KIDNEY WEEK EDITION

KIDNEY WEEK 2024

Abstract Supplement

Abstract Supplement

Abstract Publication
More than 4,000 abstracts are published in this supplement. Abstracts are arranged by the abstract type**, then by presentation date* for orals and posters, and then by chronological publication number. Abstracts with a "PUB" number will not be presented at the ASN Annual Meeting.

* TH = Thursday, FR = Friday, SA = Saturday
** OR = Oral, PO = Poster, PUB = Publication Only

The presenting author's name is underlined.

Abstract Author Index
The Author Index lists all abstract authors in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB), then the presentation day (TH, FR, or SA), and then the chronological publication number.

Abstract Keyword Index
The Keyword Index lists major keywords from each abstract in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB), then the presentation day (TH, FR, or SA), and then the chronological publication number.

Abstract Reference Format
To cite abstracts in this publication, please use the following format: Author Names: Abstract Title [Abstract]. J Am Soc Nephrol 35, 2024: Page(s).

Abstract Disclaimer and Copyright
This abstract issue of JASN® contains proprietary information belonging to the American Society of Nephrology. It is published as a service for the personal, noncommercial, and informational use only of the kidney community. Any commercial use is strictly prohibited. ASN's program materials and publications facilitate scientific discourse for educational purposes. ASN accepts no responsibility for any products, presentations, opinions, statements, or positions expressed, and inclusion of such materials within Kidney Week and other ASN publications or online postings does not constitute endorsement by ASN.

Abstract Experts
Abstract submissions were rigorously reviewed and graded by multiple experts. ASN thanks the abstract category chairs and reviewers for assistance with the abstract process. The ASN website lists all abstract experts.

ASN General Information
Kidney Week Program and Presentations
The Kidney Week program, which can be found on the ASN website, includes:

- Plenary Sessions
- Basic/Clinical Science Sessions
- Clinical Practice Sessions
- Translational Sessions
- Special Sessions
- Educational Symposia
- Oral Abstract Sessions
- Poster Sessions

Disclosure Statement
ASN requires all individuals in a position to control content for Kidney Week to complete a disclosure form. Responses are listed on the ASN website.

TH-OR01

Nonoptimal ESKD Starts before and after Medicaid Expansion

Nicholas S. Roetker,[1] Jiannong Liu,[1] Haifeng Guo,[1] David T. Gilbertson,[1,2] James B. Wetmore,[1,2] Kirsten L. Johansen.[1,2] *[1]Chronic Disease Research Group, Hennepin Healthcare Research Institute, Minneapolis, MN; [2]University of Minnesota Twin Cities, Minneapolis, MN.*

Background: Initiating in-center hemodialysis with a central venous catheter represents a nonoptimal start of end-stage kidney disease (ESKD). We studied whether nonoptimal start rates were higher in residents of 11 states that did not expand Medicaid access in 2014 relative to residents of 27 states that did.

Methods: We included yearly data from 2006-2019 for persons aged 18-64 years. We identified age, sex, and race/ethnicity state-level population estimates using US Census Bureau data and counts of nonoptimal ESKD starts from the US Renal Data System. We compared incidence rates between expansion and non-expansion states in the pre- and post-expansion periods using age, sex, and race/ethnicity adjusted Poisson regression.

Results: Before Medicaid expansion, the yearly rate of nonoptimal ESKD starts was 216.8 cases per million persons (PMP) in non-expansion states and 199.3 PMP in expansion states, with rates decreasing in both groups across this period (**Figure**). After Medicaid expansion, nonoptimal start rates were relatively stable in the expansion states (191.2 cases PMP) but increased in the non-expansion states (216.9 cases PMP). Thus, compared with the expansion states, the average yearly incidence was 17.4 (95% CI 15.8–19.1) PMP higher in non-expansion states in the pre-expansion period and 25.7 (95% CI 23.9–27.5) PMP higher in the post-expansion period (post vs pre difference in difference: 8.2; 95% CI 5.8–10.7 PMP). Notably, the difference in difference estimates were highest among the age 45-64 years (17.3; 95% CI 12.0–22.7 PMP) and non-Hispanic White (16.2; 95% CI 13.6–18.8 PMP) subgroups.

Conclusions: In the 6 years after enactment of the Affordable Care Act, rates of nonoptimal ESKD start were stable in states that expanded access to Medicaid but increased in states that did not. Further studies should examine whether increases in nonoptimal starts in non-expansion states may be attributable to less access to healthcare among uninsured persons with kidney disease.

TH-OR02

Age-Dependent Racial Differences in Kidney Function Decline between Black and White Veterans after CKD Onset

Guofen Yan,[1] Julia J. Scialla,[1] Nan Hu,[2] Wei Yu,[1] Tom Greene,[3] Robert Nee,[4] Fei Heng,[5] Alfred K. Cheung,[3] Keith C. Norris.[6] *[1]University of Virginia, Charlottesville, VA; [2]Florida International University, Miami, FL; [3]University of Utah Health, Salt Lake City, UT; [4]Walter Reed National Military Medical Center, Bethesda, MD; [5]University of North Florida, Jacksonville, FL; [6]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.*

Background: Recent research reveals that, when CKD onset was determined using the new race-free eGFR equation, Black adults still had a higher risk of subsequent progression to kidney failure than their White peers. We examined the extent to which rates of eGFR decline over time differ in Black and White veterans after CKD onset, and whether age modified the racial difference.

Methods: The study included 54,728 non-Hispanic Black and 256,479 non-Hispanic White veterans, aged 18-85 years, with new onset of CKD between 2005 and 2012 in the US Veterans Health Administration, and quarterly eGFR measurements for up to 6 years. eGFRs were calculated from outpatient serum creatinine measurements based on the 2021 CKD-EPI creatinine equation. We employed a linear spline mixed-effects model with random intercepts and random slopes to estimate age-specific rates of stable eGFR decline over 6 years from quarter 4 after CKD onset for each race, controlling for sex and calendar year of CKD onset.

Results: Upon CKD onset, the two race groups had similar mean eGFR levels (51 mL/min/1.73m^2). The rate of eGFR decline accelerated as the age of CKD onset decreased in Black veterans; the reverse was observed in White veterans (Table). As a result, racial differences in eGFR slopes were modified by the age of CKD onset, with larger differences at younger onset of CKD. For example, at age of CKD onset of 45 years old, the rate of eGFR decline was 0.79 mL/min/1.73m^2 per year faster in Black than White veterans. In distinct contrast, similar decline rates were observed in the two race groups at onset age of 85 years.

Conclusions: Racial differences in kidney function decline were larger among patients who developed CKD at a younger age, likely driven by more rapid decline in a subset of young Black patients. Delineating biological and social factors underlying the younger onset of CKD and subsequent fast progression for Black patients is warranted.

Funding: NIDDK Support

Age-specific rates of eGFR changes after CKD onset by race

Age at CKD onset (years)	Black eGFR slope (mL/min/1.73m2 per year)	White eGFR slope (mL/min/1.73m2 per year)	Difference between Black and White (mL/min/1.73m2 per year)	P value
45	-1.35	-0.56	-0.79	<0.001
55	-1.22	-0.64	-0.58	<0.001
65	-1.09	-0.72	-0.37	<0.001
75	-0.97	-0.81	-0.16	<0.001
85	-0.85	-0.89	0.04	0.25

A negative value means eGFR decline.

TH-OR03

Impact of Predialysis Nephrology Care on Incident Vascular Access Outcome among Hispanic Individuals: A Causal Mediation Analysis

Grant D. Scheiffele,[1] Serena Jingchuan Guo,[2] Wenxi Huang Huang,[2] Yi Guo,[2] Ashutosh M. Shukla.[1,2] *[1]US Department of Veterans Affairs, Gainesville, FL; [2]University of Florida, Gainesville, FL.*

Background: Predialysis care is a dominant predictor of incident vascular access outcomes. Prior studies have shown significant disparities in predialysis nephrology care among Hispanic patients with ESKD, compared to non-Hispanic Whites; however, its relative contributions to disparities in vascular access outcomes is unknown.

Methods: Analyzing patients initiating hemodialysis between 2009 and 2019 in URSDS, we examined the impact of disparities in predialysis nephrology care on incident vascular access use among Hispanic individuals, compared to non-Hispanic White individuals. Adjusting for critical patient-level variables, we conducted series of logistic regression and causal mediation analyses to dissect the attributable influence of disparities in predialysis nephrology care on vascular access use.

Results: Among the 427,340 adult Medicare recipients initiating their first-ever hemodialysis between 2010-2019; 269,697 Non-Hispanic White and 46,146 Hispanic individuals, 276,652 initiated with pure central venous catheter (CVC) without any maturing Arteriovenous Fistula (AVF) or Arteriovenous Graft (AVG) and 75,238 initiated with AVF or AVG. After adjusting for patient-level variables, compared to Non-Hispanic Whites, odds of predialysis nephrology care were 64% (95%CI: 63–66%) and odds of incident AVF/AVG use were 71% (95%CI:69-74%) amongst patients with Hispanic ethnicity. Causal mediation analysis showed that 33% (95%CI:29-37%) of the incident vascular access underuse was attributable to the disparities in predialysis renal care. Sensitivity analyses examining stronger mediators in form of more than 6-month nephrology care and predialysis kidney disease education showed even stronger mediating influence on vascular access outcomes (Table 1).

Conclusions: Disparities in predialysis nephrology care mediate nearly a third of disparities in vascular access outcomes among Hispanic ESKD population. Efforts are needed to universalize predialysis nephrology care and kidney disease education services for all Hispanic individuals at high risk of kidney failure.

Racial Disparities in Access to Preemptive Living Donor Kidney Transplantation in the United States from 2001-2023

Fawaz Al Ammary,[1] Abimereki Muzaale,[2] Simeon Adeyemo.[1] Living Donor Transplant Outcome Collaborative (LDTOC). *[1]University of California Irvine, Irvine, CA; [2]Johns Hopkins University, Baltimore, MD.*

Background: Preemptive kidney transplantation for ESRD patients, before dialysis is needed, improves patient survival. However, access depends on early referral for transplant evaluation, as patient eligibility starts when eGFR less or equal 20 ml/min/1.73m2. We studied the impact of race/ethnicity on transplant waitlisting and access to preemptive living donor kidney transplantation over time.

Methods: We used the Scientific Registry of Transplant Recipients of 111,126 adult first-time kidney transplant candidates listed preemptively between 2001 and 2020. Outcome was wait time to preemptive living donor kidney transplantation, with race/ethnicity as the exposure. We used competing risk survival to estimate the cumulative incidence of preemptive transplantation, competing with death. Multivariable Cox regression adjusted for confounders. Analyses were stratified by era (2001–2005, 2006–2010, 2011–2015, and 2016–2020). Patients were followed for 3 years, with last follow-up in Dec. 2023.

Results: Overall, the cumulative incidence of preemptive living donor transplantation for patients on waitlist varied by race [Figure]. Compared to White patients, in the eras 2001–2005, 2006–2010, 2011–2015, and 2016–2020, Black patients were less likely to be transplanted by 52%, 58%, 60%, and 65%; Hispanic patients by 19%, 20%, 25%, and 34%; and Asian patients by 54%, 47%, 42%, and 47%, respectively [Table].

Conclusions: This study highlights persistent racial disparities in access to preemptive living donor kidney transplantation over the last two decades. These findings emphasize the need for interventions to address systemic barriers and ensure equitable access to early transplant evaluation for racial minorities.

All models were adjusted for age at listing, sex, race, ABO blood type, BMI, and DM as the cause of ESRD

TH-OR05

Trends in Dialysis Facility Access in the United States from 2018-2023 and Association with Area Socioeconomic Disadvantage

Meri Varkila, Maria E. Montez-Rath, Xue Yu, Nivetha Subramanian, Glenn M. Chertow, Julie Parsonnet, Shuchi Anand. *Stanford University School of Medicine, Stanford, CA.*

Background: After several years of stable growth, recent data indicate that the dialysis market in the US may be contracting. We sought to examine trends in US dialysis facility growth and closures, and evaluate whether closures were disproportionately affecting socio-economically disadvantaged populations.

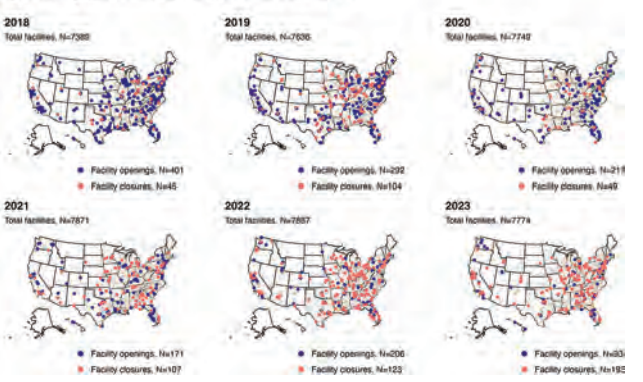
Methods: We conducted a serial cross-sectional study of dialysis facilities from 2018 until 2023 using the Provider of Services data from Centers for Medicare & Medicaid Services. We performed geospatial analysis of facility openings and closures across the U.S. and examined differential trends in dialysis facility access over time. We evaluated differences in CDC/ATSDR social vulnerability index (SVI), census region, rural or urban area designation, and racial and ethnic composition between census tracts (CT) in which the total number of dialysis facilities decreased, increased or remained unchanged between 2018 and 2023.

Results: We identified 8220 unique dialysis facilities across 7120 CTs between 2018 and 2023. During this time– as the number of individuals with prevalent end-stage renal disease rose from 782,844 in 2018 to 815,142 by the end of 2023– the annual number of facility closures increased consistently, whereas the number of newly opened facilities decreased (**Fig 1**). Facility closures and openings tended to occur in distinct CTs. Overall, access to dialysis services decreased in 563 (7.9%) neighborhoods. CTs in rural areas and in the Midwest were more likely to experience dialysis facility closures compared with urban CTs (10.5% of rural CTs vs. 8.4% of urban CTs with closures, p=0.01, and 10.3% of Midwest CTs vs. 6.2% of West CTs with closures, p <0.01). Neighborhoods with higher SVI did not experience more closures (p=0.61).

Conclusions: Trends in dialysis facility closure raise concerns about loss of access to dialysis services nationwide, with rural communities most urgently affected.

Funding: Other NIH Support - 1R21MD01939401

Figure 1. Geographic distribution of dialysis facilities in 2018-2023



TH-OR06

Quality Improvement Project Addressing Involuntary Discharged Hemodialysis Patients in an Urban, Predominantly Black US Population

Siddartha Bhandary, Zikora U. Nnadike, Anjuli Shah, Carol A. Gray, Jared A. Darrow, Jose E. Navarrete, Jason Cobb. *Emory University, Atlanta, GA.*

Background: Insurable, involuntarily discharged hemodialysis (HD) patients receiving maintenance HD in the hospital are a growing, vulnerable population. We present a quality improvement (QI) project examining second chance placement of involuntary discharged HD patients receiving maintenance HD through inpatient care in our urban predominantly Black population

Methods: QI project at Emory Hospitals and Grady Memorial Hospital. We included all patients involuntarily discharged from a HD center, and those who started HD as inpatient and were seen for inpatient dialysis >60 days, from 1/2020 – 9/2023. Clinical information followed until 3/2024

Results: We included 30 ESKD patients. 21 (70%) male Mean age 49.8 years.100% (n=30) identified as Black, and 77% (n=23) with Medicaid insurance. Most common reasons for discharge: noncompliance (n=17) & disruptive behavior (n=9). 11 (37%) patients had documented substance abuse, and 12 (40%) documented psychiatric disorders. 6 patients with HIV and 6 were homeless. 16 patients received second chance HD placement prior to QI project and 9 patients received second chance HD placement as our QI intervention (5/2023 – 9/2023). 6 of the 9 second-chance placement patients had reduced admissions. 1 patient was an outlier with 43% of HD admissions. The remaining patients had 52 admissions for HD prior, and only 5 admissions after with a 90% reduction. Average outpatient HD billing is approximately $280 to 335 per treatment and inpatient cost for HD only admissions is approximately $1300

Conclusions: This QI project brings attention to a vulnerable nephrology patient population. The subjective analyses used to adjudicate the 'lack of adherence' and 'disruptive behaviors' may be vulnerable to cultural bias and lead to discrimination against these patients. This QI project demonstrated 9 patients were successfully placed with a dramatic decrease in HD associated admissions. Considering that outpatient dialysis billing averages about 25% of the cost of inpatient dialysis admissions, this in turn adds to the significant financial costs. Further investigations of insurable HD patients receiving maintenance HD in the hospital settings are warranted to determine the prevalence, financial burden and possible interventions to improve outcomes

TH-OR07

Racial and Gender Disparities among Nephrology Fellowship Trainees: Trends over a Decade and the Impact of COVID-19

Ohm S. Tripathi. *University of Connecticut, Storrs, CT.*

Background: This study examines trends in racial and gender diversity among nephrology fellowship trainees from 2014 to 2023, evaluating representation and assessing the influence of the COVID-19 pandemic on the demographic composition of trainees.

Methods: Data from the Accreditation Council for Graduate Medical Education (ACGME) were analyzed to identify nephrology fellows during the study period, categorized by self-reported race and gender. The pre-COVID era was defined as 2017-2020, and the post-COVID era as 2020-2023. Chi-square tests assessed differences between groups and longitudinal trends.

Results: Female fellows (36.7%) were significantly underrepresented compared to males (62.9%) ($p<0.05$). Female representation remained relatively stagnant, ranging from 39.0% in 2014-2015 to 38.5% in 2022-2023, with a slight increase post-COVID (38.0%) versus pre-COVID (35.5%) ($p=0.050$). Black individuals (24.7%) were underrepresented compared to Whites and Asians ($p<0.05$). The percentage of Black fellows declined from 23.5% in 2014-2015 to 11.0% in 2022-2023, while Hispanics increased from 6.4% to 10.3%. Black fellow representation decreased significantly post-COVID (10.2%) compared to pre-COVID (23.7%) ($p<0.05$).

Conclusions: Significant gender and racial disparities persist in ACGME-accredited nephrology fellowships. While a modest increase in female fellows post-COVID is encouraging, representation remains stagnant overall. Concerningly, Black fellow representation has declined substantially, despite the disproportionate burden of kidney disease in this population. Urgent action is needed to enhance diversity and address systemic barriers for racial minorities and women in nephrology training.

TH-OR08

Improving CKD Clinical Trial Representation with Educational Videos and Generative Artificial Intelligence

Kevin Timms. *Tea Leaf Health, San Francisco, CA.*

Background: The prevalence of Chronic Kidney Disease (CKD) among underserved communities means representative study cohorts are a requirement for scientifically robust and equitable CKD clinical trials. However, despite the importance of representative cohorts and increased attention on the problem, CKD trials remain largely unrepresentative. This is largely due to the many barriers to trial enrollment faced largely by Hispanic and African-American CKD communities – things like logistics (eg, dialysis centers being more accessible than trial sites to many urban minorities), distrust of the healthcare system, and research unawareness. Efforts like peer-based recruitment & research literacy education have been promising in an effort to address those barriers and increase representative trials.

Methods: Here, we present a proof-of-concept showing how Generative AI (GenAI) can be used to address barriers to enrollment faced by diverse communities. Specifically, we show how a set of GenAI models produces 120-second videos with CKD clinical trials information, where the videos are tailored to be accessible, inclusive, and ultimately more meaningful to different local demographic CKD patients. In this research, we show a case study in which our GenAI algorithms were trained and tuned to specifically create educational videos for a ESRD study whose protocol and Informed Consent Form were downloaded from clinicaltrials.gov. Model training and tuning was based on open source GenAI models, academic research literature, public & nonpublic structured data, and subject matter expertise from Clinical Research Coordinators, IRB reviewers, and sensitivity readers.

Results: As a case study, we generated three semi-personalized videos educating about a study of Empagliflozin in ESRD patients; in each video, the GenAI adapts tone, language, visual style, and content emphasis for a unique ESRD patient profile – a 65 year old African-American female in rural Alabama, a 35 year old African-American male in Chicago, and a 25 year old Hispanic male in suburban Tampa, Florida.

Conclusions: We highlight how the GenAI's recommendations – like defining what clinical research is and why it is important for the elderly patient profile vs. describing onsite childcare options for the younger Hispanic profile – helps address underserved communities' barriers to trial enrollment more effectively.

TH-OR09

Diversity, Equity, and Inclusion in Nephrology: Assessing Artificial Intelligence's Impact on Decision-Making and Advocating for Ethical Regulation

Suryanarayanan Balakrishnan,[1] Charat Thongprayoon,[2] Jing Miao,[2] Michael A. Mao,[3] Iasmina Craici,[1] Wisit Cheungpasitporn.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Mayo Clinic Health System, Mankato, MN; [3]Mayo Clinic in Florida, Jacksonville, FL.*

Background: "Kidney Care for All" advocates for the crucial role of diversity, equity, and inclusion (EDI) in nephrology. As Artificial Intelligence, especially Large Language Models (LLMs), becomes more prevalent in healthcare, concerns about the regulatory oversight of AI applications have emerged. Without proper regulation, AI outputs could inappropriately sway nephrologists' decisions in patient care and affect inclusivity in nephrology staff recruitment. This study assesses how well the AI models, ChatGPT 3.5 and ChatGPT 4.0, handle the intricate ethical EDI considerations in nephrology-related scenarios.

Methods: In March 2024, we created 80 nephrology-focused simulation cases to evaluate AI decision-making across broad areas, such as treatment of kidney disease, organ donation ethics, transplant evaluations, and staff recruitment. Each case was developed by two nephrologists and reviewed for its medical accuracy and relevance in assessing ethical sensitivity and decision-making capabilities of ChatGPT 3.5 and 4.0.

Results: ChatGPT 3.5 consistently selected treatment choices predicted to yield the best outcomes across all questions, demonstrating a utilitarian approach that incorporates various EDI factors. However, ChatGPT 3.5 did not refuse to make decisions under any circumstances. This approach was misaligned with the fundamental EDI requirement not to base decisions on discriminatory criteria. In contrast, ChatGPT 4.0 did decline to make decisions based on potentially discriminatory criteria in 16.25% of scenarios, stating EDI factors should not affect decisions about treating patients or hiring nephrology staff.

Conclusions: ChatGPT 4.0's refusal to engage in discriminatory decision-making represents an important evolution in AI ethics. However, its occurrence in only 16.25% of scenarios highlights the need for robust AI regulation to ensure appropriate EDI principles application. We also need policies that make sure AI is used responsibly and follows principles of EDI before its application in nephrology, both in clinical settings and in the hiring of staff.

TH-OR10

Complementary Role of Transcriptomic Endotyping and Protein-Based Biomarkers for Risk Stratification in Sepsis-Associated AKI

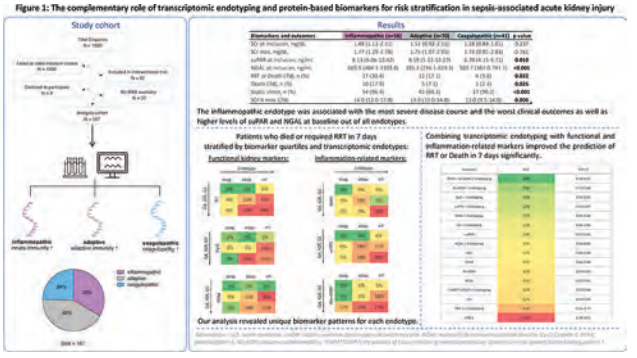
Christian Nusshag,[1] Bengi S. Tavris,[1] Christian Morath,[1] Florian Uhle,[2,4] Timothy Sweeney,[4] Oliver S. Liesenfeld,[4] Mascha O. Fiedler-Kalenka,[2] Thorsten Brenner,[3] Martin G. Zeier,[1] Markus A. Weigand.[2] Nusshag Lab. *[1]Heidelberg University Hospital, Department of Nephrology, Heidelberg, Germany; [2]University Hospital Heidelberg, Department of Anesthesiology, Heidelberg, Germany; [3]University Hospital Essen, Department of Anesthesiology, Essen, Germany; [4]Inflammatix Inc, Burlingame, CA.*

Background: Sepsis-associated acute kidney injury (SA-AKI) is the most common form of AKI in critically ill patients. Heterogeneous immune responses in sepsis contribute to the failure of uniform treatment strategies. Transcriptomic endotyping (TE) may identify septic patients with common pathophysiological drivers, enhancing risk stratification and outcome prediction. This study evaluated TE's clinical value in predicting kidney-related outcomes and its complementary role with protein-based biomarkers.

Methods: ICU patients meeting Sepsis-3 criteria were assigned to inflammopathic (IE), adaptive (AE), or coagulopathic endotype (CE) using a gene expression-based classifier. Baseline measurements included SCr, CysC, PENK, NGAL, KIM-1, suPAR, and BioADM in blood, and TIMP2*IGFBP7 in urine. Clinical outcomes were tracked for 30 days.

Results: From 167 sepsis patients, 33% were classified as IE, 42% as AE, and 24% as CE. IE was associated with the worst outcomes, including higher seven-day mortality, need for renal replacement therapy (RRT), sepsis scores, and septic shock incidence (Figure 1). Baseline NGAL and suPAR, both related to immune activation and inflammation, were highest in IE. SCr and CysC for AE; NGAL, suPAR, and TIMP2*IGFBP7 for IE; and BioADM for CE best stratified RRT or death within seven days of sepsis diagnosis. Combining TE with functional and inflammation-related markers significantly improved outcome prediction. The combination of PENK, BioADM, and TE best predicted RRT or death within seven days with an AUC of 0.84.

Conclusions: TE enhances risk stratification and predictive enrichment in sepsis patients, improving the clinical validity of protein-based biomarkers for specific endotypes. This supports a more individualized approach to managing SA-AKI, with distinct biomarker patterns reflecting different pathophysiological mechanisms.



TH-OR11

Molecular Phenotyping of Patients with Sepsis and Kidney Injury and Differential Response to Fluid Therapy: Secondary Analysis of a Clinical Trial

Elizabeth Kiernan, Leila R. Zelnick, Bryan R. Kestenbaum, Jonathan Himmelfarb, Pavan K. Bhatraju. On behalf of CLOVERS Investigators. *University of Washington, Seattle, WA.*

Background: We previously identified AKI sub-phenotypes (SP1 and SP2) characterized by differences in inflammation and endothelial dysfunction. Here we identify these sub-phenotypes in the emergency department and test for differences in treatment response to a restrictive versus liberal fluid strategy in patients with sepsis-induced hypotension in the Crystalloid Liberal or Vasopressors Early in Sepsis (CLOVERS) trial. The original CLOVERS study demonstrated no differences in clinical outcomes between treatment arms or in sub-groups with AKI or ESKD on enrollment.

Methods: We applied latent class analysis methodology to 23 study enrollment variables and applied a previously developed 3-variable model using plasma angiopietin-1 and 2, and soluble tumor necrosis factor receptor-1 to classify sub-phenotypes in patients with kidney dysfunction (AKI or end-stage kidney disease [ESKD]).

Results: Among 1289 CLOVERS patients with available plasma, 771 had AKI and 75 had ESKD on enrollment. Latent class analysis identified a two sub-phenotype model as the optimal fit for the data with high correlation to two sub-phenotypes identified with the 3-biomarker model (Cohen's Kappa 0.8). The model identified 605 as SP1 and 241 as SP2. The risk of 28 and 90-day mortality was greater in SP2 relative to SP1 independent of AKI stage and sequential organ failure assessment scores. Patients with SP2, characterized by more severe endothelial injury and inflammation, had a reduction in 28-day mortality with a restrictive fluid strategy versus a liberal fluid strategy (26% vs 41%), while patients with SP1 had no difference in 28-day mortality (10% vs 11%) (*p-value-for-interaction* = 0.03).

Conclusions: Clinically distinct sub-phenotypes can be identified in biospecimens collected in the emergency department and respond differently to fluid strategy in sepsis. This could inform a precision-guided therapeutic approach for patients with sepsis-induced hypotension and kidney injury.

AKI in the Kidney Precision Medicine Project: Acute Tubular Injury vs. Acute Interstitial Nephritis

Jennifer A. Schaub,[1] Angela M. Victoria Castro,[4] Steven Menez,[2] Yumeng Wen,[2] Rajasree Menon,[1] Pavan K. Bhatraju,[3] Francis P. Wilson,[4] Steven G. Coca,[5] Michael T. Eadon,[6] Andrew S. Bomback,[7] Dennis G. Moledina,[4] Lloyd G. Cantley,[4] Paul M. Palevsky,[8] Vivette D. D'Agati,[7] Parmjeet S. Randhawa,[8] Raghavan Murugan,[8] Charles E. Alpers,[3] Matthias Kretzler,[1] Jonathan Himmelfarb,[3,5] Chirag R. Parikh.[2] Kidney Precision Medicine Project (KPMP). *[1]University of Michigan Michigan Medicine, Ann Arbor, MI; [2]Johns Hopkins Medicine, Baltimore, MD; [3]University of Washington, Seattle, WA; [4]Yale University, New Haven, CT; [5]Icahn School of Medicine at Mount Sinai, New York, NY; [6]Indiana University, Bloomington, IN; [7]Columbia University, New York, NY; [8]University of Pittsburgh, Pittsburgh, PA.*

Background: Kidney biopsies are rarely obtained in patients with acute kidney injury (AKI) when the suspected diagnosis is acute tubular injury (ATI).

Methods: The Kidney Precision Medicine Project obtained non-clinically indicated kidney biopsies and independently adjudicated diagnosis based on the clinical history and pathology features. We evaluated the patient's clinical and pathologic features to correlate with adjudicated diagnosis.

Results: Of the 47 participants, the average age was 49 (+/-15) years; 72% were male and 40% were black. Clinical characteristics included hypertension (40%), diabetes (31%), and baseline eGFR was 58 (+/- 5) ml/min/1.73m2. On adjudication, 24 patients (51%) had a primary diagnosis of ATI, 12 (26%) patients had a diagnosis of acute interstitial nephritis (AIN), 6 had diabetic kidney disease and consensus could not be obtained for 5 patients for the primary diagnosis. A total of 30 biopsies were scored for histological descriptor features, and there was a significant increase in the number of interstitial WBCs (p=0.01), tubulitis (p=0.01), and lymphocytic tubulitis (p<0.01) in AIN compared to ATI, but the remaining 27 features were not different. We subsequently evaluated the clinician's pre-biopsy suspected diagnosis with the adjudicated diagnosis. Of the 24 ATI cases, ATI was suspected in 21 of them (88%); of the 12 AIN cases, ATI was suspected pre-biopsy in 8 (67%) (**Figure**).

Conclusions: In conclusion, kidney biopsy in the AKI setting is helpful as AIN is clinically under recognized.

AKI in Care Transitions (ACT): A Randomized Controlled Feasibility Trial

Caroline B. Ledet,[1] Heather P. May,[1] Kristin C. Cole,[1] Joan M. Griffin,[1] Joseph Herges,[1] Kianoush Kashani,[1] Andrea G. Kattah,[1] Rozalina G. Mccoy,[2] Angeliki G. Tinaglia,[1] Andrew D. Rule,[1] Erin F. Barreto.[1] ACT Study. *[1]Mayo Clinic Minnesota, Rochester, MN; [2]University System of Maryland, Baltimore, MD.*

Background: Acute kidney injury (AKI) survivors are at risk for not receiving needed follow-up medical care after discharge. This study assessed the feasibility and preliminary efficacy of a multidisciplinary AKI survivor care delivery model (AKI in Care Transitions - ACT).

Methods: This was a single-center randomized controlled trial of individuals with stage 3 AKI during a hospitalization discharged to home and not on dialysis. Patients were randomized 1:1 to the ACT intervention or usual care. The ACT intervention group received education from nurses and coordination of laboratory and clinical follow-up with a primary care provider and a pharmacist ideally within 14-days after hospital discharge. The primary objective was to determine feasibility of the ACT trial from the proportion of patients screened, who consented, randomized, and actually participated in the trial. Secondarily, efficacy outcomes were explored.

Results: Over 18 months, 118 individuals were eligible and 50 (42% of those approached) consented and were randomized. Participants were similar to nonparticipants. The ACT intervention group received education and care coordination as intended in 22 (88%) cases. More ACT intervention patients had complete clinical and laboratory follow-up in 30-days (ACT 60% vs Usual Care 24%; P = 0.01), and fewer experienced a >30% decline in estimated glomerular filtration rate at 90-days (ACT 14% vs Usual Care 38%; P = 0.088), although this difference was not statistically significant.

Conclusions: The results demonstrated the feasibility of the ACT trial and justify an adequately powered trial of the efficacy of ACT in non-dialysis dependent AKI survivors.

Clinical Predictors of Fluid-Responsive AKI

Cindy Khanh Nguyen, Abinet M. Aklilu, Yu Yamamoto, Claudia Coronel-Moreno, Bashar A. Kadhim, Francis P. Wilson. Clinical and Translational Research Accelerator. *Yale University School of Medicine, New Haven, CT.*

Background: It is challenging to predict in clinical practice whether an episode of AKI may be reversible with volume expansion. No simple tool exists to aid in this decision-making process.

Methods: We prospectively enrolled patients at Yale-New Haven Hospital with AKI, as defined by the Kidney Disease: Improving Global Outcomes creatinine criteria. We collected fluid administration data and standardized all volumes based on sodium concentration. The exposure was receiving at least 2L of normal saline (NS) equivalent in the 24h post-AKI. The outcome of interest was fluid-responsiveness–a plateau or decrease in serum creatinine within the 48h period beginning 24h post-AKI. We excluded patients meeting criteria for acute heart failure exacerbation and those who received ≥1L of NS equivalent in the 24h pre-AKI. We used inverse-probability weighting to estimate the interaction effects of receiving volume with 60 variables of interest collected in the 24h pre- or at the time of AKI on the outcome.

Results: Of 3206 patients with AKI, 2313 met inclusion criteria, and 143 received the exposure. The interaction effects of select clinical variables are shown in Figure 1. Significant positive predictors of fluid-responsiveness in AKI patients receiving volume included higher temperature, higher urine chloride, and serum calcium >10.5 mg/dL. Significant negative predictors included higher respiratory rate, higher urine protein-creatinine ratio, higher modified Sequential Organ Failure Assessment (mSOFA) score, lactate dehydrogenase >280 U/L, and having serum uric acid checked. AKI in which a nephrologist suspected pre-renal etiology (excluding cardiorenal and hepatorenal syndromes) trended toward higher odds of fluid-responsiveness.

Conclusions: Common clinical variables may be helpful in identifying who will benefit from volume challenge when the fluid-responsiveness of AKI is unclear.

Ultrasound-Guided Diuretic Therapy in Type 1 Cardiorenal Syndrome: A Randomized, Double-Blind Controlled Trial

Victor H. Gomez Johnson, Erika E. Jaime Borja, Alfredo Fuentes Mercado, Eder J. Amaro Palomo, Romeo Arias Escarpulli, Rodrigo Gopar-Nieto, Salvador L. Gil. NEEDED-Trial. *Instituto Nacional de Cardiologia Ignacio Chavez, Mexico City, Mexico*.

Background: Traditional diuretic titration in cardiorenal syndrome (CRS) relies on physical exams. New tools like VExUS show potential, but evidence is limited. This study compares VExUS-guided decongestion to physical exams in improving outcomes.

Methods: In this double-blind, randomized, controlled trial, 34 CRS patients undergoing decongestive therapy were enrolled. Clinical Congestion Score (CCS) group with a single observer assessed orthopnea, jugular venous distension, and edema on a scale of 0-3. VExUS group had a different observer evaluating inferior vena cava diameter, hepatic vein, portal vein, and intra-renal venous doppler. Both assessments continued until decongestion (CCS<3;VExUS 0-1) or 7 days.

Results: Baseline characteristics were similar, including sick patients (SCr 2.1mg/dL, LVEF 27%, NT-proBNP 19336pg/mL). VExUS-guided treatment showed better trends: higher UNa, lower discharge NT-proBNP, fewer readmissions, and lower in-hospital mortality (see table 1). 30-day mortality was lower in the VExUS-guided group (p=0.05).

Conclusions: VExUS-guided treatment was associated to lower 30-day mortality (p=0.05), increased UNa, decreased NT-proBNP at discharge, fewer readmissions, and reduced in-hospital mortality. As the trial continues, a larger population is anticipated to provide more definitive results. Further studies should assess the relevance and impact on these patients.

Table 1. Outcomes

Variables	Total n=34	Control group n=12	VExUS group n=22	p
Heart failure readmission n(%)	7(21.9)	4(33.3)	3(15)	0.37
NT-proBNP at discharge (pg/mL) Median (IQR)	9333(4064-29058)	15658(3492-34813)	7997(4500-26380)	0.19
In-hospital mortality n(%)	4(12.1)	3(25)	1(4.8)	0.12
Urinary sodium (mmol/L) Median (IQR)	86.2(65-112.6)	85.4(63.5-100.4)	91.5(69-117)	0.36
30-day mortality n(%)	2(6.2)	2(16.7)	0	0.05

Trajectories of Fluid Management after Initiation of Kidney Replacement Therapy in Critically Ill Patients: Insights from the STARRT-AKI Trial

William Beaubien-Souligny,[1] Ehsan Ghamarian,[3] Sean M. Bagshaw,[2] Kevin Thorpe,[3] Ron Wald.[4] *[1]Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [2]University of Alberta, Edmonton, AB, Canada; [3]Applied Health Research Centre, Toronto, ON, Canada; [4]St. Michael's hospital, Toronto, ON, Canada*.

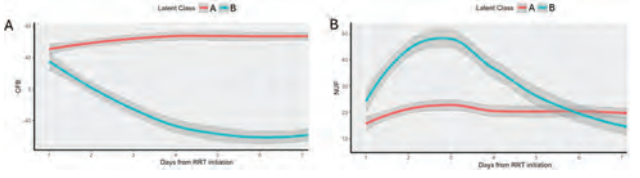
Background: Fluid management is an essential component of renal replacement therapy (RRT) in critically ill patients. Both a positive cumulative fluid balance (CFB) and high net ultrafiltration (NUF) have been associated with adverse outcomes but fluid management trajectories remain incompletely described by previous efforts. We aimed to analyze the CFB/NUF as a trajectory over the first week after the initiation of RRT.

Methods: This is a secondary analysis using fluid balance data from individuals enrolled in the standard-strategy arm of the STARRT-AKI trial who initiated RRT. Cumulative fluid balance (CFB) since RRT initiation and daily net ultrafiltration (NUF)

adjusted for body weight during the first 7 days after initiation of RRT were the main variables studied. We employed multivariable joint longitudinal models to determine the association with 90-day mortality. We then modeled the trajectory of fluid parameters using spline functions and used latent class analysis methods to identify predominant trajectories to compare patients' characteristics and outcomes.

Results: We included 855 patients in the analysis. After adjustments, an association between CFB and 90-day mortality was found (HR: 1.075 (1.04; 1.11) p<0.001) but no association with net daily NUF (HR: 0.95 (CI: 0.64; 1.39) p=0.78). Using latent class analysis, we identified two distinct CFB/NUF trajectories. Class A was characterized by a slight increase in CFB and low/stable NUF after RRT initiation while class B was characterized by an increasingly negative CFB with initially higher daily NUF during the first 4 days followed by a stabilization after day 4. In adjusted analysis, individuals classified in class A were at higher risk for 90-day mortality (aOR: 2.22 CI: 1.52; 3.28) p<0.001) compared to class B.

Conclusions: Beyond cumulative fluid balance and daily NUF rate, the overarching CFB/NUF trajectory should be considered when attempting to elucidate the safety of fluid balance management strategies.



Predominant trajectories of A) cumulative fluid balance (CFB) in mL/kg and B) daily ultrafiltration rate (UF) in mL/kg/d.

Multidisciplinary Inter-rater Reliability of Muscle Ultrasonography in Patients with AKI Requiring Continuous Kidney Replacement Therapy

J. Pedro Teixeira,[1] Felipe Gonzalez-Seguel,[2,3] Vinh Tran,[1] Chaitanya A. Pal,[1,4] Zan Shareef,[1] Hayley Israel,[1] Arimitsu Horikawa-Strakovsky,[3,5] Yuan Wen,[5,6] Benjamin R. Griffin,[7] Javier A. Neyra,[8] Kirby Mayer.[2,3] *[1]University of New Mexico School of Medicine, Albuquerque, NM; [2]University of Kentucky College of Health Sciences, Lexington, KY; [3]University of Kentucky Center for Muscle Biology, Lexington, KY; [4]Memorial Sloan Kettering Cancer Center Department of Anesthesiology and Critical Care Medicine, New York, NY; [5]University of Kentucky Institute for Biomedical Informatics, Lexington, KY; [6]University of Kentucky College of Medicine, Lexington, KY; [7]University of Iowa Hospitals and Clinics, Iowa City, IA; [8]The University of Alabama at Birmingham Department of Medicine, Birmingham, AL.*

Background: Early diagnosis of muscle wasting in critically ill patients with acute kidney injury requiring continuous kidney replacement therapy (AKI-CKRT) may improve outcomes via timely rehabilitation and nutrition. Musculoskeletal ultrasound (MSK-US) has gained traction for assessing muscle atrophy in the intensive care unit (ICU) but requires training to achieve reproducibility. We evaluated the inter-rater reliability (IRR) of MSK-US in patients with AKI-CKRT carried out by a multidisciplinary group of providers including nephrologists.

Methods: Two blinded and independent raters used portable US devices to acquire images of rectus femoris (RF) at baseline (within 48h of CKRT initiation), day 3, day 7, ICU discharge, hospital discharge, and 1–3 months after discharge. All raters were clinicians or trainees routinely caring for patients with AKI-CKRT in the ICU and were initially novices in MSK-US. They underwent three 2-h teleconference training sessions in MSK-US led by an experienced physiotherapist. IRR was evaluated with intraclass correlation coefficient (ICC) [95% confidence interval] using a 2-way random-effects model.

Results: Raters acquired 54 (27 per rater) US images from 9 subjects at baseline (n=16), day 3 (n=6), day 7 (n=8), ICU discharge (n=10), hospital discharge (n=10), and 1–3 months after discharge (n=4). The mean (± standard deviation) values of RF thickness, cross-sectional area (CSA), and echointensity (EI) were 1.7 ±1.4 cm, 4.6 ±2.7 cm^2, and 84.0 ± 17.7 AU, respectively. IRR was excellent for muscle thickness (ICC = 0.96 [0.91–0.98], p<0.001) and CSA (ICC = 0.92 [0.83–0.96], p<0.001) and moderate for EI (ICC = 0.41 [0.04–0.68], p<0.05). The absolute agreement between raters is shown by Bland-Altman plots (**Fig 1**).

Conclusions: Our results demonstrate reliable assessment of muscle quality and especially size in ICU patients with AKI-CKRT using US performed by multidisciplinary clinicians and trainees including nephrologists. This study suggests MSK-US may be a useful tool to diagose critical illness myopathy in the AKI-CKRT population.

Prognostication of 90-Day Kidney Function Recovery in Patients with AKI Receiving Outpatient Dialysis

Seda Babroudi,[1] Carolien C. Maas,[3] Daniel E. Weiner,[1] Javier A. Neyra,[2] David M. Kent,[5,1] Ronald Sanders,[4] Harold Manley,[4] Eduardo K. Lacson,[4,1] David A. Drew.[1] *[1]Tufts Medical Center, Boston, MA; [2]UAB Hospital, Birmingham, AL; [3]Erasmus MC, Rotterdam, Netherlands; [4]Dialysis Clinic Inc, Nashville, TN; [5]Tufts Medical Center Predictive Analytics and Comparative Effectiveness (PACE) Center, Boston, MA.*

Background: Prognostic uncertainty regarding kidney function recovery for patients with AKI-D may result in suboptimal dialysis care. We developed and internally validated a prognostic model for 90-day kidney function recovery to dialysis independence in patients with AKI-D.

Methods: Candidate predictors included demographic, clinical, laboratory, and dialysis characteristics readily available as part of usual care, ascertained in the first week of outpatient dialysis from a national dialysis provider. We derived a parsimonious model by applying backward selection guided by the Bayesian Information Criterion to a multivariable Cox proportional hazards model. Model calibration and discrimination were assessed. Internal-external cross-validation was performed using three geographic regions.

Results: Of 2,544 individuals with AKI-D, 771 patients recovered kidney function within 90-days of outpatient dialysis initiation (cumulative incidence 33.8%, 95% CI 31.8-35.7). Thirteen predictor variables were retained in the final model. Internal-external cross-validation suggested good external calibration and discrimination (Uno's C-index 0.70 (95% CI 0.67-0.73) Figure 1).

Conclusions: We developed a prediction model to prognosticate 90-day kidney function recovery among patients with AKI-D within the first week of outpatient dialysis initiation. The model demonstrated good performance, supporting its use to inform shared decision-making between dialysis clinicians and patients.

Multicenter Development and Validation of a Multimodal Deep Learning Model to Predict Severe AKI

Jay L. Koyner,[1] Jennifer Martin,[2] Kyle Carey,[1] John Caskey,[2] Dmtriy Dligach,[2] Majid Afshar,[2] Matthew M. Churpek.[2] *[1]University of Chicago Division of the Biological Sciences, Chicago, IL; [2]University of Wisconsin-Madison, Madison, WI.*

Background: Electronic health record(EHR) -based risk algorithms for acute kidney injury(AKI) have been reported but these have focused on structured data(e.g. vital signs & laboratory values). We aimed to develop & validate a deep learning time series model to predict AKI by combining structured data & unstructured data from clinical notes

Methods: Patients(≥18 years) admitted to the University of Wisconsin (2009-20) & the University of Chicago Medicine (2016-22) were included. Patients were excluded if they had no documented serum creatinine (SCr), an admission SCr≥3.0mg/dL, developed Stage 2 AKI before reaching the wards or intensive care unit (ICU), or if they required dialysis(RRT) within the first 48 hrs. AKI was defined by the KDIGO SCr definition. Fifty-eight structured features were used in the model, and the raw text from unstructured clinical notes were mapped to standardized Concept Unique Identifiers (CUIs) to create unstructured data features. An intermediate fusion deep learning recurrent neural network architecture was used to predict Stage ≥2 AKI within the next 48 hrs. The model was developed in the first 80% of the data by date & temporally validated in the next 20%.

Results: There were 339,998 subjects in the derivation cohort & 84,581 in the validation cohort with 12,748(3%) across both cohorts, developing Stage 2 AKI. Those with Stage 2 AKI were more likely to be older, male, have higher baseline SCr, and more likely to be in the ICU. CUIs related to intubation, ventilation, and airway management were more common in those with AKI. AUCs overall and across important subgroups were above 0.85 for most outcomes.

Conclusions: We developed and validated a novel deep-learning risk assessment tool using structured & unstructured data from the EHR in real time to predict the development of Stage 2 AKI across the entire hospital. A real-time version of this model has now been implemented at both health systems.

Funding: NIDDK Support

AUC for AKI Outcomes in the Next 48 hours

All Values AUC(95%CI)	At Least Stage 2 AKI	Receipt of RRT
All Encounters	0.87 (0.87-0.87)	0.90 (0.90-0.90)
Ward Patients	0.86 (0.86-0.86)	0.88 (0.87-0.88)
ICU Patients	0.83 (0.83-0.83)	0.84 (0.84-0.84
Baseline Creatinine < 1.0 mg/dL	0.86 (0.86-0.87)	0.89 (0.89-0.90)
Baseline Creatinine 1.0-1.99 mg/dL	0.88 (0.88-0.88)	0.90 (0.90-0.90)
Baseline Creatinine >2.0 mg/dL	0.88 (0.88-0.88)	0.87 (0.87-0.87)

Network Analysis of Paired Plasma-Urine Metabolomes Reveals Genetic Determinants of Metabolite Clusters

Pascal Schlosser,[1,2] Maren Hackenberg,[1] Sara Monteiro-Martins,[1] Stefan Haug,[1] Anna Kottgen.[1,2] *[1]Universitatsklinikum Freiburg, Freiburg, Germany; [2]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.*

Background: Metabolites are often part of biochemical pathways, regularly in complex relations that may be influenced by genetic variants in the involved enzymes. Many of the metabolic reactions driving the biological network are non-linear (e.g. cyclic). Motivated by the success of deep learning-based approaches to detect complex patterns, we investigated whether such models can provide representations of metabolomics that capture their complex, non-linear relations and provide a link to the underlying genetics.

Methods: We present an integrated analysis of data from both plasma (1,096 metabolites) and urine (1,139 metabolites) via an unsupervised method for clustering and local dimension reduction in 4,850 individuals from the GCKD study, a prospective cohort of adults diagnosed with CKD. First, we group the metabolites into modules using a sparse hierarchical clustering approach. On each module, we fit a principal component (PC) analysis and train a variational autoencoder (VAE), a type of neural network, to infer low-dimensional representations of the central factors of variation underlying the data. We then search for genetic associations of these module representations by performing genome-wide association study (GWAS).

Results: We identified 165 modules of correlated metabolites. GWAS identified significant associations (p-values<5e-8/165) with81 VAE- and 150 PC-informed representations of these clusters. An association at *NAT8* showed 575 magnitudes lower p-values when investigating metabolite modules (p-value=2.1e-2217) compared to analyses of its individual metabolites. The strongest association was observed for *PYROXD2* (module p-value=1.4e-3275). This module integrated the plasma and urine levels of six methyllysine-related metabolites, and displayed independent associations with genetic variants in *PYROXD2*, *NAT8*, their interaction, eGFR and UACR in multivariate models. This suggests interactions between these two enzymes and a core role of plasma N6-methyllysine in these associations.

Conclusions: Our results show that VAE- and PC-based representations of metabolic pathways can facilitate the detection of genetic associations beyond those identified by single-metabolite GWAS, indicating existing linear and non-linear genetic regulation on a pathway level.

Hb Co-Pilot: Machine Learning Algorithm for Real-Time Hemoglobin Estimation during Hemodialysis and a Multicenter International Validation Trial

Chin-Chi Kuo,[1,2] Sheng-Hsuan Chen,[1] Hsiu-Yin Chiang,[1] Chuan-Hu Sun,[1] Mei-Chuan Hsieh,[1] Che-yi Chou,[3,2] Stephen G. Holt.[4] *[1]Big Data Center, China Medical University Hospital, Taichung, Taiwan; [2]China Medical University Hospital Department of Internal Medicine, Taichung, Taiwan; [3]Asia University Hospital, Taichung, Taiwan; [4]SEHA Kidney Care, Abu Dhabi, United Arab Emirates.*

Background: Anemia is linked to premature death among patients receiving hemodialysis (HD). We developed and validated a timely, non-invasive, and simple smartphone APP (Hb Co-Pilot) that captures images of HD dialysis tube and predicts hemoglobin (Hb) level using a machine-learning model.

Methods: **Training & Testing Set** We enrolled adult HD patients with arteriovenous fistula (AVF) or graft at China Medical University Healthcare System (CMUHS). HD tubing photos on Fresenius 4008(s) machine were taken with a color correction matrix (CCM) on the day of blood testing. A total of 5,453 images were taken by 13 smartphones from 5 HD centers. **Feature Extraction & Modeling** Images were pre-processed to ensure similar lighting conditions. We cropped the areas of HD tube and CCM and extracted the 192-dimension vector of image features from both areas by encoding the color information in histograms using a bin size of 64 on each RGB channel. An XGBoost model was used to predict Hb >10 g/dL using image features, age, gender, and last Hb level, with a testing accuracy of 0.93. **Validation Trial** CMUHS, Asia University Hospital (AUH) in Taiwan, and SEHA Kidney Care (SKC) in Abu Dhabi participated in our validation trial, with a total of 504 images collected. The targeted area under the receiver operating curve (AUROC) was set to 0.80.

Results: In the validation study, the median age was 62 years, 67% were male, 40% from SKC, 85% had AVF, 26% had Hb ≤10 g/dL, and 40% were taken from Fresenius 5008. The mean of difference between predicted and true Hb was 0.83 g/dL. The AUROC and accuracy was both 0.81, and the sensitivity and positive predictive value both reached 0.87. The F1 and Kappa was 0.87 and 0.50, respectively.

Conclusions: Hb Co-Pilot had robust external validity in Taiwanese and Emirati across different dialysis machines. Model improvement will focus on capturing extreme Hb levels and evaluating its clinical effectiveness.

Funding: Government Support - Non-U.S.

Artificial Intelligence-Enabled Electrocardiography for Predicting Dyskalemia Using Home-Based Electrocardiography Devices

Shih-Hua P. Lin, Chih-Chien Sung, Ang Lu, Chien-Chou Chen, Chin Lin. *Tri-Service General Hospital, Taipei, Taiwan.*

Background: Dyskalemia is the common electrolytes abnormality associated with an increased morbidity and mortality. We have developed a bloodless artificial Intelligence-enabled electrocardiogram (AI-ECG) system capable of predicting hyperkalemia and hypokalemia using Philips ECG devices and providing quantitative serum potassium (K^+) detection and monitoring. This study aims to validate the application of a newly-developed home-based ECG device for dyskalemia detection.

Methods: Home-based ECG device is a portable 12-lead ECG machine developed by QT Medical (PCA500). We conducted a preliminary study with 107 hospitalized patients for various causes including acute kidney injury and advanced CKD on hemodialysis at a single academic medical center, resulting in 1033 ECG recordings. Among them, eighty-eight

ECGs had the corresponding serum K^+ concentration measured within the previous three hours. The dataset included 12 patients with hyperkalemia (Lab-K^+ ≥ 5.5 mmol/L) and 11 hypokalemia (Lab-K^+ ≤ 3.5 mmol/L).

Results: The AI-ECG system demonstrated an AUC of >0.95 for predicting hyperkalemia and an AUC of 0.809 for hypokalemia. The correlation coefficient between ECG-derived K^+ levels (ECG-K^+) and laboratory-measured K^+ levels (Lab-K^+) was 0.796, with a mean absolute error (MAE) of 0.456

Conclusions: Using this home-based ECG device, these results show that AI-ECG predict hyperkalemia better than hypokalemia and may be applied to future remote detection or monitoring of hyperkalemia in high-risk patients. A further validation with larger sample sizes is still required to confirm these findings.

Automated Extraction of Kidney Failure Concepts from Clinical Notes Using Artificial Intelligence

Luke Harris,[1] Samuele Buosi,[2] Sarah Monahan,[1] Finn Krewer,[1,4] Mohan Timilsina,[2] Niamh Corcoran,[1] Nina Deacon,[1] Michael Wrynn,[1] Richard Farnan,[1] Donal N. Reddan,[1] George S. Mellotte,[3] Peter J. Conlon,[5] Conor S. Judge.[1,4]
[1]Galway University Hospitals, Galway, Ireland; [2]Insight Data Analytics, University of Galway, Galway, Ireland; [3]HSE National Renal Office, Dublin, Ireland; [4]HRB Clinical Research Facility, Galway, Ireland; [5]Beaumont Hospital, Dublin, Ireland.

Background: The Kidney Disease Clinical Patient Management System (KDCPMS) contains structured (e.g. date of birth) and unstructured or free-text data fields (clinic notes). Unstructured data is challenging to use for audit, QI and research.

Methods: Bidirectional Encoder Representations from Transformers (BERT) are a transformer-based machine learning architecture useful for Natural Language Processing (NLP). Galway University Hospital data were extracted from KDCPMS, anonymised, pre-processed, annotated as Diabetes-Y/N and IgA Nephropathy-Y/N by physicians using Prodigy annotation software, and NLP model trained using a modified BERT algorithm running in HSE Integrated Information Services. We compared the NLP classification with an algorithmic classification using ICD-10/EDTA codes, medication and HbA1c and a retrospective chart review by physicians (gold standard).

Results: 43314 patient notes were extracted. 10000 notes were annotated by 5 physicians. Classification was performed on 33314 notes. 955 patients were classified as Diabetes-Y, 4190 as Diabetes-N, 269 as IgA Neph-Y and 2609 as IgA Neph-N. 1744 patients were then classified algorithmically as Diabetes-Y and 214 patients were classified algorithmically as IgA Neph-Y. For Diabetes, the NLP method achieved an accuracy of 79.0% (95% CI [77.4%,80.6%]), a sensitivity of 73.3% and specificity of 81.3%. Precision was 61.1%, F1 score 66.7% and macro F1 score 0.757. The algorithmic method outperformed the NLP method with an accuracy of 98.1% (95% CI [97.5%,98.6%]), sensitivity 96.7% and specificity 98.7%. Precision was 96.7%, F1 score 96.7% and macro F1 score 0.977. For IgA Nephropathy, the NLP method demonstrated high accuracy of 96.2% (95% CI [95.1%,97.2%]), with sensitivity 83.3% and specificity 97.8%. Precision was 83.3%, F1 score 83.3% and macro F1 score 0.906. The algorithmic method achieved perfect scores across all metrics, with accuracy, sensitivity, specificity, precision, F1 score, and macro F1 score all at 100.0% (95% CI [99.9%,100%]).

Conclusions: These results highlight the superior performance of the algorithmic method over the NLP method, particularly in terms of accuracy and sensitivity. However the NLP method demonstrated substantial potential, especially for IgA Nephropathy.

Improving Dietary Choices Using a Digital Health Intervention in People with CKD

Courtney J. Lightfoot, Gurneet K. Sohansoha, Ella C. Ford, Noemi Vadaszy, Thomas J. Wilkinson, Alice C. Smith, Matthew Graham-Brown. *University of Leicester, Leicester, United Kingdom.*

Background: We co-developed a digital health intervention (DHI) 'My Kidneys & Me' (MK&M) to support people with non-dialysis CKD to better self-manage health and lifestyle. MK&M includes theory-based educational and action (behaviour change) sessions about a healthy balanced diet, plus trackers for dietary goals. Here we report findings on dietary behaviours from a multicentre randomised control trial of MK&M.

Methods: 420 participants aged ≥18 years with CKD stages 3-4 were recruited from 26 hospitals and randomised 2:1 to intervention (MK&M) (n=280) or control (n=140) groups. The UK Diabetes Diet Questionnaire (UKDDQ) was collected at baseline and 20-weeks via an online survey. The UKDDQ asks respondents how often they consumed certain foods and drinks over the last month. Items are scored on the frequency of consumption and classified into "healthy", "less healthy" and "unhealthy" choices. Access to and usage data of MK&M were collected. Linear regression models, adjusted for baseline values, were conducted.

Results: Of the 280 participants assigned to the intervention group, 225 (80%) used MK&M at least once. Over 20-weeks, the diet educational session was accessed by 107 (48%) participants and viewed 10.5 (±5.4) times for 11.0 (±15.0) minutes; the diet action session was accessed by 77 (35%) participants and viewed 12.1 (±5.7) times for 7.5 (±6.7) minutes. The healthy eating tracker was used by 32 (14%) participants. 30 (13%) participants set healthy eating goals (mean:1.6±1.2). At baseline, 44% MK&M (n=122) and 40% control (n=55) participants had a UKDDQ score in the healthy range (≥4) (mean:3.3±0.4). At 20-weeks, the proportion with a UKDDQ in the healthy range increased by 45% in MK&M group (44-64%, P<0.001) and 28% in control (40-51%, P<0.001). Significant between-group differences were observed for changes in the number of healthy (±0.8, P=0.024) and less healthy dietary choices (±0.5, P=0.027), with MK&M group increasing the number of healthy food choices (+0.7, P=0.005) and decreasing the number of less healthy food choices (-0.6, P=0.009).

Conclusions: The use of MK&M DHI improved dietary food choices. People with CKD are interested in and actively engaged with DHIs to support healthy dietary habits. MK&M can be used to support people with CKD to improve their dietary behaviours.

TH-OR25

Enhancing Nephrology with Artificial Intelligence (AI)-Assisted ICD-10 Coding: Improving Health Care Reimbursement, Patient Care, Research, and Previsit Test Workflow Efficiency through Case Scenarios

Yasir Abdelgadir, Charat Thongprayoon, Jing Miao, Justin Pham, Supawadee Suppadungsuk, Iasmina Craici, Wisit Cheungpasitporn. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Accurate ICD-10 coding is crucial for healthcare reimbursement, patient care, and research. Inaccuracies in coding, can lead to issues with reimbursement, compromised patient care and skewed research findings. These challenges stem from the complexity and time-consuming nature of coding tasks, burdening physicians. AI, such as ChatGPT, has the potential to improve accuracy and reduce workload. A recent study showed that large language models (LLMs) performed poorly on medical code querying tasks. However, the assessment of AI-assisted ICD-10 coding in nephrology through case scenarios for pre-visit testing remains unexplored.

Methods: This study involved 100 simulated cases covering various nephrology conditions. Two nephrologists created these cases to mirror typical nephrology diagnoses in inpatient and outpatient settings, incorporating case scenarios and pre-visit testing data. The performance of ChatGPT versions 3.5 and 4.0 was assessed by comparing AI-generated ICD-10 codes against expected correct codes for each case. Assessments were conducted in two trials, two weeks apart, in April 2024.

Results: ChatGPT 3.5 reached an average accuracy of 89% over two trials, with a slight variation between them (91% in the first trial and 87% in the second). ChatGPT 4.0 showed a consistent and higher accuracy of 99% in both trials. This indicates that 94% of the AI-coded diagnoses correctly matched the expected ICD-10 codes. However, specific challenges were noted with ChatGPT 3.5, particularly with repeated inaccuracies in diagnosing conditions like Obstructive uropathy due to BPH and Acute Emphysematous Pyelonephritis. ChatGPT 4.0 demonstrated a more stable performance, with only one repeated misdiagnosis (Bartter Syndrome) across the trials.

Conclusions: The findings suggest that AI, particularly ChatGPT 4.0, can significantly improve the accuracy of ICD-10 coding in nephrology when provided with case scenarios and pre-visit testing data. This approach can enhance healthcare reimbursement, patient care, research, and pre-visit test nephrology workflow efficiency. However, the small percentage of errors highlights the need for ongoing review and improvement of AI diagnostic systems.

TH-OR26

Using a Smartphone Camera at the Bedside to Detect and Quantify Residual Blood Clots in Single-Use Dialyzers with Paired-Image Classification

Hugo Y. Lin,[1,2] Yi-Ren Yeh.[3] *[1]Kaohsiung Medical University Chung Ho Memorial Hospital, Kaohsiung, Taiwan; [2]Kaohsiung Municipal Ta-Tun Hospital, Kaohsiung, Taiwan; [3]National Kaohsiung Normal University, Kaohsiung, Taiwan.*

Background: Blood clot formation and subsequent blockage of the capillary fibers of dialyzers is challenging for patients with end-stage kidney disease (ESKD) on hemodialysis. This study aimed to develop a machine learning detection model that utilizes the information obtained from dialyzer images to detect blood clots of dialyzers early.

Methods: We gather dialyzer images captured at the bedside using mobile devices daily. Initially, we segment the image to extract the dialyzer part and filter out background noise unrelated to the residual blood clot analysis. Subsequently, we apply data augmentation to enhance robustness. Capturing snapshots at both ends of the dialyzer provides two distinct perspectives merged into a single composite image. Our classification task involves two classes: instances with less than 10% residual blood clots (666 samples) and those with 30% residual blood clots (538 samples). Due to the limited image dataset, we utilize a pre-trained image classification model, EfficientNet, and fine-tune it using our collected data.

Results: In our experiment, we strategically split the dataset into training (60%), validation (20%), and testing (20%) sets. Conducting ten random trials provided insights into the model's stability and consistency. The proposed model achieved an average recognition rate of 76.33%, surpassing human evaluators who scored 62.71% and 60.05% on the testing set. It demonstrates the model's superior performance and potential to enhance recognition capabilities in relevant domains. The results prove the viability of employing image-based approaches for detecting blood clots in dialyzers.

Conclusions: Our proposed framework, including data preprocessing and model training, exhibits potential for applications in various clinical scenarios where recognition relies on information derived from images. This approach involves using image data to amalgamate information from both ends of the dialyzer. By employing the EfficientNet model to detect blood clots, this integrated approach significantly improves blood clot detection in dialyzers compared to human evaluators.

Performance and Global Integration in Clinical Practice of a Fistula Failure Risk-Estimate Tool Based on Artificial Intelligence (AI)

Jasmine Ion Titapiccolo,[1] Milind Nikam,[2] Stefano Stuard,[3] Jeffrey L. Hymes,[4] John W. Larkin,[4] Suman K. Lama,[4] Sheetal Chaudhuri,[4] Francesco Bellocchio,[1] Julianna Yeung,[2] Len A. Usvyat,[4] Luca Neri.[1] *[1]Fresenius Medical Care AG, Vaiano Cremasco, Italy; [2]Fresenius Medical Care AG, Singapore, Singapore; [3]Fresenius Medical Care AG, Bad Homburg, Germany; [4]Fresenius Medical Care AG, Boston, MA.*

Background: Accurate prediction of fistula failure risk (FFR) in hemodialysis patients is critical for timely intervention and improved clinical outcomes. This study evaluates the performance of an AI-based FFR estimate tool in clinical practice. The data, collected over 12 months (February 2023-January 2024), encompass multiple countries, highlighting variations in clinical outcomes.

Methods: Data were collected from hemodialysis centers in seven countries (Australia, Czech Republic, Italy, Portugal, Singapore, Slovakia, Spain), totaling 83,126 records. The AI risk estimation tool is integrated in the clinical system EuCliD® (Fresenius Medical Care) and provides nephrologists with a monthly estimate of FFR over the next 90 days. Predictive accuracy in comparison with actual failure incidence was assess using AUC of ROC curve. Fistula failures include angioplasty (with/without stent), thrombectomy, switch to a new dialysis access, temporarily unusable fistula, and hospitalization due to fistula complication.

Results: The AI tool exhibited a varied performance across countries, with the global AUC being 78.1%. The global failure incidence percentage was 6.2%. Failure percentages for each of the four considered categories are reported in Table 1. Differences in the habit of reporting data in the clinical system can be highlighted from the table. Risk metrics also varied across countries.

Conclusions: The AI-based FFR estimate tool demonstrated robust predictive performance across diverse clinical settings. The depicted variability shows the importance of localized adaptation of AI tools.

Heparin Variants Differ in Their Effect on Fibroblast Growth Factor 23 and Fibroblast Growth Factor Receptor 4 Binding

Madison Thomas, Christopher Yanucil, Qing Li, Kylie Heitman, Abul Fajol, Svetlana Komarova, Christian Faul. *The University of Alabama at Birmingham Heersink School of Medicine, Birmingham, AL.*

Background: Fibroblast growth factor (FGF) 23 is a bone-derived hormone that targets the kidney via FGF receptor (FGFR) isoform 1c and klotho and increases phosphate excretion. In Chronic Kidney Disease (CKD) patients, renal FGF23-responsiveness is impaired, leading to high serum FGF23 levels that clinical studies have shown to be associated with cardiac hypertrophy and cardiovascular mortality. In previous studies we found that elevated FGF23 can directly target cardiac myocytes and activate FGFR4 in a klotho-independent manner, resulting in hypertrophic cell growth. Surprisingly, we also found that unfractionated heparin (UFH) increases the FGF23:FGFR4 binding affinity and when injected into mice with elevated FGF23 levels aggravates cardiac hypertrophy. Heparin exists in different variants with a large range of structures and charges. In this study, we investigate whether heparin variants differ in their ability to modulate FGF23:FGFR4 binding.

Methods: FGF23:FGFR4 binding affinity was analyzed using our plate-based binding assay. 96-well plates were coated with recombinant FGF23 protein and sequentially incubated with heparin variants, Fc-tagged FGFR4, horse radish peroxidase (HRP)-coupled anti-Fc antibody, and HRP substrate. Reactions were analyzed using a plate reader at 450 nm wavelength. All samples were run in triplicates.

Results: FGF23:FGFR4 binding affinity was increased by large UFHs, including dialysis UFH, and by low-molecular heparins. In contrast, smaller heparin variants, like the pentasaccharide fondaparinux sodium, did not increase FGF23:FGFR4 binding. Desulfated heparins only had a minor impact on FGF23:FGFR4 binding.

Conclusions: Our study indicates that the ability of heparin to mediate FGF23:FGFR4 binding depends on its length and negative charges. Small and uncharged heparin variants do not increase FGF23:FGFR4 binding affinity. Next, we will test the effects of heparin variants on FGF23-induced cardiac hypertrophy in cell culture and animal models. Most patients with end-stage kidney disease undergo hemodialysis, during which UFH is commonly administered as an anticoagulant. Since hemodialysis does not lower serum FGF23 levels, we postulate that frequent UFH infusions contribute to cardiac injury and high mortality rates and that replacing UFH with small-chain heparin variants might extend the lifespan of hemodialysis patients.

TH-OR29

Association of the Ratio of Intact-to-C-terminal Fibroblast Growth Factor 23 with Heart Failure with Preserved Ejection Fraction

Cassianne Robinson-Cohen,[1] Farzana Perwad,[2] Joachim H. Ix,[4] Valentin David,[3] Elvis A. Akwo.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]University of California San Francisco, San Francisco, CA; [3]Northwestern University Feinberg School of Medicine, Chicago, IL; [4]University of California San Diego, La Jolla, CA.*

Background: Previous studies report an association between high levels of circulating fibroblast growth factor 23 (FGF23) and the risk of heart failure with preserved ejection fraction (HFpEF) particularly in chronic kideney disease (CKD). One such mechanism for FGF23 elevation is decreased proteolytic cleavage marked by increased circulating intact-to-C-terminal FGF23 ratio (iFGF23:cFGF23). The aim of this study was to investigate the association between the iFGF23:cFGF23 ratio and the risk of HFpEF using a two-sample Mendelian Randomization (MR) approach.

Methods: Genetic instruments were independent significant single nucleotide polymorphisms (SNPs) from a genome-wide association study (GWAS) of iFGF23:cFGF23 ratio in 745 participants in the Cardiovascular Health Study. Summary-level data for HFpEF were from a GWAS conducted among 17,030 participants in Vanderbilt's DNA Biobank (BioVU). The main analysis was conducted using the random-effects inverse variance weighted (IVW) estimator. Sensitivity analyses used the weighted median and MR-Egger methods. Analyses were performed separately in individuals of European and African ancestry and then meta-analyzed.

Results: In the transethnic meta-analysis, genetically predicted higher values of the iFGF23:cFGF23 ratio were associated with greater odds of HFpEF (OR=1.07, 95% CI: 1.02-1.12, p=0.007). The MR estimate was consistent in models adjusted for eGFR (OR=1.06, 95%CI: 1.02-1.12, p=0.02) and across statistical approaches (weighted median and MR-Egger). The p-value for the MR-Egger intercept test was consistently greater than 0.05 across analytic subgroups suggesting no evidence of directional pleiotropy.

Conclusions: This MR suggests that higher values of iFGF23:cFGF23 – a marker of decreased FGF23 cleavage – is associated with greater risk of HFpEF. Additional work into the mechanisms of FGF23 elevation in CKD and its relationship with heart failure is needed.

Funding: NIDDK Support

TH-OR30

Involvement of COMMD5 in Vascular Calcification in CKD

Zewen Zhao, Shuangxin Liu. *Guangdong Provincial People's Hospital, Guangzhou, China.*

Background: Chronic kidney disease (CKD) is a prevalent and recurring health condition affecting a significant number of individuals. Among CKD patients, approximately 2-3% progress to end-stage renal disease (ESRD). Vascular calcification emerges as a prevalent complication in ESRD cases and has a strong correlation with the incidence of cardiovascular events. The disruption of calcium and phosphorus metabolism stands out as a primary factor contributing to vascular calcification. Recently, the hypertension-associated calcium regulatory gene (HCaRG) unveiled a connection with COMM domain-containing 5 (COMMD5). Identified as a gene influenced by extracellular calcium levels, COMMD5 encodes a compact intracellular protein composed of 225 amino acids. Past research suggests that parathyroidectomy (PTX) can reduce vascular calcification, and increased levels of COMMD5 are associated with decreased blood pressure. Nevertheless, the literature lacks substantial reports on the relationship between COMMD5 and vascular calcification. Our hypothesis ventures that COMMD5 could indeed be intricately linked to chronic vascular calcification.

Methods: The blood vessels of the arteriovenous fistula are tested for calcification and COMMD5 expression. Human aortic smooth muscle cells (HASMC) and rat aortas were cultured in vitro and incubated with high phosphorus.

Results: (1)COMMD5 expression is reduced in arteriovenous fistula vascular calcified tissues.(2)In comparison to the control group, the expression of COMMD5 in HASMC exhibited lower levels under high phosphorus stimulation.(3)HASMCs were subjected to stimulation using small interfering RNA (siRNA). This led to an upregulation of Runt-related transcription factor 2 (RUNX2) expression and downregulation of Anti-Smooth Muscle Antibody (α-SMA) expression in the cells.(4)Rat aortas were cultured in vitro and incubated with high phosphorus to stimulate isolated arteries. Upon conducting alizarin red staining, the group incubated with COMMD5 under high phosphorus stimulation displayed reduced levels of calcification in comparison to the high phosphorus group.

Conclusions: COMMD5 plays a crucial role in inhibiting calcification in human aortic smooth muscle cells, consequently contributing to the reduction of vascular calcification.

Spatial Detection and Consequences of Nonkidney Calcitriol Production as Assessed by Targeted Mass Spectrometry Imaging

Mark B. Meyer,[1] Seong Min Lee,[1] Shannon R. Cichanski,[1] Diego F. Cobice,[3] J. W. Pike.[2] *[1]University of Wisconsin-Madison Department of Nutritional Sciences, Madison, WI; [2]University of Wisconsin-Madison Department of Biochemistry, Madison, WI; [3]Ulster University, Coleraine, United Kingdom.*

Background: The benefits of vitamin D supplementation beyond calcium and phosphate maintenance in humans are highly clinically debated. Kidney expression of CYP27B1 is the source of endocrine $1,25(OH)_2D_3$ (active form of vitamin D) that maintains serum calcium and phosphate. $1,25(OH)_2D_3$ may also be made by the CYP27B1 enzyme in non-renal cells, like immune cells, in a process driven by cellular availability of precursor $25(OH)D_3$ and inflammation. Due to the endocrine nature of renally produced $1,25(OH)_2D_3$ in circulation, it is difficult to discern between these two sources.

Methods: We have recently created a regulatory deletion model of *Cyp27b1* (M1/M21-DIKO) where the mice have normal inflammatory-regulated *Cyp27b1* expression in non-renal tissues (unlike global *Cyp27b1*-KO), but no expression within the kidney. Using these unique M1/M21-DIKO mice, we hypothesized that vitamin D supplementation will increase $25(OH)D_3$ circulation and tissue availability, and therefore increase the production of $1,25(OH)_2D_3$ in non-renal tissues. Utilizing on-tissue chemical derivatization (OTCD) and targeted Matrix Assisted Laser Desorption Ionization-Mass Spectrometry Imaging (MALDI-MSI), we investigated the tissue distribution of $1,25(OH)_2D_3$ and $25(OH)D_3$ in the M1/M21-DIKO mice compared to *Cyp27b1*-KO mice and wildtype littermates after PBS perfusion in the kidney, liver, spleen, and thymus.

Results: MALDI-MSI demonstrated that the levels of $25(OH)D_3$ were greatly affected by vitamin D supplementation and increased in all tissues examined. We confirmed that the M1/M21-DIKO mouse, like the *Cyp27b1*-KO mouse, had no kidney production of $1,25(OH)_2D_3$ even in the animals with high levels of supplementation. However, we saw increased production of $1,25(OH)_2D_3$ in tissues outside of the kidney such as the spleen in the M1/M21-DIKO mouse. Gene expression found increased *Il4* and decreased *Tnfa* in the spleen indicating an initiation of an anti-inflammatory program as observed with vitamin D in immune cells *ex vivo*.

Conclusions: Taken together, these data verify, visualize, and quantify, for the first time, non-renal production of $1,25(OH)_2D_3$ *in vivo*, provide a consequence of non-renal $1,25(OH)_2D_3$ production in cytokine changes, and offer a benefit to elevated vitamin D supplementation in potential positive outcomes for inflammatory disease.

Bone Sialoprotein Regulates Phosphate Metabolism and Reduces Hyperparathyroidism in Mice with CKD

Marie-Helene Lafage-Proust,[1,2] Lauriane Hivert,[1] Christophe O. Soulage,[3,4] Laurent Beck,[5,6] Luc Malaval.[1] Sainbiose Lab. *[1]Université J Monnet, Inserm U1059, Saint-Etienne, France; [2]Chu Saint-Etienne, Saint-Etienne, France; [3]Université Lyon 1, Lyon, France; [4]INSA, Lyon, France; [5]UMR_S 1087 / UMR_C 6291 l'Unité de Recherche de l'Institut du Thorax, Nantes, France; [6]Nantes Universite, Nantes, France.*

Background: Bone Sialoprotein (BSP), Osteopontin (OPN), DMP1 and MEPE, regulate bone mineralization and are closely co-regulated. While DMP1 and MEPE are known to impact phosphate (Pi) metabolism, we hypothesized that BSP might also influence body Pi handling.

Methods: Nine-week-old (WT) and BSP knockout (KO) mice fed a normal Pi diet (0.55% Pi, ND). We collected 24h urine, feces, blood, femur, kidneys and gut samples for biochemical and molecular analyses.

Results: WT and KO had normal Pi and FGF23 serum levels **(s)** but KO were hypophosphaturic (-75% vs WT). KO expressed lower NaPi2c renal transporter mRNA levels ($p<0.006$ vs WT) while NPT2b and Pit1/2 gut expression were similar to WT. We suspected impaired paracellular Pi gut absorption, a key pathway under ND. Indeed, KO exhibited significant higher water (200%), K^+ (50%), Na^+ and Pi levels in feces ($p<0.01$ vs WT). Multiplex gene expression analysis of gut revealed differential regulation of genes related to matrix remodeling, including higher DMP1, confirmed by RT-PCR (x10 in KO vs WT), BSP and MEPE mRNAs being undetectable. As Chronic kidney disease (CKD) raises systemic Pi load, increasing cardiovascular mortality, we hypothesized that lack of BSP could mitigate CKD-Mineral and Bone Disorders (CKD-MBD) by reducing Pi intestinal absorption. We performed 5/6 nephrectomy (Nx) or sham surgery on 20-wk-old WT and KO mice. After 3 months of CKD, both genotypes showed higher ureamia compared to their sham controls. However, FGF23 **(s)** rose less in Nx-KO compared to Nx-WT ($p<0.05$) while serum Pi remained normal. Fractional urine Pi excretion increased in both genotypes but remained twice lower in Nx-KO than in Nx-WT ($p<0.05$). After 3 months of high Pi diet (1.65% Pi, HP), Nx-KO were neither hypophosphaturic nor had lower FGF23 **(s)** compared to Nx-WT. In addition, KO displayed higher PTH serum levels (x1.5) and cortical porosity (μCT) compared to Nx-WT.

Conclusions: Deletion of BSP, a bone-specific protein, decreased gut paracellular Pi absorption, possibly involving DMP1, known to regulate Blood Brain Barrier permeability. In CKD and under ND, the blunting of FGF23 increase in KO suggests an adverse role of BSP in Pi homeostasis, while, under HP, BSP might protect against CKD-MBD by reducing secondary hyperparathyroidism and its harmful effects on cortical bone.

TH-OR33

Exercise Mimetic Restores Muscle and Bone Outcomes in a Rat Model of CKD

Ashley D. Troutman,[1] Neal X. Chen,[2] Shruthi Srinivasan,[2] Corinne E. Metzger,[2] Kalisha O'Neill,[2] Landon Tak,[2] Michael Schulte,[2] Sharon M. Moe,[2] Keith G. Avin.[2,1] *[1]Indiana University, Department of Physical Therapy, Indianapolis, IN; [2]Indiana University School of Medicine, Indianapolis, IN.*

Background: Chronic kidney disease (CKD) progressively deteriorates skeletal muscle and bone leading to sarcopenia and CKD-bone mineral disease (CKD-MBD). Exercise studies have demonstrated variable success, which supports the need for pharmacological interventions. We used an investigational drug, Locamidazole (LAMZ), with documented muscle and bone anabolic effects that mimic exercise. We hypothesized that LAMZ would improve physical function and bone outcomes in a rat model of CKD.

Methods: We used a naturally occurring and progressive rat model of CKD (Cy/+; n=10-12/gr): 1) normal littermates (NL), 2) Cy/+ (CKD), and 3) CKD-LAMZ (LAMZ). LAMZ s.q. injections, 2x/day at 0.625mg/kg for 5 weeks, beginning at 27 weeks (CKD stage 3). At 33 weeks (end-stage renal disease), rats were terminated for specimen collection. Outcomes: serum biochemistry, electrically stimulated muscle strength and fatigue (series of 50 muscle contractions), maximal running distance, bone microarchitecture, and vascular calcification. Data analysis included one-way ANOVA with Tukey's multiple comparisons test.

Results: *Disease Effects (CKD vs NL)*- CKD was confirmed via elevated blood urea nitrogen (BUN; $p<0.0001$) and creatinine ($p<0.0001$), muscle weakness ($p<0.05$), muscle fatigue ($p<0.01$), lower running distance ($p<0.05$), increased cortical bone porosity ($p<0.001$), and reduced cortical bone area ($p<0.01$), and cortical thickness ($p<0.001$). *LAMZ Effects (CKD-LAMZ vs CKD)*- LAMZ did not impact disease progression. LAMZ improved muscle function with significantly improved maximally stimulated muscle strength ($p<0.05$) and trending improvements for electrically stimulated muscle fatigue ($p=0.08$). LAMZ improved bone health with reduced cortical porosity ($p<0.01$) and increased cortical thickness ($p<0.01$). Maximal running distance demonstrated an intermediate level of adaptation (i.e., not statistically different from NL or CKD); additional samples pending for biochemistry and vascular calcification.

Conclusions: LAMZ administered for 5 weeks significantly improved both muscle strength and bone microarchitecture. The potential for an exercise mimetic is exciting for nephrologists and patients with CKD alike, as an alternative method to improve musculoskeletal health and quality of life.

Noninvasive Method to Diagnose Renal Osteodystrophy: A Study on 19 Circulating MicroRNAs

Clement Vachey,[1,2] Roth-Visal Ung,[1] Sylvain Picard,[1] Marie-Eve Dupuis,[3] Thomas Nickolas,[4] Fabrice Mac-Way.[1,2] *[1]Centre de recherche du CHU de Québec-Université Laval Site Hôtel Dieu, Quebec, QC, Canada; [2]Universite Laval Faculte de Medecine, Quebec, QC, Canada; [3]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [4]Columbia University Irving Medical Center, New York, NY.*

Background: Current approach to manage bone fragility in chronic kidney disease (CKD) is in part based on assessment of bone turnover (BT) and mineralization. Prior work suggests that circulating microRNAs (miRNAs) identify low *vs* non-low cortical BT in CKD. We aimed to assess whether 19 miRNAs discriminate BT and biopsy proven contraindications (CI) to antiresorptive therapies (ART) in CKD patients.

Methods: Single-site cross-sectional study. Patients with stage 4-5 CKD having a high fracture risk underwent iliac crest bone biopsy for assessment of BT and mineralization levels according to ASBMR guidelines. Absolute CI to ART were defined by the presence of adynamic bone disease or osteomalacia. Relative CI were defined by the presence of mineralization defects without osteomalacia and low BT without adynamic bone. At the time of the biopsy, blood test were drawn for assessment of mineral biochemistry as per local standard and for measurement of 19 circulating miRNAs using the osteomiR kit (TAmiRNA, Austria). Each miRNA was compared between low *vs* high/normal BT, low/normal *vs* high BT, patients with absolute CI *vs* relative or no-CI to ART. Diagnostic accuracy was tested using the median and lowest tertile of each miRNA.

Results: Fourty four patients were included (women 56.8%, mean age 69.6±9.2, 45.4% dialysis). 19 had low BT, 16 normal, and 9 high BT; 7 patients had absolute CI to ART (2 osteomalacia, 5 adynamic bone). miRNA levels did not differ between low and normal/high BT groups. However, miRNA-31-5p was higher in patients with high BT (p=0,02), a value above the lowest tertile being associated with high BT status (sensitivity 100%, specificity 57,1% (95%CI: 40,8-73,5%), negative predicted value (NPV) 100%). We found 7 miRNAs (let7b5p, miRNA-141-3p, 143-3p, 17-5p, 19b-3p, 29b-3p, 550a-3p) with a very good capability to rule out CI to ART. A value above the median being associated with absolute CI to ART (sensitivity 85,7% (95%CI: 59, 8-100%), specificity<60%, NPV 95.5% (95%CI: 86.8-100%)). A value above the lowest tertile was even more discriminant (NPV 100% for 5/7).

Conclusions: Circulating miRNAs can help clinical decision in the approach of bone fragility in CKD. Large studies in heterogeneous cohorts are needed to validate these results.

TH-OR35

Reliability of Time-Lapse High-Resolution Peripheral Quantitative CT (HR-pQCT) in Determining Bone Remodeling in Patients with ESKD

Minhao Zhou,[1] Saghi Sadoughi,[1] Lauren Go,[1] Isabel Yu,[2] Po-hung Wu,[1] Isra Saeed,[1] Bo Fan,[1] Isidro B. Salusky,[3] Thomas Nickolas,[4] Joachim H. Ix,[5] Galateia J. Kazakia.[1] *[1]University of California San Francisco, San Francisco, CA; [2]University of California Berkeley, Berkeley, CA; [3]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [4]Columbia University Irving Medical Center, New York, NY; [5]University of California San Diego Department of Medicine, La Jolla, CA.*

Background: Patients with end-stage kidney disease (ESKD) have elevated fracture risk in part due to abnormally high or low bone turnover, requiring treatment from patient-specific turnover assessments. However, a reliable, accessible, and non-invasive tool to determine turnover in individual patients does not exist. High-resolution peripheral quantitative computed tomography (HR-pQCT) captures high-resolution in vivo bone microstructure. Time-lapse (TL) analysis uses longitudinal spatially-aligned HR-pQCT scans to evaluate temporospatial bone remodeling (**FigA**). This work evaluates the feasibility of TL HR-pQCT to assess turnover in patients with ESKD. We hypothesized that a 2-month TL period could capture remodeling in ESKD.

Methods: Distal tibia and radius scans were acquired on XtremeCT II. Bone formation and resorption fraction (BFF and BRF) were evaluated with respect to baseline integral, cortical, and trabecular bone volumes. Total and net bone turnover (TBT and NBT) were calculated as BFF+BRF and BFF-BRF, respectively (**FigB**). All rates were annualized (%/year). Annualized least significant change (LSC) in remodeling was established from a cohort of 15 healthy participants scanned twice ~1 year apart.

Results: Eight patients with ESKD on dialysis underwent 2 scans ~2 months apart (mean months on dialysis: 46; **FigC**). TL analysis showed that BFF and BRF in the ESKD cohort were >2- and >6-fold higher than the respective LSC (**FigD-E**). Radius cortical bone loss of 10.6%/year was found in ESKD (**FigE**).

Conclusions: This study showed that individual bone remodeling in ESKD can be captured by TL HR-pQCT in a 2-month TL period, shorter than that needed for gold standard tetracycline double-labeled bone biopsy. The assessed trabecular BFF in ESKD (9.6-21.3%/year) agrees with reported histomorphometric formation (3.5-22.4%/year), and the observed cortical bone loss aligns with known ESKD pathology, both verifying the reliability of TL HR-pQCT in ESKD bone turnover assessments. Future work will further validate TL HR-pQCT.

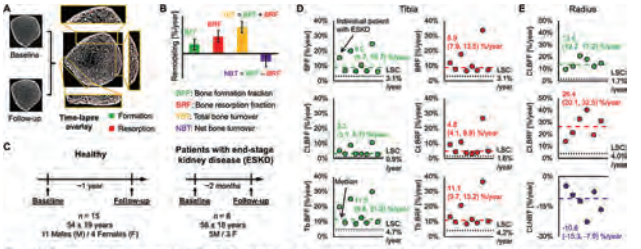

Fig (A) Representative sequential HR-pQCT scans with the time-lapse (TL) overlay visualizing bone remodeling in a patient with ESKD. **(B)** TL HR-pQCT turnover metrics. **(C)** Study design. **(D)** TL HR-pQCT turnover metrics at the distal tibia, presented as annualized median (interquartile range) by dashed lines for the integral bone, cortical (Ct.), and trabecular (Tb.) bone in ESKD (circles) vs. respective LSC (dotted lines). **(E)** TL HR-pQCT turnover metrics at the distal radius in the cortical bone, highlighting the cortical bone loss with ESKD.

TH-OR36

Acute Effect of High Fat Intake on Urinary Acidification Parameters in Uric Acid Stone Formers and Non-stone Forming Controls

Alireza Zomorodian, Xilong Li, Naim M. Maalouf, Orson W. Moe, Khashayar Sakhaee. *The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: The prevalence of uric acid nephrolithiasis (UAN) has increased contemporaneously with obesity and metabolic syndrome in recent decades. The key pathogenic factor in UAN is acidic urine pH (< 5.5), which results from reduced buffering of H^+ by ammonia ($NH_3 + H^+ \rightarrow NH_4^+$). Ammoniagenesis by the renal proximal tubule (PT) consumes amino acids and generates ATP. In this study, we tested whether provision of free fatty acid (FFA) as an alternative energy (ATP) precursor impairs renal ammoniagenesis in uric acid stone formers (UASF) and controls (Ctrl) by substrate competition.

Methods: Seven UASF and eight BMI-matched Ctrl were equilibrated on a fixed metabolic diet for 4 days. After sampling fasting urine and blood, subjects received an oral fat load (heavy cream 0.50 ml/kg body weight) hourly for 10 hours. Blood and urine samples were collected every 2 hours during this period. Outcomes: urine acid-base parameters and blood FFA and ketone bodies (KB).

Results: Both groups showed significant and similar increases in serum FFA and KB following the fat load. Urine pH (UpH) progressively decreased from 6.6 to 5.6 in the Ctrl group over the 10-hour period ($p < 0.001$), while UpH started lower (5.3) in the UASF group and remained unchanged over 10 hrs (p=0.59). While the fraction of net acid excretion (NAE) in the form of ammonium (NH_4^+) (NH_4^+/NAE) was notably lower in fasting urine in the UASF group compared to Ctrl ($p = 0.002$), this ratio significantly decreased in both groups during the 10-hour fat load (Ctrl: $p < 0.001$; UASF: $p = 0.01$).

Conclusions: Acute elevation in serum FFA by an oral fat load leads to a reduction in urine pH and NH_4^+/NAE in Ctrl, to levels comparable to UASF. These findings are compatible with a substrate switch, whereby high FFA provision in UASF reduces amino acid metabolism and nitrogen provision for ammoniagenesis, resulting in aciduria and predisposition to UAN.

Predictors of the Plasma and Fecal Metabolomes in CKD: The CRIC Gut Study

Amanda H. Anderson,[1] Robin L. Baudier,[2] Shuo Bai,[3] Hongzhe Li,[4] Gary Wu.[4] The CRIC Study. *[1]The University of Alabama at Birmingham School of Public Health, Birmingham, AL; [2]Oregon Health & Science University, Portland, OR; [3]Tulane University, New Orleans, LA; [4]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

Background: The importance of kidney function and gut microbiota relative to other clinical and behavioral factors in predicting the plasma and fecal metabolomes is unclear in CKD.

Methods: Among N=291 adults in the Chronic Renal Insufficiency Cohort (CRIC) Gut Study, we used random forest models to determine relative predictive power of clinical factors, kidney measures, diet, environmental factors, gut microbiota, and the fecal metabolome in explaining the plasma and fecal metabolomes and individual metabolite levels in CKD.

Results: The fecal metabolome and clinical factors best predicted variance in the entire plasma metabolome, while kidney measures (eGFR and proteinuria) had the highest median explained variance for individual plasma metabolites, in particular, several nucleobases and amino acids (Fig 1). By contrast, gut microbiome pathways outperformed any feature to explain variance in the fecal metabolome (Fig 2).

Conclusions: The gut microbiome strongly predicts the fecal metabolome which, in addition to kidney measures, explains the majority of variability in the plasma metabolome in CKD potentially through dysbiosis, disruption of gut barrier function, and/or reduced renal clearance of gut-derived metabolites.

TH-OR38

PURE Healthy Diet Score, Genetic Susceptibility, and New-Onset CKD

Sisi Yang, Fan Fan Hou, Xianhui Qin. *Southern Medical University Nanfang Hospital, Guangzhou, China.*

Background: The Prospective Urban Rural Epidemiology (PURE) score, a novel dietary pattern that focuses exclusively on protective foods, is more practical than highly restrictive diets. However, its association with new-onset chronic kidney disease (CKD) and its performance in comparison to some conventional dietary patterns, including Dietary Approaches to Stop Hypertension (DASH), Alternate Mediterranean diet (aMed), Alternate Healthy Eating Index-2010 (AHEI-2010), and healthful Plant-Based Diet Index (hPDI) remain unclear.

Methods: 179,569 participants without CKD and with complete dietary data at baseline from the UK Biobank were included. The PURE score was calculated based on six foods (fruits, vegetables, legumes, nuts, fish, and dairy), ranging from 6 to 30. The study outcome was new-onset CKD.

Results: During a median follow-up of 12.1 years, 4,822 participants developed CKD. The PURE score was inversely associated with new-onset CKD (per 1 quintile increment: HR, 0.92; 95%CI,0.90-0.94). Compared to participants with PURE score <14 (unhealthy PURE score) and high genetic risk, those with PURE score ≥14 (healthy PURE score) and low genetic risk had the lowest risk of CKD (HR, 0.46; 95%CI, 0.42-0.51). The inverse association between PURE score and new-onset CKD remained, regardless of the levels of DASH, aMed, AHEI-2010, hPDI, and genetic risk of CKD (all *P* for interactions >0.05). None of the conventional dietary patterns (per 1 quintile increment: HRs ranging from 0.91 to 0.96) was significantly superior to PURE score in reducing the risk of CKD.

Conclusions: Adherence to a high PURE score was associated with a lower risk of CKD, suggesting the importance of protective foods in CKD prevention.

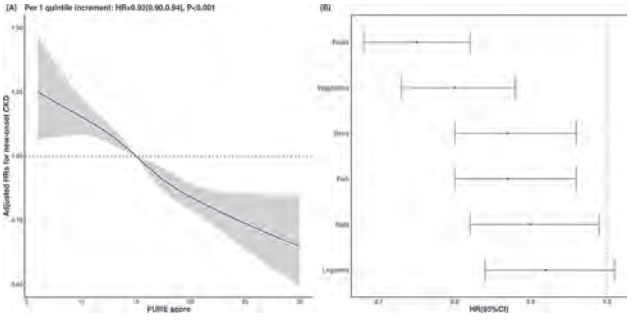

Figure 1. Associations of PURE score (A) and its components (B) with the risk of new-onset CKD.

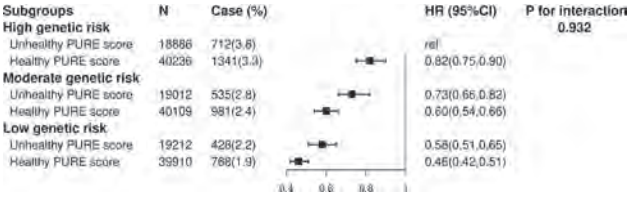

Figure 2. Joint association of PURE score and genetic susceptibility with the risk of new-onset CKD.

Mitochondrial DNA Copy Number Is Associated with Incident AKI, CKD, and Inflammatory Biomarkers

Pukhraj S. Gaheer,[1,2] Giuliano Caltagirone,[1,2] Adeera Levin,[3] Wei Q. Deng,[1,2] Michael R. Chong,[1,2] Matthew B. Lanktree.[1,2] *[1]McMaster University Faculty of Health Sciences, Hamilton, ON, Canada; [2]Population Health Research Institute, Hamilton, ON, Canada; [3]The University of British Columbia, Vancouver, BC, Canada.*

Background: Mitochondrial DNA copy number (mtDNA-CN) is an estimate of the number of mitochondria per leukocyte and a surrogate measure of net mitochondrial function. Reduced mtDNA-CN has been reported associated with diabetes, cardiovascular disease, and CKD. We sought to evaluate the association of blood mtDNA-CN with incident acute kidney injury (AKI), CKD, and inflammatory biomarkers.

Methods: mtDNA-CN was estimated from whole-genome sequencing data in the UK Biobank cohort, consisting of 38,440 samples from the general population. We estimated mtDNA-CN using a quantitative polymerase chain reaction (qPCR) in the Canadian study of prediction of death, dialysis, and interim cardiovascular events (CanPREDDICT) cohort, consisting of 1,435 patients with advanced CKD. Linear and Cox proportional hazard regressions were adjusted for blood cell counts, age, sex, and comorbidities. We

also used two-sample Mendelian randomization to test if genetically predicted mtDNA-CN was associated with eGFR. Reverse Mendelian randomization tested the opposite direction: if genetically predicted kidney function was associated with mtDNA-CN.

Results: In the UK Biobank, we observed a 12% higher risk of incident AKI (hazard ratio (HR)=0.88, 95% CI = 0.86–0.91, P=2.4x10^{-6}) and 8% increased odds of incident CKD (odds ratio=0.92, 95% CI = 0.89-0.94, P=0.0008) per 1 standard deviation (SD) decrease in mtDNA-CN while adjusting for baseline eGFR. Meta-analyzing across CanPREDDICT and UK Biobank revealed a 16% higher risk of incident kidney failure (HR=0.84, 95% CI = 0.76-0.93; P=0.0006) and a 3% increase in uACR (95% CI = 1%-5%, P=0.002) per 1 SD decrease in mtDNA-CN. In CanPREDDICT, mtDNA-CN was also associated with transforming growth factor-ß1 (TGFß1, ß=-9.5% per 1 SD decrease, P=0.0005) and C reactive protein (CRP, ß=8.9% per 1 SD decrease, P=0.005). Bidirectional Mendelian randomization analysis did not support either mtDNA-CN or eGFR as causally impacting the other (P>0.05).

Conclusions: mtDNA-CN was associated with incident AKI, CKD, and kidney failure, as well as pro-inflammatory markers TGFß1 and CRP. However, Mendelian randomization analysis did not support a causal relationship between kidney function and mtDNA-CN, suggesting a separate causal pathway mediates the association.

Kidney Volume and Risk of Incident CKD

Jianhan Wu,[1] Yifan Wang,[4] Caitlyn Vlasschaert,[2] Ricky Lali,[1] James Feiner,[1] Pukhraj S. Gaheer,[1] Serena Yang,[1] Nicolas Perrot,[5] Michael R. Chong,[5] Guillaume Pare,[1] Matthew B. Lanktree.[3] *[1]McMaster University Faculty of Health Sciences, Hamilton, ON, Canada; [2]Queen's University, Kingston, ON, Canada; [3]St. Joseph Health Care Hamilton, Hamilton, ON, Canada; [4]University of Ottawa Faculty of Medicine, Ottawa, ON, Canada; [5]Population Health Research Institute, Hamilton, ON, Canada.*

Background: Low total kidney volume (TKV) is a risk factor for CKD. However, evaluations of causal inference and prognostic utility beyond traditional biomarkers are lacking.

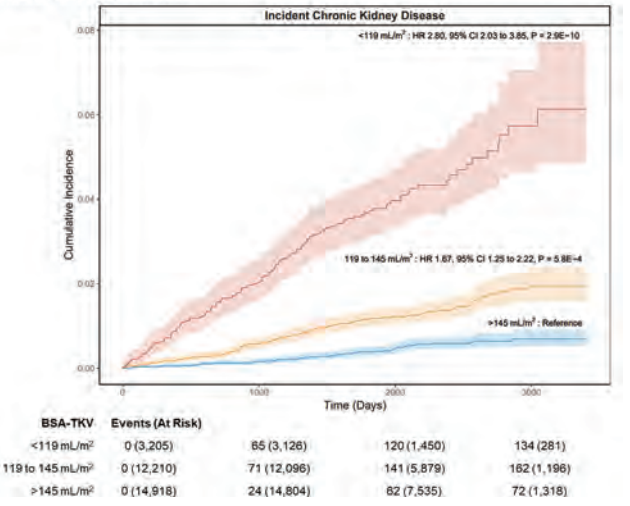
Methods: TKV of 34,595 White British ancestry participants were derived from the UK Biobank. Association with incident CKD were assessed with Cox proportional hazard models. Prognostic thresholds for CKD risk stratification were identified using a modified Mazumdar method with bootstrap resampling. Overall improvement in model performance was assessed using likelihood ratio test. Risk reclassification was evaluated with 5-fold cross-validation. Bidirectional associations of genetically predicted TKV with kidney traits were assessed using two-sample Mendelian randomization (MR).

Results: Adjusted for eGFR and albuminuria, a lower TKV of 10 mL was associated with a 6% higher risk of incident CKD (HR 1.06, 95% CI 1.03 to 1.08, P = 5.8 x 10^{-6}). Individuals below the prognostic threshold of body surface area adjusted TKV (BSA-TKV) at 119 mL/m^2 (10th percentile) exhibited 2.8-fold (95% CI 2.03 to 3.85, P = 2.9 x 10^{-10}) higher risk of incident CKD after accounting for eGFR, albuminuria, and traditional risk factors. Addition of BSA-TKV improved model performance of the CKD Prognosis Consortium Incident CKD Risk Score (likelihood ratio P = 4.8 x 10^{-14}) and improved reclassification of high-risk prognostication at a rate of 1 per 3.3 cases (95% CI 3.1 to 3.6). In MR, a lower genetically predicted TKV by 10 mL was associated with 10% higher CKD risk (OR 1.10, 95% CI 1.06 to 1.14, P = 1.3 x 10^{-7}). Reciprocally, an elevated risk of genetically predicted CKD by 2-fold was associated with a lower TKV by 7.88 mL (95% CI -9.81 to -5.95, P = 1.2 x 10^{-15}).

Conclusions: Kidney volume was associated with incident CKD independent of traditional risk factors including baseline eGFR and albuminuria. Mendelian randomi–zation demonstrated a bidirectional relationship between kidney volume and CKD.

Funding: Government Support - Non-U.S.

Figure 2: Cumulative incidence and hazard ratios of incident chronic kidney disease, adjusted for eGFR, uACR and other traditional risk factors, according to body surface area adjusted total kidney volume (BSA-TKV) thresholds.



BSA-TKV	Events (At Risk)			
<119 mL/m²	0 (3,205)	65 (3,126)	120 (1,450)	134 (281)
119 to 145 mL/m²	0 (12,210)	71 (12,096)	141 (5,879)	162 (1,196)
>145 mL/m²	0 (14,918)	24 (14,804)	62 (7,535)	72 (1,318)

Metabolomics Study of APOL1-Associated CKD Progression

Ruiyuan Zhang,[1] Tanika Kelly,[2] Morgan Grams,[3] Jing Chen,[1] Jiang He,[1] Changwei Li.[1] *[1]Tulane University, New Orleans, LA; [2]University of Illinois Chicago College of Medicine, Chicago, IL; [3]New York University Grossman School of Medicine, New York, NY.*

Background: The apolipoprotein L1 (APOL1) gene risk variants are a major cause for chronic kidney disease (CKD) and its progression in African Americans (AA). Identifying factors that can modify the genetic risk holds great promise for personalized prevention of CKD progression. However, such factors have not been well studied. We aimed to identify urinary metabolites modifying the risk of APOL1 associated CKD progression in AA patients of the Chronic Renal Insufficiency Cohort (CRIC).

Methods: By using an untargeted approach, we measured 1,350 metabolites from 24-hour urine samples collected at baseline for all 1,513 AA participants of the CRIC. CKD progression was defined as the onset of end-stage renal disease or a 50% reduction in estimated glomerular filtration rate (eGFR) during 20 years' follow-up. We tested interactions of each metabolite with APOL1 risk variants on CKD progression using Cox proportional hazard models adjusting for age, sex, study site, smoking, drinking, body mass index, systolic blood pressure, diabetes, cardiovascular disease, urine protein creatinine ratio, and eGFR. Metabolites with a false discovery rate corrected q <0.05 were deemed significant. Genome-wide analyses were performed for significant metabolites to identify genes associated with them.

Results: Two metabolites, *decadienedioic acid (C10:2-DC)* and *X_24728*, significantly modified the effect of APOL1 risk variants on CKD progression (**Figure**). The APOL1 variants only increased risk for CKD progression among those with higher than median of *C10:2-DC* (hazard ratio [HR]= 1.63, 95% confidence interval [CI]: 1.24-2.16) but not among those with less than the median (HR=0.85; 95% CI: 0.62-1,16). Similarly, the HRs for APOL1 risk variants were 0.88 (95% CI: 0.66-1,18) and 1.87 (95% CI: 1.39-2.52) for participants with lower than and higher than median of *X_24728*, respectively. In genome-wide analyses, *ACOT2* upstream variant rs11626972 was associated with urinary *C10:2-DC* (beta for the minor G allele=-0.50, P=5.04×10^{-35}, **Figure**).

Conclusions: Two urinary metabolites modified the risk of APOL1 associated CKD progression.

TH-OR42

CKD Symptoms in Patients Receiving Kidney Supportive Care (KSC)

Jennifer S. Scherer, Chen Lyu, Michal L. Melamed, Daniel Cukor, David M. Charytan. *NYU Langone Health, New York, NY.*

Background: Reducing symptoms is essential to improving quality of life in CKD. KSC can achieve this, and can be used for all treatment modalities, including conservative kidney management (CKM). However, KSC is not widely available in the US, and its impact is not well described.

Methods: Patients completed the IPOS-Renal, a CKD symptom survey for which higher scores represent greater burden, at each visit to our KSC clinic between May 2016 and December 2023.

Results: 189 patients were followed for a mean of 5 months (range 0-58), with a mean of 3 surveys/patient. 69 (37%) were on dialysis, 42 (23%) had chosen CKM, the remainder were deciding (26%), planning for dialysis (5%), or without advanced CKD (9%). Compared to dialysis patients, CKM patients were older (84 vs. 64 years), more likely to be White (69% vs. 39%), non-Hispanic (74% vs. 58%), and have a higher Charlson comorbidity score (10 vs. 6). Mean GFR of CKM patients was 12 mL/min/1.73m^2. CKM patients had a lower initial symptom burden than dialysis patients (21 vs. 29), and this was maintained over time (Figure 1). Both groups had an initial decrease in their symptoms, however, KSC was more effective at sustaining this response in CKM. Linear mixed models assessing longitudinal change over 58 months showed that IPOS renal scores were 7.7 points higher in dialysis patients than in those on CKM (p=0.03), after adjusting for comorbidities.

Conclusions: To our knowledge, this is the first US data showing that KSC appears to be an effective at reducing CKD symptoms. The benefits appear to be more sustained in patients who had chosen CKM. Additional investigation of the impact of KSC and the trajectory of CKM symptoms is warranted.

TH-OR43

Comprehensive Conservative Kidney Management among an Older Population Using a Large Administrative Claims Database

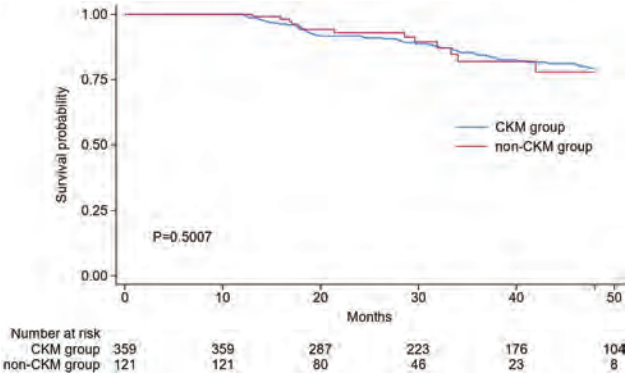
Arisa Kobayashi,[1,2] Keita Hirano,[1] Tatsuyoshi Ikenoue,[1] Takashi Yokoo,[2] Shingo Fukuma.[1] *[1]Kyoto Daigaku Daigakuin Igaku Kenkyuka Igakubu, Kyoto, Japan; [2]Tokyo Jikeikai Ika Daigaku, Minato-ku, Japan.*

Background: Choosing renal replacement therapy for the older is complex due to complications and quality of life concerns. Conservative kidney management (CKM) is increasingly accepted for older CKD patients. This study aims to examine CKM status and related factors in aging Japanese society.

Methods: This cohort study used health screening and medical claims data from April 2014 to May 2023. We included people aged 75 or older with advanced kidney disease (eGFR<8), observed for at least one year and not receiving maintenance dialysis at inclusion. The population was divided into two groups: planned initiation of dialysis (non-CKM group) and selected for CKM (CKM group). A Cox proportional hazards model with age, sex, body mass index (BMI) and frailty categorized by Electronic Frailty Index assessed factors impacting CKM selection. All-cause mortality and total hospitalizations were also examined in both groups.

Results: A total of 480 were included in this analysis (median [IQR] age, 81.1 [77.9-84.8] years; 247 women [51.5%]). Of these, 359 (74.8%) did not undergo necessary practice for dialysis and were defined as choosing CKM. Cox regression showed no significant differences in age, sex, or BMI between the groups. By contrast, the non-frail group was significantly less likely to initiate dialysis compared to the severe-frail group (HR 0.11 [95% CI, 0.02-0.82]). Cox regression analysis of all-cause mortality showed no significant difference between the groups (HR 1.25 [95% CI, 0.70-2.24]). Kaplan-Meier curves for death are shown in the Figure. Poisson regression indicated the hospitalization rate was significantly higher in the non-CKM group (IRR 1.98 [95% CI, 1.67-2.34]). In the non-CKM group, hospitalizations were significantly more frequent in the severe-frail group (OR 8.75 [95% CI, 1.36-56.3]).

Conclusions: In the older population, non-frail individuals often chose CKM. These findings suggest the importance of considering clinical backgrounds when determining CKM indications.



TH-OR44

ANU-ADRI, BDSI, CAIDE, and LIBRA as Predictors of Mild Cognitive Impairment Dementia in CKD

Amara Sarwal,[1,2] Robert E. Boucher,[1,2] Sydney E. Hartsell,[1,2] Guo Wei,[1,2] Ravinder Singh,[1,2] Niharika Katkam,[1,2] Augustine Takyi,[1,2] Akhil Ramanujam Chakravartula,[1,2] Farahnaz A. Moghaddam,[1] Srinivasan Beddhu.[1,2] *[1]University of Utah Health, Salt Lake City, UT; [2]VA Salt Lake City Health Care System, Salt Lake City, UT.*

Background: The four commonly used risk prediction scores for dementia in the general population include Australian National University Alzheimer's Disease Risk Index (ANU-ADRI), Brief Dementia Screening Indicator (BDSI), Cardiovascular Risk Factors, Aging, and Incidence of Dementia (CAIDE), and LIfestyle for BRAin Health (LIBRA). There is a paucity of data on the applicability of these scores for predicting cognitive function decline in CKD.

Methods: In Systolic Blood Pressure Intervention Trial (SPRINT)- MIND Study participants with CKD at baseline (N=2105), we compared the predictive ability of age alone, ANU-ADRI, BDSI, CAIDE and LIBRA scores for adjudicated incident mild cognitive impairment (MCI) or probable dementia (PD) in separate multivariate Cox regression models adjusted for BP group in SPRINT, age, sex, race/ethnicity, education, comorbidities such as CVD, PVD, depression and tobacco use as well as BP, BMI and eGFR.

Results: The mean age was 72 ± 9 years, 40% female and 37% African American. Mean eGFR was 47 ± 10. There was a total of 418 MCI events/9156 person years, and 137 PD events/9649 person years. As shown in Table, age had the strongest association with MCI but with modest c-statistic (0.66). Age, ANU-ADRI and BDSI were strong predictors of PD (Table and Figure) with c-statistic of 0.71, 0.74 and 0.73, respectively. CAIDE and LIBRA fared poorly for both MCI and PD.

Conclusions: ANU-ADRI and BDSI offer modestly higher concordance for predicting PD than age alone in CKD. Both age and the existing scores are poor predictors of MCI in CKD. Better tools to predict MCI in CKD are warranted.

Funding: NIDDK Support, Other NIH Support - NIA, Veterans Affairs Support

	MCI		PD	
	HR per 1 SD	C-statistic	HR per 1 SD	C-statistic
Age	1.75 (1.51, 2.03)	0.66	2.55 (1.96, 3.32)	0.71
ANU-ADRI	1.10 (0.83, 1.46)	0.65	2.45 (1.48, 4.07)	0.74
BDSI	1.23 (1.00, 1.51)	0.66	1.80 (1.23, 2.62)	0.73
CAIDE	1.10 (0.96, 1.27)	0.51	1.19 (0.94, 1.50)	0.54
LIBRA	1.01 (0.84, 1.21)	0.52	1.48 (1.08, 2.04)	0.51

Inpatient Outcomes of Gastrointestinal Bleeding in Advanced CKD: A National Analysis, 2016-2019

Mingyue He,[1] Shaan H. Desai,[1] Yichen Wang,[2] Avrum Gillespie.[1] *[1]Temple University Hospital, Philadelphia, PA; [2]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

Background: Patients with Advanced Chronic Kidney Disease (ACKD) and End-Stage Kidney Disease (ESKD) have an elevated risk of Gastrointestinal Bleeding (GIB). This study aims to investigate the incidence, causes, interventions, and outcomes of GIB among these groups compared to patients without CKD (NCKD).

Methods: Using the Nationwide Inpatient Sample, we analyzed non-elective admissions for GIB from 2016 to 2019, encompassing upper, lower, and unspecified GIB cases across ACKD (CKD stages 4 or 5), ESKD, and NCKD groups. We compared various outcomes and conducted subgroup analyses based on the timing of endoscopy within the ACKD and ESKD cohorts.

Results: The study included 2,163,929 patients. The incidence of GIB hospitalizations was higher in the ACKD (3.2%) and ESKD (3.4%) groups compared to NCKD (2.2%). ACKD and ESKD patients exhibited increased mortality (adjusted Odds Ratio 1.33 and 1.94, respectively; p<0.001) compared to NCKD. Patients with ESKD demonstrated increased rates of mechanical ventilation, pressor support, and blood transfusion, along with prolonged and costly hospitalizations ($p < 0.001$ for all). There was decreased early endoscopic evaluation (<24 h) and increased late evaluations (> 48h) in the ACKD and ESKD groups ($p < 0.001$ for all) compared to NCKD. Multivariate analysis revealed that early endoscopy was significantly associated with decreased mortality while delayed endoscopy was significantly associated with increased mortality in ACKD and ESKD patients (p<=0.001 for all). The primary causes of GIB in both the ACKD and ESKD groups were gastric/duodenal bleeding and angiodysplasia bleeding. ACKD and ESKD were independent risk factors for angiodysplasia bleeding.

Conclusions: ACKD and ESKD are independent risk factors for GIB and in-hospital mortality. ESKD patients with GIB demonstrated significantly elevated rates of adverse outcomes compared to those without CKD. Both groups had a lower rate of early endoscopy and a higher rate of delayed endoscopy, which emerged as independent risk factors for mortality. Further investigation to understand the reasons for delayed endoscopic evaluations in ESKD patients is crucial for improving patient outcomes.

TH-OR46

Finerenone in Patients with Type 2 Diabetes and CKD by SGLT2 Inhibitor and Glucagon-Like Peptide 1 Receptor Agonists Receptor Agonist Use: A FIDELITY Analysis

Ajay K. Singh,[1] Stefan D. Anker,[2] Bertram Pitt,[3] Peter Rossing,[4,5] Luis M. Ruilope,[6,7] Christiane Ahlers,[8] Youssef M. Farag,[9,10] Marc Lambelet,[11] Meike Daniela Brinker,[12] Katja Rohwedder,[13] Gerasimos Filippatos,[14] George L. Bakris.[15] *[1]Harvard Medical School, Renal Division, Brigham and Women's Hospital/Dana Farber Cancer Institute, Boston, MA; [2]Department of Cardiology (CVK) of German Heart Center Charité; German Centre for Cardiovascular Research (DZHK) partner site Berlin, Charité Universitätsmedizin, Berlin, Germany; [3]Department of Medicine, University of Michigan School of Medicine, Ann Arbor, MI; [4]Steno Diabetes Center Copenhagen, Herlev, Denmark; [5]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; [6]Cardiorenal Translational Laboratory and Hypertension Unit, Institute of Research imas12, Madrid, Spain; [7]CIBER-CV, Hospital Universitario 12 de Octubre, Madrid, Spain; [8]Statistics and Data Insights, Bayer AG, Berlin, Germany; [9]Postgraduate Medical Education, Harvard Medical School, Boston, MA; [10]Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [11]Chrestos Concept GmbH & Co. KG, Essen, Germany; [12]Cardiology and Nephrology Clinical Development, Bayer AG, Berlin, Germany; [13]Cardio-Renal Medical Affairs Department, Bayer AG, Berlin, Germany; [14]National and Kapodistrian University of Athens, School of Medicine, Department of Cardiology, Attikon University Hospital, Athens, Greece; [15]Department of Medicine, University of Chicago Medicine, Chicago, IL.*

Background: Finerenone significantly reduced the risk of cardiovascular and kidney outcomes in patients with chronic kidney disease (CKD) and type 2 diabetes (T2D) in FIDELITY, a prespecified pooled analysis of the FIDELIO-DKD and FIGARO-DKD trials. Here, we explored the treatment effect of finerenone in concomitant use with sodium-glucose co-transporter-2 inhibitor (SGLT-2i) + glucagon-like peptide-1 receptor agonist (GLP-1RA).

Methods: Patients in FIDELITY were on optimized renin–angiotensin system inhibition and randomized 1:1 to finerenone or placebo. Key outcomes in this analysis were change in urine albumin-to-creatinine ratio (UACR) over time and treatment-emergent adverse events (including serum potassium [K^+]).

Results: Of 12,990 patients analyzed, 167 received concomitant use of finerenone with SGLT-2i+GLP-1RA at baseline. Baseline characteristics were similar despite concomitant use of finerenone with SGLT2i±GLP-1RA. Finerenone led to a greater reduction in UACR from baseline to month 4 vs placebo; at month 12, reduction was 49%, 45%, 35% and 40% with concomitant use of finerenone with SGLT-2i+GLP-1RA, GLP-1RA, SGLT-2i, and finerenone alone, respectively (Fig 1A). Safety profile of finerenone was not modified by concomitant SGLT2i±GLP-1RA use. Overall, the risk of hyperkalemia leading to treatment discontinuation or hospitalization with finerenone were low. There were fewer patients with serum [K+] of >5.5/>6 mmol/l in the treatment group with concomitant use of finerenone with SGLT-2i+GLP-1RA vs finerenone alone (Fig 1B).

Conclusions: In FIDELITY, concomitant use of finerenone with SGLT-2i+GLP-1RA at baseline may have additive kidney benefits vs placebo in patients with T2D and CKD.

Urinary Clusterin as a Pharmacodynamic Response Biomarker for the Endothelin Receptor Antagonist Atrasentan

Wenjun Ju,[1] Viji Nair,[1] Priya Vart,[2] Johannes D. Smeijer,[2] Maria Larkina,[1] Kerby Shedden,[5] Edmond Lee,[1] John R. Hartman,[1] Markus Bitzer,[1] Kevin L. Duffin,[7] Maria F. Gomez,[6] Charles E. Alpers,[4] Matthias Kretzler,[1] Hiddo J. Heerspink.[2,3] SONAR. *[1]University of Michigan Michigan Medicine, Ann Arbor, MI; [2]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [3]The George Institute for Global Health, Sydney, NSW, Australia; [4]University of Washington School of Medicine, Seattle, WA; [5]University of Michigan Department of Statistics, Ann Arbor, MI; [6]Lunds universitet Institutionen for kliniska vetenskaper Malmo, Malmo, Sweden; [7]Eli Lilly and Company, Indianapolis, IN.*

Background: Endothelin-1 pathway activation in the kidney is associated with progressive kidney injury and GFR decline. The endothelin-1 receptor antagonist atrasentan reduces the risk of kidney failure in patients with diabetic kidney disease (DKD) in the phase 3 SONAR clinical trial. However, the individual patient's response varies. This study aimed to identify biomarkers predictive of atrasentan response and its underlying molecular mechanisms.

Methods: SOMAscan was used to discover urinary biomarkers associated with atrasentan response in 180 patients from the SONAR trial. Logistic regression was used to identify markers whose change from baseline to 6 weeks of treatment are predictive to response. Top candidate markers were validated using ELISA. Biomarker concentration was normalized by urine creatinine. Transcriptomic data from patients with DKD and atrasentan-treated DKD mouse model were analyzed for mechanistic insight. The top candidate biomarker was validated in the remaining SONAR cohort using a Cox proportional hazard regression model.

Results: Putative biomarkers predictive of atrasentan response were identified. Of these, urinary clusterin (uCLU) emerged as the top candidate and was further evaluated. Kidney transcriptomic data revealed that *CLU* is upregulated in DKD in mice and humans, and correlated with an endothelin activation score, generated from atrasentan-treated BTBR ob/ob mice using DKD-associated endothelin 1 pathway genes that are reversely regulated by atrasentan. Higher uCLU at baseline is significantly associated with an increased risk of a composite endpoint of kidney failure or 57% eGFR decline [HR1.09 (95% CI 1.03, 1.16; p=0.005)] in the SONAR clinical trial (N=3060). Atrasentan reduced uCLU during six weeks treatment by 42.6% and this early change in uCLU was independently associated with a lower risk of the composite kidney endpoint after adjustment for all covariates [HR 0.90 (95% CI 0.84, 0.97); p=0.009].

Conclusions: Our study identified and validated uCLU as a promising pharmacodynamic biomarker for assessing treatment response to atrasentan. This calls for further clinical evaluation and implementation, and fosters indivdualized treatment through molecular stratification.

Ephrin Signaling and the Development of Early Progressive Kidney Function Decline

Zaipul Md Dom,[1,2] Eiichiro Satake,[1,2] Sok Cin Tye,[1,2] Andrzej S. Krolewski.[1,2] *[1]Joslin Diabetes Center, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: We were the first to report a novel role of Ephrin family members in the progression of kidney failure in diabetes (Satake *et al.* JASN 2021). However, whether higher Ephrin protein levels are associated with or causally related to the development of early progressive kidney function decline (PKFD) is unknown.

Methods: We assessed EPHA2 and EFNA4 protein levels using Joslin Olink proteomics platform among participants in the Joslin Kidney Study (JKS, n=1,269) and the Chronic Renal Insufficiency Cohort study (CRIC, n=1,170). We compared baseline levels of EPHA2 and EFNA4 across albuminuria categories with T1D and T2D and evaluated their associations with kidney outcomes (kidney failure, eGFR slope and eGFR-based outcomes).

Results: EPHA2 and EFNA4 levels increased progressively from non-diabetics to normoalbuminuria (NA), microalbuminuria (MA), and proteinuria (PT) in both cohorts (Figure 1A). Significant variations were observed between T1D and T2D, and across all albuminuria categories with the highest levels observed in PT. T2D individuals consistently had higher EPHA2 and EFNA4 levels compared to T1D. Both proteins showed significant negative correlations with eGFR, particularly pronounced in MA and PT. In the CRIC cohort, EPHA2 and EFNA4 had significant positive correlations with UACR across all albuminuria categories. Baseline EPHA2 levels were significantly associated with kidney failure in models adjusted for HbA1c, eGFR and UACR (Figure 1B, JKS PT: HR [95%CI] =1.52 [1.21-1.91], p=0.00035, c-index=0.797); CRIC NA: HR [95%CI] =2.61 [1.05-6.19], p=0.029, c-index=0.789, adjusted for competing mortality).

Conclusions: Our findings suggest that elevated levels of circulating EPHA2 and EFNA4 play a role in the initiation of early PKFD and can be used as predictors for the development of early PKFD.

Advancing KidneyIntelX Precision Medicine Platform in CKD

Steven G. Coca,[1] Sharon Stapleton,[2] Katherine L. Edwards,[2] Emily Cho Kiu Au,[2] Fergus Fleming,[2] Girish N. Nadkarni.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Renalytix plc, London, United Kingdom.*

Background: NBL1 and WFDC2 have been identified in experimental animals and omics-based platforms as markers of fibrosis in diabetic kidney disease and are associated with progression to kidney failure. The kidneyintelX.dkd test is an FDA De Novo marketing authorized test that currently incorporates measurement of three biomarkers via electrochemiluminescence Meso Scale platform with clinical variables and categorizes patients at low, moderate, or high risk for progression of DKD. We aimed to advance the translation of NBL1 and WFDC2 for inclusion in future versions of the KidneyIntelX platform through clinical assay development and independent validation of prognostic performance.

Methods: We established analytical characteristics using CLSI guidelines for two biomarkers of kidney disease progression (NBL1, WFDC2). We measured plasma concentrations at baseline in a replication cohort of 601 patients with DKD from the Penn Medicine Biobank (eGFR of 30-59 ml/min/1.73 m^2 or eGFR ≥60 ml/min/1.73 m^2 with UACR ≥30 mg/g). The associations of baseline levels with a composite outcome of ≥40% sustained decline in eGFR, or kidney failure (over 5 years) were evaluated using Cox proportional hazard models.

Results: Robust analytical parameters including repeatability were demonstrated (CV ≤5.5% for NBL1 and CV ≤5.2% for WFDC2) over clinically relevant ranges. Reference intervals at 95% confidence demonstrated discrimination between healthy populations (476 to 3366 pg/mL for NBL1 and 1342 to 5880 pg/mL for WFDC2) and those with diabetic kidney disease (807 to 20102 pg/mL for NBL1 and 2566 to 26538 pg/mL for WFDC2). The replication cohort had baseline median eGFR of 56 ml/min/1.73 m^2 and median UACR of 57 mg/g with 92 (15.3%) composite events. The adjusted hazard ratio per SD increment of log2 baseline concentration for NBL1 was 1.6 (p<0.001) and was 2.5 (p<0.001) for WFDC2 after adjustment for UACR, eGFR and HbA1c.

Conclusions: NBL1 and WFDC2 assays demonstrated robust analytical performance on transfer to the KidneyIntelX clinical laboratory platform. Both biomarkers were strongly associated with the kidney outcome and therefore merit further investigation for potential incorporation into the KidneyIntelX precision medicine platform.

Identification of Circulating Microbial DNA and Its Correlation in Patients with Diabetic Kidney Disease

Hoang T. Linh, Norihiko Sakai, Miho Shimizu, Shinji Kitajima, Takashi Wada, Yasunori Iwata. *Kanazawa Daigaku, Kanazawa, Japan.*

Background: In recent years, substantial studies have been accumulated to indicate the important role of gut microbiota in diabetic kidney disease (DKD). The abnormal changes of bacterial-derived products could imply specific injuries or play beneficial or harmful roles in DKD progression. Our previous study reported a "leaky gut" was induced in mice with DKD, leading to intestine-derived *Klebsiella oxytoca* translocation to circulation and kidneys then promoting DKD progression. However, the presence of *K. oxytoca* was not investigated in DKD patients. Therefore, the present study examines the *K. oxytoca* levels in circulation and their association with clinical characteristics in patients with DKD.

Methods: We enrolled a total of 16 healthy participants, 17 patients with DKD, 5 patients with DKD needing hemodialysis (HD), and 7 patients with CKD without diabetes, who were admitted to Kanazawa University Hospital in 2021. Bacterial-derived DNA (*16S rDNA* and a specific *K. oxytoca* gene) in the blood was detected using droplet digital PCR, then investigated the relationship with clinical characteristics.

Results: The *K. oxytoca* gene was detected in all patient groups with rates of 64.7% in patients with DKD without HD, 60% in DKD with HD group, and 42.9% in the non-DKD CKD group, but only 1/11 (6.25%) in healthy participants. Patients with DKD (with or without HD) exhibited trends of higher levels of *K. oxytoca* copies and *K. oxytoca / 16S rDNA ratio* compared to patients with non-DKD CKD. Interestingly, blood *K. oxytoca* copies and *K.oxytoca/ 16S rDNA* ratio have been identified to have a positive correlation with blood creatinine (r=0.7007 and 0.6492) or BUN levels (r=0.582 and 0.5619) in DKD patients. Considering eGFR, negative correlations were observed with both *K. oxytoca* copies and the *K.oxytoca/16S rDNA* ratio, with correlation coefficients of -0.4509 and -0.4664, respectively. Moreover, there was a correlation between *K. oxytoca* gene copies and higher neutrophil percentages (r=0.4816), along with a lower lymphocyte frequency (r=-0.5558), and elevated neutrophil-to-lymphocyte ratio (r=0.4998).

Conclusions: The presence of the *K. oxytoca* gene in the circulation could serve as a biomarker reflecting reduced renal function and chronic inflammation in DKD patients.

Autophagy-Related Gene Expression in Diabetes and CKD

Christine P. Limonte,[1] Sean Eddy,[2] Sina Gharib,[1] Charles E. Alpers,[1] Laura Barisoni,[3] Rajasree Menon,[2] Viji Nair,[2] Sylvia E. Rosas,[4] Emilio D. Poggio,[5] Ian De Boer.[1] Kidney Precision Medicine Project (KPMP). *[1]University of Washington, Seattle, WA; [2]University of Michigan, Ann Arbor, MI; [3]Duke University, Durham, NC; [4]Joslin Diabetes and Endocrinology Research Center, Boston, MA; [5]Cleveland Clinic, Cleveland, OH.*

Background: Autophagy impairment is implicated in diabetic nephropathy pathophysiology. We examined autophagy-related gene (ARG) expression in human kidney biopsies from the Kidney Precision Medicine Project (KPMP).

Methods: KPMP is performing research kidney biopsies in adults with CKD. Single cell RNA sequencing has been performed in a subset of kidney biopsy samples using the 10xChromium v3 assay. We assessed differential expression of proximal tubular epithelial cell (PTEC) ARGs (n=604 genes identified from literature) in subjects with diabetes and CKD (n=32) versus controls (n=25). We used k-means consensus clustering to group subjects with diabetes and CKD by PTEC ARG expression patterns.

Results: 326 ARGs were differentially expressed between subjects with diabetes and CKD and controls. Subjects with diabetes and CKD were clustered into 3 groups based on PTEC ARG expression (Table). Adjudicated diagnoses differed across clusters, with Clusters 1, 2, and 3 including 35%, 56%, and 0% people with a primary diagnosis of diabetic nephropathy, respectively. While eGFRs were similar across clusters, Cluster 2 members had more albuminuria and higher HbA1cs. Cluster 2 members had more severe structural tubulointerstitial pathology and the greatest proportion of injured PTECs.

Conclusions: PTEC ARG expression patterns may be able to distinguish between clinically relevant phenotypes of diabetes and CKD with distinct profiles of glycemic exposure, tubulointerstitial pathology, and cellular injury.

Association of Urinary Epidermal Growth Factor with Kidney Outcomes and Effects of SGLT2 Inhibition: Results from the CANVAS and CREDENCE Trials

Erik Moedt,[1] Akihiko Koshino,[1,2] Niels Jongs,[1] Wenjun Ju,[3] Michael K. Hansen,[4] Clare G. Arnott,[5,6] Bruce Neal,[5] Stephan J. Bakker,[1] Hiddo J. Heerspink.[1,5] *[1]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [2]Kanazawa Daigaku Daigakuin Iyaku Hokengaku Sogo Kenkyuka Iyaku Hoken Gakuiki Igakurui, Kanazawa, Japan; [3]University of Michigan Department of Internal Medicine, Ann Arbor, MI; [4]Janssen Research and Development LLC, Spring House, PA; [5]The George Institute for Global Health, Sydney, NSW, Australia; [6]Royal Prince Alfred Hospital, Camperdown, NSW, Australia.*

Background: Epidermal growth factor (EGF) is involved in the regenerative processes of kidney tubular cells. Higher urinary EGF (uEGF) levels are associated with a reduced risk of kidney failure in observational studies. The SGLT2 inhibitor canagliflozin reduces the risk of kidney failure in patients with type 2 diabetes (T2D). We investigated the association of uEGF with kidney outcomes and assessed the effect of canagliflozin on uEGF.

Methods: We performed a post-hoc analysis of the combined CANVAS and CREDENCE trials, which assessed efficacy and safety of canagliflozin versus placebo in those with T2D +/- albuminuric chronic kidney disease. The primary outcome was defined as a 40% decline in eGFR, kidney failure, or death due to kidney failure. Hazard ratios were estimated using multivariate Cox regression. We examined the effect of canagliflozin 100 mg/d on change from baseline in uEGF at years 1 and 3 in 2038 CREDENCE patients (year 3 CANVAS samples were not available) using a repeated measures model.

Results: We analyzed data for 3521 (81.3% of the total cohort) CANVAS patients (mean age 62.8 years, eGFR 77.0 mL/min/1.73m^2, median UACR 11.6 mg/g) and 2457 (55.8% of the total cohort) CREDENCE patients (mean age 63.2 years, eGFR 57.0 mL/min/1.73m^2, median UACR 918 mg/g), with available urine samples. Every doubling in baseline uEGF/Cr was associated with a reduced risk of the kidney outcome (HR 0.86 [95% CI 0.79, 0.93]; p<0.001). This association was consistent across baseline eGFR and UACR subgroups. The uEGF/Cr change from baseline to year 1 was -12.5% ([95% CI -15.6, -9.1]; p<0.001) in the placebo group and -5.4% ([95% CI -8.7, -1.9]; p=0.002) in the canagliflozin group, corresponding to a between-group difference of 8.1% ([95% CI 1.1, 15.6]; p=0.016). The effect of canagliflozin on uEGF was more pronounced at week 156 with a between-group difference of 16.5% ([95% CI 2.1, 32.8]; p=0.016).

Conclusions: Higher baseline uEGF/Cr was significantly associated with lower risk of kidney disease progression in patients with T2D with and without CKD. Canagliflozin consistently attenuated the uEGF/Cr decrease compared to placebo.

Modeling Cardiorenal Protection with SGLT2 Inhibition in Type 1 Diabetes: An Analysis of EASE-2 and -3

Luxcia Kugathasan,[1] Pritha Dutta,[2] Massimo Nardone,[1] Vikas Sridhar,[1] David Campbell,[3] Anita T. Layton,[2] Bruce A. Perkins,[4] Sean Barbour,[5] Tony K. Lam,[1] Adeera Levin,[5] Leif Erik Lovblom,[1] Istvan Mucsi,[1] Remi Rabasa-Lhoret,[6] Valeria E. Rac,[1] Peter A. Senior,[7] Ronald J. Sigal,[3] Aleksandra Stanimirovic,[1] Alessandro Doria,[8] David Cherney.[1] *[1]Toronto General Research Institute, Toronto, ON, Canada; [2]University of Waterloo, Waterloo, ON, Canada; [3]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [4]Lunenfeld-Tanenbaum Research Institute, Toronto, ON, Canada; [5]The University of British Columbia, Vancouver, BC, Canada; [6]Universite de Montreal, Montreal, QC, Canada; [7]University of Alberta, Edmonton, AB, Canada; [8]Harvard Medical School, Boston, MA.*

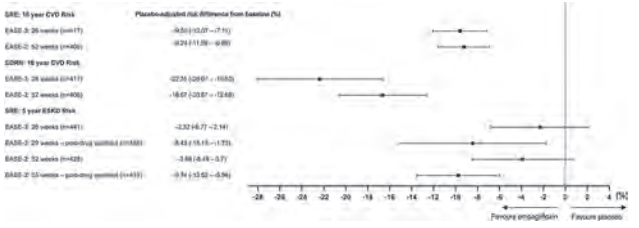
Background: Sodium-glucose cotransporter 2 (SGLT2) inhibitors significantly reduce cardiorenal risk in people with type 2 diabetes. It is unknown if these protective effects extend to individuals with type 1 diabetes (T1D). To better understand the potential benefits of SGLT2 inhibition in T1D, we applied the Steno T1 risk engine (SRE) and Scottish Diabetes Research Network (SDRN) risk prediction models to estimate risk of cardiovascular disease (CVD) and end-stage kidney disease (ESKD) in two large T1D cohorts.

Methods: Medical history, demographic and biomarker data were extracted from 730 and 960 participants with T1D from the EASE-2 and 3 trials, respectively. The SRE and SDRN risk prediction models were employed at baseline, week 26 (EASE-3) or 52 (EASE-2), and 3 weeks post drug washout to estimate the 10-year CVD and 5-year ESKD risk. Risk reduction was calculated as the percent change in estimated CVD and ESKD risk from baseline between empagliflozin (pooled 10 and 25mg) vs. placebo groups, and compared using a two-way repeated measures ANOVA.

Results: Empagliflozin significantly reduced the estimated 10-year CVD risk following 26 weeks (SRE: -9.6% [-12.1, -7.1] & SDRN: -22.4% [-28.1, -16.6]; p<0.01)

and 52 weeks (SRE: -9.2% [-11.6, -6.9] & SDRN: -16.7% [-20.7, -12.7]; p<0.01) of treatment compared with placebo. No significant reduction in 5-year ESKD risk was observed while on treatment. The ESKD risk was significantly lower after a 3-week drug washout (SRE: -8.4% [-15.1, -1.7] (EASE-3) & -9.7% [-13.5, -6.0] (EASE-2); p<0.01), in keeping with the expected rise in eGFR.

Conclusions: Empagliflozin improves predicted CVD and ESKD risk in T1D participants, thus demonstrating the need for dedicated outcome trials in patients with T1D and established kidney or cardiovascular disease. ESKD risk estimation using GFR-based models may be best implemented after drug washout as to avoid the reversible hemodynamic eGFR "dip" with SGLT2 inhibition.



TH-OR54

Glycemic Patterns of Peritoneal Dialysis Patients Assessed by Continuous Glucose Monitoring

Nathaniel Ashford,[1,2] Laura Mayeda,[2,3] Leila R. Zelnick,[1,2] Lisa D. Anderson,[1,2] Evelin N. Jones,[1,4] Subbulaxmi Trikudanathan,[4,2] Christopher Marnell,[3] Irl B. Hirsch,[4,2] Yoshio N. Hall,[1,2] Ian De Boer.[1,2] Kidney Research Institute. *[1]Kidney Research Institute, Seattle, WA; [2]University of Washington School of Medicine, Seattle, WA; [3]Northwest Kidney Centers, Seattle, WA; [4]UW Diabetes Institute, Seattle, WA.*

Background: Peritoneal dialysis (PD) utilizes hypertonic dextrose solution, resulting in known complications with the peritoneal membrane, and absorption into the systemic system. Glucose absorbed from the peritoneal cavity likely leads to insulin resistance and hyperglycemia, but we have limited knowledge about the glycemic patterns of PD patients.

Methods: The BLOSSOM study observed dysglycemia in dialysis patients. Participants wore a Dexcom G6 Pro continuous glucose monitor (CGM) for up to 10 days and completed PD prescription diaries. This interim analysis describes glycemic patterns during day (8:00-20:00) and night (20:00-8:00) in this population.

Results: We enrolled 40 participants treated with PD[AN1], 23 with diabetes mellitus (DM) with and 17 without. Hemoglobin A1C (SD) for participants with DM was 7.3% (1.7%). Mean BG was high, and time in range (TIR) was low (TIR above 70% is recommended) for PD participants with and without DM (Table). At night, high blood glucose levels were seen, and this persisted throughout the day. Dialysate 2.5% dextrose groups had the highest nighttime blood glucose levels (Figure).

Conclusions: Persistent hyperglycemia was seen in PD patients night and day. TIR was far below target for participants with DM, who spent about a third of time >250 mg/dL. PD patients without DM were in target range only about half the time. Our data suggest a need to closely monitor PD patients for dysglycemia regardless of diabetes status.

TH-OR55

Kir5.1 Is Essential to Formation of Kir4.2/Kir5.1 Heterotetramer in the Basolateral Membrane of Mouse Proximal Tubules

Wen-Hui Wang. *New York Medical College School of Medicine, Valhalla, NY.*

Background: Kir5.1 is encoded by *Kcnj16* in the mouse kidney and it is expressed in the basolateral membrane of the proximal tubule (PT), distal-convoluted-tubule (DCT) and cortical- collecting-duct. In DCT, Kir5.1 interacts with Kir4.1 to form a 40-pS K^+ channel, a main type of K^+ channel in the basolateral membrane. Moreover, Kir4.1 can also form a homotetramer in the absence of Kir5.1 and provides the basolateral K^+ conductance of DCT. In PT, Kir5.1 interacts with Kir4.2 to form Kir4.2/Kir5.1 heterotetramer, a main type basolateral K^+ channel. However, it is not clear whether Kir4.2 along is sufficient for forming a Kir4.2 homotetramer without Kir5.1 in the basolateral membrane and maintains PT membrane conductancel.

Methods: We now conduct immunofluorescence-staining and patch-clamp-experiments in Kir5.1-knockout (KO) mice and corresponding wild-type (WT) mice to examine the expression of Kir4.2 and to determine the basolateral K^+ channel activity and PT membrane potential.

Results: The single-channel-recording identified a 50-pS K^+-channel in the basolateral membrane of PT of WT mice. This 50-pS K^+-channel is a main type basolateral K^+ channel and is most likely Kir4.2/Kir5.1 heterotetramer. However, this 50-pS inwardly-rectifying-K^+-channel was completely absent in the PT of Kir5.1-KO mice. Moreover, patch-clamp-experiments failed to detect additional basolateral K^+ channels in the PT of Kir5.1-KO mice. Immunofluorescence-staining shows that Kir4.2 is exclusively expressed in the PT. While the basolateral membrane staining of Kir4.2 was clearly visible in WT mice, it was largely absent in Kir5.1-KO mice. This is in sharp contrast to Kir4.1, which has a clear basolateral membrane staining in both WT and Kir5.1-KO mice. Also, the membrane potential of PT was more positive in Kir5.1-KO mice than WT mice, suggesting that deletion of Kir5.1 impairs Kir4.2 membrane expression. Immunoblotting also showed that the expression of Kir4.2 and Na/H exchanger-3 was lower in Kir5.1-KO mice than WT mice.

Conclusions: We conclude that Kir5.1 is essential for forming the basolateral 50-pS K^+-channel in the PT and plays a role in determining Kir4.2 basolateral membrane abundance. Also, Kir4.2 could not form a homeotetrammer in the absence of Kir5.1 and the membrane potential of PT is depolarized in the Kir5.1-KO mice.

Spalt-Like Transcription Factor 3 (Sall3) Is Essential for Maintaining Distal Convoluted Tubule Differentiation

Hyun Jun Jung,[1] Boyoung Kim,[1] Mohammed Z. Ferdaus,[2] Lama Al-Qusairi,[1] Rick Grimm,[1] Eric J. Delpire,[2] Paul A. Welling.[1] *[1]The Johns Hopkins University School of Medicine, Baltimore, MD; [2]Vanderbilt University Medical Center, Nashville, TN.*

Background: Activation of the sodium chloride cotransporter (NCC) in the distal convoluted tubule (DCT) by the WNK-SPAK signaling pathway is paralleled by an adaptive remodeling process, characterized by DCT cell proliferation and hypertrophy. Regulatory networks responsible for remodeling and maintaining DCT fate have not been identified. Here we identify a DCT-specific transcription factor (TF), Sall3, that is rapidly induced by SPAK-dependent signaling, and characterize the consequences of conditionally and specifically deleting Sall3 from the DCT.

Methods: Genome-wide single-nucleus and bulk RNA sequencing (RNA-Seq) was performed in the kidney tissues of wild-type (WT) mice and mice genetically engineered to constitutively activate the SPAK kinase (CA-SPAK) in the DCT, causing constitutive NCC activation. Multimodal-bioinformatic analyses were used to identify the DCT-specific TFs that are induced downstream of SPAK-NCC. An inducible DCT-specific knockout (KO) mouse model was generated for one of the SPAK-induced TFs, Sall3, and the phenotype of the mice was characterized.

Results: RNA-Seq and bioinformatic analysis of WT and CA-SPAK mouse kidneys identified Sall3 as a key DCT TF that was significantly induced by chronic SPAK-NCC activation in the DCT. Immunolabeling confirmed that Sall3 is primarily expressed in DCT cell nuclei, and supported snRNA-Seq that Sall3 is also expressed in a minority population of AQP2-negative CNT cells. In the CA-SPAK mice, SALL3 protein abundance only significantly increased in the DCT nuclei. A similar response was observed in WT mice when WNK-SPAK was physiologically activated with low K diet. Induction of DCT-specific Sall3 KO significantly reduced the expression of DCT-specific genes, indicative of loss of DCT patterning.

Conclusions: In summary, Sall3 is a key component of the core transcriptional regulatory circuit that maintains DCT cell identity in the basal state and as the tubule expands.

TH-OR57

COP9 Signalosome CSN4 and CSN5 Subunits Protect NKCC2 against Endoplasmic Reticulum Stress and Cellular Hypoxia

Kamel Laghmani,[1,2] Stephanie Kharma,[1,2] Sylvie Demaretz,[1,2] Dalal Bakhos Al Douaihy.[1,2] *[1]Centre de Recherche des Cordeliers, Paris, France; [2]Sorbonne Université, INSERM U1138, CNRS ERL 8228, Paris, France.*

Background: MAGE-D2 mutations cause a severe but transient form of antenatal Bartter syndrome (tBS) associated with impaired expression of the sodium–chloride cotransporters NKCC2 and NCC. Cellular hypoxia is particularly interesting to elucidate the molecular basis of the disease because it is one of the major differences between the antenatal symptomatic period of MAGE-D2-related tBS and the post-natal asymptomatic stage. In support of this, MAGE-D2 was found to be required for appropriate induction of HIF-1α and the protection of NKCC2 against ER stress during hypoxia. The present study aimed to explore further the molecular mechanisms involved in the protection of NKCC2 by MAGE-D2 against ER stress and hypoxia.

Methods: A yeast two-hybrid system (Y2H) was used to identify novel NKCC2 binding partners. Protein-protein interactions were analyzed using co-immunoprecipitation (CO-IP) and co-immunolocalization assays. Cellular hypoxia was induced chemically by incubating HEK cells for 16 hours with cobalt chloride (CoCl2). NKCC2 protein expression was monitored by immunoblotting in HEK cells transfected with the co-transporter. NKCC2 stability was assessed by cycloheximide chase assay.

Results: Y2H identified the COP9 signalosome CSN4 and CSN5 subunits as novel binding partners of NKCC2. This is of particular interest because CSN5 is a MAGE-D2 interactor and also a regulator of HIF-1α stability. Co-IP and co-immunolocalization experiments confirmed CSN4 and CSN5 interactions with NKCC2. Similar to MAGE-D2, CSN4 or CSN5 overexpression increased total and surface NKCC2 abundance. Conversely, CSN4 or CSN5 knockdown enhanced the ER-associated degradation (ERAD) of the cotransporter. Subjecting HEK cells transiently with NKCC2 to cellular hypoxia, significantly decreased NKCC2 stability and maturation. Most importantly, like MAGE-D2, the effect of hypoxia on NKCC2 stability and maturation was more severe following CSN4 or CSN5 knockdown.

Conclusions: Our data reveal that CSN4 and CSN5 are novel key players in the ERAD of NKCC2 under ER stress conditions. Most importantly, our findings strongly suggest that MAGE-D2 cooperates with these COP9 signalosome subunits to protect NKCC2 against ERAD induced by cellular hypoxia, which could contribute to the transient nature of antenatal Bartter's syndrome in carriers of MAGED2 mutations.

Mucin 1 Stimulates TRPM6 Single-Channel Activity and Cell Surface Abundance by Impairing Dynamin-Dependent TRPM6 Endocytosis

Matthias T. Wolf,[1,2] Jing Zhang,[2] Julia Kozlitina,[2] Joost Hoenderop,[3] Sung Wan An.[1,2] *[1]University of Michigan Michigan Medicine, Ann Arbor, MI; [2]The University of Texas Southwestern Medical Center, Dallas, TX; [3]Radboud Universitair Medisch Centrum, Nijmegen, Netherlands.*

Background: Genome-wide association (GWAS) studies revealed an association of *Mucin 1* (*MUC1*) variants with hypomagnesemia. The role of MUC1 in Mg^{2+} homeostasis remains unclear. Therefore, we evaluated if MUC1 enhances the activity of the Mg^{2+} channel TRPM6.

Methods: We analyzed the association of *MUC1* variants and hypomagnesemia in the Dallas Heart Study (DHS), a cohort containing over 3,500 individuals. In a more focused study, 24 h urine samples of 12 control and 12 calcium-nephrolithiasis patients were analyzed for urinary electrolytes and MUC1 protein content. MUC1 and TRPM6 plasmids were co-expressed in HEK293 cells to investigate the effect of MUC1 on TRPM6 single channel and whole-cell current density by patch-clamp recording. Results were confirmed applying cell surface biotinylation and protein co-immunoprecipitation.

Results: We found that the *MUC1* variant rs4072037 associated with hypomagnesemia. Urine samples from control and calcium-nephrolithiasis patients showed significantly lower urinary MUC1 levels and hypermagnesuria in nephrolithiasis patients pointing to a stimulatory role of MUC1 towards Mg^{2+} absorption. *In vitro*, co-expression of MUC1 with TRPM6 stimulated TRPM6 single channel current and whole-cell current density. In biotinylation experiments, MUC1 enhanced TRPM6 cell surface abundance. Co-immunoprecipitation confirmed physical interaction between MUC1 and TRPM6. We found that MUC1 interferes with TRPM6 endocytosis by examining the effect of dominant-negative dynamin and dynasore with co-transfected MUC1 and TRPM6. We tested TRPM6 endocytosis more specifically by knocking down clathrin heavy chain or caveolin-1 applying siRNA. Knockdown of both proteins abolished the stimulation of TRPM6 by MUC1. Furthermore, the *N*-glycan mutant TRPM6 (N787A) was not activated by MUC1. Finally, knockdown of the endogenous urinary lectins Galectin-1 and Galectin-3 also impaired MUC1 activation of TRPM6.

Conclusions: The *MUC1* variant rs4072037 associates with hypomagnesemia. *In vitro*, MUC1 stimulates TRPM6 single channel activity, TRPM6 whole-cell current density and TRPM6 cell surface abundance by impairing dynamin-dependent TRPM6 endocytosis. TRPM6 and MUC1 physically interact and form lattice with the TRPM6 *N*-glycan N787. Urinary Galectin-1 and Galectin-3 stabilize this complex.

Role of mTORC2 in Aldosterone-Independent Potassium Regulation: Resolution of the Aldosterone Paradox

Bidisha Saha, John E. Demko, Enzo Takagi, Robert Weber, David Pearce. *University of California San Francisco, San Francisco, CA.*

Background: ENaC activity and potassium (K^+) secretion in the DCT2 and early CNT (eCNT) are not regulated by aldosterone due to constitutive activation of MR by cortisol. Under low aldosterone conditions, ENaC and ROMK activity are higher in the DCT2 and eCNT than in the late CNT and CD. Acute high K^+ (HK) loads stimulate ENaC and K^+ secretion via mTORC2 independently of aldosterone. Prolonged HK conditions involve aldosterone-dependent activation of ENaC and ROMK for maximal K^+ secretion. This study examined mTORC2's role in K+ secretion across distal nephron segments, focusing on the aldosterone-independent DCT2/eCNT and its role in the aldosterone paradox.

Methods: Rictor, a key mTORC2 component, was selectively knocked out (KO) in DCT2, CNT and CD using Calbindin as Cre-driver (CRKO) or in late CNT and CD using AQP2 as the Cre-driver (ARKO). Both wild-type (WT) and KO mice were subjected to a HK diet for 48 hours. Parameters assessed included urinary and blood electrolyte levels, plasma membrane expression and intracellular localization of renal transporters, and phosphorylation of mTORC2 targets

Results: On a normal K^+ diet, both CRKO and ARKO mice maintained Na^+ and K^+ balance with normal plasma [K^+] levels, but CRKO mice had elevated plasma aldosterone. On a HK diet, CRKO mice showed lower K^+ excretion, hyperkalemia, and elevated aldosterone. Apical αENaC was reduced in DCT2 and eCNT, while late CNT and CCD were mostly unaffected. Phosphorylation of mTORC2 targets like SGK1 and its target, Nedd4-2 was reduced in CRKO mice. In contrast, ARKO mice maintained normal Na^+ and K^+ levels, elevated aldosterone, and preserved ENaC apical localization in the late CNT and CCD.

Conclusions: The data suggest that the DCT2 and eCNT are crucial for ENaC regulation supporting K^+ secretion under HK conditions with mTORC2 playing a key role. This regulation is aldosterone-independent; so we propose the term "Aldosterone Independent Distal Nephron" (AIDN). High aldosterone action in the late CNT and CCD can partly compensate for mTORC2 deficiency to maintain ENaC activity but, ENaC activity in the more distal segments cannot fully compensate, disrupting K^+ balance. Thus, local control of K^+ secretion along the distal nephron ensures potassium homeostasis across various aldosterone levels and highlights the importance of AIDN in resolving the aldosterone paradox.

Chlorthalidone-Induced Salt Appetite Is Prevented by Afferent Renal Denervation

Babatunde S. Anidu,[1] Amanda Costa Veiga,[1,2] Jaryd Ross,[1] Rawan N. Almutlaq,[1] Alexander R. Dayton,[1] Louise C. Evans.[1] *[1]University of Minnesota Twin Cities, Minneapolis, MN; [2]Universidade de Sao Paulo, Sao Paulo, Brazil.*

Background: Excessive sodium intake is a significant public health concern, with the average American consuming approximately 3,400 mg daily, ~1g more than the American Heart Associations' recommended daily maximum. Reducing sodium intake is one of the most cost-effective ways to reduce death from non-communicable diseases and improve health outcomes. Our lab has shown that afferent renal denervation (ARDN) reduces sodium intake in male hypertensive DOCA-salt rats. We hypothesize that when the body needs to conserve sodium, afferent renal nerves are activated in response to increased sodium reabsorption in the collecting duct and this stimulates salt intake. To test this, we used chlorthalidone (CTD) to inhibit the sodium-chloride cotransporter (NCC) in the distal convoluted tubule. This increases sodium delivery to the collecting duct. We examined whether CTD causes increased sodium intake and whether this is prevented by ARDN.

Methods: Male Sprague-Dawley rats aged 10-14 weeks were divided into three groups: vehicle (peanut butter, p.o, n=9), CTD (5mg/kg, p.o, n=8), and CTD-ARDN (n=6). The CTD-ARDN group underwent bilateral ARDN (periaxonal capsaicin, 33mM). The other two groups underwent sham surgery. Telemeter catheters were inserted in the femoral artery of all rats for the assessment of mean arterial pressure (MAP). After surgical recovery, all rats had ad libitum access to a low-salt diet (0.01% NaCl) and deionized water and 1.8% saline for 14 days.

Results: Chronic CTD caused a significant increase in saline intake relative to the vehicle treated rats ($p<0.001$). This effect was specific for saline, and water intake was not higher in CTD than vehicle rats ($p=0.4$). ARDN caused a significant reduction in saline

(p=0.02) but not water (p=0.5) intake. Neither CTD nor ARDN had a significant effect on MAP. Ongoing studies are evaluating whether CTD increases salt-appetite in female rats, and if this is dependent on afferent renal nerves.

Conclusions: These studies show, for the first time, that inhibition of NCC causes a specific increase in salt appetite which is driven by the activation of the afferent renal nerves. In future studies, we will use the administration of amiloride to evaluate whether this response is dependent on the activation of ENaC.

WNK1 as an Osmolality Sensor: Mechanism and Structure-Function Studies

Xin Jin, Jian Xie, Mohammad Amir, Chou-Long Huang. *University of Iowa Health Care, Iowa City, IA.*

Background: The circumventricular organs (CVO's) of the brain lack a blood-brain barrier. CVO neurons detect serum hyperosmolality to stimulate the production and release of arginine vasopressin (AVP). We recently reported that WNK1 in CVO neurons senses hyperosmolality and activates Kv3.1 channel to increase action potential to increase AVP release. Boyd-Shiwarski et al reported that WNK1 forms condensates during cellular dehydration and activates NKCC1 to restore cell volume. The C-terminal intrinsically disordered region (IDR) is important for formation of the condensates. Here, we studied the role of OSR1/SPAK for WNK1 to activate Kv3.1 and the role of IDR in this activation.

Methods: Mice with CVO deletion of SPAK and OSR1 were produced by stereotaxic injection of Cre-recombinase-carrying AAV virus into CVO of Spak-null and Osr1-floxed mice ($Spak^{-/-}$;$Osr1^{flox/flox}$). Water homeostasis was examined in metabolic cage studies. AVP levels were measured. The Kv3.1 current was studied in HEK cells expressing recombinant WNK1 (or mutants), SPAK, and Kv3.1. Biochemical kinase activity of WNK1 was examined by western blot.

Results: Hyperosmolality increased p-OSR1/SPAK in mouse CVOs. Mice with OSR1/SPAK deletion in CVOs exhibited polyuria with decreased urine osmolality that persisted in water restriction, indicating diabetes insipidus. Circulating levels of AVP and copeptin were lower in water restricted OSR/SPAK deletion mice vs controls. In whole-cell recording with 20 mM Cl^- in the pipette (intracellular), exposure to physiological extracellular hyperosmolality (5 mM NaCl, "HTS") increased Kv3.1 currents in HEK cells expressing full-length WNK1, SPAK, and Kv3.1. Increasing pipette Cl^- to 100 mM blunted the activation of Kv3.1 by HTS. Importantly, cells expressing just the kinase domain of WNK1 (aa 1-491), SPAK, and Kv3.1 responded to HTS. Moreover, HTS induced autophosphorylation of WNK1 (1-491).

Conclusions: The WNK1-mediated osmosensation in CVO neurons involves activation of Kv3.1 through SPAK/OSR1. WNK1 kinase domain can detect extracellular hyperosmolality independently of the C-terminal IDR region. The results support the structural data that water and chloride in the cavity of WNK kinase domain negatively regulate the kinase activity. How IDR coordinates with the kinase domain to regulate downstream effectors awaits future studies.

Funding: NIDDK Support

TH-OR62

Facilitation of Mg2+ Extrusion by the Murine Distal Convoluted Tubule-Specific Isoform of SLC41A3

Gijs A. Franken,[1] Willem Bosman,[1] Hyun Jun Jung,[3] Caro Bos,[1] Femke Latta,[1] René J. Bindels,[1] Mark A. Knepper,[2] Joost Hoenderop,[1] Jeroen H. De Baaij.[1] *[1]Radboud Universitair Medisch Centrum, Nijmegen, Netherlands; [2]National Institutes of Health, Bethesda, MD; [3]Johns Hopkins Medicine, Baltimore, MD.*

Background: The distal convoluted tubule (DCT) plays an indispensable role in magnesium (Mg^{2+}) reabsorption in the kidney. Here, transcellular Mg^{2+} transport takes place, yet the extrusion mechanism is currently unknown. The solute carrier 41 A3 (SLC41A3) has been suggested to be involved in Mg^{2+} extrusion. Yet *in vitro* and *in vivo* studies could not demonstrate the molecular function of SLC41A3. In this study, we describe two distinct SLC41A3 isoforms with unique expression patterns and functions.

Methods: Using available RNA-sequencing data and RT-qPCR, expression of the two alternative *Slc41a3* transcripts, encoding isoform (iso) 1 or -2, were assessed in kidney and isolated DCT tubules. HEK293 or HAP1 cells were transfected with plasmids expressing either of the isoforms, followed by $^{25}Mg^{2+}$ uptake and extrusion studies. Identification of DCT-specific cis-regulatory elements (CRE) was achieved by combining data from available ATAC sequencing data and luciferase assays in HeLa cells.

Results: Expression studies revealed the presence of a distinct transcript of *Slc41a3* in the DCT with an alternative promoter, leading to a shorter protein with a distinct N-terminus (iso2). HEK293 cells overexpressing SLC41A3-iso2 exhibited 2.7-fold higher $^{25}Mg^{2+}$ uptake compared to mock. In contrast, SLC41A3-iso1-transfected cells increased $^{25}Mg^{2+}$ uptake by 1.7-fold, while on average protein expression of SLC41A3-iso2 was ~35 fold lower dan SLC41A3-iso1. SLC41A3-iso2 overexpressing cells showed 1.5-fold higher $^{25}Mg^{2+}$ extrusion compared to mock-transfected cells, whereas iso1-transfected cells did not show this increase. Using TRPM7 KO HAP1 and CNNM3 and -4 KO HEK293 cell models, $^{25}Mg^{2+}$ extrusion by SLC41A3-iso2 was demonstrated to be independent of these Mg^{2+} transporting proteins. Via available ATAC sequencing data, a CRE accessible in the DCT was identified, ±3.3kb upstream of the TSS of *Slc41a3-iso2*. Luciferase assays demonstrated that the presence of the CRE increased the *Slc41a3-iso2* promoter activity ±4-fold, indicating the CRE contains an enhancer function.

Conclusions: In conclusion, we identified two alternative transcripts of *Slc41a3* in mouse. *Slc41a3*-iso2 is enriched expressed within the DCT with specific gene regulatory elements. We speculate that specifically in the DCT, SLC41A3-iso2 orchestrates Mg^{2+} extrusion.

TH-OR63

Foxp1/Dmrt2/Hmx2 Transcriptional Network Regulates Intercalated Cell Differentiation in Kidney Collecting Ducts

Xiangjian Zheng, Yu Feng, Yanmiao Qi. *Tianjin Medical University, Tianjin, China.*

Background: Kidney collecting ducts are comprised of principal cells (PCs) and intercalated cells (ICs), with ICs playing a crucial role in kidney acid-base regulation through H^+ and HCO_3^- secretion. Despite its significance, the molecular mechanisms controlling IC development remain incompletely understood. Single cell sequencing analysis found Foxp1 is selective expressed in ICs relative to PCs, DMRT2 and HMX2 are selective expressed in type-A ICs and type-B ICs respectively.

Methods: To investigate the specific role of Foxp1 and its downstream trascriptional factors in kidney tubular system, we specifically deleted *Foxp1* expression in kidney distal nephrons and collecting ducts. We examined the effects of *Foxp1* on IC differentiation and urine acidification. RNA sequencing and Chip-seq were used to identify Foxp1 target genes. To dissect genetic network regulates IC differentiation, *Dmrt2 and Hmx2*-deficient mice were generated to determine the role of Dmrt2 and Hmx2 in IC differentiation. *Foxp1* deficient mice were cross with *Notch2* deficient mice to dissect the relation between Foxp1 and Notch signaling.

Results: Immunostainings confirmed Foxp1 is selectively expressed in ICs in collecting ducts. Absence of Foxp1 in kidney tubules led to the abolishment of IC differentiation in the collecting ducts, resulting in distal renal tubular acidosis. ChIP-seq and Ribo-Seq analysis found that Foxp1 binds to the promoters of Hmx2 and Dmrt2, two genes encoding transcription factors specifically expressed in type-A and -B ICs, respectively, and promotes their expression. Genetic disruption of Dmrt2 and Hmx2 expression blocks type-A and type-B IC differentiation, respectively. Deletion of Foxp1 blocks the excessive IC differentiation driven by loss-of-function of Notch2, but conditional knockin of Foxp1 do not alter the balance of PC/IC ratio in collecting ducts.

Conclusions: Foxp1 is required at the downstream of Notch signaling for the renal ICs differentiation and participated in acid-base regulation. Foxp1 regulated downstream transcriptional factors, Dmrt2 and Hmx2, which involved in the specification of distinct subsets of ICs.

Aryl Hydrocarbon Receptor Pathway Enhances Peritoneal Fibrosis in a Murine CKD Model Exposed to Peritoneal Dialysate

Pranav Yadati,[1] Saran Lotfollahzadeh,[1] Wenqing Yin,[1] Jean M. Francis,[1] Vipul C. Chitalia.[1,2] *[1]Boston University, Boston, MA; [2]VA Boston Healthcare System Jamaica Plain Campus, Boston, MA.*

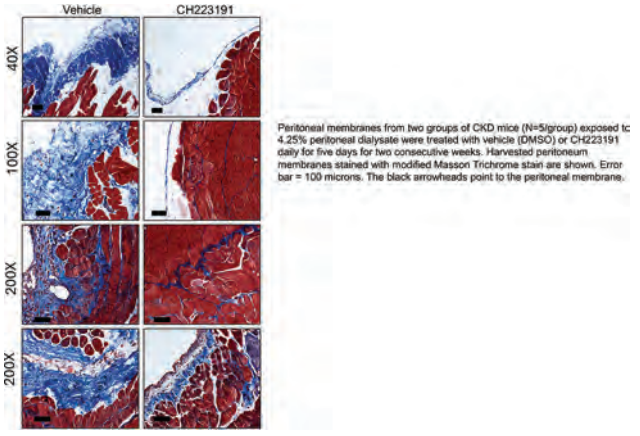
Background: Peritoneal dialysis (PD) results in profound alterations in the peritoneal membrane. Chronic kidney disease (CKD) is a profibrotic condition characterized by the retention of uremic toxins. The mechanisms contributing to the alterations in the peritoneal membrane, specifically due to uremic solutes and peritoneal dialysate remain poorly understood.

Methods: A mouse model of CKD with peritoneal dialysis was employed along with the molecular and imaging technique for mechanistic probing.

Results: We show in humans that CKD induces peritoneal membrane thickening, fibrosis, and collagen deposition and activates the Aryl Hydrocarbon Receptor pathway (AHR) in the subperitoneal vasculature. Leveraging a novel model of peritoneal dialysis in CKD mice, we confirm these CKD-induced changes in the peritoneal membrane, which are exacerbated upon exposure to the peritoneal dialysate. Peritoneal dialysate further augmented AHR activity in the endothelial cells of peritoneal microvasculature beyond CKD. Treatment of CKD mice with an AHR inhibitor in peritoneal dialysate resulted in a 5-fold decrease in subperitoneal space, a 9-fold decrease in fibrosis (see attached figure) and collagen deposition compared to vehicle-treated CKD mice. AHR inhibition reduced inflammation, subperitoneal neovascular areas, and its downstream target, tissue factor. An AHR inhibitor normalized pro-inflammatory and profibrotic cytokines, such as IL-6, MCP1, and MIP1 levels, in the peritoneal dialysate of CKD mice.

Conclusions: This study, for the first time, demonstrates the AHR activation in the endothelial cells of subperitoneal vessels in human CKD and mice, which is likely to prime the peritoneal membrane to dialysate-induced alterations. This study supports further exploration of AHR as a potential therapeutic target to preserve the structural and functional integrity of the peritoneal membrane in peritoneal dialysis.

Funding: Private Foundation Support



Peritoneal membranes from two groups of CKD mice (N=5/group) exposed to 4.25% peritoneal dialysate were treated with vehicle (DMSO) or CH223191 daily for five days for two consecutive weeks. Harvested peritoneum membranes stained with modified Masson Trichrome stain are shown. Error bar = 100 microns. The black arrowheads point to the peritoneal membrane.

TH-OR65

Unveiling the Role of Mucosal-Associated Invariant T Cells in Peritoneal Fibrosis and Its Therapeutic Targeting

Yuxiang Sun, Qiang Huang, Hui Peng. *The Third Affiliated Hospital of Sun Yet-sun University Department of Nephrology, Guangzhou, China.*

Background: One of the most common causes of discontinued peritoneal dialysis (PD) is progressive peritoneal fibrosis. Persistent low-grade inflammation induced by PD treatment is a driving force of peritoneal fibrogenesis. Mucosal-associated invariant T (MAIT) cells, known for their role in immune responses against microbial infections, have also been implicated in various inflammatory and fibrotic diseases. Despite their known importance, the specific mechanisms through which MAIT cells contribute to peritoneal fibrosis remain poorly understood.

Methods: Utilizing single-cell RNA sequencing (scRNA-seq) and flow cytometry, we characterized the activation and function of peritoneal MAIT cells from patients receiving long-term peritoneal dialysis (PD). We explored the molecular pathways activated by these cells, focusing on the MR1-mediated interaction with mesothelial cells and the subsequent activation of the mTORC1 signaling pathway. The effects of MAIT cell inhibition on fibrogenesis were examined using both in vitro models and Mr1 knockout mice.

Results: Our findings indicate that long-term PD enhances the activation of MAIT cells, specifically increasing the population of pro-inflammatory MAIT17 subtype cells. These cells contribute to peritoneal fibrosis by binding to the MR1 receptor on mesothelial cells, inducing hyperglycolysis via the mTORC1 pathway, which leads to peritoneal fibrogenesis. Furthermore, we demonstrate that blocking the MR1-MAIT interaction, either through genetic knockout or pharmacological inhibition with Ac-6-FP, mitigates fibrosis, suggesting a novel therapeutic strategy.

Conclusions: This study underscores the crucial role of MAIT cells in the pathogenesis of peritoneal fibrosis and identifies them as potential targets for therapeutic intervention. The findings suggest that while some aspects of MAIT cell involvement in fibrosis are beginning to be understood, comprehensive insights into their roles in various pathological conditions remain limited, warranting further investigation.

Iron Deficiency Increases Mortality Risk among Incident Peritoneal Dialysis Patients

Vladimir Rigodon,[1,2] Brianna Hartley,[1,3] Peter G. Pecoits,[4] John W. Larkin,[2] Yue Jiao,[2] Luca Neri,[5] Len A. Usvyat,[2] Dinesh K. Chatoth,[2] Jeffrey L. Hymes,[2] Franklin W. Maddux,[6] Jeroen Kooman,[7] Thyago P. Moraes,[1] Pasqual Barretti,[10] Peter Kotanko,[8,9] Roberto Pecoits-Filho,[1] Murilo H. Guedes.[1] *[1]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [2]Fresenius Medical Care, Waltham, MA; [3]Nova Southeastern University, Clearwater, FL; [4]Indiana University, Bloomington, IN; [5]Fresenius Medical Care, Crema, Italy; [6]Fresenius Medical Care AG, Bad Homburg, Germany; [7]Maastricht University Medical Center, Maastricht, Netherlands; [8]Renal Research Institute, New York, NY; [9]Icahn School of Medicine at Mount Sinai, New York, NY; [10]Universidade Estadual Paulista, São Paulo, Brazil.*

Background: Iron deficiency (ID) can be more common in peritoneal dialysis (PD) vs hemodialysis. Administration of IV iron can be more challenging in PD and may influence iron repletion. Outcomes related to ID in PD are undefined. We investigate mortality risk associated with transferrin saturation (TSAT) and ferritin levels among patients starting PD in a national dialysis network.

Methods: We evaluated data on adults (age ≥18 years) who started PD at a US dialysis network (Fresenius Medical Care, Waltham, MA) between December 2004 and January 2011. Patients were required to be on PD for ≥180 days, and have ≥1 value for TSAT, ferritin and hemoglobin (Hgb). We considered categories for TSAT (≤20%, >20-≤30% reference, >30-≤40%, >40-≤50% and >50%). Cox proportional hazards model assessed mortality risk with stepwise adjustment across 6 models.

Results: Of 11,261 patients, majority were male (54.4%), Caucasian (70.4%) and mean age of 55.2 years. Mean Hgb, TSAT and ferritin values at baseline (≤180 days after PD start) were 12.1 g/dL, 31% and 443.6 ng/ml, respectively. ID (TSAT ≤20%) was present in 10.4% of patients. TSAT ≤20% was found to associate with higher mortality risk across all models (fully adjusted model hazard ratio (HR)=1.30, 95% confidence interval (CI)=1.09, 1.55) (**Figure 1**). TSAT levels >20% were not associated with mortality risk.

Conclusions: We observed about 10% of patients starting PD have ID as seen by TSAT ≤20% during the first 6 months of therapy. ID in incident PD was found to associate with a 30% increased mortality risk. These findings expand upon the emerging science on ID risks in non-dialysis dependent kidney disease (Guedes M et al., JASN 2021), and highlight the importance of evaluating ID in PD, regardless of Hgb status.

Initial Evaluation of Sodium-Free Intraperitoneal 30% Icodextrin/ 10% Dextrose Solution to Test Short-Term Safety, Tolerability, and Preliminary Efficacy

Christopher W. McIntyre,[1] Patrik Deleaval,[1,2] Jarrin D. Penny,[1] Amy Freeman.[1] *[1]London Health Sciences Centre London Kidney Clinical Research Unit, London, ON, Canada; [2]Nephrocare Tassin Charcot, Sainte-Foy-les-Lyon, France.*

Background: Currently used peritoneal dialysis (PD) solutions contain salt limiting their diffusive ability to remove sodium (Na). Na removal is largely dependent on convection, and this becomes increasingly challenging with impending ultrafiltration failure, leading to accumulation of tissue based Na and contributing to increased morbidity/mortality. The aim of this study was to demonstrate the short-term safety, tolerability, and efficacy of a Na-free, PD solution (based 30% Icodextrin) to achieve high-efficiency peritoneal Na and volume removal.

Methods: We studied 10 patients in a single-arm, open label, interventional trial. Stable PD patients aged > 18 years without uncontrolled diabetes mellitus or active infections were enrolled. Study participants received one 4-6-hour dwell of a Na-free PD solution (500 ml instillation volume). They were monitored for pain, hemodynamics, serum sodium and peritoneal removal of sodium and water.

Results: Participants who completed the study reported mild to moderate abdominal pain (1-2/5 pain scale). BP, HR, cardiac output, and stroke volume did not change throughout procedure. Total Na removed per session was 5.69 ± 0.88 g (effluent), ultrafiltrate volume removed was 1975 ± 319 mL, total weight reduction 1.02 ± 0.24kg (p= 0.03). Serum Na remained stable throughout treatment (134.4 ± 5.7mmol/L - 133.3 ± 6.8mmol/L). Na concentration in effluent progressively increased each hour from 90.80 ± 12.36 to 125.4 ± 7.61 mmol/L (p = 0.002). Serum osmolality remained unchanged

Conclusions: We have demonstrated the safety, efficacy, and tolerability of a new Na-free hypertonic PD solution, able to remove >5 g of Na and approximately 2 L of fluid in a single session, without hemodynamic challenge or short term hyponatremia.

Return to Peritoneal Dialysis after a Hemodialysis Transfer: A Multistate Analysis of the Canadian Organ Replacement Register

Louis-Charles Desbiens,[1] Remi Goupil,[2] Karthik K. Tennankore,[3] Jeffrey Perl,[4] Emilie Trinh,[5] Christopher T. Chan,[6] Annie-Claire Nadeau-Fredette.[7] *[1]Universite de Montreal, Montreal, QC, Canada; [2]Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada; [3]Dalhousie University, Halifax, NS, Canada; [4]St Michael's Hospital, Toronto, ON, Canada; [5]McGill University Health Centre, Montreal, QC, Canada; [6]University Health Network, Toronto, ON, Canada; [7]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada.*

Background: Transfers to hemodialysis (HD) are challenging for patients on peritoneal dialysis (PD). Clinical outcomes after these transfers are poorly known.

Methods: We analyzed patients from the Canadian Organ Replacement Registry (CORR) who received at least 30 days of PD between 2005 and 2019. All transfers from PD to facility HD were identified, regardless of their duration. Patients were followed until December 2019 for outcomes (death, kidney transplant, transfer to home HD, return to PD) and were censored if a second PD-to-HD transfer occurred. We used a multi-state modelization approach, treating different outcomes as states between which patients can sequentially transition.

Results: From 18,956 patients entering PD, 9,746 (51%) patients experienced a total of 18,683 PD-to-HD transfers (mean 1.92 transfers/patient, range 1 to 27) after a median vintage of 1.8 years. Populational trajectories after these transfers are displayed in **Figure 1a**. A majority of patients (66%) resumed PD in the following year; this odd was highest during the first months and sharply fell afterwards (**Figure 1b**). Mortality rates were also high following a PD-to-HD transfer, but resuming PD remained more likely than death up to nine months after the transfer (**Figure 1c**). Five years after a transfer, 50% of patients had died, 6% of patients had transferred to home HD and 34% had received a transplant.

Conclusions: Transfers to HD are common among patients receiving PD in Canada, and, despite a heighten post-transfer mortality risk, a majority of patients can resume PD. These findings identify the post-transfer window as a key period to enhanced clinical care (e.g. using a nurse navigator) in order to improve patients' outcomes.

Prepivotal Study Exploring Safety, Efficacy, and Usability of the Automated Wearable Artificial Kidney (AWAK) PD Device

Marjorie W. Foo,[1] Edwina A. Brown,[3] Arsh Jain,[4] Martin J. Schreiber,[2] Sheena Gow,[2] Jason T. Lim,[2] Sanjay Singh,[2] Mandar Gori,[2] Suresha B. Venkataraya,[2] Htay Htay.[1] *[1]Singapore General Hospital, Singapore, Singapore; [2]AWAK Technologies Pte Ltd, Singapore, Singapore; [3]Imperial College London, London, United Kingdom; [4]London Health Sciences Centre, London, ON, Canada.*

Background: The AWAK PD is an innovative, wearable sorbent-based device providing tidal PD. The device, weighing about 3kg, automates fills and drains, with adjustable glucose for customized ultrafiltration (UF) requirements.

Methods: 14 subjects underwent screening (30 days), titration period (up to 21 days), washout (2 days), and a treatment period of at-home use (7 days) with an optional extension (23 days), at a single Singapore hospital. A nomogram and PD prescribing titration guide were developed to determine cartridge type, therapy duration, initial fill tonicity and glucose (absorbed/added) to achieve target UF. The primary aim was to complete at least 70% of sorbent dialysis in each therapy. Other aims included maintaining body weight within 5% of target weight, having stable plasma biochemistry and electrolytes, and assessing patients' experience using symptom and device usability questionnaires. Illness Intrusiveness Rating Scale (IIRS) was assessed in the 3 subjects using AWAK for 30 days.

Results: 11 subjects (10 male, mean±SD age 60±7 years and dialysis vintage 21±9 months) entered the 7-day treatment period, with 1 withdrawal. 3 of these subjects completed 30 days. No device-related serious adverse events occurred. 95% of therapies conducted (76/80) were completed. Optimal UF was achieved by adjusting the dextrose concentrations. All subjects remained within 5% of their target weight. Table 1 depicts plasma biochemistry and UF results. Usability scores were high; 10/11 patients agreed they were confident using the device and 8 felt the device was useful, 3 were neutral. IIRS scores improved in the 3 patients on AWAK for 30 days (average score: 38 at baseline; 20 after AWAK).

Conclusions: AWAK PD is safe to use and a reduction in the IIRS is noted after 30 days of use; reasons could range from ease of use of the device to increased flexibility to suit their lifestyle. Minor device modifications can be done to optimize solute clearance.

Comparing Care Models in Assisted Peritoneal Dialysis: Insights from the Alberta Experience

Veronica Hammer,[1] Warda Munawar,[1] Chel Lee,[4] Danielle E. Fox,[1] Robert R. Quinn,[1,2] David Ward,[1] Jennifer M. MacRae.[1,3] *[1]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [2]University of Calgary Department of Community Health Sciences, Calgary, AB, Canada; [3]University of Calgary Department of Cardiac Sciences, Calgary, AB, Canada; [4]University of Calgary, Calgary, AB, Canada.*

Background: Assisted peritoneal dialysis (aPD) provides home-based support by trained healthcare professionals for individuals otherwise ineligible for independent peritoneal dialysis (PD). Alberta Kidney Care South (AKC-S) initiated an aPD program in 2011, initially led by licensed nursing practitioners (LPNs) until transitioning to healthcare aides (HCAs) in July 2018. Our objective was to assess outcomes of participants in the aPD program based on the care delivery model (LPN vs. HCA).

Methods: This quantitative study utilized an interrupted time-series model to analyze participants in the AKC-S aPD program from its inception in 2011 until December 31, 2021. Deidentified data was extracted from the Nephrology electronic database. Participants were categorized into two phases based on the implementation of the care delivery model change from LPN to HCA on July 1, 2018. Phase one comprised participants who initiated aPD before this date, while phase two included those who began aPD after. The primary outcome was monthly median exit time from PD between the two care groups. Endpoints were defined as death, transplant, transfer to in-center HD, transfer to independent PD, or exit from the program. Secondary outcomes included reason for program exit and rates of peritonitis compared between the two phases.

Results: A total of 135 patients received aPD (mean age= 70.7 ± 11.2 years; 44.4% female). We had 57 individuals in phase one, and 55 in phase two (23 still active participants were excluded), with no difference in sex between groups (p = 0.055). We found no difference in the time spent on PD between the LPN phase (1.89 [1.02, 3.85] years) and

the HCA phase (1.41 [0.59, 3.25]), p= 0.41. There was no significant difference in the reason for exit after the change in care model (p= 0.64). The incidence rate of peritonitis in phase one was 0.403 (25 participants) and 0.466 (29 participants) in phase two, which was not statistically significant, p = 0.60.

Conclusions: Our study revealed no significant difference in the duration of peritoneal dialysis (PD), reasons for program exit, or incidence of peritonitis between the LPN and HCA care models. The HCA model offers a cost-effective alternative to in-center modalities while offering personalized, in-person services that may greatly enhance the quality of care for those undergoing peritoneal dialysis.

TH-OR71

Impact of a Home Dialysis Virtual Longitudinal Education Series

Wen Qing Wendy Ye,[1] Anjali B. Saxena,[5,6] Kerry Leigh,[4] Yuvaram N. Reddy.[2,3] *[1]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; [2]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [3]Corporal Michael J Crescenz VA Medical Center, Philadelphia, PA; [4]American Society of Nephrology, Washington, DC; [5]Stanford University School of Medicine, Stanford, CA; [6]Santa Clara Valley Medical Center, San Jose, CA.*

Background: Home dialysis has clinical benefits over in-center hemodialysis (HD), yet as of 2020, home dialysis use is low at 13.3% in the United States. One barrier to expanding home dialysis is a lack of experience amongst fellows due to inadequate training opportunities. In 2023, the American Society of Nephrology (ASN) launched the Home Dialysis Virtual Longitudinal Education Program with Home Dialysis University (HDU) to increase exposure for fellows through virtual case-based discussions. We aimed to understand the impact of this program.

Methods: We evaluated the ASN-HDU program using mixed-methods. We sampled participants from (1) fellows who attended HDU and the ASN virtual program (ASN-HDU), and (2) fellows who only attended HDU from Aug-Sep 2023. We sent a survey in Sep 2023 to assess baseline comfort in home dialysis. Results of the survey were used to design the interview guide for qualitative thematic analysis. We used a constant comparative method to identify themes that described the participant's experiences with home dialysis and the impact of the ASN-HDU program.

Results: Survey response rates were 65.5% (19/29) and 50% (33/66) in the ASN-HDU arm and HDU arm, respectively. Participants felt comfortable with management of peritoneal dialysis but not home HD (Fig 1). We completed 10 semi-structured interviews between Dec 2023 – Mar 2024, with 5 participants from the ASN-HDU arm and 5 from the HDU arm. Three themes emerged: (1) HDU complements fellowship training by filling in gaps in home dialysis knowledge, (2) the ASN virtual program provides an opportunity for longitudinal exposure to topics learned during HDU, which helps retain knowledge and incorporate learning into practice, and (3) all participants voiced desire for more exposure to home dialysis including in-person training, and expansion of the ASN-HDU program.

Conclusions: Baseline survey results suggest a lack of comfort in home HD. ASN-HDU trainees felt the program addresses training gaps in home dialysis and provides an opportunity to retain knowledge. Results from a follow-up survey, sent May 2024, will be available at Kidney Week to evaluate changes in comfort levels among ASN-HDU fellows.

Home Hemodialysis Skills Assessment Predicts Treatment Survival in Patients on Home Hemodialysis

Koji Tomori, Tsutomu Inoue, Daichi Fukaya, Hiroaki Amano, Yusuke Watanabe, Hirokazu Okada. *Saitama Ika Daigaku, Iruma-gun, Japan.*

Background: During home hemodialysis (HHD), patients require adequate skills and self-care abilities. At HHD initiation, patients are instructed in standard procedures and emergency protocols. However, adherence to these instructions may decrease as dialysis duration increases. Additionally, the required skills and self-care abilities may decline with age and changes in physical abilities, which may interfere with the proper execution of instructions. Our hospital administered the Home Hemodialysis Skills Assessment (HHSA) to patients on HHD to assess their adherence to standard procedures and emergency protocols. This study aimed to examine whether HHSA results can predict the subsequent HHD continuation rates.

Methods: This was a retrospective cohort study of patients who underwent HHSA at our hospital between January 1, 2015, and December 31, 2016. The HHSA consists of six items (45 total points): 1. Dialysis machine setup, 2. needle cannulation and initiation, 3. procedures during treatment, 4. alarm response, 5. termination procedures, and 6. Post-treatment clean-up. Patients were divided into two groups based on the median total score and followed up until failure of the HHD technique, death, or the end of the study (December 2021). The primary outcome was the treatment survival rate, while the secondary outcomes were the death-censored technique and overall survival rates.

Results: Fifty-four patients with a mean age of 56.8 years and a median HHD treatment duration of 67 months were included. The median HHSA total score was 35. There were no significant differences between the high-score group (score >35) and the low-score group (score ≤35) in terms of age, comorbidities, HHD treatment history, or training duration at HHD initiation. However, over the total follow-up period of 300 patient-years, the low-score group had higher rates of HHD discontinuation (15.3% vs. 46.4%, p = 0.023) and technique failure (35.7% vs. 11.5%, p = 0.046) than the high-score group. Multivariate analysis identified age, heart disease, and HHSA total score as predictors of survival after HHD treatment.

Conclusions: HHSA is a predictor of treatment continuation rate in patients undergoing HHD. It may predict individual capability to continue HHD and determine the appropriate timing for transitioning from HHD to in-center dialysis.

Increased Blood Pressure in Mice with Impaired Function of Afferent Renal Nerves Due to Lack of Sodium Nav1.8 Channels

Kristina Rodionova,[1] Eva Hutter,[1] Tilmann Ditting,[1,2] Nada Cordasic,[1] Karl F. Hilgers,[1] Peter Linz,[1] Mario Schiffer,[1] Roland E. Schmieder,[1] Kerstin U. Amann,[1] Roland Veelken.[1,2] *[1]Friedrich-Alexander-Universitat Erlangen-Nurnberg, Erlangen, Germany; [2]Paracelsus Medizinische Privatuniversitat - Nurnberg, Nurnberg, Germany.*

Background: Recently we demonstrated that reduced activity of the afferent renal neural pathway is associated with absent voltage-gated sodium Nav1.8 channels. Now we tested the hypothesis that Nav1.8 KO mice show elevated blood pressure and end organ damage with signs of increased sympathetic activity.

Methods: In Nav1.8 KO mice and C57BL6 (28th week of age), we measured blood pressure (BP), heart rate (HR), activity of renal afferent neurons (portion of highly active tonic neurons with renal afferents harvested from dorsal root ganglion neurons DRG Th11-L2), afferent renal nerve activity (ARNA), renal sympathetic nerve activity (RSNA) as well as infiltration and fibrosis in heart and kidney tissue (deposition of collagen 1 and 4, Counts of CD 68 and CD 3 positive cells).

Results: Blood pressure of Nav1.8 KO mice (C57BL6J-Scn10atm1Jwo) was significantly elevated compared to wild type controls (11±4.8mmHg vers 98±5.2 mmHg; Nav1.8 KO mouse vs control * $p<0.05$.) Nav1.8 KO mice showed increased Collagen Type 1 and 4, CD 68 and CD 3 cells in the kidney and heart (t-test, * $p<0.05$). In Nav1.8 KO mice, only a single cell out of 70 showed a high firing frequency in neurons with dendrites from the kidney versus C57BL6 controls 28 out of 115 (Nav1.8 KO mouse vs control, z-test, *$p<0.05$). Eventually, all data suggested reduced ARNA with disinhibition of RSNA.

Conclusions: We demonstrate for the first time that the absence of a single specific sodium channel impairing afferent renal neural pathways leads to disinhibition of sympathetic nerve traffic with increased blood pressure and end-organ damage

TH-OR74

High Phosphate-Induced Hypertension Is Mediated by Peripheral Fibroblast Growth Factor 23 Translocation into the Central Nervous System, Fibroblast Growth Factor Receptor Activation, and Sympathetic Nervous System Stimulation

Isabelle Carroll, Johanne V. Pastor, Han Kyul Kim, Wanpen Vongpatanasin, Orson W. Moe. *The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Recent research links high phosphate (P) intake to hypertension via activation of the sympathetic nervous system, but the intermediate mechanisms are unknown. P-rich diets prompt the release of fibroblast growth factor 23 (FGF23) from bone cells to promote negative P balance. In the kidney, FGF23 inhibits P reabsorption and vitamin D activation. Although FGF23 protein and its receptors are known to be present in the central nervous system (CNS), their function and specifically their role in blood pressure regulation during high P intake remain elusive.

Methods: Morphometric features and renal sympathetic nerve activity (RSNA) body weight and organ-body weight ratios were assessed in normal-P (NP) and high P-treated (HP) rats under anesthesia and after decerebration. FGF23 protein in the CNS was measured by immunoblots (IB) and immunochemistry (IHC). FGF23 translocation into the brain was measured by infrared (IR) labelled FGF23 injected intravenously. FGF23 activity blockade was achieved by intracerebroventricular injection of FGFR inhibitors.

Results: Resting mean arterial pressure was higher in HP rats compared to NP rats (P<0.01). FGF23 protein was higher in peripheral blood, cerebrospinal fluid (CSF) and brain tissue in HP rats. IHC revealed FGF23 in choroid plexus and areas of the brainstem, and IB showed higher FGF23 in the hippocampus and brainstem but not cerebral cortex. Injection of IR-FGF23 showed robust signals in choroid plexus, and parts of the brain stem. The HP-induced hypertensive effects were blocked by pharmacologic inhibition of FGFR by broad spectrum and FGFR4 inhibitors injected intracerebroventricularly; and not by the FGF23 C-terminal peptide. FGFR4 inhibition in the CNS reduced HP-induced sympathetic nervous system activation.

Conclusions: We conclude that the hypertensive effects of HP during simulated exercise are mediated by the translocation of circulating FGF23 across the blood/CSF barrier (BCSFB) and occurs independently of the canonical FGF23 pathway leading to exaggerated sympathetic outflow and elevated blood pressure during muscle contraction.

TH-OR75

Key Role of Neuroendothelial Cells in Renal Blood Flow Regulation

Georgina Gyarmati, Alejandra Becerra Calderon, Audrey Izuhara, Sachin K. Deepak, Greta H. Trogen, Janos Peti-Peterdi. *University of Southern California, Los Angeles, CA.*

Background: Transcriptomic studies identified many vascular endothelial cell (EC) subtypes in multiple organs including the kidney. However, their functions are incompletely understood. Our recent studies discovered and characterized the novel minority EC subtype named neuro-endothelial cells (NECs) with endothelial and neuronal characteristics. NECs were found exclusively in small resistance arterioles of the three most metabolically active organs that show the best blood flow regulation, with the highest density in the brain and retina> kidney >heart. Here we hypothesized that NECs are key players in organ blood flow regulation.

Methods: A comprehensive NEC research toolbox including high-resolution transcriptome analysis of mouse brain and kidney ECs, transgenic mouse models, and intravital multiphoton microscopy (MPM) were used.

Results: Single-cell transcriptome analysis demonstrated that in contrast to other ECs, NECs highly express several traditional (e.g., Nos1, Adra2c, Vegfc, Angpt1, Egfl8) and novel (e.g., Cytl1, Mgp, Gkn3) vasoactive and angiogenic factors. Gene Set Enrichment Analysis of the top NEC genes suggested the role of NECs in blood vessel diameter maintenance and vasculature development. MPM of intact kidney arterioles revealed robust NEC-specific calcium responses to acute norepinephrine challenge suggesting the role of NEC adrenoceptors in stress-induced redistribution of regional blood flow. MPM imaging of NEC-Ai27 mouse model revealed that acute optogenetic stimulation of NECs led to rapid vasodilation (D/D0=152+/-7%, p<0.0001). This effect was blunted in mice pretreated with the Nos1 specific inhibitor 7NI suggesting the main role of NEC neuronal nitric oxide synthase in the maintenance of organ blood flow. In contrast, the acute optogenetic inhibition of single NECs in NEC-Ai39 mouse model resulted in imminent vasoconstriction (D/D0=75+/-4%, p<0.01). Further, treatment with Cytl1, a novel angiogenic factor highly enriched in NECs, resulted in EC calcium responses and vasodilation acutely, and in increased capillary density and clonal EC remodeling chronically in Cdh5-GCaMP and Confetti mice, respectively.

Conclusions: In conclusion, the newly discovered NEC molecular mechanisms may play a major role in organ blood flow regulation and may be targeted in future therapeutic development for kidney diseases.

TH-OR76

Activation of the Skin Renin-Angiotensin System Exacerbates Angiotensin II-Induced Hypertension via Skin Vasoconstriction

Shinya Taguchi,[1] Kengo Azushima,[1] Kento Kitada,[2] Norihiko Morisawa,[3] Hiromichi Wakui,[1] Ryutaro Morita,[1] Kentaro Kawasoe,[1] Akira Nishiyama,[2] Kouichi Tamura.[1] *[1]Department of Medical Science and Cardiorenal Medicine, Yokohama City University Graduate School of Medicine, Yokohama, Japan; [2]Department of Pharmacology, Faculty of Medicine, Kagawa University, Kida-gun, Japan; [3]Cardiovascular and Metabolic Disorders Program, Duke-NUS Medical School, Singapore, Singapore.*

Background: Recent studies suggest skin vasoconstriction and sodium (Na^+) accumulation are linked with hypertension. The skin has a localized renin-angiotensin system (RAS), a key regulator of blood pressure (BP), but its functional role remains unclear. This study aims to investigate the role of skin RAS in hypertension.

Methods: Skin tissue from 58 individuals, including hypertensive patients, was used to evaluate the association between skin RAS component expression and office BP. Mice lacking ATRAP (type-1 angiotensin II (Ang II) receptor (AT1R)-associated protein), which selectively inhibits pathological AT1R signaling, in skin keratinocytes (KO: $K14^{Cre}$;$ATRAP^{flox}$) were generated. Hypertension was induced by Ang II (500 ng/kg/min) administration.

Results: In the human study, skin expression of ATRAP was inversely correlated with systolic BP ($r = -0.41$, $P < 0.01$). Telemetry analysis showed that BP elevation and related cardiac hypertrophy were exacerbated in KO mice compared to controls (mean BP, 123.3 ± 4.7 vs. 132.6 ± 3.1 mmHg, $P < 0.05$; heart/body weight, 4.7 ± 0.4 vs. 5.2 ± 0.7, $P < 0.05$). Ang II-infused KO mice had higher skin angiotensinogen levels ($P < 0.05$), while levels in the kidney and heart were similar in both groups. Ang II levels in the skin were also significantly higher in Ang II-infused KO mice than in controls, whereas plasma Ang II levels were comparable in both groups, suggesting skin-specific enhancement of local RAS activity. AT1R blocker treatment eliminated exaggerated Ang II-induced hypertension and enhancement of skin RAS activity in KO mice. Sympathetic nerve activity, plasma volume, and skin Na^+ content did not differ between the groups. In Ang II-infused KO mice, urine volume per water intake increased ($P < 0.001$), despite similar body weight changes in both groups, suggesting decreased extra-renal water loss. Consistent with these findings, skin blood flow and transepidermal water loss were decreased in Ang II-infused KO mice ($P < 0.001$ and $P < 0.01$, respectively). These differences, including exaggerated BP elevation, were eliminated by skin vasodilation via body temperature elevation.

Conclusions: Enhanced skin RAS activity contributes to BP elevation via skin vasoconstriction. Skin RAS may be a novel target for treating hypertension.

TH-OR77

T Cells Drive Kidney Memory for Hypertension

Katherine S. Deck, Yunmeng Liu, Christoph J. Mora, Tonya M. Rafferty, Shengyu Mu. *University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: For decades, it has been known that the kidney contains a pathogenic memory for salt-sensitive hypertension. For example, kidney transplantation may transfer salt sensitivity and high blood pressure from hypertensive donors to normotensive recipients. However, the culprit cells and mechanisms behind this memory of salt sensitivity remain elusive. Our recent findings suggest that during hypertension, CD8+ T cells (CD8Ts) persist long-term within the kidney, potentially acting as a memory population that perpetuates salt retention. Here, we hypothesize that the establishment of kidney resident memory CD8Ts (CD8Trms) generates the memory of salt sensitivity, resulting in chronic progression and recurrence of hypertension.

Methods: In this study, we utilized two mouse models of hypertension: a classic DOCA-salt model and a novel Angiotensin-II (Ang II) + high salt rechallenge-induced salt memory model. To investigate the role of Trms in the pathogenesis of salt-sensitive hypertension, we employed T-cell specific TGFβRII KO (mTSP-TGFβR KO) mice, which are deficient in Trm formation, alongside wild-type (WT) controls. Blood pressure in all mice was recorded using biotelemetry, and T cells were analyzed using flow cytometry.

Results: In DOCA-salt-treated WT mice, a significant expansion of CD8Trms occurred accompanied by elevated blood pressure. In contrast, mTsp-TGFβR KO mice, which could not develop Trm, exhibited attenuated blood pressure. Testing the recurrence of hypertension, both WT and mTSP-TGFβR KO achieved a similar degree of hypertension during the initial Ang II-salt administration. Intriguingly, only WT mice, with a significant Trm population, showed rapid recurrence of hypertension upon high salt rechallenge. In contrast, mTSP-TGFβR KO mice, lacking Trm development, appeared protected against recurrent hypertension induced by the high salt re-challenge. Flow cytometry confirmed the presence of a substantial CD8Trm population in WT mice, which was absent in mTSP-TGFβR KO mice.

Conclusions: In summary, our study elucidates the mechanisms by which immunological memory, through the formation of kidney-resident memory CD8Ts, underpins the kidney's "memory of salt sensitivity," leading to lifelong and recurring hypertension.

Endoplasmic Reticulum Stress Immediate Early Response 3 Gene Mediates Myeloid-Specific Salt-Sensitive Hypertension in Humans

Jeremiah M. Afolabi,[1] Annet Kirabo.[1,2] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt Institute for Global Health, Nashville, TN.*

Background: Salt sensitivity of blood pressure is a significant risk factor for cardiovascular morbidity and mortality, and currently lacks a diagnostic marker or established treatment protocol. Our previous research indicated that immune cells play a role in salt-sensitive hypertension, but the specific mechanisms are not fully understood. Expression of the early response gene, Immediate early response 3 (IER3) is induced by varying forms of cellular stress and proinflammatory cytokines, but its role in salt-sensitive hypertension is unknown. We hypothesize that high dietary salt intake activates IER3 expression via proinflammatory signaling thereby contributing to salt-sensitive hypertension.

Methods: To test this hypothesis, we conducted bulk RNA sequencing analysis on isolated human monocytes with and without high salt. We also performed in vivo studies on humans living with hypertension using the rigorous Weinberger protocol, followed by single-cell transcriptome profiling using RNA-Seq analysis in peripheral blood mononuclear cells (PBMCs).

Results: We found that in vitro high salt treatment increased human monocyte expression of the ER stress marker, ATF4 (5216.09 ± 343.86 vs 7566 ± 549.17, p=0.0014), in addition to TNF-α (117.09 ± 23.71 vs 357.82 ± 59.62, p=0.0013), FAS (201.45 ± 25.42 vs 422.64 ± 52.15, p=0.0024), NFKB2 (4182.18 ± 401.24 vs 6061.82 ± 692.49, p=0.0192), and IER3 (10146.64 ± 2868.74 vs 19009.09 ± 5343.53, p=0.0759) when compared to normal salt (n=11). In vivo single cell transcriptomic analysis in PBMCs revealed that in response to high salt treatment, IER3 expression changes dynamically with blood pressure (Diastolic Blood Pressure (DBP): r= -0.641, p=0.0074; Mean arterial pressure (MAP): r= -0.6321, p=0.0086; Pulse Pressure (PP): r=0.5033, p=0.0468) in salt-sensitive but not salt-resistant patients (n=8). Furthermore, changes in blood pressure were positively correlated with increased NFKB2 (SBP: r=0.5276, p=0.0357; DBP: r=0.5366, p=0.0321; MAP: r=0.5872, p=0.0168), and TNF-α (PP: r=0.4505, p=0.0799) but not FAS gene expressions in salt-sensitive, but not salt-resistant patients (n=8).

Conclusions: These findings suggest that IER3 plays a role in salt-sensitive hypertension, possibly through the NFKB signaling pathway. The IER3 gene could serve as a valuable diagnostic marker for salt-sensitive hypertension or a novel treatment approach.

TH-OR79

Renal Medullary Bilirubin and Biliverdin Reductase Attenuate Angiotensin II-Induced Hypertension

Gertrude Arthur, David E. Stec. Stec Lab. *University of Mississippi Medical Center Holmes County, Jackson, MS.*

Background: Hypertension is a risk factor for CKD and despite the major advances in drug development to target this disease, uncontrolled blood pressure is a significant problem among hypertensive patients. An increase in circulating bilirubin has been shown to attenuate angiotensin (Ang) II-induced hypertension and improve renal hemodynamics. However, the intrarenal mechanisms that mediate the anti-hypertensive effects of bilirubin are not yet known. The goal of the present study was to test the hypothesis that generation of bilirubin in the renal medulla plays an important role in the regulation of blood pressure (BP) in response to Ang II.

Methods: Twenty-week-old male C57Bl/6J mice were implanted with intrarenal medullary interstitial (IRMI) catheters following unilateral nephrectomy. After this time, biliverdin IXα was specifically infused into the kidney (3.6 mg/day) for 3 days prior to implantation with an osmotic minipump delivering Ang II (1000 ng/kg/min). BP was recorded for 3 days, 1 week after minipump infusion, in conscious mice. To further explore the antihypertensive role of renal medullary bilirubin generation, mice with specific deletion of biliverdin reductase-A (BVRA) in the thick ascending loop of Henle (TALH) were generated by crossing $BVRA^{flox/flox}$ mice with Tamm-Horsfall Cre (THP-Cre) mice. At 20 weeks, THP-Cre/$BVRA^{flox/flox}$ and control mice were infused with Ang II for 2 weeks.

Results: IRMI infusion of biliverdin significantly decreased BP as compared to mice infused with vehicle (118 ± 4 vs. 158 ± 2 mmHg, p<0.05, n=6/group). THP-Cre/$BVRA^{flox/flox}$ mice did not exhibit any differences in baseline BP as compared to $BVRA^{flox/flox}$ mice (108 ± 2 vs. 108 ± 2 mmHg, n=5/group). However, Ang-II infusion resulted in significantly higher BP measured in conscious mice 7 days after implantation in THP-Cre/$BVRA^{flox/flox}$ as compared to $BVRA^{flox/flox}$ mice (152 ± 2 vs. 140 ± 3 mmHg, p<0.05, n=5/group). Also, protein expression of renal outer medullary potassium (ROMK) channel was increased in THP-Cre/$BVRA^{flox/flox}$ mice infused with Ang II (1.05 ± 0.09 vs. 0.7 ± 0.20 AU, p<0.05, n=4/group)

Conclusions: Together, these findings show that medullary bilirubin and biliverdin reductase can improve hypertension and that mechanisms that increase bilirubin and biliverdin reductase in the renal medulla could be an effective approach to treat hypertension.

Mild Hyperuricemia Is Beneficial for Males with Salt-Sensitive Hypertension and Associated Kidney Damage

Lashodya V. Dissanayake,[1] Adrian Zietara,[1] Vladislav Levchenko,[1] Christine A. Klemens,[1,2] Oleg Palygin,[3] Alexander Staruschenko.[1,4] *[1]University of South Florida Morsani College of Medicine, Tampa, FL; [2]Hypertension and Kidney Research Center, Tampa, FL; [3]Medical University of South Carolina, Charleston, SC; [4]James A. Haley Veterans' Hospital, Tampa, FL.*

Background: Hyperuricemia is associated with worse outcomes for chronic kidney disease (CKD). In large-cohort clinical trials, attempts to control uric acid (UA) did not produce clinically meaningful benefits. Humans don't have the enzyme uricase due to an evolutionary mutation that is hypothesized to have been an adaptation to increase blood pressure under low-salt conditions. We hypothesized that mild asymptomatic hyperuricemia is beneficial in controlling the progression of salt-sensitive (SS) hypertension (HTN), a prevalent trait that occurs in half of HTN patients.

Methods: Both male and female Dahl SS rats were fed a diet with a uricase inhibitor, oxonic acid (2%) (Oxo), and high salt (HS) (4% NaCl). Radiotelemetry, immunohistochemistry, and RNA-Seq were used for analyses.

Results: After 3 wks, in response to Oxo supplementation, both sexes showed a significant increase of UA in plasma compared to their respective HS-only controls (males: 0.63±0.07 vs. 2.17±0.34; females: 0.78±0.15 vs. 2.04±0.35 mg/dl, HS vs. HS/Oxo). Interestingly, only male HS/Oxo rats showed a significant increase in uricosuria (males: 0.23±0.03 vs. 0.45±0.06; females: 0.26±0.06 vs. 0.26±0.01 UA/Cre, HS vs. HS/Oxo). Moreover, mild hyperuricemia was associated with a significant attenuation of the progression and magnitude of the mean arterial pressure in male but not female rats (males: 157±3 vs. 136±3; females: 155±6 vs. 154±5 mmHg, HS vs. HS/Oxo). The male HS/Oxo group had a lower kidney weight/body weight ratio and lower protein cast accumulation, indicating lower kidney damage. Oxo treatment led to less oxidative damage in the tubules compared to HS-only, as evidenced by the lower fluorescence intensity of 8-oxodG. RNA-Seq of male kidneys revealed that HS/Oxo treatment (vs. HS only) increased expression in *Mas1* (MAS receptor), *Klk-1* (Kallikrein-1), and *Pcsk6* (PCSK6 enzyme), which can all lead to the activation of different vasodilatory pathways.

Conclusions: Our study showed that in male but not female Dahl SS rats, asymptomatic mild hyperuricemia accompanied by hyperuricosuria ameliorates the progression of SS HTN and protects kidneys from further damage. Thus, our findings challenge the notion of hyperuricemia being inherently detrimental to health.

Glucagon-Like Peptide 1 Receptor Agonist Attenuates Cardiovascular Injury Caused by Renal Fibrosis

Ping-Chi Tsai,[1] Daniel H. See,[1] Yue-Jhu Huang,[1,2] Shin Yun Liu,[2] Jenq-wen Huang,[1,3] Chi-Ting Su.[2,3] *[1]National Taiwan University Hospital, Taipei, Taiwan; [2]National Taiwan University Cancer Center, Taipei, Taiwan; [3]National Taiwan University College of Medicine, Taipei, Taiwan.*

Background: The term "cardiorenal syndrome" has been coined to describe the condition in which a disorder of either the heart or kidneys affects the other organ. Liraglutide, a glucagon-like peptide-1 (GLP-1) analog that acts as a GLP-1 receptor agonist (GLP-1RA), exerts cardioprotective effects. We hypothesized that liraglutide treatment could alleviate secondary damage to the heart stemming from chronic kidney disease (CKD).

Methods: We fed adenine to C57BL/6 mice at the age of 9 weeks (CKD mice) to induce renal fibrosis. Renal function was evaluated using a Transdermal GFR Measurement System (MediBeacon) before, during, and after adenine feeding, with or without liraglutide, at a dose of 1 mg/kg/day. A Prospect High-Frequency Ultrasound Imaging System was used to evaluate left ventricular function. Mitochondrial function, fibrotic markers and caspase activity were studied to understand the molecular pathology in cardiac tissue. We used NHCF-V human cardiac fibroblasts (HCFs) to investigate cellular respiration by use of a Seahorse XF Analyser. Conditional media (CM) collected from hypoxic human proximal tubule (HK-2) cells were used to treat HCFs to determine reactive oxidative species (ROS) levels, inflammatory signaling and apoptosis.

Results: The echocardiography results revealed poorer ejection fraction (EF) in adenine-fed mice than in wild-type mice, which could be abrogated by liraglutide treatment (EF: 43% vs. 55%; $p<0.001$). Cardiac tissue showed higher levels of inflammatory markers (TNF-α, IL-10, VCAM-1; $p<0.001$) in CKD mice, with liraglutide treatment reducing the levels of these markers ($p<0.001$). Moreover, HCFs expressed high levels of ROS and apoptotic markers when treated with CM of hypoxic HK-2, based on results of flow cytometry assays. Liraglutide treatment reduced said oxidative stress and apoptosis. ATP production and glycolysis tended to be lower in the HCFs stressed with CM of hypoxic HK-2, and this reduction was partially reversed with liraglutide.

Conclusions: Our findings showed that renal fibrosis negatively impacts the heart. We demonstrated that GLP-1RA attenuated the damage to the heart caused by CKD to some degree. This cardioprotective effect highlights the potential therapeutic benefits of GLP-1RA in reducing secondary heart damage caused by CKD in the context of cardiorenal syndromes.

Enhanced Diagnostic Precision in APOL1-Mediated Kidney Disease with the p.N264K M1 Protective Variant

Elena Martinelli,[1,2] Juntao Ke,[1] Atlas Khan,[1] David R. Vanderwall,[7] Janewit Wongboonsin,[3,4] Tze Yin Lim,[1] Moin A. Saleem,[5] Rasheed A. Gbadegesin,[6] Friedhelm Hildebrandt,[7] Ali G. Gharavi,[1] Krzysztof Kiryluk,[1] Matt G. Sampson,[7] Martin Pollak,[8] Simone Sanna-Cherchi.[1] *[1]Columbia University, Division of Nephrology, New York, NY; [2]Universita degli Studi di Parma, Parma, Italy; [3]Renal division, Brigham and Women's Hospital, Boston, MA; [4]Renal division, Faculty of Medicine, Siriraj Hospital, Mahidol University, Bangkok, Thailand; [5]Division of Pediatric Nephrology, University of Bristol, Bristol, United Kingdom; [6]Division of Pediatric Nephrology, Duke University, Durham, NC; [7]Division of Nephrology, Boston Children Hospital, Boston, MA; [8]Division of Nephrology, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: The *APOL1* M1 (p.N264K) variant protects against G2-associated APOL1 kidney disease. Utilization of this knowledge can potentially inform precise diagnosis in individuals with *APOL1* high-risk (HR) genotypes (G1/G2, G2/G2). Here we tested two hypotheses: (I) in APOL1-HR individuals, M1 genotyping can help in guiding accurate diagnosis of APOL1 kidney disease or non APOL1 CKD; (II) in APOL1 low-risk (LR), M1 might confer an independent protective effect against FSGS and kidney disease.

Methods: We analyzed exome/genome sequencing data from 118,749 individuals with: FSGS or steroid resistant nephrotic syndrome (SRNS) (N= 3,464), kidney disease non FSGS/SRNS (N= 28,475), and non-kidney disease controls (N=86,810). We extracted G1 and G2 genotypes to infer *APOL1* HR and LR genotypes, and rs73885316 (p.N264K) to infer M1 prevalence in these groups. Pairwise M1 carrier prevalence comparisons were conducted across categories by Fisher's exact test.

Results: In the *APOL1*-HR (N=1,590), M1 was, as expected, significantly depleted in FSGS/SRNS cases (0.63%) compared to non-kidney disease controls (4.14%; $P=1.3 \times 10^{-4}$; OR=0.15, 95%CI 0.02-0.58), driven by APOL1 G2-containing genotypes. CKD non FSGS/SRNS cases were 4-fold more likely to harbor M1 as compared to FSGS/SRNS cases. Chart review identified an alternative, non APOL1, cause for CKD (autoimmune, structural, metabolic, cystic, or al) in all APOL1-HR-M1 cases. Conversely, in APOL1-LR individuals, we detected no protective effect of M1 for FSGS/SRNS.

Conclusions: We did not detect an independent protective effect of M1 in the absence of *APOL1*-HR genotypes, consistent with its role as a genetic modifier. In *APOL1*-HR individuals, M1 enhanced diagnostic precision and can help identify cases with an alternative and potentially treatable cause of CKD not driven by *APOL1*. Given the prevalence of M1 carriers in CKD, we estimate that at least 1 in 23 individuals who carry a G2-containing *APOL1*-HR genotype do not have APOL1 kidney disease or FSGS.

Genome-Wide Glomerular Allele-Specific Expression in Human Proteinuric Kidney Tissue

Ana C. Onuchic-Whitford,[1,2] Junmo Sung,[1,2] Erotokritos Sakkas,[2] Michelle Mcnulty,[2] Anya Greenberg,[2] Jihoon Yoon,[3,4] Sowmya Badina,[1,2] Matt G. Sampson,[2,5] Dongwon Lee.[2,5] NEPTUNE (Nephrotic Syndrome Study Network). *[1]Brigham and Women's Hospital, Boston, MA; [2]Boston Children's Hospital, Boston, MA; [3]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; [4]Gangnam Severance Hospital, Seoul, Republic of Korea; [5]Harvard Medical School, Boston, MA.*

Background: Regulation of gene expression plays a key role in disease pathophysiology and contributes to penetrance of pathogenic variants. Allele-specific expression (ASE), where each copy of a gene contributes differentially to total gene expression, is a robust measure of cis-regulatory effects. While this phenomenon is well described in other organs, ASE analysis in kidneys is limited, mainly to normal tissue. Here, we successfully generated a genome-wide, high-quality ASE dataset in glomerular tissue from individuals with proteinuric kidney disease in NEPTUNE, using a rigorous computational pipeline.

Methods: We leveraged whole-genome sequencing (WGS) paired with kidney biopsy-derived glomerular RNA-seq from 240 NEPTUNE participants to robustly quantify ASE events across the genome. WGS was population-phased using WhatsHap and SHAPEIT4 with a large reference panel of phased haplotypes (~500K individuals) from UK Biobank. RNA alignment was done with STAR/WASP to address read mapping bias; duplicate reads were removed. phASER was used to integrate phased WGS and RNA-seq to generate SNP- and gene-level allelic expression data for all individuals. We applied the same pipeline to 88 individuals from GTEx with kidney cortex samples and paired WGS/RNA data.

Results: Using an RNA read count >=20 cutoff, we calculated allelic expression for a mean of 7,173 genes per individual. Applying the binomial test with correction for multiple comparisons, we identified genes with significant ASE (FDR<0.05). 19,175 genes had ASE observed in ≥1 person and 14,148 of these genes were protein-coding. Individuals had a mean of 1,433 ASE genes and 55 genes with monoallelic expression. *PLA2R1* ranked 8th (genome-wide) as most common ASE gene among NEPTUNE participants, with *PLCG2* ranking 12th and *NPHS2* ranking 13th. While these key glomerular genes were also significantly expressed in GTEx kidney samples, they had less ASE among individuals, ranking as 954th (*PLA2R1*), 1719th (*PLCG2*) and 206th (*NPHS2*) most common ASE genes.

Conclusions: We generated a genome-wide dataset of ASE in proteinuric glomerular tissue through a rigorous multi-step process integrating several computational tools. Our initial analysis reveals overrepresentation of ASE in known proteinuric kidney disease-related genes among NEPTUNE participants.

Contribution of Germline TET2 Variants to the Pathogenesis of Kidney Diseases through Impaired DNA Damage Repair and Activation of Cytosolic Nucleotide Sensors

Xiujie Liang, Hongbo Liu, Hailong Hu, Jianfu Zhou, Amin Abedini, Andrea Sanchez Navarro, Konstantin A. Kloetzer, Katalin Susztak. Susztak Lab. *University of Pennsylvania, Philadelphia, PA.*

Background: Genome-wide association studies (GWAS) have identified over 800 loci associated with kidney function, yet the specific genes, variants, and pathways involved remain elusive.

Methods: To pinpoint the genes linked to kidney disease, we combined kidney function GWAS, human kidney expression quantitative trait analysis (eQTL), and methylation quantitative trait analysis (meQTL). To discover the variants that modify gene expression in kidney cells, we utilized single-cell chromatin accessibility (snATACseq) and (Crispr-based) genome editing. We created kidney-specific Tet2 knockout mice and manipulated gene expression in human kidney cells using CRISPR to study its role in kidney disease progression. We performed single-nucleus RNA sequencing studies in knock-out mice and RNA sequencing studies in TET2 knockdown tubule cells to delve into the role of Tet2.

Results: By integrating kidney function GWAS, human kidney eQTL and meQTL analyses, we identified TET2 as a novel kidney disease risk gene. Utilizing single-cell chromatin accessibility and CRISPR-based genome editing, we highlight GWAS variants that influence *TET2* expression in kidney proximal tubule cells. Experiments using kidney/tubule-specific *Tet2* knockout mice indicated its protective role in cisplatin-induced acute kidney injury, as well as chronic kidney disease and fibrosis, induced by unilateral ureteral obstruction or adenine diet. Single-cell gene profiling of kidneys from *Tet2* knockout mice and *TET2*-knock-down tubule cells revealed the altered expression of DNA damage repair and chromosome segregation genes, notably including *INO80*, another kidney function GWAS target gene itself. Remarkably both *TET2*-null and *INO80*-null cells exhibited an increased accumulation of micronuclei after injury, leading to the activation of cytosolic nucleotide sensor cGAS-STING. Genetic deletion of cGAS or STING in kidney tubules or pharmacological inhibition of STING protected TET2 null mice from disease development.

Conclusions: Our findings highlight TET2 and INO80 as key genes in the pathogenesis of kidney diseases, indicating the importance of DNA damage repair mechanisms.

Funding: NIDDK Support

TH-OR85

Implication of Heterozygous Variants in PROX1 in Congenital Anomalies of the Kidneys and Urinary Tract

Caroline M. Kolvenbach,[1] Lea M. Merz,[1] Faiza Aslam,[5] Simone Sanna-Cherchi,[3] Hila Milo Rasouly,[3] Ali G. Gharavi,[3] Sergio D. Pena,[6] Velibor Tasic,[4] Zhongwei Li,[2] Shirlee Shril,[1] Friedhelm Hildebrandt.[1] *[1]Boston Children's Hospital, Boston, MA; [2]University of Southern California Keck School of Medicine, Los Angeles, CA; [3]Columbia University Vagelos College of Physicians and Surgeons, New York, NY; [4]Saints Cyril and Methodius University in Skopje Medical Faculty, Skopje, Macedonia (the former Yugoslav Republic of); [5]Yale University School of Medicine, New Haven, CT; [6]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil.*

Background: Congenital anomalies of the kidney and urinary tract (CAKUT) constitute one of the most frequent birth defects and represent the most common cause of chronic kidney disease in the first three decades of life. Despite the discovery of numerous monogenic disease genes, the identification of an underlying molecular diagnosis often remains challenging.

Methods: We applied exome sequencing (ES) to our cohort of 229 CAKUT trios. Subsequent functional analysis of the identified candidate gene *PROX1* was performed *in vitro* and *in vivo*, employing subcellular localization analyses, luciferase reporter assays, nephron organoid studies and morpholino *knockdown* experiments in *Xenopus* larvae.

Results: Through ES and collaboration, we identified 6 individuals with CAKUT and heterozygous variants in *PROX1*, 2 of them occurring *de novo*. Of note, one individual additionally presented with lymphedema. This phenotype has been previously associated

with heterozygous variants in *PROX1* and thus connects the CAKUT phenotype together with the lymphedema manifestations to *PROX1*. In subcellular localization studies, 1/6 mutants exhibited an aberrant nuclear signal compared to the wild type, which potentially interferes with DNA-interaction of the transcription factor. Luciferase reporter assays demonstrated impaired Wnt (4/6 mutants) and retinoic acid (RA; 5/6 mutants) pathway signaling. In addition, PROX1 partially colocalized with NRIP1, a known CAKUT disease gene. NRIP1 is a key regulator of RA signaling, which we could show was influenced by coexpressing PROX1. RNA-sequencing data of nephron progenitor cells showed expression of *PROX1* at this early stage during nephron development, which persisted through the differentiation process to kidney organoids. Moreover, human disease features are replicated in *knockdown Xenopus* larvae, exhibiting abnormal tubular structure.

Conclusions: Our data indicate that *PROX1* variants cause CAKUT by interference with Wnt and RA transcriptional signaling, two major pathways of nephrogenesis.

TH-OR86

A Drosophila Model for Dent Disease

Matias Simons,[1] Olivier Devuyst,[3] Indira Dibra,[2] Salómon Christer.[2]
[1]University Hospital Heidelberg, Institute of Human Genetics, Heidelberg, Germany; [2]University Hospital Heidelberg, Institute of Human Genetics, Heidelberg, Germany; [3]Universitat Zurich, Zurich, Switzerland.

Background: Dent's disease is an inherited disease characterized by the loss of protein uptake receptors cubilin and megalin and subsequent impairment of the endocytic pathway in the proximal tubule of the kidney. The predominant cause for Dent's disease is mutations in the human *CLCN5* gene, encoding the kidney-specific chloride-proton exchanger ClC-5. Utilizing a *Drosophila* model for Dent's disease, we sought to uncover the pathogenic mechanisms behind the protein uptake receptor loss.

Methods: The functional orthologue of ClC-5, ClC-c, was knocked down in *Drosophila* Nephrocytes through UAS-GAL4 based-expression of specific RNAi constructs. The effects of knockdown of ClC-c and other genes were measured using immunofluorescence (IF) analysis or by co-expression with fluorescent reporters. Endocytic function was measured through uptake of FITC-albumin. IF analysis was additionally performed on kidney sections from age matched control and *Clcn5* knockout mice.

Results: Utillizing ClC-c-deficient *Drosophila* nephrocytes we were able to recapitulate the loss of surface cubilin and decreased endocytic activity phenotypes that are characteristic of Dent's disease. Cubilin was found to localize to the endoplasmic reticulum (ER) and, faintly, to degradative compartments. A similar ER retention of cubilin could be produced upon loss of Rab11. Dent's disease nephrocytes also displayed large autolysosomal compartments with strong cholesterol storage. Knockdown of dynamin and cubilin mimicked these phenotypes, suggesting they occur downstream of impaired endocytosis. Additionally, cortical actin accumulation and mislocalization of slit diaphragms could be observed at the cortex of ClC-c knockdown nephrocytes, in line with previously published glomerular defects in Dent's disease patients. Finally, ER retention, lysosomal cholesterol storage and actin accumulation could be reproduced in a mouse model for Dent's disease.

Conclusions: We have found that cubilin is retained in the ER which seems to occur through perturbed function of the endosomal recycling pathway. The impaired endocytosis in turn leads to reduced protein uptake, which is possibly linked to the enhanced autophagy. Our study has uncovered a broad range of evolutionarily conserved phenotypes associated with Dent's disease which may pave the way for new therapeutic strategies in Dent's disease.

Mapping the Genetic Architecture of Kidney Stones in the Million Veteran Program

Ryan Hsi,[1] Otis D. Wilson,[1,2] Hua-Chang Chen,[1,2] Jefferson L. Triozzi,[1,2] Cassianne Robinson-Cohen,[1,2] Zhihong Yu,[1,2] Guanchao Wang,[1,2] Talat Alp Ikizler,[1,2] Edward D. Siew,[1,2] Ran Tao,[1,2] Adriana Hung.[1,2] Million Veteran Program. *[1]Vanderbilt University Medical Center, Nashville, TN; [2]VA Tennessee Valley Healthcare System, Nashville, TN.*

Background: Kidney stones are common, with a 10-20% lifetime prevalence. The prevalence is higher in men and are commonly recurrent. Treatment for recurrent stones has been linked to a decline in renal function. The heritability of kidney stones is 45-50%.

Methods: We identified 29,815 veterans of European ancestry with a diagnosis of kidney stones. Patients with bladder stones, with endocrine causes, or diagnoses of gastrointestinal malabsorption, were excluded. There were 408,294 controls. GWAS was performed using logistic regression, additive model (MAF>1%), imputed to TOPMed, adjusted for age, sex, and first 10 principal components of ancestry.

Results: Mean age 62 (SD12), 4% were women and 36% had diabetes. We identified 80 SNPs in 35 loci at the significance threshold of p=5E-08. Known loci included: The strongest signal was for *UMOD/PDILT (*p-value 1.86E-37), uric acid transporter *ABCG2* (p-value 9.31E-15), alkaline phosphatase gene ALPL (p-value 9.55E-13), calcium-sensing receptor gene CASR (p value 1.23E-11), *PLCL1* associated with Alkaline phosphatase levels, *STAP2* associated with Vit D levels, *LINC02003* associated with levels of PTH. Others: *DGKD, DGKH, HIBADH, MRPL33, ZFPM1, BCAS3.* Novel loci included: NSD1(p-value 1.72E-40) associated with urate levels and BMI, polycystin 2 *PKD2* (p-value 3.22E-17), Corticotropin Releasing Hormone Receptor 1 *CRHR1* (p-value 1.58E-22) and Growth Hormone Releasing Hormone Receptor *GHRHR* (p-value 2.44E-09), Calcineurin Like EF-Hand Protein 1, CHP1(p-value 1.61E-09) all involved in calcium metabolism. Other novel loci, many of which are associated with kidney function or bone density included: *MAPT, MED1, PLEKHM1, PDE3A, TTC33, CHAF1B, PPHLN1, RAB36, WDFY1, MICA, HLA-C, EXD1, FBXL20, FGFR4, GCAT, CKD12, ARHGAP27.*

Conclusions: Our study identified several loci (13 known and 22 novel) involved in renal tubular handling of lithogenic substrates and of inhibitors of crystallization. Some of these loci may represent therapeutic targets. Future work should include functional analyses.

Development of ABO-101, a Novel Gene Editing Therapy for Primary Hyperoxaluria Type 1

Winston Yan, Tia Ditommaso, Michael Kuefner, Sneha Halwasia, Anthony J. Garrity, Sejuti Sengupta, Lijun Liu, Dan Ory, John E. Murphy. *Arbor Biotechnologies Inc, Cambridge, MA.*

Background: Primary Hyperoxaluria, or PH, is a group of rare genetic metabolic disorders characterized by the overproduction of oxalate by the liver. Oxalate builds up and accumulates in the kidneys and other organ systems, causing kidney damage and progression towards renal failure. PH1, the most common and clinically severe subtype of PH, results from a mutation of the AGXT gene which is expressed primarily in the liver. Here we present pre-clinical in vivo evidence supporting ABO-101 as a novel CRISPR-Cas-mediated gene editing therapy for the treatment of PH1. The current standard of care siRNA therapy for PH1 requires lifelong treatment and targets HAO1, which encodes the glycolate oxidase enzyme (GO) and is upstream of the mutant AGXT. Inhibition of HAO1 lowers the availability of oxalate precursors and thus results in a therapeutically meaningful reduction of oxalate levels and a corresponding increase in serum glycolate, a metabolic byproduct of HAO1 inhibition.

Methods: ABO-101 was designed to specifically inactivate the HAO1 gene in liver hepatocytes and provide a durable reduction of oxalate levels through a single course of treatment. ABO-101 is comprised of a lipid nanoparticle (LNP) which encapsulates our proprietary engineered variant of Cas12i2 (ABR-001) and a guide RNA (gRNA), selected to share 100% sequence complementarity to the cynomolgus macaque NHP HAO1 gene.

Results: In NHPs treated with ABO-101, we achieved HAO1 editing of approximately 60% in whole liver tissue, which correlates to a greater than 2x increase in serum glycolate, all with a well-tolerated safety profile. We also observed a dose-dependent increase in editing levels with a concomitant increase in serum glycolate levels and reduction of GO enzyme activity levels. In addition to both rodent and primate pharmacology data, we also describe our approach optimizing our lead gRNA, ratios of components inside the LNP, and the mRNA encoding the gene editing machinery; these optimizations resulted in our lead therapeutic candidate ABO-101.

Conclusions: Taken together, these results provide in vivo proof of pharmacology for a gene editing approach and support further advancement of ABO-101 towards the clinic as a potential treatment for PH1.

