tuning of Na+ reabsorption and it is mainly regulated by aldosterone. Aldosterone classically regulates Na+ transport through the transcellular pathway. We hypothesized that aldosterone modulates also the paracellular pathway. Paracellular ion permeability is mainly dependent on tight junction permeability. Claudin-3 is one of the main tight junction proteins expressed along the CD.

Methods: We used cultured mouse CD principal cells (mCCD) and mouse models to study the effects of aldosterone on claudin-3. Overexpression and silencing of claudin-3 were used to assess the paracellular permeability of claudin-3. WT and claudin-3 knockout male mice were fed for 7 days with either low (0.01 %), normal (0.18 %) or high sodium (1.25 %) diet. One group of mice fed a low sodium diet received 0.35 mg/100g body wt/day of spironolactone for 7 days.

Results: We showed that aldosterone increased protein levels of claudin-3 in cultured CD principal cells. Overexpression of claudin-3 was associated with a reduction in paracellular permeability to sodium and chloride, whereas silencing of claudin-3 was associated with the opposite effect. We also showed that a low-salt diet, which stimulated aldosterone secretion, was associated with increased claudin-3 abundance in the mouse kidney. Reciprocally, mice treated with spironolactone, a mineralocorticoid receptor antagonist, displayed decreased claudin-3 expression. Importantly, claudin-3 knockout mice displayed increased γ-ENaC and claudin-4 protein abundance under low-salt diet compared to WT mice.

Conclusions: Our results show that aldosterone modulates the expression of claudin-3 and that claudin-3 acts as paracellular NaCl barrier. We also show a specific adaptation of clausin-3 deficient mice to low-salt diet. Claudin-3 may then play an important role in preventing the backflow of reabsorbed NaCl.

FR-PO577

Role of H,K-ATPase 2 in the Response to Mineralocorticoid Excess

Luciana Morla,[1,2] I. Jeanette Lynch,[3] Lydie Cheval,[1,2] Samia Lasaad,[4] Justine Billiet,[1,2] Gilles Crambert,[1,2] Charles S. Wingo.[3,5] Physiologie Rénale et Tubulopathies. *[1]CNRS EMR8228, Paris, France; [2]Centre de Recherche des Cordeliers, UMRS1138, Paris, France; [3]University of Florida, Gainesville, FL; [4]Icahn School of Medicine at Mount Sinai, New York, NY; [5]North Florida/South Georgia Veterans Health System, Gainesville, FL.*

Background: Aldosterone is a key hormone in blood pressure maintenance. In excess, aldosterone induces an increase in Na retention and blood volume. Natriuretic factors come into play to inhibit renal Na absorption and escape aldosterone effects. We have recently identified a Na secretion pathway (Morla et al 2016) involving the renal H,K-ATPase type 2 (HKA2) and the basolateral, bumetanide sensitive, cotransporter NKCC1, in the collecting duct. Here we ask if HKA2 plays a role in the aldosterone escape.

Methods: We treated wild type (WT) and HKA2KO (KO) mice with a normal salt diet (0.3% NaCl) and deoxycorticosterone pivalate (DOCP), an aldosterone analogue. We performed microperfusion of cortical collecting ducts (CCD) of DOCP treated WT and HKA2KO. We determined Na net fluxes before and after adding bumetanide to the bath. We studied mice in metabolic cages to determine daily Na urine excretion before and after DOCP treatment. During the escape phase: after 2 days of DOCP treatment (D2), we tested the effect of amiloride on urine Na excretion.

Results: DOCP treated WT and KO mice CCDs showed net Na reabsorption flux which declined over time in DOCP WT mice CCDs ($p<0.04$). This decrease was blunted in KO mice CCDs and in WT mice bumetanide-treated CCDs. DOCP induced urine Na retention in both mice groups 24h after DOCP injection. WT mice recovered a normal Na balance on D2 but KO mice excreted much more Na in their urines than WT mice and failed to keep a normal Na balance. Immunoblot analysis of D2 WT and KO mice kidneys showed similar increase of the expression of the NaCl cotransporter NCC. Interestingly, we found a smaller increase of the epithelial Na channel subunit αENaC ($p<0.001$) and a greater decrease of γENaC ($p<0.05$) in DOCP treated KO mice, when compared to DOCP treated WT mice suggesting ENaC could be less active in the KO mice. To confirm our hypothesis, we compared the effect of amiloride in WT and KO mice on D2 and found KO mice excreted less Na after amiloride treatment than WT mice ($p<0.02$).

Conclusions: Our data suggest that during the aldosterone escape, renal H,K-ATPase type 2 Na secretion in the CCD is necessary for Na balance maintenance. To compensate the exagerated Na retention, WT mice secrete Na through HKA2. In HKA2KO mice, ENaC inhibition in he CCD could allow to escape at the price of a greater Na loss.

Renal Kallikrein-1 Contributes to Cleavage of Gamma-Epithelial Sodium Channel (ENaC) in Response to a Short-Term, Low-Sodium, High-Potassium Diet

Joshua N. Curry,[1] Xiao-Tong Su,[1] Yujiro Maeoka,[2] Chao-Ling Yang,[1] Eric J. Delpire,[3] Paul A. Welling,[4] David H. Ellison.[1] *[1]Oregon Health & Science University, Portland, OR; [2]Hiroshima Daigaku Byoin, Hiroshima, Japan; [3]Vanderbilt University Medical Center, Nashville, TN; [4]Johns Hopkins Medicine, Baltimore, MD.*

Background: Tissue kallikrein, encoded in part by *Klk1*, is a serine protease that has been proposed to cleave and activate Na^+ channels (ENaC). In the kidney, kallikrein-1 is found primarily in the aldosterone sensitive distal nephron, and its transcript abundance is markedly reduced by deletion of the mineralocorticoid receptor. While global deletion of kallikrein-1 leads to defective renal K^+ handling and reduced gamma-ENaC cleavage, it is not clear if these findings result from loss of renal kallikrein-1 or from systemic abnormalities observed with global kallikrein-1 loss.

Methods: In order to determine the direct effects of renal kallikrein-1 on ENaC, we generated mice with conditional deletion of kallikrein-1 in the distal nephron: *Klk1*$^{fl/fl}$ Calbindin-Cre (KS-Klk1 KO). Mice were treated with either control (Ctrl, 0.49% NaCl, 1%. KCl) or low Na^+, high K^+ (LNHK, 0.03% NaCl, 5% KCl) diet for 5 days. On Day 4, urine was collected during 24 hours. Urine electrolytes were measured by flame photometry or colorimetric assay, and kallikrein activity was measured using amidolytic assay. Western blotting was used to quantify gamma-ENaC, with or without Peptide -*N*-Glycosidase F (PNGase F).

Results: Deletion of kallikrein-1 was confirmed by western blotting; it resulted in striking, but incomplete, reduction in urinary kallikrein excretion. Serum [K^+] was similar across genotypes on both Ctrl and LNHK diets. Urine [Na^+] and [K^+] excretion rates were also similar between genotypes. Cleaved gamma-ENaC was higher on LNHK than Ctrl diet in both groups, but the ratio of cleaved:uncleaved was not as high in KS-Klk1 KO (WT 3.3+/-0.04 vs KO 2.05+/-0.55). To improve ENaC resolution, we treated kidney samples with PNGase F. Under LNHK conditions the 52 kDa (distally cleaved) gamma-ENaC band was 52% lower in KS-Klk1 KO (WT 100% vs KO 51.5%, $p=0.006$). There was also a trend towards lower phosphorylated-NCC in the KS-Klk1 KO mice on LNHK diet, suggesting a compensatory response.

Conclusions: These results suggest that kidney kallikrein-1 contributes to, but is not the only protease, that cleaves gamma-ENaC at its distal site in response to a short-term low Na^+ and high K^+ diet. Further studies are needed to better understand how renal kallikreins are produced and their role in gamma-ENaC cleavage and ENaC function.

Kir4.1/Kir5.1 Channel Inhibition Acutely Ameliorates Hyperkalemia in Male Rats with Reduced Kidney Function

Sati A. Alexander,[1] Bianca Tubalinal,[1] Kathleen A. Coleman,[1] Jenny Nguyen,[1] Oleg Palygin,[2] Mykola Mamenko.[1] *[1]Augusta University, Augusta, GA; [2]Medical University of South Carolina, Charleston, SC.*

Background: Patients with advanced chronic kidney disease (CKD) can develop hyperkalemia, a life-threatening condition causing cardiac arrhythmia, paralysis, and death. Basic science lacks a suitable animal model that accurately reflects hyperkalemic states observed in patients with CKD, and there is an unmet need for novel pharmacological approaches managing hyperkalemia in CKD, as current interventions are fraught with adverse effects. Inhibition of the renal basolateral K^+ channels, like Kir4.1 and Kir4.1/5.1, does not rely on glomerular filtration and is an attractive target to treat hyperkalemia in patients with advanced CKD. Genetic deletion of either Kir4.1 or Kir5.1 protein leads to hypokalemia and salt wasting. Here, we test the hypothesis that pharmacological blockade of these channels provides an effective treatment against hyperkalemia.

Methods: First, we established a rat model of chronic hyperkalemia. To do this, ten 35-week-old Sprague-Dawley rats of both sexes underwent 5/6-nephrectomy moderately elevating serum K^+ levels to 5.3±0.3 mEq/L in males and 5.0±0.5 mEq/L in females. Nephrectomized rats were placed on a 10% KCl diet for 7 days to achieve persistent hyperkalemia with serum K^+ significantly increased to 6.9±1.1 mEq/L in males and 6.7±0.9 mEq/L in females. To assess the effect of Kir4.1 and Kir4.1/5.1 Kir channel inhibition on circulating potassium, a commercially available antagonist, VU0134992, was administered by oral gavage (100mg/kg) and serum K^+ concentration was measured at 4 and 24 hours after the treatment.

Results: In males, serum K^+ concentration was significantly reduced to 6.0±0.6 mEq/L and 5.8±0.8 mEq/L at 4 and 24 hours after VU administration, respectively. In females administered with VU serum K^+ remained comparable to pre-treatment levels at 6.5±0.6 mEq/L and 7.4±1.2 mEq/L at 4 and 24 hours after the intervention.

Conclusions: Our study establishes 5/6 nephrectomized rats on a 10% KCl diet as a model of chronic hyperkalemia. Inhibition of Kir4.1 and Kir4.1/5.1 Kir channels acutely reduces serum K^+ levels in hyperkalemic male rats with reduced renal function, but not in females.

FR-PO580

Sex- and Cell-Specific Changes in BKα Protein Expression in the Aldosterone-Sensitive Distal Nephron (ASDN) in Response to Dietary K+

Samia Lasaad, Lisa M. Satlin, Rolando Carrisoza-Gaytan. *Icahn School of Medicine at Mount Sinai Department of Pediatrics, New York, NY.*

Background: Within the cortical collecting duct (CCD) of the ASDN, BK channels are essential for renal adaptation to a high K^+ diet (HKD) and mediate flow-induced K^+ secretion. We have previously reported that dietary K^+ loading for 10 d leads to an increase in whole-cell BKα protein expression in female rabbits and channel activity in male mice (Carrisoza-Gaytan et al. 2017, 2020). In whole kidney immunoblots, expression of BKα in females exceeds that in males (Yu et al. 2017). The purpose of this study was to examine the sex- and cell-specific responses to dietary K^+ over an 11 d period on BKα protein expression and subcellular distribution in mouse CCD.

Methods: 8-wk-old male (M) and female (F) C57BL/6 mice maintained on a control diet (2.4% K^+), were randomly switched to a low K^+ diet (LKD, 0.0%) or HKD (10%) for up to 11 d, before study at 0, 3, 5, 7, 9, and 11 d (3-4 mice/sex per day). Kidney cryosections were obtained and processed for BKα and AQP2 coimmunostaining to

identify CCD AQP2+ principal cells (PCs) and AQP2- intercalated cells (ICs) by confocal microscopy. Whole-cell BKα protein abundance and distribution were quantified in PCs and ICs and normalized to values obtained on day 0.

Results: BKα abundance was greater in F vs. M at day 0 in PCs and ICs (2.29±0.46 and 1.57±0.26, respectively, p≤0.005). With HKD, BKα abundance increased by 3 d in PCs and ICs in M (1.41±0.32 and 1.37±0.19, p≤0.001 vs. 0 d) and F (1.17±0.20 and 1.21±0.16, p≤0.05 vs. 0 d), followed by a sustained elevation after 7 d in M only (1.59±0.28 and 1.89±0.20, p≤0.001 vs. 0 d). A LKD led to a reduction in apical and sub-apical expression of BKα in ICs of M (0.53±0.09, p≤0.0001 vs. 0 d), but not F, by 7 d. Basolateral BKα expression increased in M ICs by 7 d (1.87±0.41, p≤0.0001 vs. 0 d), with no changes in F.

Conclusions: This study highlights sex- and cell-specific differences in BKα abundance and distribution in the mouse CCD in response to dietary K^+. Future efforts will be directed at unraveling the underlying sex-specific regulatory mechanisms.

Compensatory Upregulation of Renal H+/K+- ATPase Function in Pendrin-Null Mice Serving K+ Preservation

Niklas Ayasse,[1,2] Peder Berg,[2] Mads V. Sorensen,[2] Jens G. Leipziger.[2]
[1]Universitatsklinikum Mannheim, Mannheim, Germany; [2]Aarhus Universitet Institut for Biomedicin, Aarhus, Denmark.

Background: The renal Cl^-/HCO_3^- exchanger pendrin (SLC26A4) contributes to the maintenance of acid/base and intravascular volume homeostasis. Several studies have also suggested a possible role of pendrin in K^+homeostasis. The aim of this study was to identify possible compensatory K^+ retaining mechanisms in pendrin null mice. Since K^+ deficiency potently stimulates the activation of renal H^+/K^+-ATPases (HKA), we hypothesized that functional HKA activity is increased in pendrin null mice, thus allowing the preservation of K^+homeostasis. We recently suggested that benzamil can block the renal HKAs and thus may serve to functionally test its activity in vivo.

Methods: The acute effect of benzamil on urinary pH was investigated in bladder-catheterized pendrin$^{+/+}$ and pendrin$^{-/-}$mice. The magnitude of benzamil-induced urinary alkalization was used as a surrogate for the functional activity of the renal HKA. The effect was investigated under control and low K^+ diet conditions to increase HKA activity.

Results: Under control diet conditions, baseline urinary pH was lower in pendrin$^{-/-}$ mice as compared to pendrin$^{+/+}$mice. This may be caused by reduced pendrin-dependent HCO_3^- secretion or activation of an unknown tubular H^+ secretory mechanism or both. Interestingly, the magnitude of benzamil-induced urinary alkalization was greater in the pendrin$^{-/-}$ mice. Under low K^+ diet conditions, baseline urinary pH was not different between the pendrin$^{+/+}$ and the pendrin$^{-/-}$ group. Benzamil-induced urinary alkalization was larger in WTs during K^+-depletion, but not different between K^+ depleted $^{+/+}$ and $^{-/-}$ mice.

Conclusions: We propose that benzamil may function to indicate the HKA activity. Its greater effect in pendrin$^{-/-}$ mice under control diet indicates an increased baseline activity of the renal HKAs, likely caused by hypokalemia in these mice. The marked augmentation of benzamil-induced urine alkalization during low K+ conditions was confirmed in this study. The absence of dietary potassium depletion-induced increase of HKA activity in pendrin $^{-/-}$ mice could indicate a ceiling effect of the activated renal HKA. We suggest that renal HKA might indeed contribute to K^+ preservation in the absence of pendrin. This might indicate a hierarchical relationship where the need to preserve K^+ occurs at the expense of H^+ loss despite higher plasma HCO_3^- levels.

FR-PO582

Kidney Medullary Range NaCl Modulates CD8+ T Cell Survival and Function and Associates with Their Accumulation in Kidney Allografts

Peyman Falahat,[1] Adrian Goldspink,[1] Jessica Schmitz,[2] Jan H. Braesen,[2] Niklas Klümper,[1] Marieta I. Toma,[1] Sibylle Von Vietinghoff.[1]
[1]Universitatsklinikum Bonn, Bonn, Germany; [2]Medizinische Hochschule Hannover, Hannover, Germany.

Background: Recent research revealed a significant impact of electrolytes, namely NaCl, on immune responses. The role of the chief renal mobile osmolytes NaCl and urea for $CD8^+$ T cell function and accumulation in the kidney has not been systematically explored.

Methods: Human primary kidney and blood $CD8^+$ T cell survival and function was studied in elevated NaCl and urea concentrations. Renal T cell and antigen presenting cell densities were quantified in cortex and medulla of allograft biopsies in relation to diuretic therapy in a group of 66 consecutive biopsies obtained in a surveillance program 92.9±2.6 days after transplantation graded according to the Banff classification.

Results: An elevated NaCl but not urea concentration decreased human primary blood $CD8^+$ T cell and effector marker $KLRG1^+$ cell numbers. Urea inhibited $CD8^+$ T cell proliferation. NaCl, but not urea, increased apoptotic $CD8^+$ T cell death. In human kidneys in vivo, in tissues obtained during loop diuretic therapy that depletes the concentration gradient, cytotoxic $CD8^+$ T cells were significantly more abundant. This observation also was maintained if only tissues without histological rejection were included to the analysis. Ex-vivo primary renal cortical, but not medullary T cell survival and response was impaired by environmental NaCl.

Conclusions: Our data introduce a role of kidney medullary range NaCl and urea concentrations for $CD8^+$ T cell proliferation, survival and response. This is amenable to therapeutic interventions, which remain to be studied prospectively.

FR-PO583

Lymphatic Endothelial Cell Permeability Is Regulated by Sodium and Nkcc1

Jianyong Zhong, Haichun Yang, Valentina Kon, Elaine L. Shelton. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Interstitial sodium (Na+) accumulation is a halmark of proteinuric kidney disease. Lymphatic endothelial cells (LECs) play an integral role in regulating interstitial fluid uptake and transport. Interstitial fluid drains into lymphatic capillaries composed of permeable LECs with button-like cell junctions. These capillaries transition into contractile collecting vessels lined with relatively impermeable LECs with continuous zipper-like junctions, which facilitate the transport of fluid without leakage. We have previously shown that increased Na+ diminished the pumping capacity of renal lymphatic collecting vessels and reduced the activity of the Na-K-2Cl cotransporter, Nkcc1. In addition, furosemide, a Nkcc1 inhibitor, blunted lymphatic vessel pumping dynamics. Of note, ethacrynic acid, another Nkcc1 inhibitor, had no effect on vessel contractility. In this study we evaluated the effects of increased Na+ and Nkcc1 inhibition on LEC barrier formation and integrity.

Methods: Mouse LECs were cultured in normal or high Na+ conditions with or without bumetanide, a Nkcc1 inhibitor. Bulk RNA sequencing and qRT-PCR identified differentially expressed genes. LECs were also used in Trans-Epithelial Electrical Resistance (TEER) assays to measure changes in monolayer formation and barrier integrity.

Results: RNA sequencing revealed high Na+ upregulated 456 genes and downregulated 499 genes. Addition of bumetanide reversed these effects for 136 genes and augmented these effects for 2 genes. TEER assays found LECs exposed to high Na+ could establish a monolayer, but that monolayer was more permeable when compared to cells cultured in normal Na+ conditions. qRT-PCR showed tight and adherens junction genes were decreased in high Na+ conditions. Monolayer integrity further decreased with addition of bumetanide, but not ethacrynic acid.

Conclusions: These results demonstrate that Na+ avid states promote LEC permeability and that bumetanide-induced inhibition of Nkcc1 can further augment this effect. While increasing permeability in lymphatic capillary LECs may be conducive for draining excess interstitial fluid, altering the permeability of LECs in collecting vessels may cause leakage and be detrimental to fluid clearance. In addition, ethacrynic acid may be superior to other loop diuretics due to the lack of off target effects on lymphatic vessel contractility and permeability.

Urine Proteomics Captures Unique Spatial Transcriptomic Signatures of ADPKD in a Mouse Model

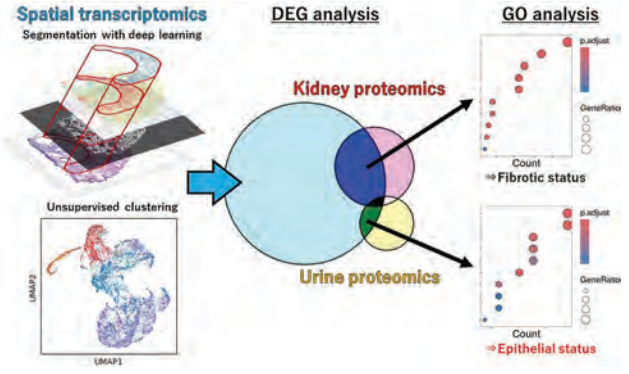
Kazuhiro Morishita, Yoshifumi Uesumi, Kohji Nagano, Naoshi Horiba, Yasuhiro Ichida. *Chugai Pharmaceutical Co. Ltd., Yokohama, Japan.*

Background: ADPKD is the most prevalent inherited kidney disease. Although the impairment of primary cilia is thought to be the cause of cyst formation, an insufficient understanding of the molecular mechanism has impeded the discovery of biomarkers reflecting PKD-specific pathology. Here, we performed multi-omics analysis to discover potential biomarkers for PKD.

Methods: Spatial transcriptomics, kidney proteomics, and urine proteomics were conducted on normal and PKD model mice. For spatial transcriptomics, we applied unsupervised clustering, spatial segmentation by deep learning, and differentially expressing gene (DEG) analysis. Kidney and urine proteomics were subjected to DEG and gene ontology (GO) analysis.

Results: Spatial transcriptomics revealed that the extent of transcriptomic change from normal mice to PKD mice varies depending on the kidney region, with the cortex along with the OSOM showing the most prominent changes. By stratifying the transcriptome with spatial information, we performed DEG analysis on the peri-cystic areas of each kidney region. Then, we investigated which DEG features could be captured with kidney or urine proteomics, but we found that there was little overlap between DEGs in kidney and urine proteomics. This suggests that these two types of proteomics capture different aspects of kidney pathology in PKD. In GO analysis, the common DEGs between kidney proteome and spatial transcriptome were associated with fibrosis, implying that kidney biopsy is likely to detect fibrotic status, a general signature of kidney inflammation. In contrast, the common DEGs between urine proteome and spatial transcriptome were associated with epithelium, suggesting that urine proteomics can effectively capture abnormalities in the tubular epithelium of PKD.

Conclusions: Our study highlights the potential of urine proteomics in terms of not only its low invasiveness but also its effectiveness in detecting epithelial changes, which could lead to the identification of novel biomarkers reflecting the unique pathology of ADPKD.



FR-PO585

In Vivo Analysis of Polycystin-1: Heterotrimeric G-protein Binding by NanoBiT

Brenda S. Magenheimer, Robin L. Maser. *The University of Kansas Medical Center, Kansas City, KS.*

Background: Polycystin-1 (PC1) is an atypical GPCR reminiscent of the Adhesion GPCR family. Both families undergo *cis*-autocatalyzed cleavage to form extracellular N-terminal and membrane-embedded C-terminal (CTF) fragments with an N-terminal CTF stalk acting as a tethered agonist. PC1-G protein regulation is central to cystogenesis, but little is known regarding mechanisms. Previous studies used truncated PC1 C-tail constructs and *in vitro* methods to show PC1-G protein binding, with little reported for full-length PC1. We are developing in vivo assays to assess PC1-G protein binding/activation. In this initial analysis, we determined the relative G protein binding preference of PC1 CTF and mutants using Nanoluciferase Binary Technology (NanoBiT) technology that relies on reconstitution of Nanoluc subunits, Large BiT (LgB) with Small BiT (SmB), to form an active enzyme with very bright luminescence.

Methods: Gα-LgB expression clones and HEK293-ΔG7 cells (KO of s,s-L, q,11,12,13, z) were provided by Drs. J. Hansen and A. Inoue. The Native Product (NP) version of SmB was fused to the C-terminus of CTF, 'stalkless' ΔstCTF and ADPKD mutants, R4136G and L4137P in the G protein activation motif. HEK293T or ΔG7 cells transfected with CTF-NP and Gα-LgB clones were assessed for Nanoluc complementation with a cell-permeable substrate. Controls included FRB-LgB+FKBP-SmB (positive), and empty vector+Gα-LgB or CTF-NP+FRB-LgB (negative). Luminescence was monitored for 40 min after substrate addition. Relative levels of CTF and Gα-LgB proteins were determined by Western blot and area under the curve was normalized to protein expression levels.

Results: NP did not affect expression or signaling of CTF proteins. CTF had a relative binding preference: Gi > Gq > Gs families in both cell lines. In ΔG7 cells, preferential binding by CTF for Gq > G11 and by ΔstCTF for Gq > Gs was lost. Analyses with a subset of Gα-LgB constructs (s, q, i1) in ΔG7 cells showed reduced binding of Gq relative to Gs for both R4136G and L4137P.

Conclusions: PC1 CTF-G protein binding is promiscuous *in vivo* and is influenced by the stalk and mutations within the G protein activation motif. Preliminary studies hint that PC1-mediated G protein regulation is complex and may be biased by multiple factors. Future experiments will examine binding in ΔG7 cells with pertussis toxin treatment, longer PC1 expression constructs, and additional mutants.

Modeling the Impact of Polycystic Kidney Disease Genetic Modifiers Using Kidney Organoids Generated from Autologous Induced Pluripotent Stem Cells

Sara Knezevic,[1,2] Jessie Davis,[2] Elhussein A. Elhassan,[3,1] Michelle Clince,[3] Katherine A. Benson,[1] Peter J. Conlon,[3] John Crean.[2] *[1]Royal College of Surgeons in Ireland Faculty of Medicine and Health Sciences, Dublin, Ireland; [2]University College Dublin, Dublin, Ireland; [3]Beaumont Hospital, Dublin, Ireland.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited renal disease caused by pathogenic variants in *PKD1* or *PKD2*. Preliminary evidence for an effect of genetic modifiers (non-pathogenic variants which modify patient phenotype) on disease severity has been reported. Kidney organoids (KO) grown from patient-derived induced pluripotent stem cells (iPSCs) can be used to inform on the variability in disease severity between family members and offer a deeper understanding of ADPKD pathogenesis. Here, iPSCs were generated from an affected individual with ADPKD.

Methods: Patient was recruited from the inherited kidney disease clinic at Beaumont Hospital (Ireland) based on their genetic risk profile. A urine sample was collected and Urinary Epithelial Cells (URECs) were isolated and cultured. URECs were reprogrammed to iPSCs (UiPSC) and validated. KOs were generated from both patient and healthy control UiPSCs and characterised by RT-qPCR and immunocytochemistry. KOs from both patient and healthy control were treated with forskolin to induce cystogenesis and assessed for tubular swelling by brightfield microscopy.

Results: The index patient, a 77-year-old female, was diagnosed with hypertension, a family history of ADPKD and reduced eGFR (35 mL/min) at the last follow-up. Imaging revealed enlarged cystic kidneys and liver cysts indicative of ADPKD. Exome sequencing revealed *PKD1* complex variants, a diagnostic variant [c.7300C>T:p.R2434W] and two genetic modifiers [c.C2755T:p.R919W and c.C8293T:p.R2765C]. URECs were successfully isolated from the patient and reprogrammed into UiPSCs. KOs generated from healthy control expressed markers of mature proximal tubule, podocyte, endothelia and stroma. Patient KOs developed cysts alone or with forskolin injury. Tubular abnormalities were evident by Day 9 and more pronounced by Day 13. Healthy control KOs formed cysts only upon forskolin treatment.

Conclusions: Autologous UiPSCs can be used to generate KOs which mimic pathogenic cystogenesis, both spontaneously and post-acute injury. Further comparative studies will examine the mechanisms through which genetic modifiers confer risk and contribute to the severity of the disease, informing future therapeutic approaches to the management of ADPKD.

FR-PO587

Generation of Kidney Organoids Model of Nephronophthisis from Human Induced Pluripotent Stem Cells (iPSCs)

Takefumi Suzuki, Koichiro Susa, Hiroaki Kikuchi, Tomoki Yanagi, Yuta Nakano, Yu Hara, Tamami Fujiki, Fumiaki Ando, Shintaro Mandai, Yutaro Mori, Takayasu Mori, Shinichi Uchida, Eisei Sohara. *Tokyo Medical and Dental University Graduate School of Medical and Dental Sciences Department of Nephrology, Bunkyo-ku, Japan.*

Background: Nephronophthisis (NPH) is an inherited kidney disease characterized by progressive tubulointerstitial fibrosis. NPH is clinically important as the most common cause of end-stage kidney disease in the juvenile period; however, no reliable animal model faithfully mimicking the pathology of human NPH is available. Consequently, the molecular mechanism of NPH caused by *NPHP1* deficiency, the most common form of NPH, has not yet been elucidated. Therefore, new models to recapitulate the pathology of NPH are required. In this study, we used human induced pluripotent stem cells (iPSCs) to generate a 3D kidney organoid model of fibrosis that provides insight into the pathogenesis of NPH.

Methods: Wild-type iPSCs and *NPHP1*$^{-/-}$ iPSCs derived from the same cell line were induced to differentiate into 3D kidney organoids, and the phenotypes associated with *NPHP1* deficiency were analyzed. First, we compared the morphology of both wild-type and *NPHP1*$^{-/-}$ organoids by immunofluorescence. Next, we induced fibrosis by treatment of IL-1β and evaluated the difference in the severity of fibrosis between the two groups.

Results: We successfully generated kidney organoids from both wild-type and NPHP1$^{-/-}$ iPSCs. In the absence of any stimulation, no difference in morphology, including nephron-like structure or fibrotic status, was observed between the two groups. This is consistent with the clinical course of human NPH caused by *NPHP1* deficiency, in which renal dysfunction does not appear during the postnatal period. On the other hand, fibrosis was induced at a significantly lower dose of IL-1β in *NPHP1*$^{-/-}$ organoids compared to wild-type organoids. This suggests that the *NPHP1*-deficient kidney is more sensitive to fibrotic stimuli than the wild-type kidney, which may explain why *NPHP1*-deficient NPH patients reach end-stage kidney disease earlier.

Conclusions: We generated *NPHP1*-deficient 3D kidney organoids; the first system capable of reproducing NPH pathology using human cells. This is an important pathological model for investigating the pathogenesis of NPH and developing therapeutic strategies.

Analysis of Pkd1 Gene Function in a Three-Dimensional Tubulogenesis Assay

Lukas Westermann,[1] Kilian Rhein,[1] Johannes Jahn,[2] Felix Schöler,[1] Matthias Niedermoser,[1] Elena Seidl,[1] Niklas Moser,[1] Shanli Seyed Tarrah,[1,3] Lea Reimund,[1] Tilman Busch,[1] Bjoern Neubauer,[1] Yong Li,[4] Anna Kottgen,[4,3] Michael Kottgen.[1,3] *[1]Renal Division, Department of Medicine, Medical Center, Faculty of Medicine, University of Freiburg, Freiburg, Germany; [2]Department of Radiology, Medical Center, Faculty of Medicine, University of Freiburg, Freiburg, Germany; [3]CIBSS - Centre for Integrative Biological Signalling Studies, Freiburg, Germany; [4]Institute of Genetic Epidemiology, Faculty of Medicine and Medical Center, University of Freiburg, Freiburg, Germany*.

Background: Autosomal-dominant polycystic kidney disease (ADPKD) is the most common monogenic kidney disease. The majority of ADPKD patients (85%) harbors mutations in *Pkd1* encoding for Polycystin-1 (PC1). PC1 function is still insufficiently understood. The establishment of a robust cellular readout for PC1 function mimicking impaired tubular morphogenesis observed in ADPKD could help to overcome these roadblocks.

Methods: Wildtype mIMCD-3 cells were seeded in a Matrigel-collagen-scaffold in the presence of hepatocyte growth factor in 96-well plates. Within 7 days, cells organized into complex tubular or spheroid structures. Structures were imaged with a confocal microscope. Data analysis was performed by training of a neural network (U-Net), followed by automated segmentation for 3D structure detection that enabled unbiased quantification and classification. Analysis of genotype-dependent morphological alterations and longitudinal transcriptomic profiling of 3D structures aimed at the identification of functional interaction partners of PC1.

Results: Automated segmentation revealed a significant reduction of mean tubules per well in *Pkd1* knockout (KO) vs isogenic control cells (71 vs 214 tubules, respectively; $p<0.0001$) as well as a significant reduction in mean tubule area (1335 vs 2811 μm^2, respectively; $p<0.0001$). This phenotype was highly robust and confirmed in multiple *Pkd1* KO and inducible *Pkd1* knockdown (KD) cells. Longitudinal differential gene expression analysis of genotype-dependent tubulogenesis identified potential signaling effectors of *Pkd1*. Transcriptomic analysis comparing early stages of tubulogenesis in wildtype and isogenic *Pkd1* KO cells revealed 118 differentially expressed genes (53 genes up-, 65 downregulated) with stringent cut-off-criteria (adjusted $p<0.01$, $\log_2$ fold change ≤-1 and ≥1). We are currently investigating whether KD of the most significantly downregulated transcripts (*GC, Scd1, C3, Chst15 and Tns1*) phenocopies PC1 loss in the 3D tubulogenesis assay.

Conclusions: We demonstrate the establishment of a robust 3D tubulogenesis assay that allows for monitoring of PC1 function with an automated image analysis platform. This cell-based assay for PC1 function enables high-throughput screening for mechanistic studies and drug discovery.

Chemical Modulation of the Ire1α-Xbp1 Pathway Reduces Cyst Size in ADPKD Mouse and Human Three-Dimensional Spheroids

Fatema Hasan,[1] Rishi Bhardwaj,[1] Michael Rehman,[1] Yiqiang Cai,[1] Ke Dong,[1] Adrian Cordido,[1] Carlotta Pioppini,[2] Duygu Elif Yilmaz,[2] Xin Tian,[1] Stefan Somlo,[1] Matteus Krappitz,[2] Sorin V. Fedeles.[1] *[1]Yale University School of Medicine, New Haven, CT; [2]Charite Universitatsmedizin Berlin, Berlin, Germany*.

Background: The Ire1α -XBP1 pathway is the most conserved UPR branch from yeast to mammals. Genetic inactivation of XBP1 leads to a significant improvement in disease severity in neonatal and adult *Pkd1*-dependent ADPKD mouse models through a pro-apoptotic mechanism driven by Ire1α kinase domain. The endoribonuclease domain of Ire1α splices an intron from the XBP1 mRNA leading to the formation of active XBP1 which acts as a transcription factor to mitigate ER stress. Here we set forth to test whether chemical inhibition of the Ire1α endoribonuclease domain through toyocamycin (previously tested in a Phase 1 study with a favorable safety profile) can alleviate cyst growth in 3D spheroid cyst models derived from ADPKD human and mouse kidney tubule cells.

Methods: Human (*PKD1*: 10594C>T (Gln3 532*)) and mouse wild-type or *Pkd1* deficient cells were grown in matrigel. At Day 1, cells were administered either ddAVP (human cells) or forskolin (mouse cells) to promote cyst growth. Following that, cells were treated with various concentrations of toyocamycin over several days followed by fixation and image processing. We calculated lumen and spheroid area (um^2) in addition to measuring cell viability via CellTiterGlo.

Results: Mouse cells (in the presence or absence of the adenylate cyclase activator, forskolin) displayed a clear genotype/phenotype correlation with the *Pkd1*-KO cells forming abundant spheroids with large lumen sizes as compared with their WT counterparts which did not exhibit almost any lumen formation. In the presence of toyocamycin (up to 500nM), we found an almost complete normalization of the lumen/spheroid area ratio compared with the untreated cells. When the human spheroids were treated with toyocamycin (from 30nM to 1uM), the spheroid area was reduced to baseline levels at all concentrations tested. This was accompanied by an increase in cell death as well as decrease in ATP levels.

Conclusions: Our results describe a relevant 3D spheroid model system in mouse and human ADPKD tubule cells that was employed to test the effect of the Ire1α-XBP1 endoribonuclease inhibitor, toyocamycin, on spheroid formation/growth. We found a very potent effect of toyocamycin on spheroid and lumen size which warrants further *in vivo* investigations.

Glis3 Is a Modifier of Cyst Progression in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Zemeng Wei, Xin Tian, Michael Rehman, Ke Dong, Yiqiang Cai, Adrian Cordido, Stefan Somlo. *Yale University Department of Internal Medicine, New Haven, CT*.

Background: ADPKD is caused by mutations affecting polycystin-1 (PC1) or -2 (PC2). The existence of a 'cilia-dependent cyst activation' (CDCA) pathway has been identified by demonstrating that structurally intact primary cilia are crucial for cyst growth following loss of polycystins. We used translating ribosome affinity purification (TRAP)-RNAseq on precystic mouse kidney cyst cells to determine the translatome that meet the criteria for CDCA and identified Glis2 as an early effector of polycystin signaling. Here, we investigate the potential role of Glis3 which, while not transcriptionally altered, encodes a cilia-localized transcription factor belonging to the same family of proteins as Glis2.

Methods: We used Glis3-EGFP and live cell imaging to study the subcellular localization of Glis3 under ciliated conditions and in the presence or absence of *Pkd1*. We generated *Glis3^{fl}* conditional allele and crossed it with *Pkd1$^{fl/fl}$; Pax8^{rtTA}; TetO^{cre}*mice to investigate the potential genetic interaction in early (postnatal day 14, P14) and adult (14 weeks) ADPKD models.

Results: Live cell confocal imaging of wild type or Pkd1 knockout mIMCD3 cells stably expressing Glis3-EGFP and the Nphp3$^{1-200}$-mApple cilia marker shows that Glis3 is localized in both the nucleus and primary cilium, and its localization does not change upon inactivation of PC1. In the P14 early onset ADPKD model, compared to *Pkd1*-only knockouts, *Glis3;Pkd1*double knockouts have increased kidney-to-body weight ratio, cystic index, and blood urea nitrogen level, indicating a significantly worsening polycystic phenotype. Histological analysis of Glis3-only knockouts shows very occasional and sporadic tubule dilation at P14, which does not affect renal function. Immunofluorescence shows intact cilia in all four genotypes. Consistent with the early model, adult inactivation of both *Glis3;Pkd1* also exacerbates cyst progression. Glis3-only knockouts evaluated at 14-, 18- and 24-weeks are all normal. Transcriptional targets of Glis3 are under investigation through multiple approaches (RNAseq, Cut&Run, and ATACseq).

Conclusions: As a primary cilium localized transcription factor, Glis3 is genetically interacting with Pkd1. Loss of Glis3 exacerbates cystic progression in both early and adult onset ADPKD mouse model.

FR-PO591

Structural Analysis of the Extracellular Portion of Polycystin-1

Sabrina Baldauf,[1] Matthew Gaines,[2] Michael Pilsl,[1] M. Gregor Madej,[1] Olga Maier,[1] Reinhard Rachel,[1] Christine M. Ziegler,[1] Bertram Daum,[2] Ralph Witzgall.[1] *[1]University of Regensburg, Regensburg, Germany; [2]University of Exeter, Exeter, United Kingdom*.

Background: *PKD1* and *PKD2* code for polycystin-1 (PC1) and polycystin-2 (PC2), respectively. Mutations in both of these genes lead to autosomal dominant polycystic kidney disease, yet the precise mechanism of cyst formation is still not completely understood. To learn more about its biological function, we have begun with the structural analysis of the extracellular NH_2-terminus of PC1 that is cleaved through cis-autoproteolysis.

Methods: HeLa cells were stably transfected with an expression plasmid encoding the StrepII-tagged extracellular NH_2-terminus of PC1 (amino acids 1-3074). For recombinant protein purification, the cell culture supernatant was loaded onto Streptactin affinity columns. Fractions of interest were concentrated for further purification by gel filtration, finally the recombinant protein was subjected to mass spectrometry, polyacrylamide gel electrophoresis combined with silver staining, and negative staining with subsequent electron microscopy. The fraction with the highest purity and concentration was plunge frozen for cryo-EM and the micrographs processed with cryoSPARC. Further characterization included deglycosylation, mass photometry and CD spectroscopy. Natural PC1 was purified from urine by sucrose density gradient ultracentrifugation. Fractions containing PC1 were identified by Western blotting and again further purified

by gel filtration. Finally, PC1 was frozen for cryo-EM, and single-particle analysis was performed with Relion and cryoSPARC.

Results: The recombinant extracellular NH_2-terminus of PC1 exists as highly glycosylated monomers. PC1 particles are filamentous and consist mostly of β-sheets as secondary structure elements. In contrast, natural PC1 purified from urine forms a very peculiar structure which can be found in different species. This peculiar structure is also present in recombinant PC1 samples although at a much lower frequency.

Conclusions: The structural characterization of the NH_2-terminus of PC1 opens new opportunities for a better understanding of its biological functions. The COOH-terminus of PC1 requires PC2 for transport, therefore the lower frequency of the peculiar PC1 structure observed in recombinant PC1 may be explained by the absence of PC2 in HeLa cells.