TH-OR89

PHYOX3: Long-Term Safety and Efficacy of Nedosiran in Patients with Primary Hyperoxaluria Type 1

John C. Lieske,[1] María Gema Ariceta Iraola,[2] Jaap Groothoff,[7] Graham Lipkin,[10] Shabbir H. Moochhala,[3] Anne-Laure A. Sellier-Leclerc,[4] Gesa Schalk,[8] Verity Rawson,[5] Sara Estupiñan Torres,[9] Jing Zhou,[5] Bernd Hoppe.[6] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Hospital Universitari Vall d'Hebron, Barcelona, Spain; [3]Royal Free Hospital, London, United Kingdom; [4]Hospices Civils de Lyon, Lyon, France; [5]Novo Nordisk A/S, Bagsvaerd, Denmark; [6]German Hyperoxaluria Center, Bonn, Germany; [7]Emma Kinderziekenhuis Amsterdam UMC, Amsterdam, Netherlands; [8]Kindernierenzentrum Bonn, Bonn, Germany; [9]Hospital Universitario de Canarias, La Laguna, Spain; [10]University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom.*

Background: Primary hyperoxaluria (PH) is a disease characterized by oxalate overproduction leading to calcium oxalate stones, nephropathy and kidney failure. Nedosiran, an RNA interference therapy, has been approved in the US for the treatment of PH type 1 (PH1), including mild to moderate renal impairment.

Methods: PHYOX3 (NCT04042402) is an open-label extension trial aiming to evaluate long-term safety and efficacy of once-monthly nedosiran in patients with PH. This interim analysis includes 40 participants with PH1 from PHYOX1 (NCT03392896; N=13) and PHYOX2 (NCT03847909; N=27) trials. No patients had previous kidney or

liver transplantation, dialysis, or evidence of systemic oxalosis. Efficacy was assessed via estimated glomerular filtration rate (eGFR), urinary oxalate (Uox) excretion, and relevant clinical outcomes. Safety and efficacy were assessed up to 42 months.

Results: Baseline, mean (SD) age was 24.9 (9.72) years (55% female; 42.5% White), eGFR mean (SD) was 80.0mL/min/1.73m^2 (28.65), and median number of kidney stone events was 3. Mean eGFR remained stable (range 71.0-81.5mL/min/1.73m^2), and reduction in mean 24-hour Uox excretion was maintained through month 42 (**Fig. 1**). Annualized stone event rate decreased from 0.40 at baseline to 0.20 (22 events/108.8 person years). Eight out of 40 participants experienced ≥1 serious adverse event (SAE), none of which were associated with nedosiran treatment. Most common non-serious treatment-related AEs were injection site reactions occurring in 6 patients (15%). Four subjects discontinued treatment (1 pregnancy and 3 withdrawals), and no deaths were reported during the study.

Conclusions: Nedosiran treatment in patients with PH1 was well-tolerated, reduced average Uox levels to normal or near-normal, reduced kidney stone occurrence, and maintained stable renal function for more than 3 years.

Funding: Commercial Support - Dicerna Pharmaceuticals, a Novo Nordisk Company

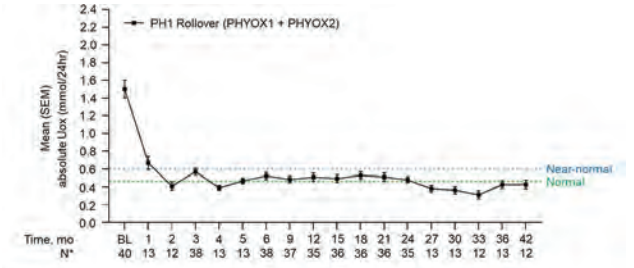

Figure 1. Mean absolute Uox over time. Dotted lines indicate normal (<0.46 mmol/24h, ULN) and near-normal (≥0.46 to <0.60 mmol/24, ≥ULN to <1.3x ULN) limits.
*Values 12-13 in the graph represent data exclusively from patients who rolled over from the PHYOX1 study.
Abbreviations: SEM, standard error of the mean; Uox, urinary oxalate; mo, month; ULN, upper limit of normal.

Development of a Nonviral Gene Therapy for X-linked Alport Syndrome by Targeted Transcutaneous Ultrasound-Mediated Gene Delivery

Katie Benthall, Bert J. Frederich, Jonathan Chan, Margarita Krivega, David Kim, Nana Ingram, Dhruv Bole, Elizabeth Del Greco, Julia Poniatowski, Surabhi Rao, Victor Foster, Charles S. Levine, Adel Alonso, Glenda Arauz, Celia Ortiz, Belinda Cabriga, Oliver Chen, David Satyadi, Tanaya Ghosh, Ivan Krivega, Steven Feinstein, Kenneth Greenberg. *SonoThera, Inc., South San Francisco, CA.*

Background: X-linked Alport syndrome (XLAS) is a genetic condition characterized by kidney disease, as well as hearing loss and eye abnormalities. Kidney disease in XLAS is caused by a dysfunction of the glomerular basement membrane (GBM), due to a mutation in the *COL4A5* gene encoding the type IV collagen a5 chain. Ultrasound mediated gene delivery (UMGD) is an effective approach for noninvasive targeted transgene delivery into kidney cells and so offers the opportunity to develop a *COL4A5* gene replacement therapy for XLAS.

Methods: Multiple codon-optimized *COL4A5* open-reading frame sequences under control of podocyte-specific promoters were engineered and screened *in vitro* in primary human kidney cells with the goal of developing a podocyte-specific *COL4A5* DNA construct. The top *COL4A5* candidate was tested *in vivo* using SonoThera's proprietary noninvasive UMGD-based gene delivery platform targeting the kidney of an XLAS mouse model. Safety of gene delivery was also evaluated using established methods.

Results: Genetic engineering and *in vitro* screening allowed for the development of an optimized podocyte-specific *COL4A5* construct, which was successfully delivered using UMGD to the kidney of the XLAS mouse model. Molecular analysis of XLAS mouse model kidney tissue samples demonstrated gene expression localized to podocytes. Established safety and tolerability endpoints were evaluated which provided an excellent safety profile without off-target delivery to liver or other non-targeted organs, supporting continued therapeutic development.

Conclusions: COL4A5 expression in podocytes of the XLAS mouse model kidney along with the favorable safety profile of noninvasive targeted UMGD delivery supports translation of this approach towards clinical development for the treatment of the XLAS.

B Cell Depleting Agents and Outcomes in Membranous Nephropathy

Salem Almaani,[1] Dhruti P. Chen,[2] Margaret Helmuth,[3] Abigail R. Smith,[4] Vimal K. Derebail.[2] CureGN Membranous Nephropathy Writing Group. *[1]The Ohio State University, Columbus, OH; [2]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [3]University of Michigan, Ann Arbor, MI; [4]Northwestern University, Evanston, IL.*

Background: B cell depleting therapy (BCDT) is increasingly used in membranous nephropathy (MN). We hypothesized that BCDT improves outcomes in MN and leads to faster remission in those with anti-PLA2R antibodies.

Methods: Use of BCDT among MN patients in Cure Glomerulonephropathy (CureGN) was reviewed. Interrupted time series analysis (IST) was done for eGFR slope prior and post treatment, including only participants with ≥2 eGFR values before and within 2 years post-therapy initiation. Time to remission was compared in those with negative vs. positive anti-PLA2R antibodies (any time), excluding those without definitive testing.

Results: In the MN cohort (n = 623), 456 (72%) patients were treated with non-B cell directed therapy and 215 (47%) of those had no BCDT use throughout their disease follow-up. 277 (44%) of MN patients had BCDT during their disease follow up, a majority (93%) were treated with rituximab. We compared eGFR trajectory pre and post therapy (n= 183 for those who received BCDT and n=88 who received other immunosuppressives but no BCDT). Among those receiving BCDT, eGFR slope (standard deviation) after treatment was -0.86 (0.93) mL/min/1.73m^2 compared to -3.04 (1.45) mL/min/1.73m^2 in patients receiving other immunosuppression (who never received BCDT), **Figure 1A**. Among those without anti-PLA2R antibodies (n=71) or with anti-PLA2R antibodies (n=113) treated with BCDT at time of active disease, there was no statistically significant difference in time to remission (median time to remission 2.4 vs. 3.8 years, respectively, logrank p = 0.097, **Figure 1B**).

Conclusions: BCDT is associated with decreased rate of eGFR decline in MN patients when compared to other therapies. Time to remission after BCDT is not influenced by anti-PLA2R status though there is a trend to faster remission among PLA2R negative patients.

MAJESTY: A Phase 3, Randomized, Open-Label, Active Comparator-Controlled, Multicenter Study Evaluating the Efficacy and Safety of Obinutuzumab in Patients with Primary Membranous Nephropathy

Fernando C. Fervenza,[1] Loreto Gesualdo,[2] Gianna Mastroianni-Kirsztajn,[3] Fan Fan Hou,[4] Gerald B. Appel,[5] Sylvie Prot,[6] Eriola Berisha,[7] Leena Khatri,[8] Tom Parsons,[7] Ed Spinks,[8] Heather Boston,[8] William Riboulet,[6] Xiaoyan Han,[9] Debbie Chen,[10] Andrew S. Bomback.[5] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Universita degli Studi di Bari Aldo Moro, Bari, Italy; [3]Universidade Federal de Sao Paulo, Sao Paulo, Brazil; [4]Nanfang Hospital, Southern Medical University, National Clinical Research Center for Kidney Disease, State Key Laboratory of Organ Failure Research, Guangdong Provincial Institute of Nephrology, Guangdong Provincial Key Laboratory of Renal Failure Research, Guangzhou, China; [5]Columbia University Irving Medical Center, New York, NY; [6]F Hoffmann-La Roche AG, Basel, Switzerland; [7]Hoffmann-La Roche Limited, Mississauga, ON, Canada; [8]Roche UK Ltd, Welwyn Garden City, United Kingdom; [9]Roche (China) Holding Ltd, Shanghai, China; [10]Genentech Inc, South San Francisco, CA.*

Background: The MENTOR study demonstrated that rituximab was superior to cyclosporine in maintaining long-term remission in primary membranous nephropathy (pMN). Obinutuzumab, a type II anti-CD20 monoclonal antibody, depletes B cells more effectively than rituximab. The MAJESTY study (NCT04629248) assesses the efficacy and safety of obinutuzumab versus tacrolimus among patients with pMN.

Methods: Participants were randomized 1:1 to receive obinutuzumab or tacrolimus (**Figure 1**). Obinutuzumab (1000 mg) is dosed on Day 1 and Weeks (Wks) 2, 24, and 26; tacrolimus (0.5 mg/kg) is given twice daily. Participants enter escape treatment with obinutuzumab if any of the following criteria are met: 1) Wk 24 urine protein-to-creatinine ratio (UPCR) >3.5 g/g and <25% decrease from baseline; 2) Wk 52 UPCR>3.5 g/g and <50% decrease from baseline; 3) Wk 52-104 UPCR >3.5 g/g after previously achieving proteinuric complete or partial remission (CR/PR); 4) tacrolimus discontinuation criteria. The primary endpoint is the proportion of patients with CR, defined as UPCR ≤0.3 g/g with a stable estimated glomerular filtration rate (eGFR) at Wk 104. Secondary endpoints include the proportion of participants who achieve CR or PR (UPCR >0.3 and ≤3.5 g/g and ≥50% decrease from baseline) at Wk 104 and the proportion who achieve CR at Wk 76.

Results: MAJESTY is fully enrolled with 142 participants across 86 sites and 11 countries. The study population comprises 31% women, and 25% Asian, 3% Black and 70% White participants; 29% received prior immunosuppressive therapy. At baseline, mean (SD) age was 51.2 (11.1) years and albumin was 2.9 (0.6) g/dL; median (IQR) eGFR was 87.0 (62.5-104.5) mL/min/1.73 m^2 and 24 hours UPCR was 6.8 (5.2-9.0) g/g. Among 110 (78%) participants with anti-PLA2R antibody >14 RU/mL, median (IQR) titer was 147 (52-287) RU/mL.

Conclusions: Full results of the MAJESTY study will be available upon completion.

Funding: Commercial Support - F. Hoffmann-La Roche Ltd.

Long-Term Outcomes of Rituximab-Treated Adults with Primary Podocytopathies

Philipp Gauckler,[1] Anna Matyjek,[1,2] Gert J. Mayer,[1] Andreas Kronbichler.[1] RITERM Study Group. *[1]Department of Internal Medicine IV (Nephrology and Hypertension), Medical University Innsbruck, Innsbruck, Austria; [2]Medical University of Lodz, Lodz, Poland.*

Background: Long-term outcomes of rituximab-treated adult patients with primary podocytopathies (either minimal change disease or focal segmental glomerulosclerosis) are largely unknown.

Methods: A retrospective study at 30 nephrology departments from 15 countries worldwide included rituximab-treated adults with primary podocytopathies and a minimum follow-up of 36 months. The primary outcome was relapse-free survival at 36-months.

Results: Of 183 rituximab-treated adults with difficult-to-treat nephrotic syndrome (68% steroid-dependent/frequently relapsing, 22% steroid-resistant, 84% previously treated with two or more lines of immunosuppressive therapy), complete or partial remission at 6 months after rituximab treatment was achieved in 83%. Eighty-three of 151 (55%) initial responders achieved long-term relapse-free survival over three years. Maintenance therapy with rituximab was associated with a better relapse-free survival (HR 2.05, 95% CI: 1.07-3.91). Relapses per year were reduced from an annual rate of 1.0 relapses/year before to 0.17 relapses/year after rituximab initiation ($p < 0.001$). During follow-up, a stable course of estimated glomerular filtration rate was observed in patients with initial treatment response, whereas non-responders experienced a reduction in eGFR reaching -11 (-33 to -6) mL/min/1.73m2 ($p < 0.001$). Concomitant immunosuppressive treatment with glucocorticoids and calcineurin inhibitors could be reduced over 36 months, especially in patients with initial response.

Conclusions: Rituximab facilitates achievement of initial and long-term response in most adult patients with difficult-to-treat primary podocytopathies. Maintenance treatment with rituximab further increases long-term relapse-free survival over three years. Non-response to initial rituximab treatment is associated with poor renal prognosis.

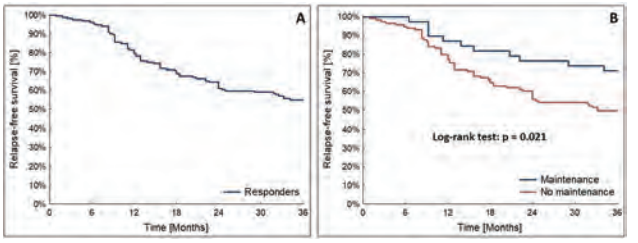

Figure 1. Three-year relapse-free survival in rituximab-responders
Kaplan-Meier plots comparing the three-year relapse-free survival in rituximab-responders in the total cohort (panel A) and subgroup comparison with maintenance (red line) versus without maintenance (blue line) treatment with rituximab (panel B).

Circulating Anti-nephrin Antibodies in Idiopathic Nephrotic Syndrome: A Large Cohort Study Testing Association with Disease Activity

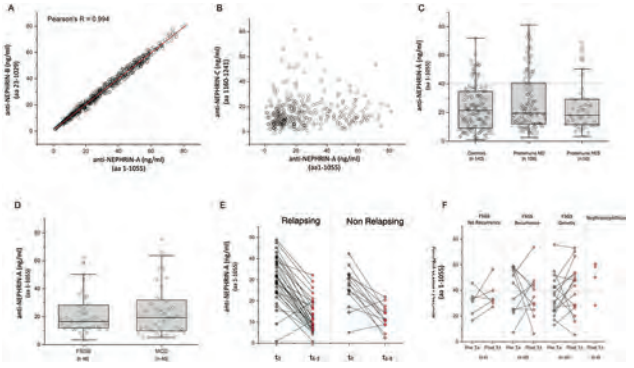
Andrea Angeletti,[1] Sonia Spinelli,[1] Xhuliana Kajana,[1] Gianluca Caridi,[1] Paolo Cravedi,[2] Francesca Lugani,[1] Carolina Bigatti,[1] Gian Marco Ghiggeri,[1] Maurizio Bruschi.[1] *[1]Istituto Giannina Gaslini, Genova, Italy; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Circulating anti-NEPHRIN antibodies (Abs) have been proposed as responsible for the disarrangement of the slit diaphragm in patients with idiopathic nephrotic syndrome (INS). However, available publications included limited cases and controls, focused on adults, and used multiple ELISAs for Abs detection, preventing comparisons across studies.

Methods: We included 156 INS patients with serum samples (396 samples), 32 kidney transplants with or not FSGS recurrence, and 143 controls. We also analyzed samples from an independent cohort of 47 INS enrolled in RCT (NCT02394119). We compared the performance of the three ELISA assays used in previous studies, two targeting the extracellular domain (NEPHRIRIN-A and B), and the intracytoplasmic domain (C).

Results: Levels of Abs against extracellular domains (anti-NEPHRIN-A, aa 1-1055 and anti-NEPHRIN-B, aa 23-1029) correlate. In contrast, not with the cytoplasmic domain (**Fig 1A-B**). Therefore, we show only the results relative to anti-NEPHRIN-A Abs. Contrary to our prediction, we did not detect a significant difference in anti-NEPHRIN Abs between controls and INS patients, regardless of proteinuria (**Fig 1C**). We identified 40ng/ml as the positivity threshold for our ELISA assay (Youden's index). Circulating anti-NEPHRIN Abs did not correlate with histology (**Fig 1D**), nor FSGS recurrence after kidney transplant (**Fig 1E**). In 47 patients enrolled in RCT, anti-NEPHRIN-A Abs significantly decreased after treatment. However, when stratified based on relapse or not at 12 months of follow-up, serum levels at $t_{6\text{-}9\ months}$ were similar in relapsing and non-relapsing subjects (**Fig 1F**).

Conclusions: Circulating anti-NEPHRIN Abs are present in a subset of INS patients and in kidney transplant recipients with FSGS recurrence, but they are not associated with disease activity. Our data are consistent with a potential pathogenic role of these antibodies, but they question their clinical utility in monitoring patients with INS.



TH-OR95

Co-localization of IgG with Nephrin in Immune-Mediated Idiopathic Nephrotic Syndrome

Yuta Inoki,[1] Yuta Ichikawa,[1] Nana Sakakibara,[1] Yuka Kimura,[1] Yu Tanaka,[1] Chika Ueda,[1] Hideaki Kitakado,[1] China Nagano,[1] Shingo Ishimori,[1] Tomoko Horinouchi,[1] Tomohiko Yamamura,[1] Kazumoto Iijima,[2,3] Kandai Nozu.[1]
[1]Department of Pediatrics, Kobe University Graduate School of Medicine, Kobe, Japan; [2]Hyogo Prefectural Kobe Children's Hospital, Kobe, Japan; [3]Department of Advanced Pediatric Medicine, Kobe University Graduate School of Medicine, Kobe, Japan.

Background: In minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS), increased serum anti-nephrin antibody titers and co-localization of nephrin and IgG in kidney tissues have been reported, indicating the involvement of anti-nephrin antibodies in nephrotic syndrome (NS). However, comprehensive studies on the association of kidney tissue-specific anti-nephrin antibodies in nephritis, including NS, are lacking.

Methods: To investigate the co-localization of IgG and nephrin, we included 52 kidney tissue samples, comprising NS in the acute phase (n = 25; MCD n=13, FSGS n=7, diffuse mesangial proliferation(DMP) n=5), NS in remission (n = 6), NS with monogenic variants (n = 3), and other kidney diseases (n = 18). The age of patients ranged from 0 to 88 years. We performed double-immunofluorescence staining of nephrin/IgG on unfixed frozen sections and subsequently evaluated the nephrin/IgG co-localization using optical sectioning in a fluorescence microscope.

Results: In acute phase NS, nephrin/IgG co-localization was observed in 80% (20/25) of cases. The proportions of observed nephrin/IgG co-localization were 88% (14 of 16) in pediatric cases (age at onset: 0-16 years) and 67% (6 of 9) in adult cases (age at onset: 47-88 years). Specifically, co-localization was observed in 85% (11 of 13) of MCD cases, 71% (5 of 7) of FSGS cases, and 80% (4 of 5) of DMP cases. Except for 1 case with NS in remission and 1 case with asymptomatic proteinuria (which later developed into NS and responded to steroids), co-localization was not observed in cases with NS in remission, NS with monogenic variants, or other kidney diseases.

Conclusions: In acute phase NS, nephrin/IgG co-localization was observed with high probability, strongly suggesting an association of anti-nephrin antibodies with the onset of idiopathic NS (INS). Staining of kidney tissue is fast, simple, and effective for investigating the pathogenesis of INS and for differential diagnosis of immune-mediated NS from other diseases, including genetic NS.

TH-OR96

Endothelial-Released CD93 Predicts Poor Clinical Outcomes in Idiopathic Nephrotic Syndrome: A Study from the NEPTUNE Consortium

Gabriel M. Cara-Fuentes,[1] Colin D. Bauer,[2] Federica Piani,[6] Jonathan P. Troost,[4] Petter Bjornstad,[2] Laura H. Mariani,[4] Matthias Kretzler,[4] Christine B. Sethna,[5] Tarak Srivastava,[3] Richard J. Johnson.[2]
[1]Nationwide Children's Hospital, Columbus, OH; [2]University of Colorado Anschutz Medical Campus, Aurora, CO; [3]Mercy Health Children's Hospital, Kansas City, MO; [4]University of Michigan, Ann Arbor, MI; [5]Northwell Health, New Hyde Park, NY; [6]Universita degli Studi di Bologna, Bologna, Italy.

Background: Idiopathic nephrotic syndrome (INS) is a complex podocytopathy with highly diverse clinical trajectories. This study investigates the role of CD93, a protein primarily expressed by endothelial cells, as a predictive biomarker in INS.

Methods: We included 298 patients with INS (unbiopsied, minimal change disease -MCD-, focal segmental glomerulosclerosis-FSGS) from the NEPTUNE study. Soluble CD93 was measured in serum (n=108) and/or urine (n=228) samples, using commercial ELISA, collected at month-4 of enrollment. Mean follow-up was 38.2 months. We evaluated the relationship between soluble CD93 and 1) kidney disease progression including time to end-stage kidney disease or 40% decline in kidney function (eGFR), 2) time to complete remission, and 3) time to develop proteinuria. Kaplan-Meier curves including CD93 quartiles were used for data visualization; and Cox-Proportional hazards models (adjusting for histological diagnosis [FSGS vs. MCD] proteinuria [log transformed UPCR], and histology [interstitial fibrosis]) were used for analyses of time to event. Experimental studies were performed to identify cellular source of soluble CD93 in INS.

Results: Soluble CD93 levels were high in urine (Figure 1a) and sera from ~90% patients during relapse, irrespective of the histological pattern. Remarkably, levels remained high in ~50% patients during remission. High urinary CD93 levels associated with faster decline in kidney function (p<0.0001, Figure 1b), slower response to immunosuppression (p<0.0001), and higher risk to develop proteinuria (p=0.06). Serum CD93 levels showed no association with the studied outcomes. In cell culture studies, sera from patients in relapse, compared to controls, stimulated human glomerular endothelial cells to release CD93.

Conclusions: High urinary CD93 is a predictor of poor clinical outcomes in INS.

Funding: Private Foundation Support

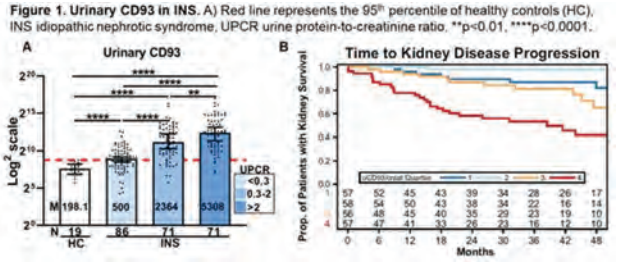


Figure 1. Urinary CD93 in INS. A) Red line represents the 95th percentile of healthy controls (HC), INS idiopathic nephrotic syndrome, UPCR urine protein-to-creatinine ratio. **p<0.01, ****p<0.0001.

Predicting Calcineurin Inhibitor Response in Glomerular Diseases

Sean Eddy,[1] Margaret Helmuth,[1] Phillip J. McCown,[1] Viji Nair,[1] Charlotte M. Boys,[3] John R. Hartman,[1] Maria Larkina,[1] Wenjun Ju,[1] Julio Saez-Rodriguez,[2,3] Laura H. Mariani,[1] Matthias Kretzler.[1]
[1]University of Michigan Michigan Medicine, Ann Arbor, MI; [2]European Bioinformatics Institute, Cambridge, United Kingdom; [3]UniversitatsKlinikum Heidelberg, Heidelberg, Germany.

Background: Glucocorticoids and calcineurin inhibitors (CNI) are part of KDIGO guidelines for treatment of steroid resistant glomerular diseases. Despite widespread use, predicting whether a patient will respond to therapy remains elusive. Given toxicities associated with prolonged CNI use, identifying patients who are both likely and unlikely to respond to CNI presents an opportunity to improve patient care. We hypothesized that patients' intrarenal molecular profile would be predictive of future CNI response, and that this profile could be linked to non-invasive markers that predict remission.

Methods: Kidney biopsy cores were obtained from participants in the Nephrotic Syndrome Study Network (n=362) and RNAseq profiles generated as previously described. Clinical phenotypes including, steroid and CNI exposure were recorded prior to biopsy and throughout study follow up. Gene co-expression network analysis was performed to identify co-expressed gene modules associated with future complete remission (CR) during CNI exposure. Functional enrichment of module genes was performed using cell type enrichment from a dataset of 1,407,781 single cell and single nuc (sn-)RNAseq profiles. MOFAcell was used to determine cell states in patients. Modules and cell states were correlated (Pearson) with 7,000 SomaScan profiles to identify candidate blood and urine markers of CNI response, which were validated by ELISA. AUC was used to determine the ability of markers to predict future CNI response.

Results: In glomeruli and tubulointerstitium (TI), we identified 42 and 24 modules, respectively. In steroid naïve patients at time of Bx, four TI modules were associated with CR during future CNI exposure (p<0.05). Functional enrichment analysis of modules indicated immune biology and angiogenesis networks associated with lack of response, consistent with cell level expression of module genes from sn-RNAseq. Plasma (KIM-1, MMP7) and urine (TNFR-2) markers were correlated with module expression. Biomarker profiles closed to CNI exposure improved CR prediction (AUC=0.85) over a base model (eGFR, UPCR, age, sex, and race) alone (AUC=0.77).

Conclusions: Co-expression modules helped identify blood and urine markers predictive of CR during future CNI exposure. Validation of these markers in independent cohorts is ongoing.

Funding: NIDDK Support, Government Support - Non-U.S.

TH-OR98

Urinary TNFR2 and Association with Kidney Injury in Patients with Nephrotic Syndrome

Viji Nair, Edmond Lee, Sean Eddy, Margaret Helmuth, Damian Fermin, Silpa Chinnakotla, Jeffrey B. Hodgin, Laura H. Mariani, Matthias Kretzler, Wenjun Ju. NEPTUNE (Nephrotic Syndrome Study Network).
University of Michigan Michigan Medicine, Ann Arbor, MI.

Background: Tumor necrosis factor receptor 2 (TNFR2) in plasma (pTNFR2) has been identified as a prognostic biomarker strongly associated with DKD progression. The association of urinary TNFR2 (uTNFR2) levels with kidney injury, clinical outcome, and intra-kidney TNFR2 expression remains poorly understood.

Methods: uTNFR2 (normalized by urine creatinine) and pTNFR2 levels were obtained using SOMAscan proteomics analysis for a subgroup of patients with nephrotic syndrome (NS) with matching urine, plasma, and kidney biopsy transcriptomic data (n=96) in the NEPTUNE cohort. uTNFR2 level was validated using ELISA. Glomeruli (glom) and tubulointerstitium (TI) expression values for *TNFRSF1B*, the gene encoding TNFR2, and the TNF pathway score (TNFPAS) were extracted from published RNA-seq profiles. Mono-nuclear white blood cells (MWBCs) were used to evaluate tubulointerstitial inflammation. Correlations were performed using Pearson's correlation. Single cell RNA-seq was used to determine the expression in kidney cells. Cox regression model was used to evaluate the association with outcome.

Results: SOMAscan uTNFR2 is tightly correlated with ELISA results (r=0.95, p=1e-043). uTNFR2 was higher in patients than healthy controls (p<0.0001). Higher uTNFR2 is correlated with lower GFR, higher proteinuria, inflammation by MWBCs, and TNFPAS. uTNFR2 is significantly correlated with TI but not glom *TNFRSF1B* mRNA. uTNFR2 was correlated with pTNFR2. Notably, pTNFR2 showed weaker correlation with above parameters than uTNFR2. Enriched expression of *TNFRSF1B* is observed in kidney endothelial and immune cells. Furthermore, uTNFR2 showed significant association with progression to composite endpoint of kidney failure or 40% reduction of baseline GFR after adjusting for age, sex, race, GFR, and UPCR (HR 2.11, 95% CI (1.03,4.31), p = 0.04).

Conclusions: uTNFR2 is significantly associated with cross-sectional and longitudinal outcome in patients with NS. The enriched expression of *TNFRSF1B* mRNA in kidney cells, and the stronger correlation of uTNFR2 over pTNFR2 with TI *TNFRSF1B* and MWBCs suggest that kidney cells could contribute to uTNFR2 level. The significant correlation of uTNFR2 with TNFPAS suggests that uTNFR2 may serve as a non-invasive biomarker for kidney TNF pathway activation.

Glenn,[7] Meryl Waldman,[6] Markus Bitzer,[8] Fadhl Alakwaa,[8] Bryce A. Kerlin,[9] Patrick H. Nachman,[10] Bruce M. Robinson,[8] Myda Khalid,[12] Vimal K. Derebail,[7] Tarak Srivastava,[14] Gentzon Hall,[15] Katherine R. Tuttle,[16] Michelle M. O'Shaughnessy,[17] Gabriel M. Cara-Fuentes,[20] Bethany A. Roehm,[19] Jarcy Zee,[18] Christine B. Sethna.[1,13] On behalf of the NEPTUNE Cardiovascular Working Group. *[1]Cohen Children's Medical Center, Queens, NY; [2]VA Loma Linda Healthcare System, Loma Linda, CA; [3]Northwestern University Feinberg School of Medicine, Chicago, IL; [4]Case Western Reserve University, Cleveland, OH; [5]Cleveland Clinic, Cleveland, OH; [6]National Institutes of Health, Bethesda, MD; [7]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [8]University of Michigan Michigan Medicine, Ann Arbor, MI; [9]Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; [10]University of Minnesota Twin Cities, Minneapolis, MN; [11]Harbor-UCLA Medical Center, Torrance, CA; [12]Riley Hospital for Children at Indiana University Health, Indianapolis, IN; [13]Northwell Health, New Hyde Park, NY; [14]Children's Mercy Kansas City, Kansas City, MO; [15]Duke Health, Durham, NC; [16]Providence St Joseph Health, Renton, WA; [17]University College Cork, Cork, Ireland; [18]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [19]The University of Texas Southwestern Medical Center, Dallas, TX; [20]Nationwide Children's Hospital, Columbus, OH.*

Background: Patients with proteinuric glomerulopathies are at increased risk for cardiovascular disease, but the relationship between *APOL1* genotype and MACE remains poorly understood.

Methods: Participants enrolled in the Nephrotic Syndrome Study Network (NEPTUNE) or Cure Glomerulonephropathy (CureGN) with completed *APOL1* genotyping and biopsy-proven minimal change disease, focal segmental glomerulosclerosis, membranous nephropathy or IgA nephropathy were included. Cox regression with an outcome of MACE, defined as time from enrollment to first stroke, heart failure or coronary artery disease (CAD), was conducted by *APOL1* genotype (high risk defined as having two copies of G1 and/or G2 risk variants). Models were adjusted for age, sex, obesity, glomerular diagnosis, urine protein:creatinine and glomerular filtration rate (eGFR) at enrollment, prior MACE and time from biopsy to enrollment.

Results: Among 3224 participants, 296 (9.2%) individuals (age 31.3 ± 20 yrs, 80% self-identified Black, 34.7% children, median 61.3 months follow-up) had the high-risk *APOL1* genotype. In the full cohort, 134 individuals (4%) experienced MACE, with a total of 158 events (39 stroke, 47 heart failure, 72 CAD). After adjustments, high-risk *APOL1* genotype was significantly associated with MACE (HR 2.84, 95% CI 1.56-5.15, p<0.001) (Figure).

Conclusions: Among participants in two large observational studies of proteinuric glomerular disease, high risk *APOL1 g*enotype had greater than a two-fold effect on MACE, independent of kidney disease risk factors. Future analyses are required to confirm this relationship at the time of diagnosis.

Funding: NIDDK Support

Defining Molecular Mechanisms in Antibody-Mediated Rejection Using Unbiased Proteomics in Donor-Specific Antibody-Positive and -Negative Recipients

Maya A. Allen,[1] Kieran Manion,[2] Rohan John,[3] Ana Konvalinka.[3]
[1]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; [2]Toronto General Research Institute, Toronto, ON, Canada; [3]University Health Network, Toronto, ON, Canada.

Background: Kidney transplantation is the optimal treatment for patients with end-stage kidney disease. Unfortunately, many kidney allografts fail prematurely due to antibody-mediated rejection (AMR). AMR is caused by donor-specific antibodies (DSAs) against human leukocyte antigens (HLA) on the graft endothelium. DSAs may cause injury through endothelial activation, complement activation, or interactions with Fcγ receptors (FcγRs) on immune cells. Intriguingly, 30-60% of DSA-positive kidney allograft recipients never develop rejection, and 30-50% of patients that exhibit AMR do not have any detectable DSAs, suggesting the presence of unidentified contributors to the pathogenicity of AMR. Our goal is to define the molecular mechanisms of AMR and uncover these underlying contributors to injury.

Methods: Indication biopsies from 115 patients with DSA+AMR, DSA-AMR, no rejection despite having DSAs (DSA+NR), and T cell mediated rejection (TCMR) were subjected to unbiased proteomics analysis using LC-MS/MS on Q-Exactive mass spectrometer. Significance between groups was established using ANOVA, with p<0.05 considered significant.

Results: We analyzed the glomerular and tubulointerstitial compartments of each biopsy separately. Of the 1203 proteins quantified in the tubulointerstitium, 30 were significantly differentially expressed, and of the 628 quantified in the glomeruli 15 were significantly differentially expressed (ANOVA, p<0.05). Importantly, the expression of complement factors was increased in DSA-AMR tubulointerstitium when compared to DSA+AMR and DSA+NR. However, in the glomeruli complement proteins were dominant in DSA+AMR. Furthermore, proteins downstream of FcγR activation and phagocytosis were increased in the glomeruli of DSA-AMR and DSA+AMR biopsies when compared to DSA+NR. In the tubulointerstitium, proteins implicated in phagocytosis were highest in DSA-AMR.

Conclusions: The differential expression of complement proteins and proteins implicated in FcγR-mediated phagocytosis suggests distinct patterns of injury in the two kidney compartments and an unanticipated role of complement and phagocytosis in DSA-AMR.

Unbiased Proteomics Distinguishes Chronic and Acute Antibody-Mediated Rejection in Donor-Specific Antibody-Positive Kidney Transplant Recipients

Kieran Manion,[1] Maya A. Allen,[1,2] Sergi Clotet Freixas,[3] Rohan John,[4,2] Ana Konvalinka.[1,2] *[1]Toronto General Research Institute, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]McMaster University, Hamilton, ON, Canada; [4]University Health Network, Toronto, ON, Canada.*

Background: Nearly a million North Americans have end-stage renal disease, for which transplantation of a new kidney is the best treatment; however, >50% of grafts fail by 10 years due mainly to antibody-mediated rejection (ABMR), where recipient donor-specific antibodies (DSA) can drive tissue injury. Unfortunately, presence of DSA alone cannot predict ABMR, as 30-60% of DSA$^+$ patients do not develop rejection. We aim to identify factors regulating kidney protein expression in DSA$^+$ kidney transplant recipients with and without ABMR.

Methods: Kidney biopsies were obtained from DSA$^+$ kidney transplant recipients with no rejection (NR; n=45) or ABMR (acute, n=25; chronic, n=25; mixed ABMR/cellular rejection, n=25). Glomeruli (glom) and tubulointerstitium (TI) extracted from kidney biopsies using laser capture microdissection were digested to peptides and analyzed by liquid chromatography mass spectrometry. MaxQuant and Perseus software were used for protein identification and differential expression. Differentially expressed proteins (ANOVA, $p<0.05$) were mapped to signaling pathways using pathDIP (FDR: BH, $q<0.05$).

Results: 180 glomerular and 325 tubulointerstitial proteins were significantly differentially expressed between DSA$^+$ patients with NR or with a subtype of ABMR (Fig 1). Proteins upregulated in acute or mixed ABMR mapped significantly to pathways for MHC and interferon (IFN) signaling in TI (MHC pathway, q=5.5e-12; IFN signaling, q=3.3e-8). In contrast, proteins upregulated in chronic ABMR mapped to the complement cascade (glom, q=2.9e-3; TI, q=6.8e-11) and extracellular matrix organization (glom, q=2.1e-7; TI, q=2.5e-4) in both compartments. DSA$^+$ patients with any ABMR subtype showed significant downregulation of proteins linked to pyruvate metabolism in both compartments compared to NR (glom, q=2.7e-4; TI, q=6.9e-14).

Conclusions: Our results suggest that while both acute and chronic ABMR in DSA$^+$ kidney transplant patients involve altered metabolism, distinct immune-mediated mechanisms may drive tissue damage in the individual subtypes.

Innate Immune Cells, Memory T Cells, and Interferon Gamma Responses Characterize Transplant Glomerulopathy of Chronic Antibody-Mediated Rejection

Alessia Giarraputo,[1,2] Ira Doressa Anne L. How,[1,2] Amaya Pankaj,[1,2] Michael Raabe,[1,2] Nicole L. Brousaides,[1,2] Robert B. Colvin,[1,2] Ivy A. Rosales.[1,2] Immunopathology Research Lab. *[1]Massachusetts General Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: Transplant glomerulopathy (TG) in chronic antibody mediated rejection (CAMR) portends poor graft survival and outcome. Despite many studies on CAMR using bulk mRNA analysis, the pathogenesis of TG remains unexplored. Here we used spatial transcript analysis on allograft biopsies to reveal potential pathogenetic mechanisms of glomerular injury in CAMR.

Methods: Five-micron sections from archived FFPE allograft biopsies with CAMR (n=10) and no evidence of rejection (NER, n=6) were mounted on slides and hybridized to the Whole Transcriptome Atlas Panel (Nanostring). Using the GeoMx Digital Spatial Profiler-NGS system (Nanostring, Illumina), slides were scanned and whole glomeruli regions of interest (ROI) were created. Oligo tags from ROIs were quantified and analyzed performing differential expression, pathway analysis, cell typing (Immune Cell Atlas) and cell deconvolution.

Results: Differential expression between 50 CAMR and 35 NER glomeruli showed enrichment of macrophage associated transcripts (*C1QA, C1QB, C1QC),* interferon-associated transcripts *(IFITM1, STAT1, CXCL9)* and increased Class II-associated transcripts (*CD74, HLA-DRA, HLA-DRB1, HLA-DPA1*) (*FDR adjusted p-value <0.05)* in CAMR, while the top significant pathways were related to MHC antigen presentation, complement system, cytokine mediated pathways and interferon-gamma response. Cell typing and deconvolution revealed increased proportions of macrophage, NK cells, CD8 and CD4 memory T cells together with neutrophils localized in CAMR glomeruli (Figure). These findings were associated with endothelial dedifferentiation (decreased *EHD3, SOST;* increased *COL4A1*) and decreased podocyte number.

Conclusions: Spatially resolved transcripts of TG in CAMR reveal immune cell-related pathways of glomerular endothelial injury, suggesting a novel interplay of endothelial dedifferentiation in the pathogenesis of TG.

Advancing a Humanized Mouse Model to Study the Regulation of Germinal Center Response in Alloimmunity

John Y. Choi,[1,2] Samuel Mon-Wei Yu,[3] Joseph V. Bonventre,[1,2] Michael Brehm,[4] Jamil R. Azzi.[1,2] *[1]Mass General Brigham Inc, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]University of Massachusetts Chan Medical School, Worcester, MA.*

Background: In a fully mismatched mouse kidney transplant model, we showed that regulatory CD8 T cells (CD8 Tregs) are essential in controlling germinal center response, thus inhibiting antibody-mediated rejection. Thus far, humanized mice models have failed to develop mature immune subsets due to a lack of proper thymic education and human cytokines, significantly hindering the clinical translatability of our pre-clinical findings. To overcome such limits, we established a novel humanized model that allows us to study the mechanism of germinal center regulation.

Methods: NSG, NSG-hu-IL6, NSG-hu-IL15, and NSG-hu-IL6/IL15 mice that produce physiological levels of respective human cytokines were engrafted with fetal bone marrow, liver, and thymus tissue (BLT). Upon human immune cell engraftment, 8 to 10 3D-kidney organoids derived from H9 or BJFF embryonic stem cells were engrafted under the host kidney capsule. Mice were sacrificed on day 20 or 30 for the analysis. Spleens were harvested for immunophenotyping. T cells isolated from the spleen were co-cultured with 2D-kidney organoids to induce memory response. Serum was obtained to measure specific human cytokine levels and the development of alloantibodies. Kidney organoid allografts were harvested for light microscopy, immunofluorescence, and immunophenotyping of graft-infiltrating immune cells.

Results: NSG-BLT mice developed mature T cells that rejected kidney organoid allografts. T cells isolated from NSG-BLT demonstrated memory response, judged by cytokine excretion (TNFa, IFNg) and proliferation upon re-exposure to the alloantigens (2D-organoids). Ex vivo human IL15 salvaged NK and CD8 Treg functionality isolated from NSG-BLT, while NSG-hu-IL15-BLT hosts naturally developed mature NK and CD8 Tregs. While NSG-BLT shows limited B Cell frequency and maturation, NSG-hu-IL6-BLT showed significantly increased Tfh, class-switched B cells as we all as memory B cells, signifying the enhanced germinal center response. Finally, reduced germinal center response was observed in NSG-hu-IL6/IL15-BLT compared to NSG-hu-IL6-BLT hosts, suggesting the immunoregulatory role of CD8 Treg.

Conclusions: Exploiting our advanced humanized mice kidney organoid transplant model, we show that human CD8 Treg plays an essential role in germinal center response in alloimmunity.

T Follicular Regulatory Cells Restrain Alloimmunity through Limiting Proinflammatory Cytokines in B Cells

Hengcheng Zhang,[1,2] Manuel A. Podestà,[1,2] Cecilia Bataglioli Cavazzoni,[1,2] Jeong-Mi Lee,[1,2] Paulo L. Raeder,[1,2] Pragya Chandrakar,[1,2] Maya G. Gempler,[1,2] Deepjyoti Ghosh,[3] Ismail Sayin,[3] Anita S. Chong,[3] Peter Sage.[1,2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]The University of Chicago, Chicago, IL.*

Background: Pathogenic antibodies produced by alloreactive B cells mediate antibody-mediated rejection (ABMR) after kidney transplantation. Follicular regulatory T (Tfr) cells modulate Tfh cell-mediated B cell responses but their roles in controlling ABMR are unknown.

Methods: Mouse models of kidney transplantation were performed. The transcriptional program and TCR clonality of Tfr cells were assessed by single-cell sequencing. Selective elimination of Tfr in mice was used to dissect the function. Donor-specific antibody (DSA) test and histology were used to monitor ABMR. I-E tetramer and a single B cell culture detected the germinal center (GC) responses. Bulk RNA-seq analyzed GC B cells to investigate transcriptional programming regulated by Tfr cells and its mechanism.

Results: Tfr cells differentiate after allogeneic transplantation and undergo development through three distinct stages. Clinical immunosuppression alters the development and disproportionately skews the subsets by decreasing GC-like Tfr cells and increasing follicular-like Tfr cells. Functionally, Tfr cell deletion early, but not late, after transplantation results in accelerated rejection and increases in alloreactive B cell clones, DSA, and ABMR leading to reduced recipient survival. At the GC level, deletion of Tfr cells results in B cells with enhanced pathogenic potential which are marked by increased production of proinflammatory cytokines IL-15. Neutralization of IL-15 rescued the accelerated rejection with Tfr deletion and prolonged survival.

Conclusions: Tfr cells are key regulators of kidney transplant ABMR with unique development signals and regulate alloimmunity by suppressing donor-specific GC B cells from the early stages of kidney transplantation.

Time Course Analysis of Serial Biopsies Post-Kidney Transplant Reveals a Time Zero Cell State Negatively Associated with Delayed Graft Function

Andrew F. Malone,[1,2] Aidan Leckie-Harre,[4] Amish Asthana,[3] Rohan S. Paul,[4] Giuseppe Orlando,[3] Benjamin D. Humphreys.[4] *[1]St Vincent's University Hospital, Dublin, Ireland; [2]University College Dublin, Dublin, Ireland; [3]Wake Forest University School of Medicine, Winston-Salem, NC; [4]Washington University in St Louis School of Medicine, St Louis, MO.*

Background: One fifth of the kidneys procured for transplantation in the US are discarded. Identification of kidneys with sufficient functional reserve at the time of procurement may increase the number of kidneys transplanted. We hypothesized that single-cell RNA-seq analysis of allograft biopsies obtained at time 0, 1 and 12 months will identify a signature of functional reserve predictive of successful graft function in marginal organs and thus minimize discard rates.

Methods: As part of the Double R study (IRB00027118) we analysed time 0, 1 and 12 month biopsies of DCD kidney allografts from 6 patients with either DGF (n=3) or no DGF (n=3). We performed single nucleus RNA-seq on snap frozen biopsies using the 10X FLEX kit. We used Seurat and Monocle2 to generate data objects and perform analyses. We also estimated the proportion of male cells with chromosome Y loss (LOY) per cell type over time.

Results: We integrated 17318 post-QC cells from 6 patients with and without DGF across three time points (0, 1, 12 months) post DCD kidney transplant. These included 5658 proximal tubule cells. Using Monocle we identified a cell state present in time 0 biopsies that did not develop DGF (figure1A+B). This cell state was absent in biopsies that progressed to DGF but recovered by 1 month. This cell state was defined by upregulation of fructose metabolism genes and had a high median LOY proportion (0.2459) (figure1C).

Conclusions: We identified a time zero cell state that is negatively associated with DGF in the setting of DCD kidney transplantation. These renal proximal tubule cells differentially express fructose metabolism genes and have a high proportion of LOY.

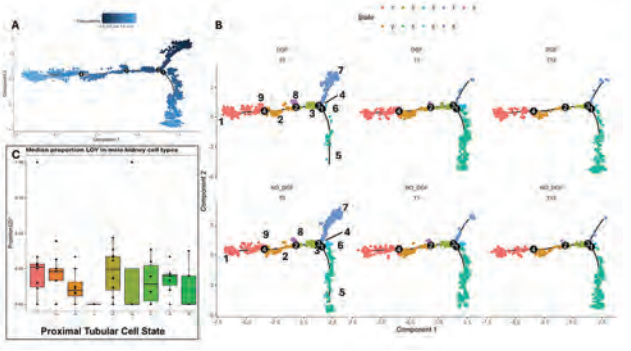

Figure1. Monocle pseudotime analysis of proximal tubule cells defines 9 cell states (A+B). Cell state 5 is absent at time 0 in biopsies that progress to DGF (B). This cell state has a high proportion of chromosome Y loss (C).

TH-OR106

Derivation of Human Leukocyte Antigen Molecular Mismatch Risk Thresholds in a Diverse Cohort of Kidney Transplant Recipients

Clarkson Crane, Elizabeth G. Ingulli, Gerald P. Morris. *University of California San Diego, La Jolla, CA.*

Background: Development of donor specific antibodies (DSA) is a known risk factor for rejection and poor allograft outcomes. HLA molecular mismatch (molMM) algorithms are increasingly being studied to risk stratify kidney transplant recipients (KTR). Studies associating incremental molMM and adverse outcomes generally consider molMM as a continuous variable. In clinical practice, use of a binary threshold is a more practical approach to assess those at high risk for de novo DSA or rejection. We derived such a cutoff and applied to our KTR cohort to compare common molMM algorithms, hypothesizing equivocal prognostic value to agMM using this approach.

Methods: KTR with high resolution recipient and donor HLA typing were identified. We fit Cox proportional hazards models using predictors of agMM, HLA-Matchmaker (ver 3), HLA-EMMA, and PIRCHE-II (ver 4) as continuous and binary (90% sensitivity of those with +DSA) variables.

Results: Of 431 KTR, 70 developed de novo DSA (16%). Correlation of molMM with agMM is seen in Fig 1. As continuous variables, all were significantly associated with dnDSA. This was consistent when using the binary cutoff, where total agMM had similar hazard to molMM for dnDSA. However, loci-specific moIMM had higher hazard for DSA than agMM (Table 1).

Conclusions: In theory, molMM provides a more granular assessment of alloimmune risk. However, this has not been consistently shown in large, diverse cohorts using a clinically relevant threshold. Our results indicate application of moIMM at a sensitive cutoff has similar prognostic value to agMM for development of dnDSA when considering total mismatch, but molMM may be superior at HLA class II loci. This merits further investigation and prior to routine clinical use, we advocate evaluation of these algorithms on a biologic level.

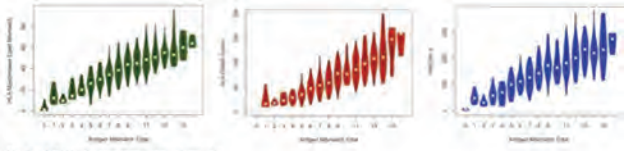

Fig 1: MolMM by total antigen mismatch.

HLA Locus	Mismatches	Hazard Ratio (CI95)	p-value
Total	Antigen	**2.4 (1.3-4.6)**	**0.007**
	HLA-Matchmaker	**2.9 (1.4-6.1)**	**0.004**
	HLA-EMMA	**3.2 (1.6-6.8)**	**0.002**
	PIRCHE-II	**2.4 (1.2-5.1)**	**0.018**
HLA-Class I	Antigen	**2.2 (1.0-4.8)**	**0.044**
	HLA-Matchmaker	**2.5 (1.3-4.9)**	**0.006**
	HLA-EMMA	**2.9 (1.1-7.6)**	**0.028**
	PIRCHE-II	2.6 (0.9-7.3)	0.079
HLA-Class II	Antigen	**1.9 (1.0-3.9)**	**0.036**
	HLA-Matchmaker	1.7 (0.8-3.8)	0.17
	HLA-EMMA	1.9 (0.9-4.2)	0.07
	PIRCHE-II	**2.4 (1.1-5.3)**	**0.029**
HLA-DRB1/3/4/5	Antigen	1.9 (0.8-4.9)	0.138
	HLA-Matchmaker	1.8 (0.5-5.9)	0.369
	HLA-EMMA	2.9 (0.9-8.9)	0.051
	PIRCHE-II	**5.7 (1.7-19.5)**	**0.005**
HLA-DQA/B	Antigen	1.9 (0.9-3.6)	0.58
	HLA-Matchmaker	**3.2 (1.5-6.8)**	**0.003**
	HLA-EMMA	**2.2 (1.1-4.7)**	**0.033**
	PIRCHE-II	**2.5 (1.0-6.5)**	**0.047**

Kidney Allograft Microvascular Inflammation Reveals Distinct Phenotypes and Outcomes: A Multinational Cohort Study

Aurelie Sannier, Marta Sablik, Gillian Divard, Olivier Aubert, Valentin Goutaudier, Carmen Lefaucheur, Alexandre Loupy. *Paris Institute for Transplantation and Organ Regeneration, Paris, France.*

Background: Microvascular inflammation (MVI) is a key predictor of adverse kidney allograft outcomes, prompting the Banff 2022 Classification to introduce two MVI categories: MVI, DSA-negative and C4d-negative (MVI+DSA-C4d-) and probable antibody-mediated rejection (probable AMR). To date, the clinical significance of these phenotypes remains unclear.

Methods: We included 6,099 kidney transplant recipients from 20 transplant centers, who underwent an allograft biopsy between 2004 and 2023. Multimodal data was integrated to classify biopsies according to the Banff 2019 and 2022 Classification. We assessed diagnostic reclassifications and their association with graft outcome, transplant glomerulopathy, and AMR episodes.

Results: Among the 14,081 transplant biopsies, MVI+DSA-C4d- and probable AMR were diagnosed in 456 (3.2%) and 265 (1.9%) biopsies, respectively. A total of 721 biopsies were reclassified, with mainly non-rejection biopsies (n=599) being reclassified as MVI+DSA-C4d- (n=361) and probable AMR (n=238). Patients reclassified as MVI+DSA-C4d- showed worse graft survival compared to non-rejection cases (HR=2.3, 95% CI: 1.6-3.3; P<0.001), but better than patients with active AMR (HR=3.0, 95% CI: 2.5-3.7; P<0.001). Those reclassified as probable AMR had a graft survival similar to non-rejection cases (HR=1.5, 95% CI: 0.9-2.5; P=0.122). We observed a similar increased risk for developing transplant glomerulopathy and an AMR episode for both MVI+DSA-C4d- and probable AMR, compared to non-rejection (P<0.001).

Conclusions: We demonstrated that MVI+DSA-C4d- and probable AMR are distinct clinical phenotypes, and reclassification of these cases refined patient risk stratification for allograft outcome. Our findings support the introduction of these phenotypes, as their clinical recognition will aid in standardizing therapeutic approaches, improving allograft outcomes.

Patterns of Care among Patients with Documented CKD in the United States

Csaba P. Kovesdy,[1] Satabdi Chatterjee,[2] Adrian R. Levy,[3] Sydnie Stackland,[4] Bonnie M. Donato,[2] Ling Zhang.[2] *[1]University of Tennesse, Memphis, TN; [2]Boehringer Ingelheim Pharmaceuticals Inc, Ridgefield, CT; [3]Dalhousie University, Halifax, NS, Canada; [4]Panalgo LLC, Boston, MA.*

Background: Guidelines for pharmacotherapy in chronic kidney disease (CKD) recommend a multifactorial strategy to slow kidney disease progression by inhibiting the renin-angiotensin-aldosterone system (RAASi; using angiotensin-converting enzyme inhibitors [ACEi] or angiotensin receptor blockers [ARB]) and lowering cardiovascular risk by using statins. In light of newer therapies available for CKD and the underdiagnosis of this condition, little is known regarding patterns of care in patients prior to documenting diagnosis. This study aimed to compare the patterns of care for RAASis and statins at the onset of CKD using laboratory data; vs documentation of CKD using ICD codes.

Methods: A retrospective study using electronic health record-linked claims data from 2009-2020 Optum® Market Clarity was conducted. The cohort included adults with two estimated glomerular filtration rate (eGFR) measures <60mL/ min/1.73 m^2, 3-12 months apart, followed by documented clinical diagnosis of CKD (using ICD 9/10 codes). The proportion of patients who were prescribed, administered, or ordered RAASis and/ or statins within ±90 days of: the second eGFR<60 mL/min/1.73 m^2 (index date), and the date of first documented diagnosis in claims were computed.

Results: A total of 1.39 million adults with laboratory evidence of CKD (mean [±SD] age 71 [±10]; 63% women; 87% Caucasian) were identified; of them, 740,088 (53.1%) received a documented diagnosis of CKD during follow-up, and formed the study cohort. Among those with documented CKD, 39% received RAASis and 36% received statins at index date; utilization increased to 46% and 45% respectively, at diagnosis. On average, use of RAASis increased from 38% between 2010-2012 to 48% between 2018-2020, while use of statins increased from 37% to 48% during the same time period.

Conclusions: Despite the utilization of RAASis and statins increasing between onset of CKD and documented diagnosis, the overall low uptake of these guideline-recommended therapies (<50%) reinforces the need to improve pharmacologic management in CKD. As new treatments become available, optimizing care using evidence-based guideline-recommended therapies offers the opportunity of reducing risk of cardiorenal syndrome, and improving outcomes in CKD.

FR-OR02

Predictors of CKD Care in African American and American Indian or Alaska Native Patients in Two Large Health Systems

Kiara Mayhand,[1] Radica Z. Alicic,[2] Lindsey M. Kornowske,[2] Cami R. Jones,[2] Kenn B. Daratha,[2] Christina Reynolds,[2] Susanne B. Nicholas,[3] Roland J. Thorpe,[1] Alex Bui,[3] Keith C. Norris,[3] Katherine R. Tuttle.[2] *[1]Johns Hopkins University, Baltimore, MD; [2]Providence St Joseph Health, Renton, WA; [3]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.*

Background: Racially minoritized populations in the United States, including African American (AA) and American Indian/Alaska Native (AI/AN), experience disproportionately higher rates of CKD and CKD risk factors compared to other populations. The study aim was to assess predictors of CKD care provided to AA and AI/AN populations.

Methods: The Center for Kidney Disease Research, Education, and Hope Registry identified AA (n=25,589), AI/AN (n=4,391), and reference (White, n=351,031) populations with CKD in 2015-2020. CKD was defined by ICD-9/10 codes, CKD-EPI 2021 estimated glomerular filtration rate <60 mL/min/1.73 m^2, urine albumin/creatinine ratio (UACR) ≥30 mg/g, or urine protein/creatinine ratio (UPCR) ≥0.15 g/g ≥90 days

apart. Patients were assessed during 1 year for: CKD guideline-directed medical therapy (GDMT) and testing for UACR/UPCR. Adjusted logistic regression identified care predictors.

Results: AA (62±17 years) and AI/AN (57±18 years) patients with CKD were younger than the reference population (68 ±17 years). Prevalence of GDMT (AA: 46%, AI/AN: 38%, reference: 40%) and UACR/UPCR testing (AA: 22%, AI/AN: 13%, reference: 14%) was suboptimal across populations. The AA population had higher odds of GDMT compared to reference. AI/AN had higher odds of GDMT, but lower odds of UACR/UPCR testing **(Figure)**. Women had lower odds of receiving GDMT or UACR/UPCR testing compared to men.

Conclusions: The disproportionate burden of CKD in AA and AI/AN populations is not solely attributable to disparities in CKD care. Women consistently experienced these disparities across race groups.

Schelling,[18] Jonathan J. Taliercio,[22] Panduranga S. Rao,[19] Jason H. Greenberg,[20] Jing Chen,[21] Michelle M. Estrella,[1,2] Joachim H. Ix,[3] Michael Shlipak.[1,2] CKD Biomarkers Consortium. *[1]University of California San Francisco, San Francisco, CA; [2]San Francisco VA Health Care System, San Francisco, CA; [3]University of California San Diego, La Jolla, CA; [4]University of Washington, Seattle, WA; [5]Tufts Medical Center, Boston, MA; [6]University of California Davis, Davis, CA; [7]University of Pennsylvania, Philadelphia, PA; [8]Boston University, Boston, MA; [9]Johns Hopkins University, Baltimore, MD; [10]Wayne State University, Detroit, MI; [11]The University of Texas Health Science Center at San Antonio, San Antonio, TX; [12]University of Illinois Chicago, Chicago, IL; [13]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [14]Icahn School of Medicine at Mount Sinai, New York, NY; [15]The University of Alabama at Birmingham, Birmingham, AL; [16]University of Vermont, Burlington, VT; [17]Brigham and Women's Hospital, Boston, MA; [18]Case Western Reserve University, Cleveland, OH; [19]University of Michigan Michigan Medicine, Ann Arbor, MI; [20]Yale University, New Haven, CT; [21]Tulane University, New Orleans, LA; [22]Cleveland Clinic, Cleveland, OH.*

Background: Individual kidney tubule biomarkers are known to be associated with risks for CKD progression and mortality in persons with diabetes. Integrating multiple kidney biomarkers using an exploratory factor analysis could define distinct dimensions of kidney health, and their associations with adverse outcomes.

Methods: We conducted a factor analysis of 17 candidate urine and plasma biomarkers in 1,256 participants with diabetes and eGFR <60 ml/min/1.73 m² from the Chronic Renal Insufficiency Cohort (CRIC; n=701) and the Reasons for Geographic and Racial Differences in Stroke (REGARDS; n=555) studies. We used Cox proportional hazards models to evaluate the associations of identified factors with CKD progression and mortality, adjusting for baseline clinical risk factors, eGFR and albuminuria.

Results: Three factors comprising 10 biomarkers were identified: *systemic inflammation and filtration* (plasma TNFR-1, TNFR-2, suPAR, SDMA), *tubular function* (urine EGF, ADMA, SDMA), and *tubular damage* (urine α1m, KIM-1, MCP-1). In CRIC, lower *tubular function* and higher *tubular damage* were jointly and independently associated with CKD progression risk. Associations in REGARDS were weaker but directionally consistent for both *tubular function* and *tubular damage*. Lower *tubular function* and higher *tubular damage* were associated with higher mortality risk in CRIC, but not REGARDS. Higher *systemic inflammation and filtration* was associated with higher mortality risk in both cohorts.

Conclusions: Three distinct kidney health dimensions were identified, and each associated with CKD progression or mortality in persons with diabetes and CKD.

No Rest for the Wicked: The Complexity of Nephrology Inpatients Is Increasing over Time

Anukul Ghimire,[1] Natasha Wiebe,[2] Braden J. Manns,[1] Brenda Hemmelgarn,[2] Marcello Tonelli.[1] *[1]University of Calgary, Calgary, AB, Canada; [2]University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada.*

Background: Patients seen by nephrologists are known to be more complex than those seen by other medical specialties. Anecdote suggests that the complexity of nephrology inpatients has increased over time, but this has not been studied. We assessed temporal trends in the complexity of inpatients seen by nephrologists.

Methods: We did a retrospective cohort study of all adults in Alberta, Canada who were seen by one or more nephrologists during a hospitalization between 2011-2020. We used validated algorithms applied to population-based administrative data to assess patient characteristics. We evaluated 10 markers of complexity; 8 were measured in the year prior to admission to minimize the competing risk of mortality (presence of ≥10 comorbidities, >15 prescribed drugs, presence of a mental health condition, presence of frailty, number of physician specialties involved in care, number of individual physicians involved in care, ≥2 prior hospitalizations, and >5 emergency visits). We assessed all-cause death and placement in long-term care (LTC) during the year following admission. Differences over time were assessed using generalized linear models.

Results: Among 45,156 inpatients, median age remained stable at 65y over 2011-2020. The table shows the secular changes in the 10 complexity markers. The proportion with a mental health condition and the likelihood of placement in LTC remained stable, whereas the risk of mortality decreased. Complexity as assessed by the remaining 7 markers increased over time, often to a substantial extent. For example, the proportion of patients with ≥10 comorbidities increased by 23%, whereas the proportion with frailty increased by 51%. Trends were similar after adjustment for age (data not shown).

Conclusions: The complexity of nephrology inpatients is increasing over time and is not explained by population aging. The secular decrease in mortality is encouraging and warrants further investigation. These findings have implications for workforce planning, nephrology training programs and physician reimbursement policies.

Complexity markers by fiscal year among inpatients seen by a nephrologist

	Fiscal year										
	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020	P for trend

Kidney-Adipose Tissue Cross-Talk during Weight Loss in Adults with Obesity and CKD

Helen L. MacLaughlin,[1,2] Ying Chun Yuen,[1] Marguerite M. Conley,[1,3] Lisa K. Philp.[1] *[1]Queensland University of Technology, Brisbane, QLD, Australia; [2]Royal Brisbane and Women's Hospital, Herston, QLD, Australia; [3]Princess Alexandra Hospital, Woolloongabba, QLD, Australia.*

Background: Mechanisms linking obesity and chronic kidney disease (CKD) include energy, adipokine and metabolic homeostasis imbalances. Adiponectin, leptin and fetuin-A play critical roles in these pathophysiological processes, contributing to insulin resistance, inflammation and kidney damage. This study investigated the effect of intentional weight loss on adipokines, fetuin-A, and urinary NGAL levels in people living with obesity and CKD.

Methods: Blood and urine samples were obtained at baseline, 3 and 6 months from 49 adults with BMI >30kg/m^2, CKD stages 1-3b and urinary protein/creatinine ratio >3mg/mmol, who were randomised to either a low energy diet and exercise intervention (LED) or usual care (UC) in the SLOW CKD feasibility study. Serum adiponectin, leptin, fetuin-A, cystatin-C and urinary NGAL levels were measured using commercially available quantitative sandwich enzyme-linked immunosorbent assays (ELISA). Median differences using Mann-Whitney tests and associations between changes in variables using linear or rank regression were examined.

Results: Median BMI, estimated glomerular filtration rate (eGFR) and urinary protein to creatinine ratio were 38.6 kg/m^2, 57 mL/min/1.73m^2 and 84 mg/mmol respectively at baseline. Median weight change was -9 kg (IQR -12 to -7) in LED and 0.5 kg (IQR -4 to 2) in UC at 6M. Biomarker data were available for 35 participants (14 LED, 21 UC). Leptin was high (41.2 ± 27.7 ng/mL), and adiponectin was low (12.6 ± 16.1 μg/mL) at baseline across groups. Adiponectin/leptin ratio improved in LED and remained unchanged in UC (p=0.45), and was inversely associated with weight loss (r=-0.49, p=0.008) and trended towards positive association with fetuin-A (r=0.42 p=0.08) at 6M. Change in leptin was associated with weight (r=0.71, p⟨0.001) and waist circumference (r=0.57, p=0.001) changes at 6M. Change in fetuin-A was inversely associated with change in cystatin-C at 6M (r=-0.59, p=0.008). Urinary NGAL was unexpectedly inversely associated with weight loss at 6M (r=-0.43, p=0.02).

Conclusions: Adults with obesity and CKD had altered leptin and adiponectin levels, and intentional weight loss resulted in favourable changes in adiponectin/leptin ratio and fetuin-A, which was associated with reduced cystatin-C. Findings demonstrate potential kidney-adipose tissue cross-talk mechanisms linking obesity and CKD.

Exercise Training and Progression of CKD (GFR-Ex): A Randomized Controlled Feasibility Study

Mark Davies,[1] Aamer Sandoo,[3] Abdulfattah Alejmi,[4] Sharlene A. Greenwood,[2] Jamie H. Macdonald.[3] *[1]NHS Wales Cardiff and Vale University Health Board, Cardiff, United Kingdom; [2]Department of Renal Medicine, King's College Hospital NHS Trust, London, United Kingdom; [3]Institute for Applied Human Physiology, Bangor University, Bangor, United Kingdom; [4]NHS Wales Betsi Cadwaladr University Health Board, Bangor, United Kingdom.*

Background: Whether exercise intervention can delay kidney function decline is not known. The GFR-Ex study assessed the feasibility of a 12-month exercise training program to attenuate the rate of decline in isotope-measured (mGFR) and estimated (eGFR) Glomerular Filtration Rate.

Methods: In a multicenter feasibility study, people with stage 3-4 kidney disease (CKD) with declining function were randomized to either 12 months exercise training (home-based aerobic and resistance program) or usual care. The primary outcome was feasibility, assessed by recruitment and retention rates, intervention adherence (target >80%), and harms. Scientific feasibility outcomes included difference in mGFR ($^{99}Tc^m$-DTPA injection) between groups at 12 months; eGFR decline (cystatin C and creatinine method); and comparison between mGFR and eGFR.

Results: Between December 2018 and July 2022, 2260 patients were screened. Seventy-four participants were randomized (mean age (SD): 56 (14) years; eGFR: 34 (13) ml/min/1.73m^2; 62% male; 61% white) and 34 completed the study (11 exercise,; 23 control). The screening eligibility rate was 11%, consent rate was 48%, and 12-month retention rate was 43% (COVID-19 was implicated in 23% of participants who withdrew). The median (IQR) exercise sessions completed was 69 (63.0, 72.0) %. No adverse events related to the exercise program were recorded. The mGFR and eGFR data are shown in Table. The mean difference (eGFR minus mGFR) was -1.6 ml/min/1.73 m^2 (95% CI: -2.6 to -0.6); the 95% limits of agreement were 8.8 and -11.7 ml/min/1.73 m^2.

Conclusions: In people with progressive, moderate CKD, a 12-month exercise training program was safe and feasible. High dropout and low exercise adherence were in part due to the COVID pandemic. Scientific feasibility was suggested by an encouraging trend for exercise to attenuate GFR decline, and eGFR being a practical and sufficiently accurate alternative to mGFR. This study supports that progression to a definitive trial is warranted, provided modifications (e.g. use of a telehealth exercise intervention) are made to enhance participant recruitment, retention and exercise adherence.

Funding: Private Foundation Support

Outcome Measure	Exercise group	Usual care group
Measured GFR at 12 months (ml/min/1.73 m^2)	36.1 (12.1)	33.8 (14.7)
eGFR decline between 0 & 12 months (ml/min/1.73 m^2/year)	-3.9 (3.4)	-5.1 (6.5)

Values are mean (SD)

FR-OR07

A Home-Based, Video-Supervised 12-Week Exercise Program Improves Physical Performance in CKD: Results from a Pilot Randomized Controlled Trial

Gwenaelle Begue,[1] Alec Foster,[1] Amanda Marie F. Lopez,[2] Lynea B. Kaethler,[2] Chenoa R. Vargas,[2] Tae Youn Kim,[2] Thomas Jue,[2] Hiba Hamdan,[2] Jorge Gamboa,[3] Baback Roshanravan.[2] *[1]California State University Sacramento, Sacramento, CA; [2]University of California Davis, Davis, CA; [3]Vanderbilt University, Nashville, TN.*

Background: Sarcopenia is prevalent in CKD and is a central component of the frailty phenotype associated with adverse clinical outcomes. Regular exercise improves muscle function and physical capacity in CKD. There is a need to test the efficacy of practical and personalized exercise program on improving physical functioning in CKD.

Methods: We performed a 12-week pilot randomized (3:1) clinical trial (NCT02923063) of home-based, personalized, and video-supervised exercise intervention (EX), compared to usual care (UC) in stage 3-5 non-dialysis CKD. Pre- and post-intervention cardiorespiratory fitness (VO2peak) and total work were measured using a graded cycle ergometer test and physical performance was assessed by the 6-minutes walking distance (6MWT) test. Linear mixed effects models were used to test changes in cardiorespiratory fitness, total work, and physical performance comparing 12-week and baseline measurements.

Results: Participants randomized to EX (n=21, 47% male, 47% diabetic) had a mean eGFR of 35±12 mL/min/1.73m2 and mean age of 63±10.3 years, compared to 32.3±12 mL/min/1.73m2 and 67.1±8.3 years for those randomized to UC (n=9, 22% male, 44% diabetic). EX led to improved endurance with significant (p<0.05) 5.25kJ increase in total work (95% CI:0.70-6.43, p=0.008) at the graded cycle test and a clinically meaningful improvement of 39m at 6MWT (95% CI:3-52, p=0.02) compared to UC (Fig. 1). Cardiorespiratory fitness (VO2 peak) did not differ between groups (p=0.3). The increase in total work was independent of change in VO2 peak, suggesting improved muscular health in EX.

Conclusions: A 12-weeks home-based video-supervised exercise program is efficacious in improving physical endurance in CKD. It provides a tool for studying metabolic and molecular health and may shed new light on the pathophysiology of sarcopenia in CKD. **Funding:** R01DK129793, R01DK125794, DCI-4112

Cardiovascular, Kidney, and Safety Outcomes with Canagliflozin in Older Adults: A Pooled Secondary Analysis of the CANVAS Program and CREDENCE Trial

Amanda Siriwardana,[1,2] Meg Jardine,[3,4] Vlado Perkovic,[2,5] Min Jun,[2] Sradha S. Kotwal,[2,6] Clare G. Arnott,[2,8] Brendon L. Neuen.[2,7] *[1]The University of Sydney School of Medicine, Sydney, NSW, Australia; [2]The George Institute for Global Health, Sydney, NSW, Australia; [3]NHMRC Clinical Trials Centre, Camperdown, NSW, Australia; [4]Concord Repatriation General Hospital, Concord, NSW, Australia; [5]University of New South Wales Medicine & Health, Sydney, NSW, Australia; [6]Prince of Wales Hospital and Community Health Services, Randwick, NSW, Australia; [7]Royal North Shore Hospital, St Leonards, NSW, Australia; [8]Royal Prince Alfred Hospital, Camperdown, NSW, Australia.*

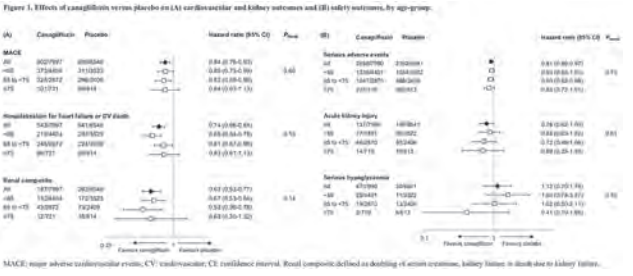
Background: Sodium glucose cotransporter 2 (SGLT2) inhibitors reduce the risk of cardiovascular and kidney outcomes in patients with type 2 diabetes (T2DM). With the growing prevalence of T2DM among older adults, it is important to understand whether the efficacy and safety of SGLT2 inhibitors differs in older individuals.

Methods: In this post hoc analysis, individual participant data from the CANVAS Program (n=10,142) and CREDENCE trial (n=4401) were pooled and analysed according

to baseline age (<65 years, 65 to <75 years, and ≥75 years). Outcomes of interest were: major adverse cardiovascular events (MACE, defined as nonfatal myocardial infarction, nonfatal stroke or cardiovascular death), hospitalisation for heart failure or cardiovascular death, CKD progression (defined as doubling of serum creatinine, kidney failure or death due to kidney failure), and safety outcomes. Hazard ratios and 95% confidence intervals were estimated using Cox proportional hazards models, stratified by age group.

Results: Among the 14,543 participants, 7,927 (54.5%) were <65 years, 5,281 (36.3%) were 65 to <75 years, and 1,335 (9.2%) were ≥75 years. Older participants had higher rates of hypertension and heart failure, longer diabetes duration, lower mean eGFR and lower median urine albumin:creatinine ratio. Across age groups, consistent relative risk reductions were observed with canagliflozin for MACE, hospitalisation for heart failure or cardiovascular death, and for CKD progression (all P trend > 0.10, **Figure 1 Panel A**). Similarly, the effects of canagliflozin on serious adverse events, acute kidney injury, and serious hypoglycaemia, were consistent across age categories (all P trend >0.10; **Figure 1 Panel B**).

Conclusions: In this pooled CANVAS and CREDENCE analysis of T2DM patients with varying degrees of kidney impairment, canagliflozin demonstrated consistent benefits across the spectrum of age for cardiovascular and kidney outcomes, with no additional safety concerns identified.



FR-OR09

Dietary Acid Reduction with Fruits and Vegetables or Sodium Bicarbonate to Avoid or Delay Need for Kidney Replacement Therapy (KRT) in Patients Initially with Stage 3 CKD: A 10-Year Randomized Trial

Nimrit Goraya,[1] Jan Simoni,[2] Maninder Kahlon,[3] Nazan Aksan,[3] Donald E. Wesson.[3] *[1]Baylor Scott and White Central Texas, Temple, TX; [2]Texas Tech University System, Lubbock, TX; [3]The University of Texas at Austin Dell Medical School, Austin, TX.*

Background: Previous studies show that dietary acid reduction with addition of either base-producing fruits and vegetables (F&V) or oral sodium bicarbonate (NaHCO3) slowed eGFR decline in study participants with CKD stage 3 (G3) hypertension-associated CKD. We examined the comparative benefits of F&V vs. NaHCO3 to avoid or delay need for KRT, a goal of kidney protective therapy

Methods: One hundred eight macroalbuminuric, non-diabetic G3 participants with mean baseline eGFR ~39 ml/min/1.73 m2 and baseline high acid-producing diets (mean potential renal acid load [PRAL] ~61 mmol/day) were randomized to F+V (n=36) to reduce dietary PRAL by half, oral NaHCO3 (HCO3, n=36) 0.4 mmol/kg bw/day to approximate the base-producing potential of F&V, or to Usual Care (UC, n=36). The primary outcome was the proportion in each group not lost to follow up who reached the need for KRT, whether or not they were alive after the 10-year follow up. We annually measured systolic blood pressure (Sys BP), eGFR, and urine albumin-to-creatinine ratio (UACR), the latter two parameters measured until the time participants began KRT.

Results: Baseline Sys BP, eGFR, and UACR were not different among groups. At 10 years, Sys BP was lower in F&V ([mean (SD)], 129.7 (5.2) mm Hg) than both, HCO3 [141.4 (5.4) mm Hg] and UC [134.2 (5.4), p< 0.01]). In addition, the F&V trajectory for UACR during follow up was lower (p< 0.01) than that for both HCO3 and UC. The likelihood of KRT when combining the two intervention groups, F&V and HCO3 (18/58 = 31.0%) relative to UC (16/31 = 51.6%), was not different (p > 0.05). When the intervention groups were NOT combined, those in the F&V arm (4/29=13.8%) had fewer participants reach KRT than those in UC or HCO3 (14/29 or 48.3%) at p<0.004

Conclusions: Dietary acid reduction with F&V but not oral NaHCO3 yielded fewer study participants reaching the need for KRT than UC, supporting greater kidney protection with ten years follow up in these participants with CKD and macroalbuminuria at study entry. Given previous data showing that F&Vs were associated with better improvement of cardiovascular disease risk indices than NaHCO3 (Am J Nephrol 49:438–448, 2019), these data support F&V over NaHCO3 as kidney protection for patients with CKD 3.

FR-OR10

Integrin α1β1 Regulates Myofibroblast Expansion in Polycystic Kidney Disease

Richard W. Naylor,[1] Celine Grenier,[1] Dorien J. Peters,[3] Ambra Pozzi,[2] Rachel Lennon.[1] Naylor Lab. *[1]The University of Manchester, Manchester, United Kingdom; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Universiteit Leiden, Leiden, Netherlands.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is the most common, potentially lethal disease, affecting 1 in 1000 individuals. A major issue preventing effective treatment is the lack of anti-fibrotic therapies to preclude the interstitial fibrosis that ultimately causes kidney failure in patients with ADPKD and other chronic kidney diseases.

Methods: Mass spectrometry (MS)-based proteomics were used to determine how extracellular matrix (ECM) protein composition changes in whole kidneys taken from a hypomorphic mouse model of ADPKD (*Pkd1*$^{nl/nl}$) and littermate controls. Postnatal day 1 (P1) and P28 were used to determine temporal changes in the proteome. scRNA-seq and immunofluorescence on mouse and human tissue was used to further investigate integrin α1.

Results: Proteomic and histological analysis at P1 showed no fibrosis, but by P28 extensive ECM deposition was observed along with other markers of fibrosis (*Acta2, Lcn2, Serpine1, Postn*). We found integrin α1 to be up-regulated, along with other cell-matrix receptors. Integrin α1 has previously been shown to regulate cell proliferation in dermal fibroblasts and regulate collagen deposition in the glomerulus. However, a role for integrin α1 in PKD has not previously been investigated. In human healthy and ADPKD kidney biopsies, integrin α1 expression was observed in the interstitial mesenchyme. scRNA-seq data confirmed integrin α1 is expressed in fibroblasts and myofibroblasts. To determine a functional role for integrin α1 in PKD, we created *Pkd1*$^{nl/nl}$*Itga1*$^{-/-}$ mice. These mice had reduced kidney weight, kidney dysfunction (BUN/uACR), and cyst size when compared to *Pkd1*$^{nl/nl}$ mice, suggesting depletion of integrin α1 is protective. Strikingly, interstitial fibrosis was significantly reduced in *Pkd1*$^{nl/nl}$*Itga1*$^{-/-}$ kidneys. Analysis of αSMA in these mice showed that, whilst myofibroblast transdifferentiation occurred, there were far fewer myofibroblasts present in *Pkd1*$^{nl/nl}$*Itga1*$^{-/-}$ kidneys. Cell proliferation assays *in vivo* and in primary fibroblast cultures determined myofibroblast expansion was reduced when integrin α1 is depleted.

Conclusions: Integrin α1 is a regulator of cell proliferation in kidney fibroblasts. Given its depletion is non-lethal, integrin α1 is likely to be and is a promising future target for anti-fibrotic therapies for kidney diseases involving interstitial fibrosis.

FR-OR11

Renal Myofibroblasts Undergo Autophagy to Support Cyst Growth in Autosomal Dominant Polycystic Kidney Disease

Abeda Jamadar, Viji Remadevi, Reena Rao. *The University of Kansas Medical Center, Kansas City, KS.*

Background: Myofibroblasts often surround renal epithelial cysts in autosomal dominant polycystic kidney disease (ADPKD). Our previous studies showed that myofibroblast depletion ameliorates disease progression in the RC/RC mouse model of ADPKD. Based on our observation that myofibroblasts in ADPKD kidneys undergo autophagy, we examined if autophagy in myofibroblasts contributes to renal cyst growth in ADPKD.

Methods: Cell proliferation of human ADPKD renal cyst epithelial cells exposed to cell culture conditioned media from human ADPKD myofibroblasts treated with vehicle or autophagy inhibitor- chloroquine was measured. Autophagy protein 5 (ATG5) is crucial for autophagy. We made myofibroblast-specific *Atg5* gene knockout- RC/RC;*Atg5* $^{f/f}$;*PDGFRb*^{cre}*ER*^{T2} mouse by breeding RC/+;*PDGFRb*^{cre}-*ER*^{T2} mouse with *Atg5*$^{f/f}$ mice. Wild type (WT), *Atg5*KO; RC/RC, RC/RC:*Atg5*KO mouse littermates were treated with vehicle or tamoxifen and sacrificed at 28 weeks of age and their kidneys were analyzed.

Results: Immunofluorescence staining in human ADPKD kidneys and RC/RC mouse kidneys showed that myofibroblasts surrounding renal cysts undergo autophagy. Human ADPKD renal cyst epithelial cells exposed to human ADPKD renal myofibroblast-conditioned media proliferated more compared to cells exposed to control media. Inhibition of autophagy in ADPKD human-renal myofibroblasts reduced the ability of their conditioned media to induce cyst epithelial cell *proliferation in vitro*. RC/RC:*Atg5*KO group had significantly lower kidney/body weight ratio, cyst number and cystic index when compared to RC/RC group. RC/RC:*Atg5*KO group had significantly reduced fibrosis and extracellular matrix related gene expression when compared to RC/RC group. No morphological changes were observed in Atg5KO mice when compared to WT.

Conclusions: Our results suggest that myofibroblasts in ADPKD kidneys undergo autophagy to support cyst growth, and inhibition of autophagy in renal myofibroblasts leads to reduced renal cyst growth and fibrosis.

Endoplasmic Reticulum (ER)-Mitochondrion Connection Is Important in the Pathogenesis of Autosomal Dominant Polycystic Kidney Disease

Biswajit Padhy, Jian Xie, Danish Idrees, Chou-Long Huang. Huang Lab. *University of Iowa Carver College of Medicine, Iowa City, IA.*

Background: Mutations on *PKD1* and *PKD2* coding for PC1 and PC2 cause ADPKD. Metabolic reprogramming/mitochondrial dysfunction is an important modifier of ADPKD cystogenesis. The cause of mitochondrial dysfunction in ADPKD remains elusive. PC2 is a cation channel that conducts monovalent cation K^+ and Na^+ more than Ca^{2+}. We have recently shown that ER-localized PC2 functions as a K^+-permeable channel to mediate K^+-Ca^{2+} exchange to facilitate ER Ca^{2+} release. TricB is an ER-restricted K^+ channel. We showed that TricB reverses ER Ca^{2+} release defect in PC2-deficient cell line and cystogenesis in Pkd2-cKO mice. ER and mitochondrion each occupies a large share of cell volume and form close inter-organelle contact known as mitochondria-associated ER membranes (MAMs). We examined the role of ER-mitochondria connection in ADPKD pathogenesis.

Methods: Mitochondria morphology in pre-cystic (4 weeks) and cystic (16 weeks) kidneys in Pax8-LC1 driven Pkd2-cKO mice were examined by transmission (TEM) and scanning electron microscopy (SEM). Mitochondrial respiration in isolated proximal tubules were studied by Seahorse oxygen consumption rate (OCR) assays. Mitochondrial DNA mass and regulator gene expression were examined by real-time PCR.

Results: TEM showed that Pkd2-cKO kidneys vs control have altered mitochondria morphology including decreased area and cristae density, and increased roundness. The distance between ER-mitochondria contact was increased and the length of contact was decreased in Pkd2-cKO. These changes occurred in pre-cystic kidneys, and no further progression from precystic to cystic kidneys. SEM with 3D rendering showed decreased individual mitochondria size. Proximal tubules isolated from cKO kidneys showed decreased OCR. Mitochondria master regulators PGC1α and PPARα, DNA mass, and mitofusin-2 (a mitochondria profusion factor and MAM regulator) were decreased in cKO kidneys. All above changes in cKO, in precystic as well cystic stages, were reversed by TricB.

Conclusions: Mitochondria defects occur in early precystic stages. ER and mitochondria are in close contact with 60% mitochondria surface in contact with ER. TricB transgene reverses cystogenesis and mitochondria defects in Pkd2-cKO mice. The results support that ER Ca^{2+} homeostasis defect is important in mitochondrial dysfunction and the pathogenesis of ADPKD.

Electrophysiological Analysis of a Gain-of-Function Polycystin-1/Polycystin-2 Ion Channel

Tobias Staudner,[1] Juthamas Khamseekaew,[1] M. Gregor Madej,[2] Linda Geiges,[1] Bardha Azemi,[1] Christine M. Ziegler,[2] Christoph Korbmacher,[1] Alexandr V. Ilyaskin.[1] *[1]Friedrich-Alexander-Universitat Erlangen-Nurnberg Institut fur Zellulare und Molekulare Physiologie, Erlangen, Germany; [2]Universitat Regensburg Fakultat fur Biologie und Vorklinische Medizin, Regensburg, Germany.*

Background: Autosomal-dominant polycystic kidney disease (ADPKD) is caused by mutations in the polycystin-1 (PC1) or polycystin-2 (PC2) coding gene. Structural data imply that PC1 and PC2 form a heterotetrameric channel with a 1:3 stoichiometry. This study investigates the assembly and ion channel properties of PC1/PC2 complexes using a novel gain-of-function (GOF) PC1 construct.

Methods: Amino acid residues identified as critical for ion permeation in the cryo-electron microscopy (cryo-EM) model of the PC1/PC2 complex [PDB ID: 6A70] were mutated to alanine in PC2 and the C-terminal fragment of PC1 (aa: 3049-4303) to obtain the known $PC2^{GOF}$ (L677A/N681A)) and a putative $PC1^{GOF}$ (R4100A/R4107A/H4111A) construct. Wildtype (WT) and mutant PC1 and PC2 were expressed in *Xenopus laevis* oocytes and analysed using the two-electrode voltage clamp technique. Cell surface expression of PC1 and PC2 was detected using a biotinylation approach. The formation of PC1/PC2 complexes was confirmed by co-immunoprecipitation experiments.

Results: Co-expression of $PC1^{WT}$ and $PC2^{GOF}$ decreased Na^+ inward currents compared to $PC2^{GOF}$ alone. Importantly, Na^+ inward currents were ~5-fold larger in oocytes co-expressing $PC1^{GOF}$/$PC2^{GOF}$ than in those co-expressing $PC2^{GOF}$/$PC1^{WT}$. A mutagenesis approach identified the residues R4107 in PC1 and L677 in PC2 as critical for the GOF effect. Homomeric $PC2^{GOF}$ channels exhibit a preference for K^+ over Na^+ and Li^+ and are inhibited by DMA^+ and DEA^+. In contrast, $PC1^{GOF}$/$PC2^{GOF}$ heteromers conduct Na^+, K^+, Li^+, and DMA^+ equally well. Intriguingly, $PC2^{GOF}$ channels exhibit a permeability for Ca^{2+}, whereas $PC1^{GOF}$/$PC2^{GOF}$ complexes do not. By varying the expression ratio of $PC1^{GOF}$ and $PC2^{GOF}$, we demonstrate that PC2 preferentially forms heteromeric complexes with PC1. A re-interpretation of the published cryo-EM map of PC1 implies that its pore-forming domain exhibits a TRP-like conformation. This interpretation is supported by cysteine-modification experiments.

Conclusions: Taken together, these results support the concept that PC2 homomers and PC1/PC2-heteromers are ion channels with distinct physiological functions. The novel $PC1^{GOF}$ construct described here may serve as a tool to investigate the effect of pathogenic ADPKD mutations on PC1/PC2 ion channel function.

A Cross-Model Single-Cell and Spatial Transcriptomic Atlas of Polycystic Kidney Disease

Kurt Zimmerman,[1] Sarah J. Miller,[1] Yi Jiang,[3] Jason R. Stubbs,[2] Qin Ma,[3] Anjun Ma.[3] *[1]The University of Oklahoma Health Sciences Center, Oklahoma City, OK; [2]The University of Kansas Medical Center, Kansas City, KS; [3]The Ohio State University, Columbus, OH.*

Background: Polycystic kidney disease (PKD) affects over 12 million people worldwide and is caused by mutations in cilia related genes. In humans, mutations in the PKD1 or PKD2 gene account for about 93% of Autosomal Dominant Polycystic kidney disease (ADPKD) cases, although recent reports highlight that other genes, such as GANAB5, DNAJB116, IFT1407, and ALG98, can also cause an ADPKD phenotype. Further adding to the complexity, different types of genetic mutations are present within the PKD1 and PKD2 family and result in varying disease severity. To model PKD in mice, researchers use both orthologous (i.e. mutations in Pkd1 or Pkd2 gene) and non-orthologous (i.e. Cys1cpk, Ift88, etc) models, which can be either congenic or inducible. Because of this, there is likely significant variation in the cellular and molecular features associated with each mouse model of disease.

Methods: To unbiasedly analyze the cellular and molecular features associated with mouse models of PKD, we generated a single cell RNA sequencing (scRNAseq) atlas comprised of 5 different mouse models of PKD as well as respective non-cystic controls. We also performed spatial transcriptomics on two of the cystic mouse models.

Results: Analyses of scRNAseq data reveal model specific differences in cell type abundance and gene expression. For example, our data indicate that rapidly progressing mouse models of PKD have little S3 nephron segment expansion whereas slowly progressing models have massive S3 nephron expansion, independent of the type of genetic mutation. Further analyses of the data indicate that almost all of the cystic epithelium in all models is derived from the distal nephron. Using the scRNAseq atlas as a reference, we mapped cell-type specific signatures to spatial transcriptomics data and inferred spatially-resolved signaling niches within cystic mice. These analyses identified several ligand-receptor interactions that were significantly enriched within cystic niches including Spp1-Cd44. Loss of Spp1 in one PKD mouse model resulted in worsened cystic disease verify the in vivo relevance of our computational approach.

Conclusions: Our single cell and spatial transcriptomic atlas in mice can be used to identify novel biological targets for treating PKD.

Characterization of Stepwise Transformation from Cysts to Carcinoma in Tsc1 Mutant Kidneys

Sara Clerici,[1] Daniel Spies,[1,2] Alessandra Boletta.[1] *[1]IRCCS Ospedale San Raffaele, Milano, Italy; [2]Universita Vita Salute San Raffaele, Milano, Italy.*

Background: A novel mouse model of Renal Cell Carcinoma (RCC) was generated by deletion of *Tsc1* using the Cadherin16 Cre (KspCre). This results in cysts undergoing epithelial transformation to cancerous lesions with time. The peculiarity of *Tsc1;kKO* model is the time-driven progression from cysts to papillae, to cystadenomas, and carcinomas with full penetrance. As the malignant phenotype progresses canonical epithelial markers are lost. To overcome this problem, we generated a *mTmG;Tsc1;kKO* mouse in which KO cells express membrane GFP (mG) upon Cre expression.

Methods: RCC kidneys were characterized by IHC, IF analysis, and FACS. scRNA-seq was performed on early- (P30) and late-stage (P80) ctrl and RCC kidneys using 10X genomics. Multiplexed error-robust FISH (MERFISH) analysis on 500 genes panel is currently being conducted to spatially resolve the clusters identified.

Results: *mTmG;Tsc1;kKO* kidneys developed cysts and malignant structures at the same rate and time as the *Tsc1;kKO*. All the structures were mG^+, with a considerable expansion of mG^+ cells in P80 kidneys analyzed by FACS, in line with the increased proliferation of *Tsc1* mutants. scRNA-seq on freshly dissociated kidneys at two time points (P30 and P80) identified clusters from all the major nephron segments in both ctrl and mutant kidneys. *Egfp* transcript was uniquely identified in several new epithelium-derived clusters, enriched at P80 in the mutant. We defined two distinct branches of progressive transformation originating from either principal or intercalated cells of the collecting duct. Interestingly, the two trajectories converge on a cluster with a papillary RCC signature. Initial pathway enrichment analysis of transcripts identified multiple metabolic pathways that are increasingly deranged during transformation. Novel, non-canonical markers were identified and used to design a MERFISH panel to spatially resolve stages of transformation in the murine kidneys and will be used to design a mini-panel to be validated on human specimens.

Conclusions: Our new RCC murine model allows to discriminate early cystogenic processes from subsequent transformation. The combination of scRNA-seq and spatial validation allows to identify new RCC populations, likely the cell of origin of the transforming clusters, and finally to define the mechanism causing the gradual transformation. Complete analysis will be presented.

Genetic Landscape in Population-Based ADPKD Cohort: Beyond PKD Type 1 and PKD Type 2

Nikola Zagorec,[1,2] Marie-Pierre Audrezet,[1,3] Jean-Michel Halimi,[4] Frank Bridoux,[5] Jean Francois Augusto,[6] Jacques Dantal,[7] Yannick Le Meur,[1,3] Emilie Cornec-Le Gall.[1,3] European Renal Association. *[1]Centre Hospitalier Regional et Universitaire de Brest, Brest, France; [2]Sveuciliste u Zagrebu Farmaceutsko-biokemijski fakultet, Zagreb, Croatia; [3]Universite de Bretagne Occidentale, Brest, France; [4]Groupement Hospitalier de Territoire Touraine-Val de Loire, Tours, France; [5]Centre Hospitalier Universitaire de Poitiers, Poitiers, France; [6]Centre Hospitalier Universitaire d'Angers, Angers, France; [7]Centre Hospitalier Universitaire de Nantes, Nantes, France.*

Background: A substantial proportion of individuals with ADPKD-like phenotype carry pathogenic variants in other cystic genes or genes phenocopying ADPKD or are genetically unresolved (GUR). Deciphering this variability is a reseach priorities highlighted in the KDIGO guidelines.

Methods: Genkyst is a population based ADPKD cohort including all patients with (a) typical ADPKD in 28 centers. A panel of 27 known or candidate genes was employed, whole exome sequencing (WES) was performed in a subset of the GUR cases.

Results: Genetic analysis was performed in 3432 individuals (48.4% males), included at the median age of 54.5y [16-95]. Likely pathogenic or pathogenic variants (LP/P) were identified in 87.1%. While *PKD1* and *PKD2* LP/P variants were identified in 66.7 and 17.7% of participants, 2.9% had atypical forms of ADPKD caused by variants in 15 different genes, the most common being *DNAJB11* (n=15), *IFT140* (n=14), *ALG8* (n=13), *HNF1B* (n=12) and *GANAB* (n=8)(Figure). WES was performed in 151 GUR cases, revealing some important ADPKD-differentials like heterozygous *COL4A4*, *OFD1* or biallelic *TULP3*, with significant clinical implications. Of interest, monoallelic loss-of-function variants were detected within 13 different ciliopathy genes (15 patients); causality is being investigated. A total of 435 individuals (416 families) remain GUR, with WES ongoing in 258. Compared to *PKD1-PKD2* patients, GUR individuals were more often males (65vs46%), significantly older (65.1vs53 y), more often diagnosed incidentally (40vs24%) with less common PKD familial history (24vs74%), and less kidney failure (16vs42%)(all P<0.01).

Conclusions: ADPKD is genetically heterogeneous, with in our cohort 8 ADPKD-associated genes and 9 phenocopies. Further genetic heterogenity is likely, with candidate genes identified by WES being currently characterized.

Small Interfering RNA (siRNA) Therapy Using Kidney Targeting Nanoparticles for Treating Polycystic Kidney Disease

Joshua Giblin, Eun ji Chung. *University of Southern California, Los Angeles, CA.*

Background: ADPKD is the most prevalent genetic kidney disease in the world, affecting over 12 million people worldwide. It is characterized by the expansion of fluid-filled cysts that result in the development of enlarged kidneys and eventually kidney failure. Despite its prevalence, the sole FDA-approved therapy, Tolvaptan, offers only modest therapeutic relief. To address the need for precise therapeutic interventions in ADPKD, our study focuses on the development of kidney targeting nanoparticles that enable siRNA-mediated knockdown of ANO1 and MCP1, genes implicated in driving cystic fluid secretion and facilitating renal macrophage infiltration, for suppressing cyst growth.

Methods: A collecting duct (CD) targeting peptide was conjugated to PEGylated lipids and collecting duct targeting peptide amphiphile micelles (CD-PAMs) were formed using thin-film hydration. The kidney targeting ability of CD-PAMs was analyzed using an ADPKD mouse model by flow cytometry and *ex vivo* organ imaging. Furthermore, CD-PAMs were loaded with siRNAs (CD-siRNA PAMs) and gene knockdown efficiency was tested on IMCD PKD1 KO cells using RT-qPCR and the impact of siRNA delivery on cyst growth was tested on a 3D cyst model. In addition, an ADPKD mouse model was used to evaluate the impact of CD-siRNA PAMs on kidney size and cystic index.

Results: CD-PAMs exhibited higher kidney accumulation after 24 hours compared to the non-targeting PAMs (NT-PAMs) (45.9% vs 35.6% NP+ kidney cells, p=0.005). Moreover, flow cytometry analysis revealed the targeting nanoparticles exhibited a pronounced affinity for collecting duct cells relative to non-targeting nanoparticles (49.9% vs. 38.5% DBA+NP+ cells, p<0.001). In addition, CD-PAMs were effectively loaded with ANO1 and MCP1 siRNA (CD-siRNA PAMs), resulting in substantial gene knockdown rates of 76% and 66% in IMCD PKD1 KO cells, respectively. Notably, these interventions successfully suppressed cyst growth in a 3D cyst model, underscoring their therapeutic potential.

Conclusions: We have successfully developed nanoparticles that can be functionalized with targeting peptides for increasing kidney accumulation. Furthermore, these nanoparticles can be loaded with small RNAs for manipulating gene expression and suppressing cyst growth in ADPKD. We are currently working to evaluate the therapeutic efficacy of our siRNA-loaded NPs in an ADPKD mouse model.

In Vivo Base Editing Rescues ADPKD in Mice

Shasha Cheng, Xiaoyan Li, Peter C. Harris, Xia Zhou, Xiaogang Li. *Mayo Clinic Minnesota, Rochester, MN.*

Background: ADPKD is the most prevalent genetic kidney disease, caused by mutations of the PKD1 and PKD2 genes, which drive renal cyst growth and extrarenal complications, including cardiac hypertrophy. Adeno-associated virus (AAV) delivered CRISPR-Cas9 base editing is a revolutionary approach for treating inherited diseases. However, thus far, the effect of AAV-BEs on DNA editing in ADPKD have not been reported.

Methods: To determine whether correction of the *Pkd1* gene mutation in $Pkd1^{RC/RC}$ mice, carrying an arginine (R) to cystine (C) mutation as in ADPKD patients, delays cyst growth and decreases heart hypertrophy, we treated $Pkd1^{RC/RC}$ mice with one dose of two newly developed ABE9-AAV9 base editors through intravenous (IV) injection. To evaluate the effect of the ABE9-AVV9 base editing on lifespan, we treated $Pkd1^{RC/null}$ mice with both base editor systems.

Results: We developed 1) a broadly expressed AAV9-ABE9 base editor system to correct *Pkd1* gene mutation in whole body, and 2) a kidney specific AAV9-ABE9 base editor system to increase the efficiency and specificity of ABE9 base editor on correction of *Pkd1* gene mutation in kidney only. We showed that one dose of broadly expressed AAV9-ABE9 base editor can effectively delay renal cyst growth and decrease cardiac hypertrophy in $Pkd1^{RC/RC}$ mice, and that one dose of kidney-specific AVV9-ABE9 base editor is selectively expressed in kidneys, but not in hearts, resulting in efficiently delaying cyst growth in $Pkd1^{RC/RC}$ kidneys. The precise editing efficiency with one dose of these two AAV9-ABE9 base editor systems remained stable in kidneys six months after treatment, increasing the expression of *Pkd1* mRNA and a decrease of cyst index, KW/BW ratios, BUN levels in $Pkd1^{RC/RC}$ mice. Treatment with AAV9-ABE9 base editors also decreased cystic cell proliferation and the accumulation of macrophages at interstitial and pericystic regions, and increased cyst lining epithelial cell apoptosis in $Pkd1^{RC/RC}$ kidneys. Treatment with one dose of either the broadly expressed or kidney specific ABE9 base editor increased the survival rate of $Pkd1^{RC/null}$ mice.

Conclusions: This is the first proof-of-principle study that use CRISPR/Cas9 base editing to correct a pathogenic single-nucleotide variant in an ADPKD mouse model, which demonstrates considerable potential for single-dose genetic therapies to correct pathogenic variants and prevent the development of ADPKD in the clinic.

Real-World Evidence on Hemodialysis Modality and Hospitalization Outcomes

Yan Zhang,[1] Anke Winter,[1] Belen Alejos,[1] Paola Carioni,[2] Otto Arkossy,[1] Len A. Usvyat,[3] Franklin W. Maddux.[4] *[1]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [2]Fresenius Medical Care Italia SpA, Palazzo Pignano, Italy; [3]Fresenius Medical Care Holdings Inc, Waltham, MA; [4]Fresenius Medical Care AG & Co. KGaA, Bad Homburg, Germany*.

Background: Recent clinical trials have highlighted the benefits of hemodiafiltration (HDF) for clinical outcomes, such as mortality. We assessed the association of dialysis modality (HDF vs hemodialysis [HD]) with hospital admission and length of stay (LOS) in a large, unselected patient population treated in real-world setting prior to and during COVID-19 pandemic.

Methods: We included 78,608 hemodialysis patients treated in 2019-2022 at NephroCare Clinics of 23 EMEA countries from European Clinical Database (EuCliD®). Rate of all-cause hospital admission and cumulative LOS was calculated separately for patients receiving at least 75% of treatments with HDF or HD during follow-up. Incident rate ratio (IRR) was estimated by negative binomial regression, accounting for patients with multiple events, and adjusted for multiple confounders. Convection volume (standardized by body surface area) specific analyses were conducted by classifying HDF patients into 3 groups: (LV-HDF, <19 L; MV-HDF,19-23 L; HV-HDF>23L).

Results: The mean age of the study population was 63.2 years and 60% were male. During a median follow-up of 22.6 months, HDF patients showed lower rate of both hospital admission and LOS (adjusted IRR [95% CI] of 0.83 [0.81–0.85] and 0.91 [0.87–0.94], respectively), compared to HD patients. Incident patients (vintage <90 days) had higher rate of hospital admission and LOS than prevalent patients (vintage ≥ 90 days) for both HDF and HD group. However, IRRs of both hospital admission and LOS for HDF group compared to HD group were lower in the incident patients than in the prevalent patients. HV-HDF and MV-HDF showed lowest and intermediate IRR of hospital admission (IRR [95% CI], 0.77 [0.75–0.79] and 0.82 [0.75–0.79], respectively) and LOS (IRR [95% CI], 0.82 [0.75–0.79] and 0.86 [0.75–0.79], respectively).

Conclusions: This study suggests that HDF was associated with reduced rate of hospitalization as well as time that patients spent in the hospital. Our findings add to the growing body of evidence that HDF provides a spectrum of clinical benefits for dialysis patients.

Table 1. The association of dialysis modality with hospital admission and length of stay (LOS)

Group	No. Patients	No. hospital admission	Hospital admission rate (/Person-Year)	Hospital LOS Rate (/Person-Year)	IRR (95% CI)* Hospital admission	IRR (95% CI)* Hospital LOS
Overall						
HD	36,012	66,773	1.02	8.30	Ref.	Ref.
HDF	42,596	78,302	0.82	7.70	0.83 (0.81 - 0.85)	0.91 (0.87 - 0.94)
Incident patients						
HD	16,198	26,548	1.27	10.20	Ref.	Ref.
HDF	13,471	23,249	1.06	9.60	0.80 (0.77 - 0.83)	0.82 (0.78 - 0.87)
Prevalent patients						
HD	19,814	40,225	0.91	7.41	Ref.	Ref.
HDF	29,125	55,053	0.75	7.14	0.84 (0.82 - 0.86)	0.95 (0.91 - 0.99)

*IRR estimated by negative binomial regression, adjusted for COVID-19 infection, age, gender, ethnicity, tobacco use, renal etiology, comorbidities at baseline (including diabetes, cardiovascular disease, infectious disease, respiratory disease, digestive disease, genitourinary disease, malignant disease), dialysis vintage at baseline, vascular access (frequency of 75% over the past 6 months prior to baseline used to define type of vascular access, if not available at baseline), average of systolic blood pressure and blood flow rate over the past 6 months prior to baseline, if not available at baseline.

FR-OR20

Mortality Risk on Hemodiafiltration Compared with High-Flux Hemodialysis: Real-World Evidence from a Large Brazilian Cohort

Maria Eugenia F. Canziani,[1] Jorge P. Strogoff-de-Matos,[2] Ana Beatriz L. Barra.[3] *[1]Universidade Federal de Sao Paulo Escola Paulista de Medicina, Sao Paulo, Brazil; [2]Universidade Federal Fluminense, Niteroi, Brazil; [3]Fresenius Medical Care AG, Rio de Janeiro, Brazil.*

Background: Patients undergoing online hemodiafiltration (HDF) have been associated with better survival compared to those on high-flux hemodialysis (HD). Recently, the use of HDF has grown markedly in Brazil, but there is no robust real-world Brazilian study on the impact of this dialysis modality on patient's outcomes.

Objective: To compare the mortality risk in patients treated with HDF and high-flux HD in a large cohort population in Brazil.

Methods: This is an observational cohort study of all adult patients on maintenance dialysis (HD and HDF) at 29 facilities in Brazil from January 1, 2022, to December 31, 2023.

Results: A total of 8,391 unselected patients were included in the study: 6,787 on high-flux HD, 1,604 on HDF only, and 1,222 who migrated from high-flux HD to HDF during the follow-up period, making a total of 2,826 patients on HDF. Patients on HDF, compared to those on HD, were older (66 vs. 62 years; $p < 0.001$) and with a higher prevalence of diabetes (36.8% vs. 32.6%; $p < 0.001$). Most patients reached the target dialysis dose along the follow-up period, with a median of 25.3 (interquartile range [IQR] 20.9 – 28.4) liters of convection volume per session for HDF patients, and a single-pool Kt/V of 1.58 (IQR 1.36 – 1.81) per session for those undergoing HD. The median follow-up was 14,3 ± 8,8 months for the patients in the two treatment groups. Death from any cause occurred in 1.243 patients, 311 in the HDF, and 932 in the HD group. The two-year survival rates in these groups were 81.2% and 77.9%, respectively ($p < 0.001$). In the analysis of the subdistribution proportional hazard ratio (sHR) by the Fine-Gray model, including the adjustment for competing outcomes and time-varying covariates, a significant reduction in the death risk was found for patients on HDF (sHR 0.75; 95% confidence interval [CI] 0.65 to 0.86]). In the analysis of subgroups, the reduction of death risk associated with HDF was more pronounced for patients aged < 65 (sHR, 0.49; 95% CI, 0.38 to 0.65) than for those aged 65 or more (sHR, 0.82; 95% CI, 0.71 to 0.95).

Conclusions: Online HDF was associated with a lower risk of death than conventional high-flux HD in a large cohort of patients in Brazil.

FR-OR21

At the Foot of the Hemodialysis Room: Online Hemodiafiltration and High-Flux Hemodialysis, a Multicenter Study

Shaira Martinez Vaquera, Antoni B. Gil, Gustavo A. Useche Bonilla, Christian I. Alfaro Sanchez, Jose Luis Pizarro Leon. *Diaverum Espana, Madrid, Spain*.

Background: Several studies highlight the relevance of convective transport versus diffusive transport in the elimination of substances of higher molecular weight with great advantages in the prevention of chronic complications. Convective techniques improve them substantially. Among them, on-line hemodiafiltration (HDF-OL) is the one that eliminates more medium and high molecular weight toxins, although high-flux hemodialysis with high permeability dialyzers comes close to the advantages offered by HDF-OL. The aim of the present study is to estimate whether there are differences in the different parameters between high-flux hemodialysis (HD-FH) and OL-HDF.

Methods: Multicenter, retrospective, descriptive study, analyzing the evolution in one year in both techniques. Variables of interest: demographics, Charlson comorbidity index, Karnofsky index, analytical parameters (urea kinetics, nutrition, inflammation, bone-mineral metabolism, anemia, dyslipidemia), interdialysis weight gain, diabetes, arterial hypertension and hospitalization among others.

Results: A total of 1674 in OL-HDF and 889 in HD-HF. No differences in: sex, diabetes, etiology of nephropathy, physical activity, smoking, months on dialysis, dry weight, interdialysis gain. There were statistically significant differences in favor of OL-HDF in: KtV, ß2-microglobulin, hemoglobin levels and PTH. In favor of HDF-HF-HDF: albumin and aluminum. The proportion of hospitalized patients was higher in the OL-HDF group (41%) compared to the high-flow HD group (37%) (p 0.044).

Conclusions: These results highlight the complexity of choosing the optimal dialysis technique, which must be customized according to the patient's specific needs and clinical situation. Although OL-HDF offers advantages in the removal of larger toxins, which is crucial to prevent chronic complications, the observed hospitalization rate suggests the need for vigilance.

Effect of Expanded Hemodialysis with Theranova Dialyzer on Preservation of Residual Kidney Function in Incident Hemodialysis Patients: THREAD Randomized Controlled Trial

Jeong-Hoon Lim, Youn sik Oh, Mingyu Kim, You Hyun Jeon, Hee-Yeon Jung, Sun-Hee Park, Chan-Duck Kim, Yong-Lim Kim, Jang-Hee Cho. *Kyungpook National University, Daegu, Republic of Korea*.

Background: Expanded hemodialysis (HDx) using a medium cut-off dialyzer can improve the clearance of middle-molecular uremic toxins compared to conventional hemodialysis (HD). However, its effect on residual kidney function (RKF) remains unclear. This study evaluated the effect of HDx on preserving RKF in incident HD patients.

Methods: Patients who initiated HD were randomized to receive dialysis with either an HDx with Theranova 400 or a high-flux (HF) dialyzer with a similar surface area over 12 months. The primary outcome was a change of glomerular filtration rate (GFR) over 12 months, as determined by the average of urea and creatinine clearance. The secondary outcome was a change in 24-hour urine volume, middle molecules, and kidney injury markers.

Results: A total of 80 HD patients (mean age: 62.7±11.9 years; male: 52 [65.0%]) underwent randomization. During 12 months, the Theranova group demonstrated a significantly smaller decrease in GFR than the HF group (−1.20 [IQR, −2.29, −0.22] mL/min/1.73m^2 vs. −2.24 [IQR, −3.62, −0.46] mL/min/1.73m^2, P=0.019) (Fig 1). No significant difference in 24-hour urine volume was observed at 12-month, whereas Theranova maintained greater 24-hour urine volume until 9-month compared to the HF dialyzer. After 12 months, the Theranova group showed a significantly lower increase in β2-microglobulin. The increase in kidney injury markers such as IGFBP-7 and KIM-1 was significantly reduced in the Theranova group compared to the HF group. The reduction ratio for κ/λ free light chains, TNF-α. and GDF-15 was higher in the Theranova group than the HF group. There were no differences in hospitalization rate or mortality between the two groups.

Conclusions: HDx using the Theranova dialyzer has preserved the decline in RKF compared to the HF dialyzer of similar size in newly initiated HD patients.

First-in-Human Trial of the NeoKidney Portable Hemodialysis Device Sorbent System

Titus W. Lau,[1,2] Christian Bluechel,[3] Paiboon Khaopaibul,[3] Han Jie Tan,[3] Yu En Toh,[3] Sabrina Haroon.[1,2] *[1]National University Hospital, Singapore, Singapore; [2]National University of Singapore, Singapore, Singapore; [3]Nextkidney, Singapore, Singapore.*

Background: The Neokidney™ is a sorbent-based regenerative hemodialysis device intended for Short Daily Hemodialysis (SDHD). Unlike conventional hemodialysis (CHD), Neokidney™ requires only 4.5L of dialysate by continuous regeneration of spent dialysate in a sorbent cartridge. The device has undergone pre-clinical testing with good treatment efficacy in animal studies.

Methods: The primary objective of this trial was to assess the clinical safety of a Neokidney™ prototype (PAK HD). The secondary objective was to assess the therapeutic efficacy of Neokidney™ sorbent therapy in comparison to CHD. We conducted a cross-over clinical trial. Each patient received one CHD therapy and one Neokidney™ sorbent therapy in the mid-week session in two consecutive weeks. The dialysis treatment prescription was similar for both therapies with 2 hours duration, use of high-flux dialyzer, a dialysate flow rate 300mL/min and a blood flow rate 300mL/min. Following two hours of therapy, all patients completed a further 2 hours of conventional dialysis therapy to receive a total of 4 hours of therapy to match their usual treatment time.

Results: A total of 3 patients were recruited. All patients tolerated and completed treatment with Neokidney™ with no adverse events. The sorbent cartridges removed approximately all urea, creatinine, and phosphate from spent dialysate during the dialysate regeneration process. The average plasma reduction ratios (RR) at 2 hours with Neokidney™ for urea, creatinine and phosphate were 54%, 52% and 58%, respectively. In comparison, the RR at 2 hours CHD were 50%, 49% and 46%, respectively. The average sodium concentration was at 139.0 mmol/L and 140.1mmol/L for regenerated and spent dialysate, respectively, thus maintained within ±0.5% of the concentration in spent dialysate, providing isonatremic dialysis. The dialysate bicarbonate concentration was maintained within ±4.7% of the concentration in spent dialysate. There were no significant differences in leukocyte count or complement concentration at the conclusion of both therapies.

Conclusions: The clinical trial demonstrated safety and efficacy of the Neokidney™ sorbent system. The toxin removal with sorbent therapy was comparable to CHD and the regenerated dialysate composition accuracy met the design specifications to provide isonatremic dialysis with stable acid-base balance.

Measurement of Cerebral Blood Flow Using Transcranial Doppler Ultrasonography: Comparison of Two Populations of Patients on Chronic Hemodialysis

Néstor H. Cruz Mendoza,[1] Noemi Del Toro-Cisneros,[1] Jose A. Geraldo Murillo,[1] Juan M. Ardavin Ituarte,[2] Ismael A. Gómez Ruiz,[1] Ricardo Correa-Rotter,[1] Olynka Vega.[1] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [2]Médica Santa Carmen, Ciudad de Mexico, Mexico.*

Background: Patients on hemodialysis (HD) experience systemic and cerebral hemodynamic changes that are associated with cognitive impairment. The objective of this study was to quantify and compare hemodynamic changes at the cerebral level during an HD session in patients with AVF vs. those with a high-flow catheter (HFC).

Methods: Cross-sectional study, controls were sought for AVF patients matched for age, sex, and time on HD. Three measurements of mean cerebral blood flow velocity (CBFV) were performed using transcranial Doppler ultrasound (during the first 15 minutes, 120 and 240 minutes after HD). Other interventions were carried out before and after HD, including measurement of cardiac output (CO), cognitive evaluation using the Montreal Cognitive Assessment (MoCA), and measurement of AVF flow velocity.

Results: Fifty patients were included, 20 women, average age 56 years, time on HD 3.2 years, 25 patients with AVF (50%). The groups were not different in their baseline characteristics. All patients presented a drop in CBFV, on average -26.5%, with the drop being greater in AVF vs. HFC (-28.2% vs -21.2%, p=0.27). The change in CO pre and post HD was also greater in those with AVF vs. HFC (-12.5% vs -7.6%, p=0.73). Regarding mean arterial pressure (MAP), the change was -11.3% in patients with AVF and -9.4% in HFC (p=0.90). (**Fig. 1**). There was no difference in MoCA score between the groups.

Conclusions: All patients studied presented a significant decrease in cerebral blood flow, CO and MAP during the HD session. Interestingly, these changes are more pronounced in patients with AVF, but no statistically significant difference was observed between the study groups.

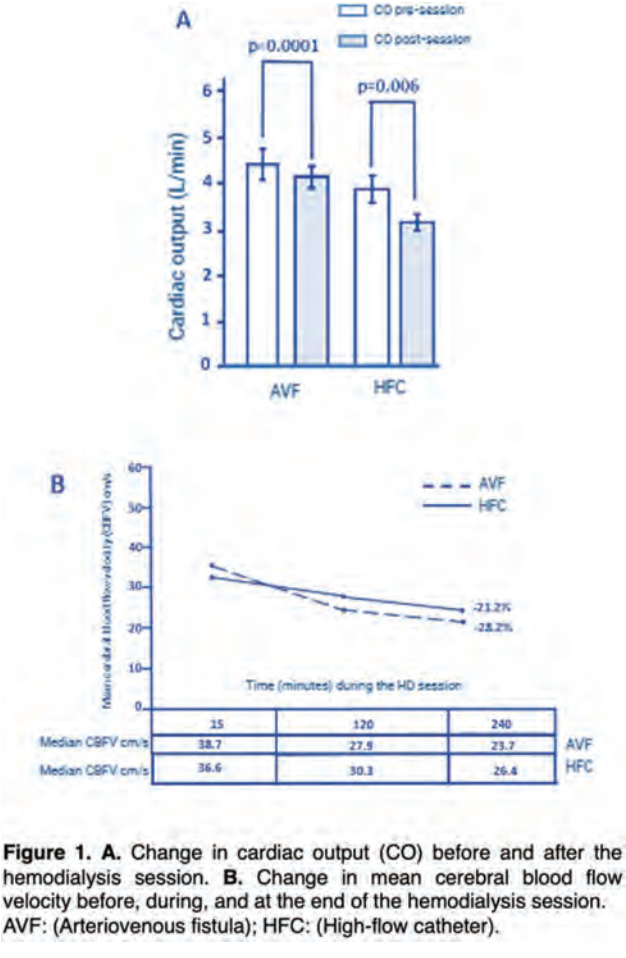

Figure 1. A. Change in cardiac output (CO) before and after the hemodialysis session. **B.** Change in mean cerebral blood flow velocity before, during, and at the end of the hemodialysis session. AVF: (Arteriovenous fistula); HFC: (High-flow catheter).

FR-OR25

Efficacy and Safety of Tool-Guided Dry Weight Adjustment among Dialysis Patients: A Meta-Analysis of Randomized Controlled Trials

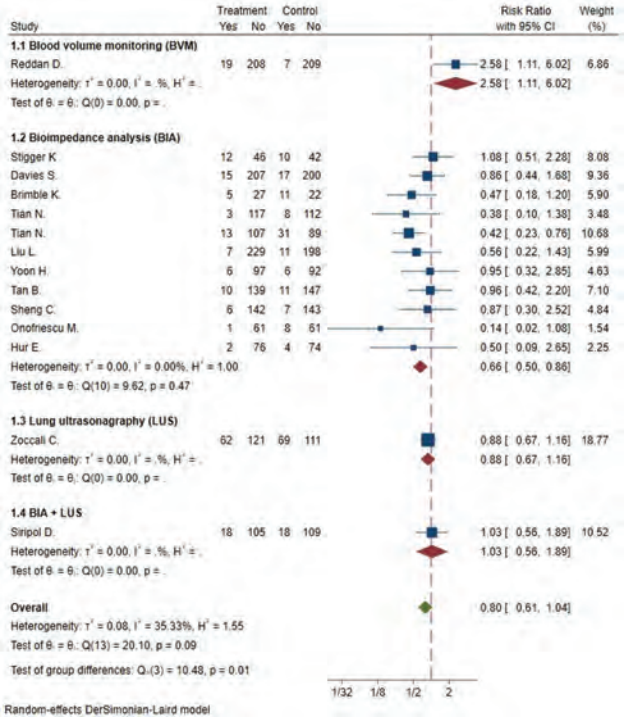
Wannasit Wathanavasin,[1,2] Charat Thongprayoon,[2] Paul W. Davis,[2] Wisit Cheungpasitporn.[2] *[1]Charoenkrung Pracharuk Hospital, Bangkok, Thailand; [2]Mayo Clinic Minnesota, Rochester, MN.*

Background: Recently, various instrumental techniques adjunct to standard clinical evaluation have been used to improve fluid balance and guide dry weight adjustments in dialysis population. We aimed to explore the efficacy and safety of using tool-guided dry weight adjustment among dialysis patients.

Methods: A systematic review was conducted in PubMed, Scopus, and Cochrane Central Register of Controlled trials for relevant RCTs published until April 28, 2024. Studies were selected if they reported at least 1 outcome of interest (e.g. mortality, cardiovascular (CV) events, hospitalization, intradialytic hypotension, hypovolemic events, cardiac arrhythmia or vascular access problems).

Results: A total of 22 RCTs involving 4,310 dialysis patients were analyzed. The meta-analysis revealed that the incorporating tool-guided dry weight adjustment was associated with a significant 21% reduction in CV events (relative risk (RR), 0.79; 95% confidence interval (CI) 0.71 to 0.88), but also resulted in a significant 28% increase in vascular access problems (RR, 1.28; 95% CI, 1.08 to 1.53). In a subgroup analysis, using BIA was associated with a significant reduction in mortality (RR, 0.66; 95% CI 0.50 to 0.86). Additionally, the intervention led to a significant reduction in systolic blood pressure and left ventricular mass index pressure (mean difference, -3.36; 95% CI -5.93 to -0.79 and -0.24; 95% CI -0.48 to 0.00, respectively).

Conclusions: The use of instrumental techniques adjunct to standard clinical evaluation for dry weight adjustment has a positive effect on cardiovascular parameters, including SBP and LVMI, and lowers the risk of CV events in dialysis patients. However, these benefits are accompanied by an increased risk of vascular access problems.



FR-OR26

Effectiveness and Safety of Apixaban Initiation following Newly Diagnosed Atrial Fibrillation in Patients with Kidney Failure on Hemodialysis

Wolfgang C. Winkelmayer,[1] Tara I. Chang,[2] Kevin F. Erickson,[1] Jingbo Niu.[1] *[1]Baylor College of Medicine Margaret M and Albert B Alkek Department of Medicine, Houston, TX; [2]Stanford University School of Medicine, Stanford, CA.*

Background: Atrial fibrillation (AF) is common in the kidney failure population. While recent guidelines deem it "reasonable to prescribe […] apixaban for oral anticoagulation to reduce the risk of stroke" in patients on dialysis, the data supporting this recommendation are limited.

Methods: We used the USRDS to retrospectively identify adult, Medicare-insured patients on hemodialysis who were newly-diagnosed with AF between 2014 and 2019 and who had not received any oral anticoagulant (OAC) prior to AF. Using propensity score methods integrating baseline demographics, comorbidities, cardiovascular medication use, and CROWNWEB clinical data we compared patients who, within 30 days after the index AF diagnosis, were newly initiated on apixaban to otherwise similar patients who were not initiated on any OAC. We compared the groups in their time to ischemic stroke, systemic thromboembolism, hemorrhagic stroke, clinically meaningful bleeding, and death. We conducted as-treated and per-protocol analyses and estimated cause-specific hazard ratios (HR) for death or sub-distribution HR for all other outcomes.

Results: Of 75,269 patients newly-diagnosed with AF, who were previously OAC-naïve, 4283 initiated apixaban, whereas 63,806 did not initiate any OAC within 30 days. Propensity matching 3985 apixaban users with 3985 OAC non-users balanced all measured baseline characteristics. Apixaban was initiated a median 5 (IQR: 2-12) days after AF. Users were mean age 68 yrs, 46% female, 63% of white and 30% of Black race, and 16% Hispanic. Median CHA_2DS_2-VASc score was 4 (IQR: 3-5). Median duration of apixaban use was 69 (IQR: 42-171) days. The rate of ischemic stroke was 46% lower (HR=0.54; 95%CI, 0.40–0.72) and that of systemic thromboembolism was 34% lower (HR=0.66; 95%CI, 0.53-0.83) in apixaban users. While there was no difference in hemorrhagic stroke (HR=0.94; 95%CI, 0.58-1.53), apixaban users had higher rates of clinically important bleeding (HR=1.20; 95%CI, 1.08-1.33) than OAC non-users. The HR for mortality was 0.39 (95%CI, 0.33-0.44) in as-treated and 0.61 (95%CI, 0.56-0.67) in per-protocol analyses.

Conclusions: Initiation of apixaban soon after newly-diagnnosed AF was associated with lower risk of ischemic stroke and systemic thromboembolism, but at the expense of higher rates of clinically meaningful bleeding.

Reduction of Calciphylaxis-Related Infections with Hexasodium Fytate Treatment in a Randomized, Double-Blind, Phase 3, Placebo-Controlled Trial

Smeeta Sinha,[1,2] Sagar U. Nigwekar,[3,4] Lisa Gould,[5] Thomas E. Serena,[6] Sharon M. Moe,[7] George R. Aronoff,[8] Dinesh K. Chatoth,[9] Jeffrey L. Hymes,[9] Gabriela Alperovich Lehrer,[10] Laurence H. Keller,[11] Alex Gold,[12,13] Peter Szecsödy,[10] Jana Radewonuk,[14] Joan Perelló,[10,15] Glenn M. Chertow.[13] CALCIPHYX Study Investigators. *[1]Northern Care Alliance NHS Foundation Trust, Salford, United Kingdom; [2]The University of Manchester, Manchester, United Kingdom; [3]Massachusetts General Hospital, Boston, MA; [4]Harvard Medical School, Boston, MA; [5]South Shore Hospital, Weymouth, MA; [6]SerenaGroup Research Foundation, Cambridge, MA; [7]Indiana University School of Medicine, Indianapolis, IN; [8]DaVita Inc, Denver, CO; [9]Fresenius Medical Care Holdings Inc, Waltham, MA; [10]Vifor Pharma Management AG, Glattbrugg, Switzerland; [11]Clinical Development Consultant, Ann Arbor, MI; [12]Clinical Development Consultant, Incline Village, NV; [13]Stanford University School of Medicine, Stanford, CA; [14]CSL Behring LLC, King of Prussia, PA; [15]Universitat de les Illes Balears, Palma de Mallorca, Spain.*

Background: CALCIPHYX was an international, phase 3, randomized, double-blind, placebo-controlled clinical trial that investigated hexasodium fytate (SNF472), an inhibitor of vascular calcification, for the treatment of calciphylaxis. Infection of calciphylaxis skin lesions is a serious complication and effective strategies to reduce the rate of calciphylaxis-related infection are lacking. In this post-hoc analysis, we compare rates of calciphylaxis-related infections between groups as randomized through Week 12.

Methods: Adults with an ulcerated calciphylaxis lesion and pain visual analog scale score ≥50/100 received double-blind hexasodium fytate 7 mg/kg or placebo intravenously during maintenance hemodialysis to Week 12 and open label hexasodium fytate to Week 24 with an end of study (EOS) visit at Week 28. Exploratory post-hoc analyses of calciphylaxis-related infection (adverse events in the Infections and Infestations system organ class) included time to first event (Kaplan-Meier, Greenwood variance with hazard ratio and confidence interval [CI] by bootstrapping Cox proportional regression and Exact Wilcoxon p-value) and rate ratios (negative binomial regression). P-values were nominal.

Results: Any calciphylaxis-related infection was reported for 1/37 patients (1 event total) in the hexasodium fytate group and 7/34 patients (10 events total) in the placebo group (Figure). The hazard ratio for hexasodium fytate vs placebo at Weeks 12 and 24 was 0.11 (95% CI: 0.00-0.64; p=0.026). Exposure-adjusted rate ratios for hexasodium fytate vs placebo were: Week 12, 0.086 (95% CI: 0.021-0.346; p<0.001); Week 24, 0.061 (95% CI: 0.015-0.250; p<0.001); and EOS, 0.057 (95% CI: 0.014-0.238; p<0.001).

Conclusions: In this exploratory analysis, hexasodium fytate treatment during hemodialysis reduced the incidence of first and multiple calciphylaxis-related infections.

Association between Cerebral Blood Flow Changes during Hemodialysis Treatment and Cognitive Function Decline in Elderly Patients Undergoing Hemodialysis

Yang Luo, Yidan Guo. *Beijing Shijitan Hospital Capital Medical University, Beijing, China.*

Background: The etiology of cognitive impairment in hemodialysis patients is multifactorial and still not clear, among those, the relationship between cerebral blood flow and cognitive function is poorly understood. Our study was to investigate the association between changes in cerebral blood flow (CBF) during hemodialysis treatment and the decline of cognitive function in elderly patients undergoing hemodialysis.

Methods: In this prospective observational cohort study of 121 elderly patients undergoing hemodialysis, we used transcranial Doppler ultrasound (TCD) to measure cerebral arterial mean flow velocity (MFV) as the index of CBF; assessed cognitive function at baseline and 12-month follow-up, and then explored associations between MFV and changes of cognitive scores.

Results: TCD recordings demonstrated a significant decline in MFV throughout dialysis, which significantly associated with combined diabetes (β=3.889, 95% CI 1.373-6.405, P=0.003), lower serum albumin (β=- 0.456, 95% CI -0.877-0.036, P=0.034), higher ultrafiltration rate (β=11.099, 95% CI 6.402-15.797, P<0.001) and the decline in systolic blood pressure throughout dialysis (β=0.062, 95% CI 0.008-0.116, P=0.026). After 12 months of follow-up, test scores of cognitive functions decreased in 5 cognitive domains (P<0.05). The decreased MFV was significantly associated with worsening scores in global cognitive function (MOCA) (β=0.066, 95% CI 0.018-0.113, P=0.007); the test of memory function (Auditory Verbal Learning Test) (β=0.050, 95% CI 0.004-0.097, P=0.035) and executive function tests including Trail Making Tests B (TMT-B) (β=1.955, 95% CI 0.457-3.453, P=0.011), and a modified version of the Stroop Color-Word Test (SCWT) (β=1.955, 95% CI 0.457-3.453, P=0.011; β=0.298, 95% CI 0.112-0.484, P=0.002) were also associated with the reduced MFV.

Conclusions: Conventional Hemodialysis may significantly reduce cerebral blood flow in elderly patients. Repetitive intradialytic decreases in CBF may be one of the underlying mechanisms for the deterioration of cognitive function in elderly hemodialysis patients.

FR-OR29

RNA Sequencing Analysis of Skeletal Muscle in Moderate to Advanced CKD

Mert Demirci,[1] Dungeng Peng,[1] Jennifer E. Norman,[2] Gwenaelle Begue,[3] Baback Roshanravan,[2] Talat Alp Ikizler,[1] Jorge Gamboa.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]University of California Davis, Davis, CA; [3]California State University Sacramento, Sacramento, CA.*

Background: Patients with moderate to advanced kidney disease suffer a higher prevalence of sarcopenia and frailty. MicroRNAs (miRNAs) play an important role in muscle cell proliferation and differentiation, as well as muscle hypertrophy and atrophy. We hypothesized that the miRNA expression profiling in skeletal muscle from patients with CKD is altered, and it would provide mechanistic insight into sarcopenia and frailty.

Methods: In a cross-sectional study, we performed small RNA sequencing analysis in skeletal muscle biopsies from three groups (matched for gender, body mass index, and history of diabetes): controls (n=13), patients with CKD 3-5 not yet on hemodialysis (n=13), and patients on maintenance hemodialysis (MHD, n=10). Total RNA was extracted and used to construct libraries for small RNA sequencing using Illumina NovaSeq 6000 system. Differentially expressed genes (DEGs) were identified with a false discovery rate (FDR) <0.05 and fold change > 2.

Results: We identified 57 DEGs between controls and MHD groups, 43 DEGs between CKD 3-5 and MHD groups, and 16 DEGs between controls and patients with CKD 3-5 (**Figure 1**). The DEGs were found to be involved in cachexia (mir-450), muscle atrophy (miR-23), and muscle wasting/protein synthesis (miR-424). In patients with CKD, we observed an upregulation of miR-542, which has been associated with promoting mitochondrial dysfunction and enhancing SMAD 2/3 phosphorylation, a downstream effect of myostatin.

Conclusions: Our results suggest that miRNA expression profiling is altered in moderate to advanced CKD. The differential expressed miRNAs may explain the loss of muscle mass in CKD. Thus, miRNAs may enhance atrophy and inhibit muscle growth pathways. Further studies should identify the specific miRNA targets to prevent sarcopenia and frailty in CKD.

Continued Activation of Hypoxia Inducible Factor 1α by Roxadustat and Inhibition of Differentiation in Skeletal Muscles

Yuya Miki, Akinobu Ochi, Hideki Uedono, Yoshinori Kakutani, Yuki Nagata, Katsuhito Mori, Yasuo Imanishi, Tetsuo Shoji, Tomoaki Morioka, Masanori Emoto. *Osaka Koritsu Daigaku, Osaka, Japan.*

Background: Patients with chronic kidney disease are prone to develop renal anemia. Hypoxia-inducible factor prolyl hydroxylase (HIF-PH) inhibitors, such as roxadustat, have recently been recognized as a viable treatment option for this condition by stabilizing hypoxia-inducible factor-1α (HIF-1α). Nonetheless, the consequences of continued HIF-1α activation on skeletal muscle differentiation are not fully understood. This study explores the effects of continued HIF-1α activation on the differentiation of skeletal muscles.

Methods: We cultured mouse C2C12 myoblasts to differentiate into myotubes using horse serum, with or without 100 μM roxadustat. We evaluated the extent of muscle differentiation and measured the expression of muscle differentiation-related proteins and genes (MyoD and myogenin) and muscle constituent proteins (myosin heavy chain, MHC). Additionally, two groups of nine-week-old male C57BL/6 mice were treated with either roxadustat or a vehicle control via intraperitoneal injections three times a week for four weeks. We analyzed the expression of HIF-1α, muscle differentiation and constituent proteins in the gastrocnemius muscle.

Results: Addition of roxadustat to C2C12 myoblast cultures results in an increased expression of HIF-1α protein. Treatment with roxadustat for 72 hours suppressed myotube formation in C2C12 cells, reducing both the differentiation and fusion indices compared to untreated controls. Gene and protein expression levels of MyoD, myogenin, and protein expression level of MHC were also lower in the roxadustat-treated C2C12 myotubes than untreated C2C12 myotubes. The decrease in MHC protein expression induced by roxadustat was attenuated by siRNA targeting HIF-1α. In the in vivo experiments, roxadustat treatment led to an increase in HIF-1α protein levels and a decrease in the protein expression of MyoD, myogenin, and MHC in the gastrocnemius muscle of the treated mice compared to controls.

Conclusions: The results indicate that continued activation of HIF-1α by roxadustat inhibits skeletal muscle differentiation.

Home-Based Exercise Improves Muscle Mitochondrial Function in CKD: Results from a Pilot Randomized, Controlled Clinical Trial

Christopher Hayden,[1] Gwenaelle Begue,[2] Usman Rehman,[1] Armin Ahmadi,[1] Chenoa R. Vargas,[1] Thomas Jue,[1] Jorge Gamboa,[3] Baback Roshanravan.[4] *[1]University of California Davis, Davis, CA; [2]California State University Sacramento, Sacramento, CA; [3]Vanderbilt University School of Medicine, Nashville, TN; [4]University of California Davis School of Medicine, Sacramento, CA.*

Background: Chronic kidney disease (CKD) leads to impaired muscle mitochondrial function contributing to mobility impairment and frailty. Exercise training improves muscle function and physical capacity, but proper equipment and instruction can be difficult to access. We tested the impact of home-based exercise on in vivo muscle mitochondrial function.

Methods: We conducted a pilot randomized controlled trial (NCT02923063) of a 12 wk home-based, virtually supervised exercise (EX) in CKD sedentary patients compared to usual care (UC). Exercise consisted of one high-intensity interval training, one resistance training, and one power walking session per week. Primary endpoint was leg muscle oxidative capacity measured using ^{31}Phosphorus Magnetic Resonance Spectroscopy. Participants performed one knee extension per second against an elastic

resistance band for 42s depleting phosphocreatine (PCr) by 25-50%. PCr recovery was measured and fit with a monoexponential equation. The rate constant of this equation (kPCr, min^{-1}) is an indicator of mitochondrial oxidative capacity. Linear mixed models were used to test the effect of exercise on kPCr.

Results: Muscle oxidative capacity was 1.23±0.33min^{-1} in UC (n=9, mean±SD age=67 ± 8yr, eGFR=32±12, 22% male, 44% diabetic) and 1.24±0.26 in EX (n=21, mean age=63.0±10yr, eGFR=35±12, 47% male, 47% diabetic) at baseline. Home-based exercise improved muscle oxidative capacity by 0.197min^{-1} (95% CI: 0.05-0.35, P=0.01) compared to usual care (Fig 1).

Conclusions: Twelve weeks of virtually supervised at-home training can improve muscle oxidative capacity in CKD patients. These results support the use of exercise to combat mitochondrial dysfunction in CKD and demonstrate the efficacy of a low barrier to access intervention.

FR-OR32

Skeletal Muscle Extracellular Matrix in Patients on Hemodialysis

Jorge Gamboa,[1] Anthony C. Dematteo,[1] Dungeng Peng,[1] Mert Demirci,[2] Jennifer E. Norman,[2] Gwenaelle Begue,[3] Tae Youn Kim,[2] Lucas R. Smith,[2] Baback Roshanravan,[2] Talat Alp Ikizler.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]University of California Davis, Davis, CA; [3]California State University Sacramento, Sacramento, CA.*

Background: Frailty and sarcopenia are common in patients with chronic kidney disease (CKD). The extracellular matrix (ECM) plays an important role in muscle proliferation as the scaffold for muscle growth. We have previously shown that ECM gene expression is altered in patients on hemodialysis (HD). We now test the hypothesis that the content of collage, the major structural protein in skeletal muscle, is decreased in patients on HD.

Methods: In a cross-sectional study, we obtained vastus lateralis muscle biopsies from three groups (matched for gender, body mass index, and history of diabetes): controls (n=13), patients with CKD 3-5 not yet on hemodialysis (n=13), and patients on maintenance hemodialysis (MHD, n=10). Using data from RNA sequencing, we evaluated the gene expression of specific ECM genes. We also evaluated the collagen content using the hydroxyproline assay.

Results: We found the downregulation of 16 ECM genes between controls and MHD groups, and 24 ECM genes between CKD 3-5 and MHD groups. There was no difference in ECM gene expression between controls and patients with CKD 3-5. *COL4A1*, which encodes for alpha 1 chain of type IV collagen, and *DCN*, which encodes for decorin, were among these genes (Figure 1 A and B). Total collagen content was also decreased in patients on MHD compared to the other two groups (Figure 1C).

Conclusions: Our results suggest a reduced content of ECM components in skeletal muscle in patients on MHD. Alterations in ECM remodeling may play a role in sarcopenia in CKD. ECM not only provides structural support but also inhibits atrophic factors, such as myostatin inhibition by decorin. Further studies should identify potential targets of the ECM pathways to prevent sarcopenia and frailty in CKD.

Altered Muscle Bioenergetic in CKD: Focus on Inorganic Phosphate and Acidosis

Dungeng Peng,[1] Zuofei Wang,[1] Anthony C. Dematteo,[1] Mert Demirci,[1] Gwenaelle Begue,[2] Thomas Jue,[3] Baback Roshanravan,[3] Talat Alp Ikizler,[1] Jorge Gamboa.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]California State University Sacramento, Sacramento, CA; [3]University of California Davis, Davis, CA.*

Background: Patients with chronic kidney disease (CKD) commonly experience fatigue. Muscle acidosis and inorganic phosphate accumulation have been widely associated with fatigue in the non-CKD population. We hypothesized that altered muscle bioenergetics (inorganic phosphate and pH) are present in patients with CKD and associated with physical performance measurements.

Methods: In a cross-sectional study, we evaluated 63 participants: 20 with CKD stage 3-5 not on hemodialysis (HD), 20 on hemodialysis, and 23 matched controls with no history of CKD). Muscle bioenergetics was evaluated using ^{31}phosphorus magnetic resonance spectroscopy at resting and after sub-maximal exercise. The relative concentration inorganic phosphate was obtained using AMARES and jMRUI. Intracellular pH was calculated from the chemical shift of the inorganic phosphate signal relative to phosphocreatine. Inorganic phosphate levels after exercise were fitted to a mono-exponential function to determine the time constant tau (τ).

Results: Groups were matched by gender, body mass index, and history of diabetes and hypertension. Plasma phosphate levels were higher in patients on HD. We found that resting intracellular pH was slightly but significantly lower in patients on HD and with CKD 3-5 compared to controls (**Figure 1A**). The concentration of inorganic phosphate at the end of exercise was significantly higher in patients on HD (**Figure 1B**). The constant tau of inorganic phosphate decrease after exercise was prolonged in patients on HD compared to the other two groups (**Figure 1C**), and it was associated with the six-minute walk distance (rho= -0.45, p<0.001). These changes were not associated with phosphate or bicarbonate levels in plasma.

Conclusions: Our results suggest that intracellular energy metabolism is impaired in patients with CKD. The changes in inorganic phosphate mirror our previous findings of impaired mitochondrial function in CKD and may play a role in physical activity in this population. Further studies should evaluate the contribution of intracellular acidosis or increased inorganic phosphate on fatigue in patients with CKD.

Cardiorespiratory Fitness in Kidney Transplant Recipients and the Effects of Home-Based Rehabilitation

Roseanne E. Billany,[1] Ella C. Ford,[2] Gurneet K. Sohansoha,[1] Stephanie E. Burns,[3] Noemi Vadaszy,[1] Zahra Mubaarak,[1] Nicolette C. Bishop,[4] Alice C. Smith,[1] Matthew Graham-Brown.[1] *[1]University of Leicester, Leicester, United Kingdom; [2]Leeds Beckett University, Leeds, United Kingdom; [3]University Hospitals of Leicester NHS Trust, Leicester, United Kingdom; [4]Loughborough University, Loughborough, United Kingdom.*

Background: Kidney transplant recipients (KTR) have an increased burden of cardiovascular disease (CVD) and poor cardiorespiratory fitness (CRF) is associated with poorer clinical outcomes; particularly cardiovascular related. The aims of this study were: (1) to compare CRF parameters in KTR and age-sex matched healthy volunteers (HV), (2) explore the CRF related effects of 12-weeks of home-based exercise rehabilitation in KTR.

Methods: 30 KTR (14 male; age 61±8 years) and 30 HV (14 male; age 61±7 years) completed a continuous ramp cardiopulmonary exercise test (CPET) to volitional exhaustion. 50 KTR (>1-year post-transplant; 50±14 years; 23 male) were randomised 1:1 to: intervention (INT: a 12-week home-based combined aerobic and resistance exercise programme) or control (CT: guideline-directed care).

Results: KTR had reduced exercise capacity and increased ventilatory response to exercise compared to HV (Fig 1). Relative VO_{2peak} was 5.29 ±1.35 ml/kg/min lower in KTRs v HV. Post-intervention VO_{2peak}, after baseline adjustment, was greater in INT v CT (+1.50 ml/kg/min (95%CI: 0.1-2.9; p=.03)) as was max power (+8 W, p<.03) and heart rate (+10 bpm, p<.04). Total number of aerobic exercise session performed was associated with greater change in VO_{2peak} (R_2=.252, p=.04).

Conclusions: CRF is impaired in KTR compared to age-sex matched HV. This may relate to low levels of physical activity, but could imply underlying cardiovascular dysfunction. Home-based rehabilitation significantly improved CRF. These results indicate the need to prioritise the development and implementation of structured exercise and educational programmes for KTR as part of routine care.

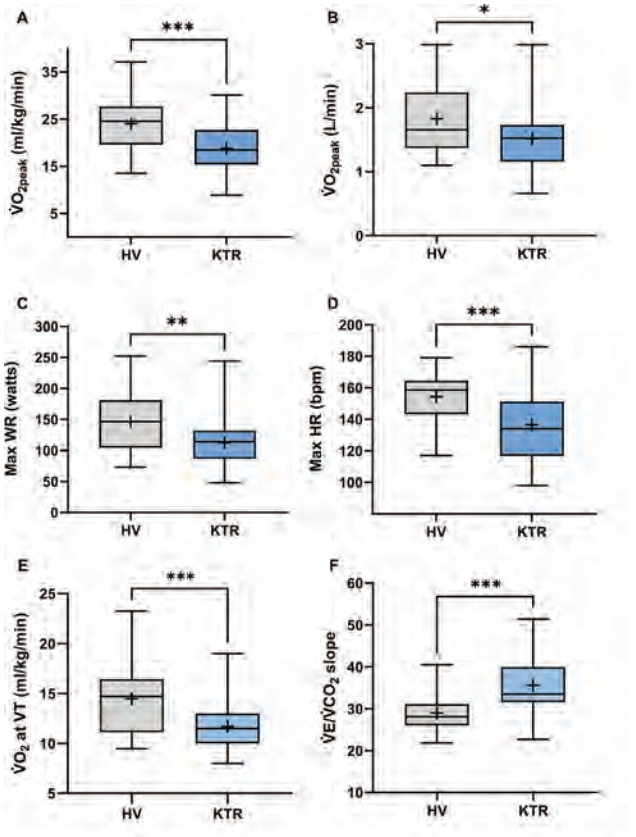

Figure 1. Distribution of values for basic peak cardiorespiratory fitness parameters in HVs and KTRs. (A, $\dot{V}O_{2peak}$ [ml/kg/min]; B, $\dot{V}O_{2peak}$ [L/min]; C, maximum work rate [watts]; D, maximum heart rate [bpm]; E, $\dot{V}O_2$ at ventilatory threshold [ml/kg/min]; F, $\dot{V}E/\dot{V}CO_2$ slope).
Abbreviations: HR, heart rate; HV, healthy volunteers; KTR, kidney transplant recipients; $\dot{V}E$, volume of air inspired or expired per minute; VT, ventilatory threshold; WR, work rate.
*p ≤.05, ** p ≤.01, ***p ≤.001. "+" indicates mean value.

FR-OR35

Efficacy of a Remote Exercise Program on Fatigue in Persons with CKD

Tae Youn Kim,[1] Hiba Hamdan,[1] Jennifer E. Norman,[1] Jesse Gipe,[1] Thomas Jue,[1] Gwenaelle Begue,[2] Jorge Gamboa,[3] Baback Roshanravan.[1] *[1]University of California Davis, Sacramento, CA; [2]California State University Sacramento, Sacramento, CA; [3]Vanderbilt University, Nashville, TN.*

Background: Physical frailty and fatigue are prevalent in persons with chronic kidney disease (CKD), contributing to poor quality of life and increased morbidity and mortality risk. While previous studies show positive impact of exercise programs on reducing inflammation and fatigue, little is known about the efficacy of a structured exercise program on immune cell mitochondrial bioenergetics and fatigue in persons with CKD.

Methods: We conducted a pilot randomized (3:1) clinical trial of a 12-week video-supervised individualized exercise program (NCT02923063). Outcomes include 1) aerobic exercise capacity (measured with a total distance of a 6-minute walk test (6MWT)), 2) peripheral blood mononuclear cells (PBMC) mitochondrial bioenergetics (measured using the high resolution respirometry), and 3) fatigue measured using a 13-item validated scale (FACIT-Fatigue). We classified exercise responders by performance on 6MWT (>=17meters). Linear mixed effects models were used to examine the association of exercise with PBMC bioenergetics and fatigue adjusting for depressive mood measured with the 8-item PROMIS Depression scale.

Results: Of 30 participants with CKD, nine were randomized in the usual care group (UC) and 21 in the exercise group (EX). No difference was found at baseline between the groups in sex (60% male), diabetes (47%), age (64±10 years), eGFR (34±12ml/min per 1.73m^2), depression (47±8.4), fatigue (38±10), and 6MWT (463±88 meters). We also found no difference in the mean values of PBMC ATP-linked respiration between the UC (1.1±0.5 pmol O2/min/10K cells) and EX (1.2±0.8) at baseline. With a mean change of 17 meters or greater for 6MWT, 12 of the 21 EX improved exercise capacity and reduced fatigue (a mean difference: 5.13, 95% CI[0.44, 9.81], p=0.03) at follow-up. Further adjustment for depression showed that each 1 standard deviation decline in PBMC ATP-linked respiration was associated with a 14-point decrease in fatigue (95%CI[-24.52, -3.48], p=0.009).

Conclusions: Among responders to our exercise program with improved 6MWT, exercise program reduced fatigue which was inversely correlated with PBMC ATP-linked respiration. Further investigation is needed to examine long-term effects of exercise on ameliorating mitochondrial dysfunction and its links to inflammation responses and fatigue in a larger cohort of CKD.

Exercise Increases Resident Macrophage Abundance and Lipoxin A4 in Kidneys

Sophia M. Sears, Ernesto H. Pena Calderin, Haley Asplund, Richa A. Singhal, Jason Hellmann, Brian Sansbury, Steven P. Jones. *University of Louisville School of Medicine, Louisville, KY.*

Background: Exercise contributes to human health via benefits to several physiological systems; however, the mechanisms by which exercise impacts renal health remain poorly understood. Although exercise can be acutely stressful on the kidneys due to transient reductions in renal blood flow, studies show that moderate intensity exercise slows the age-related decline in kidney function. Additionally, exercise protects against AKI in both ischemic and nephrotoxic rodent models. We hypothesize that exercise triggers adaptative responses in kidney resident macrophages (KRMs) including production of specialized pro-resolving lipid mediators (SPMs), which preserves hemodynamic balance in the kidneys under stress.

Methods: We performed a time course analysis of exercise-induced adaptations in the kidneys of 10 wk old C57BL/6J male mice. Mice were subjected to daily forced treadmill running at 70% capacity for 40 minutes for 1 or 2 wk. We also evaluated mice 24 h after a single bout of exhaustive exercise to discern acute responses from chronic adaptations. Sedentary mice were used as controls. We performed flow cytometry, targeted lipidomics, histopathology, and bulk mRNA sequencing to evaluate exercise-induced adaptations.

Results: We found a significant increase in KRMs (CD45$^+$CD11b$^+$F4/80^{hi}) after 2 wk of exercise compared to sedentary controls (p=0.0005). This increase was not present at either 24 h or 1 wk (**Fig 1**). We believe this was driven by expansion of KRMs rather than infiltration of monocyte derived macrophages as the population was primarily CX3CR1$^+$CCR2$^-$. Moreover, we found that 2 wk of exercise significantly increased renal lipoxin A4 (p=0.04), a vasoactive SPM that can be produced by macrophages and has been demonstrated to have renoprotective effects.

Conclusions: Taken together, these data suggest that exercise alters the immune landscape of the kidney in a way that may preserve renal blood flow and reduce renal vascular congestion during kidney injury and recovery from insults. This study provides support for the utilization of exercise programs in the management of kidney disease.

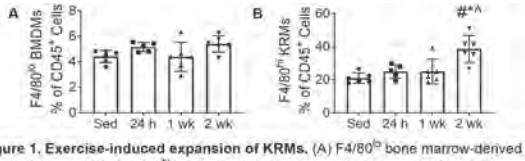

Figure 1. Exercise-induced expansion of KRMs. (A) F4/80^{lo} bone marrow-derived macrophages and (B) F4/80^{hi} KRMs in sedentary and exercised mice. Populations are identified from hierarchical gated CD45$^+$ CD3$^-$ CD19$^-$ CD11b$^+$ cells. Data are expressed as the mean±SEM of the percentage of identified cells from the CD45$^+$ pool. Results were analyzed with a one-way ANOVA and Tukey's multiple comparison test. #p<0.05 vs sedentary, *p<0.05 vs 24 h, and ^p<0.05 vs 1 wk. n=5-6 biological replicates per group.

T Cell Egress from the Kidney to the Renal Lymph Node Is Regulated by Their Activation State and Controls Tissue Inflammation

Jonas Engesser, Jan-Hendrik Riedel, Nariaki Asada, Hans-Joachim Paust, Robin Khatri, Zeba Sultana, Catherine Meyer-Schwesinger, Thorsten Wiech, Victor G. Puelles, Stefan Bonn, Christian F. Krebs, Ulf Panzer. *Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

Background: A hallmark of autoimmune diseases such as crescentic glomerulonephritis (cGN) is the infiltration of pathogenic leukocytes into the kidney. Here, especially CD4$^+$ T cells play a key role in orchestrating the immune response and driving tissue damage. While T cell infiltration is described well, little is known about T cell emigration out of the kidney via lymph vessels and its role in controlling tissue inflammation. In this study, we aim to decipher T cell emigration signals and their role on tissue injury.

Methods: Human kidney biopsies from ANCA glomerulonephritis (ANCA-GN) patients were analyzed using 3D-immunofluorescence of lymphatics, and combined scRNA-seq and spatial transcriptome analysis. To investigate the trafficking of T cells from the kidney to the draining lymph node, we developed a new experimental system using the photoconvertible *Kaede* mouse. Using this system, we labelled renal T cells by photoconversion and analyzed their *in vivo* migration under homeostatic and nephritic conditions (experimental cGN).

Results: In ANCA-GN, lymphangiogenesis was primarily observed in the inflamed areas, accompanied by a predominance of $CD4^+$ T cells and macrophages. However, during inflammation, only T cells emigrated out of the kidney via afferent lymphatics. To elucidate the mechanisms regulating T cell egress, we used our *Kaede*-mouse model to identify differential expression of the chemokine receptors CXCR6 and S1PR1 in emigrated vs. resident cells. T cell activation was linked to CXCR6 upregulation and tissue retention, while loss of activation led to CXCR6 downregulation, S1PR1 upregulation, and tissue egress. Blocking S1PR1 signaling exacerbated tissue damage by increasing T cell retention. Finally, flow cytometry and scRNA-seq analysis of human kidney, blood, and lymph fluid confirmed our observations from the murine model, including the downregulation of activation markers in tissue-emigrated T cells.

Conclusions: T cell emigration from the kidney to the renal lymph node is regulated by T cell activation signals and controls tissue inflammation and resolution. These data indicate that strategies to promote T cell egress offer potential options for treating immune mediated kidney diseases.

Setting a Pig Model of Crescentic Glomerulonephritis and Testing a Heparin-Binding Epidermal Growth Factor-Like Growth Factor (HB-EGF) Antagonist as a New Treatment

Pierre-Louis Tharaux,[1,2] Nassim Mahtal,[1] Julien Dang,[1] Sylvain Pichard,[3] Léa Resmini,[1] Daniel Gillet.[3,4] *[1]Paris Centre de Recherche Cardiovasculaire, Paris, France; [2]Universite Paris Cite UFR de Medecine, Paris, France; [3]Commissariat a l'energie atomique et aux energies alternatives Direction de la recherche fondamentale, Gif-sur-Yvette, France; [4]Universite Paris-Saclay, Gif-sur-Yvette, France.*

Background: Current crescentic glomerulonephritis (CGN) treatments are based only on drugs targeting the immune compartment responsible for glomerular injury. Despite state-of-the-art immunosuppression, many patients develop CKD and, ultimately, ESRD. Glomerular destruction following immune aggression is due to dedifferentiation and proliferation of parietal epithelial cells (PECs) and podocytes. These events are mediated by *de novo* expression of HB-EGF, a growth factor activating EGF receptor (EGFR) signaling (Bollée et al., Nat Med 2011). We developed an HB-EGF antagonizing strategy to prevent glomerular destruction during CGN. We described previously DTR8, an antagonist of HB-EGF derived by molecular evolution from the receptor-binding domain of the diphtheria toxin, a natural and highly selective binder of HB-EGF (Gillet et al., Patent WO/2013/140335). We engineered DTR8 to reach a pM affinity and reduce immunogenicity and antigenicity.

Methods: A model of CGN was induced in pigs by injection of decomplemented nephrotoxic serum (NTS) from sheep immunized against pig glomerular basement membrane. Ten pigs received intramuscular injections of 0.3 $mg.kg^{-1}$ of DTR8 twice daily for 20 days, and 12 pigs received vehicle only. Five normal control animals received pre-immune sheep serum. On day 21, the kidneys were harvested for histopathological observations.

Results: Pigs receiving NTS developed nephritic syndrome with high proteinuria, hypoalbuminemia, edema, and crescentic lesions typical of CGN. Their glomerular cells displayed immunoreactive HB-EGF, loss of podocyte differentiation markers, and exhibited phosphorylation of the EGFR. Periglomerular lymphocyte infiltration and interstitial fibrosis were observed. All these features were absent in control pigs receiving pre-immune sheep serum. Group-blinded comparison of DTR8-treated pigs showed a significant reduction of crescentic lesions ($p=0.037$), nephrin loss ($p=0.003$), EGFR phosphorylation ($p=0.016$), and interstitial fibrosis ($p=0.031$) compared to vehicle-treated animals.

Conclusions: We developed a valid model of CGN in pigs. Treatment with the HB-EGF antagonist DTR8 significantly reduced the histopathological damage. Reduction of EGFR phosphorylation highly suggests that DTR8 acts by inhibiting the HB-EGF/EGFR cascade.

Deciphering the Contribution of Macrophages to the Development of Focal Segmental Glomerulosclerosis

Claudio Sierra Gonzalez,[1,2] Jasper F. Nies,[1,2] Bastian Trinsch,[1,2] Paul Diefenhardt,[1,2] Paul T. Brinkkoetter,[1] Bernhard Schermer,[2] Thomas Benzing,[1,2] Sebastian Braehler.[1,2] *[1]Exzellenzcluster CECAD in der Universitat zu Koln, Koln, Germany; [2]University of Cologne Center for Molecular Medicine Cologne, Cologne, Germany.*

Background: FSGS is a severe kidney disease characterized by glomerular scarring, following podocyte injury. In its worst face, it leads to a significant kidney damage, resulting in nephrotic syndrome and end-stage kidney disease in both children and adults. A dysregulation of the immune system finds great acceptance as a driver of the disease. To further analyze this, we make use of a murine model of a slowly progressing FSGS.

Methods: In a longitudinal fashion, we performed flow cytometry in order to phenotype the immune cell composition during disease progression. Among clinical parameters, like ACR and BUN, we assessed the histological damage via PAS and localized immune cells via IHC and IF. To further profile these immune cells, we performed single-nucleus RNA sequencing of isolated glomeruli.

Results: Based on our snRNAseq data, we detect an inflammatory and pro-fibrotic milieu with high activation of CX3CL1 as strong immune cell-recruiting factor. In accordance with this, flow cytometry data confirms an increase in mononuclear phagocyte infiltration and moreover, suggesting a functional shift in renal macrophages from a pro-inflammatory M1–like phenotype to a pro–fibrotic M2–like phenotype in diseased mice. Immunohistochemistry and immunofluorescence analyses underline this higher abundance of M2–like macrophages along disease progression. The lack of CX3CL1 in this model leads to an aggravated disease phenotype with a slightly shortened life span, increased BUN levels and an exacerbated M1-like to M2-like phenotypical alteration.

Conclusions: We identified mononuclear phagocytes to be the most prominent immune cells to infiltrate the kidney during FSGS progression, especially macrophage subpopulations displaying a pro-fibrotic transcriptomic signature. Furthermore, our findings suggest a strong association between the CX3CL1/CX3CR1 axis and the recruitment and polarization of renal macrophages. Notably, its absence has been shown to exacerbate the M1–like to M2–like phenotype shift, highlighting its potential regulatory role in macrophage polarization. Further research is necessary to elucidate the precise mechanism of how the CX3CL1/CX3CR1 axis might contribute to renal fibrosis and understanding this could pave the way for the development of targeted therapies.

FR-OR40

The "TNFa-suPAR" Axis Links Bone Marrow Alterations to Kidney Dysfunction

Alexis P. Jimenez Uribe,[1] Ryan Spear,[1] Yanxia Cao,[1] Steve Mangos,[1] Jochen Reiser,[2] Eunsil Hahm.[1] *[1]Rush University, Chicago, IL; [2]The University of Texas Medical Branch at Galveston Development Office, Galveston, TX.*

Background: Previous study identified bone marrow (BM)-derived immature myeloid cells as the source of soluble urokinase plasminogen activator receptor (suPAR), a key inflammatory mediator causing glomerular damage and proteinuria in mice. However, the factor driving the expansion of these pathogenic myeloid cells and suPAR increase remains unknown. Preliminary data show elevated TNFα and suPAR levels in the BM of CKD patients with altered hematopoiesis. This study tests the hypothesis that TNFa induces BM alterations and subsequent suPAR increase, thereby contributing to the renal dysfunction

Methods: TNFa levels were measured from three proteinuric animal models; TGFb-Tg mice (progressive glomerulosclerosis), nephrotoxic serum (NTS)-injected mice (glomerulonephritis), and LPS-injected mice (acute kidney injury). Functional in vivo tests included TNFa blockade, suPAR-deficient mice, and TNFa injection alone or with IFNg. In vitro myelopoiesis assays were performed using human hematopoietic stem cells or HL-60 promyelocytic cell line, with or without TNFa. Immunophenotyping, secretome analysis, and metabolic evaluation were conducted using multiparametric flow cytometry, multiplex, ELISA, and Seahorse assays

Results: Our results revealed elevated TNFa levels in three proteinuric animal models characterized by high suPAR and expanded immature myeloid cells in the BM. Blocking TNFa reduced both proteinuria and suPAR levels. TNFa alone was not enough to cause renal injury without suPAR or active myelopoiesis. However, when co-injected with IFNg (a key cytokine for myelopoiesis), TNFa triggered significant myeloid cell expansion, increased suPAR levels, and proteinuria in mice. In vitro myelopoiesis assays demonstrated that TNFa attenuates granulocytic lineage development, favoring monocytic lineage differentiation. Additionally, TNFa enriched a glycolytic and oxidative metabolic phenotype in monocytic cells, enhancing suPAR and proinflammatory cytokines secretion.

Conclusions: Our study suggests that renal function is regulated by bone marrow alterations through the 'TNFa-suPAR' axis, resembling findings from CKD patients and mouse models of proteinuria. This implies that the 'TNFa-suPAR' axis serves as a common key pathway linking bone marrow alterations to renal dysfunction.

FR-OR41

Loss of CELF4 in Kidney Dorsal Root Ganglion Neurons Leads to Acute Onset of Glomerular Diseases

Lindsey A. Fitzsimons,[1,2] Madison G. Mueth,[3] Michael C. Akom,[4,5] Grant Oakley,[4,5] Benjamin J. Harrison.[2,1] *[1]University of New England, College of Osteopathic Medicine, Biddeford, ME; [2]University of New England, Center for Excellence in Neurosciences, Biddeford, ME; [3]University of Maine, Graduate School of Biomedical Science & Engineering, Orono, ME; [4]Maine Medical Center, Portland, ME; [5]Maine Medical Partners Nephrology, Portland, ME.*

Background: Sustained upregulation of renal sympathetic and sensory nerve reflexes, known as *renorenal hyperreflexia* (RRH), promote the onset/ progression of chronic kidney disease (CKD). RRH consequences are exacerbated with the onset of inflammation and secretion of trophic factors (e.g. nerve growth factor; NGF), previously shown to promote structural and functional damage to the glomerulus. Our preliminary data demonstrate that pathogenic activation of peripheral sensory nerve fibers is controlled by an RNA binding protein, known as CUGBP Elav-Like Family Member 4 (CELF4). The goal of this study was to investigate the role of CELF4 as a tonic regulator of renal DRG neuron (RDN) excitability, RRH and overall kidney function.

Methods: An inducible, *CGRP^{cre}* mouse was used to direct *Celf4*-knockout (KO) from adult sensory neurons, followed by behavior assessments of peripheral neuropathy, RDN electrophysiology, semiquantitative blood and urinalysis and histopathological analyses of kidney and glomerular cytostructure.

Results: *Celf4* KO mice displayed robust hind-paw hypersensitivity to mechanical and thermal stimuli that was further exacerbated with NGF injection. Patch-clamp recordings confirmed acutely-dissociated, capsaicin-sensitive RDN become hyperexcitable following *Celf4* KO. Immunofluorescence confirmed coexpression of CGRP, TRPV1 and CELF4 in RDN. *Celf4* KO kidneys displayed hydronephrosis and increased pre-fixation weight and semi-quantitative urinalysis revealed *Celf4* KO mice develop 2-3+ proteinuria and microscopic hematuria. Histological analyses with H&E, PAS and PAS-silver stained kidney sections revealed a novel and unexpected renal phenotype in *Celf4* KO, characterized by pronounced mesangial expansion, extracellular matrix deposition, hypercellularity and incidence of glomerular sclerosis. When combined, these findings suggest a *Celf4* KO renal phenotype that is consistent with membranoproliferative glomerulonephritis (MPGN).

Conclusions: We demonstrate that CELF4 is co-expressed with TRPV1 in CGRP+ RDN, and that loss of CELF4 increases neural excitability and sensitivity of RDN, leading to development of MPGN. These data represent preliminary data from ongoing studies in our lab investigating CELF4 as a possible protective regulator against RRH mechanisms responsible for impairing renal/glomerular function in hypertension and CKD.

Phenome-Wide Mendelian Randomization Analysis of the Plasma Proteins, Immune Cell Types, and Immune Cell Traits in IgAN

Ruilian You, Zhiying Liu, Mengshi Li, Yang Li, Xu-jie Zhou, Hong Zhang. *Peking University First Hospital, Beijing, China.*

Background: IgA nephropathy (IgAN) remains the most frequent primary glomerular disease worldwide with poor outcomes leading to end-stage renal disease. Although there were significant advances in the understanding of the pathogenesis of IgAN in the past decade, an unmet need exists for further knowledge on the contribution and cause-effect of each cell type and protein in its pathogenesis.

Methods: We conducted a Mendelian randomization phenome-wide association study (MR-pheWAS) to identify potential causal factors of IgAN (Kiryluk Lab, N=26734) among 791 plasm proteins, 17 circulating immune cells and 731 immune cell traits (118 absolute cell counts, 389 MFIs of surface antigens and 32 morphological parameters, 192 relative ratios between cell counts). FinnGen database (N=412181) of IgAN was applied for genetic replication. Reverse MR and Bayesian co-localization were performed to consolidate the results. Further, GO and KEGG pathway enrichment and protein-protein interaction of the putative proteins fowling hub module and hue genes were conducted to search for the underlying mechanism.

Results: As for the MR-pheWAS of the pQTLs, CFH was identified as a significant protective factor for IgAN (OR 0.54, 95%CI [0.45,0.65], P=1.47E-10), while CFHR1 (OR 1.21, [1.12,1.31], P=8.49E-07) and ERAP2 (OR 1.14, [1.07,1.21], P=7.33E-06) showed as the risk factors. Additional 5 common putative proteins are suggestive in both datasets. As for the circulating immune cell types, it indicated a causal association between neutrophil (OR 1.64, [1.30,2.08], P=3.95E-05), white blood cell (OR 1.47, [1.20,1.81], P=2.32E-04) and an increased risk of IgAN. Activated & secreting Treg %CD4+, CD25hi %CD4+, T cell absolute count (AC), CD4+ AC, and Central memory (CM) CD4+ AC were indicated as the top 5 risk immune cell traits of IgAN. Enrichment analysis showed the complement activation cascade is a key pathway.

Conclusions: Our results showed causal-effect clues of some key proteins, cell types, and cell traits in IgAN, highlighting complement and certain CD4+ T cells may warrant further mechanism investigation and therapy development.

FR-OR43

Single-Cell Metabolic Profiling of Kidney T Cells Reveals Key Importance of Glycolysis in Crescentic Glomerulonephritis

Jasper F. Nies,[1,2] Bastian Trinsch,[1,2] Claudio Sierra Gonzalez,[1,2] Paul Diefenhardt,[1,2] Tobias Eckey,[1,2] David L. Puetz,[1,2] Bernhard Schermer,[1,4] Thomas Benzing,[1,2] Mauro Corrado,[3,2] Paul T. Brinkkoetter,[1,2] Sebastian Braehler.[1,2] Braehler Group. *[1]Universitatsklinikum Koln, Koln, Germany; [2]University of Cologne Center for Molecular Medicine Cologne, Cologne, Germany; [3]University of Cologne, Faculty of Mathematics and Natural Sciences, Institute for Genetics, Cologne, Germany, Cologne, Germany; [4]Exzellenzcluster CECAD in der Universitat zu Koln, Koln, Germany.*

Background: Crescentic glomerulonephritis (cGN) is a devastating, T cell mediated autoimmune disease. The supply with various metabolites and their utilization is crucial for T cell function and activation. How employment of oxidative phosphorylation and glycolysis govern T cell fate and function during cGN is unclear but of central importance to expand our understanding of the disease's pathogenesis. These insights could open up new avenues for therapeutic intervention.

Methods: We use the model of nephrotoxic nephritis (NTN) to investigate T cell metabolism in homeostasis and disease. Due to the scarcity of T cells in mouse kidneys, we use single-cell-based methods including innovative immunometabolic assays in flow cytometry (SCENITH) and mass spectrometry (scMEP) as well as the analysis of scRNAseq datasets. To investigate the functional relevance of mitochondria and aerobic glycolysis in T cells, we use T cell-specific knockout mice for *Ptpmt1* (an enzyme essential for mitochondrial integrity) and *Ldha* (the key enzyme for aerobic glycolysis), respectively.

Results: Our data indicate a mitochondrial activation in T cells during NTN as measured by an increase in mitochondrial mass and mitochondrial membrane potential. Despite a strong dysregulation in T cell subsets in flow cytometry, mice with a mitochondrial dysfunction in T cells (CD4 Cre *Ptpmt1* flox) show no differences in clinical parameters during NTN compared to wildtype mice. Analysis of metabolic dependencies with SCENITH points towards a strong dependence of kidney T cells on glycolysis in the diseased state, which was not observed in spleens or kidney draining lymph nodes. This finding is further investigated in mice with a T cell-specific *Ldha* knockout.

Conclusions: Kidney T cells rewire their metabolism in the NTN model by increasing both mitochondrial and glycolytic activity. Given the strong dependence on glycolysis seen in our SCENITH analyses and the lack of a difference in the clinical outcome in mice with a mitochondrial dysfunction in T cells, we hypothesize that the glycolytic activation is functionally more relevant for the pathological activity of T cells, which would be of great interest for therapeutic intervention.

Genome Sequencing and Genetic Association Analyses of Primary Glomerular Disorders in CureGN, NEPTUNE, and Columbia CKD Biobank

Chen Wang,[1] Simone Sanna-Cherchi,[1] Matt G. Sampson,[2] Rasheed A. Gbadegesin,[3] Ali G. Gharavi,[1] Matthias Kretzler,[4] Krzysztof Kiryluk.[1] CureGN Genomics Workgroup. *[1]Columbia University, New York, NY; [2]Boston Children's Hospital, Boston, MA; [3]Duke University, Durham, NC; [4]University of Michigan, Ann Arbor, MI.*

Background: Glomerular disorders (GD) represent a heterogenous group of kidney diseases with known inherited risk contributions from genetic variants. Whole genome sequencing (WGS) provides the most comprehensive method for profiling common and rare variants. In this study, we generated the largest WGS dataset for patients with primary GD. The aim was to identify common variants (CVs) associated with GD and to comprehensively test for associations of rare variants (RVs) collapsed over genes and/or their regulatory regions.

Methods: WGS (30x) was conducted for 4,307 GD cases and 3,845 controls from the CureGN and NEPTUNE studies and the Columbia CKD Biobank. Variant calling was performed with DRAGEN for individual samples and GATK for cross-sample joint calls. Principal component (PC) analysis was used to estimate genetic ancestry and divide the cohort into 3 ancestral groups (EUR, AFR, EAS). Genome-wide association studies (GWAS) for CVs with adjustment for sex and PCs were performed within each ancestry using PLINK and meta-analyzed across ancestries with METAL. RV collapsing analyses with REGENIE included rare loss-of-function and deleterious missense variants within coding genes; and functional variants within cis-regulatory elements based on the ABC model and ENCODE annotations.

Results: The combined cohort included 1,513 participants with IgA nephropathy (IgAN), 377 with IgA vasculitis (IgAV), 1,023 with membranous nephropathy (MN),

745 with minimal change disease (MCD), 649 with focal segmental glomerulosclerosis (FSGS) and 3,845 controls. GWAS of each GD type identified genome-wide significant associations in the *MHC* region (IgAN, IgAV, MN, MCD), *PLA2R1* (MN), and *APOL1* (FSGS). Among the 45 known risk loci previously identified by GWASes, 41 had the same effect direction and 22 replicated with at least nominal significance. Due to limited power, RV collapsing analyses demonstrated no exome-wide significant signals but nominated new candidate genes and regions for follow up studies.

Conclusions: Jointly called WGS data enhanced the resolution of genetic discovery for GD. We replicated most of the known disease associations, indicating substantial potential for a planned meta-analysis incorporating the published studies. The WGS data is accessible via dbGAP (phs002480).

FR-OR45

Combined Genome and Transcriptome Sequencing of the CureGN Study Generates Comprehensive Maps of Glomerulonephritis-Specific Blood Expression Quantitative Trait Loci (eQTL) Effects

Lili Liu,[1] Chen Wang,[1] Felix H. Eichinger,[2] Damian Fermin,[2] Simone Sanna-Cherchi,[1] Matt G. Sampson,[4] Rasheed A. Gbadegesin,[3] Ali G. Gharavi,[1] Matthias Kretzler,[2] Krzysztof Kiryluk.[1] *[1]Columbia University, New York, NY; [2]University of Michigan, Ann Arbor, MI; [3]Duke University, Durham, NC; [4]Harvard Medical School, Boston, MA.*

Background: IgA nephropathy (IgAN), focal segmental glomerulosclerosis (FSGS), membranous nephropathy (MN), and minimal change disease (MCD) account for the majority of idiopathic glomerulopathies (GN). GWASes started to delineate their genetic mechanisms, but there are no adequately powered transcriptomic datasets coupled to genetic data to investigate functional consequences of identified risk alleles in different GN forms.

Methods: We performed 30x whole genome sequencing (WGS) coupled with blood RNA-seq on the CureGN cohort. In total, 1826 participants had high quality WGS and RNA-seq data for analysis. The bulk gene expression profiles were deconvolved into 6 major immune cell types using CIBERSORTx. We then generated transcriptome-wide maps of eQTL effects for FSGS (N=450), IgAN (N=403), IgA vasculitis (N=123), MCD (N=408) and MN (N=442). Cis- and trans-eQTL signals for each condition were defined using linear regression in tensorQTL, adjusting for age, sex, genetic PCs, PEER factors. The analyses were performed with and without additional adjustment for immune cell fractions. We then performed interaction eQTL mapping for each cell type as well as GN type.

Results: We identified 13,115 unique cis-eGenes (N_{FSGS}=10,004, N_{IgAN}=9,589, N_{IgAV}=3,757, N_{MCD}=9,686, and N_{MN}=9,899). About 5% of eGenes were unique to one phenotype, and 95% were shared between at least two conditions. For trans-eQTLs, 645 trans-eGenes were detected (N_{FSGS}=298, N_{IgAN}=136, N_{IgAV}=47, N_{MCD}=229, and N_{MN}=215). Interestingly, a larger proportion of trans-eGenes was disease-specific compared to cis-signals. After additionally adjusting for cell fractions, we gained extra 279 cis-eGenes and 70 trans-eGenes, but lost 362 cis-eGenes and 114 trans-eGenes. By interaction eQTL mapping, we further refined a set of cis-signals specific to each cell type and each GN form. These data were then used to prioritize candidate causal genes at the GN risk loci identified in the latest GWASes.

Conclusions: Using the CureGN dataset, we identified immune cell type-specific and GN-context-specific genomic regulators for gene expression by blood eQTL mapping. Our comprehensive eQTL maps provide a powerful resource for integrative gene discovery studies for primary GN.

FR-OR46

Acylcarnitines and Cardiovascular Outcomes in the CKD in Children (CKiD) and Chronic Renal Insufficiency Cohort (CRIC) Studies

Arthur Lee,[1] Xuan Cai,[3] Mark Mitsnefes,[12] Susan L. Furth,[1] Bradley A. Warady,[2] Tamara Isakova,[3] James P. Lash,[4] Farsad Afshinnia,[5] Jiang He,[9] Bernard G. Jaar,[6] Jordana B. Cohen,[10] Mirela A. Dobre,[11] Mahboob Rahman,[11] Morgan Grams,[7] Josef Coresh,[7] Eugene P. Rhee,[8] Michelle Denburg,[1] Rupal Mehta.[3] *[1]The Children's Hospital of Philadelphia, Philadelphia, PA; [2]Children's Mercy Kansas City, Kansas City, MO; [3]Northwestern University Feinberg School of Medicine, Chicago, IL; [4]University of Illinois Chicago College of Medicine, Chicago, IL; [5]University of Michigan Medical School, Ann Arbor, MI; [6]Johns Hopkins Medicine, Baltimore, MD; [7]New York University Grossman School of Medicine, New York, NY; [8]Massachusetts General Hospital, Boston, MA; [9]Tulane University School of Medicine, New Orleans, LA; [10]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [11]University Hospitals, Cleveland, OH; [12]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: CKD is associated with poor cardiovascular (CV) outcomes in children and adults despite differences in etiology and cardiometabolic risk factors. We hypothesize that acylcarnitines (ACs), mitochondrial dysfunction biomarkers, are associated with poor CV outcomes in children and adults with CKD.

Methods: The CKiD and CRIC studies are multicenter prospective cohorts of children and adults with CKD respectively, with echocardiographic and metabolomic data. CKiD had follow-up echocardiograms and metabolomics. CRIC had follow-up echocardiograms. Multivariable regression models assessed the associations of ACs and left ventricular mass index (LVMI), elevated filling pressure (E/e'>8) (CKID), and heart failure (HF) events (CRIC).

Results: 556 CKiD participants were included (median [interquartile range] age 11[8,15] years, eGFR 50[37,64] ml/min/1.73m^2, LVMI z-score 0.2[-0.7,1.0], 15% with E/e'>8) with 44 ACs assayed. 1747 CRIC participants were included (mean [standard deviation] age 59[11] years, eGFR 43[17] ml/min/1.73m^2, LVMI 64[24] g/m^2, 354 HF events over 10.1 years median follow-up) with 24 ACs assayed. Table 1 shows regression results of ACs and LVMI. Figure 1 shows regression results of ACs and elevated filling pressure and HF events.

Conclusions: ACs are associated with CV outcomes in both children and adults in CKD, despite their differences in CKD etiology and prevalence of diabetes and preexisting CV disease. This suggests a role for CKD-associated mitochondrial dysfunction in the development of CV disease.

Urine Ammonium Concentrations and Cardiovascular and Kidney Outcomes in SPRINT

Alexander L. Bullen,[1] Dena E. Rifkin,[1] Joachim H. Ix,[1] Ronit Katz.[2] *[1]University of California San Diego, La Jolla, CA; [2]University of Washington, Seattle, WA.*

Background: Impaired urine ammonium excretion is common in chronic kidney disease (CKD) and may identify risk of metabolic acidosis earlier than reductions in serum bicarbonate or pH, and thus may have associations with cardiovascular disease (CVD) outcomes. We evaluated the association of urine ammonium with CVD and kidney outcomes among persons with hypertension and non-diabetic CKD enrolled in a trial of blood pressure reduction.

Methods: We measured urine ammonium concentration in spot urine specimens collected at baseline among 2092 participants. We used multivariable-adjusted Cox models to evaluate associations of urine ammonium concentration with the SPRINT primary CVD composite outcome (myocardial infarction, acute coronary syndrome, stroke, heart failure, or CVD death), all-cause mortality, the SPRINT kidney composite outcome (50% kidney function decline, end stage kidney disease, or transplant), and acute kidney injury (AKI).

Results: The mean (SD) age was 73 (9) years; 40% were female; and 25% were Black participants. The mean (SD) serum bicarbonate was 25.6 (2.8) mmol/L, median (interquartile range, IQR) urine ammonium concentration was 14.4 (9.5, 23.1) mmol/L, and median (IQR) eGFR was 49 (39,55) ml/min/1.73 m^2. There were 255 CVD composite events, 143 deaths, 63 kidney composite events, and 146 AKI events during a median follow-up of 3.8 years. In multivariable models, each 2-fold higher urinary ammonium

concentration was associated with a 26% (95% CI 1.05, 1.52) higher risk of the CVD composite, whereas there was no association with all-cause mortality, the SPRINT kidney composite outcome, or AKI.

Conclusions: Among non-diabetic individuals with hypertension and CKD, higher urine ammonium concentration is associated with higher risk of CVD.

Aprocitentan in Patients with CKD: Subgroup Analysis of the PRECISION Trial

Markus P. Schlaich,[1] George L. Bakris,[2] Peter Cornelisse,[4] Roland F. Dreier,[4] Bruno Flamion,[4] Johannes F. Mann,[3,6] Patrick Rossignol.[5] *[1]The University of Western Australia Medical School, Perth, WA, Australia; [2]The University of Chicago Medicine, Chicago, IL; [3]Friedrich-Alexander-Universitat Erlangen-Nurnberg, Erlangen, Germany; [4]Idorsia Pharmaceuticals Ltd, Allschwil, Switzerland; [5]Centre Hospitalier Princesse Grace, Monaco, Monaco; [6]McMaster University, Hamilton, ON, Canada.*

Background: Resistant hypertension is common and often difficult to control in patients with CKD. Hyperkalemia and decrease in eGFR are two main limitations of available antihypertensive therapies. The phase-3 PRECISION trial demonstrated that aprocitentan, a dual endothelin receptor antagonist, lowers blood pressure in patients with resistant hypertension and is safe. We now investigated the subgroup with CKD of the PRECISION trial.

Methods: Of the 730 patients with resistant hypertension on a standardized fixed-dose combination of amlodipine, valsartan and hydrochlorothiazide, 147 were classified as high-risk or very high-risk based on the KDIGO criteria. They were randomized to 2 doses of aprocitentan or placebo in PRECISION. Changes in office systolic blood pressure (SBP), the primary endpoint in PRECISION, urinary albumin-to-creatinine ratio (UACR) and estimated glomerular filtration rate (eGFR) were assessed at multiple time points: a) the end of the double-blind treatment phase at Week 4; b) the single-blind aprocitentan 25mg treatment phase at Week 36; c) the double-blind withdrawal phase at Week 40.

Results: Changes in office SBP and UACR are summarized in Table 1. At Week 4, aprocitentan reduced office SBP by 13.5 mm Hg and 16.6 mm Hg in the 12.5 mg and 25 mg groups, respectively, compared with a 4.4 mm Hg reduction in the placebo group. At Week 36, the reduction in office SBP was maintained (16.4 mm Hg vs baseline). UACR was also reduced by 62% at Week 36 in the 25 mg group. Baseline eGFR of the subgroup was 50 ml/min/1.73 m^2. Changes in eGFR (mL/min/1.73m^2) from baseline to Week 4 were 0.5 and -2.5 in the 12.5 mg and 25 mg groups, respectively, and -0.4 in placebo. An eGFR slope of -0.9 mL/min/1.73m^2/year was observed ("chronic slope") from Week 6 to Week 36 (all patients on 25 mg aprocitentan). At Week 4, edema or fluid retention occurred in 14% and 17% of patients receiving aprocitentan 12.5mg and 25mg, respectively, vs 1% in the placebo group.

Conclusions: In patients with CKD and resistant hypertension, aprocitentan substantially reduced BP and UACR vs placebo.

Renal Denervation Is Effective in Reducing Blood Pressure in Patients with CKD: Results of a Multicenter, Prospective, Randomized, Sham-Controlled, Blinded, Investigator-Initiated Trial

Dennis Kannenkeril,[1] Roland E. Schmieder,[1] Michael Böhm,[3] Felix Mahfoud,[3] Lars C. Rump,[4] Johannes Stegbauer,[4] Markus van der Giet,[5] Mario Schiffer,[1] Roland Veelken,[1,2] Michael Uder,[6] Axel Schmid.[6] *[1]University Hospital Erlangen, Friedrich- Alexander University Erlangen-Nuremberg (FAU), Erlangen, Germany; [2]Paracelsus Private Medical School Nuremberg, Nuremberg, Germany; [3]Universitätskliniken des Saarlandes, Saarland University, Homburg, Germany; [4]University Hospital, Heinrich-Heine-University, Düsseldorf, Germany; [5]Charité – Universitätsmedizin Berlin, Berlin, Germany; [6]Institute of Radiology, University Hospital Erlangen, Friedrich-Alexander University Erlangen-Nuremberg, Erlangen, Germany.*

Background: Arterial hypertension is the predominant driving force of the progression of chronic kidney disease (CKD). The activity of the sympathetic nervous system (SNS) is increased in patients with CKD and endovascular ultrasound renal denervation (uRDN) offers the opportunity to modulate SNS activity and thereby blood pressure and renal outcome.

Methods: In a multicenter prospective randomized sham-controlled clinical trial (clingov:NCT04264403), patients with CKD stage 3 and uncontrolled hypertension despite 1-5 antihypertensive medications were enrolled. Patients were randomly allocated to either uRDN or a sham procedure. The primary endpoint was the change in mean ambulatory systolic BP (ASBP) at 6 months while on stable medication and blinding maintained. Secondary endpoints were changes of other 24h ambulatory BP values, office BP and safety. Due to slow recruitment, the trial was prematurely stopped.

Results: Of 25 randomized patients (mean age 67yrs), 20 subjects had a 6 month visit per protocol. There was no difference in clinical characteristics, pretreatment 24 hour/day/night ambulatory and office BP between the uRDN (N=10) and the sham group (N=10). After 6 months the decrease in 24h (and day) ambulatory diastolic BP (ADBP) was significantly greater in the uRDN compared with sham (p=0.035 (and 0.030)). There was a numerically greater reduction in 24h ASBP in the uRDN group compared to sham, but it did not reach statistical significance. eGFR did not change within 6 months in either group, albuminuria decreased after 3 months in the uRDN group (p=0.023), with significantly greater decrease compared to sham (p=0.029), but this was not found after 6 months. No safety concerns related to uRDN emerged.

Conclusions: In this randomized sham-controlled blinded study, in face of its premature stop leading to a small cohort, we observed a decrease of diastolic BP after uRDN and no safety signals in these hypertensive patients with CKD.

Funding: Commercial Support - Recor Medical, Inc., Palo Alto, CA, USA

Endothelial Glycocalyx Changes in Pregnancy: Relationship with Kidney Injury in Preeclampsia

Oscar A. Garcia Valencia,[1] Sonja Suvakov,[1] Natasa Milic,[1,2] Darah Dilmaghani,[1] Vladimir Dokic,[1] Paul Gavrilovici,[1] Jennet Hatamova,[1] Jing Miao,[1] Vesna D. Garovic.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Univerzitet u Beogradu, Beograd, Serbia.*

Background: Degradation of glycocalyx (GCX), a proteoglycan/glycoprotein layer lining and protecting endothelial cells, has been associated with preeclampsia (PE). Limited data exists for its changes during normotensive pregnancies (NP). We aimed to assess the longitudinal changes of GCX in NP; to correlate GCX with urinary podocyte markers, podocin-nephrin (P/N) positive extracellular vesicles; and to compare P/N ratio, a marker of podocyte/kidney injury, between NP and PE.

Methods: Plasma, urine samples and GCX measurements via non-invasive imaging, were collected at each trimester from 31 pregnant women. Twenty-six women had NP while 5 developed PE. Plasma GCX components, syndecan 1 (SDC1), heparan sulfate proteoglycan (HSPG), and hyaluronic acid (HA) were measured by ELISA; urine P/N positive extracellular vesicles were measured by flow-cytometry and expressed as a ratio.

Results: In NP, GCX degradation, assessed by the width of the perfused boundary region, significantly increased from the 1st to 2nd trimester (p=0.008) and returned to 1st trimester values in the 3rd trimester (p=0.008). Microvascular perfusion decreased from the 1st to 2nd trimester (p=0.006), and increased back to 1st trimester values (p=0.039) by the 3rd trimester. Plasma SDC1 levels increased steadily from the 1st to 2nd trimester (p<0.001), with further increase in the 3rd trimester (p<0.001); HA increased from the 1st to the 2nd trimester (p=0.016) and stabilized. GCX degradation, predominant in the 2nd trimester, was linked to higher P/N ratio from the 1st to the 2nd trimester of NP, which remained stable through the 3rd trimester. The association between GCX degradation and presence of podocyte markers was further documented by a strong correlation between P/N ratio and SDC1 and HA levels in the 3rd trimester. These physiological changes in NP were further compared to PE: comparison of P/N ratios between NP and PE showed significantly higher values in PE across all trimesters (p=0.028).

Conclusions: GCX changes during NP are associated with an increase in urinary podocyte markers. An increase of the P/N ratio in PE compared to NP across gestation provides additional evidence that podocyte injury is an extension of physiological changes in pregnancy, and that it predates the clinical presentation of PE.

FR-OR51

Outcomes of Real-World Adults with CKD Who Are Not Represented in Blood Pressure Target Trials

June Li,[1,2] Jaejin An,[3,5] Matt M. Zhou,[5] Maria E. Montez-Rath,[1] Mengjiao Huang,[2] Fang Niu,[6] John J. Sim,[4,5] Michelle Odden,[1,2] Vivek Charu,[1] Manjula Kurella Tamura.[2,1] *[1]Stanford University School of Medicine, Stanford, CA; [2]VA Palo Alto Geriatric Research Education and Clinical Center, Palo Alto, CA; [3]Kaiser Permanente Bernard J Tyson School of Medicine, Pasadena, CA; [4]Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA; [5]Kaiser Permanente Southern California Department of Research & Evaluation, Pasadena, CA; [6]Kaiser Permanente Southern California, Pasadena, CA.*

Background: Blood pressure (BP) target trials often include adults with chronic kidney disease (CKD) who are healthier and have less chronic conditions compared to their real-world counterparts. We assessed whether clinical outcomes differed between trial eligible and ineligible adults with CKD.

Methods: We identified adults with CKD and hypertension in the Veterans Health Administration (VA) and Kaiser Permanente Southern California (KPSC) in 2019 who met eligibility for one of three BP target trials, SPRINT, ACCORD, and AASK. We compared the relative and absolute risks of death, major cardiovascular events (MACE), serious adverse events (SAEs), and end stage kidney disease (ESKD) between trial eligible and ineligible adults. Patients were followed until an outcome or up to September 30, 2022.

Results: We identified 503,480 adults in the VA (76.1% ineligible) and 73,412 adults in KPSC (79.2% ineligible) with CKD and hypertension. Compared to trial eligible adults, trial ineligible adults had a moderately elevated risk of death, MACE, and SAEs (Hazard ratio (HR) ranges, VA: 1.43-4.17; KPSC: 1.11-3.60), and a markedly elevated risk of ESKD (HR ranges, VA: 4.08-6.22; KPSC: 5.93-8.38). The corresponding absolute risk differences (RD, per 1000 person-years) were largest for death, MACE, and kidney related SAEs (RD ranges, VA: 3.6-17.4; KPSC: 4.5-16.1), and smallest for ESKD (RD ranges, VA: 0.4-4.3; KPSC: 0.8-13.2). Adults ineligible due to diabetes or end-organ damage had the highest relative and absolute risks in outcomes.

Conclusions: Trial ineligible adults with CKD and hypertension have higher risks for death, MACE, ESKD and SAEs compared to trial eligible adults, but the pattern of risk differed by outcome. The benefit-risk profile of hypertension treatment in the real-world population may differ from that of adults with CKD included in trials.

FR-OR52

Long-Term Kidney Outcomes in Children and Adolescents with Hypertension

Cal Robinson,[1] Junayd Hussain,[2] Tammy M. Brady,[3] Janis M. Dionne,[4] Sabine Karam,[5] Ashlene M. McKay,[1] Rukshana Shroff,[6] Rahul Chanchlani.[7] *[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]McMaster University Michael G DeGroote School of Medicine, Hamilton, ON, Canada; [3]Johns Hopkins Children's Center, Baltimore, MD; [4]BC Children's Hospital, Vancouver, BC, Canada; [5]University of Minnesota Medical School, Minneapolis, MN; [6]University College London Faculty of Medical Sciences, London, United Kingdom; [7]McMaster Children's Hospital, Hamilton, ON, Canada.*

Background: Hypertension affects 6% of all children and its prevalence is increasing. Pediatric hypertension has been associated with elevated risks of all-cause mortality and cardiovascular events among children and adults. In children with chronic kidney disease, hypertension is associated with progression to kidney failure. However, in those with no prior kidney diseasedirect evidence linking pediatric hypertension, with long-term kidney outcomes is limited. We aim to determine the long-term risks of developing chronic kidney disease and kidney failure among children with hypertension.

Methods: Population-based retrospective cohort study of all children (ages 3-18 years) diagnosed with hypertension from 1996 to 2021 in Ontario, Canada, using validated case definitions in health administrative databases. Each case was propensity score-matched with five normotensive controls by age, sex, birthweight, maternal gestational hypertension, prior diabetes mellitus, cardiovascular surgery, and a propensity score for hypertension diagnosis. Primary outcomes were incident stage 3 chronic kidney disease and end-stage kidney disease (initiation of chronic dialysis, or receipt of kidney transplant).

Results: A total of 25,605 children and adolescents with hypertension were matched to 128,025 controls without hypertension. Children were followed until death(0.7%), emigration from Ontario(11.2%), or study end(88.1%). Median age was 15 years[IQR 11-17], 49% were female, and prior comorbidities were uncommon(1% had congenital heart disease, 1.7% malignancy, 0.4% diabetes). During a median of 12.9 years[IQR 6.8-19.9) of follow up, the incidence rate(IR) of chronic kidney disease was 4.84/1000 person-years(py) in children with hypertension vs 0.42/1000py in controls (adjusted hazard ratio(aHR) 5.9, 95% CI 5.5-6.4). Children with hypertension were also at increased risk of end-stage kidney disease (IR 1.11 vs 0.03/1000py; aHR 9.6, 95% CI 7.8-11.9) compared to controls.

Conclusions: Children and adolescents diagnosed with hypertension are at higher long-term risks of chronic kidney disease and kidney failure, compared to non-hypertensive controls. Improved pediatric hypertension recognition and control may prevent progressive kidney function decline. These findings should be confirmed by large-scale, well controlled prospective studies.

FR-OR53

Subclinical Cardiopulmonary Changes of Heart Failure with Preserved Ejection Fraction (HFpEF) in CKD

Alexis Stevenson,[1] Marija Zimkute,[1] Xuan Cai,[1] Moeed Ahmed,[1] Patrick T. Schiller,[1] Lonnie Thach,[1] Alexander J. Kula,[2] Sanjiv Shah,[1] Ravi B. Patel,[1] Rupal Mehta.[1] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Ann and Robert H Lurie Children's Hospital of Chicago Pritzker Research Library, Chicago, IL.*

Background: Phenotypic data which include dynamic measurements of cardiac mechanics and cardiopulmonary function that characterize HFpEF in patients with CKD are limited.

Methods: We performed pre-, peak- and post-exercise speckle tracking echocardiography (2D-STE) and cardiopulmonary exercise testing (CPET) in individuals with and without CKD, and without diabetes or HF as part of a primary recruitment, detailed physiologic, patient-oriented study (Figure 1), We used regression models adjusted for age, sex, race, systolic blood pressure and body mass index to test the independent association between estimated glomerular filtration rate (eGFR) and 2D-STE and CPET indices.

Results: Table 1 displays baseline characteristics of 68 individuals according to CKD status. Only 3 patients with CKD met American Heart Association 2D-echocardiographic criteria for diastolic dysfunction. However, 13/54 and 26/54 with CKD and 1/14 and 2/14 without CKD had reduced left atrial reservoir strain (LARS) and left ventricular longitudinal strain (LVLS), markers of subclinical HFpEF, on resting 2D-STE. At 50 Watts exercise, 20/53 with CKD and 5/13 without CKD had lack of LARS or LVLS augmentation (Figure 2, LVLS Strain). During exercise, 32/53 with CKD and 4/13 without CKD had depressed peak V02, a manifestation of HFpEF. eGFR was independently associated with peak V02 (β-estimate 0.11 per 1 unit increase in eGFR, p value 0.0006, Figure 3).

Conclusions: Exercise 2D-STE and CPET can elucidate relevant physiologic changes suggestive of HFpEF that may be missed on resting 2D-echocardiography. Dynamic exercise testing in patients with CKD can lead to early and more accurate HFpEF diagnoses in a population at high risk for developing HFpEF.

Funding: Other NIH Support - NHLBI K23

Performance of Creatinine and Cystatin Equations in People with Heart Failure

Silvia Titan, Sandra Herrmann, John C. Lieske, Andrew D. Rule.
Mayo Clinic Minnesota, Rochester, MN.

Background: Performance of eGFRs among patients with heart failure (HF) may be worse than in the average population, with implications for clinical care.

Methods: We retrieved cases with mGFR (urinary iothalamate) performed at Mayo Clinic between 2011-23 that had an echocardiogram performed within 1 year and serum creatinine (Cr Cohort) or Cr and cystatin (CrCysC Cohort) available within 7 days of the mGFR. Patients were then classified based on ICD codes for HF present 1 year prior to the mGFR and ejection fraction (< or >=50%). CKD-EPI and EKFC eGFRcr, eGFRcys, and eGFRcrcys were computed. Bias was defined as mGFR minus eGFR, and P30 as the proportion of people with eGFR >=30% difference to mGFR.

Results: Results are shown in Table 1. eGFRcr was the most biased equation, prone to overestimation of mGFR in HF groups compared to NoHF. eGFRcr also had the worst precision in the HF groups, with larger errors in HFrEF. eGFRcrcys was the most accurate in NoHF and HFpEF, while eGFRcysC was the most accurate in HFrEF. The CKD-EPI and EKFC performed similarly.

Conclusions: In people with HF, eGFRcr tends to overestimate mGFR and has worse precision compared to people without HF. eGFRcrcys was the most accurate in NoHF and HFpEF, while eGFRcys was the most accurate in the HFrEF group.

Optimizing IgAN Treatment: Comparing Prednisone and Budesonide Efficacy and Safety

Abhi Lohana,[1] Usman Akbar,[1] Syed Adil Mir Shah,[2] Nouman Shafique,[3] Fnu Muhibullah,[1] Neeharika Muddana.[1] *[1]Camden Clark Medical Center, Parkersburg, WV; [2]Dow Medical College, Karachi, Pakistan; [3]Nishtar Medical College and Hospital, Multan, Pakistan.*

Background: IgA nephropathy (IgAN) is characterized by mesangial deposition of dominant, polymeric, galactose-deficient IgA1 antibodies originating from the intestinal mucosal lymphoid tissue. It is one of the most common causes of chronic kidney disease worldwide, with 20-40% of patients progressing to end-stage renal disease (ESRD). According to the KDIGO guidelines, steroids, including prednisone, are recommended for patients with persistent proteinuria despite optimal conservative care. Recently, budesonide, a targeted steroid, was introduced, focusing on the gut-associated lymphoid tissue to reduce the production of IgA1. This study compares the efficacy of budesonide in the treatment of IgAN to prednisone.

Methods: We utilized the US collaborative Network database to identify patients aged 18 and above diagnosed with IgAN who received either budesonide or prednisone. Patients were characterized and matched based on propensity scores using current ICD terminology codes. Each cohort comprised 1330 patients.

Results: In comparative analysis, mortality was lower in the prednisone cohort (4.3% vs. 6.2%, risk difference -1.9%, p=0.030). However, the incidence of ESRD was significantly higher in the prednisone group (13.4% vs. 5.0%, risk difference 8.3%, p<0.001). Hematuria was more common in the prednisone cohort (12.7% vs. 9.6%, risk difference 3.1%, p=0.038), whereas microalbuminuria showed no significant difference (0.8% in both cohorts, p=0.996). Osteoporosis rates (2.8% vs. 2.4%, p=0.541), and fungal infection rates (2.4% in both cohorts, p=0.990) were similar. Proteinuria was higher in the prednisone group (35.0% vs. 25.3%, risk difference 9.7%, p=0.003). These results indicate significant differences in mortality, ESRD, hematuria, and proteinuria between the groups.

Conclusions: This study reveals that while both prednisone and budesonide are effective in managing IgAN, budesonide offers a more favourable safety profile with significantly lower rates of ESRD and proteinuria. These findings support the use of budesonide as a viable and superior alternative to prednisone for the long-term management of IgA nephropathy.

Table 1: IgA Nephropathy Outcomes Comparison

Outcome	Patients with Outcome (Prednisone)	Patients with Outcome (Budesonide)	Total Patients (Prednisone)	Total Patients (Budesonide)	Risk Difference	p-value
Mortality	57	82	1330	1332	-0.019	0.03
ESRD	115	51	861	1012	0.083	0
Hematuria	123	83	967	861	0.031	0.038
Microalbuminuria	10	10	1322	1319	0	0.996
Osteoporosis	36	30	1286	1244	0.004	0.541

NeflgArd Open-Label Extension: Efficacy and Safety of Nefecon in Patients with IgAN Who Completed the 2-Year Phase 3 Trial

Richard A. Lafayette,[1] Jens Kristensen,[2] Russell Jones,[3] Jürgen Floege,[4] Vladimir Tesar,[5] Hernan Trimarchi,[6] Heather N. Reich,[7] Hong Zhang,[8] Brad H. Rovin,[9] Jonathan Barratt.[10] *[1]Division of Nephrology, Department of Medicine, Stanford University, Stanford, CA; [2]JDK Pharmaconsulting, Espergarde, Denmark; [3]Calliditas Therapeutics AB, Stockholm, Sweden; [4]Department of Nephrology and Clinical Immunology, Rheinisch Westfälische Technische Hochschule Aachen University Hospital, Aachen, Germany; [5]Department of Nephrology, First Faculty of Medicine and General University Hospital, Charles University, Prague, Czechia; [6]Nephrology Service, Hospital Británico de Buenos Aires, Buenos Aires, Argentina; [7]Division of Nephrology, University Health Network, Department of Medicine, University of Toronto, Toronto, ON, Canada; [8]Renal Division, Peking University First Hospital, Peking University Institute of Nephrology, Beijing, China; [9]Division of Nephrology, The Ohio State University Wexner Medical Center, Columbus, OH; [10]College of Medicine Biological Sciences and Psychology, University of Leicester, Leicester, United Kingdom.*

Background: Nefecon was approved for the reduction of kidney function loss in adults with primary immunoglobulin A nephropathy (IgAN) at risk of disease progression, based on the 2-year NeflgArd trial findings (Lafayette. *Lancet* 2023;402:859). Nefecon 16 mg/d for 9 months (mo.) led to a statistically significant benefit in time-weighted average estimated glomerular filtration rate (eGFR) and a durable proteinuria reduction vs placebo. We report data from an open-label extension (OLE) study (NCT04541043) of the effect of Nefecon treatment (tx) in patients (pts) who completed the NeflgArd trial.

Methods: This Phase 3b, multicenter, OLE enrolled pts with IgAN who completed the NeflgArd trial, with persistent proteinuria ≥1 g/d or urine protein–creatinine ratio (UPCR) ≥0.8 g/g and eGFR ≥30 mL/min/1.73 m^2 despite optimized renin–angiotensin system blockade. Pts who completed a full 9-mo. course of Nefecon 16 mg/d without dose reductions were included. OLE pts received Nefecon 16 mg/d for 9 mo. (+2 wks' tapering at 8 mg/d). Blinding to previous NefIgArd tx was maintained. Primary efficacy endpoints were the ratios of eGFR and UPCR at 9 mo. vs OLE baseline. Adverse events occurring during the OLE were captured as new or ongoing from the NefIgArd trial.

Results: Of the 326 pts completing the NefIgArd trial, 119 entered the OLE (45 [38%] Nefecon-experienced; 74 [62%] Nefecon-naïve). 94 (79%) pts were men and 100 (84%) identified as white. At the OLE baseline, median eGFR in Nefecon-experienced vs Nefecon-naïve pts was 50.4 and 49.2 mL/min/1.73 m^2, respectively; median UPCR was 1.28 and 1.37 g/g, respectively. For all 119 pts, UPCR reduction from baseline at 9 mo. was 32%, with an absolute eGFR decline of 1.43 mL/min/1.73 m^2 also reported. In the OLE, similar UPCR reductions and eGFR changes after 9 mo. of Nefecon were seen in Nefecon-experienced and -naïve pts. Tx in the OLE was well tolerated without any new safety signals.

Conclusions: These study findings provide valuable insights into the efficacy and safety of additional tx with Nefecon and demonstrate that, in pts previously treated with Nefecon, a second 9-mo tx course had an effect on proteinuria and kidney function decline similar to a first tx course, without additional safety concerns.

PROTECT Subgroup Analysis: Clinical Benefits of Sparsentan (SPAR) vs. Irbesartan (IRB) in Patients with IgAN Who Have Proteinuria above and below 1 g/g

Laura Kooienga,[1] Hernan Trimarchi,[2] Jürgen Floege,[3] Priscila Preciado,[5] Edward Murphy,[5] Jai Radhakrishnan.[4] On behalf of the DUPRO Steering Committee and PROTECT Investigators. *[1]Colorado Kidney Care, Denver, CO; [2]Nephrology Service, British Hospital of Buenos Aires, Buenos Aires, Argentina; [3]Division of Nephrology, RWTH Aachen University Hospital, Aachen, Germany; [4]Division of Nephrology, Colombia University Irving Medical Center, New York, NY; [5]Travere Therapeutics, Inc., San Diego, CA.*

Background: SPAR is a nonimmunosuppressive, dual endothelin angiotensin receptor antagonist (DEARA) approved in the US and EU for adults with IgAN. In the pivotal PROTECT trial, SPAR showed sustained proteinuria reduction and better kidney function preservation vs the maximum labeled dose of IRB. Elevated proteinuria (>0.5 g/day) is associated with more rapid disease progression, and proteinuria reduction may lead to improved kidney survival. A post hoc analysis of pts in PROTECT with urine protein-to-creatinine ratio (UPCR) of <1.0 vs ≥1.0 g/g at baseline is presented.

Methods: PROTECT was a 110-week, double-blind, randomized (1:1) trial of SPAR (400 mg) vs active control IRB (300 mg) in adults with biopsy-proven IgAN, urine protein excretion of ≥1.0 g/day despite maximized renin-angiotensin system inhibition for ≥12 weeks, and estimated glomerular filtration rate (eGFR) of ≥30 mL/min/1.73 m^2. We report treatment effects in pt subgroups with UPCR of <1.0 vs ≥1.0 g/g at baseline.

Results: This analysis included 404 pts (UPCR: <1.0 g/g, n=145; ≥1.0 g/g, n=259). Baseline characteristics were well balanced between treatment arms (**Table**). Consistent with primary results, SPAR-treated pts showed a clear treatment benefit vs IRB, with a greater proteinuria reduction and smaller change in eGFR from baseline to week 110, regardless of baseline UPCR. SPAR was generally well tolerated.

Conclusions: SPAR showed clinically meaningful benefits vs IRB across baseline UPCR, supporting its use as a foundational, long-term nephroprotective treatment in pts with IgAN not traditionally considered high risk for disease progression.

Funding: Commercial Support - Travere Therapeutics, Inc.

Table. Baseline Characteristics, Key Efficacy Outcomes, and Treatment Effects of SPAR vs IRB in Pts With Baseline UPCR of <1.0 and ≥1.0 g/g Over 110 Weeks

	Baseline UPCR <1.0 g/g		Baseline UPCR ≥1.0 g/g	
Baseline characteristics	**SPAR (n=77)**	**IRB (n=68)**	**SPAR (n=125)**	**IRB (n=134)**
Age at informed consent, mean (SD), years	46.2 (12.31)	47.2 (12.21)	46.8 (13.07)	44.5 (12.02)

Immunodeposits and Urinary Complement Activation Fragments Are Linked to IgAN Activity and Progression: Findings from the CureGN Study

Virginie Royal,[1] Yasar Caliskan,[2] Krista L. Lentine,[2] Arnaud Bonnefoy,[3] Clémence Merlen,[3] Mark Schnitzler,[2] Louis-Philippe Laurin,[1] Stephan Troyanov.[4] *[1]Hôpital Maisonneuve-Rosemont, University of Montreal, Montreal, QC, Canada; [2]SSM Health Saint Louis University Hospital, Saint-Louis, MO; [3]Centre Hospitalier Universitaire Sainte-Justine, University of Montreal, Montréal, QC, Canada; [4]Hôpital du Sacré-Cœur-de-Montréal, University of Montreal, Montreal, QC, Canada.*

Background: Small cohorts have reported variable associations between immunodeposits and complement activation with clinical outcomes in IgA nephropathy (IgAN). In parallel, therapeutic trials show encouraging results using complement inhibition. We sought to confirm the value of immunofluorescence findings and urinary complement fragments in defining disease activity and progression.

Methods: Using IgAN patients with available pathology assessment from the CureGN cohort, we tested associations between immunoglobulins and C3 distribution and intensity by immunofluorescence with the Oxford MEST-C score, urinary membrane attack complex (sC5b9), proteinuria, and survival from a combined outcome; kidney failure or 40% decline in eGFR.

Results: We analyzed 247 IgAN patients, including 115 incident subjects enrolled within 6 months of kidney biopsy. IgA and C3 staining intensity were associated with mesangial hypercellularity. Localization of IgM, C3, and IgA deposits along capillaries was associated with endocapillary hypercellularity, cellular crescents, and foot process effacement. In incident subjects, urinary sC5b9 showed associations with global endocapillary hypercellularity, crescent formation, and IgM and C3 deposition along capillaries. While immunodeposits were not associated with a combined outcome, urinary sC5b9 was. When adjusting for the level of proteinuria, significant interaction existed (p=0.009), indicating elevated urinary sC5b9 correlated with a reduced outcome in those with elevated proteinuria (illustrated by Kaplan Meier curves using dichotomizing urinary measurements).

Conclusions: In IgAN, intensity and localization of immunodeposits correlate with mesangial, endocapillary, and extracapillary hypercellularity and the level of urinary sC5b9. In turn, the urinary sC5b9 is independently associated with eGFR loss.

The Anti-APRIL Antibody Sibeprenlimab Reduces Circulating Immune Complexes in Patients with IgAN: The Phase 2 ENVISION Randomized Controlled Trial

Jonathan Barratt,[1] Mohit Mathur,[2] Adrian Liew,[3] Muh Geot Wong,[4] Laura Kooienga,[5] Richard A. Lafayette,[6] Manisha Sahay,[7] Bobby Chacko,[8] Lee G. Andrews,[2] Lauren E. Olinski,[2] Elizabeth Kong,[2] Zhen Zhang,[9] Yusuke Suzuki.[10]
[1]University of Leicester, Leicester, United Kingdom; [2]Visterra Inc., Waltham, MA; [3]Mount Elizabeth Novena Hospital, Singapore, Singapore; [4]Concord Repatriation General Hospital, New South Wales, NSW, Australia; [5]Colorado Kidney Care, Denver, CO; [6]Department of Medicine, Stanford University, Stanford, CA; [7]Department of Nephrology, Osmania General Hospital and Osmania Medical College, Hyderabad, India; [8]John Hunter Hospital and University of Newcastle, New South Wales, NSW, Australia; [9]Otsuka, Princeton, NJ; [10]Juntendo University, Nephrology, Tokyo, Japan.

Background: Deposition of IgA-containing circulating immune complexes (CICs) in the kidney is a hallmark of IgA nephropathy (IgAN); A PRoliferation-Inducing Ligand (APRIL) is a driver in this pathogenesis. Sibeprenlimab, an APRIL-neutralizing, humanized IgG2 monoclonal antibody, demonstrated acceptable safety with robust reductions in circulating IgA and uPCR, with eGFR stability at 12 months in the Phase 2 ENVISION trial of patients with IgAN.[1] We now report the effect of sibeprenlimab on change in IgA-containing CICs in IgAN patients.

Methods: ENVISION (NCT04287985) was a 12-month, global, randomized, controlled trial evaluating monthly sibeprenlimab (2, 4, or 8 mg/kg IV) in adults with IgAN. Change in IgG/IgA- and IgM/IgA-CICs over time was examined as an exploratory endpoint. Serum CICs were measured using a semi-quantitative plate-based sequential electrochemiluminescence immunoassay (ECLIA). IgG/IgA- and IgM/IgA-CICs were captured with an anti-IgA antibody and detected with ruthenylated anti-IgG or anti-IgM antibody, respectively.

Results: Sibeprenlimab recipients exhibited sustained, dose-dependent, reversible reductions in IgG/IgA- and IgM/IgA-CICs vs placebo (**Figure**). Median percent of baseline at Month 12 for sibeprenlimab 2, 4, and 8 mg/kg was 81.65, 72.34, and 66.67 for IgG/IgA-CIC, respectively (placebo, 102.26), and 37.05, 30.37, and 30.11 for IgM/IgA-CIC, respectively (placebo, 95.54).

Conclusions: Sibeprenlimab demonstrated robust reduction of IgG/IgA- and IgM/IgA-CICs at all study doses. In the ENVISION trial, reduction of CICs along with galactose-deficient IgA1 and uPCR over time provide further mechanistic evidence for the effects of APRIL inhibition, resulting in stabilization of kidney function as demonstrated by reduction in proteinuria and improvement in eGFR profiles. Together, these results support the disease-modifying activity of sibeprenlimab in the treatment of IgAN. [1]Mathur M et al., *N Engl Med*. 2024;390(1):20–31.

Efficacy and Safety of Ravulizumab in IgAN: Week 50 Results from a Phase 2 Randomized Controlled Trial

James A. Tumlin,[1] Richard A. Lafayette,[2] Jonathan Barratt,[8] Mai-Szu Wu,[3] Sung Gyun Kim,[4] Jessica K. Kaufeld,[5] Shih-Han S. Huang,[6] Eric Alamartine,[9] Miguel Angel Pérez Valdivia,[7] Kara Rice,[10] Andreas Kateifides,[10] Katherine Garlo,[10] Dario Roccatello.[11]
[1]Emory University, Atlanta, GA; [2]Stanford University, Stanford, CA; [3]Taipei Medical University, Taipei, Taiwan; [4]Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea; [5]Medizinische Hochschule Hannover, Hannover, Germany; [6]London Health Sciences Centre, London, ON, Canada; [7]Hospital Universitario Virgen del Rocio, Sevilla, Spain; [8]University of Leicester, Leicester, United Kingdom; [9]Hopital Nord Service de Nephrologie, Saint Priest en Jarez, France; [10]Alexion Pharmaceuticals Inc, Boston, MA; [11]Universita degli Studi di Torino, Torino, Italy.

Background: In IgA nephropathy (IgAN), terminal complement pathway activation contributes to inflammation and glomerular damage. Early and meaningful reductions in proteinuria were demonstrated with complement C5 inhibitor ravulizumab (RAV) in the phase 2 SANCTUARY trial (NCT04564339) through 26wks; efficacy and safety data through 50wks are presented.

Methods: Adults with primary IgAN, proteinuria ≥1 g/d, eGFR ≥30 mL/min/1.73 m^2, and on stable/optimal RASi were randomized 2:1 to RAV or placebo (PBO) (IV; q8w) for 26wks. At wk26, PBO group switched to open label RAV (PBO-RAV). Primary endpoint: change in proteinuria at 26wks; secondary endpoints: change in proteinuria and eGFR at 50wks. Safety and PK/PD were assessed.

Results: Of 66 randomized patients (pts; RAV n=43; PBO n=23), 64 completed wk50. In RAV and PBO arms, respective baseline (BL) UPCR was 1.7 and 1.8 g/g; BL eGFR was 76.0 and 70.4 mL/min/1.73 m^2. At 26wks, a –33.2% treatment effect on UPCR was demonstrated with RAV vs PBO (p=0.0011). At 50wks, RAV pts had a 41.1% reduction from BL in UPCR. PBO-RAV pts had a 43.1% decrease in UPCR from BL (wk0) to wk50 (Figure). Annualized eGFR slope in RAV pts was –1.4 at 26wks and –2.3 at 50wks and in PBO-RAV pts was –6.7 and –4.1 at 26 and 50wks, respectively. The majority of AEs were mild; no serious treatment-related AEs, discontinuations from AEs, or deaths occurred.

Conclusions: Treatment with RAV was well-tolerated and demonstrated early and sustained proteinuria reduction through ~1 year, and after wk26 switch from PBO to RAV.

Effect of Iptacopan on Proteinuria and Complement Biomarkers in IgAN: Interim Analysis of the Phase 3 APPLAUSE-IgAN Study

Dana V. Rizk,[1] Dmitrij Kollins,[2] Olympia Papachristofi,[2] Thomas Hach,[2] Marie-Anne Valentin,[2] Tobias Merkel,[2] Ronny W. Renfurm,[2] Vlado Perkovic.[3]
[1]University of Alabama at Birmingham, Birmingham, AL; [2]Novartis Pharma AG, Basel, Switzerland; [3]University of New South Wales, Sydney, NSW, Australia.

Background: The alternative complement pathway (AP) plays a key role in IgAN pathogenesis and there is an unmet need for targeted disease-modifying treatments. In IgAN, the AP is often activated in urine but not in plasma, indicating renal complement activity. Iptacopan binds to Factor B and specifically inhibits the AP. In a Phase 2 study, iptacopan decreased plasma Bb and Wieslab activity, and urinary sC5b-9 decreased to almost healthy volunteer range. The APPLAUSE-IgAN trial is evaluating iptacopan vs placebo on top of optimized stable supportive therapy. In the pre-specified interim analysis (IA), iptacopan was superior to placebo in reducing proteinuria at Month 9 relative to baseline (24h urine protein-creatinine ratio reduction 38.3%; $P<0.0001$). Here, we present complement biomarker exploratory results from the IA.

Methods: APPLAUSE-IgAN (NCT04578834), a Phase 3, randomized, double-blind, placebo-controlled trial, enrolled adults with biopsy-confirmed IgAN with proteinuria ≥1 g/g despite stable supportive therapy. Patients were randomized 1:1 to iptacopan 200 mg or placebo twice daily for 24 months while remaining on supportive therapy. IA was performed when 250 patients reached Month 9 or discontinued the study. Change from baseline in biomarkers of complement activity was assessed: C3 and C4 in all patients; Bb, sC5b-9, and Wieslab were only assessed in a subset of patients.

Results: Iptacopan selectively inhibited the AP, with reductions in serum Wieslab activity, plasma Bb and sC5b-9, and increases in serum C3, while serum C4 was unchanged (**Figure**). Median decrease in urinary sC5b-9 was 97.6% (IQR 86.1-99.2) in the iptacopan arm; the Month 9 value was within the range observed in healthy individuals.

Conclusions: Iptacopan inhibited systemic and intrarenal activation of the AP in patients with IgAN at Month 9, supported by reductions in serum Wieslab, plasma Bb and sC5b-9, and urinary sC5b-9.

ALIGN Subgroup Analyses: Clinically Meaningful Urinary Protein-to-Creatinine Ratio Reductions across Subgroups

Hiddo J. Heerspink,[1] Meg Jardine,[2] Donald E. Kohan,[11] Richard A. Lafayette,[3] Adeera Levin,[4] Adrian Liew,[5] Hong Zhang,[6] Todd E. Gray,[7] Khushboo Sheth,[7] Ronny W. Renfurm,[8] Hetal S. Kocinsky,[9] Jonathan Barratt.[10]
[1]University Medical Center Groningen, Groningen, Netherlands; [2]University of Sydney, Sydney, NSW, Australia; [3]Stanford University, Stanford, CA; [4]The University of British Columbia, Vancouver, BC, Canada; [5]Mount Elizabeth Novena Hospital, Singapore, Singapore; [6]Peking University First Hospital, Beijing, China; [7]Chinook Therapeutics, a Novartis Company, Seattle, WA; [8]Novartis Pharma AG, Basel, Switzerland; [9]Chinook Therapeutics, a Novartis Company, Seattle, WA; [10]University of Leicester, Leicester, United Kingdom; [11]University of Utah Health, Salt Lake City, UT.

Background: Approximately 30% of IgAN patients (pts) with proteinuria 1–2 g/day develop kidney failure within 10 years; even pts with low levels of persistent proteinuria (<1 g/d) are at risk. Endothelin (ET)-1 upregulation and ET_A receptor activation drive proteinuria, kidney inflammation and fibrosis in IgAN. Atrasentan is a potent and selective ETA receptor antagonist. ALIGN is a Phase 3, randomized, double-blind, placebo-controlled study of the efficacy and safety of atrasentan vs placebo in adult IgAN pts on optimized supportive care (SC).

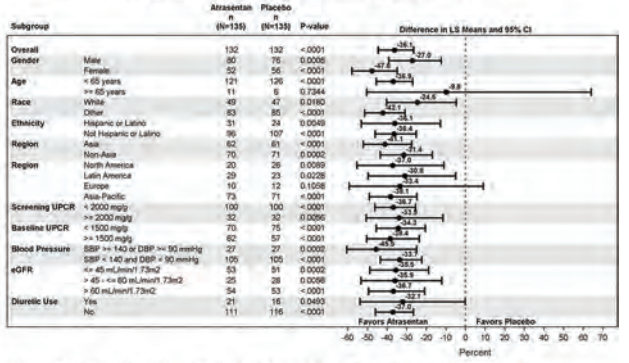
Methods: Pts with biopsy-proven IgAN and proteinuria of ≥ 1g/day were randomized to receive atrasentan 0.75 mg or placebo orally once daily for 132 weeks while continuing SC. The primary endpoint, the change from baseline (CFB) in proteinuria at Week 36, based on UPCR from 24-hour urine collection was evaluated in a prespecified interim analysis of the first 270/340 patients randomized to the main stratum. Subgroups evaluated included key demographic (gender, age, race, ethnicity and region), and baseline disease characteristics (baseline UPCR, BP, eGFR and diuretic use).

Results: The prespecified interim analysis of the primary endpoint showed a 36.1% (26.4%, 44.6%; p<0.0001) relative reduction in LS mean % UPCR CFB at Week 36. Proteinuria reduction was of similar magnitude regardless of age, sex, race, ethnicity or region, and baseline levels of proteinuria, eGFR, BP or diuretic usage (Fig). Atrasentan was well-tolerated with a favorable safety profile. Results for an exploratory SGLT2i stratum were consistent with the main stratum.

Conclusions: Clinically meaningful proteinuria reductions were observed with atrasentan in all subgroups regardless of baseline demographic or disease characteristics.

Funding: Commercial Support - Chinook Therapeutics, a Novartis company

Figure: UPCR Week 36 percentage change from baseline in LS means by subgroup: MMRM analysis primary efficacy set



Note: UPCR values are censored (excluded) for subjects with intercurrent events (i.e. restricted) medication use, chronic dialysis, kidney transplant) beginning at the start date of the earliest event. n=number of subjects included in subgroup. MMRM: mixed model repeated measures.

Sparsentan (SPAR) as First-Line Treatment of Incident Patients with IgA Nephropathy: Interim Analysis of the SPARTAN Trial

Chee Kay Cheung,[1] Stephanie Moody,[2] Neeraj Dhaun,[3] Sian V. Griffin,[4] Alexandra L. Howson,[1] Radko Komers,[2] Alex Mercer,[5] Matthew Sayer,[3] Smeeta Sinha,[6] Lisa C. Willcocks,[7] Jonathan Barratt.[1] *[1]University of Leicester & Leicester General Hospital, Leicester, United Kingdom; [2]Travere Therapeutics, Inc., San Diego, CA; [3]Department of Renal Medicine, Royal Infirmary of Edinburgh, Edinburgh, United Kingdom; [4]Department of Nephrology and Transplantation, University Hospital of Wales, Cardiff, United Kingdom; [5]JAMCO Pharma Consulting, Stockholm, Sweden; [6]Department of Renal Medicine Salford Royal Hospital Northern Care Alliance NHS Foundation Trust, Salford, United Kingdom; [7]Department of Renal Medicine, Addenbrooke's Hospital, Cambridge University Hospitals, Cambridge, United Kingdom.*

Background: SPAR is a nonimmunosuppressive, dual endothelin and angiotensin receptor antagonist (DEARA) approved in the US and EU for the treatment of adults with IgAN. SPARTAN (NCT04663204) is an open-label, single-arm, multicenter, exploratory trial investigating the safety, efficacy, and mechanistic action of SPAR as first-line therapy in patients newly diagnosed with IgAN. We report interim findings.

Methods: Twelve patients ≥18 y old with biopsy-proven IgAN, proteinuria of ≥0.5 g/d, eGFR of ≥30 mL/min/1.73 m^2, and no prior treatment with ACEis/ARBs (≤12 mo) were enrolled. SPAR is given for 110 wk with 4-wk safety follow-up. In a prespecified 24-wk interim analysis, proteinuria, GFR, BP, body weight, total body water (bioimpedance), and safety were assessed.

Results: Mean age at enrollment was 35.8 (SD 12.2) y (5 female), with median (IQR) proteinuria of 1.7 (0.6-3.3) g/d and mean eGFR of 70.2 (SD 25.0) mL/min/1.73 m^2 at baseline (BL). Proteinuria reductions were rapid (−61.9% [±SE −66.9 to −56.1] from BL to wk 4) and sustained over 24 wk (**Figure**); 58% of patients achieved complete proteinuria remission (<0.3 g/d) at any time during the first 24 wk of treatment. After an initial decrease from BL (125/78 mm Hg), BP remained stable during follow-up; eGFR, total body water, and body weight were generally stable (**Table**). The most frequent AE was dizziness (50% of patients); 1 patient discontinued due to hypotension.

Conclusions: In patients newly diagnosed with IgAN, interim findings show that SPAR as first-line treatment was generally well tolerated and reduced proteinuria ≈70% over 24 wk.

Funding: Commercial Support - Travere Therapeutics, Inc.

Summary Interim Data Over 24 Wk

Derivation of a Simple Risk Model for Cardiac Surgery-Associated AKI

Lavanya Durai,[1] Julie-Alexia Dias,[3] Samuel Short,[1] Ashraf Sabe,[1] Simone Redaelli,[2] Maximilian S. Schaefer,[2] Daniela Garcia,[2] Kamal Khabbaz,[2] Shahzad Shaefi,[2] David E. Leaf.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]Beth Israel Deaconess Medical Center, Boston, MA; [3]Harvard T H Chan School of Public Health, Boston, MA.*

Background: Cardiac surgery-associated acute kidney injury (CSA-AKI) is a frequent postoperative complication. Existing models to predict CSA-AKI have key limitations, including reliance on diagnostic codes, use of noncontemporary data, a focus on AKI requiring dialysis, and inclusion of intra/postoperative variables. Further, most studies are single-centered.

Methods: We collected detailed data from 36,658 adults who underwent cardiac surgery at 3 academic medical centers in Boston, MA, between 2008-2022. Data were derived from the Society for Thoracic Surgeons Database, which includes >1,000 perioperative variables, along with electronic medical records. Candidate predictors included demographics, comorbidities, medications, labs, illness severity, and surgical characteristics, each assessed preoperatively. The primary outcome was CSA-AKI, defined as a ≥100% increase in serum creatinine or dialysis initiation within 5 days following surgery. We used multivariable logistic regression with backward elimination.

Results: A total of 1687 patients (4.6%) developed CSA-AKI. The final model included 15 variables (**Fig. 1A**). A higher CSA-AKI score monotonically predicted a higher risk of CSA-AKI (**Fig. 1B**). Patients in the highest risk group had a 33.10-fold higher risk of CSA-AKI than those in the lowest risk group (**Fig. 1C**). The model had significantly better discrimination for CSA-AKI (AUC 0.75) than previously published models tested in the current cohort, the AUCs for which ranged from 0.64 to 0.69 (P<0.001) (**Fig. 1D**).

Conclusions: A simple 15-variable risk score predicts CSA-AKI more accurately than previously published models.

Association of Urinary CCL14 with Host-Response and Outcomes in Critically Ill Sepsis Patients with Persistent AKI

Thei S. Steenvoorden, Liffert Vogt, Frederike J. Bemelman, Marcus Schultz, Tom van der Poll, Hessel Peters-Sengers. *Amsterdam UMC Locatie AMC, Amsterdam, Netherlands.*

Background: Urinary concentrations of CC chemokine ligand 14 (CCL14) have recently been identified as a strong predictor of acute kidney injury (AKI) persistence. Whether CCL14 plays a role in the pathogenesis of AKI is still unknown. We postulated that looking at the host-response could help determine a correlation of CCL14 with specific AKI pathophysiologic pathways.

Methods: Critically ill patients with sepsis associated (SA) AKI were included from the Molecular Diagnosis and Risk Stratification of Sepsis (MARS) prospective cohort (N=92). They were grouped by high (>1.3ng/ml) and low CCL14. Plasma levels of 15 biomarkers reflective of: systemic inflammation and cytokine responses, endothelial cell activation, and coagulation activation were quantified. In a subset of 24 SA-AKI patients, whole-blood leukocyte genome-wide transcriptomes were determined.

Results: High CCL14 (n=26, 28.3%) was associated with more severe and persistent renal injury, skin and urinary tract infections compared with low CCL14 (n= 66, 71.7%). Adjusted for disesease severity, age and source of infection High CCL14 was associated with endothelial barrier dysfunction and platelet use (Figure), but also with a heightened transcription of neutrophil degranulation pathways, a dampened response in interferon signaling pathways, upregulated cellular stress response pathways, and a net upregulation of leukocyte activation pathways.

Conclusions: These findings suggest that urinary CCL14 can be used to distinguish a specific subtype of severe AKI with more prominent endothelial activation and barrier disruption, and might be a useful guide for future therapeutic strategies.

Nuclear Magnetic Resonance-Based Glomerular Filtration Rate Estimation Is More Closely Associated with Serum Vancomycin Target Trough Achievement vs. Serum Creatinine-Based Equations

Jason N. Barreto,[1] Amauri Schwäble Santamaría,[2] Marcello Grassi,[2] Andrew Robertson,[2] John C. Lieske,[1] Jeff W. Meeusen,[2] Eric Schiffer,[2] Erin F. Barreto.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Numares, Regensburg, Germany.*

Background: The clinical utility of glomerular filtrate rate (GFR) estimation based on a panel of analytes (creatinine, cystatin C, myoinositol and valine) measured by nuclear magnetic resonance spectroscopy (GFR_{NMR}) as compared to standard eGFR equations based on serum creatinine for patients receiving vancomycin is unclear.

Methods: This prospective, single-center study included consecutive adults prescribed intravenous vancomycin at Mayo Clinic in Rochester, MN, from 2022 to 2024. Vancomycin indication, dose, frequency, and goal concentration range were determined by the clinical care team. Pearson's product-moment correlation analysis and ordinary least squares regression techniques were used to compare GFR estimating equations as predictors of serum vancomycin trough concentration, accounting for relevant covariates.

Results: 66 patients were enrolled. The median (IQR) age was 61 (50, 70) years, 45 (68%) were male, and 59 (89%) were non-Hispanic White individuals. Vancomycin was most often prescribed for skin, soft tissue, or musculoskeletal infections (n=24, 32%). Thirty-five (53%) patients had a steady state trough concentration within the goal range of 10-20 mg/L. Seven (11%) patients had troughs > 20 mg/L and six (9%) patients developed AKI within seven days of vancomycin initiation. Both GFR_{NMR} and CKD-EPI 2021_{Cr} were negatively correlated with vancomycin concentrations (GFR_{NMR}: t_{64} = -6.81, p-value < 0.001, r = -0.65 [-0.77, -0.48]; CKD-EPI 2021_{Cr}: t_{62} = -4.22, p-value < 0.001, r = -0.47 [-0.64, -0.26]). In multivariable analyses, the GFR_{NMR} inclusive model for prediction of vancomycin trough concentrations had a higher adjusted R^2 (mean [95%CI]) 0.51 [0.45, 0.6] than the CKD-EPI 2021_{Cr} inclusive model at 0.34 [0.29, 0.4] (p-value = 0.008).

Conclusions: Vancomycin trough prediction models with GFR_{NMR} were more predictive than models with CKD-EPI 2021_{Cr} in hospitalized patients. Future research should evaluate the potential for GFR_{NMR} to guide individualized vancomycin dosing.

Pharmacokinetic/Toxicodynamic Approach to Evaluate Platinum Nephrotoxicity Using the Kidney Injury Molecule-1 Biomarker

Sarah C. Asby,[1] Lauren E. Thompson,[1] Avisek Ghimire,[1] Xia Wen,[3] Christine Kim,[3] Cathleen Doherty,[3] Brian Buckley,[3] Edgar A. Jaimes,[2] Lauren Aleksunes,[3] Melanie S. Joy.[1] *[1]University of Colorado Anschutz Medical Campus, Aurora, CO; [2]Memorial Sloan Kettering Cancer Center, New York, NY; [3]Rutgers The State University of New Jersey, New Brunswick, NJ.*

Background: Cisplatin is a platinum-based chemotherapeutic drug that causes acute kidney injury (AKI), as assessed by serum creatinine (SCr) in over 30% of patients. Urinary kidney injury molecule-1 (KIM-1) is an excellent biomarker to detect subclinical and clinical kidney injury secondary to cisplatin. The aim of this study was to develop a predictive population pharmacokinetic/toxicodynamic (PKTD) model of cisplatin-induced kidney injury that incorporates total platinum concentrations in plasma and structural kidney injury changes, as measured by KIM-1.

Methods: As part of study NCT03817970, cancer patients undergoing their first or second round of cisplatin chemotherapy (n=39) were prospectively randomized to one of three $5\text{-}HT_3$A antiemetics (ondansetron, granisetron, or palonosetron) and had blood and urine collected for 10 days following cisplatin administration. Plasma total platinum concentrations were quantified using ICP/MS (LOQ 0.48-2.40 ng/mL). Urinary KIM-1 concentrations were measured using a commercial ELISA kit (R&D Systems) and normalized to urinary creatinine (UCr). Plasma concentrations of total platinum and urinary concentrations of KIM-1 were used in the development of a nonlinear mixed effect population PKTD model using Phoenix® NLME (v8.3, Certara Inc.). Covariates were screened by stepwise search to determine influence on PKTD parameters.

Results: A two-compartment pharmacokinetic model for total platinum concentrations in plasma was expanded to an effect compartment Emax PKTD model using urinary KIM-1 concentrations as the toxicodynamic marker. Significant covariate effects for the PKTD model included 1) prior exposure to cisplatin on volume of distribution 1 (V1), 2) $5\text{-}HT_3$A antiemetic treatment on V2, and 3) baseline urinary KIM-1 levels on Emax. Additional analyses demonstrated that treatment with the $5\text{-}HT_3$A ondansetron resulted in a 163% increase in exposure to plasma total platinum, a 94% increase in urinary KIM-1 maximum concentrations, and a 235% increase in total urinary KIM-1 excretion compared to palonosetron treatment.

Conclusions: Inclusion of urinary biomarkers such as KIM-1 in PKTD modeling can reveal novel predictors of total plasma platinum PK and subclinical and clinical kidney injury as the TD response.

Semaglutide Improves Kidney Function and Inflammatory Status in a Mouse Model of Glomerulonephritis

Günaj Rakipovski,[1] Maria K. Ougaard,[2,1] Nicolas Belmar,[1] Mette V. Østergaard,[1] Nicole Endlich,[3] Bidda Rolin.[1] *[1]Novo Nordisk A/S, Bagsvaerd, Denmark; [2]Gubra A/S, Horsholm, Denmark; [3]NIPOKA, Greifswald, Germany.*

Background: Semaglutide, a GLP-1 receptor agonist, used for weight management and treatment of type 2 diabetes has recently shown a reduction in kidney disease progression and mortality in the FLOW trial. In this study, we used a mouse model of glomerulonephritis known as nephrotoxic serum nephritis (NTN) to evaluate the effects of semaglutide on kidney function, inflammation and morphology

Methods: Glomerulonephritis was induced in female CD1 mice (8-10 weeks old) by intravenous injection of 100 µl nephrotoxic serum (NTS) and allocated to 4 groups: semaglutide (n=12), enalapril (n=10), NTN control (n=12) and healthy control (n=10). Active compound or vehicle was administrated once daily for 14 days. Urine samples were collected in metabolic cages and urinary albumin, creatinine and neutrophil gelatinase-associated lipocalin (NGAL) excretion were measured. The glomerular filtration rate (GFR) was measured on day 12 by transcutaneous method. At termination, the kidneys were collected and processed for histopathological analyses. Renal inflammation was evaluated by staining for CD45 by immunohistochemistry and mesangial expansion was measured as a mean score of PAS stained kidney sections. The podocyte foot process morphology was assessed by measuring the filtration slit density (FSD) by staining for nephrin.

Results: Treatment with semaglutide significantly increased GFR on day 12, and significantly reduced uACR and NGAL on days 7-8 compared to the vehicle treatment. The CD45 staining was significantly reduced in kidneys from mice receiving semaglutide, indicating a reduction in inflammation. Evaluation of mesangial expansion showed that treatment with semaglutide significantly reduced renal lesions compared to the vehicle

group. Finally, semaglutide significantly improved FSD. Enalapril showed the expected efficacy by improving urinary markers of kidney function and histopathology.

Conclusions: Semaglutide improved the kidney function in the NTN mice by significantly increasing GFR and lowering uACR and NGAL. Furthermore, semaglutide significantly reduced renal inflammation and measangial expansion and improved renal filtration barrier function in the NTN mice. These data support the notion that semaglutide has anti-inflammatory properties beyond the well known diabetes and weight management properties.

Felzartamab Durably Reduces Disease-Relevant Biomarkers through Targeting of CD38+ Plasma Cells and Plasmablasts, the Upstream Drivers of IgAN

Jonathan Barratt,[1] Millie Shah,[2] Lisa Kivman,[2] Tabea Kräft,[3] Julia Rauser,[3] Rainer Boxhammer,[3] Stefan Haertle,[3] Brian M. Schwartz,[2] Paul Manser,[2] Leslie Chinn,[2] Uptal D. Patel,[2] Donna Flesher,[2] Krzysztof Kiryluk.[4]
[1]University of Leicester, Leicester, United Kingdom; [2]Human Immunology Biosciences Inc, South San Francisco, CA; [3]MorphoSys AG, Planegg, Germany; [4]Columbia University, New York, NY.

Background: IgAN is driven by antibody secreting cell (ASC) production of galactose-deficient IgA1 (Gd-IgA1) and anti-Gd-IgA1 autoantibodies resulting in immune complex deposition-induced kidney damage. Felzartamab (felza) is a fully human anti-CD38 mAb that directly depletes CD38+ ASCs, the upstream cellular mediators of disease. In a placebo-controlled IgAN Ph2 trial (NCT05065970, IGNAZ), felza resulted in clinically meaningful prolonged UPCR reductions and eGFR stabilization. Here, we evaluate disease relevant biomarkers to understand molecular mechanisms of felza efficacy and durability in IgAN.

Methods: Whole-blood and serum from IGNAZ subjects were collected at baseline, on treatment, and during follow-up of a 2-year study. Samples were assessed for immune cells (flow cytometry), polyclonal immunoglobulins (turbidometry), and Gd-IgA1 (ECLIA).

Results: Felza induced rapid and durable depletion of Gd-IgA1 and total IgA. Patients who received 9 doses over a 5-month period maintained Gd-IgA1 reduction for at least 15 months after the first dose. Similar reductions in IgA were observed for 24 months after treatment start. IgG reduction was modest (< 20%) and rebounded to baseline by 12M. Circulating plasmablasts decreased on-treatment in felza arms versus placebo. Treatment did not impact early or memory B cell subsets or survival factors. Immunomodulation of other CD38+ cell types was observed.

Conclusions: Felza targets and depletes the upstream cellular drivers of IgAN resulting in rapid reduction of major disease related biomarkers. Effects are maintained off-treatment while also preserving humoral immunity. These observations are consistent with other indications, supporting the disease modifying potential of felza in immune mediated diseases.

Metabolomic Insights into Hypoxia-Inducible Factor Prolyl Hydroxylase Inhibitors' Kidney Protection in Contrast-Induced Nephropathy

Takashi Tani, Hitomi Tani, Akiko Mii, Rei Nakazato, Natsumi Kamijo, Akira Shimizu, Yukinao Sakai. *Nihon Ika Daigaku, Bunkyo-ku, Japan.*

Background: Contrast-induced nephropathy (CIN) is an acute kidney injury (AKI) associated with the use of contrast medium. We have recently reported that administration of HIF prolyl hydroxylase (HIF-PH) inhibitor, enarodustat play a protective role in rat model of CIN, suggested by improved renal dysfunction, 24-hour creatinine clearance levels and histopathological findings compared to a vehicle-treated group. HIF-PH inhibitors are thought to restore tissue homeostasis under anaerobic conditions by activating HIF1α, 2α, contributing to organ-protective effects. This study aimed to elucidate the mechanism through metabolomics analysis.

Methods: Sprague-Dawley rats were assigned to sham (Nx-S), vehicle-treated CIN (Nx-V), or drug-treated CIN (Nx-E) groups. At 15 weeks, Nx-V and Nx-E underwent right nephrectomy. Enarodustat or vehicle was given at 10 mg/kg for 3 days pre-CIN induction. At 17 weeks, CIN was induced, and rats were sacrificed 2 days later for kidney metabolomic analysis.

Results: CE-TOFMS and CE-QqQMS metabolomic analysis differentiated Nx-S from CIN groups (Nx-V and Nx-E). Nx-S maintained normal purine metabolism, implied by abundance of sedoheptulose 7-phosphate, hypoxanthine, and uric acid. In contrast, Nx-V and Nx-E showed elevated urea and amino acid metabolites, such as *N*-carbamoylaspartic acid, indicating nitrogen waste management due to kidney injury. Oxidative stress response was suggested by increased glutathione (GSH and GSSG) levels in CIN groups. PLS analysis revealed Nx-E had higher levels of metabolites involved in energy metabolism, purine metabolism, and cellular repair, like serine, aspartic acid, and hydroxyproline, suggesting enarodustat's renoprotective effects. Additionally, reduced levels of creatinine and phosphocreatine in Nx-E implied decreased renal stress byproducts. Changes in citric acid cycle intermediates, such as citric acid and isocitric acid, in Nx-E suggested improved mitochondrial function and energy production.

Conclusions: This study has clarified the biochemical changes from contrast medium and enarodustat's modulation. Enarodustat appeared to promote a metabolic shift aiding renal recovery post-CIN. Elevated metabolites related to energy and repair in Nx-E suggested enhanced AKI protection. Reduced stress-linked metabolites supported HIF-PH inhibitors' therapeutic potential in CIN.

Snake Toxin for Treatment of Kidney Diseases: From Bench to, Hopefully, Bedside

Nicolas Gilles,[1,2] Goran Stanajic Petrovic,[2,1] Mathilde Keck,[1,2] Stefano Palea,[3] Denis Servent,[1,2] Charles Truillet.[2,1] Medicines and Healthcare Technologies Dept. *[1]Commissariat a L'energie Atomique et Aux Energies Alternatives Siege Administratif, Gif-sur-Yvette, France; [2]Universite Paris-Saclay, Gif-sur-Yvette, France; [3]Humana, Toulouse, France.*

Background: V2R blockade is a validated therapeutic strategy for hyponatremia and the autosomal polycystic kidney disease. With the aim of discovering a safe V2R antagonists, we screened animal venoms and identified the MQ1 which shown sufficiently interesting properties to be the starting point for the development of a potential drug candidate.

Methods: Toxins were synthesized. Human T-cell assays was used to mitigate MQ1 immunogenicity risk, resulting in the MQ232. The MQ232 dynamic biodistribution in mice was done by positron emission tomography using an MQ232-derived imaging agent. PK, PD and toxicity tests were performed on healthy rats. A rat experimental model of dDAVP-induced hyponatremia, an *ex vivo* mice model of renal cysts and a mice orthologous model of ADPKD were used to validate MQ232 in these pathologies.

Results: 4 mutations were introduced in MQ1 to generate the MQ232. The MQ232 safety was demonstrated by a first toxic dose as high as 3,000 nmol/kg and an absolute kidney organ selectivity by TEP imaging. In addition, TEP imaging shown almost no interaction between MQ232 and the liver. The MQ232 efficacy was demonstrated, first with an effective dose of 3 nmol/kg on hyponatremic model, second on models of kidney polycystic on which MQ232 significantly reduced cyst growth.

Conclusions: We showcased, employing diverse translational techniques MQ232's outstanding safety and efficacy. MQ232 selectively targets the kidney and showed an effective to toxic dose ratio of 1,000-fold. Its molecular identity, bio-distribution and creatinine-like clearance suggest a renal metabolism rather than a hepatic one. MQ232, as the head of a new biological class of vaptan-unrelated aquaretic agents, is a favorable candidate as a therapeutic option for untreated patients.

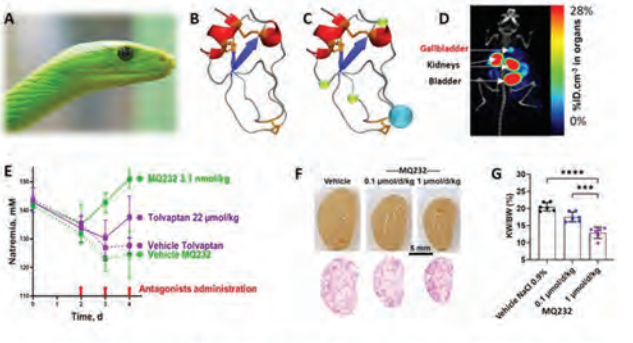

Figure 1. (A) The African snake *Dendroaspis angusticeps*. (B) The natural MQ1, K_i=4.56 nM for the hV2R. (C) The optimized drug candidate MQ232, K_i=0.37 nM for the hV2R. (D) Dual PET/CT imaging at 4 h post injection of 4.28 ± 0.18 MBq of [^{89}Zr]Zr-DFO-MQ232 i.v. injected in the tail of healthy mice. A strong signal is observed in the kidneys, whereas the liver and gallbladder exhibit minimal residual signal. The presented image showcases a composite of CT (gray scale) and PET (color scale) for enhanced subject visualization. (E) Male rat model of hyponatremia. Rats were infused through an osmotic pump with 10 ng/h of dDAVP inducing a clear hyponatremia in 2 days. Blood samples were taken just before tolvaptan per os or MQ232 i.p. administration indicated by red arrows. (F) The genotype Pkd1$^{flox/flox}$; Ksp-Cre was selected at postnatal day 2 and mice administrated s.c. with MQ232 (0.1 or 1 µmol/kg BW per day) or saline vehicle (NaCl 0.9%). Representative images at day 12 of hematoxylin/eosin staining kidney sections (lower) and kidney photography (upper) from *Pkd1$^{flox/flox}$; Ksp-Cre* mice. (G) Kidney weight (KW) indexes (KW/BW) of *Pkd1$^{flox/flox}$; Ksp-Cre* mice at day 12. *** P < 0.001, **** P < 0.0001.

Prospective and External Evaluation of an Artificial Intelligence Model for Continuous and Early Prediction of Moderate and Severe AKI in Critically Ill Patients

Kianoush Kashani,[1] Francesca Alfieri,[2] Andrea Ancona,[2] Simone Zappalà,[2] Carmine D. Votta,[3] Laura Maderna,[3] Josep S. Gomez,[4] Federico Esteban,[4] Mari C. Gilavert,[4] Maria Bodí,[4] Stefano Finazzi,[5] Alessandro Bacci,[2] Valentina Cauda.[2] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]U-Care Medical s.r.l, Torino, Italy; [3]Ospedale Maggiore di Lodi - ASST Lodi, Lodi, Italy; [4]Hospital Universitario de Tarragona Joan XXIII, Tarragona, Spain; [5]Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Bergamo, Italy.*

Background: Acute Kidney Injury (AKI) is associated with clinical and economic burdens on patients and healthcare systems. We previously proposed an AI-based model for the early and continuous prediction of moderate and severe ICU-acquired AKI episodes (ICU-A-AKI-2/3). In this study, the AI model was able to handle missing data and it was validated it in retrospective and prospective cohorts.

Methods: The predictive performance of the AI model was first internally and externally validated in retrospective cohorts in three countries (US, Netherlands, Italy; N=70107) from 176 different ICUs. Subsequently, the model was integrated and prospectively validated into the production in 2 European hospitals (Italy, Spain; N=225) from May 2023 to October 2023. The model analyses spot and temporal profiles of clinical variables from ICU patients, and its output is hourly risk-probability of developing AKI Stages 2 and 3, according to the KDIGO definition. The model only requires routinely-available clinical variables.

Results: In the multicenter external retrospective cohorts, the predictive model obtained the area under the receiver operating characteristic curve (auROC) of >0.89 for the early detection of ICU-A-AKI-2/3. In the prospective validation, the model achieved auROCs ranging from 0.82 (CI 95% 0.73, 0.92) up to 0.87 (CI 95% 0.802, 0.943) in the different hospitals, with a lead time for AKI-2/3 onset varying from 14 to 18 hours after the first day of ICU hospitalization.

Conclusions: In this study, the AI model for early prediction of ICU-A-AKI-2/3 episodes was successfully validated in both rettrospetive and prospective cohorts, achieving high predictive performances. This successful validation marks a significant milestone in integrating it into clinical workflows and represents an essential advancement in bringing the AI model to ICU settings.

FR-OR73

VHL-Deficient Human Kidney Organoids to Model Clear Cell Renal Cell Carcinoma

Yixuan Wang, Yun Xia. *Lee Kong Chian School of Medicine, Singapore, Singapore.*

Background: Renal cancer ranks among the top ten most prevalent cancers worldwide, with clear cell renal cell carcinoma (ccRCC) emerging as the predominant subtype, accounting for 70-80% of cases and displaying a relatively aggressive phenotype. The inactivation of Von Hippel-Lindau (VHL) tumor suppressor gene, found in approximately 90% of cases, was identified as the primary driver event of ccRCC development. Existing genetic engineered mouse models cannot fully capture the distinctive features of ccRCC, limiting our understanding of the role of VHL mutation in ccRCC initiation. Human pluripotent stem cell derived 3D human kidney organoid comprises of segmentally patterned nephron structures and vascular network, manifesting higher physiological relevance with the human kidney. In this study, we aim to develop VHL knockout human kidney organoids to better understand the role of VHL in tumor initiation.

Methods: CRISPR/Cas9 was utilized to generate VHL biallelic loss-of-function mutant human embryonic stem cells (ESCs). WT and VHL-/- human ESCs were differentiated into kidney organoids which were characterized via histology, immunofluorescence, PAS staining, Oil Red O staining, and qRT-PCR, etc.

Results: Immunostaining confirmed that patterned nephron segments, including glomeruli, proximal tubules, and distal tubules were successfully generated from VHL-/- human ESCs. Histological analysis revealed the emergence of a 'clear cell-like' phenotype in kidney tubular epithelium upon VHL loss. PAS and Oil Red O staining detected accumulation of glycogen and lipids in VHL-/- tubular epithelial cells. qRT-PCR analysis demonstrated metabolic alterations akin to those observed in human ccRCC patients, characterized by the upregulation of genes associated with glycolysis and lipid synthesis, alongside downregulation of genes involved in beta-oxidation. Additionally, VHL-/- kidney organoids acquired higher proliferation competency upon long-term culture.

Conclusions: Human ESC-derived VHL-/- kidney organoids effectively replicate critical morphological and metabolic features reminiscent of human ccRCC patients, thereby offering a novel in vitro platform for studying ccRCC tumorigenesis.

FR-OR74

Macrophages as Potential Mediators of Lung Cancer-Kidney Cross-Talk

Dana Hammouri, Dianet Sanchez Vega, Sophia M. Sears, Levi J. Beverly, Leah J. Siskind. *University of Louisville School of Medicine, Louisville, KY.*

Background: Cisplatin (CDDP) is a widely used chemotherapeutic agent for solid organ cancers. However, its efficacy is hindered by dose-limiting nephrotoxicity. Thirty percent of cancer patients treated with CDDP develop acute kidney injury (AKI). AKI not only complicates cancer management but also increases the risk of chronic kidney disease (CKD). Despite promising preclinical studies, there is no FDA-approved treatment for CDDP-induced kidney injury (CDDP-KI). This is partly attributed to the reliance of preclinical studies on non-cancer models of CDDP-KI, which fail to capture the complex pathophysiology of cancer patients, thus compromising clinical relevance. Our group has recently demonstrated that lung cancer adversely affects kidney function and physiology and exacerbates CDDP-KI, indicating cancer-kidney crosstalk. However, the underlying mechanism driving this interaction remains unclear. Our preliminary data indicate an accumulation of renal macrophages concomitant with the pathological alterations in the kidney of lung cancer mice, implying their role in cancer-kidney crosstalk. We hypothesize that depleting macrophages attenuates cancer-induced nephrotoxicity.

Methods: Eight-week-old B6;129 mice, with or without lung cancer, received three weekly doses of intravenous clodronate-encapsulated liposome (clodrosome) or saline-encapsulated liposome (encapsome) for 28 days. The kidney immune profile, injury, and fibrosis were then assessed.

Results: Clodrosome efficiently depleted renal macrophages and prevented kidney injury, evidenced by decreased KIM-1 expression and preservation of the proximal tubular brush border membrane. Moreover, it reduced the production of extracellular matrix components and attenuated fibrosis.

Conclusions: Our findings indicate that macrophages mediate cancer-induced nephrotoxicity and support further investigation into macrophage-based immunotherapy as a novel treatment for CDDP-KI within the context of cancer-kidney crosstalk.

Single-Cell RNA Sequencing Reveals Conserved T Cell Populations Detected across Inflamed Kidney Tissue and Urine of Patients with Immune Checkpoint Inhibitor-Associated Nephritis

Kavita Mistry,[1,2] Isabela Kernin,[2] Neal P. Smith,[2] Joie Sun,[2] Kerry Reynolds,[2] Shruti Gupta,[3] Meghan E. Sise,[2] Alexandra-Chloe Villani.[2] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Massachusetts General Hospital, Boston, MA; [3]Brigham and Women's Hospital, Boston, MA.*

Background: Immune checkpoint inhibitors inhibit the negative regulation of T cells, leading to both anti-tumor activity and immune-related adverse events such as acute interstitial nephritis (ICI-AIN). The immunologic drivers of ICI-AIN are unknown. We hypothesized that both resident and circulating CD8+ T cell subsets are present in ICI-AIN and that they are conserved across kidney tissue and the urine sediment.

Methods: To characterize the cellular populations that are enriched in ICI-AIN, we used scRNAseq to analyze epithelial and immune cells in kidney tissue and urine from a cohort of 15 patients with biopsy-proven ICI-AIN and 8 ICI-treated controls with non-AIN acute kidney injury. A total of ~200,000 cells were analyzed and revealed 23 transcriptionally distinct cell subsets, including CD8+ and CD4+ T cells, NK cells, B cells, myeloid cells, renal tubular epithelial cells, and urogenital epithelial cells.

Results: A range of T cell subsets was identified, existing on a phenotypic spectrum spanning circulation (*KLF2, SELL*) to residency (*ITGAE*), and cytotoxicity (*IFNG, GZMK*) to exhaustion (*TIGIT*). These cell subsets were conserved across both kidney tissue and urine. Gene expression analysis in ICI-AIN samples revealed populations of CD8+ T cells expressing CXCR3 and myeloid cells expressing the interferon-γ-stimulated ligands CXCL9/10, suggesting potential cell-cell interactions.

Conclusions: Taken together, our data contribute to improved understanding of the cellular perturbations in ICI-AIN and reinforce a role for the IFN-γ pathway in driving ICI-AIN. The conservation of T cell types observed across kidney tissue and urine suggests the potential for development of a non-invasive urine-based diagnostic test for ICI-AIN.

FR-OR76

Association of Novel Urine Biomarkers with Immune Checkpoint Inhibitor Nephrotoxicity

Jamie S. Lin, James P. Long, Shailbala Singh, Yanlan Dong, Cassian Yee.
The University of Texas MD Anderson Cancer Center, Houston, TX.

Background: Immune checkpoint inhibitor (ICI)-based cancer therapy saves lives, but ~20% of patients undergoing therapy develop acute kidney injury (AKI), and 2-5% face acute interstitial nephritis (AIN) with actionable consequences. Urine protein markers can correlate with specific kidney pathologies, yet exploring the urine proteome is challenging due to low concentrations of potential immunodiagnostic proteins. NUcleic acid Linked Immuno-Sandwich Assay (NULISA™) represents cutting-edge technology reported to be more sensitive than proximity extension assays like OLINK. We hypothesized that leveraging this ultrahigh sensitivity and parallel multiplexing proteomic technology could reveal novel urine or plasma biomarkers for non-invasive ICI-AIN detection.

Methods: We used NULISA™ to assess 203 proteins in urine and plasma from AKI patients on ICI therapy. Cohorts were categorized as either ICI-AIN (n = 22) or non-AIN (n = 27) based on renal biopsy pathology and/or clinical diagnosis. Sample profiling was evaluated using log2 normalized count data, with P-values computed using Wilcoxon tests, and False Discovery Rate (FDR) adjustment.

Results: Of the 203 targets, 149 (73.4%) were detectable in urine samples, and 193 (95.1%) in plasma samples. Clustering and principal component analysis (PCA) revealed distinct proteomic profiles and KEGG pathway analysis identified JAK-STAT and TNF signaling in urine compared to TLR and IL-17 signaling in plasma. Larger differences in protein levels between ICI-AIN and non-AIN were observed in urine. Top urine proteins with AUC > 0.8 (indicating a strong ability to discriminate ICI-AIN from non-AIN) and fold change > 8.0 (FDR 0.01) were associated with hypersensitivity, autoimmunity, immune checkpoint proteins, and immune cell activation. Statistical models, including L1 regularized logistic regression and CART, identified a novel 2-protein signature, as the most effective combination for identifying ICI-AIN. A logistic regression model of this ICI-AIN signature achieved an AUC of 0.94 in distinguishing ICI-AIN from non-AIN, outperforming any other marker(s) including CXCL9 (AUC 0.83).

Conclusions: Our use of state-of-the-art NULISA technology demonstrates that urine and plasma proteomic profiles exhibit distinct characteristics. Statistical modeling identified a novel ICI-AIN signature for non-invasive immune nephritis detection.

Fludeoxyglucose F 18 Positron Emission Tomography/Computed Tomography: A Novel Diagnostic Tool for Immune Checkpoint Inhibitor-Associated AKI

Shruti Gupta, Olivia Green-Lingren, Sudhir Bhimaniya, David E. Leaf. ICI-AKI Consortium. *Brigham and Women's Hospital, Boston, MA.*

Background: No clinical features reliably differentiate immune checkpoint inhibitor-associated AKI (ICI-AKI) from other AKI etiologies. We examined the role of F^{18}-FDG PET-CT in diagnosing ICI-AKI.

Methods: We used data from a multicenter international cohort study of 429 patients with ICI-AKI, along with data from 2 control groups: patients with acute tubular injury from non-ICI nephrotoxic chemotherapies or from the cancer itself, and patients treated with ICI therapy who did not have AKI. Patients were required to have PET-CT scans at baseline and within 14 days of AKI onset (or, for the second control group, a follow-up PET scan between 90-365 days following ICI initiation). Nuclear radiologists reviewed the PET-CTs at baseline and follow-up and recorded the mean radiotracer standardized uptake value (SUV_{mean}) in the renal cortices. We then calculated the average percent change in SUV_{mean} from baseline to follow-up for each patient. A receiver operating characteristic curve was generated to evaluate the accuracy of percent change in SUV_{mean} for diagnosing ICI-AKI.

Results: 53 patients were included (9 with ICI-AKI, 24 with AKI from other causes, and 20 on ICIs but without AKI). Representative images from baseline and follow-up PET-CTs are shown in **Figure 1A**. The median percent change in SUV_{mean} increased by 57.4% (IQR, 40.3-119.8) from baseline to follow-up among patients with ICI-AKI, but changed minimally among patients in the two control groups (P<0.001; **Figure 1B**). The AUC for the differentiation of ICI-AKI from the two control groups based on percent change in SUV_{mean} was 0.97 (95% CI, 0.93-1.00) **(Figure 1C)**.

Conclusions: F^{18}-FDG PET-CT may be a useful test for diagnosing ICI-AKI, particularly for patients who cannot be safely biopsied due to a contraindication.

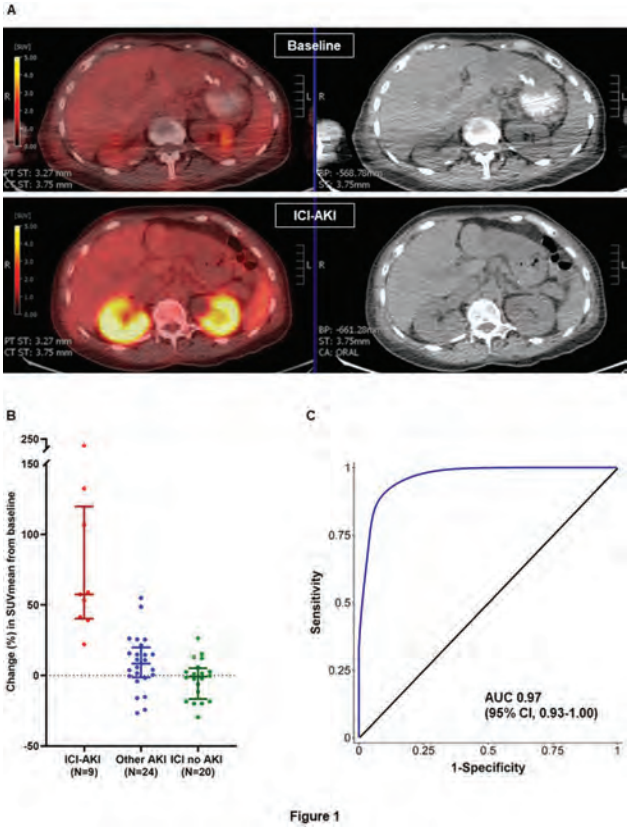

Figure 1

FR-OR78

Effect of Intravenous Magnesium on Cisplatin-Associated AKI

Shruti Gupta,[1] Ilya Glezerman,[2] Jamie S. Hirsch,[3] Sophia L. Wells,[1] Jessica L. Ortega,[1] Anip Bansal,[4] Melanie S. Joy,[4] Ala Abudayyeh,[5] David E. Leaf.[1]
[1]Brigham and Women's Hospital, Boston, MA; [2]Memorial Sloan Kettering Cancer Center, New York, NY; [3]Northwell Health, New Hyde Park, NY; [4]University of Colorado Anschutz Medical Campus, Aurora, CO; [5]The University of Texas MD Anderson Cancer Center, Houston, TX.

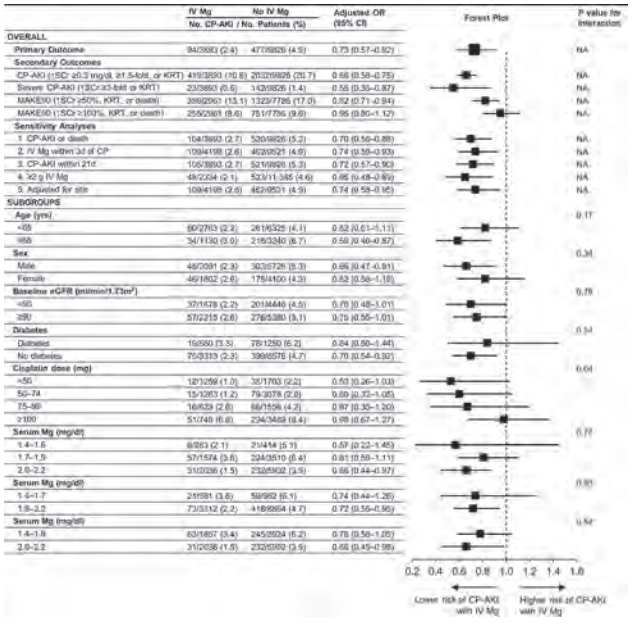
Background: In animal models, prophylactic administration of IV magnesium (Mg) attenuates cisplatin-associated acute kidney injury (CP-AKI), whereas Mg deficiency increases susceptibility to CP-AKI. These findings may be due to the direct effect of Mg on the expression of cisplatin transporters in the proximal tubules. We examined the association between IV Mg administration and risk of CP-AKI in a large cohort.

Methods: We emulated a hypothetical randomized clinical trial (RCT) in which patients receiving cisplatin did or did not receive IV Mg on the day of cisplatin administration. We used data from a multicenter cohort study of adults treated with their first dose of IV cisplatin between 2006-2022 at five major cancer centers across the US. The primary outcome was moderate-to-severe CP-AKI, defined as a ≥2-fold rise in rise in serum creatinine or receipt of dialysis within 14 days following IV cisplatin. We used multivariable logistic regression to adjust for confounders, including age, race, sex, comorbidities, baseline laboratory values, exposure to other nephrotoxic chemotherapy, and cisplatin dose.

Results: Of the 13,719 patients included in the study, 92 of 3893 patients (2.4%) who received IV Mg and 477 of the 9826 (4.9%) who did not receive IV Mg, developed CP-AKI. The adjusted odds ratio for development of CP-AKI among those who did vs. did not receive IV Mg was 0.73 (95% CI, 0.57-0.92). Findings were consistent across a number of sensitivity and subgroup analyses (**Figure**). The protective effect of IV Mg on CP-AKI was consistent across different cisplatin doses, though there was a trend toward greater benefit in patients receiving lower doses of cisplatin.

Conclusions: Administration of IV Mg may be associated with a lower risk of CP-AKI. These findings should be confirmed in a RCT.

Funding: NIDDK Support



FR-OR79

Post-transplantation Cyclophosphamide-Based Regimen for Graft-vs.-Host Disease Prophylaxis Reduces Risk of CKD in Allogenic Stem-Cell Transplant Recipients

Nathaniel Klair,[1] Shernan Holtan,[1] Nattawat Klomjit.[2] *[1]University of Minnesota Twin Cities Division of Nephrology and Hypertension, Minneapolis, MN; [2]Roswell Park Comprehensive Cancer Center, Buffalo, NY.*

Background: Allogenic stem cell transplant (Allo-SCT) is associated with higher risk of acute kidney injury (AKI) and chronic kidney disease (CKD). Post-transplantation cyclophosphamide (PTCy)-based regimen for graft-versus-host disease (GVHD) prophylaxis has emerged as a new paradigm in reducing GVHD risk by up to 40%. However, little is known about the impact of kidney outcomes in a PTCy-based regimen.

Methods: We included all adult patients (age ≥ 18 years) who underwent Allo-SCT at the University of Minnesota Medical Center between 1/1/2015 and 5/31/2022. Patients were categorized based on their GVHD prophylaxis: PTCy-based regimen (PTCy/Tacrolimus/Mycophenolate), calcineurin inhibitor (CNI) -based regimen and others. Outcomes include AKI at day 100 (D100), dialysis at D100, eGFR at 1 year and CKD at last follow-up.

Results: We included 488 patients in our cohort, of which 166 (34.0%) received PTCy, 276 (56.6%) received CNI and 46 (9.4%) received other GVHD prophylaxis. Mean age was 54.3 ±15.0 years and the majority were male (59.8%). Baseline eGFR was 107.2±16.6 ml/min/1.73m^2 and only 9 (1.8%) patients had CKD at baseline. PTCy [157 (94.6%)] and CNI-based regimens [255 (92.4%)] had a significantly higher rate of AKI at D100 than the other group [21 (45.7%)]. However, there were no difference in the rate of AKI stage 3 and dialysis among groups (p>0.05). However, eGFR at 1 year was not different. CNI toxicity was the most common cause of AKI in PTCy and CNI groups whereas pre-renal cause was the most common cause of AKI in the other group. At last follow-up, PTCy [31 (18.7%)] had the lowest rate of CKD compared to CNI-based [86 (31.2%)] and the other group [14 (30.4%)]. Multivariate analysis showed that the PTCy group had significantly lower risk of CKD compared to the CNI-based group with OR 0.23 (95% CI 0.09-0.57). Furthermore, PTCy had lower rates of thrombotic microangiopathy, veno-occlusive disease, acute GVHD and chronic GVHD compared to the CNI-based regimen

Conclusions: Although AKI is common in the PTCy regimen, most patients recover and sustain comparable eGFR to CNI and the other regimens at 1 year. PTCy also demonstrates the lowest rate of CKD and is possibly due to lower transplant-related complications such as acute and chronic GVHD.

FR-OR80

Exposure to Glucagon-Like Peptide 1 Receptor Agonists Does Not Increase the Risk of AKI Associated with Anticancer Therapy

Swetha Rani Kanduri, Rosemary Kovacic, Gavin R. Skipper, Juan Carlos Q. Velez. *Ochsner Health, New Orleans, LA.*

Background: Glucagon-like peptide-1-receptor agonists (GLP-1RA) are increasingly prescribed for patients with type 2 diabetes mellitus (T2D) and congestive heart failure (CHF). Notably, reports of GLP-1RA associated acute kidney injury (AKI) have emerged. However, the risk of GLP-1RA-associated AKI among patients on anti-cancer therapies remains unknown. Considering the vulnerability of patients with cancer to acquire AKI during administration of chemotherapy, we hypothesized that exposure to GLP-1RA may further increase the risk of AKI.

Methods: We conducted a retrospective review of medical records extracting cases of patients treated with anti-cancer therapies (cytotoxic, eg, alkylating agents, anti-metabolites; targeted therapy, eg, anti-VEGF, TKI; immunotherapy, eg, ICPI) over a 1-year period and were additionally exposed to a GLP-1RA during the same time period. AKI was defined per KDIGO criteria. Diagnosis of AKI was captured during the first 90 days of GLP-1RA exposure by using ICD codes. To assess the association of GLP-1RA and AKI risk, we conducted a logistic regression model including age, gender, CHF, T2D, chronic kidney disease (CKD) and anti-cancer therapy class.

Results: A total of 14,783 patients were included in the study. Mean age was 67 years, 64% women, 24% had T2D, 8% CHF and 13% had CKD. Nine percent were treated with a GLP-1RA. AKI occurred in 7.2% (92/1278) of those exposed to GLP-1RA versus 6.4% (862/13505) of those with no GLP-1RA exposure (p=0.25). By univariate logistic regression analysis, exposure to GLP-1RA was associated with an OR 1.14 (95% CI 0.91-1.42; p=0.25) for AKI, whereas CKD had an OR 7.26 (95% CI 6.29, 8.29, p<0.0001), CHF an OR 4.92 (95% CI 4.19, 5.76; p<0.0001), T2D an OR 2.36 (95% CI 2.06, 2.70, p<0.0001), targeted therapy an OR 2.84 (95% CI 2.49-3.24, p<0.0001), immunotherapy an OR 2.21 (95% CI 1.55, 3.14, p<0.0001) and cytotoxic chemotherapy an OR 1.89 (95% C1 1.65, 2.17, p<0.0001).

Conclusions: Contrary to our hypothesis, our data suggest that exposure to GLP-1RA is not associated with an increased risk of AKI in patients receiving anti-cancer therapies. Given the cardiovascular and anti-diabetic benefits of GLP-IRA, we suggest that these agents can be safely continued during administration of anti-cancer therapy.

FR-OR81

Cancer Incidence and Outcomes in the Dialysis Population: Nationwide Registry Analysis of Time Trends and Outcomes

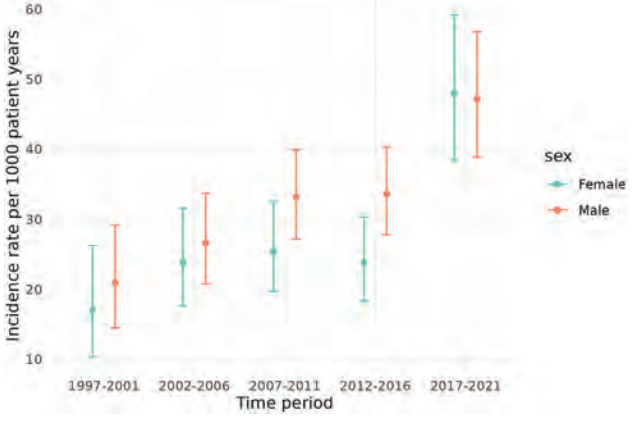
Benjamin M. Elyan,[1,2] Ailish Nimmo,[5] Patrick B. Mark,[1,2] Jennifer S. Lees,[1,2] Samira Bell.[3,4] *[1]University of Glasgow College of Medical Veterinary and Life Sciences, Glasgow, United Kingdom; [2]Queen Elizabeth University Hospital, Glasgow, United Kingdom; [3]University of Dundee School of Medicine, Dundee, United Kingdom; [4]Ninewells Hospital and Medical School, Dundee, United Kingdom; [5]NHS Lothian, Edinburgh, United Kingdom.*

Background: Individuals with end-stage kidney disease have an increased risk of developing and dying from cancer compared to the general population. It is unclear how cancer incidence has changed over time. We aimed to assess cancer incidence over time in the Scottish dialysis population.

Methods: The cohort comprised of adults receiving chronic dialysis (haemodialysis or peritoneal dialysis) in Scotland between 1997-2021. Data were linked between the Scottish Renal Registry, Scottish Cancer Registry and mortality records. Cancers were defined using the International Classification of Diseases for Oncology, 3rd Edition with codes C00-C80, excluding non-melanomatous skin cancer (C44). Cancer incidence rates per 1000 population-years (IRs) were calculated per 5-year time periods and cox regression analyses were performed to examine factors associated with the development of de-novo cancer.

Results: Of 9003 people on long-term dialysis, 727 developed de novo cancer. Median follow-up was longer for people with de-novo cancer (3.6 years vs 2.6 years, p <0.001). The most common cancers were lung (22.8%), colorectal (13.1%), haematological (7.8%), breast (6.7%) and bladder (6.7%). Incidence rate of cancer from 1997-2001 was 19.2 per 1000 patient-years. IRs for later time periods were higher (Figure). The IRR for 2017-2021 was 2.58 compared to the reference period (1997-2001). Increased hazards of de novo cancer were observed with older age at dialysis initiation (aHR 1.01 per year, 95% CI: 1.00-1.02, p=0.001) and with a diagnosis of glomerular diseases compared with other primary renal diagnoses (aHR 1.28, 95% CI 1.01-1.62, p=0.046).

Conclusions: Incidence rates of cancer in the Scottish dialysis population are increasing. These findings emphasise the importance of understanding the role of cancer screening, diagnosis and treatment pathways in dialysis patient care.



Cancer incidence rates in the dialysis population over 5-year period.

FR-OR82

Nephro-Neurovascular Interactions in the Human Kidney Using Light Sheet Fluorescence Microscopy

Liam J. McLaughlin, Bo Zhang, Amanda Knoten, Sanjay Jain.
Washington University in St Louis School of Medicine, St Louis, MO.

Background: Light sheet fluorescence microscopy (LSFM) is a powerful way to create large 3D tissue images and glean insights into kidney physiology. Here we developed imaging and analytical methods using LSFM on human kidneys to study the neurovascular connectivity of its functional tissue units (FTUs).

Methods: We developed a pipeline from processing slices of human kidney lobes to clearing, image acquisition, image processing, and analysis with available and in-house coded software. Analytical pipelines included segmentation of FTUs and neurovasculature to study patterning of kidney nerves via the creation of neural networks (Fig 1) at macro, meso, and microscopic scales.

Results: In addition to volumetric properties of organization, we report novel observations related to the patterns renal nerves establish between glomeruli and tubules. We define seven motifs of neuro-glomerular networks emanating from the renal vascular pole that organize glomeruli into communities. This includes the same nerve innervating multiple glomeruli together with nearby tubules, and/or the medullary ray, suggesting a neural feedback mechanism between communities of nephrons. Throughout the renal cortex, glomerular neural communities are interconnected through “mother glomeruli”. This organization likely permits FTUs to synchronize responses to perturbations in fluid homeostasis, utilizing mother glomeruli as network control centers. Mathematical modelling of this arrangement suggests that if a part of the network is damaged, the remaining FTUs can compensate till a threshold beyond which normal function deteriorates.

Conclusions: We provide several novel contributions ranging from 3D analytical tools to discoveries that are paradigm shifting and transformational in relation to how 3D structural relationships and organization between kidney FTU and nerves may enable the kidney to adapt to hemodynamic alterations and maintain homeostasis.

Spatial Transcriptomics Differentiates Donor-Specific Antibody-Positive and -Negative Microvascular Inflammation

Kelly D. Smith, Yuan Huang, Christopher D. Blosser, Nicolae Leca, Shreeram Akilesh. *University of Washington, Seattle, WA.*

Background: In kidney allografts, microvascular inflammation (MVI) is a hallmark of antibody-mediated rejection and can be seen in patients with and without donor-specific antibodies (DSA). The pathophysiology of MVI in DSA-negative patients is speculated to be mediated by non-HLA antibodies or cellular immune responses.

Methods: Kidney allograft biopsies from 2018-2022 that had donor-derived cell-free DNA (dd-cfDNA) and DSA testing were reviewed for allograft pathology. Clinical and pathologic data were collected. Biopsy material from representative DSA+ (n= 12) and DSA- (n= 16) cases with and without MVI were analyzed using digital spatial profiling (GeoMx, Nanostring) and compared to control biopsies. Biopsies were hybridized with the Whole Transcriptome Atlas and bound probes were collected, sequenced and quantified from glomerular and tubulointerstitial regions of interest (ROI).

Results: We analyzed 237 ROIs from glomeruli (113) and tubulointerstitium (124) from the allograft biopsies. There was strong concordance in differentially expressed genes (DEG) between MVI+ and cfDNA+ biopsies (~80% overlap). In contrast, DSA+ and DSA- biopsies with MVI showed distinct but overlapping patterns of DEG compared to controls (~30% overlap)(Fig. 1). Pathway analysis of the differentially expressed glomerular genes revealed DSA- biopsies with MVI were enriched in interferon-gamma and T cell receptor signaling compared to DSA+ biopsies with MVI.

Conclusions: DSP reveals molecular differences between DSA+ and DSA- biopsies with MVI, supporting distinct pathophysiological mechanisms for MVI-induced renal allograft pathology in the presence and absence of DSA. These results provide additional insight into the molecular pathophysiology of DSA- MVI that may help provide insight into the superior outcome and prognosis reported for these patients.

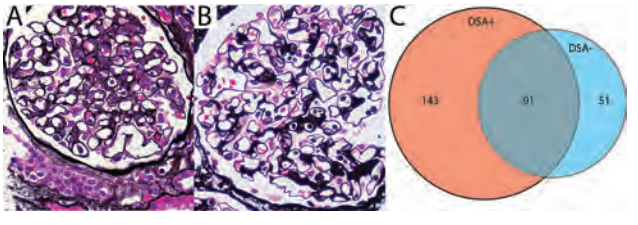

Figure 1. DSP ditinguishes DSA+ and DSA- MVI. A) Glomerulus with DSA+ MVI, and B) histologically indistinguishable glomerulus with DSA- MVI. C) Venn diagram of DEG from DSA+ and DSA- glomeruli with MVI relative to controls.

A Novel Bioinformatics Strategy to Explore Key Biomarkers in IgA Nephropathy Using Network Biomarkers and Machine Learning

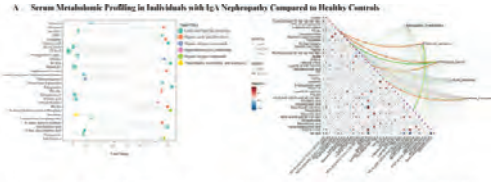
Jiantong Sun, Jiaxing Tan, Wei Qin. *West China Hospital of Sichuan University, Chengdu, China.*

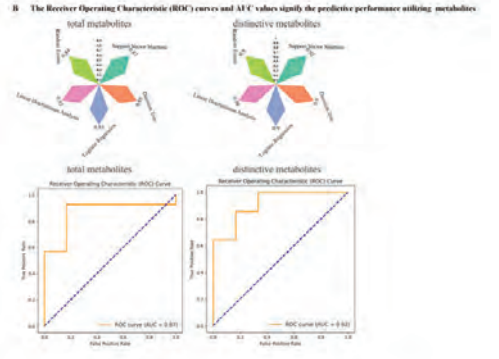
Background: Serum metabolites have been established as pivotal biomarkers for a multitude of diseases. This study explored serum metabolic differences between IgAN patients and healthy controls, aiming to identify potential biomarkers for IgAN.

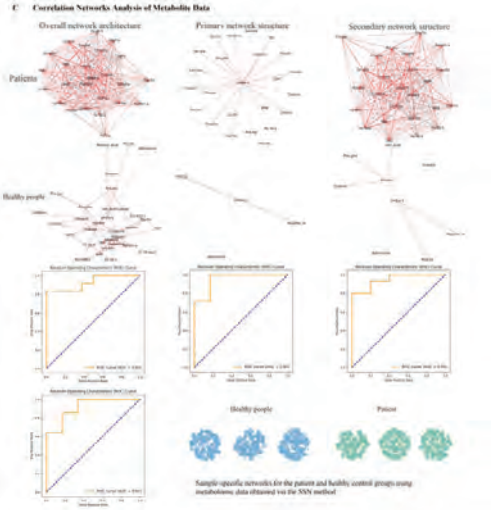
Methods: Serum from 31 healthy individuals and 65 IgAN patients was analyzed using ultra-performance liquid chromatography-mass spectrometry. Machine learning algorithms combined with traditional molecular/ network biomarkers differentiated IgAN from controls, identifying key metabolites and interaction networks. All subjects were followed for >3 years to assess their prognostic value, with mechanisms explored by Mendelian Randomization(MR), network pharmacology, and molecular docking.

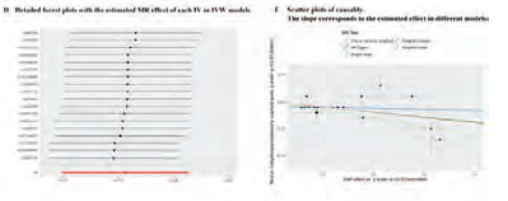
Results: Volcano plot and PLS-DA analyses showed distinct serum metabolite profiles in IgAN patients compared to healthy controls, correlating with kidney damage. A machine learning model utilizing network biomarkers also surpassed traditional biomarkers in performance. SHAP analysis recognized Dehydroepiandrosterone sulfate (DHEA-S) as a crucial differentiator, and networks differed significantly between IgAN cases and controls, supporting its strong linkage to IgAN. MR analysis established a causal link between reduced DHEA-S levels and IgAN onset. Long-term follow-up revealed higher DHEA-S levels correlated with better renal outcomes. Network pharmacology identified 42 potential targets and a protein-protein interaction network pinpointed 6 central targets; molecular docking showed stable binding of DHEA-S with 4 proteins, suggesting its involvement in signaling pathways and mechanisms in IgAN.

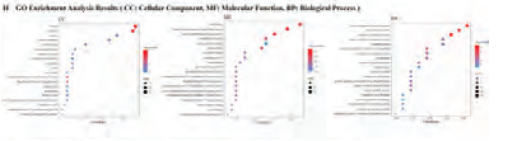
Conclusions: The network structure of serum metabolites in IgAN was significantly different from that of healthy controls, with changes of DHEA-S closely related to the progression of IgAN.

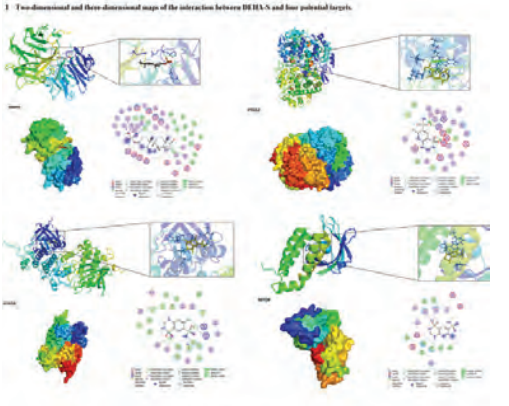












Protein	Lowest Binding Energy	Mean Binding Energy

Development and Validation of a Deep-Learning Algorithm to Estimate Human Podometrics

Kotaro Haruhara,[1] Hiroki Kawai,[2] Eisuke Kubo,[1] Takaya Sasaki,[1] Yusuke Okabayashi,[1] Nobuo Tsuboi,[1] Takashi Yokoo.[1] *[1]Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan; [2]LPIXEL Inc., Tokyo, Japan.*

Background: Podocyte depletion is a common pathway in most progressive kidney diseases. We have recently established a method for estimating podometrics, namely podocyte number and size indices, using model-based stereology by measuring the number and diameter of podocyte nuclei on a double immunofluorescence for podocyte-specific markers. However, this method is time-consuming and lacks objectivity.

Methods: In the present study, we have developed a deep learning-based algorithm using modified UNet++ for segmenting podocyte nuclei and glomerulus areas in immunofluorescence images, which includes seed prediction for watershed analysis to enhance the identification of nuclei. Data for >43,000 podocyte nuclei on >1800 glomeruli from donors and autopsy kidneys that were manually counted were used as a ground truth. Approximately 70% of these data were randomly allocated for training deep learning algorithms, and the remaining approximately 30% of data were used as a test group. As a validation cohort, independent >500 images of podocyte immunofluorescence from patients with obesity-related glomerulopathy were used (**Figure**).

Results: In the test group consisting of donors and autopsy kidneys, our algorithm showed good accuracy with a precision of 0.92 and recall of 0.95 for podocyte identification. The correlation coefficient for the diameter of podocyte nuclei was 0.80. In the validation cohort, similar results were obtained. While the manual method to identify podocyte nuclei required approximately 30 minutes per glomerulus, our algorithm could detect much faster at a few seconds per glomerulus.

Conclusions: We developed and validated a deep-learning program to estimate podometrics with good accuracy and high throughput. This technology enables us to perform further podometric studies with a large sample size of subjects and glomeruli.

Computational Characterization of Lymphocyte Topology in FSGS/ Minimal Change Disease

Xiang Li,[1] Manav P. Shah,[4] Gina Sotolongo,[1] Qian Liu,[5] Jin Zhou,[1] Jeffrey B. Hodgin,[2] Laura H. Mariani,[2] Lawrence B. Holzman,[6] Andrew Janowczyk,[3,7] Jarcy Zee,[6,5] Laura Barisoni,[1] Kyle J. Lafata.[1] *[1]Duke University, Durham, NC; [2]University of Michigan, Ann Arbor, MI; [3]Emory University, Atlanta, GA; [4]Georgia Institute of Technology, Atlanta, GA; [5]The Children's Hospital of Philadelphia, Philadelphia, PA; [6]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [7]Hopitaux Universitaires Geneve, Geneve, Switzerland.*

Background: The semi-quantitative visual scoring of inflammation does not capture the distribution of inflammatory cells in the kidney tissue. This study computationally quantified the topology of inflammation and evaluates their clinical relevance.

Methods: H&E-stained whole slide images (WSIs) of renal biopsies from N=190 NEPTUNE (104 FSGS and 86 MCD) and N=141 CureGN (75 FSGS and 66 MCD) participants were used. Deep learning models were developed to segment renal cortex and lymphocytes. Graph modeling was applied, where nodes were defined as lymphocytes and edges as the spatial connections between lymphocytes. We developed a novel graph-based clustering algorithm to capture dense vs. sparse lymphocytic regions. 30 pathomic features were extracted to capture cell density, connectivity, clustering, and centrality. The prognostic value of the features was evaluated by modeling their association with disease progression (time from biopsy to a 40% decline in eGFR or kidney replacement therapy) in the NEPTUNE dataset. To identify the most informative features, lasso regularization was applied to a Cox model. Next, L2-regularized Cox models including clinical features with and without the selected features were constructed. The selected features were then re-fitted in the CureGN dataset for validation.

Results: The selected pathomic features include topology features from both sparsely (n=8) and densely (n=11) inflamed regions. The addition of pathomic features to clinical feature increased the Concordance index from 0.71 to 0.78 in NEPTUNE and from 0.76 to 0.79 in CureGN.

Conclusions: We developed a computational approach to quantify topological characteristics of lymphocytic inflammation on WSIs. These digital signatures have potential as biomarkers of disease progression in FSGS/MCD and increase our ability to predict clinical outcome above and beyond current approaches.

Host-Cell Line Origin of Recombinant Human Nephrin Impacts Anti-nephrin Antibody Enzyme-Linked Immunosorbent Assay (ELISA): Insights into Glycan-Mediated Discrepancy

Maryam Ghasemi, Astrid Weins, Andrew J. Watts. *Brigham and Women's Hospital, Boston, MA.*

Background: We identified circulating autoantibodies targeting the extracellular domain (ECD) of human nephrin in a subset of patients with minimal change disease. We observed a discrepancy in ELISA results when utilizing human nephrin ECD expressed in a human versus a murine cell line. Nephrin is glycosylated and notably this murine cell line expresses two immunogenic glycans, galactose-α-1,3-galactose (α-Gal) and N-glycolylneuramic acid (Neu5Gc), which are not expressed in human cells. Most human sera contain immunoglobulin G (IgG) against α-Gal and Neu5Gc, which we hypothesized may account for the observed difference in the IgG binding.

Methods: Indirect ELISA for anti-nephrin antibodies in sera was conducted as previously described using affinity-purified recombinant human nephrin ECD (>90% purity) expressed in either human embryonic kidney (HEK) or non-secreting murine myeloma (NSO) cell lines, purchased from Sino Biological (Cat. 17757-H08H) and R&D systems (Cat. 9399-NN) respectively. The amino acid sequence was similar. α-Gal and Neu5Gc expression on the nephrin ECD were evaluated by ELISA. Serum was pre-incubated with porcine RBCs, which express α-Gal and Neu5Gc, and IgG binding to nephrin was evaluated pre- and post-incubation.

Results: Using healthy control sera, we observed more IgG binding to the human nephrin expressed in the NSO compared with the HEK cell line (Fig. 1). We confirmed α-Gal and Neu5Gc presence only on the NSO-expressed human nephrin. Pre-incubation of the sera with porcine RBCs abrogated this higher IgG binding with NSO-expressed nephrin to a level observed with HEK-expressed nephrin (Fig. 2)

Conclusions: We observed more IgG binding from healthy control sera to human nephrin ECD expressed in a murine NSO cell line compared with a human HEK cell line, and this was abrogated by pre-incubating the sera with porcine RBCs. This suggests that IgG binding to α-Gal and Neu5Gc may explain this difference. We therefore recommend using recombinant human nephrin specifically expressed in human cell lines when evaluating patient sera for nephrin autoantibodies by ELISA to minimize false positives.

Longitudinal In Vivo Monitoring of Kidney Fibrosis Using Collagen I Luciferase Transgenic Mice

Hualin Ma,[1,2] Jianyong Zhong,[2] Jun Zou,[3,2] Haichun Yang,[2] Agnes B. Fogo.[2]
[1]Shenzhen People's Hospital, The Second Clinical Medical College, Jinan University, The First Affiliated Hospital, Southern University of Science and Technology, Shenzhen, China; [2]Vanderbilt University Medical Center, Nashville, TN; [3]XinHua Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China.

Background: Interstitial fibrosis is closely associated with progression of chronic kidney disease. However, direct assessment of tissue-level fibrosis is limited by the invasiveness of biopsies. We investigated the potential of using collagen I-luciferase (Col(I)-Luc) transgenic mice to track dynamic changes in kidney fibrosis over time in vivo.

Methods: In Col(I)-Luc transgenic mice, the luciferase gene is driven by the collagen I promoter. We induced tubular injury in Col(I)-Luc mice by folic acid (FA) injection and treated a subgroup with dimethyloxaloylglycine (DMOG), an inhibitor of HIF-alpha prolyl hydroxylase. We also crossbred Col(I)-Luc mice with Nep25 mice, which express human CD25 under the nephrin promoter on podocytes. Podocyte injury can be induced by injection of LMB2 toxin that binds the receptor. We induced podocyte injury in Col(I)-Luc/Nep25 mice and treated a subgroup with angiotensin receptor blockers (ARB). In vivo bioluminescence imaging was performed at intervals.

Results: In vivo bioluminescence imaging captured luciferase activity in the kidneys, which correlated with kidney collagen I mRNA. The luciferase activity increased from baseline until week 6 in FA-injured mice, while the normal control had stable luciferase activity. Collagen I mRNA and protein were higher in FA vs control at week 6. DMOG reduced collagen I protein but not mRNA and luciferase activity. In the Nep25 model, low dose LMB2 induced increased proteinuria and luciferase activity at week 2, returning to normal at week 6. However, medium and high dose LMB2 markedly increased proteinuria and luciferase activity from week by week 6. ARB treatment in the high dose LMB2 mice numerically reduced luciferase activity reflecting decreased Col I mRNA but did not change the collagen I protein.

Conclusions: The Col(I)-Luc transgenic mouse model is an effective tool to longitudinally follow changes in collagen I mRNA in kidney disease. This model could be used to validate drug effects in preclinical studies. Utility will be greatest to monitor interventions that change Col I(mRNA), as the model design does not detect posttranslational changes in protein level.

Detection and Characterization of NELL1 Autoantibodies in NELL1-Positive Membranous Nephropathy

Tiffany Caza,[1] Brock A. Arivett,[2] Samar Hassen,[1] Christopher P. Larsen,[1] Dorin-Bogdan Borza.[2] *[1]Arkana Laboratories, Little Rock, AR; [2]Meharry Medical College, Nashville, TN.*

Background: Discovery of novel autoantigens in membranous nephropathy (MN) holds promise for development of serologic tests to monitor disease activity and guide treatment. Neural epidermal growth factor-like 1 (NELL1) is the second most common antigen in MN. Anti-NELL1 antibodies are currently detected within patient sera by western blotting against NELL1 recombinant protein, but no reproducible, high-throughput clinical assay is yet available.

Methods: Serum samples from 29 patients with NELL1 MN, 33 with PLA2R MN, and 25 healthy controls were collected. Samples were not obtained at the time of biopsy and serologic remission cannot be entirely excluded. We developed a quantitative enzyme-linked immunosorbent assay (ELISA) for NELL1 antibodies using a NELL1 recombinant protein as an antigen source and an indirect immunofluorescence assay for detection of anti-NELL1 antibodies using HEK-293 cells stably transfected with a NELL1-FLAG plasmid vector. IgG subclasses were examined within sera and tissue using subclass specific antibodies.

Results: We detected antibodies within patient sera against NELL1 in 16/33 NELL1 samples and 3/61 controls by ELISA with a sensitivity of 55.2% and specificity of 95.1%. Circulating anti-NELL1 antibodies were predominantly IgG1 and IgG4, with IgG1 antibodies present within all positive samples. Sensitivity of the indirect immunofluorescence assay was 71.4% and specificity 98.6%. Western blots were performed in a subset of cases with good concordance of results between all three methods.

Conclusions: Our data provide methods for serologic testing that can be utilized for serologic evaluation of NELL1-associated MN. High specificity was achieved (95.1-98.6%), however sensitivity was low, which could be due to patients being in serologic remission at the time of serum collection. Further work will establish if antibody titers correlate with disease activity and response to immunosuppressive therapy.

Purine and Pyrimidine Metabolism Decrease in the First Hour of Warm Ischemia in Kidney Tissue: Spatiotemporal Detection by Mass Spectrometry Imaging

Carine Peutz-Kootstra,[1,2] Benjamin Balluff,[3] Tim C. Van smaalen,[2] Maarten G. Snoeijs,[2] Ron M.A. Heeren,[3] Patrick A. de Hoogt.[2] *[1]Gelre Ziekenhuizen, Apeldoorn, Netherlands; [2]Maastricht Universitair Medisch Centrum+, Maastricht, Netherlands; [3]Maastricht Multimodal Molecular Imaging Institute - M4i, Maastricht, Netherlands.*

Background: Warm ischemia is an important cause of acute kidney injury. Mass Spectrometry Imaging (MSI) can visualize metabolic alterations in renal tissue biopsies.

Methods: In order to identify alternating metabolites during the first hour of warm ischemia, kidney samples from five pigs were measured by high-mass resolution matrix-assisted laser desorption/ionization (MALDI) MSI after 0, 20, 40, and 60 minutes of warm ischemia.

Results: Contrasting the metabolites' distributions with the kidney's microanatomy revealed a cortical decrease in abundance of 56 metabolite signals between 0 and 40 minutes, and of 89 signals between 0 and 60 minutes. Tandem MS identified eleven metabolites of which ten belong to the purine and pyrimidine pathways. There was an attenuated loss of adenosine tri- and diphosphate (ATP and ADP) in medullary rays. Phosphatidylserine 18:0_18:1 was decreased in the cortex, but only in the first 40 minutes of ischemia.

Conclusions: In conclusion, MSI discerns metabolites with differential spatial and temporal expression during warm ischemic injury in renal tissue. Rapid cortical, but slow medullary loss of ATP and ADP metabolism discriminates energy homeostasis pathways affected by acute kidney injury.

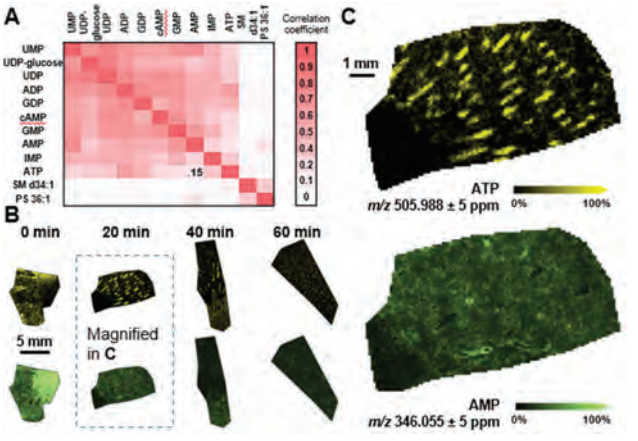

Figure 1. Different spatiotemporal expression patterns of metabolites identified by MSI and MS/MS. Heat map analysis (panel A) of the eleven identified compounds shows differences in spatial expression pattern over time. Panell B shows a different spatial expression for ATP (yellow) and AMP (green) at 0 minutes in cortex and medulla, with a decrease after 20, 40 and 60 minutes of warm ischemia. Higher magnification (panel C) shows that expression of ATP remains in the medullary rays, while AMP expression is still diffusely present in the cortex after 20 minutes of warm ischemia.

FR-OR91

Global, National, and Regional Trends in the Burden of CKD among Women from 1990-2021: A Comprehensive Global Analysis

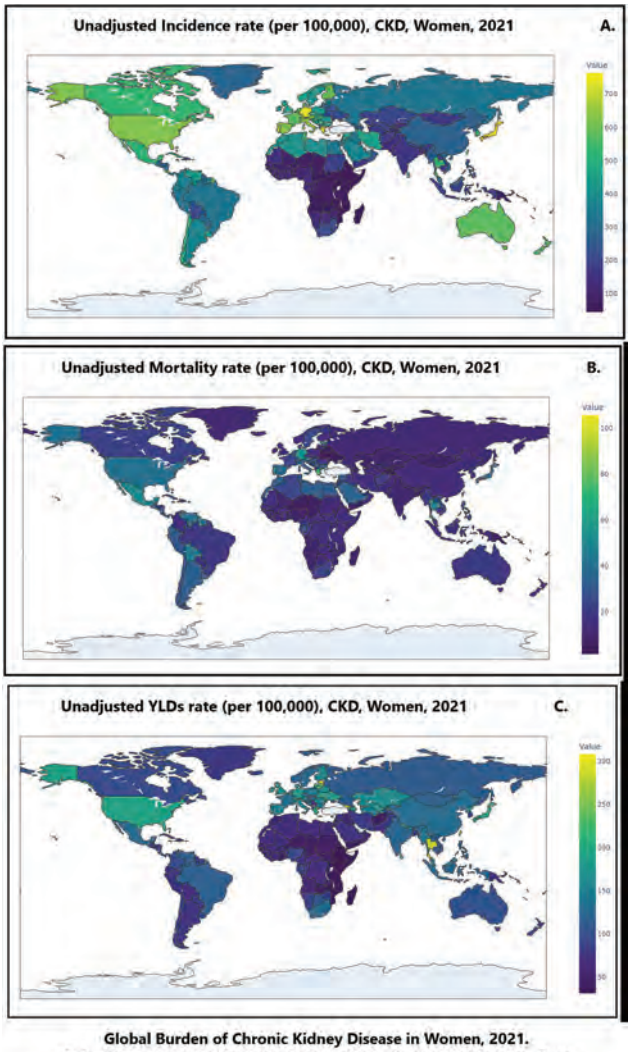
Sree Abhilekha Purohit,[1] Harsha Choudary Pudhota,[2] Ashwinikumar Shandilya,[4] Ram Prasanjith Reddy,[3] Mohit Lakkimsetti,[5] Vishrant Amin,[6] Juhi Patel,[6] Rohan Raj,[8] Hardik Desai.[7] *[1]Shadan Institute of Medical Sciences College of Nursing, Hyderabad, India; [2]Guntur Medical College, Guntur, India; [3]MediCiti Institute of Medical Sciences, Medchal, India; [4]Pravara Institute of Medical Sciences (Deemed to be University), Ahmednagar, India; [5]Mamata Medical College, Khammam, India; [6]Gujarat Medical Education and Research Society Medical College & Hospital Valsad, Valsad, India; [7]Gujarat Adani Institute of Medical Science, Bhuj, India; [8]Nalanda Medical College and Hospital, Patna, Patna, India.*

Background: Chronic Kidney Disease (CKD) ranked as the 7th leading cause of death among women in 2021. This pioneering study presents the 1st comprehensive evaluation of the global burden of CKD in women over the past 3 decades, including an analysis of the initial 2 years of the COVID-19 pandemic-a period that significantly challenged the management of non-COVID-19 diseases.

Methods: Utilizing the 2021 GBD Study framework, we estimated the prevalence, incidence, mortality, Disability Adjusted Life Years(DALYs), and Years Lived with Disability(YLDs) by age, year, and location across 204 countries and territories.

Results: The average annual percentage change(AAPC) in prevalence increased by 2.10%, mortality by 3.39%, and DALYs by 2.48%. Regionally, we observed the highest incidence rates of CKD due to Type 1 diabetes occurred in Eastern Europe (2.07 cases per 100,000 persons), while CKD due to Type 2 diabetes led in the Middle East and North Africa(MENA) with 43 cases per 100,000 persons. Additionally, CKD attributed to hypertension(HTN) (25.18 cases per 100,000 persons) and glomerulonephritis (5.69 cases per 100,000 persons) were notably prevalent in MENA and Central Latin America, respectively. The most substantial incidence counts were observed in the 70-74 age group with 1,663,821 cases, while the highest death rates occurred among those aged 85-89, totaling 92,279 in 2021.

Conclusions: Type 2 DM was the leading cause of CKD related deaths among women in 2021, followed by CKD due to HTN. There is a critical need for increased awareness, education, and comprehensive campaigns aimed at women's health involving public stakeholders and clinicians to address and mitigate these impacts.



Global Burden of Chronic Kidney Disease in Women, 2021.

Risk of Congenital Malformation in Newborns of Mothers with Kidney Diseases: A Retrospective Cohort Study Using National Health Insurance Service Data

Seung hyun Han,[1] Jeongin Song,[3] Sehoon Park,[2] Hajeong Lee.[2] *[1]Seoul National University Borame Medical Center, Seoul, Republic of Korea; [2]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [3]Dongguk University Ilsan Hospital, Ilsan, Republic of Korea.*

Background: The risk of congenital malformations in pregnancies of mothers with kidney disease, including chronic kidney disease (CKD), end-stage kidney disease (ESKD) and kidney transplant (KT) remains unclear.

Methods: A retrospective cohort study using National Health Insurance Service (NHIS) data from 2008 to 2017 was conducted in Korea, including women who delivered during this period and their newborns. The risk of congenital malformations in women with CKD, ESKD, and KT was compared with healthy controls without diabetes or hypertension. Multivariate logistic regression models were used to assess the risk of congenital malformations.

Results: A total of 2,605,422 pregnant women and their 3,637,903 children were included in the present study. Among them, 47,166 women had kidney diseases, including CKD (n = 46,930), ESKD (n = 49), and KT (n = 187). After adjusting for age, parity, hypertension, diabetes, fetal sex, smoking, BMI, preterm birth, and preeclampsia, the KT and CKD group showed a significantly increased risk of any congenital malformations (hazard ratio [HR], 1.81; 95% confidential interval [CI], 1.31-2.45; HR, 1.20; 95% CI, 1.17-1.22, respectively). The ESKD group also tended to show an increased risk of congenital malformation (HR, 1.71; p = 0.080).

Conclusions: This large-scale, population-based study indicated that neonates born to mothers with kidney diseases, especially KT and CKD, have an increased risk of congenital malformations compared to those born to healthy mothers. This highlights the need for specialized prenatal care and monitoring to improve potential fetal malformations.

FR-OR93

Pregnancy Protects against Kidney Injury in Aged Female Mice Lacking G Protein-Coupled Estrogen Receptor

Ravneet Singh,[1] Rawan N. Almutlaq,[2] Sho Sugahara,[1] Craig R. Brooks,[1] Lisa M. Curtis,[2] Eman Y. Gohar.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]University of Alabama at Birmingham, Birmingham, AL.*

Background: Chronic kidney disease affects more than 1 in 7 US adults, with prevalence increasing with age. In particular, kidney disease is one of the top ten leading causes of death for women. In female rodents, estrogen elicits protective responses against various kidney injuries through G protein-coupled estrogen receptor 1 (GPER1). GPER1-induced vasodilation in rats is increased with pregnancies. The impact of GPER1 signaling and pregnancy on long-term renal health is not clear yet. We hypothesized that GPER1 and previous pregnancies (PP) protect against kidney injury in aged female mice.

Methods: In our study, we used 16-20 month-old GPER1 wild-type (WT) and global knock-out (KO) female mice with or without a history of PP (n=6-8/group). We collected 24-hour urine samples, plasma, and kidneys. Urinary levels of kidney injury biomarkers including protein, albumin, nephrin (glomerular injury marker), kidney injury molecule 1 (KIM-1), and neutrophil gelatinase-associated lipocalin (NGAL, tubular injury marker) were measured. Plasma creatinine levels were measured. Kidney sections were stained for KIM-1 and assessed for apoptosis by the terminal deoxynucleotidyl transferase-mediated dUTP nick-end labeling (TUNEL) assay.

Results: Urinary protein, albumin and plasma creatinine were elevated and PP eliminated this difference. In aged virgin GPER1 KO mice urinary excretion of nephrin [0.63±0.12 vs. 0.36±0.07 ng/day; p=0.0488], KIM-1 [3.11±0.59 vs. 0.79±0.29 ng/day; p=0.0004], and NGAL [208.48±28.17 vs.70.55±11.32; ng/day; p<0.0001] was increased. However, aged previously pregnant KO mice elicited lower levels of excretion of nephrin [0.295±0.04 ng/day; p= 0.0159], KIM-1 [1.38±0.28 ng/day; p=0.0058], and NGAL [67.06±15.69 ng/day; p<0.0001] compared to virgin KO mice. More KIM-1 positive tubules were identified in the aged virgin KO mice compared to the aged virgin WT mice. Further, GPER1 deletion increased TUNEL-positive nuclei in the renal cortex of the virgin mice [662±42 vs. 407±30; p=0.0002]. This genotypic difference was blunted with PP [282±12; p<0.0001].

Conclusions: Our data indicates that GPER1 and former pregnancies protect from kidney injury in aged female mice. This data could provide insight into the development of renoprotective therapeutic agents for postmenopausal women.

FR-OR94

Preclinical Murine Model of Gender-Affirming Hormone Therapy

Han Eckenrode, Caroline Carwie, Rohan S. Balkawade, Chunlan Fan, Lisa M. Curtis. *The University of Alabama at Birmingham Heersink School of Medicine, Birmingham, AL.*

Background: Gender-affirming hormone therapy (GAHT) is a common part of transgender medical care, involving the alteration of sex hormone levels. Although sex hormones are known to be implicated in kidney health and disease, few studies have explicitly examined the effects of GAHT on kidney health.

Methods: Male and female C57Bl6/J mice were used. At 8 weeks of age, males were implanted with 17β-estradiol (E2) and spironolactone pellets (MH), or dose matched placebo pellets (MP). Female mice were implanted with a testosterone (T) pellet (FH), or a dose-matched placebo pellet (FP). Untreated male (MQ) and female (FQ) mice were used as comparators. During the hormonal acclimation, 24 hour urine was collected, and body composition, glomerular filtration rate (GFR), and plasma creatinine (PCr) were measured. After 11 weeks of acclimation, mice were euthanized, and tissues were collected. Plasma was collected at euthanasia.

Results: MH had higher E2 level compared to MQ, although T levels were not different. FH did not have different E or T levels compared to FP or FQ. Percent lean and fat mass did not differ between groups. IL2 in MH were decreased compared to MP, but no differences were noted in the female groups. IL5 in FH were slightly lower than FP and FQ, although significance was not reached. In MH, bone mineral density sharply increased; no significant changes were noted in other groups. No differences in PCr were noted between groups, although all groups experience a sharp increase during the acclimation, which resolved. GFR remained stable across time. Kidney expression of KIM-1 and NGAL was not detected in any groups. At 10 weeks of hormonal acclimation, an increase in urine creatinine was noted in both MH and FH.

Conclusions: Administration of exogenous sex hormones in a murine model does not independently cause kidney damage. Although a spike in PCr was noted, GFR remained stable, which may indicate an extra-renal cause. Slight modulations in cytokine levels may indicate changes in an inflammatory milieu that would be further reflected with kidney injury. Although FH did not have significantly different T levels than FP and FQ, differences in other parameters, including cytokine expression and urine creatinine, may indicate that T administration may have an effect on parameters affecting kidney function.

Assessing Kidney Function in Pregnancy

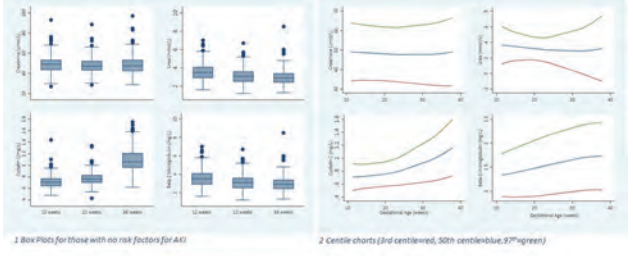
Katherine R. Clark,[1] Kathryn Dalrymple,[1] Olivia Snowball,[2] Hannah R. Judah,[2,3] Argyro Syngelaki,[1,3] Kypros Nicolaides,[2,3] Kate Bramham.[1,2] *[1]King's College London, London, United Kingdom; [2]King's College Hospital, London, United Kingdom; [3]Fetal Medicine Foundation, London, United Kingdom*.

Background: Deterioration in maternal kidney function is associated with morbidity and mortality for mother and baby. This study aims to define normal centile ranges in pregnancy for serum creatinine, urea, cystatin c and beta-2-microglobulin.

Methods: Prospective cohort study of women at two UK hospitals(2018-2021). Inclusion criteria:6+ weeks gestation, singleton pregnancy. Exclusion criteria:renal disease; previous AKI; chronic hypertension; diabetes; connective tissues disease; thrombophilia; cardiovascular disease. Venous serum samples taken at routine ultrasound scans. Participants who developed a risk factor for AKI were excluded from the centiles. Xrigls command was used in Stata 18.0 to allow reference interval estimation using generalized least squares.

Results: 739 participants. 644(87.1) had an uncomplicated pregnancy and delivery, 95(12.9%) developed a risk for AKI(T.1). Cystatin C had greater variability with increasing gestation even in those with no risk factors(F.1). Figure 2 shows centile charts for all biomarkers for those with no AKI risk factors with detail provided for serum creatinine(F.3).

Conclusions: In this ethnically diverse study creatinine values were lower than reported with >63umol/l at any gestation above the 97thcentile. Cystatin C and beta-2-microglobulin vary increasingly towards term, even in women with no AKI risk factors thus are unlikely to be useful biomarkers.



1 Box Plots for those with no risk factors for AKI

2 Centile charts (3rd centile=red, 50th centile=blue, 97th=green)

More than 16,000 Transplant Recipients and Previous Living Donors at Risk for Poor Access to Reproductive Health Care

Elizabeth M. Hendren, Gal Av-Gay, Matthew J. Kadatz, John S. Gill. *The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada*.

Background: It is imperative that kidney transplant recipients (KTR) and living kidney donors (LKD) have access to reproductive health care. Since the overturning of Roe v Wade in 2022, 14 states have banned abortion in all or almost all circumstances and 7 states have significantly restricted access (between 6-18 weeks). It is unknown how many KTR and LKD are affected by these policies.

Methods: We characterized the demographics of female KTR and LKD 18-45 years old in the United States as of May 1, 2024 from the OPTN dataset. Because policies are frequently changing, patients were stratified into 3 categories based on their home state policy for abortion as of May 1, 2024. P-values are calculated from Wilcoxon rank sum tests for continuous variables and Fisher's exact tests for categorical variables.

Results: Overall 9,001/21,673 KTR (41%) and 7,476/18,988 LKD (39%) live in states with either a total or partial restriction on abortion. KTR who live in areas with less access to reproductive care were also more likely to have additional risk factors for pregnancy complication including Black race, high BMI, and diabetes as a cause of kidney failure and were less likely to have received a living donor transplant (Table 1).

Conclusions: A significant proportion of KTR and LKD live in areas with decreased access to reproductive health care. Medical comorbidities and demographic risk factors can exacerbate the pre-existing pregnancy risk. These findings quantify the magnitude of the health challenge created by recent changes in state policies and may be useful in planning for alternative strategies and advocacy efforts to ensure KTR and past LKD receive access to essential reproductive health care.

Demographics of Female KTR by abortion access in home state

	Abortion Banned (1) n=5,333 (24.6%)	Limited Abortion Access (2) n=3,688 (17%)	Legal Access to Abortion n=12,652 (58.4%)	p-value

The Contraceptive Care Gap: Women with CKD Report Lower Rates of Contraception Use

Sarah Rokaw, Kathryn Kompa, Cancan Zhang, Kenneth J. Mukamal.
Beth Israel Deaconess Medical Center, Boston, MA.

Background: Pregnancy in patients with chronic kidney disease (CKD) is associated with complications, including low birth weight, gestational diabetes, pre-eclampsia, and pre-term birth. Clinical practice guidelines recommend contraception counseling for women with CKD of childbearing age. Furthermore, given the potential risk of complications, reproductive care should be prioritized when caring for young women with CKD. Currently, large-scale population data quantifying rates of contraception usage among women with CKD are lacking.

Methods: We utilized the Behavioral Risk Factor Surveillance System in 14 states and territories in 2017, 2019, and 2022. For women aged 21-49, we extracted data on self-reported diagnosis of CKD, contraception use, and method of contraception use. We adjusted for age, sex, race/ethnicity, US census region, reported access to a primary physician, and educational level using a log-binomial regression model. We subsequently examined factors associated with contraception use among women with CKD and explored the methods used.

Results: Women aged 21-49 with CKD were less likely to report contraception usage than women without CKD, even when adjusting for confounders (RR 0.88, 95% CI [0.80,0.97], p=0.01). This difference did not meaningfully vary over the 5-year period of our analysis (p=0.35). Among analyzed co-variates, the only factor associated with contraception use among women with CKD was age, with younger women more likely to use contraception (p<0.001). The most used methods of contraception among women with CKD were barrier methods or topical spermicide (29.1%), female or male surgical sterilization (20.7%), and hormonal methods including contraceptive pills, transdermal patches, hormonal rings, and the Depo-Provera injection (20.0%).

Conclusions: Despite substantially higher rates of pregnancy-related complications, rates of reported contraception usage were significantly lower among women of childbearing age with CKD as compared to women without CKD. Likelihood of contraception usage declined with age, even in this age group. Assuring access to and counseling about contraception among women with CKD should be a priority for physicians treating these patients.

Cellular Senescence as an Underlying Mechanism of Kidney Injury in a Mouse Model of Preeclampsia

Sonja Suvakov, Xiaoyan Li, Jennet Hatamova, Vladimir Dokic, Paul Gavrilovici, Xiaogang Li, Vesna D. Garovic. *Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN.*

Background: Preeclampsia (PE) is a hypertensive complication of pregnancy often associated with kidney injury which is characterized by proteinuria and podocyturia. The mechanism leading to kidney injury in PE, however, is poorly understood. Our recently published data indicate the presence of cellular senescence in women with PE. We hypothesized that cellular senescence is present in the kidneys of mice (IL-10KO mouse model of PE), and that senescence-associated genes are upregulated in podocytes and endothelial cells of kidneys in these animals.

Methods: We utilized the mouse model where PE is induced by i.p. injection of human PE sera into 10–12-week-old animals. PE is observed around the 18th gestational day when the animals are euthanized. Regular pregnant mice with no PE serum injected (PG) served as a control group. We measured blood pressure, proteinuria, urinary alpha Klotho (α-Klotho), and the expressions of senescence-associated genes in the kidneys (n=4-5 per group). To identify which senescence-associated genes are affected in podocytes and endothelial cells, which are injured in preeclampsia, we performed kidney single-cell RNA sequencing (scRNAseq) in the PG (n=2) and PE groups (n=3).

Results: Significant increase in blood pressure and proteinuria was observed in PE mice. Urinary α-Klotho, an anti-aging marker, was significantly decreased in PE mice compared to the PG group. Significant decrease in α-Klotho was observed in PE mice upon injection of PE serum compared to the values before injection. Kidneys of PE mice had increased expressions of senescence-associated genes p16, il6, and pai1. Using scRNAseq we clustered 15 transcriptionally different kidney cell types based on cell type-specific marker genes. Among those cells we identified five subclusters of endothelial cells and four of podocytes. We compared and identified 7 differentially expressed genes associated with senescence in endothelial cells (Ccl5, Csf2rb, Cxcl1, Cxcl10, Cxcl2, Igfbp5, and Il15) and 10 in podocytes (Angpt1, Areg, C3, Ccl7, Cxcl2, Gem, Il15, Nrg1, Pappa, Tnf).

Conclusions: These results indicate that cellular senescence could represent a potential mechanism of kidney injury in preeclampsia.

Sex Differences in Kidney Prognosis in Patients with ADPKD: Attribute-Based Medicine (ABM) Insights

Hiroshi Kataoka, Toshio Mochizuki, Shun Manabe, Yusuke Ushio, Momoko Seki, Ken Tsuchiya, Kosaku Nitta, Junichi Hoshino. *Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan.*

Background: Recently, the importance of attribute-based medicine has been emphasized. We aimed to examine the influence of sex differences to kidney disease progression of autosomal dominant polycystic kidney disease (ADPKD).

Methods: We enrolled 553 ADPKD patients who were not undergoing renal replacement therapy, with a median age of 43 years, an estimated glomerular filtration rate of 55.9 mL/min/1.73 m^2, and a total kidney volume of 1335.4 mL. The renal outcome, defined as a 50% reduction in estimated glomerular filtration rate or initiation of renal replacement therapy, was assessed using Cox regression analysis. Factors influencing kidney prognosis in ADPKD patients were compared based on sex categories (men or women).

Results: Over a median 9.1-year follow-up, renal outcomes were assessed in 189 patients. Multivariate Cox analysis identified several significant risk factors for kidney disease progression: female gender (HR=1.56), age (HR for 10-year increase=0.63), eGFR (HR for 10 mL/min/1.73 m^2 increase=0.48), urinary protein excretion (grades 0–3) (HR=2.05), total kidney volume (HR for 100 ml increase=1.02), and hypertension (HR=1.48). Significantly, interactions were observed between gender and urinary protein excretion (grades 0–3) (P=0.0158), hypertension (P=0.0065), and higher pulse pressure (≥50mmHg) (P=0.0117) concerning kidney disease progression. Subgroup analysis by gender clarified age and eGFR's association with kidney prognosis across both sub-cohorts. Conversely, hypertension (HR=2.47), pulse pressure ≥50 mmHg (HR=2.28), and urinary protein (grades 0–3) (HR=3.11) emerged as factors associated with kidney prognosis in females, whereas hypertension (HR=0.82), pulse pressure ≥50 mmHg (HR=0.90), and urinary protein (grades 0–3) (HR=1.62) were less associated with renal outcomes in males.

Conclusions: Female sex was a factor for poor renal prognosis in patients with ADPKD. Hypertension, high pulse pressure, and increased proteinuria were significantly worse factors for renal prognosis in women than in men. In recent years, treatments and research that are tailored to patient attributes have been proposed, but in the case of ADPKD patients, it is necessary to change treatment policies depending on sex attributes.

Understanding Pathophysiology of Acute Interstitial Nephritis through Spatial Characterization of Cell-Cell Interactions Using Imaging Mass Cytometry in a Human Biopsy Cohort

Megan L. Baker,[1,2] Vijayakumar R. Kakade,[1] Tifanny Budiman,[1] Marlene Weiss,[1,4] Ashish Shelar,[3] Dennis G. Moledina,[1] Lloyd G. Cantley.[1]
[1]Yale University School of Medicine, New Haven, CT; [2]Yale University Graduate School of Arts and Sciences, New Haven, CT; [3]Yale University, New Haven, CT; [4]Charite Universitatsmedizin Berlin, Berlin, Germany.

Background: Kidney damage in AIN is believed to result from immune-mediated tubular injury, with ongoing inflammation leading to fibrosis and progression to CKD. Delineation of the immune cell signature and corresponding tubular and vascular cell responses in AIN should lead to more targeted therapies.

Methods: Adjudicated human kidney biopsy tissues with AIN(13), ATI(13), DKD(7), and healthy reference tissue(13) underwent imaging mass cytometry using 34 customized metal conjugated antibodies (Fig1). Cell identities and activation states were defined in spatial context. A customized deep-learning-based algorithm (Mesmer) was used for segmentation. Downstream data analyses used open-source analytic pipelines *steinbock* and *imcRtools*.

Results: Across samples 786,580 cells were analyzed. Preliminary findings show 37 cell clusters with 17 primary cell types (Fig2). Immune populations are increased in AIN and ATI compared to reference. AIN showed the largest increase in CD4+ T cells (8.6%, 2.5% ATI, 1.6% ref, p<0.0001). Lymphatics were expanded in AIN and ATI (both 1.1%) above reference tissues(0.5%) and colocalized with lymphocyte enrichment. Mast cells also show enrichment with injury (2.4% AIN, 1.3% ATI, 0.2% ref, p<0.0001).

Conclusions: Our initial analysis is supportive of the role of CD4+ T cells, and perhaps mast cells and lymphatics, in the pathophysiology of AIN. Subsequent analyses, including subclustering for improved phenotyping, cell quantification by tissue area, neighborhood and interaction analyses, and integration with clinical data, are underway and expected to result in the identification of specific cell-cell interactions which will advance our understanding of AIN.

Stat5b SNP Reduces Sexual Dimorphism of Renal Gene Expression and Protects against Acute Injury

Jakub Jankowski, Hye kyung Lee, Lothar Hennighausen. *National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.*

Background: The extent of the single nucleotide polymorphisms' (SNP) impact on disease vulnerability is not well understood. Two *Stat5b* Y665 SNPs, Y665F and Y665H, have been found by genome sequencing of leukemia patients. They are thought to respectively increase or attenuate STAT5b activity but have not been confirmed as a disease driver.

Methods: Using base editing, we developed mice mimicking the two SNPs and investigated their phenotype. We saw an increased infiltration of CD3+ cells in the kidney tissue of the Y665F strain using immunohistochemistry, suggesting increased vulnerability to development of inflammation. To investigate, we used 30′ bilateral kidney ischemia-reperfusion injury (IRI) model and measured serum creatinine after 24 hours. To elucidate involvement of JAK/STAT pathway, we performed kidney RNA-seq analysis in WT, Y665F and Y665H strains, including male and female mice, before and after IRI.

Results: Y665F males had lower creatinine levels than controls (mean 0.66 vs 1.23, p<0.001, n=8), suggesting protection against IRI. In contrast Y665F females displayed no statistically significant difference in plasma creatinine compared to control (0.79 vs 1.04 respectively, n=5). Similar effect was absent in Y665H mice, indicating protective effect of STAT5b activation in an IRI setting. RNA-seq revealed 582 deregulated genes (DEGs) between male WT and Y665F mice at the baseline, but no statistically significant DEGs were found in females. After IRI, 1801 DEGs were found in male mice, but only six in females. Similar number of sexually dimorphic genes is present in WT and Y665F strains at the baseline (1269 vs 1290 respectively), but not after injury (1790 vs 733). Y665F DEGs include genes involved in JAK/STAT signaling and linked to kidney health and development such as *Il15*, *Xdh*, *Sepp1* or *Prickle1*, hinting at potential mechanisms of protection. We did not observe differences in *Stat5b* mRNA nor STAT5b and CD3 immunohistochemical staining after injury in WT or Y665F mice, suggesting long-term changes in renal gene transcription programming rather than acutely altered injury response.

Conclusions: Those results strongly indicate that *Stat5b* Y665 SNP has a sexually dimorphic, renoprotective effect. This work highlights the far-reaching effects of a singular SNPs and lays foundation of personalized medicine approaches incorporating patient's genome.

WWP2 Deletion Aggravates AKI by Targeting the CDC20/Autophagy Axis

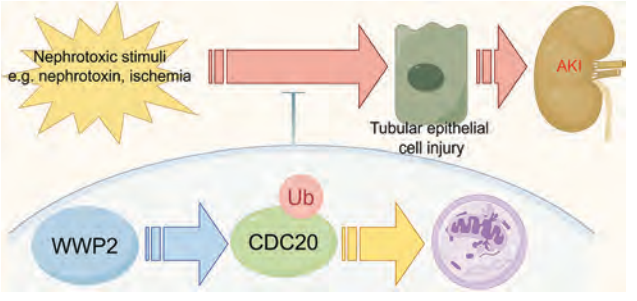
Ran You,[1,2] Yanwei Li,[1,3] Yuteng Jiang,[1,3] Zhanjun Jia,[1,2] Aihua Zhang.[1,2] *[1]Children's Hospital of Nanjing Medical University, Nanjing, China; [2]Nanjing Medical University, Nanjing, China; [3]Southeast University, Nanjing, China.*

Background: Acute kidney injury (AKI) is associated with high morbidity and mortality rates. The molecular mechanisms underlying AKI are currently being extensively investigated. WWP2 is an E3 ligase that regulates cell proliferation and differentiation. Whether WWP2 plays a regulatory role in AKI remains to be elucidated. We aimed to investigate the implication of WWP2 in AKI and its underlying mechanism in the present study.

Methods: We utilized renal tissues from patients with AKI and established AKI models in global or tubule-specific knockout (cKO) mice strains to study WWP2's implication in AKI. We also systemically analyzed ubiquitylation omics and proteomics to decipher the underlying mechanism.

Results: We found that WWP2 expression significantly increased in the tubules of kidneys with AKI. Global or tubule-specific knockout of WWP2 significantly aggravated renal dysfunction and tubular injury in AKI kidneys, whereas WWP2 overexpression significantly protected tubular epithelial cells against cisplatin. WWP2 deficiency profoundly affected autophagy in AKI kidneys. Further analysis with ubiquitylation omics, quantitative proteomics and experimental validation suggested that WWP2 mediated poly-ubiquitylation of CDC20, a negative regulator of autophagy. CDC20 was significantly decreased in AKI kidneys, and selective inhibiting CDC20 with apcin profoundly alleviated renal dysfunction and tubular injury in the cisplatin model with or without WWP2 cKO, indicating that CDC20 may serve as a downstream target of WWP2 in AKI. Inhibiting autophagy with 3-methyladenine blocked apcin's protection against cisplatin-induced renal tubular cell injury. Activating autophagy by rapamycin significantly protected against cisplatin-induced AKI in WWP2 cKO mice, whereas inhibiting autophagy by 3-methyladenine further aggravated apoptosis in cisplatin-exposed WWP2 KO cells.

Conclusions: Taken together, our data indicated that the WWP2/CDC20/autophagy may be an essential intrinsic protective mechanism against AKI. Further activating WWP2 or inhibiting CDC20 may be novel therapeutic strategies for AKI.



SA-OR04

RNA Polymerase II Subunit POLR2A/RPB1 Upregulation Is Detrimental in Kidney Injury

Sian E. Piret, Samaneh DiMartino, Maanasa S. Hanubal, Jiakang Wang, Tej Bahadur, Nehaben A. Gujarati, Sandeep K. Mallipattu. *Stony Brook University Renaissance School of Medicine, Stony Brook, NY.*

Background: Proximal tubule (PT) injury is a major factor in the severity of acute kidney injury (AKI) and transition to fibrosis. Our single nuclear RNA-sequencing (snRNA-seq) in a PT-specific nephrotoxin [aristolochic acid I (AAI)]-induced AKI in mice revealed an injured PT cluster with high enrichment of *Polr2a*, encoding RPB1, the largest subunit of RNA polymerase II (RNAPII). Our aim was to study the role of PT-specific RPB1 in AKI.

Methods: Immunofluorescence (IF) for RPB1 was undertaken in mice after multiple 2mg/kg AAI injections, 7mg/kg repeated low dose cisplatin (RLDC) for 4 weeks, or unilateral ureteral obstruction (UUO) for 3 or 7 days, or in human AA-exposed chronic kidney disease (CKD) patient samples, with PT brush border counterstaining. HK-2 cells were treated with DMSO or 25μM AAI and scrambled or *POLR2A* siRNA, with quantification of cell number (CyQuant assay); *IL6*, *CTGF*, and *CDKN1A* mRNA expression; and IF for vimentin (dedifferentiation) or gH2A.X (DNA damage) at 48 hours. Single cell ATAC-seq was undertaken in mice after one dose of AAI.

Results: Over a series of 4 AAI injections, despite PT loss, RPB1-positive (RPB1+) tubular nuclei accumulated, and were associated with dedifferentiated PT. This was replicated in mice after RLDC and UUO. Knockdown of *POLR2A* in HK-2 cells treated with AAI resulted in increased cell death, but the remaining cells expressed less *IL6* and *CTGF*, were less dedifferentiated, had less DNA damage, and more normal cell cycle,

with reduced *CDKN1A* expression. ATAC-seq indicated a new region of open chromatin in *Polr2a* intron 1 in the injured PT cluster, containing AP-1 and Krüppel-like factor 6 (KLF6) transcription factor binding sites. Trajectory and RNA velocity analysis showed that *Klf6* upregulation preceded *Polr2a* induction, suggesting regulation of *Polr2a* by KLF6. RPB1 remained high in the fibrotic phase after AAI, and mice overexpressing human KLF6 had more RPB1+ nuclei than control mice. Dedifferentiated PT in human AA-exposed CKD patients also had RPB1+ nuclei.

Conclusions: To date, this is first study to show that sustained high RPB1 expression after AKI may trap PT cells in a dedifferentiated state, and clearance of cells by *POLR2A* knockdown may be beneficial to attenuate the progression of AKI to CKD.

Endothelial Prolyl Hydroxylase 3 (PHD3) Regulates Post-Ischemic Kidney Injury Repair and Inflammation

Rajni Sharma, Ratnakar Tiwari, Gabriella Borkowski, James O'Sullivan, Pinelopi P. Kapitsinou. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Endothelial cells (EC) are prime targets for ischemia reperfusion injury (IRI) but the role of endothelial oxygen sensing in IRI remains poorly defined. Recently, we showed that post-ischemic concurrent inactivation of endothelial Phd1, Phd2 and Phd3 but not Phd2 alone promotes maladaptive kidney repair. Analysis of human and mouse scRNA-seq data suggested a potential role for the Phd1 and/or Phd3 isoforms in renal endothelial oxygen sensing. Here, we investigated the role of endothelial Phd1 and Phd3 in kidney repair following IRI.

Methods: Post-ischemic inactivation of Phd1, Phd3 and Arnt (HIFβ) in ECs was achieved by the Cdh5(PAC)CreER. Analysis was performed on day 14 post-unilateral IRI. To inactivate PHD3 and ARNT genes in-vitro in ECs we used siRNA approach, while overexpression of PHD3 was achieved by lentivirus-based transduction. IFNγ was used to induce a pro-inflammatory response in-vitro.

Results: Post-ischemic inactivation of endothelial Phd1 failed to alter post-IRI kidney repair, however, inactivation of endothelial Phd3 following IRI exacerbated kidney damage and fibrosis as indicated by significantly increased *Kim1*, *Tgf*β, and *Acta2* transcripts as well as enhanced collagen deposition and macrophage infiltration (n=5-6; $p<0.05$), compared to *Cre*$^-$ controls. A cytokine array detected increase in multiple cytokines in the injured mutant kidney. Notably, post-ischemic concurrent deletion of endothelial Phd3 and Arnt restored kidney damage as shown by mRNA expression of pro-fibrotic genes and collagen deposition (n=6-7, $p<0.05$). In vitro, PHD3 knockdown enhanced IFNγ induced pro-inflammatory responses in EC based on mRNA expression of *ICAM1*, *VCAM1*, and other IFNγ responsive genes (n=3, $p<0.05$). Concurrent silencing of endothelial PHD3 and ARNT rescued the pro-inflammatory activation of ECs by IFNγ stimulation. Importantly, lentiviral PHD3 overexpression suppressed EC activation by IFNγ.

Conclusions: Endothelial inactivation of PHD3 promotes post-ischemic AKI to CKD transition in a HIF dependent manner. Our studies a) identify PHD3 as a crucial regulator of post-ischemic kidney repair through mechanisms that involve regulation of IFNγ derived EC inflammation and b) have critical implications for the potential application of non-selective PHD inhibitors in ischemic AKI.

MARCKS Upregulation in Macrophage Reprogramming as a Therapeutic Target in Kidney Injury and Fibrosis

Ssu-Wei Hsu,[1] So-Yi Chang,[1] Purva Bhatia,[1] Vincent Kao,[2] Wen-Hsien Chang,[1] Andrew I. Chin,[1] Ching-Hsien Chen.[1] *[1]University of California Davis, Davis, CA; [2]Davis Senior High School, Davis, CA.*

Background: Acute kidney injury (AKI) is characterized by sudden, reversible kidney dysfunction, with incomplete recovery potentially leading to chronic kidney injury. Macrophage infiltration and polarization are crucial in AKI recovery, yet their roles in injury development and progression remain unclear. This study aimed to identify novel therapeutic targets within pathogenic macrophages during kidney injury and resolution.

Methods: We analyzed macrophage transcriptomes to pinpoint regulators of AKI, confirming upregulation of MARCKS in macrophages within injured kidneys. To investigate the contributions of MARCKS to macrophage-mediated inflammation and fibrosis, we conducted in vitro, ex vivo, and in vivo studies using primary macrophages, precision-cut kidney slices (PCKS), and cisplatin-exposed mice with macrophage-specific MARCKS deletion.

Results: Mice with macrophage-specific Marcks deletion exhibited improved kidney function and increased survival in a severe AKI model. Furthermore, macrophage Marcks deletion conferred protection against renal fibrosis in mice with cisplatin-induced chronic kidney disease (CKD). Notably, we observed reduced macrophage infiltration and activation within the injured kidneys in both mouse models. Bone marrow–derived monocytes (BMDMs) from Marcks-knockout mice showed downregulated MARCKS phosphorylation, podosome formation, and cell motility. Co-culturing these BMDMs with injured kidney slices led to diminished chemotactic responses to macrophage chemoattractants, decreased activation of PI3K/AKT pathways, and increased apoptosis markers. PCKS derived from macrophage-specific MARCKS-knockout mice displayed fewer fibrotic lesions, less collagen deposition, and reduced pro-fibrotic macrophage presence following exposure to fibrosis inducers. Pharmacological inhibition of MARCKS activity in macrophages not only downregulated pathogenic macrophages but also reduced serum creatinine and blood urea nitrogen levels in both cisplatin-induced AKI and AKI-to-CKD models.

Conclusions: Our findings highlight the critical role of MARCKS and its phosphorylation in driving kidney fibrosis by reprogramming macrophages and modulating their pathogenic activities. This suggests that targeting MARCKS could be an effective therapeutic strategy for managing cisplatin-induced kidney diseases.

Cell-Intrinsic C3 and Complement Factor B from Proximal Tubular Epithelial Cells Drive Post-Injury Kidney Fibrosis

Tilo Freiwald,[1,2] Md Tajmul,[3] Jorge L. Trujillo-Ochoa,[3] Daniel Chauss,[3] Nardos T. Cheru,[10] Dhaneshwar Kumar,[3] Baktiar O. Karim,[4] Julius F. Jäger,[1,2] Yubing Guo,[1,2] Maja Gunkel,[1,2] Claudia Kemper,[5] Tobias B. Huber,[1,2] Thorsten Wiech,[6] Martin Kolev,[7] Majid Kazemian,[8] Didier Portilla,[9] Behdad Afzali.[3] Immunoregulation Section. *[1]University Medical Center Hamburg-Eppendorf, III. Department of Medicine, Hamburg, Germany; [2]University Medical Center Hamburg-Eppendorf, Hamburg Center for Kidney Health (HCKH), Hamburg, Germany; [3]Immunoregulation Section, Kidney Diseases Branch, National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK), NIH, Bethesda, MD; [4]Molecular Histopathology Laboratory, Frederick National Laboratory, Leidos Biomedical Research, Frederick, MD; [5]Complement and Inflammation Research Section (CIRS), National Heart, Lung, and Blood Institute (NHLBI), National Institutes of Health (NIH), Bethesda, MD; [6]Section of Nephropathology, Institute of Pathology, University Hospital Hamburg-Eppendorf, Hamburg, Germany; [7]Apellis Pharmaceuticals Inc, Waltham, MA; [8]Departments of Biochemistry and Computer Science, Purdue University, West Lafayette, IN; [9]Division of Nephrology and Center for Immunity, Inflammation, and Regenerative Medicine, University of Virginia, Charlottesville, VA; [10]Yale University School of Medicine, New Haven, CT.*

Background: Local complement (C') deposition is strongly associated with kidney diseases. Current therapeutic efforts target plasma-circulating C', but C' components are also locally produced within tissues, where they regulate essential (patho) physiological functions, as we have previously shown in COVID-19. The role of C' made by kidney cells remains under-explored. We hypothesized that tubular epithelial cell-derived intrinsic C' regulates the local inflammatory milieu and influences outcomes.

Methods: We analyzed existing and *de novo* bulk and single-cell high-throughput data from multiple acute kidney injury (AKI) models and investigated transcription factor binding genome-wide. Mechanistic studies utilized genome editing, cell-permeable CFB inhibitors, mass spectrometry, reporter and tissue-specific gene knockout mice, metabolic profiling, histological and confocal analyses.

Results: Multiple AKI models, particularly folic acid nephropathy (FAN), showed enriched C' gene transcription. Single-nucleus RNA sequencing of FAN identified co-expression of *C3* and Factor B (*Cfb*) in Vcam1$^+$ kidney tubules, which emerged post-injury and interacted with immune cells via C3a-C3AR1 and integrins. IL-1β was the critical inducer of *C3* and *Cfb*. *Il1r1* deletion reduced *C3* and *Cfb* expression in response to injury. AP-1 and NF-κB downstream of IL-1β, were confirmed as transactivators through SCENIC-derived regulon activity, CUT&RUN, and CRISPR studies, showing binding at *C3* and *Cfb*. Confocal imaging revealed C3 trafficking to the ER, Golgi, endosomes, lysosomes, and mitochondria, co-localizing with CFB. Conditional deletion of *C3* in proximal tubular epithelial cells and chemical intracellular CFB inhibition reduced glycolysis and oxidative phosphorylation, consistent with mitochondrial localization of C3. C3 deletion also reduced fibrosis scores in FAN mice. In patients, *C3* and *CFB* correlated with each other across glomerular diseases and negatively with eGFR.

Conclusions: These data elucidate the transcriptional and post-translational regulation and subcellular trafficking of C3 within PTECs, offering therapeutic implications for targeting the intracellular complement system in inflammatory kidney diseases.

Circulating Osteopontin (OPN) Released by Kidney Injury Causes Acute and Chronic Hippocampal Neuroinflammation and Behavioral Dysfunction

Andreas Herrlich, Poornima Dilhani Ekanayake Weerasinghe Mudiyanselage, Liang Ning, Rupal Ojha, Yohei Komaru, Anusha Suresh, Stuart Friess, Marta Celorrio Navarro. *Washington University in St Louis School of Medicine, St Louis, MO.*

Background: Acute kidney injury (AKI) is very common in hospitalized patients. 50% of AKI patients show persistent neurocognitive dysfunction long after AKI is resolved and 7% of patients develop dementia within 2 years after AKI. While the pathophysiological mechanism(s) of this kidney-brain crosstalk is largely unknown, limited studies have implicated neuroinflammation as a possible cause.

Methods: AKI was induced in WT and OPN-KI mice using bilateral ischemia reperfusion injury. At different survival points after AKI mice were tested for neurocognitive function by using a battery of behavioral tests. Hippocampal inflammatory changes were assessed using flow cytometry and histological analysis.

Results: Here we show that monocytes infiltrate the hippocampus acutely and accumulate chronically long after AKI resolution in parallel with neurocognitive dysfunction. Acutely after AKI in wt mice we observed reduced exploration in the elevated plus maze test, and chronically at 1 + 6 months after AKI we observed lower recall memory to cue/context and reduced spatial learning, linking hippocampal neuroinflammation to neurocognitive dysfunction. AKI induced acute and chronic elevations of kidney and serum levels of the innate immune system activating molecule osteopontin (OPN). Although we were able to detect a small trend to increased OPN protein levels in the hippocampus after AKI, hippocampal OPN mRNA expression was not significantly elevated, suggesting either deposition from the circulation or production by infiltrating monocytes. OPN acts via its thrombin cleavage products. OPN-KI mice with an OPN mutation rendering it uncleavable by thrombin were protected acutely and chronically against monocytic neuroinflammation and neurocognitive dysfunction after AKI. OPN injection into OPN-KO mice with AKI induced hippocampal monocyte accumulation and neurocognitive dysfunction, linking circulating osteopontin released from the injured kidney to neurocognitive dysfunction after AKI.

Conclusions: Together with our previous findings that linked kidney-released OPN to kidney-lung crosstalk, our kidney-brain data highlight the involvement of this kidney-released soluble mediator in driving secondary brain complications after AKI.

Anti-inflammatory Effects of Vagus Nerve Stimulation Are Mediated by the Notch Signaling Pathway during Sepsis-Associated AKI

Shuhei Kuwabara, Hiro Inoue, William Nash, Junlan Yao, Shuqiu Zheng, Mark D. Okusa. *University of Virginia, Charlottesville, VA.*

Background: Activating the cholinergic anti-inflammatory pathway (CAP), a neuroimmune circuit, is a novel strategy for the treatment of acute kidney injury (AKI). The CAP is initiated by vagus nerve stimulation (VNS) and subsequent activation of α7-nicotinic acetylcholine receptor (α7nAChR) on macrophages (MΦ), leading to suppression of pro-inflammatory cytokine production. Our RNA-Seq analysis revealed that an increase in hairy and enhancer of split 1 (Hes1) in MΦ contributes to the kidney protective effects of CAP. Hes1 is a transcriptional factor and is involved in the Notch signaling pathway. However, a direct relationship between the CAP and Notch signaling has been unclear. In this study, we focused on Notch signaling in MΦ to unravel the detailed molecular mechanism of CAP and to determine the utility of Notch signaling in ameliorating AKI.

Methods: We used a mouse lipopolysaccharide (LPS)-induced AKI model. MΦ-specific *Notch2* KO (*Cx3cr1Cre; Notch2$^{fl/fl}$*) or WT mice were subjected to VNS 24 hours before LPS administration. The expression of cytokines and Notch components in the spleen and kidney injury was assessed. Mouse peritoneal MΦ were also used for *in vitro* experiments to examine the relationship between α7nAChR and Notch signaling.

Results: VNS suppressed an LPS-induced increase in spleen size and the levels of pro-inflammatory cytokines and chemokines such as Ccl2, M-CSF, and G-CSF (regulators of MΦ and neutrophil populations) in splenic MΦ. In the kidneys, LPS-induced inflammation including MΦ and neutrophil infiltration, and histological damage were also attenuated by VNS. These events were accompanied by an increase in Notch2 and *Hes1* expression in splenic MΦ. On the other hand, in MΦ-specific *Notch2* KO mice, the anti-inflammatory effects of VNS were attenuated in both the spleen and kidneys. We further found that during LPS treatment, chemical stimulation of α7nAChR by GTS-21 reduced Ccl2 release and upregulated *Hes1* expression in peritoneal MΦ, indicating that Notch signaling might be activated downstream of α7nAChR to dampen inflammatory responses.

Conclusions: Our findings suggest VNS protects the kidneys against sepsis-associated AKI via activation of the Notch2 signaling in MΦ.

Single-Cell Spatial Map of the Developing Human Kidney Highlights Insulin-Like Growth Factor 2-Mediated Signaling in Renewal

Jonathan Levinsohn,[1,2] Bernhard Dumoulin,[2] Amin Abedini,[2] Andi M. Bergeson,[2] Konstantin A. Kloetzer,[2] Eunji Ha,[2] Laura S. Finn,[1] Oren Pleniceanu,[3] Katalin Susztak.[2] *[1]The Children's Hospital of Philadelphia, Philadelphia, PA; [2]University of Pennsylvania, Philadelphia, PA; [3]Sheba Medical Center, Tel Hashomer, Israel.*

Background: The developing human kidney is a complex multi-lineage structure. It has long been understood that interplay between these lineages is crucial to form functional nephrons, however large gaps remain in our understanding of this process. Specifically, the mechanisms by which the nephron stem cell population is maintained are unclear.

Methods: To address this, we generated a comprehensive single cell dataset of 5 developing human kidneys and CosMx sinlge cell spatial transcriptomic map of 3 developing human kidneys. By integrating our spatial and single cell data, using a novel approach, allowing us to impute whole transcriptome expression for our spatial data.

Results: We generate an integrated atlas of spatial and single cell expression allowing is to map trajectories in space. We find that nephron progenitor renewal genes decrease in expression over gestational age, preceding nephrogenic zone exhaustion. We also use H&E histology to define neighborhoods for our spatial dataset allowing us to identify genes enriched within the blastema, early tubular structures and early glomeruli. Using this approach We identify IGF2 ligand as being specific to the blastema, where we also note increased expression of insulin signaling pathways, suggesting a specific role for *in vivo* human NPC renewal.

Conclusions: We identify potential mediators of NPC renewal in humans which localize to the blastema. Among these genes is *IGF2*. We propose that this may help explain the epidemiologic data showing that uncontrolled gestational diabetes is associated with smaller fetal kidneys and poor fetal outcomes. This analysis shows the power of an integrated approach to spatial transcriptomics.

Modeling Development and Disease from Human Pluripotent Stem Cell-Derived Mature and Functional Cortical Collecting Duct Organoid

Chennan Zhang, Zipeng Zeng, Biao Huang, Megan Schreiber, Nuria M. Pastor-Soler, Andrew P. McMahon, Zhongwei Li. *University of Southern California, Los Angeles, CA.*

Background: Directed differentiation of kidney cell types from human pluripotent stem cells (hPSCs) empowers the study of kidney development and diseases and is essential for kidney regenerative medicine. During embryogenesis, *Wnt11^{+}* ureteric progenitor cells (UPCs) self-renew and differentiate to form a tree-like collecting duct (CD) system that refines and drains the urine. Previously, we have established long-term culture platforms to expand primary mouse and human UPCs, and UPCs induced from hPSCs, in the format of 3D expandable ureteric bud (UB) organoids. Starting from expandable mouse UPCs, we generated spatially organized CD organoid consisting of principal cells (PCs) and intercalated cells (ICs). However, robust human CD organoid models with the presence of both PCs and ICs are still lacking.

Methods: Starting from expandable hPSC-derived UPCs, we developed a stepwise chemically defined culture system to generate elongated cortical human CD organoids with spatially organized PCs and ICs. Electrophysiological analysis of these generated CD organoids was demonstrated through patch clamp and ussing chamber to measure ion channel activities. CRISPR/Cas9 genome editing was used to generate an efficient and scalable organoid model for polycystic kidney disease (PKD).

Results: The elongated human CD organoids well recapitulate both maturity and functionality of human cortical CD. Differentiation from UPCs to CD recapitulates normal human CD development, with the transcriptome transitioning sequentially from UB tip, UB trunk, to the mature CD profiles. Importantly, these cortical CD organoids demonstrate electrophysiologic functions, such as active sodium, potassium, and chloride ion channel activities as recorded by patch clamp. Moreover, a robust CD organoid model of PKD was developed upon *PKD2* gene knockout, reflecting cystic phenotypes and a variety of pathogenic features of the disease. Transcriptome analyses further identified molecular features unique to cystogenesis in the kidney's CD. A scalable PKD organoid model was developed, enabling high-throughput drug screening.

Conclusions: Taken together, this mature and functional human cortical CD organoid platform opens new avenues for studying human CD development and modeling kidney diseases of the ureteric lineage.

Engineering Scalable Vascularized Kidney Organoids with the Integration of Human Endothelial Cells for In Vivo Glomerular Filtration

Murat Tekguc,[1,2] Ryuji Morizane.[1,2] Morizane Lab. *[1]Massachusetts General Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: Kidney organoids derived from human pluripotent stem cells have emerged as promising models for studying kidney disease pathogenesis and the development of novel therapeutics. However, previous conventional production methods rely on traditional static cell cultures, thereby limiting the scalability of organoids in the absence of vascularized glomeruli, a pivotal structure responsible for the kidney's blood filtration function. Here, we present a practical dynamic-flow culture protocol using a stirred tank bioreactor (STR) with a delta-wing-shaped impeller, which can overcome the limitations of current methods by boosting large-scale manufacture of kidney organoids exhibiting glomerular vascularization.

Methods: 1-Differentiation of human iPSCs (BJFF.6) and ESCs (H9) in both static and STR cultures 2-Treatment of STR organoids with the α2β1 integrin inhibitor 3-Generation and implantation of nephron sheets into immunocompromised NOD/SCID/IL-2 receptor common gamma chain-deficient (NSG) mice 4-Immunostaining, confocal microscopy, and 3D image analysis 5-Multiphoton Intravital Microscopy 6-Transmission Electron Microscopy (TEM) 7-qRT-PCR, RNA-seq Library preparation, sequencing, and RNA-seq Data Analysis

Results: The incorporation of a dynamic culture environment in delta-wing stirred bioreactors has significantly enhanced the glomerular vascularization and maturation of kidney organoids via mechanosensory integrin α2β1. This robust, scalable, labor- and cost-efficient platform provided large quantities of vascularized kidney organoids, enabling the fabrication of a nephron sheet with nephron numbers equivalent to those found in two rat kidneys. Intravital imaging of a nephron sheet implanted in a dorsal skinfold chamber of mice revealed in vivo filtration function with size selectability in the organoid glomeruli vascularized with human endothelia. In summary, we have developed a cost-effective mass-production method to manufacture functional vascularized kidney organoids, which has improved production efficiency by more than 50 times compared to conventional culture systems.

Conclusions: This work may represent a significant step towards bridging the gap between basic research and therapeutic applications for patients, paving the way towards facilitating the biofabrication of 3D large kidney tissues for kidney replacement therapy.

Integrating Collecting Systems via Nephron-Ureteric Bud Fusion in Kidney Organoids

Min Shi, Kyle McCracken. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Kidney organoids are generated from human pluripotent stem cells (hPSCs) through directed differentiation of nephrogenic mesenchyme (NM) that subsequently epithelializes to form nephron-like structures. The nephrons lack collecting ducts (CDs) and instead terminate as blind-ended tubules, a limitation that has hampered their maturation into potentially functional tissue. Here we report an innovative, developmentally inspired system that addresses this deficiency through the incorporation and integration of hPSC-derived ureteric bud (UB) progenitor tissues, the embryologic building blocks of the kidney's CDs and urinary collecting system.

Methods: We established and optimized methods to grow kidney organoids comprising both NM and UB progenitor cells derived from hPSCs, and we used fluorescently labelled cells to trace the respective lineages. Both the early development and later differentiation were extensively characterized through wholemount staining, confocal imaging, and scRNA-seq.

Results: Following recombination, NM rapidly and efficiently epithelialized into renal vesicle structures while the UB progenitors grew into extensive tubular networks. The resulting organoids contained both CDs and segmented nephrons, many of which were directly connected to the CDs via a connecting tubule-like anastomosis. The fusion process occurred during an early period of nephrogenesis, and it mimicked conserved steps by which the connection occurs *in vivo*. The ability to fuse with the UB was specific to only the distal-most nephron segments despite the greater abundance of proximal tubules, preserving normal polarity, and we identified pathways to manipulate nephron patterning and the frequency of fusion. Finally, the epithelial fusion also occurred *in vivo* following transplantation.

Conclusions: By recapitulating developmental interactions, we established a novel organoid model with organized nephron-CD architecture and the first described system that recapitulates *bona fide* anastomoses between distal nephron and CD epithelia. This innovative system provides an unparalleled platform to interrogate the mechanisms of this important fusion event, and this approach is an important advance in kidney tissue engineering since generating a continuous drainage pathway from nephrons is an obligatory step toward production of functional renal tissue.

SA-OR14

Microfluidic Tissue Chip Technologies to Study Normal and Disease Podocyte Behaviors

Balaji Karthick Subramanian, Martin Pollak. *Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Unraveling the complex behavior of healthy and diseased podocytes by analyzing the changes in their unique arrangement of foot processes, slit diaphragm, and three-dimensional (3D) morphology is a long-standing goal in kidney-glomerular research. The complexities surrounding podocyte accessibility in animal models and growing evidence of differences between human and animal systems have compelled researchers to look for alternate approaches to study podocyte behaviors. With the advent of bioengineered models, an increasingly powerful and diverse set of tools is available to develop novel podocyte culture systems.

Methods: Using multi-layer photolithography, we created a microfluidic chip to co-culture podocytes with endothelium. We used normal, INF2, and APOL1 FSGS patient-sourced induced pluripotent stem cells (IPSCs) to prepare podocytes and endothelial cells. We derived podocytes from kidney organoids while we directed the IPSCs differentiation to prepare endothelial cells. Unidirectional fluid flow for various time frames and shear stress were introduced through the system, and changes in the podocyte structure and function were examined. Changes in podocyte morphology, marker protein expression and localization, and transport properties were assessed and compared between normal and FSGS disease tissue chips.

Results: Endothelial cells formed a vessel in our chip system with proper marker protein (VE-cadherin) localization and barrier function. When podocytes were introduced to the chip system, they migrated toward endothelial cells and interacted with the outer curvature of endothelial vessels, thus recapitulating the invivo-like arrangement. Tissue characterization analysis of the tissue–-system confirmed fenestration-like structures in endothelium and foot processes-like extension in the podocyte. More importantly, podocytes recapitulated defective cell spreading, actin arrangement, and transport phenotype in the mutant-INF2 and APOL1 risk variant-based tissue chips.

Conclusions: We have developed and validated a model system to study podocyte behaviors ex vivo. Our platform will allow mechanistic studies and drug testing in an invivo-like environment. Establishing the tissue system using human iPSC-derived endothelial cells and podocytes enables researchers to study disease and test therapeutics in a personalized manner.

Developmental Programming of CKD

Hongbing Liu, Vanessa W. Menard, Joseph Harkrider, Samir S. El-Dahr, Madiha Mumtaz, Chaohui Chen. *Tulane University, New Orleans, LA.*

Background: Chronic kidney disease (CKD) is growing in prevalence throughout the world. However, the developmental origins of CKD mechanisms remain largely unknown. Gestational effect is believed to be mediated by gene expression reprogramming, including epigenetic changes.

Methods: To determine the significance of epigenetic regulation by histone deacetylases (HDACs) in the programming of CKD, we established an intrauterine growth restriction (IUGR) mouse model by feeding the pregnant mice 6% protein diet (low protein diet, LPD) throughout gestation, while the control group was fed with isocaloric 20% protein diet (normal protein diet, NPD).

Results: Gross and histological examination of IUGR mice at P0 showed smaller kidney size, smaller nephrogenic zone, fewer nephrons, increased interstitial collagen, cellular infiltration, and tubular atrophy, compared to the control group. Immunostaining results also demonstrated a diminished nephrogenic zone with a smaller Six2+ progenitor pool and nascent nephron deficit in P0 IUGR kidney ($p<0.001$, $n=4$). The glomeruli number of P21 pups was found to be about 20% reduction in LPD pups compared to NPD group. Additionally, our results indicate concurrent overactive Hdac1/2 and reduced expression of Bmp7 (both at mRNA and protein levels) in the developing kidneys of IUGR mice. To investigate transcriptional regulation of *Bmp7* by HDAC1/2 in mammalian nephron progenitor cells, we performed Chromatin Immunoprecipitation Sequencing for Hdac1 and Hdac2 in isolated E16.5 NPCs and demonstrated the binding of Hdac1/2 to *Bmp7* enhancer in vivo. Consistently, loss of *Hdac1/2* leads to an obvious augmentation of *Bmp7* expression in developing kidney of conditional knock-out mice. *Sirius red* and Masson's Trichrome Staining indicated an *increased fibrosis extracellular* in the kidneys of IUGR mice at age of 15 months. *We also detected a significantly higher level of α-SMA and fibronectin in IUGR Kidneys.*

Conclusions: Together, our findings demonstrate that IUGR predisposes to CKD by reprograming renal development via aberrant activation of Hdac1/2, which in turn represses Bmp7 expression. A mechanistic determination of how Hdac1/2-Bmp7 mediates CKD will provide a novel link between overactive HDAC1/2 to the developmental origin of CKD and effective clinical approaches to prevention and treatment of kidney disease and fibrosis.

Sall1-NuRD Cooperate in Nephron Progenitor Cells to Determine Cell Fate

Jeannine M. Basta,[1] Lynn Robbins,[2] Lisa Stout,[1] Michelle Brennan,[3] Michael I. Rauchman.[1,2] *[1]Washington University in St Louis, St Louis, MO; [2]VA Medical Center, St. Louis, MO; [3]Saint Louis University, St Louis, MO.*

Background: We created a knock-in mutant mouse (Δ*SRM*) that disrupts the interaction between the transcription factor Sall1 and the NuRD chromatin remodeling complex, resulting in accelerated nephron progenitor cell (NPC) differentiation, renal hypoplasia, and altered progenitor cell fate [Basta et al, Development (2017) 144 (17): 3080–3094].

Methods: To investigate the molecular mechanisms responsible for the altered cell fate of Δ*SRM* NPCs, we performed CUT&RUN in wild type and mutant NPCs, and 10X single-cell multiome experiments (RNA-seq and ATAC-seq in the same cell) in wild type and mutant kidney.

Results: In wild type NPCs NuRD components Mi2b and Mbd3 bound 76% of promoters also bound by Sall1. In Δ*SRM* NPCs Sall1-NuRD common binding at promoters is reduced 50% compared to wild type NPCs. Reduced binding of Sall1-NuRD components was observed at both progenitor genes (*Cited1, Meox2, Crym*) and genes induced with nephron differentiation (*Notch1, Pax8*). E17 multiome data revealed decreased expression of progenitor genes and upregulation of genes associated with nephron differentiation (*Notch1, Pax8*) in the mutant NPC cluster.

Conclusions: Loss of Sall1-NuRD binding in mutants suggests that Sall1-NuRD maintains the balance between self-renewal and differentiation by directly maintaining expression of progenitor genes and restricting activation of genes induced by differentiation signals. Our multiome data revealed that Six2+ cells in the mutant NPC cluster exhibited a mixed lineage phenotype in which some progenitor genes are reduced in expression while differentiation marker genes (*Pax8*, *Notch1*) are ectopically activated.

Funding: NIDDK Support, Private Foundation Support

CUT&RUN in control and mutant NPCs (right), blue box highlighting promoter region of *Cited1*, showing reduced binding of Mi2b, Mbd3, and Sall1 (arrows) in mutant NPCs.

SA-OR17

Transcription Factor ZEB2 Determines the Cell Fate of Kidney Stroma Progenitors and Loss of ZEB2 Protects Mice from Proteinuria

Sudhir Kumar, Simon L. Lu, Harshita Pattam, Kun Yan, Yu-Chen Liu, Chao Zhang, Weining Lu. *Boston University, Boston, MA.*

Background: ZEB2 is a transcription factor mutated in Mowat-Wilson syndrome, a congenital disorder with renal and urinary tract anomalies. ZEB2 is highly expressed in developing kidney stromal progenitors, and loss of ZEB2 in FOXD1+ developing stromal progenitors leads to abnormal kidney stroma differentiation and kidney fibrosis. Interestingly, no proteinuria can be detected in ZEB2 kidney-specific knockout mice. However, the molecular mechanism is unclear.

Methods: We analyzed the single-cell RNA sequencing (scRNA-seq) data generated from the kidney tissues isolated from *Zeb2* stroma-specific conditional knockout mice $Zeb2^{flox/flox}$;$Foxd1Cre^{+}$ (*Zeb2* cKO) and their wild-type (WT) littermate controls. We performed 10x Genomics Chromium single-cell transcriptional profiling of 3-week-old *Zeb2* cKO and WT mouse kidney tissues and analyzed the data using our in-house computational pipeline. Immunostaining and RNAscope in situ hybridization (ISH) were performed to confirm the scRNA-seq findings.

Results: After removing experimental batch effects and individual variance, our clustering analysis identified nine major cell types. We observed a significant increase in the proportion of podocytes and a decrease in macrophages in the Zeb2 cKO samples. Differential expression analysis revealed upregulation of myofibroblast markers Vimentin and Nestin in the Zeb2 cKO kidney compared to the wild-type control kidney. We also found that interstitial cells expressed podocyte and parietal cell markers such as WT1, TLE4, and claudin 1, suggesting that stroma cell takes podocyte/parietal cell fate. Trajectory and functional enrichment analysis provided further insights into the potential pathways and changes in cell differentiation influenced by Zeb2 deletion in kidney stromal progenitors. Immunostaining and RNAscope ISH results validated the scRNA-seq findings.

Conclusions: ZEB2 regulates the cell fate of FOXD1+ kidney stroma progenitors. ZEB2-deficient FOXD1+ stromal progenitors adopt podocyte and parietal-like cell fates that might strengthen the glomerular function barrier and protect mice from proteinuria.

SA-OR18

Role of Tcf21 in Mediating Renal Stromal Cell Fate Determination: Insights from Single-Cell Transcriptomics

Gal Finer,[1,2] Yalu Zhou,[2] Mohammad Daud Khan,[3] Gaurav Gadhvi,[3] George S. Yacu,[1] Joo-Seop Park,[2] Roberto Ariel Gomez,[4] Maria Luisa S. Sequeira Lopez,[4] Susan E. Quaggin,[2,5] Deborah R. Winter.[3] *[1]Division of Pediatric Nephrology, Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL; [2]Feinberg Cardiovascular and Renal Research Institute, Northwestern University Feinberg School of Medicine, Chicago, IL; [3]Division of Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL; [4]Department of Pediatrics, Child Health Research Center, University of Virginia, Charlottesville, VA; [5]Division of Nephrology and Hypertension, Northwestern Memorial Hospital, Chicago, IL.*

Background: Normal kidney development requires coordinated interactions between multiple progenitor cell lineages. The Foxd1+ stromal progenitors are critical for normal nephrogenesis and their heterogeneity is increasingly appreciated. However, the molecular mechanisms and trajectories that drive the differentiation of Foxd1+ cells into renal stroma, capsule, mesangial cells, renin cells, pericytes, and vascular smooth muscle cells are poorly understood. Our previous work demonstrated that deletion of the mesoderm-specific bHLH transcription factor Tcf21 from Foxd1+ cells leads to a significant reduction in medullary stroma size and perivascular cell number. Here we investigate the role of Tcf21 in kidney stromal cell fate determination.

Methods: We isolated single cells from kidneys of $Foxd1^{Cre/+}$;$Rosa26^{mTmG/+}$;$Tcf21^{f/f}$ cKO and $Foxd1^{Cre/+}$;$Rosa26^{mTmG/+}$;$Tcf21^{+/+}$ control mice at E14.5. Following enrichment for GFP+ cells by flow cytometry sorting, cDNA library was prepared using the 10x Genomics Chromium Platform and sequenced at a depth of 50,000 reads per cell.

Results: Clustering of the entire dataset (n=32,461) identified a large stromal population and a smaller representation of non-stromal lineages. Sub-clustering of stromal cells (n=22,355) identified seven molecularly distinct populations: medullary/perivascular, proliferating, ECM-expressing, differentiating nephron, nephrogenic, collecting duct, and ureteric-associated stroma. Loss of Tcf21 resulted in a dramatic reduction in medullary/perivascular, proliferating, nephrogenic, and collecting duct associated stroma. Lineage tracing of Foxd1 indicated a severe reduction in the medullary stromal space from E14.5 through E18.5. A novel population, expressing elevated levels of extracellular matrix components, was exclusively present in *Tcf21* cKO kidneys. DEG analysis demonstrated that members of the Tgfβ/SMAD signaling were among the upregulated genes in *Tcf21* cKO.

Conclusions: Taken together, these data underscore a role for Tcf21 in the emergence of the milieu of Foxd1+ derivatives; loss of Tcf21 leads to a shift in stromal cell fates that results in abnormal kidney development.

Neonatal Fc Receptor: More than a Transcytosis Receptor

Eileen Dahlke, Yaman Anan, Jan-Hendrik Mittag, Lea Klie, Ariane Hartkopf, Franziska Theilig. *CAU Kiel Institute of Anatomy, Kiel, Germany.*

Background: Chronic kidney disease (CKD) increases worldwide and is a high social economic burden. Diabetic kidney disease is the leading cause for the development of CKD. GWAS studies presented a strong association between the neonatal Fc receptor (FcRn) and high fructosamin levels in diabetes mellitus. Previously, we found a strong FcRn mRNA reduction in STZ-treated type 1 diabetic mice. The role of FcRn decline in the progression towards CKD remain unknown.

Methods: 3-, 6- and 15-month-old mice lacking FcRn (FcRn-/-) in comparison to wildtype mice (WT) were analyzed. Renal functional parameters and morphology were analyzed, immunohistological stainings, RNA sequencing and western blot analyses were performed. CRISPR/Cas9 FcRn knockout in BN16 yolk sac cells were used for western blotting, immunocytological and seahorse cellular respiration analyses, in addition to fructosamin treatment.

Results: A reduction in FcRn expression could be induced *in vitro* by treating BN16 cells (expressing FcRn endogeneously) with fructosamin. *In vivo*, deletion of FcRn leads to a significant reduction in the glomerular filtration rate in 3-month-old mice. After 6 month a significant reduction of renal cortices in FcRn-/- was observed and progressed over time due to shortening of proximal tubules, which was accompanied by reduced endocytosis capacity. The number of Ki-67 positive proximal tubule (PT) and endothelial cells was significantly reduced in FcRn-/- compared to WT mice. In addition, the area of the lysosomal compartment and connective tissue increased. RNAseq analysis revealed altered genes important for autophagy and ciliogenesis. An elongation of cilia in PT of FcRn-/- was confirmed immunohistologically. FcRn-/- CRISPR/Cas9 knockout cells confirm reduced proliferation and elevated autophagic flux and a higher oxygen consumption. Additionally, FcRn deletion leads to activation of mTORC1, lysomal protein expression (Lamp2), amino acid and ion transporter (B0AT1, Lat2, Lat4, NBC1).

Conclusions: In conclusion, loss of FcRn results in a switch of cellular metabolism with enhanced autophagy and respiration combined with proximal tubule reduction and functional impairment. Therefore, loss of FcRn results in a decline in kidney function mirroring some features of CKD and could contribute to the progression of DN towards CKD in diabetes mellitus.

SA-OR20

Targeting CD153+PD-1+CD4+ Senescence-Associated T Cells Ameliorates Kidney Damage by Attenuating Tertiary Lymphoid Structure Formation

Keisuke Taniguchi,[1] Takahisa Yoshikawa,[1] Yuki Sato,[1] Kenji Kohno,[2] Satoru Takahashi,[4] Satoshi Nagata,[3] Haruhiko Kamada,[3] Motoko Yanagita.[1]
[1]Kyoto Daigaku Daigakuin Igaku Kenkyuka Igakubu, Kyoto, Japan; [2]Hyogo Kenritsu Daigaku, Kobe, Japan; [3]Epitope Science Co., Ltd., Ibaraki, Japan; [4]Tsukuba Daigaku, Tsukuba, Japan.

Background: We previously reported that tertiary lymphoid structures (TLSs) develop in the aged injured kidneys, with tissue maladaptive repair. In addition, we showed that the interactions between senescence-associated T cells (SA-T cells) and age-associated B cells (ABCs) via CD153-CD30 signaling are essential for TLS expansion. However, it remained unclear whether the intervention targeting SA-T cells can improve kidney prognosis.

Methods: CD153 knocked-in (CD153KI) mice, expressing enhanced green fluorescent protein (EGFP) and human diphtheria toxin receptor (hDTR) downstream of the CD153 promoter, were generated and subjected to ischemia-reperfusion injury (IRI), followed by DT administration. In addition, we made a mouse chimeric recombinant antibody (mcRM153) by using an antibody variable domain derived from the commercially available rat-derived anti-mouse CD153 antibody (RM153) and administered it to aged C57BL/6J mice after renal IRI. In both models, injured kidneys and spleens were analyzed by flow cytometry, immunostaining, *in situ* hybridization, and quantitative PCR.

Results: In the aged CD153KI mice, EGFP and hDTR-coexpressing T cells were identified in the spleens and within renal TLSs. Flow cytometry revealed that the majority of SA-T cells and smaller populations of CD4+ memory T cells expressed EGFP in the spleen and kidney, but other types of immune cells did not. One day after the first DT administration, the number of SA-T cells was reduced in the spleen and renal TLSs. Following the decrease in SA-T cells, the expression of chemokines, such as CCL19 and CXCL9, by proinflammatory fibroblasts within TLSs decreased by day 3, and TLSs were almost completely diminished by day 7. We also found that mcRM153 markedly reduced SA-T cells in the kidneys and spleen, significantly suppressed TLS formation, and reduced the VCAM1+ failed-repair proximal tubules and fibrosis in aged injured kidneys. In both models, the intervention reduced the proportion of germinal center B cells, but not ABCs.

Conclusions: Interventions targeting CD153 inhibit the formation of TLSs, ameliorate kidney damage, and may be therapeutic for CKD.

SA-OR21

DNA Damage Sensor BRCA1 Potentiates Fibrosis by Inducing Proximal Tubule G2/M Arrest and Senescence

Amrendra K. Ajay,[1,2] Akinwande A. Akinfolarin,[3,1] Joseph V. Bonventre.[1,2]
Bonventre Laboratory. *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Dallas Nephrology Associates, Dallas, TX.*

Background: DNA damage is a major contributing factor in the progression of fibrotic renal disease. Proximal tubular epithelial cells (PTECs) are the primary site of injury caused by toxins, ischemia, and obstructive injury in the kidney, leading to DNA breaks and triggering the DNA damage response (DDR). In response to DNA damage, the ATM-mediated phosphorylation of BRCA1^{Ser1524} initiates the DDR. We hypothesized that the effect of BRCA1 on arresting the cell cycle would exacerbate maladaptive repair through the initiation of G2/M cell cycle arrest and senescence.

Methods: We utilized human CKD kidney tissues, *Slc34a1-Cre* mice crossed with *Brca1*$^{flox/flox}$ mice, yielding PTEC *Brca1 exon 11* gene deletion. We performed bilateral ischemia/reperfusion (BIRI) or aristolochic acid (AA)-induced injury models in mice. Markers of DNA damage, cell cycle arrest, senescence, and fibrosis were evaluated by immunofluorescence staining and western blot analysis of tissue sections. We utilized in vitro models of patient-derived PTCs and HKC8 cells treated with AA or cisplatin. In addition, siRNA and shRNA-mediated knockdown, followed by cisplatin or AA treatment, was employed to study the role of BRCA1 in growth arrest and senescence.

Results: Human CKD kidneys showed a significant increased expression of BRCA1 protein expression compared to kidneys without CKD. Following BIRI or AA treatment in mice, the expression of *Brca1 exon 11* was increased. Deletion of *Brca1* from PTECs protected mice from the development of fibrosis, as shown by Sirius red staining, fibronectin, collagen 1, and a-smooth muscle actin following BIRI or AA. Following BIRI or AA treatment, PTECs-Brca1 depleted mice had reduced pH3^{+} cells, a G2/M cell cycle phase marker, and reduced S-β-Gal, a senescence marker. Primary PTCs displayed increased p-BRCA1^{Ser1524} after 48h AA or cisplatin treatment, with increased activation of growth arrest genes p53 and p21. siRNA and shRNA-induced reduction of BRCA1 in HKC8 and HK2 cells decreased cell viability and increased the gene expression of pro-fibrotic factors (*Acta2*, *Fibronectin*, and *Collagen1*).

Conclusions: BRCA1 in PTECs induces G2/M cell cycle arrest and cellular senescence *in vivo* and *in vitro* following injury. Transient inhibition of BRCA1 represents a novel treatment strategy to prevent the development of fibrosis after acute injury.

KLF4 Drives Fibroblast Activation to Promote Kidney Fibrosis via YAP Signaling

Juanjuan Jiang, Kang Liu, Lishan Liu, Jiafa Ren. *The First Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: Fibroblasts are the primary cellular sources of scar-forming myofibroblasts, which synthesize excessive quantities of extracellular matrix (ECM) and contribute to kidney fibrosis. KLF4, one of the Yamanaka transcription factors, controls various essential cellular functions, including proliferation, differentiation, and embryonic development, and has been implicated in kidney diseases. However, the role and mechanism of KLF4 in regulating fibroblast phenotype transition and kidney fibrogenesis remain undefined.

Methods: In our study, we examined the expression of Klf4 in renal biopsy tissue samples from patients with chronic kidney disease (CKD), as well as in two murine models of kidney fibrosis: unilateral ureteral obstruction (UUO) and ischemia-reperfusion (IR)-induced kidney fibrosis. We generated conditional knockout mice in which KLF4 gene was selectively and inducibly ablated in fibroblasts, and subjected these mice to UUO or IR. Additionally, we treated mice with a KLF4 inhibitor after UUO or IR.

Results: In this study, we initially observed the induction of KLF4 in interstitial myofibroblasts from mouse and human fibrotic kidneys. In in vitro experiments, KLF4 expression in NRK-49F cells was induced after exposure to TGFβ1. Blocking KLF4 signaling by siRNA or KLF4 inhibitor Kenpaullone attenuated TGFβ1-induced fibroblast activation. Conversely, the KLF4 agonist Apto253 enhanced fibroblast activation induced by TGFβ1. Further in vitro studies indicated that activation of KLF4 signaling induced upregulation of Yes-associated protein (YAP) signaling in response to TGFβ1, which was reversed by KLF4 silencing. Mice with fibroblast-specific deletion of KLF4 showed reduced ECM deposition and downregulation of YAP-related signaling components compared to WT mice in both fibrotic models. Treatment with KLF4 inhibitor Kenpaullone ameliorated kidney ECM deposition in fibrotic nephropathy induced by UUO or IRI. Additionally, treatment with the YAP inhibitor VTP further reduced ECM deposition and ameliorated fibrotic nephropathy in knockout mice after UUO.

Conclusions: These findings suggest that KLF4 significantly promotes fibroblast activation and kidney fibrogenesis potentially through activating the YAP singling pathway. Targeting this singling pathway may shine light on ways to protect against kidney fibrosis in patients with chronic kidney diseases.

The Role of D-dopachrome Tautomerase (Macrophage Migration Inhibitory Factor 2) in Kidney Fibrosis

Lea Herkens,[1] Patrick Droste,[1,2] Konstantinos Karyniotakis,[1] Peter Boor,[1,2] Sonja Djudjaj.[1] Laboratory of Nephropathology. *[1]Institute of Pathology, RWTH Aachen University, Aachen, Germany; [2]Division of Nephrology and Clinical Immunology, Aachen, Germany.*

Background: The progression of most kidney diseases leads to kidney fibrosis. Numerous factors were shown to be involved in driving fibrosis, less is known about endogenous factors limiting fibrosis. One such protective factor is macrophage migration inhibitory factor (MIF), which was found to limit kidney fibrosis by abrogating the cell cycle arrest of tubular cells. Macrophage migration inhibitory factor-2 (MIF-2), also known as D-dopachrome tautomerase (D-DT), is a structural and functional homolog of MIF. Very little is known about the location, expression, and functional role of D-DT in kidney fibrosis.

Methods: The expression of D-DT in kidney fibrosis was analyzed in different animal models, i.e., unilateral ureteral obstruction (UUO), ischemia-reperfusion (IR), and patients' biopsies using immunohistochemistry, immunofluorescence, rt-PCR, RNA *in situ* hybridization, Western blot and enzyme-linked immunosorbent assay (ELISA). Publicly available datasets and arrays were also re-analyzed and complemented by *in vitro* studies using human embryonic kidney (HEK) 293T cells. The functional role of D-DT *in vivo* was analyzed in D-DT knockout (KO) mice compared to wildtype littermates (WT) and by administration of recombinant D-DT in WT mice with UUO.

Results: D-DT mRNA and protein expression were mainly located in proximal tubules in both healthy murine and human kidneys. Its expression was significantly reduced in fibrosis in patients and animals with UUO and IR. Re-analysis of *Ddt*/*DDT* expression in murine and human publicly available array data further confirmed these findings. *In vitro*, HEK293T cells showed significantly decreased D-DT expression when challenged with the profibrotic transforming growth factor-β1 (TGF-β1). *In vivo*, compared to WT, D-DT KO mice developed significantly aggravated fibrosis in the UUO model while treatment with recombinant D-DT significantly improved fibrosis.

Conclusions: The data suggested that D-DT is mainly expressed in the proximal tubules in both mice and men and similarly decreased in fibrosis in both species. *In vivo* experiments suggested a protective role of D-DT in kidney fibrosis, similar to MIF; adding a new endogenous fibrosis-limiting factor. Future work will focus on potential mechanisms of the renoprotective effects of D-DT.

RARRES1 of Renal Tubular Epithelial Cells Aggravates Renal Fibrosis through Interaction with KHDRBS1/Src to Enhance Phosphorylation of STAT3

Anqun Chen, Lin Ye. *The Second Xiangya Hospital of Central South University, Changsha, China.*

Background: The underlying mechanisms of Renal fibrosis are uncertain. RARRES1, a retinoic acid receptor protein, is normally found in podocytes but upregulates in renal tubules during disease. This study aims to investigate the role and mechanism of RARRES1 in renal fibrosis.

Methods: 1. NEPTUNE and C-PROBE cohorts studied the link between RARRES1 expression in the renal tubular interstitium and CKD outcomes. 2. RNAscope confirmed the RARRES1 gene expression in renal tubular cells in CKD patients. Using Nephroseq data, we correlated RARRES1 expression with CKD fibrosis, with validation by Immunofluorescence staining. 3. Tubular cell-specific RARRES1 knockout mice were subjected to UUO-D10 and FA-D14 models to assess renal function and evaluate fibrosis. 4. Mass Spectrometry, CO-IP, and molecular cloning identified RARRES1 interactions and specific binding domains. 5. Protein interaction analysis and genetic manipulation were used to investigate the downstream mechanism.

Results: 1. RARRES1 was upregulated in the renal tubular interstitium of CKD patients. Higher RARRES1 expression in renal tubules correlated with lower GFR and worse outcomes in CKD patients. 2. RARRES1 gene expression positively correlated with fibrosis, as validated by immunofluorescence staining of α-SMA. 3. RARRES1 knockout in tubular cells alleviated renal injury and fibrosis in UUO-D10 and FAN-D14 mouse models. 4. KHDRBS1 was identified as an interacting protein of RARRES1 by CO-IP, with amino acids 263-269 of RARRES1 being crucial for this interaction. 5. Overexpression of RARRES1 and knockdown of KHDRBS1 in HK-2 cells led to a significant decrease in fibrosis markers within renal tubular epithelial cells. 6. KHDRBS1 interacts with STAT3 and Src, and overexpression of RARRES1 in HK-2 cells lead to a notable increase in phosphorylated STAT3 (p-STAT3). Additionally, RARRES1 knockdown in primary human renal tubular epithelial cells significantly reduced fibronectin expression upon TGF-β stimulation and the nuclear translocation of p-STAT3.

Conclusions: Elevated RARRES1 in CKD renal tubular cells exacerbates fibrosis via interaction with KHDRBS1, Src and STAT3, which promotes STAT3 phosphorylation and nuclear translocation. Targeting this RARRES1-KHDRBS1-Src axis may offer a therapeutic approach for renal fibrosis.

SA-OR25

Shroom3-Rock Interaction and Profibrotic Function: Resolving the Mechanism of a CKD Genome-Wide Association Study Risk Allele

Anand Reghuvaran,[1] Ashwani Kumar,[1] Gabriel Caldato Barsotti,[1] John F. Pell,[1] E M Tanvir,[1] John C. He,[2] Madhav C. Menon.[1] *[1]Yale University School of Medicine, New Haven, CT; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: We previously showed that a common intronic SNP (A-allele at rs17319721) is an enhancer for Shroom3 expression in donor kidneys promoting fibrosis. Given known therapeutic roles for Rho-kinase (ROCK) inhibitors in CKD, and the established interaction between Shroom3 and Rock via its ASD2 domain, we proposed that Shroom3-mediated ROCK activation played a crucial role in its profibrotic function in high expressors.

Methods: To test this, we developed transgenic mice and cell lines that inducibly overexpress wild-type- (WTS3) or ASD2-domain deletion- Shroom3 (ASD2ΔS3) and evaluated in fibrosis models.

Results: Prior scRNAseq data showed Shroom3 and Rock co-expression in injured PCT, distal nephron and fibroblasts during fibrosis [Fig A]. We used tubular cell lines (mIMCD3, HEK293T) to confirm absent ROCK binding (Co-IP)[B], reduced Rock activation (phospho-MYPT1) and reduced fibroblast proliferation (3T3) in ASD2ΔS3 cells vs WTS3 tubular cells [C-D].. In vivo, we studied ureteric obstruction (UUO) and Aristolochic nephropathy (AAN) as fibrosis models ASD2ΔS3. In vivo, in AAN models, both global (CAGS) and Pan-tubular(PAX8) specific WTSh3 mice showed increased fibrosis (Trichrome [E-F] and Collagen I staining [G]), and ASD2Δ mice showed reduced Azotemia (N=5 mice each [H]). Fibroblast specific mice are pending. For therapeutics, using homology modelling we developed 7 boron-based agents to inhibit Shroom3-Rock interaction (BT1131-BT1137). BT1135-BT1137 showed significant inhibition pMYPT1 [I] and 3T3 proliferation. Subsequent dose-response efficacy and toxicity studies identify BT1137 as optimal candidate for in vivo work.

Conclusions: We show the critical role of Shroom3-Rock interaction in renal fibrosis and show druggability of this interaction with applicability to individuals with the high expressor Shroom3 risk-allele.

Promotion of Mitochondrial Recovery Prevents Proximal Tubular Cell Maladaptive Repair and AKI-to-CKD Transition

Sho Sugahara,[1,2] Tomofumi Moriyama,[1,3] Kensei Taguchi,[3] Bertha C. Elias,[1] Craig R. Brooks.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Shiga Ika Daigaku, Otsu, Japan; [3]Kurume Daigaku Igakubu Daigakuin Igaku Kenkyuka, Kurume, Japan.*

Background: Acute kidney injury (AKI) is a major clinical complication which results in a four-fold increase in mortality and predisposes patients to developing chronic kidney disease (CKD) through the AKI-to-CKD transition. Following AKI, the transition to CKD is largely driven by injured proximal tubule cells that fail to recover from injury and remain in a state of maladaptive dedifferentiation termed maladaptive repair. Here, we study whether improving the mitochondrial health of maladaptively repaired PTCs can prevent CKD progression.

Methods: In vitro, maladaptive repair was induced by treatment of LLC-PK1 cells with aristolochic acid (AA). In vivo, AKI-to-CKD transition was induced by administration of AA to 8-12 weeks old male BL57Bl/6 (WT) mice. Mitochondrial morphology was improved by pharmacological administration of the mitochondrial fusion promoter M1

or genetic deletion of Drp1 under the control of the inducible Pax8 promotor (Drp1$^{\Delta PT}$). Fibrosis and dedifferentiation markers were measured by immunofluorescence, protein expression and mRNA levels. Mitochondrial function was analyzed using Seahorse analyzer. Mitochondrial morphology was measured by super-resolution microscopy.

Results: In vivo and in vitro analysis of mitochondrial morphology revealed that maladaptively repaired cells have shorter and smaller mitochondria, indicating pathological mitochondrial fragmentation. In vitro, reversing mitochondrial fragmentation with M1 improves mitochondrial function and increases expression of mitochondrial fatty acid oxidation (FAO) genes. The increased mitochondrial function not only prevents maladaptive repair, but it also promotes redifferentiation of cells already in the maladaptively repaired state. In vivo, pharmacological treatment with M1 or deletion of Drp1 reverses the mitochondrial fragmentation, which is associated increased expression of mitochondrial FAO genes. Remarkably, improving mitochondrial morphology/function also induces redifferentiation of maladaptively repaired cells and halts progression of CKD and kidney fibrosis.

Conclusions: These data indicate that promoting mitochondrial recovery improves mitochondrial health, reverses PTC maladaptive repair, and ultimately prevents CKD progression. Future therapeutics targeting mitochondrial fragmentation have the potential to prevent AKI-to-CKD transition.

Multimodal Single-Cell and Spatial Atlas of Interstitial and Vascular Niches in Reference and Diseased Kidneys

Blue Lake,[1] Rajasree Menon,[2] Ricardo Melo Ferreira,[3] Xi Chen,[4] Jens Hansen,[7] Rachel S. Sealfon,[4] Jennifer A. Schaub,[2] Sylvia E. Rosas,[5] Joseph Gaut,[8] Laura Barisoni,[6] Matthias Kretzler,[2] Kun Zhang,[1] Jeffrey B. Hodgin,[2] Michael T. Eadon,[3] Sanjay Jain.[8] HuBMAP, KPMP. *[1]Altos Labs Inc, San Diego, CA; [2]University of Michigan, Ann Arbor, MI; [3]Indiana University School of Medicine, Indianapolis, IN; [4]Flatiron Institute, New York, NY; [5]Joslin Diabetes Center, Boston, MA; [6]Duke University School of Medicine, Durham, NC; [7]Icahn School of Medicine at Mount Sinai, New York, NY; [8]Washington University in St Louis, St Louis, MO.*

Background: Multiomic studies at a single cell and spatial resolution are powerful approaches to define molecular and cellular landscape of the human kidney and understand etiology of failed or successful repair in acute or chronic injury. We expand KPMP AtlasV1 with clinicopathological correlations and maps of immune-fibroblast-vascular niches with insights into AKI-CKD transition.

Methods: We generated data from >250 kidney KPMP and HuBMAP tissue samples (reference, AKI, CKD) using snRNA-seq, paired snRNA-ATAC-seq and scRNA-seq technologies and performed integrated analyses. 10X Visium, Slide-Seq2, CosMx and Xenium spatial transcriptomics (ST) assays were used to validate and discover putative niches, pathways associated with altered states and their associations with clinicopathological features.

Results: Analysis of 1.5M+ datasets revealed 160 cellular identities including more than ~40 immune, 20 stromal, 20 endothelial and > 70 nephron cell clusters along the cortico-medullary depth. There were ~60 unique niches identified by ST including cellular neighborhoods of profibrogenic and reparative fibroblasts associated with distinct myeloid and altered tubular cells. Several of the cell states were associated with tubular inflammation, interstitial fibrosis or reduced eGFR. This led to the identification of cellular identities that were associated with AKI or CKD. For example, two spatially distinct groups of fibroblasts localized either to perivascular or interstitial sites. Perivascular fibroblasts showed a distinct trajectory from reference fibroblasts to myofibroblasts reminiscent of failed repair and fibrosis. Cell-level functions enriched in altered states include translation, cytoskeleton dynamics, immune response activities and ECM turnover. Paired RNA-ATAC analysis revealed key transcriptional factors, regulatory circuits and accessible chromatin regions that were linked to CKD-associated GWAS variants, identifying genes potentially associated with disease pathogenesis.

Conclusions: We provide a comprehensive blueprint of spatially resolved altered cellular identities, regulatory circuits and molecular codes that inform on mechanisms of unsuccessful repair and acute and chronic kidney dysfunction.

Multiomics Reveal c-Jun and SLC4A4 as Key Drivers of Kidney Fibrosis in Diabetic Nephropathy

Qiwen Deng, Yu Liu, Vivek Charu, Gerlinde Wernig. *Stanford University School of Medicine, Stanford, CA.*

Background: Diabetic nephropathy (DN) is a major cause of chronic kidney disease globally. However, the lack of targeted treatments for renal fibrosis in DN is due to an incomplete understanding of disease progression. We generated a detailed map of human diabetic nephropathy by employing multiplexed single-cell imaging and spatial transcriptomic profiling of DN patients and controls.

Methods: We utilized an integrative multi-omic approach, combining single-cell RNA sequencing, chromatin accessibility assays, spatial transcriptomics, and CODEX multiplexed imaging. This comprehensive analysis provided unprecedented spatial and molecular resolution of kidney tissues from DN patients and controls.

Results: Our multi-omic analysis revealed novel, cell-type-specific regulatory changes and provided unique mechanistic insights into DN progression. We identified the transcription factor cJun as a novel and pivotal driver of epithelial-to-mesenchymal transition (EMT) in proximal tubule and renal fibrosis. Additionally, we discovered that the sodium bicarbonate cotransporter SLC4A4 is a crucial modulator of proximal tubular injury, causally regulated by cJun. Overexpression of SLC4A4 in human proximal epithelial cells led to reduced expression of epithelial markers (E-cadherin, cingulin), indicative of EMT. Functional assays demonstrated that intracellular pH regulation, highly dependent on SLC4A4, is critical for maintaining epithelial cell function. Disruption of this regulation promoted EMT and exacerbated tubular injury, contributing to DN progression. Using an inducible cJun mouse model, we confirmed that cJun overexpression in tubule drives renal fibrosis in chronic kidney disease. Spatially resolved transcriptomics and CODEX imaging provided detailed insights into the spatial organization of these molecular changes, emphasizing the critical role of multi-omics in uncovering these novel drivers of DN.

Conclusions: Our study underscores the power of multi-omics in identifying novel molecular drivers of diabetic nephropathy. The discovery of cJun and SLC4A4 as key regulators highlights their potential as unique therapeutic targets to mitigate renal fibrosis in DN. These findings offer a robust foundation for future research aimed at developing targeted treatments to improve outcomes for patients with DN.

A Therapeutic Lead Compound for Diabetic Kidney Disease with a Unique Lipophagy Activation Mechanism

Rachel Njeim,[1] Haley Gye,[1] Colin B. Kelly,[1] Cole M. Foster,[1] Judith T. Molina David,[1] Sandra M. Merscher,[1] Marc Giulianotti,[2] Alessia Fornoni,[1] Hassan Ali.[1] *[1]University of Miami Miller School of Medicine, Miami, FL; [2]University of Minnesota, Minneapolis, MN.*

Background: In 2021, 537 million people worldwide had diabetes, and this number is expected to increase to 783 million by 2045. Approximately 30% of individuals with diabetes develop Diabetic kidney disease (DKD), which ultimately leads to end stage renal failure. We previously demonstrated that lipid droplets (LDs) accumulation in podocytes leads to increased lipotoxicity and cell death in DKD. Furthermore, we reported that reducing LD accumulation in podocytes preserves cell function and attenuates albuminuria in experimental DKD. Drugs that reduce lipids systemically do not prevent DKD progression. We hypothesize that specifically reducing LD accumulation in podocytes prevents DKD progression.

Methods: We developed a phenotypic assay using immortalized human podocytes and deployed it to screen a combinatorial library. We identified a novel series of hit compounds, from which we generated a lead candidate with improved drug-like properties. We performed RNAseq, molecular biology and phenotypic profiling (Cell Painting) analyses to elucidate the mechanism of action (MoA) of these compounds. Finally, we tested the lead compound in a murine model of DKD.

Results: Our screen identified a series of novel compounds that effectively reduced LD accumulation in stressed podocytes. Mechanistic studies revealed that the lead candidate, compound 2726.007, activates autophagy/lipophagy, thereby reducing LD accumulation in stressed podocytes and rescuing them from cell death. When compared to other autophagy inducers with diverse MoAs, including metformin, rapamycin, and L690,330, only compound 2726.007 decreased LD accumulation in stressed podocytes and prevented cell death. Unbiased phenotypic-based profiling of these compounds further demonstrated that compound 2726.007 has a unique MoA that is not reproduced by the other autophagy inducers. Importantly, compound 2726.007 significantly reduced albuminuria and renal damage in *db/db* mice.

Conclusions: Taken together, we have developed a therapeutic lead compound that reduces LD accumulation in podocytes by activating lipophagy through a mechanism distinct from other autophagy inducers, thereby preventing DKD progression. Next steps include lead optimization and preclinical development to ultimately advance the candidate towards clinical trials.

C/EBPβ-XOR Axis Confers Genetic Predisposition to Diabetic Kidney Disease

Ubong S. Ekperikpe, Liping Yu, Ilse S. Daehn. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Diabetes-induced chronic kidney disease (CKD) is the leading cause of renal failure globally and in the United States of America. Interestingly, only about 30% of patients with diabetes develop diabetic kidney disease (DKD), underscoring the

role of genetics in the pathophysiology of DKD. Despite this observation, the underlying molecular mechanisms that confer genetic predisposition to DKD remain unclear. Glomerular injury, characterized by podocyte depletion and glomerular hypertrophy are a major feature of progressive DKD. Previously, we reported that mitochondrial dysfunction-induced oxidative damage in glomerular endothelial cells (GECs) drives podocyte loss via GEC-podocyte crosstalk in DKD-susceptible DBA/2J (D2) versus DKD-resistant C57BL/6J (B6) mice.

Methods: We mapped potential quantitative trait loci (QTL) that are associated with podocyte depletion in DKD-susceptible DBA/2J (D2) and DKD-resistant C57BL/6J (B6) mice, and in a panel of recombinant BXD mouse strains. Through this, we identified a significant *cis*-acting variant in the promoter region of xanthine oxidoreductase (*Xor*). XOR catalyzes the metabolism of purines to uric acid, generating reactive oxygen species (ROS) in the process. Via CRISPR/Cas9, we knocked-in the identified *Xor* risk variant into DKD-resistant B6 mice to generate mutant B6-*Xor*^{em1} mice that displayed markedly higher XOR activity versus wild-type B6 mice. We also determined the effect of this *Xor* risk variant on susceptibility to DKD in B6-*Xor*^{em1} mice.

Results: The identified *Xor* promoter risk variant is a transcription factor binding site for C/EBPβ. We detected higher expression of C/EBPβ in GECs from diabetic B6-*Xor*^{em1} mice. Diabetic B6-*Xor*^{em1} mice exhibited increased mitochondrial ROS in GECs, and this was associated with podocyte depletion, glomerular basement membrane thickening, glomerulosclerosis, and albuminuria. More importantly, these pathophysiologic changes were prevented by the XOR inhibitor, febuxostat. B6-*Xor*^{em1} mice also displayed age-related glomerulosclerosis and insulin resistance. Furthermore, *In vitro* studies in GECs support a possible *Xor*-mitochondrial ROS interplay in endothelial cells that resulted in GEC dysfunction.

Conclusions: High-risk variants in the promoter region of *Xor* confer genetic susceptibility to DKD and may predispose to other complications of diabetes, and aging-related renal disease.

SA-OR31

Targeting RNF145 in Renal Proximal Tubular Cells Protects against Lipotoxicity in Diabetes

Matias Simons, Lena Hipp, Angel Loza Valdes. *UniversitatsKlinikum Heidelberg, Heidelberg, Germany*.

Background: In diabetic patients, dyslipidemia is associated with both excessive deposition of triacylglycerol (TAG) in lipid droplets (LDs) and lipotoxicity. Yet, it is unclear how these two effects correlate with each other in the kidney and how they are influenced by dietary patterns. By using a diabetes mouse model, we previously found that a high fat diet enriched in the monounsaturated oleic acid (OA) caused more lipid storage in LDs in renal proximal tubular cells (PTCs), but less tubular damage than a corresponding butter diet with the saturated palmitic acid (PA). Mechanistically, endoplasmic reticulum (ER) stress was caused by elevated levels of saturated TAG precursors, reduced LD formation, and, consequently, higher membrane order in the ER (Perez-Marti et al, eLife 2022).

Methods: Rnf145 knockout induced renal epithelial cells (iRECs) were generated using adenoviral CRISPR/Cas9. Cells were treated for 16 - 18 hrs with PA and subsequently analyzed for protein and mRNA expression, cell viability (crystal violet) and apoptosis (IncuCyte). Proteomic and lipidomic analyses were performed, and mitochondrial respiration and glycolysis were measured with Seahorse.

Results: To identify pathways mediating PA-induced lipotoxicity, we applied transcriptomics to PA- and OA-treated induced renal epithelial cells (iRECs) and uncovered a set of genes differentially regulated by PA and OA, including the ER resident E3-ubiquitin ligase RNF145. Interestingly, RNF145 knockout protected iRECs against PA-mediated cytotoxicity and reduced ER stress, while its overexpression had opposite effects. Moreover, inhibition of desaturases in conditions of high lipid saturation rendered the Rnf145 depleted cells more sensitive than control cells, indicating that desaturases, such as SCD1, play a crucial role in Rnf145 deficient cells. Since proteomic analysis revealed changes in mitochondrial proteins and proteins involved in glycolysis and lipid metabolism, we confirmed that Rnf145-knockout cells undergo a shift from glycolysis towards mitochondrial respiration which might potentially contribute to the higher PA resistance.

Conclusions: Altogether, our findings suggest RNF145 as a major regulator of lipid homeostasis and cellular metabolism, providing an interesting target for counteracting lipotoxicity in renal PTCs.

SA-OR32

Characterization of a Novel ASAH2 Variant Associated with Diabetes and Kidney Failure in Tongan and Samoan Patients

Rebekah Nicholson, Jacob Taloa, John A. Maschek, Marcus G. Pezzolesi, Scott Summers. *University of Utah Health, Salt Lake City, UT*.

Background: Ceramides are bioactive lipids which modulate metabolic pathways to drive insulin resistance, apoptosis, and fibrosis. In search of novel genetic divers of high ceramides and their resulting contribution to heritable metabolic pathologies, we have identified a novel coding mutation in neutral ceramidase (*ASAH2*). The mutation is exclusive to patients of Tongan and/or Samoan ancestry, a population which faces the highest rates of obesity, diabetes, and end-stage renal disease (ESRD) of any racial or ethnic group in the United States.

Methods: We profiled circulating ceramides in 5 founder *ASAH2* point mutant (chr10:50236064C→G(hg38), c.G511C, p.V171L) carriers and characterized the effect of the mutation on neutral ceramidase activity and ASAH2 mRNA splicing *in vitro* with CRISPR Cas9 knock-in and/or mutant expression constructs in HEK293 cells. Lastly, we tested for renal and metabolic consequences of loss-of-ceramidase function in *Asah2* knockout mice challenged with high-fat diet or streptozotocin-induced diabetic kidney disease (DKD).

Results: Heterozygous carriers of the *ASAH2* mutation have 29% higher circulating ceramides compared to Polynesian non-carriers with diabetes and ESRD (p=0.009). Sequencing of RNA from ASAH2$^{c.G511C}$ knock-in cells revealed that the point mutation located at the first base pair of exon 5 causes excision of exon 5, which encodes crucial amino acids within the ASAH2 catalytic domain. Functional studies in cells overexpressing *ASAH2* lacking exon 5 confirm ablation of ceramidase activity. *In vivo*, both male and female *Asah2*$^{-/-}$ mice displayed worsened insulin sensitivity by insulin tolerance test compared to *Asah2*$^{+/+}$ littermate controls with diet-induced obesity. Additionally, female *Asah2*$^{-/-}$ mice had exacerbated albuminuria (473.3±83.6 (-/-) vs. 159.3±37.7 (+/+) ug/mg creatinine, p<0.0001), kidney hypertrophy (7.7 (-/-) vs. 5.9 (+/+) mg/g body weight, p<0.0001), and cortex expression of markers related to fibrosis (*Tgfb1, Col1a1, Col3a1, Col4a1, Fn1*) and kidney damage (*Havcr1, Lcn2*) compared to *Asah2*$^{+/+}$ littermate controls in the setting of DKD.

Conclusions: These data reveal a novel risk allele for diabetes and kidney disease that is present in 1 in 10 individuals of Tongan or Samoan descent, which could be treated with precision therapies designed to lower ceramides.

Diabetes-Specific Kidney Function Loci Identified in Genome-Wide Association Study of eGFR in 52,000 Individuals with Diabetes

Joanne B. Cole,[1] Damian Fermin,[2] Hongbo Liu,[3] Petter Bjornstad,[1] Andrew Paterson,[4] Andrzej S. Krolewski,[5] Niina Sandholm,[6] Jose C. Florez.[7]
[1]University of Colorado Anschutz Medical Campus School of Medicine, Aurora, CO; [2]University of Michigan Michigan Medicine, Ann Arbor, MI; [3]University of Pennsylvania, Philadelphia, PA; [4]Sick Kids Foundation, Toronto, ON, Canada; [5]Joslin Diabetes Center, Boston, MA; [6]Helsingin yliopisto Laaketieteellinen tiedekunta, Helsinki, Finland; [7]Mass General Brigham Inc, Boston, MA.

Background: Diabetic kidney disease (DKD) is a distinct life-altering pathological condition that is caused by both environmental and genetic factors. Previous genome-wide association studies (GWAS) have identified several loci associated with kidney disease and function both in the general population and in diabetes. While type 2 diabetes (T2D) is more common than type 1 diabetes (T1D), individuals with T2D have higher rates of kidney-damaging co-morbidities, and thus many develop non-specific kidney disease. Therefore, a comprehensive approach which incorporates T1D and T2D to maximize sample size and also integrates diabetes subtype, duration, and co-morbidities is key to improving the success of large-scale genomic discovery for DKD.

Methods: As part of the GENIE consortium, we leveraged widely available eGFR as a powerful quantitative trait to conduct the largest GWAS of eGFR in diabetes, including 17 T1D cohorts, UK Biobank, and SUMMIT Consortium T2D data with a total of 17K individuals with T1D and 36K individuals with T2D. To identify genetic loci most likely impacting kidney function via hyperglycemic pathways, we analyzed eGFR in a variety of settings that considered DKD disease status, diabetes subtype and duration, BMI, HbA1c, and the relationship between eGFR and albuminuria. We integrated multi-omics data to nominate candidate genes and elucidate mechanism.

Results: GWAS identified 13 loci associated with eGFR (P<5x10^{-8}); five were not associated or were in opposite directions with eGFR in the general population. rs11032245 near *HIPK3* had opposite effects on eGFR in DKD cases versus diabetes controls, and single-cell RNA sequencing revealed a large difference in *HIPK3* expression in podocytes between youth-onset T2D and healthy controls. rs76300256 near *LPP* had opposite effects in diabetes versus no diabetes and is a methylation QTL in kidney tissue for 3 CpGs in a kidney enhancer.

Conclusions: Together, our multi-faceted approach enabled us to identify candidate genes with diabetes-specific impact on kidney function, a critical step towards elucidating DKD pathophysiology and the development of novel more personalized therapies.

Peptide-Based PROTAC Degrader of CDA1 Suppresses Diabetic Kidney Disease

Jiao Wu, Shasha Cheng, Yingying Zhang, Xiaoyan Li, Xia Zhou, Xiaogang Li. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Diabetic kidney disease (DKD) is a leading cause of mortality and morbidity in diabetes, representing a predominant cause of renal failure worldwide. The expression of cell division autoantigen 1 (CDA1) is elevated in the kidneys of diabetic animal models, which can promote renal fibrosis through the TGF-β signaling pathway. PROTAC is a protein depletion approach that utilizes small molecules or peptides to artificially bridge a protein of interest with E3 ligase for subsequent proteasomal degradation. We hypothesize that targeting CDA1 with peptide based PROTAC may be a promising approach for attenuation of renal fibrosis and DKD.

Methods: To test the effect of a pharmacological approach of peptide-based PROTAC on the degradation of CDA1 and DKD progression, streptozotocin (STZ)-induced and db/db DKD mouse models were treated with different doses of the peptide-based PROTAC molecule CPV. The treated kidneys were collected and analyzed with H&E staining, immunofluorescence, immunohistochemistry staining and TUNEL assay. The expression of key factors in DKD were analyzed by WB and qRT-PCR analysis in DKD cells and kidneys.

Results: We generated a new peptide-based PROTAC degrader, CPV, and demonstrated that treatment with the CPV induced ubiquitin-mediated degradation of CDA1 protein in DKD cells and kidneys, indicating by that the degradation of CDA1 could be reversed by co-treatment with proteasome inhibitor MG132. Among three doses tested, treatment with a dose of 5 ug/kg of CPV already could delay disease progression in two DKD mouse models as seen by a decrease of blood urea nitrogen (BUN) levels and urinary proteins, and an increase of serum albumin. In addition, treatment with CPV mitigated interstitial fibrosis and renal inflammation as seen by a decrease of the expression of profibrotic markers, including TGF-β, a-SMA and collagen 1, and proinflammatory factors, including TNF-a, MCP-1 and IL-1. It also reduced renal extracellular matrix (ECM) accumulation and glomerular injury index. Notably, no deleterious effects were observed in other organs.

Conclusions: This study indicates that the peptide-based PROTAC degrader, CPV, can induce ubiquitin-mediated degradation of CDA1 protein in cells and kidneys from DKD mouse models, and suggest that peptide-based PROTAC therapy a safe and novel therapeutic strategy for the treatment of diabetic kidney disease.

Mapping the Microenvironment: A Single-Cell Spatial Atlas of Diabetic Nephropathy

Bernhard Dumoulin, Jonathan Levinsohn, Konstantin A. Kloetzer, Eunji Ha, Andi M. Bergeson, Katalin Susztak. Susztak Lab. *University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

Background: The kidney is an architectural masterpiece, comprising nearly 100 distinct cell types. Despite this complexity, the cellular architectural principles of the kidney in both health and disease remain poorly understood. Our study aims to elucidate these principles by profiling healthy and diabetic kidney samples at true cellular resolution. We seek to uncover the molecular and spatial signatures that characterize the disease condition.

Methods: We utilize the spatial transcriptomics platform CosMx, which enables the spatial profiling of 1,000 transcripts at true single-cell resolution. We applied deep learning-based algorithms to integrate our spatial transcriptomics dataset with human kidney single-nuclear gene expression information. This integration allows us to map annotations and cell states onto our spatial dataset, providing a comprehensive view of the kidney's cellular landscape in both health and disease.

Results: We profiled gene expression and spatial information for 1,7 million cells across healthy, diabetic, and diabetic kidney disease samples. We identified 19 distinct major cell populations within these samples. Leveraging the spatial information of these cell populations, we identified 13 distinct kidney niches. In diabetic kidney disease, we found an enrichment of injured tubular epithelial niches, as well as fibroblast and immune niches. Further subclustering of these injured epithelial populations based on their spatial location revealed microenvironments almost exclusively associated with disease. Within these microenvironments, injured epithelial cells exhibited a distinct transcriptional signature, and colocalized with immune cells. To further analyze these immune cells, we integrated seven datasets comprising approximately 150 patients and 165,000 immune cells into a single kidney immune cell atlas. Using the cell states inferred from our integrations, we mapped cell-cell interactions within these disease-specific microenvironments.

Conclusions: This study underscores the potential of spatial transcriptomics in dissecting the heterogeneity of kidney disease. By providing a detailed map of cellular and molecular landscapes, our findings pave the way for a better understanding of disease mechanisms and potential therapeutic targets.

Mitochondrial Complex I Assembly Factor NDUFAF1 Regulates Tubulointerstitial Fibrosis in Diabetic Kidney Disease via a Tricarboxylic Acid Cycle Metabolite

Koki Mise,[1,2] Jianyin Long,[2] Jun Wada,[1] Benny B. Chang,[2] Farhad R. Danesh.[2] *[1]Department of Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan; [2]Nephrology Section, The University of Texas MD Anderson Cancer Center, Houston, TX.*

Background: The mitochondrial electron transport chain (ETC) is a highly adaptive process that is crucial for meeting the metabolic demands of the cell. Dysregulation of the ETC has been associated with various clinical pathologies. We have recently highlighted the central role of NDUFS4, a subunit of Complex I, as a regulator of cristae remodeling and mitochondrial function in kidney podocytes (Mise K. et al. *Nat Commun* 2024 4;15:1965). However, the mechanism of ETC remodeling in the tubules of diabetic kidney disease (DKD) remains elusive.

Methods: We examined ETC remodeling in kidney tubules of two established mouse models of DKD, and generated DKD mice with proximal tubule-specific overexpression of Ndufaf1 (NADH: Ubiquinone Oxidoreductase Complex Assembly Factor 1, *Ins2*$^{Akita/+}$;*Ndufaf1*^{PTCTg}), an assembly factor of mitochondrial complex I, as a model to investigate the role of ETC integrity in diabetic tubules.

Results: We found that the rotenon-sensitive complex I enzymatic activity and the density of mitochondrial cristae were significantly reduced in proximal tubules of diabetic kidneys. Mitochondrial proteomic analysis revealed that several complex I assembly factors, including NDUFAF1, were significantly decreased in the tubular mitochondria of DKD mice. Importantly, the generation of diabetic mice with conditional overexpression of Ndufaf1 in proximal tubules (*Ins2*$^{Akita/+}$;*Ndufaf1*^{PTCTg}) exhibited reduced urinary KIM-1 and decreased collagen I and fibronectin along with improved cristae morphology. Primary proximal tubules from these mice exhibited increased ATP production and complex I enzymatic activity along with reduced mitochondrial ROS as compared to diabetic *Ins2*$^{Akita/+}$ mice. Mechanistically, we found that α-KG, a causal factor of renal fibrosis and enhanced TFG-β secretion, was significantly increased in the mitochondria from established models of DKD, whereas the levels of α-KG were normalized in *Ins2*$^{Akita/+}$;*Ndufaf1*^{PTCTg} mice.

Conclusions: This study discovered an unexpected role of Ndufaf1 as a powerful regulator of ETC in kidney fibrosis. These findings provide important insights into the mitochondrial mechanisms underlying the development of DKD and highlight the potential therapeutic targeting of the ETC assembly factor, NDUFAF1, for the management of this devastating condition.

PRINTcision Medicine: A Reusable, Three-Dimensional-Printed, Patient-Specific, In Vitro Model of Arteriovenous Fistulas for Endothelial Cell Studies

Nasir A. Shah,[1,2] Zoltan Endre,[1,2] Tracie Barber,[4] Blake Cochran,[3] Jonathan H. Erlich.[1,2] *[1]University of New South Wales School of Clinical Medicine, Sydney, NSW, Australia; [2]Prince of Wales Hospital and Community Health Services, Randwick, NSW, Australia; [3]University of New South Wales School of Biomedical Sciences, Sydney, NSW, Australia; [4]University of New South Wales School of Mechanical and Manufacturing Engineering, Sydney, NSW, Australia.*

Background: Approximately 850 million people worldwide have CKD. For those with end stage kidney disease on haemodialysis, vascular access is best achieved using a native AVF. Though the molecular mechanisms underpinning AVF maturation are not well-established, endothelial cells appear to play a critical role in AVF maturation. Standard cell culture provides valuable insight into endothelial cell function, but the flat surface neglects the complex physiology of disturbed blood flow through intricate vessel geometries. We have developed and refined a macrofluidic model of AVFs using true patient geometries.

Methods: Patient AVFs were imaged using a modified ultrasound machine, digitally segmented to generate AVF geometries, and 3D-printed using a water-soluble filament. Prints were cast in silicone and dissolved leaving an AVF-shaped cavity. Human dermal microvascular endothelial cells (HMEC-1) were cultured on the internal surface of these models. Custom components were fabricated to create a flow circuit using autoclave-sterilisable materials. Patient-specific AVF doppler recordings were used to program a peristaltic pump.

Results: Immunofluorescence with DAPI and Phalloidin confirmed the presence of a HMEC-1 monolayer on the luminal surface of the patent-specific AVF models. Using autoclave sterilised components, the flow circuit ran for 10 days without bacterial contamination. Pulsatile flow was successfully achieved using the programmable peristaltic pump.

Conclusions: Our macrofluidic device overcomes many of the limitations of current cell culture techniques and animal models. By using patient-specific geometries, physiologic pulsatile flow, and running flow experiments over biologically relevant timelines, this novel *in vitro* model will facilitate investigation of endothelial cell biology under patient-relevant conditions.

Light Sheet Fluorescence Microscopy: A Novel Tool for Three-Dimensional Optical Reconstructions of Mouse Arteriovenous Fistulae in Control and Uremic Animals

Unimunkh Uriyanghai,[1] Edward M. Bahnson,[2] Christine Wai,[1] Lianxia Li,[2] Eric W. Livingston,[2] Vinay A. Sudarsanam,[1] Samuel Haddad,[1] Huanjuan Su,[1] Eyla C. Arteaga,[1] Boyce E. Griffith,[2] Prabir Roy-Chaudhury,[1] Gang Xi.[1]
[1]The University of North Carolina at Chapel Hill Kidney Center, Chapel Hill, NC; [2]The University of North Carolina at Chapel Hill, Chapel Hill, NC.

Background: The arteriovenous fistula (AVF) is currently the gold standard for dialysis vascular access. Unfortunately over 50% of AVFs fail to mature, most often as a result of a venous segment stenosis. We and others have hypothesized that this is likely due to two interactive upstream pathogenetic pathways (hemodynamic stress and uremic vascular biology) which then results in two interacting downstream pathological pathways (neointimal hyperplasia and inadequate outward remodeling) that result in venous segment stenosis. To better elucidate the mechanisms involved in these processes, we have developed a novel approach termed Light Sheet Fluorescence Microscopy (LSFM), which can generate 3D optical reconstructions of AVF vessel architecture, with regard to volume, geometry, and the presence or absence of neointimal hyperplasia. The goal of this study was to describe the use of LSFM in normal and uremic animals.

Methods: Carotid-jugular AVFs were created in 16-week-old wild-type and uremic mice on a C57BL/6 background. Uremia was induced by a 5/6 nephrectomy on day 14 and Day 7 using a two-step surgical approach. Animals were sacrificed at 21d and the AVF was harvested for LSFM and conventional histomorphometry.

Results: Uremic mice had a decrease in the average (6 sections at 100 micron intervals across the venous segment) percentage luminal patency as compared to control animals on histomorphometric analysis (12±1.4% vs 36.1±11.5%, $p<0.05$) at 21 days post-surgery. Consistent with this data, the LSFM analysis documented that lesion volume within the venous segment was increased in the uremic mouse model (0.79 cubic mm versus 0.25 cubic mm) and the length of lesion was also doubled in the uremic mouse model (1mm vs 2mm) (see Fig 1).

Conclusions: Our results suggest that LSFM could be a particularly useful tool for obtaining a holistic assessment of both 3D anatomy and stenosis across the entire venous segment as opposed to looking at discreet sections every 100-200 microns. While the latter is the current technical standard, it is unfortunately prone to miss short regions of maximal stenosis.

SA-OR39

Periadventitial Delivery of Nanoparticle-Encapsulated AZD8797 Reduces Venous Stenosis in a Murine Arteriovenous Fistula Model

Prabh G. Singh, Sreenivasulu Kilari, Alaura Lemieux, Jamie Kane, Sanjay Misra. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Venous neointimal hyperplasia (VNH) and venous stenosis (VS) decrease the patency of arteriovenous fistulas (AVFs) for hemodialysis. Immune cell infiltration drives VNH/VS, with the CX3C motif chemokine receptor 1 (CX3CR1) playing a key role in leukocyte adhesion and migration. This study evaluates if the peri-adventitial delivery of nanoparticle encapsulated AZD8797, a CX3CR1 inhibitor, immediately after AVF creation prevents VNH/VS in a murine AVF model with established chronic kidney disease (CKD).

Methods: Thirty-six male C57BL/6J mice (7-8 weeks old, weighing 26.42 ± 0.29 g) underwent partial nephrectomy to induce CKD. AVFs were created 28 days later, and the mice received peri-adventitial delivery of PLGA nanoparticles in 20% Pluronic F127 hydrogel only (NP C) or the same formulation with AZD8797 (AZD8797 NP) on the outflow vein (GV). Three days post-AVF, 20 mice were sacrificed for the drug dose study, while 16 mice underwent weekly Doppler scans and were sacrificed 28 days post-AVF for histomorphometry and immunohistochemical evaluations.

Results: Drug response study showed that 50 μM AZD8797 NP significantly reduced CX3CR1 gene expression in GV. AZD8797 NP group exhibited significantly higher peak systolic velocity, wall shear stress, and blood flow, with histomorphometric analysis showing an increase in average lumen vessel area. (32,282.67 ± 4,770.40 μm^2 vs. 7,983.80 ± 1,695.85 μm^2, p=0.0027) and reduced neointimal cell density (0.0047 ± 0.0006 cells/μm^2 vs. 0.0092 ± 0.0012 cells/μm^2, p=0.0107). AZD8797 NP group showed decreased immune markers CX3CR1 (5.15 ± 1.11 vs. 15.45 ± 1.02, p=0.0001), CX3CL1 (2.78 ± 0.45 vs. 9.63 ± 1.23, p=0.0028), CD68 (4.78 ± 0.88 vs. 12.71 ± 1.19, p=0.0008) and NF-κB (1.88 ± 0.56 vs. 5.43 ± 0.37, p=0.0011) expression. Smooth muscle and fibroblast staining were significantly decreased in the AZD8797 NP group (α-SMA: 5.44 ± 0.57 vs. 19.15 ± 0.53, p=0.0015; FSP-1: 11.22 ± 0.78 vs. 16.79 ± 1.36, p=0.0117). Ki67 staining was significantly decreased (5.16 ± 0.83 vs. 8.40 ± 0.72, p=0.0229) with increased TUNEL assay in the AZD8797 NP group (2.04 ± 0.23 vs. 0.88 ± 0.19, p=0.0149).

Conclusions: Peri-adventitial delivery of AZD8797 NPs significantly reduces VNH/VS with improved vascular remodeling. This approach shows promise as a therapeutic strategy to enhance AVF patency.

National Estimates of Direct Health Care Costs Associated with Catheter-Related Bloodstream Infection among Hospitalized Hemodialysis Patients in Australia

Jayson Catiwa,[1,2] Martin P. Gallagher,[3,1] Stephen Jan,[1,7] Kevan Polkinghorne,[4] Nicholas A. Gray,[5] Kathryn Higgins,[1] Sradha S. Kotwal.[1,6] *[1]The George Institute for Global Health, Sydney, NSW, Australia; [2]University of New South Wales, Sydney, NSW, Australia; [3]University of New South Wales SWS Clinical Skills and Simulation, Liverpool, NSW, Australia; [4]Monash University Department of Epidemiology and Preventive Medicine, Melbourne, VIC, Australia; [5]Sunshine Coast University Hospital, Sunshine Coast, QLD, Australia; [6]Prince of Wales Hospital and Community Health Services, Randwick, NSW, Australia; [7]Imperial College London, London, United Kingdom.*

Background: The risk of hospitalization and complications among hemodialysis (HD) patients increases with catheter-related bloodstream infection (CRBSI). The treatment of HD CRBSI often requires substantial healthcare resource; however, the direct hospitalization cost of CRBSI in adult chronic HD patients in Australia remains unknown.

Methods: We used hospitalization records from each Australian State and Territory (excluding Western Australia) and the Australian and New Zealand Dialysis and Transplant Registry to identify national cohort of patients on chronic HD with a catheter and linked the prospectively collected REDUcing the burden of dialysis Catheter ComplicaTIOns: a National approach (REDUCCTION) trial data to identify HD CRBSI episodes. We used inpatient Australian-modified ICD 10 codes and Australian Refined Diagnosis Related Groups to define HD CRBSI-related admissions between December 2016 to March 2020. The cost per inpatient HD CRBSI episode was determined by multiplying the Australian National Weighted Average Unit (NWAU) to the annual National Efficiency Price, with estimates adjusted to USD in 2024 prices. An NWAU is a measure of health service activity weighted for its clinical complexity. The value of 1.00 NWAU in 2024 is $4,375.93.

Results: Study cohort included 10,341 linked hospitalizations among 3,775 HD patients with incident catheter enrolled into REDUCCTION within the 40-month period. Of these, there were 159 (1.5%) hospitalizations attributed to HD CRBSI across 34 participating HD services, with 83% (n = 133) involving tunneled catheters. Overall, mean age of patients was 59 years, 67% male, and 69% Caucasian. The mean NWAU for inpatient HD CRBSI was 3.88 (SD 3.85) with an attributable adjusted cost of $16,767.01 (SD $16,618.74).

Conclusions: The economic burden of inpatient HD CRBSI among chronic HD patients is substantial in Australia, which forms part of the larger actual costs of all bloodstream infections. This first economic analysis of HD CRBSI in Australia using large, linked datasets, offers invaluable insights into the considerable financial strain on health systems. The estimate of out-of-hospital and other indirect costs (social, carer, etc.) associated with HD CRBSI needs to be evaluated in future studies.

Extra Aseptic Measures in Permanent Catheter Connection: Twister System, 6-Year Experience

Miguel Suarez,[1,2] Vanesa Garcia Bernalt,[1] Pedro Dorado.[2] *[1]Servicio Extremeno de Salud, Merida, Spain; [2]Universidad de Extremadura, Badajoz, Spain.*

Background: Hemodialysis requires venous access por its performed. Arteriovenous fistula is preferable due to less associated comorbidity compared to catheter. However, in some units, catheters are a highly prevalent access. Aseptic measures are required to prevent their intraluminal contamination, The guidlines recommen rates of less than 2 events/1,000 catheter-days. The TWISTER® reverse flow device (TWR) is a closed system device that allows the flow of a catheter to be reversed without the need to manually disconnect the blood lines, which reduces exposure to blood or connection systems to air or contact with non-sterile areas, therefore reducing the risk of pathogens reaching the blood.

Methods: Retrospective study of 205 incident patients that compares the application of an extended aseptic protocol in the management of the catheter with the use of the Twisterr versus a standard protocol, as an extra measure to avoid bacteremia

Results: The number of bacteremias was 34; 2(3.6%) in the TWR group vs 32(24.4%) in the standard protocol; Confirmed bacteremia ratio by guideline criteria; 0.11 vs 0.81 /1000 catheter days. This represents a mean length of stay of 0.23+/-1.21 Vs 3.40+/-6.86 (p 0.001) in favor of the extended protocol and therefore reduces the total cost per 1000 catheter days; 4,884.6 Vs 5,992.08 euros in favor of TWR. In the binary logistic regression, the only factor (analyzed DM, Cardiopathy, catheter days, Starting Age, Sex and Chalson Index) with statistical significance is the center where the catheter is treated. P0,014

Conclusions: The use of the TWR system seems to be a useful tool in its fight. Among the weaknesses of the study are the non-randomization or extension to other areas. We believe that the design of studies for this purpose is necessary.

SA-OR42

Long-Term Outcomes of Subcutaneous vs. Transvenous Implantable Cardioverter Defibrillator Use among Dialysis Patients

Patrick H. Pun,[1,2] Li Qin,[3] Karl Minges,[3,4] Sana Al-Khatib,[1,2] Daniel J. Friedman.[1,2] *[1]Duke Clinical Research Institute, Durham, NC; [2]Duke University School of Medicine, Durham, NC; [3]Yale New Haven Health System, New Haven, CT; [4]Yale University School of Medicine, New Haven, CT.*

Background: Despite high risks of sudden cardiac death among dialysis patients, implantable cardioverter defibrillators(ICDs) have not been shown to improve mortality and are associated with high complication risks. Compared to transvenous(TV-) ICDs, subcutaneous(S-)ICDs may reduce the risk of infection, device- and vascular complications due to absence of intravascular leads. However, the long-term risks and benefits of S-ICD vs. TV-ICD in this population are unknown.

Methods: Retrospective analysis of ICD implants in Fee-For-Service Medicare beneficiary dialysis patients from 2012-2019 in the National Cardiovascular Data Registry ICD Registry. Outcomes were ascertained from Medicare claims data. We compared ICD and dialysis access complications, hospital admissions, and survival outcomes between eligible S-ICD and single chamber TV-ICD recipients using stabilized inverse probability of treatment weighting.

Results: 535 dialysis patients with S-ICDs and 842 with TV-ICDs met inclusion criteria. Median follow-up was 1.9 years. S-ICD recipients were younger, more likely to be Black, and had higher burdens of cardiac disease and prior dialysis access procedures. After propensity weighting, there was no difference in the risk of death (HR 1.12, 95%CI 0.96-1.30), device reoperation (HR 1.07, 95%CI 0.60-1.91), sepsis/bacteremia (HR 0.99, 95%CI 0.79-1.25) and hospital admission (HR 1.01, 95% CI 0.88-1.16) between ICD groups. Dialysis access interventions were more frequent among S-ICD recipients (8.4 vs 6.7% annually, p<0.01), but there was no risk difference after accounting for competing risks of death (HR 1.10, 95%CI 0.84-1.44).

Conclusions: In the largest longitudinal cohort of dialysis patients with S-ICD reported to date, compared to TV-ICD recipients, S-ICD was not associated with improved survival, device- and dialysis access-complication rates.

Use of a Digital Stethoscope to Evaluate Arteriovenous Fistulae before and after Intervention

Saad Mohammed Shariff,[1] Samuel Haddad,[1] Sora Lee,[1] Spencer Kieu,[2] George Mathew,[2] Gang Xi,[1] Prabir Roy-Chaudhury.[1,3] *[1]The University of North Carolina at Chapel Hill Kidney Center, Chapel Hill, NC; [2]Eko Health, Emeryville, CA; [3]VA Salisbury Healthcare System, Salisbury, NC.*

Background: Arteriovenous fistula (AVF) maturation failure, defined as the inability of the AVF to support dialysis via two-needle cannulation, remains a common, costly, and deleterious problem among dialysis patients, with stenosis within the venous segment a common cause. Evaluation of AVF patency and flow currently relies on imaging techniques like doppler ultrasound and fistulagrams to assess AVF dysfunction, procedures that both generally occur outside of the dialysis unit. In an attempt to develop screening tools for vascular access dysfunction that could be used in the hemodialysis unit itself, we herein present before and after phonocardiogram recordings obtained from patients undergoing AVF angioplasty for AVF maturation failure.

Methods: By physical examination, we identified the site of the arteriovenous anastomosis. We used the Eko Littman® CORE Digital Stethoscope and Eko smartphone app to obtain phonocardiogram recordings from three sites associated with the AVF: distal venous (8cm distal to the anastomosis), proximal arterial (2cm proximal to the anastomosis), and distal arterial (2cm distal to the anastomosis). De-identified recordings were labeled by location and exported prior to analysis.

Results: We observed differences in both the amplitude and profile (Fig. 1) of phonocardiogram recordings taken at the same site before and after intervention (angioplasty).

Conclusions: 1. We have demonstrated the technical feasibility of using a portable, user-friendly, digital stethoscope and smartphone app in the setting of AVF maturation failure. 2. Clear differences in both the amplitude and profile of AVF phonocardiograms suggest that the Eko device could be used to risk stratify patients at high risk of a failed angioplasty for AVF maturation. 3. The Eko phonocardiograms could be an effective, low-cost screening tool for angioplasty success or failure in the setting of AVF maturation failure in the hemodialysis unit itself.

Midterm Outcomes of a Novel First-in-Human Percutaneous Arteriovenous Fistula

Dirk M. Hentschel,[1] Robert Shahverdyan,[2] Erik van der Burg,[3] Shant M. Vartanian.[4,3] *[1]Brigham and Women's Hospital, Boston, MA; [2]Asklepios Kliniken Hamburg GmbH, Hamburg, Germany; [3]Venova Medical, Los Gatos, CA; [4]University of California San Francisco, San Francisco, CA.*

Background: Percutaneous arteriovenous fistulas (pAVF) can address barriers to starting hemodialysis with an AVF. Commercial devices often lose flow into the deep venous system, requiring reinterventions for effective cannulation. A novel implant-based pAVF was developed to create a single outflow AVF between the proximal radial artery and the cubital perforating vein, mimicking surgical AVF anatomy. The objectives of this study were to establish technical feasibility and safety.

Methods: The VENOS-1 trial (NCT 05757726) is a prospective, single-arm, early feasibility study. The primary endpoint is procedural success, and the primary safety endpoints are serious adverse device events and major reinterventions at 6 weeks. Secondary endpoints included physiologic maturation (flow > 500 ml/min and vein d. > 5 mm), reintervention rate, and functional maturation.

Results: Ten ESRD patients were enrolled with follow-up to 6 months. The average age was 45.1 yrs (range 27-61) and the BMI 24.3 kg/m^2 (SD ± 9.2). Procedural success was 100% with no safety events at 6 weeks. Mean brachial artery flow was 972 ml/min (SD ± 229 ml/min), and upper arm vein diameter increased to 6.3 mm (SD ± 1.0 mm). Physiologic maturation was achieved in all patients, on average by day 18 (range 13-40). No reinterventions were needed prior to maturation. Four of 10 patients achieved unassisted cannulation by 6 weeks, and two-needle cannulation of the cephalic vein was achieved in 70% of subjects by 6 months.

Conclusions: Mid-term results show this novel pAVF is highly effective at creating, maturing, and supporting early clinical use of a proximal forearm AVF. The method promotes rapid maturation without needing subsequent flow-diverting procedures and avoids thermal injury. These results suggest this novel pAVF could lead to more optimal starts in the HD population and warrants study in a larger patient population.

Funding: Commercial Support - Venova Medical

Photo-Activated Verteporfin-Loaded Polymeric Nanocarrier-Thermogel Hybrid System for Preventing Venous Neointimal Hyperplasia and Stenosis in Murine Arteriovenous Fistulas

Yongdong Wu, Ming Liang. *Guangzhou First People's Hospital, Guangzhou, China.*

Background: The patency of the Arteriovenous Fistula (AVF) is a prerequisite for the smooth operation of hemodialysis patients, while the dysfunction of vascular access due to endothelial hyperplasia and stenosis is an important factor in the increase of mortality in patients, and the transformation of VSMCs and their migration is an important factor in the endothelialization of AVFs. The Hippo-YAP signaling pathway regulates the proliferation and migration of VSMCs, which are involved in the process of vascular injury and remodeling. Verteporfin (VER) has great potential as a YAP inhibitor to ameliorate AVF intimal hyperplasia, but how to deliver VER to the stenosis site effectively and release VER in a controlled manner is a challenge.

Methods: 1. Expression of YAP in the neointima of arteriovenous fistula and its role in the proliferation of vascular smooth muscle cells; 2. Construction and characterization of nanoparticle/hydrogel system loaded with verteporfin; 3. The effect of blocking YAP signal by ^{TK}hbPPE/VER@PPP system on VSMCs proliferation; 4. Exploration of ^{TK}hbPPE/VER@PPP system in AVF of CKD mice.

Results: 1. The high expression of YAP in the neointima of arteriovenous fistula was associated with the migration and proliferation of vascular smooth muscle cells. 2. ^{TK}hbPPE/VER@PPP nanoparticle/hydrogel system loaded with verteporfin was successfully constructed. 3. The effect of blocking YAP signal by ^{TK}hbPPE/VER@PPP system on VSMCs proliferation. 4. Application of drug-loaded nanoparticle/hydrogel ^{TK}hbPPE/VER@PPP system in mouse blood vessels.

Conclusions: 1. There was high expression of YAP protein in the neointima of the arteriovenous fistula of mice, and YAP was involved in the proliferation and migration of vascular smooth muscle cells. 2. The drug-loading nanoparticles ^{TK}hbPPE/VER were successfully prepared and characterized, and the drug-loading nanoparticle/hydrogel system ^{TK}hbPPE/VER@PPP was constructed. 3. The system can promote the self-degradation of drug-loaded nanoparticles through red light irradiation, release VER, inhibit cell proliferation and migration by acting on VSMCs, and downregulate the expression of YAP protein in cells. 4. The g^{TK}hbPPE/VER is capable of perivascular retention and photoregulated release of VER to ameliorate AVF endothelial stenosis.

Impact of Simulated Microgravity on Human Kidney Function: Identification of Early Biomarkers and Orthostatic Intolerance during Bedrest

Giovanna Valenti, Annarita Di Mise, Marianna Ranieri, Mariangela Centrone, Maria Venneri, Angela Ferrulli, Grazia Tamma. *Universita degli Studi di Bari Aldo Moro, Bari, Italy.*

Background: Astronauts have been reported to have an unusually high rate of kidney stone formation during spaceflight, which represents a risk for the heath and for the space mission success. Studies in humans adapted to actual or simulated microgravity (bedrest) demonstrate that exposure to microgravity results in alterations of renal function, fluid redistribution, and bone loss, which is coupled to a rise of urinary calcium excretion thus increasing the risk of renal stone formation. However, high calcium delivery to the collecting duct reduces local Aquaporin 2 (AQP2)-mediated water reabsorption under vasopressin action, thus limiting the maximal urinary concentration to reduce calcium saturation. To investigate early renal adaptation into simulated microgravity, we investigated the effects of 10 days of strict bedrest in 10 healthy volunteers.

Methods: Ten young healthy, were enrolled in the study. Each subject was evaluated before and after 10 days of strict horizontal bedrest and during bedrest no deviations from the lying position was allowed. Orthostatic blood pressure was measured during supine to stand test immediately after waking up after 10 days of bedrest. For each subject, blood and spot urine samples were taken every day and urinary excretion of AQP2 was quantified by ELISA. Other biomarkers were measured in the urine or in blood.

Results: 10 days of immobilization was associated with a transient, significant decrease (day 5) in vasopressin (copeptin) paralleled by a decrease in AQP2 excretion, consistent with an increased central volume to the heart, resulting in reduced water reabsorption. Moreover, bedrest caused a significant increase in calciuria secondary to bone demineralization paralleled by a decrease in PTH. Urinary osteopontin, a glycoprotein exerting a protective effect on stone formation, was significantly reduced during bedrest. A significant increase in adrenomedullin, a peptide with vasodepressor properties, was observed at day 5, which may contribute to the known reduced orthostatic capacity postbedrest.

Conclusions: We conclude that renal function is altered in simulated microgravity and is associated with an early increase in the risk of stone formation and reduced orthostatic capacity post-bedrest within a few days of inactivity.

Plasma Sodium Correction Rates in Patients with Severe Hyponatremia Treated with Hypertonic Saline with and without Desmopressin

Zain AlShanableh,[1] Anna Ralchenko,[1] Jonathan G. Yabes,[2] Richard H. Sterns,[4] Steven D. Weisbord,[2,3] Helbert Rondon Berrios.[2,1] *[1]UPMC, Pittsburgh, PA; [2]University of Pittsburgh School of Medicine, Pittsburgh, PA; [3]VA Pittsburgh Healthcare System, Pittsburgh, PA; [4]University of Rochester School of Medicine and Dentistry, Rochester, NY.*

Background: Co-administration of desmopressin and hypertonic saline 3% (HTS) from the outset of treatment (the "DDAVP clamp") has been suggested to prevent inadvertent overcorrection of hyponatremia, but the effectiveness and safety of this strategy remain uncertain.

Methods: We identified adult patients hospitalized between 7/1/18 and 6/30/23 at four UPMC hospitals with a plasma sodium (PNa) ≤120 mEq/L at admission or during hospitalization who were treated with HTS, excluding patients on renal replacement, eGFR <15 ml/min/1.73m2, plasma glucose >300 mg/dl, prior desmopressin treatment, or absence of PNa data within 12 h of starting HTS. Between-group comparisons were performed using t-test and Chi-square or Fisher exact test.

Results: A total of 184 patient admissions (57.6% female, mean age 60.6 years) met inclusion and exclusion criteria. Hyponatremia was chronic in 92.9%; leading causes were SIAD (51.6%), hypovolemia (25.5%), and low solute intake (15.8%); and 20.1% had seizures. Cases treated with HTS and desmopressin (n=46) were compared to cases treated with HTS without desmopressin (n=138). Despite a lower baseline PNa (110.5±6.4 vs. 115.1±7.2 mmol/L, p<0.001), correction by >8 mEq/L (6.5% vs. 27.5%, p=0.006) or >10 mEq/L (0% vs. 15.2%, p=0.011) within the first 24 hours was significantly less frequent in the desmopressin group than in the non-desmopressin group. Furthermore, presumably to prevent or reverse overcorrection, desmopressin was given to 40% of patients in the non-desmopressin group within 48 h of HTS initiation. Hospital mortality (6.5% vs. 6.5%, p>0.99), length of hospital (12.2 d vs. 11.8 d, p=0.810) and ICU stays (5.8 d vs. 5.5 d, p=0.678), fluid overload (8.7% vs.9.6%, p>0.99), and worsening of hyponatremia (2.2% vs. 1.5%, p>0.99) were similar in the two groups (HTS and desmopressin vs. HTS alone) but PNa was checked significantly more often in the desmopressin group (20.7 vs. 17.4, p<0.001). No cases of osmotic demyelination syndrome were identified.

Conclusions: Treating severe hyponatremia with HTS and desmopressin was associated with lower rates of rapid correction without significant adverse events compared to HTS alone.

SA-OR48

Mortality and Neurologic Complications Associated with Rapid vs. Slow Correction of Severe Hyponatremia

Juan Carlos Ayus,[1] Pablo N. Cherne,[2,3] Nora Fuentes,[2,3] Ezequiel P. Libovich,[2,3] Sofia Vartorelli,[2,3] Camila Naudi,[2,3] Gino Bonetto,[2,3] Jessica Moreira,[2,3] Martina Flamini Marczuk,[2,3] Michael L. Moritz,[4,5] Anaclara Murujosa.[2,3] *[1]University of California Irvine School of Medicine, Irvine, CA; [2]Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; [3]Hospital Privado de Comunidad, Mar de Plata, Argentina; [4]University of Pittsburgh School of Medicine, Pittsburgh, PA; [5]UPMC Children's Hospital of Pittsburgh, Pittsburgh, PA.*

Background: Hyponatremia guidelines recommend limiting the rate of correction within the first 24 hours for patients with serum sodium (SNa) ≤ 120 mEq/L to prevent osmotic demyelination syndrome (ODS). Recent studies suggest rapid correction of ≥ 8 mEq/L in the first 24 hours may reduce mortality without increasing ODS risk.

Methods: A single-center retrospective observational study conducted in Buenos Aires, Argentina, evaluating the impact of rapid (≥ 8 mEq/L) versus slow correction (< 8 mEq/L) of severe hyponatremia on mortality and ODS. Hospitalized adults with severe hyponatremia (SNa ≤ 120 mEq/L) upon admission between 2010 and 2023 were enrolled. Analysis involved logistic regression and propensity score-inverse probability weighting, adjusting for confounders

Results: The cohort included 2037 patients. Rapid correction occurred in 53%, with mean 24-h rates of 12.4 ± 3.9 mEq/L and 4.1 ± 2.6 mEq/L for rapid and slow groups, respectively. Rapid correction was associated with lower in-hospital and 30-day mortality. The adjusted odds ratio (OR) for in-hospital mortality was 0.59 (0.44 - 0.76), adjusted OR was 0.66 (0.49 - 0.89). ODS incidence was rare (0.14%) and not linked to rapid correction.

Conclusions: Rapid correction of severe hyponatremia by ≥ 8 mEq/L within 24-h is associated with decreased adjusted mortality without an increased risk of ODS.

Rapid vs slow correction within 24-h of admission

Characteristic	< 8 mEq/l/24hours	≥ 8 mEq/l/24hours	p
No. of patients	939	1098	–
Age – years	77.8 ± 13.8	76.8 ± 14	0.149
Male sex	319 (34)	302 (27.5)	0.002
Charlson Comorbidity Index ≥ 6	298 (31.7)	356 (32.4)	0.777
SNa at admission (mEq/L)	116.6 ± 3.6	115.4 ± 4.3	< 0.001
Δ SNa at 24-hour post- admission (mEq/L)	4.1 ± 2.6	12.4 ± 3.9	< 0.001
In – hospital mortality	138 (14.7)	100 (9.1)	< 0.001
30-Day mortality	173 (18.4)	136 (12.4)	< 0.001

Model 2: Model 1 + cancer, cirrhosis, congestive heart failure, dementia, COPD and psychiatric disease
Propensity score–IPW: age, admission SNa and SK, hypertonic saline use, congestive heart failure, cirrhosis and cancer

SA-OR49

Critical Appraisal of Volume Status, Urine Sodium Concentration, and Urine Osmolality in the Differential Diagnosis of Hypotonic Hyponatremia

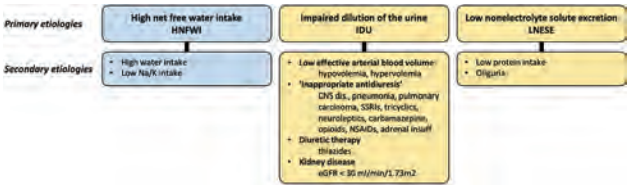
Florian Buchkremer,[1] Bettina Winzeler,[2] Stephan Segerer,[1] Mirjam Christ-Crain.[2] *[1]Kantonsspital Aarau AG, Aarau, Switzerland; [2]Universitatsspital Basel, Basel, Switzerland.*

Background: Traditional algorithms of hypotonic hyponatremia use specific thresholds of volume status, urine sodium concentration (una), and urine osmolality (uosm) to identify its most relevant pathomechanism. In contrast, we hypothesized, that different etiologic factors occur together and that these thresholds do not reliably discriminate between them.

Methods: We used patient data (n=298) from a previous, prospective, observational study. We analyzed multiple etiologies of hypotonic hyponatremia (Figure) in subgroups defined by volume status (hypo-/eu-/hypervolemia), una (<= or > 30mmol/l), and uosm (<= or > 100mosm/kg). We quantified three primary etiologies (Figure), (1) high net free water intake (HNFWI), (2) impaired dilution of the urine (IDU), and (3) low nonelectrolyte solute excretion (LNESE), by projected, equivalent treatment effects, the 'standard delta sodium' values (Buchkremer F et al., Kidney Int Rep. 2023).

Results: Prevalence and extent of all primary etiologies (Figure) showed only minor variations between hypo-, eu-, and hypervolemic patients. With una >30mmol/l, the impact of IDU was significantly higher than with una <=30mmol/l, while HNFWI and LNESE were similar in both groups. Uosm <=100mosm/kg did identify patients with very high levels of HNFWI. However, this group consisted of only 4 individuals, a mere 1.3% of the whole cohort, and less than 5% of those patients, where HNFWI had the highest quantitative impact of all primary etiologies. As a remarkable result among the secondary etiologies, we found that factors associated with 'inappropriate antidiuresis' (Figure) were present in 63.8% of all patients and that their prevalence was independent of volume status and una. Notably, two thirds of these patients showed additional secondary etiologies of IDU, that would preclude a traditional diagnosis of SIAD.

Conclusions: Current thresholds of volume status, urine sodium concentration, and urine osmolality provide only limited etiologic differentiation of hypotonic hyponatremia and do not reflect its mostly multifactorial etiology.



SA-OR50

Detection of Low Osmolar Excretion Rate for the Etiology of Hyponatremia

William Da Silva,[1,2] Alexander M. Smith,[1,2] Karthik Kovvuru,[1,2] Juan Carlos Q. Velez.[1,2] *[1]Ochsner Medical Center, New Orleans, LA; [2]The University of Queensland, Brisbane, QLD, Australia*.

Background: Low solute intake and resulting low osmolar excretion rate (OER), colloquially known as "tea/toast" diet, is a known precipitant of hyponatremia (hypoNa). However, diagnostic evaluation of hypoNa does not routinely include assessment of OER. We hypothesized that identification of low OER by a 24-hr urine collection may help unmasking low solute intake as a cause or aggravating factor of hypoNa.

Methods: A retrospective review of medical records was conducted searching for cases of hypoNa seen in our nephrology clinic who completed a 24-hr urine collection to measure volume (V), urea nitrogen (UN), sodium (Na) and potassium (K) over a 6-year period. HypoNa was defined as a serum Na < 135 mmol/L. We defined low OER as < 6 mOsm/kg/day and was calculated as: [2 (Na + K) + UN/2.8]*V. Low protein intake (< 8 g UN/day), low Na intake (< 100 mmol/day) and low K intake (< 60 mmol/day) were also estimated. In a subset of patients with low OER, we assessed the impact of increasing solute intake on correction of hypoNa (serum Na rise ≥ 4 mmol/L). SIADH was diagnosed by spot urine Na, spot urine osmolality and standard criteria.

Results: We identified 24 patients who met the criteria. Median age was 71 years, median BMI was 25 kg/m^2, median weight was 74 kg, 58% women, 96% white. Median serum Na was 130 mmol/L (range 121 – 132). By 24-hr urine, UN was assessed in all 24 patients, Na in 22 (92%) and K in 19 (79%). Full OER was completed in 17 patients: 11 (65%) had low OER. Moreover, low Na intake, low K intake, and low protein intake were found in 64%, 52% and 73%, respectively. SIADH was the cause of hyponatremia in 13/19 patients with available spot urine osmolality (68%), and among them, 9/11 (82%) had low OER. Following implementation of higher dietary solute intake, OER increased by ≥ 25% (by 69% on average) in 4/5 (80%) and hypoNa improved by ≥ 4 mEq/L (by 6 mEq on average) in all of those who increased solute intake.

Conclusions: Our findings revealed evidence of low solute intake in an ambulatory cohort of patients with chronic hypoNa. Thus, assessment of OER via 24 hour urine collection may be a useful test to identify individuals in whom low solute intake may drive or contribute to the etiology of chronic hypoNa, particularly in cases of SIADH, and to track responses to dietary therapeutic interventions.

SA-OR51

Copeptin and Body Fluid Responses to the Combined Use of an SGLT2 Inhibitor and Conventional Diuretics in Patients with CKD: The DAPA-BODY Trial

Takahiro Masuda, Maki Kinoshita, Kentaro Oka, Tetsu Akimoto, Daisuke Nagata. *Jichi Medical Univeristy, Shimotsuke, Japan*.

Background: We previously reported that SGLT2 inhibitors exert sustained fluid homeostatic actions through compensatory increases in osmotic diuresis-induced vasopressin secretion and fluid intake (Physiol Rep 2020, AJP Renal 2022). However, SGLT2 inhibitors alone do not produce durable amelioration of fluid retention.

Methods: We examined the comparative effects of the SGLT2 inhibitor dapagliflozin (SGLT2i group, n=53) and the combined use of dapagliflozin and conventional diuretics including loop diuretics and/or thiazides (SGLT2i+diuretic group, n=23) on serum copeptin, a surrogate marker of vasopressin release, and body fluid status measured by bioimpedance device (InBody S10).

Results: After six months of treatment, the change in copeptin was significantly lower in the SGLT2i+diuretic group than in the SGLT2i group (SGLT2i 31.5±56.3% vs. SGLT2i+diuretic -1.4±31.5%, p=0.0153). The change in the estimated plasma volume calculated using the Strauss formula (-1.7±5.2% vs. -2.6±5.3%, p=0.2563) and brain natriuretic peptide (26.3±84.5% vs. 4.0±60.8%, p=0.1716) were not significantly different between the two groups. Contrastingly, changes in interstitial fluid (-1.7±5.4% vs. -8.8±12.5%, p=0.0013), extracellular water (-1.7±5.4% vs. -8.8±12.5%, p=0.0013), intracellular water (-2.1±5.1% vs. -5.8±9.3%, p=0.0183), and total body water (-2.1±4.8% vs. -6.2±9.0%, p=0.0089) were significantly lower in the SGLT2i+diuretic group than in the SGLT2i group. Changes in renin (16.3±102.8% vs. 26.6±91.0%, p=0.3765) and aldosterone (9.8±48.0% vs. 20.3±52.0% p=0.2560), and absolute epinephrine levels (21.3±13.8 pg/mL vs. 21.0±10.4 pg/mL, p=0.4854) were not significantly different between the two groups.

Conclusions: The combined use of the SGLT2 inhibitor dapagliflozin and conventional diuretics inhibited the increase in copeptin levels and remarkably ameliorated fluid retention without excessively reducing plasma volume and activating the renin-angiotensin-aldosterone and sympathetic nervous systems.

SA-OR52

Anchoring Sepsis Management: A Retrospective Cohort Study on Fluid Resuscitation in Advanced and ESRD

Hunter Reed, Abraheim AL-Nasseri, Adam M. Robarge, Usman Kazi, Ahmed Eddib. *HCA Florida Citrus Hospital, Inverness, FL*.

Background: Physicians are hesitant to give fluid boluses to renal failure patients, which is significant given the frequency end stage renal disease (ESRD) patients develop sepsis and septic shock. The aim of this study was to assess the relationship between the volume of fluid given for sepsis and mortality in patients with advanced chronic kidney disease (CKD) and ESRD.

Methods: A multicenter retrospective cohort study of CKD and ESRD patients who were admitted for sepsis was conducted across 16 West Florida hospitals. Inclusion criteria was non-pregnant adult patients admitted between January 1, 2021 and December 31, 2022 with CKD4, CKD5 or ESRD for sepsis and having received a fluid bolus within 6 hours of admission. Patients (n=4,265) were grouped by Standard (greater than 30mL/kg), Conservative (15-30ml/kg), or Ultra-conservative (less than 15mL/kg) fluid bolus. Sub-analysis was then performed among those patients who were either oliguric (less than 0.5mL/kg/hr) or anuric (n=2,344). Inhospital mortality was the primary outcome assessed, with secondary outcomes of ICU admission, vasopressor use, mechanical ventilation, and inpatient initiation of dialysis (IID).

Results: In the Ultra-conservative group there was a reduction in odds ratio (OR) of vasopressor use (OR 0.723) and ICU admission (OR 0.484), with an increase in IID (OR 1.45) compared to Standard. No difference was seen in mortality or mechanical ventilation. In the Conservative group there was a reduction in vasopressor use (OR 0.717) and ICU admission (OR 0.67). No difference was seen in mortality, mechanical ventilation or IID. Within the oliguric and anuric subgroup, the Ultra-conservative group only had a significant reduction in Mechanical ventilation (OR 0.703) and ICU admissions (OR 0.536). Within the oliguric and anuric subgroup, the Conservative group had no difference in outcomes compared to Standard.

Conclusions: There was no significant difference in mortality in either decreased volume group compared to Standard, although differences in ICU, vasopressor and dialysis use were noted. This study supports physician discretion for fluid bolus to patients who have poor renal function.

Outcomes in CKD and ESRD	<15ml/kg vs >30ml/kg Ultra-conservative				15-30mL/kg vs >30mL/kg Conservative				Outcomes in CKD and ESRD with Oliguria or Anuria	<15ml/kg vs >30mL/kg Ultra-conservative				15-30mL/kg vs >30mL/kg Conservative

Identifying Opportunities to Reduce Fluid Overload: A Multicenter Quality Improvement Partnership

Adam Dziorny,[1] Ulka Kothari,[2] Stephen C. Drury,[1] Heda R. Dapul,[2] Ami Shah,[2] Julie C. Fitzgerald,[3] Chloe G. Braun,[4] Andrew J. Barbera,[4] James D. Odum,[4] Susan D. Martin,[1] Denise C. Hasson.[2] *[1]University of Rochester Medical Center, Rochester, NY; [2]New York University Grossman School of Medicine, New York, NY; [3]The Children's Hospital of Philadelphia, Philadelphia, PA; [4]The University of Alabama at Birmingham, Birmingham, AL*.

Background: Fluid overload (FO), characterized by a pathological percentage cumulative fluid balance (%CFB), is prevalent among critically ill children and is linked to extended length of stay (LOS), morbidity, and mortality. The objective of this project is to reduce FO and associated %CFB in Pediatric Intensive Care Units (PICUs). We automated data collection across this multisite quality improvement collaborative through a federated data collection framework, local analysis, and central result aggregation. By applying this paradigm alongside sampled observations and nursing surveys, we aimed to identify strategies to reduce %CFB and ultimately enhance patient outcomes.

Methods: We identified key drivers of ICU positive %CFB, developed SMART Aims, and chose key metrics including demographics, %CFB, urine occurrence counts, relationship to Holliday-Segar (H-S) maintenance fluid rates, and associations with mechanical ventilation (MV) and ICU LOS. Individual sites extracted data, ran analysis scripts, then collected rounds' discussions of FO and nursing surveys.

Results: Over a 6-month period we included 2336 ICU encounters encompassing 1984 children. Mean number (%) of patients with day 2 CFB >5% significantly differed by site (A: 153 (54.4%), B: 157 (37.6%), C: 489 (46.4%); p<0.001). Mean number of patients with urine occurrences and number of patients receiving >100% of H-S fluids on day 1 differed by site (p<0.001 for each). MV orders were significantly associated with receiving >100% of H-S fluids on day 2 at each site (A: 25.0% vs 15.4%; B: 34.0% vs 23.4%; C: 43.0% vs 15.8%). Days 1 and 2 CFB >5% was significantly associated with increased ICU LOS at each site (p<0.001). Rounds discussions (N=76 days, 791 patients) demonstrated 64.3% discussed fluid balance and 22.9% set fluid balance goal. Nurse survey results (N=117 nurses) were remarkably similar across sites, identifying barriers to accurate fluid balance capture, achievable opportunities for improvement, and desired educational opportunities.

Conclusions: Positive %CFB is a common but variable issue across multiple ICUs. Our findings pinpoint specific areas for improvement at each site, guiding the development of Plan-Do-Study-Act cycles for better fluid management.

Respiratory Alkalosis Accounts for Nearly Half of Cases of Low Serum Bicarbonate in Patients with Cirrhosis with AKI

Kirsten Johnson,[1] Dustin R. Chalmers,[4] Sumukh Shetty,[1] Montana D. Ellis,[1] Ghaith Hashem,[1] Vipin Varghese,[2] Juan Carlos Q. Velez.[3] Ochsner Group. *[1]UQ-Ochsner Clinical School, New Orleans, LA; [2]University of Michigan Division of Nephrology, Ann Arbor, MI; [3]Department of Nephrology, Ochsner Health, New Orleans, LA; [4]LSU Internal Medicine, Baton Rouge, LA.*

Background: Metabolic (Met) acidosis (Acid) is the most common acid-base disorder in the context of acute kidney injury (AKI). As a result, a low serum carbon dioxide (sCO_2) level from a chemistry panel in a patient with AKI is usually presumed to be caused by Met Acid. Respiratory (Resp) alkalosis (Alk) is the most common acid base disorder in cirrhosis. However, whether the predominance of Resp Alk prevails in cirrhosis even during AKI has not been investigated. We hypothesized that Resp Alk is a frequent cause of low sCO_2 in cirrhosis with AKI.

Methods: We prospectively collected data of patients seen in nephrology consultation for AKI who had a urine specimen subjected to microscopic examination of the urinary sediment (uSEDI) as part of the clinical evaluation. Within this cohort, we identified patients with cirrhosis with a low sCO_2 (< 22 mEq/L) in which acid-base status was assessed by either arterial blood gas (ABG) or venous blood gas (VBG) analysis. VBG results were corrected to an ABG equivalent (venous pH + 0.03 = arterial pH; venous $pCO_2 - 6$ = arterial pCO_2).