FR-PO592

Guanine Quadruplex DNA in Human PKD1 Reveals a Mechanism for Second-Hit Mutagenesis in ADPKD

Erik D. Larson, Agata M. Parsons, Gerrit J. Bouma, Greg Vanden Heuvel. *Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI.*

Background: Somatic inactivation of the *PKD1* gene causes the cystogenesis characteristic of ADPKD, however the mechanisms of mutagenesis are unresolved. *PKD1* is prone to mutation in humans, but not in mice. Both genes share similar functions, but mice do not faithfully recapitulate ADPKD. A notable difference between the genes is that human *PKD1* is repetitive in sequence, with the potential to form four-stranded guanine-quadruplex (G4) DNAs. G4 DNA structures naturally occur in the genome and have regulatory roles, but if left unresolved they inhibit polymerases and cause DNA breaks and mutagenesis.

Methods: We asked if human or mouse PKD1 form G4 DNA structures in human HEK293T or mouse mIMCD3 cells using chromatin immunoprecipitation and immunofluorescence microscopy with antibodies specific for G4 DNA. DNA break formation at the PKD1 locus was measured by chromatin immunoprecipitation with an antibody specfiic to a chromatin marker for DNA breaks, gammaH2AX.

Results: We found abundant G4 sequences in human, but not mouse, *PKD1*. Immunoprecipitations with a G4-specific antibody enriched for G4-forming regions of human *PKD1* and we observed nuclear G4 DNAs by immunofluorescence microscopy in ADPKD tissue. Antibodies to G4 also colocalizes with the *PKD1* locus, which was identified using a tagged version of dCAS9 targeted to the 3′ end of the gene. Repeat regions in *PKD1* form alternative DNA structures in vitro and stabilization of G4 DNA by culturing HEK cells with the G4 ligand Phen-DC3 resulted in phosphorylation of histone H2AX (gammaH2AX) at *PKD1*. Mouse *Pkd1* did not form G4 DNA or G4-induced DNA breaks.

Conclusions: Our results connect G4 formation with promoting the precursor DNA lesions in human *PKD1* that inactivate the gene, which provokes a pathway of cystogenesis in ADPKD individuals. This reveals a mechanism for second hit mutagenesis of human PKD1 where unresolved G4 DNAs increase the risk of DNA damage, which then leads to loss of heterozygosity and disruption of polycystin-1 activity.

mRNA Translation Reprogramming in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Charlotte Leemans,[1,2] Najla El Hachem,[2] Jean-Paul Decuypere,[3] Djalila Mekahli,[3] Francois Jouret,[1,2] Pierre Close.[2] Laboratory of Cancer Signaling, Laboratory of Translational Research in Nephrology. *[1]Centre Hospitalier Universitaire de Liege, Liege, Belgium; [2]Universite de Liege, Liege, Belgium; [3]Katholieke Universiteit Leuven Universitaire Ziekenhuizen Leuven Campus Gasthuisberg, Leuven, Belgium.*

Background: Global regulation of mRNA translation has emerged as a central mechanism driving cellular adaptation in various diseases. tRNA modifications play a specific role in promoting the reprogramming of mRNA translation. We aim to better understand the importance of mRNA translation reprogramming in the development of cysts in ADPKD.

Methods: Murine inner medullary collecting duct (IMCD) cells knocked out for *Pkd1* by CRISPR-Cas9 were grown *in vitro*. A range of different techniques were used to characterize mRNA translation regulation in these cells. First, we compared the proteome of control or *Pkd1* KO cells by label-free quantitative proteomics. In parallel, we assessed mRNA translation regulation by polysome profiling and OP-Puro incorporation. Finally, we purified tRNAs from cells and we performed a systematic analysis of most of the described tRNA modifications by LC-MS/MS analysis.

Results: We generated lists of proteins that are up- and down-regulated upon loss of *Pkd1* in IMCD cells. We focused on proteins whose expression is upregulated in *Pkd1* KO as compared to controls. Performing Gene Set Enrichment Analyses, we uncovered a series of specific cellular and molecular pathways that are significantly upregulated in *Pkd1* KO cells. We found that "tRNA modification" was enriched in cells KO for *Pkd1*: a series of enzymes, such as Dus3l or Pus10, associated with tRNA modification were specifically upregulated. We plotted enzymes known to regulate tRNA modification and compared their expression in control *versus Pkd1* KO cells. These data were corroborated with a systematic analysis of tRNA modifications. Interestingly, this approach highlighted reproducible changes in specific tRNA modifications between control and *Pkd1* KO cells. Differences in abundance of each tRNA modification were plotted and correlated with catalyzing enzyme expression.

Conclusions: Our data indicate that differences in tRNA modification pattern are observed between control and *Pkd1* KO IMCD cells and could define specific tRNA modification pathways as a new vulnerability targets in cyst formation in ADPKD.

FR-PO594

Cleavage of N-terminus of Polycystin-1 Increases Calcium Permeability of Polycystin-1/Polycystin-2 Receptor Channel Complexes

Runping Wang, Danish Idrees, Mohammad Amir, Biswajit Padhy, Jian Xie, Chou-Long Huang. Huang Lab in Dept of Internal Medicine, University of Iowa. *University of Iowa Health Care, Iowa City, IA.*

Background: Mutations on *PKD1* and *PKD2* encoding PC1 and PC2, respectively, cause autosomal-dominant polycystic kidney disease. It is postulated that PC1 and PC2 form receptor channel complexes. PC1 undergoes N-terminal autocleavage to expose a hidden "stalk" region hypothesized acting as "tethered agonist". Current studies of PC2 channel focus on patch-clamp recording on the primary cilium and gain-of-function (GOF) PC2 in *Xenopus* oocytes. Difficulty to record functional wildtype (WT) PC2 limits the progress on receptor-channel complex hypothesis.

Methods: Xenopus oocytes expressing PC2 ± PC1 or PC1 deletion mutants were recorded by two-electrode voltage-clamp.

Results: Longer expression of WT PC2 in oocytes produced functional channels with similar order of cation selectivity as in primary cilia. PC1 and PC2 formed complexes with unique biophysical properties but same order of cation selectivity as PC2 homomers. Biophysical properties of PC1 and GOF PC2 differ from WT PC1/PC2 heteromers. Deleting PC1 N-terminus to expose the stalk increased calcium permeability of PC1/PC2 heteromers that required the presence of stalk region and intracellular C-terminus. Extracellular application of synthetic stalk peptide increased calcium permeation on stalkless PC1/PC2. Pull-down assays showed Wnt9B interacted with the leucine-rich repeat (LRR) at the N-terminus of PC1. Application of Wnt9B increased calcium permeability of PC1/PC2, but not heteromers containing cleavage resistant mutant PC1. Preincubation with LRR fusion protein prevented the effect of Wnt9B from increasing calcium permeability of the PC1/PC2 complexes.

Conclusions: *Xenopus* oocytes is a good experimental system for studying wildtype polycystin function. PC1 and PC2 form heteromeric receptor-channel complexes that differ from complexes formed by PC1 and GOF-PC2. Wnt9B interacts with LRR in PC1 N-terminus to expose stalk domain of PC1 and activates heteromeric channel including increased calcium permeability. Future studies will include structure-function of the complexes, identification of additional ligands, and further elucidation of regulatory mechanism. Our study provides proof-of-principle for new therapeutic strategies for *PKD1* N-terminal mutations by direct targeting downstream regions such as TOP domain.

Functional Studies of Polycystin-1 Using a Novel Pkd1-HaloTag Mouse

Adrian Cordido,[1,2] Ke Dong,[1,2] Yiqiang Cai,[1,2] Xin Tian,[1,2] Zemeng Wei,[1,2] Michael Rehman,[1,2] Stefan Somlo.[1,2] *[1]Yale University, New Haven, CT; [2]Yale University School of Medicine, New Haven, CT.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a common genetic disease caused primarily by mutations in genes encoding Polycystin-1 (PC1) and Polycystin-2 (PC2). The physiological function of polycystins and the process through which their dysfunction leads to cystogenesis remains unclear. The localized expression of PCs, particularly PC1, in kidney and other tissues has been challenging to detect. HaloTag is a versatile protein labeling system which allows antibody independent covalent ligand-based labeling of the targeted protein and can improve the sensitivity and intensity of the protein localization signals. We applied this system to PC1 in vivo.

Methods: Based in our preliminary data in transfected cells showing that PC1-HaloTag expression can be detected by HaloTag ligand labeling in western blotting and live cell immunofluorescence, we produced a Pkd1-knockin mouse with a C-terminal fusion of 3XHA-HaloTag with PC1 ($PC1^{Halo}$). We characterized the viability and kidney phenotype of the mice and the maturation and expression of $PC1^{Halo}$ by western blotting and confocal immunofluorescence microscopy.

Results: *$Pkd1^{Halo/Halo}$* mice are born in normal Mendelian ratios and have normal renal and liver phenotypes at 6 months age indicating that $PC1^{Halo}$ is fully functional in vivo. Adult induced *$Pkd1^{fl/Halo}$; $Pax8^{rtTA}$; TetO-Cre* mice are also normal. We detected normal

maturation of PC1^{Halo} by western blot of multiple tissue lysates and primary kidney cell cultures from *Pkd1$^{Halo/Halo}$* mice. We detected endogenous PC1^{Halo} in cilia of primary kidney cell culture from *Pkd1$^{Halo/Halo}$* mice by confocal imaging following HaloTag ligand labeling in live cells as well as fixed cells.

Conclusions: PC1 C-terminal fusion with HaloTag produces a fully functional PC1^{Halo} in vivo. Endogenous PC1^{Halo} can be detected in tissue lysates and can be imaged in primary kidney cell cultures. PC1^{Halo} will be a useful tool for exploring native PC1 in vitro and in vivo.

FR-PO596

Adult-Onset Conditional Deletion of Pkd1 and Tulp3 in Mice Exert Different Effects on Kidney Cyst Formation and Mitochondria Phenotypes

Biswajit Padhy, Jian Xie, Danish Idrees, Chou-Long Huang. *University of Iowa Carver College of Medicine, Iowa City, IA.*

Background: Mutations on *PKD1* and *PKD2* coding for PC1 and PC2 cause ADPKD. PC1 and PC2 are widely expressed in multiple subcellular locations. Tulp3 (Tubby-like protein-3) is an adaptor protein that traffics membrane proteins including PC1 and PC2 into cilia. A previous study reported that mice with adult-onset deletion of Tulp3 develop mild cysts at 42 weeks old, much delayed than mice with deletion of Pkd1 or Pkd2. Metabolic reprogramming is an important modifier of ADPKD cystogenesis. The cause of mitochondrial dysfunction in ADPKD remains elusive. Here, we performed side-by-side comparison on kidney cyst and mitochondria phenotypes in mice with adult-onset deletion of Pkd1 & Tulp3 gene, respectively.

Methods: Mice 4- to 6-week-old carrying Pax8-LC1 allele and homozygous Pkd1-floxed allele or Tulp3-floxed allele were treated with doxycycline for 10 days. Kidneys were harvested from mice 16-20 weeks after Doxy induction for analysis of cyst formation and ciliary expression of PC's by H&E-stained histology and immunofluorescent staining, for mitochondria morphology by TEM, and for mito DNA mass and regulator gene expression by RT- PCR.

Results: In mice 14 weeks after Pkd1 deletion vs control, kidneys showed markedly increased cyst index. TEM showed altered mitochondria morphology including decreased mitochondria area, perimeter, cristae number and density, and increased roundness. About 60% mitochondria surface was in contact with ER forming mitochondria-associated ER membranes (MAMs). The distance between ER-mitochondria contact was increased and the length of contact was decreased in Pkd1-cKO. These changes began in precystic stages (4 weeks after Doxy). In contrast, Tulp3-deleted kidneys had relatively normal mitochondria morphology and no cysts. PC1 and PC2 were absent in cilia, but present in extra-ciliary locations of Tulp3-deleted mice. Mitochondria master regulators PGC1α and PPARα, and DNA mass were reduced in Pkd1-deleted kidneys but unchanged in Tulp3-deleted.

Conclusions: Loss of PC1 and PC2 in primary cilia of Tulp3-deleted mice is not sufficient for kidney cyst formation and mitochondria morphological changes as in Pkd1-deleted mice. Extraciliary polycystins are also important. Alternatively, other factors lost in Tulp3-deleted mice may protect against cystogenesis.

Funding: NIDDK Support

Defining Precystic vs. Cystic Alterations in Pkd1 Renal Mutants

Daniel Spies,[1,2] Sara Clerici,[1] Marco Chiaravalli,[1] Gangqi Wang,[3] Laura Cassina,[1] Ton J. Rabelink,[3] Alessandra Boletta.[1] Unit of Cystic Kidneys Disorders - Alessandra Boletta Lab. *[1]IRCCS Ospedale San Raffaele, Milano, Italy; [2]Universita Vita Salute San Raffaele, Milano, Italy; [3]Leids Universitair Medisch Centrum, Leiden, Netherlands.*

Background: ADPKD is among the most prevalent monogenic diseases. Multiple relevant orthologous animal models were generated over the years and helped defining mechanism of disease progression and identifying therapies able to retard end-stage-kidney-disease. We have previously reported that PKD tissue is characterized by a profound metabolic reprogramming. However, the initial stages of renal cystogenesis and whether metabolic re-programming is an early or late event in disease evolution is unknown. Identification of the cellular alterations occurring at the onset of cystogenesis would provide important information on mechanism of disease. Here we present a strategy aimed at identifying the earliest events occurring immediately after inactivation of the Pkd1 gene

Methods: Inducible Cre lines were used to inactivate the *Pdkd1* gene at different time-points. Characterization was done by IHC and IF analysis. For spatial metabolomic tracing 350μm thick kidney sections were incubated with either 13C labeled Glucose, Glutamine or Linoeleate before being sectioned into 10μm thick slices and subjected to MALDI-MS followed by multiplexed IF staining

Results: We developed a tamoxifen-inducible *Pkd1* mouse model carrying a fluorescent switch cassette (mT/mG) that allows identification of cells in which the Cre recombinase has been activated to study the initiating events in cystogenesis. Induction by 3 low dose injections of Tamoxifen resulted in cyst formation within two weeks. 5 days after the last injection we identified renal tubules completely green, but not cystic, while 8 days post injection green cells started to form cysts. mKspCrePkd1fl/fl;mT/mG kidneys were collected at 5 or 8 days post inactivation, and subjected either to spatial metabolic tracing by incubation with 13C labeled Glucose, Glutamine or Linoeleate followed by MALDI- MS, or subjected to scRNAseq. Data are being analyzed and the preliminary results will be presented

Conclusions: We have generated and characterized an inducible *Pkd1* mouse model that enables the study of two time windows: cells are *Pkd1* mutated but not yet cystic and cells are inactivated and cystic, in both cases carrying a GFP cassette for tracking. Our combined analysis of scRNAseq and spatial metabolic tracing will provide the first glimpse on changes of likely causative and consequential events in cyst initiation

FR-PO598

Methylation-Controlled J Protein as a Target to Alleviate Kidney Fibrosis and Cyst Growth

Marie-Louise T. Monaghan, Isabel A. Layne, Jelena Klawitter, Evgenia Dobrinskikh, Alyx E. Gray, Raphael A. Nemenoff, Michel Chonchol, Seth B. Furgeson, Katharina Hopp. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Kidney mitochondrial function is abnormal in autosomal dominant polycystic kidney disease (ADPKD) with reduced aerobic glycolysis/oxidative phosphorylation (OXPHOS). Methylation-controlled J protein (MCJ) is the only endogenous inhibitor of electron transport chain (ETC) Complex I. Loss of MCJ enhances Complex I activity, increasing OXPHOS/ATP generation, without increasing reactive oxygen species (ROS). In liver injury models, MCJ genetic or siRNA-based (siMCJ) depletion lessens liver pathology by improving OXPHOS.

Methods: We mined published/in house single nucleus/cell (sn/sc) RNAseq data of human and murine normal and ADPKD kidney samples to assess MCJ expression and mitochondrial gene set enrichment (GSE). In mice (WT/*Pkd1*$^{RC/RC}$), we assessed kidney purine metabolites via LC-MS/MS. Using unilateral ureteral obstruction (UUO) and *Pkd1*$^{RC/RC}$ mice on the MCJ$^{-/-}$ background, we assessed MCJ's role in mediating kidney fibrosis and kidney cyst growth. Fluorescence Lifetime Imaging Microscopy (FLIM, quantification of free NADH) and Electron Paramagnetic Resonance Spectroscopy (EPRS) were used to assess kidney OXPHOS and ROS levels. IV injection of naked siMCJ to WT mice was tested as a therapeutic strategy.

Results: Analysis of sn/sc RNAseq revealed global MCJ expression in kidney epithelia, with a significant increase in human ADPKD samples. GSE analyses identified OXPHOS, ATP production, and ETC as the most differentially regulated pathways in WT vs *Pkd1*$^{RC/RC}$ collecting ducts. LC-MS/MS revealed reduced energy charge (1.28-fold) and ATP/ADP ratio in *Pkd1*$^{RC/RC}$ vs WT kidneys (1.34-fold). MCJ$^{-/-}$ vs MCJ$^{+/+}$ mice had reduced kidney fibrosis 2wks post UUO (10.2% vs 14.5% fibrosis, $p<0.001$). 3mo old *Pkd1*$^{RC/RC}$;MCJ$^{-/-}$ vs *Pkd1*$^{RC/RC}$;MCJ$^{+/+}$ mice had reduced kidney/body weight (0.77-fold, $p<0.001$) and computed cyst volume (1.55-fold, $p<0.05$). FLIM showed increased OXPHOS in *Pkd1*$^{RC/RC}$;MCJ$^{-/-}$ vs *Pkd1*$^{RC/RC}$;MCJ$^{+/+}$ mice, but without increasing kidney ROS levels (EPRS). Lastly, IV injected siMCJ resulted in significantly reduced kidney MCJ levels.

Conclusions: These findings suggest that targeting MCJ corrects abnormal kidney mitochondrial function and altered metabolic pathways that contribute to kidney fibrosis and cyst growth.

Three-Dimensional Imaging and Genetic Characterisation of a Rat Model of Polycystic Kidney Disease

Maria K. Ougaard, Frederikke E. Sembach, Michael Christensen. *Gubra, Hørsholm, Denmark.*

Background: Polycystic kidney disease (PKD) is a congenital fibrocystic disorder for which there is no curative treatment. Consequently, PKD is classified as a medical condition with high unmet therapeutic need. Animal models with improved clinical translatability can optimally inform about potential efficacy of novel drug candidates for PKD. The polycystic kidney (PCK) rat is an established genetic model of PKD with natural history and renal histologic abnormalities that resemble the human disease. Gubra has established a PCK rat breeding program to enable fast turnaround time of preclinical drug discovery studies for PKD. In this study, we have characterised disease progression in the PCK rat to aid in designing future pharmacological intervention studies.

Methods: Male PCK (PCK/CrljCrl-Pkhd1pck/Crl) and control (CRL:CD(SD)) rats were randomised into groups based on body weight at the age of 10 weeks. At the age of 17 and 25 weeks, rats underwent urine collection for quantification of albuminuria, and plasma sampling for analysis of urea and creatinine levels. At termination, kidneys were collected for RNAseq and imaging where 3D and total kidney volume, cyst number and volume were analysed using quantitative 3D light sheet imaging.

Results: Compared to age-matched controls, PCK rats displayed marked albuminuria at 25 weeks of age. Plasma urea was progressively increased at both 17 and 25 weeks, while plasma creatinine was only increased at week 25. 3D light sheet imaging enabled whole-kidney counting of cysts and quantification of cyst volume (control: 11 mm^3 vs 25 wks.: 414 mm^3) as well as the total kidney volume. The PCK rats displayed differentiated expressed genes associated with angiogenesis, cellular stress, extracellular matrix remodelling, and inflammation.

Conclusions: The PCK rat displays hallmarks of PKD, characterized by age-dependent progressive increase in biomarkers and regulation of genes associated with kidney injury, kidney hypertrophy and cyst formation. Quantitative whole-kidney 3D light sheet imaging is highly instrumental for detailed assessment of progressive kidney disease in the PCK rat. Accordingly, these imaging modalities are instrumental as key endpoints for assessment of potential therapeutic effects of preclinical drug candidates in the PCK rat model.

Studying Macrophage Phenotype and Function in Slowly Progressing Models of PKD

Fariha Nusrat, Sarah J. Miller, Marybeth Humphrey, Kurt Zimmerman.
The University of Oklahoma Health Sciences Center, Oklahoma City, OK.

Background: Macrophages have been associated with the progression of polycystic kidney disease (PKD) for several decades. While data suggest that macrophages promote cyst progression through the production of pro-inflammatory cytokines, the majority of data supporting this paradigm were collected using rapidly progressing mouse models of disease. The phenotype and function of macrophages in slowly progressing forms of the disease remain poorly understood.

Methods: To understand how the rate of PKD progression impacts macrophage phenotype and function, we generated a comprehensive single-cell RNA sequencing (scRNAseq) atlas of kidney resident macrophages (KRM) isolated from slowly and rapidly progressing models of PKD as well as non-cystic controls.

Results: Using single-cell RNA sequencing (scRNAseq), our lab identified a subset of kidney resident macrophages (KRM), termed *Trem2*+ cyst associated macrophages (CAM), that were highly enriched in slowly progressing mouse models when compared to rapidly progressing models and non-cystic controls. *Trem2*+ CAM had an enrichment of genes associated with phagocytosis and the lysosome. Functional analyses indicate that *Trem2*+ CAM also had enriched lysosomal activity compared to total KRM and were located adjacent to apoptotic cystic epithelium, suggesting these cells may be restricting PKD progression through phagocytosis and lysosomal degradation of the apoptotic cystic epithelium (efferocytosis). To test this hypothesis, we crossed two PKD mouse models (*Ift88* and *Pkd1*$^{RC/RC}$) to the *Trem2*-/- background. Analysis of preliminary data indicate that loss of *Trem2* significantly worsened cystic disease as measured by 2KW/BW and BUN. Further, loss of *Trem2* resulted in increased apoptotic cystic epithelium.

Conclusions: Collectively, our data suggest that *Trem2*+ CAM restrict cyst progression through phagocytosis and lysosomal degradation of the apoptotic cystic epithelium.

Cell State Transition Associated with Cyst Development in Autosomal Dominant Polycystic Kidney Disease

Hyun Jun Jung,[1] Patricia Outeda,[2] Owen M. Woodward,[2] Terry J. Watnick,[2] Paul A. Welling.[1] *[1]The Johns Hopkins University School of Medicine, Baltimore, MD; [2]University of Maryland School of Medicine, Baltimore, MD.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD), caused by genetic mutations in the Polycystin genes (Pkd1 and Pkd2), is the most common form of polycystic kidney disease, characterized by the development of cysts in the kidneys. Mechanisms underlying the initiation of cystogenesis are poorly understood, but developmental stage plays an important role. In mouse models, cyst formation is greatly accelerated when Pkd1/2 genes are knocked out before postnatal day 13 (P13), leading severe cyst development within weeks, compared to months when Pkd1/2 knockout is induced after P13. Here, we investigated the molecular signature of cell state transitions around P13 underlying the dynamic changes in the initiation of cyst development.

Methods: To identify transcriptomic signatures and their changes associated with cell state transitions around P13, single nucleus RNA sequencing (snRNA-Seq) was performed on whole kidneys obtained from mice with an intact Pkd2 gene (Pkd2$^{fl/fl}$; Pax8-rtTA; TetO-Cre-) at P13 and P15. Nuclei (n=2 per group, 54,324 nuclei) isolated from whole kidneys were analyzed using 10x Chromium and NovaSeq6000 (50,000 read pairs per nucleus). Data were processed and analyzed using CellRanger and Seurat.

Results: snRNA-Seq identified kidney cell populations according to known kidney cell types. At both P13 and P15, a cell proliferation signature was observed in subpopulations of proximal tubule, loop of Henle, and distal tubule cells. Differential gene expression analysis (P13 vs P15) identified 142 genes commonly changed in proliferative tubular cells and revealed that these genes were enriched in calcium signaling. Further analysis of proliferative tubular cell subclusters identified 6 common genes (A330015K06Rik, Dapk2, Exoc3l2, Gli2, Greb1, and Slc14a2) and revealed that the cell proliferation signature was less prominent at P15 compared to P13. Additionally, 48 genes encoding secretory proteins exhibited cell type-selective changes within proliferative cell subpopulations.

Conclusions: We identified a transcriptomic signature of a proliferative cell state and their changes between P13 and P15. This study offers a valuable resource for understanding cell state transitions in proliferative epithelial cells, potentially implicated in the development of cystogenesis in ADPKD.

Investigating the Biogenesis and Degradation of Polycystin 2 Missense Mutants

Christopher J. Guerriero, Marcelo D. Carattino, Jeffrey L. Brodsky.
University of Pittsburgh, Pittsburgh, PA.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a prevalent inherited disorder and cause of end-stage renal disease. ADPKD arises from mutations in *PKD1* and *PKD2*, which encode polycystin 1 (PC1) and polycystin 2 (PC2). These mutations lead to aberrant signaling, cell proliferation, and fluid secretion. Given its size, complexity, and primary localization to the endoplasmic reticulum (ER), we hypothesize that PC2 missense mutants may misfold and be degraded by the ER-associated degradation (ERAD) pathway.

Methods: Disease-causing PC2 variants that were computationally predicted to be folding defective were expressed in *S. cerevisiae* and HEK293 cells to evaluate their stability and function. Stability and poly-ubiquitination levels were measured in the presence or absence of a proteasome inhibitor (MG132). TEVC studies in *Xenopus* oocytes and cell surface biotinylation revealed PC2 activity and cell surface residence. We tested the ability of PC2 missense variants to rescue growth in yeast lacking two plasma membrane potassium transporters and determined response to cold temperature correction and chemical chaperones.

Results: Select PC2 missense mutants exhibited more poly-ubiquitination and were degraded faster than wild-type PC2 in both yeast and HEK293 cells. Treatment with MG132 increased poly-ubiquitinated protein levels, suggesting proteasomal turnover of these mutants. The yeast growth assay reports on protein folding, assembly, trafficking, and activity; some mutants failed to rescue yeast growth, while others exhibited normal growth. Incubation at lower temperatures improved growth of select mutants, perhaps indicating a potential for pharmacological rescue. Some yeast growth defects were recapitulated in oocytes, validating our yeast model system. Finally, surface biotinylation of PC2 variants in HEK293 cells showed reduced amounts of unstable PC2 missense variants at the cell surface, which may contribute to the ADPKD phenotype.

Conclusions: While some PC2 alleles are stable yet dysfunctional, suggesting trafficking defects or impaired ion transport as the source of dysfunction, we find that select PC2 missense mutants are targeted for the ERAD pathway. Protein folding modulators are a rapidly expanding therapeutic strategy for ERAD-related diseases, and based on our data some PC2 mutants would be amenable to pharmacological correction.

Studying the Involvement of the Complement Receptor C5ar1 in Polycystic Kidney Disease

Audrey M. Cordova,[1] Aaron Pan,[1] Bibi Maryam,[1] Katharina Hopp,[2] Kurt Zimmerman.[1] *[1]The University of Oklahoma Health Sciences Center, Oklahoma City, OK; [2]University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Polycystic Kidney Disease (PKD) is caused by mutations in cilia-related genes and results in fluid-filled cysts throughout the kidney. Previous data indicates that immune cells, in particular macrophages, are important in regulating the progression of cystic disease. To understand possible functions of macrophages in cystic kidney disease, our lab performed single cell RNA sequencing (scRNAseq) on macrophages isolated from control and cystic mice. scRNAseq data indicate that kidney resident macrophages isolated from cystic mice have increased expression of the complement 5a receptor 1 (*C5ar1*) gene. C5ar1 is a G-protein coupled receptor that binds to the anaphylatoxin C5a that promotes inflammation and macrophage recruitment.

Methods: To test the importance of *C5ar1* in cyst progression, we crossed *C5ar1* deficient mice onto two different cystic backgrounds (*Pkd1*$^{RC/RC}$ and Cagg Cre^{ERT2} *Ift88*$^{fl/fl}$) and analyzed PKD severity and immune cell numbers using flow cytometry.

Results: Preliminary analysis of *Pkd1*$^{RC/RC}$ *C5ar1*-/- mice at three months of age indicate no effect on PKD phenotype compared to controls. In contrast, loss of *C5ar1* significantly worsened the PKD phenotype in *Pkd1*$^{RC/RC}$ mice compared to controls at 1 year of age. Likewise, loss of *C5ar1* in adult induced *Ift88* mice resulted in worsened PKD phenotype when analyzed 6-7 months post induction (~9 months of age). Analysis

of flow cytometry data in 1 year old *Pkd1*$^{RC/RC}$ and 9 month old *Ift88* mice revealed that loss of *C5ar1* resulted in significantly more Ly6c^{lo} monocytes, CD4+ T cells, and CD8+ T cells compared to controls. Surprisingly, loss of *C5ar1* resulted in significantly fewer *Mrc1+/Trem2+* KRM in *Pkd1*$^{RC/RC}$ mice but significantly more *Mrc1+/Trem2+* KRM in *Ift88* mice.

Conclusions: Collectively, our data suggest that *C5ar1* restricts PKD progression, possibly through modulation of adaptive immune cell accumulation.

FR-PO604

Polycystins Regulate Ezrin Function and Cleavage to Control Renal Cell and Tubular Morphology

Ava M. Zapf, Eryn E. Dixon, Denis Basquin, Terry J. Watnick, Owen M. Woodward. *University of Maryland School of Medicine, Baltimore, MD.*

Background: Renal cyst formation in ADPKD requires altered cell and tubular morphology. Previously, we used inducible inactivation of *Pkd2* in a 3D-tubuloid model to measure acute changes in tubuloid shape after *Pkd2* loss and observed alterations in tubule morphology before changes in overall volume, arguing that morphological changes are among the first consequences of polycystin loss. We hypothesized a direct role for the polycystin complex in regulating the apical cytoskeleton protein, ezrin (EZR), to control cell and tubular morphology.

Methods: We used clonal cell lines derived from the kidneys of *Pkd1 or Pkd2* Pax8rtTA TetOCre mice crossed with the SV40 immorto-mouse: *Pkd1-iKO* (#313) and *Pkd2-iKO* (#125). *Pkd1/2* can be efficiently deleted with addition of Doxycyline (DOX) to the cell media.

Results: We observed a strong correlation between the loss of *Pkd1/2* and increased apical cell area, as defined by ZO1, in 2D *Pkd1/2-iKO* cells. The acute loss of *Pkd1/2* also resulted in decreased ezrin abundance and altered localization. Although *Pkd1/2* deletion resulted in decreased ezrin we found upregulation of *Ezr* mRNA in both the DOX treated *Pkd2-iKO* cells and in human ADPKD cystic tissue, leading us to hypothesize that PC1/2 regulates ezrin protein more directly. Immunoprecipitation experiments of HEK293 cells transfected with ezrin, Myc-PC2 or Flag-PC1 showed both PC1 and PC2 successfully pulled down ezrin sugesting a protein interaction. Interestingly, the pull down efficiency was greater with the full length PC1 than the CTF-PC1 fragment. To confirm an endogenous interaction between ezrin and PC1 we isolated primary renal epithelial cells from a transgenic *Pkd1-HA* mouse and found again HA-PC1 successfully pulled down ezrin. Mechanistically, ezrin activity is regulated by cystine proteases calpain 1 and 2. We observed a substantial increase in the N-terminal 55KDa ezrin cleavage product after acute *Pkd2* loss in the DOX treated *Pkd2-iKO* cells as well in human APDKD cystic tissue. Chemical inhibition of either calpain 1 or calpain 2 led to increased ezrin cleavage in control cells mimicking *Pkd2* loss. However, inhibition of both calpain 1 and 2 reduced ezrin cleavage in DOX treated *Pkd2-iKO* cells to levels comparable to control cells.

Conclusions: The polycystin proteins regulate ezrin function and cleavage to control renal cell and tubular morphology.

Tubule-Specific Deletion of Adamts1 Slows Cyst Expansion in Polycystic Kidney Disease

Vijayakumar R. Kakade, Zafer Akman, Manga Motrapu, Lloyd G. Cantley. *Yale University, New Haven, CT.*

Background: Autosomal dominant polycystic kidney disease is caused by mutations in either the PKD1 or PKD2 genes leading to cyst growth. We have shown that with loss of Pkd1 the tubules can enlarge without an increase in tubular cell numbers, suggesting that tubular basement membrane (TBM) remodeling is important for cystic dilation. Bulk RNAseq and qPCR analysis of metalloproteinases showed that A Disintegrin and Metalloproteinase with Thrombospondin Motif 1 (Adamts1) expressed by proximal tubule is the most significantly upregulated metalloproteinase following loss of Pkd1 expression. We now show that Adamts1 promotes cyst growth following Pkd1 loss.

Methods: Mice were developed with inducible tubule-specific knockout of Pkd1 alone (Pkd^{TKO}) or both Pkd1 and Adamts1 (P/A^{TKO}) using doxycycline induction at age 4-6 weeks. Uninduced (UI) mice were used as controls.

Results: At 12 weeks age, P/A^{TKO} mice showed less kidney enlargement than Pkd^{TKO} mice (KW/BW ratio 0.009±0.003 vs 0.017±0.01 respectively, p<0.05) and a lower cyst index (29.1±7.2 vs 44.2±6.1 respectively, p<0.01) (Fig 1). Western blot showed a 2.5-fold increase in the 70kDa V1 neoepitope of the Adamts1 cleavage substrate versican that was prevented in P/A^{TKO} kidneys, with IF localizing the cleaved versican to the TBM in Pkd^{TKO} kidneys (Fig 2). The 70kDa cleaved versican, named versikine, has been shown to activate macrophage. Our data confirm that the decreased versikine levels in P/A^{TKO} kidneys correlate with a significant reduction in peritubular macrophage accumulation compared to Pkd^{TKO} kidneys.

Conclusions: Adamts1 is upregulated with the loss of Pkd1 expression, resulting in versican cleavage in the TBM with enhanced cyst formation and accelerated loss of kidney function.

Funding: Other U.S. Government Support

Role of Valosin-Containing Protein (VCP) in Ciliary Morphology and ADPKD: Exploring VCP as a Novel Genetic Interactor in Disease Progression

Carlotta Pioppini,[1] Rishi Bhardwaj,[2] Sorin V. Fedeles,[2] Duygu Elif Yilmaz,[1] Matteus Krappitz.[1] *[1]Charite Universitatsmedizin Berlin, Berlin, Germany; [2]Yale University, New Haven, CT.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a hereditary disorder characterized by the progressive development of fluid-filled cysts in the kidneys, leading to organ enlargement and functional impairment. The main causative genes encode for the ciliary proteins PC1 and PC2, which position ADPKD amidst the spectrum of ciliopathies. Within PKD1-deficient cells, the accumulation of misfolded PC1 and PC2 proteins triggers the unfolded protein response (UPR). In this study, we investigated the genetic relationship between an associated interactor of the UPR, Valosin-containing protein (VCP), and PC1 dependent cystogenesis. Finally, we elucidate VCP's dual engagement as a ciliary protein, as well as its regulatory role in cilia morphology.

Methods: IMCD3^{wt} and IMCD3$^{Pkd1-/-}$ were treated with both pharmacological inhibitor of VCP or anti-VCP siRNA for 24 hours. Gene and protein expressions were detected respectively via qRT-PCR and western blotting. CelltiterGlo viability assay was used for cell viability analysis. Primary cilia were isolated from Pkd1$^{V5/+}$ cells and cilia localization of VCP was detected via confocal microscopy.

Results: VCP was identified as a ciliary protein in renal epithelial cells. By inhibiting VCP using pharmacological agents and siRNA-mediated genetic suppression, ciliary length was decreased for both treatments. Importantly, inhibition of VCP selectively decreased the viability of Pkd1 deficient cells by upregulating ER-dependent apoptotic pathways. This selective response highlights a novel therapeutic approach for targeting cells responsible for cyst development in ADPKD. The findings suggest that VCP is involved in ciliary dynamics but also in cellular survival mechanisms underpinning cystogenesis.

Conclusions: This study confirms the critical involvement of VCP in regulating ciliary morphology and suggesting its potential as a therapeutic target in ADPKD. By proving that VCP inhibition selectively reduced the viability of Pkd1 deficient cells while increasing ER-dependent apoptosis, our research implicates VCP as a novel viability factor of cyst lining cells. These novel insights open new perspectives for the development of targeted therapies aimed at modulating ciliary morphology and inducing apoptosis in cyst-forming cells.

Mitochondria-Targeted Antioxidant Therapy Ameliorates Arterial Dysfunction in a Mouse Model of Autosomal Dominant Polycystic Kidney Disease

Nidhi Dwivedi, Brittany A. Stone, Zachary S. Clayton, Michel Chonchol, Berenice Y. Gitomer, Katharina Hopp, Vienna E. Brunt. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Cardiovascular diseases (CVD) are the leading cause of death in adults with ADPKD in part due to arterial dysfunction, e.g. endothelial dysfunction and aortic stiffening. ADPKD-associated arterial dysfunction appears to be mediated by impaired nitric oxide (NO) bioavailability secondary to excess mitochondria-derived reactive oxygen species. We tested efficacy of oral supplementation with mitochondrial antioxidant MitoQ (MQ) for improving arterial function in an orthologous mouse model of ADPKD.

Methods: Male/female C57Bl/6J *Pkd1*$^{RC/RC}$ mice were supplemented with 250 μM MQ in drinking water from 4-10 mo of age (i.e. mild to severe kidney disease) vs control water (n=5-8/group/sex). At intervention end, we assessed *in vivo* aortic stiffness as aortic pulse wave velocity (PWV) and endothelial function as endothelium-dependent dilation (EDD) to acetylcholine in isolated carotid arteries. Aorta rings were collected to assess aortic elastic modulus (EM), a measure of stiffness that isolates structural factors, and for histology. Key assessments were also made in wildtype (WT) mice (n=9/sex). Data are mean±SD. Stats are 1-way ANOVA with Tukey's post-hoc.

Results: Control *Pkd1*$^{RC/RC}$ (CONT) mice had impaired carotid artery EDD (peak EDD: 79±11 vs WT: 95±3 %, P<0.001) that was ameliorated by MQ (91±6%, P<0.01) via enhanced NO bioavailability (Δpeak EDD ± the NO synthase inhibitor L-NAME, CONT: 32±21 vs MQ: 48±10 %, P=0.03). There were no sex differences for endothelial function. Aortic PWV was higher in CONT *Pkd1*$^{RC/RC}$ vs WT mice (males: 447±36 vs 346±29 cm/s; females: 426±17 vs 369±26 cm/s; both P<0.01). MQ attenuated *in vivo* aortic stiffening in male (400±15 cm/s, P=0.02) but not female (427±39 cm/s, P>0.99) mice, and also lowered aortic *ex vivo* stiffness in male mice only (EM, CONT: 6437±1477 vs MQ: 4691±1790, P=0.08). However, aortic medial collagen content (Masson-trichrome, CONT: 25±12 vs MQ: 17±12%; P=0.05) was lower with MQ in both sexes, suggesting reduced fibrosis.

Conclusions: MQ supplementation in an orthologous model of ADPKD improves conduit artery endothelial function and arterial stiffness, although there may be some sex differences in efficacy. MQ represents a promising strategy for treating arterial dysfunction, and thereby reducing CVD risk, in ADPKD.

FR-PO608

IP1 Deletion Rescues Kidney Cyst Formation in Pkd1 KO Mouse Models

Ario Mohammadi,[1] Davoud Ghazanfari,[1,2] Armaghan Ayub,[1] Erica Zhou,[1] Jing Zhou.[1,2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: ADPKD (Autosomal Dominant Polycystic Kidney Disease) is a genetic disorder characterized by the development of multiple cysts in the kidneys. The disease is caused by mutations in *PKD1* and *PKD2*, encoding PC1 and PC2 respectively. To date, PC1 and PC2 have been implicated in modulating a number of cellular events such as Ca^{2+} signaling, mTOR, cyclic AMP, Wnt, PCP, and STAT3 pathways. Currently, there is limited knowledge regarding the mechanism(s) by which the *PKD1/2* mutations dysregulate these signaling pathways. Our research group and others have reported that simultaneous loss of genes including *ift88*, *Wdr19*, and *CRTC2*, in *Pkd1* KO mice models rescues cystogenesis and disease progression demonstrating potential therapeutic targets to attenuate ADPKD. It has been reported that IP1 forms a complex with PC1 and regulates multiple biological functions critical in ADPKD. Thus, IP1 is a potential therapeutic target for ADPKD.

Methods: Mice homozygous with an inducible mutation in *Pkd1* or *Pkd1IP1* genes were generated by intraperitoneal injection of tamoxifen at 3 weeks postnatal. Mice were dissected after 10 weeks. Kidney/BodyWeight (K/BW) ratios were calculated to analyze phenotype changes in the *Pkd1* KO and *Pkd1IP1* DKO mice. Various techniques such as immunohistochemistry, immunostaining, and western blotting were utilized for analysis and validation.

Results: To see if *IP1* deletion rescues *Pkd1* KO-induced cystogenesis, the *Pkd1* KO and *Pkd1IP1* DKO mice were dissected and kidneys were harvested at 10 weeks PI. The (K/BW) were significantly increased in the *Pkd1* KO mice and significantly reduced in the *Pkd1IP1* DKO. Histology analysis confirmed cyst formation in the *Pkd1* KO mice and that *IP1* deletion reduced cystogenesis. Immunostaining analysis revealed that cilia were significantly shortened in the DKO mice compared to the *Pkd1* KO mice. The western blotting analysis revealed that integrin α6 expression and Wnt and mTOR signaling pathways are dysregulated in the *Pkd1* KO mice, which was significantly reduced in the DKO mice. Further analysis is being conducted to gain more insight into the mechanism by which *IP1* deletion rescues ADPKD.

Conclusions: IP1 is a novel therapeutic target to rescue ADPKD. In vivo analysis revealed that *IP1* deletion rescues *Pkd1* KO-induced cytogenesis and shorten elongated cilia and corrected Wnt and mTOR signaling pathways in *Pkd1* KO mouse model.

FR-PO609

Segment-Specific Cyst Index (SSCI): A Quantitative Analysis of Segment-Specific Responses during Cystogenesis

Zafer Akman, Vijayakumar R. Kakade, Lloyd G. Cantley. *Yale University School of Medicine, New Haven, CT.*

Background: Polycystic kidney disease (PKD) is a genetic disease in which loss of polycystin-1 or 2 causes tubular segments to undergo proliferation and dilation leading to progressive renal dysfunction. We developed SSCI to better quantify segment-specific responses during cystogenesis

Methods: Immunofluorescence microscopy using *Lotus tetragonolobus lectin* to identify proximal tubule (PT); uromodulin for thick ascending limb (TAL); calbindin for distal convoluted tubule (DCT); and *Dolichos biflorus agglutinin* for collecting duct (CD) was performed on cortex images from *Pkd1*$^{fl/fl}$*;Pax8-rtTA;TetO-Cre* mice (treated ± doxycycline from 4-6 weeks) at 8 and 12 weeks. Lumen and tubular area quantification for each cortical tubule segment was determined by manual masking in 5-7 randomly assigned boxes. The SSCI was expressed as ratio of lumen to tubular area percentage.

Results: Uninduced (UI) control kidneys showed a slight increase in SSCI from 8 to 12 weeks in all segments likely related to growth-induced GFR increases. Pkd1 tubule knock-out (Pkd^{TKO}) led to progressive dilation of all segments. Consistent with previous observations, CD exhibited the greatest SSCI (46% at 8 weeks and 62% at 12 weeks), with PT, TAL, and DCT showing less lumen dilation (10%, 11%, and 21% at 8 weeks, and 34%, 30%, and 37% at 12 weeks, respectively). Because CD had a significantly higher baseline SSCI in UI kidneys than all other segments, the fold-increase in SSCI following Pkd1 loss was the least in CD compared to the other 3 segments (3.7-fold for CD vs 7.4-fold for PT; 4.4-fold for TAL; and 7.3-fold for DCT).

Conclusions: SSCI reveals that Pkd1 loss caused expansion of all segments at 8 and 12 weeks, with the greatest lumen area found in CD. However, CD exhibited the least fold increase in SSCI following loss of Pkd1, suggesting that the CD, despite being the most cystic, may respond less to the loss of Pkd1 than other segments

Funding: Other U.S. Government Support

FR-PO610

Labeling of Denatured Collagen in ADPKD and Comparison to Fibrotic Area

Caroline R. Sussman, Heather L. Holmes, Mohamed A. Addani, Seth M. Entriken, Damon A. Montgomery, Angel M. Obiorah, Vibhuti Amin, Kevin L. Webb, Deema Anaam, Diana Alzamareh, Slobodan Macura, Vicente E. Torres, Timothy L. Kline, Michael F. Romero, Peter C. Harris. *Mayo Foundation for Medical Education and Research, Rochester, MN.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the fourth most common cause of kidney failure, and manifests through the proliferation of countless kidney cysts. Mounting research suggests the extracellular matrix (ECM) is integral to disease progression. Collagen, the predominant protein within the ECM, is encoded by 44 genes, forming intricate supramolecular structures that constitute 28 distinct collagen types. Methods used in ADPKD for tracking total collagen histologically are primarily trichrome or Picrosirius red (PSR) staining to determine percent fibrotic area. Besides fibrosis, destruction of collagen assemblies is a hallmark of tissue injury and disease. We examined here if denatured collagen is a more sensitive disease indicator than fibrotic area.

Methods: *Pkd2*^{hi4166} zebrafish were used with heterozygous adults compared to sibling WT. *Pkd1*$^{RC/RC}$ mice were used in C57BL/6J and compared to wildtype (Jackson Laboratory). Collagen hybridizing peptide (CHP, 3Helix) was used for fluorescence labeling of denatured collagen. CHP labeling was compared to fibrotic area determined from PSR staining. PSR staining, CHP labeling, and tissue area were calculated using ImageJ. Data are shown as mean ± SEM, p-values by t-test or ANOVA.

Results: CHP labeling surrounded 47.9% ± 14.5 of tubules in *pkd2*$^{+/-}$ zebrafish (n=8 fish), while no labeling was seen in WT (n=10; p=0.002). Labeling occurred around both proximal tubules/collecting ducts (LTL+; 41.7% ± 25.0, n=4) and distal tubules (DBA+; 54.0% ± 18.2, n=4). Labeling in mouse was not clearly associated with individual tubules and was present in normal and cystic regions. Quantification of fluorescence-tagged CHP in entire kidney sections showed more labeling in *Pkd1*$^{RC/RC}$ mice (581 au ± 68.3; n=6 mice) vs WT (341 au ± 14.4; n=6; p=0.006).

Conclusions: Denatured collagen labeling by CHP showed more consistent differences than fibrotic area by PSR. Additionally denatured collagen was detected distant from cysts in *Pkd1*$^{RC/RC}$ mice and in *pkd2*$^{+/-}$ zebrafish which lack cysts. These data suggest measuring denatured collagen may allow more reliable and sensitive detection of collagen changes in ADPKD than fibrotic area.

FR-PO611

Role of Ankyrin Repeat and Single KH Domain 1 in Autosomal Dominant Polycystic Kidney Disease Pathogenesis and CyclinD1/CDK4-Induced Proliferation

Maria-Eirini Terzenidou,[1,2] Fiona Macleod,[1,2] Maria Fragiadaki.[1]
[1]Queen Mary University of London Faculty of Medicine and Dentistry, London, United Kingdom; [2]The University of Sheffield Faculty of Medicine Dentistry and Health, Sheffield, United Kingdom.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common genetic cause of renal failure worldwide. It is a multisystem and progressive disease presenting with renal cyst formation, kidney enlargement, and extrarenal organ involvement. ADPKD involves mutations in *PKD1*, which encodes for polycystin-1 (PC1), and accounts for 85% of ADPKD cases, and *PKD2*, which encodes for polycystin-2 (PC2), and contributes to 15% of cases. PC1 and PC2 play a crucial role in controlling cell proliferation, while mutations in these proteins lead to uncontrolled proliferation, is a driver of ADPKD. The only clinically approved medicine for ADPKD, Tolvaptan, has limited use due to its high cost and adverse effects, e.g. liver failure. It is crucial to develop new therapeutic approaches. Ankyrin Repeat and single KH Domain 1 (ANKHD1) is a cancer-associated protein, which drives uncontrolled cellular proliferation and growth and has never been studied in ADPKD previously. We report that ANKHD1 drives excessive proliferation in mouse and human models of ADPKD.

Methods: We used immunostaining and advanced microscopy along with Western blotting. We performed our experiments in mouse models of ADPKD and patient-derived cell lines.

Results: In this study, we find that ANKHD1 protein levels are elevated in human and murine models of ADPKD and localise in cyst-lining cells. ANKHD1 knockdown in human ADPKD-derived epithelial cells or knockout of ANKHD1 in mouse tissues results in reduced proliferation, slower cystic growth in vitro and smaller kidneys in vivo; critically leading to improved renal function. To gain mechanistic insight we coupled RNA-seq with RNA immunoprecipitation (RIP)-seq, revealing that ANKHD1 controls the CDK4/cyclin D1 axis by binding to CDK4 mRNA. ANKHD1 mediates enhancement of CyclinD1/CDK4 activity via increased retinoblastoma phosphorylation (pRB). This is a p19-dependent and p53/p21-independent mechanism.

Conclusions: Taken together, we find a novel key role for ANKHD1 in ADPKD as a regulator of Cyclin D1/CDK4 cell cycle activity and proliferation, which in the context of ADPKD contributes to disease progression.

Funding: Government Support - Non-U.S.

Activation of Toll-Like Receptor 2 Stimulated NF-κB-Mediated Inflammatory Responses and ERK-Mediated Cell Proliferation in ADPKD

Yang Zhang,[1,2] Matthew V. Plansinis,[1] Sophia Y. Peake,[1] Elisabeth G. Weber,[1] Gail Reif,[3] Darren P. Wallace,[3] Yan Zhang.[1,3] *[1]Michigan Technological University, Houghton, MI; [2]Nanchang University, Nanchang, China; [3]The University of Kansas Medical Center, Kansas City, KS.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by progressive formation of numerous fluid-filled cysts. Aberrant innate immune responses play pivotal roles in driving cyst growth and disease progression; however, the precise molecular mechanisms remain poorly understood. Toll-like receptors (TLRs) are the key components of the innate immunity. Upon ligand binding, TLRs recruit MyD88, an adaptor protein, leading to the activation of transforming growth factor-β-activated kinase 1 (TAK1). TAK1 in turn activates ERK and NF-κB, key factors regulating disease progression in ADPKD. Currently, the effect of TLR activation has not been studied in ADPKD.

Methods: We measured the expression levels of TLR2, TLR4, MyD88, IκBα, and NF-κB p65 in human ADPKD kidneys and normal human kidneys (NHK) by qPCR) and immunoblot. NF-κB p65 nuclear localization was assessed using immunohistochemistry (IHC). To determine the effects of TLR2 and TLR4 activation, cultured ADPKD and NHK cells were treated with Pam3CSK4, a synthetic TLR2 agonist, or ultra-pure LPS-EK, a specific TLR4 agonist, and NF-κB signaling pathways, phosphorylated ERK (P-ERK), and cell proliferation were assessed.

Results: mRNA levels of TLR2, TLR4, MyD88, and NF-κB were significantly elevated in human ADPKD kidneys compared to NHK. IHC analysis revealed increased nuclear localization of NF-κB p65 in human ADPKD kidneys, along with reduced IκBα protein, demonstrating that the TLRs/NF-κB is upregulated in human ADPKD kidneys. Cellular experiment showed that treatment with Pam3CSK4 for increased the phosphorylation of IκBα (P-IκBα) and decreased total IκBα in ADPKD cells. Pam3CSK4 remarkably increased nuclear levels of NF-κB p65 and consequently increased the mRNA of IL-1β, TNF-α, and MCP-1, key factors creating a pro-inflammatory microenvironment in ADPKD kidneys. Moreover, we found that Pam3CSK4 increased P-ERK/ERK and cell proliferation in ADPKD cells but not in NHK cells. LPS-EK had limited effects on NF-κB and ERK in ADPKD and NHK cells.

Conclusions: Activation of TLR2 stimulated NF-κB-mediated expression of inflammatory cytokine and chemokines and ERK-mediated proliferation in ADPKD cells, providing insight into the molecular mechanisms by which innate immunity promotes disease progression.

Activation of Apelin Receptor Inhibits Cystogenesis in a Mouse Model of Polycystic Kidney Disease

Duuamene Nyimanu, Stephen C. Parnell, Christine V. Behm, Darren P. Wallace, Alan S. Yu. *The University of Kansas Medical Center, Kansas City, KS.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a common inherited disorder characterized by increased cAMP signaling, cell proliferation, and fluid accumulation within the cysts. Tolvaptan is approved for ADPKD treatment, but its use is limited by various adverse effects, leaving an unmet clinical need for safe and effective therapy. The apelin receptor is a Gαi-coupled receptor which binds two endogenous ligands, apelin and Elabela/Toddler, to promote vasodilation, hypotension, and a decrease in cardiac hypertrophy. ADPKD patients have reduced circulating apelin which is associated with tubular damage, disease progression, and poor survival. We hypothesized that low apelin signaling in ADPKD contributes to cystogenesis and that exogenous apelin may ameliorate disease.

Methods: Male and female *Pkd1*$^{RC/RC}$; *Pkd2*$^{+/-}$ (PKD) mice were given 2 mg/kg body weight (BW) [Pyr^{1}]apelin-13, the small molecule apelin receptor agonist azelaprag (2 mg/kg), the vasopressin receptor antagonist mozavaptan (0.1% in food), or vehicle control by daily intraperitoneal injection for 27 days. Tail-cuff plethysmography was obtained, animals were euthanized, and the kidneys and heart were harvested. Kidney weight (%KW/BW) and heart weight (HW/BW), a measure of hypertrophy, were assessed. Blood urea nitrogen, an indicator of renal function, was determined by ELISA. Human ADPKD cells were cultured to form *in vitro* cysts in a 3D collagen matrix and treated with apelin receptor agonists for 7 days, and then cyst number and cystic area were analyzed.

Results: Exogenous [Pyr^{1}]apelin-13 significantly reduced %KW/BW (2.36±0.14 vs 1.70±0.04, p<0.0001) similar to mozavaptan (2.36±0.14 vs 1.75±0.06, p<0.0001), when compared to vehicle. Azelaprag, had a mild but significant reduction on %KW/BW (2.36±0.14 vs 1.93±0.06, p<0.01). Both [Pyr^{1}]apelin-13 and mozavaptan significantly reduced BUN in these animals. Cystic animals did not show any evidence for cardiac hypertrophy (HW/BW) and their blood pressure remained unaffected. Preliminary data from APDKD cells grown in 3D cell culture suggest inhibition of cyst formation by both apelin and azelaprag.

Conclusions: Targeting apelin receptor signaling may be a novel therapeutic strategy for treating ADPKD. Future experiments will explore the molecular mechanisms mediating the effects of apelin on cystogenesis.

Studying the Mechanism of Kidney Resident Macrophage Niche Filling after Temporary Depletion

Alex Yashchenko,[1,2] Kurt Zimmerman.[1,2] *[1]The University of Oklahoma Health Sciences Center, Oklahoma City, OK; [2]The University of Oklahoma Department of Medicine, Oklahoma City, OK.*

Background: ADPKD is characterized by large, bilateral fluid-filled cysts scattered throughout the kidney. Our lab and others have previously shown that kidney resident macrophages (KRM) promote cyst progression in mouse models of ADPKD and are histologically cyst-associated. Continuous pharmacological depletion of KRM reduces cystic index and slows disease progression in mice; however, long term depletion of KRM using this approach is not feasible as the depletion is non-specific, affecting resident macrophage populations in multiple tissues. Therefore, we switched our focus to temporary KRM depletion in order to 1) study the mechanism of KRM niche filling, and 2) identify and test factors responsible for engraftment of KRM precursors (monocytes) into an opened KRM niche.

Methods: To study the mechanism of KRM niche filling, we used liposomal clodronate to deplete the KRM niche in *Ms4a3*^{Cre}-*Rosa26*^{TdTomato} and *Ms4a3*^{Cre}-*Rosa26*^{TdTomato}-*Pkd1*$^{RC/RC}$ mice. We analyzed the kinetics (i.e. timing) of KRM niche filling, degree of monocyte input into the KRM niche, and intracellular Ki67 staining by flow cytometry. Disease progression was analyzed by H&E staining.

Results: Analysis of preliminary data indicate that the KRM niche in both *Ms4a3^{Cre}-Rosa26^{TdTomato}* and *Ms4a3^{Cre}-Rosa26^{TdTomato}-Pkd1$^{RC/RC}$* mice is repopulated ~12 weeks after depletion due to the recruitment, engraftment, and differentiation of bone marrow-derived monocytes and through self-replication of the remaining kidney resident macrophages. Using single cell RNA sequencing, we identified *Cx3cr1* as a gene that was possibly required for the differentiation of monocytes into KRM during post-embryonic niche filling periods. To test the importance of *Cx3cr1* expression in monocytes during niche filling, we crossed *Lyz2^{Cre}* mice to *Cx3cr1$^{f/f}$* mice. Analysis of preliminary data from *Lyz2^{Cre}-Cx3cr1$^{f/f}$* mice show that CX3CR1 protein expression is significantly reduced in monocytes and KRM compared to controls although KRM was not impacted. Ongoing studies will address the role of monocyte-specific *Cx3cr1* in niche filling after depletion in healthy and *Pkd1$^{RC/RC}$* mice.

Conclusions: Our data suggest that the open KRM niche is replenished through both monocyte recruitment and engraftment as well as self-proliferation of the remaining KRM. Ongoing studies are addressing the importance of monocyte-specific *Cx3cr1* in the process of niche filling.

LSD1 Nuclear Condensation Promotes Cyst Growth in Polycystic Kidney Disease

Xiaoyan Li,[1,2] Xia Zhou,[1] Shasha Cheng,[1,2] Xiaogang Li.[1,2] *[1]Mayo Clinic Department of Internal Medicine, Rochester, MN; [2]Mayo Clinic Department of Biochemistry and Molecular Biology, Rochester, MN.*

Background: Epigenetic regulation has been a focus of scientific investigation in ADPKD. We have investigated the role of lysine demethylase LSD1 in ADPKD and show that LSD1 is upregulated in *Pkd1* mutant cells and tissues, and inhibition of LSD1 with its inhibitor delays cyst growth in *Pkd1* mutant mice. LSD1 contains two intrinsic disordered regions (IDRs), which are frequently found in phase-separated components, suggesting that LSD1 may form liquid-liquid phase separation (LLPS) to promote target gene transcription in *Pkd1* mutant cells and kidneys.

Methods: We confirm the formation of LSD1-LLPS by 1) immunofluorescence (IF) staining in *Pkd1* mutant cells and kidneys, and 2) by generating LSD1 truncated constructs with one or two IDRs. We identify 1) co-factors of LSD1 in LLPS by immunoprecipitation and mass spectrometry (MS) analysis, and 2) LSD1 target genes by ChIP-seq and RNA-Seq analysis.

Results: We found that upregulated LSD1 formed LLPS droplets in *Pkd1* mutant kidneys, which was rare in *Pkd1* wild type kidneys. GFP-tagged LSD1 with IDR1 or both IDR1 and IDR2 formed LLPS in HEK293T cells, similar as did by full length LSD1. The DNA binding domain (DBD) was necessary for its formation, supporting by that the LSD1-IDR1-DBD (IDR1 and SWIRM) but not LSD1-IDR1 alone formed nuclear puncta in cells. LSD1 target genes identified in ChIP-seq analysis are associated with immune response, DNA, lipid and amino acid metabolic signaling pathways. We identified that CREB might be a potential co-factor of LSD1 in LLPS and CREB also bound to the promoter of LSD1 to regulate its transcription. Treatment with PKA activator FSK increased the nuclear level of LSD1 and its formation of LLPS, whereas treatment with PKA inhibitor H89 decreased the expression of LSD1 and the formation of LLPS in cells. In addition, treatment with FSK and 1,6-hexanediol (1,6-HD, a molecule known to disrupt phase separation), increased the nuclear levels of LSD1, but suppressed the formation of LSD1-CREB contained LLPS, decreased LSD1 mediated demethylation of H3K4 and H3K9, suggesting that LSD1 might promote cyst progression through LSD1-CREB LLPS mediated regulation of gene transcription.

Conclusions: In this study, we identify that LSD1 forms LLPS and CREB is co-factor in this process and confirm that the formation of LSD1-CREB mediated phase separation regulates LSD1 target gene transcription to promote cyst growth in ADPKD.

Lipid Metabolism Reprogramming in ADPKD

Davide Stefanoni,[1] Sara Clerici,[1] Daniel Spies,[1,3] Angelo D'Alessandro,[2] Alessandra Boletta.[1,3] *[1]IRCCS Ospedale San Raffaele, Milano, Italy; [2]University of Colorado Anschutz Medical Campus, Aurora, CO; [3]Universita Vita Salute San Raffaele, Milano, Italy.*

Background: ADPKD, caused by either loss of PKD1 or PKD2, is characterized by metabolic changes such as increased glycolysis, glutaminolysis, and fatty acid synthesis (FAS). Recently, our group assessed the critical role of asparagine synthase (ASNS) to fuel the TCA cycle through glutamine. We reported that antisense oligonucleotides (ASO) therapy against *Asns* results in reduced disease progression. We also showed that central carbon metabolism alterations are improved upon silencing of *Asns*. Moreover, we previously stated an upregulation of reductive carboxylation in PKD, which generates great levels of citrate broken into acetyl-CoA required to fuel FAS. Here, we asked to which extent lipids are altered in PKD kidneys and whether they can be rescued by inhibition of *Asns*.

Methods: To assess the impact of *Asns* knockdown on FAS we performed untargeted lipidomics analysis by mass spectrometry (LC-MS) using kidney tissue samples of a *TamCre;Pkd1$^{\Delta C/flox}$* mouse model in which tamoxifen was injected at P45 and mice followed up for 160 days, and treated with either scramble or *Asns*-ASO.

Results: Lipidomics profiling identified over 900 lipids, with many altered in PKD murine tissues. Specifically, KO samples exhibited 347 significant lipid changes to untreated controls. Among those only 120 lipids preserved significance following *Asns*-ASO treatment, whereas the majority were rescued. In line with this, PCA analysis revealed a clear separation between controls and KO, which *Asns*-ASO treatment largely rescued. A disease-characteristic signature emerged in KO samples as exhibited by lipid class composition analysis, which shows steryl esters, and fatty acids (FA) as the most upregulated, whereas triglycerides (TG) as the most down-regulated lipids. Volcano plot and enrichment analyses of the lipid classes confirmed these data. Of note, changes in TG were significantly rescued upon *Asns* silencing, while sterols and FA only partially, revealing a connection between ASNS and lipid dysregulation in ADPKD.

Conclusions: We previously identified *Asns* as a key player in multiple metabolic pathways in PKD including FAS. Our data show that along with central carbon metabolism, major changes in lipid composition can be observed in PKD kidneys. Unexpectedly our data seem to suggest a potential mechanistic link between ASNS and FAS and confirm the therapeutic significance of targeting *Asns* in ADPKD.

Role of Pannexin-1/P2X7 Interaction in Kidney Cyst Development

Veniamin Ivanov,[1] Sergey N. Arkhipov,[1,2] Tengis S. Pavlov.[1,2] *[1]Henry Ford Health System, Detroit, MI; [2]Wayne State University, Detroit, MI.*

Background: Active extracellular ATP release is conducted by ion channel pannexin-1 (Panx1), expressed in the kidney and previously has been shown to be upregulated in both autosomal dominant and recessive polycystic kidney disease (ADPKD, ARPKD) cystic epithelium and coupled with upregulation of P2X7. Mechanism of regulation of Panx1 channel has not well characterized. We hypothesized that activation of purinergic signaling is a major factor of cystogenesis and regulation of this signaling involves an interaction with P2X7.

Methods: We used a model of cystogenesis to test if purinergic signaling affects growth of cysts formed by mpkCCDcl4 cells in Matrigel in a presence of Forskolin with further evaluation of protein and mRNA expression. To test the regulation of purinergic signaling and interaction of Panx1 and P2X7, patch-clamp experiments in transfected or co-transfected CHO cells and co-immunoprecipitation has been performed.

Results: Stimulation of P2X receptors of mpkCCDcl4 cysts with α, βMe-ATP, an ATP analog drug, stimulates cyst growth (mean cyst size; vehicle 2903 um^2 vs 4343 um^2 treated<0.001) and Panx1 protein expression ($p<0.05$) with no effect on mRNA level. Co-immunoprecipitation experiments in $mpkCCD_{cl4}$ cells revealed that P2X7 receptors bind panx1. Treatment of CHO-K1 cells, co-transfected with PANX1 and P2X7 cDNA plasmids, with αβ-MeATP significantly and reversibly stimulated the activity of Panx1 channels. mRNA level of expression of Panx1 and P2X7 in kidney of Pkd1$^{RC/RC}$ mice was increased compared to the normal mice (Panx1 6.79-fold, $p<0.05$; P2X7 3.52-fold, $p<0.05$).

Conclusions: Stimulation of P2X7 receptor promote cystogenesis in vitro with subsequent increase of Panx1 protein expression. Activity of Panx1 channel is increased in a similar manner. Giving previously investigated data on Panx1 and P2X7 expression in cystic models, we assume that this mechanism contributes to the ATP release into the cystic space and act as a major factor in cystogenesis.

Specific Population of Urinary Extracellular Vesicles Distinguishes Pediatric Patients with ADPKD from Controls

Christian Hanna, Ryan Helland, Hana Yang, Zejfa Haskic, Luke C. Radel, David Soma, Fouad T. Chebib, Peter C. Harris, John C. Lieske, Muthuvel Jayachandran. *Mayo Clinic Minnesota, Rochester, MN.*

Background: There is an urgent need for specific cellular and molecular biomarkers to predict ADPKD progression in children. Emerging studies show that renal cell-derived urinary extracellular vesicles (EVs) are stable biomarkers of kidney pathophysiology. Animal studies suggested that certain EVs promote cyst growth. However, the excretion of EVs from specific renal tubular segments and interstitial pro-and anti-inflammatory immune cells in children with ADPKD is unknown. Thus, we quantified urinary excretion of EVs from renal tubular and interstitial immune cells in children with and without ADPKD using an established and published method of digital flow cytometer.

Methods: We collected 24-hour urine from children (9-18 years old; median 14) with genetically defined ADPKD (n=21; 12F/9M) and age-/sex-matched controls (n=18; 7F/11M). Data are presented as median (25th, 75th percentile) and analyzed by the Mann-Whitney test to identify significant ($P<0.05$) differences between groups.

Results: Excretion of EVs from papillary epithelium (cytokeratin 20 (CK20) positive/24hr urine or mg creatinine) was significantly greater in ADPKD patients

compared to controls (Fig.1). Excretion of EVs from M2 macrophages (Mϕ's; anti-inflammatory; CD206 positive/24hr urine) was significantly increased in ADPKD patients (Fig.1). Excretion of urinary EVs from the proximal tubule, thin and thick limb, distal and collecting tubules, monocytes, M1-Mϕ's, other M2-Mϕ's markers, T-cells, B-cells, NK-cells, and plasma cells did not different between groups. There was a trend toward increased excretion of phosphatidylserine and CD63-positive urinary EVs in ADPKD patients. Number of CK20 positive EVs correlated (Pearson (r) =0.57; P=0.032) with height-adjusted total kidney volume (ml/m) in ADPKD patients.

Conclusions: These results suggest that pediatric ADPKD patients have increased excretion of CK20-carrying urinary EVs, as well as EVs derived from M2-Mϕ's. The potential role and pathophysiological significance of these urinary EV biomarkers requires further study.

The Cystogenic Effects of Ouabain in Autosomal Dominant Polycystic Kidney Disease (ADPKD) Require Cell Caveolae

Jordan Trant, Jeff P. Mcdermott, Gladis S. De Blanco, Gustavo Blanco. *University of Kansas Medical Center Department of Cell Biology and Physiology, Kansas City, KS.*

Background: We have previously shown that the hormone ouabain is a circulating factor which can accelerate the progression of autosomal dominant polycystic kidney disease (ADPKD). At physiologic concentrations, ouabain increases cyst area and fibrosis in kidneys from ADPKD but not wildtype mice. These effects are mediated through ouabain binding to its specific receptor, Na,K-ATPase (NKA). In ADPKD, a fraction of the NKA has an abnormally high affinity for ouabain, leading to an over-activation of the NKA signal transduction cascade. Previous studies in cell lines suggest that ouabain's effects are mediated by the NKA located in the cell caveolae. Here, we determined the role of caveolae in NKA-mediated and ouabain-induced effects in ADPKD using a new mouse model in which caveolar formation is disrupted on the background of ADPKD (*Pkd1*$^{RC/RC}$*Cav1*$^{-/-}$).

Methods: Mice homozygous for the knockout of caveolin-1 (Cav1), a main structural component of caveolae, were crossed with *Pkd1*$^{RC/RC}$ mice to obtain the *Pkd1*$^{RC/RC}$*Cav1*$^{-/-}$ model where caveolae no longer form in the kidney. Ouabain (0.3 mg/kg) or saline was injected intraperitoneally to *Pkd1*$^{RC/RC}$ or *Pkd1*$^{RC/RC}$*Cav1*$^{-/-}$ mice daily for 5 months. Kidneys from these mice were analyzed for cyst area, kidney weight to body weight ratio (%KW/BW) and fibrosis. Cell proliferation (using Ki67 as a marker) and the activation of downstream members of ouabain-NKA signaling (ERK and Akt) were measured.

Results: The ablation of Cav1 and disruption of caveolae in the kidney was confirmed in *Pkd1*$^{RC/RC}$*Cav1*$^{-/-}$ mice by immunoblot and electron microscopy. Loss of caveolae abolished the high ouabain affinity component of NKA seen in *Pkd1*$^{RC/RC}$ mice, with all NKA having the same ouabain affinity as wildtype mice. After 5 months of ouabain administration, *Pkd1*$^{RC/RC}$*Cav1*$^{-/-}$ kidneys did not show the ouabain-induced increase in cyst number or fibrosis seen in *Pkd1*$^{RC/RC}$ mice. In addition, the ouabain-induced phosphorylation of ERK and AKT and the increase in cell proliferation in *Pkd1*$^{RC/RC}$ kidneys was blunted in the *Pkd1*$^{RC/RC}$*Cav1*$^{-/-}$ mice.

Conclusions: Our results show that disruption of caveolae through deletion of caveolin-1 abolishes the abnormal high ouabain affinity fraction of NKA and the cystic effects of ouabain in ADPKD mice, providing *in vivo* evidence for the need of cell caveolae in the signaling function of NKA.

FR-PO620

Hyper-O-GlcNAcylation of AMP-Activated Protein Kinase (AMPK) and Acetylated α-Tubulin in ADPKD Pathogenesis

Matthew A. Kavanaugh, Stephen C. Parnell, Chad Slawson, Darren P. Wallace, Pamela V. Tran. *The University of Kansas Medical Center, Kansas City, KS.*

Background: Altered cell metabolism is an important component of autosomal dominant polycystic kidney disease (ADPKD) pathogenesis, but drivers of these alterations are not understood. The addition of O-linked β-N-acetylglucosamine (O-GlcNAc) onto protein substrates by O-GlcNAc transferase (OGT) integrates multiple metabolic signals that are dysregulated in ADPKD. We have reported that protein O-GlcNAcylation is increased in kidneys of ADPKD patients and mouse models, and that genetic downregulation of O-GlcNAcylation markedly attenuates disease severity and extends mouse survival. To determine the underlying pathogenic mechanisms, we sought to identify proteins that are hyper-O-GlcNAcylated in ADPKD.

Methods: We generated juvenile and adult *Pkd1* conditional knockout (cko) and *Pkd1;Ogt* double knockout (dko) mice using the HoxB7-Cre and the doxycycline-inducible Pax8rtTA;LC1-Cre recombinases (induced from 4-6 weeks of age). Juvenile and adult mouse kidneys were analyzed on postnatal day (P)14 and at 4 months of age, respectively. Hyper-O-GlcNAcylated proteins were identified via immunoprecipitation and Western blot, after which sites were mapped via mass spectrometry with generation and analysis of relevant point mutants to follow.

Results: In juvenile mice, *Ogt* deletion in *Pkd1* cko mice reduced renal cystogenesis and kidney weight:body weight ratios (KW/BW); restrained renal cilia lengths; reduced inflammation and fibrosis; increased activation of the energy sensor AMPK; and improved kidney function. Further, while *Pkd1* cko mice die between P14-P20, *Pkd1;Ogt* dko mice survive beyond one year. In adult mice, deletion of *Ogt* in *Pkd1* cko mice reduced renal cystogenesis and KW/BW. In P14 kidney extracts, hyper-O-GlcNAcylation of metabolic regulator, AMPKα1/α2, as well as of acetylated α-tubulin, which comprises the ciliary axoneme, was observed. In AMPKα1, Ser184 was identified as an O-GlcNAc site, adjacent to the activating phosphorylation site.

Conclusions: In PKD, protein O-GlcNAcylation, including of AMPK and acetylated α-tubulin, is increased, and deletion or inhibition of OGT reduces cyst growth and disease severity, demonstrating that O-GlcNAcylation is an important driver of PKD progression. We propose that targeting O-GlcNAcylation may have therapeutic potential in ADPKD.

FR-PO621

Exploring the Role of Interferon-Gamma in Injury-Accelerated Cystic Kidney Disease

Morgan E. Smith,[1] Katharina Hopp,[2] Kurt Zimmerman.[1] [1]*The University of Oklahoma Health Sciences Center, Oklahoma City, OK;* [2]*University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Acute kidney injury (AKI) accelerates cystogenesis in mouse models of polycystic kidney disease (PKD); however, the mechanism underlying this acceleration remains unclear. Previous data from our lab indicate that genetic deletion of adaptive immune cells (T and B cells) rescues injury accelerated PKD. Additionally, single cell RNA sequencing data suggest that the cytokine interferon gamma (IFNγ), which is produced by CD4+ and CD8+ T cells, is responsible for driving the injury accelerated phenotype. Based on these data, we hypothesize that IFNγ is a significant contributor to injury accelerated PKD.

Methods: To test if IFNγ is essential for injury accelerated cystic disease, we crossed mice lacking IFNγ *(Ifng*$^{-/-}$*)* with our murine model of cystic kidney disease (Cagg Cre^{ERT2} *Ift88*$^{f/f}$). At 8-10 weeks of age, mice were induced with tamoxifen followed by intraperitoneal injection of folic acid (FA) at 11-12 weeks of age to induce kidney injury. Sodium bicarbonate solution was used as a vehicle control. Kidneys were collected 56 days post-injury and the PKD phenotype was measured by quantifying cystic index and cyst number.

Results: Analysis of preliminary data indicate that loss of IFNγ significantly reduced the severity of PKD as measured by 2KW/BW, cystic index, cystic number, and cyst size compared to controls. Likewise, loss of IFNγ was associated with reduced kidney fibrosis and improved kidney function. Analysis of immune cell numbers via flow cytometry indicate that loss of IFNγ significantly reduced the number of neutrophils and kidney resident macrophages (KRM) compared to controls. To test if CD4+ or CD8+ T cell-derived IFNγ was responsible for the observed phenotypic rescue in IFNγ deficient mice, we crossed mice deficient in CD4+ or CD8+ T cells to our mouse model of cystic kidney disease. Analysis of preliminary data indicate that loss of CD4+ T cells, but not CD8+ T cells, was associated with improved phenotypic outcome following FA induced injury. Loss of CD4+ T cells, but not CD8+ T cells, also reduced the number of KRM and neutrophils following FA induced injury.

Conclusions: Collectively, our data suggest that CD4+ T cell-derived IFNγ drives injury accelerated cystic kidney disease.

FR-PO622

Deletion of the Homeobox Gene Cux1 Decreases Ciliogenesis in a Mouse Model of Polycystic Kidney Disease

Greg Vanden Heuvel,[1] Zhi Nee Wee,[1,2] Kristi L. Bailey.[1] [1]*Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI;* [2]*Charles River Laboratories International Inc, Mattawan, MI.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is one of the most common inherited disorders affecting the kidney. Renal cyst development in ADPKD results from mutations in the PKD1 or PKD2 genes, which encode the proteins polycystin1 (PC1) and polycystin2 (PC2). PC1 and PC2 proteins are localized to primary

cilia where they are proposed to form a receptor channel complex that detects flow transmitting a calcium-mediated signal. Primary cilia are critical to the pathogenesis of ADPKD, which is one of many ciliopathies that exhibit renal cystic disease. Cux1 is a cell cycle dependent transcriptional repressor that regulates the cyclin kinase inhibitor p27. Cux1 is highly and ectopically expressed in mice carrying a collecting duct (CD) specific mutation of Pkd1 (Pkd1 knockout) and in human ADPKD cells. Mice carrying mutations in both Cux1 and Pkd1 have reduced cystic disease and an increased life span.

Methods: To begin to determine whether Cux1 regulates ciliogenesis we evaluated cilia morphology and the expression of the ciliary proteins OFD1, Ptch1, and Ift122 in kidneys isolated from Pkd1 knockout and Pkd1/Cux1 double knock out mice. Cilia morphology was assessed by immunofluorescence labeling of alpha- tubulin, a major component of cilia, and the collecting duct marker dolichos biflorus agglutinin (DBA) to identify cells in which Pkd1 was deleted.

Results: Cilia in Pkd1/Cux1 double knockout kidneys were significantly shorter than cilia in the Pkd1 knockout kidneys alone, consistent with previous studies showing that decreased cilia length corresponds to decreased cystic disease. In addition, expression of OFD1, an inhibitor of cilia formation was significantly increased in Pkd1/Cux1 double knockout kidneys compared to Pkd1 knockout kidneys alone.

Conclusions: Taken together, our results suggest a novel role for Cux1 in regulating ciliogenesis in polycystic kidney disease.

FR-PO623

NOTCH2 Mutations Associated with Alagille Syndrome Result in Longer Primary Cilia and Inactivation of Ift88 in Mice with Notch Signaling-Deficient Kidneys Partly Rescues Kidney Abnormalities

Matthew Mckillop,[1] Jennifer DeRiso,[1] Ayesha Anwer,[1] Kameswaran Surendran.[1,2] Surendran Lab. *[1]Sanford Research, Sioux Falls, SD; [2]University of South Dakota Sanford School of Medicine, Sioux Falls, SD.*

Background: Alagille Syndrome (ALGS) is an autosomal dominant congenital disorder linked to mutations in *NOTCH2*, which codes for a receptor in the Notch signaling pathway. ALGS has a variable penetrance of kidney disease with a variety of kidney abnormalities including hypoplastic and multi-cystic kidneys. Notch signaling deficiency in nascent nephrons in mice results in small multi-cystic kidneys and epithelial cells with long primary cilia. It is unknown if *NOTCH2* mutations associated with kidney disease in ALGS also result in longer cilia. Also unknown is if the long cilia mediate cyst formation in the kidney and decline in renal function in mice with Notch-signaling deficient kidneys.

Methods: We analyzed kidney structure and function in mice with inactivation of one allele of *Notch1* and two alleles of *Notch2* along with varying number of *Intraflagellar transport protein 88* (*Ift88*) alleles in developing mouse nephrons. We modeled ALGS associated *NOTCH2 R2003X* (*N2R2003X*) and *NOTCH2 Exon33 splice acceptor* (*N2Ex33sp*) mutations in Madin-Darby Canine Kidney (MDCK) and performed RNA-sequencing to identify differentially expressed genes. We also determined proteins that are proximal to Notch2 versus N2Ex33sp mutant in MDCK cells.

Results: Cystic kidney phenotype and decline in renal function in mice with *Notch1* & *2* deficient kidneys were rescued when *Ift88* is in the heterozygous state. MDCK cells with *N2R2003X* and *N2Ex33sp* mutations have longer cilia while inactivating both alleles of *Notch2* by introducing a stop codon into exon5 in MDCK (*N2-/-*) does not increase cilia length. Many primary cilia related genes are differentially expressed in *N2Ex33sp* and not in *N2-/-* cells compared with wild type cells. Many cilium assembly proteins are proximal to wild type Notch2 and not N2Ex33sp mutant.

Conclusions: ALGS associated N2+/R2003X and N2+/Ex33sp mutations, which result in truncated Notch2 proteins, likely function in a dominant manner and the long cilia phenotype is not just due to loss of Notch2. While many cilia related genes are differentially expressed in N2+/Ex33sp cells, and N2Ex33sp mutant protein has reduced proximity to cilium assembly proteins, partial inactivation of *Ift88* suppresses Notch-deficiency dependent kidney disease.

FR-PO624

Axoneme Hypoglutamylation in Primary Cilia Promotes Cystogenesis in ADPKD

Kai He, Xiaobo Sun, Jinghua Hu. *Mayo Clinic Minnesota, Rochester, MN.*

Background: ADPKD is primarily caused by mutations in the *PKD1* and *PKD2* genes, which encode the proteins PC1 and PC2, respectively. PC1 and PC2 are hypothesized to form a receptor-channel complex on primary cilia membrane, which is crucial for maintaining the normal function and structure of renal tubules. PC1 and PC2 reciprocally regulate each other's ciliary localization by unclear mechanism. Loss of PC1 and PC2 in cilia significantly contribute to the progression of PKD. Therefore, increasing the levels of PC1/2 within cilia emerges as a potential therapeutic strategy for PKD. However, feasible methods or molecular targets to increase ciliary levels of PC1 and PC2 in the context of PKD are currently lacking. Polyglutamylation (PG) is a prominent post-translational modification of tubulin that occurs on the primary cilia axoneme. The established correlation between axoneme hypoglutamylation (reduced glutamylation) and human ciliopathies, which often present with cystic kidney phenotypes, suggests a plausible link between impaired axoneme PG and PKD pathogenesis. Our prior research has revealed that axoneme is crucial for ciliary localization of PC2. In this study, we foucs on the role of axoneme hypoglutamylation in renal cystogenesis in ADPKD.