Results: Among 801 patients assessed by uSEDI over a 5-year period, 267 (33%) had cirrhosis. A low sCO_2 was recorded in 225/267 (84%). Among those with low sCO2, 109 (48%) had acid-base status assessed (77 ABG, 32 VBG). Mean age was 53 years, 44% women, 74% White, 16% Black, 4% Hispanic. Main causes of cirrhosis were alcoholic (58%) and NASH (20%). Main causes of AKI were ischemic/toxic acute tubular injury (49%) and hepatorenal syndrome (40%). Median serum creatinine at diagnosis was 3.6 mg/dL. The most common single acid-base disorders were Resp Alk in 25 (23%) and Met Acid in 24 (22%). Combined 2 disorders included Resp Alk + Met Acid in 34 (31%) and Met Acid + Resp Acid in 12 (11%) and Resp Alk and Met Alk in 6 (6%). A triple disorder was found in 16 (15%). Altogether, Resp Alk was found in 65 (60%). Furthermore, 27 (42%) of patients with isolated Resp Alk or combined Resp Alk + Met Acid (with pH > 7.35) were treated with oral or intravenous bicarbonate.

Conclusions: In patients with cirrhosis and AKI, sCO2 is often caused by Resp Alk. Default administration of bicarbonate supplementation without assessment of acid-base status should be avoided.

Extracellular Vesicles of Podocytes Impact Intraglomerular Signaling and Parietal Epithelial Cell Activation

Pamella Marie Sendon,[1] Alexander Pausch,[1] Annika Gathmann,[1] Kilian Teicher,[1] Inka C. Homeyer,[1] Moritz Lassé,[1] Anja Obser,[1] Hetty N. Wong,[2] Maja Lindenmeyer,[1] Lawrence B. Holzman,[2] Markus M. Rinschen,[1] Franz L. Ricklefs,[1] Uta Erdbruegger,[3] Victor G. Puelles,[1] Tobias B. Huber,[1] Fabian Braun.[1] Braun Lab. *[1]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]University of Pennsylvania, Philadelphia, PA; [3]University of Virginia, Charlottesville, VA.*

Background: Extracellular vesicles (EVs) have the ability to impact basic pathological processes such as malignant, metabolic and autoimmune diseases through intercellular signaling. However, we lack a concise knowledge about their role in kidney health and disease. Our study aims to characterize the intraglomerular signalling propagated by medium-sized (mEVs) and small EVs (sEVs) shed by podocytes.

Methods: Using differential (ultra-) centrifugation we separated mEVs and sEVs from cell culture supernatants, kidney tissue and urine samples. Using Western Blot, immunofluorescence microscopy employing antibody stainings and pKH membrane dyes as well as image flow cytometry and cryo-electron microscopy (cryo-EM) we investigated the release dynamics of podocyte-specific EVs in different models of murine podocyte damage *in vitro* and *in vivo*. Potential signaling factors contained in EVs were analysed through proteomics. Live microscopy and cross-culture experiments were used to determine the effect of podocyte specific EVs on parietal epithelial cells (PECs).

Results: Upon podocyte damage, we detected a unified response in the form of an increase in EV release with a size-shift towards larger vesicles revealed in Cryo-EM. Depending on EV size and the initial insult, podocyte-specific EVs exerted different effects on the migratory behavior and proliferation of PECs while proteomics revealed limited differences in the EV proteome in different stress conditions. We shortlisted the first candidate proteins potentially propagating the effect on PECs. *In vivo*, decreased EV release by podocytes resulted in reduced PEC activation and limited recruitment of macrophages in a model of crescentic glomerulonephritis.

Conclusions: We present essential insights on podocyte-specific release of different sizes of EVs, their protein contents and functional implications in health and upon podocyte damage. Ongoing experiments focus on further elucidating the impact of podocyte-specific release *in vivo* and the impact of knocking-out identified EV candidate proteins.

Rapid Podocyte Loss Triggers Formation of Intercellular Bridges

Nina Cintron Pregosin,[1] Emily T. Dang,[1] Yiqing Guo,[1] Robert Bronstein,[1] Chelsea C. Estrada,[1,2] Nehaben A. Gujarati,[1] Vivette D. D'Agati,[3] Lewis Kaufman,[4] Sandeep K. Mallipattu.[1,2] *[1]Stony Brook University Renaissance School of Medicine, Stony Brook, NY; [2]Northport VA Medical Center, Northport, NY; [3]Columbia University Irving Medical Center, New York, NY; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Podocytes are highly specialized terminally differentiated cells that are critical for maintenance of the glomerular filtration barrier. Podocyte loss triggers the activation and proliferation of PECs, leading to crescent formation and glomerular injury. We recently identified intercellular bridges between podocytes and PECs in murine models of proliferative glomerulopathy. However, the role of these bridges between podocytes and PECs is unclear. The goal of this study is to investigate the functional role of podocyte-PEC intercellular bridges in kidney diseases.

Methods: The following models of podocyte injury were used: podocyte-specific loss of *Klf4* (*Klf4*$^{\Delta Pod}$), nephrotoxic serum (NTS) treatment, diabetic kidney disease (*db/db*), HIV-1 transgenic mice (*Tg26*), lipopolysaccharide-induced podocyte injury (LPS), and human FSGS. Single-nucleus (sn)RNA-seq, immunohistochemistry, confocal, transmission and scanning electron microscopy (TEM, SEM) were performed. Bridges were studied *in vitro* using a coculture of immortalized mouse podocytes and PECs.

Results: Intercellular bridges formed in response to rapid podocyte loss (*Klf4*$^{\Delta Pod}$, *Tg26*, NTS, FSGS). In NTS-treated mice bridges formed after proteinuria occurred – suggesting bridges play a physiological, rather than pathological role. In contrast, limited bridges formed in models with slow podocyte loss (*db/db*) or no podocyte loss (LPS). SEM and TEM revealed multiple double-membraned cytoplasmic extensions on the podocyte cell body that resembled slender filopodia, with projections making bridges with neighboring cell bodies. Numerous projections extended from podocytes to the surface of cells lining the bowman's capsule. To identify a mechanism for bridge formation, snRNA-seq showed enrichment of several genes encoding trafficking proteins (BIRC3, RAB8A, RAB11A, DYNC1H1). Immunofluorescence staining of a coculture of mouse podocytes and PECs validated the presence of these proteins and mitochondria within intercellular bridges. Live imaging of DiD-labeled cells showed the transport of cellular vesicles via intercellular bridges.

Conclusions: Intercellular bridges form in response to rapid podocyte injury and may serve as a direct, physical mechanism for cellular trafficking between injured podocytes and PECs.

Intranephron Cross-Talk through Exosomes

Janina Kern,[1] Sindhu Thiagarajan,[1] Stefan Uderhardt,[2] Nina Sopel,[1] Mario Schiffer,[1] Janina Müller-Deile.[1] *[1]Universitatsklinikum Erlangen Medizinische Klinik 4 Nephrologie und Hypertensiologie, Erlangen, Germany; [2]Universitatsklinikum Erlangen Medizinische Klinik 3 Rheumatologie und Immunologie, Erlangen, Germany.*

Background: Insufficient cell-cell communication of glomerular endothelial cells (GECs) and podocytes leads to a dysfunctional glomerular filtration barrier and not much is known about the intra-glomerular as well as the glomerular to tubular signaling. Exosomes are 30 nm to 160 nm small extracellular vesicles released by multivesicular bodies from various cell types. These transport vehicles encapsulate signaling molecules such as mRNAs, microRNAs or proteins. Exosomes secreted from cells acing the urinary space might be taken up by tubular cells. However, it is unclear if exosomes can serve as mediators of GEC to podocyte crosstalk *in vivo* as it is unknown if they are able to pass the glomerular basement membrane (GBM).

Methods: RNA seq analysis and proteomics were used to characterize exosome cargo of glomerular cells. A CD63 (surface protein of exosomes) plasmid tagged with mScarlet and pHluorin (labeling intracellular exosomes in red and secreted exosomes in green) was used to investigate exosome secretion in glomerular cell culture models. By injecting zebrafish eggs in one cell stadium with a pHluorin CD63 reporter plasmid including one with a podocin promotor for podocyte specific exosome labeling, exosomes could be visualized in zebrafish larvae with a multiphoton microscope in high resolution. Moreover, *in vitro* labeled exosomes were injected in the zebrafish circulation and visualized with immunofluorescence and electron microscopy, to examine their ability to pass the GBM.

Results: *In vitro* podocytes and GECs secreted exosomes that could be live-tracked with the help of a spinning disc microscope. Live tracking analyses in 2D and 3D glomerular co-culture detected exosome-transfer from one cell type to another. Incubation of GECs derived exosomes changed expression in podocytes and likewise podocyte derived exosomes had effects on tubular cell expression. Injecting fluorescently labeled exosomes into the zebrafish circulation allowed to study the permeability of exosomes for the GBM. Using CD63 plasmids encoding podocyte-specific labeled exosomes helped to investigate cell-cell communication via exosomes originated from podocytes.

Conclusions: Live tracking experiments of glomerular cell type derived exosomes will help to get more insights into inter-glomerular and glomerular to tubular cell-cell communication.

Podocyte-Derived Soluble RARRES1: A Primary Instigator of CKD Progression via Direct Injury to Podocytes and Proximal Tubules

Ye Feng,[1] Zeguo Sun,[1] Jia Fu,[1] Fang Zhong,[1] Weijia Zhang,[1] Bi-Cheng Liu,[2] John C. He,[1] Kyung Lee.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Southeast University School of Medicine, Nanjing, China.*

Background: RARRES1 is a podocyte-enriched membrane protein, whose expression correlates with human glomerular disease progression. We previously showed that RARRES1 induces podocyte apoptosis to promote glomerulosclerosis. Interestingly, the cytopathic actions of RARRES1 are entirely dependent on its proteolytic cleavage into a soluble form (sRARRES1), as cleavage mutant RARRES1 exerted no effects. As RARRES1 expression is upregulated in glomerular diseases, here we investigated the functional consequence of podocyte-specific overexpression of RARRES1 in glomerular diseases.

Methods: Mice with podocyte-specific overexpression of human wildtype-RARRES1 (Pod-RARRES1^{WT}) were generated and subjected to adriamycin-induced FSGS and streptozotocin-induced DKD. We also examined the effects of long-term RARRES1 overexpression on slowly developing aging-induced kidney injury. Wildtype and transgenic mice with cleavage-mutant RARRES1 (Pod-RARRES1^{MT}) overexpression served as controls.

Results: Pod-RARRES1^{WT}mice had significantly worsened glomerular injuries and kidney function in all three models, while the phenotype of Pod-RARRES1^{MT} mice was indistinguishable from those of wildtype control mice. Remarkably, a direct uptake of sRARRES1 was observed in proximal tubules of injured Pod-RARRES1^{WT} mice and associated with exacerbated tubular injuries, vacuolation, and lipid accumulation in disease settings. Remarkably, the tubular uptake of sRARRES1 and injury was independent of albuminuria or glomerular injury, as RARRES1 podocyte expression alone was sufficient to induce tubular injury directly. scRNAseq analysis of mouse kidneys demonstrated RARRES1 led to a marked deregulation of lipid metabolism in proximal tubule subsets. We further identified matrix metalloproteinase 23 (MMP23) to be a podocyte-specific metalloproteinase responsible for RARRES1 cleavage in disease settings, as adeno-associated virus 9-mediated knockdown of MMP23 abrogated sRARRES1 uptake in tubular cells in vivo.

Conclusions: Our study delineates a previously unrecognized mechanism by which a podocyte-derived protein directly facilitates podocyte and tubular injury in glomerular diseases and suggests that podocyte-specific functions of RARRES1 and MMP23 may be targeted to ameliorate glomerular disease progression in vivo.

Organelle Communication and Maintenance of Podocyte Mitochondrial and Endosomal Homeostasis in Obesity-Related Kidney Diseases

Sho Hasegawa, Masaomi Nangaku, Madina Saipidin, Reiko Inagi. *Tokyo Daigaku, Bunkyo-ku, Japan.*

Background: Organelle stress exacerbates podocyte injury, contributing to perturbed lipid metabolism. Although organelles closely interact with one another at membrane contact sites, limited studies have explored their involvement in kidney homeostasis. The endoplasmic reticulum (ER) protein, PDZ domain-containing 8 (Pdzd8), is implicated in multiple organelle tethering processes and cellular lipid homeostasis. In this study, we aimed to elucidate the role of organelle communication in podocyte injury using podocyte-specific Pdzd8-knockout mice.

Methods: Podocyte-specific Pdzd8-knockout mice (podocin-Cre: Pdzd8 flox/flox) and littermate wild-type controls (Pdzd8 flox/flox) were generated. The mice were fed either a normal diet or a high-fat diet for 12 weeks. To elucidate the role of Pdzd8 in organelle stress, glomeruli were isolated for a comprehensive proteomic analysis. To corroborate *in vivo* proteomic phenotypes, cell culture experiments including lipidome analysis were performed using mouse podocyte cells.

Results: *In vivo*, Pdzd8 deletion exacerbated podocyte injury in an accelerated obesity-related kidney disease model. Proteomic analysis of isolated glomeruli revealed that Pdzd8 deletion exacerbated mitochondrial and endosomal dysfunction during podocyte lipotoxicity. Additionally, electron microscopy revealed the accumulation of "fatty abnormal endosomes" in Pdzd8-deficient podocytes during obesity-related kidney diseases. *In vitro*, Pdzd8 knockdown inhibited mitochondrial and fatty acid oxidation activity in podocytes, in association with a reduction of mitochondria-ER contact sites. In addition, enlarged endosomes were observed in palmitic acids-treated Pdzd8 knockdown podocytes, resembling *in vivo* "fatty abnormal endosomes." Lipidomic analysis indicated that glucosylceramide accumulated in Pdzd8-deficient podocytes, owing to accelerated production and decelerated degradation.

Conclusions: The organelle-tethering factor, Pdzd8, plays a crucial role in maintaining mitochondrial and endosomal homeostasis during podocyte lipotoxicity. Collectively, our findings highlight the importance of organelle communication at the three-way junction among the ER, mitochondria, and endosomes in preserving podocyte homeostasis.

Comprehensive Characterization of Podocyte Lipotoxicity to Elucidate New Mechanisms for Podocyte-Protective Strategies

Sebastian Sewerin,[1] Dylan Boone,[1] Lindsey Ross,[1] Choah Kim,[1] Juan Lorenzo B. Pablo,[1] Anna Greka.[1,2] *[1]Broad Institute, Cambridge, MA; [2]Harvard Medical School, Boston, MA.*

Background: Dyslipidemia constitutes a defining characteristic of nephrotic syndrome. Yet, its contribution to podocyte injury and how it affects their recovery potential is not well understood. Excess circulating lipids can induce a dysfunctional cell state, a phenomenon referred to as lipotoxicity. While podocyte lipotoxicity has been implicated in many diseases including diabetic kidney disease, it has only been studied in the context of a limited number of lipids. Free fatty acids (FFAs) are building blocks of many complex lipids found in human plasma and affect a wide range of cellular functions. Here, we systematically investigate the effects of a comprehensive library of >60 FFAs on podocytes using our FALCON (Fatty Acid Library for Comprehensive ONtologies) platform.

Methods: Through image-based FALCON screens, we assayed immortalized mouse podocytes for readouts such as cell morphology and viability. This allowed us to generate a functional lipotoxicity profile for podocytes which we compared to a similarly acquired profile from an immortalized human tubular epithelial cell (TEC) line. In isolated mouse glomeruli, we validated the most podocytotoxic FFA's deleterious effects using super-resolution microscopy and investigated the associated glomerular injury pattern. To assess the mechanistic underpinnings of FFA toxicity, we screened a library of 6800 small molecules for their potential to ameliorate FFA-induced podocyte injury.

Results: Screening a wide spectrum of structurally diverse FFAs, we generated a multi-dimensional lipotoxicity profile for podocytes, revealing distinct morphological states of FFA-treated cells and functionally diverse FFA clusters. This functional profile proved distinct from that of TECs. Toxic FFA-treated isolated mouse glomeruli exhibited podocyte foot process disintegration with a focal segmental glomerular injury pattern akin to focal segmental glomerulosclerosis. Targeted experiments showed that membrane rigidification and ER stress are involved in podocyte lipotoxicity. Finally, the compound library screen provided further insights into the mechanisms of lipotoxic injury.

Conclusions: Our FALCON platform and follow-on mechanistic studies provided a comprehensive characterization of lipotoxic injury in podocytes, with potential therapeutic implications for podocytopathies.

Inhibition of Sphingosine-1-Phosphate Receptor 4 Improves Renal Outcomes in a Mouse Model of Alport Syndrome

Matthew Tolerico, Arianna Carrazco, Judith T. Molina David, Armando Mendez, Alessia Fornoni, Sandra M. Merscher. Peggy and Harold Katz Family Drug Discovery Center. *University of Miami Miller School of Medicine, Miami, FL.*

Background: Col4a3 knockout (KO) mice, a model of Alport Syndrome, develop glomerular disease associated with renal neutral lipid accumulation and progressive renal failure that can be partially prevented and treated by lipid-lowering agents. Sphingosine-1-phosphate (S1P) is a bioactive sphingolipid which was found to accumulate in patients with nephrotic syndrome carrying mutations in the gene coding for S1P lyase. S1P exerts its effects by interacting with one of its five G-protein coupled receptors (S1PR1-5). The role of S1P signaling in podocytes and its therapeutic potential in glomerular disease is not well understood.

Methods: S1P levels were measured in kidney cortices of 8-week-old mice by LC-MS and normalized to protein concentration. S1PR4 expression levels in kidney cortices and cell lysates were determined by Western blot and qRT-PCR analysis. *In vitro*, podocytes were treated with an S1PR4 antagonist (CYM50358) for 24 hours. Neutral lipid levels were quantified using an enzymatic assay. Lipid droplets were stained by Nile Red staining and imaged on Opera Phenix HCS system. Apoptosis was determined by ApoTox-Glo™ Assay (Promega). CYM50358 (10mg/kg) was administered to *Col4a3*

KO by intraperitoneal injection starting at 4 weeks of age and until sacrifice at 8 weeks of age. Plasma and urine samples were collected at baseline and time of sacrifice and used to determine albumin to creatinine ratio (ACR), blood urea nitrogen (BUN), and plasma creatinine. Mesangial expansion was evaluated through Periodic Acid Schiff (PAS) staining. Renal fibrosis was evaluated by Picro-Sirius Red staining.

Results: Kidney cortices from *Col4a3* KO mice had increased levels of S1P, and S1PR4 expression. Immortalized podocytes isolated from *Col4a3* KO mice showed increased S1PR4 expression, apoptosis, and neutral lipid accumulation in form of lipid droplets. Antagonism of S1PR4 resulted in a reduction of apoptosis and neutral lipids. Treatment of *Col4a3* KO mice with a S1PR4 antagonist was sufficient to reduce ACRs, BUN, and plasma creatinine. Treated mice displayed reduced mesangial expansion and renal fibrosis.

Conclusions: Our results suggest that inhibition of S1PR4 may be beneficial in preventing glomerular disease progression in a mouse model of Alport Syndrome, possibly by reducing neutral lipid accumulation.

Early Intervention with Intravenous AAV9 Gene Therapy Significantly Improves Biomarkers and Phenotypes in a Floxed Mouse Model of X-linked Alport Syndrome

Hiroyuki Nakai,[1] Ranjan Das,[1] Taisuke Furusho,[1] Anusha Sairavi,[1] Hideyuki Hakui,[1] Shuhua Luo,[1] Lena Li,[1] Jeffrey H. Miner.[2] *[1]Oregon Health & Science University, Portland, OR; [2]Washington University in St Louis School of Medicine, St Louis, MO.*

Background: Previously, we established a novel floxed X-linked Alport syndrome (XLAS) mouse model. A delayed intervention with a higher dose of AAV-Cre (at 17 weeks of age) improved lifespan and reduced glomerulosclerosis and tubular injuries. Here, we report the results of an early intervention (before the onset of CKD) with a lower dose of AAV-Cre to these XLAS mice.

Methods: LSL-Col4a5 hemizygous male mice (n=3) were injected intravenously (IV) with 3.0 x 10^{11} vg of the AAV9-CAG-Cre vector at 4 weeks of age. They were monitored for body weight, urinary albumin-to-creatinine ratio (ACR), and blood biomarkers of chronic kidney disease (CKD). Type IV collagen expression recovery was evaluated using immunofluorescence microscopy and kidney histology was examined in H&E-stained sections.

Results: AAV-injected mice, unlike the untreated counterparts, exhibited no discernible loss of body weight until 31 weeks of age, indicating therapeutic effects. Rescue of collagens was confirmed in one of the mice at 21 weeks post-injection. The vector-treated XLAS mice showed significant rescue of Col4a4 and Col4a5 proteins in the glomerular basement membrane using anti-Col4A4 and anti-Col4A5 antibodies. A non-injected LSL-Col4a5 hemizygous mouse was used as a negative control. There was a significant reduction in urinary ACR in the vector-treated group at 10 and 13 weeks post-injection compared to the untreated control. Notable decreases in blood creatinine (treated vs. untreated: 0.3 vs. 0.7 mg/dL, n=2) and BUN (treated vs. untreated: 47 vs. 129 mg/dL, n=2) were observed in the treated group. Kidney histology revealed a noticeable reduction in glomerulosclerosis, tubular atrophy and interstitial fibrosis. These results illustrated the successful transduction of podocytes by IV-injected AAV9 vectors in juvenile mice, preceding CKD onset.

Conclusions: This study highlights a crucial advantage of early intervention with a lower AAV dose in XLAS mice in reducing blood biomarkers of nephrotic syndrome, which was not observed in a delayed intervention strategy of AAV gene therapy. Thus, this study offers pioneering evidence of the efficacy of intravenous AAV vector-mediated gene therapy for Alport syndrome, especially notable for its effectiveness at pre-CKD establishment.

Podocyte Gene Therapy Enables Glomerular Complement Modulation for IgAN Treatment

Ambra Cappelletto,[1] Rowan I. Asfahani,[1] James Matthews,[1] Alice Gennari,[1] Hannah L. Wood,[1] Sam Illingworth,[1] Gavin I. Welsh,[1,2] Alice C. Brown,[1] Moin A. Saleem.[1,2] *[1]Purespring Therapeutics, London, United Kingdom; [2]University of Bristol, Bristol, United Kingdom.*

Background: Adeno associated vector (AAV) gene therapy targeting the podocyte could pave the way to treat many glomerular diseases. We have recently shown successful podocyte targeting to rescue a genetic mutation. Here we present a novel AAV gene therapy candidate, PS-002, which targets podocytes enabling them to become 'bio-factories' secreting a complement regulator to specifically modulate complement activation in the glomerulus.

Methods: Efficacy of PS-002 was demonstrated using the grouped ddY mouse, a highly translationally relevant IgAN disease model. Safety and biodistribution of PS-002 were evaluated in Gottingen minipigs, a clinically translatable model for assessing dosing parameters via local infusion.

Results: The PS-002 candidate inhibited complement activation in grouped ddY mice as shown by reduced mesangial C3 deposits, and amelioration of disease phenotype by preservation of podocytes, reduction in mesangial expansion, inflammation and casts, and decreased proteinuria. In minipigs, we demonstrated successful gene expression across all kidney glomeruli at 28 days (100% glomeruli, n=3 pigs) and 56 days (99% glomeruli, n=3 pigs) post dosing, with a dose-response observed by RNAscope, qPCR and RT-qPCR. Low levels of AAV delivered protein were detected in the serum. These data demonstrate homogenous and sustained transduction of all kidney glomeruli using PS-002. Toxicological assessments of renal and other organ function and post-study histopathological assessments revealed no treatment-related safety concerns and only low levels of transcript were detected in the liver, with no expression in the spleen or pancreas.

Conclusions: These data demonstrate (i) the feasibility of podocyte targeted gene therapy for glomerular specific modulation of complement, (ii) substantial non-clinical data to enable translation of PS-002 to clinical development for the treatment of IgAN, and (iii) the potential to use podocyte targeting AAV candidates to regulate complement activation in diseases beyond IgAN.

SA-OR64

Ravulizumab in Atypical Hemolytic Uremic Syndrome: Final Analysis of Efficacy and Safety Outcomes in Two Phase 3 Trials

Bradley P. Dixon,[1] David Kavanagh,[9] Brigitte Adams,[10] Hee Gyung Kang,[2] Edward Wang,[3] Katherine Garlo,[3] Masayo Ogawa,[3] Spero R. Cataland,[4] Yoshitaka Miyakawa,[5] Yosu Luque,[6] Veronica Taylor,[7] Larry A. Greenbaum.[8] *[1]Renal Section, Department of Pediatrics, University of Colorado School of Medicine, Aurora, CO; [2]Division of Pediatric Nephrology, Department of Pediatrics, Seoul National University College of Medicine, Seoul, Republic of Korea; [3]Alexion, AstraZeneca Rare Disease, Boston, MA; [4]Division of Hematology, The Ohio State University Medical Center, Columbus, OH; [5]Department of Hematology, Saitama Medical University, Saitama, Japan; [6]Renal Intensive Care Unit, Nephrology Department, Tenon Hospital, Assistance Publique-Hôpitaux de Paris, Sorbonne Université, Paris, France; [7]Division of Pediatric Nephrology, University of Nebraska Medical Center, Children's Nebraska, Omaha, NE; [8]Division of Pediatric Nephrology, Emory University School of Medicine and Children's Healthcare of Atlanta, Atlanta, GA; [9]National Renal Complement Therapeutics Centre, Newcastle upon Tyne Hospitals NHS Foundation Trust and Translational and Clinical Research Institute, Newcastle University, Newcastle, United Kingdom; [10]University Hospital UZ Leuven, Leuven, Belgium.*

Background: Atypical hemolytic uremic syndrome (aHUS) is a rare thrombotic microangiopathy (TMA) caused by complement dysregulation. Ravulizumab (RAV) is a complement C5 inhibitor (C5i) approved for the treatment of aHUS.

Methods: This analysis reports final efficacy and safety data from two phase 3, single-arm clinical trials of C5i-naive adults (NCT02949128) and pediatric patients (pts) (NCT03131219) who were C5i-naive or switched to RAV from eculizumab (pediatric switch pts). Intravenous RAV was administered every 4–8 weeks, depending on body weight, in pts with aHUS. The primary endpoint was complete TMA response (platelet count normalization, lactate dehydrogenase normalization, and ≥25% improvement in serum creatinine from baseline, at two consecutive assessments ≥4 weeks apart). The primary endpoint evaluation was at Week 26; the extension period was up to 4.5 years or product approval/registration (whichever occurred first).

Results: 54 pts completed the study (C5i-naive adults: n=28; C5i-naive pediatric pts: n=16; pediatric switch pts: n=10). The median (interquartile range) treatment duration was 130 (49–178) weeks for C5i-naive adults, 131 (15–160) weeks for C5i-naive pediatric pts, and 114 (114–123) weeks for pediatric switch pts. Among pts with available genetic data, 12/45 (27%) C5i-naive adults, 10/17 (59%) C5i-naive pediatric pts, and 6/10 (60%) pediatric switch pts had complement abnormalities and entered the extension. In C5i-naive adults (n=56), complete TMA response rates were 54% at Week 26 and 64% at end of study. In C5i-naive pediatric pts (n=20), complete TMA response rates were 75% at Week 26 and 90% at end of study. Among C5i-naive adults and pediatric pts, mean eGFR gradually improved up to Week 26 and remained stable until the end of the study. Most adverse events and serious adverse events were Grade 1 or 2 and occurred up to Week 26. No meningococcal infections were reported.

Conclusions: This final analysis over a median of 114–131 weeks demonstrated that continuation of RAV treatment is associated with sustained control of aHUS and clinical benefit through improvement and long-term preservation of renal function, with no unexpected safety concerns.

Serial Measures of Urine Soluble CD163 Predict Kidney Failure in ANCA-Associated Glomerulonephritis

Sinead Stoneman,[1,2] Cliona Cowhig,[1] Conor Coughlan,[1] Niall P. Conlon,[3] Jean Dunne,[3] Jennifer Scott,[4] Julie Power,[4] Mark A. Little,[4] Michael Clarkson,[1,2] Sarah M. Moran.[1,2] On behalf of RITA-Ireland. *[1]Cork University Hospital, Cork, Ireland; [2]University College Cork, Cork, Ireland; [3]St James's Hospital, Dublin, Ireland; [4]Trinity Health Kidney Centre, Trinity College Dublin, Dublin, Ireland.*

Background: ANCA vasculitis-glomerulonephritis [AAV-GN] affects 70 – 85% of ANCA vasculitis [AAV] patients. 26% of patients progress to end-stage kidney disease [ESKD] and 43% progress without a recognised disease flare. Identifying those at highest risk of progression to kidney failure is an unmet need. Urine soluble CD163 [usCD163] has excellent biomarker characteristics and has been validated as a clinical biomarker in detecting active AAV-GN at diagnosis and flare. The use of usCD163 to predict ESKD in those considered to be in clinical remission is undefined.

Methods: We utilised longitudinal clinical data and biobank urine samples from a national multicentre rare kidney disease registry to evaluate the utility of serial usCD163 measurements to predict of kidney failure in AAV-GN. Inclusion criteria were 4 or more urine sCD163 measurements and diagnosis of AAV. The primary endpoint was kidney failure defined as death, ESKD or GFR <15mls/min/1.73m^2. Statistical analysis was performed using GraphPad Prism and R.

Results: We identified 113 participants with 4 or more usCD163 measurements over at least a 12-month period. 26 (23%) participants developed kidney failure (death (13), ESKD (17), GFR <15 (16)). Excluding the initial urine sample (generally from a period of disease activity) the median usCD163 level normalized to urine creatinine was higher in those meeting the endpoint (median 385ng/mmol vs 89ng/mmol, p<0.0001). In those with kidney failure 62.6% (128) of values were above the diagnostic threshold for active renal vasculitis. Analysis of this cohort identified the optimal diagnostic threshold for usCD163 for the future development of kidney failure as 160ng/mmol, with a sensitivity of 77.7%, a specificity of 69%, negative predictive value [NPV] of 92.3, and positive predictive value [PPV] 39.4.

Conclusions: A urine sCD163 result less than 160 ng/mmol has a strong NPV for predicting future kidney failure. This suggests that in addition to detecting active GN, urine sCD163 may provide reassurance that subclinical glomerular injury is not missed in AAV. The suppression of usCD163 associates with a significantly lower risk of progression to kidney failure, supporting a key role for undetected disease activity as the major driver of progression to kidney failure.

Efficacy and Safety of Iptacopan in Patients with C3 Glomerulopathy: 12-Month Results from the Phase 3 APPEAR-C3G Study

Carla M. Nester,[1] Richard J. Smith,[2] David Kavanagh,[3,4] Marina Vivarelli,[5] Giuseppe Remuzzi,[6] Ming-Hui Zhao,[7] Edwin K. Wong,[3,4] Yaqin Wang,[8] Angelo J. Trapani,[8] Induja Krishnan,[8] Nicholas J. Webb,[9] Matthias Meier,[9] Andrew S. Bomback.[10] *[1]The University of Iowa Stead Family Children's Hospital, Iowa City, IA; [2]The University of Iowa Roy J and Lucille A Carver College of Medicine, Iowa City, IA; [3]Newcastle University, Newcastle upon Tyne, United Kingdom; [4]National Renal Complement Therapeutics Centre. Royal Victoria Infirmary, Newcastle upon Tyne, United Kingdom; [5]Ospedale Pediatrico Bambino Gesu, Roma, Italy; [6]IRCCS Istituto di Ricerche Farmacologiche Mario Negri Centro Anna Maria Astori, Bergamo, Italy; [7]Peking Union Medical College Hospital, Beijing, China; [8]Novartis Pharmaceuticals Corporation, East Hanover, NJ; [9]Novartis Pharma AG, Basel, Switzerland; [10]Columbia University Vagelos College of Physicians and Surgeons, New York, NY.*

Background: The Phase 3 APPEAR-C3G study evaluated the efficacy, safety, and tolerability of iptacopan vs placebo in C3G patients (pts).

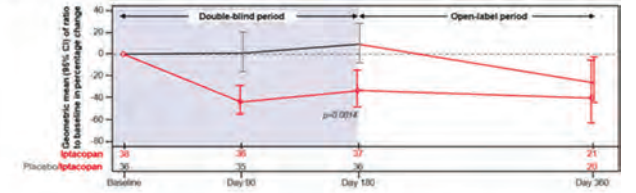
Methods: APPEAR-C3G (NCT04817618) was a multicenter, randomized, double-blind, placebo-controlled, pivotal Phase 3 study that included adult pts with biopsy confirmed C3G. The study comprised a 6 month (m) randomized double-blinded treatment with iptacopan 200mg bid. vs. placebo followed by 6m open-label iptacopan treatment, as previously described.[1]

Results: 74 pts were randomized 1:1 to either iptacopan (n=38) or placebo (n=36). Baseline pt demographics were generally balanced; the iptacopan arm exhibited a more severe disease phenotype. 43 (58.1%) pts in the iptacopan (n=22) and placebo (n=21) arms completed 12m treatment at data cut-off (when all pts completed 6m of treatment). The study met its primary endpoint, demonstrating a statistically significant reduction in 24h UPCR with iptacopan treatment at 6m (35.1%, 1-sided p=0.0014, 95% CI:13.8%, 51.1%) vs. placebo, sustained up to 12m (**Figure**). Iptacopan showed a sustained improvement in pts meeting the composite renal endpoint (≥50% reduction UPCR + ≤15% reduction in eGFR at 12m), 43.5% (iptacopan vs. placebo) and 25.0% (switched to iptacopan). Iptacopan led to improvements in the trajectory of eGFR compared to pts' historical eGFR decline. Iptacopan demonstrated a favorable safety profile with no new safety signals identified. Other 12m primary and key secondary endpoints will be presented.

Conclusions: Iptacopan demonstrated a significant and clinically meaningful proteinuria reduction on top of supportive care at 6m in the APPEAR-C3G study; sustained up to 12m. Iptacopan was well tolerated with a favorable safety profile in C3G pts. **Reference:** 1. Bomback AS, et al. *Kidney Int Rep*. 2022;7:2150–9

Funding: Commercial Support - Novartis Pharma AG

Figure. Proteinuria reduction (UPCR 24h) sustained to 12m



Full analysis set. Note that there was one intercurrent event of increasing corticosteroid dose on Day 106 in the iptacopan group
Robustness of primary endpoint results demonstrated by consistency of results across sensitivity analyses.

Avacopan beyond the 52-Week Treatment Course

Abdallah Sassine Geara,[1] Julia Ford,[2] Duvuru Geetha.[3] *[1]University of Pennsylvania, Philadelphia, PA; [2]University of Michigan, Ann Arbor, MI; [3]Johns Hopkins University, Baltimore, MD.*

Background: The landmark ADVOCATE trial treated patients with AVP for 52 weeks. In real-world use, some patients are prescribed AVP for a longer duration. In this study, we describe a multi-center experience of prolonged courses of AVP including the outcomes at 52w and adverse effects of AVP treatment beyond 52w.

Methods: We performed a multi-center retrospective cohort study of 15 pts with new and relapsing AAV treated with AVP for a duration of 52w or longer.

Results: Mean age 54 (20) years, 53% female, 10/15 MPO-AAV, 5/15 PR3-AAV 4/15 renal involvement and 5/15 relapsing AAV. RTX induction (12/15) and maintenance (14/15) All pts discontinued prednisone within the first 26w, mean eGFR rose by 15 and 18 mL/min/1.73m^2 at 26w and 52w respectively. Remission was 13/15 at 26w and 15/15 at 52w Reasons for treating with AVP beyond 52w: physician and/or patient preference in 12/15 pts, inability to give rituximab in 3/15 pts 8/15 stopped AVP after a median duration of 63 (7) w, 7/15 are still taking AVP for a median (IQR) duration of 99 (29) w Beyond 52w, 3/15 could not be maintained on rituximab During a mean follow-up period of 96 (21) w, 1/15 patients experienced AAV flare, and none progressed to ESKD. On last follow-up, the mean eGFR rise from baseline was 16 ml/min/1.73m^2. Infections were the most commonly reported adverse effects including 5 infections requiring hospitalization. No patient had to discontinue AVP due to abnormal LFTs during the follow up period.

Conclusions: This real-world experience shows that AVP is being used in real-world practice beyond week 52, with patient/physician preference being the main reason. Rituximab was used alongside AVP for remission maintenance in majority of patients. Infection complications were the most observed adverse effects. Further data on the longer-term use of AVP is needed.

Age Female	54 (20) 8
MPO PR3 Relapse	10 5 5
baseline BVAS baseline eGFR	19 (9) 36 (24)

SA-OR68

Noninvasive Assessment of the Presence or Absence of Histologic Activity in Kidney Biopsies from Patients with Lupus Nephritis

Jorge E. Rojas-Rivera,[1] Juan M. Mejia-Vilet,[2] Valeria Navarro Sanchez,[2] Brad H. Rovin.[1] *[1]The Ohio State University Wexner Medical Center, Columbus, OH; [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico.*

Background: Withdrawal of immunosuppressive therapy for lupus nephritis (LN) may be considered if histologic activity completely resolves. Soluble urine CD163 (uCD163) is released from intra-renal macrophages and strongly correlates with the LN activity index (AI). We examined whether uCD163 could differentiate histologically active from quiescent LN, avoiding the need for a repeat kidney biopsy before withdrawing therapy.

Methods: Urine collected at the time of diagnostic kidney biopsy from Ohio (OSU, discovery, n=119) and Mexican (MEX, validation, n=113) LN cohorts was assessed for uCD163 by ELISA. The relationship between uCD163 and AI was tested by Spearman's correlation. The ability of uCD163 to distinguish between the presence and absence of histologic activity was examined by receiver operating characteristic (ROC) analysis, and the strength of prediction by the area under the ROC curve (AUC).

Results: Table 1 shows the correlation between uCD163 and other commonly measured clinical parameters and components of the AI. uCD163 significantly associated with each AI component but correlated best with endocapillary hypercellularity. uCD163 distinguished the absence (AI=0) or presence (AI≥1) of biopsy histologic activity with AUCs of 0.778 (OSU) and 0.791 (MEX), and correctly classified 84% (OSU) and 93% (MEX) of patients. The AUCs to discriminate presence or absence of endocapillary hypercellularity were 0.805 (OSU) and 0.787 (MEX). The uCD193 cutoffs(Younden's Index) to differentiate AI=0 from AI ≥1 were 8.82 (OSU) and 8.83 (MEX) ng/mg creatinine.

Conclusions: Urine soluble CD163 is a robust noninvasive biomarker that accurately differentiates LN patients with ongoing disease activity from those with histologic resolution of LN. We suggest uCD163 may be used in lieu of a repeat biopsy to manage immunosuppression withdrawal in LN.

PRRC2A rs114580964 Variant as an Independent Predictor of Poor Kidney Prognosis in Chinese Patients with Lupus Nephritis

Wang Xiang, Xiuzhi Jia, Xi Xia, Rui H. Tang, Wei Chen. Chen Lab LN. *The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.*

Background: Lupus nephritis (LN) is a significant manifestation of systemic lupus erythematosus (SLE) with profound immune complex deposition in the glomerulus. The prognosis of LN varies across ethnic groups, with Asian populations often exhibiting higher rates of renal involvement and poorer outcomes. In our prior genome-wide association study, the PRRC2A variant rs114580964 was identified as a novel genetic determinant for susceptibility to LN. However, the correlation between the rs114580964 variant and clinical outcomes as well as prognosis of LN remains unclear.

Methods: This cohort study included 484 Chinese patients with LN in First Affiliated Hospital of Sun Yat-sen University. Clinical characteristics and outcomes were analyzed, with 469 patients included in the prognostic analysis after 15 patients were lost to follow-up. The primary outcome was the incidence of end-stage renal disease (ESRD).

Results: Among 484 patients, 24 (5%) had the rs114580964-AA/AC genotype, while 460 (95%) had the rs114580964-CC genotype. Patients with the rs114580964-AA/AC genotype exhibited weaker mesangial IgM deposition, lower erythrocyte sedimentation rate (ESR), and lower IgA levels compared to those with the rs114580964-CC genotype. Kidney survival analysis indicated that the rs114580964-AA/AC genotype was associated with poorer long-term kidney outcomes in LN. Cox regression analysis identified the rs114580964-AA/AC genotype as an independent risk factor for kidney survival in LN patients.

Conclusions: The PRRC2A rs114580964-AA/AC variant independently predicts poor kidney prognosis in Chinese patients with lupus nephritis.

Dispelling the Myth of Sex Differences in Lupus Nephritis (LN): A Pooled Analysis of 779 Patients

Kristina K. Nasr,[1] Ryan B. Coopergard,[1] Sisi Ma,[1] Brad H. Rovin,[2] Patrick H. Nachman.[1] *[1]University of Minnesota Medical School, Minneapolis, MN; [2]The Ohio State University Wexner Medical Center, Columbus, OH.*

Background: LN is reported to be more severe and have worse outcomes in men than women based on cohort studies with small numbers of men. We compared LN in men and women utilizing data pooled from 3 randomized controlled trials (RCT) and 7 cohort studies. We aimed to determine if differences exist for: 1- disease severity at diagnosis or flare; 2- first treatment choice; and 3- key outcomes at 1yr.

Methods: Baseline was defined as the date of LN flare. The entire data set was used to compare baseline characteristics between sexes and the outcomes at 1yr (complete renal response; composite of doubling of creatinine, dialysis, or death). Data were imputed using the median for variables with <30% missing data. Analysis of treatment choice (4 groups: cytotoxic, antimetabolite, calcineurin inhibitor, other) used only cohort data. Descriptive statistics used two-sample t-tests or Chi-square. Mixed model regression with studies as the random effects, controlled for age and race, were used to determine the effect size and p-values of sex on key clinical variables. For outcomes, we used logistic regressions controlling for treatments and baseline characteristics significantly correlated to outcomes.

Results: The pooled cohort included 94 men and 675 women (25% Asian, 11% Black, 53% White, 11% other). There were no statistically significant differences between sexes in age, race, duration of SLE or LN, C3, anti-dsDNA, LN class distribution or SLE Disease Activity Index 2K. No deaths were recorded. Key findings are in the table.

Conclusions: Compared to women, men have a lower eGFR and more proteinuria at baseline, but have similar LN class distribution and fewer have low C4. The lower eGFR may be related to markers of kidney histopathology (e.g. activity or chronicity indices) or comorbidities that were not captured. We found no significant outcome differences between sexes at 1yr adjusting for relevant variables in this large international pooled analysis.

Variable	Effect Size of Sex (M)	Raw p-value	BH corrected p-value
eGFR (ml/min/1.73m2)	-9.802	0.005	0.032
24 hr Urine Protein (g/day)	1.013	0.005	0.032
Complement C4 (% abnormal)	0.494	0.007	0.032
First Treatment Choice	N/A	0.472	N/A
Doubling S.Cr or Dialysis	0.975	0.320	0.568
Complete Renal Response	0.948	0.366	0.568

Increased Risk of Cancer in Glomerular Diseases: A Population-Level Analysis

Jialin Han,[1] Yinshan Zhao,[1] Mark Canney,[2] Mohammad Atiquzzaman,[1] Adeera Levin,[1,3] Sean Barbour.[1,3] *[1]The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada; [2]University of Ottawa, Ottawa, ON, Canada; [3]BC Provincial Renal Agency, Vancouver, BC, Canada.*

Background: Patients with glomerular disease (GN) may be at an increased risk of cancer due to immunosuppression, chronic inflammation and infection with oncogenic viruses. However, there is limited epidemiologic data such that the absolute risk of cancer and cancer-related risk factors in GN remain unknown.

Methods: We conducted a population-level analysis of all adults with biopsy-proven GN in British Columbia, Canada from 2000 to 2020, using a centralized pathology database linked to a provincial cancer database. Age- and sex- standardized incidence ratios (SIR) of cancer events were calculated. Kaplan-Meier curves were used to describe time to the first cancer event.

Results: The cohort comprised 4,006 patients, including IgAN (N=1200), membranous nephropathy (MN, N=542), FSGS (N=770), MCD (N=364), lupus nephritis (LN, N=528) and ANCA-GN (N=602). During a median of 7.9 years follow up, cancer events occurred in 386 patients (9.6%) including colon (N=56), lung (N=50), prostate (N=45), breast (N=24), kidney (N=23), lymphoma (N=22) and cervical (N=19) cancer. Those with cancer had more severe disease activity, with lower eGFR (45.3 vs 57.2 ml/min/1.73m^2) and higher proteinuria (2.5 vs 2.0 g/day), and more comorbidity burden at baseline. The risk of cancer was increased compared to the general population (SIR 1.5), including age groups 20-40, 40-60, 60-80, and >80 years (SIR 6.6, 1.7, 1.4 and 1.2 respectively). The risk of cancer was increased in ANCA-GN, FSGS, MN and MCD compared to IgAN or LN (Figure 1).

Conclusions: Patients with GN have an increased risk of cancer compared to the general population, particularly amongst younger patients who have a longer life expectancy and may benefit most from improved cancer screening. The risk of cancer varied by disease activity and type of GN, both of which may be correlated with immunosuppression use. Future steps will be to investigate risk factors for cancer in GN, including the type and extent of immunosuppression exposure.

Major Adverse Cardiovascular Events (MACE) in Proteinuric Glomerulopathies: A CureGN and NEPTUNE Study

Matthew Schuchman,[1,2] Christine B. Sethna,[1,2] Abigail R. Smith,[9] Crystal A. Gadegbeku,[3] Dorey A. Glenn,[4] Meryl Waldman,[5] Patrick H. Nachman,[6] Bryce A. Kerlin,[10] Bruce M. Robinson,[7] Fadhl Alakwaa,[7] Sharon G. Adler,[11] Agustin Gonzalez-Vicente,[8] Markus Bitzer,[7] Tarak Srivastava,[20] Myda Khalid,[17] Vimal K. Derebail,[18] Gentzon Hall,[21] Katherine R. Tuttle,[19] Michelle M. O'Shaughnessy,[22] Gabriel M. Cara-Fuentes,[16] Bethany A. Roehm,[15] Jarcy Zee,[14] Alexis C. Gomez,[12] Howard Trachtman,[7] Roy O. Mathew.[13] On behalf of the NEPTUNE Cardiovascular Working Group. *[1]Northwell Health, New Hyde Park, NY; [2]Cohen Children's Medical Center, Queens, NY; [3]Cleveland Clinic, Cleveland, OH; [4]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [5]National Institutes of Health, Bethesda, MD; [6]University of Minnesota Twin Cities, Minneapolis, MN; [7]University of Michigan Michigan Medicine, Ann Arbor, MI; [8]Case Western Reserve University, Cleveland, OH; [9]Northwestern University Feinberg School of Medicine, Chicago, IL; [10]Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; [11]Harbor-UCLA Medical Center, Torrance, CA; [12]Boston Children's Hospital, Boston, MA; [13]VA Loma Linda Healthcare System, Loma Linda, CA; [14]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [15]The University of Texas Southwestern Medical Center, Dallas, TX; [16]Nationwide Children's Hospital, Columbus, OH; [17]Indiana University, Bloomington, IN; [18]University of North Carolina Chapel Hill, Chapel Hill, NC; [19]Providence St Joseph Health, Renton, WA; [20]Children's Mercy Kansas City, Kansas City, MO; [21]Duke Health, Durham, NC; [22]University College Cork, Cork, Ireland.*

Background: Relationships between clinical characteristics and MACE have not been well characterized in patients with proteinuric glomerulopathies.

Methods: Participants in NEPTUNE and CureGN (N=3224) with biopsy-proven minimal change disease, focal segmental glomerulosclerosis, membranous nephropathy or IgA nephropathy/vasculitis were included. The primary outcome was time from enrollment to MACE (first heart failure, stroke, or coronary artery disease event). Crude Cox regressions (Table) identified clinical characteristics with p<0.2 for inclusion in multivariable Cox regression using backwards selection to find best fit for final model. Age, sex, obesity and days from biopsy were forced into the model *a priori* .

Results: Mean age was 33.3±21.5 yrs, 35% <18 yrs, median follow-up 55 months. 158 total events in 134 (4.2%) participants were recorded: 39 stroke, 47 heart failure, and 72 coronary artery disease. In multivariable modeling, older age (HR 1.04, CI 1.03-1.06 p<0.001), obesity (HR 1.56, CI 1.07-2.3 p=0.02), prior history of MACE (HR 11.46, CI 7.33-17.92, p<0.001) and chronic kidney disease (CKD) stage 5 (HR 4.41, 1.45-13.44, p<0.01) at enrollment were associated with MACE.

Conclusions: Surprisingly, proteinuria and glomerulopathies were not associated with MACE, but risk factors identified in other CKD cohorts retain importance. Further analyses will characterize additional non-traditional predictors of cardovascular disease.

Funding: NIDDK Support

Comparative Effectiveness of Immunosuppressive Medications in Nephrotic Syndrome: A Cure Glomerulonephropathy (CureGN) Study Report

Cal Robinson,[1,6] Pietro A. Canetta,[2] Gabriel M. Cara-Fuentes,[3] Larry A. Greenbaum,[4] Margaret Helmuth,[5] Michelle A. Hladunewich,[6] Jason M. Kidd,[7] Maria Larkina,[5] Kimberly J. Reidy,[8] Rulan S. Parekh.[9] *[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]Columbia University Irving Medical Center, New York, NY; [3]Nationwide Children's Hospital, Columbus, OH; [4]Emory University, Atlanta, GA; [5]University of Michigan, Ann Arbor, MI; [6]University of Toronto, Toronto, ON, Canada; [7]Virginia Commonwealth University, Richmond, VA; [8]Children's Hospital at Montefiore, New York, NY; [9]Women's College Hospital, Toronto, ON, Canada.*

Background: Rituximab is increasingly used to treat frequently-relapsing nephrotic syndrome in children and young adults. Yet, the real-world comparative effectiveness of immunosuppressive medications is unclear.

Methods: Using target trial methods, we emulated a multi-center, open-label, pragmatic randomized controlled trial with CureGN data. We included children and young adults (<40 years) diagnosed with minimal change disease (MCD) or focal segmental glomerulosclerosis (FSGS) that had prior complete remission and initiated rituximab, mycophenolate mofetil (MMF), or calcineurin inhibitors (CNI). Randomization was emulated by propensity score overlap weighting. The primary outcome was time-to-relapse using weighted Cox proportional hazards models.

Results: Of 221 eligible CureGN participants, 111 initiated rituximab, 46 MMF, and 64 CNI. Baseline characteristics were balanced after propensity score weighting. Mean age was 13.3 years and 80% had prior steroid-sparing drug use. During median 4.3-year (IQR 1.9-6.1) follow-up, relapse occurred in 56%, 46%, and 58% after rituximab, MMF, and CNI use, respectively. There was no difference in relapses after rituximab vs. MMF or CNI (weighted HR 1.16, 95%CI 0.74-1.81). There were also no differences in relapse rates, kidney function decline, or adverse events.

Conclusions: There was no difference in relapse risk after rituximab vs. MMF or CNI among children and young adults with difficult-to-treat nephrotic syndrome. Therapeutic selection should be a shared decision, considering medication-specific side-effects, costs, access, duration, and patient adherence.

Funding: Government Support - Non-U.S.

Initial Treatment of Idiopathic Nephrotic Syndrome in Children with Mycophenolate Mofetil vs. Prednisone: A Prospective, Randomized, Controlled, Multicenter, Open, Phase 3, Noninferiority Study

Marcus R. Benz,[1,2] Rasmus Ehren,[1] Britta Höcker,[3] Alexander Fichtner,[3] Uwe Querfeld,[4] Peter F. Hoyer,[5] Markus J. Kemper,[6] Dieter Haffner,[7] Jörg Dotsch,[1] Martin Konrad,[8] Anja C. Sander,[9] Jan Meis,[9] Burkhard Toenshoff,[3] Lutz T. Weber.[1] German Society of Pediatric Nephrology (GPN). *[1]University Hospital of Cologne, Cologne, Germany; [2]Pediatric Nephrology Dachau, Dachau, Germany; [3]University Children's Hospital Heidelberg, Heidelberg, Germany; [4]Charite Universitatsmedizin Berlin, Berlin, Germany; [5]Universitat Duisburg-Essen, Duisburg, Germany; [6]Asklepios Kliniken GmbH & Co KGaA, Hamburg, Germany; [7]Medizinische Hochschule Hannover Zentrum fur Kinderheilkunde und Jugendmedizin, Hannover, Germany; [8]Universitat Munster, Munster, Germany; [9]Universitat Heidelberg, Heidelberg, Germany.*

Background: Initial treatment of idiopathic nephrotic syndrome (iNS) in children requires sufficient immunosuppressive therapy to induce and sustain remission and consists of a prolonged course with glucocorticoids (GC). Even though being effective, this treatment is associated with pronounced GC associated toxicity. Mycophenolate mofetil (MMF) is effective in sustaining remission in patients with frequently relapsing or GC-dependent nephrotic syndrome. The hypothesis of the INTENT-Study (initial treatment of idiopathic nephrotic syndrome in children with mycophenolate mofetil vs. prednisone) was that MMF is not inferior to standard therapy with GC in the iNS in children with regard to maintenance of remission and subsequent recurrence rate.

Methods: 272 children (mean age at onset 4.1±2.3 years; 64.3% males) with a first episode of SSNS were randomized to either standard treatment (12 weeks of GC) or experimental treatment (MMF only after induction of remission with GC for a total treatment period of 12 weeks). Primary end-point was occurrence of treated relapse within follow-up of 24 months after completion of initial treatment. Secondary end-points included i.a. course of the disease and drug toxicities.

Results: MMF was not inferior to GC treatment in terms of the primary end-point (imputed mITT set: relapse rate 79.1% (MMF group) vs. 74.8% (GC group), difference 4.3% [-4.2%;12.7%], p=0.019; imputed per protocol set: relapse rate 79.2% (MMF group) vs. 77.7% (GC group), difference 1.5% [-7.7%;10.8%], p=0.008). In the MMF arm, there were fewer GC-related side effects, such as lower blood pressure and body mass index as well as less frequent psychological abnormalities and cushingoid appearance. Cytopenias were more frequent in the MMF group but overall rare and mild. The rate of frequently relapsing nephrotic syndrome in the follow-up was comparable between the groups (MMF: 47.2%, GC: 45.2%).

Conclusions: The presented results of the INTENT-Study show non-inferiority of the MMF arm to the standard GC arm with no safety concerns and fewer GC-related side effects. They have the potential to alter the standard of care in SSNS.

Immunomodulatory Effects of Levamisole in Children with Idiopathic Nephrotic Syndrome

Antonia Bouts,[1] Floor Veltkamp,[1] Gerarda H. Khan.[2] LEARNS Consortium. *[1]Emma Children's Hospital, Amsterdam UMC, University of Amsterdam, Amsterdam, Netherlands; [2]Amsterdam UMC Locatie AMC, Amsterdam, Netherlands.*

Background: This study aimed to systematically investigate the effects of Levamisole (LMS) on the human immune system, including its impact on isolated human immune cells in vitro. The objectives were to elucidate the immunological mechanisms underlying idiopathic nephrotic syndrome (INS) in children, assess the immunomodulatory effects of LMS, and investigate its potential therapeutic implications in INS management

Methods: Blood samples were collected from INS pediatric patients and age-matched healthy controls (HC) for flow cytometry and immunoplexing analysis. Additionally, whole blood samples from INS patients treated with LMS or placebo were stimulated with lipopolysaccharide (LPS) or anti-CD3/anti-CD28, and cytokine production was measured.

Results: Compared to HC, INS patients exhibited elevated levels of circulating T-cells, particularly CD8+ T-cells, and an increased presence of plasmablasts. Moreover, INS patients demonstrated heightened IgM production and reduced IgG levels at diagnosis, suggesting early activation of the humoral immune response. LMS-treated patients showed decreased B-cell counts and altered cytokine profiles, with enhanced production of TNF-α, IFN-γ, and IL-2 upon stimulation, and reduced levels of IL-13 compared to placebo-treated patients. Earlier work from our group has shown that LMS suppresses the proliferation and activation of both CD4+ and CD8+ T-cells by modulating gene expression associated with cell cycle progression and p53 activation [1]. Additionally, LMS treatment decreases B-cell proliferation, Ig production, and metabolism, while inducing upregulation of genes involved in plasmablast differentiation.

Conclusions: These findings highlight the immunomodulatory effects of LMS on the human immune response, shedding light on its potential therapeutic role in INS management in children. LMS appears to suppress immune cell proliferation, alter gene expression profiles, and induce DNA damage, suggesting its capacity as an immunosuppressive agent. Further research is needed to fully elucidate the therapeutic implications of LMS in immune-mediated disorders and its underlying mechanisms of action. [1]. Urine Output (UO) and AKI Diagnosis in Neonates and Infants: A Prospective Study in Cardiac Surgery Patients with Indwelling Urinary Catheters

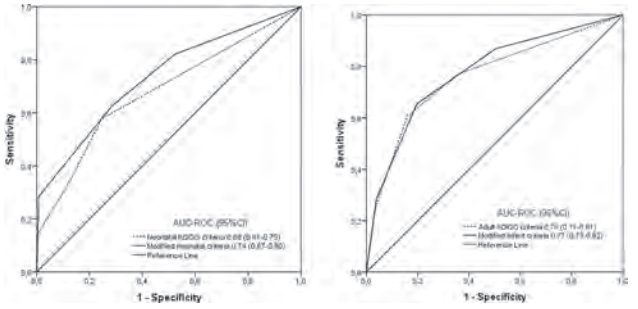
Alexandre B. Liborio, Adriana T. Girão, Candice T. Cavalcante. *Universidade de Fortaleza, Fortaleza, Brazil.*

Background: AKI in neonates and younger infants is associated with significant mortality, yet a precise definition, especially concerning UO thresholds, remains elusive. This study aimed to evaluate UO thresholds for AKI in neonates and infants (1 month to 2 years old) with indwelling urinary catheters.

Methods: Six-year prospective cohort study involving children aged 2 years or younger who were undergoing cardiac surgery. All patients had indwelling urinary catheters for accurate urine output measurements up to the second postoperative day and at least two sCr measurements—one before surgery. The main objective of this study was to determine the optimal UO thresholds for AKI definition and staging in neonates and infants compared with the currently used criteria—neonatal and KDIGO definitions. The outcome was a composite of severe AKI, KRT or hospital mortality.

Results: The study included 1,024 patients: 253 in the neonatal group and 772 in the infant group. In both groups, the lowest UO at 24 h had good discriminatory capacity for the composite outcome. In neonates, the best thresholds (evaluated by ROC curves) were 3.0, 2.0 and 1.0 mL/kg/h, and in infants, the thresholds were 1.8, 1.0 and 0.5 mL/kg/h. These values were used for modified AKI staging for each age group. In neonates, this modified criterion was associated with the best discriminatory capacity (see figure left) and net reclassification improvement (NRI) - 17.3% in comparison with the neonatal KDIGO criteria. In infants, the modified criteria was comparable to the adult KDIGO criteria, and the NRI was near zero. sensitivity analysis according to diuretic use was performed with similar results.

Conclusions: For the first time, using indwelling catheters for UO measurements, our study reinforced that the current KDIGO criteria may require adjustments to better serve the neonate population. Additionally, using the UO criteria, we validated the adult KDIGO criteria in infants.



SA-OR77

Circulating Extracellular Vesicles as Mediators of Impaired Angiogenesis in Pediatric CKD

Felix Behrens, Johannes Holle, Chia-Yu Chen, Harithaa Anandakumar, Ulrike Löber, Nicola Wilck, Hendrik Bartolomaeus, Wolfgang M. Kuebler, Szandor Simmons. *Charite - Universitatsmedizin Berlin, Berlin, Germany.*

Background: Patients with chronic kidney disease (CKD) suffer from high morbidity and mortality due to cardiovascular disease (CVD). Nonetheless, underlying mechanisms of CVD in CKD remain elusive. Extracellular vesicles (EVs) have lately been identified as facilitators of inter-organ communication and EVs of endothelial origin (EC-EVs) have been linked to CVD development. We hypothesized that altered EV release and cargo mediate CVD development in CKD.

Methods: 94 children with different CKD stages (before or on dialysis, after kidney transplantation and age-matched healthy donors), were enrolled in this study, yielding analyses on plasma EV phenotype in the absence of age-related comorbidities. The impact of CKD EVs on CVD processes was analyzed *in vitro* on transcriptomic and functional level.

Results: Concentrations of EC-EVs were increased in hemodialysis patients and decreased after kidney transplantation. According to small RNA sequencing, CKD EVs had lower abundance of 30 specific microRNAs, which were predicted to affect angiogenesis and smooth muscle cell proliferation. *In vitro*, CKD EVs altered the transcriptome of aortic endothelial cells, with most differentially enriched genes implicated in angiogenesis pathways. CKD EVs functionally impaired angiogenic properties of umbilical vein endothelial cells, as illustrated by reduced vascular tube formation with reduced vascular density, impaired migration and lowered proliferation. The combination of high shear stress, as present in arterio-venous fistulas, and the uremic toxin indoxyl sulfate was identified as trigger of increased EV formation from venous endothelial cells, which also recapitulated EV microRNA changes observed in CKD *in vivo*.

Conclusions: CKD leads to quantitative and compositional dysregulation in EV release. Altered EV microRNA cargo associates with detrimental effects of CKD EVs on angiogenesis, going in line with the cardiovascular phenotype of CKD patients. EVs and in particular their microRNA cargo could form promising targets for novel therapeutic strategies to fight CVD in CKD.

SA-OR78

Low Serum Bicarbonate and Cardiovascular Disease Risk in Children with CKD

Denver D. Brown,[1] Jennifer Roem,[2] Kimberly J. Reidy,[6] Susan L. Furth,[4] Bradley A. Warady,[3] Michal L. Melamed,[5] Tammy M. Brady.[2]
[1]Children's National Hospital, Washington, DC; [2]Johns Hopkins Medicine, Baltimore, MD; [3]Children's Mercy Kansas City, Kansas City, MO; [4]The Children's Hospital of Philadelphia, Philadelphia, PA; [5]NYU Langone Health, New York, NY; [6]Children's Hospital at Montefiore, New York, NY.

Background: In adults, metabolic acidosis (MA) has been linked to worse cardiovascular disease (CVD) outcomes but this association has not been studied in children with chronic kidney disease (CKD). We investigated if low serum bicarbonate (a MA surrogate) is associated with adverse CVD risk measurements in children with CKD.

Methods: This observational study included children ≥1 year of age enrolled in the Chronic Kidney Disease in Children (CKiD) study who had a baseline estimated glomerular filtration rate (eGFR) between 30-90 ml/min/1.73m^2, ambulatory blood pressure measurement (ABPM) and left ventricular mass (LVM) data. Linear and logistic regression models were used to characterize associations between serum bicarbonate, ABPM, and LVM. As normative values for ABPM and LVM change in childhood, index measurements were calculated for ABPM and LVM (LVMI) based on participants' age, sex, and height. Serum bicarbonate was analyzed continuously and categorized as <22mEq/L (low) and ≥22mEq/L (normal). Analyses were adjusted for age, sex, race, body mass index, CKD etiology group (nonglomerular and glomerular causes of CKD), and eGFR.

Results: The study population comprised 933 children- 696 with nonglomerular and 237 with glomerular CKD. The median age was 11 years old, 63% were males, and >50% were Caucasian. A total of 677 children were included in analyses that examined MA and ABPM and 819 children were included in analyses of MA and LVMI. In adjusted analyses, significant but opposite associations were noted between serum bicarbonate, ABPM index, and LVMI. Specifically, wake and sleep systolic and diastolic ABPM indices decreased with each 1meq/L decrease in serum bicarbonate level. However, LVMI increased with decreasing bicarbonate level: specifically, LVMI z-score increased 0.02 [0.01, 0.04] per 1mEq/L decrease in serum bicarbonate. The association with ABPM indices did not change when serum bicarbonate was categorized; however, low serum bicarbonate (<22mEq/L) was no longer significantly associated with LVMI once analyses were adjusted for eGFR.

Conclusions: Low serum bicarbonate was associated with decreasing systolic and diastolic ABPM indices, but increasing LVMI. Future studies will investigate if treatment of MA with sodium-based alkali therapies mitigates the associations between serum bicarbonate, ABPM, and LVMI.

Health Care Utilization in Infants with ESKD

Ashna Pudupakkam, Shweta S. Shah, Catherine Joseph, Sarah J. Swartz, Poyyapakkam Srivaths, Michael C. Braun. *Baylor College of Medicine, Houston, TX.*

Background: In 2021 Medicare expenditures for patients with ESRD exceeded $51 billion, with inflation adjusted per-person per year (PPPY) Medicare fee for service expenditures of nearly $68,000. With recent advances in prenatal interventions and infant specific renal replacement therapy, survival of neonates with ESRD has improved over the last decade. Dialysis in neonates with ESRD is often associated with multiple comorbidities and the need for more intensified dialysis regimens. Little is known however about the impact on the health care system of improved survival in this population. Our primary aim was to investigate healthcare utilization in infants with ESRD.

Methods: We conducted a retrospective review of patients with ESRD at Texas Children's Hospital (TCH) from 2011 to 2022. We included patients ≤ 1 year of age who initiated dialysis in the Neonatal Intensive Care Unit (NICU) at TCH. We excluded patients who started dialysis prior to transfer to TCH. Data abstracted included patient demographics, initial and subsequent length of stay, comorbidities, and pediatric sub-specialist care. Data was also collected on gross charges related to the initial hospitalization, dialytic care, and gross charges following discharge up to 2 years of age.

Results: 19 patients met inclusion criteria of which 68% were male, 79% had a gestational age ≥ 37 weeks, and 90% had a birth weight ≥2500 g. The most common etiology of ESRD was lower urinary tract obstruction (LUTO) followed by genetic causes. The average length of stay for the initial hospitalization was 200 days with an average of 8 sub-specialists consulted inpatient and 4.9 admissions following discharge. The average gross charge for the initial hospitalization was $2,868,980 of which 14% was associated with dialytic care. The aggregate average hospital gross charges was $946,205 from discharge up to age 2. 84% of patients were discharged on peritoneal dialysis;16% were discharged on hemodialysis. 89% of patients survived and 5% received a kidney transplant by age 2 years.

Conclusions: Infant ESRD is associated with significant healthcare utilization including hospitalizations, sub-specialty care, and financial expenditures that far exceed adults with ESRD. Further investigation of healthcare utilization in this patient population can help determine the need for appropriate allocation of resources to support care delivery.

SA-OR80

Risk HLA-DQ Heterodimer Mismatch Is Associated with De Novo Donor-Specific Antibodies in Pediatric Kidney Transplant Recipients

Vaka Sigurjonsdottir,[1] Kim H. Piburn,[3] Lin Wang,[5] Daniel Turudic,[4] Paul C. Grimm,[5] Anat R. Tambur,[2] Bing M. Zhang.[5] *[1]University of Miami Miller School of Medicine, Miami, FL; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]The University of Texas Health Science Center at San Antonio, San Antonio, TX; [4]University Hospital Centre Zagreb, Zagreb, Croatia; [5]Stanford University, Stanford, CA.*

Background: Recently, the role of HLA-DQα/β heterodimer mismatches in transplantation was recognized, suggesting that heterodimers including the DQα05 chain as part of the mismatched donor allele, carry a higher risk of developing de-novo donor-specific antibodies (dnDSA).

Methods: Children who underwent kidney transplantation from 1/1/2010-3/1/2018 at Stanford Children's Health, with ≥12-month follow-up, were included and followed through 9/1/2022. DQα/β heterodimers were paired based on linkage disequilibrium with HLA-DRB1 and mismatches were determined at the level of the heterodimers. A risk mismatch was defined as the presence of DQα05 heterodimer in the donor, not the recipient. Outcome of interest was development of dnDSA to HLA-DQ, defined when

detected mean fluorescence intensity (MFI) was ≥ 1000. All patients were tested for dnDSA at 0, 1, 2-, 3-, 6-, and 12 months following transplant, at least annually after that, and as clinically indicated. Survival analysis was performed by the Kaplan-Meier method and odds ratios were used to compare the relative odds.

Results: A total of 227 patients were included. The median age was 13 (IQR 9), 24% had living donor transplant and 49% were female. The median follow-up time was 68 months (IQR 40). 87 (38%) formed dnDSA against HLA-DQ. 77/227 (34%) had a DQα05-heterodimer mismatch, of those 43/77 (56%) formed dnDSA, vs. 44/150 (29%) **Figure.** The **table** shows frequency of heterodimers and dnDSA formation.

Conclusions: DQα05 heterodimer mismatch was highly associated with the formation of HLA- dnDSA in our cohort. Identification of immunogenic DQ mismatches may help optimize allocation systems, guide the selection of organs for sensitized patients, and immunologic risk stratification post-transplant to improve graft outcomes.

Table: Frequency of mismatched heterodimers in cohort. Frequency is reported if present in ≥15.

Heterodimer	Patients with mismatched heterodimer (n)	DSA (n)	No DSA (n)	Percentage that formed DSA (%)	OR	95% CI	P value
DQA1*01/DQB1*05	54	17	37	31	0.7	0.4, 1.3	0.2
DQA1*01/DQB1*06	52	10	42	19	0.3	0.1, 0.6	0.001

pOKRA Study: Biomarker-Based Diagnosis and Histological Correlation of Allograft Rejection in Pediatric Kidney Transplantation

Vikas R. Dharnidharka,[1,2] Raja Dandamudi,[1,2] Mansi Agarwal,[1] Charles Goss,[1] Megan Kelton,[3] Jodi M. Smith.[3] *[1]Washington University in St Louis, St Louis, MO; [2]Saint Louis Children's Hospital, St. Louis, MO; [3]Seattle Children's Hospital, Seattle, WA.*

Background: To improve acute rejection(AR) detection in pediatric renal transplants, we propose KidneyCare, combining AlloSure(donor-derived cell-free DNA) and AlloMap(gene expression profiling). AlloMap assesses 5 genes expression, generating a score of 0-20. AlloSure quantifies allograft tissue injury as a percentage of total circulating cell-free DNA. We suggest this combined approach may boost diagnostic accuracy and correlate with Banff lesion intensity

Methods: In the study, 72 AlloSure and 69 AlloMap samples were collected prospectively pre-biopsy from 61 patients across 3 centers in the first year post-transplant Assays were conducted at CareDx labs. Samples were categorized as AR or Quiescence. Area under the ROC assessed their ability to distinguish AR from quiescence. Principal component analysis condensed variables for logistic regression. Histology scores followed Banff 2018 update

Results: In our study, comprising 18 AR biopsy specimens and 59 without AR, median AlloSure levels were significantly higher in the AR group (1.7%;IQR, 0.42%–3.9%) compared to the quiescent group (0.28%;IQR,0.18%–0.46%). AlloMap scores were also significantly elevated in the AR group (median 13;IQR,12–14) compared to the quiescent group (median 9.9;IQR,8.2–11). The AUC for AlloSure alone to identify AR was 0.83, for AlloMap alone was 0.82, and the combined AUC improved to 0.94. The combination of tests correctly predicted and potentially avoided 40 out of 41 biopsies. AlloSure levels increased with Banff lesions:from 0.77 ± 0.13% to 3.8 ± 0.52% for glomerulitis (G grades 1-2),0.44 ± 0.01% to 2.9 ± 2.1% for peritubular capillaritis (PTC grades 0-3),0.40 ± 0.05% to 3.0 ± 0.52% for interstitial inflammation (IF grades 0-3), 0.51 ± 0.07% to 3.0 ± 0.8% for tubulitis grades 0-3,0.5 ± 0.1% to 2.6 ± 0.27% for interstitial fibrosis (IF grades 0-3), and 0.42 ± 0.8% to 3.9 ± 1.3% for tubular atrophy (TA grades 0-3). Similarly, AlloMap levels increased with Banff lesion severity: from 10 ± 2.8 to12 ± 1.6 for G1-2,9.8 ± 2.6 to14 ± 2.5 for PTC 0-3, 9.7 ± 2.1 to 14 ± 2.6 for IF0-3, 9.4 ± 2.1 to 13.0 ± 1.9 for tubulitis 0-3, 9.8 ± 2.9 to 14 ± 1 for IF 0-3, and 9.8 ± 2.8 to 13 ± 1.6 for TA 0-3.

Conclusions: Combining AlloSure and AlloMap yields highly accurate AR assessment, correlating positively with allograft tissue injury severity

Favorable Treatment Responses of Recurrent Focal Segmental Glomerulosclerosis in Children after Kidney Transplantation: A Contemporary Multicenter Electronic Health Record Data Analysis

Vikas R. Dharnidharka,[1] Rebecca R. Scobell,[2] Mahmoud Kallash,[3] Nicole Marchesani,[2] Michelle Denburg.[2] PedsNet GLEAN Investigators. *[1]Washington University in St Louis, St Louis, MO; [2]The Children's Hospital of Philadelphia, Philadelphia, PA; [3]Nationwide Children's Hospital, Columbus, OH.*

Background: Recurrence of focal segmental glomerulosclerosis (FSGS) after kidney transplant leads to significant morbidity and potentially earlier allograft loss. To date however, reported rates, risk factors and treatment outcomes have varied widely.

Methods: We applied computational phenotypes to a multicenter aggregation of electronic health records data from 7 large pediatric health systems in the USA, to identify recurrence rates, risk factors and treatment outcomes. We refined the data collection by chart review.

Results: From >7 million patients, we compared children with primary FSGS who received a kidney transplant between 2009-2020 and who either developed recurrence (n =67/165; 40.6%) or did not (n = 98/165). 64/67 had recurrence in the first week (Figure 1, panel A). Serum albumin level at time of transplant was significantly lower and recipient HLA DR7 presence was significantly higher in the recurrence group. By 36 months post-transplant, complete remission occurred in 58.2% and partial remission in 17.9% (panel B). Through 6 years post-transplant, no remission after recurrence associated with an increased risk of allograft loss over time (p<0.0001), but any remission showed similar allograft survival (panel C) and function decline (panel D) to those with no recurrence. Since treatments were used in non-random fashion, using spline curves and multivariable non-linear analyses, complete + partial remission chance was significantly higher with greater plasmapheresis sessions, CTLA4-Ig doses or LDL-apheresis sessions. Only treatment with anti-CD20, CTLA4-Ig agents or LDL-apheresis sessions were associated with complete remission (panel E). Excluding 25 patients with mutations raised the recurrence rate to a range between 45-47.14% but did not significantly change other results.

Conclusions: Our contemporary high-risk cohort had higher favorable response rates than most prior reports, from combinations of agents.

Superiority of Imlifidase over Plasma Exchange in Rapid and Efficient Elimination of All IgGs, Including Donor Specific Antibodies (DSAs) Assessed in an Antibody-Mediated Rejection (AMR) Trial

Stanley C. Jordan,[1] Georg Bohmig,[2] Lionel Couzi,[3] Carmen Lefaucheur,[4] Robert A. Montgomery,[5] Lionel Rostaing,[6] Christophe M. Legendre,[7] Peter D. Hughes,[8] Anil K. Chandraker,[9] Gunilla Einecke,[10] Kate Wyburn,[11] Anna Runström,[12] Jan G. Tollemar,[12] Paola A. Lefèvre,[12] Fabian Halleck.[13]
[1]Cedars-Sinai Medical Center, Los Angeles, CA; [2]Medizinische Universitat Wien Universitatsklinik fur Innere Medizin III, Wien, Austria; [3]Centre Hospitalier Universitaire de Bordeaux Service d'endocrinologie diabetologie et nutrition, Bordeaux, France; [4]Hopital Saint-Louis, Paris, France; [5]NYU Langone Health, New York, NY; [6]Centre Hospitalier Universitaire Grenoble Alpes, Grenoble, France; [7]Hopital Necker-Enfants Malades Service de Genetique Clinique, Paris, France; [8]The Royal Melbourne Hospital, Melbourne, VIC, Australia; [9]Brigham and Women's Hospital, Boston, MA; [10]Medizinische Hochschule Hannover, Hannover, Germany; [11]Royal Prince Alfred Hospital, Sydney, NSW, Australia; [12]Hansa Biopharma AB, Lund, Sweden; [13]Charite Universitatsmedizin Berlin, Berlin, Germany.

Background: Antibody depletion using (PLEX) is regarded as SOC in the treatment of AMR. However, PLEX has inconsistencies in removal of pathogenic IgG (i.e., DSAs) due to multiple factors including re-equilibration from IgG distributed in extravascular spaces. Imlifidase, a protease that specifically inactivates all human subclasses of soluble and membrane bound IgG. Imlifidase is currently utilized for desensitization prior to kidney transplantation with inactivation of DSAs both in the intra- and extravascular space. In this AMR trial (NCT03897205), the primary endpoint was to compare removal of IgG DSAs with imlifidase to 5-10 PLEX sessions.

Methods: The comparison occurred in a phase 2 randomized, open-label, multi-center, multi-national trial with a 6-month follow-up conducted at 14 transplant centers. The trial included 30 patients with active or chronic active AMR after kidney transplantation. The primary endpoint analyzed the maximum reduction of all DSA levels for 5 d following the start of either treatment. The purpose of this presentation is the efficacy of removing IgG between the two treatment modalities.

Results: The median reduction of DSA was 97% for imlifidase compared to 42% for PLEX on day 5. The time to median maximum DSA depletion was 15h after imlifidase compared to day 9 for a median of 6 PLEX sessions. No complement-binding DSA was detectable 24h after treatment in any imlifidase patients, whereas no reduction was seen in PLEX treated patients. After the initial elimination of DSA, a rebound occurred to approximately 70% of baseline values for both groups. On average 3% of the pre-treatment IgG level remained after imlifidase, compared to 50% after PLEX at any timepoint. No meaningful safety issues were observed in the trial.

Conclusions: In a head-to-head comparison in kidney transplant recipients with AMR, one dose of imlifidase given over a 15-min infusion was more efficacious in reducing all IgG, both in speed and magnitude, compared to several PLEX sessions. Thus, imlifidase offers a rapid and effective option of hindering any IgG-mediated attack momentarily with a beneficial safety profile.

Clazakizumab in Chronic Active Antibody-Mediated Kidney Transplant Rejection: Results of the IMAGINE Phase 3 Study

Arjang Djamali,[1] Georg Bohmig,[2] Steven J. Chadban,[3] Deepali Kumar,[4] Roslyn B. Mannon,[5] Teun van Gelder,[6] Gabriele Schultz-Hauser,[7] Gabriela Alperovich Lehrer,[8] Ralph Preiss,[9] Aparna Raychaudhuri,[10] Laurie Lee,[10] Peter W. Nickerson.[11]
[1]Maine Medical Center, Portland, ME; [2]Medical University of Vienna, Vienna, Austria; [3]Royal Prince Alfred Hospital, Sydney, NSW, Australia; [4]University of Toronto, Toronto, ON, Canada; [5]University of Nebraska Medical Center, Omaha, NE; [6]Leiden University Medical Center, Leiden, Netherlands; [7]CSL Behring, Marburg, Germany; [8]CSL Vifor, Madrid, Spain; [9]CSL Behring, Berne, Switzerland; [10]CSL Behring LLC, King of Prussia, PA; [11]University of Manitoba, Winnipeg, MB, Canada.

Background: Chronic active antibody-mediated rejection (caAMR) is a common cause of graft loss after kidney transplant with no approved therapies. Clazakizumab, a high-affinity, humanized monoclonal antibody that binds IL-6, decreased donor-specific antibody (DSA) production and microvascular inflammation and stabilized eGFR in a phase 2 study in kidney transplant recipients (KTRs) with caAMR.

Methods: IMAGINE (NCT03744910; start date: Oct 2019), a global (66 sites) double-blind phase 3 study, aimed to recruit ~350 KTRs with caAMR determined by kidney biopsy based on Banff 2015 criteria. KTRs were randomized 1:1 to clazakizumab (12.5 mg SC q4w) or placebo. Primary endpoint was time to all-cause graft loss (return to dialysis, graft nephrectomy, re-transplantation, eGFR <15 mL/min/1.73m^2, death from any cause or sustained 40% reduction in eGFR). 1-yr eGFR was accepted as a reasonably likely surrogate endpoint (RLSE) for accelerated approval by the FDA. Temporary dose reduction was allowed at investigator discretion. This interim analysis (IA) was conducted when ~100 KTRs completed 1 yr of study participation.

Results: At the time of the IA, 194 KTRs had been enrolled, and 115 were followed for 52 weeks for eGFR change from baseline. The analysis indicated that the study was unlikely to meet the primary efficacy outcome (time to composite all-cause allograft loss or irreversible loss of allograft function), and the data and safety monitoring board recommended to stop the study. No gastrointestinal perforations or other safety concerns were noted.

Conclusions: Despite encouraging phase 2 results, the data from the IMAGINE IA did not support continuation. Nonetheless, this was the largest placebo-controlled study in KTRs with caAMR and was first transplant study for which the FDA accepted a 1-yr eGFR slope as a RLSE. No safety concerns were noted. Detailed primary analyses will be presented after the database has been unblinded prior to ASN Kidney Week.

Impact of Induction Agents on Torque Teno Viral Load and Year-1 Post-transplant Complications in Kidney Transplant Recipients

Louise Benning,[1] Marvin Reineke,[1] Claudius Speer,[1] Julian Klein,[2] Christian Bundschuh,[2] Martin G. Zeier,[1] Paul Schnitzler,[2] Christian Morath.[1]
[1]Department of Nephrology, University Hospital Heidelberg, Heidelberg, Germany; [2]Medical Faculty Heidelberg, Department of Infectious Diseases, Virology, University Hospital Heidelberg, Heidelberg, Germany.

Background: Torque teno viral load (TTVL) is gaining importance as a surrogate parameter to assess immunocompetence in kidney transplant recipients and as a potential biomarker for predicting complications post-transplant. Although TTVL kinetics have been examined in several studies, it is unknown to what extent different induction therapies affect TTVL.

Methods: In this retrospective study, TTVL was quantified in 553 plasma or serum samples from 138 patients who underwent kidney transplantation between 2018 and 2021. TTVL was quantified at the time of transplantation and 30, 90, 180, and 360 days thereafter. To evaluate the influence of induction therapy on TTVL, 69 patients receiving anti-thymocyte globulin (ATG) induction were matched with 69 patients receiving an interleukin-2 receptor antagonist (IL2-RA) in terms of age, gender, and donor modality.

Results: Regardless of the type of induction therapy, there was a steep increase in TTVL post-transplant in all patients with peak viral loads at 90 days post-transplant (median TTVL [IQR] 6.62×10^6, [4.00×10^5 – 1.04×10^8]) followed by subsequently declining viral loads. Compared to patients receiving IL2-RA as induction therapy, patients receiving ATG had significantly higher peak viral loads (P=0.0006), as well as significantly higher viral loads one year post-transplant (P=0.012). Among the 69 patients who received ATG induction therapy, 17 patients underwent simultaneous pancreas-kidney transplantation, yet their TTVL did not differ significantly from others receiving ATG as induction therapy. Despite higher TTVL, patients with ATG as induction therapy did not have an increased risk of hospitalization due to infection when compared to patients receiving IL2-RA (HR=0.9363; P=0.6949). Patients whose TTVL 90 days post-transplant exceeded the currently proposed cutoff to prevent infections within the first year post-transplant [6.2 log10] had a higher risk of being hospitalized with an infection in the following 9 months, albeit without being statistically significant (HR=1.569, P=0.0899).

Conclusions: The type of induction agent used markedly affects TTVL post-transplant and should therefore urgently be considered for interpreting and applying TTVL to immunomonitor kidney transplant recipients post-transplant.

Kidney Rejection Prediction Model Combining Blood Gene Expression, Donor-Derived Cell-Free DNA, Urine Chemokines, and Torque Teno Virus

Kenny W. Chen,[1] Lihui Zhao,[1] Sujay D. Paudel,[1] Sookhyeon Park,[1] Amishi Desai,[1] Ronnie Lacombe,[2] Rohita Sinha,[2] Steven Kleiboeker,[2] John J. Friedewald.[1]
[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Eurofins Viracor BioPharma Services, Lenexa, KS.

Background: Blood gene expression (GEP), dd-cfDNA, and urine chemokines have all been shown to be useful non-invasive biomarkers in predicting kidney rejection. Torque teno virus (TTV) is an emerging biomarker of net IS. We aim to integrate these 5 biomarkers into a prediction model for kidney rejection.

Methods: We analyzed 638 biopsy-paired blood and urine samples from the CTOT-08 trial (NCT01289717). We fit a logistic regression model using log dd-cfDNA, GEP, urine CXCL9 and CXCL10 normalized to Ucreat, and log TTV viral load to predict kidney rejection. Sensitivity, specificity, PPV, NPV and AUC was used to evaluate diagnostic performance.

Results: In the 5-biomarker model, dd-cfDNA, GEP, and TTV VL were statistically significant (p-value < 0.05) adjusting for other covariates (TABLE). Model AUC was 0.816 (Figure). When maximizing Youden's index, we obtained a sensitivity of 0.71, specificity of 0.78, accuracy of 0.76, NPV of 0.87, and a PPV of 0.56. Out of all rejection

types, the model correctly predicted 51/66 AMR cases, 33/41 mixed AMR/ACR, 42/71 ACR, and 360/460 no rejection cases.

Conclusions: Combining non-invasive biomarkers into prediction models to monitor kidney allograft rejection could assist in reducing the need for biopsies and better inform safe immunosuppression titration. We found that dd-cfDNA, blood GEP and TTV VL all significantly improved the prediction model, whereas the addition of urine CXCL9/10 did not significantly impact model performance in predicting kidney rejection.

Hypothermic Perfusion in Kidney Allografts with Extended Cold Ischemia Time

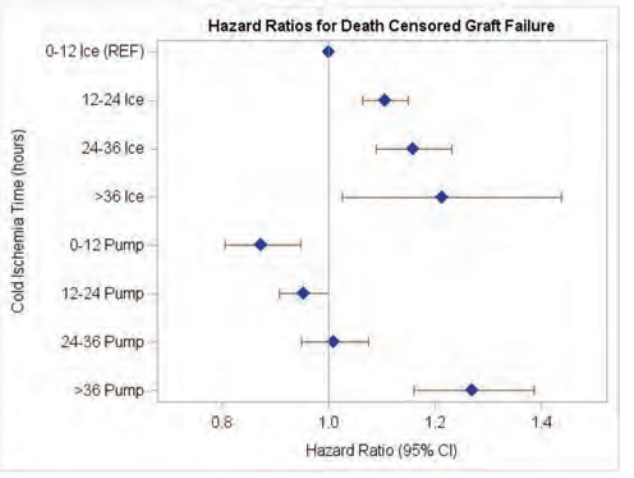
Angelica Perez-Gutierrez, Rita L. McGill. *University of Chicago Division of the Biological Sciences, Chicago, IL.*

Background: Hypothermic perfusion reduces reperfusion injury of kidney allografts. We investigated whether use of hypothermic perfusion offsets effects of extended cold ischemia time (CIT). This is important, as changes in the allocation system have increased CIT for recipient candidates located more than 250 nautical miles from the donor hospital.

Methods: UNOS Star Files were used to analyze first-time, single kidney-only allografts from deceased donors from 2005-2022, in order to compare organs preserved only with ice to organs with hypothermic perfusion; those with transient perfusion were excluded. A multivariable Cox model for death-censored graft failure (dcGF) was adjusted for recipient, donor, and transplant characteristics. CIT was categorized as ≤12 hours, 12-24 hours, 24-36 hours, and >36 hours. Kidneys on ice with ≤12 hours CIT served as a reference group, as these are normally considered acceptable for transplantation.

Results: Among 120,438 allografts, 62.7% were on ice and 37.3% were pumped. DcGF increased in a dose-dependent fashion as CIT increased, regardless of preservation method. Perfused kidneys with ≤36 hours CIT did not differ from the reference group (Figure). After 36 hours, dcGF was about 25% higher than the reference category, whether perfused kidneys or kidneys on ice. However, in the ≤12 hour, 12-24 hour, and 24-36 hour time categories, pump perfusion was associated with a 13% decrease in the hazard of dcGF (P<0.001 for all).

Conclusions: When CIT ≤36 hours, hypothermic perfusion of allografts was associated with signifcantly less dcGF compared to kidneys preserved on ice with similar CIT, with results comparable to kidneys on ice for ≤12 hours. The additional organ longevity may improve organ utilization and promote recipient safety by permitting complex recipients to have their transplant surgeries performed during daylight hours when optimal resources are available.



SA-OR88

First-in-Human Phase 2a (ATMIRe) Trial of Ex Vivo Allograft Treatment with iCM012 to Mitigate Ischemia-Reperfusion Injury in Kidney Transplantation

Ali R. Biglarnia,[1,3] Bo Nilsson,[2] Carl J. Raihle,[3] Oleg Slivca,[3] Clara H. Paul.[3] *[1]Lunds Universitet, Malmö, Sweden; [2]Uppsala universitet Rudbecklaboratoriet, Uppsala, Sweden; [3]Skanes universitetssjukhus Malmo, Malmo, Sweden.*

Background: iCM012 is an amphiphilic polymer that forms a dense protective coat on cell surfaces. In porcine transplant studies, ex vivo administration of iCM012 to kidney allografts produced a robust but transient non-toxic cell coating that consistently mitigated ischemia-reperfusion injury (IRI)-induced early thromboinflammation, reduced late systemic cytokine release, and improved allograft function. A first-in-human trial evaluated the safety and tolerability of iCM012 in clinical kidney transplantation.

Methods: A phase IIa, randomized, double-blind, placebo-controlled trial (NCT05246618) was conducted at a single center in Sweden, enrolling 18 de novo kidney transplant patients. Participants were randomized 2:1 to receive either iCM012 (n=12) or placebo (n=6). iCM012 was administered ex vivo to the retrieved kidney allografts as a single arterial infusion by gravity at the end of organ preservation. Primary endpoints were safety and tolerability over 12 months. Secondary endpoints included delayed graft function (DGF) and estimated glomerular filtration rate (eGFR) at 12 months. Urine and plasma samples were collected for exploratory analysis.

Results: Patient characteristics were balanced between the groups; however, the median Kidney Donor Profile Index was higher in the iCM012 group compared to placebo (76 [32-97] vs. 41 [30-94], P=0.062). There were no differences in cold ischemic time or use of continuous machine perfusion between groups. No DGF occurred and all transplanted kidneys showed excellent primary function, even one iCM012-treated kidney with a CIT of 25.7 hours that experienced technical complications, resulting in prolonged warm ischemia and re-anastomosis. In the iCM012 group, innate immune activation (sC5b-9) and tubular injury markers (IL-18, KIM-1, NGAL, Cystatin-C, and L-FABP) were at lower levels in 24-hour urine samples on day 1. At 12 months, there was no difference in median relative eGFR between the iCM012 and placebo groups (42 [32-58] vs. 45.5 [32-72]).

Conclusions: iCM012 demonstrated a favorable safety profile and showed promising efficacy in mitigating IRI and preserving allograft function within a 12-month follow-up. These findings strongly support further investigation in larger, multicenter trials to confirm its therapeutic potential in kidney transplantation.

Effects of Empagliflozin on Proteinuria in Kidney Transplant Recipients: Preliminary Data of a Randomized Control Trial

Chanyanuch Rakpithayanon,[1] Thunyatorn Wuttiputhanun,[1,2] Suwasin Udomkarnjananun,[1,2] Kearkiat Praditpornsilpa,[1,3] Yingyos Avihingsanon,[1,2] Natavudh Townamchai.[1,2] *[1]King Chulalongkorn Memorial Hospital Department of Internal Medicine, Bangkok, Thailand; [2]Excellence Center for Solid Organ Transplantation, Bangkok, Thailand; [3]Hemodialysis center, Benchakittipark Hospital, Bangkok, Thailand.*

Background: Post-kidney transplant proteinuria poses a substantial risk of cardiovascular events, graft loss, and mortality. Although evidence suggests the potential efficacy of empagliflozin in proteinuria reduction, a definitive comprehension of its therapeutic and safety profile in kidney transplant recipients (KTRs) remains elusive.

Methods: This preliminary double-blinded, randomized controlled trial systematically investigated the impact of empagliflozin on proteinuria in KTRs in comparison to a placebo. The inclusion criteria were stable graft function and the absence of rejection or alterations in immunosuppressive regimens within the preceding 3 months. Participants in the intervention arm were administered empagliflozin at a daily dosage of 10 mg for 3 months. The primary outcome measures included the mean differences in proteinuria, while secondary outcomes encompassed estimated glomerular filtration rate (eGFR), metabolic parameters such as blood sugar, blood pressure, and body weight.

Results: A total of 41 KTRs underwent enrollment and randomization, with both intervention and control groups exhibiting comparable baseline characteristics, including age, gender, underlying renal disease, history of rejection, and chronic calcineurin inhibitor toxicity. The intervention group demonstrated a significant proteinuria reduction with mean UPCI difference of -726.01 mg/gCr (95% CI -1426.62 to -25.41, P=0.043). The eGFR displayed no statistically significant difference (mean difference -1.82 ml/min/1.73m2, 95% CI -5.81 to 2.17, P=0.361). Evaluation of potential adverse effects, including urogenital infections, or metabolic acidosis, revealed no significant distinctions between groups.

Conclusions: Despite being underpowered by sample size, this study still demonstrates a statistically significant reduction in proteinuria with empagliflozin among kidney transplant recipients. The observed trend suggests a potential therapeutic benefit. Furthermore, the absence of notable side effects underscores the favorable safety profile of empagliflozin in this patient population.

SA-OR90

Triglyceride-Glucose Index and Risk of Cardiovascular Events, Kidney Allograft Loss, and New-Onset Diabetes after Transplantation in Kidney Transplant Recipients

Yu ho Lee,[1] Jin Sug Kim,[2] Kyunghwan Jeong,[2] Soo-Young Yoon,[2] Hyeyun Jeong,[1] Jihyun Baek,[1] So-young Lee,[1] Hyeon Seok Hwang.[2] *[1]CHA University Bundang Medical Center, Seongnam, Gyeonggi-do, Republic of Korea; [2]Kyung Hee University Medical Center, Dongdaemun-gu, Seoul, Republic of Korea.*

Background: Insulin resistance is prevalent disorder, but its clinical significance remains undermined. We explored the clinical implication of triglyceride-glucose (TyG) index in renal transplant recipients, recognizing it as a valuable marker for insulin resistance.

Methods: A total of 6,354 renal transplant recipients were enrolled from a nationwide, prospective cohort between May 2014 and December 2022. The TyG index was assessed between 6- and 12-months post-transplantation. We evaluated the association between TyG index and the risk of composite of cardiovascular events and death, renal allograft loss, and new onset diabetes after transplantation (NODAT).

Results: During the mean follow-up period of 39.2 ± 26.1 months, a total of 106 composite events of cardiovascular events and death, 174 events of renal allograft loss, and 438 events of NODAT were observed. The cumulative rate for composite events, graft loss, and NODAT was greater in patients with higher TyG quartile (all $P < 0.001$). In multivariate analysis, patients in quartile 4 TyG index was associated with an increased risk of composite events (HR 1.81, 95% CI 1.14 – 2.86), renal allograft loss (HR 2.13, 95% CI 1.28 – 3.55), and NODAT (HR 2.52, 95% CI 1.90 – 3.34). Higher quartile of TyG was associated with future graft dysfunction (adjusted mean eGFR differences of -4.72, 95% CI -7.39 – -2.04). There was a linear escalation in the risk of composite events and graft loss with the incremental rise in the TyG index, concomitant with an exponential augmentation in the risk of NODAT.

Conclusions: Renal transplant recipients with higher TyG index are associated with higher risk of composite of cardiovascular event and death, renal allograft loss, and NODAT.

TH-PO001

Retina and Deep Learning-Based CVD Biomarker in Patients with Varying eGFR Levels: Data from the UK Biobank

Yunnie Cho,[1,2] Young Su Joo,[3] Tyler H. Rim,[1,4] Jung Tak Park.[3] *[1]Mediwhale Inc., Seoul, Republic of Korea; [2]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [3]Yonsei University, Seoul, Republic of Korea; [4]Singapore Eye Research Institute, Singapore, Singapore.*

Background: Retinal imaging is a non-invasive method for assessing systemic disease risk. Reti-CVD, a deep learning-based retinal biomarker, predicts atherosclerotic cardiovascular disease (ASCVD) events with performance comparable to coronary artery calcium. Cardiovascular risk assessment is critical for patients with chronic kidney disease, given their higher CVD event risk. This study evaluates the prognostic value of Reti-CVD in patients with varying renal function, as measured by estimated glomerular filtration rate (eGFR).

Methods: A retrospective cohort study was conducted using the UK Biobank, including patients in three eGFR groups: G1 (eGFR ≥ 90; N=6600), G2 (eGFR 60-89; N=5130), and G3-G5 (eGFR < 60; N=183). Survival analysis focused on ASCVD events, with a mean follow-up duration of 9.9 years. Reti-CVD's predictive performance for each eGFR group was assessed using Cox proportional hazards models and concordance statistics. Hazard ratios (HR) of Reti-CVD were adjusted for eGFR groups, age, gender, hyperlipidemia, diabetes, and smoking status.

Results: In G1, Reti-CVD had a C-statistic of 0.715 [95% CI: 0.677 - 0.754], indicating strong predictive capability. The combined model of Reti-CVD, age, and gender improved the C-statistic to 0.727 [0.691 - 0.763]. In G2, Reti-CVD showed a C-statistic of 0.711 [0.679 - 0.744], with the combined model achieving 0.716 [0.684 - 0.748]. In G3-G5, the predictive performance of Reti-CVD was lower (0.605 [0.468 - 0.742]), but improved with age and gender (0.670 [0.521 - 0.819]). Multivariable HR analysis revealed the medium Reti-CVD category had more than double the risk compared to the low category (adjusted HR = 2.08 [1.52 - 2.94]), and the high Reti-CVD category had nearly four times the risk (3.78 [2.48 - 5.76]).

Conclusions: Reti-CVD, performing similarly to CAC in predicting cardiovascular risk, was effective in patients with kidney disease in the UK Biobank. This suggests potential for improved cardiovascular risk monitoring in chronic kidney disease patients.

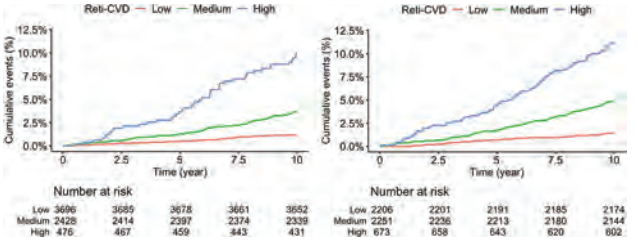

Figure1. Kaplan-Meier curves in G1 and G2 eGFR group according to Reti-CVD risk categories

Advancing Precision Medicine with scSpectra: Single-Cell Functional Profiling of Individual Patients with Kidney Diseases

Konstantin A. Kloetzer,[1,2] Amin Abedini,[1] Michael S. Balzer,[1,3] Xiujie Liang,[1] Jonathan Levinsohn,[1] Eunji Ha,[1] Max Schuller,[2] Bernhard Dumoulin,[1] Jonathan Hogan,[1,4] Kathrin Eller,[2] Roy D. Bloom,[1] Nancy Zhang,[5] Katalin Susztak.[1] *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Medizinische Universitat Graz, Graz, Austria; [3]Charite Universitatsmedizin Berlin, Berlin, Germany; [4]Cabaletta Bio Inc, Philadelphia, PA; [5]University of Pennsylvania Wharton School, Philadelphia, PA.*

Background: Single-cell RNA sequencing atlases, comprising millions of cells from hundreds of individuals, could guide molecular precision diagnostics in nephrology. However, the clinical application of single-cell transcriptomics to identify cell-type-specific molecular changes in individual patients remains unestablished.

Methods: We developed scSpectra, a novel computational tool that quantifies changes in gene expression coordination across cellular functions in individual samples. To demonstrate scSpectra's capabilities, we created the largest known human single-nuclei atlas. We expanded our cross-species integrated single-cell kidney atlas to include 150 kidney samples and biopsies from various diseases, such as diabetic kidney disease, chronic kidney disease with hypertension, acute kidney injury, and ADPKD. Comprising over 700,000 cells, our atlas, combined with scSpectra, powers our Single-Cell Functional Profiling Report, identifying the most significantly dyscoordinated pathways in each cell type of individual patients.

Results: By analyzing 100 patients, we demonstrate scSpectra's ability to distinguish diseases based on cell type involvement. For instance, a patient with IgA nephropathy showed the most significant changes in inflammation-related functions within podocytes, which was rarely observed in other diseases. Comparing the dyscoordination prevalence of thousands of cellular functions across diseases, we identified functions frequently dyscoordinated in CKD patients with hypertension but not in those without hypertension. We also found disease-specific changes for ADPKD samples, sex differences, and heterogeneity in potentially druggable pathways such as Interleukin-1-related signaling.

Conclusions: With scSpectra, we introduce one of the first computational frameworks for functional contextualization and precision diagnostics from scRNA-seq data. Based on a novel statistical approach, scSpectra revolutionizes single-cell analysis and enables a detailed examination of individual samples. Implemented in clinical investigations, scSpectra could identify patients most likely to benefit from specific treatments, advancing precision medicine in the management of complex diseases.

Development and Validation of Machine-Learning Model to Predict the Risk of Major Cardiovascular Events and Death for Patients with Kidney Failure Having Noncardiac Surgery

Gurpreet S. Pabla,[1] Navdeep Tangri,[2,4] Tyrone Harrison,[3] Thomas W. Ferguson,[4] Emir Sevinc,[3] Reid Whitlock.[4] *[1]University of Manitoba Faculty of Health Sciences, Winnipeg, MB, Canada; [2]University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; [3]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [4]Seven Oaks General Hospital, Winnipeg, MB, Canada.*

Background: Patients with kidney failure undergoing non-cardiac surgery face significantly higher risk of adverse cardiovascular events and mortality compared to those with normal kidney function. Existing risk prediction tools are limited in estimating these risks for kidney failure patients. We developed and validated a machine-learning model for major cardiovascular events and mortality in kidney failure patients within 30 days of undergoing outpatient or inpatient non-cardiac surgery in Alberta and Manitoba, Canada.

Methods: Derivation data was sourced from Manitoba Health, including adults (≥ 18 years) with kidney failure (eGFR < 15 mL/min/1.73m^2 or on maintenance dialysis) undergoing non-cardiac surgery between April 1, 2007, and December 31, 2019. We focused on a composite outcome of acute myocardial infarction, cardiac arrest, ventricular arrhythmia, and all-cause mortality. Data was split into 70% for training, 15% for validation, and 15% for testing. The training set was used to tune the hyperparameters and train the models; the validation dataset was used for feature selection and evaluate model performance, while the testing set evaluated the model's final performance. The model's performance was evaluated using C-statistics, Area Under the Precision-Recall Curve (AUC-PR), calibration plots, and Brier Score. We used XGBoost and Random Forest, selecting a model with reasonable and balanced C-statistics and AUC-PR. The final model was externally tested using Alberta data.

Results: We identified 12,082 surgeries and 569 outcomes. The final model (XGBoost) included surgery type, surgery setting (emergency inpatient, outpatient), history of myocardial infarction, albumin, and hemoglobin levels. It had an estimated C-statistic of 0.86, an AUC-PR of 0.30, and a Brier score of 0.04 in the testing cohort. External testing in Alberta showed similar performance. Calibration plots demonstrated excellent calibration, except for underestimation at the highest predicted risks.

Conclusions: Our XGBoost model for adverse peri-operative outcomes in patients with kidney failure demonstrated good performance, with improved parsimony compared to existing tools. Future work should compare these tools and test the impact of risk-guided approaches to perioperative care.

Health System Economic Burden in Patients with CKD: Insights from the Klinrisk Model

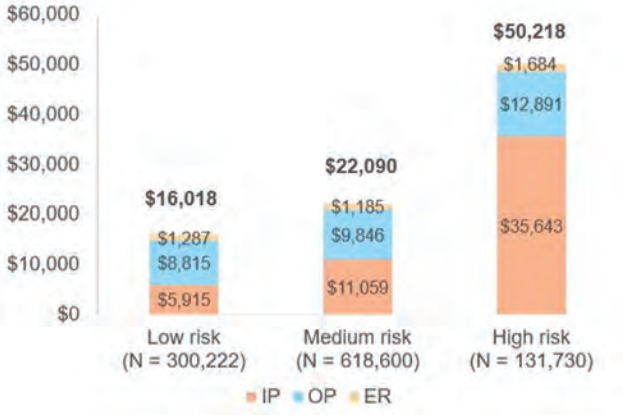
Navdeep Tangri,[1,2] Rakesh Singh,[3] Keith A. Betts,[4] Yuxian Du,[3] Sophie Gao,[4] Arvind Katta,[3] Youssef M. Farag,[3] Samuel T. Fatoba,[3] Hongjiao Liu,[4] Jingyi Chen,[4] Thomas W. Ferguson,[1] Reid Whitlock,[1] Silvia J. Leon Mantilla,[1] Ajay K. Singh.[5] *[1]University of Manitoba, Winnipeg, MB, Canada; [2]University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; [3]Bayer U.S. LLC, Whippany, NJ; [4]Analysis Group Inc, Los Angeles, CA; [5]Harvard Medical School, Boston, MA.*

Background: CKD is associated with substantial economic burden. Early identification of at-risk CKD can facilitate appropriate and timely intervention and reduce CKD-related medical costs. This study assessed the association between CKD progression risk and healthcare burden.

Methods: A retrospective observational study was conducted in 1,050,552 adult patients with CKD from Optum's electronic health records database (1/1/2007 - 9/30/2022). A previously published and validated machine learning model, Klinrisk (Tangri N, et al Clin Kidney J. 2024 Mar 6;17(4)) was applied to classify patients into 3 groups based on their risk of CKD progression (low, medium, and high). All-cause inpatient (IP) admissions, emergency room (ER) visits, outpatient (OP) visits were evaluated in each risk group during the 1 year after CKD. Average medical costs (2023 USD) were calculated as the average length of stay for IP admissions, average number of ER and OP visits multiplied by the corresponding unit costs as estimated from a prior study.

Results: Patients with higher predicted CKD progression risk had higher healthcare utilization (HRU). High-risk patients averaged 1.49 IP admissions, 0.83 ER visits, and 35.75 OP visits per year compared with 0.31 IP admissions, 0.63 ER visits, and 24.45 OP visits among low-risk patients. The total annual medical costs for low-, medium-, and high-risk patients were $16,018, $22,090, and $50,218, respectively (Figure). IP costs were the major cost driver for high-risk patients.

Conclusions: Patients at high risk of CKD progression as predicted by Klinrisk were associated with high HRU and medical costs and may benefit from early intervention with guideline-directed therapies, to reduce economic burden.



Annualized all-cause medical costs stratified by CKD progression risk

Predicting CKD Progression Using Machine Learning

Adam E. Gaweda, Salgram Jaisinghani, Vibha S. Nayak, Rosemary Ouseph. *University of Louisville, Louisville, KY.*

Background: Chronic Kidney Disease (CKD) increases morbidity and mortality. With multiple new interventions available, there will be a need for optimal combination therapies to slow or reverse the progression of CKD. We present a first step in building a computational framework for achieving this goal. We develop an Artificial Neural Network (ANN) model to predict CKD trajectory based on current patient status and selected therapeutic interventions.

Methods: Using data from Chronic Renal Insufficiency Cohort (CRIC) we predicted GFR (CKD-EPI) trajectory, based on age, BMI, smoking status, hypertension, proteinuria, diabetes, and the prescription of antidiabetic medication, beta blockers, ACE inhibitors, and ARB's. We used a transformer ANN combining Multi-Head Self-Attention with Multi-Layer Perceptron. Training was performed using 10-fold Cross-Validation. Predictive performance was assessed using Root Mean Square Error (RMSE) and R^2.

Results: The mean Cross-Validation RMSE achieved was 6.98 +- 0.37 and the R^2 was 0.83 +- 0.02 (Table 1). Figure 1 shows an example of GFR trajectory prediction for an individual subject (left) and the regression plot for one of the Cross-Validation folds.

Conclusions: Modern Machine Learning techniques facilitate sequential prediction tasks, such as modeling CKD progression. A transformer ANN model predicts individual CKD trajectories with high accuracy. The model will be used to discover optimal treatment combinations. As more data become available about the use of new classes of therapeutic agents for CKD, those data can be incorporated into the model to enhance its utility. **Acknowledgment:** CRIC data were provided by NIDDK Central Repository, a program of the National Institute of Diabetes and Digestive and Kidney Diseases

TH-PO006

Validation of Artificial Intelligence (AI)-Based Kidney Disease Progression Prediction (KDPP) Models in the US Population

Chin-Chi Kuo,[1] Yichun Chen,[4] Yi-Ching Chang,[1] Yu-Ting Lin,[1] Priyanka Arya,[3] Ricardo Aguilar,[3] Arsh Jain.[2] *[1]China Medical University Hospital, Taichung, Taiwan; [2]London Health Sciences Center, London, ON, Canada; [3]AWAK Technologies, Singapore, Singapore; [4]Ever Fortune.AI, Taichung, Taiwan.*

Background: AI and big data are revolutionizing personalized CKD management. KDPP models use deep learning to risk stratify patients for optimal treatment planning. Initially validated in Taiwan and granted **FDA breakthrough device designation**, this study tests KDPP's generalizability in U.S. using NIDDK's CRIC database.

Methods: KDPP includes 2 deep-learning models built using 9,529 CKD stage 3-5 patients from CMUH Taiwan: KDPP-RP for predicting rapid disease progression and KDPP-IR for forecasting renal replacement therapy (RRT). KDPP-IR was validated with CRIC (4,465 participants); KDPP-RP validation was limited by data scarcity. The models categorize patients into risk tiers (low, moderate, high) and are evaluated using AUC, sensitivity, specificity, and PPV/NPV.

Results: The CMUH cohort is older, has lower median eGFR (27 vs. 41.9 mL/min/1.73m^2) than CRIC. KDPP-IR accurately predicted RRT with AUCs of 0.96 for CMUH and 0.89-0.92 for CRIC, performing well across races (**Table 1**). KDPP-IR's sensitivity and precision slightly decreased, but specificity improved. It reliably identified low-risk CRIC patients with NPVs of 0.99-1.00, though PPVs for high-risk varied (0.31-0.79). Kaplan-Meier curves showed distinct risk stratification, and calibration plots showed better agreement between observed and predicted risks than KFRE. (**Figure 1**).

Conclusions: The validation demonstrated robust AUCs and generalizability for risk prediction. Future enhancements will optimize both models for diverse ethnic groups to broaden their applicability.

Funding: Commercial Support - AWAK Technologies

TH-PO007

Construction of a Predictive Equation for CKD Exacerbation by Multifactorial Analysis Using Machine Learning and Analysis on Differences in CKD Exacerbation Factors in Each CKD Stage

Koki Ogawa,[1] Hiroaki Hara,[1] Yasushi Takahashi,[2] Seiko Oana,[2] Yumiko Nakamura,[1] Akito Maeshima,[1] Hajime Hasegawa.[1] *[1]Saitama Ika Daigaku Sogo Iryo Center, Kawagoe, Japan; [2]NEC Solution Innovator Kabushiki Kaisha, Koto-ku, Japan.*

Background: Multiple factors such as comcomitant disorders, prescribed medications and physical characteristics are involved in CKD exacerbation. In recent years, machine-learning has enabled us to analyze the CKD exacerbation in relation to the multiple factors. We aimed to construct a predictive equation for the CKD exacerbation by analyzing changes in the multiple factors by machine-learning. Additionally, the differences in exacerbation factors per CKD stage were also examined.

Methods: The analysis included 3098 of CKD patients at our institution between Apr. 2006 and Mar. 2021 for which data analysis was possible more than once a year apart. For each case, 209 items such as blood test results, blood pressure, body weight, age and medications were learned and analyzed using machine learning. We defined the CKD exacerbation as "change in CKD heat map" (eg. green to yellow) because final renal outcome involves both decreased eGFR and worsening proteinuria during follow-up period. For the case in which CKD heat map exacerbated, the item of which the exacerbation contribution was large was extracted, and the difference of exacerbation factors (EF) by CKD stage was examined.

Results: The prediction equation was constructed using 85% of population, and its accuracy was verified by adapting the constructed equation to the remaining 15% of the population. The accuracy rate was 76.8% in Green group, 75.6% in Yellow group, and 70.8% in Orange group, respectively. The largest EF was the proteinuria throughout all CKD stage, and it was baseline eGFR next. Except for these two factors, EF differed according to CKD stage, and EF next to the above two factors were concomitant hypertension in Green group, elevation of serum uric acid in Yellow group, and the presence or progression of anaemia in Orange group.

Conclusions: The prediction equation constructed in this study showed sufficient accuracy for clinical use. And, that principal CKD exacerbation factors greatly differed for each stage except for proteinuria and baseline eGFR seemed to be the key knowledge for the management of CKD patients.

TH-PO008

Predicting the Risk of Albuminuria in Patients with Diabetes: A Systematic Review and Development Study

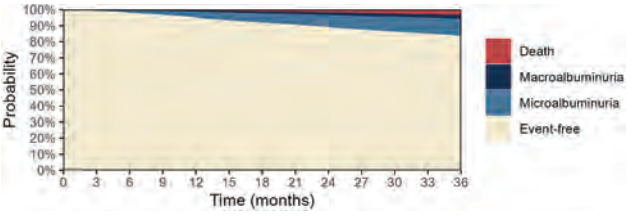
Roemer J. Janse,[1,2] Marretje W. Oomen,[1] Chava L. Ramspek,[1] Friedo W. Dekker,[1] Juan J. Carrero,[2] Merel van Diepen.[1] *[1]Leids Universitair Medisch Centrum, Leiden, Netherlands; [2]Karolinska Institutet, Stockholm, Sweden.*

Background: Patients with type 2 diabetes mellitus (T2DM) are at high risk of kidney disease, which may be ameliorated by early detection of albuminuria. Clinical prediction models (CPMs) can tailor guideline screening to the individual patient. To allow this, we aimed to 1) identify available CPMs and their shortcomings and 2) predict albuminuria risk, albuminuria-free time, and progression through albuminuria stages.

Methods: We systematically identified albuminuria CPMs and appraised their risk of bias (ROB). New models were developed in the Stockholm Creatinine Measurements cohort. We divided Stockholm residents with an albumin/creatinine test between 2006-2021 with T2DM and no albuminuria into a development and temporal validation cohort. Predictors were selected based on clinical expertise, literature, and previous CPMs. We predicted micro- and macroalbuminuria within 3 years. We predicted 1) the risk using a Fine-Gray CPM accounting for the competing risk of death, 2) the expected albuminuria-free days using an accelerated failure time (AFT) CPM, and 3) the risk of different albuminuria stages using a multi-state CPM. CPM discrimination and calibration were assessed in the development and validation cohorts.

Results: We identified 9 studies reporting on 11 CPMs. Most models were at high ROB. We developed new models on 38649 individuals with 6904 events and validated these in 45009 individuals with 6499 events. The Fine-Gray CPM had adequate discrimination internally (C-statistic, 95%CI; 0.64, 0.64-0.65) and temporally (0.66, 0.66-0.67). Calibration was good. The AFT CPM had adequate discrimination (internally: 0.63, 0.62-0.63; temporally: 0.65, 0.64-0.65), but poor calibration. An individual prediction from the multi-state CPM can be seen in **Figure 1**.

Conclusions: Predicting albuminuria in T2DM patients allows tailoring albuminuria screening to the individual. We developed multiple CPMs that provide different information on the risk of albuminuria within 3 years. These models can serve to improve albuminuria screening and ameliorate the risk of kidney damage in patients with T2DM.



TH-PO009

Artificial Intelligence (AI)-Driven Screening for Undiscovered CKD

Thomas L. Salazer,[1] Naitik Sheth,[1] Avais Masud,[1] David Serur,[1] Guillermo Hidalgo,[1] Iram Aqeel,[1] Linara Adilova,[2] Michael Kamp,[2] Tim Fitzpatrick,[2] Sriram Krishnan,[2] Kanishka Rao,[2] Bharat Rao.[2] *[1]Hackensack Meridian Health, Edison, NJ; [2]Carenostics, Philadelphia, PA.*

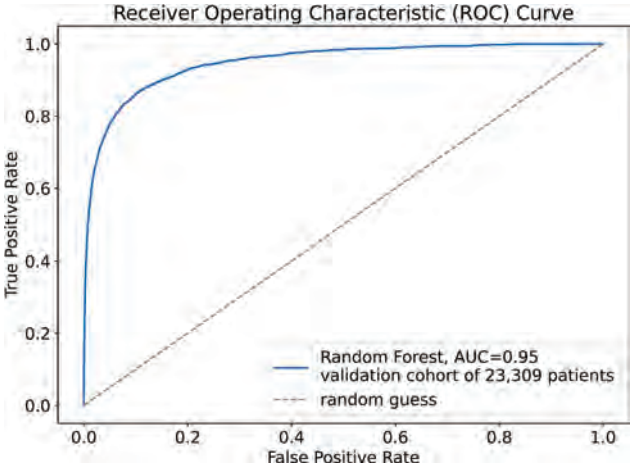
Background: We developed and validated a predictive model to identify patients at risk of undiagnosed CKD. Given the progressive nature of CKD, our model incorporates a crucial temporal dimension, allowing it to assess whether undiagnosed patients have

Stage 3 CKD based on prior EHR data. We developed the model to enable proactive evaluation and intervention on patients.

Methods: Patients aged 18 to 85 with no previous diagnosis of CKD as of January 1, 2018, were considered to identify which patients are at risk of undiagnosed CKD. The data set included patients with no prior eGFR, or at most one abnormal eGFR. We extracted 237 variables from the EHR, including demographics, labs, medications, and prior diagnoses. Multiple machine learning models were trained on a training set, and performance was measured on the test set using ROC curves, sensitivity, specificity and accuracy, as well as temporal stability.

Results: A Random Forest model trained on 46,775 patients achieved an AUC of .95 to predict whether next eGFR measured would be abnormal (eGFR < 60) on an independent test set of 23,039 patients whose eGFR was measured in the subsequent year. A selected set point achieved a sensitivity of 0.51 and PPV of 0.84. (ML models trained to predict the first abnormal eGFR in subsequent 2/3/4 years, achieved AUCs of 0.94/0.93/0.92 demonstrating the temporal stability of our approach.)

Conclusions: The model developed using a random forest machine learning algorithm was able to identify undiagnosed patients at risk of Stage 3 CKD with high accuracy and discriminatory power. This predictive model demonstrates the potential of an AI-driven approach to identify patients earlier in the disease process. In the next phase of this work, we intend to apply this model to identify high risk patients, and proactively recommend them for evaluation and targeted interventions.



Random Forest model ROC Curve

Using Machine-Learning Algorithms to Predict the Risk of AKI and CKD during the COVID-19 Pandemic Based on National Electronic Health Records

Yue Zhang, Nasrollah Ghahramani, Vernon M. Chinchilli, Djibril Ba.
Penn State College of Medicine, Hershey, PA.

Background: The application of machine learning algorithms in predicting the risk of acute kidney injury (AKI) and chronic kidney disease (CKD) has shown promise within local healthcare organizations. However, their performance using national electronic health records (EHR) remains unclear. Moreover, the impact of including COVID-19 infection histories in predictive models is not clear.

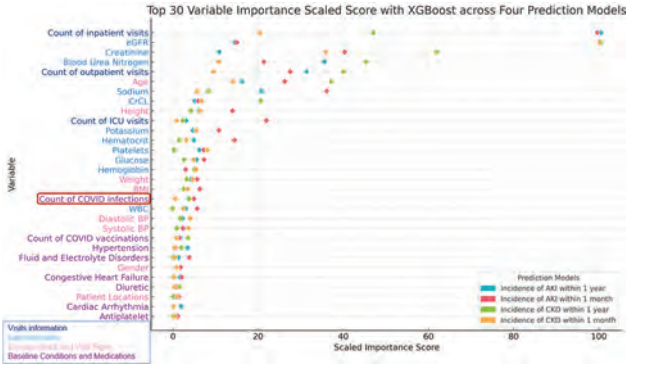
Methods: Data were sourced from the TriNetX Research Network, with study cohort period from 2022/07/01 to 2024/03/31. The incidence of AKI or CKD was extracted based on ICD-10 codes after the index date. Covariates were assessed within 1 year before the index dates, including 4 demographics, 33 comorbidities, 18 lab test results, 13 medications, 5 vital signs, 3 visit histories, and COVID-19 infections. Missing values were imputed, and upsampling methods were used to address data imbalances. Extreme gradient boosting was used to build machine learning algorithms for predicting AKI and CKD separately, for each of the two prediction windows.

Results: We included 104,565 participants. The area under the receiver operating characteristic (AUROC) curve was stable across the prediction windows, with the highest score for CKD within 1 month (0.87) and the lowest for AKI within 1 year (0.79) (Table). Counts of inpatient visits and eGFR were the most important variables for predicting AKI and CKD, respectively. The count of COVID-19 infections was the most important variable among baseline conditions (Figure).

Conclusions: Machine learning with national EHR data shows promising performance for AKI and CKD predictions. COVID-19 status should be included in the prediction model.

Performance of Predictive Models

Prediction Models	AUROC	Precision	Sensitivity	Specificity	Accuracy	F1 score
Incidence of CKD within 1 year	0.8624	0.9958	0.7944	0.7926	0.7944	0.8838
Incidence of AKI within 1 year	0.7880	0.9937	0.8081	0.6403	0.8057	0.8913
Incidence of CKD within 30 days	0.8659	0.9991	0.8410	0.7778	0.8408	0.9133
Incidence of AKI within 30 days	0.8025	0.9987	0.7681	0.7248	0.7680	0.8664



TH-PO011

Machine-Learning Model for Predicting Early Mortality in Critically Ill Patients Requiring Continuous Kidney Replacement Therapy

Kullaya Takkavatakarn,[1] Joshua Lambert,[2] Justin Kauffman,[1] Tomonori Takeuchi,[4] Augusto Cama-Olivares,[4] Stuart Goldstein,[3] Jin Chen,[4] Lili Chan,[1] Girish N. Nadkarni,[1] Javier A. Neyra.[4] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]University of Cincinnati, Cincinnati, OH; [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [4]The University of Alabama at Birmingham, Birmingham, AL.*

Background: Critically ill patients with acute kidney injury requiring continuous renal replacement therapy (CRRT) have high mortality and require significant resource utilization. Accurately predicting early mortality would facilitate clinical decision-making by identifying high morbid patients who may benefit from personalized care intensity with CRRT. We aimed to develop a model to predict mortality within the first 72 hours after initiating CRRT.

Methods: We obtained data from CRRTnet, a prospective multicenter data registry of adult patients undergoing CRRT for at least 24 hours. The cohort was divided into training and test datasets (80/20). We trained and validated XGBoost model with 10-fold cross-validation to predict mortality within 72 hours of CRRT initiation using patient demographics, laboratory results, vasopressors, fluid balance, and CRRT-related variables. We chose the parameters for the XGBoost model using Bayesian optimization. Bayesian optimization models the anticipated value of an objective function with a gaussian process over the space of all hyper parameters and uses Bayesian updating to choose parameter sets that maximize this function. Area under the receiver operating characteristic (AUROC) and precision-recall curve (AUPRC) were used to evaluate model performances. Shapley additive explanation (SHAP) value was applied to explain the model.

Results: We included 1,446 patients (59% men). Median age was 60 years (IQR 50-69), serum creatinine at CRRT initiation was 5.4 mg/dL (IQR 2.9-6.7), and APACHE II score was 29 (IQR 26-31). Among these patients, 236 (16.3%) died within 72 hours of CRRT initiation. The AUROC was 0.90 (95% CI 0.86 to 0.95), and the AUPRC was 0.64 (0.50 to 0.79) **(Fig1A,1B).** SHAP plot shows the importance of the top 20 features **(Fig1C).**

Conclusions: The proposed XGBoost model, the first to incorporate clinical and CRRT-related variables, shows promise in predicting early mortality in critically ill patients undergoing CRRT. Implementing the model could serve as an additional clinical tool for personalizing early CRRT use.

A Data-Driven Digital Health Approach to Improve CRRT Delivery in the Intensive Care Unit (ICU)

Ruben Raposo,[1,2] Javier A. Neyra,[2] Ashita J. Tolwani.[2] *[1]Dialytix Technologies Inc., Birmingham, AL; [2]The University of Alabama at Birmingham, Birmingham, AL.*

Background: Acute kidney injury (AKI) is a frequent complication in the intensive care unit (ICU). About 15% of critically ill patients with AKI require renal replacement therapy, commonly in the form of continuous renal replacement therapy (CRRT). The aims is to develop a data pipeline to feed scalable dashboards of patient- and CRRT-relevant data to monitor key performance indicators and patient outcomes.

Methods: We utilize EHR and CRRT device data from the University of Alabama at Birmingham from January 2022 to February 2024. The data from each of the 42 CRRT machines (2022 to 2024) operating UAB. We extracted the CRRT device data every month via a manual process and were then uploaded to a secure storage location for data processing. We created an ETL (extract, process, and loading) data process using Python code to clean and normalize data. We then connected the Python data pipeline to feed the visualization layer via the Tableau cloud server. We designed interactive dashboards with Tableau that show the key performance indicators for various stakeholders that want to monitor and track on a weekly or monthly basis.

Results: We developed clinical dashboards in Tableau that incorporate data visualization with KPIs, filters, and AI-powered data analytics techniques to support providers in viewing and exploring EHR data for clinicians to inform decisions and improve patient care, thereby identifying previously unnoticed patterns in EHR data to support clinical decision-making.

Conclusions: With the collection of CRRT machine data and the creation of a data processing pipeline including EHR data, we can provide our clinical, administrators, and medical researchers further data insights on the performance of the CRRT treatment and enhance the monitoring capabilities so that we can continue to understand where possible gaps are and find ways to improve on them.

NefroAssist: A Machine-Learning Prediction Model for Early Nephrology Intervention in Hospitalized Patients at Christus Muguerza Group

Mariana N. Zavala, Ricardo A. Garza Treviño, Santiago Chavez, Andres O. Nevarez, Juan O Galindo, Lilia M. Rizo Topete. *Christus Muguerza Sistemas Hospitalarios SA de CV, Monterrey, Mexico*.

Background: Delay in nephrology consultation is associated to severe AKI stages and critical illness, resulting in urgent RRT, increased mortality, reduced renal recovery, greater dialysis dependence, and higher costs. To prevent AKI, based on the article "Acute Kidney Injury Risk Assessment and the Nephrology Rapid Response Team", which describes a model based in the "Fantastic 4", to identify patients at high risk for AKI; we developed NefroAssist. This machine learning algorithm has the objective to predict the likelihood of requiring nephrology consultation for patients within the first 6 hours of admission. It employs information from the electronic medical record and allows collaboration with a nephrologist to improve outcomes.

Methods: A predictive model was developed with database from the electronic medical record system available from 2023 of 4 hospitals. The methodology for handling the data was a ETL process (extract, transformation, and load). The initial load data were 23,104 individual records. Through the elimination of irrelevant data, data imputation, and the creation of new data, a split of 80-10-10 was performed. Where 80% was allocated for training, 10% for data validation, and 10% for testing the models. In the evaluation, the logistic regression model with has been able to fit correctly the data.

Results: Using logistic regression we train a model which demonstrated optimal performance in classifying patients who will require a nephrology consultation. With a specificity of 89% and sensitivity of 73%. The factors identified from the F4 were F1: polytrauma, antibiotics, coronary angiography, major surgery, and sepsis; F2 diabetic and hypertensive patients; and F4 creatinine, proteinuria.

Conclusions: Nefroassist successfully predicted which patients will require nephrology intervention, with a sensitivity of 73% and a specificity of 88%. We have validated it retrospectively, the next step is to apply and validate it prospectively.

Artificial Intelligence/Machine Learning Externally Validated Models for AKI Risk-Classification: A Systematic Review and Meta-Analysis

Augusto Cama-Olivares,[1] Chloe G. Braun,[2] Tomonori Takeuchi,[1,3] Kathryn A. Kaiser,[4] Lama Ghazi,[5] Jin Chen,[1] Lui G. Forni,[6,7] Sandra L. Kane-Gill,[8] Marlies Ostermann,[9] Benjamin Shickel,[10] Jacob Ninan,[11] Javier A. Neyra.[1] *[1]The University of Alabama at Birmingham Division of Nephrology, Birmingham, AL; [2]The University of Alabama at Birmingham Department of Pediatrics, Birmingham, AL; [3]Tokyo Ika Shika Daigaku Daigakin Ishigaku Sogo Kenkyuka, Bunkyo-ku, Japan; [4]The University of Alabama at Birmingham Department of Health Behavior, Birmingham, AL; [5]The University of Alabama at Birmingham Department of Epidemiology, Birmingham, AL; [6]University of Surrey Department of Clinical and Experimental Medicine, Guildford, United Kingdom; [7]Royal Surrey NHS Foundation Trust, Guildford, United Kingdom; [8]University of Pittsburgh Department of Pharmacy and Therapeutics, Pittsburgh, PA; [9]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; [10]University of Florida Division of Nephrology Hypertension & Renal Transplantation, Gainesville, FL; [11]Mayo Clinic Minnesota, Rochester, MN.*

Background: Artificial Intelligence (AI) through machine learning (ML) models can provide accurate and precise acute kidney injury (AKI) risk classification, but their extent and performance in real-world settings have not been established.

Methods: PubMed, EMBASE, Web of Science, and Scopus were searched until 08/2023. Articles reporting on externally validated models for prediction of AKI onset, AKI severity, and post-AKI complications in hospitalized adult and pediatric patients were searched using text words related to AKI, AI, and ML. Two independent reviewers screened article titles, abstracts, and full texts. Areas under the receiver operating characteristic curves (AUCs) were used to compare model discrimination and pooled using random-effects model.

Results: Of 4,280 articles initially identified and screened, 85 were included with 2.8 million admissions (study sample dates ranged from 1996 to 2022). The KDIGO criteria were the most frequently used to define AKI (72.9%). We identified 291 models, with the most commonly reported being logistic regression (35.1%), random forest (9.6%), and XGBoost (9.6%). The most frequently reported predictors of AKI onset were age, sex, diabetes, serum creatinine, and hemoglobin. The pooled AUC for AKI onset was 0.82 (95% CI, 0.80-0.84) and 0.78 (95% CI, 0.76-0.80) for internal and external validation, respectively. Pooled AUC across multiple clinical settings, AKI severities, and post-AKI complications ranged from 0.78 to 0.87 for internal validation and 0.75 to 0.84 for external validation. Although data were limited, results in the pediatric population aligned with those observed in adults. Between-study heterogeneity was high for all outcomes (I^2 >90%), and most studies presented high-risk of bias (72.9%) according to the Prediction model Risk Of Bias ASsessment Tool (PROBAST).

Conclusions: Most externally validated models performed well in predicting AKI onset, AKI severity, and post-AKI complications in hospitalized adult and pediatric populations. However, heterogeneity in clinical settings, study populations, and predictors limits their generalizability and implementation.

TH-PO015

Advancements in Predicting Pediatric AKI Using Artificial Intelligence: A Systematic Review

Arwa Nada.[1,2] *[1]Loma Linda University, Loma Linda, CA; [2]The University of Tennessee Health Science Center College of Medicine, Memphis, TN.*

Background: The prediction and management of Acute Kidney Injury (AKI) in pediatric patients remain challenging due to its rapid onset and diverse etiologies. Recent advancements in artificial intelligence (AI) offer promising tools for early detection and improved clinical outcomes.

Methods: Search Strategy: Utilized PubMed with keywords and MeSH terms related to pediatric AKI and artificial intelligence. Inclusion Criteria: Studies published from 2019-2023, involving AI models for pediatric AKI prediction or management. Data Extraction: Study characteristics, AI methods, population, key findings, and references were extracted and tabulated.

Results: Table I shows summary of the studies (image of table uploaded) The studies colectively showed: high Accuracy: GBM, ensemble learning, and RF models demonstrated high predictive accuracy. Early Detection: AI models enabled early AKI detection, facilitating timely interventions. Risk Stratification: Effective in identifying high-risk patients for personalized treatment. Data Integration: AI successfully integrated diverse data sources for comprehensive analysis.

Conclusions: AI integration in clinical practice holds the potential for revolutionizing pediatric AKI management and improving patient outcomes through proactive and personalized care. Further research should focus on standardizing AI applications and ensuring equitable healthcare delivery.

Forecasting Intradialytic Hypotension: A Comparative Analysis of Machine-Learning and Deep-Learning Approaches

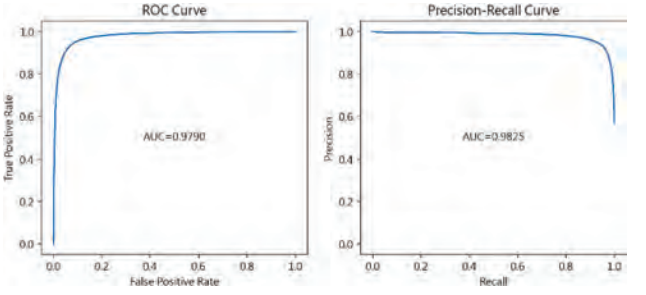
Chun-Te Huang.[1,2] *[1]Taichung Veterans General Hospital, Taichung, Taiwan; [2]National Yang Ming Chiao Tung University - Yangming Campus, Taipei, Taiwan.*

Background: Intradialytic hypotension (IDH) poses significant risks to patients undergoing dialysis, necessitating reliable predictive tools for early intervention. This study evaluates the efficacy of machine learning and deep learning models in predicting IDH.

Methods: We developed predictive models on a Taichung Veterans General Hospital dataset using XGBoost (eXtreme Gradient Boosting) and RNN (Recurrent Neural Network) algorithms. The dataset encompasses the period from 2015 to 2020, consisting of 211,535 timestamps from 20,946 hemodialysis sessions across 2,118 patients. We defined intradialytic hypotension as a decrease in systolic blood pressure ≥20 mm Hg and/or a mean arterial pressure decrease ≥10 mm Hg. The dataset was split into 80% for training, employing 5-fold cross-validation, and 20% for testing. Features selected for training included age, sex, comorbidity, vital signs, laboratory data, medication, and specific hemodialysis characteristics.

Results: The XGBoost model exhibited superior performance in predicting intradialytic hypotension, achieving an Area Under the Receiver Operating Characteristic curve (AUROC) of 0.9790 and an Area Under the Precision-Recall Curve (AUPRC) of 0.9825. While still effective, the RNN model showed slightly lower performance with an AUROC of 0.976 and an AUPRC of 0.978. These results emphasize the slight edge of XGBoost in predictive accuracy compared to the RNN model, demonstrating its enhanced capability in clinical forecasting without specifically relying on demographic variables like age and weight.

Conclusions: The findings from this study highlight the slightly superior performance of the XGBoost model over the RNN in predicting intradialytic hypotension. XGBoost demonstrated higher predictive accuracy and offers potential advantages in clinical implementation due to its less intensive computational demands. This makes it an especially viable option for real-time clinical applications with limited computational resources.



The model performance of XGBoost

Development of Artificial Intelligence for Clinical Decision Support to Optimizes Erythropoietin-Stimulating Agents in Patients with CKD

Sathit Kurathong, Pattanan Buranasaksathien, Wanjak Pongsitisak, Thananda Trakarnvanich, Tanun Ngamvichchukorn, Solos Jaturapisanukul, Punnawit Laungchuaychok, Nitcha Suphatheerawatr, Kavee Limbutara, Padoemwut Teerawongsakul. Vajira Big Data and Machine Learning for Applied in Healthcare Research Group. *Faculty of Medicine Vajira Hospital, Bangkok, Thailand.*

Background: The application of AI in predicting Hb levels and determining appropriate ESA doses for managing anemia of CKD is a promising development. Previous studies using AI for anemia of CKD treatment have demonstrated positive outcomes, such as increased percentages of patients achieving target Hb levels and reduced ESA dosages. The replication of these findings in the Thai population could have significant implications for managing anemia of CKD in Thailand.

Methods: The development of the AI model included 4 steps: data collection, feature selection, data preparation, and model selection. CKD patients with eGFR <45 ml/min/1.73m^2 who used ESA were included. The data was cleaned and prepared by removing outlier data and correcting missing values. Variables were used to create time series. Time series were divided into training and test set to create the best models (Decision Tree, Random Forest, XGBoost, and SVM). Finally, the models were evaluated by Pearson r correlation and RMSE. (Fig 1)

Results: A total of 9,935 time series were collected. The median follow-up time was 9 months. The models did not perform well in predicting weekly change of Hb level on the entire dataset (RMSE for Decision Tree was 0.141, for Random Forest was 0.135, for XGBoost was 0.137, and for SVM was 0.135), and the difference in weekly change of Hb ranged from -0.2 to 0.2 g/dL, approximately 0-40%. The best models are Random Forest, XGBoost and SVM with similar results. (Fig 2)

Conclusions: This study showed that AI model can predict weekly change in Hb level. Although the performance may not be able to accurately predict weekly changes in Hb levels. Future studies should aim to include a larger number of participants to improve the performance of the models.

Funding: Government Support - Non-U.S.

Machine-Learning Algorithm of Two Continuous Assessment Methods of Dialysis Quality Indicators-Based Prediction Scheme for Assessing Mortality Risk in Patients on Maintenance Hemodialysis

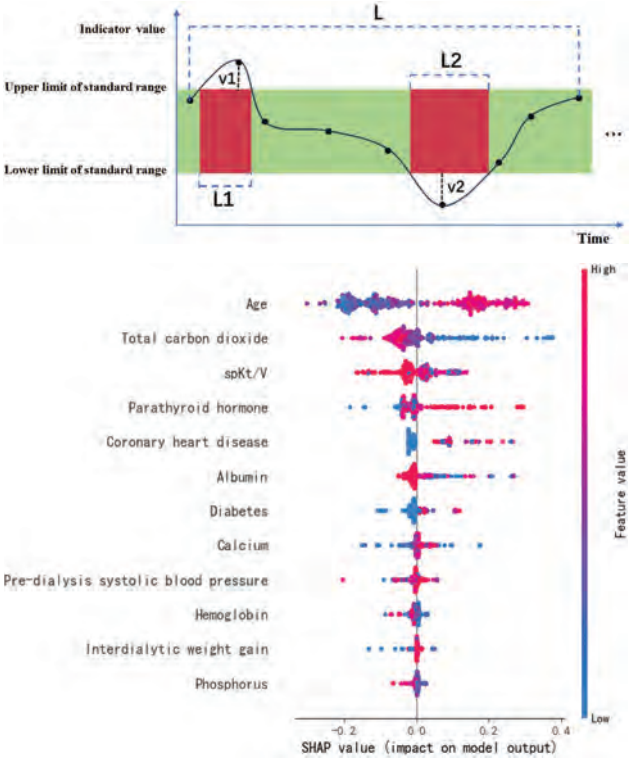
Jianhua Dong, Yongchun Ge. National Clinical Research Center of Kidney Diseases. *Nanjing General Hospital of Nanjing Military Command Research Institute of Nephrology, Nanjing, China.*

Background: Use machine learning method to analyze the impact of two continuous assessment methods of dialysis quality indicators on the prognosis of maintenance hemodialysis (HD) patients

Methods: A total of 240 patients who received HD treatment were screened, and dialysis quality was assessed more than three times a year. The indicator time-to-standard ratio and indicator fluctuation value were used as the evaluation methods for the continuous achievement of nine dialysis quality indicators. A prediction model for survival or death of HD patients after 1 year was constructed based on a machine learning algorithm. Shapley additive explanation (SHAP) values were used to measure the marginal contribution of each feature to the models.

Results: Six machine learning methods are used to build prediction models based on the indicator time-to-standard ratio and the indicator fluctuation value. The ExtraTrees model based on the indicator time-to-standard ratio has the best prediction effect, with its accuracy, precision, recall, F1 score and area under the receiver operating curve reaching 0.92, 0.86, 0.96, 0.91 and 0.93 respectively, while confirming 0.65 as the optimal probability threshold for the model. Visualization of the TreeSHAP interpretation results of the prediction model helps physicians understand the global prediction mechanism of the model and explain the importance of a patient's characteristic parameters in influencing the outcome of the patient.

Conclusions: The machine learning model based on the indicator time-to-standard ratio has a good prediction effect on the prognosis of HD patients.



TH-PO019

Development of Machine Learning-Based Models for Detection of Cognitive Impairment in Patients Receiving Maintenance Hemodialysis

Tsai-chieh Ling,[1] Chiung-Chih Chang,[3] Jia-Ling Wu,[2,1] Wei-Ren Lin,[1] Chien Yao Sun,[1] Chieh-Hsin Huang,[1] Yu T. Chang.[1,2] *[1]National Cheng Kung University Hospital, Tainan, Taiwan; [2]National Cheng Kung University, Tainan, Taiwan; [3]Chang Gung Memorial Hospital Linkou, Kaohsiung, Taiwan.*

Background: Cognitive impairment is common but frequently undiagnosed in the dialysis population. There is no recommended screening tool specifically designed for them. We aimed to develop and validate a quick and accurate screening tool composed of only a few items in the Mini-Mental State Examination (MMSE) and Cognitive Abilities Screening Instrument (CASI) using machine-learning based approaches in hemodialysis patients.

Methods: We conducted a cross-sectional observational study in which the MMSE and CASI were administered in 508 hemodialysis patients and randomly divided into a derivation set (70%) and a validation set (30%). Cognitive impairment was defined as a CASI score below the 20th percentile of age- and education-matched norms. Using three to five key items from MMSE and CASI as predictors, we developed six machine learning models, including Lasso, classification and regression tree (CART), random forest (RF), extreme gradient boosting (XGboost), support vector machine (SVM), and artificial neural networks (ANN) in derivation set. We then evaluated the predictive performance of these models in the validation set.

Results: The derivation samples (n = 357) had a mean (SD) age of 64.13 (11.92) years and a mean education level of 8.76 (4.91) years. Around 40% participants were identified as cognitive impairment according to their total CASI score. Among all the developed machine-learning models, the RF model achieved the highest performance of prediction, with an accuracy of 0.94, an area under the curve (AUC) of 0.95, and an F1 score of 0.92 in the validation set. The other models, except for CART, performed equally well in terms of AUC. The RF and SVM models demonstrated the greatest net benefit over clinical thresholds according to decision curve analysis.

Conclusions: Our study demonstrates that using machine-learning models can efficiently identify patients with CASI score < 20 percentile of age- and education-matched norms with only several questions in CASI and MMSE within 5 minutes. Since cognitive impairment implicates decision making and is associated with poor outcomes, early detection might improves patient care and enables timely referral.

Automatic Noninvasive Peritonitis Detection and Monitoring in Patients on Peritoneal Dialysis Using High-Resolution Ultrasonography and Artificial Intelligence

Maria Quero,[1] Beatrice M. Jobst,[2] Sara Guillén Fernández-Micheltorena,[2] Francesc Carandell Verdaguer,[2] Roberto F. Santos Abreu,[2] Javier Jimenez,[2] Rita Quesada,[2] Alex Andujar Asensio,[1] Ana M. Rau,[1] Yolanda Molina,[3] Fátima Moreno Guzmán,[3] Jose Jesus Broseta Monzo,[4] Ana Sanchez Escuredo,[5] Maria F. Slon Roblero,[6] Inés Rama.[1] *[1]Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, Spain; [2]Kriba, Barcelona, Spain; [3]Consorci Sanitari de Terrassa, Terrassa, Spain; [4]Hospital Clinic de Barcelona, Barcelona, Spain; [5]Hospital de Sant Joan Despi, Sant Joan Despi, Spain; [6]Complejo Hospitalario Navarra, Pamplona, Spain.*

Background: Peritonitis is a significant complication in peritoneal dialysis (PD) due to its high incidence and associated consequences, such as technique failure and mortality. Early diagnosis and treatment are crucial to reduce complications. We developed an automatic, quick, non-invasive leukocyte counting and differential method based on high-resolution ultrasound (HRUS) and artificial intelligence (AI). This method could be useful for early peritonitis detection and home monitoring in PD patients to extend technique's survival and reduce mortality.

Methods: We acquired HRUS in vitro data from polystyrene particles suspended in distilled water in drainage bags (Baxter's and Fresenius') at concentrations 0-4000 cells/μl. Four AI models were trained on these data: one to classify concentrations below and above 200 cells/μl; two models to predict leukocyte numbers in the respective range, and a fourth to classify between polymorphonuclear cells and lymphocytes. Patient effluent samples with >4000 cells/μl were automatically filtered by intensity. Each model was tested with 3 measurements on each of the 62 samples from 6 patients with confirmed peritonitis. Results were compared to laboratory measurements (LM).

Results: The counting models yielded an R^2 score of 0.94 (0-4000 cells/μl). For LM<200, containing the diagnostic threshold of 100 cells/μl, the mean error over patient samples was 18.1±22.0 cells/μl. 18/20 measurements >4000 cells/μl were correctly filtered. The remaining 2 were predicted with >2700 cells/μl. For classification below and above 100 cells/μl, we obtained a sensitivity/specificity (SE/SP) of 95.1/94.7%, respectively. Additionally, the cell-type classification model achieved an accuracy of 90.2% (SE/SP: 86.5/92.5%).

Conclusions: These results demonstrate the potential of this non-invasive AI and HRUS based leukocyte counting and differential system for early detection and objective home monitoring of peritonitis in PD patients.

A Systematic Approach to Map Downstream Effects of Proteins on the Paired Plasma and Urine Metabolome

Inga Steinbrenner,[1] Anna Kottgen,[1,2] Pascal Schlosser.[1,2] *[1]Institute of Genetic Epidemiology, Faculty of Medicine and Medical Center - University of Freiburg, Freiburg, Germany; [2]Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

Background: Proteins mediate and catalyze many metabolic functions, including enzymatic reactions or transport processes. The kidneys operate at the interface of plasma and urine by clearing molecular waste from the body while retaining valuable solutes, underscoring the importance of understanding the connection between transporters and enzymes and their substrates across biofluids. Using quantitative readouts of the proteome and metabolome, we employed hypothesis-generating genetic causal inference methods to study their molecular relations.

Methods: We conducted proteome-wide association studies (PWAS, 1,303 proteins) for the levels of 1,296 plasma and 1,399 urine metabolites as a causal inference approach, based on summary statistics from genome-wide association studies of metabolite levels (N= 7,213 and 5,023, respectively). Downstream analyses included statistical colocalization to control for the risk of genetic confounding due to linkage disequilibrium and a phenome-wide PWAS to highlight (patho-) physiological effects for the proteins with a significant metabolite association with over 4,000 phenotypes in the UK Biobank.

Results: We identified 284 putative causal effects of proteins on metabolite levels, arising from 61 unique proteins and 176 unique metabolite-biofluid combinations and balanced between plasma and urine (141 vs. 143). Colocalization analyses prioritized 169/284 findings (posterior probability of a shared causal variant > 80%). For 31 of the 61 proteins, 326 putative causal effects on health outcomes were identified (p<1.8e-7). For example, the kidney membrane enzyme DPEP1 displayed the strongest association with urine prolylglycine (p-value=1.1e-292) and was associated with 13 metabolite levels and 25 health outcomes including higher hemoglobin concentration and less frequently diagnosed high blood pressure. Another example were UGT1A1 and UGT1A6, enzymes that transform small lipophilic molecules into water-soluble, excretable metabolites. Accordingly, they were among the proteins with the highest number of associated metabolites and linked to risk of gallstone disease.

Conclusions: This hypothesis-generating *in vivo* causal inference screen of the proteome and metabolome highlights dozens of enzymes and their corresponding metabolites and clinical correlates.

Multimodal Spatial Transcriptomic Characterization of Mouse Kidney Injury and Repair

Qiao Xuanyuan, Haojia Wu, Yuhei Kirita, Yoshiharu Muto, Pierre Isnard, Benjamin D. Humphreys. *Washington University in St Louis, St Louis, MO.*

Background: Repair after acute kidney injury (AKI) involves complex interactions among epithelial, stromal, and immune cells, with incomplete recovery potentially leading to fibrosis and chronic kidney disease (CKD). Traditional single-cell sequencing technologies fail to capture the spatial context of these interactions. This study leverages high-resolution in situ sequencing (Xenium) with whole-transcriptome spatial transcriptomics (Visium) to elucidate cellular networks across the full murine kidney injury and repair timecourse.

Methods: We collected mouse kidneys at multiple stages post bilateral ischemia-reperfusion injury (sham, 4 h, 12 h, 2 d, 14 d, and 42 d). We performed analyses using Xenium (300 gene panel) and Visium on two serial sections of formalin-fixed, paraffin-embedded tissue from each time point. Data integration from both platforms mapped the spatial and temporal gene expression across the timeline.

Results: Aligning Xenium and Visium datasets revealed a strong correlation for transcript detection. Xenium analysis identified a total of 1,374,915 cells with an average detection of 123 ± 97 transcripts per cell. Unsupervised clustering resolved twenty distinct cell types and disease states. This single-cell resolution spatial data allowed us to spatially map disease cell states to different regions in the kidney throughout injury and repair. Importantly, we identified the formation of a fibrotic neighborhood dominated by failed repair proximal tubule (FR-PT) cells, immune cells, and fibroblasts during the repair phase through cell neighborhood analysis. Additionally, ligand-receptor interactions enabled the identification of FR-PT expression of *Il34* (ligand) recruiting *Csfr1+* (receptor) immune cells. Finally, integration with Visium data validated the co-expression of ligand-receptor pairs and elucidated potential mechanisms underlying the transition from AKI to CKD.

Conclusions: This study demonstrates the utility of combining high-resolution in situ sequencing with spatial transcriptomics to explore the cellular landscape during renal injury and repair.

Validation of a Cloud-Based Convolutional Neural Network Classifying Arteriovenous Access Aneurysms in a Multicenter Study

Zijun Dong,[1] Hanjie Zhang,[1] Lin-Chun Wang,[1] Sarah Ren,[1] Maggie Han,[1] Lela Tisdale,[1] Valeria Gusmao Bittencourt,[1] Laura Rosales M.,[1] Piotr Starakiewicz,[2] Denzil Douglas,[2] Norbert Shtaynberg,[2] Andrzej Kozyra,[2] Nicholas Fuca,[2] Sindhuri Prakash-Polet,[2] Stephan Thijssen,[1] Dean C. Preddie,[2] Peter Kotanko.[1,3] *[1]Renal Research Institute, New York, NY; [2]Azura Vascular Care, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Arteriovenous (AV) access aneurysms may become life-threatening, e.g., in the event of ruptures. We developed an artificial intelligence classification application (ACA) that categorizes aneurysms using AV access images. This study prospectively evaluates ACA's classification of AV aneurysms against physicians specializing in access care.

Methods: The study took place at two vascular access centers in New York, NY, USA. Subjects were assessed by physicians and classified as having "Advanced" or "Not Advanced" AV aneurysms. Six images, two from above the access and two on each side, were taken (Figure. 1c), uploaded to the cloud, and classified by a convolutional neural network within seconds (Figure. 1b). ACA classifications were compared to those made by physicians, and the area under the receiver operating characteristics (AUROC) curves were computed (Figure. 1a). Physicians were blinded to ACA results. Their assessment served as the ground truth.

Results: We included 720 images from 120 subjects (Figure. 1d). Physicians identified a 22% prevalence of advanced aneurysms. ACA classifications resulted in a mean AUROC of 0.907 (95% CI: 0.840-0.952), a median AUROC of 0.893 (95% CI: 0.823-0.942), a minimum AUROC of 0.866 (95% CI: 0.792-0.921), and a maximum AUROC of 0.910 (95% CI: 0.844-0.955) (Figure. 1e).

Conclusions: ACA demonstrated actionable accuracy in classifying AV aneurysms, even with angled images. Our results align with Zhang (CKJ, 2021), where ACA achieved an AUROC of 0.96 (n=402). Importantly, in the 2021 study physicians evaluated only images, whereas in the current study detailed physical exams were performed. ACA has potential to support aneurysm monitoring, expediting detection and interventions.

Automated Segmentation for Measuring Kidney Volume and Length in CT Images: A Cross-National Evaluation Study

Zhongyi Zhang,[1] Yiyi Hui,[2] Gang Liu,[1] Lina Sun,[3] Xiangchun Liu.[1] *[1]The Second Hospital of Shandong University, Jinan, China; [2]Shandong Provincial Qianfoshan Hospital, Jinan, China; [3]Linyi People's Hospital, Linyi, China.*

Background: Kidney structure is an essential biomarker for evaluating kidney diseases. The main kidney structure biomarkers include the total kidney volume (TKV), parenchymal kidney volume (PKV), and kidney lengths. Although the most common form of diagnostic kidney imaging is ultrasound in a 2D manner, in more complex clinical settings or emergencies, patients usually only have CT scans for other diseases, such as acute abdominal pain, or abdominal surgery; so renal physicians need to estimate the kidney structure directly from CT imaging for patients who have kidney injury to differential diagnosis between CKD and acute kidney diseases. Measuring these biomarkers is labor-intensive for radiologists to require manual declinations of

kidney boundaries slice by slice. However, an automated method of kidney structure measurements in both non-contrast and contrast CT images is still not established.

Methods: Our retrospective study included a total of 1,153 CT images with and without contrast materials from nine countries. Reference standards of kidney volumes and lengths were manually measured and validated by one experienced radiologist. We developed a deep-learning (DL) method for measuring the TKV, PKV, and kidney lengths in CT images. The DL model was trained and tuned on the development data (n=526), and then the model was tested on a held-out internal test set (n=166) and external test sets (n=461). Kidney volumes and lengths were then automatically measured using 3D kidney segmentations.

Results: DL-based total kidney segmentation achieved an internal Dice similarity coefficient (DSC) of 0.986 ± 0.013 and an external DSC of 0.967 ± 0.016. In addition, parenchymal segmentation achieved an internal DSC of 0.977 ± 0.019 and an external DSC of 0.948 ± 0.020. DL-based measurements of TKV, RPV, and kidney lengths demonstrated statistical equivalence with the reference standards across all test images ($p > 0.05$).

Conclusions: We developed a fully automated segmentation method to measure TKV, PKV, and kidney lengths in CT images. The fully automated approach achieved a radiologist-equivalent accuracy on both contrast-enhanced and unenhanced CT modalities. With public access to algorithms and segmentations, our method could identify more potential kidney disease patients and reduce the clinical workload of renal physicians and imaging experts.

Magnetic Resonance Imaging Radiomics Analysis of Noncystic Kidney Parenchyma to Differentiate among Mayo Imaging Classification Classes

Linnea E. Kremer,[1] Arlene B. Chapman,[2] Sam Armato.[1] *[1]The University of Chicago, Chicago, IL; [2]The University of Chicago Medicine, Chicago, IL.*

Background: Mayo Imaging Classification (MIC) serves as a prognostic biomarker for the prediction of kidney function decline of patients with autosomal dominant polycystic kidney disease (ADPKD). Radiomics analysis—the extraction of quantitative image features—may provide additional power in identifying patients that are fast progressors to kidney function decline. Specifically, characterizing the non-cystic kidney tissue using radiomic features extracted from magnetic resonance images (MRI) may differentiate among MIC classes. This work (1) determined whether radiomic features can differentiate between low/intermediate- and high-risk MIC classes in the non-cystic components of the kidney and (2) investigated the effect of image pre-processing on subsequent classification.

Methods: Radiomic features were extracted from T2-weighted fat saturation MRI scans of 138 MIC 1A/1B patients and 324 MIC 1C/1D/1E patients for classification. A pre-processing pipeline was developed for (1) normalization of MRI signal intensity (z-score or psoas muscle as a reference tissue), (2) pixel resampling (upsampling or downsampling) schemes, and (3) gray-level discretization (fixed bin size method with 8-256 gray levels for discretization). Area under the receiver operating characteristic curve (AUC) was used as a performance-assessment metric.

Results: The range of AUC values across pre-processing parameters was 0.69-0.85. Radiomic features for classification include gray-level co-occurrence matrix inverse difference and first-order kurtosis.

Conclusions: The results indicate the potential of radiomics to distinguish between patients based on low/intermediate- and high-risk MIC classification.

TH-PO026

Development of a Multimodal "Kidney Age" Prediction Based on Automatic Segmentation of Magnetic Resonance Imaging in Individuals with Normal Kidney Function: A Preliminary Report

Zuoxian Hou, Yixin Ma, Lubin Xu, Gu-Mu-Yang Zhang, Peng Xia, Limeng Chen. *Peking Union Medical College Hospital, Beijing, China.*

Background: Traditional kidney health assessments rely on clinical indicators and demographics. We introduced KAGE-NET, an artificial intelligence model, to predict kidney age (K-AGE) by combining auto-segmentation and radiomics features from renal MR images to understand kidney health better.

Methods: MR images (T1-weighted and T1-mapping) from UK Biobank, comprising 5693 participants, were utilized in four groups (healthy control (Normal), hypertension (HTN), diabetes (DM) and chronic kidney disease (CKD)). All data underwent auto-segmentation and image-derived phenotype extraction. Control group data was divided into an 8:2 ratio for KAGE-NET training and testing. In the disease groups, the kidney age gap (KAG) metric (K-AGE minus biological age) described the acceleration of kidney aging. KAG greater than 0 indicates accelerated kidney aging; vice versa for KAG less than 0.

Results: A total of 3007 female and 2682 male subjects were included, with a mean age of 53.7±7.8 years old and sCr of 72.28±13.92 μmol/L. Ground truth (Fig.1a) and auto-segmentation (Fig.1b) show high correlation. KAG is around 0 in control group but significantly different with disease groups (CKD: 1.16; DM: -0.58; HTN: -0.25; $p<0.01$; Fig.1c). As health conditions worsen, KAG widens significantly, especially in more complex situations (Fig.1d). Essentially, when DM co-exists without/with CKD, a heightened KAG comparison is noticeably evident (-0.75 vs. 1.52, Fig.1e). A similar outcome is detectable in the KAG comparison between HTN without/with CKD (-0.35 vs. 1.41, Fig.1f).

Conclusions: We introduced KAGE-NET based on MRI multimodal data, presenting a promising comprehensive kidney health assessment tool.

Funding: Government Support - Non-U.S.

A Deep-Learning Approach to Grading Kidney Interstitial Fibrosis: Evaluation of a VGG-16 Model on Trichrome-Stained Biopsy Images

Odianosen J. Eigbire-Molen,[1] Swathi Muni Reddy,[2] Shree G. Sharma.[1]
[1]Arkana Laboratories, Little Rock, AR; [2]University of Arkansas for Medical Sciences, Little Rock, AR.

Background: Renal interstitial fibrosis is an important morphologic predictor of outcome in kidney disease. Grading of interstitial fibrosis is routinely performed by renal pathologists during renal biopsy evaluation. The most common technique for grading interstitial fibrosis is visual estimation on stained sections, typically a trichrome stain. However, this technique is prone to interobserver variability. Deep learning models have shown good performance in image classification tasks with robust reproducibility. We present a deep learning classification model trained to grade renal interstitial fibrosis using static low magnification images of trichrome stained sections.

Methods: 505 low magnification overview images of trichrome stained renal biopsy sections were obtained from the archive of cases signed out in 2023 at Arkana Laboratories. A VGG-16 deep learning model was trained to classify the images into four categories - no fibrosis (0-5%), mild fibrosis (6-25%), moderate fibrosis (26-50%), and severe fibrosis (51-100%). The gold standard was the signout pathologist grading. The dataset was split into a train (80%), validation (10%) and test set (10%). The model consisted of a base VGG-16 model with a dense layer and softmax classifier for categorical classification (Figure 1).

Results: The deep learning model attained an overall accuracy of 95% on the training dataset and 92% on the validation dataset. In comparison to the pathologist gold standard, the deep learning model had an overall accuracy of 82% and differentiated between varying degrees of fibrosis (Figure 2).

Conclusions: This study demonstrates the application of a deep learning model to reproduce grading of renal interstitial fibrosis. The model was able to differentiate various grades of interstitial fibrosis, demonstrating a potential prognostic value.

Automated, Scalable, and Comprehensive Three-Dimensional Analysis of Glomeruli and Whole Nephrons in Kidney Tissues

Chetan Poudel,[1] David Brenes,[1] Ruben M. Sandoval,[2] Michelle M. Martinez-Irizarry,[2] Ken Dunn,[2] Pierre C. Dagher,[2] Jonathan T. Liu,[1] Joshua C. Vaughan.[1] *[1]University of Washington, Seattle, WA; [2]Indiana University School of Medicine, Indianapolis, IN.*

Background: Studying intact functional units or nephrons in 3D has so far been challenging as it requires organ-scale imaging at cellular resolution. The entire field has relied mostly on 2D assays with sparse sampling and thin tissue sections. 2D imaging, however, obscures the relationships between different parts of the same nephron, between nearby nephrons, and between nephrons and other units (e.g. vasculature, lymphatics). There is a great need for advanced imaging and analytical tools to study whole functional units in 3D.

Methods: We developed an end-to-end pipeline to stain, optically clear, image, and analyze thick kidney tissues (both mouse and human) in 3D. We used fluorescent FLARE stains and an open-top lightsheet microscope. For analysis, we trained machine learning models to segment all glomeruli in the tissue. We developed new algorithms with deep learning to dynamically travel through nephrons and accurately extract their entire paths. We can also untwist nephrons to visualize sub-segments and compare between nephrons. This enables 3D morphology analysis (location, trajectory, curvature, lengths, diameters) and in situ cytometry.

Results: We demonstrate orders of magnitude (>100X) faster analysis over manual 3D segmentation methods. The speed and scalability allow us to study a hundred nephrons in a single tissue, and extract 3D models and highly quantitative information. We applied this method to study glomeruli and nephrons in young, mid-aged, and aged mouse kidneys and correlate morphology to functional attributes. We note several interesting changes to glomeruli, glom-tubule connections, and tubule morphology in aged mice.

Conclusions: We established an automated pipeline using artificial intelligence to comprehensively assess 3D morphology of mouse and human kidney tissues. This analysis could assist organ atlas efforts by providing 3D data complementary to existing 2D assays. It could pave the way for 3D renal pathology of human biopsies.

Developing a Novel Deep Learning-Based Method for Kidney Transmission Electron Microscopy Image Analysis

Anqi Zou,[1] Jiayi Ji,[1] Xueping Fan,[1,2] Winston Tan,[1] Laura Dodd,[1] Emily Oei,[1] Hui Chen,[1,2] Yu-Chen Liu,[1] Simon L. Lu,[1] Joel M. Henderson,[1,2] Chao Zhang,[1] Weining Lu.[1,2] *[1]Boston University Chobanian & Avedisian School of Medicine, Boston, MA; [2]Boston Medical Center, Boston, MA.*

Background: Abnormal glomerular basement membrane (GBM) and podocyte foot process (PFP) widths are critical diagnostic criteria for proteinuric kidney disease. The standard method for quantifying GBM and PFP widths is unbiased stereology, which is labor-intensive and not routinely used in research or clinical diagnosis. To address this gap, we developed a novel deep learning (DL) based algorithm to quantify GBM and PFP widths from glomerular transmission electron microscopy (TEM) images.

Methods: Our algorithm has a two-stage workflow (see Figure): (a) We first used DL for image segmentation, employing a PSPNet-based model with self-training techniques to iteratively collect annotated data, reducing the manual labeling time and improving accuracy. (b) We then used image processing techniques to measure GBM and PFP widths, developing a graph-based method to refine GBM skeleton extraction and compute GBM and PFP widths. We used glomerular TEM datasets from two animal models of proteinuric kidney disease to train and validate our algorithm: the ILK podocyte-specific knockout (ILK cKO) mice and the Passive Heymann's Nephritis (PHN) rats.

Results: The segmentation performance on the validation dataset showed a mean IoU of 0.77, Dice of 0.87, and accuracy of 0.88. In a PHN rat validation dataset, the relative mean error compared to manual measurements is 0.7% for GBM width and 3% for PFP width, indicating overall interchangeability between these two methods. Comparisons of DL-based measurements between wild-type (WT) and ILK cKO groups showed significant differences in GBM width ($p = 1.5e-07$) and PFP width ($p = 3.1e-06$), suggesting that the method effectively distinguished healthy from pathological specimens.

Conclusions: We have established and validated a new DL-based algorithm for automatic GBM and PFP width measurements on rodent glomerular TEM images. This tool is compatible with human kidney biopsy TEM images, which can be translated into clinical applications.

Funding: NIDDK Support, Other U.S. Government Support

Artificial Intelligence (AI) Reveals Dynamic Morphological Shifts in Parietal Epithelial Cells after Acute Tubular Injury

Mengmeng Yin,[1] Oliver S. Zhao,[1] Yu Wang,[1] Shilin Zhao,[1] Ruining Deng,[2] Yuankai Huo,[1] Jianyong Zhong,[1] Haichun Yang,[1] Agnes B. Fogo.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University, Nashville, TN.*

Background: We previously found that pre-existing acute tubular injury (ATI) sensitizes glomeruli to subsequent injury. Through spatial transcriptomics, we identified key ligand-receptor pairs that could contribute to this sensitivity, with ligands from the proximal tubules (PTs) and their corresponding receptors on adjacent parietal epithelial cells (PECs). In this study, we utilized artificial intelligence (AI) to evaluate the morphological changes in PECs and their spatial transcriptomics profiles following ATI.

Methods: Wild type (WT) and transgenic mice (n=7/group) expressing diphtheria toxin (DT) receptor in PTs were injected with DT at week 0 and week 1 to induce ATI and sacrificed at week 7. Periodic acid-Schiff stained kidney sections from normal mice were utilized to train an AI model. Spatial transcriptomics were conducted using the NanoString GeoMx DSP platform.

Results: We utilized fluorescent staining of claudin-1 as a PEC biomarker to train an AI model for classification and segmentation of PECs. This allowed for the quantification of 246 morphological profiles for each PEC nucleus. In mice with ATI, PECs nuclei from DT transgenic mice showed increased eccentricity and a greater proportion of staining intensity at the nucleus periphery, as well as reduced form factor of roundness and texture entropy compared to WT mice, suggesting a flatter nuclear morphology with reduced complexity in DT PECs nuclei. Furthermore, 153 differentially expressed genes were detected in PEC nuclei of DT vs WT mice, with enrichments in several pathways, including actin cytoskeleton regulation and PI3K-Akt-mTOR signaling. RPS6 gene expression, a gene involved in cell size regulation, was significantly increased in PECs nuclei of DT compared to WT. In contrast, PECs immunostaining of p-RSK1, a key enzyme involved in RPS6 phosphorylation, was decreased in DT compared to WT mice, suggesting decreased activity.

Conclusions: AI reveals dynamic morphological shifts in PECs following ATI, with flatter, less round nuclei and more chromatin staining at the nuclear periphery. These altered nuclear properties could represent activation states, potentially mediated by decreased activation of the RSK1-RPS pathway. These findings have significant implications for PEC-podocyte interactions and glomerular injury responses after ATI.

TH-PO031

StarFunc: Accurate Protein Function Prediction Reveals Novel Human Proteins Involved in Ubiquitination

Chengxin Zhang, Lydia Freddolino. *University of Michigan, Ann Arbor, MI.*

Background: Even in the very well-studied human proteome, many proteins remain poorly annotated, yet may still make important contributions to health and disease. Deep learning has significantly advanced the development of novel methods for protein function prediction. Yet, even for state-of-the-art deep learning approaches, template information remains an indispensable component. While many prediction methods use templates identified through sequence homology or protein-protein interactions, very few methods detect templates through structural similarity, even though protein structures are the basis of their functions.

Methods: In this work, we developed StarFunc, a composite approach that integrates state-of-the-art deep learning models seamlessly with template information from structural similarity, sequence homology, protein-protein interaction partners, and protein domain families (**Fig. 1**).

Results: We compared the accuracy of StarFunc against 6 existing deep learning methods and 3 template-based methods on 2475 proteins. The weighted F-measure of StarFunc is 12% higher than the second-best approach. StarFunc participated in the Critical Assessment of Function Annotation 5 (CAFA5) challenge and was ranked 5th among 1625 teams from 96 countries. We applied StarFunc on all 20389 proteins from the human reference proteome curated by the neXtProt and identified significant enrichments of several important functions among the set of currently cryptic human proteins. For example, we discovered 15 uncharacterized proteins that are likely components of protein-ubiquitin transferase complexes and 1 putative deubiquitinase.

Conclusions: Large-scale benchmark demonstrates StarFunc's advantage when compared to both deep learning methods and conventional template-based predictors. Application of StarFunc on human proteome reveals novel functions of previously uncharacterized proteins, especially those involved in (de) ubiquitination, providing an entry point for studying fundamental new biology involving those proteins.

Deep Learning Tubulometrics to Stratify Tubular Injury in Whole-Slide Kidney Specimens

Martin Klaus, Philipp M. Gaßmann, Rosch Abdullah, Louisa Ehreiser, Hao Long, Julia Lichtnekert, Stefanie Steiger, Maciej Lech, Hans J. Anders. *Division of Nephrology, Department of Medicine IV, University Hospital, Ludwig-Maximilians-Universität München, Munich, Germany.*

Background: Acute kidney injury is highly prevalent and most often involves tubular injury. However, studies on detailed assessment of tubular epithelial cell morphometry within tubuli are missing. To this end, we provide a deep learning-enhanced method to segment and analyze tubular epithelial cells and tubuli ("tubulometrics") in whole slide kidney specimens of wild-type mice and mice models of acute and chronic tubular injury.

Methods: Kidneys were embedded in paraffin and stained with PAS and immunohistochemistry before digital scanning. More than 1200 tubuli and 6800 tubular epithelial cells of control mice, mice suffering ischemia-reperfusion injury or chronic

tubular injury were manually annotated. Subsequently, a deep learning algorithm was trained to segment tubuli and tubular epithelial cells and morphometric readouts were obtained. Furthermore, tubulometrics were compared to traditional tubular injury scores.

Results: Tubular area, tubular cell number and density per tubulus section were identified as morphometric readouts. These tubulometrics were able to complement a traditional tubular injury score (PAS score) and interstitial fibrosis tubular atrophy score (IFTA). In wild-type mice PAS score was 0, IFTA 0, mean tubular area 2339 [μm^2], mean tubular cell count per tubulus 7.27, and mean tubular cell density 3.09 [$10^{-3}/\mu m^2$]. In mice with ischemia-reperfusion injury PAS score was 3.44, IFTA 10%, mean tubular area 1818 [μm^2], mean tubular cell count per tubulus 2.02, mean tubular cell density 1.11 [$10^{-3}/\mu m^2$]. In mice with crystal-induced chronic tubular injury PAS score was 3.06, IFTA 40%, mean tubular area 2746 [μm^2], mean tubular cell count per tubulus 7.71, and mean tubular cell density 2.81 [$10^{-3}/\mu m^2$]. The deep learning segmentation algorithm ensured time-efficiency and scalability by taking 5 minutes per slide.

Conclusions: We propose the analysis of tubular epithelial cell morphometry in kidney specimens to better identify and stratify tubular injury. Whereas tubular epithelial cell loss was found in acute injury, tubular hypertrophy together with cell regeneration were observed in the chronic model. Integrated with existing histopathological scores a more detailed assessment of kidney biopsies might become possible. Further studies are needed to validate the findings in larger cohorts.

Artificial Intelligence Discovers a Novel Antifibrotic Drug for Preventing Chronic Kidney Failure by Targeting Macrophage-Myofibroblast Transition

Patrick Ming-Kuen Tang,[1] Yat Fai Chung,[1] Chiu Tsun Philip Tang,[1] Max Kam Kwan Chan,[1] Francis C. Wong,[4] Chi Fai Ng,[1] David J. Nikolic-Paterson,[3] Hui Y. Lan,[1] Sydney Tang.[2] *[1]The Chinese University of Hong Kong, Hong Kong, Hong Kong; [2]The University of Hong Kong, Hong Kong, Hong Kong; [3]Monash University, Melbourne, VIC, Australia; [4]Prince of Wales Hospital, Hong Kong, Hong Kong.*

Background: Kidney failure (end-stage renal disease) is one of the leading causes of death not only in patients with kidney disease but also other non-communicable diseases e.g. diabetes, cardiovascular disease, cancer. Nevertheless, effective treatments to halt the progression of kidney failure remain an unmet clinical need worldwide.

Methods: We recently discovered a novel phenomenon "Macrophage-Myofibroblast Transition" (MMT) as a key pro-fibrotic mechanism and ideal therapeutic target to prevent chronic renal failure. By single-cell RNA sequencing and unbiased bioinformatics analysis, we have identified a neural transcription factor as a key regulator of MMT [Tang et al., PNAS 2020]. Here, by using artificial intelligence (AI) drug discovery platform, we successfully identified a novel anti-fibrotic drug "ISO" for targeting the MMT-driven renal failure.

Results: We found that ISO specifically blocks DNA binding of the neural transcription factor at the molecular level, therefore preventing MMT formation on TGF-β1-stimulated macrophages *in vitro*. More importantly, by conducting macrophage-specific fate mapping with our unique LyzM-tdTomato transgenic mice, we demonstrated that ISO markedly prevents MMT-driven renal fibrosis induced by unilateral ureteral obstruction (UUO) and renal ischemia/reperfusion injury (IRI) without side effects *in vivo*.

Conclusions: Thus, our AI-guided novel anti-fibrotic drug ISO may represent a safe and effective MMT-targeted therapy for preventing chronic renal failure in clinics.

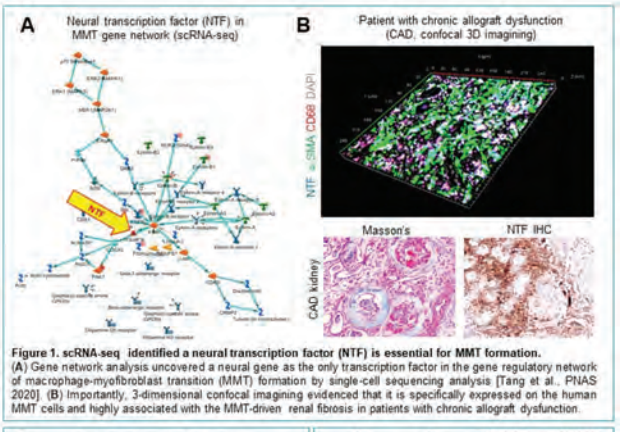

Figure 1. scRNA-seq identified a neural transcription factor (NTF) is essential for MMT formation. (A) Gene network analysis uncovered a neural gene as the only transcription factor in the gene regulatory network of macrophage-myofibroblast transition (MMT) formation by single-cell sequencing analysis [Tang et al., PNAS 2020]. (B) Importantly, 3-dimensional confocal imagining evidenced that it is specifically expressed on the human MMT cells and highly associated with the MMT-driven renal fibrosis in patients with chronic allograft dysfunction.

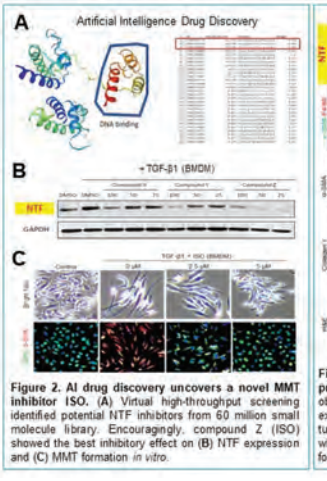

Figure 2. AI drug discovery uncovers a novel MMT inhibitor ISO. (A) Virtual high-throughput screening identified potential NTF inhibitors from 60 million small molecule library. Encouragingly, compound Z (ISO) showed the best inhibitory effect on (B) NTF expression and (C) MMT formation *in vitro*.

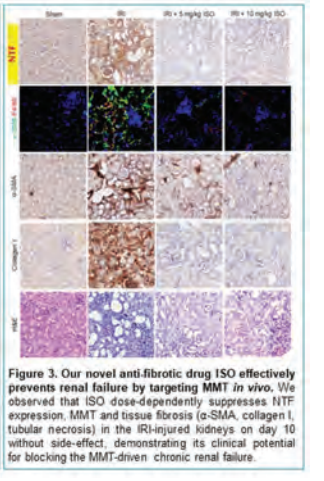

Figure 3. Our novel anti-fibrotic drug ISO effectively prevents renal failure by targeting MMT *in vivo*. We observed that ISO dose-dependently suppresses NTF expression, MMT and tissue fibrosis (α-SMA, collagen I, tubular necrosis) in the IRI-injured kidneys on day 10 without side-effect, demonstrating its clinical potential for blocking the MMT-driven chronic renal failure.

Inflammation Education-Empowered Extracellular Vesicles Targeting Inflammation-Oxidative Stress Interplay for AKI Therapy

Chuyue Zhang. Dept of Nephrology and Institute of Kidney Diseases, West China Hospital, Sichuan University. *Sichuan University, Chengdu, China.*

Background: Acute kidney injury (AKI) lacks effective pharmacological interventions, and the mutually exacerbating inflammation and oxidative stress are major pathophysiological mechanisms.

Methods: Inspired by mesenchymal stem cells' (MSCs) capability to respond to inflammatory environment, we educated them to generate primed extracellular vesicles (pEVs) endowed with anti-inflammatory properties. Further we engineered these pEVs by conjugating them with a mitochondria-targeted antioxidant SS31 using a reactive oxidative species (ROS)-responsive linker, resulting in the creation of pEV-TK-SS31.

Results: This pEV-TK-SS31 achieved kidney-targeting through the upregulation of integrin α4β1 acquired from the education process, which facilitated binding to inflammatory ligand VCAM-1 at injured sites. By analyzing renal function, pathological damage, oxidative stress and inflammation, pEV-TK-SS31 demonstrated superior therapeutic efficacy in both ischemia/reperfusion and sepsis-induced AKI models. Mechanistically, pEVs, carrying increased anti-inflammatory miRNAs due to education process, mitigated inflammation via suppressing IRAK1/TRAF6 signaling, and alleviated oxidative stress by site-specifically releasing SS31 upon ROS-induced cleavage.

Conclusions: This smart system, which could be employed for other combination therapies of customized anti-inflammatory cargo and therapeutic agents, holds promise for AKI treatment and inflammation/oxidative stress-related disorders.

Cilastatin in the Prevention and Treatment of Lipopolysaccharide-Induced AKI

Maria Angeles Gonzalez-Nicolas Gonzalez,[1,2] Alberto Lazaro Fernandez.[1,2] Renal Physiopathology Laboratory. *[1]Universidad Complutense de Madrid Facultad de Medicina, Madrid, Spain; [2]Hospital General Universitario Gregorio Maranon, Madrid, Spain.*

Background: Sepsis is a life-threatening organ dysfunction caused by a dysregulated host response to infection and a significant cause of death in critically ill patients. In hospital mortality rate for patients with sepsis is about 15%–25%. Acute kidney injury (AKI) is the most complication of sepsis and is recognized as an independent factor for elevated lethality. More than 50% of patients with sepsis develop AKI, and sepsis associated AKI increases the risk of developing chronic comorbidities. Cilastatin, a renal dehydropeptidase-I inhibitor, has demonstrated its usefulness in the protection of AKI induced by nephrotoxic drugs. Here, we evaluate the utility of cilastatin as a protector against renal damage induced by lipopolysaccharide (LPS).

Methods: Sepsis was induced in Male Wistar rats by administering LPS 10 mg/kg bw i.p. (or its vehicle). Cilastatin 150 mg/kg bw i.p. (or its vehicle), was administered concomitantly and the animals were sacrificed at 24h. Kidney function was assessed by measuring serum creatinine, blood urea nitrogen (BUN), glomerular filtration rate (GFR), proteinuria, renal tissue morphology, kidney injury molecule 1 (KIM-1), as well as apoptotic, oxidative and inflammatory parameters.

Results: LPS-administrated rats showed significant elevations in BUN, creatinine and proteinuria, and decreased the GFR when compared with control rats. These renal effects of sepsis were confirmed by the increased in the KIM-1 and exhibited severe morphological changes such as vacuolization, swelling of tubular cells, brush border loss and hyaline cast in the tubular lumen. Also, apoptotic, inflammatory and oxidative biomarkers were increased. Cilastatin, prevented these changes in renal function in LPS treated animals, decreasing significantly all other parameters (as shown by reductions of BUN, creatinine and proteinuria and increased GFR), restoring KIM-1 levels to normal control and reducing many of the histological symptoms of renal damage.

Conclusions: Our findings support the potential use of cilastatin as a useful drug in the prevention and treatment of AKI-induced by LPS. Therefore, cilastatin could be a very beneficial therapeutic strategy for septic patients susceptible to renal damage in clinical practice.

Urine-Derived Stem Cells Display Homing, Incorporation, and Repair in Human Organoid and Mouse Models of AKI

Julie Bejoy,[1] Richard C. Welch,[1] Eddie Qian,[1] Felisha M. Williams,[1] Matthew H. Wilson,[1,2] Neal Paragas,[3] Lauren E. Woodard.[1,2] Woodard Lab. *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Department of Veterans Affairs, Nashville, TN; [3]University of Washington, Seattle, WA.*

Background: Kidney lacks the regenerative capacity to replace nephrons lost during injury and disease resulting in end-stage kidney disease (ESKD). Due to their therapeutic properties, stem cells have become a promising candidate for the creation of new disease treatments including kidney injury. Urine-derived stem cells (USCs) are multipotent stem cells that originate in the kidney with high expandability, self-renewal capacity.

Methods: USCs are isolated from human urine samples and plated on gelatin coated plates for culturing *in vitro*. We employed mouse models of glycerol-induced rhabdomyolysis (Rhabdo) or unilateral nephrectomy with clamping ischemia reperfusion injury (UNI/R) to induce AKI. The homing and incorporation of luciferase transfected USCs in the mice was measured using the InVivoPLOT™ (InVivo Analytics) and were reconstructed with InVivoAx™ software at various timepoints (3h, 24h and 48h). To evaluate the therapeutic effects of USCs on injured human kidney cell types, we cultured kidney organoids from human induced pluripotent stem cells (hiPSCs). We established a nephrotoxic injury model of AKI by adding cisplatin (5 μM) to kidney organoid and followed up with a treatment of 5 x 10^4 USCs for 48h.

Results: InVivoAnalytics software confirmed the presence of luc-USCs in both Rhabdo and UNI/R models within 3h of injection and localizations persisted upto 48h. Immunostaining confirmed USC localization in renal tubules and glomeruli of injured mice. Improved morphology as well as reduced kidney injury molecule-1 (KIM-1) ($p<0.05$) were observed in treated group compared to untreated group. When treated with USCs, cisplatin-injured organoids showed reduced expression of KIM-1 as well as cytotoxicity ($p < 0.001$). USCs incorporated within injured organoids differentiated into tubule (LTL+) and glomeruli (NEPHRIN+) cells.

Conclusions: The current study explored the USC's ability to home to sites of injury in multiple models of AKI including rhabdomyolysis, IR injury, and drug-induced nephrotoxicity. USCs demonstrated a differentiation potential for renal cell types within injured kidney organoids. Taken together, these results indicate that USCs can home to a site of injury and may reduce the damage done to tubule cells during AKI suggesting requirement of further development.

TRIM27 Alleviates AKI by Reducing GLIS1 DNA Methylation and Promoting GLIS1 Expression through Inhibiting PRC2 Activity

Chongxiang Xiong. *The First Dongguan Affiliated Hospital of Guangdong Medical University, Dongguan, China.*

Background: Proliferation of dedifferentiated renal tubular epithelial cells (RTECs) is a major cellular event that contributes to renal repair after renal ischemia and reperfusion injury (RIRI)-induced acute kidney injury (AKI). Nevertheless, the underlying mechanism that initiates RTEC dedifferentiation remains unknown. Herein, the role of tri-domain proteins 27 (TRIM27) in the progression of RIRI-induced AKI was investigated.

Methods: The animal model of RIRI-induced AKI was established by IRI, and mRTECs were treated with H2O2 to establish a cell injury model in vitro. The pathological changes in kidney tissues were assessed using HE and PAS staining. Cell viability and migration were assessed by CCK-8 assay and wound healing assay, respectively. Flow cytometry was employed to determine cell apoptosis. Co-IP assay was employed to analyze the interaction between TRIM27 and EZH2. The interaction between DNMT1 and GLIS1 was analyzed by ChIP assay.

Results: TRIM27 expression was reduced in kidney tissues of IRI mice and H2O2-treated mRECs. TRIM27 overexpression enhanced mRTEC dedifferentiation, proliferation, and migration while inhibiting apoptosis after H2O2 treatment. Mechanistically, TRIM27 reduced PRC2 activity in mRTECs by mediating EZH2 ubiquitination degradation. PRC2 reduced GLIS1 expression in mRTECs through mediating H3K27me3 and DNA methylation. TRIM27 overexpression ameliorated IRI-induced AKI in mice by enhancing mRTEC dedifferentiation.

Conclusions: TRIM27 upregulation alleviated RIRI-induced AKI by reducing GLIS1 DNA methylation and promoting GLIS1 expression through inhibiting PRC2 activity.

Exercise Training Has Striking Effects on the Kidney Proteome and Protects Kidney from Ischemic Injury: The MoTrPAC Study

Takaaki Higashihara, Tiziana Caputo, Anders H. Baum, Krithika Ramachandran, Michael F. Hirshman, Laurie J. Goodyear. Molecular Transducers of Physical Activity Consortium (MoTrPAC). *Joslin Diabetes Center, Boston, MA.*

Background: Chronic kidney disease (CKD) poses a significant global health threat due to increasing rates of CKD-related morbidity and mortality, emphasizing the need for interventions to mitigate its impact. While regular exercise training is broadly recognized to promote human metabolic health, the mechanisms by which exercise may provide protection from kidney disease are poorly understood.

Methods: To elucidate the effects of exercise training on kidney, we first analyzed the data from MoTrPAC, the NIH-funded Molecular Transducers of Physical Activity Consortium, that investigates the multi-tissue molecular responses to exercise training in rats. Female rats underwent 4-8 weeks of treadmill exercise training, kidney collected and proteomics analysis performed. Next, we used a murine ischemic-reperfusion injury model (IRI) to determine the direct effects of exercise training on kidney. Female C57BL6J mice were housed in cages with or without running wheels for 11 days. Mice were then either sham or unilateral IRI-treated with no further access to running wheels. At 7 and 28 days post-IRI or sham, we conducted qPCR, western blotting, and kidney histological analysis.

Results: Kidney proteomic analysis of MoTrPAC data showed that exercise training increased fatty acid β-oxidation (FAO) related proteins (e.g. Cpt1b, Acox1). Given the importance of FAO in proximal tubule function, these results led us to investigate the hypothesis that chronic exercise can protect kidneys from tubular injury. At 7 days post IRI, prior exercise training significantly reduced IRI-induced tubular damage areas and expression of tubular damage marker genes (KIM1, NGAL). At 28 days post IRI, prior exercise training significantly ameliorated IRI-induced fibrotic area and expression of fibrotic marker protein (αSMA). Among the FAO related proteins that were up-regulated by exercise in the MoTrPAC data, we found that prior-exercise training significantly ameliorated the IRI-induced reduction of peroxisomal FAO related proteins (e.g. Acox1, Ehhadh).

Conclusions: Exercise training decreases IRI-induced kidney tubular damage, an affect associated with upregulation of FAO related proteins. Regular physical activity may provide a means to help prevent the severity of CKD.

Kidney-Protective Effect of Remote Ischemic Conditioning: Involvement of the Spleen

Man J. Livingston,[1,2] Zheng Dong.[1,2] *[1]Augusta University Medical College of Georgia, Augusta, GA; [2]Charlie Norwood Department of Veterans Affairs Medical Center, Augusta, GA.*

Background: Remote ischemic conditioning (RIC), performed at a remote site, protects multiple organs including the heart and brain, but its role in the kidney is controversial and much less understood. The signal transmission of RIC protection is also unknown. This study examined the effects of RIC on acute kidney injury (AKI) and post-AKI kidney repair using different experimental models.

Methods: Anesthetized mice were placed on a homeothermic station with the hind limbs wrapped in cuffs. RIC was conducted by 4 cycles of alternating 5-minute inflation at 200 mmHg and 5-minute deflation.

Results: RIC suppressed renal dysfunction and tubular injury during ischemic AKI. RIC also alleviated cisplatin-induced AKI and prevented body weight loss but appeared nonprotective against LPS-induced septic AKI. Daily RIC for 2 weeks after ischemic AKI promoted kidney repair, as indicated by the amelioration of kidney fibrosis and the preservation of renal function and tubular integrity. However, RIC was much less effective in promoting kidney repair after repeated low dose cisplatin treatment, showing minimal effects on renal dysfunction and kidney fibrosis. To understand how RIC signals from the limb to the kidney, we examined the spleen, an organ involved in neuroimmune modulation. Splenectomy diminished the beneficial effects of RIC on ischemic AKI and subsequent kidney repair whereas barely affected the effects of RIC in cisplatin-treated mice.

Conclusions: These results suggest that the renal protective effect of RIC and its regulation may vary depending on the etiology of AKI. Mechanistically, the spleen and associated neuroimmune modulation play a critical role in the renal effect of RIC.

TH-PO040

Early Detection of AKI Using Intraoperative Urine pO2, pCO2, and Lactate during Cardiopulmonary Bypass

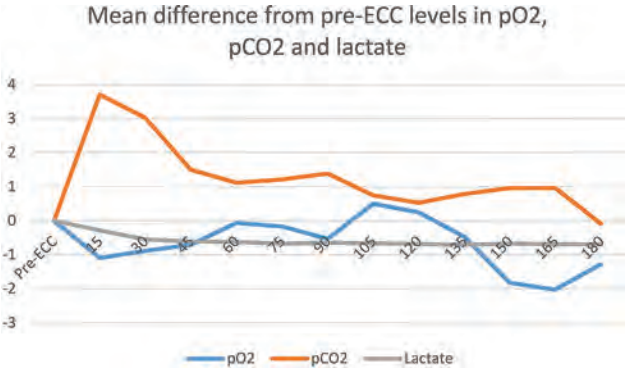
Anders S. Svensson,[1] John-Peder E. Kvitting,[2] Jonas Holm,[1] Zoltan Szabo,[1] Csaba P. Kovesdy.[3] *[1]Linkopings universitet, Linkoping, Sweden; [2]Universitetet i Oslo, Oslo, Norway; [3]The University of Tennessee Health Science Center, Memphis, TN.*

Background: Intraoperative acute kidney injury (AKI) is a common complication after cardiopulmonary bypass (CPB), and it is associated with poor outcomes. Methods to detect AKI in CPB are limited by delayed diagnosis or limited availability. Urinary biomarkers can be measured continuously in the operating room, but their role in detecting AKI is unclear.

Methods: A pilot study in 18 patients undergoing CPB at a single institution. Urine was collected immediatley prior to CPB and every 15 minutes intraoperatively until the end of CPB. Urine biomarkers (pO_2, pCO_2 and lactate) were measured in the operating room using a standard blood gas analyser. Intraoperative AKI was defined as a 0.3 mg/dl increase in serum creatinine within 48 hours post-CPB. We analysed urine biomarkers overall and in patients stratified by AKI status. We used repeated measures ANOVA and Tukey's HSD, and characterized intraindividual changes using mixed effect models adjusted for baseline demographics, EuroScore-II, precence of CKD, CRP level and intraoperative hemodilution.

Results: Five of 18 patients (28%) developed AKI. Overall, intraindividual levels of urine pO_2 (p=0,03), pCO_2 (p=<0,001) and lactate (p=<0,001) levels were significantly different in ANOVA analyses (figure). In patients with vs. without AKI, pO_2 showed more substanial decline (slope in mixed effect models:-0,06 vs. -0,005 mmHg/min); pCO_2 showed less decline (-0,006 vs. -0,11 mmHg/min); and lactate showed more increase (0,007 vs. 0,004 mmol/L/min) during CPB in adjusted mixed effect models.

Conclusions: Urine pO_2, pCO_2 and lactate show significant changes during CPB. These changes are different in patients with vs. without AKI. Intraoperative monitoring of urine biomarkers may offer a rapid and readily available means of diagnosing AKI in clinical practice. Larger studies are needed to confirm these findings.



TH-PO041

Therapeutic Efficacy of FEx-022 in Protecting the Kidneys during Ischemia-Reperfusion Injury

Sung ki Kim,[1] Jayoung Kim,[3] Wesley R. Stiles,[1] Hee Young Lee,[2] Kyung Ho Park,[2] Larry C. Park,[2] Min-Woong Kang,[3] Hak Soo Choi.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]Naason Science Inc, Osong-eup, Republic of Korea; [3]Chungnam National University, Daejeon, Republic of Korea.*

Background: Acute kidney injury (AKI) is a common yet critical clinical problem, significantly increasing the morbidity and mortality of patients, particularly in critical care settings. AKI is characterized by a sudden decline in kidney function, leading to the accumulation of waste products in the blood, an imbalance in body fluids, and potential progression to chronic kidney disease. Despite the prevalence and severity of AKI, there is currently no approved or effective treatment available in the clinic. In a previous study with rhabdomyolysis-induced AKI model, a novel polymer-drug conjugate, FEx-022, demonstrated kidney protection and ameliorated glomerular filtration rate (GFR) by two-fold compared to the negative control. In this study, we further evaluated the effectiveness of FEx-022, using an ischemia-reperfusion injury (IRI) AKI model.

Methods: FEx-022 was prepared in large scale for in vitro and in vivo assays. In the following study, mice were divided into four groups: sham control, IRI with vehicle, IRI with reference drug, and IRI with FEx-022. Plasma and urine samples were collected to analyze plasma creatinine, blood urea nitrogen (BUN), kidney injury molecule-1 (KIM-1), neutrophil gelatinase-associated lipocalin (NGAL), and GFR. Survival rates, kidney histology, and inflammatory cytokines are also evaluated.

Results: In this study, FEx-022 demonstrated kidney protection, measured in various parameters such as survival rate and GFR. Other analysis will provide deeper insights on the compound's ability to suppress reactive oxygen species (ROS) damage and cell death biomarkers, primarily through the inhibition of ferroptosis.

Conclusions: FEx-022 exhibits therapeutic effects in the IRI-AKI model, which demonstrates that FEx-022 can protect kidneys in AKI. Our findings suggest that FEx-022 could be a potential candidate as a novel therapeutic targeting AKI, offering a promising avenue to address a critical unmet need in nephrology.

TH-PO042

Characterization of Regulatory B Cells and IL-10 in Response to Ischemic Reperfusion and Potential for Infusion Therapy

Yuya Yamashita, Kensei Taguchi, Yunosuke Yokota, Tomofumi Moriyama, Kei Fukami. *Kurume Daigaku, Kurume, Japan.*

Background: Acute kidney injury (AKI) occurs in approximately 15% of hospitalized patients and it predisposes the patients to chronic kidney disease (CKD). Interleukin-10 (IL-10) is a pleiotropic cytokine, and exogenous IL-10 replacement therapy is renoprotective effect against AKI. However, the required concentration of IL-10 seems not feasible to achieve when applied to human. Subpopulation of B cells presenting with CD1dhiCD5+ (regulatory B cells; Breg) are known to be responsible for producing and secreting IL-10. Thus, in the present study, we investigated the role of Breg and the main sources in AKI. Further, we investigated whether exogenous Breg would adhere in the kidneys of the recipients and prevent the AKI-to-CKD transition.

Methods: IL10^{+}/eGFP mice were employed to trace IL-10-producing Breg in the context of AKI. Ischemia-reperfusion (IR)-AKI was induced in IL10^{+}/eGFP mice and

the number of GFP-labelled Breg were evaluated in several organs, such as kidneys and spleens. Subpopulation of B-1 cells isolated from peritoneal cavity of IL10^{+}/eGFP mice were infused into wild-type mice with IR-AKI to examine whether exogenous regulatory B cells adhere to the injured kidneys. Third, spleens, the main source of Breg, were removed before IR-AKI to explore whether deletion of Breg exacerbates AKI in IL10^{+}/eGFP mice.

Results: The number of GFP+ Breg was increased in the spleens 24 hrs after onset of IR-AKI. The number of GFP+ Breg was increased in the kidneys with the upregulation of IL-10 gene expression on day7 and 14 after IR-AKI. Furthermore, when GFP+ B-1 cells were exogenously infused, we identified GFP+ cells in kidneys of wild-type mice with IR-AKI, the number of which was increased in injured kidneys. Splenectomy in the context of AKI reduced the number of GFP+ cells in kidneys of IR-AKI with the reduction in gene expression of IL-10. Renal dysfunction and tubular damage in IR-AKI were worsened by splenectomy and immune cells infiltration, such as CD68+ microphages and CD3+ T cells, were enhanced.

Conclusions: We identified that IL-10-producing Breg were mainly released from the spleens in response to IR-AKI, which may be involved in repair process after IR-AKI via producing IL-10. In addition, the infusion with autologous Breg might be potent to promote proper repair and prevent AKI-to-CKD.

TH-PO043

Injured Tubules-Derived CCN1 Exacerbates Renal Congestion-Mediated AKI and Fibrosis

Atsushi Minamida, Tetsuro Kusaba, Tomohiro Nakata, Yuhei Kirita, Keiichi Tamagaki. *Kyoto Prefectural University of Medicine, Kyoto, Japan.*

Background: In recent studies on cardio-renal syndrome (CRS), researchers have focused on the relationship between increased renal venous pressure and renal dysfunction. We generated a novel mouse model where the inferior vena cava between the left and right renal vein was constricted, causing renal congestion only in the left kidney (Kidney Int. 2022). However, the responsible molecular mechanisms for congestion-mediated acceleration of kidney fibrosis after injury are still unclear. We found thatCellular Communication Network Factor 1 (CCN1) which is upregulated at the acute phase after kidney injury contributed to the fibroblast mobilization to the injury site. On this basis, we investigated the impact of CCN1 on the exacerbation of AKI caused by renal congestion with using proximal tubule-specific CCN1-KO mice (SLC34a1GCE/CCN1-floxed).

Methods: We performed bilateral ischemia-reperfusion injury (IRI) and unilateral renal congestion in wild-type (WT) mice and proximal tubule-specific CCN1-KO mice. Furthermore, we analyzed the role of CCN1 on the fibroblasts, tubular epithelial cells, and macrophages in vitro.

Results: One day after the injury, qPCR analysis of WT mice revealed a significant increase in CCN1 levels in the congestion-IRI group compared to the IRI group, but no difference in renal injury markers between those. Positive staining of phosphorylated focal adhesion kinase (pFAK), a downstream signaling of CCN1, was observed in the fibroblasts at injury sites in the congestion-IRI kidneys. Seven days after the injury, qPCR and histological analyses showed a significant increase in fibrosis markers in the congestion-IRI group. In vitro, CCN1 activated the phosphorylation of FAK and ERK, resulting in the acceleration of migration in the fibroblasts (NRK49F) and macrophages, but not in tubular epithelia. Lastly, we examined the effect of CCN1 deletion in tubular epithelia on congestion-mediated kidney injury in vivo. pFAK expression in injury sites was reduced in CCN1-KO mice, and tissue fibrosis was significantly ameliorated.

Conclusions: We clarified the important role of injured tubular-derived CCN1 on pFAK-mediated fibroblast migration in congestive kidneys. Inhibition of CCN1 can be an attractive therapeutic candidate for preventing renal congestion-mediated kidney injury to fibrosis transition.

TH-PO044

Urinary Acidification and Pharmacological Inhibition of OCT/OAT Reduce the Severity of Experimental Vancomycin-Induced AKI

Yosu Luque,[1,2] Thibault Le Moulec,[1] David Rozenblat,[2] Liliane Louedec,[1] Juliette Hadchouel,[3] Gaëtan Girault,[3] Marine Marquié,[3] Laurent Mesnard,[1,2] Placier Sandrine.[3] *[1]Sorbonne Universite, Paris, France; [2]Assistance Publique - Hopitaux de Paris, Paris, France; [3]INSERM, Paris, France.*

Background: Vancomycin, a glycopeptide antibiotic, is used clinically but causes nephrotoxicity in 5-43% of cases via direct tubular damage and vancomycin-uromodulin casts. While vancomycin's solubility increases in acidic media, uromodulin's decreases, complicating the prediction of urinary pH modulation effects. Vancomycin is excreted through glomerular filtration and proximal tubular secretion via organic cation (OCT) and anion (OAT) transport systems. This study investigates the effects of urinary pH modulation and OCT/OAT blockade with cimetidine and probenecid on vancomycin-induced renal lesions in a murine model.

Methods: Eight-week-old male C57BL/6J mice received an intraperitoneal injection of vancomycin at a dose of 0.5 mg/g once daily for two consecutive days, followed by euthanasia and tissue collection on the third day. Urinary alkalinization was induced by providing 0.2 M sodium bicarbonate in drinking water, while acidification was achieved by incorporating 2% ammonium chloride (NH4Cl) into their food. Cimetidine (100 mg/kg) and probenecid (150 mg/kg) were administered intraperitoneally 30 minutes before each vancomycin injection.

Results: Urinary acidification reduced vancomycin-induced renal failure, as evidenced by lower creatinine levels (31.88 ± 16.89 vs. 46.39 ± 15.47 μmol/L, p = 0.0212) and plasma urea levels (29.48 ± 15.48 vs. 46.19 ± 13.31 mmol/L, p = 0.0013). Urinary alkalinization had no effect in kidney injury. Probenecid also reduced vancomycin-induced kidney injury, as indicated by serum creatinine (16.20 ± 3.088 vs. 46.39 ± 15.47 μmol/L, p < 0.0001) and plasma urea levels (22.65 ± 12.96 vs. 47.99 ± 16.85 mmol/L, p < 0.001). Additionally, there was a significant decrease in tubular lesions and the number of casts. Cimetidine showed significant improvement in creatinine levels only (28.67 ± 10.40 vs. 46.39 ± 15.47 μmol/L, p = 0.0116).

Conclusions: Urinary acidification, but not alkalinization, prevents vancomycin-induced renal failure and kidney damage. These results suggest that uromodulin is not necessary for vancomycin cast formation. Additionally, administering probenecid before vancomycin injections also prevents renal failure and kidney damage, suggesting potential therapy options for these patients.

Dietary Supplementation with Bacillus Superoxide Dismutase Protects against Contrast-Induced AKI in Mice

Young Eun Choi,[1] Yookyung Jang,[1] Ko Yoon Sook,[1] Lee Hee Young,[1] Tai yeon Koo,[1] Sewon Oh,[1] Myung-Gyu Kim,[1] Sang-Kyung Jo,[1] Jihyun Yang.[2] *[1]Korea University Anam Hospital, Seoul, Republic of Korea; [2]Kangbuk Samsung Hospital, Jongno-gu, Seoul, Republic of Korea.*

Background: Superoxide dismutase (SOD) is a metalloenzyme that play an important role in antioxidant defense against oxidative stress. Oxidative stress was known as one of the main pathophysiology in contrast-induce acute kidney injury (CI-AKI). Based on recent data showing the important role of gut dysbiosis, using probiotics could have a potential to modify systemic oxidative stress. We investigated the renoprotective potential of orally administered enteric-coated SOD protein purified from *Bacillus amyloliquefaciens* (SOD-BA) in contrast-induced acute kidney injury (CI-AKI) in mice.

Methods: CI-AKI model was induced with unilateral nephrectomy using 5 week-old C57BL/6 male mice. Giving oral gavage SOD-BA once a day, 48 hours before intravenous contrast injection (10mg/kg) 4 weeks after unilateral nephrectomy. Serum blood urea nitrogen (BUN), creatinine, and kidney tissue NGAL were determined.

Results: SOD-BA did not have kidney toxicity in the vehicle group. The unilateral CI-AKI model showed minimal kidney function deterioration based on creatinine level. However, the serum BUN and NGAL were strikingly increased. SOD-BA oral administration group showed decreased BUN and kidney NGAL level.

Conclusions: Prophylactic treatment of oral SOD-BA could serve as a potent antioxidant in the prevention and treatment of CI-AKI.

TH-PO046

Identifying a Potential New Weapon against AKI in Cisplatin-Treated Patients

Lara Valiño Rivas,[1] Maria Angeles Gonzalez-Nicolas Gonzalez,[1,2] Estefanía Moreno-Gordaliza,[3] Elena V. Ogando,[1] Milagros Gómez-Gómez,[3] Alberto Lazaro Fernandez.[1,2] *[1]Renal Physiopathology Laboratory, Department of Nephrology, Instituto de Investigación Sanitaria Gregorio Marañón, Hospital General Universitario Gregorio Marañón., Madrid, Spain; [2]Department of Physiology, School of Medicine, Universidad Complutense de Madrid, Madrid, Spain; [3]Department of Analytical Chemistry, Faculty of Chemistry, Universidad Complutense de Madrid., Madrid, Spain.*

Background: Cisplatin is a highly effective chemotherapeutic agent, widely used in clinical practices against a large number of tumors, whose common side effect limiting its dose-duration of treatment is Acute Kidney Injury (AKI). Cisplatin-AKI is associated with a high morbidity and mortality rate and currently, there is no effective treatment for it. ALME23 (under intellectual property rights protection) is an organic anion transporters (OATs) inhibitor used at the clinical level for which some old scientific studies suggested a link with nephroprotection in AKI. In this study, we investigated *in vitro* a potential new drug against cisplatin-induced AKI.

Methods: Human proximal tubular cells (HK2) were treated with cisplatin in the presence or absence of ALME23. Apoptosis was assessed by MTT, direct microscopic observation and flow-cytometry. Apoptotic mediator's levels of the intrinsic (mitochondrial) and extrinsic (death receptor) apoptotic pathways were measured by confocal microscopy, Western Blot and JC-1 assay. Cell regeneration was also assessed by crystal violet. Some tumor cisplatin-target lines were also used to evaluate cisplatin tumorigenic activity in presence of ALME23. Intracellular accumulation of cisplatin was

measured by Inductively Coupled Plasma Mass Spectrometry (ICP-MS). Inflammation was also measured at early stages of AKI by RT-qPCR.

Results: Our results suggested that ALME23 seems to protect HK2 cells against cisplatin-induced apoptosis and both the intrinsic and extrinsic pathway, promoting cell regeneration. Furthermore, ALME23 resulted harmless to the cells without affecting their growth and viability, nor does it affect the chemotherapeutic activity of cisplatin in tumor lines, protecting them in an organ-specific manner. Cotreatment of cisplatin with ALME23 also reduced inflammatory damage in early stages of cisplatin-AKI. Regarding the mechanism of action, some of these protective effects may be due to the fact that it partially prevents cisplatin from entering the cell.

Conclusions: This study provides evidence that ALME23 could be a new therapeutic alternative to nephrotoxicity in cisplatin-treated patients without compromising its chemotherapeutic efficacy. However, studies in animal models and later in humans, will be required.

TH-PO047

Changes in eGFR after Acute Mechanical Circulatory Support in Patients with Acute Heart Failure

Nusrath Jahan,[1] Hocine Tighiouart,[2,3] Michael S. Kiernan,[2] Hannah L. Sarnak,[2] Ki Jung Lee,[2] Marcelle Tuttle,[2,3] Tatsufumi Oka,[2] Amanda I. Moises,[1] Mark J. Sarnak,[2] Wendy I. McCallum.[2] *[1]Tufts University School of Medicine, Boston, MA; [2]Tufts Medical Center, Boston, MA; [3]Tufts Clinical and Translational Science Institute, Boston, MA.*

Background: It has been suggested that estimated glomerular filtration rate (eGFR) may improve among patients admitted for acute heart failure (AHF) following hemodynamic support with acute mechanical circulatory support (MCS), but descriptions of changes in eGFR are limited.

Methods: Among adult patients admitted to an academic medical center from 2015-21 for a primary diagnosis of AHF requiring a pulmonary artery (PA) catheter, we examined the subgroup requiring acute MCS. Using the CKD-EPI 2021 equation, we examined absolute change in eGFR from one day prior to acute MCS placement to 7-days after placement. Patients on inotropes or MCS prior to admission were excluded.

Results: Of 755 patients, 53 (7%) required the use of acute MCS. Mean (SD) age was 58 (13) years, 11 (21%) were women; median [IQR] baseline eGFR was 50 [30, 69] ml/min/1.73 m^2. Initial acute MCS device was an intra-aortic balloon pump in 44 (83%), Impella in 7 (13%), and extracorporeal membrane oxygenation in 2 (4%) patients. At 1-day post-MCS, 26 patients (49%) had an eGFR increase, 26 patients (49%) had an eGFR decrease, and one patient started renal replacement therapy. By 7-days post-MCS, 7 (13%) patients had died or transitioned to hospice. Of those who survived to 7-days, overall the eGFR increased by 2.8 (IQR -2.1, 14.9) ml/min/1.73 m^2, with 32 patients (70%) had an eGFR increase (median [IQR] increase by 9.0 [2.4, 21.6] mL/min/1.73 m^2) while 14 patients (30%) had an eGFR decrease (median decrease of -10.6 [-27.7, -4.0] mL/min/1.73 m^2). There was no difference in eGFR change by device type (Table). Age, sex, baseline comorbidities including hypertension and diabetes were no different between those with eGFR increase versus decrease.

Conclusions: Among patients admitted for AHF requiring PA catheter to guide management, of the subgroup needing acute MCS support, about two-thirds had a mild improvement in eGFR with MCS support. However, one-third had a decline in eGFR despite cardiac support, without any identifiable differences in baseline characteristics to distinguish those with increase or decrease in eGFR.

Funding: NIDDK Support

Table. Descriptions of eGFR changes among Patients on Acute MCS Stratified by Device Type

	N	Age, years	Acute MCS duration, days	eGFR Change at 3-days*	eGFR Change at 7-days**	Outcomes During Follow-up		
						Received Durable LVAD	Heart Transplant	Death
Overall	53	58 (13)	7 (8)	1.6 [-3.6, 10.0]	2.8 [-2.1, 14.9]	28 (53%)	19 (36%)	21 (40%)
IABP	44	57 (13)	8 (8)	1.6 [-3.5, 7.9]	2.8 [-0.5, 16.2]	24 (55%)	16 (36%)	16 (36%)
Impella	7	66 (13)	4 (5)	-3.2 [-12.6, 15.6]	5.8 [-2.4, 14.7]	3 (43%)	3 (43%)	3 (43%)
ECMO	2	63 (5)	3 (3)	28.9 [23.4, 34.3]	-9.9 [-9.9, -9.9]	1 (50%)	0 (0%)	2 (100%)

Prognostic Significance of Total Body Surface Area in Rhabdomyolysis Assessed by Bone Scan

Sehyun Jung,[1] Seunghye Lee,[1] Hani Jang,[1] Hyun-Jung Kim,[1] Eunjin Bae,[2] Tae won Lee,[2] Dong Jun Park,[2] Se-Ho Chang.[1] *[1]Gyeongsang National University Hospital, Jinju, Republic of Korea; [2]Gyeongsang National University Changwon Hospital, Changwon, Gyeongsangnam-do, Republic of Korea.*

Background: Rhabdomyolysis involves skeletal muscle damage. Its severity ranges from asymptomatic enzyme elevation to life-threatening conditions. Bone scans can reveal muscle damage extent and location, aiding diagnosis even with normal biochemical tests. It is important to estimate the total body surface area (TBSA) of the burned area in burn injuries, using the rule of nine and Lund and Browder chart. This study aimed to determine rhabdomyolysis prognosis by applying these tools to muscle damage on bone scans.

Methods: We conducted a retrospective observational study from 2010 to 2022, enrolling 94 rhabdomyolysis patients who underwent bone scans. Cox regression analysis assessed the association between TBSA and all-cause mortality, adjusting for potential confounders.

Results: Applying the rule of nine and Lund and Browder chart to bone scan-assessed muscle damage, TBSA correlated positively with serum BUN, AST, ALT, LDH, and hospitalization length, and negatively with eGFR. Patients with rhabdomyolysis had a higher hazard ratio for all-cause death (HR 1.17; 95% CI 1.04-1.31).

Conclusions: The application of the rule of nine and Lund and Browder chart to bone scans in rhabdomyolysis patients provides a valuable prognostic tool. TBSA correlates with key biochemical markers and clinical outcomes, including mortality. Accurate muscle damage estimation is crucial in managing rhabdomyolysis and improving patient outcomes.

Risk of all-cause death

All Cause Death	levels	all	Univariable model		Multivariable model	
			HR (95% CI)	P value	HR (95% CI)	P value
Rule of nine	Mean (SD)	38.3 (20.8)	1.10 (1.03-1.17)	0.004	1.17 (1.04-1.31)	0.008
Sex (male)		60 (63.8%)	0.25 (0.04-1.37)	0.110	14.56 (0.55-385.57)	0.109
Age	Mean (SD)	51.7 (21.2)	1.02 (0.99-1.06)	0.257	1.03 (0.97-1.10)	0.313
BMI	Mean (SD)	24.1 (3.8)	0.88 (0.68-1.13)	0.314	0.65 (0.37-1.13)	0.128

Evaluation of Procalcitonin-to-Albumin Ratio (PCT/ALB) in Predicting the Prognosis of Patients with AKI Caused by Sepsis Secondary to Bloodstream Infection

Yue Gu, Han Li, Jing Zhou, Lei Yan, Fengmin Shao. *Henan Provincial People's Hospital, Zhengzhou, China.*

Background: To evaluate the procalcitonin/albumin (PCT/ALB) in predicting the prognosis of patients with acute kidney injury caused by sepsis secondary to bloodstream infection.

Methods: The S-AKI patients aged ≥18 years who were admitted to the Intensive Care Unit (ICU) from September 2018 and September 2020 were enrolled. S-AKI was defined as primary bloodstream infection, infective endocarditis, or catheter-related bloodstream infection. The enrolled patients were divided into survival group and death group based on the diagnosis of S-AKI within 28 days. Within 48 hours after ICU admission, various biochemical, Acute Physiology and Chronic Health Evaluation II (APACHE II) score, Sepsis-Related Organ Failure Assessment (SOFA) score, Glasgow Coma Scale(GCS), oxygenation index, and machine ventilation time were also recorded.

Multivariate logistic regression analysis and receiver operating characteristic curve(ROC) analysis were performed to determine risk factors for 28-day prognosis in S-AKI patients and to evaluate the PCT/ALB in predicting the prognosis.

Results: The APACHE II score, SOFA score, PCT/ALB ratio, PCT levels, C-reactive protein (CRP) levels, and international normalized ratio (INR) were higher in the death group compared to the survival group ($P<0.05$). Platelet count, total protein (TP), albumin (ALB), alanine aminotransferase (ALT), and partial pressure of carbon dioxide were lower in the death group compared to the survival group ($P<0.05$). Multivariate regression analysis revealed that PCT/ALB ratio, TP levels, and APACHE II score were independent factors influencing mortality in S-AKI patients($P<0.05$). The area under the ROC curve for predicting 28-day mortality was 0.943 for PCT/ALB ratio with a cutoff value of 0.810; sensitivity of 0.904; and specificity of 0.906. For TP levels, it was 0.661 with a cutoff value of 0.316; sensitivity of 0.731; and specificity of 0.585. The area under the ROC curve (AUC) for predicting 28-day mortality was 0.809, with a cutoff value of 0.564, sensitivity of 0.904, and specificity of 0.660.

Conclusions: PCT/ALB is an important indicator for predicting the source of primary bloodstream infection in S-AKI patients. It has certain reference value in clinical assessment.

Impact of AKI on Prognosis of Hospitalized Patients with Malignancy-Related Ascites

Mohammad A. Sohail,[1,2] Juan C. Calle.[1] *[1]Cleveland Clinic, Cleveland, OH; [2]Cleveland Clinic Glickman Urological and Kidney Institute, Cleveland, OH.*

Background: Malignant diseases can cause ascites by a variety of mechanisms, including peritoneal carcinomatosis and hepatic metastases leading to portal hypertension. Acute kidney injury (AKI) is frequently observed in hospitalized patients with malignancy-related ascites (MRA) and is associated with increased length of stay and hospital costs. Although there is robust data to support that AKI in cirrhotic patients with ascites is associated with increased mortality, to our knowledge, the prognosis of patients with MRA and AKI has not yet been described in the literature. Our study evaluates the impact of AKI severity and progression on in-hospital mortality in patients with MRA.

Methods: We conducted a retrospective cohort study of all hospitalized patients at the Cleveland Clinic from January 2012 to December 2022 with MRA who fulfilled AKI criteria at the time of admission. Baseline kidney function was defined by the serum creatinine and eGFR obtained prior to admission up to three months before hospitalization. Utilizing the Kidney Disease: Improving Global Outcomes (KDIGO) criteria, we assessed the association between AKI severity and progression with in-hospital mortality. AKI progression was defined as the increase from lower KGIDO stages of AKI to higher stages during the first seven days of hospitalization.

Results: Of the 116 patients who were reviewed in this study, 35 (30.2%) died during their hospitalization. The mean patient age was 62.9 ± 11.1 years. 64 (55.2%) and 87 (75.0%) were male and White respectively. Etiologies of MRA included peritoneal carcinomatosis (n=78; 67.2%) and portal hypertension caused by hepatic metastases (n=38; 32.8%). 45 (38.8%) patients had a baseline eGFR <60 ml/min/m^2 and 44 (37.9%) patients progressed to a higher KDIGO AKI stage after initially fulfilling AKI criteria on admission. Patients achieved a peak severity of AKI stage 1, 35.3%, stage 2, 24.2%, and stage 3, 40.5%. AKI progression and need for kidney replacement therapy were significantly more common and peak AKI stage was higher in non-survivors than in survivors ($P<0.001$).

Conclusions: AKI in hospitalized patients with MRA is frequently severe and progressive and is associated with mortality in a stage-dependent manner. Methods for earlier identification of AKI and its progression may result in improved outcomes by facilitating the targeted and prompt management of AKI.

Trend Analysis of Acute Kidney Failure-Related Mortality, 1999-2020

Mohammad Gul Yousaf Khan,[2] Hadia Ahmad,[1] Mohammad Ammar ur Rahman,[1] Luqman Munir,[1] Amna Khalid,[1] Ahsan Zil-E-Ali,[2] Umar Farooq.[2] NEURALKEy. *[1]King Edward Medical University, Lahore, Pakistan; [2]Penn State College of Medicine, Hershey, PA.*

Background: Acute renal failure (ARF), is a sudden decline in kidney function, leading to the accumulation of waste products and electrolyte imbalances. It has various causes and poses risks to patients, including increased morbidity and mortality. There is a growing incidence of fatalities attributed to ARF across the US. By employing age-adjusted mortality rates (AAMR), we examined variations across significant demographic variables and scrutinized shifts in mortality rates from 1999 to 2020.

Methods: We examined mortality data related to ARF acquired from the CDC WONDER (Wide-Ranging Online Data for Epidemiological Research) Database, from 1999-2020. Utilizing 95% confidence intervals, the Joinpoint Regression Program calculated annual percent changes (APC) and age-adjusted mortality rates (AAMR) per 1,000,000 individuals. For $p<0.05$, the parallelism test was deemed significant for non-parallel results.

Results: A total of 1,180,886 deaths have been reported in the US from 1999-2020 due to ARF. From 1999 to 2010, AAMR showed an upward trend, it declined from 2010 to 2018 and peaked again from 2018 to 2020, with an APC of 4.40 from 1999-2010, -2.28 from 2010 to 2018 and 11.28 from 2018 to 2020. Males, Blacks or African Americans, and people aged 85 years or above were the highest mortality populations. Heightened mortality rates were primarily concentrated in the southern, mid-western and non-metropolitan populations. Disparate trends were found in the tests for parallelism among male and female (0.0002), American Indian and Black (0.003), Asian and Indian American (0.002), Asian and Black (0.0013), Asian and Hispanic (0.042), Black and White (0.0004), Black and Hispanic (0.0002), White and Hispanic (0.0004) demographics. Test for parallelism shows disparity between large and small metropolitan (0.0002), large metropolitan and non-metropolitan(0.0002) areas, Northeast and Midwest (0.0002), Northeast and South (0.0002), Northeast and West (0.0002), Midwest and South (0.001).

Conclusions: Following a surge, the mortality rate attributed to ARF, having initially decreased to a certain extent, is now seeing a resurgence in the US, prompting concern. Certain demographics persistently exhibit higher mortality rates emphasizing the need for further research.

External and Temporal Validation of Acute Tubulointerstitial Nephritis (AIN) Diagnostic Index: An Electronic Health Record-Based Multivariable Diagnostic Model for Assessing Probability of Acute Interstitial Nephritis on Kidney Biopsy

Kyra A. Shelton,[1,2] Steven Menez,[3] Melissa M. Shaw,[2] Candice Kent,[1,2] Jack Bitzel,[3] Heather Thiessen Philbrook,[4] Francis P. Wilson,[1,2] David Hu,[3] Yumeng Wen,[3] Chirag R. Parikh,[3] Dennis G. Moledina.[1,2] *[1]Section of Nephrology, Department of Internal Medicine, Yale School of Medicine, New Haven, CT; [2]Clinical and Translational Research Accelerator, Department of Internal Medicine, Yale School of Medicine, New Haven, CT; [3]Division of Nephrology, Department of Medicine, Johns Hopkins School of Medicine, Baltimore, MD; [4]Division of Nephrology, Internal Medicine, Johns Hopkins School of Medicine, Baltimore, MD.*

Background: Kidney biopsy is essential in cases of suspected acute tubulointerstitial nephritis (AIN), as there are limited diagnostic tests and clinical features associated with the disorder. Previously, we developed a multivariable model for biopsy-confirmed AIN containing serum creatinine, blood urea nitrogen to creatinine ratio, urine dipstick specific gravity and protein with an AUC of 0.73, which outperformed the clinicians' prebiopsy AUC of 0.60. Here we perform validation of this diagnostic index.

Methods: In two geographically and temporally distinct cohorts of patients who received a kidney biopsy at either Johns Hopkins Hospital (JHH) or Yale between 2019-2023, we tested discrimination (area under receiver operating characteristics curve, AUC) and calibration of the diagnostic index. We used model weights from the previous model and followed TRIPOD guideline for validation of multivariable models.

Results: We included 1,973 participants, with 1,444 from JHH and 529 from Yale. The prevalence of AIN at Yale (21%) was similar to what we previously observed (23%) whereas that of JHH was lower (5%). We noted similar AUC at JHH (panel A) and Yale (panel B) as the development set. However, the JHH cohort showed poor calibration (panel C) that improved after application of an intercept correction factor, accounting for the lower prevalence of AIN in this cohort (panel D).

Conclusions: The diagnostic model retained discrimination in these two distinct cohorts but required recalibration based on the prevalence of biopsy proven AIN. This indicates that the model may be a useful tool in identifying specific clinical features associated with AIN and assisting providers in discerning whether an AIN diagnosis is warranted based on laboratory and dipstick values. TH-PO053

Heparin Prevents AKI to CKD Transition via HDAC1-Mediated Deacetylation of p65 Exerting Anti-inflammatory Effect Independent from Its Anticoagulant Properties

Anqun Chen, Lijun Yin. *The Second Xiangya Hospital of Central South University, Changsha, China.*

Background: The long-term outcome of acute kidney injury (AKI) is not good, since the survivors of AKI are prone to developing chronic kidney disease (CKD). Chronic inflammation is recognized as a pivotal determinant in the transition from AKI to CKD. Heparin, an anticoagulant, exhibits anti-inflammation/anti-complement activities, whose role in AKI to CKD transition remain elusive.

Methods: C57/B6 mice were subjected to unilateral renal ischemia-reperfusion (uIR) and folic acid (FA) intervention to construct AKI to CKD mouse models with or without low doses heparin(5 units/mouse) and its chemically modified variant lacking anticoagulant properties (N-Acetyl heparin sodium salt, NAH : 200μg/mouse) treatment. Potential mechanism of heparin was investigated by bulk RNA-seq analysis. Downstream target of heparin was screened in Swiss Target Prediction database, and detected by drug affinity responsive target stability (DARTS) analysis and cellular thermal shift assay (CETSA). BUMPT cells were used to further validate the effect and target of heparin and NAH in vitro.

Results: Treatment of low doses of heparin and its non-anticoagulant derivatives (NAH) significantly alleviated the uIR- and FA-induced renal tubular injury, and tubulointerstitial fibrosis, and improved renal function. Bulk RNA-seq analysis claimed that heparin might downregulate inflammatory pathways, including cytokine-cytokine receptor interaction, and MAPK signaling pathway, which were confirmed by decreasing immune cell infiltration and inflammatory cytokine expression in heparin-treated mice. Mechanistically, heparin and NAH bound to histone deacetylase 1 (HDAC1) independent on anticoagulant active sites in renal tubular epithelial cells and reduced the level of acetylated p65, leading to decreased expression of inflammatory factors.

Conclusions: Heparin and its non-anticoagulant derivatives inhibited inflammation by targeting HDAC1 to reduce the acetylation of p65. They inhibited the AKI to CKD transition, which could be potentially developed as a novel therapy for preventing AKI to CKD progression.

SGLT2 Inhibitors Reduce the Progression from AKI to CKD by Inhibiting Ferroptosis

Yutaro Hirashima. Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University. *Kyushu Daigaku, Fukuoka, Japan.*

Background: Sodium-glucose cotransporter 2 (SGLT2) inhibitors are known for their renoprotective effects in diabetes but their role in acute kidney injury (AKI) remains less explored. This study evaluates the impact of the SGLT2 inhibitor luseogliflozin on the transition from AKI to chronic kidney disease (CKD) in a mouse model, focusing on its anti-ferroptotic effects.

Methods: Using C57BL/6 mice, ischemic reperfusion (I/R injury was induced via bilateral renal pedicle clamping. Luseogliflozin or vehicle was administered for 2 weeks prior to and until sacrifice after the I/R injury. Renal function was assessed by serum creatinine and urea levels, and tissue damage by histological scoring. Renal fibrosis was assessed by Sirius Red Staining and Masson trichrome Staining. Metabolic shifts, oxidative stress and ferroptosis were evaluated through biochemical assays, histology, western blotting, and metabolomic analysis.

Results: Luseogliflozin significantly reduced markers of renal dysfunction and histological damage in the early post-ischemic phase. It also attenuated renal fibrosis and inflammation markers at one-week post-injury. Metabolic analysis revealed an inhibition of the glycolytic pathway and an enhancement of fatty acid oxidation and mitochondrial function. Key signaling molecules such as AMPK and Nrf2 were activated, correlating with reduced oxidative stress and suppressed ferroptosis.

Conclusions: Luseogliflozin mitigates the progression from AKI to CKD by modulating metabolic pathways and reducing oxidative stress and ferroptosis. This study suggests a potential therapeutic role for SGLT2 inhibitors in the management of AKI, advocating for further clinical investigation.

Impacts of Skeletal Muscle Mass and Quality on Kidney Recovery after AKI Receiving Continuous Kidney Replacement Therapy

Jin hyuk Paek,[1] Jiyun Jung,[3] Jeong-Hoon Lim,[4] Yong Chul Kim,[5] Tae Hyun Ban,[10] Soyoung Lee,[6] Kipyo Kim,[7] Hyosang Kim,[9] Jeongin Song,[2] Jangwook Lee,[2] Sung Joon Shin,[2] Etienne Macedo,[8] Woo Yeong Park,[1] Jae Yoon Park.[2] *[1]Keimyung University Dongsan Medical Center, Daegu, Republic of Korea; [2]Dongguk University College of Medicine, Gyeongju, Gyeongsangbuk-do, Republic of Korea; [3]Dongguk University Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea; [4]Kyungpook National University School of Medicine, Daegu, Republic of Korea; [5]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [6]Daejeon Eulji University Hospital, Daejeon, Republic of Korea; [7]Inha University School of Medicine, Incheon, Republic of Korea; [8]University of California San Diego Department of Medicine, La Jolla, CA; [9]Asan Medical Center, Songpa-gu, Seoul, Republic of Korea; [10]The Catholic University of Korea Eunpyeong St Mary's Hospital, Eunpyeong-gu, Seoul, Republic of Korea.*

Background: Recent study revealed that muscle mass was significant determinant of mortality in patients with patients with severe acute kidney injury (AKI) requiring continuous kidney replacement therapy (CKRT). However, there is little evidence on how muscle mass affects kidney recovery in these patients.