Methods: 1. 3D sephroid culture. 2. Immunofluoresent. 3. siRNA/shRNA-based knockdown. 4. Lentivirus-based overexpression.

Results: Loss of PC1 leads to marked axoneme hypoglutamylation in PKD1 mutant renal epithelial cells. Remarkably, genetically or pharmacologically reducing axoneme PG significantly promotes 3D cystogenesis, while increasing axoneme PG suppresses it in PKD1 mutant renal tubular epithelial cells. Furthermore, reducing axoneme PG decreases, while increasing axoneme PG enhances the ciliary levels of PC2. These data suggest that PC1 regulates the ciliary localization of PC2 through modulating axoneme PG, and that axoneme hypoglutamylation significantly contributes to PKD progression. Our ongoing work focuses on investigating the role of axoneme hypoglutamylation in *in vivo* cystogenesis and testing whether increasing axoneme PG could attenuate PKD progression in $Pkd1^{RC/RC}$ mice.

Conclusions: 1. PKD1 deletion leads to axoneme hypoglutamylation in renal epithelial cells. 2. Reducing axoneme PG aggrevates, while increasing axoneme PG suppresses cystogenesis in 3D culture. 3. Axoneme hypoglutamylation contributes to PC1-deficicency induced ciliary loss of PC2.

Loss of ARL13B's Guanine Nucleotide Exchange Factor Activity for ARL3 in Cilia Suppresses Cystogenesis in Adult Mouse Models of Polycystic Kidney Disease

Robert E. Van Sciver,[1] Avery Forster,[1,2] Tamara Caspary.[1] *[1]Emory University School of Medicine, Atlanta, GA; [2]Boston University College of Arts & Sciences, Boston, MA.*

Background: Polycystic kidney disease (PKD) is largely driven by mutations in *PKD1* or *PKD2*, which encode for ciliary polycystin proteins. Mouse models predict the presence of a cilia-dependent cyst activating (CDCA) pathway that functions in cilia to drive PKD cystogenesis. This CDCA pathway is normally inhibited by the polycystin proteins, yet the identity of this pro-cystic pathway remains unknown. ARL13B is an atypical ciliary GTPase which also possesses guanine nucleotide exchange factor (GEF) activity for another ARL family GTPase, ARL3. Recent work revealed a central role of ARL13B's cilia localization in cystogenesis, yet its role in the CDCA pathway is unknown.

Methods: To directly test ARL13B's role in the CDCA pathway, we engineered two distinct *Arl13b* mutant alleles at the endogenous locus in mice: (1) $Arl13b^{V358A}$, which mutates a single amino acid in ARL13B's cilia-localization motif; and (2) $Arl13b^{R79Q}$, which prevents its GEF activity for ARL3. $ARL13B^{V358A}$ retains all known ARL13B biochemical functions, is stably expressed yet is undetectable in cilia. $ARL13B^{R79Q}$ localizes to cilia, retains its GTPase activity, yet cannot activate ARL3. Combining these alleles with the kidney-specific loss *Pkd1* allowed us to directly test ARL13B's ciliary and enzymatic roles in kidney cystogenesis *in vivo*.

Results: At 18-weeks, control mouse kidneys had a kidney weight to body weight ratio (KW:BW) of 1.39±0.04. In adult induction models, loss of *Pkd1* alone led to severe cystic kidneys with KW:BW of 11.98±0.99. Ciliary exclusion of ARL13B (V358A), total loss of its GEF activity for ARL3 (R79Q), or loss of its GEF activity, specifically in cilia (V358A/R79Q) suppressed the cystic phenotype caused by loss of *Pkd1* alone with KW:BW of 2.47±0.36 and 4.09±0.78, 3.75±0.70, respectively.

Conclusions: In PKD mouse models, loss of ARL13B from cilia, its GEF activity for ARL3 everywhere, or its GEF activity specifically in cilia suppressed the severe cystic kidney phenotype caused by loss of *Pkd1* alone. These results suggest that the ARL13B–ARL3 axis are major components of the CDCA pathway. Our findings indicate that ARL13B activates a pro-cystogenic pathway via its GEF activity for ARL3 in cilia, providing a mechanism that could be targeted therapeutically.

Tryptophan Metabolism as a Link between Cilia and Mitochondria in Renal Tubule Cells

Brennan Winkler,[1] Xiaofeng Zuo,[1] Peifeng Deng,[1] Wayne R. Fitzgibbon,[1] Joshua H. Lipschutz.[1,2] *[1]Medical University of South Carolina, Charleston, SC; [2]Ralph H Johnson VA Health Care System, Charleston, SC.*

Background: Primary cilia and mitochondria are centrally involved in ADPKD. We showed that the exocyst trafficking complex is necessary for ciliogenesis, knockdown (KD) of the central exocyst component Exoc5 resulted in absent cilia with increased susceptibility to H_2O_2, overexpression (OE) of Exoc5 increased cilia length with protection from H_2O_2, and renal tubule-specific knockout (KO) of Exoc5 in mice led to PKD. Intraflagellar transport protein 88 (Ift88) is also necessary for ciliogenesis.

Methods: We performed Seahorse assays, staining for reactive oxygen species (ROS), transmission electron microscopy (TEM), and a metabolomics screen in Exoc5 OE, Exoc5 KD, Exoc5 ciliary targeting sequence point mutant (cts-mut), and control Madin-Darby canine kidney tubule (MDCK) cells, and murine Ift88 KO and rescue cells. We also crossed Exoc5$^{fl/fl}$ and Ift88$^{fl/fl}$ mice with mice expressing CreERT2 driven by the proximal tubule-specific sodium-dependent inorganic phosphate transporter and performed bilateral ischemia reperfusion (I/R).

Results: There was decreased mitochondrial respiration, increased ROS, and abnormal mitochondria in Exoc5 KD, Exoc5 cts-mut cells, and Ift88 KO cells compared to control MDCK and Ift88 rescue cells, with opposite effects seen in Exoc5 OE cells. In our metabolomics screen tryptophan levels were increased 113- and 58-fold, respectively, in Exoc5 cts-mut and Exoc5 KD compared to control cells. Concomitantly, kynurenine which is directly downstream of tryptophan was decreased in these cells. Similar results were seen in the Ift88 KO compared to rescue cells. In Exoc5 OE cells tryptophan was decreased and kynurenine was increased. Metabolism of tryptophan to kynurenine occurs via indoleamine 2, 3-dioxygenases (*IDO1 and IDO2*) and changes in mRNA levels by RT-qPCR were consistent with the metabolomics data. Proximal tubule-specific Exoc5 and Ift88 KO mice lacked cilia, had decreased levels of mitochondrial ATP synthase, increased tryptophan, and aggravated renal injury following I/R injury compared to control mice (p=0.005 for Exoc5, p=0.04 for Ift88).

Conclusions: Tryptophan metabolism may be the "cilia-dependent cyst activating" mechanism with cilia loss resulting in a metabolic derangement that prevents cell proliferation and cyst formation. We also show that loss of cilia primes renal tubule cells for injury.

Defining the Interaction Network of the CPLANE Complex Reveals Cilia and Actin Regulatory Components

Rita K. Kalot,[1,2] Sima Babayeva,[1] Elena Torban.[1,2] *[1]McGill University Health Centre, Montreal, QC, Canada; [2]McGill University, Montreal, QC, Canada.*

Background: Almost all vertebrate cells have a single primary cilium that protrudes to the extracellular space and acts as a signalling nexus. Defects in primary cilia cause a set of diseases termed ciliopathies that affect multiple organs including the kidneys. Mutations in ciliogenesis and planar cell polarity (CPLANE) genes *FUZZY, INTURNED and WDPCP* lead to human ciliopathies. Although the homologs of CPLANE proteins in *Drosophila Melanogaster* regulate the planar cell polarity and actin polymerization, their functions in ciliation and the etiology of ciliopathies remain elusive. We hypothesize that CPLANE proteins regulate ciliary and actin-regulating proteins to control primary cilia formation.

Methods: Co-immunoprecipitation assay was used to validate the interactions between IQGAP1 and CPLANE proteins. IQGAP1 knockdown was achieved by siRNA transfection in hTERT-RPE-1 cells. Ciliation and YAP localization were assessed by immunofluorescence using anti-ARL13b and anti-YAP antibody, respectively. BioID baits were genrated by gateway cloning and transfected in FlpIn TREX293 cells. Pulldown coupled to mass spectrometry was used to identify CPLANE interactors. Protein identification and analysis of interactions were done in Prohits, and SAINT.

Results: Using a preliminary Bio-ID we identified IQGAP-1(an actin-regulating protein) as a novel interactor of Fuzzy. We established that IQGAP1 interacts with all CPLANE proteins and showed that the knockdown of IQGAP1 reduces ciliation and cilia length in htERT-RPE-1 cells. Since IQGAP1 does not localize to the ciliary basal body, we propose an indirect link where IQGAP1 regulates cilia length by modulating YAP1 downstream ciliary transcriptional targets. To better understand the roles of CPLANE in ciliogenesis, we generated CPLANE BioID baits and conducted an interaction study. Coupling BioID with MS and bioinformatics we identify multiple CPLANE interactors that further link actin regulation to primary cilia functions.

Conclusions: This study unravels a link between the CPLANE complex and actin regulators. Identifying CPLANE-specific proximity interactors helps discover novel molecular components regulating ciliation, particularly through the regulation of actin dynamics. This bridges the gap between actin regulatory pathways and ciliation and proposes potenitial actin-targeting therapeutics as treatment for ciliopathies.

FR-PO628

A High-Content Screening Approach to Unveil the Molecular Mechanism of the Ciliary Response to Glutamine

Francesco Consolato, Maria Elena Steidl, Laura Cassina, Alessandra Boletta. *IRCCS Ospedale San Raffaele, Milano, Italy.*

Background: Polycystic Kidney Disease (PKD) is the most common ciliopathy, caused by malfunctioning primary cilia. Primary cilia are microtubule-based organelles at the cell surface that integrate metabolic and signaling cues, though their exact sensory function is unclear. We recently demonstrated that primary cilia sense nutrient availability and adjust the cellular metabolic response. Glutamine deprivation causes cilia elongation, while its supplementation induces shortening due to TCA cycle anaplerosis. We identified asparagine synthetase (ASNS) as a key enzyme; its silencing reduces both anaplerosis and cilia shortening. We aim to identify the full pathway driving this cilia response, believing it will be crucial in PKD.

Methods: mIMCD3 stable transfectants with Arl13b-GFP were generated, subcloned, and used to set up an automated quantification of ciliary length in response to glutamine using the ImageXpress Micro Confocal Imaging System by Molecular Devices, scalable to 384 wells. Cells were transfected with key siRNAs for setup studies, and 48 hours later, were analyzed by western blotting or for cilia length. For each well, 16 fields were acquired, measuring over 1,000 cilia per condition, with post-image analysis performed using MetaXpress Custom Modules software.

Results: To clarify the molecular mechanism behind ciliary dynamics under stress conditions, we developed a high-content screening method to automatically measure cilia length in response to various stimuli and optimized conditions for silencing known pathway components. According to literature, silencing *Ift88*, *Arl13b*, *Ccdc41*, and *Prpf8* induced ciliary shortening, while silencing *Asns*, *Vdac1*, *Kif2a*, and *Cep170* led to elongation. The system is now operational. We plan to use a whole genome siRNA library to identify pathway components that drive elongation without glutamine and promote shortening with glutamine replenishment.

Conclusions: Understanding primary cilia's role in regulating cellular metabolism is crucial for insights into their functions in health and disease. Dysfunction of primary cilia leads to various ciliopathies, including kidney disorders like PKD. Our data support using a high-content screening platform to identify novel components of the pathway responsible for the ciliary response to glutamine.

Klc3 Regulates Ciliary Trafficking and Cyst Formation in Kidney Epithelial Cells

Yejin Ahn, Gyuyeong Rah, Je Yeong Ko, Jaehee Jun, Chaewon Oh, Songyo Ma, Jong Hoon Park. *Sookmyung Women's University, Yongsan-gu, Seoul, Republic of Korea.*

Background: Primary cilia are microtubule-based organelles that extends from the cell membrane and function as biosensor to regulate intracellular signaling pathways. As primary cilia cannot synthesis proteins by themselves, trafficking of ciliary protein via the process of intraflagellar transport (IFT) is crucial for cilia maintenance and function.

Methods: Immunocytochemistry and co-IP were used to examine the effect of kinesin light chain-3 (Klc3) in ciliary trafficking. By modulating Klc3 expression levels, we evaluated the effect of Klc3 in ciliary trafficking and *in vitro* cyst formation.

Results: We identified Klc3 as ciliary trafficking regulator of kidney epithelial cells. Klc3 localized to adjacent to basal body of cilia and regulated ciliary IFT recruitments by interacting with IFT-B core-2 complex via its tetratricopeptide-repeat (TPR) domains. Also, Klc3 overexpression increased *in vitro* cyst formation of kidney epithelial cells, whereas suppression of Klc3 relieved *in vitro* cyst enlargement induced by *Pkd1* or *Pkd2* deficiency. In support our findings, ciliopathy models such as human ADPKD and animal PKD models with ciliary IFT accumulations had an increased Klc3 expression.

Conclusions: We provide conclusive evidences of KLC3 roles for regulating ciliary IFT recruitment and cyst formation in kidney epithelial cells.

ANKHD1 Has a Cytoprotective Role in Stressed Kidney Cells

Jordan Mullenger,[1,2] Martin Zeidler,[1] Maria Fragiadaki.[2,1] *[1]The University of Sheffield, Sheffield, United Kingdom; [2]Queen Mary University of London, London, United Kingdom.*

Background: ANKHD1 is a ubiquitously expressed RNA binding protein composed of ankyrin repeat domains for protein binding and a KH domain for nucleic acid binding. ANKHD1 is overexpressed in renal cancer, driving proliferation and growth. Clinically, increased expression of ANKHD1 is associated with increased metastasis and larger tumours, resulting in poorer patient prognosis. Our lab has predicted a similar function for ANKHD1 in autosomal dominant polycystic kidney disease (ADPKD). ADPKD is the most common genetic form of renal failure and is characterised by excessive proliferation resembling early tumorigenesis. The signalling pathways activated in the proliferation of cancer cells and ADPKD closely resemble one another.

Methods: Immunohistochemistry of ANKHD1 was performed in kidney sections to examine protein localisation. Recombinant ANKHD1 was produced in HEK293T cells and elevated expression was validated using western blot and RT-qPCR. The resultant protein was purified via immunoprecipitation (IP), and its interacting partners were identified via mass spectrometry (MS). Bioinformatics analysis was performed on the experimentally validated ANKHD1 interactome from BioGrid, and analysis of function was performed using online platforms. Cells were exposed to cellular stress by growth in serum-free media for 24hrs, and viability was assessed via MTT assay.

Results: In ADPKD kidneys, ANKHD1 is localised to the cyst lining epithelial cells. Recombinant constructs of human ANKHD1 and its protein interactors were expressed and purified via IP; MS identified 267 interacting proteins. Combining our MS results with published protein-interaction databases revealed 17 overlapping ANKHD1-interacting proteins, 10 of which are involved in cellular responses to stress. Hence, we decided to test the putative role of ANKHD1 in protecting from stress. Serum starvation caused a 23% reduction in cell viability, while overexpression of ANKHD1 rescued this phenotype in a proliferation and apoptosis-independent manner. Serum-starved cells showed increased stress granules, which was suppressed by ANKHD1 overexpression. A physical interaction between ANKHD1 and HSPA8, a heat-shock chaperone involved in protein folding, was also demonstrated.

Conclusions: ANKHD1 interacts with proteins involved in the cellular stress response, and has a proposed novel role as a cytoprotective molecule during cellular stress.

FR-PO631

Influence of PKD1-Mediated Apoptosis on Proliferation and Autophagy in Human Embryonic Kidney Cells

Ebtehal Ahmed, Maria Fragiadaki. Fragiadaki Group. *William Harvey Research Institute, Centre for Translational Medicine and Therapeutics (TMT), Lifelong Health Theme, Queen Mary University of London, London, United Kingdom.*

Background: Polycystic Kidney Disease (PKD) is the most common genetic cause of chronic kidney disease, affecting millions globally. The condition is characterized by kidney cysts, excessive proliferation, apoptosis, and fibrosis. PKD arises from a mutation in the PKD1 gene, encoding polycystin-1 (PC1), a transmembrane protein. Loss of PC1 is linked to centrosome amplification, genomic instability, and excessive proliferation, but the underlying mechanisms are unclear. This study examines the consequences of PC1 loss, focusing on apoptosis and its effects on proliferation and autophagy. It also investigates the potential therapeutic impact of apoptosis-inhibitory small molecules (Z-DEVD-FMK and Z-VAD-FMK) on reversing the condition in PKD1-silenced Human Embryonic Kidney Cells (HEK293T).

Methods: We silenced PKD1 and verified knockdown by sequencing. Cell viability was measured by MTT assay. Apoptosis, proliferation, and autophagy were examined by immunostaining and western blot. Apoptosis inhibitors were used to rescue PKD1-silenced cells. Lastly, we generated spheroids for the control and PKD1 silenced cells embedded in Matrigel, collagen, and ECM hydrogel to assess the effect of PKD1 deletion and apoptosis inhibition in three-dimensional cultures.

Results: PKD1 loss significantly reduced cell viability to 56.8% (p=0.0394), indicating its importance in metabolic activity. This was not due to changes in proliferation but rather due to a significant induction of apoptosis (p=0.0131) comparable to the potent apoptosis-inducer staurosporine. PKD1 silencing also reduced autophagy, decreasing LC3B expression to 2.781% (p=0.0058) of controls (10.77%). The caspase-3 inhibitor (Z-DEVD-FMK) and pan-caspase inhibitor (Z-VAD-FMK) both reduced caspase-3 expression, but the latter was more effective at reducing cleaved PARP (p=0.0257). These results highlight PKD1's critical role in regulating apoptosis and autophagy.

Conclusions: We uncover PKD1's critical role in controlling apoptosis and offer a potential therapeutic avenue to mitigate disease progression.

FR-PO632

Regulated Cell Death in the Pathogenesis of Cystic Kidney Diseases

Emilia Kieckhöfer,[1,2] Lena K. Ebert,[1,2] Thomas Benzing,[1,2] Bernhard Schermer.[1,2] Nephrolab Cologne. *[1]Department II of Internal Medicine and Center for Molecular Medicine Cologne, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany; [2]CECAD, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany.*

Background: Hereditary cystic kidney diseases, such as autosomal dominant/recessive polycystic kidney disease (ADPKD/ARPKD) or nephronophthisis (NPH) are caused by mutations in genes encoding proteins essential for the structure and function of primary cilia. Cilia are sensory organelles that project from the surface of tubular epithelial cells into the lumen, functioning like diminutive cellular antennae. In many cystic kidney diseases, a significant loss of tubular epithelial cells occurs. Consequently, we investigated the extent to which pathways of regulated cell death (RCD) are interconnected with cilia and play a role in cystic kidney pathologies.

Methods: We studied pathways of regulated cell death (including apoptosis, necroptosis, and pyroptosis) in cultured renal epithelial cells with and without primary cilia, and in *Kif3a*-deficient mouse kidneys. Additionally, we deleted *Ripk3* and *GsdmD* in the JCK mouse model of cystic kidney disease and performed renal phenotyping. To gain mechanistic insights, we conducted proteomics and single-nucleus RNA sequencing (snRNA-Seq) analyses.

Results: Loss of cilia in murine kidney epithelial cells led to an increased expression of the key kinase RIPK3 *in vitro* and *in vivo*, enhancing the susceptibility of tubular epithelial cells to necroptotic cell death. Notably, RIPK3 deletion in JCK mice resulted in a significant improvement in renal histology and function. Deleting Gasdermin D (GSDMD), an effector of pyroptosis, had a similar effect in this mouse model. Single-nucleus RNA sequencing (snRNA-Seq) analyses provided insight into the mechanisms underlying cyst formation and the beneficial effects of RIPK3 and GSDMD deletion on various cell populations, offering potential new intervention points.

Conclusions: Taken together, our data highlights the significance of RCD in the development of cystic kidney diseases and ciliopathies, suggesting a potential role of RCD as a target for future therapeutic strategies.

FR-PO633

Autophagy Knockout Results in ERK Activation, Increased Proliferation, and Apoptosis of Cyst-Lining Epithelial Cells and Worse Polycystic Kidney Disease

Daniel Atwood, Zhibin He, Makoto Miyazaki, Katharina Hopp, Charles L. Edelstein. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Studies remain contradictory and the mechanistic role of autophagy in cyst growth. Autophagy has not been detailed in rodent and cell models translational to the human disease.

Methods: Mice were treated with chloroquine at a dose of 60mg/kg from 50-120 days. An array of mTOR and autophagy proteins was measured in the kidney by immunoblot analysis. Apoptosis and proliferation were measured by TUNEL and PCNA IHC respectively. Cells were treated with 25 or 50uM tat-beclin1 peptide for 4 or 24hrs

Results: Suppressed autophagic flux (lack of increase in LC3-II in kidney 2 hrs after IP bafilomycin injection) was observed in 150 d old, but not 70 or 120 d old Pkd1RC/RC kidneys. Pharmacological inhibition of autophagy with chloroquine from an early age suppressed autophagic flux in Pkd1RC/RC kidneys, but had no effect on PKD severity. Knockout of autophagy (ATG7) in kidney tubule specific Pkd1 knockout mice, a rapid model of cyst growth, had no effect on cyst growth or kidney function. Knockout of ATG7 in Pkd1RC/RC mice, a slower and more clinically-relevant model of PKD, resulted in activation of p-ERK, a surge of apoptosis and proliferation of cyst lining epithelial cells and severely worse PKD (See Table). In human PKD 9-12 cells, autophagy induction with Tat-beclin 1 peptide resulted in increased conversion of LC3-I to LC3-II, decreased p-ERK and decreased proliferation and apoptosis (See table).

Conclusions: In vivo, autophagy knockout activates p-ERK resulting in a surge of proliferation and apoptosis in cyst lining epithelial cells and worse PKD. In vitro, autophagy induction resulted in decreased p-ERK decreased proliferation and apoptosis. In conclusion, there is an abnormal autophagy, ERK, proliferation/apoptosis axis in cells lining the cyst in ADPKD. Cre-lox technology was used to create ATG7, RC/RC double knockout mice

Funding: Veterans Affairs Support

Pkd1 Mutation Modulates Cognitive Function via N-methyl-D-aspartate Receptor-Mediated Synaptic Transmission and Autophagy

Zeba Firdaus,[1,2] Lu Li,[1,2] Xinyue Mao,[1,2] Xia Zhou,[1,2] Xiaogang Li.[1,2] *[1]Mayo Clinic Department of Internal Medicine, Rochester, MN; [2]Mayo Clinic Department of Biochemistry and Molecular Biology, Rochester, MN.*

Background: ADPKD is a prevalent, life-threatening monogenic disorder linked to *PKD* gene mutations. However, whether this mutation affects brain function is unknown. In this study, we investigate whether *PKD1* mutation activates N-methyl D aspartate receptors (NMDAR), dominant calcium channels, and impairs autophagy in brain to disrupt synaptic transmission and contribute to cognitive dysfunction.

Methods: We performed behavioral experiment (Y-maze test) to evaluate the anxiety in wild type (WT) and $Pkd1^{RC/RC}$ mice. To understand the underlying molecular mechanisms, we isolated cerebral cortex (CC) and hippocampus (HP) from WT and $Pkd1^{RC/RC}$ brain and did Western blot and qRT-PCR analysis. We also checked the effect of senolytic treatment on brain in $Pkd1^{RC/RC}$ mice. Lastly, we did the co-IP to check the interaction between GluN2a and carboxy-terminal end of PC1 using N2a cells.

Results: We observed increased anxiety-like behavior in $Pkd1^{RC/RC}$ mice compared to WT controls. The expression of NMDAR subunit GluN2A, synaptic protein PSD-95, and neurotrophic factor BDNF was increased in the CC and HP of $Pkd1^{RC/RC}$ mice compared to WT control, suggesting an increase of synaptic signaling, whereas the expression of RE-1 silencing transcription factor (REST), responsible for repression of synaptic

proteins, was downregulated in *Pkd1*$^{RC/RC}$ brains. In addition, impaired autophagy, as characterized by the increase of p62 and pTFEB and the decrease of Atg7, beclin1, and LC3 in *Pkd1*$^{RC/RC}$ mice brains compared to WT controls. Treatment with senolytic combination of Dasatinib and Quercetin (DQ), improved anxiety-like behavior in *Pkd1*$^{RC/RC}$ mice and restored the expression of above autophagy markers. Treatment with DQ also normalized the expression of synaptic proteins as seen by a decrease of the upregulated GluN2A, PSD-95, and BDNF, and an increase of the downregulated REST. Moreover, the carboxy-terminal of PC1 interacts with GluN2A, indicating that PC1 may suppress this NMDAR subunit in wild-type brains through this interaction.

Conclusions: This study finds that *Pkd1* mutation alters NMDAR and REST expression, along with impaired autophagy, leading to increased synaptic protein availability at synapses, thereby amplifying synaptic transmission and causing excitability. Consequently, *Pkd1* mutation induces anxiety in an ADPKD animal model, resulting in mild cognitive dysfunction.

FR-PO635

Neuroinflammation in Polycystic Kidney Disease

Jelena Klawitter, Garrett B. Wheeler, Katharina Hopp, Jost Klawitter, Uwe Christians. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: The incidence of intracranial aneurysms (IA) in patients with autosomal dominant polycystic kidney disease (ADPKD) is three- to four-times higher than that in the general population. Inflammation plays a key role in the development of IA and their rupture. Systemic inflammation and associated metabolic changes in the kidney are well described in ADPKD. However, the presented results describe, for the first time, the inflammation-related alterations and metabolic derangements in the brains of animals with PKD.

Methods: Brains (cortex and hippocampus) were collected from 6-mo old WT and *Pkd1*$^{RC/RC}$ (orthologous ADPKD model) mice. Proteome Profiler Mouse cytokine arrays, in conjunction with Western blot and confocal microcopy analyses, were used to assess the degree of neuroinflammation. Mass spectrometry-based metabolomics was used to assess the metabolic changes and the levels of oxidative stress.

Results: Accumulation of multiple proinflammatory proteins including several interleukins, C-reactive protein, RANTES, and Vascular Cell Adhesion Protein 1 (VCAM1) was observed in brains of both sexes *of Pkd1*$^{RC/RC}$ mice. This was accompanied by astrocyte (GFAP^{+}) and microglia (Iba1^{+}) activation. Protective cytokines such as Chemerin were downregulated in brains of *Pkd1*$^{RC/RC}$ mice. Metabolically, *Pkd1*$^{RC/RC}$ mice presented with decreased brain levels of multiple energy-supplying amino acids (ARG, LEU, ASP). TRP metabolism via kynurenine pathway was increased resulting in lower TRP availability and serotonin production. We also observed an accumulation of several uremic toxins (indoxyl- and p-cresyl sulfate) and oxidative stress markers in PKD mice. The accumulation of these uremic toxins has been shown to directly associate with increased blood-brain barrier (BBB) permeability. Together with kynurenines, they bind to aryl hydrocarbon receptor (AhR), that regulates vascular homeostasis and integrity, and whose expression we confirmed to be higher in *Pkd1*$^{RC/RC}$ brains.

Conclusions: We show that neuroinflammation is present in the brains of *Pkd1*$^{RC/RC}$ mice. Genetic polycystin deficiency and increased systemic inflammation lead to a disruption of BBB resulting in an accumulation of uremic toxins, increased oxidative stress and derangements in cellular metabolism. Increased expression of VCAM1 and AhR could further contribute to the vessel modulation and IA pathology.

FR-PO636

Genome-Wide Association Study of GFR Slope Decline in a Diverse Cohort from the Million Veteran Program

Adriana Hung,[1,2] Jefferson L. Triozzi,[1,2] Cassianne Robinson-Cohen,[1,2] Hua-Chang Chen,[1] Zhihong Yu,[1] Otis D. Wilson,[1,2] Guanchao Wang,[1] Talat Alp Ikizler,[1,2] Ryan Hsi,[1] Lee Wheless,[1,2] Edward D. Siew,[1,2] Ran Tao.[1] Million Veteran Program. *[1]Vanderbilt University Medical Center, Nashville, TN; [2]VA Tennessee Valley Healthcare System, Nashville, TN.*

Background: Rapid chronic kidney disease (CKD) progression is associated with poor outcomes and interventions to slow progression are scarce. Only a few genetic loci have been associated with kidney function decline, as assessed by eGFR slope over time. We here perform the largest and most diverse investigation of genetic determinants of eGFR slope to date.

Methods: We performed a genome-wide association study (GWAS) of eGFR decline among 541,845 individuals enrolled in the Million Veteran Program. Our primary outcome was the annualized relative slope defined as longitudinal change in outpatient eGFR (% change per year), adjusted for age, sex, and 10 principal components of ancestry. Analyses were stratified by genetic ancestry and diabetes and inverse variance-weighted fixed-effect meta-analyses were carried out using and METAL.

Results: The strongest trans-ancestry association in patients with diabetes was in *PDILT*/*UMOD* (rs77924615; p=3x10^{-42}). Other significant associations in patients with diabetes included *SLC47A1* (rs2247436 p = 1x10^{-15}), *BICC1* (rs10763564 p=3x10^{-9}), *NDST4* (rs144322816 p=5x10^{-8}). In non-diabetic individuals, associations were noted at *PDILT* (rs77924615; p= 1x10^{-45}), *BICC1* (rs1649081; p=2x10^{-10}), *AZIN2* (rs116832156; p=6x10^{-10}), *TRIM62* (rs116120304; 1x10^{-9}), *PRKGA2* (rs10265221; p=2x10-9), *WDR72* (rs689751; p=2x10^{-9}); *TPPP* (rs4990988; 1x10^{-8}), *RORA-AS1* (rs919582144; p=4x10^{-8}). In the overall meta-analysis, associations included *SLC47A1* (rs2440155; p=3x10^{-11}), *PDILT/UMOD* (rs77924615; p=3x10^{-82}), *WDR72* (rs6416452;p=1x10^{-13}), *BICC1* (rs34275789; p=3x10^{-17}), *PRKGA2* (rs10265221; p=1x10^{-13}), *RORA-AS1* (rs919582144; p=4x10^{-8}), *APOE* (rs429358, p=3x10^{-8}), *PLCH1* (rs3851357; p=1x10^{-8}), *GP2* (rs62032857;7x10^{-9}) and several intergenic loci with GWAS significance near *LINC02694*, *PRDM8*, *OR52E1*, *NIRP.*

Conclusions: Sixteen loci (three novel) were associated with longitudinal changes with GWAS significance and multiple with nominal association. *SLC47A1*, *BICC1* and *APOE* are being study as potential targets. Meta-analysis with 125,000 participants in BioVU is underway. This work will provide the basis for the construction of a diverse CKD polygenic risk score and will allow for exploration of druggable targets using actionable proteins.

Genetic GLP1R Gene Expression and Kidney Disease Progression: A Mechanistic Proteome-Wide Analysis in the Million Veteran Program

Jefferson L. Triozzi, Zhihong Yu, Otis D. Wilson, Elvis A. Akwo, Cassianne Robinson-Cohen, Talat Alp Ikizler, Ran Tao, Adriana Hung. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Glucagon-like peptide-1 receptor agonists (GLP1RA) may have nephroprotective properties beyond weight loss and glycemic control. We assessed the effect of genetically proxied GLP1RA on kidney disease progression, while accounting for its effects on obesity and diabetes as well the plasma proteome.

Methods: We assembled a national retrospective cohort of Veterans from the Million Veteran Program between 2011 and 2021. A Cox proportional hazards survival analysis assessed the association between genetically proxied GLP1RA and kidney disease progression. A proteome-wide mendelian randomization analysis examined the effect of genetically proxied GLP1RA on changes in plasma protein levels to provide mechanistic insights. The exposure was a genetic risk score for systemic *GLP1R* gene expression that was calculated for each study participant based on genetic variants associated with *GLP1R* mRNA levels within the Genotype-Tissue Expression project. The primary composite outcome was the incident 40% decline of estimated glomerular filtration rate or end-stage kidney disease. The proteome-wide analysis included up to 4907 aptamer-based plasma proteins measured by SomaScan.

Results: Among 353153 individuals, 16327 (4.6%) experienced kidney disease progression during a median (IQR) follow-up of 5.1 (3.1;7.2) years. Overall, higher genetic *GLP1R* gene expression was associated with a lower risk of kidney disease progression in the unadjusted (HR = 0.956, 95% CI [0.921 – 0.993], *p*-value = 0.022) and fully adjusted models accounting for baseline characteristics, body mass index, and the presence or absence of diabetes (HR = 0.961, 95% CI [0.925 – 0.999], *p*-value = 0.042). The results were similar in analyses stratified by diabetes or obesity status. Higher genetic *GLP1R* gene expression was associated with lower body mass index (*p*-value = 0.0087), fasting glucose (*p*-value = 0.040), and changes in metabolic plasma proteins including the downregulation of leptin (*p*-value = 0.0046).

Conclusions: Higher genetic *GLP1R* gene expression was associated with a lower risk of kidney disease progression, even after accounting for its effects on body weight and glycemic control, supporting the role of pleiotropic nephroprotective mechanisms.

Canonical Correlation Analysis Identifies Single Nucleotide Polymorphisms and Gene Expression Associated with CKD Subtypes

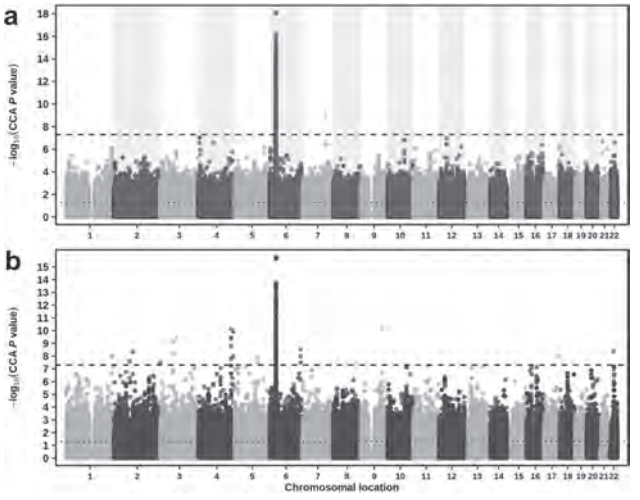
Amy J. Osborne,[1] Samantha J. Hayward,[1] Liz Colby,[1] Philip A. Kalra,[2] Olivier Radresa,[3] Philipp Skroblin,[3] Maarten W. Taal,[4] Gavin I. Welsh,[1] Moin A. Saleem,[1] Ian C. Campbell.[1] Bristol Renal. *[1]University of Bristol, Bristol, United Kingdom; [2]Northern Care Alliance NHS Foundation Trust Salford Care Organisation, Salford, United Kingdom; [3]Evotec International GmbH, Gottingen, Germany; [4]University of Nottingham, Nottingham, United Kingdom.*

Background: Genetic risk variants have been associated with chronic kidney diseases (CKD) by univariate statistical methods. Multivariate statistics such as canonical correlation analysis (CCA) have not been investigated for CKD sub-types and may provide additional insights.

Methods: We applied CCA to our NURTuRE-CKD and Salford Kidney Study (SKS) CKD single nucleotide polymorphism (SNP) datasets. We assessed expression quantitative trait loci (eQTL) colocalisation, SNP differential gene expression and allele frequency.

Results: We identified 943 replicated SNPs in the human leukocyte antigen (*HLA*) region that showed significant correlation with membranous nephropathy (MN) compared to other CKD. Most SNPs were not previously reported. The 5 lead SNPs (previously unreported) were significantly more common in both MN and diabetic nephropathy Type 1 (T1D) compared to healthy controls and showed strong eQTL colocalisation with 17 genes. Of these, five genes in blood or monocytes (*ATF6B, HLA-DQA1, HLA-DQB1, NOTCH4, RNF5*) showed differential gene expression between MN and either healthy individuals or IgA nephropathy across 11 published Gene Expression Omnibus datasets, suggesting MN-specific expression. Differential gene expression analyses suggested that the five lead SNPs affected *C4B, HLA-DQB1* and *RNF5P1* expression in CKD.

Conclusions: In summary, we found previously unreported, replicated SNPs associated with MN and T1D, likely involved in altering *HLA-DQB1* gene expression.



Single nucleotide polymorphisms for membranous nephropathy by canonical correlation analysis. Results for (a) NURTuRE-chronic kidney disease and (b) Salford Kidney Study. Each point is a SNP with chromosome and co-ordinates (x-axis) and -log10 CCA *P*-value (y-axis). The dashed line is Bonferroni-corrected 0.05 *P*-value.

FR-PO639

UMOD p.Thr62Pro Pathogenicity Is Modified by Polygenic CKD Risk

Alexander R. Chang,[1] Ian Dinsmore,[1] Bryn S. Moore,[1] Anthony J. Bleyer,[2] Tooraj Mirshahi.[1] *[1]Geisinger Health, Danville, PA; [2]Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: UMOD p.Thr62Pro has been reported as having intermediate penetrance for chronic kidney disease (CKD) with end-stage kidney disease (ESKD) occurring at a median of ~70 years of age. Since p.Thr62Pro results in an intermediate intracellular trafficking defect, we hypothesized that age and CKD polygenic risk would modify the association of Thr62Pro with estimated glomerular filtration rate (eGFR).

Methods: Using data from Geisinger MyCode/DiscovEHR, a health system-based cohort with exome sequencing and electronic health record data, we created a polygenic risk score (PRS) using summary statistics from the UK Biobank for individuals of European ancestry. Heterozygotes with UMOD p.Thr62Pro were compared to those without UMOD rare variants using linear regression for continuous outcomes and Firth logistic regression for categorical outcomes, adjusted for age, sex, and race. Primary outcome was most recent eGFR. Secondary outcomes included eGFR<60, eGFR <30, gout, and ESKD. We tested for an interaction by age ≥ or < 60 years, and conducted subgroup analyses by age group.

Results: UMOD p.Thr62Pro heterozygotes (median age 61, interquartile interval 46-72) had increased risk of ESKD (OR 2.91, 95% CI: 1.23, 6.91; p=0.02), eGFR <30 (OR 2.21, 95% CI: 1.15, 4.25; p=0.02), eGFR <60 (OR 1.64, 95% CI: 1.02, 2.64), but not gout (OR 0.48, 95% CI: 0.14, 1.71). The association of UMOD p.Thr62Pro with eGFR was stronger in adults ≥60 vs. <60 years of age (p=0.04 for interaction term) with lower eGFR for heterozygotes ≥60 years of age (-7.29 ml/min/1.73m^2, 95% CI: -2.60, -1.98) and a smaller effect for those <60 years of age (3.79, 95% CI: -1.21, 8.79; p=0.1). CKD PRS was associated with lower eGFR in UMOD p.Thr62Pro (per SD: -7.28 ml/min/1.73m2, 95% CI: -11.40, -3.16).

Conclusions: Adults with the intermediate-penetrance UMOD p.Thr62Pro variant experience increased risk of eGFR decline after 60 years of age, and risk is modified by CKD PRS.

Individuals Heterozygous for SLC34A3 Predicted Pathogenic Variants Are at Increased Risk of Nephrolithiasis

Alexander R. Chang,[1] Bryn S. Moore,[1] Jonathan Z. Luo,[1] Ion D. Bucaloiu,[1] Andrea G. Cogal,[2] Shannon K. McDonnell,[2] Jacob A. Frank,[2] Steven J. Scheinman,[1] Jun Ma,[2] Peter C. Harris,[2] John C. Lieske.[2] *[1]Geisinger Health, Danville, PA; [2]Mayo Clinic Minnesota, Rochester, MN.*

Background: Prior studies have suggested that individuals heterozygous for *SLC34A3* pathogenic variants are at risk for nephrolithiasis, but this association has not been examined comprehensively.

Methods: We used data from Geisinger MyCode/DiscovEHR (n=174,172) and the Mayo Clinic Biobank (MCBB) (n=43,743), health system-based cohorts with exome sequencing and electronic health records. An electronic phenotyping algorithm for nephrolithiasis was developed and validated in the 2 cohorts. Gene burden tests were completed using several masks based on pathogenicity predictions from LOFTEE, REVEL, and AlphaMissense (AM). We considered a Bonferroni-corrected p value <0.00714 significant. Variant-specific analyses were done using Firth logistic regression models. Analyses were adjusted for age, sex, and genetic ancestry.