Methods: We collected 1,771 AKI patients who underwent CKRT from eight medical centers between 2006 and 2021. The skeletal muscle area (SMA) was measured from the automated software from CT images at 3rd lumbar vertebra within 15 days of CKRT initiation, and classified as normal attenuation muscle area (NAMA) and low attenuation muscle area (LAMA) according to muscle density. We used Cox proportional hazard model to investigate the effects of muscle index adjusted by height^2 on kidney recovery. In addition, Fine-Gray sub-distribution hazard models were used to consider the competing risks on mortality.

Results: The average duration of dialysis was 10.7 days, and 729 patients (41.2%) were discharged from the hospital independent of dialysis. The average of SMA/height^2, NAMA/height^2, and LAMA/height^2 were 41.2cm^2, 19.0cm^2, and 22.2cm^2, respectively. SMA/height^2 (HR 1.01, 95% CI 1.00-1.02, p=0.03), NAMA/height^2 (HR 1.02, 95%CI 1.01-1.03, p < 0.01), and NAMA/LAMA ratio (HR 1.09, 95% CI 1.01-1.17, p = 0.03) were associated with an increased probability of dialysis independence (DI) at discharge. In addition, while SMA/height^2 was identified as a factor that increased the probability of DI, it was not associated with mortality in Fine-Gray sub-distribution hazard models.

Conclusions: The amount of skeletal muscle mass was related to kidney recovery after AKI requiring CKRT. And muscles of normal density particularly supported these results. Furthermore, after considering mortality as a competing risk, an increase in skeletal muscle mass was associated with a higher probability of DI.

Mitotherapy-Dependent PGC1α Activation Mitigates Mitochondrial Electron Chain Complexes Dysfunction in Cisplatin-Induced AKI

Mohammad A. Afjal,[1] Amanda S. Stayton,[1] Prisha Patel,[1] Murat Dogan,[1] Christine Watkins,[1] Canan Kuscu,[1] Cem Kuscu,[1] Navjot Pabla,[2] Amandeep Bajwa.[1] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]The Ohio State University, Columbus, OH.*

Background: Cisplatin (CP)-induced Acute kidney injury (AKI) is a significant clinical problem. While the etiology of AKI is multifactorial, evidence suggests that mitochondrial dynamics plays a critical role in its pathogenesis. Mitochondria are central to cellular energy production, and mitochondrial dysfunction decreases ATP and induces oxidative stress, apoptosis, and mitochondrial damage, all of which contribute to renal dysfunction. This study investigated the potential of mitotherapy to mitigate mitochondrial complex dysfunction in CP-induced AKI, focusing on the role of PGC1α (Peroxisome Proliferator-Activated Receptor Gamma Coactivator 1-alpha) activation.

Methods: CP was used to induce AKI in male mice. Functional assessment: BUN and plasma creatinine. Histopathological: H&E). Mitochondria source: Mouse Liver (See timeline Fig1 A)

Results: Mitotherapy improve kidney function and reduced structural damage in CP-treated mice (Fig 1 B-E). Mitotherapy enhanced activation of PGC1-α and restored OXPHOS activity (Fig 1 G&F). Mitotherapy restored the balance of mitochondrial dynamics by promoting fusion (Mfn1 and Mfn2) and attenuating fission by decreased expression of Drp1 (Fig 1 H-J). These findings suggest that mitotherapy-dependent activation of PGC1-α plays a crucial role in mitigating mitochondrial complex dysfunction and protecting against cisplatin-induced AKI.

Conclusions: This study highlights the therapeutic potential of mitotherapy in enhancing mitochondrial health and offers a promising strategy for alleviating CP-induced AKI.

JP4-039 Mitigates Cisplatin-Induced Nephrotoxicity and Prevents AKI

Merlin Airik, Rannar Airik. *University of Pittsburgh, Pittsburgh, PA.*

Background: Cisplatin is a commonly used highly effective therapeutic in cancer treatment. However, its use is limited by its nephrotoxicity which occurs in about 30 percent of patients receiving cisplatin chemotherapy. Since cisplatin induced AKI remains a major unmet medical need without any pharmacological interventions, we decided to explore the nephroprotective effects of a novel mitochondria-targeted reactive oxygen species (ROS) and electron scavenger JP4-039.

Methods: Male mice (129Sv-Elite, Charles River) were +/- treated with JP4-039 (10 mg/kg) 24 hours before or after cisplatin (10 mg/kg) injection, and kidneys analyzed 72 hours later for functional and molecular changes. Histological analysis was performed using PAS staining. Markers of tubular injury, DNA damage, lipid peroxidation, ROS and apoptosis were assessed by immunofluorescence and immunohistochemistry. Blood urea nitrogen was used to assess kidney function and qPCR was used to assess changes in gene expression.

Results: A single dose of cisplatin induced significant BUN elevation and kidney injury (KIM1, NGAL expression) in 129Sv-Elite mice after 72 hours, indicative of AKI. These pathologic changes were absent in mice who had received pre- or post-cisplatin JP4-039 injections, demonstrating a prevention of AKI. In addition, treatment with JP4-039 mitigated kidney morphology and histology in cisplatin-treated mice. Specifically, JP4-039 reduced the levels of tissue oxidative lesions, including oxidative DNA damage (8-OHdG) and lipid peroxidation (4-HNE), and mitigated tubular apoptosis. Mechanistically, we propose that JP4-039 exerts its renoprotective action by suppressing the NRF2 pathway, as the expression of NRF2 and its target genes (Nqo1, Txnrd1) was downregulated in JP4-039 kidneys. Further, JP4-039 attenuated the expression of various inflammatory cytokines associated with AKI in cisplatin injured kidneys.

Conclusions: Our data demonstrate that the novel antioxidant compound JP4-039 protects the kidneys from cisplatin induced AKI by suppressing tubular oxidative stress and inhibiting proinflammatory and proapoptotic pathways. Moreover, our studies show that JP4-039 can be administered both as a preventative or interventional therapy to suppress AKI induction.

Bardoxolone Methyl Demonstrates Mitigation of Cisplatin-Induced Kidney Injury in a Mouse Model with Cancer

Sarah C. Asby,[1] Lauren E. Thompson,[1] M. Scott Lucia,[1] Lauren Aleksunes,[2] Charles L. Edelstein,[1] Melanie S. Joy.[1] *[1]University of Colorado Anschutz Medical Campus, Aurora, CO; [2]Rutgers The State University of New Jersey, New Brunswick, NJ.*

Background: Acute kidney injury (AKI) occurs in approximately one-third of patients treated with the chemotherapeutic drug cisplatin. Multiple low-to-moderate doses of cisplatin in tumor-bearing mice recapitulates cisplatin-induced AKI in cancer patients and can be used to test potential mitigation strategies. Bardoxolone methyl (BARD) is an attractive mitigation therapeutic due to its ability to enhance anti-oxidative responses through activation of the Nrf2 transcription factor and potential anti-tumorigenic effects.

Methods: C57BL/6J mice (8-10 wk) were injected with CMT167 murine lung carcinoma cells (50,000) in the right flank and allowed to engraft for 7 days. Then, cisplatin (10-15 mg/kg) or vehicle (saline) were administered IP once weekly for 4 wks. Likewise, BARD (10 mg/kg) or vehicle (34.5% PEG-300, 30% DMSO, 30% saline, 5% propylene glycol, and 0.5% Tween-80) were injected IP 5x/wk per week. Body weight, tumor size, and survival were assessed weekly for 4 wks and urine and blood were also collected. Kidney injury was quantified by urinary kidney injury molecule-1 (KIM-1), serum creatinine (SCr) and assessment of renal histopathology.

Results: Co-treatment with BARD significantly enhanced survival of cisplatin-treated mice with cancer (p=0.01). Cisplatin treatment, with or without BARD, significantly reduced tumor growth compared to vehicle-treated mice (p<0.05). BARD did not demonstrate any significant anti-tumorigenic properties as a single agent. BARD protected the mice from cisplatin-induced kidney injury, as measured by urinary KIM-1 levels (p<0.01). BARD also mitigated the loss of kidney function caused by cisplatin, as measured by SCr (p<0.01). All Veh/CIS treated mice demonstrated tubular injury after just two doses of cisplatin and had significantly higher tubular injury scores (scores 1 or 2) than Veh/Veh and BARD/Veh mice (scores 0; p<0.05). Approximately 30% of BARD/CIS mice had no apparent tubular injury after receiving the 4 cisplatin doses, although not statistically different from Veh/CIS-treated mice.

Conclusions: Overall, the results of this study demonstrate the potential utility of using acute BARD administration during cisplatin treatment to reduce drug-induced AKI.

Trends and Racial and Geographic Disparities in AKI-Related Mortality Rate in the United States, 1999-2019

Ewuradjoa Ayirebi-Acquah,[1] Zaneta Frimpong,[4] Abena A. F. Gyamfi,[5] Nii A. Addo-Quaye,[3] Sandra Oppong-Twum,[3] Stella Nyamikeh,[2] Isaac Prempeh.[6]
[1]Lekma Hospital, Accra, Ghana; [2]37 Military Hospital, Accra, Ghana; [3]Korle Bu Teaching Hospital, Accra, Ghana; [4]University of Ghana Medical Centre, Accra, Ghana; [5]Ridge Medical Center, Accra, Ghana; [6]New Hope Specialist Hospital, Aflao, Ghana.

Background: Acute kidney injury (AKI) is associated with increased risk of death. However, previous studies before 2010 showed conflicting trends in AKI-related mortality rate (AKI-MR) in the United States (US). Also, little is known about racial disparities in AKI-MR. We examined the trends and racial disparities in AKI-MR in adults in the US from 1999 to 2019.

Methods: This was a retrospective cross-sectional analysis of national death certificate data from the CDC's Wide-ranging Online Database for Epidemiological Research from 1999-2019. We used ICD-10 codes N17 and O90.4 to identify adults >18 years old whose death certificates mentioned AKI as a cause of death. The exposure variables were calendar year, race, and geographic region. The outcome variable was the crude AKI-MR which was calculated per 100,000 population. The Mann-Whitney U test and ANOVA were used to compare groups and P<0.05 defined statistical significance. We evaluated temporal trends with Joinpoint regression, which was expressed as average annual percentage change (AAPC) with 95% confidence intervals (CI).

Results: There were 1,093,865 AKI-related deaths out of a population of 4,784,988,012 [overall crude AKI-MR 22.9 per 100,000 (95% Cl, 22.8-22.9). The AKI-MR was higher in males (24 vs 21.7 in females; P=0.03), non-Hispanic White (NHW) [26.1 vs 23.8 in non-Hispanic Black (NHB), P=0.04], rural areas (30.3 vs 21.5 in urban areas; P<0.001), and the Midwest (24.8). From 1999-2019, the overall crude AKI-MR increased from 15.3 to 24.6 (AAPC 2.4%; CI: 2.3-2.6). The AKI-MR increased for males (AAPC 2.6%; CI: 2.5-2.8), females (AAPC 2.3%, CI: 2.2-2.5), NHB (AAPC 1.6, CI: 1.4-1.8), NHW (AAPC 2.8%, CI: 2.7-2.9), urban areas (AAPC 2.4%, CI: 2.2-2.5), rural areas (AAPC 3.3%, CI: 3.1-3.6), and across all census regions. When limited to AKI as the underlying cause of death, the crude AKI-MR increased overall, and for all genders, racial groups, urban and rural areas, and all census regions.

Conclusions: The AKI-MR increased significantly in the US from 1999-2019 and it varied by race, sex, and geographic region. These underscore the public health importance of AKI as a significant contributor to mortality in adults and it is an opportunity for further studies into the optimization of the care of patients with AKI.

TH-PO060

Increased Bone Fracture Risk after Recovery from AKI

Thomas R. McCune,[1,2] Marie V. Ozanne,[3,1] Xian Qiao,[1,4] Angela J. Toepp,[1,4] Melissa A. Kacena.[5] EVMS/IU Metabolic Bone Disease Consortium.
[1]Eastern Virginia Medical School, Norfolk, VA; [2]Nephrology Associates of Tidewater LTD, Norfolk, VA; [3]Mount Holyoke College, South Hadley, MA; [4]Sentara Healthcare Inc, Norfolk, VA; [5]Indiana University Purdue University Indianapolis, Indianapolis, IN.

Background: Acute kidney injury(AKI) that requires dialysis can be a complication during hospitalization. A population study from Taiwan found that patients recovered from AKI observed an increased risk fractures in weight bearing bones the first year (HR = 6.02, 95% CI 1.43–17.22; p = 0.02). We evaluated the risk of weight bearing fractures after recovery (>6 months) in a similar population data base.

Methods: This is a retrospective cohort study using data (accesed 1/23/24) from TriNetX COVID-19 Research Network, including deidentified EHR of 115+ million individuals in 85 healthcare organizations. Inclusion criteria: inpatient encounter (1/20/20-12/2022). Exclusion criteria: ESRD (N18.6), renal transplant (Z94.0/Z48.22), COVID infection, or neoplasm (C00-D49). Age 18 to 89 years. Propensity score matching (1:1) balanced three covariates between groups. Univariate logistic regression was conducted predicting AKI and weight bearing fractures (>6 months).

Results: Table 1: Study population fracture rates Figure 1: Risk of fractures by location (ICD-10)

Conclusions: 1. AKI increases the risk of weight bearing bone fractures(>6 months) (HR=1.527, 95% CI 1.455-1.603; p=0.01). 2. All weight bearing bone groups are impacted after AKI. 3. Managemant of AKI should address alterations in bone mineral metabolism.

TH-PO061

Incidence of AKI and Kidney Replacement Therapy (RRT) after Outpatient Chimeric Antigen Receptor T (CAR-T) Cell Therapy in Patients with Hematological Malignancies

Bibi Maryam, Adolfo Diaz-Barba, Noha Soror, Taha Al-Juhaishi. *The University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: AKI is characterized by an abrupt loss of kidney function resulting in decreased GFR, reduced urine output, and increased serum creatinine. CAR-T therapy is a newer cancer immunotherapeutic treatment that utilizes genetically altered cytotoxic T cells in destroying cancer cells. There have been very few studies studying the repercussions of inpatient CAR-T therapy on kidneys, but so far no studies have covered the renal safety profile of outpatient CAR-T therapy. We performed a retrospective analysis on incidence of AKI, resolution vs progression of disease requiring RRT and devolpment of CKD, in patients who underwent outpatient CAR-T therapy at our institute.

Methods: We obtained IRB approval and identified 79 adult patients who underwent outpatient CAR-T therapy between 9/2019 to 11/2023 for hematological malignancies at our National Cancer Institutes (NCI)-designated cancer center. Then we performed a retrospective chart review and determined the rates of hospital admissions and development of AKI within 7 days of CAR-T infusion, and followed the hospital course to assess the need for RRT, resolution of AKI, and progression to CKD. We also looked at the past medical history to assess if patients had preexisting diabetes, hypertension, and CKD.

Results: Out of the 79 patients who underwent outpatient CAR-T therapy infusion, 74.6 % ended up being admitted in the hospital. Within 7 days of infusion, 3 patients developed AKI, requiring hospitalization. Among these, one patient had preexisting CKD, and developed AKI on CKD. All three had hypertension on baseline, and interestingly none had diabetes. Incidence of AKI in all patients was at 3.7 %, whereas incidence of AKI in hospitalized patients was at 5.08%. 1 patient developed severe AKI requiring

RRT, bringing incidence rate of RRT at 1.26 % among all patients and 33% among the AKI group. Kidney function returned to baseline within 30 days in two of our patients, while one patient passed away during the hospitalization. None of our patients progressed to CKD.

Conclusions: We found a lower rate of AKI compared to rates reported in previous studies for patient who underwent inpatient CAR-T therapy, favoring the theory that outpatient CAR-T has a less severe side effect profile than inpatient CAR-T.

TH-PO062

Incidence of Postsurgical AKI for Emergent Surgery and Associated Clinical Outcomes

Stuart M. Carter, Ashita J. Tolwani. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: The purpose of this study is to identify the incidence of AKI in the two weeks immediately following an emergent surgical procedure in patients that did not received dialysis prior to their surgery. Our goal is to determine how often AKI is developed after an emergent procedure with the end goal of better identifying ways to prevent post-surgical AKI.

Methods: The target population is patients with an Emergent surgical procedure during their encounter (ASA Class 1-5E) admitted between October 1st, 2023 and May of 2024 at the University of Alabama at Birmingham Medical Center. Patients with Inpatient dialysis before the surgery were excluded. AKI was determined by retrospectively analyzing serum creatinine data, using the lowest pre-surgical creatinine level during the encounter as the baseline. The KDIGO criteria were applied, excluding urine output values. Patient outcomes were compared between those who developed AKI and those who did not.

Results: After excluding patients with end-stage renal disease (ESRD) and those treated for AKI prior to surgery, 827 patients were analyzed. Of these, 137 (16.6%) developed AKI, while 680 (83.4%) did not. Significant differences were found in median length of stay (15.5 days for the AKI group vs. 6.5 days for the non-AKI group). The mortality rate was also significantly higher in the AKI group (13%). Demographics and comorbidities are provided within the table below for the two sample groups.

Conclusions: The preliminary findings indicate that a significant population develops AKI following emergent surgery, suggesting that further research is needed to identify factors contributing to post-surgical AKI and potential preventive measures.

Mortality and Kidney Function Recovery in Patients with Sepsis-Associated AKI vs. Nonseptic AKI Treated with Continuous Kidney Replacement Therapy

Marco Fiorentino, Francesco La Fergola, Sabrina Carparelli, Loreto Gesualdo. *Universita degli Studi di Bari Aldo Moro, Bari, Italy.*

Background: It was recently suggested that sepsis-associated AKI (SA-AKI) is characterized by different pathogenesis and outcomes compared to non-Septic AKI (NS-AKI). We aim to examine risk factors and outcomes of SA-AKI vs NS-AKI among critically ill patients who developed AKI requiring renal replacement therapy (RRT).

Methods: We performed a single-center retrospective analysis, including patients admitted to ICU who developed AKI requiring RRT at Policlinico of Bari (Jan. 2021 to July 2023). We classified patients in NS-AKI and SA-AKI groups based on the leading cause of AKI. The primary outcome was to assess mortality and kidney functional recovery (KFR) rate between SA-AKI and NS-AKI groups. 28-day survival probability was analyzed using the Kaplan–Meier method. Risk factors associated with in-hospital mortality were evaluated using Cox regression models.

Results: 320 patients were included in the study; 131 patients developed SA-AKI (40.9%), while the remaining 189 were classified as NS-AKI (59.1%). 268 patients (83.8%) developed AKI Stage 3 and 40 patients AKI stage 2 (12.5%). There was no significant difference in CRRT duration and median lenght of ICU stay. The timing of CRRT initiation from ICU admission was late in the SA-AKI group (3 vs 1 days, p=0.002). 184 patients (57.5%) died at 28 days, with a higher percentage in the SA-AKI (70.2 vs 48.6%, p<0.001)(**Figure 1**). In-hospital mortality was reported in 221 patients (69%), with impressive percentages in the SA-AKI group (82.45 vs 69.3%, p<0.001). KFR was significantly higher in the NS-AKI (28.5% vs 13.7%, p=0.002). Median time of KFR was similar between groups (p=0.833). Multivariate Cox Regression analysis showed that only SA-AKI (HR 1.442, 95%CI 1.052-1.978, p=0.023) was independently associated with mortality risk.

Conclusions: SA-AKI was associated with high mortality rate and lower likelihood of renal recovery compared to NS-AKI in critically ill patients requiring RRT.

	All AKI patients (n=320)	SA-AKI (n=131)	NS-AKI (n=189)	P-value
Days on RRT, days, median (IQR)	5 (3-12)	5 (3-11)	5 (3-13)	0.845
Time from ICU admission to CRRT start, days, median (IQR)	1 (0-7)	3 (1-11)	1 (0-4)	0.002
28-day renal recovery, n(%)	72 (22.5%)	18 (13.7%)	54 (28.5%)	0.002
Overall Renal recovery after AKI, n (%)	86 (26.8%)	23 (18%)	65 (34.4%)	0.001
Time of renal recovery from CRRT start, days, median (IQR)	7 (4-14)	7 (4-12)	7 (3.5-17.5)	0.833
Dialysis dependence at hospital discharge, n (%)	16 (5%)	3 (2.3%)	13 (6.8%)	0.059
Length of ICU stay, days, median (IQR)	12 (4-25)	13 (3-26)	11 (3-23)	0.422

TH-PO064

Brain-Kidney Interplay during Sepsis-Associated AKI: Results from the RACERS Study

Marco Fiorentino,[1] Maria Teresa Cimmarusti,[1] Alessandra Stasi,[1] Rossana Franzin,[1] Sabrina Carparelli,[1] Monica Campioni,[1] Rosa Losapio,[1] Gianvito Caggiano,[1] Paola Pontrelli,[1] Constance Keyserling-Peyrottes,[2] Cyrille Tupin,[2] Loreto Gesualdo.[1] [1]*Universita degli Studi di Bari Aldo Moro, Bari, Italy;* [2]*Abionyx Pharma, Toulouse, France.*

Background: Recent preclinical studies have revealed a strong association between low levels of HDL and dysregulation of the kynurenine pathway (KP) in sepsis-associated AKI and cognitive dysfunction. In our preclinical model, treatment with a new engineered HDL (CER-001) downregulated the Indolamine-2,3-dioxygenase 1 (IDO1) enzyme, a crucial mediator of KP, by reducing kynurenine/tryptophan (KYN/Trp) ratio and quinolinic acid (QA) levels. We aim to analyze the effects of treatment in mitigating brain dysfunction in a Phase 2a clinical trial.

Methods: We performed a randomized Phase 2a study (RACERS study) including 20 patients with Gram negative sepsis, randomized to receive CER-001 (twice a day on Days 1, 2, 3 and 6) or standard of care (SOC) only. We analyzed the activity of KP between patients treated with CER-001 and SOC groups, by reporting changes from baseline of specific neuroactive metabolites such as KYN, KYN/Trp ratio, kynurenic acid (KYNA), QA and serotonin values.

Results: CER-001 treatment significantly reduced bloodstream concentrations of LPS, pro-inflammatory cytokines and circulating s-VCAM-1 and s-ICAM-1. Patients presenting with AKI at enrollment presented a tendence to higher values of KYN/Trp ratio (0.22, IQR 0.12-0.46) compared to patients without any stage of AKI at enrollment (0.12, IQR 0.07-0.28). CER-001 treatment reduced QA, KYN values and KYN/Trp ratio, suggesting the downregulation of IDO1, thus reducing the production of potential neurotoxic metabolites (**Figure 1**). We showed increased levels of tryptophan and the neuroprotective KYNA during treatment course, as well as a slight increase in serotonin, supporting the different regulation of tryptophan metabolism leading to neuroprotection.

Conclusions: CER-001 treatment downregulated IDO1 and reduce neuroactive metabolites and waste accumulation.

Nephrotoxicity Associated with Vancomycin and Piperacillin/Tazobactam: Insights from Kidney Biopsy

Sofia Yamada,[1,2] Xavier F. Parada,[3,4] Sphoorthy Pasala,[1,2] Rajesh Anumolu,[1,2] Saif A. Alenizi,[1,2] Astrid Weins,[1,2] David B. Mount.[1,2] *[1]Brigham and Women's Hospital Department of Medicine, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]UMass Memorial Health, Worcester, MA; [4]University of Massachusetts Chan Medical School, Worcester, MA.*

Background: The antibiotics vancomycin and piperacillin-tazobactam are co-prescribed together in hospital settings; there are concerns regarding the potential nephrotoxicity. Both antibiotics have been independently implicated in AKI and there is no consensus about any mechanism of injury when administered together. This case series explores kidney biopsy findings in patients receiving these antibiotics, to elucidate potential mechanisms of injury, risk factors and compare them with the literature. Notably, there is minimal biopsy data for patients with AKI after this antibiotic combination

Methods: This is a single center, observational cohort study. Clinical and biopsy data were retrospectively collected from hospitalized AKI patients with recent exposure to vancomycin and piperacillin-tazobactam who underwent native kidney biopsy between Feb/2010 to Nov/2023 at Brigham and Women's Hospital. All seven included AKI patients were de-identified; since there was no interaction or intervention with human subjects, there is no need for IRB review

Results: Kidney biopsies revealed a range of pathological findings, including acute tubular necrosis (ATN), acute interstitial nephritis (AIN), and tubular injury potentially related to drug induced nephrotoxicity. Notably, among the 7 patients examined, 2 developed acute kidney injury (AKI) within 48 hours of antibiotic prophylaxis, while 1 during day 2, 3 exhibited symptoms on day 3, and 1 on day 5 following the initiation of antibiotic treatment

Conclusions: AKI after co-administration of vancomycin/ piperacillin-tazobactam is an increasingly important clinical problem, with some evidence for "pseudo-AKI" from elevated creatinine levels without acute kidney injury. Here we report that this antibiotic combination is associated with a mixture of ATN and AIN after co-administration, providing new biopsy confirmation of an association with *bona fide* AKI. Further research is necessary to elucidate underlying mechanisms and develop strategies for early detection and management of antibiotic associated renal toxicity

TH-PO066

Precipitous AKI in Association with Vancomycin Exposure: A Cohort Study

Montana D. Ellis,[1] Dustin R. Chalmers,[3] Ghaith Hashem,[1] Kirsten Johnson,[1] Danielle N. Aliano,[2] Vipin Varghese,[4] Swetha Rani Kanduri,[2,1] Juan Carlos Q. Velez.[2,1] Ochsner Group. *[1]UQ-Ochsner Clinical School, New Orleans, LA; [2]Ochsner Health, New Orleans, LA; [3]Louisiana State University, Baton Rouge, LA; [4]University of Michigan Division of Nephrology, Ann Arbor, MI.*

Background: Precipitous acute kidney injury (p-AKI) is a distinct form of AKI characterized by a steep rise in serum creatinine (sCr). An association between exposure to vancomycin and p-AKI has been previously reported via large electronic database mining, case reports, and case series. Herein, we aimed to expand our understanding of this entity by examining the relationship between exposure to vancomycin and the incidence of p-AKI in a prospectively generated AKI Cohort.

Methods: We prospectively collected data of patients seen in inpatient nephrology consultation who had a urine specimen subjected to microscopic examination of the urinary sediment (uSEDI) as part of the clinical evaluation for AKI over a 6-year period. AKI was defined by KDIGO criteria. p-AKI was defined as a rise in sCr ≥ 1.6 mg/dL within 24 +/- 2 hrs at any point during the course of the AKI episode. Within this uSEDI cohort, we identified patients who had been exposed to intravenous vancomycin during the preceding 5 days prior to the day of AKI consultation and determine its association with p-AKI occurrence.

Results: 801 patients entered the study. Median age was 60, 42% women, 59% White, 31% Black. Preexisting CKD was reported in 42%. Main etiologies of AKI were ischemic acute tubular injury (ATI) (44%), hepatorenal syndrome (13%) and toxic ATI (12%). Exposure to vancomycin was registered in 265 (33%) patients. Median sCr at the time of AKI was 3.2 (IQR 2.4-4.6) mg/dL. p-AKI occurred in 95 (12%) patients, the steepest 24-hr sCr rise recorded was 4.2 mg/dL. Exposure to vancomycin was associated with an increased risk of p-AKI [18% vs. 9%, for exposed to vancomycin vs non-exposed, respectively; odds ratio 2.24 (95% CI 1.45-3.46, z statistic=3.643, p=0.0003)].

Conclusions: Exposure to vancomycin doubles the risk of p-AKI. This study adds to a body of evidence that defines a unique AKI phenotype associated with vancomycin that should be recognized in clinical grounds. The mechanism behind the precipitous sCr rise due to vancomycin may relate to a combination of true ATI and reduced tubular sCr secretion due to injury to proximal tubular organic transporters, but more investigation is still required.

TH-PO067

A Clinicopathological Description of Kidney Features in VEXAS Syndrome

Martin Mathurin,[1] Pierre Hirsch,[1] David Buob,[1,2] Khalil El Karoui.[1,2] FRENVEX Group. *[1]Assistance Publique - Hopitaux de Paris, Paris, France; [2]INSERM, Paris, France.*

Background: VEXAS (Vacuoles, enzyme E3, X linked, Autoinflammatory, Somatic) is a recently reported autoinflammatory syndrome characterized by myeloid lineage-restricted acquired variants in the ubiquitin-activating E1 (UBA1) gene. Renal lesions of VEXAS patients are poorly characterized.

Methods: We searched for patients with kidney biopsy (KB) among 303 VEXAS cases from the french nationalVEXAS cohort. We extracted data from medical records, and performed a centralized review of renal biopsies. We investigated the presence of UBA1 mutated clones within the kidney by sequencing DNA extracted from whole kidney tissue.

Results: We identified 11 patients with KB. All were male, mean age was 70 years old. Renal presentation included progressive chronic kidney disease in 5 patients and acute kidney injury (AKI) in 6 (including two needing renal replacement therapy). AKI episodes were chronologically linked with VEXAS flares in 3 patients. Mean sCreatinine was 363 µmol/l. All patients presented with extra renal manifestations. Renal function evolution was usually favorable after treatment with corticosteroids and various immunosuppressors. Histopathological findings were heterogenous, including acute interstitial nephritis (n=4), ANCA negative pauci-immune vasculitis (n=1), IgA nephropathy superimposed with minimal change disease (n=1), IgA nephropathy (n=1), diabetic nephropathy with extensive fibrosis (n=1), acute tubular necrosis (n=2), and AA amyloidosis (n=1). Interstitial inflammatory infiltration was noticed in 8/11 cases, whatever the primary diagnosis. Immunohistochemical characterization of interstitial inflammatory cells demonstrated the presence of lymphocytes and plasma cells, admixed with macrophages and neutrophil cells. MPO and CD68 immunostaining was positive in all cases, with a variable degree of expression. We performed molecular analysis of DNA extracted from 8 available frozen samples by next generation sequencing. UBA1 variation was detected in 7/8 samples, with VAF ranging from 2% to 17% of total kidney DNA.

Conclusions: This series highlights the heterogeneous clinical and histological presentation of VEXAS-associated kidney disease. The molecular analysis of kidney tissue along with the frequent histological finding of interstitial infiltration may suggest the existence of a specific involvement of clonal cells directly targeting the kidney during VEXAS.

TH-PO068

Gut Microbiome Metagenomic Sequencing Reveals Distinct Profiles in Participants with AKI and CKD from the KPMP

Sanjeev Noel,[1] James R. White,[2] Shishir K. Patel,[1] Steven Menez,[1] Dominic S. Raj,[3] Chirag R. Parikh,[1] Hamid Rabb.[1] Kidney Precision Medicine Project (KPMP). *[1]Johns Hopkins University, Baltimore, MD; [2]Resphera Biosciences LLC, Balitmore, MD; [3]The George Washington University, Washington, DC.*

Background: Previous experimental studies using 16S RNA sequencing demonstrated distinct gut microbial changes following acute kidney injury (AKI) in mice and dysbiosis in chronic kidney disease (CKD) patients. Metagenomic whole genome sequencing (mWGS) has several advantages over 16S, including the ability to identify bacteria, fungi and viruses plus provide functional information. We applied mWGS to KPMP stool samples from AKI and CKD participants for species level identification and functional pathway analysis.

Methods: mWGS on AKI (n=7) and CKD (n=70) stool was performed to achieve >25 million reads/sample. Metagenomic data of healthy controls (n=94) from 4 published studies was downloaded from the NCBI Sequence Read Archive. Kraken2 and Metaphlan3 were used for taxonomic assignment and HUMAnN3 for functional annotation. Unsupervised clustering was performed using pheatmap, and comparisons between groups were computed with the non-parametric Mann-Whitney U test.

Results: Kraken2 analysis showed a decline in the percent mean abundance of *Ruminococcus bicirculans* in AKI (1.82) compared to CKD (6.47; p=0.07) and healthy individuals (2.42; p=0.01). Furthermore, genus *Chryseobacterium* declined in AKI (0.05) compared to CKD (0.07; p=0.05) and healthy individuals (0.20). Conversely, *Gordonibacter pamelaeae* increased in AKI (0.07) compared to healthy individuals (0.03) but was less abundant compared to CKD (0.30; p=0.05). Metaphlan3 identified a significant increase in *Clostridium asparagiforme* in AKI (11.68) compared to CKD (0.03; p=0.06) and healthy (0.01; p=0.001) individuals. *Gemmiger formicilis* was significantly reduced in AKI (0.01) compared to CKD (0.51; p=0.06) and healthy (0.26; p=0.001) individuals. HUMAnN3 analysis showed significant correlation between amino acid metabolism and *Clostridium asparagiforme* in AKI compare to CKD and healthy individuals.

Conclusions: These preliminary results demonstrate distinct microbiota profile during an episode of AKI compared to CKD and healthy individuals. Future studies with larger sample sizes are needed to confirm these findings and highlight the pathophysiologic significance of these changes.

Immunomodulatory Effect of Selective Cytopheretic Device (SCD) on Neutrophil-to-Lymphocyte Ratio (NLR) and Hematologic Parameters from Multiple AKI Trials

Sai Prasad N. Iyer,[1] Nicholas J. Ollberding,[4] Jay L. Koyner,[2] Lenar T. Yessayan,[3] Kevin K. Chung,[1] H. David Humes.[3] *[1]SeaStar Medical, Denver, CO; [2]University of Chicago Division of the Biological Sciences, Chicago, IL; [3]University of Michigan Michigan Medicine, Ann Arbor, MI; [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: SCD is an immunomodulatory cell-directed extracorporeal therapy (CDET) that targets activated neutrophils and monocytes in hyperinflammatory conditions such as AKI and sepsis. Inflammatory imbalance can be measured by examining relationships of leukocytes to other immune cells, such as NLR. High NLRs have been associated with poor outcomes across a wide range of diseases, including AKI and sepsis. We examined the effect of SCD treatment from prior AKI clinical studies on NLR and other hematological measures to gain insights into the mechanism of SCD.

Methods: Complete blood count, NLR, monocyte: lymphocyte ratio (MLR), and platelets were included from 5 prior adult and pediatric studies (pooled n=133) in patients with AKI requiring continuous kidney replacement therapy (CKRT). Patients were treated for up to 10 days with SCD + CKRT in all studies. Control CKRT only group included patients from a pivotal study (SCD-003), and from a contemporaneous matched cohort (CRRTnet) (n=32). All parameters were analyzed from the treatment period across these studies between control vs. SCD treated patients using linear mixed effects regression.

Results: Treatment with SCD reduced NLR across all studies during the treatment period. The control group in the SCD-003 study displayed an upward trend in NLR after an initial drop but was not statistically significant vs. the SCD treated group (p = 0.38). When analyzed as a pooled group, SCD treated patients demonstrated a significant reduction in NLR vs. control patients (p=0.007). This difference was maintained following sensitivity analysis excluding pediatric patients (p=0.013). No statistically significant differences were observed between groups for MLR levels or platelets in the treatment period.

Conclusions: SCD treatment demonstrated reductions in NLR across multiple AKI clinical studies. This analysis provides further mechanistic evidence of leukocyte immunomodulation in targeting inflammatory neutrophils and effector immune cell dysregulation in hyperinflammatory conditions such as AKI.

Cost Impact of an Immunomodulatory Selective Cytopheretic Device in Pediatrics (SCD-PED) in AKI Due to Sepsis (AKI-S)

Jennifer A. Kammerer,[1] Nathan L. Kleinman,[2] Alec Kleinman,[2] Kevin K. Chung,[1] Sai Prasad N. Iyer,[1] Charuhas V. Thakar.[3] *[1]SeaStar Medical, Inc, Denver, CO; [2]Kleinman Analytic Solutions LLC, Frisco, TX; [3]Queen's University Belfast, Belfast, United Kingdom.*

Background: Acute kidney injury (AKI) occurs in 3.9/1000 US pediatric hospitalizations—often with septicemia (OR 1.37 (1.32 to 1.43))—and requiring ICU care and continuous kidney replacement therapy (CKRT). Poor outcomes include prolonged stays, mechanical ventilation (MV), and up to 50% mortality. SCD-PED is an authorized humanitarian device for patients ≥10kg, age ≤22 years with AKI-S on CKRT. Using Kids' Inpatient Database (KID) and SCD-PED study data, hospitalization costs are estimated.

Methods: KID extract (2019) included patients ages 1-20 years on CKRT. Modeled from hospital perspective were inputs for length of stay (LOS), age, gender, death at discharge, vasopressor use, MV, sepsis or AKI, total parenteral nutrition (TPN), mortality risk, SCD-PED cost/number used. Mean mortality was 45% in external controls and 27% on SCD-PED. Costs are adjusted to 2024 USD. Cost savings are derived from mortality benefit or simulated for 1-day reduction in LOS. Generalized linear regression was used to model costs. All variables were significant except gender and AKI.

Results: Mean hospitalization cost was $461,736 in KID controls, reflecting heterogenous, complex cases and costly burden. With continuous 6-day SCD-PED, savings from lower mortality is predicted for device price up to $4381. With theoretically lower LOS, further savings may be realized.

Conclusions: The SCD-PED is likely cost beneficial to implement with presumed survival benefit in critically ill pediatric AKI-S. Other benefits may include clinical value of lower mortality and costs from a) reduced total or ICU LOS, b) outcomes beyond hospitalization (avoided dialysis, renal recovery), and c) sepsis or readmission quality measurements.

Intraoperative Microvascular Perfusion in Cardiac Surgery-Associated AKI: A Prospective Longitudinal Cohort

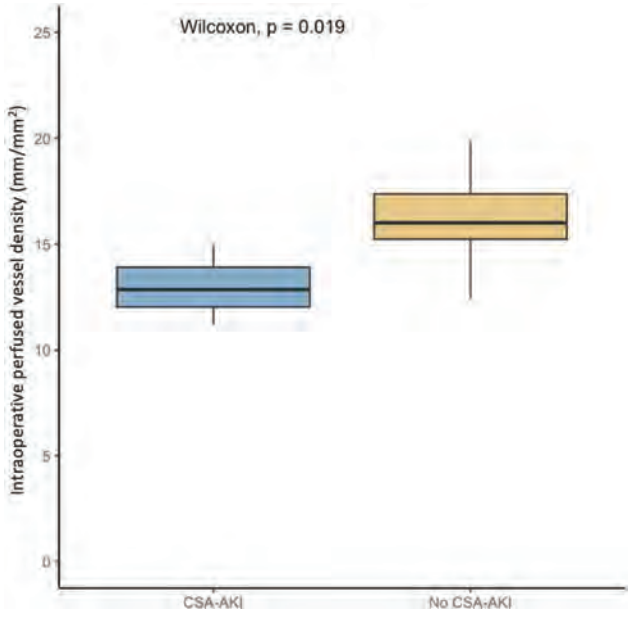
Jennifer R. Joslin,[1,2] Simon C. Satchell,[3] Claire C. Sharpe,[2] Kate Bramham.[1,2] *[1]King's College London, London, United Kingdom; [2]King's College Hospital, London, United Kingdom; [3]University of Bristol, Bristol, United Kingdom.*

Background: We have previously presented the association between intraoperative endothelial glycocalyx (EGx) degradation (quantified by plasma syndecan-1 (SDC1)) and cardiac surgery-associated acute kidney injury (CSA-AKI). This novel study aimed to explore the relationship between intraoperative microvascular perfusion and CSA-AKI.

Methods: Twenty patients selected from a prospective observational cohort study of 61 patients undergoing coronary artery bypass graft (CABG) surgery were included. Sublingual microvascular perfused vessel density (PVD) was assessed by incident dark field videomicroscopy at three time-points: preoperatively, intraoperatively after haemostasis, and immediately postoperatively. CSA-AKI within 48 hours was assessed (KDIGO criteria). Demographic, clinical and surgical variables were evaluated.

Results: 3/20 (15%) participants developed CSA-AKI. Intraoperative PVD was significantly lower in those who did develop CSA-AKI than in those who did not (Figure 1). There were no significant differences in preoperative or postoperative results between groups. There was a moderate negative correlation between intraoperative PVD and SDC1 levels measured at the same time point: R = -0.54, p = 0.015. Intraoperative PVD was the best predictor of CSA-AKI with an area under the curve of 0.92 (95% confidence interval 0.79 – 1.00).

Conclusions: This is the first demonstration of impaired intraoperative microvascular perfusion in CABG patients who later developed CSA-AKI, and highlights the association between EGx health and microvascular perfusion. These findings offer potential targets for early therapeutic intervention and / or earlier identification of patients at greatest risk of CSA-AKI.



Intraoperative PVD in patients with and without CSA-AKI

Is AKI an Independent Risk Factor for Subsequently Decreased Kidney Function after Accounting for Pre-AKI Proteinuria and Pre-AKI eGFR Slope?

Victor E. Prado,[1] Ian E. McCoy,[1] Yue Zhang,[7] Kathleen D. Liu,[1] Anthony N. Muiru,[1] Vernon M. Chinchilli,[7] Steven G. Coca,[2] Alan S. Go,[6] Jonathan Himmelfarb,[3] James S. Kaufman,[8] Paul L. Kimmel,[9] Talat Alp Ikizler,[5] Chirag R. Parikh,[4] Edward D. Siew,[5] Mark M. Wurfel,[3] Chi-yuan Hsu.[1]
[1]University of California San Francisco School of Medicine, San Francisco, CA; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]University of Washington, Seattle, WA; [4]Johns Hopkins University, Baltimore, MD; [5]Vanderbilt University, Nashville, TN; [6]Kaiser Permanente, Oakland, CA; [7]The Pennsylvania State University, University Park, PA; [8]New York University, New York, NY; [9]National Institutes of Health, Bethesda, MD.

Background: A recent Chronic Renal Insufficiency Cohort (CRIC) analysis showed that after accounting for pre-AKI eGFR slope, pre-AKI proteinuria and other confounders, an episode of mild to moderate AKI was not an independent risk factor for changes in subsequent eGFR or eGFR slope (Ann Intern Med. 2023;176:961-8). We sought to confirm or refute these findings leveraging comparable data from the ASsessment, Serial Evaluation, and Subsequent Sequelae of Acute Kidney Injury (ASSESS-AKI) study in which participants also underwent yearly study protocol driven measurements of eGFRcr (CKD-EPI 2021), eGFRcys (CKD-EPI 2012), urine protein-Cr ratio (uPCR) and had capture of interim AKI episodes by inpatient SCr values.

Methods: Hospitalized AKI was defined as ≥50% difference in nadir to peak inpatient SCr. Linear mixed-effects regression models were used to examine whether AKI was associated with abrupt loss of eGFR (i.e. incomplete recovery) or steeper eGFR slope after AKI.

Results: We analyzed all 1603 enrolled ASSESS-AKI study participants (37.6% female, 12.5% non-Hispanic Black). At baseline, mean age was 65 (SD±13) years, eGFRcr 72 (±26) mL/min/1.73 m², eGFRcys 56 (±27) mL/min/1.73 m² and median uPCR 0.13 g/g [IQR0.08 to 0.25]. 41% had diabetes mellitus, and 21% had a history of heart failure. During median follow-up of 4.6 years, 698 AKI episodes (83.1% stage 1 in severity) were observed among 407 participants. In the fully adjusted model, AKI was independently associated with a -2.22 mL/min/1.73m² abrupt loss of eGFRcr but not with steeper subsequent eGFRcr slope. Similar results were seen with eGFRcys (Table).

Conclusions: Contrary to what was observed in CRIC, among ASSESS-AKI study participants, an AKI event was associated with a loss of kidney function (i.e. incomplete recovery), even after accounting for pre-AKI proteinuria and pre-AKI eGFR slope. However, the slope of eGFR decline did not worsen after AKI.

TH-PO073

Preoperative Ionized Calcium Levels and Risk of AKI after Cardiac Surgery

Sung Jin Moon,[1] Lee Ji-Ho,[1] Jin Hyeog Lee,[1] Jae Hyun Chang,[2] Jung Tak Park,[3] Hee Byung Koh.[1] International St. Mary's Hospital, Catholic Kwandong University, Incheon, Republic of Korea. *[1]Catholic Kwandong University International Saint Mary's Hospital, Incheon, Republic of Korea; [2]Gachon University Gil Medical Center, Incheon, Republic of Korea; [3]Yonsei University Institute of Kidney Disease, Seodaemun-gu, Seoul, Republic of Korea.*

Background: Despite its close correlation with cardiovascular diseases, the association between serum calcium levels and postoperative AKI is not fully elucidated.

Methods: Patients aged ≥18 years who underwent cardiac surgery at two tertiary hospitals between 2006 and 2020 were retrospectively evaluated. Their preoperative serum ionized calcium levels were categorized into quartiles. The primary outcome was postoperative AKI within 48 hours, classified in accordance with the KDIGO criteria. AKI was further categorized into mild AKI (stage 1) and moderate-to-severe AKI (stage 2-3).

Results: Of the 9,779 patients (mean age, 64.0 years; male, 60.1%), postoperative mild AKI and moderate-to-severe AKI were noted in 3,848 (39.3%) and 719 (7.4%) patients, respectively. AKI were more prevalent in patients with lower ionized calcium levels (mild AKI: 46.9%, 38.7%, 35.1%, and 36.8%; moderate-to-severe AKI: 11.6%, 7.1%, 5.4%, and 5.3% from Q1-4, respectively, both P-trend <0.001). In logistic regression analysis, compared with Q4, the adjusted odds ratios (aORs) [95% CI] for mild AKI were 1.57 [1.38-1.79], 1.16 [1.02-1.32], and 0.99 [0.87-1,13] for Q1-3, respectively (P-trend <0.001). Similar results were observed in analysis for the moderate-to-severe AKI (aOR of Q1-3; 2.11 [1.66-2.68], 1.35 [1.05-1.73], and 1.04 [0.80-1.36] compared with Q4; P-trend <0.001). In mediation analysis, cardiopulmonary bypass time and intra-operative inotropic use explained 12.1-16.9% and 12.9-19.5% of the association between calcium levels and AKI, respectively (all of P <0.001).

Conclusions: Lower serum ionized calcium levels were associated with a higher incidence of AKI in patients undergoing cardiac surgery. Hemodynamic factors may have influenced this association, and further studies are needed to investigate the underlying mechanism.

Association between preoperative ionized calcium levels quartiles and clinical outcomes

TH-PO074

Characterising the Natural History of Kidney Recovery after AKI in a Prospective Cohort: Does Timing Matter?

Rebecca A. Noble,[1,2] Nicholas M. Selby.[1,2] Centre for Kidney Research and Innovation. *[1]University Hospitals of Derby and Burton NHS Foundation Trust, Derby, United Kingdom; [2]University of Nottingham, Nottingham, United Kingdom.*

Background: Acute kidney injury (AKI) is associated with an increased risk of chronic kidney disease (CKD). It is known that failure of recovery of serum creatinine by 90 days after AKI strongly associates with subsequent CKD, but detailed prospective descriptions of the 'renal recovery phase' between AKI and day 90 are lacking. Here we describe outcomes at serial timepoints for a prospective cohort of hospitalised inpatients with AKI in Derby, England.

Methods: Single centre, prospective cohort study of participants will all stages of AKI. Participants characterised in detail, including AKI aetiology, co-morbidities and frailty. Baseline blood and urine samples were obtained at the time of consent, day 30, 60 and 90 with clinical measurements, blood and urine sample collection. Outcomes of interest: (1) of serum creatinine to within 1.15x baseline, (2) Major Adverse kidney Events (MAKE) a composite of death, renal replacement therapy and persistent renal dysfunction, defined as a 25% or greater drop GFR.

Results: 122 participants were recruited. Most patients had more severe AKI (58% stage 3, 23% stage 2, 19% stage 1). M:F (70:52), median age 67.5yrs. Leading cause of AKI was dehydration (n=52, 42.6%). 18.9% (n=23) of participants required renal replacement therapy. Rates of non-recovery were high. Recovery of renal function (creatinine <1.15xbaseline) was seen in 45% at day 30 (n=49), 50% at day 60 (n=51) and 44% at day 90 (44%). Similar outcomes were observed using MAKE, MAKE30 n =40 (39.6%), MAKE60 n=41 (43.2%), MAKE90 n=41 (46%). There was no statistically significant difference between the baseline characteristics in the group who did and not recover, including diabetes, 38% vs 50% p=0.47 and duration of AKI, (13 days vs 5 days, p=0.21).

Conclusions: In this cohort of patients with predominantly severe AKI, rates of non-recovery of renal function were high. The lack of difference between the baseline characteristics of the recovered and non-recovered group highlights the difficulty in predicting which patients are going to recover and who will not. Whilst there is some dynamic change over time, most changes are observed by day 30, suggesting the key time for renal repair may be the first 30 days. This is important when considering the timing of future interventional strategies, suggesting that interventions need to be implemented prior to 30 days.

TH-PO075

Association of Z-codes and Mortality in Patients with AKI and Heart Failure

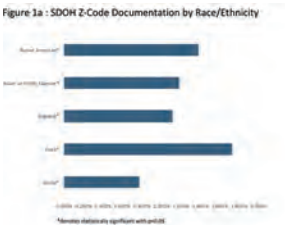
Samuel Tan, Wenchy Tan, Lili Chan. *Icahn School of Medicine at Mount Sinai, New York, NY.*

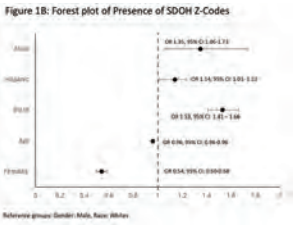
Background: Acute kidney injury (AKI) is a serious complication in patients admitted for acute decompensated heart failure (ADHF). Z-codes are part of the ICD-10-CM coding system codes for social determinants health (SDOH). There is a lack of data regarding the association of coding for SDOH on outcomes in patients admitted for ADHF.

Methods: This was a retrospective study using the National Inpatient Sample to identify patients admitted for ADHF and diagnosed with AKI from 2016 to 2020. Patients who had ESKD were excluded. The primary outcome was in-hospital all-cause mortality. Patients with Z-codes were compared to propensity matched patients without Z-codes. To determine if having Z-codes modifies the odds of requiring dialysis by race, we included an interaction term of Race x having any Z-code.

Results: There were 481,298 patients admitted for ADHF and diagnosed with AKI during their hospital stay. 4,650 patients with Z-codes were propensity matched with 4,650 patients without Z- codes. Compared to the control group, those who had Z-codes are associated with signficantly lower odds of mortality (OR: 0.96 CI:0.96 -0.97). Females (OR 0.54; CI: 0.50- 0.578) and older (OR 0.96; CI: 0.96 - 0.96) individuals were significantly less likely to have any Z-codes. Compared to Whites, Black (OR 1.53; CI: 1.41 - 1.66), Hispanic (OR 1.14; CI:1.01 - 1.23) and Asian (OR 1.35 ; CI: 1.06-1.73) patients were significantly more likely to have Z-codes. Z-Code is associated with a significantly decrease odds of dialysis (OR: 0.52; CI: 0.36 – 0.76). Compared to Whites those who are Hispanic (OR:1.21; CI: 1.11- 1.31) and Asians (OR 1.32; CI:1.15 - 1.51) are significantly more likely to end up on dialysis during their hospital stay. However, there is no significant association for odds of requiring dialysis when comparing Whites with Z-Codes and Blacks (p=0.72) and Hispanics (p=0.61) with Z-Codes.

Conclusions: We found that in matched cohorts, the presence of a Z-code lead to lower odds of mortality. Black, Hispanic, and Asian individuals were significantly more likely to have Z-codes than White individuals. These results maybe due to provider recognition and documentation of unmet SDOH, noting the importance of unmet SDOH.





TH-PO076

Urine Proteomic Signatures of Kidney Function Decline after Hospitalization

Yumeng Wen,[1,2] Steven Menez,[2] Heather Thiessen Philbrook,[2] Dennis G. Moledina,[3] Pavan K. Bhatraju,[4] Steven G. Coca,[5] Vernon M. Chinchilli,[6] Alan S. Go,[7] Edward D. Siew,[8] Paul L. Kimmel,[10] Talat Alp Ikizler,[8] Chi-yuan Hsu,[9] Jonathan Himmelfarb,[4] Lloyd G. Cantley,[3] Chirag R. Parikh.[2] Kidney Precision Medicine Project (KPMP). *[1]Genentech Inc, South San Francisco, CA; [2]Johns Hopkins Medicine, Baltimore, MD; [3]Yale University School of Medicine, New Haven, CT; [4]University of Washington School of Medicine, Seattle, WA; [5]Icahn School of Medicine at Mount Sinai, New York, NY; [6]Penn State College of Medicine, Hershey, PA; [7]Kaiser Permanente, Oakland, CA; [8]Vanderbilt University School of Medicine, Nashville, TN; [9]University of California San Francisco School of Medicine, San Francisco, CA; [10]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.*

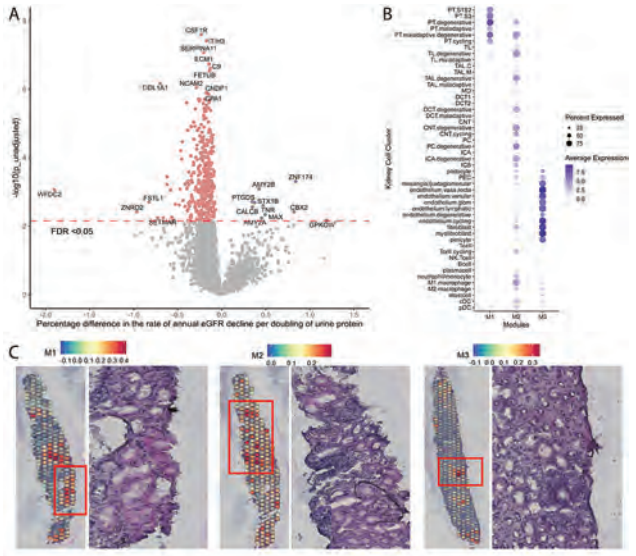
Background: Urine proteomics may identify proteins specifically excreted by the kidney that provide mechanistic insights into future adverse kidney outcomes.

Methods: In 174 patients (48% with acute kidney injury [AKI]) from the Assessment, Serial Evaluation, and Subsequent Sequelae in AKI (ASSESS-AKI) cohort, we used Olink to profile 2783 urine proteins in samples from 3 months after index hospitalization. We used linear mixed-effects models to identify proteins associated with estimated glomerular filtration rate (eGFR) decline after 4.8 years (median) follow-up. We used weighted correlation network analysis to determine proteins' cellular enrichment in the kidney transcriptome (single-cell/nucleus RNA sequencing, spatial transcriptomics) in 20 patients with diverse causes of AKI who received research kidney biopsy from the Kidney Precision Medicine Project.

Results: The ASSESS-AKI patients had median (IQR) age of 67 (59-75) years and median (IQR) eGFR of 65 (41-85) ml/min/1.73m^2 at 3 months post-discharge. We identified 387 and 10 proteins associated with faster and slower eGFR decline, respectively (**Fig. 1A**), including 283 expressed by kidney cells and 114 not expressed. The expression formed 3 clusters enriched in the proximal tubule (Module 1 [M1], **Fig.1B**), degenerative tubule and myeloid cells (M2), and stromal cells (M3), and correlated with histopathological features of AKI, such as tubular injury, interstitial inflammation, and fibrosis (**Fig.1C**).

Conclusions: By integrating the urine proteome and kidney transcriptome, we identified degenerative tubular injury, inflammation, and fibrosis as pathways associated with eGFR decline in recently hospitalized patients.

Funding: NIDDK Support



A. Proteins associated with annual eGFR decline in participants with and without AKI in the ASSESS-AKI cohort; **B.** Proteins associated with eGFR decline in ASSESS-AKI participants have genes forming 3 expression clusters in the kidney transcriptome (single-cell and single-nucleus RNA sequencing) in 20 participants with AKI receiving research biopsies in the KPMP cohort; **C.** Expression clusters of proteins associated with eGFR decline further correlated with histopathological features of AKI, including proximal tubule injury (left), inflammation (middle), and fibrosis (right) in spatial transcriptomics from participants with AKI receiving research biopsies in KPMP.

TH-PO077

Impaired De Novo NAD+ Biosynthesis Is a Feature of Pediatric AKI

Kyle Q. Vu,[1] Amanda J. Clark,[1,2] Marie Christelle Saade,[1] Anders H. Berg,[3] Samir M. Parikh.[1] *[1]The University of Texas Southwestern Medical Center, Dallas, TX; [2]Children's Medical Center Dallas, Dallas, TX; [3]Cedars-Sinai Medical Center, Los Angeles, CA.*

Background: Impaired cellular energy metabolism is a known feature of acute kidney injury (AKI). NAD+ is a critical cofactor required for ATP synthesis. Suppression of NAD+ biosynthesis, most notably the de novo pathway commencing from tryptophan, is a well-described feature of AKI and critical illness in animal models and humans. Reduction in flux through de novo NAD+ biosynthesis can be tracked non-invasively with urinary accumulation of the bottleneck metabolite quinolinate relative to tryptophan. Significantly, impaired NAD+ biosynthesis represents a therapeutic target in AKI as replacement of NAD+ via nutritional precursors of alternate NAD+ biosynthesis pathways can mitigate AKI severity in animals and early clinical trials in humans. To date, all studies evaluating de novo NAD+ biosynthesis impairment in clinical AKI have been performed in adult patients.

Methods: Discarded pediatric urine samples were collected from the laboratory of a tertiary care children's hospital and sorted into groups: AKI, ICU, control (Con), based on patient status at the time of collection obtained from the medical record. Control urines were obtained from otherwise healthy children undergoing screening evaluations. NAD+ related metabolites were measured using liquid chromatography mass spectrometry.

Results: Urines from 26 children with AKI, 44 patients in the ICU, and 40 control patients were collected. Patients with AKI and/or critical illness exhibited accumulation of de novo NAD+ biosynthesis metabolites in the urine, including elevated quinolinate:tryptophan ratio (Con 0.971, AKI 15.1, ICU 5.69, p <0.001). In critically ill children, urine quinolinate:tryptophan ratio was elevated in patients with and without AKI (6.45 and 5.30 respectively, p <0.001 and 0.037 compared to Con).

Conclusions: To our knowledge, these data provide the first demonstration that impaired de novo NAD+ biosynthesis may be a feature of pediatric AKI and pediatric critical illness, as described in adults. Therefore, children may benefit from clinical trials targeting NAD+ replacement to mitigate AKI and severity of critical illness

Urinary Apoptosis Inhibitor of Macrophage Reflects the Severity of Tubular Damage in Patients with ANCA-Associated Vasculitis

Shunsuke Takahashi,[1] Yoshinori Takei,[3] Kaori Takayanagi,[1] Keiju Hiromura,[2] Hajime Hasegawa,[1] Akito Maeshima.[1] *[1]Department of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan; [2]Department of Nephrology and Rheumatology, Gunma University Graduate School of Medicine, Maebashi, Japan; [3]Department of Nephrology, Fukaya Red Cross Hospital, Fukaya, Japan.*

Background: Apoptosis inhibitor of macrophage (AIM) produced by tissue macrophages has been implicated in a variety of pathological conditions, including acute kidney injury (AKI). AIM protects renal cells from apoptosis, modulating inflammation, and promotes tissue repair. AIM helps in maintaining kidney function by preventing excessive cell death and supporting the regeneration of damaged renal tissue in AKI. However, the role of AIM in ANCA-associated vasculitis (AAV) remains unknown. In the present study, we investigated whether AIM can be detected in the urine and kidneys of patients with AAV to evaluate the potential of urinary AIM as a marker for AAV.

Methods: AAV patients (n=34) who were treated in our departments (December 2011 to December 2022) and healthy adults (n=16) were enrolled in this study. Serum and urinary AIM were measured by ELISA. The correlation of urinary AIM with renal function, urinary protein level, clinical parameters and various AKI biomarkers were analyzed. Localization of AIM in the kidney of AAV patients was examined by immunostaining using the renal biopsy specimens. This study was approved by the Ethics Committee on Human Research of our institutions (Approval number 855, 2487). Written informed consent was obtained from all patients.

Results: Compared to healthy subjects, urinary AIM was significantly increased in AAV (0.00 ± 0.0 vs. 19.2 ± 3.6 μg/gCr, p<0.01). Urinary AIM levels significantly decreased following immunosuppressive therapy. We found a significant correlation between urinary AIM and serum creatinine, urinary protein, urinary NAG, urinary β2-microglobulin, MPO-ANCA, and C-reactive protein. However, no significant correlation was observed between urinary AIM and either urinary kidney injury molecule-1 or serum AIM. AIM was absent in normal kidney but was detected in renal tubules of the kidney of AAV patients. AIM-producing cells were positive for aquaporin-1, but was negative for uromodulin, and aquaporin-2.

Conclusions: Urinary AIM, which was produced by proximal tubules, might be useful as a marker reflecting the severity of tubular damages in patients with AAV.

TH-PO079

Infectious Complications in Critically Ill Children and Young Adults Receiving Continuous Kidney Replacement Therapy

Shina Menon,[1] Sai Prasad N. Iyer,[2] H. David Humes,[3] Stuart Goldstein,[4] Mihaela Damian,[1] Andrea Cappoli,[8] Catherine Joseph,[9] Danielle E. Soranno,[5] Michelle C. Starr,[5] Ashita J. Tolwani,[6] Kevin K. Chung,[2] Theresa A. Mottes,[7] Huaiyu Zang,[4] Nicholas J. Ollberding,[4] Katja M. Gist.[4] Worldwide Exploration of Renal Replacement Outcomes Collaborative in Kidney Disease. *[1]Stanford University School of Medicine, Stanford, CA; [2]Seastar Med, Denver, CO; [3]University of Michigan Health System, Ann Arbor, MI; [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [5]Indiana University School of Medicine, Indianapolis, IN; [6]University of Alabama at Birmingham School of Medicine, Birmingham, AL; [7]Ann & Robert H Lurie Children's Hospital of Chicago, Chicago, IL; [8]Ospedale Pediatrico Bambino Gesu, Roma, Italy; [9]Texas Children's Hospital, Houston, TX.*

Background: AKI is known to be associated with subsequent infection. The Regional Citrate *vs* Systemic Heparin for continuous renal replacement therapy (CRRT) (RICH) study reported higher infection rate in adults treated with regional citrate anticoagulation (RCA) *vs* heparin (HA). We aimed to determine if RCA was associated with development of infectious complications (positive blood, urine or respiratory culture) in children & young adults after CRRT start.

Methods: We performed 2 secondary analyses using data from Worldwide Exploration of Renal Replacement Outcomes Collaborative in Kidney Disease. We excluded patients who died ≤ 72 hours of CRRT start, had minor trauma or were post-surgical (n=169) for the first. Additional second analysis exclusions (n=709) were sepsis before CRRT, chronic immunosuppression (organ transplant/immune deficiency). Primary outcome was culture positive infection (blood, urine, respiratory) after CRRT start. Primary predictor was anticoagulation (RCA vs. other).

Results: In the first analysis (n=874) patients, post-CRRT start infection rates were higher for RCA (29%) compared to HA (23%) and others (15%) (p=0.008). Multivariable analysis showed no association between RCA and infection rates (Figure 1A). Second analysis (n=283) patients confirmed no association between RCA and infections in univariable (HA: 94 [33%], RCA: 155 [55%], other: 34 [12%]) or multivariable analyses (Figure 1B).

Conclusions: In this multinational cohort, anticoagulant type was not associated with an increased risk for infection after CRRT start. This is in contrast to the RICH study. Future work will determine if infection after CRRT start worsens outcomes.

Funding: Commercial Support - Seastar Medical

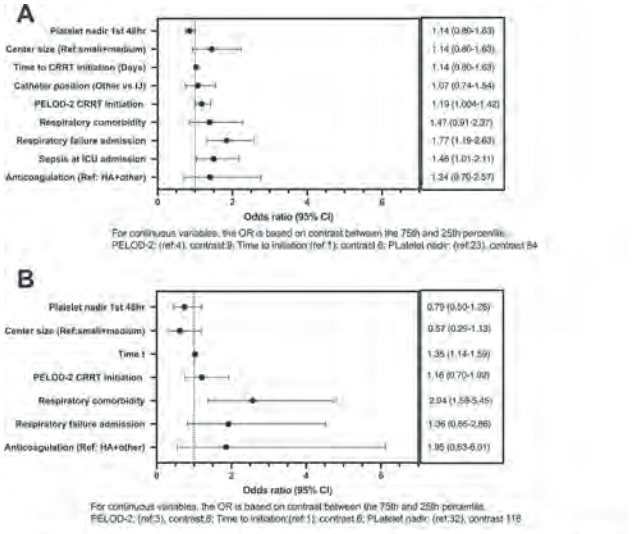

Figure 1. Forest plot demonstrating the associations with infection after CRRT initiation among the entire cohort (A) and restricted to those without immune suppression or sepsis/infection before CRRT initiation (B).

TH-PO080

Association between Hemoglobin Levels and Kidney Recovery after AKI Requiring Continuous Kidney Replacement Therapy

Jae Yoon Park,[1] Hyun Lee Ko,[2] Jiyun Jung,[1] Sung Woo Lee,[2] Yong Chul Kim,[3] Jeong-Hoon Lim,[4] Jin hyuk Paek,[5] Woo Yeong Park,[5] Kipyo Kim,[7] Jeongin Song,[1] Jangwook Lee,[1] Sung Joon Shin,[1] Etienne Macedo.[6] *[1]Dongguk University Medical Center, Goyang, Gyeonggi, Republic of Korea; [2]Eulji University Uijeongbu Eulji Medical Center, Uijeongbu, Gyeonggi-do, Republic of Korea; [3]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [4]Kyungpook National University Chilgok Hospital, Buk, Daegu, Republic of Korea; [5]Keimyung University Dongsan Medical Center, Daegu, Republic of Korea; [6]University of California San Diego, La Jolla, CA; [7]Inha University, Incheon, Republic of Korea.*

Background: Anemia is a prevalent complication in patients with acute kidney injury (AKI) who require continuous kidney replacement therapy (CKRT), and it significantly contributes to the increased mortality and morbidity rates seen in these patients. Despite its significant clinical implications, there is limited evidence on the specific serum hemoglobin (Hb) thresholds that may impede, delay, or alter the course of kidney recovery in these patients.

Methods: We conducted a retrospective analysis of 2,856 patients with AKI who underwent CKRT across four university hospitals from 2006 and 2021. Hb levels were systematically recorded during CKRT, and the mean Hb level during treatment was designated as the primary exposure variable. To assess the impact of average Hb levels on the likelihood of dialysis dependence (DD) at discharge, we calculated the odds ratio (OR) while adjusting for several variables: sex, age, Charlson Comorbidity Index, hypertension history, cause of AKI (sepsis-related or other), systolic and diastolic blood pressure, white blood cell count, serum albumin, serum creatinine, APACHE II score, SOFA score, duration of CKRT, volume of transfusions received, and use of mechanical ventilation.

Results: In our cohort, 61.6% of the patients were male, with an average age of 65.4 years. The average duration of CKRT was 7.7 days, and 65.2% of patients were dialysis-dependent at hospital discharge. A U-shaped correlation between average Hb levels and DD was evident from spline curve analysis. The range between 9.1 and 10.1 g/dL was significant for the lowest risk for DD with ORs below 1.0 and a 95% confidence interval supporting this finding. Furthermore, logistic regression using continuous average Hb levels revealed that each 1 g/dL increase in average Hb was associated with a 6% reduction in the risk of DD. Also, each additional day of Hb within this range decreased the risk of DD by 6%.

Conclusions: This study indicates that average Hb levels between 9.1 and 10.1 g/dL during CKRT were associated with the lowest ORs for DD. These findings underscore the need for further research into the optimal Hb thresholds for transfusion in patients undergoing CKRT, as this may significantly influence kidney recovery outcomes.

TH-PO081

Stress Hyperglycemia and Long-term Outcomes in Patients with AKI Requiring Continuous Kidney Replacement Therapy

Minhyung Kim, Junseok Jeon, Danbee Kang, Seungmin Song, Kyungho Lee, Jung eun Lee, Wooseong Huh, Hye Ryoun Jang. *Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.*

Background: Stress hyperglycemia is hyperglycemia that occurs during various stressful situations in patients without diabetes and is associated with poor outcomes in critically ill patients. We investigated the impact of stress hyperglycemia on outcomes during hospitalization in patients with acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT).

Methods: This retrospective cohort study using the Korean Health Insurance Review and Assessment database included 11,013 adult patients with AKI who received CRRT for ≥ 3 days between 2010 and 2019 and survived until discharge. Patients with pre-existing diabetes were excluded to evaluate stress hyperglycemia. Patients were divided into the two groups: hyperglycemia group and control group. Hyperglycemia was defined as the prescription of oral hypoglycemic agents or insulin treatment ≥ 7 days during hospitalization. Cox proportional model was used to estimate the risk of cardiovascular events, all-cause mortality, new-onset diabetes.

Results: Among the patients who survived and discharged, 2,409 (21.9%) patients have hyperglycemia during hospitalization. While overall incidence of major cardiovascular events was comparable between the groups, the hyperglycemia group had a higher risk of incident acute myocardial infarction (HR = 1.53, 95% CI = 1.11–2.12) and revascularization (HR = 1.41, 95% CI = 1.02–1.94) compared to the control group. There was no difference in mortality between the two groups (HR = 0.92, 95% CI = 0.86–0.99). Among the patients who were alive for ≥ 1 year after discharge (N = 5,944), the hyperglycemia group had a higher risk of new-onset diabetes (HR = 10.10, 95% CI = 6.92–14.73).

Conclusions: In critically ill patients with AKI requiring CRRT, stress hyperglycemia during hospitalization is associated with an increased risk of coronary events and new-onset diabetes after discharge, suggesting aggressive screening and treatment in these patients.

TH-PO082

Association of Age, Frailty, and Strategy for Initiation of Kidney Replacement Therapy: A Post Hoc Analysis of the STARRT-AKI Trial

Amanda Y Wang,[1,2] Ary Serpa Neto,[3] Martin P. Gallagher,[1,4] Ron Wald,[5] Sean M. Bagshaw,[6] Rinaldo Bellomo.[3] The STARRT-AKI Investigators. *[1]The George Institute for Global Health, University of New South Wales, Sydney, NSW, Australia; [2]The Faculty of Medicine and Health Sciences, Macquarie University, Sydney, NSW, Australia; [3]Australian and New Zealand Intensive Care Research Centre (ANZIC-RC), School of Public Health and Preventive Medicine, Melbourne, VIC, Australia; [4]Liverpool Clinical School, UNSW, Liverpool, NSW, Australia; [5]Division of Nephrology, St. Michael's Hospital, University of Toronto, Li Ka Shing Knowledge Institute of St. Michael's Hospital, Toronto, ON, Canada; [6]Department of Critical Care Medicine, Faculty of Medicine and Dentistry, University of Alberta and Alberta Health Services, Edmonton, AB, Canada.*

Background: Acute kidney injury (AKI) is a significant public health issue, and its incidence continues to rise. Older age is associated with a high risk of AKI and mortality, which often poses a clinical dilemma particularly with the implementation of invasive management such as renal-replacement therapy (RRT). The aim of this study is to assess the association of age and frailty with clinical outcomes in patients with severe AKI, according to accelerated and standard RRT initiation strategies in the STARRT-AKI trial.

Methods: This was a secondary analysis of an international randomized trial. Older age was defined as ≥65 years. Frailty was assessed using the clinical frailty scale (CFS) score and defined as a score ≥5. The primary outcome was all-cause mortality at 90 days. Secondary outcomes included RRT dependence and RRT-free days at 90 days. We used logistic and linear regression and interaction testing to explore the impact of age and frailty on clinical outcomes.

Results: Of 2927 patients randomized in the STARRT-AKI trial, 1616 (55.2%) were aged ≥ 65 years (median [IQR] 73.9 [69.4 - 78.9]). Older patients had greater comorbid cardiovascular and chronic kidney disease, were more likely to be surgical admissions and to receive vasopressors at baseline. Older patients had higher 90-day mortality (50.4% vs. 35.6%, adjusted-OR, 1.81 [1.53 to 2.13], p<0.001). There was no significant difference in RRT dependence at 90 days between older and younger patients (8.7% vs. 7.8%, adjusted-OR, 1.21 [0.82 to 1.79], p=0.325). Patients with frailty had higher mortality; but no difference in RRT dependence at 90-days. There was no significant interaction between age and CFS score in relation to mortality, RRT dependence at 90 days, and other secondary outcomes. There was no significant difference in the proportion of patients who received RRT in the standard-strategy stratified by age groups (adjusted-OR, 0.85 [0.67 to 1.08], p=0.180).

Conclusions: In this secondary analysis of the STARRT-AKI trial, older and frail patients had higher mortality at 90 days; however, there was no difference in RRT dependence. Mortality and RRT dependence were not modified by RRT initiation strategy in older or frail patients.

TH-PO083

Incidence of Hypophosphatemia and Clinical Outcomes in Patients Exposed to Kidney Replacement Therapy: A Post Hoc Analysis of the STARRT-AKI Trial

Javier A. Neyra,[1] Ehsan Ghamarian,[3] Sean M. Bagshaw,[2] Ron Wald.[3]
[1]University of Alabama at Birmingham, Birmingham, AL; [2]University of Alberta, Edmonton, AB, Canada; [3]University of Toronto, Toronto, ON, Canada.

Background: Patients receiving renal replacement therapy (RRT) are at increased risk of hypophosphatemia, which can predispose to functional muscle weakness and prolonged respiratory failure. The impact of hypophosphatemia on clinical outcomes in patients receiving RRT has been described in small retrospective studies, yet has not been evaluated in a contemporary, large prospective study. We conducted a secondary analysis of the STARRT-AKI trial to identify clinical parameters associated with incident hypophosphatemia during RRT and to examine the association of hypophosphatemia with clinical outcomes.

Methods: This was a *post hoc* study of the STARRT-AKI trial, a multinational RCT comparing 2 RRT initiation strategies in critically ill adult patients with AKI. Eligibility for this analysis included 1) receipt of RRT, 2) CRRT >24 hours or IHD/SLED >1 session, 3) normal serum phosphate on the day of RRT initiation, and 4) >1 serum phosphate measurement during RRT. A truncated hurdle model was built to determine which baseline characteristics were associated with any hypophosphatemia (<0.7 mmol/L) and severe hypophosphatemia (<0.5 mmol/L). The primary outcome of ventilator-free days (VFD) at 28 days was assessed with an inverse probability weighted zero-inflated negative binomial model and a win-ratio analysis (mortality as first hierarchy). Secondary outcomes of RRT dependence and mortality at 90 days were assessed with logistic regression.

Results: Of 1,940 patients included, hypophosphatemia occurred in 33%. Male sex, higher weight, standard-strategy arm, and higher baseline phosphate were associated with the occurrence of hypophosphatemia during RRT. Duration of hypophosphatemia was associated with lower first-day serum phosphate and the use of CRRT. Patients without severe hypophosphatemia during RRT had more VFD at 28 days (β 1.16 [95% CI 1.06- 1.27], p<0.001. A similar trend of VFD was found among those without any hypophosphatemia during RRT (β 1.06 [95% CI 1.0 - 1.1], p=0.05. These associations were consistent in the win-ratio analysis. There was no association between incident hypophosphatemia and RRT dependence or mortality at 90 days.

Conclusions: Among patients in the STARRT-AKI trial who received RRT, incident hypophosphatemia following RRT initiation was associated with fewer ventilator-free days.

TH-PO084

Kidney and Hepatic Support in Severe Septic Shock from Leptospirosis: A "Case Series" and the Adoption of a New Dialysis Protocol

Paolo Lentini, Giorgio Laudadio, Antonino Previti, Claudia Benedetti.
Nephrology, St Bassiano Hospital, Bassano del Grappa, Italy.

Background: Leptospirosis is a zoonosis caused by a gram-negative bacterium of the Spirochetales family(leptospiraceae) associated with high mortality if not treated in time. The infection is contracted through direct exposure with the urine of carrier animals. Clinical manifestations can range from pauci-symptomatic flu-like pictures, to manifestations with renal tubular damage (25-40%), to extremely severe conditions with potentially fatal multi-organ involvement (10-15%) known as Weil's disease. The aim of this work is to analyze the benefit in applying our treatment protocol in patients with septic shock with AKI and ALF in the ICU, in terms of dose reduction of vasopressors and improvement of blood chemistry parameters

Methods: The patients were all subjected to mechanical ventilation and the circulation supported by inotropes. All had severe AKI (Stage 3) and ALF (MELD Score> 16 or Bilirubin> 20 mg/dL). Patients underwent a combined treatment of CVVH (Amplya Medtronic ©) together with the use of CytoSorb ©. The CVVH was performed with Qb 150 ml/min, with a dialysis dose of at least 40 ml/kg/h (70% in pre-dilution). In four patients citrate was used as anticoagulant in the third patient the treatment was performed with a high pre-dilution (80%). The cartridge was replaced every 24 hours for three consecutive cycles. Antibiotic therapy was adequate considering an estimated removal of 40-50% of the recommended effective dose. Blood samples were taken to determine the rate of reduction of bilirubin, creatinine, WBC and PCR for each session

Results: 11 patients, all male, mean age 57 years, were enrolled following the diagnosis of leptospira-related septic shock. The starting conditions appeared homogeneous (Saps II 78 ± 6, SOFA 15 ± 5, Apache II 34 ± 6) with high total bilirubin values (> 20 mg/dl) and high inflammation indices (WBC, PCR, ESR). In all patients there was a progressive improvement in vital parameters with a reduction in the dose of vasopressors, ventilatory performance and in blood chemistry parameters (Total Bilirubin, RRS = 37.4%). All 11 patients survived after a prolonged stay in the ICU (LOS 31 +/- 3 dd).

Conclusions: Supportive treatment of hepatic and renal function in AKI and ALF performed with CVVH and Cytosorb was be safe and effective.

TH-PO085

A Young Man with an Unusual Pulmonary-Renal Syndrome

Joyita Bharati, Ashish Upadhyay. *Boston Medical Center, Boston, MA.*

Introduction: Pulmonary-renal syndrome commonly denotes an autoimmune disease characterized by pulmonary capillaritis and crescentic glomerulonephritis. Rarely, pulmonary-renal syndrome is from non-immune causes such as infections and heart failure. We report a rare cause of pulmonary-renal syndrome in a young man from Boston.

Case Description: A 27-year-old man from Boston presented with 1 week of fever, headaches, non-productive cough, and 1 day of dyspnea. He vaped nicotine and kratom and swam regularly in freshwater ponds for recreation. There were occasional rats noted at home. Physical examination was only remarkable for respiratory distress with hypoxia without hypotension or hypertension. Chest X-ray showed bilateral reticulonodular opacities. Sulfamethoxazole-trimethoprim and oral prednisone (40 mg twice daily) were started on day 1, considering pneumocystis jiroveci pneumonia. Doxycycline was started as the patient was exposed to pond water and rodents. Serum creatinine was 1.74 mg/dL on presentation and increased to 5.46 mg/dL over 72 hours with preserved urine output. Urine microscopy revealed numerous red and white blood cells without casts. On day 2, he developed one episode of hemoptysis and worsening hypoxia, requiring mechanical ventilation. Bronchoscopy was suggestive of diffuse alveolar hemorrhage (DAH). Intravenous methylprednisolone pulse 1 g daily and daily plasma exchange were then started, considering vasculitis (pulmonary-renal syndrome). ANCA and anti-GBM antibodies returned negative on day 5, and plasma exchange was stopped. Urine for leptospira PCR, sampled on admission, was reported positive on day 10. Microbiological tests were negative. The patient received doxycycline for seven days and cefepime for five days. Fever resolved in the first week of hospitalization. Kidney function, liver function, and platelets normalized within one week. Steroids were tapered and stopped after day 6. The patient was extubated on day 10. The final diagnosis was a leptospirosis-induced pulmonary-renal syndrome with hepatic and hematologic involvement.

Discussion: Leptospirosis is increasingly reported in the United States, especially in urban areas at risk of rodent exposure. It can present with severe kidney involvement and pulmonary hemorrhage with or without icterus. A high index of suspicion is crucial to reach the diagnosis in non-endemic regions.

TH-PO086

An Unfortunate Outing

Douglas R. Farrell, Martin Sedlacek. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: Tickborn illnesses are increasing in prevalence in part because of more ticks surviving milder winters. Here we present a case of AKI secondary to babesiosis induced hemolysis in a self described lifelong city dweller who spent all her life in Manhattan without travelling, except one excursion to the lower Hudson valley for a wedding where she noted an insect bite after a group hike.

Case Description: A 66 year old woman with a history of MGUS and breast cancer treated with lumpectomy, radiotherapy and on hormone therapy presented with fever, nightsweats, weight loss, dyspnea and weakness for three weeks. A month before falling ill she had noted an insect bite after a group hike on a wedding. She was cachectic on exam. The patient had pancytopenia WBC 2.8 Hb 6.5g/dl Plat 124, elevated LDH 1057U/L, acute kidney insufficiency with creatinine 1.44mg/dl and mildly elevated bilirubin 1.3g/dl, ALT 50U/L, AST 72U/L. Albumin was low 2.4g/dL, CK was normal, HIV was negative, a Coombs test was negative, her blood group was A positive, ADAMST13 activity was mildly decreased 63%, C3 low 64mg/dl and haptoglobin was undetectable. No schistocytes or inclusion bodies were seen on a blood smear. The urinalysis showed moderate blood with no RBC, typical for free heme as in hemolysis or rhabdomyolysis. The patient's AKI and mild hyponatemia resolved with IV saline. A diagnosis of babesiosis was made by PCR. There was no coinfection by oher tick borne pathogens. The patient was successfully treated with Atovaquone and azithromycin and all symptoms resolved..

Discussion: The patient had pigment induced AKI from hemolytic anemia secondary to babesiosis. Babesia is a parasitie that utlizes RBC similar to malaria but without a liver phase, a smaller genome and not responding to artemisins. Babesiosis can cause severe illness in the elderly and the immunocompromised as this patient, who is a cancer survivor. As with malaria, certain blood groups reportedly have a protective effect but did not protect our patient (Non-B and Rhesus positive). A diagnosis of babesiosis is unexpected in a self described life long Manhattan resident who does not travel but went on a single outing to the countryside for a wedding. Babesiosis is an emerging global health problem and this patient illustrates how the numer of cases of babesiosis are likely to increase, even in unexpected places.

TH-PO087

Anaplasmosis: A Rare Case of Rhabdomyolysis and Interstitial Nephritis

Jordana Yahr, Sheldon Bastacky, Jyotsana Thakkar. *UPMC, Pittsburgh, PA.*

Introduction: Human Granulocytic Anaplasmosis (HGA) is a tick-borne illness caused by the bacterium *Anaplasma phagocytophilum*. Clinical manifestations of HGA include fever, malaise, but in severe cases can lead to neurologic dysfunction, liver dysfunction, and rarely, renal dysfunction. We present a case of anaplasmosis leading to acute kidney injury (AKI) requiring kidney replacement therapy. Kidney biopsy was suggestive of rhabdomyolysis with acute tubular injury and interstitial nephritis.

Case Description: A 59-year-old man presented to the emergency department with altered mental status. One week prior, he had experienced fevers and malaise. Laboratory data was significant for a platelet count of 23 x10^9/L, mild transaminitis, and rhabdomyolysis (CPK 29,818 IU/L). Serum creatinine was 2.8 mg/dL, baseline unknown, and peaked at 9.8 mg/dL. Urinalysis showed large blood, large protein, 10 red blood cells per high power field, and muddy brown casts on sediment. Spot urine protein/creatinine ratio was 2.37 g/g. Serum polymerase chain reaction was positive for *A. phagocytophilum*. He was treated with doxycycline and his mental status improved. His renal function worsened and hemodialysis was initiated. A kidney biopsy showed interstitial inflammatory infiltrates and focal acute tubular injury with myoglobin positive casts (Figure 1). His renal function improved and hemodialysis was discontinued. He did not require corticosteroid therapy.

Discussion: HGA is a tickborne illness whose incidence is increasing in certain locations. We present a rare case of HGA causing severe AKI requiring dialysis. This case is unique in that the kidney biopsy revealed both rhabdomyolysis with acute tubular injury and interstitial nephritis. AKI from HGA requires prompt diagnosis as antimicrobial therapy can lead to significant improvement in renal function. Nephrologists should consider HGA as a cause of AKI in tick endemic areas.

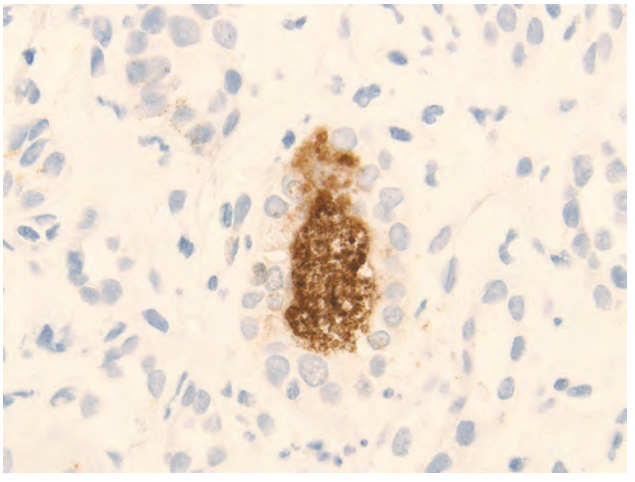

Figure 1: 600x. Myoglobin cast, myoglobin immunoperoxidase stain

TH-PO088

Perinephric Hematoma in Dengue Fever

Phoenix Xu, Melissa Notis, Daniel Stalbow, Priya Deshpande. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: Dengue is a mosquito-borne infection that presents with a wide spectrum of symptoms, including fever, multi-organ failure, dengue hemorrhagic fever, and shock. Acute kidney injury (AKI) is commonly reported with dengue. We are presenting a unique presentation of dengue hemorrhagic fever and AKI.

Case Description: A 24-year-old man with a history of epilepsy, autism, and diabetes, presented with persistent fever with Tmax 104.4 F eleven days after returning from the Dominican Republic. On day 5 of admission, he developed stage III AKI (Cr increased from 0.7mg/dL baseline to 6.5mg/dL). At this time, our differential included acute tubular injury (ATI), glomerulonephritis, and DRESS syndrome. Other labs were significant for thrombocytopenia, elevated AST/ALT, CK 1017U/L, and haptoglobin 340mg/dL. Serologies showed elevated C3/C4 and negative ANA, dsDNA, and ANCA. Urine microscopy showed granular casts. On day 6, he acutely developed significant abdominal pain and CT abdomen/pelvis revealed a 7.6x6.9x8.3 cm left perinephric hematoma (hemoglobin declined from 11.6mg/dL on admission to 9.5mg/dL). Page kidney was suspected when he developed hypertension, and he was started on captopril. However, his kidney function continued to worsen and he ultimately required dialysis for refractory hyperkalemia. Infectious workup showed dengue IgM 10.15 and IgG 6.95. His course was complicated by secondary HLH (ferritin > 16,000; positive soluble IL-2R and CXCL9) and he was given a course of methylprednisolone. On day 13, the patient defervesced and started to show kidney recovery. Dialysis treatments were discontinued and steroids were tapered. Serum Cr was 1.3mg/dL on discharge and 1mg/dL two weeks later.

Discussion: Dengue can trigger AKI through several proposed mechanisms including rhabdomyolysis, immune complex mediated glomerular damage, hemolytic uremic syndrome, cytokine storm, and bleeding diathesis (mucosal, intramuscular, retroperitoneal bleeding have been reported). While the cause of AKI in this patient is likely multifactorial, the perinephric hematoma ("page kidney") is a novel manifestation of dengue hemorrhagic fever. Page kidney results from the external compression of the kidney by subcapsular hematoma and can result in renin-angiotensin system activation, leading to hypertension.

TH-PO089

Legionella-Induced Rhabdomyolysis Unmasks Underlying Metabolic Myopathy

Najiyah Salwa, Tripti Singh. *University of Wisconsin System, Madison, WI.*

Introduction: We present a case of rhabdomyolysis that illustrates the importance of having a broad differential while evaluating the etiology of rhabdomyolysis.

Case Description: 29-year-old male without any past medical history presented to the Emergency Department with headache, diarrhea, muscle weakness and pain for past 4 days. He was taking acetaminophen 1gm daily for myalgias for the past 3 days. Family history revealed sister with sickle cell trait. On examination, Temperature 103°F, HR 140 bpm, BP 140/90 mm Hg, respiratory rate 16/min, O2 saturation 100% on room air. His physical examination was unremarkable, except for significant tenderness on palpation of lower extremities. His laboratory data showed Na 131 mmol/L, K 2.9 mmol/L, AST/ALT: 162/889 U/L, creatine of 1.3mg/dl. Urinalysis showed 3+ blood, RBC 5-10/HPF and Granular cast 30-40/HPF. CK level was elevated to 96000U/L. His chest X-Ray showed right upper lobe consolidation. The nasal swab for COVID and flu were negative, and the urine test was positive for Legionella antigen. He was started on levofloxacin for treatment of legionella pneumonia. His CK levels continued to rise to 600,000U/L. Despite intravenous fluids, he became oliguric and required hemodialysis (HD) on day 4 of hospitalization. His extensive autoimmune and Myositis panel work-up for rhabdomyolysis was negative except for total and free carnitine levels which were elevated to 140 umol/L and 83 umol/L respectively, raising suspicion for Carnitine-palmitoyl transferase 1A deficiency which could present as myopathy triggered by fasting, fever or infection. He was discharged home on day 23 of hospitalization on HD and required HD for additional 5 weeks when he had renal recovery and was taken off dialysis. His kidney function continues to improve with the most recent serum creatine 1.2 mg/dL. He has been referred to a genetic clinic for further evaluation.

Discussion: Myopathies can be dormant, until there is a second hit that can unmask them making individuals susceptible to severe rhabdomyolysis with a common condition such as legionella pneumonia. Hence, broad differential and thorough work up should be sought in the cases where clinical scenario does not explain the findings.

TH-PO090

A 20-Year-Old Woman Presenting with Hemoptysis Most Likely Caused by H1N1 Influenza-Induced Thrombotic Microangiopathy

Aman Pal, Emmanuel A. Aydin-Ghormoz, Swati Mehta, Mj Hajianpour, Krishnakumar D. Hongalgi. *Albany Medical Center, Albany, NY.*

Introduction: Thrombotic Microangiopathy (TMA) is a pathological description which clinically presents with thrombocytopenia, microangiopathic hemolytic anemia, and organ dysfunction. The etiology of TMA is broadly classified into four categories: primary hereditary, primary acquired, secondary and infection associated. H1N1 influenza is a rare etiology of complement mediated TMA (CM-TMA) with there being under 30 cases reported to date, and its presentation with hemoptysis makes it a challenging diagnosis.

Case Description: A Caucasian female in her 20s presented to the hospital with a viral prodrome in setting of a new AKI (creatinine 8.2mg/dL), thrombocytopenia (platelet count 14,000/mm^3), and H1N1 influenza positive. She developed hemoptysis the next day, with no respiratory distress. Serology for antineutrophilic cytoplasmic antibodies, anti-glomerular basement membrane, and antiphospholipid antibodies were negative. CT chest was also negative for pulmonary hemorrhage. Plasma exchange was commenced until ADAMTS13 activity returned normal. The patient was further commenced on eculizumab after an aHUS/TMA/C3G gene panel was sent. She was found to have splice site variant of MCP/CD46, which was reiterated on a renal biopsy. The genetic results were relayed, including predisposition to future events and the importance of long-term eculizumab treatment.

Discussion: CM-TMA is a consequence of alternative pathway dysregulation with genetic mutations being far more prevalent than acquired antibodies. This dysregulation is generally not causative, rather predisposes affected individuals to CM-TMA. A proposed mechanism that can unmask these latent deficits include infections, such as Influenza virus. Its pathophysiology is thought to be related to the production of neuraminidase (NA), which results in platelet aggregation and endothelial injury. Our case highlights the importance of keeping a broad differential beyond classic pulmonary-renal syndromes in patients presenting with hemoptysis and TMA, while understanding the pathophysiology of infections unmasking genetic mutations in CM-TMA.

TH-PO091

Navigating Challenges: A Case of IgA-Dominant Postinfectious Glomerulonephritis

Aashvi R. Dalal, Michael Liben, Ronald D. Villareal. *NewYork-Presbyterian Brooklyn Methodist Hospital, Brooklyn, NY.*

Introduction: IgA-dominant postinfectious glomerulonephritis (IgA-PIGN) a variant of Acute Post Infectious Glomerulonephritis is caused by immune complexes that deposit in the glomeruli with dominance or codominance of IgA with C3. Commonly associated with gram-positive infections, especially in elderly and diabetic population, it manifests as renal dysfunction, hematuria, and proteinuria. Here, we present a case highlighting diagnostic and treatment challenges in IgA-PIGN.

Case Description: A 63-year-old male with congestive heart failure, hypertension, type 2 DM, and CKD stage 4 presented to the hospital for evaluation of fever and purulent left foot ulcer. Recent previous hospitalisation involved left food osteomyelitis complicated by MSSA bacteremia. Lab results revealed leukocytosis (12.85 x 103 /ul), hyperkalemia (6.1mmol/L) and elevated creatinine (7.29 mg/dl with baseline 2-3 mg/dl). Urinalysis showed >100 rbc/hpf, and >300 mg/dl protein with UPCR of 4.4 gm. C3, C4, ANA, ANCA, and hepatitis panel were unremarkable. Renal biopsy confirmed IgA dominant mesangial immune complex disease, post infectious, cellular crescents with severe acute interstitial nephritis (AIN). Granular pattern seen for 1+ IgA and 2+ C3 on immunofluorescence. On Electron Microscopy, increase in mesangial matrix and electron dense deposit was noted. Hemodialysis was initiated due to worsening kidney function. Since infection was the culprit, antibiotics were continued and steroids were initially withheld. However, prednisone was later started due to AIN findings, with reassuring evidence of negative blood cultures and no evidence of endocarditis on echocardiogram. Partial recovery led to discharge on hemodialysis with tapering steroids.

Discussion: Distinguishing IgA-PIGN from IgA nephropathy is crucial as treatments and prognosis differ. While IgA nephropathy warrants immunosuppression, IgA-PIGN relies on antibiotics for underlying infection management. As seen with this patient, challenges arose in initiating steroids due to concurrent AIN. This case highlights the need to consider IgA-dominant PIGN in sepsis patients with worsening renal function, often misdiagnosed as acute tubular necrosis or ischemic injury. Importance of high clinical suspicion in the prompt diagnosis in infection-related AKI is crucial for accurate diagnosis and intervention of IgA-dominant APIGN.

TH-PO092

Disseminated Coinfections of Cytomegalovirus and Herpes Simplex Virus in Lupus Nephritis

Bo Sun Park, Seokjin Hwang, Kewon Baik, Soyoung Lee, Sua Lee. *Eulji University School of Medicine, Daejeon, Republic of Korea.*

Introduction: Cytomegalovirus (CMV) and herpes simplex virus (HSV) are ubiquitous virus in general population, but these viruses are critical pathogen in immunocompromised patients, particularly with HIV. We report a case of disseminated coinfections of CMV and HSV in patient without HIV.

Case Description: A 57-year-old woman visited hospital due to renal dysfunction. She had preeclampsia during first pregnancy about 30 years ago and underwent steroid therapy due to nephrotic syndrome. After that time, renal function has been stable. Laboratory findings revealed MDRD-eGFR 19.0 ml/min/1.73m2, anti-dsDNA titer 88 IU/mL and decreased complement level. In the renal biopsy findings, lupus nephritis Class IV-G was confirmed, and then methylprednisolone and cyclophosphamide were administered. After second cyclophosphamide administration, she had fever and dyspepsia. In gastrointestinal endoscopy findings, multiple patches-like lesions and ulceration with a geographic shape were observed in the antrum with immunohistochemically staining showing CMV. Esophageal ulceration with feature such as molding of nuclear contours, margination of chromatin to the periphery of nuclei was consistent with HSV esophagitis. She suddenly developed a confused mentality, and brain MRI revealed regional patchy high signal on diffusion-weighted images and fluid-attenuated inversion recovery images at the right temporal-occipital white matter. In the CSF analysis, CMV PCR positivity was confirmed. Finally, serum CMV real time-PCR revealed $1.71*10^6$ copies/mL, and HSV type 1 PCR positive finding was observed. Ganciclovir and foscarnet were administered for the disseminated coinfections of CMV and HSV type 1. After administering for 8 weeks, she was successfully recovered. After discharge, SLE activity maintained stable, and she underwent hemodialysis for end-stage kidney disease.

Discussion: It is essential to consider the possibility of multiple opportunistic coinfections in patients suspected of being immunocompromised, even if patients are HIV negative.

TH-PO093

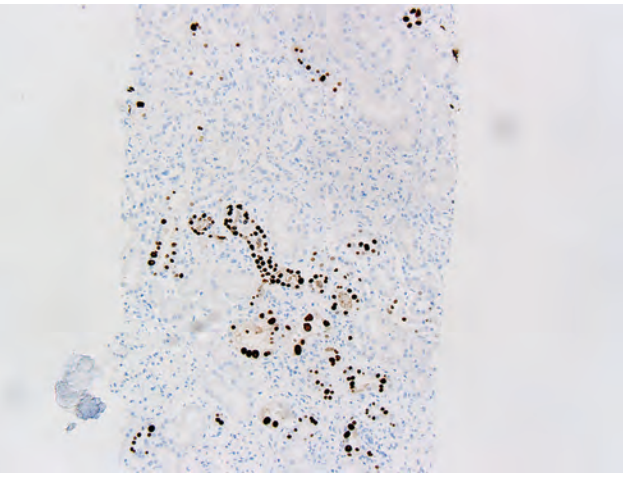
Native BK Virus Nephropathy in a Patient with Multiple Myeloma

Lynley Farmer, Manish K. Saha, Gerald A. Hladik. *The University of North Carolina at Chapel Hill Kidney Center, Chapel Hill, NC.*

Introduction: BK virus nephropathy (BKVN) is a common opportunistic infection in kidney transplant recipients and associated with increased risk of allograft dysfunction and loss; however, it is much less common for BK virus to cause harm in native kidneys.

Case Description: A 73M with PMH of IgG kappa multiple myeloma s/p autologous stem cell transplant (2010) on pomalidomide monotherapy in remission (2014) and bladder cancer s/p TURBT (2022) was admitted for worsening creatinine and hypercalcemia. Eight months prior to admission, the patient's previously normal serum creatinine (0.9 mg/dL) began to slowly rise and was stable around 1.4 mg/dL for the last several months. He established with nephrology outpatient and no etiology was determined for his CKD. On admission, labs showed elevated serum creatinine (2.59 mg/dL) and calcium (11.9 mg/dL). Symptoms only notable for fatigue. Urine sediment microscopy showed ATN. Labs also showed suppressed PTH (8.9 pg/mL) and elevated vitamin D 1,25-dihydroxy (74 pg/mL). The patient's myeloma panel was stable. A kidney biopsy was performed and showed polyoma (BK) virus nephropathy and foci of chronic (active) tubulointerstitial nephritis with eosinophils. Serum BK virus levels showed quantitative blood level of 912,000. After multidisciplinary discussion, IVIG was initiated for BKVN and viremia. The patient's pomalidomide was stopped.

Discussion: There is a growing literature of native kidney BKVN in patients with non-renal transplants, hematopoietic cell transplants, HIV infections, autoimmune disease, and hematologic malignancy. Kidney biopsy is the gold standard in diagnosis. In a recent systematic review, there are only 65 biopsy proven cases reported. BKVN needs to be on the differential diagnosis for immunosuppressed or immunocompromised patients with native kidney dysfunction and there should be a low threshold to perform a kidney biopsy in these patients.



SV40 IHC staining showing infected tubular epithelial cells

AKI as the Initial Presentation of Polycythemia Vera with von Willebrand Disease in a Young Adult

Mayara L. Bechuate,[1] Renan G. Diniz,[1] Luciana G. Lutf,[1] Milena V. Cunha,[1] Felipe L. Ledesma,[2] Gabriel T. Sales,[1] Lucia Andrade.[1] *[1]Nephrology, University of Sao Paulo School of Medicine, São Paulo, Brazil; [2]Pathology, University of Sao Paulo School of Medicine, São Paulo, Brazil.*

Introduction: Polycythemia vera (PV) is a rare myeloid neoplasm that commonly affects individuals over 60 years of age, and 97% of cases are accompanied by a JAK2 mutation. Thrombosis and leukemia are common in PV. Renal manifestations (typically podocyte injury, IgA nephropathy or CKD) are rare, as is thrombotic microangiopathy (TMA). Here, we report a case of acute kidney injury (AKI) secondary to malignant hypertension and TMA, with subsequent diagnoses of PV and acquired von Willebrand disease (VWD).

Case Description: A 22-year-old male presented with altered mental status, nausea, vomiting and severely elevated blood pressure (BP, 220/130 mmHg). Labs showed hemoglobin of 18.4 mg/dL, hematocrit of 55%, 600,000 platelets, serum creatinine (SCr) of 3.74 mg/dL, proteinuria (2.2 g/g), no hematuria and no serum markers of hemolysis. Tests for secondary hypertension were negative. The hypertension resolved after treatment with a titrated intravenous vasodilator and oral antihypertensives. Hematologic investigation revealed a JAK2 V617F mutation, and bone marrow biopsy findings were consistent with PV. The von Willebrand factor (VWF) level was normal, although the VWF activity was very low. A diagnosis of PV with acquired VWD was made. After treatment with hydroxyurea, VWF activity increased and percutaneous renal biopsy showed diffuse mesangiolysis with focal segmental scarring in the glomeruli, moderate interstitial fibrosis and vascular intimal proliferation with narrowing of the lumina and arterial hyalinosis, consistent with reparative changes in TMA. Treatment with hydroxyurea was continued, and the patient remained under outpatient care, with a sustained SCr of 2.6 mg/dL (eGFR 35 ml/min/1.73 m^2) and BP of 123/64 mmHg.

Discussion: To our knowledge, this is the first report of a young patient with PV and VWD in whom the initial presentation was AKI due to malignant hypertension and TMA.

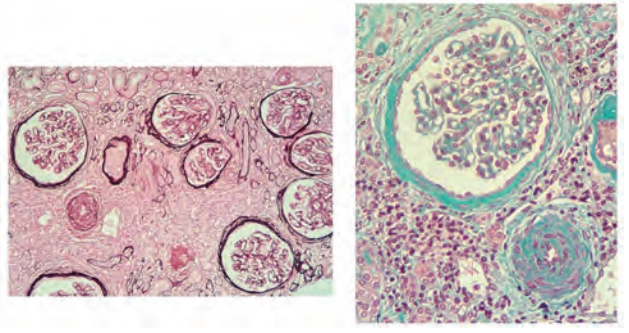

Figure 1: Findings consistent with reparative changes in TMA

TH-PO095

The Lysozyme Kidney

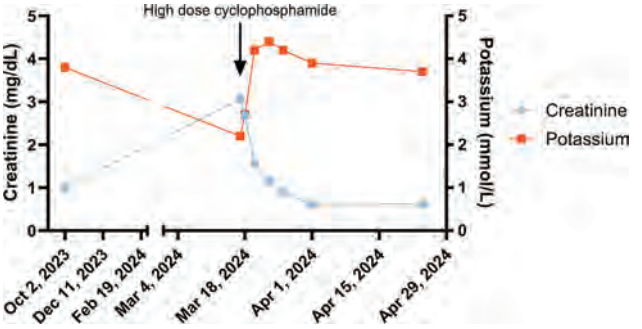
Nazish Khan, Evan Zeitler. *The University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Introduction: Acute kidney injury (AKI) is a common complication of acute leukemias. Common causes include tumor lysis syndrome (TLS), leukemic kidney infiltration and injury due to nephrotoxic chemotherapy. Less recognized is lysozyme-induced nephropathy (LyN). Differentiating between common and less common causes of AKI in acute leukemia is critical for directing therapy.

Case Description: A 37-year-old man with history of schizophrenia, and type 2 diabetes presented with chest pain and dyspnea. Vital signs were significant for tachycardia and hypoxemia and labs demonstrated WBC count of 204, hemoglobin 8.5 and platelets 61. He had severe AKI (creatinine of 3.06 mg/dl from baseline of 1 mg/dl five months prior), hypokalemia, hypophosphatemia and hyperuricemia. He was diagnosed with acute leukemia and nephrology was consulted with concern for TLS. Urine sediment exam revealed granular debris. Kidney ultrasound was negative for kidney enlargement or hydronephrosis. He was admitted to the medical ICU for cytoreductive therapy with cyclophosphamide and hydroxyurea followed by induction chemotherapy with midostaurin. Once his leukocytosis improved, his kidney function steadily improved as well and creatinine was 0.6 mg/dl at discharge. Given his presentation with acute leukemia, hypokalemia, hypophosphatemia without evidence of other kidney injury, a diagnosis of LyN was made.

Discussion: Lysozyme is a small bactericidal enzyme that is freely filtered by the glomerulus. However, in acute leukemia due to the increased production, the reabsorbed enzyme becomes toxic to the proximal tubule, resulting in tubular injury characterized by hypokalemia, hypophosphatemia and often hyperuricemia. While rare, LyN should be considered in patients presenting with acute leukemia and AKI, especially when hypokalemia is present. If identified in time, treatment of primary malignancy results in resolution of kidney injury and may obviate the need for other therapies, including KRT.

	Cairo Bishop Criteria for TLS 3 days prior to or within 7 days of cytoreductive therapy	Patient's labs on presentation
Uric Acid	> 8 mg/dL	15.8 mg/dL
Potassium	>6 meq/L	2.7 mg/dL
Phosphorus	>4.5 mg/dL	1.6 mg/dL
Calcium	<7 mg/dL	8.8 mg/dL



Creatinine trend

TH-PO096

Maximal Change Disease

Andrew Murphy, Matthew Sangoi, Evani Patel, Kwon Soo Kim. *Pennsylvania Hospital, Philadelphia, PA.*

Introduction: Minimal change disease (MCD) accounts for the majority of cases of nephrotic syndrome in children and a minority of cases in adults. We report a case of MCD in a middle-aged patient with severe acute kidney injury (AKI) requiring dialysis who did not respond to steroids but eventually improved with rituximab.

Case Description: A 64 year old male with a history of mantle cell lymphoma (in remission) presented with reduced urinary output. Physical examination was notable for anasarca. Labs showed acute kidney injury (creatinine 4.31 mg/dL, baseline 1), hypoalbuminemia (albumin 2.7 g/dL), and nephrotic range proteinuria (urine protein creatinine ratio 22 mg/mg). His AKI worsened over several days as evidenced by rising creatinine to a peak of 9.1 mg/dL, volume expansion and anuria for which hemodialysis was initiated. A renal biopsy was performed, demonstrating podocytopathy with global foot process effacement, consistent with minimal change disease. A workup for recurrent lymphoma was unrevealing. He was treated with a course of prednisone 60 mg daily followed by a taper. After no improvement in renal function was seen with prednisone, he was considered steroid-refractory, and treatment with rituximab was started. He received two infusions. He remained dialysis dependent at discharge following a two month hospital admission but was subsequently weaned off dialysis with recovery of renal function two months later.

Discussion: AKI in MCD has been reported in approximately 20-30% of adult cases, some of whom may require dialysis. The pathophysiology of AKI in MCD is usually related to acute tubular necrosis. Interestingly, there was no tubular necrosis seen on biopsy for this patient. It was unclear as to whether the history of lymphoma was a contributing factor to this patient's presentation considering there was no evidence of lymphoma recurrence. However, a retrospective review examining MCD in non-Hodgkin lymphoma found that while they most often occur simultaneously, MCD may be diagnosed before or after non-Hodgkin lymphoma. Rituximab is considered to be an effective therapy for adult patients with frequently relapsing MCD, especially for those at risk of developing adverse effects of steroids. The mechanism by which rituximab improves outcomes in MCD is not fully understood, but the depletion of CD20 expressing cells using rituximab in MCD has led to the hypothesis that B cells have a pathogenic role in the condition.

TH-PO097

A Rare Cause of AKI in an Even Rarer Syndrome

Natasha Freeman, Joshua Herbert, Anthony M. Valeri, Dominick Santoriello. *New York-Presbyterian/Columbia University Irving Medical Center, New York, NY.*

Introduction: TEMPI syndrome is a rare condition characterized by Telangiectasias, Erythrocytosis, Monoclonal gammopathy, Perinephric fluid collections, and Intrapulmonary shunting. This case presents an unexpected - but unsurprising - cause of AKI in the setting of newly-diagnosed TEMPI syndrome.

Case Description: A 58-year-old man with a history of hypertension and type 2 diabetes mellitus presented with 4 days of fatigue, weakness, and myalgias. On exam, he was noted to have widespread telangiectasias on his face, mucosal membranes, and abdomen. Labs were notable for a hemoglobin of 18, creatinine of 2.7 (baseline of 1.0), paraprotein gap of 4.8, and microscopic hematuria. Kidney ultrasound noted bilateral echogenic kidneys, as well as trace perinephric fluid adjacent to the right kidney. 24-hour urine protein electrophoresis was significant for monoclonal IgG Lambda and Lambda Bence-Jones proteins. Taken together, these findings were consistent with TEMPI syndrome. A kidney biopsy was performed, which revealed acute tubular injury, interstitial edema with scattered extravasated RBCs, marked congestion of peritubular capillaries, and a probable small venous thrombus. He was therefore started on plasma cell targeted therapy as well as serial sessions of therapeutic phlebotomy, and discharged in stable condition with planned follow-up. Unfortunately, the patient returned 2 weeks later with severe sepsis secondary to pneumonia, and subsequently died.

Discussion: This case describes an AKI in a patient with newly-diagnosed TEMPI syndrome, which is broadly characterized as a plasma cell neoplasm with associated paraneoplastic syndrome. Beyond the simple educational value of exposure to such a rare disorder, an additional lesson can be gleaned from the kidney biopsy findings. Given the profile of TEMPI syndrome, and the UPEP findings of monoclonal and Bence-Jones proteins, the patient's AKI was presumed to be yet another manifestation of his plasma cell disorder, perhaps in the form of a monoclonal gammopathy of renal significance. The biopsy, however, implicated the erythrocytosis and consequent venous congestion and thrombosis as the likely primary cause of AKI. This case serves as an ever-important reminder to overcome one's anchoring bias, as well as to consider not just the apparent manifestations of a disease, but the sequalae and downstream effects of the underlying disease process.

TH-PO098

Steroid-Responsive AKI in a Patient with Hemophagocytic Lymph Histiocytosis (HLH)

Arfa Amjad,[1] Thin Thin Soe,[1] Muhammad Azhar.[2] *[1]SUNY Downstate Health Sciences University, New York City, NY; [2]New York City Health and Hospitals Corporation, New York, NY.*

Introduction: Acute kidney injury (AKI) in patients with hemophagocytic lymphohistiocytosis (HLH) is a frequent presentation that accounts for 30% to 50% of HLH cases. Most of these patients are managed with renal replacement therapy (RRT). We present a case that showed complete recovery of renal function to its baseline with steroid therapy in HLH patients without requiring RRT.

Case Description: 64 y/o, African American Male with a history of hypertension, chronic kidney disease stage 3a who presented with 2 days of dizziness and malaise. He was febrile to 102.9 Fahrenheit and was found to be in multiorgan failure with Acute Kidney Injury, Acute liver injury & cytopenia. Labs revealed serum creatinine of 12.62 mg/dL from a baseline of ~1.28 mg/dL, thrombocytopenia, anemia, hyperferritinemia, elevated ESR & CRP with Soluble CD25: 2321.7, Urinalysis positive for cast cells of > 20. Renal ultrasound was unremarkable. His calculated HScore showed > 95% probability of HLH (hypertriglyceridemia, hyperferritinemia, cytopenia, elevated AST with liver of 14.6 cm). His AKI was likely due to acute tubular necrosis related to HLH. He was started on dexamethasone for the treatment of HLH and was noticed to have a gradual recovery of renal function to its baseline without requiring renal replacement therapy.

Discussion: Hemophagocytic lymphohistiocytosis (HLH) is a rare heterogenous clinical syndrome involving massive activation and proliferation of natural killer cells and cytotoxic T lymphocytes, resulting in cytokine storm and hemophagocytosis. Acute kidney injury in HLH results from ischemic or inflammatory lesions of the renal tubules. The most frequent presentation of renal involvement is acute tubular necrosis; an autopsy series found such lesions in up to 45 % of patients with HLH. AKI typically exhibits poor prognosis in affected HLH patients; a retrospective analysis of 600 patients showed 53.3% mortality in patients with AKI vs 17.5% without AKI. Treatment of HLH usually requires specific treatment of underlying infection or malignancy, chemoimmunotherapy to suppress inflammation, and in some cases hematopoietic stem cell transplantation. Most of these patients with AKI are managed with renal replacement therapy. Our case was interesting since the renal function normalizes with a shorter duration of steroids than what is usually prescribed in these cases.

TH-PO099

An Interesting Case of Atypical Hemolytic Uremia

Jacob Lane. Medical University of South Carolina. *Medical University of South Carolina, Charleston, SC.*

Introduction: Atypical Hemolytic Uremia Syndrome is a rare condition characterized by anemia, thrombocytopenia with evidence of hemolysis and lack of evidence of shiga toxin preset. This disease has serious health considerations such as development of hypertension, renal failure and carries a high mortality. More recently identifiable genetic mutations and newer treatments with monoclonal antibodies working to block the complement mediated pathway have revolutionized the way this disease can be treated.

Case Description: 29 year old white female patient with a past medical history of TTP, obesity, and PCOS presented to an outside hospital (OSH) with abdominal pain, fever/chills and symptoms of upper respiratory infection. She was found to have AKI and concerns for atypical hemolytic uremic syndrome recurrence. She was treated for aHUS several months prior which was thought to have been triggered by influenza infection. She was found to have anasarca, hypertension and developed new onset seizures. MRI following seizure was concerning for PRES (posterior reversible encephalopathy syndrome), she also had spinal tap performed which demonstrated elevated pressures. She was started on CVVHDF given the concerns for increased intracranial pressures. Her blood pressure was controlled and kidney biopsy was performed with findings consistent with thrombotic microangiopathy (TMA). She was started on eculizumab prior to her transfer, this was continued. Here platelets and markers of hemolysis showed signs of improvement. She had genetic studies demonstrating heterozygous CD46/MCP mutation.

Discussion: This patient was found to have a genetic mutation likely responsible for repeated occurance of atypical hemolytic uremia syndrome. She responded well to the infusion of C5 inhibitor, eculizumab. This case was marked by multiple complications including seizures, hypertension, PRES all which complicated patient care. Patient currently continues to be dialysis dependent. She is also being continued on eculizumab as an outpatient.

TH-PO100

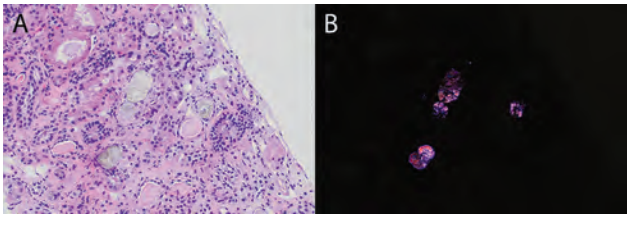
An Unusual Presentation of Oxalate Nephropathy in a Kidney Transplant Patient

Omar A. Ayah, Sarwat Gilani, Susan Wright. *The University of Texas Health Science Center at San Antonio, San Antonio, TX.*

Introduction: Hyperoxaluria results from either inherited disorders of glyoxylate metabolism leading to hepatic oxalate overproduction (primary hyperoxaluria) or increased intestinal oxalate absorption (secondary hyperoxaluria).

Case Description: A 62-year-old male with a history of deceased donor kidney transplant 7 years prior, diabetes mellitus type 2, left foot ulcer presented for acute kidney injury (AKI) evaluation. He had undergone partial ray amputation of his left 4th and 5th digits for osteomyelitis and was started on 500mg erythromycin 4 times daily and doxycycline 100 mg twice daily to complete a 6-week course. He developed diarrhea shortly after erythromycin initiation, having up to 15 bowel movements daily for 30 days. He developed an AKI with peak serum creatinine (Scr) of 3.56mg/dL (baseline 1.1 -1.4), and serum bicarb of 16mmol/L. AKI was attributed to interaction of erythromycin and tacrolimus. Scr failed to improve after discontinuation of erythromycin. Scr was 2.35mg/dL on presentation to our hospital. Renal biopsy revealed AKI and several calcium oxalate crystals, with mild interstitial fibrosis. Urine microscopy was negative for calcium oxalate crystals. He was prescribed calcium carbonate tablets to increase oxalate excretion. Chart review showed oxalate crystals had been reported on urinalysis 2 years after his kidney transplant on routine follow up without further workup. His Scr was 1mg/dL and remained as such until his recent presentation.

Discussion: We suspect our patient has baseline predisposition to hyperoxaluria which was exacerbated by antibiotic use as well as a prolonged course of diarrhea, leading to alteration/ destruction of gut microbiota, including Oxalobacter formigenes, (a bacterium which metabolizes oxalate), leading to hyperoxaluria. Plasma oxalate is excreted by the kidney via glomerular filtration and tubular secretion. Increased production, dehydration and acidosis lead to accumulation and deposition in the tubules, causing AKI and oxalate nephropathy. Oxalate nephropathy should be considered in the differential for AKI



Histologic sections show polarizable intratubular calcium oxalate crystals in renal medulla (A&B. H&E section, 200x).

TH-PO101

Uveitis in Nephrology: A Presentation of a Case of Tubulointerstitial Nephritis with Uveitis (TINU)

Hasan T. Ozpolat, Dory E. Arevalo Salazar, Erika R. Bracamonte, Iyad S. Mansour. *Banner - University Medical Center Tucson, Tucson, AZ.*

Introduction: Tubulointerstitial nephritis with uveitis is a rare oculorenal disease. Patients with TINU usually present with kidney involvement, followed by ocular involvement. Here we presented a case of TINU initially presented with uveitis.

Case Description: A 24-year-old female patient with a red eye, pain, and blurry vision was diagnosed with uveitis/episcleritis a few months ago and was treated with

prednisone and cyclopentolate eye drops with mild improvement in her symptoms. She visited her primary care physician recently for the evaluation of intermittent vomiting that started a few weeks ago with decreased oral intake. Laboratory tests revealed elevated acute phase reactant (ESR> 120 mm/h, CRP; 120 mg/dL), anemia (10.5 g/dl), significant renal failure (BUN: 43 mg/dl, creatinine 6.0 mg/dl), urinalysis was positive for WBCs, urine microscopy showed many hyaline casts, a few granular casts, and a WBC. The urine protein-to-creatinine ratio was 457 mg/day. The antinuclear antibody (ANA), and antineutrophil cytoplasmic antibody (ANCA) results were negative, and the angiotensin-converting enzyme level was within normal levels. Chest CT and echocardiography findings were unremarkable. Renal biopsy findings were consistent with acute interstitial nephritis (AIN), non-caseating granuloma, and significant eosinophilia (Figure 1). In the setting of recent uveitis with AIN, the patient was diagnosed with TINU. Pulse steroid (methyl-prednisone, 250 mg IV) was initiated, followed by a steroid tapering regimen (1 mg/kg PO). The patient was followed up in our outpatient clinic with normal kidney function.

Discussion: TINU should be considered in the differential diagnosis with other oculorenal diseases including Sjogren's syndrome, sarcoidosis, tuberculosis, and Behcet's disease.

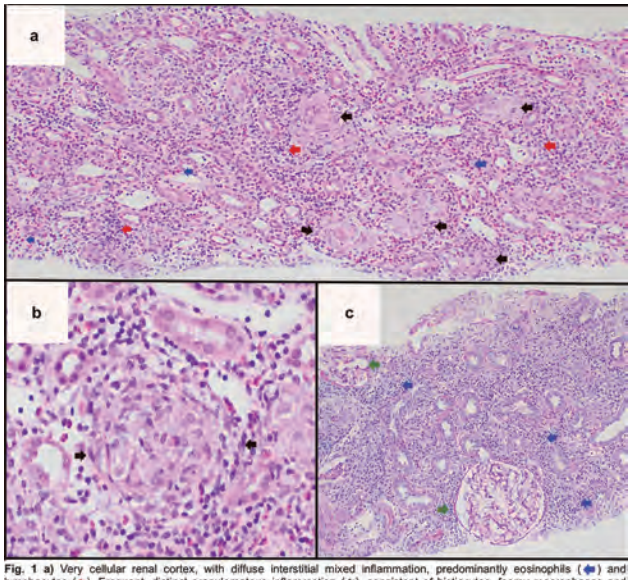


Fig. 1 a) Very cellular renal cortex, with diffuse interstitial mixed inflammation, predominantly eosinophils (⬅) and lymphocytes (⬅). Frequent, distinct granulomatous inflammation (⬅), consistent of histiocytes, foamy macrophages and loose rim of lymphocytes. [H&E x40] b) Close-up of the granulomatous inflammation (⬅), consistent of histiocytes, foamy macrophages and loose rim of lymphocytes. [H&E x400] c) Unremarkable, spare glomeruli (⬅) with a background of diffuse mixed interstitial inflammation, mostly consistent of eosinophils and lymphocytes (⬅). [PAS x40]

TH-PO102

A Unique Presentation of Thrombotic Microangiopathy with Cardiac Tamponade

Eduardo Pino Domenech,[1,2] Andrew A. Moses,[1,2] Jordan L. Rosenstock,[1,2] Maria V. DeVita,[1,2] Tasnin M. Khan,[1,2] Tina Kana.[1,2] *[1]Lenox Hill Hospital, New York, NY; [2]Donald and Barbara Zucker School of Medicine at Hofstra/ Northwell, Hempstead, NY.*

Introduction: We are presenting a unique case of TMA that was complicated by cardiac tamponade.

Case Description: 55-year-old female with hypertension, chronic tooth infection, multiple ED visits over the past month for facial and bilateral leg swelling. Workup revealed creatinine of 2.1mg/dl rising to 3.1mg/dl with 2.9g of proteinuria and hematuria. She denied diarrhea, dysuria, abdominal pain, cough, fever, headache or confusion during the last month. Lab data revealed platelets 156K and hemoglobin 8.6g/dl, with a normal coagulation panel. POCUS performed showing kidney with mildly increased echogenicity and normal size; also pericardial effusion noted. Formal Echo revealed a moderate pericardial effusion with systolic invagination of the right atrium, an evidence of Cardiac Tamponade(CT). Urgent pericardiocentesis was performed, showing hemorrhagic pericardial effusion and hemosiderin laden macrophages suggestive of subacute hemorrhage and delayed cardiac tamponade. Glomerulonephritis and infectious panel were normal, including C3/C4. sCr increased to 4.48mg/dl, platelets and hemoglobin decreased to103K and 7.6g/dl respectively; LDH level was 789 and Haptoglobin<10, with abundant schistocytes in peripheral smear. Kidney biopsy showed thrombotic microangiopathy(TMA). Atypical Hemolytic Uremic Syndrome complement functional panel resulted non-diagnostic, AdamsTS13 activity was normal, and genetic testing is pending. Patient received Eculizumab and started on dialysis. Platelets and Haptoglobin, normalized in one week after Eculizumab therapy, LDH decreased to 582, and continue down trending in further labs.

Discussion: Pericardial effusion is not a common complication of TMA, and only a few cases are reported, mostly in the pediatric literature. Many of these cases are typical Hemolytic Uremic Syndrome with confirmed E. coli O157:H7 infection, or after hematopoietic stem cell transplantation, with only one case reported complicated by CT. This case proves the wide variety of clinical signs/symptoms, laboratory, and radiologic findings that TMA can have. Prompt diagnosis with kidney biopsy is key to confirm the diagnosis. Early initiation of specific therapy correlates with higher chances of better outcomes.

TH-PO103

Renal-Limited Antiphospholipid Syndrome: No-Less-than-Catastrophic

Remy Fadel, Trevor C. Stevens, Edward Gould. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Antiphospholipid syndrome (APS) is clinically defined by recurrent vascular thrombosis or pregnancy morbidity and the presence of at least one antiphospholipid antibody (aPL). On rare occasions renal limited disease can lead to acute kidney injury. We herein describe a case of a 26-year-old female with acute renal failure secondary to APS-mediated complete cortical necrosis, whose diagnostic journey began with an elevated partial thromboplastic time (PTT).

Case Description: A 26-year-old female with no medical history presented with vomiting and diarrhea caused by adenovirus. She had a prior pregnancy with near-full-term delivery. On admission, her creatinine was elevated at 10 mg/dL, and her urine protein/creatinine ratio was 14 g/day. Her PTT was prolonged at 75s and she tested positive for aPL. Other work up, including ANA, was negative. Peripheral blood smear did not reveal schistocytes, and her complement levels and atypical hemolytic uremic syndrome panel were normal. Renal biopsy (Figure 1) showed diffuse cortical necrosis and marked TMA with extensive fibrin thrombi involving all arterioles, arteries, and glomeruli. She required long-term hemodialysis and was initiated on Warfarin with follow up with hematology. Repeat antibody testing at 6 months was negative.

Discussion: This case illustrates that intrarenal TMA can be the initial presentation of primary APS. Morphological abnormalities of TMA alone are not sufficient for a diagnosis and necessitate further investigations. In this patient's case, the biopsy findings, prolonged PTT, and positive aPL favor a diagnosis of APS nephropathy. There have been some case reports of adenovirus associated with transient aPL and thrombosis. However, the clinical significance of this remains unknown. No consensus exists on treating renal limited APS beyond standard anticoagulant therapy for APS. A deeper understanding of the pathogenic mechanisms in APS nephropathy may lead to targeted therapies.

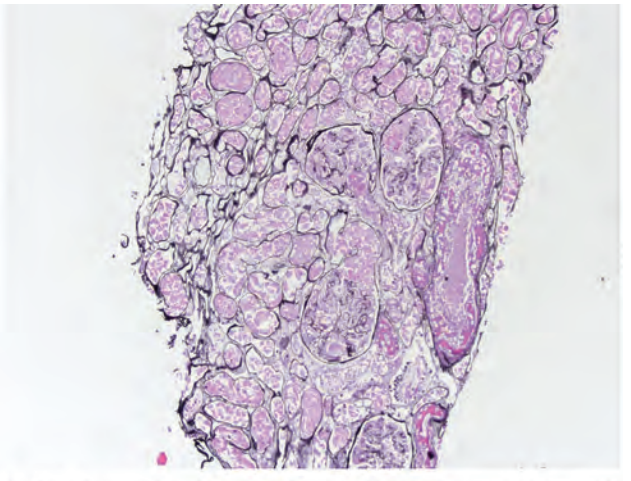

Figure 1: Light microscopy shows diffuse cortical necrosis and tubular injury. Thrombi can be observed in the arterioles and glomeruli.

Recurrent Bilateral Renal Artery Thromboembolism as a Late Complication of Bentall Procedure with Mechanical Aortic Valve

Juan Salvatierra,[1] Rohini Rao,[2] Rafael O. Duchesne.[1] *[1]Hamilton Medical Center, Dalton, GA; [2]Riverview Regional Medical Center, Gadsden, AL.*

Introduction: Thromboembolic events are uncommon in patients who have undergone ascending aorta replacement with an aortic graft and composite (mechanical or bioprosthetic) valve, also known as Bentall procedure. We present a rare case of recurrent bilateral renal infarction from a cardioembolic source, i.e. Bentall procedure with mechanical aortic valve.

Case Description: A 51-year-old man with history of right renal infarct and non-insulin-dependent diabetes presented to the emergency department complaining of left flank pain of 1 hour duration. He was compliant with warfarin. He had undergone

Bentall procedure with mechanical valve for bicuspid aortic valve fifteen years before. Examination revealed blood pressure 143/101 mmHg, a systolic murmur with opening and closing click and left flank tenderness. Laboratory analyses showed leukocytosis, creatinine 2.5 mg/dL (baseline 1.4), INR 1.64, 2+ proteinuria and 1+ hematuria. CT angiography of the abdomen revealed a clot within an anterior branch of the left renal artery and a large infarct. He was started on unfractionated heparin and hydromorphone via PCA pump. Vascular surgery deemed him not a revascularization candidate for being outside an 1-hour window. He was managed expectantly and maintained good urine output with stable creatinine. He was discharged home on a higher warfarin dose with enoxaparin bridging. On three-week follow-up, he felt well and creatinine had improved to 2 mg/dL, INR 2.45 was below goal of 2.5-3.5.

Discussion: Renal infarct should be a differential diagnosis of flank pain in patients with prosthetic heart valves. Our patient's multiple thromboembolic events were secondary to subtherapeutic INR in the setting of Bentall procedure. Revascularization with percutaneous endovascular rather than surgical approach is preferred if feasible. In patients with a mechanical valve, anticoagulation with unfractionated or low molecular weight heparin is recommended.

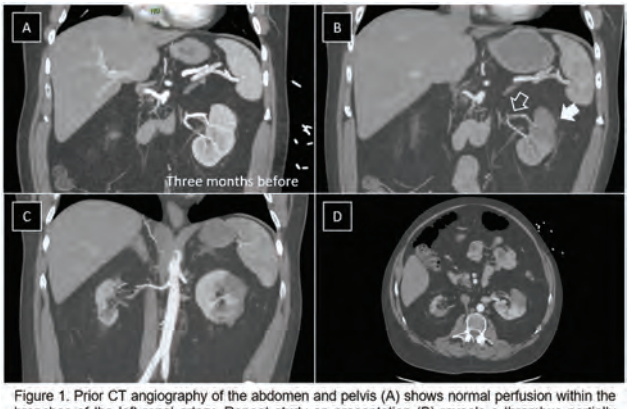

Figure 1. Prior CT angiography of the abdomen and pelvis (A) shows normal perfusion within the branches of the left renal artery. Repeat study on presentation (B) reveals a thrombus partially occluding one of these branches (hollow arrow) and a large infarct within the left kidney (solid arrow). Bilateral chronic renal infarcts with right kidney atrophy are also identified (C and D).

Renal Cortical Necrosis in Pregnancy: A Rare Yet Critical Condition with Varied Pathogenic Mechanisms

Hillary Gan, Nerihan Hadji, Prashant N. Bhenswala, Mahmoud Abdelaziz, Richard L. Barnett, Mala Sachdeva, Purva D. Sharma. *Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY.*

Introduction: Renal cortical necrosis (RCN) is a form of severe AKI characterized by ischemic necrosis of the renal cortex, resulting from severely diminished renal arterial perfusion involving vascular spasm and intravascular thrombosis. RCN is an uncommon entity, with a higher incidence in developing countries. We report two cases of RCN in the postpartum setting, each diagnosed differently, with two different pathogenetic mechanisms

Case Description: Case 1: 40-year-old female who had an uneventful dilation and evacuation (D&E) for fetal anomaly presented with weakness and decreased urination for 1 week. Labs revealed a creatinine (Cr) of 20 mg/dl, BUN of 115 mg/dl, UA revealed 30 mg/dL of protein, 1 RBC/hpf. CT abdomen/pelvis (CTAP) did not reveal obstruction. Patient underwent repeat D&E for retained products. After no improvement in kidney function, she was initiated on hemodialysis (HD). Serologic workup was negative. Renal biopsy revealed severe thrombotic microangiopathy (TMA) involving glomeruli, arterioles and arteries extensively, together with diffuse acute tubular necrosis, suggestive of cortical infarction. Given concern for a complement-mediated process in the setting of profound TMA, she received Eculizumab empirically and was evaluated for atypical hemolytic-uremic syndrome. Functional and genetic complement testing was negative. After 6 weeks, patient remains HD dependent, however with improved urine output. Case 2: 39-year-old female presented for induction of labor and subsequently had a cesarean section complicated by severe postpartum hemorrhage and shock requiring 5 Units PRBCs, 3 Units of FFP due to DIC and coagulopathy. She developed anuric AKI with a Cr of 4.8 mg/dl. CTAP revealed reverse cortical rim sign consistent with RCN. HD was initiated given worsening volume status and electrolyte abnormalities. Patient remains HD dependent.

Discussion: RCN is a rare but devastating cause of obstetrical AKI, often resulting in poor outcomes. The mechanisms can include severe hypoperfusion and vascular endothelial injury. These cases illustrate the different pathogenetic mechanisms of RCN in obstetric AKI and its possible diagnosis by imaging and kidney biopsy. Work up for an underlying cause including complement testing may be indicated in some cases and may affect management.

TH-PO106

Exertional Rhabdomyolysis Requiring Kidney Replacement Therapy in a Man with Sickle Cell Trait

Steven T. Heidt, Roger A. Rodby. *Rush University Medical Center, Chicago, IL.*

Introduction: Sickle cell trait (SCT) is generally asymptomatic. Rarely, patients with SCT develop exertional rhabdomyolysis (ER) after strenuous exercise. ER can lead to compartment syndrome, DIC, and myoglobinuric AKI. We present a case of acute oliguric renal failure requiring renal replacement therapy (RRT) secondary to ER in a patient with previously unknown SCT.

Case Description: After completion of police academy training, a 39 y/o black man developed bilateral leg weakness and muscle spasms. Exercise consisted of push-ups, sit-ups, and a one-mile run. He had no significant PMH, no FH of SS disease or trait, and took no medications. Exam was notable for weakness and diffuse muscle tenderness. Initial laboratory findings included serum creatinine 2.0 mg/dL, lactic acid 8.8 mmol/L, and creatine kinase (CK) 1,516 U/L. Urine was brown (Figure) and urinalysis had 4+ blood with 1 RBC/hpf. Urine drug screen was negative. His CK level peaked at 565,070 U/L and he was started on CVVHD for worsening acidosis. Work-up had normal TFTs and negative autoimmune and glycogen storage disease panels. Hemoglobin electrophoresis showed 35.1% hemoglobin S, consistent with SCT. He remained on RRT for 18 days. He ultimately had full recovery of renal function.

Discussion: SCT may be present in up to 300 million patients worldwide and is typically asymptomatic; ER is a very rare but established condition associated with SCT. We present a patient who completed relatively low-intensity exercise, yet still developed ER requiring RRT. Our patient developed ER because of a mandated training required for policy academy admission. Screening protocols for SCT in those whose careers involve heavy exercise, such as police work or the armed forces, can be seen as discriminatory. We conclude that further study is required in patients with SCT who develop ER to determine if secondary factors impact the risk of ER.

Tea colored urine on day one of hospital admission.

Black Urine after Surgery: Rare Cause of Rhabdomyolysis and Malignant Hyperthermia Syndrome (MHS)

Harshil Fichadiya, Marie C. Hogan. *Mayo Clinic Minnesota, Rochester, MN.*

Introduction: Mutations in RyR1, DHP, SH3 and STAC3 predispose to MHS by increasing cytosolic calcium levels. Most mutations are AD with incomplete penetrance explaining phenotypic differences. RyR1 is a Ca channel located on skeletal muscle sarcoplasmic reticulum, mediates calcium influx for muscle contraction. Activating RyR1mutations cause sustained calcium influx, muscle contraction and hypermetabolism, acidosis, hyperthermia and rhabdomyolysis, following exposure to volatile anesthetics +/- succinylcholine. In addition to MHS, RyR1 mutation has been associated with Central Core Disease, Multi-minicore disease, Centronuclear myopathy, congential fiber-type disproportion and predispose to statin-induced myopathy and exertion induced rhabdomyolysis

Case Description: 49 y/o Caucasian male s/p bony hearing aid placement for congenital mixed hearing loss developed black urine, myalgia and masseter spasm in the immediate postop period after iv succinylcholine 120 mg and propofol anesthesia. He described dark urine post OR in 2015, proximal muscle weakness after exertion, lifelong muscle cramps, + FHx of cramps, previous uncomplicated anasthesia for appendectomy at 18yr. Dipstick urinalysis revealed large hematuria, proteinuria & 3-10 RBC on microscopy, with large myoglobin. Post OR CPK was 14143U/L, peaked at 74320U/L POD1 and improved to 2682U/l on POD 5 with aggressive IVF. Electrolytes and creatinine

remained normal, improving hepatic transaminitis. Whole genome sequencing revealed heterozygous, pathogenic variant in the RYR1, specifically c.1840C>T(p. Arg614Cys)

Discussion: Pathogenic variant in RYR1 are the commonest genetic causes of MHS, wide spectrum neuromuscular disorders and congenital myopathies. MHS is characterized by a severe reaction to specific anesthetic drugs, a result of uncontrolled skeletal muscle hypermetabolism. Symptoms are preceded by specific anesthetics, with or without depolarizing muscle relaxant, like succinylcholine. Affected individuals can have severe muscle rigidity or spasms, cardiac arrhtymias, hyperthemia, rhabdomyolysis. Rarely, at risk patients demonstrate symptoms after intense physical activity. Contracture test with caffeine-halothane with high sensitivity may be used for screening. Genetic testing may not identify all involved genes, avoidance of triggers may be preferred. Treatment includes dantrolene, electrolytes management and aggressive IVF

TH-PO108

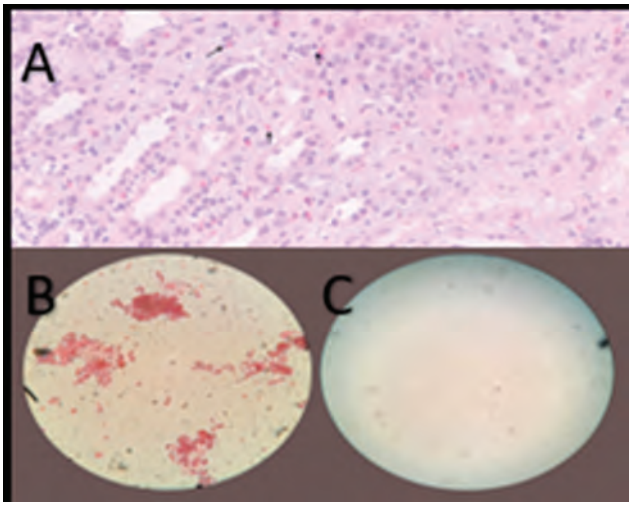
A Unique Case of Benralizumab Treatment for Drug-Induced Acute Interstitial Nephritis

Alexander Saadia, Assaf Potruch, Aviv Talmon. *Hadassah University Medical Center, Jerusalem, Israel.*

Introduction: Acute interstitial nephritis (AIN) is a common cause of acute kidney injury (AKI), which may be induced by infections, systemic and localized autoimmune processes, or most commonly drug-induced. AIN may result in fibrosis and permanent kidney damage. Treatment options for drug induced AIN mainly steroids, although evidence of efficacy is lacking.

Case Description: A 55-year-old male, presented with abdominal pain, vomiting and anuria following excessive alcohol intake. Medical history included hypertension treated with ramipril and amlodipine, and recently, etoricoxib for back pain. Patient developed severe AKI despite fluid resuscitation and cessation of Etrocoxib, and required hemodialysis. Kidney biopsy showed AIN with numerous eosinophil infiltrates (figure 1A). Prominent eosinophiluria was observed in the urianalisis persistently throughout treatment (figure 1B). High-dose steroids intravenously did not improve urine output. Following informed consent Benralizumab (30 mcg SC) was given off label. Kidney function recovered immediately, with polyuria ensuing within hours (<12 hr) of treatment, and coincided with a complete disappearance of eosinophils and leukocytes in the urine at 48 hours after treatment (figure 1C). Patient was weaned off dialysis within a few days while renal function normalized.

Discussion: Benralizumab, a humanized monoclonal antibody targeting interleukin 5 (IL5) α receptor, is used for severe eosinophilic asthma. Benralizumab has been used in different diseases in which pathophysiology mechanism implicates eosinophil-mediated response such as eosinophilic cystitis and eosinophilic esophagitis. This case highlights a future potential use of anti IL5 receptor treatment for AIN which involves rich eosinophilic inflammation of the kidneys. To our knowledge this is the first reported case of Benralizumab treatment for drug induced AIN.



TH-PO109

Fluid Conundrum: Unraveling a Case of Urinothorax

Anvitha Rangan, Mariana Vanoye Tamez, Paulo Henrique Rodrigues Assis, Vignesh Ponnusamy. *Landmark Medical Center, Woonsocket, RI.*

Introduction: Pleural effusion of extra-vascular origin (PEEVO) is an effusion that does not originate from the pleural vasculature. Urinothorax, an infrequent form of PEEVO, is the leakage of urine into the pleural cavity due to obstructive uropathy, iatrogenic, or blunt trauma to the genitourinary (GU) system. We report a case of urinothorax occurring after nephrostomy.

Case Description: A 74-year-old male with prior bilateral (B/L) obstructing renal calculi and ureteral stents presented with oliguria and acute renal failure. A nephrostogram showed severe right hydronephrosis and occluded ureteral stent. The stent was removed, and a nephrostomy tube was placed. Persistent hematuria led to tube exchange and stone removal, which revealed a large blood clot in the renal pelvis. The procedure was complicated by bleeding and limited visualization. Post-operatively, the patient developed transient hemorrhagic shock, managed with blood transfusions. A CT scan revealed right hydronephrosis, blood in the collecting system, and a new large right pleural effusion. A CT-guided chest tube drained 2L of serosanguinous fluid. Analysis showed the fluid was transudative, ruling out a hemothorax. The fluid had elevated creatinine (5) and low pH (7.0). The ratio of pleural fluid to serum creatinine (PF/SCr) >1. A renal angiogram revealed active bleeding from the right interlobar artery, which was later embolised.

Discussion: Urinothorax develops rapidly, presenting with dyspnea and chest pain. Raised intraperitoneal or retroperitoneal pressure leads to the direct flow of urine through diaphragmatic pores or indirectly via the retroperitoneal and pleural lymphatics. Identifying anatomic defects like reno-pleural fistulas and urinomas is crucial to prevent recurrence. Biochemically, urinothorax is a transudative effusion with characteristically low pH (<7.40). The glucose and protein content are low. A PF/SCr >1 is the hallmark of urinothorax, with >90% sensitivity. Renal scintigraphy can detect urine migration into the pleural space if imaging is inconclusive. This patient likely sustained an iatrogenic injury to the renal system and interlobar artery, which led to leakage of urine and blood into the retroperitoneal space, resulting in a urinothorax. This rare but underdiagnosed entity must be an important consideration for new onset pleural effusion following GU procedures or obstructive uropathy.

In Vivo Pharmacokinetic Evaluation of Molnupiravir in Patients with Severe CKD

Qiuling Fan. *Shanghai General Hospital, Shanghai, China.*

Background: This study aims to explore the plasma concentration of Molnupiravir in patients with severe renal insufficiency, providing a basis for rational clinical use of drugs.

Methods: Liquid chromatography-tandem mass spectrometry (LC-MS/MS) was used to detect the plasma concentrations of MPV and NHC. Plasma working calibration standards for MPV and NHC were prepared by diluting 1.0, 5.0, 10.0, 50.0, 100, 500, 1000, and 2500 ng/mL in blank, drug-free plasma. Add 10 μl of internal standard solution to 100 μl of plasma sample. Quality control (QC) samples include high QC (HQC: 2000 ng/mL MPV and NHC), medium QC (MQC: 200 ng/mL MPV and NHC), low QC (LQC: 2.0 ng/mL MPV and NHC), and quantitative Limit (LLOQ: 1.0 ng/mL MPV and NHC). All analytes were extracted by protein precipitation using acetonitrile at a ratio equivalent to 3:1, and QMPV and QNHC were evaluated by calculating the ratio of plasma concentrations.

Results: A total of four patients with stage 4/5 chronic kidney disease were included in the study. The blood samples collected 12 hours after taking the drug showed that the patients' MPV blood drug concentration was at a low level, while NHC and healthy subjects (C12h: Compared with patients with mild to moderate renal insufficiency (16.7 ng/mL) and patients with mild to moderate renal insufficiency (C12h: 31.1 ng/mL), patients with severe renal insufficiency have higher C12h than patients with mild to moderate renal insufficiency (43~1600 ng/mL). Among them, the NHC plasma concentration in patients with stage 5 chronic kidney disease is 1600 ng/mL, which is maintained at a relatively high level.

Conclusions: After patients with severe renal insufficiency were administered 800 mg/12 hours according to the instructions, MPV was rapidly hydrolyzed to NHC in the body and maintained at a low level. The NHC is significantly higher than that of patients with mild to moderate symptoms, especially those with stage 5 chronic kidney disease. The blood drug concentration is equivalent to Cmax, which suggests that when used clinically in patients with uremia, the dosing interval should be adjusted to avoid drug accumulation and occurrence of AEs.

A GFR-Independent Method for Measuring Kidney Tubular Function

Isaac Z. Karel,[1] Amandeep Bajwa,[2] Navjot Pabla.[1] *[1]The Ohio State University, Columbus, OH; [2]The University of Tennessee Health Science Center, Memphis, TN.*

Background: Glomerular filtration rate (GFR) is the main functional index of kidney health and disease. Currently, no methods are available to directly measure tubular mass and function. Here we report a serendipitous finding that the in vitro cell viability dye resazurin, can be used in mice as an exogenous sensor of tubular function.

Methods: Mouse models of renal ischemia reperfusion, cisplatin nephrotoxicity, and rhabdomyolysis were used to assess the utility of resazurin as a sensor of tubular function and injury. Resazurin and its metabolites were measured in the blood and urine by fluorescence and mass spectrometry measurements.

Results: Intravenously injected resazurin exhibited significant plasma protein binding and was found to mainly undergo tubular secretion. Mechanistic studies showed that the blue-colored weakly fluorescent resazurin is taken up by tubular cells through the organic anion transporters, followed by conversion to highly fluorescent pink-colored resorufin by mitochondrial and cytosolic reductases, glucuronidation of resorufin to an orange-colored resorufin β-d-glucuronide, and subsequent efflux into the urine. We report a simple method where the intravenous injection of resazurin is followed by measurement of fluorescent metabolites in the urine provides a sensitive read-out of tubular function. In bilateral ischemia reperfusion, cisplatin nephrotoxicity, and rhabdomyolysis-associated AKI models, the resazurin-based method was able to sensitively detect loss of tubular function much earlier than the increase in serum creatinine levels. Strikingly, in mice with unilateral ischemia reperfusion injury, and genetic mutation-linked kidney hypoplasia, the resazurin-based method was able to detect loss of tubular mass and function despite normal GFR levels.

Conclusions: These findings establish the preclinical utility of resazurin as a rapid and sensitive exogenous marker of tubular function and support future examination in larger animals for potential clinical translation.

An Artificial Intelligence-Based Program Significantly Reduces ESA (Erythropoiesis-Stimulating Agent) Use and Maintains Hemoglobin

Michael E. Brier,[1,2] Adam E. Gaweda.[1] *[1]University of Louisville, Louisville, KY; [2]VA Robley Rex Medical Center, Louisville, KY.*

Background: ESAs have experienced dramatic dose fluctuations prompted by reimbursement challenges, shifting targets, and poorly designed anemia management protocols (AMP). The package insert recommends using the lowest dose to avoid transfusion. Our hypothesis is that SAA is superior to the commonly used expert system approach (AMP).

Methods: SAA is an AI-powered planning and decision support system based on two components: 1) pattern matching to identify individual dose-response profile, and 2) Model Predictive Control to perform look-ahead treatment planning. PEG epoetin beta data were obtained from the USRDS 2023 annual report and from the Dosis database and the University of Louisville dialysis facilities. Collection was approved by the University of Louisville institutional review board. PEG dose in the USRDS was reported as the mean monthly dose for the year. Individual monthly doses were obtained for the treatment groups.

Results: Table shows yearly means for all PEG treatments. 95% CI show that SAA resulted in a dose reduction of between 20 and 41%. A separate analysis of PEG use in the University of Louisville dialysis facilities shows that use of SAA results in immediate changes in dose decreasing when SAA is started and increasing when withdrawn Fac3 never used SAA and had poorest performance. Fac1 and Fac2 used SAA continuously and had best performance Fac4 and Fac5 stopped use and immediately increased consumption by 50 and 43%. Simultaneously Hb fell 6 to 11% following -SAA.

Conclusions: SAA is superior to physician-based AMP. The results of the RCT are confirmed in this analysis. There is a definitive cost benefit without sacrificing quality.

	2016	2017	2018	2019	2020	2021	2022
USRDS PEG	149	151	151	149	143	139	137

TH-PO113

Effect of Continuous Venovenous Hemodialysis (CVVHD) on the Time to Reach Therapeutic Vancomycin Levels

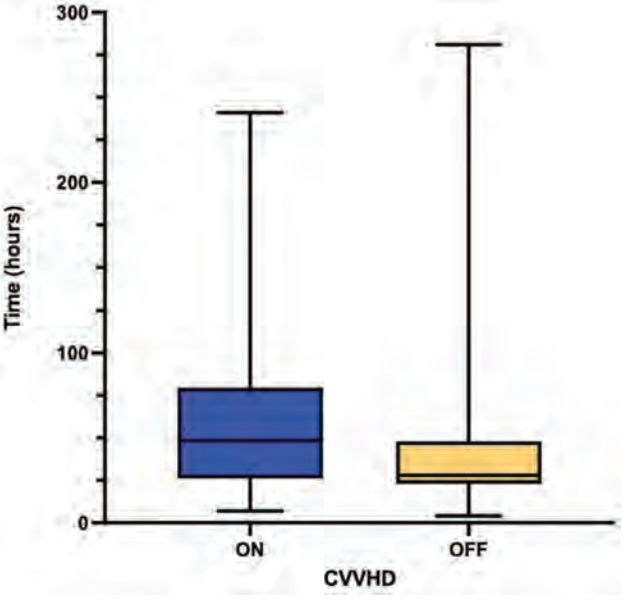
Danica Quickfall, Jay L. Koyner. *University of Chicago Division of the Biological Sciences, Chicago, IL.*

Background: Vancomycin is a commonly used antibiotic in the intensive care unit (ICU). Early attainment of therapeutic vancomycin levels is associated with lower rates of antimicrobial resistance and improved outcomes. Several studies have tried to identify the optimal dosing of vancomycin during the receipt of continuous veno-venous hemodialysis (CVVHD), but few have identified its impact on time to achieving therapeutic vancomycin levels. We sought to determine the impact of CVVHD on time to achievement of a therapeutic vancomycin level.

Methods: A retrospective chart review identified 843 patients admitted to University of Chicago Medicine between May 2016 and April 2020 who received both vancomycin and CVVHD during an ICU admission. Patients were classified based on initiation of vancomycin while on or off CVVHD. The time from initial vancomycin administration to first vancomycin level ≥ 10 mg/L was calculated. Patients were excluded if they received vancomycin within 10 days prior to starting treatment.

Results: Two hundred (23.7%) patients started vancomycin on CVVHD, while 470(55.8%) started outside the CVVHD window. Vancomycin levels were not measured in 173(20.5%) patients. Thirty patients failed to achieve a therapeutic level 17(8.5%) vs 13(2.8%) in the on- and off-CVVHD groups respectively. The median time to reach a therapeutic level was 48.9 h (IQR 26.7-78.9 h) vs 28.5h (IQR 23.4-48.3 h) for individuals on and off CVVHD respectively, see Figure 1 ($p < 0.0001$). Additionally, the incidence of vancomycin levels ≥40 mg/L is higher in patients who are not receiving CRRT (7.5% vs 17.2%, $p = 0.009$).

Conclusions: The time to reach a therapeutic vancomycin level in patients on CVVHD is significantly longer than those who are not receiving CVVHD. Supratherapeutic levels occur more often in patients who are not receiving CVVHD.



TH-PO114

Pharmacokinetics (PK) of Subcutaneous (SC) Furosemide (Furoscix) in CKD: A New Option for Outpatient Diuresis

Christian W. Mende,[1] Katie H. Luepke,[2] Phanisyam Kamineni,[2] Matthew M. Goodwin,[2] John Mohr,[2] Barbara Cornelius.[2] *[1]scPharmaceuticals, Burlington, MA; [2]University of California San Diego, La Jolla, CA.*

Background: Furoscix is approved as a 5-hour SC infusion via an on-body delivery device for treatment of congestion due to fluid overload in chronic HF. In a PK/PD study of HF patients, bioavailability was 99.6% with similar diuresis and natriuresis as IV furosemide. Purpose of analysis was to evaluate furosemide PK/PD in patients with reduced eGFR.

Methods: Furoscix 80 mg was administered SC over 5 hours in biphasic regimen (30 mg in 1st hr, 12.5 mg/hr remaining 4 hrs). IV furosemide was given as two 40 mg bolus doses 2 hours apart. Plasma was collected for furosemide concentrations and urine output (UO) was quantified over 24-hour period. Renal function was estimated using the Modification of Diet in Renal Diseases (MDRD) equation; results were stratified by eGFR. Patients with eGFR <45 mL/min/1.73m^2 were excluded from study.

Results: 15 patients were available for analysis. Despite exclusion criteria, 2 patients were enrolled with eGFR <45 mL/min/1.73 m^2. Median (min-max) eGFR was 60 (41-98) mL/min/1.73 m^2. 7/15 (47%) patients had eGFR 60-89 mL/min/1.73 m^2, 7/15 (47%) had eGFR 30-59 mL/min/1.73 m^2, 1/15 (6%) had eGFR> 90 mL/min/1.73 m^2. As eGFR declined, furosemide levels increased but mean C_{max} values from SC were lower than IV. Regardless of eGFR, neither C_{max} from SC nor IV was associated with ototoxicity (>100,000 ng/mL). Mean (SD) 8-hour UO in patients with eGFR ≥ 60 and <60 mL/min/1.73 m^2 from SC was 2818 (1034) and 2486 (1057) mL, respectively. 8-hour UO was consistent between SC and IV regardless of eGFR.

Conclusions: As eGFR declined, furosemide exposure from SC increased but remained below threshold for ototoxicity. UO between SC and IV remained consistent regardless of eGFR. Furoscix is new option for patients with CKD and fluid overload; future research needed for patients with eGFR <45 mL/min/1.73m^2.

Funding: Commercial Support - scPharmaceuticals

Furosemide Noncompartmental PK parameters after SC and IV Administration

Route	SC			IV
eGFR, mL/min/1.73 m^2	≥ 60 n=8	< 60 n=7	Overall population n=15	Overall population n=15

Baclofen Toxicity in Patients with Impaired Kidney Function: A Review of Cases in the Literature

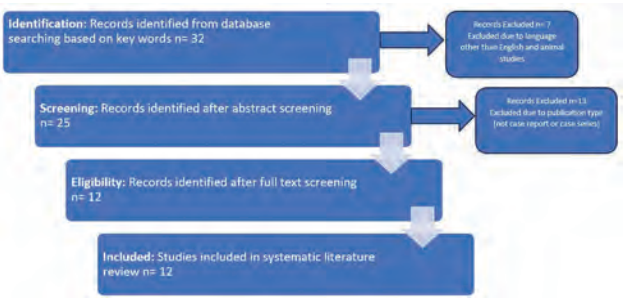
Amna Rehman, Xavier F. Parada. *Berkshire Medical Center, Pittsfield, MA.*

Background: Baclofen is a gamma-aminobutyric acid derivative that inhibits presynaptic motor neurons, resulting in central anti spasticity. It is commonly used to treat muscle spasticity caused by central nervous system disorders. Baclofen neurotoxicity cases are usually iatrogenic but are poorly recognized resulting in significant health problems, mortality, and hospital resource utilization. Therefore, we present here a review of cases published in literature in regard to baclofen induced toxicity in patients with impaired renal function.

Methods: We searched pubmed database for key words: baclofen (adverse effects, poisoning, toxicity), chronic kidney failure, chronic renal insufficiency, end stage renal disease (Figure 1).

Results: We reviewed 12 published articles, with 16 patients of avg. CKD stage IV or V who received variable baclofen dose and developed neurotoxicity (Figure 2).

Conclusions: Our review emphasizes the association of baclofen use with adverse side effects in patients with chronic kidney disease including encephalopathy, dyskinesia, lethargy and tremors. The review highlights that as providers we need to recognize contraindications of baclofen use in patients with impaired renal function and consider other treatment options. Another important aspect is that there are currently no clear guidelines for dosing of baclofen in patients with decreased kidney function. Finally, the management of baclofen toxicity remains variable with no standard recommendations especially for patients with chronic kidney disease.



AUTHOR (Location, Year)	Presenting complaints	Age	Gender	Chronic Kidney Disease (CKD)	Indication for Baclofen	Baclofen dose	Management	Outcome
Mohsin et al. (USA, 2015)	Altered mental status	57	M	CKD V (on dialysis)	Muscular spasms	10 mg BID	Daily hemodialysis (for 3 days)	After third dialysis session complete return to baseline mental status.

Evaluating Sex-Biased Adverse Event-Associated Drugs to Improve Kidney Disease Drug Prioritization

Brittany N. Lasseigne, Timothy C. Howton, Elizabeth Wilk. Lasseigne Lab. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: Sex differences impact disease pathology, including kidney diseases (e.g., polycystic kidney disease, PKD; acute kidney injury, AKI). Also, women are more likely to have drug-related adverse events (unintended medication effects), and men are more likely to experience events resulting in hospitalization or death. These sex-biased adverse events (SBAEs) are due to many factors, but it is critical to evaluate the impact of sex when prioritizing drug targets and repurposing candidates.

Methods: Previously, we evaluated sex-specific gene expression (GE) of known drug targets and metabolism enzymes for SBAE-associated drugs. We also assessed sex-biased GE and gene-regulatory network properties for 45 tissues to determine if known SBAE-associated drug targets and metabolism enzymes had sex-specific gene properties. We applied these findings to drugs approved for or in clinical trials to treat PKD, AKI, and other kidney diseases.

Results: We found ~85% of SBAE-associated targets had sex-biased GE or were core genes of sex- and tissue-specific network communities and demonstrated these data can prioritize drugs for preclinical/clinical kidney disease trials.

Conclusions: Our approach may be useful for studies seeking to explain or predict SBAEs, critical for realizing precision medicine for kidney-associated diseases.

Funding: Other NIH Support - NIH Office of the Director

Safety and Efficacy of D-mannose as Prophylaxis of Urinary Tract Infection: A Systematic Review and Meta-Analysis

Antonio M. Mutarelli,[1] Carlos E. Franca Vargas,[1] Luís Gustavo Menegardo Siqueira de Oliveira,[2] Acza K. Silva,[3] Patrícia R. Vieira,[4] Jiandra Da Luz,[5] Luis Claudio Santos Pinto.[6] *[1]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil; [2]Escola Superior de Ciencias da Santa Casa de Misericordia de Vitoria, Vitoria, Brazil; [3]Universidade Federal de Alagoas, Maceio, Brazil; [4]Universidade Estadual de Campinas, Campinas, Brazil; [5]Universidad Nacional de la Plata, La Plata, Argentina; [6]Centro Universitario da Amazonas, Manaus, Brazil.*

Background: Urinary tract infection (UTI) is the most common bacterial infection, with over 404.6 million cases and more than 230,000 deaths in 2019. Recurrent UTIs significantly impact quality of life due to symptoms, avoidance of sexual activity, persistent pain, and recurrent antibiotic use. A previous meta-analysis suggested the efficacy of D-mannose for UTI prophylaxis, but as new evidence emerges further analysis can be conducted. This systematic review and meta-analysis aimed to evaluate the efficacy of D-mannose for preventing recurrent UTIs.

Methods: Inclusion criteria were prospective randomized studies comparing D-mannose with control or antibiotics in high-risk populations for recurrent UTIs. We excluded abstracts, multi-interventional treatments including D-mannose, and studies using D-mannose for current UTI treatment rather than prophylaxis. The primary outcome was recurrent UTI, analyzed using relative risk (RR) and 95% confidence intervals (CI).

Results: We searched EMBASE, MEDLINE, and the Cochrane Library, identifying 958 articles and abstracts, with 853 remaining after deduplication. We selected 34 for full-text review and included 6 studies. These studies involved 534 patients treated with D-mannose, of whom 521 (97.6%) were women. D-mannose was not associated with a reduction in recurrent UTI compared to control (RR: 0.57, 95% CI 0.29-1.15; p<0.01) or antibiotics (RR: 0.39, 95% CI 0.12-1.25; p<0.01). Further analyses showed that D-mannose did not reduce time to recurrence of UTI and did not improve outcomes in postmenopausal women.

Conclusions: D-mannose does not reduce recurrent UTIs compared to control or antibiotics and it should not be recommended as prophylaxis. Further studies should target different populations to enhance the sample size, including postmenopausal women.

Comparative Sudden Cardiac Death Risk of Haloperidol vs. Chlorpromazine among People Receiving Hemodialysis

Sherin Ismail Atta,[1] Rebekah P. Nash,[2] Bradley N. Gaynes,[2] Jennifer E. Flythe.[2,3] *[1]The University of North Carolina at Chapel Hill Gillings School of Global Public Health, Chapel Hill, NC; [2]The University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; [3]Cecil G.Sheps Center for Health Services Research, Chapel Hill, NC.*

Background: Sudden cardiac death (SCD) is the leading cause of death in the hemodialysis population. Haloperidol and chlorpromazine are the most prescribed typical antipsychotic agents in this population, and both agents have known QT-interval prolonging potential. Data from the non-dialysis population suggest that chlorpromazine may confer higher SCD risk than haloperidol. However, the comparative cardiac safety of these agents in the hemodialysis population is unknown.

Methods: We conducted a new-user, active-comparator, cohort study using US Renal Data System data (2007-2019) to assess the comparative 1-year risk of SCD between initiators of haloperidol vs. chlorpromazine. We used inverse probability of treatment weighting and Fine and Gray proportional subdistribution hazard models to estimate adjusted hazard ratios (aHRs) and 95% confidence intervals (CIs). We used an intention-to-treat approach and treated non-SCD as a competing event. In secondary analyses, we considered broader cardiac outcomes.

Results: Among 10,225 individuals receiving maintenance hemodialysis, 6,266 (61%) initiated haloperidol and 3,959 (39%) initiated chlorpromazine. The median (interquartile range, IQR) age was 65 (55, 74) years, median (IQR) dialysis vintage was 3.1 (1.4, 5.6) years, and 34.9% were female. Haloperidol vs. chlorpromazine initiation was associated with higher relative and absolute 1-year risks of SCD, aHR (95% CI) = 1.39 (1.21, 1.59); weighted risk difference (95% CI) = 2.62% (-0.27, 5.51). The number needed to harm was 38 for haloperidol initiations. Analyses of other cardiac outcomes yielded similar findings.

Conclusions: Initiation of haloperidol vs. chlorpromazine associates with higher absolute and relative 1-year risks of SCD among hemodialysis patients. Our findings may inform prescribing decisions.

Funding: Other NIH Support - NHLBI

Unsafe Opioid Prescribing among Patients with ESKD in 2020

Joshua Mannix, Melissa L. Mccarthy. *The George Washington University Milken Institute School of Public Health, Washington, DC.*

Background: A large proportion of End Stage Renal Disease (ESRD) patients report moderate to severe pain. Opioid analgesics are commonly prescribed to address pain in this population. Opioid analgesic overuse and potential for abuse pose a cause for concern. This study measures the prevalence of unsafe opioid prescribing as defined by the CMS project "Practitioner Level Opioid Safety Measure Development."

Methods: We used 2020 annual data from the United States Renal Data System to estimate unsafe opioid use in Hemodialysis (HD) and Peritoneal Dialysis (PD) patients who had Medicare Part A,B and D coverage. Outcomes include chronic use of opioids (more than 90 days of opioid use in a year), concomitant use of opioids and benzodiazepines, daily morphine milligrams equivalents (MME) ≥ 50, and an aggregate of the three outcomes. We conducted a multivariate logistic regression model to identify factors associated with unsafe opioid prescribing.

Results: Figure 1 shows the proportion of 176,626 beneficiaries who had unsafe opioid prescribing. Our multivariate model revealed that HD and PD patients were at an increased odds of unsafe opioid prescribing if they were non-Hispanic white, female, were un-employed prior to ESRD, were dual eligible, had an ESRD vintage of 5+ years, had a diagnosis of anxiety or depression, and a higher Charlson comorbidity index.

Conclusions: The results demonstrate that unsafe opioid prescribing impacted 1 in 6 HD patients and about 1 in 7 PD patients. Given the high need for symptom management for patients with kidney failure, the results underscore the need to improve access to alternative pain management strategies and to monitor unsafe opioid prescribing for this population.

Figure 1

Outcome	HD (n 158,279) %	PD (n 18,347) %
At least one day of daily MME ≥ 50	4.2%	3.6%
At least one day of Opioid and Benzodiazepines Concomitance	6.5%	5.8%
Chronic use (Opioid use > 90 days)	13.2%	9.1%
One of more of the above	17.4%	13.9%

Evaluation of Ravulizumab Trough Levels in Pediatric Atypical Hemolytic Uremic Syndrome at Remission

Samantha Brokenshire, Samara M. Mendez Nunez, Poyyapakkam Srivaths, Shweta S. Shah, Joseph R. Angelo, Mini Michael. *Texas Children's Hospital, Houston, TX.*

Background: Ravulizumab is a complement C5 inhibitor used for atypical hemolytic uremic syndrome (aHUS). Phase III trials in adults and children suggest the standard dosing regimen provides troughs about 3-fold higher than needed to suppress the complement cascade. Ravulizumab trough monitoring as a tool for individualized dosing regimens has not been described in aHUS or in children. We describe maintenance ravulizumab use in a cohort of pediatric patients with aHUS, exploring potential for targeted dosing strategies using trough and AH50.

Methods: This single-center, retrospective cohort study included pediatric patients with aHUS at remission receiving outpatient ravulizumab infusions between 6/30/23 and 3/31/24 with at least one ravulizumab trough. Patients received maintenance ravulizumab infusions according to the standard (SR) or a modified (MR) regimen at the discretion of the nephrologist. The primary objective was to describe troughs and corresponding AH50 for patients on at least two equal doses. Secondary, exploratory outcomes included comparison of troughs for patients receiving SR and MR, and for patients with multiple troughs. Frequency of potential adverse drug events (pADE) and estimated drug costs are reported.

Results: Nine patients with 28 drug levels were included. The median weight was 17.2 kg (IQR 12.0-39.3) at ravulizumab initiation and 19.1 kg (IQR 14.6-50.8) at first trough. Four patients (44%) received a MR, where dose was not increased for weight gain (n=4) and frequency was extended due to scheduling conflicts (n=1). Rationale for MR included elevated troughs (n=4), clinical stability (n=4), and concern for pADE (n=1). The mean ravulizumab trough for the cohort was 399.9 mcg/mL (SD 104.6). All troughs exceeded goal of 175 mcg/mL and achieved AH50 <10%. There was no difference in troughs between patients receiving SR and MR (diff 30 mcg/mL, 95%CI -131 to 192). For patients with multiple troughs, intra-patient variability was low (CV <25%). Rates of pADE were similar between regimens and drug cost of MRs were lower.

Conclusions: Individualized ravulizumab regimens based on trough and complement monitoring seems to be safe and effective while reducing drug costs. Further study is needed to better understand impact on lab and clinical parameters to determine optimal ravulizumab regimen.

TH-PO121

Imperatorin Ameliorates Ferroptosis-Associated Cell Death, Inflammation, and Kidney Fibrosis in a Unilateral Ureteral Obstruction Mouse Model

Cheng-Tien Wu,[1] Ssu-chia Lin,[1] Yu-Syuan Chen,[1] Pei-Yu Weng,[1] Huey-liang Kuo,[1] Chih-Kang Chiang,[2] Shing-Hwa Liu.[2] Dept of Nutrition CMU. *[1]China Medical University Hospital, Taichung, Taiwan; [2]National Taiwan University, Taipei, Taiwan.*

Background: Chronic kidney disease (CKD) poses a global health problem with high prevalence, morbidity and mortality rates, and various complications. Imperatorin is a naturally occurring furocoumarin derivative and is found in traditional Chinese medicine *Angelica Dahurica* with anticancer, antihypertensive, and antidiabetic properties.

Methods: In this study, we aim to investigate the protective effects of imperatorin treatment and the specific underlying mechanisms on progressive CKD in a unilateral ureteral obstruction (UUO) mouse model.

Results: We found that imperatorin treatment alleviated kidney histology alternations, collagen depositions, and the protein expression of the fibrotic and EMT-related markers (**F**ibronectin, α-smooth muscle actin, E–cadherin, and **Tumor growth factor**-β). Additionally, we found the inhibition of the inflammatory cells infiltration, and moderation of the overload oxidative stress protein markers **(Catalase, superoxide dismutase 2/SOD-2, NADPH oxidase 4/NOX-4, and thioredoxin reductase 1/Trxr-1)**. More important, administration imperatorin mitigates the induced ferroptosis (Cystine transporter SLC7A11/xCT, TFR-1, and Glutathione peroxidase 4/GPX4) as well as renal cell apoptotic death.

Conclusions: Our results suggested that imperatorin treatment improves the fibrotic features of CKD, inflammatory cell infiltration, oxidative stress overload, and ferroptosis-related apoptosis in UUO mice, highlighting its potential as a therapeutic target for CKD treatment in the future.

TH-PO122

Gut Microbial-Derived Short-Chain Fatty Acids Enhance Kidney Proximal Tubule Cell Secretory Function

Rosalinde Masereeuw, Laura Giordano, Sabbir Ahmed, Thomas K. van der Made, Silvia M. Mihaila. *Universiteit Utrecht, Utrecht, Netherlands.*

Background: The organic anion transporter-1 (OAT1) in kidney proximal tubule cells is actively involved in metabolic waste excretion, including uremic toxins; yet its activity becomes impaired upon kidney disease development. Chronic kidney disease also leads to gut dysbiosis, resulting in an increased production of uremic toxins and a reduced production of nephroprotective short chain fatty acid (SCFAs), mainly acetate, propionate and butyrate, thereby contributing to disease progression. Here, we studied whether SCFAs can modulate OAT1 in human kidney proximal tubule cells and stimulate uremic toxin excretion.

Methods: The conditionally immortalized human proximal tubule epithelial cell line overexpressing OAT1 (ciPTEC-OAT1) were exposed to SCFAs for 24h at 1 mM alone or in combination (mix). OAT1 activity was measured using fluorescein as substrate and confirmed with a kidney-on-chip (KoC) system perfused basolateral with the uremic toxin and natural substrate, indoxyl sulfate (IS). Gene and protein expression of OAT1 were analyzed along with histone deacetylase (HDAC) inhibition. Bulk RNA sequencing was used to evaluate gene expression signatures.

Results: Propionate and butyrate significantly boosted OAT1 activity ($p<0.001$) by upregulating *SLC22A6* gene ($p<0.001$) encoding for OAT1 protein expression ($p<0.05$), with butyrate enhancing the secretion of IS to the luminal compartment in our KoC system ($p<0.05$). Interestingly, SCFAs were shown to act independently of GPCR activation, while instead inhibiting gene expression of class II HDAC enzymes (acetate, $p<0.05$; propionate and butyrate, $p<0.01$; SFCA mix, $p<0.001$). Transcriptome analysis suggests HDAC inhibition affects the cAMP signaling pathway, activating CREB1 and PI3K gene expressions. These regulate cell metabolism and stress responses, promote proliferation and survival, enhance SLC22A6/OAT1 function, supporting overall cellular health, function, and resilience, thus enhancing cellular fitness.

Conclusions: Propionate and butyrate exert a significant enhancement of OAT1 activity through *SLC22A6* gene upregulation. Further investigations into the direct effects of SCFAs could potentially introduce them as a novel and effective approach for restoring impaired OAT1 function and maintaining kidney health. This project was funded by EU Horizon 2020 MC STRATEGY-CKD (860329).

Gut Microbiome Signature Associated with Mycophenolate Mofetil Enterohepatic Recirculation

Guillaume C. Onyeaghala,[1,2] Duy Vo,[2] Bryan P. Brito Sanchez,[2] Abdelrahman Saqr,[1] Moataz Mohamed,[1] Christopher Staley,[1] Levi Teigen,[1] Casey R. Dorr,[2,1] Weihua Guan,[1] Rasha El-Rifai,[1] Arthur J. Matas,[1] Rory P. Remmel,[1] William S. Oetting,[1] Pamala A. Jacobson,[1] Ajay K. Israni.[2,1] *[1]University of Minnesota Twin Cities, Minneapolis, MN; [2]Hennepin Healthcare Research Institute, Minneapolis, MN.*

Background: Bacterial b-glucuronidase (BGUS) converts mycophenolic acid glucuronide back to mycophenolic acid (MPA) through enterohepatic recirculation (EHR), likely enhancing immunosuppression and toxicity in kidney transplant recipients (KTRs). We hypothesized that BGUS producing gut taxa are associated with EHR in KTRs.

Methods: Adult KTRs (n=84, 37 prospective and 47 cross-sectional) underwent simultaneous pharmacokinetic(PK) study and stool collection (71 KTRs completed a pre-PK 48hr food recall). We defined MPA %EHR as MPA $AUC_{5\text{-}12\ hr}$ / $AUC_{0\text{-}12\ hr}$ x100. Microbiome shotgun data were processed with HUMAnN3 and differentially abundant taxa associated with EHR adjusted for cohort were identified with MaAsLin2. We further adjusted for age, sex, diet and standardized creatinine clearance using zero inflated Poisson regression. In an exploratory analysis stratified by cohort, we compared the relative abundances of 12 known BGUS producers across EHR levels using the Wilcoxon sum rank test.

Results: Higher relative abundances of *Blautia obeum* and *Faecalibacillus intestinalis* were associated with high EHR ($p=0.007$ and <0.001 respectively), whereas high *Gordonibacter pamelaeae* abundance was associated with low EHR ($p= 0.001$) (FIG 1). In our exploratory analysis, high *Collinsella aerofaciens* abundance was associated with high EHR in the prospective cohort($p=0.04$). Alpha or beta-diversity at the time of PK were not associated with EHR.

Conclusions: Our findings suggest a microbiome signature including *Blautia*, a known BGUS producing taxa, associated with MPA EHR after adjusting for age, sex, diet, and standardized creatinine clearance at the time of PK. Future BGUS assesments may provide opportunities to facilitate MMF dosing based on the stool microbiome.

Funding: NIDDK Support

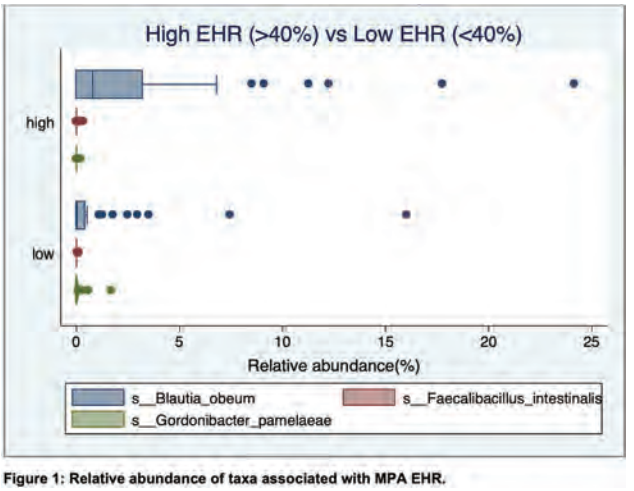

Figure 1: Relative abundance of taxa associated with MPA EHR.

Phantom Lactic Acidosis Secondary to a Drug-Drug Interaction between Ribociclib and Metformin in the Setting of CKD

Bibi Maryam, Adolfo Diaz-Barba. *The University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Introduction: Ribociclib is a CDK4 and CDK6 inhibitor widely used for treating hormone receptor-positive and human epidermal growth factor receptor 2 (HER-2)-negative metastatic breast cancers. Metformin is a biguanide, one of the most essential and primitive medications for type 2 diabetes. We present a unique drug-drug interaction between ribociclib and metformin, causing severe lactic acidosis in a 54-year-old postmenopausal woman with Invasive Ductal Carcinoma of breast, CKD stage 3, and Diabetes

Case Description: A 54-year-old woman incidentally felt a mass in the left breast and was subsequently diagnosed with Invasive Ductal Carcinoma (IDC) (ER 100%, PR 10%, Her2 -ve, Ki-67 33%), histologic grade 3 with lymphovascular invasion (T1 NO M0) by core needle biopsy. She underwent lumpectomy with sentinel lymph node biopsy. She underwent re-excision and was started on radiation therapy. Iliac bone biopsy showed metastatic poorly differentiated adenocarcinoma. She was given radiation therapy to the iliac bone, resulting in theresolution of her hip pain. She was given zoledronic acid for the bony lesions, and started on Fulvestrant and Ribociclib. 5 months later, she presented with generalized weakness and nausea, workup revealed Bicarbonate at 17, AKI on CKD with creatinine elevation from baseline of 1.7 to 2.2, potassium of 5.3, with a pH of 7.34, PCO2 of 28, and lactic acid levels at 5.1. Metformin was immediately stopped. She was started on oral and IV sodium bicarbonate and fluids. Her creatinine improved to 1.7, potassium improved to 4.4, and lactic acid dropped to 2.4. She was subsequently discharged with a follow-up lactic acid and kidney function test in clinic, which remained satisfactorily close to the baseline, and the patient remained asymptomatic.

Discussion: Ribociclib-induced AKI is usually reversible but may require treatment interruption or hemodialysis in severe cases. Metformin uptake from the circulation into renal epithelial cells occurs via OCT2, and from the renal cell into the lumen is mediated by MATE1 and MATE2-K. Ribociclib has the potential to inhibit OCT2 and MATE1, causing decreased renal clearance of metformin if administered together, leading to severe lactic acidosis. The use of metformin and ribociclib in consortium results in high metformin levels and subsequently, type B lactic acidosis, specifically in patients with preexisting CKD.

TH-PO125

Unexpected Consequences: Rosuvastatin-Induced Proteinuria and Hematuria

Badar U Din Shah, Kartik Kalra. *Geisinger Health, Danville, PA.*

Introduction: Statins have been used for treatment of hyperlipidemia with established efficacy in cardiovascular diseases. Prior clinical trials examining the safety and efficacy of high dose rosuvastatin demonstrated an increased incidence of proteinuria, hematuria, rhabdomyolysis, and other acute kidney injury of unknown cause at high doses (20 mg and above). We present 5 patients with proteinuria and microscopic hematuria with spontaneous remission after switching to alternative statin.

Case Description: Case 1: 67 y/o male with history of Chronic Kidney Disease (CKD) 4 on rosuvastatin 20 mg presents with proteinuria, 4 weeks after starting statin therapy. Spot Urine Protein/ Creatinine (PCR) ratio was 1.6 gm/gm. Case 2: 55 y/o male with a history of coronary artery disease (CAD) on rosuvastatin 40 mg presented for evaluation of proteinuria, 24-hour protein was quantified to be 1.8 gm. Case 3: 38 y/o male with family history of premature CAD on rosuvastatin 20 presents for microscopic hematuria and proteinuria evaluation. PCR 1.4 gm/gm. Case 4: 46 y/o female with hyperlipidemia on rosuvastatin 20 mg referred for microscopic hematuria evaluation. Case 5: 63 y/o male with a history of CAD (rosuvastatin 40 mg), CKD 3b complaining of foamy urine. PCR 2.1 gm/gm. All 5 cases underwent thorough immunologic workup which was negative. Rosuvastatin was held and was switched to alternative statin. Within 1-2 weeks, repeat spot urine protein quantification and UA suggested resolution of proteinuria and hematuria..

Discussion: The association of rosuvastatin with proteinuria and hematuria can be related to its renal clearance (10%–25%) when compared with other statins that are hepatically metabolized. Proposed mechanisms for proteinuria with statin use included a dose-dependent impaired albumin tubular absorption via receptor-mediated endocytosis in proximal tubules due to β-hydroxy β-methylglutaryl-coenzyme A reductase inhibition. Another study noted oxidative stress leading to mitochondrial dysfunction due to reduced ubiquinone synthesis. Proteinuria and hematuria in a patient triggers workup which may include a kidney biopsy. We recommend interval monitoring of renal function, urine protein and RBCs at baseline when starting patient on high dose rosuvastatin. The initial rosuvastatin dose should be reduced to 5 mg daily to a maximum dose of 10 mg daily in patients with severe CKD (eGFR <30 mL/min per 1.73 m2).

TH-PO126

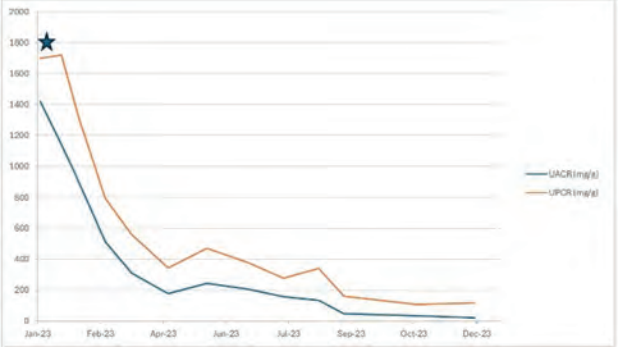
Essential Medication Reconciliation: A Hidden Cause of Proteinuria

Christine Palazzolo, Toni Sabbouh. *Pennsylvania Hospital, Philadelphia, PA.*

Introduction: Alpha-lipoic acid (ALA) is an organic compound which is becoming a popular dietary supplement in many chronic conditions. We review the case of an older male whose new proteinuria rapidly improved after discontinuation of ALA.

Case Description: A 66-year-old male with medical history significant for prostate cancer post resection and prediabetes was referred to the nephrology clinic for worsened proteinuria. He had been on multiple supplements initiated by his primary care physician including nattokinase, chromium picolinate, and ALA. He had a normal physical exam and normal creatinine between 0.9-1 mg/dL. Further workup was negative for hepatitis, HIV, syphilis, autoimmune disease, primary membranous nephropathy, and monoclonal gammopathies. The patient was initiated on an angiotensin receptor blocker and advised to stop taking ALA. Within 1 month, his proteinuria reduced by approximately 55%, and within 8 months, he had complete resolution of proteinuria. Kidney biopsy was not pursued given absence of nephrotic syndrome and stable kidney function.

Discussion: ALA is a supplement growing in popularity for its use in diabetes, multiple sclerosis, Alzheimer's, and schizophrenia to reduce neuropathic symptoms and improve weight loss, memory, and balance. ALA was thought to be the cause for this gentleman's presentation since chromium has only been associated with acute tubular necrosis and chronic kidney disease, and nattokinase has not been reported to cause proteinuria. Despite therapeutic promise, emerging evidence implicates ALA supplementation with unwarranted proteinuria. NELL1+ membranous nephropathy has been observed within 2 to 12 months of starting ALA supplementation and remission is largely achieved within 1 year of supplementation cessation, suggesting the nephropathy's reversibility. This case highlights the importance of a thorough medication reconciliation especially when approaching new proteinuria for which no other obvious risk factors are present.



Discontinuation of ALA (star) improved urine albumin creatinine ratio (UACR) and urine protein creatinine ratio (UPCR).

TH-PO127

Correlation and Dissociation Factors between Ionized, Total, and Corrected Calcium in Patients on Hemodialysis

Chiharu Aizawa, Akio Nakashima, Kazuhiko Kato, Arisa Kobayashi, Ichiro Ohkido, Takashi Yokoo. *Tokyo Jikeikai Ika Daigaku Igakubu Igakuka Jinzo Koketsuatsu Naikagaku, Minato-ku, Japan.*

Background: It is important to optimize serum calcium concentrations in dialysis patients because abnormal calcium levels are associated with the risk of all-cause mortality and cardiovascular events. Ionized calcium (iCa) has physiological activity in the body; however, the direct measurement of iCa is limited technically. Although total serum calcium (tCa) and corrected calcium (cCa) using the Payne correction formula have been utilized to assess calcium levels, their limitations have been pointed out. The degree to which the correlation between ionized, total, and corrected calcium is dissociated in dialysis patients has rarely been examined, and the factors influencing this correlation are poorly understood. This study aimed to clarify the degree of correlation and dissociation among iCa, tCa, and cCa levels in patients undergoing hemodialysis.

Methods: A cross-sectional study assessed the correlation between iCa, tCa, and cCa levels in patients undergoing hemodialysis. Factors involved in the correlation between the iCa and tCa levels were evaluated using multiple regression analysis. Based on these results, we proposed a novel iCa prediction equation.

Results: Two hundred thirteen patients were enrolled. Patients were 65 ± 10.2 years, and 67.1% of patients were male. The correlation coefficients were 0.8665 for iCa and tCa and 0.8537 for iCa and cCa. Correlations were also observed when the albumin concentration and pH were divided by known correlation factors. In multiple regression analysis of the relationship between tCa and iCa, albumin, pH, phosphorus, and Mg levels were significant factors. Based on these results, a new corrected calcium equation (mg/dL) = 0.828×total calcium - 0.314×albumin (g/dL) + 0.007×age + 2.922 was derived using age and albumin.

Conclusions: There was a correlation between iCa, tCa, and cCa in hemodialysis patients, with a stronger correlation with tCa in iCa assessments. Correcting for tCa levels may not be necessary when predicting iCa levels. We propose a novel prediction equation for estimating iCa by age and albumin without blood gas analysis.

TH-PO128

Intravenous Calcium Supplementation in Patients with Secondary Hyperparathyroidism after Total Parathyroidectomy: Serum Phosphorus as an Indicator

Wei Liang. *Wuhan University Renmin Hospital, Wuhan, China.*

Background: Intravenous calcium supplementation (ICS) regimen after parathyroidectomy (PTX) mostly relies on immediate serum calcium level(SC-ICS) to adjust the dose and maintenance time of calcium supplementation, and there is a lack of standardized treatment regimen, with a wide range of individual variations, and the short-term/long-term efficacy and safety are still unclear. In this study, we propose a serum phosphorus level-guided ICS(SP-ICS) regimen to improve the efficiency and recurrence rate of hypocalcemia treatment after PTX.

Methods: This study retrospectively analyzed the clinical data of 36 cases of SHPT patients with total parathyroidectomy (tPTX). According to ICS is divided into serum calcium-guided ICS regimen (SC-ICS) and serum phosphorus-guided ICS regimen (SP-ICS). Both groups of patients were allowed to have a free diet after the operation, and oral calcium and osteotriol supplementation were given. The occurrence of (Hungry Bone Syndrome) HBS and hypocalcemia after surgery was recorded in all patients.

Results: A total of 36 cases were recruited in the respective cohort (18 cases in SC-ICS and 18 ones in SP-ICS). There was no significant difference in the baseline data between the two groups. Postoperative serum PTH and serum calcium levels were significantly decreased in both groups and hypocalcemia occurred in all patients. Compared with the SC-ICS group, the SP-ICS group had a longer postoperative hospitalization [9.5 (7.25,12.75) vs 5.0 (5.0,9.5), p=0.015] and a greater cumulative dose of 10% GN supplementation (540 ml±100 ml vs 190 ml±50 ml, p=0.039). At 6 month postoperative follow-up, one case died of hypocalcemia in the SC-ICS group, and the incidence of hypocalcemia was lower in the SP-ICS group than in the SC-ICS group (8.3% vs. 27.3%, p=0.022), and at one-year postoperative follow-up, the incidence of hypocalcemia was lower in the SP-ICS group than in the SC-ICS group (8.3% vs. 50%, p=0.024).

Conclusions: Both SC-ICS and SP-ICS can effectively correct hypocalcemia after tPTX, and the dose and duration of calcium supplementation of SP-ICS regimen is higher than that of SC-ICS regimen, and SP-ICS regimen significantly reduces the incidence of long-term hypocalcemia and the risk of lethal hypocalcemia, and improves the quality of patient survival.

TH-PO129

Hungry Bone Syndrome after Parathyroidectomy Is Associated with Better Outcomes in ESKD

Sinee Disthabanchong. *Mahidol University Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand.*

Background: Hyperparathyroidism (HPT) is common in patients with end-stage kidney disease (ESKD). Parathyroidectomy (PTX) is still necessary for patients who do not respond adequately to medications. Hungry bone syndrome (HBS) frequently occurs after PTX. Beyond lower recurrence rates of HPT, the long-term outcomes associated with HBS are largely unexplored.

Methods: In this retrospective single-center study conducted between 2012 and 2022, 322 PTX were identified in 314 patients with ESKD. HBS was defined as serum albumin-corrected Ca levels <8.5 mg/dL occuring between 5-30 days post-PTX. The study evaluated baseline biochemical factors associated with HBS and examined adverse events, as well as changes in blood pressure, hematologic, and nutritional parameters 3-12 months after PTX, stratified by HBS status.

Results: HBS was observed in 207 cases (64%). Male sex, lower serum Ca and higher PTH levels, and lack of active vitamin D treatment at baseline were independent predictors of HBS. Adverse events were similar between the HBS and no-HBS groups. Between group comparisons revealed HBS group experienced a more significant reduction in pulse pressure after surgery. There was a greater increase in Hb and serum Cr in the HBS group. The number of cases with Hb <11 g/dL and Cr/BSA <380 mg/m^2 post-PTX was lower in the HBS group. Serum albumin levels increased significantly in both groups, with no significant difference between them. HBS was associated with a more substantial reduction in serum Ca and PO_4 but not PTH levels, from baseline. At the end of the follow-up period, serum Ca levels remained lower in the HBS group, while serum PO4 and PTH levels were comparable between the two groups.

Conclusions: In conclusion, HBS was associated with a more substantial improvment in blood pressure, anemia and muscle mass in ESKD patients.

Paricalcitol Capsule (HR081702) for Secondary Hyperparathyroidism (SHPT) in Stages 3 and 4 CKD: A Multicenter, Randomized, Double-Blind, Placebo-Controlled, Phase 3 Study

Jianghua Chen,[1,2] Jun Cheng,[1,2] Xiaoying Du,[1,2] Changhua Liu,[3] Ping Luo,[4] Wenxiu Chang,[5] Yanning Zhang,[6] Hong L. Lin,[7] Lihua Wang,[8] Hua Zhou,[9] Wenbin Li,[10] Xiaoyong Yu,[11] Wanhong Lu,[12] Chaosheng Chen,[13] Linghui Zhou,[14] Xiaoyi Sun,[15] Lingling Xu.[15] *[1]Kidney Disease Center, the First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China; [2]Zhejiang Clinical Research Center of Kidney and Urinary System Disease, Hangzhou, China; [3]Northern Jiangsu People's Hospital, Yangzhou, China; [4]The Second Hospital of Jilin University, Changchun, China; [5]Tianjin First Central Hospital, Tianjin, China; [6]General Hospital of the Northern Theatre, Shenyang, China; [7]First Affiliated Hospital of Dalian Medical University, Dalian, China; [8]Second Hospital of Shanxi Medical University, Taiyuan, China; [9]Shengjing Hospital of China Medical University, Shenyang, China; [10]The First Affiliated Hospital of Shandong First Medical University & Shandong Provincial Qianfoshan Hospital, Jinan, China; [11]Shaanxi Traditional Chinese Medicine Hospital, Xi'an, China; [12]the First Affiliated Hospital, School of Medicine, Xi'an Jiaotong University, Xi'an, China; [13]The First Affiliated Hospital of Wenzhou Medical University, Wenzhou, China; [14]The First Affiliated Hospital of Xiamen University, Xiamen, China; [15]Jiangsu Hengrui Pharmaceuticals Co., Ltd, Shanghai, China.*

Background: Paricalcitol capsule is a good choice to treat SHPT as a vitamin D analogue with a convenient dosage form for patients. This study aimed to investigate the efficacy and safety of paricalcitol capsule (HR081702) in stages 3/4 CKD patients with SHPT.

Methods: This was a multicenter, randomized, double-blind, placebo-controlled, phase 3 study in Chinese adult patients in stages 3/4 CKD with SHPT (ClinicalTrials.gov, NCT04994080). Patients were enrolled if, in the screening period and run-in period, the mean serum intact parathyroid hormone (iPTH) was ≥150 pg/mL (≥120 pg/mL in both periods), serum calcium level was between 8.0 and 10.0 mg/dL (1.99 and 2.50 mmol/L), and serum phosphorus level was ≤5.2 mg/dL (1.68 mmol/L). Eligible patients were randomized (2:1) to receive HR081702 or placebo orally once a day for 24 weeks, with the initial dose determined by iPTH level and adjusted depending on subsequent serum iPTH, calcium, and phosphorus levels. The primary endpoint was the proportion of patients with at least two consecutive iPTH reductions of ≥30% from baseline within 24 weeks of treatment.

Results: A total of 90 patients were randomized (60 in HR081702 group and 30 in placebo group) with similar baseline characteristics between the two groups. During the 24 weeks treatment period, 91.7% of patients in the HR081702 group achieved two consecutive reductions of ≥30% from baseline in iPTH levels, compared with 16.7% of patients in the placebo group (difference, 75.0% [95% CI 59.9-90.1]; P<0.0001). Furthermore, 68.3% of HR081702-treated patients achieved four consecutive decreases of ≥30% in iPTH levels from baseline, compared with 6.7% of placebo-treated patients. There were no obvious differences in the excretion of calcium and phosphorus or in the decline of kidney function between the two groups. Treatment-related adverse events were reported by 50% in HR081702 group and 26.7% in placebo group (all were mild or moderate). The most common ones were hyperphosphatemia and urinary tract infection.

Conclusions: Paricalcitol capsule (HR081702) was an effective and safe treatment for stages 3/4 CKD patients with SHPT.

TH-PO131

Central vs. Peripheral Access Samplings in Patients on Hemodialysis Induce Variations in Parathyroid Hormone Levels

Simon Schreiber, Simon Desmeules, Mohsen Agharazii, Pierre Douville, Fabrice Mac-Way. *Universite Laval Faculte de Medecine, Quebec, QC, Canada.*

Background: Parathyroid hormone (PTH) levels are routinely measured in dialysis patients, but international guidelines do not specify the optimal site from which PTH should be drawn. Previous findings suggest that centrally drawn PTH may significantly vary from peripherally sampled PTH[1]. This study aimed to compare PTH levels drawn from central venous catheters (C-PTH), peripheral veins (P-PTH) and arteriovenous fistula (AVF-PTH) in hemodialysis patients.

Methods: C-PTH, P-PTH and/or AVF-PTH were simultaneously measured in hemodialysis patients at the CHU de Québec (cohort A) and CISSS Chaudières-Appalaches (cohort B) in Canada from January 1st to February 28th, 2024. Architect Intact PTH™ (Abbott, normal range 25 to 115 ng/L) was used in cohort A and IMMULITE Intact PTH™ (Siemens, normal range 20 to 100 ng/L) in cohort B. Demographic data were collected and mineral biochemistry were measured according to local standard. PTH levels were classified as "on target" according to sampling site if they were between two and nine times the upper limit of normal.

Results: Cohort A included 69 hemodialysis patients (mean age 69 ± 13 years, dialysis vintage 69 ± 13 months, 86% with a central venous catheter). Mean C-PTH, P-PTH and AVF-PTH were respectively 546 ± 309 ng/L, 409 ± 227 ng/L and 533 ± 325 ng/L. Classification of PTH levels being "on target" were different between C-PTH and P-PTH in 29% of patients. Cohort B included 50 hemodialysis patients (mean age 67 ± 13 years, dialysis vintage 50 ± 60 months, 54% with a central venous catheter). Mean C-PTH, P-PTH and AVF-PTH were respectively 357 ± 264 ng/L, 352 ± 236 ng/L and 475 ± 255 ng/L. Similarly to cohort A, "on target" PTH levels were different between C-PTH and P-PTH in 18.3% of patients.

Conclusions: Our results suggest that sites of sampling may influence PTH levels and could impact the treatment of hyperparathyroidism in hemodialysis patient. Standardization of sampling site should therefore be recommended. 1-Vulpio C, et al. Influence of blood sampling site on intact parathyroid hormone concentrations in hemodialysis patients. Clin Chem. 2010;56(3):489-90.

Parathyroid Axis Irregularities in Patients with Hyperaldosteronism

Loai Dweik,[1] Dania Salih Bacha,[2] Vaidehi A. Mendpara,[2] Huijun Xiao,[2] George Thomas,[2] Pratibha P. Rao,[2] Georges Nakhoul,[2] Jonathan J. Taliercio,[2] Elias Bassil,[2] Ali Mehdi.[2] *[1]Cleveland Clinic, Cleveland, OH; [2]Cleveland Clinic Akron General, Akron, OH.*

Background: Patients with hyperparathyroidism (HPT) have increased cardiovascular risks. A bi-directional relationship between the renin-aldosterone axis and the parathyroid-calcium (PTH-Ca) axis has been proposed whereby PTH and aldosterone can activate one another and exacerbate vascular damage. This study aims to investigate the prevalence of PTH-Ca axis abnormalities in patients with primary aldosteronism (PA).

Methods: In this retrospective review, patients 18 years or older with PA who had PTH levels measured between 2018 and 2023 were included. Patients with secondary HPT were excluded. The prevalence of HPT, hypercalcemia (HyperCa), and hypophosphatemia (HypoP) was calculated.

Results: 164 patients were identified. Median age was 70 years and 44% were female. Primary HPT was prevalent in 13% of the cohort. HyperCa (Ca > 10.2 mg/dL on 2 occasions) and HypoP (P<2.5 mg/dL on 2 occasions) were observed in 32% and 33% of patients respectively. After excluding patients on Calcium, vitamin D supplements, or thiazides, 24% of the remaining 66 patients had HyperCa. Among patients with HyperCa and/or HypoP (N=83), median interquartile range (IQR) PTH was 59.5 pg/mL (41.0 – 88.8), median (IQR) 24-hour urinary Ca:166.5 mg/day (77.9 – 257.6), and 22% had nephrolithiasis. We then excluded patients with a diagnosis of primary HPT from this sub-cohort and were left with 65 patients. The median (IQR) PTH was unsuppressed at 47.0 pg/mL (38.0 – 79.5), median (IQR) 24-hour urinary Ca: 144.0 mg/day (101.4 – 221.7), and 24% had nephrolithiasis.

Conclusions: In a cohort of PA patients, the prevalence of PTH-Ca abnormalities is quite high. Primary HPT was seen in 13% of patients as compared to <1% in the general population. HyperCa was also seen in a third of patients, many folds higher than the general population (1-2%). This remained true even after excluding those on medications

that can raise serum Ca. Looking at patients with HyperCa and/or HypoP and excluding those with primary HPT, the biochemical profile (unsuppressed PTH and 24 urine Ca) suggested undiagnosed primary HPT. True primary HPT is likely more prevalent in this population. Further studies are needed to better understand this interaction and therapeutic implications.

TH-PO133

Parathyroid Hormone and Cardiovascular Risk in Patients with CKD

Caroline S. Pichat,[1] Ellen Linnea F. Ballegaard,[3] Iain O. Bressendorff,[1] Hanne S. Joergensen,[2,4] Nicholas Carlson,[3] Ditte Hansen.[1,5] *[1]Herlev Hospital, Herlev, Denmark; [2]Aarhus Universitetshospital Risskov, Risskov, Denmark; [3]Rigshospitalet, Kobenhavn, Denmark; [4]Aalborg Universitet, Aalborg, Denmark; [5]Kobenhavns Universitet, Kobenhavn, Denmark.*

Background: Cardiovascular disease is highly prevalent in patients with chronic kidney disease (CKD). The aim of this study was to describe the association between parathyroid hormone (PTH) level and risk of cardiovascular disease in CKDG3-5.

Methods: The cohort was based on nationwide Danish health care registries. All Danish residents ≥18 years with eGFR <60 ml/min/1.73 m2 and measured PTH were identified between 2010 and 2022. Individuals with prior kidney transplantation, multiple myeloma, suppressed PTH, hypercalcemia ≥1.4mmoL, and current dialysis therapy were excluded. PTH was standardized based on the assay-specified upper normal limit (normal, 1.1-2.0xUNL, 2.1-4.0xUNL, and ≥4.0xUNL) with comparison of cumulative incidences of major cardiovascular outcomes (cardiomyopathy, heart failure, myocardial infarction, stroke, thromboembolism, and/or peripheral artery disease) based on the Aalen-Johansen estimator and multiple cause-specific Cox regression models adjusted for age, sex, and CKD stage with death as competing risk. Results were further tested in sensitivity analyses adjusted for phosphate.

Results: A total of 80,937 individuals were included. Median age was 74 yrs (IQR 65;82), 58% were female, 87% with CKDG3, and 62% with normal PTH. Male, sex and lower eGFR were associated with higher PTH levels. A total of 17,701 events were identified during a mean follow-up of 4.4 yrs. Cumulative incidence was highest with PTH >4xUNL (Figure 1). Higher PTH associated with increased rates of cardiovascular events (Figure 2). Principal results remained unchanged following adjustment for phosphate.

Conclusions: Increasing PTH may contribute to cardiovascular disease in patients with CKDG3-5. Further studies are needed to determine the PTH targets in pre-dialysis CKD.

SHR6508, a Calcium-Sensing Receptor Agonist, in Patients on Hemodialysis Who Have Secondary Hyperparathyroidism: A Phase 2 Trial

Xueqing Yu,[1] Zhiming Ye,[1] Li Fan,[1] Yuqing Chen,[2] Pei Wang,[3] Rui Yan,[9] Bin Liu,[4] Yong Wei,[8] Hong Ye,[5] Bi hu Gao,[6] Xin Zhang,[7] Xinyu Yang,[7] Xue Yang.[7] *[1]Guangdong Provincial People's Hospital, Guangzhou, China; [2]Peking University First Hospital, Beijing, China; [3]The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; [4]Wuxi People's Hospital, Wuxi, China; [5]The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China; [6]Affiliated Zhongshan Hospital of Dalian University, Dalian, China; [7]Jiangsu Hengrui Pharmaceuticals Co Ltd, Shanghai, China; [8]The First Affiliated Hospital of Shandong First Medical University & Shandong Provincial Qianfoshan Hospital, Jinan, China; [9]The Affiliated Hospital of Guizhou Medical University, Guiyang, China.*

Background: Secondary hyperparathyroidism (SHPT) is a common clinical manifestation among patients receiving hemodialysis (HD). SHR6508 is a calcimimetic developed to reduce parathyroid hormone (PTH) secretion in HD patients with SHPT. We aimed to evaluate the efficacy and safety of SHR6508 compared with cinacalcet in HD patients with SHPT.

Methods: This was a multicenter, randomized, open-label, active-controlled, dose titration phase 2 trial conducted in 34 sites in China. Adult patients who had received HD for at least 12 weeks and with intact PTH (iPTH) ≥400 pg/ml and serum corrected calcium (cCa) ≥2.25 mmol/L were recruited. Eligible patients were randomized in a 2:2:1 ratio to SHR6508 Group 1 (slow titration), SHR6508 Group 2 (rapid titration), and cinacalcet group, stratified by the baseline iPTH level (<700 or ≥700 pg/mL). Patients in SHR6508 Group 1 and 2 received SHR6508 2.5-20 mg by intravenous injection after HD section for 16 weeks, and those in cinacalcet group received oral cinacalcet 25-100 mg once daily for 16 weeks, with the dosage adjusted based on iPTH and cCa levels. The primary outcome was percentage change in iPTH from baseline to week 16.

Results: A total of 75 HD patients were randomized (n=30 for SHR6508 Group 1 and 2, respectively; n=15 for cinacalcet). iPTH significantly declined in patients treated with SHR6508 than those treated with cinacalcet during treatment period (**Figure 1**). The percentage changes in mean iPTH from baseline to week 16 were -62.7%, -61.7% and -38.9% in SHR6508 Group 1, Group 2 and cinacalcet group, respectively ($P<0.05$). The treatment-related adverse events (TRAEs) were comparable among three groups (83.3% vs 83.3% vs 86.7%) and all SHR6508-related TRAEs were mild or moderate. Nausea (3.3% vs 3.3% vs 6.7%) and vomiting (0 vs 0 vs 13.3%) were less common in patients treated with SHR6508.

Conclusions: SHR6508 showed greater efficacy in iPTH reduction and similar safety profiles compared to cinacalcet in HD patients with SHPT.

TH-PO135

Impact of Upacicalcet on Bone Metabolism in Patients on Hemodialysis Who Have Secondary Hyperparathyroidism: Post Hoc Analysis Based on Baseline Alkaline Phosphatase

Suguru Yamamoto,[1] Shinji Yoneda,[2] Junichiro J. Kazama,[3] Ichiei Narita.[1] *[1]Division of Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [2]Medical Affairs Department, Sanwa Kagaku Kenkyusho Co., Ltd., Nagoya, Japan; [3]Division of Nephrology and Hypertension, Fukushima Medical University, Fukushima, Japan.*

Background: Secondary hyperparathyroidism (SHPT) is a major complication in hemodialysis (HD) patients. Calcimimetics have been shown to improve bone turnover by suppressing parathyroid hormone (PTH) production. However, it remains unclear whether the degree of bone turnover influences the efficacy of calcimimetics. This study aimed to evaluate the efficacy of Upacicalcet on PTH suppression and changes in bone turnover, based on baseline alkaline phosphatase levels.

Methods: A post-hoc analysis was conducted on data from a phase 3, placebo-controlled, double-blind study of Upacicalcet in HD patients with SHPT. Patients were categorized into three groups based on tertiles of baseline serum bone-specific alkaline phosphatase (BAP) concentrations. Serum concentrations of intact PTH, BAP, tartrate-resistant acid phosphatase-5b (TRACP-5b), and BAP/TRACP-5b ratio were measured. Percent change from baseline in these parameters was assessed using a mixed-effects models for repeated measures. Differences in bone turnover markers among the three BAP groups at 24 weeks were evaluated using Tukey-Kramer multiple comparison adjustment.

Results: The analysis included 103 HD patients with SHPT treated with Upacicalcet. Patients were categorized into low BAP (<12.8 μg/L), medium BAP (12.8–18.8 μg/L), and high BAP (>18.8 μg/L) groups based on baseline serum BAP concentrations. After 24 weeks intervention with Upacicalcet, intact PTH concentration decreased in all baseline BAP groups. There was a tendency for a greater decrease in PTH in the low BAP group compared to the medium (13.7±5.4%, p=0.0287) and high BAP groups (11.9±5.7%, p=0.0906). Serum concentrations of BAP and TRACP-5b decreased, while the serum BAP/TRACP-5b ratio increased in all groups.

Conclusions: Upacicalcet decreased serum intact PTH concentration regardless of the degree of bone turnover. The effect was more pronounced in patients with low BAP levels, however, Upacicalcet may improve bone turnover in HD patients with any bone metabolism state.

Comparison between the Different Doses of Preoperative Calcitriol to Prevent Hungry Bone Syndrome after Parathyroidectomy in ESKD: A Randomized Controlled Clinical Trial

Ompan Thookhamme, Pitchamon Inkong. *Phramongkutklao College of Medicine, Bangkok, Thailand.*

Background: The most common complication of parathyroidectomy in end-stage kidney disease (ESKD) is hungry bone syndrome (HBS), resulting in prolonged hospitalization. Administering calcitriol before surgery is one strategy for preventing these complications; however, limited studies on the recommended calcitriol dose. The study aims to compare the efficacy and safety of different doses of calcitriol in preventing hypocalcemia in end-stage kidney disease (ESKD).

Methods: ESKD patients on regular hemodialysis with renal hyperparathyroidism undergoing parathyroidectomy were randomly assigned to receive 4 mcg/day of calcitriol or 2 mcg/day for 3 days before surgery. The primary outcome was hungry bone syndrome, defined as severe hypocalcemia or hypocalcemia on day 7, and secondary outcomes included electrolyte disturbances and hospitalization length.

Results: 28 ESKD patients who underwent parathyroidectomy were enrolled, 14 received 4 mcg and the other 14 received 2 mcg of calcitriol. The mean age was 47.11±11.47 years, the mean serum calcium was 10.56±0.78 mg/dL, and the mean serum parathyroid hormone was 1866±677.62 pg/mL. The incidence of HBS was 62.5%, occurring in 5 (38.5%) and 10 (90.1%) participants in the high and low calcitriol groups, respectively (p = 0.008). The incidence of severe hypocalcemia within 72 hours were 5 (35.7%) in high-dose and 7 (50%) in low-dose groups, respectively (p = 0.704). Other factors including hypophosphatemia and length of hospitalization were similar in both groups. No serious adverse events were reported.

Conclusions: 4 mcg of calcitriol showed significant benefits in preventing hungry bone syndrome after parathyroidectomy compared to 2 mcg of calcitriol, without serious adverse effects.

Table 2. Primary, Secondary, and Safety outcomes

Outcomes	Calcitriol 4 mcg/d	Calcitriol 2 mcg/d	p-value
Primary outcome			
Hungry bone syndrome	5/13 (38.5%)	10/11 (90.1%)	0.008
• Severe hypocalcemia requiring IV calcium within 72 hours	5/14 (35.7%)	7/14 (50%)	0.704
• Hypocalcemia on day 7	2/12 (16.7%)	8/10 (80%)	0.008
Secondary outcomes			
Early hypocalcemia	10/14 (71.4%)	9/14 (64.3%)	1.000
Severe hypocalcemia and hypophosphatemia within 72 hours	4/14 (28.6%)	4/14 (28.6%)	1.000
Hypophosphatemia within 72 hours	9/14 (64.3%)	8/14 (57.1%)	1.000
Hypomagnesemia	0/14 (0%)	0/14 (0%)	N/A
Hyperkalemia	3/14 (21.4%)	3/14 (21.4%)	1.000
Cumulative oral calcium supplement (g)	8.31 ± 3.03	10.51 ± 7.23	0.307
Hospitalization stays*	92.43 ± 14.88	90.14 ± 36.88	0.831
Adverse events			
Hypercalcemia	0/14 (0%)	0/14 (0%)	N/A
Phlebitis	1/14 (7.1%)	0/14 (0%)	1.000
Others	1/14 (7.1%)	0/14 (0%)	1.000

TH-PO137

Vitamin D Metabolite Ratio as a Marker of Bone Turnover and Change in Volumetric Bone Mineral Density in Older Men

Emma A. Mulligan, O. Alison Potok, Joachim H. Ix, Charles Ginsberg. *University of California San Diego, La Jolla, CA.*

Background: The vitamin D metabolite ratio(VMR), calculated by the ratio of 24,25-dihydroxyvitamin D3 to 25-hydroxyvitamin D(25[OH]D3), is a marker of vitamin D stores that may be a better predictor of bone health outcomes than 25(OH)D. Previously, we found that a higher VMR was cross-sectionally associated with higher volumetric bone mineral density (vBMD) in older men. In this analysis we examined the relationship between the VMR and 25(OH)D with biomarkers of bone turnover (BTM's) and changes in vBMD in older men in the Osteoporotic Fractures in Men (MrOS) study.

Methods: We used multiple linear regression models to evaluate the relationship between the VMR and 25(OH)D with BTM's, including parathyroid hormone(PTH), C-terminal telopeptide of type I collagen(CTX-I) and N-terminal propeptide of type I procollagen(PINP). vBMD was assessed at the distal radius and tibia by high resolution peripheral quantitative computed tomography (HRpQCT). We similarly evaluated the relationship of the same vitamin D measures with annualized percent change in vBMD.

Results: 254 men with repeat measures of vBMD were included in this analysis. Mean time (SD) between scans was 6(0.6) years. Mean age of participants was 83(3.3) years, with a mean eGFR of 71(14)mL/min/1.73m^2, and 22% had chronic kidney disease (eGFR<60). Mean VMR and 25(OH)D were 6.5(2.2)[(ng/mL)/(ng/mL)] and 39(14)ng/mL, respectively. Mean PTH, CTX-I and P1NP were 50(30) pg/mL, 0.29 (0.18) ng/mL and 50(23) ng/mL, respectively. In fully adjusted models both VMR and 25(OH)D were inversely associated with parathyroid hormone concentrations (**Table**), but only the VMR was inversely associated with CTX-I. Neither VMR nor 25(OH)D was associated with a marker of bone formation or annualized change in vBMD.

Conclusions: In community living older men, only the VMR was inversely associated with a marker of bone resorption, CTX-I. Neither VMR nor 25(OH)D was associated with a marker of bone formation or annualized change in vBMD. Further studies are needed to evaluate how the VMR may affect bone longitudinally.

Funding: NIDDK Support, Other NIH Support - NIA, NIAMS, NCATS, NIH Roadmap for Medical Research

Table: The association of the VMR and 25(OH)D with biomarkers of bone turnover*

	PTH	P	CTX	P	P1NP	P
	Per SD Lower (95% CI)		Per SD Lower (95% CI)		Per SD Lower (95% CI)	
VMR	9.3 (6.2, 12.5)	<0.001	0.024 (0.004, 0.046)	0.016	1.49 (-0.97, 4.09)	0.240
25(OH)D	4.7 (2.0, 7.6)	<0.001	0.004 (-0.014, 0.022)	0.690	0.80 (-1.48, 3.21)	0.500

Alfacalcidol vs. Calcitriol in the Management of Secondary Hyperparathyroidism in CKD

Muriel Ghosn, Wasim El Nekidy, Jihad Mallat, Fadi A. Hijazi, Rakesh Madhyastha, Emna Abidi, Iyad Ghazal, Amir R. Malik. *Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates.*

Background: This study aims to assess the efficacy of alfacalcidol compared to calcitriol in reducing iPTH levels in patients with chronic kidney disease

Methods: This retrospective cohort study was conducted at our quaternary care hospital between January 1st, 2022, and December 31st, 2022. Adult Patients diagnosed with CKD stage 3 to 5 (not on dialysis) who received alfacalcidol for at least 3 months followed by calcitriol for another 3 months were included. Laboratory values were assessed at baseline, at 3 months while on alfacalcidol then at 3 months while on calcitriol. The primary outcome was the suppression of the iPTH, while the secondary outcome was the effect on total serum calcium. The study was approved by the hospital's research ethics committee

Results: Seventy adult patients were included in the analysis. Statistical analysis was conducted using Wilcoxon signed rank test and McNemer test. CKD stage 3 comprised 47.1% of the sample while stage 4 comprised 37.1%. The median dose of alfacalcidol was 0.5 (0.25-0.8) mcg, compared to 0.5 (0.25-0.5) mcg for calcitriol (p= 0.001). The median time between baseline and outcome laboratory measurements was 94 (83-106) days for alfacalcidol and 94 (78.5-110.5) for calcitriol (p= 0.676). No significant differences were observed in the use of phosphate binders or non-active vitamin D between the time periods. Alfacalcidol did not significantly suppress the iPTH levels with median values of 13.31 (8.23 - 24.4) pg/mL at baseline and 12.5 (8.86 - 24.7) pg/mL after 3 months (p= 0.937). In contrast, calcitriol significantly reduced the iPTH levels from 12.5 (8.86 - 24.7) pg/mL to 10.7 (5.7 -19) pg/mL (p= 0.017). Additionally, alfacalcidol did not significantly increase calcium levels, with values of 2.29 (2.2 - 2.3) mmol/L at baseline and 2.3 (2.23 - 2.36) mmol/L after 3 months (p=0.237), whereas calcitriol significantly increased calcium levels from 2.3 (2.23 - 2.36) mmol/L to 2.34 (2.27 - 2.43) mmol/L (p=0.001). Albumin values remained unchanged throughout the study period

Conclusions: Calcitriol, at significantly lower doses, was more effective than alfacalcidol in reducing iPTH levels and increasing calcium levels over 3 months. Larger prospective controlled studies are needed to confirm these findings

TH-PO139

Association of Serum Magnesium Levels and Calcimimetic Use for Cardiovascular Events (CVE) in Patients on Hemodialysis

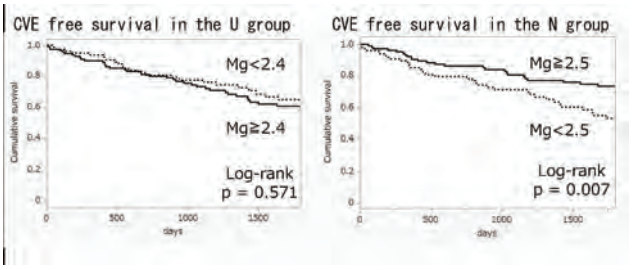
Tomohiro Saito,[1] Masahide Mizobuchi,[2] Kiryu Yoshida,[3] Tadashi Kato,[1] Noriyuki Kato,[4] Hiroaki Ogata,[3,5] Fumihiko Koiwa,[2] Hirokazu Honda.[1] *[1]Division of Nephrology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan; [2]Division of Nephrology, Department of Internal Medicine, Showa University Fujigaoka Hospital, Yokohama, Japan; [3]Division of Nephrology, Department of Internal Medicine, Showa University Northern Yokohama Hospital, Yokohama, Japan; [4]Saiyu Clinic, Saitama, Japan; [5]Department of Medical Education, Showa University School of Medicine, Tokyo, Japan.*

Background: Lower serum Mg levels have been shown to be associated with all-cause death and CVE in hemodialysis patients. Calcimimetics use is likely to reduce CVE risk. Serum Mg concentrations are suggested to affect responsiveness of calcimimetics. However, the interaction of caicmimimetics and Mg on CVE remains unclear.

Methods: We conducted a retrospective analysis on 403 HD patients (female, 36.7%; age (median), 62; HD vintage (median), 76 months) in a single facility in Japan. The patients were divided into the user (U; n=196) and the non-user groups (N; n=207), based on status of calcimimetics use at baseline. CVE included cardiovascular death, nonfatal myocardial infarction or stroke, unstable angina, transient ischemic attack, or hospitalization for heart failure or ventricular arrhythmia. Multivariable Cox regression analysis and Kaplan-Meier analysis were applied for analytical approach.

Results: Median observation period was 64 months. CVE significantly occurred in patients in the below-median Mg levels than in those in the above-median Mg levels (Hazard ratio (HR), 0.34 [95% confidence interval, 0.13-0.80]; P = 0.018) among the N group, but the incidence of CVE was comparable among the U group (HR, 1.48 [0.60-3.68]; P = 0.397). A similar trend was observed in all-cause mortality.

Conclusions: These results suggest that low Mg levels may be a predictor of CVE in hemodialysis patients without calcimimectis and the CVE benefits of Mg may be attenuated under the use of calcimimetics.



TH-PO140

Serum Magnesium and Progression of Coronary Artery Calcification: A Report from the Chronic Renal Insufficiency Cohort (CRIC) Study

Mehreen Mehmood,[1] Radhika Kanthety,[1] Zhengyi Chen,[2] Mahboob Rahman,[1] Mirela A. Dobre,[1] Lavinia A. Negrea.[1] *[1]University Hospitals, Cleveland, OH; [2]Case Western Reserve University, Cleveland, OH.*

Background: Magnesium may play a protective role against the progression of vascular calcification in chronic kidney disease (CKD), however the evidence remains scarce. Higher serum magnesium levels are consistently associated with a reduced volume of vascular calcification in CKD populations. This study aims to evaluate the association between serum magnesium level and progression of coronary artery calcification (CAC) in a cohort of individuals with CKD enrolled in the Chronic Renal Insufficiency Cohort (CRIC) study. We hypothesize that low serum magnesium level, is a risk factor for CAC progression.

Methods: Serum magnesium and CAC were measured in 862 CRIC participants at baseline and after 3 years. CAC was measured using electron beam or multidetector computed tomography and calculated using Agatston score. CAC progression was defined as follows: CAC> 0 at follow-up if CAC=0 at baseline; annualized change ≥10 Agatston units at follow-up if 0<CAC≤100 at baseline; and annualized percent change (annualized change in CAC score divided by the baseline CAC score) ≥ 10% at follow-up, if CAC > 100 at baseline. Logistic regression models were built to study the association of interest.

Results: The mean eGFR was 44±15ml/min per 1.73m^2, mean serum magnesium was 1.96± 0.28 mg/dL, and 42.7% participants had diabetes. A total of 412 (48%) participants experienced CAC progression. No significant correlation was observed between baseline magnesium level and total Agaston score (r=0.032, p=0.58). Compared to participants with high baseline magnesium level, those with low magnesium (<2 mg/dL) were more likely to have CAC >400 at baseline (59.3% vs 40.7%) but the difference was not statistically significant (p=0.62). Each mg/dL increase in magnesium level was associated with 17% lower but not statistically significant lower risk of CAC progression, in models adjusted for demographics, baseline co-morbidities, medications, calcium level, eGFR and proteinuria (OR 0.73; 95%CI: 0.32–1.64). Subgroup analyses by sex, race and CKD stages reveal similar findings.

Conclusions: In a cohort of patients with CKD stages 2-4, serum magnesium level was not associated with CAC progression. Further studies will be needed to test the magnesium's potential role to inhibit vascular calcification.

TH-PO141

Magnesium-Sensitive Changes in Serum Calciprotein Crystallization Test (T50): A Post Hoc Analysis from a Randomized Controlled Trial

Iain O. Bressendorff,[1,2] Daniel Cejka,[3] Andreas Pasch,[4,5] Morten Schou,[1] Lisbet Brandi,[2] Ditte Hansen.[1] *[1]Herlev Hospital, Herlev, Denmark; [2]Nordsjaellands Hospital, Hillerød, Denmark; [3]Ordensklinikum Linz GmbH Elisabethinen, Linz, Austria; [4]Calciscon AG, Biel, Switzerland; [5]Johannes Kepler Universitat Linz, Linz, Austria.*

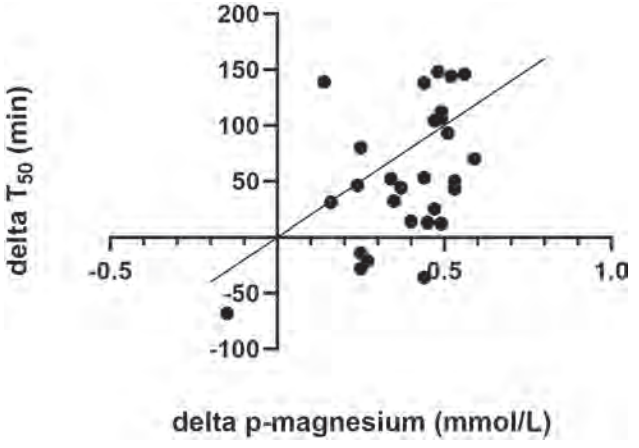
Background: Serum calciprotein crystallization test (T50) associates with risk of cardiovascular and all-cause mortality in end-stage kidney disease. We have previously demonstrated that increasing dialysate Mg also prolongs T50. We hypothesized that there is an inter-patient variability in responses in T50 to increases in plasma Mg with putatively "Mg sensitive" and "Mg resistant" patients.

Methods: Post-hoc analysis of a previous randomized controlled trial of increasing dialysate Mg from 0.5 mmol/L to 1.0 mmol/L. Based on *in vitro* data, we expected an increase in T50 of 20 min for every 0.1 mmol/L increase in plasma Mg. We plotted changes in T50 and plasma Mg for subjects randomized to dialysate Mg of 1.0 mmol/L to identify subjects with changes as expected (Mg-sensitive) or changes less than expected (Mg-resistant). We also plotted individual measurements of T50 and plasma Mg to visually inspect associations between the two.

Results: Among the 28 subjects analyzed, 13 (46%) were characterized as Mg-sensitive and 15 (54%) were characterized as Mg-resistant. Visual inspection of T50 plotted against plasma Mg showed linear associations for Mg-sensitive individuals versus scattered associations for Mg-resistant individuals. Mg-sensitive individuals had

significantly lower baseline T50 and fetuin-A, but no differences in plasma magnesium, phosphate, ionized calcium, bicarbonate, or albumin. Mg-sensitive individuals had significantly greater increases in T50 during high dialysate Mg of 1.0 mmol/L compared to Mg-resistant individuals despite similar increases in plasma Mg.

Conclusions: Patients with end-stage kidney disease have differential responses to T50 despite similar levels of plasma Mg, suggesting that some patients may benefit more than others from a targeted increase in plasma Mg. This suggests an opportunity for personalization of treatments targeting T50.



TH-PO142

Effect of Dialysate Bicarbonate on Calciprotein Crystallization Time (T50) in Hemodialysis Patients: The D-Bic Study

Daniel Cejka,[1] Peter S. Neufeld,[1] Andreas Pasch,[2,3] Edward R. Smith,[4,6] Martina M. Gaggl,[5] Maria C. Haller,[1] Jennifer D. Machacek.[1]
[1]Ordensklinikum Linz GmbH Elisabethinen, Linz, Austria; [2]Calciscon AG, Biel, Switzerland; [3]Johannes Kepler University, Faculty of Medicine, Departement of Physiology and Pathophysiology, Linz, Austria; [4]Royal Melbourne Hospital, Parkville, Department of Nephrology Victoria, Australia, Melbourne, VIC, Australia; [5]Center for Public Health, Public Health Nutrition, Medical University Vienna, Vienna, Austria; [6]Department of Medicine, University of Melbourne, Parkville, VIC, Australia.

Background: Short calciprotein crystallization time (low T50) is directly associated with increased risk of cardiovascular events and mortality. Higher serum bicarbonate levels consistently correlate with higher T50 time in observational studies. However, oral supplementation of sodium bicarbonate failed to increase T50 times in interventional studies in CKD patients. Here, we investigated whether increases in dialysate bicarbonate concentrations increase T50 times.

Methods: In a prospective, single center, single arm, interventional trial, dialysate bicarbonate was decreased from baseline settings to 27 mmol/l (D-Bic 27) in a step-wise fashion (2 mmol/l change per dialysis session), followed by a step-wise increase in dialysate bicarbonate settings to 37 mmol/l (D-Bic 37), over a course of 6 weeks. The primary endpoint was the change in T50 time between the D-Bic 27 and D-Bic 37 phase.

Results: Of 29 recruited patients, 24 completed the study per protocol. T50 time increased significantly from 246 ± 77 to 282 ± 81 minutes from the D-Bic 27 to the D-Bic 37 phase ($p<0.0001$). The hydrodynamic radius (size) of secondary calciprotein particles generated in the T50 test ($CPP\text{-}2_{Rh}$) did not differ significantly between the D-Bic 27 and D-Bic 37 phase (251± 75 vs. 240 ± 78 nm, p=0.27). Serum bicarbonate, serum pH, and intact parathyroid hormone (PTH) increased significantly, while ionized serum calcium decreased significantly from the D-Bic 27 to the D-Bic 37 phase. Serum potassium, phosphate and magnesium did not change significantly throughout the study.

Conclusions: Increases in dialysate bicarbonate led to significant increases in T50 time.

TH-PO143

ESKD, Calciphylaxis Subtypes, and Patient Demographics

Christopher El Mouhayyar, Aaron M. Seto, Houda Bouchouari, Tianqi Ouyang, Sagar U. Nigwekar. *Massachusetts General Hospital, Boston, MA.*

Background: Calciphylaxis is a rare life-threatening vascular calcification disease associated with morbidity and mortality. Calciphylaxis presents heterogeneous outcomes and poses challenges in management due to limited treatment options and poor prognosis. This study aims to assess the associations between End Stage Kidney Disease (ESKD), different calciphylaxis subtypes and demographics.

Methods: This is a prospective cohort study of calciphylaxis patients within the Partners Calciphylaxis Biorepository and Patient Registry between 2017 and 2023. We examined the associations between ESKD status, lesion location, clinical and histopathological characteristics.

Results: Among 166 adult patients with calciphylaxis, 112 had ESKD while 54 did not. Compared to non-ESKD calciphylaxis patients, ESKD patients were more likely to be Black (OR:5.20, 95% CI: 1.58,21.40, P =0.011), hypertensive (49% vs 28%, P=0.015), coronary artery disease (46 vs 28%, P=0.043), peripheral vascular disease (48%vs 24%, P=0.005). Upon diagnosis, 104 patients exhibited at least one lesion proximal to the elbows and knees and were classified as having central calciphylaxis distribution while 62 patients had lesions solely distal to the elbows and knees and were classified as having peripheral calciphylaxis distribution. Patients with peripheral lesions were more likely to be older (67 years [55, 73] vs (59 [49, 68], P=0.008), males (44% vs 27%, P=0.042), with indurations (77% vs 47% P<0.001), plaques (63% vs 40% P=0.009), and nodules (42% vs 13% P<0.001) and less likely to have a history of congestive heart failure (31% vs 51% P=0.017) compared to those with central lesions.

Conclusions: Our study identified associations between ESKD status and calciphylaxis lesion location with patient demographics and cutaneous lesion characteristics.

SEAPORT 1: An Open-label Study to Evaluate the Safety, Pharmacokinetics, and Pharmacodynamics of INZ-701 in Participants with ESKD Undergoing Hemodialysis: Interim Analysis

Asghar A. Chaudhry,[1] Steven Zeig,[4] Bruce J. Fisch,[2] Yves Sabbagh,[2] Kurt C. Gunter,[2] Sagar U. Nigwekar.[3] *[1]South Florida Nephrology Research, Coral Springs, FL; [2]Inozyme Pharma, Boston, MA; [3]Massachusetts General Hospital, Boston, MA; [4]Elixa, Hollywood, FL.*

Background: Calciphylaxis is a dire complication of end-stage kidney disease (ESKD) with high mortality and no approved therapies. It is characterized by calcification and occlusion of arterioles in the skin leading to painful lesions, ulceration, and infection. Plasma pyrophosphate (PPi), a critical inhibitor of ectopic vascular calcification, is low in chronic kidney disease (CKD) patients and even lower in ESKD patients, who are at highest risk of developing calciphylaxis. Moreover, lower PPi is associated with worse survival in calciphylaxis patients. The ectonucleotide pyrophosphatase/phosphodiesterase type 1 (ENPP1) enzyme is responsible for generating most of the body's PPi via catalysis of extracellular ATP. INZ-701 is a novel fusion protein comprised of functional ENPP1 enzyme fused to the Fc portion of human immunoglobulin 1. Treatment of a CKD rat model with INZ-701 prevented or reduced vascular calcification. Objective: To evaluate the safety, pharmacokinetics and pharmacodynamics of INZ-701 in patients with ESKD receiving hemodialysis. The primary endpoint is change from baseline in plasma PPi.

Methods: Open-label phase 1 trial of INZ-701 in individuals aged 18 – 69 years with ESKD receiving hemodialysis thrice weekly and who had low PPi (< 700 nM) at screening. Participants were administered 1.8 mg/kg of INZ-701 subcutaneously once weekly for four weeks.

Results: Thirteen participants were screened and 8 have been entered into the study to date. Median baseline age for entered participants was 67 years (range 28-69) and 5 participants (63%) were male. Six participants (75%) had type 2 diabetes. The majority of participants were Black or African American (n=5, 63%). Median (IQR) plasma PPi at baseline in the 8 entered participants was 281 nM (322). Median PPi for all screened patients was 502 nM (422).

Conclusions: Median PPi at screening in 13 patients with ESKD on hemodialysis was substantially lower than what is reported in healthy volunteers (1002-2169 nM; n=10), which supports previous findings implicating PPi in the pathophysiology of ESKD. INZ-701 safety, tolerability, pharmacokinetics, and pharmacodynamics results will be presented.

TH-PO145

Association of Damaged Cardiovascular-Bone-Skeletal Muscle Axis with All-Cause Mortality and CKD Progression in Patients with Predialysis CKD: The Fukuoka Kidney Disease Registry (FKR) Study

Shunsuke Yamada,[1] Hokuto Arase,[3] Shigeru Tanaka,[1] Kazuhiko Tsuruya,[2] Takanari Kitazono,[1] Toshiaki Nakano.[1] *[1]Kyushu University, Department of Medicine and Clinical Science, Fukuoka, Japan; [2]Nara Medical University, Department of Nephrology, Nara, Japan; [3]NHO Fukuokahigashi Medical Center, Department of Nephrology, Fukuoka, Japan.*

Background: The cardiovascular system, bones, and skeletal muscles are interrelated and often concurrently damaged in patients with chronic kidney disease (CKD). While organ-related associations such as the bone-vascular axis and osteosarcopenia have been proposed, the impact of combined disorders in these three systems on all-cause mortality and CKD progression in pre-dialysis CKD patients remains unclear.

Methods: We defined organ damage in bones, skeletal muscles, and the cardiovascular system as a history of fractures, low skeletal muscle mass, and cardiovascular disease, respectively. Skeletal muscle mass was estimated using Yamada's formula, with the first quartile classified as low skeletal muscle mass. A total of 3,792 pre-dialysis CKD patients were categorized into four groups based on the number of damaged organs: G1 (no damaged organ), G2 (one damaged organ), G3 (two damaged organs), and G4 (three damaged organs). We then evaluated the association between the number of damaged organs and all-cause mortality as well as composite renal events (defined as a 1.5-fold increase in serum creatinine, kidney transplantation, or initiation of dialysis).

Results: Over a 5-year observation period, 382 patients died, and 1,305 experienced composite renal events. The numbers of patients in the G1, G2, G3, and G4 were 2,168, 1,217, 364, and 43, respectively. Survival analysis showed that the adjusted hazard ratios (HRs) for all-cause mortality, using the G1 group as a reference, were: G2: 1.54 (95% CI: 1.16-2.06), G3: 2.07 (95% CI: 1.47-2.92), and G4: 3.54 (95% CI: 2.07-6.07). Similarly, the adjusted HRs for composite renal events were: G2: 1.25 (95% CI: 1.10-1.42), G3: 1.30 (95% CI: 1.07-1.59), and G4: 2.01 (95% CI: 1.24-3.26). When all-cause death was set as a competing risk, a Fine-Gray competing risk model showed a similar association between the number of damaged organs and the composite renal events.

Conclusions: The risk of all-cause mortality and CKD progression increases with the number of damaged organs in the cardiovascular, bone, and skeletal muscle axis in patients with pre-dialysis CKD. Protection of the cardiovascular-bone-skeletal muscle axis may be a therapeutic option for preventing death and ESKD in this population.

TH-PO146

Phosphate Loading per Nephron Predicts CKD Progression and All-Cause Death in Patients with Nondialysis-Dependent CKD: The Fukuoka Kidney Disease Registry (FKR) Study

Shunsuke Yamada,[1] Shigeru Tanaka,[2] Kazuhiko Tsuruya,[3] Takanari Kitazono,[1] Toshiaki Nakano.[1] *[1]Kyushu University, Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Fukuoka, Japan; [2]Fukuoka Dental College, Department of Medicine, Fukuouka, Japan; [3]Nara Medical University, Department of Nephrology, Nara, Japan.*

Background: CKD-MBD develops in the early stages of CKD and contributes to the increased risk of end-stage kidney disease and death. Thus, it is critical to identify new indicators that reflect early events of CKD-MBD and initiate appropriate interventions in the non-dialysis CKD population.

Methods: We examined 3,320 patients enrolled in the FKR study, a prospective observational study of patients with non-dialysis CKD stages G1–G5. We focused on the urinary phosphate excretion per nephron as an indicator of early CKD-MBD pathogenesis. Urinary phosphate excretion per nephron was determined by using the estimated urinary phosphate excretion divided by eGFR as a proxy for nephron number. Estimated phosphate excretion was calculated using estimated 24-hour creatinine (Cr) excretion and urinary Cr and phosphate concentrations. After patients were divided into quartiles(Q1-Q4) according to the baseline urinary phosphate loading per nephron, we determined the association of phosphate loading per nephron with the risk of all-cause death and composite kidney event using longitudinal data. The composite kidney event was defined as the development of end-stage kidney failure and/or a 1.5-fold increase in serum creatinine concentrations.

Results: Over 5 years, 1,132 patients developed a composite kidney event, and 295 died. Urinary phosphate loading per nephron elevated as early as an eGFR of 70 mL/min/1.73m^2 and preceded the changes in serum PTH, calcium, and phosphorus concentrations. Multivariate-adjusted Cox proportional hazard regression analyses revealed a significant association between an increased phosphate loading per nephron and a heightened risk of developing a composite renal event and all-cause death. The hazard ratios (95%CI) for all-cause death and composite kidney events in Q4 were significantly higher than those in Q1: 1.70 (1.01-2.85) and 1.57 (1.16-2.10), respectively. These associations were independent of the serum PTH, calcium, and phosphorus concentrations.

Conclusions: Phosphate loading per nephron may reflect the early stage of CKD-MBD pathophysiology and predict CKD progression and all-cause death in patients with non-dialysis CKD. Early intervention for phosphate overload may retard the progression of CKD and decrease the death risk in this population.

Getting Insights from Oral Metabolomics into Vascular Calcification among Patients with ESKD

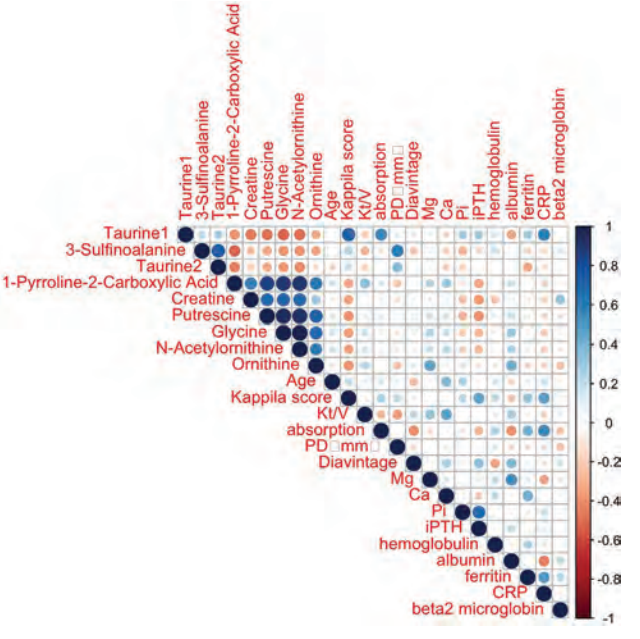
Wen Wen, Yuehong Li. *Beijing Tsinghua Changgung Hospital, Beijing, China.*

Background: Oral inflammatory diseases, chronic kidney disease (CKD), and vascular calcification (VC) are closely related. Here, we investigated the changes in oral metabolites caused by vascular calcification among patients with end-stage kidney disease.

Methods: Patients were divided into VC group (Kauppila score ≥ 8) and HC group (Kauppila < 8). The patients in the two groups were matched according to their age, gender, and diabetes status. Gingival crevicular fluid was extracted and non-target metabolomics was performed. Two normalization methods were used, one was the total amount normalization, and the other was the creatinine value normalization. Metabolites were compared between the two groups. Differential metabolites were included in the enrichment analysis to find the key metabolites and pathways. Pearson correlation analysis was performed between differential metabolites of key pathways involved in the enrichment analysis and clinical indicators.

Results: The gingival crevicular fluid samples of 30 patients (VC group 15 cases vs. HC group 15 cases) were examined. In enrichment analysis, 35 and 105 differential metabolites were observed. Four key metabolic pathways, including taurine and the secondary metabolism of taurine, arginine and proline metabolism, arginine biosynthesis, and glutathione metabolism, were discovered. It is shown that the key metabolites including taurine, 3-sulfinoalanine, 1-dihydropyrrolo-2-carboxylic acid, creatine, putamyldiamine, glycine, ornithine, and acetylornithine were found to be correlated with CKD-MBD parameters, inflammatory factors, and periodontal disease parameters.

Conclusions: Oral metabolites were diverse in ESRD patients with and without severe VC and linked closely to the CKD-MBD parameters, indicating the pivotal role of oral disease in the development of CKD-MBD.



Correlation analysis between metabolites involved in key pathways and clinical indicators

Detection of Medial Vascular Calcification in Patients with CKD Using Cost-Effective Classifiers

Bengt Lindholm,[1] Urszula Bialonczyk,[2] Malgorzata Debowska,[2] Abdul Rashid T. Qureshi,[1] Leon Bobrowski,[2] Magnus Soderberg,[3] Peter Stenvinkel,[1] Tomasz Lukaszuk,[4] Jan T. Poleszczuk.[2] *[1]Renal Medicine and Baxter Novum, Department of Clinical Science, Intervention and Technology, Karolinska Institutet, Stockholm, Sweden; [2]Nalecz Institute of Biocybernetics and Biomedical Engineering, Polish Academy of Sciences, Warsaw, Poland; [3]Pathology, Clinical Pharmacology and Safety Sciences, AstraZeneca R&D, Gothenburg, Sweden; [4]Faculty of Computer Science, Bialystok University of Technology, Bialystok, Poland.*

Background: Despite medial vascular calcification (mVC) being linked to high cardiovascular morbidity and mortality in chronic kidney disease (CKD) patients, identifying mVC remains challenging. This study evaluates the cost-effectiveness of various machine learning (ML) frameworks for mVC assessment using circulating biomarkers and traditional risk factors.

Methods: A dataset of 152 CKD patients without (n=93) or with (n=59) mVC was used as an input to classifiers combined with feature selection algorithms: 1) logistic regression (LR), 2) support vector machine (SVM), 3) random forest (RF), 4) elastic net (EN) and 5) relaxed linear separability (RLS). These methods selected features that inform about the mVC probability. Incremental cost-effectiveness ratio (ICER) was calculated for each framework, considering both performance and procedure costs. Prevalence rate and possible years gained were treated as unknown parameters.

Results: On the analyzed dataset, the number of features selected by the methods varied between 5 (LR) and 21 (SVM), but all classifiers offered similar predictive performance, Tab. 1. LR emerged as the most cost-effective option, Fig. 1.

Conclusions: The results provide novel insights into biomarkers related to mVC and support the use of ML algorithms as a complementary tool to imaging techniques. The study emphasizes considering cost-effectiveness when selecting classifiers, as minor performance improvements may not justify the additional costs of required inputs.

Mineral Bone Disease (MBD) and Glycocalyx Injury in CKD in the Dallas Heart Study (DHS)

Shota Watanabe,[1] Peter N. Van Buren.[1,2] *[1]The University of Texas Southwestern Medical Center, Dallas, TX; [2]VA North Texas Health Care System, Dallas, TX.*

Background: MBD in CKD causes vascular calcification as a cardiovascular (CV) disease mediator. High phosphate (Ph) and parathyroid hormone (PTH) promote calcification, while osteopontin (OPN) is a calcification inhibitor. In dialysis patients, high Ph also associates with endothelial cell dysfunction (ECD), which may further increase CV risk. We aimed to determine how OPN, Ph, and PTH associated with syndecan-1 (SDC1), an endothelial glycocalyx injury marker, in CKD patients enrolled in a large multiethnic cohort study.

Methods: We retrospectively analyzed baseline data of CKD patients (estimated glomerular filtration rate [eGFR] <60 mL/min or urine albumin/creatinine [UACR] >30 mg/g) enrolled in DHS. We used Pearson correlation for associations between serum SDC1, OPN, PTH, Ph, eGFR, UACR, and age. We used all variables in a linear regression model with SDC1 as the outcome also controlling for race, sex, and diabetes.

Results: In 171 participants (Table1), mean age was 47.9 (9) years, mean eGFR 86.0 (34) mL/min, and median UACR 59.5 (35, 198) mg/g. Log SDC1 correlated with log OPN (r=0.8, p<.0001; Fig1), log PTH (r=0.2, p=.03), and eGFR (r=-0.2, p=.004). OPN independently predicted SDC1 (β=0.6, p<0.001), but Ph and log PTH (p=.1, p=.2) did not.

Conclusions: In CKD patients (mostly early CKD), OPN independently and strongly predicted SDC1, an endothelial glycocalyx injury marker. While OPN inhibits calcification in the context of MBD, it may exacerbate ECD even in early CKD.

Fibroblast Growth Factor 23 (FGF-23) and Endothelial Cell Dysfunction (ECD) in the Dallas Heart Study Cohort

Peter N. Van Buren,[1,2] Jyothsna Gattineni.[1] *[1]The University of Texas Southwestern Medical Center, Dallas, TX; [2]VA North Texas Health Care System, Dallas, TX.*

Background: Mineral bone disease (MBD) and ECD are mortality risk factors that associate with each other in advanced chronic kidney disease (CKD). Phosphate (Ph) and parathyroid hormone (PTH) are late CKD MBD markers, but FGF23 is an early marker. Using data from Dallas Heart Study (DHS), a multi-ethnic cohort with largely preserved renal function, we assessed if FGF23 predicted ECD markers.

Methods: We measured FGF23 in stored DHS plasma. We compared demographic and lab measurements across FGF23 quartiles and used linear regression to identify associations with FGF23 and the following markers: asymmetric dimethylarginine (ADMA), vascular cell adhesion molecule (VCAM1), intracellular adhesion molecule (ICAM1), CD40 ligand, monocyte chemotactant protein 1 (MCP1), syndecan-1, and endoglin.

Results: In 1186 participants (37% male, 40% Black, 16% CKD), mean FGF23 was 44.0 (86) pg/mL. Across increasing FGF23 quartiles, coronary artery calcification, PTH, ADMA, MCP1, cholesterol, and CD40 ligand significantly increased while endoglin decreased (Table 1). ICAM1, VCAM1 and syndecan did not differ. Controlling for age, sex, race, diabetes, GFR, Ph, and PTH, log FGF23 independently predicted ADMA (β=0.03, p=.003), log syndecan-1 (β=0.1, p=.03), and log MCP1 (β=0.1, p=.04).

Conclusions: Multiple ECD markers associate with high FGF23. FGF23 independently predicts ADMA, syndecan-1, and MCP1 warranting prospective studies to determine if early MBD exacerbates ECD when renal function is normal or mildly reduced.

TH-PO151

Association between Serum Glycerol-3-Phosphate and Fibroblast Growth Factor 23 in Nondiabetic Incident Hemodialysis Patients

Shari J. Zaslow,[1,2] Scott M. Wilson,[2] Stephen M. Sozio,[3,4] Bernard G. Jaar,[3,4] Michelle M. Estrella,[5,6] Aline Martin,[7] Rulan S. Parekh,[8,9] Wei Chen.[2,10]; *[1]University of Vermont The Robert Larner MD College of Medicine, Burlington, VT; [2]Albert Einstein College of Medicine, Bronx, NY; [3]Johns Hopkins University, Baltimore, MD; [4]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [5]University of California San Francisco, San Francisco, CA; [6]San Francisco VA Health Care System, San Francisco, CA; [7]Northwestern University Feinberg School of Medicine, Chicago, IL; [8]Women's College Hospital, Toronto, ON, Canada; [9]The Hospital for Sick Children, Toronto, ON, Canada; [10]Montefiore Medical Center, New York, NY.*

Background: Glycerol-3-phosphate (G3P), a byproduct of glycolysis that can be derived from injured kidneys, has been identified as a stimulator of fibroblast growth factor-23 (FGF-23) production. Furthermore, G3P is strongly correlated with circulating FGF-23 in people without kidney disease and in the setting of AKI. Since FGF-23 increases risk of mortality in patients with ESKD, understanding the relationship between G3P and FGF-23 may inform our diagnostic and treatment practices.

Methods: In a cross-sectional study of 99 nondiabetic patients with ESKD on incident hemodialysis from the Predictors of Arrhythmic and Cardiovascular Risk in End Stage Renal Disease (PACE) cohort, we measured baseline G3P by mass spectrometry and C-terminal FGF-23 by ELISA. Participant characteristics were compared among G3P terciles using the Fisher's exact or Kruskal-Wallis's tests. Linear regression was used to examine the association between G3P terciles with log transformed FGF-23 while adjusting for sociodemographics, prevalent coronary artery disease, phosphorus, and parathyroid hormone.

Results: The median age of participants was 54 years (IQR 44-63), 38% were women, 71% were Black, 27% had coronary artery disease. Median FGF-23 level was 777 (IQR 222-1310) RU/mL. Participants with higher G3P were younger and had higher levels of serum phosphate and intact parathyroid hormone. Higher G3P was associated with higher FGF-23 in both unadjusted and adjusted models (p<0.001 and 0.004, respectively). Those with G3P in the highest tercile had 92% higher level of FGF-23 (95% CI: 5%, 252%; p=0.004) compared to participants within the lowest G3P tertile.

Conclusions: Higher G3P is positively associated with higher FGF-23 in those with ESKD. Our findings suggest that there may be a kidney-independent role of G3P in FGF-23 regulation. Future studies will need to address the relationship between G3P and FGF-23 with earlier stages of CKD.

TH-PO152

Soluble Klotho and Baseline Clinical Characteristics in the Systolic Blood Pressure Intervention Trial

David A. Drew,[1] Johanne V. Pastor,[3] Xilong Li,[3] Joachim H. Ix,[2] Mark J. Sarnak,[1] Orson W. Moe,[3] Javier A. Neyra.[4] *[1]Tufts Medical Center, Boston, MA; [2]UC San Diego Health, San Diego, CA; [3]The University of Texas Southwestern Medical Center, Dallas, TX; [4]The University of Alabama at Birmingham, Birmingham, AL.*

Background: αKlotho is produced within the kidney and is released into circulation as soluble klotho. Animal data demonstrate that klotho is directly correlated with GFR. Due to promising preclinical data, there is significant interest in klotho as a potential biomarker in chronic kidney disease.

Methods: Soluble klotho was measured by two distinct assays using baseline samples from the Systolic Blood Pressure Intervention Trial. All individuals had chronic kidney disease (eGFRcr-cys < 60 ml/min/1.73m²) and never-thawed serum samples available for klotho measurement. The first assay was an immuno-precipitation immunoblot assay (IP-IB) utilizing two separate anti-klotho antibodies, while the second assay was a commercially available ELISA (IBL). Demographics, clinical characteristics, and laboratory data were examined for linear trends across quartiles of klotho concentrations.

Results: There were 2291 subjects with klotho IPIB measures and 1216 subjects with klotho ELISA measures. The intra-assay CVs of the klotho assays were 6.9% and 6.1% (IPIB & ELISA respectively). The median [25th, 75th] klotho concentration was 11.0 pM [7.7,16.0] for the IP-IB and 4.6 pM [3.4,6.6] for the ELISA. For both assays, higher quartiles of klotho were significantly associated with higher eGFR. For the IPIB, higher klotho was associated with a lower proportion of current smokers and loop diuretic use, and fewer number of anti-hypertensives. Higher IP-IB klotho was associated with higher serum magnesium, calcium, and bicarbonate, higher urine calcium, and lower serum FGF-23. For the ELISA assay, there was a similar but weaker association with mineral metabolism markers.

Conclusions: Both klotho assays had acceptable performance and results were consistent with known klotho pathobiology. The IP-IB klotho concentrations were more consistently associated with other measures of mineral metabolism.

Expansion of Visceral Adipose Tissue over 12 Months Is Associated with Changes in Leptin and Fibroblast Growth Factor 23 (FGF-23) and Alterations in Vitamin D Metabolism in Patients with ESKD

Rachel M. Holden,[1] Patrick A. Norman,[2] Martin Kaufmann,[1] Mandy E. Turner,[5] Louise M. Moist,[3] Deborah Lynn Zimmerman,[4] Emilie C. Ward,[1] Martin P. Petkovich,[1] Michael A. Adams,[1] Marina Mourtzakis.[6] *[1]Queen's University, Kingston, ON, Canada; [2]Kingston Health Sciences Centre, Kingston, ON, Canada; [3]Western University, London, ON, Canada; [4]University of Ottawa, Ottawa, ON, Canada; [5]Harvard University, Cambridge, MA; [6]University of Waterloo, Waterloo, ON, Canada.*

Background: Visceral adipose tissue (VAT) is hormonally active. Leptin, produced by adipocytes, is a cytokine-like hormone that is increased with obesity. Leptin stimulates FGF-23 expression in bone and decreases kidney expression of CYP27B1 in leptin-deficient mice. The objective was to examine the relationship between visceral and subcutaneous adipose tissue and changes over 12 months with leptin, FGF-23, and vitamin D metabolism through assessment of vitamin D metabolite (VMR) ratios of $25(OH)_2D_3$ and $1,25(OH)_2D_3$ in patients with ESKD.

Methods: Visceral (VAT) and subcutaneous (SAT) adipose tissue cross sectional area (CSA) was assessed by computed tomography at the third lumbar vertebra at baseline and 12 months in hemodialysis patients. Serum vitamin D metabolites were measured by LC-MS/MS and leptin and iFGF-23 were measured by ELISA at baseline and 12 months.

Results: There were 28 participants, 61% with diabetes. At baseline, VAT CSA was associated with higher $1,24,25(OH)_3D_3$:$1,25(OH)_2D_3$ VMR with (r=0.43, p=0.04) and without (r=0.46, p=0.02) adjustment for iFGF-23. Increase in VAT was significantly associated with increase in leptin (r=0.6, p<0.001) and iFGF-23 (r=0.42, p<0.05), as well as increases in the $25(OH)D_3$:$1,25(OH)_2D_3$ VMR (r=0.5, p<0.05) and $1,24,25(OH)_3D_3$:$1,25(OH)_2D_3$ VMR (r=0.5, p<0.05). Participants with an increase in VAT over 12 months (n=17) had significantly greater percent increase in leptin (22.4 [-33.0, 113.3]) and FGF-23 (94.8[26.4,208.9]) compared to those where VAT decreased (n=10) (-54.8 [-58.2, 11.1], p=0.03 for leptin) and -3.0[-31.7, 68.9], p=0.02 for FGF-23. In a linear regression model using log-transformed variables, a 10% increase in the change leptin was associated with a 1.9% increase in the change in FGF-23 (p=0.035) after adjustment for baseline FGF-23 and PTH. In contrast to VAT, SAT CSA was not associated with any VMR at baseline and there was no difference in leptin, FGF-23 or in any VMR between participants who gained SAT versus those where SAT decreased.

Conclusions: VAT may contribute to calcitriol deficiency in patients with ESKD. Expanding VAT appears to enhance FGF-23 regulation of vitamin D metabolism possibly mediated by leptin.

Fluorine F 18 Sodium-Fluoride Positron Emission Tomography to Study Renal Osteodystrophy and Aortic Microcalcification in Patients with CKD: A Pilot Study

Aspan M. Shokrekhuda,[1] Rylen Stratford,[1] Wenzhu Mowrey,[2] Na Song,[1] Kexin Zhang,[2] Sara Saini,[2] Mario T. Didea,[1] Gabriel K. Duah,[1] Nicholas Sibinga,[2,1] Jeffrey M. Levsky,[1] Mark Travin,[1] Wei Chen.[2,1] *[1]Albert Einstein College of Medicine, Bronx, NY; [2]Montefiore Medical Center, New York, NY.*

Background: Recent advances in positron emission tomography (PET) may accelerate the adoption of ^{18}Fluorine-sodium fluoride (^{18}F-NaF) PET as a clinical diagnostic tool for renal osteodystrophy and arterial micro- or early calcification in CKD. Herein, we aimed to define the optimal timing of ^{18}F-NaF PET imaging and show its feasibility in patients with moderate CKD.

Methods: In 7 patients with CKD 3b-4 and 3 healthy controls, we acquired a 30-min dynamic scan followed by 3 static scans 15 min after the injection of ^{18}F-NaF. ECG-gated CT was done to detect macro- or advanced calcification in coronary arteries (CAC). ^{18}F-NaF uptake was quantified for regions over bilateral kidneys, lumbar spine, and lumbar aorta using tissue-to-background ratios (TBRs), which were calculated by dividing standardized uptake values (SUVs) of the regions by the SUV of reference blood pool. The Mann-Whitney U tests were used for group comparisons.

Results: Median (IQR) $eGFR_{Cys\text{-}Cr}$ for CKD patients (age: 54-80) and controls (age: 57-69) was 40 (32-43) and 95 (64-103) ml/min/1.73m^2, respectively. CKD patients had a significantly slower renal clearance of ^{18}F-NaF than controls (median biological half-life: 20 vs. 8 min, p=0.02). Time to reach optimal TBRs at lumbar spine was similar (43 vs. 44 min, p>0.99). Among CKD patients (n=7), there was a trend toward significance in correlation between mean TBR in lumbar spine at 60-min and intact PTH levels (spearman r=0.75, p=0.07). Median (IQR) Agaston CAC score was 473 (30-559), and among those with CAC (n=8), peak TBR in lumbar aorta at 60-min was positively correlated with CAC score (spearman r=0.79, p=0.048).

Conclusions: We report for the first time the renal clearance kinetics of ^{18}F-NaF and define the optimal time for its PET imaging in people with moderate CKD. We also demonstrated the feasibility of using ^{18}F-NaF PET as a promising diagnostic tool for evaluating both renal osteodystrophy and aortic micro-calcification.

Bone Histomorphometry in Patients with CKD Stage 2-5ND with or without Bone Loss Defined by Bone Densitometry

Karla M. Alves,[1] Fellype Barreto,[2] Cássia G. Santos,[2] Maria Eugenia F. Canziani,[1] Aluizio B. Carvalho.[1] *[1]Universidade Federal de Sao Paulo, São Paulo, Brazil; [2]Universidade Federal do Parana, Curitiba, Brazil.*

Background: Bone biopsy followed by histomorphometry is the gold standard for diagnosing renal osteodystrophy. New evidence has shown that bone mass loss, diagnosed by bone densitometry (DXA), could estimate the fracture risk in patients with CKD stages 3a-5D. However, there is no consensus on the relationship between DXA and bone histomorphometry in this population. This study compared bone histomorphometry in patients with CKD 2-5ND who had or did not have DXA-identified bone mass loss.

Methods: This cross-sectional study includes 50 asymptomatic patients with CKD stage 2-5ND, aged 18-70 ys. The exclusion criteria were infectious, inflammatory or neoplastic diseases, use of phosphate binders, vitamin D, corticosteroids, or bisphosphonates. Clinical evaluation included laboratory tests, DXA, and bone biopsy followed by histomorphometric analysis, proposed by ASBMR. Undecalcified bone samples were submitted to histomorphometry using the semiautomatic system Osteomeasure®. Bone mineral density (BMD) by DXA (g/cm^2), was measured at the lumbar spine (L1L4) and femoral neck (FN) on the densitometer LUNAR®. Bone loss was defined as a BMD T-score less than -1.0 SD for young subjects.

Results: A total of 50 patients, 52±10 ys, 68% men, 30% diabetics, with eGFR=34±16mL/min/1.73m^2 was included. BMD was 1.18±0.19 and 0.93±0.15g/cm2 (L1L4 and FN, respectively). BMD reduction was observed in 40% of patients in L1L4 and FN. Patients with reduced BMD, compared with those without, showed in L1L4 an increased osteoblastic (2.70±2.69 vs 1.24±1.58%;p=0.04), osteoclastic (10.5±6.5 vs 6.0±5.7%;p=0.01), and eroded (1.12±0.78 vs 0.47±0.69%;p<0.01) surfaces, respectively. Moreover, increased fibrosis (0.08±0.1 vs 0.02±0.04%;p=0.02) and bone formation rate (0.035±0.030 vs 0.014±0.015μ^3/μ^2/d;p<0.01) were observed in patients with reduced BMD. Patients with reduced BMD in FN, compared with those without, showed decreased trabecular bone volume (14.2±4.7 vs 19.1±5.5%;p<0.01) and trabecular number (1.19±0.34 vs 1.51±0.36N/mm;p<0.01), and increased trabecular separation (781.6±251.8 vs 576.1±189.6mm;p<0.01), respectively.

Conclusions: Bone loss in the lumbar spine is associated with mild hyperparathyroid bone disease, while in the femoral neck, it is associated with decreased bone volume and altered bone microarchitecture.

Bone Mineralization Deficit in Patients on Dialysis: Who Has It and Who Doesn't? What Are the Differences?

Bruna R. Rodrigues,[1] Ana Paula Gueiros,[1] Vanda Jorgetti,[2] Jose E. Gueiros.[1] *[1]Hospital das Clinicas, Recife, Brazil; [2]Universidade de Sao Paulo Faculdade de Medicina, Sao Paulo, Brazil.*

Background: Bone mineralization is essential for bone health. Defective bone mineralization can be present both in diseases with high bone turnover, such as mixed disease (MD), and in low bone turnover, in osteomalacia (OM). The objective of this study was to assess the factors associated with defective bone mineralization found in the bone biopsy (BB) of patients on dialysis.

Methods: This was a retrospective, cross-sectional study. The medical records were reviewed of patients on dialysis, who underwent BB, from January 2004 to January 2024. The clinical parameters were: age, sex, time on dialysis, etiology of chronic kidney disease, previous use of aluminum-based chelators, diagnosed with osteoporosis, occurrence of fractures, presence vascular calcification and parathyroidectomy. Laboratory parameters were: total calcium, phosphorus (mg/dL), alkaline phosphatase (ALP) (U/L), intact parathyroid hormone and 25OH vitamin D. The number of times that ALP was above the upper limit of normality (xALP) was used. A transiliac bone biopsy was performed, after double labeling with tetracycline. A comparative analysis was conducted between patients with defective mineralization (Group 1) and patients without (Group 2). Group 1 was made up of patients with MD and OM. Group 2 corresponded to patients with osteitis fibrosa and adynamic bone disease. Univariate and multivariate analyzes were performed to verify factors associated with defective mineralization.

Results: A total of 263 patients were studied, with a median age of 47 years, 87 (33%) of whom belonged to Group 1. Patients in Group 1 differed from those in Group 2 because they had been on dialysis for a longer period of time (years) (10 x 9; p=0.023); they presented lower serum phosphorus (5.1 x 5.9; p<0.001), a higher ALP level (xALP 2.28 x 1.31; p<0.001) and less aluminum toxicity (34.5% x 52.3%; p=0.006). In the multivariate analysis, phosphorus (OR 0.78, 95% CI 0.64 - 0.93; p=0.008) and ALP (xALP OR 1.21.95% CI 1,08 - 1.38; p=0.002) remained independently associated with defective mineralization.

Conclusions: Our results have demonstrated the importance of phosphorus for bone mineralization and have confirmed the role of ALP as a marker for defective mineralization. In this study, aluminum toxicity was not associated with defective mineralization

Serum Alkaline Phosphatase Is Associated with Mortality and the Incidence of Hip Fracture in Patients on Dialysis: A Nationwide Cohort Study in Japan

Yukio Maruyama,[1] Akio Nakashima,[1] Masanori Abe,[2] Norio Hanafusa,[3] Shigeru Nakai,[4] Takashi Yokoo.[1] *[1]Division of Nephrology and Hypertension, The Jikei University School of Medicine, Tokyo, Japan; [2]Division of Nephrology, Hypertension and Endocrinology, Nihon University School of Medicine, Tokyo, Japan; [3]Department of Blood Purification, Kidney Center, Tokyo Women's Medical University, Tokyo, Japan; [4]Department of Clinical Engineering, Fujita Health University, Aichi, Japan.*

Background: The monitoring of serum alkaline phosphatase (ALP) is recommended in the management of chronic kidney disease-mineral bone disorder (CKD-MBD) because of its association to poor outcome among dialysis patients. However, this association is thought to be changed due to several advances in the management for CKD-MBD in the decade.

Methods: Baseline data of 241,670 dialysis patients (age, 69 ± 12 years; male, 65.9%; median dialysis duration, 68 months) were extracted from a nationwide dialysis registry in Japan at the end of 2019. Outcomes, including all-cause mortality (ACM), cardiovascular mortality (CVM) and the hip fracture, were then evaluated using the registry at the end of 2020 and 2021. ACM was assessed using Cox regression analysis, whereas CVM and incidence of hip fracture were assessed using competing-risks regression analysis.

Results: Within two year, a total of 40,449 (16.7%) died, including 13,562 (5.6%) of CV deaths. Additionally, 4,136 (2.4%) suffered hip fracture. Higher serum ALP was independently associated with higher ACM, CVM and higher incidence of hip fracture, however the effect on CVM was marginal (hazard ratio [HR] 1.18, 95% confidence interval [CI] 1.15 to 1.21, sub-HR [SHR] 1.04, 95%CI 1.002 to 1.09 and SHR 1.27, 95%CI 1.18 to 1.37, respectively). The association between serum ALP and ACM and CVM differed according to intact parathyroid hormone (PTH) levels.

Conclusions: Higher serum ALP was independently and linearly associated with higher ACM, CVM and higher incidence of hip fracture in Japanese dialysis patients. Additionally, these associations differed by intact PTH. These findings did not change, in spite of the development of the management for CKD-MBD in the decade.

Presence and Progression of Changes in Bone Mass, Bone Quality, and Vascular Calcifications in Patients with Moderate to Advanced Reduction in Kidney Function

Hartmut H. Malluche,[1,3] Qi Qiao,[4,5] Jin Chen,[4,5] Mohamed Issa,[2] Florence Lima.[1,3] *[1]University of Kentucky College of Medicine, Lexington, KY; [2]University of Kentucky Department of Radiology, Lexington, KY; [3]University of Kentucky Division of Nephrology Bone and Mineral Metabolism, Lexington, KY; [4]University of Kentucky Department of Internal Medicine, Lexington, KY; [5]University of Kentucky Division of Biomedical Informatics, Lexington, KY.*

Background: CKD patients have serum, bone and vascular abnormalities presenting as CKD-Mineral and Bone Disorder (MBD). This study sought to identify the parameters with the greatest relative impact on progression of CKD-MBD.

Methods: This prospective study measured the impact of 262 parameters including serum markers, clinical variables and bone parameters on vascular calcifications and bone quality and quantity at baseline and after 2-3 years. These impacts were assessed using machine learning, a subset of artificial intelligence analyses.

Results: Baseline kidney function values ranged from an estimated glomerular filtration rate (eGFR) 18–70 ml/min, it declined in 52% of subjects by at least 3.3% annually during the study. Machine learning analyses was able to detect relationships between annual changes in eGFR as low as 1% annually with decreases in hip bone mineral quantity, bone mineral crystallinity and a serum resorption marker (TRAP-5b). Arterial calcifications were associated with collagen crosslinking heterogeneity, serum phosphorus level, diuretic use and atorvastatin treatment. Baseline collagen crosslinking heterogeneity was an important factor impacting progression of coronary, but not aortic calcification. Baseline serum phosphorus was a factor associated with progression of arterial calcification (Fig. 1). Median serum phosphorus levels starting as low as 4.0 mg/dl impacted progression of arterial calcification.

Conclusions: Identification of these parameters enhances our understanding of the breadth of abnormalities before dialysis requirements. Attention to these abnormalities in mild to moderate loss of kidney function should improve the management and quality of life for patients with CKD.

SGLT2 Inhibitors and Fracture Risk in Individuals with Advanced CKD

Rochell Issa,[1] Yasameen Fardi,[2] Andrei Brateanu,[1] Lavinia A. Negrea,[2] Mirela A. Dobre.[2] *[1]University Hospitals, Cleveland, OH; [2]Cleveland Clinic, Cleveland, OH.*

Background: The risk of fracture in elderly individuals with advanced chronic kidney disease (CKD) treated with sodium-glucose cotransporter-2 inhibitors (SGLT2i) is debated.

Methods: In this retrospective cohort study of electronic health records (EHRs) of approximately 105.3 million patients from 61 healthcare organizations from the US Collaborative Network TriNetX, a prevalent new-user design was applied. Two cohorts of adults age 65 or older, with CKD stages 4, 5, and 5D were assembled between January 2014 and December 2019, with follow-up until April 2024. The cohort of patients initiated on SGLT2i was matched in a 1:1 ratio, to a cohort of patients not on SGLT2i, but otherwise prescribed the same background drugs, duration of background drugs, co-morbidities, and time conditional propensity score. Cox proportional hazards models were fitted to estimate the hazard ratio (HR) and 95% confidence interval (CI) of major central or peripheral fractures separately at 6 months, 1 and 5 years.

Results: We identified a total of 18,391 (with CKD stage 4 and 5) and 11,084 (with CKD-5D) new users of an SGLT2i. The 6 month, 1 and 5 year risks of a central or peripheral fragility fracture did not significantly differ between new users of SGLT2i versus non-users (Table). Individuals with CKD 5D demonstrated the same trend. Similar results but with wider confidence intervals were obtained in analyses restricted to Canagliflozin use across all CKD stages and fracture types.

Conclusions: In this large US cohort, the use of SGLT-2i was not associated with an increased risk of either central of peripheral fractures in individuals with advanced CKD stages 4, 5, or 5D.

DKK1 Expression in Osteocytes in Patients with Type 2 Diabetes and CKD-MBD

Aline A. Deus, Cleonice Silva, Ivone B. Oliveira, Luciene dos Reis, Wagner Dominguez, Rosa M. Moyses, Vanda Jorgetti. *Laboratorio de Fisiopatologia Renal, Hospital das Clínicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo, Brazil.*

Background: Chronic kidney disease mineral bone disorder (CKD-MBD) is influenced by factors such as age, race, CKD etiology, hormones, dialysis modality. Proteins expressed in osteocytes emerged as important players in bone tissue of CKD-MBD patients as FGF23, sclerostin, DKK1, RANKL, and OPG. However, little is known about the effects of these proteins on bone tissue in patients with type 2 diabetes (DM2) and CKD-MBD.

Methods: 30 DM2 hemodialysis patients were matched with CKD patients due to other etiologies by age, sex, and time on dialysis. All underwent bone biopsies with histomorphometric analysis. Osteocyte protein expression for DMP1, MEPE, Sclerostin, FGF23, RANKL, and DKK1 was studied through immunohistochemistry.

Results: Table 1 shows that DM2 patients have lower PTH and higher BMI. Bone histomorphometry showed that bone formation parameters and Oc.S/BS were lower in DM patients. We found a significant increase in DKK1 expression in DM2 patients.

Conclusions: DKK1, known as an inhibitor of Wnt/Bcatenin pathway, was increased in bone tissue of DM patients. Although BV/TV wasn't different between the groups, formation parameters were decreased in DM patients, suggesting that DKK1 may be involved in low bone turnover observed in DM patients.

TH-PO161

Multidisciplinary Team Evaluation of Bone Health, Fracture Risk, and Incidence of Frailty in Patients on Haemodialysis

Varisha Shahzad, Lucy E. Collins, Lynn Redahan. *Mater Misericordiae University Hospital, Dublin, Ireland.*

Background: Bone disease is prevalent in patients with chronic kidney disease on dialysis (CKD-5D). It can lead to fragility fractures. The KDIGO guidelines suggest that patients with CKD G3a–G5D with evidence of mineral bone disease (MBD) and/or risk factors for osteoporosis, undergo a fracture risk assessment, if results will impact treatment decisions. Frailty is also a known risk factor for fragility fractures. The clinical frailty scale (CFS) is a nine-point validated outcome measure that is used to measure cognition, function, co-morbidities, and mobility in patients over 65 years. The aim of our service evaluation was to assess the fracture risk using the FRAX® tool for our HD patient cohort and to identify incidence of frailty using the CFS in those aged over 65 years.

Methods: In total, 76 chronic haemodialysis (HD) patients were included for the assessment of fracture risk. Acute dialysis patients were excluded. The FRAX score, the use of bone protection, and results of DEXA scanning (where available) were recorded for all patients. The CFS was calculated for 37 HD patients over the age of 65 using available clinical information. eMed and local databases were used to collect data.

Results: Average risk of major osteoporotic fracture was 10.1% and average risk of hip fracture was 4.03%. Out of 76 patients, 15 patients had a DEXA scan performed. Only three patients were in receipt of treatment with denosumab. A high incidence of frailty was recorded in the 37 HD patients aged >65 years, with 73% of patients recording a CFS of 5 (mild frailty) or greater which is significantly higher than the prevalence of frailty (7.0%) among community-dwelling individuals aged 60 years or older.

Conclusions: This data reveals a high fracture risk amongst incident HD patients. The low proportion of patients prescribed specific treatment, such as denosumab, probably reflects the challenges of diagnosing and treating low bone mineral density (BMD) in this cohort. The prevalence of frailty was high in the subgroup of elderly HD patients. Features of frailty overlap with risk factors for fragility fractures; this highlights the importance of providing patients with an integrated, multidisciplinary management plan to reduce the risk of fragility fracture, targeting CKD-MBD, low BMD and frailty.

TH-PO162

Clinical Implications of Radiopharmaceutical Uptake in the Skull as a New Marker of CKD-MBD: Findings of Bone Scintigraphy

Keunyoung Kim,[1,2] Sang Heon Song.[1,2] *[1]Pusan National University School of Medicine, Busan, Republic of Korea; [2]Pusan National University Hospital, Busan, Republic of Korea.*

Background: The aim of this study is to evaluate the potential role of radiopharmaceutical uptake in skull using bone scintigraphy as a new objective maker for CKD-MBD.

Methods: We retrospectively reviewed 122 CKD patients (M:F, 70:52) who were evaluated with bone scintigraphy. The control of 195 subjects (M:F, 66:129) who have no evidence of disease state of the breast cancer for female and the prostate cancer for male were also recruited. The quantitative indices were defined as the radiopharmaceutical uptake in skull and the ratio of the skull to the ilium (SIR). The bone mineral density (BMD) values and trabecular bone score (TBS) were acquired from dual energy X-ray absoroptiometry (DXA).

Results: In all enrolled CKD patients, median TBS showed deteriorated state compared with control group. The SIR had negatively correlation with DXA values; lumbar spine (r =-0.309, P<0.001); femoral neck (r=-0.262, P<0.001), total femur (r =-0.264, P<0.001) and TBS (r=-0.251, P<0.001). SIR and TBS were remained as the independent variables showed significant correlation with levels of parathyroid hormone, calcium and creatinine in CKD patients using multiple regression.

Conclusions: The SIR was significant for the assessment of metabolic status of CKD-MBD and may therefore potentially be used as an objective tool for the assessment of bone health in CKD patients.

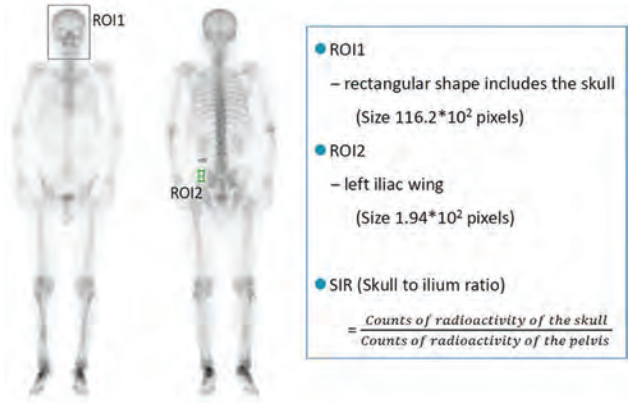

Figure 1. Quantitative Analysis of Bone scan

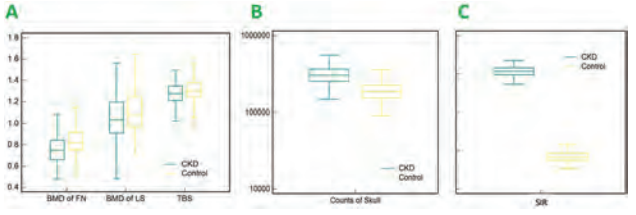

Figure 2. Representative results from the analysis

A. All values from DXA were significantly lower in the CKD patients compared with the control group.

B. The radioactivity counts in the skull was significantly higher in the CKD patients.

C. The normalized value of SIR showed exaggerated the difference between CKD and control.

Low Muscle Mass Is Associated with Low Bone Mineral Density in Patients with CKD Stages G4-5

Anahita Rashid,[1] Sabina C. Hauge,[1] Anders Nordholm,[1,2] Anne Sofie Fredberg Jørgensen,[4] Subagini Nagarajah,[4] Bo Zerahn,[5] Charlotte Suetta,[6] Morten Frost,[3,7] Ditte Hansen.[1,8] *[1]Department of Nephrology, Herlev and Gentofte, Herlev, Denmark; [2]Department of Nephrology, Rigshospitalet, Copenhagen, Denmark; [3]Department of Endocrinology, Odense University Hospital, Odense, Denmark; [4]Department of Nephrology, Odense University Hospital, Odense, Denmark; [5]Department of Nuclear Medicine, Herlev & Gentofte Hospital, Herlev, Denmark; [6]Geriatric Research Unit, Department of Medicine, Herlev & Gentofte Hospital, Herlev, Denmark; [7]Osteoporosis Clinic & Clinic for Molecular Endocrinology, Denmark; [8]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark.*

Background: Patients with chronic kidney disease (CKD) experience a decrease in bone mineral density (BMD), which raises their risk of fractures. Preclinical studies have shown a cross-talk between bone and muscle, emphasizing the importance of investigating the relationship between muscle mass and BMD in patients with CKD. Sarcopenia a condition characterized by low muscle mass and strength is common in CKD. CKD-related sarcopenia is believed to develop more rapidly and occur earlier in adult life, further increasing the risk of fractures in patients. Therefore, this study aimed to explore the association between muscle mass and BMD in patients with CKD.

Methods: This cross-sectional study included patients with CKD G4-5. All patients were examined by whole-body dual-energy x-ray absorptiometry (DXA). BMD of the spine and hips were determined. The muscle mass was measured as the appendicular skeletal muscle mass (ASMM). Linear regression analysis was performed to explore the association between BMD and ASMM, and multivariate linear regression analysis was performed, adjusting for age, gender, body mass index (BMI), and level of 25-OH-Vitamin D.

Results: We included 140 patients; 66 (47%) were female with a mean age of 68 (SD 13) years and a mean eGFR of 18 (SD 7) ml/min/1.73m^2. Thirty-five patients (25%) had a BMD of <-2.5 standard deviations below peak bone mass in at least one site (T-score). The mean ASMM was 21 kg (SD 6). Thirty-six (26%) patients had an ASMM lower than the European Working Group on Sarcopenia in Older People cut-off point. Unadjusted regression analysis revealed a significant positive association between both the right femural neck and ASMM (β=0.0175; $p < 0.001$) and the lumbar spine (L1-4) and ASMM $\beta = 0.04$; $p = 0.04$), which remained statistically significant after adjusting for factors that influence BMD, such as gender, BMI, and 25-OH-Vitamin D (right femural neck BMD β=0.01; p=0.002, BMD of the lumbar spine β= 0.04; p=0.02).

Conclusions: In patients with CKD G4-5, low appendicular skeletal muscle mass was associated with low bone mineral density in the hip and spine. The increased fracture risk in patients with CKD may be due to the co-occurrence of osteoporosis and sarcopenia, i.e., osteosarcopenia, although this requires further investigation.

Sustained Phosphate Reduction Assessed by Phosphate Area under the Curve with Tenapanor Is Associated with Reduced Fibroblast Growth Factor 23 in Patients with CKD and Hyperphosphatemia on Dialysis

Kevin J. Martin,[1] Simon Higgins,[2] Yang Yang,[2] David P. Rosenbaum,[2] David M. Spiegel.[2] *[1]Saint Louis University School of Medicine, St Louis, MO; [2]Ardelyx Inc, Waltham, MA.*

Background: The 2017 KDIGO CKD-MBD guidelines recommend that strategies for managing hyperphosphatemia (HP) be based on the use of serial measurements. Average phosphate (P) area under the curve (AUC) has been identified as a stronger predictor of outcomes than other P estimates. Intact fibroblast growth factor 23 (iFGF23) is elevated in end-stage kidney disease and is associated with increased cardiovascular mortality, but is often not well correlated to single-point estimates of P. Tenapanor (TEN) is approved to reduce serum P in adults with CKD as add-on therapy in patients (pts) who have an inadequate response to P binders (PBs) or who are intolerant of any dose of PBs. We used P AUC to assess whether better long-term P control with TEN is associated with lower iFGF23.

Methods: In a secondary analysis of the Ardelyx-supported PHREEDOM study, a 52-week, phase 3 trial of TEN as a monotherapy for HP in adults on maintenance dialysis, pts with P ≥6.0 and ≤10.0 mg/dL and a P increase ≥1.5 mg/dL after PB washout were treated for 26 weeks with TEN 30 mg bid during an open-label randomized treatment period (RTP). Correlation analyses between average daily P AUC above 4.5 mg/dL over the RTP and iFGF23 at the end of the RTP were performed along with summaries of changes in iFGF23 by P AUC categories.

Results: In the full analysis set (n=407), TEN reduced P by 1.3 (SD: 1.8) mg/dL on average at the end of the RTP. Median iFGF23 was reduced from 6417.5 pg/mL at baseline to 5051.6 pg/mL at the end of the RTP (median percent change: −23.2%). There was a positive correlation between average daily P AUC and iFGF23 (ρ=0.499, P<0.001). A trend of higher median iFGF23 was seen across categories of P AUC. Greater percent reductions from baseline in iFGF23 were seen in P AUC categories representative of better P control than categories representative of worse control (Table).

Conclusions: Improved P control with TEN, as measured by P AUC, was associated with lower iFGF23.

Association of Urinary Phosphate Excretion and Osteoporosis in Patients with CKD: Result from KNOW-CKD

Yewon Jo, Sung Joon Park, Hyuk Huh, Taehee Kim, Yeong Hoon Kim, Yunmi Kim. KNOW-CKD (The KoreaN Cohort Study on the Outcome of Chronic Kidney Disease Patients). *Inje University Busan Paik Hospital, Busan, Republic of Korea.*

Background: The mechanism of osteoporosis is more complex in patients with chronic kidney disease (CKD) than general population because of accompanying chronic kidney disease-mineral bone disorder. We aimed to investigate the association of ability to handling urinary phosphate excretion and osteoporosis.

Methods: We analyzed 1,647 patients who were enrolled in the KNOW-CKD and have baseline 24-hour urinary phosphate value and dual-energy x-ray absorptiometry results. The subjects were divided into three groups according to tertile of urinary phosphate excretion. Osteoporosis was defined as T-score of -2.5 or less for one of L1 spine, total hip, or femur neck. The association of osteoporosis and urinary phosphate excretion was evaluated.

Results: The patients with higher urinary phosphate excretion tended to be younger, have higher body mass index and higher estimated glomerular filtration rate (eGFR), lower serum phosphate level. The osteoporosis was observed in 88 patients (16.0%), 31 patients (5.7%), and 14 patients (2.5%) for 1st (< 494mg), 2nd (494-660 mg), and 3rd (>660mg) tertile, respectively. In multivariate logistic regression analysis adjusted for age, sex, body mass index, hemoglobin, serum albumin, phosphate, calcium, and eGFR, patients belonged to 2nd tertile (odds ratio 0.543, 95% confidence interval 0.338-0.857, p = 0.010), and 3rd tertile (odds ratio 0.438, 95% confidence interval 0.223-0.812,

p = 0.012) showed lower risk of osteoporosis compared to the patients in 1st tertile. In the subgroup analysis, the risk of osteoporosis was not significantly different among patients with CKD 1-2, however the decreasing risk of osteoporosis according to the tertile of urinary phosphate excretion was more prominent among patients with CKD 3-4.

Conclusions: Higher urinary phosphate excretion was associated with lower risk of osteoporosis in patients with CKD.

Pill Burden and Clinical Outcomes in Patients with Hyperphosphatemia Undergoing Hemodialysis

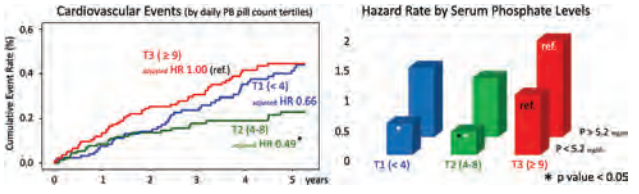
Kiryu Yoshida,[1] Tomohiro Saito,[2] Tadashi Kato,[2] Noriyuki Kato,[3] Masahide Mizobuchi,[4] Hiroaki Ogata,[1,5] Fumihiko Koiwa,[4] Hirokazu Honda.[2]
[1]Division of Nephrology, Department of Internal Medicine, Showa University Northern Yokohama Hospital, Yokohama, Japan; [2]Division of Nephrology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan; [3]Saiyu Clinic, Saitama, Japan; [4]Division of Nephrology, Department of Internal Medicine, Showa University Fujigaoka Hospital, Yokohama, Japan; [5]Department of Medical Education, Showa University School of Medicine, Tokyo, Japan.

Background: Phosphate binders (PB) improve clinical outcomes in HD patients; however, high pill burden might impair PB adherence. This study assesses association between the number of prescribed PB and clinical outcomes in patients on HD.

Methods: A retrospective study using data from 395 HD patients in a single facility in Japan, from August 2018 to November 2023. Outcomes include cardiovascular events (CVE), all-cause mortality, and fractures. Cox proportional hazards models were used to assess the relationship between PB pill count and outcomes. Baseline analysis and time-averaged analysis were performed.

Results: Patients were divided into tertiles based on baseline daily PB pill count: <4 (T1), 4-8 (T2), and ≥9 pills/day (T3), respectively. For CVE, the baseline analysis showed that, compared to T3, the hazard ratio (HR) for T1 was 0.66 (95% CI: 0.43-1.02, p=0.062) and for T2 was 0.49 (95% CI: 0.29-0.80, p=0.005). The time-averaged analysis revealed that the HR for T1 was 0.44 (95% CI: 0.27-0.71, p=0.001) and for the T2 was 0.45 (95% CI: 0.29-0.69, p<0.001). In patients with serum phosphate levels <5.2 mg/dL, the baseline analysis indicated that the HR for T1 was 0.53 (95% CI: 0.26-1.06, p=0.074) and for T2 was 0.39 (95% CI: 0.19-0.81, p=0.011). There were no significant differences in HR for all-cause mortality and fractures among the three groups.

Conclusions: A higher pill burden of PB might be associated with an increased risk of CVE, even in patients with well-controlled phosphate levels.



TH-PO167

Managing Hyperphosphatemia in Patients on Hemodialysis: A Comparison of Sucroferric Oxyhydroxide (SO) Monotherapy and Tenapanor with Other Non-SO Phosphate Binders

Meijiao Zhou, Linda Ficociello, Hao Han, Michael S. Anger. *Fresenius Medical Care Global Medical Office, Waltham, MA.*

Background: The pharmacological treatment options for managing hyperphosphatemia among dialysis patients (pts) have expanded. To examine the real-world experience with phosphate binders (PB) and phosphate absorption inhibitors, we examined serum phosphorus (sP) levels and pill burden amongst pts who switched to sucroferric oxyhydroxide (SO) monotherapy or added tenapanor (TN) to non-SO PB.

Methods: Adult Fresenius Kidney Care hemodialysis (HD) pts who switched from non-SO monotherapy at baseline to either (1) SO monotherapy (SO group) or (2) add-on TN to the baseline PB (+TN group) during 11/2023 -12/2023 were included. Eligible pts had sP the month before (-1M) and 3 months after switch (Q1; M1 to M3). To ensure comparability of baseline sP, we restricted analysis to pts with sP at -1M >7 mg/dL. PB pill burden and sP during the study period were described. General linear models were used to examine differences in sP between the two groups at M3.

Results: On average, pts in the SO group (n=262) were 56 years old with HD vintage of 49 months, while pts in the +TN group (n=63) were 51 years with vintage of 80 months. SO pts were more likely to dialyze with a catheter (23%) compared to +TN pts (11%). The reductions in sP from -1M to M3 were comparable in both groups (diff=1.25 mg/dL in the SO group and diff=1.23 mg/dL in the +TN group), however, SO group had lower pill burden (4.3 pills in SO vs 9.8 pills in the +TN group at M3). Results from univariate and adjusted linear models (controlling for age, vintage and catheter use) showed that there were no statistically significant differences in sP at M3 between the two groups.

Conclusions: For HD pts who had sP > 7 mg/dL despite treatment with non-SO monotherapy, switching to SO monotherapy or adding TN resulted in comparable reductions in sP. However, pts with SO monotherapy had less than half the PB pill burden, compared to those adding TN.

Funding: Commercial Support - Fresenius Medical Care

Figure 1. Mean sP with standard error bars during the study period in the SO and +TN groups

		-1M	M1	M2	M3
PB pills	SO group	7.0	4.1	4.1	4.2
	+TN group	8.1	9.9	10.0	9.8

TH-PO168

Hyperphosphatemia Is Associated with Kidney Prognosis in Patients with Autosomal Dominant Polycystic Kidney Disease

Kosaku Nitta. *Tokyo Women' Medical University, Tokyo, Japan.*

Background: The relationship between serum phosphate (P) levels and progression of kidney disease in patients with autosomal dominant polycystic kidney disease (ADPKD) remains unclear. Compared with other kidney disorders, patients with ADPKD typically have lower levels of serum P, potentially masking its clinical importance. This study sought to assess whether serum P levels can serve as a predictor of renal outcomes in ADPKD patients.

Methods: We included 235 patients with ADPKD who were not taking drugs to treat hyperphosphatemia. Survival analysis was performed for the renal outcome of a 50% reduction in estimated glomerular filtration rate (eGFR) or initiation of renal replacement therapy.

Results: The patients had mean age of 46 yeras, eGFR of 41.8 mL/min/1.73 m^2, and total kidney volume (TKV) of 1254.0 mL. The median follow-up period was 10.4 years, and the renal outcome was observed in 116 patients. Multivariable Cox regression analyses revealed that serum P (1 mg/dL increase, HR=2.03, P<0.0001) was a significant risk factor associated with kidney disease progression. Similarly, hyperphosphatemia (P>4.0 mg/dL, HR=1.90, P=0.0157; P>4.5 mg/dL, HR=2.78, P=0.0047; P>5.0 mg/dL, HR=27.22, P<0.0001) was significantly associated with renal prognosis. Kaplan-Meier analysis showed that kidney survival rates were significantly lower in patients with P>3.5 mg/dL than in those without hyperphosphatemia (log-rank test, P<0.0001). The 2-year kidney survival rate of ADPKD patients with P>4.0 mg/dL was 46.8% in the entire cohort and 28.2% in patients with stage 4-5 CKD, indicating an extremely poor renal prognosis.

Conclusions: Hyperphosphatemia was associated with renal prognosis in patients with ADPKD. In these patients, attention should be paid to even mild serum P elevation of P>3.5 or P>4.0 mg/dL.

TH-PO169

Tenapanor Reduces Serum Phosphate with Similar Efficacy and Tolerability Profiles When Added to Various Phosphate Binders

Stuart M. Sprague,[1] David P. Tietjen,[3] Jesslyn Roesch,[4] Yang Yang,[2] Suling Zhao,[2] Susan A. Edelstein,[2] David P. Rosenbaum,[2] David M. Spiegel.[2]
[1]NorthShore University HealthSystem University of Chicago, Chicago, IL; [2]Ardelyx Inc, Waltham, MA; [3]Nephrology Consultants, Huntsville, AL; [4]Apogee Clinical Research, Huntsville, AL.

Background: Tenapanor (TEN) is approved to reduce serum phosphorus (P) in adults with chronic kidney disease on dialysis as add-on therapy in patients (pts) who have an inadequate response to phosphate binders (PBs) or who are intolerant of any dose of PBs. While PBs are generally required in hyperphosphatemia management, they often cause gastrointestinal side effects of varying severity and have a high pill burden. This post hoc analysis examines the efficacy and tolerability of TEN when added to different PBs.

Methods: In the Ardelyx-supported AMPLIFY (NCT03824587) and OPTIMIZE (NCT04549597) trials, pts on maintenance dialysis with uncontrolled serum P (P ≥5.5 and

>5.5 mg/dL, respectively), despite stable PB doses, received TEN. In AMPLIFY, TEN was added to baseline (BL) PB therapy, which remained stable during the 4-week efficacy period. In OPTIMIZE (cohort 2), TEN was added to BL PB which was then reduced by ≥50%. After week 2, PB could be dose adjusted to achieve P ≤5.5 mg/dL during the 10-week efficacy and 16-week open-label extension periods.

Results: In AMPLIFY, P decreased when TEN was added to sevelamer (SEV)-based and non–SEV based PB regimens, with no appreciable difference in least-squares mean P reductions at week 4 between SEV- (0.9 mg/dL, n=60) and non-SEV based (1.1 mg/dL, n=56) regimens. In OPTIMIZE, a mean P reduction of 1.0 mg/dL was achieved at the end of the 10-week treatment period, regardless of whether TEN was added to PB regimens including SEV (n=52) or not including SEV (n=80). Diarrhea was the only adverse reaction that occurred in >5% of pts; pooled rates were similar when TEN was added to SEV alone (38.9%; 42/108), calcium-based PB alone (46.8%; 22/47), iron-based PB alone (33.3%; 18/54), lanthanum carbonate alone (28.6%; 2/7), and multiple PB types (56.6%; 30/53). Study discontinuation rates in pooled analyses were similar when TEN was added to SEV alone (13.0%; 14/108), calcium-based PB alone (8.5%; 4/47), iron-based PB alone (16.7%; 9/54), lanthanum carbonate alone (14.3%; 1/7), and multiple PB types (9.4%; 5/53).

Conclusions: TEN provides a clinically meaningful serum P reduction with similar efficacy and tolerability when added to PBs, regardless of the type of PB.

TH-PO170

Assessing Potential Heightened Sensitivity to Tenapanor in Japanese Patients on Hemodialysis (HD)

Mayu Iwata, Satoshi Funakoshi, Jyunichiro Hashiguchi, Shinichi Abe, Kenji Sawase. *Nagasaki Kidney Center, Nagasaki, Japan.*

Background: Hyperphosphatemia is associated with arterial calcification, bone fractures, and cardiovascular mortality, making its treatment a cornerstone of dialysis care. However, strategies for managing hyperphosphatemia in patients undergoing maintenance dialysis, such as dietary restrictions and phosphate binders, yield only moderate efficacy. Tenapanor, the world's first phosphate absorption inhibitor, holds promise for addressing this challenge.

Methods: We enrolled 88 patients with hyperphosphatemia despite the use of phosphate binders in our maintenance dialysis facility. Given that soft stools and diarrhea were the most frequently reported adverse events in previous trials, we initiated tenapanor administration at a minimal dose of 5mg once daily, gradually increasing it while monitoring gastrointestinal symptoms and phosphate reduction effects, and concurrently tapering phosphate binders.

Results: The study population comprised 88 patients: 39 males, 19 females, with a mean age of 67 ± 12.1 years, mean dialysis vintage of 9.6 ± 6.5 years, and mean weight of 54.8 ±18.3 Kg. Within the first month of starting tenapanor, 27 patients discontinued treatment due to drug-related diarrhea, resulting in a dropout rate of 30.7%. Among the evaluable 61 patients, serum phosphate levels in those receiving 5mg of tenapanor once daily (n=10) decreased nonsignificantly from 6.08 ± 1.19 mg/dL to 5.27 ± 1.11 mg/dL, whereas in those escalated to 10mg once daily (n=51), there was a significant decrease from 5.47 ± 1.0 mg/dL to 4.73 ± 0.9 mg/dL, as depicted in the figure.

Conclusions: The maintenance dosage of tenapanor has been established as 10-20mg orally twice daily in previous studies. While we observed a notably higher dropout rate due to diarrhea with tenapanor compared to previous reports, there remains potential for managing serum phosphate levels with relatively low doses of tenapanor in Japanese HD patients. The variability in tenapanor's effects, influenced not only by patient weight but also dietary habits and race, was suggested.

A Postmarketing Study Assessing Safety and Efficacy of Velphoro in Korean Adult Dialysis Patients

Weiwei Qi,[1] Won Min Hwang,[2] Shin-Young Ahn,[3] Young-Ki Lee,[4] Byung Chul Shin,[5] Jong hoon Lee,[6] Seon Gun Kim,[7] Hye-Jung Kim,[7] Manuela Stauss-Grabo,[8] Carmen So,[9] Astrid Feuersenger.[8] *[1]Fresenius Medical Care Shanghai Co Ltd, Shanghai, China; [2]Konyang University Hospital, Daejeon, Republic of Korea; [3]Korea University Guro Hospital, Guro-gu, Seoul, Republic of Korea; [4]Hallym University Kangnam Sacred Heart Hospital, Yeongdeungpo-gu, Seoul, Republic of Korea; [5]Chosun University Hospital, Gwangju, Republic of Korea; [6]Gimpo Woori hospital, Seoul, Republic of Korea; [7]Fresenius Medical Care Korea Ltd, Seoul, Republic of Korea; [8]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [9]Fresenius Medical Care Asia Pacific Ltd, Hong Kong, Hong Kong.*

Background: Hyperphosphatemia is a frequent sequalae of chronic kidney disease and often requires phosphate binders to control. Velphoro® (calcium-free polynuclear iron (III)-oxyhydroxide phosphate binder, Vifor Fresenius Medical Care Renal Pharma Ltd., Switzerland) is a chewable tablet and had been approved in adult dialysis patients in Europe and the US since 2013 and in Korea since 2018. As clinical trials may not reflect real-world use of medications, we performed a post-marketing study (PMS) to monitor the safety profile of Velphoro® in Korea.

Methods: We conducted a non-interventional, prospective PMS in 647 dialysis patients from 18 sites with a 6-week short term and 24-week long term observation. Subjects enrolled in this study should newly receive Velphoro® for up to 1 week. Both safety and efficacy information were observed.

Results: A total of 596 subjects finished short-term observation and were included in safety analysis. Of these, 82 subjects finished the long-term observation. For short-term cohort, 284 adverse events (AE) and 91 adverse drug reactions (ADR) were reported. Gastrointestinal (GI) disorders were the most common ADR reported at 10.91% mainly diarrhea (5.37%). 27 serious AEs were reported but none of them was serious ADR. Besides, unexpected ADRs were reported for 15 cases mainly GI disorders, and none was severe. The 82 subjects who comprised the long-term cohort reported 46 AEs and 3 of them were ADR. None of the ADR was serious but 2 were reported as unexpected which were chest pain and abdominal discomfort. For iron test, a small increase in ferritin was observed at week 6 (351.51±286.99ng/ml) and week 24 (420.82±325.74ng/ml) while only an increase trend at week 6 (35.65±17.38%) but no further increase was observed at week 24 (38.05±15.11%) in TSAT level. For serum phosphorus control, the average serum phosphorus reduction at week 6 was -0.97±1.6 mg/dl while at week 24 from baseline was -0.82±1.48mg/dl.

Conclusions: In this PMS, GI disorders were the main ADR. No obvious iron accumulation was observed. In conclusion, Velphoro® has a favourable safety and tolerability profile in Korean patients that is consistent with that observed in Phase 3 trial (PA-CL-05A).

TH-PO172

Leontiasis Ossea in Hyperparathyroidism Secondary to Inadequate ESKD Management

Ruby Garcia,[1] Greilys Lazcano,[2,3] Jorge A. Lamarche,[2,3] Marina Antar-Shultz,[2,3] Mohamed M. Taha,[2,3] Endri Ceka,[2] Panagiotis Zervogiannis.[2,3] *[1]University of Nevada Reno, Reno, NV; [2]University of South Florida, Tampa, FL; [3]VA James A Haley Hospital, Tampa, FL.*

Introduction: Management of PO4, Ca, and parathyroid hormone (PTH) levels is essential for proper bone health in End Stage Renal Disease (ESRD). Leontiasis ossea (LO) is a severe form of osteodystrophy characterized by skeletal growth abnormalities that occurs in ESRD with long-standing, uncontrolled overproduction of PTH. Presentation includes facial swelling and/or jaw pain. Severe cases present with facial disfigurement due to bony expansion of maxillary bones extending into the orbit, mouth, nose or sinuses. This leads to complications such as dysphagia, exophthalmos, or visual loss if compression of the optic nerve occurs.

Case Description: 28 y/o undocumented M with ESRD on hemodialysis (HD) for 19 years presented with facial swelling, dysphagia, and dysarthria (Figure 1). The patient was unable to have adequate ESRD management due to financial constrains. Laboratory tests revealed a high PTH level at 5470 pg/ml. Ca++ and PO4 levels were normal. CT scan revealed bone changes consistant with LO.

Discussion: Excess PTH production, caused by ESRD, leads to increased osteoclast and osteoblast activity. There is unprecedented unmineralized bone formation and expansion in LO. LO is rare and only presents in inadequate ESRD management. There are no standardized methods to diagnose and treat LO. Preventative treatment include strict medical management of metabolic derangements with adherence to dialysis, calcimimetics, and PO4 binders. Parathyroidectomy is an alternative when medical therapy fails and has been shown to halt bone remodeling. There is no evidence to surgically remove excess bone unless is considered to improve quality of life and to treat life-threatening complications.

Figure 1. Facial photographs of the patient presenting with facial deformation and swelling of the maxilla and mandible caused by leontiasis ossea.

TH-PO173

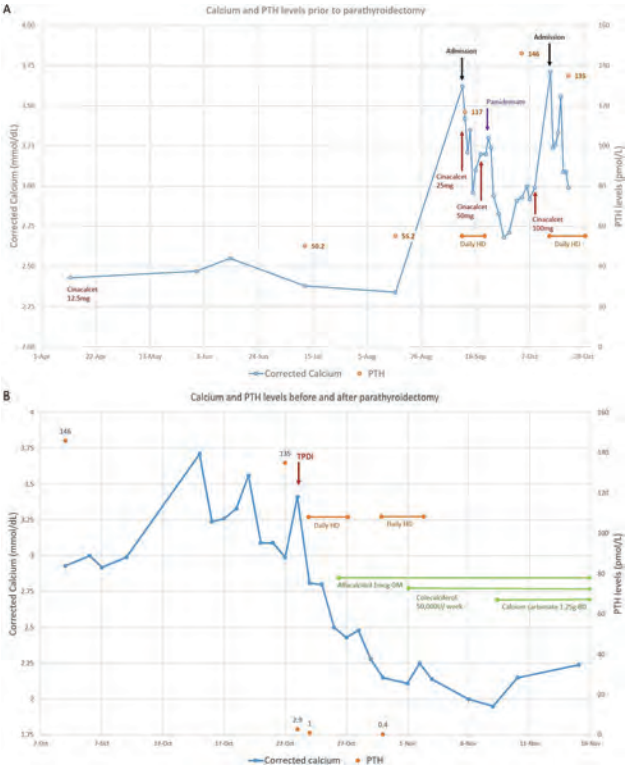
Systemic Amyloid Presenting with Rapidly Worsening Hyperparathyroidism in Patients with ESKD

Yi-Ting Ong, Julia G. Andres, Jiunn Wong. *Singapore General Hospital, Singapore, Singapore.*

Introduction: Hypercalcemia in ESKD patients is commonly associated with tertiary hyperparathyroidism and can be challenging to manage. We report a case of unusually severe PTH-mediated symptomatic hypercalcemia in a hemodialysis patient though to be secondary to rapidly deteriorating hyperparathyroidism. She failed medical therapy and underwent parathyroidectomy. Subsequent histology shows presence of amyloid deposit in the parathyroid specimen. Our case is unusual for rapidly worsening hypercalcemia and hyperparathyroidism and histology finding of amyloid deposit in the parathyroid specimen. We postulated the worsening of hyperparathyroidism and hypercalcemia was related to the amyloid infiltrate in the parathyroid gland

Case Description: A 67-year-old woman with background history of ESKD on hemodialysis who has stable hyperparathyroidism from CKD-MBD on medical therapy. She presented with two-week history of gradual functional decline and symptomatic hypercalcemia. Corrected serum calcium was markedly elevated at 3.62mmol/L, with raised iPTH at 117pmol/L. This is significantly higher than her results just 1 month prior to presentation. Ultrasound showed a well-defined 29 x 22 x 12mm hyperechoic nodule posterior to the right thyroid lower pole, consistent with a parathyroid adenoma which was congruent with a region of increased sestamibi tracer uptake with delayed tracer washout on parathyroid scintigraphy. Despite treatment with repeated sessions of hemodialysis, maximal doses of cinacalcet, calcitonin and anti-resorptives, her calcium levels remained high. She underwent parathyroidectomy with expected response in iPTH levels and improvement of hypercalcemia. Histology subsequently reviewed congo red deposit within intertrabecullar, perifollicular and paracortical stroma of parathyroid, thyroid and lymph node tissue.

Discussion: Unexplained rapidly worsening hypercalcemia in secondary hyperparathhyroidsm should prompt clinician to investigate for alternative cause of hypercalcemia and systemic amyloid may present with severe hypercalcemia and hyperparathyroidism



TH-PO174

Case Report of CyberKnife Radiosurgery Treatment for Secondary Hyperparathyroidism in a Patient Undergoing Dialysis

Bengang Huo, Rong He, Chuan Chen, Shihui Hou, Kehong Chen. *Army Medical Center of PLA, Chongqing, China.*

Introduction: We present a compelling case where CyberKnife effectively treated a patient suffering from bone pain and poor response to medication following a prior surgery for medullary thyroid carcinoma.

Case Description: A 41-year-old patient who has been undergoing peritoneal dialysis combined with hemodialysis for 7 years, underwent a total thyroidectomy for medullary thyroid cancer 4 years ago. His iPTH levels rose to 1062.66 pg/ml, leading to bone pain in shoulders, wrists, and knees 2 years ago. Cinacalcet 50mg/day was prescribed, but iPTH levels remained uncontrolled, and bone pain persisted. MIBI imaging revealed a parathyroid nodule approximately 1.5*1.1cm in size on the right neck. Cyberknife treatment of 27Gy/3F was carried out. After 11 weeks of treatment, MIBI imaging showed reduced parathyroid volume and decreased uptake (Figure 1). The iPTH changes are detailed in table 1. No adverse events were reported during follow-up.

Discussion: This is the first report of using Cyberknife to treat secondary hyperparathyroidism. After treatment, the patient's bone pain improved. MIBI imaging also indicated a decrease in parathyroid gland size and weakened uptake, suggesting treatment effectiveness. Further investigation is needed due to the limited experience in using cyberknife for SHPT. Prolonged observation is essential to assess efficacy and potential adverse effects.

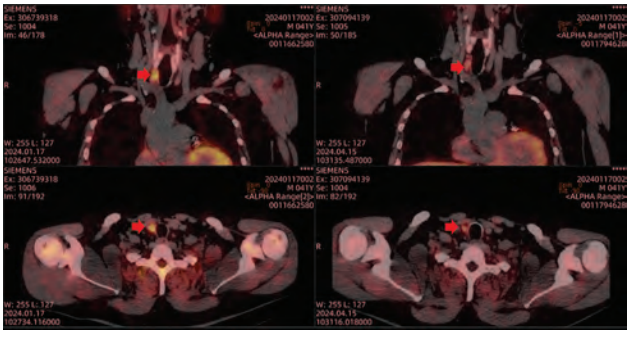


Figure 1. MIBI imaging before and after cyberknife treatment.

Table 1. Changes of iPTH, calcium and phosphorus before and after cyberknife treatment

Date	iPT (pg/ml)	Calcium (mmol/L)	Phosphate (mmol/L)	Treatment
2024-5-10	339.27	2.11	1.44	Cinacalcet 25mg/day,
2024-4-14	274.70	1.96	1.92	lanthanum carbonate
2024-3-31	161.62	2.04	2.28

TH-PO175

Heart of Stone: Cardiogenic Shock from Myocardial and Mitral Valve Calcification with Systolic Anterior Motion (SAM) Defect after Valve Replacement in a Patient on Chronic Hemodialysis (CHD)

Ashish Verma, Gregory L. Braden, Barbara A. Greco, Spencer Hodgins.
Baystate Medical Center, Springfield, MA.

Introduction: Myocardial & valve calcification has been descibed in CHD autopsy studies but has rarely been reported to be a clinical cause for CHF in CHD pts. We describe a pt who after 16 years of dialysis developed severe dyspnea & mitral stenosis from annular calcification(C) She had HFpEF & later developed cardiogenic shock & SAM after mitral replacement with severe LV outflow track obstruction. Autopsy showed severe myocardial C & 50 % myocaridal fibrosis, a new cause of clinical HFpEF in CHD pts.

Case Description: A CHD pt with years of PTH > 2000 pg/ml, hypercalcemia and CaPhosphorous(P) product 54-123 developed dyspena with mitral stenois with a 16 mmHg gradient. She was on CHD from 1988-90 & then 1992 -2006. After PTH removal in 1997 she had severe hypocalcmia, PTH < 1.0 pg/ml, & she got over 2000 mcg of iv calcitriol & 11,100 grams of CaP binders from 1992 to 2006. Cardiac studies showed a small heart with a cardiothoracic ratio of .36, LVEF 70 %, severe mitral gradient of 14-16 mmHg, LVH, & pulmonary artery presssure of 79 mmHg & mild tricuspid regurg. The coronary arteries had minimal changes. At surgery severe mitral annular calcification allowed only a pediatric St.Jude's valve. On day 3 she devleoped shock requiring fluids & 3 pressors. TEE showed marked SAM with severe obstruction of the LV ouflow track, severe pulmonay hypertension & severe tricuspid regurg & RV failure. LVEF was 65%. At death autopsy showed a small heart size despite a weight of 600 gms.with diffuse myocardial C on H&E & 50 % of the myocadium had fibrosis on trichrome stains. Calcium deposits were minimal in the coronary arteries.

Discussion: We conclude: 1) Diffuse myocardial C & fibrosis can occur in CHD pts from parathyroid & CaP dysrgulation & over use of calcium based P binders and IV Calcitriol. 2) Myocardial calcium causing severe fibrosis is a rare but important cause of dyspnea & HFpEF with a small heart in CHD pts. 3) SAM of the mitral valve has never been reported in CHD pts & can occur after mitral valve replacement 4) Prexisting tricuspid regurg & pulmonary hypertension are risk factors for severe RV failure after mitral valve replacement. 5) Simultaneous tricuspid valve replacement or repair may be needed in such pts receivng a mitral valve prosthesis.

TH-PO176

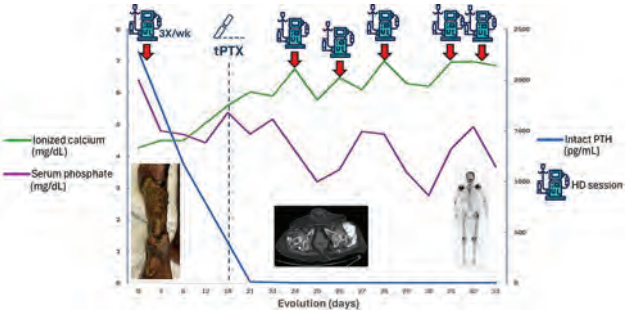
Unexpected Early Hypercalcemia after Parathyroidectomy in a Patient with Tumoral Calcinosis and Severe Calciphylaxis

Ana C. Gonzalez Medina, Vianca A. Canaviri, Ana L. Ruelas Villavicencio, Paul A. Parra, Ivan Perez Diaz, Jose A. Paz Cortes, Juan Carlos Ramirez-Sandoval.
Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico.

Introduction: Hypocalcemia due to hungry bone syndrome commonly occurs after total parathyroidectomy (tPTX) in kidney failure patients. This is a paradoxical hypercalcemia case after tPTX in a patient with severe calcific uremic arteriolopathy (CUA) and extensive extraosseous calcium deposits (tumoral calcinosis, TC).

Case Description: A 54-year-old woman with kidney failure on hemodialysis for 4 years (2X/week), admitted to the emergency room with fever and severe neuropathic pain in extremities. Physical examination showed huge ischemic ulcers on lower limbs (see figure). Additionally, asymptomatic palpable masses were found in her shoulders, knees and hips. A skin biopsy confirmed the diagnosis of CUA, while a PET-CT scan revealed extensive vascular calcifications and calcium phosphate deposits (CPD) in soft tissues and periarticular areas (TC). Lab tests revealed severe hyperparathyroidism (HPT) with iPTH 2049pg/mL, alkaline phosphatase (ALP) 245U/L, normocalcemia (free calcium 4.5 mg/dL), hyperphosphatemia (6.5 mg/dL) and low vitamin D. She received IV antibiotics, surgical debridement, hemodialysis (HD), calcimimetics and opioids. A tPTX was performed (post-surgery iPTH <50pg/mL). However, she experienced sustained elevations in calcium levels (free calcium >7mg/dL), which required frequent HD for lowering. After tPTX, pain intensity decreased as did ALP, iPTH remained low and ALP levels, yet hypercalcemia persisted. Other causes of hypercalcemia were discarded.

Discussion: We present a novel case of early hypercalcemia development post-tPTX in a patient with CUA and extensive CPD. Mobilization of calcium from extraosseus stores and a poor bone resorption (early adynamic bone disease) seem the main cause of early hypercalcemia in this case. While tPTX has proven effective in managing TC and CUA associated with severe HPT, paradoxical hypercalcemia after tPTX may occur early in cases with extensive extraosseouss CPD.



Clinical presentation and evolution

Successful Treatment Using Oral Vitamin K in a Patient on Peritoneal Dialysis with an Extensive Right Hip Lesion Due to Calcific Uremic Arteriolopathy (CUA, Calciphylaxis): A Rare but Highly Fatal Condition

Niladri Mal, Arshad Ali, Shoaib A. Chowdhury. Munson Healthcare.
Munson Healthcare Cadillac Hospital, Cadillac, MI.

Introduction: Calciphylaxis is a rare but serious disorder commonly seen in patients with end-stage renal disease, however, rarely occurs in patients with normal renal function, acute renal failure or earlier stages of chronic kidney disease (non-uremic CAU). CAU typically present as painful skin lesion as results from calcification of the medial layer of arterioles and small arteries leads to tissue ischemia and infraction, a fatal condition with one-year mortality upto 30-80%, mostly due to sepsis.

Case Description: 73 y old Female on peritoneal dialysis who presented with severe progressive calciphylaxis on her right thigh. Patient was intolerant to sodium thiosulfate therapy. The patient was given high dose (100 x of daily requirements) Vit K therapy 10 mg on Mon-Wed-Fri for 6 months, which was the principal therapy, resulted in skin healing and complete resolution of the CUA (Fig 1). Hence, CAU is a rare, fatal condition that requires prompt diagnosis and treatment and should be suspected in a dialysis patient with painful skin lesion. Although previous study shows poor effectiveness of Vitamin K therapy, our study for the first time strongly validates effectiveness of high dose Vit K therapy in treating calciphylaxis in peritoneal dialysis patients.

Discussion: Matrix G1a protein which is dependent on Vit K dependent carboxylation for its activity, may prevent vascular calcification [(1) Dobry AS]. Therefore, Warfarin use has been implicated as a risk factor for calciphylaxis and Vit K therapy has potential in treatment of calciphylaxis. In our patient, we successfully able to diagnose her early and treat her with Vit K supplement, resulted in her rapid pain relief, wound healing, and prevention of death.

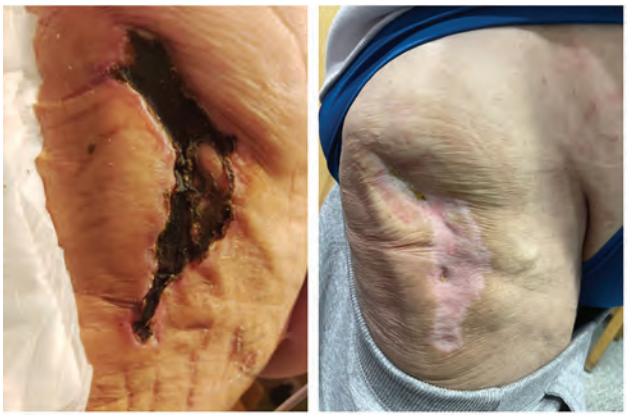

Fig 1. Shows an extensive necrotic ulcer in right thigh due to calciphylaxis (left image) and complete wound healing after completion of Vit K therapy for six months (right image).

TH-PO178

Familial Hypercalcemia and Hypercalciuria with a Novel Calcium-Sensing Receptor Mutation

Kenneth Brand,[1,2] Barbara A. Greco.[1,2] *[1]Baystate Medical Center, Springfield, MA; [2]University of Massachusetts Chan Medical School, Worcester, MA.*

Introduction: The most common cause of hereditary hypercalcemia is Familial Hypocalciuric Hypercalcemia (FHH). Over 200 loss-of-function CaSR mutations have been associated with FHH. We report a family with hypercalcemia due to a novel mutation in the CaSR with associated hypercalciuria.

Case Description: An 80-year-old white man initially presented at age 67 with longstanding hypercalcemia, no history of renal stones or osteoporosis, and on no supplemental calcium. Over the years, his serum calcium ranged from 10 to 11.6 mg/dl, phosphorus 1.9-2.9 with PTH levels between 29-50 pg/ml. Vit D and magnesium levels were normal. Several 24-hour urine collections confirmed hypercalciuria and hyperphosphaturia. Two 24-hour renal calcium to creatinine clearance ratios (CCCR) were 0.013 and 0.017. NM sestamibi scan showed no parathyroid adenoma. Genetic testing (Invitae) identified a cytosine to thymine substitution at position 1880 of the CaSR gene with threonine replacing isoleucine at position 627 in the intramembranous portion, a variant of unknown significance (VUS). Cinacalcet 30 mg daily had no effect whereas 60 mg daily normalized serum calcium. His daughter was found to be hypercalcemic and hypercalciuric (210 mg) at age 40 and her 16-year-old son had hypercalcemia, 10.6 mg/dl.

Discussion: The finding of a CaSR VUS in a family with hypercalcemia supports the diagnosis of FHH. This patient's CCCRs were nondiagnostic for differentiating primary hyperparathyroidism from FHH. Our patient had hypercalciuria and hyperphosphaturia. The mechanism is unclear but raises the question as to whether this mutation affects the function of the CaSR in the parathyroid gland and renal tubules differently- reducing the activity of the CaSR in the parathyroid and proximal tubule to a greater extent than in the thick ascending limb. Response to moderate but not low dose cinacalcet is consistent with an inactivating CaSR mutation.

Laboratory Investigations

Year	Calcium* mg/dl	Phosphorus mg/dl	PTH pg/ml	Urine Calcium mg/day	Urine phosphorus mg/day	Intervention
2010	10.2-10.7	2.2-2.9	42.9-50.6	260	1400	None

TH-PO179

Muscle-Limited Sarcoidosis Presenting as Recurrent Hypercalcemia of Unknown Origin

Atlee Baker, Ignacio A. Portales Castillo. *Washington University in St Louis, St Louis, MO.*

Introduction: Hypercalcemia is a commonly encountered clinical entity, affecting approximately 1-2% of the general population. Elevation of the parathyroid hormone (PTH), parathyroid hormone related peptide (PTHrP) or vitamin D is frequently observed in these cases. Most often, hypercalcemia is caused by elevated parathyroid hormone (PTH) levels; however, there is a broad differential for hypercalcemia. Occasionally, the cause of hypercalcemia is not apparent despite extensive work-up. We present a case of a young woman with severe and recurrent hypercalcemia of unknown origin.

Case Description: An18-year-old Amish female with history of hypothyroidism secondary to childhood thyroid toxicosis, Raynaud's disease, fibromyalgia, and spina bifida presented for evaluation of recurrent hypercalcemia. She initially presented to her community naturopathic healer after developing myalgias, fevers, night sweats, and constipation. Six months later, her symptoms worsened, and she presented to our institution. Evaluation revealed AKI with sCr 1.69mg/dL, hypercalcemia with Ca 16 mg/dL, low-normal phosphorus of 2.7mg/dl, suppressed PTH at 5pg/ml, undetectable PTHrP, low 25-vitamin D of 10ng/dL, and normal 1, 25-vitamin D of 66pg/mL. 24-hour urinary calcium was elevated at 310 mg. Additional work up including evaluation for paraprotein disease, vitamin A levels, bone marrow biopsy, and skeletal survey were all negative. After medical management with intravenous fluids and bisphosphonate she was discharged. The patient had recurrent hospital admissions with severe hypercalcemia. It was noted that she had again had normal 1-25 vitamin D levels and an elevated 24:24,25-vitamin D ratio of 33, despite very elevated intact FGF-23 of 352pg/mL, suggesting a non-regulated production of 1-25 vitamin D. Genetic investigations were negative for CYP24A1, SLC34A1 and ALPL mutations. In a search for the occult source of 1-25 vitamin D, the levels of angiotensin converting enzyme and aldolase were found to be elevated, with positive uptake noted at her shoulder in a PET scan suggestive of muscle limited sarcoidosis. She was started on plaquenil with resolution of hypercalcemia.

Discussion: We present a case of occult hypercalcemia, ultimately ascribed to muscle limited sarcoidosis which responded to Plaquenil. The case illustrates the interpretation of hormonal parameters in a challenging case of hypercalcemia.

TH-PO180

Hypercalcemia: It's Only Skin Deep

Branavan V. Ragunanthan, Clay A. Block, Charles W. Hopley. *Dartmouth Health, Lebanon, NH.*

Introduction: Hypercalcemia is a common electrolyte abnormality with multi-systemic consequences that has been associated with several etiologies including genetic conditions, various pathologies, and certain medications. Dialysis patients usually experience hypercalcemia because of hyperparathyroidism and its treatment. Here, we present a dialysis patient with parathyroid hormone (PTH)-independent hypercalcemia resulting from psoriasis treatment.

Case Description: A 43-year-old man with end-stage renal disease (ESRD) treated by home hemodialysis, and severe psoriasis presented to his home dialysis clinic with labs demonstrating up-trending monthly calcium levels between 10.7 mg/dL to 11.6 mg/dL (normal range: 8.5 – 10.5mg/dL). Corresponding PTH levels were down-trending from 699 pg/mL to 77 pg/mL (normal range: 16 – 80 pg/mL). Home medications as documented in multiple electronic medical record systems (EMR) were notable for calcitriol 0.25mg three time weekly and cholecalciferol 2000units daily - both of which were discontinued. The patient reported no significant intake of calcium supplements. Paraprotein studies were unremarkable. 25-OH and 1,25 dihydroxy vitamin D were 34.2 ng/mL (normal range: 30.0 - 100.0 ng/mL) and 118 pg/mL (normal range: 19.9 - 79.3 pg/mL) respectively. Imaging was negative for adenopathy, masses or infiltrates. Angiotensin converting enzyme was normal at 82 units/L (16 - 85 units/L). Upon further review, the patient reported seeing his dermatologist several months prior to the onset of hypercalcemia for psoriasis and received a prescription for calcipotriene cream, which he was applying liberally. Calcipotriene cream was discontinued and hypercalcemia resolved while PTH increased to 560 pg/mL.

Discussion: There are only several reports illustrating the association of hypercalcemia with calcipotriene. Calcipotriene is a topical vitamin D analog that is a cornerstone therapy for psoriasis. Cutaneous absorption can result in excessive 1,25 dihydroxy vitamin D, thereby creating a PTH-independent mechanism for hypercalcemia. This case exemplifies a pitfall of EMR medication lists if medications are not uploaded or reviewed during visits. Topical agents, drops, over the counter medications, and herbal supplements may be particularly prone to this problem. In this case, there was considerable diagnostic delay and prolonged exposure to hypercalcemia related to incomplete EMR medication list.

TH-PO181

Hypercalcemia Due to Elevated 1,25-Dihydroxyvitamin D in Severe Tophaceous Gout

Madhia B. Ahmad, Harshad Chaudhari, Smita Mahendrakar, Michael Yudd. *Rutgers Health, Newark, NJ.*

Introduction: Granulomatous disorders, like sarcoidosis and tuberculosis, can cause hypercalcemia by increasing production of calcitriol through the activation of extrarenal 1-alpha-hydroxylase by macrophages in granuloma. Patients often are asymptomatic and have low parathyroid hormone (PTH) level and elevated 1,25 dihydroxyvitamin D levels. Severe tophaceous gout can cause granulomatous inflammation and is a rare cause of hypercalcemia.

Case Description: A 68-year-old male with severe tophaceous gout and possible seronegative rheumatoid arthritis resulting in extensive deformities presented with asymptomatic hypercalcemia 13.1 mg/dL and worsening kidney function. His laboratory testing notable for creatinine 2.6 mg/dL with baseline chronic kidney disease creatinine 2.0 mg/dL, low PTH, elevated serum 1,25-dihydroxyvitamin D and angiotensin converting enzyme (ACE) levels. Extensive workup ruled out sarcoidosis, malignancy, fungal infections, and tuberculosis. He had resection of his elbow tophi which showed many granulomas. Renal Biopsy consistent with ateriosclerosis disease. Aggressive treatment of his gout with steroids and urate lowering therapy febuxostat improved his hypercalcemia.

Discussion: Our patient presented with relatively long-standing hypercalcemia with minor symptoms. This occurred in the setting of severe tophaceous gout and probable seronegative rheumatoid arthritis. In normal states, 25-hydroxyvitamin D is hydroxylated to the active 1,25-dihydroxyvitamin D in renal proximal tubular cells through the enzyme 1α-hydroxylase. In hypercalcemia this conversion is inhibited. Elevated 1,25-dihydroxyvitamin D in the setting of hypercalcemia as seen in this patient points to abnormal unregulated extrarenal conversion, typically found in granulomatous states and lymphomas.

Table 2 Review of the 6 cases found in the literature of hypercalcemia associated with tophaceous gout

Calcium Chaos: When Siliconoma Steals the Show

Anna V. De la Pena,[1,2] Celine Garcia,[1,2] Priya A. Savani,[1,2] Maryam Tajamal,[1,2] Akshay Kumar,[1,2] Danny Haddad.[2] *[1]Rutgers Health, Newark, NJ; [2]Jersey City Medical Center, Jersey City, NJ.*

Introduction: Kidney damage resulting from silicone implants is a rarely reported phenomenon. Rare complications from wound dehiscence can trigger an autoimmune response eliciting cascade of reactions causing hypercalcemia and nephrocalcinosis. We report a case of hypercalcemia-induced CKD following silicone buttock augmentation.

Case Description: A 52-year-old transgender woman with a past medical history of asthma, hypertension, and silicone injection in the glutes presented to the ED with polyuria, polydipsia, and constipation. Bloodwork showed calcium of 16 mg/dL, BUN 38 mg/dL, and creatinine 2.03 mg/dL. Further work-up revealed low PTH 6.3 pg/mL, low PTHrP 16 pg/mL, low 25-hydroxyvitamin D 15 ng/mL, and elevated 1,25-dihydroxyvitamin D 66 pg/mL. The patient was treated with IV fluids, zoledronic acid, and calcitonin for 5 days and discharged on alendronate 70 mg weekly. Four months later, she was hospitalized with symptomatic hypercalcemia and was managed similarly. Further work-up revealing a negative SPEP and immunofixation, and elevated LDH 234 U/L, elevated ACE levels 162.9 U/L, suggesting granulomatous disease. A CT of the abdomen/pelvis showed infiltration throughout the bilateral gluteal subcutaneous fat with scattered calcified granulomas. A bone scan showed diffuse radionuclide accumulation in the buttocks corresponding with soft tissue attenuation and scattered calcifications. Over the next two years of receiving denosumab 120 mg monthly, hypercalcemia persisted, leading to recurrent nephrolitiasis and hydronephrosis, which further compromised kidney function. Calcium levels began to stabilize by the third year of treatment. Unfortunately, this improvement coincided with the patient progressing to CKD stage 4.

Discussion: This case underscores the importance of considering rare causes like siliconoma in cases of recurrent hypercalcemia. Siliconoma, though difficult to treat and often leading to complications like CKD, can result from an immune reaction to silicone, causing hypercalcemia by increasing calcium absorption through the production of 1,25 Vitamin D3.(1) Normalization of calcium could be related to the development of secondary hyperparathyroidism due to advanced CKD compared to treatment response as observed in this case. Due to the challenge in removing extensive granulomas, the development of alternative management strategies is crucial.

TH-PO183

Hypercalcemia, from the Doctor's Office to the Hospital: The Path to Diagnosis in a Patient with Pott Disease

Francisco Velasco Garcia Lascurain, Mario Alamilla-Sanchez, Carolina Gonzalez-Fuentes, Juan D. Diaz Garcia, Jose L. Torres Cuevas. *Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico*.

Introduction: Mycobacterium tuberculosis is the second leading cause of death secondary to an infectious agent worldwide. The primary infection can originate from a pulmonary infection. In some cases, it can spread to the spine, known as Pott's disease. The wide variability of clinical manifestations makes timely diagnosis a challenge. This case describes a patient with CKD who came for consultation to initiate a renal transplant protocol. However, asymptomatic hypercalcemia was detected, resulting in her admission to our service for diagnostic assessment.

Case Description: A 32-year-old female with CKD diagnosed 1 year ago, underwent a transplant protocol referral while already on PD. She presented with a history of unintentional weight loss. Lab tests indicated hypercalcemia, hypoalbuminemia, normocytic normochromic anemia, and low PTH levels. Hospitalization was required for peritoneal dialysis adjustments as well as the commencement of the transplant protocol. Thoracoabdominal tomography unveiled hypodense lesions in the spine, prompting further investigation. Bronchoscopy confirmed Mycobacterium bovis, leading to treatment initiation and discharge. A month later, she was readmitted due to catheter dysfunction, and peritoneal fluid cultures tested positive for Mycobacterium. Finally the patient's condition deteriorated, ultimately resulting in her demise.

Discussion: Mycobacterium bovis is a significant cause of tuberculosis in both cattle and other mammals, particularly impacting healthcare systems in developing nations. Extrapulmonary tuberculosis affects about 2% of cases, with spinal cord involvement possible through hematological dissemination. Pott's disease presents with constitutional symptoms and progressive back pain. Limited access to diagnostic facilities and the disease's insidious nature complicate timely identification. Patients with CKD undergoing renal replacement therapy face heightened tuberculosis risk, with extrapulmonary presentations more prevalent. Renal involvement, peritonitis in peritoneal dialysis patients, and spinal column infections are notable. Hypercalcemia, driven by granuloma formation due to increased macrophage alpha-1 hydroxylase expression, aids diagnosis, as seen in our patient with Pott's disease.

TH-PO184

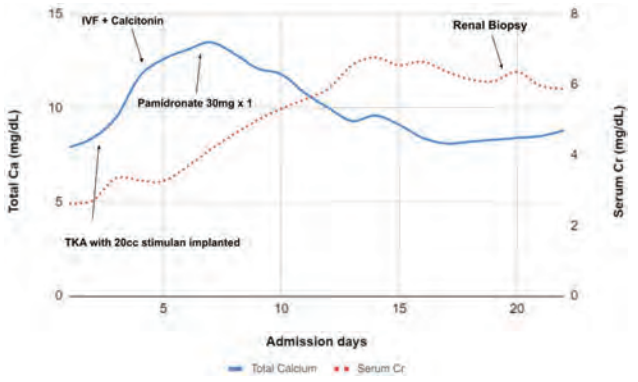
Hypercalcemia and Kidney Complications from Joint Implants

Anthony T. Nguyen, Dinna Cruz. *University of California San Diego, La Jolla, CA.*

Introduction: Acute kidney injury after revision knee and hip arthroplasty is common with rates of 20% reported. An uncommon complication for the nephrologist to be aware of is hypercalcemia, which can occur with use of calcium sulfate-based volume expanders i.e. Stimulan. These absorbable drug-eluting beads deliver local antibiotics to manage prosthetic joint infections (PJI). Complications of transient hypercalcemia are reported in 5%, with treatment required in 0.2% of cases. We present a case of symptomatic severe hypercalcemia suspected from Stimulan use.

Case Description: A 67 year old male with history of DM, HTN, CKD stage 4, and knee arthroplasty with recurrent PJI who presented for joint revision. His post-op course was complicated by non-oliguric AKI related to perioperative hemodynamic changes with low renal reserve. On POD#3, he had symptoms of constipation, nausea/vomiting; hypercalcemia was noted (Fig 1). Serological workup for hypercalcemia was unrevealing with PTH appropriately low; serum electrophoresis, PTHrp, 25-OH and 1,25-OH Vit D levels were low-normal. OR notes indicated implantation of 20mL stimulan beads during surgery. Interestingly an additional 20mL of stimulan was also implanted 6 months earlier during prior revision. Due to worsening hypercalcemia and renal function despite adequate IV hydration, pamidronate was given at reduced dosing, with subsequent normalization of Ca levels. However, he continued to have rising serum Cr suspected from bisphosphonate use. A renal biopsy showed ATN with 53% global glomerulosclerosis from HTN and 50% IFTA.

Discussion: Hypercalcemia has been reported with calcium sulfate-based volume expanders, typically associated with higher bead volumes, e.g. 30-40mL. Many cases are mild and self-resolving up to a reported 2-6 weeks. In 0.2% of cases, severe or persistent hypercalemia requires treatment similar to other causes of severe hypercalcemia including use of bisphosphonates or RANK-L receptor antibodies. Washout of beads may not be beneficial and can exacerbate hypercalcemia from bead agitation.



TH-PO185

Atypical Location of Tumor-Induced Osteomalacia (TIO) and Its Clinical Implications

Carla A. Nicolau, Miguel Bigotte Vieira. *Unidade Local de Saude Sao Jose, Lisboa, Portugal.*

Introduction: Tumor Induced Osteomalacia (TIO) is a rare but potentially treatable paraneoplastic syndrome. Thus, increasing awareness, may lead to prompt recognition and effective management of TIO, which is crucial in reducing long-term disability and morbidity.

Case Description: A 63-year-old woman was referred to our hospital with 2 years of muscle weakness and bone pain. She had progressive incapacity to walk and pathologic fractures. DEXA scan revealed osteoporosis. Initial laboratory measurements showed severe hypophosphatemia 1,6mg/dL, normal calcium, magnesium and creatinine values. Further work-up revealed low vitamin D1,25 <1,6 pg/mL, high serum alkaline phosphatase 459 U/L and high normal PTH 78 pg/mL. Urine testing showed high fractional excretion of phosphate 29%. Urinalysis didn't show proteinuria or glicosuria. FGF-23 was abnormally high (348 UA/mL) and genetic testing was normal. A bone biopsy confirmed the diagnosis of osteomalacia. A 68 Ga-DOTANOC PET/CT scan showed a cervical infiltrative lesion. Following the surgical excision of the tumor, serum phosphate and FGF-23 levels returned to normal in three weeks, and the patient regained the ability to walk. One year later, the patient reported a recurrence of musculoskeletal symptoms. Laboratory results indicated hyphosphatemia and an elevated fractional excretion of phosphate, suggesting tumoral recurrence. The patient is currently being evaluated for burosumab treatment and surgical candidacy.

Discussion: The initial presentation of TIO can be non-specific and misleading, posing a diagnostic challenge. Delayed diagnosis results in significant morbidity and, if left untreated, can be fatal. Complete surgical resection remains the optimal treatment. However, up to 14% of surgically treated cases may experience recurrence due to incomplete resection, leading to devastating implications. Historically, this condition has been treated with calcitriol and phosphate supplementation. However, this requires multiple daily doses, increasing the burden of disease and presenting risk of nephrocalcinosis and non-compliance. Additionally, in patients with CKD, dose titration is limited by renal disease and secondary hyperparathyroidism. Therefore, Burosumab, a monoclonal antibody against FGF-23, is a crucial second-line therapy for enhancing clinical outcomes and quality of life in patients with non-surgical or non-localized TIO.

TH-PO186

Transfer Learning Predicts Network Biology for Fibroblast Growth Factor 23 (FGF-23) and Cardiac Disease

Farzana Perwad,[1] Elvis A. Akwo,[2] Cassianne Robinson-Cohen.[2]
[1]University of California San Francisco, San Francisco, CA; [2]Vanderbilt University Medical Center, Nashville, TN.

Background: Multi-trait analysis of Genome-wide association (MTAG) is a novel method to explore overlapping genetic architecture between traits. We investigated genetic traits common to mineral metabolism to identify novel genetic associations for fibroblast growth factor 23 in the context of cardiac disease. We utilized transfer learning, a novel machine learning tool to enable context-specific predictions in a setting with limited data in network biology.

Methods: We applied MTAG to genetic variants common to 5 genetically correlated mineral metabolism markers (phosphorus, FGF23, calcium, vitamin D and PTH) in European-ancestry subjects from UKBioBank (n=366,484), and CHARGE consortium (n=45,779). We applied a context-aware, attention-based deep learning model, Geneformer, pre-trained on a large-scale corpus of ~ 30 million single-cell transcriptomes to enable context-specific predictions. We also queried for genes functionally related to uremia using gene reference into function database.

Results: MTAG identified independent genome-wide significant SNPs for all traits, including novel and known loci for FGF23. We identified statistical overlap of GWAS variants with Geneformer-derived genetic targets obtained from modeling single nuclear cell RNA seq from human heart transplant recipients and from deceased organ donors with healthy hearts (Figure 1). In silico gene perturbations revealed genes that, when activated or deleted, were protective against hypertrophic or dilated cardiomyopathy (Table 1). Further, we identified uremic solutes, glyoxal, erythritol and calcitonin gene-related peptide associated with both MTAG variants and pathophysiology of cardiac disease.

Conclusions: Novel genetic traits for FGF23 were identified with MTAG and associated with cardiac disease. Geneformer revealed networks that inform unique biological processes and cellular functions that could be targeted to develop therapeutics for human heart failure.

Funding: NIDDK Support

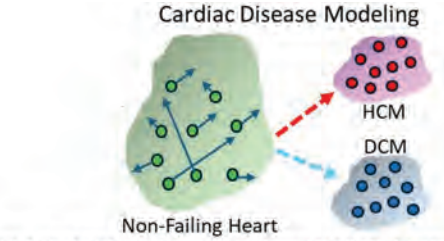


Fig. 1. Fine-tuning in Geneformer was performed to distinguish cardiomyocytes from non-failing hearts from hypertrophic (HCM) or dilated cardiomyopathy (DCM). Disease modeling is performed by in silico deletion or activation of random genes within non-failing cardiomyocytes to define the random distribution and to identify genes whose in silico deletion or activation shifts the embedding significantly towards either hypertrophic or dilated cardiomyopathy state.

Table 1. Disease modeling for hypertrophic and dilated cardiomyopathy in Geneformer

Pairing for Fisher's test	P_Value	Odds_Ratio (95% CI)	Gene Ratio
MTAG genes vs Hypertrophic cardiomyopathy_in silico gene activation	0.005	2.5 (1.3, 4.3)	14/2177
MTAG genes vs Dilated Cardiomyopathy_in silico gene activation	0.015	2.6 (1.1, 5.3)	8/1144
MTAG genes vs Hypertrophic cardiomyopathy_in silico gene deletion	0.067	3.3 (0.7, 9.9)	3/333
MTAG genes vs Dilated Cardiomyopathy_in silico_gene deletion	0.047	3.8 (0.8, 11.5)	3/288

Genes were filtered for non-failing (NF) heart, false discovery rate (FDR) < 0.01, and Shift to NF > 0. Gene ratio represents number of genes in MTAG over total number of genes that represent hypertrophic or dilated cardiomyopathy state.

TH-PO187

Prostaglandin E2 Receptor 4 Contributes to Regulating Epithelial Sodium Channel (ENaC) Activity in the Kidney Collecting Duct

Ting Yang,[1] Oleh Pochynyuk.[2] *[1]Duke University, Durham, NC; [2]The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX.*

Background: PGE_2 and its EP4 receptor (EP4R) play important role in blood pressure control. Our previous work showed conditional deletion of EP4R from whole kidney epithelia caused exacerbated blood pressure elevation, sodium retention, and increased responsiveness to ENaC inhibitor during Ang II-HTN. Thus, we hypothesize that EP4R resists the development of hypertension through actions in the CD to reduce sodium reabsorption via ENaC.

Methods: We used the patch clamp electrophyhsiology techniques in isolated CD from C57BL/6 mice to characterize the contribution of EP4 to ENaC activity. Additionally, we used an immortalized mouse collecting duct cell line (mpkCCDc14) to investigate the potential contribution of EP4 downstream signaling in regualting ENaC function.

Results: PGE_2 significantly inhibited the P_o of ENaC. This effect was abolished by EP4R antagonist (L161,982, Fig. 1). Using the mpkCCDc14 cells, we found that EP4 silencing using siRNA significantly inhibited the PGE_2 (10mM, 10min) induced phosphorylation of p-44/42 MAPK/ERK (Fig. 2).

Conclusions: Our results indicate that PGE_2 directly inhibits the kidney collecting duct ENaC channel open probability via EP4 receptor. The phosphorylation of MAPK/ERK pathway may contribute to teh ENaC regulation mediated by PGE2-EP4 signaling.

Funding: NIDDK Support

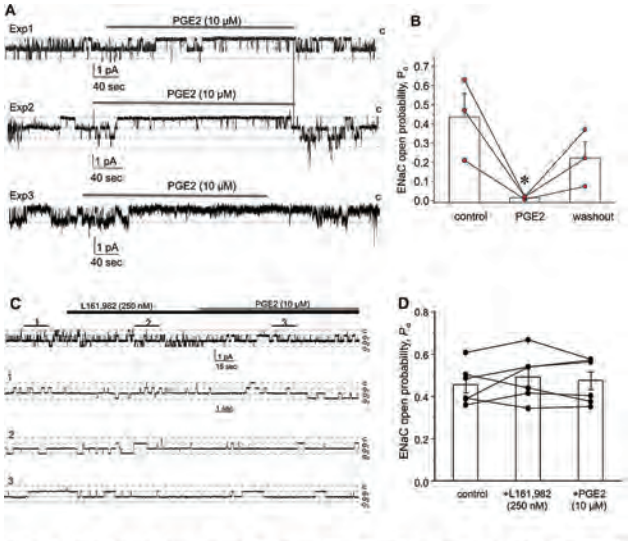

Figure 1. PGE2 inhibits ENaC activity in isolated cortical CDs via actions on EP4 receptors. (A) Current traces from patches monitoring ENaC activity in split-opened CDs under control and 10 mM of PGE2. (B) PGE2 significantly inhibits the ENaC open probability (Po). (C, D) EP4 receptor antagonist (L161,982, 250nM) abolished the PGE2 mediated inhibition of ENaC Po. * p<0.05 vs control and washout.

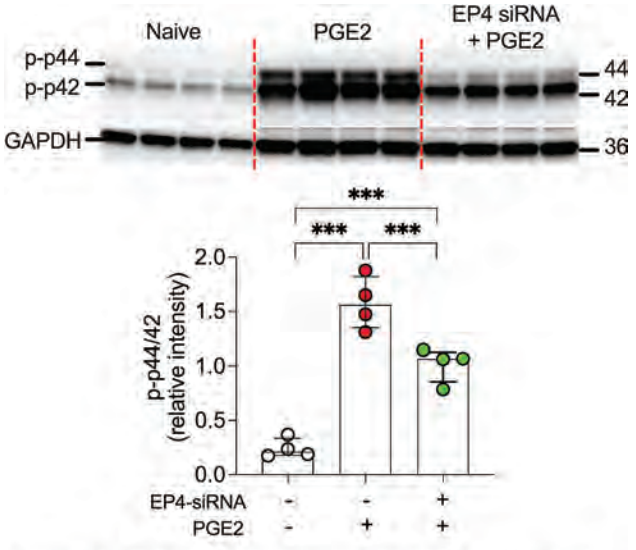

Figure 2. MAPK/ERK phosphorylation. EP4 silencing by targeted siRNA significantly reduced the PGE2 (10mM, 10 min) dependent p44/p42 MAPK phosphorylation (normalized by GAPDH). ***p<0.01.

TH-PO188

Activation and Targetability of TYMP-IL-6-TF Axis in the Skin Microenvironment in Patients with Uremic Calciphylaxis

Adam Lazowski,[1] Austin P. Morrissey,[1] Scott Krinsky,[3] Abbas Brahim Malloum,[1] Thierry Edwards,[1] Asha Jose,[1] Houda Bouchouari,[3] Wenqing Yin,[1] Rosalynn Nazarian,[3] Sagar U. Nigwekar,[3] Vipul C. Chitalia.[1,2] *[1]Boston University, Boston, MA; [2]Veterans Health Administration, Washington, DC; [3]Mass General Brigham Inc, Boston, MA.*

Background: Calciphylaxis is a rare disease characterized by calcification and thrombosis of subdermal microvessels, resulting in painful necrosis. It is seen predominantly in patients with end-stage kidney disease (ESKD) and has high mortality, elusive pathogenesis, and no approved therapies.

Methods: Sera and skin biopsies of ESKD patients with calciphylaxis were analyzed using O-linked proteomics and spatial transcriptomics, respectively. The validation and mechanistic probing were conducted using an array of techniques, including multiple ELISA, Immunofluorescence, and neutralizing assays.

Results: We demonstrate that the calciphylaxis sera upregulate IL-6, soluble IL-6 receptor (sIL-6R) levels and induce JAK2-STAT3 phosphorylation in the primary human subdermal microvascular endothelial cells (ECs) in a feedforward manner. Spatial transcriptomics and space-constrained probability analyses revealed a gain of proximal and distal IL-6 ligand-receptor interactions in calciphylaxis skin with heterogeneity between vessels, adipocytes, and eccrine glands. Microvessels served as the predominant senders and recipients of IL-6 signaling. Increased ADAM17, sIL-6R, and normal IL-6R levels in the skin microenvironment supported trans-IL-6 signaling in calciphylaxis. Additionally, calciphylaxis vessels showed an upregulation of *thymidine phosphorylase* (*TYMP*). Further mechanistic probing in ECs revealed that calciphylaxis serum-induced TYMP expression augmented IL-6 levels, which activated tissue factor (TF), the primary trigger of the extrinsic coagulation cascade. This TYMP-IL-6-TF axis was supported by strong correlations among TYMP, IL-6, and TF in calciphylaxis vessels. Calciphylaxis sera induced higher TF activity in ECs in a manner dependent on serum IL-6 levels and was suppressed by an anti-hIL-6R antibody.

Conclusions: This work, for the first time, identifies TYMP as an IL-6 regulator and characterizes calciphylaxis as a systemic state of high levels of IL-6 and a local state of activation of the TYMP-trans-IL-6-TF loop in the subdermal microenvironment perpetuating the thrombotic phenotype. Our work uncovers IL-6 as a potential biomarker and a therapeutic target for uremic calciphylaxis.

TH-PO189

Inhibition of NaPi2a Improves Pressure-Overload Heart Failure and Doxorubicin-Induced Cardiac Damage

Hiroko Yamauchi, Tomoharu Ida, Tetsuro Kusaba, Keiichi Tamagaki. *Department of Nephrology, Graduate School of Medical Science, Kyoto Prefectural University of Medicine, Kyoto, Japan.*

Background: Recently, the number of heart failure (HF) patients is increasing worldwide. Based on the success of SGLT2 inhibitor in HF treatment, targeting proximal tubular sodium channel is an attractive therapeutic strategy for HF. We hypothesized that inhibition of Sodium-phosphate co-transporter 2a (NaPi2a), predominantly expressed in the renal proximal tubule, can attenuate the progression of HF via 1) reduction in serum FGF23 levels through phosphate excretion and 2) decrease in fluid volume via sodium excretion.

Methods: Using NaPi2a-KO mice, we examined the cardioprotective effect of loss of function of NaPi2a in following HF mouse model; 1) pressure-overload heart failure induced by transverse aortic constriction (TAC), 2) Doxorubicin (Dox) cardiomyopathy and 3) uremic cardiomyopathy by 5/6 nephrectomy

Results: In the TAC model, decreased serum phosphate and FGF23, and increased urinary sodium excretion were observed in NaPi2a-KO mice. Left ventricular ejection fraction (LVEF) in echocardiography was preserved in NaPi2a-KO mice. qPCR analysis revealed that upregulation of myocardial injury and fibrosis markers by TAC surgery was ameliorated in NaPi2a-KO mice. In the Dox cardiomyopathy model, LVEF was preserved in NaPi2a-KO mice. qPCR analysis showed that the Dox-induced upregulations of myocardial fibrosis markers were ameliorated in NaPi2a-KO mice. In the uremic cardiomyopathy model, serum phosphate and FGF23 were notable increased, but there were no differences between WT and NaPi2a-KO mice. No significant differences were noted in cardiac function, or expressions of myocardial injury and fibrosis markers by qPCR between the two groups, either. FGF23 levels were not correlated with cardiac contractility in all HF models.

Conclusions: NaPi2a inhibition ameliorated the progression of cardiac injury in pressure-overload heart failure and Dox cardiomyopathy but not in uremic cardiomyopathy. Urinary sodium excretion, rather than the decrease in serum FGF23 levels, may involve the effect of NaPi2a inhibition. In the uremic cardiomyopathy model, loss of kidney parenchyma and subsequent high serum phosphorus reduced NaPi2a expression may attributed to the less cardioprotective effect by NaPi2a inhibition. NaPi2a inhibition can be a novel therapeutic candidate for HF especially in the patients with preserved renal function.

Aminopeptidase A: A Potential Novel Therapy for Angiotensin-Dependent Hypertension?

Peter Forster, Jan Wysocki, Daniel Batlle. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: We have shown that mice with a genetic deficiency in Aminopeptidase A (APA) have elevated blood pressure. APA is an enzyme that removes a single aspartate residue from the amino-terminus of several peptides in the renin-angiotensin systems (RAS), including angiotensin (Ang) II. In this study, we investigated the impact of a recombinant APA on the formation of various RAS peptides and its effect on blood pressure.

Methods: An in vitro assay was used to identify Ang peptides as substrates for APA. Ang peptides identified as APA substrates using this assay were then injected to anesthetized *WT and APA-deficient* mice to assess their pressor effect by measuring systolic blood pressure (SBP). Subsequently, murine recombinant (r)APA was used to evaluate its action on the acute SBP elevation elicited by Ang peptides that were identified to trigger pressor response.

Results: In the *in vitro* assay, Ang II (22427±3353, n=12), Ang I (21883±1692, n=3), Ang1-7 (15833±3395, n=3), Ang1-9 (15773±3395, n=3) and Ang1-12 (13170±220, n=3), were identified as a substrate for rAPA as indicated by a strong aspartate-driven fluorescence formation. When these five Ang peptides were administered to WT mice, only Ang I, Ang II and Ang 1-12 caused a significant increase in SBP. This effect was exaggerated in APA deficient mice. The SBP increase elicited by Ang I and Ang II in WT mice was markedly reduced by the pre-administration of rAPA (Fig. 1).

Conclusions: Aminopeptidase A can cleave the N-terminal aspartate from Ang II as well as from other RAS peptides that elicit (Ang 1-12, Ang I) do not elicit (Ang 1-9, Ang 1-7) pressor response in mice. APA deficiency is associated with an exaggerated SBP response to Ang I, Ang II and Ang 1-12 while the recombinant enzyme mitigates the acute hypertensive effect. rAPA markedly reduced the increase in SBP caused by Ang I and Ang II infusion suggesting that it may be used to treat hypertension resulting from RAS overactivity.

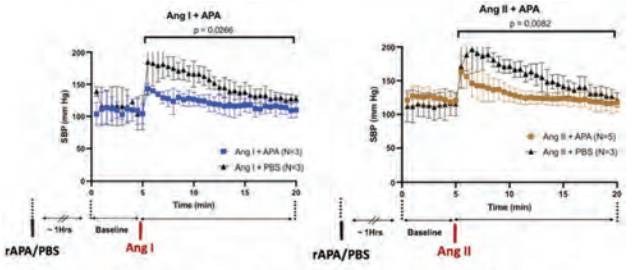

Figure 1. SBP after injection of Ang I and Ang II in WT mice that were pre-treated with either rAPA or vehicle (PBS).

Transmembrane Protein 184A (TMEM184a) Expression in Rat Medullary Thick Ascending Limbs

Darshan Jadhav,[1] Beau Forester,[1] Najeong Kim,[1] Jeffrey L. Garvin,[1] Agustin Gonzalez-Vicente.[1,2] Kidney Precision Medicine Project (KPMP). *[1]Case Western Reserve University School of Medicine, Cleveland, OH; [2]Cleveland Clinic Glickman Urological and Kidney Institute, Cleveland, OH.*

Background: Nitric oxide production by NOS3 in thick ascending limbs (TAL) is essential for proper kidney function. TMEM184A is a heparin receptor found in endothelial cells that mediates NOS3 phosphorylation. The kidneys express TMEM184A, but its localization in nephron segments expressing NOS3 remains unclear. The Kidney Precision Medicine Project (KPMP) single cell (sc) and single nuclei RNA sequencing (RNAseq) transcriptomes show TMEM184A expression in proximal tubules and inner medullary collecting ducts, but not in TALs. On the contrary, KPMP's regional transcriptomes show that TMEM184A is significantly overexpressed in the TAL (Δfc0.7; p≤0.05) as compared to other regions. The expression of Tmem184a in published rodent transcriptomes is similarly in dispute. The same laboratory reported that mouse medullary TAL had stronger TMEM184A mRNA expression than any nephron segment, while expression in rat medullary TAL was undetectable.

Methods: Consequently, we measured TMEM184A protein and mRNA expression by Western blot and scRNAseq in the outer medulla from Sprague Dawley rats.

Results: We found that the rat outer medulla expressed both, monomers and dimers of TMEM184A (Figure 1). Additionally, TMEM184A mRNA was significantly overexpressed in medullary TALs (Δfc1.7 p-Adj≤$4x10^{-18}$) when compared to other outer medullary epithelial cells types, i.e. proximal tubule S3 cells and the collecting duct principal and intercalated cells (Figure 2).

Conclusions: These data show that the rat medullary TAL express TMEM184A where it may play a role in NO production by NOS3 as it does in endothelial cells.

Modulation of Blood Pressure through Microbiome Exchange between Milan Normotensive and Hypertensive Rat Strains

Giovambattista Capasso,[1,2] Yoko Suzumoto,[1,3] Cristoforo Silvestri,[4] Abbas Shams,[1,2] Luciano D'Apolito,[1,2] Antonio Villanova,[1,2] Francesco Trepiccione,[2,1] Vincenzo Di Marzo.[4] *[1]Biogem, Biology and Molecular Genetics Institute, Ariano Irpino, Italy; [2]University of Campania 'L. Vanvitelli', Naples, Italy; [3]Institute of Biochemistry and Cell Biology, National Research Council of Italy (CNR), Naples, Italy; [4]CRIUCPQ, INAF and Centre NUTRISS, Université Laval, Québec, QC, Canada.*

Background: Hypertension constitutes a major health problem leading to cardiovascular diseases. A number of studies showed gut microbiome changes in hypertension, suggesting kidney-gut axis in hypertension. A congenic strain of Milan hypertensive (NA) rats with a mutation in α-adducin gene develops hypertension at 3 months age. Our preliminary study revealed diverse expression of renal sodium transporters in NA rats compared with normotensive strain (MN) rats, indicating

abnormal renal salt handling in NA rats. Present study aimed at investigating a possible connection between gut microbiome and blood pressure phenotype in these two strains. We evaluated whether exchange of faeces between two strains may transfer phenotypes via gut microbiome, and mechanisms underlying altered phenotypes were investigated.

Methods: NA and MN rats were subjected to 'homogenization (HOM)' of the microbiome, consisted of exchanges of bedding with faeces, followed by co-housing in the same cage (MN-HOM and NA-HOM groups). For the baseline (BSL) condition, rats were homogenized within the same strain (MN-BSL and NA-BSL). Systolic blood pressure (SBP) was measured every month. Faeces were collected for microbiota metataxonomic analysis using next generation sequencing of 16S ribosome encoding DNA.

Results: At 5 month, SBP in MN-BSL was averaged at 143.6 mmHg, while SBP of NA-BSL was 163.3 mmHg, confirming the hypertensive phenotype in NA rats at baseline. MN-HOM showed a significantly enhanced SBP compared to MN-BSL, reaching 153.5 mmHg. The average SBP of NA-HOM was163.7 mmHg, indicating that homogenization did not have impact on SBP in NA rats. The SBP of MN-HOM was still significantly lower than both the NA-BSL and NA-HOM groups. Different gut microbiota compositions were observed in the two strains of rats at baseline, and HOM altered both.

Conclusions: We have demonstrated that the hypertensive phenotype in NA rats was transferred to MN rats through homogenization, indicating that the intestinal microbiota or metabolites derived therefrom could eventually modulate SBP. Further studies are required to unveil the molecular mechanisms by which the gut microbiome modulates blood pressure.

TH-PO193

Sex Differences in Renal Blood Flow Autoregulation Do Not Explain the Sex Disparity in CKD Progression

Aaron J. Polichnowski,[1] Jacqueline M. Chivers,[1] Purva R. Chopde,[2] Geoffrey A. Williamson,[2] Karen A. Griffin.[3,4] *[1]East Tennessee State University James H Quillen College of Medicine, Johnson City, TN; [2]Illinois Institute of Technology, Chicago, IL; [3]Loyola University Chicago Stritch School of Medicine, Chicago, IL; [4]Edward Hines Junior VA Hospital, Hines, IL.*

Background: We recently demonstrated an increased susceptibility to hypertensive renal injury in male vs. female rats. Sex differences in renal blood flow (RBF) autoregulation (AR) may contribute, in part, to the sex disparity in susceptibility to hypertensive renal injury and progression of chronic kidney disease (CKD); however, there are limited data available. Here, we investigated whether sex differences exist in RBF AR in uninephrectomized (UNX) rats before and during the administration of deoxycorticosterone acetate (DOCA) + salt.

Methods: Male (n=7) and female (n=8) Sprague-Dawley (SD) rats (10-13-week-old) underwent UNX. Two weeks later, rats were instrumented with a blood pressure (BP) radiotelemeter and a RBF probe. One week later, BP and RBF were assessed in the conscious state for 2-3 hours/day over 3 consecutive days prior to (i.e., baseline) and during days 3-7 of DOCA (3.3 mg/day) + salt (1% NaCl via drinking water) administration. We assessed dynamics of RBF AR using the short-segment AR index (SSARI, PMID 31792155) applied to adjacent time segments with >2.5 mmHg BP differences, as well as transfer function analysis. A 2-way repeated measures ANOVA with Sidak post hoc test was used for analysis. Data are mean±SE and P<0.05 was considered statistically significant.

Results: As shown in Table 1, RBF was higher (P<0.05) and renal vascular resistance (RVR) lower (P<0.05) in males at baseline and during DOCA + salt administration; however, no sex differences were observed in mean arterial pressure (MAP). DOCA + salt increased RBF and decreased RVR in both sexes (P<0.05), but only increased MAP (P<0.05) in males. No significant sex differences were observed in any measure of RBF AR. DOCA + salt decreased SSARI (i.e., strengthened RBF AR) for 2.5 second segments in females (P<0.05) but not males (P=0.10), and increased (P<0.05) the operating frequency of the myogenic mechanism in both sexes. In contrast, DOCA + salt decreased (P<0.05) the fractional gain at the myogenic frequency in both sexes.

Conclusions: Sex differences in RBF AR do not appear to be playing a significant role in the sex disparity in susceptibility to hypertensive renal injury and CKD progression.

Conditional Genetic Disruption of Podocyte Cell-Specific Npr1 Provokes Kidney Dysfunction in Male and Female Mutant Mice in a Sex-Dependent Manner

Chandramohan Ramasamy, Kailash N. Pandey. *Tulane University School of Medicine, New Orleans, LA.*

Background: Atrial and brain natriuretic peptides (ANP and BNP) are cardiac hormones that induce diuresis, natriuresis, and vasorelaxation and reduce blood pressure (BP) and blood volume homeostasis via activation of transmembrane guanylyl cyclase/natriuretic peptide receptor-A (GC-A/NPR-A) with increased accumulation of intracellular cGMP. The role of ANP/NPRA/cGMP signaling in podocytes, which are highly specialized epithelial cells covering the outer surfaces of renal glomerular capillaries, is not well understood.

Methods: In this study, we determined the impact of conditional gene-knockout (KO) of podocyte (PD)-specific *Npr1* (encoding NPRA) in male and female mice. Tamoxifen-treated wild-type control (PD *Npr1* f/f; WT), heterozygous (PD-Cre-*Npr1* f/+; HT), and gene-knockout (PD-Cre-*Npr1* f/-; KO) mice were fed a normal-, low-, or high-salt diet for 28 days. Podocytes isolated from KO male and female mice exhibited a complete absence of *Npr1* mRNA and NPRA protein levels compared with WT mice.

Results: On a normal-salt diet, mean arterial pressure (MAP) and heart rate (HR) were significantly higher ($p<0.05$; $p<0.01$; $p<0.001$) in both male and female PD-*Npr1* KO mice compared with WT mice at 2, 4, 6, 8, and 12 weeks as measured by radiotelemetry. On a high-salt diet, the systolic blood pressure (SBP) was significantly ($p<0.01$; $p<0.001$) higher in the PD-*Npr1* HT mice (male:109.50 ± 1.20; female: 102.30 ± 0.60) and KO mice (male:116.20 ± 1.1; female: 104.40 ± 1.20) compared with WT mice (male: 96.30 ± 0.70; female: 92.60 ± 0.60) after 28 days as measured by computerized tail-cuff method. On normal-, low-, and high-salt diets, plasma sodium, and albumin/creatinine ratio were significantly ($p<0.05$; $p<0.01$; $p<0.001$) increased, while creatinine clearance and urinary sodium levels were significantly ($p<0.05$; $p<0.01$; $p<0.001$) reduced in the HT and KO male and female mice compared to WT mice. These changes were significantly greater in males than females. Immunofluorescence of podocin and synaptopodin were also significantly ($p<0.01$; $p<0.001$) reduced in HT and KO mice compared to WT mice.

Conclusions: These observations suggest that in podocytes, ANP/NPRA/cGMP signaling may be crucial in the maintenance and regulation of BP and GFR suggesting as a biomarker of renal function in a sex-dependent manner.

Funding: NIDDK Support

TH-PO195

Renal Solute Handling in ABCA1-Deficient Kidneys

Karin Carneiro de Oliveira,[1,2] Yuan Wei,[1,2] Rajeev Rohatgi.[1,2] *[1]James J. Peters VAMC, Bronx, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Na sensitive blood pressure (BP) and restricted cholesterol (chol) efflux are risk factors for cardiovascular mortality. Renal tubular ablation of ABCA1, a chol efflux protein, raises systolic BP (SBP) compared to wildtype (WT) mice. Enriched chol diets additionally raise SBP in mice of ABCA1 deficient kidneys while Na restriction quenches SBP difference between mice. In contrast enriched Na diets do not further raise SBP in ABCA1 deficient mice. Chol-fed ABCA1 deficient mice show increased renal NKCC2 and ENaC protein expression vs. WT chol-fed mice. The goal of this investigation is to determine whether renal solute transport is dysregulated in ABCA1 deficient mice fed a standard chol diet and whether these changes contribute to the development of high BP.

Methods: Transgenic mice, which express a doxycycline(dox)-inducible CRE in tubules, were bred with mice expressing floxed ABCA1 to produce tubule-specific deficiency of ABCA1 (FF). Mice (WT and FF) were fed dox in water, and then fed a standardNa (0.39%) and chol (0.0196%) for at least 1 week. The mice were then placed in metabolic cages to collect urine at 2 hr intervals for 6 hrs. Urine osmolality and [Na] were measured. RNAseq analysis was performed on the renal cortex.

Results: The weights of WT (n=10; 26.0±0.7 g) and FF (n=10; 25.7±0.4 g) mice did not differ. Surprisingly, FF mice excreted a larger urine volume at 2 hr (15.6±1.4 μL/g body weight[BW]) and over the entire collection period (33.7±2.2 μL/g BW) compared to WT mice (10.5±0.8 uL/g and 25.8± 2.2 uL/g BW, $p<0.05$; respectively). Urine osmolality did not differ, but osmole excretion was greater over the collection period in the FF (30.2±2.6 μosm/g BW; $p<0.05$) compared to WT (22.5±2.2 μosm/g BW). The urinary Na concentration rose over 6 hrs in WT and FF, but at 6hr the urine [Na] was greater in FF (97.4±6.9 mM; $p<0.05$) than WT (57.6±7.6 mM). Net Na excretion was greater in FF (1.49±0.15 μeq/g BW; $p<0.05$) than WT (0.92±0.17 μeq/g BW). RNAseq showed increased renal cortical Ren1 mRNA and western blot confirmed the increase of renin protein in FF (n=4) compared to WT (n=4).

Conclusions: Renal tubular ABCA1 deficiency, in mice fed a standard Na and chol diet, enhances urine volume, osmolar and Na excretion with greater renal renin expression. We speculate that loss of ABCA1 functionality mediates higher SBP via greater intra-renal renin which raises systemic BP to excrete more Na.

Novel Role of BK-Channel Activation in Ameliorating Cardiac Fibrosis in the Ischemia-Reperfusion (IR)-Induced Heart Failure Mouse Model

Xiaomao Luo,[1,2] Zimeng Liu,[1] Shuyang Bian,[1] Faten Hassounah,[1] Qiang Yue,[1] Xiaonan H. Wang,[1] Hui Cai.[1,2] *[1]Emory University, Atlanta, GA; [2]Joseph Maxwell Cleland Atlanta VA Medical Center, Decatur, GA.*

Background: Ischemic heart disease poses a significant global health challenge, impacting over 244 million adults worldwide. Our previous study has shown that the Big Potassium (BK) ion channel prevents renal fibrosis. However, it remains unclear whether BK channel has anti-fibrotic role in the heart.

Methods: Heart failure model was induced by Ischemic-Reperfusion (I/R) surgery in C57/BL6 mice. To upregulation of BKα, BMS-191011 (10 mg/kg BW) was given by IP injection daily for 8 weeks. Single channel recordings were used to analyze the activation of BKα channel. Cultured H9C2 cardiac myoblasts were used to assess the impact of BK opener (NS1916 10mM) on fibrosis markers and oxidative stress. Hydrogen peroxide (H2O2), superoxide and superoxide dismutase (SOD) were deternubed by Amplex Red Hydrogen Peroxide Kit, Dihydroethidium (DHE) Assay and colorimetric activity kit, respectively. The mRNA expression of BKα and inflammatory cytokines were assayed by qPCR.

Results: The expression of BKα mRNA and protein was decreased while cardiac fibrosis increased in the hearts of I/R mice. Fibronectin, vimentin, and αSMA were significantly elevated in I/R hearts; conversely, BMS treatment attenuated the levels of these proteins. Echocardiogram revealed an increase in left ventricular end-diastolic dimension in I/R mice, which returned to normal following BK opener treatment. Ejection fraction also improved with this treatment. In addition, the activation of BKα channel prevented I/R-induced upregulation of inflammatory cytokines, such as TNFα, IL-1β, TGFβ and phospho-smad 2/3 in the heart of I/R mice. Single channel recordings found that TGFβ inhibited BKα activity. In H9C2 cells TGFβ increased fibronectin and collagen I production, while BKα openers (NS1619) limited the TGFβ -induced increase in both proteins. TGFβ also significantly increased H_2O_2 and superoxide production in H9C2 cells. Activation of BKα channel abolished this effect along with reversing TGFβ-induced down-regulation of SOD production.

Conclusions: Our findings suggest that BK channel activation has a protective role in I/R-induced chronic heart failure by reducing cardiac fibrosis and improving cardiac function, which provide the potential therapeutic target of BK in treating fibrosis and improving heart function following cardiac I/R.

Impaired Long-Term and Short-Term Control of Sympathetic Nerve Activity in Nonhypertensive Dahl S Salt-Sensitive Rats

Eva Hutter,[1] Tilmann Ditting,[1,2] Clara Meißner,[1] Nada Cordasic,[1] Peter Linz,[1] Karl F. Hilgers,[1] Mario Schiffer,[1] Kerstin U. Amann,[1] Roland Veelken,[1,2] Kristina Rodionova.[1] *[1]Friedrich-Alexander-Universitat Erlangen-Nurnberg, Erlangen, Germany; [2]Paracelsus Medizinische Privatuniversitat - Nurnberg, Nurnberg, Germany.*

Background: Our recent research on neurons with afferent dendrites from the kidneys as well as direct renal nerve recordings suggested that the afferent renal innervation tonically inhibits sympathetic activity under normal conditions. Now, we wanted to test the hypothesis that the afferent renal innervation is already impaired in prehypertensive salt-sensitive Dahl S rats receiving a normal salt diet.

Methods: Prehypertensive Dahl salt sensitive rats (DSS) and Sprague-Dawley (SD) controls were kept on normal salt diet. Dorsal root ganglion neurons (Th11-L2) with dendrites from the kidney of both groups of rats were investigated in voltage clamp mode to assess inward currents and current clamp mode to assess action potential (AP) generation. Neurons were classified as tonic (high AP generation upon stimulation) or phasic (AP < 5 upon stimulation). Measurement of arterial blood pressure, heart rate, and direct recordings of renal sympathetic nerve activity (RSNA) were performed in both groups of rats (n=6). To assess neural control of volume homeostasis, rats underwent volume expansion (VE) (0.9% NaCl; 5% of body weight in 30 min) to decrease RSNA.

Results: In vitro, the portion of tonic highly active neurons was significantly smaller in DSS than in SD rats suggesting decreased afferent renal nerve activity (24 % tonic neurons in DSS vs. 51% in SD, *p<0.05, z-test). In vivo, the initial decrease of RSNA during volume expansion was similar for both groups, but RSNA in DSS rats returned to control levels within 15 minutes after cessation of VE but remained significantly decreased in SD rats.

Conclusions: In salt sensitive Dahl S rats on a normal salt rat chow, renal sympathetic nerve activity was likely insufficiently controlled by long term (tonic sympathoinhibitory renal afferent nerves) as well as short term (cardiopulmonary reflex) regulatory mechanisms. These findings suggest a severely impaired function of the autonomous nervous system even in the prehypertensive phase of salt sensitve Dahl S rats.

TH-PO198

Differential C-X-C Motif Chemokine Receptor 4 (CXCR4) Expression in Aldosterone-Producing vs. Nonfunctional Adenomas

Chunyi Wu.[1,2] Molecular and Integrative Physiology and Internal Medicine, University of Michigan. *[1]University of Michigan, Ann Arbor, MI; [2]Taichung Veterans General Hospital, Taichung, Taiwan.*

Background: Primary aldosteronism (PA) is the leading cause of secondary hypertension and may have detrimental renal consequences. Unilateral PA can be cured with adrenalectomy. However, subtyping into unilateral or bilateral disease can be costly, invasive, and clinically challenging. Aldosterone-producing adenoma (APA)-targeted positron emission tomography/computed tomography (PET/CT) has emerged as a potential non-invasive imaging technique for subtype determination that could circumvent the need for gold standard adrenal venous sampling (AVS). Radiolabeled probes have been developed that bind the enzyme aldosterone synthase (CYP11B2) and chemokine receptor 4 (CXCR4). However, the expression of CXCR4 in APA and non-functional adenomas (NFA) has not been extensively studied. **Objective:** To evaluate the differential expression of CXCR4 in APA versus NFA, thereby assessing its viability as a reliable biomarker in PET/CT imaging for PA subtyping.

Methods: A cohort of twenty PA patients who underwent unilateral adrenalectomy that were found to have an APA and an adjacent NFA from the university of Michigan were included in this study. Formalin-fixed, paraffin-embedded (FFPE) sections of resected adrenal tissue were used for the analysis. Aldosterone synthase (CYP11B2) immunohistochemistry (IHC) was performed to identify APA (CYP11B2 positive) and NFA (CYP11B2 negative). APA and NFA RNA was isolated followed by quantitative RT-PCR (qPCR) for *ACTB* (β-actin), *CYP11B2*, and *CXCR4*.

Results: In APA the average fold increase of *CYP11B2* mRNA relative to the adjacent NFA was 2726(± 323) (P<0.001). For *CXCR4* the average fold increase of APA relative to the adjacent NFA was 2.23(±0.83) (P=0.03). Although APA *CXCR4* mRNA expression did reach statistical significance compared to NFA, 3 of 20 patients had higher *CXCR4* transcript levels in the adjacent NFA.

Conclusions: Our finding confirm *CYP11B2* expression as a robust APA marker with significantly lower levels observed in NFA. The transcript analysis of *CXCR4*, however, raises concerns of its utility as a marker for APA over NFA. Additional studies are needed to examine CXCR4 protein levels in APA versus NFA to ensure specificity of CXCR4 as an APA marker in PET/CT imaging modalities.

TH-PO199

Aberrant Trafficking of Intestinal Immune Cells in Salt-Sensitive Hypertension

Ariana Rauch, Hendrik Bartolomaeus, Alex Yarritu, Wibke Anders, Harithaa Anandakumar, Nicola Wilck. Wilck lab. *Charite Universitatsmedizin Berlin, Berlin, Germany.*

Background: Essential hypertension is the leading risk factor for cardiovascular disease. In addition to elevated blood pressure, hypertension is characterized by an inflammatory immune response that precedes the clinical detection of organ-damage. Yet, the activation and origin of target-organ-infiltrating immune cells are not fully understood. This study takes a systems view on inflammation in hypertension and aims to investigate the extent to which the gut-associated immune cells contribute to the immune response in salt-sensitive hypertension.

Methods: Immune cell trafficking from the intestine to hypertensive target-organs was analyzed using *in vivo* labelling of intestinal immune cells via targeted UV photoconversion in *Kaede*-transgenic mice. Salt-sensitive hypertension was induced in male mice by oral L-NAME pretreatment and two 3-week periods of high-salt feeding (HSD), separated by a 2-week normal-salt (NSD) wash-out phase. Hypertensive organ damage and trafficking of photolabelled cells was analyzed 5 days after photoconversion. Subsets of mice received additionally FTY720 or an oral antibiotic cocktail or *Lactobacillus murinus* during the second HSD-period.

Results: HSD-fed mice displayed target organ damage assessed by mRNA-expression (qPCR and mRNAseq) of markers of kidney damage, inflammation and fibrosis. Intestinal immune cell trafficking was observed both in homeostasis (NSD) and disease (HSD). Infiltration of photolabelled intestinal immune cells was detected in various organs such as the spleen and kidney (flow cytometry and scRNAseq). B cells and T cells were among the major migrating populations. FTY720 strongly reduced photolabelled cells in target organs, indicating S1P-dependent immune cell trafficking. Salt-sensitive hypertension was characterized by a dysregulation of the intestinal-renal immune cell axis. Modulation of the microbiome via antibiotics or *Lactobacillus murinus* lead to a modulated immune cell trafficking.

Conclusions: Immune cells originating from the intestine migrate and populate various organs via the S1P-axis, both in homeostasis and in an aberrant manner in salt-sensitive hypertension. Our findings provide insight into mechanisms underlying hypertension-induced organ damage and could argue for interventions targeting intestinal immune cells.

Macrophage-Epithelial Sodium Channel (ENaC) Interactions Regulate Kidney Sodium Handling and Salt-Sensitive Hypertension

Alicja Czopek, Josselin Nespoux, Matthew A. Bailey, Neeraj Dhaun. Edinburgh Kidney. *The University of Edinburgh College of Medicine and Veterinary Medicine, Edinburgh, United Kingdom*.

Background: A third of people are salt-sensitive, showing an exaggerated blood pressure (BP) response to high salt intake. Salt-sensitivity is an independent cardiovascular risk factor, but its underlying causes are unresolved. Immune cells, including monocytes and macrophages (MΦ), are emerging as important regulators of both salt homeostasis and blood pressure physiology. Here, we investigated the impact of macrophage depletion on salt-sensitive hypertension in the mouse.

Methods: Male transgenic mice, with myeloid cell-specific expression of the human diphtheria toxin receptor (CD11b-DTR mice) were fed a high salt diet (8% NaCl) (HSD) for 4 weeks to develop hypertension. During the final (4th week) mice received diphtheria toxin (DT) to deplete tissue MΦ. In another group, liposomal clodronate (LC) was used as a second depletion strategy. We measured renal function, BP (by radiotelemetry) and collected kidneys for sodium transporters gene expression analysis. Renal MΦ number was assessed by immunohistochemistry.

Results: HSD increased systolic and diastolic BP by ~8mmHg and ~6mmHg from baseline. DT significantly reduced the MΦ count in renal cortex and induced complete depletion in the renal medulla. Although LC reduced the number of cortical MΦ, there was an increase in medullary MΦ count. There was also a differential effect on BP and renal Na^+ handling. DT amplified salt-sensitive hypertension by a further ~15mmHg ($p<0.0001$ *vs.* no depletion); LC had no additional effect. DT mice showed reduced urinary Na^+ excretion and hypernatremia; LC treated animals had no abnormalities in Na^+ status. High salt intake supressed aldosterone in all groups but DT depletion caused an inappropriate activation of *ENaC* at the mRNA and functional levels. ENaC blockade with benzamil significantly increased Na^+ excretion and reduced salt-sensitive hypertension in DT-treated animals.

Conclusions: We show that tissue MΦ distribution influences ENaC regulation and renal Na^+ handling independent of aldosterone, which can contribute to the development of salt-sensitive hypertension.

Role of Anaphylatoxin Receptors C5aR1 and C5aR2 in Hypertension and Hypertensive End-Organ Damage

Leonie Dreher,[1,2] Sarah Walachowski,[3] Georg R. Herrnstadt,[1,2] Nicolas Ehnert,[1] Catherine Meyer-Schwesinger,[4,2] Joerg Koehl,[5] Tobias B. Huber,[1,2] Markus Bosmann,[3] Ulrich O. Wenzel.[1,2] AG Wenzel. *[1]III. Department of Medicine, University Hospital Hamburg-Eppendorf, Hamburg, Germany; [2]Hamburg Center for Kidney Health (HCKH), Hamburg, Germany; [3]Pulmonary Center, Department of Medicine, Boston University School of Medicine, Boston, MA; [4]Department of Cellular and Integrative Physiology, University Hospital Hamburg-Eppendorf, Hamburg, Germany; [5]Institute for Systemic Inflammation Research, University Hospital Schleswig-Holstein, Lübeck, Germany*.

Background: Elevated blood pressure induces activation of the complement system. The anaphylatoxin C5a, a major inflammatory effector of the complement system, binds to the C5a receptor 1 and 2 (C5aR1, C5aR2). We have recently shown that C5aR1 knockout (KO) mice have reduced hypertensive renal injury. However, the role of the second C5a receptor and the extent of functional overlap between C5aR1 and C5aR2 remains enigmatic. We set out to examine the role of the C5aR2 and potential additional beneficial or antagonistic effects of combined deficiency of C5aR1 and C5aR2.

Methods: With single cell RNA sequencing we addressed the expression of C5aR2 in patients with hypertensive nephropathy. Murine expression of the C5aR2 was examined using a tandem dye Tomato-C5aR2 reporter mouse. For further investigation we used an aggravated model of hypertension with unilateral nephrectomy, infusion of angiotensin (Ang) II and high salt diet in both C5aR2 KO and mice with double deficiency of C5aR1 and C5aR2 (C57BL/6J-Del(7C5ar2-C5ar1)1Bosm; generated by CRISPR/Cas9 guided editing).

Results: Main expression of C5aR2 was found in myeloid cells in human kidneys with increased expression in hypertensive patients. Flow cytometric analysis of leucocytes isolated from kidneys of the tandem dye Tomato-C5aR2 reporter mice also showed main expression in myeloid cells. The expression pattern was comparable to that of C5aR1. No differences in blood pressure and renal injury (albuminuria, GFR, glomerular and tubulointerstitial injury) between hypertensive wildtype (WT) and C5aR2 KO (n=14) or C5aR1xC5aR2 KO (n=24) mice were found. To examine whether the effects are specific for Ang II induced hypertension, we also induced deoxycorticosterone acetate (DOCA) salt hypertension for 6 weeks in WT and C5aR1/2-deficient mice (n=12). Consistent with the findings in Ang II induced hypertension no significant differences regarding blood pressure or renal injury were found also in DOCA salt hypertension.

Conclusions: Both, C5aR1 and C5aR2 are mainly expressed on myeloid cells in humans and mice. While C5aR1 deficiency is potentially beneficial in hypertensive renal injury, deficiency of C5aR2 alone or in combination with C5aR1 has no effect on blood pressure and hypertensive end organ damage.

TH-PO202

SGLT2 Knockout Suppressed High Salt-Induced Organ Damage in Dahl Salt-Sensitive Rats

Hiroki Ito, Takuo Hirose, Shigemitsu Sato, Chika Takahashi, Risa Ishikawa, Akari Endo, Ikuko Yabana, Takefumi Mori. *Tohoku Ika Yakka Daigaku, Sendai, Japan*.

Background: SGLT2 (sodium-glucose cotransporter 2) inhibitors have renoprotective properties through multiple mechanisms. DahlS (Dahl salt-sensitive) rats develop renal congestion and damage as a consequence of salt-sensitive hypertension. We aimed to investigate the effects of SGLT2 deficiency on the development of hypertension and renal injury in the DahlS rats fed a high-salt diet.

Methods: The Sglt2 gene was knocked out in DahlS rats (DahlS/mcwi) using the CRISPR-Cas9 (clustered regularly interspaced short palindromic repeats-CRISPR-associated 9) system. DahlS-Sglt2$^{+/+}$ and DahlS-Sglt2$^{-/-}$ male rats (8 weeks old) were fed normal salt (0.6% NaCl) or high salt (4% NaCl) diets for 2 weeks. The kidneys and hearts were harvested and analyzed by molecular and histological techniques.

Results: Elevated blood pressure by the tail-cuff method was observed in both DahlS-Sglt2$^{+/+}$ and DahlS-Sglt2$^{-/-}$ rats following high-salt intake, with no significant difference between the two groups. Kidney and heart weights were significantly increased by the high-salt diet in DahlS-Sglt2$^{+/+}$ rats, while no changes were observed in DahlS-Sglt2$^{-/-}$ rats. The expression of tubulointerstitial damage markers; Havcr1 (Kim1) and Spp1 (Opn) and interstitial fibrosis markers; Fn1, Vim, and Acta2 (α-Sma) was elevated in DahlS-Sglt2$^{+/+}$ rats fed a high-salt diet when compared with DahlS-Sglt2$^{+/+}$ rats fed a normal-salt diet. In contrast, no significant change was observed in the expression of these markers between the normal-salt and high-salt diets in DahlS-Sglt2$^{-/-}$ rats. The levels of these markers in Dahl-Sglt2$^{-/-}$ rats were significantly lower than those of Dahl-Sglt2$^{+/+}$ fed a high salt diet. The histological analysis also confirmed the results of the molecular analysis in both DahlS-Sglt2$^{+/+}$ and DahlS-Sglt2$^{-/-}$ rats.

Conclusions: Our findings implicate that SGLT2 may play a protective role in the development of renal injury and fibrosis, independent of the increase in aortic blood pressure caused by salt-sensitive hypertension.

TH-PO203

Establishing a Mouse Model of Heart Failure with Preserved Ejection Fraction Secondary to CKD

Lauren Elizabeth Lee,[1,2] Nicholas A. Forelli,[1,4] Dhanunjay Mukhi,[1,3] Zoltan P. Arany.[1,2] *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]University of Pennsylvania Cardiovascular Institute, Philadelphia, PA; [3]Penn Division of Renal Electrolyte and Hypertension, Philadelphia, PA; [4]University of Pennsylvania Department of Medicine, Philadelphia, PA*.

Background: Chronic kidney disease (CKD) affects 37 million US adults and significantly elevates cardiovascular disease and heart failure (HF) risk, causing ≥50% of CKD mortalities. Proximal tubule cells in CKD and cardiomyocytes in HF exhibit parallel metabolic switches: increased glycolysis reliance and decreased fatty acid oxidation and oxidative phosphorylation reliance. Notably, non-diabetic CKD patients show a correlation of decreased estimated glomerular filtration rate (eGFR) with increased myocardium glucose uptake. It is unknown if CKD contributes to HF by causing cardiac metabolism to be glucose reliant. This has yet to be confirmed *in vivo* due to no reliable HF-secondary-to-CKD mouse model.

Methods: We placed wild-type 8 wk/old male mice on a 0.2% adenine diet, assessing kidney function (GFR, urine/serum markers, histology) and heart function (echocardiography, serum markers, histology) at 4 and 8 weeks. At 8 weeks, we performed an *in vivo* steady state ^{13}C-labled metabolite isotope infusion with our novel ^{13}C labeled metabolite cocktail (3-hydroxybutyrate, glutamine, valine, lactate, glucose) and ^{13}C labeled palmitate to quantify nutrient contribution to kidney and heart TCA cycle intermediates.

Results: At 4 weeks, mice develop CKD (hyperfiltration, elevated serum creatinine and urine albumin/creatinine ratio, moderate renal fibrosis) but with unchanged heart function or histology. At 8 weeks, mice progress to severe CKD (significantly decreased GFR, significantly increased serum creatinine and urine albumin/creatinine ratio, severe renal fibrosis) and have heart failure with preserved ejection fraction (increased serum markers, diastolic and strain parameters, cardiomyocyte hypertrophy). Preliminary data from our ^{13}C-labled metabolite isotope infusions indicate nutrient contribution patterns to TCA cycle intermediates in CKD are similar in kidney and heart tissue.

Conclusions: We conclusively established a mouse model of HF secondary to CKD, in which mice first develop CKD at 4 weeks, then develop heart failure with preserved ejection fraction (HFpEF) by 8 weeks, phenocopying the human literature where CKD is an independent risk factor to HFpEF. Tracing studies indicate the heart and kidney have similar nutrient use in CKD, offering insights into targeted metabolic interventions for improved CKD and HF patient outcomes.

TH-PO204

Oxidative Stress-Induced Suppression of Metabolism Pathways in Dahl Salt-Sensitive Rats

Satoshi Shimada, Chun Yang, Ranjan K. Dash, Allen W. Cowley.
Medical College of Wisconsin, Milwaukee, WI.

Background: We have reported that a high-salt (HS) diet enhances glycolysis as determined in normal Sprague Dawley (SD) rats by measuring the flux of kidney metabolites in rats chronically instrumented with a renal blood flow probe and renal arteriovenous catheters, which provided sequential samples for global metabolic analysis combined with tissue transcriptomic analyses (PMID: 37575482). In the present study, the kidney cortical (Cx) and outer medullary (OM) transcriptomic responses to a HS diet are reported in Dahl salt-sensitive (SS) rats compared to SS$^{Nox4-/-}$ rats with a global knockout of NADPH oxidase 4 (NOX4) to reduce oxidative stress, and compared to salt-resistant SD rats.

Methods: Male SS, SS$^{Nox4-/-}$ and SD rats were fed either a 0.4% diet, a 4% diet for 7 days, or for 21 days (HS21). Cx and OM were removed for mRNAseq analysis (Novogene, Inc). Comparisons with previously published SD data was performed by publicly available software (RNAseqChef and DAVID).

Results: 1724 mRNAs in Cx and 2775 in OM had FDR < 0.05 and fold change > 2, comparing SS and SD at HS21. Among these mRNAs, we selected those with patterns of response to salt that are unique in SS relative to SD and SS$^{Nox4-/-}$ by divisive clustering analysis. There were 446 mRNAs in Cx and 1550 in OM that followed this pattern. Only the "Protein digestion and absorption" pathway was significant in the pathway analysis of these mRNAs in Cx. This pathway includes Slc3a1 (amino acid transporter), and Atp1A4 (Na/K ATPase) which was consistently greater in SS. Collagen mRNAs were increased only in SS with HS. The OM, in contrast, revealed 11 pathways including "carbon metabolism", "biosynthesis of amino acid" and others. Aco1 (aconitase), Pc (pyruvate carboxylase), Pklr (pyruvate kinase) and Ass1 (argininosuccinate synthase) in these pathways were consistently low in SS.

Conclusions: Transcriptomic response to HS clearly differed when comparing kidneys of SS to SS$^{Nox4-/-}$ and SD rats. Carbon metabolism and amino acid synthesis related genes were suppressed in OM in SS which could functionally lead to lactate accumulation and eventually renal damage as energy demand increased with HS. These changes appear to be driven by increased oxidative stress given the absence of such changes in the SS$^{Nox4-/-}$ and SD rats. Metabolite responses and their relationship with transcriptomic changes are currently being analyzed.

TH-PO205

Circadian Clock Provides Beneficial Effects against Atherogenesis by Regulating Heme Oxygenase-1 Expression and Heme Synthesis

Hideyuki Negoro.[1,2] [1]*Harvard Medical School, Boston, MA;* [2]*Tokyo Daigaku Daigakuin Igakukei Kenkyuka Igakubu Seirigaku, Bunkyo-ku, Japan.*

Background: The circadian clock is a molecular mechanism that confers 24 hours variations in gene expression and function to regulate many physiological functions. Chronic circadian clock disruption is associated with vascular stiffness and dysfunction in endothelial signaling and responses. Heme is a ligand of REV-ERBα and REV-ERBβ which modulate circadian rhythms by binding to the ROR region of CLOCK or BMAL1 to suppress the expression of these genes. 5-Aminolevulinic acid (ALA) is the common precursor of porphyrin and heme. The iron ion is inserted into protoporphyrin IX to form heme in the mitochondria and incorporated into hemoproteins. Heme oxygenase-1 (HO-1) is an intracellular enzyme which catalyzes the oxidation of heme to generate ferrous iron, carbon monoxide, and biliverdin, which is subsequently converted to bilirubin. These products have anti-inflammatory, anti-apoptotic and anti-thrombotic properties. In this study, we observed if the deletion of Bmal1, a critical component of the circadian clock, can influence HO-1 which play an important part in the protection of vascular diseases.

Methods: Congenic 12- to 16-week-old male, wild-type, CLOCK-KO, and Bmal1-KO littermate mice were generated from heterozygote breeding to be used for these studies. We also knocked down Bmal1 to evaluate the protein levels of HO-1 expression in the knocked down cells. To synchronize circadian rhythms, serum stimulations were performed. Cells were also pre-incubated with or without 1 mM ALA and 0.5 mM sodium ferrous citrate (SFC).

Results: In aorta from Bmal1 KO mice, there was a reduction in HO-1 expression with a dysfunctional circadian rhythm. Bmal1 KO mice display pre-mature aging to have a dramatic prothrombotic phenotype. This phenotype is linked to the regulation of key risk factors for cardiovascular disease. These include HO-1 which is significantly reduced in Bmal1 KO mice. ALA/SFC co-incubation affected the oscillation and phase of core clock genes and led to increase of HO-1. HO-1 levels followed a circadian pattern, and this pattern was absent in Bmal1 KO mice.

Conclusions: These findings indicate that circadian clock provides beneficial effects against atherogenesis by regulating HO-1 expression and heme synthesis. This study establishes a mechanistic connection between Bmal1 and cardiovascular phenotype.

Matrix Metalloprotease Activity in Vascular Lesions of Malignant Hypertensive Rats

Andrea Hartner, Nada Cordasic, Mario Schiffer, Roland Veelken, Kerstin U. Amann, Christoph Daniel, Karl F. Hilgers. *Friedrich-Alexander-Universitat Erlangen-Nurnberg, Erlangen, Germany.*

Background: In malignant hypertension (MH), far more severe kidney injury occurs than in the "benign" form (NMH) of the disease. In a previously reported RNA-Seq analysis of renal cortical tissue from a rat model of MH, we observed an altered expression of several matrix metalloproteases (MMP). We now investigated gelatinase activity localized to the characteristic vascular lesions of MH.

Methods: Renovascular hypertension in rats was induced by placing a 0.2 mm clip on the left renal artery (2K1C), controls were sham operated. To distinguish MH from NMH, we considered weight loss and typical vascular lesions (onion-skin and fibrinoid necroses). The expression of MMPs was measured by RT-PCR; immunohistochemistry was performed for MMP-2 and 9. In-situ zymography was performed to localize gelatinase activity.

Results: Mean blood pressure measured intra-arterially was elevated to a similar degree in MH (220±7 mmHg) and NMH (192±6 mmHg), compared to controls (119±2 mmHg, $p<0.05$). MMP-2, -7, -8, -10, -12, -16 and -19 expression were all elevated in NMH and significantly higher increased in MH. The only exception was MMP-9 mRNA which barely changed in NMH but decreased by 0.2-fold in MH ($p<0.05$). In situ zymography revealed gelatinase activity predominantly in preglomerular vascular lesions of MH (52.8 ± 7.2 versus 20.5 ± 6.1 per medium power field in NMH, $p<0.05$) in right kidneys exposed to high blood pressure. The number of these gelatinase activity lesions correlated with the glomerulosclerosis score ($r=0.75$, $p<0.0001$). There was no gelatinase activity in sham operated animals, or in left (post-stenotic) kidneys of MH or NMH. MMP-2 staining was detected in, or closely surrounding, vascular lesions (3.46 ± 0.9 MMP-2 positive lesions per 10 high power fields in MH versus 0.22 ± 0.09 in NMH and 0 in sham, $p<0.05$). MMP-9 staining was observed in proximal tubules, individual interstitial cells, and intact or hypertrophic preglomerular vessels but absent from malignant vascular lesions.

Conclusions: In malignant hypertension of 2K1C rats, most MMPs are upregulated, broadly consistent with enhanced tissue injury. However, the gelatinases MMP-2 and MMP-9 exhibited a strikingly divergent regulation, with MMP-2 clearly localized to malignant vascular lesions with gelatinase activity.

Endothelial Cell-Specific Inducible G2APOL1 Risk Variant Induces Hypertension and Hypertensive Kidney Damage

Fang Li,[1,2] Junnan Wu,[1,2] Konstantin A. Kloetzer,[1,2] Katalin Susztak.[1,2]
[1]*Department of Medicine, Renal Electrolyte and Hypertension Division, University of Pennsylvania, Philadelphia, PA;* [2]*University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

Background: GWAS showed a strong association between the apolipoprotein1 (*APOL1*) gene and hypertension in AA adults. Nearly 45% of AAs carry a coding variant of the *APOL1* gene (G1 *APOL1* or G2 *APOL1*). The disease phenotypes associated with *APOL1* risk variants (RV) depend on the cell type-specific expression and toxicity of APOL1. Our recent studies (single-cell, single nuclei, and in-situ hybridization) have shown APOL1 is highly expressed in the endothelial cells of human kidneys. Individuals who carry the G1 or G2 *APOL1* RV have a high risk of developing hypertensive kidney disease. However, the direct role of APOL1 in the development of hypertension and hypertensive kidney disease remains unclear.

Methods: Endothelial-specific inducible expression of APOL1 (EC/G0-APOL1, EC/G2-APOL1) mice were generated by using Tet-off system. Upon removal of doxycycline diet, APOL1 expression was obtained in various vascular beds. For the high salt diet model, UNX surgery was performed on WT control, EC/G0-APOL1, and EC/G2-APOL1 mice, followed by a high-salt diet (4%) for 12 weeks post-surgery. We processed snRNA-seq, bulk RNA-seq, and spatial transcriptomics, and combined these with genetic and pharmacologic approaches to investigate the role of G2*APOL1* RV in the development of hypertension.

Results: Systolic blood pressure (SBP), diastolic blood pressure (DBP), and mean arterial pressure (MAP) were statically increased in Cdh5tTA/TRE-G2APOL1 mice compared to control WT/G0 mice after 14 weeks of continuous *G2APOL1* RV expression

in endothelial cells. A high-salt diet following UNX surgery further augments elevated blood pressure and induces renal dysfunction in EC/G2APOL1 mice. Comprehensive in vivo and in vitro investigations revealed that RV *APOL1* expressed in endothelial cells triggers the activation of the STING pathway, fostering the production of endothelin-1 (ET-1). STING-specific knockout in endothelial cells of Cdh5tTA/TRE-G2APOL1 mice led to reduced ET-1 production, as well as reductions in SBP, DBP, and MAP post-UNX surgery and high-salt diet.

Conclusions: Endothelial-specific expression of G2*APOL1* RV activates the STING pathway, promoting ET-1 production and contributing to hypertension development, subsequently results in renal damage.

TH-PO208

Kidney Hypoplasia Increases Kidney Injury following Reversal of Unilateral Ureteral Obstruction

Samaneh Goorani, John D. Imig. *University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: Studies have found that short-term kidney injury by unilateral ureteral obstruction (UUO) results in long-term consequences of hypertension and CKD. Not known is whether renal hypoplasticity and low nephron number increases the long-term consequences.

Methods: Male and female renal hypoplastic ROP *Os*/+ and wild type ROP +/+ mice underwent UUO, or sham surgery followed ureter clip removal on day 7 (RUUO). BP was measured by telemetry to determine SBP, MAP, and HR weekly. Renal artery resistive index (RI) was evaluated by ultrasound. Urine was collected at the end to assess CysC and NGAL. A terminal kidney tissue collection was conducted for gene expression, and histology.

Results: At baseline, ROP +/+ and ROP *Os*/+ MAP, SBP, and HR were not different in either sex of mice. SBP and MAP increased, and HR decreased in RUUO ROP *Os*/+ and RUUO ROP +/+ mice compared to sham mice groups. Interestingly, RUUO ROP *Os*/+ mice demonstrated 35-40 mmHg higher SBP and 100-150 beats lower HR than RUUO ROP +/+ mice 35 days following clip removal. RI was higher in RUUO ROP *Os*/+ and RUUO ROP +/+ mice compared to sham mice. Moreover, RUUO ROP *Os*/+ had a higher RI than RUUO ROP +/+ mice indicating a greater reduction in renal blood flow in RUUO ROP *Os*/+ mice. CysC and NGAL were 2-fold higher in RUUO ROP *Os*/+ than RUUO ROP +/+ mice. Fibrotic PCR pathway array demonstrated higher fibrotic markers in RUUO ROP *Os*/+ than RUUO ROP+/+ mice. RT-PCR confirmed markedly higher expressions of Fn1, collagen1, vimentin in RUUO ROP *Os*/+ than RUUO ROP +/+ mice. Renal tubular cast formation in RUUO ROP *Os*/+ and RUUO ROP +/+ mice was higher compared to sham mice. The increase in renal tubular cast formation was higher in RUUO ROP *Os*/+ than RUUO ROP+/+. Similarly, α-SMA deposition was higher (3 vs 2-fold) in RUUO ROP *Os*/+ compared to RUUO ROP +/+ mice. $Mac2^{+}$ inflammatory cells were increased in RUUO ROP *Os*/+ to a greater extent than RUUO ROP +/+ mice. There were no differences between male and female mice for all groups and parameters measured.

Conclusions: These data demonstrate renal hypoplasia and low nephron number ROP *Os*/+ mice had increased blood pressure, renal inflammation, and kidney injury compared to ROP +/+ mice 35 days following ureter clip removal.

SNX19 and p27 kip1 Regulate D1R Endocytosis in Renal Proximal Tubule Cells

Bibhas Amatya,[1] Laureano D. Asico,[1] Jun Feranil,[1] Raisha L. Campisi Cadme,[1] Jacob Q. Polzin,[1] Ines Armando,[1] Robin A. Felder,[2] Pedro A. Jose,[1] Hewang Lee.[1] *[1]The George Washington University School of Medicine and Health Sciences, Washington, DC; [2]University of Virginia, Charlottesville, VA.*

Background: SNX19, a member of the SNX-PXA-RGS-PXC subfamily of sorting nexin proteins, is localized in lipid raft microdomains and regulates dopamine D1 receptor (D_1R) endocytosis, renal sodium transport, and subsequently blood pressure. The interaction between SNX19 and $p27^{Kip1}$, a scaffold protein in lipid rafts, in the regulation of D_1R endocytosis is unknown.

Methods: Colocalization was observed by confocal immunofluorescence microscopy; protein-protein interaction was determined by co-immunoprecipitation. Blood pressure was measured in conscious C57BL/6 mice treated with a 7-day renal subcapsular infusion of Snx19 siRNA; mock siRNA served as the control.

Results: In human renal proximal tubule cells (RPTCs), SNX19 colocalized with caveolin-1 and flotillin-1. SNX19 and caveolin-1 or flotillin-1 also co-immunoprecipitated in human RPTCs. Fenoldopam (FEN, 25 nM, 30 mins, n=3), a D_1R/D_5R agonist, increased their co-immunoprecipitation. Interestingly, $p27^{Kip1}$, a canonical cyclin-dependent kinase inhibitor, colocalized with calveolin-1 and flotillin-1 in mouse and human RPTCs, confirming electron and confocal microscopic studies that $p27^{Kip1}$ is a lipid raft protein. Confocal immunofluorescence microscopy showed that in mouse RPTCs, FEN (25nM, 30 min) increased the colocalization of $p27^{Kip1}$ with α-tubulin which is essential in SNX19-mediated D_1R endocytosis. The D_1R/D_5R antagonist, Sch 39916 (SCH, 1 μM, 30min), prevented the FEN-mediated increase in the colocalization of $p27^{Kip1}$ with α-tubulin. Moreover, nocodazole (10 μM, 1hr), a microtubule depolymerization inhibitor, interfered with the FEN-mediated increase in the colocalization of SNX19 with D_1R, confirming the importance of the microtubule in the SNX19-mediated D_1R endocytosis. The D_1R is downstream of SNX19 because silencing *DRD1* in human RPTCs decreased D_1R but not SNX19 expression. SNX19 and D1R play a role in blood pressure regulation. In C57BL/6 mice on a normal salt diet (0.9% NaCl), renal subcapsular infusion of Snx19 siRNA (3 mg/day; 7 days) increased systolic BP (mock siRNA: 99.3 ± 1.52 mmHg, n=3; Snx19 siRNA: 114.1 ± 5.44 mmHg, n=3) and decreased renal D_1R expression.

Conclusions: SNX19 in the RPT interacts with $p27^{Kip1}$ in the lipid rafts to regulate SNX19-mediated D_1R endocytosis and subsequently, blood pressure.

Zyxin Attenuates Hypertension-Induced Kidney Fibrosis by Modulating the CDK8-YAP Axis

Wei Huang, Chun Zhang. *Union Hospital Tongji Medical College Huazhong University of Science and Technology, Wuhan, China.*

Background: Hypertensive nephropathy (HN) is characterized by progressive renal tubulointerstitial fibrosis. However, the mechanisms of tubulointerstitial fibrosis in HN remains obscure. Zyxin, a focal adhesion protein, has been implicated in hypertensive myocardial fibrosis, but its role in HN remains unclear.

Methods: A hypertensive nephropathy model was established in C57BL/6 mice using subcutaneous DOCA particles and AngII pumps. Human renal tubular epithelial cells (HK-2) were stimulated with AngII in vitro. Zyxin was knocked down or overexpressed in HK-2 cells after exposure to AngII. The expression levels of zyxin, CDK8, YAP, and TRPC3 were assessed using Western blot, PCR, immunohistochemistry, and immunofluorescence.

Results: In hypertensive kidney tissues and AngII-stimulated HK-2 cells, zyxin expression was significantly downregulated, while CDK8, YAP, and TRPC3 expressions were upregulated. Overexpression of zyxin in kidney significantly ameliorated hypertensive renal fibrosis. In HK-2 cells, zyxin overexpression inhibited AngII-induced fibrosis markers, whereas zyxin knockdown promoted them. Overexpression of zyxin attenuated the increase in CDK8 and YAP, while zyxin knockdown exacerbated it. Inhibition of TRPC3 blocked the changes in zyxin, CDK8, and YAP expressions.

Conclusions: In hypertensive conditions, activated TRPC3 in the kidney inhibits zyxin expression, thereby activating the CDK8-YAP axis and promoting renal fibrosis. These findings suggest that zyxin might be a promising therapeutic target for hypertensive nephropathy.

TH-PO211

Effect of Dual Blockade of Neprilysin and Renin-Angiotensin System in Angiotensin II-Dependent Salt-Sensitive Hypertension

Masahiro Eriguchi, Takayuki Uemura, Masatoshi Nishimoto, Kazuhiko Tsuruya. *Nara Kenritsu Ika Daigaku, Kashihara, Japan.*

Background: Neprilysin (NEP) is a Zn-metalloprotease whose substrate is brain natriuretic peptide (BNP), but also angiotensin II (Ang II). Interestingly, angiotensin converting enzyme (ACE) is also a Zn-metalloprotease, and both are strongly expressed in the brush border of the proximal tubule. These two proteases are thought to be involved in the regulation of sodium balance by regulating the Intrarenal Ang II by the degradation (NEP) and production (ACE) of Ang II.

Methods: An Ang II-dependent salt-sensitive model was induced by a 4% high-salt diet (HS) after continuous low-dose Ang II infusion for 1 week (300 ng/Kg/min). Blood pressure (BP) and salt sensitivity were examined using Wild-type, NEP KO, renal-ACE KO, and NEP/renal-ACE double-KO mice.

Results: BP of NEP KO mice significantly increased after Ang II infusion (Ang II BP), but the increase in BP 3 days after starting a high-salt diet (Ang II+HS BP) was blunted. (baseline BP: 102 mmHg, Ang II BP: 119 mmHg, Ang II+HS BP: 119 mmHg) On the other hand, in renal-ACE KO mice, no increase in BP was observed in response to Ang II infusion, but BP increased significantly after starting a high-salt diet. (baseline BP: 104 mmHg, Ang II BP: 101 mmHg, Ang II+HS BP: 119 mmHg) At the final observation (Ang II+HS for 10 days), the BP of NEP/renal-ACE double-KO mice was significantly lower than that of NEP KO, renal-ACE KO, and Wild-type mice. (NEP/renal-ACE double-KO: 122 mmHg, NEP KO: 139 mmHg, renal-ACE KO: 137 mmHg, Wild-type: 148 mmHg) Under 1-week Ang II infusion, 3-h urinary Na excretion in response to intraperitoneal saline challenge was significantly increased in NEP/renal ACE double-KO mice compared with wild-type mice. (NEP/renal-ACE double-KO: 0.193 mEq, NEP KO: 0.171 mEq, renal-ACE KO: 0.164 mEq, Wild-type: 0.113 mEq) Also, intrarenal Ang II concentration was elevated in NEP KO mice, whereas the increase in intrarenal Ang II was suppressed in renal-ACE KO and NEP/renal-ACE double-KO mice. (NEP/renal-ACE double-KO: 199 fmol/g kidney weight, NEP KO: 448 fmol/g, renal-ACE KO: 210 fmol/g, Wild-type: 294 fmol/g)

Conclusions: Dual blockade of NEP and renin-angiotensin system was shown to have a complementary anti-hypertensive effect by BNP-induced natriuresis and suppressing salt sensitivity due to an increase in intrarenal Ang II concentration.

TH-PO212

Trimethylamine N-oxide Can Trigger Cardiovascular Disease by Affecting Endothelial Cell-to-Cell Junctions through ZO-1 Expression Decreasing

Carolina A. Azevedo, Regiane S. Cunha, Guilherme Miniskiskosky, Paulo C. Gregório, Andréa M. Stinghen. *Universidade Federal do Parana, Curitiba, Brazil.*

Background: Trimethylamine N-oxide (TMAO) is a uremic toxin that is associated with the development of cardiovascular disease in patients with chronic kidney disease (CKD). At uremic concentrations, TMAO-induced vascular damage is characterized by increased expression of inflammatory markers and vascular calcification. However, there is limited understanding regarding whether this uremic toxin adversely affects endothelial cell-cell junctions and permeability. This study aims to evaluate the effects of TMAO on the expression of Zonula occludens-1 (ZO-1), a protein component of tight junctions that plays a crucial role in regulating endothelial permeability.

Methods: Human endothelial cells (EA.hy926, ATCC CRL-2922) were exposed to TMAO at normal (2.83 mg/L) and uremic concentrations (7.49 mg/L) for 24 hours. ZO-1 gene expression was assessed by RT-qPCR, while its protein levels were evaluated by western blotting and immunofluorescence.

Results: ZO-1 gene expression showed no significant difference between treatments. However, we observed a significant reduction in ZO-1 protein levels in endothelial cells exposed to TMAO at uremic concentrations compared to control cells (untreated) (Figure 1A). Immunofluorescence analysis also showed a reduction in ZO-1 immunostaining in subconfluent endothelial cells after exposure to TMAO (Figure 1B). Figure's subtitle: **Figure 1 - ZO-1 protein levels in endothelial cells exposed to TMAO at normal (TMAOn) and uremic (TMAOu) concentrations for 24 hours.** (A) Western blotting, Kruskal-Wallis test: ***P*<0.01. (B) Immunofluorescence for ZO-1 (green) and nuclear staining (DAPI, blue). The scale bar indicates 50 μm, magnification 600x.

Conclusions: Our data demonstrated a reduction in ZO-1 levels in endothelial cells, which may be related to increased endothelial permeability. Alterations in the endothelial barrier might contribute to the onset of cardiovascular diseases, notably atherosclerosis, which is highly prevalent among patients with CKD.

Activation of Aryl Hydrocarbon Receptor by an Indolic Uremic Toxin Increases the Risk of Deep Venous Thrombosis

Blanca Pina Beltran,[1] Sandrine Roffino,[1] Nathalie Mc kay,[1] Stéphane Poitevin,[1] Stephane Burtey.[1,2] *[1]Aix-Marseille Universite, Marseille, France; [2]Hôpital de la Conception, Service de Néphrologie, Marseille, France.*

Background: During chronic kidney disease (CKD), the accumulation of indolic uremic toxins, such as indoxyl sulfate (IS), occurs. Activation of the aryl hydrocarbon receptor (AHR), their receptor, leads to increased tissue factor expression, resulting in a prothrombotic state. Our goal is to explore if the activation of AHR could explain the risk of deep venous thrombosis (DVT) during CKD.

Methods: We induced DVT in mice by partially ligating the inferior vena cava (IVC) (Figure 1A). To investigate the role of AHR and uremic toxins, we administered IS or its control (KCl) to 9-week-old normorenal wild-type or $Ahr^{-/-}$ mice for 4 days prior to the IVC ligation procedure, immediately after, and 8h post-procedure. Mice were sacrificed 24h after ligation. The primary evaluation criterion was the presence of a thrombus. TAT and IS were dosed and gene expression of IS/AHR related genes at the liver level determined.

Results: Injection of IS led to increased thrombus presence (58% in IS-injected mice vs. 24% in control) without a sex-related impact. The absence of AHR significantly reduced thrombotic risk (11% in IS-injected $Ahr^{-/-}$ mice vs. 25% in control) (Figure 1B). IS appeared to increase thrombus size and weight compared to control (Figure 1C). The effect of IS is believed to be local (at the ligature site, where the blood flow is diminished), since mice showed no differences in their hypercoagulable state (similar TAT levels). Preliminary results revealed a fibrin sponge-like structure in regions with abundant red blood cells, while platelet-rich areas exhibited a more compact structure, with a higher concentration of white blood cells (Figure 2). There may also be differences in thrombus composition among the different groups.

Conclusions: Accumulation of IS and activation of AHR are associated with an increased number of thrombotic events in our murine DVT model. This likely explains the heightened risk of venous thromboembolism observed in CKD, as well as during exposure to AHR agonists such as certain pesticides or tobacco smoking.

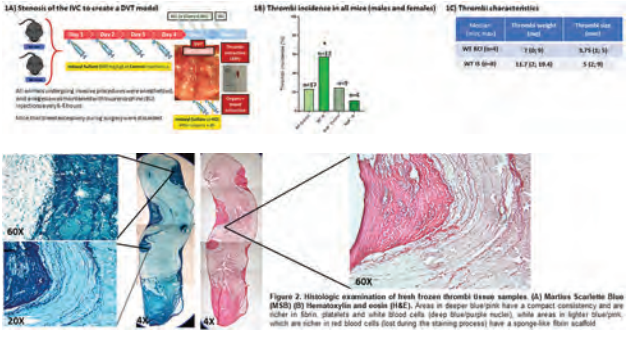

Figure 2. Histologic examination of fresh frozen thrombi tissue samples. (A) Martius Scarlette Blue (MSB) (B) Hematoxylin and eosin (H&E). Areas in deeper blue/pink have a compact consistency and are richer in fibrin, platelets and white blood cells (deep blue/purple nuclei), while areas in lighter blue/pink, which are richer in red blood cells (lost during the staining process) have a sponge-like fibrin scaffold

TH-PO214

Defining Stromal Cell Heterogeneity in the Kidney with Single-Nucleus RNA Sequencing

Arjun Lakshmanan, Susan B. Gurley, Jonathan W. Nelson. *University of Southern California Keck School of Medicine, Los Angeles, CA.*

Background: The kidney stroma are critical perivascular cells that support multiple kidney functions such as regulation of regional blood flow and maintenance of the glomerular filtration barrier. While they are commonly identified by abundant expression of Pdgfrb, recent studies have hinted at more heterogeneity. We examined their heterogeneity by performing single-nucleus RNA sequencing (snRNAseq) on nuclei that were enriched for kidney stromal cells with the goal of defining robust gene markers for unique stromal cell subpopulations.

Methods: Pdgfrb-creERT2 mice were bred to the INTACT mouse to create Pdgfrb-INTACT mice which express GFP attached to a nuclear envelope protein within stromal cells. We isolated nuclei from Pdgfrb-INTACT mice and enriched for GFP expressing nuclei with Fluorescent Activated Nuclei Sorting and then transcriptionally profiled them on the 10X Genomics platform. The resulting transcriptome data was analyzed with Seurat to perform dimensional reduction which delineated unique populations of stromal cells. We then identified differentially expressed genes (DEGs) that defined each subpopulation. The specificity of these DEGs was confirmed by RNAscope. We then analyzed a separate kidney snRNAseq dataset that was not enriched for Pdgfrb nuclei to determine whether these unique stromal cell populations were present.

Results: We transcriptionally profiled 59,349 nuclei from Pdgfrb-INTACT mice which divided into 11 subpopulations, including 4 populations of fibroblasts, 4 populations of contractile cells, 2 populations of mesangial cells, and a proliferating population. Kcnd3, 6530403H02Rik, Itgbl1, Ahrr delineated the fibroblast populations; Hpse2, Tenm2, Lhfpl3, and Mannr delineated the contractile populations; and Grip1 and Limch1 delineated the mesangial subpopulations. We localized these distinct stromal cell subpopulations in mouse kidney using population-specific DEGs with RNAscope. Analysis of a separate kidney snRNAseq dataset revealed subpopulations with similar gene expression profiles to the subpopulations we identified in the Pdgfrb-INTACT mice.

Conclusions: Stromal cells are functionally and genetically diverse and can be characterized through distinct genetic markers. Enriching for stromal cells with the Pdgfrb-INTACT mouse enabled us to identify robust genetic markers of the kidney stroma that have been previously unrecognized.

Effects of Suppressed Indoxyl Sulfate Production on Kidney Injury-Associated Cardiac Pathogenesis in Sult1a1-Deficient Mice

Aina Sugiura,[1] Kaito Makise,[1] Yuki Narita,[5] Yutaka Kakizoe,[3] Yuichiro Izumi,[3] Takashige Kuwabara,[3] Yuichiro Arima,[2] Kenichi Tsujita,[4] Hirofumi Jono,[5] Hideyuki Saito.[5] *[1]Kumamoto Daigaku Yakugakubu Daigakuin Yakugaku Kyoikubu, Kumamoto, Japan; [2]Kumamoto University Laboratory of Developmental Cardiology, Kumamoto, Japan; [3]Kumamoto University Hospital Department of Nephrology, Kumamoto, Japan; [4]Kumamoto University Hospital Department of Cardiovascular Medicine, Kumamoto, Japan; [5]Kumamoto Daigaku Byoin Yakuzaibu, Kumamoto, Japan.*

Background: Chronic kidney disease (CKD) is a risk factor for cardiovascular disease (CVD) and CVD mortality increases as renal function declines. However, no effective medication has been established to prevent the CVD progression in CKD. Therefore,

we focused on indoxyl sulfate (IS), a typical sulfo-conjugated uremic toxin, which is exclusively generated in the liver via the metabolic processes by hepatic metabolizing enzymes, CYP2E1/2E6 and Sulfotransferase (Sult)1a1. IS accumulates systemically in CKD patients, thereby being reported as one of the risk factors for developing cardio-renal disease, whereas the mechanism is unclear. Then, Sult1a1-deficient (*Sult1a1*$^{-/-}$) mice were used to examine the pathogenetic role of IS in a model of cardio-renal disease exhibiting both kidney and heart damages. In this study, cardiac pathological alterations in the model mice were investigated whether the restricted production of IS could prevent those.

Methods: C57BL/6J (WT) and *Sult1a1*$^{-/-}$ were used to create an ANS model with angiotensin II administration, nephrectomy, and saline drinking. Mice were sacrificed 4 weeks after the treatment, and blood and tissue samples were collected.

Results: In the ANS model, both WT and *Sult1a1*$^{-/-}$ showed increased BUN and expression of IL-6 and col1a1 in renal tissue. On the other hand, WT+ANS increased serum IS concentrations, while *Sult1a1*$^{-/-}$+ANS significantly suppressed IS levels (WT vs *Sult1a1*$^{-/-}$: 5.96±2.96μM vs 2.35±1.09μM). WT+ANS showed cardiac hypertrophy, upregulation of BNP, fibrotic markers TGF-βand col1a1, and oxidative stress marker NOX4 in cardiac tissue, whereas *Sult1a1*$^{-/-}$+ANS suppressed them. Furthermore, cardiac tissue fibrosis formation assessed by Sirius Red staining indicated the reduced fibrotic area in *Sult1a1*$^{-/-}$+ANS compared to WT+ANS (WT vs *Sult1a1*$^{-/-}$: 3±2% vs 1.67±2.08%), suggesting that IS could be involved in the cardiac fibrosis as an intervening toxin.

Conclusions: In *Sult1a1*$^{-/-}$, cardiac hypertrophy and fibrosis development in the ANS model were suppressed with a decreased serum IS accumulation. Therefore, suppression of IS accumulation could prevent and attenuate cardiac pathogenetic events in renal failure.

Validation of an Organoid Model for CKD-Related Vasculature Changes and Vascular Calcifications Development

Julie Bernardor,[1,2] Justine Simonin,[1] Elise Larché,[1] Claudine Blin,[1] Zakariya Caillot,[1] Maria Bartosova,[3] Claus Peter Schmitt,[3] Matthieu Rouleau.[1] Ostéoimmunologie, Niches et Inflammation. *[1]Laboratoire de Physiomédecine Moléculaire (LP2M), UMR 7370 CNRS, Nice, France; [2]University Hospital of Nice, Nice, France; [3]University Hospital Heidelberg, Heidelberg, Germany.*

Background: Chronic kidney disease (CKD) is associated with high cardiovascular risk, mainly due to vascular calcifications (VC). Mortality rate is high, due to a significant increase of the risk of cardiovascular diseases, related to vascular calcifications. Current understanding indicates that vascular calcifications in CKD involve complex mechanisms, including gene expression changes and endothelial dysfunction. To elucidate complex pathomechanisms leading to VC development, there is a critical need for an in vitro model reflecting CKD induced vascular disease.

Methods: We developed a vascular organoid model using human-induced pluripotent stem cells (hiPSCs). Organoids were formed through differentiation into mesodermal and then vascular cells, followed by embedding in a 3D-collagen matrix. Organoids were maintained in culture for over 30 days. We then induced CKD with pro-calcifying (inorganic phosphate), inflammatory (IL-1β, IL-6, TNF-α), and uremic toxin (indoxyl sulfate) treatments. Analyses included immunofluorescence for vascular markers (CD31, CD140b, αSMA, Collagen IV); RT-qPCR for gene expression; and Alizarin Red staining/ Osteosense assays for calcium deposits.

Results: The vascular organoids developed endothelial cells surrounded by pericytes and smooth muscle cells within a collagen IV-rich matrix. Cytokine treatments resulted in reduced density of endothelial and smooth muscle cells, particularly with IL-6 and TNF-α. Indoxyl sulfate also decreased vascular density. Treatment with inorganic phosphate led to decreased vascular density, increased vessel diameter, and calcium deposits, alongside with modified osteoblastic gene expression (*RUNX2; Sp7, APLP, Spp1*).

Conclusions: We successfully established a vascular organoid model that replicates key features of human vasculature networks and CKD induced changes. It now provides a valuable tool for studying CKD-related pathomechanisms and testing putative therapeutic interventions. Future research using this model should employ single-nucleus RNA sequencing (snRNA-seq), spatial transcriptomics, and CRISPR-Cas9 analyses to further investigate the CKD-related cardiovascular disease.

TH-PO217

Role of Peroxisomes in CKD-Associated Vascular Calcification

Fan He, Cailin Zhang, Qing Li. *Department of Nephrology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China.*

Background: Vascular calcification is highly prevalent and strongly correlated to all-cause and cardiovascular mortality in CKD patients. Peroxisomes are important organelles that regulate various metabolic processes, such as fatty acid oxidation and phospholipid synthesis, thus play an important role in the maintenance of cellular homeostasis. However, the regulatory role of peroxisomes in vascular calcification has not been elucidated. This study aimed to explore the role of peroxisomes in CKD associated vascular calcification.

Methods: The vascular calcification model of CKD mice was used to collect thoracic aortas for transcriptomics, fee-targeted metabolomics and lipidomics analysis. Knockdown or overexpression of peroxisome biogenesis-related genes or ether-lipid synthesis-related genes in vascular smooth muscle cells were performed to detect changes in the degree of vascular calcification. Western blotting, calcium deposition assay, ARS staining, and Von Kossa staining were used to detect vascular calcification.

Results: Combined with the results of transcriptomic analysis, we found that that the peroxisome pathway and ferroptosis pathway were elevated in response to vascular calcification. Moreover, taking advantage of RNA-seq and in vitro experiments, we found that modulating peroxisome content can modulate vascular calcification via regulating ferroptosis. In addition, lipidomic analysis revealed abnormal lipid metabolism in calcified vessels. By knocking down AGPS, the ether-lipid synthesis gene, vascular calcification can be attenuated by inhibiting ferroptosis.

Conclusions: The present results indicate that peroxisomes may regulate ferroptosis levels and ultimately vascular calcification by regulating ether-lipid synthesis.

Serum-Derived Exosomes from Patients on Dialysis Promote Endothelial-Mesenchymal Transition and Vascular Calcification

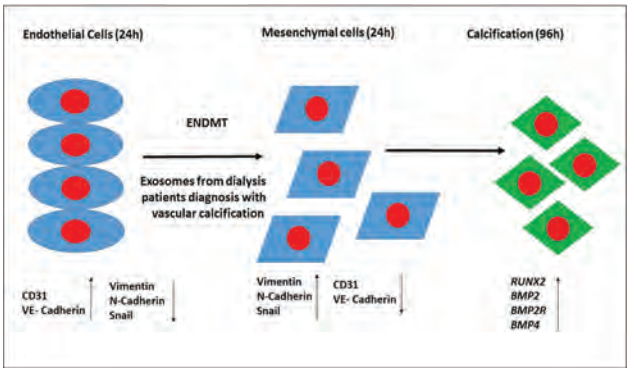
Keren Cohen-Hagai,[1,2] Eran Kuchuk,[1,2] Shelly Tartakover Matalon,[1,2] Sydney Benchetrit,[1,2] Tali Zitman Gal.[1,2] *[1]Meir Medical Center, Kfar Saba, Israel; [2]Tel Aviv University Faculty of Medicine, Tel Aviv, Israel.*

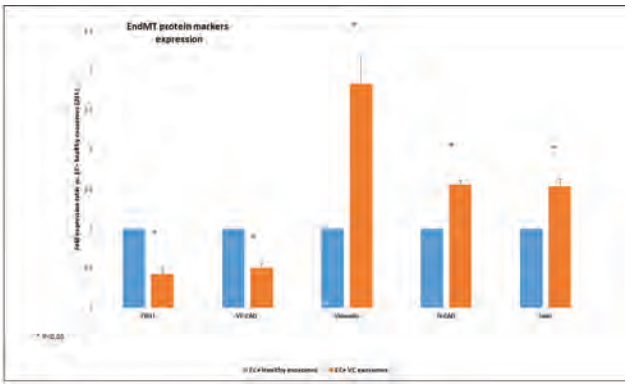
Background: Vascular calcifications (VC) is prevalent among dialysis patients and associate with Cardiovasculare events (CVE). Exosomes, small extracellular vesicles secreted by cells, are mediators of cell-cell interactions and are also involved in biological processes such as apoptosis and inflammation. Endothelial-Mesenchymal Transition (EndMT) has been observed in pathological conditions involving vascular damage and inflammation. Bone morphogenetic protein (BMP) associates with CVE and vascular inflammation. BMPs and the RUNX2 transcription factor are able to stimulate osteoblast differentiation and bone formation. We aimed to assess the effect of serum derived exosomes on EndMT and VC markers

Methods: Serum samples from Twenty dialysis patients with confirmed VC and 10 healthy volunteers were taken at dialysis initiation for exosome isolation. H*uman umbilical vein endothelial cells* (HUVECs) were treated with 100 μg/mL exosomes for 24-96 hours. At the end of incubation, cells were collected for *mRNA and protein* analysis.

Results: VC exosomes induced EndMT in HUVECs; after 24h, a decrease in endothelial markers CD31 and VE-cadherin vs. healthy exosomes (↓ 31% and ↓51%, respectively; P<0.001) N-cadherin and Vimentin vs. healthy exosomes (↑156% and ↑ 283%, respectively; P<0.001). These two cytokines upregulated the expression of Snail (↑153% ;P=0.03). After 96h of incubation, expression of genes essential for osteoblast differentiation that include bone morphogenetic genes (*BMP2, BMPR2, BMP4* and *BMP9*), as well as the transcription factor *RUNX2* were significantly elevated.

Conclusions: Exosomes derived from dialysis patients' serum induced EndMT and contributed to calcification





TH-PO219

Apolipoprotein-L1 G1 Variant Contributes to Hydrocephalus but Not to Atherosclerosis

Teruhiko Yoshida,[1,2] Zhi-Hong Yang,[3] Shinji Ashida,[4] Zu-Xi Yu,[3] Shashi Shrivastav,[1] Danielle A. Springer,[3] Matthew Starost,[5] Avi Z. Rosenberg,[6] Alan T. Remaley,[3] Jeffrey B. Kopp.[1] *[1]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [2]Tokyo Daigaku Igakubu Fuzoku Byoin, Bunkyo-ku, Japan; [3]National Heart Lung and Blood Institute, Bethesda, MD; [4]National Institute of Allergy and Infectious Diseases, Bethesda, MD; [5]National Institutes of Health Office of the Director, Bethesda, MD; [6]Johns Hopkins University, Baltimore, MD.*

Background: In the USA, six million individuals with sub-Saharan ancestry carry two apolipoprotein L1 (*APOL1)* high-risk genetic variants, which increase risk for kidney diseases. Whether APOL1 high-risk variants are independent risk factors for cardiovascular diseases requires further investigation.

Methods: Transgenic mice carrying APOL1 (G0 low-risk variant and G1 high-risk variant) on bacterial artificial chromosomes (BAC/APOL1 mice) were crossed with the apolipoprotein E knock-out (ApoE-KO) atherosclerosis mouse model. The dual transgenic mice were evaluated for the impact of APOL1 variants on systemic phenotypes. The associations between *APOL1* variants and hydrocephalus were analyzed in the NIH All of Us cohort.

Results: ApoE-KO mice carrying APOL1-G0 and APOL1-G1 transgenes did not show differences in the extent of atherosclerotic lesions or aortic calcification, as evaluated by Sudan IV staining and radiographic examination (**Figure A-C**). All these mice lacked albuminuria. However, ~21% of APOL1-G1 mice developed hydrocephalus and died early (**Figure D, E**). The hydrocephalus was likely due to excess CSF production by the choroid plexus, where epithelial cells expressed APOL1. Single-nucleus RNA-seq of choroid plexus identified multiple solute transporter upregulation and mTORC2 pathway activation in APOL1-G1-expressing epithelial cells. Further, in the NIH All of Us cohort, there was higher hydrocephalus prevalence among African-Americans with the *APOL1-G1* variant, in both recessive (odds ratio 4.35 [1.93-8.88]) and dominant models (3.86 [2.09-7.50]), supporting the mouse findings.

Conclusions: While APOL1-G1 expression in ApoE-KO mice did not worsen cardiovascular or kidney disease, we identified hydrocephalus as a novel APOL1-G1 variant-mediated phenotype. These findings extend the spectrum of APOL1-associated pathologies.

Funding: NIDDK Support

TH-PO220

Oxalate Cardiotoxicity in CKD

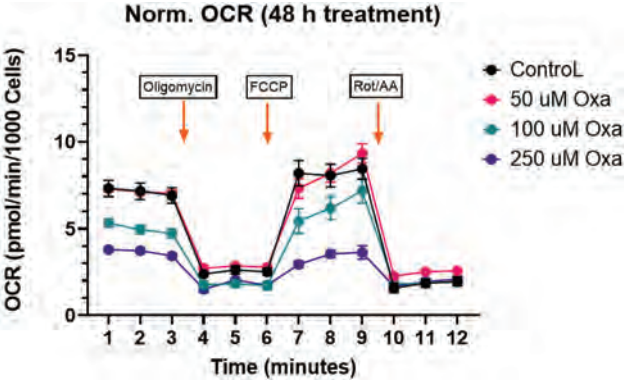
Karim Jaber,[1] Xiaozhong Xiong,[1] Kyle Merritts,[1] Yaw A. Akosah,[2] Evgeny Pavlov,[2] Lama Nazzal.[1] *[1]NYU Langone Health, New York, NY; [2]New York University College of Dentistry, New York, NY.*

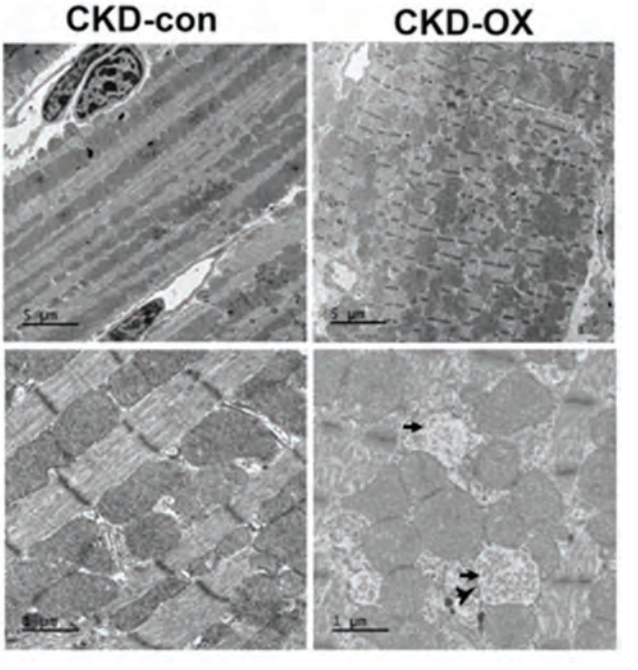
Background: Cardiovascular (CV) events are the leading cause of death among patients with chronic kidney disease (CKD), yet the underlying mechanisms remain poorly understood. Oxalate retention could significantly contribute to CVD in this population. Mitochondrial damage stands out as a potential mechanism of oxalate-induced toxicity, given its association with CKD-induced cardiac damage and oxalate nephrotoxicity. We hypothesize that oxalate-enriched diet increases plasma oxalate levels, induces CV toxicity and mitochondria dysfunction.

Methods: H9C2 cardiomyocytes were cultured and treated with 0, 50, 100 and 250 uM of sodium oxalate (NaOx) for 48 hrs. Mitochondrial function was evaluated via the Seahorse assay, and mitochondrial morphology and membrane potential were assessed through staining. 12 5/6 nephrectomy (CKD) mice were administered either a 1% sodium oxalate supplemented normal chow (NC) or NC for three months. Plasma samples were collected for oxalate and creatinine measurements. Histology and mitochondrial imaging were performed on the heart tissue at sacrifice.

Results: In vitro studies demonstrated that sodium oxalate induces mitochondrial dysfunction in a dose-dependent matter. Mice from both dietary groups showed a comparable degree of CKD at sacrifice but abnormal mitochondrial morphology was observed in the hearts of these oxalate fed mice, when compared to their controls.

Conclusions: Oxalate induces cardiotoxicity, possibly through mitochondrial damage.





TH-PO221

Role of Urokinase in Chronic Hypertension with Albuminuria in DOCA-Salt Murine Model

Marie L. Bach, Camilla Enggaard, Sai Sindhu Thangaraj, Boye Jensen. BLJ Group. *Syddansk Universitet Det Sundhedsvidenskabelige Fakultet, Odense, Denmark.*

Background: In proteinuria, aberrant filtration of urokinase-type plasminogen activator (uPA) and plasminogen (plg) leads to intratubular activation of plasmin with potential proteolytic activation of the epithelial sodium channel (ENaC). The ENaC and uPA inhibitor amiloride, reduces blood pressure in patients with treatment resistant hypertension and albuminuria. However, the non-redundant role for uPA is unresolved. Objective: The study aimed to test the hypothesis that uPA is necessary for the development of chronic hypertension in DOCA-salt murine model with albuminuria.

Methods: FVB/uPA wildtype (WT) and gene-targeted (KO) mice were anesthetized (xylazine 10 mg/kg, ketamine 100 mg/kg i.p.) and subjected to unilateral nephrectomy or sham operation. 14-days post-surgery, 4%NaCl diet was introduced and DOCA/sham-pellets were inserted subcutaneously. Blood pressure was measured by indwelling chronic femoral catheters for 15 days. A subset of mice was housed in metabolic cages for 24 hr urine collection. Kidney tissue was collected and used for immunoblotting for γENaC abundance. In a second series, angiotensin II (ANGII) (60ng/min kg) was used to compare blood pressure to low ANGII DOCA-salt mice. Normally distributed data was analyzed by two-way ANOVA followed by post-hoc Bonferroni t-test.

Results: Urine from DOCA-salt treated mice showed glomerular proteinuria with significantly increased albumin excretion (0,4 mg/24 hr/g bodyweight(BW)) compared to control (0,0007 mg/24hr/gBW) with no difference between genotypes. DOCA-salt WT urine showed plg and plasmin abundance, while KO mice only showed plg abundance. Kidney tissue showed increased cleaved γENaC/full-length γENaC abundance in DOCA-salt treated mice with no difference between uPA KO and WT. DOCA-salt increased mean arterial pressure (133 ±4 mmHg), systolic (152±4 mmHg) and diastolic (111±3mmHg) blood pressure significantly from day 1 to 15 compared to control (99±4 mmHg, 108±7 mmHg, 79±4 mmHg) with no difference between genotypes. Heart rate was unchanged (586 bpm), and no difference between day and night pressure. ANGII infusion for 7d led to similar blood pressure elevation in WT and uPA KO mice.

Conclusions: In chronic hypertension with albuminuria, uPA is necessary for activation of plasminogen to plasmin in urine, but does not contribute to hypertension, albuminuria, or kidney γENaC cleavage.

Postfilter Hematocrit Is a Predictor of Continuous Kidney Replacement Therapy Filter Life

Gwyndolyn M. Radford,[1] Javier A. Neyra,[2] Melissa L. Swee,[1] Kianoush Kashani,[3] Masaaki Yamada,[1] Mary V. Sarrazin,[1] Diana I. Jalal,[1] Benjamin R. Griffin.[1] *[1]University of Iowa Hospitals and Clinics, Iowa City, IA; [2]The University of Alabama at Birmingham, Birmingham, AL; [3]Mayo Clinic Minnesota, Rochester, MN.*

Background: Premature filter clotting occurs in up to a quarter of continuous renal replacement therapy (CRRT) filters resulting in blood loss, reduced treatment efficacy, and increased cost. Modifiable factors associated with clotting include access type and location, CRRT modality, and anticoagulation. One additional factor is post-filter hematocrit (Hct), which is a function of pre-filter Hct and filtration fraction (FF). Experts recommend monitoring and minimizing post-filter Hct to reduce clotting risk. However, post-filter Hct is not routinely measured in clinic practice due in part to a paucity of data to support these recommendations. In this study, we hypothesized that there would be an inverse relationship between post-filter Hct and CRRT filter life.

Methods: In this secondary analysis of a previously published study (PMID: 36630406), post-filter Hct was calculated using published formulas utilizing systemic Hct and FF. FF was derived from ultrafiltration rates, rates of pre- and post-filter replacement fluid, and blood flow rate. The primary outcome was filter life (hours). Circuits were excluded if they lasted <2 hours, or if any of the variables used to calculate post-filter Hct were absent. A Generalized Linear Model (GLM) was used to account for multiple filters per patient, and was adjusted for age, race, sex, illness severity, and type of anticoagulation.

Results: A total of 412 filters from 111 patients were included in the analysis. In the final GLM analysis, post-filter Hct was inversely associated with filter life (adjusted estimate = -0.53, 95% CI -0.11 to -0.96, p=0.01). For categorical classification, a post-filter Hct of 29%, the 33rd percentile, was most clinically meaningful. Filters with a post-filter Hct <29% had a median filter life of 34.7 (IQR 18.0-65.6) hours, compared to 24.0 (IQR 13.2-50.9) with post-filter Hct ≥29% (p = 0.04).

Conclusions: In patients receiving CRRT, post-filter Hct was independently associated with decreased filter life and may represent a feasible parameter to monitor during CRRT to maximize filter life. Future prospective studies should determine whether prescription adjustments based on measured post-filter Hct can prolong filter life.

TH-PO223

Hypotension at Initiation of Continuous Kidney Replacement Therapy: A Harbinger of Poor Outcomes

Sameer Thadani,[1,2] Christin N. Silos,[1,2] Kristin J. Dolan,[1,2] Poyyapakkam Srivaths,[1,2] Ayse Akcan Arikan.[1,2] *[1]Baylor College of Medicine, Houston, TX; [2]Texas Children's Hospital, Houston, TX.*

Background: Hypotension occurs in 27-50% of connections to continuous renal replacement therapy (CRRT) yet its impact on outcomes in children has not been thoroughly investigated. Using machine learning techniques and clinical expertise, we aim to build upon prior research by examining the impact of hypotension at CRRT initiation on dialysis liberation.

Methods: Single center retrospective study of critically ill children who received CRRT between 9/2016-10/2018 at Texas Children's Hospital. We utilized high resolution hemodynamics (1-minute intervals) to diagnose hypotension which was defined by a 20% decrease from baseline mean arterial pressure (MAP). Baseline MAP was the average MAP one hour prior to CRRT initiation. Illness severity was assessed using the PELOD-2 score. Liberation was defined as discontinuation of all dialytic modalities 30 days after CRRT initiation. We applied the LASSO method and clinical expertise to construct our final adjusted model.

Results: Our cohort included 59 patients with a median age and weight of 59 months (12-152) and 18 kgs (9-41) respectively. The median PELOD-2 score was 8 (6-10) and a total of 25 (42%) of patients required vasoactive medications at CRRT initiation. A total of 16 (27%) of patients had hypotension at CRRT initiation and 9 (15%) did not liberate. LASSO regression identified cardiac and gastrointestinal indications for ICU admission, history of organ transplantation, locations of hemodialysis catheter, and hypotension after initiation as significant variables. With addition of clinically relevant variables (PELOD-2, vasoactive inotropic score, age, and weight) and utilizing backwards selection, hypotension at CRRT initiation (aOR 0.21 (CI 0.04-0.98) remained negatively associated with liberation

Conclusions: Our model, which integrated machine learning and medical expertise, revealed that hypotension during CRRT initiation was associated with decreased odds of dialysis liberation. Our findings require further external validation but have identified a potentially modifiable factor associated with morbidity. Additional studies should investigate the variation in hypotension during CRRT and how its timing and duration impact patient outcomes.

TH-PO224

Troponin Clearance via Continuous Kidney Replacement Therapies in the Intensive Care Unit (ICU)

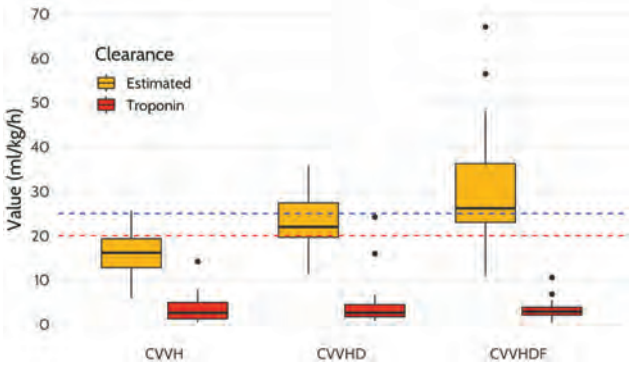
Sabina Mason,[1] Evelyn Deasy,[1] Maria Donnelly,[1] Deirdre M. D'Arcy,[3] Julio L. Chevarria,[1] Yvelynne P. Kelly.[1,2] *[1]Tallaght University Hospital, Dublin, Ireland; [2]Trinity College Dublin School of Medicine, Dublin, Ireland; [3]The University of Dublin Trinity College, Dublin, Ireland.*

Background: Our aim was to compare the clearance of cardiac troponin T via continuous venovenous haemofiltration (CVVH), continuous venovenous haemodialysis (CVVHD) and continuous venovenous haemodiafiltration (CVVHDF) as a function of circulating serum troponin levels in critically ill patients.

Methods: This was a single-centre, prospective observational study conducted at Tallaght University Hospital in Dublin. Adult patients admitted to ICU and commenced on continuous renal replacement therapy (CRRT) were included. All included patients required a serum troponin T level of greater than 50 ng/L. All patients were required to have commenced CRRT at least four hours before the first sample was taken. We took three serum samples per patient every 24 hours, i.e. over a total of 72 hours, with simultaneous sampling of the waste effluent of the RRT to measure effluent troponin. Our primary outcome measure was estimated troponin clearance according to CRRT modality.

Results: We found no significant difference in estimated troponin clearance according to CRRT modality; with an overall median troponin clearance of 2.6 ml/kg/hour. The percentage of troponin clearance was statistically significantly higher for CVVH compared to CVVHD and CVVHDF (17 vs 14 vs 12% respectively; p = 0.008), though this was not felt to be clinically significant.

Conclusions: In this single-centre, prospective observational study, we measured simultaneous blood and effluent troponin T levels in patients on either CVVHDF, CVVHD or CVVH to compare estimated troponin clearance between the three CRRT modalities. We found no significant difference in estimated troponin clearance according to CRRT modality. Our results show that clearance of troponin T on CRRT is generally small across all modalities and that therefore ongoing treatment with CRRT should not significantly impact our interpretation and tracking of troponin T results in patients with concern for acute coronary syndrome.



Estimated clearance and troponin clearance per CRRT modality

TH-PO225

Effect of Continuous Kidney Replacement Therapy (CRKT) on Thyroid Function

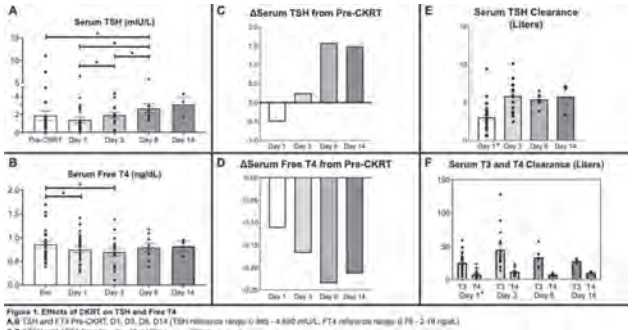
Matt R. Kennis, David Madison, North Foulon, Kayo Okamura, Sarah Haeger, Isadore Budnick, Zhibin He, Warren H. Capell, Sarah Faubel. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Thyroxine (T4) and triiodothyronine (T3) are low molecular weight proteins (0.78 and 0.65kDa, respectively) amenable to removal by CKRT. Herein, we quantified T3/T4 clearance during CKRT and tested the hypothesis that CKRT would affect the hypothalamic-pituitary-thyroid (HPT) axis and cause a rise in serum thyroid stimulating hormone (TSH).

Methods: In 24 patients undergoing continuous veno-venous hemodialysis, we measured CKRT effluent and serum levels of TSH, free T4 (FT4), free T3 (FT3), and reverse T3 (rT3) on Days 1, 3, 8 and 14 of CKRT. Baseline TSH and FT4 was measured <12 hours prior to CKRT initiation. In all cases, fresh samples were measured in the clinical lab. On each day of CKRT, sieving coefficient (SCx=[x]effluent/[x]serum), clearance (liters cleared=SCx*total effluent volume in prior 24 hours), and Sequential Organ Failure Assessment (SOFA) scores were calculated. Thyroid function tests were interpreted by an endocrinologist using prespecified definitions of euthyroid sick syndrome (ESS) and hypothyroidism.

Results: Mean SC of TSH, FT4, and FT3 was 0.15 (n=48), 0.27 (n=46), and 1.04 (n=49), respectively and did not change between days on CKRT. SOFA scores were similar on each day. Serum TSH was higher on D8 vs. D3, D8 vs. D1, D8 vs. Pre-CKRT and D3 vs. D1 (Figure 1A). Serum T4 decreased on D3 and D1 of CKRT, relative to pre-CRKT (Figure 1B). TSH, FT4, and FT3 clearance is shown in Figure 1E-F. One patient met criteria for hypothyroidism, with the remaining patients in various stages of ESS.

Conclusions: T3 and T4 removal occurs during CKRT. To our knowledge this is the first report to quantify T3 and T4 removal during CKRT and the first to describe the development of hypothyroidism after CKRT initiation (n=1). Even in patients with ESS (n=23), a physiologic effect of T3 and T4 removal on the HPT axis is suggested by the significant rise in TSH. These data suggest that hypothyroidism is a novel complication of CKRT.



TH-PO226

Hyperparathyroidism as a Cause of Low Calcium Requirement during Regional Citrate Anticoagulation: Two Case Reports

Afsheen Afzal,[1] Frank Liu.[2,1] *[1]Weill Cornell Medicine, New York, NY; [2]Rogosin Institute, New York, NY.*

Introduction: CRRT with regional citrate anticoagulation (c-CRRT) relies on a predictable calcium (Ca) balance between effluent removal and Ca replacement to maintain a stable physiologic peripheral ionized Ca (iCa). Our c-CRRT protocol utilizes Ca gluconate for replacement targeting peripheral iCa of 1.05-1.25 mmol/L. In our experience, the majority of patients require 1-2 g/hr of Ca gluconate with variation due primarily to effluent volume. Patients who have unusually low Ca requirements are in negative Ca balance, which can lead to significant demineralization of bone. Existing literature has centered on immobility hypercalcemia as the cause of unusually low Ca requirements during c-CRRT. We present 2 cases of unusually low Ca requirements due to hyperparathyroidism (HPT), which normalized after initiating cinacalcet.

Case Description: Case 1: A 44-year-old male with history of ESKD on hemodialysis (HD) and atrial fibrillation was admitted with cardiogenic/septic shock requiring c-CRRT. His pre-CRRT peripheral iCa was 1.26 mmol/L. He was noted to have unusually low Ca gluconate requirements (400 mg/hour). Subsequent workup revealed an elevated parathyroid hormone (PTH) level of 867 pg/ml. He was started on cinacalcet 30 mg daily; effluent volume was not changed. By 24h after the first dose, his Ca requirement had increased, with stabilization at 1.3 g/hr by 36h. Case 2: A 71-year-old male with history of ESKD on HD, coronary artery disease, and congestive heart failure was admitted with septic shock. His pre-CRRT peripheral iCa was 1.42 mmol/L; hypercalcemia workup was not done at that time. He was noted to have a low Ca gluconate requirement (as low as 400 mg/hr) on c-CRRT. PTH was elevated at 499 pg/ml in spite of systemic hypercalcemia (iCa 1.3 mmol/L). Cinacalcet 30 mg twice daily was initiated; effluent volume was not changed significantly. After 2 doses of cinacalcet, his Ca requirement increased, with eventual stabilization at 1.3-1.4 g/hr by 48h after cinacalcet start.

Discussion: These cases suggest that in addition to immobilization-induced hypercalcemia, HPT should be considered as a cause of hypercalcemia and unexpectedly low Ca requirements in critically ill ESKD patients on c-CRRT. In such patients, treatment of the underlying HPT with cinacalcet can minimize negative Ca balance and subsequent detrimental bone effects while on c-CRRT.

TH-PO227

Regional Citrate Anticoagulation (RCA) Compared with No Heparin in Continuous Kidney Replacement Therapy (CKRT) among Liver Patients: A Single-Center, Retrospective, Interim Analysis

Chandani Bhagat, Hari S. Meshram. *Institute of Liver and Biliary Sciences, New Delhi, India.*

Background: We divided the study population into chronic liver disease (CLD), and acute liver failure (ALF) or acute on chronic liver failure (ACLF) and compared the outcomes of RCA with no heparin.

Methods: This was an ethically approved, retrospective, single-center study conducted between 10 July 2022 to 26 Sept 2023. The study population (n = 309) was divided into CLD (n =173), ALF (n = 62) and ACLF (n = 74). CVVHDF modality was used where citrate dosing of 3 mmol/L maintaining a range of 2 mmol/L to 2.4 mmol/L was used. The primary outcome measured was difference in filter life span. Secondary outcomes were ammonia, lactate and pH improvement.

Results: 309 patients were studied.173 CLD patients, 44 received RCA and 129 received no anticoagulation. The median age of CLD was 50(40-57) years. A total of136 comprised of ALF and ACLF patients. ALF and ACLF cases were contributed by hepatitis A (43.5%) and acute alcoholic hepatitis, CLD (56.7%) respectively. In this group, 36 received RCA and 100 had no anticoagulation. The median age of this group was 38(28.75-47) years. The baseline clinical and laboratory parameters in the all the groups were statistically insignificant. The median duration of CKRT duration overall was 42 hours. In the KM analysis, RCA group had longer filter clotting time compared to no anticoagulation (log rank p-test = 0.001172). The length of stay from hospital admission to last follow-up or death was 11 days. Overall there was no difference in mortality between the groups with respect to choice of anticoagulation. There was no statistical difference in terms of pre and post CKRT serum ammonia, lactate, and blood pH in any of the sub groups.

Conclusions: CKRT at low dose RCA is feasible in liver patients including ALF and ACLF. There were no additional metabolic complications or mortality risks associated with RCA. Also, there was significant improvement in filter life span which prompts its consideration in this high risk group of patients. Further, prospective studies are encouraged to confirm our preliminary findings.

TH-PO228

Extracorporeal Carbon Dioxide Removal Instead of Mechanical Ventilation in a Patient with Respiratory Distress and Acute Kidney Failure, with Active Bleeding Using Regional Anticoagulation

Milton Kalil, Renato E. Eick, David Saitovich, Anna C. Stein, Lucas G. Da Luz, Illan G. Balestrin, Marcelo B. Gazzana, Mauricio L. André. *Hospital Moinhos de Vento, Porto Alegre, Brazil*.

Introduction: There are only a few reports so far describing the use of citrate (regional) anticoagulation for CO2 removal (ECCO2R) probably due to the metabolic complications and electrolyte disturbances that occur with the high blood flow rate (for efficient CO2 removal) and higher than usual citrate flow rate, necessary for the procedure.

Case Description: Citrate anticoagulation in continuous venovenous hemodiafiltration (CVVHDF) associated with extracorporeal carbon dioxide removal (ECCO2R) was performed in a 71 years old patient with active bleeding and severe respiratory acidosis for 5 days. This procedure was carried out with a Fresenius (multiECCO2R), a single gas exchanger combined with continuous kidney replacement therapy (CKRT). Dialysis prescription was blood flow rate of 300ml/min, sodium citrate 4% infusion rate of 300ml/h, calcium chloride 3.38% replacement solution rate of 30ml/h, and oxygen flow rate of 4.5L/min. Dialysis and replacement solutions bicarbonate and sodium concentration were respectively 10mEq/L and 129mEq/L. The patient remained without endotracheal intubation during the procedure period. A reduction of approximately 30% pCO2 was attained, respiratory acidosis was controlled and the hydroelectrolytic balance was maintained(Table1).

Discussion: In cases of CO2 removal in the context of regional anticoagulation with citrate, it is important to adjust calcium replacement according to effluent volume and also to adjust bicarbonate and sodium concentrations in dialysis solutions. We conclude that it is possible and safe to remove CO2 in a CVVHDF + multi ECCO2R single system, using sodium citrate for regional anticoagulation.

	Before procedure	After 15 minutes	Day 1	Day 2	Day 3	Day 4	Day 5
pH a	7.19	7,28	7.41	7,43	7,40	7,39	7,39

TH-PO229

Development of a Novel Protocol for Successful Discontinuation of Continuous Kidney Replacement Therapy: A Pilot Study

Daun Song,[1] Ji won Lee,[1] Se-Hee Yoon,[1] Won Min Hwang,[1] Sung-Ro Yun,[1] Sua Lee,[2] Soyoung Lee,[2] Yohan Park.[1] Div of Nephrology, Dept of Internal Medicine, Konyang University Hospital; Div of Nephrology, Dept of Internal Medicine, Daejeon Eulji Medical Center. *[1]Konyang University Hospital, Daejeon, Republic of Korea; [2]Daejeon Eulji University Hospital, Daejeon, Republic of Korea*.

Background: The discontinuation of continuous kidney replacement therapy (CKRT) lacks a well-established protocol. Creatinine and cystatin C (CysC) are well-known markers of kidney function, with molecular weights of 113 Da and 13.3 kDa, respectively. This study aimed to develop a novel CKRT discontinuation protocol by predicting kidney function using changes in serum cystatin C (CysC) levels after switching the CKRT mode to continuous veno-venous hemodialysis (CVVHD), which has a lower clearance rate for middle molecular weight solutes.

Methods: This pilot study included 17 patients undergoing CKRT. Patients who maintained stable vital signs without vasopressor support were switched from continuous veno-venous hemodiafiltration (CVVHDF) to CVVHD. Serum creatinine and CysC levels were measured at 6, 12, and 24 hours after switching to CVVHD mode, along with daily urine output. Kidney replacement therapy (KRT) reinitiation was defined as the resumption of KRT within 7 days after discontinuing CKRT.

Results: Out of 17 patients, 7 experienced KRT reinitiation. Following the switch to CVVHD mode, serum creatinine levels remained stable or decreased in all patients, whereas an increase in serum CysC was observed in the KRT reinitiated group. Receiver operating characteristic (ROC) curve analysis was conducted to predict KRT reinitiation. The 12hr CysC to baseline CysC ratio had the highest area under the ROC curve (AUROC) value of 0.857, with a cutoff value of 0.97. The AUROC value for daily urine output was 0.871, with a cutoff value of 214 mL. A multivariate model incorporating both the 12hr CysC to baseline CysC ratio and daily urine output demonstrated an AUROC value of 0.986, showing exceptional predictive performance for KRT reinitiation.

Conclusions: The multivariate model using the 12hr CysC change and daily urine output after switching to CVVHD mode proved to be an excellent predictor of KRT reinitiation. Based on this pilot study, a CKRT discontinuation protocol could be developed, and if validated in larger studies, may lead to a paradigm shift in CKRT discontinuation practices.

TH-PO230

Predicting Liberation from Continuous Kidney Replacement Therapy in Critically Ill Patients Using a Machine Learning Model

Kianoush Kashani,[1] Francesca Alfieri,[2] Andrea Ancona,[2] Simone Zappalà.[2] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]U-Care Medical s.r.l, Torino, Italy*.

Background: Continuous renal replacement therapy (CRRT) is utilized in nearly 14% of critically ill patients. Currently, there are no standardized practice guidelines to wean CRRT, apart from clinicians' discretion, as per the KDIGO guidelines. This study aims to develop and validate a model to predict successful CRRT liberation.

Methods: For this single-center, retrospective cohort study, we used data from 661 adult patients connected to 668 disinct ICU stays from MIMIC-IV dataset who received CRRT between 2008 to 2019. CRRT liberation was defined as renal replacement therapy (RRT)-free survival within seven days after the liberation. We randomly divided the cohort into derivation (70%) and validation sets [KK1] (30%). The outcomes were successful CRRT liberation vs. unsuccessful CRRT liberation and/or death. A multiclass decision tree model was developed and internally validated.

Results: The final cohort included 668 ICU stays requiring CRRT, among them 266 (39.8%) were successfully liberated from CRRT, 265(39.7%) had unsuccessful CRRT liberation, and 137(20.5%) died while on CRRT. The auROC of the model reflects its ability to discriminate between successful and unsuccessful liberation, varying from 0.797(CI 95% 0.743, 0.864) to 0.739(CI 95% 0.700, 0.810) when the model is activated at the time of CRRT liberation up to 12 hours later. Moreover, the model outputs a probability of mortality within seven days from the CRRT discontinuation, achieving auROCs from 0.746 (CI 95% 0.682, 0.861) to 0.861(CI 95% 0.795, 0.944) moving forward over time.

Conclusions: The model is designed to be used by clinicians at the time of CRRT liberation and can be consulted up to 12 hours after the discontinuation. This validated model could be integrated into the clinical practice with the aim of assisting the decision-making related to the CRRT liberation in critically ill patients with AKI hospitalized in intensive care units, facilitating a timely reinstitution of CRRT where needed and ensuring better patient outcomes.