Results: Prevalence of predicted pathogenic *SLC34A3* variants ranged from 0.00095 (LOFTEE) to 0.0037 (LOFTEE or AM or REVEL). Predicted pathogenic variants in *SLC34A3* using 4 of the 7 masks were associated with nephrolithiasis in MyCode (Table). Replication analyses in MCBB showed a modest association signal. In MyCode, several variants were associated with nephrolithiasis [Ser192Leu (OR 1.73; p=0.005) and Ser138Phe (OR 2.06; p=0.006)], or of borderline significance [Met403Arg (OR 2.36; p=0.1), Thr202Ile (OR 2.43; p=0.1), Met145Ile (OR 3.78; p=0.1), Gly518Arg (OR 4.13; p=0.05)]. Ser138Leu was the strongest association seen in MCBB (OR 4.65; p=0.001).

Conclusions: One in 270 individuals were carriers of *SLC34A3* predicted pathogenic variants, which were associated with increased risk of nephrolithiasis. Future studies are needed to understand the impact of *SLC34A3* on kidney stone severity, recurrence risk, and whether personalized treatment of these individuals can reduce nephrolithiasis burden.

FR-PO641

Predicted Pathogenic Missense Variants in CLDN10 Are Associated with CKD

Alexander R. Chang,[1] Bryn S. Moore,[1] Jonathan Z. Luo,[1] Andrew J. Mallett,[2] Erik Biros,[2] Tooraj Mirshahi,[1] John A. Sayer.[3] *[1]Geisinger Health, Danville, PA; [2]James Cook University, Townsville, QLD, Australia; [3]Newcastle University, Newcastle upon Tyne, United Kingdom.*

Background: *CLDN10* encodes the tight junction protein claudin-10. and has been linked to a non-Bartter, non-Gitelman autosomal recessive salt-losing tubulopathy. Recently, heterozygous protein truncating variants (PTVs) in *CLDN10* have been associated with higher cystatin C, creatinine, urea, and uric acid levels. In this study we

examined whether predicted pathogenic missense variants were associated with estimated glomerular filtration rate (eGFR) and other renal phenotypes.

Methods: We used data from the MyCode/DiscovEHR study, a health system-based cohort (n=174172) in central and northeast PA and the UK Biobank study (n=394,841). In the MyCode cohort, predicted pathogenic missense variants were determined using Alpha Missense, a deep learning-based prediction tool. In UK Biobank, missense variants/low confidence (LC) loss of function variants were grouped together (www.genebass.org). Renal phenotypes available in UK Biobank included plasma cystatin C, creatinine urea, urate. For MyCode, renal phenotypes examined included creatinine-based estimated glomerular filtration rate (eGFR), eGFR <60, eGFR<30, dipstick proteinuria, and gout. Age and sex-adjusted gene burden analyses for *CLDN10* predicted pathogenic missense variants were examined using linear regression for eGFR and Firth logistic regression for categorical variables.

Results: In MyCode, there were 118 individuals heterozygous for 37 predicted pathogenic *CLDN10* missense variants. Individuals heterozygous for predicted pathogenic *CLDN10* missense variants had lower eGFR (-7.30 ml/min/1.73m^2, 95% CI: -10.96, -3.64; p=9.2E-5), and higher risk of eGFR <60 (OR 2.80, 95% CI: 1.75, 4.47; p=1.6E=-05). Associations were not significant for gout (OR 1.90, 95% CI: 0.93, 3.93; p=0.08), eGFR <30 (OR 1.27, 95% CI: 0.56, 2.87; p=0.6), or dipstick proteinuria (OR 1.28, 95% CI: 0.79, 2.07; p=0.3). In UK Biobank rare missense/LC *CLDN10* variants were associated with cystatin C (p-value SKATO =8.66E-19), urea (p=1.88E-7), urate (p=6.25E-8), and creatinine (p=1.76E-7).

Conclusions: Predicted pathogenic missense variants in *CLDN10* were associated with reduced eGFR and eGFR<60.

FR-PO642

Association of Heterozygous CLDN10 Protein-Truncating Variants with CKD, Proteinuria, and Gout: Insights from the Geisinger MyCode/ DiscovEHR Study

Mohammad H. Al Khateeb, Bryn S. Moore, Ion D. Bucaloiu, Tooraj Mirshahi, Alexander R. Chang. *Geisinger Medical Center, Danville, PA.*

Background: The CLDN10 gene encoding the tight junction protein Claudin-10, is crucial for paracellular ion transport in the kidney's thick ascending limb. Previous studies have implicated CLDN10 in a Hypokalemic-Alkalotic Salt-Losing Tubulopathy, an autosomal recessive tight junction disease, characterized by reduced renal calcium and magnesium excretion. Heterozygous protein truncating variants (PTVs) in CLDN10 have been associated with increased markers of renal function, such as cystatin C, urea, urate, and creatinine. We analyzed data from the Geisinger MyCode/DiscovEHR study to expand our understanding of the renal phenotypes in individuals heterozygous for PTV's in CLDN10.

Methods: We identified individuals heterozygous for CLDN10 PTVs using data from Geisinger MyCode/DiscovEHR, an unselected health system-based cohort (n=174172) in central and northeast Pennsylvania with available exome sequencing and electronic health record data. We used linear regression, adjusted for age, sex, and genetic ancestry, to determine whether CLDN10 PTV heterozygosity was associated with lower estimated glomerular filtration rate (eGFR). Using Firth logistic regression, we also estimated risk for dipstick proteinuria, gout, hypokalemia, and hypocalcemia. Electronic medical records were examined to provide additional context on phenotypic features of CLDN10 heterozygotes.

Results: Among 42 individuals who were heterozygous for CLDN10 PTVs (mean age: 53.5 ± 6.3 years; 16 males, 26 females), 19 had hypertension, 14 had diabetes mellitus, 10 had chronic kidney disease, 15 had 1+ or greater persistent proteinuria, 4 had gout, 3 had nephrolithiasis, 1 patient had end-stage kidney disease at age 70 years attributed to diabetes; no patients had overt hypokalemia, hypercalcemia or hypermagnesemia. Compared to non-carriers, CLDN10 PTV heterozygotes had lower eGFR (-14.8, 95% CI: -26.13, -3.55; p=0.01), and were at higher risk of eGFR<60 (OR 4.16, 95% CI: 1.91, 9.04; p<0.001), 1+ persistent proteinuria (OR 2.83, 95% CI: 1.47-5.46, p=0.002, and 2+ persistent proteinuria (OR 3.13, 95% CI: 1.49, 6.60; p=0.003), and gout (OR 8.37, 95% CI: 1.81, 38.72; p=0.007).

Conclusions: *CLDN10* PTV heterozygotes are at increased risk of CKD as well as mild to moderate proteinuria and gout.

Phenome-Wide Association Study of APOL1 Risk Genotypes in the Mass General Brigham Biobank Using Data-Driven Disease Association Clustering

David R. Vanderwall,[1,2] Michelle Mcnulty,[2] Janewit Wongboonsin,[2] Matt G. Sampson.[2,3] Sampson Lab for Kidney Genomics. *[1]Harvard Medical School, Department of Cell Biology, Boston, MA; [2]Boston Children's Hospital, Division of Nephrology, Boston, MA; [3]Harvard Medical School, Boston, MA.*

Background: To identify clinical associations with APOL1 risk genotypes using genotype and ICD-10 diagnostic codes of 53,395 participants in the Mass General Brigham Biobank (MGBB).

Methods: The 53,395 participants in MGBB with exome sequencing data were queried for the presence of at least one *APOL1* kidney risk variant (rs73885319 and rs60910145, ["G1"] or rs71785313 ["G2"]). Presence of the G0 reference allele was noted. Individuals were classified as "Low-Risk (LR)" (G0/G1 or G0/G2) or "High-Risk (HR)" (G1/G1, G2/G2, or G1/G2). Demographic data and ICD-10 codes for each patient were extracted. A pairwise incidence matrix of all ICD-10 codes from qualifying participants was generated. The value at each matrix position reflects the number of patients in which both ICD-10 codes were mutually identified. Incidence data was subsequently clustered by Weighted Gene Correlation Network Analysis to produce clusters of broadly correlated ICD-10 codes, and further sub-clustered to produce small disease modules with at least 5 highly related ICD-10 codes. Disease module significance between the HR and LR cohorts was evaluated using Chi-Square test.

Results: 1,949 participants had at least one G1 or G2 variant, including 349 HR and 1,600 LR. The HR cohort was significantly enriched for CKD, Nephrotic Syndrome, and ESRD ($p < 0.0001$), but did not differ in T2D ($p = 0.821$). Discrete analysis of individual ICD-10 codes identified 55 codes enriched among the HR cohort; the most significant ICD-10 code was "Nephrotic Syndrome and FSGS" (OR= 15.4, [14.6 – 16.2]). Our network approach produced 251 disease modules of co-occurring ICD-10 codes; 31 disease modules were differentially enriched. A majority of these disease modules were specific for renal pathology. The most significant disease module included ICD-10 codes for "Hypertension Secondary to Renal Disorders," "Stage 5 CKD," and "Secondary Hyperparathyroidism of Renal Origin." 32.3% of significant modules mapped to non-kidney diseases, raising hypotheses of other consequences of HR variants on human health.

Conclusions: Disease network clustering across a large, densely phenotyped cohort offers an opportunity for discovery of potentially significant clinical associations of HR genotypes that would otherwise not be identified.

FR-PO644

Kidney Outcomes in APOL1 High-Risk and Mendelian Variant in Patients with Adult Nephrotic Syndrome in Mass General Brigham Biobank

Janewit Wongboonsin,[1,2] Anya Greenberg,[3] Michelle Mcnulty,[3] Ana C. Onuchic-Whitford,[2,3] Dongwon Lee,[3] Sagar U. Nigwekar,[5] Matt G. Sampson.[3,4] *[1]Mahidol University Faculty of Medicine Siriraj Hospital, Bangkok, Thailand; [2]Brigham and Women's Hospital, Boston, MA; [3]Boston Children's Hospital, Boston, MA; [4]Broad Institute, Cambridge, MA; [5]Massachusetts General Hospital, Boston, MA.*

Background: Published studies demonstrating the value of genetic stratification in nephrotic syndrome (NS) have often focused on children or research cohorts with specific characteristics. The prevalence and clinical correlates of known genetic forms of NS in adults are less well understood but may have important implications. The EHR-linked Biobank provides a unique opportunity to identify patients with NS for subsequent genomic discovery

Methods: Patients with NS were identified via ICD-10 diagnosis codes, reviews of renal pathology, and manual chart review. Exome data of NS patients were analyzed using VarSeq, with variants assessment using published guidelines. 192 genes associated with proteinuric kidney disease were evaluated. Clinical data were extracted from the Research Patient Data Registry. Adjudication of End-Stage Kidney Disease (ESKD) status was combined with data from the United States Renal Data System. ESKD status was evaluated by both logistic regression and time-to-event survival analysis. Longitudinal trends in laboratory data were analyzed using a linear mixed model

Results: 693 patients had NS, 358 of these have exome data. Diagnoses included FSGS (299 cases), MCD (29 cases), and MN (45 cases), with some patients having multiple diagnoses. 37 patients (11%) had pathogenic Mendelian variants (MV) considered causative of disease and 25 (7%) carried high-risk APOL1 genotype (APOL1-HR). 213 (59%) progressed to ESKD. Upon adjusting for age, sex, race, presence of hypertension, and diabetes mellitus, patients with MV had a 3.0 (1.3–7.3) increased odds for developing ESKD. Those with APOL1-HR had an OR of 7.6 (1.5–37.8). There was a higher hazards for ESKD in both genetic groups: 1.7 (1.2–2.6) for MV and 3.1 (1.8–5.3) for APOL1-HR. Genetic variants were significantly associated with increased monthly creatinine elevation compared to patients without variants (MV: 0.02 ml/min/month; APOL1-HR: 0.04 ml/min/month)

Conclusions: The Biobank presents an opportunity for assessment of genetic variant impact in rare kidney diseases like NS. In this population cohort of adults, both MV and APOL1-HR have a negative impact on kidney health. These findings emphasize the critical role of genetic characterization in predicting renal prognosis among nephrotic syndrome patients

Funding: Private Foundation Support

FR-PO645

Challenges and Results of ClinGen Gene-Disease Clinical Validity Curation for Complement-Mediated Kidney Disease

Janewit Wongboonsin,[1,2] Ryan F. Webb,[3] Pamela A. Robertson,[3] Alicia B. Byrne,[3] Yasar Caliskan,[4] Anuja Java,[5] David Kavanagh.[6,7] ClinGen Complement-Mediated Kidney Diseases Gene Curation Expert Panel. *[1]Brigham and Women's Hospital, Boston, MA; [2]Mahidol University Faculty of Medicine Siriraj Hospital, Bangkok, Thailand; [3]Broad Institute, Cambridge, MA; [4]Saint Louis University, St Louis, MO; [5]Washington University in St Louis, St Louis, MO; [6]National Renal Complement Therapeutics Center, Newcastle, United Kingdom; [7]Newcastle University, Newcastle upon Tyne, United Kingdom*.

Background: ClinGen is a National Institutes of Health-funded central resource to systematically evaluate the clinical validity of gene-disease relationships (GDRs) and assess variant pathogenicity. The ClinGen Kidney Disease Clinical Domain Working Group (CDWG) was established in 2019 to focus on monogenic kidney diseases. In 2022, the Complement-Mediated Kidney Disease Gene Curation Expert Panel (CMKD-GCEP) began its work by focusing on atypical hemolytic uremic syndrome (aHUS), and C3 glomerulopathy (C3G). GDR evaluation is crucial for clinical testing as it provides the foundational evidence necessary for variant interpretation

Methods: ClinGen's evidence-based semi-quantitative gene curation framework has been implemented across GCEPs. This framework encompasses genetic and experimental evidence. Genetic evidence includes case-level data, family segregation, and case-control data, while experimental evidence comprises data from functional assays and related models. The final clinical validity of the GDR is categorized into levels ranging from Refuted to Definitive. Curations undergo review by the GCEP, with feedback from complementologists incorporated to refine curation practices

Results: To date, CMKD-GCEP has evaluated 7 genes associated with aHUS and C3G. Well-known genes such as *C3, CFH, CFI,* and *CFB* were prioritized for curation and achieved Definitive GDR classifications for aHUS. *THBD* was refuted. We encountered a challenge in curating CFH-related proteins as the framework was tailored for small nucleotide variants (SNVs). *CFHR1* was the first gene curated with a limited number of SNV cases, resulting in insufficient evidence. Given the number of cases with structural variants (SV), the GCEP modified the framework to incorporate genetic evidence from SVs, thereby elevating the strength from Limited to Moderate. As only genes with at least Moderate evidence can be considered for clinical genetic testing, neglecting SVs would weaken evidence strength, hindering further genomic discoveries in complementopathy.

Conclusions: The CMKD-GCEP was established to offer high-quality GDR evidence to the public. With combined input from renal complementologists and ClinGen framework experts, the curation framework can be adapted to accommodate challenging kidney-affecting genes, such as *CFHR1*

FR-PO646

Genome-Wide Association Studies of Pediatric Nephrotic Syndrome Identify Variants Associated with Corticosteroid Response

Tiffany Tu,[1] Alejandro Ochoa,[1] Amika Sood,[3] Ciburn Chan,[1] Eileen T. Chambers,[1] Annette M. Jackson,[1] Adebowale A. Adeyemo,[2] Rasheed A. Gbadegesin.[1] *[1]Duke University, Durham, NC; [2]National Institutes of Health, Bethesda, MD; [3]University of Georgia, Athens, GA*.

Background: Nephrotic syndrome (NS) is one of the most common glomerular diseases seen in children. It is classified based on response to corticosteroid therapy as either steroid-sensitive nephrotic syndrome (SSNS), or steroid-resistant nephrotic syndrome (SRNS). The genetic architecture and the molecular mechanisms of NS are poorly understood, and there are currently no reliable predictors of therapeutic response. To improve our understanding of the genetic basis of NS and define predictors of therapy response, we carried out genome-wide analyses of previously unstudied multi-ancestry cohorts of children with NS.

Methods: We did genome-wide association studies (GWAS) in 994 children with NS and 3,558 ancestry matched controls using a logistic mixed-effects model as implemented in the *SAIGE* software package. Replication analysis was done on 1,483 children with NS in two additional independent cohorts. We imputed classical HLA alleles for allelic and haplotype association testing.

Results: Our GWAS showed that common genetic variants in the chromosome 6 major histocompatibility complex (MHC) region (in *HLA-DQB1, HLA-DRB1, HLA-DQA1*) are robustly associated with SSNS, but not SRNS. The top variant for SSNS is rs17843604 (OR 2.57, 95% CI 2.25-2.94). In addition, we identified a chromosome 16 locus with leading variant rs12925642 (OR 0.67, 95% CI 0.59-0.77) in *CLEC16A* as a major second genetic hit for SSNS outside of chromosome 6. Two other secondary genome-wide significant loci for NS were found on chromosomes 5 and 10. A haplotype defined by alleles at three *HLA* classical loci *HLA-DQA1*02:01~DQB1*02:02~DRB1*07:01* confers almost 4 times the risk of developing SSNS (OR 3.8, 95% CI 3.3-4.4). A GWAS using SRNS as cases and SSNS patients as controls identified a genome-wide significant *HLA-DQB1* locus (lead SNP rs9274639, OR 0.38 [95% CI 0.27-0.52]) that explains the differences in steroid responsiveness.

Conclusions: Our findings of genome-wide HLA class II variants and a robust genome-wide significant HLA haplotype of large effect across multiple ancestries indicate that SSNS, but not SRNS, is a predominantly immune-mediated disorder. The findings of additional secondary loci add to the slowly growing list of non-HLA risk loci and to our knowledge of NS mechanisms.

FR-PO647

Genetic Causal Relationship and Risk Factors Associated with Type 2 Diabetes and CKD

Weicong Zeng, Qiongqiong Yang. *Sun Yat-Sen Memorial Hospital, Guangzhou, China*.

Background: T2D is the most important risk factor of CKD.T2D-related CKD has family heritability and is heterogeneous. Compared with European and others, T2D patients in Asian are more likely to develop CKD and ESRD. But there is a lack of researchs about the genetic susceptibility of T2D-CKD in different ethnic groups and whether T2D-related genetic factors cause CKD.

Methods: We used East Asian-based GWAS of T2D and CKD from BBJ and European-based GWAS of T2D from DIAGRAM and CKD from UKB to explore the genetic causal relationship and risk genes associated with T2D-CKD in different ethnic groups. We performed: (1)LDSC to estimate the genetic correlation;(2)7 Mendelian randomization(MR) or MR-equivalent methods to infer the putative causality;(3) MAGMA and SMR to identify and verify new risk genes;(4)STRING and Reactome to predict the Protein-Protein Interaction and common biological pathways.

Results: In both East Asian and European, we all observed significant positive genetic correlation between T2D and CKD(EAS:rg=74.91%; EUR:rg=42.93%). MR also both showed causal effect of T2D on CKD. In East Asian, the OR of IVW is $1.30(P=5.84\times10^{-10})$. In European, the OR is $1.17(P=1.60\times10^{-10})$. In contrast, no evidence supports a causal effect of CKD on T2D. Between two populations, Z test showed no significant difference in genetic correlation ($P=1.74\times10^{-1}$). But in MR analysis, the IVW showed that the causality value in East Asian was significantly higher than that in European ($P=4.03\times10^{-2}$). In East Asian, MAGMA and SMR identified 3 new risk genes whose expression levels were likely involved in the putative causality of T2D on CKD. In European, 27 new risk genes were identified. STRING showed that *ZSCAN21* in East Asian was structurally similar to *ZNF195* in European, and they had gene co-expression and protein interaction. Reactome Pathways showed that they have some common biological pathways.*ARC* in East Asian and *MPP3* in European also had similar findings.

Conclusions: In both East Asian and European, we all found the genetic causal effect of T2D on CKD, and the risk of CKD in T2D patients in Asian is higher.3 and 27 new risk genes associated with T2D-CKD were respectively identified in East Asian and European. We found some Protein-Protein Interactions and common biological pathways around some of them. These findings posed new paths on guiding the prevention and early-stage diagnosis of CKD in T2D patients.

FR-PO648

Multiancestry Genome-Wide Association Meta-Analyses of Kidney Function Traits: The CKDGen Consortium R5 Project

Sahar Ghasemi,[1] Eva König,[2] Mathias Gorski,[3] Pascal Schlosser,[1] Matthias Wuttke.[1] CKDGen Consortium. *[1]Institute of Genetic Epidemiology, Medical Center – University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg im Breisgau, Germany; [2]Institute for Biomedicine, Eurac Research, Bolzano, Italy; [3]Department of Genetic Epidemiology, University of Regensburg, Regensburg, Germany*.

Background: Advancing Chronic Kidney Disease (CKD) genetics research involves aggregating genome-wide association studies (GWAS) from multiple ancestries on several kidney function phenotypes including estimated glomerular filtration rate (eGFR) and urinary albumin-to-creatinine ratio (UACR). Multi-lateral collaborations and rigorous, centralized data quality control (QC) are crucial to obtain reliable results.

Methods: We used our newly developed "metaGWASmanager" package for streamlined high-quality QC workflow. Studies imputed genotypes using state-of-the-art reference panels including low-frequency variants (SNPs/InDels), and implemented the same distributed set of scripts for standardized phenotyping and GWAS (regenie). Following ancestry alignment based on principal component analysis of allele frequencies, GWAS were combined in a hierarchical fixed-effects meta-analysis (METAL): within-ancestry meta-analysis (Step1) followed by between-ancestry meta-analyses (Step2)., GWAS were combined in a trans-ethnic meta-regression analysis (MrMega).

Results: In an ongoing effort, we already aggregated >1,500 GWAS from >100 studies, with improved representation of global diversity: 60% European (EUR), 20% East Asian (EAS), 12% African (AFR), 4% Hispanic/Latino (HIS), 3% South Asian (SAS), and 1% Middle Eastern (MID) ancestries. Employed imputation panels include 69% TopMed, 20% 1000Genomes, and 9% Haplotype Reference Consortium. Preliminary meta-analysis (METAL-Step2) verified known positive controls like *UMOD* (rs13329952, p=2.1e-269, n=2,264,920) and *CUBN* (rs1801239, p=6.0e-130, n=625,976) for eGFR and UACR, respectively. Both METAL and MrMega showed *UMOD* being heterogeneous across ancestries, while *CUBN* was homogeneous (**Table**).

Conclusions: By leveraging the large sample size, multi-ancestry representation through >100 studies, and the assessment of non-SNP genetic variations, the CKDGen Round 5 promises to substantially enhance our understanding of the genetic basis of CKD.

Insights into Kidney Protein Handling through a Genome-Wide Association Study (GWAS) of the Urine Proteome

Stefan Haug, Oleg Borisov, Yong Li, Anna Kottgen. *Institute of Genetic Epidemiology - University of Freiburg, Freiburg, Germany.*

Background: Urine contains small amounts of protein under physiological conditions. Levels of urine proteins are determined by filtration from plasma, exosomes and membrane patches of kidney and urothelial cells, and active tubular secretion and reabsorption. Genetic screens of the urine proteome and comparisons to similar plasma studies may offer insights into renal protein handling, particularly in kidney tubules.

Methods: We performed genome-wide association studies with 2886 proteins quantified by the antibody-based Olink Explore 3072 platform from urine samples of 1246 German Chronic Kidney Disease study participants with eGFR>45 and ≤60 mL/min/1.73m^2 and UACR<300 mg/g. In a discovery-replication design, we studied relations of protein levels and 6 million common genetic variants, adjusted for urine dilution and potential confounders. Significantly associated ($p<1.7x10^{-11}$) variants were assigned to protein quantitative trait loci (pQTLs). To examine significant urine pQTLs in detail, we performed finemapping and identified independent credible sets (CS) of variants most likely to cause association signals in each locus, comparisons to pQTLs from corresponding plasma proteome screens (UK Biobank), and genetic colocalization analyses.

Results: We identified 173 pQTLs, arising from 127 distinct genetic regions and 170 unique proteins. The 173 pQTLs contained 153 *cis* associations, with the index variant in close proximity to the protein's cognate gene, supporting the precision and validity of urine proteomics. Median protein variance explained by pQTLs was 10.3%, with a maximum of 67.2% for variant chr8:142681841:T:TG and prostate stem cell antigen levels (*PSCA* locus, GWAS p-value $1.2x10^{-451}$). Finemapping revealed 254 independent CS (1-8 CS per region). Colocalization with plasma pQTLs detected shared signals, reflecting genetic fingerprints on the systemic proteome recovered from urine. Urine-specific associations were found for at least 15 proteins including mucin-13, where a regulatory variant altering transcription factor binding in an enhancer region determined urine levels of this epithelial barrier protein.

Conclusions: Genetic screens of the urine proteome can reveal mechanisms involved in human renal protein handling. Our ongoing investigations include connections of pQTLs to the transcriptome, the urine and plasma metabolome, and clinical traits and diseases.

Funding: Government Support - Non-U.S.

Causal Association between Plasma Oxalate and Kidney Disease: Mendelian Randomization Analysis

Jade E. Bowers,[1,2] Jefferson L. Triozzi,[1,2] Piera A. Sosa,[1,2] Zhihong Yu,[1] Otis D. Wilson,[1,2] Guanchao Wang,[1,2] Ryan Hsi,[1,2] Christianne Roumie,[1,2] Adriana Hung.[1,2] Million Veteran Program. *[1]Vanderbilt University Medical Center, Nashville, TN; [2]VA Tennessee Valley Healthcare System, Nashville, TN.*

Background: Elevated urinary oxalate contributes to tubulointerstitial fibrosis and kidney disease progression. Plasma oxalate, however, is elevated in patients with kidney disease due to reduced filtration raising the question of whether plasma oxalate is a consequence of kidney disease or a causal factor in its development. This study investigated the potentially causal association between plasma oxalate and kidney disease.

Methods: We performed a mendelian randomization experiment to assess the effect of genetically determined plasma oxalate levels on kidney outcomes within the Million Veteran Program (MVP). The exposure was derived from a genome-wide association study (GWAS) of plasma metabolite levels measured using the Metabolon platform among European ancestry individuals (N = 6,136). The MVP outcomes were derived from GWASs of eGFR (N = 397,650), chronic kidney disease (CKD), and end stage renal disease (ESRD), with an additional urine protein-to-creatinine ratio outcome from the CKDGen Consortium. The mendelian randomization experiment was conducted utilizing the inverse variance weighted (IVW) analyses. Sensitivity analyses were performed in subgroups with or without diabetes mellitus (DM).

Results: In the mendelian randomization IVW analysis, higher genetically determined plasma oxalate levels were associated with increased risk of CKD (OR 1.12, 95% CI [1.03, 1.21], p-value = 0.007). In the sensitivity analyses, the non-DM patients did not show a significant effect but the DM patients showed a significant effect for all outcomes: eGFR (p-value = 0.01), CKD (p-value 0.04), and ESRD (p-value = 0.01). These genetic associations did not show evidence of heterogeneity or directional pleiotropy, supporting a potentially causal relationship.

Conclusions: Our genetic association study supports the hypothesis that increased plasma oxalate levels may increase the risk of kidney disease, especially among patients with DM. Further investigation of the mechanisms underlying this association including but not limited to genetic and dietary contributions.

Building a Biobank for Genetic Studies on Primary and Recurrent Focal Segmental Glomerulosclerosis

Elena Martinelli,[1,2] Tze Yin Lim,[1] Juntao Ke,[1] Ibrahim Batal,[1] Krzysztof Kiryluk,[1] Matt G. Sampson,[3] Moin A. Saleem,[4] Martin Pollak,[5] Friedhelm Hildebrandt,[3] Ali G. Gharavi,[1] Rasheed A. Gbadegesin,[6] Sumit Mohan,[1] Simone Sanna-Cherchi.[1] *[1]Columbia University, Division of Nephrology, New York, NY; [2]Universita degli Studi di Parma, Parma, Italy; [3]Division of Nephrology, Boston Children Hospital, Boston, MA; [4]Division of Pediatric Nephrology, University of Bristol, Bristol, United Kingdom; [5]Division of Nephrology, Beth Israel Deaconess Medical Center, Boston, MA; [6]Division of Pediatric Nephrology, Duke University, Durham, NC.*

Background: Primary and Recurrent focal segmental glomerulosclerosis (pFSGS/rFSGS) carry high burden of morbidity and graft loss after kidney transplant. Genetic studies are mostly directed to non-immune forms of FSGS leaving the complex genetic etiology of p/rFSGS unresolved. A hurdle in designing adequate genetic studies is the lack of large multiethnic cohorts. We propose a multicenter strategy to collect genetic data across lifespan and ancestries to perform genetic studies for unraveling targets amenable for drug development.

Methods: We ascertained 13,000 cases with nephrotic syndrome (NS)/FSGS from national and international centers across ages, response to immunosuppression and ancestries. DNA is available for all cases and genetic data have been generated in 60% of them. To identify p/rFSGS case we are conducting a sequential filtering by removal of cases with Mendelian/APOL1-FSGS, followed by chart review to remove secondary forms (prematurity, obesity, structural kidney anomalies, and other factors). Cases are further stratified in two tiers: 1) ESKD who have experienced post-transplant recurrence (rFSGS); 2) cases not transplanted but with predictors indicating high probability of rFSGS (full NS with >80% foot process effacement at EM, initial response to steroids with evolution to resistance, initial biopsy showing MCD and subsequent biopsy consistent with FSGS).

Results: A pilot analysis on 1,127 cases from 6 cohorts removed 202 cases with Mendelian/APOL1 FSGS (18%) and 121 cases with secondary FSGS, resulting in a group of 804 cases enriched for pFSGS. Database and chart review identified 52 individuals with rFSGS (Tier1): 63.3% pediatric (35/52), 65.4% male (34/52); across different genetic ancestries: European 55.1%, Admixed 12.2%, Latinx 10.2%, African 18.4%, Asian 4.1%. Tier2 analysis is ongoing.

Conclusions: Based on estimates from our pilot analysis we will identify at least 8,000 individuals with pFSGS for genome-wide association studies (GWAS) and exome-based rare variant burden analyses. We will then validate results on the Tier1 (estimated N>500) and Tier2 (N>2,000) subgroups individually or in aggregate. These datasets will power adequate genetic discovery studies for rare forms of FSGS.

Importance of Copy Number Variant Analysis in Patients with Monogenic Kidney Diseases: Insights from 8 Years of Experience in an Expert Centre's Genome Diagnostic Laboratory

Albertien M. van Eerde, Laura R. Claus, Robert F. Ernst, Martin Elferink, Hanneke W. van Deutekom, Bert Van der Zwaag. *Universitair Medisch Centrum Utrecht Genetica, Utrecht, Netherlands*.

Background: Genetic testing can reveal monogenic causes of kidney diseases, offering diagnostic, therapeutic, and prognostic benefits. While single nucleotide variants (SNVs) and copy number variants (CNVs) can result in kidney disease, CNV analysis is not always included in genetic testing. With read depth-based tools for CNV detection (e.g. ExomeDepth) emerging, massively parallel sequencing can detect both SNVs and CNVs. This makes CNV detection more efficient as it does not require a separate test (e.g. SNP-array, MLPA).

Methods: We investigated the diagnostic value of CNV analysis in 2,432 kidney disease patients genetically tested at the University Medical Centre Utrecht between 2014 and May 2022. We combined previous diagnostic testing results, encompassing SNVs and CNVs, with newly acquired results based on retrospective CNV analysis. The reported yield considers both ACMG variant classification and whether the genotype actually results in disease.

Results: We report a diagnostic yield of at least 23% for our complete diagnostic cohort. The total diagnostic yield based solely on CNVs was 2.4%. The overall contribution of CNV analysis, defined as the proportion of positive genetic tests requiring CNV analysis, was 10.5% and varied among different disease subcategories, with the highest impact seen in congenital anomalies of the kidney and urinary tract and chronic kidney disease at a young age. We highlight the efficiency of exome-based CNV calling, which reduces the need for additional diagnostic tests. Furthermore, a complex structural variant, likely a *COL4A4* founder variant, was identified. Additional findings unrelated to kidney diseases were reported in a small percentage of cases. This study also offers a comprehensive overview of our expert centre's diagnostic results over the past eight years covering both SNVs and CNVs.

Conclusions: In summary, this study demonstrates the substantial diagnostic value of CNV analysis, providing insights into its contribution to the diagnostic yield and advocating for its routine inclusion in genetic testing of kidney disease patients.

FR-PO653

Results of Genetic Testing with a 385-Gene Panel in African American Patients with Kidney Diseases

Anthony J. Bleyer,[1,2] Keisha L. Gibson,[4] Jessica Chaperon,[3] Jennifer Deyo,[3] Margaret Westemeyer,[3] Nour Baddar,[3] Michelle Bloom,[3] Sumit Punj,[3] Hannah C. Ainsworth,[1] Stanislav Kmoch,[1,2] Barry I. Freedman.[1] *[1]Wake Forest University School of Medicine, Winston-Salem, NC; [2]Univerzita Karlova, Praha, Czechia; [3]Natera, Inc., Austin, TX; [4]The University of North Carolina at Chapel Hill Kidney Center, Chapel Hill, NC*.

Background: While genetic factors like apolipoprotein 1 (*APOL1*) high-risk genotypes (HRG) account for much of the excess risk of end-stage kidney disease in African American (AA) patients, no broad studies of other monogenic kidney diseases in AA patients have been performed. Here we not only assessed the prevalence of *APOL1* HRGs, but also tested for other genetic causes of kidney disease and the combined prevalence of *APOL1* HRGs with these other genetic factors in a large cohort of AAs with kidney disease.

Methods: A retrospective analysis was performed on samples from a large cohort of self-reported AA patients who underwent testing with a 385 gene panel associated with common and rare genetic kidney diseases (the Renasight™ test).

Results: Of 8696 AA patients with kidney disease included in this study, positive genetic results were identified in 36.5% (3175/8696), of whom 62.5% (1985/3175) had a sole *APOL1* HRG finding with no other positive genetic findings. Among the remaining 1190 patients, positive results spanned 119 genes including *PKD1/2* (11.3%, n=359), *COL4A3/4/5* (9.2%, n=293), *HBB* (beta hemoglobinopathies/thalassemia) (2.6%, n=84), and 113 other genes (15.3%, n=487). The frequency of *APOL1* HRGs in patients with other genetic findings were: *PKD1/2* (12.3%; 44/359), *COL4A3/4/5* (24.9%; 73/293), *HBB* (22.6%;19/84), and other genetic diagnoses (21.8%;106/487). Compared with the reported frequency of *APOL1* HRG in the general AA population (13.0%), in our cohort, *APOL1* HRGs were present at a significantly higher frequency among AA patients with *COL4A3/4/5*, *HBB*, other genetic diagnoses ($P < 0.05$), but not with *PKD1/2*.

Conclusions: This study demonstrates that genetic factors beyond *APOL1* HRGs are prevalent among AA patients with kidney disease. The broad range of genetic etiologies identified in this study demonstrates the need for comprehensive genetic testing in AA patients with kidney disease. Further research around the clinical characteristics of patients with *APOL1* HRGs and a second positive finding will be needed to understand how kidney disease is driven by these genetic findings.

FR-PO654

Exome Sequencing Reveals a Monogenic Cause of Kidney Disease in 34% of Pediatric Patients at a Single Saudi Arabian Center

Katharina Lemberg,[1] Mohamed A. Shalaby,[2] Shirlee Shril,[1] Florian Buerger,[1,3] Ronen Schneider,[1] Kirollos Yousef,[1] Nils D. Mertens,[1] Bshara Mansour,[1] Caroline M. Kolvenbach,[1] Lea M. Merz,[1,4] Ken Saida,[1] Konstantin Deutsch,[1] Selina Hölzel,[1] Seyoung Yu,[1] Izzeldin Elmubarak,[1] Alina Braun,[1] Gijs A. Franken,[1] Sherif M. El Desoky,[2] Jameela A. Kari,[2] Friedhelm Hildebrandt.[1] Hildebrandt Lab. *[1]Boston Children's Hospital, Boston, MA; [2]King Abdulaziz University, Jeddah, Saudi Arabia; [3]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany; [4]Universitatsklinikum Leipzig, Leipzig, Germany*.

Background: In pediatric patients, the most frequent causes for end stage kidney disease (ESKD) are congenital anomalies of the kidney and urinary tract (CAKUT), followed by glomerulonephritis, steroid-resistant nephrotic syndrome (SRNS), renal ciliopathies and nephrolithiasis/nephrocalcinosis. A significant fraction of these disease entities is due to monogenic causes, ranging from ~10% in CAKUT to about ~55% in renal ciliopathies. Exome sequencing (ES) has revealed numerous disease-causing genes and pathogenic variants in these genes. Nevertheless, continuous efforts are crucial to expand the knowledge on these variants to establish unequivocal diagnoses. In this study, we report ES data from a single Saudi-Arabian center with an underrepresented population. Through this study, we aim to explore potential founder effects and determine specific genotype-phenotype correlations based on clinical diagnoses and genetic ancestry.

Methods: We consolidated 377 families with either SRNS, CAKUT, NPHP and stone disease / tubulopathy. In these families, we performed ES and analyzed the obtained data for variants in established disease genes for the respective diseases. These families were recruited between 2007 – 2023 at King Abdul Aziz University in Jeddah, Saudi Arabia.

Results: In this highly homozygous cohort (homozygosity by descent: 116 Mb (mean), 91 Mb (median)) 163/377 (43%) patients had SRNS, 155/377 (41%) had CAKUT, 36/377 (9.5%) had renal ciliopathies and 23/377 (6%) had stone disease / tubulopathies. Pathogenic variants were identified in 36% of families with SRNS, 18% of families with CAKUT, 75% of families with NPHP, and 61% of families with stone disease.

Conclusions: We identified a genetic cause of kidney disease in 33.6% of patients from a single Saudi-Arabian center. Elucidating prevalent disease genes and disease variants in a defined region and genetic ancestry group can provide important insights into variant pathogenicity assessment, disease management, and prognosis.

FR-PO655

Genetic Testing in Biopsy-Confirmed Kidney Disease

Insa M. Schmidt,[1] Ashish Verma,[1] Sophie E. Claudel,[1] Ragnar Palsson,[4] Anand Srivastava,[3] Isaac E. Stillman,[2] Sushrut S. Waikar.[1] *[1]Boston Medical Center, Boston, MA; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]University of Illinois Chicago, Chicago, IL; [4]Massachusetts General Hospital, Boston, MA*.

Background: Chronic kidney disease (CKD) is a major public health burden, with monogenic causes identified in approximately 10% of adult patients. Broad gene panels offer promising diagnostic avenues but the correlation between specific gene variants and distinct histologic patterns of injury has not been systematically explored in cohorts with biopsy-confirmed CKD.

Methods: We conducted genetic testing using a commercially available 385-gene kidney disease panel on 248 individuals who had biopsy-confirmed kidney disease and available DNA samples with pathologist-adjudicated semi-quantitative assessments of histopathology. Both pathogenic and likely pathogenic variants in autosomal dominant, X-linked, and autosomal recessive genes were reported.

Results: Positive genetic findings, specifically pathogenic variants, were identified in 8.1% (20/248) of cases. Mean baseline eGFR was 69±36 and 57±37 ml/min/1.73m^2 and median proteinuria [IQR] was 1.9 [0.2–4.6] and 1.7 [0.5–4.1] g/g creatinine in individuals with and without a positive genetic finding (p=0.19 and p=0.84, respectively). The most common primary clinicopathologic diagnosis of those with a positive genetic finding were proliferative glomerulonephritis (25.0%) and advanced chronic changes (20%) (**Figure 1A**). Positive results occurred most frequently in the *COL4A3* (19%), *COL4A1* (9.5%), *COL4A4* (9.5%), *CUBN* (9.5%), and *NF1* (9.5%) genes. Two variants in the same gene (*CUBN*) were identified in one case. **Figure 1B** illustrates the patterns of histopathologic changes observed in individuals with positive genetic findings. Pathogenic variants in genes such as *INF2*, *KMT2D*, and *KRAS* showed a trend towards severe patterns of injury, including high scores in interstitial fibrosis and tubular atrophy, glomerulosclerosis, and arterial and arteriolar sclerosis.

Conclusions: Integrating genetic data with detailed tissue-level changes may inform future research aimed at elucidating the genotype-phenotype relationships in CKD. This approach may help to identify potential areas for targeted interventions, ultimately aiming to improve patient outcomes by tailoring treatments to specific genetic and histologic profiles.

Genotype-Phenotype Correlations in Combined Kidney Histopathology and Genetic Testing on a 385-Gene Kidney Disease Panel

Cristian Riella,[1] Dan Colombo,[1] Helmut G. Rennke,[2] Isaac E. Stillman,[1] Astrid Weins,[2] Seymour Rosen,[1] Yael K. Heher,[1] Giada Bianchi,[2] Anthony J. Bleyer,[3] Stanislav Kmoch,[4] Weining Lu,[5] Peter G. Czarnecki.[1] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Wake Forest University School of Medicine, Winston-Salem, NC; [4]Univerzita Karlova, Praha, Czechia; [5]Boston University, Boston, MA.*

Background: The magnitude of causative and contributory genetic mechanisms in adult chronic kidney disease is unknown. We aimed to investigate genotype data from large kidney disease gene panel tests in the context of histopathologic findings and identify the diagnostic strengths of both methods alone and in combination. We further sought to find correlations between genetic variants and histologic and ultrastructural phenotypes.

Methods: We analyzed genetic test results, clinical parameters of kidney disease and renal histopathology findings in 115 patients from two major academic medical centers in Boston.

Results: In 37.4% of cases, kidney disease was sufficiently diagnosed by pathology, in 34.8% of cases a precision diagnosis was made by combined pathology and genetic testing, and in 33.0% of cases, pathology only delivered a less specific pattern diagnosis. Genetic testing alone led to a final diagnosis in 29.6% of cases, and it was particularly powerful in cohorts with positive family history of CKD and in the absence of diabetes, glomerulonephritis or immune deposition disease. We discovered a surprisingly high amount of TBMN-Alport-spectrum disease with no detectable collagen gene mutations (63.3%). We also demonstrate that the magnitude of age-independent global glomerulosclerosis strongly correlates with the presence of genetic variants in ADTKD-, CAKUT- and podocyte genes. In the course of our analysis, we identified variants of uncertain significance in at least 10 kidney disease genes that are potentially pathogenic.

Conclusions: Our study highlights the specific strengths of combined histopathology and genetic testing in the precision diagnosis of renal parenchymal disease, suggesting genetic causation in patients with positive family histories, absence of diabetes, glomerulonephritis and immune deposition disease. We demonstrate the genetic complexity of TBMN-Alport-spectrum disease that is far beyond collagen-IVα mutation, and we find supporting evidence for the hypothesis that age-independent global glomerulosclerosis is driven by genetic factors.

FR-PO657

Utility of Genetic Testing in Patients with CKD of Uncertain Etiology: Results from an Underserved, Predominantly African American, Urban Population

Nahida Baigam, Tammy N. Do, Annalisa B. Perez, Siddhartha D. Bajracharya, Rajesh Mohandas. *LSU Health New Orleans, New Orleans, LA.*

Background: Genetic testing is being increasingly used in the diagnosis of patients with Chronic Kidney Disease(CKD) of uncertain etiology. Most centers limit the use to young patients with unexplained CKD or those with a strong family history of kidney disease. The utility of genetic testing might vary depending on the genetic composition of the population studied. We report our experience with genetic testing in a large, urban, predominantly African American population, associated with an academic practice in New Orleans

Methods: DNA from a cheek swab of 65 patients with CKD of uncertain etiology was evaluated for 385 gene panels (the RenasightTM test).

Results: The mean age of the patient population was 55 +/- 13 years. Of those most were males 78 %, and African American 71 %. Overall, 34 % had a known pathogenic mutation while 66 % had negative tests. The mean age in the positive and negative test groups was 52.58 and 56.86 years, respectively. Many patients who did not have a pathogenic mutation had carrier status for APOLA1 or COL4.

Conclusions: CKD-focused genetic panels have significantly enhanced clinical diagnoses. In our patient population, which was not restricted by age or a positive family history, 1/3 patients had a definitive diagnosis for their CKD because of genetic testing. These findings advocate for the broader implementation of genetic test panels in the clinical care of CKD patients with unknown etiology.

FR-PO658

The RenaCARE Study: Updating Genetic Testing Results in Response to New Gene-Disease Association and Variant Upgrade

Margaret Westemeyer, Sangeeta Bhorade, Hossein Tabriziani, Dinah Clark. *Natera Inc, Austin, TX.*

Background: Genetic testing enables physicians to identify underlying molecular diagnoses and tailor treatment to optimize patient care. For chronic kidney disease (CKD), positive genetic results have been shown to impact patient management in up to 89% of cases. Genetic test results may change over time due to variant reclassification or new gene-disease associations. In such cases the testing laboratory may issue an updated report to notify physicians of new findings.

Methods: The Renasight Clinical Application, Review, and Evaluation (RenaCARE) study was conducted to evaluate the diagnostic and clinical utility of genetic test results in patients with CKD. 1624 patients (median: 55 years; range 18-96) were enrolled. Genetic testing was performed using a CKD-focused 385-gene panel (the Renasight™ test, Natera, Inc) on patient samples. Genetic testing results were compared at one year post-test with those at the original report date to determine the number and nature of cases with updated genetic test results. (e.g. establishment of new gene-disease associations, or upgrade of variant/s classified as a variant of uncertain significance (VUS) to likely pathogenic/ pathogenic variant.

Results: 338 study patients originally had positive results in 54 genes. 18 additional cases (n=356) had a new positive result at one year; these involved five genes: *COL4A3* (n=1), *IFT140* (n=9), *PKD1* (n=6), *PKD2* (n=1), and *RRM2B* (n=1). Variants in *IFT140* were previously only associated with an autosomal recessive ciliopathy; new evidence associating single IFT140 loss of function variants with ADPKD resulted in a result change from "carrier" to "positive" for all 9 patients. For the other 9 patients, incorporation of new data resulted in upgrades from VUS to pathogenic or likely pathogenic classification. These findings represent a 1.1% increase in positive rate and comprise 5.1% of positive study results at one year.

Conclusions: This study demonstrated how new evidence in gene-disease association and variant classification can impact patients who underwent genetic testing with a broad CKD-focused panel beyond their initial result. These findings are representative of the evolving findings in CKD genetic testing and can increase the diagnostic/clinical utility of the test.

Fabry Disease Genetic Diagnosis in a Large CKD Population Tested with a Broad Kidney Gene Panel

Margaret Westemeyer,[1] Jennifer Deyo,[1] David G. Warnock,[2] Eric L. Wallace.[2] *[1]Natera, Inc., Austin, TX; [2]University of Alabama at Birmingham, Birmingham, AL.*

Background: Fabry disease (FD) is a genetic disorder caused by variants in *GLA* that encode lysosomal enzyme α-galactosidase A and leads to progressive damage in various organs especially kidneys, heart, and brain, due to glycosphingolipid accumulation. Due to X-linked inheritance, FD is generally more severe in males. Females with FD exhibit heterogeneous presentation, are underdiagnosed and are expected to inherit the disease twice as often. Patients may undergo a diagnostic odyssey, with an estimate of at least 15 years between FD onset and diagnosis. Early diagnosis is key to preventing severe complications through initiation of multiple available FD treatments. We assessed the real-world prevalence and characteristics of FD detected by genetic testing in individuals with kidney disease.

Methods: Cases with a pathogenic (P) or likely pathogenic (LP) variant in *GLA* were identified in a large database of individuals that underwent genetic testing with a 385 renal gene panel (the Renasight™ test, Natera, Inc.). Available clinical and demographic data including age, ethnicity, sex, and ICD-10 codes, were collected.

Results: Out of 67,437 cases, 111 (M:50; F:61) had a positive *GLA* finding, an overall prevalence of 1:608 (0.16%). The mean age of *GLA*-positive patients at the time of testing was 43.6y (M:44.4y; F:43.0y) and 47.8% were Caucasian. Of all *GLA*-positive cases, 47.7% had a clinical FD diagnosis, representing 58.0% and 39.3% of male and female patients, respectively. 9.9% (11/111) of *GLA*-positive cases had a second positive genetic

finding, two of which had an a priori FD diagnosis. 72.7% (8/11) of cases with a second positive finding were female.

Conclusions: This study showed that broad genetic testing identified FD in kidney disease patients without a clinical diagnosis. The prevalence of FD among individuals with CKD, identified via genetic testing is significantly higher than the general population (1:40,000). The low proportion of female patients reporting FD suggests that diagnosis is less likely to be suspected in female patients with kidney disease. Furthermore, the high prevalence of dual positive findings in this cohort underscores the importance of testing with a broad genetic panel. Diagnosis of FD through genetic testing can inform the use of tailored therapeutics and diagnostic decisions.

Importance of 3-Year-Old Urinalysis in Diagnosing Alport Syndrome

Hideaki Kitakado, Yuka Kimura, Yuta Inoki, Yu Tanaka, Chika Ueda, Nana Sakakibara, China Nagano, Tomoko Horinouchi, Tomohiko Yamamura, Shingo Ishimori, Kandai Nozu. *Department of Pediatrics, Kobe University Graduate School of Medicine, Kobe, Japan.*

Background: Alport syndrome (AS) is an inherited kidney disease caused by pathogenic variants in COL4A3, COL4A4, and COL4A5, which encode the α3, α4, and α5 chains of type IV collagen. The prevalence is estimated at 1 in 5000 individuals, with autosomal dominant (ADAS), autosomal recessive (ARAS), and X-linked (XLAS) forms. Symptoms typically begin with hematuria in the early stages, progressing to increased proteinuria and eventual kidney failure. Renin-Angiotensin-Aldosterone System inhibitors can delay at which kidney failure occurs, underscoring the importance of early diagnosis and intervention, especially in patients with proteinuria. In Japan, a mass urinalysis is available for all 3-year-old children and annually for all elementary to high school students, and the 3-year-olds urinalysis has been shown to be potentially useful in the early detection of AS.

Methods: We examined diagnostic events in 337 cases of AS diagnosed by genetic testing from August 2015 to September 2023, with patients aged 18 years or younger.

Results: Among the 337 cases, 175 were males (52%), and the median age was 6 years. The most common event for detecting urinary abnormalities was the 3-year-old urine test, accounting for 102 cases (30%). Other events included the incidental detection of urinary abnormalities during the examination of other diseases (77 cases, 23%), episodes of macroscopic hematuria (76 cases, 23%), school urine tests (18 cases, 5%), and nursery urine tests (18 cases, 5%). Among the 102 cases identified by the 3-year-old urine test, the breakdown of each genetic form was XLAS males (29%), XLAS females (44%), ADAS (20%), and ARAS (7%). Of these, 42 cases showed both hematuria and proteinuria, with XLAS males accounting for 15 out of 30 cases (50%), XLAS females for 15 out of 45 cases (33%), ADAS for 6 out of 20 cases (30%), and ARAS for 6 out of 7 cases (86%).

Conclusions: The 3-year-old urine test is the most common diagnostic event for AS, encompassing all genetic forms. The proportion of cases with proteinuria is higher in ARAS and XLAS males, but it is present in all genetic forms. In over 40% of cases, urinary protein is already observed, enabling early intervention. It is important that the benefits of the 3-year-old urine test for the early detection of AS.

Familial Variability of Disease Progression in Autosomal Dominant Alport Syndrome: Results from SHRAS

Xuantong Dai, Ningning Hu, Gengru Jiang, Fujun F. Lin. *Renal Division, Department of Internal Medicine, Xin Hua Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China.*

Background: Autosomal dominant Alport syndrome (ADAS), caused by heterozygous *COL4A3* or *COL4A4* pathogenic variants, is characterized by a large variability of disease progression. This study aims to evaluate the intrafamilial variability of disease progression and the relevant predictors in Chinese ADAS patients from the Shanghai Registry of Alport syndrome (SHRAS).

Methods: SHRAS, part of the Shanghai Registry of Genetic Kidney Disease, performed collection of clinical, and genetic data of ADAS patients referred from 14 leading tertiary hospitals across China since 2006. In kindreds with ≥ 2 affected individuals, discordant disease progression were evaluated in 2 categories: age at onset of proteinuria and stage 3 chronic kidney disease (CKD). Marked intrafamilial variability was defined as the onset age across 2 categories differed ≥ 20 years in at least 2 patients in one kindred, or in kindred with both pediatric and adult patients, proteinuria or stage 3 CKD developed in at least 1 pediatric patient while the phenotype of adult patient was isolated hematuria.

Results: Among 73 kindreds of 311 ADAS patients (118 pediatric and 193 adult patients), 31 kindreds (42.47%) of 72 patients (21 pediatric and 51 adult patients) were deemed as discordant disease progression. Intrafamilial variability was not associated with family size nor genotype (Table 1). Multivariate mixed-effects model revealed concomitant kidney disease and disease onset age as risk factors of variability (Figure 1).

Conclusions: In ADAS cohort of SHRAS, marked intrafamilial variability of disease progression was observed. Our findings didn't reveal a significant genotype influence on intrafamilial variability, which necessitates a more thorough identification of relevant clinical and genotypic factors.

Table 1. Characteristics of ADAS kindreds with intrafamilial variability of disease progression

Variables	Intrafamilial variability	Concordant families	P-value
Numbers of kindreds (numbers of patients)	31 (72)	42 (96)	–
2 members per kindred, N (%)	24 (77.4)	32 (76.2)	0.902
> 2 members per kindred, N (%)	7 (22.6)	10 (23.8)	
Patients with proteinuria, N (%)	54 (75.0)	34 (35.4)	<0.001
Onset age of proteinuria	27.5 ± 19.0	35.3 ± 14.0	0.031
Patients reaching stage 3 CKD, N (%)	7 (9.7)	7 (7.3)	0.573
Onset age of stage 3 CKD	36.7 ± 13.7	55.7 ± 13.1	0.026
COL4A3/A4-truncating variants, N (%)	7 (22.6)	10 (23.8)	0.902
COL4A3/A4-nontruncating variants, N (%)	24 (77.4)	32 (76.2)	

Figure 1. Cox proportional hazard model for intrafamilial variability of ADAS disease progression

Variables	Univariate analysis	P-value	Multivariate analysis	P-value
	HR (95% CI)		HR (95% CI)	
Onset age of disease (yrs)	0.93 (0.91, 0.95)	<0.001	0.93 (0.91, 0.95)	<0.001
Male	1.05 (0.68, 1.62)	0.821		
Hypertension	0.94 (0.55, 1.60)	0.822		
COL4A3/A4-truncating variants	1.27 (0.78, 2.09)	0.339		
Concomitant kidney disease	2.17 (0.998, 4.73)	0.051	3.17 (1.43, 7.03)	0.005

The ClinGen Alport Syndrome Variant Curation Expert Panel: Guiding Variant Classification in COL4A3, COL4A4, and COL4A5

Alicia B. Byrne,[1] Janewit Wongboonsin,[2] Mary-Beth Roberts,[3] Judith A. Savige,[4] Rachel Lennon.[5] ClinGen Alport Syndrome Variant Curation Expert Panel. *[1]Broad Institute, Cambridge, MA; [2]Mahidol University Faculty of Medicine Siriraj Hospital, Bangkok, Thailand; [3]Cleveland Clinic, Cleveland, OH; [4]University of Melbourne, Melbourne, VIC, Australia; [5]The University of Manchester, Manchester, United Kingdom.*

Background: The ClinGen Alport Syndrome (AS) Variant Curation Expert Panel (VCEP) was established in 2023 with the purview to define variant classification criteria tailored for the genes *COL4A3*, *COL4A4*, and *COL4A5* in the context of AS and its associated phenotypes. These refined criteria will then be used to determine expert classifications of variant pathogenicity and interpretations of relevance to disease causality. ClinGen VCEPs across other disease areas have demonstrated that this process enhances the accuracy and consistency of variant classification, and can decrease the number of variants that are of uncertain significance.

Methods: Using the 2015 ACMG/AMP Sequence Variant Classification framework as the basis, the AS VCEP is systematically reviewing the 26 defined lines of evidence to determine ways in which they can be refined to be more specific to the known biology of collagen genes and the known characteristics of AS presentations.

Results: The lines of evidence considered in variant classification fall into two main categories: human observational data and predictive and functional data. In refining the use of human observational data-related evidence, the AS VCEP have defined the phenotypes that must be present for an individual to be considered a 'case'; a concept integral to the application of multiple of these evidence types, and established thresholds to determine whether a variant's frequency in the population is consistent with disease causality. In reviewing predictive lines of evidence, the AS VCEP is paying particular attention to glycine variants affecting the Gly-X-Y repeat in the triple helical domain, developing guidance for how to appropriately weight the known damaging impact of this established, dominant negative disease mechanism in comparison to other variant types. Finally, recommendations are also being developed to guide calibrated integration of evidence provided by functional assays.

Conclusions: The work of the AS VCEP in developing tailored criteria for the classification of variants in *COL4A3*, *COL4A4*, and *COL4A5* will provide a harmonized framework that maximizes the utility of available evidence, leading to improved accuracy in variant classification and interpretation, in turn, improving clinical care for individuals with variants in these genes.

Increased Odds of Nephrotic Syndrome and ESKD in Fin-Major Heterozygotes

Adrian O. Banerji,[1] Aarno Palotie,[2,3] Matt G. Sampson.[1,4] FinnGen.
[1]Boston Children's Hospital, Boston, MA; [2]Helsingin yliopisto, Helsinki, Finland; [3]Massachusetts General Hospital, Boston, MA; [4]Harvard Medical School, Boston, MA.

Background: *NPHS1* loss of function (LOF) variants are known to cause congenital nephrotic syndrome (NS) with recessive inheritance. Fin-Major was the first described *NPHS1* LOF variant. The clinical impact of Fin-Major in the heterozygous state is incompletely understood. We assessed the prevalence of nephrotic syndrome and end stage kidney disease (ESKD) for Fin-Major heterozygotes in the FinnGen study, in which 10% of the Finnish population (n=520,212) is enrolled.

Methods: The FinnGen database was used to identify individuals heterozygous for Fin-Major, and those without identified *NPHS1* variants. Patients homozygous for Fin-Major or with at least one other *NPHS1* variant were excluded, thereby excluding known compound heterozygotes. Individuals without identified *NPHS1* variants were used as controls. Individuals with NS or ESKD (chronic dialysis or kidney transplant) were identified by ICD-10 code. As these are chronic conditions, only individuals with repeated codes for each condition were included for further analysis.

Results: Among all FinnGen participants, 8,944 individuals were heterozygous for Fin-Major, 859 had NS, and 3,536 had ESKD. Individuals heterozygous for Fin-Major had 2 times increased odds to have nephrotic syndrome and 1.5 times increased odds to have ESKD compared to those without Fin-Major (P<0.001). After exclusion of Fin-Major heterozygotes with congenital NS (n=8), Fin-Major heterozygous individuals had 1.4 times increased odds to have nephrotic syndrome and 1.3 times increased odds to have ESKD (p=0.1, p=0.01).

Conclusions: Individuals heterozygous for the Fin-Major variant have increased risk for nephrotic syndrome and ESKD. This persists even after exclusion of individuals with congenital nephrotic syndrome. Further work, including exome sequencing of *NPHS1*, is needed to identify if this risk is due to unrecognized compound heterozygosity or if *NPHS1* haplo-insufficiency is a contributor to kidney disease risk.

A Novel Pattern of Mutations in Northern Indian Children with Steroid-Resistant Nephrotic Syndrome

Narayan Prasad, Brijesh Yadav, Jeyakumar Meyyappan. *Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.*

Background: Steroid Resistant Nephrotic Syndrome(SRNS) in children poses treatment challenges, and many had genetic mutations. Data on genetics is scarce.

Methods: A prospective study(Oct2018–April2023) enrolled children with SRNS who consented to DNA isolation and next-generation sequencing to explore genetic variants and their clinical outcomes. Clinical, histological and genetic data were recorded.

Results: Out of 680 NS patients, 121(17.8%) had SRNS and 96consented to genetic analysis. Of them 69(71.9%) were early SRNS and 27(28.1%) late nonreponder. 63(65.7%) had reportable genetic variants and genetic variant Pathogenic or likely Pathogeneic is shown in Image1, and genetic variant Variant of Unknown Significance or likely benign in Image 2. COL4A genes mutation was seen in 20(31.7%) patients. Renal biopsy showed FSGS in 31/42(74%) with variants. Complete(11%) and Partial remission(23.9%) with CNI was observed.

Conclusions: 65.7% SRNS patients had genetic variants, and COL4A variants were responsible for 31.7 %. CNI reponse was also observed.

Genetic profile of patients with genetic variant classified as Variant of Unknown Significance (VUS) or likely benign (LB)

FR-PO665

Population Frequency of Genetic Causes of Autosomal Dominant FSGS

Mary Huang, Judith A. Savige. *The University of Melbourne Faculty of Medicine Dentistry and Health Sciences, Melbourne, VIC, Australia.*

Background: Patients with autosomal dominant (AD) Focal and Segmental Glomerulosclerosis (FSGS) often have pathogenic variants in the Alport genes (*COL4A3, 4),* or in *ACTN4, INF2, PAX2, TRPC6* or *WT1*. This study determined how often 'predicted pathogenic' variants in the commonest genes affected in AD FSGS were found undiagnosed in the normal population.

Methods: Genes were downloaded from gnomAD v2.1 and annotated in ANNOVAR. Structural and null variants were 'predicted pathogenic' and missense variants assessed for predicted pathogenicity based on rarity, computational scores, and whether they affected a conserved amino acid. As an example, our approach for predicting pathogenic missense variants in *INF2* had a sensitivity of 95% and specificity of 95% when compared with 20 benign and 20 pathogenic variants reported in LOVD. The population frequencies for the genes were then compared with variants classified Pathogenic or Likely pathogenic in ClinVar. (ClinVar variant assessments are likely to be accurate but lists may be incomplete.)

Results: Predicted pathogenic variants (null, structural and missense changes) in *COL4A3* and *COL4A4* affected about one in 113 individuals. Predicted pathogenic variants in the other genes for AD FSGS affected one in 186 individuals. The number of people with a variant in an AD FSGS gene classified Pathogenic or Likely Pathogenic in Clin Var was much less, corresponding to one in 4711 of the population.

Conclusions: Predicted pathogenic variants in *COL4A3* and *COL4A4* together are more common than other genes associated with AD FSGS. The true population frequency is likely to be greater than that calculated from variants reported Pathogenic or Likely pathogenic in ClinVar and may be closer to our assessment. However the penetrance of these predicted pathogenic variants for AD FSGS is not known.

Number of people with predicted pathogenic variant in AD FSGS genes

	Total of COL4A3, 4	ACTN4	INF2	PAX2	TRPC6	WT1	Total of other genes
Null and structural variants	350 (one in 323)	22	24	28	65	109	248 (one in 436)
Missense variants – our assessment	649 (one in 174)	87	106	48	97	21	359 (one in 301)
Total with our assessment	999 (one in 113)	109	130	76	162	130	607 (one in 186)
ClinVar	824 (one in 137)	2	3	13	2	3	23 (one in 4711)

FR-PO666

Population Frequency of Common Genetic Causes of Congenital Anomalies of the Kidney and Urinary Tract (CAKUT)

Mary Huang,[1] Judith A. Savige.[2] *[1]The University of Melbourne, Melbourne Medical School, Melbourne, VIC, Australia; [2]The University of Melbourne Faculty of Medicine Dentistry and Health Sciences, Melbourne, VIC, Australia.*

Background: Congenital Anomalies of the Kidney and Urinary Tract (CAKUT) is the leading cause of kidney failure in children. Imaging suggests that CAKUT affects one in 200 newborns and genetic causes are estimated in 20% of these or one in 1000. Six genes are commonly affected and, while more than 250 have been reported, most are only found in individual families. This study determined a more accurate population frequency for genetic causes of CAKUT from the number of predicted pathogenic variants in the commonest CAKUT genes and from pathogenic variants found in variant databases.

Methods: *HNF1B, SALL1, EYA1, PBX1, GATA3, PAX2* variants were downloaded from gnomAD v.2.1, and annotated in ANNOVAR. Structural and null variants were considered pathogenic and missense variants were assessed for pathogenicity based on their rarity, scores in PP2, SIFT and MT, and whether they affected a residue conserved in vertebrates. This approach for predicted pathogenic missense variants in *HNF1B* had a sensitivity of 80% and specificity of 63%. The population frequencies for the 6 genes were then compared with those in the control gnomAD subset, and with the variants classified as pathogenic in ClinVar, LOVD or HGMD.

Results: Overall, predicted pathogenic variants in the 6 CAKUT genes affected one in 230 of the gnomAD population and one in 270 controls. The population frequency of structural and null variants alone was one in 1642. Predicted pathogenic variants causing CAKUT were least common in Ashkenazi people (one in 864) and Finns (one in 837). The population frequencies for all pathogenic variants were one in 1263 for ClinVar, one in 437 for LOVD, one in 40 for HGMD.

Conclusions: Genetic forms of CAKUT resulting from predicted pathogenic variants in the most frequently affected genes are found more often than previously suspected and may represent the major cause of CAKUT rather than environmental factors.

FR-PO667

Genetic Landscape of Glomerular Diseases and FSGS among More than 50,000 People Genetically Tested for CKD

Michelle Bloom, Dinah Clark, Robert T. Burns, Elizabeth Garrity, Sumit Punj, Stephen Andrews. *Natera Inc, Austin, TX.*

Background: Focal segmental glomerulosclerosis (FSGS) is a histologic feature that is characteristic of a variety of glomerular diseases (GD). Etiologies of FSGS can be genetic, environmental, or idiopathic. Genetic testing can directly identify the cause of disease; without it, the various forms can be indistinguishable. A recent study demonstrated the utility of genetic investigation to identify an underlying cause of FSGS, especially important given the heterogeneity and that most genetic subtypes are not responsive to steroid therapies. Here we investigate the landscape and contribution of FSGS-related genes in GD in a large cohort.

Methods: A retrospective analysis of results from patients tested with a renal gene panel (the Rensight™ test) May 2020 - July 2023 identified cases that: a) indicated a GD and/or an ICD-10 code in the N00-N08 range on the requisition form and/or b) had positive findings (1 pathogenic (P) or likely pathogenic (LP) variant in a gene associated with autosomal dominant or X-linked disease, or 2 P/LP variants or risk alleles in an autosomal recessive gene) in one of 35 FSGS-related genes. The proportion of P/LP variants in each gene and odds ratios of variants in the GD and non-GD groups were assessed.

Results: Across 57205 individuals, 15490 had a positive test result, of which 49.9% (7737) were in one or more FSGS-related genes. Of the 35 FSGS-related genes queried, positive results were identified in 26. While *APOL1* and *COL4A3/4/5* were the most prevalent findings, 10.5% (810/7737) of positive cases had findings in the remaining 22 genes. Six FSGS-related genes (*WT1, LMX1B, INF2, TRPC6, NPHS1, APOL1*) were strongly associated with GD phenotypes (odds ratios 1.86 - 10.26; $p < 0.016$).

Conclusions: Identification of causative variants spanning 26 genes in this cohort illustrates the genetic heterogeneity of FSGS. Notably, several of the FSGS-related genes with the highest prevalence of positive findings were not among those with the strongest associations with GD phenotype. This suggests that patients with these variants may have clinical presentations that are mild and/or precede GD. As FSGS is a histologic indication of later stage disease, longitudinal clinical information would provide insight into the prognosis of individuals with variants in these genes.

FR-PO668

Diagnostic Yield and Clinical Utility of Genomic Testing in Patients with Suspected Genetic Kidney Disease: Singapore's First-Year Experience

Ru Sin Lim,[1] Regina S. Lim,[1] Ziyin Wang,[1] Yaochun Zhang,[2,3] Si Ting Lim,[2,3] Mya Than,[2,3] Jun Li Ng,[2,3] Kay Yuan Chong,[5] Jing Yi Ho,[4] Esther Huimin Leow,[4] Yong Hong Ng,[4] Jason Choo Chon Jun,[5] Gek Cher Chan,[2,3] Yi Da,[3] Ruochen Du,[2] Kar Hui Ng.[2,3] Renal Alliance for Precision Diagnosis in Singapore (RAPIDS). *[1]Tan Tock Seng Hospital, Singapore, Singapore; [2]National University of Singapore Yong Loo Lin School of Medicine, Singapore, Singapore; [3]National University Health System, Singapore, Singapore; [4]KK Women's and Children's Hospital, Singapore, Singapore; [5]Singapore General Hospital, Singapore, Singapore.*

Background: The genetic diagnostic yield for monogenic kidney disease is 25-30% in children and 10-30% in adults. Recognizing genetic kidney disease (GKD) as a cause of chronic kidney disease (CKD) has clinical implications. We aim to evaluate the diagnostic yield and clinical utility of genomic testing in suspected GKD patients.

Methods: We included patients with primary glomerular diseases with suspected genetic etiology or CKD of unknown etiology. Proband samples underwent clinical-grade targeted panel testing of 84 glomerular genes or whole exome sequencing (WES). This study was conducted at four tertiary hospitals in Singapore from March 2023 to January 2024.

Results: We recruited 147 probands: 102 (69.4%) adults and 45 (30.6%) children, with 61 (41.5%) females. The mean recruitment age was 33.1 ± 18.4 years and the mean disease onset age was 24.5 ± 17.4 years. They comprised of 118 (80.2%) Chinese, 12 (8.2%) Malays and 10 (6.8%) Indians. The genetic diagnostic rate was 34/147 (23.1%): 12/45 (26.7%) in children and 22/102 (21.6%) in adults involving ten distinct disorders, of which Alport syndrome accounts for 76%. 4 probands (2.7%) had suspicious variants of uncertain significance. Female gender (OR 6.7; p=0.001), extrarenal malformations (OR 3.5; p=0.039), and Alport features on kidney biopsy (OR 17.7; p=0.029) predict a GKD diagnosis. Of those with GKD diagnosis who had post-genetic counselling (n=26), genomic testing had significant clinical impact in 20/26 (77%), entailing providing appropriate treatment in 13/26 (50%), avoiding kidney biopsy in 5/26 (19.2%), initiating extra-renal surveillance in 10/26 (38.5%), confirming the genetic diagnosis, offering closure and prognostication in 16/26 (61.5%), guiding reproductive decisions in 9/26 (34.6%), offering cascade family testing in 14/26 (53.8%), and aiding in selecting suitable living kidney donor while predicting post-transplant recurrence in 4/26 (15.4%).

Conclusions: Our study shows that genomic testing has a high diagnostic yield, impacting patient management for both positive and negative findings. This supports integrating genomic testing into standard kidney disease care and underscores its clinical utility in suspected GKD.

Trio Exome Sequencing Implicates Wnt Signaling in the Pathogenesis of Bladder-Exstrophy-Epispadias Complex

Leah Bolsius, Katelyn N. Ralston, Lily Hiltebeitel, Joseph G. Borer, Richard S. Lee, Friedhelm Hildebrandt, Ted Lee, Nina Mann. *Boston Children's Hospital, Boston, MA.*

Background: Bladder-exstrophy-epispadias complex (BEEC) describes a spectrum of lower abdominal and genitourinary midline malformations, including epispadias, bladder exstrophy, and cloacal exstrophy. Although the cause of BEEC is uncertain, increased concordance rates among monozygotic (62%) vs. dizygotic twins (11%) and previously identified BEEC candidate genes suggest a hereditary component. This study aims to uncover novel genetic causes of BEEC through exome analysis.

Methods: We performed exome sequencing for 38 BEEC case-parent trios and 57 singlet probands who received care at a single institution between 09/2022 and 04/2024. For analysis, we employed a candidate gene approach utilizing a list of 130 genes curated from previously published BEEC genomic studies and mouse models. Unbiased exome analysis was also conducted to identify novel BEEC candidate genes.

Results: We identified a *de novo* pathogenic variant in *PORCN* (c.1186C>T; p.Arg396*) in one proband with bladder exstrophy and focal dermal hypoplasia (FDH). *PORCN* is required for Wnt protein secretion, and variants have previously been described in patients with both bladder exstrophy and FDH. In addition, we detected 2 potentially deleterious heterozygous variants in Wnt pathway genes among 2 singlet probands: *WNT5A* (c.1033G>C; p.Asp345His) and *WNT8B* (c.185G>A; p.Arg62His). Both variants have deleterious *in silico* prediction scores and show a strong conservation. Interestingly, *WNT5A* knockout mice display severe defects in urethral tube formation. Through unbiased trio analysis, we also identified 2 novel candidate genes in 2 probands: *TAF5L* (c.1328C>T, p.Thr443Met) and *EVX1* (c.832C>A, p.Pro278Thr). Both variants arose *de novo*, have deleterious *in silico* prediction scores, are strongly conserved, and are absent from large population databases. *EVX1* is a transcription factor involved in cloacal membrane development and acts downstream of *WNT3A*.

Conclusions: Through exome analysis, we identified a pathogenic *PORCN* variant in one proband with bladder exstrophy and FDH, along with 3 potentially deleterious variants in Wnt pathway genes among 3 probands with BEEC. This further supports a role of Wnt signaling in disease pathogenesis.

FR-PO670

Systematic Screening of ADTKD-MUC1 27dupC Variant through Exome Sequencing

Laurent Mesnard,[1,2] Ilias Bensouna,[1,2] Thomas Robert,[4] Laure Raymond,[3] Marine Serveaux Dancer.[3] *[1]Sorbonne Universite, Paris, France; [2]INSERM, Paris, France; [3]Eurofins Biomnis Lyon, Lyon, France; [4]Assistance Publique Hopitaux de Marseille, Marseille, France.*

Background: Autosomal dominant tubulointerstitial kidney disease (ADTKD) is associated with pathological variants in the MUC1 gene. Traditional next-generation sequencing (NGS) methods struggle with the variable number tandem repeat (VNTR) region in MUC1, where the pathogenic "27DupC" variant is found in over 80% of cases. We propose a novel pipeline using a k-mer approach to detect variants in this challenging region, optimized for exome sequencing, which typically cannot identify these variations due to the VNTR.

Methods: wo tools were employed: Shark®, which targets the MUC1 region and reduces data processing time, and VNtyper®, which uses the k-mer approach for variant calling. The SharkVNTyper pipeline was first evaluated in 26 positive and 52 negative control samples. Next, retrospective analysis was conducted on 3512 patients with chronic kidney disease (CKD) and exome sequencing, and prospective analysis started in November 2023 on 825 patients. Snapshot PCR, specifically targeting 27dupC, was used to confirm positive SharkVNTyper results.

Results: SharkVNTyper identified the 27dupC variant in 25 out of 26 positive controls (96.2%) and found no variants in the 52 negative controls. Among the 4337 patients in the combined retrospective and prospective cohorts, SharkVNTyper detected a frameshift variant in 36 patients previously lacking a molecular diagnosis. Snapshot PCR confirmed the presence of 27dupC in 30 of these cases, leading to unexpected diagnoses of ADTKD-MUC1 for these patients. Patients with typical ADTKD with non-27DupC variants are under scrutiny for similar bioinformatic development.

Conclusions: Utilizing bioinformatics tools based on the k-mer method allows for effective analysis of the MUC1 VNTR. This approach facilitates the diagnosis of ADTKD-MUC1 from exome sequencing data in CKD patients, specifically identifying the critical 27dupC variant for systematic screening from the exome output.

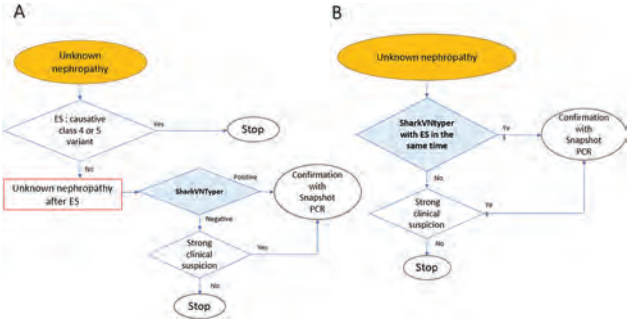

Chart 1: Proposed diagnostic framework for 27dupC detection responsible for ADTKD-*MUC1 with ES*

FR-PO671

Autosomal Dominant Tubulointerstitial Kidney Diseases

Telma Pais, Sofia C. Jorge, Marcia I. Rodrigues, José Agapito Fonseca, Iolanda Godinho, Cristina Outerelo, Estela Nogueira, Jose A. Lopes. *Unidade Local de Saude Santa Maria, Lisboa, Portugal*.

Background: Autosomal dominant tubulointerstitial kidney diseases (ADTKD) are characterized by chronic interstitial nephritis and mutations in *UMOD, MUC1, REN*, and *HNF1B* genes have been implicated. Advances in molecular diagnostics have improved the diagnosis of ADTKD. We aimed to characterize the patients evaluated for ADTKD at the Nephrogenetics Clinic of our tertiary care hospital.

Methods: Adult patients with chronic kidney disease (CKD) of unknown etiology and findings suggestive of chronic interstitial nephritis were investigated for ADTKD. Genetic study was performed stepwise: 1) Next-Generation Sequencing (NGS) analysis for *UMOD, REN, HNF1B* and *SEC61A1* genes; 2) if negative NGS, search for cytosine insertion in the variable-number tandem repeat sequence in the *MUC1* gene; 3) if negative, search for *HNF1B* deletion. Patients with undefined phenotype were analyzed using broader gene panels for CKD in young patients (173 genes), and those with cystic phenotype with a cystic disease panel (72 genes). Negative results are under review.

Results: We studied 37 families (33 with suspected ADTKD; 2 cystic; 2 with undefined phenotype) and confirmed an ATDKD genetic diagnosis in 15 families (40.5%), identifying 38 patients (pts). Genetic study revealed: pathogenic *MUC1* variants in 4 families (18 pts); *UMOD* variants in 4 families (11 pts); heterozygous *HNF1B* variants in 5 families (7 pts). In one family (5 pts) with initially negative results, further testing included whole exome sequencing (WES), and histochemical investigation of fsMUC1, the latter being positive. Reviewing negative results we found: pathogenic *COL4A3* variant in 1 family (2 pts); pathogenic homozygous *SDCCAG8* variant in 1 family (2 pts); likely pathogenic *PAX2* variant in 1 family (3 pts); likely pathogenic *PKD1* variant in 1 family (3 pts).

Conclusions: We established a genetic diagnosis of ADTKD in 40.5% of the families studied and confirmed a genetic diagnosis of CKD in 54%. The most prevalent genes implicated were *MUC1* and *UMOD*, similar to other ADTKD cohorts. Re-analysis using larger gene panels, WES, and collaboration with reference laboratories increased our diagnostic yield. Using larger gene panels initially, along with specific methods like snapshot for *MUC1*, could improve future investigations.

Assessment of Combined α-Galactosidase (α-GAL) Enzyme Activity and Lyso-GL3 for Fabry Disease Screening in Women

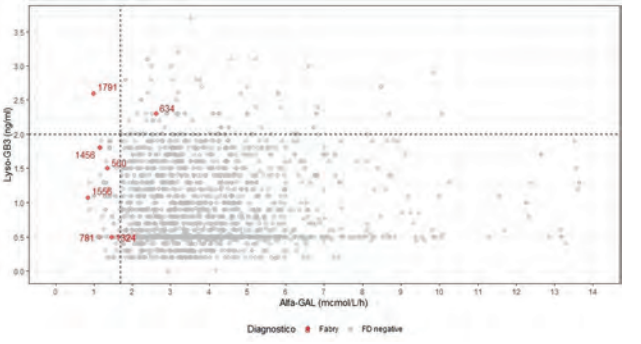
Cassiano Augusto B. Silva,[1] Fellype Barreto,[2] Osvaldo M. Vieira Neto,[3] Leandro J. Lucca,[3] Fernando A. Vieira,[4] Ana Paula Gueiros,[5] Marta V. Boger,[6] Artur Q. Silva,[7] Felipe Leite Guedes,[7] Karla Cristina P. Israel,[8] Gina Moreno Gordon,[9] Valeria Veloso,[10] Gabriela Sevignani,[11] Carolina Barretto,[12] Roberta C. Pascotto,[13] Gelzie S. Ennes,[14] Eduarda M. Souza,[15] Márcia G. Ribeiro,[16] Luis Gustavo Modelli de Andrade.[1] *[1]Universidade Estadual Paulista Julio de Mesquita Filho, Botucatu, Brazil; [2]Universidade Federal do Parana, Curitiba, Brazil; [3]Universidade de Sao Paulo Faculdade de Medicina de Ribeirao Preto, Ribeirao Preto, Brazil; [4]Clirenal, Caratinga, Brazil; [5]Instituto de Medicina Integral Professor Fernando Figueira, Recife, Brazil; [6]Metta Saúde Clínica do Rim, Foz do Iguaçu, Brazil; [7]Universidade Federal do Rio Grande do Norte, Natal, Brazil; [8]Universidade Federal do Amazonas, Manaus, Brazil; [9]Grupo Instituto do Rim do Paraná, Curitiba, Aruba; [10]Universidade Federal de Goias, Goiania, Brazil; [11]Fundação Pro-Rim, Joinville, Brazil; [12]Santa Casa de Misericórdia de Itabuna, Itabuna, Brazil; [13]Santa Casa de Maringa, Maringa, Brazil; [14]Centro de Nefrologia de Nova Friburgo, Nova Friburgo, Brazil; [15]Universidade de Sao Paulo, Sao Paulo, Brazil; [16]Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil*.

Background: The spectrum of clinical presentation of Fabry disease (FD) in women is broad and challenging. The aim is to evaluate the effectiveness of an alternative screening method for FD in women.

Methods: A collaborative multicenter cross-sectional study to evaluate the sensitivity and specificity of the combination of two tests (α-GAL enzyme activity and lyso-GL3) for the diagnosis of FD in women. We included women with CKD stages 3 to 5, receiving conservative treatment or on dialysis programs.