TH-PO231

Oxiris Membrane Performance in Patients with Septic Shock and Continuous Kidney Replacement Therapy Requirement: A Randomized Controlled Trial

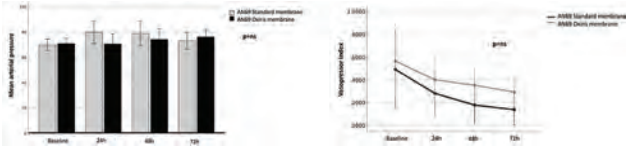
Omar Fueyo,[1] Adrián Esteban Caballero-Islas,[1] Mauricio Arvizu Hernández,[1] Ricardo Correa-Rotter,[1] Pablo E. Galindo,[2] Néstor H. Cruz Mendoza,[1] Olynka Vega.[1] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [2]Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico*.

Background: Highly selective semipermeable Oxiris membranes have shown to provide endotoxin adsorption and removal of different cytokines which could improve hemodynamic stability in patients with septic shock and continuous kidney replacement therapy (CKRT) requirement. The aim of this study was to compare the clinical efficacy of Oxiris membrane vs a conventional AN69 standard membrane to maintain the mean arterial pressure (MAP) after 72 hours in critically ill patients with CKRT requirement

Methods: Multicenter randomized controlled trial in critically ill patients and CKRT requirement. Patients were randomized to receive continuous veno-venous hemodiafiltration using either an AN69 standard membrane or an AN69 Oxiris membrane. Regional citrate anticoagulation was used, all patients had a prescribed dose of 30mL/kg/h for 72 hours, the filters were changed every 24h. Clinical variables were registered, vasopressor dependency index was calculated to express relationship between vasopressor dose and MAP

Results: Originally 36 patients were intended to be included. At the time of this cut point 30 patients have been included, 15 (50%) in the Oxiris group, 14 (46%%) in the control group and 1 (3%) had to be excluded because of death in the first 24 hours. Most common infection was pneumonia, 28% due to COVID-19, mean initial SOFA was 11 points. There were no differences in MAP between groups (Oxiris vs. Control) at 0, 24, 48 and 72 h; 66 vs 68, 71 vs 74, 73 vs 77 and 73 vs 79 respectively. **Figure 1**. The rate of vasopressors was not different as shown in **Figure 2**. Fluid removal tended to be greater in the control group with a median rate of 1.2 vs 0.5 (p = 0.03) at 24 h, 0.9 vs 1.0 at 48 h (p=0.72), and at 72 h with a rate of 1.5 vs 0.7 (p=0.03). There were no differences in daily fluid balance

Conclusions: In this study there were no differences in the requirement of vasopressors to maintain hemodynamic stability in patients with septic shock and CKRT using Oxiris membrane compared to standard membrane.



MAP and Vasopressor Index at baseline, 24, 48 and 72 h

TH-PO232

Role of Hemodiafiltration in Calcium Channel Blocker (CCB) Overdose

Steven Pham. *Unity Health, Searcy, AR.*

Introduction: Overdose of CCBs, a common medication used to treat hypertension, is associated with high mortality rates. Amlodipine, a dihydropyridine class of CCB, is a highly protein-bound medication. Current management of CCB overdose includes intravenous fluid, vasopressor, lipid emulsion, and methylene blue. However, overdose often leads to metabolic acidosis and multiorgan failures, prompting other therapies such as continuous veno-venous hemodiafiltration (CVVH) or extracorporeal membrane oxygenation support (ECMO). We report a case of amlodipine overdose resulting in refractory shock and acidosis, in which CVVH and ECMO were successful.

Case Description: A 34-year-old male was admitted due to unresponsiveness. His wife reported an empty bottle of amlodipine next to him. Upon arrival, his oxygen saturation was 70%. Blood pressure (BP) was 70/30 mmHg. Due to severe hypotension, he was started on norepinephrine and vasopressin, with phenylephrine and epinephrine soon being added. Poison control recommended starting methylene blue to reverse amlodipine's vasodilator effect. Lipid emulsion was initiated to sequester amlodipine, with the mean arterial pressure (MAP) improving from 45 to 62. He also developed acute kidney injury (AKI) with creatinine of 3.57 mg/dL and blood urea nitrogen (BUN) of 30 mg/dL. Arterial blood gas (ABG) showed pH 7.10 and pCO2 59.3 mmHg. Anion gap was 21 mmol/L and lactic acid was 9.9 mmol/L. CVVH was started, maintaining his MAP in the 70s and systolic BP in the 110s. His urine output was around 100-150 cc/hour. However, his acidosis remained refractory (last ABG showed pH of 7.22 and pCO2 of 61.9 mmHg), so he was transferred to another facility for ECMO. At the time of this writing, the patient has fully recovered.

Discussion: Hemodialysis is ineffective for eliminating protein-bound medication like amlodipine. Previous literature has suggested the use of albumin as a dialyzer to enhance clearance, although in our case, traditional CVVH was preferred due to other indications such as severe metabolic acidosis, oliguria, and AKI. Our patient's condition improved significantly following CVVH and ECMO, possibly due to restored kidney function and pH correction, thereby facilitating amlodipine clearance and enhancing responses to other treatments. Further research is warranted to explore the effectiveness of albumin over traditional CVVH in clearing overdose of protein-bound medications.

TH-PO233

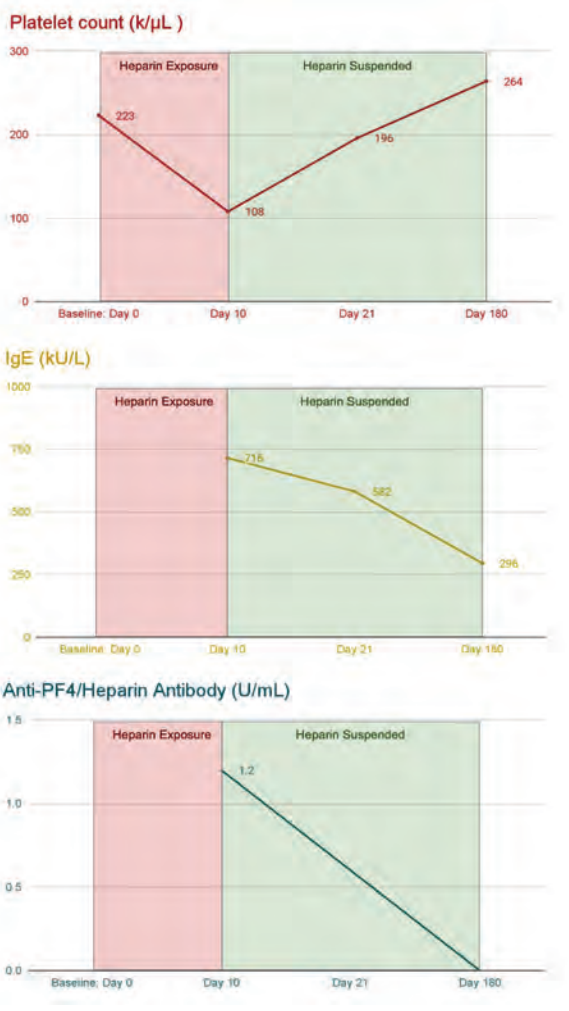
Unusual Presentation of Type II Heparin-Induced Thrombocytopenia Successfully Managed with Predilution Online Hemodiafiltration

Felipe Pascoal, Adolfo Simon, Istenio Pascoal, Juliane Lauar, Kelia Xavier, Vilber Bello. *Centro Brasiliense de Nefrologia Ltda, Brasilia, Brazil.*

Introduction: Type II heparin-induced thrombocytopenia (HIT) is portrayed by antibody production against PF4/Heparin complex. While it typically presents with thrombocytopenia and thrombosis, allergic features have also been reported. Predilution Online hemodiafiltration (OL-HDF) can dismiss heparin and is safely used when this anticoagulant is contraindicated. Herein, we present a rare case of type II HIT with wheezing, elevated IgE levels and thrombocytopenia in a dialysis patient effectively handled with predilution OL-HDF.

Case Description: An 83-year-old male with unresolved obstructive uropathy was referred to our clinic for dialysis initiation. After four uneventful sessions, he experienced wheezing, 88% oxygen saturation and high filter transmembrane pressures half an hour into the next therapies, despite switch of filter and line brands. Bloodwork revealed 108 k/µL platelets (from 223k/µL), 4Ts score was 6 (high probability) and Anti-PF4/Heparin assay yielded 1.2 U/mL (RR: < 0,6 U/mL), confirming the diagnosis of type II HIT. IgE levels were also elevated at 716 kU/L. Since equipment clotting persisted despite intermitent saline flushes and Apixaban prescription, dialysis therapy was shifted to short daily heparin free predilution OL-HDF. Sessions resumed uneventfully ever since and, six months later, IgE decreased to 296 kU/L, platelets increased to 264k/µL and Anti-PF4/Heparin levels were undetectable, as shown in the graphs attached.

Discussion: Type II HIT may display with thrombocytopenia, hypercoagulability and unusual allergic features in a manifold fashion. As management for this condition relies on heparin cessation and clot-preventing strategies, predilution OL-HDF presents a safe and effective dialysis modality in this group of patients.



TH-PO234

Comparison of Autonomic Response to Orthostatic Challenge before Hemodiafiltration in Patients with Different Intradialytic Blood Pressure Profiles

Erika E. Jaime Borja, Salvador L. Gil, Claudia Lerma, Alfredo Fuentes Mercado. *Instituto Nacional de Cardiologia Ignacio Chavez, Ciudad de Mexico, Mexico*.

Background: The heart rate variability (HRV) response to active standing (AS) has shown preserved autonomic modulation in maintenance hemodiafiltration (HDF) patients. The aim was to compare the HRV response to AS before HDF between patients with different profiles of intradialytic systolic blood pressure (SBP).

Methods: We included 55 HDF sessions from 26 patients (age 40 ± 13 years, 62% were women, and five had diabetes). Using linear regression analysis, the SBP intradialytic profile was classified into three groups: decreased SBP, increased SBP, or unchanged SBP. HRV indices were obtained during the supine position and AS. The mean values were compared by ANOVA for repeated measures, p value < 0.05 was considered significant.

Results: Age, comorbidity, total ultrafiltration volume, initial SBP, and final SBP were similar between groups. In both positions, the HRV indices were similar between groups (Table 1). Although all groups had a response to AS of faster mean heart rate and lower variability (pNN50), only the group with decreased SBP responded to AS by increasing the low-frequency (LF) power and decreasing the high-frequency (HF) power.

Conclusions: The autonomic response to an active orthostatic challenge before HDF shows a preserved sympathetic increase and parasympathetic decrease only in those patients who had an intradialytic SBP decrease in the subsequent HDF session.

Table 1. HRV indices grouped by intradialytic SBP response.

TH-PO235

Adequate Convective Volume Can Be Achieved in Majority of Multiethnic Asian Patients Receiving Hemodiafiltration in Singapore

Cindy Chan,[1] Yan Zhang,[2] Yan Yi Cheung,[3] Nandakumar Mooppil,[3] Tripti Singh,[3] Anke Winter,[2] Franklin W. Maddux,[4] Jeffrey L. Hymes,[4] Milind Nikam.[3] *[1]Fresenius Medical Care Asia Pacific Ltd, Hong Kong, Hong Kong; [2]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [3]Fresenius Medical Care Asia Pacific Ltd, Singapore, Singapore; [4]Fresenius Medical Care Holdings Inc, Waltham, MA.*

Background: High volume hemodiafiltration (HDF) has been shown to improve patient outcomes. However, there is a very common concern amongst healthcare practitioners about the feasibility of achieving optimal convective volume (CV) in Asian patients.

Methods: A 5-year retrospective cohort analysis was conducted on patients dialyzing at Fresenius Kidney Care clinics in Singapore from 2019 to 2023, aiming to evaluate HDF practice patterns and outcomes. We adjusted the CV to body surface area (BSA) as has been suggested by some publications.

Results: A total of 1404 patients received 291,822 HDF sessions during the study period. At baseline, the cohort's mean age was 64 (±13) years and it was followed up for 34 (±17) months on average, with 60% males. The majority were Chinese (51%), followed by Malay (11%) and Indian (4%) patients. The most common modality was post-dilutional HDF (70%) followed by pre-dilutional in 25% cases. In 5% cases the modality was not recorded. The CVs achieved in various sub-groups in this cohort are listed in Table 1.

Conclusions: Contrary to the common belief, adequate CVs can be achieved in majority of Asian patients. With growing interest and experience of HDF, this is likely to improve further. Of note, Malay patients had lower CV compared to those of Chinese and Indian ethnicity – a further study of patient and practice related factors in Asian geographies on CV achievement is warranted.

TH-PO236

Hemodiafiltration Is Associated with Lower Hospitalization Rates Compared with Hemodialysis in a Singapore Cohort

Cindy Chan,[1] Yan Zhang,[2] Yan Yi Cheung,[3] Nandakumar Mooppil,[3] Tripti Singh,[3] Anke Winter,[2] Franklin W. Maddux,[2] Jeffrey L. Hymes,[4] Milind Nikam.[3] *[1]Fresenius Medical Care AG, Hong Kong, Hong Kong; [2]Fresenius Medical Care AG, Bad Homburg, Germany; [3]Fresenius Medical Care AG, Singapore, Singapore; [4]Fresenius Medical Care AG, West Nashville, TN.*

Background: Hemodialysis (HD) patients suffer from high rates of hospitalization leading to significant morbidity, mortality, and costs. Hemodiafiltration (HDF) has been shown to improve patient outcomes.

Methods: A retrospective cohort analysis was conducted on patients receiving HD at Fresenius Kidney Care clinics in Singapore between 2019 and 2023. Clinical data were extracted from the electronic information system – EuCliD® to assess the association of dialysis modality with hospitalization outcomes. Patients were classified into 3 groups, i.e., HD and HDF groups, comprising of patients receiving ≥75% of treatments with HD or HDF, respectively, and others as the mixed group. Negative binomial regression was applied to estimate the incident rate ratio (IRR) of hospitalization and length of stay (LOS), adjusted for confounders.

Results: A total of 3298 patients were included, with 59% males. The mean age was 64(±13) years, and dialysis vintage as 26(±48) months. The modality group distribution was: HD: 75%, HDF: 16% and mixed: 9%. The HDF group had a lower hospitalization rate per person-year compared to the mixed and HD groups (HDF: 1.18, Mixed: 1.40, HD: 1.76), with a significantly lower IRR of 0.80 [95% CI: 0.72, 0.88] compared to the HD group (Table 1). Also, the HDF group had a lower number of hospitalization days per person-year than the other groups (HDF: 8.99, Mixed: 11.38, HD: 15.13; IRR, 0.73 [95% CI: 0.63, 0.84]).

Conclusions: In this cohort, HDF showed significantly lower hospitalization rates and shorter LOS compared to conventional HD and the mixed modality groups.

Funding: Commercial Support - Fresenius Medical Care

Table 1. Incident Rate Ratios of hospitalization outcomes

Dialysis modality (HD as reference group)	Hospitalization events (per patient-year) IRR (95% CI)*	Hospital days (per patient-year) IRR (95% CI)*
HDF	0.80 (0.72 – 0.88)	0.73 (0.63 – 0.84)
Mixed	0.92 (0.80 – 1.05)	0.87 (0.73 – 1.03)

*Adjusted for COVID-19 status, age, sex, race, dialysis vintage, pre-existing diabetes, cardiovascular disease, hypertension, Charlson comorbidity index, BMI, dialysis frequency, effective treatment time, OCM Kt/V, blood flow rate, systolic and diastolic blood pressure at baseline, and most frequent vascular access during follow-up.

TH-PO237

Exploring the Impact of Hemodialysis Modalities on NETosis in Diabetic and Nondiabetic Patients

Etty Kruzel-Davila,[1,2] Olga O. Vdovich,[1,2] Lital Remez.[1,2] *[1]Galilee Medical Center, Nahariya, Israel; [2]Bar-Ilan University The Azrieli Faculty of Medicine, Ramat Gan, Israel.*

Background: Patients suffering from chronic kidney disease (CKD) and diabetes mellitus (DM) face an increased risk of developing cardiovascular complications and infections. Neutrophils are recruited to sites of infection and form Neutrophil extracellular traps, a conserved mechanism known as NETosis, function to eradicate pathogens by releasing decondensed chromatin decorated with proteins from neutrophil intracytoplasmic granules. However, when NETosis becomes dysregulated, it can potentially exacerbate the detrimental inflammatory pathways linked to complications of CKD and diabetes. Considering the higher survival rates observed among patients treated with hemodiafiltration (HDF) as opposed to hemodialysis (HD), along with the dysregulated NETosis observed in individuals with HD and DM, our objective is to investigate the impact of hemodialysis modality on NETosis in patients undergoing hemodialysis, with and without diabetes.

Methods: Twenty hemodialysis patients participated in the study, comprising 10 diabetic patients, 10 non-diabetic patients, and 10 healthy controls. Blood samples were obtained from patients undergoing hemodiafiltration (HDF) and subsequently transitioning to high flux hemodialysis (HFHD). Neutrophils were isolated from these samples and stimulated with 100 nM PMA for one hour. Subsequently, they were stained for markers of NETosis such as PAD4, PE, MPO, Histone H3, and 7AAD Viability Dye. Data acquisition was performed using a flow cytometry.

Results: Our findings reveal significantly reduced levels of NETosis activation and NETosis markers following HDF treatment compared to HD, irrespective of diabetes status ($p<0.05$). Furthermore, diabetic patients exhibited lower NETosis activation compared to non-diabetic patients ($p=0.03$, 0.01, for HD and HDF respectively).

Conclusions: The study suggests that the reduction in dysregulated NETosis may contribute to the favorable outcomes of HDF, ultimately leading to decreased mortality among hemodialysis patients.

Serum (1-3)-β-D-glucan Levels after Oral β-D-glucan Load in Controls and People with ESKD on High-Flux Hemodialysis (HD) and Hemodialysis Filtration (HDF)

Oscar Swift,[1,2] Malcolm A. Finkelman,[3] Yonglong Zhang,[3] Sivakumar Sridharan,[1,2] Enric Vilar,[1,2] Ken Farrington.[1,2] *[1]East and North Hertfordshire NHS Trust, Stevenage, United Kingdom; [2]University of Hertfordshire, Hatfield, United Kingdom; [3]Associates Of Cape Cod Inc, East Falmouth, MA.*

Background: (1-3)-β-D glucan (BDG) is elevated in ESKD in the absence of active infection. Elevated levels may reflect increased gut permeability. This study aimed to: 1. Establish differences in serum levels of BDG in controls and individuals with ESKD following an oral BDG load. 2. Evaluate relationships between fasting pre- and post-HD BDG levels and high-flux HD and HDF in a larger cohort.

Methods: 1. 20 adults with ESKD receiving high-flux HD (n=5) or HDF (n=15) with chronic inflammation (baseline hs-CRP ≥5mg/L) and 20 controls were recruited. Following a BDG oral load, serial serum BDG levels were taken. One participant (HDF subgroup) was excluded post-hoc due to acute diverticulitis soon after study participation. 2. Fasting serum BDG samples from 443 outpatients receiving high flux-HD (n=156) or HDF (n=287) were obtained pre- and post-HD.

Results: 1. Serum BDG was higher at all timepoints in the ESKD group compared to controls. There were no differences in change from baseline BDG in either group post-BDG load (Figure 1a), but levels in the HDF subgroup were higher (Figure 1b). 2. Pre-HD fasting BDG levels were similar in high flux-HD and HDF groups (57(42) vs 64(45)pg/ml; p = 0.057). Weight, hs-CRP, and presence of diabetes and liver disease were independent predictors of pre-HD BDG. BDG levels (high flux-HD group) were similar pre- and post-HD (57(42) vs 53(53); p=0.132). In contrast, BDG levels (HDF group) were higher post-HD (64(45) vs 76.6(51)pg/ml; p<0.001).

Conclusions: BDG levels were higher at baseline in ESKD compared to controls. Following an oral BDG load, there was a significant increase in BDG levels from baseline in the HDF subgroup but not high-flux HD. Higher BDG levels were also observed post-HD in patients receiving HDF in the absence of an oral BDG load. This finding is unexpected and warrants further investigation as HDF is theoretically associated with greater haemodynamic stability and should protect against gut permeability and systemic translocation of BDG-rich material.

Funding: Other NIH Support - National Institute for Health and Care Research (NIHR) Research Capability Funding and funding from East and North Hertfordshire Hospitals Charity, Commercial Support - Associates of Cape Cod provided assays for BDG measurements gratis

TH-PO239

Comparison of Protein-Bound and Large Molecular-Weight Uremic Toxin Removals with Novel Super High-Flux Dialyzer between Hemodialysis (HD) and High-Volume Online Hemodiafiltration Modalities: A Cross-Over Randomized Controlled Study

Rossanun Shoosanglertwijit, Khajohn Tiranathanagul. *King Chulalongkorn Memorial Hospital Department of Internal Medicine, Bangkok, Thailand.*

Background: Protein-bound uremic toxins (PUBT) and large molecular weight uremic toxins (LMWT) are poorly removed by the standard hemodialysis (HD) using high-flux dialyzer (HF) and associated with long-term morbidity and mortality in end-stage kidney disease (ESKD) patients undergoing chronic HD. Two removal enhancing approaches including modality upgrade from HD to higher cost high-volume online hemodiafiltration (HDF) with HF or dialyzer upgrade from HF to novel super high-flux dialyzers (SHF) (such as ELISIO-21HX) with standard HD have been innovated and provide comparably improving both PUBT and LMWT removals. Whether the combined approaches, HDF using SHF, could yield additional benefit when compared with single approach, HD using SHF, were explored in the present crossover randomized controlled study.

Methods: Fourteen ESKD patients treated with HDF using HF were included. After a run-in period, the patients were randomly allocated to receive either 8-week of HDF using SHF, ELISIO-21HX, or HD using SHF as the control treatment. After a wash-out period of HDF using HF, they were crossovered to receive the other treatment for 8 weeks. The removal capacities in-term of plasma reduction ratio (RR) of PBUT (free and total indoxyl sulfate, IS) and LMWT (β2-microglobulin, kappa and lambda free light chains) as well as the adverse albumin loss in dialysate were assessed. The 8-week longitudinal changes of these plasma parameters were also compared.

Results: There was no significant reduction ratio between free and total indoxyl sulfate between SHF-HD and SHF-HDF at 8 weeks period. The reduction ratio of kappa and lambda free light chain were higher in SHF-HDF and kappa was more eliminated. There were no significant reduction ratio between β2-microglobulin and urea. There was no significant dialysate albumin loss (0.7 vs 1.2 g/session, P-value 0.14) between both groups and did not affect the serum albumin at 8th weeks.

Conclusions: SHF-HD and SHF-HDF provided comparable PBUTs removal but higher large middle molecule uremic toxin reduction. SHF-HD might be the alternative treatment for PBUTs and LMWTs removals. SHF-HDF may be an option for further LMWT (i.e. kappa and lambda FLC) removal. Longer intervention and follow up period should be further conducted.

A Randomized Trial of Middle Molecule Clearance in Patients on Chronic Hemodialysis: Results from the ROCKeT Study

Li Zuo,[1] Liangying Gan,[1] Leyi Gu,[3] Yongchun Ge,[4] Hong L. Lin,[12] Yiwen Li,[9] Fengling Chen,[7] Wenge Li,[6] Bi hu Gao,[5] Feng Ding,[8] Xinzhou Zhang,[10] Zhenwei Shi,[11] Jiayao Ji,[2] Qiang Yao,[2] Brad Keller,[2] Surupa Sarkar.[2] *[1]Peking University People's Hospital, Beijing, China; [2]Baxter Healthcare Corporation, Round Lake, IL; [3]Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital, Shanghai, China; [4]General Hospital of Eastern Theatre Command, Nanjing, China; [5]Affiliated Zhongshan Hospital of Dalian University, Dalian, China; [6]China-Japan Friendship Hospital, Beijing, China; [7]First Affiliated Hospital of Soochow University, Suzhou, China; [8]Shanghai Jiao Tong University School of Medicine Affiliated Ninth People's Hospital, Shanghai, China; [9]Zhejiang Provincial People's Hospital, Hangzhou, China; [10]Shenzhen People's Hospital, Shenzhen, China; [11]Beijng Huaxin Hospital First Hospital of Tsinghua University, Beijing, China; [12]First Affiliated Hospital of Dalian Medical University, Dalian, China.*

Background: This study aimed to establish noninferiority of λ FLC and β2M molecular clearance with HDx therapy using Theranova 400 compared to post-dilution online HDF therapy using FX800 (control arm) in Chinese patients with kidney failure.

Methods: The clearance of λ FLC, β2M, urea, α1-MG, YKL-40, CFD, myoglobin, and κ FLC was measured using the reduction ratio (RR) of the molecule after treatment at the mid-week dialysis session. Kt/V_{urea} was assessed to establish dialysis adequacy. Two-sample t-tests were performed to compare the 95% CI of the difference in RRs for λ FLC and β2M in the HDx arm against predefined noninferiority margins of -3.783 and -7.848, respectively (10% of assumed mean RR). Any noninferior RRs were then tested for superiority using hierarchical testing. The safety profile of the Theranova dialyzer was also assessed.

Results: 274 adult patients receiving thrice-weekly dialysis were randomized (N=138 on HDx; N=136 on HDF). No differences were observed between the arms in terms of demographics, baseline characteristics and treatment parameters. The average utilized replacement volume in the HDF arm was 17±2.4L. The RR of λ FLC in the HDx arm was both noninferior and superior to the HDF arm; ΔRR=17.0% (14.8%,19.2%). The RR of β2M in the HDx arm was noninferior to the HDF arm; ΔRR=-1.2% (-2.5%,0.2%).

Overall, Kt/V_{urea} and urea RRs were similar between the arms (p=0.37 and p=0.45, respectively). The HDx arm had significantly higher clearance of α1-MG, YKL-40, CFD, myoglobin, and κ FLC than the HDF arm. No difference was observed in the incidence rate of complications between the arms (p=0.15).

Conclusions: Our study demonstrates the effectiveness of HDx theraphy in clearing multiple middle molecules when compared to HDF therapy, with no observed differences in the overall safety or efficacy of dialysis.

TH-PO241

Transitioning from Frequent High-Flux Hemodialysis to Frequent Online Hemodiafiltration: Successive Paradigm Shifts towards Optimal Dialysis Therapy

Istenio Pascoal, Adolfo Simon, Vilber Bello, Kelia Xavier, Andre Fernandes, Juliane Lauar. *Centro Brasiliense de Nefrologia e Dialise, Brasilia, Brazil.*

Background: Frequent highflux hemodialysis (fHD) has improved outcomes compared to conventional thrice-weekly schedule (cHD). Likewise, thrice-weekly high-volume online hemodiafiltration has shown benefits compared to cHD. We previously established the feasibility, safety, and potential advantages of fHDF over fHD and transitioned our long-term in-center dialysis program from short daily highflux hemodialysis (SDHD) to short daily high-volume online hemodiafiltration (SDHDF). This study aims to delineate the transition process of implementing fHDF as the standard therapy in our in-center dialysis program.

Methods: We documented patient demographics including number, age, dialysis vintage, presence of diabetes, vascular access type and kidney transplantation (KTx) waitlist. The fHDF parameters encompassed 6 x 2-hour sessions/week, 350 ml/min blood flow and 500 ml/min dialysate flow. Equipment included the Aquaboss Osmosis System, BBraun Diálog+HDF and IQ-HDF Machines with Xevonta Hi23 single-use dialyzer. Anticoagulation adjustments, HDF modalities and substitution volume goals were assessed. We also analyzed this transtion's cost implications for providers and payors.

Results: In November 2023, seventy patients were switched from SDHD to SDHDF, 40Males/30Females, age 63.2±15.2 years (29-91), dialysis vintage 53.5±55.1 months (3-227), 38% diabetes, 53% AVF, 38% PermCath, 9% Graft, 44% waitlisted for KTx, 90% post-dilution HDF and 10% pre-dilution HDF due to limited blood flow rate, substitution volume aimed for post-dilution HDF: 12.5 L/2h-session (75 L/week) or pre-dilution HDF: 25 L/2h-session (150 L/week). There was a 23% mean increase in heparin doses. Cost of consumables increased about 21%, while mean reimbursement by payors increased 35.3%. In Brazil, each new HDF machine costs 4,000.00-7,500.00 US dollars more than a new HD machine.

Conclusions: The transition from in-center fHD to fHDF represents a second paradigm shift in our dialysis program (cHD to fHD was the first, in 2006). Whilst requiring comprehensive evaluation of patient demographics, treatment parameters, equipment considerations and cost implications, this successfully managed modality switch yields potential clinical benefits towards optimizing modern dialysis care.

TH-PO242

Increased Dialyzer Membrane Hydrophilicity Improves Hemocompatibility and Performance: A Randomized Investigation

Petra Ronova,[1] Maria Krizsan,[2] Bettina Griesshaber,[5] Ansgar Erlenkoetter,[7] Adam M. Zawada,[7] Robert Nitschel,[7] Bertram Ottillinger,[6] Bingbin Zhao,[3] Natalia Korolev,[5] Jennifer Braun,[5] John W. Larkin,[4] Manuela Stauss-Grabo.[5] *[1]Fresenius Nephrocare Praha 9, Praha, Czechia; [2]Péterfy II. Dialízis Központ, Budapest, Hungary; [3]Fresenius Medical Care, Beijing, China; [4]Fresenius Medical Care, Waltham, MA; [5]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [6]Ottillinger Life Sciences, Brunnthal (Munich), Germany; [7]Fresenius Medical Care Deutschland GmbH, Sankt Wendel, Germany.*

Background: Dialyzer performance and hemocompatibility can get compromised during treatment due to adsorption of plasma proteins to the membrane. Increased membrane hydrophilicity reduces membrane fouling and was implemented in the novel FX CorAL dialyzer. In a randomized trial we investigated the performance and hemocompatibility profiles of the FX CorAL dialyzer vs. two comparators during post-dilution online hemodiafiltration (HDF).

Methods: This prospective, multicentric, crossover study with 4-week randomized treatment sequences compared the FX CorAL 600 vs. FX CorDiax 600 (both Fresenius Medical Care Germany) and xevonta Hi 15 (B. Braun). Primary outcome was β2-microglobulin removal rate (β2-m RR). Secondary endpoints were RR and clearance of small and middle molecules, and intra-/interdialytic profiles of hemocompatibility markers. Further endpoints were patient reported outcomes (PROs) and clinical safety.

Results: 82 subjects (76 Intention-to-treat group) were enrolled. FX CorAL showed the highest β2-m RR (76.28%), followed by FX CorDiax (75.69%) and xevonta (74.48%), which was non-inferior to both comparators ($p<0.0001$ each) and superior to xevonta ($p<0.0001$). Secondary endpoints related to middle molecules affirmed these results; small molecule performance was comparable between dialyzers. For intradialytic hemocompatibility, the typical drop in leucocytes, monocyte, and neutrophil during dialysis as well as the rise of complement, cell and platelet activation markers were lower during treatment with FX CorAL vs comparators (Figure 1). There were no differences in interdialytic hemocompatibility, PROs, or clinical safety.

Conclusions: During HDF, the novel FX CorAL with increased membrane hydrophilicity showed high performance and a favorable hemocompatibility profile as compared to other commonly used dialyzers. Further long-term investigations are warranted to examine if the benefits of FX CorAL translate into improved cardiovascular and mortality endpoints.

Funding: Commercial Support - Fresenius Medical Care Deutschland GmbH

TH-PO243

Middle-Molecular Weight Toxin Removal: Asymmetric Cellulose Triacetate vs. Helicoidal Polysulfone during Online Hemodiafiltration (CHORALS Study)

Marco Ferrarini,[1] Niccolò Morisi,[1] Silvia Giovanella,[1] Giulia Ligabue,[1] Gaetano Alfano,[1] Dario Troise,[2] Giovanni Stallone,[2] Gabriele Donati.[1] *[1]Universita degli Studi di Modena e Reggio Emilia, Modena, Italy; [2]Universita degli Studi di Foggia, Foggia, Italy.*

Background: Middle-molecular weight toxins (MMT) are involved in cardiovascular and neurological morbidity and in a high risk of mortality of HD patients. In this study we evaluate the efficiency of Asymmetric Cellulose Triacetate (ATA) vs Helicoidal Polysulfone (PS) in MMT removal during online hemodiafiltration (OLHDF).

Methods: Twenty anuric HD patients who needed OLHDF were selected. Ten patients underwent PS OLHDF as gold standard treatment, 10 patients underwent ATA OLHDF when a history of hypersensitivity was ascertained. B2 Microglobulin (B2M) and K light chain (Lk) were assayed hourly on blood and on spent dialysate. Total clearance (Ktot) and Sieving coefficient (S) were firstly evaluated separately through time for each filter with ANOVA. To compare Ktot and S between filters, we performed t-test on data from each hour separately and 2-way ANOVA on the whole series.

Results: No significant efficiency variation over time was observed in the ATA filter. The PS filter showed significant variation of B2M Ktot and S due to rising efficiency at the first hour (Ktot p=0.001, S p=0.001) but not in Lk. Considering the whole series, Ktot and S of B2M were significantly higher for PS ($p<0.0001$). Comparing filters, PS showed significantly higher Ktot and S after 1 hour of treatment for both B2M (Ktot p=0.001, S p=0.001) and Lk (Ktot p=0.022, S p=0.02) and after 2 hours of treatment for B2M only

(Ktot p=0.015, S p=0.008). No significant Ktot and S variation was observed between filters at other time points (Figure 1).

Conclusions: Globally, removal performance of MMT is similar for both filters tested. Given the features of ATA membrane, which is predicted to be more biocompatible for hypersensitivity prone patients, slightly lower performances are observed in the first half of treatment. As a consequence, the choice of ATA membrane should be considered suitable for MMT removal in patients with hypersensitivity.

Use of the Seraph 100 Dialysis Filter in a Patient with Toxic Shock Syndrome from Streptococcus pyogenes Bacteremia

Hernan Rincon-Choles, Sunny R. Parmar, Sydney Moseley. *Cleveland Clinic, Cleveland, OH.*

Introduction: The Seraph 100 Microbind Affinity Blood Filter (Seraph 100) is a hemoperfusion dialysis filter which employs pathogen adsorption therapy using heparin-coated polyethylene beads. Data exists supporting its effectiveness among COVID-19 patients where the filter was allowed under emergency use authorization by the FDA. It has been shown to bind various pathogens (with affinity for streptococcus pyogenes (GAS)), endotoxins and cytokines, allowing their removal from the bloodstream.

Case Description: A 26 year-old female who gave birth four days prior was admitted to the intensive care unit with high fevers and septic shock requiring 3 vasopressors causing severe lactic acidosis (to 11.6 mmol/L). For GAS bacteremia causing toxic shock syndrome (TSS) she received meropenem, clindamycin, and vancomycin. She suffered necrosis of her nose, fingers and toes as well as disseminated intravascular coagulation (DIC). She also suffered anuric renal failure requiring continuous renal replacement therapy (CRRT). Five days into hospitalization, despite emergent hysterectomy for source control, intravenous hydroxycobalamin, and methylene blue, she still required 3 vasopressors for persistent shock. The Seraph 100 filter was obtained and was installed in series with an M100 filter in a PrismaFlex dialysis machine. The day after installation, her shock completely resolved, then enabling fluid removal with CRRT and initiation of feeding. With shock resolved, her necrotic lesions showed some improvement and did not auto-amputate. Additionally, her DIC improved which enabled her to be treated with heparin for thrombi in distal extremities. Each night, clotting of the Seraph 100 filter would require its replacement the following day; in total 8 filters were used.

Discussion: This case demonstrates use of the Seraph 100 filter in a patient suffering from persistent GAS-related TSS after source control. By improving rapidly she avoided further complications of shock, including worsening of necrosis which may be attributed to vasopressor induced acute limb ischemia, as well as improved ultrafiltration enabling weaning off mechanical ventilation. No clear adverse events were attributed to use of this filter. Given the high mortality rate associated with TSS, future studies should evaluate for this filter's efficacy in improving outcomes for such patients.

TH-PO245

Changes in Coronary Artery Calcification Score in ESKD: Comparison of Hemodialysis and Online Hemodiafiltration

Toshiki Doi,[1,2] Kenichi Morii,[1,2] Aiko Okubo,[1] Sonoo Mizuiri,[1] Yoshiko Nishizawa,[1] Takao Masaki.[2] *[1]Iryo Hojin Ichiyokai Harada Byoin, Hiroshima, Japan; [2]Hiroshima Daigaku Byoin, Hiroshima, Japan.*

Background: It has been shown that high-dose hemodiafiltration (OHDF) reduces the risk of all-cause mortality compared to conventional high-flux hemodialysis (HD) (N Engl J Med. 389: 700, 2023). The primary reason for this reduction was a decrease in infections. Still, there are also many reports that OHDF reduces the risk of cardiovascular death, a significant cause of mortality in dialysis patients, compared to HD (Nephrol Dial Transplant. 31: 978, 2016) (Cochrane Database Syst Rev. 2015: CD006258, 2015). The coronary artery calcification score (CACS), measured by multi-slice CT, has significant evidence linking it to cardiovascular events, and its usefulness has been reported in dialysis patients (Clin Exp Nephrol. 8: 54, 2004). In this study, we compared changes in CACS between standard HD treatment and OHDF treatment in maintenance dialysis patients.

Methods: A retrospective cohort study was conducted on hemodialysis patients who underwent CACS evaluation using CT at our institution from January 2018 to February 2021. Patients who did not undergo re-evaluation after one year and those with a logarithmically transformed initial Agatston CACS of less than 100 were excluded. The patients were classified into the HD treatment group and the OHDF treatment group. Propensity score matching was performed based on age, sex, dialysis vintage, presence of diabetes, Ca, P, Mg, TSAT levels, and initial Agatston CACS. The aim was to examine whether there was a difference in the change rate of the Agatston CACS after one year between the HD and OHDF groups. The data were presented as medians and interquartile ranges, and JMP16 was used for analysis. Pearson's chi-square and Mann-Whitney U tests were used for statistical testing.

Results: Of the 560 patients who underwent CACS evaluation during the study period, 263 were included in the study. Through propensity score matching, 49 patients were selected for each group. No significant differences were observed in the baseline characteristics between the groups. The median increase rate of the Agatston CACS after one year was 15.8% (interquartile range 3.2 - 37.2) in the HD group and 6.6% (0.6 - 17.2) in the OHDF group (p = 0.02).

Conclusions: OHDF may suppress coronary artery calcification compared to HD in patients with end-stage renal disease.

TH-PO246

Hemoperfusion Is Associated with Reduced Mortality in Outpatient Maintenance Hemodialysis Patients with COVID-19

Wenjun Lin. *Department of Nephrology, Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China.*

Background: High mortality rates have been observed in patients with COVID-19 undergoing maintenance hemodialysis, potentially attributable to exacerbated inflammatory responses. Hemoperfusion, a therapeutic technique based on adsorption for removing inflammatory mediators, presents a promising therapeutic approach. However, its efficacy in improving outcomes for this patient population remains to be established.

Methods: This was a single-center retrospective cohort study conducted from December 7, 2022, to May 24, 2023, following the cancellation of the 'Dynamic Zero-COVID' policy during the Omicron variant surge. Patients with COVID-19 were stratified based on their hemoperfusion treatment status. We investigated all-cause mortality as the primary outcome, using adjusted Cox regression analysis. The risk of hospitalization, our secondary outcome, was examined through logistic regression models.

Results: Among the 224 patients who met the eligibility criteria, 118 (52.7%) underwent hemoperfusion treatment. The cohort's mean age was 62.8 ± 13.1 years, predominantly male (71.0%), with 89.3% lacking prior immunity to SARS-CoV-2. Over a 120-day follow-up, 25 patients succumbed, with mortality rates of 18.9% (20 patients) in the control group compared to 4.2% (5 patients) in the hemoperfusion group (p=0.001). Hemoperfusion was significantly associated with a reduced risk of all-cause mortality (HR, 0.234; 95% CI, 0.079 to 0.696; p=0.012) and hospitalization (OR, 0.423; 95% CI, 0.196 to 0.917; p=0.029), compared to controls. Additionally, the hemoperfusion group exhibited significantly lower mean changes in CRP, D-dimer, and serum ferritin levels than the control group within one month after COVID-19.

Conclusions: Hemoperfusion treatment in patients with COVID-19 on maintenance hemodialysis was linked to a decreased risk of all-cause mortality and a reduced in early inflammatory markers. These findings suggest that hemoperfusion may be a beneficial therapeutic strategy for COVID-19 management in the hemodialysis population, meriting further exploration.

TH-PO247

Evaluation of the Performance of the HA130 Hemoperfusion Cartridge in Patients Treated with Postdilution Hemodiafiltration (HDF): A Comparative Study with HDF Online Alone

Matteo Floris,[1] Alice Atzeni,[1] Claudia Puddu,[1] Giulia Spanu,[1] Cristina Pani,[1] Francesco Trevisani,[2] Andrea Angioi,[1] Nicola Lepori,[1] Gianfranca Cabiddu,[1] Antonello Pani.[1] *[1]Azienda Ospedaliera Brotzu, Cagliari, Italy; [2]IRCCS Ospedale San Raffaele, Milano, Italy.*

Background: Adsorption is a new frontier in extracorporeal purification for continuous and intermittent RRT. Evidence mainly comes from its use with bicarbonate dialysis. As OL-HDF is the new standard, we explored its benefits in HDF. This pilot study assesses the efficacy, safety, and tolerability of the HA130 cartridge with HDF-POST, compared to HDF alone.

Methods: Ten ESRD patients with AVF were treated with hemoperfusion using the HA-130 cartridge in series with POST-HDF with a TCA membrane (Solacea™ 1.7 and 1.9), reaching a 23 L x 1.73 m^2 exchange volume. A control group of ten similar patients received POST-HDF with the Solacea filter alone. Removal rates (RR) for various markers were evaluated and corrected for hemoconcentration. Session tolerability was assessed by monitoring intradialytic symptoms and circuit coagulation.

Results: For the HA130 + Solacea group, the exchanged infusion volumes were 22.9 ± 1L. The treatment was generally well tolerated without significant intradialytic symptoms or circuit coagulation. For the Solacea alone group, the exchanged infusion volumes were 23 ± 1L. The treatment was also well tolerated without significant intradialytic symptoms or circuit coagulation. The RR data for both groups are reported in Table 2 and Figure 1.

Conclusions: The combined HDF-POST + hemoperfusion treatment demonstrated superior depurative efficacy with high RRs for medium and high molecular weight molecules compared to the Solacea filter alone. The high tolerability and absence of significant complications during HDF-POST sessions highlight the potential of this technological combination in high-efficiency RRT settings.

Table 1. Treatment characteristics

Parameter	HA130 + Solacea	Solacea Alone	p-value

TH-PO248

Hemodialysis Coupled with Hemadsorption: Benefits on Uremic Toxins Retention and Oxidative Stress

Matteo Marcello,[1] Grazia Maria Virzì,[1] Vincenzo Cantaluppi,[2] Alessandra Brendolan,[1] Claudio Ronco.[1] *[1]Ospedale San Bortolo di Vicenza, Vicenza, Italy; [2]Universita degli Studi del Piemonte Orientale Amedeo Avogadro Scuola di Medicina, Novara, Italy.*

Background: Retention of middle-molecules and Protein Bound Uraemic Toxins (PBUT) in dialysis patients increases morbidity and mortality. Current dialysis techniques do not adequately clear these toxins. Furthermore, in dialysis patients, there's an increased inflammation and oxidative stress only partially attenuated by biocompatibility of newly developed membranes. This pathologic inflammatory response is associated to a particular form of programmed cellular death involving red blood cells, called Eryptosis. This study aimed to assess the safety of dialysis coupled with hemadsorption (HA+HD) in terms of biocompatibility and efficacy in terms of removal of middle-molecules and PBUTs.

Methods: This analysis of a multicentre observational study evaluated 4 dialysis sessions focusing on 7 chronic dialysis patients of our dialysis center. Patients were treated with HA+HD with HA130 cartridge (Jafron) in the early-week dialysis session and then returned to their usual prescription. Blood samples were taken before and after the dialysis session to measure Eryptosis as a marker of biocompatibility and a few uremic toxins to assess the efficacy of the treatment by using Removal Ratio.

Results: This study was carried out on 7 patients (4 women) with a mean age of 65.7 ± 11.5 years and a median dialysis vintage of 33 months (IQR 28-51). All patients had AVF with Qb of 330 ml/min. Dialysis lenght was 210 minutes. We didn't find any differences between Eryptosis values measured before and after dialysis (Table 1), and between different timepoints. We found significant reduction of PTH (pre: 391.5 ng/L, IQR 206.5-602.8 vs post: 162.0 ng/L, IQR 95.0-363.3; p=0.005) and β2-microglobulin (pre: 23.10 mg/L, IQR 22.1-24.1 vs post: 6.72 mg/L, IQR 6.2-8.3;p>0.005) throughout the HA+HD session.

Conclusions: We found that the addition of Hemadsorption allows a great removal of middle molecular-weight uremic toxins without compromising biocompatibility and thus represents a better treatment option in patients with high retention of these toxins.

Eryptosis values pre and post dialysis session

	pre	post	p
session 1	0.40, IQR 0.3-0.55	0.25, IQR 0.2-0.38	0.31
session 2	0.20, IQR 0.2-0.35	0.30, IQR 0.2-0.4	0.37
session 3	0.20, IQR 0.2-0.45	0.40, IQR 0.25-0.55	
session 4	0.30, IQR 0.15-2.9	0.20, IQR 0.15-0.35

Molecular Adsorbent Recirculating System (MARS) in Pediatric Patients

Kenneth M. Delgado, Kelli A. Krallman, Stuart Goldstein, Francisco X. Flores. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: The Molecular Adsorbent Recirculating System (MARS®) uses an albumin enriched dialysis solution to remove protein-bound molecules that are not removed by conventional renal replacement therapy. Its use was approved in the United States for management of drug overdose and intoxication. Other proposed indications include acute liver failure and Data regarding the efficacy of MARS® in pediatric patients remain scarce.

Methods: Retrospective analysis of patients who received MARS® therapy at Cincinnati Children's Hospital Medical Center between January 1st, 2018 and November 30th, 2020. Collected data included age, sex, laboratory data, medical history, vascular catheter size, specifics of therapy, complications, and outcomes. Data existing in the electronic medical record were transcribed by investigators into a secure database.

Results: 17/25 patients demonstrated at least one sign of clinical improvement. 13/22 patients experienced improvement in encephalopathy. 6/20 patients demonstrated hepatic recovery. 6/18 patients experienced renal recovery. 4/21 patients underwent liver transplant. 16/25 patients survived until ICU discharge. Youngest patient to receive MARS® was 29 days old. Lowest weight was 2.1 kilograms.

Conclusions: We provide data on pediatric patients receiving MARS® at a high-volume tertiary care center. To our knowledge, this is the largest study on pediatric MARS® to date. We plan to expand this analysis to include data from 2014 – 2018 and 2020 – 2024.

TH-PO250

Innovative Microfluidic Dialyzer: Redefining Care for Patients on Dialysis

Daniel R. Greene, Saeed Moghaddam. *University of Florida, Gainesville, FL.*

Background: Development of a miniature dialyzer can benefit patients with kidney failure, especially infants and patients that perform in-home low-flow-rate dialysis. Despite a few decades of research, an alternative to the existing bulky dialyzers has remained elusive. Here, a breakthrough microfluidic dialyzer with an order of magnitude smaller size and blood compartment volume compared to the existing dialyzers is presented.

Methods: A miniature microfluidic dialyzer (MD) has been developed and its hydrodynamics and sieving characteristics have been analyzed through comprehensive numerical and experimental studies. An iterative design process has been pursued to minimize the dialyzer pressure drop well below that of the existing dialyzers such that it could also be operated with the arterial blood pressure. Measurements at different flow rates and urea removal under static and variable hemodynamic conditions have been performed, aimed at characterizing the device performance and control measures for reliable dialysis.

Results: The new dialyzer has a blood compartment volume of 16.3 mL substantially smaller than ~100 mL blood volume of the current dialyzers. It operates on a reduced blood flow rate of 100 mL/min compared to the typical 300-500 mL/min practiced in conventional dialyzers as planned for eventually targeted patient groups. A dialyzer with a pressure drop of 6.2 ± 1.4 mmHg has been developed for a blood flow rate of 100 ml/min. This pressure drop is an order of magnitude less than that of a conventional dialyzer with a pressure drop of 31.1 ± 3.4 mmHg, tested under identical conditions. The urea sieving coefficient of the developed microfluidic dialyzer is 0.74, only marginally lower than that of a conventional dialyzer of 0.83 measured under identical conditions. The accompanying numerical models for pressure drop and urea removal predicted the outcomes of the tests.

Conclusions: The innovative microfluidic dialyzer represents a significant advancement in dialysis technology, offering a smaller size, lower pressure drop, and comparable urea removal efficiency compared to conventional dialyzers. This breakthrough has the potential to greatly benefit patients with kidney failure, particularly infants and those requiring in-home low-flow-rate dialysis.

TH-PO251

Intradialytic Microvascular Tissue Perfusion Is Affected by Dialyzer Membrane Characteristics

Barry Janssen,[1,2] Yanmin Zhang,[2,1] Lisa Hur,[1,2] Alireza Akbari,[1,2] Christopher W. McIntyre.[1,2] *[1]Lawson Health Research Institute, London, ON, Canada; [2]Western University, London, ON, Canada.*

Background: During hemodialysis (HD), microvascular perfusion in tissues and organs is often compromised. The role of dialyzer clearance characteristics and general biocompatibility in this process is unknown. This study compared the effects of HD using either conventional high flux polysulfone (PSF) or newer mid-cut-off (MCO) dialyzers (characterized by an extended clearance spectrum into the middle molecule range) on microvascular perfusion in an established rat model of HD. We hypothesize that using different dialyzer membranes will result in different microvascular responses, affecting the quality of tissue blood flow.

Methods: HD using in-house-designed mini-dialyzers was performed on male Wistar Kyoto rats, and microvascular perfusion in skeletal muscle was observed using intravital video microscopy. A carotid catheter was used for hemodynamic monitoring, while indwelling catheters in the left femoral artery and left femoral vein were connected to the mini-dialyzer. Blood samples were taken for biochemical analysis, a C5b-9 ELISA assay and hematocrit determination to ensure the procedure was euvolemic.

Results: HD using PSF dialyzers significantly reduced microvascular muscle perfusion, unlike the MCO dialyzers (Fig 1). Blood pressure reduction was similar between the two groups, with a better conservation of the cardiac response in the MCO group. There were no differences in small solute clearance or circulating electrolyte levels. Analysis of [C5b-9] plasma levels shows significantly higher levels after a two-hour HD procedure with PSF dialyzers.

Conclusions: Our analysis indicates that the separate effects of the different dialyzers on microvascular perfusion may be related to differences in complement activation. The exact mechanisms underlying these differences warrant further study. This small animal model allows us to preclinically evaluate membrane materials and dialyzer designs, facilitating the design of subsequent human studies.

A Novel Anticoagulation-Free Hemodialysis Paradigm: A Second-Generation Hemodialysis Filter Rotator Prototype Using the NxStage Machine Is Ready for Clinical Trials

Macaulay A. Onuigbo. *The University of Vermont Medical Center, Burlington, VT.*

Background: There is a critically unmet need for a new method of anticoagulation-free hemodialysis (AFHD). Current alternatives are often ineffective, expensive, technically challenging and/or with potential serious adverse effects. In the 2021 Mayo Clinic Proceedings Innovations Quality Outcomes journal, we described the 'Locke-Onuigbo maneuver', a new original hemodialysis filter rotational approach to achieve AFHD using the NxStage HD machine. We completed the design and development of an advanced second-generation HD filter rotator (HDFR) prototype in 2023.

Methods: This was a Capstone Project from "bedside to manufacture" translational research utilizing the 'Locke-Onuigbo maneuver'.

Results: In 2023, we completed the design and development of an advanced second-generation HDFR prototype that is now ready for clinical testing (Figures). These Youtube links show some of the demonstrations: https://www.youtube.com/watch?v=nCDraOlZZF8 and https://youtube.com/shorts/ncR3VieJkEY?feature=share.

Conclusions: There is a long overdue imperative for a robust, safe, and sustainable modality for AFHD. Our second-generation HDFR prototype with its enhanced new features of increased resilience, longer running times, enhanced angle and speed consistency, improved ergonomics, solid state sensors for temperature and angle fidelity verifications, and an accompanying user-friendly versatile smartphone App with Bluetooth Connectivity to facilitate ease and convenience of monitoring and control of the HDFR, is the solution for this long overdue imperative for anticoagulation-free hemodialysis. It is ready for clinical testing.

New Kirpa Kit: A Manual Dialysis Device for Low- and Middle-Income Countries in Catastrophic Environments

Lilia M. Rizo Topete, Paola Borbolla-Flores, Mara C. Olivo Gutierrez, Juan P. Gomez Villarreal, Ricardo A. Garza Treviño, Sofia Lopez-Guzman. *Hospital Universitario Dr Jose Eleuterio Gonzalez, Monterrey, Mexico*.

Background: Alarming data about the increased incidence of acute kidney injury (AKI) in low- and middle-income countries around the globe is a trigger to research. While much is being done to prevent AKI, we must also investigate easy and economic options for renal replacement therapy (RRT) in resource-limited environments. After *in vitro* experiments showed promising results, we decided to join forces with Dialysis Without Borders to find a way to help these vulnerable populations.

Methods: Last year we witnessed in our hospital increased incidence of AKI from heatwave. We commonly treat patients who present late to care because they live in low-resource, rural settings or even un urban Mexico. To improve treatment options, we look forward to using a manual dialysis equipment for acute ultrafiltration, and if necessary, hemodialysis to treat life threatening conditions, as a temporary treatment or bridge to the treatment needed.

Results: We introduce the KIRPA Kit, a manual dialysis device without the need for electricity, at very low cost. We can draw out blood (60 ml) from the patient via the bypass line into Syringe 1. Then the blood will be pushed out of the syringe through the filter and be returned to the patient. While the blood passes through the filter, the dialysate (for purposes of HD) will come from the syringe 3 through the filter. While for the ultrafiltration, this will get to the effluent bag through the syringe 2. There is a syringe that acts as a deaeration chamber located proximal to the patient that may serve to pull off any air bubbles visualized in the circuit (syringe 4).

Conclusions: It is quite important the learning and training before the use of KIRPA in humans. Although it is simple and quickly. The manual dialysis may serve as a future tool for patients without timely access to necessary RRT. It is a new and innovative therapy for clinical scenarios where deficiencies, sometimes even of light, wreak havoc on patients with fluid overload or require RRT.

TH-PO254

Pseudo-Blood Leak Alarm and Pseudo-Lactic Acidosis: A Hydroxocobalamin-Ethylene Glycol Combination

Nathaniel Leonardi, Jonathan Hall, David A. Mcmillan, Ryan Mullane. *University of Nebraska Medical Center, Omaha, NE*.

Introduction: Blood leak alarms exist on intermittent hemodialysis machines to prevent contaminated blood from returning to the patient when errors occur. While the risk of this occurring is low, hydroxocobalamin has been linked with causing pseudo-blood leak alarms. Ethylene glycol intoxication, while deadly, has been associated with pseudo-lactic acidosis on whole blood analysis. We present a case of a pseudo-blood leak and pseudo-lactic acidosis from hydroxocobalamin and ethylene glycol.

Case Description: A 23-year-old female presented to the hospital for encephalopathy. Initial labs revealed: potassium of 6.5 mmol/L, chloride of 112 mmol/L, bicarbonate of 5 mmol/L, Blood Urea Nitrogen of 11 mg/dL, and serum creatinine of 1.11 mg/dL. Venous blood gas revealed a pH of 6.8 and pCO2 of 21. The whole blood analysis lactate was 26 mmol/L; however, serum lactate was 2.4 mmol/L. Due to concern for acute cyanide ingestion, the patient was given hydroxocobalamin. Serum osmolality was 326 mOSM/KG, with an osmolar gap of 29. Ethylene Glycol level was 31 mg/dL. Urine microscopy revealed calcium oxalate monohydrate crystals. Given acute intoxication with ethylene glycol, fomepizole was administered, and intermittent hemodialysis was initiated with a Fresenius 2008T hemodialysis machine. A blood leak alarm then occurred. A second Fresenius 2008T was used, however a recurrent blood leak alarm triggered. The patient was transitioned to continuous kidney replacement therapy with NxStage, which functioned appropriately. The patient survived and was weaned from kidney replacement therapy.

Discussion: This case presents a phenomenon of hydroxocobalamin-induced blood leak alarms in certain intermittent hemodialysis machines. Given the increase in use of hydroxocobalamin, as it is deemed a safe treatment for cyanide poisoning, treatment of other toxic ingestions with dialysis may be impacted. This may lead to a delay in appropriate treatment for toxic ingestions as it may disrupt the ability to start clearance of toxins by dialysis. Pseudo-lactic acidosis can occur during ethylene glycol breakdown and excretion, as glycolic acid is created. Glycolic acid is reported as lactic acid on whole blood analysis, causing a pseudo-lactic acidosis, which is not present when measured in serum lactic acid levels.

TH-PO255

Innovation in Dialysis: Air Trap Level Management

Stephanie Wall, Vitas B, Emiline Victoria Hernandez, Nicholas Hyun, Clayton Poppe, Osman Khawar. *Diality, Inc., Irvine, CA.*

Background: Millions with end-stage kidney disease rely on hemodialysis, making the safety of dialysis devices crucial. Air traps in these devices prevent air embolism by removing air bubbles. However, traditional air traps often fail to remove all air, detect microbubbles, or operate autonomously thus increasing the risk for care disruptions and complications.

Methods: The Moda-flx Hemodialysis System™ uses a dual mechanism to manage air infusion. The primary system includes an air trap/drip chamber with a level control system. Additionally, a venous air sensor detects air downstream of the air trap. This design ensures introduced air is vented or detected before reaching the patient. Testing scenarios use Dialin to simulate air bubbles in various operational modes. System performance and fault conditions are evaluated at low, moderate, and high rates of continuous air infusion. See Figure 1.

Results: At low air infusion rates, the system vents excess air, preventing air from entering the venous line. At moderate rates, if the blood level in the air trap doesn't recover quickly, the system triggers an alarm, stops the blood pump, and clamps the venous line. At high rates, rapid blood level drops prevent quick venting, allowing air into the venous line. The system triggers an alarm, stops the blood pump, clamps the venous line, and activates dialysate bypass. Comprehensive testing confirms Moda-flx effectively manages air infusion at all rates.

Conclusions: The Moda-flx Hemodialysis System™ introduces an innovative approach to air trap management, significantly enhancing patient safety in dialysis treatments. The primary air trap level control system maintains optimal blood levels within the air trap and is complemented by a secondary venous air bubble detection system, ensuring comprehensive risk mitigation. This dual mechanism represents advancements in dialysis device design, ensuring reliable protection in all conditions.

TH-PO256

Enhanced Dialysis Efficiency through Reverse Filtration in a Novel Single-Needle Dialysis System: A Pilot Study

Hideki Kawanishi.[1,2] *[1]Tsuchiya Sogo Byoin, Hiroshima, Japan; [2]Akane-medical Corporation Tsuchiya General Hospital, Hiroshima, Japan.*

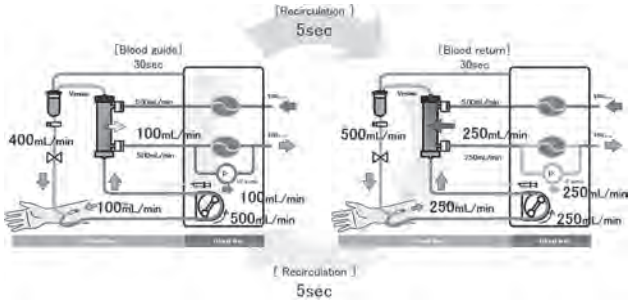
Background: As the population of elderly dialysis patients increases, addressing vascular access issues becomes paramount. The single needle dialysis system (SN) has emerged as a potential solution, yet its efficacy is hampered by inadequate blood flow and recirculation. This study introduces a novel approach utilizing reverse filtration to enhance solute removal efficiency in single needle dialysis (NSN).

Methods: Building upon automated dialysis principles (on-line HDF system, GG-X01, JMS, Co. Japan), the system alternates between ultrafiltration and reverse filtration to optimize treatment outcomes The process of NSN repeats itself: guiding circulating, returning and circulating of blood. Blood is constantly circulated, and during the guiding process, the ultrafiltration pump is rotated to filter the blood until a set amount of guiding is

achieved. Subsequent circulation agitates the blood in the circuit and diffuses substances. In the return phase, the ultrafiltration pump is reversed and returned to the circuit (Figure). A two-armed crossover pilot study of NSN vs SN involving five patients evaluated the system's efficacy compared to conventional methods. Dialysis efficiency was evaluated by measuring the solute of urea, and β2microglobulin (BMG) removal rate (RR), the amount removal volume (RV) into the spend dialysate and Kt/Urea.

Results: Blood flow rate 250mL/min, Dialysate flow rate 500mL/min, 4 hour and dialyzer NVF26H (Tore Co, Japan) were sated. Mean Kt/Vurea 1.26, RR (urea 66.3, BMG 70.2%) and RV(urea 8.4g, BMG 23.5mg) at NSN, an increase over SN was obtained.

Conclusions: Newly development of single needle system used reverse filtration creased dialysis efficiency, especially for middle molecule. However, further study is needed to improve the efficiency of the system.



TH-PO257

Dynamic Patient-Reported Outcome Measures Evaluate Durability of Expanded Hemodialysis on Health-Related Quality of Life (HR-QoL) and Symptom Variability

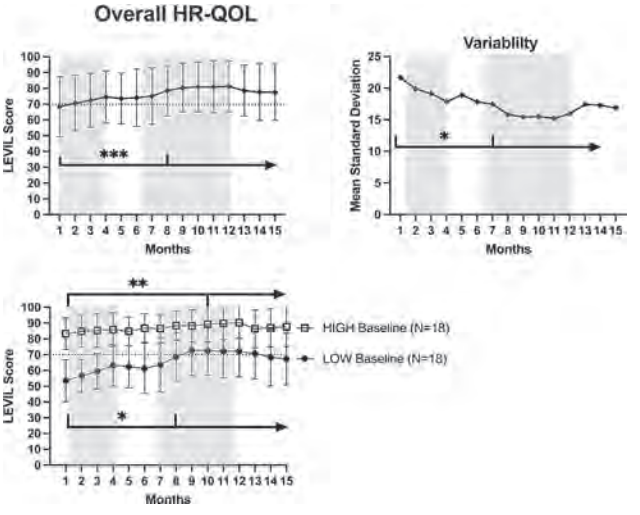
Jarrin D. Penny,[1,2] Christopher W. McIntyre.[1,2] *[1]London Health Sciences Centre, London, ON, Canada; [2]Lawson Health Research Institute, London, ON, Canada.*

Background: Current hemodialysis (HD) utilizing high-flux dialyzers, is handicapped by clearance limitations contributing to poor health-related quality-of-life (HR-QoL) and symptom-burden. Recent international guideline-setting efforts have prioritized identification and management of symptoms and subjective experience. This study aimed to utilize dynamic patient-reported-outcome-measurement tool (PROM), London Evaluation of Illness (LEVIL), to iteratively interrogate patient-experience and benefits of the use of expanded hemodialysis (HDx) on HR-QoL and symptom burden, including durability-of-effects, variability of symptoms and impact of HDx withdrawal.

Methods: Multi-centre interventional study in 47 patients established on conventional thrice weekly centre-based HD in Ontario, Canada. Study was 15-months with five phases 1) one-month observation (high-flux-HD), 2) three-months HDx 3) two-month wash-out (high-flux-HD), 4) six-months HDx, 5) three-month wash-out (high-flux-HD). HR-QoL and symptom-burden were evaluated using LEVIL throughout study.

Results: HDx-therapy improved HR-QoL p 0.0006 (19%) and a variety of symptoms including general wellbeing p 0.005 (23%), energy p 0.004 (33%), sleep-quality p 0.001 (33%), pruritus 0.003 (30%), pain p 0.01 (19%), restless leg syndrome p 0.0006 (15%), mood p 0.02 (12%), appetite p 0.03 (9%), breathlessness p 0.001 (9%), and HD-recovery p 0.004 (26%). Response was more pronounced in those with poorer HR-QoL and higher symptom-burden. Improvements were durable over time with less symptom-variability. Improvements diminished with return to high-flux-HD. Drivers of poor HR-QoL were general-wellbeing, energy, sleep-quality, pruritus, and bodily pain.

Conclusions: Dynamic PROM effectively evaluates HR-QoL and impact of therapy. HDx improved subjective outcomes that are durable and associated with less variation in important symptomx than patients experience with conventional high-flux-HD.



TH-PO258

Clinical Evidence of Frequent Home Hemodialysis Therapy in the Gulf Cooperation Council (GCC) Countries: A Preliminary Study of a Unique Experience

Satarupa Gogoi. *HHD Home Healthcare LLC, Dubai, United Arab Emirates.*

Background: Frequent home hemodialysis is more prevelant and in trend as one of the practical dialysis treatment option. Nurse Assisted Home Hemodialysis (NAHHD) treating active, autonomous, and relatively, healthy dialysis patients and mostly debilitated and frail patients with comorbidities at home and long-term care facilities. Presenting clinical outcomes of Home Hemodialysis treatment, at HHD, service provider in the GCC.

Methods: This is a prospective observational study including 447 patients undergoing frequent home hemodialysis treatment, for more than 3 months with a portable HD machine at home. Patients received adequate frequent dialysis with average 4 sessions/ week (min-3.5; max-5). Estimated the HD adequacy and key performance indicators (KPI) with a target standardised KT/V ≥2.1.

Results: A study group of 477 patients (>3months on HHD). Female- 53% and Male- 47%. The mean average age of the patients, 68.11 ± 15.96 (17 ≤ X ≤ 108 yrs.). The average comorbidities: 6.3 ± 3.45 (Min-2, Max-14). The vascular access: AVF/ AVG- 39.6%, PC- 60.4%. One year average of the biological KPI with HD adequacy are shown in Table 1.

Conclusions: Patients treated with frequent home hemodialysis showed better clinical health outcomes and better quality of life with more energy, better sleep, flexibility in active schedule and feeling more in control. Considering the outcomes of the presented data, frequent home hemodialysis can deliver much beneficial experience.

Longitudinal Assessment of Clinical Outcomes for Transitional Care Units

Derek M. Blankenship, Michael A. Kraus. *Fresenius Medical Care Holdings Inc, Waltham, MA.*

Background: Transitional Care Units (TCUs) are designed to enhance patient support at time of dialysis initiation and provide comprehensive education on renal replacement therapies. We previously published a Propensity Score Matched (PSM) study and reported dialysis patients attending a TCU had higher rates of transplant referral (TR) and preferred modality compared to controls and no difference in mortality and hospitalizations (Blankenship 2022). The purpose of this project was to further understand the potential impact of TCUs throughout the follow-up of the original study. Specifically, TR, modality, mortality, and hospitalizations were assessed for their consistency and timing of results over the 2-year study period.

Methods: The study identified Fresenius Kidney Care (FKC) patients new to dialysis and starting incenter hemodialysis (ICHD) within a TCU between Oct. 1st, 2019 and Sept. 30th, 2020 with a follow-up through Oct. 1st, 2021. This 2-year study period was divided into 8 quarters consisting of the patients and outcome information available at each look. PSM and statistical methods were performed as in the published analysis at each time point.

Results: Modality and TR were consistently significant after 6 months and throughout the remainder of the study. At 6 months, 19% of TCU patients chose a home modality as compared to 4% of controls, and 52% of TCU patients were at least referred for transplantation as compared to 36% of controls. Hospitalization was not statistically significant after correcting for multiple tests. Interestingly, mortality trended positive and was statistically significant after 1 year. At a time corresponding with an initial wave of COVID-19, mortality was no longer statistically significant at 15 months, but trended positive thereafter.

Conclusions: This study found the positive association of TCUs with chosen modality and TR was relatively early at 6 months and consistent thereafter. Although mortality was not statistically significant in the original analysis, the longitudinal analysis determined TCU patients had favorable mortality outcomes after 1 year (HR=0.16) which were negated during the first year of COVID-19 pandemic. This finding warrants further investigation and follow-up. **Funding:** Commercial Support-Fresenius Medical Care

Funding: Commercial Support - Fresenius Medical Care

TH-PO260

Personalized Hemodialysis vs. Standard Therapy: Is a Change Needed?

Miguel Suarez,[1,2] Vanesa Garcia Bernalt,[1] Pedro Dorado.[2] *[1]Servicio Extremeno de Salud, Merida, Spain; [2]Universidad de Extremadura, Badajoz, Spain.*

Background: In our unit, hemodialysis therapy is personalized based on patient characteristics and available techniques: conventional versus incremental, high-flow, extended, supra-HD, in-line, or mid-dilution. Since 1970 we have reduced the objective to an adequate KT/V, forgetting about other uremic toxins until the arrival of the online modality. In the study area there are two concerted centers with standard therapy (90% High-Flow and 10% Postdilutional On-line) and public centers with personalized therapy.

Methods: Retrospective study of 205 (n 84 vs 121) incident patients comparing the application of a personalized hemodialysis protocol vs. standard therapy. Study period 2015-2021 with a minimum observation period of 24 months or until event. Costs obtained from the prices of public tenders and contracted personnel for HD performance. Determine whether personalization is justified compared to standard therapy, compared to the associated clinical variables (pharmaceutical expenditure, hospital admission and mortality).

Results: Number of admissions 84 (72.4%) vs 32 (27.6%) in favor of the personalized therapy group; this represents an average of 10.78 vs 4.97 ($p < 0.005$) days of admission per 365 days of treatment. Risk Estimate 0.082 (0.335-0.666) vs 0.295 (1.374-2.516). According to public tenders, the price per session for Personalized vs Standard is €173.4 vs €129. The indirect cost per year for Personalized vs Standard is: in Pharmacy €2,988 vs €6,308 in Admission €4,478.46 vs €9,713.85 and in Incremental HD - €1,484.06 vs - €0. Costs that fall on the hospital center. Total cost is the sum of direct plus indirect cost: €27,050.4 + €2,988 + €4,478.46 - €1,484.06 vs €20,124 + €6,308 + €9,713.85 - €0 therefore €33,032.26 in personalized therapy vs €36,145.85 standard therapy. In the binary logistic regression, the factors related to the risk of admission (analyzed DM, Cardiopathy, catheter days, Age of Start, Sex and Chalson Index) with statistical significance are personalized therapy, initial vascular access and sex.

Conclusions: Despite the limitations of the study, retrospective and observational, personalizing therapy seems to reduce the morbidity and mortality associated with the technique, achieving greater efficiency of it. It is necessary to design a study to this effect to determine the need to personalize therapies in the SES authorized centers.

TH-PO261

Clinical Features of a Multiethnic Cohort of Patients on Twice-Weekly Incremental Hemodialysis

Lewis Simon,[1,2] Diana Tran,[2,3] Rina Takahashi,[2] Adnan M. Ismail,[2,3] Peter Sohn,[4] Ji Hoon Yoon,[2] Lisa Le,[2] Andrea C. Daza Aguilar,[2] Alejandra Novoa Vargas,[2] Yongen Chang,[3] Lili Tong,[3] Connie Rhee,[2] Kamyar Kalantar-Zadeh.[2,3] *[1]University of California Irvine, Irvine, CA; [2]The Lundquist Institute, Torrance, CA; [3]VA Long Beach Healthcare System, Long Beach, CA; [4]SoCal Kidney Consultants, Garden Grove, CA.*

Background: While current KDOQI guidelines support starting incident ESRD patients with substantial KRU on incremental hemodialysis (HD), many of these patients are started on thrice-weekly HD regardless of KRU. Few studies have examined characteristics of diverse ESRD patients on incremental twice-weekly incident HD patients in the United States. We aimed to characterize a diverse cohort of ESRD patients started on incident HD and explore factors associated with their transition to conventional HD.

Methods: We conducted a case-series of 59 incident incremental HD patients at a local dialysis center, with patients observed from September 2021 to May 2022. Data such as KRU, incremental HD duration, HD schedule and demographics were extracted from EMR. Differences were examined across sex and ethnicity and across two subgroups- those who transitioned from incremental to conventional HD and those who did not.

Results: The cohort was 64% Hispanic and 41% female. Mean age at HD start and transition were 51.9 and 49.6 years, respectively. Thirty-eight (64.4%) patients transitioned to thrice-weekly HD, most often due to volume overload (34%). The most prevalent incremental HD schedules were Monday/Friday (42%) and Tuesday/Saturday (44%). Mean twice-weekly HD duration for transitioners was 47 weeks. Mean baseline and transition KRU were 3.8 and 1.7 mL/min./1.73m^2, respectively. Non-Hispanic Whites had higher transition rates compared to Asians and Hispanics but these differences were not significant ($p=0.12$). Among transitioners, males had longer incremental HD duration ($p=0.03$), and females had higher transition rates by the 52-week mark ($p=0.04$). Median weeks-to-transition was 24.3 (95% CI: 20.5-30.0) for males and 16.0 (95% CI: 14.7-16.6) for females.

Conclusions: We characterized a diverse cohort of twice-weekly incremental HD patients. Differences in incremental HD duration and incremental-to-conventional HD transition rates across sex and ethnicity were identified. These findings can inform researchers and clinicians regarding disparities in incremental HD effects across diverse ESRD populations. More research is needed to further assess the long-term effects of incremental HD, particularly in underrepresented and underserved ESRD patient populations.

TH-PO262

Incremental Hemodialysis (IHD) Is a Cost-Effective and Patient-Centered Kidney Replacement Therapy

Toshimasa Takahashi.[1,2] *[1]Bosei Shinjyuku-Minamiguchi Clinic, Tokyo, Japan; [2]Organization for Kidney and Metabolic Disease Treatment, Tokyo, Japan.*

Background: Hemodialysis (HD) in Japan is the highest quality of Renal Replacement Therapy (RRT) in the world, but its cost is increasing continuously. The conventional thrice-weekly regimen is a common way to introduce HD but not Incremental hemodialysis (IHD) in Japan. When HD patients' conditions are sufficiently managed by once-/twice-weekly HD with good adherence to their diet, its cost-reduction effect can be expected.

Methods: We selected 62 CKDG5 outpatients with good adherence to diet, we initiated IHD considered residual renal function individually and careful follow-ups from 2013 to 2023. The average age was 62 (21 to 90), and 74% was men. Their causes of ESRD include chronic glomerulonephritis (35%), diabetic kidney disease (34%), nephrosclerosis (21%), and others (10%; polycystic kidney disease, chronic interstitial nephritis, Hypoplastic kidney).

Results: 4.3, Ccr was 5.9mL/min, and mean urine volume (UV) was 1586 mL/day. 24 patients were treated with twice-weekly HD; their mean eGFR was 4.4, Ccr was 4.8mL/min, and mean UV was 1273 mL/day. We determined the number of dialysis cycles, taking into account the patient's background, underlying disease, and compliance before the initiation of dialysis, and individually studied the dialysis conditions based on laboratory data and weight gain. A significant difference was observed in UV between once-weekly and twice-weekly HD (The data were analyzed for statistical student's t-test. Difference was assessed with a two-sided test with a level of 0.05.) and no significant difference in eGFR and Ccr. The overall 1-year survival rate of IHD was 98.4%, and the 5-year survival rate was 81.2%. In these 62 patients, the total number of once-weekly HD was 357M (8.7M/person), the total number of twice-weekly HD was 1234M (23.7M/person), and the cost reduction during this period was 41.8% compared with that all patients did thrice-weekly HD. Limitation: The cost of dialysis was based on the Japanese medical insurance system in 2023. Selection bias cannot be avoided.

Conclusions: IHD is a patient centered RRT that provides cost-effective and sustainable treatment for ESRD patients.

TH-PO263

Vascular Access Survival with Thrice-Weekly, In-Center, Nocturnal Haemodialysis

Katherine L. Hull,[1,2] Ann Bugeja,[3,4] Matthew Graham-Brown,[1,2] Lindsay Reid,[4] Aiden J. Smith,[5] Brigit C. van Jaarsveld,[6] James Burton.[1,2] *[1]University of Leicester Department of Cardiovascular Sciences, Leicester, United Kingdom; [2]University Hospitals of Leicester NHS Trust, Leicester, United Kingdom; [3]Ottawa Hospital, Ottawa, ON, Canada; [4]University of Ottawa, Ottawa, ON, Canada; [5]University of Leicester Department of Population Health Sciences, Leicester, United Kingdom; [6]Amsterdam Universitair Medische Centra, Amsterdam, Netherlands.*

Background: This study explores vascular access complications in patients established on in-centre nocturnal haemodialysis (INHD) compared to conventional haemodialysis.

Methods: Retrospective cohort study with patients acting as their own control. Data were collected from: Leicester Renal Network, UK (project number 12494) and The Ottawa Hospital, Canada (project number 20230336-01H). Adults established on INHD (intervention period) preceded by usual daytime in-centre haemodialysis (control period) with an established vascular access were eligible. Data were collected between 01/01/2009-31/12/2021. The primary outcome measure was a composite of outcomes due to vascular access complication: hospitalisation, intervention, change in vascular access modality, change in dialysis modality and death. The primary outcome was evaluated by time-to-event rate in days using Kaplan-Meier plots. Statistical significance was accepted at $P<0.05$.

Results: 123 individuals were included (UK, n=66; Canada, n=57). The mean age was 51.2 years (±17.0), 69.1% (n=85) were male, 56.1% (n=69) were white. There was no difference in the primary outcome for the intervention period (n=33, 26.8%) and the control period (n=31, 25.2%): $P=0.868$. The 12-month vascular access survival probability was 69.8% (95%CI 61.0–78.6%) for the intervention period and 70.5% (95%CI 61.5-79.5%) for the control period (Figure 1). During the intervention period, arteriovenous grafts were associated with lower vascular access survival ($P<0.001$), and during the control period, regular vitamin K antagonist use was associated with lower vascular access survival ($P=0.002$).

Conclusions: Vascular access type and use of regular anticoagulation were associated with a reduced vascular access survival probability. There does not appear to be an increased risk to vascular access survival and safety for INHD compared to conventional haemodialysis.

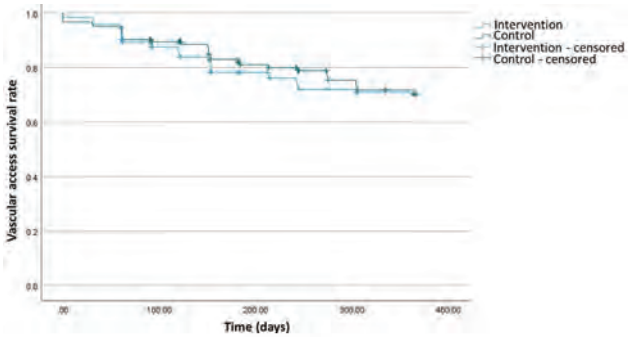

Figure 1 – Kaplan-Meier plot demonstrating vascular access time-to-event rate

TH-PO264

Exploring the Adoption of Thrice-Weekly, Extended-Hours, In-Center, Nocturnal Hemodialysis in Routine Clinical Practice through the NightLife Study: A Qualitative Content Analysis

Katherine L. Hull,[1,2] Victoria Cluley,[3] Matthew Graham-Brown,[1,2] James Burton.[1,2] *[1]University of Leicester Department of Cardiovascular Sciences, Leicester, United Kingdom; [2]University Hospitals of Leicester NHS Trust, Leicester, United Kingdom; [3]University of Nottingham School of Sociology and Social Policy, Nottingham, United Kingdom.*

Background: In-centre nocturnal haemodialysis (INHD) is a complex intervention and little is known about the factors influencing implementation. NightLife (ISRCTN87042063) is a randomised controlled trial comparing the clinical and cost-effectiveness of INHD to usual care. This study aims to understand the facilitators and barriers to INHD adoption within the NightLife trial, focusing on the infrastructure, research environment and healthcare professional perspective.

Methods: This study was completed as a qualitative content analysis, using an inductive approach following Braun and Clarke's framework for reflexive thematic analysis. Content for analysis was derived over a three-year period from three business cases, 80 e-mail discussions (each discussion containing one to 10 e-mails), one internal pilot report, 60 meeting minutes, and seven semi-structured interviews with members of the multidisciplinary team.

Results: Four key themes were identified: 1. Inequity: differential access to healthcare resources specific to dialysis treatment. 2. Role of knowledge and evidence: the impact of known benefits of INHD and the need for more research. 3. Staff perception and experience: motivation to start and continue with INHD site set-up. 4. Resources, support and complexity: multiple logistical challenges to negotiate and the impact of support from clinical and research teams. These four themes contributed to both the adoption and non-adoption of INHD within the NightLife study.

Conclusions: Site set-up and INHD service delivery have been the greatest challenges to NightLife study progression. Although each site appears to have unique challenges, this qualitative content analysis demonstrates commonality in the facilitators and barriers to dialysis service innovation. Utilising these findings will support site set-up of INHD within the NightLife study and are transferable to the development and evaluation of future complex interventions for the dialysis community.

TH-PO265

Survival Sex Differences among Pediatric and Young Adult Hemodialysis Patients in the Global MONDO Registry

Xiaoling Ye,[1] Ana Catalina Alvarez-Elias,[1] Rasha H. Hussein,[1] Guido Filler,[3] Maria E. Ferris,[2] Peter Kotanko.[1] MONDO Initiative. *[1]Renal Research Institute, New York, NY; [2]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [3]Western University, London, ON, Canada.*

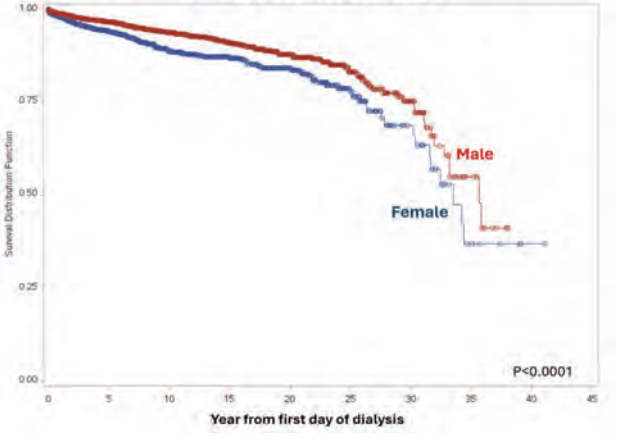
Background: For all age groups, women with ESKD on HD have higher rates of cardiovascular (CV) events compared to men, but their all-cause mortality is reduced. Survival in pediatric and young adult HD patients (pts) from across the globe is understudied.

Methods: In this retrospective cohort study, we included all the ptsaged from 0-40 and treated with HD from the global MONDO database (2000 - 2012). Primary cause of ESKD were identified at dialysis initiation. Kaplan-Meier estimate was used to study the survival of male versus female in all age group and each of the age group (0- ≤12, >12-≤18, >18-≤26, >26-≤33, and >33-40) separately.

Results: Of the 21,450 pts, 8,765 (40.9%) were females. Totally, 398,1.9% were 0-≤12; 13,92 (6.5%) were >12-≤18; 4,657 (21.7%) were >18-≤26; 6,398 (29.8%) were >26-≤33; and 8,623 (40.2%) were >33-40. Etiology by condition included 23.9% glomerular disease, 6.5% congenital and acquired urinary diseases, 32.1% other diagnoses, and 37.5% unknown causes of ESKD. There were no difference of pts with CV comorbidity in male vs. females (13%vs.11%). Pts distribution by region included 26.5% from Asia, 41.3% from Europe, 27.7% from Latin America and 4.5% from the US. The median survival time in both sexes was 32 years. Overall, males had a slightly better survival (p=0.0022). Age-stratified survival analysis revealed that males had a better survival than females (P=0.1099) significantly better survival in the >18≤26 age cohort (P<0.0001); all other stratified age groups showed no difference.

Conclusions: In the global MONDO Registry, of 0–40-year-old HD pts, only young adult males (>18≤26 years) had slightly better survival. Otherwise, there is no sex difference. In contrast to the existing literature for all age groups, we did not observe an inequity of survival in male HD pts<40 years old.

Figure 1. Sex differences in survival among HD patients (Age >18- <=26) in the global registry PICCOLO MONDO



TH-PO266

Colon Collectibles: Unearthing Coin-Shaped Treasures in Kidney Disease

Remy Fadel, Saud A. Alsaleh, Megha Salani. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Differentiating ingested foreign bodies and radio-opaque medications is critical due to their similar radiographic appearances. We present a case of a patient with end-stage kidney disease (ESKD) who was found to have sucroferric oxyhydroxide tablets in his colon, initially misinterpreted as metallic foreign bodies.

Case Description: A 69-year-old man with ESKD on hemodialysis presented with symptoms of nausea and vomiting. A CT scan of the abdomen revealed rounded, hyperattenuating intraluminal foci throughout the colon, possibly coins or buttons (Figure 1). General surgery was consulted and opted for a watchful management approach as there was no perforation. Further investigation revealed that the patient had been swallowing his phosphate binders, sucroferric oxyhydroxide, whole rather than chewing them. Radiology confirmed that the coin-shaped anomalies detected on imaging matched the size and shape of these tablets. Subsequently, the tablets were recovered intact from the patient's stool.

Discussion: Ingestion of foreign bodies can pose serious risks, necessitating prompt identification and management to prevent potentially life-threatening complications. It is imperative to differentiate such cases from instances of ingesting radio-opaque medications. The CHIPS mnemonic (chloral hydrate, heavy metals, iron, phenothiazines, and slow-release preparations) was developed to aid in identifying culprit medications. Sucroferric oxyhydroxide, a chewable iron-based phosphate binder, has negligible systemic absorption. Due to its insoluble iron content, unchewed sucroferric oxyhydroxide tablets appear as highly radio-opaque round objects on imaging. Understanding the properties and absorption mechanisms of such medications, coupled with thorough patient history-taking, can mitigate the need for invasive interventions and guide appropriate management strategies.

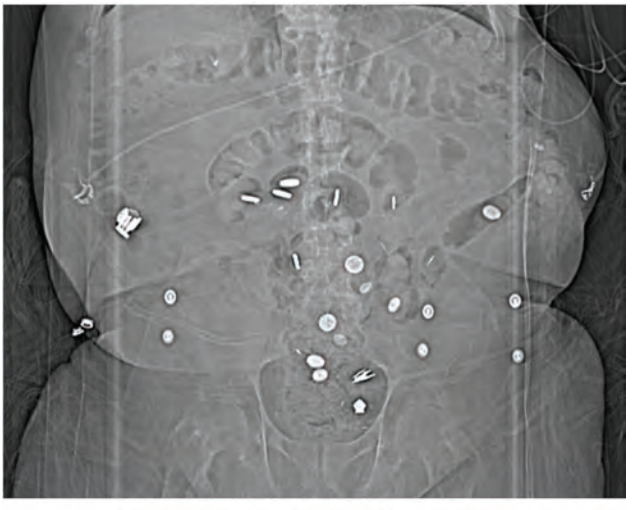


Figure 1 - CT Scan image showing rounded, hyperattenuating intraluminal foci throughout the colon

TH-PO267

Contrast-Induced Encephalopathy: A Rare Complication of Angiography in a Patient on Dialysis

David G. Sanders, Chloe West, Koyal Jain. *The University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Introduction: Contrast-induced encephalopathy (CIE) is a rare complication of contrast use in angiographic procedures. The kidneys filter iodinated contrast agents, making patients with end-stage kidney disease (ESKD) higher risk for CIE. We present a case of CIE to highlight the gravity of early diagnosis in patients with reduced kidney function.

Case Description: A 66-year-old woman with hypertension and ESKD on home hemodialysis (HD)(4 times/week; no missed sessions) underwent diagnostic cerebral angiography for aneurysms noted incidentally on MRA during renal transplant evaluation. 300mg of iohexol was given intra-arterially. Patient was initially alert but 30 minutes later was disoriented, aphasic and not following commands. CT head showed no infarction or hemorrhage but noted extensive intracranial arterial atherosclerotic calcifications. Vitals and labs were normal, making other diagnoses unlikely. CIE was considered given the timeline. Mental status improved with urgent dialysis and was baseline after 2 sessions. To our knowledge, this is the first report of CIE in a patient receiving home HD.

Discussion: CIE is a severe complication in <0.1% of patients receiving contrast. Incidence increases in CKD(6.8%) and ESKD(37.5%). Pre-existing diabetes, hypotension, dehydration, and large contrast volume also increase risk. Intracranial arterial atherosclerotic calcifications likely affected the disease process in this case. CIE is thought to occur from disruption of the blood-brain barrier and direct neurotoxicity of iodinated contrast. It presents with confusion, headache and agitation to seizures, blindness and stroke-like symptoms onset minutes-days after contrast. Transient cortical blindness is often reported. Treatment is discontinuing contrast, IV hydration, and early and frequent HD in HD patients. Failure to treat in severe cases can cause permanent neurologic damage and death. How the type/timing of dialysis impacts CIE risk is not well understood due to rarity of cases. Our patient recovered following 2 HD sessions, suggesting early and frequent HD is an effective treatment in patients already on HD. This rare case highlights the importance of early CIE recognition to avoid prolonged complications. It is important to also recognize that contrast use has other risks even in patients on dialysis and should be used cautiously.

TH-PO268

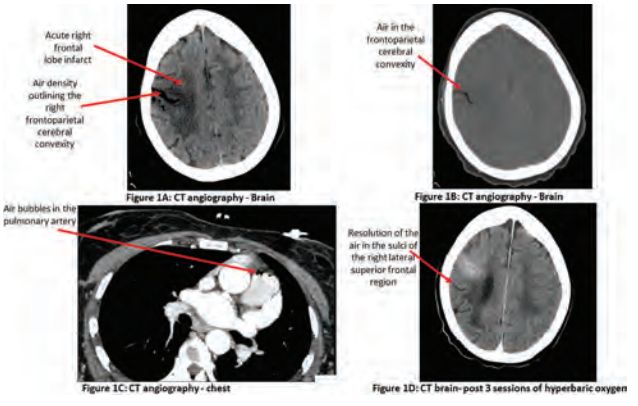
Unveiling a Rare Complication: Arterial Air Embolism during Hemodialysis without Intracardiac Shunt

Matthew W. Gross, C. E. Cervantes, Mohamad A. Hanouneh. *Johns Hopkins University, Baltimore, MD.*

Introduction: Air embolism is a rare complication during hemodialysis, due to safety measures like venous air traps and alarms. It's typically linked to the use of central venous catheters or the administration of anticoagulation or saline during dialysis. We report a case of arterial air embolization during dialysis in a patient without intracardiac shunt.

Case Description: A 56-year-old woman with ESRD on intermittent hemodialysis via a central venous catheter experienced facial droop and left-sided weakness during hemodialysis soon after receiving a heparin bolus with saline flushes. Her vitals remained stable. The venous line clamped, treatment was terminated, and the patient was positioned in trendelenburg. A CT scan showed an acute right frontal lobe infarct due to an air embolism (Figure 1A and 1B) and bubbles in the pulmonary artery (Figure 1C). Patient underwent three sessions of hyperbaric oxygen therapy. Her neurologic exam returned to baseline, and imaging confirmed resolution of air in the sulci of the right lateral superior frontal region (Fig 1D). Transthoracic echocardiography with agitated saline was done twice and did not demonstrate any intracardiac shunt.

Discussion: The usual manifestation of air embolism during hemodialysis is related to the air entering the cardiopulmonary circulation and includes chest pain, dyspnea and hypotension. Arterial air embolization, while less prevalent, presents a heightened risk, potentially leading to seizures or strokes. Such occurrences may arise in the presence of a right-to-left shunt or, as in our case, if pulmonary capillaries fail to adequately purge a significant volume of air, thereby overburdening the filtration capacity of the pulmonary vasculature. Quick identification is crucial, and treatment involves administering 100% oxygen, placing the patient in the trendelenburg position to contain the air in the right ventricle apex, clamping the venous line, stopping the blood pump, addressing any catheter disruptions, and providing intubation and cardiopulmonary support if needed.



TH-PO269

Complete Kidney Recovery after Prolonged Hemodialysis Dependency in Multiple Myeloma-Associated Kidney Failure: A Case Report

Hyun Joon Cho,[1] Bassam H. Rao,[2] Minahil Mukhtar,[2] Jee H. Kim,[1] Stela Teferici,[1] Mohamad Bakro,[1] Dawn Maldonado,[1] Hameeda T. Khan,[1] Nitzy N. Munoz Casablanca.[1] *[1]Mount Sinai Health System, New York, NY; [2]Shifa College of Medicine, Islamabad, Pakistan.*

Introduction: Renal impairment is an important complication of Multiple Myeloma (MM), with 20-40% of patients demonstrating some renal injury at diagnosis, related primarily to light chain cast nephropathy. Bortezomib and steroid based therapy are the

backbone for MM management, compounded with hemodialysis in patients with renal failure. Here, we present a case of MM associated renal failure requiring hemodialysis for 11 months, with subsequent spontaneous renal recovery.

Case Description: A 49 year-old male, without any significant past medical/surgical history who had 1 month of intermittent urinary symptoms, weakness, nausea and loss of appetite and was prompted to come to the ED when outpatient workup revealed anemia with Hb 8.4 g/dL and serum creatinine (Cr) levels of 11 mg, without known previous baseline. Initial workup showed markedly elevated serum lambda light chains at 1435 mg/dL. Urinalysis with trace protein, but a urine protein creatinine ratio of 3.5g. The patient underwent kidney biopsy which came back positive for light chain (myeloma) cast nephropathy, lambda type, minimal interstitial fibrosis, tubular atrophy and unremarkable vessels. Bone marrow biopsy was also consistent with multiple myeloma. He was initiated on renal replacement therapy and continued for 11 months. Patient was treated with cyclophosphamide, bortezomib and dexamethasone and then subsequently with Bortezonib, Lenalidomide and Dexamethasone. After being on hemodialysis for 11 months, his eGFR gradually improved, and a decision was made to withhold hemodialysis. Since then, the patient's renal function has been stable, with Cr around 2 mg/dL and eGFR >30.

Discussion: The burden of renal disease in MM can be ascertained from its place as the second leading cause of mortality, with lack of renal recovery bearing a poor prognosis. In recent times, high cut-off hemodialysis has emerged as an adjunct to steroids and bortezomib based chemotherapy in this class of patients for improving renal outcomes. The data on this however, remains sparse. Although the patient was managed as per standard guidelines, our unique case signifies the potential space of renal recovery even after prolonged hemodialysis dependance in MM patients.

TH-PO270

Morphological Changes in a Nephrectomized End-Stage Kidney 10 Years after Hemodialysis (HD) Initiation for Atypical Hemolytic Uremic Syndrome (aHUS)

Kruti Shah,[1] Tiane Dai,[1] Cynthia C. Nast,[2] Sharon G. Adler.[1] *[1]Harbor-UCLA Medical Center, Torrance, CA; [2]Cedars-Sinai Medical Center, Los Angeles, CA.*

Introduction: A nephrectomy (Nx) for renal cell carcinoma (RCC) in a patient on long-term dialysis receiving C5 inhibitor treatment (C5i) for aHUS afforded the opportunity to morphologically evaluate changes in the end-stage kidney due to end-stage kidney disease (ESKD) milieu, hyperparathyroidism, and treated aHUS.

Case Description: A 23-year-old man presented in 2014 with uremic symptoms and hypertensive emergency (BP 200/120 mmHg). His serum creatinine was 12 mg/dL. He had low complement C3, normal C4, no thrombocytopenia or microangiopathic hemolytic anemia. Renal biopsy showed a large artery with thrombotic microangiopathy (TMA) and immune complex-mediated membranoproliferative Type I pattern of injury. Additional studies showed low Complement Factors B, H (CFH), and I (CFI). Genotyping revealed a novel nonsense mutation in CFI predicted to prematurely truncate the CFI protein and 3 heterozygous polymorphisms in CFH, common in healthy people but enriched in aHUS. Eculizumab was not started because of hematologically silent aHUS and functionally end-stage kidneys. In time, he required parathyroidectomy for tertiary hyperparathyroidism. Subsequently, he presented with right-sided numbness and a cerebrovascular lesion coinciding with the sensory symptom distribution. At this time C5 inhibitor was started for presumptive cerebral TMA, with resolution of aHUS symptoms. After 10 years of dialysis, he developed erythrocytosis, kidney cysts, and renal cell carcinoma (RCC) necessitating nephrectomy (Nx). Nx showed acquired cystic disease, RCC, diffusely calcified glomeruli likely due to tertiary hyperparathyroidism, and chronic TMA with minimal activity, likely reflecting the beneficial effect of long-term complement C5 inhibitor treatment.

Discussion: Nx was done for RCC after 10 years of dialysis and ESKD from aHUS secondary to CFI mutation. This afforded the opportunity to observe the rare finding of diffuse glomerular calcification likely due to tertiary hyperparathyroidism. Additionally, there was chronic and minimally active TMA, likely reflecting long-term complement C5 inhibition.

TH-PO271

Community Hemodialysis for a Patient with a Left Ventricular Assist Device: A Case Report

April Toh, Zheng Xi Kog, Hui-Lin Choong, Jiunn Wong. *Singapore General Hospital, Singapore, Singapore.*

Introduction: Heart transplant remain the treatment of choice for patient with advance heart failure. However, due to lack of donor organ, left ventricular assist devices (LVADs) are used as a bridge until donor organs becomes available. We are seeing more patients with advanced heart failure where LVADs are being used for long term. These patients are surviving longer and hence it is not uncommon for them develop ESKD requiring dialysis. We presents a case of a patients who was on LVAD for 2 years prior to developing ESKD and how we transit her from hospital to community for her dialysis.

Case Description: Ms K is a 33 year old lady who suffered from doxorubicin induced cardiomyopathy following treatment of childhood Acute Myeloid Leukemia. She presented with intra-partum decompensated heart failure requiring inotropic and ECMO support in 2021. She eventually underwent LVAD implantation. Her peri-operative and postoperative period was complicated with multiple infective issues and complications. During tthat admission she developed AKI following cardiac surgery requiring dialysis for 3 months before weaning off dialysis. Unfortunately, she had recurrent admissions over the next 2 years and developed recurrent episodes of AKI, ultimately leading to her becoming dialysis dependent. She recieve intermittent dialysis in hospital setting and was subsequently successfully transited to outpatient community dialysis after 2 month stay in hospital.

Discussion: There are numerous challenges a LVAD patient on dialysis faces compared to the routine patient on maintenance dialysis. For patient on LVAD, the blood flow is none pulsatile and traditional method of measuring BP would not be able to accurately record BP. US Doppler BP measurement for mean arterial pressure is the only way to measure BP in these patients. Besides difference in monitoring, resuscitation plan also differs from routine dialysis patients. CPR peformed on these patients may disloge the LVAD and cause more harm than good. This is the first case of a patient on LVAD undergoing successful transition from the inpatient setting to community dialysis in Singapore. With more LVAD procedures being performed and patient surviving longer on LVAD, dialysis center would need to adapt to care for these patients. Dialysis nurses need to have knowlege and training in order to care for patients on LVAD.

Abstract Withdrawn

TH-PO273

Correlation between Intradialytic Blood Pressure Variability and Cognitive Impairment in Patients on Maintenance Hemodialysis

Jingfang Wan, Jun Liu, Yani He, Kehong Chen. *Army Medical Center of PLA, Chongqing, China.*

Background: Cognitive impairment (CI) is a risk factor for death and poor prognosis in maintenance hemodialysis (MHD) patients. MHD patients are more likely to have fluctuating BP during dialysis, which may have a greater impact on CI. Our present study aimed to illustrate the correlation between intradialysis BPV and CI in MHD patients.

Methods: Overall cognitive function was assessed by the Beijing version of the Montreal Cognitive Assessment (MoCA-B) scale. The patient's SBP was converted to the following 4 candidate BPV indices: standard deviation (SD), coefficient of variation (CV), average real variability (ARV), RANGE. $P < 0.05$ was considered statistically significant.

Results: 170 patients were enrolled, with a total of 6,662 dialysis recordings and 26,580 SBP measurement recordings. The mean age of the patients was 57.99 years. The proportion of males was 58.24%, and CI prevalence was 78.24%. SBP ARV is an independent risk factor for CI (Table 1). We observed a non-linear relationship between SBP ARV and CI (Figure 1). We compared two fitting models to explore the curved associations, the p-value of the log-likelihood ratio test is 0.008. The inflection point of SBP ARV was 7.52. When SBP ARV ≥ 7.52, the risk of CI increased as the SBP ARV increased (OR: 4.10, 95 % CI1.61-10.46, P = 0.003). When SBP ARV < 7.52, there was no significant correlation between SBP ARV and CI (OR = 0.43, 95 % CI 0.15-1.26, p = 0.125).

Conclusions: Intradialytic BPV was associated with CI in MHD patients. Intradialytic SBP ARV may be a better candidate for predicting CI in MHD patients, with nonlinear dose-response relationship.

Neurofilament Light Chain and Cognitive Function in Patients Undergoing Hemodialysis: A Cross-Sectional Study

Kazuhiko Kato, Akio Nakashima, Arisa Kobayashi, Ichiro Ohkido, Takashi Yokoo. *Tokyo Jikeikai Ika Daigaku, Minato-ku, Japan.*

Background: Dementia poses a global challenge for geriatric care and social welfare, including for aging dialysis patients. In recent years, non-invasive blood biomarkers have garnered increasing attention in predicting the development of Alzheimer's disease. Within the general populace, neurofilament light chain (NFL) prognosticates forthcoming cognitive function alongside amyloid-beta (Aβ). Nevertheless, investigation into this matter has yet to be extended to chronic kidney disease patients, including those undergoing hemodialysis.

Methods: A cross-sectional study of hemodialysis patients investigated the association between serum Aβ (1-42) and NFL levels with cognitive function as assessed by the Montreal Cognitive Assessment (MoCA) and Mini-Mental State Examination (MMSE).

Results: This study involved 362 patients whose median age was 74 (interquartile range 70-80) years and who had been receiving hemodialysis for a median of 87 (36-168) months. Aβ (1-42) exhibited a median of 2.84 (1.84-4.27) pmol/L, and NFL exhibited a median of 196.2 (146.5-262.2) pg/mL with a non-parametric distribution. The median MoCA and MMSE scores were 25 (22-26) and 28 (26-29). NFL levels transformed by the natural logarithm significantly negatively correlated with cognitive function in a multivariate linear regression analysis, including confounding factors (β coefficient [95% confidence interval], -0.98 [-1.76, -0.2]; P=0.014 for MoCA, and -0.67 [-1.3, -0.05]; P=0.034 for MMSE). No significant associations existed between cognitive function and Aβ (1-42) levels.

Conclusions: Low levels of NFL were associated with preserved cognitive function in patients undergoing hemodialysis.

How Pervasive Is Pervasive Sensing in Hemodialysis? Results from a Clinical Research Survey of Urban Dialysis Clinics

Maggie Han,[1] Lemuel Rivera Fuentes,[1] Lin-Chun Wang,[1] Ohnmar Thwin,[1] Lela Tisdale,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Currently, there is a wealth of commercially available activity and fitness trackers that have become available, allowing insights into physical activity, sleep, heart rate, and a plethora of other parameters that could lead to timely intervention prior to a manifest clinical decline. We aimed to determine the percentage of in-center hemodialysis (HD) patients using commercially available wearable devices.

Methods: Patients from four HD clinics located in New York City, NY, were surveyed. The study was exempt from the requirement of collecting informed consent by the Western Institutional Research Board (ES-21-004). In March 2021, patients were asked if they owned a wearable activity tracker, and if so, what type of device they owned (Fitbit, Garmin, Apple Watch, Samsung, etc.).

Results: Census data of these four HD clinics from September 2020 indicated that the population is 51 % black, 31 % Hispanic, and 59 % male. In total, 502 patients were approached, and 434 (86.5 %) agreed to respond. Of the responders to the survey, 52 (12 %) owned a wearable activity tracker, 380 (87.6 %) did not, and 2 (0.5 %) were unsure if they did. Of those 52 patients who owned a wearable activity tracker, 9 (17%) patients owned an Apple Watch, 31 (60%) a Fitbit, 4 (8%) a Samsung, and 8 (15%) owned another device or did not specify brand (**Figure 1**).

Conclusions: In our study of urban in-center HD patients, only a small proportion (around 10%) own wearable activity trackers. Possible barriers to the adoption of these devices are lack of access to the internet and smartphones, and technology literacy.

Trends in Physical Activity before Hospitalization: A Prospective Observational Study in Patients on Hemodialysis Using Wearable Activity Trackers

Maggie Han,[1] Yuedong Wang,[2] Xia Tao,[1] Priscila Preciado,[1] Lela Tisdale,[1] Ohnmar Thwin,[1] Peter Kotanko.[1,3] *[1]Renal Research Institute, New York, NY; [2]University of California Santa Barbara, Santa Barbara, CA; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Data collected by wearable devices may lead to timely intervention prior to a marked clinical decline. We aimed to determine if physical activity levels, measured with a wearable activity tracker, changed prior to hospitalization in hemodialysis (HD) patients.

Methods: HD patients from 4 New York City clinics were enrolled starting in June 2018 and followed for up to 1 year. Ambulatory patients ≥18 years, on maintenance HD, and owning a mobile device were included. Each patient was provided with and taught how to use a wearable activity tracker (Fitbit Charge 2®), and they were instructed to wear the device continuously. Hospitalization events were recorded and separated into two categories: unexpected hospitalizations and expected hospitalizations (vascular access procedure, scheduled surgeries). Rehospitalizations were not included in the analysis. We fit cubic spline models to daily averages of total steps 30 days prior to expected and unexpected hospitalizations, respectively, and compute p-values for testing the hypothesis of a constant function prior to hospitalizations using the bootstrap method.

Results: 42 patients (54±13 years, 57% Black, 71% male, 33% diabetic) were included in this analysis. 59 hospitalizations were recorded, with 51 unexpected and 8 expected hospitalizations. Prior to unexpected hospitalizations, the number of steps per day declined significantly (p=0.030) **(Figure 1a)**. In contrast, steps per day increased significantly in expected hospitalizations (p=0.039) **(Figure 1b)**.

Conclusions: Physical activity levels decline prior to unexpected hospitalizations. A marked decrease in steps per day may be an early indication of subsequent clinical decline. Additional research is warranted to further investigate the relationship between wearables data, clinical events, and intervention strategies.

Figure 1. Steps per day prior to hospitalization
a) total steps decreased prior to unexpected hospitalization (p=0.030). A notable decline starts about two weeks prior hospitalization.
b) total steps increased prior to expected hospitalization (p=0.039). We hypothesize that the increase may be related to errands prior expected hospitalization.

Virtual Reality (VR)-Based Exercise and Exergaming for Patients on Hemodialysis: Rapid Systematic Review and Meta-Analysis

Davey Li,[1] Yunan Han,[1] Tanika Kelly,[2] Takeshi Hasegawa,[4] Erika Ota,[3] Hisashi Noma,[5] Taihei Suzuki,[4] Yoshitaka Watanabe,[9] Naonori Tashiro,[6] Hiroki Nishiwaki.[7,8] *[1]University of Illinois Chicago College of Medicine, Chicago, IL; [2]University of Illinois Chicago, Chicago, IL; [3]St.Luke's International University, Chuo, Japan; [4]Showa University, Shinagawa, Japan; [5]Institute of Statistical Mathematics, Tachikawa, Japan; [6]Showa University Fujigaoka Rehabilitation Hospital, Yokohama, Japan; [7]University of Illinois Chicago, Chicago, IL; [8]Showa University Fujigaoka Hospital, Yokohama, Japan; [9]Showa University Northern Yokohama Hospital, Yokohama, Japan.*

Background: Hemodialysis (HD) patients are at high risk for CVD; approaches to reducing the risk of CVD include pharmacologic therapies and nonpharmacologic interventions, with exercise representing an important nonpharmacologic intervention. Recently, conventional exercise interventions have been supplemented with technological advancements like virtual reality (VR) and exergaming, providing engaging, multisensory rehabilitation options.

Methods: In this systematic review and meta-analysis, we searched MEDLINE, and CENTRAL through April 2024 for interventional studies involving VR-based exercise and exergaming interventions among patients on HD. Study quality was assessed using the Cochrane Collaboration risk-of-bias 2.0 tools. Across eligible studies, random-effects meta-analyses were used to combine effects of VR-based exercise and exergaming on four study endpoints, exercise tolerance, gait speed, and depression in HD patients.

Results: Out of the 45 references, 14 studies consisting were applicable, 5 of which reported eligible outcomes (3 for exercise tolerance, 4 for gait speed, and 2 for depression). VR-based exercise and exergaming were associated with significantly increased exercise tolerance, with an average increase 78.3 m [95% CI 31.6 to 125.0, I^2=31%] in distance on the 6-minute walk compared to the control group (**Fig1**). Likewise, walking speed was increased an average of 0.16 m/sec [95%CI 0.09-0.24, I^2=0%] among those in the intervention group (**Fig2**), and depression was decreased, with standardized mean difference (hedge's g) of -0.49 [95% -0.84 to -0.19, I^2=0%] (**Fig3**).

Conclusions: VR-based exercise and exergaming increased exercise tolerance and gait speed, and decreased depression in the current meta-analysis.

Use of β2-Microglobulin Adsorption Columns for More than 10 Years Contributes to the Maintenance of Physical Activity in Patients on Long-Term Dialysis Who Have Hemodialysis-Related Amyloidosis

Junichiro J. Kazama,[1] Suguru Yamamoto.[2] *[1]Fukushima Kenritsu Ika Daigaku, Fukushima, Japan; [2]Niigata Daigaku Ishigaku Sogo Byoin, Niigata, Japan.*

Background: The β2-microglobulin adsorption column (BMC) was developed in the 1990s to prevent the progression of dialysis-related amyloidosis (DRA) by removing β2-microglobulin from blood in conjunction with hemodialysis. However, the long-term effects of its use are still not well understood. We investigated the condition of dialysis patients who have been using BMC for over 10 years.

Methods: We selected maintenance hemodialysis patients in Japan who have been continuously treated with BMC for over 10 years and conducted interviews with patients who provided consent. The study protocol was approved by the Ethics Review Committee of Fukushima Medical University (FMU23-066).

Results: We obtained responses from 59 patients (70.0±7.2 years old, 22 males and 37 females, dialysis history of 38.2±6.0 years, BMC usage period of 15.0±3.9 years) across 35 facilities. Histological evidence of the deposition of Aβ2M amyloid fibrils was confirmed in all of these patients. Among the 59 patients, 38 had symptoms such as pain in the hands or fingers, hand numbness, hand stiffness, shoulder pain, and lower limb numbness before using BMC. Of these 38 patients, 35 (92.1%) reported a reduction in these symptoms. Eighteen patients experienced a recurrence of these symptoms when BMC treatment was interrupted. Eight patients testified that BMC improved symptoms compared to hemodiafiltration (HDF), while no testimonies indicated that HDF improved symptoms compared to BMC. The daily living abilities evaluated by the Eastern Cooperative Oncology Group Performance Status (ECOG) were PS0: 8.6%, PS1: 34.5%, PS2: 46.6%, PS3: 6.9%, and PS4: 3.4%. The proportions of PS0, PS3, and PS4 were lower, and the proportion of PS2 was higher compared to the data of general maintenance dialysis patients with over 30 years of dialysis history in previous reports.

Conclusions: The pain relief effect of BMC in this study was almost at the same level as previously reported. The pain-relieving effect of BMC observed in this study may have contributed to maintaining the motor function of these patients, preventing their progression to PS3 and PS4 over time. Thus, the long-term use of BMC may contribute to the maintenance of physical activity in dialysis patients with DRA.

Do Baseline Parathyroid Hormone Levels Influence the Effect of Intradialytic Exercise on Bone Turnover Markers in Patients on Haemodialysis?

Diogo V. Leal,[1,2] Daniela F. Cardoso,[1,2] Francini P. Andrade,[1,2] Pedro M. Martins,[1,5] Manuel A. Ferreira,[5,6] Luke A. Baker,[3,4] Alice C. Smith,[3,4] Joao L. Viana.[1,2] *[1]Centro de Investigacao em Desporto Saude e Desenvolvimento Humano, Maia, Portugal; [2]Universidade da Maia, Maia, Portugal; [3]Leicester Kidney Lifestyle Team, Leicester, United Kingdom; [4]University of Leicester College of Life Sciences, Leicester, United Kingdom; [5]Nephrocare Portugal SA, Lisboa, Portugal; [6]Universidade Nova de Lisboa Medical School, Lisboa, Portugal.*

Background: Mineral and bone disorders are common in patients on haemodialysis (HD). We previously observed that regardless of type, exercise appears to have had a modulatory effect on bone remodelling by attenuating bone resorption and maintaining its formation. Parathyroid hormone (PTH) exerts impactful effects on skeletal homeostasis through many mechanisms, with continuous hyperparathyroidism exacerbating both bone formation and resorption. Here we aimed to investigate whether PTH influences the sensitivity of bone biomarkers' responses to exercise training.

Methods: This is a secondary analysis from an RCT completed on 88 HD patients who undertook a 6-week run-in period followed by 12 weeks of intradialytic aerobic (n= 36, male: 66%, age: 67±14 years), or resistance exercise (n= 29, male: 74%, age: 65±14 years), where we combined the exercise groups and stratified patients in low <150 pg/mL (L-PTH), normal 150-600 pg/mL (N-PTH), or high PTH >600 pg/mL (H-PTH). Circulating TRAP-5b, sclerostin, RANKL, osteoprotegerin, and osteocalcin (OCN) were measured by ELISA.

Results: At baseline, there were 15 patients in L-PTH, 55 in N_PTH, and 7 in H-PTH. Most biomarkers were unchanged after the control period, except for a reduction in OCN observed in L-PTH only (p= 0.026). Following exercise, an elevation in TRAP-5b was observed in both L-PTH and N-PTH (p<0.001). No changes in bone biomarkers were observed in patients with H-PTH at any timepoint (p>0.05 in all).

Conclusions: Exercise led to increased bone resorption in patients with low and normal PTH levels and maintained bone formation in patients with low PTH levels, but no such effects were observed in those with high PTH levels. This differential response suggests a protective effect of exercise in patients with low PTH by activating the cycle of bone formation through and increase in resorption and conservation of bone formation, which might be clinically relevant considering their reduced bone turnover. Funding: The Research Center in Sports Sciences, Health Sciences and Human Development is funded by the Portuguese Foundation of Science and Technology (UID/04045/2020). DC is supported by an FCT doctoral grant (SFRH/BD/138940/2018).

Decreased Skeletal Muscle Mass as a Risk Factor for the Progression of Peripheral Artery Disease (PAD) in Patients Receiving Maintenance Hemodialysis: 10-Year Outcomes of the Q-Cohort Study

Masumi Shojima,[1] Shunsuke Yamada,[1] Tatsuya Suenaga,[1] Kazuhiro Okamura,[1] Hiromasa Kitamura,[2] Hiroto Hiyamuta,[5] Masatomo Taniguchi,[4] Kazuhiko Tsuruya,[3] Takanari Kitazono,[1] Toshiaki Nakano.[1] *[1]Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [2]Department of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan; [3]Department of Nephrology, Nara Medical University, Kashihara, Japan; [4]Fukuoka Renal Clinic, Fukuoka, Japan; [5]Department of Nephrology, Steel Memorial Yawata Hospital, Fukuoka, Japan.*

Background: Peripheral arterial disease (PAD) is a life-threatening complication in patients undergoing hemodialysis. It is unclear whether sarcopenia, as evidenced by a lower value of skeletal muscle mass surrogates, is a risk factor for PAD.

Methods: A total of 3,506 patients receiving hemodialysis registered in the multicenter, prospective, observational study were followed up for 10 years. The primary outcome was an intervention for PAD composed of endovascular therapy, revascularization, and amputation. The main exposure was the modified creatinine index, a surrogate of skeletal muscle mass calculated by age, sex, pre-dialysis serum creatinine, and Kt/V for urea. The patients were divided into sex-specific quartiles (Q1-Q4) according to the modified creatinine index level at baseline. Cox proportional hazard risk models were employed to estimate the intervention risks for PAD.

Results: In total, 257 patients required intervention for PAD during a median follow-up period of 8.2 years. The multivariable-adjusted Cox proportional hazards risk model showed that the risks of intervention for PAD in the lower quartiles (Q1 and Q2) were significantly (P<0.05) higher than the highest quartile (Q4): hazard ratio (95% confidence interval) for Q1 and Q2 were 1.75 (1.01–3.04) and 1.63 (1.04–2.58), respectively. Each 1 mg/kg/day decrease in the modified creatinine index was significantly (P=0.017) associated with the elevated risk of the intervention for PAD: hazard ratio (95% confidence interval) was 1.11 (1.01–1.22).

Conclusions: Sarcopenia, as expressed by a lower modified creatinine index level, was an independent risk factor for intervention for PAD in patients undergoing hemodialysis.

TH-PO281

Association of Serum Urotensin II with Sarcopenia and Mortality in Patients on Hemodialysis

Chi-Ta Hsieh, Lim Paik Seong. *Tungs' Taichung MetroHarbor Hospital, Taichung, Taiwan.*

Background: Sarcopenia significantly impacts dialysis patients. Our prior research evaluated 6 muscle biomarkers for early sarcopenia detection and found that Urotensin II (UT II) had a strong correlation with sarcopenia. This study further investigates UT II's effectiveness in predicting cardiovascular (CV) mortality.

Methods: A cross-sectional study was conducted on 175 stable HD patients at Tungs' Taichung Metroharbour Hospital. The associations of these biomarkers with CV mortality and sarcopenia were analyzed using multivariate Cox regression models, categorizing biomarkers into quartiles for statistical analysis. The predictive value of UT II against sarcopenia diagnosed by DEXA was also compared. Statistical analyses were performed using SAS software version 9.4.

Results: In this cohort, Cox regression analysis revealed that elevated UT II levels were significantly associated with increased CV mortality (aHR = 5.209, p = 0.0146, Fig. 1). Further analysis, integrating UT II with DEXA measurements, confirmed the significant predictive value of UT II (aHR = 6.040, p = 0.0216, Fig. 1) for CV mortality, while sarcopenia and presarcopenia diagnosed via DEXA were non-significant (Fig. 2).

Conclusions: UT II emerges as a better biomarker for predicting CV mortality in HD patients. This study emphasizes that serum UT II reflects not only muscle wasting but protein-energy wasting (PEW), which are related to CV diseases.

Table 1 Cox multivariate regression of Muscle Biomarkers for CV mortality

Variables	Cardiovascular mortality Adjusted hazard ratio (95%CI)	P

TH-PO282

Paricalcitol Treatment Upregulates Exosome-Derived Muscle Tissue-Specific MicroRNAs in Sarcopenic Male Patients on Hemodialysis

Hyeong cheon Park,[1] Hoon Young Choi,[1] Hyung Jong Kim,[2] Hyo Jeong Kim.[1] *[1]Division of Nephrology, Department of Internal Medicine, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea; [2]Department of Internal Medicine, CHA Bundang Medical Center, CHA University, Seongnam, Republic of Korea.*

Background: Muscle tissue specific microRNAs (myomiRNAs) are special group of miRNAs that play important roles by targeting genes involved in muscle development, differentiation, and regeneration. Vitamin D administration has been reported to have beneficial effects on skeletal muscle. Aim was to compare myomiRNAs between sarcopenic and non-sarcopenic patients on hemodialysis treatment and assess the effects of paricalcitol treatment on their expression.

Methods: Fifty male patients undergoing hemodialysis were included in the study and were given paricalcitol (Alvogen Korea) according to KDIGO clinical practice guidelines for treatment of secondary hyperparathyroidism for 12 weeks. Skeletal muscle index (SMI) value was derived by bioimpedance measurement and study subjects were classified into sarcopenia (n=13) or non-sarcopenia (=37) according to the criteria of the Asian Working Group for Sarcopenia 2019. The patients' blood derived exosomes were isolated and evaluated for expression of skeletal myomiRNAs (miR; miR-1, miR-133a, miR-206, miR-499),), associated with enhanced skeletal muscle differentiation and myoblast proliferation, using real-time quantitative PCR.

Results: The mean age was 67.3 ± 10.8 years and mean hemodialysis vintage was 9.4±6.2 years. Mean SMI value was 6.0±0.4 and 7.4±0.4, respectively in sarcopenia and non-sarcopenia group. Sarcopenia group showed significantly decreased expression of exosomal myomiRNAs (miR-1, miR-133a, miR-206, miR-499) compared to non-sarcopenia group [RQ: relative quantification; mean, (standard deviation)]: 0.40 (0.13), 0.49 (0.10), 0.37 (0.08), and 0.43 (0.09) (p<0.01) Paricalcitol treatment for 12 weeks significantly increased expression of all exosomal myomiRNAs in sarcopenia group whereas non-sarcopenia group showed increase in miR-1, miR-133a, and miR-206. Interestingly, the response to paricalcitol treatment was independent of serum vitamin D levels.

Conclusions: Sarcopenic hemodialysis patients showed decreased myomiRNA expression for skeletal muscle differentiation and myoblast profliferation that was upregulated by short term vitamin D treatment. Therefore, vitamin D treatment may have beneficial roles in treatment of sarcopenia.

TH-PO283

Sarcopenia Is Associated with Increased Major Adverse Cardiovascular Event Incidence in Patients on Maintenance Hemodialysis: A Prospective Cohort Study and Mediation Analysis

Lu Jiang, Huijuan Mao. *Nanjing Medical University, Nanjing, China*.

Background: Few studies have investigated the relationship between sarcopenia and the incidence of major adverse cardiovascular events (MACE) in maintenance hemodialysis (MHD) patients. This study thus explored the association between sarcopenia and MACE in a prospective cohort with mediation analysis.

Methods: The exposure was sarcopenia. The primary endpoint was the occurrence of MACE, defined as the composite of all-cause mortality or hospital admission with a primary diagnosis of acute myocardial infarction, stroke, or heart failure during a 3-year follow-up period. Multivariate Cox regression analyses were used to test the association between sarcopenia and subsequent MACE incidence. Mediation analyses were used to investigate whether potential mediators influenced the association between sarcopenia and MACE.

Results: Of the 230 patients enrolled, 57% were male, and a median dialysis vintage of 67 months (IQR: 32 to 119). The prevalence of sarcopenia was 45.2%. The presence of sarcopenia was significantly correlated with age (Spearman's r = 0.47, $P < 0.001$), C-reactive protein (Spearman's r = 0.13, $P = 0.044$), serum albumin (Spearman's r = –0.22, $P < 0.001$), 25(OH) vitamin D (Spearman's r = –0.26, $P < 0.001$), and coronary artery calcification score (Spearman's r = 0.20, $P = 0.002$). Over the 3-year follow-up period, MACE were observed in 59/104 (56.7%) patients with sarcopenia and 38/126 (30.2%) patients without sarcopenia (log-rank $P < 0.001$). After accounting for potential confounders, patients with sarcopenia presented a 66% (4–168%, $P = 0.035$) increase in their risk of MACE incidence as compared to non-sarcopenic individuals. However, adjusted mediation analyses did not detect any indication of a causal mediation pathway linking the effects of sarcopenic status on coronary artery calcification score, C-reactive protein, serum albumin, or 25(OH) vitamin D levels to MACE outcomes. Conversely, sarcopenia exhibited a direct effect (average direct effect range: –0.50 to –0.69, all $P < 0.05$) on MACE incidence.

Conclusions: The presence of sarcopenia was associated with a higher incidence of MACE in MHD patients. The putative effects of sarcopenia on this cardiovascular endpoint appear to be direct and not mediated by any causal pathways that include vascular calcification, inflammation, hypoalbuminemia, or vitamin D.

Relationship between Muscle Mass, Strength, and Physical Performance in Patients on Maintenance Hemodialysis

Daeun Park, Seok hui Kang. *Yeungnam University School of Medicine and College of Medicine, Daegu, Republic of Korea*.

Background: A relationship between muscle mass, muscle strengh, and physical performance in hemodialysis (HD) patients could be not established by a unidirectional pathway. This study aimed to assess the causal association of the aforementioned three variables using a mediation analysis.

Methods: We included 84 HD patients. The collected data included appendicular lean mass index (ALM/Ht^2), handgrip strength (HGS), gait speed (GS), five-times sit-to-stand test, 30-s-sit-to-stand test (STS30), 6-min walk test (6MWT), timed up and go test, and short physical performance battery. Mediation analysis was done using Baron and Kenny's regression approach to investigate the mediating effect.

Results: The mean ALM/Ht^2 and HGS were 6.6 ± 1.0 kg/m^2 and 26.1 ± 7.4 kg, respectively. ALM/Ht^2 or HGS showed a positive association with GS, STS30, or 6MWT, and the association between ALM/Ht^2 and HGS was significant. After adjusting for HGS, the association between ALM/Ht^2 and three physical performances did not remain significant; however, after adjusting for ALM/Ht^2, the association between HGS and three physical performances remained significant.

Conclusions: The present study demonstrated that physical performance tests were associated with both ALM/Ht^2 and HGS, but the association between ALM/Ht^2 and physical performance tests is completely mediated by HGS.

TH-PO285

Gait Speed as a Crucial Independent Predictor of Mortality and Cardiovascular Risk in Patients on Maintenance Hemodialysis

Yuan Luo, Bing Zhuang, Guiling Wei, Hong Ye, Chunsun Dai. *The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China*.

Background: Low gait speed is an important criterion for diagnosing sarcopenia, which is prevalent in maintenance hemodialysis (MHD) patients. This prospective cohort study evaluated the impact of sarcopenia on myocardial structure and function, survival, hospitalization, and cardiovascular events (CVE) in MHD patients.

Methods: Participants were derived from a single dialysis center. Skeletal muscle mass, handgrip strength, gait speed (GS), and echocardiography were assessed. GS is measured by a 6-minute walk test. Lower gait speed was defined at <0.8m/s. The primary endpoints were CVE, hospitalization, and all-cause mortality.

Results: We studied 307 participants, 46 (15.0%) with lower gait speed. Participants with lower gait speed were characterized by older age (68.1±9.8 years vs. 57.2±12.3 years, P<0.001) and a higher prevalence of diabetes (12.8% vs. 33.1%, P<0.001). Participants with lower gait speed had higher left ventricular posterior wall (12.33±0.93 vs 12.09±0.98 mm, P=0.040), higher interventricular septum thickness (13.36±1.07 vs 13.10±1.06 mm, P=0.037), higher right ventricular wall (10.28±1.12 vs 9.79±1.12 mm, P<0.001), and faster tricuspid valve regurgitation velocity (1.51±0.79 vs 1.19±0.50 cm/s, P=0.001). Lower gait speed participants also had higher left ventricular mass index (129.2±27.6 vs 120.7±23.9, P=0.005), a higher proportion of right ventricular diastolic dysfunction (60.0% vs 35.8%, P=0.016), and a higher proportion of valve calcification (57.9% vs 34.9%, P=0.006). Lower gait speed was strongly negatively correlated with left ventricular mass (LVM) (r =-0.273, P< 0.001). Within 24 months of followup, gait speed was independently predicted CVE (adjusted hazard ratio (HR)=0.402; 95% CI [0.190–0.850]; P=0.017), hospitalization (HR=0.316; 95% CI [0.193–0.518]; P<0.001), and all-cause mortality (HR=0.082; 95% CI [0.028–0.244]; P<0.001).

Conclusions: Gait speed is associated with left ventricular mass and right ventricular dysfunction in MHD patients. Gait speed is an independent predictor of all-cause mortality, hospitalization, and cardiovascular risk in Maintenance Hemodialysis Patients.

TH-PO286

Risk Factors and Characterization of Falls in Patients on Hemodialysis: A Multicenter Study

Yan-ru Chen, Huifen Han, Xiaoxia Gu, Qiuyan Li, Zengchun Ye, Hui Peng. *The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*.

Background: Hemodialysis (HD) patients have an increased risk of falls, which raises healthcare expenses in addition to morbidity and mortality. The purpose of this study was to assess the risk factors and characterize the features of falls in hemodialysis patients to provide direction for developing prevention strategies.

Methods: 820 HD patients from four hemodialysis facilities participated in this multi-center cross-sectional study. Online self-made questionnaires was used to gather general information about HD patients as well as fall characteristics. We analyzed the characteristics of fall patients and employed the multivariate logistic regression model to assess the risk factors of falls.

Results: A total of 820 hemodialysis patients were actually included in the statistics, consisting of 60.1% males (493 patients) and 39.9% females (327 patients), with an average age of 58.5±14.3 years old and a median dialysis vintage of 42 months. A total of 187 patients (22.8%) experienced falls, with an average age of 60.5 ± 14.6 years old. The incidence of falls was 19.7% (97 fallers) in males and 27.5% (90 fallers) in females. 358 falls occurred overall, of which 50.8% happened during daytime activity. 78.8% of falls led to varying degrees of injury, with the most common injury being soft tissue contusion. Falls most often occur in the living room or bedroom of the home. The leading symptoms in hemodialysis patients before falling was dizziness (26.3%) or lower limb weakness (34.4%). The results of multivariate logistic regression analysis indicated that age 65 and over (OR=1.699, 95%CI: 1.183-2.439, P=0.004), females (OR=1.505, 95%CI:1.070-2.118, P=0.019), and longer dialysis vintage (OR=1.475, 95%CI:1.224-1.779, P=0.000) were independent risk factors for falls among hemodialysis patients.

Conclusions: In summary, our results showed that the incidence of falls was higher in hemodialysis patients (22.8%), with females having a higher incidence than males. Female gender, age older than 65 years, and longer dialysis vintage are critical risk factors for falls among hemodialysis patients. Future research should explore specific interventions to reduce the risk of falls and improve the overall safety and quality of life for hemodialysis patients.

TH-PO287

Comparison of Daily Physical Activity between Dialysis Periods in Patients Undergoing Sessions Three Times per Week

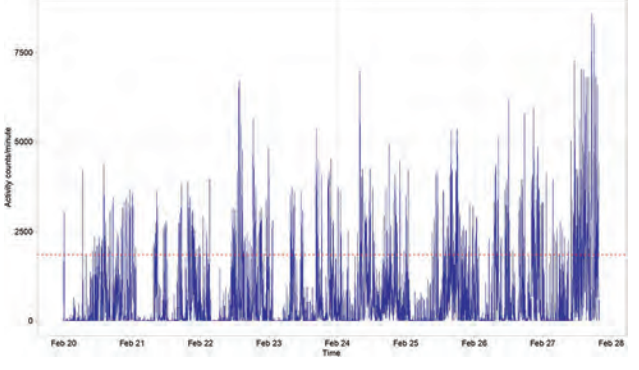
Alfredo Fuentes Mercado,[1] Salvador L. Gil,[1] Erika E. Jaime Borja,[1] Rodrigo Gopar-Nieto,[1] Pablo Martinez Amezcua.[2] *[1]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico City, Mexico; [2]Johns Hopkins University, Baltimore, MD.*

Background: Patients undergoing hemodialysis are significantly less active than healthy sedentary controls. Particularly on hemodialysis days, they have fewer steps than on interdialytic days. Accelerometers are non-invasive wearable devices that measure the acceleration of the body part they are attached to. We aimed to describe daily physical activity in patients undergoing hemodialysis sessions thrice a week and quantify differences in daily activity across inter-dialytic days and dialytic days.

Methods: This was a cross-sectional study. Patients 18 and older undergoing HD without contraindications for physical activity or major mobility limitations were included. Physical activity was measured with a wrist-worn triaxial accelerometer (ActiGraph GT9X, Pensacola, FL). Participants wore the device continuously on the non-dominant wrist for 4-8 days. Valid days had≥90% of wear time. We derived total activity counts (TAC), daily active time, and the active-to-sedentary transition probability (ASTP–a measure of activity fragmentation). We estimated differences in activity measures across interdialytic periods with mixed-effects linear models to account for the clustering of observations.

Results: Among 27 participants (mean age=39.6, [SD=12.5]; 40.7% female), the mean TAC was 2.34 million (SD=0.77 million), mean active time was 446.8 (SD=137.12) minutes, and mean ASTP was 0.25 (SD=0.07). Physical activity was lower (mean active time= -103 minutes [1 hr and 43 mins], 95% CI: -148.5 to –58.6; TAC –0.7 million, 95% CI –0.9 to -0.4), and more fragmented (AST= 0.05, 95% CI 0.03 to 0.07) on dialysis days compared to interdialytic days.

Conclusions: Our findings indicate that physical activity levels are lower and more fragmented during dialysis than interdialytic days. Future efforts should focus on promoting physical activity on dialytic days.



Activity count for a week of one of the participants in our study, an example of the data we analize for the results.

TH-PO288

Fragmented Physical Activity and Mortality in Patients on Hemodialysis: Insights from the Fitbit Study

Rakesh Malhotra,[1] Britta Larsen,[1] Subhasis Dasgupta,[1] Tushar Chopra,[6] Sarah J. Schrauben,[5] David A. Drew,[3] Talat Alp Ikizler,[4] Peter Kotanko,[2] Joachim H. Ix.[1] *[1]University of California San Diego, La Jolla, CA; [2]Renal Research Institute, New York, NY; [3]Tufts Medical Center, Boston, MA; [4]Vanderbilt University, Nashville, TN; [5]University of Pennsylvania, Philadelphia, PA; [6]University of Virginia, Charlottesville, VA.*

Background: Limited data suggest that lower physical activity (PA) overall is associated with poor health outcomes in hemodialysis (HD). Above and beyond total PA, little is known about fragmentation of PA (activity time before breaks). This study evaluates the association between PA fragmentation, and mortality risk among HD patients.

Methods: HD patients wore wearable activity trackers (Fitbit) between March 2018 and April 2020, with mortality data collected until December 2023. Minute-by-minute activity data over a 7-day period were used to categorize each minute as active (≥10 steps/minute) or sedentary (<10 steps/minute). Activity was further categorized by activity patterns: activity fragmentation (active to sedentary transition probability, calculated as the reciprocal of the average active bout duration), and segment length of consecutive active minutes (<5, 5-10, and ≥10 minutes). Cox proportional hazards models were used to assess the associations between activity patterns and mortality risk, adjusting for demographic, device wear time and comorbidities.

Results: We collected data on 85 HD patients (mean [SD] age, 62 [13] years; 45% women), 37 died (44%) during follow-up (mean [SD] of 3.1 [1.6] years. Participants who died tended to have a 10% higher activity fragmentation (mean [SD], 47% [6%] vs 37% [8%]; P<0.001), and a higher percentage of short activity segments (<5 minutes) (mean [SD], 51% [12%] vs 35% [10%]; P<0.001), than those who were alive at follow-up. In fully adjusted analyses, greater activity fragmentation was linked to an increased mortality risk (HR 1.54, 95% CI, 1.08-2.04). Short activity segments of < 5 minutes were associated with higher mortality risk (HR 1.32, 95% CI, 1.08-1.66) but activity segments of 5-10 and ≥ to minutes were not associated with mortality risk (Figure 1).

Conclusions: Our findings suggest that fragmented daily physical activity, especially short activity bouts < 5 minutes, is associated with mortality risk in HD patients.

Figure 1. Hazard Ratios for Activity Fragmentation, and Time Spent in Various Bout Lengths

Variables	Hazard ratio Unadjusted	Model 1	Model 2
Activity fragmentation*	1.80 (1.18-2.21)	1.78 (1.20-2.14)	1.54 (1.08-2.04)
Activity spent in bouts, %**			
<5 min	1.49 (1.12-1.72)	1.40 (1.14-1.75)	1.32 (1.08-1.66)
5-10 min	1.05 (0.80-1.51)	1.04 (0.81-1.54)	1.12 (0.95-1.42)
≥10 min	0.88 (0.72-0.99)	0.87 (0.70-1.16)	0.94 (0.72-1.13)

Model 1: Adjusted for baseline age, sex, and race/ethnicity.
Model 2: Model 1 + device wear time + diabetes, hypertension, heart disease, pulmonary disease
*Scaled per 10% higher degree of activity fragmentation, or a 10% higher probability of transitioning from an active to a sedentary state.
** Scaled per 10% higher activity fragmentation,

TH-PO289

Move More: Development, Testing, and Feasibility of a Patient-Centered Physical Activity Program with a Maintenance Phase for Patients on Hemodialysis

Alexis King,[1,2] Ashley Morgan.[1] *[1]University of Illinois Urbana-Champaign, Urbana, IL; [2]University of the Pacific College of the Pacific, Stockton, CA.*

Background: Individuals with end-stage kidney disease (ESKD) receiving maintenance hemodialysis (HD) often experience low physical activity (PA) levels and poor physical function (PF), contributing to reduced quality of life (QOL) and increased mortality risk. Exercise programs frequently fail to significantly improve these outcomes. This study compares the efficacy of an individualized patient-centered PA program, Move More (MM), to a standard intradialytic cycling (IDC) program in improving PF and QOL among HD patients.

Methods: Twenty-three HD participants were randomly assigned to MM (N=13) or IDC (N=10) for 14 weeks. Primary outcomes measured PA participation via a logbook and point system. Secondary outcomes assessed PF (STS-60, max handgrip strength, and normal 4-meter gait speed walk), patient reported outcomes (depression, fatigue, and perceived wellness), and program feasibility. Participants assigned to MM were encouraged to continue the program during a 12-week maintenance phase, with seven opting to proceed. The study evaluated participants' behavior towards PA participation by using the Behavior Stages of Change Questionnaire.

Results: Mean age was 63.1 (± 10) years; 73.9% male; and 65.2% Black with an average BMI of 36 (± 10.3). At 14 weeks, MM participants showed significant improvements in total PA minutes compared to IDC at 14 weeks (p=0.001) and marked improvements in 4-meter gait speed walk (p=0.006) and handgrip strength (p=0.014). No significant changes were found between groups in PF changes, though trends towards increased handgrip strength were observed (p=0.077). Additionally, MM participants PA levels and PF were maintained during the maintenance phase.

Conclusions: The MM program increased PA levels more than the standard IDC program. However, further research with larger cohorts is necessary to ascertain if MM can lead to substantial improvements in PF. The study highlights the value of a personalized PA program to diverse physical abilities and preferences, suggesting MM's potential for sustainable effectiveness in fostering a long-term PA engagement in HD patients.

TH-PO290

Chronic Pain Characteristics and Associated Symptoms in Patients on Maintenance Hemodialysis: Findings from the HOPE Consortium Trial

Michael J. Fischer,[1] Jesse Y. Hsu,[1] Joanna Walsh,[1] David M. Charytan,[1] Susan T. Crowley,[1] Daniel Cukor,[1] Laura M. Dember,[1] Ardith Z. Doorenbos,[1] Denise Esserman,[1] Manisha Jhamb,[1] Kirsten L. Johansen,[1] Francis J. Keefe,[1] Paul L. Kimmel,[2] Mark Lockwood,[1] Rajnish Mehrotra,[1] Benjamin J. Morasco,[1] Sagar U. Nigwekar,[1] Patrick H. Pun,[1] Raghd Qamhiyeh,[1] Jennifer S. Scherer,[1] Rebecca J. Schmidt,[1] Jennifer L. Steel,[1] Mark L. Unruh,[1] Jonathan G. Yabes,[1] Sahir Kalim.[1] *[1]HOPE Trial Consortium, Philadelphia, PA; [2]National Institutes of Health, Bethesda, MD.*

Background: Pain is one of the symptoms reported most frequently by maintenance hemodialysis (HD) patients. However, there is limited information on its etiologies, characteristics, and associations with other symptoms.

Methods: The HOPE Consortium Trial to Reduce Pain and Opioid Use in Hemodialysis is a multicenter randomized trial to address chronic pain in adults receiving maintenance HD. We enrolled patients with moderate or severe chronic pain on maintenance HD at 103 dialysis facilities across the US from January 2021 to April 2023. Pain interference and severity were assessed by the Brief Pain Inventory (BPI) [range 0-10]. We used multivariable regression with LASSO to examine associations between pain interference/severity and participant characteristics, and Pearson's correlation to examine relationships between pain interference/severity and other symptoms at enrollment.

Results: Among 643 participants, the median (IQR) BPI interference score was 6.6 (5.1-7.8) and severity score was 6.0 (4.5-7.5). 84% of participants experienced pain >1 year and 75% had daily pain. 89% of participants cited musculoskeletal pain and 66% cited neuropathic pain. The median (IQR) number of painful body regions was 8 (4-14), and the most common were lower back (~70%), knees (~50%), feet (~45%), neck (~40%), and hands (~40%). In multivariable regression analyses, female sex, unemployment, diabetes, cardiovascular disease, anxiety, and depression were associated with significantly greater pain interference whereas White race, non-Hispanic ethnicity, higher education, and greater years on dialysis were associated with significantly lower pain interference. PCS SF-6 (pain catastrophizing), PROMIS fatigue, PHQ-9 (depression), and GAD-7 (anxiety) scores were moderately correlated with BPI interference (r>0.4).

Conclusions: Among HD patients with chronic pain, pain characteristics were heterogeneous. Sociodemographic and psychological were more strongly associated with pain interference and severity than comorbidity and dialysis factors.

Cannabis Use in Patients on Maintenance Hemodialysis (HD) with Chronic Pain: A Secondary Analysis of the HOPE Trial

Jennifer S. Scherer,[1] Wenbo Wu,[1] James B. Wetmore,[1] Jane Liebschutz,[1] Elenore P. Bhatraju,[1] Kerri L. Cavanaugh,[1] Benjamin J. Morasco,[1] Jesse Y. Hsu,[1] Laura M. Dember,[1] Paul L. Kimmel,[2] Sahir Kalim,[1] Martin Cheatle,[1] Christopher C. Holden,[1] Joanna Walsh,[1] Caroline M. Wilkie,[1] William Becker,[1] David M. Charytan.[1] *[1]HOPE Trial Consortium, Philadelphia, PA; [2]National Institutes of Health, Bethesda, MD.*

Background: Legalization may increase cannabis use by maintenance hemodialysis (HD) patients. Data on frequency or factors associated with use by HD patients are limited.

Methods: The HOPE Consortium Trial to Reduce Pain and Opioid Use in HD is a multicenter randomized trial that enrolled patients with at least moderate chronic pain receiving HD at 103 US dialysis facilities from 01/2024 to 04/2023. Demographics, social and medical history, cannabis use, pain intensity and interference, depression, and anxiety, were collected at baseline. Multi-variable logistic regression was used to examine associations of cannabis use with baseline data.

Results: Among 643 participants, 102 (16%) reported current cannabis use, 133 (21%) former use, and 408 (63%) never used. Of current users, 39% resided in states with full cannabis legality, 40% in states that legalized use during the study, 15% in states with medical use legality, and 5% in states where medical use was legalized during enrollment. Compared to non-users/past users, current cannabis users were younger (54 vs. 63 years), more likely to be disabled (79% vs. 66%), to have received dialysis for >5 years (40% vs. 30%), to have a diagnosis of depression (41% vs. 31%), anxiety (28% vs. 20%), or any psychological disorder (51% vs. 38%), and less likely to be married (16% vs. 34%). In adjusted models, there was a lower likelihood of cannabis use in older individuals (OR=0.23 [95%CI 0.12-0.44], 0.25 [0.14-0.50], in age groups 55-65, and 65-75 respectively, compared to ages 18-55, p<0.01) and in married individuals (OR=0.49 [0.26-0.93], p =0.03). Use was more likely in current (OR=2.95 [1.51-5.76]) or former (OR=2.16 [1.20-3.91]) smokers, and alcohol users (OR=2.67 [1.32-5.41]). We did not find significant associations of cannibas use with pain or psychological measurements.

Conclusions: Cannabis use is common in HD patients with chronic pain. Younger, unmarried individuals, who use other substances may be the most likely to use cannabis.

Music Therapy for People with CKD Undergoing Haemodialysis: Rapid Systematic Review and Meta-Analysis

Yunan Han,[1] Davey Li,[1] Tanika Kelly,[2] Takeshi Hasegawa,[4] Hisashi Noma,[5] Erika Ota,[3] Taihei Suzuki,[4] Yoshitaka Watanabe,[6] Hiroi Tomioka,[6] Hiroki Nishiwaki.[2,7] *[1]University of Illinois Chicago College of Medicine, Chicago, IL; [2]University of Illinois Chicago, Chicago, IL; [3]St.Luke's International University, Chuo, Japan; [4]Showa University, Shinagawa, Japan; [5]Institute of Statistical Mathematics, Tachikawa, Japan; [6]Showa University Nortern Yokohama Hospital, Yokohama, Japan; [7]Showa University Fujigaoka Hospital, Yokohama, Japan.*

Background: Patients receiving hemodialysis (HD) experience various types of symptom burden. Anxiety, depression, and pain are common comorbidities for patients with CKD receiving HD. Randomized controlled trials have shown music to have positive health benefits among patients receiving HD.

Methods: In this systematic review and meta-analysis, we searched MEDLINE, and CENTRAL through April 2024 for interventional studies involving music-based interventions among patients on HD. Study quality was assessed using the Cochrane Collaboration risk-of-bias 2.0 tools. Across eligible studies, random-effects meta-analyses were used to combine effects of music intervention on three study endpoints; anxiety, depression, and pain in hemodialysis patients.

Results: Among the 83 citations identified by our search strategy, 19 studies met our eligibility criteria for inclusion, and 11 (total n =765) reported effect sizes and measures of variance for quantitative synthesis (7 for anxiety, 3 for depression, and 4 for pain). Music was associated with significantly decreased anxiety, with standardized mean difference (hedge's g) of -0.65 [95% CI -1.10 to -0.20, I^2=76%] compared to the control group (**Figure 1**). Depression, on the other hand, showed no statistically significant difference with a standardized mean difference of -0.56 [95% CI -1.27 to 0.15, I^2=61%] for the intervention group compared to the control group (**Figure 2**). Pain was decreased in the intervention group compared to the control group, with standardized mean difference of -1.91 [95% -2.74 to -1.35, I^2=11%] in visual analog scale (**Figure 3**).

Conclusions: Music decreased anxiety and pain among the patients with HD in the current meta-analysis.

Point-of-Care Ultrasound-Guided Cannulation of Arteriovenous Fistula Comparison with Standard Cannulation Technique: A Systematic Review and Meta-Analysis

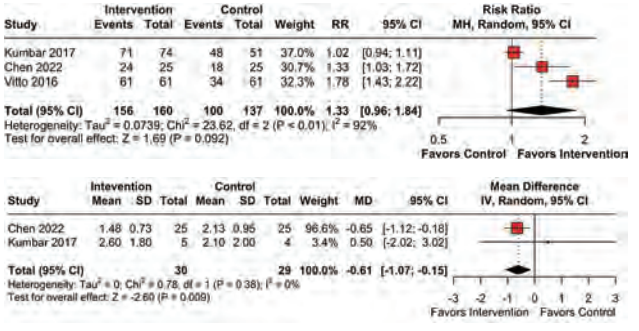
Luis Claudio Santos Pinto,[1] Jiandra Da Luz,[2] Lucas Barbosa,[3] Ofonime Chantal Udoma-Udofa,[4] João L. de Magalhães Leal Moreira,[5] Lucianna B. Luborrigueiro.[6]
[1]Metropolitan University Center of Amazon, Belem, Brazil; [2]Universidad Nacional de la Plata, La Plata, Argentina; [3]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil; [4]Universidade Federal de Juiz de Fora, Juiz de Fora, Brazil; [5]Universidade Estadual de Feira de Santana, Feira de Santana, Brazil; [6]European Atlantic University, Santander, Spain.

Background: Ultrasound-guided (US-guided) cannulation in arteriovenous fistulas (AVF) is a well-established practice for patients with kidney disease undergoing hemodialysis. Although there is no absolute consensus, studies demonstrated that US guidance increases cannulation success rates compared with conventional techniques. This meta-analysis aims to evaluate the effectiveness of US-guided compared with the standard cannulation technique.

Methods: We systematically searched PubMed, Embase, and Cochrane databases to identify randomized controlled trials (RCTs) comparing US-guided versus standard cannulation in hemodialysis patients. The primary outcome of interest was the cannulation success rate. The pain score was evaluated using the VAS score. We pooled risk ratios (RR) for binary outcomes, and mean difference (MD) for continuous endpoints with 95% confidence intervals (CI), employing a random-effects model. We used R version 4.3.2 for all statistical analysis.

Results: Our study included 5 RCTs comprising 224 patients who underwent either US-guided (40.6%) or standard cannulation(40.2%). US-guided and standard cannulation had a similar success rate (RR 1.33; 95%CI 0.96 to 1.84; p=0.09; I2=). US-guided cannulation was associated with a reduction in pain score (MD -0.61; 95%CI -1.07 to -0.15; p<0.05; I2=). There was no significant difference between groups in procedure length (MD -20.87 min; 95%CI -82.94 to 41.20; p=0.51; I2=) and complication rate (RR 0.89; 95%CI 0.55 to 1.44; p=0.64; I2=).

Conclusions: In patients undergoing hemodialysis, US-guided cannulation had a similar success rate compared with the standard technique. However, it showed a difference, albeit small, associated with reduced pain perception, providing greater comfort to the patient.



TH-PO294

Efficacy and Safety of Difelikefalin Compared with Placebo in Patients Receiving Concomitant Opioid Medication

James Burton,[1] Thilo Schaufler,[2] Satkiran Grewal,[3] Despina Ruessmann,[2] Murray Lowe,[2] Warren Wen,[4] Steven Fishbane.[5] *[1]University of Leicester Department of Cardiovascular Sciences, Leicester, United Kingdom; [2]CSL Vifor, Glattbrugg, Switzerland; [3]CleanSlate Centers Inc, Philadelphia, PA; [4]Cara Therapeutics Inc, Stamford, CT; [5]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY.*

Background: Difelikefalin (DFK) is a selective kappa opioid receptor agonist approved to treat moderate to severe CKD-associated pruritus (CKD-aP) in patients on hemodialysis (HD). Pruritus is a known side effect of mu opioid receptor agonistic drugs, but it is unknown if their concomitant use influences the antipruritic effects or safety of DFK.

Methods: Phase-3 studies KALM-1 and -2 established the efficacy and safety of DFK over placebo (PBO) in HD patients with CKD-aP. Itch intensity was assessed with the weekly mean of the Worst Itching Intensity Numerical Rating Scale (WI-NRS) measured at baseline and after 12 weeks of treatment. Patients were asked daily for the worst itch intensity in the past 24 hours from 0 (no itch) to 10 (worst itch imaginable). This exploratory post-hoc analysis of pooled KALM trial data assesses the efficacy and safety of DFK compared to PBO, dependent upon exposure to concomitant opioid medication.

Results: Of participants randomized to receiving DFK/PBO, 24.2%/30.4% were taking concomitant opioid medications. More patients treated with DFK vs. PBO achieved WI-NRS improvements of ≥3point, ≥4point and complete response (defined as ≥80% of daily scores 0 or 1) at week 12, regardless of their concomitant use of opioids (Figure). More patients on concomitant opioids reported any non-fatal treatment emergent adverse event (TEAE) independent of treatment exposure (concomitant vs. no concomitant opioid exposure: DFK: 44.7% vs. 19.0%; PBO: 38.0% vs. 15.9%). Similarly, severe TEAEs were more common in patients on concomitant opioids (concomitant vs. no concomitant opioid exposure: DFK: 22.3% vs. 10.9%; PBO: 23.3% vs. 8.1%).

Conclusions: This exploratory analysis confirms that DFK can effectively relieve CKD-aP in HD patients despite the use of concomitant opioid medications. The higher rate of TEAEs in patients receiving either DFK or PBO in combination with opioids makes careful assessment of continued use of opioid medications advisable.

TH-PO295

Influence of Concomitant Opioid Medications on Antipruritic Effect and Safety of Difelikefalin in Patients on Hemodialysis

James Burton,[1] Thilo Schaufler,[2] Satkiran Grewal,[3] Despina Ruessmann,[2] Murray Lowe,[2] Warren Wen,[4] Steven Fishbane.[5] *[1]University of Leicester Department of Cardiovascular Sciences, Leicester, United Kingdom; [2]CSL Vifor, Glattbrugg, Switzerland; [3]CleanSlate Centers Inc, Philadelphia, PA; [4]Cara Therapeutics Inc, Stamford, CT; [5]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY.*

Background: Pruritus is a known side-effect seen with mu-opioid receptor agonists, and hemodialysis (HD) patients receive such treatments. Difelikefalin (DFK) is a selective kappa-opioid receptor agonist indicated to treat moderate to severe CKD-associated pruritus (CKD-aP) in patients on HD. This exploratory post-hoc analysis assesses if using concomitant opioid medications affects efficacy or safety of DFK.

Methods: Phase-3 clinical studies KALM-1 & -2 randomized patients to receive either DFK or placebo (PBO) for 12 weeks after each HD session. Itch severity was measured daily with the Worst Itching Intensity Numerical Rating Scale (WI-NRS); patients indicated their worst itch intensity in the past 24 hours from 0 (no itch) to 10 (worst itch imaginable). We analyzed pooled KALM study data based on concomitant exposure to opioid medications.

Results: Of patients randomized to DFK/PBO, 24.2%/30.4% received other opioids. In both groups the likelihood of achieving improvements at 12 weeks in weekly mean WI-NRS scores of ≥3point, ≥4point or complete response (defined as ≥80% of daily scores 0 or 1) was not influenced by exposure to opioids (Figure). Concomitant opioid medication use was associated with a higher incidence of treatment-emergent adverse events (TEAEs) in both the DFK and PBO groups. Patients receiving opioids experienced TEAEs at a rate of 44.7% (DFK) & 38.0% (PBO) compared to 19.0% (DFK) & 15.9% (PBO) in those not on opioids. The incidence of severe TEAEs was 22.3% (DFK) & 23.3% (PBO) in patients using opioids compared to those who were not (10.9% for DFK & 8.1% for PBO).

Conclusions: Concomitant use of opioid medications did not influence the efficacy of DFK to relieve CKD-aP in HD patients. The increase in TEAEs in patients prescribed concomitant opioids in either the DFK or PBO arms indicates the importance of carefully evaluating polypharmacy, especially continuation of opioid treatments in HD patients treated with DFK for CKD-aP.

TH-PO296

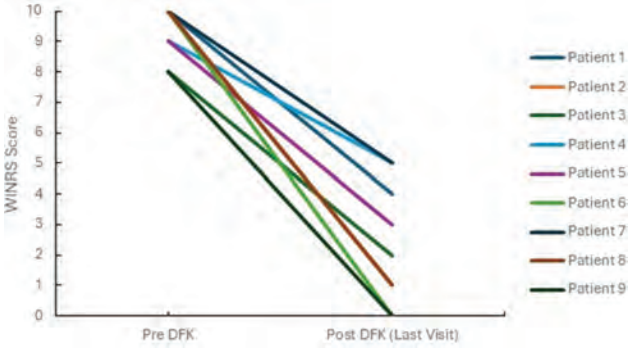
Single-Center Experience from Quebec with Intravenous Difelikefalin to Treat CKD-Associated Pruritus

Isabelle I. Letourneau, Karine Cousineau. *Centre Integre de Sante et de Services Sociaux de Lanaudiere du Quebec, Joliette, QC, Canada.*

Introduction: Chronic kidney disease-associated pruritus (CKD-aP) is a debilitating condition associated with several adverse outcomes in end-stage kidney disease patients including reduced quality of life, sleep quality, and increased mortality. There is a lack of formalized practice guidelines integrating approved new treatments for CKD-aP. Difelikefalin (DFK), a highly selective peripherally acting κ-opioid receptor agonist was approved by Health Canada in 2022 for the treatment of moderate-to-severe CKD-aP.

Case Description: Here, we report implementation of a practice changing initiative in our hemodialysis center as well as a treatment algorithm for CKD-aP. First, we screened patients for pruritus by asking them about itch. We then used the Worst Itch Numerical Rating Scale (WI-NRS) and Self-Assessed Disease Severity (SADS) scales to measure the intensity of pruritus and evaluate its impact on the patient's quality of life respectively. If WI-NRS score was ≥7 (severe) and SADS was B (moderate) or C (severe), DFK was prescribed as first-line therapy. In total, 303 patients were screened. Twelve patients had severe pruritus and were prescribed DFK. Of these patients, 9 responded with a reduction by at least 3 points on their WI-NRS and 4 patients had a complete response (Figure). In some patients, these changes correlated with an improvement in the quality of life as measured by SADS. Safety profile was acceptable. Two patients discontinued treatment due to adverse events of gait disturbance and fatigue in one and somnolence/mental status change in the other. A third patient discontinued treatment due to diagnosis of bullous pemphigus.

Discussion: Our protocol has helped us identify patients with CKD-aP in our hemodialysis center and has allowed to improve patient quality of life. Our experience represents well the feasibility to incorporate framework for screening and diagnosis as well as a treatment algorithm of CKD-aP published in a recent Canadian narrative review.



TH-PO297

Validity of a Single Worst Itch Numeric Rating Scale (WI-NRS) Measurement to Identify Patients with Moderate or Severe CKD-Associated Pruritus

Kieran Mccafferty,[1] Thilo Schaufler,[2] Isabelle Morin,[2] Warren Wen,[3] Lili Chan.[4] *[1]Barts Health NHS Trust, London, United Kingdom; [2]CSL Vifor, Glattbrugg, Switzerland; [3]Cara Therapeutics Inc, Stamford, CT; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Clinical studies use the mean of repeat measurements with the Worst Itching Intensity Numerical Rating Scale (WI-NRS) to assess itch intensity in patients. This is often difficult to implement in daily dialysis practice, raising the question whether a single measurement with the WI-NRS is sufficiently reliable to guide treatment decisions.

Methods: The WI-NRS asks patients to indicate the worst itch intensity in the past 24 hours (range 0 [no itch] to 10 [worst itch imaginable]). Phase 3 clinical studies KALM-1 and -2 demonstrated the favorable benefit–risk profile of difelikefalin over placebo in patients on hemodialysis with moderate to severe chronic kidney disease-associated pruritus (CKD-aP) and calculated the weekly mean of daily WI-NRS measurements to assess baseline itch intensity and change from baseline over up to 12 weeks of treatment. This post-hoc analysis uses the data collected to assess the Pearson correlation between the WI-NRS measurements collected on study days 29, 57, 71 and 85 and the weekly mean of the daily measurements in the respective previous study week (weeks 4, 8, 10 and 12).

Results: The Pearson correlation across all time points for the overall study population was consistent and very high (≥0.93, p<0.0001), indicating a strong correlation between the mean of multiple measurements versus a single WI-NRS measurement. A similar picture was seen when assessing the difelikefalin and placebo arm separately (Table).

Conclusions: A one-off measurement of the WI-NRS can reliably assess itch intensity and identify patients suffering from bothersome itch. Patients reporting a value of ≥4 on a single WI-NRS can be considered to suffer from moderate or severe CKD-aP, and those with a reduction of ≥3 points between two WI-NRS measurements to have a clinically meaningful improvement of their itch. These findings confirm that the WI-NRS is an easy-to-use and consistent tool that can be implemented in daily dialysis care without relevant disruptions to routine tasks.

Table: Pearson correlation between single WI-NRS and mean of the previous week's WI-NRS measurements (all p<0.0001)

	One-off, single WI-NRS (Overall / Placebo / Difelikefalin)			
Weekly mean WI-NRS	Day 29	Day 57	Day 71	Day 85
Week 4	0.930 (N=768) / 0.930 (N=388) / 0.927 (N=380)			
Week 8		0.935 (N=760) / 0.948 (N=388) / 0.920 (N=372)		
Week 10			0.940 (N=742) / 0.948 (N=382) / 0.927 (N=360)	
Week 12				0.956 (N=672) / 0.960 (N=343) / 0.950 (N=329)

TH-PO298

Gabapentin Use and Adverse Effects among Hemodialysis Patients Diagnosed with Pruritus or Neuropathic Pain in US Claims Data

Claudio Rigatto,[1] Ting Lu,[2] Thilo Schaufler,[3] Despina Ruessmann,[3] Ronald L. Pisoni,[2] Brian Bieber,[2] Angelo Karaboyas,[2] Michael Strupp.[4] *[1]Seven Oaks General Hospital, Winnipeg, MB, Canada; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Vifor Pharma Management AG, Glattbrugg, Switzerland; [4]Ludwig-Maximilians-Universitat Munchen, Munchen, Germany.*

Background: Chronic kidney disease-associated pruritus (CKD-aP) is linked with numerous clinical and patient-reported outcomes. Gabapentin (Gaba) is indicated for neuropathic pain (NP), and also used off-label to reduce pruritus symptoms. There are, however, concerns about adverse events (AEs), namely altered mental status and risk of falls. We explored real-world Gaba utilization patterns and relevant AEs in US hemodialysis (HD) patients, and how they may differ by diagnosis of CKD-aP vs. NP.

Methods: We used claims data from 533,232 adult HD patients in the USRDS database between 2016-2020 with Fee-For-Service Medicare Part D coverage. Gaba use, dose, and time to discontinuation were stratified by time-updated diagnosis of CKD-aP or NP. The associations between time-varying Gaba dose – defined as current prescription updated continuously – and six AEs were analysed by recurrent event Andersen-Gill model and adjusted for potential confounders, separately by time-updated diagnosis of CKD-aP or NP.

Results: Point-prevalence of Gaba prescription was 13.9% overall, and was higher among patients with NP (21.1%) than with CKD-aP (11.0%). Median [IQR] time to discontinuation was 5.2 [2.0, 13.0] months in the NP group and 4.2 [1.5, 11.6] months in the CKD-aP group. Mean Gaba dose was higher (503 vs. 433 mg/day) in the NP vs. CKD-aP group, and increased during the first year of use from 410 to 494 mg/day. AE rates ranged from 9.3 (fracture) to 37.8 (altered mental status) per 100 patient-years. We observed a strong dose-response association between Gaba dose and AEs, particularly among patients with CKD-aP (**Table**).

Conclusions: Use of Gaba in HD patients was associated with a higher risk of AEs (including altered mental status, dizziness, falls, and fracture), even at doses as low as 100 mg/day. The increase was greater when Gaba was used off-label in CKD-aP patients. Prescribers should consider the clinically relevant side effects of Gaba when providing treatment options to their patients with CKD-aP.

Among Gaba users, dose distribution was 17% with 100, 15% with 200, 29% with 300, 19% with 400-800, and 20% with 900+ mg/day

TH-PO299

Dedicated Patient Optimization Program Improves Lives of Vulnerable Patients

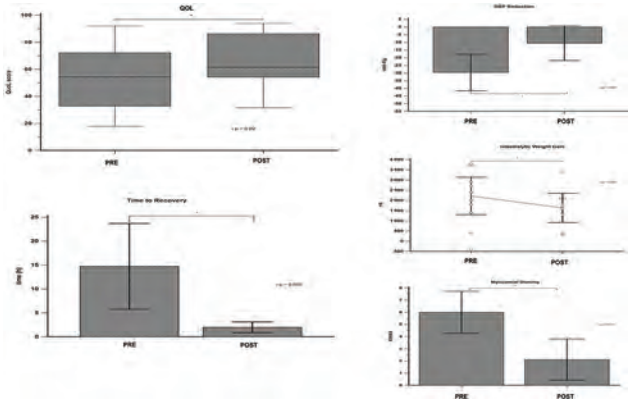
Jarrin D. Penny,[1,3] Patrik Deleaval,[2,1] Christopher W. McIntyre.[1,3] *[1]London Health Sciences Centre, London, ON, Canada; [2]NephroCare Tassin-Charcot, Saint Foy-les-Lyon, France; [3]Lawson Health Research Institute, London, ON, Canada.*

Background: Industrialized 'one size fits all' approaches to care and reliance on single intervention-based strategies results in negative outcomes for many. In response we developed and applied a systematic patient optimization program (POP) applying individualization and complex interventions to support the needs of the most vulnerable patients aiming to improve both the subjective experience and objective tolerability of dialysis.

Methods: Patients (19) with inadequate response to conventional care were identified over a 12-month period. A series of comprehensive baseline objective (physiological, hemodynamic) and subjective assessments were performed and complex foundational/patient-disease specific interventions applied and rigorously evaluated over two weeks. Subjective impact was assessed using dynamic daily patient reported outcome measures. Objective assessments (inclusion and monitoring response) included continuous hemodynamic monitoring, tissue perfusion, vascular ultrasound and intradialytic echocardiography with assessment of HD-induced cardiac injury (myocardial stunning).

Results: Nineteen patients, largely with issues related to hypotension & failure to achieve target weight- in concert with a range of negative symptoms. All patients had multiple components of dialysis altered. POP was associated with a marked improvement in a range of subjective and objective outcomes. QOL improved by 20% (p0.02), recovery time by 86% (p0.005). Reductions in intradialytic systolic BP improved by 19% (p<0.01), interdialytic weight gain 33% (p0.01) and myocardial stunning was significantly reduced (by 63% p0.01) with tight association between changes in BP (p<0.001) and ultrafiltration (p<0.05). At inclusion all patients had been declined transplantation listing, after re-evaluation 3/19 were listed and two successfully received graft.

Conclusions: A complex intervention delivered in a systematic POP improves the subjective wellbeing and objective tolerability of HD in the most challenging patients.



TH-PO300

Improving Treatment Adherence in Patients on In-Center Hemodialysis through Daily Targeted Reporting and Intervention

Sheetal Chaudhuri,[1] Joanna Willetts,[1] Trevor Halliday,[2] Melissa Hosey,[2] Len A. Usvyat,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care AG, Bad Homburg, Germany; [2]Fresenius Medical Care Holdings Inc, Waltham, MA.*

Background: In-center hemodialysis (ICHD) patients who miss prescribed treatments have an increased risk of hospitalization and mortality. We implemented daily targeted reporting (DTR) to identify patients who missed their scheduled treatment the day prior, followed by a tailored intervention to reschedule these missed treatments. Our goal is to describe treatment adherence before and after implementation of DTR and intervention.

Methods: We analyzed clinical data from ICHD patients in the periods before and after introduction of DTR across 16 clinics from a large dialysis organization. Targeted reporting of missed treatments began on 01Mar2024. Missed and ordered treatments, documented in patients' electronic health records, were summarized in the two months before (01Jan2024-29Feb2024) and after (01Mar2024-30Apr2024) initiation of DTR. DTR provided clinic staff with a list of patients who were absent during the scheduled treatment the previous day, enabling staff to reschedule treatments accordingly. Missed treatments were reported as a percent of ordered treatments and as a crude rate per patient per year (ppy). We used Analysis of Variance to test the difference in crude missed treatment rate (ppy) before and after implementation of DTR and intervention.

Results: There were 745 ICHD patients before and 722 ICHD patients after the DTR in the 16 clinics in this analysis. Demographic information for patients before and after DTR showed no significant differences. The percent of documented missed treatments decreased by nearly 6% following introduction of DTR. Crude rate ratio was 0.96 (95% confidence interval 0.80, 1.15) (Table 1).

Conclusions: Although not statistically significant, implementation of DTR suggests a reduction in missed treatments and improvement in treatment adherence in the short term. Future work includes monitoring missed treatments in these clinics to determine if DTR provides sustained reduction in missed treatment rate. Furthermore, conducting a matched analysis could offer insights into the magnitude of the effect.

Funding: Commercial Support - Fresenius Medical Care

Percent of missed treatments and missed treatment rate (ppy) before and after daily targeted reporting/intervention.

	Before (95% CI)	After (95% CI)	% Change	Rate Ratio (95% CI)	P-value
% Missed Treatments	5.34	5.02	-5.99%		
Crude Missed Treatment Rate (ppy, 95% CI)	8.06 (7.12, 9.13)	7.73 (6.79, 8.82)	-4.09%	0.96 (0.80, 1.15)	0.6497

TH-PO301

Self-Management Barriers in Patients on Dialysis: A Potential Target for Improving Clinical and Patient-Reported Outcomes

Esmee Driehuis,[1,2] Yvette Meuleman,[3] Anna A. Bonenkamp,[2] Friedo W. Dekker,[3] Alferso C. Abrahams,[1] Brigit C. van Jaarsveld.[2] DOMESTICO Study Group. *[1]Universitair Medisch Centrum Utrecht, Utrecht, Netherlands; [2]Amsterdam UMC Locatie VUmc, Amsterdam, Netherlands; [3]Leids Universitair Medisch Centrum, Leiden, Netherlands.*

Background: Self-management skills are important to dialysis patients, as they may lead to better health outcomes. However, knowledge is lacking on self-management barriers in these patients, hereby impeding identification of patients in whom self-management may be improved and how these barriers impact health. Thus, we aimed to 1) identify self-management barriers in dialysis patients, 2) assess their relation to patient characteristics and 3) assess their effect on clinical and patient-reported outcomes.

Methods: Patients from the DOMESTICO study, a cohort study in adult incident dialysis, who filled in the Self-Management Screening questionnaire were included. Descriptives of self-management barriers were reported. We determined the barriers' associations with sex, age, educational level, cohabitation, modality (hemodialysis [HD] vs. peritoneal dialysis [PD]) and multimorbidity using point bi-serial correlations. Effects of self-management barriers on health outcomes at 6 and 12 months were investigated using linear and quasi-binomial regression with adjustment for confounding.

Results: In 1518 patients, the presence of self-management barriers varied widely. For instance, most felt confident in their own abilities (self-efficacy; 84.3%), while only 43.6% reported good problem-solving coping skills. Many patient characteristics were related to self-management barriers. For example, age was associated with almost all barriers, PD patients were more willing to perform self-care (r 0.23, 95%CI 0.18;0.28), and patients with more comorbidities were less willing (-0.09, -0.14;-0.04). At 6 months, in patients with more barriers, diastolic blood pressure (DBP) was lower (β -0.51, 95%CI -0.81;-0.20), interdialytic weight gain (IDWG) was higher (0.03, 0.01;0.05), symptom burden was higher (1.99, 1.45;2.55), physical health-related quality of life (HRQoL) was lower (-0.81, -1.04;-0.57) and mental HRQoL was lower (-1.14, -1.38;-0.90). Except for IDWG, these effects persisted at 12 months.

Conclusions: We identified important self-management barriers in incident dialysis patients and their relation to patient characteristics. These barriers impact patients' DBP, IDWG, symptom burden and HRQoL, hence they may be a potential target to improve clinical and patient-reported outcomes.

TH-PO302

Translation of Interventional Study Findings into Clinical Guidelines for Adults Requiring Maintenance Dialysis

Katherine L. Hull,[1,2] Sherna F. Adenwalla,[1,2] Victoria Cluley,[4] Daniel S. March,[1] Matthew Graham-Brown,[1,2] Rahma Said,[3] James Burton.[1,2] *[1]University of Leicester Department of Cardiovascular Sciences, Leicester, United Kingdom; [2]University Hospitals of Leicester NHS Trust, Leicester, United Kingdom; [3]University of Leicester Department of Population Health Sciences, Leicester, United Kingdom; [4]University of Nottingham School of Sociology and Social Policy, Nottingham, United Kingdom.*

Background: There is a substantial gap between the evidence-base from randomised controlled trials (RCTs) and the implementation within clinical care in nephrology. This study aims to understand the factors that influence the utilisation of RCT data in nephrology clinical practice guidelines for the maintenance dialysis population.

Methods: The systematic review was registered prospectively on National Institute for Health Research's International Prospective Register of Systematic Reviews (PROSPERO, CRD42021249460). Searches were completed in MEDLINE, Embase, CINAHL, and CENTRAL. There were no limits on language or location. The search strategy was limited by publication date 01/01/2015 - 31/12/2018. Descriptive statistics are reported as frequencies with percentages and statistical testing included binomial logistic regression.

Results: 7844 records were identified; 268 RCTs with 305 associated reports were eligible. None of the eligible RCTs reported a Patient and Public Involvement and Engagement statement. Twenty-two (8.2%) of the RCTs were utilised in the nephrology clinical guidelines through 24 (7.9%) associated reports. None of the RCTs included in the guidelines were unique to the peritoneal dialysis (PD) population. Binomial logistic regression modelling suggests that RCTs included in the clinical guidelines are more likely to: have clinical effectiveness as their primary purpose; report a clinical trials registration; originate from North America; have a longer follow-up time; and publish adverse event data (Table 1).

Conclusions: Nephrology clinical guidelines are not utilising the full evidence-base of RCTs, with a preference for North American led research. There is an absence of documented patient involvement. The PD population are underrepresented. Poor study design, inconsistent reporting and a lack of external validity appears to impact the utility of RCT data in guidelines.

Variable for RCT characteristic	Co-efficient (β)	Standard Error	Odds Ratio	95% confidence interval
Constant	-4.060	0.686

TH-PO303

Evaluating Dialysis Decision-Making in Hepatorenal Syndrome

Kunal Bailoor,[1,2] Elliot Tapper,[1] Julie A. Wright Nunes.[1] *[1]University of Michigan, Ann Arbor, MI; [2]University of Michigan Center for Bioethics and Social Sciences in Medicine, Ann Arbor, MI.*

Background: Hepatorenal syndrome has been traditionally felt to have universally high in-hospital mortality without transplantation. However, the underlying data is uncertain. The question of whether to recommend initiation of hemodialysis for patients with HRS who are not considered candidates for liver transplant is therefore both clinically and emotionally difficult.

Methods: We conducted a vignette-based survey of clinicians across 3 internal medicine sub-specialties (nephrology, critical care, and palliative care) who are involved in decision making regarding dialysis initiation for critically ill patients with hepatorenal syndrome. Our vignette included a case of a critically ill patient with hepatorenal syndrome requiring multiple vasopressors who was not felt to be a candidate for liver transplantation.

Results: 53 clinicians (19 nephrology, 21 critical care, 9 palliative care, 4 trainees) responded; the majority of clinicians (77%) did not recommend hemodialysis. High distress around this decision was reported (Figure 1); this was measured with a validated scale. There were varying degrees of comfort with dialysis-decision making (Figure 2), with nephrologists reporting the lowest comfort (2.6 on 4 point Likert scale) and critical care physicians reporting the highest (2.9/4). Nephrologists reported the highest increase in distress when colleagues disagreed with their decision; all clinicians reported increases in distress with family disagreement.

Conclusions: Decision making about dialysis initiation in the critically ill patient with hepatorenal syndrome provokes distress in all clinicians involved, though distress and comfort with decision making varies among specialties. Further research into what underlies these differences and how best to support clinicians is needed.

Figure 1: Clinician Distress by Specialty

TH-PO304

Uncoordinated Care: Decreasing Unnecessary Lab Work in Patients on Dialysis

Jonathan Hall, Sesha Pavan K. Myneni, Nathaniel Leonardi, David A. Mcmillan, Ryan Mullane. *University of Nebraska Medical Center, Omaha, NE.*

Background: The KDOQI clinical practice guidelines recommend avoiding unnecessary venipuncture in patients with end-stage kidney disease (ESKD). Patients on maintenance dialysis have routine blood work. Redundant diagnostics at primary care clinics result in increased frequency of venipuncture, cost of care, and administrative burden. Unfortunately, dialysis unit diagnostics are not consistently available to primary care providers (PCP). We present a quality initiative to identify the extent of this problem and address it through an iterative process of improvement.

Methods: A deidentified analytics report included patients with ESKD based on ICD-10 codes who had lab work ordered at our affiliated primary care clinics. Kidney transplant recipients were excluded. Institutional lab components were used to collect information on ambulatory orders redundant with dialysis labs. This included the number of orders over a specified period and the ordering clinic. PCPs completed surveys regarding how they access dialysis labs, if such access would decrease the number of tests ordered, and their familiarity with what routine dialysis studies entail. Education on access to certain dialysis units' lab results and what labs are routinely ordered was sent by email followed by a repeat survey.

Results: Between February 2023 and January 2024, 191 patients with ESKD underwent at least 1536 venipuncture events for redundant testing. The median number of metabolic panels per patient was 5 (IQR 3-11). Initial surveys were completed by 42 of 113 PCPs (37%). 90% could not access dialysis labs and 92% would order less tests with access to these results. Three months post-education, 3 of 20 clinics decreased the number of metabolic panels ordered on ESKD patients by 16.9-41.7%, but no significant change was noted overall. 27 PCPs (24%) completed repeat surveys. 85% still could not access dialysis labs and 83% were not familiar with what these studies entail.

Conclusions: Dialysis patients frequently undergo unnecessary diagnostics. Access to dialysis studies and familiarity with dialysis lab monitoring could decrease redundant ordering practices. An estimation of the costs of care is underway. Focus groups and in-person provider education will be held at primary care clinics. Further progress will require collaboration with PCPs, dialysis units, and health system informatics.

TH-PO305

Inpatient vs. Outpatient Dialysis Transition and Hospitalization Outcomes in a National Cohort of Patients with Advanced CKD

Ji Hoon Yoon,[1] Kamyar Kalantar-Zadeh,[2] Yoko Narasaki,[1] Amy S. You,[1] John J. Sim,[4] Csaba P. Kovesdy,[3] Alejandra Novoa Vargas,[1] Danh V. Nguyen,[5] Connie Rhee.[1] *[1]University of California Los Angeles, Los Angeles, CA; [2]Harbor-UCLA Medical Center, Torrance, CA; [3]The University of Tennessee Health Science Center, Memphis, TN; [4]Kaiser Permanente Southern California, Pasadena, CA; [5]University of California Irvine, Irvine, CA.*

Background: Advanced CKD patients transitioning to ESKD have high morbidity and mortality in the first few months of dialysis initiation. We sought to determine whether transitioning to dialysis in the inpatient vs. outpatient setting is associated with differential hospitalization outcomes among incident ESKD patients.

Methods: We examined advanced CKD patients (≥2 eGFRs <25 separated by ≥90 days) who transitioned to dialysis within 2-yrs of their 1st (index) eGFR <25 over 1/1/07-6/30/20 from the OptumLabs® Data Warehouse (OLDW), which contains de-identified administrative claims, including medical/pharmacy claims and enrollment records for commercial/Medicare enrollees, and EHR data. We compared hospitalization rates among patients who transitioned to dialysis in the inpatient vs. outpatient setting matched by propensity score (PS) in a 1:1 ratio with a caliper distance of ≤0.2 to address confounding by indication in Poisson models.

Results: Among 84,915 advanced CKD patients who transitioned to dialysis, 20,617 patients who transitioned to dialysis in the outpatient setting were PS-matched to 20,617 patients who transitioned to dialysis in the inpatient setting. In PS-matched models, outpatient dialysis transition was associated with lower hospitalization rates vs. inpatient dialysis transition within 1-yr and 2-yrs after the index eGFR date: IRRs (95%CI) 0.54 (0.53-0.54) and 0.60 (0.60, 0.61), respectively. Similar findings were observed in sensitivity analyses doubly-adjusted for PS-score covariates.

Conclusions: In a national cohort of advanced CKD patients transitioning to ESKD, outpatient dialysis was associated with lower hospitalization rates vs. inpatient dialysis transition.

TH-PO306

Association of Primary Care Continuity with Home Dialysis, Transplantation, and Utilization of Medical Services for Patients Starting Hemodialysis

Cole Wyman,[1] Maya Djerboua,[2] Kristin Clemens,[3,2] Manish M. Sood,[4] Samuel A. Silver.[2,5] *[1]Queen's University, Kingston, ON, Canada; [2]Institute for Clinical Evaluative Sciences, Toronto, ON, Canada; [3]Division of Endocrinology and Metabolism and Department of Epidemiology and Biostatistics, Western University, London, ON, Canada; [4]University of Ottawa Faculty of Medicine, Ottawa, ON, Canada; [5]Division of Nephrology, Kingston Health Sciences Center, Queen's University, Kingston, ON, Canada.*

Background: Primary care involvement may help patients starting dialysis with care coordination and support. It is unknown whether higher primary care physician (PCP) continuity associates with increased utilization of medical services or helps support patients towards home dialysis and kidney transplantation.

Methods: Using administrative databases in Ontario, Canada, we conducted a population-based study of patients initiating maintenance hemodialysis between 2007 and 2017. We defined PCP continuity as a high usual provider of care index, >75% of PCP visits with the same PCP in the 2 years before dialysis (an established measure of PCP continuity). We used propensity scores to match patients with high and low continuity so that indicators of baseline health were similar. The primary outcomes were time to home dialysis (peritoneal or hemodialysis) and kidney transplantation, adjusted for the competing risk of death. Secondary outcomes included specialist visits, cancer screening, influenza vaccination, and measures of diabetes care.

Results: We identified 9530 matched pairs. High PCP continuity was not associated with increased home dialysis transfer (14.0 events per 100 person-years versus 14.0 events per 100 person-years; hazard ratio 1.00; 95% CI 0.97-1.04) or kidney transplantation (4.3 events per 100 person-years versus 4.5 events per 100 person-years; hazard ratio 0.97; 95% CI 0.90-1.04). There were no differences in utilization of medical services, with the exception of high PCP continuity associated with greater colon cancer screening (hazard ratio 1.07, 95% CI 1.01-1.14), influenza vaccination (hazard ratio 1.33, 95% CI 1.27-1.39), and comprehensive diabetes care (hazard ratio 1.23, 95% CI 1.14-1.33).

Conclusions: High PCP continuity during the transition to dialysis was not associated with increased utilization of home dialysis or transplantation and had only small effects on preventative services outside of influenza vaccination and comprehensive diabetes care. Given the competing health and time demands of patients on maintenance hemodialysis, additional work is needed to clarify how primary care may benefit this patient population.

TH-PO307

Review of Hospital Admissions for Urgent Dialysis Initiation among Patients with Stage 5 CKD

Johanna Marie S. Orejo. *Boston Medical Center, Boston, MA.*

Background: Patients with advanced CKD may present to the emergency department with unplanned and urgent indications to start dialysis. Lack of patient preparedness and an urgent start to dialysis are associated with higher morbidity.

Methods: This QI project utilizes EMR for chart review of adult patients who were admitted to our institution from January 2023 to December 2023, and who required hemodialysis initiation. We particularly focused on the review of the CKD stage 5 patients that were followed in the CKD clinic.

Results: There was a total of 146 patients who were admitted for urgent dialysis initiation. 74 patients (51%) had CKD stage 5. Among this cohort, 59 of these patients were followed in our CKD clinic. 42 patients (71%) did not have any vascular access, 11 patients (19%) had mature AVF/ AVG, and 6 patients (10%) either had non-mature or non-functioning AVF/AVG. The average length of hospital stay was 22.5 days. 11 patients (18%) required medical ICU admission for emergent dialysis start. A review of the CKD clinic visits reveals that in 67% of the patients, dialysis education with Kidney Smart (Davita) was offered, however, only half attended and expressed their modality of choice. 21% of the patients had short (<6 months) dialysis planning time due to their advanced presentation and lost to follow-up, and 12% were not interested in GOC discussion, kidney education, and dialysis planning. Other factors that were identified include language barrier, lack of social support, untimely Nephrology and Vascular surgery referral, late initiation of GOC discussion, and unpredictable timing of kidney function decline and symptoms.

Conclusions: Among CKD5 patients, suboptimal dialysis planning leads to urgent and unplanned admission for HD initiation. These patients receive a higher intensity of care, have longer hospital stays, and have higher medical costs. Factors are multifactorial including lack of patient education, untimely Nephrology and Vascular referral, and late initiation of GOC discussion, among others. Optimal dialysis planning should focus on early patient education and GOC discussion and improving pre-dialysis care that involves a multidisciplinary team, timely referral, frequent follow-up, and access to different members of the care team. A risk prediction tool (KFRE) and a dialysis planning list (EPIC smart phrase) may be of utility.

TH-PO308

Association of Heavy Precipitation with In-Center Dialysis Treatment Absenteeism

Adam G. Walker,[1] Carey Colson,[1] Scott Sibbel,[1] Mesbah Ahmad,[2] Francesca Tentori,[1] Steven M. Brunelli.[1] *[1]Davita Clinical Research, Minneapolis, MN; [2]DaVita Inc, Denver, CO.*

Background: Dialysis treatment absenteeism (i.e., skipping a treatment for reasons other than hospitalization) is associated with greater risk for poor clinical outcomes. Adverse weather (e.g., excessive rainfall or snow accumulation) may pose additional challenges to treatment attendance for dialysis patients dependent upon public transportation or ride assistance. We sought to examine the impact of heavy precipitation on absentee rates.

Methods: This study retrospectively compared absentee patterns at 2,780 dialysis clinics at a kidney care organization in the United States on days with and without precipitation during the first half of 2022 (rain or snow, considered separately). Precipitation data was gathered from the Global Historical Climatology Network

(GHCN) for weather stations near all clinics included in the analysis. Weather patterns and absences were considered daily for each clinic during the study periods (excluding Sundays). Associations were estimated using a linear mixed model with a random intercept for clinic using a zero-inflated Poisson distribution adjusted for day of the week, calendar month, and United States census region. The number of absences attributed to precipitation during the study period were estimated using a recycled predictions method based on observed proportion of days above the thresholds for rain or snow.

Results: Average absences were 4.0% relatively greater on days with ≥ 0.5 inches of rain than on days with <0.5 inch of rain (4.2% vs. 3.8%). Absences were 52% relatively greater on days with snow vs. days without snow (6.5% vs. 3.8%). Snow related absentee rates are higher for the Southern region (12.5%) than the Midwestern, Northeastern, or Western regions of the US (6.2%, 4.8%, and 5.4% respectively).

Conclusions: These results suggest that weather patterns are associated with dialysis absences; snow had a greater impact compared to rain. Proactive rescheduling during periods of inclement weather may represent an opportunity to improve clinical outcomes and treatment adherence. Transit authorities that facilitate nonemergent medical transportation should ensure outreach to dialysis patients before arrival of inclement weather.

	Rain <0.50 inches	Rain 0.50+ inches	Did not snow	Snowed
Treatments, n	10,738,565	562,196	6,968,714	467,833
Missed Treatments, n (%)	412,906 (3.8%)	23,470 (4.2%)	265,008 (3.8%)	30,632 (6.5%)
aIRR (95% CI) [a]	-	1.04 (1.03-1.06)	-	1.52 (1.49-1.55)

Cardiac Arrest in Dialysis Units: A National Cross-Sectional Survey Evaluating the Experience of Dialysis Technicians

Benjamin P. Catanese,[1,2] Laura J. Fish,[4] Jeeyon G. Rim,[1,2] Audrey L. Blewer,[3] Margaret Falkovic,[4] Patrick H. Pun.[1,2] *[1]Duke University Health System, Durham, NC; [2]Duke University Duke Clinical Research Institute, Durham, NC; [3]Duke University School of Medicine, Durham, NC; [4]Duke University, Durham, NC.*

Background: Cardiac arrest is the number one cause of death for hemodialysis patients, and often occurs in outpatient dialysis clinics. Immediate cardiopulmonary resuscitation (CPR) decreases mortality, but CPR is not performed during some cardiac arrests in dialysis clinics. Dialysis technicians are the most common first line providers within US outpatient dialysis clinics, but little is known about their training, experience, and preparedness to provide CPR. We conducted a nationwide survey to understand barriers to CPR among dialysis technicians.

Methods: We conducted a cross-sectional survey of National Association of Nephrology Technicians/Technologists members. The survey was distributed via email and at a national conference. Questions included details about current dialysis unit, demographics, basic life support (BLS) training, experience with cardiac arrests, confidence in performing the steps of BLS, and rating of potential barriers to CPR in the dialysis clinic. Data were analyzed using descriptive statistics.

Results: 101 technicians completed the survey, with a median work experience of 10 years. 75% reported BLS training within the past year, 88% had knowledge of a unit-specific CPR protocol and 74% had participated in mock codes. 80% witnessed a dialysis clinic cardiac arrest (median 4 cardiac arrests witnessed). For patients who had an in chair intradialytic cardiac arrest, technicians reported that CPR was performed 53% of the time in the dialysis chair and 47% on the floor (moved from the chair). Respondents reported high levels of confidence for performing each step of BLS (65%±7% selecting the highest level on a 5-point Likert scale), but only 33% reported the same level of confidence that their dialysis team could resuscitate a patient that arrested. The most significant barriers to performing CPR in the dialysis clinic were delay in recognizing the patient had a cardiac arrest (44%) and fear of harming the patient (41%).

Conclusions: Despite a high proportion citing completion of best practice CPR training, 2/3 of dialysis technicians did not feel highly confident that their teams could resuscitate patients. Novel barriers to CPR include delay in cardiac arrest recognition, lack of agreement in positioning of patients for CPR, and fear of harming patients during CPR.

Is the Preferred Place of Death Met in Patients on Dialysis? A Systematic Review

Marc L. Boereboom,[1] Joost Verbruggen,[1] Maurice Theunissen,[2] Jmh Joosten,[3] Marieke H. van den Beuken-van Everdingen,[2] Marc H. Hemmelder,[4,5] Pim Bouwmans.[4,5] *[1]Universiteit Maastricht Faculty of Health Medicine and Life Sciences, Maastricht, Netherlands; [2]Center of Expertise for Palliative Care, MUMC+, Maastricht, Netherlands; [3]Division of General Medicine, Department of Internal Medicine, Section of Geriatric Medicine, MUMC+, Maastricht, Netherlands; [4]Department of Internal Medicine, Division of Nephrology, Maastricht University Medical Center, Maastricht, Netherlands; [5]CARIM School for Cardiovascular Diseases, University of Maastricht, Maastricht, Netherlands.*

Background: Dialysis patients' palliative care needs are frequently unmet. An important aspect of palliative care is to timely determine the preferred place of death. In this study, we questioned what the preferred place of death is in dialysis patients, and whether this is met at time of death.

Methods: A systematic review was performed searching PubMed for studies on palliative care and preferred place of death in adult dialysis patients. Articles were screened by two observers on title, abstract and full text. Risk-of-bias was assessed with a tool for prevalence studies (Hoy et al.).

Results: We included nine studies that reported a preferred place of death. The majority of patients (67-75%) preferred to die out-of-hospital. Janssen et al. reported the preferred place of death in 206 Dutch patients with end-stage organ failure as being at-home in 51%, in a hospital in 30%, in a nursing home or hospice in 10%, and unknown in 9%. Davison et al. observed similar rates of preferred death out-of-hospital in 238 Canadian predialysis patients, 295 dialysis patients and 51 kidney transplant recipients. Other studies did not specify the preferred out-of-hospital place of death. Four studies reported the actual place of death and observed an out-of-hospital death in between 42 and 80% of cases. Out-of-hospital death was reported more frequently in patients who were receiving palliative care, had advance care planning or opted for dialysis withdrawal. Most out-of-hospital deaths occurred at home. Janssen et al. observed that 39% of patients died at their preferred place of death.

Conclusions: A large majority of dialysis patients prefer to die out-of-hospital, yet their preference is often not met at time of death. Advance care planning, palliative care and dialysis withdrawal emerged as factors that promote an out-of-hospital death. Comprehensive documentation of wants, values and needs for palliative care is warranted to enhance alignment with dialysis patients' preferences.

TH-PO311

A Comparative Study of Health-Related Quality of Life between Patients on Maintenance Hemodialysis and Kidney Transplant Recipients

Bala Waziri,[1] Aishatu M. Nalado.[2] *[1]Ibrahim Badamasi Babangida University, Lapai, Nigeria; [2]Aminu Kano Teaching Hospital, Kano, Nigeria.*

Background: It is generally recommended that patients with end stage kidney disease (ESKD) should be offered kidney transplantation, as this modality of renal replacement therapy (RRT) has been shown to improve health related quality of life (HRQOL) and a better life expectancy.

Methods: This cross-sectional multicenter study included KTRs with functioning grafts and patients on MHD from three major transplant centers and five dialysis units in Nigeria. Quality of life was assessed with the Kidney Disease QOL-SF-36 (version 1.3) questionnaire. Multivariable linear regression was used to assess differences in mean HRQOL scores between KTRs and HD patients.

Results: Four hundred and ninety-nine (293 HD patients, 98 KTRs, and 108 healthy controls) participants were enrolled into the study. Both HD patients (47.2±14.0 years) and KTRs (46.5±11.4 years) were significantly older than the healthy controls (32.2±9.7 years, p<.0001). Higher proportion of KTRs (81.6%) obtained tertiary education as compared with HD patients (66.9%). The distribution of gender was similar between HD patients and KTRs. With the exception of bodily pain, KTRs had significantly higher HRQOL mean scores in the eight subscales of the SF-36 than HD patients: physical functioning (73.8 ±25.3 versus 52.7±27.5;p<.0001), log role-physical (4.4±0.4 versus 3.8±0.6; p<.0001), bodily pain (79.1±25.8 versus72.7±25.5; p=0.10), general health (73.8±23.2;p<.0001), vitality(65.1±15.0 versus 57.2 ;p=0.002), social functioning (62.5±24.6 versus 50.6±25.0; p<.0001), log role emotional (4.3±0.4 versus 4.1±0.5; p=0.01) and mental health (84.7±16.7 versus 72.3±17.9; p<.001). Except for mental health and social functioning, the subscale scores and the two Mental Component Summary (MCS) and Physical Component Summary (PCS) measures for KTRs and healthy controls did not differ. KTRs have higher PCS (46.8±9.1 versus 38.2±8.8; p< .0001) and MCS (50.1±8.1 versus 43.9±9.1; p<.0001) scores than HD patients. Having kidney transplant is significantly associated with higher PCS score (β coefficient: 8.33; 95% confidence interval: 5.08- 11.58; P<.0001) and higher MCS score (β coefficient: 6. 29; 95% confidence interval: 3.11-9.47; P<.0001).

Conclusions: Kidney transplant recipients have a better health related quality of life than hemodialysis patients and comparable HRQOL scores to healthy individuals

TH-PO312

Usefulness of Central Concentrate Delivery System for Health Care Workers: A Questionnaire Survey

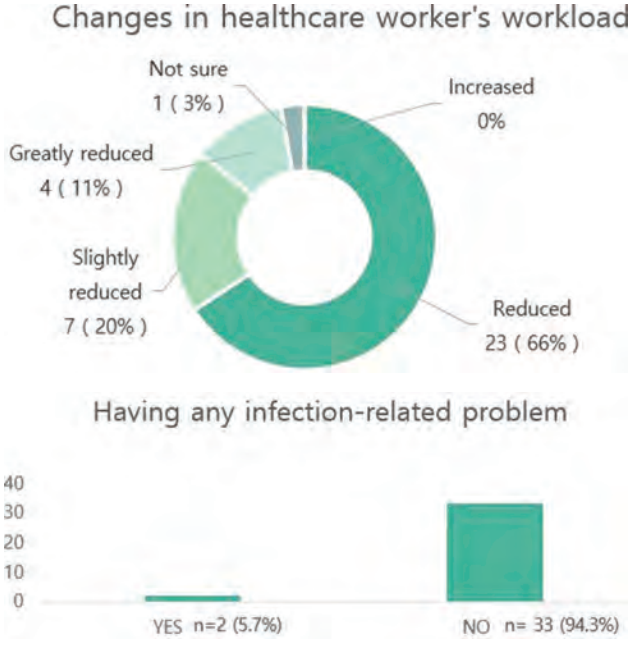
Seokjin Hwang, Sua Lee, Soyoung Lee, Bo Sun Park, Kewon Baik.
Daejeon Eulji University Hospital, Daejeon, Republic of Korea.

Background: In South Korea, the Central Concentrate Delivery System (CCDS), which centralizes the preparation of dialysate with concentrate solutions for multiple patients and distributes it to each dialysis machines, was introduced in the early 2000s. However, there was a lack of research conducted from the perspective of the healthcare workers. Therefore, this study revealed the usefulness of CCDS for healthcare workers.

Methods: Among the dialysis hospitals currently using CCDS, questionnaires were sent to 60 dialysis facilities whose address and contact address were confirmed.

Results: Responses from 35 institutions were received and analyzed. Of the institutions that responded, 21 (60%) were primary healthcare facilities, 4 (11%) were secondary healthcare facilities, and 7 (20%) were tertiary institutions. The average usage period of CCDS across all facilities was 8.1±4.2 years. The most common reasons for introducing CCDS were for reducing healthcare workers' loading and creating a pleasant environment. Economic feasibility was second reason for introducing CCDS. In terms of healthcare workers' workload after the implementation of CCDS, none of the respondents reported an increase. 65% stated that there had been a decrease, and 12% reported a substantial decrease. This indicates that overall, the workload has significantly reduced. When asked if they had ever had an infection-related problem in dialysis system, 2 of the 35 institutions surveyed reported, had an infection problem while using CCDS, and the remaining institutions reported no infection problem.

Conclusions: The CCDS appear to be labor-saving and environmentally friendly in the dialysis facilities without increasing infection-related problem. Further study is needed to determine the effect and safety of CCDS.



TH-PO313

Plastic Neutrality in Green Dialysis: A Pilot Study Exploring Plastoconcrete for Circularity

Ravichandran Palani. *Saveetha Medical College Department of General Medicine, Chennai, India.*

Background: Dialysis treatment generates substantial plastic waste, with 41% constituting the total waste stream. Traditional disposal methods (incineration, pyrolysis) worsen carbon emissions. landfill or recycling are legally restricted. This study investigates plastic neutrality as a solution, focusing on the use of surrogate plastic pebbles in plastoconcrete (PC) for a circular economy.

Methods: We converted 2,000 dialysis-equivalent plastic waste units into pebbles and distributed them to institutions for conversion into PC bricks, planters, and Ganesha idols. After six months, we compared PC products against traditional alternatives (kiln-baked bricks, plastic pots) in terms of strength, durability, and cost-effectiveness. Additionally, we assessed the effectiveness of Ganesha idols in raising awareness.

Results: Our findings demonstrate successful conversion of 4 tonnes of plastic waste into 2.8 tonnes of pebbles. Six polytechnic colleges and four NGOs utilized the pebbles, each processing an average of 250 kg. PC bricks exhibited superior strength, reduced weight, and cost-competitiveness compared to kiln-baked bricks (cost: 50 cents/kg). PC planters offered enhanced durability and aesthetics, effectively replacing plastic pots in college gardens. The distribution of Ganesha idols to healthcare professionals served as impactful awareness tools.

Conclusions: Plastoconcrete is a promising solution for achieving plastic neutrality and fostering a circular economy in green dialysis. Future research will focus on scalability, long-term impact, and the integration of a plastic credit model into green dialysis.

Institution Students making plastoconcrete bricks, pots and finished items

TH-PO314

Canadian Wildfires of 2023 and Risk of Mortality and Hospitalization among ESKD Patients

Hyeonjin Song. *University of Maryland College Park, College Park, MD.*

Background: Climate change driven droughts are increasing frequency and intensity of wildfires, a significant source of air pollution. Smoke plumes from the 2023 Canadian wildfires travelled long distances and negatively impacted air quality across large swaths of eastern US. We investigated the association between exposure to 2023 Canadian wildfire-related air pollutants and risk of mortality and hospitalization among hemodialysis patients in New England, the Mid-Atlantic, and the Midwest U.S.

Methods: The study population includes the end stage kidney disease patients (N=52,995) receiving hemodialysis treatment at Fresenius Kidney Care clinics located in New England, the Mid-Atlantic, and the Midwest U.S. during June-July 2023. Daily number of all-cause deaths, all-cause hospitalizations, respiratory disease hospitalizations, and cardiovascular disease hospitalizations were counted for each hemodialysis clinic. Presence and absence of wildfire smoke plume and wildfire-related fine particulate matter ($PM_{2.5}$) concentration were assessed using both satellite-derived smoke polygons and ground-based $PM_{2.5}$ monitors. We constructed a retrospective observational study using a time-stratified case-crossover analysis with a conditional quasi-Poisson model to investigate the risk of mortality and hospitalization associated with exposures to wildfire-related air pollutants.

Results: Canadian wildfires of 2023 significantly increased air pollution level across the dialysis clinics in the study area, with the highest daily wildfire-related $PM_{2.5}$ concentration reaching 251.1μg/m^3. The presence of wildfire smoke plume was associated with an 18% increase in risk of same day (lag0) all-cause mortality (rate ratio [RR]:1.18; 95% confidence interval [CI], 1.13-1.24) and a 3% increase in risk of all-cause hospitalization (RR:1.03; 95% CI, 1.00-1.07). A 10-μg/m3 increase in wildfire-related $PM_{2.5}$ was associated with a 139% increase in same day all-cause mortality (RR: 2.39; 95% CI, 1.79-3.18), and a 33% increase in all-cause hospitalization (RR:1.33; 95% CI, 1.10-1.62).

Conclusions: Our data suggest that air pollution from the 2023 Canadian wildfires resulted in increased risk of mortality and hospitalization among hemodialysis patients in New England, the Mid-Atlantic, and the Midwest U.S.

TH-PO315

Impact of Comprehensive Predialysis Education (CoPE) on Rural Veterans' Informed Kidney Replacement Therapy (KRT) Selection

Anuradha Wadhwa,[1] Shobha Subhash,[2] Kailyn Pearce,[2] Grant D. Scheiffele,[2] Xiangyang Ye,[3] Adhish Agarwal,[3] Ashutosh M. Shukla.[2,4] *[1]Edward Hines Junior VA Hospital, Hines, IL; [2]VA North Florida South Georgia Veterans Health System, Gainesville, FL; [3]VA Salt Lake City Health Care System, Salt Lake City, UT; [4]University of Florida Health, Gainesville, FL.*

Background: CoPE has a significant impact on patients' informed KRT modality choice; however, the prevalent state of informed dialysis selection patterns and the impact of CoPE among rural Veterans is unknown.

Methods: We conducted a prospective cohort study across five Veteran Healthcare systems in FL, UT, and IL to evaluate the impact of CoPE on rural Veterans' KRT decision-making. Informed modality selection was defined as KRT modality selection with more than 60% confidence on a 0-100%, 5-point Likert scale. Differences in ability to make a modality selection were assessed pre- and post-CoPE by various patient-level characteristics.

Results: Of the 218 Veterans with advanced CKD who received CoPE during fiscal years 2023 and 2024, only 9.0% reported receiving prior CoPE. Pre-CoPE, fewer than half (38.5%) of patients endorsed a hypothetical KRT modality; however, post-CoPE nearly all (94.5%) did. Home dialysis KRT preferences additionally rose significantly from 21% pre-CoPE to 82% post-CoPE (p=0.04, Table 1). Optimal health literacy score, advanced (Stage 5) CKD, and hypertension comorbidity were each independently associated with higher odds of KRT selection pre-intervention; however, post-CoPE KRT modality endorsement differed significantly only by CKD/ESRD awareness measures ($p<0.05$).

Conclusions: Our study shows significant deficits in access to CoPE and poor baseline state of dialysis decision-making among rural Veterans with advanced CKD. Substantial improvement both in Veterans' confidence in modality selection and selection of home dialysis KRT methods were noted after provision of education. Importantly, CoPE appeared to attenuate patient-level differences in ability to endorse a KRT modality preference in our sample. System-wide assessment and implementation of CoPE can improve Veteran confidence in dialysis selection and home dialysis utilization.

Funding: Veterans Affairs Support

KRT selections pre- vs. post-CoPE

Patient Selection	Pre-CoPE	Post-CoPE
Peritoneal dialysis	16 (7.5%)	160 (73.4%)
Home hemodialysis	30 (13.8%)	19 (8.7%)
In-center hemodialysis	17 (7.8%)	18 (8.3%)
Conservative care	21 (10.0%)	9 (4.1%)
Informed KRT Selection		
Yes (61 – 100% confident)	34 (15.6%)	187 (85.8%)
No (0 – 60% confident)	50 (22.9%)	19 (8.7%)

TH-PO316

Towards a Greener Practice: Implementation of Continuous Kidney Replacement Therapy Waste Reduction

Megan M. Moore,[1] Theresa A. Mottes,[3] Jennifer L. Daniel,[4] Gracious Sarasak,[1] Sameer Thadani,[2,1] Kristin J. Dolan,[2,1] Michael C. Braun,[2,1] Ayse Akcan Arikan.[2,1] *[1]Texas Children's Hospital, Houston, TX; [2]Baylor College of Medicine, Houston, TX; [3]Ann and Robert H Lurie Children's Hospital of Chicago Foundation, Chicago, IL; [4]Imagine Pediatrics LLC, Nashville, TN.*

Background: Dialytic therapies are significant contributors to the medical carbon footprint. With the increasing prevalence of continuous renal replacement therapy (CRRT) in pediatric patients, there is a need to implement systematic waste-reduction strategies to mitigate the environmental impact and increase long-term sustainability. We noted 12% of CRRT fluid bags dispensed monthly were wasted for a multitude of reasons within our health system. We utilized implementation science methodology to unpack the complex workflow and identify barriers and facilitators of pharmacy and other system processes to reduce medical waste for our CRRT program.

Methods: We leveraged Expert Recommendations for Implementing Change (ERIC) to assess drivers of CRRT waste and manage change. A multidisciplinary expert panel was assembled to map change objectives and manage change. We identified process problems (incorrectly timed daily dispensing [before daily rounds]), prescriber and pharmacist knowledge gaps, communication barriers between unit pharmacists and prescribers as barriers. Between 2019 and 2022, numerous interventions were implemented to decrease dialysate and replacement fluid bag waste including increasing awareness to the problem through education, process standardization, electronic medical record (EMR) embedded decision aids, and standardization of replacement fluids.

Results: Following the first phase of multidisciplinary team education, monthly fluid waste decreased from 12% to 9.3% over 13-months from July 2019 to July 2020. With EMR optimization and process enhancement in August 2020, monthly waste decreased by another 1.8% to 7.5% by February 2022. With standardization of replacement fluids, our monthly waste decreased by an additional 3.7% to 3.8% by December 2023. Overall, our interventions reduced monthly waste by 8.2% for an annual cost savings of $34,079 (28%).

Conclusions: Identification of systematic processes resulting in waste with structured change management through multidisciplinary team engagement can lead to reductions in overall dialytic therapies related waste. Future studies should continue to evaluate methods to decrease the impact of dialytic therapies on our environment.

TH-PO317

When the Crystals Do Not Align: A Rare Case of Sevelamer-Induced Colonic Ulceration and Crystal Deposition

Uma Mahesh R. Avula, Aun Muhammad, Saleha Aziz, Namrata Paladugu, Mohammad Atari, Mohamed Hassanein. *The University of Mississippi Medical Center, Jackson, MS.*

Introduction: Sevelamer is a commonly used non-calcium-based phosphate-binding agent designed to reduce serum phosphate levels in patients with end-stage kidney disease (ESKD). Severe gastrointestinal injury induced by Sevelamer is uncommon but noteworthy. We present a rare case of Sevelamer-induced colonic ulceration with crystal deposition and colitis.

Case Description: A 64-year-old male with a history of heart failure with reduced ejection fraction, coronary artery disease, ESKD on intermittent hemodialysis, and a previous cerebrovascular accident was admitted for acute hypoxic respiratory failure and septic shock. His hospital course was complicated by atrial flutter, which required a heparin drip that was discontinued after he developed melena with severe anemia. A gastroenterology consultation led to a colonoscopy with biopsy, which revealed a fragment of granulation tissue with ulceration containing Sevelamer crystals consistent with Sevelamer-induced colitis. There were no chronic ischemic changes in the intact colonic mucosa, suggesting the possibility of acute ischemia or Sevelamer-related injury. Consequently, Sevelamer was discontinued. Due to the worsening of his comorbid conditions, the patient was transitioned to comfort care, and dialysis was withdrawn.

Discussion: Crystal deposition by ion-exchange resins like Sevelamer can result in inflammation, mucosal damage, and ulceration. While Sevelamer is generally well tolerated while causing mild gastrointestinal side effects such as nausea, vomiting, constipation, flatulence, and diarrhea, cases of more severe gastrointestinal mucosal injury have been associated with its use. Albeit rare, Sevelamer-induced colitis should be included in the differential diagnosis of gastrointestinal bleeding in patients with ESKD. This case contributes to the growing evidence of significant gastrointestinal complications related to Sevelamer.

TH-PO318

Blood Volume Monitoring in Hospitalized Patients with ESKD and Heart Failure

Christopher El Mouhayyar, Ayman Al Jurdi, Tianqi Ouyang, Mengyao Tang, Sahir Kalim, Sagar U. Nigwekar, Annie Liu. *Massachusetts General Hospital, Boston, MA.*

Background: Heart failure (HF) is the leading cause of hospitalization in people with end-stage kidney disease (ESKD). The co-occurrence of ESKD and HF increases this likelihood. This study assesses the association between blood volume monitoring (BVM) guided hemodialysis (HD) and clinical outcomes in ESKD patients with HF admitted for HF exacerbation.

Methods: This multicenter retrospective cohort study, conducted between January 2017 and January 2020, included 278 hospitalized HD-dependent individuals with HF admitted for HF exacerbation. BVM was either applied or not according to the admitting hospital's protocols. BVM use was confirmed based on manual patient chart review. Data for demographics, comorbidities, and clinical parameters were extracted from the electronic health records.

Results: 278 patients were hospitalized between 2017 and 2020 (mean age: 70 years, 58% males, 62% white) with an average index hospitalization of 7 days [(interquartile range) IQR: 4.00, 11.75]. 168 patients (58%) were dialyzed with BVM while 118 (42%) were dialyzed without BVM during hospitalization. Multivariable adjusted analyses showed that BVM-guided HD was associated with a shorter length of stay (difference of -2.00 days, 95% confidence interval (CI) -3.90 to -0.13), reduced number of readmissions within 90- (adjusted Beta Coefficient= -0.27, 95% CI: -0.48, -0.06) and 180-days post-discharge (adjusted Beta Coefficient= -0.47, 95% CI: -0.48, -0.06) compared to assignment to without BVM guidance. During 2015 and 2017, BVM was not utilized at MGH and BWH, 100 patients dialyzed independent of BVM showed no difference in all endpoints.

Conclusions: BVM use was associated with shorter length of stay and lower number of readmits in patients with ESKD hospitalized for HF.

Associations of Blood Water Cleared during a Dialysis Session Scaled to Body Surface Area with Weight-Specific Mortality Risk

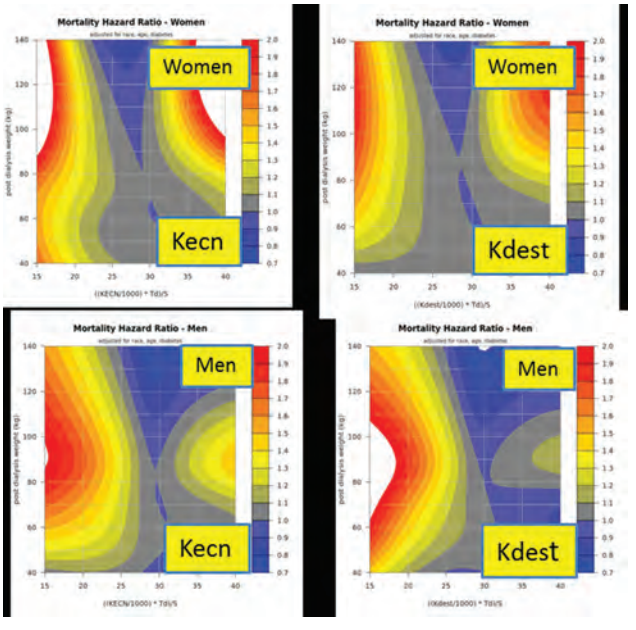
John T. Daugirdas,[1] Ariella E. Mermelstein,[2] Yuedong Wang,[3] Jochen G. Raimann,[2] Peter Kotanko.[2,4] *[1]University of Illinois Chicago College of Medicine, Chicago, IL; [2]Renal Research Institute, New York, NY; [3]University of California Santa Barbara, Santa Barbara, CA; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Lowrie et al (Kidney Int, 2005) suggested using volume of blood water cleared during a dialysis session (K x t) normalized to body surface area (S) for a size-dependent adequacy target.

Methods: We examined associations between estimated K (Kdest, vivo/vitro KoA ratio of 0.43) or measured K (conductivity, Kecn) scaled to S (Dubois equation) and survival for different strata of post-dialysis weights (W). Mean dialysis dose data were analyzed from the US Fresenius Kidney Care database for 1 year after dialysis initiation (baseline) and deaths were counted over the next 2 years. To investigate the joint effect of Kt/V or Kt/S and W on survival, we fit Cox proportional hazards models using bivariate tensor product spline functions and constructed contour plots of W-specific mortality hazard ratios over the entire range of dialysis dose values and W.

Results: In 233,293 patients, mean Kecn x t was 57 ± 7.4 liters/session in men, 53 ± 7.1 in women. Mean Kdest was 57 ± 6.2 liters/session in men, 53 ± 6.3 in women. Contour plots suggested a Kt/S target which decreased risk had somewhat plateaued of 37 – 10/W liters/m^2 for either sex, for both Kecn and Kdest, but mortality risk increased more steeply in men when dose fell below this value. For unknown reasons, mortality risk was higher in heavier patients (>80 kg), especially women, when Kt/S was greater than 32 liters/m^2.

Conclusions: Our findings agreed with Lowrie et al, that a Kt/S adequacy target would need to be scaled to patient size (either as S or W). Increased mortality in patients given very high doses of dialysis was a surprising finding and deserves further study.



TH-PO320

Low-Cardiac Output State in Children and Young Adults on Maintenance Hemodialysis

Golnaz Sadeghiani,[1,4] Sameer Thadani,[1,4] Jessica Geer,[1] Christin N. Silos,[1,4] Alexandra Idrovo,[3] Rinaldo Bellomo,[2] Poyyapakkam Srivaths,[1,4] Ayse Akcan Arikan.[1,4] *[1]Texas Children's Hospital, Houston, TX; [2]Centre for Integrated Critical Care, The University of Melbourne, Melbourne, VIC, Australia; [3]The University of Texas Southwestern Medical Center, Dallas, TX; [4]Baylor College of Medicine, Houston, TX.*

Background: Intermittent hemodialysis (iHD) induces circulatory strain and impairs myocardial dynamics. Maturing cardiovascular system in children may create an additional risk for iHD induced myocardial dysfunction. We used continuous electrocardiometry to measure cardiac index (CI) and stroke volume index (SVI) in children on maintenance iHD.

Methods: Prospective observational study of patients <21 years on 3/week 4-hour maintenance iHD at Texas Children Hospital. We collected hemodynamic data (CI, SVI) with ICON (Berlin Germany Ospky medical) during the first treatment of the week. Baseline CI and SVI were measured at the initiation of iHD and continuously thereafter for 240 minutes.

Results: 14 patients with median iHD vintage 14 months (9-24) were included. The median ultrafiltration rate was 10ml/kg/hr (6-13) The baseline CI was 3.37 +/- 0.69 L/min/m^2 while the nadir CI was 2.60 +/-0.48 L/min/m^2. 3 (21%) patients had a baseline CI <3L/min/m^2. CI decreased in the majority of patients (13/14, 93%). The mean change in CI was - 21%+/- 14% (Figure 1). The baseline SVI was 39.7 +/- 7.3 ml/m^2 and the nadir SVI was 29.7 +/- 5.4 mL/m^2. SVI decreased by 23% +/- 15% (Figure 2). 7 (50%) patients developed a low cardiac output state (CI<2.5).

Conclusions: Asymptomatic children and young adults on maintenance iHD experience >20% decrease in CI and SVI. Despite fewer cardiovascular comorbidities than their adult counterparts, iHD can induce myocardial dysfunction in children. Association of these cardiovascular changes with markers of other end organ injury should be further investigated.

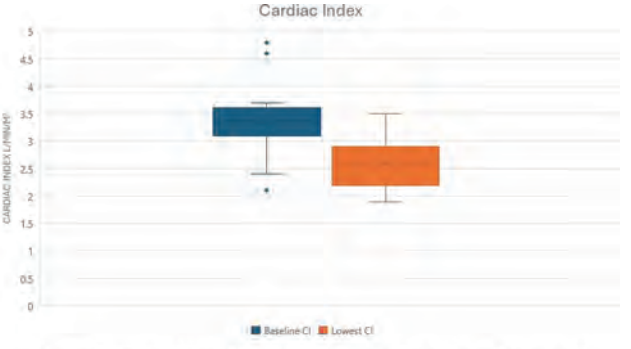


Figure 1: Baseline (blue), Lowest (orange) cardiac index during intermittent hemodialysis.

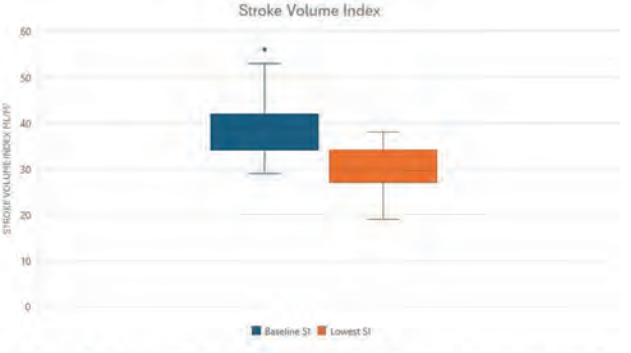

Figure 2: Baseline (blue), lowest (orange) stroke volume index during intermittent hemodialysis.

TH-PO321

Changes in Relative Blood Volume during Hemodialysis: An Extensive US Cohort

Vincent Filardi,[1] Andrea Nandorine Ban,[1] Lin-Chun Wang,[1] Xiaoling Ye,[1] Peter Kotanko,[1,2] Hanjie Zhang.[1] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Specific hourly intradialytic relative blood volume (RBV) ranges are associated with lower all-cause mortality in chronic hemodialysis (HD) patients (Preciado, NDT 2019). However, the intradialytic RBV levels in large US population is unknown. The goal of our research was to fill this knowledge gap by exploring the intradialytic RBV levels at a session level in a large US HD population.

Methods: Hematocrit was measured every 10 seconds during an HD session with the Crit-Line Monitor (CLM; Fresenius Medical Care, Waltham, MA). The CLM then reports the RBV every 10 seconds. Data were uploaded to the cloud in real time. We analyzed CLM data collected from 1/14/2021 to 7/30/2023. We aggregated RBV values into intervals at 30, 60, 90, 120, 150, 180, 210, and 240 minutes into the HD session. To accomplish this, we averaged the RBV data between 20 and 40 minutes as the 30-minute interval, 50 and 70 minutes as the 60-minute interval, and so on. Sessions with less than 1 hour of data or an average RBV value outside the 90% to 110% range during 5 to 20 minutes into the treatment were excluded. Finally, an interval was excluded if it had less than 5 minutes of data or an average value outside 75% to 115%.

Results: We analyzed 71,984 patients from 719 HD clinics. Over the final 4,798,225 treatment sessions, Figure 1A shows the distribution of intradialytic RBV per 30-minute interval. Figure 1B shows the distribution of treatments relative to the favorable RBV ranges by hours into the HD session.

Conclusions: Our findings indicate, at the session level, a slightly higher prevalence within the favorable hourly RBV ranges, lower prevalence above the ranges, and higher prevalence below the ranges when compared to Preciado (NDT, 2019). We hypothesize that this variation may indicate improved fluid management. The clinical correlates of this finding warrants further research. TH-PO322

Evaluating Microcirculation Changes in Patients with ESKD during Hemodialysis Using Conjunctival Capillaroscopy

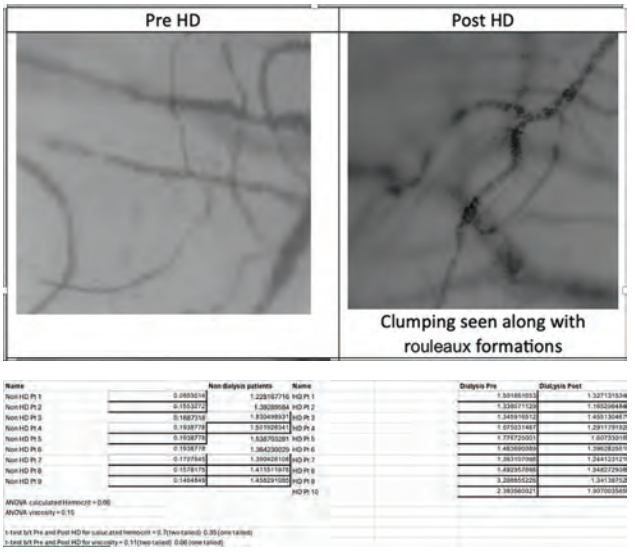
Sylvester Barnes IV,[1,2] Bruce I. Gaynes,[1,2] Abedelkarim M. Murrar.[3] *[1]Loyola University Medical Center, Chicago, IL; [2]Edward Hines Junior VA Hospital, Hines, IL; [3]University of Illinois Chicago, Chicago, IL.*

Background: During hemodialysis, there appears to be an internal viscosity change in RBCs, leading to a decrease in their deformability. This change results in a rouleau formation with concurrent changes in microcirculation viscosity.

Methods: Microcirculation impairment is an independent predictor of organ dysfunction and death. Sublingual capillaroscopy has been utilized to visualize capillary flow; however, microcirculation flow in the eye is more representative of the cerebral circulation. We have adapted a commercial sublingual capillaroscopy for use in the conjunctival tissue bed to obtain vessel diameter and blood flow velocity. From Pries et al. discharge hematocrit (Hd) $v_b / v = H_D + (1 - H_D) * (1 + 1.7e^{(-0.415D)} - 0.6e^{(-0.011D)})$ was obtained, then in-vivo viscosity using $\eta_{vivo} = [1 + (\eta - 1) * ((1 - H_D)^C - 1) / ((1 - 0.45)^C - 1) * (D / (D - 1.1))^2] * (D / (D - 1.1))^2$ where $\eta = 6e^{(-0.085D)} + 3.2 - 2.44e^{(-0.06D^0.445)}$ was calculated. Previously non-physiologic viscosity was reported.

Results: Our previosuly reported findings in ESRD patients appear to demonstrate profound abnormalities in RBC aggregation and RBC density in the microvasculature post-HD (Figure 1). We postulated that this would cause a significant change in in-vivo viscosity. However, there was no statistical difference between calculated hematocrit levels or viscosity levels, although with a p-value of 0.06, the decrease in viscosity is close.

Conclusions: Our sample size limits the power of the study. These results show promise in that measured velocity values using capillaroscopy, with calculated in vivo vessel hematocrit and in-vivo viscosity, are within physiological range and provide a valuable way to measure real-time in-vivo blood flow characteristics pre and post HD. With more patient recruitment the power of sour study should increase.



TH-PO323

Hyponatremia Treatment: Improving the Rate of Overcorrection

Shlomo Greenberg, Sanjeev Gupta, George N. Coritsidis. *Westchester Medical Center, Valhalla, NY.*

Background: Hyponatremia, an electrolyte disorder resulting from impaired free water excretion, requires tailored treatment based on its etiology and severity. The goal of treatment is to raise serum sodium (Na+) levels safely to avoid osmotic demyelination syndrome (ODS). The object of this study was to institute a protocol in the emergency department (ED) that would decrease the incidence of overcorrection.

Methods: A prospective, single-center study was conducted at Westchester Medical Center (WMC) between January and April 2024. Adult patients presenting to the ED with Na+ ≤125 mmol/L were included. A protocol was initiated requiring the ED physician to assess urine Na and osmolality (osm), implement cautious use of intravenous (IV) fluids, and consult nephrology. Overcorrection was defined as a serum Na+ correction exceeding 8 mmol/L within the first 24-hours. Excluded from the study were transfer patients, patients with hyperglycemia induced hyponatremia, and patients who didn't stay a full 24 hrs. Data was collected on patient comorbidities, urine and serum osm, use of IV fluids, and efforts to slow overcorrection. The data was compared to retrospective data of adult patients presenting to the WMC ED between 2019 and 2022 with serum Na+ ≤125 mmol/L.

Results: Between 2019-2022, 89 out of 477 patients (19%) experienced overcorrection. Notably, 42% were on medications associated with hyponatremia (thiazides or psychiatric drugs), and 15% had cirrhosis or congestive heart failure. Most patients (76%) received empiric IV fluids, and 68% had urine osmolality <300 mmol/L. After implementing the protocol (January to April 2024), 11 patients had a Na+ ≤125 mmol/L. Four patients were excluded. Among the remaining 7 patients, 2 (29%) were on hyponatremia-associated medications, and 3 (42%) had cirrhosis or CHF. Only 1 patient (14%) overcorrected, and that patient had received empiric IV fluids and had an initial urine osm<300. This patient corrected by 9 mmol/L, and D5W was administered to rectify the overcorrection.

Conclusions: Our retrospective data highlights a 19% overcorrection rate in hyponatremia, a potentially significant risk for ODS. Early renal intervention, as observed in our prospective study, improved the overcorrection rate through collaboration between the ED and the nephrology division. Further investigation is warranted to further analyze the benefits of the hyponatremia protocol.

TH-PO324

Efficacy of Low-Dosage Tolvaptan for Treatment of Profound Hyponatremia in Syndrome of Inappropriate Antidiuresis: An Open-Label Randomized Controlled Trial

Pajaree Krisanapan, Sutatip Chinpraditsuk, Narongchai Jaiyen, Pichaya Tantiyavarong, Pattharawin Pattharanitima. *Thammasat University Hospital, Khlong Nueng, Thailand.*

Background: It is commonly accepted that the first-line treatment of syndrome of inappropriate antidiuresis (SIAD) is fluid restriction (FR). However, the second-line treatments are still controversial among guidelines. This study investigates whether

tolvaptan is more effective than FR combined with furosemide (FSM) and sodium chloride (NaCl) tablets in treating SIAD patients who likely to fail from FR alone.

Methods: We conducted a 28-day single-center, open-label, randomized controlled trial in patients with profound hyponatremia (serum sodium concentration, [Na+] ≤ 125 mmol/L) who showed signs of FR failure in SIAD. Patients were randomly assigned to either the tolvaptan group (received tolvaptan 7.5 mg/day) or the control group (received FR of 800 ml/day, FSM 20–40 mg/day, and NaCl 3 g/day). The primary endpoint measured the change in [Na+] from baseline to day 4. The protocol was registered on thaiclinicaltrial.gov (TCTR20210628004).

Results: In the analysis of 29 patients (13 on tolvaptan and 16 on control), baseline [Na+] averaged was 120 ± 3 mmol/L in both groups. Tolvaptan significantly increased the change in mean [Na+] on day 4 compared to the control with 12.2±3.4 and 6.3±6.0 mmol/L (p=0.004), respectively. Notable differences persisted days 7 and 14 but not at day 28 (Figure 1A). The actual [Na^+] was shown on Figure 1B. At days 4, the proportion of patients with [Na+] ≥ 130 mmol/L was achieved by 76.9% on tolvaptan and 25% on control (p = 0.009). Median time [IQR] to restore [Na+] ≥ 130 mmol/L was 2 [1, 14] days with tolvaptan and 14 [3, 14] days with control (p=0.059). In terms of safety, tolvaptan showed fewer cases of hypokalemia (p=0.044) than the control. However, 3 tolvaptan patients developed sodium overcorrection without statistical significance (p=0.078).

Conclusions: In profound SIAD with clinical features suggesting failure with fluid restriction alone, tolvaptan significantly increases [Na+] without causing significant sodium overcorrection.

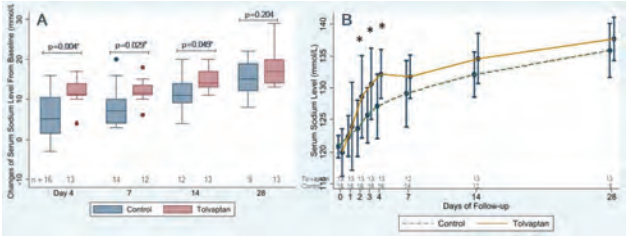


Figure 1A and 1B

TH-PO325

Electronic Alerts (E-alerts) for Electrolyte Disturbances

Miho Murashima,[1,2] Minamo Ono,[1] Masashi Mizuno,[1] Kodai Suzuki,[1] Yuki Miyaguchi,[1] Takahisa Kasugai,[1] Tatsuya Tomonari,[1] Takayuki Hamano.[1]
[1]Nagoya Shiritsu Daigaku, Nagoya, Japan; [2]Kinki Daigaku, Higashiosaka, Japan.

Background: The impacts of e-alerts for acute kidney injury on outcomes have been debated. We implemented e-alerts for electrolyte disturbances, which are common but often overlooked or mismanaged. The study aims to examine the changes introduced by e-alerts for electrolyte disturbances.

Methods: This is a retrospective observational study at Nagoya City University Hospital. E-alerts for electrolyte disturbances were implemented in May 2021. The criteria for e-alerts were serum sodium <125 or >160 mEq/L, potassium <2.5 or >6.0 mEq/L, corrected calcium <7.5 or 11.5 mg/dL, and magnesium <1.0 or >4.0 mg/dL. The following outcomes were compared 1 year before and after the initiation of the e-alerts: nephrology referral for electrolyte disturbances; for those with hyponatremia, the proportion of patients with measurement of urinary sodium concentration and osmolarity, length of stay, the number of falls during hospitalization, and overcorrection of hyponatremia. Descriptive statistics were used except for the number of referrals and falls, which were compared by Poisson and negative binomial regression, respectively.

Results: The number of electrolyte measurements was 185,305 and 19,238 one year before and after the initiation of e-alerts. The nephrology referrals for electrolyte disturbance increased from 5.6 to 9.7 per month (incidence rate ratio [IRR]: 1.75 (1.13-2.76)). Among those with hyponatremia, the proportion of patients with urinary sodium concentration and osmolarity measured increased from 34.9% to 47.2%. The length of stay decreased from 27 (15-47) to 20 (12-36) days for those with hyponatremia, whereas the length of stay did not change for those without hyponatremia. The number of falls was lower after initiating e-alerts (IRR: 0.82 (0.44-1.50)), though not statistically significant. The number of overcorrections of hyponatremia decreased from 22.1% to 15.3%. Eight out of 27 patients referred for hyponatremia within 1 year after the initiation of e-alerts were diagnosed with syndrome of inappropriate antidiuretic hormone secretion and tolvaptan improved hyponatremia in 4 patients.

Conclusions: E-alerts for electrolyte disturbances increased nephrology referral, urinary sodium and osmolarity measurements, decreased length of stay, falls, and the overcorrection of hyponatremia.

TH-PO326

Exploring the Effectiveness of Urea in Hyponatremia Due to Syndrome of Inappropriate Antidiuretic Hormone Secretion: A Comprehensive Systematic Review and Meta-Analysis

Abhi Lohana,[1] Fnu Shivani,[5] Sejal Neel,[4] Subhash Chander,[3] Syed Adil Mir Shah,[2] Neeharika Muddana.[1] *[1]Camden Clark Medical Center, Parkersburg, WV; [2]Dow Medical College, Karachi, Pakistan; [3]Mount Sinai Beth Israel Hospital, New York, NY; [4]Hackensack Meridian Jersey Shore University Medical Center, Neptune, NJ; [5]Ascension Saint Joseph - Chicago, Chicago, IL.*

Background: Syndrome of Inappropriate Antidiuretic Hormone Secretion (SIADH) often leads to hyponatremia, posing significant health risks. Management strategies include urea administration, targeting osmotic diuresis, and Vaptan Receptor Antagonists (VRAs). This study systematically reviews the effectiveness of urea compared to VRAs and other interventions in increasing plasma sodium concentration among SIADH patients.

Methods: A comprehensive search yielded 16 relevant studies on urea treatment for SIADH-related hyponatremia. Meta-analysis assessed serum sodium level changes, considering treatment duration and SIADH severity. Safety profile analysis included adverse events.

Results: Urea significantly increased serum sodium levels (MD = 9.08, 95%CI: 7.64, 10.52, P < 0.01), with enduring efficacy over varying time frames. Subgroup analyses revealed comparable outcomes across different treatment durations and a severity-dependent effect favouring urea in severe SIADH cases. Serum urea levels significantly rose post-treatment (MD = 31.66, 95%CI: 16.05, 47.26, P < 0.01). Urea outperformed fluid restriction in increasing serum sodium (MD = 7.99, 95%CI: 6.25, 9.72, P < 0.01), with similar efficacy to VRAs. Meta-regression indicated urea's efficacy correlated inversely with SIADH severity. Urea was generally tolerable, with distaste as the primary adverse event.

Conclusions: Urea demonstrates consistent efficacy in raising serum sodium levels in SIADH-related hyponatremia, with a safety profile comparable to other treatments. Its enduring impact, even in severe cases, underscores its clinical significance as a management option. However, further randomized controlled trials are warranted to validate these findings and elucidate optimal treatment protocols.

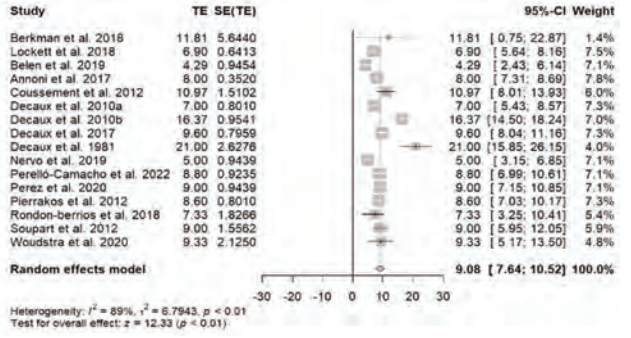

Figure 1. Forest plot shows serum sodium level change from the baseline after urea administration.

TH-PO327

Analysis of Sodium in Inpatients, Outcomes, and Nephrology Engagement (ASIN-ONE): A Study on Nephrology Referral Timing in Hyponatremic Adult Patients at a Tertiary Hospital

Charles Michael T. Herrera, Andrew Timothy Qua, Adrian L. Santos, Janice Jill Lao.
Philippine General Hospital, Manila, Philippines.

Background: Hyponatremia is the most common inpatient electrolyte abnormality. Earlier referral to a nephrologist may shorten hospitalization and improve patient survival.

Methods: This was a 6-month retrospective cohort study of nephrology referrals in a tertiary hospital. We analyzed four groups based on days from admission to referral (<1d, 1-<3d, 3-7d, and >7d) for length of stay, in-hospital mortality, and hyponatremia resolution. Kaplan-Meier curves and Cox proportional hazard regression were done.

Results: Of the 800 patients analyzed, overall mortality was 31.87%. Those referred <1d from admission had significantly shorter hospitalization (median 8.41 vs. 24.57 days) and significantly lower mortality (26.04% vs. 51.35%) than the >7d group. The 3-7d group had a higher risk of death than the <1d group (HR 2.91, 95% CI, 1.94–4.36). Kaplan-Meier curves revealed decreased survival in patients referred >72 hours from admission. There was no significant difference across groups in terms of normonatremia attainment prior to discharge or mortality.

Conclusions: Earlier nephrology referral was associated with decreased hospital stay and mortality. Significant divergence in in-hospital mortality was seen in hyponatremic patients referred more than 72 hours from admission.

Hospital Outcomes	Timing of Referral from Admission (Days)				
	<1 Day	1-<3 Days	3-7 Days	>7 Days	p-value
Length of Stay, Days [Median (IQR)]	8.41 (10.15)	10.55 (10.255)	10.27 (12.82)	24.565 (27.62)	<0.001
In-hospital Mortality [Frequency (%)]	132 (26.04%)	46 (31.94%)	39 (52.00%)	38 (51.35%)	<0.001

Genotype, Phenotype, and Follow-Up in Taiwanese Patients with Congenital Nephrogenic Diabetes Insipidus

Min-hua Tseng,[1] Shih-Hua P. Lin.[2] *[1]Chang Gung Memorial Hospital Linkou, Taoyuan, Taiwan; [2]Tri-Service General Hospital, Taipei, Taiwan.*

Background: Genotype, phenotype, and follow-up outcome in Taiwanese patients with congenital nephrogenic diabetes insipidus (CNDI) due to arginine vasopressin V2 receptor (*AVPR2*) and the aquaporin 2 (*AQP2*) genetic mutations are not well evaluated. To investigate the phenotypic, genetic characteristics, and outcomes in the Taiwanese families with CNDI.

Methods: Twenty-seven patients (M:F=21:6, age 22 ± 17) with CNDI belonging to eighteen unrelated Taiwanese families were enrolled. Genomic DNA from blood leukocytes was analyzed for *AVPR2* and *AQP2* genes mutations. deamino D-arginine vasopressin (dDAVP) stimulation was administered to separate these two gene mutations. Clinical symptoms and biochemical studies at the first presentation as well as follow-up were examined.

Results: Of the 27 patients with CNDI, 17 have *AVPR2* mutations and 10 have *AQP2* mutations. Eleven mutations, including 6 missense, 3 novel small deletion, and 2 large deletion mutation, and four mutations, including Q57P, G100V, 592InsC, and R253Dfs*82 were identified in *AVPR2* and *AQP2* gene, respectively. Q57P and G100V of *AQP2* were recurrent, and Q57P exerted a founder effect. All patients developed phenotypic polyuria and polydipsia. All patients with *AVPR2* mutations lack of normal hypotensive and coagulation responses to dDAVP. One symptomatic female patient with heterozygous V115X mutation in *AVPR2* gene had inactivated X chromosome in another allele. Three patients who carried same mutation (F178Q) from one family have different phenotypic severity. Seven patients have non-obstructive hydroureteronephrosis. Seven patients, 4 *AVPR2* and 3 *AQP2* mutations, reached chronic kidney disease (CKD, stage III-V) during the follow-up.

Conclusions: Q57P in *AQP2* is the Taiwanese founder mutation. Non-obstructive hydroureteronephrosis is not uncommon complication. Chronic kidney disease should be aware in congenital NDI cases caused by either *AVPR2* or *AQP2* mutations.

Funding: Government Support - Non-U.S.

X Marks the Salt: A Case of Pseudohyponatremia Due to Lipoprotein X

Madison B. Calder,[1] John M. Duch.[2] *[1]The University of Texas Health Science Center at San Antonio, San Antonio, TX; [2]Audie L Murphy Memorial Veterans' Hospital, San Antonio, TX.*

Introduction: Pseudohyponatremia is a lab artifact produced when *indirect* ion-selective electrode (I-ISE) laboratory instruments, which incorporate a pre-measurement dilution step, measure serum sodium in the presence of abnormally increased non-aqueous components (e.g., protein/lipid). Instruments utilizing *direct* ion-selective electrode (D-ISE) technology are not affected; a marked discrepancy in serum sodium concentrations obtained with I-ISE and D-ISE instruments can be revealing. We present a case of pseudohyponatremia due to lipoprotein X (Lp-X).

Case Description: A 34-year-old man was admitted to the hospital with jaundice and abdominal pain. Examination was notable for normal mentation, scleral icterus, and hepatomegaly. Abdominal ultrasonography demonstrated severe hepatic steatosis. Initial laboratory studies performed using an I-ISE autoanalyzer were notable for severe hyponatremia, mild hyperglycemia, hyperbilirubinemia, and elevated ethanol level. Further diagnostic workup revealed significantly elevated lipids and a sodium value within normal limits obtained using a D-ISE analyzer. Subsequent agarose gel lipid pheresis suggested markedly elevated Lp-X. His clinical status and lab values improved with supportive care, nearly normalizing by six months after ethanol cessation (**Table 1**).

Discussion: Lp-X is an abnormal lipoprotein rich in unesterified cholesterol and phospholipids with similar density to low density lipoprotein molecules. Obstructive cholestasis causes reflux of lipid fractions from bile into plasma and can lead to serum Lp-X elevations. Treatment involves reversing the cholestatic liver disease. Importantly, our patient's triglyceride level of 1252 mg/dL would only be expected to lower his serum sodium by approximately 2 mEq/L using proposed estimating equations, much less than was observed. Until Lp-X levels normalize, accurate serum sodium determination requires *direct* potentiometry analysis. Failure to promptly recognize pseudohyponatremia can lead to inappropriate therapy with disastrous consequences.

	Day 0	Day 1	Day 7	Day 200	Reference
Serum sodium, I-ISE (mEq/L)	112	114	120	140	136-145
Serum sodium, D-ISE (mEq/L)	–	137	137	137	136-145
BUN (mg/dL)	11	8	14	–	8-20
Glucose (mg/dL)	143	128	97	–	70-99
Ethanol (mg/dL)	117	<10	–	–	< 5
Serum osmolality (mOsm/kg H_2O)	285	278	–	–	275-295
Cholesterol (mg/dL)	1862	2004	1620	274	<200
Triglycerides (mg/dL)	1252	880	–	–	<150
Total bilirubin (mg/dL)	17.9	15.0	5.5	0.2	.3-1.0
Alkaline phosphatase (U/L)	637	611	484	89	30-120
Total protein (g/dL)	3.8	3.4	4.2	7.4	5.5-9.0

Table 1. Laboratory value trends throughout the patient's hospitalization managed with supportive care and alcohol cessation. Day 0 represents the date of initial hospital admission. Na, sodium; BUN, blood urea nitrogen; I-ISE, indirect ion sensitive electrode / indirect potentiometry; D-ISE, direct ion sensitive electrode / indirect potentiometry.

TH-PO330

A Case of Acute Symptomatic Hyponatremia from Self-Infusion of D5W into the Abdomen and Scrotum

Nicholas M. Malchione,[1] Benjamin S. Horowitz,[2] Jonathan Lebowitz.[3]
[1]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; [2]Columbia University Irving Medical Center, New York, NY; [3]Princeton Hypertension Nephrology Associates, Princeton Junction, NJ.

Introduction: Hyponatremia can develop when the amount of free water intake is greater than the free water excretory capacity of the kidneys. This is most commonly seen in primary polydipsia, which is characterized by large intake of water typically in patients with psychiatric conditions. Here we present a case of acute symptomatic hyponatremia as a consequence of self-infusion of D5W into the abdominal and scrotal space; such a presentation has not been previously reported.

Case Description: A 24-year-old man with history of depression presented with lightheadedness, dizziness, nausea, vomiting and one episode of loss of consciousness. He was found to have a serum sodium of 123 mEq/L. Upon further investigation it was determined that earlier in the day the patient had self-infused 3-4 liters of D5W into his abdomen and 1 liter into his scrotum for self-pleasure purposes via needles and equipment obtained from a medical supply company. Exam was notable for a non-tender, distended abdomen and swelling of the scrotum. Laboratory results were notable for a serum sodium of 123 mEq/L, serum glucose 122 mg/dL and urinalysis with a specific gravity of 1.005. Repeat serum sodium 1 hour later was further decreased to 121 mEq/L. The patient was started on sodium chloride 3% infusion and placed on a free water fluid restriction. Given the known acute time course and inciting event the patient was allowed to re-equilibrate quickly with a low concern for osmotic demyelination syndrome. Serum sodium corrected to 133 mEq/L over the course of approximately 10 hours. His symptoms resolved and serum sodium remained within normal limits for the remainder of his hospitalization.

Discussion: This practice termed "inflation" has rarely been reported in medical literature and to our knowledge no prior articles have reported hyponatremia as an adverse event. This case highlights the importance of obtaining a detailed history in patients presenting with hyponatremia in order to identify the underlying etiology and appropriate treatment strategy. Additionally, the case emphasizes the importance of interdisciplinary teamwork for patients at high risk of such behaviors, or for primary polydipsia, to try to prevent such behavior from happening, or if it does happen, to have appropriate monitoring and more rapid recognition and treatment of severe complications.

TH-PO331

Polyuria without Thirst: Adipsic Arginine Vasopressin Deficiency as a Sequela of Pituitary Surgery

Nabeel Siddiqui, Kevin Meek, Rupinder Kaur, Muhammad Qureshi, Bhoomi Shah, Nowoghomwenma C. Ibie. *Southeast Health, Dothan, AL.*

Introduction: Arginine vasopressin deficiency (AVP-D) stems from impairment or absence of vasopressinergic neurons in the hypothalamus and posterior pituitary, resulting in an inability to concentrate urine. Patients typically present with polyuria and polydipsia. Acute AVP-D mostly occurs following surgery for pituitary tumors. Here, we present a case of AVP-D following surgical resection of a suprasellar mass and an unusual absence of thirst response indicative of adipsia.

Case Description: 26-year-old female with complaints of headache, nausea, vomiting, loss of appetite, and unintentional weight loss. She had low TSH, ACTH, cortisol, and IGF-1. MRI head showed a large sellar and suprasellar mass abutting her optic chiasm. She underwent a total macroscopic transcranial resection with findings of extensive sellar and suprasellar lesions displacing the optic nerve and compressing the pituitary. Post-surgery, she had polyuria, a sodium level of 183 with decreased density, serum osmolality of 396, and urine osmolality of 182. The maximum urine output recorded was 5.6 liters in 24 hours. She was treated with desmopressin. Despite sodium levels in the 170s, she denied experiencing thirst.

Discussion: Postoperative AVP-D involves disruption of the hypothalamic-pituitary axis during surgery. Classically, patients with AVP-D experience polyuria and compensatory polydipsia. Increased plasma sodium levels typically trigger the thirst response. Adipsic AVP-D is a rare subset that results when injury to the hypothalamus impairs thirst osmoreceptors and ADH-synthesizing neurons, leading to the absence of thirst in response to hypernatremia. AVP-D following pituitary tumor surgery is a challenging complication requiring comprehensive evaluation and management. Early recognition, appropriate fluid and electrolyte replacement, and tailored ADH replacement therapy are crucial for optimal patient outcomes. This case underscores the importance of prompt recognition and tailored management of AVP-D post-surgery, particularly in patients with complications such as adipsia. Further research is needed to refine diagnostic approaches, optimize treatment strategies, and improve long-term outcomes for patients with postoperative AVP-D.

TH-PO332

A Painful Way to Get Hyponatremia: Acute Intermittent Porphyria

Naman Gupta, Jason M. Kidd, Graham T. Gipson. *Virginia Commonwealth University Medical Center, Richmond, VA.*

Introduction: Acute intermittent porphyria (AIP) is a rare metabolic disorder caused by abnormal enzyme activity in the heme biosynthesis pathway. Symptoms can be nonspecific which can make it challenging to diagnose and treat. Hyponatremia is seen in severe cases and thought to be due to syndrome of inappropriate antidiuretic hormone (SIADH). We present a case of AIP in a young woman presenting with SIADH and recurrent hospitalizations for abdominal pain.

Case Description: A 22-year-old female with a history of endometriosis presented with acute abdominal pain. Vital signs revealed a blood pressure of 137/82 mm Hg. Abdominal examination was significant for diffuse tenderness to palpation without rebound or guarding. She reported experiencing similar episodes in the past year and underwent extensive evaluation and prior hospitalization. Initial laboratory results were significant for sodium (Na) level of 143 mmol/L that rapidly decreased to 122 mmol/L the next day. She was aggressively fluid resuscitated, and Na decreased to 118 mmol/L. Serum osmolality was 257 mosm/kg, urine sodium was 149 mosm/L, and urine osmolality was 642 mosm/kg, consistent with SIADH that was attributed to pain. Sodium did not improve despite medical management including 3% saline infusion. Abdominal imaging revealed an ileus. Due to the combination of her symptoms, AIP was considered. Urine porphobilinogen was checked and was found to be elevated 176.8 mg/L consistent with AIP. A Hemin infusion was started and the patient's pain and hyponatremia improved. Genetic testing was done, which later confirmed AIP.

Discussion: AIP is characterized by neurovisceral attacks associated with high accumulation of early porphyrin precursors. This presence of SIADH in AIP is thought to be multifactorial. Firstly, pain because of visceral spasms is a direct stimulator for ADH. Secondly, presence of paralytic ileus, as in our case, accompanying abdominal pain, leads to intestinal sequestration of water and electrolytes. This leads to activation of angiotensin II and subsequent stimulation of ADH. Treatment includes prompt administration of hemin. Delays in recognizing and treating attacks can lead to serious complications including motor axonal neuropathy, seizures, psychosis and severe hyponatremia. This case highlights the importance of considering the diagnosis of AIP in patients presenting with recurrent abdominal pain and hyponatremia.

TH-PO333

Challenges in Identifying and Managing Lithium-Induced Arginine-Vasopressin Resistance

Michelle Neuman, Abigail Bradner, Jennifer Bergeron. *West Virginia University, Morgantown, WV.*

Introduction: Arginine vasopressin resistance (AVP-R), formerly nephrogenic diabetes insipidus, is the inability to concentrate urine due to resistance to AVP. Lithium is a classic cause of AVP-R, but identifying and managing AVP-R is not always textbook. In this case of AVP-R in lithium toxicity, UTI and dysphagia significantly delayed the diagnosis and improvement in symptoms.

Case Description: A 71-year-old female with bipolar disorder on chronic lithium, CKD3, and hypertension was admitted for 1 week of confusion, vomiting, and diarrhea. Labs were remarkable for creatinine 3.3mg/dL and sodium 133mEq/L (1 year ago 1.2 and 141 respectively). UA showed a UTI, which was presumed to be the cause of her symptoms. She was given fluids and her Cr improved to 2.5mg/dL. The case seemed closed. Surprisingly, the next day, her sodium was 154mEq/L with >3.5L urine output. Urine osmolality (UOsm) was 189mOsm/kg consistent with water diuresis, triggering a lithium level to be sent. It was 1.92mEq/L, consistent with lithium toxicity given her symptoms. Lithium was held and Nephrology conducted a desmopressin challenge without improvement in her Uosm, confirming AVP-R. She was given ample free water. Despite 5 days without lithium, her UOsm fell to 79mOsm/kg. With amiloride daily, Uosm rose to 137mOm/kg, but for days her sodium continued to fluctuate. HCTZ did not help. Eventually, we noted that she had a thickened liquids diet. The thickener is 5.5g modified food starch with 15mg of sodium in 4oz water. Once she was cleared for thin liquids, her sodium stabilized at 142mEq/L. Unfortunately, 11 days later she continued to have neuro symptoms, requiring inpatient rehab discharge for Syndrome of Irreversible Lithium-Effectuated NeuroToxicity (SILENT).

Discussion: This case reveals that lithium induced AVP-R can be masked by volume depletion from UTI and gives evidence that AVP-R can manifest quickly and worsen even after lithium is stopped. Furthermore, it demonstrates how lithium neurotoxicity complicates achieving euvolemia and free water and low solute/protein intake. We found that thickeners add tonicity (and aversion) to otherwise good fluid intake. This case demonstrates the importance of prompt diagnosis and multi-faceted management of lithium toxicities to prevent prolonged hospitalization and permanent life-altering neuromuscular symptoms.

Exploring the Cause of Acute Severe Hyponatremia: Cytarabine vs. Suspected Brain Lesion Due to Acute Myeloid Leukemia

Emily Vazquez Morales, Juan J. Adams Chahin, Ileana E. Ocasio Melendez. *Universidad de Puerto Rico Recinto de Ciencias Medicas, San Juan, Puerto Rico.*

Introduction: Hyponatremia is a serious electrolyte disorder associated with life-threatening neurological complications with a 47% prevalence in cancer patients. This case involves a patient diagnosed with acute myeloid leukemia (AML) and suspected central nervous system involvement, presenting with hyponatremia.

Case Description: A 54-year-old female with a history of AML was admitted to the Oncology ward for suspected AML relapse. A brain MRI revealed a homogenously enhancing lesion, lymphoproliferative in nature. Due to worsening leukocytosis (increasing from 61K to 126K), cytoreductive therapy with Cytarabine was initiated. After therapy was started, the patient developed an acute symptomatic hyponatremia of 120 mEq/L and Nephrology service was consulted. On examination, the patient was disoriented and lethargic with moist oral mucosa and no signs of volume overload. Serum osmolality was 253 mOsm/kg, and TSH levels were within normal limits. Urine spots were ordered, and 3% saline bolus was administered for a stated sodium correction goal of 4-6 mEq/L in 24 hours. The patient's hyponatremia was attributed to the syndrome of inappropriate antidiuretic hormone (SIADH) secretion, potentially precipitated her intracranial lesion or Cytarabine infusion. After 3% saline bolus administration, sodium level improved to 123 mEq/L, but case was complicated by spontaneous ICH and fur further workup for the patient's hyponatremia was not able to be ined due to the patient's untimely death.

Discussion: Although laboratory evidence identifying SIADH as the primary cause of patient's hyponatremia was insufficient, clinical suspicion was high. While cytarabine-induced SIADH is a rare occurrence, it has been documented in medical literature. Furthermore, in cases involving an intracranial lesion that may predispose a patient to SIADH, should we avoid the use of alkylating agents such as cytarabine, or should we instead implement closer monitoring if such agents are administered?

TH-PO335

Polyuria-Polydipsia in Pregnancy: A Case Report of Newly Diagnosed Arginine-Vasopressin Deficiency and Cushing Disease

Juan J. Adams Chahin, Janice M. Cuevas Rivera, Ileana E. Ocasio Melendez, Carlos G. Rivera-Bermudez. *Universidad de Puerto Rico Recinto de Ciencias Medicas, San Juan, Puerto Rico*.

Introduction: Polyuria and polydipsia during pregnancy can often present a diagnostic challenge due to the physiological changes inherent to gestation. Persistent, disruptive symptoms necessitate thorough investigation. We report a case of a pregnant woman with polyuria and polydipsia in the second trimester, unveiling arginine vasopressin deficiency and Cushing's disease, rare endocrine disorders.

Case Description: 30-year-old G5P3A1 at 16 weeks gestation with hypertension presented with excessive thirst and urination for about 4 weeks before admission. Vital signs were remarkable for elevated blood pressures. Physical exam revealed round facies, dorsocervical fat pad, facial and chest acne, hirsutism, and diffuse purple striae. A systolic murmur was also noted. Laboratories showed hyperglycemia (305), hypernatremia (154), hypokalemia (2.2), and metabolic alkalosis (34) with a urine output of 11 liters/day. Urine workup indicated low specific gravity: 1.002 and osmolarity: 100 mOsm/kg. Elevated nocturnal salivary cortisol (35 ng/mL) and ACTH levels (132 pg/dL) were noted. Initial treatment involved fluid and potassium replacement, followed by a single dose of IV desmopressin 4mcg, leading to improved hypernatremia and polyuria (3 liters/day, urine osmolarity: 630 mOsm/kg), indicating arginine vasopressin deficiency (previously known as central diabetes insipidus) along with concomitant Cushing's disease. Pregnancy termination did not resolve polyuria. While on intranasal desmopressin (10mcg q8 hours), she developed shortness of breath and pulmonary congestion. Severe mitral regurgitation was detected on 2D-echo, necessitating reduced desmopressin frequency to allow increased diuresis. Abdominopelvic CT was unremarkable, but brain MRI revealed a pituitary macroadenoma, scheduled for neurosurgical removal.

Discussion: This case underscores the diagnostic challenges posed by polyuria-polydipsia symptoms during pregnancy and emphasizes the importance of thorough investigation in such cases. It highlights the intricate interplay between pregnancy and endocrine disorders, which are rare yet significant contributors to polyuria-polydipsia presentations. Prompt recognition and management are crucial to mitigate complications and improve outcomes

TH-PO336

Severe Hyponatremia: An Unconventional Presentation

Philip Fermano, Rija Ahmad, Habib Nazir. *Bayonne Medical Center, Bayonne, NJ*.

Introduction: Hyponatremia management is a time sensitive correction that requires close monitoring. Irreplaceable neurologic damage could be done if not effectively managed. Hyponatremia has many different etiologies, and it is imperative to identify the cause to treat it. We present a case of a patient who presented to the emergency department with severe hyponatremia and able to recover without any neurologic disturbances.

Case Description: A 61 y/o male with history of alcohol abuse presented with melena. Patient was admitted for GI bleed with covid infection, beer potomania and severe hyponatremia. The patient was found to have Na of 104 on presentation. Patient was oriented only to person due to alcohol intoxication. Pt did not present with neurologic symptoms which was unusual for these Na levels. Initially, the patient was thought to be hypervolemic given 3+ pitting edema in his lower extremities. The patient was given Lasix which brought his Na levels further down. Urine studies supported Hypovolemic Hyponatremia as the urine osmolality was not low initially (351) and then decreased further (99) after administration of hypertonic saline indicating that volume reduced ADH release. Pt was given 1L of NS bolus which failed to improve his Na levels. Pt was given 70cc 3% hypertonic saline two separate times with a D5W maintenance fluid which improved the Na over the next week. It was found by the treating Nephrologist that patient never experienced severe neurological disturbances such as nausea, vomiting, seizure activity, or blurred vision because although patients Na was severely depleted, his osmolarity was maintained by his heavy alcohol consumption. The patient's initial serum osmolality was higher than expected (257). The cause of hypovolemia was a lower GI bleed.

Discussion: In this complex case, the Na correction must be maintained at a rate of 8mmol in 24 hours to avoid complications like osmotic demyelination syndrome. Urine and serum osmolarity are vital indicators of volume state. On presentation, the patient's physical exam and history of alcohol abuse suggested a hypervolemic state, but the elevated urine osmolarity along with the acute drop in Na from 126 to 103 in setting of GI bleed indicated volume depletion. Our recommendation is that careful consideration should be taken into account in patients with multiple causes of hyponatremia regardless of neurologic symptoms of the patient on presentation.

TH-PO337

Unusual Presentation of Arginine-Vasopressin Deficiency: Long Story Short, Decades of Polyuria without Proper Diagnosis

Sundus Sardar, Rafael Portela, Aidaliz Llorens, Umar Farooq. *Penn State Health Milton S Hershey Medical Center, Hershey, PA.*

Introduction: Arginine Vasopressin Deficiency (AVP-D), formerly Diabetes Insipidus, is a rare disorder causing polyuria and free water loss. Typical findings include hypernatremia and low urine osmolality. A positive response to desmopressin (DDAVP) indicates central deficiency. This case underscores the importance of thorough history and high suspicion for AVP-D despite normal electrolytes to ensure prompt diagnosis and improvement in quality of life.

Case Description: 33-year-old female with no past medical history who presented to our nephrology clinic by referral from PCP. Chief complaint was decades of polyuria. Since the age of 7, she remembers having trouble with nocturia. She recalls multiple sleepovers at 11 years of age. She had to sneak out multiple times at night to urinate to a point she needed to use 'pull ups" at sleepovers. In her words: " every road trip We had I remember how my family would say we would have gotten there much faster if they didnt have to stop multiple times to pee". To a point she would just use a "pull up" to "get there faster". In school, her teachers would not let her go to the bathroom as often as she needed it, they blamed "you are just going to fix your make-up". At work during her first job, but being so embarrassed of how often she needed to use the bathroom that she went to other floors in the building so her co-workers would not notice. Her first medical appointment at 7yrs old had cystoscopy done which was normal, few years later was reevaluated and was treated for "overactive bladder". During her pregnancy her polyuria was blamed on bladder pressure from the baby and was complicated by polyhydramnios and post-partum hemorrhage. At 30 yrs of age she presented to our nephrology clinic. 24 hour urine with self imposed fluid restriction revealed 5.7L of urine. Brain MRI was normal, genetic testing was unrevealing, no history of head trauma or surgery. Patient was diagnosed with idiopathic AVP-D and started on DDAVP and since then her life changed forever.

Discussion: This case emphasizes the need to consider AVP-D in chronic polyuria cases, even without typical hypernatremia. Delayed diagnosis of AVP-D led to decades of distress for this patient. Early recognition and treatment with DDAVP drastically improved her quality of life, underscoring the necessity for vigilance in cases like this.

TH-PO338

Renal Salt Wasting in Acute Myeloid Leukemia

Martin Brigham, Neev Patel, Adrian P. Sequeira. LSU Health Shreveport Nephrology. *LSU Health Shreveport, Shreveport, LA.*

Introduction: The idea of a salt wasting disease distinct from syndrome of inappropriate antidiuretic hormone (SIADH) has been a point of skepticism among nephrologists for decades. Discernment between hypovolemia and isovolemia easily runs afoul when fewer methods of evaluation are employed. Integrating Point Of Care Ultrasound (POCUS) bolsters confidence for clinicians trying to group patients into specific volume categories; which is demonstrated in the case below.

Case Description: Our patient was a 52 yo caucasian female with cerebral palsy who was diagnosed with Acute Myeloid leukemia (AML) and admitted for platelet transfusion. Prior to her admission she had completed one cycle of azacitidine and ventecolax. She began her second cycle of chemotherapy with this admission. Nephrology was consulted for chronic hypotonic hyponatremia occurring for the past month. She was euvolemic on exam. Her urine output could not be quantified. At the time of consultation her sodium was 125 mmol/L with a serum osmolality of 272 mOsm/kg and a urine osmolality of 599 mOsm/kg. Uric acid was 2.5 g/dL Interestingly, low serum uric acid characterized the entire duration of her hyponatremia. Her urinalysis was significant for a specific gravity > 1.030 with a urine sodium, potassium, and creatinine of 77 mmol/L, 41 mmol/L, and 63 mg/dl. TSH, serum cortisol, and renal functions were normal & BNP was 43. POCUS of the inferior vena cava (IVC) was performed for further clarification of the patient's volume status. The max IVC diameter was 0.5 cm during expiration while being completely collapsed on inspiration. Collectively, these findings painted a picture of hypovolemia, which favored a diagnosis of RSW over SIADH. Recommendations were given to hydrate with IV normal saline. Over the course of 3 days, the patient's hypotonicity resolved and her serum sodium improved to a value of 141 mmol/L.

Discussion: Resolution of our patient's hyponatremia depended on an accurate volume assessment, as overt hypovolemia excluded SIADH as a diagnosis. Improvement in serum sodium with IV fluids confirmed RSW as the cause of hyponatremia. Supplementing physical exam with POCUS was an effective tool for discerning between SIADH and the more rare diagnosis of RSW. Further research is needed into optimal diagnostic strategies for RSW, including the incorporation of POCUS, which may help to address a lack of data on the disorder's prevalence.

TH-PO339

Rapid Correction of Measured Sodium Levels Despite Relatively Stable Corrected Sodium Levels Can Lead to Osmotic Demyelination Syndrome

Dhairya Salvi,[1,2] Pedro A. Pineiro De Jesus.[1,2] *[1]Ascension Providence Rochester Hospital, Rochester, MI; [2]Wayne State University, Detroit, MI.*

Introduction: Hyperglycemia causes osmotic shift of water from the intracellular to the extracellular space, causing a dilutional hyponatremia. We refer to the sodium level corrected for hyperglycemia in such situations. We present a case that stresses the importance of measured sodium levels (Na_M) rather than corrected sodium levels for hyperglycemia(Na_C).

Case Description: A 59-year-old well-nourished, non-alcoholic male presented with polyuria, polydipsia, and generalized weakness for 2 weeks. On admission, he was dry with an unremarkable neurological exam. His labs suggested Hyperosmolar Hyperglycemic state (HHS) with blood glucose 844 mg/dL, Na_M 129 mmol/L (Na_C 141), bicarbonate 24 mmol/L, anion gap 14, blood urea nitrogen 29 mg/dL and a normal beta-hydroxybutyrate level. HbA1c was >14%. He received 2 liters of normal saline bolus and 15 units of regular insulin. Four hours later, glucose improved to 464 mg/dL with Na_M 137 mmol/L (Na_C 143). He was further started on a basal-bolus insulin regimen. Approximately 16 hours from arrival, he had a transient episode of dysarthria and right hemiplegia. Labs then showed glucose 178 mg/dL and Na_M 139 mmol/L (Na_C 140). CT scan of the head did not show any acute findings. MRI brain showed abnormal restricted diffusion and abnormal increased T2 signal intensity in the pons concerning for osmotic demyelination syndrome (ODS). The patient was later discharged safely without any residual neurological deficits.

Discussion: ODS develops as a result of relative hypertonic insult. Patients with HHS are particularly susceptible to a rapid rise in sodium levels, as the relative lack of insulin allows the development of higher glucose and thus lower sodium levels over a longer course as opposed to DKA patients which present more acutely. In this case, the corrected sodium levels were relatively stable, however, there was a rapid rise in the measured sodium levels, which most likely precipitated the event. Rapid lowering of blood glucose has also been proposed as a triggering factor for ODS in HHS. However, it is refutable as it causes a relatively hypotonic insult. This raises the question of whether we are being falsely reassured by relatively stable corrected sodium levels(Na_C) even when the measured sodium levels(Na_M) fluctuate and have the potential to lead to deleterious consequences.

TH-PO340

Low-Dosage Tolvaptan for Refractory Hyponatremia in Fontan-Associated Cardiac Cirrhosis

Prashant N. Bhenswala,[1,2] Pratap Kumar Upadrista,[1,2] Purva D. Sharma.[1,2] *[1]Northwell Health, New Hyde Park, NY; [2]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

Introduction: Hyponatremia in cardiac cirrhosis is challenging to manage. Fontan surgery is a palliative procedure for patients with single ventricle congenital heart lesions that diverts blood from the great veins to the pulmonary arteries, bypassing the right ventricle. Patients develop elevated CVP and cardiac cirrhosis with hyponatremia that is typically managed with a combination of loop diuretics and mineralocorticoid receptor antagonists. Our patient had refractory fluid overload and hyponatremia necessitating Tolvaptan use with good results and no adverse events.

Case Description: A 45-year-old male with hx of Fontan procedure complicated by Fontan Associated Liver Disease requiring paracenteses every 3 weeks, came to the ED for a serum Na of 122 mEq/L. He was on 1 L water restriction and maximally tolerated diuretics of Furosemide 40 mg and Spironolactone 25 mg daily but remained hyponatremic needing more frequent paracenteses and hospitalizations. Physical exam revealed a BP of 85/48 mm Hg, thin appearing male, with ascites and anasarca. Serum osmolality was 266 mosmol/kg. Urine studies: sodium 7 mmol/L, potassium 45 mmol/L, osmolality of 628 mosm/kg indicative of ADH mediated hyponatremia. Despite his history of cirrhosis, low dose Tolvaptan (7.5 mg) was given. Serum Na level appropriately increased from 125 mEq/L to 135 mEq/L over 4 days. The patient was discharged on Tolvaptan 7.5 mg once a week in addition to his home diuretics and has remained stable with a serum Na of 130-133 mEq/L with a reduced need for hospitalizations and paracenteses. Serum creatinine has remained stable at 1.2 mg/dL.

Discussion: Tolvaptan is an arginine vasopressor V2 receptor antagonist promoting excretion of free water. While not contraindicated, it is recommended to avoid use of Tolvaptan in patients with cirrhosis due to the risk of liver failure and variceal bleed. However, owing to the refractory nature of this patient's hyponatremia and limited alternative therapies, low dose weekly Tolvaptan was initiated. Treatment led to controlled and sustained correction of serum Na level and reduction in hospitalizations for fluid overload. Tolvaptan should be considered as alternative therapy for refractory hyponatremia in cirrhosis. Altered pharmacokinetics of the drug in cirrhosis may enable use of a lower dose and frequency for the same effect with no appreciable adverse events.

Navigating Hyponatremia in a Patient with Superior Vena Cava Obstruction from Retained Pacer Wires and Portal Hypertension

George J. Kavalam, Rucci Marcus C. Foo, Solab Chitrakar, Matthias Bergmann, Samer S. Nasser. *Beth Israel Deaconess Medical Center, Boston, MA.*

Introduction: Managing hyponatremia proves challenging when multifactorial, involving hypervolemia and continuous total body sodium losses. A 54-year-old male with biopsy-proven nodular regenerative hyperplasia, grade 2 liver fibrosis with portal hypertension, and complete heart block (CHB) attributed to Lyme disease, requiring a pacemaker. Subsequent recovery prompted the removal of the device, resulting in retained pacer wires that precipitated superior vena cava (SVC) obstruction years later. Deemed too risky for extraction, the patient developed recurrent pleural effusions, necessitating management with a Pleur-X catheter. Within two weeks, severe hyponatremia (serum sodium 121 mEq/L) ensued, leading to a prolonged and complex hospitalization.

Case Description: Initially diagnosed with hypovolemic hyponatremia due to sodium losses from frequent pleural fluid drainage, the patient's sodium levels improved with isotonic fluid replacement. However, he developed hypervolemia and respiratory compromise. Despite treatment with fluid restriction, urea packets, salt tablets, intravenous diuretics, and Tolvaptan, limited success was achieved, with progressive renal failure further complicating the clinical picture. SVC recanalization and stent placement were performed; however, hyponatremia persisted, necessitating continuous renal replacement therapy (CRRT) for volume removal. His course was further complicated by SVC stent migration, precipitating cardiogenic shock requiring extracorporeal membrane oxygenation (ECMO). Subsequently, epicardial lead extraction and SVC reconstruction were performed, restoring kidney function and normalizing sodium levels.

Discussion: This case underscores the complexities of managing hyponatremia caused by volume overload and total body sodium depletion. Managing volume status and electrolyte balance required a multidisciplinary approach involving hepatologists, cardiologists, and nephrologists. The successful preoperative use of CRRT to optimize volume status and electrolytes, followed by complex surgical interventions to treat the underlying problem, highlights the potential of advanced therapeutic modalities when conventional treatments fail. Tailored, collaborative care significantly improves outcomes in complex medical conditions like treatment-resistant hyponatremia.

TH-PO342

Critical Importance of Close Monitoring of Sodium and Fluid Balance in Labor and Delivery

Stefani M. Thompson, Sandeep S. Soman. *Henry Ford Health System, Detroit, MI.*

Introduction: Hyponatremia (hypoNa) is the most common electrolyte disorder seen in clinical practice; due to its many causes, it can be difficult to diagnose and manage. In this case report, we present a unique case of rapid hypoNa associated with pregnancy and the concurrent use of oxytocin and ketorolac. Oxytocin exerts antidiuretic effects similar to those of vasopressin, leading to water retention and dilutional hypoNa. The risk of oxytocin-induced hypoNa is heightened by concomitant fluid administration, making it a well-recognized but potentially preventable complication in obstetric practice. Ketorolac has also been associated with hypoNa, due to the inhibition of renal prostaglandin synthesis, which affects renal water handling and sodium (Na) balance. Additionally, while healthy women can typically excrete about 900 ml of water per hour, this ability decreases by about 1/3rd in late pregnancy, further complicating the management of fluid balance and hypoNa.

Case Description: We present a case of a 35-year-old G1P1 female with a past medical history notable for depression and anxiety who presented 32 weeks pregnant with preeclampsia with severe features. She was started on a magnesium infusion and underwent a cesarian section. During the procedure she had 500 ml blood loss, she received 30 units of oxytocin and 900 ml of lactated ringers (LR). Post procedure she was started on LR at 75 ml/hr and ketorolac every 6 hours for pain control. Eight hours later the patient was found to be lethargic. Stat labs showed a Na of 122 mmol/L (Na was 134 mmol/L on admission). LR was changed to normal saline (NS) and Na further dropped to 119 mmol/L. Urine Na and osmols were 123 mmol/L and 629 mOsm/kg respectively. The patient denied excessive fluid intake and pain. NS and ketorolac were discontinued, and water restriction was initiated. The Na improved to 130 mmol/L within 24 hours.

Discussion: This case presents a rare but significant complication of acute hypoNa precipitated by the concurrent administration of oxytocin and ketorolac in a patient population with decreased free water clearance. Prompt recognition and management of hypoNa is vital to prevent serious neurological complications and ensure favorable patient outcomes. This case highlights the need for electrolyte and fluid balance monitoring, particularly in patients receiving medications known to cause hypoNa.

TH-PO343

Unveiling the West Nile Virus's Sodium Surprise: A Unique Case of Hyponatremia

Justin D. Tse, Jackson Wang. *Sutter Health, Roseville, CA.*

Introduction: West Nile virus (WNV) is a vector-borne flavivirus typically transmitted by the Aedes and Anopheles mosquitos. WNV infection typically manifests with symptoms consistent with viral meningitis and is typically self-resolving, lasting anywhere from 3-10 days. Although uncommon, 30% of patients with WNV encephalitis can be afflicted with hyponatremia, although the etiology is unclear. It can be speculated that because of encephalitis, neuroinflammation may be involved in the deterioration of adrenal signalling, leading to salt wasting.

Case Description: We present a 75-year-old man who presented with meningeal signs and viral illness symptoms. He was found to be hyponatremic with a sodium of 117 mmol/L and was started on 3% saline, fluid restriction, and salt tablets. After ruling out more organic causes of hyponatremia, there was ongoing concern for SIADH in the setting of positive WNV titers. CSF analysis was fairly bland. A paraneoplastic panel was negative, copeptin levels were elevated, and an MRI of the brain revealed the absence of the posterior pituitary bright spot, suggesting a SIADH pathology. He continued to do well with IVF resuscitation and salt tablets, and eventually, his sodium returned to normal levels, with the most recent measure at 138 mmol/L.

Discussion: WNV infection typically manifests with symptoms consistent with viral meningitis and encephalitis. Although there have been cases of mosquito-borne infections with subsequent encephalitis, this is the first known reported case of SIADH related to WNV infection reported to date. The association between WNV and SIADH resulting in hyponatremia adds a new dimension to our understanding of the neurological consequences of mosquito-borne illnesses. The negative paraneoplastic panel, elevated copeptin levels, and the established pathophysiology of WNV encephalitis suggest that SIADH occurred because of neuroinflammation and neuroendocrine disruption. These findings, coupled with supporting imaging demonstrating the loss of the pituitary bright spot, which suggests alterations in the posterior pituitary's functional integrity, support our proposed pathophysiology of WNV-induced encephalitis causing SIADH. This case underscores the intricate interplay between WNV encephalitis, neuroinflammation, and hormonal dysregulation, emphasizing the diagnostic complexity and management challenges in this and other similar clinical scenarios.

TH-PO344

Development of Pediatric Hypokalemia Prediction Deep-Learning System Based on Wearable Single-Lead Electrocardiography in Real Time

Naye Choi,[1] Hyun Kyung Lee,[2] Ji hyun Kim,[4] Hee Gyung Kang.[3]
[1]Korea University Anam Hospital, Seoul, Republic of Korea; [2]Chung Ang University Hospital, Seoul, Republic of Korea; [3]Seoul National University Children's Hospital, Seoul, Republic of Korea; [4]Seoul National University Bundang Hospital, Seongnam, Republic of Korea.

Background: Bartter syndrome (BS) is one of the most well-known hereditary tubular disorders, posing significant challenges for patients in maintaining electrolyte and fluid balance. In severe cases, muscle weakness, paralysis, arrhythmias, and even sudden death can occur, emphasizing the importance of continuous potassium level monitoring for appropriate management. While recent studies have explored deep learning models using 12-lead electrocardiograms to predict abnormal potassium levels, research on monitoring serum potassium levels in patients' home settings is lacking. Therefore, this study aims to develop a deep learning model for detecting hypokalemia using wearable devices' electrocardiogram data.

Methods: This study employed oversampling of positive data and utilizing a generative adversarial neural network-based data augmentation process. A classification model is employed to verify the quality of data, ensuring the utilization of high-quality datasets. Subsequently, the study selects ResNet-50, MobileNet-v3, and EfficientNet-B3 models to compare their performance following dataset augmentation.

Results: The performance of hypokalemia prediction models was evaluated by comparing ROC (Receiver Operating Characteristic) curve values. The best AUC (Area Under the Curve) of the hypokalemia detection model was 0.98.

Conclusions: This study developed a deep learning model for hypokalemia detection using data measured by wearable devices, focusing on pediatric patients with BS. Continuous monitoring of potassium levels through wearable devices to predict abnormal potassium concentrations in the bloodstream is expected to aid in the healthcare management of patients with BS and support medical decision-making by healthcare professionals.

Role of Artificial Intelligence-Enabled Electrocardiography in the Management and Outcome Prediction of Coexisting Hyperkalemia and Bradycardia

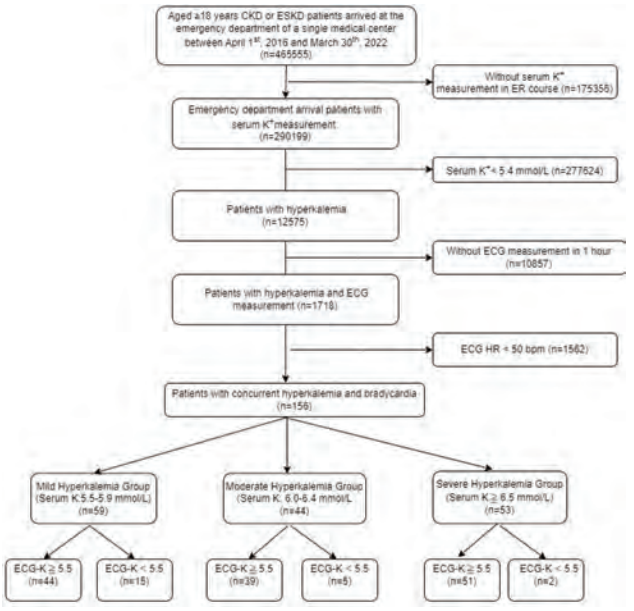
Chien-Chou Chen,[1] Chin Lin,[2] Chi Wei Shih,[3] Ang Lu,[3] Shih-Hua P. Lin.[3]
[1]Tri-Service General Hospital Songshan Branch, Taipei, Taiwan; [2]National Defense Medical Center, Taipei City, Taiwan; [3]Tri-Service General Hospital Department of Medicine, Taipei, Taiwan.

Background: Concomitant hyperkalemia and bradycardia as a life-threatening urgency requires rapid management. Although artificial intelligence-enabled electrocardiography (AI-ECG) has been developed to rapidly detect hyperkalemia and bradycardia, its application in management and outcome prediction has not been evaluated.

Methods: This retrospective study was performed at the emergency department of a single medical center over 8 years. Patients with hyperkalemia≥5.5 mmol/L and ECG showing bradycardia less than 50 bpm were included. Both the cardiologists and nephrologists were consulted for pacemaker placement (PP) and emergent hemodialysis (HD) evaluation. Patients' characteristics, treatment including PP and HD, and outcome were examined. AI-ECG-K^+ quantified by ECG12Net analysis showing ECG-K^+≥5.5 was defined as ECG-K^+ hyperkalemia.

Results: A total of 156 patients who met the inclusion criteria had mild (5.5-5.9 mmol/L, n=59), moderate (6.0-6.4 mmol/L, n=44), and severe hyperkalemia (≥6.5 mmol/L, n=53). Their mean heart rate (HR) was 39.6±8.1 bpm, with atrioventricular block in 68 patients. Most of them had acute kidney injury, chronic kidney disease, or chronic HD. Approximately 50% of them had the drugs affecting HR. The sensitivity for AI-ECG to predict mild, moderate, and severe hyperkalemia was 74.6%, 88.6%, and 96.2%, respectively. Patients with positive ECG-K^+ (ECG-K^+≥5.5) had significantly higher rate of emergent PP (29.9% vs 18.2%), HD (43.3% vs 13.6%), and in-hospital mortality (19.4% vs 9.1%) compared to those with negative ECG-K^+ (ECG-K^+<5.5).

Conclusions: AI-ECG-K^+ may help offer management suggestion and predict the outcomes in the patients with coexisting hyperkalemia and bradycardia, even in the mild to moderate hyperkalemia.



TH-PO346

Safety and Efficacy of WS016 in Patients with Hyperkalemia in China from a Phase 2 Study

Aiyun Song,[1] Li Zuo,[11] Jianrong Zhao,[12] Zhen H. Ji,[7] Qingfeng Peng,[2] Wen C. Xu,[4] N a Tian,[6] Qinghong Zhang,[5] Xianjun Xue,[10] Xinzhong Huang,[8] Changyou Sun,[9] Jianying Niu,[3] Fan Yan,[1] Faming Zhang.[1] WS016 Phase 2 China Study Group. *[1]Waterstone Pharmaceutical (Wuhan) Co., LTD, Wuhan, China; [2]Zhuzhou Central Hospital, Zhuzhou, China; [3]Fifth People's Hospital of Shanghai Fudan University, Shanghai, China; [4]Wuhan Fourth Hospital, Wuhan, China; [5]Taihe Hospital of Shiyan City, Shiyan, China; [6]Affiliated Hospital of Ningxia Medical University, Yinchuan, China; [7]Central Hospital affiliated to Shenyang Medical College, Shenyang, China; [8]Affiliated Hospital of Nantong Medical University, Nantong, China; [9]Tancheng County First People's Hospital, Tancheng, China; [10]Puyang Oilfield General Hospital, Puyang, China; [11]Peking University People's Hospital, Beijing, China; [12]The Affiliated Hospital of Inner Mongolia Medical University, Hohhot, China*.

Background: Hyperkalemia is a common electrolyte disorder that is associated with serious cardiac dysrhythmias and increased mortality. WS016 is a highly selective cation exchanger that entraps potassium in the intestinal tract thus could lower serum potassium levels in patients with hyperkalemia.

Methods: 140 patients with hyperkalemia were randomly assigned to receive either WS016(dose of 3g, 6g, 12g) or placebo three times daily for 48 hours(acute phase) in this multicenter, two-stage, double-blind, phase 2 trial. Patients with normokalemia at 48 hour in WS016 group were randomly assigned to receive WS016 or placebo once daily from day 3 to day 14(maintenance phase). The primary endpoint was the exponential rate of change of serum potassium at 48 hour.

Results: At 48 hours, there were absolute mean reduction of 0.58 mmol/L,0.51 mmol/L,0.86 mmol/L in the 3g, 6g, 12g group respectively, and 0.35 mmol/L in placebo group. The reduction at 1 hour after the first 3g dose of WS016 was 0.24mmol/L, while 0.05 mmol/L in the placebo group, respectively. The maxim reduction was 0.98,1.16 mmol/L in 3g and 12g group, 0.50 mmol/L in placebo group at 26 hour. The proportion of patients who reached the normokalemia were 71.4%, 70%,80%,45.7% in 3g, 6g, 12g, and placebo group. At the end of 12-day maintenance treatment, the proportion of patients who maintain normokalemia was 63% in treatment group and 40% in placebo group. The mean increase was 0.27 VS.0.44 mmol/L in 6g and its corresponding placebo group, 0.49 VS.0.68 mmol/L in 12g and its corresponding placebo group. During acute phase adverse events were reported in 26.9% patients in the WS016 group and 20% in the placebo group; and 32.3% patients in the WS016 group and 35.3% in the placebo group during the maintenance phase. Most of AEs were grade 1. There is only 1 SAE found in 12g group, and is not related with WS016. Only 2 patients were reported with hypokalemia graded as 1 in 12g group and recovered without rescue treatment. No patients reported with other abnormal electrolytes and edema.

Conclusions: WS016 can reduce potassium levels during 48 hours rapidly and maintain more patients within the normokalemia duiring 12-day maintenance phase compared with placebo. It was suggested that WS016 is effective and safety for hyperkalemic patients.

TH-PO347

Intermittent Sodium Zirconium Cyclosilicate for the Prevention of Hyperkalemia in CKD

Cheuk-Chun Szeto, Winston W. Fung, Jack K. Ng. *The Chinese University of Hong Kong, Hong Kong, Hong Kong*.

Background: Sodium zirconium cyclosilicate emerged as an effective short-term treatment for acute hyperkalemia. Recent evidence supports its use for long-term control of hyperkalemia, but the recommended daily dosage is expensive and may not be well tolerated. We determined the efficacy and safety of intermittent sodium zirconium cyclosilicate therapy for the prevention of hyperkalemia in CKD patients.

Methods: We reviewed 36 patients who received intermittent (1 to 2 doses weekly) sodium zirconium cyclosilicate for more than 3 months. We analyzed plasma potassium levels, episodes of hyperkalemia, emergency room attendance, and hospitalizations before and during sodium zirconium cyclosilicate treatment.

Results: The total duration of observation was 274 patient-months with Lokelma treatment and 216 patient months in the control period; the median duration of Lokelma treatment was 4.4 months (IQR 3.0 – 10.4 months). The median plasma potassium level decreased from 5.10 (IQR 4.91 – 5.40) to 4.73 (IQR 4.50 – 5.10) mmol/l (p = 0.0003). There were 114 episodes of hyperkalemia during the control period and 57 episodes during Lokelma treatment. The median incidene of hyperkalemia reduced from 5.0 (IQR 2.0 – 8.0) to 1.9 (IQR 0.0 – 4.7) episode per patient-year (p = 0.0001). Similarly, the incidence of moderate hyperkalemia reduced from 2.0 (IQR 0.0 – 4.0) to 0.0 (IQR 0.0 – 0.2) episode per patient-year (p = 0.001). There was no significant difference in the total hospitalization or attendance to the Emergency Department.

Conclusions: Intermittent low dose sodium zirconium cyclosilicate is effective for potassium control and enhances the management of hyperkalemia in CKD.

TH-PO348

Updated Design and Status of CONTINUITY: A Phase 4 Study of Continued Postdischarge Sodium Zirconium Cyclosilicate in CKD

James Burton,[1] Alpesh Amin,[8] Maria Jesus Izquierdo,[2] Cecilia Linde,[3] Nicolas R. Robles,[4] Manish M. Sood,[5] Alaster Allum,[6] James M. Eudicone,[7] Katie Mohan.[6] *[1]University of Leicester and University Hospitals of Leicester, Leicester, United Kingdom; [2]Hospital Universitario de Burgos, Burgos, Spain; [3]Karolinska Institutet, Stockholm, Sweden; [4]Universidad de Extremadura, Badajoz, Spain; [5]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [6]AstraZeneca, Cambridge, United Kingdom; [7]AstraZeneca, Wilmington, DE; [8]University of California Irvine, Irvine, CA.*

Background: Patients (pts) hospitalized with hyperkalemia (HK) have increased risk of recurrent HK and re-hospitalization. The ongoing CONTINUITY study (NCT05347693) compares efficacy of continued post-discharge sodium zirconium cyclosilicate (SZC) treatment vs standard of care (SoC) in hospitalized pts with chronic kidney disease (CKD) and HK. We present protocol changes made to clarify eligibility criteria, better align inclusion/exclusion criteria with local practice, and ensure a more clinically relevant main secondary endpoint (Figure).

Methods: CONTINUITY is a randomized, open-label study across 6 European countries. Pts with CKD admitted to hospital with HK will be treated in hospital with SZC. At discharge, pts with normokalemia (NK; serum potassium [sK^+] 3.5–5.0 mmol/L) are randomized 1:1 to SZC:SoC, per local label/practice, for 180 days. The primary endpoint evaluates SZC efficacy as part of discharge medications, vs SoC, in maintaining NK. The main secondary endpoint evaluates the effect of SZC as part of discharge medications, vs SoC, in reducing incidence of the composite outcome of all-cause hospital admissions, or emergency department visits with HK as a contributing factor, or all-cause death, or use of rescue-therapy for HK.

Results: As of May 2024, 179 pts were enrolled and 129 randomized (SZC n=65; SoC n=64) from Belgium (n=2), France (n=6), Italy (n=9), the Netherlands (n=1), Spain (n=109), and the UK (n=2); mean age 72 years, 29% female. Further baseline demographics/characteristics will be presented at Kidney Week 2024.

Conclusions: The CONTINUITY study (estimated completion: Dec 2024) will provide important evidence supporting either SoC or more active sK^+ management with a K^+ binder post discharge for pts with CKD admitted with HK. Protocol changes allow inclusion of a wider pt population and the potential to improve the clinical relevance of the results.

Funding: Commercial Support - AstraZeneca

Hyperkalemia-Related Health Care Resource Use (HRU) Associated with Short-Term vs. Long-Term Sodium Zirconium Cyclosilicate (SZC) Therapy in Patients with ESKD: The GALVANIZE Outcomes Study

Arun Malhotra,[1] Abiy Agiro,[1] Erin Cook,[2] Fan Mu,[2] Alexandra Greatsinger,[2] Jingyi Chen,[2] Manasvi Sundar,[2] Ellen Colman,[1] Neela Kumar,[1] Connie Rhee.[3]
[1]AstraZeneca Pharmaceuticals LP, Wilmington, DE; [2]Analysis Group Inc, Boston, MA; [3]University of California Los Angeles, Los Angeles, CA.

Background: Long-term sodium zirconium cyclosilicate (SZC) therapy use has been shown to be associated with lower rates of hyperkalemia (HK)-related healthcare resource use (HRU) than short-term SZC therapy. However, this association has not been evaluated in patients with end-stage kidney disease (ESKD). The GALVANIZE Outcome real-world study compared HRU between long-term and short-term SZC users in patients with ESKD.

Methods: Adults with a diagnosis of ESKD initiating SZC in the outpatient setting from 7/2018-12/2022 were identified from a large US insurance claims database. Patients with long-term SZC use (>90 days) were exactly and propensity score matched on key baseline characteristics to patients with short-term SZC use (≤30 days). Rates of HK-related hospitalizations and/or emergency department (ED) visits, HK-related hospitalizations, and HK-related ED visits after SZC initiation were compared using generalized estimating equations (also done for all-cause).

Results: Of 1,010 matched pairs with ESKD, 60% were male, the mean age was 57 years. Insurance coverage included 41% of patients with Medicare Advantage, 26% with Medicaid, and 31% with commercial insurance. Hypertension (86%) and diabetes (67%) were the most common comorbidities. Patients with long-term SZC use had a 34% lower rate of HK-related hospitalizations or ED visits (p<0.001), a 34% lower rate of HK-related hospitalizations (p<0.001), and a 34% lower rate of HK-related ED visits (p<0.05) than patients with short-term SZC use.

Conclusions: Long-term SZC use among patients with ESKD was associated with significantly lower rates of HK-related HRU compared to short-term SZC use.

Funding: Commercial Support - AstraZeneca

Background: SZC is a non-absorbed cation exchanger approved in China for treating HK (serum potassium level [sK^+] >5.0 mmol/L). Actualize is the first real-world study to assess the effectiveness, safety, and treatment patterns of SZC in Chinese patients (pts) with HK.

Methods: This study included adult HK pts taking/willing to take SZC from 40 sites in China. All pts completed 6- month follow-up. As per Chinese label, treatment was categorized as correction (FAS-P1) and maintenance phase (FAS-P2); treatment was discontinued as per the HK threshold at each site (mostly 5.3 or 5.5 mmol/L). The study evaluated changes in sK^+ and the incidence of adverse events (AEs).

Results: 442 and 878 pts were included in FAS-P1 and FAS-P2, respectively. In FAS-P1, with a mean daily SZC dose of 9.5g, mean sK^+ reduced significantly from 5.8 mmol/L at baseline to 5.0 mmol/L. After correction phase, 51% and 80% of pts had sK^+ between 3.5-5.0 and 3.5-5.5 mmol/L, respectively. In FAS-P2, with a mean daily SZC dose of 4.2 g, the mean sK^+ over 6 months was 5.1 mmol/L. The proportions of normokalaemic pts at 6 months by chronic kidney disease (CKD) stage at enrollment are shown in **Table 1**; in pts with stage 3–4, stage 5/non-hemodialytic and hemodialytic CKD, 59.0%, 63.2% and 51.5%, respectively, had sK^+ between 3.5-5.0 mmol/L. Incidence rate (per 100 person-days) of AEs was 2.9% and 0.5% in FAS-P1 and FAS-P2, respectively, and that of severe AEs was 0.2% in both. There was no AE leading to treatment discontinuation in FAS-P2 and 0.1% in FAS-P1. Overall, 3.8% and 6.5% of pts experienced oedema and hypokalemia, respectively.

Conclusions: SZC was effective and safe in treating HK in CKD pts, and can be considered as standard treatment for acute and chronic HK in China.

Funding: Commercial Support - AstraZeneca China

Prolonged Hypokalemia Long after Causative Factor Elimination in Pseudo-Bartter/Gitelman Syndrome

Atsushi Kondo,[1,2] Tomoko Horinouchi,[1] Yuta Inoki,[1] Yu Tanaka,[1] Hideaki Kitakado,[1] Chika Ueda,[1] Nana Sakakibara,[1] China Nagano,[1] Junya Fujimura,[2] Tomohiko Yamamura,[1] Shingo Ishimori,[1] Kandai Nozu.[1] *[1]Kobe Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Kobe, Japan; [2]Kakogawa Chuo Shimin Byoin, Kakogawa, Japan.*

Background: Pseudo-Bartter/Gitelman syndrome (PBS/PGS) is a medication- and lifestyle-related disorder characterized by hypokalemia and a tendency to renal dysfunction. Treatment involves the elimination of the causative factor and potassium supplementation. However, PBS/PGS symptoms may persist long after the removal of causative factors, and its pathogenesis remains unclear.

Methods: We included 157 cases in which no pathogenic variant was identified despite comprehensive genetic testing, including targeted next-generation sequencing, for suspected inherited salt-losing tubulopathy. Among these, we examined 49 cases with a clear medical history confirming the cause of PBS/PGS. They were categorized into two groups: the current group (n=39), where causative factors persisted, and the past group (n=10), where more than one year had elapsed since the elimination of the causative factors at the time of examination. A retrospective comparative analysis was conducted between these groups.

Results: All patients were female, except for two in the current group. The median age at the time of genetic testing was 44.0 years (range 16–60 years) in the current group and 37.5 years (range 29–58 years) in the past group. The median time since the elimination of causes in the past group was 7.5 years. Blood tests revealed evident hypokalemia in the current and past groups, with a median of 2.4 vs. 2.6 mEq/L (p=0.51), respectively. Renal dysfunction was observed in both groups, with the median estimated glomerular filtration rate 57.6 vs. 60.7 mL/min/1.73 m^2 (p=0.84). Notably, overactivation of the renin-angiotensin system was observed in both groups, as evidenced by a median plasma renin activity of 21.2 vs. 13.2 ng/mL/h (p=0.24) and a median plasma aldosterone concentration of 253 vs. 165 pg/mL (p=0.031).

Conclusions: This study is the first to reveal the possibility of persistent PBS/PGS findings even after removing causative factors. Regarding pathogenesis, we suspect that prolonged hypokalemia may result in a low set point for serum potassium levels being fixed in the renal tubules. While swift removal of the cause of PBS/PGS is crucial, long-term post-removal monitoring is essential to improve renal prognosis.

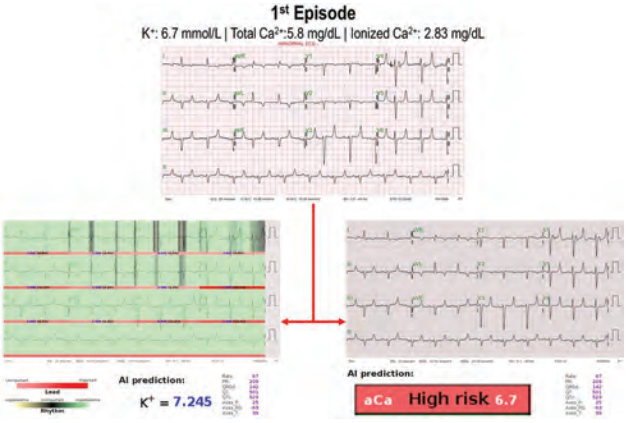
A 57-Year-Old Uremic Man with Recurrent Hyperkalemia following Parathyroidectomy

Ang Lu,[1] Chin Lin,[2] Shih-Hua P. Lin.[2] *[1]Tri-Service General Hospital, Taipei, Taiwan; [2]National Defense Medical Center, Taipei, Taiwan.*

Introduction: Hyperkalemia, associated with an increased mortality risk in hemodialysis (HD) patients, with a higher incidence during the post-parathyroidectomy period, can be divided into shifting causes and non-shifting causes. We present a case of recurrent hyperkalemia associated with severe hypocalcemia following parathyroidectomy rapidly recognized by artificial intelligence electrocardiography (AI-ECG).

Case Description: A 57-year-old uremic male on maintenance HD four times per week presented to the emergency department (ED) at night with muscle twitching and carpopedal spasm. His medication regimen was unchanged, and he had no prior hyperkalemia episode. One week earlier, he underwent parathyroidectomy with autograft implantation for severe secondary hyperparathyroidism, renal osteodystrophy, and pruritus unresponsive to phosphate binder, calcitriol, and calcimimetic. On the 8th postoperative day, he returned to the ED with palpitations and tetany. An AI-ECG alerted hyperkalemia predicting 7.25 mmol/L. Confirmed with hypocalcemia (ionized calcium 2.83 mg/dL) and hyperkalemia (6.7 mmol/L), the tetany resolved within 2 hours following calcium infusion and emergency HD. Despite oral calcium polystyrene sulfonate treatment, he returned to the ED on the 10th postoperative day with the same symptoms and received the same management, leading to symptom resolution.

Discussion: Despite being a known issue, hyperkalemia is often under-managed in HD patients, particularly following parathyroidectomy, where it primarily arises from potassium shifting. A preventive strategy of quantifying calcium supplement dosage postoperatively based on the estimated bone turnover rate is crucial. The risk of HD patients being vulnerable to potassium accumulation and redistribution can be mitigated by advanced AI technology. Increased vigilance and rapid treatment of hyperkalemia in this high-risk population are warranted.



The ECG and AI analysis model from 1st tenancy episode

TH-PO353

Rebound Hyperkalemia in Thyrotoxicosis: A Case Report

Richard Raymund R. Ragasa. *University of the Philippines System, Manila, Philippines.*

Introduction: Thyroid hormones play a significant role in potassium homeostasis through increasing expression of the Na/K ATPase pump. This increases the complexity of repleting potassium in patients with hyperthyroidism. This is a case of unexpected rebound hyperkalemia after potassium repletion in a patient with thyroid storm.

Case Description: A 57-year-old woman with multinodular toxic goiter presented with hematochezia, tachycardia, seizure, and jaundice. Initial workup showed thyrotoxicosis (FT4 55 pmol/L) associated with hypercoagulability (INR 6.0) with subdural hematoma, and cholestatic jaundice. Potassium level on admission was 2.3 mEq/L, which was attributed to intracellular shifting of potassium from thyrotoxicosis and low magnesium at 0.6 mmol/L. Thyroid storm was managed in the ICU with propylthiouracil, hydrocortisone, and potassium iodide. Cryoprecipitate was transfused with resolution of hypercoagulability and bleeding. Patient also underwent hematoma evacuation with neurosurgery. Postoperatively, potassium ranged from 2.6 to 4.7 mEq/L, magnesium at 0.65 to 0.99 mmol/L, and were repleted as necessary. On hospital day 18, potassium was found to be low at 1.8 mEq/L with normal magnesium. EKG showed sinus bradycardia with prominent u waves. Continuous intravenous potassium repletion was started at 8-10 mEq/h on top of oral repletion. Urine K/Crea was found to be <13 mEq/g suggesting intracellular potassium shift. Several hours after around 220 mEq repleted, patient was noted to have wide complex tachycardia and went into cardiopulmonary arrest. Advanced cardiac life support was performed without return of spontaneous circulation. Blood chemistry sent minutes prior to the arrhythmia showed serum potassium of 7.7 mEq/L confirmed by plasma potassium of 7.4 mEq/L. It was unexpected that the repletion resulted in disproportionate and precipitous rise in serum levels.

Discussion: In the thyrotoxic state, intracellular redistribution of potassium decreases serum potassium without changing total body potassium. In about 1 of 4 patients with thyrotoxicosis, paradoxical hypokalemia is observed even with repletion and this was associated with higher thyroxine levels and more pronounced rebound hyperkalemia. This phenomenon makes it difficult to anticipate response to repletion. Potassium repletion in these situations, particularly through the intravenous route, should be done cautiously under close monitoring.

TH-PO354

Primary Hyperaldosteronism with Syndrome of Inappropriate Antidiuretic Hormone (SIADH) and Nephrocalcinosis

Misah White, Rob Rope. *Oregon Health & Science University, Portland, OR.*

Introduction: Primary hyperaldosteronism (PA), traditionally characterized by hypertension, sodium retention, and hypokalemic metabolic alkalosis, is often managed effectively with mineralocorticoid receptor antagonists. We present a case of PA management complicated by concurrent SIADH, hypercalciuria, and nephrocalcinosis.

Case Description: Our 39 year-old woman presented in 2019 with hypertension due to primary hyperaldosteronism, without hypokalemia or metabolic alkalosis. Serum aldosterone ranged from 16-70 ng/dL, plasma renin activity 0.1-0.5 ng/mL/hr, with elevated aldosterone:renin ratios of 140-350. Oral salt load did not suppress aldosterone excretion. On CT, adrenals were normal, and adrenal vein sampling showed bilateral disease. Genetic testing was negative for glucocorticoid-remediable aldosteronism. Spironolactone was initiated then discontinued due to a worsening of chronic hyponatremia to 123 mEq/L. Serum sodium on eplerenone ranged from 127-131 mEq/L; hyponatremia did not resolve off MRAs. Hyponatremia workup was consistent with SIADH without

identifiable cause. Her hyponatremia responded well to oral urea, however dosing has been limited by worsening hypercalciuria and noted medullary nephrocalcinosis on CT.

Discussion: PA is typically effectively managed with MRAs, however this strategy can be limited with concurrent SIADH. Hypercalciuria and nephrocalcinosis further complicates management. For example, increasing solute therapy or adding loop diuretics is contraindicated. There are few other case reports of PA associated with nephrocalcinosis. PA has been observed with increased urinary calcium excretion and oxalate crystal formation, though proposed mechanisms including prolonged hypokalemia, hypocitraturia, and urine acidification are not present in our patient. Thus far no unifying etiology has been identified, including tubulopathies (no proteinuria, hematuria) or rheumatic disease, to link these conditions. The next management step for this patient will be repeat eplerenone trial with oral urea for hyponatremia. Amiloride could also be considered.

Serum (S) Aldo	16-70 ng/dL
Renin	0.1-0.5 ng/mL/hr
ARR	140-350
Urine catecholamines	Normal
Cortisol, dexamethasone suppressed	1.3 ug/dL
GRA genetic test	negative
CT abdomen	Normal adrenals, nephrocalcinosis
S Na	123-134 mEq/L
S K	4.0-4.5 mEq/L
S Ca	9.0-9.5 mg/dL
PTH, TSH, ACTH, ACE	normal
24Hr urine (U) Ca	348-592 mg (H)
U Citrate	1304-1414 mg
U Phos	1.07-1.83 mg (H)
U Uric acid	1.03-1.22 mg (H)
U pH	6.32-6.63

TH-PO355

Wasting K, the Ampicillin Way: An Uncommon Cause of Hypokalemia

Isaac Swartzman,[1,2] Jack Luo,[1] Natalie M. Beck.[1] *[1]University of California Davis, Davis, CA; [2]Travis Air Force Base, Travis AFB, CA.*

Introduction: Hypokalemia arises from transcellular shift, reduced intake or increased loss of potassium (K). Elevated urinary K in a hypokalemic individual prompts further workup for renal K loss. We describe a case of renal K-wasting secondary to high dose intravenous (IV) ampicillin use.

Case Description: A 49-year-old male with a history of multidrug resistant disseminated tuberculosis (TB) was hospitalized with abdominal pain and nausea and found to have a small bowel obstruction secondary to an ileal stricture. His home TB regimen was converted to IV linezolid and moxifloxacin. Initial labs revealed normal electrolytes and renal function. On hospital day (HD) 6, he resumed a liquid diet. The following day, he was initiated on ampicillin/sulbactam 3 g TID and meropenem 2 g TID to replace long-acting bedaquiline from his home regimen. On HD 8, he became hypokalemic to 2.8 mmol/L and hypophosphatemic to nadir of 1.2 mg/dL with normal serum magnesium and bicarbonate. Blood pressures were low-normal range. Refeeding syndrome was considered but thought less likely given the persistence of hypokalemia several days after the patient resumed eating, prompting quantification of urinary K. On HD 15, urine studies revealed a spot K:Cr ratio of 155 mEq/g (normal < 13) and a 24-hour K excretion of 143 mmol with a urine anion gap of 110. These findings supported renal K wasting due to nonreabsorbable anions, most likely ampicillin and/or meropenem. He continued on antibiotic therapy and was able to maintain a normal serum K on oral repletion for the remainder of the hospitalization. He resumed his home oral antibiotics upon discharge on HD 22.

Discussion: Workup for renal K loss includes assessing mineralocorticoid activity, acid-base status, and the presence of a urine anion gap if concerned for renal tubular acidosis (RTA). This patient had a low-normal blood pressure and no metabolic alkalosis or acidosis to suggest increased mineralocorticoid activity or RTA, respectively. Hypokalemia associated with antibiotics is a known risk factor, with few cases associated with high dose ampicillin described in the literature. In our case, the high urine anion gap suggests the presence of nonreabsorbable anions. The proposed mechanism is the inability to reabsorb the anion along the nephron, preserving a negative luminal charge and resulting in K secretion at the distal tubule.

TH-PO356

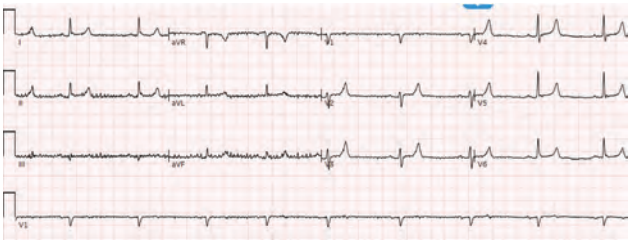
Sea Moss Supplement-Induced Hyperkalemia with Electrocardiographic (EKG) Changes

Marim Zoma,[1] Emma Rochlin,[1] Mohammed A. Abourahma,[2] Agnes R. Libot.[2] *[1]Loyola University Chicago Stritch School of Medicine, Chicago, IL; [2]Loyola University Medical Center, Maywood, IL.*

Introduction: Sea Moss is a widely available herbal supplement, gaining popularity for its supposed health and weight loss benefits. It is high in calcium, magnesium, potassium, and iodine. Sea moss has known risks associated with the excessive iodine, particularly for those with thyroid issues. Our patient experienced hyperkalemia after two weeks on a restrictive sea moss diet, indicating possible additional risks of this supplement.

Case Description: A 72-year-old male with a history of hyperthyroidism, HLD, HTN, CKD stage 3A presented to the emergency department with a one-day history of non-bloody emesis, fatigue and dizziness. In an attempt to lose weight, he was participating in a two-week "sea moss" diet consisting of fruit, water, and sea moss supplements. He continued to take his prescribed medications, including amlodipine and losartan. In the ED, the patient was hypotensive (85/53) and bradycardic (pulse in 40s). Other vital signs remained stable. Physical examination was benign. Labs were notable for: Sodium 130, Potassium 7.1, BUN 54, Cr 4.77 (baseline 1.9), and TSH of 0.26. CBC and troponin levels were within normal limits. The initial EKG displayed peaked T waves and sinus bradycardia, indicative of hyperkalemia. Assessment of renal function showed prerenal AKI, but was otherwise unremarkable. The patient received a 3L IV fluid bolus, calcium gluconate, insulin, and kayexalate to manage hyperkalemia and stabilize cardiac membranes. Antihypertensive medications were stopped, and the patient was continued on maintenance fluids. After a 4-day hospitalization and fluid-resuscitation, the patient's AKI resolved, potassium levels improved to 4.4, and EKG normalized.

Discussion: This report outlines a case of hyperkalemia with associated arrhythmias provoked by excessive sea moss supplementation in a patient taking losartan. This case highlights the growing trend of supplement usage for health management, often without full awareness of their physiological effects and drug interactions. It's crucial for healthcare providers to proactively inquire about patients' supplement use and prioritize discussions on the associated risks.



Abnormal EKG

TH-PO357

Plentiful Peeing in Pregnancy: Could It Be Potassium?

Sruthi Sundaram, Sana Waheed. *Emory University School of Medicine, Atlanta, GA.*

Introduction: In pregnant patients with polyuria, it is important to consider diabetes insipidus (DI). To highlight this, we present a case of complete nephrogenic DI in pregnancy.

Case Description: A 15-year-old G1P0 female with gestational hypertension was admitted at 35 weeks of gestation with polyuria, polydipsia, and in preterm labor. She had persistent hypokalemia during pregnancy which was attributed to vomiting. Ongoing hypokalemia K < 3.0 meq/L and hypernatremia Na > 145 meq/L were noted. Urine output was 5-7 L per day. Plasma renin activity and aldosterone were normal. Urine osmolality was < 100 mosm/L and urine potassium was < 10 mEq/L. Desmopressin (DDAVP) test revealed complete arginine vasopressin-resistance (AVP-R) (Figure 1). Common causes were ruled out, and AVP-R was deemed most likely due to prolonged severe hypokalemia. The patient delivered a healthy preterm infant at 36 weeks, her vomiting resolved, and her serum potassium normalized with supplementation. However, her polyuria persisted, and a thiazide diuretic was initiated until it resolved.

Discussion: The original leading differential was gestational DI caused by placental production of vasopressinase and AVP breakdown; however, this would cause AVP-deficiency and is at odds with the result of the DDAVP test. Hypokalemia causes autophagic degradation of aquaporin-2 and decreased response to AVP causing AVP-R. Typically, the concentrating defect is mild, and symptomatic polydipsia and polyuria is rare. Our patient likely had severe degradation of aquaporin-2 caused by months of persistent hypokalemia resulting in complete AVP-R. Potassium supplementation was unsuccessful until after delivery due to intractable vomiting. Since there is data regarding safety of thiazides while breastfeeding, that was used to treat her persistent AVP-R postpartum. This case

highlights the importance of considering nephrogenic DI in pregnant patients with polyuria and that the DDAVP test can be carried out safely. Fortunately, our patient only required treatment with a thiazide diuretic for 6 weeks postpartum, retained her ability to breastfeed her infant, and was able to be taken off treatment after resolution of AVP-R in a consistently normokalemic state.

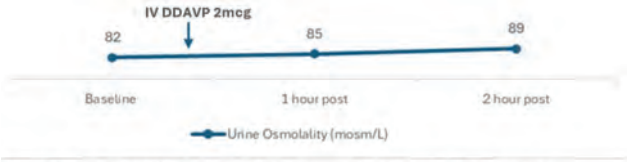


Figure 1: Results of DDAVP challenge. Baseline serum Na 146 meq/L. Baseline serum osmolality 299 mosm/L.

TH-PO358

Unraveling an Uncommon Encounter: Hypokalemic Periodic Paralysis with Brugada Phenocopy Amidst Hypokalemia

Elie El-Charabaty,[1,2] Syed Salman Hamid Hashmi,[1,2] Suzanne E. El Sayegh.[1,2]
[1]Staten Island University Hospital, Staten Island, NY; [2]Northwell Health Feinstein Institutes for Medical Research, Manhasset, NY.

Introduction: Hypokalemic Periodic Paralysis (HPP) presents a diagnostic challenge due to its painless muscle weakness, often linked to ion channel dysregulation. This paper discusses Brugada Phenocopies (BrP), showcasing Electrocardiography (ECG) patterns resembling Brugada Syndrome without the genetic condition. The case contributes to understanding BrP induced by hypokalemia alongside HPP, possibly the seventh documented instance.

Case Description: A 43-year-old man with a medical history significant for hypertension and coronary artery disease presented to the emergency department with lower limb weakness. He reported normal muscular strength the day prior but experienced weakness upon waking the next morning. He attributed his symptoms to a substantial meal consumed after breaking his Ramadhan fast, recalling a similar episode following heavy meals in the past. He had a family history of early cardiac-related deaths. The patient was alert and oriented but demonstrated reduced strength in both upper (3/5) and lower (0/5 bilaterally) limbs. ECG revealed a Brugada type 1 pattern. Laboratory analysis revealed hypokalemia (2.5 mmol/L), elevated creatine kinase (326 U/L), and normal thyroid function. Following potassium supplementation, his symptoms resolved, ECG normalized and subsequent tests demonstrated improvement in potassium levels. A neurology evaluation yielded no significant findings. The patient was discharged with plans for outpatient follow-up.

Discussion: HPP occurs in the context of increased carbohydrate intake, potentially leading to rapid insulin release and activation of Na-K ATPase, enhancing cellular potassium absorption and lowering serum potassium levels. Symptoms range from weakness and fatigue to severe neuromuscular weakness and cardiac arrhythmias. Investigating hypokalemia requires excluding hypomagnesemia, thyroid function tests, and metabolic acidosis/alkalosis before considering HPP. Management involves gradual oral potassium repletion to avoid the risk of hyperkalemia associated with intravenous administration. Clinicians should consider including HPP in differential diagnoses of patients presenting with weakness. An electrophysiological evaluation suggested Brugada pattern induced by hypokalemia, which resolved during the hospitalization. In this case, the association with Brugada phenocopies is intriguing.

TH-PO359

How Low Can You Go? Unlocking the Mystery of Persistent Hypokalemia in Pregnancy

Sadhana Gonuguntla, Lakshmi Kattamuri, Lisa A. Hechanova, Adeel Ahmad.
Texas Tech University Health Sciences Center El Paso, El Paso, TX.

Introduction: Geller syndrome is a very uncommon cause of persistent hypokalemia during pregnancy, first described by Geller et al in 2000, which is caused by a gain of function mutation in the mineralocorticoid receptor gene MRS810L which allows progesterone to activate the mineralocorticoid receptor during pregnancy, causing both hypertension and persistent hypokalemia. We present one such case.

Case Description: 29-year-old G2P1 female at 33 weeks of gestation admitted for preeclampsia with a BP 180/100, also noted to have persistent asymptomatic hypokalemia despite adequate repletion (serum potassium 2.5mMol/L). Her 24 hour urine protein was 0.6g/day. Her urine potassium was 20 mmol/L, urine creatinine 68 mg/dl and random urine potassium to creatinine ratio was 3.3, suggesting renal potassium wasting. Serum renin 2.6ng/ml/h, Serum aldosterone 1ng/dl, and aldosterone renin ratio was 0.3 signifying suppressed aldosterone. She was managed conservatively, and subsequently underwent cesarean section at 34 weeks of gestation after failed induction of labor. 24 hours after delivery, her blood pressure and potassium level returned to normal without needing antihypertensive medications or further potassium supplementation.

Discussion: As mentioned above, Geller syndrome is a rare form of monogenic hypertension, which results from a gain of function mutation in the mineralocorticoid receptor gene MRS810L. It typically presents with hypertension and persistent hypokalemia in the third trimester of pregnancy. In humans, progesterone works as an antagonist on mineralocorticoid receptors but in Geller syndrome, this mutation causes progesterone into an agonist of the mineralocorticoid receptors which causes activation of mineralocorticoid receptors during the third trimester of pregnancy due to high progesterone state, causing hypertension and hypokalemia refractory to correction. Amiloride can be used to treat hypokalemia with some benefit. Interestingly it's been noted that Spironolactone, even though a mineralocorticoid receptor antagonist, seems to have an agonist effect on the mutated MR receptor gene worsening the hypokalemia. We must consider Geller syndrome in the differential for hypertension and persistent hypokalemia during pregnancy. Recognition of this entity can prevent unnecessary early delivery, especially if the patient does not actually have preeclampsia.

TH-PO360

Ectopic Adrenocorticotropic Hormone (ACTH) Syndrome Presenting with Hypokalemia in a Patient with Prostate Cancer

Muhammed N. Rehmani,[1] Sreedhar A. Mandayam.[2] *[1]The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX; [2]The University of Texas MD Anderson Cancer Center, Houston, TX.*

Introduction: Cushing's syndrome is a disorder resulting from excess cortisol levels in the body. Most common clinical manifestations are hypertension, weight gain, excess abdominal fat and hirsutism. We present the case of a patient who presented with refractory hypokalemia and was found to have Cushing's syndrome from ectopic ACTH production despite no clinical signs. Ectopic ACTH syndrome (EAS) is most commonly seen in neuroendocrine tumors however it is rarely also seen in those with primary prostate cancer.

Case Description: A 61-year-old-male with metastatic castrate-resistant prostate cancer and hypertension was admitted for severe hypokalemia. Nephrology was consulted for persistent hypokalemia, with serum potassium levels between 2-3 mmol/L despite multiple enteral and parenteral replacements. His blood work was remarkable for serum sodium of 149 mmol/L, serum pH of 7.66 and serum bicarbonate of 30 mmol/L suggestive of metabolic alkalosis. Of note, he had routine labs one month prior, including electrolytes, which were normal. Further work up revealed elevated serum cortisol and ACTH levels. Dexamethasone suppression test was performed which showed ectopic ACTH production. He underwent extensive imaging, but no source of ectopic ACTH production could be identified. He was therefore diagnosed with EAS secondary to prostate cancer and started on daily metyrapone. Due to poor prognosis, he was discharged to hospice.

Discussion: Cushing's syndrome is rare, and diagnosis is frequently delayed due to non-specific symptoms. Our patient had normal labs one month ago and had no clinical manifestations commonly seen in Cushing's syndrome. Prompt workup of refractory hypokalemia led to a timely diagnosis. Had this patient remained outpatient, diagnosis could have been delayed potentially leading to complications from hypokalemia. This patient also had prostate cancer which does not commonly cause ectopic ACTH production. However, there are growing number of cases in patients with castrate-resistant prostate cancer with treatment related neuroendocrine differentiation as a cause of EAS. Key take-away from this case is that it is important for clinicians to have a high index of suspicion for atypical presentations such as electrolyte disturbances as a presenting sign for underlying Cushing's syndrome.

TH-PO361

Potassium of 8? It May Be Okay to Wait

Tammy N. Do, Arash Ataei, Nahida Baigam, Farshid Yazdi, Rajesh Mohandas.
LSU Health New Orleans, New Orleans, LA.

Introduction: Tumor Lysis Syndrome (TLS) can cause renal failure and life-threatening hyperkalemia due to the release of intracellular potassium. We report an unusual cause of severe hyperkalemia, resistant to therapy, in a patient with suspected tumor lysis syndrome.

Case Description: A 69-year old man undergoing chemotherapy with Bendamustine and Rituximab for Chronic Lymphocytic Leukemia (CLL) was admitted for possible tumor lysis syndrome. On admission, his labs were significant for WBC 364,000/uL, Hb 9.1 gm/dL, K 6.9 mmol/L, Cr 1.77 mg/dL (baseline ~1.4-1.6), BUN 22 mg/dL, Phos 3.4 mg/dL, uric acid 9.7 mg/dL, and Ca 7.8 mg/dL. He was started on IV fluids and allopurinol for TLS and given calcium gluconate, albuterol, Lasix, and insulin for hyperkalemia. His renal function improved to a Cr of 1.5 mg/dL and BUN of 18 mg/dL; however, his hyperkalemia persisted, ranging from 5.5 to 6.5 mmol/L, for which he was repeatedly shifted and started on sodium zirconium cyclosilicate TID. On hospital day 3, patient's hyperkalemia acutely worsened to 7.6 mmol/L and nephrology service was consulted. EKG did not show characteristic changes of hyperkalemia. A venous blood gas with electrolytes was performed, which showed a K of 3.8 mmol/L, confirming the diagnosis of pseudo-hyperkalemia.

Discussion: TLS often complicates hematological malignancies and can result in acute renal failure and hyperkalemia. Although TLS was initially suspected because of hyperkalemia and hyperuricemia in this patient with CLL, the stable or worsening WBC counts and lack of hyperphosphatemia or hypocalcemia all raised questions about TLS. The absence of symptoms, EKG changes, response to therapy, and stable renal function pointed to pseudo-hyperkalemia. Hyperkalemia in CLL is thought to be due to lysis of white cells during the centrifugation step necessary for measuring plasma or serum K. Blood gas analyzers use capillary or venous whole blood samples and do not require centrifugation. Timely recognition of pseudo-hyperkalemia is required to avoid unnecessary and potentially hazardous therapy.

TH-PO362

Urine Chemistry: A Valuable Link Binding Kidney Physiology to Patient Care

Anas R. Alshwayat, Nithin Karakala, Joseph H. Holthoff. *University of Arkansas for Medical Sciences, Little Rock, AR.*

Introduction: The intricate dance of electrolytes within the human body orchestrates vital physiological functions, particularly within the renal system. Amidst the myriad diagnostic tools available, the analysis of urine electrolytes emerges as a cornerstone in unraveling the mysteries of renal channel dysfunction. By Analyzing the composition of electrolytes excreted in urine, clinicians gain invaluable insights into the renal handling of these essential ions. We delve into the significance of urine electrolyte analysis as a diagnostic modality for identifying dysfunctional renal channels. We explore the physiological principles underpinning electrolyte handling in the kidneys, elucidate the mechanisms of channel dysfunction, and discuss the clinical implications of aberrant urine electrolyte patterns.

Case Description: A 17-year-old African American pregnant female, G1P0 at 34 weeks gestation, presented to triage three times with muscle weakness. During one episode, she fell because her legs gave out and was unable to stand again due to the leg weakness. Her potassium level in the ED was 2 mEq/L. This was her first experience of such weakness. We ordered spot urine potassium and creatinine tests, which revealed a K/Cr ratio of 20 mEq/g and a fractional excretion of potassium (FeK) of 4%. This high FeK in the context of hypokalemia prompted us to proceed with a 24-hour urine collection for electrolytes to confirm renal potassium loss. The 24-hour urine results showed undetectable calcium levels, and elevated levels of sodium, chloride, magnesium, and uric acid in the urine, with normal potassium levels (which are considered high for a patient with hypokalemia). These findings confirmed renal potassium loss and implicated thiazide-sensitive NCC channels as the defective mechanism. Genetic testing revealed a mutation in the NOTCH2 gene of unknown significance, potentially causing NCC channel dysfunction, as NOTCH genes affect the expression of SLC12A3 (the gene responsible for NCC channel function). Additionally, the patient had a mutation in the SCN4A gene, which can cause periodic hypokalemic paralysis.

Discussion: The urine studies are extremely valuable in assessing perturbations in renal physiology that can help in determining the management of patients with electrolyte abnormalities

TH-PO363

A Novel Form of Apparent Hypokalemia

Fiona E. Karet, Elizabeth Norgett. *Dept of Medical Genetics/Cambridge Institute for Medical Research, University of Cambridge, Cambridge, United Kingdom.*

Introduction: In contrast to commonly observed rises in blood potassium levels when sample processing is delayed, pseudohypokalemia (an *ex vivo* fall in plasma potassium level) has previously been reported only rarely. Here we describe pseudohypokalemia as a novel clinical phenomenon in a group of patients with hereditary spherocytosis (HS) and *SLC4A1* mutations.

Case Description: Four patients were referred to our renal clinic for investigation of hypokalemia discovered in primary care. All were male and had HS with general malaise. All lived considerable distances from sites of sample processing. *In vitro* time-course experiments revealed marked falls from normal plasma K in patient samples during the first few hours after phlebotomy that were absent from unselected HS blood or a panel of normal controls. This *ex vivo* finding was most marked (up to 1 mEq/L drop) at 25°C, also observed at 18 and 37°C, but absent at 4°C. Three pseudohypokalemics carried mutations in *SLC4A1* (gene encoding the chloride-bicarbonate exchanger AE1). There was no evidence of renal K wasting and acid-base balance was normal. K supplements were stopped without incident; freshly drawn K levels remained normal. The *in vitro* K falls were abolished by ouabain but not bumetanide, implicating the Na/K-ATPase and excluding NKCC1. Na/K-ATPase activity of patient erythrocyte membranes was increased, concomitant with increased Na/K-ATPase protein levels. In *Xenopus* oocytes, mutant AE1 proteins failed to reach and/or exchange chloride at the cell membrane.

Discussion: Hypokalemia is frequently encountered in biochemistry laboratories and during routine patient management. The differential diagnosis is wide, including whole body K depletion and K redistribution into cells. The latter occurs temporarily with insulin treatment of diabetic ketoacidosis; in alkalosis; catecholamine excess; hypothermia; hypokalemic periodic paralysis and in various leukemias (where K is redistributed into the leukemic cells). An abnormally increased rate of K movement into the cells of whole blood in non-leukemic patients has not been previously documented. Here we have demonstrated this phenomenon *in vitro* in selected individuals with HS, associated with AE1 malfunction. Pseudohypokalemia should be considered in any patient with apparent hypokalemia where there has been a delay in sample processing, particularly in the summer, and a blood film examined, looking for red cell dysmorphology.

TH-PO364

Association of Bartter Syndrome in a Filipino Patient with Overlap Syndrome

Wilmark N. Gular, Ivy Kathryn A. Ilagan-Asis, Abigail Kristine S. Juat. *St. Luke's Medical Center-Global City, Taguig, Philippines.*

Introduction: Bartter Syndrome is a genetic tubulopathy resulting in hypokalemia and hypochloremic alkalosis. It has been reported to exist with autoimmune diseases. We describe, possibly the first case of an acquired Bartter Syndrome in a patient with Overlap syndrome.

Case Description: We present a 34-year old Filipino woman with two-month history of generalized weakness. Work-up revealed hypokalemia, urine potassium wasting, metabolic alkalosis consistent with Bartter Syndrome. Oral and intravenous potassium were given with return of potassium to normal. However, weakness persisted. EMG-NCV done showed findings of demyelinating polyneuropathy consistent with Guillain-Barre Syndrome. She was treated with Intravenous Immunoglobulin with resolution of the weakness. The patient had recurrence of weakness two months later, this time with dysphagia. Physical exam revealed diffuse skin thickening with sclerodactyly with an mRSS score of 18 for Systemic sclerosis. ANA was at 1:160. Complements were low with high Anti-dsDNA pointing to lupus. Repeat EMG-NCV showed diffuse distal and proximal sensory-motor polyradiculoneuropathy suggestive of myositis. Rheumatoid factor was positive though she had no joint pains. Serum potassium was low at 3.4. Management included oral potassium with Spironolactone and Methylprednisolone Pulse Therapy which led to significant improvement.

Discussion: We presented a case of an acquired Bartter Syndrome with Overlap Syndrome (Systemic Sclerosis, SLE, pre-clinical Rheumatoid Arthritis and Myositis). This case highlighted the temporal evolution of autoimmune disease and its association with a renal tubular disorder. Management involved potassium supplementation and treatment of the underlying disorder.

Serum Chemistry	Result	Reference Range
Crea	0.54	0.55-1.2 mg/dL
BUN	5	9-23 mg/dL
Na	139	136-145 mEqs/L

Abiraterone-Induced Hypokalemia Refractory to Exogenous Glucocorticoids Successfully Managed with Amiloride

Natalia R. Nombera,[1] Juan Carlos Q. Velez.[2,3] Ochsner Group. [1]*Universidad Peruana Cayetano Heredia, Lima, Peru;* [2]*UQ-Ochsner Clinical School, Brisbane, QLD, Australia;* [3]*Ochsner Health, New Orleans, LA.*

Introduction: Abiraterone acetate irreversibly inhibits CYP17 blocking androgen synthesis in tumors, testes, and adrenal glands, and is used for prostate cancer treatment. Diversion of this enzymatic pathway leads to increased production of the mineralocorticoid

molecules deoxycorticosterone and corticosterone. By virtue of its enzymatic blockade, abiraterone also decreases cortisol, leading to a compensatory rise in ACTH and further rise in mineralocorticoid production, leading to hypokalemia. These effects can be mitigated by ACTH suppression with prednisone. Herein, we report an unusual case of abiraterone-induced hypokalemia despite glucocorticosteroid coadministration, successfully managed with amiloride.

Case Description: A 70-year-old man with prostate cancer receiving chronic treatment with abiraterone and prednisone, presented with dyspnea, emesis and low back pain. He had recently undergone bronchoscopy due to an abnormal CT scan concerning for a granulomatous lesion. Review of old records revealed several episodes of serum potassium (K) of 2.5 – 3.0 mEq/L for the last 3 years. On arrival, blood pressure was 173/107 mmHg, pulse 109/min. Physical exam was normal. Pertinent serum laboratory data revealed a K level of 2.5 mEq/L, sodium 145 mEq/L, creatinine (Cr) 0.8 mg/dL, and carbon dioxide 20 mEq/L. Despite aggressive oral and intravenous KCl supplementation, hypokalemia persisted. Urine K-to-Cr ratio was 82 mEq/g. Plasma renin activity was 0.6 ng/mL/hr and plasma aldosterone concentration was 21 ng/dL. ACTH was 56 pg/mL (normal range 0-46). Corticosterone level was obtained: 6190 ng/dL (normal range 53-1560). A diagnosis of glucocorticoid-refractory abiraterone-induced hypokalemia was made.

Discussion: Amiloride was initiated, and aggressive repletion of potassium was continued. After discussion with Oncology, abiraterone was discontinued. Serum K normalized to 4.0 mEq/L in 2 days and remained normal 2 weeks post-discharge. Amiloride was discontinued and serum K remained normal therafter. This case exemplifies how abiraterone can lead to severe symptomatic hypokalemia despite chronic glococorticoidsteroid mitigating therapy. Elevated ACTH and corticosterone levels confirm the diagnosis. Direct blockade of the epithelial sodium channel (EnaC) with amiloride is an effective therapy.

TH-PO366

Medullary Thyroid Carcinoma Presenting with Severe Hypokalemia

Areej Zaheer. *Henry Ford Macomb Hospital, Clinton Township, MI.*

Introduction: Medullary thyroid carcinoma (MTC) accounts for about 1-2% of all thyroid malignancies. 70 % of most medullary thyroid carcinomas are sporadic in nature. The typical age at initial presentation ranges between 41 and 55 years. Approximately 0.6% of cases of MTC have ectopic production of ACTH. The objective of this case is to bring attention to the association between ectopic ACTH or CRH causing symptoms in the setting of medullary thyroid carcinoma

Case Description: Thirty-eight-year-old male, presented to the hospital due to left upper extremity swelling, redness, and pain. He was diagnosed with acute cellulitis and started on appropriate antibiotics. At the same time, aggressive replacement of potassium resulted in only minimal improvement and recurrence of severe hypokalemia prompting further workup. Urine electrolyte panel results were suggestive of renal potassium wasting defect. The aldosterone level was normal and direct renin level was normal The random cortisol level was increased. Dexamethasone suppression test was done which showed elevated cortisol levels confirming ACTH production. Brain MRI revealed no pituitary lesions. Due to a lack of improvement in the left arm swelling, the patient underwent a CT scan with IV contrast to look for possible obstruction which showed a mass in the thyroid region with abdominal lymph nodes, and multiple hepatic lesions. A liver biopsy was done which was consistent with medullary thyroid carcinoma. The patient was started on metyrapone with an improvement in cortisol levels. The patient was then started on Selpercatinib 160 mg twice per day, with regular follow-ups with heme/onc, nephrology, and endocrinology. His potassium and glucose were well controlled. However, he developed a recurrence of cancer.

Discussion: The diagnosis of ectopic ACTH production secondary to MTC is based on the presence of hypercortisolism not suppressed by high cortisol, absence of pituitary adenoma, and Cushing syndrome symptoms. MTC can spread to lymph nodes, and the lungs, liver, and brain via blood. Treatment for ACTH production includes adrenolytic agents or suppression of steroidogenesis. In extreme cases, bilateral adrenalectomy may be needed. Tyrosine kinase inhibitors including selpercatinib, sorafenib, vandetanib, and cabozantinib are used for chemotherapy for MTC. Due to the high resistance rates of MTC to tyrosine kinase inhibitors, screening for recurrence is essential.

TH-PO367

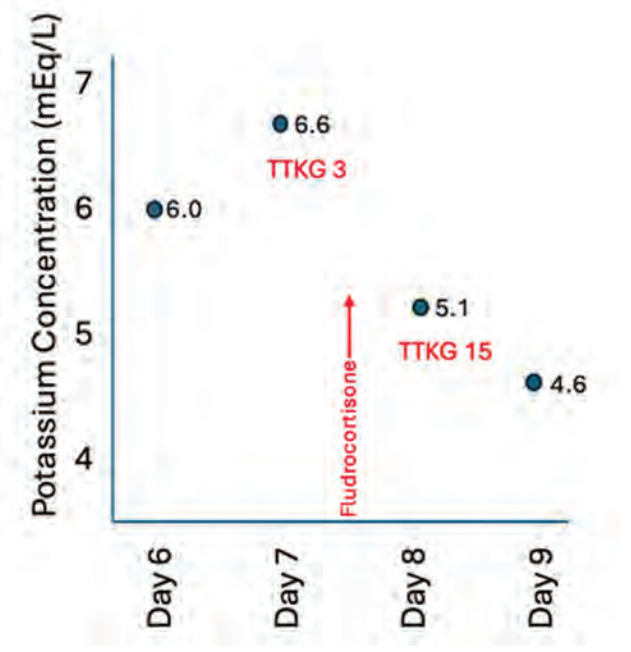
AKI Confounding Heparin-Induced Hyperkalemia

Levan Gakhokidze, Nicole Wyatt, Juan Pablo Arroyo Ornelas. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Heparin induced hypoaldosteronism is an uncommon etiology of hyperkalemia in hospitalized patients. It poses a challenge from diagnostic and management perspectives especially when it occurs in conjunction with other causes of hyperkalemia. We present a a patient with pre-renal acute kidney injury as well as hyperkalemia where transtubular potassium gradient (TTKG) was successfully used for diagnosis and management.

Case Description: A 70 year-old male with an end-ileostomy, CKD3b secondary to recurrent pre-renal acute kidney injury (AKI) from high ostomy output was admitted with atrial fibrillation with a rapid ventricular rate and hypotension. He was started on heparin infusion and cardioverted. The hospital course was complicated with pre-renal non-oliguric AKI thought to be from volume depletion from high ostomy output. Despite improving renal function (creatinine 4.3 - > 2.6 mg/dL) and with appropriate urine output (>1.3L) hyperkalemia progressively worsened (Table 1). There was no evidence of hemolysis or rhabdomyloysis. TTK calculated on day six was 3, suggestive of impaired distal tubular potassium secretion. The patient was initiated on fludrocortisone resulting in prompt improvement of hyperkalemia and increase of TTKG to 15.

Discussion: Heparin induced hyperkalemia is due to decreased renal excretion secondary to decreased aldosterone activity in the distal tubule. Heparin is thought to directly interfere with production of aldosterone. TTKG can assess hypoaldosteronism (cutoff < 5-7). Increase to > 10 after fludrocortisone administration confirmatory. In above case, Fludrocortisone was shown be a successful therapy in addition other conventional treatments of such hyperkalemia. This case highlights that in non-oliguric acute kidney injury with refractory hyperkalemia, heparin must be considered as a potential culprit.



TH-PO368

Semaglutide (S) Completely Reverses the Severe Chronic Myopathy of Hyperkalemic Periodic Paralysis

Kenneth Brand, Daniel L. Landry, Jeffrey Mulhern, Gregory L. Braden. Kidney Care and Transplant Services of New England. *Baystate Medical Center, Springfield, MA.*

Introduction: Hyperkalemic Periodic Paralysis (HPP) is caused by a gene mutation in skeletal muscle Na channel, SCN4a, causing sustained muscle depolarization, hyperkalemia & muscle weakness. After 3 decades most patients develop severe muscle weakness leading to life in a wheelchair. We describe a patient with HPP with severe chronic myopathy & after starting S for weight loss he regained normal strength.

Case Description: A 48 year-male with HPP at age 4 had a Na channel point mutation in the SCN4A gene at 704 with methionine replacing threonine. His father, uncle, sister, & 3 nephews have the same mutation. He was treated with acetazolamide, albuterol, & daranide without success. S was given due to a body mass index greater than 40. We studied the Short Phyicsal Performance Battery (SPPB) pre S & at 4, 7 & 12 months of S. After the third weekly dose sub q of 0.25 mg he noted less weakness. Before the S he could not rise out of a chair without help & his gait was very slow. The table shows his dramatic results & he was normal at 7 months. He stopped S after having GI side effects on 2.4 mg/week & his weakness returned. He is now on 1.7 mg/week with a normal SPPB and muscle strength at 1 year..

Discussion: S is a glucagon like peptide (GLP-1) agonist that inhibits glucagon release, enhances the growth of pancreatic beta cells, and increases their production of insulin. Meals on S increase insulin levels 5 fold which shift K intracellularly. As in animal studies, GLP-1 stimulation of its receptors on skeletal muscle can reverse myopathy by promoting muscle cell growth and inhibiting muscle atrophy. By altering insulin signaling and skeletal muscle physiology, S increases intracellular potassium storage and decreases myopathy in HPP. S is an excellent & novel once weekly option that treats not just the hyperkalemic periodic paralysis but also the skeletal muscle weakness in a multimodal way.

Familial Hypokalemic Periodic Paralysis: A Case Induced by Concurrent Hyperthyroidism

Leanne Brown,[1] Zein Alabdin Hannouneh,[2] C. E. Cervantes,[1] John Sperati,[1] Mohamad A. Hanouneh.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]Al Andalus University for Medical Sciences, Tartus, Syrian Arab Republic.*

Introduction: Familial hypokalemic periodic paralysis (HypoPP) is an uncommon genetic channelopathy marked by recurrent episodes of flaccid skeletal muscle paralysis accompanied by hypokalemia.

Case Description: A 40-year-old African American man was admitted with profound muscle weakness after eating high salt diet. He was unable to move his extremities or sit upright. He had a family history of hyperthyroidism and hypokalemia in his brother and mother. Physical examination revealed profound weakness in extremities. Laboratory results are shown in Figure 1. Swift replacement of hypokalemia alleviated his symptoms. Genetic testing revealed a heterozygous pathogenic variant in *CACNA1S* [c.1583 G>A (p. R528H)] and normal sequencing of *SCN4A* and *KCNJ18*. The patient was diagnosed with familial HypoPP and hyperthyroidism due to Graves' disease. He was started on PO methimazole 10 mg three times a day and PO acetazolamide 250 mg twice a day. He was advised to follow a low carbohydrate and low salt diet.

Discussion: The main triggers for HypoPP episodes are vigorous exercise and high carbohydrate diet, with occasional links to viral infections, stress, salt intake, and medications. Familial HypoPP is linked to gene variants: SCN4A in 20% or CACNA1S in 60% of patients, affecting skeletal muscle sodium and calcium channels, respectively. Generally, hyperthyroidism is linked to thyrotoxic periodic paralysis (TPP) in Asian populations. KCNJ18 variants are associated with TPP susceptibility. TPP likelihood is low in this case due to non-Asian ethnicity, a family history of HypoPP, and absence of KCNJ18 variants. Nevertheless, Graves' disease and a high-salt diet are likely the triggers of the HypoPP episode in this case. Treating acute paralytic episodes involves potassium replacements with monitoring for potential post-treatment hyperkalemia. Changing lifestyle and diet to avoid triggers is crucial. Carbonic anhydrase inhibitors and potassium-sparing diuretic have shown effectiveness in decreasing the frequency of familiar HypoPP episodes.

Basic Laboratory Tests

Blood Tests	Reference Range & Units	Results
Sodium	136 - 145 mmol/L	139
Potassium	3.5 - 5.1 mmol/L	<1.5
Chloride	98 - 107 mmol/L	105
CO2 Total	22 - 29 mmol/L	21
Anion Gap	7 - 18	13
BUN	6 - 23 mg/dL	18
Creatinine	0.67 - 1.17 mg/dL	0.91
eGFR	>=60	109
Glucose	70 - 99 mg/dL	142
Calcium	8.6 - 10.2 mg/dL	9.3
Calcium Ionized	1.17 - 1.38 mmol/L	1.32
Magnesium	1.6 - 2.6 mg/dL	1.9
Phosphorus	2.5 - 4.5 mg/dL	2.1
Total Protein	6.6 - 8.7 g/dL	7.2
Albumin	3.5 - 5.2 g/dL	3.9
Globulin	2.5 - 4.0 g/dL	3.3

Gitelman Syndrome-Related Hypokalemic Nephropathy

Kamyar Pournazari,[1,2] Maria C. Browne,[1,2] Stephen L. Seliger,[1,2] Abutaleb A. Ejaz.[1,2] *[1]University of Maryland School of Medicine, Baltimore, MD; [2]VA Maryland Health Care System, Baltimore, MD.*

Introduction: Gitelman syndrome (GS) is a rare, inherited renal tubular disorder, usually considered a benign tubulopathy wherein progressive CKD is not a common feature. We present a 56-year-old WF with progressive decline in eGFR related to suspected Gitelman syndrome-associated hypokalemia.

Case Description: PMH of bipolar disorder, presented with asymptomatic, persistent hypokalemia and incidental CT finding of bilateral single kidney stone ~3mm. Current medications include bupropion HCL, Topiramate, diazepam and levothyroxine. Patient declined all K supplementation for years. Exam remarkable for thin body habitus, wt 112lbs, BP 102/59. Labs showed persistent hypokalemia and hyperbicarbonatemia over the past decade, SCR 1.66mg/dL, eGFR 36mL/min, CysC 1.68mg/dL, CysC-eGFR 37mL/min, Ca 10.1mg/dL, Mg 2.2mg/dL, UACR<7, UpH 5.5 and SG 1.021, PTH 34.1. eGFR declined from 76mL/min to 34mL/min over a 12-year period. Serum Aldo 9ng/dL, PRA 10.6ng/mL/hr. Gitelman syndrome was suspected and amiloride started, while 24hr urine studies were pending. (Figure 1)

Discussion: Hypokalemia is associated with interstitial fibrosis related to intrarenal vasoconstriction, increased RAS activation and inflammation, leading to tubular atrophy and dropout. Clinically, our patient had intact urine concentration and acidifying capacity. Reungjui et al have proposed another mechanism that involves decreased renal angiogenesis. Accordingly, macrophage-associated cytokines (IL-1β, IL-6, TNF-α) inhibit VEGF expression that causes progressive capillary loss, reduced EC proliferation and decline in GFR. The decade long direct correlation of persistent hypokalemia and progressive loss of eGFR in our patient substantiates our suspicion of Gitelman syndrome-related hypokalemic nephropathy. Ref: **Reungjui S**, Roncal CA, Sato W, Glushakova OY, Croker BP, Suga S, Ouyang X, Tungsanga K, Nakagawa T, Johnson RJ, Mu W. Hypokalemic nephropathy is associated with impaired angiogenesis. TH-PO371

Back to Basics: Multiple Episodes of Hyperkalemia Due to Different Etiologies All Explained by Basic Physiologic Principles

Rafael Portela, Ahmad Matarneh, Sundus Sardar, Aidaliz Llorens, Muhammad Abdulbasit. *Penn State Health Milton S Hershey Medical Center, Hershey, PA.*

Introduction: Potassium handling by the nephron is an important concept taught in medical school but, an intricate understanding of these processes usually develops during nephrology fellowship. Potassium disturbances are greatly influenced by intake, excretion and cellular shifts. We present a case of multiple episodes of hyperkalemia due to different etiologies all explained by basic physiology of potassium handling.

Case Description: 57 year old female with chronic kidney disease stage 3a, MEN 2a syndrome status post right adrenal resection and gastric outlet obstruction with gastrojejunal (GJ) tube who presented for GJ tube dysfunction and stage 1 acute kidney injury. After unclogging the GJ tube, Peptamen 1.0 tube feeds (TF) were started (6 cans per day). After 48 hours, she developed unexplained hypotension. CT Chest revealed partial loculated pleural effusion. Labs showed hyperkalemia of 7.1 meq/L. She was treated medically and nephrology was consulted. At this point, acute kidney injury had resolved, but non anion gap metabolic acidosis (NAGMA) persisted (bicarbonate 20meq/L). Up to this point, hyperkalemia etiology was thought to be multifactorial: excess intake of potassium by TF (11 meq per bottle of Peptamen 1.0), NAGMA and underlying untreated primary adrenal crisis. Morning cortisol was low at 9.9 mcg/dL, consistent with our suspicion of primary adrenal insufficiency. She was treated with IV steroids accordingly and TF potassium content decreased and potassium remained stable at 4-5 meq/L. After 48 hours, had another hyperkalemic episode of 7.7 meq/L with worsening hyperglycemia of 409 mg/dL. Nephrology was reengaged and treatment with insulin was recommended. At this time, the culprit for hyperkalemia was increased insulin resistance in the setting of high dose steroid use, so steroids were tapered. Identifying each etiology of hyperkalemia episode led to prompt management and resolution of severe hyperkalemia.

Discussion: Here we portray multiple etiologies of hyperkalemia that every nephrologist should be aware. Prompt recognition of reversible causes of hyperkalemia such as increased dietary potassium intake, metabolic acidosis, adrenal insufficiency and insulin resistance are life saving and cost effective when managing admitted patients, avoiding invasive procedures, such as hemodialysis.

TH-PO372

Unexpected Discovery: A Case of Adrenocortical Carcinoma

Olamide Olowoyo, Kartik Kalra. *Geisinger Health, Danville, PA.*

Introduction: Adrenocortical carcinoma (ACC) is a rare disease that could present in an unusual pattern. We present a case of a patient with rapid onset, severe hypokalemia and worsening blood pressure (BP) leading to diagnosis of ACC.

Case Description: 67-year-old female, with history of hypertension (well controlled on Amlodipine 5mg daily) presented with gradual onset generalized muscle weakness for 10 days. Her blood pressure (BP) had been poorly controlled over the past 2 weeks and was 180/110 mmHg at presentation. She denied drug abuse, diuretics, or liquorice use. Lab testing (image 1) revealed severe hypokalemia with EKG changes (elongated QT interval and U wave). She was managed medically and discharged on oral potassium supplements in addition to multiple BP medications (Telmisartan 80 mg, Amlodipine 10 mg, Spironolactone 25 mg). Further evaluation in the office revealed elevated Aldosterone/PRA ratio (image 1) raising suspicion for primary hyperaldosteronism (PHA). A CT of the abdomen with adrenal protocol revealed a lobulated right adrenal nodule with adenomatous thickening. Adrenal venous sampling lateralized to the right adrenal gland, and she was referred for a laparoscopic right adrenalectomy. Adrenal gland histology revealed a high grade myxoid ACC. The patient was started on cisplatin, etoposide and mitotane.

Discussion: ACC is a rare and potentially aggressive malignancy. The incidence of ACC worldwide is 0.5 to 2 per 1 million people annually. It could present with hormonal changes from hyperaldosteronism, hyperandrogenism or hypercortisolism, non-specific symptoms or as an incidental finding. It could also be part of some familial cancer syndromes. A high index of suspicion is therefore needed when it presents in an unusual manner such as was seen in our patient with rapid onset hypokalemia and worsening HTN suggestive of hyperaldosteronism. Treatment is with surgery and adjuvant chemotherapy/ radiation therapy. It has a high risk of recurrence.

Parameter	Results at presentation	Normal range	Unit
Serum potassium	1.4	3.5 – 5.1	mmol/L
Creatinine	0.6	0.5 – 1.0	mg/dL
eGFR	>90	>90	mL/min/1.73m²
CO2	34	22-32	mmol/L
Magnesium	2.1	1.5-2.6	mg/dL
Potassium, 24-hour urine	89	25-120	mmol/24 hours
24-hour urine free Cortisol	13.8	4.0 – 50.0	mcg/24 hours

Parameter	Results at presentation	Results after surgery	Normal range	Unit
Aldosterone level	38	2	<28 (Upright)	ng/dL
Plasma renin activity	0.07	0.81	0.25-5.82	ng/ml/h

How Low Can You Go? Abiraterone-Mediated Mineralocorticoid Excess Despite Prednisone Use

Ahmad Al-Tamari, Patricia Khalil, Amr Habbach. *Allegheny Health Network, Pittsburgh, PA.*

Introduction: Abiraterone is approved for the treatment of castration-resistant prostate cancer by inhibiting androgen synthesis. Through this mechanism, however, it also leads to decreased Cortisol synthesis and increased ACTH production. If not given with sufficient dose of oral steroids, this can lead to ACTH mediated mineralocorticoid excess (AME). We present a case of Abiraterone-Induced AME despite glucocorticoid use.

Case Description: 71-year-old male with prostate cancer, presenting with 4 weeks of weakness, and myalgia. Evaluation showed profound hypokalemia with potassium of 1.6 mEq/L and Rhabdomyolysis with a CK level of 7700 U/L, creatinine remained normal. He also had resistant hypertension despite being on multiple oral agents. Further testing suggested potassium wasting with a potassium/Creatinine ratio of 58 mmol/g. Aldosterone level was at less than the detectable range and Renin levels low suggesting a diagnosis of Abiraterone-Induced AME. Abiraterone was discontinued and he was started on Eplerenone with oral potassium supplementation leading to resolution of hypokalemia and hypertension.

Discussion: Profound hypokalemia can lead to life threatening complications, and it is imperative for nephrologists to recognize the presence of AME picture and identify potential rare causes. Abiraterone suppresses androgen production by inhibiting CYP17A1 enzyme. This enzyme is also key in cortisol production pathway. Decreased cortisol levels can lead to increased ACTH secretion causing an increase in Deoxycorticosterone which is a potent mineralocorticoid itself. This leasds to the clinical picture of hypertension, metabolic alkalosis, and hypokalemia. Oral Prednisone is used to suppress ACTH and prevent AME. Close monitoring of potassium levels while on Abiraterone is needed and will likely lead to early identification and need for treatment. However, our case highlights the need for the addition of mineralocorticoid receptor blocker such as Eplerenone to the Prednisone to fully prevent this complication. This case sheds light on Abiraterone as a rare yet significant cause of AME and the need for further investigation of the effective therapy to prevent Abiraterone induced AME.

TH-PO374

Let's Break It Down! A Case of Hypokalemia-Induced Rhabdomyolysis

Shaylor Klein, Gary Sirken, Anna Dymarsky. *Jefferson Health Northeast, Philadelphia, PA.*

Introduction: Severe hypokalemia can result in life-threatening complications such as fatal dysrhythmias and respiratory muscle paralysis. It is the most common, but often unrecognized, electrolyte-induced cause of rhabdomyolysis.

Case Description: A 54-year-old female presented with 6 months of progressive paresthesias, generalized weakness, and fatigue. Her medical history included depression, fibromyalgia, GERD, HLD, IBS, and left breast cancer. Review of systems was positive for anorexia, palpitations, myalgias, and chronic diarrhea. Medications were Anastrozole, Atorvastatin, Cyclobenzaprine, Omeprazole, and Paroxetine. She denied the use of herbal medications, alcohol, or illicit drugs. Vital signs revealed HR 141, BP 150/63, SpO2 98%, T 36.8ºC, and Wt 101 kg. Physical exam revealed a fatigued woman with dry mucous membranes, an irregular cardiac rhythm without murmurs, clear breath sounds, abdomen soft and non-distended, 4/5 strength in the distal bilateral upper extremities, soft compartments, and no dermatological lesions. An ECG revealed frequent PVCs with bigeminy. She was treated with IV fluids, potassium, and magnesium with subsequent ECG normalization. During her hospitalization, her symptoms resolved with electrolyte repletion in conjunction with nephrology input. Her FeNa was 0.1%. Her TTKG was 2.

Discussion: Hypokalemia-induced rhabdomyolysis occurs from cellular potassium depletion, causing vasoconstriction and skeletal muscle ischemia. Our patient had severe hypokalemia causing muscle breakdown and dysrhythmias from chronic diarrhea and anorexia. She had risk factors for other causes of non-traumatic rhabdomyolysis. She was on the lowest dose of Atorvastatin, which has a dose-dependent risk of myotoxicity. Anastrozole and Omeprazole are CYP3A4 inhibitors, however, her Anastrozole dose was reduced and Omeprazole is a weak inhibitor.

Mulethi ("Stick Made Out of Root"): Two Cases of Store-Bought Licorice Toxicity

Brendan L. Ho, Sandeep Aggarwal, Alexander M. Pennekamp, Kirstin Knox. *University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

Introduction: There are many OTC supplements and foods with clinically significant adverse effects. One such compound is licorice, which can result in a syndrome similar to apparent mineralocorticoid excess when consumed in excess. The metabolism of licorice produces glycyrrhizic acid, which competitively inhibits 11β-hydroxysteroid dehydrogenase and allows for inappropriate cortisol binding to renal mineralocorticoid receptors. In this case series, we present two cases in which ingestion of store-bought licorice and its derivatives presents with classic and non-classical manifestations.

Case Description: CASE 1: A 77M with neurocognitive disorder, HCV, HTN, recent poor intake and frailty presented with asymptomatic hypokalemia noted on outpatient labs. On admission, K was 2.5, Mg was 2.0, and HCO3 was 30. BP was 160/92, increased from previous. He received IV and PO repletions of KCl with limited improvement to 3.7 by day 3. He denied recent diuretic & laxative use, vomiting, or diarrhea, so his hypokalemia was initially thought to be due to poor intake. However, further questioning uncovered that he had been consuming bags of black licorice from multiple brands. Plasma aldosterone was <1.0. K was gradually repleted to 4.0 and he was discharged on day 5. CASE 2: A 75M with HTN, CAD s/p PCI presented with fatigue and dyspnea on exertion. In the ED, he was hypotensive, bradycardic, and hypokalemic with ST-depressions and U-waves on EKG. Careful history taking revealed that he had been taking licorice root extract for the past three weeks to treat fatigue. Serum K was 1.2, fractional excretion of K was 45%. Licorice was d/c'd, K was corrected, and bradycardia resolved, at which point he was found to be hypertensive.

Discussion: Licorice and its derivatives are among many foods and OTC supplements with documented harmful effects in the appropriate setting. Other examples include tyramine in aged cheese (Hypertensive Emergency), St. John's Wart (CYP-450 induction, Serotonin Syndrome), and gingko biloba (bleeding risk). Unfortunately, many potentially harmful products are easily purchased at grocery stores and pharmacies without warning labels – an issue compounded by an abundance of claims regarding potentially beneficial effects. Improved regulation and preventative measures to increase awareness about adverse effects could prevent potentially significant complications.

TH-PO376

A Case of Decreased Urine Output with Loop Diuretics

Chanwoo Nam, Negiin Pourafshar, Christopher S. Wilcox. *MedStar Georgetown University Hospital Nephrology Services, Washington, DC.*

Introduction: Loop diuretics are used in escalating doses to treat volume overload and to overcome diuretics resistance. We present a case of a patient who had a decreased urine output despite receiving high doses of intravenous loop diuretics.

Case Description: A 65-year-old obese male presented with acute hypoxic/hypercapnic respiratory failure requiring intubation. He had non pitting edema, without other clinical or radiological evidence of pulmonary edema. His Right atrial pressure was elevated 13 mmHg, right ventricular pressure of 85/15 mmHg, and pulmonary artery pressure of 87/27 mmHg with normal ejection fraction. Due to inability to wean the patient off ventilator, he received a trial of high dose furosemide infusion for 4 days. Over the course of diuretic therapy, his blood urea nitrogen (BUN) and Serum Creatinine (Scr) increased from 13 to 38 mg/dl, and from 0.97 to 2.43 mg/dl respectively. He was given furosemide 200-300 mg/day with less than 1 L urine output and urine sodium (UNa) of 10 during diuretic therapy. Following nephrology recommendation, diuretic administration ceased, resulting in a subsequent increase in urine output to 100-150 ml/hr within 4 hours.

Discussion: This case presents a fascinating unusual antidiuretic response to furosemide with the swift and complete reversal upon diuretic withdrawal is particularly noteworthy. The underlying mechanism is likely rooted in an extreme hemodynamic event within the kidney, precipitated by severe pulmonary hypertension, heightened right heart pressure, and cor pulmonale, possibly from obesity related Pickwickian syndrome. Increased right heart pressure with omental fat deposits in a recumbent position elevates systemic and renal venous pressures, exacerbated by positive pressure ventilation. In the above situation, loop diuretics exacerbates tubular fluid accumulation, increasing renal pressures, reducing net filtration pressure, resulting in a decrease in estimated glomerular filtration rate (eGFR) and urine output. Increased interstitial pressure contributes further compresses capillaries, hindering renal blood flow. Discontinuation of diuretics rapidly alleviates tubular pressure, facilitating the renal function recovery. This underscores the importance of tailored interventions in managing patients with such intricate pathophysiological profiles.

TH-PO377

Aquapheresis: An Alternative Method of Controlled Fluid Removal in the Setting of Hypervolemia and Refractory Gout in Sickle Nephropathy

Hatem Najar, Urmiya Rashid, JingJing Zhang, Hasan Arif, Omar H. Maarouf. *Thomas Jefferson University Hospital, Philadelphia, PA.*

Introduction: Gout flares and vaso-occlusive attacks complicate acute diuresis in patients with sickle cell nephropathy and volume overload (VO). Loop diuretics are considered first line therapy in the management of VO. We present a case in which aquapheresis (AQ) was used as an alternative and more effective method of fluid removal in a patient with sickle cell nephropathy and secondary pulmonary hypertension complicated by refractory gout and sickle pains upon IV diuresis.

Case Description: A 48-year-old patient with sickle cell nephropathy, gout, pulmonary hypertension presented with shortness of breath and bone pain. The physical exam was significant for hypoxia, lower extremity edema and bone tenderness. Chest x-ray showed pulmonary edema. The patient was diagnosed with sickle cell crisis and hypoxic respiratory failure secondary to VO. He was initiated on IV furosemide and analgesics. With diuresis, he developed severe right wrist pain consistent with an acute gout attack despite appropriate treatment. His vaso-occlusive attacks worsened. Upon decreasing the IV diuretic dose, he developed hypervolemic respiratory failure. His kidney function remained stable. Aquapheresis (AQ) consists of the extracorporeal extraction of plasma fluid from the vascular space across a semipermeable membrane. In AQ, fluid removal is controlled by specifying an hourly ultrafiltration rate. This modality offers controlled fluid removal. Upon initiating AQ and stopping IV diuresis, the patient's weight dropped by 10 Kg over several days. He had significant improvement in his respiratory status and remission in his gout flare with a drop in his serum uric acid levels (10.6 to 4.9 mg/dL). His vaso-occlusive pains improved.

Discussion: In summary, AQ was successful in treating hypervolemia in a patient with sickle cell nephropathy and a stable renal function. Uncontrolled and excessive fluid removal using IV diuresis can exacerbate vaso-occlusive disease and precipitate gout flares in patients with sickle cell nephropathy. Controlled fluid removal using AQ reversed the acute rise in uric acid mitigating gout flares and alleviating vaso-occlusive

disease with improved pain control. AQ promises to be a superior method for controlled fluid removal in hypervolemia in patients with sickle cell nephropathy complicated by VO and hypoxia.

TH-PO378

Association between Urine Volume, Urine pH, and Urine H+ Excretion

Robert H. Yenchek, Kalani L. Raphael. *University of Utah Health, Salt Lake City, UT.*

Background: Fluid intake is the cornerstone of nephrolithiasis prevention by increasing 24-hour urine volume. Increasing urine volume could raise urine pH through a dilutional effect on urine [H+] yet not impact H+ excretion rate. We evaluated the association between urine volume, pH, and H+ excretion rate in calcium stone formers. Dietary acids and alkali absorption affect the 24-hour urine pH and modulate nephrolithiasis risk. It is unknown whether fluid intake independently affects urine pH via a dilution effect on the urine H+ excretion rate.

Methods: We evaluated cross-sectional associations between 24-hour urine volume, urine pH, and urinary free H+ excretion rate in 165 adult treatment-naïve, calcium stone formers. All urine parameters were measured using laboratory derived 24-hour urine collection data. 24-hour free H+ excretion was calculated based on urine pH and urine volume. Dietary alkali was estimated by calculating GI alkali absorption (GIAA) and urine sulfate was used as an estimate of dietary acid intake. Linear regression models were used to evaluate the association between 24-hour urine volume and 1) urine pH and 2) 24-hour free urine H+ excretion rate. Models were adjusted for GIAA, urine sulfate, age, sex, BMI, urine creatinine, and urine ammonium.

Results: Mean age was 51 years, 49% were female. Mean urine pH was 5.9 and mean 24-hour urine volume was 1.8 L/d. Urine volume was not associated with urine pH in the adjusted model. However, each 1 liter increase in 24-hour urine volume was associated with a 0.42 (0.33, 0.51) increase in log 24 hour H+ excretion rate in the adjusted model, (see Figure 1).

Conclusions: Contrary to our hypothesis, urine volume was not associated with urine pH but was associated with higher free H+ excretion rate, perhaps due to increased urine flow. Increased H+ excretion rate may offset the expected increase in urine pH from dilution alone.

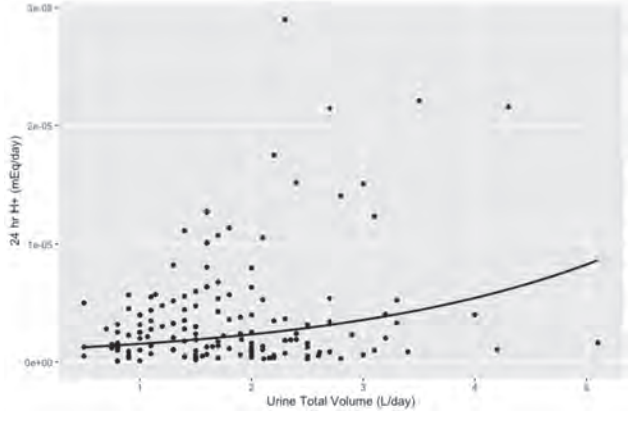

Figure 1.

TH-PO379

Estimating Arterial Bicarbonate (HCO3) from Venous Blood Using the Kidney Electrolyte Panel

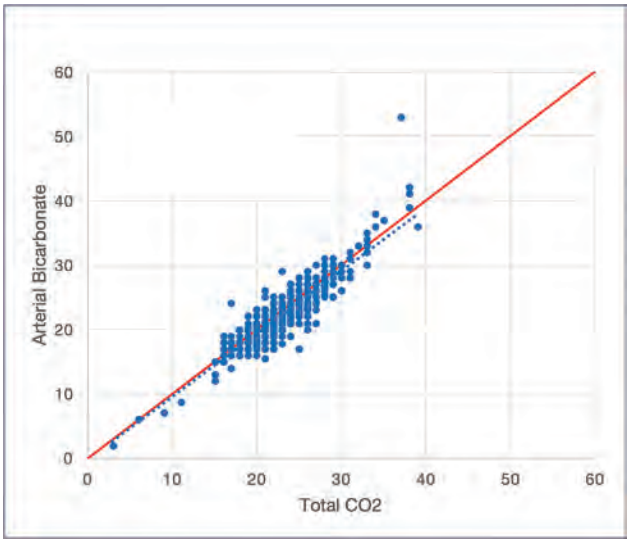
Romy S. Fischer, Crisel I. Rivero Gonzalez, Mohammed Z. Rehman, Carlos A. Rueda Mantilla, Robert M. Rosa, Daniel Batlle. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Arterial blood gas (ABG) analysis remains the gold standard for diagnosis and management of acid-base disorders. Venous blood is much more easily obtainable but there is a need for reliable data to convert venous to arterial data. At last year's ASN meeting we presented results from 7470 samples where blood pCO2 and pH had been measured at the same time for pH and pCO2. We now report on how to best calculate arterial HCO3 from venous blood using a subset of those samples (n=1425) where total venous CO2 had also been obtained at the same time.

Methods: Data were extracted from the medical records of totally de-identified subjects. A total of 1425 samples where it was verified that not only the sampling for venous and arterial blood gas was performed at the same time but that there were also concurrent measurements of total CO2 from an electrolyte panel All measurements were done from samples delivered at the laboratories of Northwestern Medicine over a period of 7 years. The information was provided to us by an independent data analyst and Linear regression and Bland Altman plots were used.

Results: The relationship between venous HCO3 and arterial HCO3 was strong (r=0.89). From the equation defining this relationship venous HCO3 was corrected and plotted against the total CO2 obtained from the venous electrolyte panel. The correlation was also strong (r=0.84) (figure) indicating that the total CO2 can be used to replace arterial bicarbonate in the Henderson Hasselbalch equation.

Conclusions: Using a large database with concurrent measurements of arterial and venous blood accurate estimations of arterial bicarbonate could be made from the venous total CO2 in the renal electrolyte panel. This information has been integrated in an App that allows conversion of venous to arterial blood gas data.



TH-PO380

Pax8 Maintains the Epithelial Phenotype of Proximal Tubule Cells via Distal Regulatory Elements

Jeffrey A. Beamish, Madison C. McElliott, Greg R. Dressler. *University of Michigan, Ann Arbor, MI.*

Background: Pax2 and Pax8 are homologous DNA-binding proteins that orchestrate kidney development, regulate urine concentration in the kidney medulla, and dictate sensitivity to ischemic injury in the kidney cortex. However, the targets of Pax proteins that mediate these functions remain poorly defined. The goal of this project was to identify genes regulated by Pax proteins in the proximal tubule.

Methods: A line of Pax8-conditional, Pax2-null immortalized proximal tubule epithelial cells with a constitutive driver of tamoxifen-dependent Cre (Rosa26-CreER) were derived from adult transgenic mice. A line with spontaneous loss of Pax2 was selected to focus on the effects of Pax8, which is expressed at higher levels in the proximal tubule. Pax8 can be depleted from these cells by addition of 4-OH tamoxifen (4-OHT) to the culture medium. RNA and chromatin samples were collected before and after genetic depletion of Pax8 and submitted for RNA sequencing and chromatin-immunoprecipitation sequencing (ChIP-seq) for Pax8 and histone H3 lysine 4 trimethylation (H3K4me3).

Results: Pax8 protein was depleted by 2 days after 4-OHT exposure. By day 3, cells lost cobblestone epithelial morphology and organization of cell-cell junction proteins. Cell proliferation also slowed. RNA sequencing showed upregulated genes were associated with epithelial-to-mesenchymal transition and inflammatory responses. Downregulated genes were associated with oxidative metabolism. These expression changes mimicked those observed in vivo after proximal-tubule-selective depletion of Pax8. ChIP-seq was used to assess the correlation between gene expression and Pax8 chromatin binding. Promoters bound by Pax8 showed a small but significant reduction in H3K4me3 after Pax8 depletion relative to those lacking Pax8. However, differential gene expression was most strongly enriched with genes associated with distal Pax8 binding sites, between 3-100 kb from the transcription start site. These sites had low H3K4me3 signal.

Conclusions: Pax8 is necessary for the maintenance of differentiated epithelial phenotype in proximal tubule epithelial cells. Differential gene expression induced by Pax8 depletion was strongly associated with Pax8 binding at distal regulatory elements with low H3K4me3. This finding suggests Pax8 maintains gene expression of proximal tubules cells via binding at enhancer elements.

SLC25A48 Is a Human Mitochondrial Choline Transporter

Suraj Dasharath Patil,[1,2] Oleg Borisov,[3] Nora Scherer,[3,2] Christophe Wirth,[4] Pascal Schlosser,[1] Matthias Wuttke,[3] Luciana Hannibal,[8] Kai-Uwe Eckardt,[5,6] Bjoern Neubauer,[1] Anna Kottgen,[3,7] Michael Kottgen.[1,7] *[1]Department of Medicine IV - Nephrology and Primary Care, Faculty of Medicine and Medical Center, University of Freiburg, Freiburg im Breisgau, Germany; [2]Spemann Graduate School of Biology and Medicine (SGBM), University of Freiburg, Freiburg im Breisgau, Germany; [3]Institute of Genetic Epidemiology, Faculty of Medicine and Medical Center–University of Freiburg, Freiburg im Breisgau, Germany; [4]Institute of Biochemistry and Molecular Biology, ZBMZ, Faculty of Medicine, University of Freiburg, Freiburg im Breisgau, Germany; [5]Department of Nephrology and Medical Intensive Care, Charité–Universitätsmedizin Berlin, Berlin, Germany; [6]Department of Nephrology and Hypertension, University Hospital Erlangen, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany; [7]CIBSS - Centre for Integrative Biological Signalling Studies, University of Freiburg, Freiburg im Breisgau, Germany; [8]Laboratory of Clinical Biochemistry and Metabolism, Department of General Pediatrics, Adolescent Medicine and Neonatology, Faculty of Medicine, Medical Center, University of Freiburg, Freiburg im Breisgau, Germany*.

Background: Choline has important physiological functions as a precursor for essential cell components and signalling molecules including phospholipids and the neurotransmitter acetylcholine. Choline is a water-soluble charged molecule and therefore requires transport proteins to cross biological membranes. Its transport across phospholipid bilayer membranes remains incompletely understood. Using metabolite genome-wide association studies, we uncovered that common variants of human *SLC25A48* are associated with altered choline levels in plasma and urine supporting the hypothesis that the orphan solute carrier SLC25A48 may be a choline transporter.

Methods: We used mGWAS, mitochondrial isolation, radioactive uptake assay, LC/MS, immunofluorescence, western blotting, qPCR, and structural modelling.

Results: Overexpression of SLC25A48 revealed mitochondrial localization and increased choline uptake in human epithelial cells compared to control cells. We identified rare putatively damaging variants in *SLC25A48* in humans, which showed an association with elevated urine and plasma choline levels. These mutations exhibited impaired choline transport into mitochondria. Through the combination of immunofluorescence, western blotting, and structural modelling, we revealed distinct mechanisms causing functional impairment of specific damaging variants in *SLC25A48*.

Conclusions: In summary, we showed that the physiological function of SLC25A48 in humans is choline import into mitochondria. The deorphanization of SLC25A48 defines its molecular function in humans and enables future studies addressing its role in health and disease.

Identifying Molecular Regulators of Kidney Collecting Duct Cell Type Plasticity

Alicia L. Simmons,[1,2] Malini Mukherjee,[1] Oduduabasi Isaiah,[1] Michael S. Kareta,[1,3] Kameswaran Surendran.[1,3] Surendran Lab. *[1]Sanford Research, Sioux Falls, SD; [2]University of South Dakota, Vermillion, SD; [3]University of South Dakota Sanford School of Medicine, Sioux Falls, SD*.

Background: Remodeling of kidney collecting duct segments by altering the cell type composition may underlie adaptive capacity when it occurs in a limited manner but may also be part of pathological states. Deficiencies in the machinery and number of principal cells (PCs) are associated with acquired Nephrogenic Diabetes Insipidus (NDI). Conversion of PCs to intercalated cells (ICs) results in loss of PCs when Notch signaling is blocked in adult mouse kidneys resulting in a NDI-like phenotype. Here we use rodent Notch-signaling deficient kidneys to identify the molecular mediators of PC to IC conversion.

Methods: We profiled the wild type versus littermate mice with inactivation of *Hes1* in adult kidney epithelia for 7 days by total kidney RNA-sequencing and by single cell RNA-sequencing of samples enriched for epithelial cells of the loop of Henle, distal nephron and collecting duct segments. We used the mpkccdc14, a principal cell line, with ectopic Hes1-FLAG expression to identify the genes directly regulated by Hes1 by performing Hes1-FLAG-chromatin immunoprecipitation (ChIP) followed by sequencing and qPCR. The spatial pattern of the differentially expressed genes in Hes1 deficient kidneys versus the control wild type littermates were analyzed by RNAscope, and immunohistochemistry.

Results: Hes1-deficiency altered expression of signaling components of Hedgehog, mTOR, and Wnt pathways. Sub-clustering cells expressing PC and/or IC markers as determined by scRNA-seq revealed two PC clusters, two IC clusters and a fifth transitional cell (TC) cluster with both PC and IC marker expression. Comparison of TC versus PC cluster revealed higher expression of IC specific genes and down-regulation of PC specific genes. Some of the upregulated genes in the TCs, such as irs1, were identified as potential direct targets of Hes1 by Hes1-FLAG-ChIP-qPCR.

Conclusions: Hes1-deficient kidneys are useful to identify transcriptional signature and potential mediators of PC to IC conversion that occurs in adult kidneys. Considering that lithium treatment increased PC to IC conversion as determined by lineage tracing, identifying the molecular mediators of PC to IC conversion will allow us to test if these mechanisms are conserved in different forms of acquired of NDI, such as lithium induced or low K+ diets.

TH-PO383

β-Catenin Phosphorylation at Ser552 Impairs Expression of β-Catenin-TCF/LEF Target Genes in Mouse Collecting Duct

Shuo-Ming Ou, Hiroaki Kikuchi, Lihe Chen, Chung-Lin Chou, Mark A. Knepper. *National Institutes of Health, Bethesda, MD*.

Background: Prior phospho-proteomics studies in both cultured and native collecting duct cells showed that vasopressin strongly increases phosphorylation of β-catenin at Ser552 in a protein kinase A (PKA)-dependent manner. In contrast to the N-terminal sites of β-catenin that are phosphorylated as part of canonical Wnt signaling, little is known about the role of Ser552 phosphorylation.

Methods: To address its role in the mature renal collecting duct, we have inserted an Ser552Ala mutation in mice using CRISPR-Cas9.

Results: The mutation did not affect the abundance of the vasopressin-regulated water channel aquaporin-2 (AQP2), urinary osmolality, serum chemistries, and there were no abnormalities of structure of collecting ducts or kidneys or other organs. RNA-seq in microdissected cortical collecting ducts (CDs) of unstressed mice revealed relatively few transcripts that underwent changes in abundance, and no changes in abundances of mRNAs coding for major collecting duct transport proteins, indicative of sustained collecting-duct differentiation. However, when stressed by vasopressin infusion, RNA-seq in microdissected cortical CDs revealed extensive changes in the transcriptome in response to the Ser552Ala mutation, associated with increases in transcriptional targets of the Wnt/β-catenin/TCF pathway. Enriched *Gene Ontology-Biological Process* terms included “cell development“, “collecting duct development“, “ureteric bud development“ and “Wnt signaling pathway“.

Conclusions: Overall, vasopressin-mediated phosphorylation of β-catenin at S552 appears to serve as an “off-switch” for the Wnt/β-catenin/TCF pathway in the collecting duct in the presence of high levels of vasopressin.

TH-PO384

Influence of Gravity on Ureteric Bud Branching and Organ Morphology

Miguel A. Rocha,[1,2] Simone Reichelt-Wurm,[3] Morgan Hamon,[2,1] Hsiao-Min Chang,[2,1] Norimoto Yanagawa,[2] Miriam C. Banas,[3] Peter V. Hauser.[2,1] *[1]VA Greater Los Angeles Healthcare System, Los Angeles, CA; [2]University of California Los Angeles, Los Angeles, CA; [3]Universitat Regensburg Fakultat fur Medizin, Regensburg, Germany*.

Background: In vitro organ culture of metanephroi is a standard technique to study renal development and regeneration. While many aspects of the renal anatomy develop normally, the overall morphology of cultured kidneys appears mono-dimensional (pancake-like). We aimed to study the influence of gravity on 3D morphology and branching to grow kidneys with organotypic anatomy.

Methods: E12.5 kidneys obtained from *Hoxb7*^{Venus} mice were cultured in vitro under static, or dynamic conditions for up to 144h. Ureteric bud (UB) branching morphogenesis was imaged by confocal microscopy on kidneys at 72h + 96h. 3D images were used to measure Branching length, diameter, and branching angle, utilizing gradient vector-based software (TreeSurveyor). Micro Computer Tomography (mCT) images were generated from kidneys at 48h, 72h, 96h, and 120h to compare 3D morphology and volume. Microarray analysis, using GeneChip Mouse Gene 2.0 ST arrays, was performed to uncover gene expression of samples at 72h + 144h. Liquid Chromatography tandem mass spectrometry was used to compare protein expression in samples after 96h of static and dynamic culture.

Results: mCT imaging showed that dynamic culture supports organotypic morphology in contrast to static cultured kidneys, which present mono-dimensional. Cell count of kidneys showed no significant differences between the groups from 0h to 144h, demonstrating normal cell growth in both conditions. UB branching showed similar branch lengths and diameters, but the branching angle average was greater in dynamically cultured kidneys compared to static conditions. Microarray analysis displayed that dynamic culture induced significant differential regulation of genes associated with extracellular matrix (ECM) and receptor interaction, down-regulation of apoptotic processes, mechanical stimulation, bone mineralization, blood pressure regulation, cell migration, and others. Proteomic analysis identified >4000 different proteins. Dynamic culture conditions induced changes in the abundance of proteins associated with focal segmental glomerulosclerosis, Wnt signaling, ECM, pluripotency pathways, and more.

Conclusions: We think dynamic in vitro culture of metanephroi supports organotypic morphology of the developing kidney. Studies are under way to delineate the effect on specific pathways associated with mechanical stimulation.

TH-PO385

α-Parvin, an Integrin-Related Scaffold Protein, Regulates Actin Dynamics to Facilitate Kidney Ureteric Bud Branching Morphogenesis

Xinyu Dong,[1,2] Fabian Bock,[2] Ambra Pozzi,[2] Roy Zent.[2] *[1]Vanderbilt University, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN.*

Background: The kidney collecting system is developed from the ureteric bud (UB), which undergoes branching and tubule elongation via cell division and movement. Multiple factors, including growth factor-dependent signaling, cell-extracellular matrix (ECM) interactions, and actin dynamics are required. While extensive information exists on how growth factors regulate branching morphogenesis, significantly less is known about the roles of cell-ECM receptors and actin dynamics. Integrins, the major cell-ECM receptors, are crucial for mediating cell adhesion and signaling. Integrin function is partly mediated by the recruitment of scaffold proteins like α-parvin. Our previous research demonstrated that a global knockout of α-parvin results in kidney agenesis. However, the specific role of α-parvin in ureteric bud branching morphogenesis remains unexplored.

Methods: We deleted α-Parvin at the initiation of UB development (E10.5) by crossing the α-Parvin$^{fl/fl}$ with HOXB7^{Cre} mice. To allow *ex vivo* imaging and cell tracking, we utilized membrane-tethered (mTmG) GFP mice. To study the molecular function of α-Parvin, we isolated CD cells from 8-week-old α-parvin mice and deleted the gene *in vitro* using adenovirus-mediated delivery of a Cre recombinase.

Results: In this study, we show that a-parvin, an integrin-associating and actin-binding protein, plays a critical role in UB development by regulating ureteric bud cell movement. We observed that the α-parvin$^{fl/fl}$:HoxB7^{Cre} mice exhibited severely dysmorphic kidneys and died within 2-3 months. Mutant kidneys in different embryonic stages showed a significant decrease in size and branching tips, along with widened tubules. Direct *ex vivo* imaging and cell tracking using the mTmG mice demonstrated that a-parvin regulates neighbor exchanges (cell intercalation) and motion persistence, which are essential for tubule narrowing. Isolated α-parvin-null CD cells had increased cell adhesion and spreading but impaired migration. Surprisingly, a-parvin mediated these effects only by regulating Rho family GTPase-dependent depolymerization of F-actin via cofilin and not by affecting integrin function.

Conclusions: We conclude that the integrin scaffold protein, α-parvin, regulates branching morphogenesis and tubule elongation of the UB by controlling actin dynamics.

TH-PO386

Integrin-Binding Proteins Kindlins Regulate Kidney Branching Morphogenic in Both Integrin β1-Dependent and -Independent Mechanisms

Shensen Li, Fabian Bock, Xinyu Dong, Olga Viquez, Ambra Pozzi, Roy Zent. Zent Lab. *Vanderbilt University Medical Center, Nashville, TN.*

Background: The kidney collecting system derives from the branching of the ureteric bud (UB). This process is dependent on growth factor (GF) signaling and the interactions between integrins and the extracellular matrix. Integrin function requires binding of structural intracelluar proteins such as kindlins to highly conserved NxxY motifs to the β cytoplasmic tails. The kidney contains two Kindlins, namely Kindlin 1 and 2, yet their role in govering β1-mediated UB branching is currently unknown.

Methods: Two mutations in the β1 cytoplasmic tail can abrogate kindlin-β1 binding (TT/AA (amino acids 800-801) and Y795A). We expressed these mutations in the developing mouse UB using the Hoxb7 promoter (Hoxb7:TTAA, and Hoxb7:Y795A) and assessed 3D branching. We compared this phenotype to mice lacking both Kindlin 1 and 2 in the UB (Hoxb7:K1/K2). Furthermore, we generated collecting duct (CD) cells *in vitro* expressing these mutations or lacking kindlins and assessed tubulogenesis, polarity, adhesion, migration, proliferation, and GF-dependent signaling.

Results: Hoxb7:TTAA and Hoxb7:Y795A mice displayed mildly dysplastic collecting systems with a mild branching morphogenesis defect. CD cells expressing TTAA or Y795A mutations had moderate abnormalities in tubulogenesis, cell adhesion, migration, proliferation, and polarity, while matrix-induced and GF-dependent signaling was largely intact. In contrast, mice lacking both kindlins in the UB failed to form kidneys due to a lack of UB budding. In addition, the K1/K2 KO CD cells had severe spreading, and polarity defects, and were unable to adhere or transduce GF signaling.

Conclusions: This study shows that kindlins are essential for UB formation and that they control UB branching through mechanisms that are largely independent of β1 integrin binding.

TH-PO387

Deletion of Notch Signaling in the Developing Mouse Kidney Results in Expanded Expression of Arf6, Reduced Expression of E-cadherin, and Dilation of Collecting Ducts

Greg Vanden Heuvel, Kristi L. Bailey. *Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI.*

Background: The Notch pathway is an evolutionary conserved signaling pathway that affects cellular differentiation and proliferation. Notch signaling regulates proximal/distal patterning of the nephron in the mammalian kidney. There are four Notch receptors and five ligands, and during kidney development, Notch receptors are activated by binding to ligands on neighboring cells. This results in a series of proteolytic cleavages that lead to the expression of Notch target genes. Deletion of Notch signaling in the developing collecting duct results in collecting duct dilatations and hydronephrosis. While cells lining the medullary cavity formed from hydronephrosis are highly proliferative, cells lining the cortical dilations do not label with markers of proliferation, and the cell cycle regulator Cux1 is reduced in these cells.

Methods: To determine whether the dilated collecting ducts in Notch mutant kidneys, called RBPJ/k^{CD}, resulted from changes in cell-cell interactions we evaluated the expression of the ADP-ribosylation factor GTPase Arf6 and its target of regulation, E-cadherin. To determine whether reduced Notch signaling had an effect on ciliogenesis, cilia morphology was assessed by immunofluorescence labeling of alpha-tubulin.

Results: Newborn RBPJ/k^{CD} mice exhibited medullary and cortical dilatations. Staining with DBA lectin and cytokeratin confirmed the collecting duct origin of the dilatations. Postnatal day 14 (P14), RBPJ/k^{CD} mice exhibited hydronephrosis and cortical dilatations. Cells lining the dilated collecting ducts exhibited expanded expression of the ADP-ribosylation factor GTPase Arf6, which is normally restricted to the apical membranes. This was associated with a reduction in the expression of E-cadherin in the RBPJ/k^{CD} collecting ducts. However, no differences in N-cadherin expression were observed. In addition, there was no difference in cilia length between wild type and RBPJ/k^{CD} mice.

Conclusions: Taken together, our results suggest that Notch signaling is required for normal kidney collecting duct development, and that reduced Notch signaling may disrupt cell-cell interactions leading to hydronephrosis.

TH-PO388

Transcription Factor Tcf21 Is Required for Specifying Foxd1 Cells to the Juxtaglomerular Cell Lineage

Gal Finer,[1,2] Hina Anjum,[1] George S. Yacu,[1] Silvia Medrano,[3] Roberto Ariel Gomez,[3] Maria Luisa S. Sequeira Lopez,[3] Susan E. Quaggin.[2,4] *[1]Division of Pediatric Nephrology, Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL; [2]Feinberg Cardiovascular and Renal Research Institute, Northwestern University Feinberg School of Medicine, Chicago, IL; [3]Department of Pediatrics, Child Health Research Center, University of Virginia, Charlottesville, VA; [4]Division of Nephrology and Hypertension, Northwestern Memorial Hospital, Chicago, IL.*

Background: Renin is crucial for blood pressure regulation and electrolyte balance. Renin expressing cells are known to arise from the Foxd1+ stromal progenitors; however, the factors guiding Foxd1+ cells towards the renin-secreting cell fate remain poorly understood. Tcf21 is a bHLH transcription factor of the metanephric mesenchyme that plays a crucial role in kidney development. We have previously shown that deletion of Tcf21 in Foxd1+ cells (*Foxd1$^{Cre/+}$;Tcf21$^{f/f}$*) results in paucity of vascular mural cells and in disorganized renal arterial tree. Here, we sought to examine the relationship between Tcf21 and renin cells during kidney development and test whether Tcf21 is implicated in juxtaglomerular cell differentiation.

Methods: We performed histological examination of kidney samples from two mouse models and littermate controls: one with conditional inactivation of *Tcf21* in Foxd1+ expressing cells (*Foxd1$^{Cre/+}$ Tcf21$^{f/f}$*) and the other with inactivation of *Tcf21* in renin-expressing cells (*Ren1d$^{Cre/+}$ Tcf21$^{f/f}$*).

Results: Immunostaining for renin demonstrated that kidneys of *Foxd1$^{Cre/+}$;Tcf21$^{f/f}$* have fewer renin-positive spots at E16.5 and E18.5 compared with controls. In-situ hybridization for *renin* mRNA showed reduced expression in *Foxd1$^{Cre/+}$;Tcf21$^{f/f}$* kidneys at E14.5, E16.5, and E18.5. Together, these data suggest that stromal expression of Tcf21 is required for the emergence of renin cells. To dissect the role of Tcf21 in juxtaglomerular (JG) cells, we deleted Tcf21 upon renin promoter activation (*Ren1$^{dCre/+}$;Tcf21$^{f/f}$*). Interestingly, the *Ren1$^{dCre/+}$;Tcf21$^{f/f}$* kidney showed normal arterial tree at E16.5 identical to controls. Furthermore, inactivation of Tcf21 upon renin expression did not alter kidney morphology in two- and four-month-old mice. Finally, expression *renin* mRNA was similar between *Ren1$^{dCre/+}$;Tcf21$^{f/f}$* and controls at 2 months.

Conclusions: Taken together, our findings suggest that Tcf21 expression in Foxd1+ cells is essential for specifying the fate of these cells into juxtaglomerular cells. However, once renin cell identity is assumed, Tcf21 is dispensable.

Funding: NIDDK Support

TH-PO389

Bridging the Gap of Late-Gestation Human Nephrogenesis Using a Nonhuman Primate Model

Kairavee Thakkar,[1] Sunitha Yarlagadda,[1] Lyan Alkhudairy,[1] Andrew Potter,[1] Konrad Thorner,[1] Nathan Salomonis,[1,2] Raphael Kopan,[1,2] Meredith P. Schuh.[1,2] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]University of Cincinnati College of Medicine, Cincinnati, OH.*

Background: Prematurity is associated with low nephron endowment and an increased risk of chronic kidney disease. Human nephrogenesis is complete at 34-36 weeks gestation, with 60% of nephrons forming during 3rd trimester through lateral branch nephrogenesis (LBN). To overcome the barriers of studying late-gestation human tissue, we utilized a non-human primate model (rhesus macaque) to study LBN.

Methods: Single-cell RNA-sequencing (scRNA-Seq) was performed on 9 cortically-enriched fetal rhesus kidneys from late second trimester and third trimester during LBN. This data was integrated with publicly available human scRNA-seq datasets from 8-18 weeks gestation kidneys (n=8) using state-of-the-art bioinformatics pipelines. Ligand-receptor interactions were assessed and validated on human and rhesus archival tissue using RNAScope.

Results: scRNA-Seq of 64,782 rhesus cells revealed 37 transcriptionally distinct cell populations, including four nephron progenitor cell (NPC) clusters (7937 cells) (Figure 1). We noted increased *SFRP1*, *FZD4*, *FZD6*, and *TLE2* and decreased *FZD7*, *SHISA2*, *SHISA3*, and *TLE4* within the rhesus late-gestation NPC compared to mid-gestation human NPC, supporting a compositional shift in WNT signaling within the naive NPC population during LBN. We identified changes in constitution of the FGF and Semaphorin (SEMA3) pathways as well.

Conclusions: The rhesus macaque uniquely enables molecular studies of late gestation primate nephrogenesis. Our study supports the hypothesis that a compositional shift in key pathways within the naive NPC population during LBN may underly the switch from branch phase nephrogenesis to lateral branching. Future studies will focus on maintaining this signaling environment to promote nephron formation in preterm infants.

Regulators of Intermediate Mesoderm Development Impact Neighboring Vessel Progenitor Specification

Elliot Perens,[1,2] Elizabeth Willemijn Stouthart,[1] Matthew Nunes,[1] Deborah Yelon.[1] *[1]University of California San Diego, La Jolla, CA; [2]Rady Children's Hospital San Diego, San Diego, CA.*

Background: Congenital anomalies of the kidney and urinary tract (CAKUT) are diagnosed in 1 out of 500 live births, and pathogenic mutations have been identified more than 50 genes. Many of these genes, including the two most frequently mutated genes, *PAX2* and *HNF1β*, have been implicated in early aspects of kidney development. The first step in kidney development is the specification of kidney progenitors within the intermediate mesoderm (IM), a pair of bilateral territories within the posterior mesoderm, flanked by tissues that give rise to vessels, blood, muscle, bone, and peritoneum. Our previous work in the zebrafish model system highlighted a coupling of IM formation with the development of neighboring vessel progenitors (VPs). We demonstrated that the transcription factors Hand2 and Osr1 act in opposition at the lateral border of the IM to balance the specification of IM and VPs (Perens et al., 2016; Perens et al., 2021). More recently we found that the transcription factor Npas4l (Cloche), an early essential regulator of VP formation, is required to inhibit IM formation at both the lateral and medial IM borders (Perens and Yelon, 2024).

Methods: Genetic analyses, molecular anatomical studies, single cell RNA-seq, genetic lineage analysis

Results: First, surprisingly, our genetic analyses suggest that genes expressed in and necessary for IM development – *pax2a* and *pax8* – are required for formation of VPs at the lateral IM border while inhibiting excessive VP formation at the medial border. Second, we observe that lateral VPs co-express genes associated with VP (ie. *etv2*) and IM fates (ie. *pax2a*). Third, our preliminary scRNA-seq data on IM cells (obtained by sorting cells double positive for *pax2a* and *hnf1βa* transgenes) further suggest that the IM is divided into subdomains with unique transcriptional signatures and divergent developmental potentials, including a domain capable of generating IM and VPs.

Conclusions: Together, our data further highlight intriguing genetic and lineage relationships between the IM and neighboring VPs.

Forming Nephrons Promote Nephron Progenitor Maintenance via Paracrine BMP4 Signaling

Alexander N. Combes, Julie L. Moreau. *Monash University, Melbourne, VIC, Australia.*

Background: Current models propose that interactions between stromal, ureteric, and nephron progenitors are sufficient to drive kidney development. In this study, we aimed to investigate whether the forming nephron is a passive product of the niche, or whether it is an active partner in the signalling interactions required for ongoing progenitor maintenance and branching morphogenesis.

Methods: Kidney size and morphology were assessed in global *Wnt4* knockout (KO, *Wnt4*$^{GCE/GCE}$), and conditional *Wnt4* knockout (cKO, *Six2*TGC-*Wnt4*$^{fl/fl}$) mice using brightfield imaging, histology and immunofluorescence at embryonic day (E) 17.5. Nephron progenitor cell number, dispersal, proliferation and death were examined through wholemount and section immunofluorescence at E14.5 and E17.5. Conditional deletion of *Wnt4* was assessed by ddPCR in sorted *Six2*GFP+ and LTL+ cells. Transcriptional changes were assessed with bulk and single cell RNAseq in KO and cKO kidneys; select results were validated by quantitative hybridisation chain reaction (HCR). Nephron progenitor cell dispersal from the tip was assessed by confocal microscopy in wholemount wildtype and *Wnt4* KO kidneys after culture with or without 100ng/mL BMP4.

Results: Kidney size, branching, and nephron progenitor cell number were severely reduced in *Wnt4* KO kidneys. Conditional deletion of *Wnt4* with *Six2*Cre was incomplete but led to decreased kidney size, lower nephron progenitor cell number, increased cell death and dispersal from the tip, and reduced branching morphogenesis. Single cell RNAseq revealed a downregulation of BMP signalling effectors *Id1* and *Id3* in nephron progenitor cells, implicating *Wnt4* target BMP4 as a paracrine signal mediating feedback from the committing nephron. Reduced expression of *Bmp4, Id1*, and *Id3* was validated by HCR; *Fgf8* was unchanged. Recombinant BMP4 restored nephron progenitor compaction in cultured *Wnt4* mutant kidneys and blocked differentiation in wildtype controls, mirroring the role of BMP7-MAPK signalling in progenitor self-renewal.

Conclusions: This study illustrates a crucial role for developing nephrons in maintaining the nephron progenitor population, partly via paracrine BMP4 signalling. These results suggest an indirect relationship between nephron formation and branching morphogenesis and shed light on the mechanisms of renal hypodysplasia associated with human *WNT4* mutations.

Transcriptional Control of Early Nephrogenesis in Xenopus tropicalis

Paulina Ogar,[1] Maike Getwan,[1] Yuya Sugano,[1] Thomas Naert,[2,1] Soeren S. Lienkamp.[1] *[1]Universitat Zurich, Zurich, Switzerland; [2]Universiteit Gent, Gent, Belgium.*

Background: The transcription factors Pax8, Hnf1b, and Sall1 underpin embryonic kidney development, and are linked to Congenital Anomalies of the Kidney and Urinary Tract (CAKUT). They are localised in distinct regions within the ureteric bud epithelium, and metanephric mesenchyme, which interact to orchestrate kidney formation. Intriguingly, however, these factors are roughly co-expressed within the same developing pronephric region in *Xenopus*. Further understanding of their functions could unveil insights into the transcriptome underlying nephrogenesis.

Methods: We visualised cells in the developing pronephros, by confocal microscopy. Injections were combined with CRISPR/Cas9 knock-out (KO) of *pax8*, *hnf1b*, or *sall1* to analyse effects on kidney morphology. Termed single embryo transcriptomics (seRNA-seq), we performed CRISPR/Cas9 KO of *pax8*, *hnf1b* and *sall1* in individual embryos and bulk RNA-seq at an early stage. To filter for renal genes, seRNA-seq was intersected with a kidney-enriched *X. tropicalis* dataset. Localisation of seRNA-seq targets was performed using *in situ* hybridisation (ISH).

Results: We characterised pronephros development in molecular detail, highlighting key stages, from mesenchyme condensation to epithelialisation. KO of *pax8*, *hnf1b*, or *sall1* disrupted size, cell organisation and the basement membrane, underscoring their importance in proper pronephros formation. Considering this, we explored their roles in the transcriptional network using CRISPR/Cas9 and seRNA-seq. Renal and morphogenetic genes were identified (e.g. *slc12a1* up- and downregulated in *pax8 and hnf1b* KO respectively, *twist1* upregulated in *pax8* and *hnf1b* KO). Extracellular matrix genes (*lama1*, *col4a6*) were downregulated in the *sall1* KO. ISH validation of seRNA-seq revealed expression of several targets within the early and developed pronephros (e.g. *agpat3*, *traf4*, and *epha4*).

Conclusions: Pax8, Hnf1b and Sall1 are key regulators of nephrogenesis, and influence a network of renal and morphogenetic targets in *X. tropicalis*. Clarifying their roles will improve understanding of inherited kidney malformations and disease.

TH-PO393

Alternative Oxidase Expression Restores Kidney Progenitor Differentiation in Mice with Mitochondrial Complex lll Disruption

Ryoichi Bessho, Hanako Kobayashi, Volker H. Haase. *Vanderbilt University School of Medicine, Nashville, TN.*

Background: Oxidative metabolism in mitochondria generates ATP through oxidative phosphorylation, regulates cellular differentiation and gene expression through intermediary metabolism and produces reactive oxygen species (ROS). The specific roles of different mt functions in kidney development and pathogenesis are not well understood. We previously reported that disruption of mitochondrial (mt) complex III in cap mesenchyme resulted in severe kidney dysplasia and perinatal death (Guan N, *et al. Kidney Int* 2022). For the disruption of mt complex III, we targeted ubiquinone binding protein QPC using the *Six2-Cre* transgene (*Six2-Qpc*$^{-/-}$ mutants). This resulted in decreased proliferation of renal progenitors and their complete failure to differentiate into tubular epithelium. QPC inactivation disrupted mt electron flux and oxidative phosphorylation and decreased total kidney tricarboxylic acid (TCA) cycle metabolites and amino acid levels.

Methods: To investigate the contribution of TCA cycle dysfunction to the *Six2-Qpc*$^{-/-}$ phenotype, we generated mice expressing alternative oxidase (AOX) in *Qpc*$^{-/-}$ renal progenitors. AOX is derived from sea squirt and restores mt electron transport and TCA cycle flux. We performed morphological, immunohistochemical, gene expression, as well as targeted and untargeted metabolomic analyses of kidneys at postnatal day 0.

Results: AOX expression in *Qpc*$^{-/-}$ renal progenitors rescued postnatal lethality. Immunohistochemical staining and gene expression analyses of tubular differentiation markers, such as megalin, demonstrated restoration of proximal tubular differentiation. AOX expression, however, did not completely restore kidney weight to normal values and all AOX-expressing *Six2-Qpc*$^{-/-}$ mutants died by postnatal day 14. The results from metabolomic analyses will be presented in detail at the meeting.

Conclusions: Taken together, restoration of TCA cycle flux by AOX induced tubular differentiation in mice with mt electron chain disruption in SIX2 nephron progenitors but did not generate functional adult kidneys. Although, our studies suggest a critical role for TCA cycle flux and TCA cycle-regulated gene expression in nephron progenitor differentiation, other mt functions, such as oxidative phosphorylation and ROS production, are required for cell proliferation and postnatal growth of the kidney.

Interrogating Progenitor Fate Processes in the Developing Zebrafish Pronephros Using Mathematical Models

Matthew R. Hawkins, Stuart Jones, Hannah M. Wesselman, Cecilia A. Cesa, Rebecca A. Wingert. *University of Notre Dame, Notre Dame, IN.*

Background: A core component of developmental and regenerative nephrology is aimed at determining critical relationships between renal progenitors, cells with stem-like qualities, and their progeny. Zebrafish, a vertebrate model well suited for studies involving nephrogenesis and neonephrogenesis, presents with a unique progenitor-rich environment that allows us to characterize and hypothesize qualities and relationships that these precursors hold. Previously, much of the work using this model has been aimed at better understanding conserved genetic regulators of renal development. While this work has been foundational to our understanding of pronephros development, there is still much to be uncovered with respect to the cellular relationships present in early nephrogenesis. Using mathematical models, we are able to hypothesize and interrogate these properties and relationships that precursor populations hold during zebrafish pronephros development.

Methods: To parameterize our model, we have utilized techniques such as whole-mount and fluorescent in situ hybridization as well as immunohistochemistry. For our mathematical modeling, we have used both ordinary differential equations as well as statistical models to characterize multiple cellular populations present in the zebrafish pronephros. For our algorithmic approaches to model parameterization, we have utilized the Nelder-Mead method.

Results: Using the aforementioned methods, we have constructed models that contain different forms of fate processes during nephrogenesis including asymmetric differentiation as well as division independent differentiation. From these models, we can speculate how and when precursors differentiate during pronephros development in the zebrafish model. Using ordinary differential equations that represent multiple cell populations through time and by using multiple goodness of fit indicators to compare model outcomes to biological data, we can arrive at properties of progenitor populations.

Conclusions: Using this model for pronephric development, we test hypotheses on the necessity for division dependent/ asymmetric fate processes, characterize progenitor activity in the earliest stages of renal development, and demonstrate the need for independent qualities among progenitor populations that exist in nephrogenesis.

Assembly of a Functionally Mature Synthetic Kidney Organoid with Spatial Patterning from the Self-Organization of Expandable Kidney Progenitors

Pedro Medina, Biao Huang, Chennan Zhang, Megan Schreiber, Nuria M. Pastor-Soler, Andrew P. McMahon, Zhongwei Li. *Keck Medicine of USC, Los Angeles, CA.*

Background: The prospect of utilizing stem cells to rebuild a kidney holds great promise as an alternative organ source for kidney transplantation. During kidney development, nephron progenitor cells (NPCs) give rise to the nephrons, and ureteric progenitor cells (UPCs). We have previously established systems to expand mouse and human NPCs and UPCs. Here we investigate whether we can assemble a functionally mature synthetic kidney organoid with patterned and interconnected nephrons to the collecting ducts from expandable NPCs and UPCs.

Methods: Culture conditions were tested to enhance the natural reciprocal interactions between NPCs and UPCs. The resulting synthetic kidney organoids were characterized in a time-course manner and compared to the native kidney development. Single-cell multiome, and physiological assays were performed to characterize the development and functionality of the synthetic kidney organoids.

Results: Under optimal culture conditions, we assembled synthetic kidney organoids from expandable NPCs and UPCs. Synthetic kidney organoids can recapitulate the major developmental stages of the native kidney *in vitro* as that *in vivo*: NPCs undergo the subsequent stages of nephrogenesis before forming around 150 well-segmented nephrons; UPCs undergo dramatic branching morphogenesis, eventually forming a central collecting duct system interconnected to the distal ends of the nephrons formed from the NPCs. snRNA-seq and snATAC-seq confirmed the formation of all major nephron and collecting duct cell types with a transcriptome comparable to a postnatal kidney. Surprisingly, the major kidney stromal cell types are also formed, in a mechanism that involves the plasticity of a subset of NPCs adopting interstitial progenitor cell fate, the third kidney progenitor cell type that gives rise to the kidney stromal cells. Functional assays validate the renal epithelia's physiological and major endocrine roles similar to the native kidney. Upon transplantation, the synthetic kidney organoids are properly vascularized and produce primitive urine.

Conclusions: The generation of a functionally mature, and spatially organized synthetic kidney organoid model represents a major step toward the development of transplantable synthetic kidneys, and other therapeutic modalities.

A Scalable Platform for Generating Uniform Human-Induced Pluripotent Stem Cell (hiPSC)-Derived Kidney Organoids Using Micropatterning

Samera Nademi, Benjamin S. Freedman. *University of Washington School of Medicine, Seattle, WA.*

Background: Organoids hold immense potential for modeling complex diseases, drug discovery, and regenerative medicine. However, current methods for generating organoids suffer from limitations in reproducibility and scalability, hindering their use in high-throughput applications. We present a novel approach to overcome these limitations by developing a standardized micropatterned platform for generating human induced pluripotent stem cell (hiPSC)-derived kidney organoids. Micropatterning has shown promise in improving the development and drug screening capabilities of other organoid types, such as neural organoids. However, its application to hiPSC-derived kidney organoids remains unexplored.

Methods: Here, we describe the first-of-its-kind method for generating uniform hiPSC-derived kidney organoids in various micropatterns, including linear, square, and hexagonal shapes, with customizable patterns and sizes.

Results: Our micropatterning method successfully generated hiPSC cultures in various geometries, including linear, square, and hexagonal shapes. We achieved precise control over both the pattern and size of the cultured hiPSCs, enabling customization for specific experimental needs.

Conclusions: In conclusion, our micropatterning method has established a foundation for the development of standardized hiPSC cultures. The precise control over patterning and size paves the way for tailored experiments and potentially unlocks a new era of consistent and scalable hiPSC-derived organoid generation. We now investigate if micropatterned hiPSCs differentiate into more uniform kidney organoids (size and structure) compared to conventional methods. This analysis, involving comparisons between patterned and non-patterned organoids, will determine if our approach enables large-scale production of consistent kidney organoids for disease modeling, drug screening, and potentially, future kidney regeneration.

TH-PO397

Generation of Human Expanded Pluripotent Stem Cell-Derived Kidney Organoids with Patterned Nephron by Regulating Hippo-YAP Pathway

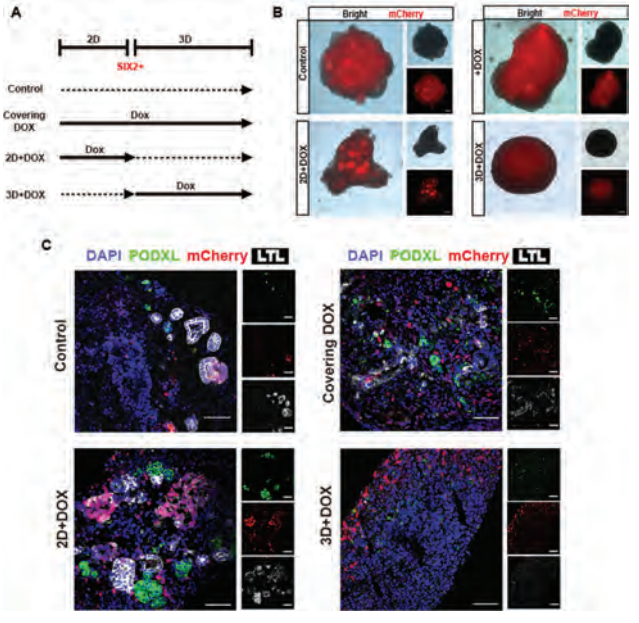
Liangzhong Sun. *Southern Medical University, Guangzhou, China.*

Background: Numerous cultivation protocols for kidney organoids, differentiation efficiency remains generally low. This study aims to investigate the influence of the Hippo-YAP pathway on induced differentiation of kidney organoids and elucidate its molecular mechanisms, thereby providing efficient induction strategies for kidney organoid construction.

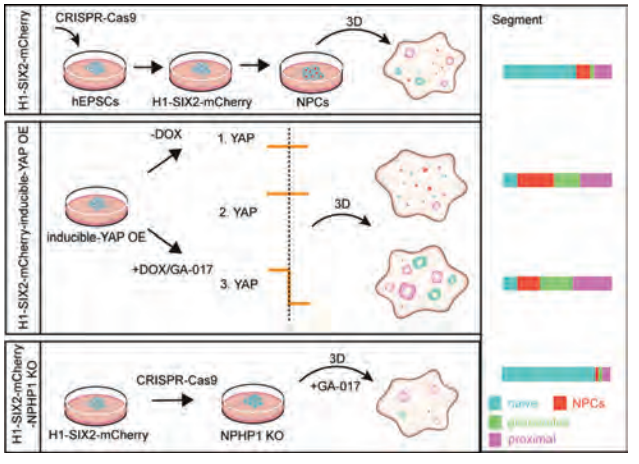
Methods: We used CRISPR-Cas9 technology for a reporter gene cell line was constructed based on human Expanded Pluripotent Stem Cells (hEPSC). Besides, an inducible YAP overexpression cell line and a NPHP1 knock-out cell line were constructed on this basis. The differentiation of kidney organoids under genetic and chemical schemes were compared.

Results: We have developed a methodology to generate kidney organoids with pattern nerphron, differentiated from SIX2-mCherry knock-in reporter hEPSCs, by regulating Hippo-YAP signaling pathway. We find that inhibiting the Hippo-YAP pathway during early differentiation stages effectively increased the number of nephron progenitor cells, resulting in more pattern nerphron.

Conclusions: Regulating the Hippo-YAP pathway during early stages of kidney organoid differentiation facilitates their maturation, offering effective induction strategies to enhance the efficiency of kidney organoid differentiation.



The result for regualting YAP expression



Schematic showing regulating Hippo-YAP pathway for kidney organoids with patterned nephron

Controlling Proximal Nephron Arrangement and Maturity in Stem Cell-Derived Engineered Kidney Tissue

Jessica M. Vanslambrouck,[1,2] Ker sin Tan,[1] Sophia Ying Yii Mah,[1] Kathleen Dominic,[1] Melissa H. Little.[1,2] Kidney Regeneration, Stem Cell Medicine Theme. *[1]The Novo Nordisk Foundation Centre for Stem Cell Medicine (reNEW), Murdoch Children's Research Institute, Parkville, Melbourne, VIC, Australia; [2]Department of Paediatrics, Faculty of Medicine, Dentistry and Health Sciences, The University of Melbourne, Parkville, Melbourne, VIC, Australia.*

Background: The proximal tubule (PT) structure is critical to the metabolic, endocrine, immune, and general homeostatic functions of the kidney. However, its acute vulnerability to damage and disease has made the generation of stable and accurate PTs a key objective of kidney disease research and treatment advances. While human pluripotent stem (hPSC)-derived kidney organoids are one approach, their immature PTs and disorganised nephron spatial arrangement remain a barrier to translational applications. We have previously developed PT-enhanced kidney organoids with elongated and functionalised proximal tubules. Here we report a breakthrough in the control of proximal nephron spatial arrangement achieved by exploiting biophysical parameters. This approach supports the formation of physiologically relevant S1/S2/S3 PT segmentation and is transferable to organ-on-a-chip platforms.

Methods: Standard and reporter hPSCs were differentiated to enhanced nephron progenitors prior to organoid formation (Vanslambrouck *et al. Nature Protocols*, 2023). Progenitors and PT-enhanced organoids were generated using standard or extrusion-based 3D cellular bioprinting techniques in combination with novel organ-on-a-chip platforms, metabolic-supportive media, and comprehensive analyses using high-content confocal imaging, transcriptional profiling, and transporter functional assays.

Results: Here we show that stringent control of organoid biophysical parameters can be used to guide the spatial arrangement of nephrons within hPSC-derived PT-enhanced kidney tissue. Using appropriate metabolic support for maturing organoid cells populations, increased levels of transporters and the formation of distinct PT cell subtypes was observed. Finally, the generation of appropriately patterned PT was possible from cryopreserved progenitors, simplifying manufacture and scale up.

Conclusions: The advances to our protocol have founded an improved PT platform likely to provide more accurate disease modelling and drug/toxicity screening opportunities.

Selective Induction of Renal Interstitial Progenitor Cell Lineages from Human-Induced Pluripotent Stem Cells (hiPSCs) for Understanding of Mesangial and Erythropoietin (EPO)-Producing Cell Development and Kidney Regeneration

Hiraku Tsujimoto,[1,2] Azusa Hoshina,[1,3] Shin-ichi Mae,[1] Toshikazu Araoka,[1] Cecilia Graneli,[4] Kevin Woollard,[4] Kenji Osafune.[1] *[1]Center for iPS Cell Research and Application (CiRA), Kyoto University, Kyoto, Japan; [2]Rege Nephro Co., Ltd., Kyoto, Japan; [3]Shiga Kenritsu Sogo Byoin, Moriyama, Japan; [4]AstraZeneca PLC, Cambridge, United Kingdom.*

Background: Recent regenerative studies using human pluripotent stem cells (hPSCs) have developed multiple kidney-lineage cells and organoids. To further form functional segments of the kidney, the interactions of epithelial and interstitial cells are required. By selectively generating one lineage, we can detail developmental signals in complex organ development. Renal interstitial progenitor cells (IPCs) are useful for elucidating the function and pathology of renal interstitium. Renin-producing mesangial lineage cells contribute to hypertension and EPO-producing cells are key in kidney fibrosis. We aim to develop a method to selectively induce renal IPCs and their derivatives from human induced pluripotent stem cells (hiPSCs) and reveal the developmental mechanisms of IPC-lineage cells.

Methods: We modified our previously reported induction method for nephron progenitor cells (NPCs) from hiPSCs by modulating developmental signals involved in the transition from primitive streak to renal IPCs, which were identified by single-cell RNA-sequencing (scRNA-seq) analysis of mouse embryos. We established OSR1-GFP/FOXD1-tdTomato double knock-in hiPSC lines.

Results: We developed a method to generate IPC-like cells (IPLCs) over 80% of induction efficiency. Our IPLCs combined with hiPSC-derived NPCs and nephric duct cells form nephrogenic niche- and mesangium-like structures *in vitro*. Furthermore, we successfully induced mesangial and EPO-producing cell lineages *in vitro* by screening differentiation-inducing factors. We confirmed that p38 MAPK and vascular endothelial growth factor (VEGF) signaling pathways are involved in the differentiation of mesangial-lineage cells. Re-analysis of public scRNA-seq data of human embryonic kidneys and an organ culture experiment using mouse embryonic kidneys supports p38 MAPK activation upon the differentiation of mesangial-lineage cells. Furthermore, using small molecules, we revealed that Sonic Hedgehog signaling is involved in the differentiation from IPLCs to EPO-producing cells *in vitro*.

Conclusions: Our IPC-lineage induction method contributes to kidney regeneration and developmental research.

Amniotic Fluid Organoids as Personalized Real-Time Models of the Fetal Kidney and Lung

Oren Pleniceanu,[1,2] Olga Babosova,[1,2] Boaz Weisz,[1,2] Grace Rabinowitz,[1] Tammir Jubany,[1,2] Hagai Avnet,[1,2] Noam Pardo,[1,2] Iris Barshack,[1,2] Dorit Omer,[1] Zohar A. Dotan,[1,2] Benjamin Dekel,[1,2] Rena Levin-Klein,[1] Pazit Beckerman.[1,2] Kidney Research Lab, Sheba Medical Center. *[1]Sheba Medical Center, Tel Hashomer, Israel; [2]Tel Aviv University, Tel Aviv, Israel.*

Background: As fetuses are largely inaccessible, human development remains poorly understood, and many developmental disorders, such as kidney anomalies, lack therapy. We aimed to use amniotic fluid (AF), which comprises fetal urine and lung secretions, to model fetal kidneys and lungs.

Methods: AF was seeded in 'kidney' or 'lung' media, which select for the respective progenitors, generating 3D organoids mirroring both organs. These were analyzed by immunostainings, single cell RNA-seq and functional tests.

Results: We established single cell-derived AF kidney (AFKO) and lung organoids (AFLO). AFKO harbor nephrogenic, urothelial and stromal cells, and uptake albumin. Upon injection to human fetal kidney explants, AFKO cells populate the progenitor niche and contribute to nascent tubules. AFLO habor alveolar and airway cells, upregulate surfactant levels upon steroid treatment and show active CFTR channels.

Conclusions: We present a new tool for personalized modeling of fetal organs, applicable to virtually any fetus. This provides accessible means to study normal and abnormal development via bona fide human fetal cells, which until now has been difficult.

Funding: Private Foundation Support, Government Support - Non-U.S.

Development of a Fetal Kidney Failure Model through Nephron Progenitor Cell Ablation via the Intrinsic Apoptosis Pathway

Kenji Matsui, Shuichiro Yamanaka, Kei Matsumoto, Takashi Yokoo. Div of Nephrology and Hypertension, Dept of Internal Medicine. *Tokyo Jikeikai Ika Daigaku, Minato-ku, Japan.*

Background: Fetal organ failure models are promising for xenotransplantation targeting fetuses and developmental and pathological research. Conventional knockout models often result in fetal lethality, while tamoxifen-inducible conditional ablation models are harmful to fetuses and lack both rapidity and completeness. In this study, we introduce inducible caspase 9 (iC9) to mouse fetuses for the first time, creating a viable CKD model with an easily adjustable phenotype.

Methods: We developed Six2-iC9 mice that express iC9 in nephron progenitor cells (NPCs). To generate a congenital CKD model, we administered a chemical inducer of dimerization (CID) to pregnant mothers intraperitoneally, introducing NPC ablation in Six2-iC9$^{+/+}$ offspring. This system's efficiency and speed of cell ablation were verified in the culture of Six2-iC9$^{+/+}$ and Six2-iC9$^{+/-}$ fetal kidneys. Additionally, we developed loxP-iC9 mice and Six2-iC9 rats.

Results: A single intraperitoneal CID administration resulted in complete NPC ablation, with the severity adjustable depending on timing. Offspring treated at E13.5 survived, exhibiting significant increases in BUN and urinary albumin from as early as one month old. Histology demonstrated reduced glomeruli with compensatory hypertrophy, tubular dilation, and interstitial fibrosis. In whole-organ cultures of Six2-iC9$^{+/+}$ fetal kidneys, NPC apoptosis began 6 hours after CID addition, with an ablation efficiency of 94%. Ablation was not induced in Six2-iC9$^{+/-}$, confirming the existence of a threshold for iC9 expression. However, in dissociated and re-aggregated sphere cultures of Six2-iC9$^{+/-}$ kidneys, NPC ablation was achieved. RNA-seq suggested that DNA damage from cell dissociation made cells more susceptible to apoptosis. Even in whole-organ cultures, co-administering XIAP inhibitor with CID facilitated NPC ablation in Six2-iC9$^{+/-}$. NPC ablation was also induced in loxP-iC9 mice crossed with Six2-Cre mice and in Six2-iC9 rats.

Conclusions: We established a congenital CKD model utilizing the intrinsic apoptosis pathway. Our findings indicate that iC9 expression levels and cell conditions influence this system's effectiveness. The successful implementation of the loxP system promises applications in other cell types, and the development of rat models will advance fetal xenotransplantation research.

Hypoxic Injury Triggers Maladaptive Repair in Human Kidney Organoids

Ana B. Nunez Nescolarde,[1] Mehran Piran,[1] Zhengqi Cheng,[3] Christine A. Wells,[3] David J. Nikolic-Paterson,[2,1] Alexander N. Combes.[1] *[1]Monash University, Melbourne, VIC, Australia; [2]Monash Medical Centre, Clayton, VIC, Australia; [3]The University of Melbourne, Melbourne, VIC, Australia.*

Background: Hypoxia is an important driver of AKI. Individuals who survive AKI often develop CKD through a maladaptive repair process characterised by failed epithelial regeneration, fibrosis, inflammation and metabolic dysregulation. Despite detailed knowledge built in rodent models, translational challenges underscore a need for human models.

Methods: Kidney organoids were generated from three independent human induced pluripotent stem cell lines and cultured for 48h in hypoxic (1% O2) or normoxic conditions from day (d) 18 to 20 of differentiation. Organoids were collected at d20 to assess immediate injury, or at d25, after 5d of culture in normoxic conditions, to assess repair. The response was analysed using transcriptomics, proteomics and metabolomics analyses. In addition, the role of the hypoxia regulator, *HIF1A*, was evaluated by exposing to hypoxia CRISPR edited *HIF1A*$^{-/-}$ organoids. Finally, direct co-culture with human induced macrophages was performed and their location and expression signatures were interrogated using immunoassays and spatial transcriptomics.

Results: Kidney organoids exposed to hypoxia upregulated hypoxic response genes (*VEGFA*, *HK1*), tubular injury markers (*JUN*, *TGFB1*, *GDF15*), and transcriptional signatures of AKI-associated cell stress and death pathways (apoptosis, ferroptosis). Deletion of *HIF1A* abrogated most of the hypoxic transcriptional response. However, we found the expression of *GDF15* to be HIF1A-independent. Instead, *GDF15* expression seemed to be mediated by the increase in *DDIT3* due to endoplasmic reticulum stress. At d25, injured organoids had increased ceramide production, elevated levels of maladaptive repair markers (S100A8, S100A9), and genes associated with collagen production, inflammation and fibrotic mediators. Dysregulation of iron metabolism (*HMOX1*, *FTL*) and lipid peroxidation were also lasting effects of the hypoxic injury. Single-cell RNAseq localised expression of maladaptive repair genes, and activation of TNF, NF-κB and JAK-STAT signalling pathways to tubular epithelial cells. Furthermore, co-cultured with macrophages modified the hypoxic response by enhancing TNF-α signalling via NF-kB and TGF-ß signalling pathways.

Conclusions: This multi-omic analysis provides compelling evidence supporting the use of organoids as *in vitro* models of ischemic AKI and maladaptive repair.

Funding: Government Support - Non-U.S.

Pax2 Mutant Mice Have Dysregulated Nuclear Maintenance, Cell Proliferation, and Motility Associated with Abnormal Glomerular Repair

Joanna Cunanan,[1,2] Jasmeet K. Benepal,[1,2] Vanessa S. De Gregorio,[1,2] Samantha Ricardo,[1,2] Emine B. Caparali,[1] Ana Konvalinka,[1,2] Moumita Barua.[1,2] *[1]Division of Nephrology, Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada; [2]Institute of Medical Science, Temerty Faculty of Medicine, University of Toronto, Toronto, ON, Canada.*

Background: Focal segmental glomerulosclerosis (FSGS) is characterized by podocyte loss. Parietal epithelial cells (PECs) that express PAX2, a regulator of cellular and morphological changes during glomerular development, can regenerate podocytes after injury. We previously found that pathogenic *PAX2* missense variants account for 4% of adult FSGS, and mutant PAX2+ PECs display impaired podocyte regeneration resulting in worsened FSGS in mice with a *Pax2* missense variant (*Pax2*-MV) (**Figure 1A-B**). In this study, we report the molecular mechanisms of impaired podocyte regeneration in *Pax2*-MV.

Methods: FSGS was induced by Adriamycin (ADR) in *Pax2*-MV and wildtype mice. Isolated glomeruli were subjected to mass spectrometry-based proteomics and analyzed by Gene Ontology (GO) and Reactome pathway enrichment analysis.

Results: Downregulated processes in ADR-injured *Pax2*-MV compared to wildtype glomeruli include decreased metabolic processes and actin cytoskeleton structure regulation (**Figure 1C**), consistent with worsened podocyte loss observed in these mice. Upregulated processes in ADR-injured *Pax2*-MV include those involved in nuclear abnormalities, cell proliferation and motility (**Figure 1D**). These are consistent with the increased glomerular tuft cell proliferation observed in ADR-injured *Pax2*-MV mice. This suggests a maladaptive attempt to regenerate podocytes due to the lack of regeneration from mutant PAX2+ PECs.

Conclusions: In ADR-injured *Pax2*-MV, downregulated metabolism and cytoskeleton structure are typical signatures of podocyte loss. However, our novel findings are the upregulated pathways that are consistent with dysregulated PAX2 signaling, including nuclear abnormalities, cell proliferation and motility.

Funding: Government Support - Non-U.S.

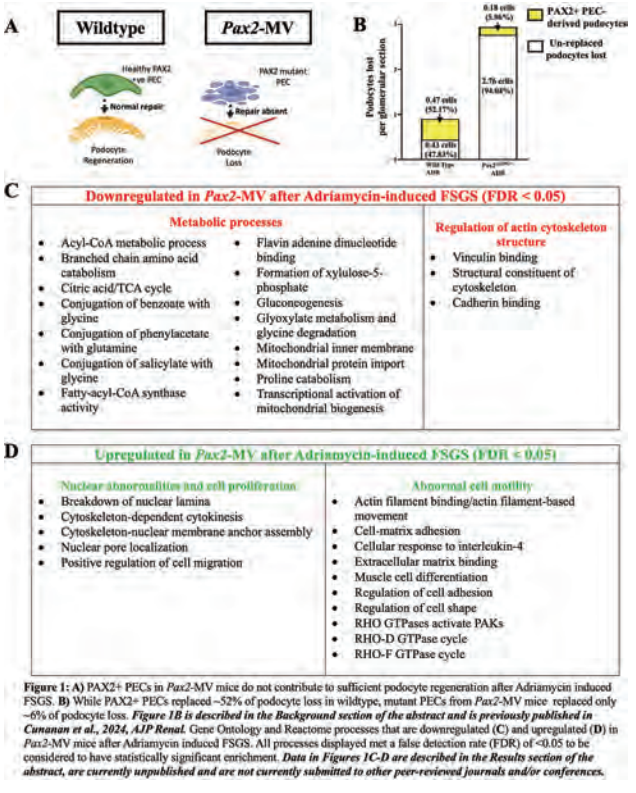

Figure 1: A) PAX2+ PECs in *Pax2*-MV mice do not contribute to sufficient podocyte regeneration after Adriamycin induced FSGS. **B)** While PAX2+ PECs replaced ~52% of podocyte loss in wildtype, mutant PECs from *Pax2*-MV mice replaced only ~6% of podocyte loss. ***Figure 1B is described in the Background section of the abstract and is previously published in Cunanan et al., 2024, AJP Renal.*** Gene Ontology and Reactome processes that are downregulated (**C**) and upregulated (**D**) in *Pax2*-MV mice after Adriamycin induced FSGS. All processes displayed met a false detection rate (FDR) of <0.05 to be considered to have statistically significant enrichment. ***Data in Figures 1C-D are described in the Results section of the abstract, are currently unpublished and are not currently submitted to other peer-reviewed journals and/or conferences.***

Piezo1 Promotes Podocyte Survival and Regeneration by Regulating F-actin Remodeling

Maria Elena Melica,[1] Giulia Antonelli,[1] Giulia Carangelo,[1] Maria Lucia Angelotti,[1] Elena Lazzeri,[1] Carolina Conte,[1] Anna J. Peired,[1] Letizia De Chiara,[1] Benedetta Mazzinghi,[2] Paola Romagnani,[1,2] Laura Lasagni.[1] *[1]Universita degli Studi di Firenze, Firenze, Italy; [2]Meyer - Azienda Ospedaliera Universitaria, Firenze, Italy.*

Background: Podocytes and podocyte progenitors are interdependent components of the kidney's glomerular structure, with podocytes forming the glomerular filtration barrier and progenitors being key players in podocyte regeneration during pathophysiological processes. Both cell types are subjected to constant mechanical forces, whose alterations can initiate podocytopathy and worsen glomerular injury. Despite this, the specific mechanosensors and mechanotransduction pathways involved in their response to mechanical cues remain partially explored.

Methods: We used transcriptomics, immunofluorescence, and silencing experiments on human primary progenitor cell cultures to demonstrate the expression and function of Piezo1 channels. We generated podocyte- and podocyte progenitor-specific Piezo1 knockout mice and evaluated the effects of Piezo1 loss in the context of Adriamycin nephropathy (ADN) and aging.

Results: Silencing of Piezo1 in progenitors triggered F-actin remodelling, induced cell shape modification and nuclear envelope defects with accumulation of DNA damage that lead to mitotic catastrophe in differentiated podocytes. Podocyte progenitor-specific knockout of Piezo1 in mouse resulted in severe albuminuria following ADN. Podocyte-specific knockout of Piezo1 not only induced higher susceptibility to podocyte injury in ADN but also led to accumulation of DNA damage and albuminuria throughout aging.

Conclusions: These results underline the central role of mechanical force perception and mechanotransduction in the pathogenesis of glomerular disease and identify Piezo1 as a potential target of mechanodrugs in disease conditions.

Impact of Renin on the Migration of Renin-Positive Cells in the Course of CKD

Shila Azizolli,[1] Sagor Halder,[1] Maria Schuster,[1] Florian Gembardt,[1] Jan Sradnick,[1] Ulf Panzer,[2] Christian Hugo.[1] *[1]Universitatsklinikum Carl Gustav Carus, Dresden, Germany; [2]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

Background: Renin-positive juxtaglomerular cells (RPC) have been shown to serve as precursors for various glomerular cell types in models of acute kidney injury. Specifically, we have previously demonstrated their ability to migrate intraglomerularly and differentiate into mesangial cells upon losing their renin-positivity. However, the role of RPC and their mechanisms in chronic injury models remains unknown. Therefore, we aimed to evaluate the role of renin and RPC migration in the chronic disease model of anti-glomerular basement membrane (anti-GBM), using an inducible renin-knockout (RenKO) mouse line.

Methods: Inducible transgenic renin-reporter (WT) and RenKO 8-12 week mice were used. The injury model was initiated by an intraperitoneal (i.p) injection of TNF-α. Two hours later, anti-GBM serum was administered i.p. To examine the effects of the model, a uni-nephrectomy was performed on day 10 after serum injection, followed by the final biopsy on day 21. PAS staining was used to assess the renal damage. RPC migration was analyzed using immunofluorescence staining against tdTomato, a8-Integrin, and renin. The extent of RPC migration was determined by the glomerular tdTomato-positive areas.

Results: PAS staining of the samples from both WT and RenKO groups, revealed substantial glomerular injury upon anti-GBM model induction. The damage was marked by the emergence of tubular casts, high PAS-positivity, and crescent formation. The immunofluorescence staining revealed significant differences between the groups in terms of RPC migration. At day 10, RPC migration was observed in 45% and 13% (p-value < 0.0001) of the overall glomeruli in WT and RenKO after anti-GBM induction, respectively. Additionally, at day 21 RPC migration was observed in 50% and 12% (p-value = 0.0002) of the overall glomeruli in WT and RenKO respectively.

Conclusions: In conclusion, we were able to demonstrate for the first time, RPC migration during a chronically progressive kidney injury model. Since renin depletion leads to significantly reduced migration, renin itself appears to be involved in this process. Next, a thorough analysis of the injury advancement between the groups, and a characterization of the transcriptomic landscape of the RPC under healthy and pathological conditions will provide further clarity on this mechanism.

Deciphering Cellular Mechanisms in Cells of Renin Lineage-Mediated Kidney Regeneration under SGLT2 Inhibition

Loïs van der Pluijm,[1] Juliette A. de Klerk,[2] Angela Koudijs,[2] Joris I. Rotmans,[2] Kenneth W. Gross,[3] Michael P. Pieper,[4] Anton J. Van Zonneveld,[2] Roel Bijkerk.[2] Einthoven Laboratory for Vascular and Regenerative Medicine. *[1]Leids Universitair Medisch Centrum, Leiden, Netherlands; [2]Leids Universitair Medisch Centrum, Leiden, Netherlands; [3]Roswell Park Comprehensive Cancer Center, Buffalo, NY; [4]Boehringer Ingelheim Pharma GmbH & Co KG, Biberach an der Riss, Germany.*

Background: A newly discovered, promising source of renal intrinsic regenerative cells comprise the cells of renin lineage (CoRL). Juxtaglomerular CoRL can repopulate essential glomerular cells like podocytes and mesangial cells post-injury, a process that can be enhanced by inhibiting the sodium glucose co transporter 2 (SGLT2). Despite its potential, the underlying cellular mechanisms remain largely elusive. Our study aims to identify the key genes driving this reparative process.

Methods: We employed a chronic kidney disease (CKD) model of 5/6 nephrectomy (5/6NX) in Ren1cre-tdTomato CoRL-lineage trace mice while daily administering the SGLT2 inhibitor empagliflozin (10mg/kg) for two weeks. Renal CoRL were isolated using fluorescent automated cell sorting (FACS) and subjected to single cell RNA sequencing.

Results: As determined by blood urea levels and GFR measurements throughout the study, we demonstrated enhanced kidney function recovery upon SGLT2 inhibition post kidney injury. In addition, SGLT2 inhibition led to increased numbers of CoRL-derived intraglomerular cells, specifically due to a rise in CoRL-derived podocytes. Single-cell RNA sequencing of CoRL revealed several distinct cell type clusters and confirmed the presence of a CoRL-derived podocyte cluster. Currently, pseudo-time trajectory analyses are being conducted to further elucidate differentiation dynamics of CoRL, particularly under SGLT2 inhibition.

Conclusions: Our findings highlight the potential of SGLT2 inhibition in promoting CoRL-mediated intrinsic kidney regeneration. Ongoing investigations aim to further decode the gene expression patterns during the phenotypic commitment shift of CoRL post-injury under SGLT2 inhibition. These insights may pave the way for novel, targeted approaches to augment the kidney's regenerative capacity.

Targeting MicroRNA-132 Decreases Kidney Fibrosis: A Role for Altered Plasticity of Cells of Renin Lineage?

Loïs van der Pluijm,[1] Angela Koudijs,[1] Joris I. Rotmans,[1] Kenneth W. Gross,[2] Anton J. Van Zonneveld,[1] Roel Bijkerk.[1] *[1]Leids Universitair Medisch Centrum, Leiden, Netherlands; [2]Roswell Park Comprehensive Cancer Center, Buffalo, NY.*

Background: Recent research has highlighted the potential of cells of renin lineage (CoRL) in promoting intrinsic kidney regeneration. The juxtaglomerular CoRL can repopulate crucial glomerular cells such as podocytes and mesangial cells following renal injury. Besides beneficial redifferentiation, CoRL can give rise to pericytes and subsequently myofibroblasts, contributing to fibrotic tissue formation. Our recent findings suggest that cellular responses to injury are largely regulated at the post-transcriptional level, with microRNA-132 (miR-132) playing a pivotal role. Induced by high-salt conditions, miR-132 directly stimulates renin release from CoRL, while miR-132 also regulates genes involved in cell proliferation and kidney fibrosis. The current study aims to investigate the role of MiR-132 in CoRL plasticity.

Methods: We employed various experimental kidney injury models in Ren1cre-tdTomato CoRL-lineage trace mice, including 5/6 nephrectomy (5/6NX), uni- and bilateral ischemic reperfusion injury (uIRI and bIRI), while administering locked nucleic acid (LNA) antisense oligonucleotide inhibitor of miR-132 (antimir-132).

Results: Blood urea levels indicated improved kidney function in the loss-of-function models 5/6NX and bIRI upon miR-132 interference. Histological analysis showed a strong trend towards decreased fibrosis with miR-132 inhibition in all models, as well as an association of miR-132 knockdown with altered renin activity (PRA). Upon miR-132 knockdown, we observed a reduction in interstitial tdTomato+ cells, suggesting a decrease in CoRL-derived myofibroblasts. Intraglomerular cell fates of CoRL upon miR-132 modulation in the various injury models are currently explored.

Conclusions: Our study sheds light on the intricate role of miR-132 in kidney fibrosis and modulating the plasticity of CoRL therein. These findings suggest a potential therapeutic opportunity for targeting miR-132 to mitigate renal fibrosis. However, further investigation will be essential to fully elucidate the mechanisms underlying CoRL plasticity and the specific effects of miR-132 inhibition in different injury contexts.

Heparanase 2 Is an Important Regulator of Glomerular Glycocalyx and Influences Albuminuria in Zebrafish via Vascular Endothelial Growth Factor A (VEGF-A) and Fibroblast Growth Factor (FGF) Signaling

Hermann Haller. *MDIBL, Bar Harbor, ME.*

Background: The endothelial glycocalyx (eGCX) is a glycan-rich layer important for vascular homeostasis. Shedding of heparan sulfates (HS) from the eGCX by heparanase leads to endothelial dysfunction. Heparanase 2 (Hpa2) is known to interact with (HS). We investigated the role of Hpa2 for the vascular system in zebrafish to establish a novel vertebrate model to study of eGCX in renal and vascular disease.

Methods: We use zebrafish larvae as research model. Expression and localization of Hpa2 was examined by *in situ* hybridization and immune fluorescence. *hpse2* loss-of-function (LOF) was induced by CRISPR-Cas9 or morpholino antisense strategies and eGCX was quantified. Endothelial permeability was analyzed in *Tg(l-fabp:VDB-EGFP)* fish. EC morphology, and expression profiles were examined in *Tg(flia1:eGFP)* fish and by transmission electron microscopy. Recombinant Hpa2 was injected into *hpse2* LOF fish and its effect on vascular pathology analyzed. Hpa2 was applied in EC cell cultures to study signal transduction of FGF2 and VEGFA.

Results: *hpse2 was detected* in hepatic tissue of zebrafish from 72 hpf onwards and localized the protein in blood vessels. *hpse2* LOF caused a vascular phenotype. *hpse2* LOF reduces eGCX and causes changes in the endothelial transcriptome characterized by genes involved in ECM-receptor interaction and signal transduction regulation. Recombinant hHpa2 rescued the *hpse2* LOF phenotype in zebrafish. *In vitro* studies showed that Hpa2 competes with heparin-binding growth factors FGF2 and VEGFA for binding on the EC surface and consequently reduces the cellular response these factors cause. Pharmacological inhibition of VEGFR2 and FGFR in alleviated the *hpse2* LOF phenotype in zebrafish.

Conclusions: We conclude that Hpa2 is necessary to maintain EC homeostasis by preventing HS breakdown. Recombinant Hpa2 prevents endothelial dysfunction and reduces proteinuria. Hpa2 induced maintenance of HS glycans strongly regulates growth factor-dependent signaling in EC. These findings may translate into novel treatment strategies with recombinant Hpa2.

Podocyte-Specific Partitioning Defective Par1a/b Deletion Increases Susceptibility to Adriamycin Nephropathy

Aparajita Mishra,[1] Zhongfang Du,[2] Selin Kurt,[3] Lanny T. DiFranza,[3] Catherine E. Brennan,[2] Kimberly J. Reidy.[1] *[1]Children's Hospital at Montefiore, New York, NY; [2]Albert Einstein College of Medicine, Bronx, NY; [3]Montefiore Medical Center, Bronx, NY.*

Background: The Partitioning-defective (Par1) proteins are serine threonine kinase members of a family of apico-basal polarity proteins that contribute to nephrocyte and podocyte differentiation and glomerular development in Drosophila and Mus musculus, respectively. However the role of Par1a/b following podocyte injury is not known. We hypothesized Par1a/b (aka Mark2 and Mark3) are protective against podocyte injury.

Methods: We examined correlation of glomerular Par1a/b (MARK2/3) gene expression with proteinuria using publicly available data from Nephroseq. Next, to test our hypothesis, we generated podocyte specific Par1a/b knockout (podocyte Par1a/b cKO): NPHS2-Cre: Mark2flox/flox: Mark3flox/flox which were maintained on a C57BL6 background. To determine the effect on podocyte injury, adult 8-week-old podocyte Par1a/b cKO mice were injected with adriamycin (15mg/kg). Controls included adriamycin injected Mark2flox/flox:Mark3flox/flox mice and vehicle injected mice. Mice were euthanized at 14 weeks to analyze the kidney phenotype. To analyze the severity of adriamycin nephropathy, Periodic-acid Schiff staining and urine albumin creatinine ratio were performed.

Results: Glomerular Par1a/MARK3 and Par1b/MARK2 expression was inversely correlated with proteinuria in multiple human gene expression data sets from subjects with glomerular disease ($p<0.05$). Podocyte Par1a/b cKO mice survive to adulthood, but more adriamycin treated Podocyte Par1a/b cKO died than Adriamycin treated flox/flox mice. Adriamycin treated Podocyte Par1a/b cKO mice had more global sclerosis and segmental sclerosis compared to the Adriamycin treated flox/flox controls ($p<0.05$). Adriamycin treated Podocyte Par1a/b cKO mice showed more albuminuria compared to the adriamycin flox/flox treated controls ($p<0.05$). Serum creatinine measurement showed no statistical difference among the groups.

Conclusions: Decreased Par1a/b (MARK2/3) expression correlates with more proteinuria in human glomerular disease. Podocyte Par1a/b deletion increased susceptibility to Adriamycin nephropathy, suggesting Par1a/b is protective following podocyte injury. Ongoing studies are examining the mechanism(s) by which podocyte Par1a/b deletion affects susceptibility to glomerular injury

Single-Cell and Spatial Transcriptomics Identify Immediate Early Genes as Central Transcriptomic Factors during Renal Endothelial Regeneration In Vivo

Jan Sradnick, Meike Seitz, Patrick Arndt, Anika Wirth, Maria Schuster, Hannah Weissbach, Christian Hugo. *Universitatsklinikum Carl Gustav Carus, Dresden, Germany*.

Background: Immediate early genes play a central role in the regulation of cell stress, cell proliferation and differentiation. Individual studies indicate that immediate early genes significantly influence vascular repair, of aortic and lung endothelial cells. Less is known about the regenerative mechanisms in renal endothelial cells. To test the relevance of mediated early genes in the kidney, renal endothelial injury was induced. Transcriptomic patterns of the endothelium were evaluated on a single-cell level to uncover potential mechanisms of renal vascular regeneration.

Methods: For single-cell transcriptomics (scRNA), endothelial-specific injury was induced in Tie2 eGFP reporter mice (n=48) by renal arterial perfusion with Concanavalin A (ConA) /anti-ConA. Nineteen mice served as sham-operated controls. Kidneys were harvested 24 hours, 48 hours, 4 days, and 7 days after injury induction. For scRNA transcriptomics, cells were isolated from glomerular and extraglomerular renal tissue. Biopsies from 15 mice were used to perform 10x Xenium spatial transcriptomics. Endothelial cell damage was evaluated using periodic acid–Schiff and endomucin stainings.

Results: Both endothelial cell injury (24h) and remarkable regeneration (d4-d7) were observed using glomerular injury evaluation. Following quality control measurements, 10 glomerular and 7 peritubular endothelial cell subclusters were identified. Based on scRNA transcriptomics, we identified cells which increased significantly with proportions of 6% (d2), 17% (d4), and 20% (d7), along with the detected healing process. Immediate early genes like *Atf3*, *Erg1*, *Fos*, and *Junb* were differentially expressed in these cell population. A similar pattern was observed in peritubular endothelial cells. With the help of spatial transcriptomics, findings were successfully confirmed.

Conclusions: In summary, state-of-the-art transcriptomics allowed us to initially identify endothelial renal subpopulations expressing the immediate early genes, which potentially regulate the subsequent endothelial cell repair mediated by cell differentiation and proliferation. Next, gene expression has to be modified by depletion or overactivation to evaluate the participation of immediate early response genes in renal regenerative processes.

TH-PO411

Endothelial Cells of Afferent Arteriole: Novel Potential Regenerative Niche of Glomerular Endothelial Regeneration?

Meike Seitz, Jan Sradnick, Maria Schuster, Anika Wirth, Hannah Weissbach, Patrick Arndt, Christian Hugo. *Universitatsklinikum Carl Gustav Carus, Dresden, Germany*.

Background: Recent research has demonstrated that endothelial cells (EC) exhibit significant heterogeneity, displaying remarkable plasticity in both normal and pathophysiological conditions. However, the precise cellular responses of renal EC during injury and regeneration remain poorly understood. Therefore, we characterize the process of regeneration of renal EC using single-cell RNA sequencing (SC RNA-seq). This approach enables the identification of differentially expressed genes (DEG) at the single-cell level, which may facilitate the identification of potential regenerative gene patterns or niches within the renal endothelium.

Methods: EC-specific injury was induced in Tie2-eGFP reporter mice (n=48) by renal arterial perfusion with ConcanavalinA (ConA)/anti-ConA serum. Ten mice served as sham-operated controls. Kidneys were harvested at 24h, 48h, 4 days, and 7 days post-injury induction. For SC RNA-seq more than 40,000 glomerular (gEC) and peritubular (pEC) endothelial cells were isolated and further separated using fluorescence-activated cell sorting (FACS). EC damage was evaluated by endomucin staining. Bioinformatic analyses of the SC RNAseq data were conducted using the Seurat, clusterProfiler, and venn. diagram packages for R.

Results: EC injury (24 h) and remarkable regeneration (d4-d7) were observed in histology and SC RNA-seq data. In addition to known glomerular and peritubular endothelial subclusters, Gene Set Enrichment Analyses (GSEA) revealed several clusters with DEG associated with injury, a transition from injury to regeneration, remodeling, regeneration and proliferation. A strong resemblance between the regeneration cluster and the already known afferent arteriole-associated cluster was evident. 29% of the DEG of the regeneration cluster can also be found in the afferent arteriole associated cluster. A lot of these DEG are associated with regenerative processes. In contrast, only 1% of the regenerative cluster DEG can be found in the cluster linked with the EC of the efferent arteriole.

Conclusions: In conclusion, our SC RNA-seq data illuminates the transcriptional changes that occur during injury and regeneration of renal EC. The analyses strongly suggest a role of the EC of afferent arteriole in initiating or transducing regeneration processes in the renal endothelium.

TH-PO412

A New Subtype of Glomerular Capillary Endothelial Cells Was Found in the Human Glomerular Single-Cell Transcriptome

Jinjie Zhong, Qilin Chen, Shuying Li, Wan JunLi, Li Qiu. *Department of Nephrology Children's Hospital of Chongqing Medical University, Chongqing, China*.

Background: Kidney endothelial cells from different sites with different phenotypes coexist in three anatomical and functional compartments of the kidney, namely the glomerulus, the cortex and the medulla, supporting specific renal tasks. However, the heterogeneity of glomerular capillary endothelial cells (EC-GCs) is still poorly addressed and not as widely recognized as the heterogeneity of renal medullary and cortical endothelium.

Methods: We carried out scRNA-seqand spatial transcription sequencing (ST-seq) of children's kidney tissues near the cortex. Human glomeruli were rapidly enriched and human glomerular cell atlas was successfully constructed. The molecular signatures of the identified human EC-GCs were validated at the protein level. Combined scRNA-seq data from mouse glomeruli and bulk RNA-seq data from human renal disease glomeruli were synthesized and deconvoluted to clarify the alterations of different glomerular cell subtypes in disease.

Results: (1) Combined scRNA-seq and ST-seq of human kidney tissues, the human glomerular cell atlas was successfully constructed, which comprehensively demonstrated the molecular features of human glomerular cells. (2) EC-GCs might consist of a group of TOP2A$^+$EC-GCs with proliferative function, a group of EMS1$^+$EC-GCs with high expression of THBS1 and GJA1, a group of THBD$^+$EC-GCs with high expression of PTGS1 and FABP5, and a group of classical EC-GCs. (3) THBD$^+$EC-GCs was associated with shear stress, and the source of differentiation of other cellular subtypes of EC-GCs. And shear stress might be a key factor driving this differentiation. (4) The diversity of human EC-GCs identified in this study is also present in mice. Deconvolutional analysis of bulk RNA-seq of glomeruli in human kidney disease revealed that both cellular proportions and characteristic molecules of glomerular cells are significantly altered in the disease, and that a significant increase in the number of shear stress -associated EC-GCs may be among the characteristic changes.

Conclusions: EC-GCs are composed of multiple subtypes of cells with different molecular characteristics, and that shear stress -related THBD$^+$EC-GCs might be the source of the development of EC-GCs. Shear stress -associated molecular features are significantly altered in glomerular diseases, which may be the key pathological molecular features of EC-GCs.

Development of Novel Cell Therapeutic Strategies for AKI and CKD Using Human Induced Pluripotent Stem Cell (iPSC)-Derived Nephron Progenitor Cells

Toshikazu Araoka, Kosuke Toyohara, Makoto Ryosaka, Maasa Matsuura, Kenji Osafune. *Center for iPS Cell Research and Application (CiRA), Kyoto University, Kyoto, Japan*.

Background: The therapeutic effect of human iPS cell-derived nephron progenitor cells (hiPSC-NPCs) on acute kidney injury (AKI) has been reported in mice but has not been clinically confirmed. No reported studies have examined the therapeutic potential of hiPSC-NPCs on chronic kidney disease (CKD). On the other hand, it was recently reported that the properties of hiPSC-NPCs differ depending on differences in iPSC lines and batches among experiments. Therefore, a large number of uniform hiPSC-NPCs are required to realize cell therapies for AKI and CKD, but effective expansion cultures remain to be developed.

Methods: We screened culture conditions that maintained the function of hiPSC-NPCs by multiple combinations of the low-molecular-weight compounds and growth factors. Furthermore, we transplanted expanded hiPSC-NPCs into the renal subcapsule of cisplatin-induced AKI model (cis-AKI) mice and aristolochic acid-induced CKD model (AA-CKD) mice and evaluated renal function and histological changes. We also administered conditioned medium (CM) produced by expanded hiPSC-NPCs to cis-AKI mice to examine the therapeutic effects, and performed mass spectrometry of CM and RNA-sequencing of hiPSC-NPCs.

Results: We established a novel expansion culture condition (CFY medium) that enables more than 1,000-fold proliferation of hiPSC-NPCs in three passages while maintaining NPC marker expression. We demonstrated that hiPSC-NPCs expanded by CFY medium attenuate kidney injury and improve survival rate in cis-AKI mice. Furthermore, we found that hiPSC-NPCs prevent kidney functional decline, interstitial fibrosis, and senescence in AA-CKD mice. In addition, the contralateral kidneys transplanted with hiPSC-NPCs in AKI and CKD mice were also treated, suggesting that the therapeutic effects of hiPSC-NPCs were due to reno-protective factors. Therefore, we administered CM produced by expanded hiPSC-NPCs to cis-AKI mice, which prevented kidney functional decline and improved survival rate. Furthermore, we identified some reno-protective factors contained in CM and demonstrated that angiogenesis in the injured kidney is involved as part of the mechanisms by which hiPSC-NPCs exert therapeutic effects.

Conclusions: The expanded hiPSC-NPCs are useful for cell therapies for AKI and CKD and will open new avenues in the treatment of kidney diseases.

Induced Kidney Progenitor Cells Provide a Rapid One-Pot Starting Material for Nephron Regeneration

Thomas Vincent,[1] Michael Namestnikov,[3] Benjamin Dekel,[2] Benjamin S. Freedman.[1] *[1]University of Washington, Seattle, WA; [2]Sheba Medical Center, Tel Hashomer, Israel; [3]Tel Aviv University, Tel Aviv, Israel.*

Background: For human kidney embryonic rudiment transplantation, there is an early window of opportunity that promotes enhanced graft formation. Protocols to differentiate kidney organoids from human stem cells mimics *in vivo* organogenesis as cells progress through intermediate mesoderm, metanephric mesenchyme, and progenitor cell stages. This raises the possibility of achieving tissue engineered therapeutics to restore renal function. We therefore tested the impact of early organoids on patterns of *in vivo* engraftment.

Methods: Organoids were differentiated from stem cells using a brief CHIR pulse. Cells were characterized temporally through qPCR and immunofluorescence staining. Implanted material was collected at multiple timepoints (days 4, 7, and 15) by scraping cells from an adherent 24-well plate. These pellets were inserted beneath the kidney capsules of NOD-SCID mice. Kidneys were excised after 3-weeks and analyzed through immunofluorescent staining.

Results: Here we show that 4 days of differentiation generates an induced metanephric mesenchyme-like population. When implanted beneath the kidney capsule, they develop into well-vascularized glomeruli containing human podocytes and GATA3$^+$, PDGFRβ$^+$ mesangial cells contiguous with tubular structures (**Fig 1**). Implanting of d7 cells consistently produced grafts with more PODXL$^+$ and LTL$^+$ structures than d15 late-stage kidney organoid implantations (**Fig 2**).

Conclusions: These results suggest using progenitor cells as starting material may have advantages in the development of future therapeutics over late-stage organoids. We are currently working to use these engraftments to study drug delivery and create novel disease models. In the future, we hope to address challenges related to distal tubule connections in order to achieve successful urine drainage from the graft and begin to assess function.

TH-PO415

Phase 3 Clinical Trial Candidate Rilparencel Demonstrates Consistent Phenotypic Characteristics during Ex Vivo Culture Expansion Process

Evan Trudeau, Andrew T. Bruce, Dominic M. Justewicz. Bioanalytical Development. *ProKidney, Morrisville, NC.*

Background: A variety of transitional cell states allow for kidney cell replacement. This regenerative heterogeneity challenges the assessment of renal identity. We characterize rilparencel, a renal autologous cell therapy, to elucidate its cellular dynamics during bioprocessing.

Methods: Banked source material and drug product samples from the manufacture of rilparencel from kidney biopsies of five patients with T2D and CKD (NCT02836574, investigative clinical trial of T2D with stage 3a-4 CKD) were evaluated using reagents specific for canonical renal cell markers associated with tissue healing. Comparison followed with samples from discarded kidneys (n=3; National Disease Research Interchange) and key reference cells (ATCC). Cell composition was evaluated by flow cytometry using BD FACS Lyric and analysis by FlowJo and FlowSOM.

Results: Epithelial cells making up rilparencel maintain their renal identity throughout the manufacturing process, showing colocalization and biological activity of anchored cell markers of the proximal tubule (*e.g.*, GGT, CD13, EpCAM). CD146 expression, a reliable marker of tubular cells, was also confirmed – it is essential for kidney vasculature development (*i.e.*, epithelial and endothelial cell differentiation). This along with data for CD151 and CD156c suggests that rilparencel may play an important role in migration and remodeling within the host tissue. Complementary is the dynamic appearance of an array of key indicators of repair-related biological processes (*e.g.*, self-renewal, regulation of proliferation, cell re-/de-differentiation, and epithelialization, including CD24, CD44, CD90, CD133, CD106, Pax2, and Bmi-1) which may be self-protective against further renal damage in the host patient. Further, there is genomic stability (*e.g.*, cell cycle and DNA content) and absence of cellular senescence (*e.g.*, CD74-negative). Finally, the cell phenotype of rilparencel, manufactured from diseased kidney tissue, resembles that found in batches made from reference control cells.

Conclusions: The autologous cell-based therapeutic rilparencel shows a robust potential for successful kidney restoration, providing a roadmap to unveil mechanisms(s) of action.

Protective Effect of Tonsil-Derived Mesenchymal Stem Cells on Peritoneal Fibrosis by Inhibiting Oxidative Stress

Duk-Hee Kang, Dal-Ah Kim, Chor ho Jo. *Ewha Womans University College of Medicine, Seoul, Republic of Korea.*

Background: Mesenchymal stem cells (MSCs) have regenerative capability and exert paracrine actions on damaged tissues and have recently received a new attention due to its preventive effect on organ fibrosis by inhibiting epithelial-to-mesenchymal transition (EMT). The EMT of mesothelial cells (MCs) is an early mechanism of peritoneal dysfunction in peritoneal dialysis (PD). This study was undertaken to investigate the role of Tonsil-derived MSCs (T-MSCs) in TGFβ-induced EMT of human peritoneal mesothelial cells (HPMCs) and its mechanism.

Methods: Transwell co-culture system was used in which MCs were cultured with T-MSCs or T-MSC-conditioned medium (T-MSC-CM). EMT was evaluated by the changes in morphology and markers of epithelial and mesenchymal cells. ROS generation was assessed by DCF-DA and MitoSox^R staining. Animal model of PD was established by daily infusion of 4.25% glucose-based dialysate with methylglyoxal for 3 weeks via intraperitoneal catheter in Sprague-Dawley rats. T-MSC (1.0 x 10^7cells, i.p.) was injected at 14 days of catheter insertion, and peritoneal tissue was isolated in 7 days of T-MSC injection. Markers of oxidative stress, ER-stress, apoptosis, and NLRP3 inflammasome were evaluated with peritoneal equilibrium test (PET) and histologic analysis.

Results: Co-culture of HPMCs and T-MSC or T-MSC-CM inhibited TGFβ-induced EMT (increased ZO-1 and E-cadherin and decreased αSMA) and oxidative stress (decreased ROS generation). In PD, T-MSCs alleviated EMT and peritoneal fibrosis and reduced Bax, cleaved caspase and increased Bcl-2, and also decreased 8-OHdG with an increase in GSH and SOD2. T-MSC led to a decrease in proteins of ER stress and NLRP3 inflammasome. T-MSCs treated rats had a higher D_2/D_0 glucose and a lower D_2/P_2 creatinine. Anti-human nuclei staining revealed scattered positive staining along peritoneal mesothelial layer.

Conclusions: T-MSCs represent a promising approach to prevent peritoneal fibrosis by providing anti-fibrosis and anti-oxidant effects in the peritoneal cavity and ameliorating the phenotype transition of peritoneal mesothelial cells.

Thrombomodulin-Overexpressing Adipose-Derived Mesenchymal Stem Cells Prevent Thromboembolism and Ameliorate Kidney Fibrosis in Rats

Yoshiki Tanaka,[1] Ayumu Nakashima,[3] Naoki Ishiuchi,[2] Kisho Miyasako,[1] Keisuke Morimoto,[1] Kensuke Sasaki,[2] Takao Masaki.[2] *[1]Hiroshima Daigaku Daigakuin Ikei Kagaku Kenkyuka, Hiroshima, Japan; [2]Hiroshima Daigaku Byoin, Hiroshima, Japan; [3]Yamanashi Daigaku, Kofu, Japan.*

Background: Adipose-derived mesenchymal stem cells (ASCs) exhibit anti-inflammatory and anti-fibrotic effects via their paracrine action, and thereby are expected to be a new therapy for kidney disease. Meanwhile, ASCs reportedly exhibit procoagulant activity compared to other mesenchymal stem cell types, raising concerns about thrombogenic risk. Thrombomodulin (TM) on the cell surface acts as an anticoagulant and antifibrinolytic factor by binding to thrombin, a procoagulant factor. This led us to the hypothesis that ASCs overexpressing TM can be safely used for cell therapy by reducing the risk of thromboembolism.

Methods: ASCs infected with adeno-associated virus (AAV) carrying TM cDNA or an empty AAV were designated as "TM-ASC" or "null-ASC", respectively. To examine the risk of renal infarction induced by ASCs, 5.0×10^5 ASCs were administered via renal artery into rats with unilateral ischemia reperfusion injury (IRI) and contralateral nephrectomy (renal infarction model). To assess the risk of pulmonary embolism caused by ASCs, 7.5×10^6 ASCs were injected into rats via tail vein (pulmonary embolism model). Additionally, we examined the anti-inflammatory and anti-fibrotic effects of TM-ASC using IRI rats treated with TM-ASC and null-ASC.

Results: In the renal infarction model, 36% (n = 4/11) of the rats in the null-ASC group died by day 3, whereas all of rats (n = 11/11) in the TM-ASC group were alive. In the pulmonary embolism model, 40% (n = 3/12) of the rats in the null-ASC group died within 24 hours, while all of rats (n = 12/12) in the TM-ASC group were alive. Intravascular thrombus was identified in 30/120 fields in the null-ASC group and decreased to 3/120 fields in the TM-ASC group in hematoxylin and eosin staining of rat lung tissues. In addition, administration of TM-ASC more potently alleviated renal inflammation and fibrosis induced by IRI compared to that of null-ASC.

Conclusions: These findings indicate that TM-overexpressing ASCs not only increase treatment safety, but also enhance their therapeutic efficacy. Administration of TM-overexpressing ASCs is a promising therapeutic strategy to prevent progression from organ damage to failure.