Results: We evaluated 1,874 patients. Isolated decreased α-GAL activity was found in 64 patients, while isolated increased lyso-GL3 levels were found in 67 patients, with one patient presenting alterations in both tests. All cases with low α-GAL activity and/or increased lyso-GL3 levels underwent genetic analysis for FD variants (132 patients). Low α-GAL activity had higher sensitivity and specificity to detect FD compared to the other measures (elevated lyso-GL3 alone or both altered). The negative predictive value (NPV) of α-GAL activity was 99%, and the positive predictive value (PPV) was 9.2%. For lyso-GL3 assay, the specificity was 99.7% and the PPV was 2.9%, therefore considered inferior to α-GAL assay. Both assays altered, had higher PPV (100%) and higher NPV (99.7%) considered the best method. We found 7 cases of GLA gene variants, resulting in an prevalence of 0.37% for FD in this sample female population.

Conclusions: This study contributes to the diagnostic value of this biomarkers in the context of FD in women with CKD. The combination of these biomarkers was an effective approach for the diagnosis, with high PPV and NPV.



The relationship between α-GAL and lyso-GL3 levels and the presence of Fabry disease.

FR-PO673

Screening for Fabry Disease in Haemodialysis Population (SoFAH) Study

Khai Ping Ng,[1] Manjinder K. Sandhu,[2] Tarekegn Geberhiwot,[2] Indranil Dasgupta.[2] *[1]University Hospitals of Derby and Burton NHS Foundation Trust, Derby, United Kingdom; [2]University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom*.

Background: Fabry disease is an X-linked inherited lysosomal storage disorder with an estimated prevalence amongst end-stage kidney disease (ESRD) population of 0.3% in men and 0.1% in women. Due to its non-specific manifestations, Fabry disease especially the later-onset variant, is often under-diagnosed. We aimed to estimate its prevalence in a large haemodialysis (HD) population in the UK.

Methods: SoFAH is a cross-sectional, multi-centre screening study. All adult HD patients at 8 renal units in the Midlands, UK were invited to the study. All male participants are tested using dried blood spot alfa-galactosidase enzyme and Lyso-Gb3 assay. If either the enzyme (≤2.8 μmol/L/H) or Lyso-Gb3 (≥ 3.5 ng/mL) level was abnormal, genetic testing for GLA mutation was performed. All females had alfa-galactosidase enzyme, Lyso-GB3 and genetic tests. We also performed symptoms' survey. The study was approved by the UK Health Research Authority.

Results: Of the 2,452 HD patients, 1323 consented to the study. Their mean age was 68 (SD 15) year-old, 67% male, 64% white ethnicity, dialysis vintage of 2.6 (IQR 8.1) months and 32% had renal biopsy. Diabetic nephropathy (28%) was the most common cause of ESRD. 21% had no known cause of ESRD and 9% had hypertensive/ischaemic nephropathy. Majority had cardiovascular disease (85%), including 10% with heart failure. 27% self-reported burning pain in extremities, 25% heat intolerance, 25% gastrointestinal symptoms without a cause, 22% family history of renal disease and 41% family history of heart disease or stroke. Overall, 216 (16%, 156 male) had low enzyme level but all had normal Lyso-Gb3 level. Only 3 (0.2%) had abnormal Lyso-Gb3 but all had normal enzyme level. One female participant with normal enzyme and Lyso-Gb3 levels but GLA variant, heterozygous c.937G>T (p.(Asp313Tyr), which was deemed to be non-pathogenic variant.

Conclusions: Despite implementing stringent screening in both male and female to avoid false negative, we did not identify any new cases of Fabry disease in 1,323 HD patients. This finding suggested lower prevalence of Fabry disease than previously reported but might also be influenced by our cohort's demography and older age. Symptoms commonly associated with Fabry disease were non-specific and self-reported in almost a quarter of the participants.

FR-PO674

A Real-World Study on the Clinical Characteristics and Treatments of Complement-Mediated Kidney Diseases in China

Sheng Nie,[1] Qing Zou,[1] Shiyu Zhou,[1] Fei Gao,[2] Tianwei Zhang.[2] *[1]Division of Nephrology, National Clinical Research Center for Kidney Disease, State Key Laboratory of Organ Failure Research, Nanfang Hospital, Southern Medical University, Guangzhou, China; [2]Beijing Novartis Pharma. Co. Ltd, Shanghai, China.*

Background: Complement-mediated kidney diseases (CMKDs) are partly caused by overactivation of the alternative complement pathway, including C3 glomerulopathy (C3G), atypical hemolytic uremic syndrome (aHUS), Immunoglobulin A nephropathy (IgAN), membranous nephropathy (MN), lupus nephritis (LN), among others. Despite their significant impact, studies on epidemiology and treatment patterns of CMKD in China are relatively scarce.

Methods: This is a retrospective, observational study using a nationwide real-world medical database in China (CRDS). Patients with CMKD were diagnosed at 24 regional central hospitals between 31 December 1998 until May 08, 2023. Descriptive analysis was performed on demographics, clinical characteristics and treatment approaches.

Results: A total of 57086 CMKD patients were included in the study, including 102, 843, 27456, 10988, and 17697 patients with C3G, aHUS, IgAN, MN and LN, respectively, with an average age of 46.8 years and 39.1% being males. 22.3% of CMKD patients had an eGFR<60ml/min/1.73m^2, 47.8% had low serum complement C3, and 18.5% had low serum C4. Among 11715 patients with kidney biopsy report, 69.1% was positive in C3 immunofluorescent staining and 17.5% was positive in C1q immunofluorescent staining (Table 1). Among all CMKD patients, 35.4% received corticosteroids, followed by Renin-angiotensin system inhibitor (28.6%) and non-steroid immunosuppressants (22.2%) (Table 2), and the treatment pattern was significantly different among subtypes of CMKD.

Conclusions: The clinical characteristics and treatment of CMKDs varied among subtypes. The overall treatment proportion at baseline was low. This may suggest that the current treatment strategies for CMKDmay be insufficient, and treatment programs need further improvement.

Rare Diseases: Significance of Molecular Genetic Analyses in Finding a Diagnosis

Annette D. Wagner,[1] Sena Hoffer,[1] Christian Beger,[1] Christian Kempf,[2] Friedmar R. Kreuz,[2] Saskia Biskup,[2] Heinz Gabriel.[2] *[1]Medizinische Hochschule Hannover, Hannover, Germany; [2]Center for Human Genetics, Tübingen, Germany.*

Background: Diagnosing rare diseases remains a challenge despite improved diagnostic methods. In the past, it often took patients years to receive a final diagnosis. We aim to show that genetic testing should be used as one of the first steps in the diagnostic process of patients with rare diseases. Whereas in the past only single-gene diagnostics were available, today a large number of genes can be sequenced in parallel using next-generation sequencing.

Methods: In the outpatient clinic for rare inflammatory diseases 85 patients with unclear diagnoses have undergone molecular genetic analyses over the last years. Most diagnoses could be made by whole exome sequencing (WES). This involves sequencing of the coding regions of all human genes. Using bioinformatic methods, the genes that can be associated with the symptoms are “filtered out” from the data set. This has the great advantage that the selection of genes can be kept up-to-date and flexible.

Results: In the case of atypical courses or non-response to treatment, genetic tests were arranged, which led to the correct diagnosis in a total of 85 patients. In addition to a larger group of 25 patients with periodic fever syndromes, neurological disorders could be identified in 14 patients. Among this group 8 patients were diagnosed with tuberous sclerosis. 12 Patients were affected by a disorder of the skeletal system (mostly hypophosphatasia). In 7 patients a muscle disease was found. The other patients were classified as follows: kidney disease (6x), hereditary cancer syndromes (6x), immunological disorder (5x), metabolic disorder (2x), hepatic disorder (1x), ophthalmological disorder (1x), heart defect (1x), connective tissue disorder (1x) and 3 patients with other conditions.

Conclusions: The recent changes in the field of genetics have an impact on our work in outpatient clinics for rare diseases. The diagnostic direction from “phenotype to genotype” has therefore often been reversed to “genotype to phenotype”. Frequently, several single-gene analyses were carried out in succession until the causative pathogenic variant could be identified. In our clinic, diagnoses could mostly be made by WES. Thanks to the close co-operation between our outpatient clinic and a genetic diagnostics laboratory, a final diagnosis can be made in many cases within a few weeks.

Pathogenic Mutations in Ras-MAPK Pathway Genes in Patients with Lupus Nephritis

Changming Zhang,[1] Xiaoman Jing,[2] Yangyang Zhang,[1] Ying Jin,[1] Zhihong Liu.[1] *[1]National Clinical Research Center for Kidney Diseases, Jinling Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, China; [2]Southeast University School of Medicine, Nanjing, China.*

Background: Pathogenic mutations in genes encoding components of Ras-MAPK pathway cause RASopathy, which include several clinically overlapping disorders, such as Noonan syndrome, Costello syndrome and neurofibromatosis. Here we describe five unrelated patients with lupus nephritis (LN) carrying mutations in components of Ras-MAPK pathway.

Methods: Causative mutations in the five LN patients were identified by whole-exome/genome sequencing and validated by Sanger sequencing.

Results: Five pathogenic mutations was identified in four Ras-MAPK genes, including NRAS:c.G38A: p.G13D; ARAF:c.C1435T: p.R479C; KRAS:c.T341C: p.V114A; PTPN11:c.G455A: p.R152H; NRAS:c.G34A: p.G12S. Three of them have been identified as pathogenic in individuals with Noonan syndrome and/or lupus. Two novel variants (R479C in ARAF and V114A in KRAS) are classified as likely pathogenic according to American College of Medical Genetics and Genomics criteria. The patients commonly manifested in early childhood and adolescence (range: 7-42 years of age). Kidney injury was the main feature, presenting with nephrotic syndrome (2/5), proteinuria and hematuria (2/5). Acute kidney injury and rapidly progressive nephritic syndrome was noted in one patient each. Other clinical features included mucocutaneous lesions (5/5), cardiac involvement (4/5, such as myocardial hypertrophy, pulmonary hypertension, enlargement of left atrium and ventricular), and arthralgia (3/5). Laboratory abnormalities included hypocomplementemia (5/5), presence of antiphospholipid (4/5), decreased Treg cells (3/3 patients tested), pancytopenia (3/5, one consistent with Evans syndrome), and persistent monocytosis (two with NRAS mutations). Histopathological findings included LN-V in two, LN-IV+V and LN-III+V in one patient each. All patients received methylprednisolone pulse therapy, followed by prednisone combined with cyclophosphamide or mycophenolate mofetil or tacrolimus. The patient with NRAS p.G12S mutation also received Rituximab therapy. Most patients responded well, with the exception of the patient with NRAS p.G13D mutation who died.

Conclusions: Kidney involvement may be the main feature of the clinical spectrum of RASopathy. Genetic screening should be considered for early-onset LN patients.

Genetic Analysis of Familial Mediterranean Fever in an ESKD Cohort

Ahmed Al-Sheyyab,[1] Rania A. Wahdan,[2] Anas Bani Hani,[1] Mohammad H. Al-thnaibat,[1] Salem Yasin,[1] Lubna H. Tahtamouni.[1] *[1]The Hashemite University, Zarqa, Jordan; [2]Ministry of Health, The Hashemite Kingdom of Jordan, Amman, Jordan.*

Background: Familial Meditiranean Fever (FMF) is an autoinflammatory genetic disorder that results from a mutation in MEFV gene. FMF increases the risk of secondary amyloidosis (i.e., renal amyloidosis). Limited FMF research have studied populations with the ultimate hard outcome of renal amyloidosis, or End-Stage-Renal-Disease

patients (ESRD). Our study aimed to assess the frequency rate of FMF gene variants in an ESRD cohort and correlate it with the general population.

Methods: The study was a prospective study of hemodialysis a jordanian cohort. Enrolled patients underwent laboratory screening for FMF by conducting Polymerase Chain Reaction and reverse hybridization. Patients with a positive FMF genetic screening were offered colonoscopy with multiple rectal biopsies. Amyloid staining were used to assess for pathological evidence of amyloidosis. Genetic data for control subjects where obtained from GnomAD v4.0.0 database, those with Middle Eastern Ancestry were segregated and used as our control group.

Results: Our study demonstrated that our studied ESRD patients, when compared with healthy controls, carry a higher allele frequency rate of all FMF variants (30% Vs 11.1%). For patients with a positive FMF gene, two patients demonstrated symptoms of FMF. The remaining asymptomatic patients, one out of 5 patients who consented for colonscopy, had confirmed pathological evidence of amyloidoisis.

Conclusions: Among our Jordanian cohort, patients with ESRD carry higher allele frequency of FMF variants than healthy controls.

	Dialysis cohort n (%), n = 79	Middle Eastern controls n (%), n = 6,602

FR-PO678

Exome Sequencing in Patients with Loin Pain Hematuria Syndrome

Bhanu Prasad,[1] Aditi Sharma,[2] Aarti Garg,[2] Clara Schott,[3] Dervla M. Connaughton,[3] Matthew B. Lanktree.[4] *[1]Regina General Hospital, Regina, SK, Canada; [2]University of Regina, Regina, SK, Canada; [3]Western University Schulich School of Medicine & Dentistry, London, ON, Canada; [4]McMaster University Faculty of Health Sciences, Hamilton, ON, Canada.*

Background: Loin pain hematuria syndrome (LPHS) is a rare clinical syndrome with a reported prevalence of ~1 in 10,000 characterized by severe pain localized to the kidney, and gross or microscopic hematuria. Because of an inadequate understanding of the pathophysiology of the disease, the goal of management has been limited to symptomatic pain management. We used whole exome sequencing to investigate the genetic factors affecting the glomerular filtration barrier, contributing to hematuria in patients with LPHS. We describe herein their phenotypes and variant spectra.

Methods: In this single-center study, 17 consecutive patients with LPHS underwent whole exome sequencing (WES) from Jan 2022 to Jan 2023. A bioinformatically created hematuria gene panel (n = 143) was evaluated. American College of Medical Genetics and Genomics (ACMG) guidelines were followed for interpreting the identified variants.

Results: Among the 17 patients, 13 exhibited overt hematuria, while 4 had microscopic hematuria. 9/17 (53%) patients had a preceding history of kidney stones, but none had an obstructing stone on imaging at the time. Analysis of pedigree charts revealed that 8/17 (43%) patients had a family history of kidney stones, and 3/17 (18%) had a family history of hematuria. None of the 17 patients had a family history of LPHS. A total of 35 variants were identified in 25 of 143 hematuria gene panel genes in 14 patients. 29 of the 35 were variants of uncertain significance. We detected 3 pathogenic or likely pathogenic mutations, including two heterozygous missense variants and a frameshift deletion in COL4A3/4 genes.

Conclusions: In 17 patients with LPHS, 35 variants of uncertain significance were identified among 25 genes reported to impact the glomerular basement membrane and cause hematuria. Determining the causality of these variants is challenging.

FR-PO679

Founder Effect for the APOE Tokyo-Maebashi Variant in the Northern Chinese Population

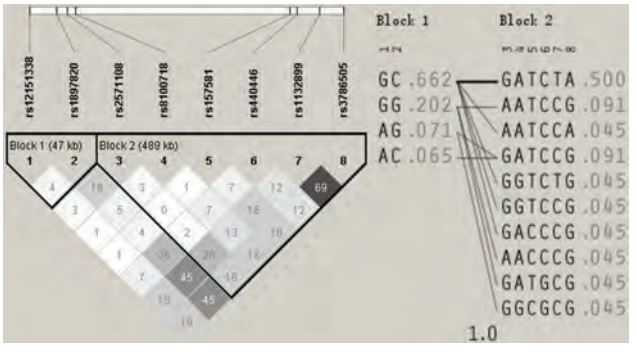
Mengshi Li, Ruilian You, Zhiying Liu, Yang Li, Xu-jie Zhou, Hong Zhang. *Peking University First Hospital, Beijing, China.*

Background: Lipoprotein glomerulopathy (LPG) is a rare hereditary kidney disorder characterized by lipoprotein thrombi in glomeruli, often linked to APOE gene mutations. Predominantly found in China and Japan, LPG remains understudied. Notable regional APOE mutations include APOE Kyoto (p.R43C) in West China and APOE-Sendai (p.R163P) in eastern Japan. This study investigates the genetic causes of LPG in northern Han Chinese and explores genotype-phenotype correlations.

Methods: Patients suspected or diagnosed with LPG were recruited at a nephrology center in Northern China from 2000 to 2023. Inclusion criteria: (1) Renal biopsy showing Oil Red O-positive lipid thrombi in glomeruli; (2) Known pathogenic APOE mutations via genetic testing. Exclusion criteria: Incomplete genetic testing post-biopsy or unavailable DNA samples. Whole exome sequencing (WES) was used to identify mutations, with clinical data collected at enrollment.

Results: The study included 28 LPG patients from 24 families, with an average age of 34.2 years (range 17-54). The male-to-female ratio was 19:9. The mean proteinuria level was 4.94 g/24h, the mean eGFR was 78.3 mL/min/1.73 m2, and hyperlipidemia was observed in all cases. Three variants were identified in 25 cases: 15 had APOE Tokyo-Maebashi (p.L162_K164del), 8 had APOE Kyoto (p.C43R), and 2 had APOE Chengdu (p.L173P). APOE Tokyo-Maebashi was most frequent, mainly in Hebei Province. Haplotype analysis suggested a founder effect for APOE Tokyo-Maebashi. Genotype-phenotype analysis showed a trend towards higher eGFR and lower urinary total protein (UTP) and urinary red blood cells (URBC) in APOE Tokyo-Maebashi carriers, though differences were not statistically significant.

Conclusions: WES is instrumental in identifying molecular pathogenic variants in LPG patients and genetic hotspot mutations in specific populations. Despite high phenotypic variability in APOE-associated LPG, the APOE Tokyo-Maebashi variant is the most common mutation in Northern China, presenting with relatively milder clinical manifestations.



FR-PO680

Establishment of a High-Throughput Screening System for Membrane Expression of Mutant Nephrin

Haruki Tsuhako, Mary Ann Suico, Tsuyoshi Shuto, Hirofumi Kai. *Kumamoto Daigaku, Kumamoto, Japan.*

Background: Congenital Nephrotic syndrome of the Finnish type (CNF) is caused by a mutation in the *NPHS1* gene that hinders the cell surface expression of nephrin and disrupts slit membrane formation. In this study, we constructed a novel evaluation system to search for compounds promoting the expression of nephrin on the cell membrane.

Methods: To detect the membrane-expressed nephrin, we used the HiBiT nanoluciferase system by tagging Nephrin wild-type (wt) and mutants (mt) with HiBiT. For high throughput screening (HTS), we generated stable expression cell lines of HiBiT- wt and mutant nephrin (HiBiT-Neph) using the Flp-In™ System. Phosphorylated-Nephrin, which indicates the ability to be translocated to the surface, was also assessed by immunoblotting.

Results: In contrast to wt HiBiT-Neph, most mutants did not produce luminescence and were not phosphorylated. Furthermore, among the mutants, we confirmed that the reduction of HiBiT activity in the S366R and E725D stable mutant cells met the HTS criteria. Using E725D stable cells, we screened several chemical chaperones and a natural products compound library. Chemical chaperone β-alanine, a CFTR corrector (Corr-4a), and 78 compounds from the library increased the HiBiT-Neph E725D. Cytotoxicity

assays and further validation by immunoblotting of phosphorylated nephrin trimmed the candidate compounds to ten. Focusing on these compounds, we revealed their effects on post-translational modifications and degradation rates of Nephrin to promote the expression of nephrin mutants on the membrane.

Conclusions: The HTS evaluation system identified compounds that increased mutant nephrin phosphorylation and cell surface expression and showed that this evaluation system is useful as a drug discovery platform for CNF. Moreover, the identified compounds help to elucidate the mechanisms of mutant nephrin cell regulation.

FR-PO681

Prematurity Reprograms Nephron Progenitor Cells, Impairing Nephrogenesis and Kidney Health

Athar Amleh,[1] Mehran Piran,[2] Julie L. Moreau,[2] Morris Nechama,[1] Alexander N. Combes,[2] Oded Volovelsky.[1] *[1]Hadassah University Medical Center, Jerusalem, Israel; [2]Monash University, Melbourne, VIC, Australia.*

Background: Premature birth is linked to reduced nephron number and an increased risk of chronic kidney disease. Despite insight from surgical models, the molecular mechanisms by which preterm birth affects nephron formation remain incompletely understood. We aimed to study the changes in nephrogenesis after preterm birth.

Methods: We used a mouse model of induced preterm birth at gestational day 18 using mifepristone, a progesterone antagonist. Nephrons were counted using acid maceration. Kidney function was evaluated via serum sampling and 24-hour urine collection in metabolic cages. Immunofluorescence was used to assess the duration of nephrogenesis (SIX2), nephron progenitor cell (NPC) apoptosis (CASP3), and proliferation (Ki67, BrdU). NPCs were sorted using Six2-GFP and profiled using RNA-sequencing and RT-PCR.

Results: At postnatal day 30, preterm offspring exhibited significantly decreased kidney/body weight ratio and 30% less nephrons alongside elevated serum urea and 24-hour urine albumin levels compared to term counterparts. Notably, the duration of nephrogenesis was extended by one day in preterm kidneys. In preterm kidneys, proliferation was increased in Six2+ NPCs at post-consumption (PC) day 20.5, with no change in apoptosis. Gene expression profiling of NPCs revealed dysregulated Wnt signaling, cell proliferation, hypoxic response, and differentiation signatures in preterm kidneys but not term controls. Preterm NPCs had decreased *Six2* but increased *Lhx1*, *Jag1*, and *Bmp2* expression. Altogether, these results indicate that preterm birth reduces nephron number by altering NPC differentiation and proliferation state.

Conclusions: Preterm birth reduces nephron endowment by altering NPC self-renewal and differentiation dynamics. Therapeutic attempts to boost nephrogenesis after preterm birth may protect against adult kidney morbidity.

FR-PO682

Role of Angiotensinogen in Children with a History of Preterm Birth and Nephron Hypertrophy

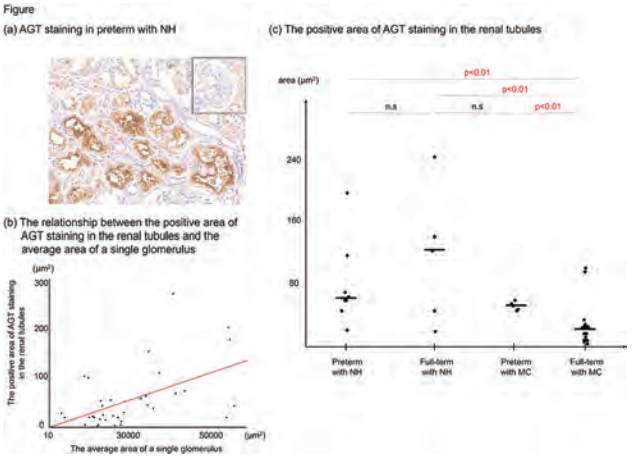
Shingo Ishimori,[1,2] Yuka Kimura,[1] Hideaki Kitakado,[1] Chika Ueda,[1] Yuta Inoki,[1] Yu Tanaka,[1] Junya Fujimura,[3] Tomoko Horinouchi,[1] Tomohiko Yamamura,[1] Nana Sakakibara,[1] China Nagano,[1] Kandai Nozu.[1] *[1]Kobe University Graduate School of Medicine, Kobe, Japan; [2]Takatsuki General Hospital, Takatsuki, Japan; [3]Kakogawa Chuo Shimin Byoin, Kakogawa, Japan.*

Background: A history of preterm birth and low birth weight (preterm) is a risk factor for chronic kidney disease, which is primarily characterized by tubulointerstitial damage resulting from a decrease in nephron number and compensatory nephron hypertrophy (NH). While the renin–angiotensin system (RAS) plays a crucial role in renal development, no pathological studies have examined the association between RAS and tubulointerstitial lesions in children with a history of preterm birth.

Methods: We performed immunohistochemical staining of renal biopsy specimens collected from 2000 to 2023. Patients were eligible if they had pathological minimal change (MC) or NH without other types of nephritis, and if the indication for renal biopsy was asymptomatic proteinuria, nephrotic syndrome, or decreased renal function. Immunohistochemical staining of angiotensinogen (AGT) was used as a marker of intrarenal RAS, and angiotensin II was used as a marker of systemic RAS.

Results: We enrolled 36 children with a median age at the renal biopsy of 13.4 years. AGT staining was negative in the glomeruli of children with NH but positive in the renal tubules (Fig. a). The positive area of AGT staining in the renal tubules was significantly correlated with an increase in the average area of a single glomerulus ($p<0.01$, Fig. b). The positive area of AGT staining in the renal tubules of preterm children with NH (n=8), full-term children with NH (n=5), and preterm children with MC (n=5) was significantly more extensive than that in full-term children with MC (n=18) (65.8, 153.2, and 53.0 μm^2 vs 19.4 μm^2, all $p<0.01$; Fig. c). Angiotensin II staining was weakly positive in the renal tubules across all four groups, with no significant difference between the groups.

Conclusions: AGT may play a major role as an indicator of intrarenal RAS in preterm children even before the onset of NH.



FR-PO683

Dysregulation of Podocyte Clock-Controlled Autophagy in a Neonatal Hyperoxia Model

Joanne Duara,[1,2] Rachel Njeim,[2,3] Jeffrey D. Pressly,[2,3] Pingping Chen,[1] Sandra M. Merscher,[2,3] Alessia Fornoni.[2,3] *[1]University of Miami Batchelor Children's Research Institute, Miami, FL; [2]Peggy and Harold Katz Family Drug Discovery Center, Department of Medicine, University of Miami, Miller School of Medicine, Miami, FL; [3]Katz Family Division of Nephrology and Hypertension, Department of Medicine, University of Miami, Miller School of Medicine, Miami, FL.*

Background: Premature birth and low birthweight, prevalent in around 11% of pregnancies and disproportionately affecting Black Americans, amplify the long-term risk of chronic kidney disease (CKD). Neonatal hyperoxia leads to impaired development of the renal tubules, renal corpuscle enlargement, tubular necrosis, interstitial inflammation, and fibrosis. Furthermore, global kidney health is a mounting concern with CKD affecting both children and adults. Emerging evidence links Chaperone-Mediated Autophagy (CMA) to the degradation of oxidized proteins within cells, a process intensified during oxidative stress through mechanisms involving substrate protein modifications and transcriptional up-regulation of the Lysosome-associated membrane glycoprotein 2 (LAMP2A) at the lysosome. We hypothesize that in neonate, hyperoxia-induced oxidative stress triggers adaptive increases in CMA, which although protective initially, may lead to impaired CMA activity over time due to persistent oxidative conditions.

Methods: Sprague Dawley rat pups were reared in hyperoxic (HYP) with FiO2 of 0.85 or normoxic (RA) conditions until 10 days of life. Urine was sent for Urine Protein and Creatinine levels. Western blot and immunofluorescence were performed on kidney cortices. Immortalized human podocytes were cultured and exposed to hyperoxia or normoxia for 48 hours. Bulk RNA Sequencing analysis was conducted on rat kidney cortices and human podocytes.

Results: Urinalysis of hyperoxia-exposed rats revealed worsened proteinuria (Urine protein 132 mg/dl vs 20 mg/dl) and higher Urine protein/Creatinine ratio (14.2 vs 4.2). Western blot analysis of protein lysates from rat kidney cortices reveals a reduction in p62 expression in HYP rats with an increase in LC3 II/I ratio in HYP rats when compared to RA animals indicating an activation of autophagy. RNA sequencing results reveal decreased podocyte expression of circadian clock -controlled autophagy markers in bone metabolism including BHLHE41, CHRD, MAP1LC3A and TGFB1.

Conclusions: Taken together, these results indicate a role for altered circadian clock-mediated autophagy in hyperoxia-exposed podocytes affecting renal function.

FR-PO684

A Missense Mutation in Exon 10 of WT1 Might Lead to Focal Segmental Glomerulosclerosis Due to Its Mislocalization and Downstream Dysregulation

Toru Kanamori,[1] Tomohiro Udagawa,[2] Mika Okutsu,[1] Takayasu Mori,[2] Eisei Sohara,[2] Shinichi Uchida.[2] *[1]Tokyo Ika Shika Daigaku Daigakin Ishigaku Sogo Kenkyuka, Bunkyo-ku, Japan; [2]Tokyo Ika Shika Daigaku, Bunkyo-ku, Japan.*

Background: Wilms' tumor suppressor gene 1 (WT1) is associated with the development of the urogenital system and regulates genes involved in sex differentiation. While mutation of exon 8 or 9, and intron 9 of WT1 are known as a cause of focal segmental glomerulosclerosis (FSGS) and sexual disorders, the pathological role of the mutation in exon 10 is largely unknown in FSGS. We found a missense Arg495Gly in a Japanese boy with FSGS connecting to the end stage kidney disease. His renal podocytes histopathology showed that WT1 is localized in not only the cytoplasm but also the

nucleus. Additionally, his kidney sample's expressions of NPHS1 were patchy pattern rather than normal smooth and linear pattern.

Methods: To analyze the pathogenic mechanism of the mutation in FSGS, we evaluated WT1 localization in cultured HEK293T cell transfected with expression constructs encoding the wildtype or $WT1^{R495Q}$ protein by immunofluorescence staining and western blotting with nuclear/cytoplasm fractionations. Then, to examine the effect of $WT1^{R495Q}$ on the regulation of key podocyte genes, we quantitatively assessed mRNA expression levels isolated from wild type or mutation-expressing cells by qPCR.

Results: The WT1 localization was different between cells transfected WT1wildtype/$WT1^{R495Q}$ under phosphorylation-accelerated conditions induced by Forskolin. $WT1^{R495Q}$ is not affected by Forskolin stimulation, while WT1wildtype affected by Forskolin stimulation and expression of WT1 in the nuclear is decreased and in the cytoplasm is increased. Compared to wild types, the expression of the NPHS1 gene is decreased in the cells transfected with $WT1^{R495Q}$. When wild type and mutant WT1 were co-transfected with the same dose, the expression of NPHS1 was the same as when only the mutant was transfected and its expression was reduced in a mutant dose-dependent manner.

Conclusions: We demonstrated $WT1^{R495Q}$ mutation could affect on WT1 protein localization and dysregulates NPHS1 expression in podocytes. This type of WT1 mutation on exon10 could be loss of function mutation and have a dominant negative effect on expression of podocyte genes. These may have influence podocyte recovery systems using phosphorylation which is essential for regulation of podocyte-specific protein.

FR-PO685

Recessive Variants in the Intergenic NOS1AP-C1orf226 Locus Cause Monogenic Kidney Disease

Florian Buerger,[1,2] Victoria C. Gauntner,[1] Vineeta Sharma,[1] Sergio Guerrero Castillo,[2] Liang Sun,[1] Alexis C. Gomez,[1,3] Michelle Mcnulty,[1,4] Matt G. Sampson,[1,4] Mohamed Al-hamed,[5] James P. Fawcett,[6] Friedhelm Hildebrandt,[1] Amar J. Majmundar.[1] *[1]Boston Children's Hospital, Boston, MA; [2]University Children's Hospital, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [3]Brigham and Women's Hospital, Boston, MA; [4]Broad Institute, Cambridge, MA; [5]King Fahad Medical City, Riyadh, Saudi Arabia; [6]Dalhousie University, Halifax, NS, Canada*.

Background: An accurate expression landscape of disease genes is crucial to enable precise genetic diagnoses. Canonical NOS1AP, encoding nitric oxide synthase 1 (NOS1) adaptor protein, is known to regulate hippocampal neuronal functions through C-terminal interactions with the enzyme NOS1 (Jaffrey *Neuron* 1998; Zhu *Nat Med* 2014). We previously discovered that N-terminal variants in *NOS1AP* cause monogenic nephrotic syndrome (NS) in humans and mice (Majmundar *Sci Adv* 2021). However, the role of the NOS1AP C-terminus in NS pathogenesis was unclear.

Methods: Transcriptomics and proteomics data of human and murine kidney samples were evaluated. Exome sequencing was performed in human NS subjects. Mouse models altering the *Nos1ap* locus were evaluated for features of NS.

Results: We, here, detected intergenic splice products of *NOS1AP/Nos1ap* and the neighboring open reading frame *C1orf226/Gm7694* as the predominant isoform in both human and mouse kidney tissue in contrast to brain tissue. In this isoform, the canonical C-terminal NOS1-binding domain is replaced by C1orf226 or Gm7694, respectively. In line with our previously published Nos1ap-deficient mice, exclusive disruption of the intergenic product in $Gm7694^{-/-}$ mice similarly resulted in NS features including albuminuria, podocyte foot process effacement, and glomerular basement membrane thickening. We, next, evaluated whether recessive variants exclusively impacting the intergenic splice form can be detected in NS patients. For this, we reanalyzed NS exome sequencing data and thereby identified a likely pathogenic *NOS1AP-C1orf226* essential splice site variant (c.1258+1G>C) in a patient with congenital NS. Of note, this variant was initially misclassified as benign due to annotation based on the canonical transcript (c.1259G>C, p.G420A).

Conclusions: Mendelian variants impacting an intergenic product in the *NOS1AP-C1orf226* locus cause NS, suggesting that, unlike in the brain, NOS1AP functions in the kidney through NOS1-independent mechanisms. Moreover, this highlights the importance of understanding tissue-specific splicing to facilitate discovery and clinical diagnosis of Mendelian disorders.

FR-PO686

Role of Eicosanoids in Hyperfiltration-Mediated Injury: Insights from Human Participants and a Mouse Model

Tarak Srivastava,[1] Ginger L. Milne,[3] Mukut Sharma.[2] *[1]Children's Mercy Kansas City, Kansas City, MO; [2]Kansas City VA Medical Center, Kansas City, MO; [3]Vanderbilt University, Nashville, TN*.

Background: The mechanism of hyperfiltration-mediated kidney injury in children with a solitary functioning kidney (SFK) is not known. Changes in vasoactive metabolites including Prostaglandin E_2 (PGE_2) modulate glomerular hemodynamics. We demonstrated upregulation of the cyclooxygenase-2-PGE_2-Prostanoid receptor EP2 (COX2-PGE_2-EP2) pathway in unilateral nephrectomy (UNX) mouse model of hyperfiltration-mediated kidney injury and its attenuation using EP2 and EP4 agonists and antagonists. Following these results, we hypothesize altered urinary eicosanoid profile in children with SFK and altered expression of eicosanoid metabolizing enzymes and receptors in UNX mice.

Methods: Children with SFK (n=57, 37 boys) and healthy children with monosymptomatic enuresis (N=72, 49 boys) were included. Data on age, gender, height, weight, blood pressure (BP) and a urine sample were collected during the clinic visit. Urinary metabolites of various eicosanoids were measured using liquid chromatography-tandem mass spectrometry (Eicosanoid Core Laboratory, University of Nashville TN). The Wilcoxon test was used for non-parametric analysis of human data. sv129 mice (4 weeks old) were used for Sham or UNX surgery and observed for 6 months. Mouse kidney cortical tissue was used for transcriptomic and proteomic analysis at the University of Missouri Core Facilities, Columbia MO, followed by bioinformatic analysis.

Results: Healthy children and children with SFK did not differ significantly in age, Z-scores for height, weight, and BP. However, urinary PGE_2 (p=0.013), TxB_2 (p=0.024), 11,12-DHET (p=0.003), and 14,15-DHET (p=0.011) were elevated in children with SFK compared to healthy children. No significant differences were found for other eicosanoids. Transcriptomic and proteomic analyses of mouse kidney tissue showed that the expression of proteins related to PGE_2 and TxB_2 metabolism and activity, as well as cytochrome P450 enzymes, were significantly altered in the UNX group. Expression of Cbr1, Ptgr2, Akr1c14, Cyp2d12, and Cyp2j5 showed changes at both the gene and protein expression level ($p<0.05$).

Conclusions: Present data from children with SFK and UNX mouse model corroborate previous findings and suggest the importance of eicosanoids and related enzymes and receptor proteins in hyperfiltration-mediated kidney injury in SFK.

MAGED2 Enhances Sodium Chloride Cotransporter (NCC) Expression at the Plasma Membrane by Inhibiting Its Ubiquitination and Lysosomal Degradation under Hypoxia

Aline N. Radi, Sadiq Nasrah, Michelle Auer, Stefanie Weber, Elie Seaayfan, Martin Kömhoff. *Department of Pediatrics, Philipps-University Marburg, Marburg, Germany*.

Background: Transient antenatal Bartter's syndrome (tBS) is characterized by massive polyhydramnios, impaired expression of the cAMP-sensitive renal salt-transporters NKCC2 and NCC, marked perinatal mortality and preterm birth followed by spontaneous recovery from polyuria in survivors. tBS is caused by mutations in the gene encoding MAGED2, which inhibits endocytosis of Gαs under hypoxia, a prerequisite for generation of cAMP by membrane-bound adenylate cyclase (mAC). As spontaneous recovery from renal salt wasting overlaps with developmental increase of renal oxygenation, lack of MAGED2 dependent cAMP generation under hypoxia explains, at least in part, the severe but transient renal salt loss in tBS patients. The present study aims to elucidate how MAGED2 controls NCC-trafficking.

Methods: Cell-surface biotinylation, endocytosis, exocytosis and activity of NCC were analyzed in HEK293 and HeLa cells under hypoxia with or without MAGED2-depletion (siMAGED2). Results were assessed using western blotting, immunocytochemistry and CoroNa Green, a sodium ion indicator.

Results: In renal cells exposed to hypoxia, siMAGED2 significantly reduced the expression of total and plasma membrane-bound NCC as well as its activity. Conversely, MAGED2 overexpression promoted expression of both total and plasma membrane-bound NCC, whereas Gαs depletion led to the opposite. Interestingly, forskolin abrogated the effect of siMAGED2 on NCC expression and localization at the plasma-membrane, the latter of which was recapitulated by immunocytochemistry in HeLa cells. Of note, MAGED2 overexpression did not rescue NCC expression in Gαs-depleted cells, confirming functioning of Gαs downstream of MAGED2. Reduced expression of NCC at the cell surface resulted from decreased NCC exocytosis and enhanced endocytosis in MAGED2-depleted cells. Additionally, siMAGED2 enhanced NCC lysosomal degradation by increasing its ubiquitination.

Conclusions: In conclusion, our study demonstrates the crucial role of MAGED2 under hypoxic conditions in regulating NCC lysosomal degradation and its trafficking to the plasma membrane. This sheds light on the underlying mechanisms of tBS and offers potential avenues for therapeutic intervention by targeting MAGED2-mediated pathways.

FR-PO688

Severe Kidney Dysplastic Phenotypes Caused by WT1 Exon 9 Missense Variants

Huong Quynh Tran Thuy,[1] Tuyen T. Nguyen,[2,3] Kenji Fukui,[4] China Nagano,[5] Kandai Nozu,[5] Riku Hamada,[6] Hiroyasu Tsukaguchi.[1,7] *[1]Kansai Medical University, Second Department of Internal Medicine, Hirakata, Japan; [2]Kansai Medical University, Department of Genome Editing, Hirakata, Japan; [3]Children's Hospital 1- Ho Chi Minh City, Neonatology 2, Metabolic and Genetic Department, Ho Chi Minh, Viet Nam; [4]Osaka Medical and Pharmaceutical University, Faculty of Medicine, Department of Biochemistry, Takatsuki, Japan; [5]Kobe University Graduate School of Medicine, Department of Pediatrics, Kobe, Japan; [6]Tokyo Metropolitan Childrens Medical Center, Department of Nephrology, Fuchu, Japan; [7]Kansai Medical University Hospital, Clinical Genetics Center, Hirakata, Japan.*

Introduction: Mutations of the Wilms tumor suppressor-1 gene (*WT1*) are typically linked to a triad of glomerulopathy, defective genital development, and Wilms' tumor. The hallmark clinical phenotype Denys-Drash Syndrome (DDS, OMIM194080) is caused by Exon 9 missense variants. p.Arg467Trp is the most commonly reported and accounts for approximately 50% of DDS.

Case Description: We recently found the *WT1* p.Arg467Gln variants in five neonates with early onset ESRD (3 males, 2 females). Most cases developed ESRD within the first month of their life (median 8 days, range one day to 90 days). Three of them underwent bilateral nephrectomy remain healthy after kidney transplantation. Two (cases 1 and 2) show hyperechoic, normal or smaller kidneys on ultrasonography. Renal histology (case 3) revealed severe mesangial sclerosis with tubular dysgenesis and some overgrowth of stromal elements. Two males showed external genital abnormality (cryptorchidism, hypospadias, etc). One child (case 2) had lung hypoplasia (Potter syndrome). All were sporadic with the exception of case 1 affecting the two siblings. The pathogenic p.Arg467Gln variant, which substitutes the most frequent, hot-spot Arg467 residue in the 3rd zinc finger and typically causes Denys-Drash syndrome. Structural modeling predicted that an Arg-to-Trp substitution confers obvious structural hinderance for the 3rd Zinc finger to bind the DNA, consistent with the inability to transactivate the luciferase functional assay. On the other hand, an Arg-to-Gln substitution modestly altered the hydrogen bonding for the DNA binding. Reviews of previous clinical reports showed that p.Arg467Gln leads to earlier onset NS and faster progression to ESRD compared to the p.Arg467Trp (p.Arg467Gln *n*=6, onset 0.04±0.02 year, ESRD 0.17±0.07 year, *vs* p.Arg467Trp *n*=40, onset 1.4±0.2 year, ESRD 2.29±0.4 year).

Discussion: We found that *WT1* p.Arg467Gln tend to cause severe kidney dysplastic phenotype compared to the classic DDS variant p.Arg467Trp. Further study is necessary to see whether p.Arg467Gln have functionally more deteriorating effects on transcription predisposing to severe nephron dysplasia than does p.Arg467Trp or other second genetic factors contribute to modify the severe nephron developmental defects.

FR-PO689

Structured Application of Nephrogenetics in a Pediatric Kidney Clinic Is Clinically Impactful and Challenging

Jordy Salcedo-Giraldo, Krista R. Wink, Andrew Freiman, Lisa M. Guay-Woodford, Louise C. Pyle, Ashima Gulati. *Children's National Hospital, Washington, DC.*

Background: As clinical genetic testing becomes more accessible, their use as a diagnostic tool for kidney disease is becoming more common. While the utility of genetic testing has been described in adult nephrology clinics, its application and impact in pediatric kidney clinics is less clear.

Methods: We retrospectively reviewed 10-years of clinical and genetic data on patients presenting to our pediatric kidney genetics program. The data analyzed includes genetic variants classified as pathogenic (P) or likely pathogenic (LP) by the ACMG criteria and their impact on clinical care. Details on genetic testing strategies and variants of uncertain significance (VUS) were collected.

Results: Among 331 patients, with a mean age of 8.6 ± 6.7 years, N=166 (50%) received clinical genetic testing. Of these, 106/166 had informative genetic test results: 75% of which had a P or LP variant explaining their condition, while 25% had a P/LP variant non-explanatory for the kidney disease condition. Top genes with P/LP variants were *PKD1* (N=16), *PKHD1* (N=12, 11 were biallelic), *TSC2* (N=11), *HNF1B* (N=9), *AVPR2* (N=4). A carrier state unrelated to the kidney condition was reported in 28/166 patients, most commonly in *APOL1* (N=9) and *NPHS2* (N=4). A VUS was reported in 77/166 patients, with 49% of these having a VUS in ≥ 5 genes, most frequently in *PKHD1* (N=15) and *PKD1* (N=13). Testing strategies included a broad gene panel (>50 genes; N=40/166), limited gene panel (≤ 50 genes; N=49/166), exome sequencing (N=11/166), chromosomal microarray, (N=4/166) or combinations (N=13/166). Clinical impact measured for patients with P/LP variants included reclassification of diagnosis (38/106), disease-modifying therapy initiation (37/106), and avoidance of unnecessary procedures (22/106) and medications (44/106). Genetic results assisted in transplant evaluation (4/166), extra-renal screening (70/106), and reproductive counseling (42/106).

Conclusions: In a select cohort of children referred to a kidney genetics program, genetic testing was used in 50% of cases and is clinically impactful in patients with a P/LP variant explaining the disease condition. Genetic variants not directly related to the disease condition are frequent and pose a challenge for interpretation and counseling.

FR-PO690

Single-Center Experience in Establishing a Pediatric Kidney Genetics Clinic

Bree E. Martin, Friedhelm Hildebrandt, Nina Mann, Amar J. Majmundar. *Boston Children's Hospital, Boston, MA.*

Background: Genetic testing is recommended by KDIGO to establish a cause of chronic kidney disease. However, providing this service requires expertise in kidney genetics and genetic counseling and organizational support for navigating insurance approval. Here we describe our experience in establishing a pediatric kidney genetics clinic (KGC) at a single center.

Methods: We performed a retrospective chart review of patients referred over 18 months (11/22-4/24) to the Boston Children's Hospital KGC (Boston, MA, USA) led by two pediatric nephrologists and a certified genetic counselor with expertise in genetic kidney disease. We analyzed clinical and laboratory characteristics, genetic testing results, and clinical utility.

Results: 86 patients were referred to the KGC. 53 (61%) were referred for genetic testing after evaluation and pre-test counseling. 46/53 (87%) patients had renal disease while 7/53 (13%) were asymptomatic individuals referred based on a family history of kidney disease. Glomerular and cystic kidney diseases were the most frequent clinical diagnoses (16/53 and 15/53, respectively). We performed genetic testing in 32/53 (60%) patients while 11 families declined testing after counseling. Kidney phenotype-specific (16) or broad kidney disease panels (11) were most frequently ordered. 20/32 (62%) had a pathogenic/likely pathogenic variant identified. The remaining 33 patients seen in the KGC were referred for counseling for prior testing performed by the primary nephrologist or other subspecialty (26/33 and 4/33, respectively) or for CLIA-confirmation of research results (3/33). Of all testing conducted by our clinic, the majority were through a traditional insurance approval process (22/36 tests) while 14/36 were company-based. All variants (including those of uncertain significance) were manually adjudicated by the KGC team, and KGC reanalysis of uncertain variants led to genetic diagnoses in 3 cases. Ultimately, 50/86 (58%) patients seen in our KGC had a genetic diagnosis in one of 29 genes. Alport Syndrome (*COL4A3*/4/5) was the most frequent genetic diagnosis (11/50 patients). Overall, genetic testing impacted clinical management in 41/65 cases (63%).

Conclusions: A dedicated KGC provides utility in providing genetic counseling and expertise in kidney genetic disease as well as streamlining insurance approval.

FR-PO691

Artificial Intelligence for Total Kidney Volume Measurements in Pediatric ADPKD: Comparison of Three-Dimensional Ultrasonography with Magnetic Resonance Imaging

Adriana Gregory, Ryan Helland, Kate Knoll, Kendra Petersen, Hana Yang, Fouad T. Chebib, Maria V. Irazabal, Peter C. Harris, Timothy L. Kline, Christian Hanna. *Mayo Clinic Minnesota, Rochester, MN.*

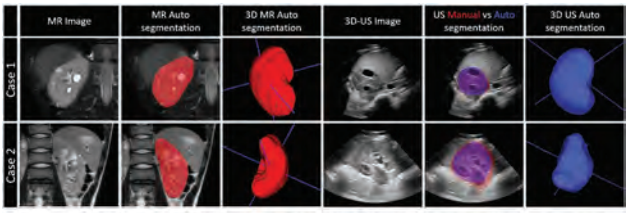
Background: Identifying biomarkers to predict ADPKD progression in children is imperative. Total kidney volume (TKV), utilized in adults, holds promise as a biomarker for children as well. MRI, the standard method for measuring TKV, is often impractical for children. Recently, 3D ultrasound (US) has emerged as a low-cost, accessible alternative. This study aims to use 3D US and Artificial Intelligence (AI) deep learning techniques to measure TKV in pediatric ADPKD patients accurately. We will validate 3D US measurements by comparing them to AI MR-based TKV measurements.

Methods: Using a Philips EPIQ scanner with a panoramic 3D X6-1 matrix array probe and MR scanners with 3T and 1.5T magnetic field strength, we acquired volumetric 3D-US images and MR images to segment the kidney automatically. A deep convolutional network was trained on retrospective 3D US images (n=130) of ADPKD adult subjects using a C5-1 probe and evaluated on prospectively acquired 3D US volumes (n=22). Training employed 5-fold cross-validation with images stratified by patient and kidney volume into training and validation (80/20) cohorts. We compared AI 3D US-based and MR-based TKV measurements using linear regression and Bland–Altman plots.

Results: We analyzed 11 patients with genetically defined ADPKD carrying either *PKD1* or *PKD2* pathogenic variants. A significant correlation was observed between the reference standard total kidney volume (TKV) measured by MRI and both manual and automated 3D ultrasound (US) volumes (r=0.95, P<0.001 and r=0.86, P=0.001, respectively). The US volumes were lower compared to MR volumes, with a bias of -20.5% and -43.3% for the manual and automated measurements, respectively. **Figure 1** illustrates two representative cases from the study.

Conclusions: Volumetric TKV measurements in pediatric ADPKD are feasible through 3D US images. Enhanced model training, incorporating pediatric data utilizing the X6-1 probe, is anticipated to enhance segmentation performance.

Funding: NIDDK Support



Example cases of volumetric kidney segmentation performed on MR and 3D US imaging. Case 1, a 14-year-old female's right kidney, showed volumes of 180ml on MR, 134ml on manually segmented US, and 131ml predicted by automated US. In Case 2, a 13-year-old male's left kidney had volumes of 223ml on MR, 192ml on manually segmented US, and 148ml predicted by automated US.

FR-PO692

Clinical Features of Cystinosis and Practice Patterns: A Report of the NAPRTCS Cystinosis Registry

Jodi M. Smith,[1] Sara A. Boynton,[2] Paul C. Grimm,[3] Larry A. Greenbaum,[4] Alicia Neu,[2] Bradley A. Warady.[5] *[1]Seattle Children's Hospital, Seattle, WA; [2]Johns Hopkins University, Baltimore, MD; [3]Stanford University, Stanford, CA; [4]Emory University, Atlanta, GA; [5]Children's Mercy Kansas City, Kansas City, MO.*

Background: The NAPRTCS Cystinosis Registry is a prospective cohort study of children & young adults with cystinosis whose objective is to describe clinical features of cystinosis and practice patterns of providers.

Methods: Children & young adults (< 25 yrs) with cystinosis at any NAPRTCS center are eligible. At enrollment, demographic & clinical data from time of initial presentation with cystinosis, time of enrollment, and every 6 months.

Results: Data were collected from 30 centers on 104 subjects diagnosed from 12/1999 to 8/2023 (Table 1). The most commonly reported medications at diagnosis included cystine lowering medications (81.8%), cysteamine eye drops (34.3%), and phosphorus and potassium supplementation (43.4%, 42.4%). During longitudinal follow-up more than 90% of patients remained on cysteamine oral therapy. The type varied over time with an increase in Procysbi use following FDA approval in 2013. Median creatinine at registry enrollment was 0.73 mg/dL (eGFR 69.0 ml/min/1.73m2) and 0.94 mg/dL (58.3 ml/min/1.73m2) at 36 months post enrollment. Almost half of patients (48.9%) had a g-tube at registry entry. Over 90% of patients were at grade level with 34.8% receiving special services. The majority of patients reported 1 to 2 nephrology visits in the past 6 months. The most common subspecialty visits were ophthalmology (28.4%), endocrinology (24.2%) and GI (17.9%).

Conclusions: Children with cystinosis present early in life with majority of patients diagnosed under 2 years of age. Patients typically present with 6 months of symptoms before a diagnosis is made with failure to thrive present in more than 50%. Children and young adults with cystinosis have complex care needs which are often met through non-local, multispecialty care providers.

Table 1. Demographics of the Cystinosis Registry

	n=104
Age at diagnosis	**16.5 months (12, 33)**
Age at registry entry	**9 years (6, 14)**
Time since dx	**6 years (3, 11)**
Male	**55 (52.9%)**
Race	
White	81 (77.9%)
Black	4 (3.8%)
Asian	2 (1.9%)
Multi-racial	9 (8.7%)
Not reported or Unknown	8 (7.7%)
Ethnicity	
Hispanic or Latino	7 (7.7%)
Not Hispanic or Latino	72 (79.1%)
Not reported or Unknown	12 (13.2%)
Insurance	
Private	47 (45.2%)
Medicaid	27 (26.0%)
Distance from center (n=62)	
<20 miles	23 (20.8%)
20-50 miles	19 (18.3%)
>50 miles	30 (28.8%)
Median duration of symptoms prior to	**6.0 months (2.0, 10.0)**
Findings at presentation	
Failure to thrive	54 (54.5%)
Vomiting	39 (39.4%)
Corneal crystals	32 (32.3%)
Dehydration	31 (31.3%)
Other	28 (28.3%)
Labs at diagnosis	
WBC cystine level by assay	
Granulocyte (n=35)	5.06 nmol/mg protein (2.7, 9.0)
Leukocyte (n=22)	2.99 nmol/mg protein (2.1, 4.4)
Genetic analysis	26 (26.3%)

FR-PO693

Thiamine beyond Beriberi

Sandra Iragorri, Brett Boyer, Aditi Tiwari. *Oregon Health & Science University, Portland, OR.*

Introduction: In resource-abundant settings thiamine deficiency is usually limited to those on daily diuretics, alcohol use disorder, very restrictive diets, and post gastric bypass. Children are rarely affected. We present two cases highlighting other at-risk populations with unusual manifestations and potential dire consequences if unrecognized and untreated.

Case Description: Case 1 is a 13-year-old with relapsed ALL post CAR Tcell therapy admitted after 4 weeks of poor dietary intake due to typhlitis and C diff infection, who suddenly developed a severe unexplained lactic acidosis. Recognizing the Warburg effect as the source of the lactic acidosis, lead to thiamine supplementation. Within three hours the lactate dropped from 19 to 3 mmol/L, TCO2 increased from 14 to 26 mmol/L, and the serum pH was 7.46. Unfortunately, a few weeks later the patient died of complications of ALL Case 2 is a 9-year-old with long-standing self-injurious behavior, vomiting, and restricted oral intake, who presented with altered mental status, hypertonia, hyperreflexia, and seizures, leading to intubation and anticonvulsant therapy. Initial laboratories showed AKI and serum sodium of 197 mmol/L. The FeNa of 0.13% and the urine osmolality of 1005 mOsm/kg support the diagnosis of functional AKI. The water deficit was estimated at 7 liters. The admit CK was 777 U/L but despite an initial downtrend, from day 4 onwards (when the serum Na was down by only 37 mmol/L) it steadily rose by 10.000 units/day, peaking at 136,900 U/L on day 9, and steadily dropping thereafter. Thiamine supplementation was started on day 6 following a brain MRI which showed diffusion restriction consistent with either extra pontine myelinolysis or Wernicke's encephalopathy. Clinically the patient improved with inpatient rehab, but to communicate verbally they required an AAC.

Discussion: The Warburg effect refers to a situation where thiamine deficiency prevents pyruvate entry into the oxidative phosphorylation cycle, staying in the cytosol where it is fermented to lactate. The second case underscores how thiamine deficiency impairs the generation of ATP, which in the myocyte is essential for muscle relaxation. An active calcium ATPase, returns calcium from the sarcoplasm to the sarcoplasmic reticulum, leading to relaxation. When contraction persists, rhabdomyolysis ensues. These cases remind us of the diverse and essential biochemical functions of thiamine manifesting as clinical conundrums.

FR-PO694

Defining the Urine Proteome in Boys with Posterior Urethral Valves

Xin Wang,[1,2] Liwen Zhang,[3] Brian Becknell,[1,2] Daryl J. Mcleod.[1,2]
[1]Kidney and Urinary Tract Center, Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]Nationwide Children's Hospital, Columbus, OH; [3]The Ohio State University Wexner Medical Center, Columbus, OH.

Background: Posterior urethral valves (PUV) occur in 1 in 4000 live male births and are a leading cause of pediatric end-stage kidney disease (ESKD). Among patients with PUV, estimated glomerular filtration rate (eGFR) often remains unchanged until late in the disease process due to adequate renal reserve, limiting proactive intervention opportunities. Distinguishing changes in eGFR due to the natural progression of disease vs. modifiable factors is also challenging. Therefore, measures of chronic kidney disease (CKD) progression that are both timely and specific to PUV are critically needed.

Methods: Boys with PUV (cases) and age- and sex-matched healthy children (controls) were recruited from our multispecialty uronephrology clinic and general pediatric clinics, respectively. Urine was obtained through clean catch, catheterization, or urine bag. Urinary proteins from 20 cases and 20 controls were detected using LC/MS/MS. Differential expression analysis identified proteins that varied between cases and controls, and between cases with normal vs. low eGFR. Functional enrichment analysis was profiled to detect specific biological functions. Correlation analyses examined relationships between these proteins and clinical factors, such as eGFR, creatinine, age, and weight.

Results: We identified conserved urine proteins and biological pathways that are dysregulated in cases compared to controls, along with differences in the urinary proteome between cases with normal versus reduced eGFR. Unique subgroups among cases emerged, each characterized by distinctive urine protein profiles and pathways. Cases with low eGFR accumulate angiogenesis-associated proteins, such as AGT, VCAM1, and CDH5, while exhibiting reduced levels of IGFBP7 and L1CAM. Correlation analyses between eGFR and urinary proteins revealed 31 proteins highly correlated in cases, helping to trace the development of obstruction nephropathy.

Conclusions: These results enhance our understanding of kidney injury in PUV and identify potential urine biomarkers for further investigation. The discovery of these markers and pathways could aid in early diagnosis of obstructive nephropathy, providing healthcare providers with tools for proactive intervention and more precise therapeutic strategies.

MIP Assay-Based Targeted Gene Resequencing Identifies 22 Novel and Extremely Rare Variants in Known and Putative New Candidate Genes in Lower Urinary Tract Obstruction

Markus H. Zeilmann,[1] Arif Ekici,[11] Clara Vidic,[9] Wolfgang Krebs,[10] Marcin Zaniew,[12] Agnieszka Szmigielska,[4] Monika Miklaszewska,[5] Maria Szczepanska,[6,7] Katarzyna Taranta-Janusz,[8] Przemyslaw Sikora,[13] Katarzyna Zachwieja,[5] Friedhelm Hildebrandt,[3] Alina Hilger.[1,2] CaRE for LUTO.
[1]Department of Pediatrics and Adolescent Medicine, Friedrich-Alexander University of Erlangen-Nürnberg, Erlangen, Germany; [2]Research Center On Rare Kidney Diseases (RECORD), University Hospital Erlangen, Erlangen, Germany; [3]Division of Pediatric Nephrology, Boston Children's Hospital, Boston, MA; [4]Department of Pediatrics and Nephrology, Warsaw Medical University, Warsaw, Poland; [5]Department of Pediatric Nephrology and Hypertension, Cracow Medical College of the Jagiellonian University, Cracow, Poland; [6]Department of Pediatrics, Silesian Medical University, Faculty of Medical Sciences in Zabrze, Zabrze, Poland; [7]Department of Pediatrics, Silesian Medical University in Katowice, Katowice, Poland; [8]Department of Pediatrics and Nephrology, Medical University of Bialystok, Bialystok, Poland; [9]Department of Human Genetics, Rheinische Friedrich-Wilhelms-Universitat Bonn, Erlangen, Germany; [10]IT Unit, Nuremberg Institute of Technology, Nuremburg, Germany; [11]Department of Human Genetics, Friedrich-Alexander University of Erlangen-Nürnberg, Erlangen, Germany; [12]Department of Pediatrics, University of Zielona Góra, Zielona Góra, Poland; [13]Department of Pediatric Nephrology, Medical University of Lublin, Lublin, Poland.

Background: Lower urinary tract obstruction (LUTO) is the main cause of kidney failure in childhood. In about 60% LUTO occurs as posterior urethral valves (PUV). To date, little is known about the genetic causes of LUTO. Hence, we aimed to decipher the contribution of the known and previously identified candidate genes to the development of LUTO in our cohort of 500 individuals.

Methods: Therefore, 17 candidate genes were evaluated, using single-molecule molecular inversion probe (MIP) assay. After NextGen sequencing, data was filtered using a stringent algorithm including the quality of the reads, population frequency, and pathogenicity in prediction programs as the CADD-phred score to determine novel and extremely rare variants. The filtered variants were subjected to Sanger sequencing for validation and familial segregation if available.

Results: In total 22 different variants were identified in 20 patients in 11 of the re-sequenced genes (figure 1). Four genes were previously described as possible LUTO disease genes, 4 genes were found to reside in close proximity to regions identified in previous LUTO genome-wide association studies (GWAS) and 3 genes are newly identified candidate genes by our group. All variants matched the known or assumed inheritance patterns for the respective genes.

Conclusions: We suggest that the identified potentially disease-causing variants provide evidence that the underlying genes may be involved in the development of LUTO. Nevertheless, possibly disease-causing variants could only be identified in just 1,8% of all investigated LUTO individuals showing that LUTO is very heterogeneous. Still, the identification of new candidate genes, followed by warranted functional studies on these genes, will lead to a deeper understanding of the development of LUTO.

Ribonuclease Inhibitor Regulates Host Antimicrobial Activity toward Uropathogenic Escherichia coli

Yusuf Ali,[1,2] Hanna H. Cortado,[1,2] Birong Li,[1,2] Brian Becknell.[1,2] [1]*Kidney and Urinary Tract Center, Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH;* [2]*Nationwide Children's Hospital, Columbus, OH.*

Background: Members of the Ribonuclease A Superfamily exert bactericidal activity toward uropathogenic *Escherichia coli* (UPEC) and their activity is regulated by an endogenously expressed high affinity binding partner, Ribonuclease inhibitor (RI). Here, we tested the hypothesis that RI serves a critical role in regulating the antimicrobial activity of RNase 3.

Methods: UPEC colony forming units (CFU) were enumerated to assess the antimicrobial activity of recombinant RNase 3 protein in the presence and absence of RI. We tested the interaction, colocalization and UPEC mediated regulation of RNase 3 by RI in human MOLM-13 cells, monocytes, and neutrophils by co-immunoprecipitation (Co-IP), Western blotting and immunofluorescence (IF). Binding of RNase 3 with RI was studied by native gel electrophoresis and visualized by silver staining. Using Cre/LoxP recombination, we deleted RI in murine phagocytes. We transurethrally inoculated control and RI conditional knockout mice with UPEC and enumerated bacterial burden in urinary tract tissues.

Results: RNase 3 exhibited potent antimicrobial activity towards UPEC, which was suppressed by the addition of RI. RI and RNase 3 colocalize and form a complex in monocytes and neutrophils that dissociates with UPEC treatment. Recombinant RNase 3 and RI proteins associate directly in cell-free conditions, and this is disrupted by pre-incubation with H_2O_2, suggesting a redox dependent interaction. Phagocyte-specific RI conditional knockout mice exhibited augmented UPEC clearance during experimental UTI, consistent with a model in which RI limits antimicrobial RNase activity.

Conclusions: RI forms a reversible complex with RNase 3 to limit its antimicrobial activity toward UPEC. UPEC infection dissociates this complex – possibly as a consequence of oxidation - resulting in augmented RNase 3 activity and UPEC clearance. Studies in RI knockout mice substantiate its role as a negative regulator of phagocyte antimicrobial activity *in vivo*.

Single-Center Case Series of Congenital Anomalies of the Kidney and Urinary Tract and Hepatoblastoma

Rebecca Farr,[1] Julie Bonn,[1,2] Mohamad Eyad Khorki,[1] Stuart Goldstein,[1,2] Alexander Bondoc,[1,2] Greg Tiao,[1,2] Katherine Somers,[1,2] James I. Geller,[1,2] Meredith P. Schuh.[1,2] [1]*Cincinnati Children's Hospital Medical Center, Cincinnati, OH;* [2]*University of Cincinnati College of Medicine, Cincinnati, OH.*

Introduction: Hepatoblastoma (HB) is the most common pediatric primary liver malignancy. Several congenital anomalies and syndromes are associated with an increased incidence of HB and have recommended HB screening guidelines. While multiple case reports describe HB in children with congenital anomalies of the kidney and urinary tract (CAKUT), true incidence is unknown and screening guidelines do not exist. We report a case series of eight patients with bilateral CAKUT and HB.

Case Description: All patients were male, preterm (gestational age 24-34 weeks), and diagnosed with HB between 5 months and 2 years from 2008-2022. Seven patients initiated dialysis (median start 54 days of life). Five were found to have HB incidentally on imaging obtained for surgical planning, two had imaging due to abdominal pain/distension and vomiting, and one had imaging as part of an evaluation for hypercalcemia. Four patients achieved successful remission with a combination of chemotherapy and surgical resection, while four patients were offered liver transplant due to the extent of their disease after chemotherapy. In this small cohort, neither the age at diagnosis, length of time on dialysis prior to diagnosis, nor alpha fetal protein (AFP) concentration at diagnosis (26-545,797ng/mL) was associated with the extent of disease or outcome (Table 1).

Discussion: This case series highlights bilateral CAKUT and HB at our center and represents 3.5% of bilateral CAKUT seen within the study period. Importantly, most were diagnosed with HB incidentally, and half needed liver transplantation due to the extent of their disease. We suggest a proactive screening protocol in patients with bilateral CAKUT has potential to identify HB at an earlier stage, thus possibly negating the need for liver transplantation. Further multicenter studies are needed to define the true incidence of HB in bilateral CAKUT and identify specific patient factors, such as genetic predisposition, to inform screening protocols.

Pt #	Sex	Race	GA at Birth (weeks)	Birth Weight (g)	BCAKUT diagnosis	Age at initiation of KRT (days)	Age at HB Dx (months)	Time from KRT start to HB Dx (months)	Clinical Presentation at diagnosis	AFP at diagnosis (ng/mL)	PRETEXT	Surgical Therapy	Long term Outcome
1	M	White	33	2530	PUV, kidney dysplasia	130	24	2	Incidental imaging (CT angiography) obtained for kidney transplant evaluation	180,153	II	Resection	Transitioned care
2	M	Unknown	33	Unknown	PUV, kidney dysplasia	7	29	28.8	Incidental imaging (abdominal ultrasound) obtained prior to bladder augmentation surgery	889	III	Offered (unknown liver/kidney)	Family pursued listing at different institution.
3	M	White	34	2045	ARPKD	99	5	6	Found on imaging (abdominal ultrasound) obtained for abdominal pain and vomiting	121	III	Failed resection, liver/kidney transplant	Transplanted 6 years ago, no recurrent disease.
4	M	White	24	460	Bilateral dysplastic cystic kidneys	N/A	12	N/A	Found on imaging (kidney ultrasound) obtained for hypercalcemia workup	545,797	IV	Liver/kidney transplant	Deceased 5 days after transplant.
5	M	Black	33	3445	Bladder outlet obstruction	54	22	20.2	Incidental imaging (abdominal ultrasound) obtained for kidney transplant evaluation	8,536	I	Resection	Off therapy for 21 months no recurrent disease.
6	M	White	34	2830	Multicystic dysplastic kidneys	29	5	3	Incidental imaging (CT venogram) obtained for dialysis catheter placement	9,702	IV	Liver/kidney transplant	Transplanted 5 years ago, no recurrent disease.
7	M	Middle Eastern	32	Unknown	Presumed PUV, kidney dysplasia	100	26	3	Found on imaging (abdominal ultrasound) obtained for abdominal distension and vomiting	26	II	Resection	Lost to follow up 7 years ago. Has been off therapy 3.5 years with no recurrent disease.
8	M	White	33	Unknown	Bilateral [illegible] PUV	2	2	4.9	Found incidentally on routine imaging (kidney ultrasound)	2,226	II	Resection	Deceased: [illegible] failure after 2nd chemo cycle (cancer free at time).

Table 1. GA = gestational age, BCAKUT = bilateral congenital anomalies of the kidney and urinary tract, KRT = kidney replacement therapy, AFP = Alpha-fetoprotein, PRETEXT = pre-treatment extent of disease staging system, Dx = diagnosis.

Regulation of Urinary Tract Infection (UTI) Susceptibility by Stat3-Driven DMBT1 Expression

Sudipti Gupta, Shradha Rajak, Brian Becknell, John D. Spencer, Christina B. Ching. *Nationwide Children's Hospital, Columbus, OH.*

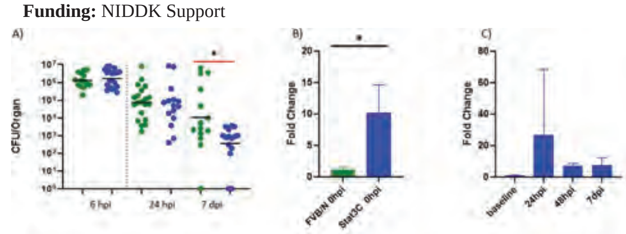
Background: Innate immune effectors like antimicrobial peptides exist to reduce UTI susceptibility in humans. We focus on studying the regulation of innate immune mechanisms by transcription factor, Stat3, to limit UTI susceptibility. Deleted in Malignant Brain Tumors-1 (DMBT1) protein is an antimicrobial peptide with antibacterial properties likely due to its function as a pattern recognition receptor. A clinical study shows lower DNA copy number of *DMBT1* leads to increase the odds of recurrent UTI. While DMBT1 has been demonstrated to be regulated by Stat3 in models of Crohn's disease, it has not been associated with Stat3 expression in models of UTI. We hypothesized that Stat3 manipulation in UTI would impact DMBT1 expression.

Methods: 6-8 weeks old female FVB/N wild type (WT) and constitutively active Stat3 (Stat3C) mice underwent experimental UTI. Urine and bladder tissue was collected up to 7 days post infection (dpi). Dilution plating was performed to quantify bladder and urine bacterial burden. Qiagen RT^2 profiler PCR mouse antimicrobial array was performed on bladders followed by confirmatory qRT-PCR. Results were evaluated by unpaired t-test or Mann-Whitney U test when appropriate, with $p<0.05$ being significant.

Results: Stat3C mice demonstrated reduced urine and then bladder burden by 7 dpi (p=0.0123). Evaluation of antibacterial responses on PCR array between the Stat3C and WT mice demonstrated significant differences in DMBT1 at baseline, peaking at 24hpi, and then persisting at 7dpi (p<0.01). Upon confirmatory qRT-PCR, DMBT1 was significantly elevated at baseline and 24hpi between Stat3C and WT mice (p<0.008). DMBT1 induction in infected Stat3C mice peaked at 24hpi with a 46-fold increase over baseline. This induction persisted even at 7dpi (8 fold over baseline).

Conclusions: Urothelial Stat3 overexpression results in baseline up-regulation of DMBT1 gene expression with a further increase during infection, particularly peaking at 24hpi. This is the first evidence of DMBT1 expression being regulated by Stat3 during UTI.

Funding: NIDDK Support



A) Stat3C mice have significantly decreased bladder burden in a delayed manner after UTI (7dpi)
B) Significantly higher induction of certain DMBT1 at baseline Stat3C mice on qRT-PCR
C) Time course DMBT1 fold induction following eUTI

Phagocyte-Derived Ribonuclease 3 Promotes Bacterial Clearance during Urinary Tract Infection

Hanna H. Cortado,[1,2] Macie M. Kercsmar,[1,2] Birong Li,[1,2] Sudipti Gupta,[1,2] Christina B. Ching,[1,2] Ashley R. Jackson,[1,2] Juan de Dios Ruiz-Rosado,[1,2] Brian Becknell.[1,2] *[1]Nationwide Children's Hospital, Columbus, OH; [2]Kidney and Urinary Tract Center, Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH.*

Background: Urinary tract infections (UTI) are common, serious bacterial infections in children, most often caused by uropathogenic *Escherichia coli* (UPEC), and can lead to urosepsis, acute kidney injury, and renal scarring. Identifying mechanisms of host defense against UTI is crucial in the development of innovative and effective strategies to mitigate these sequelae. The production of antimicrobial peptides (AMPs) is an important component of the innate host immune response against uropathogens. Our group is focused on identifying AMPs within the RNase A superfamily that play a role in controlling UTI. Here, we determine the contribution of human RNase3 to host UTI defense *in vivo* and its impact on phagocyte antimicrobial activities.

Methods: Urine RNase3 levels were measured by ELISA in girls with UTI and compared to unaffected controls. Humanized *RNASE3* transgenic mice underwent transurethral inoculation of UPEC, and bacterial colony forming units (CFU) were enumerated in urinary tract organs. We utilized immunofluorescence microscopy and intracellular flow cytometry to identify cellular sources of RNase3. The bactericidal activity of RNase3 toward UPEC was investigated using recombinant RNase3 and *RNASE3* transgenic phagocytes.

Results: RNase3 amino-terminal peptide exhibited dose dependent antimicrobial activity towards UPEC. RNase3 levels were elevated in urine from pediatric patients with UTI compared to healthy controls. Studies in *RNASE3* transgenic mice and human tissues evince that RNase3 is expressed by neutrophils, monocytes and macrophages that infiltrate the infected kidney and bladder following UPEC exposure. *RNASE3* transgenic mice are protected from ascending UPEC infection, and *RNASE3* transgenic phagocytes are more adept at UPEC killing compared to non-transgenic controls.

Conclusions: Our data establish that RNase3 is an antimicrobial peptide induced during human UTI with potent bactericidal activity toward UPEC. Functionally, evidence in *RNASE3* transgenic mice and phagocytes demonstrates that RNase3 effectively limits disseminated UPEC infection.

Impact of MicroRNA Depletion on Maintenance of Adult Bladder Urothelium

Macie M. Kercsmar,[1,2] Hanna H. Cortado,[1,2] Kelly Grounds,[1,2] Ashley R. Jackson,[1,2] Brian Becknell.[1,2] *[1]Kidney and Urinary Tract Center, Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]Nationwide Children's Hospital, Columbus, OH.*

Background: MicroRNA (miRNA) serve essential roles in epithelial cell development, maintenance, and response to injury through the regulation of mRNA and protein expression, however their functions in urothelium remains unknown. To address this knowledge gap, we engineered mice with temporally-restricted, urothelium specific inactivation of Dicer, an exonuclease required for miRNA biogenesis.

Methods: We generated tamoxifen-inducible urothelial Dicer conditional knockout mice by intercrossing *Dicer*$^{fl/fl}$ and *Upk2*CreERT$_2$ or *Shh*CreERT$_2$ animals. A tdTomato (tdT) fluorescent protein was expressed in a Cre/LoxP dependent manner to identify cells in which *Dicer* inactivation had occurred. Urothelial lineage markers were evaluated by immunofluorescence microscopy, Western blotting, and QRT-PCR.

Results: Bladders from control animals showed the expected urothelial morphology with three distinct layers: Krt5+;Krt14+ basal (B) cells, Krt5+;Upk+ intermediate (I) cells, and Upk+;FABP4+ superficial (S) cells. In contrast, adult bladders with *Upk2*CreERT$_2$-specific *Dicer* inactivation displayed rounded and exfoliated S cells with discontinuous Fabp4 expression. This coincided with increased Krt5 and Krt14 protein expression, whereas *Krt5* and *Krt14* mRNA levels were unaffected. In contrast, *Shh*CreERT$_2$-specific *Dicer* knockout mice displayed immature B cells and abundant I cells, whereas S cells maintained FABP expression but exhibited a round and more columnar morphology.

Conclusions: Dicer serves essential roles in urothelial structural integrity by promoting the maintenance of superficial, intermediate, and basal cells. This justifies further studies to identify specific miRNA responsible for this role.

MicroRNA 146a Is a Negative Regulator of the Host Innate Immune Response to Urinary Tract Infection

Birong Li,[1,2] Macie M. Kercsmar,[1,2] Hanna H. Cortado,[1,2] Brian Becknell.[1,2] *[1]Kidney and Urinary Tract Center, Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]Nationwide Children's Hospital, Columbus, OH.*

Background: Urinary tract infections (UTIs) rank among the most common bacterial infections in children and adults. The innate immune response is essential for pathogen detection and eradication during UTI, but excessive inflammation can lead to renal injury and scarring. MicroRNA (miR) are small, non-coding RNA with key roles in regulating renal inflammation and tissue remodeling, but their expression and function in UTI are unknown. We investigated miR dynamics and the specific role of miR146a in the setting of experimental cystitis.

Methods: Female C57BL/6J mice underwent transurethral inoculation with uropathogenic *Escherichia coli* (UPEC). Bladders were harvested 7 days post infection for miR and total RNA sequencing. Transcriptome analysis was performed using GO and Ingenuity. Differential miR expression was validated by QRT-PCR during experimental cystitis. *miR146a* deficient and control mice were challenged with experimental UTI to investigate differences in susceptibility.

Results: UPEC infection led to dynamic changes in the bladder miRome, and miR146a was identified as the miR with the greatest fold-change. QRT-PCR validated induction of miR146a, and analysis of the predicted targets of miR-146a suggest its regulatory role in reducing inflammation. Mice with global *miR146a* deficiency were more susceptible to experimental UTI.

Conclusions: MiR146a is a negative regulator of the host innate immune response during UTI. Further studies are justified to identify the direct targets of miR146a and the therapeutic impact of miR146a mimetics during UTI.

FR-PO702

Predictive Value of Initial Diagnostic Imaging for Congenital Ureteropelvic Junction Obstruction Requiring Pyeloplasty

Adaobi Solarin,[1,2] Shivam Joshi,[3] Sudipti Gupta,[1,2] Christina B. Ching,[1,2] Brian Becknell.[1,2] *[1]Kidney and Urinary Tract Center, Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]Nationwide Children's Hospital, Columbus, OH; [3]The Ohio State University Wexner Medical Center, Columbus, OH.*

Background: Hydronephrosis is one of the most common findings on prenatal ultrasound. While prenatal hydronephrosis resolves in most instances, 6% of cases represent ureteropelvic junction obstruction (UPJO) that will require pyeloplasty, and differentiating between obstructive and non-obstructive hydronephrosis remains an unmet challenge. Usually, a combination of factors such as the Society of Fetal Urology (SFU) grade, drainage pattern, and differential renal function (DRF) on diuretic renogram are used in assessing the severity of hydronephrosis. We sought to identify predictive features on initial postnatal imaging for pyeloplasty among children with suspected UPJO.

Methods: We conducted a prospective, single-center study of children with prenatal hydronephrosis, postnatal imaging suggestive of isolated UPJO without other congenital anomalies, and two years of follow-up. Demographic, clinical and radiologic data from initial postnatal imaging were retrieved. Chi-squared test or Fisher's exact test was used to examine associations between categorical variables and surgical intervention, and Wilcoxon rank sum test identified the differences in the distribution of continuous variables across surgical interventions. A logistic regression model was utilized to identify potential predictors of surgical intervention.

Results: There were 98 cases of UPJO, of whom 49 (50%) underwent pyeloplasty. The median age at initial imaging was 4.4 months, 77 (79%) were male and 81 (84%) Caucasian. The initial SFU grade and gravity assisted drainage (GAD) on radionuclide imaging were associated with pyeloplasty. Logistic regression analysis indicated that age (p=0.0090), GAD (p=0.0009), and DRF (p=0.0422) are significant predictors of pyeloplasty. The model explained 45% of the variance in the outcome and correctly classified 83% (AUC=0.83) of cases undergoing pyeloplasty.

Conclusions: The initial diagnostic imaging has shown an excellent performance in predicting surgical intervention with age, DRF and GAD as significant predictors. Ongoing studies seek to extend these observations in an independent patient cohort and superimpose candidate urinary biomarkers to further discriminate UPJO from non-obstructive hydronephrosis at the time of initial postnatal imaging.

FR-PO703

Long-Term Kidney Outcomes in Pediatric Renal Vein Thrombosis

Mayra A. Oseguera,[1] Myda Khalid,[2] Bryce A. Kerlin.[3,1] *[1]Nationwide Children's Hospital, Columbus, OH; [2]Indiana University School of Medicine, Indianapolis, IN; [3]Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH.*

Background: Pediatric renal vein thrombosis (RVT) may increase the long-term risk for adverse renal outcomes. Most literature focuses on neonatal RVT, with low emphasis on long-term renal outcomes. There is sparse data on renal outcomes following RVT in older children. The goal of this project is to determine long-term renal outcomes of RVT across the pediatric age spectrum.

Methods: The PHIS (Pediatric Health Information System) database was used to identify patients from birth to 21 years of age with a diagnosis of RVT. We looked for the occurrence and persistence of hypertension, proteinuria, and eGFR reduction. Secondary outcomes analyzed were end stage renal disease and mortality.

Results: We identified 516 children with a diagnosis of RV in the PHIS database (Table 1). 51.9% were male. The mean age for RVT diagnosis was 2.6 years, the most common age at diagnosis was in the neonates. Children as old as 17 years of age were also identified. 20% of the affected individuals had residual CKD. Residual HTN occurred in 30.6% of the patients. (Table 1).

Conclusions: Pediatric RVT is a risk factor for the development of CKD and hypertension regardless of age at RVT diagnosis. Survivors of pediatric RVT should be routinely screened for evolving CKD and/or hypertension. We plan a deeper analysis of these data to determine if anticoagulant therapy alters long-term renal outcomes following pediatric RVT.

Characteristic	N (%)
Unique patients	516
Male sex	268 (51.9)
Age at RVT, years	2.6 (0.01–11.1)
Renal complex chronic condition flag (before or after RVT)	319 (61.8)
Mortality	66 (12.8)
Renal Outcomes	190 (36.8)
AKI	106 (20.5)
CKD	103 (20.0)
Kidney failure	3 (0.6)
Atrophy of kidney	13 (2.5)
Small kidney	5 (1.0)
Infarction of the kidney	21 (4.1)
Dialysis dependent	26 (5.0)
HTN	158 (30.6)
Proteinuria	15 (2.9)
